#### Abstract

The effect of one or several substituents $\mathrm{X}_{i}$ on a molecular property $f$ (reaction rate, spectroscopic property, etc.) is often described in terms of substituent parameters $\lambda_{i}(\mathrm{X})$ depending on the nature X of the substituent, and the position $i$ of substitution. We call selfparametrization the case when the substituents are parameterized by the value $\lambda_{i}(\mathrm{X})=f_{i}(\mathrm{X})$ of $f$ itself in the molecule monosubstituted by X in position $i$. On the example of the linear plus cross-term models, we show that self-parametrization implies that the coefficients of the model are interdependent. The theoretical relations between them are given, for equivalent or nonequivalent positions of substitution, and tested on measured acid-base equilibrium constants, and NMR coupling constants.

KEY WORDS: molecular property, substituents, self-parameterization

## 1. Introduction

Most of the properties which can be measured on molecules have been studied in series of compounds, as functions of the nature of the substituents $X_{i}$ that are present in one or several positions $i$. These properties are chemical equilibrium constants, reaction rates, NMR chemical shifts or coupling constants, bond vibration frequencies, and others [1-6]. In many cases, the effect of a substituent X on a property $f$ can be represented by a scalar parameter $\lambda_{i}(\mathrm{X})$ (or several $\lambda_{i}^{(k)}$, i.e., a vector parameter $\lambda_{i}$ ), which depends on the position $i$ of the substituent, and on its nature X . The function $\lambda_{i}$ can be either a physicochemical constant, or a parameter optimized from the data (indicator variable) [7-9]. For $n$ substituents, we have

$$
\begin{equation*}
f\left(\mathrm{X}_{1}, \ldots, \mathrm{X}_{n}\right)=F\left[\lambda_{1}\left(\mathrm{X}_{1}\right), \ldots, \lambda_{n}\left(\mathrm{X}_{n}\right)\right] \tag{1}
\end{equation*}
$$

where $F$ is a scalar function of $n$ variables.
Let us denote by $f_{i}(\mathrm{X}) \equiv f(\mathrm{H}, \ldots, \mathrm{H}, \mathrm{X}, \mathrm{H}, \ldots, \mathrm{H})$ the value of $f$ measured in the molecule monosubstituted by X in position $i$, i.e., having hydrogen atoms in the
$n-1$ other positions of substitution. We shall call self-parametrization the case when the scalar function

$$
\begin{equation*}
\lambda_{i}(\mathrm{X})=f_{i}(\mathrm{X}) \tag{2}
\end{equation*}
$$

is chosen to parameterize the substituent X in position $i$. In this case, equation (1) can be written as

$$
\begin{equation*}
f\left(\mathrm{X}_{1}, \ldots, \mathrm{X}_{n}\right)=F\left[f_{1}\left(\mathrm{X}_{1}\right), \ldots, f_{n}\left(\mathrm{X}_{n}\right)\right] . \tag{3}
\end{equation*}
$$

In the present article we shall study the self-parametrization in the case when the function $F$ is a linear plus cross-term model,

$$
\begin{align*}
f\left(\mathrm{X}_{1}, \ldots \mathrm{X}_{n}\right) & =a_{0}+\sum_{i=1}^{n} a_{1 i} \lambda_{i}\left(\mathrm{X}_{i}\right)+\sum_{i=1}^{n} \sum_{j=1, j>i}^{n} a_{2 i j} \lambda_{i}\left(\mathrm{X}_{i}\right) \lambda_{j}\left(\mathrm{X}_{j}\right)  \tag{4}\\
& =a_{0}+\sum_{i=1}^{n} a_{1 i} f_{i}\left(\mathrm{X}_{i}\right)+\sum_{i=1}^{n} \sum_{j=1, j>i}^{n} a_{2 i j} f_{i}\left(\mathrm{X}_{i}\right) f_{j}\left(\mathrm{X}_{j}\right) . \tag{5}
\end{align*}
$$

Equation (4) is a simple model to be tried [10] when nonadditive substituent effects are observed on a property $f$. We will show that the coefficients $a$ 's of equation (5) are interdependent, and we shall verify this interdependence on several chemical examples.

To simplify the notations, the substituents have been indexed by only one index $i$ in equations (1)-(5), agreeing that different indices $i, j$ sometimes represent the same position of substitution. This replaces double sums $\sum_{p} \sum_{s}(p$ position of substitution, $s$ substituent) [7] by only one sum $\sum_{i}$, and avoids fourfold summations in equations (4), (5).

