## INTRODUCTION

1-Benzopyranopyridine derivatives have found diverse application in the field of medicinal chemistry. 1-Benzo-pyrano[3,4-c]pyridine-5-ones act as human dopamine $\mathrm{D}_{4}$ receptor antagonists and serve as potential antipsychotic agents [1]. Some nonsteroidal human androgen receptor agonists were synthesized based on 4-(trifluoromethyl)-2H-pyrano[3,2-g]-2-quinolone [2]. 1-Benzopyrano[2,3-b]pyridine-2,5-dione $1\left(\mathrm{R}^{2}=\mathrm{H}, \mathrm{G}=\mathrm{COCH}_{2} \mathrm{COCH}_{3}\right)$ functions as a polyketide, which are involved in the biosynthesis of natural products [3]. Some chromenopyridines are designed and synthesized as an analogue of tetracycline [4]. 5-Salicyloyl-2-oxopyridine-3-carbonitriles play comparable roles as the nonglycosidic cardiotonic agents milrinone or amrinone [5]. Compounds $\mathbf{1}\left(\mathrm{R}^{2}=\mathrm{H}, \mathrm{G}=\mathrm{CN}, \mathrm{CO}_{2} \mathrm{R}, \mathrm{CO}_{2} \mathrm{H}\right)$ exhibit antiallergic properties and are used in the preparation of bronchodialators [6]. 1-Benzopyrano[2,3-b]pyridine-4,5-dione having a $\mathrm{CO}_{2} \mathrm{H}$ group at 3-position provides $100 \%$ inhibition in the passive cutaneous anaphylaxis screen when applied in a dose of $0.9 \mathrm{mg} / \mathrm{kg}$ [7]. Recently, some chromenopyridines are proved to be effective sensitizers for europium and terbium luminescence [8].

Synthesis of the 1-Benzopyrano[2,3-b]pyridine motif have been accomplished (a) from chromone-3-carboni-
trile by reaction either with acetylacetone in the presence of piperidine [9] or with 1-ethoxy-1,3-bis(trime-thylsilyloxy)-1,3-butadiene in the presence of $\mathrm{Me}_{3} \mathrm{SiOTf}$ [10], (b) from chromone-3-carbaldehyde by the reaction of 2-aminochromone [11] or with aniline in the presence of TMSCl in DMF [12]. 2-Aminochromone-3-carbaldehyde $3\left(\mathrm{R}^{2}=\mathrm{H}\right)$ has also been used for the synthesis of $\mathbf{1}\left(\mathrm{R}^{2}=\mathrm{H}\right)$ [13].

Although the reactions of 2-aminochromone-3-carbaldehyde $3\left(\mathrm{R}^{2}=\mathrm{H}\right)$ and 2-( $N, N$-dialkylamino)chromone-3-carbaldehyde $\mathbf{3}\left(\mathrm{NR}_{2}\right.$ in place of $\left.\mathrm{NHR}^{2}\right)$ have been studied in detail [13], the chemistry of 2-(mono substituted amino)chromone-3-carbaldehyde $\mathbf{3}$ has only been little explored. Most of its reactions were carried out by converting it into $N, N$-disubstituted analogue [14a,b]. Reaction of $\mathbf{3}$ with primary amine produces corresponding Schiff base [14], but with aliphatic secondary amines like diethylamine or piperidine compound $3\left(R^{2}\right.$ $=$ aryl) produces 1-benzopyranoquinolones (A) (Scheme 1) [15]. Recently, diethyl 1-benzopyrano[2,3-b]pyridine-2,3-dicarboxylate has been synthesized from $\mathbf{3}$ and diethyl acetylenedicarboxylate in the presence of $\mathrm{Ph}_{3} \mathrm{P}$ [16]. Synthesis of 2-pyridone moiety having ester or carbamoyl functionality at its 3 -positions from $\beta$-formyl- $\beta$ nitroenamine has recently been reported [17].

