#### Abstract

13,14-Benzo-5,8-dihydro-2,4,9,11-tetramethyl-1,5,8,12-tetraazacyclotetradeca-1,3,9,11-tetraene and 13,14-benzo-3,10-di( $p$-[X]benzoyl)-5,8-dihydro-2,4,9,11-tetramethyl-1,5,8,12-tetraazacyclotetradeca-1,3,9,11-tetraene, wherein $\mathrm{X}=\mathrm{CH}_{3}, \mathrm{H}, \mathrm{Cl}, \mathrm{NO}_{2}$ and $\mathrm{OCH}_{3}$, were synthesized and characterized. IR spectra of the benzoylated compounds showed an intense band assigned to the stretching modes of $\mathrm{C}=\mathrm{O}$ in the region $1632 \sim 1638 \mathrm{~cm}^{-1}$. Hammett plot of the energies of $\pi \rightarrow \pi^{*}$ for the compounds was linear with a positive slope $(+0.923) .{ }^{1} \mathrm{H}$ NMR signals exhibited a deshielding effect due to benzoyl groups, while methyl protons only exhibited the shielding effect by the magnetic anisotropy of the group. The substituent effect on ${ }^{13} \mathrm{C}$ NMR was similar to that on proton NMR. The cyclic voltammograms of the compounds mostly showed two one-electron irreversible oxidation peaks and one or two reduction waves between -0.280 and -2.500 V depending on the substituents. Hammett plots of 1st and 2nd oxidation potentials $\left(E_{\mathrm{op}(1)}\right.$ and $\left.E_{\mathrm{op}(2)}\right)$ were linear with slopes of +0.036 and +0.045 , respectively. The structure of the compound 4 (monoclinic, $\mathrm{C} 2 / c, a=26.0059$ (19), $b=6.9058$ (5), $c=33.082$ (2), $\beta=109.5930^{\circ}, Z=8$ ) was determined using X-ray diffraction method.

## Introduction

Although much attention has been paid to the spectroscopic and electrochemical properties of transition metal complexes with tetraaza[14]annulene ligands, there have been few studies of ligands as free bases, except for symmetrical dibenzotetraaza[14]annulenes [1-10]. The reactivities of such compounds were also studied and reported by Sakata et al. [11, 12] and Dabrowiak et al. [13]. However, until now the reactions of asymmetrical free base, monobenzotetraaza[14]annulene have scarcely been studied irrespective of their substituents.

In this paper, we attempted to synthesize a new asymmetrical free base ligands, dihydromonobenzotetraaza[14]annulenes with $p$-substituted benzoyl group through demetallation process, wherein the substituents were $\mathrm{CH}_{3}, \mathrm{H}, \mathrm{Cl}, \mathrm{NO}_{2}$ and $\mathrm{OCH}_{3}$. The transition metal complexes with the free base ligands will be used in the oxidation and reduction of some substrates such as styrene derivatives or simple inorganic compounds. The compounds synthesized were characterized by means of

[^0]elemental analyses, infrared, electronic, ${ }^{1} \mathrm{H}$ NMR and ${ }^{13} \mathrm{C}$ NMR spectra and cyclic voltammetry. The crystal structure of the compound, 13,14-benzo-3,10-di( $p$-chlo-robenzoyl)-5,8-dihydro-2,4,9,11-tetramethyl-1,5,8,12-tetra-azacyclotetradeca-1,3,9,11-tetraene, was identified by X-ray diffraction analysis.

## Experimental

## Materials and measurements

$\mathrm{Ni}(\mathrm{OAc})_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}, 1,2$-phenylenediamine, 1,2-diaminoethane, 2,4-pentandione, and $p$-substituted benzoyl chloride (substituents $=\mathrm{CH}_{3}, \mathrm{H}, \mathrm{Cl}, \mathrm{NO}_{2}$ and $\mathrm{OCH}_{3}$ ) were purchased from Aldrich. Solvents such as methanol, ethanol and dichloromethane were refluxed over calcium hydride under nitrogen, and checked for purities by GC just before use. Dimethylsulfoxide (DMSO) was purchased from Merck and used without further purification. Tetraethylammonium perchlorate (TEAP) used as a supporting electrolyte was prepared and purified by the method described in the literature [14].