## 2. Alternative sets $\lambda_{i}$ of substituent parametrizations compatible with equation (4)

Let $f\left(\mathrm{X}_{1}, \ldots, \mathrm{X}_{n}\right)$ be a scalar property depending on the substituents placed in $n$ positions on a molecular substrate. We assume that, for each position of substitution $i$, there exists a parametrization $\lambda_{i}(\mathrm{X})$ such that $f$ can be computed by equation (4).
(a) Clearly, any set $\left(\lambda_{i}^{\prime}\right)$ of substituent parametrizations such that each $\lambda_{i}^{\prime}$ is in an affine relationship with $\lambda_{i}$,

$$
\begin{equation*}
\lambda_{i}^{\prime}=\alpha_{i}+\beta_{i} \lambda_{i} \quad\left(\beta_{i} \neq 0\right), \tag{6}
\end{equation*}
$$

does not change the form of equation (4). Then, the coefficients of equation (4) are changed into

$$
\begin{equation*}
a_{0}^{\prime}=a_{0}-\sum_{i=1}^{n} a_{1 i} \frac{\alpha_{i}}{\beta_{i}}+\sum_{i} \sum_{j, j>i} a_{2 i j} \frac{\alpha_{i} \alpha_{j}}{\beta_{i} \beta_{j}}, \tag{7}
\end{equation*}
$$

$$
\begin{align*}
a_{1 i}^{\prime}=\frac{1}{\beta_{i}}\left(a_{1 i}-\sum_{j \neq i} a_{2 i j} \frac{\alpha_{j}}{\beta_{j}}\right) & (i=1, \ldots, n)  \tag{8}\\
a_{2 i j}^{\prime}=\frac{a_{2 i j}}{\beta_{i} \beta_{j}} & (i, j=1, \ldots, n) \tag{9}
\end{align*}
$$

We notice that some of the coefficients $a_{0}, a_{1 i}, a_{2 i j}$ could be removed, in choosing appropriate constants $\alpha_{i}, \beta_{i}$ in equation (6).
(b) Among the sets $\left(\lambda_{i}^{\prime}\right)$ of parametrizations defined by equation (6), one is the selfparametrization $\left(f_{i}\right)$. Indeed, we have

$$
\begin{equation*}
f_{i}(\mathrm{X})=\alpha_{i}+\beta_{i} \lambda_{i}(\mathrm{X}) \quad(i=1, \ldots, n) \tag{10}
\end{equation*}
$$

with the constants

$$
\begin{align*}
\alpha_{i} & =a_{0}+\sum_{j, j \neq i} a_{1 j} \lambda_{j}(\mathrm{H})+\sum_{j, j \neq i} \sum_{k, k>j, k \neq i} a_{2 j k} \lambda_{j}(\mathrm{H}) \lambda_{k}(\mathrm{H})  \tag{11}\\
\beta_{i} & =a_{1 i}+\sum_{j, j \neq i} a_{2 i j} \lambda_{j}(\mathrm{H}) \tag{12}
\end{align*}
$$

(c) Reciprocally, there are no other sets $\left(\lambda_{i}^{\prime}\right)$ of parametrizations compatible with equation (4), than those defined by equation (6). In fact, if two sets $\left(\lambda_{i}\right)$ and $\left(\lambda_{i}^{\prime}\right)$ are compatible with the form of equation (4), they satisfy equation (10) and similarly

$$
\begin{equation*}
f_{i}(\mathrm{X})=\alpha_{i}^{\prime}+\beta_{i}^{\prime} \lambda_{i}^{\prime}(\mathrm{X}) \tag{13}
\end{equation*}
$$

This shows that one also passes from $\lambda_{i}$ to $\lambda_{i}^{\prime}$ by an affine relationship.
(d) Finally, let us consider the particular case when the $n$ positions of substitution are equivalent with respect to the measured property $f$ (for example, identical positions, or symmetrical positions with respect to the active site of the molecule, when the property is a reaction rate). Then, a common substituent parametrization $\lambda_{i}=\lambda$ can be used for all the positions, and the coefficients $a_{1 i}=a_{1}$ are equal, as well as the coefficients $a_{2 i j}=a_{2}$. Equations (6) and (7)-(9) for the change of parametrization can be simply written as

$$
\begin{equation*}
\lambda^{\prime}=\alpha+\beta \lambda \tag{14}
\end{equation*}
$$

and

$$
\begin{align*}
& a_{0}^{\prime}=a_{0}-n \frac{\alpha}{\beta} a_{1}+\frac{n(n-1)}{2} \frac{\alpha^{2}}{\beta^{2}} a_{2}  \tag{15}\\
& a_{1}^{\prime}=\frac{1}{\beta}\left[a_{1}-(n-1) \frac{\alpha}{\beta} a_{2}\right]  \tag{16}\\
& a_{2}^{\prime}=\frac{a_{2}}{\beta^{2}} \tag{17}
\end{align*}
$$

