Chromatographic and Spectroscopic Profiles of *Cannabis* of Different Origins: Part I

REFERENCE: Brenneisen, R. and ElSohly, M. A., "Chromatographic and Spectroscopic Profiles of Cannabis of Different Origins: Part I," Journal of Forensic Sciences, JFSCA, Vol. 33, No. 6, Nov. 1988, pp. 1385-1404.

ABSTRACT: High-resolution capillary gas chromatography with flame ionization detection and mass spectrometry (GC and GC/MS) and high-performance liquid chromatography (HPLC) were used to establish complex chemical profiles (chemical signatures) of *Cannabis* samples of known origin. Over 100 compounds could be differentiated, including noncannabinoids (terpenes, alkanes) as well as minor and major cannabinoids and their acids. A characteristic peak pattern was found within a limited number of specimens of identical origin. Correlation studies on the basis of peak area ratios [A(x)/A(i.s.)] showed the feasibility of tracing *Cannabis* chemically to its country of origin. Several forensic science applications for the chromatographic and spectroscopic profiles of confiscated *Cannabis* samples are discussed, such as detection of additives (phencyclidine), differentiation of chemotypes, and monitoring of tetrahydrocannabinol (THC) potency.

KEYWORDS: toxicology, marijuana, chemical analysis, Cannabis

Herbal Cannabis (Cannabis, marijuana), Cannabis resin (hashish), and extracts of Cannabis resin (hashish oil) are still the most abused illicit drugs of the world. It is estimated that over 8000 tons (725 mg) of Cannabis are being consumed in the United States each year. The majority of this material is smuggled into the country from major Cannabis-producing countries such as Colombia, Mexico, Jamaica, and Thailand. More recently an increase of the domestic production has been observed.

In an effort to combat drug abuse, the current U.S. Administration policy has been multifaceted. One of the major efforts to reduce availability of the drug is through enforcement and interdiction. To have a successful interdiction program, it is important to know where the illicit drug is coming from so that resources can be allocated where most needed to stop shipments. There are reasons to believe that *Cannabis* from one country is being shipped to the United States through intermediate countries, for example, Colombian or Thai *Cannabis* through Mexico to the United States. Consequently, a seizure of *Cannabis* at the Mexican border does not necessarily mean that it is produced in Mexico. A procedure to deter-

mine the country of origin of a *Cannabis* sample is thus of great importance in law enforcement and forensic science applications.

Attempts have been made in the past to classify *Cannabis* based on its country of origin with little success [1-3]. This is due to the fact that only major cannabinoids (tetrahydrocannabinol, cannabidol, cannabichromene, and so forth) were examined. In addition, methods having low resolution power and specificity, like conventional gas chromatography (GC) on packed columns and with flame ionization detection, were used. A more recent suggestion is that minor cannabinoids and noncannabinoids be analyzed for tracing *Cannabis* products to their geographical origin [4, 5].

In 1976, Novotny et al. [6] reported preliminary data relative to the use of a high-resolution glass capillary column for GC analysis of marijuana samples of different origin. The authors indicated that the chromatograms appeared to be different in certain details and suggested that a correlation between chromatographic data and geographical origin of marijuana samples might be possible.

In the present study, we report on an analytical procedure which allows acquisition of complex chemical profiles of *Cannabis* samples. The chromatographic and spectroscopic data of a *limited* number of samples confiscated in five different countries are given. Several forensic science and law enforcement applications for the proposed method are discussed.

Method and Materials

Cannabis Samples

Illicit marijuana and hashish samples were obtained from the Drug Enforcement Administration (DEA). They were seized at different locations in Mexico, Colombia, Jamaica, Thailand, and the United States. One sample was taken from legal *Cannabis* cultivations at the University of Mississippi.

