The 3,5-diacetyl-4-methylpyrazole diketone has been synthesized and its crystal structure has been determined. This diketone reacts with hydroxylamine hydrochloride to give the dioxime derivative. This reaction, conducted in presence of copper II ions, leads to the formation of $\mathrm{L}_{2} \mathrm{M}_{2}$ copper II complexes.
J. Heterocyclic Chem., 47, 1025 (2010).

## INTRODUCTION

Research on transition metal complexes is a flourishing field with major interests focused on biological mimicry and cooperative phenomena in catalysis and magnetism. In this respect, pyrazol-based ligands have received a great deal of attention over the last decades due to their interesting coordination chemistry [1]. The pyrazole entity appears indeed particularly suited owing to its ability to bind simultaneously two metal centers in close proximity providing moreover an intramolecular pathway for spin-exchange interactions [2-9]. Further control of the metal-metal separation as well as the steric and electronic properties of the individual metal ions can be achieved by appropriates chelating side arms. Attached to the 3 and 5 positions of the heterocycle, these side arms are able to afford bis( $\mu$-pyrazolato) bridged species $L_{2} \mathrm{M}_{2}$.

In most cases, e.g. in type 1 complexes, the chelated metal atoms form only five-membered rings involving the four nitrogen atoms of the two depronated pyrazole rings and the four chelating heteroatoms bore by the 3,5 -substituted side arms as shown in Scheme 1 [4-9]. Interestingly, the use of functional groups such as oximes as chelating side arms has a singular attractiveness. Oximes are indeed not only generally easy to prepare but can also take advantage of two different bridg-
ing modes as shown in Scheme 1 (type 2). In type 2 complexes, the metal atom can bind either to the N atom, either to the deprotonated O -atom of the oxime moiety thus forming a six-membered ring. In this purpose, we have already employed pyridazine and pyrazolate units, such as 3,6-diformylpyridazines [10,11], 3,6dibenzoylpyridazines [10], and 3,5-diacetyl-4-methylpyrazole [12] and related dioxime species. The synthesis, crystal structure, and magnetic properties of two binuclear copper (II) complexes of the 3,5-diacetyl-4-methylpyrazole dioxime (dampdoH ${ }_{3}$ ), involving the two bridging modes of the oxime function has been also reported [13]. In the present study, we describe the synthesis and crystal structure of the 3,5-diacetyl-4-methylpyrazole ligand used in a new one-step preparation of $\mathrm{L}_{2} \mathrm{M}_{2}$ copper II complexes.

## RESULTS AND DISCUSSION

The 3,5-diacetyl-4-methylpyrazole is prepared by the method of Wolff [12]. Reduced by $\mathrm{Zn} / \mathrm{H}_{2} \mathrm{SO}_{4}$, the isonitrosoacetylacetone (2) gives the aminoacetylacetone (3). This compound is then diazoted by sodium nitrite in acid medium (Scheme 2), affording the crude diazoacetylacetone (4) as an oily product which was in fact expected to be the 4-acetyl-5-methyl-oxadiazole (4').

Type 1

Type 2

To provide insight into the thermodynamics and kinetics of the possible internal cyclization of diazoacetylacetone (4) affording 4-acetyl-5-methyl-1,2,3-oxadiazole ( $4^{\prime}$ ), theoretical calculations were carried out at the B3LYP/6-31+g(d) DFT level. A thorough inspection of the frontier orbitals (HOMO and LUMO) of diazoacety-

Scheme 2. Synthesis of 3,5-diacetyl-4-methylpyrazole.

lacetone (4) was first performed. The HOMO and LUMO for its most stable geometry in gas-phase show energy values of -7.5 and -2.7 eV , respectively. As depicted in Figure 1, the two frontier orbitals are distributed in the molecular plane. Although HOMO is mainly composed by lone pairs of the two carbonyl oxygen atoms, LUMO is an antibonding- $\pi$ orbital located exclusively around the $\mathrm{N} \equiv \mathrm{N}$ triple bond. This orbital distribution suggests that the unique pathway for the internal cyclization of diazoacetylacetone (4) should reside in the attack of one of carbonyl oxygen atom lone pairs at the $\pi$-orbital located on the terminal nitrogen atom of the diazonium moiety.

