Received November 13, 2001; revised March 22, 2002

A two-dimensional HSQC-based NMR method, ${}^{15}\text{N}$ -COSMO-HSQC, is presented for the rapid determination of homonuclear ${}^3J_{\text{HNH}\alpha}$ couplings in ${}^{15}\text{N}$ -labeled proteins in solution. Scalar couplings are extracted by comparing the intensity of two separate datasets recorded with and without decoupling of the ${}^3J_{\text{HNH}\alpha}$ during a preparation period. The scalar couplings are introduced through a cosine modulation of the peak intensities. The experiment relies on a BIRD sandwich to selectively invert all amide protons H^{N} and is very simple to implement. ${}^3J_{\text{HNH}\alpha}$ couplings were determined using both the ${}^{15}\text{N}$ -COSMO-HSQC and quantitative- J on ${}^{15}\text{N}$ -labeled chemokine RANTES. The two experiments show well-correlated values. © 2002 Elsevier Science (USA)

INTRODUCTION

Several different methods are currently available for the measurement of vicinal ${}^1\text{H}$ - ${}^1\text{H}$ scalar couplings between amide and alpha protons, ${}^3J_{\text{HNH}\alpha}$. First, three-dimensional experiments requiring ${}^{13}\text{C}$, ${}^{15}\text{N}$ -labeled proteins such as E.COSY methods (1–3) and DQ/ZQ experiments (4). The most widely used method for ${}^{15}\text{N}$ -labeled proteins is the three-dimensional quantitative- J experiment in which the ratio of cross to diagonal peaks is directly related via a tangent function to the scalar coupling (5–7). Couplings can also be obtained from multiplet splittings as in J -modulated HMQC (8) or from two-dimensional spectra in J -modulated HSQC (9), S^3E , and S^3CT (10) that require a transfer of ${}^1\text{H}$ magnetization via NOESY or TOCSY, J -multiplied HSQC (11), CT-HMQC-HA/HN (12, 13), and CT-HSQC-HA/HN (13). In these last methods, a pair of two-dimensional spectra are recorded with and without selective decoupling of the targeted scalar coupling evolution. The ratio of the cross peaks in these two datasets gives direct access to a cosine function of the ${}^3J_{\text{HNH}\alpha}$ coupling. In the constant-time J -modulated HSQC sequence (13), selective H^{α} decouplings of

different durations are required which can induce sample heating and can be rather difficult to implement successfully. The ${}^{15}\text{N}$ -COSMO-HSQC method presented here achieves clean and simple refocusing of all ${}^3J_{\text{HNH}\alpha}$ couplings by a BIRD sandwich (14, 15) that selectively inverts all ${}^{15}\text{N}$ -bound amide protons H^{N} . In addition, pulsed field gradient sensitivity enhancement (16) was included.

RESULTS AND DISCUSSION

Figure 1 shows the pulse sequence of the ${}^{15}\text{N}$ -COSMO-HSQC experiment. The sequence is composed of an initial period of total duration $2\tau + 2\delta_1$ during which in-phase ${}^1\text{H}$ coherence is either labeled by a cosine modulation of the ${}^3J_{\text{HNH}\alpha}$ coupling or left unperturbed. After this preparation, a filter followed by sensitivity-enhanced HSQC is applied (16). ${}^{15}\text{N}$ chemical shifts are recorded in the indirect dimension and ${}^1\text{H}$ signal is detected.

After an initial purging of residual ${}^{15}\text{N}$ magnetization, transverse proton magnetization is excited by a $90^\circ({}^1\text{H})$ pulse and let to evolve under the effect of homonuclear couplings leading to a superposition of in-phase (H_y^{N}) and antiphase ($2H_x^{\text{N}}H_z^{\alpha}$) magnetization at point **a** in the sequence. The $180^\circ({}^1\text{H})$ proton pulse applied at $\tau/2$ refocuses evolution under the effect of both chemical shifts and ${}^1\text{H}$ - ${}^{15}\text{N}$ heteronuclear scalar couplings during the τ period. A BIRD sandwich (14, 15) of duration $2\delta_1 = 1/{}^1J_{\text{NHN}}$ is then applied. At point **a** in the sequence, in-phase coherence H_y^{N} is converted into longitudinal magnetization H_z^{N} , while the antiphase term $2H_x^{\text{N}}H_z^{\alpha}$ is transformed into a superposition of zero- and double-quantum coherence $2H_x^{\text{N}}H_y^{\alpha}$. For a $180^\circ({}^{15}\text{N})$ pulse, the multiple quantum coherences are modulated by $\cos(\pi {}^1J_{\text{NHN}} 2\delta_1)$, while ${}^3J_{\text{HNH}\alpha}$ homonuclear scalar couplings are effectively decoupled. For a BIRD sandwich delay tuned to $2\delta_1 = 1/{}^1J_{\text{NHN}}$, $\cos(\pi {}^1J_{\text{NHN}} 2\delta_1) = -1$ and the result is a net inversion of the zero- and double-quantum terms $2H_x^{\text{N}}H_y^{\alpha}$. On the other hand when a $0^\circ({}^{15}\text{N})$ pulse is applied, the zero- and double-quantum term $2H_x^{\text{N}}H_y^{\alpha}$ is left unperturbed. The following $90^\circ({}^1\text{H})$ pulse converts $2H_x^{\text{N}}H_y^{\alpha}$ back into antiphase

