**Abstract**  $\text{CaNdFeO}_4$  ceramics were prepared using a solid-state process, and their crystal structure was identified by Rietveld method, while the electrical conductivity was evaluated as a function of sintering and testing temperatures.  $\text{CaNdFeO}_4$  ceramics had an orthorhombic  $\text{K}_2\text{NiF}_4$  structure, and a secondary perovskite phase  $(\text{Ca,Nd})\text{FeO}_{3\pm\delta}$  was observed in the samples. The DC electrical conductivity of  $\text{CaNdFeO}_4$  ceramics increased firstly to a maximum value,  $0.065 \text{ Scm}^{-1}$ , and then decreased with increasing sintering temperature. The relationship between electrical conductivity of  $\text{CaNdFeO}_4$  ceramics and testing temperature obeyed the Arrhenius law.

**Keywords**  $\text{CaNdFeO}_4 \cdot \text{K}_2\text{NiF}_4$  structure · Rietveld method · Electrical conductivity · Arrhenius law

## 1 Introduction

Many compounds with the  $\text{K}_2\text{NiF}_4$ -type structure have attracted much attention from the discovery of the high temperature superconductivity in  $\text{La}_{1.85}\text{Ba}_{0.15}\text{CuO}_4$  ceramics [1]. The structure can be described as  $\text{NiF}_6$  octahedra interleaved with the rocksalt KF layers along the *c*-direction. The space group of ideal  $\text{K}_2\text{NiF}_4$  structure is  $I4/mmm$ , and it will be translated to orthorhombic  $Bmab$  through the

distortion of  $\text{NiF}_6$  octahedra, which is originated from the two-dimensional lattice mismatch between two intergrowth layers [2].

Among the  $\text{K}_2\text{NiF}_4$ -type  $\text{ARMO}_4$  ceramics ( $A = \text{Sr, Ca}$ ;  $R = \text{rare earth}$ ;  $M = \text{Ni, Mn, Fe, Co, Cr}$ ),  $\text{CaNdMO}_4$  ceramics have been relatively less investigated [2–5]. The space group of  $\text{CaNdCoO}_4$  is  $I4/mmm$ , while it is  $Bmab$  for  $\text{CaNdCrO}_4$  and  $\text{CaNdFeO}_4$ . Although Oyama et al. have reported the crystal structure and spin orientation of  $\text{CaNdFeO}_4$ , the electrical properties of the ceramics have not been investigated.

In the present paper,  $\text{CaNdFeO}_4$  ceramics were prepared, and the crystal structure and electrical conductivity were characterized.

## 2 Experimental procedure

Reagent-grade  $\text{CaCO}_3$  (99%),  $\text{Nd}_2\text{O}_3$  (99%) and  $\text{Fe}_2\text{O}_3$  (99%) in a 2:1:1 molar ratio were mixed by ball milling in deionized water using zirconia balls for 24 h. The slurry was dried and then calcined at  $1100^\circ\text{C}$  in air for 3 h to prepare  $\text{CaNdFeO}_4$  powders. The calcined powders, with 8 wt% PVA (polyvinyl alcohol) added, were pressed into disc compacts of 12 mm in diameter and around 5 mm in height, and these compacts were sintered at temperatures from  $1225^\circ\text{C}$  to  $1325^\circ\text{C}$  in air for 3 h.

The phase constitution of the composite ceramics was characterized by powder X-ray diffraction (XRD, RIGAKU D/max 2550 PC, Rigaku Co., Tokyo, Japan) analysis using  $\text{CuK}\alpha$  radiation. XRD data for Rietveld refinement were collected on the sample sintered at  $1325^\circ\text{C}$  in air for 3 h, and the intensity data were collected over a range  $8\text{--}130^\circ$  with a step interval of  $0.02^\circ$  and a counting time of 5 s per step. The Rietveld refinement was performed using the

FULLPROF program [6], and a pseudo-Voigt profile function with preferred orientation was used.

The DC conductivity was measured by a digital multimeter (Agilent 34401A) from room temperature to  $550^\circ\text{C}$  with an interval of  $50^\circ\text{C}$ .

### 3 Results and discussion

$\text{CaNdFeO}_4$  with  $\text{K}_2\text{NiF}_4$  structure can not be obtained when the calcining temperature is lower than  $1100^\circ\text{C}$ , and the dominated phase is perovskite  $(\text{Ca,Nd})\text{FeO}_{3\pm\delta}$  phase as shown in Fig. 1. There is also minor perovskite (Ca,

**Fig. 2** X-ray powder diffraction patterns obtained at room temperature (circles) and calculated (solid line) of  $\text{CaNdFeO}_4$  ceramics. Vertical marks show the position of allowed structural Bragg reflections for (a)  $\text{CaNdFeO}_4$  and (b)  $(\text{Ca,Nd})\text{FeO}_{3\pm\delta}$  ceramics. A difference curve is plotted at the bottom of the pattern

$\text{Nd})\text{FeO}_{3\pm\delta}$  phase indicated as inverted open triangle in Fig. 1 even when the calcining temperature reaches  $1100^\circ\text{C}$ . Dense  $\text{CaNdFeO}_4$  ceramics with minor secondary phase can be obtained by sintering at  $1225$ – $1325^\circ\text{C}$  in air for 3 h.

