Analysis of Y-STR Loci in a Population Sample from Northeast China

POPULATION: A total of 141 unrelated Chinese Han male individuals living in Liaoning in northeast China.

KEYWORDS: forensic science, short tandem repeat, Y-chromosome, haplotype, Han population, Liaoning of northeast China, DNA typing, population genetics, DYS389I, DYS389II, DYS439, DYS438, DYS392, DYS393, DYS19, DYS390, DYS391, DYS385

The distribution of allele frequencies and haplotypes for 10 microsatellites (short tandem repeat (STR) loci, DYS389I, DYS389II, DYS439, DYS438, DYS392, DYS393, DYS19, DYS390, DYS391, and DYS385 on the Y-chromosome were determined in 141 DNA samples of unrelated Chinese Han male individuals living in Liaoning of northeast China, using Y-PLEXTM 5 and Y-PLEXTM 6 (ReliaGene Technologies, New Orleans, LA). The Y-STR genotypes were determined using the ABI PRISMTM 310 Genetic Analyzer and the GeneScan analysis software (Applied Biosystems, Foster City, CA). During the 10 Y-STR loci analysis, altogether 65 alleles and 135 haplotypes were identified in these Chinese male individuals, and the haplotype diversity was raised to 0.9998. The results indicate that DYS389I, DYS389II, DYS439, DYS438, DYS392, DYS393, DYS19, DYS390, DYS391, and DYS385 are useful Y-specific STR markers for forensic sciences.

DNA extraction: The DNA was extracted from the blood of 141 unrelated healthy Chinese Han male individuals living in Liaoning by using John's method (1).

PCR amplification: For amplification of 10 Y-STR loci, a multiplex polymerase chain reaction (PCR) was performed using a combination of the Y-PLEXTM 5 and Y-PLEXTM 6 kit (ReliaGene Technologies). The PCR amplification reactions were performed in a GeneAmp PCR system 9700 (Applied Biosystems) under the following conditions: 30 cycles of initial denaturation at 95°C for 10 min, amplification with denaturation at 94°C for 30 s, annealing at 59°C for 1 min, and extension at 70°C for 1 min, followed by a final extension at 60°C for 60 min.

Genotyping: Detection of the amplified PCR products for 10 Y-STR loci was carried out using the ABI PRISMTM 310 Genetic Analyzer (Applied Biosystems). 0.5 μL of PCR products were mixed with 20 μL of formamide and 1 μL of GS-500 ROX (Applied Biosystems) and denatured for 5 min. Allele designations

were performed using the GeneScan analysis software (Applied Biosystems) and reference-sequenced ladders (Y-PLEXTM 5 and Y-PLEXTM 6, ReliaGene Technologies).

Data analysis: Analysis of data was carried out using the ARLEQUIN package (2). Gene diversity and haplotype diversity were estimated according to Nei (3).

Results: See Tables 1 and 2.

The distribution of allele frequencies and gene diversity for the 10 Y-STR loci were estimated from 141 Chinese Han male individuals living in Liaoning in northeast China. A total of 66 alleles were identified in DYS389I, DYS389II, DYS439, DYS438, DYS392, DYS393, DYS19, DYS390, DYS391, and DYS385. The gene diversity values for each locus ranged from 0.4869 (DYS391) to 0.8921 (DYS385a/b). A total of 135 haplotypes were observed in 141 northeast Chinese male individuals for haplotypes constructs of the 10 Y-STR loci; the haplotype diversity was raised to 0.9998.

Other remarks: The comparison of allele frequencies and haplotype diversity between the 141 Chinese samples and other Chinese samples (4,5) showed no special variation for 10 Y-STR loci. Some micro alleles (11 & 15 of DYS389I, 14 of DYS439, 10 of DYS392) were observed in this study, and allele 6 of DYS391 and 7 of DYS392 were not found. The distribution of allele frequencies between different populations showed considerable differences in 10 Y-STR loci (6–10). The gene diversity of each locus and 10 loci haplotype diversity were compared with Japanese, Italian, Caucasian, African American, Hispanic, Pakistani, and Bangladeshi populations (Table 3). Gene diversity values between different populations are different for the 10 Y-STR loci. The haplotype diversity values of 10 Y-STR loci were high in all populations.

These gene and haplotype diversities indicated that the 10 Y-STR polymorphism markers are highly discriminating in the Chinese population, and they may be very powerful for establishing Y-STR database, understanding human origin, paternity testing, and personal identification.

The complete data set is available to any interested researcher at <http://www.med.nihon-u.ac.jp/~legalmed/jtie//Ling-Y-PLEX-JFS.doc>

*A total gene diversity.

The number of superscript in the frequencies: observed number of the allele.

STR, short tandem repeat; HD, haplotype diversity.
