magnetic moment. As we did not succeed in locating the H atom, we do not know whether the $\pi$ bond is actually formed by the $d_{x y}$ or $d_{x z}$ AO's, although the observed deformations in the coordination polyhedron seem to indicate that the last AO is more probably used. In fact the greater repulsion exerted by oxygen towards the P atoms, which could not be explained by the balance of the intramolecular contacts, can be understood in terms of increased angular space occupied by the $\pi \mathrm{MO}$ in the $\mathrm{P}(1)-\mathrm{Re}-\mathrm{P}(2)$ plane.

A comparison of the $\mathrm{Re}-\mathrm{P}$ and $\mathrm{Re}-\mathrm{Cl}$ distances observed in the present compound with those found in oxo complexes of $\mathrm{Re}^{\mathrm{v}}$ is reported in Table 4. The mean $\mathrm{Re}-\mathrm{P}$ distance of $2.47 \AA$ agrees well with that observed in the other molecules studied, with the exception of $\left[\mathrm{ReOCl}_{2}\left(\mathrm{PPh}_{3}\right)(\mathrm{acac})\right]$, where this distance was found significantly shorter ( $2.43 \AA$ ). The $\mathrm{Re}-\mathrm{Cl}$ distances deserve more attention. Data of Table 4 show that $\mathrm{Re}-\mathrm{Cl}$ distances are systematically longer when the Cl atom is trans to a ligand known to exert a relevant trans influence (like thiourea or $\mathrm{P} R_{3}$ ) and that a similar lengthening of the $\mathrm{Re}-\mathrm{Cl}$ bond trans to the multiply bonded O atom is observed in the compound under examination. However, whether or not such an effect can be interpreted in terms of trans weakening remains controversial, as Bright \& Ibers (1969) believe that the weakening of bonds trans to multiply bonded nitrido or imino ligands is essentially caused by steric repulsion of other ligands, while Shustorovich, PoraiKoshits \& Buslaev (1975) uphold with theoretical arguments and structural data the point of view of a true trans influence exerted by a multiple metal-ligand bond.

The authors thank Professor L. Magon (University of Ferrara, Italy) for helpful discussions and Mr G. Bertocchi for technical assistance. This work has been financially supported by the CNR (Rome).

#### Abstract

$\mathrm{C}_{16} \mathrm{H}_{16} \mathrm{ClN}_{2} \mathrm{O}_{3} \mathrm{Re}, M_{r}=505.9$, is monoclinic, space group $I 2 / c ; a=20.731(4), b=11.949$ (3), $c=$ 13.578 (3) $\AA, \beta=94.13(2)^{\circ}, Z=8, D_{c}=2.00 \mathrm{Mg}$

0567-7408̄/82/010100-05\$01.00
$\mathrm{m}^{-3}, \mu(\mathrm{Mo} K \bar{\alpha})=7.08 \mathrm{~mm}^{-1}$. The crystal structure has been determined and refined to an $R$ value of 0.028 for 2767 observed reflections. The coordination around the Re atom is approximately octahedral. The two bidentate ligands are mutually orthogonal and the oxygen of © 1982 International Union of Crystallography
one of them is trans to the multiply bonded $\mathrm{O}_{0 \times 0}$ atom. The reasons for this arrangement are discussed in terms of the trans influence of the $\mathrm{Re} \equiv \mathrm{O}$ bond.