Elemental analyses of the complex and the free-based ligands prepared were carried out on a Carlo-Ebra, EA 1108 instrument. Infrared spectra were recorded on a Matteson Instruments, Inc. Galaxy 7020 A using KBr Pellets. ${ }^{1} \mathrm{H}$ NMR ( 300 MHz ) spectra were recorded on a Brucker instrument at room temperature and chemical shifts in $\mathrm{CDCl}_{3}$ were given in ppm relative to tetramethylsilane as an internal reference. Electronic absorption spectra were obtained on a Shimadzu UV265 spectrophotometer.

Cyclic voltammetry was performed using a Bioanalytical System (BAS) CV-50W electrochemical analyzer and a C2 cell stand at room temperature. A three-electrode system composed of a glassy carbon electrode as a working electrode, $\mathrm{Ag} / \mathrm{Ag}^{+}(0.01 \mathrm{M} \mathrm{AgNO} 3$ in 0.1 M TEAP-DMSO solution) as a reference electrode, and a platinum wire as an auxiliary electrode for the electrochemical measurement was used.

## Synthesis

## 13,14-Benzo-5,8-dihydro-2,4,9,11-tetramethyl-1,5,8, 12-tetraazacyclotetradeca-1,3,9,11-tetraene (1)

This compound was prepared and purified by the previously published methods [15].

## 13,14-Benzo-3,10-di(p-methyl benzoyl)-5,8-dihydro-2,4,9,11-tetramethyl-1,5,8,12-tetraazacyclotetradeca-1,3,9,11-tetraene (2)

Compound $1(0.296 \mathrm{~g}, 0.001 \mathrm{~mol})$ was dissolved in benzene $\left(50 \mathrm{~cm}^{3}\right)$ containing triethylamine $(0.203 \mathrm{~g}$, 0.002 mol ) and the corresponding $p$-methylbenzoyl chloride ( 0.002 mol ) in benzene ( $30 \mathrm{~cm}^{3}$ ) was added using a dropping funnel. The mixture was heated under reflux for 4 h with stirring and bubbling nitrogen gas to protect against moisture. Then the reaction mixture stood for around 24 h at room temperature and filtered. The filtrate was evaporated to dryness under reduced pressure and the resulting solid was recrystallized from a 1:2 mixture of dichloromethane and methyl alcohol. Yield 0.149 g (28\%). Anal. Calcd. (\%) for $\mathrm{C}_{34} \mathrm{H}_{36} \mathrm{~N}_{4} \mathrm{O}_{2}$ (2): C, 76.66 ; H , 6.68; N, 10.52; Found: C, 76.64; H, 6.60; N, 10.55. EIMS: m/z $564[\mathrm{M}]^{+}$.

## X-ray crystallographic analysis

Preliminary examination and data collection for crystal of the compound 4 were performed with $\mathrm{Mo}-\mathrm{K} \alpha$ radiation $(\lambda=0.71073 \AA$ ) on an Enraf-Nonius CAD4 computer controlling a $k$-axis diffractometer equipped with a graphite crystal, incident-beam monochromator. Cell constants and orientation matrices for data collection were obtained from least-squares refinement, using the setting angles of 25 reflections. The data were collected for Lorentz-polarization and absorption corrections were applied to the data. The structure was solved by direct methods using SHELXS-86 [16] and refined by full-matrix least-squares calculations with SHELXL-97 [17]. The final cycle of the refinement converged with $R$ $=0.0487$ and $w R=0.1146$.

