where $0<\delta\ll 1$. Our proof strategy borrows heavily from Ref. 20. For these systems, the secondary Melnikov function[20] depends on the $\mathcal{O}(1)$ phase t_0, and the existence of secondary intersection points is established by the zeroes of the function. In contrast, our second-order and Nth-order ($N>2$) adiabatic Melnikov functions which depend on slowly varying $\mathcal{O}(\varepsilon)$ phases. Also, we work directly on (1.1), whereas the Whisker map is used in Ref. 20.

The theory of multi-pulse homoclinic orbits has also been developed recently in a number of other contexts. For n degree of freedom Hamiltonian systems subject to small amplitude perturbations, dubbed as system I in Ref. 19, the work in Refs. 21 and 22 has shown the existence of different types of multi-pulse orbits. For the same types of systems, Ref. 23 develops a higher-order Melnikov theory. In each of these works, the central variable is a rapidly—($\mathcal{O}(1)$)—varying phase. The energy function of Ref. 21, the Melnikov functions used in Ref. 22, and the higher-order Melnikov function of Ref. 23 are functions of the appropriate $\mathcal{O}(1)$ variable, in contrast to our higher-order Melnikov function which is a function of a slowly varying parameter. In addition, the techniques of proof are fundamentally different.

Finally, homoclinic explosions (and implosions) in which infinitely many multi-pulse homoclinic orbits are created (disappear) have recently been discovered[24] in a slowly varying Hamiltonian system. This system is related to the Ginzburg–Landau equation and may be written in the form of (1.1) by replacing the third component of the vector field by a particular function of the form $\varepsilon F(q,p,z)$ and then analyzing the bifurcations that occur along the persistent slow manifold.

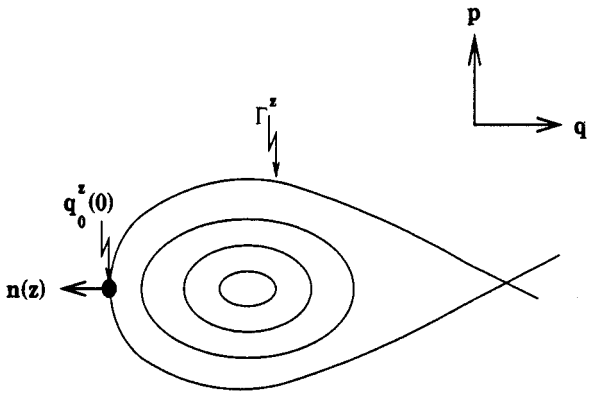

FIG. 1. The geometry of the unperturbed system.

The paper is organized as follows. We state the two structural assumptions on (1.1) in Sec. II. In Sec. III, we present a heuristic derivation of the Nth-order Melnikov function for the (1.1) with $\mu=0$. This heuristic derivation is extended to (1.1) with $\mu\neq 0$ in Sec. VIII. We state the main theorem for (1.1) with $\mu=0$ and its corollary for (1.1) with $\mu\neq 0$ in Sec. IV. We present an example in Sec. V. Section VI contains local estimates that are necessary for the proof of the Theorem. Finally, the theorem and corollary are proven in Secs. VII and VIII, respectively.

II. STRUCTURAL ASSUMPTION

We begin by making the following assumption on (1.1) when $\varepsilon=0$:

Assumption 1: For each fixed z in a finite interval, the instantaneous or frozen system

$$\dot{q}=\frac{\partial H}{\partial p}(q,p,z), \quad \dot{p}=-\frac{\partial H}{\partial q}(q,p,z), \quad \dot{z}=0, \tag{2.1}$$

has a saddle fixed point at $(q_e(z),p_e(z))$ *that satisfies the condition* $H(q_e(z),p_e(z),z)=0$. *For each z, this saddle is connected to itself by a homoclinic orbit* Γ^z. *The graph of* Γ^z *varies smoothly with z, and* Γ^z *is parametrized by the solution* $\mathbf{q}_0^z(t)\equiv(q_0^z(t),p_0^z(t),z)$. *Finally, the interior of the region bounded by* $(q_e(z),p_e(z))\cup\Gamma^z$ *is filled with a continuous family of periodic orbits,* $\mathbf{q}_\alpha^z$, *for* $\alpha\in(-1,0)$, *each with energy* $h_z^\alpha<0$ *and period* $P_z^\alpha=P(h_z^\alpha)$. *Moreover,* P_z^α *is differentiable in* $h^\alpha(z)$, *and* $dP_z^\alpha/dh_z^\alpha<0$.

For definiteness and without loss of generality, we take Γ^z to be as shown in Fig. 1. Let $\mathbf{n}(z)$ denote the unit normal vector to Γ^z at the point $\mathbf{q}_0^z(0)$ in the $q-p$ plane. In $q-p-z$ space, the union of the saddle equilibria over z forms a one-dimensional normally hyperbolic manifold γ_0 that must be either compact (e.g., H is periodic in z) or with boundary and that has two-dimensional stable and unstable manifolds $W^s(\gamma_0)$ and $W^u(\gamma_0)$, respectively. We remark that when $\epsilon=0$, one branch of each of these manifolds coincide in a homoclinic manifold, which is simply the union of the homoclinic orbits Γ^z over all z. The results of Sec. IV are readily generalized to the case in which (2.1) possesses heteroclinic orbits, and hence they are applicable to all of the examples cited in the Introduction.

III. HEURISTIC DERIVATION OF THE *N*TH-ORDER MELNIKOV FUNCTION

Consider the system (1.1) with $\mu=0$:

$$\dot{q}=\frac{\partial H}{\partial p}(q,p,z), \quad \dot{p}=-\frac{\partial H}{\partial q}(q,p,z), \quad \dot{z}=\varepsilon. \tag{3.1}$$

Fenichel theory,[25] states that for ε sufficiently small, γ_0 persists as a slow manifold γ_ε along with its two-dimensional local stable and unstable manifolds, $W^s_{\rm loc}(\gamma_\varepsilon)$ and $W^u_{\rm loc}(\gamma_\varepsilon)$, respectively. The global counterparts of these perturbed manifolds no longer coincide in general, and instead they can transversely intersect one another. We now present a heuristic derivation of the *N*th-order Melnikov function used to detect the *N*th-order transverse intersections of $W^s(\gamma_\varepsilon)$ and $W^u(\gamma_\varepsilon)$ in which the *N*-pulse orbits homoclinic to γ_ε lie for $N=2,3,\ldots$. This derivation will be extended to the $\mu\neq 0$ case in Sec. VIII.

Let $\mathbf{q}^u(t;z_0,\varepsilon)=(x^u(t),y^u(t),z)$ be a solution on the unstable manifold $W^u(\gamma_\varepsilon)$ that crosses the normal $\mathbf{n}(z)$ for the first time with $z=z_0=\varepsilon t_0$, and hits the negative x axis near γ_ε at $t=t_1^*$ with energy $H_1<0$. See Fig. 2 for a sketch. This solution exists when ε is sufficiently small. Using the chain rule, we compute

$$H_1\equiv\int_{-\infty}^{t_1^*}\frac{dH}{dt}(\mathbf{q}^u(t;z_0,\varepsilon))dt=\varepsilon\int_{-\infty}^{t_1^*}\frac{\partial H}{\partial z}(\mathbf{q}^u(t;z_0,\varepsilon))dt. \tag{3.2}$$

At a time $z_0-\Delta z$, for some fixed Δz, $\mathbf{q}^u(t;z_0,\varepsilon)$ is exponentially close to γ_ε; i.e., $|\mathbf{q}^u(t;z_0,\varepsilon)|=\mathcal{O}(e^{-c/\varepsilon})$, for some $c>0$. So for all $z<z_0-\Delta z$, we know that $|\partial H/\partial z(\mathbf{q}^u(t;z_0,\varepsilon))| = \mathcal{O}(e^{-c_1/\varepsilon})$, with $c_1>0$. For $z\in[z_0-\Delta z,\, z_0]$, we Taylor expand $\partial H/\partial z(\mathbf{q}^u(t;z_0,\varepsilon))$ about $\mathbf{q}=\mathbf{q}_0^{z_0}(t)$ and make an error of $\mathcal{O}(\varepsilon)$. This expansion holds for all $z\in[z_0-\Delta z,\, z_0+\Delta z]$. Hence, (3.2) becomes

$$H_1=\varepsilon\int_{-\infty}^{t_1^*}\left[\frac{\partial H}{\partial z}(\mathbf{q}_0^{z_0}(t))+\mathcal{O}(\varepsilon)\right]dt.$$

We introduce the following definitions to keep the length of formulas under control. Let $h_1(z_0)\equiv\int_{-\infty}^{\infty}(\partial H/\partial z)(\mathbf{q}_0^{z_0}(t))dt$, and let $R_s(z_0,t_1^*)\equiv-\varepsilon\int_{t_1^*}^{\infty}\partial H/\partial z(\mathbf{q}_0^{z_0}(t))dt+\mathcal{O}(\varepsilon^2)$. In terms of these new symbols, the above formula for H_1 becomes

$$H_1=\varepsilon h_1(z_0)+R_s(z_0,t_1^*). \tag{3.3}$$

We remark that $h_1(z_0)$ is precisely the (one-pulse) adiabatic Melnikov function $M_A(z_0)$.[2,4,14,15]

We will classify systems of the form (1.1) that satisfy our assumption as systems of type I or of type II. Systems of type I satisfy the extra condition

$$\frac{\partial H}{\partial z}=\alpha(z)L(q,p,z), \quad \text{where} \quad \int_{-\infty}^{\infty}(\mathbf{q}_0{}^z(t))dt>0 \quad \text{for all } z.$$

Thus, for systems of type I the adiabatic Melnikov function is written as $M_A(z)=\alpha(z)\int_{-\infty}^{\infty}(\mathbf{q}_0{}^z(t);\, u)dt$, where for μ sufficiently small, this last integral is positive and $\hat{L}(\mathbf{q}_0{}^z(t);0)\equiv L(\mathbf{q}_0{}^z(t))$. We call systems of type II those that do not satisfy it.

We have chosen the form given in (3.3) to express H_1, since we will show in Sec. VII A that the remainders are of higher order. In fact, for type I systems $R_s(z_0,t_1^*)=\mathcal{O}(\varepsilon^2)$ as $\varepsilon\to 0$ for systems of type II, $R_s(z_0,t_1^*)=\mathcal{O}(\varepsilon^2\ln(1/\varepsilon))$ as $\varepsilon\to 0$. This completes the first part of the heuristic derivation.

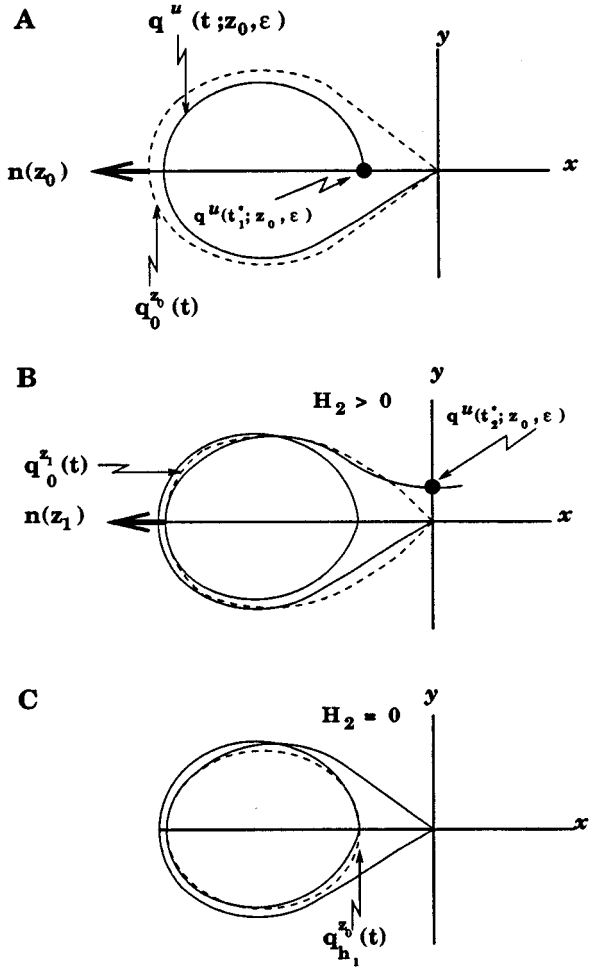

FIG. 2. Projections onto the $x-y$ plane of the perturbed solution $\mathbf{q}^u(t;z_0,\varepsilon)$ on the unstable manifold $W^u(\gamma_\varepsilon)$. (a) The projection is up to time $t=t_1^*$. The dotted curve represents the unperturbed homoclinic orbit $\mathbf{q}_0^{z_0}$ at $z=z_0$. (b) When $H_2>0$, $\mathbf{q}^u(t_2^*;z_0,\varepsilon)$ is on the positive y axis. The dotted curve corresponds to the unperturbed homoclinic $\mathbf{q}_0^{z_1}$. (c) When $H_2=0$, we have that t_2^* is infinite. The dotted curve represents the unperturbed periodic orbit $\mathbf{q}_{h_1}^{z_0}$ at $z=z_0$, with energy εh_1.

Now, since we assumed $H_1<0$, we know that $\mathbf{q}^u(t;z_0,\varepsilon)$ is not a primary homoclinic solution. As we follow this solution beyond t_1^*, it will make a second fast excursion away from γ_ε, crossing $\mathbf{n}(z)$ now at some $z=z_1=\varepsilon t_1$, and then it will come back to the neighborhood of γ_ε, again for ε sufficiently small. Moreover, in this neighborhood this solution either hits the x axis or the y axis at $t=t_2^*$ with energy H_2, or it is forward asymptotic to γ_ε (when $H_2=0$ and t_2^* is infinite). An exact computation yields

$$H_2=H_1+\int_{t_1^*}^{t_2^*}\frac{dH}{dt}\,(\mathbf{q}^u(t;z_0,\varepsilon))dt.$$

In order to arrive at a suitable approximation of H_2, we proceed as we did with the first excursion and write the second fast excursion as an expansion about the instantaneous separatrix at $z=z_1$:

$$H_2=H_1+\varepsilon\int_{-\infty}^{\infty}\frac{\partial H}{\partial z}(\mathbf{q}_0^{z_1}(t))dt-\varepsilon\int_{-\infty}^{t_1^*}\frac{\partial H}{\partial z}(\mathbf{q}_0^{z_1}(t))dt-\varepsilon\int_{t_2^*}^{\infty}\frac{\partial H}{\partial z}(\mathbf{q}_0^{z_1}(t))dt+\mathcal{O}(\varepsilon^2).$$

Therefore, using the remainder notation introduced above, we rewrite this formula as

$$H_2=\varepsilon(h_1(z_0)+h_1(z_1))+R_s(z_0,t_1^*)+R_s(z_1,t_2^*)+R_u(z_1,t_1^*), \tag{3.4}$$

where $R_u(z_1,t_1^*)\equiv-\varepsilon\int_{-\infty}^{t_1^*}(\partial H/\partial z)(\mathbf{q}_0^{z_1}(t))dt+\mathcal{O}(\varepsilon^2)$.

Finally, we use an asymptotic relation between z_0 and z_1. Since z_1-z_0 is the amount of slow time between consecutive crossings of $\mathbf{q}^u(t;z_0,\varepsilon)$ with $\mathbf{n}(z)$, we expect that the period $P(H_1)$ of the unperturbed periodic orbit of the frozen system (2.1) with $z=z_0$, with energy $H_1=h^{\alpha}_{z_0}$, where α is determined by H_1, provides a good approximation of the amount of time the solution $\mathbf{q}^u(t;z_0,\varepsilon)$ spends in the oscillatory regime. In fact, using (3.3), the leading order asymptotic behavior as $\varepsilon\to0$ will be shown in Sec. VII B to be

$$z_1\sim z_0+\varepsilon P(\varepsilon h_1(z_0)). \tag{3.5}$$

Therefore, the above results motivate us to study the function

$$h_2(z_0,\varepsilon)\equiv h_1(z_0)+h_1(z_0+\varepsilon P(h_1(z_0))), \tag{3.6}$$

whose zeroes will be shown to correspond to secondary homoclinic orbits. For N-pulse homoclinic orbits, the value of the function H after N excursions is given exactly as

$$\begin{aligned}H_N&=H_{N-1}+\int_{t_{N-1}^*}^{t_N^*}\frac{dH}{dt}(\mathbf{q}_0^u(t;z_0,\varepsilon))dt\\&=H_{N-1}+\varepsilon h_1(z_{N-1})+R_s(z_{N-1},t_N^*)+R_u(z_{N-1},t_{N-1}^*).\end{aligned} \tag{3.7}$$

Hence, we need the inductively defined function

$$h_N(z_0,\varepsilon)\equiv h_{N-1}(z_0,\varepsilon)+h_1\left(z_0+\varepsilon\sum_{j=1}^{N-1}P(\varepsilon h_j)\right), \tag{3.8}$$

where $h_1\equiv h_1(z_0)$ and $h_j\equiv h_j(z_0,\varepsilon)$ for $j=2,\ldots,N-1$.

This completes the heuristic derivation. As remarked above, $h_1(z_0)=M_A(z_0)$. We will also use $M_{1,A}(z_0)$ to denote $M_A(z_0)$. Therefore, the functions $h_1,\ldots,h_N$ lead us to define the second order and Nth-order for $N\geqslant2$ adiabatic Melnikov functions inductively as

$$\begin{aligned}M_{2,A}(z_0,\varepsilon)&=M_{1,A}(z_0)+M_{1,A}(z_0+\varepsilon P(\varepsilon h_1)),\\M_{N,A}(z_0,\varepsilon)&=M_{N-1,A}(z_0,\varepsilon)+M_{1,A}\left(z_0+\varepsilon\sum_{j=1}^{N-1}P(\varepsilon h_j)\right).\end{aligned} \tag{3.9}$$

The theorem for $\mu=0$ and the corollary for $\mu\neq0$ formulated in the next section show that $\varepsilon M_{N,A}(z_0,\varepsilon)$ is a good approximation to H_N for $N=2,\ldots$, and that simple zeroes of $M_{N,A}(z_0,\varepsilon)$ imply simple zeroes of H_N, and hence transverse Nth-order intersections for systems (1.1).

Remark 1: There is an alternative derivation of H_N which we briefly present for the $N=2$ case. Let $\mathbf{q}^u(t;z_0,\varepsilon)$ be as above, and $\mathbf{q}^s(t;z_1,\varepsilon)$ be a solution on the stable manifold $W^s(\gamma_\varepsilon)$ that in backward time crosses the normal $\mathbf{n}(z_1)$ for the first time at $z=z_1$, and hits the negative x axis in the neighborhood of γ_ε at $t = t_1^*$. The difference in the value of H for these two orbits at the time $t = t_1^*$, when both of them are on the x axis (see Fig. 3), is also a measure of the distance between $W^u(\gamma_\varepsilon)$ and $W^s(\gamma_\varepsilon)$. This difference is given by

$$\Delta H = \int_{-\infty}^{t_1^*} \frac{dH}{dt}\,(\mathbf{q}^u(t;z_0,\varepsilon))dt - \int_{\infty}^{t_1^*} \frac{dH}{dt}\,(\mathbf{q}^s(t;z_1,\varepsilon))dt.$$

After approximating $\mathbf{q}^u(t;z_0,\varepsilon)$ with $\mathbf{q}_0^{z_0}$ the solution on the instantaneous separatrix, and $\mathbf{q}^s(t;z_1,\varepsilon)$ with $\mathbf{q}_0^{z_1}$, we obtain

$$\begin{aligned}\Delta H &= \int_{-\infty}^{\infty} \frac{dH}{dt}\,(\mathbf{q}_0^{z_0}(t))dt + \int_{-\infty}^{\infty} \frac{dH}{dt}\,(\mathbf{q}_0^{z_1}(t))dt + R_s(z_0,t_1^*) + R_u(z_1,t_1^*)\\ &= \varepsilon(h_1(z_0)+h_1(z_1)) + R_s(z_0,t_1^*) + R_u(z_1,t_1^*). \qquad (3.10)\end{aligned}$$

So ΔH is H_2 up to a remainder term and so H_2 can be interpreted as the signed distance between $W^u(\gamma_\varepsilon)$ and $W^s(\gamma_\varepsilon)$ in the neighborhood of γ_ε. For general $N\geqslant 2$, H_N can similarly be interpreted as the signed distance between these two manifolds. When N is even, this distance is measured along the x axis in the neighborhood of γ_ε, while for odd N, the distance is measured along some normal $\mathbf{n}(z)$.

Remark 2: In some cases, the symmetries of the Hamiltonian allow us to improve the error in (3.10), and therefore in (3.4). If $H(q,p,z)$ is invariant under the change of coordinates $p\to -p$, then the remainder terms $R_s(z_0,t_1^*)$ and $R_u(z_1,t_1^*)$ cancel each other out, and (3.10) becomes $\Delta H=\varepsilon(h_1(z_0)+h_1(z_1))+\mathcal{O}(\varepsilon^2)$.

IV. STATEMENT OF THE MAIN RESULT

Theorem 1: *Let (3.1) satisfy Assumption 1. Let $M_{N,A}(z,\varepsilon)$ denote the Nth-order adiabatic Melnikov function for (3.1), where N is a fixed positive integer. If (z_0,ε_0) is such that*

(1) $M_{N,A}(z_0,\varepsilon_0)=0$,
(2) $M_{1,A}(z_0)<-\kappa<0$ *and* $M_{j,A}(z_0,\varepsilon_0)<-\kappa<0$ *for* $j=2,\ldots,N-1$, *and*
(3) $dM_{N,A}/dz(z_0,\varepsilon_0)>\nu>0$,

then there exists a constant $\hat{\varepsilon}=\hat{\varepsilon}(\kappa,\nu,\alpha,\beta)$ where $0<\beta<\alpha<\frac{1}{2}$, such that for every $\varepsilon<\hat{\varepsilon}$ in an $\mathcal{O}(\varepsilon_0^{1+\alpha})$ size neighborhood of ε_0, and for some $z\in[z_0-\Delta z,z_0+\Delta z]$ with $\Delta z=\mathcal{O}(\varepsilon_0^{\beta})$, $W_\varepsilon^u(\gamma_\varepsilon)$ and $W_\varepsilon^s(\gamma_\varepsilon)$ intersect transversely in an N-pulse homoclinic orbit. Furthermore, the remainder terms in calculating M_N are $\mathcal{O}(\varepsilon^2)$ for type I systems and of $\mathcal{O}(\varepsilon^2\ln(1/\varepsilon))$ for type II systems.

When the expansion of $h_1(z_0+\varepsilon\Sigma_{j=1}^{N-1}P(\varepsilon j_j))$ in ε about z_0 is considered in expression (3.9), the first and second terms of this asymptotic expansion are significant for systems of type I, while for type II systems, the second term in this expansion is of the same order as the remainder.

Remark 3: If the system (2.1) possesses multiple homoclinic orbits, the theory can be applied to each one separately, and further homoclinic orbits might be possible in which near-separatrix excursions occur near different homoclinic loops. Also, the theory can be immediately extended to the case of one or more heteroclinic orbits, with the relevant integrals being evaluated along the appropriate heteroclinic, as opposed to homoclinic, orbits. Finally, the second condition of the theorem can be relaxed by just requiring that $M_{1,A}(z_0)$ and $M_{j,A}(z_0,\varepsilon_0)$ for $j=2,\ldots,N-1$ are bounded away from zero. In systems where the topography is correct, such as a slowly varying Duffing equation, this extension enables the detection of a wider class of homoclinic solutions. In

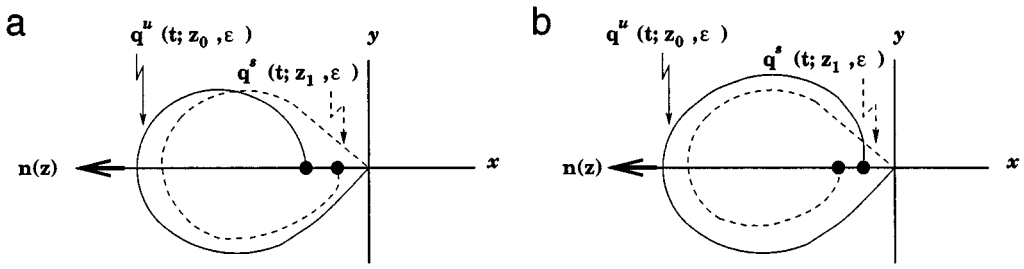

FIG. 3. Illustration of Remark 1 showing projections onto the $x-y$ plane of the solutions $\mathbf{q}^u(t;z_0,\varepsilon)$ on $W^u(\gamma_\varepsilon)$ (solid curve) and $\mathbf{q}^s(t;z_1,\varepsilon)$ on $W^s(\gamma_\varepsilon)$ (dashed curve). At time $t=t_1^*$ both solutions are on the x axis. Depending on the sign of $H(\mathbf{q}^u(t_1^*;z_0,\varepsilon),z_1^*)-H(\mathbf{q}^s(t_1^*;z_0,\varepsilon),z_1^*)$ we have (a) $H_2<0$ and (b) $H_2>0$.

some geometries, such as the slowly varying cubic, however, this extension is not relevant, since orbits with $M_{j,A}>0$ for some j never return to the neighborhood of γ_ε. In fact, in the example below, they escape from the slowly varying potential well.

Corollary 1: For the full damped and forced system (1.1) with $\mu\neq 0$ satisfying Assumption 1, with $M_{N,A}(z,\varepsilon)$ denoting its corresponding adiabatic Melnikov function, and for values (z_0,ε_0) that satisfy conditions (1), (2), and (3) of Theorem 1, the results of Theorem 1 hold.

Theorem 1 is proven in Secs. VI and VII, and the Corollary is proven in Sec. VIII.

V. AN EXAMPLE

In this section, we will deal with the case in which the Hamiltonian is periodic in z:

$$\dot{q}=p,\quad \dot{p}=q^2-F(z)-\varepsilon\mu p,\quad \dot{z}=\varepsilon, \tag{5.1}$$

where $F(z)\equiv 1+c+\cos(z)$, $c>0$, and $\mu>0$ is the dissipation parameter.[7,12] Its Hamiltonian has a slowly varying cubic potential: $H(p,q;z)=p^2/2-q^3/3+qF(z)-\frac{2}{3}F(z)^{3/2}$. System (5.1) is of type I and clearly satisfies our assumption: the $\varepsilon=0$ or frozen system has a saddle at $(q=-F(z)^{1/2}, p=0)$ for each $z\in[0,2\pi)$ so that γ_0 is compact and boundaryless. Each saddle is connected to itself by a homoclinic orbit Γ^z. Γ^z is parametrized by t as follows:

$$(F^{1/2}(z)(1-3\,\mathrm{sech}^2(F^{1/4}(z)t/\sqrt{2})),3\sqrt{2}F^{3/4}(z)\mathrm{sech}^2(F^{1/4}(z)t/\sqrt{2})\tanh(F^{1/4}(z)t/\sqrt{2})).$$

This expression for the instantaneous separatrix facilitates a direct computation of the adiabatic Melnikov function:

$$M_{1,A}(z_0;\mu)=\int_{-\infty}^{\infty}\frac{\partial H}{\partial z}(\mathbf{q}_0^{z_0}(t))dt=6\sqrt{2}F^{1/4}(z_0)\left(\sin(z_0)-\frac{4}{5}\mu F(z_0)\right).$$

Figure 4(a) shows plots of $M_{1,A}(z_0;\mu)$ as a function of z_0, for some values of μ. Each of its simple zeroes implies (via the implicit function theorem) a transverse intersection of $W^u(\gamma_\varepsilon)$ and $W^s(\gamma_\varepsilon)$. In the rest of the figures and the subsequent discussion, we set $\mu=0$ to simplify the numerical computations. We comment on the $\mu>0$ case in the remarks, as well as on the more general case in which the Hamiltonian is not periodic in z.

The zeroes of $M_{1,A}(z_0;0)\equiv M_{1,A}(z_0)$ of the form $\hat{z}_0=2k\pi$, where k is any integer (for which $M'_{1,A}(\hat{z}_0)>0$), correspond to a homoclinic orbit of (5.1) with a fast excursion near a maximum instantaneous separatrix. Each zero of the form $\hat{z}_0=(2k+1)\pi$ [for which $M'_{1,A}(\hat{z}_0)<0$] corresponds to a homoclinic orbit with a fast excursion near a minimum instantaneous separatrix.

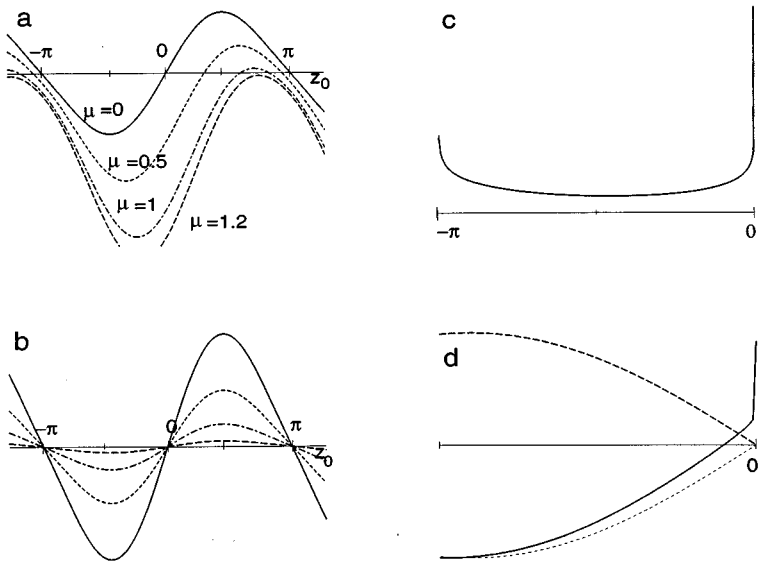

FIG. 4. Analysis of the example in Sec. V. (a) Plots of $M_{1,A}(z_0;\mu)$ for different values of μ. (b) Plots of $\varepsilon M_{1,A}(z_0;0)=\varepsilon M_{1,A}(z_0)$ for different values of ε: $\varepsilon=1$ (solid curve), $\varepsilon=0.5$ (long dashed curve), $\varepsilon=0.2$ (short and long dashed curve), and $\varepsilon=0.05$ (short dashed curve). (c) Behavior of $P(\varepsilon h_1(z_0))=P(\varepsilon M_{1,A}(z_0;0))$. (d) Intersection of $M_{1,A}(z_0+\varepsilon P(\varepsilon h_1(z_0)))$ (solid curve) with $-M_{1,A}(z_0)$ (long dashed curve). $M_{1,A}(z_0)$ (dotted curve) is also shown for $z_0\in(-\pi/2,0]$.

Figure 5 displays the intersection of $W^u(\gamma_\varepsilon)$ and $W^s(\gamma_\varepsilon)$ with the Poincaré section at $z=0$, $\Pi_{z=0}$, for some values of ε as ε decreases. In what follows, we denote $W^u(\gamma_\varepsilon)\cap\Pi_{z=0}$ by W^u, and $W^s(\gamma_\varepsilon)\cap\Pi_{z=0}$ by W^s. We label the primary intersection points of W^u and W^s by P_1; P_{1m}^{π}, $P_{1m}^{-\pi}$, where P_1 belongs to the homoclinic orbit with an excursion close to the maximum instantaneous separatrix at $z=0$. The orbits through P_{1m}^{π} and $P_{1m}^{-\pi}$ are the principal homoclinic orbits with excursions at the minimum instantaneous separatrices at $z=\pi$ and $z=-\pi$, respectively.

We proceed to find the intersection points that belong to the N-pulse homoclinic orbits described in Theorem 1. Beginning with $N=2$, the secondary adiabatic Melnikov function is:

$$M_{2,A}(z_0,\varepsilon)=M_{1,A}(z_0)+M_{1,A}(z_0+\varepsilon P(\varepsilon h_1(z_0))). \tag{5.2}$$

We look for zeroes of (5.2) that satisfy conditions 2 and 3 of Theorem 1. From Fig. 4(a), we see that z_0 must belong to the interval $(-\pi/2,0)$. To find these zeroes, we look first at the expression $\varepsilon P(\varepsilon h_1(z_0))$ in the argument of the second term of (5.2). Figure 4(b) shows plots of $\varepsilon h_1(z_0)=\varepsilon M_{1,A}(z_0)$ as ε decreases, and Fig. 4(c) displays the behavior of $P(\varepsilon h_1(z_0))$, where for each z_0, $P(\varepsilon h_1(z_0))$ denotes the period of the periodic orbit of the frozen system (system (5.1) with $\varepsilon=0$) with $z=z_0$, with energy $\varepsilon h_1(z_0)$. Thus, $P(\varepsilon h_1(z_0))$ can be obtained via complete elliptic integrals of the first kind. For ε small, $P(\varepsilon h_1(z_0))=\mathcal{O}(\ln(1/\varepsilon h_1(z_0)))$; hence the graph in Fig. 4(c) diverges at $z_0=0$. However, as $\varepsilon\to 0$, $\varepsilon P(\varepsilon h_1(z_0))\to 0$, at least for $h_1(z_0)$ not exponentially small. Thus, for ε small, the graph of $M_{1,A}(z_0+\varepsilon P(\varepsilon h_1(z_0)))$ is the graph of $M_{1,A}(z_0)$ slightly translated (nonuniformly) to the left. Finally, as Fig. 4(d) shows, the zero $z_{0,2}$ of $M_{2,A}(z_0,\varepsilon)$ is obtained by the intersection of the graph of $M_{1,A}(z_0+\varepsilon P(\varepsilon h_1(z_0)))$ and that of $-M_{1,A}(z_0,\varepsilon)$.

We now use our estimate of $\varepsilon P(\varepsilon h_1(z_0))$ to obtain an estimate on the size of $z_{0,2}$. We expand $M_{1,A}(z_0+\varepsilon P(\varepsilon h_1(z_0)))$ about z_0: $M_{1,A}(z_0+\varepsilon P(\varepsilon h_1(z_0)))=M_{1,A}(z_0)+M'_{1,A}(z_0)\mathcal{O}(\varepsilon\ln 1/\varepsilon)+\mathcal{O}(\varepsilon^2\ln^2 1/\varepsilon)$. Equation (5.2) becomes

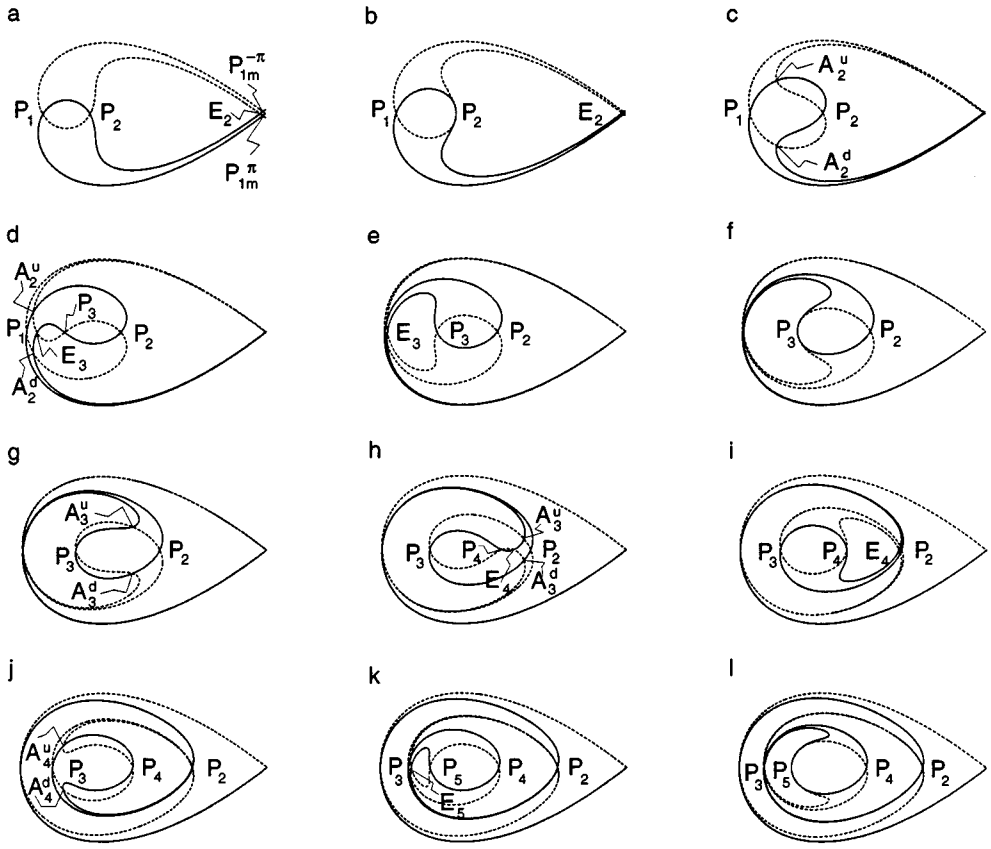

FIG. 5. Poincaré sections at $z=0$ of the intersections of W^u (solid) and W^s (dashed) for system (5.1) with $\mu=0$ for decreasing values of ε. Intersection points are labelled as P_i, E_i, and $A_i^{u,d}$. The P_i intersection points correspond to the i-pulse homoclinic orbits whose existence is established via Theorem 1. These pictures were obtained by numerical simulations based on the algorithm also used in Ref. 17. We used a symplectic integration method, and the code was developed by Steven P. Weibel. The values of ε in each of the panels are (a) $\varepsilon=1$, (b) $\varepsilon=0.9$, (c) $\varepsilon=0.8$, (d) $\varepsilon=0.68$, (e) $\varepsilon=0.6$, (f) $\varepsilon=0.54$, (g) $\varepsilon=0.5$, (h) $\varepsilon=0.45$, (i) $\varepsilon=0.4$, (j) $\varepsilon=0.35$, (k) $\varepsilon=0.325$, and (l) $\varepsilon=0.3$.

$$M_{2,A}(z_0,\varepsilon)=2M_{1,A}(z_0)+M'_{1,A}(z_0)\mathcal{O}\left(\varepsilon\ \ln\frac{1}{\varepsilon}\right)+\mathcal{O}\left(\varepsilon^2\ \ln^2\frac{1}{\varepsilon}\right),$$

where we are interested in the case $M'_{1,A}(z_0)>0$. Note that $M'_{1,A}(z_0)=\mathcal{O}(1)$. Then, $M_{2,A}(z_0,\varepsilon)=0$ implies

$$0=2M_{1,A}(z_{0,2})+M'_{1,A}(z_{0,2})\mathcal{O}\left(\varepsilon\ \ln\frac{1}{\varepsilon}\right)+\mathcal{O}\left(\varepsilon^2\ \ln^2\frac{1}{\varepsilon}\right).$$

The first two terms on the right cancel each other out when $M_{1,A}(z_{0,2})$ is itself $\mathcal{O}(\varepsilon \ln 1/\varepsilon)$, which in turn makes $z_{0,2}$ of $\mathcal{O}(\varepsilon \ln 1/\varepsilon)$. In fact, $z_{0,2}$ is $\mathcal{O}(\varepsilon \ln 1/\varepsilon)$ to the left of the zero $z=0$ of $M_{1,A}$. From Theorem 1, we conclude that $W^u(\gamma_\varepsilon)$ and $W^s(\gamma_\varepsilon)$ intersect in a two-pulse homoclinic orbit that makes two excursions near the maximum separatrix. The first excursion reaches its minimum in q at $z=z_{0,2}=\mathcal{O}(\varepsilon \ln 1/\varepsilon)$ to the left of $z=0$. It is not difficult to see that the second fast excursion reaches its minimum in q at $z=z_{1,2}=\mathcal{O}(\varepsilon \ln 1/\varepsilon)$ to the right of $z=0$, since we can

always write $M_{2,A}(z_1,\varepsilon)=M_{1,A}(z_1-\varepsilon P(\varepsilon h_1(z_1)))+M_{1,A}(z_1,\varepsilon)$, where z_1 corresponds to the second time the solution $\mathbf{q}^u(t;z_0,\varepsilon)$ reaches a normal $\mathbf{n}(z)$. In Fig. 5, this two-pulse homoclinic orbit corresponds to the intersection point labelled as P_2.

Remark 4: When the Hamiltonian is odd about its zero, as in this example with $\mu=0$ in (5.1), the points $z_{0,2}$ and $z_{1,2}$ are equidistant from $z=0$, a zero of $M_{1,A}$. Using (3.4), and expanding z_0 and z_1 about $z=0$, we get $M_{2,A} = 2h_1(0) + h_1'(0)z_0 + h_1'(0)z_1 + h_1''(0)z_0^2 + h_1''(0)z_1^2 + \mathcal{O}(z_0^3;z_1^3)$. Since $h_1(0) = h_1''(0) = 0$, then $M_{2,A}=0$ implies $z_0=-z_1$, at least up to $\mathcal{O}(\varepsilon^2)$ terms. See Remark 2. However, when the Hamiltonian is not odd about its zero as in the case of $\mu>0$ in (5.1), $h''(0)\neq 0$, and then the equality $z_0=-z_1$ holds up to $\mathcal{O}(\varepsilon^2 \ln^2 1/\varepsilon)$ terms.

We proceed now to consider the tertiary Melnikov function:

$$M_{3,A}(z_0,\varepsilon)=M_{2,A}(z_0,\varepsilon)+M_{1,A}(z_0+\varepsilon P(\varepsilon h_1(z_0))+\varepsilon P(\varepsilon h_2(z_0))). \tag{5.3}$$

Again, asymptotically as $\varepsilon\to 0$, $\varepsilon P(\varepsilon h_1(z_0))+\varepsilon P(\varepsilon h_2(z_0))=\mathcal{O}(\varepsilon \ln 1/\varepsilon)$, so (5.3) can be written as follows:

$$M_{3,A}(z_0,\varepsilon)=3M_{1,A}(z_0,\varepsilon)+2M_{1,A}'(z_0)\mathcal{O}\left(\varepsilon \ln\frac{1}{\varepsilon}\right)+\mathcal{O}\left(\varepsilon^2 \ln^2\frac{1}{\varepsilon}\right),$$

which yields that the zero $z_{0,3}$ of this function is $\mathcal{O}(\varepsilon \ln 1/\varepsilon)$ to the left of $z_{0,2}$, for ε sufficiently small. The intersection point corresponding to this three-pulse homoclinic orbit is labelled as P_3 in Fig. 5.

Proceeding in the same manner, for any finite N, and for ε sufficiently small, we find that

$$M_{N,A}(z_0,\varepsilon)=NM_{1,A}(z_0,\varepsilon)+(N-1)M_{1,A}'(z_0)\mathcal{O}\left(\varepsilon \ln\frac{1}{\varepsilon}\right)+\mathcal{O}\left(\varepsilon^2 \ln^2\frac{1}{\varepsilon}\right).$$

Hence, our N-pulse homoclinic orbits make N excursions close to the maximum instantaneous separatrix, and its successive minima in q are $\mathcal{O}(\varepsilon \ln 1/\varepsilon)$ apart. These orbits correspond to the intersection points labeled as P_2, P_3, P_4, P_5,... in Fig. 5.

In what follows we discuss the intersection points labeled E_i and A_i in Fig. 5. Consider first Figs. 5(a) and 5(b). Let $S[P_1,\ P_{1m}^{-\pi}]$ be the segment of W^s between the two primary intersection points (pips) P_1 and $P_{1m}^{-\pi}$. After one period, all points in this segment of W^s will be mapped to the neighborhood of γ_ε, and will remain there forever after. Similarly, let $U[P_{1m}^{\pi},\ P_1]$ be the segment of W^u between the pips P_{1m}^{π} and P_1. All previous images of this segment under the Poincaré map stay in the neighborhood of γ_ε.

Now, consider the point $E_2\in S[P_1,\ P_{1m}^{-\pi}]$. All of its forward images under the Poincaré map will stay in the neighborhood of γ_ε, getting closer and closer to it. Also, since $E_2\in U[P_{1m}^{\pi},\ P_1]$, all of its preimages were in the neighborhood of γ_ε. Here E_2 is on the q axis, inside a box $\mathcal{B}$ in the neighborhood of γ_ε. See Sec. VI for the definition of $\mathcal{B}$. In Sec. VI, we write a normal form [see Eq. (6.1)] for Eqs. (5.1) in $\mathcal{B}$. Using this normal form, we conclude that the orbit through E_2 should leave the box $\mathcal{B}$, and therefore it should make another excursion away from γ_ε to finally asymptote to γ_ε. We do a similar analysis for the backward orbit through E_2. Thus, E_2 corresponds to a two-pulse homoclinic orbit. As $\varepsilon\to 0$, the distance between E_2 and $P_{1m}^{-\pi}$ gets exponentially small, as measured on $U[P_1,\ P_{1m}^{-\pi}]$.

The same reasoning applies to P_2: its image after one period is in the neighborhood of γ_ε, and remains there ever after. All of its preimages are in the neighborhood of γ_ε. Note also, as measured in arclength along $U[P_1,\ P_{1m}^{-\pi}]$, that P_1 is closer to P_2 than E_2, so P_2 must correspond to the two-pulse homoclinic whose existence is guaranteed by the zero of $M_{2,A}(z_0,\varepsilon)$. The main difference between P_2 and E_2 is the time their orbits spend in between their fast excursions away from γ_ε. As $\varepsilon\to 0$, the orbit through P_2 takes an $\mathcal{O}(\varepsilon \ln 1/\varepsilon)$ amount of z-time during this excursion, while the one through E_2 spends an $\mathcal{O}(1)$ amount of z-time, since it gets exponentially close

to γ_ε the second time it reaches the q axis. See Figs. 5(b) and 5(c). Also, since it is exponentially close to $P_{1m}^{-\pi}$ along $U[P_1, P_{1m}^{-\pi}]$, and exponentially close to P_{1m}^{π} along $S[P_{1m}^{\pi}, P_1]$, we expect this two-pulse homoclinic orbit to make its fast excursions exponentially close to the primary homoclinic orbits at the minimum separatrices occuring at $z=-\pi$ and $z=\pi$. See Fig. 6.

Each of the points labelled by A_2^d and A_2^u (the letter A is chosen to refer to asymmetric) corresponds also to a two-pulse homoclinic orbit. These orbits are born when, as ε decreases, the angle formed by the segment of W^u and that of W^s at their intersection at P_2 changes sign, that is, when W^u and W^s are tangent at P_2. See Fig. 5(b). Once born, as $\varepsilon\to 0$, these points get exponentially close to P_1 [see the cases 5(d) and 5(e)]. Thus, their corresponding homoclinic orbits make one excursion at a maximum separatrix and one at a minimum one. A_2^d first makes an excursion exponentially close to the one-pulse homoclinic orbit with a fast excursion at $z=-\pi$, and another one exponentially close to the one-pulse homoclinic that makes a fast excursion at $z=0$. A_2^u makes first an excursion exponentially close to the maximum principal homoclinic orbit (at $z=0$) and then one exponentially close to the minimum one (at $z=\pi$). See Fig. 6.

Remark 5: In principle, the tangency in which A_2^u and A_2^d are born can be detected by computing higher derivatives of $H_2(z_0,\varepsilon)$. When $H_2(z_0^*,\varepsilon^*)=0$, there are three different ways for W^u and W^s to intersect at P_2, as is shown in Fig. 7. Using the interpretation of $H_2(z_0,\varepsilon)$ as a signed distance between W^u and W^s (see Remark 1 in Sec. III), one can distinguish among these three possibilities by looking at the sign of $\partial H_2/\partial z_0$. Thus, the tangency at which A_2^u and A_2^d are born occurs at the value of ε that satisfies

$$H_2(z_0^*,\varepsilon^*)=0, \quad \frac{\partial H_2}{\partial z_0}(z_0^*,\varepsilon^*)=0, \quad \text{and} \quad \frac{\partial^2 H_2}{\partial \varepsilon\, \partial z_0}(z_0^*,\varepsilon^*)<0.$$

However, we cannot compute this ε^*, since our results for approximating H_2 with εh_2 are valid asymptotically as $\varepsilon\to 0$, and for ε sufficiently small it is always the case that $\partial h_2/\partial z_0>0$. For example, from Fig. 5(b), we can see that the value for (5.1) is $\varepsilon^*\approx 0.9$.

We now continue with the description of Fig. 5. As ε decreases, one notices that more and more intersection points appear. In Fig. 5(d), two tertiary intersection points have been born: P_3 and E_3. P_3 corresponds to the three-pulse homoclinic orbit obtained from the zero of $M_{3,A}(z_0,\varepsilon)$. The intersection point E_3 gets exponentially close to P_1 as $\varepsilon\to 0$, which means that its corresponding homoclinic orbit spends $\mathcal{O}(1)$ amount of z-time in between its fast excursions; these excursions occur at $z=-\pi$, $z=0$, and $z=\pi$, each of which is exponentially close to the corresponding one-pulse homoclinic. In Fig. 5(g), A_3^u and A_3^d have appeared. They were born in the tangency of the segments of W^u and W^s at P_3. See case 5(f). We point out that this is the same type of tangency that gave birth to A_2^u and A_2^d. As $\varepsilon\to 0$, A_3^u and A_3^d get exponentially close to P_2, and the corresponding three-pulse homoclinic orbits look like those shown in Fig. 6.

As ε continues to decrease, we see that P_4 and E_4 appear, followed by A_4^u and A_4^d. Then P_5 and E_5 are born, and so on. Figure 8 summarizes the location of some of these intersection points with respect to the q axis.

All the intersection points labeled as P_i correspond to the i-pulse homoclinic orbits that are detected by the zeroes of $M_{i,A}(z_0,\varepsilon)$, as explained at the beginning of this section. As $\varepsilon\to 0$, the homoclinic orbits corresponding to E_i intersection points make fast excursions that are exponentially close to the minimum instantaneous separatrix $z=-\pi$, then to the homoclinic orbit corresponding to P_{i-2}, and finally to the minimum instantaneous separatrix at $z=\pi$. The ones corresponding to the $A_i^{u,d}$ intersection points make an excursion exponentially close to the homoclinic orbit of P_{i-1}, and to one of the minimum instantaneous separatrices (see Fig. 6). All the $A_i^{u,d}$ intersection points are born when W^u and W^s are tangent at P_i. As mentioned in Remark 5, these tangencies can be detected, in principle, via the higher derivatives of H_i.

Although the existence of all the P_i, E_i, and $A_i^{u,d}$ intersection points in the z periodic Hamiltonian case follows automatically from the existence of primary intersection points, a de-

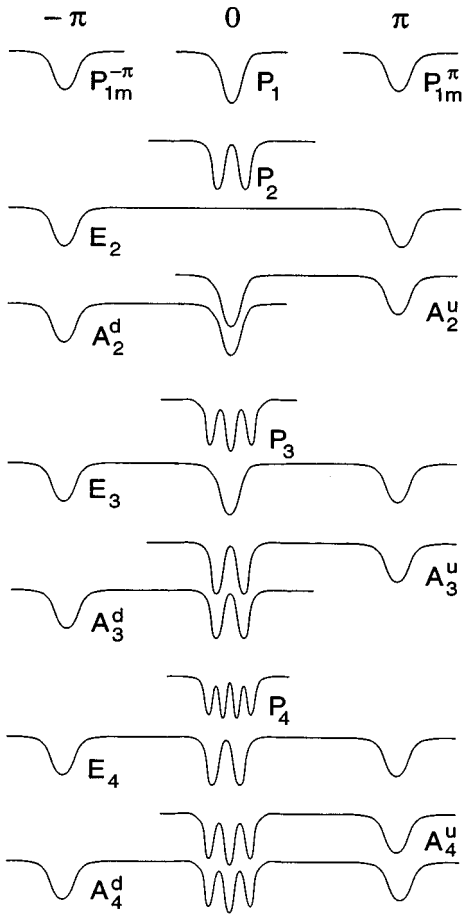

FIG. 6. Diagram of the behavior of the multi-pulse homoclinic orbits corresponding to the different intersection points described in Fig. 5 for ε sufficiently small. Slow time z increases from left to right. The top three curves represent the principal homoclinic orbits, whose existence is established by the zeroes of the one-pulse adiabatic Melnikov function. The curves labelled as P_i for $i \geq 2$ represent homoclinic orbits with i fast excursions close to the maximum instantaneous separatrix. The curves labelled as E_i for $i \geq 2$ correspond to homoclinic orbits that make a fast excursion exponentially close to the principal homoclinic orbit with a fast excursion at $z = -\pi$, then make $i-2$ fast excursions exponentially close to the fast excursions of the homoclinic orbit corresponding to P_{i-2}, and finally they make another fast excursion exponentially close to the fast excursion of the principal homoclinic orbit that makes its fast excursion close to the minimum instantaneous separatrix at $z = \pi$.

tailed characterization of the corresponding homoclinic orbits is given by the above results. As we have shown, Theorem 1 can be used to obtain asymptotics of the homoclinic orbits corresponding to the P_i. Moreover, the existence and local uniqueness of the orbits corresponding to the E_i and $A_i^{u,d}$ intersection points is rigorously shown using the techniques developed in Refs. 10 and 22. This method has the advantage that, in addition to providing a more detailed description of the location in phase space of these multi-pulse homoclinic orbits, it also can be used in the dissipative case, in the nonperiodic Hamiltonian case, and in other higher-dimensional[22] and non-Hamiltonian systems.[26,27] We now briefly describe the use of this method in the case of the two-pulse homoclinic orbit corresponding to E_2 for our example. The main idea is to construct it as the transverse intersection of two invariant manifolds. One of these manifolds, $\mathcal{M}_\varepsilon$, is chosen so that all initial conditions on it leave the neighborhood of γ_ε exponentially close to $W^u(\gamma_\varepsilon)$ in an open interval of z values containing $z = \pi$. Since $\mathcal{M}_\varepsilon$ is exponentially close to $W^u(\gamma_\varepsilon)$ on exit and since

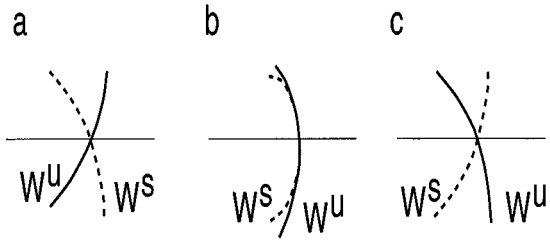

FIG. 7. Intersections of W^u and W^s at P_2. Case (a) corresponds to $\partial H_2/\partial z_0<0$, case (b) to $\partial H_2/\partial z_0=0$, and case (c) to $\partial H_2/\partial z_0>0$.

$W^u(\gamma_\varepsilon)$ and $W^s(\gamma_\varepsilon)$ intersect transversely in the principal homoclinic orbit close to the minimum instantaneous separatrix with a fast excursion at $z=\pi$, then $\mathscr{M}_\varepsilon$ and $W^s(\gamma_\varepsilon)$ will intersect transversely, yielding the orbit corresponding to E_2 for positive z. A similar construction gives the orbit segment for negative z. Note, however that the extra symmetry in the Hamiltonian yields the same result (and also the symmetry of the homoclinic orbit through E_2).

Remark 6: Once it has been established that a system of the form (3.1), whose Hamiltonian is periodic in z, possesses (for ε sufficiently small) an N-pulse homoclinic orbit that corresponds to the P_N intersection point, we can show that there is a periodic orbit close to it. The method of proof is that of Ref. 10, where we construct the periodic orbit as the transverse intersection of two invariant manifolds, say $\mathscr{M}_\varepsilon$ and $\mathscr{N}_\varepsilon$. $\mathscr{M}_\varepsilon$ is obtained by flowing an appropriate set of ''initial conditions'' forward in time, and the other invariant manifold, $\mathscr{N}_\varepsilon$, by flowing a set of ''final conditions'' backward in time. These sets of initial and final conditions are chosen so that when $\mathscr{M}_\varepsilon$ and $\mathscr{N}_\varepsilon$ leave the neighborhood $\mathscr{B}$ of γ_ε, they do so exponentially close to $W^u(\gamma_\varepsilon)$ and $W^s(\gamma_\varepsilon)$, respectively. [This result requires the use of a technical tool, ELESE,[28] that allows the tracking of invariant manifolds while orbits on them spend $\mathscr{O}(1/\varepsilon)$ amounts of time near a slow manifold.] Furthermore, $\mathscr{M}_\varepsilon$ and $\mathscr{N}_\varepsilon$ are $\mathscr{C}^1$-exponentially close to $W^u(\gamma_\varepsilon)$ and $W^s(\gamma_\varepsilon)$ in the regions where $W^u(\gamma_\varepsilon)$ and $W^s(\gamma_\varepsilon)$ intersect transversely in an N-pulse homoclinic orbit. Thus, automatically, our invariant manifolds also intersect transversely, and their intersection is exponentially close to the N-pulse homoclinic orbit during its fast excursions away from γ_ε. Finally, if the sets of initial and final conditions are chosen properly, the resulting orbit is periodic.

Remark 7: The identification of the intersection points of W^u and W^s that we have carried out for the system (5.1) with $\mu=0$ suggests that the periodic orbits obtained in Remark 6 may be related to (and may even be the same as) the periodic orbits that were found via topological shooting in Ref. 7, and via matched asymptotic expansions in Ref. 12. The asymptotics of the periodic orbits obtained in Remark 6 satisfy the properties of the spikes of the periodic orbits in Ref. 7. In Ref. 7 the periodic orbits were labelled as (i,j), for $i=0,1,2,3...$, and $j=0,1$; i denotes the number of fast excursions the orbit makes in the neighborhood of the maximum instantaneous

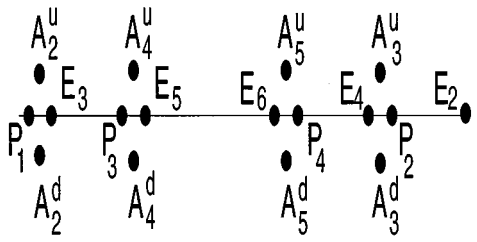

FIG. 8. A schematic representation of the location of the intersection points (up to $i=6$) of W^u and W^s of system (5.1) with $\mu=0$ with respect to the q axis.

separatrix, and j corresponds to either zero or one excursions close to the instantaneous minimum separatrix. Borrowing the same (i,j) labelling, our $(i,0)$ periodic orbits are close to the i-pulse homoclinic orbits whose existence we show via the zero of $M_{i,A}(z_0,\varepsilon)$ and correspond to the intersection point P_i, and the $(i,1)$ periodic orbits are close to the i-pulse homoclinic orbits associated to the A^u_{i-1} intersection point. We point out that, for ε sufficiently small, the homoclinic orbits corresponding to the P_i intersection points which make i fast excursions, occur only close to the maximum instantaneous separatrix, not to the minimum one. This suggests that the periodic orbits found by the method of Remark 6 may not have more than one excursion near the minimum instantaneous separatrix, as is the case for those found in Ref. 7 and 12.

VI. LOCAL ESTIMATES

In this section, we present a local analysis of (3.1) near γ_ε when $0<\varepsilon\ll 1$ and near γ_0 when $\varepsilon=0$. In particular, we study the Fenichel normal forms for both systems. The first one gives the local behavior of Eqs. (3.1) in a neighborhood $\hat{\mathscr{B}}$ of γ_ε. The second one is for Eqs. (3.1) with $\varepsilon=0$ and $z=z_0$ fixed; i.e., for the unperturbed case. Then, using these normal forms, we compute in Lemma 1 the time that $\mathbf{q}^{z_0}_{h_1}$, the unperturbed periodic solution with $z=z_0$ and energy εh_1, spends inside $\hat{\mathscr{B}}$. In Lemma 2, we perform a similar computation for the perturbed trajectory $\mathbf{q}^u(t;z_0,\varepsilon)$ on $W^u(\gamma_\varepsilon)$ that has energy H_1 at time $t=t_1^*$. To homogenize notation, we call this solution $\mathbf{q}^u_{H_1}$.

We begin by deriving the Fenichel normal form for Eqs. (3.1) in a neighborhood $\hat{\mathscr{B}}$ of γ_ε. The instantaneous eigenvalues for the linearization about the saddle $(q_e(z),p_e(z))$ are $\pm S(z)$, where $S(z)\equiv[H^2_{qp}-H_{pp}H_{qq}]^{1/2}(q_e(z),p_e(z),z)$. Hence, using the instantaneous eigenvectors as new coordinate axes, we define the variables

$$\xi\equiv-\left(\frac{1}{2}+\frac{H_{qp}}{2S(z)}\right)x-\frac{H_{pp}}{2S(z)}\,y,$$

$$\eta\equiv-\left(\frac{1}{2}-\frac{H_{qp}}{2S(z)}\right)x+\frac{H_{pp}}{2S(z)}\,y,$$

where all partial derivatives are evaluated at $(q_e(z),p_e(z),z)$. The inverse coordinate change is then given by:

$$x\equiv-\xi-\eta,$$

$$y\equiv-\left(\frac{S(z)-H_{qp}}{H_{pp}}\right)\xi+\left(\frac{S(z)+H_{qp}}{H_{pp}}\right)\eta.$$

In terms of these new coordinates, Eqs. (3.1) can be written as

$$\dot{\xi}=S(z)\xi+\tilde{g}_1(\xi,\eta,z;\varepsilon),\quad \dot{\eta}=-S(z)\eta+\tilde{g}_2(\xi,\eta,z;\varepsilon),\quad \dot{z}=\varepsilon,$$

in the neighborhood of γ_ε, where $\tilde{g}_i$, $i=1,2$, are C^r functions representing terms that are nonlinear in ξ and η, as well as linear terms in ξ and η that are $\mathscr{O}(\varepsilon)$. This form of the equations is almost good enough. We need only one more coordinate change to bring the system into its most useful form.

Fenichel theory[25] (see also Ref. 29) asserts the existence of C^r smooth functions $\varphi^s(\eta,z;\varepsilon)$ and $\varphi^u(\xi,z;\varepsilon)$, for any $r>0$, defined for ξ and η in $\hat{\mathscr{B}}$ such that the sets

$$\{\xi=\varphi^s(\eta,z;\varepsilon)\}\quad\text{and}\quad\{\eta=\varphi^u(\xi,z;\varepsilon)\}$$

are the invariant manifolds $W^s_{\rm loc}(\gamma_\varepsilon)$ and $W^u_{\rm loc}(\gamma_\varepsilon)$, respectively. Moreover, these functions satisfy the properties $\varphi^s(0,z;\varepsilon)=0$, $(\partial\varphi^s/\partial\eta)(0,z;\varepsilon)=0$, $\varphi^u(0,z;\varepsilon)=0$, and $(\partial\varphi^u/\partial\xi)(0,z;\varepsilon)=0$. Hence, defining final variables as

$$a\equiv\xi-\varphi^s(\eta,z;\varepsilon) \quad \text{and} \quad b\equiv\eta-\varphi^u(\xi,z;\varepsilon),$$

the local manifolds are straightened out and given by the sets $\{a=0\}$ and $\{b=0\}$. Therefore, since these sets are invariant, Eqs. (3.1) can be written in the neighborhood of γ_ε as

$$\begin{aligned}\dot a&=S(z)a+g_1(a,b,z;\varepsilon)a,\\ \dot b&=-S(z)b+g_2(a,b,z;\varepsilon)b,\\ \dot z&=\varepsilon.\end{aligned}\tag{6.1}$$

This completes the derivation for the perturbed normal form in $\hat{\mathscr{B}}$. For $\Delta>0$ small, let $\mathscr{B}=\{(a,b,z):|a|\leqslant\Delta,|b|\leqslant\Delta\}$ be a neighborhood of γ_ε for which the normal form (6.1) is valid. From this point on, we replace $\hat{\mathscr{B}}$ with $\mathscr{B}$.

For the system (3.1), with $\varepsilon=0$ and $z=z_0$ we follow the same procedure as above to obtain nice local coordinates. First, we perform a linear coordinate change in the neighborhood of the saddle fixed point, which turns its eigenvectors into the coordinate axes. To avoid confusion with the $\varepsilon>0$ case, these coordinates will have the superscript "o". Thus (2.1) becomes

$$\begin{aligned}\dot\xi^o&=S(z_0)\xi^o+g_1^o(\eta^o,\xi^o;z_0),\\ \dot\eta^o&=S(z_0)\eta^o+g_2^o(\eta^o,\xi^o;z_0).\end{aligned}\tag{6.2}$$

Then we make another change of coordinates that will make the stable and unstable manifolds of the saddle fixed point become the new coordinate axes:

$$\begin{aligned}\dot a^o&=S(z_0)a^o+G_1(a^o,b^o;z_0)a^o,\\ \dot b^o&=-S(z_0)b^o+G_2(a^o,b^o;z_0)b^o.\end{aligned}\tag{6.3}$$

This Fenichel normal form holds inside a neighborhood of the form $\mathscr{B}^o=\{(a^o,b^o,z_0):|a^o|\leqslant\Delta_1,|b^o|\leqslant\Delta_1\}$, where we take Δ_1 such that $\mathscr{B}\subset\mathscr{B}^o$.

In the two following lemmas, we estimate the time for both the perturbed $\mathbf{q}^u_{H_1}$ and unperturbed $\mathbf{q}^{z_0}_{h_1}$ trajectories inside $\mathscr{B}$, where both (6.1) and (6.3) are valid. These results will be used in Sec. VII for the proof of Theorem 1. The reader may skip their proofs on an initial reading.

For clarity of notation, the times for the unperturbed system will also have a superscript "o". We split the time the unperturbed periodic orbit $\mathbf{q}^{z_0}_{h_1}$ spends in $\mathscr{B}$ in two intervals: first, from the entrance to the box at $t^o_{\rm in}$, to the x axis at t^{o*}_1, and second, from the x axis to the exit of $\mathscr{B}$ at $t^o_{\rm out}$. Let $(a^o_{\rm in},b^o_{\rm in})$ be the (a^o,b^o) coordinates at entry at $t^o_{\rm in}$ and (a^{o*},b^{o*}) the coordinates upon reaching the x axis at t^{o*}_1. Given the way the a^o and b^o coordinate axes were set up the trajectory has positive a^o and b^o coordinates throughout the flight inside $\mathscr{B}$ (see Fig. 9). By choice of construction, $b^o_{\rm in}=\Delta+\mathscr{O}(\varepsilon)$ and $a^o_{\rm out}=\Delta+\mathscr{O}(\varepsilon)$. We now introduce similar notation for the perturbed trajectory $\mathbf{q}^u_{H_1}$. Let $t_{\rm in}$ and $t_{\rm out}$ be the entry and exit times of $\mathbf{q}^u_{H_1}$ to and from the box $\mathscr{B}$, so that $b(t_{\rm in})=\Delta$ and $a(t_{\rm out})=\Delta$. Here t^*_1 is the time at which this trajectory reaches the x axis, with local coordinates (a^*,b^*). The time of flight of $\mathbf{q}^u_{H_1}$ in $\mathscr{B}$ will be also divided in two intervals, the first one being $t^*_1-t_{\rm in}$ and the second one $t_{\rm out}-t^*_1$.

Lemma 1: The amount of (fast) time $t^o_{\rm out}-t^o_{\rm in}$ the periodic orbit $\mathbf{q}^{z_0}_{h_1}$ spends in the box $\mathscr{B}$ is

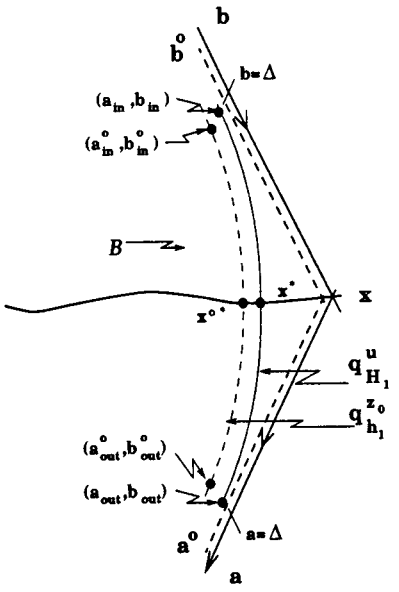

FIG. 9. Schematic representation of the perturbed $\mathbf{q}^{u}_{H_1}$ and unperturbed $\mathbf{q}^{z_0}_{h_1}$ trajectories inside the box $\mathscr{B}$.

$$\frac{-1}{S(z_0)}\left[\ln\left(\frac{1}{2V(z_0)}\sqrt{\frac{|\varepsilon h_1|}{a_3(z_0)}}\right)+\ln\left(\frac{1}{2U(z_0)}\sqrt{\frac{|\varepsilon h_1|}{a_3(z_0)}}\right)\right]+\frac{2}{S(z_0)}\ln\Delta+\mathscr{O}(\Delta,\varepsilon^{1/3}),$$

where

$$V(z_0)\equiv\frac{S(z_0)}{S(z_0)-H_{qp}(q_e(z_0),p_e(z_0))}\quad\text{and}\quad U(z_0)\equiv\frac{S(z_0)}{S(z_0)+H_{qp}(q_e(z_0),p_e(z_0))}.$$

Proof: We will use the second equation of (6.3) to estimate the first part of the flight $t_1^{o*}-t_{\text{in}}^{o}$ since we have control of the b^o coordinate on entry. The first equation in (6.3) will be used for the second interval $t_{\text{out}}^{o}-t_1^{o*}$.

The time $t_1^{o*}-t_{\text{in}}^{o}$ for the orbit $\mathbf{q}^{z_0}_{h_1}$ to travel from $(a^o_{\text{in}},b^o_{\text{in}})$ to (a^{o*},b^{o*}) is

$$\int_{t_{\text{in}}^{o}}^{t_1^{o*}}dt=\int_{b_{\text{in}}^{o}}^{b^{o*}}\frac{db^o}{-S(z_0)b^o+G_2(a^o,b^o;z_0)b^o}. \tag{6.4}$$

The singular part of the integrand is $-1/S(z_0)b^o$, so we add it and subtract it in the integrand above, to obtain

$$t_1^{o*}-t_{\text{in}}^{o}=\int_{b_{\text{in}}^{o}}^{b^{o*}}\frac{db^o}{-S(z_0)b^o}+\int_{b_{\text{in}}^{o}}^{b^{o*}}\frac{\overline{G_2}db^o}{-S(z_0)b^o(1-\overline{G_2})}, \tag{6.5}$$

where $\overline{G_2}\equiv G_2(a^o,b^o;z_0)/S(z_0)=k_1(z_0)a^o+k_2(z_0)b^o+k_3(z_0)a^{o2}+k_4(z_0)a^ob^o+k_5(z_0)b^{o2}+\mathscr{O}(a^{o3},a^{o2},\underline{b^o},a^ob^{o2},b^{o3})$. By directly computing the first integral in (6.5), and by using the expansion of G_2 together with the binomial expansion of $1/(1-G_2)$ in the second integral, (6.5) implies to leading order:

$$t_1^{o*}-t_{\rm in}^o=\frac{-1}{S(z_0)}\ln b^{o*}+\frac{1}{S(z_0)}\ln b_{\rm in}^o+\frac{-1}{S(z_0)}I^o, \tag{6.6}$$

where $I^o\equiv k_1(z_0)\,I_1^o+k_2(z_0)\,I_2^o+(k_1^2(z_0)+k_3(z_0))\,I_3^o+(2k_1(z_0)\,k_2(z_0)+k_4(z_0))\,I_4^o+(k_2^2(z_0)+k_5(z_0))I_5^o$. Here $I_1^o\equiv\int_{b_{\rm in}^o}^{b^{o*}}(a^o/b^o)db^o$, $I_2^o\equiv\int_{b_{\rm in}^o}^{b^{o*}}db^o$, $I_3^o\equiv\int_{b_{\rm in}^o}^{b^{o*}}a^{o2}/b^o db^o$, $I_4^o\equiv\int_{b_{\rm in}^o}^{b^{o*}}a^o db^o$ and $I_5^o\equiv\int_{b_{\rm in}^o}^{b^{o*}}b^o db^o$. In (6.6), higher-order terms involving integrands of $\mathcal{O}(3)$ have been neglected.

Now we relate b^{o*} to $x^{o*}\equiv x(t_1^{o*})$, the x-coordinate of $\mathbf{q}_{h_1}^{z_0}$ when it reaches the x axis. From the changes of coordinates that led us to (6.2), and since $y(t_1^{o*})=0$, we have $\xi^{o*}=-x^{o*}/2U(z_0)$, $\eta^{o*}=-x^{o*}/2V(z_0)$. The latter expressions give, to leading order, $a^{o*}=-x^{o*}/2U(z_0)$ and $b^{o*}=-x^{o*}/2V(z_0)$. Next, we relate x^{o*} to the ''energy'' εh_1 that the orbit has at time t_1^{o*}, using an expansion of the frozen Hamiltonian and recalling that $y(t_1^{o*})=0$, we obtain $H_1=-a_3(z_0)(x^{o*})^2+\mathcal{O}(3)$, where $a_3(z_0)>0$. Thus, $x^{o*}=-\sqrt{|\varepsilon h_1|/a_3(z_0)}(1+\mathcal{O}(\sqrt{\varepsilon}))$, which yields

$$\begin{aligned} a^{o*}&=\frac{1}{2U(z_0)}\sqrt{\frac{|\varepsilon h_1|}{a_3(z_0)}}\,(1+\mathcal{O}(\sqrt{\varepsilon})),\\ b^{o*}&=\frac{1}{2V(z_0)}\sqrt{\frac{|\varepsilon h_1|}{a_3(z_0)}}\,(1+\mathcal{O}(\sqrt{\varepsilon})). \end{aligned} \tag{6.7}$$

Replacing b^{o*} in the first logarithmic term of (6.6) with (6.7), and $b_{\rm in}^o$ with $\Delta+\mathcal{O}(\varepsilon)$ in the second logarithmic term, (6.6) becomes

$$t_1^{o*}-t_{\rm in}^o=\frac{-1}{S(z_0)}\ln\left(\frac{1}{2V(z_0)}\sqrt{\frac{|\varepsilon h_1|}{a_3(z_0)}}\right)+\frac{1}{S(z_0)}\ln\Delta-\frac{1}{S(z_0)}I^o+\mathcal{O}(\sqrt{\varepsilon}). \tag{6.8}$$

Thus, we have almost obtained the desired result for the first part of the trajectory. It remains to be shown that I^o is $\mathcal{O}(\Delta,\varepsilon^{1/3})$. We now estimate I_i^o for $i=1,2,...,5$.

I_2^o and I_5^o can be directly integrated: $I_2^o=b^{o*}-b_{\rm in}^o$, $I_5=\frac{1}{2}(b^{o*2}-b_{\rm in}^{o2})$. Next, since a^o is at most $\mathcal{O}(a^{o*})$ and b^o is at least $\mathcal{O}(b^{o*})$, I_3^o and I_4^o can be immediately estimated: $I_3^o=\mathcal{O}(a^{o*}|b^{o*}-b_{\rm in}^o|)$, and $I_4^o=\mathcal{O}(a^{o*}|b^{o*}-b_{\rm in}^o|)$. And, since $b_{\rm in}^o=\Delta+\mathcal{O}(\varepsilon)$, $b^{o*}=\mathcal{O}(\sqrt{\varepsilon})$, and $a^{o*}=\mathcal{O}(\sqrt{\varepsilon})$, we obtain

$$I_2^o=\mathcal{O}(\Delta,\sqrt{\varepsilon}),\quad I_3^o=\mathcal{O}(\sqrt{\varepsilon}),\quad I_4^o=\mathcal{O}(\sqrt{\varepsilon}),\quad \text{and } I_5^o=\mathcal{O}(\Delta^2,\sqrt{\varepsilon}). \tag{6.9}$$

To estimate I_1^o, we divide the interval of integration in two parts. The first part, from $b_{\rm in}^o$ to some $b_{\rm int}^o$ (an intermediate value of b^o to be specified later), and the second part from $b_{\rm int}^o$ to b^{o*}. Thus

$$I_1^o=\int_{b_{\rm in}^o}^{b_{\rm int}^o}\frac{a^o}{b^o}\,db^o+\int_{b_{\rm int}^o}^{b^{o*}}\frac{a^o}{b^o}\,db^o.$$

In the first integral, we take $a^o=\mathcal{O}(\sqrt{\varepsilon})$, and in the second one we use that a^o/b^o is at most a^{o*}/b^{o*}, which is $\mathcal{O}(1)$. Thus

$$I_1^o=\mathcal{O}(\sqrt{\varepsilon}|\ln b_{\rm int}^o-\ln b_{\rm in}^o|)+\mathcal{O}(|b^{o*}-b_{\rm int}^o|).$$

So, choosing $b_{\rm int}^o=\mathcal{O}(\varepsilon^\alpha)$ for $0<\alpha<\frac{1}{2}$ the last term of the above expression is $O(\varepsilon^\alpha)$. Without loss of generality, we let $\alpha=\frac{1}{3}$. Hence

$$I_1^o = \mathcal{O}(\sqrt{\varepsilon}\ \ln\ \varepsilon^{-1}, \varepsilon^{1/3}).$$

Combined with (6.9) this last estimate allows us to write

$$t_1^{o*} - t_{\text{in}}^o = \frac{-1}{S(z_0)} \ln\left(\frac{1}{2V(z_0)} \sqrt{\frac{|\varepsilon h_1|}{a_3(z_0)}} \right) + \frac{1}{S(z_0)} \ln\ \Delta + \mathcal{O}(\Delta, \varepsilon^{1/3}). \tag{6.10}$$

Thus, the desired difference is obtained for the first part of the flight inside $\mathcal{B}$. To estimate the time it takes for the second part of the flight inside, we start with the first equation of (6.3) and get

$$\int_{t_1^{o*}}^{t_{\text{out}}^o} dt = \int_{a^{o*}}^{a_{\text{out}}^o} \frac{da^o}{S(z_0)a^o + G_1(a^o, b^o; z_0)a^o}.$$

Then, we perform similar computations as above to obtain

$$t_{\text{out}}^o - t_1^{o*} = \frac{-1}{S(z_0)} \ln\left(\frac{1}{2U(z_0)} \sqrt{\frac{|\varepsilon h_1|}{a_3(z_0)}} \right) + \frac{1}{S(z_0)} \ln\ \Delta + \mathcal{O}(\Delta, \varepsilon^{1/3}). \tag{6.11}$$

Hence after adding (6.10) and (6.11), we arrive at the result claimed in Lemma 1.

Lemma 2: The (fast) time it takes for the solution $\mathbf{q}_{H_1}^u$ *on the unstable manifold to travel inside* $\mathcal{B}$ *is given by*

$$\frac{-1}{S(z_0)} \left[\ln\left(\frac{1}{2V(z_0)} \sqrt{\frac{|H_1|}{a_3(z_0)}} \right) + \ln\left(\frac{1}{2U(z_0)} \sqrt{\frac{|H_1|}{a_3(z_0)}} \right) \right] + \frac{2}{S(z_0)} \ln\ \Delta + \mathcal{O}(\Delta, |H_1|^{1/3}). \tag{6.12}$$

Remark 8: It will be seen in Sec. VII that $|H_1| = \mathcal{O}(\varepsilon)$, thus $\mathcal{O}(\Delta)$ is the dominant error. Also, we do not explicitly write out higher-order terms that are bounded by $\mathcal{O}(\sqrt{\varepsilon}\ \ln|H_1|^{-1})$.

Proof: Although the estimates are slightly more involved than for the unperturbed case, the calculation proceeds in the same fashion. Assume ε is small enough so that $\mathbf{q}_{H_1}^u(t_1^*)$ is in $\mathcal{B}$. Using Fenichel theory, we can explicitly state what the relationships between the nonlinear terms in the perturbed and unperturbed normal forms (6.1) and (6.3) are. We know that γ_ε and γ_0 are $\mathcal{C}^r$ $\mathcal{O}(\varepsilon)$ close. Also, $W_{\text{loc}}^s(\gamma_\varepsilon)$ and $W_{\text{loc}}^s(\gamma_0)$ are $\mathcal{C}^r$ $\mathcal{O}(\varepsilon)$ close, and so are $W_{\text{loc}}^u(\gamma_\varepsilon)$ and $W_{\text{loc}}^u(\gamma_0)$. Furthermore, the functions whose graphs are the perturbed stable and unstable manifolds are r times differentiable in z. See Ref. 25, or the exposition in Ref. 29. Taking these facts into consideration, one can see that for $i = 1,2$,

$$g_i(a,b,z;\varepsilon) = G_i(a,b;z_0) + \frac{\partial g_i}{\partial z}(a,b,z_0;0)(z - z_0) + \mathcal{O}(\varepsilon, (z-z_0)^2). \tag{6.13}$$

We now start by expanding $S(z)$ about z_0 and using (6.13) in the second equation of (6.1):

$$\dot{b} = -S(z_0)b + [G_2(a,b;z_0) + \mu(a,b;z_0)(z - z_0) + \mathcal{O}(\varepsilon, (z-z_0)^2)]b, \tag{6.14}$$

where $\mu(a,b;z_0) \equiv -S_z(z_0)/2S(z_0) + (\partial g_2/\partial z)(a,b,z_0;0)$. Then, we recall that $b^* \equiv b(t_1^*)$, so

$$\int_{t_{\text{in}}}^{t_1^*} dt = \int_{\Delta}^{b^*} \frac{db}{-S(z_0)b + [G_2 + \mu(z - z_0) + \mathcal{O}(\varepsilon, (z-z_0)^2)]b},$$

where G_2 and μ denote $G_2(a,b;z_0)$ and $\mu(a,b;z_0)$, respectively. We now add and subtract the singular part in the integrand to obtain

$$t_1^* - t_{\rm in} = \int_\Delta^{b^*} \frac{-db}{S(z_0)b} + \int_\Delta^{b^*} \frac{F db}{-S(z_0)b(1-F)}, \tag{6.15}$$

where $F \equiv \overline{G_2} + \overline{\mu}(z-z_0) + \mathcal{O}(\varepsilon,(z-z_0)^2)$, $\overline{G_2} \equiv G_2/S(z_0)$, and $\overline{\mu} \equiv \mu/S(z_0)$. Direct evaluation of the first integral gives

$$\int_\Delta^{b^*} \frac{-db}{S(z_0)b} = \frac{-1}{S(z_0)} \ln b^* + \frac{1}{S(z_0)} \ln \Delta.$$

To write b^* in terms of the energy of $\mathbf{q}^u_{H_1}$, we first write it in terms of its x coordinate x^* and then write this x^* in terms of H_1. Going back to the coordinate transformations described before Lemma 1, and recalling that $y^u(t_1^*) = 0$, we have

$$\xi^* = \frac{-1}{2U(z)} x^* \quad \text{and} \quad \eta^* = \frac{-1}{2V(z)} x^*.$$

In addition, using the properties of φ^s and φ^u, we know that

$$a^* \equiv a(t_1^*) = \xi^* + \mathcal{O}(\eta^{*2}) \quad \text{and} \quad b^* \equiv b(t_1^*) = \eta^* + \mathcal{O}(\xi^{*2}).$$

Hence, to leading order

$$x^* = -2V(z)b^* \quad \text{or} \quad x^* = -2U(z)a^*. \tag{6.16}$$

We then use the Taylor expansions of $V(z)$ and $U(z)$ around z_0,

$$\begin{aligned} V(z) &= V(z_0) + \varepsilon V'(z_0)(t_1^* - t_0) + \mathcal{O}(\varepsilon^2) \\ &= V(z_0) + \varepsilon V'(z_0)(t_1^* - t_{\rm in}) + \varepsilon V'(z_0)(t_{\rm in} - t_0) + \mathcal{O}(\varepsilon^2) = V(z_0)[1 + \mathcal{O}(\varepsilon(t_1^* - t_{\rm in}))], \end{aligned}$$

$$U(z) = U(z_0)[1 + \mathcal{O}(\varepsilon(t_1^* - t_{\rm in}))],$$

and substitute this in (6.16) to get

$$a^* = \frac{-x^*}{2U(z_0)} (1 + \mathcal{O}(\varepsilon(t_1^* - t_{\rm in}))) \quad \text{and} \quad b^* = \frac{-x^*}{2V(z_0)} (1 + \mathcal{O}(\varepsilon(t_1^* - t_{\rm in}))). \tag{6.17}$$

Now we proceed to estimate x^* in terms of the energy H_1 of the orbit we are studying when $x^u(t_1^*) = x^*$. By definition, we have $H_1 = H(x^*, 0, z_0 + \varepsilon r_1^*)$, where $t_1^* = z_0/\varepsilon + r_1^*$. In a neighborhood of γ_ε,

$$H_1 = -a_3(z)x^{*2} + a_4(z)x^{*3} + \mathcal{O}(4). \tag{6.18}$$

Solving (6.18) for x^* yields

$$x^* = -|H_1|^{1/2} \left[\frac{1}{\sqrt{a_3(z_0)}} - \frac{1}{2} \frac{a_3'(z_0)}{a_3^{3/2}(z_0)} \varepsilon r_1^* + \mathcal{O}(\varepsilon^2) \right] \left(1 + \frac{1}{2} \frac{a_4(z)}{a_3(z)} x^* + \mathcal{O}((x^*)^2) \right).$$

Hence,

$$x^* = \frac{-|H_1|^{1/2}}{\sqrt{a_3(z_0)}} [1 + \mathcal{O}(\varepsilon(t_1^* - t_{\rm in}), |H_1|^{1/2})]. \tag{6.19}$$

Using (6.17) and (6.19) in the integral for the singular part, we get

$$\int_{\Delta}^{b^*} \frac{-db}{S(z_0)b} = \frac{-1}{S(z_0)} \ln\left(\frac{1}{2V(z_0)} \sqrt{\frac{|H_1|}{a_3(z_0)}} \right) + \frac{1}{S(z_0)} \ln \Delta + \mathcal{O}(\varepsilon(t_1^* - t_{\text{in}}), \sqrt{|H_1|}). \quad (6.20)$$

Next, we estimate the second integral in (6.15). First, we decompose it:

$$\int_{\Delta}^{b^*} \frac{F db}{-S(z_0)b(1-F)} = \frac{-1}{S(z_0)} (I_g + I_\mu).$$

Here,

$$\begin{aligned} I_g \equiv & k_1(z_0)I_1 + k_2(z_0)I_2 + (k_1^2(z_0) + k_3(z_0))I_3 \\ & + (2k_1(z_0)k_2(z_0) + k_4(z_0))I_4 + (k_2^2(z_0) + k_3(z_0))I_5, \end{aligned}$$

where

$$I_1 \equiv \int_{\Delta}^{b^*} \frac{a}{b}\, db, \quad I_2 \equiv \int_{\Delta}^{b^*} db, \quad I_3 \equiv \int_{\Delta}^{b^*} \frac{a^2}{b}\, db, \quad I_4 \equiv \int_{\Delta}^{b^*} a\, db, \quad I_5 \equiv \int_{\Delta}^{b^*} b\, db,$$

and

$$\begin{aligned} I_\mu \equiv \int_{\Delta}^{b^*} \frac{1}{b} [& \overline{\mu}(z - z_0) + 2(k_1(z_0)a + k_2(z_0)b)\overline{\mu}(z - z_0) \\ & + \mathcal{O}((z - z_0)^2, a^2(z - z_0), ab(z - z_0), b^2(z - z_0), a(z - z_0)^2, b(z - z_0)^2, \varepsilon)] db. \end{aligned}$$

We note here that the integrands of I_i have the same form as those of I_i^o for $i = 1,...,5$.

We can directly integrate I_2 and I_5:

$$I_2 = b^* - \Delta, \quad I_5 = \tfrac{1}{2}(b^{*2} - \Delta^2).$$

Since a is at most $\mathcal{O}(a^*)$ and b is at least $\mathcal{O}(b^*)$, we get $I_3 = \mathcal{O}(a^*|b^* - \Delta|)$ and $I_4 = \mathcal{O}(a^*|b^* - \Delta|)$. Now, using (6.19) in (6.17), we obtain

$$\begin{aligned} a^* &= \mathcal{O}(\sqrt{|H_1|}, \sqrt{|H_1|}\varepsilon(t_1^* - t_{\text{in}})), \\ b^* &= \mathcal{O}(\sqrt{|H_1|}, \sqrt{|H_1|}\varepsilon(t_1^* - t_{\text{in}})), \end{aligned} \quad (6.21)$$

which yields

$$I_2 = \mathcal{O}(\Delta), \quad I_3 = \mathcal{O}(\sqrt{|H_1|}), \quad I_4 = \mathcal{O}(\sqrt{|H_1|}), \quad \text{and } I_5 = \mathcal{O}(\Delta^2).$$

To estimate I_1, we break the interval of integration in two:

$$I_1 = \int_{\Delta}^{b_{\text{int}}} \frac{a}{b}\, db + \int_{b_{\text{int}}}^{b^*} \frac{a}{b}\, db$$

where $b_{\text{int}} = \mathcal{O}(|H_1|^{1/3})$. This is similar to what we did for estimating I_1 in the unperturbed case and yields $I_1 = \mathcal{O}(\sqrt{|H_1|}\, \ln|H_1|^{-1}, |H_1|^{1/3})$ and hence

$$I_g = \mathcal{O}(\Delta, |H_1|^{1/3}).$$

Next, we estimate I_μ:

$$I_\mu \sim M\varepsilon(t_1^*-t_{\text{in}})|\ln b^*-\ln\Delta|+2M\varepsilon(t_1^*-t_{\text{in}})(k_2(z_0)|b^*-\Delta|+k_1(z_0)|H_1|^{1/3}), \quad (6.22)$$

where $M=\max\mu$, and since $b^*=\mathcal{O}(\sqrt{|H_1|})$,

$$I_\mu=\mathcal{O}(\varepsilon\ \ln|H_1|^{-1}(t_1^*-t_{\text{in}})).$$

Putting the estimates for I_g and I_μ together we arrive at the estimate for the first part of the flight inside $\mathcal{B}$.

$$t_1^*-t_{\text{in}}=\frac{-1}{S(z_0)}\ln\left(\frac{1}{2V(z_0)}\sqrt{\frac{|H_1|}{a_3(z_0)}}\right)+\frac{1}{S(z_0)}\ln\Delta+\mathcal{O}(\Delta,|H_1|^{1/3}). \quad (6.23)$$

Similarly, using the second equation of (6.3) and the fact that $a_{\text{out}}=a_{\text{out}}^o+\mathcal{O}(\varepsilon)$, the second part of the flight in $\mathcal{B}$ is

$$t_{\text{out}}-t_1^*=\frac{-1}{S(z_0)}\ln\left(\frac{1}{2U(z_0)}\sqrt{\frac{|H_1|}{a_3(z_0)}}\right)+\frac{1}{S(z_0)}\ln\Delta+\mathcal{O}(\Delta,|H_1|^{1/3}). \quad (6.24)$$

Finally adding (6.23) and (6.24), Lemma 2 is proved.

Remark 9: The technicality of splitting the trajectory at some intermediate b value was also used in adiabatic separatrix crossing theories (see Ref. 5, for example). It reflects the singular perturbation nature of the problem, with the trajectory from b_{in} to b_{int} being part of the inner solution extended into the overlap domain, and the trajectory from b_{int} to b^* being part of the outer solution similarly extended.

VII. PROOF OF THEOREM 1

We will divide the proof of Theorem 1 in five steps. The first step consists of showing $R_u(z_0,t_1^*)=\mathcal{O}(\varepsilon^2)$ as $\varepsilon\to 0$ for type I systems, and $R_u(z_0,t_1^*)=\mathcal{O}(\varepsilon^2\ln(1/\varepsilon))$ as $\varepsilon\to 0$ for type II systems. Thus, the value H_1 of the function H that the solution $\mathbf{q}^u(t;z_0,\varepsilon)$ has upon reaching the x axis at $t=t_1^*$ is $\varepsilon h_1(z_0)$ to leading order. We remark that this same proof shows that the remainders (3.7) involved in the N-pulse homoclinic orbits are also $\mathcal{O}(\varepsilon^2)$ for type I systems, while for type II systems they are $\mathcal{O}(\varepsilon^2\ln 1/\varepsilon)$. In step 2, we show that $z_1-z_0\sim\varepsilon P(\varepsilon h_1(z_0))$ as $\varepsilon\to 0$. Next, in step 3, we show that H_2 is given to leading order by $\varepsilon h_2(z_0,\varepsilon)=\varepsilon M_{2,A}(z_0,\varepsilon)$. Then, we show in step 4 that simple zeroes of h_2 [i.e., of the secondary Melnikov function $M_{2,A}(z_0,\varepsilon)$] correspond to simple zeroes of H_2. Thus step 4 shows how to obtain the existence of double pulse homoclinic orbits. Finally, we extend the double pulse result to a criterion for the existence of N-pulse homoclinic orbits involving the Nth-order Melnikov function $M_{N,A}(z_0,\varepsilon)$ in step 5. All the estimates in steps 3 through 5 have been carried out for type II systems, since their remainder terms are larger than those for type I systems. The estimates for type I systems are identical, with the estimates of the remainders improved as in Step 1.

A. Step 1

In this subsection we show that for systems of type I, $R_s(z_0,t_1^*)=\mathcal{O}(\varepsilon^2,\varepsilon|H_1|^{3/2}\ \ln|H_1|)$ and for type II systems, $R_s(z_0,t_1^*)=\mathcal{O}(|H_1|\varepsilon\ \ln 1/\varepsilon,\varepsilon^2)$ where we also obtain $H_1=\theta(\varepsilon)$ so the remainders are as claimed above. We start by recalling

$$-\varepsilon\int_{t_1^*}^{\infty}\frac{\partial H}{\partial z}(\mathbf{q}_0^{z_0}(t))dt=-\int_{t_1^*}^{\infty}\frac{dH}{dt}(\mathbf{q}_0^{z_0}(t))dt=H(\mathbf{q}_0^{z_0}(t_1^*),z_1^*),$$

where $z_1^*=\varepsilon t_1^*$. We expand this last expression in the z variable about z_0:

$$H(x_0^{z_0}(t_1^*),y_0^{z_0}(t_1^*),z_1^*)=\frac{\partial H}{\partial z}\,(x_0^{z_0}(t_1^*),y_0^{z_0}(t_1^*),z_0)(z_0-z_1^*)+\mathcal{O}((z_0-z_1^*)^2). \tag{7.1}$$

Here we have used $H(x_0^{z_0},y_0^{z_0},z_0)=0$, since we are evaluating H on an instantaneous separatrix. We first estimate $\mathbf{q}_0^{z_0}(t_1^*)\equiv(x_0^{z_0}(t_1^*),y_0^{z_0}(t_1^*),z_0)$, and then evaluate the partial derivative of H using $\partial H/\partial z=\mathcal{O}(x^2,xy,y^2)$ in the neighborhood of γ_ε. Moreover, $z_0-z_1^*=\mathcal{O}(\varepsilon\,\ln|H_1|)$ by (6.23) in Lemma 2. Putting these estimates together yields the desired result.

The linear approximation of the x coordinate of the instantaneous separatrix $\mathbf{q}_0^{z_0}$ is $x_0^{z_0}(t)\sim Ce^{-S(z_0)(t-t_{\rm in})}$, for large t. Hence, for $t=t_1^*$,

$$x_0^{z_0}(t_1^*)\sim Ce^{-S(z_0)(t_1^*-t_{\rm in})}.$$

Replacing $t_1^*-t_{\rm in}$ by the right-hand side of (6.23), we obtain

$$x_0^{z_0}(t_1^*)\sim C\left(\frac{1}{2V(z_0)\Delta}\,\sqrt{\frac{|H_1|}{a_3(z_0)}}\right)\exp(\mathcal{O}(\Delta,|H_1|^{1/3},\varepsilon(\ln|H_1|^{-1})^2,\sqrt{|H_1|}\,\ln|H_1|^{-1})),$$

which upon expansion yields

$$x_0^{z_0}(t_1^*)\sim C(1+\mathcal{O}(\Delta))\left(\frac{1}{2V(z_0)\Delta}\,\sqrt{\frac{|H_1|}{a_3(z_0)}}\right)+\mathcal{O}(|H_1|^{5/6}).$$

Similarly, we obtain $y_0^{z_0}(t_1^*)=\mathcal{O}(\sqrt{|H_1|})$. Putting these estimates of $x_0^{z_0}(t_1^*)$ and $y_0^{z_0}(t_1^*)$ into the expansion for $\partial H/\partial z$ yields $\partial H/\partial z(x_0^{z_0}(t_1^*),y_0^{z_0}(t_1^*),z_0)=\mathcal{O}(|H_1|)$ for type II systems. Thus, (7.1) becomes

$$H(\mathbf{q}_0^{z_0}(t_1^*),z_1^*)=\mathcal{O}(\varepsilon|H_1|\ln|H_1|).$$

For type I systems we can improve the estimate of the remainder. Since the z_0 we are interested in are $\mathcal{O}(\varepsilon\,\ln|H_1|)$ to the zero of $M_A(z)$, by (3.4) we have that $\alpha(z_0)=\mathcal{O}(\varepsilon\,\ln|H_1|)$, which together with the Taylor expansion of H in (x,y) about $(x,y)=(0,0)$ yields $(\partial H/\partial z)(x_0^{z_0}(t_1^*),\,y_0^{z_0}(t_1^*),z_0)=\mathcal{O}(|H_1|\varepsilon\,\ln|H_1|)$. Therefore (7.1) becomes of $\mathcal{O}(\varepsilon^2,\varepsilon^2|H_1|\ln^2|H_1|)$ and we have the desired result.

In conclusion, we now have

$$H_1=\varepsilon h_1+\mathcal{O}(\varepsilon^2),$$

$$H_1=\varepsilon h_1+\mathcal{O}\left(\varepsilon^2\,\ln\frac{1}{\varepsilon}\right) \tag{7.2}$$

for type I and type II systems, respectively.

B. Step 2

In this second step, we compare the (slow) time, z_1-z_0, that $\mathbf{q}_{H_1}^{\mu}$ spends in the oscillating regime with the period (in slow time), $\varepsilon P(\varepsilon h_1)$, of $\mathbf{q}_{h_1}^{z_0}$. The difference will be shown to be $\mathcal{O}(\varepsilon^{4/3})$. The proof holds for both type I and type II systems.

To accomplish this, we recall Lemmas 1 and 2 in which the time each of these trajectories spends inside $\mathcal{B}$ is computed. The difference in these slow times is calculated as $\mathcal{O}(\varepsilon^{4/3})$ in Corollary 2. Then, we show that the difference in the slow times of flight of these two trajectories outside of $\mathcal{B}$ is $\mathcal{O}(\varepsilon^{3/2})$. Hence, the total difference is $\mathcal{O}(\varepsilon^{4/3})$.

Corollary 2: Inside the box $\mathscr{B}$, the (fast) times of passage of $\mathbf{q}_{h_1}^{z_0}$ and $\mathbf{q}_{H_1}^{u}$ differ by $\mathscr{O}(|\varepsilon h_1|^{1/3})$, so that the slow times differ by $\mathscr{O}(\varepsilon^{4/3})$.

Proof: We rewrite (6.23), the first part of the time of flight of $\mathbf{q}_{H_1}^{u}$ inside $\mathscr{B}$, using (7.2):

$$t_1^* - t_{\text{in}} = -\frac{1}{S(z_0)} \ln\left(\frac{1}{2V(z_0)} \sqrt{\frac{|\varepsilon h_1|}{a_3(z_0)}} \right) + \frac{1}{S(z_0)} \ln \Delta - \frac{1}{S(z_0)} (I_g + I_\mu) + \mathscr{O}(\sqrt{\varepsilon}), \quad (7.3)$$

where, recall, $I_g = k_2(z_0) I_2 + (k_2^2(z_0) + k_5(z_0)) I_5 + \mathscr{O}(|\varepsilon h_1|^{1/3})$, $I_2 = b^* - \Delta$, $I_5 = \frac{1}{2}(b^{*2} - \Delta^2)$, and $I_\mu = \mathscr{O}(\varepsilon(\ln|\varepsilon h_1|^{-1})^2)$.

We compare this expression with (6.8), which corresponds to the time that the unperturbed periodic orbit $\mathbf{q}_{h_1}^{z_0}$ takes in its first part of the flight inside $\mathscr{B}$:

$$t_1^{o*} - t_{\text{in}}^{o} = -\frac{1}{S(z_0)} \ln\left(\frac{1}{2V(z_0)} \sqrt{\frac{|\varepsilon h_1|}{a_3(z_0)}} \right) + \frac{1}{S(z_0)} \ln \Delta - \frac{1}{S(z_0)} I^o + \mathscr{O}(\sqrt{\varepsilon})$$

where $I^o = k_2(z_0) I_2^o + (k_2^2(z_0) + k_5(z_0)) I_5^o + \mathscr{O}(\varepsilon^{1/3})$, $I_2^o = (b^{o*} - b_{\text{in}}^o)$ and $I_5^o = \frac{1}{2}(b^{o*2} - b_{\text{in}}^{o2})$. Thus, substituting $b_{\text{in}}^o = \Delta + \mathscr{O}(\sqrt{\varepsilon})$ and $b^{o*} = b^*(1 + \mathscr{O}(\sqrt{\varepsilon}))$ in I_2^o and I_5^o, we get

$$I_2 = I_2^o + \mathscr{O}(\sqrt{\varepsilon}) \quad \text{and} \quad I_5 = I_5^o + \mathscr{O}(\sqrt{\varepsilon}).$$

Hence, we can now compare the two time intervals:

$$t_1^* - t_{\text{in}} = t_1^{o*} - t_{\text{in}}^o + \mathscr{O}(\varepsilon^{1/3}).$$

A similar result is obtained when we compare the second half of the flights inside $\mathscr{B}$. This completes the proof of the corollary.

We now complete Step 2. By choice of construction, we know that the trajectories we are tracking satisfy $b_{\text{in}}^o = b_{\text{in}} + \mathscr{O}(\varepsilon) = \Delta + \mathscr{O}(\varepsilon)$ on entry to $\mathscr{B}$, and $a_{\text{out}}^o = a_{\text{out}} + \mathscr{O}(\varepsilon) = \Delta + \mathscr{O}(\varepsilon)$ upon exiting. On the other hand, given that a^{o*} is $\mathscr{O}(\sqrt{\varepsilon})$ and that the periodic orbit $\mathbf{q}_{h_1}^{z_0}$ takes an $\mathscr{O}(\ln|\varepsilon h_1|^{-1})$ amount of time in its first part of the flight in $\mathscr{B}$, we must have $a_{\text{in}}^o \ll \sqrt{\varepsilon}$ by (6.3). Similarly, for the perturbed trajectory $\mathbf{q}_{H_1}^{u}$: a^* is $\mathscr{O}(\sqrt{\varepsilon})$ and the first part of the flight in $\mathscr{B}$ takes an $\mathscr{O}(\ln|H_1|^{-1})$ amount of time. Hence, we must also have $a_{\text{in}} \ll \sqrt{\varepsilon}$ by (3.1). Now, since γ_0 and γ_ε are $\mathscr{C}^r\mathscr{O}(\varepsilon)$ close, and so are their local stable manifolds (given respectively by the sets $\{a^o = 0\}$ and $\{a = 0\}$) and the unstable ones (given by the sets $\{b^o = 0\}$ and $\{b = 0\}$), it follows that a_{in}^o and a_{in} are at least $\mathscr{O}(\sqrt{\varepsilon})$ close. Thus, $a_{\text{in}}^o = a_{\text{in}} + \mathscr{O}(\sqrt{\varepsilon})$. A similar argument shows that $b_{\text{out}}^o = b_{\text{out}} + \mathscr{O}(\sqrt{\varepsilon})$.

To compute the time difference outside $\mathscr{B}$, we start by using the result from the previous discussion for $\mathbf{q}_{H_1}^{u}$ and $\mathbf{q}_{h_1}^{z_0}$ at the exit of $\mathscr{B}$. Upon exiting $\mathscr{B}$, the orbits are $\mathscr{O}(\varepsilon^{1/2})$ close. Gronwall-type estimates guarantee that they will remain $\mathscr{O}(\varepsilon^{1/2})$ close when $\mathbf{q}_{h_1}^{z_0}$ reaches a maximum of the norm of its q coordinate at time t_1^o, since it spends an $\mathscr{O}(1)$ amount of time outside $\mathscr{B}$. This means that at this moment, $\mathbf{q}_{H_1}^{u}$ will be $\mathscr{O}(\varepsilon^{1/2})$ close to the q axis. Now, it will take $\mathbf{q}_{H_1}^{u}$ an $\mathscr{O}(\varepsilon^{1/2})$ amount of time to reach the normal $\mathbf{n}(z)$ at $t_1 = z_1/\varepsilon$, since the vector field is $\mathscr{O}(1)$ there. Thus in this part of the flight outside $\mathscr{B}$, the difference in the respective times of flight is $\mathscr{O}(\varepsilon^{1/2})$. Hence, $t_1 - t_1^* = t_1^o - t_1^{o*} + \mathscr{O}(\varepsilon^{1/2})$. For the other part of the flight outside $\mathscr{B}$, the difference is also $\mathscr{O}(\varepsilon^{1/2})$. Combining this time difference for the times spent outside $\mathscr{B}$ with the estimate in Corollary 2 for the difference while in $\mathscr{B}$, we have shown that

$$\varepsilon P(\varepsilon h_1(z_0)) = z_1 - z_0 + \mathscr{O}(|\varepsilon h_1|^{4/3}). \quad (7.4)$$

C. Step 3

We now proceed to compute the estimate of H_2. Recall that we are carrying out the estimates in this and all further steps explicitly for type II systems. Those for type I systems are identical with the improved estimate of the remainder as given in Step 1. So far, for the orbit $\mathbf{q}^u(t;z_0,\varepsilon)$, we have

$$H_2 = H_1 + \int_{t_1^*}^{t_2^*} \frac{dH}{dt}\,dt = \varepsilon h_1(z_0) + \varepsilon h_1(z_1) + \mathcal{O}\left(|\varepsilon h_1|\varepsilon \ln\frac{1}{\varepsilon}, |\varepsilon h_2|\varepsilon \ln\frac{1}{\varepsilon}, \varepsilon^2 \right),$$

where the result of Step 1 has been used in all of the remainder terms in (3.4). The leading error terms are $\mathcal{O}(\varepsilon^2 \ln 1/\varepsilon)$, since h_1 and h_2 are $\mathcal{O}(1)$.

We now substitute the relationship (7.4) between z_1 and z_0 computed in Step 2 for $\varepsilon h_1(z_1)$ in the above equation:

$$H_2 = \varepsilon[M_A(z_0) + M_A((z_0 + \varepsilon P(\varepsilon h_1(z_0)) + \mathcal{O}(\varepsilon^{4/3}))] + \mathcal{O}\left(\varepsilon^2 \ln\frac{1}{\varepsilon}\right).$$

Finally, we recall that $h_2(z_0,\varepsilon) \equiv M_A(z_0) + M_A(z_0 + \varepsilon P(\varepsilon h_1(z_0)))$, so that for $z_0 \in \{z : M_A(z) \leqslant \kappa < 0\}$, we take the Taylor expansion of H_2 and conclude

$$H_2(z_0,\varepsilon) = \varepsilon h_2(z_0,\varepsilon) + \mathcal{O}\left(\varepsilon^2 \ln\frac{1}{\varepsilon}\right). \tag{7.5}$$

D. Step 4

We now show that the existence of a simple zero of h_2 at $(z = z_0,\ \varepsilon = \varepsilon_0)$ guarantees that H_2 has a simple zero for some (z,ε) near (z_0,ε_0). Our method follows closely the strategy used in Ref. 20, since the implicit function theorem cannot be used because $N = 2,3,...$, pulse homoclinic orbits do not exist when $\varepsilon = 0$.

Let $0 < \beta < \alpha < \frac{1}{2}$, $\Delta z = K\varepsilon_0^\beta$, where $K > 0$, and $\Delta\varepsilon = J\varepsilon_0^{1+\alpha}$, where $J \in \mathbb{R}$. We will prove that $H_2(z_0 - \Delta z, \varepsilon_0 + \Delta\varepsilon)$ and $H_2(z_0 + \Delta z, \varepsilon_0 + \Delta\varepsilon)$ are of different signs.

We begin by considering the Taylor expansion of H_2 about (z_0,ε_0):

$$\begin{aligned} H_2(z_0 + \Delta z, \varepsilon_0 + \Delta\varepsilon) = {} & H_2(z_0,\varepsilon_0) + \frac{\partial H_2}{\partial z}(z_0,\varepsilon_0) K\varepsilon_0^\beta + \frac{1}{2}\frac{\partial^2 H_2}{\partial z^2}(z_0,\varepsilon_0) K^2 \varepsilon_0^{2\beta} \\ & + \frac{\partial^2 H_2}{\partial z\,\partial\varepsilon}(z_0,\varepsilon_0) KJ\varepsilon_0^{1+\alpha+\beta} + \frac{\partial H_2}{\partial\varepsilon}(z_0,\varepsilon_0) J\varepsilon_0^{1+\alpha} \\ & + \mathcal{O}(\varepsilon_0^{3\beta}, \varepsilon_0^{2(1+\alpha)}, \varepsilon^{1+\alpha+2\beta}). \end{aligned}$$

Then we use the asymptotic formula (7.5) derived in Step 3 to replace H_2 with h_2:

$$\begin{aligned} H_2(z_0 + \Delta z, \varepsilon_0 + \Delta\varepsilon) = {} & K\frac{\partial h_2}{\partial z}(z_0,\varepsilon_0)\varepsilon_0^{1+\beta} + K^2\frac{1}{2}\frac{\partial^2 h_2}{\partial z^2}\varepsilon_0^{1+2\beta} + KJ\frac{\partial^2(\varepsilon h_2)}{\partial z\,\partial\varepsilon}(z_0,\varepsilon_0)\varepsilon_0^{1+\alpha+\beta} \\ & + J\frac{\partial(\varepsilon h_2)}{\partial\varepsilon}(z_0,\varepsilon_0)\varepsilon_0^{1+\alpha} + \mathcal{O}\left(\varepsilon_0^2 \ln\frac{1}{\varepsilon_0}, \varepsilon_0^{3\beta+1}\right), \end{aligned} \tag{7.6}$$

where we have used the fact that $h_2(z_0,\varepsilon_0) = 0$. Next, we make the following estimates. First, $P(\varepsilon h_1(z_0)) = \mathcal{O}(\ln|\varepsilon h_1|^{1/2}) = \mathcal{O}(\ln 1/\varepsilon)$; and, second, $\partial(\varepsilon h_2)/\partial\varepsilon = \varepsilon\,\partial h_2/\partial\varepsilon + h_2$, where

$$\frac{\partial h_2}{\partial \varepsilon} = M_A'(z_0)\left[\varepsilon\,\frac{dP}{d\varepsilon} + P(\varepsilon h_1(z_0))\right] = M_A'(z_0)\left[\mathcal{O}(1) + \mathcal{O}\left(\ln\frac{1}{\varepsilon}\right)\right] = \mathcal{O}\left(\ln\frac{1}{\varepsilon}\right),$$

and we have used the fact that $dP/d\varepsilon$ also has an asymptotic expansion as $\varepsilon \to 0$, namely $dP/d\varepsilon = \mathcal{O}(1/\varepsilon)$.

Finally, note that $K(\partial h_2/\partial z)(z_0,\varepsilon_0)\varepsilon_0^{1+\beta}$ is the dominant term, since the two terms with partial derivatives in ε in (7.6) are $\mathcal{O}(\varepsilon_0^{2+\alpha+\beta}\ln(1/\varepsilon_0))$ and $\mathcal{O}(\varepsilon_0^{2+\alpha}\ln(1/\varepsilon_0))$, respectively. Thus, we write

$$H_2(z_0+\Delta z,\varepsilon_0+\Delta\varepsilon) = K\,\frac{\partial h_2}{\partial z}\,(z_0,\varepsilon_0)\varepsilon_0^{1+\beta} + \mathcal{O}\left(\varepsilon_0^{1+2\beta}, \varepsilon_0^2\,\ln\frac{1}{\varepsilon_0}\right), \tag{7.7}$$

and similarly

$$H_2(z_0-\Delta z,\varepsilon_0+\Delta\varepsilon) = -K\,\frac{\partial h_2}{\partial z}\,(z_0,\varepsilon_0)\varepsilon_0^{1+\beta} + \mathcal{O}\left(\varepsilon_0^{1+2\beta}, \varepsilon_0^2\,\ln\frac{1}{\varepsilon_0}\right). \tag{7.8}$$

Since by hypothesis $(\partial h_2/\partial z)(z_0,\varepsilon_0) \neq 0$, we see from the two expressions above that H_2 has a simple zero when $z_0 \in [z_0-\Delta z, z_0+\Delta z]$, for every ε in an interval of size $\mathcal{O}(\varepsilon_0^{1+\alpha})$ about ε_0.

E. Step 5

In this final step, we prove inductively that

$$H_N(z_0,\varepsilon) = \varepsilon h_N + \mathcal{O}\left(\varepsilon^2\,\ln\frac{1}{\varepsilon}\right) \tag{7.9}$$

by making use of the results in Steps 1–3 at each step of the induction process. The proof that simple zeroes of h_N imply simple zeroes of H_N is identical to the one presented for $N=2$ in Step 4, and we omit it.

Assume $H_j(z_0,\varepsilon) = \varepsilon h_j + \mathcal{O}(\varepsilon^2 \ln 1/\varepsilon)$ holds for $j=1,\ldots,N-1$. From (3.7) we have

$$H_N = H_{N-1} + \varepsilon h_1(z_{N-1}) + \mathcal{O}\left(\varepsilon^2|h_{N-1}|\ln\frac{1}{\varepsilon}, \varepsilon^2|h_N|\ln\frac{1}{\varepsilon}, \varepsilon^2\right),$$

where the last term was obtained by combining the remainder terms in (3.7) and using the result from Step 1.

We consider the second term

$$\varepsilon h_1(z_{N-1}) = \varepsilon h_1(z_{N-2} + \varepsilon P(\varepsilon h_{N-1})) + \mathcal{O}(\varepsilon^{7/3}),$$

where we have used the result from Step 2; i.e.,

$$z_{N-1} = z_{N-2} + \varepsilon P(\varepsilon h_{N-1}) + \mathcal{O}(|\varepsilon h_{N-1}|^{4/3}).$$

Proceeding inductively, we see that

$$\varepsilon h_1(z_{N-1}) = \varepsilon h_1\left(z_0 + \varepsilon\sum_{j=1}^{N-1} P(\varepsilon h_j)\right) + \mathcal{O}(\varepsilon^{7/3}).$$

Finally, using the above expression and our induction hypothesis $H_{N-1} = \varepsilon h_{N-1}(z_0,\varepsilon) + \mathcal{O}(\varepsilon^2 \ln 1/\varepsilon)$ in the expression for H_N, we obtain

$$H_N = \varepsilon h_{N-1} + \varepsilon h_1\left(z_0 + \varepsilon \sum_{j=1}^{N-1} P(\varepsilon h_j)\right) + \mathcal{O}\left(\varepsilon^2 \ln \frac{1}{\varepsilon}\right).$$

Recalling the definition for h_N, we finally obtain

$$H_N(z_0,\varepsilon) = \varepsilon h_N + \mathcal{O}\left(\varepsilon^2 \ln \frac{1}{\varepsilon}\right),$$

which completes the proof of the Theorem.

VIII. EXTENSION TO (1.1) WITH $\mu>0$

Up until now, we have dealt with slowly varying Hamiltonian systems without any damping or forcing. The above proof of Theorem 1 can now readily be extended to systems of the form (1.1) with $\mu \neq 0$ and satisfying Assumption 1, to show that Corollary 1 holds.

We will begin by showing that an Nth-order adiabatic Melnikov function can be derived in a manner that totally parallels the heuristic derivation for the slowly varying Hamiltonian case in Sec. III. The main difference is that we no longer can talk about the ''energy'' of the system. However, we will exploit the fact that for every z fixed, the level curves of the function H provide us with a system of reference curves that help us set up nice coordinates along $\mathbf{n}(z)$.

We specifically derive $M_{2,A}(z_0,\varepsilon,\mu)$, since the generalization to $M_{N,A}(z_0,\varepsilon,\mu)$ is evident. Again, let $\mathbf{q}^u(t;z_0,\varepsilon,\mu)$ be a solution on $W^u(\gamma_\varepsilon)$ that crosses the normal $\mathbf{n}(z)$ at a time $z=z_0=\varepsilon t_0$ and reaches the negative x axis in the neighborhood of γ_ε at a time t_1^*. At that point, it will cross some level curve of H, with value $H_1 = H(\mathbf{q}^u(t_1^*;z_0,\varepsilon,\mu),\varepsilon t_1^*)$, that can be computed as

$$\begin{aligned} H_1 &= \int_{-\infty}^{t_1^*} \frac{dH}{dt}(\mathbf{q}^u(t;z_0,\varepsilon,\mu))dt \\ &= \varepsilon \int_{-\infty}^{t_1^*} \frac{\partial H}{\partial z}(\mathbf{q}^u(t;z_0,\varepsilon,\mu))dt + \varepsilon\mu \int_{-\infty}^{t_1^*} (f_2(\mathbf{q}^u(t;z_0,\varepsilon,\mu))\dot{q}^u(t;z_0,\varepsilon,\mu) \\ &\quad - f_1(\mathbf{q}^u(t;z_0,\varepsilon,\mu))\dot{p}^u(t;z_0,\varepsilon,\mu))dt, \end{aligned}$$

which reduces to (3.2) when $\mu=0$.

As we did in Sec. III, we then approximate $\mathbf{q}^u(t;z_0,\varepsilon,\mu)$ with the unperturbed separatrix at $z=z_0$, so (3.3) now becomes

$$H_1 = \varepsilon M_A(z_0,\mu) + R_s(z_0,\mu,t_1^*)$$

where

$$\begin{aligned} M_A(z_0,\mu) \equiv & \int_{-\infty}^{t_1^*} \frac{\partial H}{\partial z}(\mathbf{q}^u(t;z_0,\varepsilon,\mu))dt + \mu \int_{-\infty}^{t_1^*} (f_2(\mathbf{q}^u(t;z_0,\varepsilon,\mu))\dot{q}^u(t;z_0,\varepsilon,\mu) \\ & - f_1(\mathbf{q}^u(t;z_0,\varepsilon,\mu))\dot{p}^u(t;z_0,\varepsilon,\mu))dt, \end{aligned}$$

and the remainder term is

$$R_s(z_0,\mu,t_1^*) = -\varepsilon \int_{t_1^*}^{\infty} \frac{dH}{dt}(\mathbf{q}_0^{z_0}(t))dt + \mathcal{O}(\varepsilon^2) = H(\mathbf{q}_0^{z_0}(t_1^*)) + \mathcal{O}(\varepsilon^2).$$

From here, just as in the undamped case,

$$H_2 = \int_{-\infty}^{t_2^*} \frac{dH}{dt}(\mathbf{q}^u(t;z_0,\varepsilon,\mu))dt$$
$$= \varepsilon M_A(z_0,\mu) + \varepsilon M_A(z_1,\mu)$$
$$+ R_s(z_0,\mu,t_1^*) + R_s(z_1,\mu,t_2^*) + R_u(z_1,\mu,t_1^*), \tag{8.1}$$

where z_1 is the second (slow) time of crossing the normal $\mathbf{n}(z)$.

Now, the very same arguments we used in the $\mu=0$ case to estimate the time spent in the rotating regime [and, in fact, the same proof presented in Step 2 with the obvious changes in the expressions of the Fenichel normal forms (6.1) and (6.3)] yield

$$z_1 \sim z_0 + \varepsilon P(\varepsilon M_A(z_0,\mu)).$$

Combining these last two expressions, we arrive at the secondary adiabatic Melnikov function

$$M_{2,A}(z_0,\varepsilon,\mu) \equiv M_A(z_0,\mu) + M_A(z_0+\varepsilon P(\varepsilon M_A(z_0,\mu)),\mu).$$

Finally, we point out that the proof that all the remainders in (8.1) are of higher order, namely, $\mathcal{O}(\varepsilon^2)$ for type I systems, and for type II systems they are $\mathcal{O}(\varepsilon^2 \ln 1/\varepsilon)$, is identical to that for the $\mu=0$ case. The proofs of all the five steps are identical as well.

Probing quantum gravity through exactly soluble midi-superspaces I

A. Ashtekar and M. Pierri
Center for Gravitational Physics and Geometry, The Pennsylvania State University, Department of Physics, University Park, Pennsylvania 16802

(Received 26 June 1996; accepted for publication 8 July 1996)

It is well-known that the Einstein-Rosen solutions to the 3+1- dimensional vacuum Einstein's equations are in one to one correspondence with solutions of 2+1-dimensional general relativity coupled to axi-symmetric, zero rest mass scalar fields. We first re-examine the quantization of this midi-superspace paying special attention to the asymptotically flat boundary conditions and to certain functional analytic subtleties associated with regularization. We then use the resulting quantum theory to analyze several conceptual and technical issues of quantum gravity. © *1996 American Institute of Physics.* [S0022-2488(96)02312-2]

I. INTRODUCTION

Many of the central problems of quantum gravity can be traced back to two main difficulties: (i) the absence of a background space-time metric and (ii) the presence of an infinite number of degrees of freedom.

Let us begin with the first set of issues. The absence of a background geometry implies that the theory has to be diffeomorphism invariant and this feature makes it difficult to construct observables and formulate precisely questions of direct physical interest. It also gives rise to the celebrated ''problem of time'': if there is no background metric, what are we to make of the notion of ''time evolution''? Indeed, if the diffeomorphisms are to be regarded as gauge, at first sight, dynamics also appears as a part of gauge. Can one disentangle dynamics from gauge unambiguously? These questions are of course not new. (For a detailed discussion, see, e.g. Ref. 1.) To gain insight into these issues, a number of mini-superspace models have been discussed in the literature (see, e.g., Ref. 2). In Bianchi models, for example, one restricts attention only to spatially homogeneous solutions of Einstein's equations and, in the quantum theory, addresses the issue of time via ''de-parametrization.'' Perhaps a more striking model is presented by 2+1-dimensional vacuum general relativity which, like the 3+1 theory, is fully diffeomorphism invariant. Quantization of this model[3,4] has shed light on the notion of observables, role of discrete symmetries, etc. These models have also given us considerable insights into the technical problems that arise due to the underlying diffeomorphism invariance. For example, since we have no Poincaré group to help us, the problem of finding the correct inner-product on the space of quantum states requires a new strategy. The 2+1 model has provided a method which, moreover, is free of ambiguities that arise, e.g., in the de-parametrization procedure.

However, these models do not come to grips with the second main difficulty mentioned above: the presence of an infinite number of degrees of freedom. To face this difficulty, we need to consider genuine field theories which do not require a background space-time metric. An obvious strategy would be to again consider symmetry reductions which, however, are mild enough to leave behind *local* degrees of freedom. To locate convenient choices, let us briefly return to the 2+1-dimensional vacuum general relativity. This theory can be obtained by a symmetry reduction of 3+1-dimensional general relativity with respect to a single space-like Killing field which is hyper-surface orthogonal and whose norm is *constant*. Therefore, as a next step, it is natural to drop the severe condition on the norm. The symmetry reduced system now has an infinite number of degrees of freedom. In fact it is now equivalent to 2+1-dimensional general relativity coupled to a zero rest mass scalar field (which is given by the logarithm of the norm of

0022-2488/96/37(12)/6250/21/$10.00

the Killing field).[5,6] Unfortunately, this midi-superspace is a bit too complicated in that the issue of global existence of such solutions is still largely unexplored in the classical theory. However, if we require that there be another hyper-surface orthogonal Killing field in the 3+1 theory which commutes with the first one, the situation simplifies dramatically. For now one can in effect ''decouple'' gravity and the scalar field. More precisely, the equation satisfied by the scalar field on the curved 2+1-dimensional space-time is equivalent to the wave equation on a fictitious *flat* 2+1-dimensional space-time. Therefore, one can first solve the second equation without any reference to the physical metric and then use the solution to obtain the physical metric by simple integration. Classically, one now has complete control on the issue of global existence.