## Introduction

$\mathrm{Re}^{\mathrm{v}}$ is known to give three different classes of complexes with multiple $\mathrm{Re}-X$ bonds, i.e. nitrido-, imino- and oxo-rhenium derivatives. In all these compounds $\mathrm{Re}-X$ stretching frequencies, magnetic properties, X-ray-determined bond distances and AO symmetry considerations seem to agree in indicating the formation of a strong triple $\mathrm{Re} \equiv X$ bond. Recently some of us have been interested (Mazzi, Roncari, Rossi, Bertolasi, Traverso \& Magon, 1980) in the reaction of $\left[\mathrm{ReOX}_{3}\left(\mathrm{P}_{3}\right)\right](X=\mathrm{Cl}$ or Br$)$ with substituted salicylideneimine ' $R$-salH' $(R=\mathrm{Me}, \mathrm{Ph})$ and have shown that the reaction leads to two different classes of oxo derivatives of $\mathrm{Re}^{\mathrm{v}}$, having the formula $\left[\mathrm{ReO} X_{2}\left(\mathrm{PR}_{3}\right)\left(R\right.\right.$-sal)] or $\left[\mathrm{ReOX}(R \text {-sal })_{2}\right]$ and whose configurations were determined mainly by IR and ${ }^{1} \mathrm{H}$ NMR spectroscopy. At the same time the crystalstructure determinations of some of them were undertaken and the present paper reports the structure of $\left[\mathrm{ReOCl}(N \text {-methylsalicylideneiminato })_{2}\right]$ \{hereafter $\left.\left[\mathrm{ReOCl}(\mathrm{Me}-\mathrm{sal})_{2}\right]\right\}$, which belongs to the class of the $\left[\mathrm{ReO} X(R \text {-sal) })_{2}\right.$ ] derivatives. No other crystal structure has been reported so far in this class of compounds, while a single structure determination is known of compounds having the general formula [ $\mathrm{ReO} X_{2}\left(\mathrm{PR}_{3}\right)$ ( $R$-sal)], namely that of $\left[\mathrm{Re}_{2} \mathrm{O}_{2} \mathrm{Cl}_{4}\left(\mathrm{PPh}_{3}\right)_{2}\right.$ (salen)] (Bombieri, Mazzi, Gilli \& Hernández-Cano, 1978). In this complex the 'salen' ligand [salen $=N, N$ '-ethylenebis(salicylideneiminato)] was found to bridge two Re atoms which present a distorted octahedral coordination with the $\mathrm{O}_{\text {oxo }}$ trans to the O of the ligand itself.

It will be shown here that this configuration $\left(R-\mathrm{O}^{-}\right.$ trans to $\mathrm{O}_{\mathrm{oxo}}$ ) is the most common in this class of complexes and can be justified on the grounds of simple theoretical arguments and, moreover, that the deformations from the octahedral coordination are not casual but follow a general scheme, which is common to $\mathrm{Re}^{\mathrm{v}}$ nitrido complexes.

## Experimental

Intensity data have been collected by means of an automatic Siemens AED diffractometer using Zr filtered Mo $K \alpha$ radiation and an $\omega / 2 \theta$ scan technique ( $\theta$ $\leq 26^{\circ}$ ). The dimensions of the crystal used were $0.4 \times$ $0.1 \times 0.1 \mathrm{~mm}$ in the [001], [110] and [110] directions respectively. Out of 3290 reflections measured, 2767 having $I_{o} \geq 3 \sigma\left(I_{o}\right)$ were used in the refinement. Irradiated crystals were stable during the data-collection time. Polarization and Lorentz corrections were

applied as usual; absorption correction was applied by geometrical methods. Scattering factors were taken from International Tables for X-ray Crystallography (1974) and computations were mainly carried out by means of the SHELX 76 (Sheldrick, 1976) system of crystallographic programs.

The structure was solved by Patterson and Fourier methods, and refined by full-matrix least squares with anisotropic temperature factors for all the non- H atoms. H atoms were assigned calculated positions ( $\mathrm{C}-\mathrm{H}$ bond length of $1.08 \AA$ ) and isotropic temperature factors $10 \%$ greater than the average $U_{i i}$ 's of the bonded atoms. Weights were given according to the scheme $k_{1} / w=\sigma^{2}\left(F_{o}\right)+k_{2}\left|F_{o}\right|^{2}$, were $k_{1}$ and $k_{2}$ are constants to be determined. In the last cycle $R(=$ $\left.\sum|\Delta| / \sum\left|F_{o}\right|\right)$ and $R_{w}\left[=\left(\sum|\Delta|^{2} / \sum w\left|F_{o}\right|^{2}\right)^{1 / 2}\right]$ were respectively 0.028 and 0.038 . It may be of interest to remark that the geometrical absorption correction reduced $R$ from 0.049 to its current value ( 0.028 ). Final values of the positional parameters and $U_{\text {eq }}$ (Hamilton, 1959) are given in Table 1.*

## Discussion

The structure consists of a van der Waals packing of single molecules without significantly short inter-

[^0]molecular contacts. An ORTEP (Johnson, 1971) view of the molecule is shown in Fig. 1 and bond distances and angles are reported in Table 2.