## Results and discussions

## Synthesis of nonsymmetric monobenzotetraazacyclo[14]annulenes

Compounds $\mathbf{1} \sim \mathbf{6}$ were prepared according to the processes illustrated in Scheme 1. The reactions of $\mathbf{1}$ with $p$-substituted benzoyl chloride in a 1:2 molar ratio in the existence of triethylamine were carried out under refluxing benzene and then led to the corresponding 3,10-dibenzoylated products with a range of yields from 18 to $35 \%$. Purification of the crude products was achieved by recrystallizing from mixtures of dichloromethane and methyl alcohol. Compound 1 underwent an electrophilic substitution reaction at the olefinic carbons of methine sites of its macrocyclic ring as the olefinic carbon of the 3-position in metal acetylacetonate [12, 18]. Elemental analyses given in the Experimental section were consistent with their formulations.

Scheme 1.

## IR and electronic spectra

As described in the Experimental section, the stretching modes of the $\mathrm{C}=\mathrm{C}$ and $\mathrm{C}=\mathrm{N}$ bonds of compound $\mathbf{1}$ appeared at 1502 and $1562 \mathrm{~cm}^{-1}$, respectively, while those of compounds $\mathbf{2 \sim 6}$ showed at around $1553 \sim 1575$ and $1586 \sim 1605 \mathrm{~cm}^{-1}$, respectively. The $\mathrm{C}=\mathrm{C}$ and $\mathrm{C}=\mathrm{N}$ stretching modes after benzoylation moved to higher frequencies around $50 \sim 70$ and $20 \sim 40 \mathrm{~cm}^{-1}$, respectively, depending on the substituent of the benzoyl groups. The asymmetrical monobenzotetraazacyclo[14]annulenes with dibenzoyl groups typically exhibited a strong band attributed to the $\mathrm{C}=\mathrm{O}$ stretching mode in the regions $1632 \sim 1638 \mathrm{~cm}^{-1}$, reflecting successive benzoylation.

The electronic absorption spectra of the compounds typically exhibited a very intense band at around $300 \sim 320 \mathrm{~nm}$, which might be assigned to a $\pi \rightarrow \pi^{*}$ transitions within a macrocyclic ring. Compound 1 showed at 322 nm , while the band after benzoylation was slightly shifted to a higher frequency with respect to the electron-withdrawing substituents. As illustrated in Figure 1, the Hammett plot of $1 / \lambda_{\text {max }}$ against substituent constants ( $2 \sigma_{p}$ : see reference [19]) was not good linearity. However, the values of $1 / \lambda_{\max }$ were gradually and positively dependent on the electron-withdrawing groups with the slope +0.923 (correlation coeff. 0.9440 ). It could be demonstrated from such results for asymmetrical dibenzoylated monobenzotetraaza[14]annulenes that the energies of $\pi \rightarrow \pi^{*}$ transition were correlated with inductive effects of the substituents on benzoyl group in order; $\mathrm{NO}_{2}>\mathrm{Cl}>\mathrm{H}>\mathrm{CH}_{3}>\mathrm{OCH}_{3}$.

