form occurs. In this conformation the steric hindrance due to ring substituents is relieved, while an intermediate stabilization via the anomeric interaction can remain. Bond lengths and valence angles are given in Table 4. The As-Cl bond is longer than normal [ 2.258 vs $2 \cdot 161 \AA$ in $\mathrm{AsCl}_{3}$ and $\mathrm{As}\left(\mathrm{CH}_{3}\right)_{2} \mathrm{Cl}$ (Sutton, 1965)] in accordance with the anomeric effect. The $n(\mathrm{O})-\sigma^{*}$ (As-Cl) delocalization causes an increase in electron density in the anti-bonding $\sigma^{*}$ (As-Cl) orbital with a consequent lengthening of the bond and a decrease of the force constant. One also notices that the $\mathrm{C}-\mathrm{O}$ bonds are longer than those normally encountered in ethers and alcohols ( $1.43-1.44 \AA$ ). The same phenomenon was observed in cyclic sulfites (Petit, 1982) and cyclic phosphates (Van Nuffel, Lenstra \& Geise, 1980, 1981, 1982).

Bond angles are found to be normal. The As-O-C angles ( 123.6 and $126.3^{\circ}$ ) may seem large, but similar values were observed for $\mathrm{P}-\mathrm{O}-\mathrm{C}$ in 2 -chloro-5,5-dimethyl-1,3,2-dioxaphosphorinane 2 -oxide (Silver \& Rudman, 1972) and in $2 \alpha$-bromo- $5 \beta$-bromo-ethyl-5 $\alpha$-methyl-1,3,2-dioxaphosphorinane $\quad 2$-oxide
(Beineke, 1969). Again, such values fit in with the anomeric effect, since the delocalization increases the $s p^{2}$ character of the O atoms in the ring.

One of us (PVN) thanks the Belgian Organization IWONL for a predoctoral grant.

infinite chains parallel to the $c$ axis; $\mathrm{Cu}-\mathrm{Br} 2.44-$ $2.52 \AA, \mathrm{Cu}-\mathrm{S} 2 \cdot 27-2 \cdot 33 \AA$. There may be weak $\mathrm{Cu} \cdots \mathrm{Cu}$ interactions.

Introduction. The polymeric title compound (I) was reported (Walton, 1966) as the major product of the reaction of 1,4 -oxathiane ( tx ) with $\mathrm{CuBr}_{2}$ in ethanol. It occurs as fine, almost colourless needles readily separated under the microscope from the minor product, green $\mathrm{CuBr}_{2} .2 \mathrm{tx}$. The structure has been determined as part of a programme to investigate the roles in which 1,4-oxathiane occurs as a bridging ligand.

As (I) is not stable in air on prolonged exposure crystals were mounted in capillaries or else varnished. Weissenberg photographs were taken with $\mathrm{Cu} K \alpha$ radiation for the levels $h k(0-9)$ where $c$ is the needle axis and levels ( $0-3$ ) for a crystal mounted on the $a b$ diagonal. Intensities of 1302 reflexions above background were measured with a computerized microdensitometer (SRC Service, Daresbury Laboratory). Unfortunately, the 20 strongest reflexions proved to be too intense to be measured on any of the films; these intensities were estimated visually and added to the data set along with 495 reflexions not observed above background which were assigned $I=\frac{1}{2} I_{\min }$.

All calculations were performed using SHELX 76 (Sheldrick, 1976) and XANADU (Roberts \& Sheldrick, 1975). Neutral-atom scattering factors were taken from International Tables for X-ray Crystallography (1974).

Preliminary calculations showed that the (uuu) reflexions of the $F$ lattice were systematically less intense than the ( $g g g$ ) reflexions. For all $E$ maps the data were renormalized to bring some (uuu) reflexions above the limit $E>1 \cdot 2$. The $E$ maps were dominated by false symmetry but the sixth map in rank gave the desired pattern of two heavy and four medium weight peaks, interpreted as two Br , two Cu and two S atoms.

