Equations are constructed for determining the relative strains and stresses in an infinite plate of viscoelastic material exposed to symmetrical heating. Possible methods of solving these equations are examined in relation to various models.

The application of the time-temperature superposition principle considerably simplifies the solution of problems of the theory of thermoviscoelasticity. However, for certain structural plastics, including a number of glass-reinforced plastics, this principle is either inapplicable or can be applied only within a very limited temperature range. For these materials it is necessary to obtain a solution with allowance for the temperature dependence of the mechanical characteristics of viscosity and elasticity.

We will consider one of the simplest of these problems. An infinitely long plate (Fig. 1) of width 2R is subjected to nonstationary heating symmetrical about the X-axis. In this case the cross sections of the plate are free of bending moments about the Y-axis, and the relative strains in the direction of the longitudinal X-axis do not depend on the Z coordinate and are equal ( $\varepsilon_x = \text{const}$ ).

We will determine the time dependence of the relative strains and stresses in the plate in the directions of the axes X, Y, Z.

1. Hooke material. For this material the stressstrain relation for uniaxial states of stress has the form

$$\sigma = E \varepsilon - E \alpha T. \tag{1}$$

Applying this relation to our problem, we obtain

$$\sigma_x = E \varepsilon_x - E \alpha T, \quad \sigma_y = E \varepsilon_y - E \alpha T = 0,$$
  
$$\sigma_z = E \varepsilon_z - E \alpha T = 0. \tag{2}$$

Fig. 1. Model of temperature action on plate.

From the first of Eqs. (2) we find that in the absence of external forces  $P_x = P_y = P_z = 0$  with allowance for heating symmetry

$$\int_{0}^{R} E \, e_x \, dZ \, - \, \int_{0}^{R} E \, \alpha \, T dZ = P_x = 0. \tag{3}$$

We will denote mean integral values of the quantities over the width of the plate by a bar; then from Eq. (3) with  $\alpha$  = const we find that

$$\varepsilon_{x} = \frac{\alpha \int_{0}^{R} ETdZ}{\int_{0}^{R} EdZ} = \frac{\alpha \overline{ET}}{\overline{E}} .$$
 (4)

Similarly, for the other two directions  $\varepsilon_y = \alpha T$ ;  $\varepsilon_z = \alpha \widetilde{T}$ .

In these expressions the temperature T is a function of the coordinate X and time t: T = T(Z,t). In accordance with (2),

$$\sigma_{x} = E \alpha \left( \frac{\overline{ET}}{\overline{E}} - T \right) ,$$
  
$$\sigma_{y} = 0, \quad \sigma_{z} = 0.$$
(5)

In the particular case with E = const it follows from (5) that

$$\sigma_r = E \alpha \, (\overline{T} - T)^{*)}. \tag{6}$$

Using (6) we can obtain the analytic dependence  $\sigma_{\rm Z}({\rm Z},t)$ , if the law of temperature valation T(Z,t) is given. Thus, for boundary conditions of the first kind the exact solution of the problem has the form [1]

$$\sigma_x(Z, t) = E \alpha (T_0 - T_s) \times$$
$$\times \sum_{l=1}^{\infty} \left( B_n - A_n \cos \mu_n \frac{Z}{R} \right) \exp \left( - \mu_n^2 \operatorname{Fo} \right).$$
(7)

Starting from a certain instant of time (Fo = Fo<sub>1</sub> > > 0.1) with a high degree of accuracy we can confine ourselves to a single term of series (7):

\*The formulas obtained relate to a maximally thin plate ( $\delta \ll R$ ). If the thickness of the plate is commensurable with the width ( $\delta \approx R$ ), then  $\sigma_z = 0$ ,  $\sigma_x =$ =  $\sigma_v = (E\alpha/(1 - \mu)(\overline{T} - T))$ .

$$\sigma_{x}(Z, t) = E \alpha (T_{0} - T_{s}) \times \left(B_{1} - A_{1} \cos \mu_{1} \frac{Z}{R}\right) \exp \left(-\mu_{n}^{2} \operatorname{Fo}\right).$$
(8)