Fig. 1. An ORTEP (Johnson, 1971) view of the molecule showing the thermal ellipsoids at $40 \%$ probability.

The coordination around the Re atom is approximately octahedral and a stereographic projection of the coordination polyhedron with the $\mathrm{O}_{\text {oxo }}$ located at the south pole is reported in Fig. 2. It shows that the two chelate rings are almost mutually orthogonal, one ligand bridging an equatorial and an apical position and the other two equatorial ones. Accordingly the molecule is chiral and both enantiomers are contained in the centrosymmetric crystal. That shown in Fig. 1 corresponds to the $\Lambda$ absolute configuration.

Re, $N(1)$ and $N(2)$ define a plane which is nearly equatorial, the angle between this plane and the $\mathrm{Re}-\mathrm{O}_{\text {oxo }}$ line being actually $88 \cdot 0^{\circ}$. The Cl and $\mathrm{O}(3)$ atoms are out of the plane by 0.32 and $0.43 \AA$ respectively and the $\mathrm{Re}-\mathrm{O}(2)$ line is displaced from its normal by $10 \cdot 0^{\circ}$. It is seen that $\mathrm{O}(1)$ repels the cis ligands in the order $\mathrm{O}(3)>\mathrm{Cl}>\mathrm{N}(1) \simeq \mathrm{N}(2)$. The $\mathrm{O}(3)$ and Cl atoms, which are pushed upwards out of the equatorial plane, displace the $\mathrm{O}(2)$ atom from the vertical, causing a compression field which reduces the bite of the ligand bridging the equatorial and apical positions, as can be seen from the $O(2)-N(1)$ distance of $2.720(4) \AA$ and $\mathrm{O}(2)-\mathrm{Re}-\mathrm{N}(1)$ angle of $83 \cdot 1(2)^{\circ}$, when compared with the corresponding values for the other ligand, 2.933 (4) $\AA$ and 91.4 (2) ${ }^{\circ}$ respectively. The different repulsion exerted by $O(1)$ on the equatorial atoms cannot be accounted for on the grounds of the sums of the van der Waals radii (Bondi, 1964) of the neutral atoms; in fact such a sum is 0.36 and $0.42 \AA$ greater than the intramolecular contact distances for $\mathrm{O}(1)-\mathrm{N}(1)$ and $\mathrm{O}(1)-\mathrm{N}(2)$, while it is only 0.17 and $0.12 \AA$ greater for $\mathrm{O}(1)-\mathrm{O}(3)$ and $\mathrm{O}(1)-\mathrm{Cl}$ respectively.

Nevertheless, the observed deformation is not accidental and data of Table 3 show that the $\mathrm{O}_{\mathrm{oxo}}-$ $\mathrm{Re}-X_{\text {cis }}$ angle is systematically larger for $X=\mathrm{O}^{-}$or $\mathrm{Cl}^{-}$than for $X=\mathrm{P}$ or N and that a similar effect occurs in octahedral or square-pyramidal $\mathrm{Re}^{\mathrm{v}}$ nitrido complexes. To all appearances the $\pi$ electron density associated with the multiple $\mathrm{Re} \equiv \mathrm{O}$ or $\mathrm{Re} \equiv \mathrm{N}$ bond repels more ligands connected by formally covalent $L^{-}: \rightarrow M^{+}$than donor-acceptor $L: \rightarrow M$ bonds and this could be interpreted in terms of increased steric

Fig. 2. Stereographic projection of the coordination polyhedron. The $\mathrm{O}_{\mathrm{oxo}}$ is located at the south pole.

* Angle possibly affected by the small bite of the ligand bridging the equatorial and apical positions.
hindrance of the more electronegative substituents in consequence of the increased population of their orbitals.

It has to be remarked that the model given here for the distortion of the coordination polyhedron is widely inconsistent with the model proposed by Bright \& Ibers (1969), who suggested that the stereochemical configurations of this class of compounds were mainly determined by intramolecular packing forces. However, two main criticisms can be made of this latter theory. First, it is prevalently based on structures of overcrowded molecules, where steric effects likely override any other factor and, secondly, it leads to a purely steric explanation of the lengthening of the $\mathrm{Re}-L$ bond trans to the multiply bonded ligand which, as will be shown later, does not fit all the experimental data.

