#### Abstract

(1)5,7-Dimethoxy-1',3',3'-trimethylspiro[2H-1,4benzoxazine-2,2'-indoline],  $C_{20}H_{22}N_2O_3$ ,  $M_r = 338.4$ , monoclinic,  $P2_1/c$ , a = 12.151 (2), b = 12.090 (4), c =24.836 (4) Å,  $\beta = 90.31$  (1)°, V = 3648 (2) Å<sup>3</sup>, Z = 8,  $D_x = 1.23 \text{ Mg m}^{-3}, \quad \lambda(\text{Cu } K\alpha) = 1.54178 \text{ Å}, \quad \mu =$  $0.637 \text{ mm}^{-1}$ , F(000) = 1440, T = 296 K, R = 0.063for 3106 unique observed reflections. (2) 5,5',7-Trimethoxy-1',3',3'-trimethylspiro[2H-1,4-benzoxazine-2,2'-indoline],  $C_{21}H_{24}N_2O_4$ ,  $M_r = 368.4$ , monoclinic,  $P2_1/c$ , a = 8.025 (2), b = 12.415 (3), c = 19.319 (4) Å,  $\beta = 99.31 \ (2)^{\circ},$ V = 1899.4 (8) Å<sup>3</sup>, Z = 4,  $D_x =$ 1.288 Mg m<sup>-3</sup>,  $\lambda$ (Cu  $K\alpha$ ) = 1.54178 Å,  $\mu$  = 0.084 mm<sup>-1</sup>, F(000) = 784, T = 173 K, R = 0.0486 for 1611 unique observed reflections. (3) 5'-Fluoro-5,7-dimethoxy-1',3',3'-trimethylspiro[2H-1,4-benzoxazine-2,2'-indoline],  $C_{20}H_{21}N_2O_3F$ ,  $M_r = 356.4$ , monoclinic,  $P2_1/c$ , a = 11.484 (3), b = 13.832 (2), c =11.511 (1) Å,  $\beta = 98.90$  (1)°, V = 1810.4 (6) Å<sup>3</sup>, Z =4,  $D_x = 1.308 \text{ Mg m}^{-3}$ ,  $\lambda(\text{Cu } K\alpha) = 1.54178 \text{ Å}$ ,  $\mu =$  $0.754 \text{ mm}^{-1}$ , F(000) = 752, T = 173 K, R = 0.0468for 2229 unique observed reflections. These three monomeric compounds consist of a substituted benzoxazine ring orthogonally coupled to an indoline ring through a spiro C atom.

#### Introduction

Organic photochromic materials have broad commercial applications due to their ability to reversibly alter their spectroscopic characteristics. Additionally, these very important materials vary in color, intensity, rate of reaction, stability and solubility (Clegg, *et al.*, 1991, and references therein). In the past, development of these materials has occurred *via* synthesis of a large number of analogs followed by chemical purification, characterization and finally measurement of spectral properties. Recent advances have allowed for a more directed approach towards rational molecular design through the use of computational chemistry and X-ray diffractometry, coupled to organic synthesis methods. This paper examines a series of photochromic molecules and their properties through several spectroscopic techniques, as well as a semiempirical quantum mechanical method.

#### Crystallography

[Data for (2) and (3) are given in parentheses when they differ from those of (1)]. Colorless, parallelepiped shaped crystals,  $0.14 \times 0.23 \times 0.31$ ,  $(0.18 \times$  $0.21 \times 0.25$ ) and  $(0.25 \times 0.40 \times 0.50 \text{ mm})$ , were mounted along the largest dimension and data were collected with a Rigaku AFC-6R diffractometer equipped with a copper rotating anode and a highly oriented graphite monochromator. A constant scan speed of  $8^{\circ}$  min<sup>-1</sup> in  $\omega$  was used and the weak reflections,  $[I < 5\sigma(I)]$  for (1) and (2) and  $[I < 6\sigma(I)]$ for (3), were rescanned to a maximum of four times and the counts accumulated to assure good counting statistics. The intensities of three monitor reflections measured after every 200 reflections did not change significantly during 73, 28 and 34 h of X-ray exposure. Unit-cell dimensions and standard deviations were obtained by least-squares fit to 25, 15 and 25 reflections  $50 < 2\theta < 80$ ,  $(40 < 2\theta < 60)$  and  $(60 < \theta < 60)$ 

<sup>\*</sup> Current address: Rhone-Poulenc Ago Company, Research Triangle Park, Durham, NC 27709, USA.

<sup>†</sup> Current address: NuMega Resonance Labs, Inc., 11855 Sorrento Valley Road, Suite J, San Diego, CA 92121, USA.

<sup>‡</sup> Current address: The Scripps Research Institute, 10666 N. Torrey Pines Road, La Jolla, CA 92037, USA.

 $2\theta < 80^{\circ}$ ): the data were corrected for Lorentz and polarization effects and not for absorption due to a low  $\mu$  value. See Tables 1, 2 and 3 for cell parameters and other relevant data.