There are two infinities of sets of coefficients $\left(a_{0}, a_{1}, a_{2}\right)$ that are equivalent in equation (4), corresponding to the choice of $\alpha$ and $\beta$ in equation (14). In other words, it is possible to impose the values of two parameters chosen among $a_{0}, a_{1}, a_{2}$, for example, $a_{0}$ and $a_{1}$. Therefore, there must be a combination of the three parameters which is invariant in the transformation (14). Indeed, by eliminating $\alpha$ and $\beta$ between equations (15)-(17), we see that the quantity $4 a_{0}-3 a_{1}^{2} / a_{2}$ is invariant, i.e., we have

$$
\begin{equation*}
4 a_{0}-\frac{3 a_{1}^{2}}{a_{2}}=4 a_{0}^{\prime}-\frac{3 a_{1}^{\prime 2}}{a_{2}^{\prime}} . \tag{18}
\end{equation*}
$$

Note that equation (18) does not mean that the coefficients $a_{0}, a_{1}, a_{2}$ are interdependent: examples can be provided where $a_{0}, a_{1}, a_{2}$ are equal to any given number.

## 3. The self-parametrization $\lambda_{i}(\mathrm{X})=f_{i}(\mathrm{X})$

(a) For the hydrogen substituent $(\mathrm{X}=\mathrm{H})$ the $n$ parametrizations $f_{i}$ take the common value

$$
\begin{equation*}
f_{i}(\mathrm{H})=f(\mathrm{H}, \ldots, \mathrm{H}), \tag{19}
\end{equation*}
$$

which will be denoted simply by $f(\mathrm{H})$. By substracting this constant from $f$, we define a new property

$$
\begin{equation*}
g\left(\mathrm{X}_{1}, \ldots, \mathrm{X}_{\mathrm{n}}\right)=f\left(\mathrm{X}_{1}, \ldots, \mathrm{X}_{\mathrm{n}}\right)-f(\mathrm{H}) \tag{20}
\end{equation*}
$$

In this section, we shall assume that the property $f$ can be represented by an equation of the form (4), and, therefore, by an equation of the form (5) (see section 2). Clearly, the property $g$ also satisfies an equation of the form (5),

$$
\begin{equation*}
g\left(\mathrm{X}_{1}, \ldots, \mathrm{X}_{\mathrm{n}}\right)=b_{0}+\sum_{i=1}^{n} b_{1 i} g_{i}\left(\mathrm{X}_{\mathrm{i}}\right)+\sum_{i=1}^{n} \sum_{j, j>i} b_{2 i j} g_{i}\left(\mathrm{X}_{\mathrm{i}}\right) g_{j}\left(\mathrm{X}_{\mathrm{j}}\right), \tag{21}
\end{equation*}
$$

where

$$
\begin{equation*}
g_{i}(\mathrm{X})=g(\mathrm{H}, \ldots, \mathrm{H}, \mathrm{X}, \mathrm{H}, \ldots, \mathrm{H}) \tag{22}
\end{equation*}
$$

is the self-parametrization associated with $g$. The definition (20) implies

$$
\begin{equation*}
g(\mathrm{H})=g_{i}(\mathrm{H})=g(\mathrm{H}, \ldots, \mathrm{H})=0, \tag{23}
\end{equation*}
$$

which shows that $b_{0}$ equals zero. In addition, equation (23) implies

$$
\begin{equation*}
g_{i}(\mathrm{X})\left[b_{1 i}-1\right]=0 \tag{24}
\end{equation*}
$$

for any X and $i$. All the $b_{1 i}$ 's are therefore equal to one, and equation (21) can be rewritten as

$$
\begin{equation*}
g\left(\mathrm{X}_{1}, \ldots, \mathrm{X}_{\mathrm{n}}\right)=\sum_{i=1}^{n} g_{i}\left(\mathrm{X}_{\mathrm{i}}\right)+\sum_{i=1}^{n} \sum_{j, j>i} b_{2 i j} g_{i}\left(\mathrm{X}_{\mathrm{i}}\right) g_{j}\left(\mathrm{X}_{\mathrm{j}}\right) . \tag{25}
\end{equation*}
$$