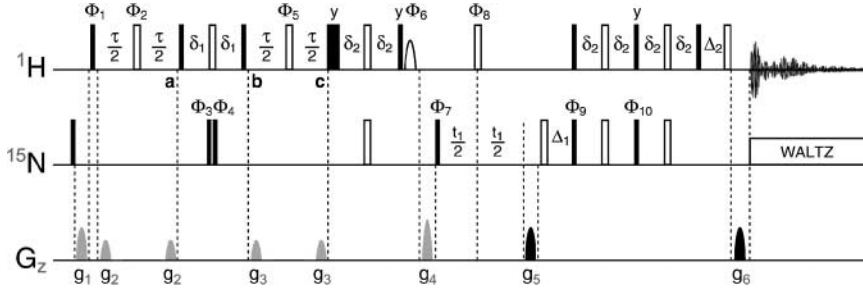

FIG. 1. ^{15}N -COSMO-HSQC pulse sequence for the determination of $^3J_{\text{HNH}\alpha}$ coupling constants in ^{15}N -labeled proteins. Black (white) rectangles are 90° (180°) pulses, the shaped pulse on ^1H is a water flip-back 90° pulse of 1.7 ms, and the large black rectangle is a 1-ms purging pulse. The total time for the build-up of cosine modulation is 2τ ($40 \text{ ms} < 2\tau < 60 \text{ ms}$), $2\delta_1 = 1/{}^1J_{\text{NHN}} = 10.7 \text{ ms}$ is the duration of the BIRD sandwich, $2\delta_2 = 1/(2{}^1J_{\text{NHN}}) = 5.4 \text{ ms}$ is the duration of the INEPT, $\Delta_1 = 1.306 \text{ ms}$ is a compensating delay for optimum phase in t_1 and $\Delta_2 = 1.154 \text{ ms}$ a compensating delay for optimum phase and intensities in t_2 . Phase cycling: $\phi_1 = x, -x$; $\phi_2 = 8(x), 8(-x)$; $\phi_3 = x$; $\phi_4 = x$ (for $180^\circ(^{15}\text{N})$) or $-x$ (for $0^\circ(^{15}\text{N})$); $\phi_5 = 16(x), 16(-x)$; $\phi_6 = -x, x$; $\phi_7 = 2(x), 2(-x)$; $\phi_8 = 4(x), 4(-x)$; $\phi_9 = 4(x), 4(-x)$; $\phi_{10} = 4(y), 4(-y)$ and $\phi_{\text{rec}} = x, -x, -x, x, -x, x, x, -x$. Gradients were either of $500 \mu\text{s}$ (g_2 and g_3) or of 1 ms (g_1, g_4, g_5 , and g_6) and of amplitude in G/cm: $g_1 = 22.5, g_2 = 1.5, g_3 = 2.5, g_4 = 35.5, g_5 = 40$, and $g_6 = \pm 4.05$ on alternate t_1 -increments for echo-antiecho phase-sensitive acquisition in the indirect dimension.

coherence and the longitudinal term H_z^{N} into transverse single quantum coherence. During the following delay τ , evolution of the coherences happens as for the first τ -period. The purge applied at the end of the delay τ (point **c** in the sequence) prevents the conversion of antiphase magnetization $2H_x^{\text{N}}H_z^{\alpha}$ by the INEPT transfer into a superposition of single- and triple-quantum coherence ($4H_y^{\text{N}}H_x^{\alpha}N_y$). After the sensitivity-enhancement scheme (16), those terms would lead to observable magnetization and distort the resulting signals in the ^{15}N -COSMO-HSQC spectra.

