# 1-Isoquinolyl(phenyl)methanol 

By Ewa Skrzypczak-Jankun and Zygmunt Kaluski<br>Institute of Chemistry, Adam Mickiewicz University, Grunwaldzka 6, 60-780 Poznañ, Poland

(Received 28 July 1980; accepted 12 November 1980)

Abstract. $\mathrm{C}_{16} \mathrm{H}_{13} \mathrm{NO}, M_{r}=235 \cdot 3$, monoclinic, $P 2_{1} / c$, $a=7.875$ (1), $b=9.770(1), c=15.883$ (2) $\AA, \beta=$ $100.42(1)^{\circ}, V=1201.9 \AA^{3}, D_{x}=1.30 \mathrm{Mg} \mathrm{m}^{-3}, Z=$ $4, F(000)=496, \mu(\mathrm{Cu} \mathrm{Ka})=0.65 \mathrm{~mm}^{-1}$. The structure was solved by direct methods and refined with 1287 observed $\mathrm{Cu} K \alpha$ diffractometer data to $R=0.04$. Two molecules of 1 -isoquinolyl(phenyl)methanol are linked by bifurcated hydrogen bonds (intra- and intermolecular) forming dimers about centers of symmetry $\left(0, \frac{1}{2}, 0 ; 0,0, \frac{1}{2}\right)$ in the crystal. The $\mathrm{N} \cdots \mathrm{O}$ distances are 2.682 (2) and 2.974 (2) $\AA$ for the intra- and intermolecular interactions respectively. The mean $\mathrm{H} \cdots \mathrm{N}$ distance is 2.23 (4) $\AA$.
Introduction. This work is a continuation of our study of 1-isoquinolylcarbinols:

[^0]Crystals of the title compound (I $h$ ) suitable for X-ray analysis were obtained from ethanol solution. Reflections were collected on a Syntex $P 2_{1}$ diffractometer with graphite-monochromatized $\mathrm{Cu} K \alpha$ radiation within the range $2 \theta<116^{\circ}$, in a $2 \theta-\omega$ scan mode, at a scanning rate of $2^{\circ} \min ^{-1}$. The background and integrated intensity for each reflection were evaluated by a profile-analysis procedure (Lehmann \& Larsen, 1974). The intensities were corrected for Lorentz and polarization effects and for absorption from empirical $\varphi$-scan data. Of the 1641 independent reflections measured 1287 had $F_{o} \geq 3.92 \sigma\left(F_{o}\right)$ and were used in the subsequent calculations. The structure was solved by direct methods using MULTAN (Germain, Main \& Woolfson, 1971) and refined by the full-matrix leastsquares method. A difference Fourier synthesis revealed all the H atoms, including that of the hydroxyl group, which corresponded to the lowest peak on this map. Positional and isotropic temperature factors of all H atoms were included in the last cycles of refinement and allowed to vary. The final discrepancy factors are: $R=0.040$ and $R_{w}=0.043$. The function minimized was $\sum w\left|F_{o}-F_{c}\right|^{2}$, where $w=\left(F_{o} / 4 \cdot 75\right)^{2}$ for $F_{o}<4.75, w=1$ for $4.75 \leq F_{o} \leq 12 \cdot 25$, and $w=$ $\left(12 \cdot 25 / F_{o}\right)^{2}$ for $F_{o}>12 \cdot 25$. In the final cycle of

least-squares refinement only the $y$ coordinate of $\mathrm{H}(\mathrm{O})$ had a $\Delta / \sigma$ value different from zero ( $0 \cdot 02$ ). The final difference function was flat and featureless.

All calculations were performed on a NOVA 1200 computer with the program PRAN (Jaskólski, 1979) for profile analysis and the programs from XTL/ E-XTL Structure Determination System (Syntex, 1976). Final positional and thermal parameters are given in Table 1.*

Discussion. The atom-numbering system, bond distances and angles are given in Fig. 1. There is nothing abnormal about the bond lengths in the ring systems. The atoms of the isoquinolyl system are nearly coplanar, though with small but significant deviations (data for the best least-squares planes have been deposited).* The molecule is slightly bent around the

$\mathrm{C}(9)-\mathrm{C}(10)$ bond; the dihedral angle between planes defined by the pyridine and benzene rings from the isoquinoline is $0.7^{\circ}$. The molecular geometry of 1 -isoquinolyl(phenyl)methanol (Ih) is very similar to those observed for the ethyl carbonate of 1 -isoquinolyl(phenyl)methanol (Ia; Skrzypczak-Jankun \& Katuski, 1977) and 1 -isoquinolyl(phenyl)methyl benzoate (Ib; Skrzypczak-Jankun et al., 1979). However, the torsion angle $\mathrm{N}(2)-\mathrm{C}(1)-\mathrm{C}(11)-\mathrm{O}(1),-27.60(2)^{\circ}$, differs from the same angles obtained for structures ( $\mathrm{I} a$ ) and ( $\mathrm{I} b)\left(+12.8\right.$ and $+9.0^{\circ}$ respectively), which have bulky substituents $(R)$ at $\mathrm{O}(1)$. This is probably due to interactions between the neighboring molecules. In contrast to the structures (Ia), (Ib) and (Ic), this isoquinoline derivative ( $\mathrm{I} h$ ) has basic properties ( $\mathrm{pKa}=4 \cdot 1$; Rozwadowska, 1977) and possesses a hydroxyl group, which could act as a proton donor. The higher e.s.d.'s in the positional parameters, the large shifts in the $y$ direction during the refinement process, a relatively high $B_{\text {iso }}$ for the $\mathrm{H}(\mathrm{O})$ atom and the $\mathrm{O}-\mathrm{H}$ distance of 0.92 (4) $\AA$, as well as the short contacts $\mathrm{O} \cdots \mathrm{N}$ and $\mathrm{O} \cdots \mathrm{N}^{\prime}(-x,-y,-z)$, suggested that the H atom from the hydroxyl group is shared between the $\mathrm{N}, \mathrm{N}^{\prime}$ and O atoms.