2. Maxwell material. The stress-strain relation for this material in uniaxial states of stress is given by

$$E(\dot{\mathbf{e}}-\alpha\,\dot{T})=n\,\boldsymbol{\sigma}+\dot{\boldsymbol{\sigma}}.\tag{9}$$

Going over to finite differences, on the basis of (9) for the instant of time t + 1 we can write

$$\sigma_{t+1} = E \varepsilon_{t+1} - E \varepsilon_t + E \alpha T_t - E \alpha T_{t+1} - n \sigma_t \Delta t + \sigma_t.$$
(10)

We use Eq. (10) to calculate the stresses in the plate. Since there are no external forces,

$$\sum_{1}^{k} \sigma_{i,t+1} \Delta Z = P_{x} = 0 \quad (i = 1, 2, ..., k).$$
(11)

On the basis of (10)

$$\varepsilon_{t+1} = \varepsilon_t + \frac{\Delta t \sum_{i=1}^{k} n_i \sigma_{i,t} \Delta Z}{\sum_{i=1}^{k} E_i \Delta Z} + \frac{\sum_{i=1}^{k} E_i \alpha T_{i,t+1} \Delta Z - \sum_{i=1}^{k} E_i \alpha T_{i,t} \Delta Z}{\sum_{i=1}^{k} E_i \Delta Z}, \quad (12)$$

whence, again going over to infinitesimals,

$$\varepsilon_{x} = \frac{\int_{0}^{R} n \,\sigma_{x} \, dZ}{\int_{0}^{R} E dZ} + \alpha \frac{\frac{d}{dt} \int_{0}^{R} E T dZ}{\int_{0}^{R} E dZ} .$$
(13)

Using our mean-integral notation, we finally write Eq. (13) in the form

$$\vec{Ee} - \alpha \, \vec{TE} = \vec{n \sigma} \, . \tag{14}$$

In structure this equation is analogous to relation (9), but contains the averaged values of the corresponding quantities.

Eliminating the relative strain  $\varepsilon_{\rm X}$  from (9) and (4), we establish that

$$\frac{\overline{E}}{\overline{E}} (n\sigma + \dot{\sigma}) + \overline{E} \alpha \dot{T} - \alpha \quad \overline{ET} - \overline{n\sigma} - \dot{\sigma} = 0.$$
(15)

At  $\alpha = 0$ 

$$\frac{\overline{E}}{\overline{E}} (n \, \sigma + \dot{\sigma}) - \overline{n \, \sigma} - \dot{\overline{\sigma}} = 0.$$
(16)

Equation (15) is an integral equation in the unknown function  $\sigma(Z, t)$ ; in the general case it admits of only an approximate analytic or numerical solution. One of the possible approximate methods of solving this equation is the collocation method. In accordance with

the collocation procedure [2], the solution of Eq. (15) is found in the form of a sum of known (coordinate) functions:

$$\sigma_m(Z,t) = \sum_{i=1}^{m} C_i \varphi_i(Z,t), \qquad (17)$$

where  $C_1$ ,  $C_2$ ,  $C_3$ , ...,  $C_m$  are unspecified coefficients. Substituting (17) into Eq. (18), we obtain the error

$$R(\sigma_m) = \frac{\overline{E}}{\overline{E}} [n \sigma_m(Z, t) + \dot{\sigma}_m(Z, t)] - n \overline{\sigma}_m(Z, t) - \dot{\overline{\sigma}}_m(Z, t) + \overline{E} \alpha \overline{T} - \alpha \overline{ET}.$$
(18)

We then select the parameters  $C_1$ ,  $C_2$ ,...,  $C_m$ so that the error  $R(\sigma_m)$  vanishes in the given system of points  $Z_i$  (i = 1, 2, 3, ..., m) on the interval (0, R(Z)) (collocation points), i.e., we assume that

$$R[\sigma_m(Z_i)] = 0 \quad (i = 1, 2, ..., m),$$
  
$$0 \leq Z_1 < Z_2 < ... < Z_{m-1} < Z_m < R(Z).$$
(19)

