# $A b$ initio structure determination of the hygroscopic anhydrous form of $\boldsymbol{a}$-lactose by powder X-ray diffraction 

#### Abstract

Annealing of $\alpha$-lactose monohydrate at 408 K yielded a mixture of this compound with hygroscopic anhydrous $\alpha$-lactose. A powder X-ray diffraction pattern of this mixture was recorded at room temperature. The starting structural model of hygroscopic $\alpha$-lactose was found by a Monte Carlo simulated-annealing method. The final structure was obtained through Rietveld refinements, with soft restraints on interatomic bond lengths and bond angles, and crystalline energy minimization to locate the H atoms of the hydroxy groups. The crystalline cohesion is achieved by networks of $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds that differ from those of the monohydrate phase. The width of the Bragg peaks is interpreted by a phenomenological microstructural approach in terms of isotropic size effects and anisotropic strain effects.

## 1. Introduction

Lactose (4- $O$ - $\beta$-D-galactopyranosyl-D-glucopyranose), also called milk sugar, is a carbohydrate comprising one galactose moiety linked to a glucose molecule through a $\beta-1,4$ linkage. Lactose exhibits two anomeric forms, $\alpha$-lactose and $\beta$-lactose, which differ in the configuration of the terminal hydroxy group of the glucose unit for the $\beta$-form; the atoms $\mathrm{O}^{\prime}$ and $\mathrm{H}^{\prime}$ of Fig. 2 are inverted. In the solid state, lactose can be amorphous or crystallized, and five crystalline forms are known (Garnier, 2001): $\alpha$-lactose monohydrate (hereafter named $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ ), hygroscopic anhydrous $\alpha$-lactose $\left(\alpha \mathrm{L}_{\mathrm{H}}\right)$, stable anhydrous $\alpha$-lactose $\left(\alpha \mathrm{L}_{\mathrm{s}}\right), \beta$-lactose $(\beta \mathrm{L})$ and mixed compounds, $\alpha / \beta$, with different stoichiometries $(\alpha / \beta \mathrm{L})$. The crystalline structures have been solved for only two of these five forms: they are $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ (Fries et al., 1971; Beevers \& Hansen, 1971; Noordik et al., 1984) and $\beta \mathrm{L}$ (Hirotsu \& Shimada, 1974). These are the only two forms that are commercially available and that give single crystals of adequate size for a single-crystal structure determination.

The $\alpha \mathrm{L}_{\mathrm{H}}$ phase was observed for the first time by Buma \& Wiegers (1967). It is obtained by heat-drying the $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ form at $\sim 403 \mathrm{~K}$. This form is unstable because it returns to the $\alpha \mathrm{L}-$ $\mathrm{H}_{2} \mathrm{O}$ form when the temperature is lowered and, upon heating, the $\alpha \mathrm{L}_{s}$ phase appears (van Kreveld, 1969). It is therefore impossible to grow single crystals suitable for X-ray automatic diffractometer experiments; only powder diffraction patterns can be used for the crystalline structure determination of the $\alpha \mathrm{L}_{\mathrm{H}}$ phase.

The aim of this paper is the structure determination of the $\alpha \mathrm{L}_{\mathrm{H}}$ form from powder X-ray diffraction experiments using the Rietveld method. In order to locate the H atoms of the hydroxy groups involved in hydrogen bonds, Rietveld refinements are complemented by energy minimization.

## 2. Experimental

### 2.1. Procedure to obtain the $\boldsymbol{\alpha} \mathrm{L}_{\mathrm{H}}$ phase

Commercially available $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ was used for this experiment (Sigma). It is well known that this compound always contains a component of $\beta \mathrm{L}$ (Noordik et al., 1984; $4 \%$ for $\alpha \mathrm{L}$ $\mathrm{H}_{2} \mathrm{O}$ from Sigma). A preliminary X-ray powder diffraction pattern of this compound does not exhibit Bragg peaks corresponding to the $\beta \mathrm{L}$ phase; there is no $\beta \mathrm{L}$ crystallite, but $\beta \mathrm{L}$ molecules can substitute for $\alpha \mathrm{L}$ molecules in the monohydrate.

