#### Abstract

The crystal structures of $\left[\mathrm{N}\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4}\right]\left[\mathrm{InCl}_{4}\right]$ (I), $\left.\left[\mathrm{N}\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4}\right]\left[\mathrm{InBrCl}_{3}\right] \quad(\mathrm{II}), \quad\left[\mathrm{N}\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)\right)_{4}\right]\left[\mathrm{InBr}_{3} \mathrm{Cl}\right]$ (III), and $\left[\mathrm{N}\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4}\right]\left[\mathrm{InBr}_{4}\right]$ (IV) have been determined by X-ray analysis which showed that the four structures are isomorphous, with the orthorhombic space group Pnna and $Z=4$. The cell dimensions are: (I) $a=18.479$ (5), $b=11.657$ (3), $c=11.525$ (3) $\AA$, $V=2483$ (1) $\AA^{3}$; (II) $a=18.524$ (5), $b=11.715$ (4), $c=$ 11.575 (4) $\AA, V=2512$ (1) $\AA^{3}$; (III) $a=18.650$ (4), $b=11.860$ (3), $c=11.745$ (2) $\AA, V=2598$ (1) $\AA^{3}$; (IV) $a=18.676$ (3), $b=11.905$ (2), $c=11.787$ (3) $\AA, V=$ 2621 (1) $\AA^{3}$. (Final $R=0.057,0.060,0.049$ and 0.053 for 1165, 768, 711 and 691 observed reflections respectively.) Each structure consists of fourcoordinate $\operatorname{In} X_{4}^{-}$or $\operatorname{In} X_{3} Y^{-}$anions ( $X \neq Y=\mathrm{Cl}, \mathrm{Br}$ ) which have distorted-tetrahedral or $C_{2 \nu}$ symmetry, and [ $\left.\mathrm{N}\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4}\right]^{+}$cations. The $\operatorname{In} \mathrm{X}_{3} \mathrm{Y}^{-}$anions are disordered and the odd halogen atom is assumed to have $25 \%$ occupancy on all four coordination sites.

## Introduction

A recent paper from this laboratory (Drake, Hencher, Khasrou, Tuck \& Victoriano, 1980) described the preparation of tetra- $n$-butylammonium salts of $\operatorname{In} X_{3} Y^{-}$ and $\operatorname{In} X_{2} Y_{2}^{-}$anions $(X \neq Y=\mathrm{Cl}, \mathrm{Br}, \mathrm{I})$ by the oxidation of the appropriate salts of $\operatorname{In}_{2} X_{6}^{2-}$ or $\operatorname{In} X_{2}^{-}$ with halogen $\left(Y_{2}\right)$. Vibrational spectra served to identify the products as individual complexes, rather than the appropriate mixture of $\operatorname{In} X_{4}^{-}$and $\operatorname{In} Y_{4}^{-}$complexes, and also permitted the calculation of force constants for the various vibrational modes. A later study of the solution chemistry of these and related anionic complexes by ${ }^{115}$ In NMR spectroscopy (McGarvey, Trudell, Tuck \& Victoriano, 1980) showed that rapid ligand-redistribution reactions occur in non-aqueous solutions, although the parent $\operatorname{In} X_{n} Y_{4-n}^{-}$salt is again obtained on crystallization.
These mixed-halide complexes are unusual in that they give rise to stable crystalline solids, and a series of single-crystal structure determinations has now been carried out with the aim of obtaining the bond lengths

0567-7408/82/030803-04\$01.00
and angles. The only directly comparable analogues are the corresponding thallium(III) complexes, for which X-ray powder experiments were reported for the series $\mathrm{TlBr}_{n} \mathrm{I}_{4-n}^{-n}(n=0-4)$ (Matthews \& Walton, 1968), and a study of $\left[\mathrm{N}\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4}\right]\left[\mathrm{GaBrCl}_{3}\right]$, which on the basis of cell volume is said to be structurally similar to $\left[\mathrm{N}\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4}\right]\left[\mathrm{TlCl}_{4}\right]$ (Efremov, Grigor'ev, Spiridonov \& Mikheeva, 1974). In the event, the present work gave the desired structural details for the $\mathrm{InCl}_{4}^{-}$and $\mathrm{InBr}_{4}^{-}$ salts, but disorder prevented the measurement of the individual $\operatorname{In}-X$ and $\operatorname{In}-Y$ bond lengths for $\mathrm{InBrCl}_{3}^{-}$ and $\mathrm{InBr}_{3} \mathrm{Cl}^{-}$.