Scheme 1

A literature survey revealed that functionlization at the 3 -position of 1-benzopyrano [2,3-b]pyridine-2,5dione made this system medicinally efficacius [6]. 1-Benzopyrano[2,3-b]pyridine-2,5-dione (B) having no functionality at its 3-position had been synthesized by the reaction of $3\left(\mathrm{R}^{2}=\mathrm{Ph}\right)$ with ethyl (triphenylphosphoranylidene)acetate followed by heating in benzene (Scheme 1) [18].

Our objective was to synthesize 1 with varying substituents at its 3-position utilizing the C3N1 building block of the $\beta$-amino- $\alpha$, $\beta$-unsaturated aldehyde moiety of $\mathbf{3}$. We report herein a few new one-pot syntheses of compound $\mathbf{1}$ from 3 by condensation with 2,2-dimethyl-1,3-dioxan-4,6-dione (Meldrum's acid), $N$-benzoylglycine (hippuric acid), 4-hydroxycoumarin, and other active methylene compounds under suitable reaction conditions. Compound 3 can readily be obtained from N -alkyl/aryl-C-(4-oxo-4H-1-benzopyran-3-yl)nitrones 2 [19] or directly from chromone-3-carbaldehyde [20].

## RESULTS AND DISCUSSION

Meldrum's acid (4), an active methylene compound having strong electrophillic centres, has made its position in the synthesis of many organic compounds having use in the fields of drugs and pharmaceuticals [21]. Very recently, its chemical bonding and structure-reactivity relation have been studied both experimentally and theoretically [22]. Its chemical versatility has also been discussed in several review articles [23]. We have used Meldrum's acid in the synthesis of 1-benzopyr-ano[2,3-b]pyridine-2,5-dione moiety from 3.

An equimolar mixture of $\mathbf{3}$ and $\mathbf{4}$ was heated under reflux in ethanol in the presence of catalytic amount of pyridine for $2-4 \mathrm{~h}$. White solids (1a-e) were found to precipitate under this reaction condition in moderate to good yields (Table 1, entries 1-5). Compound 3 undergoes Knoevenagel condensation with Meldrum's acid to form 5 , which cyclizes to 1 a-e under the reaction condition (Scheme 2, path-a). The structures of the

compounds were established on the basis of IR, ${ }^{1} \mathrm{H}$ NMR, and mass spectral analysis. It is to be mentioned here that the carboxylic acid protons for compounds $\mathbf{1 a}$ and 1b were not observed in their ${ }^{1} \mathrm{H}$ NMR spectra. The presence of carboxylic acid group in 1a and $\mathbf{1 b}$ was confirmed from their mass spectral analyses and the singlet appearance of $\mathrm{C}_{4}-\mathrm{H}$ in the ${ }^{1} \mathrm{H}$ NMR spectra of $\mathbf{1 a}, \mathbf{b}$.

In connection to our earlier studies [24] on the reactions of different nitrogenous nucleophiles on 4-[(4-oxo-4H-1-benzopyran-3-yl)methylene]-2-phenyl-5-oxazolone $7\left(\mathrm{R}^{1}=\mathrm{NHR}^{2}=\mathrm{H}\right)($ Scheme 2$)$, derived from 3-formylchromone, it has been observed that nitrogenous nucleophiles are prone to interact on the carbonyl function of oxazolone moiety. Compound $\mathbf{3}$ can be considered as 3 -formylchromone moiety having an inbuilt amino function in appropriate position. To utilize this special structural feature of $\mathbf{3}$, an equimolar mixture of $3\left(\mathrm{R}^{2}=\right.$ aryl) and hippuric acid (6) was heated in the presence of excess amount of fused sodium acetate in acetic anhydride on water bath for $6-7 \mathrm{~h}$ and after usual work-up, compounds $\mathbf{1 f}-\mathbf{h}$ were obtained as white solids in moderate yields (Table 1, entries 6-8). On similar treatment of $3\left(R^{2}=\right.$ alkyl $)$, the reaction mixture yielded $\mathbf{1 i}$ and $\mathbf{1} \mathbf{j}$ (entries 9,10 ) after chromatographic separation on silica gel using $10 \%$ ethyl acetate in benzene as eluent. Formation of $\mathbf{1 f}-\mathbf{j}$ from $\mathbf{3}$ may be rationalized by the initial formation of azlactone 7, followed by intramolecular attack of the amino function to the carbonyl carbon of oxazolone moiety (Scheme 2, pathb).