In order to obtain the $\alpha \mathrm{L}_{\mathrm{H}}$ phase, the following procedure was used: $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ powder contained in a crystallizer was annealed in an oven for 30 min at temperature $T$. To avoid possible rehydration, the powder was introduced into a Lindemann glass capillary and then sealed rapidly for the Xray powder diffraction experiment. Attempts were performed at different temperatures. For temperatures lower than 393 K , only the peaks of the $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ phase were present in the patterns. From 398-408 K, in addition to the peaks of the $\alpha \mathrm{L}$ $\mathrm{H}_{2} \mathrm{O}$ phase, new peaks appear, which correspond to the $\alpha \mathrm{L}_{\mathrm{H}}$ phase according to Buma \& Wiegers (1967). At 413 K , the $\alpha \mathrm{L}-$ $\mathrm{H}_{2} \mathrm{O}$ form disappears and, as well as the peaks of the $\alpha \mathrm{L}_{\mathrm{H}}$ form, there are new diffraction peaks characterizing the $\alpha \mathrm{L}_{\mathrm{S}}$ phase (van Kreveld, 1969). Powder not used for the X-ray experiment was kept in air. After a week, this powder was analysed by X-ray diffraction and only the $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ phase was found. This experiment confirms that the supplementary peaks correspond to the unstable hygroscopic $\alpha \mathrm{L}_{\mathrm{H}}$ phase.

In conclusion, the $\alpha \mathrm{L}_{\mathrm{H}}$ form is always present with the $\alpha \mathrm{L}$ $\mathrm{H}_{2} \mathrm{O}$ phase. Consequently, the pattern recorded at 408 K was chosen for structure determination, because this pattern has the best ratio of $\alpha \mathrm{L}_{\mathrm{H}}$ to $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$.

### 2.2. Data collection

The powder X-ray diffraction patterns were measured on a laboratory diffractometer equipped with an INEL curved, position-sensitive detector (CPS120). A bent quartz monochromator allowed selection of the $K \alpha_{1}$ wavelength of a Cu Xray tube $(\lambda=1.54056 \AA)$. The powder was introduced in a Lindemann glass capillary (diameter 0.7 mm ) mounted on the axis of the diffractometer. The capillary was rotated during the experiment in order to reduce the effect of possible preferential orientations. Calibration of the curved detector was performed with an X-ray diffraction pattern of the standard compound $\mathrm{Na}_{2} \mathrm{Ca}_{3} \mathrm{Al}_{2} \mathrm{~F}_{14}$ (NAC; Evain et al., 1993). A cubic spline interpolation was performed between the peaks of NAC. The curved detector has 4096 channels, the $2 \theta$ range recorded was $0.3-114.7^{\circ}$ and the step between two channels was $0.029^{\circ}$. The pattern of NAC was also used to determine the shape and the parameters of the experimental resolution; it is a pseudo-Voigt function, with the Caglioti function for the $\theta$ dependence of the Gaussian component (Caglioti et al., 1958). The values of the parameters are $U_{\mathrm{ins}}=0.0166$ (4), $V_{\mathrm{ins}}=-0.0163(4)$ and $W_{\mathrm{ins}}=0.0101(2) \mathrm{deg}^{2}$. The $\theta$ dependence of the Lorentzian component is such that

$$
\Gamma_{\mathrm{L}}=X_{\mathrm{ins}} \tan \theta+Y_{\mathrm{ins}} / \cos \theta
$$

with $X_{\text {ins }}=0.0076(14)$ and $Y_{\text {ins }}=0.0197(7)^{\circ}$. Data were collected at room temperature with a total counting time of 16 h 40 min .

### 2.3. Structure solution and refinement

For the determination of the lattice parameters of $\alpha \mathrm{L}_{\mathrm{H}}$, the profiles of the 58 reflections with a $2 \theta$ angle lower than $40^{\circ}$ were refined individually with the program WinPlotr (Roisnel \& Rodriguez-Carvajal, 2002) in order to obtain their $2 \theta$ positions. The positions of the Bragg peaks of the $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ phase can be calculated from the lattice parameters obtained during structure determination (Fries et al., 1971). Among these 58 reflections, 14 of them, ranging from 9 to $33^{\circ}$, do not belong unambiguously to the $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ phase. The $2 \theta$ values of these reflections were input to the program TREOR (Werner et al., 1985) and these reflections were indexed completely, with a monoclinic cell, yielding the following parameters: $a=$ $7.766, b=19.698, c=4.901 \AA, \beta=103.59^{\circ}$ and $V=728.8 \AA^{3}$. The calculated figures of merit are $M(14)=16$ and $F(14)=20$ (0.017, 41) (de Wolff, 1968; Smith \& Snyder, 1979). The volume found with $T R E O R$ is almost the same as that obtained for the cell of the $\beta \mathrm{L}$ phase $\left(V=716.7 \AA^{3}\right.$; Hirotsu \& Shimada, 1974) and that for $\beta$-cellobiose, which is a disaccharide with a $\beta-1,4$ linkage ( $V=728.8 \AA^{3}$; Chu \& Jeffrey, 1968). Therefore, the three cells have the same number of molecules $(Z=2)$.

