### Summary

To date, some non-selective  $\beta$ -adrenoceptor ( $\beta$ -AR) positron emission tomography (PET) radioligands are in clinical use, but no PET radioligand for the selective imaging of cardiac  $\beta_1$ -ARs is clinically available. Therefore, the aim of this study was to develop a potential high-affinity PET radioligand for the  $\beta_1$ -subtype of ARs. Here, the synthesis and in vitro evaluation of (S)- and (R)-N-[2-[3-(2-cyano-phenoxy)-2-hydroxy-propylamino]-ethyl]-N'-[4-(2-fluoro-ethoxy)-phenyl]-urea (8a-b), derivatives of the well-characterized  $\beta_1$ -AR selective antagonist, ICI 89,406, are described. The (S)-isomer **8a** shows both higher  $\beta_1$ -AR selectivity and  $\beta_1$ -AR affinity than the (R)-enantiomer **8b** (selectivity: 40 800 vs 1580; affinity:  $K_{I1} = 0.049 \text{ nM}$  vs  $K_{I1} = 0.297 \text{ nM}$ ). Therefore, the <sup>18</sup>F-labelled analogue **8e** of compound **8a** was synthesized. While the direct nucleophilic <sup>18</sup>F-fluorination of the tosylate precursor 8d produced 8e in low radiochemical vields ( $\leq 2.9\%$  decay-corrected) and specific activities ( $\leq 3.5$  GBg/µmol at the end of synthesis (EOS), n = 9) the alternative two-step synthesis of **8e** from ethylene glycol *di-p*-tosylate 9,  $[^{18}F]$  fluoride ion and phenol precursor 8f gave satisfying results  $(16.4 \pm 3.2\%$  radiochemical yield (decay-corrected),  $99.7 \pm 0.5\%$  radiochemical purity,  $40 \pm 8 \,\text{GBq}/\mu\text{mol}$  specific activity at the EOS within  $174 \pm 3 \,\text{min}$  from the end of bombardment (EOB) (n = 5)). # Introduction

Postsynaptic  $\beta$ -adrenoceptors ( $\beta$ -ARs) are classified as rhodopsin/ $\beta_2$ -AR-like receptors that belong to one of three major subfamilies of the G-proteincoupled-receptors (GPCRs).<sup>1</sup> The  $\beta$ -AR family is subdivided into at least three discrete subtypes, the  $\beta_1$ -,  $\beta_2$ -AR<sup>2</sup> and the atypical  $\beta_3$ -AR.<sup>3,4</sup> Additionally, a putative subtype has been identified in cardiac tissue, classified as the  $\beta_4$ -AR.<sup>5</sup>

Within the left ventricle of the healthy human heart the  $\beta_1$ - to  $\beta_2$ -AR ratio is approximately 3:1.<sup>6</sup> In heart disease, both the  $\beta$ -AR density and the  $\beta_1$ - to  $\beta_2$ -AR ratio may change. Several conditions, including hypertension, heart failure, ischemia, hypertrophic and dilated cardiomyopathy (HCM, DCM) are accompanied by a reduced  $\beta$ -AR density in the heart.<sup>7-12</sup> In addition, the failing human heart is often characterized by a selective reduction in  $\beta_1$ -adrenoceptors ( $\beta_1$ -ARs) without change in  $\beta_2$ -AR density.<sup>6</sup>

For this reason a non-invasive method for the visualization and quantification of the  $\beta_1$ -AR density rather than total  $\beta$ -AR density in the human heart is of great interest in basic research and clinical application.<sup>13</sup> PET is an unique technique for this task, quantitatively and dynamically determining local radioactivity concentrations in vivo from which receptor concentrations can be calculated.<sup>14</sup> Non-selective radioligands for the imaging of  $\beta$ -ARs with positron emission tomography (PET), such as (S)-[<sup>11</sup>C]CGP 12177, whose racemate was described by Delforge et al. in 1991,<sup>15</sup> were used in PET studies to quantify myocardial  $\beta$ -AR density in heart disease.<sup>11,16,17</sup> Elsinga *et al.* established (S)- $[^{11}C]CGP$  12388, a straightforward accessible radioligand, for non-selectively targeting  $\beta$ -ARs in vivo. In a recent study (S)-[<sup>11</sup>C]CGP 12388 was administered as an aerosol for PET visualization of pulmonary  $\beta$ -ARs in healthy volunteers.<sup>18</sup> The radiosynthesis of an <sup>18</sup>F-labelled analogue of CGP 12388 has also been described.<sup>19,20</sup> In contrast, the clinical application of candidate  $\beta_1$ -AR selective radioligands, such as (+/-)-[<sup>11</sup>C]HX-CH 44,<sup>21</sup> (S)-[<sup>11</sup>C]bisoprolol,<sup>22</sup> or [<sup>11</sup>C]CGP 20712A<sup>23</sup> and its (S)-enantiomer [<sup>11</sup>C]CGP 26505,<sup>24</sup> is limited due to high non-specific binding, rapid metabolism or a tissue uptake that does not reflect binding to  $\beta$ -ARs.<sup>21–24</sup> In summary, no  $\beta_1$ -selective radioligand suitable for the non-invasive assessment of cardiac  $\beta_1$ -AR is clinically established for single photon emission computed tomography (SPECT) or PET.

An early example of a  $\beta_1$ -selective AR antagonist is the compound ICI 89,406 (Scheme 1). Membrane studies show that the (S)-enantiomer possess higher affinity than the antipode, but even the application of the racemate produces effective  $\beta_1$ -AR blockade during exercise in patients with angina pectoris.<sup>30–32</sup>

ICI 89,406 was chosen as the lead structure for the development of new  $\beta_1$ -selective AR radiotracers for application in nuclear medical imaging. After identification of several ICI 89,406 derivatives with high  $\beta_1$ -AR binding affinity<sup>33</sup> two  $\beta_1$ -AR radioligands labelled with <sup>123</sup>I and <sup>125</sup>I were synthesized

ICI 89,406: X = CN, Y = H, racemic; I-ICI-H: X =  ${}^{125}$ I or  ${}^{123}$ I, Y = H, racemic; I-ICI-COOH: X =  ${}^{125}$ I or  ${}^{123}$ I, Y = COOH, (S) or racemic; ICI-OMe: X = CN, Y = O<sup>11</sup>CH<sub>3</sub>, (S) or (R)

# Scheme 1. Lead structure ICI 89,406 and its radiolabelled derivatives<sup>25–29</sup>

and evaluated *in vitro* and *in vivo* (I-ICI-H and I-ICI-COOH, Scheme 1). Drawbacks of these radioiodinated compounds regarding binding specificity and *in vivo* stability in the chosen animal models prevented further evaluation.<sup>25,26</sup> It seems that high non-specific binding and rapid deiodination *in vivo* preclude the use of such iodinated ligands for SPECT or PET. However, *in vitro* application of these radioligands seems possible, if <sup>125</sup>I-labelled analogues are considered, Radioligands labelled with positron-emitting <sup>11</sup>C ( $t_{1/2} = 20.4$  min) or <sup>18</sup>F ( $t_{1/2} = 109.7$  min) may be less susceptible to rapid metabolism. An <sup>11</sup>C-labelled ICI 89,406 derivative was recently introduced by our group as a potential high-affinity  $\beta_1$ -AR radioligand (ICI-OMe, Scheme 1).<sup>27–29</sup> At present this radioligand is being evaluated *in vivo*.

