RADIOTRACERS IN FLUORINE CHEMISTRY. PART VIII.  
FLUORINE-18 EXCHANGE REACTIONS INVOLVING URANIUM(VI) OR URANIUM(V)  
FLUORIDES. EVIDENCE FOR SURFACE COMPLEXATION AND COMPARISONS  
WITH LIGAND EXCHANGE REACTIONS [1]

SUMMARY

Fluorine-18 exchange between  $UF_6$ ,  $\beta$ - $UF_5$ , or the  $UF_6^-$  anion and [ $^{18}F$ ]-labelled  $BF_3$  or  $Me_3SiF$  is observed readily at ambient temperature and below, both under heterogeneous conditions and in acetonitrile solution. The behaviour of [ $^{18}F$ ]-labelled  $BF_3$ ,  $PF_5$ , or  $SF_4$  towards  $\beta$ - $UF_5$  is significantly different from that towards  $\alpha$ - $UF_5$ , and suggests that small quantities of the Lewis acid fluorides are retained by  $\beta$ - $UF_5$ . This is confirmed for  $SF_4$  by  $^{35}S$  studies. The lability of  $U^V$ -F bonds with respect to substitution implied by the  $^{18}F$  results, is confirmed by the formation of  $U^V$  chlorofluoride mixtures from reactions of  $\beta$ - $UF_5$ , or  $UF_5$  in MeCN with  $BCl_3$  or  $B[OCCl(CF_3)_2]_3$ . Complete replacement of F- by MeO-ligands in reactions between  $UF_5$  and  $Me_3SiOMe$  in MeCN is not observed. An insoluble solid is formed whose stoichiometry is  $UF_3(OMe)_2$ .

INTRODUCTION

The radiotracer fluorine-18 is a useful means of probing fluorine exchange between covalent fluorides in situations where  $^{19}F$  n.m.r. spectroscopy is not applicable [2]. In this paper we describe the results of  $^{18}F$  exchange reactions between uranium hexafluoride,  $\alpha$ - or  $\beta$ - uranium pentafluoride, or the hexafluorouranate (V) anion and various

Lewis acid fluorides under heterogeneous conditions, and in acetonitrile solution. Comparisons are made between  $^{18}\text{F}$  exchange and ligand substitution reactions, and evidence for the formation of surface complexes involving  $\beta\text{-UF}_5$  is presented.

## RESULTS AND DISCUSSION

Exchange reactions are discussed in terms of  $^{18}\text{F}$  transferred from the initially labelled, to the initially unlabelled reactant, the fraction of activity exchanged ( $f$ ) being defined by the relationship

Fraction of  $^{18}\text{F}$  in the initially unlabelled fluoride after reaction  
 Fraction of total F (mg atom) in the initially unlabelled fluoride

Complete exchange corresponds to  $f = 1$ . When  $f$  is  $> 1$ , an interaction additional to  $^{18}\text{F}$  exchange has occurred, for example retention of  $\text{SF}_3^{18}\text{F}$  by  $\text{CsF}$  [3]. This situation was encountered in many of the reactions studied in the present work; its observation is a reflection of the sensitivity of the radiotracer technique.

$^{18}\text{F}$  Exchange between  $\text{UF}_6$  and  $\text{BF}_2^{18}\text{F}$  or  $\text{Me}_3\text{Si}^{18}\text{F}$

Exchange between  $\text{UF}_6$  and [ $^{18}\text{F}$ ]-labelled boron trifluoride is readily observed at room temperature, and the reaction is a good method for the preparation of  $\text{UF}_5^{18}\text{F}$ . Representative results are given in Table 1. Values of  $f$  are  $\geq 0.88$ , and in one reaction  $f > 1$  was observed. However, there was no evidence for any interaction apart from  $^{18}\text{F}$  exchange. Although these reactions were carried out nominally under heterogeneous conditions, the homogeneous, gas-phase reaction will be an important pathway.  $^{18}\text{F}$  exchange also occurs readily between  $\text{UF}_6$  and trimethylsilyl [ $^{18}\text{F}$ ]-fluoride, and is observable at ca. 210 K (Table 1). Mixtures of these compounds are dark violet or brown, however there was no evidence for a chemical reaction at this temperature. A reaction does occur to a small extent at ambient temperature.

The behaviour of  $\text{UF}_6$  towards  $\text{Me}_3\text{Si}^{18}\text{F}$  may be compared with our earlier study of hexafluoride,  $\text{Et}_3\text{Si}^{18}\text{F}$  reactions [2] to obtain a qualitative order of hexafluoride bond lability towards  $\text{R}_3\text{Si}^{18}\text{F}$ . The order is  $\text{UF}_6 \sim \text{MoF}_6 > \text{WF}_6 > \text{TeF}_6$ . The behaviour of  $\text{BF}_3$  towards

$\text{Et}_3\text{Si}^{18}\text{F}$  is intermediate between that of  $\text{MoF}_6$  and  $\text{WF}_6$ . In view of the rapid exchange between  $\text{UF}_6$  and  $\text{BF}_2^{18}\text{F}$  or  $\text{Me}_3\text{Si}^{18}\text{F}$ , a detailed mechanistic study was not attempted, but it can be argued that the lability of a  $\text{U}^{\text{VI}}-\text{F}$  bond is the result both of the effective Lewis acid centre,  $\text{U}^{\text{VI}}$ , and of the donor properties of F bound to  $\text{U}^{\text{VI}}$ .