The powder X-ray diffraction pattern from 8.5 to $62^{\circ} 2 \theta$ was refined with the 'profile matching' option [Le Bail et al. (1988) profile refinement] of the program FullProf (RodriguezCarvajal, 2001). The refined angular range starts at $8.5^{\circ}$, in order to include the first reflection of the pattern at $\sim 9^{\circ}$; the upper limit was chosen to be $62^{\circ}$, since the intensities of the peaks become very low at higher angles. The monoclinic cell of Fries et al. (1971), with space group $P 2_{1}$ for the $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ phase, and the previous cell for $\alpha \mathrm{L}_{\mathrm{H}}$, with space group P2 (a space group without systematic extinction), were used in FullProf. The profile of the reflections was fitted with a pseudo-Voigt function with the same FWHM for the Gaussian and the Lorentzian components. This FWHM has a $\theta$ dependence according to the Caglioti law (Caglioti et al., 1958), and the Lorentzian contribution to the pseudo-Voigt function is a linear function of $2 \theta$. The parameters to fit the profile of the reflections are different for the two phases. The asymmetry of the peaks was taken into account according to the Bérar \& Baldinozzi (1993) function, with common parameters for the two phases. The background was determined with a linear interpolation between 26 points regularly distributed from 8.5 to $62^{\circ}$.

For $\alpha \mathrm{L}_{\mathrm{H}}$, the systematic absence of $0 k 0$ reflections with $k$ odd lead to the space group $P 2_{1}$, and the asymmetric unit contains one molecule. At the end of the Le Bail refinements, the profile reliability factors are $R_{\mathrm{p}}=0.0799, R_{\mathrm{wp}}=0.0850, R_{\text {exp }}$ $=0.0217$ and $\chi^{2}=15.3$; the lattice parameters of the $\alpha \mathrm{L}_{\mathrm{H}}$ phase are $a=7.7692(5), b=19.6971$ (13), $c=4.9040(4) \AA, \beta=$ $103.731(5)^{\circ}$ and $V=729.0$ (1) $\AA^{3}$.

Table 1
Values of the bond lengths ( $(\AA)$ and bond angles $\left({ }^{\circ}\right)$ used for the soft restraints.

The index 'int' represents internal atoms of the cycles and 'per' the peripheral atoms; C and O atoms of the methanol groups are named $\mathrm{C}_{\mathrm{m}}$ and $\mathrm{O}_{\mathrm{m}} ; \mathrm{O}_{\text {link }}$ is the O atom linking the two units.

| $\mathrm{C}_{\text {int }}-\mathrm{O}_{\text {link }}-\mathrm{C}_{\text {int }}$ | 107.9 |

In order to obtain a starting structural model, the 'parallel tempering' algorithm of the program FOX (Favre-Nicolin \& Cerny, 2002) was used. The $2 \theta$ angular range used in $F O X$ was $8.5-50^{\circ}$. Lattice and profile parameters for the two phases, and the zero point and interpolated background calculated with the Le Bail refinements, were used in this program. For the $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ phase, the reduced coordinates of the C and O atoms found in the structure determination of Fries et al. (1971) were input to $F O X$, and these were refined in the following way. For the $\alpha \mathrm{L}_{\mathrm{H}}$ phase, a molecule of $\alpha$-lactose, with C and O atoms only, was modelled with bond lengths, bond angles and torsion angles calculated from the atomic coordinates of Fries et al. (1971). This molecule was introduced randomly into the cell. During the calculation, all bond lengths and bond angles were kept constant, and the two central cycles of the galactose and glucose units were kept rigid. Torsion angles of the central linkage and those of peripheral O and C atoms were treated as free parameters, leading to 19 degrees of freedom: two translations (for space group $P 2_{1}$, the translation along $b$ must be restrained) and three rotations of the whole molecule, ten torsion angles for the peripheral atoms and four torsion angles for the central linkage. The temperature factors of the C and O atoms of the two phases could vary. The displacement parameters of the C and O atoms of the two phases were also refined freely. After about ten million trials, the $R_{\mathrm{w}}$ factor was 0.097 , and no significant improvement of this factor was observed when more trials were carried out. The coordinates of non-H atoms found by $F O X$ for the $\alpha \mathrm{L}_{\mathrm{H}}$ phase can be considered as a starting solution for the Rietveld refinements.