In a further step we aimed at the development of an <sup>18</sup>F-labelled ICI 89,406 derivative due to the superior physical decay characteristics (longer half-life, shorter average positron range) of <sup>18</sup>F compared to <sup>11</sup>C. The work presented here includes the synthesis of (*S*)-*N*-[2-[3-(2-cyano-phenoxy)-2-hydroxy-propylamino]-ethyl]-*N'*-[4-(2-[<sup>18</sup>F]fluoro-ethoxy)phenyl]-urea **8e** as a putative high affinity  $\beta_1$ -AR PET radioligand as well as the *in vitro* evaluation of the non-radioactive enantiomers **8a–b**.

#### **Results and discussion**

The ureas **8a–d**, that serve as precursor or reference compounds for the <sup>18</sup>F-labelled target **8e**, were synthesized in a seven- to nine-step sequence (Schemes 2 and 3). The nucleophilic substitution at the homochiral glycidyl-3-nitrobenzene sulphonates **2a** and **2b** with 2-cyano-phenol **1** under basic conditions provided the corresponding oxiranes **3a** and **3b** in good yields (85–92%). Comparison of the measured optical rotations with literature values showed that the stereochemistry was retained; the absolute  $[\alpha]_D$  values were within errors.<sup>34</sup> The preparation of the second synthon, the hydrochlorides **7a–b**, started with the aniline derivatives **4a–b** that were prepared in two steps similar to those previously described (steps not shown in Scheme 2).<sup>35–38</sup> Compounds **4a–b** were converted into the corresponding

Reagents: (a) K<sub>2</sub>CO<sub>3</sub>, 2-butanone,  $\Delta$ ; (b) trichloromethyl chloroformate, ethyl acetate,  $\Delta$ ; (c) *N*-mono-(*t*.-butyloxycarbonyl)ethylenediamine, diethylether, 0°C; (d) HCl, MeOH; (e) NaOH, *n*-propanol, H<sub>2</sub>O,  $\Delta$ ; (f) silver *p*-toluenesulfonate, MeCN,  $\Delta$ ; (g) [<sup>18</sup>F]K(Kryptofix 2.2.2)F, K<sub>2</sub>CO<sub>3</sub>, MeCN,  $\Delta$ .

#### Scheme 2. Synthesis of the chiral $\beta_1$ -AR ligands 8a–e

phenylisocyanates **5a–b** with trichloromethyl chloroformate (51–94%). The addition reaction of **5a–b** with *N*-mono-(*t*.-butyloxycarbonyl)ethylenediamine yielded the ureas **6a–b** (86–89%). After deprotection of **6a–b** that proceeded nearly quantitatively (94–96%) the target compounds **8a–c** were formed from the resulting hydrochlorides **7a–b** plus oxiranes **3a–b** via nucleophilic ring opening under basic reaction conditions. The chemical yields were low and ranged from 9 to 22% due to extensive purification procedures for the ureas **8a–c** (Scheme 2). An attempt to improve the yield of the bromide **8c** starting from the free amine **7c**, that was made from **7b** and NaOH, and oxirane **3b**

<sup>a</sup>Displacement of specifically bound non-selective  $\beta$ -AR ligand [<sup>125</sup>I]ICYP binding at  $\beta_1$ - and  $\beta_2$ -ARs expressed in mouse ventricular membrane preparations as mean  $\pm$  SEM, n = 3.

<sup>b</sup>The ratios of the low- over the high-affinity inhibition constants ( $K_{12}/K_{11}$ ) indicate the  $\beta_1$ -selectivities of the non-radioactive  $\beta_1$ -AR ligands, noted as mean  $\pm$  SEM, n = 3.

<sup>c</sup>log *P* values of the neutral form and log *D* values calculated by ACD/log *D* Suite (log  $D = \log P$  at physiological pH 7.4 with consideration of charged species). <sup>d</sup> from Reference<sup>27</sup>.

did not succeed and provided, besides a low yield of urea 8c (11%), mainly polymeric side products (Scheme 3). Finally, the bromide 8c was converted with silver *p*-toluenesulphonate into the tosylate precursor 8d in 46% yield (Scheme 2).

To assess the structure–activity relationships (SAR) between the ligands and  $\beta_1$ -ARs, competition studies using [<sup>125</sup>I]iodocyanopindolol ([<sup>125</sup>I]ICYP) and mouse ventricular membrane preparations were performed. The high- and low-affinity IC<sub>50</sub> values for the  $\beta_1$ - and  $\beta_2$ -ARs of the non-radioactive 3-aryloxy-2-propanolamine derivatives **8a–c** were calculated by non-linear regression analysis of membrane bound radioactivity. From the IC<sub>50</sub> values the high- and low-affinity inhibition constants ( $K_{I1}$  for the  $\beta_1$ -ARs and  $K_{I2}$  for the  $\beta_2$ -ARs) were obtained by the method of Cheng–Prusoff<sup>39</sup> using the previously determined  $K_D$  value of [<sup>125</sup>I]ICYP (32.3 ± 1.9 pM)<sup>33</sup> (Table 1). The  $\beta_1$ -selectivities of the unlabelled compounds **8a–c** are defined by the ratios of the low- to high-affinity inhibition constants ( $K_{I2}/K_{I1}$ ). To indicate the change in lipophilicities caused by the chemical modifications of the lead compound ICI 89,406 the calculated log *P* and log *D* values (ACD/log *D* Suite) of compounds **8a–c** are additionally listed in Table 1. The log *P* value of the nonradioactive target compounds **8a** and **8b** (log *P* = 1.44) is similar to the value for (S)-CGP 12177 (log P = 1.81)<sup>40</sup> whose <sup>11</sup>C-labelled counterpart is an effective radioligand for imaging cell surface  $\beta$ -ARs in the human myocardium with PET.<sup>16,17</sup> The compounds **8a–c** are characterized both by high  $\beta_1$ -AR binding affinities and  $\beta_1$ -AR selectivities. They possess  $\beta_1$ -AR affinities in the subnanomolar range ( $K_{II} = 0.049 - 0.297$  nM) and favour  $\beta_1$ -AR binding over  $\beta_2$ -AR binding resulting in high  $\beta_1$ -selectivities (1580–40800). The enantiomers **8a** and **8b** display a normal binding behaviour for  $\beta_1$ -ARs, since the (S)-enantiomer 8a possesses a higher affinity for this receptor subtype than the (R)-enantiomer 8b ( $K_{I1} = 0.049 \text{ nM}$  vs  $K_{I1} = 0.297 \text{ nM}$ ). Up to 100-fold higher  $\beta$ -AR affinities of (S)-enantiomers compared to the corresponding (R)-enantiomers have been documented.<sup>41,42</sup> A second feature of the enantiomer pair **8a** and **8b** is the 26-fold higher  $\beta_1$ -AR selectivity of **8a** (40 800 vs 1580). The (S)-enantiomer of the bromo substituted ligand 8c shows similar  $\beta_1$ -AR affinity but nearly three times less  $\beta_1$ -AR selectivity than the (S)-fluoro counterpart 8a ( $K_{11} = 0.063 \text{ nM}$  vs  $K_{11} = 0.049 \text{ nM}$ , 14100 vs 40800). Obviously a more sterically demanding halogen (covalent radius Br = 114 pm, covalent radius F = 72 pm) at the 2-ethoxy position in 8c reduces the  $\beta_2$ -AR binding affinity less dramatically than the small-sized fluorine in **8a** resulting in a higher  $\beta_1$ -AR selectivity for **8a**. In summary, each ligand **8a–c** possesses higher  $\beta_1$ -AR binding affinities as well as  $\beta_1$ -AR selectivities than the racemic lead compound ICI 89,406 ( $K_{I1} = 0.28$  nM, selectivity: 149).

