## ABSTRACT

The propagation and termination rate constants ( $k_{p}$ and $k_{t}$ ) for the radical polymerization of ethyl $\alpha$-chloroacrylate (ECA) were determined by the rotating sector method; $\mathrm{k}_{\mathrm{p}}=1660$ and $k_{t}=3.33 \times 10^{8} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$ at $30^{\circ} \mathrm{C}$. The absolute rate constants for cross-propagations in copolymerization were evaluated from the $k_{p}$ determined for ECA or those for common monomers and the monomer reactivity ratios. The reactivities of ECA and poly(ECA) radicals estimated as the rate constants of cross-propagations were accounted for by using equations relating these rate constants to the polar and resonance effects of the substituents. ECA was highly reactive toward various polymer radicals as expected from the resonance effects of the carbethoxy and chloro substituents. The poly(ECA) radical was found to be more reactive than common polymer radicals. The reactivity of a polymer radical in cross-propagation seemed to increase with increasing electron-accepting power by facilitating electron transfer from a monomer required for the new $\mathrm{C}-\mathrm{C}$ bond formation.

## INTRODUCTION

Although absolute rate constants of the elementary reactions in radical polymerization of number of monomers have been determined mainly by a rotating sector method [1], none of the 1,1 disubstituted ethylenes except for methacrylic monomers has been utilized for detailed kinetic studies. In the course of study on the radical polymerization of $\alpha$-substituted acrylic esters [2], ethyl $\alpha$ chloroacrylate (ECA) was chosen as one of the monomers of which rate constants of propagation ( $k_{p}$ ) and termination ( $k_{t}$ ) could be deter-
mined.

Since among the elementary reactions involved in radical polymerization, propagation directly relates to the polymerization ability of a monomer, determination of the $k_{p}$ value enables us to discuss the reactivities of the monomer and the polymer radical quantitatively. From this point of view, the absolute values of $k_{p}$ and $k_{t}$ for ethyl $\alpha-$ cyanoacrylate (ECNA) were determined in a previous paper [3].

In this paper the determination of $k_{p}$ and $k_{t}$ for bulk polymerization of ECA by a rotating sector method at $30^{\circ} \mathrm{C}$ and evaluation of the rate constants for cross-propagations in copolymerization are described. On the basis of these rate data, the effects of carbethoxy and chloro substitutions on the reaction centers of the monomer and the polymer radical are discussed. Furthermore, equations relating these rate constants to the polar and resonance effects of the substituents are developed, and the corresponding rate constants of common monomers and polymer radicals are accounted for by use of the equation derived.

## EXPERIMENTAL

Materials

ECA was prepared by continuous distillation from an equimolar mixture of ethyl $\alpha, \beta$-dichloropropionate and quinoline under reduced pressure. Methyl $\alpha$-methoxyacrylate, ethyl $\alpha$-bromoacrylate, $\alpha$ methoxyacrylonitrile, and ethyl $\alpha$-fluoroacrylate (EFA) were synthesized as described elsewhere [2, 4] . Commercially available styrene (St), methyl methacrylate (MMA), methyl acrylate (MA), acrylonitrile, methacrylonitrile, vinyl acetate (VAc), and the synthesized monomers were distilled in a nitrogen stream under atmospheric or reduced pressure before use.

2,2'-Azobisisobutyronitrile(AIBN) and 1,1'-azobiscyclohexane-1carbonitrile (ACN) were purified by recrystallization from ethanol. Diphenylpicrylhydrazyl (DPPH) was recrystallized from benzene and used as the benzene complex. p-Benzoquinone was purified by sub-
limation after recrystallization from ligroine. 1,3,5-Triphenylverdazyl was prepared by the reported reactions and recrystallized from methanol [5].

Polymerization

Polymerizations were carried out with AIBN and ACN as the thermal- and photoinitiators. Overall rates of polymerization ( $\mathrm{R}_{\mathrm{p}}$ ) were measured by dilatometry at $30 \pm 0.005^{\circ} \mathrm{C}$. Details of the rotating sector method have been described elsewhere [6]. In order to suppress photopolymerization of ECA, a concentrated sulfuric acid solution of picric acid [7] was used as the filter for cutting off wavelengths shorter than 380 nm .