The optimized geometry for transition state joining compounds (4) and (4) on the potential energy surface has a single imaginary frequency ( $v_{\mathrm{i}}=163 \mathrm{~cm}^{-1}$ ) corresponding to the stretching vibration of the forming $\mathrm{N}-\mathrm{O}$ bond. The distance of the $\mathrm{N}-\mathrm{O}$ forming bond in transition state geometry is $1.902 \AA$. The reaction from diazoacetylacetone (4) leading to the formation of oxadiazole $\left(\mathbf{4}^{\prime}\right)$ is predicted slightly endothermic (+7.3 kcal/ mol in gas-phase and $8.5 \mathrm{kcal} / \mathrm{mol}$ in water). Diazoacetylacetone (4) is then thermodynamically more stable than 4-acetyl-5-methyl-1,2,3-oxadiazole ( $4^{\prime}$ ).

Furthermore, the barrier height calculated from diazoacetylacetone (4) is $8.0 \mathrm{kcal} / \mathrm{mol}(9.3 \mathrm{kcal} / \mathrm{mol}$ in water) indicating that formation of 4 -acetyl-5-methyl-1,2,3-oxadiazole $\left(4^{\prime}\right)$ is not kinetically favored, at least at ambient temperature. This product is thus very unstable and must react immediately with carbanion of the 2,4 -pentanedione as previously described [14]. This condensation and the subsequent heterocyclization give a pyrazoline (6), which was not isolated. In aqueous acidic medium, this compound gives the pyrazole (7) after elimination of acetic acid as described in Scheme 2. Slow evaporation of an ethanolic solution of 7 gives finally single crystals suitable for X-ray diffraction.

The main features of the crystal structure of compound dampH (7) result from the planarity of the whole entity (Figs. 2 and 3).

The crystal structure is formed by layers of planar dampH molecules stacked along the axis c direction.

Figure 4. View of dampH crystal structure with its stabilizing hydrogen bond network (dashed lines). [Color figure can be viewed in the online issue, which is available at wileyonlinelibrary.com.]

Scheme 3. Synthesis of dampdoH $\mathrm{H}_{3}$.

The layered crystal structure is also stabilized by an intermolecular hydrogen bond network forming dimeric ligand associations. The hydrogen bond interactions between two coplanar and adjacent 3,5-diacetyl-4-methylpyrazole ligands are mediated by a water molecule. The oxygen atom O 3 of this water molecule gives an hydrogen bond with the hydrogen atom H 1 bound to the nitrogen atom of pyrazole ring in the first ligand ( $\mathrm{O} 3-\mathrm{H} 1=1.9571 \AA$ ). Furthermore, one of the two hydrogen atoms H1w of the water molecule is also involved in a second hydrogen bond interaction with the oxygen atom O 2 of the ketonic function of the second ligand molecule ( $\mathrm{H} 1 \mathrm{w}-\mathrm{O} 1=1.9207 \AA$ ) (Fig. 4).

This diketone (7) reacts with hydroxylamine hydrochloride to give the diacetyl dioxime derivative (damp$\mathrm{doH}_{3}$ ) as described in Scheme 3. On reaction with copper II cations dampdo $\mathrm{H}_{3}$ leads to the bis( $\mu$-pyrazolato) bridged $\mathrm{L}_{2} \mathrm{M}_{2}$ species [13] as described in Scheme 4, with $\mathrm{L}=$ dampdoH.

From dampdoH $H_{3}\left(\mathrm{H}_{2} \mathrm{~L}\right)$ and $\mathrm{CuCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$, two structurally isomeric complexes $\left[\mathrm{Cu}_{2}\left(\mathrm{HL}_{2} \mathrm{Cl}_{2}\right] 6 \mathrm{H}_{2} \mathrm{O}\right.$, which differ only from the hydrogen bonding, were previously obtained [10]. One of these complexes can be obtained directly from 7 by a one-step reaction with copper II ions in the presence of hydroxylamine hydrochloride. This reaction using $\mathrm{CuCl}_{2}, \mathrm{CuClO}_{4}, \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}$, or $\mathrm{CuSO}_{4}$, leads, after several days, to the formation of dark green crystals of the copper II complexes previously described [13]. In this complex, the axial ligand is a chloride ion even in presence of perchlorate, nitrate, or sulphate ions, indicating that chloride ions are better complexing species.