Standards and Chemicals

Cannabinoids— The following compounds were isolated from cannabis or synthesized at the Research Institute of Pharmaceutical Sciences, University of Mississippi, or supplied by the National Institute on Drug Abuse (NIDA): cannabigerol (CBG), cannabichromenic acid (CBCA), cannabichromene (CBC), cannabidiolic acid (CBDA), cannabidiol (CBD), Δ^9 -(trans)-tetrahydrocannabinolic acid A (THCA-A), Δ^9 -(trans)-tetrahydrocannabinolic acid B (THCA-B), Δ^9 -(trans)-tetrahydrocannabinol (THC), Δ^9 -(trans)-tetrahydrocannabinolic (8-THC), cannabicyclol (CBL), cannabielsoin (CBE), cannabinolic acid (CBNA), cannabinol (CBN), cannabivarin (CBV), 9,10-dihydroxy- $\Delta^{6a(10a)}$ -tetrahydrocannabinol (DHTHC), cannabicitran (CBT), and cannabiripsol (CBR).

Spiro-indans—Cannabispirol (CBS), cannabispirenone (CBSO), cannabispiran (CBSA), and canniprene (CPR) were isolated from cannabis.

Terpenes—Caryophyllene oxide was obtained from Aldrich Chemical Co. Inc. (Milwaukee, Wisconsin), α -terpineol and β -caryophyllene were supplied by Roth Co. Chemische Fabrik (Karlsruhe, Federal Republic of Germany) through Atomergic Chemetals Corp. (Plainview, New York), allo-aromadendrene and longifolene by Fluka Chemical Corp. (New York).

Alkanes—Heptacosane and nonacosane were obtained from Aldrich and heneicosane from Varian Association (Houston, Texas). Phencyclidine hydrochloride (PCP) was obtained from the U.S. Pharmacopea standards, phenanthrene (internal standard [i.s.]) from Aldrich.

Solvents-High-performance liquid chromatography (HPLC) grade or reagent grade

quality, obtained from Fisher Scientific Co. (Fair Lawn, New Jersey) or Baker Chemical Co. (Phillipsburg, New Jersey).

Silylation reagent—N, O-bis(trimethylsilyl)trifluoroacetamide (BSTFA) + 1% trimethylchlorosilane (TMCS) was obtained from Pierce Chemical Co., Rockford, Illinois.

Extraction

Dried, pulverized herbal Cannabis, 100 mg, or Cannabis resin, 50 mg, was extracted with 1.0 mL of methanol-chloroform (9:1), containing 0.2-mg/mL phenanthrene as internal standard, by sonication during 15 min. An aliquot of 2 μ L of the filtered extract was used for HPLC analysis. For GC and gas chromatographic/mass spectrometric (GC/MS) analysis, 100 μ L of the extract was diluted with 900 μ L of methanol and aliquots of 1 μ L were injected.

Capillary Gas Chromatography (GC)

The GC profiles of *Cannabis* extracts were all generated in the splitless mode (split vent activation time: 30 s) with a Varian 3300 gas chromatograph (Varian Instruments, Palo Alto, California), fitted with a Durabond fused silica capillary column (30- by 0.25-mm inside diameter [ID]) coated with DB-1 (J & W Scientific, Inc., Rancho Cordova, California) at a film thickness of $0.25 \,\mu$ m. The (FID) signal was recorded on a Fisher Recordall recorder 5000 in series with a Hewlett-Packard 3390 A integrator. The oven temperature was programmed from 70 to 250°C at a rate of 5/min. The injector and detector were maintained at 250 and 300°C, respectively. Helium was used as the carrier gas at a velocity of about 25 cm/s, air at 300 mL/min and hydrogen at 30 mL/min as detector gases, and helium at 30 mL/min as makeup gas. All GC profiles were recorded at an attenuation of 8 and a chart speed of 0.5 cm/min.

