# Transmission electron microscopy on the microstructure of 7050 aluminium alloy in the T74 condition 

JIN YAN, LI CHUNZHI, YAN MINGGAO<br>Institute of Aeronautical Materials, Beijing 100095, People's Republic of China

#### Abstract

The microstructure of 7050 aluminium alloy in the T74 condition has been investigated by transmission electron microscopy. It was found that the alloy contains the superlattice $\mathrm{Al}_{3} \mathrm{Zr}$ phase, $\eta^{\prime}$ phase and $\mathrm{Al}_{7} \mathrm{Cu}_{2} \mathrm{Fe}$ constituent phase. The $\eta^{\prime}$ phase is proposed to have an orthorhombic crystal structure with $a=0.492 \mathrm{~nm}, b=0.852 \mathrm{~nm}$ and $c=0.701 \mathrm{~nm}$. The orientation relationship between the matrix and $\eta^{\prime}$ phase is $\left[\begin{array}{lll}11-2\end{array}\right]_{\mathrm{m}} / /\left[\begin{array}{lll}1 & 0 & 0\end{array}\right]_{\eta^{\prime}} ;\left[\begin{array}{lll}1 & -10\end{array}\right]_{\mathrm{m}} / /\left[\begin{array}{lll}0 & 1 & 0\end{array}\right]_{\eta^{\prime}}$; $\left[\begin{array}{lll}-1 & -1 & -1\end{array}\right]_{\mathrm{m}} / /\left[\begin{array}{lll}0 & 1\end{array}\right]_{\eta^{\prime}}$. The phases on the small-angle grain boundary are found to be mainly $\eta^{\prime}$ phase and $\mathrm{Cu} / \mathrm{Si}$-rich phase, whereas on the large-angle grain boundary there is only $\eta$ phase.

## 1. Introduction

7050 aluminium ( Al ) alloy is one of the most popular age-hardenable $\mathrm{Al}-\mathrm{Zn}-\mathrm{Mg}$ alloys. Therefore, an investigation of its microstructure after various heat treatments is necessary.

There are two kinds of $\mathrm{Al}_{3} \mathrm{Zr}$ phase: stable $\mathrm{Al}_{3} \mathrm{Zr}$ phase and metastable $\mathrm{Al}_{3} \mathrm{Zr}$ phase. The stable $\mathrm{Al}_{3} \mathrm{Zr}$ phase has a tetragonal crystal structure with $a=0.6066 \mathrm{~nm}, c=0.4874 \mathrm{~nm}$ and space group $\mathrm{I} 4 / \mathrm{mmm}$ [1]. The metastable $\mathrm{Al}_{3} \mathrm{Zr}$ phase has an $\mathrm{A}_{3} \mathrm{~B}-$ type superlattice structure [2]. It has been proved that only the superlattice $\mathrm{Al}_{3} \mathrm{Zr}$ can produce the function of grain refinement [3, 4].
$\eta^{\prime}$ phase is the most important age-hardenable precipitate in $\mathrm{Al}-\mathrm{Zn}-\mathrm{Mg}$ alloys. There are now three different views about its structure: (1) Mondolfo et al. proposed that the $\eta^{\prime}$ phase has a hexagonal structure with $a=0.496 \mathrm{~nm}$ and $c=0.868 \mathrm{~nm}$. The orientation relationship between matrix and the $\eta^{\prime}$ phase is $(10,0)_{\eta^{\prime}} / /(110)_{\mathrm{m}},[00,1]_{\eta^{\prime}} / /[111]_{\mathrm{m}}[5,6]$; (2) Graf and colleagues suggested that the $\eta^{\prime}$ phase has a hexagonal structure with $a=0.496 \mathrm{~nm}$ and $c=1.403 \mathrm{~nm}$. The orientation relationship is similar to that in View 1 [7-11]; (3) Gjonnes and Simenson held that the $\eta^{\prime}$ phase has a monoclinic structure with $a=0.497 \mathrm{~nm}, c$ $=0.544 \mathrm{~nm}$ and $\gamma=120^{\circ}$. The orientation relationship between matrix and the $\eta^{\prime}$ phase is $(001)_{\eta^{\prime}} / /(1$ $-11)_{m},(100)_{\eta^{\prime}} /(110)_{m}[12]$.
The $\eta\left(\mathrm{MgZn}_{2}\right)$ phase has a hexagonal crystal structure with $a=0.521 \mathrm{~nm}$ and $c=0.860 \mathrm{~nm}$, and space group $\mathrm{P}_{3} / \mathrm{mmc}$. It has been reported that the $\eta$ phase has nine different orientation relationships with the matrix [13-15].