## Copolymerization

Copolymerizations of ECA were run in sealed tubes at $60^{\circ} \mathrm{C}$. Copolymer compositions were calculated from chlorine analysis, and the monomer reactivity ratios were determined by a nonlinear least squares procedure [8].

Number-Average Molecular Weight and Intrinsic Viscosity

The number-average molecular weight ( $\bar{M}_{n}$ ) of poly(ECA) was measured by osmometry in 1,2 -dichloroethane as the solvent using a Knauer membrane osmometer. The intrinsic viscosity ( $[\eta]$ ) of the polymer in the same solvent was measured by an Ubbelohde viscometer at $30^{\circ} \mathrm{C}$. The number-average degree of polymerization $\left(\bar{P}_{n}\right)$ was calculated from $\bar{M}_{n}$.

## RESULTS

Contraction-Conversion Factor

In order to monitor the polymerization by a dilatometer, the relationship between the conversion and the contraction in volume during polymerization should be known. The relationship for bulk polymerization was calculated from the difference in density between ECA monomer and the amount of poly(ECA) dissolved. According to the linear relationship shown in Fig. 1, the percentage volume contraction corresponding to $100 \%$ conversion is 20.3 .

FIG. 1. Relationship between conversion and contraction during bulk polymerization of ECA at $30^{\circ} \mathrm{C}$.

## $[\eta]-\bar{M}_{n}$ Equation

By measuring $[\eta]$ ( $\mathrm{dL} / \mathrm{g}$ ) of various $\overline{\mathrm{M}}_{\mathrm{n}}$ samples of poly(ECA), the following equation was derived from the present study over the range of $\bar{M}_{n}$ from 214,900 to $4,169,500$ in 1,2 -dichloroethane at $30^{\circ} \mathrm{C}$ :
$[\eta]=9.57 \times 10^{-5} \bar{M}_{n}^{0.74}$
Values of $R_{p}$

Because the rotating sector method requires that chain polymerization be initiated photochemically and terminated with the bimolecular reaction of the polymer radicals, the kinetic order with respect to AIBN and ECA should be 0.5 and 1.0, respectively. As shown in Fig. 2, it was confirmed that $R_{p}$ obeyed the following equation:

$$
R_{p}=k[A I B N]^{0.5}[E C A]^{1 \cdot 0}
$$

The overall activation energy of the polymerization initiated with AIBN was $21.5 \mathrm{kcal} / \mathrm{mol}$ over the temperature range 25 to $50^{\circ} \mathrm{C}$.

FIG. 2. Dependencies of polymerization rate on ECA concentration and on AIBN concentration.

Calculation of $k_{p}{ }^{2} / k_{t}$ from Initiation Rate
The value of $k_{p}^{2} / k_{t}$ may be calculated from $R_{p}$ and the initiation rate ( $R_{i}$ ) according to

$$
k_{p}^{2} / k_{t}=R_{p}^{2} /\left(R_{i}[M]^{2}\right)
$$

Since $R_{p}$ was measurable, $R_{i}$ was determined by the length of the inhibition periods of an appropriate inhibitor. DPPH and verdazyl, the preferred inhibitors, were not used because ECA caused the characteristic colors of the solutions of these inhibitors to fade. p-Benzoquinone was found to function as a retarder because of its long period of retardation. Thus, determination of $R_{i}$ by the inhibition method was unsuccessful, so it was estimated from the assumed efficiency of initiation (f) and the decomposition rate of the initiator.

