# The Structure of the 1:2 Complex 4,4-Dimethylmorpholinium 7,7,8,8-Tetracy anoquinodimethanide, DMM(TCNQ) $)_{2}$, at 294 K 

By Piet Kamminga and Bert van Bodegom<br>Laboratorium voor Chemische Fysica, Materials Science Center, Rijksuniversiteit Groningen, Nijenborgh 16, 9747 AG Groningen, The Netherlands

(Received 16 May 1980; accepted 16 September 1980)

#### Abstract

$\mathrm{C}_{6} \mathrm{H}_{14} \mathrm{NO}^{+} .2 \mathrm{C}_{12} \mathrm{H}_{4} \mathrm{~N}_{4}^{-1 / 2}$, $\mathrm{DMM}(\mathrm{TCNQ})_{2}$, is monoclinic, space group $P 2_{1} / m$ (with disorder of DMM), $a=$ 7.792 (7), $b=26.814$ (8), $c=7.594$ (7) $\AA, \beta=$ 58.44 (6) ${ }^{\circ}, U=1352 \AA^{3}, Z=2 ; d_{c}=1.289, d_{m}=$ $1.301 \mathrm{Mg} \mathrm{m}{ }^{-3}$. Final $R_{w}(F)=0.070$ for 2701 independent reflections. The structure contains columns of TCNQ units located in sheets parallel to (010) separated by DMM molecules. Each column consists of TCNQ dimers with an interplanar spacing of 3.25 (1) $\AA$ and a considerable overlap of the shifted ringring type. The interplanar spacing between the dimers is only slightly larger, 3.29 (1) $\AA$, but here large shifts parallel to the TCNQ plane make the overlap small. The DMM molecule is disordered, possessing two positions related by the mirror plane in the structure.

## Introduction

Earlier structural studies of the $1: 2$ complexes of TCNQ with 4-methyl-4-ethylmorpholinium (MEM) at 113 K and 4,4-diethylmorpholinium (DEM) at 294 K (Bosch \& van Bodegom, 1977; Morssink \& van Bodegom, 1981) showed that the TCNQ packing modes in the two compounds are not the same. In the
triclinic DEM (TCNQ) ${ }_{2}$ structure there are two types of sheets, only one of which is similar to the sheet in $\operatorname{MEM}(\mathrm{TCNQ})_{2}$. As the sheet structure of TCNQ complexes influences their physical behaviour, the differences found stimulated us to study the structures of further 1:2 $N$-substituted morpholinium-TCNQ complexes. In the present paper the X -ray diffraction study of $\mathrm{DMM}(\mathrm{TCNQ})_{2}$ is described (DMM = 4,4-dimethylmorpholinium). Not much is known yet of its physical properties, apart from the fact that it has one phase transition above room temperature $[475 \mathrm{~K}$; Guinier photographs; Dr G. A. Wiegers, Department of Inorganic Chemistry, Rijksuniversiteit Groningen].

## Experimental work

Dark violet crystals were grown from a mixture of hot solutions of 4,4-dimethylmorpholinium iodide and TCNQ in acetonitrile. Table 1 gives the results of a chemical analysis of the crystals. Room-temperature cell constants were obtained by least squares from the $\theta, \chi$ and $\varphi$ values of 77 reflections measured on an automatic Nonius CAD-3 diffractometer, Table 2. Weissenberg and rotation photographs gave the symmetry relation $I(h k l)=I(h \bar{k} l)=I(\bar{h} \bar{k} \bar{l})$ and the systematic absences $0 k 0$ for $k$ odd, thus giving as possible space groups $P 2_{1}$ and $P 2_{1} / m$.