Such space-times were considered by Einstein and Rosen in the thirties for the case when the first Killing field is a translation in the ''z-direction'' and the second is a ''x-y rotation.'' Thus, they represent cylindrical gravitational waves (with only one polarization because of the hyper-surface orthogonality requirement.) Their quantization was considered in a remarkable paper by Kuchař[7] already in 1971. The problem was considered again from a 2+1-dimensional perspective by Allen[8] in 1987 (without, however, realizing that this is precisely a symmetry reduced version of Ref. 7.) In the present paper, we shall return to this midi-superspace. Our purpose is two-fold: (i) to supplement the analyses by Kuchař and Allen with a careful treatment of boundary conditions in the classical theory and of certain functional analytic issues in the quantum theory and (ii) to use the resulting quantum theory to analyze several conceptual and technical problems of quantum gravity. Since the model itself is simple enough to be exactly soluble, it provides a concrete arena to examine these vexing issues and to see how they can be resolved in practice.

Specifically, following Refs. 7 and 8, we will use a canonical approach. Since in this approach one *begins* with a 2+1 decomposition of space-time, *a priori* it is not clear if quantized *space-time* geometries can emerge in the final theory. Indeed, one often hears the criticism that, since it is tied to space-like surfaces, the canonical approach may be inadequate to handle ''space-time issues'' such as ''fluctuations of the light cone.'' Here, we have a complete quantum theory. It is therefore natural to ask: are there operators on the final Hilbert space corresponding to space-time geometries? If so, is there adequate structure to analyze how the light cones fluctuate? More generally, can we tie the canonically quantized theory to the quantum description that emerges from covariant approaches? Can we compute S-matrices? In the classical theory, there is a positive energy theorem.[6,9] Does it continue to hold in the quantum theory? Is the true ground state ''peaked around'' Minkowski space-time? Or, does the ground state contain wild quantum fluctuations with Planck energy density as suggested by Wheeler?[10] If so, the true ground state would not have much resemblance to Minkowski space, except perhaps on a suitable coarse-graining. Another question which plays an important role in semi-classical considerations is: Are there ''coherent states'' which are peaked at classical solutions?

There is a non-perturbative approach to full quantum gravity which is based on connections and triads (see, e.g., Ref. 4). A basic assumption in that approach is that the ''Wilson-loop operators,'' which correspond to traces of holonomies of a connection around space-like loops, should be well-defined. *A priori* it is not clear if this assumption is a reasonable one since in the definition of these operators, one appears to smear a quantum field along a *one*-dimensional object (rather than three or four). It is natural to ask for the status of this assumption in a completely solved model. Are these Wilson loop operators well-defined on the explicitly known quantum Hilbert space?

Of course, the fact that such questions are answered in one way in a specific solution to this model does not imply that they would not be answered in another way in another solution and, more importantly, in full 3+1-dimensional quantum gravity. Nonetheless, the ability to answer them in detail in an explicit solution can contribute substantially to our overall intuition for quantum gravity. Our analysis is primarily motivated by such considerations. We will find that most of these questions can be answered in detail but that the analysis involves several rather subtle points.

The plan of the paper is as follows. In section II, we consider the classical Hamiltonian formulation and isolate the true degrees of freedom by a gauge fixing procedure. Because we are in an asymptotically flat situation, by treating the boundary conditions carefully, we can distinguish gauge from dynamics. In particular, the true degrees of freedom are naturally subject to non-trivial dynamics (without the need of any ''deparametrization.'') In section III, we calculate the classical Wilson loop functions and express them in terms of the true degrees of freedom. Quantization is taken up in section IV. As in Refs. 7 and 8 the Hilbert space of states is a Fock space for scalar fields in $2+1$ dimensions. Subtleties arise, however, because the geometrical observables, such as the space-time metric and the Wilson loops, are expressed as integrals of quadratic functionals of these elementary excitations. Thus, in a rough terminology, geometric excitations arise as non-local ''collective modes'' of the primary mathematical entity, the quantum scalar field. Finally, questions raised earlier in this section are analyzed within this solution. Section V summarizes the main results and points out directions for further work.

II. HAMILTONIAN FORMULATION

A. The midi-superspace

Let us begin with a precise specification of our midi-superspace. For definiteness, we will work in the $2+1$-dimensional formulation. Thus, we will consider asymptotically flat, axi-symmetric solutions of $2+1$-dimensional general relativity coupled to zero rest mass scalar-fields (where the rotational Killing field is hyper-surface orthogonal). The underlying manifold M will be topologically R^3 and the space-time metric will have signature $-,+,+$. For simplicity, we will assume that all fields under consideration are C^∞.

Denote by σ^a the rotational Killing field. Hyper-surface orthogonality of σ^a implies that the space-time metric g_{ab} has the form

$$g_{ab}=h_{ab}+R^2\nabla_a\sigma\nabla_b\sigma, \tag{1}$$

where R is the norm of the Killing field and σ is the ''angular coordinate''; $\nabla_a\sigma=R^{-2}g_{ab}\sigma^b$. The field h_{ab} so defined is a metric of signature $-$, $+$ on the two-manifolds orthogonal to σ^a. Let us introduce a space-like foliation of this two-manifold by lines $t=\text{const}$ and a dynamical vector field $t^a=Nn^a+N^r\hat{r}^a$, where n^a is the unit, time-like normal to the foliation and $\hat{r}^a$ the unit (outgoing) vector field within each slice. The pair N,N^r constitutes the lapse and the shift. If we now introduce a radial coordinate r on any one leaf such that $r=0$ at the axis (i.e., where $R=0$) and r tends to infinity at spatial infinity, the two-metric h_{ab} can be written as

$$h_{ab}=(-N^2+(N^r)^2)\nabla_a t\nabla_b t+2N^r\nabla_{(a}t\nabla_{b)}r+e^\gamma\nabla_a r\nabla_b r, \tag{2}$$

where N,N^r and γ are functions of r and t. It is because of axi-symmetry that the three-metric g_{ab} has only four independent components and they are functions only of two variables.

Thus, our midi-superspace consists of five functions (N,N^r,γ,R,ψ) on the space-time manifold M where ψ is the zero rest mass scalar field (which is also Lie-dragged by the rotational Killing field). The five fields are subject to the following field equations:

$$G_{ab}=T_{ab} \quad \text{and} \quad g^{ab}\nabla_a\nabla_b\psi=0\,, \tag{3}$$

where G_{ab} is the Einstein tensor of g_{ab} which is determined by the fields (N,N^r,γ,R) via (2) and T_{ab} is the stress-energy tensor of the scalar field ψ:

$$T_{ab}=\nabla_a\psi\nabla_b\psi-\frac{1}{2}(g^{cd}\nabla_c\psi\nabla_d\psi)g_{ab}\,. \tag{4}$$

(Here, we have used a normalization that arises naturally in the reduction from the 3+1 theory to the 2+1. From the 2+1 perspective, it is natural to regard $\phi := \psi/\sqrt{8\pi G}$ as the physical Klein-Gordon field, where G is Newton's constant.)

Asymptotic flatness and regularity at the axis imply certain boundary conditions on our dynamical fields. We first note that g_{ab} reduces to a Minkowskian metric when $N=1$, $N^r=0$, $\gamma=0$, $R=r$ and $\psi=0$. The general asymptotic flatness conditions can be written as

$$N=1+N_1(r,t), \quad N^r=N^r_o(t)+N^r_1(r,t),$$
$$\gamma(r,t)=\gamma_\infty(t)+\gamma_1(r,t), \quad R(r,t)=r(1+R_1(r,t)), \tag{5}$$

where, on any $t=$const surface, $N_1, N^r_1, \gamma_1, R_1$ and the scalar fields ψ are of asymptotic order $O(1/r)$. (We will say that a function $f(r)$ is of asymptotic order $1/r$ if $rf(r), r^2f'(r)$ and $r^3f''(r)$ admits limits as r tends to infinity, where a prime denotes a derivative with respect to r.) While the conditions imposed on N, N^r, R and ψ are the obvious ones, the condition on the field γ seems surprising at first. For, even at infinity, γ is not required to approach its Minkowskian value, 0. The reason is that the asymptotic value of γ contains the information about mass: If $\gamma_\infty=0$, the spatial metric has a deficit angle at infinity which measures the ADM mass.[6,9] Thus, there is a striking contrast with asymptotic flatness in 3+1 dimensions; the space-time metrics in our midi-superspace do *not* approach a fixed Minkowskian metric at infinity. Note finally that these boundary conditions are somewhat simpler than those used in Ref. 9 where general 2+1-dimensional space-times were considered. Here, we can exploit the fact that we are now working in a highly restrictive context of cylindrical waves.

Finally, regularity at the axis is ensured by requiring that N^r, γ and R vanish there for all t. (Recall also that by assumption, N, N^r, γ, R^2 and ψ are C^∞ everywhere and, in particular, at $r=0$.)

B. Phase space

Let us begin with the three-dimensional action with appropriate boundary terms:

$$S(g,\psi) := \frac{1}{16\pi G}\int_{M'} d^3x\sqrt{g}[\mathscr{R} - g^{ab}\nabla_a\psi\nabla_b\psi] + \frac{1}{8\pi G}\oint_{\partial M'} d^2x[K\sqrt{h} - K_o\sqrt{h_o}], \tag{6}$$

where M' is an open set in M; $\partial M'$, its boundary in M; $\mathscr{R}$, the scalar curvature of g; K and h, the trace of the extrinsic curvature of, and the determinant of the intrinsic metric on $\partial M'$ induced by g_{ab}; and K_o and h_o are the corresponding fields induced by the Minkowski metric $\mathring{g}_{ab}$ (obtained by setting $N=1$, $N^r=0$, $\gamma=0$, $R=r$ and $\psi=0$).

To pass to the Hamiltonian formulation, one performs a 2+1-decomposition. Let us substitute in (6) the form of the metric given by Eqs. (1) and (2). Then, the action reduces to the standard form:

$$S = \frac{1}{8G}\int dt(dr(p_\gamma\dot{\gamma} + p_R\dot{R} + p_\psi\dot{\psi}) - H[N,N^r]) \tag{7}$$

The Hamiltonian H is given by

$$H[N,N^r] = \frac{1}{8G}\int dr(NC + N^rC_r) + \frac{1}{4G}(1-e^{-\gamma_\infty/2}), \tag{8}$$

where C and C_r are functions of the canonical variables,

$$C = e^{-\gamma/2}(2R'' - \gamma'R' - p_\gamma p_R) + \frac{1}{2}Re^{-\gamma/2}\left(\frac{p_\psi{}^2}{R^2} + \psi'^2\right),$$

$$C_r = e^{-\gamma}(-2p'_\gamma + \gamma' p_\gamma + R' p_R) + e^{-\gamma} p_\psi \psi', \tag{9}$$

and γ_∞ is the value of γ at $r=\infty$. (Here primes denote derivatives with respect to r.)

As expected, the lapse and shift functions N, N^r appear as Lagrange multipliers; they are not dynamical variables. Thus, the phase-space Γ consists of three canonically conjugate pairs, $(\gamma, p_\gamma; R, p_R; \psi, p_\psi)$, on a two-manifold Σ which is topologically R^2. The boundary conditions on the configuration variables (γ, R, ψ) have already been discussed. The conditions on the momenta can be deduced from their definitions in terms of these fields and their time derivatives. At infinity, p_γ and p_R fall off as $O(1/r^2)$ while p_ψ falls off as $O(1/r)$. (Note that these conditions imply that action $\int dr p_\gamma \delta\gamma, \int dr p_R \delta R$ and $\int dr p_\psi \delta\psi$ of the momenta on the tangent vectors $\delta\gamma, \delta R, \delta\psi$ to our configuration space are all finite, so that we have a well-defined (weakly non-degenerate) symplectic structure.) There are two first class constraints, $C=0$ and $C_r=0$, obtained by varying the action with respect to the Lagrange multipliers N and N^r. The Hamiltonian is given by H. (It is because of the underlying axi-symmetry that we have only one diffeomorphism constraint, C_r.)

Let us begin by analyzing the canonical transformations generated by constraints. For this, we have to first smear the constraints and obtain well-defined functions on the phase space, say, $C[N_g] := \int dr N_g C$ and $C[N^r_g] = \int dr N^r_g C_r$. Using the boundary conditions on the phase space variables, it is straightforward to verify that these functions are well-defined *and* differentiable on the phase space if N_g vanishes on the axis and is of asymptotic order $O(1/r)$ and N^r_g admits a limit at infinity. (From now on, the subscript g on smearing fields will indicate that they satisfy these boundary conditions.) Since the constraints are of first class, and since we are in the asymptotically flat context, the canonical transformations generated by these constraints can be regarded as ''gauge'' in an appropriate sense. As one might expect, $C[N_g]$ generates ''bubble time evolutions'' via lapses which go to zero at infinity while $C[N^r_g]$ generates spatial diffeomorphisms which are bounded at infinity. The situation with the Hamiltonian constraint is the same as the one we normally encounter in the 3+1-dimensional theory. For the diffeomorphism constraint, on the other hand, the situation is quite different since the diffeomorphisms generated by $N^r_g \hat{r}^a$ are not necessarily asymptotically identity. This is, however, the standard situation in 2+1 dimensions (see e.g., Refs. 6 and 9): In 2+1 dimensions, there are no asymptotic Killing fields corresponding to spatial translations and the ADM two-momentum vanishes.

To obtain genuine time translations, we have to allow lapses which tend to 1 at infinity and on the axis. When this is done, the constraint function $C[N]$ continues to exist everywhere on the phase space. However, due to the presence of the first two terms involving derivatives of γ and R in the expression of C, the function $C[N]$ fails to be differentiable. To make it differentiable, one has to add a surface term. As one might expect, this is precisely the surface term in the expression (8) of the Hamiltonian. Thus, the function which generates the canonical transformation corresponding to (asymptotically unit) time translation is precisely the Hamiltonian $H[N]$ (obtained by setting $N^r=0$ in Eq. (8)). On physical states, i.e., when the constraints are satisfied, the numerical value of the Hamiltonian is given by the surface term in (8):

$$E = \frac{1}{4G}(1 - e^{-(1/2)\gamma_\infty}), \tag{10}$$

As usual, in the space-time picture, the evolution generated by the Hamiltonian on the phase space corresponds to motions along the vector field t^a.

Let us summarize the discussion of this sub-section. Because we are in the asymptotically flat context, there is a clean separation between gauge and dynamics. As usual, when it comes to physical interpretation, the ''gauge transformations'' of general relativity have a somewhat different status from that in Yang-Mills theory. It is not that the diffeomorphisms generated by $C[N_g]$ and $C[N^r_g]$ are ''unphysical.'' Rather, they are ''redundant'' when it comes to extracting

the physical content of the theory. As we will see below, we can gauge fix these constraints and extract the true degrees of freedom. The Hamiltonian generates ''time evolution'' among these gauge fixed points. Knowing this evolution, we can reconstruct the entire solution; motions generated by constraints are not needed and are in this sense ''redundant.''

C. Gauge fixing

Since the canonical transformations generated by $C[N_g]$ and $C[N_g^r]$ are to be regarded as gauge, as in Yang-Mills theory, to gauge fix the system we need to extract one point from each orbit of the corresponding Hamiltonian vector fields. This is achieved by imposing gauge fixing conditions which, together with the constraints, constitute a second class system. As in Ref. 7, we will choose these conditions to make the space-time geometry transparent. Let us demand

$$R(r)=r \quad \text{and} \quad p_\gamma(r)=0. \tag{11}$$

The first condition is motivated by the fact that, in any solution to the field equations (satisfying our boundary conditions), the gradient $\nabla_a R$ of the norm of the Killing field $\partial/\partial\sigma$ is space-like everywhere on M.[11] Since furthermore $R\sim r$ at the axis and at infinity, it is natural to use R itself as the radial coordinate. After this condition is imposed, R will no longer be a dynamical variable. The second gauge fixing condition will remove γ from our list of dynamical variables. Thus, if these conditions are admissible, the true degrees of freedom will all reside in the field ψ, in accordance with our general expectation that in $2+1$ dimensions, all the local degrees of freedom are carried by matter fields.

To see if our gauge fixing conditions are admissible, let us compute their Poisson brackets with the constraints. We have

$$\{R(r)-r,\, C_r[N_g^r]\}=N_g^r e^{-\gamma}R',$$

$$\{p_\gamma,\, C[N_g]\}=\left[\frac{N_g}{2}\left(-p_\gamma p_R+\frac{p_\psi^2}{2R}+\frac{R}{2}\psi'^2\right)-N_g' R'\right]e^{-\gamma/2}, \tag{12}$$

where, as before, N_g^r and N_g are pure gauge lapses and shifts. If $N_g^r \neq 0$ and $N_g \neq 0$, the right sides of (12) do not vanish at any point on the intersection of the surfaces defined by constraints and gauge fixing conditions (11). Hence, as needed, the gauge fixed surface intersects the gauge orbits transversely.

The question now is whether we can choose lapse and shift such that the dynamical evolution generated by the Hamiltonian $H[N,N^r]$ preserves the gauge conditions. More precisely, since the Hamiltonian $H[N,N^r]$ weakly commutes with the constraints $C[N_g],C[N_g^r]$, we know that the dynamical evolution it generates maps entire gauge orbits to entire gauge orbits. The question is if we can select N,N^r such that the image under evolution of any gauge fixed point on the constraint surface is another gauge fixed point. General considerations from symplectic geometry imply that if such a pair exists, it is unique. We will now establish the existence. Let us begin with the Poisson brackets between the gauge conditions and the Hamiltonian:

$$\{R(r)-r,\, H[N,N^r]\}\approx N^r e^{-\gamma},$$

$$\{p_\gamma(r),\, H[N,N^r]\}\approx\left[\frac{N}{4r}(p_\psi^2+r^2\psi'^2)-N'\right]e^{-\gamma/2},$$

where $\approx$ stands for equality modulo constraints and gauge conditions. We seek N and N^r which satisfy our boundary conditions (namely, $N=1+O(1/r)$ and $N^r=N_o^r+O(1/r)$ at infinity) and for which the right hand sides of (13) vanish (modulo constraints and gauge conditions). The only solutions are

$$N(r)=\exp-\frac{1}{4}\int_r^\infty dr_1 r_1\left(\frac{(p_\psi)^2}{r_1^2}+(\psi')^2\right) \quad \text{and} \quad N^r(r)=0. \tag{14}$$

Finally, let us extract the true degrees of freedom of the theory. In order to accomplish this, we need to eliminate redundant variables by solving the set of second class constraints (9) and use gauge conditions (11). By setting $R=r$ and $p_\gamma=0$ in (9), we can trivially solve for γ and p_R in terms of ψ and p_ψ (using the Hamiltonian and the diffeomorphism constraints respectively). The result is

$$\gamma(R)=\frac{1}{2}\int_0^R dR_1 R_1\left(\frac{{p_\psi}^2}{R_1^2}+{\psi'}^2\right), \tag{15}$$

$$p_R=-p_\psi\psi'. \tag{16}$$

Substituting (15) in (14), we can also express the lapse N in terms of γ. Thus, as expected, the true degrees of freedom reside just in the matter variables. Indeed, the space-time metric is now completely determined by ψ and p_ψ:

$$g_{ab}=e^{\gamma(R,t)}(-e^{-\gamma_\infty}\nabla_a t\nabla_b t+\nabla_a R\nabla_b R)+R^2\nabla_a\sigma\nabla_b\sigma, \tag{17}$$

where, from now on, γ will only serve as an abbreviation for the right side of (15).

D. Reduced phase space

It is obvious from the above discussion that the reduced phase space $\overline{\Gamma}$ can be coordinatized by the pair $(\psi(R),p_\psi(R))$. The (non-degenerate) symplectic structure on the reduced phase space Γ is the pull-back of the symplectic structure on Γ. Thus,

$$\{\psi(R_1),p_\psi(R_2)\}=\delta(R_1,R_2) \tag{18}$$

on $\overline{\Gamma}$. Next, let us write the reduced action by substituting (11), (15) and (16) in (6),

$$S[\psi,p_\psi]=\frac{1}{8G}\int dt\left[\int dR(p_\psi\dot{\psi})-2(1-e^{-(1/2)\gamma_\infty})\right], \tag{19}$$

where, as before, $\gamma_\infty=\gamma(r=\infty)$. By varying the action (19) with respect to ψ and p_ψ we then obtain equations of motion:

$$\dot{\psi}=e^{-(1/2)\gamma_\infty}\frac{p_\psi}{R} \quad \text{and} \quad \dot{p}_\psi=e^{-(1/2)\gamma_\infty}(R\psi')'. \tag{20}$$

Due to the presence of $\exp(-\gamma_\infty/2)$ factors, these equations are highly non-linear. However, using (20) it is straightforward to check that $\gamma_\infty(t)$ is a *constant of motion*. Hence, given any *one* solution, we can define a new time coordinate T on M via a constant rescaling: $T:=(\exp-\frac{1}{2}\gamma_\infty)t$. Then, the field ψ satisfies the following *linear* second-order equation of motion:

$$-\frac{\partial^2\psi}{\partial T^2}+\frac{\partial^2\psi}{\partial R^2}+\frac{1}{R}\frac{\partial\psi}{\partial R}=0. \tag{21}$$

This is *exactly* the Klein-Gordon equation for a scalar field propagating on a Minkowskian background g^o_{ab}, given by

$$g^o_{ab} = -\nabla_a T \nabla_b T + \nabla_a R \nabla_b R + R^2 \nabla_a \sigma \nabla_b \sigma. \tag{22}$$

Thus, a remarkable simplification has occurred. We can just solve for a free scalar field ψ in Minkowski space (M, g^o_{ab}), *define* a function γ through (15), and construct a curved metric g_{ab} through (17). Then the pair (g_{ab}, ψ) satisfies the non-linear Einstein–Klein–Gordon equations.

This decoupling is not surprising from the space-time perspective. Indeed, it has been exploited repeatedly in the literature. However, it is illuminating to see how the decoupling comes about from a phase space perspective especially since the dynamics of the true degrees of freedom is driven only by the boundary term Hamiltonian which, furthermore, seems quite complicated at first sight. Note also that, while from a space-time perspective the passage between t and T involves only a constant rescaling, since the constant varies from solution to solution, from a phase space perspective it is a rather complicated ''q-number'' transformation. Thus, in quantum theory, if one variable in the pair (t, T) is taken as a ''time-parameter,'' the other will be a genuine operator. It is therefore instructive to contrast the two notions of time. By construction, t can be identified with the affine parameter along the Hamiltonian vector field defined by (8) on the phase space. Given any dynamical trajectory, we obtain a space-time metric g_{ab} and t can then be thought of as a time coordinate on M with the property that $\partial/\partial t$ generates a *unit* time translation at infinity. The parameter T, on the other hand, does not have a direct and simple physical interpretation in our phase space framework. Its most direct interpretation comes from the fiducial Minkowskian metric g^o_{ab} on M. Even at infinity, the norm of the vector field $\partial/\partial T$ varies from one physical metric g_{ab} to another. For the decoupling procedure, on the other hand, it is natural to fix, once and for all, the Minkowskian metric g^o_{ab} on M and regard g_{ab} simply as a ''derived'' quantity. Then T does have a natural interpretation of time. Finally, note that this somewhat peculiar situation arose because, in $2+1$ dimensions, the physical metrics g_{ab} do not approach a fixed Minkowskian metric even at infinity (or alternatively, because in $3+1$ dimensions, cylindrical waves fail to be asymptotically flat in the conventional sense.)

We will conclude this section with a remark. To begin with, one can ignore the broad physical problem of interest and focus just on a free scalar field satisfying the wave equation on the Minkowskian background (M, g^o_{ab}). The phase space for this system is the same as our reduced phase space and the Hamiltonian is given by γ_∞. However, γ_∞ does *not* have a direct physical interpretation in terms of the original coupled system; the physical energy of our system is given by (10).

III. HOLONOMY

As explained in the introduction, there is a non-perturbative approach[4] to quantum general relativity in $3+1$ dimensions which is based on the assumption that traces of holonomies of a certain connection are well-defined operators in the quantum theory. We would like to investigate the status of this assumption in the context of our midi-superspace. Therefore, in this section, we will make a short detour to compute the holonomy in question in the classical theory. Readers who are not familiar with this approach to quantum gravity may skip this section without loss of continuity.

In the first-order (Palatini) formalism for $2+1$ general relativity the fundamental variables are triads e^I_a and connection one-forms which take values in the Lie-algebra of $SU(1,1)$.[4,12] Let us denote the $SO(2,1)$ connection by ${}^3A^I_a$ and its pull-back to the two-dimensional slice Σ by A^I_a, where $I, J, \cdots = 0,1,2$ are internal indices with respect to a basis τ_I in the Lie algebra of $SU(1,1)$. The internal indices are raised and lowered with a Minkowski metric η_{IJ} with signature $(-,+,+)$.

A. $SO(2,1)$ connection

To obtain the internal connection for the space-time metric (17), we need to fix the internal (i.e., $SU(1,1)$) gauge. This is accomplished by fixing the triads e^I_a. Our choice will be

$$e^I_a \tau_I = \sqrt{2} e^{(1/2)\,(\gamma(R,t)-\gamma_\infty)} (\nabla_a t)\,\tau_0 + \sqrt{2} e^{(1/2)\,\gamma(R,t)} (\nabla_a R)\,\tau_1 + \sqrt{2} R (\nabla_a \sigma)\,\tau_2 . \tag{23}$$

It is straightforward to check that the space-time metric (17) is recovered via $g_{ab} = \eta_{IJ} e^I_a e^J_b$ with the convention $\eta_{IJ} = 2Tr(\tau_I \tau_J)$.

The triad determines the (Christoffel symbols and the) internal connection ${}^3A^I_a$ uniquely. Its pull-back to the spatial slice Σ turns out to be

$$A_a = A^I_a \tau_I = \frac{\dot{\gamma}}{2} e^{(1/2)\,\gamma_\infty} (\nabla_a R)\,\tau_2 + e^{-(1/2)\,\gamma} (\nabla_a \sigma)\,\tau_0 . \tag{24}$$

Note, however, that since R, σ fail to be smooth at $R=0$ our connection also fails to be smooth there. However, our boundary conditions do ensure that all physical fields are smooth at the origin. Thus, this singularity is merely a reflection of a bad choice of gauge (which has in effect introduced a ''source'' at the origin). We can remedy this situation by a gauge transformation. The general form of gauge transformations is

$$A'_a = g A_a g^{-1} - (\partial_a g) g^{-1} \quad \text{with} \quad g = e^{\tau_I \Lambda^I(R,\sigma)} . \tag{25}$$

By choosing the transformation parameters to be $\Lambda^0 = e^{-(1/2)\,\gamma(0)} \sigma$ and $\Lambda^1 = \Lambda^2 = 0$, we obtain a smooth connection as desired:

$$A'_a = A'^I_a \tau_I = \frac{\dot{\gamma}}{2} e^{(1/2)\,\gamma_\infty} \nabla_a R [\cos\,\sigma \tau_2 - \sin\,\sigma \tau_1] + [e^{-(1/2)\,\gamma} - 1] \nabla_a \sigma \tau_0 . \tag{26}$$

B. Holonomy computation

The holonomy of A'^I_a along a loop η is given by a path ordered exponential of the integral of A'^I_a along η:

$$U_\eta[A] := \mathscr{P} \exp\left(\oint_\eta A_a dS^a \right) . \tag{27}$$

For quantum considerations, it turns out that the most interesting loops are the integral curves of the rotational Killing vector σ^a. Note that, along these curves, only the second term in the expression (26) of the connection contributes. Since the internal vector in this term is constant, this part of the connection is effectively Abelian. Recall that in the case of an Abelian connection the path ordered exponential reduces to an ordinary exponential. Hence, if η is chosen to be the integral curve of the Killing field with radius r_o, the holonomy can be easily evaluated. We have

$$U_\eta[A'] = \cos[\pi(1 - e^{-(1/2)\,\gamma(r_o)})] - 2\tau_0\, \sin[\pi(1 - e^{-(1/2)\gamma(r_o)})], \tag{28}$$

where we have used the fundamental representation of $SU(1,1)$. For our purposes, it will suffice to consider these particular loops.

Of special interest to the quantization program under consideration are the functions $T^0_\eta[A]$ of connections defined by the trace of the holonomy. Taking the trace of (28) yields

$$T^0_\eta[A'] = 2 \cos[\pi(1 - e^{-(1/2)\,\gamma(r_o)})] . \tag{29}$$

Note, incidentally, that if η is chosen to be the loop at infinity, $T^0_\eta[A]$ reduces to a simple function of the total energy of the coupled system. For the reduced system, $\gamma(r_o)$ represents precisely the energy of ψ in a box of radius r_o (where ψ is regarded as a scalar field propagating on the

Minkowskian background.) The question of whether the T^0_η can be promoted to a well-defined operator will therefore reduce to the question of whether the operator corresponding to the energy of a scalar field in a box can be satisfactorily regulated.

IV. QUANTUM THEORY

A. Quantization

The reduced phase space of section II D serves as the natural point of departure for quantization. Since the constraints have been solved, the algebra $\mathscr{A}$ of observables is easy to construct. The obvious complete set of classical observables is given by the smeared fields and momenta, $\psi(f) := \int dr f(r)\psi(r)$ and $p_\psi(g) := \int dr g(r) p_\psi(r)$, where f,g belong to the Schwartz space $\mathscr{S}$ of smooth test functions with rapid decay at infinity. Thus, the quantum algebra $\mathscr{A}$ is generated by operators $\hat{\psi}(f)$ and $\hat{p}_\psi(g)$, subject to the canonical commutation relations:

$$[\hat{\psi}(f),\hat{\psi}(g)]=0, \quad [\hat{p}_\psi(f),\hat{p}_\psi(g)]=0, \quad [\hat{\psi}(f),\hat{p}_\psi(g)]=i\int dr f g \hat{I}. \tag{30}$$

Our task is to find a representation of $\mathscr{A}$ which, furthermore, carries a well-defined Hamiltonian operator $\hat{H}$, the quantum analog of $(1/4G)(1-\exp(-\gamma_\infty/2))$.

For technical simplicity, we will regard $\hat{\psi}$ and $\hat{p}_\psi$ as operator-valued distributions in two (space) dimensions and incorporate rotational symmetry by restricting the states to be axisymmetric at the very end. Our experience from low dimensional, interacting scalar quantum field theories now suggests that we use as our Hilbert space $\mathscr{H}=L^2(\mathscr{S}',d\mu)$ where $\mathscr{S}'$ is the space of all tempered distributions on R^2, and μ a suitable measure thereon. (For details, see, e.g., Ref. 13). Since γ_∞ is the Hamiltonian of the free scalar field in Minkowski space, to make the quantum Hamiltonian operator well-defined, it is natural to use for μ the standard Gaussian measure for a free, massless scalar field with covariance $\frac{1}{2}\triangle^{-1/2}$, where $\triangle$ is the Laplacian on R^2 with respect to the flat metric

$$q^o_{ab}=\nabla_a R \nabla_b R + r^2 \nabla_a \theta \nabla_b \theta.$$

Thus, μ is defined by

$$\int_{\mathscr{S}'} d\mu e^{i\int d^2x f(\vec{x})\tilde{\psi}(\vec{x})} = e^{-(1/2)\int d^2x f(\vec{x})\triangle^{-1/2} f(\vec{x})}, \tag{31}$$

where $\tilde{\psi} \in \mathscr{S}'$. (Heuristically, ''$d\mu=[\exp-\frac{1}{2}\int d^2x(\psi\triangle^{1/2}\psi)]\mathscr{D}\psi$.'') The action of the basic operators is then given by

$$\hat{\psi}(f)\cdot\Psi(\psi)=\left(\int d^2x f\psi\right)\Psi(\psi) \quad \text{and} \quad \hat{p}_\psi(g)\cdot\Psi(\psi)=-i\int d^2x\left[g\frac{\delta}{\delta\psi}+\frac{1}{2}\psi\triangle^{1/2}g\right]\Psi(\psi) \tag{32}$$

where Ψ belongs to the dense sub-space of cylindrical functions in $\mathscr{H}$. The operators $\hat{\psi}(f)$ and $\hat{p}_\psi(f)$ admit self-adjoint extensions to $\mathscr{H}$. We will see below that the Hamiltonian is also represented by a self-adjoint operator and that, like its classical counterpart, it is positive.

This choice of representation is also suggested by the mathematical equivalence between our physical system and a free massless scalar field on Minkowski space defined by g^o_{ab} (see Eq. (21)). Thus, although our viewpoint is somewhat different, our final choice of representation is the same as that of Refs. 7 and 8.

In a more familiar terminology, our representation can be obtained by introducing an operator-valued distribution $\hat{\psi}(\vec{x},T)$ in the fictitious Minkowskian background (M,g^o_{ab}):

$$\hat{\psi}(\vec{x},T)=\frac{1}{2\pi}\int\frac{d^2k}{\sqrt{2\omega_k}}[\hat{A}(\vec{k})e^{i(\vec{k}\cdot\vec{x}-\omega_k T)}+\hat{A}^\dagger(\vec{k})e^{-i(\vec{k}\cdot\vec{x}-\omega_k T)}], \tag{33}$$

where $\omega_k=\sqrt{\vec{k}\cdot\vec{k}}$, and $\hat{A}(\vec{k})$ and $\hat{A}^\dagger(\vec{k})$ are the standard creation and annihilation operators. The Hilbert space $\mathscr{H}$ can be generated by repeated actions of creation operators on the vacuum. There is a well-defined self-adjoint operator $\hat{L}_\sigma$ on $\mathscr{H}$ which represents the total angular momentum along the Killing field $\partial/\partial\sigma$. The physical Hilbert space $\mathscr{H}_P$ is the eigenspace of $\hat{L}_\sigma$ with zero eigenvalue. Since zero is a discrete eigenvalue, $\mathscr{H}_P$ is a sub-space of $\mathscr{H}$.

The physical Hilbert space can also be obtained more directly by using, instead of (33), an operator valued distribution in which the zero angular momentum constraint has already been incorporated, namely,

$$\hat{\psi}(R,T)=\int_0^\infty dk[f_k^+(R,T)\hat{A}(k)+f_k^-(R,T)\hat{A}^\dagger(k)]. \tag{34}$$

Here $f_k^+(R,T)=[f_k^-(R,T)]^*=(1/\sqrt{2})J_0(kR)e^{-i\omega_k T}$, where, from now on, $J_n(kR)$ will denote the n-th order Bessel function of the first kind. Note that $f_k^+(R)$ are solutions of the equation of motion (21) and provide an orthonormal basis for the one-particle Hilbert space with respect to the Klein-Gordon inner-product. (Our normalization is such that the creation and annihilation operators satisfy the commutation relations $[\hat{A}(k),\hat{A}^\dagger(k')]=\delta(k,k')$.) The physical Hilbert space $\mathscr{H}_P$ can be generated by repeatedly acting on the vacuum by the creation operators $\hat{A}^\dagger(k)$. In what follows, we will use both the two-dimensional as well as the one-dimensional descriptions given by (33) and (34).

We will conclude this sub-section with three remarks.

(1) Since the physical Hilbert space has a Fock structure, it is tempting to refer to the quanta created by $\hat{A}^\dagger(k)$ as (scalar) ''particles'' and we will often do so. Note, however, that from the point of view of the coupled Einstein-Klein-Gordon system we began with, this description is gauge dependent. The system has one local degree of freedom and we chose to put it in the scalar field. Another gauge choice could put it in the gravitational field and the interpretation of quantum states would then be different. However, the interpretation *is* unambiguous at null infinity, i.e., for asymptotic states, because one does not need to fix gauge there (see below).

(2) We now have the full Hilbert space of states. So, it is natural to examine if one can generate a picture of space-*time*, as opposed to just spatial, quantum geometry in spite of our use of the canonical approach. As one might expect from our gauge-fixing procedure, the answer is in the affirmative. In the fixed chart (T,R,σ) on M, the metric operator can be (heuristically) written as

$$\text{``}\hat{g}_{ab}=:e^{\hat{\gamma}(R,T)}:(-\nabla_a T\nabla_b T+\nabla_a R\nabla_b R)+R^2\nabla_a\sigma\nabla_b\sigma,\text{''} \tag{35}$$

where, as usual, the double-dots indicate normal ordering. (The reason behind the qualification ''heuristic'' and the quotes will become clear in section IV C.)

We can now ask if there are well-defined semi-classical states peaked at classical solutions. The answer is again in the affirmative. Consider, in the Fock space, a coherent state $|\Psi_c\rangle$ which is peaked at a classical solution $c(R,T)$ of (21). In the configuration representation, these are Gaussians for which the uncertainty in the field operator and its momentum are ''shared equally,'' the product of the two uncertainties being minimum *for all times T*. On these states, the expectation value of the metric operator (35) *is well-defined* and is given just by

$$\langle\Psi_c|\hat{g}_{ab}|\Psi_c\rangle=e^{\gamma[c,p_c]}(-\nabla_a T\nabla_b T+\nabla_a R\nabla_b R)+R^2\nabla_a\sigma\nabla_b\sigma, \tag{36}$$

where $\gamma[c,p_c]$ is the right side of (16), evaluated on the initial data of the classical solution c. Thus, every coherent states in our physical Hilbert space $\mathscr{H}_o$ remains peaked at a classical scalar field c *and* a metric g_{ab}, satisfying the coupled Einstein-Klein-Gordon equation. While the result is technically rather simple, conceptually it is somewhat surprising. For the coupled system satisfies highly non-linear equations and the wave packets do not disperse in spite of these non-linearities.

(3) It is well-known that there exist an infinite number of unitarily inequivalent representations of the algebra $\mathscr{A}$. Our additional requirements are that the Hamiltonian operator be well-defined and that the physical states be invariant under the rotational symmetry corresponding to $\partial/\partial\sigma$. Unfortunately, these requirements by themselves are not strong enough to select a representation uniquely. To single out the Fock representation in Minkowskian quantum field theories, one needs additional conditions that refer to the action of the Poincaré group. In our case, the Minkowski space-time (M,g^o_{ab}) is only a fictitious background and its Poincaré group has no physical significance in the full, coupled system.

Nonetheless, it *is* possible to single out our representation by two methods. The first involves the imposition of reality conditions as indicated in Ref. 4: The measure μ on $\mathscr{S}'$ is singled out by the condition that the operators $\hat{\psi}(f)$ and $\hat{p}_\psi(g)$ of (32) be self-adjoint. The second method invokes the S-matrix theory. It turns out that the Einstein-Rosen waves are all asymptotically flat at null infinity in $2+1$ dimensions.[14] Furthermore, the classical S-matrix is well-defined: the data on past null infinity determines the solution uniquely which in turn determines the data on future null infinity. Hence, it is natural to use the asymptotic quantization scheme[15] to quantize the coupled system *at* past and future null infinity. It turns out that our Fock representation is naturally isomorphic to the simplest representation obtained by asymptotic quantization (either at past *or* future null infinity). Details will appear elsewhere.

B. Hamiltonian and time

Recall that, after reduction, the classical Hamiltonian is given by $H=(1/4G)[1-\exp-(\frac{1}{2}\gamma_\infty)]$. Since γ_∞ is the Hamiltonian of a free scalar field in Minkowski space, the normal-ordered operator $:\hat{\gamma}_\infty:$ admits the standard self-adjoint extension which, for simplicity, we will denote also by $:\hat{\gamma}_\infty:$. Then, the standard spectral theorems ensure that

$$\hat{H} := \frac{1}{4G}(1-e^{-(1/2):\hat{\gamma}_\infty:}) \equiv \frac{1}{4G}(1-e^{-\int k dk \hat{A}^\dagger(k)\hat{A}(k)}) \tag{37}$$

is a well-defined, self-adjoint operator. Since $:\hat{\gamma}_\infty:$ is a non-negative, unbounded operator and since $f(\lambda)=(1-e^{-\lambda/2})$ takes values in $[0,1]$ for $\lambda \in [0,\infty]$, it follows that the spectrum of H is given by $[0, 1/4G]$. If we consider states in $\mathscr{H}_P$ with higher and higher frequency, the expectation value of $\hat{\gamma}_\infty$, i.e., the energy in the field from the mathematical, Minkowskian perspective, increases unboundedly. However, the expectation value of the *physical* Hamiltonian $\hat{H}$ remains bounded and tends to the limit $1/4G$. Thus, the situation is completely analogous to that in the classical theory.[6]

Let us now examine the ground state. Since $|0\rangle$ is the unique ground state of $:\hat{\gamma}_\infty:$ on $\mathscr{H}_P$, it follows immediately that it is also the unique ground state of $\hat{H}$. Since $|0\rangle$ is, in particular, a coherent state, it is peaked at a classical solution to the coupled system. As one might expect, the solution is: $\psi=0$ and $g_{ab}=g^o_{ab}$ Thus, the quantum ground state is peaked on Minkowski space-time. The ground state geometry is thus quite tame; there is no evidence of wild fluctuations at the Planck scale.

What is the situation with general coherent states? Given a coherent state $|\Psi_c\rangle := \exp[\int dk c(k)\hat{A}^\dagger(k)]\cdot|0\rangle$, peaked at a classical solution c, we have

$$\left[\exp-\frac{1}{2}:\hat{\gamma}_\infty:\right]\cdot\Psi_c=\left[\exp\int dke^k c(k)\hat{A}^\dagger(k)\right]\cdot|0\rangle=:\Psi_{c'}, \tag{38}$$

where $c'(k)=e^k c(k)$. Thus, the image is again a coherent state but its peak is shifted. Therefore, the expectation value of the Hamiltonian in a coherent state Ψ_c is given by

$$\frac{\langle\Psi_c,\hat{H}\cdot\Psi_c\rangle}{\langle\Psi_c,\Psi_c\rangle}=\frac{1}{4G}\left[1-\exp\frac{1}{\hbar}\int dk(e^{-\hbar k}-1)|c(k)|^2\right], \tag{39}$$

where, to bring out the quantum effects, we have restored the factors of $\hbar$. (Recall also that, from the perspective of the 2+1-dimensional theory, the scalar field has to be rescaled by factors involving $\sqrt{G}$. The net effect is to replace $\hbar$ in (39) by $\hbar G$ which has the physical dimension of length.) In contrast, the classical energy (10) of the solution to the Einstein-Klein-Gordon equation determined by c is $E(c)=(1/4G)\,[1-\exp-\int dkk|c(k)|^2]$. If we expand out $\exp-\hbar k$ in (39), the leading term yields the classical answer. In general, the classical energy is a good approximation to the expectation value of the quantum Hamiltonian if $c(k)$ is concentrated on low frequencies. Quantum corrections (of order $(G\hbar)$ and higher) become more and more significant if the support of $c(k)$ is shifted to higher and higher frequencies.

Next, let us consider the issue of time. Recall that, in the classical theory, the Hamiltonian evolution is tied to time t, the affine parameter along the Hamiltonian vector field in the phase space. Each dynamical trajectory gives rise to a space-time and t can then be interpreted as a time coordinate in *that* space-time, $\partial/\partial t$ being an unit asymptotic time translation. From the decoupling viewpoint, on the other hand, it is the variable T that arises naturally; it represents time in the fixed Minkowskian background. What is the situation in the quantum theory? Now, our measure μ on $\mathscr{S}'$ which dictates the Hilbert structure is rooted in the flat two-geometry induced by g^o_{ab} or, alternatively, in the positive and negative frequency decomposition with respect to the Minkowskian time T. Indeed, since the field equation (20) in terms of t is non-linear, positive frequency decomposition with respect to t is not meaningful *a priori*. Thus, while t and T are on equal footing in the classical theory, our choice of representation breaks this symmetry in the quantum theory.

We can mimic the situation in the classical theory and introduce a dynamical parameter λ, analogous to the classical t, associated with the Hamiltonian:

$$i\hbar\frac{\partial\Psi}{\partial\lambda}=\hat{H}\cdot\Psi. \tag{40}$$

However, unlike in the classical theory, now a solution to the dynamical equation does *not* define a hyperbolic space-time and hence we can not interpret λ as a time parameter in the familiar sense, i.e., in space-time terms. However, a key simplification occurs if we restrict ourselves to coherent states Ψ_c. Since each of these states is peaked at a classical space-time, we can ask if, given any one of these states, we can interpret λ as a time parameter in the corresponding classical space-time. The answer is in the affirmative. In fact λ can be identified with the time coordinate t of that space-time! Thus, as one might have hoped, the familiar notion of time re-emerges in the semi-classical regime. In the full quantum theory, however, the dynamical parameter defined by the Hamiltonian does not have a simple space-time interpretation.

We will conclude this discussion with a remark. There is an obvious alternative form for the Hamiltonian: We can further normal-order $\hat{H}$ and define a new Hamiltonian $\hat{H}'=:\hat{H}:$. One can verify that $\hat{H}'$ is densely defined and admits a self-adjoint extension. It also annihilates $|0\rangle$. Furthermore, the expectation values of $\hat{H}'$ on a coherent state $|\Psi_c\rangle$ equals the classical energy of c. It thus appears to be an attractive alternative. However, its spectrum is the *entire real line*! This comes about because the overall normal ordering ensures that, while acting on n-particle states,

only the first $n+1$ terms in the expansion of the exponential in $\hat{H}'$ have non-vanishing contributions. Thus, for example, on one-particle states, $\hat{H}'$ has the same action as $\frac{1}{8}:\hat{\gamma}_\infty:$, which is unbounded above. Similarly, on two particle states, it is unbounded below. Given that the classically allowed energy values lie in the interval $[0, 1/4G]$, we can not take $\hat{H}'$ as the physically admissible quantum analog of the classical Hamiltonian.

C. Metric operator

Since we are dealing with a system with an infinite number of degrees of freedom, operators corresponding to physical observables have to be regulated. For the Hamiltonian, this was achieved via normal ordering. In this section, we will focus on the metric operator.

A formal expression for the metric operator was already given in (35), where regularization again consisted of normal ordering. Consider the sub-space of $\mathscr{H}_{\mathscr{P}}$ which is spanned by finite linear combinations of coherent states. It is easy to show that the sub-space is dense and that the matrix elements of the metric operator $\hat{g}_{ab}$ are well-defined on it. Thus, the formal expression (35) does lead to a well-defined *quadratic form*; in a field theory terminology, $\hat{g}_{ab}$ exists in the LSZ sense. However, this does *not* imply that $\hat{g}_{ab}$ is well-defined *as an operator* on this sub-space. Note that this is *not* a peculiarity of quantum field theory; one encounters such situations already in non-relativistic quantum mechanics. Consider, for example, a one-dimensional harmonic oscillator. The operator $\exp(\alpha a^\dagger a^\dagger)$ has finite matrix elements on the basis $|n\rangle$ for all complex numbers α. However, if $|\alpha|>1$, the norm $\|e^{\alpha a^\dagger a^\dagger}|n\rangle\|$ diverges for any $|n\rangle$, whence the operator fails to be defined on the sub-space spanned by these basis vectors.

It turns out that the situation with the metric operator is quite analogous (which is the reason behind the quotes in (35)). To see this, let us begin with the first non-trivial term in the expansion of $\hat{g}_{RR}$ or $\hat{g}_{TT}$. Setting for simplicity $T=0$ in (34), we have

$$:\hat{\gamma}(R):=\frac{1}{2}\int dk_1\int dk_2[2F_+(R,k_1,k_2)(\hat{A}^\dagger(k_1)\hat{A}(k_2)) + F_-(R,k_1,k_2)(\hat{A}(k_1)\hat{A}(k_2)+\hat{A}^\dagger(k_1)\hat{A}^\dagger(k_2))], \tag{41}$$

where

$$F_\pm(R,k_1,k_2)=\pm k_1k_2\int_0^R rdr(J_0(k_1r)J_0(k_2r)\pm J_1(k_1r)J_1(k_2r)). \tag{42}$$

For any fixed R, one can regard the coefficient $F_-(R,k_1,k_2)$ of $\hat{A}^\dagger(k_1)\hat{A}^\dagger(k_2)$ as a ''potential two-particle state'' in the Fock space. However, a direct calculation shows that its norm is ultraviolet divergent. This immediately implies that the norm $\|:\hat{\gamma}(R):|0\rangle\|$ also diverges, whence the operator fails to be well-defined on the vacuum state. Further calculations show that the same result holds for any coherent state.

What is the origin of this divergence? Recall that $:\hat{\gamma}(R,T):$, obtained by promoting (15) to an operator, has the same functional form as the restriction of the Hamiltonian of a scalar field to a box of size R. That is,

$$:\hat{\gamma}(R):=\frac{1}{2}\int_0^\infty dr\,\theta(R-r):\left(\frac{\hat{p}_\psi{}^2}{r}+r(\hat{\psi}')^2\right):, \tag{43}$$

where $\theta(R-r)$ denotes the Heaviside step-function, which equals 1 if $r<R$ and 0 otherwise. Normal ordering softens the singularity that arises from the fact that fields are being multiplied at

the same point. However, this turns out to be insufficient because of two simultaneous pathologies: the operator contains products of derivatives of the field $\hat{\psi}(R,T)$ and these are integrated on a region with *sharp* boundary.

Now, a natural strategy to obtain a well-defined metric operator in such circumstance is to soften the sharp boundary of the box. This can be achieved by replacing the Heaviside function $\theta(R-r)$ in (43) with a smooth function $f_R(r)$ which equals 1 for $r\leqslant R-\epsilon$, then it smoothly decreases to zero and equals zero for $r\geqslant R+\epsilon$, where ϵ is a small parameter. An example of such a regulator is

$$f_R(r)=\begin{cases}1, & \text{if } r\leqslant R-\epsilon,\\ \exp\left(-\dfrac{4\epsilon^2}{[r-(R+\epsilon)]^2}+1\right), & \text{if } R-\epsilon\leqslant r\leqslant R+\epsilon,\\ 0, & \text{if } r\geqslant R+\epsilon.\end{cases}$$

Now, in Minkowskian field theories, while one can begin with such a regulator, after suitable renormalization, one has to take the regulator away to ensure Poincaré invariance. In the present case, however, we need only respect the rotational symmetry and hence there is no *a priori* need to take the limit $\epsilon\to 0$. Indeed, the Planck length is now a natural candidate for ϵ.

Let us therefore fix a regulator f_R and consider the smeared version of (41):

$$:\hat{\gamma}(f_R,T):=\frac{1}{2}\int dk_1\int dk_2[2F_+(f_R,k_1,k_2)(\hat{A}^\dagger(k_1)\hat{A}(k_2)e^{i(k_1-k_2)T})+F_-(f_R,k_1,k_2)$$
$$\times(\hat{A}(k_1)\hat{A}(k_2)e^{-i(k_1+k_2)T}+\hat{A}^\dagger(k_1)\hat{A}^\dagger(k_2)e^{i(k_1+k_2)T})], \tag{44}$$

where

$$F_\pm(f_R,k_1,k_2)=\pm k_1k_2\int_0^\infty dr f_R(r)r(J_0(k_1r)J_0(k_2r)\pm J_1(k_1r)J_1(k_2r)). \tag{45}$$

The rest of this section is devoted to showing that this operator is well-defined so long as the smearing function f_R belongs to the Schwartz space $\mathscr{S}$.

The proof is technically simpler if we adopt the two-dimensional version of the Fock space introduced before (see (33)). For, we can then mimic the proofs of analogous statements from Ref. 16. Now, we can take as our smearing fields, elements $f_R(\vec{x})$ of the Schwartz space on R^2. (Thus, the results will in fact be slightly more general than what is need; $f_R(r)$ above is a special case of $f_R(\vec{x})$.)

Let us then write the smeared version of the operator (43) expressed in terms of the creation and annihilation operators given by (33). We have

$$:\hat{\gamma}(f_R,T):=\frac{1}{8\pi}\int d^2k_1\int d^2k_2[2G_+(f_R,\vec{k}_1,\vec{k}_2)\hat{A}^\dagger(\vec{k}_1)\hat{A}(\vec{k}_2)e^{i(\omega_{k_1}-\omega_{k_2})T}-G_-(f_R,\vec{k}_1,\vec{k}_2)$$
$$\times(\hat{A}(\vec{k}_1)\hat{A}(\vec{k}_2)e^{-i(\omega_{k_1}+\omega_{k_2})T}+\hat{A}^\dagger(\vec{k}_1)\hat{A}^\dagger(\vec{k}_2)e^{i(\omega_{k_1}+\omega_{k_2})T})], \tag{46}$$

where

$$G_\pm(f_R,\vec{k}_1,\vec{k}_2)=\pm\left(\frac{\omega_{k_1}\omega_{k_2}+\vec{k}_1\cdot\vec{k}_2}{\sqrt{\omega_{k_1}\omega_{k_2}}}\right)f(\vec{k}_1\mp\vec{k}_2), \tag{47}$$

and $f(\vec{k}_1 \pm \vec{k}_2)$ is the Fourier transform of the smearing function,

$$f(\vec{k}_1 \pm \vec{k}_2) = \frac{1}{2\pi} \int d^2x f_R(\vec{x}) e^{i(\vec{k}_1 \pm \vec{k}_2)\cdot \vec{x}}. \tag{48}$$

Let us begin by showing that the action of the operator (46) is well-defined on the vacuum state. Since $\hat{A}(\vec{k})$ annihilates the vacuum state, we have

$$\| :\hat{\gamma}(f_R): |0\rangle \|^2 = \int d^2k_1 \int d^2k_2 |G_-(f_R, \vec{k}_1, \vec{k}_2)|^2. \tag{49}$$

It follows immediately from (47) that this integral has no infra-red divergences. Therefore, from now on, let us concentrate only on the ultra-violet behavior of the integrand. The factor in the round brackets is ultra-violet divergent. The multiplicative factor f provides a damping, but only for large $|\vec{k_1} + \vec{k_2}|$. However, using simple algebra one can bound $G_-(f_R, \vec{k}_1, \vec{k}_2)$ of Eq (47) by

$$|G_-(f_R, \vec{k}_1, \vec{k}_2)| \leqslant \frac{|\vec{k}_1 + \vec{k}_2|^2 |f(\vec{k}_1 + \vec{k}_2)}{\sqrt{\omega_{k_1} \omega_{k_2}}}. \tag{50}$$

Now, because the smearing function $f_R(\vec{x})$ belongs to the Schwartz space, its Fourier transform $f(\vec{k}_1 + \vec{k}_2)$ falls faster than any polynomial in $|\vec{k_1} + \vec{k_2}|$. This in turn implies that $G_-(f_R, \vec{k}_1, \vec{k}_2)$ is square integrable. Note that the smearing function plays a crucial role in this argument. Had we replaced $f_R(\vec{x})$ by the Heaviside function θ the corresponding Fourier transformed function $f(\vec{k}_1 + \vec{k}_2)$ would behave as $1/|\vec{k}_1 + \vec{k}_2|$ which would not be sufficient to ensure square-integrability of $G_-(f_R, \vec{k}_1, \vec{k}_2)$ (see (50)). Finally, as a side remark, note that the procedure followed above to prove that $G_-(f_R, \vec{k}_1, \vec{k}_2)$ is square integrable does not go through for G_+ because of the minus sign in the argument of the function $f(\vec{k}_1 - \vec{k}_2)$ (see (47)).

Next, one can show that the action of this operator is in fact well-defined on a generic n-particle state on the Fock space,

$$|\Psi_n\rangle = \int d^2k_1 \cdots d^2k_n g^{(n)}(\vec{k}_1, \cdots, \vec{k}_n) \hat{A}^\dagger(\vec{k}_1) \cdots \hat{A}^\dagger(\vec{k}_n) |0\rangle, \tag{51}$$

where $g^{(n)}(\vec{k}_1, \cdots, \vec{k}_n) = \langle \vec{k}_1, \cdots, \vec{k}_n | \Psi_n \rangle$, and $\int d^2k |g^{(n)}(\cdots, \vec{k}, \cdots)|^2 < \infty$. Now the terms involving annihilation operators will also contribute. The final result is that $\| :\hat{\gamma}(f_R): |\Psi_n\rangle \|$ is finite provided that $|\Psi_n\rangle$ is a state such that $\int d^2k |\vec{k}|^2 |g^{(n)}(\cdots, \vec{k}, \cdots)|^2 < \infty$. (This restriction comes from the ''particle number preserving term'' in (46).) Since finite linear combinations of these states form a dense subset of the Hilbert space, we have now established that the operator $:\hat{\gamma}(f_R):$ is densely defined on $\mathscr{H}_{\mathscr{F}}$.

By inspection, it is also symmetric on this space. We will now show that it admits a self-adjoint extension to $\mathscr{H}_P$. For this, by a theorem due to Von-Neumann,[17] it is sufficient to exhibit on $\mathscr{H}_P$ an anti-linear operator $\hat{C}$ with $\hat{C}^2 = 1$ which leaves the domain of $:\hat{\gamma}(f_R):$ invariant and commutes with it. We can take $\hat{C}$ to be the complex-conjugation operator on $\mathscr{H}_P = L^2(\mathscr{S}', d\mu)$. It is straightforward to show that $\hat{C}$ commutes with $\hat{\psi}(\vec{x}, T)$ whence $\hat{C}\hat{A}(\vec{k}) = \hat{A}(-\vec{k})\hat{C}$ and $\hat{C}\hat{A}^\dagger(\vec{k}) = \hat{A}^\dagger(-\vec{k})\hat{C}$. Finally, since $G_\pm(f_R, \vec{k}_1, \vec{k}_2)$ is real and equals $G_\pm(f_R, -\vec{k}_1, -\vec{k}_2)$, it follows that $\hat{C}$ satisfies the conditions of Von-Neumann's theorem. Again, for notational simplicity, we will denote the self-adjoint extension also by $:\hat{\gamma}(f_R):$.

We can now return to the metric. Since $:\hat{\gamma}(f_R):$ is a self-adjoint operator on $\mathscr{H}_P$, it follows that $\exp:\hat{\gamma}(f_R):$ is also self-adjoint. Thus, we can now give meaning to the formal expression (35) and define a regulated operator for the full space-*time* metric:

$$\hat{g}_{ab}(f) = e^{:\hat{\gamma}:(f_R,T)}(-\nabla_a T\nabla_b T + \nabla_a R\nabla_b R) + R^2\nabla_a\sigma\nabla_b\sigma, \tag{52}$$

within canonical quantization. In the classical theory, the existence theorems ensure that a space-time metric can be recovered from the canonical framework. There is, however, no such general result in the quantum theory. Our success can be traced back to the use of a well-suited gauge fixing procedure. (Whether a different choice of gauge will give equivalent results is far from being clear.)

At first, it is somewhat confusing that while we do not need a smearing function to obtain a well-defined quadratic form, we need one to obtain a well-defined operator. Note, however, that the situation is rather similar even in the classical theory! The metric component $\exp\gamma(R)$ is a well-defined functional on (a dense sub-space of) the reduced phase space. However, precisely because of the sharpness of the boundary, this functional *fails* to give rise to a well-defined Hamiltonian vector field. To obtain a Hamiltonian vector field, one again needs to soften the boundaries using a smearing function. The fact that the unsmeared functional is well-defined is analogous to the fact that, in the quantum theory, the quadratic form is well-defined without smearing. The smeared quantum operator is the analog of the smeared classical observable with a well-defined Hamiltonian vector field. From this perspective, in fact it would have been surprising if a self-adjoint metric operator had existed without smearing; it would then have defined a one-parameter group of motions on the Hilbert space which would have no classical counterpart.

D. Quantum geometry

We will now briefly investigate three consequences of the results obtained in the last three sub-sections. The discussion will be rather general and we will only indicate the directions along which more detailed work could be done.

The first concerns the issue of vacuum fluctuations of geometry. To compute these, we need a well-defined operator; quadratic forms do not suffice. Let us therefore consider the regulated metric operator (52). Since it is completely determined by $:\hat{\gamma}(f_R,T):$, let us focus on this latter operator. The vacuum expectation value of this operator is zero. However, because of the vacuum fluctuations, there is a non-zero probability of finding other values as well. A qualitative measure of these probabilities is given by the uncertainty

$$[\delta:\hat{\gamma}(f_R,T):]^2 := \langle 0|(:\hat{\gamma}(f_R,T):)^2|0\rangle - \langle 0|:\hat{\gamma}(f_R,T):|0\rangle^2 = \int dk_1 dk_2 |F_-(f_R,k_1,k_2)|^2. \tag{53}$$

The right side is a measure of the fluctuation of the metric coefficients around the mean. An immediate consequence of the above result is the existence of the fluctuations of the light cone. To see this, consider a vector k^a in the tangent space of a point (T,R,σ) which is null with respect to g^o_{ab}. Now, due to the vacuum fluctuations of the metric operator, the value of the norm of k^a is uncertain and, since the fluctuation can have either sign, there is in general a non-zero probability for k^a to be space-like or time-like. The exception occurs if the vector k^a is radial, i.e., orthogonal to $\partial/\partial\sigma$. Then, because of the specific form (52) of the metric operator, k^a continues to be null. (Similar considerations obviously apply to time-like and space-like vectors.) This simple example illustrates that, contrary to an oft-expressed view, the canonical framework *is* capable of addressing space-*time* issues such as the fluctuations of the causal structure.

The second feature we wish to discuss concerns the commutator of the metric operators at the same value of T. Again, in this calculation, quadratic forms do not suffice and we must use the regulated operator (52). A straightforward calculation yields

$$[:\hat{\gamma}(f_R):,:\hat{\gamma}(g_{R'}):]=\frac{i}{2}\int d^2x(f(\vec{x})\nabla^a g(\vec{x})-g(\vec{x})\nabla^a f(\vec{x}))\times:(\hat{p}_\psi(\vec{x})\nabla_a\hat{\psi}(\vec{x})+\nabla_a\hat{\psi}(\vec{x})\hat{p}_\psi(\vec{x})):. \tag{54}$$

Thus, the commutator does *not* vanish; the non-vanishing contribution comes from the smeared boundary at the smaller of R and R'. At first the result seems surprising since $\hat{\gamma}(f_R)$ and $\hat{\gamma}(g_{R'})$ dictate the ''value'' of the metric operator at points R and R' which can be widely separated (and have the same value of T). However, the result does not contradict any physical principle. For, although the basic field operators $\hat{\psi}$ and $\hat{p}_\psi$ associated with such points do commute, the metric operator is a *non-local* functional of these.

Indeed, the result has a classical analog. As we pointed out at the end of the last sub-section, the unsmeared metric g_{ab} does not define a Hamiltonian vector field on the reduced phase space. Hence, to evaluate Poisson brackets, we are forced to use the smeared metric. Then, it is easy to verify that the Poisson brackets between the functionals $\gamma(f_R)$ and $\gamma(g_{R'})$ fail to vanish even when R and R' are widely separated. In fact these Poisson brackets just mirror the commutators given above.

The last point we wish to discuss concerns the holonomies computed in section III. We found that the expression of the holonomy involves the exponential of the integral of the connection along a loop on Σ. Now, as we indicated in the Introduction, there is a canonical quantization program which is based on the assumption that the quantum analogs of these holonomies are well-defined operators. The present model provides a good testing ground for the validity of this assumption.

To see that the issue is non-trivial, let us first recall the situation in the well-understood Maxwell theory, say in $2+1$ dimensions. There, the connection is generally promoted to an operator-valued distribution and the holonomies (of real connections) fail to be well-defined in the standard Fock representation. For in a $2+1$-dimensional theory, the operator-valued connection has to be smeared with two-dimensional test fields while loops have only one-dimensional support. In the present case, we are also using a Fock representation. A natural question therefore arises: Is the situation then analogous to the Maxwell theory? If so, the basic assumption mentioned above would fail to hold in our solution.

Now, because of axi-symmetry, smearing along a path in the radial direction in effect corresponds to a two-dimensional smearing. Hence, the acid test is provided by loops $R=\text{const}$ where one can not take advantage of axi-symmetry. Can the classical expression (29) of the trace of the holonomy along such a loop, η, be promoted to a well-defined, regulated operator? Following the procedure we used in section IV C, we find that the answer is in the affirmative. The quantum operator is given by

$$\hat{T}^0_\eta=2\cos[\pi(1-e^{-(1/2):\hat{\gamma}(f_R):})]. \tag{55}$$

The standard spectral theorems ensure that the operator on the right is well-defined, self-adjoint and has spectrum bounded between -1 and $+1$. Thus, the situation is very different from that in the Maxwell case. Indeed, in the present case, it is the scalar field that is subject to Fock quantization. The connection, like the metric, is a *non-local* functional of the elementary scalar field; its expression involves two-dimensional integrals of the basic fields. It is because of this that the trace of the holonomy can be promoted to a well-defined operator on $\mathscr{H}_P$. As in the case of the metric, if we were interested only in quadratic forms, there would be no need to use any smearing fields; they are needed only if one wishes to obtain genuine operators.

V. DISCUSSION

The mathematical structure of the classical Einstein-Rosen waves has been well-known for a long time. In light of those results, it is not at all surprising that the true degrees of freedom can

be coded in a scalar field satisfying the wave equation with respect to a fictitious Minkowski space and quantization of this field in itself is trivial. Thus, the underlying structure of our final theory is the expected one. The main purpose of the analysis was, rather, to apply the standard canonical quantization method, which is applicable in the more general context, to arrive at this final picture systematically. That is, since the model is technically sufficiently simple to be exactly soluble, we used it to better understand the standard quantization techniques and to probe conceptual and technical issues of quantum general relativity.

Indeed, the analysis shed light on a number of these. At the classical level, we saw that one can effectively exploit asymptotic flatness to disentangle gauge from dynamics. Gauge conditions can be imposed to handle constraints and to extract the true degrees of freedom. In the final picture, we are still left with a non-trivial Hamiltonian. Consequently, the issue of deparametrization never enters our analysis. Similarly, we did not find it necessary to introduce ''clock degrees of freedom''[18] at infinity to extract dynamics. In the quantum theory, we saw that there exist semi-classical states which are peaked at classical solutions of the coupled Einstein-scalar field system. The positive energy theorem goes over to the quantum theory and the quantum Hamiltonian has the same upper bound as the classical one. The solution also confirms the general expectation about the issue of time in quantum theory in the asymptotically flat context. The parameter t arises as the affine parameter along the Hamiltonian vector field on the classical phase space and has the space-time interpretation of time in the three-metric defined by any dynamical trajectory in the phase space. (This is also the situation in full general relativity.) In the quantum theory, an analogous parameter enters the Schrödinger equation (40). However, since general quantum states do not correspond to classical space-times, this parameter does not have the standard interpretation of time. This interpretation emerges only in the semi-classical regime: in any coherent state, the parameter can be identified with the classical t. Finally, we saw that the regulated metric and holonomy operators can be constructed by a careful smearing procedure which smoothens the sharp boundaries that enter the definition of their classical analogs. The associated functional analysis subtleties are non-trivial even from the mathematical perspective of a free field in Minkowski space.

In the technical discussion, we made a liberal use of the fictitious Minkowskian background g^o_{ab} and the associated time parameter T. However, this was done primarily for pedagogical reasons, i.e., to bring out the relation between the final quantum theory and the expected one. We could have arrived at our Hilbert space of states directly from the reduced phase space either by making use of the ''reality condition'' strategy[4] or by making an appeal to null infinity and the S-matrix theory, without having to explicitly introduce g^o_{ab}.

How do these results compare with those available in the literature? Our analysis is closely related to that of Refs. 7 and 8. In the classical theory, the main difference lies in our systematic handling of the asymptotically flat boundary conditions. In particular, in our treatment, the true Hamiltonian arose directly from the boundary term in the action. This point could not have been realized in the early analyses because the relation between $3+1$- and $2+1$-dimensional theories was not well-known and, more importantly, because a clear understanding of asymptotic flatness in $2+1$ dimensions has emerged only recently. (Indeed, given what was known in the early seventies, the treatment of Ref. 7 seems to be surprisingly ahead of its time!) In the quantum theory, the difference lies in the treatment of certain functional analytical subtleties. That it is necessary to regularize the metric operator was realized in Ref. 8. However, the suggestion there that the softening of the sharp boundaries can be brought about by a simple ultra-violet cut off in the momentum space is incorrect; one needs suitable smearing fields *in space-time*. Thus, our regularization differs from that in Ref. 8. Finally, our isolation of true degrees of freedom was carried out in $2+1$ dimensions. When translated to a $3+1$-dimensional perspective, our result is equivalent to the definition of true observables given in Ref. 19.

Since the model has been solved exactly within the standard canonical framework, it opens

doors for further analysis in a number of directions. We will conclude by mentioning a few of these.

First, we can now explore quantum field theory on a *quantum* geometry. Part of the motivation here is similar to that of quantum field theory in curved space-times; one wishes to investigate the effects of a non-trivial background geometry on quantum fields. Furthermore, this analysis can also shed light on the nature of quantum geometry itself. For instance, we may choose as our background a coherent state. The geometry influences the dynamical evolution of the quantum field because the metric appears in the expression of the Hamiltonian of the test field. Now, in the quantum theory, we have two alternatives. First, we can consider just the quadratic form that is determined by the (normal-ordered, unsmeared) metric (35) and substitute its value in a coherent state in the expression of the Hamiltonian. Since this value is just the classical metric, this would lead us just to the standard quantum field theory in curved space-times. To probe the effects of the *quantum* nature of geometry, we would have to look beyond just the expectation values. This can not be handled by a quadratic form alone; we need a genuine operator. Thus, the second, and much more interesting, possibility is to use the smeared metric operator in the expression of the Hamiltonian of the test field. Then, one would see the effects of the quantum geometry on the evolution of the matter, even in the case when the geometry is assumed to be in the vacuum state (initially). This analysis would be interesting because much of the standard apparatus of quantum field theory in curved space-times uses the fixed causal structure of the classcial geometry which is now absent. Using the canonical framework, one would be able to do quantum theory of test fields even when the causal structure is subject to quantum fluctuations of its own.

Recall that, in the regularization of the metric operator, we needed a smearing function f_R. There is, however, no ''canonical'' choice; while we know what the qualitative behavior of f_R should be, there is considerable freedom in its detailed form. Thus, we do not have a ''canonical'' regularized metric operator. All choices provide the required ultra-violet cut-offs but the precise damping depends on the specific form of f_R. The differences will show up, for example, in the evolution of test fields. It would be interesting to investigate these differences and see if one can restrict the choice of the smearing functions through thought experiments. If one can not, there would a genuine quantization ambiguity. The situation would be similar to that in non-relativistic quantum mechanics where, in general, the factor ordering ambiguities can not be resolved purely on theoretical grounds.

We saw that the regularized operators corresponding to the traces of holonomies of connections are well-defined on the quantum Hilbert space. Now, in the approach to quantum gravity based on these holonomies,[4] a striking picture of quantum geometry has emerged in which geometrical operators such as areas and volumes have a *discrete* spectrum. It is therefore natural to ask if the same is true in the present case. The question is now manageable, thanks to the regularized metric operators. Since the basic operator $:\hat{\gamma}:$ is the regularized version of the restriction of the Hamiltonian in a box, it is quite likely that its spectrum is discrete. If so, the lengths in the radial directions and areas will be quantized. This would be a striking result coming from a Fock-like representation.

Another direction for further investigation is provided by the Gowdy models. Since these are spatially compact and have initial curvature singularities, new issues arise. These will be discussed in the sequel to this paper. While both these problems deal only with the ''one polarization'' case—the two Killing fields are hyper-surface orthogonal in the $3+1$-dimensional picture—one can also investigate the two polarization case.[11] In the case when the translational Killing field is time-like, this case was analyzed in detail by Korotkin and Nicolai[20] recently. Their quantization is mathematically complete but somewhat unconventional in the sense that the relation between their Hamiltonian description and the standard Poisson-brackets of classical general relativity is unclear. It would be interesting to compare the results obtained here with the reduction of their model to the one polarization case. More recently, an infinite number of conserved quantities have been constructed in the classical theory with two polarizations.[21] Using these, one may be able to

extract the true degrees of freedom in this more general case and quantize the model along the lines of this paper.

Finally, the present model itself offers an attractive setting to explore the idea of ''fuzzing'' of space-time points using techniques involving null infinity.[22] As mentioned in section IV A, the $2+1$-dimensional space-times considered here are asymptotically flat at null infinity.[14] Furthermore, since the form of the metric is sufficiently simple, it should be possible to integrate the null geodesics and express the ''light cone cuts of null infinity'' explicitly in terms of the initial data for the scalar field at null infinity. These cuts label space-time points. The asymptotic quantization of the scalar field,[15] which is equivalent to the quantization presented here, would then lead to fuzzy points. So far, in this approach, detailed calculations have been carried out only in the linearized approximation.[22] The underlying simplicity of cylindrical waves provides an interesting arena where these results can be extended beyond the linear context.

(Received 4 April 1996; accepted for publication 22 May 1996)

We compute the loop variables for a class of space–times with topological defects. In particular we compute these quantities for multiple moving cosmic strings and two plane topological defects crossed by a cosmic string, showing that these quantities are elements of the homogeneous Lorentz group. We also compute the loop variables for a multi-chiral cone and we show that in the context of Einstein theory the loop variables are elements of the inhomogeneous Lorentz group, but in the context of Einstein-Cartan theory they are elements of the homogeneous Lorentz group. © *1996 American Institute of Physics.* [S0022-2488(96)00411-2]

I. INTRODUCTION

In the loop space formalism for gauge theories[1] the fields depend on paths rather than on space–time points, and a gauge field is described by associating with each path in space–time an element of the corresponding gauge group. The fundamental quantity that arises from this path-dependent approach, the non-integrable phase factor[2] (or loop variable) represents the electromagnetic field or a general gauge field more adequately than the field strength or the integral of the vector potential.[2] In the electromagnetic case, for example, as observed by Wu and Yang,[2] in a situation where global aspects are taken into consideration the field strength underdescribes the theory and the integral of the vector potential for every loop overdescribes it. The exact description is given by the factor $\exp((ie/\hbar c)\oint_c A_\mu dx^\mu)$.

The extension of the loop formalism to the theory of gravity was first considered by Mandelstam[3] who established several equations involving the loop variables, and also by Voronov and Makeenko.[4] Recently, Bollini *et al.*[5] computed the loop variables for the gravitational field corresponding to the Kerr metric.

The loop variables in the theory of gravity are matrices representing parallel transport along contours in a space–time with a given affine connection. They are connected with the holonomy transformations which contain important topological information. These mathematical objects contain information, for example, about how vectors change when parallel transported around a closed curve. The computation of these quantities is definitely interesting, although perhaps its main significance is for a fairly narrow area of physics.

Suppose that we have a vector v^α at a point P in a space–time and a closed curve C which begins and ends at P. Then, one can produce a vector $\overline{v^\alpha}$ at P which, in general, will be different from v^α, by parallel transporting v^α around C. In this case, we associate with the point P and the curve C a linear map U^α_β such that for any vector v^α at P, the vector $\overline{v^\alpha}$ at P results from parallel transporting v^α around C and is given by $\overline{v^\alpha}=U^\alpha_\beta v^\beta$. The linear map U^α_β is called holonomy transformation associated with the point P and the curve C. If we choose a tetrad frame and a

a)Electronic mail: cendifi58@brufpb.bitnet
b)Electronic mail: letelier@ime.unicamp.br

parameter $\lambda \in [0,1]$ for the curve C such that $C(0)=C(1)=P$, then in parallel transporting a vector v^{α} from $C(\lambda)$ to $C(\lambda+d\lambda)$, the vector components change by $\delta v^{\alpha}=M^{\alpha}_{\beta}[x(\lambda)]v^{\beta}$, where M^{α}_{β} is a linear map which depends on the tetrad, the affine connection of the space–time and the value of λ. Then, it follows that the holonomy transformation U^{α}_{β} is given by the ordered matrix product of the N linear maps,

$$U^{\alpha}_{\beta}=\lim_{N\to\infty}\prod_{i=1}^{N}\left\{\delta_{\alpha\beta}+\frac{1}{N}M^{\alpha}_{\beta}[x(\lambda)]_{\lambda=i/N}\right\}. \tag{1.1}$$

One often writes the expression in Eq. (1.1) as

$$U(C)=P\ \exp\left(\int_{C}M\right), \tag{1.2}$$

where P means ordered product along a curve C. Equation (1.2) should be understood as an abbreviation of the right hand side of Eq. (1.1). Note that if M^{α}_{β} is independent of λ, then it follows from Eq. (1.1) that U^{α}_{β} is given by $U^{\alpha}_{\beta}=(\exp M)^{\alpha}_{\beta}$.

In this paper we shall use the notation

$$U_{BA}(C)=P\ \exp\left(\int_{A}^{B}\Gamma_{\mu}(x(\lambda))\frac{dx^{\mu}}{d\lambda}d\lambda\right), \tag{1.3}$$

where Γ_{μ} is the tetradic connection and A,B are the initial and final points, respectively, of the path. Then, associated with every path C from a point A to point B, we have a loop variable given by Eq. (1.3) which is a function of the path C as a geometrical object.

The purpose of this paper is to compute loop variables and holonomy transformations for some conical space–times and show how these quantities depend on the parameters defining the topological defects. In particular, we compute the loop variables in a space–time with a topological defect corresponding to the multiple parallel chiral strings in the context of Einstein[6] and Einstein-Cartan theories,[7] and the multiple moving crossed cosmic strings.[8] Finally, we consider the topological defects corresponding to two domain walls crossed by a cosmic string[9] and two plane topological defects crossed by a cosmic string[9] also.

II. LOOP VARIABLES IN THE SPACE-TIME OF MULTIPLE MOVING CROSSED COSMIC STRINGS

Recently, Letelier and Gal'tsov[8] found an exact solution of the Einstein equations describing an arbitrary number of non-parallel straight infinitely long cosmic strings moving with different constant velocities. The metric corresponding to this configuration of strings is given by

$$ds^2=-e^{-4V}(dx+F_1dt+G_1dz)^2-e^{-4V}(dy+F_2dt+G_2dz)-dz^2+dt^2, \tag{2.1}$$

where $V=2\Sigma_{i=1}^{N}\mu_i\ln r_i$, with $r_i=|\zeta-\alpha_i|$ and $\zeta=x+iy$, $\alpha_j=v_{xj}t+m_{xj}z+x_{0j}+i(v_{yj}t+m_{yj}z+y_{0j})$. The functions $F_1(G_1)$ and $F_2(G_2)$ are the real and imaginary parts of two analytic functions on the variable ζ; also these functions depend on t and z through the combinations α_i. The explicit form of these functions will not play a major role in our analysis, and they can be found in Ref. 8.

Our interest in computing loop variables for this space–time is to show how we can construct the parallel transport operators using the tetrad formalism, a subject which is definitely interesting. To do this let us introduce a set of four vectors $e^{\mu}_{(a)}$ ($a=1,2,3,4$ is a tetradic index) which are orthonormal at each point with respect to the metric with Minkowski signature, that is,

$g_{\mu\nu}e^{\mu}_{(a)}e^{\nu}_{(b)}=\eta_{ab}=\mathrm{diag}(-1,-1,-1,+1)$. We assume that the $e^{\mu}_{(a)}$'s are matrix invertible, that is, that there exists an inverse frame $e^{(a)}_{\mu}$ given by $e^{(a)}_{\mu}e^{\nu}_{(a)}=\delta^{\nu}_{\mu}$ and $e^{(a)}_{\mu}e^{\mu}_{(b)}=\delta^{a}_{b}$.

Now define the 1-forms θ^a as

$$\theta^1=e^{-2V}(dx+F_1dt+G_1dz),$$

$$\theta^2=e^{-2V}(dy+F_2dt+G_2dz), \tag{2.2}$$

$$\theta^3=dz, \quad \theta^4=dt.$$

Then, in the coordinate system $(x^1=x,\ x^2=y,\ x^3=z,\ x^4=t)$, the tetrad frame defined by $\theta^a=e^{(a)}_{\mu}dx^{\mu}$ is given by

$$e^{(1)}_1=e^{-2V}, \quad e^{(1)}_3=e^{-2V}G_1, \quad e^{(1)}_4=e^{-2V}F_1, \quad e^{(2)}_2=e^{-2V},$$
$$e^{(2)}_3=e^{-2V}G_2, \quad e^{(2)}_4=e^{-2V}F_2, \quad e^{(3)}_3=1, \quad e^{(4)}_4=1. \tag{2.3}$$

Using Cartan's structure equations $d\theta^a+\omega^a_b\wedge\theta^b=0$, for arbitrary functions V, F_1, G_1, F_2 and G_2 we get the following expressions for the tetradic connection:

$$\Gamma^1_{\mu3}dx^{\mu}=-e^{-2V}\chi_1dx-\tfrac{1}{2}e^{-2V}(\chi_2+2F_1\chi_1)dt-e^{-2V}G_1\chi_1dz=-\Gamma^3_{\mu1}dx^{\mu},$$

$$\Gamma^2_{\mu1}dx^{\mu}=-2\frac{\partial V}{\partial y}dx-2\frac{\partial V}{\partial x}dy+\frac{1}{2}\left(\xi_1+4F_2\frac{\partial V}{\partial x}-4F_1\frac{\partial V}{\partial y}\right)dt+\left(2G_2\frac{\partial V}{\partial x}-2G_1\frac{\partial V}{\partial y}+\xi_2\right)dz$$
$$=-\Gamma^1_{\mu2}dx^{\mu},$$

$$\Gamma^2_{\mu3}dx^{\mu}=e^{-2V}\chi_1dy+e^{-2V}G_2\chi_1)dz=-\Gamma^3_{\mu2}dx^{\mu}, \tag{2.4}$$

$$\Gamma^3_{\mu4}dx^{\mu}=\frac{1}{2}e^{-4V}\eta_1(dy+F_2dt+G_2dz)+\frac{1}{2}e^{-4V}\chi_2(dx+F_1dt+G_1dz)=\Gamma^4_{\mu3}dx^{\mu},$$

$$\Gamma^4_{\mu1}dx^{\mu}=e^{-2V}\chi_4dx+e^{-2V}F_1\chi_3dt+\frac{1}{2}e^{-2V}(\chi_2+2G_2\chi_3)dz=\Gamma^1_{\mu4}dx^{\mu},$$

$$\Gamma^4_{\mu2}dx^{\mu}=e^{-2V}F_2\eta_2dt+e^{-2V}\eta_2dy+\frac{1}{2}e^{-2V}(2G_2\eta_2+\eta_1)dz=\Gamma^2_{\mu4}dx^{\mu},$$

where

$$
\begin{aligned}
\eta_1 &= -\frac{\partial G_2}{\partial t}+\frac{\partial G_2}{\partial x}F_1+\frac{\partial G_2}{\partial y}F_2-\frac{\partial F_2}{\partial x}G_1-\frac{\partial F_2}{\partial y}G_2+\frac{\partial F_2}{\partial z},\\
\eta_2 &= 2\frac{\partial V}{\partial t}-2\frac{\partial V}{\partial x}F_1-2\frac{\partial V}{\partial y}F_2+\frac{\partial F_2}{\partial y},\\
\chi_1 &= 2\frac{\partial V}{\partial x}G_1+2\frac{\partial V}{\partial y}G_2-2\frac{\partial V}{\partial z}-\frac{\partial G_1}{\partial x},\\
\chi_2 &= -\frac{\partial G_1}{\partial t}+\frac{\partial G_1}{\partial x}F_1+\frac{\partial G_1}{\partial y}F_2-\frac{\partial F_1}{\partial x}G_1-\frac{\partial F_1}{\partial y}G_2+\frac{\partial F_1}{\partial z},\\
\chi_3 &= 2\frac{\partial V}{\partial t}-2\frac{\partial V}{\partial x}F_1-2\frac{\partial V}{\partial y}F_2+\frac{\partial F_1}{\partial x},\\
\xi_1 &= \frac{\partial F_1}{\partial y}+\frac{\partial F_2}{\partial x},\quad \xi_2=\frac{\partial G_1}{\partial y}-\frac{\partial F_2}{\partial x}.
\end{aligned}
\tag{2.5}
$$

In obtaining Eq. (2.5), we have used the property of analycity of the function $F(x+iy)=F_1+iF_2$ and similarly of $G=G_1+iG_2$.

Using the tetradic connections given by Eq. (2.4) we can compute the loop variables. In our case we are interested in computing the loop variables for segments in the t, x, y and z directions. For a translation in time $\Gamma_\mu dx^\mu=\Gamma_t dt$ with Γ_t being

$$
\Gamma_t=\begin{pmatrix} 0 & B & C & A\\ B & 0 & -F & -D\\ C & F & 0 & E\\ A & D & -E & 0 \end{pmatrix}=-iFJ_{12}-iDJ_{13}-iEJ_{23}-iBJ_{41}-iCJ_{42}-iAJ_{43}, \tag{2.6}
$$

where the boost parameters A, B, C are given by

$$
A=\tfrac{1}{2}e^{-4V}(\eta_1F_2+\chi_2F_1),\quad B=e^{-2V}\chi_3F_1,\quad C=e^{-2V}\eta_2F_2, \tag{2.7}
$$

and the rotation parameters D, E, F are

$$
\begin{aligned}
D &= -\frac{1}{2}e^{-2V}(\chi_2+2F_1\chi_1),\quad E=e^{-2V}\chi_1F_2,\\
F &= -\frac{1}{2}\left(\xi_1+4F_2\frac{\partial V}{\partial x}-4F_1\frac{\partial V}{\partial y}\right).
\end{aligned}
\tag{2.8}
$$

In Eq. (2.6), J_{23}, J_{13} and J_{12} are, respectively, generators of rotations about the x, y and z axis in the three-dimensional space, and J_{41}, J_{42} and J_{43} are, respectively, the generators of boosts in the Ox, Oy and Oz directions.

Then, for a segment in the time direction, the loop variable is a combination of boosts in all directions and rotations around the three axis in space.

Using Eq. (2.6) we get, for a time translation between t_1 and t_2, the following expression for the loop variable:

$$
U_{t_2t_1}(C)=\exp\left[\int_{t_1}^{t_2}(-iFJ_{12}-iDJ_{13}-iEJ_{23}-iBJ_{41}-iCJ_{42}-iAJ_{43})dt\right]. \tag{2.9}
$$

Now, let us consider a segment in the z-direction. In this case we have $\Gamma_{\mu 3}dx^{\mu}=\Gamma_z dz$, where

$$\Gamma_z=\begin{pmatrix} 0 & B' & C' & A' \\ B' & 0 & -F' & -D' \\ C' & F' & 0 & E' \\ A' & D' & -E' & 0 \end{pmatrix}=-iF'J_{12}-iD'J_{13}-iE'J_{23}-iB'J_{41}-iC'J_{42}-iA'J_{43}, \tag{2.10}$$

where

$$A'=\tfrac{1}{2}e^{-4V}(\eta_1 G_2+\chi_2 G_1),\quad B'=\tfrac{1}{2}e^{-2V}(\chi_2+2\chi_3 G_1),$$
$$C'=\tfrac{1}{2}e^{-2V}(2\chi_3 G_2+\eta_1),\quad D'=-e^{-2V}\chi_1 G_1, \tag{2.11}$$
$$E'=e^{-2V}\chi_1 G_2,\quad F'=-2\left(G_2\frac{\partial V}{\partial x}-G_1\frac{\partial V}{\partial y}\right).$$

As in the previous case, the loop variable along the z-direction is a combination of boosts and rotations. For a segment that goes from z_1 to z_2, the loop variable is given by

$$U_{z_2 z_1}(C)=\exp\left[\int_{z_1}^{z_2}(-iF'J_{12}-iD'J_{13}-iE'J_{23}-iB'J_{41}-iC'J_{42}-iA'J_{43})dz\right]. \tag{2.12}$$

Similarly, if we consider segments in the x- and y-directions, at fixed t and z, we get that

$$U_{x_2 x_1}(C)=\exp\left[\int_{x_1}^{x_2}\left(-2i\frac{\partial V}{\partial y}J_{12}-i\overline{D}J_{13}-i\overline{A}J_{43}-i\overline{B}J_{41}\right)dx\right] \tag{2.13}$$

and

$$U_{y_2 y_1}(C)=\exp\left[\int_{y_1}^{y_2}\left(-2i\frac{\partial V}{\partial x}J_{12}-i\overline{E}J_{23}-i\overline{A'}J_{43}-i\overline{C}J_{42}\right)dy\right], \tag{2.14}$$

where

$$\overline{A}=\tfrac{1}{2}e^{-4V}\chi_2,\quad \overline{B}=e^{-2V}\chi_3,\quad \overline{C}=e^{-2V}\eta_2,$$
$$\overline{A'}=\tfrac{1}{2}e^{-4V}\eta_1,\quad \overline{D}=e^{-2V}\chi_1,\quad \overline{E}=\tfrac{1}{2}e^{-4V}\chi_1. \tag{2.15}$$

Using previous results, we can write a general expression for $U(C)$. In the general case, $U(C)$ reads as

$$U(C)=P\ \exp\left(-\frac{i}{2}\int_C \Gamma_{\mu}^{ab}J_{ab}dx^{\mu}\right), \tag{2.16}$$

where J_{ab} are the generators of the Lorentz group $SO(3,1)$ and Γ_{μ}^{ab} are the appropriate tetradic connections. In general, J_{ab} generate the representation of the Lorentz group which acts on the transported quantity (a vector or a spinor). In the spinor case, instead of the group $SO(3,1)$, we have a covering group of this one. Therefore, when we have fermions, the loop variables are elements of the covering group of the Lorentz group.

III. LOOP VARIABLES IN A MULTIPLE CHIRAL CONICAL SPACE–TIME

In a recent paper Gal'tsov and Letelier[6] showed that the chiral conical space–time arises naturally from the spinning particle solution of (2+1)-dimensional gravity by an appropriate boost. This chiral conical space–time provides the gravitational counterpart for the infinitely thin straight chiral strings in the same way that an ordinary conical space–time is associated with the usual string.[10] The metric associated to the chiral conical space–time[6] (spinning string with cosmic dislocation) is given by

$$ds^2=-\overline{r^{8\mu}}(dr^2+r^2d\varphi^2)-(dz+4J^zd\varphi)^2+(dt+4J^td\varphi)^2, \tag{3.1}$$

where J^t represents the string angular momentum, $2J^z/\pi$ is the analogous of the Burgers-vector of dislocation and μ is the linear mass density of the string. The angle φ takes the values $0\leqslant\varphi\leqslant 2\pi$, and the other variables: $-\infty<t<\infty$, $0<r<\infty$, and $-\infty<z<\infty$. If we consider a Cartesian system of coordinates $x=r\cos\varphi$, $y=r\sin\varphi$, we can write Eq. (3.1) as

$$ds^2=-e^{-4V}(dx^2+dy^2)-\left(dz+4J^z\,\frac{xdy-ydx}{r^2}\right)^2+\left(dt-4J^t\,\frac{xdy-ydx}{r^2}\right)^2, \tag{3.2}$$

with $V=2\mu\ln r$.

The generalization of the chiral cone to a multiple chiral cone can[6] be obtained by introducing the parameters μ_i, J_i^t, J_i^z, $i=1,2,\ldots,N$, defining each chiral string located at the points $\vec{r}=\vec{r}_i$ of the plane $z=0$. The resulting metric has the form of Eq. (3.2) with the following interchanges:

$$\begin{aligned}
&J^t\,\frac{xdy-ydx}{r^2}\to\sum_{i=1}^{N}J_i^t\,\frac{(x-x_i)dy-(y-y_i)dx}{|\vec{r}-\vec{r}_i|^2},\\
&J^z\,\frac{xdy-ydx}{r^2}\to\sum_{i=1}^{N}J_i^z\,\frac{(x-x_i)dy-(y-y_i)dx}{|\vec{r}-\vec{r}_i|^2},\\
&V=2\mu\,\ln r\to V=\sum_{i=1}^{N}\mu_i\,\ln[r^2-2rr_i\cos(\varphi-\varphi_i)+r_i^2].
\end{aligned} \tag{3.3}$$

As a consequence of Eq. (3.3), the space–time generated by N multiple chiral cosmic string can be written as[6]

$$ds^2=-e^{-4V}(dx^2+dy^2)-\left[dz-\sum_{i=1}^{N}B_i(W_i^1dy-W_i^2dx)\right]^2+\left[dt-\sum_{i=1}^{N}A_i(W_i^1dy-W_i^2dx)\right]^2, \tag{3.4}$$

where

$$A_i=4J_i^t,\quad B_i=4J_i^z,\quad W_i^1=\frac{x-x_i}{|\vec{r}-\vec{r}_i|^2},\quad W_i^2=\frac{y-y_i}{|\vec{r}-\vec{r}_i|^2}. \tag{3.5}$$

In the previous case, static one, the loop variable was calculated directly from the metric. For the present case, stationary one, it is possible to do the same, but with a slight redefinition of the loop variables. This can be done because this solution of the Einstein equation can be patched together from flat coordinates patches but connected by some additional matching condition in order to take into account the time helical structure and the shift in the z-direction. First of all let us recover a previous result concerning the holonomy in the static case,[11] specifically in the space of a multiple cosmic string.[12] In this case one calculates the holonomy transformation correspond-

ing to circles in the xy-plane directly from the metric. Then, when we parallel transport a vector around multiple cosmic strings at rest at $\vec{r}=\vec{r}_i$ along a circle, this vector acquires a phase given by[11] $U(C)=\exp[-8\pi i(\Sigma_{j=1}^{N}\mu_j)J_{12}]$, where J_{12} is the generator of rotations in the xy-plane, around the z-axis. Therefore, when we go around the multiple cosmic string from the point $(\vec{x},t)$ to $(\vec{x}',t')$, the column vectors $(\vec{x},t)$ and $(\vec{x}',t')$ are related by

$$\begin{pmatrix} x' \\ y' \\ z' \\ t' \end{pmatrix} = \begin{pmatrix} \cos(8\pi\tilde{\mu}) & \sin(8\pi\tilde{\mu}) & 0 & 0 \\ -\sin(8\pi\tilde{\mu}) & \cos(8\pi\tilde{\mu}) & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \\ t \end{pmatrix}, \tag{3.6}$$

where we have set

$$\tilde{\mu}=\sum_{j=1}^{N}\mu_j . \tag{3.7}$$

Since the space-time outside the multiple cosmic string is locally flat, we can describe the analytic solution purely in terms of space–time patches with Minkowski metric, but connected by some matching conditions which are given by Eq. (3.6), that relates points $(\vec{x},t)$ and $(\vec{x}',t')$ along the edges.

As in the multiple cosmic string case, the space-time of the multiple chiral cosmic string is locally flat, and consequently we can describe it in terms of space–time patches with Minkowski metric, but connected by some conditions which are the same as in the static multiple string case, except those concerning the t and z coordinates. These conditions are expressed by relating points $(\vec{x},t)$ and $(\vec{x}',t')$ as follows:

$$x'=\cos(8\pi\tilde{\mu})x+\sin(8\pi\tilde{\mu})y, \quad y'=-\sin(8\pi\tilde{\mu})x+\cos(8\pi\tilde{\mu})y, \tag{3.8}$$

$$z'=z+8\pi\left(\frac{r}{|\vec{r}-\vec{r}_i|^2}\right)^2 J_i^z, \quad t'=t+8\pi\left(\frac{r}{|\vec{r}-\vec{r}_i|^2}\right)^2 J_i^t,$$

where we are considering as paths circles in the xy-plane.

The transformations given by Eq. (3.8) can be cast in the form of a homogeneous matrix multiplication as follows: let M_A^B be a five dimensional matrix, with A and B running from 1 to 5. We take M_ν^μ equal to the rotation matrix given by,[11] $U(C)=\exp(-8\pi i\tilde{\mu}J_{12})$, $M_5^4=8\pi(r/|\vec{r}-\vec{r}_i|^2)^2 J_i^t$ and $M_5^5=8\pi(r/|\vec{r}-\vec{r}_i|^2)^2 J_i^z$, so that

$$\begin{pmatrix} x' \\ y' \\ z' \\ t' \\ 1 \end{pmatrix} = \begin{pmatrix} \cos(8\pi\tilde{\mu}) & \sin(8\pi\tilde{\mu}) & 0 & 0 & 0 \\ -\sin(8\pi\tilde{\mu}) & \cos(8\pi\tilde{\mu}) & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 8\pi\left(\frac{r}{|\vec{r}-\vec{r}_i|^2}\right)^2 J_i^z \\ 0 & 0 & 0 & 1 & 8\pi\left(\frac{r}{|\vec{r}-\vec{r}_i|^2}\right)^2 J_i^z \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \\ t \\ 1 \end{pmatrix}$$

$$= \exp\left[-8\pi\left(\frac{r}{|\vec{r}-\vec{r}_k|^2}\right)^2 J_k^z M_3\right] \exp\left[-8\pi\left(\frac{r}{|\vec{r}-\vec{r}_k|^2}\right)^2 J_k^t M_4\right] \exp(-8\pi\tilde{\mu} J_{12}) \begin{pmatrix} x \\ y \\ z \\ t \\ 1 \end{pmatrix}, \tag{3.9}$$

where M_3 and M_4 are the following matrices:

$$M_3 = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & i \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \quad M_4 = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & i \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}. \tag{3.10}$$

Equation (3.9) is the exact expression for the holonomy for circles in the space-time. By defining $y^A=(y^\mu,1)$ we can cast the conditions (3.8) as $y'^A = M^A_B y^B$ which tells us that the points $(\vec{x},t)$ and $(\vec{x}',t')$ along the edges are related by the phase given by Eq. (3.9) that depends on the parameters μ_j, J_j^t and J_j^z.

The existence of locally flat coordinates in this space-time permits us to consider Eq. (3.9) as a ''parallel transport'' matrix. Then we can say that when we carry a vector along a circle in this space-time it acquires a phase that depends on μ_j, J_j^t and J_j^z which prevents it from being equal to the unit matrix. This effect is exclusively due to the non-trivial topology of the space-time under consideration. This is a gravitational analogue[11,13] of the Aharanov-Bohm effect,[14] but in this case, purely at the classical level.

We can also compute the holonomy transformations for circles in the multiple chiral conical space-time in the context of the Einstein-Cartan theory. In this case the connection 1-forms appropriately chosen give us[7]

$$\Gamma^1_{\mu 2} dx^\mu = 2(\partial_x V dy - \partial_y V dx) = -\Gamma^2_{\mu 1} dx^\mu, \tag{3.11}$$

which can be written in cylindrical coordinates $(x^1=r,\ x^2=\varphi,\ x^3=z,\ x^4=t)$ as

$$\Gamma^1_{\mu 2} dx^\mu = -\frac{2}{r}\frac{\partial V}{\partial \varphi} dr - \left(1 - 2r\frac{\partial V}{\partial r}\right) d\varphi = -\Gamma^2_{\mu 1} dx^\mu. \tag{3.12}$$

Now, consider the same previous circle, at constant time. In this case $U_{2\pi,0}(C)$ is given by

$$U_{2\pi,0}(C) = \exp\left(\int_0^{2\pi} \Gamma_\varphi d\varphi\right) = \exp\left[-8\pi i\left(\sum_{j=1}^{N} \mu_j\right) J_{12}\right], \tag{3.13}$$

where

$$\Gamma_{\varphi}=i\left[1-4\sum_{j=1}^{N}\mu_j\frac{R(R-r_i\cos(\varphi-\varphi_i))}{(R^2-2Rr_i\cos(\varphi-\varphi_i)+r_i^2)}\right]J_{12}, \tag{3.14}$$

R being the radius of the circle. Into Eq. (3.12) we have dropped out the factor $\exp(-2\pi i J_{12})$ which is equal to the 4×4 identity matrix. Note that in this case the holonomy transformation has a simple expression and it belongs to the homogeneous Lorentz group. In this context it does not carry information concerning angular momentum and torsion and coincides with a previous result[11] concerning the multiple cosmic string solution.[12] Then, the concept of holonomy can be used to detect different connections that come out from Einstein and Einstein-Cartan theories. The holonomy for a single chiral string has been studied recently in Ref. 15.

From Eq. (3.13), we conclude that the phase factor acquired by a vector when parallel transported in the space-time corresponding to a multiple chiral cosmic string is affected by chiral strings inside the curves along which the vector is parallel transported. Then, from the global point of view the space-time surrounding n strings ($n\leqslant N$) can be seen to correspond to a chiral cone with deficiency angle $\Sigma_{j=1}^{n}\mu_j$. The chiral strings with $n\geqslant N$ do not contribute to the phase.

It is interesting to call attention to the fact that in the context of Einstein theory, the resulting holonomy transformation is an element of the inhomogeneous Lorentz group. The appearance of the group ISO(3,1) as a holonomy group is fascinating and can suggest important parallel with the better understood $(2+1)$ dimensional case, in which gravity is equivalent to an $ISO(2,1)$ Chern-Simons gauge theory,[16] in which case the triad $e_{(a)}^{\mu}$ is a gauge field. As far as we know there is no corresponding result in $(3+1)$ dimensional gravity, in general. Our result, evidently, is valid for the special case under consideration.

IV. LOOP VARIABLES IN OTHER CONICAL SPACE–TIMES

The purpose of this section is to complete a previous work[17] in which we computed the loop variables for some curves in space–times with a topological defect. We considered a single domain wall crossed by multiple cosmic strings. Other simple examples of conical space–times include two domain walls crossed by a cosmic string of linear mass density μ and two planes topological defects plus a cosmic string. A variety of conical space–time of different topologies can be found in Ref. 9.

Now let us consider two domain walls parallels to the xy-plane that intersect the z-axis at $\pm h$ and crossed by a single cosmic string. The metric corresponding to the space-time generated by this configuration is

$$ds^2=e^{-4\pi\sigma|h^2-z^2|}[-e^{4\pi\sigma t}\rho^{-4\mu}(d\rho^2+\rho^2d\varphi^2)-4z^2dz^2+dt^2], \tag{4.1}$$

where σ is the matter density of the wall and μ is the linear mass density of the cosmic string.

Proceeding in the same way of the previous cases let us define the appropriate 1-forms θ^a that give the usual flat space–time limit $\sigma=0$, $\mu=0$ as

$$\begin{aligned}\theta^1&=e^{-2\pi\sigma|h^2-z^2|+2\pi\sigma t}(\rho^{-2\mu}\cos\varphi d\rho-\rho^{-2\mu+1}\sin\varphi d\varphi),\\ \theta^2&=e^{-2\pi\sigma|h^2-z^2|+2\pi\sigma t}(\rho^{-2\mu}\sin\varphi d\rho+\rho^{-2\mu+1}\cos\varphi d\varphi),\\ \theta^3&=2ze^{-2\pi\sigma|h^2-z^2|}dz,\quad \theta^4=e^{-2\pi\sigma|h^2-z^2|}dt.\end{aligned} \tag{4.2}$$

In a coordinate system $(x^1=\rho,\ x^2=\varphi,\ x^3=z,\ x^4=t)$, the tetrad vectors are given by

$$e_1^{(1)}=\rho^{-2\mu}e^{-2\pi\sigma|h^2-z^2|+2\pi\sigma t}\cos\varphi,\quad e_2^{(1)}=-\rho^{-2\mu+1}e^{-2\pi\sigma|h^2-z^2|+2\pi\sigma t}\sin\varphi,$$

$$e_1^{(2)}=\rho^{-2\mu}e^{-2\pi\sigma|h^2-z^2|+2\pi\sigma t}\sin\varphi,\quad e_2^{(2)}=\rho^{-2\mu+1}e^{-2\pi\sigma|h^2-z^2|+2\pi\sigma t}\cos\varphi, \tag{4.3}$$

$$e_3^{(3)}=2ze^{-2\pi\sigma|h^2-z^2|},\quad e_4^{(4)}=e^{-2\pi\sigma|h^2-z^2|}.$$

Using these results we can compute the tetradic connections which are

$$\Gamma^1_{\mu 2}dx^\mu=(1-4\mu)d\varphi=-\Gamma^2_{\mu 1}dx^\mu,$$

$$\Gamma^1_{\mu 3}dx^\mu=2\pi\sigma\,\frac{|h^2-z^2|}{h^2-z^2}\,e^{2\pi\sigma t}\rho^{-4\mu}d\varphi=-\Gamma^3_{\mu 1}dx^\mu,$$

$$\Gamma^2_{\mu 3}dx^\mu=2\pi\sigma\,\frac{|h^2-z^2|}{h^2-z^2}\,e^{2\pi\sigma t}\rho^{-4\mu+1}d\varphi=-\Gamma^3_{\mu 2}dx^\mu,$$

$$\Gamma^4_{\mu 1}dx^\mu=2\pi\sigma e^{2\pi\sigma t}\rho^{-4\mu}d\varphi=\Gamma^1_{\mu 4}dx^\mu, \tag{4.4}$$

$$\Gamma^4_{\mu 2}dx^\mu=2\pi\sigma e^{2\pi\sigma t}\rho^{-4\mu+1}d\varphi=\Gamma^2_{\mu 4}dx^\mu,$$

$$\Gamma^4_{\mu 3}dx^\mu=2\pi\sigma\,\frac{|h^2-z^2|}{h^2-z^2}\,dt=\Gamma^3_{\mu 4}dx^\mu.$$

Let us consider the path C as a circle centered on the z axis with radius R lying on a plane parallel to the xy-plane at a fixed time. In this case we have that $\Gamma_\mu dx^\mu=\Gamma_\varphi d\varphi$ where

$$\Gamma_\mu=i(1-4\mu)J_{12}-2\pi i\sigma e^{2\pi\sigma t}\rho^{-4\mu+1}\left(J_{24}+\frac{|h^2-z^2|}{h^2-z^2}\,J_{23}\right). \tag{4.5}$$

From Eq. (4.5) we get

$$U_{2\pi,0}(C)=\exp\left[-8\pi i\mu J_{12}-4\pi^2 i\sigma e^{2\pi\sigma t}\rho^{-4\mu+1}\left(J_{24}+\frac{|h^2-z^2|}{h^2-z^2}\,J_{23}\right)\right]. \tag{4.6}$$

Equation (4.6) is the exact expression for the holonomy transformation for a circle with center at the cosmic string and that is parallel to the domain walls.

The holonomy transformation associated to the circle C that corresponds to the domain walls only ($\mu=0$) and to the cosmic string only ($\sigma=0$) are given, respectively, by

$$U_{2\pi,0}(C)=\exp\left[-4\pi^2 i\sigma e^{2\pi\sigma t}\rho\left(J_{24}-\frac{|h^2-z^2|}{h^2-z^2}\,J_{23}\right)\right] \tag{4.7}$$

and

$$U_{2\pi,0}(C)=\exp(-8\pi i\mu J_{12}). \tag{4.8}$$

From these results we see that the holonomy transformations detect the topological defects in all cases. In particular, for the domain walls plus a cosmic string, the value of $U_{2\pi,0}(C)$ depends on the radius of the circle. Note that $U_{2\pi,0}(C)$ distinguishes the regions $z<-h$, $-h<z<h$ and $z>h$ in the cases of two domain walls crossed by a cosmic string and two domain walls only.

In the case of two planes topological defects crossed by a cosmic string with an equation of state $p=-\gamma\sigma(\gamma<1)$, the metric is given by

$$ds^2=-\rho^{-8\mu}e^H(d\rho^2+\rho^2d\varphi^2)+e^F(-4z^2dz^2+dt^2), \tag{4.9}$$

where

$$\begin{aligned} e^H&=(t-|h^2-z^2|)^{1/2(1-\gamma)},\\ e^F&=\frac{1}{8\pi\sigma(1-\gamma)}\,\frac{1}{t-|h^2-z^2|}\left[\frac{t-|h^2-z^2|}{t+|h^2-z^2|}\right]^{1/4(\gamma-1)}. \end{aligned} \tag{4.10}$$

The holonomy transformation for the same circle C described above is given by

$$U_{2\pi,0}(C)=\exp\left[-8\pi i\mu J_{12}-\frac{\pi i e^{(H-F)/2}}{4(1-\gamma)(t-|h^2-z^2|)}\,\rho^{-4\mu+1}\left(J_{24}-\frac{|h^2-z^2|}{h^2-z^2}\,J_{23}\right)\right]. \tag{4.11}$$

To get Eq. (4.11), we have used the following relations between the tetradic connections:

$$\begin{aligned} &\Gamma^1_{\mu2}dx^\mu=(1-4\mu)dy=-\Gamma^2_{\mu1}dx^\mu,\\ &\Gamma^1_{\mu3}dx^\mu=\frac{e^{-F/2}}{2z}\,\frac{\partial}{\partial z}\,(e^{H/2})\rho^{-4\mu}d\rho=-\Gamma^3_{\mu1}dx^\mu,\\ &\Gamma^2_{\mu3}dx^\mu=\frac{e^{-F/2}}{2z}\,\frac{\partial}{\partial z}\,(e^{H/2})\rho^{-4\mu+1}d\varphi=-\Gamma^3_{\mu2}dx^\mu,\\ &\Gamma^4_{\mu1}dx^\mu=e^{-F/2}\,\frac{\partial}{\partial t}\,(e^{H/2})\rho^{-4\mu}d\rho=\Gamma^1_{\mu4}dx^\mu,\\ &\Gamma^4_{\mu2}dx^\mu=e^{-F/2}\,\frac{\partial}{\partial t}\,(e^{H/2})\rho^{-4\mu+1}d\varphi=\Gamma^2_{\mu4}dx^\mu,\\ &\Gamma^4_{\mu3}dx^\mu=\frac{e^{-F/2}}{2z}\,\frac{\partial}{\partial z}\,(e^{F/2})dt+2ze^{-F/2}\,\frac{\partial}{\partial t}\,(e^{F/2})dz=\Gamma^3_{\mu4}dx^\mu. \end{aligned} \tag{4.12}$$

As in the previous case corresponding to two domain walls plus a string, the presence of the topological defect is coded in the holonomy transformation, which distinguishes the different regions $z<-h$, $-h<z<h$ and $z>h$. Also in this case, the holonomy transformation is an element of the Lorentz group.

V. CONCLUDING REMARKS

We have shown by explicit computation from the metric corresponding to a multiple parallel chiral cosmic string that the loop variables are combinations of rotations around the three axis and boosts with appropriate parameters that depend on the characteristics of each chiral string defined by μ_i, J^t_i and J^z_i. The holonomy transformation, in this space–time, are elements of the inhomogeneous Lorentz group. It assumes a simple form in the context of the Einstein-Cartan theory which recover an expression for the case of multiple cosmic strings. The loop variables associated with the multiple moving crossed cosmic strings are also combinations of rotations and boosts in the directions of the three spatial axis. They are elements of the homogeneous Lorentz group.

In the two domain walls and two planes topological defects plus the cosmic string, the holonomy transformation distinguishes the presence of strings and membranes and depends on whether the loop encircles the strings and in which side of the planes topological defects are located. Again, they are elements of $SO(3,1)$.

Our approach provides a unified way to obtain the phase factor acquired by a vector or a spinor when parallel transported in these gravitational fields, showing up the dependence of the phase factors with the parameters associated with the defects.

Asymptotic behavior of a class of inhomogeneous scalar field cosmologies

J. Ibáñez and I. Olasagasti

(Received 9 February 1996; accepted for publication 12 June 1996)

The asymptotic behavior of a class of inhomogeneous scalar field cosmologies with a Liouville type of potential is studied. We define a set of new variables for which the phase space of the system of Einstein equations is bounded. This allows us to perform a complete analysis of the evolution of these cosmologies. We also discuss the extension of the cosmic no-hair theorem. © *1996 American Institute of Physics.* [S0022-2488(96)03311-7]

I. INTRODUCTION

Since the proposal by Misner[1] of the ''chaotic cosmology program,'' the idea that the Universe emerged from a highly irregular state and that the inhomogeneities and the anisotropies were washed away giving place to a highly symmetric universe, has been one of the most attractive ideas in cosmology. In spite of the theorem proved by Collins and Hawking[2] which states that only a subclass of measure zero of the space of homogeneous solutions approach isotropy and the alternative approaches that postulated, according to the second law of thermodynamics,[3] that the universe began in a highly regular state, Misner's idea has come back due to the success of the inflationary scenarios.

The cosmic ''no-hair'' theorems of Wald[4] for homogeneous models and of Jensen and Stein-Schabes[5] for inhomogeneous space–times pointed out how the introduction of a cosmological constant, which can be considered as induced by a scalar field (inflaton), allows the models to isotropize approaching the de Sitter solution. This situation, however, may dramatically change if one takes into account the dynamical behavior of the scalar field. Heusler,[6] for example, extending the theorem of Collins and Hawking to the case of convex and positive potentials of the scalar field possessing a local minimum, has shown that only the homogeneous Bianchi models which admit a FRW solution as a particular case approach isotropy. Kitada and Maeda[7] and Ibáñez *et al.*[8] have shown that when one assumes a Liouville type of potential for the scalar field (exponential potential), the Wald theorem for homogeneous solutions still applies if the exponential potential is quite flat.

Although Jensen and Stein-Schabes[5] extended the Wald theorem to inhomogeneous solutions, little is known about the effect of the dynamics of the scalar field on the asymptotic behavior of the models. The first attempts to incorporate the effect of the dynamical evolution of the scalar field was made by Goldwirth and Piran[9] using numerical studies of inhomogeneous models and, later on, by Calzetta and Sakellariadou[10] by studying the evolution of a family of inhomogeneous Cauchy data. The first inhomogeneous scalar field exact solutions with exponential potential of the Einstein field equations were obtained by Feinstein and Ibáñez[11] and it was shown there that the scalar field does not guarantee by itself that the model inflates or isotropizes. Although there are some exact inhomogeneous solutions obtained up to now, we are lacking a result similar to Heusler's. In particular, for the exponential potential, it would be interesting to study the conditions on the scalar field leading to inflation and isotropization.

The asymptotic behavior of homogeneous but anisotropic solutions for a perfect fluid has been widely studied. By using the kinematical quantities of the fluid as variables, the field equations can be written as an autonomous system of ordinary differential equations.[12] One of the most distinctive features is that the equilibrium points of these systems are self-similar solutions. This analysis

has recently been extended to the case when the matter source is a scalar field with exponential potential.[13] Since the scalar field is homogeneous, one can globally associate with it a perfect fluid, and then, by using the kinematical variables of the fluid, the Einstein field equations decouple and the phase space of the system becomes bounded.

The main difficulty in analyzing the asymptotic behavior of inhomogeneous solutions is related to the fact that the field equations involve partial derivatives. The study of such systems was initiated in Ref. 14, where a particular family of self-similar solutions with perfect fluid, for which the Einstein equations reduced to an autonomous system, was studied. Since the source of the metric was a perfect fluid, the kinematical quantities could be used again to analyze the asymptotic behavior of the system, as in the homogeneous case.

In dealing with an inhomogeneous scalar field one can not apply the analysis developed in Ref. 14 due to the fact that one can not globally interpret the scalar field as a perfect fluid. Therefore in order to investigate whether the inhomogeneous scalar field cosmologies undergo an inflationary epoch leading to the homogenization and the isotropization of the space–time, one does have to look for a different way to tackle this problem.

In this paper we initiate the study of the asymptotic behavior of the scalar field cosmologies by considering, as a first step, a two-parameter family of G_2 self-similar solutions. The fact that the scalar field is not equivalent to a perfect fluid prevents the use of the kinematical quantities to describe the evolution of the solutions. Despite the lack of a preferred timelike congruence in the space–time, we manage to find a set of new variables in terms of which the phase space of the system becomes bounded. This allows us to perform a complete analysis of the asymptotic behavior of these space–times. In addition, the way to introduce the set of new variables is a promising method for dealing with more general solutions.

The plan of the paper is as follows: in Sec. II we present the metric and introduce the new variables. Section III is devoted to the analysis of the phase space and in Sec. IV we discuss the results.

II. THE METRIC AND THE COMPACTIFIED PHASE SPACE

We will consider solutions with one-dimensional inhomogeneity. These metrics are described by the generalized Einstein–Rosen space–times which admit an Abelian group of isometries G_2. If the two Killing vectors are hypersurface orthogonal, the line element can be written as

$$ds^2 = e^F(-dt^2+dz^2)+G(e^h dx^2+e^{-h}dy^2), \tag{1}$$

where the metric functions depend on t and z and the Killing vectors are ∂_x and ∂_y.

The matter source for the metric is that of a minimally coupled scalar field with potential, for which the stress-energy tensor is given by

$$T_{ab} = \overline{\phi}_{,a}\overline{\phi}_{,b} - g_{ab}\left(\tfrac{1}{2}\,\overline{\phi}_{,c}\overline{\phi}^{,c} + V(\overline{\phi})\right) \tag{2}$$

(Latin indices run from 0–3), with the Liouville type of the potential

$$V(\overline{\phi}) = \Lambda e^{k\overline{\phi}}, \quad \Lambda \geqslant 0. \tag{3}$$

It is well known[15] that as long as the gradient of the scalar field remains timelike, (2) can be rewritten as a perfect fluid stress-energy tensor.

To simplify the equations we will concentrate in this paper on the class of solutions for which the element of transitivity surface G is homogeneous,

$$G = G(t), \tag{4}$$

which is suitable for a description of cosmological models.

It was shown in Ref. 16 that if one assumes separability of the metric and separability, in the additive sense, of the scalar field one obtains, from the field equations, that the dependence of these functions on the variable z is linear;

$$h(t,z)=p(t)+az, \quad F(t,z)=f(t)+cz, \quad \overline{\phi}(t,z)=\phi(t)+bz, \tag{5}$$

where a, b, and c are arbitrary constants which drive the inhomogeneity. This linear behavior for the inhomogeneity has been recently considered, in a different context, by Vilenkin.[17] The general solution for this class of metrics and the study of a few particular examples were given in Ref. 11.

Before going to the field equations, it is worth mentioning that the metric (1)–(5) admits a homothetic vector field given by

$$\mathbf{H}=\frac{2}{c}\frac{\partial}{\partial \mathbf{z}}+\left(1-\frac{a}{c}\right)x\frac{\partial}{\partial \mathbf{x}}+\left(1+\frac{a}{c}\right)y\frac{\partial}{\partial \mathbf{y}}. \tag{6}$$

It was conjectured in Ref. 14 that the self-similar solutions could be the attractors of the G_2 cosmologies and in this sense the metric (1)–(5) would play an important role in the study of the asymptotic behavior of the inhomogeneous solutions. The metric (1)–(5) is similar to the metric studied by Hewitt *et al.*[14] [it is obtained interchanging t by z in (5)]. Both metrics, however, differ in the character of the orbits of the similarity group and in the type of the source. In our case the orbits of (6) are spacelike given by $t=$constant and the scalar field is inhomogeneous and, therefore, it is not equivalent, in general, to a perfect fluid.

The Einstein equations and the Klein–Gordon equation for the scalar field with the ansatz (5) are given by

$$\frac{\ddot{G}}{G}-2V(\overline{\phi})e^{F}=0, \tag{7}$$

$$\ddot{p}+\frac{\dot{G}}{G}\dot{p}=0, \tag{8}$$

$$a\dot{p}-c\frac{\dot{G}}{G}+2b\dot{\phi}=0, \tag{9}$$

$$\frac{\ddot{G}}{G}-\frac{1}{2}\left(\frac{\dot{G}}{G}\right)^2-\dot{f}\frac{\dot{G}}{G}+\frac{1}{2}\dot{p}^2+\dot{\phi}^2+\frac{1}{2}a^2+b^2=0, \tag{10}$$

$$\ddot{f}-\frac{1}{2}\left(\frac{\dot{G}}{G}\right)^2+\frac{1}{2}\dot{p}^2+\dot{\phi}^2-\frac{1}{2}a^2-b^2=0, \tag{11}$$

$$\ddot{\phi}+\frac{\dot{G}}{G}\dot{\phi}+kV(\overline{\phi})e^{F}=0. \tag{12}$$

For a massless scalar field, $V=0$, the former system of equations turns out to be easily integrable, giving the following solution;

$$\begin{aligned} &p(t)=A\ \ln t, \quad \phi(t)=B\ \ln t, \quad G(t)=t,\\ &f(t)=(\tfrac{1}{2}A^2+B^2-\tfrac{1}{2})\ln t+\tfrac{1}{2}(\tfrac{1}{2}a^2+b^2)t^2, \end{aligned} \tag{13}$$

where A and B are constants subject to the condition

$$aA - c + 2bB = 0. \tag{14}$$

When $V \neq 0$, from (7) or (12), and due to the exponential form of the potential,

$$c = -kb. \tag{15}$$

In this case if the constant $b=0$, then, from (9), either $\dot{p}=0$ and the metric is Bianchi type VI_0, or $a=0$ and the metric is Bianchi type I. Let us note that whatever value V takes, when $a=b=0$ the metric is Bianchi type I.

In order to look for a suitable set of new variables to compactify the phase space, we write the generalized Friedman equation which is obtained from (7) and (10):

$$-\frac{1}{2}\left(\frac{\dot{G}}{G}\right)^2 - \dot{f}\,\frac{\dot{G}}{G} + \frac{1}{2}\,\dot{p}^2 + \dot{\phi}^2 + \frac{1}{2}\,a^2 + b^2 + 2V(\phi)e^f = 0. \tag{16}$$

This equation suggests the introduction of the following set of variables

$$\begin{aligned} \beta &= \frac{\dot{p}}{\dot{G}/G + \dot{f}}, \quad \Psi = \sqrt{2}\,\frac{\dot{\phi}}{\dot{G}/G + \dot{f}}, \\ \Phi &= \frac{\dot{f}}{\dot{G}/G + \dot{f}}, \quad \Gamma = \frac{2\sqrt{Ve^f}}{\dot{G}/G + \dot{f}}. \end{aligned} \tag{17}$$

In terms of these new variables, (16) is written as

$$1 - \beta^2 - \Psi^2 - \Phi^2 - \Gamma^2 = \frac{(a^2 + 2b^2)}{(\dot{G}/G + \dot{f})^2} \geqslant 0. \tag{18}$$

Therefore the space of solutions described by the variables (17) is bounded to the inside of the four-sphere (18). Let us note that, from (16), $\dot{G}/G + \dot{f}$ has to be different from zero, unless Λ be negative.

In dealing with perfect fluid models new variables were defined as the kinematical quantities of the fluid divided by an appropriate power of the rate of expansion θ. This assures good behavior of these variables near the initial singularity. Let us note that our new variables (17) are divided by the quantity $\dot{G}/G + \dot{f}$, which is not related to the expansion of any timelike congruence. Nevertheless, from the general behavior near the initial singularity found by Belinskii *et al.*[18] and from the work of Isenberg and Moncrief[19] we can assume that the metric (1)–(5), near the initial singularity behaves, for each value of the coordinate z, like a Kasner model. Therefore, when $t \to 0$

$$G \sim t, \quad f \sim p \sim \phi \sim \ln t, \tag{19}$$

and the variables (17) remain bounded when t tends to zero.

From (18) we see that the points on the surface of the four-sphere represent either homogeneous Bianchi type I solutions (when constants a and b are zero) or the initial singularity of the models.