Capillary Gas Chromatography-Mass Spectrometry (GC/MS)

For the acquisition of the GC/MS profiles, the same GC and separation system as described above was used. The column was linked via open-split interface with a Finnigan Ion Trap Detector System (Finnigan MAT, San Jose, California) consisting of an ion trap detector (ITD), an IBM XT personal computer, and an Epson FX-80 II printer. The ITD system was operated with software version 3.0. The temperature of the transfer line and the ion trap manifold was set at 250 and 220°C, respectively. The scan range was m/z 70 to 500, and the scan rate was set at 1 scan/s. The peak area ratios [peak (x)/peak (i.s.)] were calculated by peak integration using the quantitation program.

Cannabinoid acids and polar noncannabinoids isolated by semipreparative HPLC were identified by GC/MS as their trimethylsilyl (TMS) derivatives. After evaporation of the HPLC fractions, the residue was dissolved in 50 μ L acetonitrile and 50 μ L BSTFA (+ 1% TMCS), sonicated and heated during 15 min at 50 to 60°C. The reaction mixture was evaporated under a stream of nitrogen just to dryness, redissolved in 100 μ L hexane by sonication, and 1 to 2 μ L injected into the GC/MS system.

High-Performance Liquid Chromatography (HPLC)

The HPLC profiles were acquired on a system consisting of a Waters M 6000-A pump, a U6K injector (Waters Assoc., Milford, Massachusetts), an LDC/Milton Roy variable-wavelength ultraviolet (UV) detector (Laboratory Data Control, Riviera Beach, Florida), and a Fisher Recordall recorder 5000 (Bausch & Lomb, Houston Instrument, Austin, Texas) with a HP 3390 A integrator (Hewlett-Packard, Palo Alto, California). Separation of *Cannabis* extracts was performed at ambient temperature on a Beckman Ultrasphere 3-µm ODS

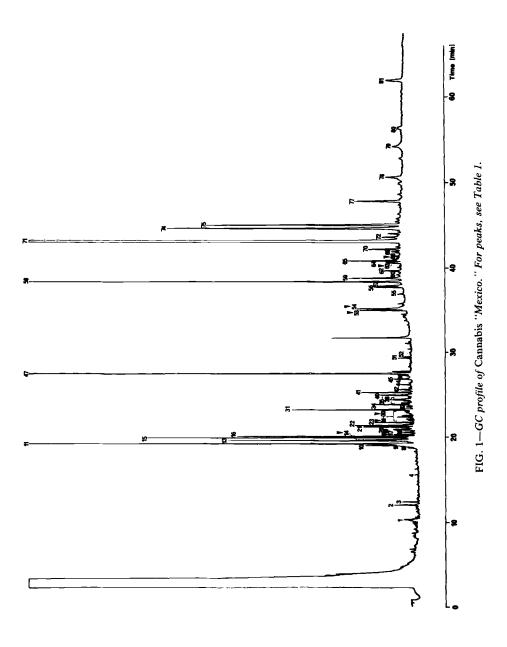

column (75- by 4.6-mm ID; Rainin Instrument Co., Inc., Woburn, Massachusetts) using a mobile phase of methanol: water containing 1% acetic acid 77:23 at a flow rate of 1.8 mL/ min. The profiles were recorded at 230 nm and 0.1 AU full scale. For peak identification by GC/MS the main compounds were isolated by analytical-preparative HPLC, using a self-packed Spherisorb $5-\mu$ m ODS-1 column (250 by 4.6 mm ID) [7] and methanol: water containing 5% acetic acid 85:15 as mobile phase at a flow rate 1.5 mL/min.