At this point only the 1302 measured reflexions were retained and absorption corrections were applied (crystal size $0.20 \times 0.20 \times 0.54 \mathrm{~mm}$ ). A Fourier map then revealed all the remaining non- H atoms $(R=$ 0.25 ). Refinement continued by least squares and Fourier methods. As in other 1,4-oxathiane complexes examined recently (Barnes, Blyth \& Paton, 1982), the dimensions found for the oxathiane molecules were unsatisfactory, and the refinement stopped at $R=0 \cdot 14$. Inclusion of the oxathiane as a restrained group defined by $\mathrm{C}-\mathrm{S} 1.81, \mathrm{C}-\mathrm{O} 1.45, \mathrm{C}-\mathrm{C} 1.54 \AA$ with S as the pivot atom allowed refinement to continue to $R=$ 0.071 with anisotropic $\mathrm{Cu}, \mathrm{Br}$ and S and to convergence at $R=0.067$ with all non- H atoms anisotropic and H atoms included on calculated positions. Two reflexions for which secondary extinction appeared to be severe were excluded from the
final calculation. The weighting scheme used was $w=$ $72 \cdot 2342 /\left[\sigma^{2}(F)+0.0100 F^{2}\right]$.*

Discussion. Atomic coordinates for (I) are given in Table 1; bond lengths and angles are in Table 2. The structure consists of $\mathrm{Cu}_{2} \mathrm{Br}_{2}$ rings alternately normal to the $c$ axis $\left[\mathrm{Cu}(1), \operatorname{Br}(2), \mathrm{Cu}(1)^{\prime}, \operatorname{Br}(2)^{\prime}\right]$ and normal to the $a$ axis $\left[\mathrm{Cu}(2), \mathrm{Br}(1), \mathrm{Cu}(3), \mathrm{Br}(1)^{\prime}\right]$. These planar rings are linked into chains parallel to the $c$ axis by the $S$ atoms of the oxathiane molecules. $\mathrm{S}(11)$ joins $\mathrm{Cu}(1)$ to $\mathrm{Cu}(2)$ and $\mathrm{S}(21)$ joins $\mathrm{Cu}(1)$ to $\mathrm{Cu}(3)$, so that each Cu atom has approximately tetrahedral geometry (Fig. 1). The $O$ atoms of the oxathiane molecules take no

Fig. 1. The title compound viewed normal to the $b c$ plane.
part in complex formation. The two oxathiane molecules are approximately eclipsed when viewed down the $c$ axis. There are approximate local centres of inversion at the centres of the $\mathrm{Cu}_{2} \mathrm{Br}_{2}$ rings.