## Experimental

## Preparative

The tetra- $n$-butylammonium salts of $\mathrm{InCl}_{4}^{-}$and $\mathrm{InBr}_{4}^{-}$were prepared by crystallizing ethanol solutions of $\operatorname{In} X_{3}+\left[\mathrm{N}\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4}\right] X$ (Gislason, Lloyd \& Tuck, 1971). The mixed-halide species were obtained by oxidizing indium(II) complexes (Drake et al., 1980).

## $X$-ray studies

Additional crystal data (see also Abstract) and refinement data for the compounds, labelled (I)-(IV), are summarized in Table 1, from which it is clear that all four compounds display similar crystal morphologies.

In each determination, a colourless acicular crystal was mounted along the largest dimension, which was subsequently shown to be the $b$ axis, and data were collected with a Syntex $P 2_{1}$ diffractometer following the procedure described previously (Khan, Steevensz, Tuck, Noltes \& Corfield, 1980). The intensities of three monitor reflections did not change significantly during the data-collection process for compounds (I), (III), and (IV), and decreased by $5 \%$ for (II). In each case, the appropriate scaling factor was applied during the data reduction. The space group Pnna (No. 52) was determined from the systematic absences ( $0 k l, k+l=$ $2 n+1 ; h 0 l, l+h=2 n+1 ; h k 0, h=2 n+1)$. The data were corrected for Lorentz and polarization effects, and analytical absorption corrections were applied.

The similar crystal morphologies and cell dimensions, and the identity of the space group suggested that all four compounds have isomorphous crystal structures, and this was confirmed by the final refinements.

The cell dimensions for $\left.\left[\mathrm{N}\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4}\right][\mathrm{InBrCl}]_{3}\right]$ are similar to those reported for the analogous gallium compound (Efremov, Grigor'ev, Spiridonov \& Mikheeva, 1974).

The first structure to be solved was that of $\left[\mathrm{N}\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4}\right]\left[\mathrm{InBr}{ }_{3} \mathrm{Cl}\right]$ (III). A three-dimensional Patterson map revealed that the In position is on a twofold axis, which requires Br and Cl to be symmetrically equivalent and hence means that the orientations of the $\operatorname{In} \mathrm{Br}_{3} \mathrm{Cl}^{-}$ions are disordered. In the Patterson map, two peaks initially attributed to $\operatorname{In}-X$ vectors differed in height by approximately $40 \%$, and we therefore tentatively identified the higher peak as being from sites of pure $\mathrm{In}-\mathrm{Br}$ vector, and the lower peaks as arising from the disordered sites. In fact, the Patterson maps for compounds (I) and (IV) also showed this same pattern of differing peak heights, so that this explanation was rejected. Further analysis centred on three models: (i) $50 \% \mathrm{Br}, 50 \% \mathrm{Cl}$ for $X(1)$; (ii) $50 \%$ $\mathrm{Br}, 50 \% \mathrm{Cl}$ for $X(2)$; (iii) $75 \% \mathrm{Br}, 25 \% \mathrm{Cl}$; of these, model (iii) gave significantly the best refinement. Similarly, the best refinement for the $\mathrm{InBrCl}_{3}^{-}$salt (II) was obtained with a $75 \% \mathrm{Cl}, 25 \% \mathrm{Br}$ model. We therefore conclude that for (II) and (III) the disorder in

the anions is at all four sites, and that the lower peaks in the Patterson map are due to the unusually large thermal motion of those atoms. Scattering factors (including the anomalous-dispersion terms for the heavy atoms) were taken from Ibers \& Hamilton (1974).

Each structure was refined anisotropically by fullmatrix least-squares methods, the function $\sum w\left(\left|F_{o}\right|-\right.$ $\left.\left|F_{c}\right|\right)^{2}$ being minimized. Unit weights were used in the initial stages of refinement, while in the final cycles of calculation a weighting scheme of the form $w=$ $\left\{1 /\left[\sigma^{2}(F)+p F^{2}\right]\right\}$ was employed, with a final $p$ value of 0.01 in each case. Convergence to the final $R$ values was achieved in six to ten cycles. H atoms were not visible in the final difference maps and no attempt was made to include them. The refinement data for compounds (I)-(IV) are summarized in Table 1. The final coordinates and the standard deviations are given in Table $2^{*}$ and the important interatomic distances

[^0]

Fig. 1. Packing of $\mathrm{N}\left(n-\mathrm{C}_{4} \mathrm{H}_{9}\right)_{4}^{+}$and $\operatorname{In} X_{4}^{-}$ions.
and angles are in Tables 3 and 4. Fig. 1 shows the packing.