In terms of $f$, equation (25) is equivalent to equation (5) with the coefficients

$$
\begin{align*}
& a_{0}=f(\mathrm{H})\left[1-n+f(\mathrm{H}) \sum_{i=1}^{n} \sum_{j, j>i} a_{2 i j}\right],  \tag{26}\\
& a_{1 i}=1-f(\mathrm{H}) \sum_{j, j \neq i} a_{2 i j},  \tag{27}\\
& a_{2 i j} \text { arbitrary. } \tag{28}
\end{align*}
$$

Eliminating the constant $f(\mathrm{H})$ between the $n+1$ equations (26), (27), we draw $n$ relations linking the $\left(n^{2}+n+2\right) / 2$ coefficients $a_{0}, a_{1 i}, a_{2 i j}$. These relations can be written in an infinite number of manners, since they can be combined algebraically. A simple system of $n$ equations is obtained as follows. The $n$ equations (27) give the $n-1$ relations

$$
\begin{equation*}
\frac{1-a_{11}}{\sum_{j, j \neq 1} a_{21 j}}=\frac{1-a_{1 i}}{\sum_{j, j \neq i} a_{2 i j}} \quad(i=2, \ldots, n) . \tag{29}
\end{equation*}
$$

The $n$th relation will be obtained in a symmetrical form with respect to the coefficients $a_{1 i}, a_{2 i j}$. Let us introduce the sums of the coefficients

$$
\begin{align*}
& S_{1}=\sum_{i=1}^{n} a_{1 i},  \tag{30}\\
& S_{2}=\sum_{i=1}^{n} \sum_{j, j>i} a_{2 i j} . \tag{31}
\end{align*}
$$

Summing the numerators and the denominators of the fractions (29), we have

$$
\begin{equation*}
f(\mathrm{H})=\frac{\sum_{i=1}^{n}\left(1-a_{1 i}\right)}{\sum_{i=1}^{n} \sum_{j, j \neq i} a_{2 i j}}=\frac{n-S_{1}}{2 S_{2}} . \tag{32}
\end{equation*}
$$

Eliminating $f(\mathrm{H})$ between equations (26) and (32), we obtain

$$
\begin{equation*}
4 a_{0} S_{2}=\left(S_{1}-n\right)\left(S_{1}+n-2\right) \tag{33}
\end{equation*}
$$

The number of coefficients and the number of relations indicated above are maximal values that may be reduced for symmetry reasons. In section 4, the relations (29) and (33) will be examplified in several common cases.
(b) There are no other relations between the coefficients $a_{0}, a_{1 i}, a_{2 i j}$ than the preceding ones (or their algebraic combinations). Indeed, let us choose arbitrary substituent parametrizations $g_{i}(\mathrm{X})$, each of them being equal to zero for $\mathrm{X}=\mathrm{H}$, and arbitrary coefficients $b_{2 i j}$. Then, the property $g$ defined by equation (25) is compatible with the definition (22) of the $g_{i}$ 's. Next, choosing an arbitrary constant $f(\mathrm{H})$, we can define with equation (20) a property $f$ which satisfies equation (5), and whose coefficients $a_{0}, a_{1 i}, a_{2 i j}$ are submitted to no other conditions than equations (26), (27).

Let us incidentally notice that, except their common value (19) for $\mathrm{X}=\mathrm{H}$, there are no general relationships between the parametrizations $f_{i}$ (since the $g_{i}$ 's can be chosen arbitrarily). In particular, two parametrizations $f_{i}$ and $f_{j}$ are not necessarily linked by an affine relationship.
(c) For a linear model without cross-term, we simply set $a_{2 i j}=0$ in equations (26), (27), which yields $a_{1 i}=1$ for any $i$, and $a_{0}=(1-n) f(\mathrm{H})$.