TABLE I

$^{18}\text{F}$  Exchange reactions between  $\text{UF}_6$  and  $\text{BF}_2^{18}\text{F}$  or  $\text{Me}_3\text{Si}^{18}\text{F}$

$\text{UF}_6$	$\text{BF}_2^{18}\text{F}$ or $\text{Me}_3\text{Si}^{18}\text{F}$	Time	Temperature	Fraction exchanged

0.87	$\text{Me}_3\text{Si}^{18}\text{F}$	10.39	65	207	0.93

Comparison between  $^{18}\text{F}$  exchange and ligand substitution reactions involving  $\text{UF}_6$

A close similarity between reactions of tungsten (VI) fluoride, methoxides with  $\text{Me}_3\text{Si}^{18}\text{F}$  or  $\text{Me}_3\text{SiOMe}$  has been noted previously [2], and a similar situation obtains for  $\text{UF}_6$ . For example, the lability of  $\text{UF}_6$  towards  $\text{Me}_3\text{Si}^{18}\text{F}$  is paralleled by facile, low-temperature substitution reactions between  $\text{UF}_6$  and  $\text{Me}_3\text{SiOMe}$  to give  $\text{UF}_{6-n}(\text{OMe})_n$ ,  $n = 1 - 6$ . The fluorine ligands in the products undergo rapid, intermolecular exchange [4]. Reactions between  $\text{UF}_6$  and  $\text{BCl}_3$  [5] or  $\text{B}(\text{OTeF}_5)_3$  [6] which lead to  $\text{UCl}_6$  and  $\text{U}(\text{OTeF}_5)_6$  respectively, may be

ompared with the behaviour of  $UF_6$  towards  $BF_2^{18}F$ . Substitution reactions involving  $WF_6$  are very much slower, and complete replacement of F- by other ligands is often not achieved [e.g.2]. The difference in lability between a  $U^{VI}-F$  and a  $W^{VI}-F$  bond is one of the factors responsible for the difference in chemical reactivity between the two hexafluorides.

### $^{18}F$ Exchange between $UF_6^-$ and $BF_2^{18}F$ or $UF_5^{18}F$

$^{18}F$  exchange reactions between the hexafluorouranate(V) anion, with  $Cu^{II}$  or  $Tl^{III}$  counter-cations, and  $BF_2^{18}F$  at room temperature result in values of  $f > 1$ , both in MeCN solution and under heterogeneous conditions (Table 2). The most obvious explanation is that both  $^{18}F$  exchange, and retention of small quantities of  $BF_2^{18}F$  by the salts, occur. Mass balance data are consistent with retention, and the near i.r. spectrum of  $UF_6^-$  in MeCN, to which  $BF_3$  has been added, shows that both  $UF_6^-$  and  $UF_5(NCMe)_x$  [7] are present. Evidently transfer of  $F^-$  ion from  $UF_6^-$  to  $BF_3 \cdot NCMe$  occurs to some extent. Although it is possible that the  $^{18}F$  activity is retained as  $BF_2^{18}F \cdot NCMe$  rather than  $BF_3^{18}F^-$ , this is less likely in view of the high degree of dissociation found for  $BF_3 \cdot NCMe$  in the gas phase at ambient temperature [8].

$^{18}F$  exchange between solid  $UF_6^-$  salts and gaseous  $UF_5^{18}F$  at room temperature is substantial,  $f > 0.72$  (Table 2), but there is no evidence for retention. Rapid exchange between these species in MeCN has been reported previously [9].

Clearly the  $UF_6^-$  ion is a good donor in both thermodynamic and kinetic senses. In this respect it is similar to the hexafluorotungstate(V) anion [10].

### $^{18}F$ Exchange between $\alpha$ - or $\beta$ - $UF_5$ and Lewis acid fluorides under heterogeneous conditions

The two structural modifications of uranium pentafluoride behave very differently towards  $BF_2^{18}F$  at room temperature. For  $\beta$ -  $UF_5$  under the conditions used,  $f > 1$ , whereas between  $\alpha$ -  $UF_5$  and  $BF_2^{18}F$  far less interaction is observed (Table 3). Mass balance data from  $\beta$ -  $UF_5$  reactions indicate the possible retention of  $BF_3$  by  $\beta$ -  $UF_5$ , although attempts to verify this spectroscopically were unsuccessful.