A projection of the structure along $a$, illustrating the packing of the molecules, is shown in Fig. 2. It can be seen that the principal interaction is the formation of centrosymmetric dimers through hydrogen bonds involving $\mathrm{N}(2)$ from the isoquinoline moiety and the hydroxyl groups. Fig. 3 gives a detailed description of the hydrogen-bonded dimer. A similar situation was found in 1 -chloro- 3 -isoquinolinol, where the two molecules are linked together into a centrosymmetric dimer by hydrogen bonds, $\mathrm{N} \cdots \mathrm{O}=2 \cdot 83, \mathrm{~N} \cdots \mathrm{H}=$ $2.03 \AA, \angle \mathrm{NHO}=171^{\circ}$ (Ammon \& Wheeler, 1974). In 1-isoquinolyl(phenyl)methanol, apart from the intermolecular distance $\mathrm{N} \cdots \mathrm{O}=2.974$ (2) $\AA$, there is a short intra-annular contact, $\mathrm{N} \cdots \mathrm{O}=2 \cdot 682$ (2) $\AA$. The five-membered ring formed in this way prevents the interaction being as strong as in 5-hydroxy-1-(3-methyl-1-isoquinolyl)-3-phenylpyrazole, where the intra-annular bond through the six-membered ring has an $\mathrm{N} \cdots \mathrm{O}$ distance of $2.51 \AA$ (King \& Reimlinger,
1971). Nevertheless, the intra- and intermolecular $\mathrm{H} \cdot \mathrm{N}$ distances noted here, $2 \cdot 21$ (4) and $2 \cdot 24$ (4) $\AA$, are equal within the range of the experimental errors and are considerably shorter than the sum of the van der Waals radii. So, we can state that the interaction $\mathrm{O}-\mathrm{H}^{\circ} \cdot \cdots \mathrm{N} \cdot \mathrm{N}^{\prime} \cdot \cdots \cdot \cdot \mathrm{H}-\mathrm{O}^{\prime}$ observed in the crystal structure of 1 -isoquinolyl(phenyl)methanol is an interesting example of a bifurcated hydrogen bond.

# The Structure of 2-(2-Aminobenzoyl)benzoic Acid 

By Z. Skrzat and A. Roszak<br>Institute of Chemistry, N. Copernicus University, ul. Gagarina 7, 87-100 Toruń, Poland

(Received 28 July 1980; accepted 12 November 1980)

#### Abstract

C}_{14} \mathrm{H}_{11} \mathrm{NO}_{3}\), orthorhombic, $\mathrm{Pca}_{1}, a=$ $13.860(1), b=10.135(1), c=8.286$ (1) $\AA, Z=4$, $V=1163.9 \AA^{3}, D_{x}=1.38, D_{m}=1.37 \mathrm{Mg} \mathrm{m}^{-3}$, $F(000)=504$. The crystal structure was solved from diffractometer data by direct methods and refined by full-matrix least-squares procedures to an $R$ of 0.040 for 844 observed reflexions. The packing of the molecules in the crystals is stabilized by hydrogen bonds: $\mathrm{O}(15)-\mathrm{H}(11) \cdots \mathrm{O}(17)=2.663(21)$ and $\mathrm{N}(18)-\mathrm{H}(2) \cdots \mathrm{O}(16)=3.194(13) \AA$. An intramolecular hydrogen bond, $\mathrm{N}(18)-\mathrm{H}(1) \cdots \mathrm{O}(17)=$ $2 \cdot 690$ (8) $\AA$, is present.

Introduction. This determination of the crystal and molecular structure of 2-(2-aminobenzoyl)benzoic acid is a continuation of our studies on substituted 2 aroylbenzoic acids. Suitable crystals for X-ray analysis were kindly provided by Professor J. Gronowska of the Organic Chemistry Department of this University.

Crystal symmetry and approximate cell parameters were determined from rotation and Weissenberg photographs. Space group Pca2 ${ }_{1}$ or Pcam was deduced from systematic absences. On the basis of the distribution of normalized structure factors the noncentrosymmetric space group Pca2 ${ }_{1}$ was selected.

Accurate cell dimensions and intensities were measured on an automated Syntex $P 2_{1}$ four-circle

diffractometer, with $\mathrm{Cu} K \alpha$ radiation and a graphite monochromator. Reflexions were collected up to $2 \theta_{\max }$ $=116^{\circ} .844$ reflexions from the data set had $I>$