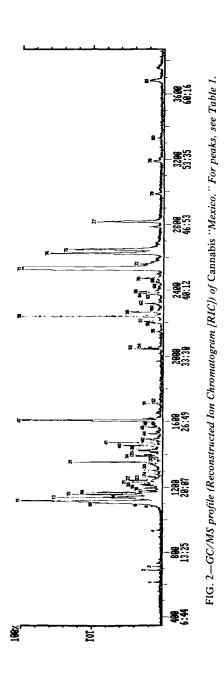

Results and Discussion

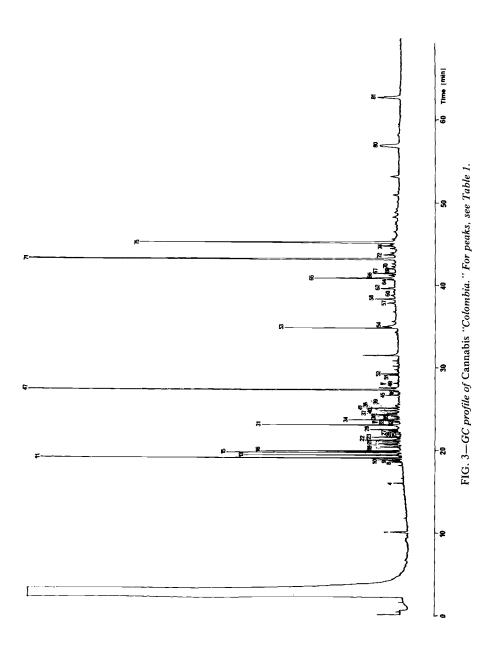

For the acquisition and the comparison of a large number of complex chemical profiles, it is important to use a simple, rapid, efficient, and standardized *extraction procedure*. Among the tested solvents (methanol, chloroform, dichloromethane, cyclohexane) a mixture of methanol-chloroform (9:1) was found to extract over a wide polarity range the highest amount of noncannabinoids and cannabinoids. Especially for milligram-scale specimens and thermolabile compounds, for example, cannabinoid acids, we recommend the use of an ultrasonic bath for extraction and not a soxhlet apparatus as proposed by Novotny et al. [6]. The resulting extracts, which contain phenanthrene as internal standard, can be used without further purification or partition for the chromatographic and spectroscopic characterization by capillary GC and by HPLC.

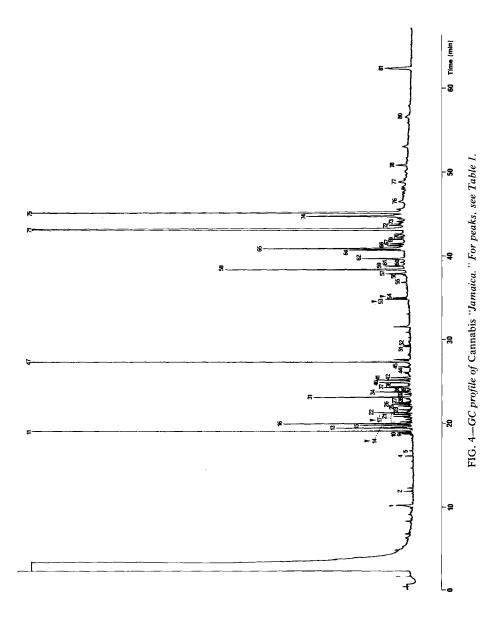

A DB-1 fused silica capillary column showed the necessary separation power to establish GC profiles with more than 100 different compounds (Figs. 1 to 8). A high number of peaks is important to minimize the risk of coincidental agreement of profiles. Mono- and sesquiterpenes, alkanes, spiro-indans, cannabinoids, and nitrogen-containing compounds (for example, phencyclidine [PCP], Fig. 8) can be analyzed within the same run. The same column was also used in our laboratories for the determination of gasoline residues and alkaloids in coca paste specimens [8]. Even after several hundred runs, the column still provided excellent resolution, good peak shape, and high baseline stability during temperature programming. The reproducibility of the GC method (extraction included) was examined by repetitive runs of an identical specimen and measuring the relative retention times (RRT) and the peak area ratios A(x)/A(i.s.). The coefficient of variation was found to be less than 1% for RRT and A(x)/A(i.s.). The splitless injection technique together with FID and the specific MS detection provide the required high sensitivity and allow "chromatographic fingerprinting" down to the picogram level. The identity of 22 compounds was established by comparing RRT and mass spectra with those of standards. Some peaks (Table 1) were identified tentatively by using published MS data [9-11]. The chromatographic and spectroscopic data of all detected compounds are summarized in Table 1, and the chemical structures, pharmacological activities, and so forth of identified compounds are reviewed in Ref 12. The quantitative evaluation of the profiles was done by calculating A(x)/A(i.s.) of identified and unidentified compounds versus the internal standard phenanthrene (i.s.).