TABLE 2

 $^{18}\text{F}$  Exchange reactions between  $\text{UF}_6^-$  and  $\text{BF}_2^{18}\text{F}$  or  $\text{UF}_5^{18}\text{F}$ 

	Reactants		Time min	Temperature K	Fraction exchanged f
	mmol				
$\text{UF}_6^-$ , $\text{Cu}^{\text{II}}$ Salt in MeCN	0.59	$\text{BF}_2^{18}\text{F}$ 0.61	75	293	1.38
$\text{UF}_6^-$ , $\text{Tl}^{\text{III}}$ Salt in MeCN	0.73	$\text{BF}_2^{18}\text{F}$ 0.46	60	294	1.18
$\text{Cu}(\text{UF}_6)_2$ 5MeCN	0.35	$\text{BF}_2^{18}\text{F}$ 0.61	60	293	1.34
$\text{Tl}(\text{UF}_6)_2$ 5MeCN	0.12	$\text{BF}_2^{18}\text{F}$ 0.46	65	294	1.48
$\text{Cu}(\text{UF}_6)_2$ 5MeCN	0.29	$\text{UF}_5^{18}\text{F}$ 0.91	40	292	0.72
$\text{Cu}(\text{UF}_6)_2$ 5MeCN	0.24	$\text{UF}_5^{18}\text{F}$ 0.55	40	293	0.81

Although  $\text{UF}_5$  forms complexes with the strong Lewis acid antimony pentafluoride [11], and evidence for complexation with arsenic pentafluoride in anhydrous HF below room temperature has been reported [12], the possibility of complexation between  $\beta\text{-UF}_5$  and the weaker Lewis acid,  $\text{BF}_3$  was surprising. Accordingly interactions between  $\beta\text{-}$  or  $\alpha\text{-UF}_5$  and [ $^{18}\text{F}$ ]-labelled  $\text{BF}_3$ , phosphorus pentafluoride, or sulphur tetrafluoride were examined in more detail by following the transfer of  $^{18}\text{F}$  activity from gas-to-solid with time. Typical plots of  $^{18}\text{F}$  count rate versus time for gas-plus-solid, gas only, and the derived plot of solid count rate versus time are shown in Figure 1 for the  $\text{BF}_2^{18}\text{F}$ ,  $\beta\text{-UF}_5$  system. Derived solid count rate versus time plots for the systems  $\beta\text{-UF}_5$ ,  $\text{PF}_4^{18}\text{F}$  or  $\text{SF}_3^{18}\text{F}$  are shown in Figure 2.

In all cases the decrease in  $^{18}\text{F}$  count rate observed in the gas phase is too great to be accounted for solely by  $^{18}\text{F}$  exchange. This, and the rapid increase in the  $\beta\text{-UF}_5$  count rate with time, can be accounted for if  $^{18}\text{F}$  exchange occurs via a strongly adsorbed, surface species which is retained to some extent by  $\beta\text{-UF}_5$ . Equilibrium

TABLE 3

 $^{18}\text{F}$  Exchange reactions between  $\text{BF}_2^{18}\text{F}$  and  $\beta$ - or  $\alpha$ -  $\text{UF}_5$ 

$\text{UF}_5$	$\text{BF}_2^{18}\text{F}$	Time	Temperature	Fraction exchanged	
mmol	mmol	min	K	f	
$\beta$ - $\text{UF}_5$	0.23	0.22	50	293	1.29
$\beta$ - $\text{UF}_5$	0.29	0.61	55	293	1.24
$\beta$ - $\text{UF}_5$	1.11	0.93	60	293	1.15
$\beta$ - $\text{UF}_5$	0.14	0.22	100	293	1.25
$\alpha$ - $\text{UF}_5$	0.48	0.70	55	293	0.24
$\alpha$ - $\text{UF}_5$	0.26	0.70	55	293	0.30
$\alpha$ - $\text{UF}_5$	0.21	2.73	60	293	0.22

distribution of  $^{18}\text{F}$  was not observed in these experiments unless a very small sample of  $\beta$ -  $\text{UF}_5$  was used, however the f values obtained (Table 4) indicate that the degree of interaction increases in the order  $\text{SF}_3^{18}\text{F} < \text{BF}_2^{18}\text{F} < \text{PF}_4^{18}\text{F}$ , the order of increasing Lewis acidity. Similar behaviour was found between  $\beta$ -  $\text{UF}_5$  and [ $^{18}\text{F}$ ]-labelled gaseous  $\text{UF}_6$ ,  $\text{WF}_6$ , or  $\text{Me}_3\text{SiF}$ , however interpretation of these systems is complicated by condensation at the  $\beta$ -  $\text{UF}_5$  surface during the reaction.

Confirmation of a surface species formed by  $\text{SF}_4$  at  $\beta$ -  $\text{UF}_5$  is provided by using  $^{35}\text{S}$  as a tracer. Admission of  $^{35}\text{SF}_4$  to  $\beta$ -  $\text{UF}_5$  results in the immediate detection of a surface  $\beta^-$  count rate which remains constant over 2h. It is unaffected by removal of gaseous  $^{35}\text{SF}_4$ , admission of additional  $^{35}\text{SF}_4$ , or by admission of inactive  $\text{SF}_4$ .