By using (17), (9) is written as

$$a\beta + b\sqrt{2}\Psi - c(1 - \Phi) = 0. \tag{20}$$

Except for the trivial case when $a=b=0$, this equation gives a constraint for the constants a and b. Alternatively, if a and b are fixed, one can look at this equation as giving a plane, the

intersection of which with the sphere (18) describes the phase space. In the study of the equilibrium points in the next section, a and b will be arbitrary, chosen constrained by (20).

Using the variables (17), (7) becomes

$$\frac{\ddot{G}}{G}=\frac{1}{2}\left(\frac{\Gamma}{1-\Phi}\right)^2\left(\frac{\dot{G}}{G}\right)^2. \tag{21}$$

This equation decouples from the rest of the field equations if we introduce a new time coordinate

$$\frac{d\tau}{dt}=\frac{\dot{G}}{G}+\dot{f}=\frac{1}{1-\Phi}\frac{\dot{G}}{G}. \tag{22}$$

Near the initial singularity

$$\frac{d\tau}{dt}\sim\frac{1}{t}\Rightarrow\tau\rightarrow-\infty, \tag{23}$$

thus τ varies from $-\infty$ to $+\infty$. In terms of this new time the field equations are written as

$$\beta'=-\beta(1-\beta^2-\Psi^2-\Phi^2), \tag{24}$$

$$\Psi'=-\Psi(1-\beta^2-\Psi^2-\Phi^2)-\frac{k}{2\sqrt{2}}\Gamma^2, \tag{25}$$

$$\Phi'=(1-\Phi)(1-\beta^2-\Psi^2-\Phi^2)-\tfrac{1}{2}\Gamma^2, \tag{26}$$

$$\Gamma'=-\Gamma\left(-\beta^2-\Psi^2-\Phi^2+\frac{1}{2}\Phi-\frac{k}{2\sqrt{2}}\Psi\right), \tag{27}$$

where $'$ means derivative with respect to the new time τ. Differentiating (20) with respect to τ one can easily see that the constraint equation (20) holds for all values of τ, as long as the initial conditions verify the equation (20). Therefore (24)–(27) along with the constraint equation (20) describe the evolution of the metric (1)–(5).

III. THE EQUILIBRIUM POINTS AND THE INVARIANT SETS

In this section we shall study the qualitative behavior of the trajectories of the system (24)–(27). Let us first note that the system admits the discrete symmetry $\Gamma\rightarrow-\Gamma$, and, therefore, without loss of generality the study of the equilibrium points will be restricted to $\Gamma\geqslant 0$.

A. Equilibrium points

The equilibrium points of an autonomous system play an important role in describing the qualitative behavior of its solutions. The local stability of the equilibrium points are given by the eigenvalues of the linearized differential equations. The equilibrium points of the system (24)–(27) can be found explicitly and we now give them and their character:

$$\text{(I)}\quad\left\{\beta=0\quad\Psi=-\frac{k\sqrt{2}}{2+k^2}\quad\Phi=\frac{k^2}{2+k^2}\quad\Gamma=\frac{2\sqrt{2}}{2+k^2}\right\}.$$

This point is outside the sphere when $k^2<2$ and it is on the surface of the sphere when $k^2=2$. The constraint equation (20) is trivially satisfied for all values of the constants a and b. The corresponding metric and the scalar field when $k^2>2$ are

$$ds^2 = Ce^{k^2At/2-kbz}(-dt^2+dz^2)+e^{At}(e^{az}dx^2+e^{-az}dy^2),$$
$$\phi = -\frac{k}{2}At+bz, \tag{28}$$

where

$$C=\frac{A^2}{\Lambda}, \quad A=\sqrt{\frac{2(a^2+2b^2)}{k^2-2}}. \tag{29}$$

This metric was obtained in Ref. 11 and is of Bianchi type VI. The eigenvalues of the linearized system are

$$\frac{-2}{k^2+2}, \quad \frac{-2}{k^2+2}, \quad \frac{-1+\sqrt{5-2k^2}}{k^2+2}, \quad \frac{-1-\sqrt{5-2k^2}}{k^2+2}. \tag{30}$$

When $k^2<\frac{5}{2}$, the equilibrium point is a stable node and when $k^2>5/2$ it is a stable focus.

$$\text{(II)} \quad \left\{\beta=0 \quad \Psi=-\frac{k}{2\sqrt{2}} \quad \Phi=\frac{1}{2} \quad \Gamma=\frac{\sqrt{6-k^2}}{2\sqrt{2}}\right\}.$$

This equilibrium point is on the surface of the sphere. It disappears when $k^2>6$ and coincides with the former equilibrium point when $k^2=2$. Substituting the former values of the variables of the equilibrium point into (17) one easily gets that the solution corresponds to a homogeneous Bianchi type I solution ($a=b=0$). The line element and the scalar field are

$$ds^2=Ct^m(-dt^2+dz^2)+t^m(dy^2+dz^2), \quad m=\frac{4}{k^2-2}, \quad \phi=-\frac{2k}{k^2-2}\ln t, \tag{31}$$

where

$$C=\frac{2(6-k^2)}{\Lambda(k^2-2)^2}, \tag{32}$$

and the metric represents the FRW universe with massless minimally coupled scalar field as a source. The eigenvalues of the linearized system are

$$-\tfrac{1}{8}(6-k^2), \quad -\tfrac{1}{4}(2-k^2), \quad -\tfrac{1}{8}(6-k^2), \quad -\tfrac{1}{8}(6-k^2). \tag{33}$$

When $k^2<2$ this equilibrium point is a stable node, but when $2<k^2<6$ it is a saddle point.

It is important to note that the constraint equation (20) is satisfied not only because a and b vanish but because $\beta=0$ and $\sqrt{2}\Psi+k(1-\Phi)=0$. If we look into the evolution in time of a particular solution with a and b different from zero, and with $k^2<2$, β, Ψ, and Φ will take values such that the constraint equation will be always satisfied and as $t\to\infty$ the solution will approach this equilibrium point becoming, therefore, homogeneous and isotropic.

$$\text{(III)} \quad \{\beta^2+\Psi^2+\Phi^2=1, \quad \Gamma=0\}.$$

This ring of equilibrium points belongs to the surface of the sphere and represents, therefore, Bianchi type I solutions with a minimally coupled massless scalar field. By choosing a particular point on the surface, i.e., $\beta=a_1$, $\Psi=a_2$, and $\Phi=a_3$ with $a_1^2+a_2^2+a_3^2=1$, the eigenvalues of the linearized system are

$$\frac{1}{2}\left(2-a_3+\frac{k}{\sqrt{2}}\,a_2\right),\quad 2(1-a_3),\quad 0,\quad 0. \tag{34}$$

Hence, any of these points are unstable, except when $\Phi=1$ ($a_3=1$), which corresponds to the Minkowski space–time.

B. Invariant sets

Besides the equilibrium points, the existence of invariant sets help to describe the qualitative behavior of the solutions of an autonomous system. In our case, there are three invariant sets, two of them describing massless and exponential potential scalar field solutions, respectively, while the third gives the Bianchi type I solutions.

The points with $\Gamma=0$ (massless scalar field space–times) compose an invariant set of the dynamical system (24)–(27) whose solutions are given by (13) and (14). The dynamics of the points of this subspace can be easily studied: when $\Gamma=0$, the dynamical system reduces to

$$\begin{aligned}\beta' &= -\beta(1-\beta^2-\Psi^2-\Phi^2),\\ \Psi' &= -\Psi(1-\beta^2-\Psi^2-\Phi^2),\\ \Phi' &= (1-\Phi)(1-\beta^2-\Psi^2-\Phi^2),\end{aligned} \tag{35}$$

with straight lines as solutions:

$$\Phi=\frac{\Phi_0-1}{\beta_0}\,\beta+1,\quad \Psi=\frac{\Psi_0}{\beta_0}\,\beta. \tag{36}$$

These lines start on the surface of the sphere $\beta^2+\Psi^2+\Phi^2=1$ and intersect at the point $\beta=\Psi=0$, $\Phi=1$. Thus the solutions evolve from the Kasner initial singularity to the Minkowski space–time.

The second invariant set is given by the points with $\Gamma>0$ (and by symmetry $\Gamma<0$), with equilibrium points being the points I and II described above.

Finally, the third invariant set is given by the points on the surface of the sphere ($\beta^2+\Psi^2+\Phi^2+\Gamma^2=1$). In this case the dynamical system is reduced to

$$\begin{aligned}\beta' &= -\beta(1-\beta^2-\Psi^2-\Phi^2),\\ \Psi' &= -\left(\Psi+\frac{k}{2\sqrt{2}}\right)(1-\beta^2-\Psi^2-\Phi^2),\\ \Phi' &= (\tfrac{1}{2}-\Phi)(1-\beta^2-\Psi^2-\Phi^2).\end{aligned} \tag{37}$$

The solutions of this system are again straight lines:

$$\Phi=\left(\Phi_0-\frac{1}{2}\right)\frac{\beta}{\beta_0}+1,\quad \Psi=\left(\Psi_0+\frac{k}{2\sqrt{2}}\right)\frac{\beta}{\beta_0}-\frac{k}{2\sqrt{2}}, \tag{38}$$

and the equilibrium points of the system (37) are the points II and III.

The behavior of the system (24)–(27) can be visualized in Fig. 1 where the phase space for $\beta=0$ and $\Gamma\geqslant 0$ is depicted for different values of the constant k. The positions of the equilibrium point I as a function of k are represented by the dashed line. All the solutions start on the circle $\Phi^2+\Psi^2=1$, $\Gamma=0$. When $\Gamma=0$ (massless scalar field), for all the cases, the solutions tend to the

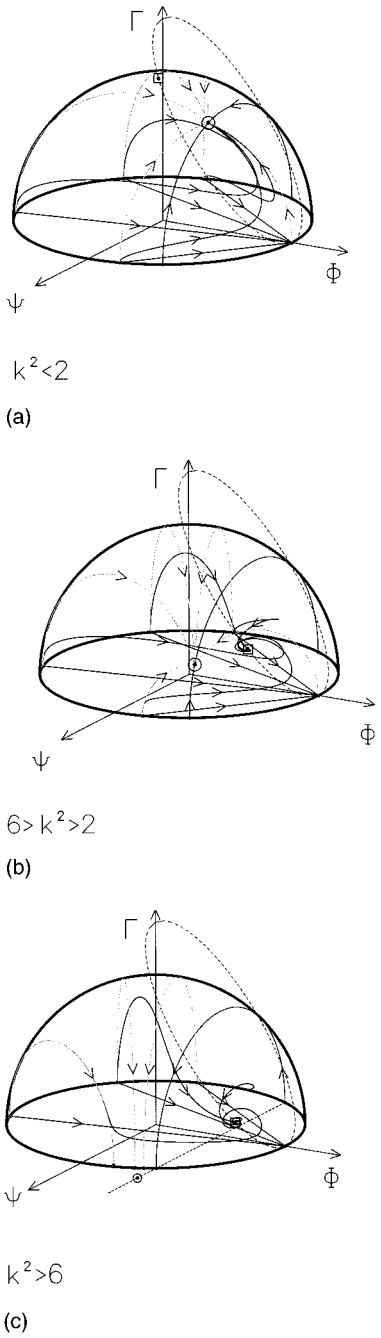

FIG. 1. Phase space when $\beta=0$ and $\Gamma\geqslant 0$, and for different values of the constant k. The equilibrium point I is represented by a square and the equilibrium point II by a circle. The dashed line describes the position of the point I for different values of k. Faded lines represent the trajectories of the solutions lying on the surface of the sphere which is an invariant set. The plane $\Gamma=0$ is an invariant set describing the massless scalar field solutions.

point $\Phi=1$, $\Psi=0$. When $k^2<2$, the point I is outside the sphere and the solutions tend to the equilibrium point II. When $2<k^2<6$, point I is inside the sphere and the solutions evolve either to the point I (those that go inside the sphere) or to the point II (those that lie on the boundary of the sphere). When $k^2>6$, the only attracting point is point I (inside the sphere). The trajectories on the

surface start and finish on the circle $\Phi^2+\Psi^2=1$, $\Gamma=0$, in such a way that their projections on the plane $\Gamma=0$ are a straight line directed to the point $\Psi=-(k/2\sqrt{2})$ $\Phi=\frac{1}{2}$ which is outside the surface.

The behavior described above remains the same when β is different from zero.

IV. CONCLUSIONS

We have studied in this paper the asymptotic behavior of a particular class of inhomogeneous solutions with a minimally coupled scalar field with an exponential potential. The metric belongs to the class of G_2 cosmologies.

We have succeeded in defining a set of new variables for which the entire phase space is bounded by a four-sphere. From the analysis of the dynamical system obtained for this metric, we deduce the following:

(i) As in the homogeneous case,[13] the dynamical behavior of the metric depends on the parameter k which is related to the mass of the scalar field. The parameters a and b which drive the inhomogeneity do not play a significant role in this behavior.

(ii) When $k^2<2$, the only equilibrium point is that given by the FRW universe. The trajectories evolve from the surface of the four-sphere, representing the Kasner regime near the initial singularity, towards the isotropic equilibrium point II. When $k^2>2$, there are two equilibrium points: one is the homogeneous Bianchi type VI (point I) and the second is the FRW solution which is a saddle point and, therefore, unstable against small changes of the initial conditions. This means that the cosmic no-hair theorem holds in this case provided $k^2<2$.

The behavior described above is almost identical to that of homogeneous models,[13] indicating that the introduction of the inhomogeneity through the constants a and b does not affect remarkably the dynamical system. It is likely that the presence of a more ''strong'' inhomogeneity, assuming another dependence on the spatial coordinate, may change the behavior of the solutions and the conditions to isotropize. We consider, therefore, that it is important to extend this analysis to a more general class of inhomogeneous scalar field solutions.

As to the inflation of the models, for inhomogeneous solutions there is no natural way to see whether the models inflate. The hypersurfaces $\phi=$constant do not define a globally timelike observer and, therefore, one should use a weaker way to specify the inflationary behavior. It has been suggested,[20] for example, to look at the fulfillment of the strong energy condition, the breaking of which is a necessary condition for a model to inflate. The energy density and the pressure of the scalar field are given by

$$\rho=-\tfrac{1}{2}\,\overline{\phi}_{,a}\overline{\phi}^{,a}+V,\quad p=-\tfrac{1}{2}\overline{\phi}_{,a}\overline{\phi}^{,a}-V. \tag{39}$$

In terms of the new variables, the breaking of the energy condition is written as

$$3p+\rho=e^{-F}\left(\frac{\dot{G}}{G}+\dot{f}\right)^2\left[\Psi^2-\frac{1}{2}\,\Gamma^2-\frac{2b^2}{(\dot{G}/G+\dot{f})^2}\right]<0. \tag{40}$$

For the equilibrium points I and II the expression $\Psi^2-\frac{1}{2}\Gamma^2$ turns out to be

$$\frac{2(k^2-2)}{(2+k^2)^2}\quad\text{and}\quad\frac{3(k^2-2)}{16}, \tag{41}$$

respectively. That means that if $k^2<2$, both points describe space–times inflating, but if $k^2>2$, the energy condition could be broken only by the solution represented by the point I depending on the value of b. This behavior is similar again to that of the homogeneous models.[8]

On the distribution of gravitational energy in the de Sitter space

José W. Maluf[a)]
Universidade de Brasília, C.P. 04385, 70.919-970 Brasília DF, Brazil

(Received 16 January 1996; accepted for publication 17 July 1996)

We calculate the total gravitational energy and the gravitational energy density of the de Sitter space using the definition of localized gravitational energy that naturally arises in the framework of the teleparallel equivalent of general relativity. We find that the gravitational energy can only be defined within the cosmological horizon and is largely concentrated in regions far from the center of spherical symmetry, i.e., in the vicinity of the maximal spacelike radial coordinate $R = \sqrt{3/\Lambda}$. The smaller the cosmological constant, the farther the concentration of energy. This result complies with the phenomenological features of the de Sitter solution, namely, the existence of a radial acceleration directed away from the center of symmetry experienced by a test particle in the de Sitter space. Einstein already contemplated the de Sitter solution as a world with a surface distribution of matter, a picture which is in agreement with the present analysis. © *1996 American Institute of Physics.* [S0022-2488(96)01012-2]

I. INTRODUCTION

The difficulty in defining gravitational energy density within the framework of the Hilbert–Einstein Lagrangian formulation has led to the belief that the gravitational energy cannot be localized. It is widely assumed that an expression for the localized energy density of the gravitational field does not exist. However, it is well known that the total energy of a given asymptotically flat space–time can be calculated by means of pseudotensor methods, which make use of coordinate-dependent expressions. A different approach to the construction of an energy expression for the gravitational field is based on the idea of quasilocal energy. The quasilocal definition of energy, momentum, and angular momentum associates these quantities to an arbitrary spacelike two-surface S in an arbitrary space–time manifold. The inexistence of an unequivocal definition of gravitational energy still remains an actual problem, important in its own right. Furthermore, such definition may play a major role in the thermodynamics of self-gravitating systems. This problem has been recently addressed in Ref. 1, where a comprehensive bibliography on quasi-local energy is presented. Although all attempts so far have led to interesting mathematical developments, they did not allow the achievement of a definite solution, either because of conceptual or mathematical difficulties.

Recently the problem of localization of energy in general relativity has been reconsidered in the framework of the teleparallel equivalent of general relativity (TEGR).[2] The Lagrangian formulation of the TEGR is established by means of the tetrad field $e^a{}_\mu$ and the spin affine connection $\omega_{\mu ab}$, which are taken to be completely independent field variables, even at the level of field equations. This formulation has been investigated in the past in the context of Poincaré gauge theories.[3,4] However, as we will explain ahead, this is not an alternative theory of gravity. This is just an *alternative formulation* of general relativity, in which the curvature tensor constructed out of $\omega_{\mu ab}$ vanishes, but the torsion tensor is nonvanishing. The physical content of the theory is dictated by Einstein's equations. As we will show, in this alternative geometrical formulation the gravitational energy density can be naturally defined.

[a)]Electronic mail address: wadih@guarany.cpd.unb.br

The expression for the localized energy density of the gravitational field has arisen in the context of the Hamiltonian formulation of the TEGR.[5] It has been demonstrated that under a suitable gauge fixing of $\omega_{\mu ab}$, already at the Lagrangian level, the Hamiltonian formulation of the TEGR is well defined.[5] The resulting constraints are first class constraints. In fact, the Hamiltonian formulation looks very similar to the usual Arnowitt–Deser–Misner (ADM) formulation.[6] However, there are crucial differences. The integral form of the Hamiltonian constraint equation $C=0$ in the TEGR can be written in the form $C=H-E_{\mathrm{ADM}}=0$, when we restrict considerations to asymptotically flat space–times.[2] The quantity $\varepsilon(x)$ which appears in the expression of C and which under intergration yields E_{ADM} is recognized as the gravitational energy density. We have applied the expression of $\varepsilon(x)$ to the calculation of the energy inside a surface of constant radius, both for the Schwarzschild[2] and for the Kerr metric,[7] and the results are remarkably the same as those obtained by means of the quasilocal energy definition proposed by Brown and York.[1] Moreover, the calculational scheme is rather simple, as we will see shortly, and is exempt of some complications inherent to the latter. Therefore, for asymptotically flat space–times, the gravitational energy density has a definite and unambiguous expression within the framework of the TEGR.

We recall that the gravitational energy can also be calculated by means of the surface term that appears in the expression of the gravitational Hamiltonian.[8,9] However, such surface term yields only the *total* gravitational energy, as the integration has to be necessarily carried out over the whole three-dimensional spacelike hypersurface, in which case the lapse function $N(x)$ goes over into its asymptotic value $N\rightarrow 1$ at spatial infinity.

The action integrals for space–times with different topologies require surface terms that are specific to each topology. Thus the corresponding Hamiltonian also acquires a surface term that is determined by the topological boundary conditions.[10] However, the Hamiltonian constraint for a space–time foliated by spacelike hypersurfaces always has the same basic structure, irrespective of boundary conditions [*additional* terms such as the cosmological constant may appear in the Hamiltonian constraint, as we will see ahead in Eq. (10)].

Therefore the question immediately arises as to whether the Hamiltonian constraint equation in the TEGR can always be written as $C=H-E=0$, in which case $\varepsilon(x)$ would be the gravitational energy density for any curved space–time.

One of the simplest deviations from asymptotically flat geometries are space–times with conical defects. We have applied our expression of gravitational energy density to the calculation of the energy per unit length of defects of topological nature, which include disclinations, i.e., cosmic strings, and dislocations.[11] The result is quite encouraging. We arrive at precisely the same well-known expression for the energy per unit length of a cosmic string (not even multiplicative factors have to be adjusted). Moreover, the total energy of a dislocation is zero, a result which is in close analogy with the statements of the theory of elasticity, which asserts that disclinations and dislocations are defects which require high energy and low energy, respectively.

In this paper we consider the de Sitter space, which is topologically of the type $S^3\times R$. We restrict the considerations to the static region within the cosmological horizon (i.e., the region for which $-g_{00}>0$) and calculate both the total energy and the distribution of energy along the radial direction. Again the result is rather remarkable. We will show that the cosmological constant induces a distribution of gravitational energy in such a way that the energy is largely concentrated in the peripheral region, i.e., in the vicinity of the maximal spacelike radial coordinate $R=\sqrt{3/\Lambda}$. As we will show in Sec. III, this picture is in total agreement with the phenomenological features of the de Sitter solution, and is as well in agreement with Einstein's belief, according to which the de Sitter's solution represents a space–time with a surface distribution of matter.[12] This fact strongly supports the validity of our expression for the gravitational energy density and also represents a clear indication that the Hamiltonian constraint equation in the TEGR can be unambiguously interpreted as an energy equation of the type $H-E=0$.

Notation: The space–time indices $\mu,\nu,\ldots$, and local Lorentz indices $a, b,\ldots$, run from 0–3. In

the 3+1 decomposition, Latin indices from the middle of the alphabet indicate space indices according to $\mu=0,i$, $a=(0),(i)$. The tetrad field $e^a{}_\mu$ and the spin connection $\omega_{\mu ab}$ yield the usual definitions of the torsion and curvature tensors: $R^a{}_{b\mu\nu}=\partial_\mu\omega_\nu{}^a{}_b+\omega_\mu{}^a{}_c\omega_\nu{}^c{}_b-\cdots$, $T^a{}_{\mu\nu}=\partial_\mu e^a{}_\nu+\omega_\mu{}^a{}_b e^b{}_\nu-\cdots$. The flat space–time metric is fixed by $\eta_{(0)(0)}=-1$.

II. THE LAGRANGIAN AND HAMILTONIAN FORMULATIONS OF THE TEGR

In the TEGR the tetrad field $e^a{}_\mu$ and the spin connection $\omega_{\mu ab}$ are independent field variables, not related by any of the field equations. The spin connection is enforced to satisfy the condition of zero curvature. The Lagrangian density in empty space–time is given by[2,5]

$$L(e,\omega,\lambda)=-ke(\tfrac{1}{4}T^{abc}T_{abc}+\tfrac{1}{2}T^{abc}T_{bac}-T^aT_a)+e\lambda^{ab\mu\nu}R_{ab\mu\nu}(\omega), \tag{1}$$

where $k=1/16\pi G$, G is the gravitational constant, $e=\det(e^a{}_\mu)$, $\lambda^{ab\mu\nu}$ are Lagrange multipliers, and T_a is the trace of the torsion tensor defined by $T_a=T^b{}_{ba}$.

The equivalence of the TEGR with Einstein's general relativity is guaranteed by the identity

$$eR(e,\omega)=eR(e)+e(\tfrac{1}{4}T^{abc}T_{abc}+\tfrac{1}{2}T^{abc}T_{acb}-T^aT_a)-2\partial_\mu(eT^\mu), \tag{2}$$

which is obtained by just substituting the arbitrary spin connection $\omega_{\mu ab}={}^0\omega_{\mu ab}(e)+K_{\mu ab}$ in the scalar curvature tensor $R(e,\omega)$ on the left-hand side of (2); ${}^0\omega_{\mu ab}(e)$ is the Levi–Civita connection and $K_{\mu ab}=\frac{1}{2}e_a{}^\lambda e_b{}^\nu(T_{\lambda\mu\nu}+T_{\nu\lambda\mu}-T_{\mu\nu\lambda})$ is the contorsion tensor. The vanishing of $R^a{}_{b\mu\nu}(\omega)$, which is one of the field equations derived from (1), implies the equivalence of the scalar curvature $R(e)$, constructed out of $e^a{}_\mu$ only, and the quadratic combination of the torsion tensor. It also ensures that the field equation arising from the variation of L with respect to $e^a{}_\mu$ is strictly equivalent to Einstein's equations in tetrad form. Let $\delta L/\delta e^{a\mu}=0$ denote the field equation satisfied by $e_{a\mu}$. It can be shown by explicit calculations that

$$\frac{\delta L}{\delta e^{a\mu}}=\frac{1}{2}\left\{R_{a\mu}(e)-\frac{1}{2}\,e_{a\mu}R(e)\right\}$$

(we refer the reader to Ref. 5 for additional details).

For *asymptoticaly flat* space–times the total divergence in (2) does *not* contribute to the action integral. Therefore the latter does not require additional surface terms, as it is already invariant under coordinate transformations that preserve the asymptotic structure of the field quantities.[9] It is well known that for compact geometries a surface term has to be included in the action, in order to make the variations of the field variables well defined. This surface term is constructed out of the trace of the extrinsic curvature on the boundary. However, we will no longer worry about surface terms in the Lagrangian or in the Hamiltonian, as we will be interested only in the constraint structure of the theory.

The Hamiltonian formulation of the TEGR can be successfully implemented if we fix the gauge $\omega_{0ab}=0$ from the outset, since in this case the constraints constitute a *first class* set.[5] The condition $\omega_{0ab}=0$ is achieved by breaking the local Lorentz symmetry of (1). We still make use of the residual time-independent gauge symmetry to fix the usual time gauge condition $e_{(k)}{}^0=e_{(0)i}=0$. Because of $\omega_{0ab}=0$, H does not depend on P^{kab}, the momentum canonically conjugated to ω_{kab}. Therefore arbitrary variations of $L=p\dot{q}-H$ with respect to P^{kab} yields $\dot{\omega}_{kab}=0$. Thus in view of $\omega_{0ab}=0$, ω_{kab} drops out from our considerations. The above gauge fixing can be understood as the fixation of a *global* reference frame.

Under the above gauge fixing, the canonical action integral obtained from (1) becomes[5]

$$A_{TL}=\int d^4x\{\Pi^{(j)k}\dot{e}_{(j)k}-H\}, \tag{3}$$

$$H = NC + N^i C_i + \Sigma_{mn}\Pi^{mn}. \tag{4}$$

In expression (4) above we are omitting surface terms. Here N and N^i are the lapse and shift functions and $\Pi^{mn} = e_{(j)}{}^m \Pi^{(j)n}$ and $\Sigma_{mn} = -\Sigma_{nm}$ are Lagrange multipliers. The constraints are defined by

$$C = \partial_j(2keT^j) - ke\Sigma^{kij}T_{kij} - \frac{1}{4ke}\left(\Pi^{ij}\Pi_{ji} - \frac{1}{2}\Pi^2\right), \tag{5}$$

$$C_k = -e_{(j)k}\partial_i \Pi^{(j)i} - \Pi^{(j)i}T_{(j)ik}, \tag{6}$$

with $e = \det(e_{(j)k})$, $T^i = g^{ik}e^{(j)l}T_{(j)lk}$, and $T_{(j)lk} = \partial_l e_{(j)k} - \partial_k e_{(j)l}$. We remark that (3) and (4) are invariant under *global* SO(3) and general coordinate transformations. [In Eqs. (1) and (2), e is the determinant of the *space–time* tetrad field; from Eq. (3) on, e stands for the determinant of the triads restricted to the three-dimensional spacelike hypersurface.]

If we assume the asymptotic behavior $e_{(j)k} \approx \eta_{jk} + \frac{1}{2}h_{jk}(1/r)$ for $r \to \infty$, which is appropriate for an asymptotically flat space–time, then in view of the relation

$$\frac{1}{8\pi G}\int d^3x \partial_j(eT^j) = \frac{1}{16\pi G}\int_S dS_k(\partial_i h_{ik} - \partial_k h_{ii}) \equiv E_{\mathrm{ADM}}, \tag{7}$$

where the surface integral is evaluated for $r \to \infty$, we note that the integral form of the Hamiltonian constraint $C = 0$ may be rewritten as

$$\int d^3x \left\{ ke\Sigma^{kij}T_{kij} + \frac{1}{4ke}\left(\Pi^{ij}\Pi_{ji} - \frac{1}{2}\Pi^2\right)\right\} = E_{\mathrm{ADM}}. \tag{8}$$

The integration is over the whole three-dimensional space. Given that $\partial_j(eT^j)$ is a scalar density, from (7) and (8) we define the gravitational energy density enclosed by a volume V of the space as[2]

$$E_g = \frac{1}{8\pi G}\int_V d^3x \partial_j(eT^j). \tag{9}$$

It must be noted that this expression is also invariant under global SO(3) transformations.

One is immediately led to ask whether the Hamiltonian constraint for topologically different space–times can also be written as Eq. (8). In the next section we will consider the de Sitter space. Before addressing the latter, let us recall here some applications of E_g. We have calculated the gravitational energy inside a surface of constant radius r_0 both for the Schwarzschild[2] and for the Kerr solution,[7] using Boyer and Lindquist coordinates.[13,14] These quantities have also been calculated by means of Brown and York's procedure, in Refs. 1 and 15, respectively. The expressions found by using (9) are in total agreement with those obtained via the method of Ref. 1. Moreover, E_g can be calculated for any volume in the three-dimensional spacelike hypersurface, at least through numerical integration, whereas the evaluation of the energy in Ref. 15 can only be carried out in the limit of slow rotation of the black hole (the application of Brown and York's procedure to the Kerr solution with arbitrary parameters meets some technical difficulties, as discussed in Ref. 15).

Definition (9) has also been applied to a class of conical space–time defects, in which disclinations (cosmic strings) and dislocations are considered altogether. For the space–time of a single cosmic string, i.e., for a pure disclination, we obtain precisely the well-known value of energy per unit length of the string.[11] Furthermore, the *total* gravitational energy for a pure dislocation vanishes. This is a very interesting result, because we know from the theory of elasticity that

disclinations are defects that require a large amount of energy to be formed, whereas dislocations require low energy (see sections 6.3.2 and 6.5 of Ref. 16 for a discussion as to why the energy demanded for the formation of a disclination in a crystal is very high). Therefore the above calculations of energy are in close agreement with the statements of the theory of elasticity [in this respect we recall that attempts were made a long time ago which envisaged the space–time as a continuum with microstructure (see Ref. 4, section 1.2)].

III. GRAVITATIONAL ENERGY IN THE dE SITTER SPACE

We will consider now the theory defined by the Lagrangian density (1) supplemented by a term containing the cosmological constant Λ. Thus we add to (1) the quantity $2^4e\Lambda$, where ${}^4e = Ne$ is the determinant of the *space–time* tetrad field $e_{a\mu}$. This additional term will contribute to the action integral (3) only as an extra term of the Hamiltonian constraint. The new Hamiltonian constraint reads

$$C=\partial_j(2keT^j)-ke\Sigma^{kij}T_{kij}-\frac{1}{4ke}\left(\Pi^{ij}\Pi_{ji}-\frac{1}{2}\,\Pi^2\right)-2e\Lambda. \tag{10}$$

The most general spherically symmetric solution of the field equations with a positive cosmological constant is the Schwarzschild–de Sitter solution (throughout this section we will make $G=1$):

$$ds^2=-\left(1-\frac{2m}{r}-\frac{r^2}{R^2}\right)dt^2+\left(1-\frac{2m}{r}-\frac{r^2}{R^2}\right)^{-1}dr^2+r^2\ d\theta^2+r^2\ \sin^2\ \theta d\phi^2. \tag{11}$$

This metric represents the gravitational field of a particle of mass m located at the origin of a globally hyperbolic space–time. The vacuum solution, obtained by setting $m=0$ in (11), is the de Sitter solution. Here R is the maximal spacelike radial coordinate for the (vacuum) de Sitter space and is given by $R=\sqrt{3/\Lambda}$.

Strictly speaking, de Sitter space–time corresponds to a four-dimensional surface in a flat five-dimensional space with metric $(-,+,+,+,+)$ described by

$$-z_0^2+z_1^2+z_2^2+z_3^2+z_3^2+z_4^2=\frac{3}{\Lambda},\quad \Lambda>0.$$

The coordinates (t,r,θ,ϕ) in (11) cover only half of the space defined by the relation above. However we will be interested just in (11), as it suffices for our purposes. Moreover, we will restrict the considerations to the physical region between the Schwarzschild (black hole) and the cosmological horizons.

Expression (9) allows us to calculate the gravitational energy for any volume in space. We wish to obtain the energy contained within a surface of constant radius r_0. For this purpose we will calculate $eT^1=eT^r$ for a space–time whose spacelike section is described by the line element

$$dl^2=\alpha^2dr^2+r^2d\theta^2+r^2\ \sin^2\ \theta d\phi^2, \tag{12}$$

where α is a function of the coordinate r. The triads that correspond to (12) are given by

$$e_{(k)i}=\begin{pmatrix} \alpha\ \sin\ \theta\ \cos\ \phi & r\ \cos\ \theta\ \cos\ \phi & -r\ \sin\ \theta\ \sin\ \phi \\ \alpha\ \sin\ \theta\ \sin\ \phi & r\ \cos\ \theta\ \sin\ \phi & r\ \sin\ \theta\ \cos\ \phi \\ \alpha\ \cos\ \theta & -r\ \sin\ \theta & 0 \end{pmatrix}. \tag{13}$$

Here (k) is the line index and i is the column index.

The determinant e of (13) reads $e=\alpha r^2 \sin\theta$. After a lengthy but otherwise straightforward calculation of

$$eT^1 = eg^{1j}g^{im}e^{(k)}{}_m T_{(k)ij},$$

we arrive at

$$eT^1 = 2r \sin\theta\left(1-\frac{1}{\alpha}\right). \tag{14}$$

Therefore for the Schwarzschild–de Sitter solution we have

$$eT^1 = 2r \sin\theta\left(1-\sqrt{1-\frac{2m}{r}-\frac{r^2}{R^2}}\right). \tag{15}$$

The energy contained within a surface of constant radius r_0 is thus given by

$$E_g = \frac{1}{8\pi}\int_S d\theta d\phi eT^1 = r_0\left(1-\sqrt{1-\frac{2m}{r_0}-\frac{r_0^2}{R^2}}\right), \tag{16}$$

where S is a surface of constant radius r_0.

Let us evaluate expression (16) for the range of values of r_0 such that

$$\frac{2m}{r_0} \ll 1, \quad \frac{r_0^2}{R^2} \ll 1,$$

in which case we assume the cosmological constant to be very small. Expanding (16) and neglecting all powers of both $2m/r_0$ and r_0^2/R^2 we arrive at

$$E_g = r_0 + m \equiv E_{dS} + m. \tag{17}$$

Here E_{dS} is the value of energy we would obtain in the absence of the mass m, and therefore it represents the background (vacuum) energy. Upon subtraction of this term we obtain the standard ADM value of energy for a particle of mass m. Of course in (17) we expect r_0 to be much larger than m.

The total gravitational energy contained within the cosmological horizon can be easily calculated, but for this purpose one has to find the roots of the equation $1-2m/r-r^2/R^2=0$. The result is not illuminating. If $R \gg m$, we find that $E_g^{\text{total}} = r_{\max}$, where $r_{\max}$ is slightly smaller than R and is a solution of the equation above. In what follows we will rather consider the vacuum de Sitter solution only, since in this case the analysis of the energy density is most easily carried out, and the main features are not altered by the introduction of a mass m at $r=0$.

Before proceeding we mention that the present analysis is different from that carried out by Abbott and Deser.[17] These authors provide an expression for the energy of the gravitational field *about* the de Sitter background, i.e., they calculate the energy of a field configuration that deviates from the de Sitter metric and which vanish at infinity. In contrast, by means of expression (9) we can compute the energy of the whole gravitational field configuration, including the background.

The total gravitational energy E_{dS} contained in the physical region of the vacuum de Sitter space is obtained from (16) by making $m=0$ and $r_0=R$:

$$E_{dS} = R = \sqrt{\frac{3}{\Lambda}}. \tag{18}$$

The total volume of the compact spacelike section equals $2\pi^2R^3$. Therefore the average energy density is given by

$$\frac{E_{dS}}{2\pi^2R^3}=\frac{\Lambda}{6\pi^2}. \tag{19}$$

Let us obtain now the distribution of gravitational energy in the de Sitter space. In view of the spherical symmetry we will be interested in calculating the density of energy per unit radial distance $\varepsilon(r)$, which is obtained by integrating $(1/8\pi)\partial_r(eT^1{}_1)$ in θ and ϕ. Thus $\varepsilon(r)$ yields the gravitational energy contained between the spherical shells of radii r and $r+dr$. Considering $m=0$ in (15) we obtain upon integration in the angular variables and differentiation in r:

$$\varepsilon(r)=1+\frac{2\beta^2-1}{\sqrt{1-\beta^2}}. \tag{20}$$

where we have set $\beta^2=r^2/R^2$. The function $\varepsilon(r)$ has the following properties. In the range $0\leqslant\beta\leqslant1$, $\varepsilon(r)$ vanishes only for $r=0$. Moreover for $\beta=1$ it diverges: $\varepsilon(\beta=1)\to\infty$. It is straightforward to check that this is a monotonically increasing function, largely concentrated in the vicinity of $\beta=1$: $\varepsilon(\beta=0.1)=0.015$; $\varepsilon(\beta=0.5)=0.423$; $\varepsilon(\beta=0.9)=2,422$. The total energy contained inside the surfaces of radii $0.1R$, $0.5R$, and $0.9R$ are given by $E_g=5.01\times10^{-4}R$, $E_g=0,067R$, and $E_g=0.51R$, respectively.

Therefore almost half of the gravitational energy is located between $\beta=0.9$ and $\beta=1$. This result is in total agreement with the phenomenological features of the de Sitter solution, and can be verified in the following way. The g_{00} component of (11) can be written as

$$g_{00}=1+2\phi,$$

where ϕ is given by

$$\phi=-\frac{m}{r}-\frac{1}{6}\Lambda r^2.$$

Here ϕ is the potential in classical mechanics which would induce motion of a test particle approximately along the geodesics of (11). Therefore even in the absence of a mass m a test particle would be subject to a radial acceleration

$$a=\tfrac{1}{3}\Lambda r,$$

directed away from $r=0$.

The acceleration increases with the distance r, indicating that the gravitational field is more intense at points far from the origin. Therefore when $m=0$ the gravitational field given by (11) acts on physical bodies as if there were a radially symmetric distribution of matter about the origin, beyond the cosmological horizon, just as m represents the mass of a black hole, concentrated inside the black hole horizon.

This is precisely the picture we obtain from (20). By applying (9) to the de Sitter solution we find that the cosmological constant induces a spherically symmetric distribution of gravitational energy, concentrated in regions distant from the origin, due to the gravitational field that acts on a test particle placed in the vacuum de Sitter space. Such a field can be thought of as due to some matter distribution.

One may think of (11) as representing the gravitational field of a spherical cavity inside some spherically symmetric distribution of matter (this idea is discussed, for instance, in Ref. 18). In this respect we recall that Einstein already conjectured that the de Sitter solution would correspond to

a world with a surface distribution of matter.[12] Such conjecture has found a natural explanation within the present geometrical framework, and shows that (9) yields a consistent expression for the gravitational energy in the de Sitter space.

We will briefly discuss how our procedure applies to the anti-de Sitter solution. The latter is obtained by making the replacement $r^2/R^2 \to -r^2/R^2$ in (11). The anti-de Sitter space is a noncompact manifold with constant negative curvature. The energy contained within a surface of constant radius r_0 can be easily calculated and reads

$$E_g = r_0\left(1 - \sqrt{1+\frac{r_0^2}{R^2}}\right), \tag{21}$$

where we have ignored the mass term m. Here r_0 ranges from 0 to ∞. Therefore as $r_0 \to \infty$, we find that $E_g \to -\infty$. This is an expected result, since the anti-de Sitter space is noncompact. The density of energy per unit radial distance $\varepsilon(r)$ in this case is given by

$$\varepsilon(r) = 1 - \frac{1+\dfrac{2r^2}{R^2}}{\sqrt{1+\dfrac{r^2}{R^2}}}. \tag{22}$$

We find that $\varepsilon(r)=0$ only for $r=0$. This point is also the only global maximum for $\varepsilon(r)$; for $r \to \infty$ we clearly see that $\varepsilon(r) \to -\infty$. Thus $\varepsilon(r)$ is a nonpositive monotonically decreasing function.

IV. DISCUSSION

The definition of gravitational energy is a long-standing problem in the theory of general relativity. Numerous attempts have been made in the past for a solution. This problem still attracts considerable attention in the literature, and remains an important issue to be settled. Essentially all of these previous attempts are in one or another way unsatisfactory. In particular it is widely claimed that the gravitational energy cannot be localized. We do not share this opinion. The mathematical structure of the TEGR shows that not only do we have a consistent and unambiguous definition of gravitational energy for asymptotically flat space–times, naturally built in the Hamiltonian formulation, but also that the gravitational energy is localized. The gravitational energy in the framework of the TEGR is given by expression (9). This expression has been successfully applied to a number of space–times, as we mentioned in Sec. II, whose gravitational energy is already known. A justification for the extension of this definition to more general space–times is not straightforward. In the case of asymptotically flat space–times, the Hamiltonian constraint equation can be written as $C = H - E_{\mathrm{ADM}} = 0$. We assume that this form of the constraint is a general feature of the theory, namely, that we can write the Hamiltonian constraint as $C = H - E$ for an arbitrary space–time, since the constraint structure in general relativity is fixed and does not depend on any particular topology.

In the above we considered the de Sitter solution and concluded that the cosmological constant induces a distribution of gravitational energy largely concentrated in the vicinity of the maximal spacelike radial distance R. This result is in total agreement with the fact that a test particle in the de Sitter space is subject to a radial acceleration directed away from the center of symmetry. Therefore the outcome of our analysis complies with the phenomenological behavior of a test particle in the de Sitter space. To our knowledge this is the first time that such analysis has been provided.

By inspecting Eq. (18) we see that if we make $\Lambda \to 0$ the total energy E_g diverges. The vanishing of Λ in (11) amounts to a change from a compact to a noncompact topology. Therefore such a change is not smooth, as it requires an infinite amount of energy. This fact seems to indicate that, at the classical level, topology changing processes are forbidden.

Gravitational energy of rotating black holes

J. W. Maluf,[a] E. F. Martins, and A. Kneip
Departamento de Física, Universidade de Brasília, C.P. 04385, 70.919-970 Brasília, DF, Brazil

In the teleparallel equivalent of general relativity the energy density of asymptotically flat gravitational fields can be naturally defined as a scalar density restricted to a three-dimensional spacelike hypersurface Σ. Integration over the whole Σ yields the standard ADM energy. Here we obtain the formal expression of the localized energy for a Kerr black hole. The expression of the energy inside a surface of constant radius can be explicitly calculated in the limit of small a, the specific angular momentum. Such expression turns out to be exactly the same as the one obtained by means of the method proposed recently by Brown and York [Phys. Rev. D **47**, 1407 (1993)]. We also calculate the energy contained within the outer horizon of the black hole, for *any* value of a. The result is practically indistinguishable from $E=2M_{ir}$, where M_{ir} is the irreducible mass of the black hole. © *1996 American Institute of Physics.* [S0022-2488(96)02912-X]

I. INTRODUCTION

Although it is widely believed that Einstein's equations describe the dynamics of the gravitational field, it has not been possible so far to arrive at a definite expression for the gravitational energy in the context of Einstein's general relativity. Attempts based on the Hilbert–Einstein action integral fail to yield an expression for the gravitational energy *density*.[1,2] The *total* gravitational energy is normally obtained from surface terms in the action or in the Hamiltonian,[3,4] or from pseudotensor methods which make use of coordinate dependent expressions.

Recently an expression for quasilocal energy has been proposed by Brown and York.[5] Such expression is derived directly from the action functional A_{cl}. The latter is identified as Hamilton's principal function and, in similarity with the classical Hamilton–Jacobi equation, which expresses the energy of a classical solution as minus the time rate of the change of the action, the quasilocal gravitational energy is identified as minus the proper time rate of change of the Hilbert-Einstein action (with surface terms included). Expressions for the quasilocal energy have been obtained for the Schwarzschild solution[5] and for the Kerr solution.[6]

Einstein's equations can also be obtained from the teleparallel equivalent of general relativity (TEGR). The Lagrangian formulation of the TEGR is established by means of the tetrad field $e^{a}{}_{\mu}$ and the spin affine connection $\omega_{\mu ab}$, which are taken to be completely independent field variables, even at the level of field equations. This formulation has been investigated in the past in the context of Poincaré gauge theories.[7,8] However, as we will explain ahead, this is not an alternative theory of gravity. This is just an *alternative formulation* of general relativity, in which the curvature tensor constructed out of $\omega_{\mu ab}$ vanishes, but the torsion tensor is nonvanishing. The physical content of the theory is dictated by Einsten's equations. In this alternative geometrical formulation the gravitational energy density can be naturally defined.

The expression for the gravitational energy density arises in the framework of the Hamiltonian formulation of the TEGR.[9] It has been demonstrated that under a suitable gauge fixing of $\omega_{\mu ab}$, already at the Lagrangian level, the Hamiltonian formulation of the TEGR is well defined. The resulting constraints are first class constraints.[9] The Hamiltonian formulation turns out to be very much similar to the usual ADM formulation.[3] However, there are crucial differences. The integral form of the Hamiltonian constraint equation $C=0$ in the TEGR can be written in the form

0022-2488/96/37(12)/6302/9/$10.00

$C=H-E_{\mathrm{ADM}}=0$, when we restrict considerations to asymptotically flat space–times.[10] The quantity $\varepsilon(x)$, which appears in the expression of C and which under integration yields E_{ADM}, is recognized as the gravitational energy density.

We have calculated the energy inside a sphere of radius r_0 in a Schwarzschild space–time by means of $\varepsilon(x)$.[10] The expression turns out to be exactly the same as the one obtained by means of the procedure of Ref. 5 [expression (6.14) of Ref. 5]. In this paper we consider the Kerr black hole. We obtain the formal expression for the energy contained in any space volume in terms of nontrivial integrals. In the limit of slow rotation (small specific angular momentum) the energy contained within a surface of constant radius r_0 can be calculated. Again the result obtained here is exactly the same as that obtained by Martinez[6] who adopted Brown and York's procedure. The advantage of our procedure rests on the fact that the localized energy associated with a Kerr space–time can be calculated in the general case, without recourse to particular limits, at least by means of numerical integration, whereas in Brown and York's procedure one has to calculate the subtraction term ε^0 and for this purpose it is necessary to embed an arbitrary two-dimensional boundary surface of the Kerr space Σ in the appropriate reference space (E^3, say), which is not always possible.[6]

We have also calculated the energy contained within the outer horizon of the black hole. Such a quantity has been obtained by Martinez[6] in the limit of small a, and reads $E=2M_{ir}$ [plus corrections of order $O(a^4/M_{ir}^4)$], where M_{ir} is the irreducible mass of the black hole. The concept of irreducible mass was introduced by Christodoulou.[11] He showed that the mass of a rotating black hole cannot be decreased to values below M_{ir} by means of Penrose's process of extraction of energy. One would thus consider $E=2M_{ir}$ to be the energy that cannot escape from the black hole. Here we obtain the expression of the energy contained within the horizon for *any* value of a. The result is striking. The numerical values of this expression are practically coincident with $2M_{ir}$ in the whole range $0\leqslant a\leqslant m$, although the expression is algebraically different from $2M_{ir}$.

In Sec. II we present the mathematical preliminaries of the TEGR, its Hamiltonian formulation, and the expression of the energy for an arbitrary asymptotically flat space–time. The establishment of a reference space–time, whose gravitational energy is zero, is performed in Sec. III. In Sec. IV we carry out the construction of triads for a three-dimensional spacelike hypersurface of the Kerr type, obtain the general expression of the energy contained in a volume V of space, and provide the exact expression of the latter in the limit of slow rotation. Comments and conclusions are presented in Sec. V.

Notation: space–time indices $\mu,\nu,\ldots$, and local Lorentz indices $a,b,\ldots$, run from 0–3. In the 3+1 decomposition Latin indices from the middle of the alphabet indicate space indices according to $\mu=0,i$, $a=(0),(i)$. The tetrad field $e^a{}_\mu$ and the spin connection $\omega_{\mu ab}$ yield the usual definitions of the torsion and curvature tensors: $R^a{}_{b\mu\nu}=\partial_\mu\omega_\nu{}^a{}_b+\omega_\mu{}^a{}_c\ \ \omega_\nu{}^c{}_b-\ldots$, $T^a{}_{\mu\nu}=\partial_\mu e^a{}_\nu+\omega_\mu{}^a{}_b e^b{}_\nu-\cdots$. The flat space–time metric is fixed by $\eta_{(0)(0)}=-1$.

II. THE TEGR IN HAMILTONIAN FORM

In the TEGR the tetrad field $e^a{}_\mu$ and the spin connection $\omega_{\mu ab}$ are completely independent field variables. The latter is enforced to satisfy the condition of zero curvature. The Lagrangian density in empty space–time is given by

$$L(e,\omega,\lambda)=-ke(\tfrac{1}{4}T^{abc}T_{abc}+\tfrac{1}{2}T^{abc}T_{bac}-T^aT_a)+e\lambda^{ab\mu\nu}R_{ab\mu\nu}(\omega), \tag{1}$$

where $k=1/16\pi G$, G is the gravitational constant, $e=\det(e^a{}_\mu)$, $\lambda^{ab\mu\nu}$ are Lagrange multipliers, and T_a is the trace of the torsion tensor defined by $T_a=T^b{}_{ba}$.

The equivalence of the TEGR with Einstein's general relativity is based on the identity

$$eR(e,\omega)=eR(e)+e(\tfrac{1}{4}T^{abc}T_{abc}+T^{abc}T_{bac}-T^aT_a)-2\partial_\mu(eT^\mu), \tag{2}$$

which is obtained by just substituting the arbitrary spin connection $\omega_{\mu ab}={}^{o}\omega_{\mu ab}(e)+K_{\mu ab}$ in the scalar curvature tensor $R(e,\omega)$ on the left-hand side; ${}^{o}\omega_{\mu ab}(e)$ is the Levi-Civita connection and $K_{\mu ab}=\frac{1}{2}e_a{}^{\lambda}e_b{}^{\nu}(T_{\lambda\mu\nu}+T_{\nu\lambda\mu}-T_{\mu\nu\lambda})$ is the contorsion tensor. The vanishing of $R^{a}{}_{b\mu\nu}(\omega)$, which is one of the field equations derived from (1), implies the equivalence of the scalar curvature $R(e)$, constructed out of $e^{a}{}_{\mu}$ only, and the quadratic combination of the torsion tensor. It also ensures that the field equation arising from the variation of L with respect to $e^{a}{}_{\mu}$ is strictly equivalent to Einstein's equations in tetrad form. Let $\delta L/\delta e^{a\mu}=0$ denote the field equations satisfied by $e^{a\mu}$. It can be shown by explicit calculations that

$$\frac{\delta L}{\delta e^{a\mu}}=\frac{1}{2}\left\{R_{a\mu}(e)-\frac{1}{2}\,e_{a\mu}R(e)\right\} \tag{3}$$

(we refer the reader to Ref. 9 for additional details).

It is important to notice that for asymptotically flat space–times the total divergence in (2) does *not* contribute to the action integral. This term is a scalar density that falls off as $1/r^3$ when $r\to\infty$. In this limit we should consider variations in $g_{\mu\nu}$ or in $e_{a\mu}$ that preserve the asymptotic structure of the flat space–time metric; the allowed coordinate transformations must be of the Poincaré type. The variation of $\partial_{\mu}(eT^{\mu})$ at infinity under such variations of $e_{a\mu}$ vanishes. Moreover all surface integrals arising from partial integration in the variation of the action integral vanish as well. Therefore the action does not require additional surface terms, as it is invariant under transformations that preserve the asymptotic structure of the field quantities. This property fixes the action integral, together with the requirement that the variation of the latter must yield Einstein's equations (the Hilbert–Einstein Lagrangian requires the addition of a surface term for the variation of the action to be well defined; a clear discussion of this point is given in Ref. 12). In what follows we will be interested in asymptotically flat space–times.

The Hamiltonian formulation of the TEGR can be successfully implemented if we fix the gauge $\omega_{0ab}=0$ from the outset, since in this case the constraints (to be shown below) constitute a *first class* set.[9] The condition $\omega_{0ab}=0$ is achieved by breaking the local Lorentz symmetry of (1). We still make use of the residual time-independent gauge symmetry to fix the usual time gauge condition $e_{(k)}{}^{0}=e_{(0)i}=0$. Because of $\omega_{0ab}=0$, H does not depend on P^{kab}, the momentum canonically conjugated to ω_{kab}. Therefore arbitrary variations of $L=p\dot{q}-H$ with respect to P^{kab} yields $\dot{\omega}_{kab}=0$. Thus in view of $\omega_{0ab}=0$, ω_{kab} drops out from our considerations. The above gauge fixing can be understood as the fixation of a *global* reference frame.

Under the above gauge fixing the canonical action integral obtained from (1) becomes[9]

$$A_{TL}=\int d^4x\{\Pi^{(j)k}\dot{e}_{(j)k}-H\}, \tag{4}$$

$$H=NC+N^{i}C_i+\Sigma_{mn}\Pi^{mn}+\frac{1}{8\pi G}\,\partial_k(NeT^{k})+\partial_k(\Pi^{jk}N_j). \tag{5}$$

Here N and N^{i} are the lapse and shift functions, and $\Sigma_{mn}=-\Sigma_{nm}$ are Lagrange multipliers.

The constraints are defined by

$$C=\partial_j(2keT^{j})-ke\Sigma^{kij}T_{kij}-\frac{1}{4ke}\left(\Pi^{ij}\Pi_{ji}-\frac{1}{2}\,\Pi^{2}\right), \tag{6}$$

$$C_k=-e_{(j)k}\,\partial_i\Pi^{(j)i}-\Pi^{(j)i}T_{(j)ik}, \tag{7}$$

with $e=\det(e_{(j)k})$ and $T^{i}=g^{ik}e^{(j)l}T_{(j)lk}$, where $T_{(j)lk}=\partial_l e_{(j)k}-\partial_k e_{(j)l}$. We remark that (4) and (5) are invariant under global SO(3) and general coordinate transformations.

We assume the asymptotic behavior $e_{(j)k}\approx\eta_{jk}+\frac{1}{2}h_{jk}(1/r)$ for $r\to\infty$. In view of the relation

$$\frac{1}{8\pi G}\int d^3x\ \partial_j(eT^j)=\frac{1}{16\pi G}\int_S dS_k(\partial_i h_{ik}-\partial_k h_{ii})=E_{\mathrm{ADM}}, \tag{8}$$

where the surface integral is evaluated for $r\to\infty$, the integral form of the Hamiltonian constraint $C=0$ may be rewritten as

$$\int d^3x\left\{ke\Sigma^{kij}T_{kij}+\frac{1}{4ke}\left(\Pi^{ij}\Pi_{ji}-\frac{1}{2}\Pi^2\right)\right\}=E_{\mathrm{ADM}}. \tag{9}$$

The integration is over the whole three-dimensional space. Given that $\partial_j(eT^j)$ is a scalar density, from (7) and (8) we define the gravitational energy density enclosed by a volume V of the space as

$$E_g=\frac{1}{8\pi G}\int_V d^3x\ \partial_j(eT^j). \tag{10}$$

It must be noted that E_g depends only on the triads $e_{(k)i}$ restricted to a three-dimensional spacelike hypersurface; the inverse quantities $e^{(k)i}$ can be written in terms of $e_{(k)i}$. From the identity (3) we observe that the dynamics of the triads does not depend on $\omega_{\mu ab}$. Therefore E_g given above does not depend on the fixation of any gauge for $\omega_{\mu ab}$.

III. THE REFERENCE SPACE–TIME

One of the motivations for considering the TEGR was the possibility of establishing a kind of background structure, a space–time on which the gravitational field would be defined, just like the other ordinary fields are defined on Minkowski space–time. This property would follow from the vanishing of $R_{ab\mu\nu}(\omega)$, but eventually is not achieved. Rather than obtaining such a background structure, we arrive at a *reference space–time*, which can be understood as follows. Consider a space with coordinates q^a such that $ds^2=\eta_{ab}\,dq^a\,dq^b$. We can make a coordinate transformation $dq^a=e^a{}_\mu(x)dx^\mu$ and rewrite the infinitesimal element as $ds^2=\eta_{ab}e^a{}_\mu(x)e^b{}_\nu(x)dx^\mu\,dx^\nu=g_{\mu\nu}\,dx^\mu\,dx^\nu$. This transformation can be *holonomic* or *anholonomic*.

Since we are concerned with the Hamiltonian formulation, we will restrict the considerations to spatial coordinates only. In this case the transformation is given by $dq^{(i)}=e^{(i)}{}_j\,dx^j$. As a simple example, consider

$$x^j=(r,\theta,\phi),\quad q^{(i)}=(r\sin\theta\sin\phi, r\sin\theta\cos\phi, r\cos\theta).$$

The infinitesimals $dq^{(i)}$ and dx^j are related by

$$e^{(i)}{}_j(x)=\frac{\partial q^{(i)}}{\partial x^j}=\begin{pmatrix}\sin\theta\cos\phi & r\cos\theta\cos\phi & -r\sin\theta\sin\phi\\ \sin\theta\sin\phi & r\cos\theta\sin\phi & r\sin\theta\cos\phi\\ \cos\theta & -r\sin\theta & 0\end{pmatrix},$$

where (i) is the line index and j the column index. Since the relation $dq^{(i)}=e^{(i)}{}_j\,dx^j$ can be integrated over the whole three-dimensional space, the transformation $q^{(i)}\to x^i$ does correspond to a single-valued global transformation and therefore it is called holonomic. Both sets of coordinates, $\{q^{(i)}\}$ and $\{x^j\}$, describe the three-dimensional Euclidean space.

However, in the general case this relation cannot be globally integrated, since $e^{(i)}{}_j$ may not be written as the gradient of a function, i.e., in general $e^{(i)}{}_j$ is not of the type $\partial q^{(i)}/\partial x^j$. If the quantities $e^{(i)}{}_j$ are such that $\partial_j e^{(i)}{}_k-\partial_k e^{(i)}{}_j\neq 0$, then the transformation is called anholonomic.

For the triads above the torsion tensor $T_{(i)jk}=\partial_j e_{(i)k}-\partial_k e_{(i)j}$ vanishes identically. A crucial result is that $T_{(i)jk}$ vanishes if and only if $\{e^{(i)}{}_j\}$ are gradient vectors.[13] The Levi-Civita connection

${}^{o}\omega_{m(i)(j)} = -\frac{1}{2}e^{(k)}{}_{m}(\Omega_{(i)(j)(k)} - \Omega_{(j)(i)(k)} - \Omega_{(k)(i)(j)})$, $\Omega_{(i)(j)(k)}=e_{(i)m}(e_{(j)}{}^{n}\,\partial_n e_{(k)}{}^{m} - e_{(k)}{}^{n}\,\partial_n e_{(j)}{}^{m})$, constructed out of triads which are gradient vectors, vanishes identically, and so does the curvature tensor $R_{(i)(j)mn}({}^{o}\omega)$. Thus the triads $e^{(i)}{}_{j}=\partial_j q^{(i)}$ are necessarily equivalent to the triads of the flat Euclidean space (the metric $g_{ij}=\partial_i q^{(m)}\,\partial_j q^{(n)}\,\eta_{(m)(n)}$ can be interpreted as a coordinate transformation of the constant flat metric).

In the framework of the Hamiltonian formulation of the TEGR the gravitational field corresponds to a configuration for which $T_{(i)jk}\neq 0$. Therefore *every* gravitational field is *anholonomically* related to the three-dimensional Euclidean space, which is to be taken as the reference space. Since the torsion tensor vanishes for the latter, as we have seen, the total gravitational energy of the reference space is zero (the gravitational energy density vanishes as well).

IV. ENERGY OF THE KERR GEOMETRY

The Kerr solution[14] describes the field of a rotating black hole. In terms of Boyer and Lindquist coordinates[15] (t,r,θ,ϕ) it is described by the metric

$$ds^2=-\frac{\Delta}{\rho^2}\,[dt-a\,\sin^2\,\theta\,d\phi]^2+\frac{\sin^2\,\theta}{\rho^2}\,[(r^2+a^2)d\phi-a\,dt]^2+\frac{\rho^2}{\Delta}\,dr^2+\rho^2\,d\theta^2,$$

$$\Delta\equiv r^2-2mr+a^2, \tag{11}$$

$$\rho^2\equiv r^2+a^2\,\cos^2\,\theta;$$

a is the specific angular momentum defined by $a=J/m$. The components of the metric restricted to the three-dimensional spacelike hypersurface are given by $g_{11}=\rho^2/\Delta$, $g_{22}=\rho^2$, and $g_{33}=(\Sigma^2/\rho^2)\sin^2\,\theta$, where Σ is defined by

$$\Sigma^2=(r^2+a^2)^2-\Delta a^2\,\sin^2\,\theta.$$

We define the triads $e_{(k)i}$ as

$$e_{(k)i}=\begin{pmatrix} \frac{\rho}{\sqrt{\Delta}}\sin\,\theta\,\cos\,\phi & \rho\,\cos\,\theta\,\cos\,\phi & -\frac{\Sigma}{\rho}\sin\,\theta\,\sin\,\phi \\ \frac{\rho}{\sqrt{\Delta}}\sin\,\theta\,\sin\,\phi & \rho\,\cos\,\theta\,\sin\,\phi & \frac{\Sigma}{\rho}\sin\,\theta\,\cos\,\phi \\ \frac{\rho}{\sqrt{\Delta}}\cos\,\theta & -\rho\,\sin\,\theta & 0 \end{pmatrix}, \tag{12}$$

(k) is the line index and i is the column index. The one form $e^{(k)}$ is defined by

$$e^{(k)}=e^{(k)}{}_{r}\,dr+e^{(k)}{}_{\theta}\,d\theta+e^{(k)}{}_{\phi}\,d\phi;$$

from what follows

$$e^{(k)}e_{(k)}=\frac{\rho^2}{\Delta}\,dr^2+\rho^2\,d\theta^2+\frac{\Sigma^2}{\rho^2}\,\sin^2\,\theta\,d\phi^2.$$

We also obtain $e=\det(e_{(k)i})=(\rho\Sigma/\sqrt{\Delta})\sin\,\theta$. Therefore the triads given by (12) describe the components of the Kerr solution restricted to the three-dimensional spacelike hypersurface.

One readily notices that there is another set of triads that yields the Kerr solution, namely, the set which is diagonal and whose entries are given by the square roots of g_{ii}. This set is not

appropriate for our purposes, and the reason can be understood even in the simple clase of flat space–time. In the limit when both a and m go to zero, (12) describes flat space: the curvature tensor *and* the torsion tensor vanish in this case, as we have seen in Sec. III. However, for the diagonal set of triads (again requiring $a\to 0$ and $m\to 0$),

$$e^{(r)}=dr, \quad e^{(\theta)}=r d\theta, \quad e^{(\phi)}=r\ \sin\ \theta\ d\phi,$$

some components of the torsion tensor do not vanish, $T_{(2)12}=1$, $T_{(3)13}=\sin\theta$, and E_g calculated out of the diagonal set above diverges when integrated over the whole space. Therefore the use of (12) is mandatory in the present context, as it is the only possible choice [modulo global SO(3) rotations].

The components of the torsion tensor can be calculated in a straightforward way from (12). Only $T_{(3)13}$ and $T_{(3)23}$ are vanishing. The others are given by

$$T_{(1)12}=\cos\ \theta\ \cos\ \phi\left(\frac{r}{\rho}+\frac{a^2}{\rho\sqrt{\Delta}}\sin^2\ \theta-\frac{\rho}{\sqrt{\Delta}}\right),$$

$$T_{(1)13}=\sin\ \theta\ \sin\ \phi\left\{-\frac{1}{\rho\Sigma}\left[2r(r^2+a^2)-a^2\ \sin^2\ \theta(r-m)\right]+\frac{r\Sigma}{\rho^3}+\frac{\rho}{\sqrt{\Delta}}\right\},$$

$$T_{(1)23}=\cos\ \theta\ \sin\ \phi\left\{\rho-\frac{\Sigma}{\rho}+a^2\ \sin^2\ \theta\left(\frac{\Delta}{\rho\Sigma}-\frac{\Sigma}{\rho^3}\right)\right\},$$

$$T_{(2)12}=\cos\ \theta\ \sin\ \phi\left(\frac{r}{\rho}+\frac{a^2}{\rho\sqrt{\Delta}}\sin^2\ \theta-\frac{\rho}{\sqrt{\Delta}}\right),$$

$$T_{(2)13}=-\sin\ \theta\ \cos\ \phi\left\{-\frac{1}{\rho\Sigma}\left[2r(r^2+a^2)-a^2\ \sin^2\ \theta(r-m)\right]+\frac{r\Sigma}{\rho^3}+\frac{\rho}{\sqrt{\Delta}}\right\},$$

$$T_{(2)23}=-\cos\ \theta\ \cos\ \phi\left\{\rho-\frac{\Sigma}{\rho}+a^2\ \sin^2\ \theta\left(\frac{\Delta}{\rho\Sigma}-\frac{\Sigma}{\rho^3}\right)\right\},$$

$$T_{(3)12}=\sin\ \theta\left[-\frac{r}{\rho}+\frac{\rho}{\sqrt{\Delta}}+\frac{a^2}{\rho\sqrt{\Delta}}\cos^2\ \theta\right].$$

In order to evaluate (9) we need to obtain T^i. After a long calculation we arrive at

$$T^1=\frac{\sqrt{\Delta}}{\rho^2}+\frac{\sqrt{\Delta}}{\Sigma}-\frac{\Delta}{\rho^2\Sigma^2}\left[2r(r^2+a^2)-a^2\ \sin^2\ \theta(r-m)\right],$$

$$T^2=\sin\ \theta\ \cos\ \theta\frac{a^2}{\rho^4}+\frac{1}{\rho\Sigma}\frac{\cos\ \theta}{\sin\ \theta}\left[\rho-\frac{\Sigma}{\rho}+a^2\ \sin^2\ \theta\left(\frac{\Delta}{\rho\Sigma}-\frac{\Sigma}{\rho^3}\right)\right],$$

$$T^3=0.$$

The gravitational energy density inside a volume V of a three-dimensional spacelike hypersurface of the Kerr solution can now be easily calculated (in what follows we will make $G=1$). It is given by

$$E_g=\frac{1}{8\pi}\int_V dr\ d\theta\ d\phi\Bigg\{\frac{\partial}{\partial r}\left[\sin\theta\left[\rho+\frac{\Sigma}{\rho}-\frac{\sqrt{\Delta}}{\rho\Sigma}\left(2r(r^2+a^2)-a^2\sin^2\theta(r-m)\right)\right]\right]$$
$$+\frac{\partial}{\partial\theta}\left[\frac{\Sigma a^2}{\sqrt{\Delta}\rho^3}\sin^2\theta\cos\theta+\frac{\cos\theta}{\sqrt{\Delta}}\left(\rho-\frac{\Sigma}{\rho}+a^2\sin^2\theta\left(\frac{\Delta}{\rho\Sigma}-\frac{\Sigma}{\rho^3}\right)\right)\right]\Bigg\}. \tag{13}$$

Next we specialize E_g to the case when the volume V is contained within a surface with constant radius $r=r_o$ assuming $r_o\geqslant r_+$, where $r_+=m+\sqrt{m^2-a^2}$ is the outer horizon of the black hole. The integrations in ϕ and r are trivial. Also, because we integrate θ between 0 and π, the second line of the expression above vanishes. We then obtain

$$E_g=\frac{1}{4}\int_0^\pi d\theta\sin\theta\left\{\rho+\frac{\Sigma}{\rho}-\frac{\sqrt{\Delta}}{\rho\Sigma}\left(2r(r^2+a^2)-a^2\sin^2\theta(r-m)\right)\right\}_{r=r_o}. \tag{14}$$

We have not managed to evaluate exactly the integral above. However, in the limit of slow rotation, namely, when $a/r_o\ll 1$, all integrals have a simple structure and we can obtain the approximate expression of E_g. It reads

$$E_g=r_o\left(1-\sqrt{1-\frac{2m}{r_o}+\frac{a^2}{r_o^2}}\right)+\frac{a^2}{6r_o}\left[2+\frac{2m}{r_o}+\left(1+\frac{2m}{r_o}\right)\sqrt{1-\frac{2m}{r_o}+\frac{a^2}{r_o^2}}\right]. \tag{15}$$

This is exactly the expression found by Martinez[6] for the energy inside the surface of constant radius r_o in a spacelike hypersurface of a Kerr black hole, in the limit of small specific angular momentum. As in Ref. 6, we have not expanded the square root which appears in (15) in powers in a^2/r_o^2.

We remark that the expansion of $\rho+\Sigma/\rho$ in the integrand of (14) yields $-\varepsilon_0$, whereas the remaining term corresponds exactly to ε, expressions (3.17) and (3.1), respectively, of Ref. 6. It does not seem to be possible, however, to split $\partial_i(eT^i)$ into two terms such that their integrals arise in the form $\varepsilon-\varepsilon_0$.

As a very interesting application of (14), let us calculate the energy contained within the outer horizon, i.e., we will calculate (14) when the surface of constant radius is defined by $r_o=r_+$. This surface is characterized by $\Delta=0$. The integral can be calculated exactly for *any* value of a. The latter is parametrized in terms of the black hole mass m according to

$$a=km,\quad 0\leqslant k\leqslant 1.$$

After a number of integrations we arrive at

$$E_g=m\left[\frac{\sqrt{2p}}{4}+\frac{6p-k^2}{4k}\ln\left(\frac{\sqrt{2p}+k}{p}\right)\right], \tag{16}$$

where p is defined by

$$p=1+\sqrt{1-k^2}.$$

This is the amount of energy expected not to escape from the black hole by any process in which the black hole interacts with external particles. It is then important to compare (16) with $E=2M_{ir}$.

We recall that a rotating black hole can have its mass decreased by means of Penrose's process of extraction of energy.[16] The idea is the following. We consider a particle that is emitted towards the black hole and penetrates into the ergosphere. Suppose we arrange the particle to break up into two fragments, in such a way that one of the fragments has total negative energy.

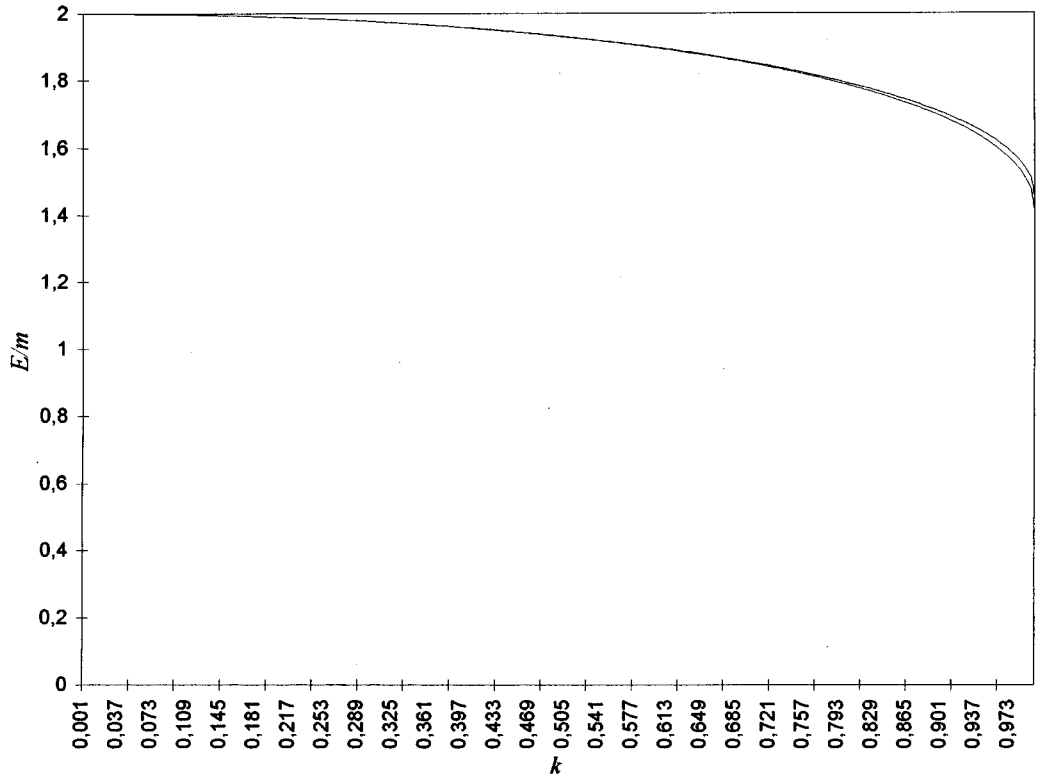

FIG. 1. E/m against k. The upper curve represents the energy expression (16), the lower one (17).

This is possible in principle, since the energy need not be positive in the ergosphere. By conservation of energy, the fragment with positive energy has an energy greater than that of the incident particle. Thus energy will be extracted from the black hole if the positive energy particle escapes to infinity, while the black hole absorbs the negative energy one. As a consequence, the mass of the black hole is decreased. We expect, however, that not the whole energy of the black hole can be extracted in this manner. The existence of the horizon certainly prevents one from exhausting the total energy. Christodoulou[11] has given an argument to determine how much energy can be extracted from the black hole by Penrose's process. He concluded that at the end of this process (when the ergosphere disappears and the black hole becomes static) the final (irreducible) mass of the black hole is given by

$$M_{ir}=\tfrac{1}{2}\sqrt{r_+^2+a^2}.$$

Martinez[6] has calculated the energy inside the horizon of the Kerr black hole in the limit of small a. He arrived at $E=2M_{ir}[1+O(a^4/M_{ir}^4)]$. A similar result (in the same approximation) has been obtained by Zaslavskii[17] in the analysis of a generic axially symmetric space–time. The question immediately arises as to whether this relationship holds for *any* value of a. This is, in fact, the conjecture made in Ref. 6.

Since expressions (14) and (16) are valid for *any* value of a in the appropriate range, it is worth comparing (16) with $2M_{ir}$. In our parametrization we have

$$E=2M_{ir}=m\sqrt{2p}. \tag{17}$$

The expression above certainly looks different from (16). However, in the range $0 \leqslant a \leqslant m$ expressions (16) and (17) as functions of k are strikingly indistinguishable, as we can see in Fig. 1. In the latter we have plotted E/m against k. The upper curve represents (16), the lower one (17). We see that for small values of the parameter k the two curves are essentially coincident. A tiny deviation occurs for values of k near 1. Inspite of this deviation, this is a remarkable result in favor of (14).

Unfortunately we have not been able to explain such small deviation between (16) and (17) for values of k near 1, although we expect such explanation to be of fundamental importance. It might be related to some physical property of the Kerr black hole which we do not understand yet.

V. COMMENTS

The gravitational energy E_g defined by (14) can be evaluated for an arbitrary value of a by means of numerical integration. This is the major advantage of our procedure as compared to that of Brown and York.[5] By means of the latter one cannot construct expressions like (13) and (14), which may be useful in the study of astrophysical problems, since in a general situation Brown and York's procedure requires the embedding of an arbitrary two-dimensional boundary surface of the Kerr space in the reference space E^3, a construction which is not possible in general[6] (the evaluation of ε_0 in Ref. 6 is only possible in the limit $a/r_0 \ll 1$). Therefore the present approach is more general than that of Ref. 6. Finally we remark that we expect expression (10) to be useful in the study of the thermodynamics of self-gravitating systems, where the gravitational energy plays the role of the thermodynamical internal energy that is conjugate to the inverse temperature. We hope to come to this issue in the future.

Subalgebras with converging star products in deformation quantization: An algebraic construction for $\mathbb{C}P^n$

M. Bordemann,[a] M. Brischle,[b] C. Emmrich,[c] and S. Waldmann[d]
Fakultät für Physik, Universität Freiburg, Hermann-Herder-Str. 3, 79104 Freiburg i. Br., Germany

(Received 6 June 1996; accepted for publication 2 July 1996)

Based on a closed formula for a star product of Wick type on $\mathbb{C}P^n$, which has been discovered in an earlier article of the authors, we explicitly construct a subalgebra of the formal star algebra (with coefficients contained in the uniformly dense subspace of representative functions with respect to the canonical action of the unitary group) that consists of *converging* power series in the formal parameter, thereby giving an elementary algebraic proof of a convergence result already obtained by Cahen, Gutt, and Rawnsley. In this subalgebra the formal parameter can be substituted by a real number α: the resulting associative algebras are infinite dimensional, except for the case $\alpha=1/K$, K a positive integer, where they turn out to be isomorphic to the finite-dimensional algebra of linear operators in the Kth energy eigenspace of an isotropic harmonic oscillator with $n+1$ degrees of freedom. Other examples like the $2n$ torus and the Poincaré disk are discussed. © *1996 American Institute of Physics.* [S0022-2488(96)04112-6]

I. INTRODUCTION

The concept of deformation quantization as defined by Bayen *et al.* in 1978 (cf. Ref. 1) consists in a formal local deformation of the commutative algebra (a so-called star product) of all smooth complex-valued functions on a symplectic manifold, such that the first-order commutator equals the Poisson bracket and pointwise complex conjugation remains an antilinear involution. The existence of star products on every symplectic manifold was proved by DeWilde and Lecomte in 1983 (cf. Ref. 2) and independently by Fedosov in 1985.[3,4] A third existence proof was given by Omori, Maeda, and Yoshioka.[5]

One of the problems with these star products is the fact that the formal series involved is shown to never converge on the space of *all* complex-valued smooth functions (see, e.g., Ref. 6), i.e. for every complex number there are two functions whose star product diverges when the formal parameter is substituted for that number.

This paper is a continuation of our work[7] in which we gave a closed formula for a star product of the Wick type on complex projective space by a version of quantum phase space reduction. Star products on complex projective space have already been constructed by Omori, Maeda, and Yoshioka[8] and by Moreno[9] in a less explicit way. $\mathbb{C}P^n$ can also be regarded as a coadjoint orbit of the unitary group $U(n+1)$ (see the work of Arnal, Ludwig, and Masmoudi for the existence of covariant star products on more general coadjoint orbits in Ref. 10 and references therein).

The aim of the present paper is twofold: first, we use our formula to explicitly compute the star product for a uniformly dense subalgebra of representative functions for the $U(n+1)$ action on complex projective space. Second, we would like to use the example $\mathbb{C}P^n$ in order to illustrate the following *algebraic* procedure to deal with the above convergence problem.

(i) Find a complex subalgebra $\mathscr{A}$ of the $*$ algebra of all formal power series in ν with smooth

[a]Electronic mail: mbor@phyq1.physik.uni-freiburg.de
[b]Electronic mail: brischle@phyq1.physik.uni-freiburg.de
[c]Electronic mail: cemm@phyq1.physik.uni-freiburg.de
[d]Electronic mail: waldman@phyq1.physik.uni-freiburg.de

coefficients, such that (1) all elements of $\mathscr{U}$ are power series with infinite radius of convergence in ν, and (2) their coefficients may be chosen in a ''sufficiently large'' (e.g., uniformly dense) subspace of the space of all smooth complex-valued functions.

(ii) Verify whether the subspace $\mathscr{I}_\alpha$ of $\mathscr{U}$ defined by

$$\mathscr{I}_\alpha := \{\Phi(\nu) \in \mathscr{U} | \Phi(\alpha) = 0\}, \tag{1}$$

is a star ideal of $\mathscr{U}$.

(iii) Identify the quotient $\mathscr{U}/\mathscr{I}_\alpha$ with the associative algebra of quantum observables related to the ''$\hbar$ value'' α and try to find a representation of this quotient in some Hilbert space.

From the physical point of view it is often required that the subalgebra $\mathscr{U}$ contains certain ''important observables,'' which are in some cases related to the presence of additional symmetries of the classical phase space. For a general symplectic manifold the viability of the above procedure (in particular the existence of a sufficiently large subalgebra $\mathscr{U}$) is—to our best knowledge—an open problem in the theory of deformation quantization.

Nevertheless, in several examples having a large symmetry group (e.g., the Moyal product on the 2-torus or the Wick product on $\mathbb{C}^{n+1}$) the above program may be carried out. For such manifolds the space of representative functions of the symmetry group plays a prominent role for the construction of $\mathscr{U}$: in a remarkable article of Cahen, Gutt, and Rawnsley[11] the convergence of a star product for these functions has been proved for all compact Hermitian spaces (in particular, for $\mathbb{C}P^n$) by analytic methods of complex differential geometry. They start from the finite-dimensional operator algebras of geometric quantization in tensor powers of a very ample regular prequantum line bundle over a compact Kähler manifold and use coherent states (see Refs. 12 and 13) to first construct star products for the Berezin–Rawnsley symbols (Refs. 12 and 13) for each tensor power separately. In a second step an asymptotic expansion of these star products in the inverse tensor power is shown to define a local star product on the manifold where the formal parameter appears as a sort of interpolation of the inverse tensor powers.

The approach of this paper is in some sense reverse to the program of Cahen, Gutt, and Rawnsley (cf. Refs. 14, 11, 15, and 16) and only makes use of elementary algebraic methods: We start from the explicit star product on $\mathbb{C}P^n$ (see Ref. 7) and define $\mathscr{U}$ as a certain proper subspace of the space of all polynomials in the formal parameter with coefficients in the uniformly dense subspace of representative functions for the unitary group $U(n+1)$. Since all occurring star products can explicitly be computed the analysis of the ideals $\mathscr{I}_\alpha$ and the quotient algebras $\mathscr{U}/\mathscr{I}_\alpha$ becomes relatively simple. The main result is that for inverse integer values of the formal parameter ν the quotient algebras turn out to be finite-dimensional full complex matrix algebras, whereas all noninteger quotients are of infinite dimension and define converging star products on the space of representative functions for these values, as has been stated in Ref. 11.

From the physical point of view one can regard the finite-dimensional quantum algebras as the set of all quantum observables restricted to the eigenspace of integral energy of a harmonic oscillator of $n+1$ degrees of freedom (where the ground state energy is zero for the Wick quantization rule).

The advantage of the above algebraic program of prescribing a real value to the formal parameter of deformation quantization is that one may hope to transfer it to physical situations with an infinite number of degrees of freedom, i.e. field theories, where the powerful analytical methods in the theory of finite-dimensional manifolds are no longer well defined.

The paper is organized as follows: after briefly reviewing the concepts and formulas of our last paper,[7] in Sec. II we compute the star product of two Berezin–Rawnsley symbols in Sec. III and discuss the unitary symmetry action on the star product. Section IV is then devoted to defining the algebra $\mathscr{U}$, to compute the ideals $\mathscr{I}_\alpha$ and the quotient algebras $\mathscr{U}/\mathscr{I}_\alpha$. In Sec. V we briefly consider other phase spaces already dealt with in the literature for which the above program works: the complex vector space $\mathbb{C}^{n+1}$ with the Wick product, the $2n$-torus T^{2n} with the Moyal

product, and the Poincaré disk. For this last example we can recover the formula of the star product for the corresponding Berezin–Rawnsley symbols given by Cahen, Gutt, and Rawnsley in Ref. 15.

Notation: Throughout this paper we use the Einstein summation convention, i.e. summation over repeated indices is automatic. Moreover, the symbol $F(z)$ for a complex-valued function F of a complex vector z does *not* necessarily imply that F is holomorphic.

II. REVIEW OF STAR PRODUCTS ON COMPLEX PROJECTIVE SPACE

In this section we shall give a short review of earlier work[7] in which we derived an explicit formula for a star product of the Wick type on the complex projective space $\mathbb{C}P^n$.

Let $\pi:\mathbb{C}^{n+1}\backslash\{0\}\to\mathbb{C}P^n$ be the canonical projection of a complex vector z onto the complex ray through it. Let $x:=\overline{z^l}z^i$. The usual Wick product on $\mathbb{C}^{n+1}\backslash\{0\}$ of two complex-valued functions $F,G\in C^\infty(\mathbb{C}^{n+1}\backslash\{0\})$ is given as the following formal power series in the parameter λ:

$$F*G=\sum_{r=0}^{\infty}\frac{\lambda^r}{r!}\frac{\partial^r F}{\partial z^{i_1}\cdots\partial z^{i_r}}\frac{\partial^r G}{\partial\overline{z^{i_1}}\cdots\partial\overline{z^{i_r}}}. \tag{2}$$

We have called a function $F\in C^\infty(\mathbb{C}^{n+1}\backslash\{0\})$ *homogeneous* iff it is invariant under the natural action of the group $\mathbb{C}\backslash\{0\}$. These functions are precisely given by pullbacks of functions $f\in C^\infty(\mathbb{C}P^n)$, $F=f\circ\pi=\pi^*f$. We have called a function $R\in C^\infty(\mathbb{C}^{n+1}\backslash\{0\})$ *radial* iff it is a function of x, i.e. iff there is a smooth function $\rho:\mathbb{R}^+\to\mathbb{C}$ such that $R=\rho\circ x$. We have defined a formal differential operator $S:C^\infty(\mathbb{C}^{n+1}\backslash\{0\})[[\lambda]]\to C^\infty(\mathbb{C}^{n+1}\backslash\{0\})[[\lambda]]$ depending only on x and $\partial_x:=(1/2x)(z^i\partial_{z^i}+\overline{z^i}\partial_{\overline{z^i}})$ whose standard symbol $\hat{S}(x,\alpha):=(Se_\alpha)(x)e^{-\alpha x}$ (e_α denoting the exponential function $x\mapsto e^{\alpha x}$ for $\alpha\in\mathbb{R}$) is given by [setting the series D in Ref. 7, Eq. (9) equal to 1]:

$$\hat{S}(x,\alpha)=\exp\left(\frac{x}{\lambda}(\log(1+\lambda\alpha)-\lambda\alpha)\right). \tag{3}$$

S and its inverse S^{-1} act trivially on homogeneous functions, i.e. $SF=F=S^{-1}F$, but do in general transform radial functions into radial ones, in particular (for a non-negative integer r) [Ref. 7, Eq. (14)]

$$Sx=x,\quad Sx^r=x^r\prod_{k=0}^{r}\left(1-k\frac{\lambda}{x}\right),\quad Sx^{-r}=x^{-r}\prod_{k=0}^{r}\left(1+k\frac{\lambda}{x}\right)^{-1}. \tag{4}$$

We have used S as an equivalence transformation for a modified Wick product of two functions $F,G\in C^\infty(\mathbb{C}^{n+1}\backslash\{0\})$:

$$F\tilde{*}G:=S(S^{-1}F*S^{-1}G). \tag{5}$$

For two radial functions R_1, R_2 and a homogeneous function F on $\mathbb{C}^{n+1}\backslash\{0\}$ this new star product is just pointwise multiplication [Ref. 7, Eq. (12)]:

$$R_1\tilde{*}R_2=R_1R_2=R_2\tilde{*}R_1,\quad R_1\tilde{*}F=R_1F=F\tilde{*}R_1, \tag{6}$$

whereas for two smooth homogeneous functions F,G we obtain

$$(F\tilde{*}G)(z)=\sum_{r=0}^{\infty}\frac{1}{r!}\left(\frac{\lambda}{x}\right)^r\prod_{k=1}^{r}\left(1+k\frac{\lambda}{x}\right)^{-1}x^r\frac{\partial^r F}{\partial z^{i_1}\cdots\partial z^{i_r}}(z)\frac{\partial^r G}{\partial\overline{z^{i_1}}\cdots\partial\overline{z^{i_r}}}(z). \tag{7}$$

The main result of Ref. 7 was the fact that this formula can directly be projected to $\mathbb{C}P^n$ by phase space reduction via the $U(1)$-momentum map $J:\mathbb{C}^{n+1}\backslash\{0\}\to\mathbb{R}:z\mapsto -x/2$ of the canonical $U(1)$ action on $\mathbb{C}^{n+1}\backslash\{0\}$: for a negative real number μ and a $U(1)$ invariant function F in $C^\infty(\mathbb{C}^{n+1}\backslash\{0\})$ we write F_μ for the unique function in $C^\infty(\mathbb{C}P^n)$ obtained by first restricting F to the odd sphere $J^{-1}(\mu)$ and then projecting it to $\mathbb{C}P^n$ (Ref. 17, Sec. 4.3). Then the formula,

$$F_\mu *^\mu G_\mu := (F\tilde{*}G)_\mu, \tag{8}$$

was shown to define a star product on $\mathbb{C}P^n$. The explicit form of $*^\mu$ is obtained by replacing λ/x by $\lambda/(-2\mu)$ in (7) and noting that the bidifferential operator $\tilde{M}_r(f,g)(\pi(z)) := x^r[\partial^r \pi^* f(z)/\partial z^{i_1}\cdots\partial z^{i_r}][\partial^r \pi^* g(z)/\partial \overline{z^{i_1}}\cdots\partial \overline{z^{i_r}}]$ is well defined on $f,g\in C^\infty(\mathbb{C}P^n)$. For simplicity we shall work with the redefined formal parameter $\nu:=\lambda/(-2\mu)$ in what follows.

Lemma 1: The standard symbol of S^{-1} is described by the formula

$$\widehat{S^{-1}}(x,\alpha) = e^{(x/\lambda)(e^{\alpha\lambda}-1-\alpha\lambda)} = e^{*\alpha x}e^{-\alpha x}, \tag{9}$$

where the last term involves the star exponential[1] of the function x with respect to the usual Wick product (2).

Proof: Since $Se_\beta = e_{(1/\lambda)\log(1+\beta\lambda)}$ we obviously get $e_\beta = S^{-1}e_{(1/\lambda)\log(1+\beta\lambda)}$, which proves the first equation after the substitution $\alpha:=(1/\lambda)\log(1+\beta\lambda)$. Second, note that

$$e^{*\alpha x} = S^{-1}Se^{*\alpha S^{-1}x} = S^{-1}e^{\tilde{*}\alpha x} \overset{(6)}{=} S^{-1}e^{\alpha x} = \widehat{S^{-1}}(x,\alpha)e^{\alpha x},$$

which proves the second equality. □

Remark: Note that the function $H:=1/2x$ equals the usual Hamiltonian function of an isotropic harmonic oscillator in $n+1$ degrees of freedom. The above star exponential of x for $\alpha=-it/2\hbar$ and $\lambda=2\hbar$ then corresponds to the quantum mechanical time development operator for this system.

III. A STAR PRODUCT FOR REPRESENTATIVE FUNCTIONS ON COMPLEX PROJECTIVE SPACE

Let $p:\mathbb{C}^{n+1}\to\mathbb{C}:z\mapsto P(z)$ be a polynomial function (in the $2n+2$ variables $z^0,\ldots,z^n,\overline{z^0},\ldots,\overline{z^n}$). We shall call *$p$ homogeneous of degree (k,k)* for a non-negative integer k iff $p(\lambda z)=(\lambda\lambda)^k p(z)$ for all $\lambda\in\mathbb{C}\backslash\{0\}$. We denote by $\mathscr{E}_k$ the following subspace of $C^\infty(\mathbb{C}P^n)$:

$$\mathscr{E}_k := \left\{ \phi \;\middle|\; \text{there is a homogeneous polynomial } p_k \text{ of degree } (k,k) \text{ s.t. } (\pi^*\phi)(z) = \frac{1}{x^k}\, p_k(z) \right\}. \tag{10}$$

Lemma 2:

(i) For each integer $k\geqslant:\mathscr{E}_k\subset\mathscr{E}_{k+1}$.

(ii) $\mathscr{E}:=\cup_{k=0}^\infty \mathscr{E}_k$ is a filtered subalgebra of $C^\infty(\mathbb{C}P^n)$ with respect to the pointwise multiplication. It is closed under complex conjugation.

(iii) $\mathscr{E}$ separates points and is therefore a dense subalgebra of $C^\infty(\mathbb{C}P^n)$ with respect to the uniform topology.

Proof: (i) Clearly $p_k/x^k = xp_k/x^{k+1}\in\pi^*\mathscr{E}_{k+1}$. (ii) This is obvious. (iii) Consider the complex rays $\pi(z_{(1)})\neq\pi(z_{(2)})$ for $z_{(1)},z_{(2)}\in\mathbb{C}^{n+1}\backslash 0$. This is true iff $z_{(1)},z_{(2)}$ are linearly independent iff there is a $y\in\mathbb{C}^{n+1}$, such that $\langle y,z_{(1)}\rangle=1$ and $\langle y,z_{(2)}\rangle=0$, where $\langle y,z\rangle$ denotes the standard ses-

quilinear form $\langle y,z\rangle=\overline{y^k}z^k$. Then $\phi\in\mathscr{E}_1$ defined by $\phi(\pi(z)):=|\langle y,z\rangle|^2/x$ separates $\pi(z_{(1)})$ and $\pi(z_{(2)})$. The density of $\mathscr{E}$ follows from the Stone–Weierstrass Theorem. □

Consider the standard action of the unitary group $U(n+1)$ on $\mathbb{C}^{n+1}\backslash\{0\}$: $(g,z)\mapsto gz=:\Phi_g(z)$ and its induced action on $\mathbb{C}P^n$: $(g,\pi(z))\mapsto\pi(gz)=:\Psi_g(\pi(z))$. A smooth complex-valued function f on $\mathbb{C}P^n$ is called *representative* with respect to the $U(n+1)$ action iff

$$\mathbb{C}\text{-span}\{f\circ\Psi_g|g\in U(n+1)\}\ \text{ is finite dimensional.} \tag{11}$$

We now get a characterization of $\mathscr{E}$ that should be fairly standard (see Ref. 11, Sec. 3, Lemma 1).

Lemma 3: The algebra $\mathscr{E}$ is equal to the set of all representative functions on $\mathbb{C}P^n$.

Proof: Since x and the finite-dimensional space of all homogeneous polynomials of degree (k,k) are invariant under $U(n+1)$, it follows that $\mathscr{E}$ consists of representative functions. In order to prove the reversed inclusion we can use a more general argument: $\mathbb{C}P^n$ is a homogeneous space G/H for the compact Lie group $G=U(n+1)$ with compact isotropy subgroup $H=U(1)\times U(n)$. Now the space of all representative functions f on G/H [defined as in (11) with $U(n+1)$ replaced by any compact Lie group G] is clearly in one-to-one correspondence with the space of its pullback to G under the natural projection $G\to G/H$: this in turn is given by the space of all H right invariant representative functions on G with respect to left multiplication. Both this space and the pullback of $\mathscr{E}$ to G are G modules and are therefore closed in the space of all representative functions on G with respect to the uniform topology on G [see, e.g., Ref. 18, p. 126, Prop. (1.4) (iii)]. Since the pullback obviously is a continuous closed linear map with respect to the uniform topologies and $\mathscr{E}$ is dense in the space of all representative functions on G/H; thanks to the previous Lemma it follows that $\mathscr{E}$ is equal to that space. □

Yet another equivalent description of $\mathscr{E}$ is obtained in terms of the *Berezin–Rawnsley symbols* known from geometric quantization (Refs. 12–14): for a fixed non-negative integer k take the vector space $\mathscr{H}^{(k)}$ of complex-valued holomorphic polynomials ψ on $\mathbb{C}^{n+1}$, which are homogeneous of degree k, i.e. $\psi(\lambda z)=\lambda^k\psi(z)$ for all complex numbers λ. The dimension of this space is clearly $N:=\binom{n+k}{k}$ and we shall henceforth identify $\mathscr{H}^{(k)}$ with $\mathbb{C}^N$ by means of the base $(z^{i_1}\cdots z^{i_k})$. Consider the space $B(\mathscr{H}^{(k)})$ of complex linear endomorphisms of $\mathscr{H}^{(k)}$. Any $A\in B(\mathscr{H}^{(k)})$ can be viewed as a complex $N\times N$ matrix $A_{i_1\cdots i_k,j_1\cdots j_k}$, where each of the indices $i_1,\ldots,i_k,j_1,\ldots,j_k$ ranges over 0,1,...,n and the matrix elements are symmetric with respect to all permutations among the $i_1,\ldots,i_k$ and among the $j_1,\ldots,j_k$. To each $A\in B(\mathscr{H}^{(k)})$ one can associate the polynomial function,

$$\widetilde{\sigma}(A):\mathbb{C}^{n+1}\to\mathbb{C}:z\mapsto\overline{z^{i_1}}\cdots\overline{z^{i_k}}z^{j_1}\cdots z^{j_k}A_{i_1\cdots i_k,j_1\cdots j_k}. \tag{12}$$

Clearly, $\widetilde{\sigma}(A)$ is homogeneous of degree (k,k), and by counting dimensions it can be seen that every homogeneous polynomial function of degree (k,k) is of that form. The *Berezin–Rawnsley symbol $\sigma(A)$ associated to A* is then defined by

$$\sigma(A):\mathbb{C}P^n\to\mathbb{C}:\pi(z)\mapsto\frac{\widetilde{\sigma}(A)(z)}{x^k}. \tag{13}$$

Then the following corollary is clear.

Corollary 1: For each nonnegative integer k the space $\mathscr{E}_k$ is spanned by all the Berezin–Rawnsley symbols $\sigma(A)$ associated to $A\in B(\mathscr{H}^{(k)})$.

Both on $\mathbb{C}^{n+1}\backslash\{0\}$ and $\mathbb{C}P^n$ there are momentum maps (see Ref. 17 for general definitions) for the $U(n+1)$ action, which can be expressed in terms of Berezin–Rawnsley symbols contained in $\mathscr{E}_1$.

Lemma 4: Let $\mathfrak{u}(n+1)$ denote the space of complex anti-Hermitean $(n+1)\times(n+1)$ matrices, i.e. the Lie algebra of the unitary group $U(n+1)$. Then the following occurs.

(i) The following map:

$$\widetilde{P}:\mathbb{C}^{n+1}\backslash\{0\}\to\mathfrak{u}(n+1)^*:z\mapsto(A\mapsto\widetilde{\sigma}(A)) \tag{14}$$

is a momentum map for the $U(n+1)$ action on $\mathbb{C}^{n+1}\backslash\{0\}$.

(ii) The following map:

$$P:=\widetilde{P}_\mu:\mathbb{C}P^n\to\mathfrak{u}(n+1)^*:\pi(z)\mapsto(A\mapsto-2\mu\sigma(A)(\pi(z))=\widetilde{\sigma}(A)_\mu(\pi(z))) \tag{15}$$

is a momentum map for the $U(n+1)$ action on $\mathbb{C}P^n$.

Recall that the index μ refers to the $U(1)$-phase space reduction of $\mathbb{C}^{n+1}\backslash\{0\}$ by the $U(1)$ momentum map $J(z)=-x/2$.

Proof: (i) The Hamiltonian vector field of $P(A)$ is given by $X_{\widetilde{\sigma}(A)}(z) = (2/i)(A_{ij}z^j\partial_{z^i} + A_{ij}\overline{z^j}\partial_{\overline{z^i}})$, since $A_{ij}=-A_{ji}$, which obviously equals the infinitesimal generator $A_{\mathbb{C}^{n+1}\backslash\{0\}}$ of the $U(n+1)$ action. The Ad^* equivariance of this map is obvious.

(ii) Recall the projection $\pi_\mu:J^{-1}(\mu)\to\mathbb{C}P^n$ to the reduced phase space (compare Ref. 17, Sec. 4.3). Since $\Phi_g\circ\pi_\mu=\pi_\mu\circ\Psi_g$ it is clear that $T\pi_\mu A_{\mathbb{C}^{n+1}\backslash\{0\}} = A_{\mathbb{C}P^n}\pi_\mu$, where $A_{\mathbb{C}P^n}$ is the infinitesimal generator of the $U(n+1)$ action on $\mathbb{C}P^n$. Using the identity $A_{\mathbb{C}P^n}\pi_\mu(z) = X_{\widetilde{\sigma}(A)_\mu}\pi(z)$ we get by phase-space reduction

$$T_z\pi_\mu X_{\widetilde{\sigma}(A)_\mu}(z)=T_z\pi_\mu A_{\mathbb{C}^{n+1}\backslash\{0\}}(z)=X_{\widetilde{\sigma}(A)_\mu}(\pi(z)).$$

The Ad^* equivariance of this map follows at once from the Ad^* equivariance of $\widetilde{P}$. □

We shall now compute star products for elements of $\mathscr{E}$: Set $\nu:=\lambda/(-2\mu)$, $\nu^{(0)}:=1$, $\nu^{(1)}:=1$ and

$$\nu^{(k)}:=(1-\nu)\cdots(1-(k-1)\nu). \tag{16}$$

Theorem 1: *For $f\in\mathscr{E}_k$, $g\in\mathscr{E}_l$ we get*

$$(\pi^*f)\widetilde{*}(\pi^*g)(z)=\sum_{r=0}^{\min(k,l)}\frac{\lambda^r}{r!}\frac{S(x^{k+l-r})}{(Sx^k)(Sx^l)}\frac{1}{x^{k+l-r}}\frac{\partial^r(x^k\pi^*f)}{\partial z^{i_1}\cdots\partial z^{i_r}}(z)\frac{\partial^r(x^l\pi^*g)}{\partial\overline{z^{i_1}}\cdots\partial\overline{z^{i_r}}}(z) \tag{17}$$

and

$$f*^\mu g=\sum_{r=0}^{\min(k,l)}\frac{\nu^r}{r!}\frac{\nu^{(k+l-r)}}{\nu^{(k)}\nu^{(l)}}M_r^{(k,l)}(f,g), \tag{18}$$

with the following bidifferential operator on $C^\infty(\mathbb{C}P^n)$:

$$\pi^*M_r^{(k,l)}(f,g):=\frac{1}{x^{k+l-r}}\frac{\partial^r(x^k\pi^*f)}{\partial z^{i_1}\cdots\partial z^{i_r}}\frac{\partial^r(x^l\pi^*g)}{\partial\overline{z^{i_1}}\cdots\partial\overline{z^{i_r}}}. \tag{19}$$

Proof: The usual Wick product (2) of the two *polynomials* $\widetilde{f}_k:=x^k\pi^*f$, $\widetilde{g}_l:=x^l\pi^*g$ is given by

$$\widetilde{f}_k*\widetilde{g}_l=\sum_{r=0}^{\min(k,l)}\frac{\lambda^r}{r!}\frac{\partial^r\widetilde{f}_k}{\partial z^{i_1}\cdots\partial z^{i_r}}\frac{\partial^r\widetilde{g}_l}{\partial\overline{z^{i_1}}\cdots\partial\overline{z^{i_r}}}. \tag{20}$$

Using definition (5) and the formulas (6) and (4), we find

$$(Sx^k)(Sx^l)(\pi^*f)\widetilde{*}(\pi^*g)=(S(x^k\pi^*f))\widetilde{*}(S(x^l\pi^*g))=S((x^k\pi^*f)*(x^l\pi^*g))$$
$$=S\left(\sum_{r=0}^{\min(k,l)}\frac{\lambda^r}{r!}\frac{\partial^r\widetilde{f}_k}{\partial z^{i_1}\cdots\partial z^{i_r}}\frac{\partial^r\widetilde{g}_l}{\partial\overline{z^{i_1}}\cdots\partial\overline{z^{i_r}}}\right)$$

$$= \sum_{r=0}^{\min(k,l)} \frac{\lambda^r}{r!} S\left(x^{k+l-r} \frac{1}{x^{k+l-r}} \frac{\partial^r \widetilde{f}_k}{\partial z^{i_1} \cdots \partial z^{i_r}} \frac{\partial^r \widetilde{g}_l}{\partial \overline{z^{i_1}} \cdots \partial \overline{z^{i_r}}} \right)$$

$$= \sum_{r=0}^{\min(k,l)} \frac{\lambda^r}{r!} S(x^{k+l-r}) \frac{1}{x^{k+l-r}} \frac{\partial^r \widetilde{f}_k}{\partial z^{i_1} \cdots \partial z^{i_r}} \frac{\partial^r \widetilde{g}_l}{\partial \overline{z^{i_1}} \cdots \partial \overline{z^{i_r}}},$$

which proves the first equation. The second equation immediately follows by the reduction formula (8). □

Remark: Thanks to the straightforward recursion formulas $M_r^{(k+1,l)} = M_r^{(k,l)} + r(l-(r-1))M_{r-1}^{(k,l)}$ and $M_r^{(k,l+1)} = M_r^{(k,l)} + r(k-(r-1))M_{r-1}^{(k,l)}$ it can easily be checked that the right-hand side of (17) is well defined, i.e., if, e.g., f is regarded as an element of $\mathscr{E}_{k+a}$ for a positive integer a.

Corollary 2: For $A,B \in B(\mathscr{H}^{(1)})$ we have

$$\sigma(A)^k *^\mu \sigma(B)^l = \sum_{r=0}^{\min(k,l)} \frac{\nu^r}{r!} \frac{k!l!}{(k-r)!(l-r)!} \frac{\nu^{(k+l-r)}}{\nu^{(k)}\nu^{(l)}} \sigma(AB)^r \sigma(A)^{k-r} \sigma(B)^{l-r}. \tag{21}$$

Proof: This is easily seen by setting $f=\sigma(A)^k$ and $g=\sigma(B)^l$ and using Theorem 1. □

We shall now show that the momentum map P for the $U(n+1)$ action on $\mathbb{C}P^n$ is even a quantum momentum map. More precisely we see the following.

Lemma 5: P is a quantum momentum mapping on $\mathbb{C}P^n$ for the $U(n+1)$ action, i.e. for every smooth function $\phi:\mathbb{C}P^n \to \mathbb{C}$ the following equation holds:

$$P(A) *^\mu \phi - \phi *^\mu P(A) = \frac{i\lambda}{2} \{P(A), \phi\}_\mu, \tag{22}$$

i.e. the star product $*^\mu$ is strongly $U(n+1)$ invariant.

Proof: First we prove the equation $\pi^*\sigma(A) \widetilde{*} f - f \widetilde{*} \pi^*\sigma(A) = (i\lambda/2)\{\pi^*\sigma(A), f\}$ for $f=\pi^*\phi$. Then Eq. (22) follows Eq. (8). We have the strong invariance of the Wick product,

$$\widetilde{\sigma}(A) * f - f * \widetilde{\sigma}(A) = \frac{i\lambda}{2} \{\widetilde{\sigma}(A), f\}.$$

With the equivalence transformation S we find

$$S^{-1}(S\widetilde{\sigma}(A) \widetilde{*} Sf - Sf \widetilde{*} S\widetilde{\sigma}(A)) = \frac{i\lambda}{2} \{\widetilde{\sigma}(A), f\},$$

and with $\pi^*\sigma(A) = x\widetilde{\sigma}(A)$ and $Sf=f$ this leads to

$$Sx(\pi^*\sigma(A) \widetilde{*} f - f \widetilde{*} \pi^*\sigma(A)) = \frac{i\lambda}{2} S(\{x\pi^*\sigma(A), f\}).$$

The Poisson bracket $\{x\pi^*\sigma(A), f\} = x\{\pi^*\sigma(A), f\}$ is again homogeneous. Hence the right-hand side of the last equation is simply $x\{\pi^*\sigma(A), f\}$. With $Sx=x$ the proof is complete. □

Remark: The case $k=l=1$ in Corollary, Eq. (2) shows that the functions $\sigma(A)$ and $\sigma(B)$ commute with respect to $*^\mu$ iff the operators A and B commute. Let $A_1,\ldots,A_n$ be a linearly independent set of commuting traceless Hermitian matrices. It follows in particular that the functions $\sigma(A_1),\ldots,\sigma(A_n)$ are functionally independent and in involution, i.e., the Poisson bracket of $\sigma(A_i)$ with $\sigma(A_j)$ vanishes for all i,j. In other words they form a *completely integrable system* in the sense of Liouville on $\mathbb{C}P^n$. Note that this system is nontrivial in the sense that there is no global chart of action-angle variables, i.e. $\mathbb{C}P^n$ is not symplectomorphic to some $T^r \times \mathbb{R}^{2n-r}$ for a

non-negative integer $r \leqslant n$. The above Corollary now implies that these functions also commute with respect to the star product and can be viewed as a *quantum integrable system* on $\mathbb{C}P^n$.

IV. CONSTRUCTION OF THE SUBALGEBRA $\mathscr{U}$, THE IDEALS $\mathscr{I}_\alpha$, AND THE QUOTIENTS $\mathscr{U}/\mathscr{I}_\alpha$

If we take two functions $\phi_k \in \mathscr{E}_k$ and $\psi_l \in \mathscr{E}_l$ and multiply them with the ν polynomial $\nu^{(k)}$ and $\nu^{(l)}$, respectively, then formula (18) shows that their $*^\mu$ product contains only polynomials in the parameter ν. Moreover, that particular combination is restored, i.e. the functions $M_t^{(k,l)}(\phi_k, \psi_l) \in \mathscr{E}_{k+l-t}$ appear only in combination with $\nu^{(k+l-t)}$.This motivates the definition of the following subspaces of $C^\infty(\mathbb{C}P^n)[[\nu]]$:

$$\mathscr{U}_0 := \mathscr{E}_0 \quad \text{and} \quad \mathscr{U}_k := \nu^{(k)}\mathscr{E}_k + \nu\nu^{(k-1)}\mathscr{E}_{k-1} + \cdots + \nu^{k-1}\nu^{(1)}\mathscr{E}_1 + \nu^k\mathscr{E}_0, \quad \forall k \in \mathbb{N}, \tag{23}$$

where each $\mathscr{U}_k$ is a (not necessarily direct) sum of subspaces of $C^\infty(\mathbb{C}P^n)[[\nu]]$. We denote by $\mathscr{E}[\nu]$ the *polynomials* in ν with coefficients in $\mathscr{E}$. The following theorem describes the structure of $\mathscr{U}$.

Theorem 2:

(i) For each integer k: $\mathscr{U}_k \subset \mathscr{U}_{k+1}$. Define $\mathscr{U} := \cup_k^\infty \mathscr{U}_k$. Then $\mathscr{U}$ is a proper $\mathbb{C}[\nu]$ submodule of $\mathscr{E}[\nu]$.

(ii) $\mathscr{U}$ is a filtered subalgebra of $C^\infty(\mathbb{C}P^n)[[\nu]]$ with respect to $*^\mu$, i.e.

$$\mathscr{U}_k *^\mu \mathscr{U}_l \subset \mathscr{U}_{k+l}.$$

Proof: (i) Let $\Phi \in \mathscr{U}_k$. Φ is of the form $\Phi = \Sigma_{r=0}^k \nu^r \nu^{(k-r)} \phi_{k-r}$ with $\phi_{k-r} \in \mathscr{E}_{k-r}$. The filtration of $\mathscr{E}$ implies $\phi_{k-r} \in \mathscr{E}_{k-r+1}$ so $\nu^r \nu^{(k-r+1)} \phi_{k-r} \in \mathscr{U}_{k+1}$. The element $\nu^{r+1}\nu^{(k-r)}\phi_{k-r}$ is also contained in $\mathscr{U}_{k+1}$. By Eq. (16) we get $\nu^{(k-r+1)} = (1-(k-r)\nu)\nu^{(k-r)}$. Hence

$$\nu^r \nu^{(k-r)} \phi_{k-r} = \nu^r \nu^{(k-r+1)} \phi_{k-r} + (k-r)\nu^{r+1}\nu^{(k-r)}\phi_{k-r} \in \mathscr{U}_{k+1},$$

which proves the inclusion $\mathscr{U}_k \subset \mathscr{U}_{k+1}$. It is clear from the definition (23) that $\nu\mathscr{U}_k \subset \mathscr{U}_{k+1} \subset \mathscr{E}[\nu]$ whence $\mathscr{U}$ is $\mathbb{C}[\nu]$ submodule of $\mathscr{E}[\nu]$. Note that for fixed $y \in \mathbb{C}^{n+1}\backslash\{0\}$ the function $\pi(z) \mapsto |\langle y, z\rangle|^4/x^2 \in \mathscr{E}_2$ is not contained in $\mathscr{U}$. (*ii*) By Theorem 1 the star product for arbitrary $\Phi_k = \Sigma_{r=0}^k \nu^{k-r}\nu^{(r)}\phi_r \in \mathscr{U}_k$ and $\Psi_l = \Sigma_{s=0}^l \nu^{l-s}\nu^{(s)}\psi_s \in \mathscr{U}_l$ with $\phi_r \in \mathscr{E}_r$ and $\psi_s \in \mathscr{E}_s$ is given by

$$\Phi_k *^\mu \Psi_l = \sum_{r=0}^{k} \sum_{s=0}^{l} \sum_{t=0}^{\min(r,s)} \frac{1}{t!}\, \nu^{k-r+l-s+t}\nu^{(r+s-t)} M_t^{(r,s)}(\phi_r, \psi_s),$$

hence each summand is an element of $\mathscr{U}_{k+l}$. This proves the second part. □

We should now like to substitute the formal parameter ν for a fixed nonzero real number α. In the subalgebra $\mathscr{U}$ this is well defined because $\mathscr{U}$ only contains polynomials in ν. The kernel of the substitution homomorphism,

$$\mathscr{I}_\alpha := \{\Phi(\nu) \in \mathscr{U} \,|\, \Phi(\alpha) = 0\}, \tag{24}$$

will turn out to be a $*^\mu$ ideal.

Lemma 6: $\mathscr{I}_\alpha$ is a $*^\mu$ ideal and the general form of an element $\Phi \in \mathscr{I}_\alpha \cap \mathscr{U}_k$ is the following: (i) for $\alpha \in \{1, 1/2, 1/3, \ldots\}$,

$$\Phi(\nu) = (\nu - \alpha) u_{k-1}(\nu), \quad \textit{with} \quad u_{k-1}(\nu) \in \mathscr{U}_{k-1}; \tag{25}$$

(ii) for $\alpha = 1/K$ with $K \in \mathbb{N}\backslash\{0\}$ for $k \leqslant K$,

$$\Phi(\nu) = \left(\nu - \frac{1}{K}\right) u_{k-1}(\nu), \tag{26}$$

and for $k>K$,

$$\Phi(\nu)=\nu^{(k)}\phi_k+\cdots+\nu^{k-K-1}\nu^{(k-K+1)}\phi_{k-K+1}+\left(\nu-\frac{1}{K}\right)u_{k-1}(\nu), \tag{27}$$

with some $u_{k-1}(\nu)\in\mathscr{U}_{k-1}$ *and* $\phi_r\in\mathscr{E}_r$.

Proof: It is clear that $\mathscr{T}_\alpha$ is a $*^\mu$ ideal if Eq. (25), resp. (26), and (27) are valid because of the form of $\nu^{(k)}$ in Eq. (16) and Eq. (18) for the $*^\mu$ product. So we only have to prove Eq. (25) and Eqs. (26) and (27).

Case (i). $\alpha\notin\{1,1/2,1/3,...\}$ We prove (25) by induction on k. With $\mathscr{U}_1=\nu\mathscr{E}_0+\mathscr{E}_1$ we get $\Phi(\nu)=c+\nu\sigma(A)$ for some $c\in\mathbb{C}$ and $\sigma(A)\in\mathscr{E}_1$. $\Phi(\alpha)=0$ implies $A=-(c/\alpha)\mathbf{1}$, where $\mathbf{1}$ is the unit matrix. So we have $\Phi(\nu)=c(1-\nu/\alpha)$. This proves the case $k=1$.

Consider now the induction step $k-1\to k$. Since $\mathscr{U}_k=\nu^{(k)}\mathscr{E}_k+\nu\mathscr{U}_{k-1}$ we write for $\Phi\in\mathscr{U}_k$

$$\Phi(\nu)=\nu^{(k)}\phi_k+\nu u_{k-1}(\nu),\quad \text{with}\quad \phi_k\in\mathscr{E}_k\quad\text{and}\quad u_{k-1}(\nu)\in\mathscr{U}_{k-1}.$$

Then $\Phi(\alpha)=0$ implies $\phi_k=-[\alpha/\alpha^{(k)}]u_{k-1}(\alpha)\in\mathscr{E}_{k-1}$ because $\alpha^{(k)}\neq 0$. Writing $\nu^{(k)}=(1-(k-1)\nu)\nu^{(k-1)}$ we get

$$\Phi(\nu)=\nu^{(k-1)}\phi_k+\nu(-(k-1)\nu^{(k-1)}\phi_k+u_{k-1}(\nu))=:\nu^{(k-1)}\phi_k+\nu u'_{k-1}(\nu),$$

with $u'_{k-1}(\nu)\in\mathscr{U}_{k-1}$. In $\Phi(\nu)=(\nu-\alpha)u'_{k-1}(\nu)+\nu^{(k-1)}\phi_k+\alpha u'_{k-1}(\nu)$ the first term vanishes at $\nu=\alpha$, so we have

$$\nu^{(k-1)}\phi_k+\alpha u'_{k-1}(\nu)\big|_{\nu=\alpha}=0.$$

But $\nu^{(k-1)}\phi_k+\alpha u'_{k-1}(\nu)$ is an element in $\mathscr{U}_{k-1}$ so we can apply the induction and conclude

$$\Phi(\nu)=(\nu-\alpha)u'_{k-1}(\nu)+(\nu-\alpha)u''_{k_2}(\nu),$$

with some $u''_{k-2}(\nu)\in\mathscr{U}_{k-2}$. This proves the first part.

Case (ii). Let $\alpha=1/K$ with $K\in\mathbb{N}\setminus\{0\}$ and $\Phi(\nu)\in\mathscr{U}_k$. We have to consider the two cases $k\leqslant K$ and $k>K$ separately:

(a) For $k\leqslant K$ we have $(1/K)^{(k)}\neq 0$, and we can apply the same arguments as in the first part; hence $\Phi(\nu)=(\nu-1/K)u_{k-1}(\nu)$ with $u_{k-1}(\nu)\in\mathscr{U}_{k-1}$.

(b) For $k>K$ we have for $r\geqslant 1$ $\nu^{(K+r)}\big|_{\nu=1/K}=0$ according to the definition (16) of $\nu^{(k)}$. Hence, in every $\Phi(\nu)\in\mathscr{U}_k$,

$$\Phi(\nu)=\nu^{(k)}\phi_k+\cdots+\nu^{k-K-1}\nu^{(K+1)}\phi_{K+1}+\nu^{k-K}u_K(\nu),$$

the first terms are automatically elements of $\mathscr{T}_{1/K}$ and $\Phi(1/K)=0$ implies $u_K(1/K)=0$. But this is an element of $\mathscr{U}_K$ and we can apply case (a). Hence $u_K(\nu)=(\nu-1/K)u'_{K-1}(\nu)$, which proves the second part. □

The quotient algebras $\mathscr{U}/\mathscr{T}_\alpha$ can now easily be described.

Theorem 3: *The quotient algebra* $\mathscr{A}_\alpha:=\mathscr{U}/\mathscr{T}_\alpha$ *is isomorphic to one of the following algebras.*

(*i*) *For* α *not equal to one of the rational numbers 1,1/2,1/3,..., the algebra* $\mathscr{A}_\alpha$ *is isomorphic to the vector space of representative functions* $\mathscr{E}$ *equipped with the multiplication* $*_\alpha$ *defined by* ($f\in\mathscr{E}_k$, $g\in\mathscr{E}_l$; $k,l\in\mathbb{N}$):

$$f*_\alpha g:=\sum_{r=0}^{\min(k,l)}\frac{\alpha^r}{r!}\frac{\alpha^{(k+l-r)}}{\alpha^{(k)}\alpha^{(l)}}M_r^{(k,l)}(f,g), \tag{28}$$

where the real number $\alpha^{(k)}$ *is defined by the formula (16) and* $M_r^{(k,l)}(f,g)$ *is given in (19).*

(ii) *Let* α *be equal to* $1/K$ *with* K *a positive integer. Then* $\mathscr{A}_\alpha$ *is isomorphic to the finite-dimensional complex algebra of linear endomorphisms of* $\mathbb{C}^N$ *with* $N:=\binom{n+K}{K}$. *The isomorphism is given by the map*

$$A\mapsto \frac{\nu^{(K)}}{(1/K)^{(K)}}\,\sigma(A) \mod \mathscr{T}_{1/K}, \tag{29}$$

where $\sigma(A)$ *is the Berezin-Rawnsley symbol of the complex* $N\times N$*-matrix* A *[see (13)]. The matrix product* $(AB)_{i_1\cdots i_K,j_1\cdots j_K}$ *is given by* $A_{i_1\cdots i_K,a_1\cdots a_K}B_{a_1\cdots a_K,j_1\cdots j_K}$.

Proof: (i) According to the preceding Lemma the ideal $\mathscr{T}_\alpha$ is equal to $(\nu-\alpha)\mathscr{U}$, which amounts to simply substituting $\nu=\alpha$ in (18) which is obviously well defined.

(ii) According to the second part of the preceding Lemma we get $\mathscr{U}_k/\mathscr{T}_{1/K}=\mathscr{U}_K/\mathscr{T}_{1/K}$ for $k\geqslant K$. For $\mathscr{U}_K$ we may substitute ν for $1/K$ since $(1/K)^{(k)}\neq 0$ for $k\leqslant K$. Hence $\dim \mathscr{A}_{1/K}=\dim \mathscr{E}_K=\binom{n+K}{K}^2$. Moreover,

$$\begin{aligned}
&\frac{\nu^{(K)}}{(1/K)^{(K)}}\,\sigma(A)*^{\mu}\frac{\nu^{(K)}}{(1/K)^{(K)}}\,\sigma(B) \mod \mathscr{T}_{1/K}\\
&\quad=\sum_{r=0}^{K}\frac{\nu^r}{r!}\,\frac{\nu^{(2K-r)}}{(1/K)^{(K)}(1/K)^{(K)}}\,M_r^{(K,K)}(\sigma(A),\sigma(B)) \mod \mathscr{T}_{1/K}\\
&\quad=\frac{(1/K)^K}{K!}\,\frac{\nu^{(K)}}{(1/K)^{(K)}(1/K)^{(K)}}\,M_K^{(K,K)}(\sigma(A),\sigma(B)) \mod \mathscr{T}_{1/K}\\
&\quad=\frac{\nu^{(K)}}{(1/K)^{(K)}}\,\sigma(AB) \mod \mathscr{T}_{1/K},
\end{aligned}$$

since a simple calculation shows that

$$\pi^*(M_K^{(K,K)}(\sigma(A),\sigma(B)))(z)=K!K!\,\frac{\widetilde{\sigma}(AB)(z)}{x^K}.$$

This proves the Theorem. □

Remarks: Note that for each $A\in\mathfrak{u}(n+1)$ the Berezin–Rawnsley symbol $\sigma(A)$ is contained in $\mathscr{E}_K$ and thus uniquely corresponds to a linear operator in $B(\mathscr{H}^{(K)})$, which is mapped via the linear map (29) to $\mathscr{A}_{1/K}$. By Lemma 5 it follows that this defines a *representation* of $\mathfrak{u}(n+1)$ in $\mathbb{C}^N$, which is *irreducible*: in fact, by Lemma 5 we know that the momentum map $P(A)$ star commutes with some function iff it Poisson commutes with that function, which is only possible iff that function is constant since the unitary group acts transitively on $\mathbb{C}P^n$. Since the Poisson bracket with $P(A)$ obviously preserves each $\mathscr{E}_k$, it follows that this reasoning carries over to the quotient by $\mathscr{T}_{1/K}$.

