## Author's Response

Sir:

Mr. Promish appears to have missed one of the major points put forth in my article. Many of the bullets within a box do not resemble others from the same box any more than they resemble bullets from other manufacturers. This was illustrated graphically in Fig. 2 on page 1024. Calculating an "average" elemental composition for a box, and then showing that individual bullets from that box more closely resemble that average than they do averages of other boxes is meaningless. What matters, in a real case scenario, is whether known and questioned bullets match.

The purpose of bullet lead analysis, in most situations, is not to brand identify unknown bullets, as suggested in the final paragraph of Mr. Promish's letter. This is because the trace elemental composition of bullets from a single manufacturer can vary almost continuously over time, depending on the source for the lead. The analyst's opinion is usually limited to stating that the suspect bullet is consistent with (or could have come from) the same source as the known bullet. This is the same standard that applies to other forms of trace evidence as well, such as paint chips, glass fragments, and fibers, in the absence of a physical match. The "scalar products," or correlation values, were calculated in an effort to quantitate the quality of the match between two bullets, and arrive at a means of unambiguously distinguishing between known matching and non-matching bullet leads.

While statistical approaches to data interpretation may be useful, they are, as stated in the final paragraph of my paper, "not a substitute for direct comparison of the raw elemental data when formulating an opinion as to the similarity of two bullets". A 95% probability that two bullets match means little when a look at the raw data shows that they could not be from the same melt.

I appreciate Mr. Promish's enthusiasm, and applaud his volunteering his probabilistic approach. More of this type of thinking needs to be applied to the forensic sciences. However, it must be applied with caution. I question the advisability of using the probability of a bullet match as a decision threshold for arrest, prosecution, or finding of guilt. Such decisions can only be based on a much broader scope of evidence, which could include bullet comparison. The bullet analyst cannot be expected to give a qualified opinion as to the certainty of a match; his findings must be either positive or negative to be of use.

## Verbal Conventions for Handwriting Opinions

Sir:

A paper of mine in *Science and Justice* (1) on reporting conventions was recently the subject of a spirited debate on Docexam\_L,

the forensic document examiners e-mail forum (membership enquiries to andersonc@doceexam.com.au). The rough and tumble of an e-mail discussion is all very well but it seems to me that if the core issues are to be resolved then the appropriate forum lies within the pages of a peer-reviewed journal. Nothing of what I say here is original and the subject has been covered in greater detail elsewhere but it seems to me to be appropriate that I should state my case in the journal that carried the letter that announced the reporting convention with which I take issue.

The letter from McAlexander, Beck and Dick (2) is to be applauded for its motivation. It promotes the idea that there is a need for standardization of terminology among experts when they express opinions. It also argues convincingly for the need to consider handwriting evidence probabilistically. Rightly, the authors pointed to the weaknesses of phrases which appear, regrettably, to be in widespread use in the forensic science world: I refer, in particular to the use of "could have" and "consistent with." I agree with McAlexander et al. that these phrases should have no place in any convention for expressing the weight of an item of scientific evidence.

The letter described a reporting convention which became the subject of ASTM standard E 1658-96 (3). My copy is headed "Standard Terminology for Expressing Conclusions of Forensic Document" (sic).

Laudable though the attempt at standardization undoubtedly is, I must point out that there is a serious problem with the manner in which the convention uses the notion of probability. In my opinion, the reporting convention is incompatible with a logical approach to evidence interpretation. Whether or not one agrees with me that this is a problem depends on whether or not one wishes to view handwriting comparison as having a scientific rationale. If it is scientific, it has to be logical; it follows that if probability is to be invoked, then the laws of probability cannot be violated.

Probabilistic thinking in relation to forensic science has, until comparatively recently, been seen to be something that evolved in the 1970's, when the paper by Finkelstein and Fairley (4) was an important milestone—though that, in turn, had evolved to some extent from lines of reasoning followed by Mosteller and Wallace (5) in considering the authorship of *The Federalist* papers. However, recent research at the University of Lausanne (6) has pinpointed the work of Poincaré, Darboux, and Appell as, apparently, the first example of what we now call the Bayesian view of forensic evidence. It is particularly germane that the reasoning of Poincaré and his colleagues was concerned with a critical review of Bertillon's evidence in a notorious handwriting case: the trial of Dreyfus for treason. In modern parlance, we would say that Bertillon committed what Thompson and Schumann (7) called the "prosecutor's fallacy". Poincaré and his colleagues pointed out the error.

It is not necessary for me to explain the Bayesian view here because of the extensive body of literature that now exists in the forensic sphere. Useful introductions to the ideas are provided by Robertson and Vignaux (8) and Aitken and Stoney (9). The key principles that emerge from this view include, first, the notion that the forensic scientist should always consider (at least) two propositions that, in the adversary system of justice, will represent the defence and prosecution positions. Next, the fundamental principle is that the scientist must address questions of the kind "what is the probability of the evidence given the proposition?". Questions of the kind "what is the probability of the proposition given the evidence?" are the province of the jurors, who will not only take into
