The novel oxonitridoaluminosilicates (sialons)  $\text{Sr}_3\text{Ln}_{10}\text{Si}_{18}\text{Al}_{12}\text{O}_{18}\text{N}_{36}$  (Ln = Ce, Pr, Nd) were obtained by the reaction of the respective lanthanide metals with  $\text{Si}(\text{NH})_2$ ,  $\text{SrCO}_3$ , and  $\text{AlN}$  using a radiofrequency furnace at temperatures between 1550–1650 °C. The crystal structures of the isotypic sialons were determined by single-crystal X-ray investigations ( $\text{Sr}_3\text{Ce}_{10}\text{Si}_{18}\text{Al}_{12}\text{O}_{18}\text{N}_{36}$ :  $I\bar{4}3m$ ,  $Z=2$ ,  $a=1338.2(2)$  pm,  $R1=0.0333$ ;  $\text{Sr}_3\text{Pr}_{10}\text{Si}_{18}\text{Al}_{12}\text{O}_{18}\text{N}_{36}$ :  $a=1334.54(6)$  pm,  $R1=0.0296$ ;  $\text{Sr}_3\text{Nd}_{10}\text{Si}_{18}\text{Al}_{12}\text{O}_{18}\text{N}_{36}$ :  $a=1332.85(6)$  pm,  $R1=0.0271$ ) and in the case of  $\text{Sr}_3\text{Pr}_{10}\text{Si}_{18}\text{Al}_{12}\text{O}_{18}\text{N}_{36}$  with powder neutron diffraction as well. The three-dimensional sialon network is built up by  $\text{SiON}_3$ ,  $\text{SiN}_4$ , and  $\text{AlON}_3$  tetrahedra. Besides the bridging O and N atoms of the sialon network there are isolated  $\text{O}^{2-}$  which are tetrahedrally coordinated by Sr and Ln. The crystallographic differentiation of Si/Al and O/N seemed to be possible by a careful evaluation of the single-crystal X-ray diffraction data combined with lattice energy calculations using the MAPLE concept (Madelung Part of Lattice Energy). In the case of  $\text{Sr}_3\text{Pr}_{10}\text{Si}_{18}\text{Al}_{12}\text{O}_{18}\text{N}_{36}$  the differentiation of O and N and the proposed ordering was completely confirmed by powder neutron diffraction.

## 1 Introduction

Oxonitridoaluminosilicates (sialons) are excellent materials due to their high mechanical hardness and strength, and their exceptional thermal and chemical stability.<sup>1–3</sup> The first members of this class of compound have been synthesised by the reaction of  $\text{Si}_3\text{N}_4$  and  $\text{Al}_2\text{O}_3$ .<sup>4–6</sup> The crystallographic structures of these sialons derive from those of  $\alpha$ - and  $\beta$ - $\text{Si}_3\text{N}_4$ . Therefore, these sialons have been called  $\alpha$ - or  $\beta$ -sialons, respectively. In the meantime sialons have been synthesised which are structurally related to oxygen containing compounds like melilite (M-phase), apatite (H-Phase), or wollastonite (K-phase).<sup>7</sup> Concerning their solid-state chemistry most of these compounds have been only insufficiently characterised. Detailed structural information was missing as single-crystal data only for one compound, the so called Nd-U-phase, has been obtained.<sup>8–13</sup>

Our synthetic approach using a radiofrequency (rf) furnace and silicon diimide and metals as starting compounds led to a considerable number of novel nitridosilicates.<sup>14,15</sup> This synthetic strategy has now been successfully transferred to the synthesis of new oxonitridoaluminosilicates (sialons) and oxonitridosilicates (sions), namely  $\text{SrSiAl}_2\text{O}_3\text{N}_2$ ,<sup>16</sup>  $\text{SrErSiAl}_3\text{O}_3\text{N}_4$ ,<sup>17</sup>  $\text{Sm}_2\text{Si}_3\text{O}_3\text{N}_4$  and  $\text{Ln}_2\text{Si}_{2.5}\text{Al}_{0.5}\text{O}_{3.5}\text{N}_{3.5}$  (Ln = Ce, Pr, Nd, Sm, Gd),<sup>18</sup>  $\text{Nd}_3\text{Si}_5\text{AlON}_{10}$ ,<sup>19</sup> and most recently  $\text{Ce}_{16}\text{Si}_{15}\text{O}_6\text{N}_{32}$ .<sup>20,21</sup>