Since the literature data suggest that the f value closely relating to the cage effect of AIBN is about 0.5 [9-11], the choice of $f=0.5$ for ECA polymerization seemed to be reasonable. The thermal decomposition rate constant of AIBN has been reported to be $8.9 \times$ $10^{-8} \mathrm{~s}^{-1}$ at $30^{\circ} \mathrm{C}[12]$. Hence, at $[\mathrm{AIBN}]=4.88 \times 10^{-2} \mathrm{~mol} / \mathrm{L}$,

$$
\mathrm{R}_{\mathrm{i}}=4.34 \times 10^{-9} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}
$$

By using

$$
R_{p}=4.91 \times 10^{-5} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{~s}
$$

at the same concentration of AIBN in bulk, the value of $k_{p}^{2} / k_{t}$ was
obtained:

$$
\mathrm{k}_{\mathrm{p}}^{2} / \mathrm{k}_{\mathrm{t}}=8.27 \times 10^{-3} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{~s}
$$

Calculation of $k_{p}{ }^{2} / k_{t}$ from $\bar{P}_{n}$
In a typical radical polymerization the value of $k_{p}{ }^{2} / k_{t}$ may be calculated from $\bar{P}_{\mathrm{n}}$ by using

$$
1 / \bar{P}_{n}=k_{t}(1+x) R_{p} /\left(2 k_{p}^{2}[M]^{2}\right)+C_{m}
$$

where $C_{m}$ is the chain transfer constant of the monomer and $x$ is the contribution of disporportionation in termination.

Plots of $1 / \bar{P}_{n}$ versus $R_{p} /[\mathrm{M}]^{2}$ for ECA polymerization at $30^{\circ} \mathrm{C}$, shown in Fig. 3, yield a straight line with a slope equal to $k_{t}(1+x) /$ $2 k_{p}{ }^{2}$. However, the $x$ value is not known and the prediction of $x$ based on the structure of the polymer radical seems to be difficult [ 10,11 ]. Consequently, the value of $\mathrm{k}_{\mathrm{p}}^{2} / \mathrm{k}_{\mathrm{t}}$ was obtained as a range from 1.13 $\times 10^{-3}$ for complete combination ( $x=0$ ) to $2.26 \times 10^{-3} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$ for complete disproportionation $(x=1)$. The value of $k_{p}^{2} / k_{t}$ at $x=0$ is close to that calculated from $R_{i}$, and similar values obtained by different methods suggest that $k_{p}^{2} / k_{t}$ evaluated by assuming $f$ is adequate.

From the intercept of the $1 / \overline{\bar{P}}_{n}-R_{p} /[\mathrm{M}]^{2}$ plot, $\mathrm{C}_{\mathrm{m}}$ of ECA was found to be $6.3 \times 10^{-5}$ at $30^{\circ} \mathrm{C}$.

## Average Lifetime of Growing Radical

The polymerization rate under intermittent irradiation of UV light ( $R_{\mathrm{sp}}$ ) depends on the flash time and the average lifetime of the growing radical ( $\tau$ ) [13]. Figure 4 shows a plot of the ratio of the rates $R_{s p} / R_{p}^{\prime}$ against the flash time, where $R_{p}$ ' is the polymerization rate under steady irradiation of UV light and $y$ denotes contribution of polymerization in the dark. The theoretical curve for $\tau=0.97 \mathrm{~s}$ and $y=0.05$ was found to fit best for the experimental points. Since $R_{p}{ }^{\prime}$

FIG. 3. Determination of $k_{p}^{2} / k_{t}$ from polymerization rate and degree of polymerization.

FIG. 4. Rate of photosensitized polymerization under intermittent irradiation of UV light as a function of flash time at $30^{\circ} \mathrm{C}$ : (-) $\tau=$ 1.0 s and $\mathrm{y}=0,(--) \tau=0.97 \mathrm{~s}$ and $\mathrm{y}=0$.
was $4.24 \times 10^{-5} \mathrm{~mol} / \mathrm{L} \cdot \mathrm{s}$, the value of $\mathrm{k}_{\mathrm{p}} / \mathrm{k}_{\mathrm{t}}$ obtained by using the
following equation was $4.99 \times 10^{-6}$ :

$$
k_{p} / k_{t}=R_{p}^{\prime} \tau /[E C A]
$$

Absolute Values of $k_{p}$ and $k_{t}$
Combining the numerical values of $k_{p}{ }^{2} / k_{t}$ and $k_{p} / k_{t}$ yields the absolute values of $k_{p}$ and $k_{t}$ :

$$
\begin{aligned}
& \mathrm{k}_{\mathrm{p}}=1660 \mathrm{~L} / \mathrm{mol} \cdot \mathrm{~s} \\
& \mathrm{k}_{\mathrm{t}}=3.33 \times 10^{8} \mathrm{~L} / \mathrm{mol} \cdot \mathrm{~s}
\end{aligned}
$$

In Table 1 the absolute values of the rate constants determined by the rotating sector method at $30^{\circ} \mathrm{C}$ are summarized.