In marked contrast to the behaviour of  $\beta$ -  $\text{UF}_5$ ,  $^{18}\text{F}$  count rates produced in a  $\alpha$ -  $\text{UF}_5$  by reaction with  $\text{BF}_2^{18}\text{F}$ ,  $\text{PF}_4^{18}\text{F}$ , or  $\text{SF}_3^{18}\text{F}$  are small, and only small increases with time are observed. Under conditions comparable to those used in Figures 1 and 2 and Table 4, f values are  $< 0.1$ . A small surface  $^{35}\text{S}$  count rate is detectable when  $^{35}\text{SF}_4$  is admitted to  $\alpha$ -  $\text{UF}_5$  but it decreases to zero when the gas is removed, and no retention is observed.

Fig. 1.  $^{18}\text{F}$  count rate vs. time for  $\beta\text{-UF}_5$  (0.93 mmol) +  $\text{BF}_2^{18}\text{F}$  (2.81 mmol); (a) gas + solid, (b) gas, (c) solid, derived from (a) - (b).

Fig. 2. Derived  $^{18}\text{F}$  count rate vs. time from solid; (a)  $\beta\text{-UF}_5$  (0.42 mmol) +  $\text{PF}_4^{18}\text{F}$  (2.75 mmol), (b)  $\beta\text{-UF}_5$  (0.66 mmol) +  $\text{SF}_3^{18}\text{F}$  (2.75 mmol).

TABLE 4

$^{18}\text{F}$  Exchange reactions at room temperature between  $\beta\text{-UF}_5$  and  $\text{BF}_2^{18}\text{F}$ ,  $\text{PF}_4^{18}\text{F}$ , or  $\text{SF}_3^{18}\text{F}$

$\beta\text{-UF}_5$	$\text{XF}_n$	Time	Fraction exchanged
mmol	mmol	min	f
0.93	2.81 ( $\text{BF}_2^{18}\text{F}$ )	95	0.91
0.93	2.95 ( $\text{BF}_2^{18}\text{F}$ )	95	0.66
0.24	1.80 ( $\text{BF}_2^{18}\text{F}$ )	82	1.58
0.45	3.08 ( $\text{PF}_4^{18}\text{F}$ )	120	2.34
0.42	2.75 ( $\text{PF}_4^{18}\text{F}$ )	120	2.04
0.52	1.62 ( $\text{SF}_3^{18}\text{F}$ )	120	0.72
0.66	2.75 ( $\text{SF}_3^{18}\text{F}$ )	100	0.67

The different behaviour of  $\alpha\text{-}$  and  $\beta\text{-UF}_5$  towards these Lewis acid fluorides can be compared with their structures.  $\alpha\text{-UF}_5$  contains octahedrally coordinated  $\text{U}^{\text{V}}$  with trans-F-bridges [13], whereas  $\beta\text{-UF}_5$  is  $[\text{UF}_{6/2}\text{F}_2]_{\infty}$ , in which the coordination polyhedron about  $\text{U}^{\text{V}}$  is intermediate between a square antiprism and a dodecahedron [14]. Retention of  $^{35}\text{SF}_4$  by a CsF fluoride surface has been demonstrated previously [15], and the retention of  $^{35}\text{SF}_4$  by  $\beta\text{-UF}_5$ , and by implication that of  $\text{BF}_2^{18}\text{F}$  and  $\text{PF}_4^{18}\text{F}$ , suggests that  $\beta\text{-UF}_5$  has more basic surface sites for the adsorption of Lewis acid fluorides than does  $\alpha\text{-UF}_5$ . This may be a consequence of the greater extent of F-bridging in the  $\beta\text{-}$  isomer.

$^{18}\text{F}$  Exchange and ligand substitution reactions involving  $\text{UF}_5$

The behaviour of  $\text{BF}_2^{18}\text{F}$  towards  $\text{UF}_5$  in MeCN at room temperature is very similar to that observed for  $\beta\text{-UF}_5$  in the absence of a solvent in that  $f$  values  $> 1$  are observed (Table 5).  $\text{Me}_3\text{Si}^{18}\text{F}$  behaves similarly, and even below room temperature, significant interaction is observed (Table 5). In view of these results, substitution of F- ligands in  $\text{UF}_5$  using  $\text{BX}_3$  or  $\text{Me}_3\text{SiX}$  reagents should be facile.

TABLE 5

\* In MeCN ( $3\text{cm}^3$ ). <sup>+</sup> Heterogeneous conditions, no solvent,  $\beta\text{-UF}_5$ .