DMM molecules symmetrically related by the mirror plane $m$. Under the assumption of random disorder for the DMM molecule, first a refinement of the structure in space group $P 2_{1} / m$ was carried out. The $y$ coordinates of $\mathrm{N}(33), \mathrm{C}(34)$ and $\mathrm{C}(35)$, lying close to or on the mirror plane at $y=0.25$, were constrained at 0.25 and the temperature parameters $U_{12}$ and $U_{23}$ of these atoms were set to $0 \cdot 0$. The remaining atoms of the DMM groups were given a population $0 \cdot 5$. After anisotropic refinement of the non-hydrogen atoms, a difference map showed peaks for all H atoms at the

[^1]expected positions. H atoms were constrained at $1.08 \AA$ relative to their respective C atoms; only their isotropic temperature parameters were varied. For the non-hydrogen atoms scattering curves were taken from Cromer \& Mann (1968) and for H atoms from Stewart, Davidson \& Simpson (1965). Blocked-matrix least-squares refinement, with anisotropic temperature parameters for the non-hydrogen atoms, decreased $R=$ $\sum\left|\left|F_{o}\right|-\left|F_{c}\right|\right| / \sum\left|F_{o}\right|$ to 0.074 and $R_{w}=\left[\sum w\left(\left|F_{o}\right|-\right.\right.$ $\left.\left|F_{c}\right|\right)^{o} /\left.\left.\sum_{w \mid F_{o}}\right|^{\mid 2}\right|^{1 / 2}$ to $0 \cdot 070 ; 2701$ reflections with $\left|F_{o}\right|$ $>2 \sigma_{c}\left(F_{o}\right)$ and weights $w=\left[\sigma_{c}^{2}\left(F_{o}\right)+E\left|F_{o}\right|^{2}\right]^{-1}$ were used; $E=0.0006$. The goodness-of-fit $G=\left[\sum w\left(\left|F_{o}\right|\right.\right.$ $\left.-\left|F_{c}\right|\right)^{2} /\left.\left(N_{o}-N_{v}\right)\right|^{1 / 2}=1.57$, with $N_{o}=2701$ and $N_{v}$ (number of variables) $=226$. During the last cycle parameter shifts were all $<0.05 \sigma$. Final positional parameters are given in Table 3.* To check whether a better fit to the observed intensities could be obtained by omitting the inversion centre and mirror plane, the refinement was repeated in space group $P 2_{1}$. Two independent TCNQ units and one DMM group, without disorder, were considered. Refinement with the same reflections, weighting scheme and H constraints gave $R=0.085, R_{w}=0.091$ and $G=2.12\left(N_{v}=384\right)$. A difference map showed the four highest peaks, from 0.36 to $0.56 \mathrm{e} \AA^{-3}$, at positions symmetrically related to those of $\mathrm{C}(37), \mathrm{C}(38), \mathrm{C}(39)$ and O . The e.s.d. of the difference map $\sigma_{d}=(1 / V)\left[2 \sum_{H}\left(F_{o}-F_{c}\right)^{2}\right]^{1 / 2}=$ $0.07 \mathrm{e} \AA^{-3}$, with the summation over all reflections corresponding with those included in the refinement (Cruickshank, 1949). Correlation coefficients for the atoms of the TCNQ groups ranged from 0.53 to 0.73 . From the fact that the refinement indices and the difference map get worse, in spite of the increasing number of variables, we conclude that the structure has to be described in space group $P 2_{1} / m$ under the assumption of random disorder for the DMM group.

## Description of the structure

## Packing

The projections of the structure along [001] and [100] are given in Figs. 1 and 2. It is seen that the TCNQ molecules are located in sheets parallel to (010) separated by DMM molecules. There is only one type of sheet, successive sheets being related by the $2_{1}$ axis. The disordered DMM groups possess two symmetrically related positions around each of the mirror planes.

[^2]

Fig. 1. Projection of the structure of $\mathrm{DMM}(\mathrm{TCNQ})_{2}$ along [001] onto the plane perpendicular to 10011 . The DMM group is disordered. Only one of the two molecules related by the mirror plane $m$ is shown. $a_{p}, b_{p}$ and $c_{p}$ denote projections of axes.

Fig. 2. Projection of the structure of $\mathrm{DMM}(\mathrm{TCNQ})_{2}$ along [100] onto the plane perpendicular to [100]. The DMM group is disordered. Only one molecule is shown.

Fig. 3. Normal projection of the sheet of TCNQ molecules in $\mathrm{DMM}(\mathrm{TCNQ})_{2}$ along the longest molecular axis.

