**Key words:** *ab initio* calculations, cyclodextrin inclusion, europium(III) tris- $\beta$ -diketonate, luminescence spectroscopy

### Abstract

A 1 : 1 inclusion compound between  $\gamma$ -CD and the tris chelate complex  $\text{Eu}(\text{NTA})_3 \cdot 2\text{H}_2\text{O}$  [NTA = 1-(2-naphthoyl)-3,3,3-trifluoroacetone] was prepared and characterized in the solid-state by powder X-ray diffraction, thermogravimetric analysis, FTIR, <sup>13</sup>C CP MAS NMR and photoluminescence spectroscopy. Possible host-guest interaction geometries were generated from *ab initio* calculations. The photoluminescence results reveal the presence of a metal-to-ligand energy transfer that is much more efficient than that previously reported for the analogous  $\beta$ -CD adduct.

### Introduction

The interaction of cyclodextrins (CDs) with metal complexes is an important phenomenon because, in the resulting inclusion compounds, the cyclodextrin host can be considered as a second-sphere ligand non-covalently bonded to the first sphere ligand(s) [1]. This offers the possibility of subtly modifying the properties of the guest, for example in their ligand substitution/insertion reactions [2] and photoluminescent properties [3]. The last example refers to the encapsulation of tris(dibenzoylmethane)europium(III) dihydrate by  $\beta$ -CD. We subsequently prepared inclusion compounds between  $\beta$ -CD and europium(III)/gadolinium(III) tris chelates of 1-(2-naphthoyl)-3,3,3-trifluoroacetone (NTA) [4]. This work followed on from a study of the luminescence features and the absolute quantum yields of europium(III) tris[1-(2-naphthoyl)-3,3,3-trifluoroacetate] complexes,  $\text{Eu}(\text{NTA})_3 \cdot 2\text{L}$  (L = H<sub>2</sub>O and DMSO, dimethyl sulfoxide) [5]. It was found that the DMSO adduct  $\text{Eu}(\text{NTA})_3 \cdot 2\text{DMSO}$  exhibits an experimental quantum yield of 0.75, one of the highest so far reported for solid-state europium complexes. In the present work we describe the preparation and characterization of an inclusion compound between  $\gamma$ -CD and  $\text{Eu}(\text{NTA})_3 \cdot 2\text{H}_2\text{O}$ . In particular, the luminescence characteristics are compared with the corresponding  $\beta$ -CD complex. *Ab initio* calculations have also been performed to shed light on possible host-guest inclusion geometries.

### Experimental

#### Instrumentation and analysis

Infrared spectra were recorded with a Unicam Mattson Mod 7000 FTIR spectrophotometer using KBr pellets. Thermogravimetric analysis (TGA) studies were performed under air (30 mL min<sup>-1</sup>) using a Shimadzu TGA-50 analyzer, with a heating rate of 1 °C min<sup>-1</sup>. Powder X-ray diffraction (XRD) data were collected on a Philips X'pert diffractometer using Cu-*K<sub>a</sub>* radiation filtered by Ni ( $\lambda = 1.5418 \text{ \AA}$ ). Microanalyses were performed at the Technical University of Munich. Room-temperature solid-state <sup>13</sup>C NMR spectra were recorded at 100.62 MHz on a (9.4 T) Bruker MSL 400P spectrometer. <sup>13</sup>C CP MAS NMR spectra were recorded with a 4.5  $\mu\text{s}$  <sup>1</sup>H 90° pulse, 2 ms contact time, a spinning rate of 9 kHz and 12 s recycle delays. Chemical shifts are quoted in parts per million from tetramethylsilane (TMS). The photoluminescence spectra (14–300 K) were recorded on a Jobin Yvon-Spex spectrometer (HR 460) coupled to a R928 Hamamatsu photomultiplier. A 150 W Xe arc lamp coupled and a monochromator Jobin Yvon-Spex (TRIAx 180) was used as excitation source. All the spectra were corrected for the response of the detector. The time-resolved measurements were carried out using a pulsed Xe arc lamp (5 mJ/pulse, 3 ms bandwidth) coupled to the monochromator Kratos GM-252 and a Spex 1934 C phosphorimeter.

