# Structure of strontium hydroxide octahydrate, $\mathrm{Sr}(\mathrm{OH})_{2} \cdot \mathbf{8 H} \mathrm{H}_{2} \mathrm{O}$, at 20,100 and 200 K from neutron diffraction 

The crystal structure of $\mathrm{Sr}(\mathrm{OH})_{2} \cdot 8 \mathrm{H}_{2} \mathrm{O}$ has been determined at 20,100 and 200 K from neutron diffraction data. The structure consists of double layers of $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{OH}^{-}$ions separated by $\mathrm{Sr}^{2+}$ along the $c$ axis. The $\mathrm{Sr}^{2+}$ ions are eightcoordinated by water O atoms in a square antiprism configuration. Each $\mathrm{H}_{2} \mathrm{O}$ molecule is engaged in three hydrogen bonds. The $\mathrm{OH}^{-}$ions form chains of acceptor and donor bonds along the fourfold axis with O atoms engaged in four bonds with $\mathrm{H}_{2} \mathrm{O}$ molecules, such that both non-equivalent O atoms have square-pyramidal environments of five H atoms and the overall bonding configurations of distorted octahedra.

## 1. Introduction

This neutron diffraction study was undertaken because of the paucity of structural information on ionic hydroxides, especially with regard to the involvement of the $\mathrm{OH}^{-}$ion in hydrogen bonding. Four previous reports of the crystal structure of $\mathrm{Sr}(\mathrm{OH})_{2} \cdot 8 \mathrm{H}_{2} \mathrm{O}$ (Natta, 1928; Mellor, 1938; Smith, 1953) have resulted in various structures and yielded four different space-group assignments. Owing to structural ambiguities not resolvable by X-ray diffraction, Smith chose an Archimedian antiprism over a cubic arrangement of the eight $\mathrm{H}_{2} \mathrm{O}$ molecules about the $\mathrm{Sr}^{2+}$ ion on the basis of maximizing the hydrogen bonding, whereby all 72 H atoms in the unit cell are utilized. The structure proposed provides a rare example of $\mathrm{OH}^{-}$ions engaged as hydrogen donors in the solid state. As Smith has pointed out, the structural ambiguities would be resolvable upon location of the H -atom positions. Our study confirms his results. The neutron data were measured at three temperatures in order to evaluate the effects of thermal motion on molecular dimensions and hydrogen-bonding parameters.

## 2. Experimental

The diffraction data were measured at the Brookhaven High Flux Beam Reactor on the H6S four-circle instrument. A monochromated neutron beam was obtained from the (220) planes of a germanium crystal in transmission geometry. The wavelength was calibrated against a KBr crystal ( $a_{o}=6.6000 \AA$ at 295 K ). The $\mathrm{Sr}(\mathrm{OH})_{2} \cdot 8 \mathrm{H}_{2} \mathrm{O}$ crystal was obtained from Baker Chemical Co. and was covered with halocarbon grease to prevent reaction with $\mathrm{CO}_{2}$. The sample was attached to an aluminium pin and sealed under helium gas inside an aluminium canister. During measurements, the sample temperature

[^2]was held within $0.1^{\circ}$ of preset values using a double-stage DISPLEX helium cryostat. ${ }^{1}$ The diffraction data were obtained in order of increasing temperature. The lattice parameters of $\mathrm{Sr}(\mathrm{OH})_{2} \cdot 8 \mathrm{H}_{2} \mathrm{O}$ (Table 1) were determined by least-squares fits to $\sin ^{2} \theta$ values for 32 reflections. Intensity data for reflections comprising two equivalent sectors were collected using the $\omega / 2 \theta$ step scan method. Scan widths were fixed at $\Delta 2 \theta=2.4^{\circ}$ for $\sin \theta / \lambda<0.40 \AA^{-1}$ and were varied as $\Delta 2 \theta=(1.18+3.00 \tan \theta)^{\circ}$ at higher angles up to $\sin \theta / \lambda \leq$ $0.70 \AA^{-1}$. The extinction rules of space group $P 4 / n c c$ were verified at 20 K from measured intensities of all $h k l$ reflections with $\sin \theta / \lambda<0.40 \AA^{-1}$. The intensities of two reflections ( $2 \overline{4} 7 ; 60 \overline{4}$ ) measured at regular intervals were constant within $2 \%$. The integrated intensity, $I_{0}$, of each reflection was

[^3]evaluated taking the first and last tenth parts of the scan as the background; the variance, $\sigma^{2}\left(I_{o}\right)$, was obtained from counting statistics. Absorption corrections (de Meulenaer \& Tompa, 1965; Templeton \& Templeton, 1973) were applied using the $\mu / \rho$ value of $2.642 \mathrm{~cm}^{2} \mathrm{~g}^{-1}$ (Koetzle \& McMullan, 1980) for hydrogen at $\lambda_{n}=1.1594 \AA$. Minimum and maximum transmission factors were 0.486 and 0.596 . Averaging $F_{o}^{2}\left(\sin 2 \theta \cdot I_{o}\right)$ values for symmetry-related ( $h k l$ and $k h I$ ) pairs gave agreement factors $<0.02$ and provided the 699 ( 20 K ), 701 ( 100 K ), 703 ( 200 K ) observations (Table 1) used in the structure determination.