The systematic absences (0k0, k=2n+1 and h0l), l=2n+1) indicated the space group  $P2_1/c$ . The structure was solved by direct methods using SHELXS86 (Sheldrick, 1990a). For (1), the structure was refined by a block-diagonal least-squares matrix method as follows: O1a and O1b every cycle; O2a-C20a and O2b-C20b in alternate cycles with C25-C77. All non-H atoms were refined anisotropically and the function minimized was  $\sum w(|F_o| - |F_c|)^2$ . H atoms were placed in ideal positions with a fixed isotropic U value of 0.08 Å<sup>2</sup>. For (2), all non-H atoms were refined anisotropically by the full-matrix least squares method. The function minimized was  $\sum w(|F_o| - |F_c|)^2$ . H atoms were placed in ideal positions with a fixed isotropic U value of 0.08 Å<sup>2</sup>. For (3), all non-H atoms were refined anisotropically, while H atoms were refined isotropically by the full-matrix least squares method. The function minimized was  $\sum w(|F_c| - |F_c|)^2$ .

A weighting scheme of the form  $w = 1/[\sigma^2(F) +$  $gF^2$ ], with g = 0.004, 0.002 and 0.0015, was used. There was no evidence of secondary extinction; therefore, it was not applied. The refinement converged to the R indices given in Table 4, which also includes  $\Delta/\sigma$  and  $\Delta\rho_{\rm max}$  in the last cycles of refinement. The final difference map was devoid of significant features.

All calculations were performed on a Silicon Graphics personal iris 4D/35 and an IBM compatible PC using the programs TEXSAN (Molecular Structure Corporation, 1985) for data reduction, SHELXS86 (Sheldrick, 1990a) for structure solution and SHELXTL/PC (Sheldrick, 1990b) for refinement and plotting. Final atomic coordinates are listed in Tables 5, 6 and 7, and selected bond lengths and angles are listed in Tables 8, 9 and 10.\*

#### **Synthesis**

Preparations of (1), (2) and (3) have been previously synthesized by Kwak & Hurditch (1989) and are crystallized and characterized as follows: The crude photochromic compounds were purified on a silica gel column using a mixture of ethyl acetate and hexane as the eluant. The photochromic fractions were collected and the solvent removed under vacuum. The products were crystallized using an

† AM1 semiempirical molecular orbital theory.

<sup>‡</sup> Molecule A of (1) (crystal structure).

§ Molecule B of (1) (crystal structure).

theoretical and experimental results were within coincidence by 0.02–0.04 Å for bond lengths and  $2-3^{\circ}$  bond angles, with minor exceptions. The calculated bond lengths and angles are summarized and compared with the crystallographic results in Tables 4 and 11 for (1), Tables 12 and 13 for (2), and in Tables 14 and 15 for (3), respectively.

As can been seen in Tables 4, 12 and 14, the agreement between the theoretical and crystallographic bond lengths is within 0.002-0.004 Å, with few exceptions. As can be seen in Tables 11, 13 and 15, theoretical bond angles agree to within  $2-3^{\circ}$  of the experimental values, with few exceptions. In Tables 4 and 12–15, the AM1 data are generally similar to the crystallographic data and in better agreement than the molecular mechanics CVFF Table 12. Compound (2) bond lengths (Å)

\* Molecular mechanics with Biosym CVFF Force Field (Biosym Technologies, 1992).

† AM1 semiempirical molecular orbital theory.

‡ Crystal structure.

force-field study results (Biosym Technologies, 1992). However, the molecular mechanics results are likely to improve, as more accurate force fields are developed.

The differences in bond lengths or angles which are > 0.002 Å or  $2-3^{\circ}$  are likely due to phase and temperature differences. The experimental studies are in the crystal phase at either 173 or 296 K, while the theoretical studies are for isolated molecules at 0 K. In this respect, theoretical studies can be used to identify regions of molecules significantly impacted by phase changes or temperature differences.

With regard to relative changes in bond lengths and angles, as shown in Tables 4 and 11–15, both theoretical methods predict relative changes, in

Fig. 4. Crystal structure of molecule A of (1). The non-H atoms are drawn with 30% probability ellipsoids, H atoms are drawn arbitrarily small. Molecule B is only slightly different in bond lengths and angles.

‡ Crystal structure.

accord with the experiment. The few exceptions may be due to omission of crystal packing forces in the theoretical methods and temperature differences, as discussed above. Of particular interest is the C—O bond which is cleaved in each of the compounds when exposed to light. In comparing the bond lengths [C10—O1 for (1) and (3) and C11—O2 for

§ Crystal structure at 296 K.

(2)], as noted in Figs. 4, 5 and 6 for (1), (2) and (3), both theoretical methods predict no change in bond lengths, while experimental data show a maximum change of only 0.01 Å. Little or no change in the theoretical and experimental bond lengths indicates that it is unlikely there is significant differences in bond strengths in either isolated molecules or the crystal phase.

Fig. 6. Crystal structure of (3). The non-H atoms are drawn with 30% probability ellipsoids, while H atoms are drawn arbitrarily small.