All calculations were made on the Amdhal computer at the Wayne State University or the IBM 3031 computer at the University of Windsor. Programs used include ORFLS [structure factor calculations and full-matrix least-squares refinement by Busing, Martin \& Levy (1962)], ABSORB (analytical absorption correction by D. Templeton and L. Templeton), ORTEP (Johnson, 1965), and SHELX 77 [full-matrix least-squares refinement and Fourier synthesis by Sheldrick (1977)].

## Discussion

## Structures of $\mathrm{InCl}_{4}^{-}$and $\operatorname{InBr}_{4}^{-}$

The most directly comparable previous work is that on $\left[\mathrm{NEt}_{4}\right]\left[\mathrm{InCl}_{4}\right]$ (Trotter, Einstein \& Tuck, 1969) in which the anion has $C_{3 v}$ symmetry with reported $\operatorname{In}-\mathrm{Cl}$ bond lengths of 2.30 (2) and 2.36 (3) $\AA$, in good agreement with the more accurate values of 2.345 (3) and 2.355 (3) $\AA$ now found for compound (I). The $\mathrm{Cl}-\mathrm{In}-\mathrm{Cl}$ angles also agree within experimental error. The only other comparable indium(III) anionic species is $\mathrm{CH}_{3} \mathrm{InCl}_{3}$, in which the $\mathrm{In}-\mathrm{Cl}$ bond lengths are 2.409 (3), 2.394 (3) and 2.397 (4) $\AA$ (Guder, Schwartz, Weidlein, Widler \& Hausen, 1976), demonstrating a significant lengthening ( $\sim 0.05 \AA$ ) consequent upon the substitution of a methyl group for one chloride.

The structure of $\mathrm{InBr}_{4}^{-}$confirms previous spectroscopic work which identified this as a tetrahedral ion in solution (Woodward \& Bill, 1955) and solid (Gislason, Lloyd \& Tuck, 1971). Taken together with an earlier determination of the structure of $\mathrm{InI}_{4}^{-}$(Einstein \& Tuck, 1970), the results give a reliable set of $\operatorname{In}-X$ bond lengths for the three $\operatorname{In} X_{4}^{-}$anions: $\operatorname{InCl}_{4}^{-}$
2.350 (2) (present work), $\mathrm{InBr}_{4}^{-} 2.479$ (2) (present work),* $\operatorname{InI}_{4}^{-} 2.71$ (1) $\AA$ (Einstein \& Tuck, 1970). As might be expected, these values show a monotonic relation with such parameters as ligand electronegativity, stretching force constant, etc.

## Structures of $\mathrm{InBrCl}_{3}^{-}$and $\mathrm{InBr}_{3} \mathrm{Cl}^{-}$

It is unfortunate that the disorder problem noted above prevented the measurement of the individual $\mathrm{In}-\mathrm{Br}$ and $\mathrm{In}-\mathrm{Cl}$ bond lengths in these complexes. The bond lengths in Table 3 do not permit any analysis of possible changes in the $\mathrm{In}-\mathrm{Cl}$ or $\mathrm{In}-\mathrm{Br}$ bonds between (say) $\mathrm{InCl}_{4}^{-}$and $\mathrm{InBrCl}_{3}^{-}$. From the average values for the $\mathrm{In}-\mathrm{Cl}$ bond distance in (I) $[2 \cdot 350(2) \AA]$ and the $\mathrm{In}-\mathrm{Br}$ bond in (IV) $[2.479$ (2) $\AA$ ], the weighted mean distances for $\operatorname{In} \mathrm{BrCl}_{3}^{-}$and $\mathrm{InBr}_{3} \mathrm{Cl}^{-}$are calculated as 2.382 and $2.447 \AA$ respectively, values which are not significantly different from the observed $\operatorname{In}-X$ distances in these ions. There are no significant changes in bond angles within the series of anions studied. In addition to the disorder problem the large thermal parameters noted earlier must serve to obscure any structural differences which might exist.

## Tetra-n-butylammonium cations

Given the large estimated standard deviations in bond lengths and angles (Tables 3 and 4), there are no significant differences in corresponding $\mathrm{C}-\mathrm{C}$ or $\mathrm{C}-\mathrm{N}$ bonds in the cations in the four compounds studied, and we conclude that the cations are essentially identical in structure in each of the salts. The thermal parameters are again large, and the whole structure is clearly undergoing considerable vibrational motion at the temperature of the study ( $\sim 298 \mathrm{~K}$ ).

This work was supported by Operating Grants (to DGT) from the Natural Sciences and Engineering

[^1]Research Council of Canada. We thank Mr Luis Victoriano for supplying the crystals, and Professor Milton Glick and Dr P. W. R. Corfield (Wayne State University) for helpful discussions, and for computing facilities.