From the physical point of view the second part of the preceding Theorem can be viewed as follows: The classical phase space reduction of $\mathbb{C}^{n+1}\backslash\{0\}$ to $\mathbb{C}P^n$ was motivated by the $U(1)$ action on $\mathbb{C}^{n+1}\backslash\{0\}$, which is just the flow of the classical isotropic $(n+1)$-dimensional harmonic oscillator with Hamiltonian $H=1/2x$ (the frequency and mass are normalized to 1). Passing from $\mathbb{C}^{n+1}\backslash\{0\}$ to $\mathbb{C}P^n$ for a fixed value $\mu\in\mathbb{R}^-$ of the momentum mapping $J=-1/2x$ means classically that the harmonic oscillator is considered at a fixed energy $E=-\mu$. This is also true in the quantum mechanical case, but now the energy is quantized. Only for the discrete values $1/K$, K a positive integer, of the formal parameter $\nu=\lambda/(-2\mu)$ one obtains *finite-dimensional* algebras of observables $\mathscr{U}/\mathscr{T}_{1/K}$ as one would physically expect for the *compact phase space* $\mathbb{C}P^n$ because the

phase volume is finite and each state ''occupies a phase cell of volume not smaller than $\hbar^n$,'' which results in a finite-dimensional Hilbert space for the quantum mechanical states. With $\lambda=2\hbar$ the quantized energy is given by

$$E_K=\hbar K$$

[where the usual ground state energy $1/2\hbar(n+1)$ is absent because of the Wick ordering]. Note that in this interpretation the formal parameter $\lambda=2\hbar$ is *not* quantized but the energy $E=-\mu$ is. The dimensions of the operator algebras for a fixed $K\in\mathbb{N}$ correspond to the well-known degeneracy of the Kth energy eigenvalue of the isotropic harmonic oszillator [see, e.g., Ref. 19, Eq. (XII.64)].

V. OTHER EXAMPLES

In this section we briefly sketch how the program mentioned in the Introduction applies to the deformation quantization of other phase spaces that have been dealt with in the literature.

(1) Consider complex $n+1$ space $\mathbb{C}^{n+1}$ as a symplectic manifold in the usual manner, i.e. with symplectic form $\omega=i/2\Sigma_{i=0}^{n}dz^i\wedge d\overline{z^i}$. The Wick product (2) then defines a star product on this space. It is natural to consider the action of $\mathbb{C}^{n+1}$ on itself by translations. Suppose that the smooth complex-valued function F on $\mathbb{C}^{n+1}$ is representative with respect to this group action, i.e. there is a finite number L of linearly independent smooth complex-valued functions $F_1,\ldots,F_L$ on $\mathbb{C}^{n+1}$ such that $F(z+v)=\Sigma_{a=1}^{L}\beta_a(v)F_a(z)$ with smooth complex-valued coefficients β_a. The same equation holds for each F_a thus giving rise to a coefficient matrix $\beta_{ab}(v)$. Since $\mathbb{C}^{n+1}$ is Abelian, $\beta_{ab}(v)$ commutes with each $\beta_{ab}(w)$ whence all these matrices can simultaneously be transformed to the Jordan normal form. It can easily be seen that the generalized eigenvectors of $\beta_{ab}(v)$ are of the form $p(z)e^{b_iz^i+c_i\overline{z^i}}$, where p is a complex-valued polynomial function of $(z,\overline{z})$ and b_i,c_j are complex numbers. Conversely, it is easy to see that each linear combination of the functions of this form is indeed representative. Since this space of functions is a subalgebra of the algebra of all smooth complex-valued functions on $\mathbb{C}^{n+1}$ (with respect to pointwise multiplication), which clearly is closed under complex conjugation, contains a unit element, and separates points it is dense in $C^\infty(\mathbb{C}^{n+1})$ with respect to the uniform topology on compacta thanks to the Stone–Weierstrass Theorem. Note that the space of polynomials is a dense proper $\mathbb{C}^{n+1}$ submodule of representative functions that would be impossible for compact Lie groups (compare the proof of Lemma 3).

Writing $e_{(a,b)}$ for the exponential function $z\mapsto e^{a_iz^i+b_i\overline{z^i}}$ parameterized by two complex vectors $a,b\in\mathbb{C}^{n+1}$, we easily obtain the following formula:

$$e_{(\alpha+\rho,b+\sigma)}*e_{(a'+\rho',b'+\sigma')}=e^{\lambda(a_i+\rho_i)(b_i'+\sigma_i')}e_{(a+\rho,b+\sigma)}e_{(a'+\rho',b'+\sigma')}, \tag{30}$$

where a, a', b, b', ρ, ρ', σ, $\sigma'\in\mathbb{C}^{n+1}$. After differentiating this formula a finite number of times with respect to the components of ρ, ρ', σ, σ' at $\rho=\rho'=\sigma=\sigma'=0$ (which generates polynomial prefactors), we see that the Wick product of two representative functions is again representative and entirely analytic in the formal parameter λ. Therefore the algebra $\mathscr{U}$ can be chosen to be the subalgebra of $C^\infty(\mathbb{C}^{n+1})[[\lambda]]$ which consists of polynomials in λ with coefficients in the space of representative functions. Substituting λ for a real number α then is straightforward.

(2) Consider now the $2n$-torus $T^{2n}:=S^1\times\cdots\times S^1$ ($2n$ factors). Let $(\varphi^1,\ldots,\varphi^{2n})=:\varphi$, $0\leqslant\varphi^i<1$, denote the standard angle coordinates on T^{2n} and take any nondegenerate complex $2n\times 2n$ matrix (Λ_{ij}). The Moyal product may then be defined by for two smooth, complex-valued functions f,g on T^{2n} as follows:

$$f*g:=\sum_{r=0}^{\infty}\frac{(\lambda/2\pi\mathbf{i})^r}{r!}\Lambda^{i_1j_1}\cdots\Lambda^{i_rj_r}\frac{\partial^r f}{\partial\varphi^{i_1}\cdots\varphi^{i_r}}\frac{\partial^r g}{\partial\varphi^{j_1}\cdots\varphi^{j_r}}. \tag{31}$$

It is known that this formula defines an associative deformation for the pointwise multiplication in $C^\infty(T^{2n})$ (see, e.g., Ref. 1). The space of representative functions for the torus action on itself is spanned by the Fourier modes $T_k(\varphi) := e^{2\pi \mathbf{i} k_i \varphi^i}$, $k \in \mathbb{Z}^{2n}$: indeed, it is clear that the complex span of the Fourier modes consists of representative functions. Since it is a subalgebra of $C^\infty(T^{2n})$ that is closed under complex conjugation and contains a unit element, and separates points, it is a dense T^{2n} submodule of the space of all representative functions (by the Stone–Weierstrass Theorem) that has to be equal to that space since T^{2n} is compact [compare again the proof of Lemma (3)]. The Moyal product of two Fourier modes is then simply computed by

$$T_k * T_{k'} = e^{2\pi \mathbf{i} \lambda \Lambda^{ij} k_i k'_j} T_k T_{k'}, \tag{32}$$

which again is an entire function in the formal parameter λ, whence the choice of $\mathscr{U}$ and the substitution of the formal parameter is completely analogous to the previous example.

Suppose now that the matrix (Λ^{ij}) is integral and the greatest common divisor of the matrix elements is equal to 1. Choosing $\lambda = 1/K$, K a positive integer, it is easily seen from the above formula (32) that the subspace $\mathscr{T}_{1/K}$ spanned by all elements of the form $T_k - T_{k+Kk'}$ with $k, k' \in \mathbb{Z}^{2n}$ is a $*$ ideal in the $*$ algebra of representative functions. It can be shown (see Ref. 20) that the quotient algebra is a simple complex algebra of dimension K^{2n}, which is related to the geometric quantization on the $2n$ torus in the theta bundle and its tensor powers.

(3) Let $\mathbb{D} := \{v \in \mathbb{C} \,|\, |v|^2 < 1\}$ be the Poincaré disk in the complex plane. As we have indicated in the last section of Ref. 7, we can use the projective representation of $\mathbb{D}$: in $\mathbb{C}^2 \setminus \{0\}$. Consider the open subset defined by the inequality $0 < y := |z^0|^2 - |z^1|^2$ (the function y was defined with an erroneous sign in Ref. 7). The image of this open set under the projection π is an open set of $\mathbb{C}P^1$ that is holomorphically diffeomorphic to $\mathbb{D}$ via $\pi(z) \mapsto v := z^1/z^0$. In their article,[15] Cahen, Gutt, and Rawnsley have considered the following functions $f_{p,q}(v)$ $(p, q \in \mathbb{N})$ on $\mathbb{D}$:

$$f_{p,q}(v) := v^p \left(\frac{\overline{v}}{1 - |v|^2} \right)^q. \tag{33}$$

Their pullback to $\mathbb{C}^2 \setminus \{0\}$ is simply given by $(\pi^* f_{p,q})(z) = (z^1/z^0)^p (z^0 \overline{z^1})^q / y^q$. In Ref. 7 we have defined a star product on $\mathbb{D}$ by essentially replacing x by y and the operators M_r by

$$\check{M}_r(G, H) := y^r g^{i_1 j_1} \cdots g^{i_r j_r} \frac{\partial^r G}{\partial z^{i_1} \cdots \partial z^{i_r}} \frac{\partial^r G}{\partial \overline{z^{j_1}} \cdots \partial \overline{z^{j_r}}}, \tag{34}$$

with $g^{ij} := \mathrm{diag}(1, -1)$. Observing that Eqs. (17) and (18) remain valid for arbitrary smooth complex-valued functions when the upper bound of the sum is ∞ and that these formulas pass to the noncompact case with the above replacements and adapting the sign and ordering conventions of Ref. 15, we obtain the following star product:

$$\begin{aligned}
(f_{p,q} * f_{r,s})(\pi(z)) = \sum_{m=0}^{\infty} & \frac{(-\nu)^m}{m!} \frac{(-\nu)^{(q+s-m)}}{(-\nu)^{(q)} (-\nu)^{(s)}} y^{m-q-s} g^{i_1 j_1} \cdots g^{i_m j_m} \frac{\partial^r (y^q \pi^* f_{p,q})}{\partial \overline{z^{i_1}} \cdots \partial \overline{z^{i_m}}}(z) \\
& \times \frac{\partial^r (y^s \pi^* f_{r,s})}{\partial z^{j_1} \cdots \partial z^{j_m}}(z) \\
= \sum_{m=0}^{\infty} & \frac{(-\nu)^m}{m!} \frac{(-\nu)^{(q+s-m)}}{(-\nu)^{(q)} (-\nu)^{(s)}} y^{m-q-s} (-1)^m \\
& \times \frac{\partial^m ((z^1/z^0)^p (z^0 \overline{z^1})^q)}{\partial (\overline{z^1})^m}(z) \frac{\partial^m ((z^1/z^0)^r (z^0 \overline{z^1})^s)}{\partial (z^1)^m}(z)
\end{aligned}$$

$$= \sum_{m=0}^{\min(q,r)} \frac{\nu^m}{m!} \frac{(-\nu)^{(q+s-m)}}{(-\nu)^{(q)}(-\nu)^{(s)}} \frac{q!}{(q-m)!} \frac{r!}{(r-m)!} f_{p+r-m,q+s-m}(\pi(z)),$$

which reproduces the result of Ref. 15. In Ref. 16 star products were computed on more general bounded symmetric domains.

(Received 2 October 1995; accepted for publication 26 July 1996)

We study relations between the deformed cotangent bundle $(T^*\mathcal{B})_q$ for the Borel subgroup $\mathcal{B}$ of a given simple Lie group G, the quantum Lie algebra $\mathcal{J}_q$ associated with the corresponding quantum group G_q and the matrices generating Clebsch–Gordan coefficients for $\mathcal{J}_q$. We reveal the connection of these objects to quantum analog of the model space $\mathcal{M}$ and q-tensor operators. © *1996 American Institute of Physics.* [S0022-2488(96)00612-3]

I. INTRODUCTION

Among different representations of a given compact Lie group G the model space $\mathcal{M}$ plays a distinguished role. By definition,[1] the model space is a direct sum of all irreducible representations $\mathcal{H}_j$ with multiplicity one

$$\mathcal{M}=\sum_j \oplus \mathcal{H}_j \tag{1.1}$$

realized in some universal way. A most popular form of $\mathcal{M}$ is a space of holomorphic functions on the Borel subgroup $\mathcal{B}$ of complexified form of the group G. In this construction the Borel subgroup is considered as an affine space.

A study of model spaces provides a natural language for investigation of physical models. For example, the popular model of two-dimensional quantum gravity, introduced by Polyakov,[2] may be interpreted in terms of the model space of Virasoro algebra.[3] A finite-dimensional quantum group with deformation parameter, depending on the central charge, naturally appears in this context.

In the present paper, which was written with an intent to find new applications of model space in modern mathematical physics, we discuss a q-analog of the model space related to q-deformed Lie group G_q. For this purpose we introduce and examine several ''coordinatizations'' of the quantum space $(T^*\mathcal{B})_q$. As a by-product we obtain some generating matrices for the set of Clebsch–Gordan coefficients (CGC). To our knowledge this result is new even for the nondeformed case.

Throughout the paper we systematically and intentionally make use of the R-matrix formalism, which we believe is the most convenient and powerful tool to get explicit results in the domain of quantum groups.

To avoid the known difficulties with compact forms of quantum groups we adopt here a convention to work with complexified objects (groups, algebras) and their finite-dimensional

representations on a formal algebraic level. We also do not discuss subtleties arising in the case of q being a root of unity.

Most of formulas given in this paper in R-matrix form have universal validity. However, the concrete results are illustrated on the simplest example $G_q=\mathrm{SL}_q(2)$. The generalization to other groups needs more technical details such as an explicit structure of R-matrices and related objects.

Mentioned above, ''coordinatizations'' of $(T^*\mathscr{B})_q$ arise from two possible decompositions of the matrix L (in usual notations $L=L_+L_-^{-1}$, it comprises all generators of the corresponding quantum Lie algebra):

$$L=UDU^{-1} \quad \text{and} \quad L=ABA^{-1},$$

where D is a diagonal unimodular matrix, U is a deformation of unitary matrix, and A and B are unimodular upper and lower triangular matrices. As we shall clarify below, the matrices A and B admit a natural interpretation as the coordinates in the base and in the fiber of $(T^*\mathscr{B})_q$, whereas entries of the matrix U will be shown to provide basic shifts on the model space $\mathscr{M}$ and generate q-analogs of Clebsch–Gordan coefficients for the quantum group G_q. The explicit connection between U and (A,B) will be demonstrated on the example of $\mathrm{SL}_q(2)$.

It should be mentioned that an object like the matrix U appeared first in Refs. 4 and 5 (later it was used also in Ref. 6), where it was interpreted as a ''chiral'' component of the quantum grouplike element g. In the present paper we give another interpretation and application of the matrix U in the context of a model space.

Let us briefly describe the contents of the present paper. In Sec. II the definition of the cotangent bundle for a quantum group is reminded. Next we introduce an object of especial interest for us—the algebra $\mathscr{U}$ generated by the entries of the matrix U which diagonalizes the coordinate in a fiber of $(T^*G)_q$. We derive explicit relations for this algebra in the case of $G=\mathrm{SL}(2)$.

In Sec. III we consider a nondeformed limit ($q=1$) of the algebra $\mathscr{U}$ and construct an explicit representation. For the case of $G=\mathrm{SL}(2)$ we show that the matrix U_0 generates Clebsch–Gordan coefficients (CGC) for the corresponding nondeformed Lie algebra. The Borel subgroup $\mathscr{B}$ and the space $T^*\mathscr{B}$ naturally appear here. Finally, we discuss a connection of our results with the Wigner–Eckart theorem.

In Sec. IV we construct representations of the algebra $\mathscr{U}$ (for $q\neq 1$) for the case of SL(2) in two different ways. The first one uses the language of q-oscillators. The second is based on explicit realization of $(T^*\mathscr{B})_q$ and hence involves a notion of quantum model space. Here we show that the matrix U is a ''generating matrix'' for CGC for deformed Lie algebra. We also give some comments on the generalized version of the Wigner–Eckart theorem.

II. $(T^*G)_q$ AND RELATED OBJECTS

There exist three symplectic manifolds (from the physical point of view they are phase spaces) naturally related to a given Lie group G and its Lie algebra $\mathscr{J}$:

(1) T^*G—the cotangent bundle for the group G;
(2) $T^*\mathscr{B}$—the cotangent bundle for the Borel subgroup $\mathscr{B}$;
(3) $\mathscr{O}$—an orbit of the coadjoint action of G on $\mathscr{J}^*$.

For instance, in the case of $G=\mathrm{SL}(2)$ (which will be our main example) these spaces are six-, four-, and two-dimensional, correspondingly.

The method of geometric quantization[7] provides a representation theory for (1), (2), (3). Turning from classical to quantum groups, one can try to construct a representation theory for the deformed analogs of these manifolds. In the present paper we shall deal with deformations of the spaces (1) and (2).

A. Description of $(T^*G)_q$

Let G_q be a deformation of the Lie group G and $\mathscr{J}_q$ be a deformation of the corresponding Lie algebra $\mathscr{J}$. The deformed cotangent bundle $(T^*G)_q$ is a noncommutative manifold, i.e., according to the ideology developed by A. Connes,[8] its coordinates are (noncommuting) generators of some associative algebra. A point on this manifold is parametrized by the pair (g,L), where $g \in G_q$ is a coordinate in the base of the bundle, and L is a coordinate in a fiber.

The structure of $(T^*G)_q$ is defined via commutation relations between the coordinates in the base and in a fiber. An appropriate R-matrix form of these relations was proposed in Ref. 5:

$$\overset{1\,2}{R}_{\pm} \overset{2\,1}{g g} = \overset{2\,1}{g g} \overset{1}{R}_{\pm}, \tag{2.1}$$

$$\overset{1\,2}{R}_{-} \overset{2}{g} \overset{1}{L} = \overset{2}{L} \overset{1}{R}_{+} \overset{1}{g}, \tag{2.2}$$

$$\overset{1}{L} \overset{-1}{R}_{-} \overset{2}{L} \overset{2}{R}_{-} = \overset{-1}{R}_{+} \overset{2}{L} \overset{1}{R}_{+} \overset{1}{L}. \tag{2.3}$$

Here and below we use the formalism developed in Ref. 9, i.e., objects like g and L are considered as matrices (say, $L \in \mathscr{J}_q \otimes V$, where V stands for auxiliary space). We use the standard notations for tensor products: $\overset{1}{L} = L \otimes I \in \mathscr{J}_q \otimes V \otimes V$, etc.

Let us take the parameter q, which appears in the theory of quantum groups, in the following form:

$$q = e^{\gamma \hbar}, \tag{2.4}$$

where $\hbar$ is the Planck constant (the parameter of quantization) and γ is the deformation parameter. In physical applications it is most natural to suppose that γ is either pure real (q belongs to the real axis) or pure imaginary (q belongs to the unit circle at the complex plane).

The second form of q is typical for the WZW theory.[4,6,10] For $|q|=1$ we suppose also that q is not a root of unity. It should be mentioned that for both variants of choice of γ in (2.4) the definition of q-number

$$[x] \equiv \frac{q^x - q^{-x}}{q - q^{-1}} \tag{2.5}$$

is invariant with respect to complex conjugation of q, i.e., $\overline{[x]} = [\overline{x}]$. This property becomes important if one discusses involutions of deformed Lie algebras.

Definition 1: The algebra $\mathscr{L}$ is an associative algebra generated by entries of the matrix L which obeys relation (2.3).

An important fact—the connection of algebra $\mathscr{L}$ with the corresponding quantum Lie algebra $\mathscr{J}_q$ was established in Ref. 11 in the following form:

Proposition 1: Let matrices L_+ and L_- obey the following exchange relations:

$$\overset{1\,2}{R}_{\pm} \overset{1\,2}{L_+ L_+} = \overset{2\,1}{L_+ L_+} \overset{1}{R}_{\pm}, \quad \overset{1\,2}{R}_{\pm} \overset{1\,2}{L_- L_-} = \overset{2\,1}{L_- L_-} \overset{1}{R}_{\pm}, \quad \overset{1\,2}{R}_{+} \overset{1\,2}{L_+ L_-} = \overset{2\,1}{L_- L_+} \overset{1}{R}_{+}. \tag{2.6}$$

Then the matrix $L = L_+ L_-^{-1}$ satisfies the relation (2.3).

This statement implies that the algebra $\mathscr{L}$ is isomorphic (up to some technical details which we do not discuss here) to corresponding quantum Lie algebra $U_q(\mathscr{J})$ [which is defined by (2.6), see, e.g., Ref. 9].

Consider now the relations (2.1)–(2.3) for g and L being 2×2 matrices,

$$g=\begin{pmatrix} g_1 & g_2 \\ g_3 & g_4 \end{pmatrix}, \quad L=\begin{pmatrix} A & B \\ C & D \end{pmatrix} \tag{2.7}$$

and the R-matrices taken in the form

$$R_+=q^{-1/2}\begin{pmatrix} q & 0 & 0 & 0 \\ 0 & 1 & \omega & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & q \end{pmatrix}, \quad \omega\equiv q-q^{-1}; \quad R_-=PR_+^{-1}P \tag{2.8}$$

(P denotes the permutation operator: $Pg^{1}P=g^{2}$, etc.). In this case (2.1)–(2.3) define the cotangent bundle for the quantum group $G_q=\mathrm{GL}_q(2)$; each of R-matrix equations (2.1) and (2.3) is equivalent to six independent relations:

$$\begin{gathered} qg_1g_2=g_2g_1, \quad qg_1g_3=g_3g_1, \quad qg_2g_4=g_4g_2, \quad qg_3g_4=g_4g_3, \\ g_2g_3=g_3g_2, \quad g_1g_4-q^{-1}g_4g_1=-\omega g_2g_3; \end{gathered} \tag{2.9}$$

and

$$\begin{gathered} [A,B]=-q^{-1}\omega BD, \quad [A,C]=q^{-1}\omega DC, \quad [A,D]=0, \\ CD=q^2DC, \quad BD=q^{-2}DB, \quad [B,C]=q^{-1}\omega D(D-A). \end{gathered} \tag{2.10}$$

The equation (2.2) gives the following relations:

$$\begin{gathered} g_1A=qAg_1+\omega Bg_3, \quad g_1B=Bg_1, \\ g_2A=qAg_2+\omega Bg_4, \quad g_2B=Bg_2, \\ g_3A=q^{-1}Ag_3+\omega g_1C, \quad g_3B=Bg_3+\omega g_1D, \\ g_4A=q^{-1}Ag_4+\omega g_2C, \quad g_4B=Bg_4+\omega g_2D, \\ g_1C=Cg_1+q^{-1}\omega Dg_3, \quad g_1D=q^{-1}Dg_1, \\ g_2C=Cg_2+q^{-1}\omega Dg_4, \quad g_2D=q^{-1}Dg_2, \\ g_3C=Cg_3, \quad g_3D=qDg_3, \\ g_4C=Cg_4, \quad g_4D=qDg_4. \end{gathered} \tag{2.11}$$

Next, let us recall the well-known statement (see, e.g., Ref. 9):

Proposition 2: The algebra generated by the entries of the matrix g obeying (2.9) possesses the central element (''deformed determinant'')

$$\det_q g=g_1g_4-q^{-1}g_2g_3. \tag{2.12}$$

Similarly, for the algebra $\mathscr{L}$ in the case of $\mathrm{GL}_q(2)$ one can check the following.

Proposition 3: The algebra with generators A,B,C,D obeying (2.10) possesses two central elements:

$$K_1 = qA + q^{-1}D, \quad K_2 = q^{-1}AD - qBC. \tag{2.13}$$

Finally, using the commutation relations (2.11), one can check the following.

Proposition 4: The operators $\det_q g$ *and* K_2 *commute with all entries of the matrices* g *and* L.

This implies that, fixing values of $\det_q g$ and K_2, one gets a certain subalgebra of the algebra defined by (2.9)–(2.11).

Definition 2: Relations (2.9)–(2.11) for $\det_q g = 1$ *and* $K_2 = \text{const}$ *define the cotangent bundle for the quantum group* $G_q = \mathrm{SL}_q(2)$.

Let us underline that the above definitions and statements can be easily generalized, say to the case of $\mathrm{SL}_q(N)$.

In our case the algebra $\mathscr{L}$ is isomorphic to the quantum Lie algebra $\mathscr{J}_q = U_q(\mathrm{sl}(2))$ (introduced first in Ref. 12) which is defined by the relations

$$[l_+, l_-] = \frac{q^{2l_3} - q^{-2l_3}}{q - q^{-1}} \equiv [2l_3], \quad q^{l_3} l_\pm = q^{\pm 1} l_\pm q^{l_3}, \tag{2.14}$$

and the matrices $L_\pm$ can be chosen as follows:

$$L_+ = \begin{pmatrix} q^{l_3} & \omega q^{1/2} l_- \\ 0 & q^{-l_3} \end{pmatrix}, \quad L_- = \begin{pmatrix} q^{-l_3} & 0 \\ -\omega q^{-1/2} l_+ & q^{l_3} \end{pmatrix}. \tag{2.15}$$

Note that the matrix L in the Proposition 1 is defined only up to a scaling factor. Thus, for L_+ and L_- given in (2.15), we may choose L as follows:

$$L = q^2 L_+ L_-^{-1} = \begin{pmatrix} qC - q^{-2l_3} & q^{5/2} \omega l_- q^{-l_3} \\ q^{-1/2} \omega l_+ q^{-l_3} & q^2 q^{-2l_3} \end{pmatrix}. \tag{2.16}$$

Here C stands for the Casimir operator of $\mathrm{U}_q(\mathrm{sl}(2))$:

$$C = \omega^2 l_- l_+ + q^{2l_3+1} + q^{-(2l_3+1)} = q^{2\hat{j}+1} + q^{-(2\hat{j}+1)}, \tag{2.17}$$

where $\hat{j}$ is the operator of spin.

According to Proposition 1, the matrix (2.16) satisfies (2.3). Therefore, it provides a (fundamental) representation of the algebra $\mathscr{L}$ for $\mathrm{U}_q(\mathrm{sl}(2))$. In this representation the central elements (2.13) are given by

$$K_1 = q^2 C, \quad K_2 = q^3, \tag{2.18}$$

Note that the scaling factor q^2 introduced in (2.16) has changed the values of K_1 and K_2. The choice of such a normalization in (2.16) will be explained later.

B. Connection with quantum 6*j*-symbols

Let us remember the theorem which describes an important property of the algebra $\mathscr{L}$ for $U_q(\mathrm{sl}(2))$ (this statement first appeared in Ref. 5).

Theorem 1: *Let* $D \equiv D(p)$ *be the unimodular diagonal matrix*

$$D = \begin{pmatrix} q^{p/\hbar} & \\ & q^{-p/\hbar} \end{pmatrix}, \tag{2.19}$$

and let 2×2 *matrix* U *satisfy the following exchange relations:*

$$\overset{1\ 2}{D}\overset{2\ 1}{U}=\overset{2\ 1}{U}\overset{1\ 2}{D}\sigma, \quad \overset{2\ 1}{D}\overset{1\ 2}{U}=\overset{1\ 2}{U}\overset{2\ 1}{D}\sigma, \quad \sigma=\mathrm{diag}(q^{-1},q,q,q^{-1}), \tag{2.20}$$

$$R_+\overset{1\ 2}{U}\overset{2\ 1}{U}=\overset{2\ 1}{U}\overset{1\ 2}{U}\mathscr{R}_+(p), \quad R_-\overset{1\ 2}{U}\overset{2\ 1}{U}=\overset{2\ 1}{U}\overset{1\ 2}{U}\mathscr{R}_-(p), \tag{2.21}$$

where $R_\pm$ are the standard R-matrices (2.8) and

$$\mathscr{R}_+(p)=P\mathscr{R}_-^{-1}(p)P=q^{-1/2}\begin{pmatrix} q & & & \\ & \dfrac{\sqrt{[p/\hbar+1][p/\hbar-1]}}{[p/\hbar]} & \dfrac{q^{p/\hbar}}{[p/\hbar]} & \\ & -\dfrac{q^{-p/\hbar}}{[p/\hbar]} & \dfrac{\sqrt{[p/\hbar+1][p/\hbar-1]}}{[p/\hbar]} & \\ & & & q \end{pmatrix}, \tag{2.22}$$

(here $[x]$ denotes a ''q-number'' (2.5)). Then matrix L constructed by means of the similarity transformation

$$L=UDU^{-1}, \tag{2.23}$$

satisfies the relation (2.3) and therefore its entries generate an algebra $\mathscr{L}$ isomorphic to $\mathrm{U}_q(\mathrm{sl}(2))$.

The proof is given in Appendix A. It makes use of the identity

$$\mathscr{R}_-(p)=\overset{1}{(D)}^{-1}\mathscr{R}_+(p)\sigma\overset{1}{D}. \tag{2.24}$$

Remark: A consequence of (2.20) is the commutativity of L and D

$$\overset{1\ 2}{L}\overset{2\ 1}{D}=\overset{2\ 1}{D}\overset{1\ 2}{L}, \tag{2.25}$$

which implies that p commutes with all elements of $\mathscr{L}$. Later we shall interpret p as the operator of spin.

Remark: Properly generalizing objects which enter Theorem 1, one can extend this theorem to the case of any quantum semisimple Lie algebra.[13] In particular, the matrix D for $\mathrm{U}_q(\mathrm{sl}(N))$ is found to be: $D(\mathbf{p}) = \mathrm{const}\cdot q^{\mathbf{H}\otimes\mathbf{p}}$, where $\mathbf{p}$ consists of the operators corresponding to components of the weight vector (i.e., on each irreducible representation they are multiples of unity) and $\mathbf{H}$ consists of the generators H_i of the Cartan subalgebra. An explicit form of $\mathscr{R}(p)$ for $\mathrm{U}_q(\mathrm{sl}(N))$ was obtained in Ref. 14.

Remark: The matrix $\mathscr{R}(p)$ obeys the deformed Yang–Baxter equation,[5,14–16] which can be written, for example, as follows:

$$\overset{1\ 23}{Q}\mathscr{R}_+(p)\overset{1}{(Q)}^{-1}\mathscr{R}_+(p)\overset{3\ 12}{Q}\mathscr{R}_+(p)\overset{3}{(Q)}^{-1}=\mathscr{R}_+(p)\overset{2\ 13}{Q}\mathscr{R}_+(p)\overset{2}{(Q)}^{-1}\mathscr{R}_+(p), \tag{2.26}$$

where for $\mathscr{J}_q=\mathrm{U}_q(\mathrm{sl}(2))$ the matrix $Q = \begin{pmatrix} e^{i\xi} & \\ & e^{-i\xi} \end{pmatrix}$ contains an extra variable ξ, conjugated with p:

$$[p,\ \xi]=-i\hbar, \quad q^{p/\hbar}e^{i\xi}=qe^{i\xi}q^{p/\hbar}. \tag{2.27}$$

This variable ξ belongs to the algebra $\mathscr{U}$ but does not enter matrix L. An explicit expression for ξ will be given below. The general form of Q for $\mathrm{U}_q(\mathrm{sl}(N))$ can be easily found:[13] $Q = e^{i\mathbf{H}\otimes\boldsymbol{\xi}}$, where components ξ_i are operators conjugated to p_i: $[p_j, \xi_k] = -i\hbar\,\delta_{jk}$.

The matrix $\mathscr{R}(p)$ was discussed in physical literature in different contexts. In particular, it plays significant role in studies of quantum Liouville[15,16] and WZW[4–6] models; its relation to the Calogero–Moser model was recently discussed in Ref. 17. But for us the more important fact is a connection of $\mathscr{R}(p)$ with the quantum $6j$-symbols: the entries of (2.22) calculated on irreducible representations coincide (up to some normalization) with the values of some $6j$-symbols for $\mathrm{U}_q(\mathrm{sl}(2))$ (exact formulas are given in Ref. 20, generalizations are discussed in Ref. 13). This connection allows us to assume that objects like the matrix U should be interpreted in terms of Clebsch–Gordan coefficients (CGC). Below we demonstrate that U is indeed a ''generating matrix'' for CGC and clarify its relation to $(T^*\mathscr{B})_q$.

C. Algebra $\mathscr{U}$

Definition 3: The algebra $\mathscr{U}$ is an associative algebra generated by entries of matrix

$$U=\begin{pmatrix} U_1 & U_2 \\ U_3 & U_4 \end{pmatrix}$$

and the operator p such that relations (2.19)–(2.22) hold.

Remark: For simplicity we restricted our consideration to the case of $\mathscr{U}$ associated with $U_q(\mathrm{sl}(2))$. Let us stress that the case of $\mathscr{U}$ associated with $\mathrm{U}_q(\mathrm{sl}(N))$ can be studied similarly but it will involve more technical details. On the other hand, it might be rather cumbrous to obtain exact formulas for $\mathscr{U}$ associated with $\mathrm{U}_q(\mathscr{F})$ in the case of $\mathscr{F}$ being generic semisimple Lie algebra.

Let us give an explicit form of the defining relations (2.21):

$$U_1U_3=q^{-1}U_3U_1, \quad U_2U_4=q^{-1}U_4U_2, \tag{2.28}$$

$$U_1U_2=U_2U_1\sqrt{\frac{[p/\hbar-1]}{[p/\hbar+1]}}, \quad U_3U_4=U_4U_3\sqrt{\frac{[p/\hbar-1]}{[p/\hbar+1]}}, \tag{2.29}$$

$$U_1U_4=U_4U_1\,\frac{\sqrt{[p/\hbar+1][p/\hbar-1]}}{[p/\hbar]}-U_3U_2\,\frac{q^{p/\hbar}}{[p/\hbar]}, \tag{2.30}$$

$$U_3U_2=U_2U_3\,\frac{\sqrt{[p/\hbar+1][p/\hbar-1]}}{[p/\hbar]}-U_1U_4\,\frac{q^{-p/\hbar}}{[p/\hbar]}. \tag{2.31}$$

The rest of the relations contained in (2.21) are not independent and can be deduced from (2.28)–(2.31).

Additionally, from (2.20) one gets

$$\begin{aligned} &q^{p/\hbar}U_1=q^{-1}U_1q^{p/\hbar}, \quad q^{p/\hbar}U_2=qU_2q^{p/\hbar}, \\ &q^{p/\hbar}U_3=q^{-1}U_3q^{p/\hbar}, \quad q^{p/\hbar}U_4=qU_4p^{p/\hbar}. \end{aligned} \tag{2.32}$$

Thus, relations (2.28)–(2.32) describe the algebra $\mathscr{U}$. Using them, one may verify the following statement:

Proposition 5: A central element of $\mathscr{U}$ is given by the ''deformed'' determinant of the matrix U:

$$\text{Det } U \equiv U_1 U_4 \sqrt{\frac{[p/\hbar+1]}{[p/\hbar]}} - U_2 U_3 \sqrt{\frac{[p/\hbar-1]}{[p/\hbar]}} = q U_4 U_1 \sqrt{\frac{[p/\hbar-1]}{[p/\hbar]}} - q U_3 U_2 \sqrt{\frac{[p/\hbar+1]}{[p/\hbar]}}. \tag{2.33}$$

For a fixed value of Det U, the algebra $\mathscr{U}$ contains only four independent generators. In classical limit ($\hbar=0$) they become the coordinates on four-dimensional phase space.

For further discussion it is convenient to introduce new variables instead of U_i:

$$\hat{U}_i = U_i \sqrt{[p/\hbar]}. \tag{2.34}$$

The coordinates $\{p, \hat{U}_i\}$ form a new set of generators of the algebra $\mathscr{U}$. The commutation relations (2.28)–(2.32) rewritten in terms of the new generators acquire a simpler form:

$$\hat{U}_1 \hat{U}_3 = q^{-1} \hat{U}_3 \hat{U}_1, \quad \hat{U}_2 \hat{U}_4 = q^{-1} \hat{U}_4 \hat{U}_2, \quad \hat{U}_1 \hat{U}_2 = \hat{U}_2 \hat{U}_1, \quad \hat{U}_3 \hat{U}_4 = \hat{U}_4 \hat{U}_3 \tag{2.35}$$

$$\hat{U}_1 \hat{U}_4 = \hat{U}_4 \hat{U}_1 \frac{[p/\hbar+1]}{[p/\hbar]} - \hat{U}_3 \hat{U}_2 \frac{q^{p/\hbar}}{[p/\hbar]}, \tag{2.36}$$

$$\hat{U}_3 \hat{U}_2 = \hat{U}_2 \hat{U}_3 \frac{[p/\hbar+1]}{[p/\hbar]} - \hat{U}_1 \hat{U}_4 \frac{q^{-p/\hbar}}{[p/\hbar]}, \tag{2.37}$$

$$\begin{aligned} &q^{p/\hbar} \hat{U}_1 = q^{-1} \hat{U}_1 q^{p/\hbar}, \quad q^{p/\hbar} \hat{U}_2 = q \hat{U}_2 q^{p/\hbar}, \\ &q^{p/\hbar} \hat{U}_3 = q^{-1} \hat{U}_3 q^{p/\hbar}, \quad q^{p/\hbar} \hat{U}_4 = q \hat{U}_4 q^{p/\hbar}. \end{aligned} \tag{2.38}$$

The central element (2.33) in new variables looks as follows:

$$\text{Det } U \equiv (\hat{U}_1 \hat{U}_4 - \hat{U}_2 \hat{U}_3) \frac{1}{[p/\hbar]} = (\hat{U}_4 \hat{U}_1 - \hat{U}_3 \hat{U}_2) \frac{q}{[p/\hbar]}. \tag{2.39}$$

The explicit form of the matrix inverse to $\hat{U}$, which we shall need later, is

$$\hat{U}^{-1} = \frac{1}{\text{Det } U} \begin{pmatrix} \hat{U}_4 & -q\hat{U}_2 \\ -\hat{U}_3 & q\hat{U}_1 \end{pmatrix} \frac{1}{[p/\hbar]}. \tag{2.40}$$

Finally, from (2.34) we conclude that the expression (2.23) for the matrix L looks similar in terms of new matrix $\hat{U}$:

$$L = UDU^{-1} = \hat{U} D \hat{U}^{-1}. \tag{2.41}$$

III. NONDEFORMED CASE

A. Representation of algebra $\mathscr{U}_0$

First, we consider the limit $\gamma \to 0$, $\hbar \neq 0$ (note that q-numbers turn into ordinary numbers), i.e., here we deal with a well understood situation—the representation theory of SL(2). An investigation of this simple nondeformed case will make further results more transparent.

Let us denote the corresponding limit algebra as $\mathscr{U}_0$. The defining R-matrix relations (2.21) now degenerate to

$$\overset{1}{U_0}\overset{2}{U_0} = \overset{2}{U_0}\overset{1}{U_0} \mathscr{R}^{0}_{\pm}(p), \tag{3.1}$$

where

$$\mathscr{R}^0_+(p)=\mathscr{R}^0_-(p)=\begin{pmatrix} 1 & & & \\ & \dfrac{\sqrt{(p/\hbar+1)(p/\hbar-1)}}{(p/\hbar)} & \dfrac{\hbar}{p} & \\ & -\dfrac{\hbar}{p} & \dfrac{\sqrt{(p/\hbar+1)(p/\hbar-1)}}{(p/\hbar)} & \\ & & & 1 \end{pmatrix}. \tag{3.2}$$

The analogs of relations (2.35)–(2.38) for $\mathscr{U}_0$ are (from now on we omit the index 0 for the generators of $\mathscr{U}_0$)

$$p\hat{U}_1=\hat{U}_1(p-\hbar),\quad p\hat{U}_2=\hat{U}_2(p+\hbar),\quad p\hat{U}_3=\hat{U}_3(p-\hbar),\quad p\hat{U}_4=\hat{U}_4(p+\hbar), \tag{3.3}$$

$$[\hat{U}_1,\hat{U}_2]=[\hat{U}_1,\hat{U}_3]=[\hat{U}_2,\hat{U}_4]=[\hat{U}_3,\hat{U}_4]=0, \tag{3.4}$$

$$[\hat{U}_1,\hat{U}_4]=\mathrm{Det}\ U_0,\quad [\hat{U}_3,\hat{U}_2]=-\mathrm{Det}\ U_0, \tag{3.5}$$

where Det U_0 stands for a limit version of (2.39):

$$\mathrm{Det}\ U_0=(\hat{U}_1\hat{U}_4-\hat{U}_2\hat{U}_3)\,\frac{\hbar}{p}=(\hat{U}_4\hat{U}_1-\hat{U}_3\hat{U}_2)\,\frac{\hbar}{p}. \tag{3.6}$$

Proposition 6: A possible solution for (3.3)–(3.6) is

$$\hat{U}_1=\partial_1,\quad \hat{U}_2=z_2,\quad \hat{U}_3=-\partial_2,\quad \hat{U}_4=z_1; \tag{3.7}$$

$$p=\hbar(z_1\partial_1+z_2\partial_2+1), \tag{3.8}$$

where we denote $\partial_i\equiv\partial/\partial z_i$.

Remark: The representation given by (3.7) and (3.8) is not unique. In particular, the rescaling $\hat{U}_i\to c_i\hat{U}_i$ (where c_i are numerical constants such that $c_1c_4=c_2c_3$) is allowable.

Proposition 6 together with the connection formula (2.34) allows us to write out the explicit form of the matrix U_0:

$$U_0=\begin{pmatrix} \partial_1 & z_2 \\ -\partial_2 & z_1 \end{pmatrix}\sqrt{\frac{\hbar}{p}}. \tag{3.9}$$

Note that this matrix is ''unimodular,'' i.e., Det $U_0=(\partial_1z_1+z_2\partial_2)\hbar/p=1$.

To describe the obtained representation of the algebra $\mathscr{U}_0$ completely one has to define a space where operators (3.7)–(3.9) act. It is natural to think that this space is $D(z_1,z_2)$—a space of holomorphic functions of two complex variables.

Let us recall that $D(z_1,z_2)$ is a space spanned on the vectors

$$|j,m\rangle=\frac{z_1^{j+m}z_2^{j-m}}{\sqrt{(j+m)!(j-m)!}},\quad j=0,\ \tfrac{1}{2},\ 1,\ \tfrac{3}{2},\ldots,\quad m=-j,\ldots,j, \tag{3.10}$$

and equipped with the scalar product

$$\langle f,g\rangle=\frac{1}{(2\pi i)^2}\int \overline{f(z_1,z_2)}g(z_1,z_2)e^{-z_1\overline{z}_1-z_2\overline{z}_2}dz_1d\overline{z_1}dz_2d\overline{z_2}. \tag{3.11}$$

The system (3.10) is orthonormal with respect to the scalar product (3.11), that is $\langle j,m|j',m'\rangle = \delta_{jj'}\delta_{mm'}$. For the given scalar product a rule of conjugation of operators looks as follows:

$$(z_i)^* = \partial_i, \quad (\partial_i)^* = z_i. \tag{3.12}$$

The question concerning unitarity of the matrix U_0 is discussed in Appendix B.

B. Connection with $T^*\mathscr{B}$

The generators of sl(2) can be realized on $D(z_1,z_2)$ as differential operators:

$$l_+ = z_1\partial_2, \quad l_- = z_2\partial_1, \quad l_3 = \tfrac{1}{2}(z_1\partial_1 - z_2\partial_2). \tag{3.13}$$

Using these expressions we can compare the representation of the algebra $\mathscr{L}$ (or, more precisely, its limit version $\mathscr{L}_0$) given by Theorem 1 with the representation given by Proposition 1.

Indeed, in the limit $\gamma\to 0$ the initial formula (2.23) acquires the form

$$L = I + \gamma L_0 + O(\gamma^2), \quad L_0 = U_0 \begin{pmatrix} p & \\ & -p \end{pmatrix} U_0^{-1}. \tag{3.14}$$

Substituting here the explicit expressions for p, U_0, (3.8) and (3.9) and using the representation (3.13) for generators of sl(2), one derives the following limit form of the L-operator:

$$L_0 = \hbar \begin{pmatrix} 2 + z_1\partial_1 - z_2\partial_2 & 2z_2\partial_1 \\ 2z_1\partial_2 & 2 - z_1\partial_1 + z_2\partial_2 \end{pmatrix} = 2\hbar \begin{pmatrix} 1 + l_3 & l_- \\ l_+ & 1 - l_3 \end{pmatrix}. \tag{3.15}$$

Notice that (3.15) exactly coincides with (2.16) taken in the limit $\gamma\to 0$. This explains why we had to introduce the factor q^2 in (2.16).

The next observation concerning the limit of the L-operator reads as follows.

Proposition 7: The matrix L_0 in the representation (3.15) admits the decomposition

$$L_0 = A_0 B_0 A_0^{-1}, \tag{3.16}$$

where

$$A_0 = \begin{pmatrix} z_1^{-1/2} & -z_1^{-1/2} z_2 \\ 0 & z_1^{1/2} \end{pmatrix}, \quad B_0 = \hbar \begin{pmatrix} p/\hbar + 1/2 & 0 \\ 2\partial_2 & -(p/\hbar - 1/2) \end{pmatrix} \tag{3.17}$$

and p is defined as in (3.8).

This statement can be verified directly.

Let us comment on the meaning of this proposition. First, note that A_0 is a realization of a grouplike element of the Borel subgroup of SL(2). Moreover, this explicit form of A_0 is straightly connected with the construction of the model space $\mathscr{M}$ developed by Gelfand *et al.*[1] Indeed, the space $D(z_1,z_2)$ being a realization of the model space for SL(2) [compare (1.1) and (3.10)] is spanned on monomials with arguments which are combinations of the entries of A_0. On the other hand, B_0 is of opposite (with respect to A_0) triangularity and its entries are operators acting on a given realization of the model space. Therefore, B_0 can be regarded as an element of the space dual to the corresponding Borel subalgebra.

Thus, A_0 and B_0 are coordinates in the base and in a fiber of the cotangent bundle $T^*\mathscr{B}$. At this stage the appearance of $T^*\mathscr{B}$ ''inside'' the algebra $\mathscr{L}$ looks somewhat mysterious, but we shall clarify it later.

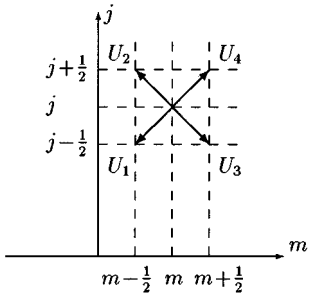

FIG. 1. Action of the operators U_i on the model space.

C. Clebsch–Gordan coefficients

Let us consider an action of the generators of the algebra $\mathscr{U}_0$ defined in (3.8) and (3.9) on the space $D(z_1,z_2)$ (which is a realization of the model space). The action of these operators on the basic vectors (3.10) is given by

$$p|j,m\rangle=(2j+1)\hbar|j,m\rangle, \tag{3.18}$$

$$U_1|j,m\rangle=\left(\frac{j+m}{2j+1}\right)^{1/2}|j-\frac{1}{2},m-\frac{1}{2}\rangle,\quad U_2|j,m\rangle=\left(\frac{j-m+1}{2j+1}\right)^{1/2}|j+\frac{1}{2},m-\frac{1}{2}\rangle,$$
$$U_3|j,m\rangle=-\left(\frac{j-m}{2j+1}\right)^{1/2}|j-\frac{1}{2},m+\frac{1}{2}\rangle,\quad U_4|j,m\rangle=\left(\frac{j+m+1}{2j+1}\right)^{1/2}|j+\frac{1}{2},m+\frac{1}{2}\rangle. \tag{3.19}$$

Formula (3.18) allows us to identify the operator p as $p=2\hat{j}+1$, where $\hat{j}$ is the operator of spin. Hence, invariant subspaces of p on the model space are those with fixed value of spin j.

Formulas (3.19) show that U_i are generators of the basic shifts on the model space (as illustrated on Fig. 1). This observation is very important. As we shall see later, the same picture holds for $q\neq 1$.

Now comparing the matrix elements $\langle j'',m''|U_i|j,m\rangle$ following from (3.19) with values of the Clebsch–Gordon coefficients (CGC) for decomposition of the tensor product of irreducible representations $V_j\otimes V_{1/2}$ for sl(2) which are given by the Van-der-Waerden formula

$$\begin{Bmatrix} j & \frac{1}{2} & j'' \\ m & m' & m'' \end{Bmatrix}=\delta_{m'',m+m'}\sqrt{\frac{(j+\frac{1}{2}-j'')!(j+j''-\frac{1}{2})!(j''+\frac{1}{2}-j)!}{(j+j''+\frac{3}{2})!}}$$
$$\times\sum_{r\geqslant 0}\frac{(-1)^r\sqrt{(j+m)!(j-m)!(j''+m'')!(j''-m'')!(2j''+1)}}{r!(j+\frac{1}{2}-j''-r)!(j-m-r)!(\frac{1}{2}+m'-r)!(j''-\frac{1}{2}+m+r)!(j''-j-m'+r)!}, \tag{3.20}$$

we establish the following correspondence:

$$\langle j'',m''|U_1|j,m\rangle=\delta_{j'',j-1/2}\begin{Bmatrix} j & \frac{1}{2} & j'' \\ m & -\frac{1}{2} & m'' \end{Bmatrix},\quad \langle j'',m''|U_2|j,m\rangle=\delta_{j'',j+1/2}\begin{Bmatrix} j & \frac{1}{2} & j'' \\ m & -\frac{1}{2} & m'' \end{Bmatrix},$$
$$\langle j'',m''|U_3|j,m\rangle=\delta_{j'',j-1/2}\begin{Bmatrix} j & \frac{1}{2} & j'' \\ m & \frac{1}{2} & m'' \end{Bmatrix},\quad \langle j'',m''|U_4|j,m\rangle=\delta_{j'',j+1/2}\begin{Bmatrix} j & \frac{1}{2} & j'' \\ m & \frac{1}{2} & m'' \end{Bmatrix}. \tag{3.21}$$

Thus, we proved the following statement:

Proposition 8: The generators U_i of the algebra $\mathscr{U}_0$ are operators of the basic shifts on the model space for sl(2) *and they generate the Clebsch–Gordan coefficients corresponding to decomposition of the product $V_j\otimes V_{1/2}$ of the irreps of* sl*(2).*

This statement allows us to call the matrix U_0 a ''generating matrix'' (by analogy with the notion of a generating function) for CGC.

Remark: Usually, introducing a generating object (well-known examples are the generating functions for different sets of polynomials, e.g., for the Legendre polynomials), one makes properties of the objects under consideration more evident. We think that the notion of generating matrix will be useful for calculations involving CGC of classical and quantum algebras.

D. Wigner–Eckart theorem

One should underline a connection of the results obtained above (Proposition 8) and the well-known mathematical construction—Wigner–Eckart theorem,[18] which has important applications in quantum mechanics.

Let us remember that the Wigner–Eckart theorem gives CGC for classical Lie algebra $\mathscr{J}$ as matrix elements of some set of operators. These operators are called *tensor operators*. They map the corresponding model space $\mathscr{M}$ onto itself and have special transformation properties under adjoint action of the algebra. In the case of $\mathscr{J}=$sl(2) the Wigner–Eckart theorem reads as follows.

Theorem 2: *Let l_+, l_- and l_3 be the generators of* sl(2) *and let T^j_m, $m=-j,\ldots,j$, be a system of operators acting on $\mathscr{M}$ and obeying the commutation relations*

$$[l_3,T^j_m]=mT^j_m,\quad [l_\pm,\,T^j_m]=\sqrt{(j\mp m)(j\pm m+1)}\,T^j_{m\pm1}, \tag{3.22}$$

where $j(j+1)$ is an eigenvalue of the Casimir operator for sl(2). *Then the matrix elements of T^j_m on $\mathscr{M}$ are proportional to Clebsch–Gordan coefficients:*

$$\langle j''m''|T^j_m|j'm'\rangle=C^j_{j''j'}\begin{Bmatrix} j' & j & j'' \\ m' & m & m'' \end{Bmatrix},$$

where the coefficients $C^j_{j''j'}$ do not depend on m, m', m''.

Proposition 8 says that any tensor operators of spin $j=1/2$ (that is, $\{T^{1/2}_{1/2},T^{1/2}_{-1/2}\}$, $T^{1/2}_m: V_j\mapsto V_j\otimes V_{1/2}=V_{j+1/2}\oplus V_{j-1/2}$) may be constructed via the operators U_i (in fact, it is evident from Fig. 1). Indeed, comparing the commutation relations obtained directly from (3.9) and (3.13)

$$\begin{gathered}[l_+,U_1]=U_3,\quad [l_+,U_2]=U_4,\quad [l_+,U_3]=0,\quad [l_+,U_4]=0,\\ [l_-,U_1]=0,\quad [l_-,U_2]=0,\quad [l_-,U_3]=U_1,\quad [l_-,U_4]=U_2,\\ [l_3,U_1]=-\tfrac{1}{2}U_1,\quad [l_3,U_2]=-\tfrac{1}{2}U_2,\quad [l_3,U_3]=\tfrac{1}{2}U_3,\quad [l_3,U_4]=\tfrac{1}{2}U_4\end{gathered} \tag{3.23}$$

with Theorem 2, we get the following.

Proposition 9: The generators U_i of the algebra $\mathscr{U}_0$ form a basis for tensor operators of spin 1/2, that is components $T^{1/2}_{1/2}$ and $T^{1/2}_{-1/2}$ of any tensor operator of spin 1/2 can be realized as linear combinations of U_i:

$$T^{1/2}_{-1/2}=\mu(p)U_1+\nu(p)U_2, \quad T^{1/2}_{1/2}=\mu(p)U_3+\nu(p)U_4, \tag{3.24}$$

where $\mu(p)$ and $\nu(p)$ are functions only of $p=2\hat{j}+1$.

IV. DEFORMED CASE

Now we want to extend the results obtained in the previous section to the case of $q\neq 1$. In particular, we are going to examine the representations of the algebra $\mathscr{U}$ (see Definition 3 above) and to show that the corresponding matrix U generates Clebsch–Gordan coefficients for the deformed Lie algebra. For these purposes we shall exploit a natural connection of $\mathscr{U}$ with $(T^*\mathscr{B})_q$.

A. The q-oscillators approach

There exist different ways to obtain desirable representations of the algebra $\mathscr{U}$. First we describe a more direct but less instructive method, which is similar to that used in the nondeformed case.

By analogy with the nondeformed case studied above, one can assume that the entries of the matrix U might be realized as operators (deformations of those obtained in Proposition 6) acting on the space of two complex variables. Indeed, using the definition (2.33) of the central element of $\mathscr{U}$ and taking into account the identity for q-numbers

$$[a]q^b+[b]q^{-a}=[a+b], \tag{4.1}$$

we can rewrite (2.35)–(2.37) in the following way:

$$\hat{U}_1\hat{U}_3=q^{-1}\hat{U}_3\hat{U}_1, \quad \hat{U}_2\hat{U}_4=q^{-1}\hat{U}_4\hat{U}_2, \quad \hat{U}_1\hat{U}_2=\hat{U}_2\hat{U}_1, \quad \hat{U}_3\hat{U}_4=\hat{U}_4\hat{U}_3, \tag{4.2}$$

$$\hat{U}_1\hat{U}_4-q^{-1}\hat{U}_4\hat{U}_1=q^{-1}\ \mathrm{Det}\ U\ q^{p/\hbar}, \quad \hat{U}_3\hat{U}_2-q\hat{U}_2\hat{U}_3=-\mathrm{Det}\ U\ q^{-p/\hbar}. \tag{4.3}$$

The relations (4.3) are well known in the theory of q-oscillators (q-bosons).[19] Recall that q-analogs of creation, annihilation, and number operators form a deformed Heisenberg algebra defined by the commutation relations

$$aa^+-qa^+a=N^{-1}, \quad Na=q^{-1}aN, \quad Na^+=qa^+N, \tag{4.4}$$

and they can be realized in terms of multiplication and difference operators:

$$a^+=z, \quad a=z^{-1}[z\partial_z], \quad N=q^{z\partial_z}. \tag{4.5}$$

Using two pairs of generators of the deformed Heisenberg algebra, one can construct the generators of $\mathrm{U}_q(\mathrm{sl}(2))$: $l_+=a_1^+a_2$, $l_-=a_2^+a_1$, and $q^{l_3}=N_1^{1/2}N_2^{-1/2}$. Applying here the representation (4.5) one gets

$$l_+=z_1z_2^{-1}[z_2\partial_2], \quad l_-=z_2z_1^{-1}[z_1\partial_1], \quad q^{l_3}=q^{1/2(z_1\partial_1-z_2\partial_2)}. \tag{4.6}$$

The Casimir operator (2.17) of $\mathrm{U}_q(\mathrm{sl}(2))$ in this realization is given by

$$C=qN_1N_2+q^{-1}N_1^{-1}N_2^{-1}. \tag{4.7}$$

Now, comparing, (4.2) and (4.3) with (4.4), it is easy to conclude that the pairs $(\hat{U}_1, \hat{U}_4)$ and $(\hat{U}_2, \hat{U}_3)$ are similar to two pairs of q-boson operators.

Taking into account the Weyl-like form of relations (4.2) and having already found explicit expressions (3.7) and (3.8) for the generators of algebra $\mathscr{U}_0$, one gets an answer for D and $\hat{U}$ in terms of q-oscillators. More precisely, a straightforward calculation allows us to verify the following statement:

Proposition 10: Equations (4.2) and (4.3) have the family of solutions:

$$q^{p/\hbar} = qN_1N_2, \quad \hat{U} = \begin{pmatrix} \alpha_0 a_1 N_1^{\alpha} N_2^{-\beta} & \beta_0 a_2^+ N_1^{\beta} N_2^{-\alpha} \\ -\gamma_0 a_2 N_1^{-(1+\beta)} N_2^{\alpha} & \delta_0 a_1^+ N_1^{-\alpha} N_2^{1+\beta} \end{pmatrix}, \tag{4.8}$$

where $\alpha_0\delta_0 = q\beta_0\gamma_0$.

Let us note that this form of $\hat{U}$ is consistent with the condition (2.32).

Taking into account the connection formula (2.34) and applying to the generators a_i, a_i^+, and N_i the representation (4.5), one obtains from (4.8) a family of representations of the algebra $\mathscr{U}$. To select some of them, we have to impose an additional condition.

As mentioned above [see (3.14) and (3.15)], in the nondeformed case substitution of the generating matrix U_0 in the formula (2.23) gives the matrix L_0 which exactly coincides with the limit version of the matrix (2.16). It is natural to suppose that the generating matrix U corresponding to deformed algebra produces in the same way the matrix (2.16) itself. Bearing in mind the property (2.41), we obtain the following.

Proposition 11: The condition $\hat{U}D\hat{U}^{-1} = L$, *where* L *is the matrix (2.16),* D *is given by*

$$D = \begin{pmatrix} p^{p/\hbar} & \\ & q^{-p/\hbar} \end{pmatrix} = \begin{pmatrix} qN_1N_2 & \\ & q^{-1}N_1^{-1}N_2^{-1} \end{pmatrix}, \tag{4.9}$$

and $\hat{U}$ is given by (4.8), imposes the following restrictions:

$$\alpha + \beta + \tfrac{1}{2} = 0, \quad \alpha_0 = q\gamma_0, \quad \beta_0 = \delta_0. \tag{4.10}$$

Substitution of (4.10) into (4.8) completes description of $\hat{U}$ in terms of q-oscillators.

B. Connection with $(T^*\mathscr{B})_q$

Now we are going to develop another approach to constructing representations of $\mathscr{U}$. It is more universal since it is based on the connection (which takes place for arbitrary quantum Lie algebra) of the algebra $\mathscr{L}$ (see Definition 1) with $(T^*\mathscr{B})_q$ and on the interpretation of the deformed Borel subgroup $\mathscr{B}_q$ as a quantum model space.

To clarify the announced connection we start with the following theorem (this is a version of the theorem given in Ref. 10 for L-operators with nonultralocal relations).

Theorem 3: *Let the matrices* A and B *obey the relations of type (2.1),*

$$R_{\pm}^{12} A^2 A^1 = A^2 A^1 R_{\pm}^{21}, \quad R_{\pm}^{12} B^2 B^1 = B^2 B^1 R_{\pm}^{21}, \tag{4.11}$$

and the additional exchange relation

$$A^1 B^2 = B^2 A^1 R_+^{21}, \quad A^2 B^1 R_-^{21} = B^1 A^2. \tag{4.12}$$

Then the L*-operator constructed by means of similarity transformation*

$$L = ABA^{-1} \tag{4.13}$$

satisfies the relation (2.3).

Remark: Since (4.11) defines a quantum group structure, A^{-1} in (4.13) should be understood as an antipode of A.

Proof of Theorem 3 is straightforward:

$$\begin{aligned} \overset{1}{L}\overset{-1}{R}\overset{2}{L}\overset{}{R}_- &= \overset{1\,1}{A}\overset{1}{B}(A)^{-1}\overset{-1}{R}\overset{2\,2}{A}\overset{2}{B}(A)^{-1}R_- = \overset{1\,1\,2}{ABA}\overset{-1}{R}\overset{1}{(A)}^{-1}\overset{2}{B}\overset{2}{(A)}^{-1}R_- \\ &= \overset{1\,2\,1\,2}{AABB}\overset{-1}{R}\overset{1}{(A)}^{-1}\overset{2}{(A)}^{-1}R_- = \overset{-1}{R}\overset{2\,1\,2\,1}{AABB}R_-\overset{2}{(A)}^{-1}\overset{1}{(A)}^{-1} \\ &= \overset{-1}{R}\overset{2\,2\,1}{ABA}R_+\overset{2}{(A)}^{-1}\overset{1\,1}{B}(A)^{-1} = \overset{-1}{R}\overset{2\,2\,2}{AB}(A)^{-1}R_+\overset{1\,1\,1}{AB}(A)^{-1} = \overset{-1}{R}\overset{2}{L}\overset{}{R}_+\overset{1}{L}. \end{aligned}$$

Thus, for a given quantum group G_q, the algebra $\mathscr{S}$ is embedded into the algebra generated by entries of A and B obeying (4.11) and (4.12). To argue that (4.11) and (4.12) describe a q-analog of $T^*\mathscr{B}$, let us notice that the nonsymmetric (with respect to R-matrices) form of the relations (4.12) imposes some restriction on the structure of the matrices A and B. Say, if R_+ is an upper triangular matrix, then A and B must be upper and lower triangular, respectively. Therefore, one may think of A and B as coordinates in the deformed Borel subgroup $\mathscr{B}_q$ and in the dual quantum space, respectively. In other words, the matrices A and B are coordinate and momentum on the deformed phase space $(T^*\mathscr{B})_q$, respectively. Thus (4.11) and (4.12) may be regarded as a definition of $(T^*\mathscr{B})_q$ (for additional comments see Ref. 10).

We should underline here that, although the matrices A and B look similar on the quantum level, they transform into different objects when $q\to 1$. Indeed, in the limit $q\to 1$ one has $L\to I+\gamma\hbar L_0$ and the corresponding limit forms of A and B are

$$A\to A_0, \quad B\to I+\gamma\hbar B_0, \tag{4.14}$$

where A_0 is a grouplike element, whereas B_0 is rather an element of algebra [see (3.17) as an example of A_0 and B_0 for sl(2)].

Comparing the statements of Theorems 1 and 3 and taking into account the equality (2.41), we get the formula

$$L=ABA^{-1}=\hat{U}D\hat{U}^{-1}, \tag{4.15}$$

which points out a possibility to construct the matrix $\hat{U}$ obeying (2.35)–(2.38) via the generators of $(T^*\mathscr{B})_q$. This connection is very important; below we consider it for $\mathrm{SL}_q(2)$ in all details.

Now let us turn to the example of $\mathrm{SL}_q(2)$. For $R_\pm$ defined as in (2.8) one can choose

$$A=\begin{pmatrix} a & c \\ 0 & a^{-1} \end{pmatrix}, \quad B=\begin{pmatrix} b & 0 \\ d & b^{-1} \end{pmatrix}. \tag{4.16}$$

Explicit relations for the generators of $(T^*\mathscr{B})_q$ following from (4.11) and (4.12) are

$$ac=q^{-1}ca, \quad bc=q^{1/2}cb, \quad ab=q^{1/2}ba; \tag{4.17}$$

$$bd=q^{-1}db, \quad ad=q^{1/2}da, \quad cd=q^{-1/2}dc+q^{-1/2}\omega b^{-1}a. \tag{4.18}$$

Performing the following decomposition,

$$d=d_0+d_1=d_0+q^{1/2}c^{-1}b^{-1}a, \tag{4.19}$$

we transform (4.18) to homogeneous form:

$$bd_0 = q^{-1}d_0 b, \quad ad_0 = q^{1/2}d_0 a, \quad cd_0 = q^{-1/2}d_0 c. \tag{4.20}$$

Thus, (4.17) and (4.20) describe four variables obeying Weyl-like commutation relations. Using the jargon of conformal field theory, we shall call these formulas ''free field representation'' and the generators a, b, c, and d_0 ''free field'' variables.

Remark: The last of equations (4.18) is nothing but a commutation relation entering the definition of deformed Heisenberg algebra. Indeed, comparing (4.17) and (4.18) with (4.4), one can establish the following correspondence (ρ stands for arbitrary numerical constant):

$$c \sim N^{\rho} a^{+}, \quad d \sim -\omega N^{-1/2-\rho} a, \quad b^{-1}a \sim q^{\rho} N^{-3/2}.$$

Thus, the transformation (4.19) can be interpreted as ''bosonization'' of q-oscillators.

Now, substituting (4.16) in (4.13), we get

$$\begin{aligned} L &= q^{1/2} \begin{pmatrix} a & c \\ 0 & a^{-1} \end{pmatrix} \begin{pmatrix} b & 0 \\ d & b^{-1} \end{pmatrix} \begin{pmatrix} a^{-1} & -qc \\ 0 & a \end{pmatrix} \\ &= \begin{pmatrix} q(b+b^{-1}) + a^{-1}cd_0 & -q^2 ac(b + qa^{-1}cd_0) \\ (ac)^{-1}(b^{-1} + q^{-1}a^{-1}cd_0) & -q^2 a^{-1}cd_0 \end{pmatrix}. \end{aligned} \tag{4.21}$$

This matrix provides a ''free field'' realization of the algebra $\mathscr{L}$ for $U_q(\mathrm{sl}(2))$. Note that the additional scaling factor $q^{1/2}$ was introduced in (4.21) to ensure a coincidence of the Casimir operators calculated by formulas (2.13) for the matrix (4.21):

$$K_1 = q^2(b + b^{-1}), \quad K_2 = q^3 \tag{4.22}$$

with those for the matrix (2.16). In fact, we redefined the matrix B in (4.16) as

$$\widetilde{B} = q^{1/2} B. \tag{4.23}$$

Comparing the Casimir operator K_1 given by (4.22) with one given by (2.18), we identify the operator b with the power of the operator of spin $\hat{j}$:

$$b = q^{2\hat{j}+1}. \tag{4.24}$$

It follows from (4.22) that matrix L contains only three independent variables [it is easy to see from the explicit form (4.21) that these are b, ac, and $a^{-1}cd_0$]. Moreover, direct calculation using (4.17) and (4.20) shows that all elements of the matrix L commute with operator b. That agrees with the property (2.25).

Now exploiting the connection described by formula (4.15), one can obtain an exact expression for $\hat{U}$.

Theorem 4: *The algebra $\mathscr{U} \equiv \{\hat{U}, p\}$ with defining relations (2.35)–(2.38) has the following realization in terms of generators a, b, c,* and d_0:

$$b = q^{p/\hbar}, \quad \hat{U} = \begin{pmatrix} \dfrac{1}{\omega}\, a(b + a^{-1}cd_0)e^{-i\xi/2} & ce^{i\xi/2} \\ \dfrac{1}{\omega}\, c^{-1}(b^{-1} + q^{-1}a^{-1}cd_0)e^{-i\xi/2} & a^{-1}e^{i\xi/2} \end{pmatrix}, \tag{4.25}$$

where $\omega \equiv q - q^{-1}$, d_0 is defined in (4.19), and

$$e^{i\xi}=a^{-1}b^{\gamma}c^{-1}d_0^{-1} \tag{4.26}$$

with γ being an arbitrary constant.

This theorem gives a ''free field'' representation of the algebra $\mathscr{U}$. Let us remark that the remaining freedom in (4.26) corresponds only to canonical transformations (since ξ and p are conjugate variables).

The formulated theorem will be proved in several steps. First, we introduce a lower-triangular matrix which diagonalizes the matrix $\widetilde{B}$:

$$V=\begin{pmatrix} v_1 & 0 \\ v_3 & v_2 \end{pmatrix}, \quad \widetilde{B}=V\widetilde{B}_0V^{-1}, \quad \widetilde{B}_0=\begin{pmatrix} q^{1/2}b & 0 \\ 0 & q^{1/2}b^{-1} \end{pmatrix}\equiv q^{1/2}B_0. \tag{4.27}$$

Proposition 12: A possible solution for the matrix V is

$$v_1=v_1(b), \quad v_2=v_2(b), \quad v_3=dv_1(b)f(b), \tag{4.28}$$

where $v_1(b)$ and $v_2(b)$ are arbitrary functions of b and $f(b)=(b-qb^{-1})^{-1}$.

Thus, matrix L given by (4.21) admits a decomposition of the form

$$L=\hat{U}_0\widetilde{B}_0\hat{U}_0^{-1}, \quad \hat{U}_0=AV. \tag{4.29}$$

However, this diagonalization is not unique. Using an arbitrary power of the diagonal matrix Q, which depends on the variable conjugate to b,

$$Q=\begin{pmatrix} e^{i\xi} & \\ & e^{-i\xi} \end{pmatrix}, \quad be^{i\xi}=qe^{i\xi}b, \tag{4.30}$$

we obtain a family of diagonalizing matrices:

$$L=\hat{U}_\delta\,\widetilde{B}_\delta\,\hat{U}_\delta^{-1}, \quad \hat{U}_\delta=AVQ^\delta, \quad \widetilde{B}_\delta=Q^{-\delta}\widetilde{B}_0Q^\delta=q^\delta\widetilde{B}_0=q^{\delta+1/2}B_0. \tag{4.31}$$

An explicit form of the diagonalizing matrix is

$$\hat{U}_\delta=AVQ^\delta=\begin{pmatrix} (av_1+cdv_1f\ )e^{i\delta\xi} & cv_2e^{-i\delta\xi} \\ a^{-1}dv_1fe^{i\delta\xi} & a^{-1}v_2e^{-i\delta\xi} \end{pmatrix}. \tag{4.32}$$

Here we should describe a new object $e^{i\xi}$ which appeared in the matrix $\hat{U}$. We assume that the following Weyl-like relations hold:

$$ae^{i\xi}=q^\alpha e^{i\xi}a, \quad be^{i\xi}=qe^{i\xi}b, \quad ce^{i\xi}=q^\beta e^{i\xi}c, \quad d_0e^{i\xi}=q^\gamma e^{i\xi}d_0. \tag{4.33}$$

Proposition 13: The set of equations (4.33) is equivalent to

$$e^{i\xi}=a^{\beta+(\gamma-1)/2}b^\gamma c^{(\gamma-1)/2-\alpha}d_0^{-1}. \tag{4.34}$$

Now we have to remember that the matrix U (and $\hat{U}$ as well) described in Theorem 1 has to satisfy the relation (2.20) or, equivalently, the relation

$$\overset{1}{B}_0\overset{2}{\hat{U}}_\delta=\overset{2}{\hat{U}}_\delta\overset{1}{B}_0\sigma, \tag{4.35}$$

where σ and B_0 were introduced in (2.20) and (4.27), respectively. A straightforward calculation using (4.17) and (4.18) leads to the following.

Proposition 14: The matrix $\hat{U}_\delta$ given by (4.32) satisfies the relation (4.35) only for $\delta=-1/2$.

It is worth mentioning that such a choice of δ exactly compensates the renormalization of the matrix B in (4.23), i.e., $\widetilde{B}_{-1/2}=B_0$.

Bearing in mind the formula (4.19), one can rewrite (4.32) for $\delta=-1/2$ as follows,

$$\hat{U}\equiv\hat{U}_{-1/2}=\begin{pmatrix} a(b+a^{-1}cd_0)we^{-i\xi/2} & cve^{i\xi/2} \\ c^{-1}(b^{-1}+q^{-1}a^{-1}cd_0)we^{-i\xi/2} & a^{-1}ve^{i\xi/2} \end{pmatrix}, \tag{4.36}$$

where $w\equiv f(b)v_1(b)$ and $v\equiv v_2(b)$.

Finally, a direct check shows (see Appendix C) that the matrix (4.36) obeys Eqs. (2.35)–(2.38) if the functions w and v are constant [we chose them as follows: $v(b)=1$, $w(b)=1/\omega$] and the coefficients in (4.33) and (4.34) satisfy the conditions $\beta=-\alpha$ and $\gamma=\alpha-\beta-1=2\alpha-1$. Thus, Theorem 4 is proven.

Let us end the discussion of relation of $(T^*\mathscr{B})_q$ to algebras $\mathscr{L}$ and $\mathscr{U}$ with one more statement:

Theorem 5: *The algebra generated by coordinates on $(T^*\mathscr{B})_q$ is isomorphic to the algebra generated by entries of the matrix L and Q.*

Proof: Indeed, formulas (4.21) and (4.26) provide explicit expressions for entries of L and Q via the generators a, b, c, and d_0 [up to unessential canonical transformation in (4.26)]. Conversely, suppose matrix L and the element $e^{i\xi}$ are given. Then, as it follows from (4.21), one can construct from entries of L the combinations b, ac, and $a^{-1}cd_0$. Together with (4.26) this allows us to recover the ''coordinates'' a, b, c, and d_0.

Although we considered this theorem only for the case of $\mathrm{SL}_q(2)$, there is, evidence that it holds for the generic case. For example, in the case of $G_q=\mathrm{SL}_q(N)$ a point on the quantum bundle $(T^*\mathscr{B})_q$ is parametrized by $N\times N$ matrices A and B. As above, the matrix $L=ABA^{-1}$ satisfies (2.3) and therefore its entries generate the corresponding algebra $\mathscr{L}$. However, the dimension of $(T^*\mathscr{B})_q$ exceeds the dimension of $\mathscr{L}$: $\dim(T^*\mathscr{B})_q-\dim\mathscr{L}=(N^2+N-2)-(N^2-1)=N-1$. It is very probable that the remaining $(N-1)$ generators are exactly those that enter the diagonal unimodular $N\times N$ matrix Q.

C. Explicit representation

Now we face the problem of constructing an explicit representation for the generators a, b, c, and d_0. A Weyl-like form of the commutation relations (4.17) and (4.20) points out the possibility of getting a realization for these generators in terms of two pairs of canonical variables. This also means [due to the interpretation of (4.19) as ''bosonization'' of q-oscillators] that the generators a, b, c, and d admit a realization via q-oscillators. Evidently, such a representation is not unique.

It is natural to realize a, b, c, and d_0 as operators acting on the q-analog of the space $D(z_1,z_2)$. We shall denote this space as $D_q(z_1,z_2)$. The space $D_q(z_1,z_2)$ is spanned on the basic vectors of form (remember that $[x]$ stands for q-numbers)

$$|j,m\rangle=\frac{z_1^{j+m}z_2^{j-m}}{\sqrt{[j+m]![j-m]!}},\ j=0,\ \tfrac{1}{2},\ 1,\ \tfrac{3}{2},\ldots,\quad m=-j,..,j. \tag{4.37}$$

One can define on $D_q(z_1,z_2)$ such a scalar product that the system (4.37) is orthonormal, that is $\langle j,m|j',m'\rangle=\delta_{jj'}\delta_{mm'}$.

Remark: This scalar product is a deformation of (3.11). Its explicit form makes use of the q-exponent and the Jackson integral. See Ref. 19 for details.

In all formulas concerning the space $D_q(z_1,z_2)$ we suppose that q is chosen as described in Sec. II (i.e., it belongs either to the real axis or to the unit circle at the complex plane). In this case an analog of the rule of conjugation (3.12) is

$$(z_i)^* = z_i^{-1}[z_i\partial_i], \quad (z_i\partial_i)^* = z_i\partial_i\,. \tag{4.38}$$

The formulas (4.24) and (4.25) imply that the generator b is a power of the operator of spin. Hence, on the space $D_q(z_1,z_2)$ it is given by

$$b = q^{z_1\partial_1 + z_2\partial_2 + 1} = qN_1N_2\,. \tag{4.39}$$

Next, let us remember that we already know the limit versions of the generators a, b, c, and d [see Proposition 7; one should take into account the rescaling (4.23)]. Their appropriate deformations for generic q are described by

Proposition 15: The set of operators (with arbitrary constants λ_i, ν_i*)*

$$\begin{gathered} a = q^{\lambda_0} z_1^{-1/2}\, N_1^{\lambda_1}, \quad c = q^{\nu_0}\, z_1^{-1/2} z_2\, N_1^{\lambda_1 - 2} N_2^{\nu_2}, \\ b = qN_1N_2, \quad d = -q^{\lambda_0 - \nu_0 + \nu_2}\, z_2^{-1}(N_2 - N_2^{-1}) N_1 N_2^{-\nu_2} \end{gathered} \tag{4.40}$$

satisfies (4.17) and (4.18) and gives in the limit $\gamma \to 0$ *the generators found in (3.17).*

Although due to Theorem 4 this proposition gives a family of representations for $\mathscr{U}$, we again should impose an additional condition using the matrix (2.16) as a standard (justification for this trick was given above).

Proposition 16: Matrix L given by (4.21) coincides with the matrix (2.16) taken in the representation (4.6) provided that

$$b = qN_1N_2, \quad ac = q^{-1/2} z_1^{-1} z_2 N_1^{-1/2} N_2^{-1/2}, \quad a^{-1} c d_0 = -N_1^{-1} N_2\,. \tag{4.41}$$

Comparing the statements of Propositions 15 and 16, we derive

$$\begin{gathered} a = q^{\lambda_0} z_1^{-1/2} N_1^{3/4}, \quad b = qN_1N_2, \quad c = q^{\nu_0} z_1^{-1/2} z_2 N_1^{-5/4} N_2^{-1/2}, \\ d_0 = -q^{\lambda_0 - \nu_0 - 1/2} z_2^{-1} N_1 N_2^{3/2}, \quad q^{\lambda_0 + \nu_0} = q^{-1/8}. \end{gathered} \tag{4.42}$$

Substituting (4.42) into (4.26) [and remember that (4.26) is defined only up to a coefficient], we get

$$e^{i\xi} = q^{2\epsilon} z_1 N_1^{\gamma - 1/2} N_2^{\gamma - 1}, \tag{4.43}$$

where γ and ϵ are arbitrary. Finally, substituting (4.42) and (4.43) into (4.36), we obtain (one should remember that U and $\hat{U}$ are defined only up to arbitrary scaling factor)

$$\hat{U} = \begin{pmatrix} \dfrac{1}{\omega}\, \alpha_0 z_1^{-1} N_1^{1-\gamma/2} N_2^{3/2-\gamma/2} (N_1 - N_1^{-1}) & \beta_0 z_2 N_1^{\gamma/2 - 3/2} N_2^{\gamma/2 - 1} \\ -\dfrac{1}{\omega}\, q^{-1} \alpha_0 z_2^{-1} N_1^{1/2-\gamma/2} N_2^{1-\gamma/2} (N_2 - N_2^{-1}) & \beta_0 z_1 N_1^{\gamma/2 - 1} N_2^{\gamma/2 - 1/2} \end{pmatrix}. \tag{4.44}$$

It is easy to check that the family of matrices (4.44) exactly coincides with what was obtained in q-oscillator approach (see Propositions 10 and 11).

D. Quantum Clebsch–Gordan coefficients

Using the connection formula (2.34) we get from (4.44) a family of matrices U which provide possible representations of the algebra $\mathscr{U}$. It is natural to study an action of the entries of these matrices on the space $D_q(z_1,z_2)$ described above. On the basic vectors (4.37) these operators act as follows:

$$
\begin{aligned}
U_1|j,m\rangle &= C_1 q^{(1/2)(j-m+1)} \sqrt{\frac{[j+m]}{[2j+1]}}\,|j-\tfrac{1}{2},m-\tfrac{1}{2}\rangle,\\
U_2|j,m\rangle &= C_2 q^{-(1/2)(j+m)} \sqrt{\frac{[j-m+1]}{[2j+1}}|j+\tfrac{1}{2},m-\tfrac{1}{2}\rangle,\\
U_3|j,m\rangle &= -C_3 q^{-(1/2)(j+m+1)} \sqrt{\frac{[j-m]}{[2j+1]}}\,|j-\tfrac{1}{2},m+\tfrac{1}{2}\rangle,\\
U_4|j,m\rangle &= C_4 q^{(1/2)(j-m)} \sqrt{\frac{[j+m+1]}{[2j+1]}}\,|j+\tfrac{1}{2},m+\tfrac{1}{2}\rangle,
\end{aligned}
\tag{4.45}
$$

where the coefficients C_i do not depend on m.

Note that, similar to the classical case, the operators U_i correspond to the basic shifts on the model space. Comparing the matrix elements $\langle j',m'|U_i|j,m\rangle$ following from (4.45) to values of CGC for $\mathrm{U}_q(\mathrm{sl}(2))$ given by q-analog of the Van-der-Waerden formula,[20,21] which for the decomposition of $V_j\otimes V_{1/2}$ looks like following,

$$
\begin{aligned}
&\begin{Bmatrix} j & \frac{1}{2} & j'' \\ m & m' & m'' \end{Bmatrix}_q \\
&= \delta_{m'',m+m'} \left(\frac{[j+\frac{1}{2}-j'']![j+j''-\frac{1}{2}]![j''+\frac{1}{2}-j]!}{[j+j''+\frac{3}{2}]!} \right)^{1/2} q^{(1/2)(j+1/2-j'')(j+j''+3/2)+jm'-(1/2)m} \\
&\times \sum_{r\geqslant 0} \frac{(-1)^r q^{-r(j+j''+3/2)}([j+m]![j-m]![j''+m'']![j''-m'']![2j''+1])^{1/2}}{[r]![j+\frac{1}{2}-j''-r]![j-m-r]![\frac{1}{2}+m'-r]![j''-\frac{1}{2}+m+r]![j''-j-m'+r]!},
\end{aligned}
\tag{4.46}
$$

we establish the following correspondence:

$$
\begin{aligned}
\langle j'',m''|U_1|j,m\rangle &= \delta_{j'',j-1/2}\ \alpha_0\ q^{(1-\gamma/2)j-1/2} \begin{Bmatrix} j & \frac{1}{2} & j'' \\ m & -\frac{1}{2} & m'' \end{Bmatrix}_q,\\
\langle j'',m''|U_2|j,m\rangle &= \delta_{j'',j+1/2}\ \beta_0\ q^{(\gamma/2-1)j} \begin{Bmatrix} j & \frac{1}{2} & j'' \\ m & -\frac{1}{2} & m'' \end{Bmatrix}_q,\\
\langle j'',m''|U_3|j,m\rangle &= \delta_{j'',j-1/2}\ \alpha_0\ q^{(1-\gamma/2)j-1/2} \begin{Bmatrix} j & \frac{1}{2} & j'' \\ m & \frac{1}{2} & m'' \end{Bmatrix}_q,\\
\langle j'',m''|U_4|j,m\rangle &= \delta_{j'',j+1/2}\ \beta_0\ q^{(\gamma/2-1)j} \begin{Bmatrix} j & \frac{1}{2} & j'' \\ m & \frac{1}{2} & m'' \end{Bmatrix}_q.
\end{aligned}
$$

Thus we derive an analog of Proposition 8:

Proposition 17: The generators U_i of the algebra $\mathscr{U}$ are operators of the basic shifts on the model space for $\mathrm{U}_q(\mathrm{sl}(2))$ *and they generate the q-Clebsch–Gordan coefficients corresponding to decomposition of the product $V_j\otimes V_{1/2}$ of irreps of* $\mathrm{U}_q(\mathrm{sl}(2))$.

Remark: Putting $\alpha_0=q^{1/2}$, $\beta_0=1$, and $\gamma=2$ in (4.44), we get the following generating matrix:

$$U=\begin{pmatrix} z_1^{-1}[z_1\partial_1]q^{(1/2)(z_2\partial_2+1)} & z_2q^{-(1/2)z_1\partial_1} \\ -z_2^{-1}[z_2\partial_2]q^{-(1/2)(z_1\partial_1+1)} & z_1q^{(1/2)z_2\partial_2} \end{pmatrix}\frac{1}{\sqrt{[p/\hbar]}},\quad \text{Det } U=q^{1/2}, \tag{4.47}$$

which may be called ''exact'' as it satisfies (4.45) with $C_i=1$. The question about unitarity of the matrix (4.47) is discussed in Appendix B.

E. Generalized Wigner–Eckart theorem

As we demonstrated in the previous section, entries of the matrix U_0 are tensor operators of spin 1/2 for $\mathscr{J}=\mathrm{sl}(2)$, hence they provide a realization of the Wigner–Eckart theorem. Let us now consider the matrix U from this point of view.

The theory of tensor operators for quantum algebras was discussed by many authors (see, e.g., Ref. 22). In particular, the generalized Wigner–Eckart theorem [in the case of $\mathscr{J}_q=U_q(\mathrm{sl}(2))$] reads as follows.

Theorem 6: *Let l_+, l_-, and l_3 be the generators of $U_q(\mathrm{sl}(2))$ and let T^j_m, $m=-j,..,j$, be a system of operators acting on the deformed model space $\mathscr{M}$ and obeying the commutation relations*

$$[l_3,\ T^j_m]=mT^j_m,\quad l_\pm T^j_m q^{l_3}-q^{l_3\mp 1}T^j_m l_\pm=\sqrt{[j\mp m][j\pm m+1]}\,T^j_{m\pm 1}. \tag{4.48}$$

Then the matrix elements of T^j_m on $\mathscr{M}$ are proportional to q-Clebsch–Gordan coefficients:

$$\langle j''m''|T^j_m|j'm'\rangle=C^j_{j''j'}\begin{Bmatrix} j' & j & j'' \\ m' & m & m'' \end{Bmatrix}_q,$$

where the coefficients $C^j_{j''j'}$ do not depend on m, m', and m''.

Proposition 17 implies that U_i may be regarded as q-tensor operators. Indeed, using (4.44) and (4.6), one can check that U_i satisfy (4.48) [one obtains for U_i deformations of relations (3.23)]. Similarly to the classical case we have the following.

Proposition 18: The generators U_i of the algebra $\mathscr{U}$ form a basis for q-tensor operators of spin 1/2, that is components $T^{1/2}_{1/2}$ and $T^{1/2}_{-1/2}$ of any q-tensor operator of spin 1/2 can be realized as linear combinations of U_i:

$$T^{1/2}_{-1/2}=\mu(p)U_1+\nu(p)U_2,\quad T^{1/2}_{1/2}=\mu(p)U_3+\nu(p)U_4, \tag{4.49}$$

where $\mu(p)$ and $\nu(p)$ are functions only of p.

Remark: Unlike the classical case, solution (4.44) gives a family of matrices U. However, the corresponding matrix elements $\langle j''m''|U_i|j'm'\rangle$ differ only by factors which do not depend on m' and m''. Thus, any representative of the obtained family of matrices U may be used in Proposition 18.

Let us end the description of the algebra $\mathscr{U}$ from the point of view of theory of q-tensor operators with the following statement:

Proposition 19: The matrices U and L defined in Theorem 1 obey the relation

$$R_-\overset{1\,2}{U}L=L\overset{2}{R}_+\overset{1}{U}. \tag{4.50}$$

The proof is straightforward:

$$R_{-}^{1\,2}UL = R_{-}^{1\,2}UU^{2}D(U)^{-1} = U^{2}U^{1}\mathscr{R}_{-}D^{2}(U)^{-1} = U^{2}U^{1}D^{2}\sigma\mathscr{R}_{+}^{2}(U)^{-1}$$

$$= U^{2}D^{2}U^{1}\mathscr{R}_{+}^{2}(U)^{-1} = U^{2}D^{2}(U)^{-1}R_{+}^{1}U^{2}L^{1} = LR_{+}U;$$

it makes use of the relations (2.20) and (2.21) and the property (2.24).

A remarkable fact is that (4.50) may be used for definition of q-tensor operators instead of (4.48). Indeed, in the limit $\gamma\to 0$ it turns into

$$[U_0^{1}, L_0^{2}] = \Lambda U_0^{1}, \quad \Lambda = \begin{pmatrix} 1/2 & & & \\ & -1/2 & 1 & \\ & 1 & -1/2 & \\ & & & 1/2 \end{pmatrix}. \tag{4.51}$$

Using the explicit form of L_0 given in (3.14), one can easily check that this matrix relation is equivalent to (3.23). More on R-matrix description of q-tensor operators is given in Ref. 23.

V. CONCLUSION

In this paper we have constructed the q-analog of the phase space $T^*\mathscr{B}$ and clarified its role in description of the model representation of the corresponding quantum group G_q. We unraveled a connection between the algebras generated by entries of matrix (A,B), (U,D), and (L,Q). The general formulas were concretized by the example of $G=\mathrm{SL}(2)$.

An extension of the described scheme to the case of arbitrary group G will definitely improve understanding of the role played by the matrix $\mathscr{R}(p)$ which so far has been discussed in the literature much less than standard matrix R.

The results of this paper can be generalized in several directions even for the case of SL(2). The first is a consideration of the matrix U with an auxiliary space corresponding to the higher spin representation. It must lead to an exact form of the generating matrix for all CGC. The work in this direction is in progress now. The second point to be discussed is the case of q being a root of unity. The structure of $\mathscr{R}(p)$ allows us to hope that reduction on so-called ''good'' representations will be quite natural in our formalism. However, this case is to be examined more carefully.

ACKNOWLEDGMENTS

We are grateful to A. Yu. Alekseev, P. P. Kulish, and V. Schomerus for stimulating discussions and useful comments. We would like to thank Professor A. Niemi for hospitality at TFT, University of Helsinki, where this work was begun.

APPENDIX A: PROOF OF THEOREM 1

Using (2.20) and (2.21) together with the identity (2.24) and taking into account that matrices D^{1}, D^{2}, and σ mutually commute, we check

$$
\begin{aligned}
\overset{1}{L}\overset{-1}{R}_{-}\overset{2}{L}R_{-} &= \overset{1\,1}{U}\overset{1}{D}(U)^{-1}\overset{-1}{R}_{-}\overset{2\,2}{U}\overset{2}{D}(U)^{-1}R_{-} \\
&= \overset{1\,1\,2}{U}D\overset{-1}{U}\mathscr{R}_{-}(p)(\overset{1}{U})^{-1}\overset{2\,2}{D}(U)^{-1}R_{-} \\
&= \overset{1\,2\,1}{U}U D\sigma\mathscr{R}_{-}^{-1}(p)\overset{2}{D}\sigma(\overset{1}{U})^{-1}(\overset{2}{U})^{-1}R_{-} \\
&= R_{+}^{-1}\overset{2\,1}{U}U\mathscr{R}_{+}(p)\overset{1}{D}\sigma\mathscr{R}_{-}^{-1}(p)\overset{2}{D}\sigma\mathscr{R}_{-}(p)(\overset{2}{U})^{-1}(\overset{1}{U})^{-1} \\
&= R_{+}^{-1}\overset{2\,1\,2}{U}UD\sigma\overset{1}{D}\mathscr{R}_{-}(p)(\overset{2}{U})^{-1}(\overset{1}{U})^{-1} \\
&= R_{+}^{-1}\overset{2\,2\,1}{U}DU\mathscr{R}_{+}(p)\sigma\overset{1}{D}(\overset{2}{U})^{-1}(\overset{1}{U})^{-1} \\
&= R_{+}^{-1}\overset{2\,2\,1}{U}DU\mathscr{R}_{+}(p)(\overset{2}{U})^{-1}\overset{1}{D}(\overset{1}{U})^{-1} \\
&= R_{+}^{-1}\overset{2\,2}{U}\overset{2}{D}(U)^{-1}R_{+}\overset{1\,1}{U}\overset{1}{D}(U)^{-1} = \overset{-1}{R}_{+}\overset{2}{L}R_{+}\overset{1}{L}.
\end{aligned}
$$

APPENDIX B: ON CONJUGATION OF U_0 AND U

First we consider the matrix U_0. Using the rules of conjugation (3.12) (and taking into account that $p^*=p$), one can check that the matrix conjugated to U_0 does not coincide with U_0^{-1}; that is, the matrix U_0 itself is not unitary. However, it turns out that the transposed matrix [one should remember that in general $(U^T)^{-1}\neq(U^{-1})^T$ for matrices with noncommuting entries]

$$
U_0^T=\begin{pmatrix} \partial_1 & -\partial_2 \\ z_2 & z_1 \end{pmatrix}\sqrt{\frac{\hbar}{p}}
$$

satisfies the unitarity condition:

$$
(U_0^T)^*=\sqrt{\frac{\hbar}{p}}\begin{pmatrix} z_1 & \partial_2 \\ -z_2 & \partial_1 \end{pmatrix}=(U_0^T)^{-1}.
$$

In the deformed case (recall that q can be either real or $|q|=1$) the matrix U includes the operator N which conjugates in different ways for the different choices of q. Let us consider the matrix U given by (4.47). The conjugated matrix can be constructed according to the rules (4.38). Using the formula (4.1), one can check that the unitarity condition $(U^T)^*U^T=U^T(U^T)^*=I$ (i.e., the same as in the nondeformed case) for the transposed matrix holds only for real q. For $|q|=1$, see Ref. 13.

APPENDIX C: PROOF OF THEOREM 4

Here we complete the proof of Theorem 4, i.e., we have to prove that matrix (4.36) satisfies (2.35)–(2.37) if the following conditions,

$$
\alpha+\beta=0, \quad \gamma+\beta-\alpha+1=0, \quad v(b)=1, \quad w(b)=1/\omega, \tag{C1}
$$

are fulfilled.

First, using relations (4.17), (4.20), and (4.33) and conditions (C1), we check

$$\hat{U}_1\hat{U}_2 = a(b+a^{-1}cd_0)e^{-i\xi}ce^{i\xi} = q^{-1/2+\beta/2}ca(b+qa^{-1}cd_0)e^{i\xi}e^{-i\xi}$$
$$= q^{\alpha/2+\beta/2}ce^{i\xi}a(b+q^{(\gamma+\beta-\alpha+1)/2}a^{-1}cd_0)e^{-i\xi} = \hat{U}_2\hat{U}_1,$$

$$\hat{U}_1\hat{U}_3 = a(b+a^{-1}cd_0)e^{-i\xi}c^{-1}(b^{-1}+q^{-1}a^{-1}cd_0)e^{-i\xi}$$
$$= q^{1/2-\beta/2}c^{-1}a(b+q^{-1}a^{-1}cd_0)e^{-i\xi}(b^{-1}+q^{-1}a^{-1}cd_0)e^{-i\xi}$$
$$= q^{-\beta/2}c^{-1}a(b^{-1}+q^{-1}a^{-1}cd_0)(b+q^{-1}a^{-1}cd_0)e^{-i\xi}e^{-i\xi}$$
$$= q^{-1/2-\beta/2}c^{-1}(b^{-1}+q^{-1}a^{-1}cd_0)a(b+q^{-1}a^{-1}cd_0)e^{-i\xi}e^{-i\xi}$$
$$= q^{-1-\alpha/2-\beta/2}c^{-1}(b^{-1}+q^{-1}a^{-1}cd_0)ae^{-i\xi}(b+a^{-1}cd_0)e^{-i\xi}$$
$$= q^{-1}\hat{U}_3\hat{U}_1.$$

The rest of relations (2.35) can be proved similarly.

Next, note that relation (2.36) can be rewritten as follows:

$$\hat{U}_1\hat{U}_4(b-b^{-1}) - \hat{U}_4\hat{U}_1(qb-q^{-1}b^{-1}) = -\omega\hat{U}_3\hat{U}_2b. \tag{C2}$$

To prove this quality we transform its lhs and rhs as follows

$$\hat{U}_1\hat{U}_4(b-b^{-1}) - \hat{U}_4\hat{U}_1(qb-q^{-1}b^{-1})$$
$$= a(b+a^{-1}cd_0)e^{-i\xi}a^{-1}e^{i\xi}(b-b^{-1}) - a^{-1}e^{i\xi}a(b+a^{-1}cd_0)e^{-i\xi}(qb-q^{-1}b^{-1})$$
$$= q^{-\alpha/2}(q^{1/2}b+q^{-1/2}a^{-1}cd_0)(b-b^{-1}) - q^{-\alpha/2}(q^{-1/2}b+q^{1/2}a^{-1}cd_0)(qb-q^{-1}b^{-1})$$
$$= -q^{-\alpha/2}\omega(q^{1/2}a^{-1}cd_0b+q^{-1/2});$$

$$\hat{U}_3\hat{U}_2b = c^{-1}(b^{-1}+q^{-1}a^{-1}cd_0)e^{-i\xi}ce^{i\xi}b$$
$$= q^{\beta/2}(q^{-1/2}b^{-1}+q^{1/2}a^{-1}cd_0)b = q^{\beta/2}(q^{-1/2}+q^{1/2}a^{-1}cd_0b).$$

Thus, the equality (C2) is fulfilled if conditions (C1) are valid. The relation (2.37) can be proved in the same way.

Relations between the Casimir operators of sl(1|2) and osp(2|2) superalgebras

Michel Daumens and Pierre Minnaert
Université Bordeaux I, Centre de Physique Théorique et Modélisation, Rue du Solarium, 33174 Gradignan Cedex, France

(Received 21 May 1996; accepted for publication 15 July 1996)

The superalgebras sl(1|2) and osp(2|2) are isomorphic. Their Casimir operators have been published in the form of a quadratic (K_2) and a cubic (K_3) operator for sl(1|2) and a quadratic (I_2) and a quartic (I_4) operator for osp(2|2). In this note we derive the algebraic relations between both sets of Casimir operators. © *1996 American Institute of Physics.* [S0022-2488(96)02511-X]

I. INTRODUCTION

The special linear superalgebra sl(1|2) and the orthosymplectic superalgebra osp(2|2) are isomorphic.[1] The independent Casimir operators of both superalgebras have been published in the literature in the following form:

(i) a quadratic (K_2) and a cubic (K_3) operator for sl(1|2),[2] and
(ii) a quadratic (I_2) and a quartic (I_4) operator for osp(2|2).[3]

Because of the isomorphy between both superalgebras, there must exist algebraic relations between both sets (I_2, I_4) and (K_2, K_3). The aim of this letter is to exhibit these relations.

In 1977, Scheunert, Nahm, and Rittenberg[4] introduced the concept of grade star representation for superalgebras. Also, they defined two types of representations:

(i) the *typical representations*, such that the even and the odd parts of the representation space have the same dimension, and
(ii) the *atypical representations*, such that the even and the odd parts of the representation space do not have the same dimension.

Only typical representations can be characterized by the eigenvalues of the Casimir operators, since these vanish for the atypical representations.

II. CASIMIR OPERATORS OF sl(1|2) SUPERALGEBRA

Considering the bosonic subalgebra gl(1)⊕sl(2), Scheunert, Nahm, and Rittenberg[2] showed that the irreducible representations of sl(1|2) are characterized by two numbers (b,q), $b \in \mathbb{R}$, $2q \in \mathbb{N}$, and by the parity λ that takes the value 0 or 1. These representations are typical if $|b| \neq q$ and atypical if $|b| = q$. Then, using a *positive definite* scalar product in the representation space, Scheunert *et al.* derived the star and the grade star representations of sl(1|2). They found two classes $\mathscr{S}^{\pm}$ of star representations for $\pm b > q$, and one class of grade star representations for $q = \frac{1}{2}$ and $|b| < \frac{1}{2}$. They concluded that considering grade star representations of sl(1|2) is almost useless.

In a recent article,[5] these results have been extended by consideration of the embedding of osp(1|2) in sl(1|2), and making use of a *nonpositive definite* scalar product which generalizes that defined by Minnaert and Mozrzymas for osp(1|2).[6] For typical representations, there are three classes of grade star representations

$$\mathscr{G}^{\pm}, \quad \text{for} \quad \pm b > q \quad \text{and} \quad \mathscr{G}^{0}, \quad \text{for} \quad |b| < q.$$

The classes $\mathscr{G}^{\pm}$ are equivalent to $\mathscr{S}^{\pm}$ for star representations while $\mathscr{G}^{0}$ generalizes the grade star representation class defined in Ref. 2 for positive definite scalar product.

The two independent Casimir operators K_2 and K_3 of the sl(1|2) superalgebra are built in the following way.[7] Let X_μ be the generators of sl(1|2). One defines metric forms

$$g_{\mu\nu}=\mathrm{Tr}(\gamma X_\mu X_\nu), \quad g_{\mu\nu\rho}=\mathrm{Tr}(\gamma X_\mu X_\nu X_\rho), \tag{1}$$

where γ is a diagonal matrix with eigenvalues $+1$ (resp. -1) in the even (resp. odd) subspace. Then, the Casimir operators are simply defined by

$$K_2=g_{\mu\nu}X^\mu X^\nu, \quad K_3=g_{\mu\nu\rho}X^\mu X^\nu X^\rho, \tag{2}$$

where $X^\mu=g^{\mu\nu}X_\nu$.

Explicitly, with the notations of Ref. 2, the sl(1|2) generators $\{\mathbf{Q}, B, V_\alpha, W_\alpha\}$ $(\alpha=\pm\frac{1}{2})$ satisfy the (anti)commutation relations

$$\begin{aligned}
&[Q_i,Q_j]=i\varepsilon_{ijk}Q_k, \quad [B,V_\alpha]=\tfrac{1}{2}V_\alpha, \quad [B,W_\alpha]=-\tfrac{1}{2}W_\alpha,\\
&[\mathbf{Q},B]=0, \quad [\mathbf{Q},V_\alpha]=\tfrac{1}{2}V_\beta(\boldsymbol{\tau})^\beta{}_\alpha, \quad [\mathbf{Q},W_\alpha]=\tfrac{1}{2}W_\beta(\boldsymbol{\tau})^\beta{}_\alpha,\\
&\{V_\alpha,V_\beta\}=\{W_\alpha,W_\beta\}=0, \quad \{V_\alpha,W_\beta\}=(C\boldsymbol{\tau})_{\alpha\beta}\cdot\mathbf{Q}+C_{\alpha\beta}B,
\end{aligned} \tag{3}$$

where $\boldsymbol{\tau}$ are the usual Pauli matrices and $C=i\tau_2$ is the charge conjugation matrix. Then, the expressions of the Casimir operators K_2 and K_3 of sl(1|2) are

$$K_2=\mathbf{Q}^2-B^2+\tfrac{1}{2}(VCW+WCV), \tag{4}$$

$$K_3=BK_2+\tfrac{1}{4}B(VCW+WCV)+\tfrac{1}{6}(V\mathbf{Q}\cdot\boldsymbol{\tau}\mathbf{C}\mathbf{W}-W\mathbf{Q}\cdot\boldsymbol{\tau}CV)+\tfrac{1}{12}(V\boldsymbol{\tau}CW-W\boldsymbol{\tau}CV)\cdot\mathbf{Q}. \tag{5}$$

Note that, as pointed out by V. Rittenberg,[8] there is a misprint in the original article: the coefficient of the second term in K_3 is indeed $\frac{1}{4}$ instead of $\frac{1}{2}$. This misprint was reproduced in Refs. 1 and 5.

In the grade star (b,q)-representation of sl(1|2), the eigenvalues k_2 and k_3 of the Casimir operators K_2 and K_3 take the values

$$k_2=q^2-b^2 \quad \text{and} \quad k_3=b(q^2-b^2). \tag{6}$$

III. CASIMIR OPERATORS OF osp(2|2) SUPERALGEBRA

The osp(2|2) superalgebra can be described in a compact form by a super-antisymmetric tensor $T=\{T_{ab}\}$ $(a,b=1,2,\pm\frac{1}{2})$, i.e.,

$$T_{ba}=-(-1)^{ab}T_{ab},$$

with the short notations $(-1)^{ab}=(-1)^{\nu(a)\nu(b)}$ and $(-1)^{a+b}=(-1)^{\nu(a)+\nu(b)}$, where the Grassman degree $\nu(a)=0$ for $a=1,2$ and $\nu(a)=1$ for $a=\pm\frac{1}{2}$. The supercommutator of two tensor components is defined as

$$[T_{ab},T_{cd}]_s=T_{ab}T_{cd}-(-1)^{(a+b)(c+d)}T_{cd}T_{ab}.$$

Then, the T tensor components verify the following supercommutation relation that characterizes the osp(2|2) super algebra

$$[T_{ab},T_{cd}]_s=\frac{1}{i}\{g_{bc}T_{ad}-(-1)^{cd}g_{bd}T_{ac}-(-1)^{ab}g_{ac}T_{bd}+(-1)^{ab+cd}g_{ad}T_{bc}\},$$

where the metric tensor g_{ab} is defined as $g_{ab}=(\delta_{ij},-C_{\alpha\beta})$. The contravariant tensor g^{ab}, such that $g_{ab}g^{bc}=g^{cb}g_{ba}=\delta_a^c$, writes $g^{ab}=(\delta_{ij},C_{\alpha\beta})=g_{ba}=(-1)^{ab}g^{ba}$. Because the T tensor is super-antisymmetric, its trace vanishes: $\mathrm{Tr}(T)\equiv g^{ab}T_{ab}=0$. The contracted products are tensors ($n\in N^*$)

$$(T^2)_{ab}=T_{ac}g^{cd}T_{db},\quad (T^n)_{ab}=T_{ac}g^{cd}(T^{n-1})_{db},$$

and their traces are invariant, $[\mathrm{Tr}(T^n),\ T_{ab}]_s=0$.

The osp(2|2) superalgebra possesses two independent Casimir operators. Because of the identity $\mathrm{Tr}(T^3)=i\ \mathrm{Tr}(T^2)$, these Casimir operators can be chosen as

$$I_2=-\tfrac{1}{2}(T^2)\quad\text{and}\quad I_4=\tfrac{1}{2}(T^4). \tag{7}$$

Note that an equivalent description of this superalgebra is given in Ref. 3.

Up to an equivalence, the finite-dimensional irreducible representations of the osp(2|2) superalgebra can be characterized by two integer or half-integer non-negative numbers (p,q) and by a parity λ taking the value 0 or 1. For such representations, the eigenvalues i_2 and i_4 of the Casimir operators I_2 and I_4 are

$$i_2=p^2-4q^2, \tag{8}$$

$$i_4=(p^2-4q^2)(p^2+4q^2+1). \tag{9}$$

IV. RELATIONS BETWEEN CASIMIR OPERATORS

The isomorphism of the two superalgebras sl(1|2) and osp(2|2) can be expressed by the following relations between the eight generators of sl(1|2), cf. Eq. (3), and the components of the tensor T_{ab}:

$$B=\frac{1}{2}T_{12},\quad \mathbf{Q}=\frac{i}{4}(\boldsymbol{\tau}C)^{\alpha\beta}T_{\alpha\beta}, \tag{10}$$

$$V_\alpha=\frac{1}{2i}(T_{1\alpha}+iT_{2\alpha}),\quad W_\alpha=\frac{1}{2i}(T_{1\alpha}-iT_{2\alpha}). \tag{11}$$

Then, it is easy to see that the parameters p and b satisfy the relation $p=2b$ and that both quadratic operators I_2 and K_2 are proportional:

$$I_2=-4K_2, \tag{12}$$

An algebraic relation between the other Casimir operators I_4 and K_3 can be derived by elimination of the parameters $p(p=2b)$ and q between the expressions (6) and (9) of the eigenvalues k_3 and i_4 in a (p,q)-representation. The result is a relation that involves also the eigenvalue k_2 of the quadratic operator

$$k_2i_4+32k_3^2+16k_2^3+4k_2^2=0. \tag{13}$$

General theorems in the theory of algebra representations imply that such relations between eigenvalues can be extended to relations between Casimir operators themselves. Therefore, the Casimir operators must satisfy the following algebraic relation:

$$K_2 I_4 + 32K_3^2 + 16K_2^3 + 4K_2^2 = 0, \tag{14}$$

which is of sixth degree in the generators. Indeed, this relation can be verified directly on the operators, using the definitions (4), (5), and (7) of Casimir operators and the relations (10) and (11) between both sets of generators.

ACKNOWLEDGMENTS

We would like to thank Professor V. Rittenberg for fruitful discussions and for pointing out an unfortunate misprint in the expression of K_3 in Ref. 2.

Wavelet frames and admissibility in higher dimensions

Hartmut Führ[a)]
Mathematisches Institut, Technische Universität München, D-80290 München, Germany

(Received 12 March 1996; accepted for publication 12 August 1996)

This paper is concerned with the relations between discrete and continuous wavelet transforms on k-dimensional Euclidean space. We start with the construction of continuous wavelet transforms with the help of square-integrable representations of certain semidirect products, thereby generalizing results of Bernier and Taylor. We then turn to frames of $L^2(\mathbb{R}^k)$ and to the question, when the functions occurring in a given frame are admissible for a given continuous wavelet transform. For certain frames we give a characterization which generalizes a result of Daubechies to higher dimensions. © *1996 American Institute of Physics.*

I. INTRODUCTION

The usual approach to the construction of multivariate wavelets uses the notions of multiresolution analysis and frames. In this context, a wavelet is a function f in $L^2(\mathbb{R}^k)$, such that certain translates and dilates of f constitute a frame of the space $L^2(\mathbb{R}^k)$ (possibly along with translates and dilates of other functions). A different approach, introduced to wavelet theory by Grossmann, Morlet and Paul,[1] uses the theory of square-integrable representations of nonunimodular groups, as it was developed independently by Duflo and Moore[2] and Carey.[3] Murenzi[4] as well as Bernier and Taylor[5] followed this approach to construct higher-dimensional analogues of the one-dimensional continuous wavelet transform. They considered the semidirect product of $\mathbb{R}^k$ with certain matrix groups (which served as dilations) and constructed natural representations of these groups on $L^2(\mathbb{R}^k)$, which under suitable conditions turned out to be square-integrable. The general theory then supplies a continuous wavelet transform on $L^2(\mathbb{R}^k)$. Now, in the group-theoretical setting, a wavelet is understood to be an admissible element in the sense that the positive-definite function associated to it is square-integrable.

Hence, depending on whether one generalizes the discrete or the continuous wavelet transform to higher dimensions, one arrives at different concepts, and the relations between these concepts are not clear. In the one-dimensional case, it has been shown by Daubechies,[6] that both notions are equivalent. In the higher-dimensional case, while there has been work done concerning discretization of the continuous wavelet transforms associated to square-integrable representations[5,7,8] to our knowledge there has been no attempt to reverse the process, i.e. consider the question of admissibility of the functions constituting a frame. This is mainly due to the greater practical use of frames for implementation, whereas the continuous wavelet transform rather serves as a vehicle for the construction of frames. Moreover, in higher dimensions the number of groups in question increases (and, at the same time, the number of different notions of admissibility), making it hard to decide which is the natural choice. However, such notions as multiresolution analysis should have some interpretation in terms of group representations, and the question of admissibility of the functions spanning the multiresolution analysis suggests itself as a means of judging the relationship between a given continuous and discrete wavelet transform.

In section II we establish some notation and preliminary results. In particular we introduce the class of semidirect products and their quasiregular representations on $L^2(\mathbb{R}^k)$, which we are going to use for the construction of continuous wavelet transforms.

[a)]Electronic mail: fuehr@mathematik.tu-muenchen.de

In sections III and IV we decide which of these quasiregular representations actually yield continuous wavelet transforms, section III being devoted to irreducibility and section IV to square-integrability.

Section V gives an admissibility criterion for the continuous wavelet transform which is analogous to the well-known integral criterion for univariate wavelets.

Section VI gives two short examples.

In section VII we turn to frames and to the question of admissibility of the functions constituting a given frame. For certain frames we give a characterization which generalizes a result from Ref. 6 to higher dimensions.

II. PRELIMINARIES AND NOTATION

As a natural generalization of the one-dimensional affine group and the wavelet-transform associated to it, D. Bernier and K. Taylor suggest the following construction:[5] Given the k-dimensional vector group $\mathbb{R}^k$ and a closed subgroup H of $\mathrm{GL}(k,\mathbb{R})$, let G denote the semidirect product $\mathbb{R}^k \rtimes H$. Then G acts on $\mathbb{R}^k$ by translations (corresponding to the elements of the vector group) and dilations (corresponding to elements of H), which gives rise to a natural unitary representation π of G on $\mathrm{L}^2(\mathbb{R}^k)$, defined as follows: For a given pair $(x,h) \in G$ and $f \in \mathrm{L}^2(\mathbb{R}^k)$, let $\pi(x,h)f$ be the function defined almost everywhere by

$$\pi(x,h)f(y) = |\det(h)|^{-1/2} f(h^{-1}(y-x)).$$

We study this setup with a view to constructing continuous wavelet transforms, which means that we are interested in the case where π is square-integrable or at least has square-integrable subrepresentations. For the group $H := \mathbb{R}^+ \cdot \mathbf{SO}(k)$, Murenzi showed that indeed we obtain a square-integrable representation. The authors of Ref. 5 considered a whole family of groups H which yield square-integrable representations. However their results do not cover Murenzi's group (at least not for $k>2$), which suggested that there was room for generalizations.

Hence, in the first half of our paper, we examine the situation sketched above with focus on the following questions:

(i) When does π have square-integrable subrepresentations?
(ii) Which are the admissible functions? Is there an admissibility criterion similar to that of the one-dimensional affine case?

It will be seen that, if the action of H on the dual space $\widehat{\mathbb{R}^k}$ satisfies a certain regularity condition, these questions can be answered in a quite satisfactory way. On the other hand, if the regularity condition fails, things seem to become all the more difficult.

Let us now fix some notation and collect the basic facts used in this paper. λ denotes the standard Lebesgue measure on $\mathbb{R}^k$ (or $\widehat{\mathbb{R}^k}$). We will denote the left Haar measure on a locally compact group G by μ_G and its modular function by Δ_G. In our case of the semidirect product $G = \mathbb{R}^k \rtimes H$, we have Haar measure

$$d\mu_G(x,h) = |\det(h)|^{-1} d\lambda(x) d\mu_H(h),$$

and the modular function on G is given by

$$\Delta_G(x,h) = \Delta_H(h) |\det(h)|^{-1}.$$

We use $\widehat{\ }$ to denote both Plancherel and Fourier transform, the exact meaning being clear from the context. $\check{\ }$ denotes the inverse Plancherel transform. By a representation we mean a strongly continuous unitary group representation.

It is useful to calculate the action of π on the Plancherel transform side. Proposition 1 from Ref. 5 provides the following formula, for all $(x,h) \in G$ and all $f \in L^2(\mathbb{R}^k)$:

$$(\pi(x,h)f)^\wedge(\gamma) = |\det(h)|^{1/2} e^{2\pi i \gamma x} \hat{f}(\gamma h), \text{ for almost all } \gamma \in \widehat{\mathbb{R}^k}. \tag{1}$$

III. IRREDUCIBLE SUBREPRESENTATIONS OF THE QUASIREGULAR REPRESENTATION

This section is devoted to finding all irreducible subrepresentations of π, which can be done quite systematically: We give a characterization of the invariant subspaces which is transparent enough to identify the irreducible subspaces.

As was already observed in Ref. 5, the key to invariant subspaces lies in the dual action of H on $\widehat{\mathbb{R}^k}$. If one identifies $\widehat{\mathbb{R}^k}$ as row vectors and defines the duality between $\mathbb{R}^k$ and $\widehat{\mathbb{R}^k}$ by $\langle x,\xi\rangle = e^{2\pi i \xi x}$, then the dual action of H is just matrix multiplication on the right. It will be seen that a very promising class of subspaces is contained in the following definition:

Definition 1: Let $U \subset \widehat{\mathbb{R}^k}$ be measurable. We let $\mathscr{H}_U$ be the closed subspace of $L^2(\mathbb{R}^k)$ consisting of all $f \in L^2(\mathbb{R}^k)$, whose Plancherel transforms $\hat{f}$ satisfy $\hat{f}(\xi) = 0$ for almost all ξ outside of U.

The space $\mathscr{H}_U$ is sometimes called the *generalized Hardy space belonging to U*. The following theorem shows that generalized Hardy spaces are suitable candidates for invariant subspaces:

Theorem 2: *Let $U \subset \widehat{\mathbb{R}^k}$ be invariant under the action of H. Then the Hardy space $\mathscr{H}_U$ is G-invariant. On the other hand: For every G-invariant subspace $\mathscr{H}$ there is an H-invariant subset U of $\widehat{\mathbb{R}^k}$ such that $\mathscr{H} = \mathscr{H}_U$.*

Proof: We start by observing that every G-invariant subspace $\mathscr{H}$ is in particular translation-invariant, and by general Fourier theory[9] this entails $\mathscr{H} = \mathscr{H}_U$ for some measurable $U \subset \widehat{\mathbb{R}^k}$. However, since changing U by any set of measure zero does not affect $\mathscr{H}_U$, U cannot be expected to be H-invariant.

The first step towards finding an equivalent invariant set is the observation that, since $\mathscr{H}_U$ is translation-invariant, $\mathscr{H}_U$ is G-invariant if it is H-invariant. By Eq. (1) from above we know that for every $f \in L^2(\mathbb{R}^k)$ and almost every $\gamma \in \widehat{\mathbb{R}^k}$,

$$(\pi(0,h)f)^\wedge(\gamma) = |\det(h)|^{1/2} \hat{f}(\gamma h).$$

As an immediate consequence: If U is H-invariant, then so is $\mathscr{H}_U$ (with respect to a different action of course), which settles the first part of our theorem.

Now suppose that $\mathscr{H}_U$ is H-invariant. We then claim that U is *invariant up to sets of measure zero*, i.e. for all $h \in H$ we have $\lambda(U \triangle Uh) = 0$, where $\triangle$ denotes the symmetric difference.

For the proof, assume the contrary. Then there exist a set $A \subset U$ having positive finite measure and $h \in H$ such that $Ah^{-1} \cap U = \emptyset$. Let $f \in L^2(\mathbb{R}^k)$ be the function having Plancherel transform χ_A. Then, by Eq. (1),

$$(\pi(0,h)f)^\wedge(\xi) = |\det(h)|^{1/2} \chi_A(\xi h) = |\det(h)|^{1/2} \chi_{Ah^{-1}}(\xi),$$

hence, since Ah^{-1} does not have measure zero, $\pi(0,h)f \notin \mathscr{H}_U$.

Since Lebesgue measure on $\widehat{\mathbb{R}^k}$ is quasi-invariant under matrix multiplication (and hence under the action of H), H acts on the Boolean algebra of equivalence classes of measurable sets modulo sets of measure zero. The equivalence class of U is then invariant under the action on the Boolean algebra, and hence the following theorem by Mackey provides a set V which is equivalent to U and H-invariant, hence $\mathscr{H} = \mathscr{H}_U = \mathscr{H}_V$ as desired.

The missing part of our proof is provided by the following theorem, which is Theorem 3 of Ref. 10. The finiteness of the measure required in the theorem is no real obstacle (replace λ by an equivalent finite measure μ).

Theorem 3 (Mackey): *Let S be a standard Borel G-space, where G is separable and locally compact. Let μ be a finite quasi-invariant measure defined on the Borel subsets of S. Let E be a Borel set in S such that the corresponding Boolean-algebra element is invariant under G. Then E differs by a null set from a Borel set which is invariant under G.*

From now on let U be an H-invariant subset of $\widehat{\mathbb{R}^k}$, and let π_U be the restriction of π to $\mathscr{H}_U$. We can now easily classify the irreducible subrepresentations:

Corollary 4: Let $U \subset \mathbb{R}^k$ be measurable and H-invariant. Then π_U is irreducible iff the action of H on U is ergodic.

Proof: By Theorem 2, any decomposition of $\mathscr{H}_U$ into nontrivial invariant subspaces corresponds to a decomposition of U into H-invariant subsets of positive measure and vice versa.

We now take a closer look at the dual action. The first thing to note is that, H being σ-compact, every orbit is measurable. We are particularly interested in the case where the H-orbits in $\widehat{\mathbb{R}^k}$ are *countably separated*; i.e. there exists a countable family $(U_n)_{n\in\mathbb{N}}$ of measurable H-invariant sets separating the orbits. This is the above-mentioned regularity condition. One well-known consequence of this condition is that in this case ergodicity is essentially the same as transitivity (compare Ref. 11, 6.36):

Proposition 5: Let G be a locally compact group acting ergodically on the locally compact space X with regular Borel measure μ. If the orbits of G are countably separated, then there is an orbit $\mathscr{O}$ such that $\mu(X\backslash\mathscr{O})=0$.

The following corollary summarizes the results of our search for irreducible subrepresentations:

Corollary 6: Let H be a closed subgroup of $GL(k,\mathbb{R})$, and let G and π be constructed as above. Then π has an irreducible subrepresentation iff H acts ergodically on a subset $U \subset \widehat{\mathbb{R}^k}$ of positive measure.

If the orbits are countably separated, then π has an irreducible subrepresentation iff there exists an H-orbit of positive measure.

IV. SQUARE-INTEGRABILITY OF π_U

Now suppose we are given an H-invariant subset U of positive measure on which H acts ergodically. Our next aim is to determine when π_U is square-integrable. Recall that this means that for some nontrivial $f,g \in \mathscr{H}_U$, the matrix coefficient

$$V_{f,g}: G \ni (x,h) \mapsto \langle f, \pi(x,h)g \rangle,$$

is a square-integrable function on G. By the results of Duflo and Moore,[2] the square-integrability of $V_{f,g}$ for some nontrivial f implies square-integrability of $V_{f,g}$ for every f. g is then called *admissible* and the mapping

$$\mathrm{L}^2(\mathbb{R}^k) \ni f \mapsto V_{f,g} \in \mathrm{L}^2(G)$$

is a multiple of an isometry, the so-called *continuous wavelet-transform associated to the wavelet g*.

For the remainder of the paper, we restrict our attention to the case of countably separated orbits. This simplifies matters in two ways: On the one hand, as was seen above, we can assume U to be an orbit. In addition, according to the following well-known theorem by Glimm,[12] nice measure-theoretic behavior (i.e., countable separatedness) of the action is related to nice topological behavior. The latter will also be useful in our further discussion.

