# The Structure of Trichlorotris(tetrahydrofuran)titanium(III) 

By M. Handlovič, D. Mikloš and M. Zikmund<br>Institute of Inorganic Chemistry, Slovak Academy of Sciences, 80934 Bratislava, Czechoslovakia

(Received 16 May 1980; accepted 1 July 1980)

#### Abstract

$\mathrm{Ti}\left(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right)_{3} \mathrm{Cl}_{3}, \mathrm{C}_{12} \mathrm{H}_{24} \mathrm{Cl}_{3} \mathrm{O}_{3} \mathrm{Ti}$, crystallizes in space group $P 2_{1} / c$, with $a=17.63$ (5), $b=12.62$ (2), $c=$ 15.26 (3) $\AA, \beta=91.7$ (2) ${ }^{\circ}, Z=8$. Final $R=0.071$ for 2333 observed reflexions. The complex is neutral with octahedrally coordinated $\mathrm{Ti}^{1 I I}$ and meridional configuration of the Cl atoms. The two independent molecules in the asymmetric unit are similarly oriented, with the exception of the tetrahydrofuran ligands trans to Cl atoms.

## Introduction

Clark, Lewis, Machin \& Nyholm (1963) determined the space group and cell parameters of the complex. They called attention to the fact that the crystals must contain either four dimers or two sets of four monomers with different orientation of two independent molecules in the asymmetric unit. The magnetic data measured in the temperature range $77-300 \mathrm{~K}$ [ $\mu_{\text {eff }}$ (293 $\mathrm{K})=1.82 \mathrm{BM}, * \theta=-37 \mathrm{~K}]$ are in agreement with the monomeric structure and distorted octahedral coordination of the central $\mathrm{Ti}^{1 I I}$ atom (Zikmund, Valent, Hrnčiarová \& Kohútová, 1969; Zikmund, Kohútová, Handlovič \& Mikloš, 1979; see also close values 1.80 BM, Pregaglia, Mazzanti \& Morero, 1959; and 1.83 BM, Schläfer \& Götz, 1964). A diffuse reflectance spectrum, typical for this coordination, was observed (Clark, Lewis, Machin \& Nyholm, 1963; Zikmund \& Śtepničková, 1969; Zikmund, Kohútová, Handlovič \& Mikloš, 1979). From the number of modes active in the infrared it has been concluded that the tetrahydrofuran adduct $\mathrm{Ti}\left(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right){ }_{3} \mathrm{Cl}_{3}$ adopts the trans $\left(\mathrm{C}_{2 v}\right)$ configuration (Clark, 1965).

Investigation of thermal properties did not yield consistent results. Pregaglia, Mazzanti \& Morero (1959) observed only formation of $\mathrm{Ti}\left(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right)_{2} \mathrm{Cl}_{3}$, while Kern (1962) and Clark (1968) reported formation of $\mathrm{Ti}\left(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right) \mathrm{Cl}_{3}$. Our studies (Zikmund \& Stepničková, 1969), however, showed that in the course of thermal decomposition first the monomeric five-

$$
{ }^{*} 1 \mathrm{BM} \equiv 9.27 \times 10^{-24} \mathrm{JT}^{-1}
$$

coordinate complex $\mathrm{Ti}\left(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right)_{2} \mathrm{Cl}_{3}$ and then the coordination polymer $\mathrm{Ti}\left(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right) \mathrm{Cl}_{3}$ are formed.

## Experimental

Blue-green prismatic crystals of $\mathrm{Ti}\left(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right)_{3} \mathrm{Cl}_{3}$ were prepared by evaporating a tetrahydrofuran solution of the complex. Because of the extreme reactivity of the $\mathrm{Ti}^{\mathrm{III}}$ compounds with oxygen and moisture, all reactions and operations were carried out in an atmosphere of dry oxygen-free nitrogen. Suitable crystals were sealed in Lindemann-glass capillaries in an inert atmosphere (Zikmund \& Valent, 1969). The capillaries were then coated with lacquer containing a noncoordinating solvent. A suitable crystal was selected by rotation, Weissenberg and precession methods. Intensities were collected on a Syntex $P 2_{1}$ diffractometer with graphite-monochromated Mo $K \alpha$ radiation out to $2 \theta=45^{\circ}$ in the $\theta-2 \theta$ scan mode. Two check reflexions showed no significant change of intensity. 4103 independent reflexions were recorded; of these, 2333, for which $I_{h k l}>1.96 \sigma_{I}$, were considered to be observed. The data were corrected for Lorentz and polarization effects but not for absorption ( $\mu=0.99$ $\left.\mathrm{mm}^{-1}\right)$. Crystal data: $\mathrm{Ti}\left(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right)_{3} \mathrm{Cl}_{3} ; M_{r}=370 \cdot 58$; space group $P 2_{1} / c ; a=17.63$ (5), $b=12.62$ (2), $c=$ 15.26 (3) $\AA, \beta=91.7(2)^{\circ} ; V=3393.7 \AA^{3} ; Z=8$; $D_{c}=1.45, D_{m}$ (flotation method) $=1.45 \mathrm{Mg} \mathrm{m}^{-3}$; crystal size $0.3 \times 0.4 \times 0.6 \mathrm{~mm}$.