## 4. Two or three substituents in equivalent or nonequivalent positions

(a) We first consider two positions of substitution, which can be equivalent or nonequivalent, with respect to the measured property $f$. For two substituents, there is only one coefficient $a_{2 i j}=a_{2}$. The two coefficients $a_{1 i}$ are equal, since equation (27) gives

$$
\begin{equation*}
a_{11}=1-f(\mathrm{H}) a_{2}=a_{12} . \tag{34}
\end{equation*}
$$

Equation (33) simplifies into

$$
\begin{equation*}
a_{0} a_{2}=a_{1}\left(a_{1}-1\right) . \tag{35}
\end{equation*}
$$

(b) For three substituents there are seven coefficients, $a_{0}, a_{11}, a_{12}, a_{13}, a_{2,12}, a_{2,23}, a_{2,31}$, linked by the three relations

$$
\begin{equation*}
\frac{1-a_{11}}{a_{2,12}+a_{2,31}}=\frac{1-a_{12}}{a_{2,23}+a_{2,12}}=\frac{1-a_{13}}{a_{2,31}+a_{2,23}} \tag{36}
\end{equation*}
$$

and

$$
\begin{equation*}
4 a_{0} S_{2}=\left(S_{1}-3\right)\left(S_{1}+1\right) . \tag{37}
\end{equation*}
$$

When the positions of substitution are equivalent, equation (5) can be written as

$$
\begin{align*}
f(\mathrm{X}, \mathrm{Y}, \mathrm{Z})= & a_{0}+a_{1}[f(\mathrm{X})+f(\mathrm{Y})+f(\mathrm{Z})] \\
& +a_{2}[f(\mathrm{X}) f(\mathrm{Y})+f(\mathrm{Y}) f(\mathrm{Z})+f(\mathrm{Z}) f(\mathrm{X})], \tag{38}
\end{align*}
$$

and equation (37) simplifies into

$$
\begin{equation*}
4 a_{0} a_{2}=\left(a_{1}-1\right)\left(3 a_{1}+1\right) . \tag{39}
\end{equation*}
$$

Since equation (38) can also be used to treat the case of two substituents only (by setting $\mathrm{Z}=\mathrm{H}$ ), we should verify that equations (35) and (39) are compatible. Indeed, when we fix $\mathrm{Z}=\mathrm{H}$ in equation (38), we get an equation for two substituents only, whose coefficients $a_{0}^{\prime}, a_{1}^{\prime}, a_{2}^{\prime}$,

$$
\begin{align*}
& a_{0}^{\prime}=a_{0}+a_{1} f(\mathrm{H})+a_{2} f^{2}(\mathrm{H}),  \tag{40}\\
& a_{1}^{\prime}=a_{1}+a_{2} f(\mathrm{H}),  \tag{41}\\
& a_{2}^{\prime}=a_{2}, \tag{42}
\end{align*}
$$

differ from those $a_{0}, a_{1}, a_{2}$ of equation (38), and satisfy equation (35).

## 5. Examples chosen in acid-base equilibria

In this section, and the following one, we shall apply the previous results to experimental values of several physicochemical properties. Our purpose is not to study these physicochemical properties in detail, but only to verify the validity of equations (29), (33) (or their particular cases (36), (37), (39)).
(i) The dissociation constant of carboxylic acids is an example of molecular property $f$ depending on the substituents. Let us consider a family of mono- and disubstituted acetic acids $\mathrm{CH}_{2} \mathrm{X}-\mathrm{COOH}$ or CHXY- COOH , whose $\mathrm{p} K$ values (denoted by $\mathrm{p} K_{\mathrm{X}}$ or $\mathrm{p} K_{\mathrm{XY}}$ ) have been measured (table 1). If we choose the monosubstituted value $\lambda_{\mathrm{X}}=\mathrm{p} K_{\mathrm{X}}$ as a parameter describing the substituent X , we have equation (5):

$$
\begin{equation*}
\mathrm{p} K_{\mathrm{XY}}=a_{0}+a_{1}\left(\mathrm{p} K_{\mathrm{X}}+\mathrm{p} K_{\mathrm{Y}}\right)+a_{2} \mathrm{p} K_{\mathrm{X}} \mathrm{p} K_{\mathrm{Y}} ; \tag{43}
\end{equation*}
$$