For the sample comparison, only area ratios were used of peaks, which (1) could be detected by FID and MS, (2) had a minimal peak area of 200 counts and a minimal signal-tonoise ratio of 5:1, (3) exhibited a reasonable mass spectrum, and (4) were not obviously GC artifacts. As demonstrated by Figs. 1 and 2, showing the GC and GC/MS profiles of a Mexican specimen, a good correlation was usually found between chromatograms obtained by FID and those obtained by MS detection. Figures 3 to 6 show the GC profiles of *Cannabis* originating from Jamaica, the United States, Colombia, and Thailand. Some of the main characteristic differences in the peak pattern are indicated by an arrow (\forall). The corresponding peak area ratios in Table 1 are italicized. The chemical signature given here for one *Cannabis* specimen per origin was found to be typical for a limited number of specimens. Only two (Jamaica) to five (Mexico, Colombia, Thailand) *Cannabis* specimens with authenticated origin other than the United States were available to develop the methods for profiling and to study the feasibility of tracing *Cannabis* chemically to its country of origin.

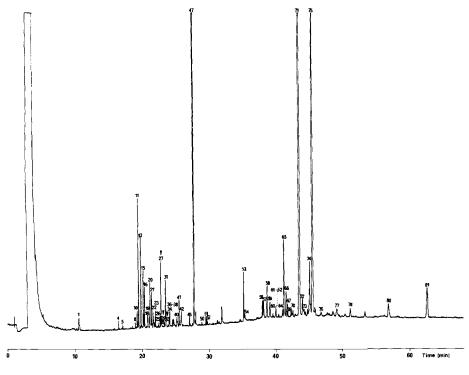

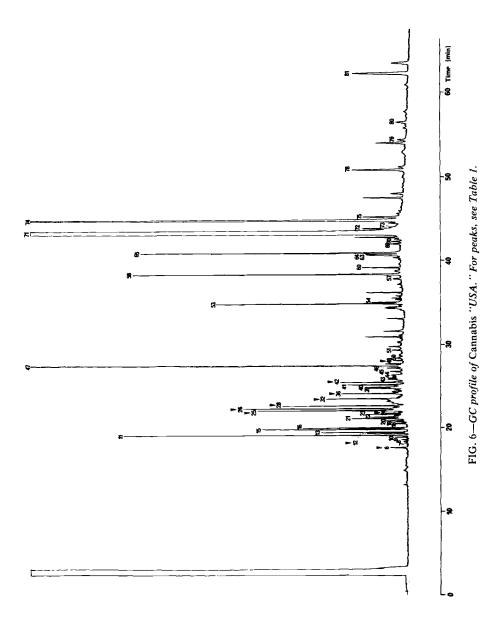

FIG. 5-GC profile of Cannabis "Thailand." For peaks, see Table 1.

Most of the diagnostically important peaks are present in the terpene region (RRT <1.000). For example, Peak 12 is typical for *Cannabis* "USA," Peaks 14 and 17 (allo-aromadendrene) are only found in *Cannabis* "Mexico" and "Jamaica," Peaks 30 and 68 only in *Cannabis* "Mexico." Peak 27 and 29 are characteristic for *Cannabis* "Thailand," Peak 49 for *Cannabis* "Colombia." Similar ratios of Peak 53 (heneicosane, C-21 alkane) and 54 (tetrahydrocannabiorcol) are characteristic for *Cannabis* "Mexico" and "Jamaica," whereas Peak 53 dominates in all other origins.

Note the missing Peak 31 in *Cannabis* "USA," identified as caryophyllene oxide. This sesquiterpene is formed by oxidation from caryophyllene (11) and is supposed to be the essential volatile compound sniffed by narcotic dogs [13]. The influence of maturity, age, storage conditions, and so forth on Compound 31 and other terpenes is subject of ongoing work.

