Published online 1 April 2011 in Wiley Online Library (wileyonlinelibrary.com).

Regio- and stereoselective syntheses of tetracyclic compounds having chromone, pyrrolidine, and piperidine rings have been accomplished by an intramolecular [3+2] cycloaddition reaction involving azomethine ylide. The reactions were carried out thermally as well as by irradiation with microwave. The latter process accelerates the reaction. The selectivities were investigated by density functional theory computation.

J. Heterocyclic Chem., **48**, 763 (2011).

INTRODUCTION

Intramolecular 1,3-dipolar cycloaddition reaction is an effective method for double annulation in a single-step reaction [1]. Intramolecular nitron–olefin cycloaddition reaction has been widely used for the synthesis of complex heterocyclic compounds including alkaloids [2,3], modified nucleosides [4], β -lactam antibiotics [5], and natural products [6]. *O*-Allylated salicylaldehyde [7,8], 4-allylamino-3-formyl- α -pyrone [9], and 2-allylamino-3-formylchromone [10] have been used in intramolecular [3+2] nitron–olefin cycloaddition reaction for the synthesis of isoxazolidines fused with different heterocycles [11–15]. Analogous pyrrolidine derivatives, which may be obtained by azomethine ylide–olefin cycloaddition, possess antiviral [16] and local anesthetic activities [17]. Some of them are potential antileukemic and anticonvulsant agents [18]. Benzopyranopyridines or pyrrolidines act as selective dopamine D₃ receptor antagonist [19,20], can bind with DNA [21], and have potential antiplatelet activities [22]. Compounds having piperidine substructures display spasmolytic activity and potent cytotoxicity toward human Molt 4/C8 and CEM T-lymphocytes as well as Murine P 388 and L 1210 leukemic

cells [23]. Some naturally occurring chromone-based alkaloids such as schumanniphytine and isoschumanniphytine were found to possess antiviral activity [24,25]. [3+2] Cycloaddition reaction involving azomethine ylide for the synthesis of pyrrolidine moiety has been studied by ultrasonication [26], microwave irradiation [27] in addition to classical heating condition. However, reports on intramolecular cycloaddition reaction involving azomethine ylide, assisted by microwave irradiation or by ultrasonication, are few [28].

2-Alkyl/arylamino-3-formylchromone **3** has become an attractive building block for the synthesis of various heterocycles. Synthesis of **3** was achieved directly from 3-formylchromone **1** [29] or by the rearrangement of nitron **2** [30,31]. Use of **3** as a synthon has drawn attention markedly in this decade [32–38]. In most of the cases, **3** was further alkylated and nucleophilic substitution reactions were studied using suitable nucleophiles [32–34]. Recently, we have reported deformylative Mannich reaction [39] on **3** for the synthesis of bischromones [36], reactions of different amines with **3** [37], and conversion of **3** into chromeno[2,3-*b*]pyridines with various substituents at their 3-position [38]. attempts for the intramolecular nitron–olefin cycloaddition reaction using *N*-allyl-*N*-arylamino-3-formylchromone (**4**) led to nitron–amide rearrangement. However, intramolecular [3+2] cycloaddition was accomplished only under cold condition using MeNHOH as nitron precursor [10]. Our recent interest on azomethine ylides [40,41] prompted us to generate azomethine ylide on **4**. Earlier reports on the reaction of sarcosine (**5**) with **1** revealed that azomethine ylide derived from **1** and **5** underwent [3+2] cycloaddition and electrocyclic ring

closure reactions [40,42–44]. We report herein the results of intramolecular [3+2] cycloaddition reactions involving azomethine ylide derived from **4** and **5** under various conditions.