Theorem 7 (Glimm): *Let G be a locally compact second countable group, acting on a locally compact space X. Then the following are equivalent*:

(i) *The G-orbits are countably separated.*
(ii) *For every $x \in X$ the natural mapping $G/G_x \to Gx$, where $G_x < G$ is the stability subgroup of x, is a homeomorphism.*
(iii) *Every G-orbit is locally closed in X; or, equivalently, is locally compact in the relative topology.*

The following simple observation is a first step towards calculating the L^2-norm of $V_{f,g}$:

Lemma 8: For $\gamma \in U$ let $p_\gamma : H \to U$, $h \mapsto \gamma h$. Then, for any two $\gamma, \delta \in U$ and any positive measurable function g on U we have the following equality:

$$\int_H (g \circ p_\gamma)(h) d\mu_H(h) = \int_H (g \circ p_\delta)(h) d\mu_H(h).$$

Proof: Since U is an orbit, there exists $k \in H$ such that $\gamma = \delta k$. Then we have

$$\begin{aligned}\int_H (g \circ p_\gamma)(h) d\mu_H(h) &= \int_H g(\gamma h) d\mu_H(h) = \int_H g(\delta k h) d\mu_H(h) \\ &= \int_H g(\delta h) d\mu_H(h) = \int_H (g \circ p_\delta)(h) d\mu_H(h).\end{aligned}$$

Now we are able to give a formula for the L^2-norm of $V_{f,g}$:

Lemma 9: Let $f, g \in \mathscr{H}_U$. Then, for any $\gamma_0 \in U$,

$$\|V_{f,g}\|_{L^2(G)} = \|f\|_{L^2(\mathbb{R}^k)} \|\hat{g} \circ p_{\gamma_0}\|_{L^2(H)}.$$

Hence, g is admissible iff $\hat{g} \circ p_{\gamma_0} \in L^2(H)$.

Proof: The following calculation is essentially the same as in Ref. 5. We include it for the sake of completeness:

$$\begin{aligned}\|V_{f,g}\|^2_{L^2(G)} &= \int_G \left| \langle f, \pi(x,h) g \rangle \right|^2 d\mu_G(x,h) = \int_G \left| \langle \hat{f}, (\pi(x,h) g)^\wedge \rangle \right|^2 d\mu_G(x,h) \\ &= \int_G \left| \int_{\widehat{\mathbb{R}^k}} \hat{f}(\gamma) \left| \det(h) \right|^{1/2} e^{-2\pi i \gamma x} \overline{\hat{g}(\gamma h)} d\lambda(\gamma) \right|^2 d\mu_G(x,h) \\ &= \int_H \int_{\mathbb{R}^k} \left| \int_{\widehat{\mathbb{R}^k}} \hat{f}(\gamma) e^{-2\pi i \gamma x} \overline{\hat{g}(\gamma h)} d\lambda(\gamma) \right|^2 d\lambda(x) d\mu_H(h) \\ &= \int_H \int_{\mathbb{R}^k} \left| \mathscr{F}(\phi_h)(x) \right|^2 d\lambda(x) d\mu_H(h), \qquad (2)\end{aligned}$$

where $\phi_h(\gamma) = \hat{f}(\gamma) \overline{\hat{g}(\gamma h)}$, which is in $L^1(\widehat{\mathbb{R}^k})$, and $\mathscr{F}$ denotes the Fourier transform on $L^1(\widehat{\mathbb{R}^k})$. After an application of Plancherel's formula, (2) becomes

$$\int_H \int_{\widehat{\mathbb{R}}^k} |\phi_h(\gamma)|^2 d\lambda(\gamma) d\mu_H(h) = \int_H \int_{\widehat{\mathbb{R}}^k} |\hat{f}(\gamma)|^2 |\hat{g}(\gamma h)|^2 d\lambda(\gamma) d\mu_H(h)$$
$$= \int_{\widehat{\mathbb{R}}^k} |\hat{f}(\gamma)|^2 \left(\int_H \left| \hat{g}(\gamma h) \right|^2 d\mu_H(h) \right) d\lambda(\gamma)$$
$$= \int_{\mathbb{R}^k} |f(x)|^2 d\lambda(x) \int_H |\hat{g}(\gamma_0 h)|^2 d\mu_H(h),$$

the last equation being due to Lemma 8. This proves the statement except for one technicality: By referring to $\hat{g} \circ p_{\gamma_0}$ as an element of $L^2(G)$ we have implicitly assumed that changing $\hat{g}$ on a null set results in changing $\hat{g} \circ p_{\gamma_0}$ on a null set. This assumption holds because by Glimm's theorem we can identify U and H/H_γ, and then Ref. 11, Theorem 2.64 yields that preimages of null sets are again null sets.

Theorem 10: *π_U is square-integrable iff the stabilizers associated to the orbit U are compact.*

Proof: By the previous lemma, $g \in \mathscr{H}_U$ is admissible iff $\hat{g} \circ p_\gamma \in L^2(H)$, for some (and hence every) $\gamma \in U$. Now, if the stabilizer H_γ of some $\gamma \in U$ is compact and $\hat{g}$ is the characteristic function of some compact set with positive measure, then so is $\hat{g} \circ p_\gamma$. In particular g is admissible.

On the other hand, suppose $g \in \mathscr{H}_U$ is admissible and let $\gamma \in U$. $|\hat{g}|^2$ can be approximated from below by simple functions, hence there is a measurable subset $A \subset U$ having positive, finite measure and such that $\chi_A \leqslant c|\hat{g}|^2$, for some positive constant c. Since $\hat{g} \circ p_\gamma$ is square-integrable, $\mu_H(p_\gamma^{-1}(A)) < \infty$. Moreover, by Ref. 11, Theorem 2.64, $\mu_H(p_\gamma^{-1}(A)) > 0$. We have $H_\gamma p_\gamma^{-1}(A) = p_\gamma^{-1}(A)$, hence, by the following lemma, H_γ is compact.

The following can be viewed as a generalization of the well-known fact that a group having finite Haar measure is compact,[13] and indeed its proof consists of a slight modification of the proof to that result. We include it for the sake of completeness.

Lemma 11: Let H be a locally compact group, $H_0 < H$ a closed noncompact subgroup. Then, for any measurable subset A of H satisfying either $AH_0 = A$ or $H_0 A = A$, we have $\mu_H(A) \in \{0, \infty\}$.

Proof: Suppose that $AH_0 = A$, and $\mu_H(A) \neq 0$. By regularity of μ there is a compact subset $C \subset A$ having positive measure. Pick any $x_0 \in H_0$ and recursively

$$x_{n+1} \in H_0 \setminus \left(\left(\bigcup_{i=1}^{n} C^{-1} C x_i \right) \cup \left(\bigcup_{i=1}^{n} x_i C^{-1} C \right) \right).$$

x_{n+1} exists since H_0 is not compact. Then, for $m \neq n$, we have $Cx_n \cap Cx_m = \emptyset$ and $Cx_n^{-1} \cap Cx_m^{-1} = \emptyset$. Now suppose $\mu_H(A)$ is finite. Because of $\cup_n Cx_n \subset CH_0 \subset AH_0 \subset A$ we have

$$\infty > \mu_H(A) \geqslant \sum_{n=1}^{\infty} \mu_H(Cx_n) = \mu_H(C) \sum_{n=1}^{\infty} \Delta_H(x_n)^{-1},$$

implying that $\Delta_H(x_n)^{-1} \to 0$, as n tends to ∞. On the other hand, using the same argument for Cx_n^{-1}, we get

$$\infty > \mu_H(C) \sum_{n=1}^{\infty} \Delta_H(x_n),$$

but the latter tends to infinity. Hence $\mu_H(A) = \infty$.

The proof for the case $H_0 A = A$ uses the same idea, the argument being simplified by left invariance of μ_H.

Remark 12: At this point let us roughly sketch the case where H acts ergodically but not transitively on a set U of positive measure. Then, for every $g \in \mathscr{H}_U$, the map

$$U \ni \gamma \mapsto \int_H |\hat{g}(\gamma h)|^2 d\mu_H(h)$$

is measurable and H-invariant, hence, by ergodicity, it is constant almost everywhere. By the same calculation as in the proof of Lemma 9 we see that g is admissible if the constant is finite. We can apply this criterion to show that for the construction of square-integrable representations discrete groups of dilations are useless:

Let $H < \mathrm{GL}(\mathbb{R},k)$ be a discrete subgroup acting ergodically on some invariant subset U of $\widehat{\mathbb{R}^k}$. (For instance, take $\mathrm{SL}(2,\mathbb{Z})$, which acts ergodically on $\widehat{\mathbb{R}^2}$.[14]) We will show that π_U is not square-integrable. Clearly it suffices to show that for every measurable subset $A \subset U$ having finite positive measure the function $(\chi_A)^\vee$ is not admissible. By the admissibility criterion from above, this amounts to showing that the set $\gamma H \cap A$ is infinite for almost every $\gamma \in U$. To see this, choose a sequence $(A_n)_{n\in\mathbb{N}}$ of pairwise disjoint subsets of A satisfying $\lambda(A_n) > 0$. Then, for any fixed n, the set $B_n := \{\gamma \in U : \gamma H \cap A_n \neq \emptyset\}$ is H-invariant and contains A_n, hence, by ergodicity, it is a conull set. Then the intersection B of all B_n is a conull set, and for every $\gamma \in B$ the set $\gamma H \cap A$ is infinite, the A_n being disjoint.

Arguing as in the proof of Theorem 10, we see that also in the case of H acting ergodically but not transitively on U, the stabilizer of almost every $\gamma \in U$ must be compact. But as the example of $\mathrm{SL}(2,\mathbb{Z})$ shows, the compactness is no longer sufficient: It is easily seen that the stabilizer of $\gamma \in \widehat{\mathbb{R}^2}$ is trivial whenever the coordinates of γ have irrational quotient, i.e. the stabilizer is trivial a.e.

Summarizing the results of our search for square-integrable representations, we could say that the task lies in finding a group H ''having just the right size:'' It should be ''big enough'' to yield orbits of positive measure and ''small enough'' to have compact stabilizers.

V. THE ADMISSIBILITY CONDITION FOR π_U

Our next aim is to find a more concrete admissibility criterion than the one given in the last section. In particular, we would like to be able to replace integration on H by integration on U, as has been done previously.[4,5] It will be seen that, due to the compactness of the stabilizers, this is indeed possible in much the same way as in the paper of Bernier and Taylor.[5] Also, the formal dimension operator associated to π_U as in Ref. 2 can easily be calculated.

Theorem 13: *Fix $\gamma \in U$. Define a function Ψ on U by*

$$\Psi(\gamma h) := \Delta_H(h)|\det(h)|^{-1}.$$

Then Ψ is a well-defined continuous function on U and for every $g \in \mathscr{H}_U$:

$$g \text{ is admissible} \Leftrightarrow \int_U |\hat{g}(\xi)|^2 \Psi(\xi) d\lambda(\xi) < \infty.$$

Proof: For a measurable subset $A \subset U$, let $\tilde{\mu}(A) := \mu_H(p_\gamma^{-1}(A))$. This defines a regular Borel measure $\tilde{\mu}$ on U, as is readily seen using the compactness of the stabilizers. Moreover, $\tilde{\mu}$ is strongly quasi-invariant under the action of H. To be more precise, if the translate $\tilde{\mu}_h$ of $\tilde{\mu}$ is defined by $\tilde{\mu}_h(A) := \tilde{\mu}(Ah^{-1})$, the Radon–Nikodym-derivative is given by

$$\frac{d\tilde{\mu}_h}{d\tilde{\mu}}(\gamma) = \Delta_H(h).$$

On the other hand, the measure λ on U is strongly quasi-invariant with Radon–Nikodym-derivative

$$\frac{d\lambda_h}{d\lambda}(\gamma)=|\det(h)|.$$

Note that, the operation being on the right, in both cases the translation of the measure by h consists of multiplication of the argument by h^{-1}. By Theorem 2.59 from Ref. 11, λ arises from a so-called **rho-function** on H, i.e. there is a function ρ_λ on H such that

$$\int_U f(\xi)d\lambda(\xi)=\int_H f(\gamma h^{-1})\rho_\lambda(h)d\mu_H(h),$$

for every positive measurable function f on U. Here we have once again used the fact that U and H/H_γ are homeomorphic. Analogously, let $\rho_{\tilde{\mu}}$ be the ρ-function belonging to $\tilde{\mu}$. By Theorem 2.56 from Ref. 11, we can calculate the ρ-functions from the Radon–Nikodym-derivatives, obtaining the equations:

$$\rho_{\tilde{\mu}}(h)=\rho_{\tilde{\mu}}(1)\Delta_H(h),$$

$$\rho_\lambda(h)=\rho_\lambda(1)|\det(h)|.$$

The Radon–Nikodym-derivative of $\tilde{\mu}$ with respect to λ can then be calculated as the quotient of the ρ-functions:

$$\frac{d\tilde{\mu}}{d\lambda}(\gamma h)=\frac{\rho_{\tilde{\mu}}(h)}{\rho_\lambda(h)}=c_0\Psi(\gamma h),$$

with $c_0=\rho_{\tilde{\mu}}(1)/\rho_\lambda(1)$. In particular: Ψ is well-defined and continuous, since the ρ-functions are continuous. Finally, we have for $g\in\mathscr{H}_U$

$$\begin{aligned}\int_H|(\hat{g}\circ p_\gamma)(h)|^2d\mu_H(h)&\\ =\int_U|\hat{g}(\xi)|^2d\tilde{\mu}(\xi)&\\ =\int_U|\hat{g}(\xi)|^2\frac{d\tilde{\mu}}{d\lambda}(\xi)d\lambda(\xi)=\int_U|\hat{g}(\xi)|^2c_0\Psi(\xi)d\lambda(\xi),&\end{aligned}$$

which, along with Lemma 9, proves the admissibility criterion.

Remark 14: Just as in the cases considered in Ref. 5, Ψ allows a concrete interpretation of the (usually unbounded) formal dimension operator K associated to π_U as in Ref. 2: If T denotes the densely defined operator on $L^2(U)$ obtained by pointwise multiplication with $(c_0\Psi)^{-1}$ (c_0 as defined in the proof), then $K=\mathscr{P}^{-1}T\mathscr{P}$, where $\mathscr{P}$ is the Plancherel transform.

VI. EXAMPLES

In this section we apply our results to two groups which we will need for further discussion.

Example 15 [Bernier/Taylor]: Let $H<\mathrm{GL}(k,\mathbb{R})$ be the group consisting of diagonal matrices. Then H acts freely on the orbit $U=\{(\xi_1,\xi_2,\ldots,\xi_n):\Pi\xi_i\neq 0\}=(1,1,\ldots,1)H$, whose complement

has measure zero. Hence π is a square-integrable representation on $L^2(\mathbb{R}^k)$. H is unimodular, and for any $\xi \in U$, the group element h mapping (1,1,…,1) to ξ has determinant $\xi_1\xi_2\cdots\xi_n$. Hence the admissibility criterion is given by:

$$g \text{ is admissible} \Leftrightarrow \int_U \frac{|\hat{g}(\xi)|^2}{|\xi_1\xi_2\ldots\xi_n|}\,d\lambda(\xi)<\infty.$$

Example 16 [Murenzi]: Let $H:=\mathbb{R}^+\cdot\mathbf{SO}(k)$. Then $\widehat{\mathbb{R}^k}\backslash\{0\}$ and $\{0\}$ are the only two orbits, hence π is irreducible. Moreover, the stabilizer of (1,0,…,0) is isomorphic to $\mathbf{SO}(k\text{-}1)$, hence compact, whence we conclude that π is square-integrable. Again H is unimodular. For a given $\xi \in \widehat{\mathbb{R}^k}\backslash\{0\}$, an element $h \in H$ mapping (1,0,…,0) to ξ is obtained by rotating (1,0,…,0) to $\xi/|\xi|$ and then multiplying by $|\xi|$. Hence, $|\det(h)|=|\xi|^k$, which leads to the following admissibility criterion:

$$g \text{ is admissible} \Leftrightarrow \int_U \frac{|\hat{g}(\xi)|^2}{|\xi|^k}\,d\lambda(\xi)<\infty.$$

VII. WAVELET FRAMES AND ADMISSIBILITY

We now turn to frames and the question, whether for a given square-integrable representation π_U as constructed above, the functions involved are admissible. In this paper we will only consider frames of a certain kind, as they arise from multiresolution analysis. To be more precise, we study frames obtained in the following way:

Definition 17: Let $\psi_1,\ldots,\psi_N \in \mathscr{H}_U$, $a_0>0$ *be such that* $a_0 \in H$ (*identifying* a_0 *with* $a_0\cdot\mathbf{id}$). *We say that* $(\psi_1,\ldots,\psi_N;a_0;\mathbb{Z}^k)$ **determines a frame of** $\mathscr{H}_U$ *if the set*

$$\{\pi_U(a_0^m n, a_0^m)\psi_i : m\in\mathbb{Z}, n\in\mathbb{Z}^k, \quad 1\leqslant i\leqslant N\}$$

constitutes a frame of $\mathscr{H}_U$.

The condition that the dilation a_0 be in H is natural, since we want to interpret the dilation as an element of the group G. The following example shows that this condition alone does not guarantee that the functions constituting the frame are admissible:

Example 18: Let ϕ be a continuous scaling function of a dyadic multiresolution which is not a wavelet, i.e. not admissible with respect to the affine group. In fact, any scaling function with compact support and nonzero integral would do (for instance one of Daubechies's scaling functions), by 1.1.5 of Ref. 15. Let ψ be any wavelet belonging to ϕ. Then taking the tensor products yields a dyadic multiresolution of $L^2(\mathbb{R}^2)$, which means that $(\psi\otimes\phi,\phi\otimes\psi,\psi\otimes\psi;2;\mathbb{Z}^2)$ determines a frame in $L^2(\mathbb{R}^2)$ (see Ref. 15, 2.2.16). Let $H<\mathrm{GL}(2,\mathbb{R})$ be the two-dimensional diagonal group. Then 2 is an element of H, hence it makes sense to consider the question of admissibility w.r.t. the quasiregular representation. In order to apply the admissibility criterion from Example 15, we calculate

$$\begin{aligned}\int_{\widehat{\mathbb{R}^2}} \frac{|(\psi\otimes\phi)\hat{}(\xi)|^2}{|\xi_1\xi_2|}\,d\lambda(\xi_1,\xi_2) &= \int_{\widehat{\mathbb{R}^2}} \frac{|\hat{\psi}(\xi_1)\hat{\phi}(\xi_2)|^2}{|\xi_1\xi_2|}\,d\lambda(\xi_1,\xi_2)\\ &= \int_{\hat{\mathbb{R}}} \frac{|\hat{\psi}(\xi)|^2}{|\xi|}\,d\lambda(\xi)\int_{\hat{\mathbb{R}}} \frac{|\hat{\phi}(\xi)|^2}{|\xi|}\,d\lambda(\xi).\end{aligned}$$

Since ϕ is not admissible, the latter integral diverges, hence $\psi\otimes\phi$, as well as $\phi\otimes\psi$, is not admissible.

From now on let H_0 denote the subgroup of H generated by a_0. Since a_0 is in the center of H, H_0 is a normal subgroup. We normalize the Haar measure μ_{H/H_0} such that Weil's formula holds (see Ref. 11, 2.65), i.e. for all positive measurable f we have

$$\int_H f(x)d\mu_H(x)=\int_{H/H_0}\sum_{n\in\mathbb{Z}} f(xa_0^m)d\mu_{H/H_0}(xH_0).$$

The remainder of this paper will be devoted to proving the next theorem, which links the L^2-norms of certain matrix coefficients with the measure μ_{H/H_0} and thus leads to a compactness condition on H/H_0. It is the analogue of Daubechies's result for univariate wavelets,[6] and the proof is modelled after the proof of that statement.

Theorem 19: *Suppose that* $(\psi_1,\ldots,\psi_N;a_0;\mathbb{Z}^k)$ *determines a frame of* $\mathscr{H}_U$, *with* $a_0\in H$. *Then all* ψ_i *are admissible iff* μ_{H/H_0} *is finite,* i.e. *iff* H/H_0 *is compact.*

To be more precise: If $\phi\in\mathscr{H}_U$ *is normed and admissible, and* $0<A<B<\infty$ *are lower and upper frame bounds (respectively), the following inequalities hold:*

$$A\mu_{H/H_0}(H/H_0)\leqslant\sum_{i=1}^{n}\|V_{\phi,\psi_i}\|^2_{L^2(G)}\leqslant B\mu_{H/H_0}(H/H_0).$$

Remark 20: Since a_0 is in the kernel of Δ_H, the compactness criterion of Theorem 19 implies that H is unimodular.

Remark 21: Applying Theorem 19 to the tensor wavelets of example 18 and Murenzi's group $H:=\mathbb{R}^+\cdot\mathbf{SO}(k)$, we see that since H/H_0 is compact, the tensor wavelets are admissible w.r.t. the quasiregular representation of $\mathbb{R}^k\rtimes H$. (Here H_0 denotes the subgroup generated by 2.) In fact any frame arising from a dyadic multiresolution analysis consists of admissible vectors.

On the other hand, since the quotient of the diagonal group by H_0 is noncompact, we see that every wavelet frame obtained from a dyadic multiresolution contains at least one function which is not admissible w.r.t. the quasiregular representation associated to the diagonal group.

The proof of the theorem uses a family of auxiliary functions t_λ on G. We start by constructing suitable functions on $\mathbb{R}^k$.

Lemma 22: Let $f\in C_c^\infty(\mathbb{R})$, *and let* $f_k:\mathbb{R}^k\to\mathbb{R}$ *be the k-fold tensor product of f. Suppose that f is positive and has* L^1*-norm* 1. *Then, for every* $m\in\mathbb{N}_0$, *there exists a constant* $c_{m,k}$ *such that for every positive real number a and every* $y\in\mathbb{R}^k$, *we have*

$$\left|a^{-k}-\sum_{n\in\mathbb{Z}^k} f_k(y+an)\right|\leqslant a^m c_{m,k}.$$

Proof: We will only need the $c_{0,k}$ later on, but the stronger result has an easier inductive proof. We start with $k=1$. We can treat the cases $a\geqslant 1$ and $a<1$ separately and note that the statement is obvious for $a\geqslant 1$. For a given $0<a<1$ and $y\in\mathbb{R}$ pick $N\in\mathbb{N}$ such that $\mathrm{supp}(f)\subset[y-aN,y+aN]$. In particular, for $l\in\mathbb{N}$, we have $f^{(2l+2)}(y\pm aN)=0$, hence, by Euler–MacLaurin's formula:[16]

$$\sum_{n=-\infty}^{\infty} f(y+an)=\sum_{n=-N}^{N} f(y+an)=a^{-1}\int_{y-aN}^{y+aN} f(t)d\lambda(t)+a^{2l+1}\frac{B_{2l+2}}{(2l+2)!}f^{(2l+2)}(x)$$

$$=a^{-1}+a^{2l+1}\frac{B_{2l+2}}{(2l+2)!}f^{(2l+2)}(x),$$

for some $x\in\mathrm{supp}(f)$, with B_n being the nth Bernoulli number. Hence,

$$\left| a^{-1} - \sum_{n=-\infty}^{\infty} f(y+an) \right| \leq a^{2l+1} \frac{|B_{2l+2}|}{(2l+2)!} \sup_{x \in \mathrm{supp}(f)} |f^{(2l+2)}(x)|,$$

which proves the statement for all odd m. Since $a<1$, the statement for the even m follows immediately.

Now suppose the $c_{m,k}$ are given for $k \geq 1$ and all $m \in \mathbb{N}_0$. Again we can restrict our attention to the case $a<1$. Letting $\tilde{y}=(y_2,\ldots,y_{k+1}) \in \mathbb{R}^k$, we calculate:

$$\begin{aligned}
\left| a^{-k-1} - \sum_{n \in \mathbb{Z}^{k+1}} f_{k+1}(an+y) \right| &= \left| a^{-1}a^{-k} - \left(\sum_{n \in \mathbb{Z}} f(an+y_1) \right) \left(\sum_{l \in \mathbb{Z}^k} f_k(al+\tilde{y}) \right) \right| \\
&\leq \left| a^{-1} - \sum_{n \in \mathbb{Z}} f(an+y_1) \right| a^{-k} \\
&\quad + \left| a^{-k} - \sum_{l \in \mathbb{Z}^k} f_k(al+\tilde{y}) \right| \left| \sum_{n \in \mathbb{Z}} f(an+y_1) \right|.
\end{aligned}$$

Applying the induction hypothesis, we see that the first term is less or equal to $a^m c_{m+k,1}$ and the second term is less or equal to $a^{m+1} c_{m+1,k}(a^{-1}+c_{0,1})$. Hence, since $a<1$, the sum can be estimated by $a^m(c_{m+1,k}+c_{0,1}+c_{m+k,1})$.

From now on fix f and f_k as in Lemma 22. Let $C \subset H$ be a measurable fundamental domain for the subgroup H_0, i.e. $CH_0=H$ and $C \cap a_0^m C = \emptyset$, for all $0 \neq m \in \mathbb{Z}$.[17] Define, for $\lambda>0$, a function t_λ on G by

$$t_\lambda(x,h) := \chi_C(h) f_k(\lambda \Delta_G(x,h)^{1/k} x).$$

The next two lemmas collect the properties of t_λ needed for the proof.

Lemma 23: t_λ is a positive measurable function with

$$\int_G t_\lambda(x,h)\, d\mu_G(x,h) = \lambda^{-k} \mu_H(C).$$

Proof: Straightforward computation, observing that $\mu_H(C) = \mu_H(C^{-1})$ by Weil's formula, both C and C^{-1} being fundamental domains.

Lemma 24: For every $(x,h) \in G$, we have

$$\left| \lambda^{-k} \Delta_G(x,h)^{-1} - \sum_{m \in \mathbb{Z}} \sum_{n \in \mathbb{Z}^k} t_\lambda((a_0^m n, a_0^m) \cdot (x,h)) \right| \leq c_{0,k}.$$

Proof: The proof consists of rather straightforward calculations:

$$\begin{aligned}
\sum_{m \in \mathbb{Z}} \sum_{n \in \mathbb{Z}^k} t_\lambda((a_0^m n, a_0^m) \cdot (x,h)) &= \sum_{m \in \mathbb{Z}} \sum_{n \in \mathbb{Z}^k} t_\lambda((a_0^m(n+x), a_0^m h)) \\
&= \sum_{m \in \mathbb{Z}} \sum_{n \in \mathbb{Z}^k} \chi_C(a_0^m h) f_k(\lambda \Delta_G(a_0^m(n+x), a_0^m h)^{1/k} a_0^m(n+x)) \\
&= \sum_{m \in \mathbb{Z}} \sum_{n \in \mathbb{Z}^k} \chi_C(a_0^m h) f_k(\lambda \Delta_H(a_0^m h)^{1/k} |\det(a_0^m h)|^{-1/k} a_0^m(n+x))
\end{aligned}$$

$$= \sum_{m\in\mathbb{Z}} \sum_{n\in\mathbb{Z}^k} \chi_C(a_0^m h) f_k(\lambda \Delta_H(h)^{1/k} |\det(h)|^{-1/k}(n+x))$$
$$= \left(\sum_{m\in\mathbb{Z}} \chi_C(a_0^m h) \right) \left(\sum_{n\in\mathbb{Z}^k} f_k(\lambda \Delta_H(h)^{1/k} |\det(h)|^{-1/k}(n+x)) \right)$$
$$= \left(\sum_{m\in\mathbb{Z}} \chi_C(a_0^m h) \right) \left(\sum_{n\in\mathbb{Z}^k} f_k(\lambda \Delta_G(x,h)^{1/k}(n+x)) \right).$$

By choice of C, the first factor equals one, and using Lemma 22, we can estimate the second factor by

$$\left| \sum_{n\in\mathbb{Z}^k} f_k(\lambda \Delta_G(x,h)^{1/k}(n+x)) - \lambda^{-k} \Delta_G(x,h)^{-1} \right| \leq c_{0,k}.$$

Proof of Theorem 19: We only prove the inequalities, starting with the second one. Let A,B be the frame bounds and let ϕ be a normed admissible vector. By Weil's formula, we have $\mu_H(C) = \mu_{H/H_0}(H/H_0)$, hence, by Lemma 23,

$$\lambda^{-k} B \mu_{H/H_0}(H/H_0) = \int_G B t_\lambda(x,h) d\mu_G(x,h) = \int_G t_\lambda(x,h) B \| \pi_U(x,h)\phi \|^2 d\mu_G(x,h).$$

Since B is an upper bound of the frame, we can estimate the last integral by

$$\int_G t_\lambda(x,h) B \| \pi_U(x,h)\phi \|^2 d\mu_G(x,h) \geq \int_G t_\lambda(x,h) \sum_{i,m,n} |\langle \pi_U(x,h)\phi, \pi_U(a_0^m n, a_0^m)\psi_i \rangle|^2 d\mu_G(x,h)$$
$$= \sum_{i,m,n} \int_G t_\lambda(x,h) |\langle \pi_U((a_0^m n, a_0^m)^{-1} \cdot (x,h))\phi, \psi_i \rangle|^2 d\mu_G(x,h)$$
$$= \sum_{i,m,n} \int_G t_\lambda((a_0^m n, a_0^m)\cdot(x,h)) |\langle \pi_U(x,h)\phi, \psi_i \rangle|^2 d\mu_G(x,h)$$
$$= \sum_i \int_G \sum_{m,n} t_\lambda((a_0^m n, a_0^m)\cdot(x,h)) \times |\langle \pi_U(x,h)\phi, \psi_i \rangle|^2 d\mu_G(x,h).$$

Note that all functions involved are positive, hence Fubini's Theorem is applicable. Now we can apply Lemma 24:

$$\sum_i \int_G \sum_{m,n} t_\lambda((a_0^m n, a_0^m)\cdot(x,h)) |\langle \pi_U(x,h)\phi, \psi_i \rangle|^2 d\mu_G(x,h)$$
$$\geq \sum_i \int_G (\lambda^{-k} \Delta_G(x,h)^{-1} - c_{0,k}) |\langle \pi_U(x,h)\phi, \psi_i \rangle|^2 d\mu_G(x,h)$$

$$= \sum_i \left(-c_{0,k} \left\| V_{\psi_i,\phi} \right\|^2_{\mathrm{L}^2(G)} + \lambda^{-k} \int_G \Delta_G(x,h)^{-1} |\langle \pi_U(x,h)\phi, \psi_i \rangle|^2 d\mu_G(x,h) \right)$$

$$= \sum_i \left(-c_{0,k} \left\| V_{\psi_i,\phi} \right\|^2_{\mathrm{L}^2(G)} + \lambda^{-k} \int_G |\langle \pi_U((x,h)^{-1})\phi, \psi_i \rangle|^2 d\mu_G(x,h) \right)$$

$$= \sum_i \left(-c_{0,k} \| V_{\psi_i,\phi} \|^2_{\mathrm{L}^2(G)} + \lambda^{-k} \| V_{\phi,\psi_i} \|^2_{\mathrm{L}^2(G)} \right).$$

We have thus derived the inequality

$$B\mu_{H/H_0}(H/H_0) \geqslant \sum_i \| V_{\phi,\psi_i} \|^2_{\mathrm{L}^2(G)} - \lambda^k c_{0,k} \sum_i \| V_{\psi_i,\phi} \|^2_{\mathrm{L}^2(G)}.$$

Since ϕ is admissible, $\Sigma_i \| V_{\psi_i,\phi} \|^2_{\mathrm{L}^2(G)}$ is finite. Hence, letting λ tend to zero, we obtain the desired inequality.

The first inequality is obtained in quite the same fashion: Using the lower inequality of the frame property, we arrive at

$$A\mu_{H/H_0}(H/H_0) \leqslant \sum_i \| V_{\phi,\psi_i} \|^2_{\mathrm{L}^2(G)} + \lambda^k c_{0,k} \sum_i \| V_{\psi_i,\phi} \|^2_{\mathrm{L}^2(G)},$$

and letting λ tend to zero gives the desired result.

VIII. CONCLUDING REMARKS

The usual procedure to construct discrete wavelet transforms from square-integrable representations[5,7,8] consists of finding a certain discrete subset of the underlying group and certain admissible functions $\psi_1, \ldots, \psi_n$. The discrete wavelet transform of an element f is then obtained by sampling the continuous wavelet transforms V_{f,ψ_i} on the discrete subset. The difficulty lies in choosing the sampling set and the admissible functions such that, by letting the subset of the group act on the admissible functions, we obtain a frame. Theorem 19 considers this situation in reverse perspective: Here a sampling set

$$\{(a_0^m n, a_0^m) : m \in \mathbb{Z}, n \in \mathbb{Z}^k, 1 \leqslant i \leqslant N\}$$

and a set of functions $\psi_1, \ldots, \psi_n$ yielding a frame (under the action of the sampling set) are given, and the question of admissibility is decided by looking at the relationship between the sampling set and the whole group. It would be desirable to find ways to incorporate both approaches into one result relating sampling sets, frames and admissibility.

A more concrete generalization of Theorem 19 would consist of considering other lattices than $\mathbb{Z}^k$ and (finite sets of) nonscalar dilations a_0. While taking a different lattice causes no serious problems, the use of a nonscalar dilation has graver consequences: In the first place, the choice of the auxiliary functions t_λ requires more care. Moreover, since a_0 need not be central any more, $H/\langle a_0 \rangle$ might not even carry an invariant measure, hence we cannot expect to obtain a compactness (or at least finite measure) condition on $H/\langle a_0 \rangle$.

While this paper is concerned only with wavelet transforms arising from representations which are square-integrable in the strict sense, there are generalizations which yield similar transforms for a wider class of representations.[18,19] The notion used here is that of square-integrability on homogeneous spaces. It may be expected that this approach allows the construction of wavelet transforms under somewhat weaker requirements than the compactness condition of Theorem 10.

We construct a $\mathbb{C}$-algebra $\mathscr{C}$ associated with an R-matrix of the 2-state chiral Potts model. This algebra will be shown to coincide with the Sklyanin algebra at an 8-torsion point and, in the self-dual case, with $U_q(sl_2)$ at the fourth root of unity.
 [S0022-2488(96)02212-8]

I. INTRODUCTION

In this paper we will construct an algebra associated with an R-matrix of the 2-state chiral Potts model by so-called RLL formalism (Theorem 1), and reveal that our algebra $\mathscr{C}$ coincides with the Sklyanin algebra $\mathscr{A}_\eta$ (Ref. 1) when η is an 8-torsion point on an elliptic curve. Moreover, we will show that the quantum group $U_q(sl_2)$ when $q^4=1$ is derived from our algebra in the self-dual case.

Our R-matrix here is defined according to the discussion of Gaudin.[2] It is described by the quadratic formula of the Boltzmann weights of the 2-state chiral Potts model so that it is different from those in Refs. 3 or 4.

Let us recall the definition of the Sklyanin algebra $\mathscr{A}_\eta$: Let σ_α ($\alpha=0,...,3$) be the Pauli matrices. In Ref. 1, Sklyanin defined the well-known Sklyanin algebra $\mathscr{A}_\eta$ as a $\mathbb{C}$-algebra generated by $\{S_0,S_1,S_2,S_3\}$ with the fundamental relation

$$R(u-v)L_1(u)L_2(v)=L_2(v)L_1(u)R(u-v) \quad (u,v\in\mathbb{C}). \tag{1}$$

Here $R(u)$ is Baxter's elliptic R-matrix which has the form

$$R(u)=\sigma_0\otimes\sigma_0+\sum_{\alpha=1}^{3} w_\alpha(u)\sigma_\alpha\otimes\sigma_\alpha \tag{2}$$

and the L-operator $L(u)$ is defined by

$$L(u)=\sigma_0 S_0+\sum_{\alpha=1}^{3} w_\alpha(u)\sigma_\alpha S_\alpha\in \mathrm{End}(\mathbb{C}^2)\otimes\mathscr{A}_\eta, \tag{3}$$

where the coefficients $w_\alpha(u)$ are expressed by the elliptic theta functions (cf. Ref. 5). Then it is seen that (1) is equivalent to the following commutation relations:

$$[S_0,S_\alpha]_-=\sqrt{-1}J_{\beta\gamma}[S_\beta,S_\gamma]_+, \quad [S_\alpha,S_\beta]_-=\sqrt{-1}[S_0,S_\gamma]_+. \tag{4}$$

Here (α,β,γ) are cyclic permutations of (1,2,3), and $J_{\alpha\beta}$ are the structure constants described by

$$\begin{aligned} J_{12}&=k'^2\,\frac{\mathrm{sn}^2}{\mathrm{cn}^2\mathrm{dn}^2}(\eta,k),\\ J_{23}&=k^2\,\frac{\mathrm{sn}^2\mathrm{cn}^2}{\mathrm{dn}^2}(\eta,k), \quad J_{31}=-\frac{\mathrm{sn}^2\mathrm{dn}^2}{\mathrm{cn}^2}(\eta,k). \end{aligned} \tag{5}$$

Letting $\eta=K/2$ (i.e., η is an 8-torsion point), we will show that $\mathscr{A}_{K/2}$ coincides with our quantum algebra $\mathscr{C}$. Furthermore, we will show that our algebra $\mathscr{C}$ in the self-dual case gives $U_q(sl_2)$ at the fourth root of unity.

This paper is organized as follows: In Sec. II we summarize the results of Au-Yang and Perk,[6] and introduce an R-matrix by combining two Boltzmann weights of the N-state chiral Potts model (cf. Ref. 2). In Sec. III we construct a quantum algebra $\mathscr{C}$ which comes from the 2-state chiral Potts model (Theorem 1), and give the proof by using the addition theorems for the theta functions. Further, the link between the Sklyanin algebra and our algebra $\mathscr{C}$ will be clarified. In Sec. IV we give another proof of Theorem 1 by using the star-triangle relation that holds among the Boltzmann weights. Moreover, our quantum algebra $\mathscr{C}$ in the self-dual case will be shown to coincide with $U_q(sl_2)$ when $q=\sqrt{-1}$. Finally, in Sec. V we mention the significance of extending our result to the N-state, i.e., the higher-genus case.

II. *N*-STATE CHIRAL POTTS MODEL

In Ref. 6, Au-Yang and Perk introduced the Boltzmann weights $W_{pq}(n)$ and $\overline{W}_{pq}(n)$ of the N-state chiral Potts model through

$$\begin{aligned}\frac{W_{pq}(n)}{W_{pq}(0)}&=\prod_{j=1}^{n}\left(\frac{d_pb_q-a_pc_q\omega^j}{b_pd_q-c_pa_q\omega^j}\right),\\ \frac{\overline{W}_{pq}(n)}{\overline{W}_{pq}(0)}&=\prod_{j=1}^{n}\left(\frac{\omega a_pd_q-d_pa_q\omega^j}{c_pb_q-b_pc_q\omega^j}\right),\end{aligned}\tag{6}$$

where $\omega:=e^{2\pi\sqrt{-1}/N}$. The parameters (a_p,b_p,c_p,d_p) and (a_q,b_q,c_q,d_q) denote points on an algebraic curve

$$a^N+k'b^N=kd^N,\quad k'a^N+b^N=kc^N,\quad (k^2+k'^2=1),\tag{7}$$

which has the genus $g=N^2(N-2)+1$. Then these Boltzmann weights satisfy the periodic condition

$$W_{pq}(n+N)=W_{pq}(n),\quad \overline{W}_{pq}(n+N)=\overline{W}_{pq}(n)$$

and the star–triangle relation (STR)

$$\sum_{l=1}^{N}\overline{W}_{qr}(j-l)W_{pr}(i-l)\overline{W}_{pq}(l-k)=R_{pqr}W_{pq}(i-j)\overline{W}_{pr}(j-k)W_{qr}(i-k).\tag{8}$$

Here the states i, j, and k belong to $\mathbb{Z}_N$, and R_{pqr} is a constant that is independent of these states. Furthermore, the constant R_{pqr} has the following form (Matveev and Smirnov[7]):

$$\begin{aligned}R^N_{pqr}&=\frac{f^N_{pq}f^N_{qr}}{f^N_{pr}},\\ f_{pq}&:=\left[\prod_{m=1}^{N}\left(\sum_{k=1}^{N}\omega^{mk}\overline{W}_{pq}(k)\right)\Big/\prod_{m=1}^{N}W_{pq}(m)\right]^{1/N}.\end{aligned}\tag{9}$$

Next we introduce an R-matrix associated with the N-state chiral Potts model: Following the discussion of Gaudin in the self-dual case,[2] we put a matrix $R(p,q)\in\mathrm{End}(V^{\otimes 2})$ $(V:=\mathbb{C}^N)$ by

$$R(p,q):=\sum_{i,j,k,l\in\mathbb{Z}_N} R_{ij}^{kl}(p,q)E_{ik}\otimes E_{jl},$$
$$R_{ij}^{kl}(p,q):=\overline{W}_{pq}(j-k)W_{pq}(i+j)\delta_{i+j,k+l}. \tag{10}$$

It is easily proved that $R(p,q)$ satisfies the Yang–Baxter equation (YBE)

$$R_{12}(p,q)R_{13}(p,r)R_{23}(q,r)=R_{23}(q,r)R_{13}(p,r)R_{12}(p,q) \quad \text{on} \quad V^{\otimes 3}. \tag{11}$$

Now we rewrite (10) in a more convenient form. Introducing X and $Y\in\mathrm{End}(V)$ through

$$X:=\begin{pmatrix} 1 & & & \\ & \omega & & \\ & & \ddots & \\ & & & \omega^{N-1} \end{pmatrix}, \quad Y:=\begin{pmatrix} 0 & 1 & & \\ & \ddots & \ddots & \\ & & 0 & 1 \\ 1 & & & 0 \end{pmatrix},$$

we see that

$$R(p,q)=\frac{1}{N}\sum_{\alpha,\alpha',\beta,\beta'\in\mathbb{Z}_N}\{\omega^{(\alpha+\beta)(\alpha'-\beta')}\hat{W}_{pq}(\beta)\overline{W}_{pq}(\beta')(X^{-\alpha-2\beta}Y^{-\alpha'}\otimes X^{\alpha}Y^{\alpha'})\}, \tag{12}$$

where $\hat{W}_{pq}$ is the Fourier transform

$$\hat{W}_{pq}(m)=\frac{1}{N}\sum_{k\in\mathbb{Z}_N}\omega^{mk}W_{pq}(k).$$

III. QUANTUM ALGEBRA ARISING FROM 2-STATE CHIRAL POTTS MODEL

In analogy with the construction of the Sklyanin algebra,[1] let us define the L-operator $L(p,q)$ for our R-matrix (12) by

$$L(p,q):=\frac{1}{N}\sum_{\alpha,\alpha',\beta,\beta'\in\mathbb{Z}_N}\{\omega^{(\alpha+\beta)(\alpha'-\beta')}\hat{W}_{pq}(\beta)\overline{W}_{pq}(\beta')X^{-\alpha-2\beta}Y^{-\alpha'}S_{\alpha\alpha'}\}, \tag{13}$$

where $\{S_{\alpha\alpha'}\}_{0\leqslant\alpha,\alpha'\leqslant N-1}$ are temporarily unknown quantities. Then we impose on the L-operator (13) a relation

$$R(p,q)L_1(p,r)L_2(q,r)=L_2(q,r)L_1(p,r)R(p,q) \quad \text{for all } p,q, \text{ and } r, \tag{14}$$

where $L_1=L\otimes I$ and $L_2=I\otimes L$.

We will consider only the 2-state case in the following. In this case the genus of the curve (7) is equal to 1, namely, the curve is elliptic. The parameters (a_p,b_p,c_p,d_p) can be expressed by Jacobi's theta functions[6]

$$(a_p,b_p,c_p,d_p)=(-H(p),H_1(p),\Theta_1(p),\Theta(p)). \tag{15}$$

We obtain the following theorem.

Theorem 1: *In the case of $N=2$, (14) is equivalent to the following commutation relations for the variables $\{S_{00},S_{01},S_{10},S_{11}\}$:*

$$
\begin{aligned}
&[S_{00},S_{01}]_-=[S_{10},S_{11}]_+, && [S_{00},S_{01}]_+=[S_{10},S_{11}]_-,\\
&[S_{00},S_{10}]_-=-[S_{01},S_{11}]_+, && [S_{00},S_{10}]_+=-[S_{01},S_{11}]_-,\\
&[S_{00},S_{11}]_-=\frac{1-k'}{1+k'}[S_{01},S_{10}]_+, && [S_{00},S_{11}]_+=-[S_{01},S_{10}]_-.
\end{aligned}
\tag{16}
$$

Proof: Here we will derive the third formula in (16) below. In the 2-state case (12) and (13) have the following forms:

$$
R(p,q)=\begin{pmatrix}
\overline{W}_{pq}(0)W_{pq}(0) & & & \overline{W}_{pq}(1)W_{pq}(0)\\
& \overline{W}_{pq}(1)W_{pq}(1) & \overline{W}_{pq}(0)W_{pq}(1) & \\
& \overline{W}_{pq}(0)W_{pq}(1) & \overline{W}_{pq}(1)W_{pq}(1) & \\
\overline{W}_{pq}(1)W_{pq}(0) & & & \overline{W}_{pq}(0)W_{pq}(0)
\end{pmatrix}, \tag{17}
$$

$$
L(p,q)=\frac{1}{2}\begin{pmatrix}
\overline{W}_{\underline{pq}}(0)W_{pq}(0)(S_{00}+S_{10}) & \overline{W}_{\underline{pq}}(0)W_{pq}(1)(S_{01}-S_{11})\\
+W_{pq}(1)W_{pq}(1)(S_{00}-S_{10}) & +W_{pq}(1)W_{pq}(0)(S_{01}+S_{11})\\
\overline{W}_{\underline{pq}}(0)W_{pq}(1)(S_{01}+S_{11}) & \overline{W}_{\underline{pq}}(0)W_{pq}(0)(S_{00}-S_{10})\\
+W_{pq}(1)W_{pq}(0)(S_{01}-S_{11}) & +W_{pq}(1)W_{pq}(1)(S_{00}+S_{10})
\end{pmatrix}. \tag{18}
$$

Here the Boltzmann weights are expressed by

$$
\frac{W_{pq}(1)}{W_{pq}(0)}=\frac{d_pb_q+a_pc_q}{b_pd_q+c_pa_q},\quad \frac{\overline{W}_{pq}(1)}{\overline{W}_{pq}(0)}=\frac{-a_pd_q+d_pa_q}{c_pb_q+b_pc_q}, \tag{19}
$$

where

$$
a^2+k'b^2=kd^2,\quad k'a^2+b^2=kc^2,\quad (k^2+k'^2=1). \tag{20}
$$

Substituting (17) and (18) in (14), we see that there exists the following relation between $[S_{00},S_{11}]_-$ and $[S_{01},S_{10}]_+$:

$$
A_{pqr}[S_{00},S_{11}]_-+B_{pqr}[S_{01},S_{10}]_+=0, \tag{21}
$$

where

$$
\begin{aligned}
A_{pqr}:=&(-\overline{W}_{pq}(0)W_{pq}(1)+\overline{W}_{pq}(1)W_{pq}(0))\\
&\times(\overline{W}_{pr}(0)W_{pr}(0)+\overline{W}_{pr}(1)W_{pr}(1))(-\overline{W}_{qr}(0)W_{qr}(1)+\overline{W}_{qr}(1)W_{qr}(0))\\
&+(\overline{W}_{pq}(0)W_{pq}(0)+\overline{W}_{pq}(1)W_{pq}(1))\\
&\times(-\overline{W}_{pr}(0)W_{pr}(1)+\overline{W}_{pr}(1)W_{pr}(0))(\overline{W}_{qr}(0)W_{qr}(0)+\overline{W}_{qr}(1)W_{qr}(1)),\\
B_{pqr}:=&(\overline{W}_{pq}(0)W_{pq}(1)+\overline{W}_{pq}(1)W_{pq}(0))\\
&\times(\overline{W}_{pr}(0)W_{pr}(0)-\overline{W}_{pr}(1)W_{pr}(1))(\overline{W}_{qr}(0)W_{qr}(1)+\overline{W}_{qr}(1)W_{qr}(0))\\
&-(\overline{W}_{pq}(0)W_{pq}(0)-\overline{W}_{pq}(1)W_{pq}(1))\\
&\times(\overline{W}_{pr}(0)W_{pr}(1)+\overline{W}_{pr}(1)W_{pr}(0))(\overline{W}_{qr}(0)W_{qr}(0)-\overline{W}_{qr}(1)W_{qr}(1)).
\end{aligned}
\tag{22}
$$

Using the parametrizations (15) and the identity

$$
\Theta(u)H(v)+H(u)\Theta(v)=\frac{2H\left(\frac{u+v}{2}\right)\Theta\left(\frac{u+v}{2}\right)H_1\left(\frac{u-v}{2}\right)\Theta_1\left(\frac{u-v}{2}\right)}{H_1(0)\Theta_1(0)}
$$

in Ref. 8, we obtain the following lemma.

Lemma 1: We can rewrite (19) in the form

$$\frac{W_{pq}(1)}{W_{pq}(0)}=-\frac{H\left(\frac{p-q}{2}-\frac{K}{2}\right)\Theta\left(\frac{p-q}{2}-\frac{K}{2}\right)}{H_1\left(\frac{p-q}{2}-\frac{K}{2}\right)\Theta_1\left(\frac{p-q}{2}-\frac{K}{2}\right)},$$
$$\frac{\overline{W}_{pq}(1)}{\overline{W}_{pq}(0)}=\frac{H\left(\frac{p-q}{2}\right)\Theta\left(\frac{p-q}{2}\right)}{H_1\left(\frac{p-q}{2}\right)\Theta_1\left(\frac{p-q}{2}\right)}, \tag{23}$$

where K is the complete elliptic integral of the first kind.

Substituting (23) in (22) and using the identity

$$H(u)\Theta(u)H_1(v)\Theta_1(v)-H(v)\Theta(v)H_1(u)\Theta_1(u)=H(u-v)\Theta(u+v)H_1(0)\Theta_1(0)$$

in Ref. 8, we have

$$\frac{B_{pqr}}{A_{pqr}}=\left\{\frac{H\left(\frac{K}{2}\right)}{\Theta\left(\frac{K}{2}\right)}\right\}^4\frac{S(u,v)}{T(u,v)}. \tag{24}$$

Here

$$\begin{aligned}S(u,v):=&\Theta\left(u-\frac{K}{2}\right)\Theta_1\left(u+v-\frac{K}{2}\right)\Theta\left(v-\frac{K}{2}\right)\Theta_1\left(\frac{K}{2}\right)\\&-\Theta_1\left(u-\frac{K}{2}\right)\Theta\left(u+v-\frac{K}{2}\right)\Theta_1\left(v-\frac{K}{2}\right)\Theta\left(\frac{K}{2}\right),\\T(u,v):=&H\left(u-\frac{K}{2}\right)H_1\left(u+v-\frac{K}{2}\right)H\left(v-\frac{K}{2}\right)H_1\left(\frac{K}{2}\right)\\&+H_1\left(u-\frac{K}{2}\right)H\left(u+v-\frac{K}{2}\right)H_1\left(v-\frac{K}{2}\right)H\left(\frac{K}{2}\right),\end{aligned}$$

and $u:=p-q$, $v:=q-r$. In (24), making use of the addition theorem for the theta functions

$$\begin{aligned}&\vartheta_{00}(x)\vartheta_{00}(y)\vartheta_{01}(u)\vartheta_{01}(v)-\vartheta_{01}(x)\vartheta_{01}(y)\vartheta_{00}(u)\vartheta_{00}(v)\\&\quad+\vartheta_{10}(x)\vartheta_{10}(y)\vartheta_{11}(u)\vartheta_{11}(v)-\vartheta_{11}(x)\vartheta_{11}(y)\vartheta_{10}(u)\vartheta_{10}(v)\\&=-2\,\vartheta_{11}\left(\frac{x+y+u+v}{2}\right)\vartheta_{11}\left(\frac{x+y-u-v}{2}\right)\vartheta_{10}\left(\frac{x-y+u-v}{2}\right)\vartheta_{10}\left(\frac{x-y-u+v}{2}\right)\end{aligned}$$

in Ref. 9 and the identities

$$\frac{H(u)}{\Theta(u)}=k^{1/2}\,\mathrm{sn}(u),\quad \mathrm{sn}\left(\frac{K}{2}\right)=(1+k')^{-1/2},$$

we conclude that (21) is equivalent to

$$[S_{00},S_{11}]_- = \frac{1-k'}{1+k'}\,[S_{01},S_{10}]_+ .$$

Other relations can be proved in a similar way.

Definition 1: The quantum algebra $\mathscr{C}$ is defined to be a $\mathbb{C}$-algebra on the generators $\{S_{00},S_{01},S_{10},S_{11}\}$ subject to the relations (16).

We observe that our quantum algebra $\mathscr{C}$ is a special case of the Sklyanin algebra $\mathscr{A}_\eta(4)$. Actually, substituting $\eta=K/2$ in the structure constants $J_{\alpha\beta}$ that are given by (5), we have

$$(J_{12},J_{23},J_{31}) = \left(1, \frac{1-k'}{1+k'}, -1\right).$$

Therefore, we obtain the following proposition.

Proposition 1: The quantum algebra $\mathscr{C}$ coincides with the Sklyanin algebra $\mathscr{A}_\eta$ when η is an 8-torsion point ($\eta=K/2$) by replacing $(S_{00},\sqrt{-1}S_{11},S_{01},S_{10})$ by (S_0,S_1,S_2,S_3).

Remark 1: We observe the meaning of the 8-torsion point from the viewpoint of the R-matrix. Making use of Lemma 1, we obtain the following relation between our R-matrix (17) and that of the 8-vertex model:

$$\frac{2}{H\left(\frac{K}{2}\right)\Theta\left(\frac{K}{2}\right)H_1(0)\Theta_1(0)}\,R_{2-\text{state chiral Potts}} = P^{-1}R_{8\text{-vertex at the 8-torsion point}}P,$$

$$P := \begin{pmatrix} 1 & & & \\ & 1 & & \\ & & 1 & \\ & & & -1 \end{pmatrix}.$$

Further it is also known that the 8-vertex model at the 8-torsion point corresponds to the double Ising model.[8]

IV. ANOTHER DERIVATION OF THE QUANTUM ALGEBRA

We will prove Theorem 1 in another way, which is to use the star–triangle relation (8). Let us recall the relations (21) and (22) as mentioned in Sec. III. We can read (22) as

$$\begin{aligned} A_{pqr} &= \sum_{i,j=0}^{1}\left\{(-1)^{i+j}W_{pq}(j)\overline{W_{pr}}(i+j-1)W_{qr}(i)\sum_{k=0}^{1}\overline{W_{pq}}(i+k)W_{pr}(k)\overline{W_{qr}}(j-k)\right\} \\ &\quad + \sum_{i,j=0}^{1}\left\{W_{pq}(j+1)\overline{W_{pr}}(i+j)W_{qr}(i+1)\sum_{k=0}^{1}(-1)^{k}\overline{W_{pq}}(i+k)W_{pr}(k)\overline{W_{qr}}(j-k)\right\}, \\ B_{pqr} &= \sum_{i,j=0}^{1}\left\{(-1)^{i+j-1}W_{pq}(j)\overline{W_{pr}}(i+j-1)W_{qr}(i)\sum_{k=0}^{1}\overline{W_{pq}}(i+k)W_{pr}(k)\overline{W_{qr}}(j-k)\right\} \\ &\quad + \sum_{i,j=0}^{1}\left\{W_{pq}(j+1)\overline{W_{pr}}(i+j)W_{qr}(i+1)\sum_{k=0}^{1}(-1)^{k}\overline{W_{pq}}(i+k)W_{pr}(k)\overline{W_{qr}}(j-k)\right\}. \end{aligned} \tag{25}$$

Deforming (25) by using the STR in this case

$$\begin{aligned}
&\overline{W}_{pq}(0)W_{pr}(0)\overline{W}_{qr}(0)+\overline{W}_{pq}(1)W_{pr}(1)\overline{W}_{qr}(1)=R_{pqr}W_{pq}(0)\overline{W}_{pr}(0)W_{qr}(0),\\
&\overline{W}_{pq}(1)W_{pr}(0)\overline{W}_{qr}(0)+\overline{W}_{pq}(0)W_{pr}(1)\overline{W}_{qr}(1)=R_{pqr}W_{pq}(0)\overline{W}_{pr}(1)W_{qr}(1),\\
&\overline{W}_{pq}(0)W_{pr}(0)\overline{W}_{qr}(1)+\overline{W}_{pq}(1)W_{pr}(1)\overline{W}_{qr}(0)=R_{pqr}W_{pq}(1)\overline{W}_{pr}(1)W_{qr}(0),\\
&\overline{W}_{pq}(1)W_{pr}(0)\overline{W}_{qr}(1)+\overline{W}_{pq}(0)W_{pr}(1)\overline{W}_{qr}(0)=R_{pqr}W_{pq}(1)\overline{W}_{pr}(0)W_{qr}(1),
\end{aligned}$$

we have

$$\begin{aligned}
A_{pqr}=&\frac{1}{R_{pqr}}\{R_{pqr}^2(W_{pq}(0)^2-W_{pq}(1)^2)(\overline{W}_{pr}(1)\overline{W}_{pr}(0))(W_{qr}(0)^2-W_{qr}(1)^2)\\
&+4(\overline{W}_{pq}(1)\overline{W}_{pq}(0))(W_{pr}(0)^2-W_{pr}(1)^2)(\overline{W}_{qr}(1)\overline{W}_{qr}(0))\},\\
B_{pqr}=&\frac{-1}{R_{pqr}}\{R_{pqr}^2(W_{pq}(0)^2-W_{pq}(1)^2)(\overline{W}_{pr}(1)\overline{W}_{pr}(0))(W_{qr}(0)^2-W_{qr}(1)^2)\\
&-4(\overline{W}_{pq}(1)\overline{W}_{pq}(0))(W_{pr}(0)^2-W_{pr}(1)^2)(\overline{W}_{qr}(1)\overline{W}_{qr}(0))\}.
\end{aligned}\tag{26}$$

Here the constant R_{pqr} (9) has the form

$$R_{pqr}^2=\frac{(\overline{W}_{pq}(0)^2-\overline{W}_{pq}(1)^2)(W_{pr}(1)W_{pr}(0))(\overline{W}_{qr}(0)^2-\overline{W}_{qr}(1)^2)}{(W_{pq}(1)W_{pq}(0))(\overline{W}_{pr}(0)^2-\overline{W}_{pr}(1)^2)(W_{qr}(1)W_{qr}(0))}.\tag{27}$$

Substituting (27) and (19) in (26), we can express A_{pqr} and B_{pqr} as polynomials of the parameters (a,b,c,d). Actually, letting

$$\begin{aligned}
U_{pq}:=&\{(c_pb_q+b_pc_q)^2-(-a_pd_q+d_pa_q)^2\}\{(b_pd_q+c_pa_q)^2-(d_pb_q+a_pc_q)^2\},\\
V_{pq}:=&(c_pb_q+b_pc_q)(-a_pd_q+d_pa_q)(b_pd_q+c_pa_q)(d_pb_q+a_pc_q),
\end{aligned}\tag{28}$$

we obtain

$$\frac{B_{pqr}}{A_{pqr}}=-\frac{U_{pq}V_{pr}U_{qr}-4V_{pq}U_{pr}V_{qr}}{U_{pq}V_{pr}U_{qr}+4V_{pq}U_{pr}V_{qr}}.$$

Moreover, using relations (20) in (28), we have

$$V_{pq}=\frac{k'}{4}U_{pq}.$$

Therefore, we conclude that relation (21) is equivalent to

$$[S_{00},S_{11}]_-=\frac{1-k'}{1+k'}[S_{01},S_{10}]_+.$$

The proofs of other relations are likewise.

Finally, we observe that our quantum algebra $\mathscr{C}$ in the self-dual case coincides with the quantum group $U_q(sl_2)$ at the fourth root of unity. The self-dual case means that the Boltzmann weights satisfy the relation $\hat{W}_{pq}(n)=W_{pq}(n)$, which is realized by the limit

$$k' \to 1, \quad c = d \to 1.$$

In this case the third formula of the defining relations (16) is modified to

$$[S_{00}, S_{11}]_- = 0. \tag{29}$$

Next let

$$E_\pm := \frac{1}{\sqrt{2}} (S_{01} \pm S_{10}), \quad S_\pm := \frac{1}{\sqrt{2}} (S_{00} \pm S_{11}).$$

From (29) it is assured that S_+ and S_- are commutative. In order to make clear the link between $U_q(sl_2)$ and our algebra $\mathscr{C}$, we need to impose a further assumption that $(S_+ S_-)^2 = 1$ in the following. Let $q := \sqrt{-1}$, and z_1, z_2 be normalizing factors that satisfy the relation $z_1 z_2 = q - q^{-1} = 2\sqrt{-1}$. Then we define e, f, and t by

$$z_1 e := E_+, \quad z_2 f := E_-, \quad t := S_+^2.$$

We obtain from (16) and (29) that $\{e, f, t^{\pm 1}\}$ satisfy the fundamental relations of $U_q(sl_2)$

$$tt^{-1} = 1 = t^{-1}t, \quad tet^{-1} = q^2 e, \quad tft^{-1} = q^{-2} f, \quad [e,f]_- = \frac{t - t^{-1}}{q - q^{-1}}.$$

V. DISCUSSION

We proved our main theorem in two ways: One is to make use of the addition theorems for the theta functions since the Boltzmann weights are associated with the elliptic curve, the other is to use the STR. The latter is applicable to the N-state, i.e., the higher-genus case. In this paper we observe the 2-state case and clarify the natural link between the Sklyanin algebra and our result (Proposition 1, Remark 1). It is important to generalize our algebra $\mathscr{C}$ to the N-state case by the latter method because there is a possibility that a quantum algebra attached to algebraic curves of genus >1 is constructed. For the first step to achieve this program, we are now studying the 3-state case (genus 10).

Cohomology and connections on fiber bundles and applications to field theories

Christian Gross
Fachbereich Mathematik, TH Darmstadt, Germany

(Received 12 March 1996; accepted for publication 4 June 1996)

Given any connection on a fiber bundle $B(M,F,G)$, we discuss the question which closed differential forms on the fiber F can be extended to closed forms on the whole bundle B in a canonical way such that the horizontal parts of the extended forms are given in terms of the gauge fields. Such questions arise for many models in theoretical physics such as the skyrmion bundle and related theories with non-Abelian groups G. We introduce the notion of a G-transgressive form as a sufficient condition for the form to be extendable to any bundle which comes along with a given left action $L:G\times F\to F$. Using Lie algebra cohomology we prove that if the structure group G of the bundle is semisimple, then every closed n-form, $n\leqslant 2$, on the fiber which is invariant under L is G-transgressive and thus defines a unique de Rham cohomology class on any bundle which comes along with L. © *1996 American Institute of Physics.* [S0022-2488(96)02011-7]

I. MOTIVATION

In theoretical physics the following general problem quite often occurs: suppose a field theory is defined for some manifold F, i.e., we have matter fields described by differentiable maps $f:M\to F$ from space-time M to the manifold F. (Examples are wide-spread, let us only mention case of Dirac spinors, where $F=\mathbb{C}^4$, or the Skyrme model and related theories, where $F=\mathrm{SU}_n$, cf. Skyrme,[1] Witten,[2] and Zahed and Brown.[3]) For computations one has integrals like the action integral, where the Lagrangian is combined with the volume form of space-time, but also integrals over closed differential forms ϕ on F (i.e., $d\phi=0$), which are integrated over space-time by means of the pullbacks $f^\star$.

Next suppose, we also have a symmetry group G and we gauge our field theory with respect to this Lie group. From the mathematicians point of view, one has to construct a fiber bundle B with base manifold M, (global) projection $\pi:B\to M$, (standard) fiber F and structure group G, that acts on F via an effective left action $L:G\times F\to F$, cf. Steenrod[4] or Kobayashi and Numizu.[5] For a cover $\mathfrak{U}=\{U_\alpha\}_{\alpha\in A}$ of the base manifold M, we have a bundle atlas $\{(U_\alpha,\psi_\alpha)\}_{\alpha\in A}$ with local trivializations $\psi_\alpha:\pi^{-1}(U_\alpha)\to U_\alpha\times F$, local projections $\pi_\alpha=\mathrm{pr}_F\circ\psi_\alpha$ onto F and local injections $i_{\alpha,x}=(\pi_{\alpha,x})^{-1}$ of F onto the fiber over $x\in M$, where $\pi_{\alpha,x}:=\pi_\alpha|_{\pi^{-1}(x)}:\pi^{-1}(x)\to F$. For every $f\in F$ and $g\in G$ define $L^f:G\to F$ and $L_g:F\to F$ by $L^f(g)=L_g(f)=L(g,f)$. Then on every overlap region $U_{\alpha\beta}=U_\alpha\cap U_\beta$ the change of bundle charts is given by transition functions $g_{\alpha\beta}:U_{\alpha\beta}=U_\alpha\cap U_\beta\to G$, such that $\pi_{\alpha,x}\circ(\pi_{\beta,x})^{-1}=\pi_{\alpha,x}\circ i_{\beta,x}=L_{g_{\alpha\beta}(x)}$ for all $x\in U_{\alpha\beta}$.

The bundle $B(M,F,G)$ is associated to a principal bundle $P(M,G)$, where the structure group acts on itself by left multiplication. We will use the same symbols π, ψ_α, π_α, etc., for the bundles P and B. On the principle bundle we also have a free right action $R:P\times G\to P$ and a connection Γ defined by a connection 1-form ω^Γ and its exterior covariant derivative, the curvature 2-form Ω^Γ. Let e denote the neutral element of G and $\sigma_{\alpha,e}:U_\alpha\to\pi^{-1}(U_\alpha)=P|_{U_\alpha}$ denote the local sections given by $\sigma_{\alpha,e}(x):=\psi_\alpha^{-1}(x,e)$. (Recall that a section σ obeys $\pi\circ\sigma=\mathrm{id}_M$.) Then the gauge potentials A^α and the gauge fields F^α of the field theory are the local forms on the sets U_α defined by $\mathrm{A}^\alpha=\sigma_{\alpha,e}^\star\omega^\Gamma$, resp., $\mathrm{F}^\alpha=\sigma_{\alpha,e}^\star\Omega^\Gamma$.

Now the problem is as follows: since the matter fields now appear as global sections $f:M\to B$, it is necessary to ''generalize'' the given closed differential forms $\phi\in\mathscr{A}(F)$ to the bundle case (such that the pullbacks $f^\star\phi$ are well-defined): one needs a closed form $\psi\in\mathscr{A}(B)$

such that ψ reproduces ϕ when restricted to the fibers: $\phi = i^{\star}_{\alpha,x}\psi$ for all $\alpha \in A$ and all $x \in U_\alpha$.

Recall that the de Rham cohomology of a manifold denotes the vector space of the closed forms modulo the exact forms on the manifold, i.e., it denotes the kernel of the exterior derivative $d: \mathscr{A}(M) \to \mathscr{A}(M), \mathscr{A}_{p-1}(M) \to \mathscr{A}_p(M)$ modulo its image. Since d is a differential operator ($d \circ d = 0$), all exact forms are closed and thus the vector space of the closed modulo the exact p-forms is well-defined. This quotient space is called the p-th de Rham cohomology group $H^p(M)$ and the (total) cohomology of M means the direct sum $H^*(M) := \oplus_{p=0}^{\infty} H^p(M)$.

We may reformulate the problem in terms of the de Rham cohomology: Given a cohomology class $[\phi] \in H^*(F)$ we ask whether $[\phi]$ generates a cohomology class in $[\psi] \in H^*(B)$, such that $[\phi] = [i^{\star}_{\alpha,x}][\psi]$. Moreover, we also need a representative ψ for this generated cohomology class.

The problem of computing the cohomology of a fiber bundle from $H^*(M)$ and $H^*(F)$ is a delicate mathematical problem. For a trivial bundle, i.e., a direct product $M \times F$, we have the Künneth formula

$$H^*(M \times F) \cong H^*(M) \otimes H^*(F).$$

This formula is based on the fact that we have two global projections pr_M and pr_F. Using their pullbacks we may extend any form on M and F to the bundle. Since d commutes with pullbacks, this also holds for the cohomology classes. For a nontrivial bundle we only have one global projection π, which indeed allows us to lift any form on M and any cohomology class in $H^*(M)$ onto the bundle. (Nevertheless, the induced homomorphism $[\pi^*]: H^*(M) \to H^*(B)$ needs not be injective nor surjective.) Yet there is no such mean for forms on F and thus the situation becomes much more complicated as in the trivial case and leads to the theory of spectral sequences, cf. Bott and Tu.[6] Spectral sequences compute $H^*(B)$ from $H^*(M)$ and $H^*(F)$. They also answer the question which closed forms on the fiber can be extended to closed forms on the bundle and thus generate a unique cohomology class in $H^*(B)$ in the manner above. We call these forms 0-transgressive. Not all closed forms on F are 0-transgressive. In general it will depend on the structure of the bundle whether a given form is 0-transgressive: obviously for trivial bundles all closed forms on F are 0-transgressive.

If a form $\phi \in \mathscr{A}(F)$ is 0-transgressive, spectral sequences also provide a formula for ψ (Ref. 6, Prop. 9.5). Nevertheless this ''Collating formula'' involves a partition of unity subordinate to the given cover $\mathfrak{U}$ of M. For any such partition the formula gives a different form ψ within the generated cohomology class. (Note that, a priori, ψ is not unique but defined only up to an exact form on B, whose restriction to the fibers is zero.)

From the physicists point of view, this situation is quite unsatisfactory since a partition of unity does not bear any physical meaning and there is no reason why one partition — and the corresponding form ψ — should be better than another. In fact one would like to obtain a representative ψ for the generated cohomology class that can be associated with the physics in question, that is the gauge potentials and the gauge fields of the field theory.

This takes us back to connections on fiber bundles. Recall that a connection on a fiber bundle defines global horizontal and vertical projections of vector fields such that the $C^\infty(B)$-module $\mathscr{D}^1(B)$ of the vector fields on B splits: $\mathscr{D}^1(B) = h\mathscr{D}^1(B) \oplus v\mathscr{D}^1(B)$. Once a connection on a principal bundle is defined via ω^Γ, resp., the gauge potentials A^α, it also defines connections on all associated fiber bundles, cf. Section III.

In addition, Γ defines lifts of vector fields on the base onto horizontal fields on the bundle and projections of forms on the bundle. These lifts and projections now can be used to extend forms on the fiber to the bundle. In fact, for every differential form $\phi \in \mathscr{A}(F)$ that is invariant under the given left action L (i.e., $L_g^{\star}\phi = \phi$ for all $g \in G$), there exists exactly one vertical form on the bundle, say $\phi v \in \mathscr{A}(B)$, such that $\phi v|_{\pi^{-1}(x)} = \phi$. From the physicists point of view, this seems to be a satisfactory generalization, but unfortunately we are not done with that, since the diagram in Figure 1 does *not* commute.

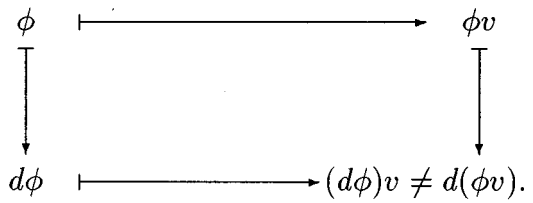

FIG. 1. Exterior derivative and vertical projection do not commute.

Thus although we start with a closed form ϕ, the generated vertical form ϕv needs not be closed. In general, we are not able to find a vertical representative for this cohomology class generated by a 0-transgressive form, but we need to admit horizontal terms. Thus the question will be whether we can find such a representative where these horizontal terms are ''naturally'' given by the connection Γ, in fact, by the gauge fields. In that case, we call the resulting form adapted to Γ. Those forms are candidates for the desired generalizations of closed forms in field theories.

II. BASIC DEFINITIONS

Let M denote any manifold and V,W finite dimensional vector spaces. Every vector field $\mathscr{X} \in \mathscr{D}^1(M)$ differentiably associates with every $x \in M$ an element $\mathscr{X}_x$ in the tangent space $T_x(M)$. Now $\mathscr{D}_p(M,V)$, resp., $\mathscr{A}_p(M,V)$, denote the $C^\infty(M)$-modules of p-linear, resp., alternating p-linear, maps $\phi_p : \mathscr{D}^1(M) \times \cdots \times \mathscr{D}^1(M) \to C^\infty(M,V)$. They associate with every $x \in M$ an element $\phi_x = (\phi_p)_x$ in $\mathrm{Hom}(\otimes^p T_x(M), V)$, resp., in $\mathrm{Alt}_p(T_x(M),V)$, where $\mathrm{Alt}_p(W,V)$ means the vector space of all alternating p-linear maps from W^p to V. The alternations $A_p : \mathscr{D}_p(M,V) \to \mathscr{D}_p(M,V)$ are the canonical projections of $\mathscr{D}_p(M,V)$ onto $\mathscr{A}_p(M,V)$. The exterior product (or wedge product) of forms will be denoted by $\wedge$: for $\phi_p \in \mathscr{A}_p(M)$ and $\phi_r \in \mathscr{A}_r(M)$ we have $\phi_p \wedge \phi_r := A_{p+r}(\phi_p \otimes \phi_r) \in \mathscr{A}_{p+r}(M)$.

Also if a bilinear mapping $\varphi : V \times V \to V$ is given, $\wedge$ extends to an exterior product $\wedge_\varphi$ of V-valued differential forms. For $\phi = \hat{\phi} \otimes v \in \mathscr{A}(M) \otimes V \cong \mathscr{A}(M,V)$ and $\psi = \hat{\psi} \otimes w \in \mathscr{A}(M) \otimes V$, the exterior product is given by

$$\phi \wedge_\varphi \psi := (\hat{\phi} \wedge \hat{\psi}) \otimes \varphi(v,w). \tag{1}$$

Everything in the sequel will also work for infinite dimensional vector spaces V, if we consider $\mathscr{A}(M) \otimes V$ instead of $\mathscr{A}(M,V)$. Yet for our purposes, we will restrict ourselves to finite dimensional V and identify $\mathscr{A}(M) \otimes V$ and $\mathscr{A}(M,V)$.

As mentioned above, we are heading for differential forms whose horizontal parts are given in terms of the gauge fields. Let us denote the $C^\infty(B)$-module of horizontal forms on B by $\mathscr{A}(B)h$ and the vertical counterpart by $\mathscr{A}(B)v$. (Note that only $\mathscr{A}_1(B)$ splits into $\mathscr{A}_1(B)h \oplus \mathscr{A}_1(B)v$, whereas $\mathscr{A}_0(B)h = \mathscr{A}_0(B)v = \mathscr{A}_0(B) = C^\infty(B)$ and for $p \geqslant 2$ $\mathscr{A}_p(B)$ contains also ''mixed'' forms, i.e., exterior products of horizontal and vertical forms.) Normally one would try to split a form into a sum $\phi = \Sigma_{i \in I} \phi_i$, where the ϕ_i are given by $\phi_i = \phi_i^1 \wedge \phi_i^2$ with $\phi_i^1 \in \mathscr{A}(B)h$ and $\phi_i^2 \in \mathscr{A}(B)v$.

Yet in our case such a splitting is impossible, since the gauge fields and the gauge potentials are Lie algebra valued differential forms: $\mathrm{A}^\alpha \in \mathscr{A}_1(U_\alpha, \mathfrak{g})$ and $\mathrm{F}^\alpha \in \mathscr{A}_2(U_\alpha, \mathfrak{g})$, where $\mathfrak{g}$ denotes the Lie algebra of the structure group G. In contrast, $\phi \in \mathscr{A}(F)$ — and thus also $\psi \in \mathscr{A}(B)$ — will be real or complex valued. Thus we need a generalization of the wedge product that combines $\mathfrak{g}$-valued forms with $(\mathfrak{g} \otimes \cdots \otimes \mathfrak{g})^*$-valued forms in order to produce real or complex valued forms. This is the task of the following definition.

Definition II.1: For $\chi_r^s \in \mathscr{A}_r(M, \mathrm{Hom}(\otimes^s \mathfrak{g}, V))$ *and* $\phi_p \in \mathscr{A}_p(M, \mathfrak{g})$, $p,r,s-1 \in \mathbb{N}_0$, *let* $d_{r+sp} \in \mathscr{D}_{r+sp}(M,V)$ *with*

$$d_{r+sp}(\mathscr{X}^1,\ldots,\mathscr{X}^{r+sp})(x):=[\chi_x(\mathscr{X}^1_x,\ldots,\mathscr{X}^r_x)]\circ[\phi_x(\mathscr{X}^{r+1}_x,\ldots,\mathscr{X}^{r+p}_x)$$

$$\otimes\cdots\otimes\phi_x(\mathscr{X}^{r+(s-1)p+1}_x,\ldots,\mathscr{X}^{r+sp}_x)]$$

for all $x\in M$ and define $\chi^s_r\bullet\phi_p:=A_{r+sp}(d_{r+sp})\in\mathscr{A}_{r+sp}(M,V)$ and $\chi^0_r\bullet\phi_p:=\chi^0_r$.

Roughly speaking, the bullet operator means the following: for any $x\in M$ and $\mathscr{X}^i\in\mathscr{D}^1(M)$, $\chi_x(\mathscr{X}^1_x,\ldots,\mathscr{X}^r_x)$ defines an element in $\mathrm{Hom}(\otimes^s\mathfrak{g},V)$. Thus we need s vectors in $\mathfrak{g}$ as input for this map. But again for any $x\in M$ and $\mathscr{Y}^i\in\mathscr{D}^1(M)$, $\phi_x(\mathscr{Y}^1_x,\ldots,\mathscr{Y}^p_x)$ defines such a vector in $\mathfrak{g}$. Altogether the combination of χ and s factors ϕ defines an element $d^{sq}_{r+sp}\in\mathscr{D}_{r+sp}(M,V)$. Using the alternation A_{r+sp}, we finally obtain a form in $\mathscr{A}_{r+sp}(M,V)$.

Note that this construction works with any finite dimensional vector space W instead of $\mathfrak{g}$, and even with differential forms $\phi^q_p\in\mathscr{A}_p(M,\mathrm{Hom}(\otimes^qX,W))$, where X is another finite dimensional vector space. In the latter case the construction produces a differential form $\chi^s_r\bullet\phi^q_p\in\mathscr{A}_{r+sp}(M,\mathrm{Hom}(\otimes^{sq}X,V))$. Yet we only need $\bullet$ in the way defined above, especially for $V=\mathbb{R},\mathbb{C}$ and $\chi^s_r\in\mathscr{A}_r(M,\mathrm{Sym}_s(\mathfrak{g},V))$, where $\mathrm{Sym}_s(\mathfrak{g},V)$ denotes the vector space of symmetric s-linear maps from $\mathfrak{g}^s$ to V, i.e., the image of the canonical symmetrization $\mathrm{Sym}:\mathrm{Hom}(\otimes^s\mathfrak{g},V)\to\mathrm{Hom}(\otimes^s\mathfrak{g},V)$.

For vectors $E_j\in\mathfrak{g}$, $j=1,\ldots,s$, let $E_1\otimes\cdots\otimes E_s$: $\mathrm{Hom}(\otimes^s\mathfrak{g},V)\to V$ denote the canonical (evaluation) morphism. For any form $\chi^s_r\in\mathscr{A}_r(M,\mathrm{Hom}(\otimes^s\mathfrak{g},V))$ define $\chi^{E_1,\ldots,E_s}_r\in\mathscr{A}_r(M,V)$ to be the push-out of χ^s_r under this morphism: $\chi^{E_1,\ldots,E_s}_r:=(E_1\otimes\cdots\otimes E_s)_\star\chi^s_r$ i.e., for all $x\in M$ and $\mathscr{X}^i\in\mathscr{D}^1(M)$, $i=1,\ldots,r$,

$$(\chi^{E_1,\ldots,E_s}_r)_x(\mathscr{X}^1_x,\ldots,\mathscr{X}^r_x):=(E_1\otimes\cdots\otimes E_s)\circ(\chi^s_r)_x(\mathscr{X}^1_x,\ldots,\mathscr{X}^r_x)$$

$$=[(\chi^s_r)_x(\mathscr{X}^1_x,\ldots,\mathscr{X}^r_x)](E_1\otimes\cdots\otimes E_s). \tag{2}$$

With this convention we obtain the following lemma:

Lemma II.2: Let $p,r,s-1\in\mathbb{N}_0$. If $\phi_p=\Sigma^m_{i=1}\phi^i\otimes E_i$ with $\phi^i\in\mathscr{A}_p(M)$ and $E_i\in\mathfrak{g}$, then

$$\chi^s_r\bullet\phi_p=\sum_{i_1,\ldots,i_s=1}^{m}\chi^{E_{i_1},\ldots,E_{i_s}}_r\wedge\phi^{i_1}\wedge\cdots\wedge\phi^{i_s}.$$

Proof: Take $x\in M$ and $\mathscr{X}^i\in\mathscr{D}^1(M)$. Then for d_{r+sp} in Definition II we obtain

$$\begin{aligned}
&(d_{r+sp})_x(\mathscr{X}^1_x,\ldots,\mathscr{X}^{r+sp}_x):\\
&\quad=[\chi_x(\mathscr{X}^1_x,\ldots,\mathscr{X}^r_x)](\phi_x(\mathscr{X}^{r+1}_x,\ldots,\mathscr{X}^{r+p}_x)\\
&\qquad\otimes\cdots\otimes\phi_x(\mathscr{X}^{r+(s-1)p+1}_x,\ldots,\mathscr{X}^{r+sp}_x))\\
&\quad=\sum_{i_1,\ldots,i_s=1}^{m}[\chi_x(\mathscr{X}^1_x,\ldots,\mathscr{X}^r_x)]\Big((E_{i_1}\otimes\cdots\otimes E_{i_s})\\
&\qquad\cdot\prod_{j=1}^{s}\phi^{i_j}_x(\mathscr{X}^{r+(j-1)p+1}_x,\ldots,\mathscr{X}^{r+jp}_x)\Big)\\
&\quad=\sum_{i_1,\ldots,i_s=1}^{m}[(\chi^{E_{i_1},\ldots,E_{i_s}}_r)_x(\mathscr{X}^1_x,\ldots,\mathscr{X}^r_x)]\\
&\qquad\cdot\prod_{j=1}^{s}\phi^{i_j}_x(\mathscr{X}^{r+(j-1)p+1}_x,\ldots,\mathscr{X}^{r+jp}_x).
\end{aligned}$$

Thus if S_{r+sp} denotes the group of permutations of $r+sp$ elements and $(-1)^\rho$ means the signum of $\rho \in S_{r+sp}$, we get

$$
\begin{aligned}
(\chi_r^s \bullet \phi_p)_x(\mathscr{X}_x^1, \ldots, \mathscr{X}_x^{r+sp}) &:= [A_{r+sp}(d_{r+sp})]_x(\mathscr{X}_x^1, \ldots, \mathscr{X}_x^{r+sp}) \\
&= \sum_{\rho \in S_{r+sp}} \frac{(-1)^\rho}{(r+sp)!} \sum_{i_1, \ldots, i_s=1}^{m} [(\chi_r^{E_{i_1}, \ldots, E_{i_s}})_x(\mathscr{X}_x^{\rho(1)}, \ldots, \mathscr{X}_x^{\rho(r)})] \\
&\quad \cdot \prod_{j=1}^{s} \phi_x^{i_j}(\mathscr{X}_x^{\rho(r+(j-1)p+1)}, \ldots, \mathscr{X}_x^{\rho(r+jp)}) \\
&= \sum_{i_1, \ldots, i_s=1}^{m} [A_{r+sp}(\chi_r^{E_{i_1}, \ldots, E_{i_s}} \otimes \phi^{i_1} \otimes \cdots \otimes \phi^{i_s})]_x(\mathscr{X}_x^1, \ldots, \mathscr{X}_x^{r+sp}) \\
&= \left(\sum_{i_1, \ldots, i_s=1}^{m} \chi_r^{E_{i_1}, \ldots, E_{i_s}} \wedge \phi^{i_1} \wedge \cdots \wedge \phi^{i_s} \right)_x (\mathscr{X}_x^1, \ldots, \mathscr{X}_x^{r+sp}),
\end{aligned}
$$

where the last identity follows immediately from the definition of the exterior product $\wedge$. □

Lemma II.2 proves that if p is even, then only the symmetric part of χ_r^s counts: $\chi_r^s \bullet \phi_p = (\mathrm{Sym}_\star \chi_r^s) \bullet \phi_p$. Thus we may concentrate on $\chi_r^s \in \mathscr{A}_r(M, \mathrm{Sym}_s(\mathfrak{g}, V))$, in order to construct forms $\chi_r^s \bullet \mathrm{F}$ with the 2-forms F^α.

Let $\mathrm{Ad}^\star : G \times \mathrm{Hom}(\otimes^s \mathfrak{g}, V) \to \mathrm{Hom}(\otimes^s \mathfrak{g}, V)$ denote the right representation induced by the adjoint action: for $K \in \mathrm{Hom}(\otimes^s \mathfrak{g}, V)$, $g \in G$ and $E_i \in \mathfrak{g}$, it is defined by

$$
(\mathrm{Ad}(g)^\star K)(E_1, \ldots, E_s) := K(\mathrm{Ad}(g)E_1, \ldots, \mathrm{Ad}(g)E_s).
$$

A differential form $\chi_n^s \in \mathscr{A}_n(F, \mathrm{Hom}(\otimes^s \mathfrak{g}, V))$ is called (G-)equivariant if $L_g^\star \chi_n^s = (\mathrm{Ad}(g^{-1})^\star)_\star \chi_n^s$. (For $s=0$ this obviously means that χ_n^0 is invariant under L.) On the other hand a differential form $\phi \in \mathscr{A}(F, \mathfrak{g})$ is called (G-)equivariant if $L_g^\star \phi = \mathrm{Ad}(g)_\star \phi$, e.g., $\omega^\Gamma \in \mathscr{A}_1(P, \mathfrak{g})$ and $\Omega^\Gamma \in \mathscr{A}_2(P, \mathfrak{g})$ are equivariant, since $R_g^\star \omega^\Gamma = \mathrm{Ad}(g^{-1})_\star \omega^\Gamma$, resp., $R_g^\star \Omega^\Gamma = \mathrm{Ad}(g^{-1})_\star \Omega^\Gamma$. We denote the sets of these equivariant differential forms by $\mathscr{A}(F, \mathrm{Hom}(\otimes^s \mathfrak{g}, V))_{\mathrm{equiv}}$, resp., $\mathscr{A}(F, \mathfrak{g})_{\mathrm{equiv}}$. They are modules of the exterior algebra $\mathscr{A}(P)_{\mathrm{inv}}$ of invariant differential forms.

Lemma II.3: If $\chi_n^s \in \mathscr{A}_n(F, \mathrm{Hom}(\otimes^s \mathfrak{g}, V))_{\mathrm{equiv}}$ and $\phi_p \in \mathscr{A}_p(F, \mathfrak{g})_{\mathrm{equiv}}$, then $\chi_n^s \bullet \phi_p$ is invariant.

For our purposes we also need further operators on differential forms that transform V-valued forms into $\mathrm{Alt}_i(\mathfrak{g}, V)$-valued forms. Recall that for any Lie group action $L : G \times F \to F$, every $X \in \mathfrak{g}$ canonically induces a vector field $\mathscr{L}_X \in \mathscr{D}^1(F)$ by $(\mathscr{L}_X)_f := (dL^f)_e(X)$, where $(dL^f)_e : T_e(G) \to T_f(F)$ denotes the differential of the map L^f. The operator $-\mathscr{L} : \mathfrak{g} \to \mathscr{D}^1(F)$ is a Lie algebra homomorphism, in fact we have

$$
[\mathscr{L}_X, \mathscr{L}_Y] = \mathscr{L}_{[Y,X]} = -\mathscr{L}_{[X,Y]} \text{ for all } X, Y \in \mathfrak{g}, \tag{3}
$$

$$
(L_g)_\star \mathscr{L}_X = \mathscr{L}_{\mathrm{Ad}(g)X} \text{ for all } g \in G, X \in \mathfrak{g}. \tag{4}
$$

Analogously for the right action R on a principal bundle, $\mathscr{R} : \mathfrak{g} \to \mathscr{D}^1(P)$ is a Lie algebra homomorphism, and the $\mathscr{R}_X$ are the so-called fundamental vector fields on P. Now we may define:

Definition II.4: Let L be a Lie group action of G on F and $\omega_n \in \mathscr{A}_n(F, V)$. We define differential forms $L_\bullet^i \omega_n \in \mathscr{A}_{n-i}(F, \mathrm{Alt}_i(\mathfrak{g}, V))$, $i = 0, \ldots, n$, for all $\mathscr{X}^j \in \mathscr{D}^1(F)$, $E_k \in \mathfrak{g}$ and $f \in F$ by

$$[(L^i_\bullet \omega_n)(\mathscr{X}^1,\ldots,\mathscr{X}^{n-i})(f)](E_1,\ldots,E_i) := \frac{n!}{(n-i)!}\,\omega_n(\mathscr{L}^1,\ldots,\mathscr{L}^i,\mathscr{X}^1,\ldots,\mathscr{X}^{n-i})(f) \in V,$$

where $\mathscr{L}^i := \mathscr{L}_{E_i}$. *For* $i>n$ *we put* $L^i_\bullet \omega_n = 0$. *In the case* $i=1$ *we also define for* $\chi^s_n \in \mathscr{A}_n(F,\mathrm{Hom}(\otimes^s \mathfrak{g},V))$

$$L^\vee_\bullet \chi^s_n := \mathrm{Sym}_\star(L_\bullet \chi^s_n) \in \mathscr{A}_{n-1}(F,\mathrm{Sym}_{s+1}(\mathfrak{g},V)).$$

(Obviously $\mathrm{Sym}_\star(L^i_\bullet \chi^s_n)=0$ for $i>1$.) Now if $\imath_{\mathscr{X}}:\mathscr{A}_n(M,V)\to\mathscr{A}_{n-1}(M,V)$ denotes the interior product with respect to $\mathscr{X}\in\mathscr{D}^1(M)$, which is given by

$$(\imath_{\mathscr{X}}\omega_n)(\mathscr{Y}^1,\ldots,\mathscr{Y}^{n-1}) := n\,\omega_n(\mathscr{X},\mathscr{Y}^1,\ldots,\mathscr{Y}^{n-1}),$$

then we have the following relation with regard to our convention (2):

$$(L^i_\bullet \omega_n)^{E_1,\ldots,E_i}_{n-i} = (\imath_{\mathscr{L}^i}\circ\cdots\circ\imath_{\mathscr{L}^1})\,\omega_n .$$

The following lemma is quite immediate by (4):

Lemma II.5: For all $i\leqslant n$, *the operator* $L^i_\bullet:\mathscr{A}_n(F,V)\to\mathscr{A}_{n-i}(F,\mathrm{Alt}_i(\mathfrak{g},V))$ *is* $C^\infty(F)$*-linear. For* $\omega_n\in\mathscr{A}_n(F,V)$ *and* $\chi^s_n\in\mathscr{A}_n(F,\mathrm{Hom}(\otimes^s\mathfrak{g},V))_{\mathrm{equiv}}$ *we have*

$$L^0_\bullet\omega_n=\omega_n,\quad (L^n_\bullet\omega_n)(f)=n!\,[(L^f)^\star\omega_n]_e \text{ for all } f\in F, \tag{5}$$

$$L^\star_g(L^i_\bullet\omega_n)=(\mathrm{Ad}(g^{-1})^\star)_\star[L^i_\bullet(L^\star_g\omega_n)],\quad \text{thus} \tag{6}$$

$$L^\star_g(L^i_\bullet\chi^s_n)=(\mathrm{Ad}(g^{-1})^\star)_\star(L^i_\bullet\chi^s_n) \text{ and } \quad L^\star_g(L^\vee_\bullet\chi^s_n)=(\mathrm{Ad}(g^{-1})^\star)_\star(L^\vee_\bullet\chi^s_n). \tag{7}$$

Equation (7) yields that $L^i_\bullet\omega_n$ and $L^\vee_\bullet\omega_n$ are G-equivariant if ω_n is invariant under L.

III. EXTENDING FORMS TO THE BUNDLE

If P is a principal bundle with free right Lie group action R, and L is a left effective Lie group action of G on a manifold F, then the associated fiber bundle with fiber F that comes along with L is the quotient manifold $B(M,F,G)=P\times_G F$ of the direct product $P\times F$ under the free right action $\widetilde{R}:(P\times F)\times G\to P\times F$, which is defined by

$$\widetilde{R}_g(p,f) := (R_g(p),L_{g^{-1}}(f)) \text{ for all } p\in P, f\in F.$$

In fact, $P\times F$ is a principal bundle over B with projection $\widetilde{\pi}$ and fiber G. Every connection Γ on a principal bundle, given by a connection 1-form ω^Γ, canonically induces a connection $\widetilde{\Gamma}$ on $(P\times F)(B,G)$ by $\widetilde{\omega}^{\widetilde{\Gamma}}=\mathrm{pr}_P^\star\omega^\Gamma$. In turn, $\widetilde{\Gamma}$ defines horizontal lifts of vector fields $\widetilde{\mathbb{L}}:\mathscr{D}^1(B)\to\widetilde{h}\mathscr{D}^1(P\times F)_{\mathrm{inv}}$. $\widetilde{\mathbb{L}}$ is a $C^\infty(B)$-module isomorphism with inverse morphism $d\widetilde{\pi}$. If h^{nat} and v^{nat} denote the natural projections of vector fields on the direct product $P\times F$, then we also have projections h, v on $\mathscr{D}^1(B)$

$$h=d\widetilde{\pi}h^{\mathrm{nat}}\widetilde{\mathbb{L}},\quad v=d\widetilde{\pi}v^{\mathrm{nat}}\widetilde{\mathbb{L}},$$

so

$$\mathscr{D}^1(B)=h\mathscr{D}^1(B)\oplus v\mathscr{D}^1(B).$$

This is the induced connection on the associated bundle B, as mentioned above. Let $\mathscr{X}^i \in \mathscr{D}^1(B)$, then for any $\omega_n \in \mathscr{A}_n(B,V)$, $n>0$, the horizontal and vertical projections $\omega_n h \in \mathscr{A}_n(B,V)h$, resp., $\omega_n v \in \mathscr{A}_n(B,V)v$, are given by

$$\omega_n h(\mathscr{X}^1, \ldots, \mathscr{X}^n) := \omega_n(h\mathscr{X}^1, \ldots, h\mathscr{X}^n),$$

$$\omega_n v(\mathscr{X}^1, \ldots, \mathscr{X}^n) := \omega_n(v\mathscr{X}^1, \ldots, v\mathscr{X}^n).$$

Obviously these projections commute with $\bullet$, i.e.,

$$(\chi_n^s \bullet \phi_p)h = \chi_n^s h \bullet \phi_p h, \quad (\chi_n^s \bullet \phi_p)v = \chi_n^s v \bullet \phi_p v.$$

Recall that, by definition, ω^Γ is a vertical form. The exterior covariant derivative of forms on P is defined by $d^\Gamma\phi := (d\phi)h$. Thus $\Omega^\Gamma = d^\Gamma\omega^\Gamma = (d\omega^\Gamma)h$ is a horizontal form.

If ϕ is a differential form on F, then $\mathrm{pr}_F^\star\phi$ is a form on $P\times F$, and if $\mathscr{Y}^i$ are vector fields on B, then $(\mathrm{pr}_F^\star\phi)(\ldots, \widetilde{\mathbb{L}}\mathscr{Y}^i, \ldots)$ is a function on $P\times F$. Now if ϕ is invariant under L, one can prove that this function is invariant under $\widetilde{R}$ and thus defines a map on B. But this defines a form on B. In fact, we have the following proposition:[7]

Proposition III.1: $\phi \in \mathscr{A}(F,V)$ defines a vertical V-valued form ϕv on $B(M,F,G)$ iff ϕ is invariant under all $L_g^\star$ For such a ϕ and all $\mathscr{Y}^i \in \mathscr{D}^1(B)$ then there exists $f \in C^\infty(B,V)$ with

$$(\mathrm{pr}_F^\star\phi)(\ldots, \widetilde{\mathbb{L}}\mathscr{Y}^i, \ldots) = f \circ \widetilde{\pi}.$$

If h^α and v^α denote the local projections of fields and forms induced by Γ, then this generated form ϕv locally is given by

$$\phi v\big|_{\pi^{-1}(U_\alpha)} = (\pi_\alpha^\star\phi)v^\alpha. \tag{8}$$

Proposition III.1 is a special case of the following theorem:

Theorem III.2: *If $\chi_n^s \in \mathscr{A}_n(F, \mathrm{Hom}(\otimes^s\mathfrak{g}, V))_{\mathrm{equiv}}$ and $\phi \in \mathscr{A}_p(P,\mathfrak{g})_{\mathrm{equiv}}$, $p \in \mathbb{N}_0$, then $(\mathrm{pr}_F^\star\chi_n^s)\bullet(\mathrm{pr}_P^\star\phi) \in \mathscr{A}_{n+sp}(P\times F, V)$ defines a V-valued form on B: for all vector fields $\mathscr{Y}^i \in \mathscr{D}^1(B)$ then there exists $f \in C^\infty(B,V)$ such that*

$$[(\mathrm{pr}_F^\star\chi_n^s)\bullet(\mathrm{pr}_P^\star\phi)](\ldots, \widetilde{\mathbb{L}}\mathscr{Y}^i, \ldots)$$
$$= [(\mathrm{pr}_F^\star\chi_n^s)\bullet(\mathrm{pr}_P^\star\phi h)](\ldots, \widetilde{\mathbb{L}}\mathscr{Y}^i, \ldots) = f \circ \widetilde{\pi}.$$

$(\mathrm{pr}_F^\star\chi)$ defines the vertical and $(\mathrm{pr}_P^\star\phi)$ defines the horizontal part of the form.

The proof of Theorem III.2 relies on Lemma II.3: under the assumed conditions one shows that $(\mathrm{pr}_F^\star\chi_n^s)$ and $(\mathrm{pr}_P^\star\phi)$ are equivariant with respect to $\widetilde{R}$, and thus $(\mathrm{pr}_F^\star\chi_n^s)\bullet(\mathrm{pr}_P^\star\phi)$ is invariant by Lemma II.3.

Natural candidates for $\phi \in \mathscr{A}_p(P,\mathfrak{g})_{\mathrm{equiv}}$ are ω^Γ and Ω^Γ. Nevertheless, since ω^Γ is vertical, Theorem III.2 yields that the generated form on B is zero. For Ω^Γ, the generated form is locally given by

$$[(\pi_\alpha^\star\chi_n^s)v^\alpha]\bullet(\pi^\star\mathrm{F}^\alpha) \in \mathscr{A}_{n+2s}(\pi^{-1}(U_\alpha), V).$$

For that reason, we will denote this generated form by $(\chi_n^s v)\bullet\mathrm{F}$ or simply $\chi v\bullet\mathrm{F}$.

Finally we need to compute the exterior derivative of these generated differential forms. We thus cite the following theorem from Ref. 8:

Theorem III.3: *Let* Γ *be a connection on a principal fiber bundle* $P(M,G)$ *and let* $B(M,F,G)$ *be an associated bundle,* V *any vector space,* $\chi_n^s \in \mathscr{A}_n(F)\otimes \mathrm{Hom}(\otimes^s \mathfrak{g},V)$ *be* G*-equivariant and* $\phi_n \in \mathscr{A}_n(F)\otimes V$ *be invariant under* G*. Then*

$$\begin{aligned} d(\chi_n^s v\bullet \mathrm{F}) &= [(d\chi_n^s)v]_{n+1}^s \bullet \mathrm{F} + [(L_\bullet \chi_n^s)v]_{n-1}^{s+1}\bullet \mathrm{F}, \\ &= [(d\chi_n^s)v]_{n+1}^s \bullet \mathrm{F} + [(L_\bullet^\vee \chi_n^s)v]_{n-1}^{s+1}\bullet \mathrm{F}, \end{aligned}$$

$$d(\phi_n v) = (d\phi_n)v + [(L_\bullet \phi_n)v]_{n-1}^1 \bullet \mathrm{F}.$$

Note that the second identity follows from the already mentioned fact that, in combination with F, only the symmetric part of $(L_\bullet \chi_n^s)v$ counts, cf. Lemma II.2. The last identity is a simple corollary to the first one, since for $s=0$, G-equivariance means invariance, $\mathrm{Hom}(\otimes^0 \mathfrak{g},V)=V$, and $\chi_r^0\bullet \mathrm{F}=\chi_r^0$ by definition.

Theorem III.3 proves that the diagram in Section I does not commute in general. Only for 0-forms ϕ, i.e., functions $\phi \in C^\infty(F,V)$, we know that $L_\bullet \phi = 0$.

IV. Γ-ADAPTED AND *G*-TRANSGRESSIVE DIFFERENTIAL FORMS

Now we are prepared for the notion of Γ-adapted differential forms on a bundle:

Definition IV.1: Let Γ *be a connection on* $P(M,G)$ *and* $B=P\times_G F$*. A differential form* $\phi^A \in \mathscr{A}(B,V)$ *is called* Γ-adapted if $\chi^i \in \mathscr{A}_{n(i)}(F,\mathrm{Hom}(\otimes^{s(i)}\mathfrak{g},V))_{\mathrm{equiv}}$ *are given such that*

$$\phi^A = \sum_i \chi^i v\bullet \mathrm{F}.$$

It is this splitting into a sum of $\chi^i v\bullet \mathrm{F}$ that we have in mind when we say that a form can be presented in such a way that all horizontal terms are given by the gauge fields F^α.

We will be concerned with the question whether we can find such a Γ-adapted representative for a cohomology class in $H^*(B)$ that is generated by a 0-transgressive invariant form $\phi \in \mathscr{A}(F)$. For the physical applications in mind, this concentration on invariant forms is no real restriction. Recall from the general theory of fiber bundles that, for every bundle over a paracompact manifold M with a connected structure group G, this Lie group G is reducible to its maximal compact connected subgroup K, i.e., G may be *a priori* chosen to be compact. For example, if we are dealing with electromagnetic interactions, we have $G=\mathrm{U}_1$; if we are dealing with electroweak interactions within the Glashow, Salam and Weinberg theory, then $G=\mathrm{SU}_2\times \mathrm{U}_1$; and for strong interactions covered by quantum chromodynamics (QCD), $G=\mathrm{SU}_3$. In general, for Yang-Mills theories we have $G=\mathrm{U}_n\times \mathrm{U}_n$ or a subgroup $H<G$.

For any compact Lie group we have the normalized Haar measure μ, and we can project any form $\phi \in \mathscr{A}(F,V)$ onto an invariant form ϕ_{inv} defined by

$$\phi_{\mathrm{inv}} := \int_G L_g^\star \phi \, d\mu(g). \tag{9}$$

(Analogous projections onto equivariant forms also exist.) On the other hand, if G is connected, then all maps L_g are homotopic to the identity map $L_e=\mathrm{id}_F$, which yields that $[L_g^\star]=\mathrm{id}_{H^*(F)}$. Thus, if we denote the cohomology of the invariant closed forms on F modulo the invariant exact forms by $H^*_{\mathrm{inv}}(F)$, we have the following proposition:

Proposition IV.2: If G *is a compact connected Lie group acting on* F*, then* $H^*(F)\cong H^*_{\mathrm{inv}}(F)$*, and the isomorphims are induced by the above projection onto invariant forms, resp., the injection* $i:\mathscr{A}(F)_{\mathrm{inv}}\to \mathscr{A}(F)$.

$\mathscr{A}(F,V)_{\mathrm{inv}}$ contains an important subset, whose elements we will call G-transgressive forms. Let $[r]:=\max_{z\in\mathbb{Z}}\{z\leqslant r\}$ for all $r\in\mathbb{R}$. Then their definition is as follows:

Definition IV.3: Let $L:G\times F\to F$ be a left Lie group action. An invariant closed differential form $\phi_n\in\mathscr{A}_n(F,V)_{\mathrm{inv}}$ will be called G-transgressive if equivariant differential forms $\chi^i\in\mathscr{A}_{n-2i}(F,\mathrm{Sym}_i(\mathfrak{g},V))_{\mathrm{equiv}}$ exist for $0\leqslant i\leqslant[n/2]$ with

$$\chi^0=\phi_n,\ -L^{\vee}_{\bullet}\chi^i=d\chi^{i+1}\ \text{for all}\ \ 0\leqslant i\leqslant[n/2]-1\ \text{and}\ \ L^{\vee}_{\bullet}\chi^{[n/2]}=0. \tag{10}$$

Denote the set of all G-transgressive forms on F by $\mathscr{A}(F,V)_{G-\mathrm{trans}}$.

Note IV.4: The reader who is familiar with equivariant cohomology will recognize that G-transgressive forms define equivariant cohomology classes for the given G-manifold F, cf. Atiyah and Bott[9] or Mathai and Quillen[10] and Section VIII.

Recall the definition of the exterior product of vector valued differential forms from (1). For $K_r\in\mathrm{Sym}_r(\mathfrak{g},\mathbb{R})$ and $K_s\in\mathrm{Sym}_s(\mathfrak{g},\mathbb{R})$ we have the symmetric product $K_r\vee K_s:=\mathrm{Sym}(K_r\otimes K_s)$. For any bilinear $\varphi:V\times V\to V$ this extends to a bilinear mapping on the (infinite dimensional) vector space $\mathrm{Sym}(\mathfrak{g},V):=\oplus_{s=0}^{\infty}\mathrm{Sym}_s(\mathfrak{g},V)$ analogously to (1), which we also denote by $\vee$. This in turn defines the exterior product $\wedge_{\vee}$. With respect to $\wedge_{\vee}$, the set $\mathscr{A}(F)\otimes\mathrm{Sym}(\mathfrak{g},V)$ is an exterior algebra with subalgebra $\mathscr{A}(F)_{\mathrm{equiv}}\otimes\mathrm{Sym}(\mathfrak{g},V)$.

Lemma IV.5: d and $L^{\vee}_{\bullet}$ are skew-derivations of degree 1, *resp.* -1, *of the algebras $\mathscr{A}(P)\otimes\mathrm{Sym}(\mathfrak{g},V)$ and $\mathscr{A}(P)_{\mathrm{equiv}}\otimes\mathrm{Sym}(\mathfrak{g},V)$. For all $\alpha_n\in\mathscr{A}_n(P)\otimes\mathrm{Sym}(\mathfrak{g},V)$ and $\omega\in\mathscr{A}(P)\otimes\mathrm{Sym}(\mathfrak{g},V)$,*

$$d(\alpha_n\wedge_{\vee}\omega)=(d\alpha_n)\wedge_{\vee}\omega+(-1)^n\alpha_n\wedge_{\vee}(d\omega),$$

$$L^{\vee}_{\bullet}(\alpha_n\wedge_{\vee}\omega)=(L^{\vee}_{\bullet}\alpha_n)\wedge_{\vee}\omega+(-1)^n\alpha_n\wedge_{\vee}(L^{\vee}_{\bullet}\omega).$$

Lemma IV.5 is the main ingredient in the proof of the following proposition:

*Proposition IV.6: $\mathscr{A}(F,V)_{G-\mathrm{trans}}$ is a $\mathbb{R}$-subalgebra of $\mathscr{A}(F,V)$, whenever a bilinear map $\varphi:V\times V\to V$ and thus a wedge product $\wedge_{\varphi}$ is defined. If ϕ_m and ψ_n are G-transgressive and $\chi^i\in\mathscr{A}_{m-2i}(F,\mathrm{Sym}_i(\mathfrak{g},V))_{\mathrm{equiv}}$, resp. $\xi^i\in\mathscr{A}_{n-2j}(F,\mathrm{Sym}_j(\mathfrak{g},V))_{\mathrm{equiv}}$, are the differential forms given by (*10) *for ϕ_m, resp. ψ_n, then*

$$\zeta^k:=\sum_{i+j=k}\chi^i\wedge_{\vee}\xi^j\in\mathscr{A}_{m+n-2k}(F,\mathrm{Sym}_k(\mathfrak{g},V))_{\mathrm{equiv}}$$

for $0\leqslant k\leqslant[m/2]+[n/2]$ (and $\zeta^{[(m+n)/2]}:=0$ if m and n are odd) are the corresponding forms for $\phi_m\wedge_{\vee}\psi_n$.

Proof: Obviously $\mathscr{A}(F,V)_{G-\mathrm{trans}}$ is a $\mathbb{R}$-subspace of $\mathscr{A}(F,V)$. Hence we only have to check if the ζ^k, for $0\leqslant k\leqslant[(m+n)/2]$, obey the identities (10) for $\phi_m\wedge_{\vee}\psi_n=\phi_m\wedge_{\varphi}\psi_n\in\mathscr{A}_{m+n}(F,V)_{\mathrm{inv}}$. Obviously $\phi_m\wedge_{\vee}\psi_n$ is closed and $\zeta^0=\chi^0\wedge_{\vee}\xi^0=\phi_m\wedge_{\vee}\psi_n$. By definition of $\wedge_{\vee}$, the differential forms ζ^k are elements of $\mathscr{A}_{m+n-2k}(F,\mathrm{Sym}_k(\mathfrak{g},V))$ and

$$L_g^{\star}\zeta^k=\sum_{i+j=k}L_g^{\star}\chi^i\wedge_{\vee}L_g^{\star}\xi^j=\sum_{i+j=k}(\mathrm{Ad}(g^{-1})^{\star})_{\star}\chi^i\wedge_{\vee}(\mathrm{Ad}(g^{-1})^{\star})_{\star}\xi^j=(\mathrm{Ad}(g^{-1})^{\star})_{\star}\zeta^k,$$

whence all ζ^k are G-equivariant. Next for $0\leqslant k\leqslant[m/2]+[n/2]-1$, we obtain from Lemma IV.5, using $d\chi^0=d\xi^0=0$,

$$
\begin{aligned}
d\zeta^{k+1} &= \sum_{i+j=k+1} d(\chi^i \wedge_\vee \xi^j) \\
&= \sum_{i+j=k+1} [d\chi^i \wedge_\vee \xi^j + (-1)^{m-2i} \chi^i \wedge_\vee d\xi^j] \\
&= d\chi^0 \wedge_\vee \xi^{k+1} + \sum_{i+j=k} [d\chi^{i+1} \wedge_\vee \xi^j + (-1)^m \chi^i \wedge_\vee d\xi^{j+1}] \\
&\quad + (-1)^m \chi^{k+1} \wedge_\vee d\xi^0 \\
&= -\sum_{i+j=k} [L_\bullet^\vee \chi^i \wedge_\vee \xi^j + (-1)^m \chi^i \wedge_\vee L_\bullet^\vee \xi^j] \\
&= -\sum_{i+j=k} L_\bullet^\vee (\chi^i \wedge_\vee \xi^j) = -L_\bullet^\vee \zeta^k.
\end{aligned}
$$

Analogously, since $L_\bullet^\vee \chi^{[m/2]} = L_\bullet^\vee \xi^{[n/2]} = 0$,

$$
\begin{aligned}
L_\bullet^\vee \zeta^{[m/2]+[n/2]} &= \sum_{i+j=[m/2]+[n/2]} L_\bullet^\vee (\chi^i \wedge_\vee \xi^j) \\
&= L_\bullet^\vee \chi^{[m/2]} \wedge_\vee \xi^{[n/2]} + (-1)^m \chi^{[m/2]} \wedge_\vee L_\bullet^\vee \xi^{[n/2]} = 0.
\end{aligned}
$$

But $[m/2]+[n/2]=[(m+n)/2]$, except if m and n are both odd, where $[m/2]+[n/2]=[(m+n)/2]-1$. In that case, we have just shown that $-L_\bullet^\vee \zeta^{[(m+n)/2]-1}=0$, whence we may choose $\zeta^{[(m+n)/2]} := 0$. This completes the proof that $\phi_m \wedge_\vee \psi_n$ is G-transgressive. □

Now we are ready for the following theorem:

Theorem IV.7: *Let Γ be a connection on a principal bundle $P(M,G)$ and $B=P\times_G F$ an associated bundle with left Lie group action $L: G\times F \to F$. Let V denote any vector space. If the form $\phi_n \in \mathscr{A}_n(F,V)_{\text{inv}}$ is G-transgressive and the equivariant forms $\chi^i_{n-2i} \in \mathscr{A}_{n-2i}(F, \text{Sym}_i(\mathfrak{g},V))_{\text{equiv}}$ are given by (*10), then

$$
\phi_n^A := \sum_{i=0}^{[n/2]} (\chi^i_{n-2i} v) \bullet \mathrm{F} \in \mathscr{A}_n(B,V)
$$

is closed and Γ-adapted. Its restriction to the fibers is ϕ_n, i.e., for any $\alpha \in A$ and all $x \in U_\alpha$, we have $i^\star_{\alpha,x} \phi_n^A = \phi_n$.

Proof: ϕ_n^A is obviously adapted to Γ. Furthermore Theorem III.3 yields

$$
\begin{aligned}
d\phi_n^A &= \sum_{i=0}^{[n/2]} (d\chi^i_{n-2i}) v \bullet \mathrm{F} + (L_\bullet^\vee \chi^i_{n-2i}) v \bullet \mathrm{F} \\
&= (d\phi_n) v + \sum_{i=0}^{[n/2]-1} (d\chi^{i+1}_{n-2i-2} + L_\bullet^\vee \chi^i_{n-2i}) v \bullet \mathrm{F} + (L_\bullet^\vee \chi^{[n/2]}_{n-2[n/2]}) v \bullet \mathrm{F} = 0,
\end{aligned}
$$

since ϕ_n is G-transgressive. Finally, since $i^\star_{\alpha,x} \pi^\star \mathrm{F}^\alpha = 0$ for all $x \in U_\alpha$, we obtain $i^\star_{\alpha,x} \phi_n^A = i^\star_{\alpha,x}(\chi^0 v) = i^\star_{\alpha,x}(\phi_n v)$. But naturally $i^\star_{\alpha,x}(\phi_n v) = \phi_n$. □

Note that the property of being G-transgressive only depends on L and F. Thus G-transgressive forms define de Rham cohomology classes on all fiber bundles where L is the

action of the structure group G on the fiber F. In particular, this condition is independent of the base M and of the question whether the bundle is trivial or not. Indeed we have the following:

Corollary IV.8: Let $L:G\times F\to F$ be a left Lie group action. If a form $\phi_n \in \mathscr{A}_n(F)$ is G-transgressive, it is 0-transgressive for any bundle $B(M,F,G)$ that comes along with L. Thus ϕ_n defines a unique cohomology class $[\phi_n^A] \in H^n(B)$ with $[i_{\alpha,x}^\star][\phi_n^A]=[\phi_n] \in H^n(F)$, independently of the paracompact base M and the transition functions $g_{\alpha\beta}$.

Proof: By the existence theorem for connections, every principal bundle $P(M,G)$ over a paracompact manifold M admits a connection Γ (Ref. 5, p. 67). Thus ϕ_n^A is well-defined and Theorem IV applies. □

Corollary IV.9: If Γ and Γ' are two connections on $P(M,G)$ and $\phi\in\mathscr{A}(F)$ is G-transgressive, then there exists $\psi \in \mathscr{A}(B)$ such that the forms ϕ^A and $\phi^{A'}$ obey:

$$\phi^A-\phi^{A'}=d\psi \quad \text{with} \quad d(i_{\alpha,x}^\star\psi)=0.$$

Let us derive the analogue to Theorem IV.7 for 1-dimensional Abelian Lie groups G like the electromagnetic structure group $G_{\text{em}}\cong \mathrm{U}_1\cong \mathbb{S}^1$. According to the following lemma, we may reformulate the notion of G-transgressive forms in that case:

Lemma IV.10: If G is Abelian with $\mathfrak{g}=E\mathbb{R}$, then $\phi_n\in\mathscr{A}(F,V)_{\text{inv}}$ is G-transgressive iff $\chi^i \in \mathscr{A}_{n-2i}(F,V)_{\text{inv}}$ exist for $0\leqslant i\leqslant[n/2]$ such that with $\nu^i:=\imath_{\mathscr{Z}_E}\chi^i$ the following equations hold:

$$\chi^0=\phi_n,\ -\nu^i=d\chi^{i+1} \text{ for all } \ 0\leqslant i\leqslant[n/2]-1 \text{ and} \nu^{[n/2]}=0. \tag{11}$$

Also since $\mathfrak{g}\cong\mathbb{R}$, we can replace $\bullet$ by the exterior product and as a corollary to Theorem IV.7 and Lemma II.2 we obtain the following.

Theorem IV.11: *Let Γ be a connection on a principal bundle $P(M,G)$, where G is Abelian with $\mathfrak{g}=E\mathbb{R}$, and let $B=P\times_G F$ be any associated bundle with left Lie group action $L:G\times F\to F$. If $\phi_n \in \mathscr{A}_n(F,V)_{\text{inv}}$ is G-transgressive and $\chi^i_{n-2i} \in \mathscr{A}_{n-2i}(F,V)_{\text{inv}}$ are given by (11), then with $\widetilde{\mathrm{F}}:=1/E\ \pi^\star\mathrm{F} \in \mathscr{A}_2(B)$,*

$$\phi_n^A=\sum_{i=0}^{[n/2]}(\chi^i_{n-2i}v)\underbrace{\widetilde{\mathrm{F}}\wedge\cdots\wedge\widetilde{\mathrm{F}}}_{i}$$

$$=\sum_{i=0}^{[n/2]}\underbrace{\widetilde{\mathrm{F}}\text{-}\wedge\cdots\wedge\widetilde{\mathrm{F}}}_{i}\wedge(\chi^i_{n-2i}v)\in\mathscr{A}_n(B,V)$$

is closed and Γ-adapted. Its restriction to the fibers is ϕ_n, i.e., for any $x \in U_\alpha$, $i_{\alpha,x}^\star\phi_n^A=\phi_n$.

Finally, in order to evaluate Theorem IV.11, we note that for any form $\phi\in\mathscr{A}(F,V)$, the vertical projections (8) are given by

$$\phi v|_{\pi^{-1}(U_\alpha)}=(\pi_\alpha^\star\phi)v^\alpha=\pi_\alpha^\star\phi+\widetilde{\mathrm{A}}^\alpha\wedge\pi_\alpha^\star(\imath_{\mathscr{Z}_E}\phi) \tag{12}$$

with $\widetilde{\mathrm{A}}^\alpha:=1/E\ \pi^\star\mathrm{A}^\alpha$.[7] Hence, since $(\imath_{\mathscr{Z}_E})^2=0$, we have $(\imath_{\mathscr{Z}_E}\phi)v|_{\pi^{-1}(U_\alpha)}=\pi_\alpha^\star(\imath_{\mathscr{Z}_E}\phi)$.

V. SKYRMION BUNDLE AND RELATED YANG–MILLS THEORIES

These results are quite important for the skyrmion bundle in theoretical nuclear physics which treats interactions of mesons and baryons — described within the (ungauged) Skyrme model[1,3] —

with electromagnetic fields.[11–13] In order to show this, we need some basic results from current algebra. Denote the left and right invariant 1-forms on a Lie group $H \leqslant \mathrm{Gl}_n(\mathbb{C})$ by $\Theta^L \in \mathscr{A}_1^L(H,\mathfrak{h})$, resp., $\Theta^R \in \mathscr{A}_1^R(H,\mathfrak{h})$, i.e.,

$$\Theta_h^L(h\cdot X)=\Theta_h^R(X\cdot h)=X \quad \text{for all} \quad h\in H, X\in\mathfrak{h},$$

where $h\cdot X$ and $X\cdot h$ are elements of $T_h(H)$. In the literature, these forms are also called invariant ''currents'' and we find the notations $h^{-1}dh$ and L for Θ^L, resp., dhh^{-1} and R for Θ^R. If $\wedge$ denotes the exterior product of matrix-valued forms with respect to matrix multiplication, then for all $k\in\mathbb{N}$,

$$(\Theta^L)^k := \underbrace{\Theta^L\wedge\cdots\wedge\Theta^L}_{k} \in \mathscr{A}_k^L(H,\mathbb{C}^{n\times n})$$

and

$$(\Theta^R)^k := \underbrace{\Theta^R\wedge\cdots\wedge\Theta^R}_{k} \in \mathscr{A}_k^R(H,\mathbb{C}^{n\times n})$$

are well-defined left, resp., right, invariant k-forms on H, and so are

$$\lambda_k^M := \mathrm{Tr}[M\cdot(\Theta^L)^k]\in\mathscr{A}_k^L(H,\mathbb{C})$$

and

$$\rho_k^M := \mathrm{Tr}[M\cdot(\Theta^R)^k]\in\mathscr{A}_k^R(H,\mathbb{C}),$$

for any matrix $M\in\mathbb{C}^{n\times n}$. Especially for $M=\mathbb{1}$, we obtain the bi-invariant

$$\omega_k := \lambda_k^{\mathbb{1}}=\rho_k^{\mathbb{1}}\in\mathscr{A}_k(H,\mathbb{C})_{\mathrm{inv}},$$

and one easily checks that $\omega_{2k}=0$. Now the Maurer–Cartan identities yield the following.

Lemma V.1: $d(\Theta^L)^{2k-1}=-(\Theta^L)^{2k}$ *and* $d(\Theta^R)^{2k-1}=(\Theta^R)^{2k}$. *As a consequence for any matrix* $M\in\mathbb{C}^{n\times n}$, *we have* $d\lambda_{2k-1}^M=-\lambda_{2k}^M$, $d\rho_{2k-1}^M=\rho_{2k}^M$ *hence* $d\omega_{2k-1}=0$ *and* $d\lambda_{2k}^M=d\rho_{2k}^M=0$.