## Copolymerization

In Table 2 the monomer reactivity ratios for the copolymerizations of ECA ( $M_{1}$ ) with a variety of monomers ( $M_{2}$ ) are shown. The e and $Q$ values calculated from the copolymerization with St were 1.14 and 3.01 , respectively [14]. According to the definition of the monomer reactivity ratios, the absolute rate constants for the addition of poly (ECA) radical to the monomers are evaluated by

where $k_{11}$ is equal to $k_{p}$ of ECA. Because the monomer reactivity ratios have been known to be independent of polymerization temperature, the reactivity ratios at $30^{\circ} \mathrm{C}$ are approximated by those at $60^{\circ} \mathrm{C}$.

The rate constants for the addition of $\mathrm{M}_{2}$ radical to ECA were evaluated by using the $k_{p}$ values of St, MMA, MA, VAc, EFA, and ECNA given in Table 1.

$$
k_{21}=k_{22} / r_{2}
$$

where $k_{22}$ is identical to $k_{p}$ of the $M_{2}$ monomer. The absolute values of $k_{12}$ and $k_{21}$ are tabulated in Tables 2 and 3, respectively. When $M_{1}=M_{2}=E C A$, both $k_{12}$ and $k_{12}$ become the $k_{p}$ of ECA.

DISCUSSION
$k_{p}$ Value

Propagation in homopolymerization consists of the addition of a polymer radical to a monomer, leading to the formation of a polymer radical. A comparison of the $k_{p}$ values of common monomers shows that the monomer with a larger $Q$ value may have a smaller $k_{p}$ value because of forming a less reactive polymer radical during propagation. According to this expectation, the $\mathrm{k}_{\mathrm{p}}$ value of ECA should be the second smallest one among those in Table 1. Apparently this is

TABLE 3. Rate Constant for Cross-Propagation ( $\mathrm{k}_{21}$ ) at $30^{\circ} \mathrm{C}, \mathrm{M}_{1}=$ ECA

not the case. Therefore, the magnitudes of $k_{p}$, especially those of the 1,1-disubstituted ethylenes, were considered on the basis of the reactivities of the monomers and the polymer radicals evaluated as the rate constants of cross-propagations.

## Reactivity of Poly(ECA) Radical

As reported in a previous paper [2], the reactivities of the 1,1disubstituted ethylenes ( $M_{2}$ ) having substituents $X$ and $Y$ toward a certain polymer radical $\left(\mathrm{M}_{1} \cdot\right)$ are correlated with the polar and resonance effects of the substituents:

$$
\begin{equation*}
\log k_{12}=\rho\left(\sigma_{\mathbf{X}}+\sigma_{Y}\right)+\mathbf{A}\left(\Delta \log Q_{\mathbf{X}}+\Delta \log Q_{Y}\right)+\left(\log k_{12}\right)_{0} \tag{1}
\end{equation*}
$$

where $\Delta \log Q$ is a parameter showing the resonance effect of the substituent and $\sigma$ is Hammett's polar substituent constant. $\rho$ and $A$ are reaction constants, and the last term, $\left(\log \mathrm{k}_{12}\right){ }_{0}$, is also a constant corresponding to the logarithm of the rate constant for addition of the reference radical ( $M_{1} \cdot$ ) to ethylene, $X=Y=H$. Steric effects were ignored in developing this equation.