As a result of these binding affinity and selectivity measurements, the more potent (S)-enantiomer 8a (in comparison to its (R)-enantiomer 8b) was chosen for conversion into a corresponding <sup>18</sup>F-labelled radioligand **8e** expected to have high affinity and selectivity for the  $\beta_1$ -AR subtype, for the use with PET. Two synthetic routes for the target compound 8e were explored. The first one started with the tosylate precursor **8d** and  $[^{18}F]K(Kryptofix 2.2.2)F$ . Via nucleophilic substitution, the <sup>18</sup>F-labelled **8e** was obtained in one step (Scheme 2). This approach is however characterized by low radiochemical yields and specific activities ( $\leq 2.9\%$  (decay-corrected),  $\leq 3.5 \,\text{GBq}/\mu\text{mol}$  at the end of synthesis (EOS), n = 9) that could not be improved by varying the reaction parameters (e.g. precursor concentration, reaction time and temperature). The specific activities may have been greatly underestimated due to incomplete HPLC-resolution of the radioligand 8e from the non-radioactive by-products of the labelling procedure. Due to the low radiochemical yield this approach was not investigated further. The second approach (Scheme 4), a twostep synthesis, started with ethylene glycol di-*p*-tosylate **9** and  $[^{18}F]K(Kryptofix)$ 2.2.2)F to yield 1-[<sup>18</sup>F]fluoro-2-(tosyloxy)ethane 10 (radiochemical yield of 42.8 + 2.8% (noted as mean + SD), decay-corrected, n = 5). This well-known labelling synthon was used to alkylate the phenol compound 8f under basic reaction conditions. Compound 8f was prepared as previously described.<sup>27</sup> The second step provided the desired 8e with a radiochemical yield of

Reagents: (a) [<sup>18</sup>F]K(Kryptofix 2.2.2)F, K<sub>2</sub>CO<sub>3</sub>, MeCN, Δ; (b) NaOH, DMF, Δ.

#### Scheme 4. Alternative synthesis of the chiral $\beta_1$ -AR radioligand 8e

 $38.3 \pm 5.5\%$  (decay-corrected, n = 5). The overall radiochemical yield of **8e** for both steps was  $16.4 \pm 3.2\%$  (decay-corrected). The synthesis was realized with a radiochemical purity of  $99.7 \pm 0.5\%$  in  $174 \pm 3$  min from end of bombardment (EOB) and a calculated specific radioactivity of  $40 \pm 8$  GBq/µmol (30–50 GBq/µmol) at the EOS (n = 5). In summary, the two-step approach of **8e** provided more satisfying results regarding the radiochemical yield and specific radioactivity compared to the one-step procedure and is now being used to evaluate this <sup>18</sup>F-labelled compound in animals with PET.

#### **Experimental**

#### General methods

All chemicals, reagents, and solvents for the synthesis of the compounds were analytical grade and purchased from commercial sources. [<sup>125</sup>I]ICYP was purchased from Perkin-Elmer.

The melting points (uncorrected) were determined on a Stuart Scientific SMP3 capillary melting point apparatus. <sup>1</sup>H-NMR and <sup>13</sup>C-NMR spectra were recorded on a Bruker ARX 300 and AMX 400 spectrometer, respectively. Mass spectrometry was performed via a Varian MAT 212 (EI = 70 eV) spectrometer and a Bruker MALDI-TOF-MS Reflex IV (matrix: DHB). Exact mass analyses were conducted on a Bruker MicroTof apparatus.  $[\alpha]_D$  values were determined on a Perkin-Elmer 341 polarimeter. Elemental analysis was realized by a Vario EL III analyser. Radiosynthesis were partly carried out using an automated PET tracer synthesizer (TRACERLab Fx<sub>FDG</sub> Synthesizer; GE Functional Imaging GmbH). The recorded data were processed by the TRACERLab Fx software (GE Functional Imaging GmbH). Separation of the radiosynthesized compounds was performed by gradient radio-HPLC using a Knauer K-500 and a Latek P 402 pump, a Knauer K-2000

UV-detector (wavelength 254 nm) and a Crismatec Na(Tl) Scintibloc 51 SP51  $\gamma$ -detector, a Nucleosil 100-5 C18 column (250 × 4.6 mm<sup>2</sup>) with a corresponding precolumn (20 × 4.0 mm<sup>2</sup>) or a Nucleosil 100-10 C18 column (250 × 8 mm<sup>2</sup>). Sample injection was carried out using a Rheodyne injector block (type 7125 incl. 200 µl or 1000 µl loop). The recorded data were processed by the NINA version 4.9 software (GE Functional Imaging GmbH). The radiochemical purities and the specific activities were acquired with a radio-HPLC system composed of a Syknm S1021 pump, a Knauer K-2501 UV-detector (wavelength 254 nm), a Crismatec Na(Tl) Scintibloc 51 SP51  $\gamma$ -detector, a Nucleosil 100-3 C18 column (200 × 3 mm<sup>2</sup>), a VICI injector block (type C1 incl. 20 µl loop) and the NINA version 4.8, Rev. 4 software (GE Functional Imaging GmbH).

### Synthetic methods

# Synthesis of oxiranes $(3a-b)^{27}$

General procedure. 2-Cyano-phenol 1 (2 eq.), (S)-glycidyl-3-nitrobenzene sulphonate **2a** or (R)-glycidyl-3-nitrobenzene sulphonate **2b** (1 eq.) and anhydrous  $K_2CO_3$  (6 eq.) were refluxed in dry 2-butanone (3.8 ml/mmol sulphonate) for 6–7 h and then stirred at RT for 16–72 h under an argon atmosphere. The mixture was filtered and the filter cake was washed with 2-butanone. The combined filtrates were evaporated to dryness. The residue was dissolved in water and CH<sub>2</sub>Cl<sub>2</sub>. The pH of the aqueous layer was adjusted to be within the range 11–13 and the aqueous layer was extracted. The layers were separated. The aqueous layer was twice extracted with CH<sub>2</sub>Cl<sub>2</sub>, the combined organic layers were dried (Na<sub>2</sub>SO<sub>4</sub>) and the solvent evaporated off. The residue was recrystallized from diisopropyl ether-CHCl<sub>3</sub> (~3:2 v/v) at  $-30^{\circ}$ C to provide **3a–b** as colourless solids.