The initial strontium and oxygen coordinates were those reported by Smith (1953); hydrogen coordinates were obtained from difference Fourier maps. The refinements were by full-matrix least-squares methods; $\Sigma w\left|F_{o}^{2}-F_{c}^{2}\right|^{2}$ was minimized with weights $w=\left[\sigma^{2}\left(F_{o}^{2}\right)+\left(0.02 F_{o}^{2}\right)^{2}\right]^{-1}$, where the sums were over all independent observations. Coherent neutron scattering lengths were taken from Koester \& Yelon

(1983). The variable parameters were: the free coordinates and anisotropic displacement parameters, one scale factor and the isotropic secondary extinction parameter (type I crystal;

Figure 1
Stereoview of tetragonal $\mathrm{Sr}(\mathrm{OH})_{2} \cdot 8 \mathrm{H}_{2} \mathrm{O}$ at 20 K . The displacement ellipsoids are shown at the $50 \%$ probability level (Johnson, 1976). For a view down the fourfold axis, see Fig. 3 in Smith (1953).

Becker \& Coppens, 1974; Lorentzian distribution in mosaic spread; Thornley \& Nelmes, 1974). The data were severely affected by extinction: 10 reflections in each set had applied corrections on $F_{o}^{2}>2.0$, the largest being 3.57 for the reflection (554). The 10 reflections affected were omitted from the three data sets in the final refinements, but were included in computing the agreement indices listed in Table 1. Parameter shifts $P_{i} /$ $\sigma_{i}$ were $<0.01$ in the final cycles. The largest residual densities which were $|\Delta \rho| \simeq 2 \%$ of $\rho$ at an oxygen position were of no clear structural significance. Computations were carried out using the programs of Lundgren (1982) and with locally written programs. The final nuclear positional and displacement parameters are given in the supplementary material. ${ }^{2}$ Distances and angles are listed in Table 2.

## 3. Results and discussion

### 3.1. Crystal structure

Tetragonal $\mathrm{Sr}(\mathrm{OH})_{2} \cdot 8 \mathrm{H}_{2} \mathrm{O}$ has the structure shown in Fig. 1 at 20, 100 and 200 K, and is the same as that described by Smith (1953) for the room-temperature structure. The four equivalent $\mathrm{Sr}^{2+}$ ions are eight-coordinated by O atoms of $\mathrm{H}_{2} \mathrm{O}$ in a square antiprism configuration with $D_{2 d}$ symmetry. Double layers of hydrogen-bonded $\mathrm{OH}^{-}$ ions and $\mathrm{H}_{2} \mathrm{O}$ molecules separate planes of $\mathrm{Sr}^{2+}$ ions along the $c$ direction. Adjacent double layers are linked externally through hydroxide H 2 atoms, which lie near the planes of the $\mathrm{Sr}^{2+}$ ions at $z=\frac{1}{4}, \frac{3}{4}$. Linear chains of $\mathrm{O}-\mathrm{H}$ ions are parallel to the $c$ axis. The $\mathrm{OH}^{-}$ions form $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}-\mathrm{H}$ chains, which have alternate directions (Fig. 1). The unique hydrogen-bonded planar units within the double layers are shown in Fig. 2; equations for the least-squares planes are given in Table 3. Fig. 3 illustrates the unusual hydrogen-bonding geometry of $\mathrm{OH}^{-}$ions. The two non-equivalent ions, OH 1 and OH 2 , form chains of donor and acceptor bonds along fourfold axes. Each hydroxyl oxygen is also engaged in four acceptor bonds. The $\mathrm{H}_{2} \mathrm{O}$ molecules are in a square-pyramidal environment of H atoms or an overall distorted octahedral environment of H atoms. Similar $\mathrm{OH}^{-}$configurations are found with donor and acceptor $\mathrm{H}_{2} \mathrm{O}$ molecules in axial positions in the $\mathrm{NaOH} \cdot 4 \mathrm{H}_{2} \mathrm{O}$ structure (Seidel \& Mootz, 1988). In the present structure, the four coplanar H atoms are in an eclipsed configuration at the longer $\mathrm{O} 1 \cdots \mathrm{O} 2$ distance and staggered at the shorter

$\mathrm{O} 1 \cdots \mathrm{O} 2$ distance. In the following discussion, the distances and angles refer to the 20 K values, unless otherwise specified.

