# 8 $\beta$-Angeloyloxymaximilianin* 

By William H. Watson $\dagger$ and Volker Zabel<br>FASTBIOS Laboratory, Department of Chemistry, Texas Christian University, Fort Worth, Texas 76129, USA

(Received 10 September 1981; accepted 24 November 1981)

#### Abstract

Angeloyloxymaximilianin, $\Delta^{3,4,}, 4^{11,13}$ $8 \beta, 10 \alpha$-dihydroguaianolide 8 -angelate, is a guaianolidetype sesquiterpene lactone isolated from Helianthus maximiliani. $\mathrm{C}_{20} \mathrm{H}_{26} \mathrm{O}_{5}$, monoclinic, space group $P 2_{1}$, $a=10.116$ (2), $b=11.979$ (2), $c=7.787$ (2) $\AA, \beta=$ $92.30(2)^{\circ}, V=942.8(3) \AA^{3}, Z=2, d_{c}=1.22 \mathrm{Mg}$ $\mathrm{m}^{-3}$ and $\mu=5.9 \mathrm{~cm}^{-1}$. The structure was solved by direct methods and refined by full-matrix least-squares techniques (non-H atoms anisotropic, H atoms isotropic) to a final $R$ of 0.056 for 1716 independent observed reflexions. The five- and seven-membered carbocyclic rings are cis fused while the lactone ring exhibits a trans ring juncture. The two five-membered rings are in flattened envelope conformations while the seven-membered ring can be described as a twist chair. An angelate side chain is found at $C(8)$.

Introduction. Helianthus L. (Tribe Heliantheae, Family Compositae) is a genus of about 50 species which are native to North America. The genus has been a source of food and medicine for thousands of years to the inhabitants of North America (Heiser, 1976) and has become the second most important vegetable-oil source in the world (Putt, 1978). Surprisingly, little chemical work has been reported on this genus, and the genus is still not well understood systematically (Heiser, 1969). It is anticipated that a detailed phytochemical investigation will lead to a better understanding of the interspecific boundaries and the evolutionary interrelationships in the genus (Gershenzon, Ohno \& Mabry, 1981). The expansion of cultivation of the main oil-producing sunflower species in the United States is limited by insect damage (Schulz, 1978). Many wild sunflower species appear to be resistant to insect predation; however, there is no obvious morphological feature in the resistant plants which might account for their resistance to insect attack. A number of terpenoid compounds have been implicated in plant defence mechanisms against insects (Mabry \& Gill, 1979), and it is anticipated that resistance in wild sunflower species may be related to chemical composition. We would like

[^0]0567-7408/82/051608-03\$01.00
to report the structure of $8 \beta$-angeloyloxymaximilianin (1). At present $H$. maximiliani is the only species of Helianthus known to produce guaianolidetype sesquiterpenoids (Gershenzon et al., 1981).

(1)

Good single crystals of $8 \beta$-angeloyloxymaximilianin could be obtained from hot ethyl acetate solutions. A crystal of dimensions $0.35 \times 0.6 \times 0.35 \mathrm{~mm}$ was selected for X-ray analysis. All data were collected on a Syntex $P 2_{1}$ diffractometer by the $\theta: 2 \theta$ scanning technique using a variable scan speed, Cu Ka radiation ( $\lambda=1.54178 \AA$ ) and a graphite monochromator. Room-temperature lattice parameters were refined by a least-squares procedure using 15 reflexions whose angles were measured by a centering routine associated with the diffractometer. Systematic absences were consistent with space group $P 2_{1}$. A periodically monitored reflexion showed no significant change in intensity. Of the 1737 independent reflexions measured $\left(2 \theta<140^{\circ}\right), 1716$ had intensities greater than $2 \sigma(I)$. Lorentz and polarization corrections were applied, but no absorption corrections were made.

The direct-methods program MULTAN 78 (Main, Lessinger, Woolfson, Germain \& Declercq, 1978) was used to calculate phases for the $|E|$ values greater than $1 \cdot 3$. The phase set with the highest combined figure of merit was selected, and the $E$ map calculated with these phases revealed the positions of all non-H atoms. After several cycles of least-squares refinement all H atoms except those associated with $C(14)$ were located in a difference Fourier map. Five reflexions showing significant secondary extinction were omitted from further refinement. Full-matrix least-squares refinement converged to an $R$ of 0.056 where $R=\sum\left|F_{o}\right|-$ $\left|F_{c}\right|\left|/ \sum\right| F_{o} \mid$. The function minimized in the refinement c 1982 International Union of Crystallography
was $\sum w\left(\left|F_{o}\right|-\left|F_{c}\right|\right)^{2}$ where $w\left[=1 / \sigma^{2}\left(F_{o}\right)\right]$ was determined from counting statistics.

A final difference map showed no peak larger than 0.2 e $\AA^{-3}$. Atomic scattering factors were calculated by the XRAY program (Stewart, Machin, Dickinson, Ammon, Heck \& Flack, 1976) while the real and imaginary contributions to the anomalous dispersion were taken from International Tables for X-ray Crystallography (1974). Atomic positional parameters

configuration was not established by this investigation, it is believed to be that shown in Fig. 1 (Fischer, Olivier \& Fischer, 1979), and all refinements were based upon this assignment.

Discussion. Fig. 1 is an ORTEP drawing (Johnson, 1971) of $8 \beta$-angeloyloxymaximilianin. Cycloheptane rings can exist in boat and chair forms ( $C_{s}$ symmetry) and may undergo pseudorotation with twist forms ( $C_{2}$ symmetry) being the most stable in each series (Hendrickson, 1961). The seven-membered ring in most guaianolide-type sesquiterpenoids most closely approximates the $C$ twist-chair conformation although there are considerable deviations from this ideal form (Hendrickson, 1963; McPhail \& Sim, 1973). The sum ( $\Sigma$ ) of the absolute values of the sums of symmetryrelated torsion angles has been used as a measure of deviation from the ideal form. The $\sum$ value for $C_{2}$ symmetry of the chair series is $47^{\circ}$ for $8 \beta$-angeloyloxymaximilianin which may be compared with the ideal twist-chair value of $0^{\circ}$ (Hendrickson, 1961) and the $19-60^{\circ}$ observed for a series of guaianolide-type sesquiterpenoids (McPhail \& Sim, 1973). The average valency angle in cycloheptane rings of the above series ranges from $114.5-115.9^{\circ}$ which is consistent with the $115^{\circ}$ value found for $8 \beta$-angeloyloxymaximilianin. The cyclopentene ring exhibits an envelope conformation while the $\alpha, \beta$-unsaturated $\gamma$-lactone can be described as a flattened envelope.

The side chain at $\mathrm{C}(8)$ is composed of two planar segments rotated from coplanarity by a twist about the $\mathrm{C}(16)-\mathrm{C}(17)$ bond, $\mathrm{O}(8) \mathrm{C}(16) \mathrm{C}(17) \mathrm{C}(18) 32 \cdot 7$ (3) ${ }^{\circ}$. An intermolecular hydrogen bond is formed between the hydroxyl at $\mathrm{C}(10)$ and the $\mathrm{O}(12)$ keto oxygen, $\mathrm{O}(10) \cdots \mathrm{O}(12)\left(1-x, \frac{1}{2}+y, 1-z\right) 2 \cdot 889(3)$, $\mathrm{H}(10) \cdots \mathrm{O}(12) 1.86(4)$ and $\mathrm{O}(10)-\mathrm{H}(10) 1.04$ (4) $\AA$.

We thank the Robert A. Welch Foundation (P-074) for financial support. This is FASTBIOS contribution No. 92 .