Neither 'Me-sal' ligand is planar. Atoms $\mathrm{C}(1)-$ $C(7)$ define a plane ( $\chi^{2}=8.0$ ), from which the $O(2)$, $\mathrm{N}(1)$ and $\mathrm{C}(8)$ atoms are displaced by 0.04 , -0.14 and $-0.08 \AA$ respectively; the Re atom is out of this plane by $-0.47 \AA$. A similar plane through the other ligand [atoms $\mathbf{C}(9)-\mathrm{C}(15)$ ] has a $\chi^{2}$ as large as 173 and the $\mathrm{O}(3), \mathrm{N}(2), \mathrm{C}(16)$ and Re atoms are displaced from it by $0.05,-0.09,-0.38$ and $0.33 \AA$ respectively.

The most important bond distances are reported in Table 3, together with the corresponding values found in other similar complexes of $\mathrm{Re}^{\mathrm{v}}$.

The $\mathrm{Re}-\mathrm{Cl}$ distance of 2.399 (2) $\AA$ is somewhat longer than that observed in other oxo complexes in the absence of a trans influence ( $2.36 \pm 0.02 \AA$ ). The $\mathrm{Re}-\mathrm{O}$ (1) distance is 1.680 (4) $\AA$; it agrees with the values found in other oxo complexes of $\mathrm{Re}^{\mathrm{v}}$ and is, by itself, indicative of triple bonding, as the $\mathrm{Re}-\mathrm{O}$ single-bond distance is found to be in the range $1.90-2 \cdot 10 \AA$, and that of a double bond, determined only once in $\left[\operatorname{Re}(\mathrm{IV})(\mathrm{OH}) \mathrm{Cl}_{3}\left(\mathrm{PPhEt}_{2}\right)_{2}\right]$ (Sacerdoti,

Bertolasi, Gilli \& Duatti, 1982), is 1.795 (4) $\AA$. The most convincing proof of the existence of a real triple $\mathrm{R} \equiv \mathrm{O}$ bonding in $\mathrm{Re}^{\mathrm{V}}$ octahedral oxo complexes is given, however, by their magnetic properties. In fact, the $\pi$ overlapping of two of the $t_{2 g}$ orbitals with the two doubly filled $p_{x}$ and $p_{y}$ AO's of the oxygen (if the $z$ axis is pointing in the $\mathrm{Re}-\mathrm{O}$ direction), giving a total of two bonding, one non-bonding and two antibonding orbitals occupied by six electrons, remains the best way for explaining the diamagnetism of the $d^{2} \mathrm{Re}^{\mathrm{v}}$ complexes.

The single bond $\mathrm{Re}-\mathrm{O}[\mathrm{Re}-\mathrm{O}(2)=1.979$ (4) and $\mathrm{Re}-\mathrm{O}(3)=1.995(4) \AA]$ and $\mathrm{Re}-\mathrm{N}$ distances $[\operatorname{Re}-\mathrm{N}(1)=2 \cdot 120(5)$ and $\operatorname{Re}-\mathrm{N}(2)=2 \cdot 103$ (5) $\AA]$ are in good agreement with those reported in Table 3. The $\operatorname{Re}-\mathrm{N}$ bond is significantly longer than the $\mathrm{Re}-\mathrm{O}$ bond (on average $0 \cdot 12 \AA$ ) and this effect is known to occur only in complexes of metal ions in high oxidation state, e.g. $\left[\mathrm{Ti}(\mathrm{IV}) \mathrm{Cl}_{2}(\right.$ salen $\left.)\right]$ (Gilli, Cruickshank, Beddoes \& Mills, 1972), $[\mathrm{Fe}(\mathrm{III}) \mathrm{Cl}($ salen $)]$ (Gerloch \& Mabbs, 1967) and $\left[\mathrm{Re}_{2}(\mathrm{~V}) \mathrm{O}_{2} \mathrm{Cl}_{4}\left(\mathrm{PPh}_{3}\right)_{2}\right.$ (salen)] (Bombieri et al., 1978), where the difference between the $M-\mathrm{N}$ and $M-\mathrm{O}$ bonds is $0.25,0.20$ and $0.22 \AA$ respectively; it can be understood in terms of Pearson's hard-soft acid-base theory (Pearson, 1963), as hard Lewis acids $\mathrm{Re}^{\mathrm{V}}, \mathrm{Ti}^{\mathrm{IV}}$ and $\mathrm{Fe}^{\mathrm{II} \mathrm{I}}$ must form stronger bonds with oxygen rather than with the comparatively softer base nitrogen.