As a function of the angle of the ^{15}N pulse located in the middle of the BIRD sandwich, $^3J_{\text{HNH}\alpha}$ couplings are either effectively decoupled ($180^\circ(^{15}\text{N})$ pulse) or evolving for a time 2τ ($0^\circ(^{15}\text{N})$ pulse) leading to a $\cos(\pi^3J_{\text{HNH}\alpha}2\tau)$ modulation of the spectrum. In proteins, one-bond scalar couplings $^1J_{\text{NHN}}$ are relatively uniform between 91 and 94 Hz and therefore a BIRD sandwich is an efficient way to selectively invert all amide protons with minimal losses.

Neglecting relaxation, the ratio of cross-peak intensity of those two datasets is directly related to the $^3J_{\text{HNH}\alpha}$ coupling constant:

$$\frac{I^{\text{mod}}(\tau)}{I^{\text{dec}}(\tau)} = \cos(\pi^3J_{\text{HNH}\alpha}2\tau). \quad [1]$$

where I^{mod} is the intensity of a peak in the cosine modulated spectrum obtained by ^{15}N -COSMO-HSQC with a $0^\circ(^{15}\text{N})$ pulse, and I^{dec} is the intensity of a peak in the decoupled spectrum from a ^{15}N -COSMO-HSQC experiment with a $180^\circ(^{15}\text{N})$ pulse.

Any differential relaxation mechanisms affecting the signal intensities have to be considered in detail and accounted for. First, relaxation of antiphase terms is known to be affected by the spin-flip rate of the H^α and the contribution is nearly linearly proportional to the correlation time τ_c (5, 12). The antiphase component of magnetization, $2H_x^{\text{N}}H_z^{\alpha}$, will relax faster during

the preparation time 2τ than the in-phase magnetization component H_y^{N} by a relaxation rate increased by $T_{1\text{sel}} = 1/\Delta\rho$. In order to describe the evolution of magnetization during the first delay τ , the following equation has to be integrated (6, 12),

$$\frac{d}{dt} \begin{pmatrix} i(t) \\ a(t) \end{pmatrix} = \begin{pmatrix} -\rho & \pi J_{\text{true}} \\ -\pi J_{\text{true}} & -(\rho + \Delta\rho) \end{pmatrix} \begin{pmatrix} i(t) \\ a(t) \end{pmatrix}, \quad [2]$$

where $i(t)$ is the intensity of the in-phase component H_y^{N} relaxing with an auto-relaxation rate ρ , $a(t)$ is the intensity of the antiphase component $2H_x^{\text{N}}H_z^{\alpha}$ relaxing with an auto-relaxation rate $\rho + \Delta\rho$, and J_{true} is the true coupling constant that could be observed if relaxation could be neglected. The analytical solutions to Eq. [2] were given by Pongstingl and Otting (12),

$$i(t) = \left[i_0 \left(\cos(\pi J_{\text{scaled}} t) + \frac{\eta}{\sqrt{1-\eta^2}} \sin(\pi J_{\text{scaled}} t) \right) + a_0 \left(\frac{1}{\sqrt{1-\eta^2}} \sin(\pi J_{\text{scaled}} t) \right) \right] \exp \left\{ - \left(\rho + \frac{\Delta\rho}{2} \right) t \right\} \quad [3]$$

$$a(t) = \left[a_0 \left(\cos(2\pi J_{\text{scaled}} t) - \frac{\eta}{\sqrt{1-\eta^2}} \sin(\pi J_{\text{scaled}} t) \right) - i_0 \left(\frac{1}{\sqrt{1-\eta^2}} \sin(\pi J_{\text{scaled}} t) \right) \right] \exp \left\{ - \left(\rho + \frac{\Delta\rho}{2} \right) t \right\}, \quad [4]$$

where J_{scaled} is the value of the scalar coupling scaled by $T_{1\text{sel}}$ relaxation according to

$$J_{\text{scaled}} = J_{\text{true}} \sqrt{1-\eta^2} \quad [5]$$

and η is defined as:

$$\eta = \frac{\Delta\rho}{2\pi J_{\text{true}}}. \quad [6]$$

When the initial conditions are prepared to be $i(0) = -1$ and $a(0) = 0$ at a time $t = \tau$ (point **a** in the sequence), the intensities are given by:

$$i(\tau) = \left[-\cos(\pi J_{\text{scaled}}\tau) - \frac{\eta}{\sqrt{1-\eta^2}} \sin(\pi J_{\text{scaled}}\tau) \right] \times \exp\left\{-\left(\rho + \frac{\Delta\rho}{2}\right)\tau\right\} \quad [7]$$

$$a(\tau) = \frac{1}{\sqrt{1-\eta^2}} \sin(\pi J_{\text{scaled}}\tau) \exp\left\{-\left(\rho + \frac{\Delta\rho}{2}\right)\tau\right\}. \quad [8]$$

