#### Abstract

Au}\left(\mathrm{C}_{18} \mathrm{H}_{15} \mathrm{P}\right)_{2}(\mathrm{SCN})\right], \mathrm{C}_{37} \mathrm{H}_{30} \mathrm{AuNP}_{2} \mathrm{~S}\), is monoclinic, $P 2_{1} / n, M_{r}=779.6 . a=11.823$ (2), $b=$ 19.795 (6), $c=13.887$ (5) $\AA, \beta=91.73$ (5) ${ }^{\circ}, Z=4$, $\mu($ Mo $K a)=4.52 \mathrm{~mm}^{-1}, D_{c}=1.594, D_{x}=1.61$ (1) $\mathrm{Mg} \mathrm{m}^{-3}, V=3248.6 \AA^{3}$. Final $R=0.075$ for 3414 unique reflections. The complex crystallizes as a trig-onal-planar, three-coordinate gold compound, similar to the analogous chloro complex.

Introduction. The title compound was obtained as part of a study of possible three- or four-coordinate gold complexes with thiocyanate and phosphine ligands. $\left[\mathrm{Au}\left\{\mathrm{P}\left(\text { cyclo- } \mathrm{C}_{6} \mathrm{H}_{11}\right)_{3}\right\}_{2}\right][\mathrm{SCN}]$ was shown to form a linear two-coordinate complex with an ionic thiocyanate anion (Muir, Muir \& Lorca, 1980). In contrast, $\left[\mathrm{Au}\left\{\mathbf{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right\}_{2} \mathrm{Cl}\right]$ forms a trigonal-planar three-coordinate complex (Baenziger, Dittemore \& Doyle, 1974). In addition, preliminary results for $\left[\mathrm{Au}\left\{\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right\}_{3}(\mathrm{SCN})\right]$ show that it forms a fourcoordinate complex having extremely long $\mathrm{Au}-\mathrm{P}$ and $\mathrm{Au}-\mathrm{S}$ distances (Muir, Muir, Arias, Campana \& Dwight, 1981). It therefore seemed of interest to study related gold complexes, such as $\left\{\mathrm{Au}\left\{\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right\}_{2}\right.$ (SCN)], in order to understand better the structure and bonding involved.

The title compound was prepared, somewhat accidentally, using the method reported for $\left[\mathrm{Au}\left\{\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right\}(\mathrm{SCN})\right]$ (DeStefano \& Burmeister, 1971). A solution of $0.32 \mathrm{~g}(4.0 \mathrm{mmol})$ of NaSCN in 20 ml of ethanol was added to $0.40 \mathrm{~g}(1.0 \mathrm{mmol})$ of $\mathrm{NaAuCl} 4.2 \mathrm{H}_{2} \mathrm{O}$ in 10 ml ethanol. After 10 min of stirring, NaCl was removed by filtration. A solution of $0.53 \mathrm{~g}(2.0 \mathrm{mmol})$ of triphenylphosphine in 30 ml ethanol was added to the blood-red filtrate, causing the mixture to become colorless. After stirring for 15 min , the solvent was then removed until crytals began to form. The product was filtered, washed with ethanol and ether and dried over $\mathrm{CaSO}_{4}$ in vacuum. It is probable that reduction from $\mathrm{Au}^{\mathrm{III}}$ to $\mathrm{Au}^{1}$ was due to reaction with $\mathrm{SCN}^{-}$and not to reaction with phosphine, since both moles of phosphine were coordinated to the $A u^{1}$ product. This is consistent with equilibrium data for reaction of $\mathrm{AuCl}_{4}^{-}$with $\mathrm{SCN}^{-}$ (Elding, Gröning \& Olsson, 1980).

Elemental analyses of $57.41 \% \mathrm{C}, 3.99 \% \mathrm{H}$ and $1.78 \% \mathrm{~N}$ were obtained. The theoretical composition includes $57.00 \%$ C, $3.88 \% \mathrm{H}$ and $1.80 \% \mathrm{~N}$. Pre-

liminary analyses of crystals by Weissenberg and precession techniques showed systematically absent reflections of $k=2 n+1$ in the $0 k 0$ zone with $h+l=$ $2 n+1$ in the $h 0 l$ zone, indicating space group $P 2_{1} / n$.