A specific problem during the structural characterisation of the sialons and sions arises from the question, whether the Si/Al and O/N atoms, respectively, are crystallographically ordered. And if they are ordered, how this ordering can be exactly proved.  $\text{Si}^{4+}/\text{Al}^{3+}$  and  $\text{O}^{2-}/\text{N}^{3-}$ , respectively, have very similar atomic form factors. Therefore X-ray diffraction

methods are not reliable for their differentiation and neutron diffraction experiments have to be performed.

In this paper we present the new sialons  $\text{Sr}_3\text{Ln}_{10}\text{Si}_{18}\text{Al}_{12}\text{O}_{18}\text{N}_{36}$  (Ln = Ce, Pr, Nd). These compounds are the first representatives of a new structure type. The ordering of the Si/Al and O/N atoms, respectively, was determined by X-ray single-crystal investigations, lattice energy calculations using the MAPLE concept and in the case of  $\text{Sr}_3\text{Pr}_{10}\text{Si}_{18}\text{Al}_{12}\text{O}_{18}\text{N}_{36}$  by neutron powder diffraction.

## 2 Experimental procedure

The synthetic procedure using a radiofrequency furnace for the high-temperature syntheses has been developed primarily in our laboratory for the preparation of nitridosilicates. We now have adopted this method for the synthesis of several new sialons and sions. Details of the experimental setup are given in ref. 17. As starting materials for the preparation of  $\text{Sr}_3\text{Ln}_{10}\text{Si}_{18}\text{Al}_{12}\text{O}_{18}\text{N}_{36}$  (Ln = Ce, Pr, Nd) we used silicon diimide ( $\text{Si}(\text{NH})_2$ ),  $\text{AlN}$ ,  $\text{SrCO}_3$  (Merck, p.a.), and the powdered metals Ce, Pr, or Nd (ABCR, purity 99.9%), respectively.

### 2.1 Synthesis of silicon diimide ( $\text{Si}(\text{NH})_2$ )

Using  $\text{Si}(\text{NH})_2$  instead of the relatively unreactive  $\text{Si}_3\text{N}_4$  as the starting material proved to be advantageous for the synthesis of the nitridosilicates and this also holds for the sialons.<sup>14,15</sup>  $\text{Si}(\text{NH})_2$  was obtained by ammonolysis of  $\text{SiCl}_4$  in  $\text{CH}_2\text{Cl}_2$  followed by a thermal treatment at 600 °C under an atmosphere of pure  $\text{NH}_3$  [eqn. (1)].

A detailed description of the synthesis of Si(NH)<sub>2</sub> is given in ref. 22. Si(NH)<sub>2</sub> was yielded as an X-ray amorphous and relatively undefined but reactive product which is converted to amorphous Si<sub>3</sub>N<sub>4</sub> at temperatures above 900 °C. It is an important precursor for the technical production of Si<sub>3</sub>N<sub>4</sub> ceramics.<sup>22</sup>

## 2.2 Synthesis of aluminium nitride

Single-phase and crystalline AlN was obtained by the reaction of Al (purity >99%, Fluka) in a continuous stream of nitrogen (purity 5.0, Linde). Five reaction cycles of 2 h each at 900 °C (heating rate 1 °C min<sup>-1</sup>, cooling rate 20 °C min<sup>-1</sup>) with subsequent grinding of the sintered product were performed. IR-spectroscopic investigations excluded the presence of N–H groups in the product. Furthermore the purity was checked by X-ray powder diffraction.

