# The Structure of Antimony(III) Phosphite 

By J. Loub<br>Department of Inorganic Chemistry, Charles University, Albertov 2030, 12840 Praha 2, Czechoslovakia<br>and H. Paulus<br>Institut für Physikalische Chemie, Technische Hochschule, Petersenstrasse 20, 61 Darmstadt, Federal Republic of Germany

(Received 15 November 1980; accepted 8 December 1980)

#### Abstract

Sb}_{2}\left(\mathrm{HPO}_{3}\right)_{3}, \quad P \overline{1}, \quad a=9.182(1), \quad b=\) 8.353 (1), $\quad c=7.220$ (1) $\AA, \quad a=68.21$ (1), $\quad \beta=$ $79.52(1), \gamma=66.47(1)^{\circ}$ at $297 \mathrm{~K}, Z=2, D_{o}=$ 3.33 (4) at $296 \mathrm{~K}, D_{c}=3.41 \mathrm{Mg} \mathrm{m}^{-3} . R=0.020$ for 2150 reflexions. The structure consists of isolated $\mathrm{HPO}_{3}$ tetrahedra and Sb atoms coordinated to four O atoms.

Introduction. The title compound was studied as part of an investigation of phosphites. Reaction of antimony trioxide with a concentrated aqueous solution of phosphorous acid ( $3.5 \mathrm{mmol} \mathrm{Sb} \mathrm{O}_{3}, 30-150 \mathrm{mmol}$ $\mathrm{H}_{3} \mathrm{PO}_{3}$, and water to 15 ml ) gave a voluminous precipitate from which, after standing for more than one year at 298 K , brownish crystals of the title compound were obtained (Vojtišek, 1979), with well developed faces $\{100\}$ and $\{011\}$ of maximum prism dimensions $0.3 \times 0.3 \times 0.5 \mathrm{~mm} .4428$ intensities were collected ( $\omega / 2 \theta$ scan) in the range $3 \leq 2 \theta \leq 55^{\circ}$ from a crystal of volume $0.0157 \mathrm{~mm}^{3}$ on a Stoe four-circle diffractometer with graphite-monochromated Mo Ka radiation ( $\lambda=0.71069 \AA$ ). 2163 reflexions were unique; those with $F<2 \sigma(F)$ were treated as unobserved. The remaining 2150 reflexions were corrected for Lp and absorption effects ( $\mu=6.24 \mathrm{~mm}^{-1}$ ).

The cell dimensions were determined by least squares from the $2 \theta$ angles of 40 reflexions measured on the same instrument. The positions of the non-H atoms were obtained by direct methods and refined by least squares to $R=\sum| | F_{n}\left|-\left|F_{c}\right|\right| / \sum\left|F_{o}\right|=0.056$ with isotropic temperature factors. Further cycles with anisotropic temperature factors gave $R=0.020$ and $R_{w}=\left[\sum w\left(\left|F_{o}\right|-\left|F_{c}\right|\right)^{2} / \sum w\left|F_{o}\right|^{2}\right]^{1 / 2}=0.019$ with
weights based on counting statistics. A difference map showed no electron density maximum $>1 \cdot 1 \mathrm{e} \AA^{-3}$. The H atoms were placed in optimum tetrahedral positions with $\mathrm{P}-\mathrm{H}=1.38 \AA$ and $U=0.02 \AA^{2}$. The final $R$ and $R_{w}$ values were 0.020 and 0.019 . A final difference map showed no residual electron density $>0.7 \mathrm{e}^{-3}$. Scattering factors for neutral atoms were taken from International Tables for X-ray Crystallography (1974). All calculations were performed with SHELX 76 (Sheldrick, 1976), modified for use on a small computer (Data General Nova 3).

Discussion. Final atomic parameters are given in Table 1.* The more important interatomic distances, bond angles and the symmetry code are given in Table 2. A projection of the structure in the $X Y$ plane is depicted in Fig. 1. $\mathrm{Sb}(1), \mathrm{Sb}(2), \mathrm{Sb}\left(1^{1}\right)$ and $\mathrm{Sb}\left(2^{1}\right)$ form a slightly distorted parallelogram. $\mathrm{The} \mathrm{Sb}-\mathrm{O}$ distances show that eight out of nine phosphite O atoms are relatively strongly coordinated to two Sb atoms. O (33), with the shortest $\mathrm{P}-\mathrm{O}$ distance, is uncoordinated. The coordination polyhedron of Sb is trigonal bipyramidal with one of the equatorial corners occupied by the lone pair of electrons. The means of the shorter equatorial

(iii) $x, 1+y, 1-z$
(iv) $1-x, 1-y, 1-z$

Fig. 1. Projection of the structure in the $X Y$ plane.
distances and the angles are $2.02 \AA$ and $86.0^{\circ}$; the means of the longer axial distances and the angles are $2.18 \AA$ and $159.4^{\circ}$. The other O atoms are at distances $>2.47 \AA$. The distances and angles in the bipyramids agree with literature data (Bovin, 1976).

The average $\mathrm{P}-\mathrm{O}$ distance, 1.52 (2) $\AA$, and the average $\mathrm{O}-\mathrm{P}-\mathrm{O}$ angle, $111(3)^{\circ}$, also agree with literature data, e.g. for $\mathrm{Na}_{2} \mathrm{HPO}_{3} .5 \mathrm{H}_{2} \mathrm{O}$ (Brodalla, Goeters, Kniep, Mootz \& Wunderlich, 1978), $\mathrm{CuHPO}_{3} .2 \mathrm{H}_{2} \mathrm{O}$ (Handlovič, 1969) or $\mathrm{MgHPO}_{3} .6 \mathrm{H}_{2} \mathrm{O}$ (Corbridge, 1956). The longest intramolecular $\mathrm{O}-\mathrm{O}$ distance is $2.569 \AA$ [ $\mathrm{O}(11)-\mathrm{O}(12)]$, the shortest intermolecular $\mathrm{O}-\mathrm{O}$ distance is $2.631 \AA\left[\mathrm{O}(13)-\mathrm{O}\left(31^{1}\right)\right]$.

We thank Professors M. Ebert, W. Haase and E. Wölfel for making the work possible.