### Synthesis of the isocyanate derivatives (5a–b)

General procedure. A solution of 4-(2-fluoro-ethoxy)-aniline **4a**, prepared from 4-acetamido-phenol and toluene-4-sulphonic acid-(2-fluoro-ethyl ester) in two steps similar to those previously described,<sup>35,36</sup> or 4-(2-bromo-ethoxy)-aniline **4b**, prepared from 4-nitro-phenol and 1,2-dibromoethane in two steps as previously described,<sup>37,38</sup> in dry ethyl acetate (0.6–1.0 mmol/ml) was slowly added to a solution of 1 eq. trichloromethyl chloroformate in dry ethyl acetate (0.6 mmol/ml) at RT. The mixture was refluxed for 2h and evaporated to dryness. The residue was distilled in a Kugelrohr to provide the phenyliso-cyanates **5a–b** as colourless oils.

4-(2-fluoro-ethoxy)-phenylisocyanate (**5a**). Yield: 94%. Bp. (1.2 mbar): ≤165°C. <sup>1</sup>H-NMR (300 MHz, CDCl<sub>3</sub>): δ [ppm]: 7.01 (dd,  ${}^{3}J = 9.0$  Hz,  ${}^{4}J = 0.9$  Hz, 2H, HAryl), 6.86 (dd,  ${}^{3}J = 9.0$  Hz,  ${}^{4}J = 0.9$  Hz, 2H, H<sub>Aryl</sub>), 4.73 (dt,  ${}^{2}J = 47.4$  Hz,  ${}^{3}J = 4.2$  Hz, 2H, FCH<sub>2</sub>), 4.18 (dt,  ${}^{3}J = 27.6$  Hz,  ${}^{3}J = 4.2$  Hz, 2H, CH<sub>2</sub>O). <sup>13</sup>C-NMR (75.5 MHz, CDCl<sub>3</sub>): δ [ppm]: 156.30, 126.66, 125.71, 115.65, 81.82 (d,  ${}^{1}J = 170.4$  Hz), 67.56 (d,  ${}^{2}J = 19.9$  Hz). <sup>19</sup>F-NMR (282 MHz, DMSO-d<sub>6</sub>): δ [ppm]: -223.91. Analytically calculated for C<sub>9</sub>H<sub>8</sub>FNO<sub>2</sub>: C 59.67, H 4.45, N 7.73. Found: C 59.55, H 4.20, N 7.65.

4-(2-bromo-ethoxy)-phenylisocyanate (**5b**). Yield: 51%. Bp. (1.4 mbar): 160–170°C. <sup>1</sup>H-NMR (400 MHz, CDCl<sub>3</sub>):  $\delta$  [ppm]: 7.01 (d, <sup>3</sup>J = 9.0 Hz, 2H, H<sub>Aryl</sub>), 6.84 (d, <sup>3</sup>J = 9.0 Hz, 2H, H<sub>Aryl</sub>), 4.26 (t, <sup>3</sup>J = 6.6 Hz, 2H, CH<sub>2</sub>O), 3.62 (t, <sup>3</sup>J = 6.6 Hz, 2H, BrCH<sub>2</sub>). <sup>13</sup>C-NMR (100.6 MHz, CDCl<sub>3</sub>):  $\delta$  [ppm]: 155.91, 126.79, 125.73, 115.65, 68.29, 28.84. MS (EI): *m*/*z* (intensity %): 243 (M<sup>•+</sup>, 100), 241 (M<sup>•+</sup>, 94), 135 (39), 134 (47), 109 (74), 107 (78), 106 (18). Analytically calculated for C<sub>9</sub>H<sub>8</sub>BrNO<sub>2</sub>: C 44.66, H 3.33, N 5.79. Found: C 44.63, H 3.18, N 5.85.

# *Synthesis of the [2-[3-(4-(2-halogeno-ethoxy)-phenyl)-ureido]-ethyl]-carbamic acid t.-butyl ester derivatives* (6a–b)

*General procedure*. 4-(2-Fluoro-ethoxy)-phenylisocyanate **5a** or 4-(2-bromo-ethoxy)-phenylisocyanate **5b** in dry diethyl ether (0.3-0.7 mmol/ml) was added slowly to 1 eq. *N*-mono-(*t*.-butyloxycarbonyl)ethylenediamine in dry diethyl ether (1.3-1.4 mmol/ml) at 0°C. The mixture was stirred for further 30 min at

 $0^{\circ}$ C and cooled to  $-30^{\circ}$ C for 1–14 h. After filtration the filter cake was washed with diethyl ether and dried *in vacuo* to provide [2-[3-(4-(2-halogeno-ethoxy)-phenyl)-ureido]-ethyl]-carbamic acid *t*.-butyl ester **6a–b** as colourless solids.

[2-[3-(4-(2-fluoro-ethoxy)-phenyl)-ureido]-ethyl]-carbamic acid t.-butyl ester (**6a**). Yield: 86%. Mp.: 163–164°C. <sup>1</sup>H-NMR (300 MHz, DMSO-d<sub>6</sub>):  $\delta$  [ppm]: 8.29 (s, broad, 1H, NH), 7.28 (dt, <sup>3</sup>J = 9.0 Hz, <sup>4</sup>J = 2.7 Hz, 2H, H<sub>Aryl</sub>), 6.83 (dt, <sup>3</sup>J = 9.3 Hz, <sup>4</sup>J = 2.8 Hz, 2H, H<sub>Aryl</sub>), 6.78 (s, broad, 1H, NH), 6.03 (t, <sup>3</sup>J = 5.6 Hz, 1H, NH), 4.69 (dt, <sup>2</sup>J = 47.7 Hz, <sup>3</sup>J = 4.0 Hz, 2H, FCH<sub>2</sub>), 4.14 (dt, <sup>3</sup>J = 30.0 Hz, <sup>3</sup>J = 3.9 Hz, 2H, CH<sub>2</sub>O), 3.11 (q, <sup>3</sup>J = 5.8 Hz, 2H, CH<sub>2</sub>), 2.99 (q, <sup>3</sup>J = 5.9 Hz, 2H, CH<sub>2</sub>), 1.37 (s, 9H, C(CH<sub>3</sub>)<sub>3</sub>). <sup>13</sup>C-NMR (75.5 MHz, DMSO-d<sub>6</sub>):  $\delta$  [ppm]: 155.84, 155.62, 152.90, 134.20, 119.56, 114.82, 82.34 (d, <sup>1</sup>J = 166.6 Hz), 77.75, 67.43 (d, <sup>2</sup>J = 19.1 Hz), 40.69, 39.22, 28.36. <sup>19</sup>F-NMR (282 MHz, DMSO-d<sub>6</sub>):  $\delta$  [ppm]: -217.45. MS (MALDI-TOF): *m*/*z*: 364 (M+Na)<sup>+</sup>. Analytically calculated for C<sub>16</sub>H<sub>24</sub>FN<sub>3</sub>O<sub>4</sub>: C 56.29, H 7.09, N 12.31. Found: C 56.12, H 6.99, N 12.41.