## 2.3 Synthesis of the sialons Sr<sub>3</sub>Ln<sub>10</sub>Si<sub>18</sub>Al<sub>12</sub>O<sub>18</sub>N<sub>36</sub> (Ln = Ce, Pr, Nd)

The sialons Sr<sub>3</sub>Ln<sub>10</sub>Si<sub>18</sub>Al<sub>12</sub>O<sub>18</sub>N<sub>36</sub> (Ln = Ce, Pr, Nd) were obtained by high-temperature reaction of SrCO<sub>3</sub>, Si(NH)<sub>2</sub>, AlN, and the respective powdered lanthanide metals Ce, Pr, and Nd using an rf furnace. Under an atmosphere of pure argon the respective starting compounds were placed in a tungsten crucible which was positioned in the centre of the induction coil of an rf furnace. The reaction was then performed under a pure atmosphere of nitrogen (purified by silica gel, potassium hydroxide, molecular sieve, P<sub>4</sub>O<sub>10</sub>, and a BTS catalyst). The compositions of the starting compounds and the respective reaction conditions are summarised in Tables 1 and 2.

The sialons Sr<sub>3</sub>Ln<sub>10</sub>Si<sub>18</sub>Al<sub>12</sub>O<sub>18</sub>N<sub>36</sub> (Ln = Ce, Pr, Nd) were yielded as coarsely crystalline materials. In the case of the Pr compound the average yield was nearly 75%. For the Ce and the Nd compounds the yields range between 30–40%. As by-products the individually coloured N-containing melilites<sup>18</sup> were obtained. Furthermore X-ray amorphous strontium-rich sialons were observed. The title compounds can easily be separated from their by-products due to their differing colour and the crystal habit (Fig. 1). Each of the sialons Sr<sub>3</sub>Ln<sub>10</sub>Si<sub>18</sub>Al<sub>12</sub>O<sub>18</sub>N<sub>36</sub> (Ln = Ce, Pr, Nd) shows a specific colour: Ce: orange, Pr: dark green, Nd: blue violet. The materials are very hard (see hardness investigations later), scratching agate while grinding.

The compositions of the products were analysed by energy-dispersive X-ray microanalysis (JEOL, JSM 6400, Institute of Materials Research, University of Bayreuth, Germany). The analyses revealed the molar ratios of Sr, Ln, Si, Al, O, and N (Ln = Ce, Pr, Nd) as theoretically expected. Additionally, the amount of nitrogen was checked by photometric determination after digestion of the compounds by microwave treatment using a matrix of conc. H<sub>2</sub>SO<sub>4</sub>, aqueous conc. HF, and aqueous conc. H<sub>2</sub>O<sub>2</sub> in a volume proportion of 5 : 1 : 1. The absence of hydrogen (N–H) in the reaction products was proved by IR spectroscopy. The title compounds exhibit great chemical and

thermal stability. They are stable up to more than 1700 °C and they are resistant against hot acid and alkaline solutions.

## 3 Crystal structure analysis and lattice energy calculations

X-Ray diffraction data of the title compounds were collected on a four-circle diffractometer (Siemens P4). According to the observed extinction conditions of the cubic lattice (only reflections *hkl* with *h+k+l=2n* and *h00* with *h=2n*) the space groups *I23*, *I213*, *Im3*, *I432*, *I43m*, and *Im3m* were considered. The structure solution and refinement was only possible choosing space group *I43m* (no. 217). The crystal structures of Sr<sub>3</sub>Ln<sub>10</sub>Si<sub>18</sub>Al<sub>12</sub>O<sub>18</sub>N<sub>36</sub> (Ln = Ce, Pr, Nd) were solved by direct methods using SHELXTL<sup>23</sup> and refined with anisotropic displacement parameters for all atoms. Furthermore all reflections detected by X-ray powder diffraction (Siemens D5000) of single-phase Sr<sub>3</sub>Ln<sub>10</sub>Si<sub>18</sub>Al<sub>12</sub>O<sub>18</sub>N<sub>36</sub> (Ln = Ce, Pr, Nd) have been indexed and their observed intensities are in good agreement with the calculated diffraction patterns based on the single-crystal data. The relevant crystallographic data and further details of the X-ray data collection are summarised in Tables 3–5. Table 6 shows the positional and displacement parameters for all atoms. In Table 7 selected interatomic distances and angles are listed.