It has been shown elsewhere that  $\alpha\text{-}$  or  $\beta\text{-UF}_5$  react with a large excess of boron trichloride at ambient temperature, in the absence of a solvent, to give  $\beta\text{-uranium pentachloride}$  [16]. We find that when the mole ratio  $\beta\text{-UF}_5:\text{BCl}_3$  is 1:2, substitution is not complete. The products are a mixture of haloboranes,  $\text{BF}_{3-n}\text{Cl}_n$ ,  $n = 0 - 3$ , and a brown solid whose near i.r. spectrum in MeCN (Figure 3a) indicates the presence of  $\text{U}^{\text{V}}$  chlorofluorides. The spectrum is distinct from that of  $\text{UCl}_5$  in MeCN, but resembles that of ' $\text{UF}_2\text{Cl}_3$ ' the product obtained from the reaction of  $\text{UF}_5$  in MeCN with trimethylchlorosilane,

Fig. 3. Near i.r. - visible spectra in MeCN of (a) the solid product from  $\beta$ - $\text{UF}_5 + 2\text{BCl}_3$  [ $\text{U}^{\text{V}}$ ]  $\sim 0.2 \text{ mol dm}^{-3}$ , (b) the solid product from  $\text{UF}_5 + \text{B}[\text{OCCl}(\text{CF}_3)_2]_3$  in MeCN, [ $\text{U}^{\text{V}}$ ]  $\sim 0.3 \text{ mol dm}^{-3}$ , (c) the reaction mixture  $2.9 \text{ UF}_5 + \text{B}[\text{OCCl}(\text{CF}_3)_2]_3$  in MeCN, [ $\text{U}^{\text{V}}$ ]  $\sim 0.1 \text{ mol dm}^{-3}$ , (d)  $\text{UF}_5 \sim 0.14 \text{ mol dm}^{-3}$ .

1:3 mole ratio. This may not be a single compound [17]. Similar behaviour is observed for  $\text{UF}_5$  and  $\text{BCl}_3$ , 1:1 mole ratio, in MeCN. Redistribution reactions of F and Cl at boron are facile, both in the gas phase [18] and in MeCN solution [19], also  $\text{UF}_5$  and  $\text{UCl}_5$  undergo halogen redistribution in MeCN [17]. However, these reactions alone are not sufficient to account for the behaviour observed, and it is necessary to postulate that at least some of the halogen exchange reactions between  $\text{U}^{\text{V}}$  and boron chlorofluorides are reversible. This is not the case for  $\text{Me}_3\text{Si}^-$  versus  $\text{U}^{\text{V}}$  exchange [17].

Reactions between  $UF_5$  and tris[1-chloro-1-(trifluoromethyl)-2,2,2-trifluoroethyl] borate in MeCN are facile at room temperature, but do not yield the expected  $UF_{5-n}[OCCl(CF_3)_2]_n$  derivatives. The products obtained are  $BF_3$ , hexafluoroacetone, and  $U^V$  chlorofluorides. To some extent the identities of the latter depend on the stoichiometry used. The near i.r. spectrum of the product from a 1:1 reaction is virtually identical to that obtained from  $UF_5 + 2BCl_3$  (Figure 3a and b), and an identical spectrum is obtained from a 3:2,  $UF_5 : B[OCCl(CF_3)_2]_3$  reaction mixture in MeCN. The spectrum of  $3UF_5 + B[OCCl(CF_3)_2]_3$  in MeCN is intermediate between those of  $UF_5$  and the 1:1 product (Figure 3 b,c, and d), and resembles the spectrum of ' $UF_4Cl$ ', obtained from  $UF_5$  and  $Me_3SiCl$ , 1:1 mole ratio, in MeCN [17].

Apparently the  $U^V-OCCl(CF_3)_2$  moiety is unstable with respect to the elimination of  $(CF_3)_2CO$  and the formation of a  $U^V-Cl$  bond. The alternative explanation, that  $B[OCCl(CF_3)_2]_3$  decomposes to give  $BCl_3$  and  $(CF_3)_2CO$  in the presence of  $UF_5(NCMe)_x$ , seems less plausible.

Trimethyl(methoxy)silane reacts with  $UF_5$  in MeCN at ambient temperature to give  $Me_3SiF$ , in essentially quantitative yield for  $UF_5 : Me_3SiOMe$  mole ratios up to 1:2. The major uranium-containing compound under all conditions, mole ratios up to 1:50, is an insoluble, yellow-green solid, which analyses as  $UF_3(OMe)_2$ . The solid's electronic spectrum shows the presence of  $U^V$ , but is distinct from those of  $UF_5(NCMe)$  and  $\beta-UF_5$ . A prominent i.r. band at  $1030\text{cm}^{-1}$  suggests that bridging, rather than terminal MeO- ligands are present [20], and a strong absorption at  $465, 505(\text{sh})\text{cm}^{-1}$  is presumed to be due to  $U^V-F$  stretching modes. Solid  $UF_3(OMe)_2$  undergoes substantial  $^{18}F$  exchange with  $Me_3Si^{18}F$  at room temperature (Table 6), but little or no reaction occurs between  $UF_3(OMe)_2$  and  $Me_3SiOMe$  in the presence of MeCN. A small quantity of a brown solid, soluble in MeCN and in benzene, is obtained after one week. Its electronic spectrum suggests that it is  $U(OMe)_5$  or a related species [21], but insufficient material was obtained for characterisation. An identical material is obtained as a trace product in reactions between  $UF_5$  and  $Me_3SiOMe$  in MeCN, when the solution is dilute.