Parameters obtained from FOX were introduced into the program FullProf. It is well known that accurate determination of the positions of H atoms from powder X-ray diffraction experiments is impossible. In the present case, the positions of some of the H atoms can be deduced from geometrical arguments, as is the case for the H atoms of the CH and $\mathrm{CH}_{2}$ groups. For H atoms of OH groups involved in hydrogen
bonds, an additional lattice energy minimization is needed as an aid to the X-ray experiments. The positions of the H atoms were calculated with the program DEBVIN (Brückner \& Immirzi, 1997). For the CH groups, the H atoms were positioned such that the tetrahedron contained three equal C -$\mathrm{C}-\mathrm{H}$ or $\mathrm{O}-\mathrm{C}-\mathrm{H}$ angles, with a $\mathrm{C}-\mathrm{H}$ bond length of $1.00 \AA$. For the $\mathrm{CH}_{2}$ groups, the $\mathrm{H}-\mathrm{C}-\mathrm{H}$ bond angle is $108^{\circ}$, the $\mathrm{C}-$ H bond length is $1.00 \AA$ and the $\mathrm{H} / \mathrm{C} / \mathrm{H}$ plane is perpendicular to the $\mathrm{C} / \mathrm{C} / \mathrm{O}$ plane, the two H atoms being symmetrically located with respect to the $\mathrm{C} / \mathrm{C} / \mathrm{O}$ plane. Before energy calculations, and provisionally, the H atoms of hydroxy groups were positioned such that the $\mathrm{C}, \mathrm{O}$ and H atoms are aligned. During the following refinements, this procedure was repeated several times in order to determine the correct positions of the H atoms.

The $2 \theta$ range for the Rietveld refinements was $8.5-80^{\circ}$. The reduced coordinates of the 23 non- H atoms were adjusted (the $y$ coordinate of the central O atom was fixed at 0 and chosen as the origin). Owing to the large number of free parameters, soft restraints on all bond lengths and all bond angles were introduced. The values of these restraints were taken to be the mean values found in some disaccharides with a $\beta$-1,4 linkage (Chu \& Jeffrey, 1968; Ham \& Williams, 1970, Fries et al., 1971; Hirotsu \& Shimada, 1974). Table 1 gives these values for the different combinations of atoms involved in lactose. For the $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ phase, the input coordinates of the $\mathrm{C}, \mathrm{O}$ and H atoms were those obtained by Fries et al. (1971); the molecule of lactose was taken to be a rigid body, which can translate and rotate around its mass centre. For each phase, all atoms were assigned a common isotropic displacement parameter. Intensities were corrected to the absorption effects for a cylindrical sample with a $\mu R$ value of 0.40 .

For the peak-shape function, a Thompson-Cox-Hastings profile function (Thompson et al., 1987) was used, taking into account experimental resolution, and strain and size effects. The angular dependencies of the FWHM of the Gaussian $\left(H_{\mathrm{Gf}}\right)$ and Lorentzian $\left(H_{\mathrm{Lf}}\right)$ components of the peak profile due to strain and size effects are given by Rodriguez-Carvajal \& Roisnel (2004). ${ }^{1}$

For the $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ phase, the less abundant form in the powder, the two effects were taken as isotropic. For the $\alpha \mathrm{L}_{\mathrm{H}}$ phase, among the four possibilities, the best choice, in terms of agreement factors, is when isotropic size effects and anisotropic strain effects are considered (for isotropic strains, $R_{\mathrm{wp}}=$ 0.0995 , and it becomes equal to 0.0733 when they are taken as anisotropic). In this case, the Stephens (1999) formulation is

[^0]and
\[

$$
\begin{aligned}
H_{\mathrm{Lf}}= & {\left[X_{\mathrm{ins}}+X_{\mathrm{ST}}+\xi D_{\mathrm{ST}}\left(a_{\mathrm{ST}}\right)\right] \tan \theta } \\
& +\left[Y_{\mathrm{ins}}+Y_{\mathrm{SZ}}+F_{\mathrm{SZ}}\left(S_{\mathrm{SZ}}\right) / \cos \theta\right]
\end{aligned}
$$
\]

where the subscript ST represents strain effects and SZ size effects.

Figure 1
Final Rietveld plot. Observed data points are indicated by dots; the best-fit profile (upper trace) and the difference pattern (lower trace) are shown as solid lines. The vertical bars correspond to the positions of Bragg peaks (upper bars for $\alpha L_{H}$, lower bars for $\alpha L-H_{2} O$ ).
used for $D_{\mathrm{ST}}\left(a_{\mathrm{ST}}\right) . X_{\mathrm{ST}}$ and $\xi$ are zero and the anisotropic strain effects only have Gaussian components.

The March (1932) and Dollase (1986) function was used to take into account the preferred orientations. After several trials, the best agreement factors were obtained for preferred orientations along [001] for $\alpha \mathrm{L}_{\mathrm{H}}$ and [010] for $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$.

