## Abstract

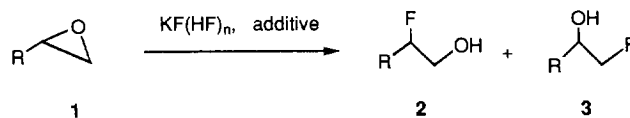

The ring-opening reaction of aliphatic epoxides with potassium fluoride–poly(hydrogen fluoride) is enhanced by a catalytic amount of triphenylphosphine. It is assumed that phosphonium fluoride species formed from triphenylphosphine work as fluorinating agents in this reaction. © 1997 Elsevier Science S.A.

## 1. Introduction

Potassium fluoride–poly(hydrogen fluoride) ( $\text{KF}(\text{HF})_n$ ) salts are easy-to-handle solid reagents which are easily prepared from potassium fluoride and anhydrous hydrogen fluoride [1]. From the viewpoint that they are poly(hydrogen fluoride) species, they are expected to be solid alternatives to anhydrous hydrogen fluoride or amine–HF, which are effective nucleophilic fluorinating agents [2]. Recently, we have demonstrated the utility of  $\text{KF}(\text{HF})_n$  as nucleophilic fluorinating agents for the first time [3,4]. When  $\text{KF}(\text{HF})_n$  is used for ring-opening reactions of epoxides and for halo-fluorination of alkenes, the reactions proceed in a regio- and stereoselective manner to afford the corresponding fluorohydrins and halo-fluorides respectively. Especially, the stereoselectivity of the ring-opening reaction is quite unique, namely the reaction proceeds via predominantly cis-addition of hydrogen fluoride to the epoxide.

Concerning this ring-opening of epoxides, however, the substrate is limited only to aromatic epoxides, such as styrene oxide. If aliphatic epoxides are reacted with  $\text{KF}(\text{HF})_n$ , the yields of corresponding fluorohydrins are very low [3]. In this study, we investigate the ring-opening of aliphatic epoxides with  $\text{KF}(\text{HF})_n$  and find that a catalytic amount of triphenylphosphine enhances this reaction.

## 2. Results and discussion

The reaction of 1-dodecene oxide (**1a**) with  $\text{KH}_2\text{F}_3$  was initially attempted (Scheme 1). Without additives, although the ring-opening reaction proceeded at  $80^\circ\text{C}$ , the yields of corresponding fluorohydrins (**2a** and **3a**) were very low because of undesirable side reactions such as polymerization (Table 1, entry 1). However, the yield was improved when the reaction was carried out in the presence of a catalytic amount of trialkylphosphine (entry 2). And when triphenylphosphine ( $\text{Ph}_3\text{P}$ ) was used as an additive, the fluorohydrins were obtained in 64% yield (entry 3).

The effect of  $\text{Ph}_3\text{P}$  on the reaction using other  $\text{KF}(\text{HF})_n$  or substrates was examined. When **1a** was reacted with  $\text{K}_2\text{H}_3\text{F}_7$ , the ring-opening reaction proceeded at room temperature, but the combined yield of **2a** and **3a** was only 12% (entry 5). If a catalytic amount of  $\text{Ph}_3\text{P}$  was used as an additive, the yield was improved to 44% (entry 6). And although the reaction of phenyl glycidyl ether (**1b**) with  $\text{KH}_2\text{F}_3$  did not proceed at all (entry 7), the reaction proceeded

<sup>a</sup> Epoxide (1 mmol), KF(HF)<sub>n</sub> (5 mmol), and an additive (0.1–0.2 mmol) were stirred at 80 °C in 1,2-dichloroethane.

<sup>b</sup> Yield and selectivity were determined by <sup>19</sup>F-NMR of the crude product (C<sub>6</sub>H<sub>5</sub>CF<sub>3</sub> was used as internal standard).

<sup>c</sup> The substrate (ca. 30%) was recovered.

<sup>d</sup> The reaction was conducted at room temperature.

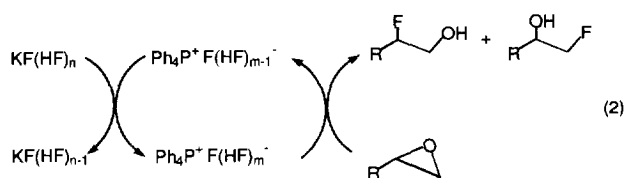

<sup>e</sup> The substrate (100%) was recovered.

<sup>f</sup> The substrate (ca. 45%) was recovered.