Figure 1. Correlation between the maximum energy of the $\pi \rightarrow \pi^{*}$ of the compounds $2 \sim \mathbf{6}$ and Hammett parameters ( $2 \sigma_{p}$ ).
${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra
${ }^{1} \mathrm{H}$ NMR data for asymmetrical free base, monobenzotetraaza[14]annulene and its dibenzoylated compounds prepared were presented in Table 1. Their assignments were made by comparing to their spectra with those of other tetraaza[14]annulenes [20, 21]. The proton signal of the methine sites of compound 1 appeared at 4.757 ppm , while those of compounds $\mathbf{2} \sim \mathbf{6}$ disappeared because of the benzoylation. The 5 - and 8 -amine proton peaks of the compounds were generally broad and moved to downfield by $1.036 \sim 1.432 \mathrm{ppm}$ relative to that of compound $\mathbf{1}$. For compounds $\mathbf{2} \sim \mathbf{6}$, the resonances of the 4 - and 9-methyl protons were moved to upfield to a greater extent than that those of 2- and 11-methyl. This reflects the fact that the benzoyl groups might not be perpendicular but distorted on macrocycle ring plane. That is, the methyl groups are subjected to the shielding effect of substituted benzoyl group. The ethylene proton peaks for compounds $2 \sim 6$ were also shifted to downfield by $0.121 \sim 0.206 \mathrm{ppm}$ relative to that of $\mathbf{1}$. The effects of the substituents on the resonances of amine and ethylene protons were examined by means of a Hammett plot. As shown in Figure 2, the relationship between $\Delta p\left(\delta_{\mathrm{X}}-\right.$ $\delta_{\mathrm{H}}: \mathrm{X}=$ substituents) and $2 \sigma_{p}$ was linearly and positively related with a slopes $(\rho)$ of +0.185 (correlation coeff. 0.9973 ) for amine and +0.040 (correlation coeff. $0.9884)$ for ethylene proton, respectively. The $\Delta p$ values are similarly affected by the substituents on benzoyl group as the effect on $1 / \lambda_{\text {max }}$ values.
${ }^{13} \mathrm{C}$ NMR data and their assignments for the compounds were also presented in Table 2. The carbon resonances of the $\mathbf{2} \sim \mathbf{6}$ were appreciably shifted to the downfield (around $12 \sim 13 \mathrm{ppm}$ ) relative to that of $\mathbf{1}$, indicating successive benzoylation, except for the imine carbon because of its localizing effect. The carbon

Table 1. ${ }^{1} \mathrm{H}$ NMR data for the compounds $\mathbf{1} \sim \mathbf{6}^{\mathrm{a}}$

${ }^{\text {a }}$ Chemical shifts in ppm from internal TMS; measured in chloroform- $d$; multiplicity of a proton signal is given in parentheses after $\delta$ value; singlet (s), doublet (d), broad (br), multiplet (m).
${ }^{6}$ Ref. 17.
signals of these asymmetrical free-based tetraaza[14]annulenes generally were shifted to upfield comparing to those of nickel(II) complexes with these free bases [21]. These results might be attributed to the abundant electron density of free base ligands obtained by demetallating tetraaza[14]annulene nickel(II) complex.

## Cyclic voltammograms

Redox potentials of the compounds measured in TEAPDMSO $(0.1 \mathrm{M})$ solutions vs. $\mathrm{Ag} / \mathrm{Ag}^{+}(0.01 \mathrm{M})$ at $25^{\circ} \mathrm{C}$ and sweep rates of $100 \mathrm{mVs}^{-1}$ were listed in Table 3 and

Figure 2. Correlation between the $\Delta P$ of the compounds $2 \sim 6$ and Hammett parameters $\left(2 \sigma_{p}\right) . \Delta P=\delta_{\mathrm{X}}-\delta_{\mathrm{H}} ; \mathrm{X}=$ substituents).
the cyclic voltammograms in the potential range from +1.10 to -3.00 V vs. $\mathrm{Ag} / \mathrm{Ag}^{+}$were shown in Figure 3. Compound 1 showed only two irreversible oxidation peaks at +0.168 and +0.577 V . After dibenzoylation, the voltammograms exhibited two irreversible oxidation peaks and one or two reduction ones in the ranges of +0.280 to +0.870 V and -1.200 to -2.500 V , respectively, as illustrated in Figure 3. The oxidation potentials of compounds 4 and 5 with the electronwithdrawing substituents of the benzoyl group were shifted to high voltage comparing to compound $\mathbf{1}$. The reduction peaks might be attributed to benzoyl groups because there could not be any wave for compound $\mathbf{1}$ around the potential (Figure 3). The substituent effect on the oxidation potentials was also examined by means of a Hammett plot. As shown in Figure 4, the relationships between the 1st and 2nd oxidation potentials $\left(E_{\mathrm{op}(1)}\right.$ and $\left.E_{\mathrm{op}(2)}\right)$ and $2 \sigma_{p}$ were linearly and positively related with slopes of +0.036 (correlation coeff. 0.9520) for the first oxidation potential and +0.045 (correlation coeff. 0.9750 ) for the second oxidation potential, respectively. The observation reflects that the electron density of the oxidation sites is considerably affected by the substituent on the benzoyl group.