Calculations were performed using the $D L_{-} P O L Y$ molecular modelling package (Smith \& Forester, 1996) on a system of $N=80(4 \times 2 \times 5$ crystalline cells $)$ lactose molecules using periodic boundary conditions. Each molecule is described by its 45 atoms, which interact through the Ha forcefield (Ha et al., 1988) developed for carbohydrates. Electro-

Figure 2

static interactions were handled by the Ewald method. We worked in the NVE statistical ensemble, where the number of atoms ( $N$ ), the volume ( $V$ ) and the energy $(E)$ are fixed. A cut-off radius of $10 \AA$ was used. In order to determine the positions of the hydroxy H atoms, energy minimization calculations ( $T=0$ ) were carried out from the structure obtained experimentally. The $\mathrm{C}-\mathrm{O}-\mathrm{H}$ angles were initially chosen to be $180^{\circ}$. No dihedral interaction is applied to the hydroxy H atoms. During minimization, only H atoms of the hydroxy groups are allowed to move, in order to maintain the experimental structure as much as possible.

In the final Rietveld refinements and for a $2 \theta$ range of $8.5-80^{\circ}$, there were 136 adjustable parameters:
(i) 18 profile parameters: the zeropoint parameter, four lattice parameters, $Y_{\mathrm{SZ}}, G_{\mathrm{SZ}}$, nine parameters for the anisotropic strain effects and two parameters of the Bérar \& Baldinozzi (1993) function for the asymmetry of the peaks.
(ii) 71 structural parameters: the scale factor, 68 adjustable coordinates, a parameter $\left(G_{1}\right)$ linked to preferred orientations [March (1932) and Dollase (1986) function] and a global isotropic displacement parameter. The number of adjustable parameters is, in fact, reduced by the introduction of 24 soft restraints on bond lengths and 35 on bond angles.
(iii) 15 parameters for the $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ phase: the scale factor, four lattice parameters, two degrees of translation and three degrees of rotation of the whole molecule of lactose, $U_{\mathrm{ST}}, Y_{\mathrm{SZ}}$ and $G_{\mathrm{SZ}}$ for the profile of the peaks, $G_{1}$ for the preferred orientation function, and a global isotropic displacement parameter.
(iv) 32 points to define the background.

The final Rietveld agreement factors are $R_{\mathrm{p}}=0.0657$, $R_{\mathrm{wp}}=0.0733, R_{\mathrm{exp}}=0.0222$ and $\chi^{2}=10.9$. For the $\alpha \mathrm{L}_{\mathrm{H}}$ phase, $R_{\mathrm{B}}=0.0163$ and $R_{\mathrm{F}}=0.0223$; for the $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ phase, $R_{\mathrm{B}}=0.0468$ and $R_{\mathrm{F}}=0.0338$. The mean deviations from the soft restraints are $0.009 \AA$ for the bond lengths and $4.4^{\circ}$ for the bond angles. A plot of the X-ray pattern is given Fig. 1. The calculated specific percentage of the $\alpha \mathrm{L}_{\mathrm{H}}$ phase contained in the powder is $83(1) \%$. A view of the molecule of lactose drawn with $O R T E P-3$ (Farrugia, 1997) and showing the atomic numbering scheme is presented in Fig. 2. Crystallographic data, and profile and structural parameters, are reported in Tables 2 and 3, respectively. ${ }^{2}$