## The TCNQ sheet

Fig. 3 gives a drawing of the stacking of the TCNQ units as seen along their longest molecular axes. Fig. 4 shows the different types of overlap between the TCNQ units, while shortest intermolecular distances are given in Table 4. Table 5 lists numerical values for the relative shifts of the molecules parallel to the quinodimethane least-squares plane, along and perpendicular to the longest molecular axis. From Figs. 3 and 4 it is seen that the overlap between $A$ and $A^{\prime \prime}$ is much larger than between $A$ and $A^{\prime}$ and that the overlap between $A$ and $A^{\prime \prime \prime}$ is very small. Therefore in the sheet of TCNQ molecules columns can be recognized along $\mathbf{c}$ consisting of dimerized TCNQ units. The intradimer overlap is of the shifted ring-ring type. The distances between the quinodimethane planes of the successive TCNQ units in the column are 3.25 (1), within the

dimer, and 3.29 (1) $\AA$, between the dimers. Successive molecules $A$ (like $A^{\prime}, A^{\prime \prime \prime}$ etc.) show electrostatic interaction via short $\mathrm{N} \cdots \mathrm{H}$ distances (Table 4).

## The TCNQ group

In Fig. 5 the molecular geometry of the TCNQ ion is shown. Within $2 \sigma$ the group satisfies mmm symmetry with respect to its bond lengths; average values for bond lengths are given in Table 6. A least-squares plane was calculated through the eight heavy atoms of the quinodimethane group. Results are given in Table 7. It is seen that the TCNQ molecule as a whole is not planar, and that the cyano groups in particular deviate from the plane. The normal to the quinodimethane plane makes an angle of $30 \cdot 6(0.5)^{\circ}$ with $\mathbf{c}$.

## The DMM group

The ring of the DMM group is in a chair conformation as has been found for all morpholinium derivatives in complexes with TCNQ whose structures are so far known (Bosch \& van Bodegom, 1977; Sundaresan \& Wallwork, 1972; Morssink \& van

Fig. 5. Molecular geometry of the TCNQ unit in DMM(TCNQ) ${ }_{2}$. Values for bond lengths $(\AA)$ and angles $\left(^{\circ}\right)$ are not corrected for libration effects. ( $a$ ) Bond lengths; ( $b$ ) bond angles.

Bodegom, 1981). Owing to a large correlation between the two disordered groups the molecular geometry could not be determined accurately. In Fig. 6, which shows the bond lengths and angles, the least-squares e.s.d.'s have been omitted as they strongly underestimate the errors in the molecular geometry.

Fig. 6. Molecular geometry of the DMM molecule (disordered) in DMM (TCNQ) $)_{2}$. Bond lengths in $\AA$, bond angles in ${ }^{\circ}$. The angles $\mathrm{C}(37)-\mathrm{N}(33)-\mathrm{C}(39)$ and $\mathrm{C}(38)-\mathrm{N}(33)-\mathrm{C}(34)$ are 111 and $102^{\circ}$ respectively.

## Discussion

In MEM(TCNQ) $)_{2}$ at 113 K all TCNQ sheets are translationally equivalent. In both $\operatorname{DMM}(\mathrm{TCNQ})_{2}$ and $\mathrm{DEM}(\mathrm{TCNQ})_{2}$ alternating sheets along the $\mathbf{b}$ direction are not translationally equivalent. In $\mathrm{DMM}(\mathrm{TCNQ})_{2}$ the sheets are related, however, by the twofold screw axis along $\mathbf{b}$, whereas in $\operatorname{DEM}(T C N Q)_{2}$ the two sheets have a different character. The sheet in DMM (TCNQ) ${ }_{2}$ is analogous to that in MEM (TCNQ) $)_{2}$ in that both sheets contain pseudo-one-dimensional dimerized TCNQ stacks. The intradimer overlap in the two stacks is different, however, being of the shifted ring-ring type in $\mathrm{DMM}(\mathrm{TCNQ})_{2}$ and of the ring-external-bond type in MEM(TCNQ) $2_{2}$. The $\mathrm{DMM}(\mathrm{TCNQ})_{2}$ sheet is not analogous with either of the two sheets in DEM(TCNQ) $)_{2}$. One of the sheets in DEM(TCNQ) ${ }_{2}$ has its pseudo-one-dimensional character, but not its intradimer overlap mode, in common with the $\mathrm{DMM}(\mathrm{TCNQ})_{2}$ sheet, whereas the second sheet in $\mathrm{DEM}(\mathrm{TCNQ})_{2}$ shares its intradimer overlap with the DMM(TCNQ) ${ }_{2}$ sheet, but not its pseudo-onedimensional character. Further studies of the physical properties of the TCNQ compounds are necessary to obtain a clear insight into the impact of their sheet structures on their physical behaviour.