From this condition we obtain an algebraic linear system of equations in the unknowns  $C_1, C_2, \ldots, C_m$ :

$$R\left[\sum_{1}^{m} C_{i} \varphi_{i}(Z, t)\right] = 0.$$
(20)

By this method, provided that  $\sigma_m$  converges to the exact solution (as m tends to infinity), we can find the approximate solution with any degree of accuracy by taking a sufficiently large number of parameters  $C_1$ ,  $C_2$ , ...,  $C_m$ .

As an example we will obtain the solution of Eq. (15) for the heating of a plate at constant surface temperature (boundary conditions of the first kind). For simplicity we set E = const and assume that  $C_2 = C_3 = \ldots = C_m = 0$ . We find the solution (for Fo > 0.1) taking (10) into account in the form in which the elastic solution was obtained:

$$\sigma = E \alpha \left(T_0 - T_s\right) \times$$

$$C_1 \left(B_1 - A_1 \cos \mu_1 \frac{Z}{R}\right) \exp\left(-\mu_1^2 \operatorname{Fo}\right). \quad (21)$$

Here, C<sub>1</sub> is an unspecified coefficient.

х

We substitute (21) into Eq. (17). Making the substitutions  ${}$ 

$$B_1 = \frac{8}{\pi^2}; \ A_1 = \frac{4}{\pi}; \ \mu_1 = \frac{\pi}{2}$$

for the collocation point Z = R we find that

$$C_{1} = \frac{\pi^{2} a}{\pi^{2} a + 4 R^{2} \left( \overline{n} - n - \frac{\pi}{2} n \overline{\cos} \frac{\pi Z}{2R} \right)} \quad . (22)$$

The value of  $C_1$  is finally calculated from the given temperature dependence of the parameter n of the Maxwell material.

The graphs in Fig. 2 represent the variation of the stresses with time in a plate 10 mm wide at  $T_0 = 20^{\circ}$  C and  $T_s = 60^{\circ}$  C. The mechanical and thermophysical properties of the plate material correspond to the

Fig. 2. Variation of the stresses (kg/cm<sup>2</sup>) with time (sec). The figures on the curves are the coordinates of the points in mm over the thickness of the plate. Solid lines—elastic solution, dashed lines—solution for a Maxwell material.

properties of polymethyl methacrylate. The solid lines represent the stresses calculated from Eq. (8) on the assumption that the material is elastic. The dashed lines correspond to solution (21). As follows from the graph, starting from a certain moment of time (Fo = = 0.1) the stresses in the plate vary exponentially. Taking the viscous properties into account reduces the stress levels at all points of the plate.

3. Voigt material. The stress-strain relation for a Voigt material in uniaxial states of stress is

$$\sigma = E \left( \varepsilon - \alpha T \right) - \eta \left( \dot{\varepsilon} - \alpha \dot{T} \right). \tag{23}$$

To solve the problem we write this equation in finite differences:

$$\sigma_{t} = E \varepsilon_{t} + \eta \left( \frac{\varepsilon_{t+1} - \varepsilon_{t}}{\Delta t} - \alpha \frac{T_{t+1} - T_{t}}{\Delta t} \right) - E \alpha T_{t} . (24)$$

Since there are no external forces, by analogy with (13) we write

$$\sum_{1}^{k} \sigma_{t} \Delta Z = P = 0.$$

Summing and going back again from  $\Delta Z$  to infinitesimals dZ, we find that for symmetrical heating

$$\overline{\sigma} = \overline{E} \varepsilon - \alpha \, \overline{TE} + \overline{\eta} \, \varepsilon - \alpha \overline{\eta T}. \tag{25}$$

In this expression  $\overline{\sigma}$  is the mean integral value of the stress in the direction of the X-axis, equal to the external force P divided by the cross-sectional area. If  $P \neq 0$ , the structure of Eq. (25) coincides with that of (23); however, (25) contains the quantities  $\overline{E}$  and  $\overline{\eta}$  averaged over the width of the plate.