0.36	3.30	50	294	0.64

Although the evidence is not definitive, the solid  $\text{UF}_3(\text{OMe})_2$  appears to be a single compound rather than a fortuitous mixture. Its difference in behaviour towards  $\text{Me}_3\text{Si}^{18}\text{F}$  and  $\text{Me}_3\text{SiOMe}$  could be a thermodynamic consequence of the presumably, polymeric solid.

#### CONCLUSIONS

Although the interpretation of  $^{18}\text{F}$  exchange reactions involving  $\text{UF}_6$ ,  $\text{UF}_5$ , or  $\text{UF}_6^-$  is complicated by additional reactions which occur, notably complexation between Lewis acid fluorides and  $\beta\text{-UF}_5$ , the results of this study indicate that both  $\text{U}^{\text{VI}}\text{-F}$  bonds in  $\text{UF}_6$ , and  $\text{U}^{\text{V}}\text{-F}$  bonds in a variety of environments, are labile with respect to substitution by  $^{18}\text{F}$ . Their lability is an important factor in accounting for the chemical reactivity of these fluorides, and in some cases there is a close analogy between  $^{18}\text{F}$  exchange and ligand substitution behaviour.

The relationship between the lability and the electronic properties of a bond is speculative, but in a recent X-ray P.E. spectroscopic investigation of uranium halides, it has been proposed that the ionicity of uranium-halogen bonds increases with increasing oxidation state of U,

and with the halogen's electronegativity [22]. A degree of ionic character in U-F bonds is implied by the crystal structures of  $\text{SbF}_5$  adducts with  $\text{UF}_5$  [11b],  $\text{UOF}_4$ , and  $\text{UO}_2\text{F}_2$  [23], and would account for the behaviour observed in this  $^{18}\text{F}$  study.

## EXPERIMENTAL

All operations were carried in vacuo or in an Ar-atmosphere glove box ( $\text{H}_2\text{O} < 5$  p.p.m.). Synthesis and spectroscopic procedures have been described previously [24]. The fluorides  $\text{UF}_6$ ,  $\text{WF}_6$ ,  $\text{PF}_5$ , and  $\text{BF}_3$  were commercial products which were purified by low temperature trap-to-trap distillation over activated NaF.  $\text{SF}_4$  was prepared from  $\text{S}_8$  and  $\text{IF}_5$  and purified via its  $\text{BF}_3$  adduct [25]. The reagents  $\text{Me}_3\text{SiF}$ ,  $\text{Me}_3\text{SiOMe}$ , and  $\text{BCl}_3$  (all commercial products) were purified by low temperature distillation, and were stored over activated 4A molecular sieves.  $\text{B}[\text{OCCl}(\text{CF}_3)]_3$  was prepared from  $\text{BCl}_3$  and  $(\text{CF}_3)_2\text{CO}$  [26]; its mp. agreed with that previously reported.  $\text{Cu}^{\text{II}}$  and  $\text{Tl}^{\text{III}}$  hexafluorouranates(V) were prepared as reported previously [9], and  $\alpha$ - and  $\beta$ -  $\text{UF}_5$  according to literature methods [13,7]. MeCN (Rathburn HPLC grade) was purified and dried by a modification of a standard procedure [27].

### Radioactivity measurement

$^{18}\text{F}$  activity was determined using a NaI well scintillation counter (Ekco and Nuclear Enterprises), well dimensions 1.56 x 0.78 ins. diameter, samples being contained in calibrated Pyrex ampoules (ca. 7 or 62  $\text{cm}^3$ ) fitted with P.T.F.E., glass stop-cocks. Calibrated double limb counting tubes (ca. 62  $\text{cm}^3$ ) were used to study exchange with time in gas-solid reactions, each limb being intercalibrated before use. Reproducible counts were obtained in all cases, and linear count-rate versus pressure relationships were obtained for all volatile compounds studied.

Experiments involving  $^{35}\text{S}$  were performed in an evacuable Pyrex reaction vessel incorporating two, intercalibrated Geiger-Müller detectors to allow surface  $^{35}\text{S}$  activity to be determined directly [28].