The alloy studied may contain various kinds of constituent phase. But the dominant one may be the $\mathrm{Al}_{7} \mathrm{Cu}_{2} \mathrm{Fe}$ phase. It has been proposed by several authors that the $\mathrm{Al}_{7} \mathrm{Cu}_{2} \mathrm{Fe}$ phase has a tetragonal
crystal structure with $a=0.6336 \mathrm{~nm}, c=1.487 \mathrm{~nm}$, and space group $\mathrm{P} 4 / \mathrm{mnc}$ [16-18].

The grain-boundary (GB) structure and grainboundary phase (GBP) are now believed to have a profound effect on the stress corrosion properties of the $\mathrm{Al}-\mathrm{Zn}-\mathrm{Mg}$ alloys. The precipitate-free-zone (PFZ) is the GB phenomena that was studied earliest [19, 20]. The interest of researchers is now mainly on the GBP and its relationship with stress corrosion cracking of the alloys. Rao [21] proposed that there is a $\mathrm{Cu} /$ Si-rich phase on the GB; Park and Ardell [22] suggested that only $\eta$ GBP forms on large-angle GBs.

In the present work, the microstructure of AA7050-T74 was studied by transmission electron microscopy. The various phases in the alloy were identified. The GB structure and GBP were also investigated.

## 2. Experimental procedure

The alloy studied was laboratory-melt-made to the specification of 7050 Al alloy. The chemical composition ( $\mathrm{wt} \%$ ) of the experimental alloy was 6.20 Zn , $2.28 \mathrm{Mg}, 2.30 \mathrm{Cu}, 0.08 \mathrm{Zr}$ and 0.033 Ti . The specimens were heat-treated in the T74 condition.

The samples for observation were prepared by conventional jet-polishing techniques. The electrolyte contained one part of $\mathrm{HNO}_{3}$ and three parts of $\mathrm{NH}_{3} \mathrm{OH}$ (by volume). Observations were performed in an H-800 transmission electron microscope. The accelerating voltage was 200 kV . The method for selected-area diffraction (SAD) pattern analysis was proposed by Li Chunzhi and Yan Minggao [23]. The software for dynamical diffraction simulation was provided by the Beijing Laboratory of Electron Microscopy.

Figure 1 SAD patterns of $\mathrm{Al}_{3} \mathrm{Zr}$ and $\eta^{\prime}$ phases for (a) $[001]_{\mathrm{m}}$, (b) $\left[\begin{array}{lll}0 & 1 & 1\end{array}\right]_{\mathrm{m}}$ and (c) $\left[\begin{array}{lll}1 & 1 & 2\end{array}\right]_{\mathrm{m}}$.

## 3. Results and discussion

## 3.1. $\mathrm{Al}_{3} \mathrm{Zr}$ phase

Fig. $1 \mathrm{a}, \mathrm{b}$ and c are the SAD patterns of $\mathrm{Al}_{3} \mathrm{Zr}$ phase and $\eta^{\prime}$ phase for $[001]_{\mathrm{m}},\left[\begin{array}{lll}0 & 1 & 1\end{array}\right]_{\mathrm{m}}$ and $\left[\begin{array}{lll}1 & 1 & 2\end{array}\right]_{\mathrm{m}}$, respectively. There are three types of diffraction spot on the photograph: Type A are those of the matrix, which have the maximum intensity; Type $\mathbf{B}$ those of the $\mathrm{Al}_{3} \mathrm{Zr}$ phase which has an $\mathrm{A}_{3} \mathrm{~B}$-type superlattice structure; Type C those of $\eta^{\prime}$ phase, which are rather weak and diffusive. In Fig. 2c, the diffraction spots of $\eta^{\prime}$ phase are elongated along and perpendicular to $\left[\begin{array}{ll}-1 & -11\end{array}\right]_{\mathrm{m}^{*}}$ direction.