Equation (25) has an exact solution, and namely,

$$\varepsilon = \left[\int_{0}^{t} Q\left(\exp\int_{0}^{t} \frac{\overline{E}}{\overline{\eta}} dt\right) dt + \varepsilon_{0}\right] \exp\left(-\int_{0}^{t} \frac{\overline{E}}{\overline{\eta}} dt\right),$$
$$Q = \frac{\alpha \overline{TE}}{\overline{\eta}} + \frac{\alpha \overline{\eta} \overline{T}}{\overline{\eta}}.$$
(26)

At large relative strains measured in tens and hundreds of percent, such as are typical, for example, of thermoplastic molding processes, in view of the smallness of the temperature strains we can assume that  $Q \approx 0$ . Then (26) takes the form

$$\varepsilon = \varepsilon_0 \exp\left(-\int_0^t \frac{\overline{E}}{\overline{\eta}} dt\right) . \qquad (26')$$

4. Hereditary material. The stress-strain relation for a linear hereditary material is established by the expressions

$$\sigma = E\left(\varepsilon - \alpha T\right) - E \int_{0}^{t} R\left(t - s\right)\left(\varepsilon - \alpha T\right) ds, \quad (27)$$

$$\varepsilon = \frac{\sigma}{E} + \frac{1}{E} \int_{0}^{t} K(t-s) \sigma \, ds + \alpha \, T.$$
 (28)

Each of these equations can be used for describing the  $\sigma(t)$  relation in an individual layer of the plate. We divide the time interval 0-t into t segments  $\Delta t$ . In accordance with (28), for the first time segment 0 + 1 we can write that in the i-th layer

$$\varepsilon_{0+1} = \frac{\sigma_{i,0+1}}{E_i} + \frac{1}{E_i} K_i(\Delta t) \sigma_{i,0+1} \Delta t + \alpha T_i.$$
 (29)

Hence the stress in that layer

$$\sigma_{i,0+1} = \frac{E_i(\varepsilon_{0+1} - \alpha T_i)}{1 + K_i(\Delta t) \Delta t} .$$
(30)

Summing the stresses over all the layers, we find that

$$\sum_{i}^{k} \sigma_{i,0+1} = \sum_{i}^{k} \frac{E_{i} (\varepsilon_{0+1} - \alpha T_{i})}{1 + K_{i} (\Delta t) \Delta t} .$$
 (31)

Hence, considering that at  $t = 1 \cdot \Delta t$ ,  $\lim_{\Delta t \to 0} K_i(\Delta t) \to idem$ ,

$$\varepsilon_{0+1} = \frac{P + \sum_{i=1}^{k} \frac{E_i \alpha T_i}{1 + K_i (\Delta t) \Delta t}}{\sum_{i=1}^{k} \frac{E_i}{1 + K_i (\Delta t) \Delta t}} .$$
 (32)

For the time  $0 + 2\Delta t$  we correspondingly obtain

 $\epsilon_{0+2} =$ 

$$=\frac{P+\sum_{i=1}^{k}\frac{E_{i}\,\alpha\,T_{i}}{1+K_{i}\left(\Delta t\right)\Delta t}+\sum_{i=1}^{k}\frac{K_{i}\left(2\,\Delta t\right)\sigma_{i,0+1}}{1+K\left(\Delta t\right)\Delta t}}{\sum_{i=1}^{k}\frac{E_{i}}{1+K_{i}\left(\Delta t\right)\Delta t}}$$
(33)

We similarly establish that at time 0 + t

$$\varepsilon_{0+t} = \left(\sum_{i}^{k} \alpha E_{i}T_{i} + P\left[1 + K_{i}\left(\Delta t\right)\Delta t\right] + \Delta t\sum_{i}^{k} K_{i}\left(t\Delta t\right)\sigma_{0+1}\right) \left(\sum_{i}^{k} E_{i}\right)^{-1} + \dots + \frac{\Delta t\sum_{i}^{k} (2\Delta t)\sigma_{0+(t-1)}}{\sum_{i}^{k} E_{i}}.$$
(34)

