PERFLUOROALKYLATION OF 2-MERCAPTOBENZOTHI AZOLE AND ITS ANALOGUES
WITH PERFLUOROALKYL IODIDES BY AN S RN 1 REACTION

QING-YUN CHEN* and MEI-JIN CHEN

Shanghai Institute of Organic Chemistry,Academia Sinica, 345 Lingling Lu,Shanghai 200032 (China)

## SUMMARY

The thiolates, generated in situ by the reaction of 2 -mercaptobenzothiazole (1) and its analogues (2) and (3) with sodium hydride, react under $U V$ irradiation with perfluoroalkyl iodides (4)-(8) to give the corresponding heteroaromatic perfluoroalkyl sulfides (9)-(18) in 50-98\% yields. The fact that the uV irradiation increases the conversion of perfluoroalkyl iodides and that the radical scavenger di-tert-butylnitroxide suppresses the reaction demonstrates that the reaction proceeds via an $S_{R N} l$ mechanism.

## INTRODUCTION

The single electron transfer (SET) process is now well recognised as a fundamental reaction in organic chemistry and in the last two decades it has increased in importance in organofluorine chemistry [1]. The $S$-perfluoroalkylation of aromatic [2-4], heteroaromatic [5] and aliphatic thiols [2,6] with perfluoroalkyl iodides has been described in a series of papers,but so far, no reports on N-perfluoroalkylation have appeared. Beugelmans et al [7] reported that amino groups (NH) of heterocycles react by an $\mathrm{S}_{\mathrm{RN}}{ }^{1}$ mechanism with p -nitrobenzyl chloride and gem-holonitroalkanes to give $N$-alkylation products. Similar heterocycles such as imidazole and benzotriazole react with long
chain perfluoroalkyl iodides, however, to give $C$-perEluoroalkylation products [8]. Recently, in our laboratory, it was noted that $\beta$-halogenperfluoroethyl halides could be successfully used for heterocyclic $\underline{N}$-perfluoroalkylation, which was preliminarily thought to proceed via an SET-induced anionic chain mechanism (Scheme 1) [9]. We have now extended these studies to 2 -mercap-

Scheme 1.
tobenzothiazole (1) and its analogues 2-mercaptobenzimidazole (2) and 2-mercaptobenzoxazole (3), in which the $N$ and $S$ atoms, through a tautomeric equilibrium, could both undergo perfluoroalkylation.

## RESULTS AND DISCUSSION

Treatment of the appropriate perfluoroalkyl iodides (4)-(7) under ultraviolet (UV) irradiation with the sodium salt, generated in situ from 2 -mercaptobenzothiazole (1) and sodium hydride in DMF, gave medium to excellent yields of perfluoroalkyl sulfides (9), (11), (13) and (15) (see Scheme 2 and Entries 1,7,13 and 15 in rable l). The pertluoroalkyl groups were mainly directed to the $S$ atom resulting in the products of $S$-perfluoroalkylation and partially gave the corresponding hydrogenabstracted products (19)-(22). The photochemical product (17) may be prepared similarly by treating (1) with diiodide (8) (2:1, molar ratio), one end of which is attached to the sulfur atom (Entry 17). The use of (1) often affords the coupling product(24).

Treatment of perfluoroalkyl iodides (4)-(7) and (2) rather than (1) under UV irradiation afforded similar results (Entrios 4,10,14 and 16 ). The reaction mainly led to the formation of perfluoroalkyl sulfides (10).(12),(14) and (16).

When 2 -mercaptobenzoxazole (3) was employed as substrate, aryl sulfide (18) was obtained in a lower yield. Instead, a large amount of hydroperfluoroalkane (20) was the main product, accomplished with $35.6 \%$ isolated yield of heterocycle (25) (Entry 18 in Tablc l).

Proofs of structures for the assigned heterocycles are based on elemental analyses, mass, NMR, infrared and ultraviolet spectra (see Table 2 and Table 3). The IR absorption at $1450 \mathrm{~cm}^{-1}$ reveals the presence of $\mathrm{C}=\mathrm{N}$ bond. The characteristic fluorine signals of the $\mathrm{SCF}_{2}$ moiety are observed around $\delta 8-9.6 p \mathrm{~m}$ as a singlet. The ultraviolet spectra contain two characteristic long-wave absorption maxima: one in the region of 217-2.35 mu, and the other at $\sim 285 \mathrm{~m} \mathrm{\mu}$, which are attributable to the $\underline{s}^{-}$ substituted derivatives [10,11].

The formation of $S$ - rather than $N$-perfluoroalkylation may be because the sulfur anion is more nucleophilic towards carbon than the nitrogen anion, i.e. nucleophilicity is the dominating factor [12].

In order to get further evidence, comparative reactions were carried out in daylight $\left(70^{\circ} \mathrm{C}\right)$ instead of under uv irradiation. The conversion of (4) in reaction with (1) was lowered from $72 \%$ to $8 \%$, and in reaction with (2) was decreased from $67 \%$ to $3 \%$ (compare Entry 1 with 2 , and Entry 4 with 5). No reactions were observed on treatment of (5) with (1) and (2) (Entry 8 and ll).

From the results,it was anticipated that addition of a radical inhibitor would suppress the reaction and this has been found to be the case. The repeated reactions under UV light,with addition of 208 molar di-tert-butylnitroxide, an SET scavenger, indicate that the conversion ratios of perfluoroalkyl iodides are noticeably reduced (compare Entry 1 with 3 , Entry 4 with 6 , Entry 7 with 9 and Entry 10 with 12).

The S-perfluoroalkylation of thiolates is formed via an $S_{\text {RN }}{ }^{1}$ mechanism, which was proposed and was well investigated previously [6]. The fact that $u v$ irradiation promotes the reactions and that the inhibitor, in contrast to $U V$ light,
suppresses the process plus the known resistance to displacement of halides from perfluoroalkyl halides by $S_{N} 1$ or $S_{N} 2$ processes $[13,14]$ supports the proposed $S_{R N} l$ mechanism. The isolation of coupling product (24) is a convincing evidence that radicals occur in the reaction system and further confirms the mechanism described in Scheme 3.

Scheme 3.

Detailed insight into the formation of (25) was not sought, but the literature showed that (27) can readily undergo rearrangement to afford (25) [15,16]. It is assumed that (27) is an intermediate, which might be formed by the attack of (26) on (18) and from which the observed product (25) is offered in a four-centered mechanism as in Scheme 4.

[^1]
## EXPERIMENTAL

General procedure: Under a nitrogen atmosphere, $80 \%$ pure sodium hydride (10-20 mmole) was added to lonl DMF solution of 2-mercaptobenzoheterocycle (l0 mmole) in a Pyrex flask. After stirring for several minutes, the corresponding perfluoroalkyl iodide was added and was exposed to a high pressure mercury lamp (400w) at a distance of about 15 cm from the flask for $10 \mathrm{~h}\left(70^{\circ} \mathrm{C}\right)$. The conversion rate was determined and the $R_{f} H$ was detected by ${ }^{19} \mathrm{~F}$ NMR as noted in Table 1 . To the reaction inixture was added 2 ml ethanol, then 20 ml water and 20 ml ethyl acetate. Product (24) was collected by filtration. The-mixture was extracted with ethyl acetate, washed with water and isolated by chromatographic techniques and/or crystallization from ethanol(see Tables 1 and 2).