Due to their identical electronic configuration and their very similar atomic form factors the unequivocal differentiation of N<sup>3-</sup>/O<sup>2-</sup> and Al<sup>3+</sup>/Si<sup>4+</sup>, respectively, by X-ray diffraction methods is not reliable. We therefore refined an approach leading to the differentiation of N/O and Al/Si, respectively, by a careful examination of the single-crystal X-ray diffraction data combined with lattice energy calculations using the MAPLE concept (MAPLE = Madelung Part of Lattice Energy).<sup>24–26</sup>

On the other hand neutron diffraction is an excellent tool for the differentiation of O and N because their scattering lengths differ significantly (*b*(N) = 9.36 × 10<sup>-15</sup> m, *b*(O) = 5.803 × 10<sup>-15</sup> m).<sup>27</sup> However, it is much more difficult to discriminate between Al<sup>3+</sup> and Si<sup>4+</sup> due to their more similar scattering lengths (*b*(Al) = 3.449 × 10<sup>-15</sup> m, *b*(Si) = 4.149 × 10<sup>-15</sup> m).<sup>27</sup> In the case of Sr<sub>3</sub>Pr<sub>10</sub>Si<sub>18</sub>Al<sub>12</sub>O<sub>18</sub>N<sub>36</sub> we were able to synthesise a sufficient amount to perform neutron powder diffraction. For the diffraction experiments the time-of-flight method (TOF) was used. About 250 mg of the pure sample were enclosed into a vanadium cylinder. The investigation was performed both at the POLARIS instrument of the ISIS/Rutherford Appleton Laboratory, Chilton, UK, and the D2B beamline at the Institute Laue Langevin (ILL), Grenoble, France, which permits the measurement of relatively small samples due to high flux. The Rietveld refinement was performed with the program GSAS<sup>28</sup> using the single-crystal X-ray data of Sr<sub>3</sub>Pr<sub>10</sub>Si<sub>18</sub>Al<sub>12</sub>O<sub>18</sub>N<sub>36</sub> as a starting model. The results of the Rietveld refinement of the neutron diffraction data are shown in Fig. 2, the details of the final refinement are listed in Table 8. Both structure refinements gave similar atomic coordinates and displacement parameters. Initially Si/Al and O/N were located on the same crystallographic positions, respectively, and their occupation factors were dependently refined. An unequivocal discrimination between

O and N was possible and the results match exactly the O/N distribution obtained by the single-crystal X-ray structure determination and the MAPLE calculations. According to the refined occupancy factors (Table 8) which are unity within twice the standard deviations full crystallographic ordering of O and N sites was proved. Due to their similar scattering lengths of Al<sup>3+</sup> and Si<sup>4+</sup> (see above) the free refinement of their occupancy factors was not possible on the basis of the obtained neutron diffraction data. However an iterative MAPLE calculation on the basis of the O/N sites determined by neutron diffraction yielded strong evidence for the crystallographic ordering of Al and Si (Table 9).

For the exact differentiation of Si/Al and O/N, respectively, we performed lattice energy calculations using the MAPLE concept. As a result of these calculations each atom in a crystal structure has a particular range of partial MAPLE values

**Fig. 2** Observed (crosses) and calculated (line) TOF neutron diffraction pattern as well as the difference profile of the Rietveld refinement. The lower row of vertical lines indicates possible peak positions of Sr<sub>3</sub>Pr<sub>10</sub>Si<sub>18</sub>Al<sub>12</sub>O<sub>18</sub>N<sub>36</sub> (upper row: vanadium of the sample container; middle row: AlN impurities).

(Si<sup>4+</sup>: 9100–10200 kJ mol<sup>-1</sup>, Al<sup>3+</sup>: 5500–6000 kJ mol<sup>-1</sup>, O<sup>2-</sup>: 1870–3300 kJ mol<sup>-1</sup>, N<sup>3-</sup>: 5000–6200 kJ mol<sup>-1</sup>) assigned. The ranges are characteristic for the concerned elements. Atoms on a specific site which have been assigned to a wrong atom type (e.g. Si instead of Al or O instead of N) normally exhibit a partial MAPLE value, which significantly differs from the characteristic range. These effects indicate a wrong occupation of the concerned crystallographic site (Table 9).