$\mathrm{p} K_{\mathrm{X}}$ and $\mathrm{p} K_{\mathrm{Y}}$ are multiplied by the same coefficient $a_{1}$, as shown in section 4 (the equivalence of the geminal positions of X and Y , with respect to the measured property $\mathrm{p} K$, need not be put forward here).
Using all the mono- and disubstituted values given in table 1 , the coefficients $a_{0}, a_{1}, a_{2}$ can be optimized in equation (43). When the values obtained, $a_{0}=-0.9784, a_{1}=0.1919, a_{2}=0.1731$, are substituted into equation (43), we obtain a satisfactory model, since the standard deviation on $f$ is 0.11 . These coefficients approximately satisfy equation (35), since they give $a_{0} a_{2}=-0.1694$ and $a_{1}\left(a_{1}-1\right)=-0.1550$ (ratio 1.09). Since equation (35) expresses the compatibility of equations (26) and (27), its best testing consists in comparing the values of $f(\mathrm{H})$ drawn independently from equations (26) and (27). These values, 4.528 and 4.668 , are close, and close from the $\mathrm{p} K$ of acetic acid $(4.756[12,13])$ which is a measure of $f(\mathrm{H})$.
(ii) Similarly, the dissociation constants of the trisubstituted acids can be modelled by an equation of the form (44):

$$
\begin{align*}
\mathrm{p} K_{\mathrm{XYZ}}= & a_{0}+a_{1}\left(\mathrm{p} K_{\mathrm{X}}+\mathrm{p} K_{\mathrm{Y}}+\mathrm{p} K_{\mathrm{Z}}\right) \\
& +a_{2}\left(\mathrm{p} K_{\mathrm{X}} \mathrm{p} K_{\mathrm{Y}}+\mathrm{p} K_{\mathrm{Y}} \mathrm{p} K_{\mathrm{Z}}+\mathrm{p} K_{\mathrm{Z}} \mathrm{p} K_{\mathrm{X}}\right) . \tag{44}
\end{align*}
$$

By linear regression, we obtain the coefficients $a_{0}=0.5664, a_{1}=-0.4695$, $a_{2}=0.1619$. Equation (39) is only very approximately satisfied, since we have $4 a_{0} a_{2}=0.3668$ and $\left(a_{1}-1\right)\left(3 a_{1}+1\right)=0.6004$ (ratio 1.63). This result is explained by the bad quality of the model (the standard deviation on $f$ is 0.87 , due namely to the abnormal molecules $\left(\mathrm{CH}_{3}, \mathrm{CN}, \mathrm{CN}\right)$ and $(\mathrm{Ph}, \mathrm{OH}, \mathrm{F})$ ). However, the compatibility of the equations (26) and (27) is good enough, since the values of $f(\mathrm{H})$ drawn independently from these equations, 4.383 and 4.538, are close (and close to 4.756).

Table 1
$\mathrm{p} K$ of mono-, di-, and trisubstituted acetic acids CXYZ-COOH in water, at $25^{\circ} \mathrm{C}$ (except otherwise stated). The experimental values $\mathrm{p} K^{\exp }$ of the mono- and disubstituted acids are used to determine $a_{0}, a_{1}, a_{2}$ by regression in equation (43); those of the mono- and trisubstituted acids are used to determine $a_{0}, a_{1}, a_{2}$ in equation (44). Abbreviations: $\mathrm{Et}=$ ethyl, $\mathrm{iPr}=$ isopropyl, $\mathrm{Ph}=$ phenyl.

## 6. An example in NMR

The NMR vicinal coupling constant $J$ between two hydrogen atoms is another example of property $f$ which has been studied as a function of the substituents. We consider a family of ethanes $\mathrm{CH}_{2} \mathrm{X}-\mathrm{CH}_{3}$ or $\mathrm{CHXY}-\mathrm{CH}_{3}$ bearing one substituent X or two geminal substituents X , Y. The corresponding $\mathrm{H} \cdots \mathrm{H}$ coupling constant (denoted by $J_{\mathrm{X}}$ or $J_{\mathrm{XY}}$ ), taken from the literature, or newly measured, are given in table 2 . Choosing the parameter $\lambda_{\mathrm{X}}=J_{\mathrm{X}}$ to represent the substituent X , we have

$$
\begin{equation*}
J_{\mathrm{XY}}=a_{0}+a_{1}\left(J_{\mathrm{X}}+J_{\mathrm{Y}}\right)+a_{2} J_{\mathrm{X}} J_{\mathrm{Y}} \tag{45}
\end{equation*}
$$

By regression in equation (45), using all the measured coupling constants of table 2, we obtain $a_{0}=-178.69, a_{1}=23.621, a_{2}=-2.9972$. These coefficients satisfy equation (35), since they give $a_{0} a_{2}=535.57$ and $a_{1}\left(a_{1}-1\right)=534.33$ (ratio 1.002). The compatibility of equations (26) and (27) is excellent since the values of $f(\mathrm{H})$ drawn from them are 7.556 and 7.547 , respectively. These results are good, when compared to the mean quality of the regression (the standard deviation on $J$ is 0.23 , due namely to the abnormal molecules ( $\mathrm{OAc}, \mathrm{C}(=\mathrm{O}) \mathrm{Me})$ and $(\mathrm{F}, \mathrm{F})$ ).