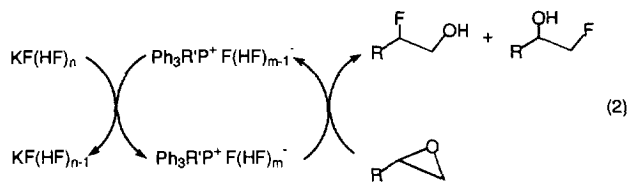

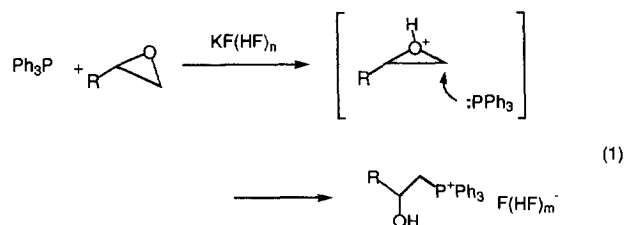

in the presence of a catalytic amount of Ph<sub>3</sub>P and afforded **2b** and **3b** in 33% yield (entry 8).

To consider the mechanism of this reaction, the reaction of **1a** with KH<sub>2</sub>F<sub>3</sub> was attempted in the presence of a catalytic amount of tetraphenylphosphonium bromide (Ph<sub>4</sub>P<sup>+</sup>Br<sup>-</sup>) (entry 4). As a result, the corresponding fluorohydrins were obtained in 66% yield and the regioselectivity **2a**:**3a** was 68:32, which was almost the same result as the reaction using Ph<sub>3</sub>P (entry 3). This result suggests that the mechanism of the reaction using Ph<sub>3</sub>P is similar to that using Ph<sub>4</sub>P<sup>+</sup>Br<sup>-</sup>.

It has been reported that tetraphenylphosphonium fluoride species, such as Ph<sub>4</sub>P<sup>+</sup>HF<sub>2</sub><sup>-</sup>, form from Ph<sub>4</sub>P<sup>+</sup>Br<sup>-</sup> and hydrogen fluoride [5], and that these phosphonium fluorides work as nucleophilic fluorinating agents [5,6]. Consequently, it is assumed that the ring-opening of epoxides with KH<sub>2</sub>F<sub>3</sub> in the presence of a catalytic amount of Ph<sub>4</sub>P<sup>+</sup>Br<sup>-</sup> proceeds via formation of tetraphenylphosphonium fluoride species such as Ph<sub>4</sub>P<sup>+</sup>F(HF)<sub>m</sub><sup>-</sup> and that fluorination with the phosphonium fluoride follows, as shown in Scheme 2. Similarly, ring-opening reactions in the presence of Ph<sub>3</sub>P would also proceed by fluorination with phosphonium fluoride species. It is known that ring-opening of epoxides with Ph<sub>3</sub>P in the presence of acid readily occurs to form β-hydroxyalkyl-triphenylphosphonium salts [7]. Consequently, in the case of the ring-opening of epoxides with KF(HF)<sub>n</sub> in the pres-

Scheme 2.

Scheme 3.

ence of a catalytic amount of Ph<sub>3</sub>P, it is assumed that β-hydroxyalkyltriphenylphosphonium fluoride species such as RCH(OH)CH<sub>2</sub>-Ph<sub>3</sub>P<sup>+</sup>F(HF)<sub>m</sub><sup>-</sup> are formed from epoxide, Ph<sub>3</sub>P, and KF(HF)<sub>n</sub>. RCH(OH)CH<sub>2</sub>-Ph<sub>3</sub>P<sup>+</sup>F(HF)<sub>m</sub><sup>-</sup> then fluorinates more epoxide to form RCH(OH)CH<sub>2</sub>-Ph<sub>3</sub>P<sup>+</sup>F(HF)<sub>m-1</sub><sup>-</sup>, and RCH(OH)CH<sub>2</sub>-Ph<sub>3</sub>P<sup>+</sup>F(HF)<sub>m</sub><sup>-</sup> is regenerated with KF(HF)<sub>n</sub> (Scheme 3).

### 3. Experimental details

A typical experimental procedure is as follows. To KH<sub>2</sub>F<sub>3</sub> (5 mmol) in a Teflon® (PFA) vessel was added a solution of the epoxide (1 mmol) and an additive (0.1–0.2 mmol) in 1,2-dichloroethane (5 ml). The reaction mixture was stirred at 80 °C for a period indicated in Table 1, and quenched with aqueous sat. NaHCO<sub>3</sub>. After the usual work up, yields and selectivity of the products were determined by <sup>19</sup>F-NMR of

the crude product ( $C_6H_5CF_3$  was used as internal standard). The products were purified and identified by comparison of their IR,  $^1H$ -NMR, and  $^{19}F$ -NMR spectra with those of authentic samples [8–10].

#### 4. Conclusion

We have demonstrated the effect of triphenylphosphine on ring-opening reactions of aliphatic epoxides with  $KF(HF)_n$ . A catalytic amount of triphenylphosphine enhances this reaction and it has been suggested that phosphonium fluoride species form from triphenylphosphine,  $KF(HF)_n$ , and epoxide, and act as fluorinating agents in this reaction.