#### Synthesis

$\gamma$ -CD was kindly supplied by Wacker-Chemie (Berlin, Germany) and used as received. 1-(2-Naphthoyl)-3,3,3-trifluoroacetone was purchased from Aldrich and used as

Figure 1. Powder XRD of (a)  $\text{Eu}(\text{NTA})_3 \cdot 2\text{H}_2\text{O}$  (**1**), (b)  $\beta$ -CD hydrate, (c)  $\text{Eu}(\text{NTA})_3 \cdot \beta$ -CD (**2**), (d)  $\gamma$ -CD hydrate and (e)  $\text{Eu}(\text{NTA})_3 \cdot \gamma$ -CD (**3**).

received.  $\text{Eu}(\text{NTA})_3 \cdot 2\text{H}_2\text{O}$  (**1**) was prepared as described in the literature [6]. IR,  $^1\text{H}$  NMR and  $^{13}\text{C}$  NMR data for **1** were in agreement with that reported previously [4]. The preparation and characterization of the 1 : 1 complex between  $\beta$ -CD and **1**, hereafter referred to as  $\text{Eu}(\text{NTA})_3 \cdot \beta$ -CD (**2**), is described in detail in ref. [4]. The same method was used to prepare the corresponding compound with  $\gamma$ -CD,  $\text{Eu}(\text{NTA})_3 \cdot \gamma$ -CD (**3**). Thus, a solution of  $\text{Eu}(\text{NTA})_3 \cdot 2\text{H}_2\text{O}$  (0.076 mmol) in ethanol (7 mL) was added dropwise to an aqueous solution (5 mL) of  $\gamma$ -CD (0.076 mmol) and the mixture kept at 40 °C for 30 min. The resulting suspension was centrifuged, the supernatant decanted, and the yellow microcrystalline powder washed with water and dried in a desiccator for several days (0.16 g, 91% yield). Anal. Calcd. for  $(\text{EuC}_{42}\text{H}_{24}\text{F}_9\text{O}_6) \cdot (\text{C}_{48}\text{H}_{80}\text{O}_{40}) \cdot 8\text{H}_2\text{O}$  (2388.9): C, 45.25; H, 5.06; Eu, 6.36. Found: C, 45.68; H, 5.15; Eu, 6.37. ## Results and discussion

### Synthesis and characterization of $\gamma$ -CD inclusion compound

Elemental analysis indicated a 1 : 1 host-to-guest stoichiometry for  $\text{Eu}(\text{NTA})_3 \cdot \gamma$ -CD (**3**), as found previously for the corresponding  $\beta$ -CD adduct  $\text{Eu}(\text{NTA})_3 \cdot \beta$ -CD (**2**). Compound **3** was further characterized in the solid-state by IR, powder XRD, TGA and  $^{13}\text{C}$  CP MAS NMR. The two products **2** and **3** give rise to substantially different powder XRD patterns, and it is evident that neither compound contains measurable amounts of phases corresponding to either pure  $\text{Eu}(\text{NTA})_3 \cdot 2\text{H}_2\text{O}$  (**1**) or the corresponding pristine cyclodextrin hydrate (Figure 1). This is an initial indication for the formation of true inclusion compounds [7]. The  $\gamma$ -CD adduct **3** is more crystalline than **2** and in this respect is comparable to pristine  $\gamma$ -CD hydrate. TGA was also useful for the recognition of complex formation in **3** (not shown). Decomposition takes place in two steps up to 450 °C, the first of these occurring between 190 and 330 °C (51% mass loss), and the second between 400 and 450 °C (21% mass loss). The onset of decomposition (190 °C) is intermediate between that of **1** (120 °C) and  $\gamma$ -CD hydrate (which begins to melt and decompose at 260 °C). Loss of hydrated water occurs in the temperature range 25–150 °C (5.7%, ca. 8 water molecules per formula unit). Overall, the TG behavior of **3** is quite similar to that found previously for **2** [4]. The KBr IR spectrum of **3** shows the typical bands previously reported for bulk KBr spectra of  $\beta$ -CD, indicating no chemical modification of the cyclodextrin host [8]. In addition,

Figure 2.  $^{13}\text{C}$  CP MAS NMR spectra of (a)  $\gamma$ -CD hydrate, (b)  $\text{Eu}(\text{NTA})_3 \cdot 2\text{H}_2\text{O}$  (**1**) and (c)  $\text{Eu}(\text{NTA})_3 \cdot \gamma\text{-CD}$  (**3**).

several characteristic absorption bands of the guest are observed. The small or nonexistent shifts in the positions of these bands relative to those of the “free” tris( $\beta$ -diketonate) complex indicates that the structural integrity of **1** is largely retained upon inclusion complexation with  $\gamma$ -CD. It follows that the host : guest interactions are not particularly strong.