The effect of the BIRD sandwich is applied to Eqs. [7] and [8]. Neglecting relaxation during the BIRD sandwich, the $180^\circ(^{15}\text{N})$ pulse yields

$$a(\tau + 2\delta_1) = -a(\tau), \quad [9]$$

while for the $0^\circ(^{15}\text{N})$ pulse:

$$a(\tau + 2\delta_1) = a(\tau). \quad [10]$$

Applying Eqs. [3] and [4] with initial condition from point **b** in the sequence given by Eqs. [7] to [10], the final in-phase magnetization at $t = 2\tau$ for a $180^\circ(^{15}\text{N})$ pulse is given by

$$i(2\tau) = \left[\cos^2(\pi J_{\text{scaled}}\tau) + \frac{1+\eta^2}{1-\eta^2} \sin^2(\pi J_{\text{scaled}}\tau) + \frac{\eta}{\sqrt{1-\eta^2}} \sin(\pi J_{\text{scaled}}2\tau) \right] \exp\left\{-\left(\rho + \frac{\Delta\rho}{2}\right)2\tau\right\} \quad [11]$$

and for a $0^\circ(^{15}\text{N})$ pulse:

$$i(2\tau) = \left[\cos(\pi J_{\text{scaled}}2\tau) + \frac{\eta}{\sqrt{1-\eta^2}} \sin(\pi J_{\text{scaled}}2\tau) \right] \times \exp\left\{-\left(\rho + \frac{\Delta\rho}{2}\right)2\tau\right\}. \quad [12]$$

An additional relaxation effect needs to be considered: the terms present during the BIRD sandwich duration $2\delta_1$ will experience differential relaxation. The zero- and double-quantum term $2H_x^N H_y^\alpha$ will decay with a rate given by $1/T_2^{\text{ZQ/DQ}}$, which is much faster than the $1/T_1$ relaxation rate of the longitudinal term H_z^N . This can be described by a factor α defined as:

$$\alpha = \exp\left(\frac{-2\delta_1}{T_2^{\text{ZQ/DQ}}}\right). \quad [13]$$

The antiphase term $a(t)$ will be transformed as

$$a(\tau + 2\delta_1) = \alpha a(\tau), \quad [14]$$

while for the in-phase term

$$i(\tau + 2\delta_1) = i(\tau) \quad [15]$$

since during the BIRD sandwich of duration $2\delta_1$, the longitudinal

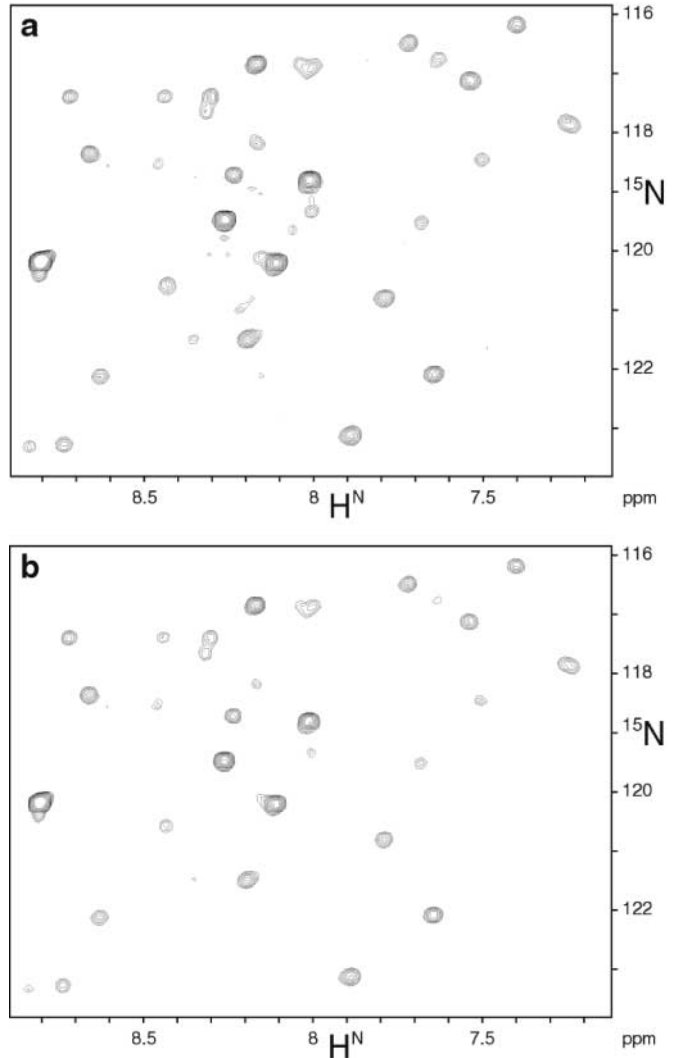

FIG. 2. ^{15}N -COSMO-HSQC spectra with $2\tau = 60$ ms for the determination of $^3J_{\text{HNH}\alpha}$ coupling constants in ^{15}N -labeled RANTES. Eight scans were acquired with 128 complex points in t_1 for a total recording time of 45 min. (a) Decoupled spectrum obtained with $\phi_4 = \phi_3$, i.e., applying a $180^\circ(^{15}\text{N})$ pulse in the middle of the BIRD sandwich. (b) Cosine-modulated spectrum obtained with $\phi_4 = -\phi_3$, i.e., applying a $0^\circ(^{15}\text{N})$ pulse in the middle of the BIRD sandwich.

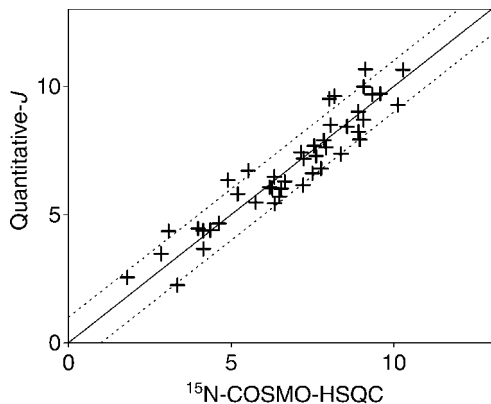

FIG. 3. Comparison of ${}^3J_{\text{HNH}\alpha}$ coupling constants in ${}^{15}\text{N}$ -labeled RANTES measured by quantitative- J and ${}^{15}\text{N}$ -COSMO-HSQC. Dotted line indicates ± 1 -Hz deviations from ideal correlation.

relaxation of H_z^{N} can safely be neglected. A relaxation time $T_2^{\text{ZQ/DQ}}$ of 20 ms yields a decrease of antiphase magnetization of about 40% for a BIRD sandwich tuned to a ${}^1J_{\text{NHN}}$ coupling of 92 Hz ($2\delta_1 = 10.9$ ms). Estimation with other $T_2^{\text{ZQ/DQ}}$ times (10 to 30 ms) yield very similar ${}^3J_{\text{HNH}\alpha}$ coupling constant values and a relaxation time of 20 ms was taken for the fitting and found to be satisfactory for a protein the size of RANTES, i.e., a homodimer of 16 kDa. As a result of the inclusion of relaxation, the magnetization components can be expressed as follows for the $180^\circ({}^{15}\text{N})$ pulse:

$$-i(2\tau) = \left[\cos^2(\pi J_{\text{scaled}}\tau) + \frac{\alpha + \eta^2}{1 - \eta^2} \sin^2(\pi J_{\text{scaled}}\tau) + \frac{\eta}{\sqrt{1 - \eta^2}} \sin(\pi J_{\text{scaled}}2\tau) \right] \exp\left\{ -\left(\rho + \frac{\Delta\rho}{2}\right)2\tau \right\} \quad [16]$$

and for the $0^\circ({}^{15}\text{N})$ pulse:

$$i(2\tau) = \left[\cos^2(\pi J_{\text{scaled}}\tau) - \frac{\alpha - \eta^2}{1 - \eta^2} \sin^2(\pi J_{\text{scaled}}\tau) + \frac{\eta}{\sqrt{1 - \eta^2}} \sin(\pi J_{\text{scaled}}2\tau) \right] \exp\left\{ -\left(\rho + \frac{\Delta\rho}{2}\right)2\tau \right\}. \quad [17]$$