#### 4 Results and discussion of the structure refinements

The sialons Sr<sub>3</sub>Ln<sub>10</sub>Si<sub>18</sub>Al<sub>12</sub>O<sub>18</sub>N<sub>36</sub> (Ln = Ce, Pr, Nd) are the first representatives of a new structure type. In the solid the structure consists of a three-dimensional network of corner sharing SiO<sub>4</sub>, AlO<sub>4</sub>, and Si<sub>3</sub>N<sub>4</sub> tetrahedra (all Q<sup>4</sup> type). According to Pauling's rules<sup>29</sup> in sialons and sialons nitrogen normally prefers sites in which the N atoms in comparison with the O atoms are directly bound to the same or a higher number of neighbouring Si or Al atoms.<sup>17</sup> Therefore, the N atoms in Sr<sub>3</sub>Ln<sub>10</sub>Si<sub>18</sub>Al<sub>12</sub>O<sub>18</sub>N<sub>36</sub> (Ln = Ce, Pr, Nd) are connecting two (N<sup>[2]</sup>) or three tetrahedral centres (N<sup>[3]</sup>) while the oxygen atoms are only connecting two (O<sup>[2]</sup>) of them or they are isolated (O<sup>[0]</sup>). According to the formula Sr<sub>3</sub>Ln<sub>10</sub>[Si<sub>18</sub>Al<sub>12</sub>O<sub>12</sub>N<sub>36</sub>]O<sub>6</sub> the

**Fig. 3** Double three-rings of SiO<sub>3</sub> (black) and AlO<sub>3</sub> tetrahedra (grey) are the characteristic building blocks of the  $\frac{3}{2}[(\text{Si}_{18}^{[4]}\text{Al}_{12}^{[4]}\text{O}_{12}^{[2]}\text{N}_{12}^{[3]})]$  network in Sr<sub>3</sub>Ln<sub>10</sub>Si<sub>18</sub>Al<sub>12</sub>O<sub>18</sub>N<sub>36</sub> (Ln = Ce, Pr, Nd).

title compounds may be described as strontium lanthanoid oxonitridoaluminosilicate oxides.

The mean bond lengths from the tetrahedral centres T (T = Si, Al) show a significant differentiation T–N > T–O and Si–N<sup>[3]</sup> > Si–N<sup>[2]</sup> (Si–N<sup>[2]</sup>: 170.2(8)–172.4(4) pm; Si–N<sup>[3]</sup>: 173.9(6)–176.5(4) pm; Al–N<sup>[3]</sup>: 177.8(6)–179.5(5) pm; Si–O<sup>[2]</sup>: 166.1(6)–168.2(8) pm; Al–O<sup>[2]</sup>: 170.5(4)–171.1(6) pm). The bond angles at the N<sup>[2]</sup> atoms are in the range 111.6(4)–112.2(5)°, for the O<sup>[2]</sup> atoms in the range 161.8(3)–162.2(5)°. The sums of the bond angles at the N<sup>[3]</sup> atoms amount to 356–358°. The molar ratio T : X (T = Si, Al; X = O, N) for the Si–Al–

O–N network of Sr<sub>3</sub>Ln<sub>10</sub>Si<sub>18</sub>Al<sub>12</sub>O<sub>18</sub>N<sub>36</sub> (Ln = Ce, Pr, Nd) amounts to 0.63. Accordingly these sialons may be classified as highly condensed (*i.e.* they exhibit a degree of condensation T : X > 0.5, which is the maximum value of pure oxosilicates).