Figure 2 shows the  $^{13}\text{C}$  CP MAS NMR spectrum of **3**, pristine  $\gamma$ -CD and the guest precursor  $\text{Eu}(\text{NTA})_3 \cdot 2\text{H}_2\text{O}$  (**1**). Like  $\beta$ -CD hydrate,  $\gamma$ -CD hydrate exhibits multiple resonances for each type of carbon atom, assigned to C-1 (98–105 ppm), C-4 (78–84 ppm), C-2,3,5 (71–76 ppm) and C-6 (60–64 ppm). This has been mainly correlated with different torsion angles about the (1  $\rightarrow$  4) linkages for C-1 and C-4 [9a, b], and with torsion angles describing the orientation of the hydroxyl groups [9c]. By contrast, the corresponding carbons for **3** (and **2**) are observed as single broad peaks. A possible interpretation is that the conformation of the CD is more symmetrical in the complexes, with each glucose unit in a similar environment, as a consequence of the inclusion of aromatic groups in the host cavities [10, 11]. The spectrum of **3** also shows a broad peak centered at 125 ppm (with a shoulder at 134 ppm) due to the carbon atoms of the naphthalene groups. A peak for the methylene carbon

atom of the chelate ring is not observed in the spectrum of **3** (expected at about 93 ppm).

#### Luminescence behavior

The 14 K emission spectra of both  $\text{Eu}(\text{NTA})_3 \cdot \beta\text{-CD}$  (**2**) and  $\text{Eu}(\text{NTA})_3 \cdot \gamma\text{-CD}$  (**3**), for the excitation wavelength that maximizes the cation luminescence intensity, are plotted in Figure 3. The spectra are composed of a series of yellow-red sharp lines, assigned to intra- $4f^6$  transitions between the  $^5\text{D}_0$  and the  $^7\text{F}_{0-4}$  levels, that overlap a large broad band in the purple-blue region (420–570 nm). This large broad band, associated with excited states of the ligands [4], is much more evident for **2**, suggesting that the inclusion of the complex into the  $\gamma$ -CD cavity induces a more efficient ligand-to-metal ion energy transfer pathway. This is confirmed by lifetime measurements. While for  $\text{Eu}(\text{NTA})_3 \cdot \gamma\text{-CD}$  the  $^5\text{D}_0$  decay curve is well fitted by a single-exponential function, corresponding to a lifetime around 0.40 ms, the decay profile of the  $\text{Eu}(\text{NTA})_3 \cdot \beta\text{-CD}$  compound unequivocally exhibits a non-exponential behavior for shorter times, associated with an energy transfer pathway involving the  $\text{Eu}^{3+}$  first coordination shell and the excited states of the ligands [4]. This inefficient energy transfer step present in the  $\beta$ -CD adduct

