

Fig. 2. Projection of the crystal structure along the $c$ axis. Broken lines indicate hydrogen bonds.

The positions of the H atoms do not allow the formation of an intramolecular hydrogen bond between the two OH groups in the cis position.

In the crystal (Fig. 2), the molecules are fully hydrogen bonded. Each hydroxyl group is involved in two linear hydrogen bonds to symmetry-related molecules. $\mathrm{O}(1)$ is the donor to $\mathrm{O}(2)$ across the diad axis $\quad[\mathrm{O}(1) \cdots \mathrm{O}(2) \quad 2 \cdot 85, \quad \mathrm{H}(1) \cdots \mathrm{O}(2) \quad 2.15 \AA$, $\mathrm{O}(1) \cdots \mathrm{H}(1) \cdots \mathrm{O}(2) 163^{\circ}$, giving rise to dimeric molecules which are bonded helically, via the $\mathrm{O}(2)$
donor bonds, along the screw axes $\mid \mathrm{O}(1) \cdots \mathrm{O}(2) 2 \cdot 86$, $\mathrm{H}(2) \cdots \mathrm{O}(1) 2.00 \AA, \mathrm{O}(1) \cdots \mathrm{H}(2) \cdots \mathrm{O}(2) 162^{\circ} \mathrm{J}$. The packing distances fall within the normal range except for the $\mathrm{S}(1)$ atom which is involved in a rather short intermolecular contact $\mid \mathrm{S}(1)(x, y, z) ; \mathrm{S}(1)\left(x-y,-y, \frac{2}{3}-\right.$ z) | of $3.37 \AA$, which is well below the sum of the van der Waals radii ( $3.7 \AA$ ).

# Structure of p-Hydroxyephedrine Hydrochloride 

By J. K. Dattagupta, Rekha R. Pattanayek and N. N. Saha Crystallography and Molecular Biology Division, Saha Institute of Nuclear Physics, 92 APC Road, Calcutta 700009, India

(Received 31 October 1980; accepted 9 February 1981)

Abstract. $\mathrm{C}_{10} \mathrm{H}_{15} \mathrm{NO}_{2} \cdot \mathrm{HCl}, M_{r}=217 \cdot 7$, orthorhombic, $P 2_{1} 2_{1} 2_{1}, a=6.388(3), b=7.555(3), c=$ 23.854 (5) $\AA, V=1151.23 \AA^{3}, Z=4, D_{m}=1 \cdot 26$, $D_{c}=1.26 \mathrm{Mg} \mathrm{m}^{-3}, \lambda(\mathrm{Cu} K \alpha)=1.5418 \AA, \mu(\mathrm{Cu} K \alpha)=$ $2.773 \mathrm{~mm}^{-1}$. The structure was solved by direct methods and refined to an $R$ value of 0.047 for 1088 diffractometer data using block-diagonal least-squares methods. The ethylamine side chain is in the extended form, the $\mathrm{C}-\mathrm{C}-\mathrm{C}-\mathrm{N}^{+}$torsion angle being $178 \cdot 1^{\circ}$. The mean plane through these atoms makes an angle of $81 \cdot 1^{\circ}$ with the plane of the phenol ring. The distance of the amino N atom from the centre of the phenyl ring is $5 \cdot 16 \AA$. The crystal structure is stabilized by a network
of $\mathrm{N}-\mathrm{H} \cdots \mathrm{Cl}, \mathrm{O}-\mathrm{H} \cdots \mathrm{Cl}$ and $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds.

Introduction. $p$-Hydroxyephedrine, $p$-hydroxy- $\alpha-[1-$ (methylamino)ethyllbenzyl alcohol, a sympathomimetic amine, pharmacologically resembles $p$-aminoephedrine which is about twice as active, and half as toxic, as ephedrine (McLean, 1960). Since such biogenic amines are found to assume a favoured conformation (Carlström, Bergin \& Falkenberg, 1973), it was thought worthwhile to determine the crystal structure of $p$-hydroxyephedrine hydrochloride.
(C) 1981 International Union of Crystallography

Single crystals were grown by slow evaporation of an aqueous solution of the title compound. The unit-cell dimensions were first determined from rotation and Weissenberg photographs and later more accurately on a Stoe four-circle single-crystal diffractometer using Cu $K \propto$ radiation. Systenatic absences indicate the space group $P 2_{1} 2_{1} 2_{1}$.