## 3. Discussion

The mean values of the bond lengths are 1.528 (9) $\AA$ for $\mathrm{C}_{\text {int }}-$ $\mathrm{C}_{\text {int }}$, 1.434 (12) $\AA$ for $\mathrm{C}_{\text {int }}-\mathrm{O}_{\text {int }}$ and 1.420 (9) $\AA$ for $\mathrm{C}_{\text {int }}-\mathrm{O}_{\text {per }}$, $\mathrm{C}_{\text {int }}-\mathrm{O}_{\text {link }}$ and $\mathrm{C}_{\mathrm{m}}-\mathrm{O}_{\mathrm{m}}$. These values are close to the mean values obtained in other disaccharides with a $\beta$-1,4 linkage (see Table 1). The maximum deviation from these mean values ( $0.020 \AA$ ) occurs for the $\mathrm{C} 2-\mathrm{O} 2$ bond. For the $\beta-1,4$ linkage, the $\mathrm{C} 1-\mathrm{O} 1$ and $\mathrm{C}^{\prime}-\mathrm{O} 1$ bonds lengths are similar ( 1.427 and $1.432 \AA$, respectively), while the difference between these two bond lengths is of the order of $0.05 \AA$ in other disaccharides [see, for example, Table 5 of Hirotsu \& Shimada (1974)]. For the bond angles, the mean values are $109(3)^{\circ}$ for $\mathrm{C}_{\text {int }}-\mathrm{C}_{\text {int }}-$ $\mathrm{C}_{\text {int }}, 118$ (4) ${ }^{\circ}$ for $\mathrm{C}_{\text {int }}-\mathrm{C}_{\text {int }}-\mathrm{O}_{\text {int }}, 106.3$ (3) ${ }^{\circ}$ for $\mathrm{C}_{\text {int }}-\mathrm{O}_{\text {int }}-$ $\mathrm{C}_{\text {int }}$ and 111 (4) ${ }^{\circ}$ for $\mathrm{C}_{\text {int }}-\mathrm{C}_{\text {int }}-\mathrm{O}_{\text {per }}$. The mean values of the angles involving $\mathrm{O}_{\text {int }}$ atoms differ from those found in other disaccharides: by about $7^{\circ}$ for $\mathrm{C}_{\text {int }}-\mathrm{C}_{\text {int }}-\mathrm{O}_{\text {int }}$ and $6^{\circ}$ for $\mathrm{C}_{\text {int }}-$ $\mathrm{O}_{\text {int }}-\mathrm{C}_{\text {int }}$. The value of the linkage angle $\mathrm{C} 1-\mathrm{O} 1-\mathrm{C} 4^{\prime}$ is $111.5(5)^{\circ}$, that is, $5^{\circ}$ smaller than in other disaccharides [see Table 6 of Hirotsu \& Shimada (1974)]. Table 4 reports the torsion angle values of the $\beta$-1,4 linkage for some disaccharides. The two forms of $\alpha$-lactose exhibit a symmetrical twist about the bridging bond, with very similar torsion angles: $\psi_{1}=$ -92.3 and $\psi_{2}=91.1^{\circ}$ for $\alpha \mathrm{L}_{\mathrm{H}}$, and $\psi_{1}=-92.6$ and $\psi_{2}=94.6^{\circ}$ for $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ (Fries et al., 1971). In contrast to the $\alpha$-lactose structures, an asymmetric twist about the bridging bond is found in $\beta \mathrm{L}$ (Hirotsu \& Shimada, 1974) and $\beta$-cellobiose (Chu \& Jeffrey, 1968), with a difference $\left|\psi_{2}\right|-\left|\psi_{1}\right|$ of the order of $34^{\circ}$. Methyl $\beta$-cellobioside (Ham \& Williams, 1970) has an intermediate conformation, with a $\left|\psi_{2}\right|-\left|\psi_{1}\right|$ value of ca $11^{\circ}$.

$\dagger$ This paper. $\ddagger$ Fries et al. (1971). § Hirotsu \& Shimada (1974). ब $\beta$-Cellobiose (Chu \& Jeffrey, 1968). $\dagger \dagger$ Methyl $\beta$-cellobioside (Ham \& Williams, 1970).

As for other disaccharides with a $\beta-1,4$ linkage, the $\mathrm{O}^{\prime}-$ $\mathrm{HO}^{\prime} \cdots \mathrm{O} 5$ intramolecular hydrogen bond exists in $\alpha \mathrm{L}_{\mathrm{H}}$ and plays a fundamental role in the molecular conformation.

In both $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ and $\alpha \mathrm{L}_{\mathrm{H}}$, the molecules are oriented with their long axis parallel to the twofold screw axis. As a consequence, the two forms have the same space group, $P 2_{1}$, and their lattice parameters are similar: $a=7.7795, b=19.693, c=$ $4.9064 \AA$ and $\beta=103.69^{\circ}$ for $\alpha \mathrm{L}_{\mathrm{H}}$, and $a=7.9423, b=21.599, c$ $=4.8168 \AA$ and $\beta=109.75^{\circ}$ for $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$, obtained with a Rietveld refinement from the commercial powder used to obtain the $\alpha \mathrm{L}_{\mathrm{H}}$ phase by annealing. The loss of the water molecule leads to a significant decrease of the $b$ parameter only. The ratio between the two unit-cell volumes ( $V_{\alpha \mathrm{LH}} /$ $V_{\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}}=0.939$ ) is close to the ratio of the number of atoms in the cells $(45 / 48=0.938)$.

