$$
\left[\mathrm{Co}_{2}\left(\mathrm{NH}_{3}\right)_{10}\left(\mathrm{O}_{2}\right)\right]\left(\mathrm{HSO}_{4}\right)\left(\mathrm{SO}_{4}\right)_{2} \cdot 3 \mathrm{H}_{2} \mathrm{O}
$$

of the three water molecules, there is no profit in attempting to unravel a detailed hydrogen-bonding scheme. There are many $\mathrm{N} \cdots \mathrm{O}$ and $\mathrm{H}_{2} \mathrm{O} \cdots \mathrm{O}$ distances in the range $2 \cdot 8-3 \cdot 1 \AA$; the shortest, at $2 \cdot 64 \AA$, is to an O atom of group $\mathrm{S}(3)$ and hence has a large and unspecified uncertainty.

We thank Dr Sten Samson for valuable advice and aid in the data collection. This work was supported in part by the National Institutes of Health under Grant No. HL-12395.

#### Abstract

Ca}_{2} \mathrm{Cu}\), orthorhombic, Pnma, $a=6.126$ (2), $b=4.161$ (4), $c=14.53$ (1) $\AA, Z=4, D_{c}=2.58 \mathrm{Mg}$ $\mathrm{m}^{-3}, \mu(\mathrm{Mo} K a)=8.4 \mathrm{~mm}^{-1}$. The structure was solved by direct methods and refined isotropically to an $R$ value of 0.082 for 118 reflexions. The structure of $\mathrm{Ca}_{2} \mathrm{Cu}$ is built up by stacking Cu -centered trigonal prisms of Ca atoms in such a way that they share two rectangular faces. This arrangement allows infinite zigzag chains of Cu atoms to be formed, giving a close relationship with the FeB-type structure.

Introduction. In the phase diagram studied by Bruzzone (1971) three phases exist: $\mathrm{CaCu}_{5}$ with its own well known structure, CaCu present in two modifications [both stacking variants of the $\mathrm{FeB}-\mathrm{CrB}$ types (Merlo \& Fornasini, 1981)], and $\mathrm{Ca}_{2} \mathrm{Cu}$ with unknown structure. The purpose of this work was to determine the crystal structure of this last phase.

In order to avoid the formation of the more stable compound CaCu , an alloy of nominal composition $7 \mathrm{Ca}: 3 \mathrm{Cu}$ was prepared by melting the two metals ( Ca $99.9, \mathrm{Cu} 99.999 \%$ purity) in an iron crucible and annealing at 723 K for two months.

The softness and oxidizability of the alloy prevented good crystals being easily found; their diffraction spots were in every case elongated and intensities dropped at high $\theta$ values. After many trials a plate-like single crystal of acceptable quality and dimensions $0.02 \times$ $0.06 \times 0.17 \mathrm{~mm}$ was chosen for the X-ray analysis.

Precession photographs showed orthorhombic symmetry with $0 k l$ reflexions present only for $k+l=2 n$ and $h k 0$ present only for $h=2 n$, indicating space groups $P n 2_{1} a$ and Pnma.

The crystal was then mounted on an Enraf-Nonius CAD-4 automatic diffractometer and 1212 hkl and $h k l$ reflexions were measured with graphite-monochromated Mo $K a$ radiation in the $\omega-2 \theta$ scan mode ( $3 \leq$ $\theta \leq 30^{\circ}$ ). A check reflexion was employed to test the stability of the crystal; this faded at the end of the data collection. A decay correction, as a function of the elapsed time, was then applied, together with Lorentz and polarization corrections. Absorption was taken into account using the semi-empirical method of North, Phillips \& Mathews (1968) with $18 \psi$-scan data of a strong reflexion. Finally, averaging gave 609 independent reflexions.

The lattice constants were obtained from a leastsquares refinement of 24 diffractometer-measured reflexions, and by comparing the cell volume with that calculated using the elemental atomic volumes, four $\mathrm{Ca}_{2} \mathrm{Cu}$ formulae per cell could be assigned.

For the structure resolution and refinement the SHELX 76 program (Sheldrick, 1976) was used, taking atomic scattering factors and anomalousdispersion corrections from International Tables for X-ray Crystallography (1974). Direct methods in the space group Pnma gave a solution compatible with both cell content and geometrical requirements. An (c) 1982 International Union of Crystallography

Table 1. Atomic parameters for $\mathrm{Ca}_{2} \mathrm{Cu}$ (space group Pnma), with e.s.d.'s in parentheses

The thermal factors are defined as $\exp \left[-8 \pi^{2} U(\sin \theta / \lambda)^{2}\right]$.

|  | $x$ | $y$ | $z$ | $U\left(\AA^{2}\right)$ |
| :--- | :---: | :---: | :---: | :---: |
| $\mathrm{Ca}(1)$ | $0.363(3)$ | 0.25 | $0.6669(9)$ | $0.020(5)$ |
| $\mathrm{Ca}(2)$ | $0.134(3)$ | 0.25 | $0.4070(8)$ | $0.013(4)$ |
| Cu | $0.109(2)$ | 0.25 | $0.0147(5)$ | $0.011(3)$ |

isotropic least-squares refinement of ten parameters was made for 118 reflexions with $F_{o}>2 \sigma\left(F_{o}\right)$ and $w=$ $1 / \sigma^{2}\left(F_{o}\right)$, and converged to an $R$ value of 0.082 . The final atomic parameters are listed in Table 1.*

Discussion. In the structure of $\mathrm{Ca}_{2} \mathrm{Cu}$ (Fig. 1a) the Ca atoms form slabs of trigonal prisms alternately inclined $\pm 19^{\circ}$ about the $c$ axis. The prisms share two rectangular faces with two other prisms, originating rows in the [010] direction, and are centered by Cu atoms which form infinite zigzag chains in the same direction.