## Crystal structure of compound $\mathbf{4}$

The molecular structure of 13,14-benzo-3,10-di(p-chlo-robenzoyl)-5, 8-dihydro-2, 4, 9, 11-tetramethyl-1,5,8,12-tetraazacyclotetradeca-1,3,9,11-tetraene was illustrated in Figure 5. Crystal data and refinement parameters were listed in Table 4. The selected bond distances and angles were presented in Table 5. The compound 4 adopting a saddle-shaped conformation was tilted to opposite sides of the plane defined by four nitrogen atoms. The distortion from planarity might be owing to steric interactions of $\beta$-substituents (two methyl groups) with the $o$-phenyl ring, which in general exhibited for the

derivatives of symmetrical dibenzotetraaza[14]annulene ligands [22-25]. The hydrogen bond distances and angles were presented in Table 6. The molecule had two $\mathrm{N}-\mathrm{H} \cdots \mathrm{N}$ hydrogen bonds in the central tetraaza part of the molecule. The two H -atoms $[\mathrm{H}(2 \mathrm{~N})$ and $\mathrm{H}(3 \mathrm{~N})]$ also participated weak interactions with the N1 and N4 atoms, respectively. The $\mathrm{N}(2)-\mathrm{H}(2 \mathrm{~N})$ and $\mathrm{N}(3)-\mathrm{H}(3 \mathrm{~N})$ distances (both $0.85(3) \AA$ ) were roughly $0.3 \AA$ shorter than those of symmetry dibenzotetraaza[14] annulene [23, 25]. The amino hydrogens showed not trans but cis (the nitrogen of ethylene group) to each other in the macrocycle. The imino $\mathrm{C}=\mathrm{N}$ bonds $[\mathrm{N}(1)-$ $\mathrm{C}(7)=1.297 \AA$ and $\mathrm{N}(4)-\mathrm{C}(14)=1.304 \AA]$ were about $0.03 \AA$ shorter than the amino type $[\mathrm{N}(2)-$ $\mathrm{C}(9)=1.324 \AA$ and $\mathrm{N}(3)-\mathrm{C}(12)=1.326 \AA]$. The $\mathrm{C}-\mathrm{N}-$ C average angles (about $122.45^{\circ}$ ) of imino type exhibited typical $s p^{2}$ character. The ethylene of between $\mathrm{N}(2)$ and $\mathrm{N}(3)$ on the macrocycle ring impressively exhibited two conformations $\mathrm{N}(2) \mathrm{C}(10 \mathrm{~A}) \mathrm{C}(11 \mathrm{~A}) \mathrm{N}(3)$ and $\mathrm{N}(2) \mathrm{C}(10 \mathrm{~B})$

Figure 3. Cyclic voltammograms of compounds $\mathbf{1} \sim \mathbf{6}$ in 0.1 M TEAPDMSO solutions vs. $\mathrm{Ag} / \mathrm{Ag}^{+}$in $[\mathrm{comp}]=1.0 \times 10^{-3} \mathrm{M}$ and at $25^{\circ}$.

Figure 4. Hammet plot of the 1st and 2nd oxidation potentials of the compound $\mathbf{2} \sim \mathbf{6}, E_{\mathrm{op}(1)}$ and $E_{\mathrm{op}(2)}$ vs. $2 \sigma_{p}$.