This reaction was further extended by using 4-hydroxycoumarin (8). On heating an equimolar mixture of $\mathbf{3}$
and 8 in ethanol under reflux for $5-6 \mathrm{~h}$ in the presence of catalytic amount of pyridine, the reaction mixture produced compound $\mathbf{1 0}$ in good yields via the Knoevenagel condensate 9 (Scheme 3) (Table 1, entries 11-13). Suitably placed $\mathrm{NHR}^{2}$ group in 9 reacted intramolecularly on the carbonyl function with a lesser decrease in entropy compared to the Michael addition of second molecule of 8 , which is the common feature for the reaction of an aldehyde with $\mathbf{8}$ [25].

With an endeavor to synthesize $\mathbf{1}\left(\mathrm{G}=\mathrm{CO}_{2} \mathrm{Et}\right)$, compound $3\left(\mathrm{R}^{2}=\right.$ aryl $)$ was stirred at room temperature with diethyl malonate in pyridine, but no change in $\mathbf{3}$ was observed (Table 2, entry 1). Ethyl acetoacetate also failed to cause any change in $\mathbf{3}$ on stirring at room temperature in pyridine (entry 2 ), even on heating 3 with ethyl acetoacetate in ethanol for 25 h in the presence of pyridine showed no considerable change (entry 3). On stirring an ethanolic solution of $\mathbf{3}\left(\mathrm{R}^{2}=\right.$ aryl $)$ with diethyl malonate at room temperature in the presence of piperidine for 40 h resulted in the formation of 1-benzo-pyrano[2,3-b]-12-quinolone (A) [15,18,19] (Scheme 1) (Table 2, entry 4). No pure compound could be isolated from the reaction mixture obtained by heating a mixture of 3, diethyl malonate, fused NaOAc in $\mathrm{Ac}_{2} \mathrm{O}$ on a water bath for 5 h (entry 5). Surprisingly, compound 3 reacted with diethyl malonate in $\mathrm{CHCl}_{3}$ under reflux in the presence of piperidine to produce $\mathbf{1 k}, \mathbf{l}$ (entries 6,7 ) (Scheme 4). It was observed that more than stoichiometric amounts of diethyl malonate ( 1.5 equiv) and piperidine ( 1.5 equiv) were required for complete consumption of 3. This methodology was then applied for the synthesis of $\mathbf{1}$ having various substituents at its 3-position. On heating 3 ( $\mathrm{R}^{2}=$ aryl) with ethyl acetoacetate and piperidine in equimolar amounts in $\mathrm{CHCl}_{3}$ for 4 h produced 10 (entry 8 ). Similarly, ethyl benzoylacetate reacted stoichiometrically with $3\left(\mathrm{R}^{2}=\right.$ aryl) within 2 h to produce 1q,r (entries 9, 10).

a $80 \% 3$ was recovered.
${ }^{\mathrm{b}} 40 \%$ of compound $\mathbf{A}$ was isolated.