According to the additivity of $\log \mathrm{Q}$ value, $\Delta \log \mathrm{Q}$ values have been defined and evaluated by

$$
\begin{aligned}
\Delta \log Q_{X} & =\log Q_{\mathrm{CH}_{2}}=\mathrm{CXY} \\
& =\log \mathrm{Q}_{\mathrm{CH}_{2}}=\mathrm{CHY} \\
& Q_{\mathrm{CH}_{2}}=\mathrm{CXH}
\end{aligned}{ }^{-\log Q_{\mathrm{CH}_{2}}=\mathrm{CH}_{2}}
$$

where $Q_{\mathrm{CH}_{2}=C X Y}, Q_{\mathrm{CH}_{2}=\mathrm{CXH}}, \mathrm{Q}_{\mathrm{CH}_{2}=\mathrm{CHY}}$, and $\mathrm{Q}_{\mathrm{CH}_{2}=\mathrm{CH}_{2}}$ are the $Q$ values of $\mathrm{CH}_{2}=\mathrm{CXY}, \mathrm{CH}_{2}=\mathrm{CXH}, \mathrm{CH}_{2}=\mathrm{CHY}$, and $\mathrm{CH}_{2}=\mathrm{CH}_{2}$, respectively. In Table 4, $\Delta \log Q$ and $\sigma$ values are summarized, and as discussed before [2], the $\sigma$ value for the acetoxy group is -0.05 instead of 0.31 [22] in radical polymerization.

As in Fig. 5, a plot of $\left[\log k_{12}-\left(\Delta \log Q_{X}+\Delta \log Q_{Y}\right)\right]$ against $\left(\sigma_{X}+\sigma_{Y}\right)$ for the addition of poly(ECA) radical to various monomers gives a straight line with a slope equal to -0.95 . The experimental point for $M_{2}=E C A$ also fits the straight line, revealing that the $k_{p}$ value of ECA can be accounted for in terms of the effects of the carbethoxy and chloro substituents as well as the rate constants for addition of the poly(ECA) radical to the other monomers. The reaction

constants obtained for the poly(ECA) radical are shown in Table 5. In this table the reaction constants determined by the same procedure based on the $k_{p}$ values in Table 1 and the monomer reactivity ratios in the literature $[3,4,19,23]$ are also summarized.

The reaction constant $\rho$, representing the polar character of the polymer radical, has a negative value for the poly(ECA) radical, consistent with the electron-withdrawing character of the carbethoxy and chloro-substituents. Another reaction constant, A, related to the resonance stabilization of the transition state, seems to be constant regardless of the structure of the polymer radical. Moreover, comparing the ( $\left.\log k_{12}\right)_{0}$ values corresponding to the rate constants for addition of the respective polymer radicals to ethylene ( $\mathrm{X}=\mathrm{Y}=\mathrm{H}$ ) shows that the poly(ECA) and poly (ECNA) radical add faster than the other polymer radicals. As already mentioned for the inherent reactivity of the poly(ECNA) radical [3], the reactivity of a polymer radical tends to increase with increasing electron-accepting power because a growing polymer radical is required to accept one of the $\pi$ electrons being taken from a monomer for the new $\sigma$ bond formation.

Reactivity of ECA Monomer

As for Eq. (1), we tried to correlate $\mathrm{k}_{21}$ with the resonance and polar effects of the substituents. Contrary to the monomer reactivities given by $\mathrm{k}_{12}$, the rate constants for the addition of polymer radicals to ECA, as expressed by $\mathrm{k}_{21}$, should decrease with increasing resonance stabilization of the attacking radicals. The following equation was developed:

$$
\begin{equation*}
\log k_{21}=\rho^{\prime}\left(\sigma_{X}+\sigma_{Y}\right)-A^{\prime}\left(\Delta \log Q_{X}+\Delta \log Q_{Y}\right)+\left(\log k_{21}\right)_{0} \tag{2}
\end{equation*}
$$

where $\rho^{\prime}$ and $A^{\prime}$ are the reaction constants corresponding to $\rho$ and $A$ in Eq. (1), respectively. The last term $\left(\log k_{21}\right)$ denotes the logarithm of the rate constant for the addition of the polyethylene radical ( $\mathbf{X}=\mathbf{Y}$ $=H$ ) to ECA. The substituent constants $\sigma$ and $\Delta \log Q$ refer to $X$ and $Y$ bound to the $\alpha$-carbon of the attacking polymer radical.