RESULTS AND DISCUSSION

On heating an equimolar mixture of **4** (R³ = R⁴ = H) and **5** in methanol under reflux for 30 h produced no suitable result (Table 1, entry 1), but produced **6** (R³ =

Scheme 2

$R^4 = H$) in 64% yield when heated in toluene for 26 h (entry 2; Scheme 1). Addition of TsOH in the above reaction mixture showed adverse effect and no suitable product was isolated (entry 3). Compound **6** with different substituents was synthesized by heating **4** ($R^3 = R^4 = H$) and **5** in freshly distilled toluene for 25–30 h (entries 4–6). Use of DMF as solvent in the presence of Et_3N shortens the reaction time markedly but isolated yield of **6** was poor (entry 7). When an equimolar mixture of **4** and **5** was irradiated by microwave, surprisingly, it yielded **6** within 3–5 min in moderate to good yields (entries 8–11). Compound **4** ($R^3 = H$, $R^4 = \text{Ph}$) produced **6** ($R^3 = H$, $R^4 = \text{Ph}$) in better yield both by classical heating (entries 12 and 13) and by microwave-induced cycloaddition reaction (entries 14 and 15). Although microwave irradiation does not improve the yield, it shortens the reaction time markedly. When the above reactions were performed under sonication, the reactions were not complete even after 40 h.

The structure of compound **6** was established on the basis of IR, $^1\text{H-NMR}$, $^{13}\text{C-NMR}$, and mass spectral analysis. Formation of **6** may be rationalized as follows: compound **4** reacts with **5** to produce an azomethine ylide intermediate **7** (Scheme 1), which undergoes intra-

molecular [3+2] cycloaddition reaction to give **6**. Structure of **6** was supported by its mass spectrum. $^1\text{H-NMR}$ spectrum of **6** showed the disappearance of vinylic as well as aldehydic protons of **4**. The stereochemistry of C/D ring juncture of **6** deserves special mention. Literature survey revealed that reduced form of pyrano[4,3-*b*]pyrrole system exhibited trans-fusion with J -values 10–12 Hz and corresponding cis-fusion with J -values 5–7 Hz in their $^1\text{H-NMR}$ spectra [11,15,45–47]. However, a recent report claimed that reduced form of pyridino[4,3-*c*]isoxazole in the trans-fused condition exhibited negligible coupling (broad singlet) [10]. In the $^1\text{H-NMR}$ spectrum of **6**, $\text{C}_{11\text{b}}\text{-H}$ appears around δ 3.7 (for **6a–6d**) and around δ 4.3 (for **6e**, **6f**) with a small coupling constant ($J = 3\text{--}5$ Hz), which supports cis-fusion [15,45–47]. ^1H NOESY experiments on **6a** exhibited a very strong cross peak between protons $\text{C}_{3\text{a}}\text{-H}$ and $\text{C}_{11\text{b}}\text{-H}$. This corroborates the cis-fusion. The C–H attachments were established with the help of $^1\text{H-}^{13}\text{C}$ correlation spectroscopy. Irradiation of proton at $\text{C}_{11\text{b}}$ showed NOE enhancement of the signal for the proton at $\text{C}_{3\text{b}}$, which further supports the cis-fusion.

The probable modes of approaches of the 1,3-dipolar azomethine ylide and olefin moieties in the intermediate **7** were considered (Scheme 2). Of the four probable approaches (A–D), A or B and C or D can produce two different regioisomers **6** and **8**, respectively.

For a critical understanding of the mechanistic pathways for the regio- and stereoselective formation of the various possible products, a detailed density functional theory (DFT) computation was performed at the B3LYP/6-31+G(d) level [48–50]. All the calculations were performed in Gaussian 03 suite of program [51]. Geometry optimization was performed on all the structures without any symmetry constraints for locating the minimum energy structures as well as the transition-state geometries. Additional frequency calculations were performed on all the geometries to confirm the absence of any imaginary frequencies in the harmonic vibrational modes for the minimum energy structures and one imaginary mode corresponding to the saddle-points in the transition states (TSs). The reactive intermediate **7** (Scheme 1) can exist in two isomeric forms **A** or **B**

Figure 1. Model structures for DFT calculation.

Figure 2. Exothermicity (ΔG) and free energies for activation (ΔG^\ddagger ; in kcal/mol) of the various pathways leading to different products. [Color figure can be viewed in the online issue, which is available at wileyonlinelibrary.com.]

(Scheme 2), which are designated by **M1** and **M2**, respectively, in the model (Fig. 1), which keep the active reaction site similar to that of the experimental molecules.