## Structure determination and refinement

A Patterson synthesis was calculated with all reflexions. The distribution of peaks around the origin indicates that the $\mathrm{Ti}^{\mathrm{III}}$ atoms are octahedrally coordinated, the two independent octahedra have the same orientation and the Cl atoms are in trans positions. The distribution of peaks at $y=0$ and $\frac{1}{2}$ showed that the

Table 1. Distribution of $E^{2}$ by parity groups

| eee | eoe | eoo | eeo | ooo | oee | oeo | ooe |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

octahedra are shifted approximately by $\mathbf{a} / 2$. Accordingly, the diffractions $h k l$ with $h=2 n+1$ are generally weaker than those with $h=2 n$, Table 1 .

Hence it was decided first to solve the fictitious superposition structure with $\mathbf{a}^{\prime}=\mathbf{a} / 2$ corresponding to the subset of diffractions with $h=2 n$ in the same space group $P 2_{1} / c$. The application of TANFOR (Drew \& Larson, 1968) confirmed the octahedral coordination of $\mathrm{Ti}^{1 \mathrm{II}}$ and showed its correct position out of two possibilities allowed by the Patterson synthesis. The superposition structure could be refined to $R=0 \cdot 18$. After a few unsuccessful trials to separate the two independent molecules in the true unit cell, MULTAN (Main, Woolfson \& Germain, 1975) was used with the 426 highest renormalized $E$ values to guarantee the presence of all parity groups. The calculation was stopped when a combination of phases for $h=2 n$ appeared to be identical with that for the superposition structure. The corresponding $E$ map showed the positions of 20 atoms and the next $F_{o}$ synthesis showed the correct positions of all non-hydrogen atoms.

The isotropic full-matrix least-squares cycles yielded $R=0 \cdot 13$. Anisotropic block-diagonal least-squares refinement lowered $R$ to 0.09 . At this stage H atoms with calculated positional parameters and thermal parameters of corresponding C atoms were included in the refinement. The final $R$ is 0.071 for 2333 observed reflexions, which appears to be satisfactory with respect to experimental difficulties. The final ( $F_{o}-F_{c}$ ) synthesis showed no significant features. The calculations were performed on a Syntex XTL system and a Siemens 4004/150 [Fourier synthesis program DRF (Zalkin, 1970); TANFOR (Drew \& Larson, 1968); NRC crystallographic programs (Ahmed, Hall, Pippy \& Huber, 1966)].*

## Results and discussion

The analysis confirmed that the complex is neutral. The asymmetric part of the unit cell contains two monomers of trichlorotris(tetrahydrofuran)titanium(III), Fig. 1. Atomic coordinates are listed in Table 2. Both $\mathrm{Ti}^{\mathrm{II}}$ atoms are octahedrally coordinated. The Cl atoms are in meridional configuration, their distances from the central atom being very similar, Table 3.

The distances $\mathrm{Ti}-\mathrm{O}$ are significantly longer for the O atoms that are trans to the Cl atoms $[2 \cdot 18$ (1) $\AA$ ] than for the remaining two O atoms [2.08 (1), 2.09 (1) and $2 \cdot 10$ (1), $2 \cdot 11$ (1) $\AA$ respectively]. It seems probable that these tetrahydrofuran molecules are released in the first step of the thermal decomposition, leaving