Several studies have shown the daily and monthly fluctuation of major cannabinoids (THC, CBD, CBC, and so forth) in *Cannabis* independent of its geographical origin [14, 15]. Therefore, their ratios are not significant and cannot be correlated to any geographical origin. Until now it is not known if the minor cannabinoids, for example, cannabicumaronone (66) or C-4 analogs (63), undergo the same cyclic variation as the major cannabinoids. A large number of specimens has to be analyzed to verify if the presence (or absence) of such cannabinoids is typical for a certain origin.

As can be seen in Fig. 7, the GC profile of a hashish specimen is characterized by a larger number of peaks in the terpene region. Hashish and hashish oil are much more frequently encountered in the European illicit market. This is illustrated by the fact that in 1983 there was more than twice as much hashish confiscated in Europe as marijuana (94 714 kg of hashish, 40 826 kg of marijuana, and 455 kg of hashish oil) [16]. Profiling and correlation studies of hashish and hashish oil specimens will also be part of extensive future work on chemical signatures and pattern recognition of these products.

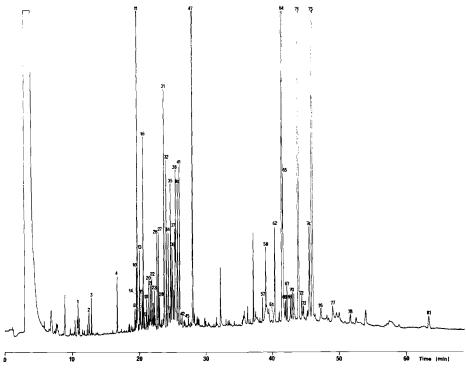

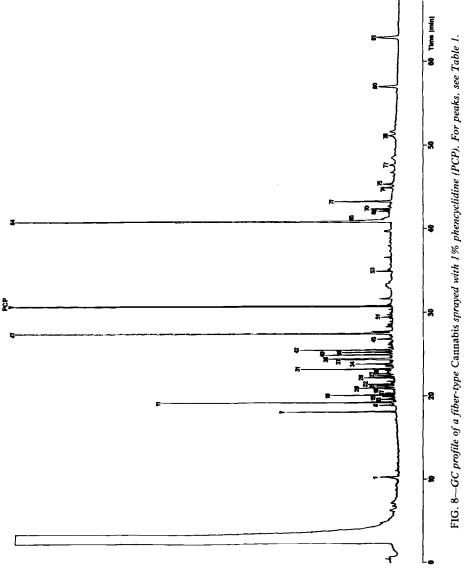

FIG. 7-GC profile of a hashish sample. For peaks, see Table 1.

The usefulness of GC and GC/MS profiles to detect adulterants or additives is demonstrated with Fig. 8 showing the GC profile of a *Cannabis* fiber type sprayed with 1% phencyclidine (PCP). The PCP peak appears at RRT 1.114 and shows a mass spectrum with m/z243 (M⁺) and 200 (base peak). Phenylhexene, the thermal decomposition product of PCP, gives a peak at RRT 0.651 with m/z 158 (M⁺) and 129 (base peak). Most of the *Cannabis* street samples containing PCP are confiscated in the Washington area today.

Because the complex chemical profiles are unique for a given specimen, the characteristic peak pattern could be used for comparison of samples confiscated at different locations but presumably originating from a common lot. More data are necessary to support this application, which could be important for drug enforcement and intelligence.