[2-[3-(4-(2-bromo-ethoxy)-phenyl)-ureido]-ethyl]-carbamic acid t.-butyl ester (**6b**). Yield: 89%. Mp.: 126–127°C. <sup>1</sup>H-NMR (300 MHz, DMSO-d<sub>6</sub>):  $\delta$  [ppm]: 8.31 (s, 1H, NH), 7.27 (d, <sup>3</sup>J = 8.7 Hz, 2H, H<sub>Aryl</sub>), 6.83 (d, <sup>3</sup>J = 9.0 Hz, 2H, H<sub>Aryl</sub>), 6.77 (s, broad, 1H, NH), 6.04 (t, <sup>3</sup>J = 5.3 Hz, 1H, NH), 4.23 (t, <sup>3</sup>J = 5.3 Hz, 2H, CH<sub>2</sub>O), 3.74 (t, <sup>3</sup>J = 5.6 Hz, 2H, BrCH<sub>2</sub>), 3.10 (q, <sup>3</sup>J = 6.0 Hz, 2H, CH<sub>2</sub>), 2.99 (q, <sup>3</sup>J = 5.8 Hz, 2H, CH<sub>2</sub>), 1.37 (s, 9H, C(CH<sub>3</sub>)<sub>3</sub>). <sup>13</sup>C-NMR (75.5 MHz, DMSO-d<sub>6</sub>):  $\delta$  [ppm]: 155.65, 155.61, 152.60, 134.35, 119.51, 115.06, 77.74, 68.20, 40.66, 39.21, 31.66, 28.34. # Synthesis of the N-(2-amino-ethyl)-N'-[4-(2-halogeno-ethoxy)-phenyl]-urea hydrochloride derivatives (7a-b)

General procedure. [2-[3-(4-(2-Fluoro-ethoxy)-phenyl)-ureido]-ethyl]-carbamic acid t.-butyl ester **6a** or [2-[3-(4-(2-bromo-ethoxy)-phenyl)-ureido]-ethyl]-carbamic acid t.-butyl ester **6b** was dissolved in a c. HCl-MeOH mixture (1:1 v/v, 0.6–0.7 mmol/ml). The solvents were evaporated *in vacuo* within 1 h. The residue was treated with 25 ml anhydrous acetone and the solvent was removed *in vacuo*. This procedure was repeated three times to provide the hydrochlorides **7a–b** as colourless solids that were dried *in vacuo*.

*N*-(2-amino-ethyl)-*N*'-[4-(2-fluoro-ethoxy)-phenyl]-urea hydrochloride (7a). Yield: 96%. Mp.: 204°C decomposition. <sup>1</sup>H-NMR (300 MHz, DMSO-d<sub>6</sub>):  $\delta$  [ppm]: 8.91 (s, <sup>1</sup>H, NH), 8.09 (s, broad, 3H, NH<sub>3</sub><sup>+</sup>), 7.31 (dt, <sup>3</sup>J = 9.3 Hz, <sup>4</sup>J = 2.9 Hz,

2H, H<sub>Aryl</sub>), 6.83 (dt,  ${}^{3}J = 9.0$  Hz,  ${}^{4}J = 2.8$  Hz, 2H, H<sub>Aryl</sub>), 6.64 (s, broad, 1H, NH), 4.68 (dt,  ${}^{2}J = 47.7$  Hz,  ${}^{3}J = 4.0$  Hz, 2H, FCH<sub>2</sub>), 4.13 (dt,  ${}^{3}J = 30.3$  Hz,  ${}^{3}J = 3.9$  Hz, 2H, CH<sub>2</sub>O), 3.31 ('d', J = 4.5 Hz, 2H, CH<sub>2</sub>), 2.86 (q,  ${}^{3}J = 5.8$  Hz, 2H, CH<sub>2</sub>).  ${}^{13}$ C-NMR (75.5 MHz, DMSO-d<sub>6</sub>):  $\delta$  [ppm]: 156.18, 152.99, 134.07, 119.63, 114.82, 82.40 (d,  ${}^{1}J = 166.7$  Hz), 67.42 (d,  ${}^{2}J = 19.3$  Hz), 39.53, 37.34.  ${}^{19}$ F-NMR (282 MHz, DMSO-d<sub>6</sub>):  $\delta$  [ppm]: -217.41. MS (MAL-DI-TOF): m/z: 264 (M-HCl+Na)<sup>+</sup>, 242 (M-HCl+H)<sup>+</sup>. Analytically calculated for C<sub>11</sub>H<sub>17</sub>ClFN<sub>3</sub>O<sub>2</sub>: C 47.57, H 6.17, N 15.13. Found: C 47.22, H 6.01, N 15.09.

*N*-(2-amino-ethyl)-*N*<sup>*i*</sup>-[4-(2-bromo-ethoxy)-phenyl]-urea hydrochloride (**7b**). Yield: 94%. Mp.: 176°C decomposition. <sup>1</sup>H-NMR (400 MHz, DMSO-d<sub>6</sub>): δ [ppm]: 8.85 (s, 1H, NH), 7.99 (s, broad, 3H, NH<sub>3</sub><sup>+</sup>), 7.31 (d, <sup>3</sup>*J* = 8.8 Hz, 2H, H<sub>Aryl</sub>), 6.82 (d, <sup>3</sup>*J* = 7.6 Hz, 2H, H<sub>Aryl</sub>), 6.55 (s, broad, 1H, NH), 4.22–3.73 (m, 4H, CH<sub>2</sub>O and BrCH<sub>2</sub>), 3.31–2.85 (m, 4H, 2CH<sub>2</sub>). <sup>13</sup>C-NMR (100.6 MHz, DMSO-d<sub>6</sub>): δ [ppm]: 156.12, 152.74, 134.18, 119.65, 115.04, 68.22, 43.37, 39.55, 37.33. MS (MALDI-TOF): m/z: 326 (M-HCl+Na)<sup>+</sup>, 324 (M-HCl+Na)<sup>+</sup>, 304 (M-HCl+H)<sup>+</sup>, 302 (M-HCl+H)<sup>+</sup>. Analytically calculated for C<sub>11</sub>H<sub>17</sub>BrClN<sub>3</sub>O<sub>2</sub>: C 39.02, H 5.06, N 12.41. Found: C 38.87, H 5.17, N 12.56.