Increasing the number of intervals (m  $\rightarrow \infty$  and  $\Delta t \rightarrow 0$ ), in the limit we obtain

$$\varepsilon = \frac{P}{\overline{E}} + \frac{1}{\overline{E}} \int_{0}^{t} \int_{0}^{R} K(t-s) \sigma \, dZ ds + \alpha \, \frac{\overline{ET}}{\overline{E}}$$

or

$$\varepsilon = \frac{P}{\overline{E}} + \frac{1}{\overline{E}} \int_{0}^{R} \int_{0}^{t} \frac{\overline{K(t-s)\sigma} \, dZ ds + \alpha \, \frac{\overline{ET}}{\overline{E}} \, . \quad (35)$$

In structure the latter equation corresponds to the starting relation (28), but contains characteristics averaged over the width of the plate. The analytic solution of this equation for specific temperature conditions can be obtained by the collocation method in the form of a sum of coordinate functions:

$$\sigma_{mn}(Z, t) = \sum_{1}^{m} \sum_{i=1}^{n} C_{ij} \varphi_i(t) \psi_j(Z),$$
  

$$i = 1, 2, 3, ..., m; \ j = 1, 2, 3, ..., n.$$
(36)

As distinct from the solution for a Maxwell material the collocation points are assigned along two axes: on the interval 0-R along the Z coordinate axis and on the interval 0-t along the time axis. Summation with respect to two indices considerably increases the labor of calculation when Eq. (36) is employed. Accordingly, the most effective methods of solving Eq. (35) may be numerical, for example, the method of finite sums.

In calculations based on equations (22), (26), (26'), (36) finding the means  $\overline{n}$ ,  $\overline{E}$ ,  $\overline{\eta}$  etc. presents certain difficulties. The procedure can be simplified by approximating the experimental relations n(T), E(T),  $\eta$ (T) with linear functions: n(T) = n<sub>0</sub> + aT; E(T) = E<sub>0</sub> + bT;  $\eta$ (T) = =  $\eta_0$  + cT.

Averaging over the interval 0-R, we obtain

$$\overline{n} = n_0 + a\overline{T}, \ \overline{E} = E_0 + b\overline{T}, \ \overline{\eta} = \eta_0 = c\overline{T}.$$

The function  $\overline{T}$  has been tabulated for a series of solutions of the heat conduction equation in [1].

In conclusion, we present an example of the complete calculation of the strains and stresses in a polymethyl methacrylate plate on the assumption that the mechanical properties of the material satisfy Voigt's equation.

Conditions of the problem. The plate is initially stretched in the high-elastic state at a temperature  $T = 130^{\circ}$  C to a strain  $\varepsilon_0 = 15.2\%$  and then slowly cooled in the stretched state. These and greater strains occur when polymethyl methacrylate is vacuum-formed. The initial temperature of the plate T = $= 20^{\circ}$  C is constant over the thickness 2R = 4 mm. At time t = 0 the temperature of the plate surfaces becomes equal to  $T_s = 100^{\circ}$  C and remains constant in time. It is required to calculate the change in the relative deformation of the plate as a function of time. The thermal diffusivity of polymethyl methacrylate  $a = 4 \cdot 10^{-4} \text{ m}^2/\text{hr}$ .

