#### Abstract

Pt}\left(\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{~N}_{4} \mathrm{O}_{2}\right)_{2}\right]\left[\mathrm{Pt}\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{~N}_{4} \mathrm{O}_{2}\right)\left(\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{~N}_{4}\right.\right.\) $\left.\left.\mathrm{O}_{2}\right)\right]_{2}\left(\mathrm{SO}_{4}\right)_{2} \cdot 8 \mathrm{H}_{2} \mathrm{O}, \quad \mathrm{C}_{4} \mathrm{H}_{12} \mathrm{~N}_{8} \mathrm{O}_{4} \mathrm{Pt}^{2+} .2 \mathrm{C}_{4} \mathrm{H}_{11} \mathrm{~N}_{8} \mathrm{O}_{4}-$ $\mathrm{Pt}^{+} .2 \mathrm{SO}_{4}^{2-} .8 \mathrm{H}_{2} \mathrm{O}, \quad M_{r}=1628.09$, is triclinic, $P \overline{1}$, with $a=8.659$ (2), $b=10.339$ (2), $c=$ 14.218 (3) $\AA, a=107.02(2), \beta=93.93$ (2), $\gamma=$ $114.75(1)^{\circ}, V=1078 \AA^{3}, Z=1, d_{c}=2.51 \mathrm{Mg} \mathrm{m}^{-3}$. Final $R=0.028$ for 5270 independent diffractometer data. The compound is isomorphous with the analogous Pd complex. The unit cell contains one centrosymmetric dipositive and two noncentrosymmetric monopositive complex cations forming stacks of triples in the crystal, interspersed with sulfate anions.

Introduction. Oxamide oxime ( $\mathrm{oaOH}_{2}$ ) (Ephraim, 1889) forms a variety of complexes with the elements of the Ni triad, depending on the metal and on the crystallization conditions (Endres \& Weiss, 1981, and references cited therein). The title compound is obtained by adding sulfuric acid to a slurry of $\mathrm{Pt}\left(\mathrm{oaOH}_{2}\right)_{2} \mathrm{Cl}_{2}$ (Endres \& Schlicksupp, 1979) in boiling $\mathrm{H}_{2} \mathrm{O}$ until a clear yellow solution forms, from which the yellow-orange crystals precipitate on slow cooling. Lattice constants were derived from the setting angles of 25 reflections centered on a diffractometer (Syntex $R 3$, monochromatic Mo Ka radiation). Data collection ( $\theta-2 \theta$ scans, background-peak-background, $2 \theta<66^{\circ}$ ) yielded 5270 observed independent reflections with $I>$ $2 \cdot 5 \sigma(I)$. Lorentz and polarization corrections as well as an empirical ( $\psi$ scans) absorption correction were applied. The structure was solved by Patterson and Fourier methods and refined with anisotropic temperature factors by a cascade matrix procedure to a weighted $R=0.028$ (unweighted $R=0.031$ ).* The weighting scheme was $w=1 / \sigma^{2}(F)$. H atoms could not be located. Calculations were carried out on a NOVA 3 computer, plots were drawn on a Tektronix

[^0]ploter. The program package was SHELXTL (Sheldrick, 1979).

Discussion. The compound is isomorphous with the analogous Pd complex, grown by a diffusion process

(Endres \& Weiss, 1981). The lattice accommodates a centrosymmetric $\left[\mathrm{Pt}\left(\mathrm{OaOH}_{2}\right)_{2}\right]^{2+}$ dication (I) with Pt at the-origin (Fig. 1), and a noncentrosymmetric monopositive cation $\left[\mathrm{Pt}(\mathrm{oaOH})\left(\mathrm{oaOH}_{2}\right)\right]^{+}$with Pt at a general position (II) (Fig. 2). Atomic coordinates are listed in Table 1. Table 2 contains bond lengths and angles in the sulfate ion. The $\mathrm{Pt}-\mathrm{N}$ distances and angles in this compound do not differ significantly from those in the Pd complex. The dication does not exhibit intramolecular H bridges; in the monocation only one intramolecular H bridge has formed. The complex

Fig. 3. View of two triples repeating along b. The molecules are projected parallel to the mean plane through the central molecule of a triple.
molecules are arranged in triples with (I) at the center and two species (II), related by an inversion center, forming the outer molecules of the triple. The molecular overlap within a triple is very pronounced and corresponds to the one found in the Pd complex (Endres \& Weiss, 1981). The triples pile up into stacks in the $\mathbf{b}$ direction, with a much larger slip of adjacent molecules between the triples than within the triples. This kind of stacking is indicated in Fig. 3 which shows the repeat of the triples along $\mathbf{b}$. Even if the interplanar distances $(3.4 \AA)$ are identical within and between the triples the term 'triple' is justified by the different molecular overlap, the same as found in the Pd compound. With the Pt compound described here and its Pd analogue an isomorphous pair of oxamide oxime complexes of the metals of the Ni triad has been found for the first time. Normally, the crystal and molecular structures are quite different for the different metals, in contrast to the normal behavior of $\alpha, \beta$-dione dioximato complexes of the Ni triad (Endres, Keller, Lehmann, Poveda, Rupp \& van de Sand, 1977).