Preparation of labelled compounds

$^{18}\text{F}$  was prepared by the sequence  $^6\text{Li}(n,\alpha)^3\text{H}$ ;  $^{16}\text{O}(^3\text{H},n)^{18}\text{F}$  using the Scottish Universities' Research Reactor, East Kilbride. Work up of the irradiated product gave  $\text{Cs}^{18}\text{F}(\text{aq.})$  [29] which was evaporated to dryness and dried in vacuo above 373 K. Volatile fluorides were labelled by exchange (1h) with  $\text{Cs}^{18}\text{F}$  (ca. 1g; 20  $\mu\text{Ci}$ ) in a Monel metal bomb (95  $\text{cm}^3$ ) under the following conditions:  $\text{BF}_2^{18}\text{F}$ , 2.5 - 3.0  $\times 10^3$  Torr, 358 K;  $\text{PF}_4^{18}\text{F}$ , 2.5 - 3.0  $\times 10^3$  Torr, 378 K;  $\text{Me}_3\text{Si}^{18}\text{F}$ , 10-20 mmol, 298 K;  $\text{WF}_5^{18}\text{F}$ , 2-5 mmol, 313 K;  $\text{UF}_5^{18}\text{F}$  and  $\text{SF}_3^{18}\text{F}$  were prepared by exchange with  $\text{BF}_2^{18}\text{F}$  at 298 and 95 K respectively, exchange in the latter case occurring via  $[\text{F}^{18}]\text{-SF}_3^+\text{BF}_4^-$  which was decomposed using  $\text{Et}_2\text{O}$ .  $^{35}\text{SF}_4$  was prepared as previously described [25]. Radiochemical purity of  $[\text{F}^{18}]$ -labelled compounds was established by  $\gamma$ -ray spectrum and half-life determinations.

Exchange reactions

$^{18}\text{F}$  exchange reactions were carried out in counting vessels, mixtures being made up by weight, or, in the case of  $[\text{F}^{18}]$ -labelled  $\text{BF}_3$ ,  $\text{PF}_5$ , or  $\text{SF}_4$ , using a calibrated manifold and Bourdon gauge (Heise,  $\pm 1$  Torr). The initially active reagent was counted prior to its addition, and both components were counted after their separation by vacuum distillation. Radiochemical balances were  $> 95\%$  and mass balances  $> 98\%$ , however in reactions involving  $\beta\text{-UF}_5$  or  $\text{UF}_6^-$  salts, the solids consistently showed small mass increases ( $> 35$  mg) after reaction. The stoichiometries and specific activities used were chosen to minimise counting errors.

Exchange behaviour was compared in terms of the fraction of  $^{18}\text{F}$  activity exchanged ( $f$ ) determined by

$$f = \frac{A_1}{A_1 + A_2} \left( \frac{xm_1}{xm_1 + ym_2} \right)^{-1} = \frac{(A_0 - A_2)(xm_1 + ym_2)}{A_0 xm_1}$$

$A_1$  and  $A_2$  count  $s^{-1}$  are the count rates, corrected for decay, after exchange between  $m_1$  and  $m_2$  mmol of reactants (1 being inactive initially) containing respectively  $x$  and  $y$  F atoms.  $A_0$  count  $s^{-1}$  is the corrected count rate of reactant 2 before exchange. The second relationship was used in gas-solid reactions, where counting efficiencies of the two reactants were significantly different.

The distribution of  $^{18}\text{F}$  activity with time in  $\text{UF}_5$ ,  $\text{XF}_n$  systems was studied by loading a known mass of  $\text{UF}_5$  into one limb of a double limb counting vessel, and condensing a measured quantity of  $[\text{F}^{18}]\text{-XF}_n$ , whose count rate had been determined, into the other limb. The gas was warmed rapidly to room temperature, and count rates were determined from alternate limbs at regular intervals. After a specified time, the components were counted separately, and  $f$  values calculated. Count rates for the solid component at various times during the reaction were obtained by subtraction of the gas count rate from that of gas-plus-solid, using the plots of count rate versus time.

The interaction of  $^{35}\text{SF}_4$  with  $\alpha$ - or  $\beta$ - $\text{UF}_5$  was studied using the procedure previously developed for  $^{35}\text{SF}_4$  or  $^{36}\text{ClF}$  with  $\text{CsF}$  [10]. In some experiments treatment of  $\alpha$ - $\text{UF}_5$  with  $^{35}\text{SF}_4$  or  $\text{SF}_3^{18}\text{F}$  resulted in a green colouration of the solid's surface, suggesting the possibility of  $\alpha \rightarrow \beta$  isomerisation. However the radiochemical behaviour of the two isomers was always different, and there was no evidence of a chemical reaction.  $\alpha$ - $\text{UF}_5$  appeared to be more susceptible to trace hydrolysis than was the  $\beta$ - isomer.