X-ray intensities were collected using a crystal of dimensions $0.10 \times 0.15 \times 0.35 \mathrm{~mm}$ in the $2 \theta / \omega$ scan mode on an automated Stoe diffractometer and corrected for geometrical factors but not for absorption. Altogether 1093 reflections were measured and three check reflections monitored every 100 measurements showed no significant change in intensity. The structure was solved with MULTAN (Main, Germain \& Woolfson, 1970). Full-matrix isotropic refinement and block-diagonal anisotropic refinement converged at $R=\sum| | F_{o}\left|-\left|F_{c}\right|\right| / \sum\left|F_{o}\right|=0 \cdot 10$ for all 1093 measured data. The function minimized was $\sum w\left(\left|F_{o}\right|-\left|F_{c}\right|\right)^{2}$ with $w=1 / \sigma^{2}(F)$. Scattering factors were taken from International Tables for X-ray Crystallography (1974). H atoms were located at this stage from a difference Fourier map, utilizing stereochemical considerations as an additional aid. They were assigned fixed isotropic thermal parameters of $4.0 \AA^{2}$, and their locations were not varied; the non- H atoms, however, were refined anisotropically. A prominent extinction effect was observed at this stage for five reflections and these were excluded from subsequent refinement which was stopped when the average parameter shifts were less than their standard deviations; the last cycle gave an $R$ value of 0.047 for 1088 reflections. The positional parameters of the atoms along with their e.s.d.'s are given in Table 1.*

Discussion. The intramolecular bond distances and angles are listed in Table 2. The numbering scheme is indicated in Fig. 1. The individual values for intramolecular bond lengths and angles are normal and do not show any remarkable deviation from the average model (Hebert, 1979) obtained by averaging pertinent bond lengths and angles for 34 similar compounds. The aromatic $\mathrm{C}-\mathrm{C}$ bond distances in the molecule vary from 1.381 to $1.399 \AA$, the average being $1.392 \AA$. The $\mathrm{C}(8)-\mathrm{N}$ and $\mathrm{C}(10)-\mathrm{N}$ bond distances are larger than the corresponding values in similar compounds but are not significantly different from a standard $\mathrm{C}-\mathrm{N}^{+}$bond length $1.505 \AA$ (Hahn, 1957). An observation to be noted is the slightly distorted tetrahedral arrangement around the $\mathrm{C}(7), \mathrm{C}(8)$ and N atoms with significant deviation of the angles $\mathrm{O}(2)-\mathrm{C}(7)-\mathrm{C}(8), \mathrm{C}(7)-\mathrm{C}(8)-$ $\mathrm{C}(9), \mathrm{C}(7)-\mathrm{C}(8)-\mathrm{N}$ and $\mathrm{C}(8)-\mathrm{N}-\mathrm{C}(10)$ from $109^{\circ}$. A comparison of some relevant intramolecular angles in various ephedrine structures is made in Table 3 and it is interesting that similar distortions [angles $\mathrm{O}(2)-\mathrm{C}(7)-$ $C(8), C(7)-C(8)-N$ are smaller and angles $C(7)-$ $\mathrm{C}(8)-\mathrm{C}(9), \mathrm{C}(8)-\mathrm{N}-\mathrm{C}(10)$ are larger than standard values) are present in nearly all the ephedrine compounds studied so far. Interactions between neighbouring groups may be responsible for such deviations.

References: (1) Present study; (2) Bergin (1971); (3) Hearn \& Bugg (1972); (4) Mathew \& Palenik (1977); (5) Hearn, Freeman \& Bugg (1973); (6) Hebert (1979).

Atoms $\mathrm{O}(1)$ and $\mathrm{C}(7)$ are on the same side of the least-squares plane of the benzene ring and a similar observation has been made in the case of tyramine hydrochloride (Podder, Dattagupta \& Saha, 1979) and octopamine hydrochloride (Paxton \& Hamor, 1977) which also have a hydroxy group attached to the phenyl ring at the para position. The ethylamine side chain is coplanar and is in the extended form and the dihedral angle between this plane and the plane of the phenyl ring is $81 \cdot 1^{\circ}$. The conformation can be described in terms of the torsion angles in Table 4. The $\mathrm{O}(2)-\mathrm{C}(7)-\mathrm{C}(8)-\mathrm{N}$ torsion angle is $-59.7^{\circ}$ which is a common conformation for $\mathrm{O}-\mathrm{C}-\mathrm{C}-\mathrm{N}^{+}$groupings (Paxton \& Hamor, 1977).
The distance, $D_{\mathrm{N}}$, of the N atom from the centre of the ring is $5 \cdot 16 \AA$. In other similar biologically active amines $D_{\mathrm{N}}$ has been found to be around $5 \AA$ (Hebert, 1979; Post \& Kennard, 1974; Giesecke, 1973) and this appears to be a significant requirement for a compound to have sympathomimetic property. Hydrogen-bond distances are given in Table 5. Molecules and their packing within the unit cell as viewed down $\mathbf{b}$ are shown in Fig. 1. All the four H atoms available for hydrogen-