### 3.2. Strontium-ion coordination

The two distinct $\mathrm{Sr} \cdots \mathrm{O}$ distances $[2.6031$ (6) and 2.6275 (6) $\AA$, see Table 2a] are shorter than the sum ( $2.65 \AA$ ) of the crystal radii (Shannon \& Prewitt, 1969) and increase marginally ( 3 e.s.d.'s) with temperature. The $\mathrm{O} \cdots \mathrm{O}$ distances defining edges of the antiprism exceed van der Waals contacts and involve no hydrogen bonding. The two shorter $\mathrm{O} \cdots \mathrm{O}$

Figure 2
Planar $\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}$ and $\left(\mathrm{H}_{2} \mathrm{O} \cdot \mathrm{HO}^{-}\right)_{2}$ units of oxygen double layers, viewed normal to the $c$ axis (cf. Fig. 1). Molecular planes of water O 3 and O 4 atoms lie approximately parallel and normal to the $a b$ plane, respectively. The distances ( $\AA$ ) and displacement ellipsoids ( $95 \%$ probability) are 20 K values.
distances occur in the square faces of the antiprism and are approximately $0.3 \AA$ shorter than the three unique distances forming the connecting edges. Compared with an ideal antiprism with equal edge lengths, the $\mathrm{SrO}_{8}$ polyhedron becomes less regular with increasing temperature. In monoclinic $\mathrm{Ba}(\mathrm{OH})_{2} \cdot 8 \mathrm{H}_{2} \mathrm{O}$ (Manohar \& Ramaseshan, 1964), the $\mathrm{BaO}_{8}$ antiprism is less regular with the two square faces displaced relative to each other.

### 3.3. Water molecule

The bonding environment of the two independent $\mathrm{H}_{2} \mathrm{O}$ molecules with dimensions at 20 K is illustrated in Fig. 4. In each molecule the two $\mathrm{O}-\mathrm{H}$ bonds differ greatly, 0.980 (1) versus 1.004 (1) $\AA$ and 0.974 (1) versus 1.007 (1) $\AA$, compared with the $\mathrm{O}-\mathrm{H}$ bond length of $0.9687 \AA$ in gas phase $\mathrm{H}_{2} \mathrm{O}$. H atoms of longer bonds are involved as donors to $\mathrm{OH}^{-}$ions, while H atoms in the shorter $\mathrm{O}-\mathrm{H}$ bonds are involved as donors to $\mathrm{H}_{2} \mathrm{O}$ molecules. The observed asymmetry of the $\mathrm{H}_{2} \mathrm{O}$ molecules is attributed to the considerable difference between $\mathrm{OH}^{-}$and $\mathrm{H}_{2} \mathrm{O}$ as acceptors in hydrogen bonding. The two molecules differ in the degree of distortion: the shorter and stronger the $\mathrm{H} \cdots \mathrm{OH}^{-}$bond, the greater the distortion of the water molecule. A comparable bonding situation exists in $\mathrm{LiOH} \cdot \mathrm{H}_{2} \mathrm{O}$, as shown by a precise neutron diffraction study (Hermansson \& Thomas, 1982). The two water H atoms are engaged in equivalent donor bonds to $\mathrm{OH}^{-}$ ions, resulting in covalent $\mathrm{O}-\mathrm{H}$ bond lengths of 1.002 (1) $\AA$, similar to those found in this study. The covalent angles,

### 3.4. Hydroxide ion

The two distinct hydroxide ions have similar bonding environments, as shown in Fig. 3. In each oxygen configuration the $\mathrm{H} \cdots \mathrm{H}$ van der Waals separation distances are unusually short. The shortest $\mathrm{H} 1 \cdots \mathrm{H} 3,2.064$ (2) $\AA$, and $\mathrm{H} 2 \cdots \mathrm{H} 5$, 2.033 (2) $\AA$, distances are approximately $0.35 \AA$ less than the sum of the hydrogen van der Waals radii, $1.2 \AA$. Neither value changes significantly with temperature. The in-plane $\mathrm{H} \cdots \mathrm{H}$ separations are 2.317 (2) $\AA$ for $\mathrm{H} 3 \cdots \mathrm{H} 3$ and 2.313 (2) $\AA$ for $\mathrm{H} 5 \cdots \mathrm{H} 5$ at 20 K and are $0.006 \AA$ longer at 200 K . The O1 and O 2 atoms are displaced 0.287 and $0.246 \AA$, respectively, from the H3 and H5 planes along fourfold axes toward the covalently bonded H atoms. These displacements provide a means of accommodating the unusually short $\mathrm{H} \cdots \mathrm{H}$ van der Waals contacts and are also not changed significantly with increasing temperature. The two covalent $\mathrm{O}-\mathrm{H}$ bonds are equal to within $2 \sigma$ and are longer $(0.014 \AA, 7 \sigma)$ than the $\mathrm{O}-\mathrm{H}$ bond in