The reaction was extended with 3 ( $\mathrm{R}^{2}=$ alkyl). Ethyl benzoylacetate (entries 11,12), ethyl acetoacetate (entry 13 ), and diethyl malonate (entries 14,15 ) produced corresponding $\mathbf{1}$ but in lower yields. On changing the solvent from $\mathrm{CHCl}_{3}$ to ethanol, the yield of $\mathbf{1}\left(\mathrm{R}^{2}=\right.$ alkyl $)$ was found to improve, but a little longer reaction time was required (entries 12,16 and 13, 18). Similar reaction with $3\left(\mathrm{R}^{2}=\right.$ aryl) in ethanol always produced some 1 benzopyrano quinolone (A) along with 1 (entry 17). Use of triethylamine or pyridine as a base in the reaction between 3 and $\mathrm{PhCOCH}_{2} \mathrm{CO}_{2} \mathrm{Et}$ either in $\mathrm{CHCl}_{3}$ or in EtOH failed to show the formation of $\mathbf{1}$ even after heating under reflux for 30 h . Piperidine was found to be a better reagent than morpholine or diethylamine for this transformation (entries 9, 19, 20).

Compound 3 reacted differently when ethyl cyanoacetate or malononitrile were used as active methylene component. On stirring an equimolar mixture of $\mathbf{3}$ and ethyl cyanoacetate in ethanol in the presence of piperidine at room temperature, followed by usual work-up [vide experimental Section "General procedure for the reaction of ethyl cyanoacetate on 2-alkyl/arylaminochromone-3-carbaldehyde (3)"]and chromatographic purification produced $11\left(\mathrm{G}^{\prime}=\mathrm{CO}_{2} \mathrm{Et}\right)$ (Scheme 5, path a). But malononitrile yielded $\mathbf{1 2}$ when reacted with $\mathbf{3}$ under similar reaction condition (Scheme 5, path b). In an attempt to purify compound $12\left(\mathrm{G}^{\prime}=\mathrm{CN}\right)$ by column chromatography, a partial
change in $\mathbf{1 2}$ was observed and finally the new compound was assigned to be $\mathbf{1 1}\left(\mathrm{G}^{\prime}=\mathrm{CN}\right)$. This observation led us to check the silica-induced conversion of $\mathbf{1 2}\left(\mathrm{G}^{\prime}=\mathrm{CN}\right)$ to $11\left(\mathrm{G}^{\prime}=\mathrm{CN}\right)$. A chloroform solution of $\mathbf{1 2}\left(\mathrm{G}^{\prime}=\mathrm{CN}\right)$ containing some silica gel was heated under reflux for 5 h with stirring. Indeed, complete conversion of $\mathbf{1 2}\left(\mathrm{G}^{\prime}=\right.$ $\mathrm{CN})$ to $\mathbf{1 1}\left(\mathrm{G}^{\prime}=\mathrm{CN}\right)$ was observed. Use of benzene in place of chloroform also accomplished this transformation under identical condition. However, on heating under reflux in ordinary $\mathrm{CHCl}_{3}$ or benzene in the absence of silica gel, compound $\mathbf{1 2}$ failed to show any change. In an earlier report [17], $\beta$-allylamino-2-nitroacrolein was made to react with malononitrile and was supposed to