For intensity-data collection a colorless plate-like crystal having approximate dimensions $0.20 \times 0.10 \times$ 0.05 mm was mounted with its $b$ axis parallel to the $\varphi$ axis of an Enraf-Nonius CAD-4 diffractometer. Intensity data were collected and reduced to structure factors by the Molecular Structure Corporation, College Station, Texas. Cell constants and an orientation matrix for data collection were obtained from least-squares refinement of the setting angles of 24 reflections.

4381 unique reflections were collected, of which 3414 had non-zero intensities and were included in the final refinement. As a check on the stability of the crystal and the electronics, three check reflections were measured every 41 min , and their intensities were found to remain constant within experimental error. Lp corrections were applied, as was an empirical absorption correction based on a series of $\psi$ scans.

A three-dimensional Patterson synthesis revealed the location of the Au atom. Least-squares refinement and difference Fourier syntheses were applied, beginning with an $R$ value of 0.22 for the single, isotropic Au atom, and proceeding without difficulty to final isotropic values of $R=0.081$ and $R^{\prime}=\sum w^{1 / 2} \Delta /$ $\sum w^{1 / 2}\left|F_{o}\right|=0.067$. When the $\mathrm{Au}, \mathrm{P}$ and S atoms were allowed to refine anisotropically, final values of $R=0.075$ and $R^{\prime}=0.061$ were reached. At this point the highest remaining peaks in a difference Fourier map not associated with the Au atom were approximately $1.0 \mathrm{e} \AA^{-3}$, and were identified as H -atom peaks about the phenyl rings.

The weighting scheme used was $w^{-1}=\sigma_{F}^{2}$, where $\sigma_{F}$ was derived from counting statistics only. Neutral-atom scattering factors were used, except for $\mathrm{Au}^{\mathrm{I}}$. The analysis of variance was flat. The atomic coordinates
and thermal parameters are given in Table 1, and the resulting interatomic distances and angles in Table 2.*

Discussion. The coordination about the Au atom is shown in Fig. 1. The geometry is close to ideal trigonal planar - the Au atom is only $0.04 \AA$ out of the least-squares plane through the $P$ and $S$ atoms, while the $\mathrm{P}-\mathrm{Au}-\mathrm{P}$ angle is $127.8(1)^{\circ}$. Au- P distances are 2.346 (4) and 2.349 (4) $\AA$ while $A u-S$ is 2.468 (4). $\left\{\mathrm{Au}\left\{\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right\}_{2} \mathrm{Cl} \mid\right.$ is very similar, with the Au atom $0.01 \AA$ from the plane, and $\mathrm{Au}-\mathrm{P}$ distances of 2.323 (4) and 2.339 (4) $\AA$. The geometry is less ideal, since the $\mathrm{P}-\mathrm{Au}-\mathrm{P}$ angle is now $132 \cdot 1$ (1) $)^{\circ}$. Ionic trigonal-planar complexes with three identical phosphine ligands are also similar: $\left\{\mathrm{Au}\left\{\mathbf{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right\}_{3}\right\}$ $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}\right]$ has $\mathrm{Au}-\mathrm{P} 2.365,2.384,2.403 \AA$, $\mathrm{P}-$ $\mathrm{Au}-\mathrm{P} 115.2,119.3,125.4^{\circ}$, the Au atom lies $0.06 \AA$

[^1]

Fig. 1. The $\left\{\mathrm{Au}\left\{\mathrm{P}_{\left.\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right\}_{2}(\mathrm{SCN}) \mid \text { molecule. Phenyl rings are }}\right.\right.$ labelled as in Table 2.
out of the $\mathrm{P}_{3}$ plane (Jones, 1980), while $\left|\mathrm{Au}\left\{\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right\}_{3}\right|\left|\mathrm{B}_{9} \mathrm{H}_{12} \mathrm{~S}\right|$ has $\mathrm{Au}-\mathrm{P} 2.345,2.384$. $2.389 \AA, \mathrm{P}-\mathrm{Au}-\mathrm{P} 112.3,121.5,124.1^{\circ}$, the Au atom lies $0.2 \AA$ out of the $P_{3}$ plane (Guggenberger, 1974). In contrast to all of these $\left|\mathrm{Au}\left\{\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right\}_{3}(\mathrm{SCN})\right|$ displays four-coordinate geometry, with much longer Au-P distances $(2.384,2.401$ and $2.413 \AA$ ), and a very much longer $\mathrm{Au}-\mathrm{S}$ distance of $2.791 \AA$. The similarity in structure of the trigonal $\left\{\mathrm{Au}\left\{\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right\}_{2}\right.$ $(\mathrm{SCN}) \mid$ and $\left|\mathrm{Au}\left\{\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right\}_{2} \mathrm{Cl}\right|$ in contrast to the linear $\left\{\mathrm{Au}\left\{\mathrm{P}\left(\text { cyclo- } \mathrm{C}_{6} \mathrm{H}_{11}\right)_{3}\right\}_{2} \| \mathrm{SCN} \mid\right.$ suggests that the steric requirements of the phosphine are the determining factor in the structure.