In addition, recall that the cohomology of SU_n and U_n is generated as an algebra by ω_3, ω_5, $\ldots$, ω_{2n-1} for SU_n, resp., by ω_1, ω_3, $\ldots$, ω_{2n-1} for U_n, cf. Greub, Halperin, and Vanstone.[14]

In the ungauged Skyrme model, the meson fields occur as maps $U:M\to\mathrm{SU}_n$, where M denotes space–time and n denotes the number of flavors in QCD. The configuration $U\equiv\mathbb{1}$ represents the vacuum. Baryons appear as topological soliton solutions, as ''skyrmions,'' of these fields. The number of baryons represented by a given mesonic field configuration is computed by an integration of $U^\star\omega_3$ over the space manifold (which is compactified at infinity, where the fields are required to tend to the vacuum value $\mathbb{1}$). For $n\geqslant 3$, the action integral splits into two parts, the nonamomalous action and the Wess–Zumino term. The latter is an integral over the differential form ω_5.[2]

In order to treat interactions with electromagnetic fields (especially those of magnetic monopoles,[11,12]) one constructs a fiber bundle $B(M,\mathrm{SU}_n,G_{\mathrm{em}})$, cf. Section I. If e denotes the electric unit charge, then the left action of $G_{\mathrm{em}}=1/e\cdot\mathbb{S}^1$ on SU_n is given by the inner automorphisms

$$L(g,U):=e^{-iegQ}Ue^{+iegQ} \tag{13}$$

for $g\in G_{\mathrm{em}}$ and $U\in\mathrm{SU}_n$. Q is the $n\times n$-matrix containing the quark charges in units of e: for $n=2,3$,

$$Q=\begin{pmatrix} \frac{2}{3} & 0 \\ 0 & -\frac{1}{3} \end{pmatrix}, \text{ resp., } Q=\begin{pmatrix} \frac{2}{3} & 0 & 0 \\ 0 & -\frac{1}{3} & 0 \\ 0 & 0 & -\frac{1}{3} \end{pmatrix}.$$

We put $\phi^\alpha:=\pi_\alpha^\star\phi$ for any $\phi\in\mathscr{A}(F,V)$. Under a change of bundle charts we then have

$$U^\alpha(x)=L(g_{\alpha\beta},U^\beta)(x)=e^{-ieg_{\alpha\beta}(x)Q}U^\beta(x)e^{+ieg_{\alpha\beta}(x)Q},$$

and for the canonical vector field $\mathscr{S}_E\in\mathscr{D}^1(\mathrm{SU}_n)$ induced by $E=1/e\in\mathfrak{g}$, we obtain

$$\mathscr{S}_E(U)=-i[Q,U] \text{ for all } U\in\mathrm{SU}_n. \tag{14}$$

Now (12) yields

$$(dU^\alpha)v=dU^\alpha-ie\mathrm{A}^\alpha[Q,U^\alpha].$$

For the invariant forms ρ_k^Q, λ_k^Q and ω_{2k+1}, we obtain the following lemma:[13]

*Lemma V.2: For the action given in (*13),

$$\imath_{\mathscr{S}_E}\omega_{2k+1}=-(2k+1)i(\rho_{2k}^Q-\lambda_{2k}^Q),$$

$$\imath_{\mathscr{S}_E}(\rho_{2k}^Q-\lambda_{2k}^Q)=0,$$

$$\begin{aligned}\imath_{\mathscr{S}_E}(\rho_{2k+1}^Q+\lambda_{2k+1}^Q)=&-2i\sum_{j=1}^{k}\mathrm{Tr}[QU(\Theta^L)^{2j-1}Q(\Theta^L)^{2k-2j+1}U^{-1}]\\&-i\sum_{j=0}^{k}\mathrm{Tr}[Q(\Theta^R)^{2j}Q(\Theta^R)^{2k-2j}-Q(\Theta^L)^{2j}Q(\Theta^L)^{2k-2j}].\end{aligned}$$

In order to define a baryon number and an anomalous action for the skyrmion bundle, we have to extend the forms ω_3 and ω_5 to the bundle. Several approaches ''by trial and error'' have been made to ''generalize'' ω_3 and ω_5, cf. Callan and Witten,[11] Kaymakcalan *et al.*,[15] or Pak and Rossi.[16] In terms of the language we are using, we would like to obtain differential forms ω_3^{A} and ω_5^{A} that are adapted to the Maxwell connection given by the electromagnetic fields. Thus we will examine whether ω_3 and ω_5 are G_{em}-transgressive.

This is indeed the case. According to Lemma IV.10 we have to find $\chi_{n-2i}^i\in\mathscr{A}_n(\mathrm{SU}_n,\mathbb{C})$ and $\nu_{n-2i-1}^i=\imath_{\mathscr{S}_E}\chi_{n-2i}^i$ that obey (11) for $\phi=\omega_3$, resp., $\phi=\omega_5$. From Lemma V.2 we conclude that for $\phi=\omega_{2k+1}$, we have $\nu_{2k}^0=-(2k+1)i(\rho_{2k}^Q-\lambda_{2k}^Q)$. Now Lemma V.1 yields that

$\rho^Q_{2k}-\lambda^Q_{2k}=d(\rho^Q_{2k-1}+\lambda^Q_{2k-1})$, so $\chi^1_{2n-1}=(2k+1)i(\rho^Q_{2k-1}+\lambda^Q_{2k-1})$. For ω_3 we are already done, since χ^1_1 is global and vertical due to Lemma V.2: $\nu^1_0=0$. For χ^1_3, again Lemma V.2 yields $\nu^2_2=-10i^2\mathrm{Tr}[Q^2((\Theta^R)^2-(\Theta^L)^2)+QdU^{-1}\wedge QdU]$. One easily verifies that

$$\chi^2_1=10i^2(\rho_1^{Q^2}+\lambda_1^{Q^2})+5i^2\mathrm{Tr}(QdUQU^{-1}-QUQdU^{-1})+ri^2d\mathrm{Tr}(QU^{-1}QU),r\in\mathbb{R},$$

is an admissible choice and that $\nu^2_0=0$, thus χ^2_1 is global and vertical. For physical reasons (parity invariance[15]), we put $r=0$. We thus obtain from Theorem IV.11:[13] the following.

Theorem V.3: *ω_3 and ω_5 are G_{em}-transgressive and generate de Rham cohomology groups isomorphic to $\mathbb{R}$ for any skyrmion bundle. Representatives for the generated cohomology groups, that are adapted to the Maxwell connection, are*

$$\begin{aligned}\omega^{\mathrm{A}}_3&=\omega_3 v+ie\mathrm{F}\wedge\chi^1_1 v\\&=[\omega^\alpha_3-3ie\mathrm{A}^\alpha\wedge(\rho^Q_2-\lambda^Q_2)]+3ie\mathrm{F}\wedge(\rho^Q_1+\lambda^Q_1),\end{aligned}$$

$$\begin{aligned}\omega^{\mathrm{A}}_5&=\omega_5 v+ie\mathrm{F}\wedge\chi^1_3 v+(ie)^2\mathrm{F}\wedge\mathrm{F}\wedge\chi^2_1 v\\&=[\omega^\alpha_5-5ie\mathrm{A}^\alpha\wedge(\rho^Q_4-\lambda^Q_4)]+5ie\mathrm{F}\wedge\{(\rho^Q_3+\lambda^Q_3)^\alpha\\&\quad-2ie\mathrm{A}^\alpha\wedge\mathrm{Tr}[Q^2((\Theta^R)^2-(\Theta^L)^2)+QdU^{-1}\wedge QdU]^\alpha\}+5(ie)^2\mathrm{F}\wedge\mathrm{F}\wedge[2(\rho_1^{Q^2}+\lambda_1^{Q^2})^\alpha\\&\quad+\mathrm{Tr}(QdUQU^{-1}-QUQdU^{-1})^\alpha].\end{aligned}$$

In fact, one can prove that all differential forms ω_{2k-1} are G_{em}-transgressive.[17]

In comparison to the literature cited, our formalism has led to quite compact notations for ω^{A}_3 and ω^{A}_5. This advantage becomes even more obvious when generalizations to other gauge groups, especially non-Abelian gauge groups, are considered, e.g., instead of $G\cong\mathbb{S}^1$ and $F=\mathrm{SU}_n$ take a Yang–Mills theory where $G=\mathrm{U}^L_n\times\mathrm{U}^R_n$ and $F=\mathrm{U}_n$ with $L_{(g_L,g_R)}(U)=g_LUg_R^{-1}$. As a generalization of (14) we have for all $(X_L,X_R)\in\mathrm{u}^L_n\oplus\mathrm{u}^R_n$

$$\mathscr{L}_{(X_L,X_R)}(U)=X_LU-UX_R\quad\text{for all}\quad U\in\mathrm{SU}_n.\tag{15}$$

Now the gauge fields take their values in $\mathrm{u}^L_n\oplus\mathrm{u}^R_n$, i.e., $\mathrm{A}^\alpha=(\mathrm{A}^\alpha_L,\mathrm{A}^\alpha_R)\in\mathscr{A}(U_\alpha,\mathrm{u}^L_n\oplus\mathrm{u}^R_n)$ define the connection Γ on $P(M,G)$. In this case, omitting the superscripts α, we obtain $dUv=dU+\mathrm{A}_LU-U\mathrm{A}_R$, hence

$$\Theta^Lv=\Theta^L+U^{-1}\mathrm{A}_LU-\mathrm{A}_R,$$

$$\Theta^Rv=\Theta^R+\mathrm{A}_L-U\mathrm{A}_RU^{-1},$$

$$\omega_1v=\omega_1+\mathrm{Tr}(\mathrm{A}_L-\mathrm{A}_R).$$

Moreover, we have $L_\bullet\omega_1=\mathrm{Tr}(\pi_L-\pi_R)$ with the projections $\pi^{L/R}:\mathfrak{g}=\mathrm{u}^L_n\oplus\mathrm{u}^R_n\to\mathrm{u}^{L/R}_n$. Thus for any LIE subgroup $H<G$, the closed invariant form ω_1 is H-transgressive iff $\mathrm{Tr}(X_L-X_R)=0$ for all $(X_L,X_R)\in\mathfrak{h}$, e.g., we could choose a subgroup of the diagonal $D_n=\mathrm{U}^L_n\times\mathrm{U}^L_n$ in G such that $g_L=g_R$ for all $(g_L,g_R)\in D_n$. (Note that this is the case for the skyrmion bundle.) Or we could choose $H=\mathrm{SU}^L_n\times\mathrm{SU}^R_n$, resp., a subgroup of H. In Section VII we will prove that in the latter case, ω_1 is necessarily H-transgressive because $\mathrm{SU}^L_n\times\mathrm{SU}^R_n$ is semisimple for $n>2$, cf. Theorem VII.4.

For ω_3 we obtain $L_\bullet\omega_3=3\mathrm{Tr}[(\Theta^R)^2\pi^L-(\Theta^L)^2\pi^R]$, thus

$$\chi^1_1:=-3\mathrm{Tr}(\Theta^R\pi^L+\Theta^L\pi^R)\in\mathscr{A}_1(\mathrm{U}_n,\mathrm{Hom}(\mathfrak{g},\mathbb{C}))$$

obeys $d\chi_1^1 = -L_\bullet \omega_3$ due to Lemma V.1. Omitting the symmetrization $\vee$, we compute $L_\bullet^\vee \chi_1^1 = 3\mathrm{Tr}(\pi^R\pi^R - \pi^L\pi^L)$, i.e.,

$$(L_\bullet^\vee \chi_1^1)((X_L,X_R),(Y_L,Y_R)) = 3\mathrm{Tr}(X_R Y_R - X_L Y_L) \neq 0.$$

Thus ω_3 is not G-transgressive. In fact, take any $\tilde{\chi}_1^1 \in \mathscr{A}_1(U_n, \mathrm{Hom}(\mathfrak{g},\mathbb{C}))_{\mathrm{equiv}}$ with $d\tilde{\chi}_1^1 = -L_\bullet \omega_3$. Then $\xi_1^1 := \tilde{\chi}_1^1 - \chi_1^1 \in \mathscr{A}_1(U_n, \mathrm{Hom}(\mathfrak{g},\mathbb{C}))_{\mathrm{equiv}}$ with $d\xi_1^1 = 0$. Since $H^1(\mathrm{SU}_n) = 0$, we find $\xi_0^1 \in C^\infty(U_n, \mathrm{Hom}(\mathfrak{g},\mathbb{C}))$ with $d\xi_0^1 = \xi_1^1$. In fact, we may choose ξ_0^1 equivariant, because SU_n is compact, analogously to (9). But then for all $X, Y \in \mathfrak{g}$,

$$\begin{aligned} L_\bullet^\vee \xi_1^1(X,Y) &= (\imath_{\mathscr{L}_X} d\xi_0^1)(Y) + (\imath_{\mathscr{L}_Y} d\xi_0^1)(X) \\ &= \mathscr{L}_X(\xi_0^1)(Y) + \mathscr{L}_Y(\xi_0^1)(X) \\ &= \xi_0^1([Y,X]) + \xi_0^1([X,Y]) = 0. \end{aligned}$$

Thus $(L_\bullet^\vee \tilde{\chi}_1^1) = (L_\bullet^\vee \chi_1^1) \neq 0$. Since ω_3 is not G-transgressive, the generated Γ-adapted form

$$\omega_3^{\mathrm{A}} = \omega_3 v + \chi_1^1 v \bullet \mathrm{F} \in \mathscr{A}_3(B(M, \mathrm{U}_n, G), \mathbb{C})$$

is not closed in general: $d\omega_3^{\mathrm{A}} = (L_\bullet^\vee \chi_1^1) v \bullet \mathrm{F} = (L_\bullet^\vee \chi_1^1) \bullet \mathrm{F}$. Yet if we again restrict L to a subgroup $H < G$ with generators $X^\sigma = (X_L^\sigma, X_R^\sigma)$, $\sigma \in I$, such that $\mathrm{Tr}(X_L^\sigma X_L^\tau) = \mathrm{Tr}(X_R^\sigma X_R^\tau)$ for all $\sigma, \tau \in I$, then $L_\bullet^\vee \chi_1^1 = 0$ and ω_3 is H-transgressive. Note that this condition holds for any subgroup of the diagonal D_n and thus for the skyrmion bundle.

Finally, some cumbersome calculations show that the voluminous expressions for the Wess-Zumino term in Ref. 15, (4.18), resp., Ref. 2, (24), are equal to the integral over the Γ-adapted differential form

$$\omega_5^{\mathrm{A}} = \omega_5 v + \chi_3^1 v \bullet \mathrm{F} + \chi_1^2 v \bullet \mathrm{F} \in \mathscr{A}_5(B(M, \mathrm{U}_n, G), \mathbb{C}),$$

where the forms $\chi_{5-2l}^l \in \mathscr{A}_{5-2l}(\mathrm{U}_n, \mathrm{Sym}_l(\mathfrak{g},\mathbb{C}))_{\mathrm{equiv}}$ are given by

$$\chi_3^1 := -5\mathrm{Tr}[(\Theta^R)^3 \pi^L + (\Theta^L)^3 \pi^R],$$

$$\chi_1^2 := 10\mathrm{Tr}[(\Theta^R)\pi^L\pi^L + (\Theta^L)\pi^R\pi^R] + 5\mathrm{Tr}(dU\pi^R U^{-1}\pi^L - d(U^{-1})\pi^L U \pi^R).$$

Analogously to the skyrmion case, one may add a term

$$r[d\mathrm{Tr}(\pi^L U \pi^R U^{-1}) v] \bullet \mathrm{F} = r d\mathrm{Tr}(F_L U F_R U^{-1}), r \in \mathbb{C},$$

or exclude it by parity invariance.[15] Also in this case, the differential form ω_5 is not G-transgressive: we obtain $L_\bullet^\vee \chi_1^2 = 10\mathrm{Tr}(\pi^L\pi^L\pi^L - \pi^R\pi^R\pi^R)$, thus again ω_5 is H-transgressive for any subgroup $H \leqslant D$. More generally, ω_5 is H-transgressive if and only if the generators of H obey $\mathrm{Tr}(X_L^\sigma X_L^\tau X_L^\upsilon) = \mathrm{Tr}(X_R^\sigma X_R^\tau X_R^\upsilon)$ for all $\sigma, \tau, \upsilon \in I$, specifically, only if $\mathrm{Tr}[(X_L^\sigma)^3] = \mathrm{Tr}[(X_R^\sigma)^3]$ for all $\sigma \in I$, which is the usual condition for cancellation of anomalies on the quark level.[2]

Nevertheless note that $d\omega_5^{\mathrm{A}} = (L_\bullet^\vee \chi_1^2) \bullet \mathrm{F}$ consists of a 6-form on the base. Thus as long as we stick to space–time M — or even a five-dimensional extension — this form vanishes and ω_5^{A} is in fact closed. The same holds for ω_3^{A}: although it might not be closed on space–time M, ω_3^{A} is closed, of course, when restricted to three-dimensional space.

VI. LIE ALGEBRA COHOMOLOGY

Back to the general case, we want to derive which closed invariant n-forms ϕ_n on the fiber F are G-transgressive in the cases where $n=0$, 1 or 2. To this purpose we need some basic results on Lie algebra cohomology.

Suppose $\mathfrak{g}$ is a $\mathbb{K}$-Lie algebra (for $\mathbb{K}=\mathbb{R},\mathbb{C}$) and $l:\mathfrak{g}\to\mathrm{gl}(V)$ is a (left) representation of $\mathfrak{g}$ on a (possibly infinte dimensional) $\mathbb{K}$-vector space V. Then $\mathrm{Alt}(\mathfrak{g},V)=\oplus_{p=0}^{\infty}\mathrm{Alt}_p(\mathfrak{g},V)$ becomes a differential complex C_l with the following differential operator $\mathbf{d}^l=(\mathbf{d}_p^l: C_l^p\to C_l^{p+1})_{p\in\mathbb{N}_0}$: for $c\in C_l^p:=\mathrm{Alt}_p(\mathfrak{g},V)$ and $X_i\in\mathfrak{g}$,

$$\mathbf{d}_p^l c(X_1,\ldots,X_{p+1}):=\sum_{i=1}^{p+1}(-1)^{i+1}l(X_i)(c(\ldots,\widehat{X_i},\ldots))+\sum_{i=1}^{p}\sum_{j=i+1}^{p+1}(-1)^i c(\ldots,\widehat{X_i},\ldots,X_{j-1},[X_i,X_j],X_{j+1},\ldots)$$

(where $\widehat{\ }$ indicates that the term is omitted).

Our definition of $\mathbf{d}^l$ differs slightly from the definitions in Ref. 14, resp., in Hilgert and Neeb,[18] where analogously to the definition of the exertior derivative d, the second term reads

$$+\sum_{i=1}^{p}\sum_{j=i+1}^{p+1}(-1)^{i+j}c([X_i,X_j],X_1,\ldots,\widehat{X_i},\ldots,\widehat{X_j},\ldots).$$

Obviously both definitions coincide on C_l. Nevertheless with our definition not only $\mathrm{Alt}(\mathfrak{g},V)$ becomes a differential complex, but also $\mathrm{Hom}(\mathscr{T}(\mathfrak{g}),V)$ becomes a complex C_l with subcomplex C_l. [$\mathscr{T}(\mathfrak{g})$ denotes the tensor algebra of $\mathfrak{g}$.] Indeed we can prove — analogously to the proof for $d^2=0$ — that $\mathbf{d}_{p+1}^l\circ\mathbf{d}_p^l=0$ on C_l for any representation $l:\mathfrak{g}\to\mathrm{gl}(V)$ of $\mathfrak{g}$. Now the cohomology of this complex, $H_l^p(\mathfrak{g},V):=H_{\mathbf{d}}^p(C_l)$ is called the pth (Chevalley) cohomology space of $\mathfrak{g}$ with values in V with regard to l. We put $H_l^p(\mathfrak{g}):=H_l^p(\mathfrak{g},\mathbb{K})$. Analogously, $\overline{H_l^p}(\mathfrak{g},V):=\overline{H_{\mathbf{d}}^p}(C_l)$ and $\overline{H_l^p}(\mathfrak{g}):=\overline{H_l^p}(\mathfrak{g},\mathbb{K})$.

Lemma VI.1: Let $o:\mathfrak{g}\to\mathrm{gl}(V)$ denote the trivial representation of $\mathfrak{g}$. Then

(1) $H_o^0(\mathfrak{g},V)=\overline{H_o^0}(\mathfrak{g},V)=V$.
(2) $H_o^1(\mathfrak{g},V)=\overline{H_o^1}(\mathfrak{g},V)=\{c\in\mathrm{Hom}(\mathfrak{g},V)\,|\,c([\mathfrak{g},\mathfrak{g}])=\{0\}\leqslant V\}=[\mathfrak{g},\mathfrak{g}]^{\perp}$, *thus $\mathbf{d}_1^o$ is injective and $H_o^1(\mathfrak{g},V)=\{0\}$ for all Lie algebras $\mathfrak{g}$ with $\mathfrak{g}=[\mathfrak{g},\mathfrak{g}]$*, e.g., *semisimple Lie algebras.*
(3) *If $\mathfrak{a}$ is Abelian, then $H_o^p(\mathfrak{a},V)=\mathrm{Alt}_p(\mathfrak{a},V)$ and $H_o^p(\mathfrak{a},V)=\mathrm{Hom}(\otimes^p\mathfrak{a},V)$.*

Moreover, if V is finite dimensional, then Whitehead's lemmas yield that $H_l^1(\mathfrak{g},V)=H_l^2(\mathfrak{g},V)=0$ for any representation $l:\mathfrak{g}\to\mathrm{gl}(V)$ of a semisimple Lie algebra $\mathfrak{g}$.

Recall that a double complex $C^{*,*}:=\oplus_{p,q\in\mathbb{N}_0}C^{p,q}$ is a doubly graded differential complex with two commuting differential operators, a horizontal operator $\delta:C^{p,q}\to C^{p+1,q}$ and a vertical operator $d:C^{p,q}\to C^{p,q+1}$. Every double complex is associated with a singly graded complex C^* by summing along the antidiagonal lines, i.e., C^n is given by $C^n=\oplus_{p+q=n}C^{p,q}$. The (total) cohomology of such a double complex is then defined to be the cohomology of the associated singly graded complex with regard to the differential operator $D=\delta+(-1)^p d$ on $C^{p,q}$. Note that indeed $D:C^n\to C^{n+1}$. The alternating sign guaranties that $D\circ D=0$.[6]

Given a Lie group action $L:G\times F\to F$, we want to combine the invariant cohomology on F with the Lie algebra cohomology of $\mathfrak{g}$. To this purpose, we form the double complex

$$C^{*,*}:=\mathscr{A}(F)\otimes\mathrm{Hom}(\mathscr{T}(\mathfrak{g}),V)=\oplus_{p,q\in\mathbb{N}_0}\mathscr{A}_q(F,\mathrm{Hom}(\otimes^p\mathfrak{g},V)).$$

$(-1)^p d_{(q)}: C^{p,q} \to C^{p,q+1}$ is the vertical operator, and for the horizontal operator we have $\delta := -\mathbf{d}^l_{(q)}: C^{p,q} \to C^{p+1,q}$. For the representation $l: \mathfrak{g} \to \mathrm{gl}(\mathscr{A}(F,V))$ several choices are possible. e. g., one can take the trivial representation o. Then $\mathbf{d}^o$ and d obviously commute.

Instead we choose l defined by $l(X) := -L_{\mathscr{L}_X}$, where $L_{\mathscr{X}}: \mathscr{A}(F,V) \to \mathscr{A}(F,V)$ denotes the Lie derivative of forms with respect to a vector field $\mathscr{X} \in \mathscr{D}^1(F)$. Recall that $L_{\mathscr{X}}$ is given by $L_{\mathscr{X}} = d \circ \imath_{\mathscr{X}} + \imath_{\mathscr{X}} \circ d$. Since Lie differentiation and exterior differentiation commute, δ and d commute on the double complex and define an operator D.

With regard to these operators we obtain (Ref. 8, Lemma 3.4) the following.

Lemma VI.2: For all $\omega_n \in \mathscr{A}_n(F,V)$ and all $i \leqslant n+1$,

$$L^i_\bullet d\omega_n - (-1)^i dL^i_\bullet \omega_n = \delta_{i-1} L^{i-1}_\bullet \omega_n .$$

$A^{*,*} := \mathscr{A}(F) \otimes \mathrm{Alt}(\mathfrak{g},V)$ is a subcomplex of $C^{*,*}$ and $A^{*,*}_{\mathrm{inv}} := \mathscr{A}(F)_{\mathrm{inv}} \otimes \mathrm{Alt}(\mathfrak{g},V)$ and $A^{*,*}_{\mathrm{equiv}} := \mathscr{A}(F)_{\mathrm{equiv}} \otimes \mathrm{Alt}(\mathfrak{g},V)$ are subcomplexes of $A^{*,*}$, on which the horizontal operators are given by $\delta = -\mathbf{d}^o$, resp., $\delta = +\mathbf{d}^o$.

Recall that a chain map $f: A \to B$ between two differential complexes A and B is a homomorphism that commutes with the differential operators of A and B: $f \circ D_A = D_B \circ f$, e.g., all pullbacks $f^\star: \mathscr{A}(M,V) \to \mathscr{A}(N,V)$ are chain maps.

Definition VI.3: For any Lie group action $L: G \times F \to F$, the homomorphism $\mathbf{L}: \mathscr{A}(F,V) \to \mathscr{A}(F) \otimes \mathrm{Alt}(\mathfrak{g},V)$ *is defined by* $\mathbf{L}\omega_n := \Sigma_{i=0}^n L^i_\bullet \omega_n$ *for all* $\omega_n \in \mathscr{A}_n(F,V)$.

The homomorphism $L^*_\bullet: \mathscr{A}(F,V) \to \mathrm{Alt}(\mathfrak{g},V)$ *is given by* $L^*_\bullet \omega := \Sigma_{n=0}^\infty L^n_\bullet \omega_n$ *for all* $\omega = \Sigma_{n=0}^\infty \omega_n$ *with* $\omega_n \in \mathscr{A}_n(F,V)$.

Let $p_0: \mathscr{A}(F) \otimes \mathrm{Alt}(\mathfrak{g},V) \to \mathscr{A}(P,V)$ denote the canonical projection. Since $p_0 \circ D = d \circ p_0$, p_0 is a chain map. Obviously $p_0 \circ \mathbf{L} = \mathrm{id}_{\mathscr{A}(F,V)}$, thus if $\mathbf{L}$ is a chain map, we obtain $[p_0] \circ [\mathbf{L}] = \mathrm{id}_{H^*(P,V)}$ and $[\mathbf{L}]$ is injective. Indeed we find the following.

Proposition VI.4:

(1) $\mathbf{L}$ *is a chain map and induces an injective homomorphism*

$$[\mathbf{L}]: H^*(F,V) \to H^*_D(\mathscr{A}(F) \otimes \mathrm{Alt}(\mathfrak{g},V)).$$

(2) $L^*_\bullet$ *is a chain map and thus induces a homomorphism*

$$[L^*_\bullet]: H^*(F,V) \to H^*_l(\mathfrak{g},V).$$

Proof:

(1) By Lemma VI.2 we have

$$\begin{aligned} D(\mathbf{L}\omega) &= \sum_{i=0}^n D(L^i_\bullet \omega_n) = \sum_{i=0}^n [\delta_i L^i_\bullet \omega_n + (-1)^i dL^i_\bullet \omega_n] \\ &= \sum_{i=0}^n [L^{i+1}_\bullet d\omega_n + (-1)^i dL^{i+1}_\bullet \omega_n + (-1)^i dL^i_\bullet \omega_n] \\ &= \sum_{i=0}^n (L^{i+1}_\bullet d\omega_n) + (-1)^n dL^{n+1}_\bullet \omega_n + d\omega_n \\ &= \mathbf{L}(d\omega_n) \end{aligned}$$

since $L^{n+1}_\bullet \omega_n = 0$.

(2) follows from Lemma VI.2 if we put $i = n+1$. □

Finally we find the following result with regard to our purposes:

Theorem VI.5: *If the Lie algebra* $\mathfrak{g}$ *is semisimple and the form* $\omega \in \mathscr{A}_2(F,V)_{\text{inv}}$ *is closed, then there exists a unique* $\chi \in \mathscr{A}_0(F,\text{Alt}_1(\mathfrak{g},V))_{\text{equiv}}$, *such that*

$$d\chi = -L_\bullet \omega \quad \text{and} \quad \delta\chi = L^2_\bullet \omega.$$

Proof: By Lemma VI.2, $\delta L^2_\bullet \omega = 0$ holds. Since $H^2_o(\mathfrak{g},V) = 0$ by Whitehead's second lemma, we find $\chi \in \mathscr{A}_0(F,\text{Alt}_1(\mathfrak{g},V))_{\text{equiv}}$ with $\delta\chi = L^2_\bullet \omega$. Lemma VI.1 yields that δ_1 is injective, so χ is unique. On the other hand we know from $D\mathbf{L}\omega = \mathbf{L}d\omega = 0$ that $-\delta L_\bullet \omega = dL^2_\bullet \omega = d\,\delta\chi = \delta d\chi$. Thus $d\chi + L_\bullet \omega \in \ker\delta_1$. But δ_1 is injective. □

VII. *G*-TRANSGRESSIVE *N*-FORMS FOR $N \leqslant 2$

Now we are prepared to compute which closed invariant n-forms ϕ_n, $n \leqslant 2$, on the fiber are G-transgressive.

$d\phi_0 = 0$ means that $\phi_0 \in C^\infty(F)$ is locally constant. Obviously $L^\vee_\bullet \phi_0 = 0$. So every closed G-invariant $\phi_0 \in C^\infty(F)$ is G-transgressive. Since ϕ_0 is invariant, it is global and vertical. Thus $(\phi_0^A)^\alpha = \pi_\alpha^\star \phi_0$ and $[i^\star_{\alpha,x}][\phi_0^A] = [\phi_0]$. This proves the following.

Lemma VII.1: Every closed G-invariant $\phi_0 \in C^\infty(F)$ *is G-transgressive and thus for any* $\alpha \in A$ *and* $x \in U_\alpha$, $[i^\star_{\alpha,x}]: H^0(B(M,F,G)) \to H^0_{\text{inv}}(F)$ *is surjective.*

[Note that this also implies $H^0_{\text{inv}}(F) \leqslant H^0(F)$, if we put $B := \{x\} \times F$, but this is nothing new.]

For $n = 1$ and $\phi_1 \in \mathscr{A}(F)_{\text{inv}}$, Lemma VI.2 yields that $d\phi_1 = 0$ implies $\mathbf{d}_1^0 L_\bullet \phi_1 = 0$, i.e., for all $f \in F$, $[L_\bullet \phi_1(f)] \in [\mathfrak{g},\mathfrak{g}]^\perp$ by Lemma VI.1. Thus for a semisimple Lie algebra $\mathfrak{g}$, $L_\bullet \phi_1 = 0$. As a consequence for any bundle $B(M,F,G)$ that comes along with L, $\{\pi_\alpha^\star \phi_1\}_{\alpha \in A}$ defines a global vertical form on B. We have proved the following.

Lemma VII.2: If L *is a Lie group action of a semisimple Lie group* G *on* F, *then every closed invariant* 1*-form* $\phi_1 \in \mathscr{A}_1(F)_{\text{inv}}$ *is G-transgressive and defines a unique cohomology class* $[\phi_1 v] = [\{\pi_\alpha^\star \phi_1\}_{\alpha \in A}] \in H^1(B)$ *for any bundle* $B(M,F,G)$ *that comes along with* L. *Thus for any* $x \in U_\alpha$, $[i^\star_{\alpha,x}]: H^1(B(M,F,G)) \to H^1_{\text{inv}}(F)$ *is surjective.*

To show that the condition ''G semisimple'' is necessary, take $G = \mathbb{S}^1 \cong \mathbb{R}/\mathbb{Z}$ acting on itself by left multiplication, thus $\mathfrak{g} = \mathbb{R}$. For every Lie group, the (left) canonical 1-form $\Theta^L \in \mathscr{A}_1(G,\mathfrak{g})$, defined by $\Theta^L_g(\mathscr{X}_g) := d\lambda_{g^{-1}}(\mathscr{X}_g)$, is (left) invariant by definition. Since $\mathbb{S}^1$ is Abelian, $d\Theta^L = 0$ in this case. Θ^L is the volume form on $\mathbb{S}^1$ and generates $H^1_{\text{inv}}(\mathbb{S}^1) \cong H^1(\mathbb{S}^1) \cong \mathbb{R}$, cf. Proposition IV.2. Yet $(L_\bullet \Theta^L)(X) = \Theta^L(\mathscr{L}_X) = X$ for all $X \in \mathbb{R}$. Thus $L_\bullet \Theta^L = \text{id}_{\mathbb{R}}$ and Θ^L is *not* $\mathbb{S}^1$-transgressive.

In fact, take the principal bundles $P_m(\mathbb{S}^2,\mathbb{S}^1)$, $m \in \mathbb{Z}$, that classify all fiber bundles over $\mathbb{S}^2$ with structure group $\mathbb{S}^1$ according to the Classification theorem (Ref. 4, p. 99). For $m = 0$ we have the trivial bundle $\mathbb{S}^2 \times \mathbb{S}^1$ and for $m = 1$ we obtain the Hopf fibering of the 3-sphere, $\pi: \mathbb{S}^3 \to \mathbb{S}^2$. For the de Rham cohomology $H^*(P_m)$ one obtains from the spectral sequence for P_m with $m \neq 0$:

$$H^0(P_m) \cong \mathbb{R}, \quad H^1(P_m) = 0, \quad H^2(P_m) = 0, \quad H^3(P_m) \cong \mathbb{R}.$$

So no $[i^\star_{\alpha,x}]: H^1(P_m) \to H^1_{\text{inv}}(G)$ is surjective. Moreover, we always have $\Theta^L v = \omega^\Gamma$, even for $m = 0$. Since $d\omega^\Gamma = d^\Gamma \omega^\Gamma = \Omega^\Gamma$, our canonical construction does not produce closed forms on P_m, in general.

Finally we consider the case $n = 2$ for semisimple Lie groups. Using Theorem VI.5 we obtain that every closed invariant 2-form on F is G-transgressive. Thus we have the following.

Corollary VII.3: If L *is a Lie group action of a semisimple Lie group* G *on* F, *then every closed invariant* 2*-form* $\phi_2 \in \mathscr{A}_2(F)_{\text{inv}}$ *is G-transgressive and defines a unique cohomology class* $[\phi_2^A] \in H^2(B)$ *for any bundle* $B(M,F,G)$ *that comes along with* L. *If* $\chi_0^1 \in C^\infty(F)_{\text{equiv}} \otimes \text{Hom}(\mathfrak{g},\mathbb{R})$ *is the unique map with* $d\chi_0^1 = -L_\bullet \phi_2$ *and* $\delta\chi_0^1 = L^2_\bullet \phi_2$ *according to* Theorem VI.5, *then* ϕ_2^A *is given by*

$$\phi_2^A = \phi_2 v + (\chi_0^1 v)\bullet \mathrm{F} \in \mathscr{A}_2(B).$$

Thus for any $x \in U_\alpha$, $[i_{\alpha,x}^\star]: H^2(B(M,F,G)) \to H^2_{\mathrm{inv}}(F)$ *is surjective.*

In view of Proposition IV.2 we thus have proved the following.

Theorem VII.4: *If* L *is a Lie group action of a semisimple Lie group* G *on* F*, then every closed invariant* $\phi_n \in \mathscr{A}_n(F)_{\mathrm{inv}}$, $n \leqslant 2$*, is* G*-transgressive and defines a unique cohomology class* $[\phi_n^A] \in H^n(B)$ *for any bundle* $B(M,F,G)$ *that comes along with* L*. For any* $x \in U_\alpha$, $[i_{\alpha,x}^\star]: H^n(B(M,F,G)) \to H^n_{\mathrm{inv}}(F)$ *is surjective.*

If in addition, G *is compact and connected, then* $H^n_{\mathrm{inv}}(F) \cong H^n(F)$*. Thus for every bundle* $B(M,F,G)$, $H^n(B)$ *contains a subgroup isomorphic to* $H^n(F)$ *for* $n \leqslant 2$.

Theorem VII.4 applies to QCD, where $G \cong \mathrm{SU}_3$ and to Yang–Mills theories with $G < \mathrm{SU}_n \times \mathrm{SU}_n$.

This theorem is sharp in the sense that it does not hold for $n = 3$, e.g., take $G = \mathbb{S}^3 \cong \mathrm{SU}_2$ acting on itself by left multiplication. Then the volume form on $\mathbb{S}^3$ is closed and invariant and generates $H^3(\mathbb{S}^3) \cong \mathbb{R}$. If this form were G-transgressive, then for all principal bundles $P(M,\mathbb{S}^3)$, the cohomology group $H^3(P)$ would contain a subgroup isomorphic to $\mathbb{R}$, independently of M and the transition functions $g_{\alpha\beta}$. Yet we know that $\mathbb{S}^7$ is a principal bundle over $\mathbb{S}^4$ with fiber $\mathbb{S}^3$, and $H^3(\mathbb{S}^7) = 0$. Thus the volume form on $\mathbb{S}^3$ cannot be G-transgressive.

VIII. FINAL REMARKS

According to Corollary IV.8, every G-transgressive form is 0-transgressive for all bundles with fiber and left action L. The reverse is also true for compact connected Lie groups. This can be proved, e.g., in terms of universal bundles, the Weil algebra and the equivariant cohomology of the G-manifold F.[9,10] In fact, G-transgressive forms are exactly those forms on F that generate equivariant cohomology classes (but not every equivariant cohomology class is generated by a form on F). Now there is a natural isomorphism between this equivariant cohomology and the de Rham cohomology of the universal bundle for the given left action L, which yields that equivariant cohomology classes define de Rham cohomology classes on all bundles that come with L.

We have not used these notions here for several reasons: First of all, we did not want to restrict ourselves *a priori* to compact connected Lie groups, where equivariant cohomology is usually settled. Second, we were not interested in the whole cohomology of the bundles (resp., the whole equivariant cohomology), but only in those cohomology classes that have their origin in forms on F. And last, for the applications in theoretical physics, we were interested in explicit formulas for the generated differential forms and not in a more abstract notion like the Weil algebra.

For non-compact Lie groups the reverse of Corollary IV.8 is false, e.g., take $G = \mathbb{R}$ and define $L: \mathbb{R} \times \mathbb{R}^k \to \mathbb{R}^k$ by $L(r,\vec{v}) = \vec{v} + r\vec{z}$ with $\vec{z} \in \mathbb{R}^k$. Then all forms ϕ_n with constant coefficients are closed and invariant. Because every bundle with structure group $\mathbb{R}$ (even more general, with $G \cong \mathbb{R}^m$) is trivial, every ϕ_n defines a closed form $\mathrm{pr}_{\mathbb{R}^k}^\star \phi_n$ on the bundle. But ϕ_n is not G-transgressive, in general, e.g., for $\phi_1 \in \mathscr{A}_1(\mathbb{R}^k)$ defined by $\phi_1(\vec{v})(\vec{x}) := \langle \vec{v}, \vec{z} \rangle$ for all $\vec{x} \in \mathbb{R}^k$ and $\vec{v} \in T_{\vec{x}}(\mathbb{R}^k)$, where $L_\bullet \phi_1(\vec{x}) = \mathrm{id}_{\mathbb{R}} \neq 0$. Thus ϕ_1 is not G-transgressive.

An Itzykson–Zuber-like integral and diffusion for complex ordinary and supermatrices

Thomas Guhr[a)] and Tilo Wettig[b)]
Max Planck Institut für Kernphysik, Postfach 103980, 69029 Heidelberg, Germany

(Received 21 May 1996; accepted for publication 26 August 1996)

We compute an analogue of the Itzykson–Zuber integral for the case of arbitrary complex matrices. The calculation is done for both ordinary and supermatrices by transferring the Itzykson–Zuber diffusion equation method to the space of arbitrary complex matrices. The integral is of interest for applications in quantum chromodynamics and the theory of two-dimensional quantum gravity. © *1996 American Institute of Physics.* [S0022-2488(96)03412-3]

I. INTRODUCTION

In 1980, Itzykson and Zuber[1] presented their result on a certain integral over the unitary group which had great impact in several areas of mathematical physics. Let U be a matrix parameterizing the unitary group $U(N)$ with the invariant Haar measure $d\mu(U)$. Moreover, consider two diagonal matrices x and y with entries x_n and y_n, respectively, where $n=1,\ldots,N$. The Itzykson–Zuber integral can then be written in the form

$$\int d\mu(U)\exp(i\ \mathrm{tr}\ U^{-1}xUy)=\frac{\det[\exp(ix_ny_m)]_{n,m=1,\ldots,N}}{\Delta_N(x)\Delta_N(y)}, \tag{1.1}$$

where the function

$$\Delta_N(x)=\prod_{n<m}(x_n-x_m) \tag{1.2}$$

is the Vandermonde determinant of order N. Although it was later realized that this formula is a special case of a more general result due to Harish–Chandra,[2] it prompted many investigations in various fields. In 1983, Mehta and Pandey[3,4] used this formula to work out, in the framework of random matrix theory, the spectral correlations of a generic quantum chaotic system which undergoes a transition from conserved to broken time-reversal invariance. There are also numerous applications in field theory, particularly in the theory of two-dimensional quantum gravity; a review can be found in Ref. 5.

Recently, Shatashvili[6] showed that the integral (1.1) itself and all correlations in the Itzykson–Zuber model can be evaluated using the Gelfand–Tzetlin coordinates for an explicit calculation. Remarkably, Itzykson and Zuber had not derived their result by an explicit calculation but related the integral (1.1) to a diffusion process. They showed that it can be viewed as the kernel of a diffusion equation in the curved space of the eigenvalues of Hermitian matrices. Since the space of Hermitian matrices is Cartesian and, therefore, easy to treat, the result (1.1) can be found by comparison with the curved space without actually calculating it explicitly. The crucial point is the separability of the Laplacian operator in the curved space of the eigenvalues. This diffusion equation technique turned out to be a very powerful tool.

Some years ago, it was realized by one of the present authors[7] that the Itzykson–Zuber diffusion can be directly transferred to supermathematics. After the pioneering mathematical

[a)]Electronic mail: guhr@pluto.mpi-hd.mpg.de
[b)]Electronic mail: tilo@pluto.mpi-hd.mpg.de

achievements of Berezin,[8] supermathematics was brought into the theory of matrix models by Efetov[9] and Verbaarschot, Weidenmüller, and Zirnbauer.[10] In Ref. 7 it was shown that there is, completely analogously to the case of ordinary matrices, a diffusion equation in the space of the eigenvalues of Hermitian supermatrices whose kernel is the supersymmetric generalization of the Itzykson–Zuber integral (1.1). Thus the integral can be worked out generalizing the methods of Ref. 1. Again, the crucial point is the separability of the Laplacian in the curved space of the eigenvalues.[7] The result has been used to evaluate, in the framework of random matrix theory, the effect of symmetry breaking on the spectral correlations of a chaotic time-reversal non-invariant system.[11] Recently, it was shown that the supersymmetric generalization of the Itzykson–Zuber diffusion has not only a mathematical, but also a physical meaning: In random matrix theory, it describes the transition from arbitrary to chaotic fluctuations.[12] These results could be used to work out the crossover from Poisson regularity to chaos in a time-reversal non-invariant system.

Let u be a supermatrix, parameterizing the unitary supergroup $U(k_1/k_2)$, with invariant Haar–Berezin measure $d\mu(u)$, and let s and r be diagonal matrices, both having the form $s=\mathrm{diag}(s_1, is_2)$ with $s_j=\mathrm{diag}(s_{1j},\ldots,s_{k_j j})$, $j=1,2$. Then, in its most general form, the supersymmetric Itzykson–Zuber integral[7] can be written as[13,14]

$$\int d\mu(u)\exp(i\ \mathrm{trg}\ usu^{-1}r)=\frac{\det[\exp(is_{p1}r_{p'1})]_{p,p'=1,\ldots,k_1}\ \det[\exp(is_{q2}r_{q'2})]_{q,q'=1,\ldots,k_2}}{B_{k_1k_2}(s)B_{k_1k_2}(r)}, \tag{1.3}$$

where the symbol trg stands for the supertrace, often also denoted by str. The supersymmetric generalization of the Vandermonde determinant is given by

$$B_{k_1k_2}(s)=\frac{\Delta_{k_1}(s_1)\Delta_{k_2}(is_2)}{\Pi_{p,q}(s_{p1}-is_{q2})}. \tag{1.4}$$

It is worth mentioning that $B_{k_1k_2}(s)$ reduces to a determinant[7] via Cauchy's lemma in the case $k_1=k_2$ such that $B_{k_1k_1}(s) = \det[1/(s_{p1} - is_{q2})]_{p,q=1,\ldots,k_1}$. Furthermore, by setting $k_1=N$ and $k_2=0$, one easily sees that formula (1.3) includes formula (1.1) as desired. However, for k_1 and k_2 both non-zero, there is an important caveat: In superanalysis, a change of variables can induce a certain class of singularities. Here, this implies that, if further integration over, say, the s-variables in Eq. (1.3) is required, we have to deal with new types of boundary contributions which have no analogue in ordinary analysis. The general theory of this effect, which is sometimes overlooked in the literature, was given by Rothstein.[15] In Refs. 7 and 16 it was shown how to treat these contributions in the case of the supersymmetric Itzykson–Zuber integral. Regarding integrations over the supersymmetric Itzykson–Zuber integral, yet another comment is in order: In applications in statistical mechanics,[3,4,7,11,12] the integrand, containing formulae (1.1) or (1.3), possesses some invariances under permutations. This allows one to replace the numerator of the right hand sides of these equations by $\exp(i\ \mathrm{tr}\ xy)$ or $\exp(i\ \mathrm{trg}\ sr)$, respectively, which makes the calculations more transparent. We emphasize this trivial point since it has stirred some confusion lately.

It is the purpose of this work to transfer all the results which have been reviewed so far from Hermitian to arbitrary complex matrices. We will do this for the case of ordinary and supermatrices. We will derive closed formulae for the analogues of the ordinary and the supersymmetric Itzykson–Zuber integral in the space of complex matrices. To the best of our knowledge, those have not been worked out yet. Our results are of considerable interest in the theory of matrix models. Several models in two-dimensional quantum gravity involve complex instead of Hermitian matrices.[17,18] Recently, the so-called chiral Gaussian ensembles,[19] also based on complex matrices, have been introduced and proved to be very useful in studying certain aspects of quantum chromodynamics (QCD).[20–23] In particular, the integral we compute will be crucial for a further analysis of the spectral correlations of the Dirac operator of QCD in the framework of

random-matrix models at finite temperatures, in the presence of mass terms, or at finite chemical potential. Via the Banks–Casher formula,[24] such analysis is also important for the study of questions related to the chiral phase transition of QCD.

To derive our results, we transfer the diffusion equation technique to complex ordinary and supermatrices. Again, the crucial point turns out to be the separability in the curved space of, in this case, radial coordinates. We have no doubt that the explicit formula could also be evaluated using other techniques. Especially, Gelfand–Tzetlin coordinates could be used as in Ref. 6 for ordinary Hermitian matrices. Recently, Gelfand–Tzetlin coordinates were derived for Hermitian supermatrices[14] such that this method could also be used for complex supermatrices. Moreover, regarding the case of ordinary matrices, we do not exclude the possibility that our results might be derivable directly from Harish–Chandra's formula.[2] To the best of our knowledge, Harish–Chandra's result has not been transferred to superanalysis yet. Nevertheless, here we will focus on the diffusion equation technique. So far, this technique was, for Hermitian matrices, viewed as a purely mathematical tool. However, as mentioned before, the diffusion in superspace describes the transition from arbitrary to chaotic fluctuations in random matrix theory[12] and, therefore, also has a direct physical meaning. We strongly believe that similar features are likely to exist in the case of the diffusion in the space of complex matrices which we will discuss in the present work.

The paper is organized as follows. In Sec. II, we state our results and derive them by constructing an eigenvalue equation. In Sec. III, we discuss the diffusion and questions related to it. We summarize and discuss our results in Sec. IV. Three appendices are provided for the derivation of intermediate results used in the text. In a fourth appendix, we discuss some boundary contributions which occur in the case of Hermitian supermatrices.

II. DERIVATION OF THE INTEGRAL BY CONSTRUCTING AN EIGENVALUE EQUATION

In Sec. II A, we state the integral for both cases, for ordinary and supermatrices. The derivation is performed for ordinary and supermatrices in Secs. II B and II C, respectively.

A. Statement of the integral

Let X be an arbitrary, square, complex ordinary matrix of dimension N. It is well known[25] that it can be written in the so-called pseudo-diagonal form

$$X = UxV \quad \text{with} \quad x = \mathrm{diag}(x_1,\ldots,x_N), \tag{2.1}$$

where the N variables x_n are real and non-negative. Note that these are not eigenvalues, they will be referred to as radial coordinates. While the matrix U explores the full parameter space of the unitary group $U(N)$, the matrix V is, in order to remove a double counting of phases, restricted to a subspace defined as the quotient of the unitary group and the Cartan subgroup, hence we have $U \in U(N)$ and $V \in U(N)/U^N(1)$.

We now multiply X by a diagonal matrix y of the same form as x and consider the expression i Re tr $UxVy$. The integral we wish to compute is the angular average over both unitary matrices of the exponential of this trace,

$$\Phi(x,y) = \int d\mu(U) \int d\mu(V) \exp(i \ \mathrm{Re\ tr}\ UxVy), \tag{2.2}$$

with $d\mu(U)$ and $d\mu(V)$ being the corresponding invariant Haar measures. We show that this integral is given by

$$\Phi(x,y) = \frac{(2\pi)^{N^2}}{N!} \frac{\det[J_0(x_n y_m)]_{n,m=1,\ldots,N}}{\Delta_N(x^2)\Delta_N(y^2)}, \tag{2.3}$$

where $J_0(z)$ is the ordinary Bessel function of zeroth order. The Vandermonde determinant was defined in Eq. (1.2).

Remarkably and fully analogously to the case of Hermitian matrices, this result can straightforwardly be generalized to supermatrices. An arbitrary complex supermatrix σ of dimension k_1+k_2 can be written as

$$\sigma = us\overline{v} \quad \text{with} \quad s = \mathrm{diag}(s_1, is_2) \tag{2.4}$$

and $s_j = \mathrm{diag}(s_{1j},...,s_{k_j j})$ for $j=1,2$. Again, while the matrix u explores the full parameter space of the unitary supergroup, the matrix $\overline{v}$ has to be restricted to a subspace in order to remove phases, we thus have $u \in U(k_1/k_2)$ and $\overline{v} \in U(k_1/k_2)/U^{k_1+k_2}(1)$.

Analogously to the case of ordinary matrices, we multiply the matrix σ by a diagonal matrix r of the same form as s and consider the expression $i\,\mathrm{Re\,trg}\,us\overline{v}r$. The generalization of the integral in the ordinary case is given by replacing the trace by the supertrace and the invariant measures by the corresponding ones in superspace, $d\mu(u)$ and $d\mu(\overline{v})$, respectively. We show that the double average

$$\varphi(s,r) = \int d\mu(u) \int d\mu(\overline{v}) \exp(i\ \mathrm{Re\ trg}\ us\overline{v}r) \tag{2.5}$$

is given by

$$\varphi(s,r) = \frac{(2\pi)^{(k_1-k_2)^2}}{2^{2k_1k_2}k_1!k_2!} \frac{\det[J_0(s_{p1}r_{p'1})]_{p,p'=1,\ldots,k_1} \det[J_0(s_{q2}r_{q'2})]_{q,q'=1,\ldots,k_2}}{B_{k_1k_2}(s^2)B_{k_1k_2}(r^2)} \tag{2.6}$$

where the generalized Vandermonde determinant was defined in Eq. (1.4).

Obviously, formula (2.6) includes formula (2.3) as can be seen by putting $k_1=N$ and $k_2=0$. Hence, in principle, it is sufficient to perform the derivation solely in superspace. However, we decided not to do so. We prove both results separately, first, in order to give those readers with little interest in supermathematics the opportunity to understand the ordinary case without being burdened by undesired information and, second, in order to help those readers with little experience in supermathematics to approach this area starting from more familiar grounds.

Note that our discussion is related to the harmonic analysis in the corresponding matrix spaces. The functions $\Phi(x,y)$ and $\varphi(s,r)$ can be viewed as the lowest order Bessel functions in these spaces.

B. Derivation for ordinary matrices

Besides X, we introduce a second arbitrary complex matrix Y of dimension N whose pseudodiagonalization reads $Y=U'yV'$ with y defined in Sec. II A. We have $U' \in U(N)$ and $V' \in U(N)/U^N(1)$. We observe that the ''plane wave''

$$W(X,Y) = \exp(i\ \mathrm{Re\ tr}\ XY^\dagger) \tag{2.7}$$

in this matrix space obeys the ''wave equation''

$$\Delta W(X,Y) = -(\mathrm{tr}YY^\dagger)W(X,Y). \tag{2.8}$$

where the Laplacian is defined as

$$\Delta = \sum_{n,m} \left(\frac{\partial^2}{\partial(\mathrm{Re}\ X_{nm})^2} + \frac{\partial^2}{\partial(\mathrm{Im}\ X_{nm})^2} \right). \tag{2.9}$$

Due to the invariance of the Haar measures we can express the function (2.2) as the angular average of the matrix plane wave,

$$\Phi(x,y)=\int d\mu(U')\int d\mu(\overline{V'})W(X,Y). \tag{2.10}$$

The crucial observation is now, just as in the case of Hermitian matrices, that $\Phi(x,y)$ satisfies the wave equation (2.8). This can be seen by averaging both sides of (2.8) over the matrices U' and V' using $\mathrm{tr}\, YY^{\dagger}=\mathrm{tr}\, y^2$. Consequently, since $\Phi(x,y)$ depends only on the radial coordinates, we can replace the Laplacian Δ by its radial part Δ_x. To construct it we have to transform the Cartesian volume element

$$d[X]=\prod_{n,m} d\ \mathrm{Re}\ X_{nm} d\ \mathrm{Im}\ X_{nm} \tag{2.11}$$

to radial and angular coordinates,

$$d[X]=J(x)d[x]d\mu(U)d\mu(\overline{V}),$$

$$d[x]=\prod_{n=1}^{N} dx_n, \quad J(x)=\Delta_N^2(x^2)\prod_{n=1}^{N} x_n, \tag{2.12}$$

where the Jacobian $J(x)$ was worked out in Ref. 25. It is then easily shown that the radial part of the Laplace operator reads

$$\Delta_x=\sum_{n=1}^{N} \frac{1}{J(x)}\frac{\partial}{\partial x_n} J(x)\ \frac{\partial}{\partial x_n}, \tag{2.13}$$

and we thus arrive at the eigenvalue equation

$$\Delta_x\Phi(x,y)=-(\mathrm{tr}\, y^2)\Phi(x,y) \tag{2.14}$$

in the curved space of the radial coordinates.

The key to the solution of the above equation is the separability of the radial Laplacian. For an arbitrary function $\Lambda(x)$ we have the identity

$$\Delta_x \frac{\Lambda(x)}{\Delta_N(x^2)}=\frac{1}{\Delta_N(x^2)}\ \Delta_x'\Lambda(x). \tag{2.15}$$

where the reduced part of the radial Laplacian is

$$\Delta_x'=\sum_{n=1}^{N}\left(\frac{\partial^2}{\partial x_n^2}+\frac{1}{x_n}\frac{\partial}{\partial x_n}\right). \tag{2.16}$$

The proof of this fact is given in Appendix A. Hence, the ansatz

$$\Phi(x,y)=\frac{\Psi(x,y)}{\Delta_N(x^2)\Delta_N(y^2)} \tag{2.17}$$

in which, for symmetry reasons, x and y are treated on the same footing, reduces the radial equation (2.14) to the much simpler form

$$\Delta_x' \Psi(x,y) = -(\mathrm{tr}\, y^2)\Psi(x,y). \tag{2.18}$$

This equation is again separable by a product ansatz for $\Psi(x,y)$ which yields N Bessel differential equations of zeroth order for each of the N functions. Hence, each of them can be written as a linear combination of the Bessel and Weber functions J_0 and N_0, respectively. Note that the indices of the eigenvalues y_n^2 of these N Bessel differential equations can be permuted arbitrarily implying that the most general solution is a linear combination of all these permuted products. However, the integral representation (2.2) imposes certain boundary conditions on the solution of the differential equation (2.18). Since the integral has a finite value for all x and y we have to exclude the Weber function from the solution. Additionally, we have to take into account that the integral is invariant under permutations of the indices. Since $\Delta_N(x^2)$, the Vandermonde determinant, is really a determinant, the function $\Psi(x,y)$ has to have the same properties under permutations of the indices. Incorporating these boundary conditions we find

$$\Psi(x,y) = \frac{(2\pi)^{N^2}}{N!} \det[J_0(x_n y_m)]_{n,m=1,\ldots,N}, \tag{2.19}$$

which yields immediately the result (2.3). Of course, the normalization constant is arbitrary. We will show later why our choice is useful.

C. Derivation for supermatrices

All steps are completely analogous to the ordinary case. In order to make the notation more transparent, we write the supermatrix σ in the boson-fermion block form[7,10]

$$\sigma = \begin{bmatrix} \sigma^{11} & \sigma^{12} \\ \sigma^{21} & i\sigma^{22} \end{bmatrix}, \tag{2.20}$$

where σ^{jl} is a $k_j \times k_l$ complex matrix whose entries are commuting if $j=l$ and anticommuting if $j \neq l$. The factor i in front of σ^{22} is, as usual, introduced to ensure convergence.[9,10] Again, besides σ, we introduce a second arbitrary complex supermatrix ρ of the same form whose pseudo-diagonalization reads $\rho = u' r \overline{v'}$ with r defined in Sec. II A and with $u' \in U(k_1/k_2)$ and $\overline{v'} \in U(k_1/k_2)/U^{k_1+k_2}(1)$. There is also a ''plane wave''

$$w(\sigma,\rho) = \exp(i\ \mathrm{Re\ trg}\ \sigma\rho^\dagger) \tag{2.21}$$

in this matrix space. Note that the expression $\mathrm{Re\,trg}\,\sigma\rho^\dagger$ has, for explicit calculations, to be interpreted as half the sum of $\mathrm{trg}\,\sigma\rho^\dagger$ and its complex conjugate since we will not introduce the real and the imaginary part of Grassmann variables. The plane wave satisfies the ''wave equation''

$$\Delta w(\sigma,\rho) = -(\mathrm{trg}\ \rho\rho^\dagger) w(\sigma,\rho), \tag{2.22}$$

where the Laplacian is defined as

$$\Delta = \sum_{j=1}^{2} \sum_{p,q} \left(\frac{\partial^2}{\partial(\mathrm{Re}\ \sigma_{pq}^{jj})^2} + \frac{\partial^2}{\partial(\mathrm{Im}\ \sigma_{pq}^{jj})^2} \right) + 4 \sum_{j \neq l} \sum_{p,q} \frac{\partial^2}{\partial \sigma_{pq}^{jl} \sigma_{pq}^{jl*}}. \tag{2.23}$$

The invariance of the Haar measures allows us to express the function (2.5) as the angular average of the matrix plane wave,

$$\varphi(s,r) = \int d\mu(u') \int d\mu(\overline{v'}) w(\sigma,\rho). \tag{2.24}$$

As in the ordinary case, we integrate both sides of the wave equation over the matrices u' and $\overline{v'}$ using $\mathrm{trg}\,\rho\rho^{\dagger}=\mathrm{trg}\,r^2$ and observe that $\varphi(s,r)$ satisfies the wave equation (2.22). Again, since $\varphi(s,r)$ depends only on the radial coordinates, we can replace the Laplacian Δ by its radial part Δ_s. The transformation of the Cartesian volume element

$$d[\sigma]=\prod_{j=1}^{2}\prod_{p,q} d(\mathrm{Re}\ \sigma_{pq}^{jj})d(\mathrm{Im}\ \sigma_{pq}^{jj})\prod_{j\neq l}\prod_{p,q} d\sigma_{pq}^{jl*}\ \ d\sigma_{pq}^{jl} \tag{2.25}$$

to radial and angular coordinates reads

$$\begin{aligned} d[\sigma]&=J(s)d[s]d\mu(u)d\mu(\overline{v}),\\ d[s]&=\prod_{j=1}^{2}\prod_{p=1}^{k_j} ds_{pj}, \quad J(s)=B_{k_1k_2}^{2}(s^2)\prod_{j=1}^{2}\prod_{p=1}^{k_j} s_{pj}, \end{aligned} \tag{2.26}$$

where the Jacobian or Berezinian $J(s)$ is computed in Appendix B. The radial part of the Laplace operator takes the form

$$\Delta_s=\sum_{j=1}^{2}\sum_{p=1}^{k_j}\ \frac{1}{J(s)}\frac{\partial}{\partial s_{pj}}J(s)\ \frac{\partial}{\partial s_{pj}}, \tag{2.27}$$

details are given in Appendix B. Hence, we have to solve the equation

$$\Delta_s\varphi(s,r)=-(\mathrm{trg}\ r^2)\varphi(s,r) \tag{2.28}$$

in the curved space of the radial coordinates.

In the case of ordinary matrices, the key for the solution was the separability of the radial Laplacian. It is essential that this feature is also present in the case of supermatrices. This closely parallels the situation for Hermitian matrices.[7] For an arbitrary function $\lambda(s)$ we find

$$\Delta_s\ \frac{\lambda(s)}{B_{k_1k_2}(s^2)}=\frac{1}{B_{k_1k_2}(s^2)}\ \Delta_s'\lambda(s), \tag{2.29}$$

where the reduced part of the Laplacian reads

$$\Delta_s'=\sum_{j=1}^{2}\sum_{p=1}^{k_j}\left(\frac{\partial^2}{\partial s_{pj}^2}+\frac{1}{s_{pj}}\frac{\partial}{\partial s_{pj}}\right). \tag{2.30}$$

The derivation is given in Appendix C. Thus the ansatz

$$\varphi(s,r)=\frac{\psi(s,r)}{B_{k_1k_2}(s^2)B_{k_1k_2}(r^2)} \tag{2.31}$$

yields the reduced equation

$$\Delta_s'\psi(s,r)=-(\mathrm{trg}\ r^2)\psi(s,r) \tag{2.32}$$

which, again, is separable by a product ansatz for $\psi(s,r)$. We obtain k_1+k_2 Bessel differential equations of zeroth order. The boundary conditions imposed by the integral representation (2.5) are very similar to the ones in the ordinary case. First, we have to construct the solution using the Bessel function J_0 and to reject the Weber function N_0. Second, we have to take into account the

invariance under permutations. Here, however, we see from the Jacobian that this invariance exists only within the boson-boson or fermion-fermion block, respectively. Since these boundary conditions imply that the solution is given by

$$\psi(s,r)=\frac{(2\pi)^{(k_1-k_2)^2}}{2^{2k_1k_2}k_1!k_2!}\det[J_0(s_{p1}r_{p'1})]_{p,p'=1,\ldots,k_1}\det[J_0(s_{q2}r_{q'2})]_{q,q'=1,\ldots,k_2}, \tag{2.33}$$

we arrive at the final result (2.6). Again, the normalization constant is arbitrary, we will comment on our choice later.

III. DIFFUSION EQUATION AND FOURIER TRANSFORM

We now discuss a diffusion equation which is closely related to the plane waves and the eigenvalue equations we constructed in the previous section. Our goal is to show that the concept of diffusion equations which is so useful in the case of Hermitian matrices can be transferred straightforwardly to arbitrary complex matrices. However, since these considerations are more of conceptual interest and do not require so many explicit calculations, we study only the case of supermatrices. The case of ordinary matrices is always recovered by setting $k_1=N$ and $k_2=0$. In Sec. III A, we introduce the concepts in Cartesian space. We go over to the curved space of the radial coordinates in Sec. III B. In Sec. III C, we discuss some questions related to boundary terms.

A. Cartesian space

We introduce a time coordinate t and consider the diffusion equation

$$\frac{1}{2}\Delta F(\sigma,t)=\frac{\partial}{\partial t}F(\sigma,t) \tag{3.1}$$

for a given initial condition $F_0(\sigma)$ such that

$$\lim_{t\to 0}F(\sigma,t)=F_0(\sigma). \tag{3.2}$$

The kernel of this diffusion satisfies the equations

$$\frac{1}{2}\Delta G(\sigma,t)=\frac{\partial}{\partial t}G(\sigma,t)\quad\text{and}\quad\lim_{t\to 0}G(\sigma,t)=\delta(\sigma), \tag{3.3}$$

where the δ-function is given by

$$\delta(\sigma)=\prod_{j=1}^{2}\prod_{p,q}\delta(\mathrm{Re}\ \sigma_{pq}^{jj})\delta(\mathrm{Im}\ \sigma_{pq}^{jj})\prod_{j\neq l}\prod_{p,q}\delta(\sigma_{pq}^{jl*})\delta(\sigma_{pq}^{jl}). \tag{3.4}$$

The δ-function of an anticommuting variable β is defined by $\delta(\beta)=\sqrt{2\pi}\beta$.[7,10] Similar to the discussion in Refs. 1 and 16, the kernel is the Gaussian

$$G(\sigma,t)=\frac{2^{2k_1k_2}}{(2\pi t)^{(k_1-k_2)^2}}\exp\left(-\frac{1}{2t}\,\mathrm{trg}\ \sigma\sigma^{\dagger}\right). \tag{3.5}$$

and the solution of the diffusion process can be written as the convolution

$$F(\sigma,t)=\int G(\sigma-\sigma',t)F_0(\sigma')d[\sigma']. \tag{3.6}$$

Moreover, this solution is also expressible as

$$F(\sigma,t)=\exp\left(\frac{t}{2}\,\Delta\right)F_0(\sigma) \tag{3.7}$$

which has to be viewed as a formal power series.

We will now show how the diffusion can be related to the plane waves of the previous section and to the theory of Fourier transforms. To this end, we remark that the δ-function (3.4) can be expanded in the plane waves (2.21),

$$\delta(\sigma)=\frac{2^{4k_1k_2}}{(2\pi)^{2(k_1-k_2)^2}}\int w(\sigma,\rho)d[\rho], \tag{3.8}$$

which allows us to introduce the Fourier transform $\widetilde{P}(\rho)$ of a function $P(\sigma)$ and its inverse by

$$\widetilde{P}(\rho)=\frac{2^{2k_1k_2}}{(2\pi)^{(k_1-k_2)^2}}\int P(\sigma)w^*(\sigma,\rho)d[\sigma] \quad \text{and} \quad P(\sigma)=\frac{2^{2k_1k_2}}{(2\pi)^{(k_1-k_2)^2}}\int \widetilde{P}(\rho)w(\sigma,\rho)d[\rho]. \tag{3.9}$$

The Fourier transform can be used to derive the explicit form (3.5) of the diffusion kernel defined in Eq. (3.3), this works as follows. The diffusion kernel can, according to Eq. (3.7), be expressed in the form

$$G(\sigma,t)=\exp\left(\frac{t}{2}\,\Delta\right)\delta(\sigma) \tag{3.10}$$

in which we insert the expansion (3.8),

$$G(\sigma,t)=\frac{2^{4k_1k_2}}{(2\pi)^{2(k_1-k_2)^2}}\int \exp\left(\frac{t}{2}\,\Delta\right)w(\sigma,\rho)d[\rho]. \tag{3.11}$$

We write the exponential as a power series and, by virtue of the eigenvalue equation (2.22), perform all derivatives. The resummation of the series gives the diffusion kernel as the Fourier transform of a Gaussian

$$G(\sigma,t)=\frac{2^{4k_1k_2}}{(2\pi)^{2(k_1-k_2)^2}}\int \exp\left(-\frac{t}{2}\,\mathrm{trg}\;\rho\rho^{\dagger}\right)w(\sigma,\rho)d[\rho], \tag{3.12}$$

which is in agreement with Eq. (3.5).

B. Curved space of the radial coordinates

We now assume that the initial condition depends only on the radial coordinates, i.e., $F_0(\sigma)=F_0(s)$. Thus it is useful to use the coordinates (2.4) in the integral representation (3.6) of the solution of the diffusion equation (3.1). This has some important consequences. The invariance of the Haar measures implies that this solution is also a function of the radial coordinates only, hence we have $F(\sigma,t)=F(s,t)$. Consequently, the diffusion takes place in the curved space of the radial coordinates alone,

$$\tfrac{1}{2}\,\Delta_s F(s,t)=\frac{\partial}{\partial t}F(s,t) \quad \text{and} \quad \lim_{t\to 0}F(s,t)=F_0(s), \tag{3.13}$$

where Δ_s is the radial part of the Laplacian defined in Eq. (2.27). Moreover, we may conclude from the integral representation (3.6) that the kernel of the diffusion (3.13) is given by

$$\Gamma(s,s',t)=\int d\mu(u)\int d\mu(\overline{v})G(us\overline{v}-s',t). \tag{3.14}$$

There are two ways of evaluating this double average. First, since the kernel $G(\sigma,t)$ is Gaussian, a direct comparison of Eq. (3.5) with Eq. (2.5) shows that

$$\Gamma(s,s',t)=\frac{2^{2k_1k_2}}{(2\pi t)^{(k_1-k_2)^2}}\exp\left(-\frac{1}{2t}\,\mathrm{trg}(s^2+s'^2)\right)\varphi(-is/t,s'), \tag{3.15}$$

which means that this double average can be expressed in terms of the one we have calculated in the previous section. Hence, with the help of the result (2.6) and after a reordering of factors, we can write the diffusion kernel in the curved space in the form

$$\Gamma(s,s',t)=\frac{1}{k_1!k_2!}\,\frac{\det[\,\gamma(s_{p1},s'_{p'1},t)]_{p,p'=1,\ldots,k_1}\,\det[\,\gamma(s_{q2},s'_{q'2},t)]_{q,q'=1,\ldots,k_2}}{B_{k_1k_2}(s^2)B_{k_1k_2}(s'^2)}, \tag{3.16}$$

in which the entries of the determinants are given by the function

$$\gamma(s_{pj},s'_{qj},t)=\frac{1}{t}\exp\left(-\frac{s_{pj}^2+s_{qj}'^2}{2t}\right)I_0\left(\frac{s_{pj}s'_{qj}}{t}\right) \tag{3.17}$$

for all values of $j=1,2$ and $p,q=1,\ldots,k_j$. The function $I_0(z)$ is the modified Bessel function of zeroth order.

Alternatively, if the result (2.6) was unknown, formula (3.16) could be derived by a procedure similar to the one in Sec. II C. The separability of the radial part Δ_s leads to a reduced diffusion equation involving the reduced operator Δ_s' defined in (2.30). This equation can be solved by a product ansatz leading to the diffusion equation

$$\frac{1}{2}\left(\frac{\partial^2}{\partial s_{pj}^2}+\frac{1}{s_{pj}}\,\frac{\partial}{\partial s_{pj}}\right)\gamma(s_{pj},s'_{qj},t)=\frac{\partial}{\partial t}\,\gamma(s_{pj},s'_{qj},t), \tag{3.18}$$

where the differential operator is just the radial part of the Laplacian in a two-dimensional space. In order to construct the solution, we express it as the formal series

$$\gamma(s_{pj},s'_{qj},t)=\exp\left(\frac{t}{2}\left(\frac{\partial^2}{\partial s_{pj}^2}+\frac{1}{s_{pj}}\,\frac{\partial}{\partial s_{pj}}\right)\right)\,\frac{\delta(s_{pj}-s'_{qj})}{\sqrt{s_{pj}s'_{qj}}} \tag{3.19}$$

acting on the proper radial δ-function in this two-dimensional space. Inserting Hankel's expansion [Ref. 26, 14·4.(1)] of this δ-function,

$$\frac{\delta(s_{pj}-s'_{qj})}{\sqrt{s_{pj}s'_{qj}}}=\int_0^\infty J_0(s_{pj}z)J_0(s'_{qj}z)z\;dz, \tag{3.20}$$

we can perform all derivatives and resum the series. We arrive at

$$\gamma(s_{pj},s'_{qj},t)=\int_0^\infty \exp\left(-\frac{t}{2}\,z^2\right)J_0(s_{pj}z)J_0(s'_{qj}z)z\;dz, \tag{3.21}$$

which is precisely Weber's representation [Ref. 26, 13·31.(1)] of the function (3.17). It is easy to see in a direct calculation that this function is indeed the kernel of the diffusion equation (3.18). According to an elementary result [Ref. 26, 13·3.(1)] of the theory of Bessel functions, $\gamma(s_{pj},s'_{qj},t)$ is properly normalized,

$$\int_0^\infty \gamma(s_{pj},s'_{qj},t)s_{pj}\,ds_{pj}=1, \tag{3.22}$$

where we have used the radial part $s_{pj}\,ds_{pj}$ of the measure in the two-dimensional space. Furthermore, since $I_0(z)$ behaves like $\exp(z)/\sqrt{2\pi z}$ for large values of the argument, the function $\gamma(s_{pj},r_{qj},t)$ approaches the δ-function

$$\lim_{t\to 0}\ \gamma(s_{pj},s'_{qj},t)=\frac{\delta(s_{pj}-s'_{qj})}{\sqrt{s_{pj}s'_{qj}}} \tag{3.23}$$

for vanishing time t.

The limit relation (3.23) implies that the kernel (3.16) satisfies the correct limit relation in the curved space of all radial coordinates, we write this in the form

$$\begin{aligned}\lim_{t\to 0}\Gamma(s,s',t)&=\int d\mu(u)\int d\mu(\overline{v})\delta(us\overline{v}-s')\\ &=\frac{1}{k_1!k_2!}\,\frac{\det[\,\delta(s_{p1}-s'_{p'1})]_{p,p'=1,\ldots,k_1}\,\det[\,\delta(s_{q2}-s'_{q'2})]_{q,q'=1,\ldots,k_2}}{\sqrt{J(s)J(s')}}\end{aligned} \tag{3.24}$$

where the Berezinian $J(s)$ is defined in Eq. (2.26). Using this result, it is easily checked that the constant $1/k_1!k_2!$ ensures the correct normalization. This, in turn, motivates our choice of the normalization constants in Eqs. (2.19) and (2.33).

C. Questions related to boundary contributions

The function $\Gamma(s,s',t)$ given in Eq. (3.16) is, as we have shown, the kernel of the diffusion equation (3.13) in the curved space of the radial coordinates. Thus the solution of the integral (3.14) as it stands is indeed given by formula (3.16). However, there is a very subtle point about kernels of this type which has an important impact on applications. Although we will present some applications of our results to physical problems in a forthcoming publication, we already give a short, more intuitive, discussion of this subtlety here. We do so to acquaint the reader who is not yet familiar with supersymmetry with this point which is sometimes overlooked in the literature.

In Cartesian space, the normalization of the Gaussian diffusion kernel (3.5) implies that the equation

$$\int\ G(\sigma-\sigma',t)d[\sigma']=1 \tag{3.25}$$

holds for all values of t and for all matrices σ. Thus after performing the angular integration, one would naively assume that the radial integral

$$\eta(s,t)=\int\Gamma(s,s',t)J(s')d[s'] \tag{3.26}$$

also yields unity for all values of t and for all diagonal matrices s. In the ordinary case, i.e., for $k_1=N$ and $k_2=0$, it can be checked by a straightforward, direct calculation that we indeed have

$\eta(s,t)=1$. However, in the case of supermatrices this is, for non-trivial reasons, no longer true. The singularities of the Berezinian $J(s)$ compensate the vanishing of some angular Grassmann integrals such that a finite, non-zero result remains. This effect leads to certain contributions to the integral which are often called Efetov–Wegner–Parisi–Sourlas terms in the more physics-oriented literature. There are various methods to construct those contributions in the applications of supersymmetry.[7,9–11,27] From a strictly mathematical point of view, these terms arise as boundary contributions due to the fact that the integrals are ill-defined for non-compact supermanifolds. A full-fledged theory can be found in Ref. 15. It is instructive to think of these boundary contributions as being necessary to restore the translational invariance of the integrals in Cartesian space, as obvious in Eq. (3.25), which is broken in Eq. (3.26) if $\eta(s,t)$ differs from unity.[28] To illustrate this, we calculate the function $\eta(s,t)$ for the simplest non-trivial case, namely $k_1=k_2=1$. We have

$$\eta(s,t)=(s_{11}^2+s_{12}^2)\int_0^\infty\int_0^\infty ds'_{11}ds'_{12}\,\frac{s'_{11}s'_{12}}{s'^2_{11}+s'^2_{12}}\,\gamma(s_{11},s'_{11},t)\,\gamma(s_{12},s'_{12},t). \tag{3.27}$$

By expressing the denominator of the Berezinian as the integral

$$\frac{1}{s'^2_{11}+s'^2_{12}}=\int_0^\infty \exp(-(s'^2_{11}+s'^2_{12})z)dz, \tag{3.28}$$

we can evaluate the double integral (3.27) by standard methods [Ref. 26, 13·3 (1)]. We arrive at

$$\eta(s,t)=1-\exp\left(-\frac{s_{11}^2+s_{12}^2}{2t}\right) \tag{3.29}$$

which equals unity only in the limit $t\to 0$. Note that the exponential is, apart from a numerical factor, nothing else but the Cartesian kernel at $\sigma'=0$ which is just $G(\sigma,t)=G(s,t)$. This is, of course, no accidental coincidence.

The case $k_1=k_2$, where k_1 is arbitrary, is physically the most interesting one. Due to the determinant structure of the function $B_{k_1k_1}(s'^2)$, the evaluation of the function $\eta(s,t)$ reduces to the double integral (3.27) already computed, and we arrive at

$$\eta(s,t)=\frac{1}{B_{k_1k_1}(s^2)}\det\left[\frac{1}{s_{p1}^2+s_{q2}^2}\,1\left(-\exp\left(-\frac{s_{p1}^2+s_{q2}^2}{2t}\right)\right)\right]_{p,q=1,\ldots,k_1}. \tag{3.30}$$

As evident from the definition (3.26), this function is a solution of diffusion equation (3.13), we have

$$\frac{1}{2}\,\Delta_s\eta(s,t)=\frac{\partial}{\partial t}\,\eta(s,t). \tag{3.31}$$

However, it is not a kernel of the diffusion process in the usual sense since it obeys different limit relations,

$$\lim_{t\to 0}\eta(s,t)\big|_{s\neq 0}=1 \quad\text{and}\quad \lim_{t\to\infty}\eta(s,t)=0, \tag{3.32}$$

which reflect the existence of the new boundary contributions. The function $\eta(s,t)$ can be viewed as the envelope solution corresponding to the kernel $\Gamma(s,s',t)$. The function $B_{k_1k_1}(s^2)\Gamma(s,s',t)$ possesses a product structure in the kernels $\gamma(s_{p1},s'_{q2},t)$. Due to the integration, this property has

vanished in $B_{k_1 k_1}(s^2)\,\eta(s,t)$, which factorizes only in functions of the combinations $s_{p1}^2+s_{q2}^2$. Along the lines given in Refs. 7, 10, and 28, one can show that the diffusion kernel in the curved space of the radial coordinates has to be replaced by

$$\Gamma(s,s',t)\to(1-\eta(s,t))\,\frac{\delta(s')}{J(s')}+\Gamma(s,s',t) \tag{3.33}$$

if further integration over the primed variables s' is required. This replacement cures the problem of the boundary contributions for $k_1=k_2$ in the physically most interesting cases. Hence, for a well-behaved initial condition $F_0(s)$, the solution $F(s,t)$ of the diffusion equation in the curved space of the radial coordinates reads

$$F(s,t)=(1-\eta(s,t))F_0(0)+\int \Gamma(s,s',t)F_0(s')J(s')d[s']. \tag{3.34}$$

We emphasize that this result is really a solution of the diffusion process (3.13), including its initial condition. Note that there are very peculiar cases in which further boundary contributions can arise. Those, however, have to be constructed using the full theory which is given in Ref. 15.

In Appendix D, we reconsider the boundary contributions to the supersymmetric Itzykson–Zuber integral for Hermitian supermatrices as derived in Ref. 7.

IV. SUMMARY AND DISCUSSION

We have calculated an analogue of the Itzykson–Zuber integral in the space of arbitrary complex matrices. We arrived at explicit formulae for the case of ordinary and supermatrices, where the latter includes the former. We performed our calculation by transferring the diffusion equation technique of Itzykson and Zuber for Hermitian matrices, which works in ordinary[1] and in superspace,[7,13] to complex matrices. For the actual derivation, we used an eigenvalue equation for the plane waves in these matrix spaces which is closely related to this diffusion. Similar to the Hermitian case, the integral in question turns out to be the kernel of the diffusion in the curved spaces of the radial coordinates. The explicit results can be computed due to a separability of the Laplacian in these radial spaces. We discussed certain types of boundary contributions to the full solution of the diffusion equation which can arise in superspace.

We have no doubts that our explicit results can also be derived by other methods. In particular, the use of Gelfand–Tzetlin coordinates for the unitary group in ordinary[6] and superspace[14] ought to be mentioned here since it allows a recursive evaluation of correlation functions in the corresponding matrix models. Most importantly, as far as the case of ordinary matrices is concerned, it does not seem unlikely that the explicit formula for the integral we presented here can be derived directly from the Harish–Chandra integral. At first sight, one would not think so since the Harish–Chandra integral is an average over one unitary matrix whereas our result is a double average over two unitary matrices. This can be seen from the fact that our explicit formula contains Bessel functions where the Itzykson–Zuber integrals contain exponentials, i.e., plane waves. The Bessel function of zeroth order is just the angular average over a plane wave in a two-dimensional space. This might indicate that the angular average over two unitary matrices is essential and cannot be replaced by an average over one unitary matrix. Nevertheless, we do not exclude the possibility that a clever reordering of the trace in the matrix plane waves which combines these two unitary matrices can be done in such a way that the essential part of the calculation reduces to an application of the Harish–Chandra formula. These considerations, however, do not apply to the case of supermatrices, for which, to the best of our knowledge, Harish–Chandra's result has not been transferred yet.

For the reasons discussed above, we do not want to present our explicit formulae for the integrals as our most important findings. Rather, we consider the Itzykson–Zuber-like diffusion

which we constructed here as our most interesting result. We strongly believe that this diffusion is more than a mathematical tool to calculate integrals. In the case of Hermitian supermatrices, it was shown[12] that the Itzykson–Zuber diffusion models the transition from arbitrary to chaotic fluctuations of all orders in a very general way. We are convinced that the diffusion in the space of complex matrices also has a physical meaning of similar significance.

ACKNOWLEDGMENTS

We are grateful to J. Ambjørn and Yu. Makeenko for informing us about the relevance of complex matrix models in the theory of two-dimensional quantum gravity. We thank P.-B. Gossiaux for fruitful discussions regarding the boundary contributions. T.G. acknowledges financial support from a Habilitanden-Stipendium of the Deutsche Forschungsgemeinschaft.

APPENDIX A: SEPARABILITY IN ORDINARY SPACE

We use a more convenient form of Δ_x.

$$\Delta_x = \sum_{n=1}^{N} \left(\frac{\partial^2}{\partial x_n^2} + \frac{\partial \ln J(x)}{\partial x_n} \frac{\partial}{\partial x_n} \right). \tag{A1}$$

The derivatives in Eq. (2.15) are evaluated in a straightforward manner, and we arrive at the intermediate result

$$\Delta_x \frac{\Lambda(x)}{\Delta_N(x^2)} = \frac{1}{\Delta_N(x^2)} \sum_{n=1}^{N} \left(\frac{\partial^2}{\partial x_n^2} + \frac{1}{x_n} \frac{\partial}{\partial x_n} - 4D_n \right) \Lambda(x), \tag{A2}$$

where $D_n = S_n + x_n^2(S_n^2 - T_n)$ with

$$S_n = \sum_{\substack{m=1 \\ m \neq n}}^{N} \frac{1}{x_n^2 - x_m^2} \quad \text{and} \quad T_n = \sum_{\substack{m=1 \\ m \neq n}}^{N} \frac{1}{(x_n^2 - x_m^2)^2}. \tag{A3}$$

We now show that $\Sigma_{n=1}^{N} D_n = 0$. The fact that

$$\sum_{n=1}^{N} S_n = \sum_{m \neq n} \frac{1}{x_n^2 - x_m^2} = 0 \tag{A4}$$

is easily seen by renaming summation indices. The remaining term is

$$R = \sum_{n=1}^{N} x_n^2 (S_n^2 - T_n) = \sum_{\Omega(n,m,m')} \frac{x_n^2}{(x_n^2 - x_m^2)(x_n^2 - x_{m'}^2)}, \tag{A5}$$

where the symbol $\Omega(n,m,m')$ denotes summation over three indices n,m,m' which are pairwise different. We now rename $n \leftrightarrow m$ and $n \leftrightarrow m'$ to obtain

$$2R = \sum_{\Omega(n,m,m')} \left[\frac{x_m^2}{(x_m^2 - x_n^2)(x_m^2 - x_{m'}^2)} + \frac{x_{m'}^2}{(x_{m'}^2 - x_m^2)(x_{m'}^2 - x_n^2)} \right] = -R, \tag{A6}$$

from which $R = 0$ follows immediately. This completes the proof.

APPENDIX B: DERIVATION OF THE BEREZINIAN AND THE RADIAL PART OF THE LAPLACIAN

We wish to compute the Berezinian of the transformation $\sigma = us\overline{v}$, defined in Eq. (2.4). We first construct

$$d\sigma = u(u^\dagger\, du\, s + ds + s\, d\overline{v\, v^\dagger})\overline{v}. \tag{B1}$$

Writing $u^\dagger\, du = du'$ and $d\overline{v\, v^\dagger} = d\overline{v'}$, and noting that $s^\dagger = s$, we obtain the invariant length element

$$\mathrm{trg}\; d\sigma\; d\sigma^\dagger = \mathrm{trg}(du'\, s + ds + s\, d\overline{v'})(s\, du'^\dagger + ds + d\overline{v'^\dagger}\, s) \tag{B2}$$

from which the Berezinian can be read off. Since du' and $d\overline{v'}$ are also in the algebra we are entitled to drop the primes. This gives

$$\mathrm{trg}\; d\sigma\; d\sigma^\dagger = \mathrm{trg}\; ds^2 + \mathrm{trg}\; s\; ds(du + du^\dagger + d\overline{v} + d\overline{v^\dagger}) + \mathrm{trg}(du\, s + s\, d\overline{v})(s\, du^\dagger + d\overline{v^\dagger}\, s). \tag{B3}$$

where we have made use of the fact that s and ds are diagonal. Since du and $d\overline{v}$ are anti-Hermitian, the second term in the above expression yields zero. The vanishing of this term also shows that the Laplace operator separates into two sums over radial and angular coordinates, respectively, a fact which has been used in Sec. II C. The first term in Eq. (B3) contributes a factor of 1 to the Berezinian so that we are left with the third term only. Using boson-fermion block notation, we write

$$du = \begin{bmatrix} du^{C_1} & du^A \\ -du^{A^\dagger} & du^{C_2} \end{bmatrix}. \tag{B4}$$

A note about the number of degrees of freedom: du^{C_j} is an anti-Hermitian matrix with k_j^2 commuting degrees of freedom whereas du^A and $du^{A^\dagger}$ each have $k_1 k_2$ anticommuting degrees of freedom. Similar notation is used for $d\overline{v}$, the main difference being that the diagonal elements of $d\overline{v}^{C_j}$ are zero. It is convenient to separate the diagonal elements of du^{C_j} and to define

$$du\, s + s\, d\overline{v} = \eta + \omega = \begin{bmatrix} \eta^{11} & 0 \\ 0 & \eta^{22} \end{bmatrix} + \begin{bmatrix} \omega^{11} & \omega^{12} \\ \omega^{21} & \omega^{22} \end{bmatrix}. \tag{B5}$$

where $\eta^{11} = \mathrm{diag}(du_{11}^{C_1}\, s_{11}, \ldots, du_{k_1 k_1}^{C_1}\, s_{k_1 1})$, $\eta^{22} = \mathrm{diag}(du_{11}^{C_2}\, is_{12}, \ldots, du_{k_2 k_2}^{C_2}\, is_{k_2 2})$, the diagonal elements of ω^{11} and ω^{22} are zero, and

$$\begin{aligned} \omega_{pp'}^{11} &= du_{pp'}^{C_1}\, s_{p'1} + s_{p1}\, d\overline{v}_{pp'}^{C_1}, \quad (p \neq p'), \\ \omega_{qq'}^{22} &= du_{qq'}^{C_2}\, is_{q'2} + is_{q2}\, d\overline{v}_{qq'}^{C_2}, \quad (q \neq q'), \\ \omega_{pq}^{12} &= du_{pq}^{A}\, is_{q2} + s_{p1}\, d\overline{v}_{pq}^{A}, \\ \omega_{qp}^{21} &= -du_{qp}^{A^\dagger}\, s_{p1} - is_{q2}\, d\overline{v}_{qp}^{A^\dagger}. \end{aligned} \tag{B6}$$

We now consider

$$\begin{aligned} \mathrm{trg}(\eta + \omega)(\eta^\dagger + \omega^\dagger) = \mathrm{trg}(\eta\eta^\dagger + \omega\omega^\dagger) = \mathrm{trg}\; \eta\eta^\dagger + \mathrm{tr}\; \omega^{11}\omega^{11\dagger} - \mathrm{tr}\; \omega^{22}\omega^{22\dagger} \\ - \mathrm{tr}(\omega^{12}\omega^{12\dagger} + \omega^{21}\omega^{21\dagger}). \end{aligned} \tag{B7}$$

where in the first equality we have employed the fact that η is diagonal and that the diagonal elements of ω are zero by definition. Each independent variable appears in one and only one of the four terms in the above expression so that their contribution to the Berezinian is multiplicative. The contribution from the first term can be read off immediately, we obtain

$$\mathrm{trg}\ \eta\eta^{\dagger}\rightarrow\prod_{j=1}^{2}\prod_{p=1}^{k_j} s_{pj}\,. \tag{B8}$$

We now write $\mathrm{tr}\ \omega^{11}\omega^{11\dagger}=\Sigma_{p<p'}(|\omega^{11}_{pp'}|^2+|\omega^{11}_{p'p}|^2)$. Each term in the sum contains only independent variables which do not appear in any other term so that the contribution of these terms to the Berezinian is multiplicative again. Using Eq. (B6) and the anti-Hermiticity of du^{C_1} and $d\overline{v^{C_1}}$ we obtain for the contribution to the Berezinian

$$\mathrm{tr}\ \omega^{11}\omega^{11\dagger}\rightarrow\prod_{p<p'}^{k_1}(s^2_{p1}-s^2_{p'1})^2=\Delta^2_{k_1}(s^2_1). \tag{B9}$$

In complete analogy,

$$-\mathrm{tr}\ \omega^{22}\omega^{22\dagger}\rightarrow\prod_{q<q'}^{k_2}(s^2_{q2}-s^2_{q'2})^2=\Delta^2_{k_2}(s^2_s). \tag{B10}$$

Similar arguments are made for the remaining term in Eq. (B7). Since ω^{12} and ω^{21} couple commuting and anticommuting variables, their contribution to the Berezinian appears in the denominator. Specifically, we obtain

$$-\mathrm{tr}(\omega^{12}\omega^{12\dagger}+\omega^{21}\omega^{21\dagger})\rightarrow\left(\prod_{p=1}^{k_1}\prod_{q=1}^{k_2}(s^2_{p1}+s^2_{q2})\right)^{-2}. \tag{B11}$$

Collecting terms, we finally obtain the Berezinian (2.26).

Since Eq. (B3) implies that the metric tensor in the subspace of the radial coordinates is just the unit matrix, the radial part of the Laplacian has the form (2.27).

APPENDIX C: SEPARABILITY IN SUPERSPACE

Again, we write Δ_s in a more convenient form,

$$\Delta_s=\sum_{j=1}^{2}\sum_{p=1}^{k_j}\left(\frac{\partial^2}{\partial s^2_{pj}}+\frac{\partial\ \ln J(s)}{\partial s_{pj}}\frac{\partial}{\partial s_{pj}}\right). \tag{C1}$$

We now evaluate the derivatives in Eq. (2.29) in analogy to the case of ordinary matrices. The calculation is somewhat more involved but still reasonably straightforward so that we only mention the intermediate result

$$\Delta_s\frac{\lambda(s)}{B_{k_1k_2}(s^2)}=\frac{1}{B_{k_1k_2}(s^2)}\sum_{j=1}^{2}\sum_{p=1}^{k_j}\left(\frac{\partial^2}{\partial s^2_{pj}}+\frac{1}{s_{pj}}\frac{\partial}{\partial s_{pj}}-4D_{pj}\right)\lambda(s), \tag{C2}$$

where $D_{pj}=s_{pj}+s^2_{pj}(S^2_{pj}-T_{pj})$. Here, $S_{pj}=\widetilde{S}_{pj}-\overline{S_{pj}}$ and $T_{pj}=\widetilde{T}_{pj}-\overline{T_{pj}}$ with

$$\widetilde{S}_{pj}=\sum_{\substack{q=1\\q\neq p}}^{k_j}\frac{1}{s^2_{pj}-s^2_{qj}},\quad \overline{S_{pj}}=\sum_{q=1}^{k_{\chi(j)}}\frac{1}{s^2_{pj}+s^2_{q\chi(j)}}, \tag{C3}$$

$$\widetilde{T}_{pj}=\sum_{\substack{q=1\\q\neq p}}^{k_j}\frac{1}{(s_{pj}^2-s_{qj}^2)^2},\quad \overline{T_{pj}}=\sum_{q=1}^{k_{\chi(j)}}\frac{1}{(s_{pj}^2+s_{q\chi(j)}^2)^2}. \tag{C4}$$

In the above, we have introduced the convention

$$\chi(j)=\begin{cases}1 & \text{if } j=2\\ 2 & \text{if } j=1\end{cases}. \tag{C5}$$

We now show that $\Sigma_{j=1}^{2}\Sigma_{p=1}^{k_j}D_{pj}=0$. According to the definition, we have

$$D_{pj}=\widetilde{S}_{pj}+s_{pj}^2(\widetilde{S}_{pj}^2-\widetilde{T}_{pj})-\overline{S_{pj}}+s_{pj}^2(\overline{S_{pj}^2}-2\widetilde{S}_{pj}\overline{S_{pj}}+\overline{T_{pj}}). \tag{C6}$$

For each j, the sum over p of the first two terms is zero in analogy to the case of ordinary matrices which was discussed in Appendix A. We are thus left with the remaining two terms which we denote by $-D'_{pj}$. Summing over p and j, some algebra leads to

$$\sum_{j=1}^{2}\sum_{p=1}^{k_j}D'_{pj}=\sum_{p=1}^{k_1}\sum_{q=1}^{k_2}\frac{1}{s_{p1}^2+s_{q2}^2}\left(\sum_{\substack{p'=1\\p'\neq p}}^{k_1}\frac{s_{q2}^2(s_{p1}^2+s_{p'1}^2)+2s_{p1}^2s_{p'1}^2}{(s_{p1}^2-s_{p'1}^2)(s_{p'1}^2+s_{q2}^2)}\right.$$
$$\left.+\sum_{\substack{q'=1\\q'\neq q}}^{k_2}\frac{s_{p1}^2(s_{q2}^2+s_{q'2}^2)+2s_{q2}^2s_{q'2}^2}{(s_{q2}^2-s_{q'2}^2)(s_{p1}^2+s_{q'2}^2)}\right). \tag{C7}$$

Renaming $p\leftrightarrow p'$ and $q\leftrightarrow q'$ in the first and second term, respectively, shows that each of the two sums yields zero individually. This completes the proof.

APPENDIX D: ON BOUNDARY CONTRIBUTIONS IN THE CASE OF HERMITIAN SUPERMATRICES

The purpose of this Appendix is to clarify the role of some boundary contributions to the supersymmetric Itzykson–Zuber integral which arise in the case of Hermitian supermatrices. This discussion is not directly related to the main content of the present paper.

After we had computed the result (3.30) for the function $\eta(s,t)$, P.-B. Gossiaux pointed out to us that the structure of these contributions in the case of Hermitian supermatrices ought to be very similar. Indeed, this is true. A careful reexamination of the considerations following Eq. (B33) in Appendix B of Ref. 7 leads to additional terms very similar to the ones in Eq. (3.30). To clarify this, we calculate the function

$$\eta(s,t)=\frac{1}{B_k(s)}\det[\,\widetilde{\eta}(s_{p1},is_{q2},t)\,]_{p,q=1,\ldots,k} \tag{D1}$$

in the case of Hermitian supermatrices for $k_1=k_2=k$. Here, the entries of the determinant are given by

$$\widetilde{\eta}(s_{p1},is_{q2},t)=\frac{1}{2\pi t}\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}\frac{dr_1\,dr_2}{r_1-ir_2}\exp\left(-\frac{1}{2t}\left((s_{p1}-r_1)^2+(s_{p2}-r_2)^2\right)\right). \tag{D2}$$

We introduce polar coordinates $r_1+ir_2=\kappa\exp(i\vartheta)$ and $s_{p1}+is_{q2}=\mu\exp(i\psi)$ and find

$$\tilde{\eta}(s_{p1}, is_{q2}, t) = \frac{1}{2\pi t} \int_0^\infty d\kappa \, \exp\left(-\frac{1}{2t} (\kappa^2 + \mu^2) \right) \int_0^{2\pi} d\vartheta \, \exp(i\vartheta) \exp\left(\frac{\kappa\mu}{t} \cos(\vartheta - \psi) \right). \tag{D3}$$

The angular integration yields the modified Bessel function $I_1(\kappa\mu/t)$ [Ref. 26, 3·71.(9) and 6·22.(4)]. The radial integration can then be performed using standard methods [Ref. 26, 13·3.(2)]. Collecting everything, we arrive at

$$\eta(s,t) = \frac{1}{B_k(s)} \det\left[\frac{1}{s_{p1} - is_{q2}} \left(1 - \exp\left(-\frac{s_{p1}^2 + s_{q2}^2}{2t} \right) \right) \right]_{p,q=1,\ldots,k}. \tag{D4}$$

As in the case of complex matrices, this function satisfies the diffusion equation

$$\frac{1}{2} \Delta_s \eta(s,t) = \frac{\partial}{\partial t} \eta(s,t), \tag{D5}$$

where the radial part Δ_s of the Laplacian is defined in Eq. (B19) of Ref. 7. The main results of Ref. 7 do not change due to these additional contributions.

NOTE ADDED IN PROOF

After submission of the manuscript, we learned that our results Eq. (2.3) and Eq. (2.6) were also obtained independently by Jackson, Şener, and Verbaarschot [A. D. Jackson, M. K. Şener, and J. J. M. Verbaarschot (preprint hep-th/9605183)] who also generalized Eq. (2.3) to rectangular ordinary matrices.

Furthermore, we were informed by G. Olshanski that the integral for complex rectangular ordinary matrices had already appeared in a short note in Russian by F. A. Berezin and F. I. Karpelevich [F. A. Berezin and F. I. Karpelevich, Doklady Akad. Nauk SSSR **118**, 9–12 (1958)]. We thank G. Olshanski for sending us this paper and V. Kagalovsky for help with the translation. Our main result Eq. (2.6), however, has not been derived before to the best of our knowledge.

In the meantime, we have also generalized our result Eq. (2.6) to rectangular supermatrices. Let σ be a complex supermatrix whose boson-boson and fermion-fermion blocks have dimension $k_1 \times k_1'$ and $k_2 \times k_2'$, respectively. Such a matrix can only be pseudodiagonalized as $\sigma = usv^{-1}$ if the condition $(k_1' - k_1)(k_2' - k_2) \geqslant 0$ is satisfied. For definiteness, let us assume that $k_1' \geqslant k_1$ and $k_2' \geqslant k_2$ and define $d = k_1' - k_1 - (k_2' - k_2)$, $d_1 = d$, $d_2 = -d$. The Berezinian analogous to (2.26) is then given by

$$J(s) = B_{k_1 k_2}^2(s^2) \prod_{j=1}^{2} \prod_{p=1}^{k_j} s_{pj}^{1+2d_j}. \tag{I}$$

The reduced part of the Laplacian analogous to (2.30) becomes

$$\Delta_s' = \sum_{j=1}^{2} \sum_{p=1}^{k_j} \left(\frac{\partial^2}{\partial s_{pj}^2} + \frac{1 + 2d_j}{s_{pj}} \frac{\partial}{\partial s_{pj}} \right). \tag{II}$$

The integral analogous to (2.6) yields

$$\varphi(s,r) = \frac{(2\pi)^{(k_1 - k_2)(k_1' - k_2')}}{2^{k_1 k_2' + k_1' k_2} k_1! k_2!} \frac{\det[J_{d_1}(s_{p1} r_{p'1})]_{p,p'=1,\ldots,k_1} \det[J_{d_2}(s_{q2} r_{q'2})]_{q,q'=1,\ldots,k_2}}{B_{k_1 k_2}(s^2) B_{k_1 k_2}(r^2) \prod_{j=1}^{2} \prod_{p=1}^{k_j} (s_{pj} r_{pj})^{d_j}}. \tag{III}$$

It should be emphasized that the appearance of additional singularities in the Berezinian (I) gives rise to further contributions to the Efetov–Wegner term $\eta(s,t)$.

(Received 11 March 1996; accepted for publication 4 June 1996)

In this paper we characterize the possible symmetry groups of wave equations and certain evolutionary generalizations, in a single time variable and one or more spatial variables. Furthermore, we describe a complete classification of two-dimensional wave equations $u_{tt}=F[u]$ and potential evolutionary equations $u_{xt}=F[u]$ having a point or contact symmetry group. The results rely on Lie's classification of planar transformation groups and their relative differential invariants. © *1996 American Institute of Physics.* [S0022-2488(96)03211-2]

I. INTRODUCTION

One of the most basic constructions of modern physics is the formulation of field equations (or variational principles) admitting a known symmetry group. It has been known since the days of Sophus Lie that this can be readily done, in the regular case, by assembling suitable combinations of differential invariants of the transformation group. Although Lie's general theorem would appear to completely resolve the issue of classifying differential equations admitting prescribed symmetry groups, a more subtle question has recently been of importance, and cannot be quite so immediately answered. The problem is to classify invariant differential equations of a specified form admitting a prescribed symmetry group. For example, the classification of geometric diffusion equations admitting symmetry groups of visual significance is a problem of importance in computer vision and image processing. In Refs. 1 and 2, a complete classification for subgroups of the projective group was determined. More generally, one can ask for a complete list of invariant evolution equations admitting a prescribed symmetry group, and the latter problem was completely solved in Ref. 3, using the theory of relative invariants. It was found that any transformation group in the field and spatial variables (but fixing the time variable) always admits an infinite collection of invariant evolution equations; see Theorem 4.11 below and also the work of Sokolov.[4] The reason why this problem is not an immediate consequence of the classification of differential invariants for the transformation group in question is that it may not be so evident which combinations of differential invariants, *if any*, can be used to produce the equation having the specified form. In the case of evolution equations, the fact that the time variable introduces an additional coordinate into the picture implies that one needs to compute a new basis of fundamental differential invariants, even when the purely spatial derivative invariants are known.

In this paper, we shall consider the classification of wave equations in both one and several space variables, and a single time variable admitting a prescribed finite-dimensional symmetry group. This problem is of interest in computer vision and other applications, first since one might desire to use hyperbolic, rather than parabolic, processing on an image. A second reason arises in image enhancement, in which one uses a hyperbolic regularization to effect a backwards (and hence ill-posed) parabolic equation (cf. Ref. 5). (See also Ref. 6 for equations of Euler–Poisson–Darboux type.) Since the image smoothing was done in a group-invariant manner, one might reasonably ask for similarly invariant hyperbolic enhancers. Surprisingly, the above-mentioned

0022-2488/96/37(12)/6414/25/$10.00

result for evolution equations is no longer valid—*not* every spatial transformation group admits an invariant hyperbolic wave equation. We determine a complete set of conditions that a transformation group admit an invariant evolutionary or wave equation. Further, using the differential invariants for the groups, completely characterize all possible invariant equations admitted by a symmetry group of the prescribed type. In the planar case (one independent spatial variable and one dependent variable), we then use Lie's complete classification of groups of point and contact transformations in the plane to find a complete list of invariant wave equations.

We shall assume that the reader is familiar with the basic theory of symmetry groups of differential equations, as presented in Refs. 7 and 8. We shall make extensive use of the theory of differential invariants, as presented in the latter book, as well as in Refs. 9 and 10. Since we are relying on Lie's classification of finite-dimensional transformation groups acting on a two-dimensional complex manifold cf. (Refs. 8 and 11); we shall assume that the variables are, in general, complex valued. In the case of point transformation groups, the extension of these results to real differential equations is not difficult. Unfortunately, there is, as far as we know, no complete classification of real groups of contact transformations acting in two dimensions. The present paper can be viewed as a start towards the classification of differential invariants for surfaces under transformation groups in three-dimensional space, where the group acts completely trivially on the time coordinate. In Ref. 12 Lie describes a partial classification of three-dimensional transformation groups, and claims that he has completed it but these results never appeared in print. An important task awaiting completion is the complete classification of the differential invariants of Lie's three-dimensional transformation groups.

II. JET SPACES AND PROLONGATIONS

Before proceeding to a detailed discussion of our results, we need to first review the theory of differential invariants and, more generally, relative differential invariants. Since all our considerations are local, we will not lose any generality by working in Euclidean space. We will consider the total space $E \simeq X \times U$, where, in the cases considered in this paper, $U \simeq \mathbb{R}$ has coordinate u, the scalar-dependent variable, whereas $X \simeq \mathbb{R}^p$, has coordinates $x = (x^1, \dots, x^p)$, representing the spatial independent variables. The nth jet space $\mathrm{J}^n E$ thus has coordinates $(x, u^{(n)})$, where $u^{(n)}$ stands for all partial derivatives

$$u_K = \frac{\partial^k u}{(\partial x^1)^{k_1} \cdots (\partial x^p)^{k_p}}, \quad \text{where} \quad \begin{matrix} K = (k_1, \dots, k_p), \\ k = \#K = k_1 + \cdots + k_p \leqslant n. \end{matrix} \tag{2.1}$$

We will use the basic multi-indices e_i, $i = 0, \dots, p$, which has a single 1 in the ith position and zeros elsewhere. Thus $u_i = u_{e_i} = \partial u / \partial x^i$. Moreover, we write $L \subseteq K$ if all entries of L are less than or equal to those of K, so $0 \leqslant l_j \leqslant k_j$, $j = 0, \dots, p$. Similarly, we write $L \subset K$ if $L \subseteq K$, but $L \neq K$. Note that the difference $K - L$ is a well-defined multi-index if and only if $L \subseteq K$. Finally, we write $\binom{K}{L}$ for the standard multinomial coefficient, which is nonzero provided $L \subseteq K$. A function $F(x, u^{(n)})$ depending on independent and dependent variables and their derivatives is known as a *differential function*, and $n = \operatorname{ord} F$ is its order, which means that F really does depend on nth-order derivatives of u.

We shall consider both point transformation groups, which are local transformation groups $G = G^{(0)}$ acting on the space $E = X \times U$, and contact transformation groups, which, by Bäcklund's Theorem,[13,8] are at most first order, and thus realized as a local transformation group $G^{(1)}$ on the first jet space $\mathrm{J}^1 E$ preserving the contact ideal generated by the contact form $\theta = du - \sum_{i=1}^p u_i dx^i$. In both cases, the group induces a corresponding transformation group $G^{(n)}$ on the nth jet space $\mathrm{J}^n E$, called the nth prolongation of G, which can be uniquely characterized as the nth-order contact transformation group projecting back to the original group action.

We let $\mathfrak{g}$ denote the Lie algebra of G. Consider an infinitesimal generator of the group action

$$\mathbf{v}^{(0)}=\sum_{i=1}^{p}\ \xi^i\ \frac{\partial}{\partial x^i}+\varphi\ \frac{\partial}{\partial u},\tag{2.2}$$

corresponding to the Lie algebra element $\mathbf{v}\in\mathfrak{g}$. In the case of point transformations, the coefficients ξ^i and φ of $\mathbf{v}^{(0)}$ depend on x and u. The group is fiber preserving (or projectable[7]) if $\xi^i=\xi^i(x)$ only depend on the independent variables. Finally, the group consists of *affine bundle maps* if it consists of transformations $(x,u)\mapsto(\Phi(x),A(x)u+B(x))$ which are fiber preserving and affine in the dependent variable u at each point; the infinitesimal generators have $\varphi=\alpha(x)u+\beta(x)$. For instance, most linear partial differential equations have affine bundle symmetry groups. The infinitesimal generators of a contact transformation group have the same form (2.2), but the coefficients ξ^i and φ are allowed to depend on the first-order derivatives of u provided they satisfy the *contact conditions*

$$\frac{\partial\varphi}{\partial u_k}=\sum_{i=1}^{p}\ u_i\ \frac{\partial\xi^i}{\partial u_k},\quad k=1,\ldots,p.\tag{2.3}$$

In all cases, the *characteristic* of the vector field (2.2) is defined to be the first-order differential function

$$Q(x,u^{(1)})=\varphi-\sum_{i=1}^{p}\ \xi^i u_i\,.\tag{2.4}$$

The vector field can be recovered from its characteristic by solving (2.4) for φ and using

$$\xi^i(x,u^{(1)})=-\frac{\partial Q(x,u^{(1)})}{\partial u_i},\tag{2.5}$$

which is a consequence of the contact conditions (2.3), to construct the coefficients ξ^i. The corresponding infinitesimal generator

$$\mathbf{v}^{(n)}=\sum_{i=1}^{p}\ \xi^i\ \frac{\partial}{\partial x^i}+\sum_{\#K\leqslant n}\ \varphi^K\ \frac{\partial}{\partial u_K}\tag{2.6}$$

of $G^{(n)}$ defines the nth prolongation of $\mathbf{v}$, whose coefficients are given by the standard prolongation formula

$$\varphi^K=D_KQ+\sum_{i=1}^{p}\ \xi^i u_{Ki}\,.\tag{2.7}$$

Here D_K is the total derivative corresponding to the multi-index K, and we use the notation $u_{Ki}=u_{K+e_i}=D_iu_K$.

For later reference, we require some elementary formulas for higher-order total derivatives of certain types of differential functions. Both results are easy to prove by induction using Leibniz' rule.

Lemma 2.1: Suppose $\varphi(x,u)$ is a zeroth-order differential function. Then its first and second-order total derivatives have the form

$$D_i\varphi=\frac{\partial\varphi}{\partial u}\ u_i+\frac{\partial\varphi}{\partial x^i},$$

$$D_iD_j\varphi=\frac{\partial\varphi}{\partial u}\,u_{ij}+\frac{\partial^2\varphi}{\partial u^2}\,u_iu_j+\frac{\partial^2\varphi}{\partial u\,\partial x^i}\,u_j+\frac{\partial^2\varphi}{\partial u\,\partial x^j}\,u_i+\frac{\partial^2\varphi}{\partial x^i\partial x^j}. \tag{2.8}$$

Furthermore, for any multi-index K with $k=\#K\geqslant 3$,

$$D_K\varphi=\varphi_u u_K+\sum_{i=1}^{p} k_i(D_i\varphi_u)u_{K-e_i}+F(x,u^{(k-2)}), \tag{2.9}$$

where F is a differential function depending on at most $(k-2)$*nd-order derivatives of u*

Lemma 2.2: Suppose $Q(x,u^{(1)})$ *is a first-order differential function. Then its first- and second-order total derivatives have the form*

$$\begin{aligned} D_iQ&=\sum_{l=1}^{p}\frac{\partial Q}{\partial u_l}\,u_{il}+\frac{\partial Q}{\partial u}\,u_i+\frac{\partial Q}{\partial x^i},\\ D_iD_jQ&=\sum_{l=1}^{p}\frac{\partial Q}{\partial u_l}\,u_{ijl}+\sum_{l,m=1}^{p}\frac{\partial^2 Q}{\partial u_l\partial u_m}\,u_{il}u_{jm}+\frac{\partial Q}{\partial u}\,u_{ij}\\ &\quad+\sum_{l=1}^{p}\left(\frac{\partial^2 Q}{\partial u_l\partial u}\,(u_ju_{il}+u_iu_{jl})+\frac{\partial^2 Q}{\partial u_l\partial x^i}\,u_{jl}+\frac{\partial^2 Q}{\partial u_l\partial x^j}\,u_{il}\right)+R(x,u^{(1)}), \end{aligned} \tag{2.10}$$

where R is a first-order differential function. Furthermore, for any multi-index K with $k=\#K\geqslant 3$,

$$D_KQ=\sum_{l=1}^{p}\frac{\partial Q}{\partial u_l}\,u_{Kl}+Q_uu_K+\sum_{i,l=1}^{p}k_iD_i\left(\frac{\partial Q}{\partial u_l}\right)u_{K-e_i+e_l}+R(x,u^{(k-1)}), \tag{2.11}$$

where R is a differential function depending on at most $(k-1)$*st-order derivatives of u*.

Note that in both sets of formulas, the multi-indices of orders 1 and 2 do not fit into the general higher-order pattern.

III. RELATIVE DIFFERENTIAL INVARIANTS

Throughout this section, we let G be a transformation group (either point or contact) acting via prolongation on the jet spaces J^nE over a bundle $E=X\times U$. Recall that an (absolute) differential invariant is an invariant differential function for a prolonged group action. A differential operator is said to be G-invariant if it maps differential invariants to higher-order differential invariants, and thus, by iteration, produces hierarchies of differential invariants of arbitrarily large order. A general theorem guarantees the existence of sufficiently many such differential operators so as to completely generate all the higher-order independent differential invariants of the group by successively differentiating lower-order differential invariants. Thus, a complete description of all the differential invariants is provided by a collection of low-order ''fundamental'' differential invariants along with the requisite invariant differential operators.

Theorem 3.1: *Suppose that G is a group of point or contact transformations. Then there exist* $p=\dim X$ *invariant differential operators* $\mathscr{D}_1,\ldots,\mathscr{D}_p$, *and a system of fundamental differential invariants* $J_1,\ldots,J_m$, *such that, locally, every differential invariant can be written as a function of the iterated derivatives* $\mathscr{D}_{j_1}\ldots\mathscr{D}_{j_\kappa}J_\nu$.

A relative differential invariant is, roughly speaking, a differential function which is invariant, up to a factor, under the prolonged group action. The theory of relative differential invariants is a particular case of the general theory of relative invariants of transformation group actions, in which the group acts by prolongation on a suitable jet space (cf. Ref. 8). See Ref. 14 for a detailed development and recent results describing general classification of relative invariants.

Definition 3.2: A differential multiplier of order n is a linear map $\mathbf{v}\mapsto H_{\mathbf{v}}(x,u^{(n)})$ that maps each Lie algebra element $\mathbf{v}\in\mathfrak{g}$ to a differential function $H_{\mathbf{v}}(x,u^{(n)})$, and satisfies the *cocycle condition*

$$\mathbf{v}^{(n)}(H_{\mathbf{w}}(x,u^{(n)}))-\mathbf{w}^{(n)}(H_{\mathbf{v}}(x,u^{(n)}))=H_{[\mathbf{v},\mathbf{w}]}(x,u^{(n)}). \tag{3.1}$$

The cocycle condition (3.1) implies that the associated infinitesimal generators of the differential multiplier representation

$$\mathscr{D}_{\mathbf{v}}=\mathbf{v}^{(n)}-H_{\mathbf{v}}(x,u^{(n)}) \tag{3.2}$$

form a Lie algebra of first-order differential operators on J^nE having the same commutation relations as the Lie algebra $\mathfrak{g}$. In this paper, we only need consider scalar multipliers, although extensions to matrix-valued multipliers are straightforward.[14,8]

Definition 3.3: A differential function $R(x,u^{(n)})$ is called a *relative differential invariant* for the differential multiplier $H_{\mathbf{v}}$ if it satisfies

$$\mathscr{D}_{\mathbf{v}}(R)=\mathbf{v}^{(n)}(R)-H_{\mathbf{v}}\cdot R=0, \quad \text{for all} \quad \mathbf{v}\in\mathfrak{g}. \tag{3.3}$$

Thus ordinary (or absolute) differential invariants are relative differential invariants for the trivial differential multiplier $H_{\mathbf{v}}\equiv 0$. Note that if R is a relative differential invariant for the multiplier $H_{\mathbf{v}}$ and S is a relative differential invariant for the multiplier $K_{\mathbf{v}}$, then the product $R\cdot S$ is a relative differential invariant for the sum $H_{\mathbf{v}}+K_{\mathbf{v}}$. If R_0 is one particular relative differential invariant of weight $H_{\mathbf{v}}$, then every other such relative differential invariant has the form $R=IR_0$, where I is an arbitrary absolute differential invariant.

Relative differential invariants can be used to construct invariant differential equations. The following result is standard; see Ref. 14 for a proof and Ref. 15 for additional applications.

Theorem 3.4: *A regular partial differential equation $\Delta(x,u^{(n)})=0$ admits G as a symmetry group if and only if Δ is a relative differential invariant for some differential multiplier of G.*

Proposition 3.5: Suppose $R(x,u^{(n)})$ is a relative differential invariant of weight $H_{\mathbf{v}}$. Then the partial differential equation $R(x,u^{(n)})=S(x,u^{(n)})$ admits G as a symmetry group if and only if $S(x,u^{(n)})$ is also a relative differential invariant of weight $H_{\mathbf{v}}$.

The existence of relative differential invariants of sufficiently high order is a consequence of general results in Refs. 8 and 10; see also Ref. 14 for generalizations. Recall that a group is said to act *effectively freely* on the manifold M if the quotient group G/G_0 of G by its global isotropy subgroup $G_0=\{g\in G\,|\,g\cdot x=x \text{ for all } x\in M\}$ acts freely.

Theorem 3.6: *Let $H_{\mathbf{v}}(x,u^{(n)})$ be an nth-order differential multiplier. If $G^{(n)}$ acts effectively freely on (an open subset of) J^nE, then there exists a nontrivial relative invariant of weight $H_{\mathbf{v}}$.*

The next theorem is originally due to Ovsiannikov;[10] see also Ref. 8.

Theorem 3.7: *If G is a local transformation group on E, then, for n sufficiently large, G acts effectively freely on the open subset of J^nE where its orbits have maximal dimension.*

Combining Theorems 3.6 and 3.7, we conclude that any transformation group admits a nontrivial relative differential invariant, provided we allow it to have a sufficiently high order.

Theorem 3.8: *Any differential multiplier $H_{\mathbf{v}}(x,u^{(n)})$ of a transformation group G admits a nonzero relative invariant $R_0(x,u^{(m)})\not\equiv 0$. Moreover, every other relative invariant of weight $H_{\mathbf{v}}$ has the form $R=I\cdot R_0$, where I is an arbitrary absolute differential invariant of G.*

Example 3.9: The total divergence multiplier $D_{\mathbf{v}}$ is defined as the total divergence of the independent variable coefficients of the infinitesimal generator (2.2), so that

$$D_{\mathbf{v}}=\operatorname{Div}\boldsymbol{\xi}=\sum_{i=1}^{p} D_i\xi^i. \tag{3.4}$$

The total divergence multiplier arises in the study of invariant variational problems. The standard infinitesimal invariance criterion[7] that G be a strict variational symmetry group (i.e., without divergence terms) of a variational problem $\int L(x,u^{(n)})dx$ is

$$\mathbf{v}^{(n)}(L)+L\ \mathrm{Div}\ \boldsymbol{\xi}=0. \tag{3.5}$$

However, (3.5) is just the condition that the Lagrangian $L(x,u^{(n)})$ is a relative differential invariant for the negative total divergence multiplier $\widetilde{D}_{\mathbf{v}}=-\mathrm{Div}\ \boldsymbol{\xi}$. For example, if $X=\mathbb{R}^2$, then the usual surface area integral,

$$\mathscr{S}[u]=\int \sqrt{1+u_x^2+u_y^2}\,dx\wedge dy, \tag{3.6}$$

clearly admits the Euclidean group $G=\mathrm{E}(3)$, consisting of translations and rotations in the three-dimensional space coordinatized by (x,y,u), as a symmetry group. This means that $S=\sqrt{1+u_x^2+u_y^2}$ is a relative differential invariant for $D_{\mathbf{v}}=-D_x\xi-D_y\eta$, corresponding to the infinitesimal generator $\mathbf{v}^{(0)}=\xi\partial_x+\eta\partial_y+\varphi\partial_u$.

Example 3.10: A second important differential multiplier is the *characteristic multiplier*

$$K_{\mathbf{v}}=Q_u, \tag{3.7}$$

where $Q(x,u^{(1)})$ is the characteristic of the vector field (2.2) given in (2.4). The importance of this differential multiplier lies in its connection with the Euler–Lagrange equations for invariant variational problems. See Refs. 8 and 3 for the proof of the following result.

Theorem 3.11: *Let G be a transformation group. Suppose that $\int L(x,u^{(n)})dx$ is a G-invariant variational problem, so that L is a relative differential invariant for the total divergence multiplier. Then its Euler–Lagrange expression* $\mathrm{E}(L)$ *is a relative differential invariant of weight* $-Q_u-\mathrm{Div}\ \boldsymbol{\xi}$.

If one chooses the G-invariant volume element $\int L\,dx$ as the invariant variational problem, then the Euler–Lagrange equation forms the G-invariant minimal hypersurface equation in E. For example, if $G=\mathrm{E}(3)$ is the Euclidean group in $\mathbb{R}^3$, then the Euler–Lagrange equation for the surface area integral (3.6) is the standard (Euclidean-invariant) three-dimensional minimal surface equation

$$0=\mathrm{E}(S)=-D_x(S_{u_x})-D_y(S_{u_y})=\frac{-(1+u_y^2)u_{xx}+2u_xu_yu_{xy}-(1+u_x^2)u_{yy}}{(1+u_x^2+u_y^2)^{3/2}}.$$

The right-hand side of this equation is a relative invariant of weight $-Q_u-D_x\xi-D_y\eta$.

Using the multiplicative property of relative invariants, we readily establish the following useful result.

Corollary 3.12: Every relative invariant for the characteristic multiplier $K_{\mathbf{v}}=Q_u$ has the form

$$F=\frac{L}{\mathrm{E}(L)}\,I, \tag{3.8}$$

where I is an arbitrary differential invariant of G, and $\int L(x,u^{(n)})dx$ is a G-invariant variational problem having nontrivial Euler–Lagrange expression $\mathrm{E}(L)\not\equiv 0$.

IV. INVARIANCE CONDITIONS

Our primary purpose is determining symmetry groups of evolutionary-type equations, and so we shall extend the preceding considerations to include an additional independent variable, the ''time'' t. Now, the total space is $\hat{E}\simeq\mathbb{R}\times E\simeq Z\times U$, where $U\simeq\mathbb{R}$ has coordinate u, whereas

$Z \simeq \mathbb{R}\times\mathbb{R}^p$ has coordinates $t=x^0$, representing time, and $x=(x^1,\dots,x^p)$, representing the spatial independent variables. The nth jet space $\mathrm{J}^n\hat{E}$ thus has coordinates[16] $(x,u^{[n]})$, where $u^{[n]}$ stands for all partial derivatives

$$u_K=\frac{\partial^k u}{(\partial t)^{k_0}(\partial x^1)^{k_1}\cdots(\partial x^p)^{k_p}}, \quad \text{where} \quad \begin{matrix} K=(k_0,k_1,\dots,k_p), \\ k=\#K=k_0+k_1+\cdots+k_p\leqslant n. \end{matrix} \tag{4.1}$$

In this framework, an nth-order *evolution equation* is a partial differential equation of the form

$$u_t=F[u], \tag{4.2}$$

where $F:\mathrm{J}^nE\to\mathbb{R}$ is a smooth differential function, depending on spatial derivatives of u up to order n. More generally, we consider higher-order *evolutionary-type equations*

$$u_K=F[u], \tag{4.3}$$

where $K=L+e_0$ is a multi-index that contains at least one time derivative in it, so $k_0\geqslant 1$, and F is again a spatial differential function. Particular cases include the *wave equation*

$$u_{tt}=F[u], \tag{4.4}$$

where $K=2e_0=(2,0,\dots,0)$, and the *potential evolution equation*

$$\frac{\partial^2 u}{\partial t\,\partial x^i}=u_{it}=F[u], \tag{4.5}$$

where $K=e_0+e_i$. Note that differentiating the evolution equation (4.2) with respect to x^i, or replacing u by its ith potential function $u\mapsto u_i$, will convert (4.2) into an equation of the form (4.5). In each of these examples, one could, of course, go further and allow F to also depend on some lower-order temporal derivatives of u; for example, one might allow the right-hand side of the wave equation (4.4) to depend on u_t. However, for most of our results, we will restrict attention to purely spatial right-hand sides; extensions will be briefly discussed in Sec. VI.