The fact that the $\mathrm{Re}-\mathrm{O}(2)$ bond, which is trans to the oxo ligand, is slightly shorter than the cis $\mathrm{Re}-\mathrm{O}(3)$ bond definitely excludes trans weakening due to the strong $\pi$ bonding of the oxo group. This was observed also in $\left[\mathrm{Re}_{2} \mathrm{O}_{2} \mathrm{Cl}_{4}\left(\mathrm{PPh}_{3}\right)_{2}\right.$ (salen) $]$ (Bombieri et al., 1978) and is in apparent agreement with Bright \& Ibers (1969) theory that trans lengthening in this class of compounds can be observed only in the case of relevant steric hindrance of the cis ligands. This theory, however, is unable to explain why in all known quasi-octahedral $\mathrm{Re}^{\mathrm{v}}$ oxo complexes with oxygenated
bidentate ligands (see Table 3) the $R-\mathrm{O}^{-}$group has been found to be trans to the $\mathrm{Re} \equiv \mathrm{O}_{\text {oxo }}$ multiple bond. There appears to be a definite gain in energy associated with such a configuration and this has been confirmed by recent studies (Mazzi, Roncari, Rossi, Duatti \& Magon, 1981) on the reaction between trans$\left[\operatorname{Re}(\mathrm{V}) \mathrm{OCl}_{3}\left(\mathrm{PPh}_{3}\right)_{2}\right]$ or $\left[\operatorname{Re}(\mathrm{V}) \mathrm{OBr}_{3}\left(\mathrm{PPh}_{3}\right)_{2}\right]$ and 'salH' derivatives, where all final products were shown to correspond to the trans $\mathrm{O} \equiv \mathrm{Re}^{+}-\mathrm{O}^{-} R$ arrangement, most likely as a consequence of the chelate-ring closure in a first substitution product of $\mathrm{PPh}_{3}$ by imino nitrogen. It is evident that the observed behavior of these compounds can be more easily understood by admitting a definite trans influence (and therefore a trans weakening) caused by the $\mathrm{Re} \equiv \mathrm{O}_{\mathrm{ox}}$ bond, which increases according to the trans ligand, $L$, in the order $R \mathrm{O}^{-}<\mathrm{Cl}^{-}, \mathrm{Br}^{-}<R_{3} \mathrm{~N}$. This hypothesis is supported by several different arguments, the first being that the suggested sequence corresponds, in inverse order, to the expected strength sequence of the bonds formed with $L$ by hard acid $\mathrm{Re}^{\vee}$, fitting the intuitive idea that the trans weakening is greater, the weaker the $M-L$ bond. In general, the most convincing proof of the trans influence exerted by multiply bonded ligands ( $X$ ) in quasi-octahedral $M X L_{5}$ transition-metal complexes has been collected by Shustorovich, Porai-Koshits \& Buslaev (1975). They came to the conclusion, based on structural data as well as on theoretical arguments, that the trans influence caused by the $M-X$ bond increases according to $X$ in the sequence $R-\mathrm{N} \geqq<\mathrm{O} \xrightarrow{\geqq}$ $<\mathrm{N} \equiv$ and, which is more important here, is much greater for neutral ( $L=\mathrm{H}_{2} \mathrm{O}, \mathrm{N}_{3}, \mathrm{CH}_{3} \mathrm{CN}$, etc.) than for anionic ligands ( $R-\mathrm{O}^{-}, \mathrm{Cl}^{-}, \mathrm{Br}^{-}$, etc.). A final point in favor of the idea that the trans $\mathrm{O} \equiv \mathrm{Re}^{+}-\mathrm{O}^{-} R$ configuration is preferred in that it corresponds to a minimum of trans weakening is given by the absence of any trans elongation in the $\mathrm{Re}-\mathrm{O}$ single bond when compared with the small but unquestionable elongation observed for the $\mathrm{Re}-\mathrm{Cl}$ bond (see data reported by Shustorovich et al., 1975).

The authors thank Professor L. Magon (University of Ferrara, Italy) for helpful discussions and Mr G. Bertocchi for technical assistance. This work has been financially supported by the CNR (Rome).