For carbohydrates, the cohesion lattice energy is mostly provided by $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds, and for this discussion, it is interesting to compare the hydrogen-bonding networks of the two forms of $\alpha$-lactose ( $\alpha \mathrm{L}_{\mathrm{H}}$ and $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ ) and to try to draw some conclusions about the instability of the $\alpha \mathrm{L}_{\mathrm{H}}$ form. The hydrogen-bonding distances and angles for the $\alpha \mathrm{L}_{\mathrm{H}}$ form are listed in Table 5. Fig. 3 gives an ORTEP plot (Farrugia, 1997) of the projection of the cell along $c^{*}$, and Fig. 4 shows the projection of the cell along the twofold axis, with only the molecules around $y=0$. In these plots, the hydrogen

Symmetry codes: (i) $x+1, y, z$; (ii) $-x+1, y+\frac{1}{2},-z+2$; (iii) $-x, y+\frac{1}{2},-z+1$; (iv) $x-1, y, z-1$; (v) $-x+1, y-\frac{1}{2},-z+1$; (vi) $x, y, z-1$; (vii) $-x+1, y-\frac{1}{2},-z+2$; (viii) $x, y, z+1$; (ix) $x-1, y, z$.
bonds are drawn as dashed lines. The O atoms of the eight hydroxy groups of the molecule are all donors; atoms $\mathrm{O} 2, \mathrm{O} 3$, O5 and O6 of the galactose unit are acceptors, and for the glucose unit, the acceptor atoms are $\mathrm{O}^{\prime}, \mathrm{O}^{\prime}, \mathrm{O}^{\prime}$ and $\mathrm{O}^{\prime}$. As reported for $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$, atoms $\mathrm{O} 1, \mathrm{O} 4$ and $\mathrm{O}^{\prime}$ in $\alpha \mathrm{L}_{\mathrm{H}}$, the central and furthest O atoms of the rings, are not acceptors. The $\mathrm{O} \cdots \mathrm{O}$ distances range from 2.674 (19) to 2.854 (21) $\AA$, with a mean value of 2.77 (7) A. The $\mathrm{H} \cdots \mathrm{O}$ bond lengths range from 1.789 (18) to 2.078 (16) $\AA$, with a mean of 1.89 (10) $\AA$. These distances are in agreement with those generally found in carbohydrates (Jeffrey, 1990). The O$\mathrm{H} \cdots \mathrm{O}$ bond angles range from 129.2 (13) to $164.2(15)^{\circ}$; the maximum value given by Jeffrey (1990) for this angle is $\sim 160^{\circ}$.

Both forms contain an infinite chain of hydrogen bonds; the successive hydrogen bonds are as follows ${ }^{3}$ (symmetry codes are given at the bottom of Table 5)

$$
\rightarrow \mathrm{O} 2 \rightarrow \mathrm{O}^{\mathrm{i}} \rightarrow \mathrm{O}^{\mathrm{vi}} \rightarrow
$$

The molecule at the origin of this chain is first connected to its neighbour along $a$; then, the last molecule is linked to the molecule at $(x, y, z-1)$. These chains of hydrogen bonds lie along the $c$ axis, but there are strong interactions between neighbouring molecules located in the same monoclinic ac plane. The two forms also have a common finite chain

$$
\mathrm{O}^{\mathrm{vii}} \rightarrow \mathrm{O}^{\prime v \mathrm{viii}} \rightarrow \mathrm{O}^{\text {,ix }} \rightarrow \mathrm{O}^{\prime} \rightarrow \mathrm{O} 5
$$

This chain includes the intramolecular $\mathrm{O}^{\prime}-\mathrm{HO}^{\prime} \cdots \mathrm{O} 5$ hydrogen bond. Among the other hydrogen bonds, two of them involve molecules in the same monoclinic plane, and only the $\mathrm{O} 4-\mathrm{HO} 4 \cdots \mathrm{O} 2^{\prime}$ bond connects molecules along the twofold screw axis. The chains containing the remaining hydrogen bonds are different for the two forms. For $\alpha \mathrm{L}_{\mathrm{H}}$, there is a small finite chain

$$
\mathrm{O}^{\prime} \rightarrow \mathrm{O}^{\mathrm{v}} \rightarrow \mathrm{O}^{\prime \mathrm{vi}}
$$

However, in the case of $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$, the remaining H atoms of the hydroxy groups are connected to the water molecule, and

[^2]the H atoms of the water molecule also form new hydrogen bonds

with an $\mathrm{O} 3 \rightarrow \mathrm{OW} \rightarrow \mathrm{O} 3$ infinite chain. The $\mathrm{O}^{\prime}{ }^{\prime}$ atom is twice an acceptor and the $\mathrm{O} W \rightarrow \mathrm{O} 2^{\prime}$ hydrogen bond connects this infinite chain to the finite chain $\mathrm{O}^{\text {vii }} \rightarrow \mathrm{O}^{\prime \text { viii }} \rightarrow \mathrm{O}^{\prime \text { ix }} \rightarrow$ $\mathrm{O}^{\prime} \rightarrow \mathrm{O} 5$. The interconnections between hydrogen-bonding