We are interested in classifying the *spatial* symmetry groups of such evolutionary-type equations. The restriction to spatial implies that the time variable t is not affected by the group transformations, and so we consider a connected Lie group G of either point or contact transformations, which acts on the space $E=X\times U$ of spatial coordinates, and hence determines the corresponding spatially prolonged actions $G^{(n)}$ on the jet space J^nE. In addition, one can include the time t as an additional variable not affected by the group transformations, and thus induce a temporal prolongation $G^{[n]}$ acting on the extended jet space $\mathrm{J}^n\hat{E}$. In the point transformation case, this is found by prolonging the extended action $(t,x,u)\mapsto(t,g\cdot(x,u))$ on $\hat{E}\simeq\mathbb{R}\times E$; in the case of contact transformations, we extend the action to $\mathrm{J}^1\hat{E}\simeq\mathbb{R}^2\times\mathrm{J}^1E$, so that the t variable is not affected, while the action on the time derivative coordinate u_t is determined by the chain rule:

$$\overline{u_t}=\left(\frac{\partial\Phi}{\partial u}-\sum_{i=1}^{p}\overline{u_i}\,\frac{\partial\Xi^i}{\partial u}\right)u_t, \quad \text{where} \quad \begin{matrix} \overline{t}=t, & \overline{x^i}=\Xi^i(x,u^{(1)}), \\ \overline{u}=\Phi(x,u^{(1)}), & \overline{u_i}=\Psi_i(x,u^{(1)}). \end{matrix} \tag{4.6}$$

In this manner, a contact transformation on J^1E extends in a natural way to a contact transformation on $\mathrm{J}^1\hat{E}$.

Given a Lie algebra element $\mathbf{v}\in\mathfrak{g}$, the corresponding infinitesimal generator $\mathbf{v}^{(0)}$ is a spatial vector field, as in (2.2), whose extended action on $\hat{E}=\mathbb{R}\times E$ has the same form, $\mathbf{v}^{[0]}=\mathbf{v}^{(0)}$, since the time variable is not changed. Let $\mathbf{v}^{[n]}$ denote the nth prolongation of $\mathbf{v}$ to $\mathrm{J}^n\hat{E}$. Note that, according

to the prolongation formula, the coefficients of temporal and mixed derivatives in $\mathbf{v}^{[n]}$ are *not* necessarily trivial even though t is unaffected by the group transformations; for instance, using (2.5), the coefficient of ∂_{u_t} is

$$\varphi^t = D_t Q + \sum_{i=1}^{p} \xi^i u_{it} = Q_u u_t . \tag{4.7}$$

Thus $\mathbf{v}^{[1]}(u_t) = Q_u u_t$, and we discover that u_t is a relative differential invariant for the characteristic multiplier Q_u. Proposition 3.5 thus implies that the evolution equation (4.2) admits G as a symmetry group if and only if the right-hand side $F[u]$ is also a relative differential invariant of weight Q_u. Combining this observation with the characterization of such relative differential invariants in Corollary 3.12 produces the main result of Ref. 3.

Theorem 4.1: *An evolution equation $u_t = F[u]$ admits the connected spatial transformation group G as a symmetry group if and only if F is a relative invariant of weight Q_u, and hence of the form (3.8).*

In particular, every spatial transformation group admits an invariant evolution equation! The most effective method for analyzing the symmetry groups of differential equations is by use of infinitesimal generators. Our starting point is the standard infinitesimal invariance criterion for differential equations.

Theorem 4.2: *An evolutionary-type equation $u_K = F$ admits a connected transformation group G as a symmetry group if and only if*

$$\mathbf{v}^{[n]}(u_K - F) = 0 \quad \text{whenever} \quad u_K = F. \tag{4.8}$$

We proceed to analyze this criterion for spatial transformation groups. The prolongation formula (2.6), coupled with (2.7) and (2.4), implies that we can replace (4.8) by

$$D_K Q + \sum_{i=1}^{p} \xi^i u_{Ki} = \mathbf{v}^{(n)}(F) \quad \text{whenever} \quad u_K = F. \tag{4.9}$$

Recall that $k = \#K$ is the order of K, which contains at least one t derivative. Note first that the left-hand side of (4.9) does not contain any terms involving derivatives of order $k+1$ since the terms $\xi^i u_{Ki}$ cancel the corresponding terms obtained by differentiating the characteristic. [This still holds for contact transformations due to the contact conditions (2.5).]

We begin by assuming that K has order $k = \#K \geqslant 3$, postponing the analysis of the second-order cases, namely the wave equation (4.4) and potential evolution equations (4.5), until later. However, unless specifically stated otherwise, the intervening theorems also apply to second-order equations, albeit with slightly different proofs. For $\#K \geqslant 3$, according (2.11), the only terms on the left-hand side of (4.9) which involve derivatives of order k are

$$Q_u u_K - \sum_{i=1}^{p} \sum_{j=0}^{p} k_j (D_j \xi^i) u_{K - e_j + e_i}, \tag{4.10}$$

where we have used (2.5) to identify the derivatives of the characteristic with respect to the derivative variables u_i. On solutions to (4.3) we can replace u_K by F, and hence the terms involving u_K in (4.10) only depend on spatial derivatives of u. On the other hand, because the coefficients φ and ξ^i do not depend on t, all other terms on the left-hand side of (4.9) will involve at least one temporal derivative of u, which cannot be replaced by a spatial derivative. Therefore, the infinitesimal invariance condition (4.9) splits into three components. The first part contains only spatial derivatives of u, and is obtained by equating the terms involving u_K in (4.10) to the right-hand side of (4.9), leading to our first key result.

Theorem 4.3: *If the evolutionary-type equation $u_K = F[u]$ admits a spatial symmetry group G, then the right-hand side satisfies*

$$\mathbf{v}^{(n)}(F) = \left(Q_u - \sum_{i=1}^{p} k_i D_i \xi^i \right) F, \quad \text{for all} \quad \mathbf{v} \in \mathfrak{g}. \tag{4.11}$$

Thus, Eq. (4.11) says that the right-hand side F of an invariant differential equation of evolutionary type forms a relative differential invariant for the differential multiplier

$$H^K_{\mathbf{v}}(x, u^{(2)}) = Q_u - \sum_{i=1}^{p} k_i D_i \xi^i. \tag{4.12}$$

In particular, the order of t differentiation on the left-hand side of the equation does not affect the type of relative invariant that the right-hand side assumes.

Corollary 4.4: If a purely temporal evolutionary-type equation,

$$\frac{\partial^n u}{\partial t^n} = F[u], \tag{4.13}$$

admits G as a symmetry group, then F is relative invariant of weight Q_u, and hence of the form (3.8).

Thus if (4.13) admits G, then so does the evolution equation (4.2) with the same right-hand side. The converse, though, is *not* true since there are additional invariance conditions that (4.13) must satisfy that are not required for the invariance of the simple evolution equation (4.2). The additional terms on the left-hand side of the infinitesimal condition (4.9) will end up providing fairly severe restrictions on the types of transformation groups which have, say, invariant wave equations.

Corollary 4.5: If an equation of the form (4.13) admits a symmetry group G, then the corresponding evolution equation $u_t = F$ is also G-invariant. The converse holds provided G fulfills the symmetry conditions in Theorem 4.11 below.

The second set of invariance conditions arise from the other kth-order terms in (4.10), which are equated to 0. We find

$$D_j \xi^i = 0, \quad \text{whenever} \quad k_j > 0, \quad j = 0, \dots, p, \quad j \neq i. \tag{4.14}$$

In particular, $k_0 \geqslant 1$ by assumption, and hence (4.14) implies $D_t \xi^i = 0$, $i = 1, \dots, p$. This automatically requires that $\xi^i = \xi^i(x)$ depends only on the spatial variables, and hence the symmetry group is fiber preserving.

Proposition 4.6: If G is a symmetry group of an evolutionary-type equation (4.3) with left-hand side of order $\#K \geqslant 3$, then G is necessarily a fiber-preserving transformation group.

$$Q(x, u^{(1)}) = \varphi(x, u) - \sum_{i=1}^{p} \xi^i(x) u_i. \tag{4.15}$$

Given a multi-index $K = (k_0, k_1, \dots, k_p)$, let us divide the spatial variables into two sets: the *principal spatial variables*, which are those appearing in the derivative u_K, and the *parametric spatial variables*, which are all the rest. Thus x^j, $1 \leqslant j \leqslant p$, is principal if $k_j > 0$, and parametric if $k_j = 0$. In particular, for the purely temporal evolutionary-type equation (4.13), all spatial variables are parametric. For notational convenience, let us number the spatial variables so that the first s, namely $x^1, \dots, x^s$, are principal, while the remainder $x^{s+1}, \dots, x^p$ are parametric.

Proposition 4.7: Suppose G is a symmetry group of an evolutionary-type equation $u_K = F[u]$ in which $\#K \geqslant 3$. Let $\mathbf{v} \in \mathfrak{g}$ determine an infinitesimal generator (2.2). Then the coefficients $\xi^{s+1},\dots,\xi^p$ corresponding to the parametric spatial variables $x^{s+1},\dots,x^p$ depend only on parametric variables:

$$\xi^i = \xi^i(x^{s+1},\dots,x^p), \quad i = s+1,\dots,p, \tag{4.16}$$

while the coefficients corresponding to the principal spatial variables $x^1,\dots,x^s$ have the form

$$\xi^i = \xi^i(x^i,x^{s+1},\dots,x^p), \quad i = 1,\dots,s. \tag{4.17}$$

Proposition 4.7 allows us to properly justify the statement in Theorem 4.3. In fact, if G is an arbitrary spatial transformation group, then the function (4.12) is, in fact, not an infinitesimal multiplier. However, the additional conditions contained in Proposition 4.7 are precisely those needed to make (4.12) satisfy the infinitesimal multiplier conditions (3.1). Indeed, we can readily produce a basic relative invariant that is associated with (4.12).

Proposition 4.8: Let us split the independent variables into parametric and principal variables in accordance with the multi-index K. Suppose G is a spatial transformation group satisfying the conditions in Proposition 4.7. Suppose that

$$\omega = \sum_{i=1}^{p} A_i(x,u^{(n)})\,dx^i \tag{4.18}$$

is a G-invariant one-form. Then, for each principal variable x^i, the coefficient A_i satisfies[17]

$$\mathbf{v}^{(n)}(A_i) + (D_i\xi^i)A_i = 0, \tag{4.19}$$

and hence defines a relative invariant of weight $-D_i\xi^i$.

Proof: The infinitesimal invariance conditions for a horizontal one-form (4.18) on J^n (up to contact forms—see Ref. 8) are

$$0 = \mathbf{v}^{(n)}(\omega) = \sum_{i=1}^{p} \{\mathbf{v}^{(n)}(A_i)\,dx^i + A_i \mathrm{D}\xi^i\}, \tag{4.20}$$

where

$$\mathrm{D}\xi^i = \sum_{j=1}^{p} D_j\xi^i\,dx^j \tag{4.21}$$

is the total (or horizontal) differential of ξ^i. On the other hand, according to the conditions (4.14), for any principal variable x^i, only the term when $j = i$ contributes to the coefficient of dx^i. Therefore, the coefficient of dx^i in (4.20) is precisely the left-hand side of (4.19). Q.E.D.

Theorem 4.9: *If the evolutionary-type equation $u_K = F[u]$ admits a spatial symmetry group G, then its right-hand side is necessarily of the form*

$$F = \frac{A^K L}{\mathrm{E}(L)}\, I. \tag{4.22}$$

Here I is an arbitrary absolute differential invariant, $\int L(x,u^{(n)})\,dx$ is a G-invariant variational problem with Euler–Lagrange expression $\mathrm{E}(L) \not\equiv 0$, and $\omega = A_1\,dx^1 + \cdots + A_p\,dx^p$ is a G-invariant one-form, such that the product

$$A^K=\prod_{i=1}^{s}(A_i)^{k_i}\not\equiv 0.$$

It is worth reemphasizing at this point that not every spatial transformation group admits an invariant evolutionary-type equation of a prescribed form. For equations in more than two spatial variables, Proposition 4.7 provides some restrictions on the types of symmetry groups allowed. Further restrictions are obtained by analyzing the lower-order terms in the infinitesimal invariance conditions (4.9).

We have already analyzed the terms depending on kth-order derivatives. All remaining terms in (4.8) must vanish since they involve lower-order temporal derivatives of u. We number the spatial variables so that $x^1,\dots,x^s$ are the principal variables, and $x^{s+1},\dots,x^p$ are the parametric variables. We now use Leibniz' rule and (2.9) to find that the terms involving derivatives of order $k-1$ are

$$\sum_{i=0}^{p} k_i(D_i\varphi_u)u_{K-e_i}-\sum_{j=1}^{p}\binom{k_j}{2}(D_j^2\xi^j)u_{K-e_j}=0. \tag{4.23}$$

In particular, setting $i=0$ in the first summation shows that $D_t\varphi_u=0$, and hence

$$\varphi(x,u)=\eta(x)u+\sigma(x). \tag{4.24}$$

This implies that the group consists of affine bundle maps.

Proposition 4.10: A connected symmetry group of an evolutionary-type equation which is not an evolution equation or a potential evolution equation consists of affine bundle maps.

(The case of a wave equation will be demonstrated later.) The additional terms in (4.23) imply that

$$\frac{\partial\eta}{\partial x^i}=\frac{k_i-1}{2}\frac{\partial^2\xi^i}{(\partial x^i)^2},\quad k_i\neq 0. \tag{4.25}$$

In the ordinary case, the group is fiber preserving, and so hence, in terms of the principal variables,

$$\eta(x)=\sum_{i=1}^{s}\frac{k_i-1}{2}\frac{\partial\xi^i}{\partial x^i}+\zeta(x^{s+1},\dots,x^p). \tag{4.26}$$

Furthermore, if $k_i\geqslant 2$, then the $(k-2)$nd-order derivative u_{K-2e_i} in (4.9) has coefficient

$$\binom{k_i}{2}D_i^2\eta=\binom{k_i}{3}D_i^3\xi^i,\quad \text{or}\quad D_i^2\eta=\frac{k_i-2}{3}D_i^3\xi^i,\quad k_i\geqslant 2. \tag{4.27}$$

However, differentiating (4.25) and subtracting, we find

$$D_i^3\xi^i=0,\quad \text{whenever}\quad k_i\geqslant 2. \tag{4.28}$$

Therefore

$$\xi^i=\alpha^i(x^i)^2+\beta^i x^i+\gamma^i,\quad k_i\geqslant 2, \tag{4.29}$$

where α^i, β^i, and γ^i are functions of the parametric variables $x^{s+1},\dots,x^p$ only. This implies all the lower-order derivative terms are also zero; indeed the only term left unaccounted for is $D_K\sigma=0$; but this is automatic since σ only depends on spatial coordinates and K contains at least

one time derivative. We have completed our analysis of the infinitesimal symmetry conditions (4.8) for $\#K \geqslant 3$, and therefore characterized the possible symmetry groups for higher-order evolutionary-type equations.

The analysis in the second-order cases proceeds similarly. The wave equation case (4.4) is completely analogous, using (2.8) and (2.10) instead of the higher-order counterparts, and left to the reader. On the other hand, if the equation is a potential evolution equation, (4.5) (with $i=1$ for consistency in notation), then the conditions arising from second-order derivatives in (4.9) require

$$\frac{\partial^2 Q}{\partial u_l \partial u_m} = \frac{\partial^2 Q}{\partial u_l \partial x^1} = 0 \quad \text{whenever} \quad l, m \neq 1,$$

whereas

$$\frac{\partial^2 Q}{\partial u \partial u_j} = \frac{\partial^2 Q}{\partial u^2} = \frac{\partial^2 Q}{\partial u \partial x^1} = 0 \qquad \text{for} \quad \text{all} \quad j = 1, \dots, p.$$

These imply that the characteristic must have the special form

$$Q(x, u^{(1)}) = \theta(x, u_1) + \zeta(x^2, \dots, x^p) u - \sum_{i=2}^{p} \xi^i(x^2, \dots, x^p) u_i . \tag{4.30}$$

Therefore, potential evolution equations can admit contact symmetry groups, but only of a very special type, with infinitesimal generators of the form

$$-\frac{\partial \theta}{\partial u_1} \frac{\partial}{\partial x^1} + \sum_{i=2}^{p} \xi^i(x^2, \dots, x^p) \frac{\partial}{\partial x^i} + \left[\zeta(x^2, \dots, x^p) u + \theta(x, u_1) + u_1 \frac{\partial \theta}{\partial u_1} \right] \frac{\partial}{\partial u}. \tag{4.31}$$

We have thus completed our analysis of the infinitesimal symmetry conditions (4.8), and have thus proved the following general result governing the possible symmetry groups of evolutionary-type equations.

Theorem 4.11: *Let G be a connected spatial transformation group, and suppose that $u_K = F[u]$, $k_0 > 0$, is an evolutionary-type equation admitting G as a symmetry group. Assume that $x^1, \dots, x^s$ are the principal variables, and $x^{s+1}, \dots, x^p$ are the parametric variables.*

(i) *If the equation is an evolution equation, $u_t = F$, then there are no conditions on G.*

(ii) *If the equation is a potential evolution equation, $u_{xt} = F$, where $x = x^1$, then G can be a contact transformation group whose generators have the form (4.31).*

(iii) *In all other cases, the group is necessarily a group of affine bundle maps, whose infinitesimal generators have coefficients of the form (4.16), (4.17), (4.24), and (4.26). Moreover, if the left-hand side contains a principal derivative having order 2 or more, i.e., $k_i \geqslant 2$, then the corresponding coefficient has the form (4.29).*

In all cases, a group G of the prescribed form does admit a nontrivial invariant evolutionary-type equation $u_K = F_0$ with $F_0 \not\equiv 0$ a relative invariant of weight (4.12) as given in (4.22). Moreover, the most general G-invariant equation of this form is $u_K = I F_0$, where I is an arbitrary absolute differential invariant of G.

Proof: The only part left to demonstrate is the existence of a suitably invariant evolution equation. This follows from the general existence result for relative invariants given in Theorem 3.8. Q.E.D.

Remark: The equation $u_K = 0$ is invariant under any transformation group that meets the invariance conditions in Theorem 4.11.

Remark: If the right-hand side of an evolutionary-type equation is nontrivial, $F \not\equiv 0$, then u_K/F is an (absolute) differential invariant of the group G acting on $\mathrm{J}^n\hat{E}$.

A useful observation is that in every case, the symmetry group admits an invariant foliation, namely that provided by the vertical fibration $\{x=c\}$ of either E or, in the contact case, J^1E, and hence, by definition, must form an imprimitive group of transformations on E. Indeed, Proposition 4.7 implies that the group is ''multiply imprimitive'' since any collection of independent variables that includes all the parametric variables also defines an invariant foliation.

Proposition 4.12: Any connected symmetry group of an evolutionary-type equation $u_K=F[u]$ which is not *an evolution equation is necessarily an imprimitive transformation group.*

This result is of great value in simplifying the classification procedure, since it allows us to immediately eliminate many geometrically important transformation groups (which tend to act primitively) from consideration.

An alternative mechanism for generating invariant evolutionary-type equations whose left-hand sides have higher-order spatial derivatives is by differentiating lower-order equations of evolutionary type. The preceding remark shows how this may be used to provide alternative absolute temporal differential invariants.

Theorem 4.13: *If the evolutionary-type equation $u_K=F[u]$ admits a spatial symmetry group G, then any spatial derivative $u_{K+L}=D_LF$, where $l_0=0$, also admits G as a symmetry group provided G satisfies the restrictions for the differentiated evolutionary-type equation prescribed in Theorem 4.11.*

Proof: This is a direct consequence of the standard commutation formula

$$\mathbf{v}^{(n+1)}\cdot D_i = D_i\cdot \mathbf{v}^{(n)} - \sum_{j=1}^{p} (D_i\xi^j) D_j, \tag{4.32}$$

between prolonged vector fields and total derivatives (cf. Ref. 7). Suppose $L=e_i$, so that x^i is now a principal variable for $K+L=K+e_i$, whether or not it was one for K. Assume first that G satisfies the conditions of Proposition 4.7, with K replaced by $K+L=K+e_i$. Thus, if F satisfies (4.11), then (4.8) implies

$$\begin{aligned}\mathbf{v}^{(n+1)}D_iF = D_i\mathbf{v}^{(n)}(F) - (D_i\xi^i)D_iF &= D_i\left[\left(Q_u - \sum_{j=1}^{p} k_j D_j\xi^j\right)F\right] - (D_i\xi^i)D_iF \\ &= \left(Q_u - \sum_{j=1}^{p} l_j D_j\xi^j\right)D_iF + [D_i\phi - k_iD_i^2\xi^i]F. \end{aligned}\tag{4.33}$$

Now (4.25), which, according to our hypothesis, must hold with k_i replaced by $l_i=k_i+1$, implies that the coefficient of F in the final term in (4.33) vanishes, and so D_iF is a relative invariant of the correct weight for the multi-index L [cf. (4.12)]. Q.E.D.

An interesting question is how to connect this approach with that in Theorem 4.9.

V. CLASSIFICATION IN ONE SPACE DIMENSION

The previous sections dealt with the general theory of invariant equations of evolutionary type in multidimensional space. We now restrict our attention to evolutionary-type equations in one space dimension, so that $p=1$ and there is a single spatial variable, x. The advantage here is that the spatial transformation groups act on a two-dimensional space $E\simeq\mathbb{R}^2$, or, in the complex case $E\simeq\mathbb{C}^2$, and hence we can use Lie's classification of transformation groups acting on two-dimensional manifolds—see the Tables below, which are based on Ref. 11, as simplified in Ref. 8. Our goal now is to classify *all* the invariant equations in a single spatial variable for each of the finite-dimensional transformation groups in the plane. (We leave aside the classification of equations admitting infinite-dimensional pseudo-groups, since, by a linearization theorem of Bluman

and Kumei,[18,8] most of these differential equations can be linearized.) For simplicity, we restrict to the complex case here, although extensions to the five additional real forms[19,8] are readily done utilizing the same methods.

Thus we consider an evolutionary-type equation

$$u_{mn}=\frac{\partial^{m+n}u}{\partial x^m \partial t^n}=F[u], \tag{5.1}$$

where $n\geqslant 1$, and F depends on x, u, and the spatial derivatives $u_k=D_x^k u$ of u. The symmetry generators are vector fields of the form

$$\mathbf{v}^{(0)}=\xi(x,u,u_x)\partial_x+\sigma(x,u,u_x)\partial_u, \tag{5.2}$$

where the dependence on the derivative $u_x=u_1$ allows us to also admit contact transformation groups. Let $N=\max\{m+n,\operatorname{ord} F\}$ denote the order of the partial differential equation (5.1). Let us begin by restating our basic Theorem 4.11 in the scalar spatial case.

Theorem 5.1: *Let G be a connected spatial transformation group acting on $E=X\times U\simeq\mathbb{R}^2$ which is a symmetry group of an evolutionary-type equation (5.1).*

(i) *$m=0$, $n=1$: If the equation is an evolution equation, $u_t=F$, then there are no conditions on G.*

(ii) *$m=0$, $n\geqslant 2$: If the equation is purely evolutionary, i.e., of the form $\partial^n u/\partial t^n=F$, then the infinitesimal generators of G have the form*

$$\mathbf{v}^{(0)}=\xi(x)\partial_x+[\eta(x)u+f(x)]\partial_u, \tag{5.3}$$

where ξ,η,f are functions of x.

(iii) *$m=1$, $n=1$: If the equation is a potential evolution equation, $u_{xt}=F$, then G can be a contact transformation group whose infinitesimal generators have the form*

$$\mathbf{v}^{(0)}=\xi(x,u_x)\partial_x+[ku+\theta(x,u_x)]\partial_u, \tag{5.4}$$

where k is a constant.

(iv) *$m=1$, $n\geqslant 2$: If the equation is the potential form of a higher-order purely evolution equation, $u_{xn}=F$ with $n\geqslant 2$, then the infinitesimal generators of G have the form*

$$\mathbf{v}^{(0)}=\xi(x)\partial_x+[ku+f(x)]\partial_u, \tag{5.5}$$

where k is a constant and ξ and f are functions of x.

(v) *$m\geqslant 2$: In all other cases, the infinitesimal generators have the form*

$$\mathbf{v}^{(0)}=[a_2x^2+a_1x+a_0]\partial_x+[(m-1)a_2u+b_0]\partial_u, \tag{5.6}$$

where a_0, a_1, a_2, and b_0 are constants (and thus the symmetry group is at most four-dimensional).

We also generalize Theorem 4.9 to the scalar case. Now the G-invariant one-form can be taken to be the same as the G-invariant Lagrangian $\omega=L\,dx$.

Theorem 5.2. *In one spatial variable, if an evolutionary-type equation (5.1) admits a spatial transformation group G, then its right-hand side satisfies*

$$\mathbf{v}^{(N)}(F)=(Q_u-mD_x\xi)F, \tag{5.7}$$

and hence is a relative differential invariant of the form

$$F=\frac{L^{m+1}}{E(L)}\,I. \tag{5.8}$$

TABLE I. Lie algebras of point transformations in $\mathbb{C}^2$.

	Generators	Dim	Structure

1.9	$\partial_x, \partial_u, x\partial_x, u\partial_u, x\partial_u, x^2\partial_u, \ldots, x^{k-1}\partial_u$	$k+3$	$(\mathfrak{a}(1)\oplus\mathbb{C})\ltimes\mathbb{C}^k$
1.10	$\partial_x, \partial_u, 2x\partial_x + (k-1)u\partial_u, x^2\partial_x + (k-1)xu\partial_u, x\partial_u, x^2\partial_u, \ldots, x^{k-1}\partial_u$	$k+3$	$\mathfrak{sl}(2)\ltimes\mathbb{C}^k$
1.11	$\partial_x, \partial_u, x\partial_x, u\partial_u, x^2\partial_x + (k-1)xu\partial_u, x\partial_u, x^2\partial_u, \ldots, x^{k-1}\partial_u$	$k+4$	$\mathfrak{gl}(2)\ltimes\mathbb{C}^k$
2.1	$\partial_x, \partial_u, x\partial_x - u\partial_u, u\partial_x, x\partial_u$	5	$\mathfrak{sa}(2)$
2.2	$\partial_x, \partial_u, x\partial_x, u\partial_x, x\partial_u, u\partial_u$	6	$\mathfrak{a}(2)$
2.3	$\partial_x, \partial_u, x\partial_x, u\partial_x, x\partial_u, u\partial_u, x^2\partial_x + xu\partial_u, xu\partial_x + u^2\partial_u$	8	$\mathfrak{sl}(3)$
3.1	$\zeta_1(x)\partial_u, \ldots, \zeta_k(x)\partial_u$	k	$\mathbb{C}^k$
3.2	$\zeta_1(x)\partial_u, \ldots, \zeta_k(x)\partial_u, u\partial_u$	$k+1$	$\mathbb{C}\ltimes\mathbb{C}^k$
3.3	$\partial_x, x\partial_x, x^2\partial_x$	3	$\mathfrak{sl}(2)$

In Cases 1.5 and 1.6, the functions $\eta_1(x),\ldots,\eta_k(x)$ satisfy a kth-order constant coefficient homogeneous linear ordinary differential equation $\mathscr{D}[u]=0$. In Cases 3.1 and 3.2, the functions $\zeta_1(x),\ldots,\zeta_k(x)$ are arbitrary. In Cases 1.5–1.11 we require $k\geqslant 1$.

Note: We use $\mathfrak{a}(n)$ to denote the Lie algebra of the affine group of $\mathbb{C}^n$, and $\mathfrak{sa}(n)$ for the Lie algebra of the special affine group consisting of volume-preserving affine transformations.

Here I is an arbitrary differential invariant of G, and $\omega = L(x,u^{(n)})dx$ is a G-invariant one-form having nontrivial Euler–Lagrange expression $\mathrm{E}(L)\not\equiv 0$.

Lie's local classification of nonsingular transformation groups[20] that act on a two-dimensional complex manifold appears in Tables I and II. Table I provides a complete list of canonical forms for the infinitesimal generators of all possible finite-dimensional transformation groups in the plane. In this case, two transformation groups are equivalent if they can be mapped to each other by a point transformation. Cases 1.1–1.11 list the transitive imprimitive groups; Cases 2.1–2.3 list the primitive transformation groups; and Cases 3.1–3.3 list the intransitive cases. As for contact transformation groups, there are three additional cases not equivalent to point transformation groups, given in Table II. Any other finite-dimensional contact transformation group is equivalent, now via a contact transformation, to one of these three or one of the previously listed point

TABLE II. Lie algebras of contact transformations in $\mathbb{C}^2$.

	Generators
4.1	$\partial_x, x\partial_x, \partial_u, x\partial_u, x^2\partial_u, 2u_x\partial_x + u_x^2\partial_u$
4.2	$\partial_x, x\partial_x, u\partial_u, \partial_u, x\partial_u, x^2\partial_u, 2u_x\partial_x + u_x^2\partial_u$
4.3	$\partial_x, x\partial_x, \partial_u, x\partial_u, x^2\partial_u, u\partial_u, (2-x)x\partial_x, 2u_x\partial_x + u_x^2\partial_u, xu_x^2\partial_u - 2(u-xu_x)\partial_x,$ $2x(2u-xu_x)\partial_x + (2u-xu_x)(2u+xu_x)\partial_u$

It is convenient to separate some special cases of the families of algebras given in Tables I and II. Thus 1.7a, 1.7b and 1.7c denote family 1.7 with $\alpha\neq k$, $\alpha=0$, and $\alpha=k$, respectively. Any starred designation 1.5$*$–1.11$*$ means the respective family of algebras with the parameter k set to 1. Analogously, 1.11$**$ is 1.11 with $k=2$.

In the following tables we give the fundamental differential invariants and invariant derivatives of the algebras of Tables I and II. First the action on the jet space of variables (x,u) is considered, denoted as ''2-D.'' The last two columns refer to the action on the jet space of (t,x,u). When no invariant derivative with a component in D_t is given in the third column, D_t is meant to be the second invariant derivative.

TABLE III. Differential invariants.

	2-D invariant derivative	2-D fundamental invariant(s)	Invariant derivatives	Fundamental invariants

1.11**	$\frac{u_{xx}}{\sqrt{Q_4}}D_x$	$Q_4^{-3/2}S_5$	$\sqrt{\frac{u_t}{u_{xx}}}D_x$	$\frac{u_{tt}}{u_t}, \frac{W_3}{\sqrt{u_tu_{xx}^3}}, \frac{u_{xxt}}{u_{xx}}$

transformation groups. [Some of the point transformation canonical forms are equivalent under a contact transformation—one example is the two transitive actions of SL(2) given in 1.1 and 1.2.]

We proceed to classify the possible evolutionary-type equations that admit a finite-dimensional symmetry groups. We leave aside evolution equations, since any transformation group admits an invariant evolution equation. Thus, according to Proposition 4.12 we can immediately restrict our attention to the imprimitive groups. The first step of the classification is to check if the representative Lie algebra of a class fulfills the invariance conditions. If this is so, then, according to Theorem 5.2, knowledge of the fundamental absolute invariants, a relative invariant $R=L/E(L)$, and a nontrivial Lagrangian L of the group allows us to generate all invariant equations (5.1). In Tables III and IV we give all the fundamental absolute invariants and invariant derivatives of the algebras acting over E (two-dimensional action) and $\hat{E}$. The Lagrangian L is the reciprocal of the coefficient of D_x in the invariant two-dimensional derivative. In Table V we give the simplest invariant evolution equations, its right-hand side serving as the needed relative invariant R [not necessarily equal to $L/E(L)$], together with the corresponding invariant wave and potential evolution equations.

TABLE IV. Differential invariants.

	2-D invariant derivative	2-D fundamental invariants	Invariant derivatives	Fundamental invariants

Regardless of the existence of invariant equations for the representative algebra, the possibility remains that a change of variables could yield a point or contact-equivalent algebra satisfying the invariance conditions, and hence admitting invariant equations in the new coordinates. Alternatively, we can think that the representative algebra admits an invariant equation which is not of the prescribed form (4.2), but that can be converted into one by an appropriate equivalence transformation, which leaves its invariance untouched.

The second step is to find the required changes of variables, and the corresponding additional invariant equations. We begin with the case of point transformations, which, by Theorem 5.1, covers all but the potential evolution equations. Consider a change of variables

$$\overline{x} = \chi(x,u), \quad \overline{u} = \psi(x,u). \tag{5.9}$$

TABLE IV. (*Continued.*)

In the previous tables, given functions $\eta_1(x),\dots,\eta_k(x)$, we let $\mathscr{D}$ be a kth-order linear ordinary differential operator whose kernel is spanned by $\eta_1(x),\dots,\eta_k(x)$, and let $W(x)$ denote their Wronskian determinant. Furthermore,

$Q_{k+2}=(k+1)u_k u_{k+2}-(k+2)u_{k+1}^2$,
$R_4=3u_2u_4-5u_3^2$,
$\widetilde{R}_5=3u_3u_5-5u_4^2$,
$S_{k+3}=(k+1)^2u_k^2u_{k+3}-3(k+1)(k+3)u_k u_{k+1}u_{k+2}+2(k+2)(k+3)u_{k+1}^3$,
$\widetilde{S}_6=9u_3^2u_6-45u_3u_4u_5+40u_4^3$,
$U_5=u_1^2[Q_3D_x^2Q_3-\frac{5}{4}(D_xQ_3)^2]+u_1u_2Q_3D_xQ_3-(2u_1u_3-u_2^2)Q_3^2$,
$V_7=u_2^2[S_5D_x^2S_5-\frac{7}{6}(D_xS_5)^2]+u_2u_3S_5D_xS_5-\frac{1}{2}(9u_2u_4-7u_3^2)S_5^2$,
$Z_9=u_3^2[T_7D_x^2T_7-\frac{9}{8}(D_xT_7)^2]+u_3u_4T_7D_xT_7-\frac{4}{5}(7u_3u_5-5u_4^2)T_7^2$,
$T_7=10u_3^3u_7-70u_3^2u_4u_6-49u_3^2u_5^2+280u_3u_4^2u_5-175u_4^4$,

$C_3=u_{xt}^3u_{ttt}-3u_{xt}^2u_{tt}u_{xtt}+3u_{xt}u_{tt}^2u_{xxt}-u_{tt}^3u_{xxx}$,
$D_3=4u_t^2u_{xxx}u_{xtt}-4u_t^2u_{xxt}^2+4u_tu_{xt}^2u_{xxt}-4u_tu_{xt}u_{tt}u_{xxx}-u_{xt}^4$,
$E_3=4u_t^3u_{xxx}^2u_{ttt}-12u_t^3u_{xxx}u_{xxt}u_{xtt}+6u_t^2u_{xt}^2u_{xxx}u_{xtt}+8u_t^3u_{xxt}^3-12u_t^2u_{xt}^2u_{xxt}^2+12u_t^2u_{xt}u_{tt}u_{xxx}u_{xxt}+6u_tu_{xt}^4u_{xxt}$
$-6u_t^2u_{tt}^2u_{xxx}^2-6u_tu_{xt}^3u_{tt}u_{xxx}-u_{xt}^6$,
$F_4=2u_t^2u_{xxx}u_{xxxt}-2u_t^2u_{xxt}u_{xxxx}+u_tu_{xt}^2u_{xxxx}-4u_tu_{xt}u_{xxx}u_{xxt}+u_tu_{tt}u_{xxx}^2+2u_{xt}^3u_{xxx}$.

If the transformed group admits an invariant equation, it must be generated by vector fields of the form

$$\overline{\mathbf{v}}=\overline{\xi(x)}\partial_{\bar{x}}+[k(\overline{xu}+f(\overline{x})]\partial_{\bar{u}}=\overline{\xi(\chi)}\partial_{\bar{x}}+[k(\chi)\psi+f(\chi)]\partial_{\bar{u}},$$

with the appropriate form of k depending on the type of the invariant equation considered. This means that

$$\begin{aligned}\mathbf{v}(\chi)&=\overline{\xi(\chi)},\\ \mathbf{v}(\psi)&=\xi\psi_x+\varphi\psi_u=k(\chi)\psi+f(\chi),\end{aligned}\tag{5.10}$$

and thus the level sets of the function χ form an invariant foliation. In terms of the intermediate variables

$$(\widetilde{x},\widetilde{u})=\begin{cases}(\chi,u), & \text{if } \chi_x\neq 0,\\ (\chi,x), & \text{if } \chi_x=0,\end{cases}$$

4.3	$\dfrac{u_{xxx}^4}{T_7^{3/4}}$	$\cdots$	$\cdots$

we have

$$\widetilde{\mathbf{v}}=\widetilde{\xi}(\widetilde{x})\,\partial_{\widetilde{x}}+\widetilde{\varphi}(\widetilde{x},\overline{u})\,\partial_{\overline{u}}.$$

Differentiating (5.10) with respect to $\overline{u}$ we obtain

$$\widetilde{\xi}\psi_{\widetilde{x}\,\overline{u}}+\widetilde{\varphi}_{\overline{u}}\psi_{\widetilde{u}}+\widetilde{\varphi}\psi_{\widetilde{u}\,\overline{u}}=k\psi_{\overline{u}},$$

that is to say,

$$\widetilde{\mathbf{v}}(\psi_{\overline{u}})-(k-\widetilde{\varphi}_{\overline{u}})\psi_{\overline{u}}=0.$$

Therefore the function $\phi_{\overline{u}}$ *must be a relative invariant* of weight $k-\widetilde{\varphi}_{\overline{u}}$. Explicitly in the original variables we have

TABLE VI. Invariant foliations.

Algebra	Invariant foliation
1.1,1.2,1.3,1.5,1.6,1.7,1.8,1.9,1.10,1.11,3.1,3.2	$x=\lambda$
1.4,1.9*,1.10*,1.11*,3.2*,3.3	$x=\lambda,\ u=\mu$
1.5*,1.6*,1.7bc*	$ax+bu=\lambda$
3.1*	$u-f(x)=\lambda$
4.1,4.2	$x=\lambda,\ u_x=\mu$

$$(\widetilde{\varphi}_{\overline{u}},\psi_{\overline{u}})=\begin{cases}\left(\varphi_u-\dfrac{\chi_u}{\chi_x}\,\varphi_x,\psi_u-\dfrac{\chi_u}{\chi_x}\,\psi_x\right), & \text{if } \chi_x\neq 0,\\ (\varphi_x,\psi_x), & \text{if } \chi_x=0.\end{cases}$$

Contact transformations can be treated analogously. Consider a contact transformation

$$\overline{x}=\chi(x,u,u_x),\quad \overline{u}=\psi(x,u,u_x),\quad \chi D_x\psi=\psi D_x\chi.$$

The transformed group is now generated by vector fields of the form

$$\overline{\mathbf{v}}=\overline{\xi}(\overline{x},\overline{u_x})\partial_{\overline{x}}+[k(\overline{x},\overline{u_x})\overline{u}+f(\overline{x},\overline{u_x})]\partial_{\overline{u_x}}=\overline{\xi}(\chi,\overline{u_x})\partial_{\overline{x}}+\left[k\left(\chi,\frac{D_x\psi}{D_x\chi}\right)\psi+f\left(\chi,\frac{D_x\psi}{D_x\chi}\right)\right]\partial_{\overline{u}}.$$

Beginning with an invariant foliation by lines $\chi(x,u,u_x)=\lambda$, and $\eta(x,u,u_x)=\mu$ of the space J^1E, we conclude that the function

$$\Psi=\Psi(x,u,u_x)=-\frac{(\chi_u\eta_{u_x}-\chi_{u_x}\eta_u)\psi_x-(\chi_u\eta_x-\chi_x\eta_u)\psi_{u_x}}{\chi_x\eta_{u_x}-\chi_{u_x}\eta_x}+\psi_u$$

must be a relative invariant:

$$\mathbf{v}(\Psi)-\left(k+\frac{(\chi_u\eta_{u_x}-\chi_{u_x}\eta_u)\varphi_x-(\chi_u\eta_x-\chi_x\eta_u)\varphi_{u_x}}{\chi_x\eta_{u_x}-\chi_{u_x}\eta_x}-\varphi_u\right)\Psi=0.$$

In Table VI we give the invariant foliations of the actions of the considered groups, needed for determining changes of variables discussed above. Given an invariant foliation $\chi(x,u)$ there exists always a class of ''affine transformations''

$$\overline{x}=\chi,\quad \overline{u}=c(\chi)u+d(\chi)$$

that respects the form and symmetries of a family of invariant equations. We have found that there exists only one class of algebras having two inequivalent representatives with invariant equations, related by a *non*-affine transformation. It is class 1.1, and the additional representative is studied in Table VII.

TABLE VII. Additional algebra with invariant equations.

	Change	Algebra	Invariant derivative	2-D fundamental invariant	Fundamental invariants	$u_t=F$	$u_{xt}=F$
1.1	$\psi=u^{-1}$	$\partial_x, x\partial_x-\partial_u,$ $x^2\partial_x-2x\partial_u$	$\dfrac{D_x}{e^u}$	$\dfrac{2u_{xx}-u_x^2}{e^{2u}}$	$u_t,\ \dfrac{2u_{xx}-u_x^2}{e^{2u}}$	$\dfrac{2u_{xx}-u_x^2}{e^{2u}}$	$\dfrac{2u_{xx}-u_x^2}{e^{u}}$

VI. GENERALIZATIONS

So far we have restricted our attention to evolutionary-type equations in which the right-hand side is purely a function of the spatial variables and spatial derivatives of the dependent variable. In this section, we relax this condition by permitting the right-hand side to also depend on time derivatives of u. Here the computations become more complicated because there is not an immediate separation in the infinitesimal symmetry criteria into purely spatial and temporal parts.

According to Theorem 3.4, a general scalar differential equation

$$R(x,u^{(n)})=0 \tag{6.1}$$

is invariant under a group of transformations if and only if R forms a relative differential invariant of the group, and so satisfies (3.3) for some differential multiplier $H_{\mathbf{v}}$. However, if we solve the differential equation (6.1) for one of the derivatives,

$$u_K=F[u], \quad F:\mathrm{J}^n\hat{E}\to\mathbb{R}, \tag{6.2}$$

then the two components u_K and F may or may not form individual relative differential invariants. (If they do, then Proposition 3.5 implies that they must have the same weight.) As we have seen, this splitting of the equation into relative invariants does occur if (6.2) is of evolutionary type, meaning that K has at least one time derivative, and F depends on purely spatial derivatives. However, in more general situations, F is an ''inhomogeneous relative differential invariant,'' and the existence is more problematic (cf. Ref. 14). This has an advantage and a disadvantage. The disadvantage of studying equations with an isolated variable is then the inhomogeneity of the associated relative invariant. The advantage is that the weights are precisely determined, allowing a more systematic approach. The following result, which is analogous to Theorem 4.3 for an evolutionary-type equation, characterizes the right-hand side of the general equation (6.2) as an inhomogeneous relative differential invariant.

Proposition 6.1: If the general equation $u_K=F[u]$ admits a spatial symmetry group G, then the right-hand side satisfies

$$\mathbf{v}^{[n]}(F)=\left(Q_u-\sum_{i=1}^{p}k_iD_i\xi^i\right)F+\left[D_KQ-\left(Q_u-\sum_{i=1}^{p}k_iD_i\xi^i\right)u_K\right], \tag{6.3}$$

for all infinitesimal generators $\mathbf{v}\in\mathfrak{g}$.

Our first result characterizes those equations that impose an affine symmetry condition on its symmetry group.

Proposition 6.2: Consider a differential equation

$$u_K=F(t,x,u,u_t,u_1,\ldots,u_p,\ldots,u_L,\ldots), \tag{6.4}$$

with the right-hand side depending on variables u_L with temporal derivatives of lower order than the one on the left-hand side. That is to say, if $K=(k_0,k_1,\ldots,k_p)$ and $L=(l_0,l_1,\ldots,l_p)$, then $l_0<k_0$ for all variables u_L in F. If K is not a purely temporal multi-index, $K\neq k_0e_0$, then any connected spatial symmetry group of equation (6.4) is composed of affine bundle maps.

Proof: Apply Theorem 4.2, and expand the infinitesimal symmetry condition (4.8) to obtain

$$D_KQ+\sum_{i=1}^{p}\xi^iu_{Ki}=\mathbf{v}^{[n]}(F), \tag{6.5}$$

in analogy to (4.9). Consider terms on the left-hand side of maximal and submaximal orders k and $k-1$, but with maximal temporal order k_0. The right-hand side of (6.5) does not contain temporal

derivatives of order k_0, and then equating to zero the corresponding coefficients we obtain conditions (4.14) and $D_j Q_u = 0$, where j runs over principal spatial variables. Q.E.D.

In the case of an equation (6.4), the right-hand side of (6.5) contains terms depending on temporal derivatives [compare with (4.9)]. This means that now the expression on the left can contain them also, and that the term on u_K will not be the only one different from zero, i.e., $G \neq 0$ and instead of Theorem 4.3, Proposition 6.1 must be used.

Theorem 6.3: *Let G be a connected spatial symmetry group of an equation of type*

$$\frac{\partial^{m+n} u}{\partial x^m \partial t^n} = F(x, u^{(N)}, u_t) = F(x, u, u_x, u_t, u_{xx}, u_{xt}, \ldots, u_{kl}, \ldots), \quad l < n. \tag{6.6}$$

i.e., with right-hand sides that can depend on temporal derivatives of order $l < n$.

(i) *If the equation is purely evolutionary, i.e., of the form $\partial^n u / \partial t^n = F$, then there are no restrictions on G.*

(ii) *If the equation is the potential form $\partial^{n+1} u / \partial x \partial t^n$ of a purely evolutionary equation, then G can be a contact transformation group whose infinitesimal generators have the form*

$$\mathbf{v}^{(0)} = \xi(x, u_x)\partial_x + (ku + f(x, u_x))\partial_u, \tag{6.7}$$

where k is a constant.

(iii) *All the remaining equations, with $m \geqslant 2$, have the same type of symmetry groups as the corresponding evolutionary-type equations (5.1).*

We can also generalize Theorem 4.9 and Theorem 5.2 to this case. (The existence of suitable inhomogeneous relative invariants is, however, not immediate.)

Theorem 6.4: *In one spatial variable, if an equation (6.4) admits a spatial transformation group G, then its right-hand side satisfies*

$$\mathbf{v}^{(N)}(F) - (Q_u - m D_x \xi) F = H, \tag{6.8}$$

where the form of H follows from (6.3). Thus F is an inhomogeneous relative differential invariant of the form

$$F = \frac{L^{m+1}}{\mathrm{E}(L)} I + F_0, \tag{6.9}$$

where I is an absolute differential invariant of G depending on temporal derivatives of u of order less than n, $\omega = L(x, u^{(n)})dx$ is a G-invariant one-form having nontrivial Euler–Lagrange expression $\mathrm{E}(L) \not\equiv 0$, and F_0 is a particular inhomogeneous differential invariant of the same weight as F.

As our final examples, let us apply the previous ideas to general wave equations of type (6.4) and to potential evolution equations with an additional dependence on u_t on the right-hand side.

Example 6.5: In this example we discuss invariant wave equations of type (6.4):

$$u_{tt} = F(x, u, u_t, u_x, u_{xt}, \ldots, u_{m-1}, u_{m-1,t}), \tag{6.10}$$

i.e., those whose right-hand sides are allowed to depend on spatial derivatives of u and on first-order time derivatives. According to Theorem 6.3, the symmetry group G can be any group of transformations—imprimitive, primitive, and contact. Moreover F must be an inhomogeneous relative invariant (6.9) satisfying

$$\mathbf{v}^{(N)}(F) - Q_u F = u_t D_t Q_u - u_{xt} D_t \xi. \tag{6.11}$$

TABLE VIII. Invariant equations of the form $u_{xt}=F[x,u_t]$.

4.2	$(u_t^2 u_{xxx})^{1/3}$	0
4.3	$(u_t^2 u_{xxx})^{1/3}$	$\frac{u_x T_7^{1/4}}{u_{xxx}}+\frac{u_x Z_8}{2u_{xxx}T_7}$

In Table VIII we give the simplest homogeneous part of F, corresponding to some relative invariant $R=L^2I/\mathrm{E}(L)$, and the simplest inhomogeneous part F_0.

Example 6.6: In this example we discuss invariant potential evolution equations

$$u_{xt}=F(x,u,u_t,u_x,u_{xx},\ldots,u_m) \tag{6.12}$$

whose right-hand sides are allowed to depend on spatial derivatives of u and the time derivative u_t. Note that potential evolution equations do not belong to the class (6.4), and can be invariant, in principle, under any kind of transformation group. We find that the right-hand side F must be an inhomogeneous relative invariant (6.9) satisfying

$$\mathbf{v}^{(N)}(F)-(Q_u-D_x\xi)F=u_t D_x Q_u\,. \tag{6.13}$$

In this work we examine the basis functions for those classical and quantum mechanical systems in two dimensions which admit separation of variables in at least two coordinate systems. We do this for the corresponding systems defined in Euclidean space and on the two-dimensional sphere. We present all of these cases from a unified point of view. In particular, all of the special functions that arise via variable separation have their essential features expressed in terms of their zeros. The principal new results are the details of the polynomial bases for each of the nonsubgroup bases, not just the subgroup Cartesian and polar coordinate cases, and the details of the structure of the quadratic algebras. We also study the polynomial eigenfunctions in elliptic coordinates of the n-dimensional isotropic quantum oscillator. © *1996 American Institute of Physics.* [S0022-2488(96)03212-4]

I. INTRODUCTION

It has long been known that there are potentials for which a given Hamiltonian system in classical mechanics admits a solution via separation of variables in more than one coordinate system.[1] The methodical search for such potentials was initiated by Smorodinsky and Winternitz *et al.* in two and three dimensions,[2–4] and there has been a considerable amount of work for various examples.[5–9] A subset of such systems is called *maximal* in dimension N if there exist $2N-1$ functionally independent integrals of motion. In some papers, such systems are called *superintegrable*.[10,11] In this work we examine the basis functions for those classical and quantum mechanical systems in two dimensions which admit separation of variables in at least two coordinate systems. We do this for the corresponding systems defined in Euclidean space and on the two-dimensional sphere. In a subsequent work we shall study systems defined in two-dimensional hyperbolic spaces and in complex two-dimensional spaces.

For each of the superintegrable systems we observe that, for the discrete spectrum of the quantum mechanical Hamiltonian, one can consider this operator as acting on a space of polynomials.[12] Each eigenvalue is multiply degenerate. However, each separable coordinate system gives rise to an orthonormal basis of polynomial eigenfunctions in this space and breaks the degeneracy. These bases are characterized as simultaneous eigenfunctions of second-order symmetry operators for the Hamiltonian.[13] We show that under commutation these symmetry operators close to form a quadratic algebra.[14] The superintegral systems are of two types: the ''normal type'' in which the original Hamiltonian is diagonalized, and the ''conformal type'' in which the Hamiltonian is modified by multiplying the eigenvalue equation by a function and considering the energy as fixed. The modified equation is then interpreted as the eigenvalue equation for a Hamiltonian on a conformal Euclidean space with a ''charge'' as the eigenvalue. We present all of these cases from a unified point of view. In particular, all of the special functions that arise via variable separation have their essential features expressed in terms of their zeros. The principal new results

are the details of the polynomial bases for each of the nonsubgroup bases, not just the subgroup Cartesian and polar coordinate cases, and the details of the structure of the quadratic algebras. (For those coordinate systems which correspond to subgroup type coordinates, the finite solutions have already been found. The contribution of this article is to indicate how the remaining finite solutions can be obtained. This invariably involves the use of a Niven-type ansatz for the finite solutions; every quantity of interest can be computed in terms of the zeros of the corresponding polynomial solutions.) For the sake of completeness we list all the finite solutions that are possible. We analyze each of the potentials systematically.

In Secs. II and III we consider the superintegrable systems in Euclidean two-space and on the two-dimensional sphere, respectively. In Sec. IV we examine the polynomial eigenfunctions in elliptic coordinates of the n-dimensional isotropic quantum oscillator.

II. TWO-DIMENSIONAL EUCLIDEAN SPACE

As is well known[1,13] there are exactly four coordinate systems on the Euclidean plane in which the free particle Schrödinger equation separates: Cartesian, polar, parabolic, and elliptic. We describe these coordinate systems. Let x and y be the **Cartesian coordinates. Polar coordinates** are defined by

$$\begin{aligned} x&=r\ \cos\ \theta, \quad r>0,\\ y&=r\ \sin\ \theta, \quad 0\leqslant\theta<2\pi. \end{aligned} \tag{1}$$

Parabolic coordinates. We can define two mutually perpendicular parabolic systems:

$$x=\tfrac{1}{2}(\xi^2-\eta^2), \quad y=\xi\eta, \quad \xi\in\mathbf{R}, \eta>0, \tag{2}$$

and

$$x=\overline{\xi}\,\overline{\eta}, \quad y=\tfrac{1}{2}(\overline{\xi^2}-\overline{\eta^2}), \quad \overline{\xi}\in\mathbf{R}, \overline{\eta}>0. \tag{3}$$

The connection $(\xi,\eta)\mapsto(\overline{\xi},\overline{\eta})$ is a rotation of angle $\pi/4$ in the (ξ,η) space. The transformation $(x,y)\mapsto(\xi,\eta)$ actually is the two-dimensional realization of the Levi-Civita transformation[15] which has the form

$$x=\xi^2-\eta^2, \quad y=2\xi\eta, \quad \xi\in\mathbf{R}, \eta>0. \tag{4}$$

Elliptic coordinates in algebraic form are defined by $(e_1<u_1<e_2<u_2)$

$$x^2=\frac{(u_1-e_1)(u_2-e_1)}{e_2-e_1}, \quad y^2=\frac{(u_1-e_2)(u_2-e_2)}{e_1-e_2}. \tag{5}$$

Replacing $x\mapsto x+\sqrt{e_2-e_1}$ yields a coordinate system which is called *elliptic II coordinates*:[16]

$$x=\sqrt{\frac{(u_1-e_1)(u_2-e_1)}{e_2-e_1}}+\sqrt{e_2-e_1}, \quad y=\sqrt{\frac{(u_1-e_2)(u_2-e_2)}{e_1-e_2}}. \tag{6}$$

It is interesting that the two elliptic coordinates are connected by the Levi-Civita transformation. Indeed, if we use parabolic coordinates (ξ,η) in Eq. (4) as Cartesian coordinates in Eq. (5), we have

$$x=\sqrt{\frac{(\overline{u_1}-\overline{e_1})(\overline{u_2}-\overline{e_1})}{\overline{e_2}-\overline{e_1}}}+\sqrt{\overline{e_2}-\overline{e_1}}, \quad y=\sqrt{\frac{(\overline{u_1}-\overline{e_2})(\overline{u_2}-\overline{e_2})}{\overline{e_1}-\overline{e_2}}}, \tag{7}$$

TABLE I. The two-dimensional superintegrable potentials.

Potential $V(x,y)$	Coordinate system
$V_1=\frac{1}{2}\omega^2(x^2+y^2)+\frac{1}{2}\left(\frac{k_1^2-\frac{1}{4}}{x^2}+\frac{k_2^2-\frac{1}{4}}{y^2}\right)$	Cartesian polar elliptic
$V_2=\frac{1}{2}\omega^2(4x^2+y^2)+k_1x+\frac{1}{2}\frac{k_2^2-\frac{1}{4}}{y^2}$	Cartesian parabolic
$V_3=-\frac{\alpha}{\sqrt{x^2+y^2}}+\frac{1}{4}\frac{1}{\sqrt{x^2+y^2}}$ $\times\left(\frac{k_1^2-\frac{1}{4}}{\sqrt{x^2+y^2}+x}+\frac{k_2^2-\frac{1}{4}}{\sqrt{x^2+y^2}-x}\right)$	Polar elliptic II parabolic
$V_4=-\frac{\alpha}{\sqrt{x^2+y^2}}+\frac{1}{4}\frac{1}{\sqrt{x^2+y^2}}$ $\times(\beta_1\sqrt{\sqrt{x^2+y^2}+x}+\beta_2\sqrt{\sqrt{x^2+y^2}-x})$	Mutually parabolic

where

$$\overline{u_i}=u_i^2-u_1(e_1+e_2),\quad \overline{e_1}=-\tfrac{1}{4}(e_1+e_2)^2,\quad \overline{e_2}=-e_1e_2. \tag{8}$$

As shown in Refs. 2–4 there are four classes of potentials for which multiple separation occurs in Euclidean space (see Table I).

We treat the cases in order. In each case the Schrödinger equation is ($\hbar=m=1$)

$$-\tfrac{1}{2}\Delta\Psi+V_i(x,y)\Psi=E\Psi,\quad i=1,\ldots,4. \tag{9}$$

(i) The potential in the first case is

$$V_1(x,y)=\frac{1}{2}\,\omega^2(x^2+y^2)+\frac{1}{2}\left(\frac{k_1^2-\frac{1}{4}}{x^2}+\frac{k_2^2-\frac{1}{4}}{y^2}\right). \tag{10}$$

The corresponding Schrödinger equation is ($k_1,k_2>0$)

$$\left[\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}\right]\Psi+\left[2E-\omega^2(x^2+y^2)-\frac{k_1^2-\frac{1}{4}}{x^2}-\frac{k_2^2-\frac{1}{4}}{y^2}\right]\Psi=0.$$

See Refs. 2, 3, and 16–18 for an earlier treatment. This equation separates in three different separable coordinate systems: Cartesian, polar, and elliptical coordinates.

If we rewrite the Schrödinger equation by putting

$$\Psi=e^{-\omega(x^2+y^2)/2}x^{1/2\pm k_1}y^{1/2\pm k_2}\Phi(x,y), \tag{11}$$

then the equation for $\Phi(x,y)$ is $Q\Phi=-2E\Phi$ or

$$\left[\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+\left(\frac{1\pm 2k_1}{x}-2\omega x\right)\frac{\partial}{\partial x}+\left(\frac{1\pm 2k_2}{y^2}-2\omega y\right)\frac{\partial}{\partial y}-2\omega(2\pm k_1\pm k_2)\right]\Phi=-2E\Phi. \tag{12}$$

Clearly the operator Q maps polynomials (in x^2,y^2) into polynomials, without increasing the order. Since the original Hamiltonian is self-adjoint with respect to the measure $dx\ dy$ in the plane, the operator Q acting on polynomials in x^2 and y^2 is self-adjoint with respect to the measure

$$d\rho(x,y)=e^{-\omega(x^2+y^2)}x^{1\pm 2k_1}y^{1\pm 2k_2}\ dx\ dy$$

in the quadrant $x>0$, $y>0$. We assume that the positive sign at the k_i has to be taken if $k_i>\frac{1}{2}$ and both the positive and the negative sign must be taken if $0<k_i<\frac{1}{2}$, so that the polynomials have finite norm.[16]

To find the eigenfunctions in the case of Cartesian coordinates we look for separable solutions $\Phi(x,y)=X(x)Y(y)$. Then the separation equation in x becomes

$$\left[\frac{\partial^2}{\partial x^2}+\left(-2\omega+\frac{1\pm 2k_1}{x^2}\right)x\frac{\partial}{\partial x}-(1\pm 2k_1)\omega\right]X=2\lambda_1 X. \tag{13}$$

If we look for solutions of the form

$$X(x)=\prod_{m=1}^{q}(x^2-\theta_m),$$

the θ_m must satisfy

$$\omega\theta_\ell=1\pm k_1+2\sum_{j\neq\ell}\frac{\theta_\ell}{\theta_\ell-\theta_j}$$

and

$$\lambda_1=-\omega(2q\pm k_1+\tfrac{1}{2}),$$

where q is a non-negative integer. The solutions are $X(x)=L_q^{k_1}(\omega x^2)$ where $L_n^{\alpha}(z)$ is a Laguerre polynomial.

Thus the corresponding set of orthonormal eigenfunctions which are normalized in quadrant $x>0$, $y>0$ by

$$\int_0^\infty dx\int_0^\infty dy\,\Psi^*_{n_1'n_2'}(x,y)\Psi_{n_1n_2}(x,y)=\frac{1}{4}\,\delta_{n_1'n_1}\delta_{n_2'n_2} \tag{14}$$

is

$$\Psi(x,y)\equiv\Psi^{(k_1,k_2)}_{n_1,n_2}(x,y)=\sqrt{\frac{\omega n_1!n_2!}{\Gamma(n_1\pm k_1+1)\Gamma(n_2\pm k_2+1)}}\,(\sqrt{\omega}x)^{1/2\pm k_1}(\sqrt{\omega}y)^{1/2\pm k_2}$$
$$\times e^{-(\omega/2)(x^2+y^2)}L_{n_1}^{\pm k_1}(\omega x^2)L_{n_2}^{\pm k_2}(\omega y^2), \tag{15}$$

where $E_n=\omega(2n\pm k_1\pm k_2+2)$ and $n=n_1+n_2$ is the principal quantum number.

The corresponding classical operator is

$$L_1 = p_x^2 - \left(\omega^2 x^2 + \frac{k_1^2 - \frac{1}{4}}{x^2} \right).$$

These eigenfunctions satisfy

$$\hat{L}_1 \Psi = \left(\frac{\partial^2}{\partial x^2} - \omega^2 x^2 - \frac{k_1^2 - \frac{1}{4}}{x^2} \right) \Psi = 2\lambda_1 \Psi. \tag{16}$$

In polar coordinates the Schrödinger equation is

$$\left(\frac{\partial^2}{\partial r^2} + \frac{1}{r}\frac{\partial}{\partial r} + \frac{1}{r^2}\frac{\partial^2}{\partial \theta^2} \right) \Psi + \left[2E - \omega^2 r^2 \Psi - \frac{1}{r^2} \left(\frac{k_1^2 - \frac{1}{4}}{\cos^2 \theta} + \frac{k_2^2 - \frac{1}{4}}{\sin^2 \theta} \right) \right] \Psi = 0.$$

If we write $\Psi = R(r)T(\theta)$, then the separation equation for $T(\theta)$ is

$$\frac{d^2}{d\theta^2} T(\theta) - \left(\frac{k_1^2 - \frac{1}{4}}{\cos^2 \theta} + \frac{k_2^2 - \frac{1}{4}}{\sin^2 \theta} \right) T(\theta) = \lambda T(\theta).$$

If we now put

$$T(\theta) = (\cos \theta)^{1/2 \pm k_1} (\sin \theta)^{1/2 \pm k_2} P(z),$$

where $z = \cos 2\theta$, this separation equation becomes

$$\left\{ (1 - z^2) \frac{\partial^2}{\partial z^2} - [(2 \pm k_1 \pm k_2)z + (\pm k_1 \mp k_2)] \frac{\partial}{\partial z} - \frac{1}{4} [\lambda + (1 \pm k_1 \pm k_2)^2] \right\} P(z) = 0.$$

If we try solutions of the form $P(z) = \Pi_{m=1}^{q} (z - \theta_m)$, we find that the zeros of the polynomial $P(z)$ satisfy

$$2 \sum_{m \neq l} \frac{1}{\theta_l - \theta_m} = \frac{1 \pm k_2}{(1 - \theta_l)} - \frac{1 \pm k_1}{(1 + \theta_l)}, \tag{17}$$

where $\lambda = -(2q \pm k_1 \pm k_2 + 1)^2$. These are just the equations satisfied by the zeros of the Jacobi polynomials. In fact the solutions of this eigenvalue equation have the form

$$T(\theta) = (\cos \theta)^{1/2 \pm k_1} (\sin \theta)^{1/2 \pm k_2} P_q^{(\pm k_1, \pm k_2)} (\cos 2\theta).$$

The classical constant of the motion is

$$L_2 = (x p_y - y p_x)^2 - \left[\frac{k_1^2 - \frac{1}{4}}{x^2} + \frac{k_2^2 - \frac{1}{4}}{y^2} \right] (x^2 + y^2)$$

and the corresponding eigenvalue equation satisfied by the eigenfunctions Ψ is

$$\hat{L}_2 \Psi = \left[\left(x \frac{\partial}{\partial y} - y \frac{\partial}{\partial x} \right)^2 + \left(\frac{\frac{1}{4} - k_1^2}{x^2} + \frac{\frac{1}{4} - k_2^2}{y^2} \right) (x^2 + y^2) \right] \Psi = \lambda \Psi. \tag{18}$$

The orthonormal [as in Eq. (14)] eigenfunctions in these coordinates are

$$\Psi(r,\theta)\equiv\Psi_{n_r,q}^{(\pm k_1,\pm k_2)}(r,\theta)=\Phi_q^{(\pm k_1,\pm k_2)}(\theta)\sqrt{\frac{2\omega n!}{\Gamma(n+2q\pm k_1\pm k_2+1)}}$$
$$\times e^{-\omega r^2/2}(\sqrt{\omega}r)^{(2q\pm k_1\pm k_2+1)}L_n^{2q\pm k_1\pm k_2+1}(\omega r^2), \tag{19}$$

where

$$\Phi_q^{(\pm k_1,\pm k_2)}(\theta)=\sqrt{\frac{(2q\pm k_1\pm k_2+1)q!\Gamma(q\pm k_1\pm k_2+1)}{2\Gamma(q\pm k_2+1)\Gamma(q\pm k_1+1)}}$$
$$\times(\cos\theta)^{1/2\pm k_1}(\sin\theta)^{1/2\pm k_2}P_q^{(\pm k_1,\pm k_2)}(\cos 2\theta) \tag{20}$$

and $E=\omega(2n\pm k_1\pm k_2+2)$, with $n=n_r+q$. Using (11) we can easily split off the polynomial portion of (20) from the multiplier.

In elliptical coordinates we adopt a similar approach. Using the identity

$$\frac{x^2}{\theta-e_1}+\frac{y^2}{\theta-e_2}-1=-\frac{(u_1-\theta)(u_2-\theta)}{(\theta-e_1)(\theta-e_2)}, \tag{21}$$

we look for solutions (11) of the form[19]

$$\Phi(x,y)=\prod_{m=1}^{q}\left(\frac{x^2}{\theta_m-e_1}+\frac{y^2}{\theta_m-e_2}-1\right).$$

The θ_m must satisfy

$$\frac{1\pm k_1}{\theta_m-e_1}+\frac{1\pm k_2}{\theta_m-e_2}+\sum_{j\neq m}\frac{2}{(\theta_m-\theta_j)}-\omega=0, \tag{22}$$

where $E=\omega(2q\pm k_1\pm k_2+2)$. If we write the Schrödinger equation for this potential in elliptical coordinates we obtain

$$\frac{4(u_1-e_1)(u_1-e_2)}{u_1-u_2}\left[\frac{\partial^2\Psi}{\partial u_1^2}+\frac{1}{2}\left(\frac{1}{u_1-e_1}+\frac{1}{u_1-e_2}\right)\frac{\partial\Psi}{\partial u_1}\right]$$
$$+\frac{4(u_2-e_1)(u_2-e_2)}{u_2-u_1}\left[\frac{\partial^2\Psi}{\partial u_2^2}+\frac{1}{2}\left(\frac{1}{u_2-e_1}+\frac{1}{u_2-e_2}\right)\frac{\partial\Psi}{\partial u_2}\right]$$
$$+\left[2E-\omega^2(u_1+u_2-e_1-e_2)+\frac{(\frac{1}{4}-k_1^2)(e_2-e_1)}{(u_1-e_1)(u_2-e_1)}+\frac{(\frac{1}{4}-k_2^2)(e_1-e_2)}{(u_1-e_2)(u_2-e_2)}\right]\Psi=0.$$

This equation admits separable solutions $\Psi=U_1(u_1)U_2(u_2)$ and separation equations

$$\left\{4(u_i-e_1)(u_i-e_2)\left[\frac{\partial^2}{\partial u_i^2}+\frac{1}{2}\left(\frac{1}{u_i-e_1}+\frac{1}{u_i-e_2}\right)\frac{\partial}{\partial u_i}\right]-\omega^2[u_i^2-(e_1+e_2)u_i]\right.$$
$$\left.+\frac{(k_1^2-\frac{1}{4})(e_1-e_2)}{(u_1-e_1)}+\frac{(k_2^2-\frac{1}{4})(e_2-e_1)}{(u_1-e_2)}+2Eu_i+\lambda\right\}U_i(u_i)=0,\quad i=1,2.$$

The additional operator describing this coordinate system is

$$\hat{L}_3\Psi=\frac{4u_2(u_1-e_1)(u_1-e_2)}{u_1-u_2}\left[\frac{\partial^2\Psi}{\partial u_1^2}+\frac{1}{2}\left(\frac{1}{u_1-e_1}+\frac{1}{u_1-e_2}\right)\frac{\partial\Psi}{\partial u_1}\right]$$
$$+\frac{4u_1(u_2-e_1)(u_2-e_2)}{u_2-u_1}\left[\frac{\partial^2\Psi}{\partial u_2^2}+\frac{1}{2}\left(\frac{1}{u_2-e_1}+\frac{1}{u_2-e_2}\right)\frac{\partial\Psi}{\partial u_2}\right]$$
$$+\left[-u_1u_2\omega^2+\frac{(k_1^2-\frac{1}{4})(e_1-e_2)}{(u_1-e_1)(u_2-e_1)}+\frac{(k_2^2-\frac{1}{4})(e_1-e_2)}{(u_1-e_2)(u_2-e_2)}\right]\Psi$$
$$=\left[\left(x\frac{\partial}{\partial y}-y\frac{\partial}{\partial x}\right)^2+e_2\frac{\partial^2}{\partial x^2}+e_1\frac{\partial^2}{\partial y^2}-\omega^2(e_2x^2+e_1y^2+e_1e_2)\right.$$
$$\left.+\frac{\frac{1}{4}-k_1^2}{x^2}(x^2+y^2+e_2)+\frac{\frac{1}{4}-k_2^2}{y^2}(x^2+y^2+e_1)\right]\Psi=\lambda\Psi, \tag{23}$$

where

$$\lambda=-(1\pm k_1\pm k_2)^2-2e_2\omega(1\pm k_1)-2e_1\omega(1\pm k_2)-\omega^2e_1e_2-4\sum_{m=1}^{q}\left[e_2\frac{1\pm k_1}{\theta_m-e_1}+e_1\frac{1\pm k_2}{\theta_m-e_2}\right].$$

The corresponding classical operator is

$$L_3=(xp_y-yp_x)^2+e_2p_x^2+e_1p_y^2-\omega^2(e_2x^2+e_1y^2+e_1e_2)$$
$$+\frac{(\frac{1}{4}-k_1^2)}{x^2}(x^2+y^2+e_2)+\frac{(\frac{1}{4}-k_2^2)}{y^2}(x^2+y^2+e_1). \tag{24}$$

If we now use the redefined operators

$$M_1=L_1,\quad M_2=L_2-\tfrac{1}{2}+k_1^2+k_2^2,\quad M_3=L_3-\tfrac{1}{2}+k_1^2+k_2^2,$$

and

$$H=p_x^2+p_y^2-\omega^2(x^2+y^2)+\frac{\frac{1}{4}-k_1^2}{x^2}+\frac{\frac{1}{4}-k_2^2}{y^2},$$

we observe the following relations:

$$M_{12}=\{M_1,M_2\}=4(xp_y-yp_x)(p_xp_y-\omega^2xy)+\frac{\frac{1}{4}-k_2^2}{y^2}xp_x-\frac{\frac{1}{4}-k_1^2}{x^2}yp_y, \tag{25}$$

$$\{M_{12},M_1\}=8(M_1^2-M_1H)-16\omega^2M_2, \tag{26}$$

$$\{M_{12},M_2\}=8M_2(H-2M_1)-4(1-4k_2^2)M_2+4(1-4k_1^2)(H-M_1), \tag{27}$$

$$M_{12}^2=16M_1M_2(H-M_1)+16\omega^2L_2^2-4(1-4k_2^2)M_1^2-4(1-4k_2^2)(H-M_1)^2$$
$$+4\omega^2(1-4k_1^2)(1-4k_2^2).$$

We have not included M_3 in these calculations as it is linearly dependent on H, M_1 and M_2 via the relation $M_3=M_2+(e_2-e_1)M_1+e_1H$. The constants of the motion M_1, M_2 and H generate a quadratic algebra.

(ii) The potential is now

$$V_2(x,y)=\frac{1}{2}\,\omega^2(4x^2+y^2)+\frac{k_2^2-\frac{1}{4}}{2y^2}. \tag{28}$$

For $k_1=0$ this potential is also known as a Holt potential.[20] The Schrödinger equation for $k_1=0$ has the form

$$\left(\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}\right)\Psi-\left[\omega^2(4x^2+y^2)+\frac{k_2^2-\frac{1}{4}}{y^2}\right]\Psi=-2E\Psi.$$

There are two coordinate systems of relevance here: Cartesian coordinates x,y and parabolic coordinates ξ,η. If we express solutions of the Schrödinger equations in the form

$$\Psi=e^{-\omega x^2-\omega y^2/2}y^{1/2\pm k_2}\Phi(x,y), \tag{29}$$

then the function $\Phi(x,y)$ satisfies the equation $R\Phi=-2E\Phi$ or

$$\left[\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+\frac{(1\pm 2k_2)}{y}\,\frac{\partial}{\partial y}-2\omega\left(2x\,\frac{\partial}{\partial x}+y\,\frac{\partial}{\partial y}\right)-2\omega(2\pm k_2)\right]\Phi(x,y)=-2E\Phi. \tag{30}$$

It follows that the operator R maps polynomials (in x,y^2) into polynomials, without increasing the order. Since the original Hamiltonian is self-adjoint with respect to the measure $dx\,dy$ in the plane, the operator R, acting on polynomials in x,y^2 is self-adjoint with respect to the measure

$$d\rho(x,y)=e^{-\omega(x^2+y^2)}y^{1\pm 2k_2}\,dx\,dy$$

in the upper half-plane $y>0$. We assume that the positive sign at the k_2 has to be taken if $k_2>\frac{1}{2}$ and both the positive and the negative sign must be taken if $0<k_2<\frac{1}{2}$, so that the polynomials have finite norm.[16]

Equation (30) admits a separable solution of the form $\Phi=X(x)Y(y)$ where the function $X(x)$ satisfies the separation equation

$$\left[\frac{\partial^2}{\partial x^2}-4\omega x\,\frac{\partial}{\partial x}-2\omega-\lambda\right]X=0.$$

If we try solutions of the form $X=\Pi_{m=1}^{q}(x-\theta_m)$, the relations among the θ_m are

$$4\omega\theta_\ell=\sum_{m\neq\ell}\frac{1}{\theta_\ell-\theta_m} \tag{31}$$

and the eigenvalues are $\lambda=-2(2q+1)\omega$ with solutions $X=H_q(\sqrt{2\omega}x)$. The solutions for the function $Y(y)$ correspond exactly to those given for the potential V_1 viz

$$Y(y)=L_n^{\pm k_2}(y^2).$$

The orthonormal eigenfunctions are

$$\Psi(x,y)=\sqrt{2}\,\omega^{(1/2)(1\pm k_2)}\sqrt{\frac{n!}{\Gamma(n\pm k_2+1)}}\,y^{1/2\pm k_2}e^{-1/2\omega y^2}L_n^{\pm k_2}(\omega y^2)$$
$$\times\left(\frac{2\omega}{\pi}\right)^{1/4}\frac{1}{\sqrt{2^q q!}}\,e^{-\omega x^2}H_q(\sqrt{2\omega}x). \tag{32}$$

The energy E takes the values $E=\omega[2(q+n+1)\pm k_2]$.

In the case of *parabolic coordinates* we note that

$$\frac{y^2}{\lambda^2}+2x-\lambda^2=\frac{(\xi^2-\lambda^2)(\eta^2+\lambda^2)}{\lambda^2}.$$

If we try a solution of (30) in the form

$$\Phi(x,y)=\prod_{\ell=1}^{q}\left(\frac{y^2}{\lambda_\ell^2}+2x-\lambda_\ell^2\right), \tag{33}$$

it follows that the λ_ℓ must satisfy

$$\frac{1}{\lambda_\ell^2}+\sum_{m\neq\ell}\frac{4}{\lambda_\ell^2-\lambda_m^2}-2\omega\lambda_\ell^2=0$$

and $E=\omega(2q+2\pm k_2)$. The Schrödinger equation written in terms of parabolic coordinates is

$$\frac{1}{\xi^2+\eta^2}\left(\frac{\partial^2\Psi}{\partial\xi^2}+\frac{\partial^2\Psi}{\partial\eta^2}\right)+\left[2E-\omega^2(\xi^4-\xi^2\eta^2+\eta^4)+\frac{\frac{1}{4}-k_2^2}{\xi^2\eta^2}\right]\Psi=0. \tag{34}$$

If we look for separable solutions of the form $\Psi=X_1(\xi)X_2(\eta)$, the separation equations are

$$\left[\frac{\partial^2}{\partial\mu^2}+\left(-\omega^2\mu^6+\frac{\frac{1}{4}-k_2^2}{\mu^2}+2E\mu^2+\lambda\right)\right]X_j=0,$$

where $\mu=\xi$ if $j=1$ and $\mu=\eta$ if $j=2$. The operator whose eigenvalue is λ is

$$\hat{L}_2\Psi=\frac{1}{\xi^2+\eta^2}\left[\xi^2\frac{\partial^2\Psi}{\partial\eta^2}-\eta^2\frac{\partial^2\Psi}{\partial\xi^2}\right]+\left[\omega^2\xi^2\eta^2+\frac{\frac{1}{4}-k_2^2}{\xi^2\eta^2}\right](\xi^2-\eta^2)\Psi$$
$$=2x\frac{\partial^2\Psi}{\partial y^2}-2y\frac{\partial^2\Psi}{\partial x\partial y}-\frac{\partial\Psi}{\partial x}+\left[2\omega^2xy^2+\frac{\frac{1}{4}-k_2^2}{y^2}x\right]\Psi. \tag{35}$$

The eigenvalues are

$$\lambda=2(k_2+1)\prod_{j=1}^{q}\lambda_j^2\left(\sum_{m=1}^{q}\lambda_m^{-2}\right).$$

If we define the classical operators associated with this separable system as

$$H=p_x^2+p_y^2-\omega^2(4x^2+y^2)+\frac{\frac{1}{4}-k_2^2}{y^2},$$

$$L_1=p_x^2-4\omega^2x^2,\quad L_2=2p_y(xp_y-yp_x)+2\omega^2xy^2+\frac{\frac{1}{4}-k_2^2}{y^2}\,x,$$

then the defining relations of the quadratic algebra are

$$L_{12}=\{L_1,L_2\}=4\left[p_xp_y^2+\omega^2y^2p_x+2\,\frac{\frac{1}{4}-k_2^2}{y^2}\,p_x-4\omega^2xyp_y\right],$$

$$L_{12}^2=16(H-L_1)^2L_1+16\omega^2L_2^2+16\omega^2(1-4k_2^2),\quad \{L_1,L_{12}\}=-16\omega^2L_2, \tag{36}$$

$$\{L_2,L_{12}\}=16L_1(H-L_1)-8(H-L_1)^2-8\omega^2(1-4k_2^2).$$

(iii) The potential is now

$$V_3=\frac{-\alpha}{\sqrt{x^2+y^2}}+\frac{1}{4\sqrt{x^2+y^2}}\left[\frac{k_1^2-\frac{1}{4}}{\sqrt{x^2+y^2}+x}+\frac{k_2^2-\frac{1}{4}}{\sqrt{x^2+y^2}-x}\right]. \tag{37}$$

The Schrödinger equation separates variables in polar coordinates, parabolic coordinates, and modified elliptic coordinates. If we look for solutions of the Schrödinger equation of the form

$$\Psi=e^{-(1/2)\sqrt{-2E}(\xi^2+\eta^2)}\xi^{1/2\pm k_1}\eta^{1/2\pm k_2}\Phi(\xi,\eta), \tag{38}$$

where ξ and η are *parabolic coordinates*, we find that the equation for $\Phi(\xi,\eta)$ is $S\Phi=-4\alpha\Phi$ or

$$\left[\frac{\partial^2\Phi}{\partial\xi^2}+\frac{\partial^2\Phi}{\partial\eta^2}+\frac{(1\pm2k_1)}{\xi}\,\frac{\partial\Phi}{\partial\xi}+\frac{(1\pm2k_2)}{\eta}\,\frac{\partial\Phi}{\partial\eta}\right.$$
$$\left.+2\sqrt{-2E}\left(\xi\,\frac{\partial\Phi}{\partial\xi}+\eta\,\frac{\partial\Phi}{\partial\eta}\right)-2\sqrt{-2E}(2\pm k_1\pm k_2)\right]\Phi=-4\alpha\Phi. \tag{39}$$

For fixed E we can consider this as an eigenvalue equation for S with eigenvalue -4α. Moreover, S maps polynomials (in ξ^2, η^2, or, what is the same thing, in $r=\sqrt{x^2+y^2}$, x) into polynomials, without increasing the order. Since the original Hamiltonian is self-adjoint with respect to the measure $dx\,dy$ in the plane, the operator S, acting on polynomials in ξ^2 and η^2, is self-adjoint with respect to the measure

$$d\rho(x,y)=e^{-\sqrt{-2E}(\xi^2+\eta^2)}\xi^{1\pm2k_1}\eta^{1\pm2k_2}(\xi^2+\eta^2)d\xi\,d\eta.$$

We assume that the positive sign at the k_i has to be taken if $k_i>\frac{1}{2}$ and both the positive and the negative sign must be taken if $0<k_i<\frac{1}{2}$, so that the polynomials have finite norm.[16] For polynomial eigenfunctions we must have the quantisation condition

$$2\alpha=\sqrt{-2E}[2(q+1)\pm k_1\pm k_2] \tag{40}$$

for integer q.

In *polar coordinates* with potential V_3 the Schrödinger equation has the form

$$\left[\frac{\partial^2}{\partial r^2}+\frac{1}{r}\,\frac{\partial}{\partial r}+\frac{1}{r^2}\,\frac{\partial^2}{\partial\theta^2}\right]\Psi+\left[2E+\frac{2\alpha}{r}+\frac{1}{2r^2}\left(\frac{\frac{1}{4}-k_1^2}{1+\cos\,\theta}+\frac{\frac{1}{4}-k_2^2}{1-\cos\,\theta}\right)\right]\Psi=0.$$

If we write solutions Ψ in the form

$$\Psi = R(r)S(\theta),$$

the θ separation equation is

$$\frac{d^2}{d\theta^2}S(\theta) + \frac{1}{16}\left[\frac{1-4k_1^2}{\cos^2(\theta/2)} + \frac{1-4k_2^2}{\sin^2(\theta/2)}\right]S(\theta) = -\lambda^2 S(\theta), \tag{41}$$

which has solutions

$$S(\theta) = \left(\sin\frac{\theta}{2}\right)^{1/2\pm k_2}\left(\cos\frac{\theta}{2}\right)^{1/2\pm k_1} P_m^{(\pm k_1, \pm k_2)}(\cos\,\theta),$$

where $\lambda = m + \frac{1}{2}(1 \pm k_1 \pm k_2)$. The separation equation for $R(r)$ is

$$\left[\frac{\partial^2}{\partial r^2} + \frac{1}{r}\frac{\partial}{\partial r} - \frac{\lambda^2}{r^2} + \frac{2\alpha}{r} + 2E\right]R(r) = 0, \tag{42}$$

which has the solution

$$R_{n\lambda}(r) = e^{-\sqrt{-2E}r}(2\sqrt{-2E}r)^{\lambda} L_n^{\lambda}(2\sqrt{-2E}r),$$

where

$$E = \frac{-2\alpha^2}{[2(m+n+1) \pm k_1 \pm k_2]^2}.$$

The orthonormal basis of eigenfunctions is

$$\Psi = \sqrt{\frac{\alpha n!}{\Gamma(2n+2\lambda+1)(2n+2\lambda+1)}}\, R_{n\lambda}(r)\Phi_n^{(\pm k_2, \pm k_1)}\left(\frac{\theta}{2}\right). \tag{43}$$

The operator whose eigenvalue is μ^2 is, in Cartesian coordinates,

$$L_1\Psi = \left[\left(x\frac{\partial}{\partial y} - y\frac{\partial}{\partial x}\right)^2 - \frac{1}{2}\sqrt{x^2+y^2}\left(\frac{k_1^2-\frac{1}{4}}{\sqrt{x^2+y^2}+x} + \frac{k_2^2-\frac{1}{4}}{\sqrt{x^2+y^2}-x}\right)\right]\Psi. \tag{44}$$

In *parabolic coordinates* Schrödinger's equation has the form

$$H\Psi = \frac{1}{\xi^2+\eta^2}\left[\frac{\partial^2\Psi}{\partial\xi^2} + \frac{\partial^2\Psi}{\partial\eta^2}\right] + \left[4\alpha + \left(\frac{\frac{1}{4}-k_1^2}{\xi^2} + \frac{\frac{1}{4}-k_2^2}{\eta^2}\right)\right]\Psi = -2E\Psi.$$

The separation equations are

$$\frac{\partial^2}{\partial\mu^2}X_j + \left(\frac{\frac{1}{4}-k_j^2}{\mu^2} + 2E\mu^2 + \lambda_j\right)X_j = 0 \tag{45}$$

with $\lambda_1+\lambda_2=4\alpha$. The orthonormal bound state eigenfunctions of Schrödinger's equation in these coordinates are

$$\begin{aligned}\Psi &= X_1(\xi)X_2(\eta)\\ &= \sqrt{\frac{\alpha}{[2(n_1+n_2)\pm k_1\pm k_2+2]^3}}\ \sqrt{\frac{n_1!n_2!}{\Gamma(n_1\pm k_1+1)\Gamma(n_2\pm k_2+1)}}\ e^{-(1/2)\sqrt{-2E}(\xi^2+\eta^2)}\\ &\quad\times(\sqrt{-2E}\,\xi)^{1/2\pm k_1}(\sqrt{-2E}\,\eta)^{1/2\pm k_2}L_{n_1}^{\pm k_1}(\sqrt{-2E}\,\xi^2)L_{n_2}^{\pm k_2}(\sqrt{-2E}\,\eta^2),\end{aligned}\tag{46}$$

where $\lambda_j=2\sqrt{-2E}(2n_j\pm k_j+1)$, $j=1,2$, and

$$E=-\frac{2\alpha^2}{[2(n_1+n_2)\pm k_1\pm k_2+2]^2}.$$

If we choose $\lambda_1=2\alpha+\lambda$ and $\lambda_2=2\alpha-\lambda$, then the symmetry operator with eigenvalue λ is

$$\begin{aligned}L_2\Psi &= 2x\frac{\partial^2\Psi}{\partial y^2}-2y\frac{\partial^2\Psi}{\partial x\partial y}-\frac{\partial\Psi}{\partial x}+\left[-\left(k_1^2-\frac{1}{4}\right)\frac{\sqrt{x^2+y^2}-x}{\sqrt{x^2+y^2}(\sqrt{x^2+y^2}+x)}\right.\\ &\quad\left.+\left(k_2^2-\frac{1}{4}\right)\frac{\sqrt{x^2+y^2}+x}{\sqrt{x^2+y^2}(\sqrt{x^2+y^2}-x)}+\frac{4\alpha}{\sqrt{x^2+y^2}}\right]\Psi\\ &= \frac{1}{\xi^2+\eta^2}\left[\xi^2\frac{\partial^2\Psi}{\partial\eta^2}-\eta^2\frac{\partial^2\Psi}{\partial\xi^2}\right]+\left[\left(\frac{1}{4}-k_1^2\right)\frac{\eta^2}{\xi^2(\xi^2+\eta^2)}\right.\\ &\quad\left.+\left(k_2^2-\frac{1}{4}\right)\frac{\xi^2}{\eta^2(\xi^2+\eta^2)}+2\alpha\frac{\xi^2-\eta^2}{\xi^2+\eta^2}\right]\Psi.\end{aligned}$$

For the case of *elliptical coordinates* we proceed as follows. The normal elliptical coordinates will not separate variables. However, if we compare (12) and (39) we are motivated to choose coordinates such that

$$\xi^2=\frac{(u_1-e_1)(u_2-e_1)}{e_1-e_2},\quad \eta^2=\frac{(u_1-e_2)(u_2-e_2)}{e_2-e_1}.\tag{47}$$

If we then try a solution of (39) in the form

$$\Phi(\xi,\eta)=\prod_{m=1}^{q}\left[\frac{\xi^2}{\theta_m-e_1}+\frac{\eta^2}{\theta_m-e_2}-1\right],\tag{48}$$

we see that the θ_m must satisfy

$$\frac{1\pm k_1}{\theta_m-e_1}+\frac{1\pm k_2}{\theta_m-e_2}+\sum_{j\neq m}\frac{2}{\theta_m-\theta_j}-\sqrt{-2E}=0,$$

and the quantization condition (40). In this choice of coordinates the Schrödinger equation has the form

$$\frac{4(u_1-e_1)(u_1-e_2)}{u_1-u_2}\left[\frac{\partial^2\Phi}{\partial u_1^2}+\frac{1}{2}\left(\frac{1}{u_1-e_1}+\frac{1}{u_1-e_2}\right)\frac{\partial\Phi}{\partial u_1}\right]$$

$$+\frac{4(u_2-e_1)(u_2-e_2)}{u_2-u_1}\left[\frac{\partial^2\Phi}{\partial u_2^2}+\frac{1}{2}\left(\frac{1}{u_2-e_1}+\frac{1}{u_2-e_2}\right)\frac{\partial\Phi}{\partial u_2}\right]$$

$$+\left[2E(u_1+u_2-e_1-e_2)+\frac{(\frac{1}{4}-k_1^2)(e_2-e_1)}{(u_1-e_1)(u_2-e_1)}+\frac{(\frac{1}{4}-k_2^2)(e_1-e_2)}{(u_1-e_2)(u_2-e_2)}+4\alpha\right]\Phi=0.$$

This equation admits separable solutions $\Phi=U_1(u_1)U_2(u_2)$ and separation equations

$$\left\{4(u_i-e_1)(u_i-e_2)\left(\frac{\partial^2}{\partial u_i^2}+\frac{1}{2}\left[\frac{1}{u_i-e_1}+\frac{1}{u_i-e_2}\right]\frac{\partial}{\partial u_i}\right)+2E[u_i^2-(e_1+e_2)u_i]\right.$$

$$\left.+\frac{(k_1^2-\frac{1}{4})(e_1-e_2)}{u_1-e_1}+\frac{(k_2^2-\frac{1}{4})(e_2-e_1)}{u_1-e_2}+4\alpha u_i+\lambda\right\}U_i(u_i)=0,\quad i=1,2. \tag{49}$$

The additional operator describing this coordinate system is

$$\hat{L}_3\Phi=\frac{4}{(u_1-u_2)(u_1+u_2-e_1-e_2)}\left\{u_2(u_1-e_1)(u_1-e_2)\left(\frac{\partial^2\Phi}{\partial u_1^2}+\frac{1}{2}\left[\frac{1}{u_1-e_1}+\frac{1}{u_1-e_2}\right]\frac{\partial\Phi}{\partial u_1}\right)\right.$$

$$\left.-u_1(u_2-e_1)(u_2-e_2)\left(\frac{\partial^2\Phi}{\partial u_2^2}+\frac{1}{2}\left[\frac{1}{u_2-e_1}+\frac{1}{u_2-e_2}\right]\frac{\partial\Phi}{\partial u_2}\right)\right\}$$

$$+\frac{k_1^2-\frac{1}{4}}{(u_1-e_1)(u_2-e_1)}\left\{u_1+u_2-e_1-e_2-\frac{[(u_1-e_2)(u_2-e_2)+e_1e_2]}{(u_1+u_2-e_1-e_2)}\right\}\Phi$$

$$+\frac{k_2^2-\frac{1}{4}}{(u_1-e_2)(u_2-e_2)}\left\{u_1+u_2-e_1-e_2-\frac{[(u_1-e_1)(u_2-e_1)+e_1e_2]}{(u_1+u_2-e_1-e_2)}\right\}\Phi$$

$$+\frac{4\alpha u_1u_2}{u_1+u_2-e_1-e_2}\Phi. \tag{50}$$

In Cartesian coordinates the solutions have the form

$$\Psi=e^{-\sqrt{-2E}(x^2+y^2)}(\sqrt{x^2+y^2}+x)^{(1/4)(1\pm2k_1)}(\sqrt{x^2+y^2}-x)^{(1/4)(1\pm2k_2)}$$

$$\times\prod_{m=1}^{q}\left(\frac{\sqrt{x^2+y^2}+x}{\theta_m-e_1}+\frac{\sqrt{x^2+y^2}-x}{\theta_m-e_2}-1\right). \tag{51}$$

Acting on the functions Ψ the operator L_3 has the form

$$L_3\Psi=\left[\left(\xi\frac{\partial}{\partial\eta}-\eta\frac{\partial}{\partial\xi}\right)^2+e_2\frac{\partial^2}{\partial\xi^2}+e_1\frac{\partial^2}{\partial\eta^2}-(e_2\xi^2+e_1\eta^2+e_1e_2)H\right.$$
$$\left.+\left(\frac{1}{4}-k_1^2\right)\frac{(\xi^2+\eta^2+e_2)}{\xi^2}+\left(\frac{1}{4}-k_2^2\right)\frac{(\xi^2+\eta^2+e_2)}{\eta^2}\right]\Psi$$
$$=\left[-4\left(x\frac{\partial}{\partial y}-y\frac{\partial}{\partial x}\right)^2-(e_1-e_2)\left(2x\frac{\partial^2}{\partial y^2}-2y\frac{\partial^2}{\partial x\partial y}-\frac{\partial}{\partial x}\right)-e_1e_2H\right.$$
$$-\frac{2\alpha}{\sqrt{x^2+y^2}}[e_1(\sqrt{x^2+y^2}-x)+e_2(\sqrt{x^2+y^2}+x)]-\left(\frac{1}{4}-k_1^2\right)$$
$$\times\frac{(e_1-e_2)(\sqrt{x^2+y^2}-x)}{2\sqrt{x^2+y^2}(\sqrt{x^2+y^2}+x)}-\left(\frac{1}{4}-k_2^2\right)\frac{(e_1-e_2)(\sqrt{x^2+y^2}+x)}{2\sqrt{x^2+y^2}(\sqrt{x^2+y^2}-x)}$$
$$\left.+\left(\frac{1}{4}-k_1^2\right)\frac{\sqrt{x^2+y^2}-x}{\sqrt{x^2+y^2}+x}+\left(\frac{1}{4}-k_2^2\right)\frac{\sqrt{x^2+y^2}+x}{\sqrt{x^2+y^2}-x}+\frac{1}{2}-k_1^2-k_2^2\right]\Psi, \tag{52}$$

where in Cartesian coordinates

$$H\Psi=\frac{\partial^2\Psi}{\partial x^2}+\frac{\partial^2\Psi}{\partial y^2}+\left[\frac{-\alpha}{\sqrt{x^2+y^2}}+\frac{1}{4\sqrt{x^2+y^2}}\left[\frac{k_1^2-\frac{1}{4}}{\sqrt{x^2+y^2}+x}+\frac{k_2^2-\frac{1}{4}}{\sqrt{x^2+y^2}-x}\right]\right]\Psi.$$

The eigenvalues of the operator L_3 are

$$\lambda=-(1\pm k_1\pm k_2)^2-2\sqrt{-2E}[e_2(1\pm k_1)-2e_1(1\pm k_2)]$$
$$+2Ee_1e_2-4\sum_{m=1}^{q}\left[e_2\frac{k_1+1}{\theta_m-e_1}+e_1\frac{k_2+1}{\theta_m-e_2}\right]. \tag{53}$$

The corresponding quadratic algebra can be generated by the classical constants

$$L_1=(\xi p_\eta-\eta p_\xi)^2+(\xi^2+\eta^2)\left[\frac{\frac{1}{4}-k_1^2}{\xi^2}+\frac{\frac{1}{4}-k_2^2}{\eta^2}\right],$$

$$L_2=\frac{1}{\xi^2+\eta^2}\left[\xi^2p_\eta^2-\eta^2p_\xi^2-\frac{\eta^2}{\xi^2}\left(\frac{1}{4}-k_1^2\right)-\frac{\xi^2}{\eta^2}\left(\frac{1}{4}-k_2^2\right)+2\alpha(\xi^2-\eta^2)\right],$$

$$L_3=(\xi p_\eta-\eta p_\xi)^2+e_2p_\xi^2+e_1p_\eta^2-(e_2\xi^2+e_1\eta^2)H$$
$$+\left(\frac{1}{4}-k_1^2\right)\frac{(\xi^2+\eta^2+e_2)}{\xi^2}+\left(\frac{1}{4}-k_2^2\right)\frac{(\xi^2+\eta^2+e_2)}{\eta^2},$$

$$H=\frac{1}{\xi^2+\eta^2}\left[p_\xi^2+p_\eta^2+4\alpha+\left(\frac{\frac{1}{4}-k_1^2}{\xi^2}+\frac{\frac{1}{4}-k_2^2}{\eta^2}\right)\right].$$

Here, L_1, L_2, and L_3 are functionally dependent via the relation

$$L_3^2=L_1^2+2(e_1-e_2)L_1L_2+(e_1-e_2)^2L_2^2-2[(k_1+k_2)+2(e_1+e_2)\alpha]L_1$$
$$-[4\alpha^2(e_1^2-e_2^2)+2(e_1-e_2)(k_1+k_2)]L_2-(k_1+k_2+2\alpha(e_1+e_2))^2. \tag{54}$$

The only additional quantity that we need is

$$L_{12}=\{L_1,L_2\}=\frac{1}{\xi^2+\eta^2}\left[4(\xi p_\eta-\eta p_\xi)^2(\xi p_\xi-\eta p_\eta)-16\xi\eta(\xi p_\eta-\eta p_\xi)\right.$$
$$+\left[\left(4\frac{\xi^3}{\eta^2}+8\xi\right)\left(\frac{1}{4}-k_2^2\right)+4\frac{\eta^2}{\xi}\left(\frac{1}{4}-k_1^2\right)\right]p_\xi$$
$$\left.-\left[\left(4\frac{\eta^3}{\xi^2}+8\eta\right)\left(\frac{1}{4}-k_1^2\right)+4\frac{\xi^2}{\eta}\left(\frac{1}{4}-k_2^2\right)\right]p_\eta\right].$$

The nontrivial independent commutation relations are

$$\{L_{12},L_1\}=-16L_1L_2+32\alpha(k_1^2-k_2^2),\quad \{L_{12},L_2\}=-16HL_1+8L_2^2. \tag{55}$$

We should also observe the relations

$$\{L_1,L_3\}=(e_1-e_2)\{L_1,L_2\},\quad \{L_1,L_2\}=\{L_3,L_2\},$$
$$\{L_{12},L_3\}=16(e_1-e_2)HL_1-8(e_1-e_2)L_2^2-16L_1L_2$$
$$-16(e_1-e_2)H-32\alpha(\alpha(e_1-e_2)+(k_1^2-k_2^2)). \tag{56}$$

(iv) The fourth potential is

$$V_4=\frac{-\alpha}{\sqrt{x^2+y^2}}+\frac{B_1}{4}\frac{\sqrt{\sqrt{x^2+y^2}+x}}{\sqrt{x^2+y^2}}+\frac{B_2}{4}\frac{\sqrt{\sqrt{x^2+y^2}-x}}{\sqrt{x^2+y^2}}. \tag{57}$$

The corresponding Schrödinger equation separates in two versions of parabolic coordinates.

In *regular parabolic coordinates* (2) the Schrödinger equation has the form

$$\frac{1}{\xi^2+\eta^2}\left[\frac{\partial^2\Psi}{\partial\xi^2}+\frac{\partial^2\Psi}{\partial\eta^2}+(4\alpha-B_1\xi-B_2\eta)\Psi\right]=-2E\Psi. \tag{58}$$

If we write the solutions Ψ in the form $X(\xi)Y(\eta)$, the separation equations are

$$\frac{\partial^2X}{\partial\xi^2}+(2\alpha-\lambda-B_1\xi+2E\xi^2)X=0,\quad \frac{\partial^2Y}{\partial\eta^2}+(2\alpha+\lambda-B_2\eta+2E\eta^2)Y=0.$$

The solutions of these equations are

$$X(\xi)=e^{(1/2\sqrt{-2E})[-2E\xi^2+B_1\xi]}H_n\left(\sqrt{-2E}\left(\xi-\frac{B_1}{4E}\right)\right) \tag{59}$$

and

$$Y(\eta)=e^{(1/2\sqrt{-2E})[-2E\eta^2+B_2\eta]}H_m\left(\sqrt{-2E}\left(\eta-\frac{B_2}{4E}\right)\right), \tag{60}$$

where

$$2\alpha-\lambda-\frac{B_1^2}{8E}=-(n+1)\sqrt{-2E},\quad 2\alpha+\lambda-\frac{B_2^2}{8E}=-(m+1)\sqrt{-2E}.$$

From this we see that the energy eigenstates are solutions of

$$4\alpha-\frac{1}{8E}(B_1^2+B_2^2)=-(m+n+2)\sqrt{-2E}. \tag{61}$$

Moreover, it follows from (59) and (60) that

$$\Psi(\xi,\eta)=e^{(1/2\sqrt{-2E})[-2E(\xi^2+\eta^2)+B_1\xi+B_2\eta]}\Phi(\xi,\eta),$$

where Φ is a polynomial in ξ and η. If (58) is written as a differential equation for Φ, it can be interpreted as an eigenvalue equation, with eigenvalue -4α, for an E-dependent operator acting on a space of polynomials. The operator whose eigenvalue is λ is

$$\begin{aligned}L_1\Psi&=\frac{1}{\xi^2+\eta^2}\left\{\eta^2\frac{\partial^2\Psi}{\partial\xi^2}-\xi^2\frac{\partial^2\Psi}{\partial\eta^2}+[-B_1\xi\eta^2+B_2\eta\xi^2+2(\eta^2-\xi^2)\alpha]\Psi\right\}\\&=-2x\frac{\partial^2\Psi}{\partial y^2}+2y\frac{\partial^2\Psi}{\partial x\partial y}+\frac{\partial\Psi}{\partial x}+\left[\frac{B_1}{2}\sqrt{\sqrt{x^2+y^2}+x}\left(1-\frac{x}{\sqrt{x^2+y^2}}\right)\right.\\&\quad\left.+\frac{B_2}{2}\sqrt{\sqrt{x^2+y^2}-x}\left(1+\frac{x}{\sqrt{x^2+y^2}}\right)-\frac{2x\alpha}{\sqrt{x^2+y^2}}\right]\Psi.\end{aligned} \tag{62}$$

The second coordinate system is a *variant of parabolic coordinates* (3) in terms of which the Schrödinger equation has the form

$$\frac{1}{\mu^2+\nu^2}\left\{\frac{\partial^2\Psi}{\partial\mu^2}+\frac{\partial^2\Psi}{\partial\nu^2}+\left[4\alpha-\frac{B_1}{\sqrt{2}}(\mu+\nu)-\frac{B_2}{\sqrt{2}}(\mu-\nu)\right]\Psi\right\}=-2E\Psi.$$

The separation equations for $\Psi=X(\mu)Y(\nu)$ are

$$\frac{\partial^2X}{\partial\mu^2}+\left(2\alpha-\lambda-\frac{1}{\sqrt{2}}(B_1+B_2)\mu+2E\mu^2\right)X=0,$$

$$\frac{\partial^2Y}{\partial\nu^2}+\left(2\alpha+\lambda-\frac{1}{\sqrt{2}}(B_1-B_2)\nu+2E\nu^2\right)Y=0.$$

The operator whose eigenvalue is λ is

$$\begin{aligned}L_2\Psi&=\frac{1}{\mu^2+\nu^2}\left[\nu^2\frac{\partial^2\Psi}{\partial\mu^2}-\mu^2\frac{\partial^2\Psi}{\partial\nu^2}-\frac{\mu\nu^2}{\sqrt{2}}(B_1+B_2)\Psi+\frac{\nu\mu^2}{\sqrt{2}}(B_1-B_2)\Psi+2(\nu^2-\mu^2)\alpha\Psi\right]\\&=-2y\frac{\partial^2\Psi}{\partial x^2}+2x\frac{\partial^2\Psi}{\partial x\partial y}+\frac{\partial\Psi}{\partial y}+\left[-\frac{1}{2\sqrt{2}}(B_1+B_2)\sqrt{\sqrt{x^2+y^2}+x}\left(1-\frac{x}{\sqrt{x^2+y^2}}\right)\right.\\&\quad\left.+\frac{1}{2\sqrt{2}}(B_1-B_2)\sqrt{\sqrt{x^2+y^2}-x}\left(1+\frac{x}{\sqrt{x^2+y^2}}\right)-\frac{2x\alpha}{\sqrt{x^2+y^2}}\right]\Psi.\end{aligned} \tag{63}$$

The space of polynomials in ξ,η coincides with the space of polynomials in ν,μ. The classical operators associated with this separable system are, using the ξ,η coordinates,

$$L_1=\frac{1}{\xi^2+\eta^2}\,[\,\eta^2 p_\xi^2-\xi^2 p_\eta^2-B_1\xi\eta^2+B_2\eta\xi^2+2(\eta^2-\xi^2)\alpha],$$

$$L_2=\frac{1}{\xi^2+\eta^2}\left[(\xi p_\xi-\eta p_\eta)(\xi p_\eta-\eta p_\xi)-4\xi\eta\alpha+\frac{1}{2}(\xi^2-\eta^2)(\eta B_1-\xi B_2)\right],$$

$$H=\frac{1}{\xi^2+\eta^2}\,[p_\xi^2+p_\eta^2+(4\alpha-B_1\xi-B_2\eta)],$$

together with

$$L_{12}=\{L_1,L_2\}=\frac{1}{\xi^2+\eta^2}\,[2(\xi p_\eta-\eta p_\xi)(p_\xi^2+p_\eta^2)+8\alpha(\xi p_\eta-\eta p_\xi)$$
$$+((\eta^2-\xi^2)p_\eta+2\xi\eta p_\xi)B_1+((\eta^2-\xi^2)p_\xi+2\xi\eta p_\eta)B_2].$$

The defining relations of the quadratic algebra are

$$L_{12}^2=4L_1^2H+4L_2^2H-16\alpha^2H+(B_2^2-B_1^2)L_1-2B_1B_2L_2-2\alpha^2(B_1^2+B_2^2),$$
$$\{L_{12},L_1\}=-4L_1^2H+B_1B_2,\quad \{L_{12},L_2\}=4L_1H-\tfrac{1}{2}(B_1^2-B_2^2). \tag{64}$$

There are, of course, quantum analogs for all the quadratic algebras that occur for each potential. These operator algebras can be obtained via the replacement of the Poisson bracket by the commutator bracket. [Indeed the relations (64) for the classical version of the algebras remain unchanged under this replacement.] One can ask the question what are the consequences of such an algebra on the eigenfunction spaces of the operators L_1 and L_2? Let the eigenspace corresponding to a fixed bound state energy E be of dimension N. This eigenspace can be spanned by eigenfunctions of both L_1 and L_2. Let the corresponding eigenvectors be ϕ_m and ψ_m, respectively, satisfying

$$L_1\phi_m=\lambda_m\phi_m,\quad L_2\psi_n=\rho_n\psi_n,$$

where $\lambda_n=2\alpha-B_1^2/8E-(2n+1)\sqrt{-2E}$ and $\rho_m=2\alpha-(B_1+B_2)^2/16E-(2m+1)\sqrt{-2E}$. Using the quantum version of the defining relations of the quadratic algebra, what can we deduce? If we use the second of the relations (64) acting on ψ_n and write $L_1\psi_n=\Sigma_{\tau=1}^N C_{n\tau}\psi_\tau$ we deduce that

$$[(\rho_n-\rho_\tau)^2+8E]C_{n\tau}=-[\tfrac{1}{2}(B_1^2-B_2^2)+16\alpha E]\,\delta_{n\tau}.$$

This relation implies that $C_{nn}=-[\frac{1}{2}(B_1^2-B_2^2)+16\alpha E]/8E$ and $C_{pq}\neq 0$ if $|p-q|\leqslant 1$ and zero otherwise. Here we have used the relation $(\rho_n-\rho_\tau)^2+8E=0$ for $|n-\tau|=1$. If we apply the second relation to the function ψ_n we obtain the relation

$$\sum_{\tau=1}^{N} C_{n\tau}C_{\tau\sigma}(2\rho_\tau-\rho_n-\rho_\sigma)=(8E\rho_n+B_1B_2+16\alpha E)\,\delta_{n\sigma}.$$

If we assume that the basis functions ψ_n are orthonormal and observe that the operator L_1 is self-adjoint, then we can assume $C_{n+1,n}=C_{n,n+1}^*$. The only nontrivial consequence of this relation is when $n=\sigma$. The result is

$$4\sqrt{-2E}(|C_{n,n+1}|^2-|C_{n-1,n}|^2)=8E\rho_n+B_1B_2+16\alpha E.$$

If we act on the functions ϕ_m, we generate similar relations. In fact, if we write $L_2\phi_m=\Sigma_{\tau=1}^N D_{m\tau}\phi_\tau$, the corresponding results are

$$D_{nn}=-(B_1B_2+16\alpha E)/8E$$

and $D_{pq}\neq 0$ if $|p-q|\leqslant 1$ and is zero otherwise. Furthermore,

$$4\sqrt{-2E}(|D_{n,n+1}|^2-|D_{n-1,n}|^2)=-8\lambda_\sigma E-\tfrac{1}{2}(B_1^2-B_2^2)-16\alpha E.$$

From these relations we can, in principle, calculate the matrices C_{pq} and D_{pq}. Once these are known, relations are also implied for the matrices relating the two bases. If we denote $\langle\phi_m,\psi_q\rangle=A_{mq}$, then these matrices must satisfy

$$C_{tr}=\sum_{m=1}^N \lambda_m A_{mr}^* A_{mt}, \quad D_{tr}=\sum_{m=1}^N \rho_m A_{mr} A_{mt}^*.$$

Thus, from the consequences of the quadratic algebra we can, in principle, calculate the overlap functions A_{rs}. The only ambiguity is in the choice of the phases of the wavefunctions.

III. THE TWO-DIMENSIONAL SPHERE

In the case of the two-dimensional sphere there are two potentials that are separable in more than one coordinate system, and these each separate in two systems. To work with the two-dimensional sphere it is convenient to use projective coordinates: s_i, $i=1,2,3$, $s_1^2+s_2^2+s_3^2=1$.

(i) The first superintegrable potential on the sphere is

$$V_1=\frac{1}{2}\left(\frac{k_1^2-\frac{1}{4}}{s_1^2}+\frac{k_2^2-\frac{1}{4}}{s_2^2}+\frac{k_3^2-\frac{1}{4}}{s_3^2}\right). \tag{65}$$

In terms of *spherical coordinates*

$$s_1=\sin\,\theta\,\cos\,\varphi, \quad s_2=\sin\,\theta\,\sin\,\varphi, \quad s_3=\cos\,\theta, \tag{66}$$

the corresponding Schrödinger equation has the form

$$\left[\left(s_1\frac{\partial}{\partial s_2}-s_2\frac{\partial}{\partial s_1}\right)^2+\left(s_1\frac{\partial}{\partial s_3}-s_3\frac{\partial}{\partial s_1}\right)^2+\left(s_3\frac{\partial}{\partial s_2}-s_2\frac{\partial}{\partial s_3}\right)^2\right]\Psi$$
$$-\left[\frac{k_1^2-\frac{1}{4}}{s_1^2}+\frac{k_2^2-\frac{1}{4}}{s_2^2}+\frac{k_3^2-\frac{1}{4}}{s_3^2}\right]\Psi=-2E\Psi, \tag{67}$$

or, in terms of θ and φ,

$$\frac{1}{\sin\,\theta}\frac{\partial}{\partial\theta}\left(\sin\,\theta\,\frac{\partial\Psi}{\partial\theta}\right)+\frac{1}{\sin^2\,\theta}\frac{\partial^2\Psi}{\partial\varphi^2}+\frac{1}{\sin^2\,\theta}\left(\frac{\frac{1}{4}-k_1^2}{\cos^2\,\varphi}+\frac{\frac{1}{4}-k_2^2}{\sin^2\,\varphi}\right)\Psi+\frac{\frac{1}{4}-k_3^2}{\cos^2\,\theta}\,\Psi=-2E\Psi.$$

This equation admits separable solutions of the form $\Psi=T(\theta)\Phi(\varphi)$ such that

$$\frac{\partial^2\Phi}{\partial\varphi^2}+\left(\frac{\frac{1}{4}-k_1^2}{\cos^2\varphi}+\frac{\frac{1}{4}-k_2^2}{\sin^2\varphi}\right)\Phi=-\lambda\Phi,$$

$$\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial T}{\partial\theta}\right)+\frac{1}{\sin^2\theta}\lambda T+\frac{\frac{1}{4}-k_3^2}{\cos^2\theta}T=-2ET.$$

These equations have the solutions

$$\Phi=(\sin\varphi)^{k_2+1/2}(\cos\varphi)^{k_1+1/2}P_n^{(k_2,k_1)}(\cos 2\varphi),$$

where $\lambda=(2n+1+k_1+k_2)^2$ and n is an integer, and

$$T(\theta)=(\cos\theta)^{k_3+1/2}(\sin\theta)^{2n+k_1+k_2+1}P_m^{(2n+k_1+k_2+1,k_3)}(\cos 2\theta),$$

where $E=\frac{1}{2}[2(m+n+1)+(k_1+k_2+k_3)]^2-\frac{1}{8}$. The orthonormal basis eigenfunctions are

$$\Psi=(\sin\theta)^{-1}\Phi_n^{(k_2,k_1)}(\varphi)\Phi^{(2n+k_1+k_2,k_3)}(\theta). \tag{68}$$

The operator which characterizes this solution and separation is

$$L_1\Psi=\left[\left(s_1\frac{\partial}{\partial s_2}-s_2\frac{\partial}{\partial s_1}\right)^2+\left(\frac{1}{4}-k_1^2\right)\frac{s_1^2+s_2^2}{s_1^2}+\left(\frac{1}{4}-k_2^2\right)\frac{s_1^2+s_2^2}{s_2^2}\right]\Psi=\lambda\Psi. \tag{69}$$

Note that after the multiplier $(\sin\varphi)^{k_2+1/2}(\cos\varphi)^{k_1+1/2}(\cos\theta)^{k_3+1/2}(\sin\theta)^{k_1+k_2+1}=\Pi_{\ell=1}^3 s_\ell^{k_\ell+1/2}$ is split off, the eigenfunctions are polynomials in the variables s_2^2 and s_2^3. See Refs. 21–24 for a complete discussion of the polynomial setting for this eigenvalue equation.