*N*-(2-amino-ethyl)-*N*'-[4-(2-bromo-ethoxy)-phenyl]-urea (**7c**). 14.00 g (41.3 mmol) *N*-(2-Amino-ethyl)-*N*'-[4-(2-bromo-ethoxy)-phenyl]-urea hydrochloride **7b** were dissolved in 150 ml water. The pH value was adjusted with 1 N NaOH to 9.0 and 200 ml CH<sub>2</sub>Cl<sub>2</sub> were added. The aqueous layer was extracted and the twophase mixture was filtered. The crude product on the filter was washed with 50 ml water and 50 ml CH<sub>2</sub>Cl<sub>2</sub> and dried *in vacuo* over P<sub>2</sub>O<sub>5</sub> to yield **7c** as a colourless solid. Yield: 82%. Mp.: 74–75°C. <sup>1</sup>H-NMR (300 MHz, DMSO-d<sub>6</sub>): δ [ppm]: 7.33–7.26 (m, 2H, H<sub>Aryl</sub>), 6.86–6.80 (m, 2H, H<sub>Aryl</sub>), 6.33 (t, <sup>3</sup>J = 5.4 Hz, 1H, NH), 6.18 (s, broad, 1H, NH), 4.24–3.73 (m, 4H, CH<sub>2</sub>O and BrCH<sub>2</sub>), 3.31–2.84 (m, 4H, 2CH<sub>2</sub>), 2.72 (t, <sup>3</sup>J = 5.2 Hz, 2H, NH<sub>2</sub>). <sup>13</sup>C-NMR (100.6 MHz, DMSO-d<sub>6</sub>): δ [ppm]: 156.05, 152.80, 134.06, 119.75, 115.05, 68.20, 47.88, 39.81, 37.70. Analytically calculated for C<sub>11</sub>H<sub>16</sub>BrN<sub>3</sub>O<sub>2</sub> · 0.5 H<sub>2</sub>O: C 42.46, H 5.51, N 13.50. Found: C 42.81, H 5.48, N 13.72.

# *Synthesis of the N-aryl-N'-[2-[3-aryloxy-2-hydroxy-propylamino]-ethyl]-urea derivatives* (8a–c)

General procedure of Scheme 2 (8a–c). 1 eq. 3a or 3b, an equimolar amount N-(2-amino-ethyl)-N'-[4-(2-halogeno-ethoxy)-phenyl]-urea hydrochloride 7a or 7b and 1.05 eq. of 10 N NaOH were heated in *n*-propanol (1.9–2.8 ml/mmol oxirane) and water (0.14–2.4 ml/mmol oxirane) up to 90°C for 3.5 h.

J Label Compd Radiopharm 2006; 49: 177-195

Purification procedure A (8a–b). The mixture was stored for crystallization at  $+4^{\circ}$ C, the product was filtered off, washed with water (100 ml) and diethyl ether (100 ml), and was purified by silica gel chromatography (ethyl acetate–MeOH 4:1). The product fraction was evaporated and recrystallized from MeOH.

*Purification procedure B* (8c). Water was added (4.2 ml/mmol urea), the mixture was extracted with ethyl acetate three times, the combined organic layers were dried over Na<sub>2</sub>SO<sub>4</sub>, and the solvent was evaporated. The crude product was purified by silica gel chromatography (ethyl acetate–MeOH 4:1). The urea derivatives 8a a were obtained as colourless solids.

The urea derivatives **8a-c** were obtained as colourless solids.

Procedure of Scheme 3 (8c). 9.50 g (31.4 mmol) N-(2-Amino-ethyl)-N'-[4-(2-bromo-ethoxy)-phenyl]-urea 7c were dissolved in 500 ml dry MeCN. Then 5.50 g (31.4 mmol) (S)-2-(2-cyano-phenoxymethyl)-oxirane 3a were added. The solution was refluxed for 10 h. In the meantime, the mixture was decanted from the insoluble polymeric products three times. After 15 h stirring at RT it was refluxed for 5 h. The solution was evaporated at RT and the crude product was purified by silica gel chromatography (ethyl acetate–MeOH 4:1).

(*S*)-*N*-[2-[3-(2-cyano-phenoxy)-2-hydroxy-propylamino]-ethyl]-*N*'-[4-(2-fluoroethoxy)-phenyl]-urea (**8a**). Yield: 9%. Mp.: 142–143°C. <sup>1</sup>H-NMR (300 MHz, DMSO-d<sub>6</sub>): δ [ppm]: 8.32 (s, 1H, NH), 7.69 (dd,  ${}^{3}J = 7.7$  Hz,  ${}^{4}J = 1.7$  Hz, 1H, H<sub>Aryl</sub>), 7.61 (ddd,  ${}^{3}J = 8.9$  Hz,  ${}^{3}J = 7.2$  Hz,  ${}^{4}J = 1.5$  Hz, 1H, H<sub>Aryl</sub>), 7.30–7.23 (m, 3H, H<sub>Aryl</sub>), 7.06 (dt,  ${}^{3}J = 7.7$  Hz,  ${}^{4}J = 0.8$  Hz, 1H, H<sub>Aryl</sub>), 6.82 (d,  ${}^{3}J = 9.0$  Hz, 2H, H<sub>Aryl</sub>), 6.04 (t,  ${}^{3}J = 5.6$  Hz, 1H, NH), 5.01 (s, broad, 1H, OH), 4.69 (dt,  ${}^{2}J = 47.8$  Hz,  ${}^{3}J = 4.0$  Hz, 2H, FCH<sub>2</sub>), 4.20–3.90 (m, 5H, 2OCH<sub>2</sub> and CH), 3.14 (q,  ${}^{3}J = 5.8$  Hz, 2H, CH<sub>2</sub>), 2.76–2.60 (m, 4H, 2CH<sub>2</sub>), 1.93 (s, broad, 1H, NH). <sup>13</sup>C-NMR (75.5 MHz, DMSO-d<sub>6</sub>): δ [ppm]: 160.51, 155.65, 152.83, 135.13, 134.32, 133.77, 121.12, 119.41, 116.55, 114.83, 113.36, 100.81, 82.37 (d,  ${}^{1}J = 166.6$  Hz), 71.77, 68.08, 67.42 (d,  ${}^{2}J = 19.3$  Hz), 52.12, 49.50, 31.45. <sup>19</sup>F-NMR (282 MHz, DMSO-d<sub>6</sub>): δ [ppm]: -217.36. Toluene-4-sulphonic acid 2-[4-(3-{2-[3-(2-cvano-phenoxv)-2-hvdroxv-propylamino]-ethyl}-ureido)-phenoxy]-ethyl ester (8d). Under an Ar-atmosphere 600 mg (1.26 mmol) (S)-N-[4-(2-bromo-ethoxy)-phenyl]-N'-[2-[3-(2-cyano-phenoxy)-2-hydroxy-propylamino]-ethyl]-urea 8c and 2.98g (6.28 mmol) silver p-toluenesulphonate were refluxed in 80 ml dry MeCN for 70 h. The mixture was filtered and the filtrate was evaporated at RT. Then 30 ml of acetone was added, the mixture was stirred for 5 min, filtered and the filtrate was evaporated at RT. The crude product was purified by two silica gel chromatographies (ethyl acetate-MeOH 4:1) and 8d was obtained as a pale yellow oil that solidified at 4°C. Yield: 46%. Mp.: 252°C decomposition. <sup>1</sup>H-NMR (400 MHz, CDCl<sub>3</sub>):  $\delta$  [ppm]: 7.76 (d, <sup>3</sup>J = 6.0 Hz, 2H, H<sub>Arvl</sub>), 7.68 (s, broad, 1H, NH), 7.46–7.41 (m, 2H,  $H_{Arvl}$ ), 7.31 (d,  ${}^{3}J = 6.0$  Hz, 2H,  $H_{Arvl}$ ), 7.16 (d,  ${}^{3}J = 6.6$  Hz, 2H, H<sub>Arvl</sub>), 6.95 (t,  ${}^{3}J = 5.7$  Hz, 1H, H<sub>Arvl</sub>), 6.85 (d,  ${}^{3}J = 6.6$  Hz, 1H, H<sub>Arvl</sub>), 6.59 (d,  ${}^{3}J = 6.9$  Hz, 2H, H<sub>Arvl</sub>), 6.08 (s, broad, 1H, NH), 4.26-3.98 (m, 7H, 3OCH2 and CH), 3.39-3.34 (m, 2H, CH2), 2.95-2.84 (m, 4H, 2CH<sub>2</sub>), 2.40 (s, 3H, CH<sub>3</sub>). <sup>13</sup>C-NMR (100.6 MHz, CDCl<sub>3</sub>): δ [ppm]: 160.35, 157.11, 153.96, 145.04, 134.72, 133.55, 129.94, 129.16, 128.01, 125.84, 121.74, 121.32, 116.76, 115.13, 112.63, 101.73, 68.37, 66.98, 65.93, 51.32, 49.59, 31.97, 29.73, 21.67. ### Radiochemical experiments