Table 5
Values for differences $\left(\AA^{2}\right)$ in mean-square displacements, $\Delta=\left\langle u_{H}^{2}\right\rangle-$ $\left\langle u_{o}^{2}\right\rangle$, along the $\mathrm{H}-\mathrm{O}$ bond, derived from the $U^{i j}$ parameters (Table 2).

Values of $v\left(\mathrm{~cm}^{-1}\right)$ are estimated for $\mathrm{H}-\mathrm{O}$ stretching frequencies from $\Delta$. The average e.s.d. for $v$ is $350 \mathrm{~cm}^{-1}$.

$\mathrm{LiOH} \cdot \mathrm{H}_{2} \mathrm{O}$. This lengthening of the $\mathrm{O}-\mathrm{H}$ bonds in $\mathrm{Sr}(\mathrm{OH})_{2} \cdot 8 \mathrm{H}_{2} \mathrm{O}$ appears attributable to the stronger hydrogenbond interactions, which occur at $\mathrm{O} \cdots \mathrm{H}$ distances that are $\sim 0.35 \AA$ shorter than those in $\mathrm{LiOH} \cdot \mathrm{H}_{2} \mathrm{O}$. However, the gasphase $\mathrm{O}-\mathrm{H}$ bond of length 0.96431 (4) $\AA$ is reported from the vibration-rotation spectrum of the $\left(\mathrm{OH}^{-}\right)$anion (Owrutsky et al., 1985), in good agreement with those in the present hydrogen-bonded network.

### 3.5. Hydrogen-bond parameters

The hydrogen-bond distances and angles are listed in Table 2(b). The $\mathrm{O} \cdots \mathrm{O}$ distances which range between 2.660 and $2.928 \AA$ represent a large deviation, $\pm 0.129$ (1) $\AA$, from the usual oxygen van der Waals separation of $2.8 \AA$. There are six distinct hydrogen bonds, two each of the types $\mathrm{OH}^{-} \ldots \mathrm{OH}^{-}$, $\mathrm{H}_{2} \mathrm{O} \cdots \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{HO}^{-} \cdots \mathrm{H}_{2} \mathrm{O}$. The shortest and strongest $\mathrm{O} \cdots \mathrm{H}$ bonds link the $\mathrm{OH}^{-}$ion and $\mathrm{H}_{2} \mathrm{O}$ molecules at distances of 1.654 and $1.664 \AA$. These fall in the lower range of short hydrogen bonds of crystalline hydrates (Ferraris et al., 1986). In general, the $\mathrm{H} \cdots \mathrm{O}$ bonds along the $c$ axis are longer than those in the $a b$ plane, with the notable exception of the $\mathrm{OH} 2^{-} \ldots \mathrm{OH} 1^{-}$distance at $1.868 \AA$. H 2 atoms link networks (Fig. 2) along the $c$ axis and lie in planes of the $\mathrm{Sr}^{2+}$ ions. The $\mathrm{H} 2 \cdots \mathrm{O} 1$ distances are dependent on the $c$-axial components of the $\mathrm{Sr}-\mathrm{O}$ bond lengths, i.e. the distance between square faces of the $\mathrm{SrO}_{8}$ antiprism (Fig. 1). Thus, the $\mathrm{H} 2 \cdots \mathrm{O} 1$ interaction distance appears to be foreshortened from the $\mathrm{H} 1 \cdots \mathrm{O} 2$ value, $1.961 \AA$, in agreement with the $\mathrm{Sr}^{2+} \cdots \mathrm{H}_{2} \mathrm{O}$ ion-dipole interaction. Fig. 5 shows the correlations $\mathrm{H} \cdots \mathrm{O}$ versus $\mathrm{O}-\mathrm{H}$ and $\mathrm{H} \cdots \mathrm{O}$ versus $\mathrm{O} \cdots \mathrm{O}$ for the six distinct hydrogen bonds. In both cases the correlations are found to be remarkably strong, with linear correlations coefficients $r(20)=-0.9981$ and 0.9982 , respectively. The correlations

Figure 4
Bonding configurations of the two independent $\mathrm{H}_{2} \mathrm{O}$ molecules. The distances $(\AA)$ and displacement ellipsoids ( $95 \%$ probability) are 20 K values.