### Substitution reactions of $\text{UF}_5$

#### (a) With $\text{BCl}_3$

A mixture of  $\beta$ - $\text{UF}_5$  (1.74 mmol) and  $\text{BCl}_3$  (3.48 mmol), allowed to react at room temperature for 0.5 h, gave a dark brown solid and volatile material. The latter was identified by i.r. spectroscopy as a mixture of  $\text{BCl}_{3-n}\text{F}_n$ ,  $n = 0-3$  [18]. Addition of MeCN to the solid produced initially a yellow, and finally a green solution, whose electronic spectrum (Figure 3a) indicated that  $\text{U}^{\text{V}}$  chlorofluorides [17] were present. A mixture of  $\beta$ - $\text{UF}_5$  (1.84 mmol) and  $\text{BCl}_3$  (1.81 mmol) in MeCN ( $6 \text{ cm}^3$ ), allowed to react at room temperature for 18 h, gave a

green solid after removal of  $\text{BCl}_{3-n}\text{F}_n$ . The i.r. spectrum of the solid indicated the presence of co-ordinated MeCN, in particular the presence of  $\text{BCl}_3\cdot\text{NCMe}$  [30]. The electronic spectrum of the solid redissolved in MeCN, was very similar to Figure 3a, being identical in the 600-700 and 900-1100 nm region, and differing only in relative intensities of the bands in the 1200-1500 nm region.

(b) With  $\text{B}[\text{OCCl}(\text{CF}_3)_2]_3$

A mixture of  $\beta\text{-UF}_5$  (1.56 mmol) and  $\text{B}[\text{OCCl}(\text{CF}_3)_2]_3$  (1.54 mmol) in MeCN ( $6\text{ cm}^3$ ), allowed to react at room temperature for 18 h, gave a yellow-green solution. Removal of volatile material, shown to be a mixture of  $(\text{CF}_3)_2\text{CO}$ ,  $\text{BF}_3$ , and MeCN by i.r. spectroscopy, left a green solid. The electronic spectrum of the latter, redissolved in MeCN, (Figure 3b) was almost identical to that obtained from  $\beta\text{-UF}_5 + 2\text{BCl}_3$ . The solid's i.r. spectrum contained bands due to co-ordinated MeCN, and a strong band at  $505\text{ cm}^{-1}$ . The electronic spectrum of  $\beta\text{-UF}_5$  (0.38 mmol) and  $\text{B}[\text{OCCl}(\text{CF}_3)_2]_3$  (0.28 mmol) in MeCN ( $4\text{ cm}^3$ ) was identical to Figure 3b, and that obtained from  $\beta\text{-UF}_5$  (0.41 mmol) and  $\text{B}[\text{OCCl}(\text{CF}_3)_2]_3$  (0.14 mmol) in MeCN ( $4\text{ cm}^3$ ) (Figure 3c) was intermediate between those of Figure 3b and  $\text{UF}_5$  in MeCN (Figure 3d). In neither case did the spectrum change with time. The reaction between  $\beta\text{-UF}_5$  (0.62 mmol) and  $\text{B}[\text{OCCl}(\text{CF}_3)_2]_3$  (1.86 mmol) in MeCN ( $6\text{ cm}^3$ ) was similar to those described above, but the solid product appeared to contain unreacted borate.

(c) With  $\text{Me}_3\text{SiOMe}$

A mixture of  $\beta\text{-UF}_5$  (0.33 mmol),  $\text{Me}_3\text{SiOMe}$  (0.33 mmol) and MeCN (2.08 g), allowed to react at room temperature for 1h, gave a yellow-green solid and a brown solution. The volatile material was a mixture of MeCN and  $\text{Me}_3\text{SiF}$  (0.35 mmol), identified by i.r. spectroscopy. A similar reaction between  $\beta\text{-UF}_5$  (0.47 mmol) and  $\text{Me}_3\text{SiOMe}$  (0.94 mmol) in MeCN (3.71 g) gave  $\text{Me}_3\text{SiF}$  (0.89 mmol). Analysis of the yellow-green, insoluble solid isolated from  $\beta\text{-UF}_5$  (3.3 mmol) and  $\text{Me}_3\text{SiOMe}$  (21.3 mmol) corresponded to uranium(V) trifluoride dimethoxide. Found C, 6.6; H, 1.6; F, 15.8; U, 66.7.  $\text{C}_2\text{H}_6\text{F}_3\text{O}_2\text{U}$  requires C, 6.7; H, 1.7; F, 16.0; U, 66.7%. The electronic spectrum of

UF<sub>3</sub>(OMe)<sub>2</sub> (Nujol mull) was:  $\lambda_{\max}$  1565(m), 1430(w,br), 1045(m), 885(sh) nm. The spectrum of  $\beta$ -UF<sub>5</sub>, obtained under similar conditions was:  $\lambda_{\max}$  1400(s), 1370(s), 1200(m, br), 935(s), 900(sh) nm, and that of solid UF<sub>5</sub>(NCMe) was:  $\lambda_{\max}$  1430(s), 1405(sh), 1330(vw), 1170(sh), 1122(w, br), 700(w, br) nm. The spectra of solid products obtained using different mole ratios of reactants were identical.

#### ACKNOWLEDGEMENTS

We thank R.R. Spence and Staff at the Scottish Universities Research Reactor Centre, East Kilbride, for technical assistance, British Nuclear Fuels, PLC, for a gift of UF<sub>6</sub>, and the SERC for financial support.