## EXPERIMENTAL

Melting points were determined on an IA 9000 series Electrothermal apparatus and are uncorrected. Elemental analyses of C, H, N, and S were performed at the Elemental Analysis service of CNRS, Vernaison, France. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were recorded on a Bruker F.T. AC 300 spectrometer (300 MHz for ${ }^{1} \mathrm{H}$ NMR and 75 MHz for ${ }^{13} \mathrm{C}$ NMR) using chloroform $\left(\mathrm{CDCl}_{3}\right)$ as solvent. Matrix-assisted laser desorption ionization (MALDI) and time-of-flight mass spectrometry (TOFMS) are used to record the mass spectra of the correspondent compounds. All starting materials were of reagent grade and were used as purchased.
All theoretical calculations were performed using the Gaussian 03 suite of programs [15]. The gas-phase geometries of diazoacetylacetone (4), 4-acetyl-5-methyl-1,2,3-oxadiazole (4'), and related transition state were optimized using hybrid density functional theory (B3LYP) [16] and the $6-31+g(d)$ basis set. Frequency calculations were used to verify the nature of the computed stationary points. Geometries obtained for $\mathbf{4}$ and $4^{\prime}$ were real minima with all real vibrational frequencies while that of transition state was indeed a first-order saddle point with a single imaginary frequency. To ensure that the transition state joins the two compounds (4) and $\left(\mathbf{4}^{\prime}\right)$ on the potential energy surface, an intrinsic reaction coordinate (IRC) [17] analysis was performed. Frequency calculations also allowed us to calculate the zero-point energy (ZPE) corrections, which were finally added to electronic energies. The energies computed in water include the ZPE-corrected electronic energy plus the solvation energy as obtained from the polarizable continuum model (PCM) [18].

Single crystals of 3,5-diacetyl-4-methylpyrazole hydrated (dampH) were obtained in the form of brown needles, by slow evaporation at room temperature in aqueous solution of

dampH. A single crystal of compound 7 was mounted on a Brucker AXS SMART three-circle diffractometer using graphite monochromated $\mathrm{MoK} \alpha$ radiation $(\lambda=0.71073 \AA)$, equipped with a CCD 4 K two-dimensional detector [19]. A total of 1653 independent reflections were collected in the range of $2.22<\theta<31.03$ with $R_{\text {int }}=2.64$. Data were corrected for Lorentz and polarization using program SaintPlus (Table 1). Atomic positions were determined using SHELXS [20] and refined using full matrix least squares [21]. Hydrogen positions were calculated and included in the final cycles of refinement in constrained positions and with fixed isotropic

thermal parameters. Absorption corrections were not made due to the small value of the absorption coefficients (Table 1). Extinction was refined for all the three structures but was minimal. Figure 2 shows a perspective view of this compound with the numbering scheme, while in Table 2 bond distances and angles in the molecule ( dampH ) are reported. Atomic coordinates and equivalent displacement for dampH are reported in Table 3; anisotropic displacement parameters for dampH are reported in Table 4.

General procedure for the synthesis of compounds 1,4 , and 7. Starting material acetylacetone (1) was commercialized. The formula of the parent compounds with corresponding numbers to carbons scheme is given below.

Synthesis of isonitroacetylacetone (2). A suspension of acetylacetone (1) ( $50 \mathrm{~g}, 0.5 \mathrm{~mol}$ ) in $7 \%$ sulphuric acid ( 500 mL ) was stirred until it was completely dissolved. Sodium nitrite ( $35 \mathrm{~g}, 0.5 \mathrm{~mol}$ ) in water $(150 \mathrm{~mL})$ was added, and the stirring was continued for 90 min . The reaction mixture was extracted with ether, dried (magnesium sulfate), filtered, and evaporated. The solid was recrystallized from ethanol: $\mathrm{mp} 75^{\circ} \mathrm{C}$, yield 50 g, $77.5 \%$.

Synthesis of the acetylacetonate diazonium (4). Isonitrosoacetylacetone $2(10 \mathrm{~g}, 0.07 \mathrm{~mol})$ dissolved in $30 \%$ sulphuric acid ( 100 mL ) was cooled under $0^{\circ} \mathrm{C}$. Zinc powder ( $15 \mathrm{~g}, 0.23 \mathrm{~mol}$ ) was added, and the reaction mixture was allowed for 15 min . The limpid solution was filtered and diluted with water. A solution of sodium nitrite ( $6 \mathrm{~g}, 0.085$ $\mathrm{mol})$ in water ( 30 mL ) was added and cooled. The reaction mixture was extracted with ether, and treated with $5 \%$ sodium carbonate. The residue was dried (magnesium sulfate), filtered, and evaporated to give an oil product: yield $4 \mathrm{~g}, 45 \%$. The
crude powder was used for the next step for the synthesis without further purification.