Figure 5
Regression lines $d_{\mathrm{O} \cdots \mathrm{O}}$ versus $d_{\mathrm{O} \cdots \mathrm{H}}$ (dashed) and $d_{\mathrm{O}-\mathrm{H}}$ versus $d_{\mathrm{O} \cdots \mathrm{H}}$ (solid) for 20 K data. Correlation coefficient $r=0.998$ for first and $r=$ -0.998 for second regression. The point for $\mathrm{O} 2-\mathrm{H} 2 \cdots \mathrm{O} 1$ is omitted from the second fit as explained in the text.
are equally strong at 100 and $200 \mathrm{~K}, r(100)=-0.9908,0.9989$; $r(200)=-0.9983,0.9991$. The disparate values for $[\mathrm{O} 2-\mathrm{H} 2$, $\mathrm{O} 1 \cdots \mathrm{H} 2$ ] involving interactions external to the hydrogenbonded oxygen double layers have been omitted from the regression fits. The $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ angles and corresponding $\mathrm{H} \cdots \mathrm{O}$ lengths appear to be uncorrelated.

### 3.6. Temperature effects on structure parameters

Among the hydrogen bonds, the strongest temperature dependencies are observed for the weaker $\mathrm{O} \cdots \mathrm{H}$ interactions along the $c$ axis (Fig. 2); these increase up to 0.018 (2) $\AA$ between 20 and 200 K . By contrast in the $a b$ plane, the hydrogen bonds between $\mathrm{OH}^{-}$and $\mathrm{H}_{2} \mathrm{O}$ are lengthened only marginally, 0.004 (2) and 0.005 (2) $\AA$; those between $\mathrm{H}_{2} \mathrm{O}$ molecules show somewhat larger increases of 0.012 (2) $\AA$. The corresponding hydrogen-bond $\mathrm{O} \cdots \mathrm{O}$ distances (Table $2 b$ ) show similar temperature dependencies, as expected. The $\mathrm{O}-$ $\mathrm{H} \cdots \mathrm{O}$ angles lie between 167.8 and $180.0^{\circ}$ and show no dependency on temperature. Between 20 and 200 K the covalent $\mathrm{O}-\mathrm{H}$ bond lengths, which are uncorrected for thermal motion, show no significant trend, with the largest change being on $\mathrm{O} 1-\mathrm{H} 1$ which decreases by $0.006 \AA(1.7 \sigma)$ in this range. The apparent absence of thermal effects on covalently bonded hydrogen has been attributed to opposing effects of anharmonic stretching and librational motion (Craven \& Swaminathan, 1984; Jeffrey \& Ruble, 1984). This would seem to be fortuitous over the wide temperature range of these measurements. Over the range $20-200 \mathrm{~K}$, bond lengths (Table $2 b$ ) corrected for riding motion (Busing \& Levy, 1964) increased uniformly by $0.020 \pm 0.002 \AA$ for all $\mathrm{O}-\mathrm{H}$, except for those of $\mathrm{H}_{2} \mathrm{O}$ involved in strong $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ donor interactions with the $\mathrm{OH}^{-}$ions. The latter bonds are length-
ened by $0.013 \pm 0.002 \AA$. The dampening effect of hydrogen bonding on thermal vibrations (Fig. 2) makes the applicability of the riding model questionable. At each temperature, differences in the mean-square amplitudes of vibration, $\Delta$, along the $\mathrm{O}-\mathrm{H}$ bonds were computed from the harmonic $U^{i j}$ displacement parameters.

Table 4 list the values for differences in mean-square displacements, $\Delta=\left\langle u_{H}^{2}\right\rangle-\left\langle u_{O}^{2}\right\rangle$, along the $\mathrm{H}-\mathrm{O}$ bond, derived from the $U^{i j}$ parameters. These are close to the expected value of $0.005 \AA^{2}$ as found by Eriksson \& Hermansson (1983). The average values at 20 and 100 K are about the same ( 0.0058 and $0.0057 \AA^{2}$, respectively), while the average value increases to $0.0065 \AA^{2}$ at 200 K , but this is not significant.

This research was carried out at Brookhaven National Laboratory under contract DE-AC02-76CH00016 with the US Department of Energy and supported by its Office of Basic Energy Sciences. We are grateful to Messrs D. A. Rathjen and J. H. Guthy for technical assistance.
