Angola Population Data with AmpF ℓ STRTM Profiler Plus

POPULATION: West Africa population sample ($n = 116$) from Angola

KEYWORDS: forensic science, DNA typing, population genetics, West Africa, short tandem repeats, polymerase chain reaction, Profiler Plus, D3S1358, vWA, FGA, D8S1179, D21S11, D18S51, D5S818, D13S317, D7S820

Blood stains from 116 unrelated individuals from Angola (West Africa) were stored using bloodstain card and extracted with the standard Chelex method. PCR amplification was performed in a GeneAmp[®] PCR System 9600, using the AmpF ℓ STR[®] Profiler PlusTM Amplification Kit, according to the manufacturer's recommendations. Electrophoresis of the PCR products was carried out in an ABI PrismTM 377 DNA Sequencer, using 5% denaturing Long Ranger[®] gels. Sample genotypes were determined with Genotyper[®] (version 2.0), by comparison with supplied allelic ladders and an internal size standard (GS-500Rox).

Analysis of data—Allele frequency distribution data for this West African population from Angola is presented in Table 1. Based on χ^2 test, the nine loci meet HWE expectations ($p > 0.05$). Statistical forensic parameters were calculated—minimum allele frequency, heterozygosity, power of discrimination and probability of exclusion (1–4). Genetic diversity parameters for almost all loci were consistently higher than those reported for Portuguese Caucasian population (5). The combined values for power of discrimination and probability of exclusion were, respectively, PD = 0.999999999942 and PE = 0.999905.

High genetic variability was observed in this West Africa population due to high polymorphism and rare alleles. Several uncommon alleles have been detected: allele 11 in vWA; allele 8 in D8S1179; alleles 33.1, 37 and 38 in D21S11; allele 14.2 in D18S51 and allele 7 in D5S818 and D7S820. In all loci alleles with lower frequency than minimum allele frequency was observed. Rare alleles have also been noticed in several loci: FGA-allele 31.2 and D21S11-allele 29.1.

Comparing with other reported data of African populations (6–8), significant differences were detected in D3S1358, vWA and D21S11, namely the non-presence of small alleles in D3S1358 and the highest prevalence of allele 17 and allele 30 in vWA and D21S11, respectively.

Quality control: Proficiency testings of GEP-ISFG and ESWG-ISFG.