The Rietveld refinement results of  $\text{CaNdFeO}_4$  ceramics sintered at  $1325^\circ\text{C}$  in air for 3 h are shown in Fig. 2 and Table 1. A  $(\text{Ca,Nd})\text{FeO}_{3\pm\delta}$  perovskite secondary phase is present in the sample. The results show that  $\text{CaNdFeO}_4$  has orthorhombic  $\text{K}_2\text{NiF}_4$  structure (Bmab), with lattice parameters of  $a=5.4115(1)$  Å,  $b=5.4713(1)$  Å, and  $c=12.0820(2)$  Å. The orthorhombic distortion can be evaluated through the orthorhombic strain parameter  $S_o$  [2], and  $\text{CaNdFeO}_4$  ceramics ( $S_o=1.098(9)\times 10^{-2}$ ) have a larger orthorhombic distortion than  $\text{CaNdCrO}_4$  ceramics. This structure should be originated from the ideal tetragonal  $\text{K}_2\text{NiF}_4$  structure via the  $\text{FeO}_6$  octahedra tilting at the same angle clockwise and counterclockwise alternatively in  $[010]$  direction. The tilting can be quantified by  $\alpha_1$  and  $\alpha_2$  angles, where  $\alpha_1$  is formed by the equatorial plane of the octahedron and the basal plane  $ab$  of the unit cell, and  $\alpha_2$  is defined by the Fe–O axial bond of the octahedron and the  $c$ -axis of the unit cell [2]. The values of  $\alpha_1$  and  $\alpha_2$  are  $6.62$  and  $7.58^\circ$  (see Table 2), respectively, which are larger than those of  $\text{CaNdCrO}_4$ , and this is consistent with the result of orthorhombic strain parameter  $S_o$ . The neodymium and calcium atoms are nine-fold coordinated polyhedron, and the polyhedron is strongly distorted with six different distances (see Table 2). While there are only two different distances of Fe–O bond, and this shows that the  $\text{FeO}_6$  octahedra are tetragonally distortion with a  $d_{\text{Fe-O}_a}/d_{\text{Fe-O}_e}=1.098$ .

				2×Ca/Nd–O2=2.7373(9) Å		

The DC electrical conductivity of CaNdFeO<sub>4</sub> ceramics at room temperature is shown in Table 3. The conductivity increases firstly and then decreases with increasing sintering temperature. The maximum value of conductivity reaches 0.065 Scm<sup>-1</sup> for the ceramics sintered at 1250°C for 3 h, and this value is larger than that of SrNdFeO<sub>4</sub> [7] and CaNdCoO<sub>4</sub> [8] ceramics. The electrical conductivity of CaNdFeO<sub>4</sub> ceramics should be affected by three different factors: the relative density, the content of oxygen vacancy and secondary phase. The relative densities of CaNdFeO<sub>4</sub> ceramics increase to a maximum value then decrease with increasing sintering temperature (see Table 3), so the variation of electrical conductivities should obey the same law as that of relative density. During cooling after sintering, re-oxidation will occur to compensate oxygen vacancies generated during soaking, and the concentration of oxygen vacancy is in proportion to the grain size since the re-oxidation process will be more difficult to penetrate the coarse grains. The grain sizes of CaNdFeO<sub>4</sub> ceramics should increase with increasing sintering temperature, and this will lead to the increased content of oxygen vacancies and in turn the electrical conductivities of ceramics. The contents of (Ca,Nd)FeO<sub>3±δ</sub> secondary phase increase with the sintering temperature (see Fig. 1), and the electrical conductivity should decrease for (Ca,Nd)FeO<sub>3±δ</sub> phase is an antiferromagnetic insulator [9]. The variation of electrical conductivity of CaNdFeO<sub>4</sub> ceramics should be the combined effects of above three factors. Figure 3 shows the

**Table 3** Relative densities, DC conductivities at room temperature and parameters of Arrhenius model for CaNdFeO<sub>4</sub> ceramics.

Sintering temperature	Relative density (%)	Conductivity (Scm <sup>-1</sup> )	E <sub>a</sub> (eV)	σ <sub>0</sub> (Scm <sup>-1</sup> )
1225°C	91.7	0.058	0.057	0.275
1250°C	93.6	0.065	0.038	0.344
1275°C	94.5	0.049	0.049	0.279
1300°C	93.5	0.025	0.050	0.236
1325°C	93.3	0.030	0.040	0.286

relationship between the logarithm of the electrical conductivity of CaNdFeO<sub>4</sub> ceramics sintered under different conditions and the reciprocal of testing temperature. The logσ–1000/T curves of all samples are almost linear below 550°C and it obeyed the Arrhenius law. These results indicate that the CaNdFeO<sub>4</sub> ceramics is capable of a semiconductive behavior. The activation energy E<sub>a</sub> and the pre-factors σ<sub>0</sub> calculated from the linear portion of logσ–1000/T curves are shown in Table 3. The E<sub>a</sub> values of CaNdFeO<sub>4</sub> ceramics are in the range from 0.038 to 0.057 eV, which are one magnitude lower than those of CaNdCoO<sub>4</sub> ceramics.

**4 Conclusions**

CaNdFeO<sub>4</sub> ceramics with a (Ca,Nd)FeO<sub>3±δ</sub> perovskite secondary phase had been obtained using a solid-state process. CaNdFeO<sub>4</sub> ceramics had an orthorhombic K<sub>2</sub>NiF<sub>4</sub>

**Fig. 3** Relationship between the logarithm of the electrical conductivity of CaNdFeO<sub>4</sub> ceramics sintered under different conditions and the reciprocal of testing temperature

structure which was deduced from the ideal tetragonal phase by the  $\text{FeO}_6$  octahedra tilt. The DC electrical conductivity of  $\text{CaNdFeO}_4$  ceramics increased firstly to a maximum value,  $0.065 \text{ Scm}^{-1}$ , and then decreased with increasing sintering temperature, which should be contributed from the combined effects of the relative density, the content of oxygen vacancy and secondary phase. The relationship between the electrical conductivity and testing temperature obeyed the Arrhenius law, and the activation energies were very low.