Fig. 2 shows the dark-field image of $\mathrm{Al}_{3} \mathrm{Zr}$ phase. It appears elliptical with maximum size 50 nm . This is a little different from previous opinions that the $\mathrm{Al}_{3} \mathrm{Zr}$ phase is sphere-like.

Figure 2 Dark-field image of $\mathrm{Al}_{3} \mathrm{Zr}$ phase.

In order to clarify further the crystal structure of $\mathrm{Al}_{3} \mathrm{Zr}$ phase in the alloy, a dynamical diffraction simulation was undertaken. Fig. 3 shows the crystal structure model of superlattice $\mathrm{Al}_{3} \mathrm{Zr}$ phase. Fig. 4 c and $d$ are the simulated dynamical diffraction patterns of $\mathrm{Al}_{3} \mathrm{Zr}$ phase for [001] and [011] directions, according to the model in Fig. 3. Fig. $4 a$ and $b$ are the simulated dynamical diffraction patterns of the matrix for [ 001 1] and [ 0111 ] directions. Compared with Fig. 1, the overlapping pattern of Fig. 4a and c conforms well with the observed pattern in Fig. 1a. The overlapping pattern of Fig. 4b and d also conforms well with the observed pattern in Fig. 1b. Thus it is further proved that the $\mathrm{Al}_{3} \mathrm{Zr}$ phase in the alloy is metastable $\mathrm{Al}_{3} \mathrm{Zr}$ superlattice phase.

## 3.2. $\eta^{\prime}$ phase

Fig. 5 shows the dark-field image of $\eta^{\prime}$ phase. The electron beam is incident in the $\left[\begin{array}{lll}1 & 1 & 2\end{array}\right]_{\mathrm{m}}$ direction. The $\eta^{\prime}$ phase appears to be plate-like and has two directions of growth, parallel or perpendicular to ( -1 $-11)_{\mathrm{m}}$ (designated A and B, respectively). This agrees with the results in Fig. 1c. However, it was found that the above three SAD patterns of $\eta^{\prime}$ phase in Fig. 1 could not be indexed precisely, according to Views 1, 2 or 3 . Therefore, a better description of $\eta^{\prime}$ phase must be sought.

By means of the conventional method of choosing a two-dimensional reciprocal unit cell, the corresponding parameters of the SAD patterns of $\eta^{\prime}$ phase in Fig. 1 have been measured and are given in Table I, where $\boldsymbol{R}_{1}$ and $\boldsymbol{R}_{2}$ are the shortest and second-shortest reciprocal vectors, respectively, $\theta$ is the angle between

| Phase | Structure | Parameter (nm) | Axis | $\begin{aligned} & \widehat{\boldsymbol{A}_{1} \boldsymbol{A}_{2}} \\ & \text { (deg) } \end{aligned}$ | $\begin{aligned} & \widehat{\boldsymbol{A}_{2} \boldsymbol{A}_{3}} \\ & \text { (deg) } \end{aligned}$ | $\begin{aligned} & \widehat{\boldsymbol{A}_{3} \boldsymbol{A}_{1}} \\ & (\mathrm{deg}) \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| matrix | fcc | $a=0.405$ | $\begin{aligned} & A_{1}=\left[\begin{array}{lll} 0 & 0 & 1 \end{array}\right] \\ & A_{2}=\left[\begin{array}{lll} 0 & 1 & 1 \end{array}\right] \\ & A_{3}=\left[\begin{array}{lll} 1 & 1 & 2 \end{array}\right] \end{aligned}$ | 45.0 | 30.0 | 35.3 |
| $\eta^{\prime}$ | Orth. | $\begin{aligned} & a=0.492 \\ & b=0.852 \\ & c=0.701 \end{aligned}$ | $\begin{aligned} & A_{1}=\left[\begin{array}{lll} 2 & 0 & 1 \end{array}\right] \\ & A_{2}=\left[\begin{array}{lll} 1 & 1 & 2 \end{array}\right] \\ & A_{3}=\left[\begin{array}{lll} 1 & 0 & 2 \end{array}\right] \end{aligned}$ | 44.8 | 29.8 | 35.1 |

Figure 6 Indexed patterns corresponding to the SAD patterns of $\eta^{\prime}$ phase in Fig. 1.