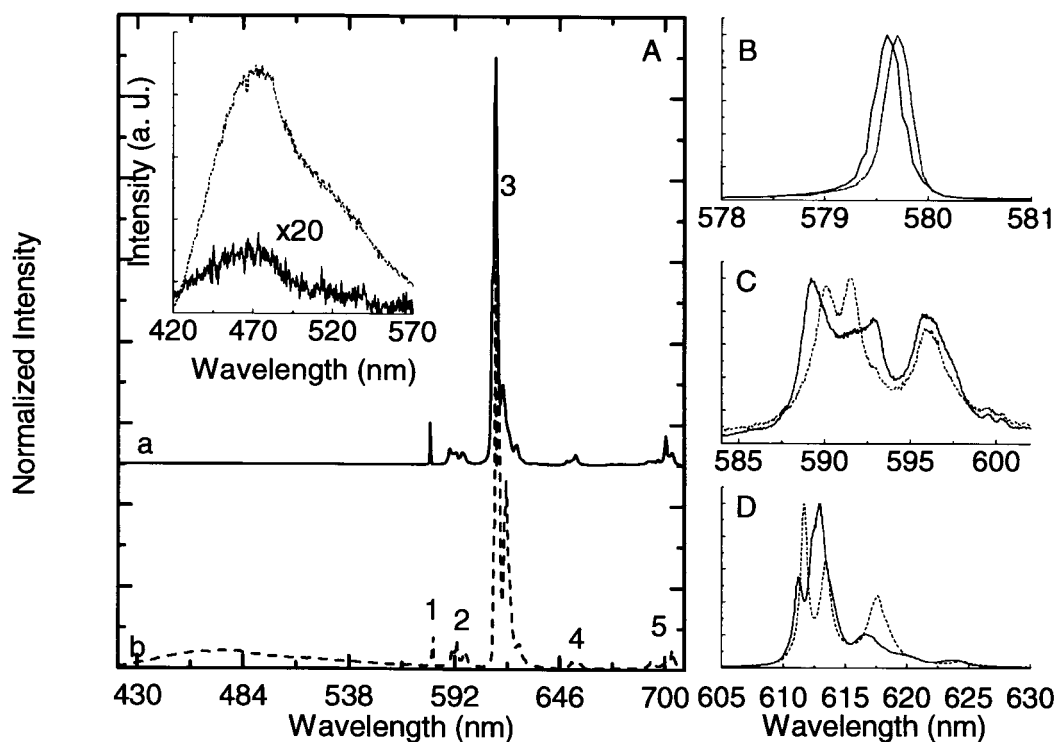

Figure 3. (A) Emission spectra (14 K) of  $\text{Eu}(\text{NTA})_3 \cdot \beta\text{-CD}$  (2) (dashed line) and  $\text{Eu}(\text{NTA})_3 \cdot \gamma\text{-CD}$  (3) (solid line), excited at 395 nm. (1), (2), (3), (4) and (5) denote the  ${}^5\text{D}_0 \rightarrow {}^7\text{F}_{0-4}$  transitions. The inset compares the relative intensity of the large broad band in both compounds. Figures B, C and D show, for the two inclusion compounds, the  ${}^5\text{D}_0 \rightarrow {}^7\text{F}_{0,1,2}$  transitions, respectively.

is not observed in the  $\gamma\text{-CD}$  complex, and as a result the latter exhibits an increase in the quantum efficiency.

#### Ab initio calculations

*Ab initio* calculations were carried out using the Gaussian98 program package, running on a personal computer. The modeling of both the free complex and the inclusion compound was performed by single point calculations scanning, using the point charge approach of Cundari *et al.* for the metallic center [12] and the two layer approximation of Morokuma *et al.* [13] (ONIOM keyword of Gaussian98) for the first and second ligand sphere (B3LYP: CEP-4G). Figure 4 shows the best geometry found for  $\text{Eu}(\text{NTA})_3 \cdot \gamma\text{-CD}$  (3). The NTA ligands assume a propeller-like orientation, with the two water molecules above and below this framework. The calculations show that it is possible for each of the three naphthalene fragments to be included in a separate  $\gamma\text{-CD}$  molecule, suggesting that 1 : 3 inclusion compounds may be feasible in addition to the 1 : 1 compound reported here. This would not be surprising since 1 : 1 and 1 : 3 adducts were characterized previously with  $\beta\text{-CD}$  as the host [4].

#### Conclusions

$\text{Eu}(\text{NTA})_3 \cdot 2\text{H}_2\text{O}$  readily forms 1 : 1 inclusion compounds in the solid-state with both  $\beta\text{-}$  and  $\gamma\text{-CD}$ , as evidenced by elemental analysis, powder XRD, IR and  ${}^{13}\text{C}$  CP MAS NMR spectroscopy, and supported by *ab initio* calculations. Although the host-guest interaction is weak, it has been

Figure 4. *Ab initio* structure of the lowest energy inclusion geometry for  $\text{Eu}(\text{NTA})_3 \cdot \gamma\text{-CD}$  (3).

shown that the photoluminescence properties of the guest are affected by the type of host (and also the host-guest stoichiometry). Further work will expand on this idea of using

inclusion chemistry to modify the luminescence properties of lanthanide complexes.