Production of  $[{}^{18}F]$ fluoride ion and synthesis of  $[{}^{18}F]K(Kryptofix 2.2.2)F$ . No-carrier-added aqueous  $[{}^{18}F]$ fluoride ion was produced on a CTI-RDS-111 cyclotron by irradiation of a 1.2 ml water target using 10 MeV proton beams on 97.0% enriched  $[{}^{18}O]$ water by the  ${}^{18}O(p,n){}^{18}F$  nuclear reaction. A typical batch was 7.4 GBq of  $[{}^{18}F]$ fluoride ion at EOB for currents of 32 µA and irradiation time of 12 min. To recover the  $[{}^{18}O]$ water, the batch of aqueous  $[{}^{18}F]$ fluoride ion was passed through an anion exchange resin (Sep-Pak<sup>®</sup> Light Waters Accell<sup>TM</sup> Plus QMA cartridge, preconditioned with 5 ml 1 M K<sub>2</sub>CO<sub>3</sub> and 10 ml water).  $[{}^{18}F]$ Fluoride ion was eluted from the resin with a mixture of 15 µl 1 M K<sub>2</sub>CO<sub>3</sub>, 200 µl water for injection, and 800 µl DNA-grade MeCN containing 15 mg Kryptofix<sup>®</sup> 2.2.2. Subsequently, the aqueous  $[{}^{18}F]$ K(Kryptofix 2.2.2)F solution was carefully evaporated to dryness *in vacuo*.

Radiosynthesis of (S)-N-[2-[3-(2-cyano-phenoxy)-2-hydroxy-propylamino]-ethyl]-N'-[4-(2-[<sup>18</sup>F]fluoro-ethoxy)phenyl]-urea (**8e**) via direct nucleophilic fluorination (one-step procedure). Compound 8e was prepared by treating 1.7 mg (2.98  $\mu$ mol) tosylate precursor **8d** with the carefully dried [<sup>18</sup>F]K(Kryptofix 2.2.2)F residue in 1ml DNA-grade MeCN at 84°C for 5min. After cooling to RT the crude reaction mixture was diluted with 10 ml water for injection and passed through a Waters Sep-Pak<sup>®</sup> Light C18 cartridge. The cartridge was washed with additional 10 ml water for injection, dried in a He-flow for 3 min, followed by elution of the raw 8e with 1.5 ml MeOH. The solution was evaporated to a volume of 0.2 ml and fractionized using a gradient radio-HPLC procedure (conditions:  $\lambda = 254$  nm; flow = 2 ml/min; eluents: A = MeCN-H<sub>2</sub>O-TFA, 950/50/1, B = MeCN-H<sub>2</sub>O-TFA, 50/950/1; column: Nucleosil 100-5 C18  $(250 \times 4.6 \text{ mm}^2)$  with corresponding precolumn  $(20 \times 4.0 \text{ mm}^2)$ ; time programme: eluent B from 92 to 30% in 45 min, halt 5 min, from 30 to 92% in 8 min) resulting in 8e with a radiochemical yield of 2.9% (decay-corrected) and a radiochemical purity >99% (retention time  $R_t = 35.0$  min). The time of synthesis and purification was 91 min from the EOB. The determined specific radioactivity was 3.5 GBq/µmol at the EOS. The specific activity of 8e was estimated by comparing the peak area of the UV channel of purified 8e with a standard curve of known concentrations of reference compound 8a realized with a RP-HPLC system (conditions:  $\lambda = 254$  nm; flow = 0.3 ml/min; eluent: MeCN-H<sub>2</sub>O-TFA, 700/300/1; column: Nucleosil 100-3 C18 ( $200 \times 3 \text{ mm}^2$ )). Chemical identity of **8e** was proved by

coinjection and coelution of **8e** and non-radioactive counterpart **8a** on the mentioned HPLC system.