M1 having cis relationship between CH_2^- and chromonyl moiety is more stable than **M2**, where the relationship is trans by 3.1 kcal/mol (Fig. 2). Although the low energy intermediate (**M1**) can produce two regiomers **cis-P1** and product **cis-P2** via the TSs TSI ($\Delta G^\ddagger = 8.7$ kcal/mol) and TS III ($\Delta G^\ddagger = 19.4$ kcal/mol), respectively, the high energy intermediate (**M2**) can produce only **trans-P1** via TS II ($\Delta G^\ddagger = 19.5$ kcal/mol). An attempt to get an energy-minimized structure of the model compound corresponding to **8D** (Scheme 2), the corresponding cis-isomer (**cis-P2**) was obtained, hence, the possibility of getting other regiomers from **M2** was ruled out. The energy profile diagram (Fig. 2) explains the preferable formation of cis-isomer via the TS TSI and this finding corroborates the results of the spectral analysis. So, both kinetic and thermodynamic preferences for the regio- and stereoselective synthesis of **6** may be predicted.

CONCLUSIONS

In conclusion, we have reported a microwave-accelerated intramolecular [3+2] cycloaddition reaction involv-

ing azomethine ylide. This led to a one-pot regio- and stereoselective synthesis of hitherto unreported chromone-fused pyrrolidino-piperidines in moderate yields. The selectivities have been supported by DFT calculations.

EXPERIMENTAL

General. The recorded melting points are uncorrected. IR spectra were recorded in KBr on a Beckman IR 20a, $^1\text{H-NMR}/^{13}\text{C-NMR}$ spectra on a Bruker 300 MHz/75 MHz spectrometer in CDCl_3 unless stated otherwise, mass spectra on a Qtof micro YA 263 instrument, and elemental analysis on a Perkin-Elmer 240c elemental analyzer. Light petroleum refers to the fraction with 60–80°C. All chemicals used are of commercial grade and are used as such.

General procedure for the synthesis of 2-[N-aryl-N-allylamino]-4-oxo-4H-1-benzopyran-3-carboxaldehyde (4a-f). A mixture of **3** (4 mmol), anhydrous K_2CO_3 (2 g), NaI (50 mg), and **9** [8 mmol for ($\text{R}^3 = \text{R}^4 = \text{H}$) and 6 mmol for ($\text{R}^3 = \text{H}$; $\text{R}^4 = \text{Ph}$)] in dry acetonitrile (100 mL) was heated under reflux with stirring for 9 h. The reaction mixture was filtered hot and the residue was washed with acetonitrile. All the washings and the filtrate were mixed together and solvent was removed under reduced pressure. The residue was purified by column chromatography over silica gel using 10% ethyl acetate in benzene as eluent to produce white crystalline solid **4**.

General procedure for the synthesis of 1-benzopyrano[2,3-*b*]pyrrolo[2,3-*d*]pyridines (6a–f). Method A: A mixture of **4** (1 mmol) and **5** (1 mmol) was heated under reflux in freshly distilled toluene (15 mL) for several hours (Table 1). The progress of the reaction was monitored by TLC. Solvent from the reaction mixture was removed under reduced pressure. The residual mass was dissolved in CHCl_3 , the organic extract was washed with water, dried over Na_2SO_4 , and chromatographed over silica gel (100–200) using 10% methanol in ethyl acetate to afford **6a–6d** as a white crystalline solid, and **6e** and **6f** were obtained as a semisolid mass when eluted with 1:1 benzene–ethyl acetate mixture.

Method B: A well-ground mixture of **4** (1 mmol) and **5** (1.1 mmol) in a small conical flask was irradiated in a domestic microwave oven (Bajaj 1700MT, operating frequency 2450 MHz, 1200 W) with full capacity for 3–5 min. Absence of **4** in the reaction mixture was monitored by TLC. The resultant mixture was dissolved in CHCl_3 . The CHCl_3 solution was washed with water and dried over Na_2SO_4 , and compound **6** was isolated by column chromatography as described above.