Figure 7 Bright-field image of constituent phase.
from the previous opinions. Table II shows the calculated values corresponding to Fig. 1. A comparison of Tables I and II reveals a good conformance.

Because the $\eta^{\prime}$ phase has a definite orientation relationship with the matrix, the reciprocal planes of $\eta^{\prime}$ phase in Table II must also be parallel to the corresponding planes of the matrix, in addition to the agreement between each plane. Therefore, the angles between the reciprocal planes of $\eta^{\prime}$ phase in Table II must be equal to those of the matrix. Table III shows the values of the angles between $\left[\begin{array}{llll}0 & 1\end{array}\right]_{\mathrm{m}},\left[\begin{array}{lll}0 & 1 & 1\end{array}\right]_{\mathrm{m}}$, $\left[\begin{array}{lll}1 & 1 & 2\end{array}\right]_{\mathrm{m}}$, and the angles between $[201]_{\eta^{\prime}},\left[\begin{array}{lll}1 & 1 & 2\end{array}\right]_{\eta^{\prime}}$, $\left[\begin{array}{lll}1 & 0 & 2\end{array}\right]_{n^{\prime}}$. The results reveal that these also have a good agreement. Thus the SAD patterns in Fig. 1 can be indexed. The results are shown in Fig. 6. The orienta-

Figure 9 Indexed patterns corresponding to Fig. 8.
tion relationships between the matrix and the $\eta^{\prime}$ phase in the above directions are
a $\quad(2-20)_{\mathrm{m}} / /(020)_{\eta^{\prime}} ;[001]_{\mathrm{m}} / /[-20-1]_{\eta^{\prime}}$
b $\quad(0-22)_{\mathrm{m}} / /(-110)_{\eta^{\prime}} ;\left[\begin{array}{lll}0 & 1 & 1\end{array}\right]_{\mathrm{m}} / /\left[\begin{array}{lll}-1 & -1 & -2\end{array}\right]_{\eta^{\prime}}$
c $\quad(2-20)_{\mathrm{m}} / /(020)_{\eta^{\prime}} ;\left[\begin{array}{lll}1 & 1 & 2\end{array}\right]_{\mathrm{m}} / /\left[\begin{array}{lll}-1 & -2\end{array}\right]_{\eta^{\prime}}$
which correspond to a typical orientation relationship $\left[\begin{array}{lll}1 & 1 & -2\end{array}\right]_{\mathrm{m}} / /\left[\begin{array}{lll}1 & 0 & 0\end{array}\right]_{\eta^{\prime}} ; \quad\left[\begin{array}{lll}1 & -1 & 0\end{array}\right]_{\mathrm{m}} / /\left[\begin{array}{lll}0 & 1 & 0\end{array}\right]_{\eta^{\prime}} ; \quad\left[\begin{array}{ll}-1 & -1\end{array}\right.$ $-1]_{\mathrm{m}} / /[001]_{\eta^{\prime}}$. The corresponding transformation matrix of direction indices is

$$
B=\left[\begin{array}{rrr}
0.336 & 0.336 & -0.672 \\
0.336 & -0.336 & 0.000 \\
-0.334 & -0.334 & -0.334
\end{array}\right]
$$

Figure 8 SAD patterns corresponding to the constituent phase in Fig. 7.

Figure 10 Various morphologies of $\mathrm{Al}_{7} \mathrm{Cu}_{2} \mathrm{Fe}$ phase.

### 3.3. Constituent phase

Fig. 7 shows the typical image of the constituent phase in the alloy. The phase appears sphere-like with a size larger than $1 \mu \mathrm{~m}$. Around the phase there is a pre-cipitate-free zone of $\mathrm{Al}_{3} \mathrm{Zr}$ phase and $\eta^{\prime}$ phase.