As the temperature of the plate rises, owing to the action of the internal "frozen" stresses the heating and softening of the material is accompanied by a process of shrinkage and shortening of the dimensions to the initial values. The given temperature interval is quite broad (130-20-100°) and includes the glass transition temperature of polymethyl methacrylate. In the presence of such a considerable temperature change the principle of the time-temperature analogy does not apply. Since the strain component due to thermal expansion is much less than the initial value of the total strain ( $\alpha \Delta T = 8 \cdot 10^{-5}$  (100- $20^{\circ}$ ) = 0.64%), Eq. (26') will be used for calculation purposes. We first calculate E and  $\overline{\eta}$  for various values of the time t. The results of the calculation are presented in the table. We replace the interval in (26') by the sum

$$\int_{0}^{t} \frac{\overline{E}}{\overline{\eta}} dt \cong \sum_{0}^{t_{m}} \frac{\overline{E}_{t}}{\overline{\eta}_{t}} \Delta t.$$

The calculated values of the integral and the function  $\varepsilon(t)$  are also presented in the table. The  $\varepsilon(t)$ relation is plotted in Fig. 3, which also gives the results of an experimental verification. A plate of polymethyl methacrylate measuring  $17 \times 24 \times 4$  mm was lowered into boiling water, the long dimension of the plate was measured periodically, and the relative deformation calculated. As a comparison shows, best agreement with the calculation is observed at small heating times and also after the plate has been fully heated (Fo > 1). The greatest discrepancy (up to 27%) between the calculated and experimental values of the specimen length is observed on the interval 140-300 sec, which is primarily attributable to the nature of the assumptions made,\* and also to the relative inaccuracy of the input data. In spite of this, the relation obtained gives a qualitatively correct reflection of the shrinkage process.

\*The linear approximation of E(T) and  $\eta(T)$ , the use of the Voigt equation, and the condition a = const.

Fig. 3. Variation of the length of a polymethyl methacrylate specimen (mm) and the stresses  $\sigma_y$  and  $\sigma_n$ (kg/cm<sup>2</sup>) as a result of temperature action: 1) l = l (t); 2)  $\sigma_y = \sigma_y(t)$ ; 3)  $\sigma_n = \sigma_n(t)$ ; 4) experimental results for l = l (t).

In the calculation we employed a linear approximation of the temperature dependence of the mechanical properties of polymethyl methacrylate, namely,

> $E = 3.8 \cdot 10^4 - 3.79 \cdot 10^2 \ T \ \text{kg/cm}^2 ,$  $\eta = 1.9 \cdot 10^7 - 1.89 \cdot 10^5 \ T \ \text{kg/cm}^2 \cdot \text{sec.}$

Obviously, more accurate results can be obtained if, for example, the approximation takes the form

> $E = a_1 + a_2 T + a_3 T^2$ ,  $\eta = b_1 + b_2 T + b_3 T^2$ .

The table also includes the values of the parameters needed for calculating the stresses in the middle surface ( $\sigma_y$ ) and the surface stresses ( $\sigma_n$ ). The sign of the stress is determined according to the rule

 $\varepsilon \leq 0, \quad \sigma(\varepsilon) = E \varepsilon \leq 0,$  $\dot{\varepsilon} \leq 0, \quad \sigma(\dot{\varepsilon}) = \eta \dot{\varepsilon} \leq 0.$ 

In accordance with (23)

$$\sigma = \sigma \left( \epsilon \right) + \sigma \left( \epsilon \right)$$

The time dependence of the stresses  $\sigma_y$  and  $\sigma_n$  is shown graphically in Fig. 3.

The equations obtained above take into account the variation of the mechanical properties of the viscoelastic material with respect to time and the space coordinate. Therefore they can be used for calculating the stresses and strains due not only to temperature effects but also to other factors leading to similar changes, including moisture content [3], aggressive media, radiation, etc., in other words, factors that create a nonstationary field of variation of the mechanical characteristics in a plate of viscoelastic material.

## NOTATION

 $T_0$  is the initial temperature of plate;  $T_s$  is the surface temperature of plate;  $\mu_n$  are the roots of

characteristic equations;  $A_n$  and  $B_n$  are constant coefficients; Fo =  $at/R^2$  is the Fourier number; k is the number of divisions  $\Delta Z$  with respect to the Z coordinate;  $\varepsilon_0$  is the initial deformation; m is the number of intervals  $\Delta t$ .