The dimensions of the $\mathrm{Cu}_{2} \mathrm{Br}_{2}$ rings are appreciably different. For the ring $\mathrm{Cu}(1), \operatorname{Br}(2), \mathrm{Cu}(1)^{\prime}, \operatorname{Br}(2)^{\prime}$ the average CuBr distance is $2.537 \AA$ and the average $\mathrm{Cu}-\mathrm{S}$ distance is $2.281 \AA$. The angles about the Cu atom range from 96.9 to $151 \cdot 8^{\circ}$. $\mathrm{S}(11)$ and $\mathrm{S}(21)$ both use axial lone pairs for bonding to $\mathrm{Cu}^{1}$. In the ring $\mathrm{Cu}(2), \mathrm{Br}(1), \mathrm{Cu}(3), \mathrm{Br}(1)^{\prime}$ the average $\mathrm{Cu}-\mathrm{Br}$ distance is $2.470 \AA$ and the average $\mathrm{Cu}-\mathrm{S}$ distance $2.340 \AA$. The angles about the Cu atoms all lie between 107.3 and $110.9^{\circ}$. The S atoms use equatorial lone pairs for binding to $\mathrm{Cu}(2)$ and $\mathrm{Cu}(3)$. The $\mathrm{Cu}-\mathrm{S}$ distances in tetrahedral Cutx ${ }_{4}^{+}$(Barnes et al., 1982) range from 2.279 to $2.370 \AA$ with no correlation between bond
length and the choice of axial or equatorial directions at the S atoms.
There does not appear to be a close analogue to the structure of (I). $\mathrm{CuBr}\left(\mathrm{Et}_{2} \mathrm{P} . \mathrm{PEt}_{2}\right.$ ) (Hartung, 1970) contains chains made up of $\mathrm{Cu}_{2} \mathrm{Br}_{2}$ and $\mathrm{Cu}_{2} \mathrm{P}_{4}$ rings but with only a single orientation for the $\mathrm{Cu}_{2} \mathrm{Br}_{2}$ rings.
$\mathrm{Cu}-\mathrm{Cu}$ bonds have been postulated in several structures containing $\mathrm{Cu}_{2} X_{2}$ rings, typically $\mathrm{Cu}-\mathrm{Cu}$ $2.60 \AA$ in $\left[\mathrm{CuI}\left(\mathrm{AsEt}_{3}\right)\right]_{4}$ (Mann, Purdie \& Wells, 1936). However, the $\mathrm{Cu}_{2} \mathrm{Cl}_{2}$ ring in cyclooctadienyl CuCl (Van der Hende \& Baird, 1963) has $\mathrm{Cu} \cdots \mathrm{Cu}$ $2.944 \AA$ and $\mathrm{CuBr}\left(\mathrm{Et}_{2} \mathrm{P} . \mathrm{PEt}_{2}\right)$ has $\mathrm{Cu} \cdots \mathrm{Cu} 3.49 \AA$ with $\mathrm{Cu}-\mathrm{Br} 2.55 \AA$. In (I) the $\mathrm{Cu} \cdots \mathrm{Cu}$ distances 2.740 (3) and 2.865 (4) $\AA$ and the very acute $\mathrm{Cu}-\mathrm{Br}-\mathrm{Cu}$ angles 65.4 and $70.9^{\circ}$ suggest some $\mathrm{Cu} \cdots \mathrm{Cu}$ interaction.

By Aarne Pajunen and Selija Pajunen<br>Department of Inorganic Chemistry, University of Helsinki, Vuorikatu 20, SF-00100 Helsinki 10, Finland

(Received 26 April 1982; accepted 8 July 1982)

#### Abstract

C}_{9} \mathrm{H}_{14} \mathrm{CuN}_{2} \mathrm{O}_{5}\), monoclinic, $P 2_{1} / n, a=$ 7.178 (4), $b=14.425$ (11), $c=11 \cdot 147$ (9) $\AA, \beta=$ $106.25(5)^{\circ}, Z=4, V=1108 \cdot 1$ (8) $\AA^{3}, D_{m}=1 \cdot 76$, $D_{c}=1.76 \mathrm{Mg} \mathrm{m}^{-3}, \mu(\mathrm{Mo} K \alpha)=2.06 \mathrm{~mm}^{-1}$. The structure was refined to $R=0.035$ for 2114 observed reflections. The structure consists of discrete fivecoordinate square-pyramidal neutral complexes. The tetradentate ligand is bonded in a square plane about Cu with $\mathrm{Cu}-\mathrm{N}=1.984$ (3) and 1.972 (3) $\AA$ and $\mathrm{Cu}-\mathrm{O}=1.958$ (3) and 1.953 (3) $\AA$. The apical position is occupied by a water O atom at a distance of $2 \cdot 310$ (3) $\AA$.

Introduction. The title compound was first prepared by Nakahara, Yamamoto \& Matsumoto (1964) in connection with their studies on the stability of fused five- and six-membered rings in metal chelates. The blue needleshaped crystals were prepared from 1,3-propanediamine, pyruvic acid and freshly precipitated $\mathrm{Cu}(\mathrm{OH})_{2}$ and recrystallized from water (Nakahara et al., 1964). Systematic absences of the type $h 0 l, h+l=2 n+1$ and $0 k 0, k=2 n+1$ indicated space group $P 2_{1} / n$. The crystal chosen for data collection had dimensions 0.40 $\times 0.08 \times 0.05 \mathrm{~mm}$. Cell constants were calculated from angular settings of 16 reflections measured on a