Typical of the crystal structure are double three-rings of three SiO<sub>3</sub> and three AlO<sub>3</sub> tetrahedra. Within these units each SiO<sub>3</sub> is connected to a AlO<sub>3</sub> tetrahedron through an O atom. Thus within the double three-ring the bridges Si–N–Si, Al–N–Al, and Al–O–Si occur (Fig. 3). The Si<sub>3</sub>N<sub>3</sub> and Al<sub>3</sub>N<sub>3</sub> rings of these units exhibit the chair conformation, the resulting four-rings Al<sub>2</sub>Si<sub>2</sub>N<sub>2</sub>O<sub>2</sub> the saddle conformation. Furthermore,

the double three-rings are connected via SiN<sub>4</sub> tetrahedra forming a three dimensional network  $^3[(\text{Si}_{18}^{[4]}\text{Al}_{12}^{[4]}\text{O}_{12}^{[2]}\text{N}_{12}^{[2]}\text{N}_{24}^{[3]})]$  (Fig. 4).

Among the O<sup>[2]</sup>, N<sup>[2]</sup>, and N<sup>[3]</sup> atoms, which are bridging two or three tetrahedral centres there are (O<sup>[0]</sup>)<sup>2-</sup> ions which are not directly bound to Si or Al. These O(2) ions are tetrahedrally coordinated by four metal cations. A free refinement of the respective site occupation factors revealed that the respective

metal positions are statistically occupied by Ln<sup>3+</sup> and Sr<sup>2+</sup> with a molar ratio 5 : 1. The exact site occupation factors gave a ratio of 0.415(15) : 0.085(15), which is very similar to the ratio of 0.417 : 0.083 calculated from the idealised stoichiometric formulae. In spite of this accordance a certain phase width cannot be excluded. Charge compensation by variation not only of the O/N ratio but also of the Al/Si ratio would be possible. However, in accordance with the powder neutron

## 5 Single-crystal hardness investigations of $\text{Sr}_3\text{Pr}_{10}\text{Si}_{18}\text{Al}_{12}\text{O}_{18}\text{N}_{36}$

For the first time we performed hardness investigations on sialon single crystals. The usual method to determine the hardness of small single crystals (edge lengths 0.3 mm) is the Vickers method. Isolated single crystals of  $\text{Sr}_3\text{Pr}_{10}\text{Si}_{18}\text{Al}_{12}\text{O}_{18}\text{N}_{36}$  were merged for adjustment into a cylindrically formed polymer matrix (diameter: 2 cm). As test load 0.1 N and a time interval of 30 s as suitable parameters were chosen. The hardness investigations (nine independent measurements) exhibit an averaged Vickers hardness for  $\text{Sr}_3\text{Pr}_{10}\text{Si}_{18}\text{Al}_{12}\text{O}_{18}\text{N}_{36}$  single crystals of 22.0 GPa. The measured hardness value of  $\text{Sr}_3\text{Pr}_{10}\text{Si}_{18}\text{Al}_{12}\text{O}_{18}\text{N}_{36}$  is in the same range as the highest known values for sintered polycrystalline  $\alpha$ -sialons<sup>30–33</sup> and  $\alpha$ -Al<sub>2</sub>O<sub>3</sub>.<sup>34</sup>

Recently, we obtained the oxonitridosilicate oxide  $\text{Ce}_4[\text{Si}_4\text{O}_4\text{N}_6]\text{O}$ , which contains a hyperbolically layered structure of Q<sup>3</sup> type SiON<sub>3</sub> tetrahedra and tetrahedral  $[\text{Ce}_4\text{O}]^{10+}$  ions. The differentiation of O and N was possible by lattice energy calculations with the MAPLE concept and it was confirmed by powder neutron diffraction.<sup>35</sup>

## Acknowledgements

The preparative work of this publication was done at the Laboratory of Inorganic Chemistry, University of Bayreuth, Germany. The authors thank Bernd Putz for his helpful support during the practical work, the Institute of Materials Research, University of Bayreuth, for the help during the X-ray microanalyses and the hardness investigations. Furthermore, special thanks are owed to Dr. Thomas Hansen, Institute Laue Langevin, Grenoble, for his help during the neutron diffraction experiments.

This work was supported by the Fonds der Chemischen Industrie and especially by the Deutsche Forschungsgemeinschaft (Schwerpunktprogramm "Nitridobrücken" and Gottfried-Wilhelm-Leibniz-Programm).