The $A^{\prime}$ value was changed from 0 to 1 to give a linear relationship between $\left[\log k_{21}+A\left(\Delta \log Q_{X}+\Delta \log Q_{Y}\right)\right]$ and $\left(\sigma_{X}+\sigma_{Y}\right)$. For the addition of polymer radicals to ECA, $\rho^{\prime}=+0.21$ and $A^{\prime}=0.5$ were obtained as shown in Fig. 6. Equation (2) seemed to be appropriate to represent the reactivities toward various monomers. The $\mathrm{k}_{21}$ values for several monomers were calculated from the $k_{p}$ values in Table 1 and the monomer reactivity ratios of copolymerization in the literature [3, 4, 19, 23]. The reaction constants $\rho^{\prime}, A^{\prime}$, and ( $\log$ $\left.\mathrm{k}_{21}\right)_{0}$ for the monomers are summarized in Table 6.

Poly(ECA) radicals added faster to electron-donating monomers than to electron-accepting ones, as can be seen in Fig. 5, if the resonance effect due to the substituents of the monomer was excluded. Nevertheless, ECA is apparently nucleophilic in character ( $\rho^{\prime}=+0.21$ )

FIG. 6. Application of Eq. (2) to reactivities of polymer radicals toward ECA monomer: plots of $\log k_{21}$ versus $\left(\sigma_{X}+\sigma_{Y}\right)(0)$ and $\left[\log k_{21}+\left(\Delta \log Q_{X}+\Delta \log Q_{Y}\right)\right]$ versus $\left(\sigma_{X}+\sigma_{Y}\right)(\bullet)$. 1, Poly (vinyl acetate) radical; 2, polystyrene radical; 3, poly(methyl methacrylate) radical; 4, poly(methyl acrylate) radical; 5, poly(ethyl $\alpha$ fluoroacrylate) radical; 6, poly(ECA) radical; 7, poly(ethyl $\alpha$-cyanoacrylate) radical.

FIG. 7. Plot of $\rho^{\prime}$ value for monomer against $\rho$ value for polymer radical.
because the increasing electron-accepting power of the attacking polymer radical facilitates electron transfer from the monomer. The $\rho^{\prime}$ values for the monomers are consistently greater than the $\rho$ values for the corresponding polymer radicals. This trend is obvious when the $\rho^{\prime}$ value for a monomer is plotted against the $\rho$ value of the corresponding polymer radical as in Fig. 7, and the $\rho^{\prime}$ values may be correlated with the $\rho$ values by

$$
\rho^{\prime}=1.19 \rho+1.72
$$

This ensures that the polar character of the monomer is not independent of that of the polymer radical.

The same tendency has been found by comparing the polar characters of p-substituted styrenes and alkyl methacrylates with poly(psubstituted styrene) and poly(alkyl methacrylate) radicals, respectively [14, 24].

Furthermore, the smaller contribution of $\left(\Delta \log Q_{X}+\Delta \log Q_{Y}\right)$ for the $\log k_{21}$ value than that for the $\log k_{12}$ value $\left(A=1.0\right.$ and $A^{\prime}=$ 0 or 0.5 ) suggests that an increase in $k_{21}$ value with increasing electron-accepting power of the polymer radical is more pronounced than the decrease with increasing resonance stabilization by the substituents of the radical. In agreement with this view, the reactivities of p-substituted styrenes toward certain poly(p-substituted styrene) radicals have been correlated with the polar effect of the substituents of the monomers and not to the resonance effect [14].

Although the accumulation of more data may be required before we have a better understanding of the influence of the structure of the polymer radical, Eq. (2) is considered to be valid for relating $\mathrm{k}_{21}$ values with the effects of the substituents $X$ and $Y$ in $M_{2} \cdot$. Therefore, as a result of using carbethoxy and chloro-substituents to yield large $\mathrm{k}_{12}$ and $\mathrm{k}_{21}$ values, the $\mathrm{k}_{\mathrm{p}}$ of ECA was observed to be as large as $1660 \mathrm{~L} / \mathrm{mol} \cdot \mathrm{s}$ when $\mathrm{M}_{1}=\mathrm{M}_{2}=$ ECA.