Fig. 8 shows the corresponding SAD patterns for different directions. The analysis of SAD patterns reveals that the phase has a tetragonal crystal structure with $a=0.630 \mathrm{~nm}$ and $c=1.440 \mathrm{~nm}$. This is

Figure 11 Grain-boundary phases on small-angle grain boundaries.
quite close to that of $\mathrm{Al}_{7} \mathrm{Cu}_{2}$ Fe phase. From Fig. 8, it is also found that double-diffraction appears along the [001]* direction. The corresponding forbidden diffraction condition is $00 l: l=2 n+1$. This accords

Figure 12 Grain-boundary phases on a large-angle grain boundary.

Figure 13 Moiré fringe zone around a large-angle grain boundary.
with the characteristics of space group $\mathrm{P} 4 / \mathrm{mnc}$. Therefore, the impurity phase studied is $\mathrm{Al}_{7} \mathrm{Cu}_{2} \mathrm{Fe}$ phase. The SAD patterns then can be indexed. This is shown in Fig. 9.

The constituent phase may have various morphologies as shown in Fig. 10. The analysis of the corresponding SAD patterns indicates that they are all $\mathrm{Al}_{7} \mathrm{Cu}_{2} \mathrm{Fe}$ phase. No other kinds of constituent phase have been observed.

### 3.4. Grain-boundary phases (GBP)

Fig. 11 shows the GBPs on small-angle grain boundaries. There are two kinds of GBP. One is the platelike $\eta^{\prime}$ phase which grows along the GB (Fig. 11a). The other is the $\mathrm{Cu} / \mathrm{Si}$-rich phase that has been studied by Rao [21] (Fig. 11b). An apparent precipitate-free zone (PFZ) has also been observed.
Fig. 12 shows the GBPs on large-angle grain boundaries. It was determined that they were all $\eta$ phase but with two different shapes: spherical capshaped (Fig. 12a) and rod-shaped (Fig. 12b). The rodlike GBP in Fig. 11b has a definite orientation relationship with grain $B$, and grows across the GB into grain $A$. These phenomena are quite similar to those studied by Park and Ardell [22] in 7075 Al alloy. No apparent PFZ has been observed on large-angle GBs.
Fig. 13 shows the phenomenon of a Moiré fringe zone around a large-angle GB with a width of about $0.2 \mu \mathrm{~m}$. The spacing between the Moire fringes is measured as 7 nm . But on the grain boundary, there are no Moiré fringes. The existence of the Moiré fringe zone on the GB indicates the overlap of two grains [24]. This may substantially increase the width of the GB. Thus it is beneficial to the stress corrosion of the alloy. The formation of this phenomenon has not been explained satisfactorily.

## 4. Conclusions

1. The 7050 Al alloy after T 74 heat treatment contains the superlattice $\mathrm{Al}_{3} \mathrm{Zr}$ phase, the $\eta^{\prime}$ phase and $\mathrm{Al}_{7} \mathrm{Cu}_{2} \mathrm{Fe}$ constituent phase.
2. The $\eta^{\prime}$ phase has a face-centred orthorhombic crystal structure with $a=0.492 \mathrm{~nm}, b=0.852 \mathrm{~nm}$ and $c=0.701 \mathrm{~nm}$. The orientation relationship between the matrix and $\eta^{\prime}$ phase is $[11-2]_{m} / /[100]_{\eta^{\prime}}$; $\left[\begin{array}{lll}1 & -1 & 0\end{array}\right]_{\mathrm{m}} / /\left[\begin{array}{lll}0 & 1 & 0\end{array}\right]_{\eta^{\prime}} ;\left[\begin{array}{lll}-1 & -1 & -1\end{array}\right]_{\mathrm{m}} / /\left[\begin{array}{lll}0 & 0 & 1\end{array}\right]_{\eta^{\prime}}$.
3. The GBPs on a small-angle grain boundary are mainly plate-like $\eta^{\prime}$ phase and $\mathrm{Cu} / \mathrm{Si}$-rich phase. The GBPs on a large-angle grain boundary are mainly $\eta$ phase.
4. PFZs apparently only exist on small-angle grain boundaries.