The authors thank Dr J. L. de Boer for his help during the collection of the data, $\operatorname{Dr}$ G. A. Wiegers of the Department of Inorganic Chemistry, for taking the Guinier photographs, and Mr A. B. Verweij, who grew the crystals. The current interest and advice of Professor Dr A. Vos were very stimulating. The investigations were supported (in part) by the Netherlands Foundation for Chemical Research (SON) with financial aid from the Netherlands Organization for the Advancement of Pure Research (ZWO). The computations were carried out at the Computing Center of the University of Groningen.

#### Abstract

$\mathrm{C}_{6} \mathrm{H}_{14} \mathrm{NO}^{+} .2 \mathrm{C}_{12} \mathrm{H}_{4} \mathrm{~N}_{4}^{-1 / 2}$, $\mathrm{HEM}(\mathrm{TCNQ})_{2}$, is triclinic, space group $P 1$, with $a=14.177$ (2), $b=7.558$ (1), $c=13.427$ (2) $\AA, \alpha=92.29(2), \quad \beta=80.81$ (1), $\gamma=$ $105.68(1)^{\circ}, \quad U=1367 \AA^{3}, Z=2 ; d_{c}=1.275, d_{m}=$ $1.267 \mathrm{Mg} \mathrm{m}^{-3}$. Final $R_{w}(F)=0.071$ for 5291 independent reflections. The structure consists of sheets of TCNQ molecules parallel to (100), separated by HEM groups. Within the sheet TCNQ molecules, united in tetramers, form columns along c. Each tetramer is built up of two dimers related by an inversion centre. The distance between TCNQ molecules within a dimer is 3.23 (1) $\AA$; the intradimer overlap is of the ring-external-bond type. Within a tetramer the separation between the dimers is 3.31 (1) $\AA$, and between successive tetramers 3.42 (1) $\AA$, with overlaps of the shifted ring-ring and ring-external-bond type, respectively. At the HEM positions two randomly disordered molecules are found which differ in orientation. Their main conformational difference is the location of the ethyl $\mathrm{CH}_{3}$ group with respect to the ring. Owing to Coulomb interaction with the HEM molecules there is a localization of charge on the two symmetrically related inner TCNQ molecules of the tetramers.

## Introduction

This paper is one of a series of structural studies of $1: 2$ complexes of $N$-substituted morpholinium and TCNQ, carried out to obtain a structural basis for the discussion of the physical properties of these com-
pounds. The compounds investigated so far are $\operatorname{MEM}(\mathrm{TCNQ})_{2}$ at 113 K (MEM = 4-methyl-4-ethylmorpholinium; Bosch \& van Bodegom, 1977), $\mathrm{DEM}(\mathrm{TCNQ})_{2}$ at room temperature $(\mathrm{DEM}=4,4$ diethylmorpholinium; Morssink \& van Bodegom, 1981) and $\mathrm{DMM}(\mathrm{TCNQ})_{2}$ at room temperature ( $\mathrm{DMM}=4,4$-dimethylmorpholinium; Kamminga \& van Bodegom, 1981). In the present paper the X-ray study of $\mathrm{HEM}(\mathrm{TCNQ})_{2}$ at room temperature is described (HEM $=4$-ethylmorpholinium). Guinier photographs have shown that $\mathrm{HEM}(\mathrm{TCNQ})_{2}$ has one phase transition above room temperature ( $T_{c}=456 \mathrm{~K}$ ). Its magnetic behaviour at room temperature shows a strong analogy to that of MEM(TCNQ) 2 below its phase transition at 19 K (Huizinga, 1979).

## Experimental work

Dark violet crystals were grown from a mixture of hot solutions of 4-ethylmorpholinium iodide and TCNQ in acetonitrile. Table 1 gives the results of a chemical analysis of the crystals. Room-temperature cell constants were obtained by least squares from the $\sin ^{2} \theta / \lambda^{2}$ values of 235 reflections obtained from zero-layer

Table 1. Chemical analysis of $\mathrm{HEM}(T C N Q)_{2}$