Figure 5
Strain values on the $\alpha \mathrm{L}_{\mathrm{H}}$ phase for different directions of the lattice (black curves) (a) in the monoclinic plane, and $(b),(c)$ and $(d)$ in planes formed by the twofold axis and a direction of an extreme value of the strain in the monoclinic plane ( $\varphi$ is the angle between the lattice parameter $a$ and this direction). (b) $\varphi=21.5^{\circ}$, (c) $\varphi=81^{\circ}$ and (d) $\varphi=142^{\circ}$. The red curves correspond to the strain values for commercial $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$.
chains, absent from the $\alpha \mathrm{L}_{\mathrm{H}}$ form, must be an important factor for the stability of the $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ form. In this form, atoms O1 and $\mathrm{O} 3^{\mathrm{v}}$ are 4.662 (12) $\AA$ apart and are connected via the OW atom. In the $\alpha \mathrm{L}_{\mathrm{H}}$ phase, with the loss of the water molecule, the two atoms move closer and form a hydrogen bond with an $\mathrm{O} 1^{\prime} \cdots \mathrm{O}^{\mathrm{v}}$ distance of 2.736 (20) $\AA$.

An original aspect given by the powder diffraction pattern is the possibility of deducing from the shape and the width of the Bragg peaks the average size of the crystallites and the strain of the cell. In the present case, for the $\alpha \mathrm{L}_{\mathrm{H}}$ phase, the size effects are considered as isotropic and the strain effects as anisotropic, and for the $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ phase, the two effects are taken as isotropic. Isotropic size effects (spherical shape of the crystallites) for the two phases are consistent with the calculated effects of the preferred orientations; for $\alpha \mathrm{L}_{\mathrm{H}}, G_{1}=$ 1.089 (4) for the [001] preferred direction, corresponding to a weak platy habit of the crystallites. For the $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ phase, where $G_{1}=1.011$ (6), there is, in practice, no preferred orientation.

Preliminary Rietveld refinements for the commercial $\alpha \mathrm{L}$ $\mathrm{H}_{2} \mathrm{O}$ powder lead to an average diameter of $1400 \AA$ for the crystallites and an average strain of the cell of $11.1 \times 10^{-4}$. After annealing at 408 K , the corresponding values become $730 \AA$ and $9.0 \times 10^{-4}$ for the $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ phase, and $790 \AA$ and $31.2 \times 10^{-4}$ for the $\alpha \mathrm{L}_{\mathrm{H}}$ phase. The size of the crystallites is almost identical for the two phases and is about one-half of the size of the starting compound, the size reduction being due to breakage of the crystallites when the powder is heated. The strain effects are, generally, due to defects in the lattice (vacancies, impurities etc.), and in a lattice such as $\alpha \mathrm{L}_{\mathrm{H}}$, possible defects are the breaking of a hydrogen bond or the presence of a residual water molecule. The average values of these strain effects are similar in the $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$ phase before and after annealing. For $\alpha \mathrm{L}_{\mathrm{H}}$, the average value is three times greater than that of $\alpha \mathrm{L}-\mathrm{H}_{2} \mathrm{O}$. In fact, these strain effects have a strong anisotropic character, and Fig. 5 shows the value of this strain for different planes of the lattice. The value of the strain ranges from $17.2 \times 10^{-4}$ for the 120 reflection to $48.4 \times 10^{-4}$ for 103. In the monoclinic plane, the minimum value of the strain $\left(22.0 \times 10^{-4}\right)$ occurs for $\varphi=21.5^{\circ}$, and the strain has a value higher than $43.0 \times 10^{-4}$ for a large area around the $c$ axis $\left(\varphi=60-155^{\circ}\right)$. As seen above, the cohesion energy in the monoclinic plane is provided by hydrogen bonds. From Fig. 4, it can be concluded that no hydrogen bond exists in the monoclinic plane for $\varphi \simeq 21^{\circ}$. Conversely, there are several hydrogen bonds around the direction of the lattice parameter $c$, and the high value of the strain can indicate a breaking of chains of the hydrogen-bonding networks. Along the twofold axis, the strain has an intermediate value $\left(26.5 \times 10^{-4}\right)$ corresponding to the absence of residual water molecules and an almost complete formation of the hydrogen bonds characteristic of the $\alpha \mathrm{L}_{\mathrm{H}}$ phase.

To conclude, the structure determination of the hygroscopic phase of $\alpha$-lactose is consistent with two possible reasons for the instability of this phase: the destruction of the hydrogenbonding networks along the twofold axis when the water molecule is removed and the existence of many defects in the hydrogen-bonded chains.