Each of the tetrahydrofuran ligands (Table 4) has a different degree of conformation. Only one of the six tetrahydrofuran rings (Fig. 2) has the envelope conformation, the others have a propeller-like form. If the plane through $\mathrm{O}(i j), \mathrm{C}(i j 1)$ and $\mathrm{C}(i j 4)$ is taken as the reference plane, the deviations of $\mathrm{C}(i j 2)$ and $\mathrm{C}(i j 3)$ from it and the torsion angles $\tau_{i j}[\mathrm{C}(i j 1)-\mathrm{C}(i j 2)-$ $\mathrm{C}(i j 3)-\mathrm{C}(i j 4)]$ may serve as a measure of the deformation of rings, Table 5. The bond lengths $\mathrm{O}-\mathrm{C}$ vary from 1.44 to $1.50 \AA$, the bond lengths $\mathrm{C}-\mathrm{C}$ from 1.39 to $1.52 \AA$. Similar variations in bond lengths for coordinated tetrahydrofuran rings were observed in $\mathrm{Sc}\left(\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right)_{3} \mathrm{Cl}_{3}$ (Atwood \& Smith, 1974). The angles $\varphi_{i j}$ between bonds $\mathrm{Ti}(i)-\mathrm{O}(i j)$ and the corresponding reference planes are rather small (from $2 \cdot 2$ to $11 \cdot 4^{\circ}$ ).

With respect to the bond lengths within coordination polyhedra it seems that packing conditions are mainly responsible for the variation of tetrahydrofuran rings as the most flexible part of the structure.

The authors thank Dr V. S. Kuzmin for help in using the XTL system.

# The Structures of the fac and mer Isomers of Trichlorotris[dimethyl(phenyl)phosphine]iridium(III) 

By Glen B. Robertson and Paul A. Tucker<br>Research School of Chemistry, The Australian National University, PO Box 4, Canberra, ACT, Australia 2600

(Received 25 March 1980; accepted 8 December 1980)

#### Abstract

The structure of the facial isomer of trichlorotris[dimethyl(phenyl)phosphine]iridium(III) has been determined, and that of the meridional isomer has been redetermined. $f a c$ - $\left[\mathrm{Ir}^{\mathrm{III}} \mathrm{Cl}_{3}\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{3}\right](1)$ crystallizes in space group $I a$ with $a=16 \cdot 198$ (2), $b=14.923$ (2), $c=22.024(2) \AA, \quad \beta=96.37(2)^{\circ}, \quad Z=8 . \quad$ mer$\left[\mathrm{Ir}^{\mathrm{III}} \mathrm{Cl}_{3}\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{3}\right]$ (2) crystallizes in space group $P 2_{1} / n \quad$ with $\quad a=10.814(1), \quad b=38.894$ (3), $\quad c=$ 13.663 (1) $\AA, \beta=107.15$ (1) ${ }^{\circ}, Z=8$. The structures were refined to $R=0.025[(1), 5471$ independent reflections] and 0.031 [(2), 12556 independent reflections]. Metal-ligand distances in (1) are $\mathrm{Ir}-\mathrm{Cl}$ 2.456 (2)-2.468(2) $\AA$ (trans to $P$ ) and $\mathrm{Ir}-\mathrm{P}$ 2.285 (2)-2.295 (2) $\AA$ (trans to Cl ). Metal-ligand distances in (2) do not differ significantly from those reported earlier but are more precise and reveal the existence of small differences between chemically equivalent bonds due to inequivalence of intramolecular non-bonding interactions. Values from this

experiment are: $\mathrm{Ir}-\mathrm{Cl} 2.434$ (1)- 2.439 (1) $\AA$ (trans to P ) and $2.359(1)-2.368$ (1) $\AA$ (trans to Cl ), $\mathrm{Ir}-\mathrm{P} \quad 2.278(1)-2.282(1) \AA$ (trans to Cl ) and 2.363 (1)-2.384 (1) A (trans to P ).

## Introduction

Recently, we have carried out a series of X-ray analyses (and in some cases neutron analyses) on the series of complexes $L_{3} \mathrm{H}_{(3-n)} \mathrm{Cl}_{n} \mathrm{Ir}^{\text {III }}$ ( $L=\mathrm{PMe}_{2} \mathrm{Ph}$, $n=0,1,2,3$ ). Clearly, metal-ligand bond lengths in such a series are not only a function of the primary ligand type $(\mathrm{Cl}, \mathrm{H}, L)$. Other determinants include the isomeric arrangement of the ligands (cis, trans, mer, $f a c$ ), the differing steric requirements of differing substituents ( Cl or H ), and differing bond compression and angle deformations due to changes in non-bonding interactions to the methyl and phenyl substituents of the phosphine ligands (as the $\mathrm{PMe}_{2} \mathrm{Ph}$ configurations alter). The present series of experiments are intended to © 1981 International Union of Crystallography