The efficiency of $3 \ \mu m$ reversed-phase columns for the *HPLC profiling* of cannabinoids in *Cannabis* products and quantitative screening of THC metabolites of urine specimens has already been reported previously [7, 17, 18]. On a short ODS-column (75 mm), with acidified methanol-water as mobile phase and operating under isocratic conditions, up to 45 different compounds were observed in a Mexican marijuana specimen using UV detection (Fig. 9). Longer columns (150 to 250 mm) require gradient-elution to avoid excessive retention times and peak broadening of compounds with high κ' -values. More than 20 compounds, including minor and major cannabinoids and their acids as well as some highly polar noncannabinoid phenols, could be identified. This was done by comparing the RRT with those of standards and by isolating the peaks with semipreparative HPLC followed by GC/MS analysis. The chromatographic and spectroscopic data of the HPLC profiles are given in Table 2.

HPLC is the preferred method to acquire profiles of thermolabile and highly polar *Canna*bis constituents which need a derivatization procedure (silylation, acetylation, methylation) for GC analysis. Such compounds include cannabinoid acids (THCA, CBDA, CBCA, and so forth) and dihydroxylated noncannabinoid phenols (cannabispirol, canniprene, and so

"Peak area ratios of compound (x) versus internal standard (i.s.), multiplied by 1000. Italic ratios are characteristic. MEX = Mexico, COL = Colombia, JAM = Jamaica, THA = Thailand, USA = United States. Phenanthrene. 'Identified on the basis of literature data [g-II].

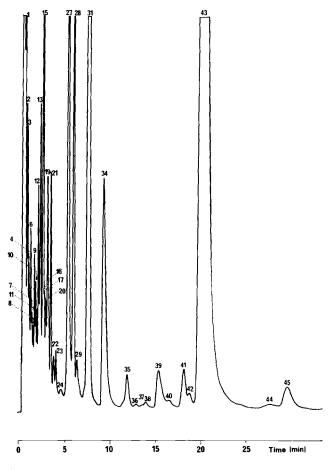

FIG. 9-HPLC profile of Cannabis "Mexico." For peaks, see Table 2.

forth). Because the ratios of cannabinoid acids and their decarboxylation products (THC, CBD, CBC, and so forth) strongly depend on age and storage conditions of the analyzed material [7], HPLC profiles may provide useful information about the history of a *Cannabis* specimen. The ratios of CBD and THC allow a quick differentiation of *Cannabis* chemotypes (drug, fiber, intermediate) or monitoring of the THC potency of confiscated samples. Because HPLC profiles established on reversed-phase columns and with UV detection do not give any information about lipophilic compounds such as mono- and sesquiterpenes, their use for correlating peak patterns and origins is limited.

Conclusions

High-resolution capillary gas chromatography (GC) with FID and MS detection is the method of choice for the chromatographic and spectroscopic profiling of cannabis products. High-performance liquid chromatography (HPLC) on small-particle size columns is recommended for the screening and ratioing of neutral and acidic cannabinoids and the rapid discrimination of different *Cannabis* types (drug, fiber, and so forth). The GC profiles of

"Peak area ratios of compound (x) versus internal standard (i.s.), multiplied by 1000. MEX = Mexico, COL = Colombia, JAM = Jamaica, THA = Thailand, USA = United States. "Phenanthrene"

Cannabis specimens with the same authenticated origin show a similar, characteristic peak pattern. Correlation studies with a limited number of specimens indicate that it could be possible to determine the origin of a Cannabis specimen on the basis of its chemical signature. A confirmation of this approach will need to be carried out through the analysis of a large number of specimens of known provenance. Other factors than the geographical origin that could influence the chemical profiles, such as time of harvesting (maturity), age of the samples, storage conditions, and seed shipment from one country to the other, have to be studied. The statistical evaluation of the chromatographic and spectroscopic data would be facilitated by the use of an automated data acquisition system and special software for pattern recognition.

Acknowledgments

This work was supported in part by the National Institute on Drug Abuse (NIDA), the Drug Enforcement Administration (DEA), the Research Institute of Pharmaceutical Sciences, the University of Mississippi, and the University of Berne, Switzerland. The authors wish to thank NIDA for providing cannabinoid standards and the Drug Enforcement Administration (DEA), Special Testing and Research Laboratory, McLean, VA, for providing the *Cannabis* samples of known geographical origin.