Radiosynthesis of  $(S)-N-[2-[3-(2-cyano-phenoxy)-2-hydroxy-propylamino]-ethyl]-N'-[4-(2-[^{18}F]fluoro-ethoxy)phenyl]-urea (8e) via <math>1-[^{18}F]fluoro-2-(to-phenox)phenyl]$ syloxy)ethane (10) (two-step procedure). 4.0 mg (10.8 µmol) Ethylene glycol *di-p*-tosylate **9** and the carefully dried  $[^{18}F]K(Kryptofix 2.2.2)F$  residue were heated at 84°C in 1 ml DNA-grade MeCN for 4 min. The mixture was cooled to RT, diluted with 10 ml water for injection and passed through a Waters Sep-Pak® Light C18 cartridge. The cartridge was washed with additional 10 ml water for injection and eluted with 1.0 ml DNA-grade MeCN to yield raw 10. The solution was purified using a gradient radio-HPLC procedure (conditions:  $\lambda = 254$  nm; flow = 5 ml/min; eluents: A = MeCN-H<sub>2</sub>O-TFA, 950/50/1, B = MeCN-H<sub>2</sub>O-TFA, 50/950/1; column: Nucleosil 100-10 C18 (250 × 8 mm<sup>2</sup>); time programme: eluent B from 92 to 30% in 20 min, halt 5 min, from 30 to 92% in 5 min). The product fraction of 10 (retention time  $R_t = 19.4$  min) was evaporated to a volume of 2 ml, diluted with 10 ml water for injection and passed through a Waters Sep-Pak<sup>®</sup> Light C18 cartridge. After washing the cartridge with additional 5 ml water for injection it was dried in a He-flow for 10 min, followed by elution of 10 with 0.4 ml DMF that was tempered to 125°C before elution. Compound 10 was obtained with a radiochemical yield of  $42.8 \pm 2.8\%$  (decay-corrected, n = 5).  $4.0 \,\mathrm{mg}$  (10.8 µmol) Compound 8f, prepared as previously described,<sup>27</sup> in 0.1 ml DMF and 16.4 µl 1 N NaOH were added to the eluate of 10 (comment: the solution of 8f, NaOH in DMF was prepared 3 h before reaction start and turned brown after 2 h). The reaction mixture was stirred at 125°C for 15 min, diluted with 0.5 ml water for injection and purified with a gradient radio-HPLC system (conditions:  $\lambda = 254$  nm; flow = 5 ml/min; eluents: A = MeCN-H<sub>2</sub>O-TFA, 950/50/1, B = MeCN-H<sub>2</sub>O-TFA, 50/950/1; column: Nucleosil 100-10 C18 ( $250 \times 8 \text{ mm}^2$ ); time programme: eluent B from 92 to 30% in 45 min, halt 5 min, from 30 to 92% in 5 min). After isolation of **8e** (retention time  $R_t = 28.4$  min) the fraction was evaporated to a volume of 2 ml, diluted with 12 ml water for injection and passed through a Waters Sep-Pak<sup>®</sup> Light C18 cartridge. The cartridge was washed with 5 ml water for injection and eluted with 1 ml EtOH, that was tempered to  $60^{\circ}C$ before elution. For in vivo investigations the EtOH solution can be diluted with an appropriate amount of 0.9% NaCl or water for injection, respectively. In this second step the target compound 8e was obtained with a radiochemical yield of  $38.3 \pm 5.5\%$  (decay-corrected, n = 5). The overall radiochemical yield of **8e** for both steps was 16.4 + 3.2% (decay-corrected). Target compound **8e** was prepared with a radiochemical purity of 99.7  $\pm$  0.5% in 174  $\pm$  3 min from EOB. The determined specific radioactivity was  $40 \pm 8 \text{ GBq}/\mu\text{mol}$  at the EOS (n = 5) (see under one-step procedure).

# Radioligand binding assay

Microsomes were prepared by homogenizing heart ventricles from DBA mice at 4°C for 90s in buffer A (1 ml) containing 10 mM EDTA, 10 mM HEPES and 0.1 mM benzamidine (pH 7.4), using a Polytron PT 3000 (Kinematica, Lucerne, Switzerland). Homogenates were centrifuged at  $45000 \times g_{max}$  for 15 min at 4°C. The pellets were resuspended again in buffer B (1 ml) containing 1mM EDTA, 10mM HEPES and 0.1mM benzamidine (pH 7.4) and recentrifuged at  $45\,000 \times g_{\text{max}}$  for 15 min at 4°C. The pellets were resuspended in buffer B (1 ml) and centrifuged at  $10\,000 \times g_{\text{max}}$  for 10 min at 4°C. The supernatants were recentrifuged at  $45\,000 \times g_{\text{max}}$  for 15 min at 4°C. The pellets, partially enriched membranes, were resuspended in buffer C (50 mM Tris  $\cdot$  HCl, 5 mM MgCl<sub>2</sub> (pH 7.4)), and stored frozen at  $-80^{\circ}$ C. For competition binding studies, the prepared membranes were resuspended in buffer D (10 mM Tris · HCl, 154 mM NaCl, 0.1 mM ascorbic acid, pH 7.4). 15µg of membranes were incubated with a constant concentration of  $[^{125}I]ICYP$  (80 pM) and with varying concentrations (1 pM-100  $\mu$ M) of compounds 8a-c (Scheme 2). Reactions were conducted at 37°C for 60 min. Reactions were stopped by filtering onto Whatman GF/B filters and washed with water for injection. The membrane bound radioactivity was determined in a  $\gamma$ -scintillation counter. Competition binding curves were analysed by nonlinear regression analysis as previously described<sup>43–45</sup> using the XMGRACE programme (Linux software). The data of the ligands 8a-c fitted a two-site model significantly better than a one-site model (F = 2.15, p < 0.05). The resulting high- and low-affinity IC<sub>50</sub> values of the non-radioactive 3-aryloxy-2propanolamine derivatives 8a-c were converted into the high- and low-affinity inhibition constants ( $K_{I1}$  for the  $\beta_1$ -ARs and  $K_{I2}$  for the  $\beta_2$ -ARs) by the method of Cheng–Prusoff<sup>39</sup> using the experimentally determined  $K_D$  value of  $[^{125}I]ICYP (32.3 \pm 1.9 \text{ pM}).^{33}$  The ratios of the low- to high-affinity inhibition constants  $(K_{12}/K_{11})$  yield the  $\beta_1$ -selectivities of the unlabelled derivatives **8a–c** (Table 1). These compounds show a significantly higher affinity to  $\beta_1$ - than to  $\beta_2$ -ARs. Additionally, the calculated log P and log D values (ACD/log D Suite) for compounds 8a-c are listed in Table 1 to emphasise the changes of the lipophilicities caused by the chemical modifications of the lead compound, ICI 89,406.

# Conclusion

The synthesis, radiosynthesis and *in vitro* pharmacology of (S)- and (R)-N-[2-[3-(2-cyano-phenoxy)-2-hydroxy-propylamino]-ethyl]-N'-[4-(2-fluoro-ethoxy)phenyl]-urea (**8a** and **8b**, respectively), and the <sup>18</sup>F-labelled (S)-enantiomer (**8e**), a potential new high-affinity  $\beta_1$ -AR selective PET radioligand, are reported. The non-radioactive counterpart **8a** of the radiolabelled target compound **8e** displays a high  $\beta$ -AR binding potency as well as a high  $\beta_1$ -AR selectivity in murine myocardial membranes and a moderate lipophilicity comparable with the known non-selective PET radioligand (*S*)-[<sup>11</sup>C]CGP 12177. The radiosynthesis of **8e** was achieved in two alternative routes. The two-step synthesis of **8e** with 1-[<sup>18</sup>F]fluoro-2-(tosyloxy)ethane **10** as intermediate shaped up as the superior route compared to the one-step procedure starting with the tosylate precursor **8d**. The two-step synthesis route yielded the target compound **8e** with reasonable radiochemical yields and specific activities. The formulation of the preparations is suitable for preclinical *in vivo* studies using small animal PET.