Scalar coupling constants are extracted by taking the ratio of Eqs. [16] and [17],

$$\frac{I^{\text{mod}}}{I^{\text{dec}}} = \frac{\cos^2(\pi J_{\text{scaled}}\tau) - \frac{\alpha - \eta^2}{1 - \eta^2} \sin^2(\pi J_{\text{scaled}}\tau) + \frac{\eta}{\sqrt{1 - \eta^2}} \sin(\pi J_{\text{scaled}}2\tau)}{\cos^2(\pi J_{\text{scaled}}\tau) + \frac{\alpha + \eta^2}{1 - \eta^2} \sin^2(\pi J_{\text{scaled}}\tau) + \frac{\eta}{\sqrt{1 - \eta^2}} \sin(\pi J_{\text{scaled}}2\tau)}, \quad [18]$$

where I^{mod} is the intensity measured from the cosine modulated ${}^{15}\text{N}$ -COSMO-HSQC spectrum recorded with a $0^\circ({}^{15}\text{N})$ pulse in the BIRD sandwich and I^{dec} the intensity measured from the decoupled ${}^{15}\text{N}$ -COSMO-HSQC spectrum recorded with a $180^\circ({}^{15}\text{N})$ pulse in the BIRD sandwich.

The scalar couplings are directly obtained from Eq. [18] by inserting Eqs. [5], [6], and [13] into Eq. [18], which was used as such to fit the value of J_{true} . T_{1sel} was set to 100 ms (5).

The chemokine RANTES is a carbohydrate binding protein (17) involved in recruitment and activation of inflammatory leukocytes via differential attraction of CD4 + T-cells. Its structure was solved by NMR (18, 19): the protein is a homodimer at 1-mM concentration with each monomer composed of a three-stranded antiparallel β -sheet in a Greek key motif with the C-terminal α -helix packed across the sheet. ${}^3J_{\text{HNH}\alpha}$ coupling constants were determined using quantitative- J (5) and using the ${}^{15}\text{N}$ -COSMO-HSQC sequence. The decoupled ${}^{15}\text{N}$ -COSMO-HSQC spectrum is shown in Fig. 2a, while the cosine-modulated dataset is shown in Fig. 2b. For most resolved peaks, a value of the ${}^3J_{\text{HNH}\alpha}$ coupling constant could be obtained both by quantitative- J and by ${}^{15}\text{N}$ -COSMO-HSQC. Both methods give very similar results. The comparison shown in Fig. 3 indicates that the determination of ${}^3J_{\text{HNH}\alpha}$ coupling constants using the fitting function of Eq. [18] with one single uniform relaxation

FIG. 4. Comparison of ϕ angles determined from ${}^3J_{\text{HNH}\alpha}$ coupling constants in ${}^{15}\text{N}$ -labeled RANTES measured by ${}^{15}\text{N}$ -COSMO-HSQC (full circles) with the ϕ angles given by the structure published by Skelton *et al.* (19), PDB #1rtn (empty circles). The error bars represent one standard deviation of the ϕ angles ($\pm 1\sigma$) as measured in the solution structure.

rate for zero- and double-quantum terms of 20 ms is entirely satisfactory.

The values of the ${}^3J_{\text{HNH}\alpha}$ coupling constants obtained by ${}^{15}\text{N}$ -COSMO-HSQC yield structural information as can be seen by the comparison of the ϕ angles obtained using the scalar coupling values and the appropriately parametrized Karplus relationship (5),

$$J(\phi) = A \cos^2(\phi - 60) + B \cos(\phi - 60) + C, \quad [19]$$

with $A = 6.51$, $B = -1.76$, and $C = 1.60$ (5). Figure 4 shows that coupling values determined by ${}^{15}\text{N}$ -COSMO-HSQC are consistent with the NMR structure of RANTES by Skelton *et al.* (19), at the exception of K25 and K56, both of whose ϕ angles determined by ${}^{15}\text{N}$ -COSMO-HSQC fit with the angles found in the other NMR structure of RANTES by Chung *et al.* (18).

CONCLUSIONS

In this communication, a novel NMR experiment, ${}^{15}\text{N}$ -COSMO-HSQC, was presented for the measurement of ${}^3J_{\text{HNH}\alpha}$ couplings. The use of a BIRD sandwich for the selective inversion of amide protons allows an efficient homonuclear decoupling scheme whatever the chemical shift range of the amide and α -protons. Also, in contrast to the CT-HSQC-HA/HN sequences using selective H^α decoupling, no complications are expected from nonperfect offset profile and no additional pulse calibrations are requested. The ${}^{15}\text{N}$ -COSMO-HSQC experiment is highly sensitive and directly applicable to ${}^{15}\text{N}$ -labeled samples.