pass through an amidine like intermediate as in $\mathbf{1 2}$, but the intermediate could not be isolated. Isolation of $\mathbf{1 2}\left(\mathrm{G}^{\prime}=\right.$ CN ) gave us an impetus to take an attempt for the isolation of $\mathbf{1 2}\left(\mathrm{G}^{\prime}=\mathrm{CO}_{2} \mathrm{Et}\right)$. But careful investigation of the solid [vide experimental Section "General procedure for the reaction of ethyl cyanoacetate on 2-alkyl/arylaminochro-mone-3-carbaldehyde (3)"] obtained from the reaction mixture of $3\left(\mathrm{R}^{1}=\mathrm{H}, \mathrm{R}^{2}=\mathrm{Ph}\right)$ and ethyl cyanoacetate revealed that there was more than one product (TLC). However, chromatographic separation yielded only 11a in moderate yield. The other components were separated by preparative TLC and the bands corresponding to two different spots were extracted separately with $\mathrm{CHCl}_{3}$. Unfortunately, the isolated compounds were same in both cases and the compound was 11a. Compound $12\left(\mathrm{R}^{2}=\right.$ aryl, $\mathrm{G}^{\prime}=\mathrm{CO}_{2} \mathrm{Et}$ ) could not be isolated even after using neutral $\mathrm{Al}_{2} \mathrm{O}_{3}$ as adsorbent in the column chromatography. The only such compound $\mathbf{1 2 d}$ was obtained by stirring a pyridine solution of $\mathbf{3}\left(\mathrm{R}^{1}=\mathrm{Me}, \mathrm{R}^{2}=\mathrm{Et}\right)$ and ethyl cyanoacetate at room temperature. Compound $\mathbf{1 2 d}$ was readily converted to $\mathbf{1 1 d}$ within 1 h when heated in ordinary $\mathrm{CHCl}_{3}$ in the presence of silica gel. Formation of $\mathbf{1 2}$ can be rationalized via the Knoevenagel condensate $\mathbf{1 3}$ (Scheme 5). It was presumed that the conversion of $\mathbf{1 2}$ to 11 took place by silica-induced hydration. The source of water was supposed to be from silica adsorbent or solvent or atmosphere. Water molecule attacks $\mathbf{1 2}$ and opens the pyran ring to form 14 and subsequently tautomerizes to 11. To justify this presumption, compound $\mathbf{1 2}$ was heated in dry $\mathrm{CHCl}_{3}$ in the presence of dry silica gel and under argon atmosphere and indeed compound $\mathbf{1 2}$ failed to show any change.

## CONCLUSION

We have reported a few new efficient one-pot methods for the synthesis of 1-benzopyrano [2,3-b]pyridine-

2,5-dione moiety bearing various functionalities at its 3position. The differential behavior of the active methylene compounds bearing cyano group toward $\mathbf{3}$ has also been reported.

General procedure for the synthesis of 3-benzoylamino-1-alkyl/aryl-2H,5H-1-benzopyrano[2,3-b]pyridine-2,5-diones (1f-j). A mixture of $\mathbf{3}(1 \mathrm{mmol}), \mathbf{6}(180 \mathrm{mg}, 1 \mathrm{mmol}), \mathrm{NaOAc}$ $(250 \mathrm{mg}, 3 \mathrm{mmol})$, and acetic anhydride $(5 \mathrm{~mL})$ was heated on water bath for $6-7 \mathrm{~h}$. Crushed ice ( 50 g ) was then added to the cold reaction mixture. A solid mass was separated when the reaction was carried out with $3\left(\mathrm{R}^{2}=\right.$ aryl $)$. The solid was filtered off, washed with water, dried in air, and recrystallized from $\mathrm{CHCl}_{3}$ to afford $\mathbf{1 f}-\mathbf{h}$. But the reaction mixture obtained from $3\left(\mathrm{R}^{2}=\right.$ alkyl) afforded a semisolid mass when ice-water was added. The semisolid mass was extracted with $\mathrm{CHCl}_{3}$. The organic layer was washed with water, dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and chromatographed over silica gel (100-200) using $10 \%$ EtOAc in benzene as eluent to get $\mathbf{1 i} \mathbf{-} \mathbf{j}$ as white crystalline solid.

Silica-induced hydrolysis of 12 to 1 -alkyl/aryl-2-amino-1,6-dihydro-5-(salicyloyl)-6-oxo-pyridine-3-carbonitrile (11f). Compound 12 ( 1 mmol ) was dissolved in $\mathrm{CHCl}_{3}$ (25 $\mathrm{mL})$. Silica gel $(1 \mathrm{~g})$ was added to the $\mathrm{CHCl}_{3}$ solution and the resultant mixture was heated under reflux with stirring for 5 h . Silica gel was filtered off and it was eluted with $20 \%$ ethyl acetate in benzene. Filtrate $\left(\mathrm{CHCl}_{3}\right.$ solution) and eluents were mixed together and was concentrated under reduced pressure. The residue was crystallized from benzene to afford 11f-i.