Synthesis of 3,5-diacetyl-4-methylpyrazole (7). A mixture of the acetylacetonate diazonium (4) ( $2 \mathrm{~g}, 0.016 \mathrm{~mol}$ ), acetylacetone (1) ( $1.6 \mathrm{~g}, 0.015 \mathrm{~mol}$ ), and sodium hydroxide ( 0.6 g , $0.015 \mathrm{~mol})$ in water ( 30 mL ) was heated at $50^{\circ} \mathrm{C}$ for 90 min . The resulting solution was concentrated under vacuum using a rotatory evaporator. After cooling, the obtained solution was neutralized by slow addition of aqueous sulfuric acid solution $(0.5 M)$. The obtained solid was filtered and recrystallized from ethanol: mp $112^{\circ} \mathrm{C}$; yield $2 \mathrm{~g}, 75 \% ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta$ (ppm) $10.78(\mathrm{~s}, 1 \mathrm{H}) ; 2.51(\mathrm{~s}, 6 \mathrm{H}) ; 2.46(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right) \quad \delta(\mathrm{ppm}) \quad 192.96 ; 144.94 ; 121.58 ; 28.57 ; 10.21$. MALDI-TOFMS: $m / z 167$ (M +1). Anal. Calcd for $\mathrm{C}_{8} \mathrm{H}_{10} \mathrm{~N}_{2} \mathrm{O}_{2}$ : C, $57.82 ; \mathrm{H}, 6.08 ; \mathrm{N}, 16.86$. Found: C, $58.02 ; \mathrm{H}$, 5.98; N, 16.75.

Synthesis of 3,5-diacetyl-4-methylpyrazole dioxime. A solution of hydroxylamine hydrochloride ( $1.4 \mathrm{~g}, 20 \mathrm{mmol}$ ) and $\mathrm{NaOH}(0.8 \mathrm{~g}, 20 \mathrm{mmol}$ ) in methanol/water solution (in ratio $50: 50$ ) was added to a solution of 3,5-diacetyl-4-methylpyrazole ( $1.5 \mathrm{~g}, 9 \mathrm{mmol}$ ) in water ( 20 mL ) and heated under reflux for 2 h . After cooling, the solid product was filtered and recrystalized from ethanol: mp $218^{\circ} \mathrm{C}$; yield $81 \%$; ${ }^{1} \mathrm{H}$ NMR (DMSO-d6) $\delta(\mathrm{ppm}) 12.96(\mathrm{~s}, \mathrm{H}, \mathrm{NH}) ; 11.33(\mathrm{~s}, 1 \mathrm{H}, \mathrm{OH}) ;$ $10.97(\mathrm{~s}, 1 \mathrm{H}, \mathrm{OH}) ; 2.27(\mathrm{~s}, 3 \mathrm{H}) ; 2.14(\mathrm{~s}, 6 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR (DMSO-d6) $\delta(\mathrm{ppm}) 150.39 ; 141.51 ; 134.62 ; 111.88 ; 11.70$. MALDI-TOFMS: $m / z 197(\mathrm{M}+1)$. Anal. Calcd for $\mathrm{C}_{8} \mathrm{H}_{12} \mathrm{~N}_{4} \mathrm{O}_{2}$ : C, 48.97; H, 6.16; N, 28,56. Found: C, 49.02; H, 5.98; N, 28.78.

Preparation of complexes. A solution of copper II chloride dehydrate ( $85 \mathrm{mg}, 0.5 \mathrm{mmol}$ ) and hydroxylamine hydrochloride $(69,5 \mathrm{mg}, 1 \mathrm{mmol})$ in water $(20 \mathrm{~mL})$ was added to a solution of dampH ( $92 \mathrm{mg}, 0.5 \mathrm{mmol}$ ) in ethanol ( 10 mL ) and heated under reflux a few minutes. The mixture was filtered to remove any precipitated material. Slow evaporation at room temperature during 3 days affords dark green crystals which were filtered, washed with water and dried in vacuo. The crystals were found to have the formula $\left.\left[\mathrm{Cu}_{2}(\text { dampdoH })_{2} \mathrm{Cl}_{2}\right)_{2} \mathrm{H}_{2} \mathrm{O}\right]$ yield $110 \mathrm{mg} ; 70 \%$. Anal. Calcd: C, $30.75 ; \mathrm{H}, 4.20 ; \mathrm{Cl}, 11.35 ; \mathrm{Cu}, 20.35$; N, 17.95; O, 15.40 Found: C, 30.69; H, 4.21; Cl, 11.37; Cu, 20.29; N, 18.00; O, 15.44 .