Table 2
Vicinal $\mathrm{H} \cdots \mathrm{H}$ NMR coupling constants in mono- or disubstituted ethanes $\mathrm{CHXY}-\mathrm{CH}_{3}$. Solvent $\mathrm{CDCl}_{3}$. The coupling constants referenced with $a$ were measured by J.-C. Ziegler on a 400 MHz spectrometer at $25^{\circ} \mathrm{C}$ temperature, and at a $2 \%$ concentration in weight (solid) or in volume (liquid). The experimental values $J^{\text {exp }}$ of the mono- and disubstituted ethanes are used to determine $a_{0}, a_{1}, a_{2}$ by regression in equation (43). Abbreviations: $\mathrm{Me}=$ methyl, $\mathrm{Et}=$ ethyl, $\mathrm{iPr}=$ isopropyl, $\mathrm{Ac}=$ acetyl, $\mathrm{Bz}=$ benzyl, Ts = tosyl.

## 7. Conclusion

All the alternative sets $\left(\lambda_{i}\right)$ of substituent parametrizations which are compatible with a linear plus cross-term model (4) are affine transforms (6) of one another. For arbitrary parametrizations $\lambda_{i}$ there is no general relationship between the coefficients $a_{0}, a_{1 i}$, $a_{2 i j}$ of the model. In the case of equivalent positions of substitution, the expression (18) is invariant in a change of parametrization.

The self-parametrization $\left(f_{i}\right)$ (the case when the monosubstituted value $f_{i}(\mathrm{X})$ of $f$ is chosen as the parameter representing the substituent X in position $i$ ) is one of the
alternative sets $\left(\lambda_{i}\right)$. In this case, we have shown that the coefficients $a_{0}, a_{1 i}, a_{2 i j}$ of equation (5) are linked by the $n$ important relations (29) and (33).

For two substituents in equivalent positions, the coefficients $a_{0}, a_{1}, a_{2}$ are connected by the simple relation (35). It is a nonintuitive result that, for two nonequivalent positions, the coefficients $a_{1 i}$ and $a_{1 j}$ still coincide, and that the relation (35) is still valid. For three substituents in equivalent positions, the coefficients $a_{0}, a_{1}, a_{2}$ are linked by equation (39). We have verified that these relations are well or roughly satisfied by the coefficients $a_{0}, a_{1}, a_{2}$ optimized from measured acid-base dissociation constants, or from NMR coupling constants.

Having a set of measured values of a molecular property $f$, one has two possibilities for creating a linear plus cross-term model: either (i) take the relations (35) or (39) into account to reduce the number of coefficients to be optimized (this is interesting when one has few experimental points); or (ii) ignore these relations and optimize all the coefficients as if they were independent, to get a better model (more coefficients give a more accurate model). However, even when one makes the choice (ii), it is essential to be aware that the coefficients are theoretically dependent, and to know the relations linking them.

In this article, the study of self-parametrization was restricted to the linear plus cross-term models. It is clear that similar reasonings can be applied to other forms of model equations, showing also that the coefficients are interdependent, but with different relations.

We have chosen the substituent H as the reference substituent in the definition of the $f_{i}$ 's, and throughout this article. However, any type of substituent can be chosen instead of H , with the same results. Moreover, the reasoning, and the equations obtained, are still valid when the notion of substituent is extended into any structural element which modifies the environment of the active site of the molecule. For example, a chain of atoms bonded on its two ends to the substrate can be considered as a substituent.

We have assumed in the introduction that $f$ was a scalar property. Selfparametrization can also be considered for a vector property $f=\left(f^{(1)}, \ldots, f^{(p)}\right)$. Then, several parameters $\lambda_{i}^{(k)}(\mathrm{X})=f_{i}^{(k)}(\mathrm{X})$ will represent the influence of a substituent X in position $i$, and tensor coefficients $a$ will be needed.