Table 4. Crystal data and structure refinement for compound 4

| Empirical formula | $\mathrm{C}_{32} \mathrm{H}_{30} \mathrm{Cl}_{2} \mathrm{~N}_{4} \mathrm{O}_{2}$ |
| :--- | :--- |
| Formula weight | 573.50 |
| Temperature | $173(2) \mathrm{K}$ |
| Wavelength | $0.71073 \AA$ |
| Crystal system | Monoclinic |
| Space group | $\mathrm{C} 2 / c$ |
| Unit cell dimensions | $a=26.0059(19) \AA \alpha=90^{\circ}$. |
|  | $b=6.9058(5) \AA \beta=109.5930^{\circ}$. |
|  | $c=33.082(2) \AA \gamma=90^{\circ}$. |
| Volume | $5597.2(7) \AA^{3}$ |
| $Z$ | 8 |
| Density (calculated) | 1.361 Mg m |
| Absorption coefficient | $0.270 \mathrm{~mm} \mathrm{~m}^{-1}$ |
| $F(000)$ | 2400 |
| Crystal size | $0.50 \times 0.25 \times 0.25 \mathrm{~mm}{ }^{3}$ |
| $\theta$ range for data collection | $1.31-28.32^{\circ}$ |
| Index ranges | $-34 \leq h \leq 28$ |
|  | $-8 \leq k \leq 9$ |
|  | $-28 \leq l \leq 43$ |
| Reflections collected | 16,910 |
| Independent reflections | $6688[R($ int $)=0.0332]$ |
| Completeness to $\theta=28.32^{\circ}$ | $96.1 \%$ |
| Absorption correction | $\mathrm{Semi}-\mathrm{empirical}$ from equivalents |
| Max. and min. transmission | 0.9357 and 0.8770 |
| Refinement method | $\mathrm{Full-matrix} \mathrm{least-squares} \mathrm{on} F^{2}$ |
| Data/restraints/parameters | $6688 / 0 / 460$ |
| Goodness-of-fit on $F^{2}$ | 1.024 |
| Final $R$ indices $[I>2$ sigma $(I)]$ | $R 1=0.0487, w R 2=0.1146$ |
| $R$ indices (all data) | $R 1=0.0904, w R 2=0.1318$ |
| Largest diff. peak and hole | 0.462 and $-0.399 \mathrm{e} . \AA^{-3}$ |
|  |  |

Figure 5. Crystal structure of 13,14-benzo-3,10-di(p-chlorobenzoyl)-5,8-dihydro-2,4,9,11-tetramethyl-1,5,8,12-tetraazacyclotetradeca-1,3,9, 11-tetraene.
$\mathrm{C}(11 \mathrm{~B}) \mathrm{N}(3)$ as shown in Figure 5. Thus, the angles of amine type had two kinds of $\mathrm{C}(9)-\mathrm{N}(2)-\mathrm{C}(10 \mathrm{~A}) 137.6(3)^{\circ}$ and $\mathrm{C}(9)-\mathrm{N}(2)-\mathrm{C}(10 \mathrm{~B}) 114.4(3)^{\circ}$ (or $\mathrm{C}(12)-\mathrm{N}(3)-\mathrm{C}(11 \mathrm{~A})$ $116.3(3)^{\circ}$ and $\left.\mathrm{C}(12)-\mathrm{N}(3)-\mathrm{C}(11 \mathrm{~B}) \quad 135.3(3)^{\circ}\right)$ as first example for tetraazaannulene compounds. On the other hand, the angles of $\mathrm{C}(10 \mathrm{~A})-\mathrm{N}(2)-\mathrm{C}(10 \mathrm{~B})$ and $\mathrm{C}(11 \mathrm{~A})-$ $\mathrm{N}(3)-\mathrm{C}(11 \mathrm{~B})$ were $37.0(2)^{\circ}$ and $35.3(2)^{\circ}$, respectively. These results indicate that the $\pi$-electrons are highly localized on the macrocycle ring compared with tetraaza[14]annulene metal complexes [23, 26].

## Supplementary material

Crystallographic data for the structural analysis have been deposited at the CCDC, 12 Union Road, Cambridge CB2 1EZ, UK on request, quoting the deposition number CCDC 222448. Copies of this information can be obtained free of charge via E-mail: deposit@ccdc.cam.ac.uk or www: http://www.ccdc.cam. ac.uk; Tel: +44-1233-336031; Fax: +44-1223-336033.