Computer programs used included SHELX 76 (Sheldrick, 1976), XANADU (Roberts \& Sheldrick. 1975) and PLUTO (Motherwell \& Clegg, 1978).

We are grateful to the University of Puerto Rico Computing Service for generous grants of time on the IBM 370/148 computer, and to L. Bird for helpful discussions. Research was supported in part by grant RR-8102 from the Division of Research Resources. National Institutes of Health.

# The Structure of $\boldsymbol{\mu}$-Thio-bis[tribenzylgermanium(IV)] 

By Christopher Glidewell* and David C. Liles<br>Chemistry' Department, University of St Andrews, St Andrew's, Fife KY16 9ST, Scotland

(Received 2 Novemher 1981: accepted 2 December 1981)

#### Abstract

C}_{42} \mathrm{H}_{42} \mathrm{Ge}_{2} \mathrm{~S}\), monoclinic. $C 2 / c$, $a=$ 25.448 (7), $b=9.344$ (2), $c=17.304$ (3) $\AA, ~ \beta=$ $118.31(2)^{\circ}, U=3622.6 \AA^{3}, M_{r}=724.04, D_{c}=$ $1.327 \mathrm{Mg} \mathrm{m}^{-3}$ for $Z=4, F(000)=1496$. Mo $K a$ radiation, $\lambda=0.71069 \AA, \mu($ Mo $K())=1.674 \mathrm{~mm}^{-1} ; R$ $=0.0861$ for 1512 reflections. The structure consists of molecules lying across the twofold axes of the unit cell: the GeSGe angle is $106 \cdot 6(2)^{\circ}$ and the $\mathrm{Ge}-\mathrm{S}$ distance 2.233 (4) A.

Introduction. As part of a study of hexa-organo substituted triatomics, $X\left(R_{3} M\right)_{2}$, we have previously reported the structures of $\mathrm{O}\left(\mathrm{Ph}_{3} \mathrm{Ge}\right)_{2}$ (Glidewell \& Liles, $1978 a$ ) and $\mathrm{O}\left(\mathrm{PhCH}_{2}\right)_{3} \mathrm{Gel}_{2}$ (Glidewell \& Liles.

[^2]1979a). The structure of $\mathrm{S}\left(\mathrm{Ph}_{3} \mathrm{Ge}\right)_{2}$ has also been reported (Krebs \& Korte, 1979). $\mathrm{O}\left(\mathrm{Ph}_{3} \mathrm{Ge}\right)_{2}$ and $\mathrm{Ol}\left(\mathrm{PhCH}_{2}\right)_{3} \mathrm{Ge}_{2}$ both have very wide GeOGe angles, $135 \cdot 2(2)$ and $180 \cdot 0(0)^{\circ}$ respectively: the former can be ascribed to a 'hard atom' contact between the Ge atoms (Glidewell \& Liles, 1978a) and the latter can be accounted for in terms of a second-order Jahn-Teller effect (Glidewell, 1978a,b). To test whether a similar effect could be observed when the central $O$ atom was replaced by an $S$ atom - thus reducing the electronegativity difference between the central atom and the $\left(\mathrm{PhCH}_{2}\right)_{3} \mathrm{Ge}$ groups - we have determined the structure of $\mathrm{S} \mid\left(\mathrm{PhCH}_{2}\right)_{3} \mathrm{Ge}_{2}$.
$\mathrm{S} \mid\left(\mathrm{PhCH}_{2}\right)_{3} \mathrm{Gel}_{2}$ was prepared from $\left(\mathrm{PhCH}_{2}\right)_{3} \mathrm{GeBr}$ (Bauer \& Burschkies, 1934) by the action of $\mathrm{Na}_{2} \mathrm{~S}$ in ethanol solution (Burschkies, 1935). Crystals suitable for X-ray examination were obtained from $60-80$ petrol solution.