This structure can be related to that of the FeB type (Fig. 1b): if alternate slabs of trigonal prisms are translated $b / 2$ and then joined together by shifting along the $c$ axis, the atomic arrangement of the FeB structure is derived. Such a connexion is not surprising, as stacking variants of the $\mathrm{FeB}-\mathrm{CrB}$ types exist for the two modifications, $\alpha$ and $\beta$, of the phase CaCu (Merlo \& Fornasini, 1981), which show features very similar to those of the $\mathrm{Ca}_{2} \mathrm{Cu}$ structure. Indeed, the prism inclination angle, the prism dimensions and the coordination around the Cu atoms are practically the same in the three structures. Cu always has six Ca neighbors at the vertices of a trigonal prism, while a seventh Ca and two Cu atoms capping the rectangular faces complete the coordination.

[^0]Fig. 1. Projection of $(a)$ the $\mathrm{Ca}_{2} \mathrm{Cu}$ and (b) the FeB structures along the short axis. Open circles: Ca or Fe ; full circles: Cu or B . Large circles are in the plane of the sheet, small circles are above and below the plane of the sheet. Trigonal prisms are indicated by thick lines.

Table 2. Interatomic distances $(\AA)$ in $\mathrm{Ca}_{2} \mathrm{Cu}$
E.s.d.'s are given in parentheses.

| $\mathrm{Ca}(1)-1 \mathrm{Cu}$ | $3.04(2)$ | $\mathrm{Cu}-2 \mathrm{Cu}$ | $2.51(1)$ |
| :---: | :---: | :---: | :---: |
| -2 Cu | $3.04(1)$ | $-1 \mathrm{Ca}(1)$ | $3.04(2)$ |
| $-2 \mathrm{Ca}(2)$ | $3.84(2)$ | $-2 \mathrm{Ca}(1)$ | $3.04(1)$ |
| $-2 \mathrm{Ca}(2)$ | $3.87(2)$ | $-2 \mathrm{Ca}(2)$ | $3.04(1)$ |
| $-2 \mathrm{Ca}(1)$ | $3.90(2)$ | $-1 \mathrm{Ca}(2)$ | $3.12(2)$ |
| $-1 \mathrm{Ca}(2)$ | $4.03(2)$ | $-1 \mathrm{Ca}(2)$ | $3.41(2)$ |
| $-2 \mathrm{Ca}(2)$ | $4.06(2)$ |  |  |
| $-2 \mathrm{Ca}(1)$ | $4.16(1)$ |  |  |
| $\mathrm{Ca}(2)-2 \mathrm{Cu}$ | $3.04(1)$ | $\mathrm{Ca}(2)-2 \mathrm{Ca}(1)$ | $3.87(2)$ |
| -1 Cu | $3.12(2)$ | $-1 \mathrm{Ca}(1)$ | $4.03(2)$ |
| -1 Cu | $3.41(2)$ | $-2 \mathrm{Ca}(1)$ | $4.06(2)$ |
| $-2 \mathrm{Ca}(2)$ | $3.79(2)$ | $-2 \mathrm{Ca}(2)$ | $4 \cdot 16(1)$ |
| $-2 \mathrm{Ca}(1)$ | $3.84(2)$ |  |  |

As can be seen in Table 2, interatomic distances in $\mathrm{Ca}_{2} \mathrm{Cu}$ are also very close to those of $\alpha$ - and $\beta-\mathrm{CaCu}$, having a maximum contraction (6\%) with respect to the sum of the metallic radii in the $\mathrm{Ca}-\mathrm{Cu}$ distances within the prism. However, the volume contraction, calculated on the basis of the elemental atomic volumes for $\mathrm{Ca}_{2} \mathrm{Cu}$ and for $\alpha$ - and $\beta-\mathrm{CaCu}$, are 6.4, 11.7 and $11.9 \%$, respectively, indicating on the whole a less dense space filling for the $\mathrm{Ca}_{2} \mathrm{Cu}$ structure. In fact, the prism slabs, linked in the direction of the $c$ axis only by $\mathrm{Ca}-\mathrm{Ca}$ bonds, generate in between tetrahedral and octahedral holes, which are absent in FeB and in its stacking variants.
Interestingly, $\mathrm{Ca}_{2} \mathrm{Cu}$ does not adopt the anti $-\mathrm{PbCl}_{2}-$ type structure, which occurs for several $M_{2} X$ compounds of alkaline earths with $\mathrm{Hg}, \mathrm{Si}, \mathrm{Ge}, \mathrm{Sn}$ and Pb , although it is also based on trigonal-prismatic coordination around the $X$ atom. In spite of the same linkage coefficient, as defined by Parthé \& Moreau (1977), which is 3 for both structures, the prism arrangement is quite different: in the anti- $\mathrm{PbCl}_{2}$ type the prisms share their triangular faces to give columns, each column being connected to two other columns by sharing two lateral edges of the prisms. So, no $X-X$ contact is allowable and the atom centering the prisms displays only hetero-atomic bonds. The possibility of Cu forming chains, as in the dimorphic CaCu phase, could explain why $\mathrm{Ca}_{2} \mathrm{Cu}$ presents this new structure.