For the second coordinate system we choose *Lamé coordinates* given by

$$s_i^2=\frac{(u_1-e_i)(u_2-e_i)}{(e_i-e_j)(e_i-e_k)},\quad i,j,k=1,2,3,\quad \text{and } i,j,k \text{ pairwise distinct.}$$

The Schrödinger equation written in terms of these coordinates is

$$\begin{aligned}&\frac{4}{(u_1-u_2)}\left[(u_1-e_1)(u_1-e_2)(u_1-e_3)\left[\frac{\partial^2\Psi}{\partial u_1^2}+\frac{1}{2}\left(\frac{1}{u_1-e_1}+\frac{1}{u_1-e_2}+\frac{1}{u_1-e_3}\right)\frac{\partial\Psi}{\partial u_1}\right]\right.\\&\quad\left.-(u_2-e_1)(u_2-e_2)(u_2-e_3)\left[\frac{\partial^2\Psi}{\partial u_2^2}-\frac{1}{2}\left(\frac{1}{u_2-e_1}+\frac{1}{u_2-e_2}+\frac{1}{u_2-e_3}\right)\frac{\partial\Psi}{\partial u_2}\right]\right]\\&\quad+\left[\left(k_1^2-\frac{1}{4}\right)\frac{(e_1-e_2)(e_1-e_3)}{(u_1-e_1)(u_2-e_1)}+\left(k_2^2-\frac{1}{4}\right)\frac{(e_2-e_1)(e_2-e_3)}{(u_1-e_2)(u_2-e_2)}\right.\\&\quad\left.+\left(k_3^2-\frac{1}{4}\right)\frac{(e_3-e_2)(e_3-e_1)}{(u_1-e_3)(u_2-e_3)}\right]\Psi=2E\Psi.\end{aligned} \tag{70}$$

The separation equations are

$$(\rho-e_1)(\rho-e_2)(\rho-e_3)\left[\frac{\partial^2}{\partial\rho^2}+\frac{1}{2}\left(\frac{1}{\rho-e_1}+\frac{1}{\rho-e_2}+\frac{1}{\rho-e_3}\right)\frac{\partial\Psi}{\partial\rho}\right]-\left[\left(k_1^2-\frac{1}{4}\right)\frac{(e_1-e_2)(e_1-e_3)}{\rho-e_1}\right.$$
$$\left.+\left(k_2^2-\frac{1}{4}\right)\frac{(e_2-e_1)(e_2-e_3)}{\rho-e_2}+\left(k_3^2-\frac{1}{4}\right)\frac{(e_3-e_2)(e_3-e_1)}{\rho-e_3}+2E\rho+\mu\right]\Psi=0, \tag{71}$$

where $\rho=u_1, u_2$. The operator whose eigenvalue is μ is

$$L_2\Psi=\frac{-4}{(u_1-u_2)}\left[u_2\left[(u_1-e_1)(u_1-e_2)(u_1-e_3)\left[\frac{\partial^2\Psi}{\partial u_1^2}+\frac{1}{2}\left(\frac{1}{u_1-e_1}+\frac{1}{u_1-e_2}+\frac{1}{u_1-e_3}\right)\frac{\partial\Psi}{\partial u_1}\right]\right]\right.$$
$$-u_1\left[(u_2-e_1)(u_2-e_2)(u_2-e_3)\left[\frac{\partial^2\Psi}{\partial u_2^2}-\frac{1}{2}\left(\frac{1}{u_2-e_1}+\frac{1}{u_2-e_2}+\frac{1}{u_2-e_3}\right)\frac{\partial\Psi}{\partial u_2}\right]\right]$$
$$+\left[\left(k_1^2-\frac{1}{4}\right)\frac{(e_1-e_2)(e_1-e_3)}{(u_1-e_1)(u_2-e_1)}(u_1+u_2-e_1)+\left(k_2^2-\frac{1}{4}\right)\frac{(e_2-e_1)(e_2-e_3)}{(u_1-e_2)(u_2-e_2)}\right.$$
$$\left.\left.\times(u_1+u_2-e_2)+\left(k_3^2-\frac{1}{4}\right)\frac{(e_3-e_2)(e_3-e_1)}{(u_1-e_3)(u_2-e_3)}(u_1+u_2-e_3)\right]\Psi. \right. \tag{72}$$

Expressed in terms of coordinates on the sphere this has the form

$$L_2=e_3\left(s_1\frac{\partial}{\partial s_2}-s_2\frac{\partial}{\partial s_1}\right)^2+e_2\left(s_1\frac{\partial}{\partial s_3}-s_3\frac{\partial}{\partial s_1}\right)^2+e_1\left(s_3\frac{\partial}{\partial s_2}-s_2\frac{\partial}{\partial s_3}\right)^2+\left(\frac{1}{4}-k_1^2\right)\left[\frac{e_2s_2^2+e_3s_3^2}{s_1^2}\right.$$
$$\left.+e_1-e_2-e_3\right]+\left(\frac{1}{4}-k_2^2\right)\left[\frac{e_1s_1^2+e_3s_3^2}{s_2^2}+e_2-e_1-e_3\right]+\left(\frac{1}{4}-k_3^2\right)\left[\frac{e_2s_2^2+e_1s_1^2}{s_3^2}+e_3-e_2-e_1\right]. \tag{73}$$

The eigenfunctions Ψ can readily be calculated from the Schrödinger equation (67). In order to find the bound state solutions we try a solution of the form

$$\Psi=\left(\prod_{\ell=1}^{3}s_\ell^{k_\ell+1/2}\right)\prod_{j=1}^{q}\left(\frac{s_1^2}{\theta_j-e_1}+\frac{s_2^2}{\theta_j-e_2}+\frac{s_3^2}{\theta_j-e_3}\right) \tag{74}$$

(Ref. 19) and observe that

$$\frac{s_1^2}{\theta_j-e_1}+\frac{s_2^2}{\theta_j-e_2}+\frac{s_3^2}{\theta_j-e_3}=\frac{\Pi_{\ell=1}^2(u_\ell-\theta_j)}{\Pi_{m=1}^3(\theta_j-e_m)}.$$

For solutions, the zeros θ_p must satisfy the equations

$$\frac{k_1+1}{\theta_m-e_1}+\frac{k_2+1}{\theta_m-e_2}+\frac{k_3+1}{\theta_m-e_3}+\sum_{j\neq m}\frac{2}{\theta_m-\theta_j}=0, \tag{75}$$

and the eigenvalues E and μ in this case are

$$E=\tfrac{1}{2}(2q+2+k_1+k_2+k_3)^2-\tfrac{1}{8},$$

$$\mu=-2[k_1(e_2+e_3)+k_2(e_1+e_3)+k_3(e_2+e_1)+e_3k_1k_2+e_2k_1k_3+e_1k_2k_3]$$
$$-\frac{3}{2}(e_1+e_2+e_3)-4e_2e_3(k_1+1)\sum_{m=1}^{q}\frac{1}{(\theta_m-e_1)}-4e_1e_3(k_2+1)$$
$$\times\sum_{m=1}^{q}\frac{1}{(\theta_m-e_2)}-4e_2e_1(k_3+1)\sum_{m=1}^{q}\frac{1}{(\theta_m-e_3)}.$$

If we take the constants of the motion to be

$$H=M_{12}^2+M_{13}^2+M_{23}^2+\frac{k_1^2-\frac{1}{4}}{s_1^2}(s_2^2+s_3^2)+\frac{k_2^2-\frac{1}{4}}{s_2^2}(s_1^2+s_3^2)+\frac{k_3^2-\frac{1}{4}}{s_3^2}(s_2^2+s_1^2),$$

$$L_1=M_{12}^2+\left(k_1^2-\frac{1}{4}\right)\frac{s_2^2}{s_1^2}+\left(k_2^2-\frac{1}{4}\right)\frac{s_1^2}{s_2^2},$$

$$L_2=e_3M_{12}^2+e_2M_{13}^2+e_1M_{32}^2+\frac{k_1^2-\frac{1}{4}}{s_1^2}(e_3s_2^2+e_2s_3^2)+\frac{k_2^2-\frac{1}{4}}{s_2^2}(e_3s_1^2+e_1s_3^2)+\frac{k_3^2-\frac{1}{4}}{s_3^2}(e_1s_2^2+e_2s_1^2),$$

the corresponding defining relations are

$$L_{12}=\{L_1,L_2\}=4(e_1-e_2)\left[M_{12}M_{13}M_{32}-\left(k_1^2-\frac{1}{4}\right)\frac{s_3s_2}{s_1^2}M_{23}\right.$$
$$\left.-(k_2^2-\tfrac{1}{4})\frac{s_3s_1}{s_2^2}M_{31}-\left(k_3^2-\frac{1}{4}\right)\frac{s_1s_2}{s_3^2}M_{12}\right],$$

$$\begin{aligned}L_{12}^2=&-16L_1(e_2H+(e_3-e_2)L_1-L_2)(e_1H+(e_3-e_1)L_1-L_2)\\&-16\left(k_3^2-\frac{1}{4}\right)(e_1-e_2)^2L_1^2\\&-16\left(k_1^2-\frac{1}{4}\right)(e_2H+(e_3-e_2)L_1-L_2)^2\\&-16\left(k_2^2-\frac{1}{4}\right)(e_1H+(e_3-e_1)L_1-L_2)^2-\frac{4}{3}\prod_{\ell=1}^{3}\left(k_\ell^2-\frac{1}{4}\right)(e_1-e_2)^2,\end{aligned}\tag{76}$$

$$\{L_{12},L_1\}=-(8L_1+16)\left(k_2^2-\frac{1}{4}\right)(e_1H+(e_3-e_1)L_1-L_2)$$
$$-(8L_1+16)\left(k_1^2-\frac{1}{4}\right)(e_2H+(e_3-e_2)L_1-L_2),$$

$$\{L_{12},L_2\}=-8(e_2H+(e_3-e_2)L_1-L_2)(e_1H+(e_3-e_1)L_1-L_2)-8(e_2-e_3)L_1(e_1H+(e_3-e_1)L_1-L_2)-8(e_1-e_3)L_1(e_2H+(e_3-e_2)L_1-L_2)+16\left(\left(k_1^2-\frac{1}{4}\right)(e_3-e_2)+\left(k_2^2-\frac{1}{4}\right)(e_3-e_1)\right)L_2-16\left(\left(k_1^2-\frac{1}{4}\right)(e_3-e_2)^2+\left(k_2^2-\frac{1}{4}\right)\times(e_3-e_1)^2+\left(k_3^2-\frac{1}{4}\right)(e_1-e_2)^2\right)L_1+16e_1(e_1-e_3)\left(k_2^2-\frac{1}{4}\right)+16e_2(e_2-e_3)H.$$

(ii) The second potential on the sphere is

$$V_2=\frac{-\alpha s_3}{2\sqrt{s_1^2+s_2^2}}+\frac{1}{4\sqrt{s_1^2+s_2^2}}\left[\frac{k_1^2-\frac{1}{4}}{\sqrt{s_1^2+s_2^2}+s_1}+\frac{k_2^2-\frac{1}{4}}{\sqrt{s_1^2+s_2^2}-s_1}\right]. \tag{77}$$

In *polar coordinates* the Schrödinger equation has the form

$$\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial\Psi}{\partial\theta}\right)+\frac{1}{\sin^2\theta}\frac{\partial^2\Psi}{\partial\varphi^2}+\frac{\alpha\cos\theta}{\sin\theta}\Psi+\frac{1}{2\sin^2\theta}\left(\frac{\frac{1}{4}-k_1^2}{1+\cos\varphi}+\frac{\frac{1}{4}-k_2^2}{1-\cos\varphi}\right)\Psi=-2E\Psi.$$

This equation can be solved by a separation of variables via the substitution $\Psi=T(\theta)\Phi(\varphi)$, and the separation equations are

$$\frac{\partial^2\Phi}{\partial\varphi^2}+\frac{1}{2}\left(\frac{\frac{1}{4}-k_1^2}{1+\cos\varphi}+\frac{\frac{1}{4}-k_2^2}{1-\cos\varphi}\right)\Phi=-\lambda^2\Phi,$$

$$\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial T}{\partial\theta}\right)+\frac{\alpha\cos\theta}{\sin\theta}T-\frac{\lambda^2}{\sin^2\theta}T=-2ET.$$

The solutions of the first equation are $\Phi_m^{(k_1,k_2)}(\varphi/2)$ [see (20)], where $\lambda^2=\frac{1}{4}(2m+k_1+k_2+1)^2$. The solution of the θ separation equation is given by

$$S_{nm}(\theta)=\frac{1}{\Gamma(2m+2+k_1+k_2)}\sqrt{\left(1+\frac{\alpha^2}{(n+m+1+\frac{1}{2}(k_1+k_2))^4}\right)\frac{\Gamma(n+2(m+1)+k_1+k_2)\Gamma(i\sigma+m+1+\frac{1}{2}(k_1+k_2))}{m!\Gamma(i\sigma+m+\frac{1}{2}(k_1+k_2))}}\times(2\sin\theta)^{m+1+(1/2)(k_1+k_2)}e^{i\theta(i\sigma-n)}{}_2F_1(-n,i\sigma+m+1+\tfrac{1}{2}(k_1+k_2);2m+2+k_1+k_2;1-e^{2i\theta}), \tag{78}$$

where $\sigma=\alpha/(n+m+1+\frac{1}{2}(k_1+k_2))$, and the orthonormal eigenfunctions are

$$\Psi=S_{nm}(\theta)\Phi_m^{(k_1,k_2)}\left(\frac{\varphi}{2}\right).$$

The operator which characterizes the separable solutions in this coordinate system is

$$L_1\Psi=\left[\left(s_1\frac{\partial}{\partial s_2}-s_2\frac{\partial}{\partial s_1}\right)^2+\left(\frac{1}{4}-k_1^2\right)\frac{\sqrt{s_1^2+s_2^2}}{2(\sqrt{s_1^2+s_2^2}+s_1)}+\left(\frac{1}{4}-k_2^2\right)\frac{\sqrt{s_1^2+s_2^2}}{2(\sqrt{s_1^2+s_2^2}-s_1)}\right]\Psi$$
$$=-\lambda^2\Psi.$$

For the second coordinate system we must choose a *variant of the standard elliptical coordinates*. A suitable choice is

$$s_1=\cos f\, x_1+\sin f\, x_3,\quad s_2=x_2,\quad s_3=-\sin f\, x_1+\cos f\, x_3,$$

where

$$x_i^2=\frac{(y_1-e_i)(y_2-e_i)}{(e_i-e_j)(e_i-e_k)},\quad i,j,k=1,2,3\quad\text{and } i,j,k\text{ pairwise distinct},\quad \sin f=\sqrt{\frac{e_2-e_1}{e_3-e_1}}.$$

To see how this works it is convenient to define the new variables E_+, E_-, Z_1, and Z_2 according to

$$e_1=e_2+\frac{1}{4}(E_++E_-)^2,\quad e_3=e_2+\frac{1}{4}(E_+-E_-)^2,$$

$$y_j=e_2+\frac{1}{4}(E_+^2+E_-^2)+\frac{1}{4}E_+E_-\left(Z_j+\frac{1}{Z_j}\right).$$

In terms of these variables Schrödinger's equation has the form

$$-\frac{4Z_1Z_2}{(Z_1-Z_2)(Z_1Z_2-1)}\left[(Z_1+\Omega_+)(Z_1+\Omega_-)Z_1\left[\frac{\partial^2\Psi}{\partial Z_1^2}+\frac{1}{2}\left(\frac{1}{Z_1+\Omega_+}+\frac{1}{Z_1+\Omega_-}+\frac{1}{Z_1}\right)\frac{\partial\Psi}{\partial Z_1}\right]\right.$$
$$\left.-(Z_2+\Omega_+)(Z_2+\Omega_-)Z_2\left[\frac{\partial^2\Psi}{\partial Z_2^2}+\frac{1}{2}\left(\frac{1}{Z_2+\Omega_+}+\frac{1}{Z_2+\Omega_-}+\frac{1}{Z_2}\right)\frac{\partial\Psi}{\partial Z_2}\right]\right]$$
$$+\left[\frac{2i\alpha(Z_1Z_2+1)}{(Z_1Z_2-1)}+\left(k_1^2-\frac{1}{4}\right)\frac{(1-\Omega_-^2)Z_1Z_2}{(Z_1Z_2-1)(Z_2+\Omega_+)(Z_1+\Omega_+)}\right.$$
$$\left.+\left(k_2^2-\frac{1}{4}\right)\frac{(1-\Omega_+^2)Z_1Z_2}{(Z_1Z_2-1)(Z_2+\Omega_-)(Z_1+\Omega_-)}\right]\Psi=-2E\Psi,\tag{79}$$

where $\Omega_+=E_+/E_-$ and $\Omega_-=E_-/E_+$, so $\Omega_+\Omega_-=1$. The separation equations are

$$4(Z_j+\Omega_+)(Z_j+\Omega_-)Z_j\left[\frac{\partial^2\Psi}{\partial Z_j^2}+\frac{1}{2}\left(\frac{1}{Z_j+\Omega_+}+\frac{1}{Z_j+\Omega_-}+\frac{1}{Z_j}\right)\frac{\partial\Psi}{\partial Z_j}\right]$$
$$+\left[2(-i\alpha+E)Z_j+2(i\alpha+E)\frac{1}{Z_j}+\frac{(k_1^2-\frac{1}{4})(\Omega_-^2-1)}{Z_j+\Omega_-}+\frac{(k_2^2-\frac{1}{4})(\Omega_+^2-1)}{Z_j+\Omega_+}+\mu\right]\Psi=0.$$

In terms of the variables Z_j the operator which describes the separation is

$$L_2\Psi=\frac{4}{(Z_1-Z_2)(Z_1Z_2-1)}\Bigg[-(Z_2+1)Z_1(Z_1+\Omega_+)(Z_1+\Omega_-)$$
$$\times\left[\frac{\partial^2\Psi}{\partial Z_1^2}+\frac{1}{2}\left(\frac{1}{Z_1+\Omega_+}+\frac{1}{Z_1+\Omega_-}+\frac{1}{Z_1}\right)\frac{\partial\Psi}{\partial Z_1}\right]$$
$$+(Z_1+1)Z_2(Z_2+\Omega_+)(Z_2+\Omega_-)\left[\frac{\partial^2\Psi}{\partial Z_2^2}+\frac{1}{2}\left(\frac{1}{Z_2+\Omega_+}+\frac{1}{Z_2+\Omega_-}+\frac{1}{Z_2}\right)\frac{\partial\Psi}{\partial Z_2}\right]\Bigg]$$
$$+\left[\frac{(1-\Omega_-^2)(Z_1Z_2(Z_1+Z_2)+\Omega_-(Z_1Z_2-1))}{(Z_1Z_2-1)(Z_1+\Omega_-)(Z_2+\Omega_-)}\left(k_1^2-\frac{1}{4}\right)\right.$$
$$\left.+\frac{(1-\Omega_+^2)(Z_1Z_2(Z_1+Z_2)+\Omega_+(Z_1Z_2-1))}{(Z_1Z_2-1)(Z_1+\Omega_+)(Z_2+\Omega_+)}\left(k_2^2-\frac{1}{4}\right)+\frac{4i\alpha(Z_1+Z_2)}{Z_1Z_2-1}\right]\Psi. \tag{80}$$

Indeed if we consider the elliptical coordinates

$$U_3^2=Z_1Z_2,\quad U_1^2=\frac{(Z_1+\Omega_-)(Z_2+\Omega_-)}{\Omega_-^2-1},\quad U_2^2=\frac{(Z_1+\Omega_+)(Z_2+\Omega_+)}{\Omega_+^2-1}, \tag{81}$$

then putting $k_3=\sqrt{\frac{1}{4}+2(E-i\alpha)}$ and $\widetilde{E}=i\alpha+E$ and multiplying the Schrödinger equation by $(1/Z_1Z_2-1)$ we see that the resulting equation has the form

$$H\Psi=\frac{\partial^2\Psi}{\partial U_1^2}+\frac{\partial^2\Psi}{\partial U_2^2}+\frac{\partial^2\Psi}{\partial U_3^2}-\left(U_1\frac{\partial}{\partial U_1}+U_2\frac{\partial}{\partial U_2}+U_3\frac{\partial}{\partial U_3}\right)^2\Psi$$
$$-\left(U_1\frac{\partial\Psi}{\partial U_1}+U_2\frac{\partial\Psi}{\partial U_2}+U_3\frac{\partial\Psi}{\partial U_3}\right)+\left[\frac{\frac{1}{4}-k_1^2}{U_1^2}+\frac{\frac{1}{4}-k_2^2}{U_2^2}+\frac{\frac{1}{4}-k_3^2}{U_3^2}\right]\Psi+2\widetilde{E}\Psi=0. \tag{82}$$

We recognize this as Eq. (67) that we obtained in the case of the potential V_1. Thus the solutions are of the form

$$\Psi=\left(\prod_{\ell=1}^{3}U_\ell^{k_\ell+1/2}\right)\prod_{j=1}^{q}\left(\frac{U_1^2}{\theta_j-e_1}+\frac{U_2^2}{\theta_j-e_2}+\frac{U_3^2}{\theta_j-e_3}\right). \tag{83}$$

The zeros θ_p satisfy the equations

$$\frac{k_1+1}{\theta_m+\Omega_-}+\frac{k_2+1}{\theta_m+\Omega_+}+\frac{\sqrt{\frac{1}{4}+2(E-i\alpha)}+1}{\theta_m}+\sum_{j\neq m}\frac{2}{\theta_m-\theta_j}=0, \tag{84}$$

and the eigenvalues E and μ are determined by

$$E=\frac{1}{2}\left(2q+2+k_1+k_2+\sqrt{\frac{1}{4}+2(E-i\alpha)}\right)^2-\frac{1}{8},$$

$$\begin{aligned}\mu=&2\left[\Omega_-\left(k_2+\sqrt{\frac{1}{4}+2(E-i\alpha)}\right)+\Omega_+\left(k_1+\sqrt{\frac{1}{4}+2(E-i\alpha)}\right)\right]\\&+2[\Omega_+k_1+\Omega_-k_2]\sqrt{\frac{1}{4}+2(E-i\alpha)}+\frac{3}{2}(\Omega_++\Omega_-)+\sqrt{\frac{1}{4}+2(E-i\alpha)}\\&\times\left[4\Omega_+(k_1+1)\sum_{m=1}^{q}\frac{1}{(\theta_m+\Omega_-)}+4\Omega_-(k_2+1)\sum_{m=1}^{q}\frac{1}{(\theta_m+\Omega_+)}\right]\\&-4\Omega_+\Omega_-\left(\sqrt{\frac{1}{4}+2(E-i\alpha)}+1\right)\sum_{m=1}^{q}\frac{1}{\theta_m}.\end{aligned}\tag{85}$$

The classical constants of the motion associated with this potential are

$$\begin{aligned}H=&-\frac{4Z_1Z_2}{(Z_1-Z_2)(Z_1Z_2-1)}[(Z_1+\Omega_+)(Z_1+\Omega_-)Z_1P_{Z_1}^2-(Z_2+\Omega_+)(Z_2+\Omega_-)Z_2P_{Z_2}^2]\\&+\left[\frac{2i\alpha(Z_1Z_2+1)}{(Z_1Z_2-1)}+\left(k_1^2-\frac{1}{4}\right)\frac{(1-\Omega_-^2)Z_1Z_2}{(Z_1Z_2-1)(Z_2+\Omega_+)(Z_1+\Omega_+)}\right.\\&\left.+\left(k_2^2-\frac{1}{4}\right)\frac{(1-\Omega_+^2)Z_1Z_2}{(Z_1Z_2-1)(Z_2+\Omega_-)(Z_1+\Omega_-)}\right],\end{aligned}$$

$$\begin{aligned}L_2=&\frac{4}{(Z_1-Z_2)(Z_1Z_2-1)}[-(Z_2+1)Z_1(Z_1+\Omega_+)(Z_1+\Omega_-)P_{Z_1}^2\\&+(Z_1+1)Z_2(Z_2+\Omega_+)(Z_2+\Omega_-)P_{Z_2}^2]\\&+\frac{(1-\Omega_-^2)(Z_1Z_2(Z_1+Z_2)+\Omega_-(Z_1Z_2-1))}{(Z_1Z_2-1)(Z_1+\Omega_-)(Z_2+\Omega_-)}\left(k_1^2-\frac{1}{4}\right)\\&+\frac{(1-\Omega_+^2)(Z_1Z_2(Z_1+Z_2)+\Omega_+(Z_1Z_2-1))}{(Z_1Z_2-1)(Z_1+\Omega_+)(Z_2+\Omega_+)}\left(k_2^2-\frac{1}{4}\right)+\frac{4i\alpha(Z_1+Z_2)}{Z_1Z_2-1}\\=&(\Omega_++\Omega_-)(M_{12}^2-M_{13}^2-M_{23}^2)-2i(\Omega_--\Omega_+)M_{12}M_{13}+\left[\frac{\Omega_+(s_3-is_1)+\Omega_-(s_3+is_1)}{\sqrt{s_1^2+s_2^2}}\right]\alpha\\&+\frac{k_1^2-\frac{1}{4}}{2(\sqrt{s_1^2+s_2^2}+s_1)}\left[\frac{\Omega_+(s_3-is_1)+\Omega_-(s_3+is_1)}{\sqrt{s_1^2+s_2^2}(\sqrt{s_1^2+s_2^2}-s_3)}+\Omega_-(\sqrt{s_1^2+s_2^2}+is_3)\right]\\&+\frac{k_2^2-\frac{1}{4}}{2(\sqrt{s_1^2+s_2^2}-s_1)}\left[\frac{\Omega_+(s_3-is_1)+\Omega_-(s_3+is_1)}{\sqrt{s_1^2+s_2^2}(\sqrt{s_1^2+s_2^2}-s_3)}+\Omega_+(\sqrt{s_1^2+s_2^2}+is_3)\right],\end{aligned}$$

$$L_1=-\frac{(Z_1+\Omega_+)(Z_1+\Omega_-)(Z_2+\Omega_+)(Z_2+\Omega_-)}{(Z_1-Z_2)^2}(Z_1P_{Z_1}-Z_2P_{Z_2})^2$$
$$+\frac{1}{4}\left(k_2^2-\frac{1}{4}\right)\frac{(\Omega_+^2-1)(Z_1Z_2-1)}{(Z_1+\Omega_+)(Z_2+\Omega_+)}+\frac{1}{4}\left(k_1^2-\frac{1}{4}\right)\frac{(\Omega_-^2-1)(Z_1Z_2-1)}{(Z_1+\Omega_-)(Z_2+\Omega_-)}$$
$$=M_{12}^2-\frac{1}{2}\left[\frac{\sqrt{s_1^2+s_2^2}}{\sqrt{s_1^2+s_2^2}+s_1}\left(k_1^2-\frac{1}{4}\right)+\frac{\sqrt{s_1^2+s_2^2}}{\sqrt{s_1^2+s_2^2}-s_1}\left(k_2^2-\frac{1}{4}\right)\right].$$

The corresponding defining relations for the quadratic algebra are

$$L_{12}^2=-64L_1^2-4(\Omega_++\Omega_-)^2H^2L_1+64HL_2^2+16(\Omega_++\Omega_-)L_3L_2^2-4L_1L_2^2-8(\Omega_++\Omega_-)L_1L_2H$$
$$+(\Omega_+-\Omega_-)-4(\Omega_-(4k_1^2-1)-\Omega_+(4k_2^2-1))L_1^2-4(\Omega_-(1-k_2^2-3k_1^2)$$
$$-\Omega_+(1-k_1^2-3k_2^2))HL_1+4(k_1^2-k_2^2)L_1L_2-4i\alpha(k_1^2-k_2^2)L_2+8i\alpha(\Omega_-(k_2^2-k_1^2-2i\alpha)$$
$$+\Omega_+(k_1^2-k_2^2+2i\alpha))L_1-(k_1^2-k_2^2)(\Omega_-(k_2^2-k_1^2+4i\alpha)+\Omega_+(k_1^2-k_2^2+4i\alpha))H$$
$$+2i\alpha(\Omega_+-\Omega_-)((k_1^2-k_2^2)^2+2i\alpha(2(k_1^2+k_2^2)-1)),$$

$$\{L_{12},L_1\}=8(\Omega_++\Omega_-)L_1^2-4L_1L_2-4(\Omega_++\Omega_-)L_1H+2(k_1^2-k_2^2)L_1$$
$$-2i\alpha(k_1^2-k_2^2)(\Omega_+-\Omega_-), \tag{86}$$

$$\{L_{12},L_2\}=-2(\Omega_++\Omega_-)^2H^2-96L_1^2-2L_2^2+16L_2L_1-4(\Omega_++\Omega_-)L_2H-2L_1H(\Omega_+-\Omega_-)$$
$$\times[\Omega_+(k_1^2+3k_2^2-1)-\Omega_-(k_2^2+3k_1^2-1)]H-4(\Omega_+(1-4k_2^2)-\Omega_+(1-4k_2^2))L_1$$
$$+4i\alpha((k_1^2-k_2^2)(\Omega_+-\Omega_-)+2i\alpha(\Omega_+-\Omega_-)).$$

IV. THE *n*-DIMENSIONAL ISOTROPIC OSCILLATOR

It is well known that the quantum isotropic harmonic oscillator can be solved by the method of separation of variables in a number of coordinate systems, including Cartesian coordinates and elliptical coordinates (see, e.g., Refs. 25 and 26). We present a new derivation of the eigenfunctions associated with *elliptic coordinates*. We will adopt the convention of defining this equation by

$$H\Psi=[-\tfrac{1}{2}\Delta+\tfrac{1}{2}\omega^2(x_1^2+\cdots+x_n^2)]\Psi=E\Psi, \tag{87}$$

where $\Delta=\partial_{x_1}^2+\cdots+\partial_{x_n}^2$. Elliptical coordinates in Euclidean n space are defined by

$$x_j^2=\frac{\Pi_{\ell=1}^n(u_\ell-e_j)}{\Pi_{k\neq j}(e_k-e_j)} \tag{88}$$

for $e_1<u_1<e_2<\cdots<e_n<u_n$. To obtain polynomial solutions of this equation in these coordinates we note the identity

$$\sum_{k=1}^n\frac{x_k^2}{\theta-e_k}-1=-\frac{\Pi_{h=1}^n(\theta-u_h)}{\Pi_{\ell=1}^n(\theta-e_\ell)}.$$

If we rewrite Eq. (87) in terms of Φ where $\Psi=\exp[-1/2\omega^2r^2]\Phi$ and r is the radial coordinate, we obtain the eigenvalue equation

$$\left[\Delta-2\omega\left(\sum_{m=1}^{n} x_m\,\partial_{x_m}\right)-n\omega\right]\Phi=-2E\Phi. \tag{89}$$

Note that the operator on the left-hand side maps polynomials in the variables x_j to polynomials, without increasing the order. For this equation we look for solutions of the form

$$\Phi=\prod_{\ell=1}^{q} x_\ell^{\alpha_\ell}\zeta(x_1,\ldots,x_n),$$

where $\alpha_\ell=0$ or 1. The equation for ζ is then

$$\left[\Delta+\sum_{m=1}^{n}\left(\frac{2\alpha_m}{x_m}\,\partial_{x_m}-2\omega x_m\partial_{x_m}\right)\right]\zeta=\left(-2E+n\omega+2\omega\sum_{\ell=1}^{n}\alpha_\ell\right)\zeta.$$

We now look for solutions of the form

$$\zeta=\prod_{m=1}^{q}\left[\sum_{k=1}^{n}\frac{x_k^2}{\theta_m-e_k}-1\right]. \tag{90}$$

Substituting this ansatz into the equation for ζ we obtain the requirements

$$\sum_{k=1}^{n}\frac{1+2\alpha_k}{\theta_\ell-e_k}+\sum_{j\neq\ell}\frac{4}{\theta_\ell-\theta_j}=-2\omega,\quad E=\omega\left(2m+\frac{n}{2}+\sum_{p=1}^{n}\alpha_p\right). \tag{91}$$

The operators which describe the separation constants are

$$\Lambda_j=\sum_{k\neq\ell}S_{j-1}^{k\ell}M_{kl}^2+\sum_{\ell\neq j}S_j^{\ell}Q_{\ell\ell},\quad j=1,\ldots,n-1,$$

where $M_{k\ell}=x_k\partial_{x_\ell}-x_\ell\partial_{x_k}$, and

$$Q_{ik}=\partial_{x_i}\partial_{x_k}-\omega^2x_ix_k,\quad S_j^{kl}=\frac{1}{j!}\sum_{i_1,\ldots,i_j}e_{i_1}\cdots e_{i_j},$$

where $i_m\neq i_{m'}$, $i_m\neq k,l$ for $m\neq m'$ and $m,m'=1\cdots j$, and

$$S_j^k=S_j^k[e_1,\ldots,e_n]=\frac{1}{j!}\sum_{i_1,\ldots,i_j}e_{i_1}\cdots e_{i_j},\quad i_1,\ldots,i_j \text{ pairwise distinct},$$

where $i_m\neq i_{m'}$, $i_m\neq k$ for $m\neq m'$ and $m,m'=1\cdots j$. In coordinate form these operators are

$$\Lambda_j=\sum_{k=1}^{n}\frac{S_j^k[u_1,\ldots,u_n]}{\Pi_{\ell\neq k}(u_\ell-u_k)}\left(4\sqrt{\Pi_{\ell=1}^{n}(u_k-e_\ell)}\,\partial_{u_k}\sqrt{\Pi_{\ell=1}^{n}(u_k-e_\ell)}\,\partial_{u_k}-\omega^2\Pi_{\ell=1}^{n}(u_k-e_\ell)\right). \tag{92}$$

They have the eigenvalues

$$\sum_{\ell}S_j^{\ell}\left[\omega(2\alpha_\ell+1)-\sum_{m=1}^{q}\frac{2(\alpha_\ell+1)}{\theta_m-e_\ell}\right]. \tag{93}$$

These operators form a closed algebra under the commutation relations

$$[M_{kl},\ M_{ij}]=M_{lj}\delta_{ki}+M_{ki}\delta_{lj}-M_{kj}\delta_{li}-M_{li}\delta_{kj},$$

$$[Q_{ik},\ Q_{jl}]=\omega^2[M_{ij}\delta_{lk}+M_{il}\delta_{jk}+M_{kj}\delta_{li}+M_{kl}\delta_{ji}],$$

$$[Q_{ik},\ M_{jl}]=Q_{ij}\delta_{kl}+Q_{kj}\delta_{il}+Q_{il}\delta_{kj}+Q_{kl}\delta_{ij}.$$

The eigenfunctions can be normalized by using their representation in terms of Cartesian coordinates. For the assumed form of the eigenfunctions given above the norm N is readily calculated to be

$$N^2=\sum_{p=0}^{n}\sum_{s_{i_1}s_{i_2},\ldots,s_{i_p}}\sum_{i_1,\ldots,i_p\neq}(-1)^q\omega^{-(n/2+\Sigma_{h=1}^{n}\alpha_h)}$$
$$\times\frac{\Pi_{j=1}^{p}[(-\omega)^{-A_{i_j}}\Gamma(\alpha_{i_j}+s_{i_j}+\tfrac{1}{2})]\Pi_{k=p+1}^{n}\Gamma(\alpha_{i_k}+\tfrac{1}{2})}{\Pi_{r=1}^{p}\Pi_{\not r}^{s_{i_r}}(\theta_{i_r\not r}-e_{i_r})},\tag{94}$$

where $0\leqslant s_{i_j}\leqslant 2q$, $0\leqslant\Sigma_{j=1}^{p}s_{i_j}\leqslant 2q$, $0\leqslant p\leqslant n$. Each of the s_{i_j} are integers, $\theta_{i_r\not r}\in\{\theta_1,\ldots,\theta_m\}$ and $\theta_{i_r\not r}\neq\theta_{j_w\not w}$ if $i_r\neq j_w$, and if i_r is fixed then at most two $\theta_{i_r\not r}$ can be equal. From these results we have the satisfactory situation that both the eigenvalues and the normalizations can be computed in terms of the zeros $\theta_1,\ldots,\theta_m$.

As an example of the simplest normalized eigenfunction we give the following:

$$\Psi=\sqrt{\frac{\omega}{\pi}}\left[\frac{3}{4\omega^2}\left(\frac{1}{(\theta-e_1)^2}+\frac{1}{(\theta-e_2)^2}\right)+\frac{1}{2\omega^2(\theta-e_1)(\theta-e_2)}+1\right]^{-1/2}$$
$$\times e^{-(x^2+y^2)/2}\left[\frac{x^2}{\theta-e_1}+\frac{y^2}{\theta-e_2}-1\right].$$

For this eigenfunction the varable θ is a solution of

$$\frac{1}{(\theta-e_1)}+\frac{1}{(\theta-e_2)}=0,$$

i.e., $\theta=(e_1+e_2)/2$. If we substitute this into the above equations we obtain

$$\Psi=\sqrt{\frac{\omega}{\pi}}\left[\left(\frac{2}{\omega(e_1-e_2)}\right)^2+1\right]^{-1/2}e^{-\omega(x^2+y^2)/2}\left[\frac{2(x^2-y^2)}{(e_2-e_1)}-1\right].$$

The orthonormalized eigenfunctions calculated in this way form a complete set.

In this paper we have established that once the zeros of a given set of special eigenfunctions, which are essentially polynomials, are known, then all the other properties such as normalization and eigenvalues can be determined from them in terms of algebraic expressions.

(Received 26 April 1996; accepted for publication 12 July 1996)

Decomposing tensor products of irreducible representations of compact groups almost always involves multiplicity, wherein some irreducible representations occur more than once in the direct sum decomposition. We show that the multiplicity can always be specified by polynomial group invariants. The setting is a Bargmann–Segal–Fock space in $n\times N$ complex variables, where n is the number of labels needed to specify the tensor product and N is the dimension of the fundamental representation of the compact group. Both the tensor product and direct sum bases are realized as polynomials in this space, and it is shown how Clebsch–Gordan and Racah coefficients can be computed by suitably differentiating these polynomials. The example of SU(N) is discussed in detail, and it is shown that the multiplicity can be computed as the solution of certain diophantine equations arising from powers of group invariants, namely minors of determinants. © *1996 American Institute of Physics.* [S0022-2488(96)02711-9]

I. INTRODUCTION

Clebsch–Gordan and Racah coefficients for SU(2) are well known, and closed form expressions for them are available, as well as programs for explicitly evaluating any desired coefficients. For other compact groups much less is known about these coefficients. Some procedures and partial results for SU(3) have been published,[1–3] but beyond this almost nothing is known. In this paper we will present techniques for calculating Clebsch–Gordan and Racah coefficients for arbitrary tensor products of the compact groups, using Bargmann space techniques developed in earlier papers.[4]

The general problem can be stated as follows. Given a compact G, whose irreducible representations are all assumed known, choose a basis $|\lambda,\xi\rangle$ in the irreducible representation space V^{λ}. Form the p-fold tensor product $\lambda_1\otimes\lambda_2\otimes\cdots\otimes\lambda_p$ and calculate the number of times the irreducible representation λ occurs in the tensor product. There are a number of ways for computing this multiplicity, but most of them are rather long and tedious. We will show a relatively simple way for computing this multiplicity, as solutions of diophantine equations arising from group invariants. In any event we assume the multiplicity is known. Next choose a (possibly new) basis in V^{λ}, say $|\lambda,\zeta\rangle$; then the Clebsch–Gordan coefficients are the overlap between the tensor product basis and the direct sum basis in the tensor product decomposition, namely $\langle\lambda_1\xi_1\cdots\lambda_p\xi_p|\lambda\zeta\eta\rangle$. Similarly, the Racah coefficients are the overlap between direct sum bases with different multiplicity labels: $\langle\lambda\zeta\eta'|\lambda\zeta\eta\rangle$. Here η and η' are multiplicity labels, that is, labels that distinguish the equivalent representations. For SU(2) the Clebsch–Gordan and Racah coefficients are reasonably well known for $p=3,4,5$, when η refers to a stepwise coupling set of labels, generated by intermediate angular momenta, in which case the Racah coefficients are called $6J$, $9J$, $12J$, etc. symbols.

If $\lambda_1=\lambda_2=\cdots=\lambda_p$, a new symmetry occurs, a permutation symmetry that can be used to help label the multiplicity. Moreover, it is often desirable to have coefficients that have definite per-

0022-2488/96/37(12)/6468/18/$10.00

mutation symmetry; we will show that such permutation symmetry arises naturally using the techniques presented in this paper.

Our procedure for computing Clebsch–Gordan and Racah coefficients is as follows: we realize all irreducible representations of G on Bargmann space; in particular, the states $|\lambda,\xi\rangle$ are realized as polynomials $f_{|\lambda,\xi\rangle}(Z)$ of a multicomponent complex variable Z. The tensor product states can then also be realized as polynomials $|\lambda_1,\xi_1,\ldots,\lambda_p,\xi_p\rangle \rightarrow f_{|\lambda_1,\xi_1,\ldots,\lambda_p,\xi_p\rangle}(Z)$. The problem is how to realize the state $|\lambda,\zeta,\eta\rangle$ as a polynomial. If this were known, using the differentiation inner product [see Eq. (2.1)] in Bargmann space, the Clebsch–Gordan coefficients would be

$$\langle \lambda_1,\xi_1,\ldots,\lambda_p,\xi_p|\lambda,\zeta,\eta\rangle = f^*_{|\lambda\zeta\eta'\rangle}(D) f_{|\lambda\zeta\eta\rangle}(Z)|_{Z=0}$$

and the Racah coefficients

$$\langle \lambda,\zeta,\eta'|\lambda,\zeta,\eta\rangle = f^*_{|\lambda\eta'\rangle}(D) f_{|\lambda\zeta\eta\rangle}(Z)|_{Z=0}.$$

The Racah coefficients are actually basis independent, so that the basis element ζ can be conveniently chosen as the highest weight. Though the Clebsch–Gordan coefficients are not basis independent, it often suffices to compute these coefficients for the highest weight and then get the other coefficients using raising and lowering operators from the Lie algebra of G. However, the techniques discussed in the next sections allow one to calculate Clebsch–Gordan coefficients directly in any basis of interest.

Our strategy for realizing $|\lambda,\zeta,\eta\rangle$ as a polynomial is as follows: instead of computing the number of times λ occurs in the tensor product $\lambda_1\otimes\cdots\otimes\lambda_p$ we look at what is equivalent, namely the number of times the identity representation occurs in the augmented tensor product $\lambda_1\otimes\cdots\otimes\lambda_p\otimes\lambda^{\surd}$, where $\lambda^{\surd}$ is the contragradient representation of λ. For completeness we show in Sec. II that these multiplicities are the same; that is,

$$\#(\lambda\subset\lambda_1\otimes\cdots\otimes\lambda_p)=\#(1\subset\lambda_1\otimes\cdots\otimes\lambda_p\otimes\lambda^{\surd}),$$

where # means ''number of times.'' Shifting the problem to a study of the multiplicity of the identity representation means that the full power of invariant theory can be brought to bear on computing $f_{|\lambda\zeta\eta\rangle}(Z)$.

Assume that a set of functionally independent invariants $I_\eta(Z,W)$ in the augmented tensor product space is known [i.e., $I_\eta(Zg,Wg)=I_\eta(Z,W)$ for all $g\in G$]. Then as will be shown in Sec. II, the polynomial $f^*_{|\lambda^{\surd}\zeta^{\surd}\rangle}(D_w)I_\eta(Z,W)_{W=0}$ transforms under G as the polynomial $f_{|\lambda\zeta\eta\rangle}(Z)$ and, if properly normalized, can be used to calculate the Clebsch–Gordan and Racah coefficients of G.

The goal of this paper is to prove these theorems (Sec. II) and then apply them to $G=\mathrm{SU}(N)$ (Sec. III), where use is made of the fact that all $\mathrm{SU}(N)$ invariants are minors of determinants. The invariants $I_\eta(Z,W)$ are then products of minors of determinants with certain transformation properties.

Finally in Sec. IV we give a number of examples to demonstrate the power and generality of our methods. These examples show that although we cannot calculate closed form expressions for Clebsch–Gordan and Racah coefficients, we have reduced the computation of these coefficients to solving linear diophantine equations and differentiating certain polynomials. With the availability of symbolic manipulation computer programs, this is almost equivalent to having closed form expressions.

II. GENERAL THEORY

Let $\mathbb{C}^{n\times N}$ denote the vector space of all $n\times N$ complex matrices. If $Z=(Z_{ij})$ is an element of $\mathbb{C}^{n\times N}$, let Z^* denote its complex conjugate and write $Z_{ij}=X_{ij}+\sqrt{-1}Y_{ij}$; $1\leqslant i\leqslant n$, $1\leqslant j\leqslant N$. If dX_{ij} (resp. dY_{ij}) denotes Lebesque measure on $\mathbb{R}$, we let dZ denote the Lebesque product measure on $\mathbb{R}^{nN}$. Define a Gaussian measure $d\mu$ on $\mathbb{C}^{n\times N}$ by

$$d\mu(Z)=\pi^{-nN}\exp[-\mathrm{tr}(ZZ^{\dagger})]dZ,$$

where tr denotes the trace of a matrix and $Z^{\dagger}$ is the transpose of Z^*.

A function $f:\mathbb{C}^{n\times N}\to\mathbb{C}$ is *holomorphic square integrable* if it is holomorphic on the entire domain $\mathbb{C}^{n\times N}$, and if

$$\int_{\mathbb{C}^{n\times N}}|f(Z)|^2 d\mu(Z)<\infty.$$

Clearly the holomorphic square-integrable functions form a Hilbert space, the *Bargmann–Segal–Fock space*, with respect to the inner product

$$\langle f_1|f_2\rangle=\int_{\mathbb{C}^{n\times N}}f_1^*(Z)f_2(Z)d\mu(Z).$$

Let $\mathscr{F}\equiv\mathscr{F}(\mathbb{C}^{n\times N})$ denote this Hilbert space. From Ref. 4 this inner product also can be defined by the following formula:

$$\langle f_1|f_2\rangle=f_1^*(D)f_2(Z)|_{Z=0}, \tag{2.1}$$

where $f(D)$ is the differential operator obtained by formally replacing Z_{ij} by the partial derivative $\partial/\partial Z_{ij}$ $(1\leqslant i\leqslant n,\ 1\leqslant j\leqslant N)$. It follows that the representation R of $U(N)$ of $\mathscr{F}$ defined by $[R(g)f](Z)=f(Zg)$, $g\in U(N)$, is unitary.

Let G be a closed subgroup of $\mathrm{SU}(N)$ [the important cases are the classical groups $G=\mathrm{SU}(N)$, $\mathrm{SO}(N)$, or $\mathrm{Sp}(N)$, N even for the latter]. Then by the Borel–Weil theorem an irreducible representation R^{λ} of G of signature λ can be realized on a space of polynomial functions V^{λ} that can be embedded in $\mathscr{F}$ where G acts by right translation on V^{λ}. Since G is a closed subgroup of $\mathrm{SU}(N)$, the contragradient (or in this case complex conjugate) of the representation R^{λ} can also be realized on a subspace of polynomial functions V^{λ^*} of $\mathscr{F}$ [for example, if $G=\mathrm{SU}(3)$, $\lambda=(4,1,0)$ then $\lambda^*=(4,3,0)$].

A polynomial function $f\in\mathscr{F}$ is said to be G-invariant if $R(g)f=f$ for all $g\in G$. The following theorem relates the multiplicity of an irreducible representation R^{λ} in the p-fold tensor product $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}\subset\mathscr{F}$ with the G-invariant polynomial functions in $\mathscr{F}$.

Theorem 2.1: *Let G be a closed subgroup of* $\mathrm{SU}(N)$ *and let $(R^{\lambda},V^{\lambda})$ denote an irreducible representation of G with signature λ. Then the multiplicity of the irreducible representation R^{λ} in the tensor product $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}\subset\mathscr{F}$ is equal to the dimension of the G-invariant subspace in $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}\otimes V^{\lambda^*}\subset\mathscr{F}$.*

Proof: To prove the theorem we use the following well-known fact which we prove for the sake of completeness.

Lemma 2.2: Let G be a compact group and let ρ_i, $i=1,2$, be irreducible unitary representations of G on the Hilbert spaces H_i, $i=1,2$, respectively. Then the identity representation of G occurs in $\rho_1\otimes\rho_2^*|G$ (with multiplicity exactly 1) if and only if ρ_1 is equivalent to ρ_2.

Proof of the lemma: If ρ is a representation of G, let χ_{ρ} denote the character of ρ. Let I denote the identity representation of G. For all $g\in G$ it is well known that $\chi_I(g)=1$ and $\chi_{\rho_1\otimes\rho_2^*}(g,g)$

$= \chi_{\rho_1}(g)\chi_{\rho_2^*}(g)$. If $[\rho\otimes\rho^*|_G : I]$ denotes the multiplicity of the identity representation in $\rho_1 \otimes \rho_2^*|_G$, then the Schur orthogonality relations for compact groups imply that

$$[\rho_1\otimes\rho_2^*|_G : I] = \int_G \chi_{\rho_1\otimes\rho_2^*}(g,g)\chi_I^*(g)dg,$$

where dg denotes the normalized Haar measure of G. However, as remarked above, we have

$$\int_G \chi_{\rho_1\otimes\rho_2^*}(g,g)\chi_I^*(g)dg = \int_G \chi_{\rho_1}(g)\chi_{\rho_2^*}(g)dg,$$

which, again by the Schur orthogonality relations, is equal to

$$\delta_{\rho_1,\rho_2} = \begin{cases} 1 & \text{if } \rho_1 \approx \rho_2, \\ 0 & \text{if } \rho_1 \not\approx \rho_2. \end{cases}$$

This achieves the proof of the lemma.

From the lemma it follows immediately by iteration that the multiplicity of R^λ in $V^{\lambda_1} \otimes \cdots \otimes V^{\lambda_p}$ is equal to the multiplicity of the identity representation I in $V^{\lambda_1} \otimes \cdots \otimes V^{\lambda_p} \otimes V^{\lambda^*}$. Since $V^{\lambda_1} \otimes \cdots \otimes V^{\lambda_p} \otimes V^{\lambda^*}$ consists of polynomial functions in $\mathscr{F}$ and G acts on $V^{\lambda_1} \otimes \cdots \otimes V^{\lambda_p} \otimes V^{\lambda^*}$ by right translation, it follows that the identity representation occurs in $V^{\lambda_1} \otimes \cdots \otimes V^{\lambda_p} \otimes V^{\lambda^*}$ if and only if there exist polynomial functions $f \in V^{\lambda_1} \otimes \cdots \otimes V^{\lambda_p} \otimes V^{\lambda^*}$ such that $R^\lambda(g)f = R(g)f = f$ for all $g \in G$, i.e., f is G-invariant. Each of these polynomial functions f spans a one-dimensional subspace of $V^{\lambda_1} \otimes \cdots \otimes V^{\lambda_p} \otimes V^{\lambda^*}$. This implies immediately that the dimension of the G-invariant subspace of $V^{\lambda_1} \otimes \cdots \otimes V^{\lambda_p} \otimes V^{\lambda^*}$ is equal to the multiplicity of R^λ in $V^{\lambda_1} \otimes \cdots \otimes V^{\lambda_p}$.

The next theorem will give us a very simple way to compute Clebsch–Gordan coefficients for the tensor product $V^{\lambda_1} \otimes \cdots \otimes V^{\lambda_p}$. The proof of the theorem relies heavily on the properties of the ''differentiation'' inner product (2.1) of $\mathscr{F}$. Thus we start by establishing some properties of this inner product. For $f \in \mathscr{F}$, the polynomial differential operator with constant coefficients $f(D)$ also acts on $\mathscr{F}$ in the obvious fashion. If $y \in \mathrm{GL}(N,\mathbb{C})$, then it can be shown (cf. Ref. 5a) that

$$R(y)f(D)R(y^{-1}) = (R(y^\vee)f)(D), \tag{2.2}$$

where $y^\vee = (y^{-1})^t$; in particular, if $y \in U(N)$, then $y^\vee = y^*$, the complex-conjugate of y. For $f \in \mathscr{F}$ we define the linear functional $\Phi(f)$ on $\mathscr{F}$ by

$$[\Phi f](h) = \langle f|h\rangle = f^*(D)h(Z)|_{Z=0}, \quad h \in \mathscr{F}.$$

Then Φ is a *conjugate-linear isomorphism* (or anti-isomorphism) of $\mathscr{F}$ onto its dual $\mathscr{F}^*$. If R is a representation of a closed subgroup G of $\mathrm{SU}(N)$ which is defined by right translation on a subspace V of $\mathscr{F}$, then we can define the contragradient $R^\vee$ (or in this case the complex-conjugate R^*) by the equation

$$[R^\vee(g)\Phi(f)](h) := [\Phi(f)](R(g^{-1})h) = \langle f|R(g^{-1})h\rangle = \langle R(g)f|h\rangle = [\Phi(R(g)f)](h)$$

for all $g \in G$ and $h, f \in \mathscr{F}$.

It follows that

$$[R^{\vee}(g_1g_2)\Phi(f)](h)=[\Phi(R(g_1g_2)f)](h)=[\Phi(R(g_1)(R(g_2)f))](h)$$
$$=[R^{\vee}(g_1)\Phi(R(g_2)f)](h)$$
$$=[R^{\vee}(g_1)R^{\vee}(g_2)\Phi f](h),$$

for all $g_1,g_2\in G$ and $f,h\in\mathscr{F}$. Thus Φ is a *conjugate-linear isomorphism* (or *anti-isomorphism*) *intertwining operator*. In particular if $(R^{\lambda},V^{\lambda})$ is an irreducible representation of G, then $(R^{\lambda^{\vee}},\Phi(V^{\lambda}))$ is also an irreducible unitary representation of G. Since G is a subgroup of SU(N) the G-module $(R^{\lambda^{\vee}},\Phi(V^{\lambda}))$ can be unitarily mapped onto $(R^{\lambda^*},V^{\lambda^*})$, a G-submodule of $\mathscr{F}$. [In the Appendix this map is carried out explicitly for the case $G=\mathrm{SU}(N)$.] Thus $V^{\lambda_i}(V^{\lambda^*})$ can be realized as a subspace of holomorphic square-integrable functions on $\mathbb{C}^{r_i\times N}(\mathbb{C}^{s\times N})$ which *transform covariantly with respect* to $B_i(B_s)$, $1\leqslant i\leqslant p$, i.e., $f(b_iZ_i)=\lambda_i(b_i)f(Z_i)$, $Z_i\in\mathbb{C}^{r_i\times N}$, and which may satisfy some additional properties [for example, when $G=\mathrm{SO}(N)$ or $\mathrm{Sp}(N)$, $V^{\lambda_i}(V^{\lambda^*})$ must also be G-harmonic polynomials (see Refs. 5a and 5b)]. For $Z_i\in\mathbb{C}^{r_i\times N}$, $1\leqslant i\leqslant p$, write

$$Z=(Z_1,\ldots,Z_p)\equiv\begin{bmatrix}Z_1\\ \vdots\\ Z_p\end{bmatrix},$$

and for $W\in\mathbb{C}^{s\times N}$ write $(Z,W)\equiv\begin{bmatrix}Z\\ W\end{bmatrix}$. Let $d\mu(Z)$, $d\mu(W)$, and $d\mu(Z,W)$ denote the Gaussian measures on $\mathbb{C}^{r\times N}(r=\Sigma_{i=1}^{p}r_i)$, $\mathbb{C}^{s\times N}$, and $\mathbb{C}^{(r+s)\times N}$, respectively. Let $\mathscr{I}\equiv\mathscr{I}(V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}\otimes V^{\lambda^*})$ denote the space of G-invariants in $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}\otimes V^{\lambda^*}$ as in Theorem 2.1. Then we have the following:

Theorem 2.3: *Let $\{f^{\lambda_i}_{\xi_i}\}_{\xi_i}$ be a basis of state vectors in V^{λ_i}, $1\leqslant i\leqslant p$. Let $\{f^{\lambda}_{\zeta}\}_{\zeta}$ be a basis of state vectors in V^{λ} and let $\{f^{\lambda^*}_{\xi^*}\}$ be its anti-isomorphic image in V^{λ^*}. Let $\{\mathscr{I}_{\eta}\}_{\eta}$ be a basis of state vectors in $\mathscr{I}$. Let*

$$\tilde{f}^{\lambda,\eta}_{\zeta}(Z)=f^{*\lambda^*}_{\zeta^*}(D)\mathscr{I}_{\eta}(Z,W)|_{W=0}\equiv\int_{\mathbb{C}^{s\times N}}f^{\lambda^*}_{\zeta^*}(W)I_{\eta}(Z,W)d\mu(W).\tag{2.3}$$

Then $\{\tilde{f}^{\lambda,\eta}_{\zeta}\}_{\zeta}$ is an isomorphic image of $\{f^{\lambda}_{\zeta}\}_{\zeta}$ in $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}$ indexed by the multiplicity label η and we have the following relation of Clebsch–Gordan coefficients,

$$\langle f^{\lambda_1}_{\xi_1}f^{\lambda_2}_{\xi_2}\cdots f^{\lambda_p}_{\xi_p}f^{\lambda^*}_{\zeta^*}|\mathscr{I}_{\eta}\rangle=\langle f^{\lambda_1}_{\xi_1}\cdots f^{\lambda_p}_{\xi_p}|\tilde{f}^{\lambda,\eta}_{\zeta}\rangle.\tag{2.4}$$

Proof: Let A: $\phi(V^{\lambda})\to V^{\lambda^*}$ denote the linear isomorphism intertwining $\phi(V^{\lambda})$ and V^{λ^*}. Then $f^{\lambda^*}_{\zeta^*}=A\Phi(f^{\lambda}_{\zeta})$. Using the inner product (2.1) or its equivalent integral inner product, we have

$$\tilde{f}^{\lambda,\eta}_{\zeta}(Z)=f^{*\lambda^*}_{\zeta^*}(D)I_{\eta}(Z,W)|_{W=0}=\int_{\mathbb{C}^{s\times N}}\overline{f^{\lambda^*}_{\zeta^*}(W)}\mathscr{I}_{\eta}(Z,W)d\mu(W).$$

Note that in Eq. (2.3) $\tilde{f}^{\lambda,\eta}_{\zeta}(Z)$ is the inner product $\langle f^{\lambda^*}_{\zeta^*},I_{\eta}\rangle$, where I_{η} is considered as a function of the variable W. Clearly $\tilde{f}^{\lambda,\eta}_{\zeta}(Z)$ is a polynomial function in Z and if $b=(b_1,\ldots,b_p)\in B_1\times\cdots\times B_p$, then

$$\tilde{f}^{\lambda,\eta}_{\zeta}(Z)=f^{\lambda,\eta}_{\zeta}(b_1Z_1,\ldots,b_pZ_p)=\int_{\mathbb{C}^{s\times N}}\overline{f^{\lambda^*}_{\zeta^*}(W)}\mathscr{I}_{\eta}(b_1Z_1,\ldots,b_pZ_p,W)d\mu(W).$$

Since I_η is an element of $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}\otimes V^{\lambda^*}$, it follows immediately that

$$\mathscr{T}_\eta(b_1Z_1,\ldots,b_pZ_p,W)=\lambda_1(b_1),\ldots,\lambda_p(b_p)\mathscr{T}_\eta(Z_1,\ldots,Z_p,W).$$

Hence

$$\tilde{f}^{\lambda,\eta}_{\zeta}(bZ)=\lambda_1(b_1),\ldots,\lambda_p(b_p)\tilde{f}^{\lambda,\eta}_{\zeta}(Z).$$

Moreover, if $\mathscr{T}_\eta(Z,W)$ is required to satisfy any additional property in order for it to belong to $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}\otimes V^{\lambda^*}$, then it follows that $\tilde{f}^{\lambda,\eta}_{\zeta}$ must satisfy a similar property in order for it to belong to $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}$ [for example, if $\mathscr{T}_\eta(Z,W)$ must be a G-harmonic polynomial, then by interchanging differentiation and integration, that is, differentiating under the integral sign, one can easily show that $\tilde{f}^{\lambda,\eta}_{\zeta}(Z)$ is G-harmonic polynomial in the variable Z]. In conclusion, $\tilde{f}^{\lambda,\eta}_{\zeta}$ belong to $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}$. Then

$$\begin{aligned}R(g)\tilde{f}^{\lambda}_{\zeta}&=R(g)f^{*\lambda^*}_{\zeta^*}(D)\mathscr{T}_\eta\\&=\underbrace{(R(g)f^{*\lambda^*}_{\zeta^*}(D)R(g^{-1}))}(R(g)\mathscr{T}_\eta)\\&=(R(g^*)f^{*\lambda^*}_{\zeta^*})(D)\mathscr{T}_\eta\end{aligned}$$

by Eq. (2.2) and the fact that $\mathscr{T}_\eta$ is G-invariant. Now $R(g^*)f^{*\lambda^*}_{\zeta^*}=(R(g)f^{\lambda^*}_{\zeta^*})^*$, and

$$R(g)f^{\lambda^*}_{\zeta^*}=R(g)A\Phi(f^{\lambda}_{\zeta})=A\Phi(R(g)f^{\mu}_{\xi}).$$

However, $R(g)f^{\lambda}_{\zeta}=\Sigma_{\xi'}D^{\mu}_{\xi'\xi}(g)f^{\mu}_{\xi'}$, where $D^{\mu}_{\zeta'\zeta}$ are the D-functions of R^λ. So

$$R(g)f^{\lambda^*}_{\zeta^*}=\sum_{\zeta'}D^{*\lambda}_{\zeta'\zeta}(g)A\phi(f^{\lambda}_{\zeta'}),$$

where in the last equality we use the fact that Φ is a conjugate-linear isomorphism. It follows that

$$(R(g)f^{\lambda^*}_{\zeta^*})^*=\sum_{\zeta'}D^{\lambda}_{\zeta'\zeta}(g)f^{\lambda^*}_{\zeta^*},$$

and

$$R(g)\tilde{f}^{\lambda}_{\zeta}=\sum_{\zeta'}D^{\lambda}_{\zeta'\zeta}(g)(f^{\lambda^*}_{\zeta^*},(D)\mathscr{T}_\eta)=\sum_{\zeta'}D^{\lambda}_{\zeta'\zeta}(g)\tilde{f}^{\lambda}_{\zeta'}.$$

This last equality shows that $\{\tilde{f}^{\lambda}_{\zeta}\}$ transforms under R in the same manner as $\{f^{\lambda}_{\zeta}\}$.

Now

$$\begin{aligned}\langle f^{\lambda_1}_{\xi_1}\cdots f^{\lambda_p}_{\xi_p}f^{\lambda^*}_{\zeta^*}|\mathscr{T}_\eta\rangle&=f^{*\lambda_1}_{\xi_1}(D)\cdots f^{*\lambda_p^*}_{\xi_p}(D)f^{*\lambda^*}_{\zeta^*}(D)\mathscr{T}_\eta(Z,W)|_{(Z,W)=(0,0)}\\&=f^{*\lambda_1}_{\xi_1}(D)\cdots f^{*\lambda_p}_{\xi_p}(D)\tilde{f}^{\lambda,\eta}_{\zeta}(Z)|_{Z=0}=\langle f^{\lambda_1}_{\xi_1}\cdots f^{\lambda_p}_{\xi_p}|\tilde{f}^{\lambda,\eta}_{\zeta}\rangle\end{aligned}$$

which is Eq. (2.4).

Remark 2.4: (i) In Eq. (2.3) the invariant polynomial $\mathscr{I}_\eta(Z,W)$ can be viewed as a kernel function and the index η can be used as the multiplicity label of the representation λ in the tensor product $\lambda_1\otimes\cdots\otimes\lambda_p$.

(ii) We could also use the integration inner product to give another proof of Theorem 2.3. Indeed, for $g\in G$ we have from Eq. (2.3)

$$R(g)\tilde{f}^{\lambda,\eta}_{\zeta}(Z)=\tilde{f}^{\lambda,\eta}_{\zeta}(Zg)=\int_{\mathbb{C}^{s\times N}} f^{\lambda *}_{\zeta *}(W)\mathscr{I}_\eta(Zg,W)d\mu(W).$$

However, $\mathscr{I}_\eta(Zg,W)=\mathscr{I}_\eta(Zgg^{-1},Wg^{-1})=\mathscr{I}_\eta(Z,Wg^{-1})$ since $\mathscr{I}_\eta$ is G-invariant. In making the change of variable $W'=Wg^{-1}$ and using the fact that the measure $d\mu(W)$ is G-invariant, we obtain

$$R(g)\tilde{f}^{\lambda,\eta}_{\zeta}(Z)=\int_{\mathbb{C}^{s\times N}}\overline{f^{\lambda *}_{\zeta *}(W'g)}\mathscr{I}_\eta(Z,W')d\mu(W').$$

Now

$$\begin{aligned} f^{\lambda *}_{\zeta *}(Wg)=[R(g)A\Phi(f^{\lambda}_{\zeta})](W)=[A\Phi R(g)f^{\lambda}_{\zeta}](W)&=\left[A\Phi\sum_{\zeta'}D^{\lambda}_{\zeta'\zeta}(g)f^{\lambda}_{\zeta'}\right](W)\\ &=\sum_{\zeta'}\overline{D^{\lambda}_{\zeta'\zeta}(g)}[A\Phi f^{\lambda}_{\zeta'}(W)]\\ &=\sum_{\zeta'}\overline{D^{\lambda}_{\zeta'\zeta}(g)}f^{\lambda *}_{\zeta *'}(W).\end{aligned}$$

Therefore,

$$\begin{aligned} R(g)\tilde{f}^{\lambda,\eta}_{\zeta}(Z)&=\int_{\mathbb{C}^{s\times N}}\overline{\left(\sum_{\zeta'}\overline{D^{\lambda}_{\zeta'\zeta}(g)}f^{\lambda *}_{\zeta *'}\right)}(W')\mathscr{I}_\eta(Z,W')d\mu(W')\\ &=\sum_{\zeta'}D^{\lambda}_{\zeta'\zeta}(g)\int_{\mathbb{C}^{s\times N}}f^{\lambda *}_{\zeta *'}(W')\mathscr{I}_\eta(Z,W')d\mu(W')\\ &=\sum_{\zeta'}D^{\lambda}_{\zeta'\zeta}(g)\tilde{f}^{\lambda,\eta}_{\zeta'}(Z).\end{aligned}$$

Also,

$$\langle f^{\lambda_1}_{\xi_1}\cdots f^{\lambda_p}_{\xi_p}f^{\lambda *}_{\zeta *}|\mathscr{I}_\eta\rangle=\int_{\mathbb{C}^{(r+s)\times N}}\overline{f^{\lambda_1}_{\xi_1}(Z_1)\cdots f^{\lambda_p}_{\xi_p}(Z_p)f^{\lambda *}_{\zeta *}(W)}f(Z,W)d\mu(Z,\mu),$$

which by Fubini's theorem is equal to

$$\begin{aligned}&\int_{\mathbb{C}^{r\times N}}d\mu(Z)\overline{f^{\lambda_1}_{\xi_1}(Z_1)\cdots f^{\lambda_p}_{\xi_p}(Z_p)}\left(\int_{\mathbb{C}^{s\times N}}d\mu(W)\overline{f^{\lambda *}_{\zeta *}}(W)\mathscr{I}_\eta(Z,W)\right)\\ &=\int_{\mathbb{C}^{r\times N}}\overline{f^{\lambda_1}_{\xi_1}(Z_1)\cdots f^{\lambda_p}_{\xi_p}(Z_p)}\tilde{f}^{\lambda,\eta}_{\zeta}(Z)d\mu(Z)\\ &=\langle f^{\lambda_1}_{\xi_1}\cdots f^{\lambda_p}_{\xi_p}|\tilde{f}^{\lambda,\eta}_{\zeta}\rangle.\end{aligned}$$

III. APPLICATION TO SU(*N*)

We have shown that the problem of finding the multiplicity of an irreducible unitary representation R^{λ} in the tensor product $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}$ of p irreducible unitary representations of a closed subgroup of SU(N) is equivalent to that of finding the dimension of the G-invariant subspace in $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}\otimes V^{\lambda^*}$ (Theorem 2.1). Also, the Clebsch–Gordan coefficients of R^{λ} in $R^{\lambda_1}\otimes\cdots\otimes R^{\lambda_p}$ are essentially inner products of state vectors $f^{\lambda_1}_{\zeta_1}\cdots f^{\lambda_p}_{\zeta_p}f^{\lambda^*}_{\xi^*}$ with basis vectors of G-invariants in $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}\otimes V^{\lambda^*}$ (Theorem 2.3). It is therefore crucial to find explicit bases for the space $\mathscr{T}\equiv\mathscr{T}^{\lambda_1,\ldots,\lambda_p,\lambda^*}$ of G-invariant polynomial functions in $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}\otimes V^{\lambda^*}$. This also will give a resolution of the multiplicity problem, i.e., the problem of labelling different isomorphic copies of an irreducible representation R^{λ} which occurs in $R^{\lambda_1}\otimes\cdots\otimes R^{\lambda_p}$. However, the theory of polynomial invariants of the classical groups is well known (see Ref. 6, for example), and for many other reductive groups this problem has been thoroughly investigated (see Ref. 7, for example). We start in this paper with the simplest but nevertheless very important case when $G=\mathrm{SU}(N)$. For this the ''first main theorem'' of invariants of $\mathrm{SL}(N,\mathbb{C})$ [and hence of SU(N)] can be stated as (see Ref. 7, Ch. II):

Theorem 3.1: *Let* $\mathbb{P}(\mathbb{C}^{k\times N})$, $k\geqslant N$, *be the subspace of* $\mathscr{T}(\mathbb{C}^{n\times N})$, $n\geqslant k$, *of all polynomial functions on* $\mathbb{C}^{k\times N}$. *Then the algebra of all* $\mathrm{SL}(N,\mathbb{C})$*-invariant polynomials in* $\mathbb{P}(\mathbb{C}^{k\times N})$ *is generated by the polynomials*

$$\Delta^{i_1\ldots i_N}_{1,2\ldots N}(Z),\quad Z\in\mathbb{C}^{k\times N},$$

where $(i_1,\ldots,i_N)$ *is an N-shuffle, i.e., a strictly increasing sequence of integers in the segment* $[1,k]$, *and* $\Delta^{i_1\ldots i_N}_{12\ldots N}(Z)$ *is the determinant of the* $N\times N$ *matrix formed by the rows* $i_1,\ldots,i_N$ *and the columns* 1,...,N of Z.

Next we consider tensor products of p irreducible SU(N)-modules V^{λ_i} with $V^{(\lambda^*)}$. Each signature λ_i and λ^* can be labelled by a highest weight of the form $(m^i_1,\ldots,m^i_{N-1},0)$ where the integers $m^i_1,\ldots,m^i_{N-1}$ satisfy the dominant condition $m^i_1\geqslant m^i_2\geqslant\cdots\geqslant m^i_{N-1}\geqslant 0$. We discard those m^i_j which are equal to zero and form the k-tuple of positive integers $(m^1_1,\ldots,m^1_{r_1},m^2_1,\ldots,m_{r_2},\ldots,m^p_1,\ldots,m^p_{r_p},M_1,\ldots,M_s)$, where

$$\underbrace{(M_1,\ldots,M_s,0,\ldots,0)}_{N}$$

is the highest weight of λ^* and $m^i_1\geqslant m^i_2\geqslant m^i_r>0$ for $i=1,\ldots,p$. Let B_i denote the subgroup of $\mathrm{GL}(r_i,\mathbb{C})$ consisting of all lower triangular matrices, $i=1,\ldots,p$, and let B_s denote the lower triangular subgroup of $\mathrm{GL}(s,\mathbb{C})$. Then the group $B_1\times B_2\times\ldots\times B_p\times B_s$ can be identified with the group of all $k\times k$ lower triangular block matrices β of the form

$$\begin{array}{l} r_1\\ r_2\\ \vdots\\ r_p\\ s \end{array}\begin{pmatrix} \boxed{b_1} & & & & \\ & \boxed{b_2} & & \bigcirc & \\ & & \ddots & & \\ & \bigcirc & & \boxed{b_p} & \\ & & & & \boxed{b_s} \end{pmatrix} b_1\in B_i, b_s\in B_s.$$

Then we have the following:

Theorem 3.2: *Let* $\mathbb{P}(\mathbb{C}^{k\times N})$, $k\geqslant N$, *be the subspace of* $\mathscr{T}(\mathbb{C}^{n\times N})$, $n\geqslant k$, *of all polynomial functions on* $\mathbb{C}^{k\times N}$. *Then the tensor product* $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}\otimes V^{\lambda^*}$ *of irreducible unitary SU(N)-modules can be realized as the subspace of* $\mathbb{P}(\mathbb{C}^{k\times N})$ *of all polynomial functions* f *which satisfy the covariant condition*

$$f(\beta Z)=\left(\prod_{i=1,\ldots,p}\lambda_i(b_i)\right)\lambda^*(b_s)f(Z), \tag{3.2}$$

where $Z\in\mathbb{C}^{k\times N}$, β *is given by Eq. (3.1), and* $\lambda_i(b_i)=(b_i)_{11}^{m_1^i}\cdots(b_i)_{r_ir_i}^{m_{ri}^i}$, $\lambda^*(b_s)=(b_s)_{11}^{M_1}\cdots(b_s)_{ss}^{M_s}$. *The SU(N)-invariant polynomials in* $V^{\lambda_1}\otimes\ldots\otimes V^{\lambda_p}\otimes V^{\lambda^*}$ *are linear combinations of polynomials of the form*

$$(\Delta_{12\ldots N}^{12\ldots N}(Z))^{\ell_{1\ldots N}}\cdots(\Delta_{1\ldots N}^{i_1\ldots i_N}(Z))^{\ell_{i_1\ldots i_N}}\cdots(\Delta_{1,\ldots,N}^{k-N+1,\ldots,k}(Z))^{\ell_{k-N+1,\ldots,k}}, \tag{3.3}$$

with

$$\begin{aligned}
&\ell_{12\ldots N}+\cdots+\ell_{1i_2\ldots i_N}+\cdots\ell_{1,\ldots,k}=m_1^1,\\
&\ell_{12\ldots N}+\cdots+\ell_{12\ldots i_N}+\cdots\ell_{2,\ldots,k}=m_2^1,\\
&\qquad\vdots\\
&\ell_{1\ldots k}+\cdots+\ell_{i_1\ldots i_{N-1,k}}+\cdots+\ell_{k-N+1,\ldots,k}=M_s,
\end{aligned} \tag{3.4}$$

where in Eq. (3.3) a minor $\Delta_{1\ldots N}^{i_1\ldots i_N}(Z)$ *appears if and only if it satisfies*

$$\Delta_{1\ldots N}^{i_1\ldots i_N}(\beta Z)=\beta_{i_1i_1}\cdots\beta_{i_Ni_N}\Delta_{1\ldots N}^{i_1\ldots i_N}(Z), \tag{3.5}$$

and where in Eq. (3.4) the $l_{i_1\ldots i_N}$ *are non-negative integers and the shuffles* $(i_1\ldots i_N)$ *are lexicographically ordered. Moreover, the number of linearly independent solutions of Eq. (3.3) which satisfy the constraints (3.5) and the system of linear diophantine equations (3.4) is the multiplicity of* λ *in the Clebsch–Gordan series of* $\lambda_1\otimes\ldots\otimes\lambda_p$.

Proof: The fact that the tensor product $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}\otimes V^{\lambda^*}$ of irreducible SU(N)-modules can be realized as the subspace of all polynomial functions in $\mathcal{P}(\mathbb{C}^{k\times N})$ which satisfy the covariant condition (3.2) is a consequence of the Borel–Weil theorem and a detailed proof can be found in Ref. 4a. It remains to show that the SU(N)-invariant polynomials in $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}\otimes V^{\lambda^*}$ are spanned by polynomials of the form (3.3) which satisfy the constraints (3.4) and (3.5). From Theorem 3.1 it follows that the polynomials of the form (3.3) will span the subspace of SU(N)-invariants in $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}\otimes V^{\lambda^*}$ if and only if they also satisfy the covariant condition (3.2). Thus it remains to show that a polynomial of the form (3.3) satisfies the covariant condition (3.2) if and only if it satisfies the constraints (3.4) and (3.5). Since in a polynomial of the form (3.3), where only the minors $\Delta_{1\ldots N}^{i_1\ldots i_N}$ which satisfy (3.5) occur, the constraints (3.4) imply the condition (3.2), it is clear that the condition is sufficient. To show that the condition is necessary we first observe that it is easy to verify that

$$\Delta_{1\ldots N}^{i_1\ldots i_N}(yZ)=\sum_{j_1<\cdots<j_N}\Delta_{j_1\ldots j_N}^{i_1\ldots i_N}(y)\Delta_{1\ldots N}^{j_1\ldots j_N}(Z) \tag{3.6}$$

for all $y\in\mathbb{C}^{k\times k}$ and $Z\in\mathbb{C}^{k\times N}$, and where in Eq. (3.6) the summation ranges over all N-shuffles $(j_1,\ldots,j_N)$. Next, let f be an element of the form (3.3) and consider a typical factor $(\Delta_{1\ldots N}^{i_1\ldots i_N})^{l_1\ldots l_N}$ of f. The condition that f must satisfy Eq. (3.2) together with the equality (3.6) with $y=\beta$, a matrix of form (3.1), force $\Delta_{j_1\ldots j_N}^{i_1\ldots i_N}(\beta)=0$ if the shuffle $(j_1,\ldots,j_N)$ is different from $(i_1,\ldots,i_N)$. Thus Eq. (3.6) becomes

$$\Delta^{i_1\cdots i_N}_{1\cdots N}(\beta Z)=\Delta^{i_1\cdots i_N}_{i_1\cdots i_N}(\beta)\Delta^{i_1\cdots i_N}_{1\cdots N}(Z). \tag{3.7}$$

However, in Eq. (3.7) β is an invertible lower triangular matrix, therefore,

$$\Delta^{i_1\cdots i_N}_{i_1\cdots i_N}(\beta)=\beta_{i_1 i_1}\cdots\beta_{i_N i_N}.$$

It follows immediately that in order that f satisfies Eq. (3.2), it is necessary that the minors $\Delta^{i_1\cdots i_N}_{1\cdots N}$ appearing in f must satisfy Eq. (3.5) and the exponents $l_{i_1\cdots i_N}$ must satisfy the constraints (3.4).

Remark 3.3: For any concrete example it is very easy to determine which minors $\Delta^{i_1\cdots i_N}_{1\cdots N}(Z)$ satisfy condition (3.5). This reduces the problem of finding the subspace of SU(N)-invariant polynomials in $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}\otimes V^{\lambda *}$ to that of solving the system of linear diophantine equations (3.4), which is a well-studied problem in integer programming (e.g., the Branch bound method). In general, the polynomials given by Eq. (3.3) which satisfy the constraints (3.4) are not necessarily linearly independent, as we shall see in an example in the next section. However, the problem of finding a basis for a spanning set of polynomial functions is also well studied in computer programming.

IV. EXAMPLES

To illustrate our procedures we consider below several examples.

Example 1: This is the same example given in Refs. 4b and 4c. It will serve to prove the power and the simplicity of our present method versus the more elaborate one in the former. Consider the tensor product $V^{(2,0,0)}\otimes V^{(2,0,0)}\otimes V^{(1,0,0)}$ of SU(3) which has the following Clebsch–Gordan series,

$$(2,0)\otimes(2,0)\otimes(1,0)=(5,0)+2(4,1)+(3,2)+(2,0)+(1,1), \tag{4.1}$$

where in Eq. (4.1) only two integers are needed to label an irreducible representation of SU(3). The representation with signature (4,1) occurs with multiplicity two and its contragradient representation has signature (4,3). So in accordance with Theorem 3.2 we consider the polynomial space $\mathscr{P}(\mathbb{C}^{5\times 3})$. The minors $\Delta^{i_1 i_2 i_3}_{123}(Z)$ which satisfy the condition (3.5) for $z\in\mathbb{C}^{5\times 3}$ and

$$\beta=\begin{bmatrix}\beta_{11} & & & & \\ & \beta_{22} & & & \\ & & \beta_{33} & & \\ & & & \beta_{44} & 0 \\ & & & \beta_{54} & \beta_{55}\end{bmatrix}$$

are

$$\Delta^{123}_{123},\quad \Delta^{124}_{123},\quad \Delta^{134}_{123},\quad \Delta^{145}_{123},\quad \Delta^{234}_{123},\quad \Delta^{245}_{123},\quad \text{and}\quad \Delta^{345}_{123}.$$

So the diophantine linear equation (3.4) for this case is

$$\ell_{123}+\ell_{124}+\ell_{134}+\ell_{145}=2,$$

$$\ell_{123}+\ell_{124}+\ell_{234}+\ell_{245}=2,$$

$$\ell_{123}+\ell_{134}+\ell_{234}+\ell_{345}=1,$$

$$\ell_{124}+\ell_{134}+\ell_{145}+\ell_{234}+\ell_{245}+\ell_{345}=4,$$

$$\ell_{145}+\ell_{245}+\ell_{345}=3,$$

which, using a Maple V program, gives the solutions

$$\ell_{123}=\ell_{134}=\ell_{234}=0,\quad \ell_{124}=\ell_{145}=\ell_{245}=\ell_{345}=1,$$

$$\ell_{123}=\ell_{124}=\ell_{134}=\ell_{345}=0,\quad \ell_{145}=2,\quad \ell_{234}=\ell_{245}=1,$$

and

$$\ell_{123}=\ell_{124}=\ell_{234}=\ell_{345}=0,\quad \ell_{134}=\ell_{145}=1,\quad \ell_{245}=2.$$

It follows that the polynomials

$$\Delta^{124}_{123}(Z)\Delta^{145}_{123}(Z)\Delta^{245}_{123}(Z)\Delta^{345}_{123}(Z),\quad (\Delta^{145}_{123}(Z))^2\Delta^{234}_{123}(Z)\Delta^{245}_{123}(Z),\quad \text{and}\quad \Delta^{134}_{123}(Z)\Delta^{145}_{123}(Z)(\Delta^{245}_{123}(Z))^2,$$

which are easily verified to be linearly dependent [in fact, $\Delta^{124}_{123}(Z)\Delta^{145}_{123}(Z)\Delta^{245}_{123}(Z)\times\Delta^{345}_{123}(Z)+(\Delta^{145}_{123}(Z))^2\Delta^{234}_{123}(Z)\Delta^{245}_{123}(Z)=\Delta^{134}_{123}(Z)\Delta^{145}_{123}(Z)(\Delta^{245}_{123}(Z))^2$], span the two-dimensional subspace of all SU(3)-invariants in the tensor product

$$V^{(2,0,0)}\otimes V^{(2,0,0)}\otimes V^{(1,0,0)}\otimes V^{(4,3,0)}.$$

In Eq. (4.1) the other irreducible representation which occurs with multiplicity two is (3,2). Its contragradient representation has signature (3,1). So proceeding as above, we obtain the polynomials

$$f_1(Z)=(\Delta^{124}_{123}(Z))^2\Delta^{345}_{123}(Z),\quad f_2(Z)=\Delta^{124}_{123}(Z)\Delta^{134}_{123}(Z)\Delta^{245}_{123}(Z),$$

and

$$f_3(Z)=\Delta^{124}_{123}(Z)\Delta^{145}_{123}(Z)\Delta^{234}_{123}(Z)$$

which span the subspace of all SU(3)-invariants in the tensor product.

$$V^{(2,0,0)}\otimes V^{(2,0,0)}\otimes V^{(1,0,0)}\otimes V^{(3,1,0)}.$$

Using a Maple V program, we easily verify the f_1, f_2, and f_3 span a two-dimensional vector space with $f_1+f_3-f_2=0$.

Example 2: Threefold tensor products of SU(2) and S_3 permutation symmetry.

We consider in this example the threefold SU(2) tensor product $j\otimes j\otimes j$, which, since all the irreducible representations are the same, generates an S_3 permutation symmetry. The decomposition into irreducible representations is

$$j\otimes j\otimes j=3j\oplus(3j-1)\oplus(3j-2)\oplus\cdots,$$

$$\text{Symmetry type}=S\quad M\quad S,M\ldots,$$

$$\text{Multiplicity}=1\quad 2\quad 3\ldots.$$

The Clebsch–Gordan coefficients are not particularly difficult to compute for $J=3j-1,3j-2$; here we simply wish to show how the polynomial invariants carry a representation of S_3. According to the general formalism set up in Secs. II and III, we have the augmented Bargmann–Segal–Fock space $\mathcal{P}(\mathbb{C}^{4\times 2})$ of all polynomial functions f which satisfy the covariant condition

$$f(dZ)=d_1^{2j}d_2^{2j}d_3^{2j}d_4^{2J}f(Z),\quad \text{for all}\quad d=\begin{bmatrix} d_1 & & & \\ & d_2 & & \\ & & d_3 & \\ & & & d_4 \end{bmatrix}\quad \text{and}\quad Z\in\mathbb{C}^{4\times 2},\tag{4.2}$$

with invariants of the form $(\Delta_{12}^{12}(Z))^{\ell_{12}}(\Delta_{12}^{13}(Z))^{\ell_{13}}\cdots(\Delta_{12}^{34}(Z))^{\ell_{34}}$. The non-negative integers ℓ_{ij} must be chosen to satisfy Eq. (4.2). That means the equations

$$\begin{aligned} &\ell_{12}+\ell_{13}+\ell_{14}=2j,\quad \ell_{12}+\ell_{23}+\ell_{24}=2j,\\ &\ell_{13}+\ell_{23}+\ell_{34}=2j,\quad \ell_{14}+\ell_{24}+\ell_{34}=2J \end{aligned}\tag{4.3}$$

must be satisfied. For $J=3j-1$ the solutions are

$$\begin{aligned} f_1(Z)&=(\Delta_{12}^{14}(Z))^{2j}(\Delta_{12}^{24}(Z))^{2j-1}(\Delta_{12}^{34}(Z))^{2j-1}(\Delta_{12}^{23}(Z)),\\ f_2(Z)&=(\Delta_{12}^{14}(Z))^{2j-1}(\Delta_{12}^{24}(Z))^{2j}(\Delta_{12}^{34}(Z))^{2j-1}(\Delta_{12}^{13}(Z)),\\ f_3(Z)&=(\Delta_{12}^{14}(Z))^{2j-1}(\Delta_{12}^{24}(Z))^{2j-1}(\Delta_{12}^{34}(Z))^{2j}(\Delta_{12}^{12}(Z)). \end{aligned}\tag{4.4}$$

However, the multiplicity for $J=3j-1$ is 2, not 3, so we see that the f_i must be linearly dependent. To extract the permutation symmetry, we note that

$$(L_\sigma f\ )(Z)=f(\sigma^{-1}Z),\quad \sigma\in S_3,\tag{4.5}$$

defines the action of the permutation group S_3 on the subspace of invariants. Applied to f_i gives

$$\begin{aligned} &L_{(12)(3)}f_1=f_2,\quad L_{(12)(3)}f_2=f_1,\quad L_{(12)(3)}f_3=-f_2,\\ &L_{(123)}f_1=-f_2,\quad L_{(132)}f_2=-f_3,\quad L_{(132)}f_3=f_1, \end{aligned}\tag{4.6}$$

which means the f_i carry a mixed and antisymmetric representation of S_3. From this it follows that the antisymmetric linear combination, f_A, must give the linear dependence:

$$f_A:=f_1-f_2+f_3=0.\tag{4.7}$$

The mixed representation can be chosen such that the S_2 subgroup carries a symmetric and antisymmetric representation. Then

$$f_\pm=f_1\pm f_2=(\Delta_{12}^{14})^{2j-1}(\Delta_{12}^{24})^{2j-1}(\Delta_{12}^{34})^{2j-1}[\Delta_{12}^{14}\Delta_{12}^{23}\pm\Delta_{12}^{24}\Delta_{12}^{13}]\tag{4.8}$$

gives the two mixed representation states needed to calculate the Clebsch–Gordan coefficients

$$\langle j,m_1;j,m_2;j,m_3|J=3j-1,M;\pm\rangle.$$

Similarly for $J=3j-2$, with threefold degeneracy, the solutions to Eq. (4.3) are

$$\begin{aligned} f_1&:=(\Delta_{12}^{14})^{2j-2}(\Delta_{12}^{24})^{2j-1}(\Delta_{12}^{34})^{2j-1}\Delta_{12}^{12}\Delta_{12}^{13},\\ f_2&:=(\Delta_{12}^{14})^{2j-1}(\Delta_{12}^{24})^{2j-1}(\Delta_{12}^{34})^{2j-1}\Delta_{12}^{12}\Delta_{12}^{23},\\ f_3&:=(\Delta_{12}^{14})^{2j-1}(\Delta_{12}^{24})^{2j-1}(\Delta_{12}^{34})^{2j-2}\Delta_{12}^{13}\Delta_{12}^{23}, \end{aligned}\tag{4.9}$$

and since the multiplicity for $J=3j-2$ is 3, these f_i must all be linearly independent. To get the permutation type, we again use Eq. (4.5) to get

$$\begin{gathered} L_{(12)(3)}f_1=-f_2, \quad L_{(12)(3)}f_2=-f_1, \quad L_{(12)(3)}f_3=-f_3, \\ L_{(132)}f_1=-f_2, \quad L_{(132)}f_2=-f_3, \quad L_{(132)}f_3=f_1, \end{gathered} \tag{4.10}$$

from which it follows that the symmetry types are S (symmetric) and M (mixed) with

$$f_S=f_1-f_2+f_3, \quad f_{M,\pm}=f_1\mp f_2. \tag{4.11}$$

We conclude this example with a computation of the polynomial invariants where the Clebsch–Gordan coefficients are not so easy to compute by conventional means, namely the lowest weights in the tensor product decomposition. Consider first the case where j is an integer; the lowest weight is $J=0$ with multiplicity 1. Using Eq. (4.3) with $J=0$ gives

$$f_A=(\Delta_{12}^{12})^{2j}(\Delta_{12}^{13})^{2j}(\Delta_{12}^{23})^{2j} \tag{4.12}$$

and is always antisymmetric as can be checked by computing $L_{(12)(3)}f_A=-f_A$. The coefficients are given directly by

$$\begin{aligned} &\frac{\|f_A\|^{-1}}{\sqrt{(j+m_1)!(j-m_1)!(j+m_2)!(j-m_2)!(j+m_3)!(j-m_3)!}} \\ &\quad\times\frac{\partial^{j+m_1}}{\partial z_{11}^{j+m_1}}\frac{\partial^{j-m}}{\partial z_{12}^{j-m_1}}\frac{\partial^{j+m_2}}{\partial z_{21}^{j+m_2}}\frac{\partial^{j-m_2}}{\partial z_{22}^{j-m_2}}\frac{\partial^{j+m_3}}{\partial z_{31}^{j+m_3}}\frac{\partial^{j-m_3}}{\partial z_{32}^{j-m_3}}f_A(Z)|_{Z=0} \\ &\quad=\langle j,m_1;j_1m_2;j,m_3|J=0\rangle. \end{aligned} \tag{4.13}$$

For j a half-odd integer the lowest weight is $J=\frac{1}{2}$ with multiplicity 2. Using Eq. (4.3) gives three polynomials, namely,

$$\begin{aligned} f_1&:=(\Delta_{12}^{12})^{j-1/2}(\Delta_{12}^{13})^{j-1/2}(\Delta_{12}^{23})^{j+1/2}\Delta_{12}^{14}, \\ f_2&:=(\Delta_{12}^{12})^{j-1/2}(\Delta_{12}^{13})^{j+1/2}(\Delta_{12}^{23})^{j-1/2}\Delta_{12}^{24}, \\ f_3&:=(\Delta_{12}^{12})^{j+1/2}(\Delta_{12}^{13})^{j-1/2}(\Delta_{12}^{23})^{j-1/2}\Delta_{12}^{34}, \end{aligned} \tag{4.14}$$

with permutation structure

$$\begin{gathered} L_{(12)(3)}f_1=(-1)^{j-1/2}f_2, \quad L_{(12)(3)}f_2=(-1)^{j-1/2}f_1, \quad L_{(12)(3)}f_3=(-1)^{j+1/2}f_3, \\ L_{(132)}f_1=(-1)^{2j}f_2, \quad L_{(132)}f_2=(-1)^{2j}f_1, \quad L_{(132)}f_3=f_1, \end{gathered} \tag{4.15}$$

which gives a mixed representation and symmetric or antisymmetric depending on whether $(-1)^{j+1/2}$ is one or minus one. However, for any half-odd integer j, the linear dependence is given by

$$f=f_1-f_2+f_3=0 \tag{4.16}$$

and $L_{(12)(3)}(f_1\pm f_2)=\pm(-1)^{j-1/2}(f_1\pm f_2)$ gives the two mixed representation polynomials.

V. CONCLUSION

Calculating Clebsch–Gordan and Racah coefficients for tensor products of irreducible representations of compact groups almost always involves multiplicity. We have shown how the multiplicity problem can be restated in terms of group invariants, polynomials in $n\times N$ complex variables that are invariant under the right action of the group. Our setting is the Bargmann–Segal–Fock space $\mathscr{F}(\mathbb{C}^{n\times N})$, defined in Sec. II, where n refers to the number of labels needed to specify the tensor product and N is the dimension of the fundamental representation of the group.

We have shown in previous papers that all of the irreducible representations of the compact groups can be realized as polynomials in an appropriate Bargmann–Segal–Fock space; these we write as $f_{|\lambda\zeta\eta\rangle}(Z)$, where λ is the irreducible representation label and ξ is a basis label in the irreducible representation space. A p-fold tensor product state is then a product of these polynomials, written as $f_{|\lambda_1\xi_1\ldots\lambda_p\xi_p\rangle}(Z)\in\mathscr{F}(\mathbb{C}^{n\times N})$, where the irreducible representation labels $\lambda_1,\ldots,\lambda_p$ provide a total of n (nonzero) labels.

What is needed to compute Clebsch–Gordan and Racah coefficients are polynomial realizations of the direct sum basis elements, written $f_{|\lambda\zeta\eta\rangle}(Z)\in\mathscr{F}(\mathbb{C}^{n\times N})$. Here ζ is a (possibly new) set of basis labels in the λ irreducible representation space and η are multiplicity labels. The polynomials $f_{|\lambda\zeta\eta\rangle}(Z)$ are obtained by augmenting the tensor product $\lambda_1\otimes\cdots\otimes\lambda_p$ to $\lambda_1\otimes\cdots\otimes\lambda_p\otimes\lambda^{\vee}$, where $\lambda^{\vee}$ is the representation contragradient to λ, and looking for a set of functionally independent polynomial group invariants $\mathscr{I}_\eta(Z,W)$ in the augmented Bargmann–Segal–Fock space. As shown in Sec. II the number of such functionally independent polynomial invariants is just the multiplicity—the number of times the augmented tensor product contains the identity representation. In Sec. II we then showed that the polynomial $f_{|\lambda\zeta\eta\rangle}(Z)$ is, up to a normalization constant, the polynomial $f^{*}_{|\lambda^{\vee}\zeta^{\vee}\rangle}(D_w)\mathscr{I}_\eta(Z,W)|_{W=0}$.

There are many different ways of choosing a set of functionally independent group invariants to label the multiplicity. As shown through the example of SU(N) in Sec. III, these sets arise as products of fundamental group invariants satisfying certain transformation properties [see Eq. (3.2)]. As such they can be orthogonalized and used to label the multiplicity. However, it is desirable to have a more systematic procedure in which the invariants are manipulated to become eigenvectors of operators. The natural choice here are operators from the centralizer of the outer product group $G\times\cdots\times G$ with respect to G itself. That is, the operators are chosen from that set of operators in the universal enveloping algebra of the Lie algebra of $G\times\cdots\times G$ that commute with G. These operators can be specified more precisely by passing to the duals of $G\times\cdots\times G$ and G on $\mathscr{F}(\mathbb{C}^{n\times N})$. We plan to address the issue of operators from the centralizer being used to diagonalize invariant polynomials in a future paper. In any event, it is clear that the conventional Racah coefficients for SU(2), called $6J,9J,\ldots$ symbols, are all defined via centralizer elements; in this case these operators correspond to various choices of intermediate angular momentum operators.

The use of polynomial invariants allows for great flexibility in computing Clebsch–Gordan and Racah coefficients. It is possible to use any basis for both the tensor product and direct sum states. The price paid is that no attempt is made to find closed form expressions for the coefficients. Rather the goal is to specify procedures to a computer to obtain coefficients of physical interest. This is to be contrasted with other methods, such as that of Vilenkin and Klimyk (Ref. 2) or Prakash and Sharatchandra (Ref. 3), where basis choices are made at the outset [for SU(N) the Gelfand–Zetlin basis] and a specific choice for multiplicity is made (Vilenkin and Klimyk use the Biedenharn–Louck tensor operators). The goal is to find closed form expressions; the complexity of these coefficients, even for SU(3), suggests that while it would be nice to have such expressions, for physical applications much less is needed.

For example, often the irreducible representations generating the tensor product are the same; such is the case for various quark models, where p refers to the number of bound state quarks and the tensor product is the p-fold product of the fundamental representation of SU(6), with $N=6$

coming from the product of $SU(2)_{spin}$ and $SU(3)_{flavor}$. When $p=3$ one gets the standard picture of a baryon-one object (such as a proton) as a bound state of three quarks. However, there has been interest in five quark bound states, where one quark is a heavy anticharm quark, bound to four lighter quarks; then $p=4$.

In this situation it is desirable to label (direct sum) states by their permutation symmetry (in order to respect Pauli statistics). For $p=4$ the relevant group is S_4, the permutation group on four letters. However, this is equivalent to demanding that the invariant polynomials $\mathcal{I}_\eta(Z,W)$ transform as irreducible representations under S_4. In Sec. IV we have worked out several examples of invariant polynomials with definite permutation symmetry for the simpler SU(2) group to show how the multiplicity arising from threefold tensor products can be labeled by irreducible representations of S_3.

There remains the problem of using the known fundamental invariant polynomials of subgroups of SU(N) to calculate the invariants $\mathcal{I}_\eta(Z,W)$ for tensor products of subgroups such as SO(N) and Sp(N). This we intend to take up in a subsequent publication. Here again it should be possible to use computers to obtain invariant polynomials, and by differentiating these polynomials in the right way, compute Clebsch–Gordan and Racah coefficients for arbitrary tensor products of any compact group.

APPENDIX: HOLOMORPHIC REPRESENTATIONS OF GL(N,$\mathbb{C}$)

In this Appendix we will review some facts on holomorphic representations of GL(N,$\mathbb{C}$) and show explicitly how raising and lowering operators of an irreducible GL(N,$\mathbb{C}$)-module are mapped onto lowering and raising operators, respectively, of the corresponding contragradient module. Also we shall see how the highest weight vector is mapped onto the lowest weight vector in this correspondence. This theory allows us to realize explicitly the contragradient SU(N)-module V^{λ^*}, and have the tensor product $V^{\lambda_1}\otimes\cdots\otimes V^{\lambda_p}\otimes V^{\lambda^*}$, as a subspace of the Bargmann–Segal–Fock space $\mathcal{F}(\mathbb{C}^{n\times N})$ discussed in Secs. II–IV.

For $g\in\mathrm{GL}(N,\mathbb{C})$ we set

$$\Delta_\ell(g)=\begin{vmatrix} g_{11} & \cdots & g_{1\ell} \\ \vdots & & \\ g_{\ell 1} & \cdots & g_{\ell\ell} \end{vmatrix},$$

the ℓth minor of g, $1\leqslant\ell\leqslant N$. Then g is called *regular* if $\Delta_\ell(g)\neq 0$ for all ℓ. Let D_N, U_N^-, and U_N^+ denote the diagonal, lower triangular unipotent, and upper triangular unipotent subgroups of GL(N,$\mathbb{C}$), respectively. Then every regular element $g\in G$ can be uniquely represented in the form $g=duv$, where $d\in D_N$, $u\in U_N^-$, and $v\in U_N^+$ (see, e.g., Ref. 8, Chap. VI). Let T be a representation of GL(N,$\mathbb{C}$) in a finite-dimensional complex vector space V. Then a nonzero vector $f\in V$ is called a *weight vector* of *weight* α of the representation T with respect to D_N if $T(d)f=\alpha(d)f$, for all $d\in D_N$, where α is holomorphic character of D_N. A nonzero vector $f_{\max}\in V$ is called a *highest weight vector* with *highest weight* α of the representation T if, in addition to being a weight vector, $f_{\max}$ also satisfies

$$T(v)f_{\max}=f_{\max},\quad \text{for all } v\in U_N^+.$$

Similarly, a nonzero vector $f_{\min}\in V$ is called a *lowest weight vector* of *lowest weight* β if

$$T(d)f_{\min}=\beta(d)f_{\min},\quad \text{and}\quad T(u)f_{\min}=f_{\min}\quad \text{for all } d\in D_N, u\in U_N^-.$$

Now let V^λ denote an irreducible holomorphic representation of GL(N,$\mathbb{C}$) with signature λ. Then V^λ can be explicitly realized on a space of holomorphic functions on $\mathbb{C}^{N\times N}$. The signature $\lambda\equiv\lambda_{(m)}$ is a holomorphic character of D_N defined by

$$\lambda(d)=d_1^{m_1}\cdots d_N^{m_N},\quad d=(d_1,\ldots,d_N)\in D_N,$$

where the m_is are integers which satisfy the dominant condition $m_1\geqslant m_2\geqslant\cdots\geqslant m_N$. Then the space V^λ consists of all holomorphic functions f on $\mathbb{C}^{N\times N}$ which satisfy the covariant condition

$$f(duZ)=\lambda(d)f(Z),\quad \text{for all}\quad d\in D_N, u\in U_N^-,$$

and $Z\in\mathbb{C}^{N\times N}$. The representation R^λ is defined on V^λ by the formula

$$[R^\lambda(g)f](Z)=f(Zg),\quad \text{for all}\quad g\in \mathrm{GL}(N,\mathbb{C}).$$

Then it can be shown (see, e.g., Ref. 3, Chap. VI) that V^λ admits a ''unique'' (i.e., up to a nonzero scalar multiple) highest weight vector $f_{\max}$ of weight $\lambda_{(m)}=(m_1,\ldots,m_N)$, and a ''unique'' lowest weight vector $f_{\min}$ of weight $(m_N,m_{N-1},\ldots,m_1)$. In fact, $f_{\max}$ can be defined as

$$f_{\max}(Z)=\Delta_1^{m_1-m_2}(Z)\Delta_2^{m_2-m_3}(Z)\cdots\Delta_N^{m_N}(Z),$$

and it is straightforward to verify that $f_{\max}(dZ)=d_1^{m_1}\cdots d_N^{m_N}f_{\max}(Z)$, and $f_{\max}(Zv)=f_{\max}$, for all $d\in D_N$ and $v\in U_N^+$. Let

$$s=\begin{bmatrix} & & 1\\ & \iddots & \\ 1 & & \end{bmatrix}$$

be the $N\times N$ matrix with 1's on the reverse diagonal and 0 elsewhere, and define $f_{\min}=R^\lambda(s)f_{\max}$. Then

$$Z_s=\begin{bmatrix} Z_{1N} & Z_{1,N-1} & \ldots Z_{12} & Z_{11}\\ \vdots & \vdots & \vdots & \vdots\\ Z_{NN} & Z_{N,N-1} & \ldots Z_{N2} & Z_{N1}\end{bmatrix},$$

$$\Delta_\ell(Zs)=\begin{vmatrix} Z_{1N} & \ldots & Z_{1,N-i+1}\\ \vdots & & \vdots\\ Z_{\ell,N} & & Z_{\ell,N-i+1}\end{vmatrix}=(-1)\mathrm{sgn}(\sigma)\begin{vmatrix} Z_{1,N-i+1} & \ldots & Z_{1N}\\ \vdots & & \\ Z_{\ell,N-i+1} & \ldots & Z_{\ell,N}\end{vmatrix},$$

where $\mathrm{sgn}(\sigma)$ is the sign of the permutation

$$\sigma=\begin{pmatrix} N-\ell+1 & N-\ell+2 & \ldots & N\\ N & N-1 & & N-\ell+1\end{pmatrix},$$

and

$$f_{\min}(Z)=(\Delta_1(Zs))^{m_1-m_2}\cdots(\Delta_N(Zs))^{m_N}.$$

It follows that

$$[R^\lambda(d)f_{\min}](Z)=[R^\lambda(d)(R^\lambda(s)f_{\max})](Z)=f_{\max}(Zds)=f_{\max}(Zs(sds))=d_1^{m_N}\cdots d_N^{m_1}f_{\max}(Zs)$$
$$=d_1^{m_N}\cdots d_N^{m_1}f_{\min}(Z)$$

since $s=s^{-1}$ and $sds=(d_N,\ldots,d_1)$. Also,

$$[R^{\lambda}(u)f_{\min}(Z)=[R^{\lambda}(u)(R^{\lambda}(s)f_{\max})](Z)=f_{\max}(Zus)=f_{\max}(Zs(sus)),\quad u\in U^{-}.$$

However, it is easy to verify that $sus\in U^{+}$ so that

$$f_{\max}(Zs(sus))=f_{\max}(Zs)=f_{\min}(Z).$$

The differential representation of R^{λ} is given by the infinitesimal generators

$$R^{\lambda}_{ij}=\sum_{s=1,\ldots,N} Z_{is}\frac{\partial}{\partial Z_{js}},\quad 1\leqslant i,j\leqslant N.$$

The differential operators R^{λ}_{ij} with $i<j$ (resp. $i>j$) are called *raising* (resp. lowering) operators. It follows immediately that, in terms of raising and lowering operators, a highest vector $f_{\max}$ (resp. lowest weight vector $f_{\min}$) is characterized by the condition

$$R^{\lambda}_{ij}f_{\max}=0,\quad \forall i<j(\text{resp. } R^{\lambda}_{ij}f_{\min}=0,\forall i>j).$$

Let $(R^{\lambda})^{\vee}$ denote the contragradient representation of R^{λ} on $(V^{\lambda})^{*}$, the dual of V. Then $(R^{\lambda})^{\vee}$ is defined by the equation

$$[(R^{\lambda})^{\vee}(g)f^{*}](h)=f^{*}(R^{\lambda}(g^{-1})h),\quad \text{for all } g\in \mathrm{GL}(N,\mathbb{C}),f^{*}\in(V^{\lambda})^{*},\quad \text{and } h\in V^{\lambda}.$$

Let Φ: $V^{\lambda}\to(V^{\lambda})^{*}$ denote the conjugate-linear isomorphism introduced in Sec. II. Then it is easy to show, using Eq. (2.2), that Φ intertwines R^{λ} and $(R^{\lambda})^{\vee}$. We have the following:

Theorem A1: *Let* $(R^{\lambda},V^{\lambda})$ *be an irreducible holomorphic representation of* $\mathrm{GL}(N,\mathbb{C})$ *and let* $((R^{\lambda})^{\vee},(V^{\lambda})^{*})$ *be the contragradient* $\mathrm{GL}(N,\mathbb{C})$*-module. Under the map* Φ: $V^{\lambda}\to(V^{\lambda})^{*}$ *defined above, the raising operators of* R^{λ} *are mapped onto the lowering operators of* $(R^{\lambda})^{\vee}$ *and vice versa. Moreover, the highest weight vector of* R^{λ} *is mapped onto the lowest weight vector of* $(R^{\lambda})^{\vee}$*, and vice versa.*

Proof: Let $\mathscr{B}=\{f_i\}$ be a basis for V^{λ} and let $\mathscr{B}^{*}=\{f_i^{*}\}$ be its dual basis defined by

$$f_i^{*}(f_j)=\delta_{ij},\quad \forall i_{ij}.$$

Then $(R^{\lambda})^{\vee}(g)f_i^{*}=\Sigma_k(D^{\lambda})^{\vee}_{ki}(g)f_k^{*}$, where $(D_{\lambda})^{\vee}_{ki}(g)$ are the matrix coefficients of $(R^{\lambda})^{\vee}(g)$ relative to $\mathscr{B}^{*}$. Therefore,

$$[(R^{\lambda})^{\vee}(g)f_i^{*}](f_j)=\sum_k (D^{\lambda})^{\vee}_{ki}(g)f_k^{*}(f_j)=(D^{\lambda})^{\vee}_{ji}(g).$$

On the other hand, by definition

$$[(R^{\lambda})^{Nr}(g)(fi^{*})](f_i):=f_i^{*}((R^{\lambda})(g^{-1})f_j)=f_i^{*}\left(\sum_k D^{\lambda}_{kj}(g^{-1})f_k\right)=\sum_k D^{\lambda}_{kj}(g^{-1})f_i^{*}(f_k)$$

$$=D^{\lambda}_{ij}(g^{-1}).$$

Thus we have the following equations:

$$(D^{\lambda})^{\vee}_{ij}(g)=D^{\lambda}_{ji}(g^{-1})\quad \forall i,j,\quad \text{or } [(R^{\lambda})^{\vee}(g)]_{\mathscr{B}^{*}}=[R^{\lambda}(g^{-1})]^{t}_{\mathscr{B}}. \tag{A1}$$

From the matrix form of Eq. (A1) it follows that the infinitesimal operators of R^{λ} and $(R^{\lambda})^{\vee}$ are in a one-to-one correspondence:

$$(R^{\lambda})^{\surd}_{ij} \leftrightarrow -R^{\lambda}_{ji}, \quad 1 \leqslant i,j \leqslant N. \tag{A2}$$

From Eq. (A2) it follows that raising operators of R^{λ} correspond to lowering operators of $(R^{\lambda})^{\surd}$, and vice versa.

If $f_{\max}$ is a highest weight vector of R^{λ}, then by definition

$$\begin{aligned} R^{\lambda}_{ii} f_{\max} &= m_i f_{\max} \quad \forall i = 1,\ldots,N, \\ R^{\lambda}_{ij} f_{\max} &= 0 \quad \forall \leqslant i < j \leqslant N. \end{aligned} \tag{A3}$$

Using the fact that Φ: $V^{\lambda} \rightarrow (V^{\lambda})^*$ is a conjugate-linear intertwining operator and Eq. (A2) we see that

$$\begin{aligned} (R^{\lambda})^{\surd}_{ii} \Phi(f_{\max}) &= \Phi(-R^{\lambda}_{ii} f_{\max}) = -m_i \Phi(f_{\max}) \quad \forall i = 1,\ldots,N, \\ (R^{\lambda})^{\surd}_{ij} \Phi(f_{\max}) &= \Phi(-R^{\lambda}_{ij} f_{\max}) = \Phi(0) \quad \text{for all } 1 \leqslant i < j \leqslant N. \end{aligned} \tag{A4}$$

Equation (A4) shows that $\Phi(f_{\max})$ is the lowest weight vector of $(R^{\lambda})^{\surd}$ [where $\lambda^{\surd} = -(m_N,\ldots,-m_1)$] with weight $(-m_1,\ldots,-m_N)$. Similarly, one can show that $\Phi(f_{\min})$ is the highest weight vector of $(R^{\lambda})^{\surd}$ with weight $(-m_N,\ldots,-m_1)$. □

On the essential spectrum of transport operators on L_1-spaces

Khalid Latrach and Aref Jeribi
Département de Mathématiques, Université de Corse, Quartier Grossetti B.P. 52, 20250 Corte, France

(Received 8 June 1995; accepted for publication 16 July 1996)

In a recent article by the first author [J. Math. Phys. **35**, 6199–6212 (1994)] the essential spectrum of transport operator was analyzed in L_p-spaces for $p \in (1,+\infty)$. The purpose of the present work is to extend this analysis to the case of L_1-spaces. After establishing preliminary results we define the notion of the weak spectrum which we characterize by means of Fredholm operators. We show, in particular, that in L_1-spaces the weak spectrum is nothing else but the essential spectrum. Using the same techniques as in the above-mentioned work, we prove the stability of the essential spectrum of a one-dimensional transport operator with general boundary conditions where an abstract boundary operator relates the incoming and the outgoing fluxes. Sufficient conditions are given in terms of boundary and collision operators, assuring the stability of the essential spectrum. We show also that our results remain valid for neutron transport operators in arbitrary dimension.
 [S0022-2488(96)02811-3]

I. INTRODUCTION

In this article we are concerned with the essential spectrum of the following integrodifferential operator

$$A_H\psi(x,\xi) = -\xi\,\frac{\partial\psi}{\partial x}(x,\xi)\sigma(\xi)\psi(x,\xi) + \int_{-1}^{1}\kappa(\xi,\xi')\psi(x,\xi')d\xi' = T_H\psi + K\psi \tag{1.1}$$

with general boundary conditions where $x \in [-a,\ a]$ for a parameter $0<a<\infty$ and $\xi\in[-1,\ 1]$. This operator describes the transport of particles (neutrons, photons, molecules of gas, etc.) in a plane parallel domain with a width of $2a$ mean free paths. The function $\psi(x,\xi)$ represents the number (or probability) density of gas particles having the position x and the direction cosine of propagation ξ. The function $\sigma(.)$ and $\kappa(.,.)$ are called, respectively, the collision frequency and the scattering kernel. The boundary conditions are modeled by

$$\psi_{|\Gamma_-} = H(\psi_{|\Gamma_+}), \tag{1.2}$$

where Γ_- (resp. Γ_+) is the incoming (resp. outgoing) part of the phase space boundary, $\psi_{|\Gamma_-}$ (resp. $\psi_{|\Gamma_+}$) is the restriction of ψ to Γ_- (resp. Γ_+), and H is a linear bounded operator from a suitable function space on Γ_- to a similar one on Γ_+. The known classical boundary conditions (vacuum boundary, specular reflections, periodic, diffuse reflections, generalized and mixed type boundary conditions[1–5]) are special examples of our general framework. Our general assumptions are

$$\begin{cases} \sigma(.) \in L^{\infty}(-1,1), \\ H \text{ is a bounded boundary operator}, \\ K \in \mathscr{L}(L_1[(-a,a)\times(-1,1)]), \end{cases}$$

0022-2488/96/37(12)/6486/9/$10.00

where K is the partially integral operator with kernel $\kappa(\xi,\xi')$.

In Ref. 6, the essential spectrum of the operator (1.1) supplemented with the boundary conditions (1.2) was investigated on L_p-spaces for $p\in(1,+\infty)$. In particular, it has been proved that if K is regular (see Definition 4.1), then $\sigma_{\text{ess}}(T_H+K)=\sigma_{\text{ess}}(T_H)$ regardless of the boundary operator H [$\sigma_{\text{ess}}(.)$ denotes the essential spectrum]. Further, sufficient conditions on the boundary operator H under which $\sigma_{\text{ess}}(T_H)=\sigma_{\text{ess}}(T_0)$ were given where T_0 is the well-known streaming operator in neutron transport theory ($H=0$) whose spectrum was analyzed in detail in Ref. 6.

Note that even though the spectral theory of transport operators is a classical theme in transport theory, generally, the analysis focuses on the point spectrum of these operators (see, for instance, any of Refs. 7–13). In fact, the knowledge of the (peripheral) point spectrum permits us to obtain a simple description of the time asymptotic behavior ($t\to\infty$) of the solution of the associated Cauchy problem (cf. Ref. 7, 12, 14, or 15).

The purpose of the present work is to investigate the essential spectrum of a one-dimensional transport operator with general boundary conditions and to extend the results obtained in Ref. 6 to L_1-spaces. The idea may be summarized as follows:

Let (Ω,Σ,μ) be an arbitrary positive measure space. After some abstract preliminary results, we define the notion of the weak spectrum [which we denote by $\sigma_w(.)$] on $L_1(\Omega,d\mu)$ and we prove that if B and C are closed densely defined linear operators on $L_1(\Omega,d\mu)$ and if for some $\lambda\in\rho(B)\cap\rho(C)$, the operator $(\lambda-B)^{-1}-(\lambda-C)^{-1}$ is a weakly compact, then $\sigma_w(B)=\sigma_w(C)$. Second, we show the equality (in the sense of the inclusion) of the sets $\sigma_{\text{ess}}(.)$ and $\sigma_w(.)$ on $L_1(\Omega,d\mu)$. Finally, using these remarks, the same strategy as in Ref. 6 leads to the desired results on $L_1[(-a,a)\times(-1,1),dxd\xi]$.

The plan of this article is as follows. In Sec. II, some preliminary abstract results concerning Fredholm operators needed in the sequel are given. Section III is devoted to the analysis of the weak spectrum on L_1-spaces. The main results of this section are Theorems 3.1 and 3.2. In Sec. IV we take advantage of the results of the previous sections to prove the stability of the essential spectrum of a one-dimensional transport operator with general boundary conditions. Sufficient conditions in terms of H and K assuring the stability of the essential spectrum are given. We close this section by discussing the essential spectrum of a transport operator with vacuum boundary conditions in arbitrary dimension.

II. PRELIMINARY RESULTS

Let Z be a Banach space. A closed densely defined linear operator A with domain $D(A)$ is said to be Fredholm if $R(A)$ is closed and both $\alpha(A)=\dim[N(A)]$ and $\beta(A)=\operatorname{codim}[R(A)]$ are finite where $R(A)$ and $N(A)$ are, respectively, the range and the null space of A. The set of Fredholm operators on Z is denoted by $\Phi(Z)$ while the number $i(A)=\alpha(A)-\beta(A)$ is called the index of A. We denote by Φ_A the set

$$\Phi_A:=\{\lambda\in\mathbf{C}\ \text{such that}\ \lambda-A\ \text{is a Fredholm operator on}\ Z\}.$$

We define the essential spectrum of A by

$$\sigma_{\text{ess}}(A)=\bigcap_{C\in\mathscr{K}(Z)}\sigma(A+C),$$

where $\mathscr{K}(Z)$ stands for the ideal of all compact operators on Z.

Similarly, we define the weak spectrum of A by

$$\sigma_w(A)=\bigcap_{F\in\mathscr{F}(Z)}\sigma(A+F),$$

where $\mathscr{F}(Z)$ denotes the set of all weakly compact operators on Z.

Let $\mathscr{P}(Z)$ denote the set

$$\mathscr{P}(Z)=\{F\in\mathscr{L}(Z) \text{ such that there exists } r\in\mathbf{N}^* \text{ satisfying } F^r\in\mathscr{K}(Z)\}.$$

We first prove the following auxiliary lemma:

Lemma 2.1: Let F be an arbitrary element of $\mathscr{P}(Z)$ and set $A=I-F$. Then

(i) *dim*$[N(A)]<\infty$,

(ii) $R(A)$ *is closed,*

(iii) *codim*$[R(A)]<\infty$. ◇

Proof: (i) Since $F\in\mathscr{P}(Z)$, there exists $r\in N^*$ such that $F^r\in.\mathscr{K}(Z)$. Let $x\in N(A)$, then $F^rx=x$, i.e., $x\in N(I-F^r)$ and therefore $N(A)\subset N(I-F^r)$. On the other hand, the identity I restricted to the kernel of $(I-F^r)$ is equal to F^r and consequently compact. Hence $N(I-F^r)$ is finite dimensional and therefore dim$[N(A)]<\infty$.

(ii) Since A commutes with I, Newton's binomial formula gives

$$F^r=(I-A)^r=I+\sum_{k=1}^{r}(-1)^kC_r^kA^k. \tag{2.1}$$

Let E be a closed complement for $N(A)$, so that $Z=N(A)\oplus E$. Thus, we obtain two linear continuous maps $A_{|E}:E\to Z$ and $F_{|E}:E\to Z$, the restrictions of A and F to E. It is clear that the kernel of $A_{|E}$ is $\{0\}$. In order to conclude, it suffices to show that $A_{|E}(E)=A(E)=A(Z)$ is closed. For this it suffices to show that the map $(A_{|E})^{-1}:A(E)\to E$ is continuous. By linearity, it even suffices to prove that $(A_{|E})^{-1}$ is continuous at 0. Suppose that this is not the case. Then we can find a sequence $\{x_n\}$ in E such that $Ax_n\to 0$, but $\{x_n\}$ does not converge to 0. Selecting a suitable subsequence we can assume without loss of generality that $\|x_n\|\geqslant\eta>0$ for all n. Then $1/\|x_n\|\leqslant 1/\eta$ for all n and consequently $A(x_n/\|x_n\|)$ also converges to 0. Furthermore, $x_n/\|x_n\|$ has norm 1, and hence some subsequence of $F^r(x_n/\|x_n\|)$ converges. It follows from (2.1) that $x_n/\|x_n\|$ has a converging subsequence to an element z in E verifying $\|z\|=1$ and $F^r(z)=z$. On the other hand, $F^r=F-FA-F^2A-\cdots-F^{r-1}A$ and so we get $F^r(z)=F(z)$. Hence, we infer that $F(z)-z=0$, which implies that $z\in N(A)$. This contradicts the fact that $E\cap N(A)=\{0\}$ (because $\|z\|=1$) and completes the proof of (ii).

(iii) If $A(Z)$ does not have finite codimension, we can find a sequence of closed subspaces

$$A(Z)=M_0\subset M_1\subset M_2\subset\cdots\subset M_n\subset\cdots$$

such that each M_n is closed and of codimension 1 in M_{n+1} just by adding one-dimensional spaces to $A(Z)$ inductively. By Riesz's lemma (Ref. 16, Lemma 3, p. 578) we can find in each M_n an element x_n such that $\|x_n\|=1$ and $\|x_n-y\|\geqslant 1-\varepsilon$ for all y in M_{n-1} with $0<\varepsilon<1$. Then, by using (2.1) together with the fact that $Z\supset R(A)\supset R(A^2)\supset\cdots\supset R(A^n)\supset\cdots$, for all $k<n$ we get

$$\begin{aligned}\|F^rx_n-F^rx_k\|&=\left\|x_n-\sum_{i=1}^{r}(-1)^iC_r^iA^ix_n-x_k+\sum_{i=1}^{r}(-1)^iC_r^iA^ix_k\right\|\\&=\left\|x_n-x_k-\sum_{i=1}^{r}(-1)^iC_r^iA^i(x_n-x_k)\right\|\geqslant 1-\epsilon\end{aligned}$$

because $x_k+\Sigma_{i=1}^{r}(-1)^iC_r^iA^i(x_n-x_k)\in M_{n-1}$. This proves that the sequence $(F^rx_n)_n$ cannot have a convergent subsequence, and contradicts the compactness of F^r. Q.E.D.

Theorem 2.1: *Assume that the hypothesis of Lemma 2.1 holds. Then $A=I-F$ is a Fredholm operator and $i(A)=0$.* ◇

Proof: The first part of the theorem follows from Lemma 2.1. In order to complete the proof it suffices to show that dim$[N(A)]=$dim$[R(A)^{\perp}]$. To do this, note first that the operator dual A' of A is given by $A'=I'-F'$. The use of Schauder's theorem and Lemma 2.1 (i) gives

$\dim[N(A')]<\infty$. Accordingly, by using the relation $R(A)^{\perp}=N(A')$, we need only to prove $\dim[N(A)]=\dim[N(A')]$. Now the rest of the proof may be sketched in a similar way to that in Ref. 17, pp. 94–100. It suffices to replace $\|Fz_n-Fz_m\|$ by $\|F^r z_n-F^r z_m\|$ and to use the relation $F^r=F-FA-F^2A-\cdots-F^{r-}A$. The details are therefore omitted.

Q.E.D.

Remark 2.1: Note that for $r=1$, Theorem 2.1 is nothing but the classical Riesz's theorem for compact operators (see, for instance, Ref. 17, Theorem 3.2, p. 94). ◇

We close this section with the following result which we need in the sequel.

Theorem 2.2: *Let A be a closed densely defined operator on Z. Suppose that there exist $A_1, A_2 \in \mathscr{L}(Z)$, $F_1, F_2 \in \mathscr{F}(Z)$ such that $A_1A=I-F_1$ on $D(A)$ and $AA_2=I-F_2$ on Z. Then $A \in \Phi(Z)$.* ◇

Proof: In view of the fact that $N(A)\subset N(A_1A)$, we have $\alpha(A)\leqslant\alpha(I-F_1)$. On the other hand, $R(A)\supset R(AA_2)=R(I-F_2)$ and therefore $R(A)^{\perp}\subset R(I-F_2)^{\perp}$. Accordingly, we have $\beta(A)\leqslant\alpha(I'-F_2')$. Now Theorem 2.1 together with Schauder's theorem gives $\alpha(A)<\infty$ and $\beta(A)<\infty$. In order to complete the proof it suffices to show that $R(A)$ is closed. This last assertion follows from Ref. 17, Lemma 2.2, p. 111. Q.E.D.

Theorem 2.2 generalizes Theorem 1.2, p. 163, in Ref. 17.

III. THE IDENTITY OF $\sigma_w(.)$ AND $\sigma_{ess}(.)$ ON L_1-SPACES

In this section we are concerned with the study of the essential spectrum on L_1-spaces. In particular, we prove the equality (in the sense of the inclusion) of the sets $\sigma_w(A)$ and $\sigma_{ess}(A)$, where A is a closed densely defined linear operator. The analysis is essentially based on the results obtained in the previous section.

Let (Ω,Σ,μ) be an arbitrary positive measure space. Throughout this section X_1 denotes the space $L_1(\Omega,d\mu)$.

Theorem 3.1: *Let A be a closed densely defined linear operator on X_1. Then we have*

$$\sigma_w(A)=\sigma_{ess}(A).$$

. ◇

Proof: From $\mathscr{K}(X_1)\subset\mathscr{F}(X_1)$ we infer that $\sigma_w(A)\subset\sigma_{ess}(A)$. In order to conclude, it suffices to show that $\sigma_{ess}(A)\subset\sigma_w(A)$. To this end, suppose that $\lambda\notin\sigma_w(A)$. Then there exists $F\in\mathscr{F}(X_1)$ such that $\lambda\in\rho(A+F)$. This implies that $\lambda\in\Phi_{(A+F)}$ and $i(\lambda-A-F)=0$. Since $F\in\mathscr{F}(X_1)$ we have $(\lambda-A-F)^{-1}F\in\mathscr{F}(X_1)$. Hence by Ref. 16, Corollary 13, p. 510, we get $[(\lambda-A-F)^{-1}F]^2\in\mathscr{K}(X_1)$. Now by representing $\lambda-A$ as $\lambda-A=(\lambda-A-F)[I+(\lambda-A-F)^{-1}F]$ and by using Ref. 17, Theorem 1.3, p. 163, together with Theorem 2.1, we obtain $\lambda\in\Phi_A$ and $i(\lambda-A)=0$. Now Ref. 18, Theorem 4.5, p. 15, gives the wanted inclusion and achieves the proof. Q.E.D.

By Theorem 3.1 and Ref. 6, Lemma 4.1, we have the following:

Corollary 3.1: Let A be a closed densely defined linear operator on X_1. Then

(i) $\sigma C(A)\subset\sigma_w(A)$,
(ii) $\sigma R(A)\subset\sigma_w(A)$,

where $\sigma C(A)$ [resp. $\sigma R(A)$] denotes the continuous spectrum (resp. the residual spectrum) of A. ◇

The following result provides a characterization of the weak spectrum on L_1-spaces.

Corollary 3.2: Let A be a closed densely defined linear operator on X_1. Then

$$\lambda\notin\sigma_w(A) \text{ if and only if } \lambda\in\Phi_A \text{ and } i(\lambda-A)=0.$$

◇

Proof: This corollary immediately follows from Theorem 3.1 and Ref. 18, Theorem 4.5, p. 15. Q.E.D.

We end this section with the following result which provides a practical criterion for the stability of the weak spectrum on L_1-spaces.

Theorem 3.2: *Let A, B be closed densely defined operators on X_1. If for some $\lambda \in \rho(A) \cap \rho(B)$ the operator $(\lambda - A)^{-1} - (\lambda - B)^{-1}$ is weakly compact on X_1, then*

$$\sigma_w(A) = \sigma_w(B).$$

◇

Proof: Without loss of generality, suppose $\lambda = 0$. Thus $A^{-1} = B^{-1} + F$ where F is a weakly compact operator on X_1. Let $\mu \in \Phi_{A^{-1}}$. Then by Ref. 17, Theorem 2.1, p. 110, there exist $A_1, A_2 \in \mathscr{L}(X_1)$ and $K_1, K_2 \in \mathscr{K}(X_1)$ such that $(\mu - A^{-1})A_1 = I - K_1$ and $A_2(\mu - A^{-1}) = I - K_2$. This implies

$$(\mu - B^{-1})A_1 = I - K_1 + FA_1 = I - F_1,$$

$$A_2(\mu - B^{-1}) = I - K_2 + A_2F = I - F_2,$$

where $F_1 = K_1 - FA_1$ and $F_2 = K_2 - A_2F$ are weakly compact. It follows from Theorem 2.2 that $\mu \in \Phi_{B^{-1}}$, i.e., $\Phi_{A^{-1}} \subset \Phi_{B^{-1}}$. Similarly, by writing $B^{-1} = A^{-1} - F$, we obtain $\Phi_{B^{-1}} \subset \Phi_{A^{-1}}$ and consequently $\Phi_{A^{-1}} = \Phi_{B^{-1}}$. On the other hand, the weak compactness of F_1 and F_2, Ref. 16, Corollary 13, p. 510, and Theorem 2.1 give $i(\mu - A^{-1}) = i(\mu - B^{-1})$ for all $\mu \in \Phi_{A^{-1}}$. Hence, by using Ref. 18, Lemma 4.6, p. 16, we obtain $\Phi_A = \Phi_B$ and $i(\tau - A) = i(\tau - B)$ for all $\tau \in \Phi_A$. The result is now a consequence of Corollary 3.2. Q.E.D.

IV. APPLICATION TO TRANSPORT EQUATIONS

The aim of this section is the analysis of the essential spectrum of one-dimensional transport operators with abstract boundary conditions on L_1-spaces. Our analysis uses the results of Secs. II and III and follows closely Ref. 6.

Let

$$X = L_1[(-a,a) \times (-1,1); dx d\xi], \quad a > 0,$$

and

$$X^o := L_1[\{-a\} \times (-1,0); |\xi| d\xi] \times L_1[\{a\} \times (0,1); |\xi| d\xi] := X_1^o \times X_2^o$$

equipped with the norm

$$\|\psi^o; X^o\| = \|\psi_1^o; X_1^o\| + \|\psi_2^o; X_2^o\| = \int_{-1}^{0} |\psi(-a,\xi)||\xi| d\xi + \int_{0}^{1} |\psi(a,\xi)||\xi| d\xi,$$

and

$$X^i := L_1[\{-a\} \times (0,1); |\xi| d\xi] \times L_1[\{a\} \times (-1,0); |\xi| d\xi] := X_1^i \times X_2^i$$

equipped with the norm

$$\|\psi^i; X^i\| = \|\psi_1^i; X_1^i\| + \|\psi_2^i; X_2^i\| = \int_{0}^{1} |\psi(-a,\xi)||\xi| d\xi + \int_{-1}^{0} |\psi(a,\xi)||\xi| d\xi.$$

We define the partial Sobolev space W by

$$W=\left\{\psi\in X \text{ such that } \xi\frac{\partial\psi}{\partial x}\in X\right\}.$$

It is well known that any function $\psi\in W$ has traces on $\{-a\}$ and $\{a\}$ in X^o and X^i (see, for instance, Ref. 19 or 20). They are denoted, respectively, by ψ^o and ψ^i, and represent the outgoing and the incoming fluxes (''o'' for outgoing and ''i'' for incoming).

Let H be the following boundary operator:

$$\begin{cases} H:X^o\to X^i, \\ u\to Hu, \\ Hu:=\begin{pmatrix} H_{11} & H_{12}\\ H_{21} & H_{22}\end{pmatrix}\begin{pmatrix} u_1\\ u_2\end{pmatrix}, \end{cases}$$

where $H_{11}\in\mathscr{L}(X_1^o,X_1^i)$, $H_{12}\in\mathscr{L}(X_2^o,X_1^i)$, $H_{21}\in\mathscr{L}(X_1^o,X_2^i)$, and $H_{22}\in\mathscr{L}(X_2^o,X_2^i)$.

We define the streaming operator T_H by

$$\begin{cases} T_H:D(T_H)\subset X\to X, \\ \psi\to T_H\psi(x,\xi)=-\xi\dfrac{\partial\psi}{\partial x}-\sigma(\xi)\psi(x,\xi), \\ D(T_H)=\{\psi\in W \text{ such that } H\psi^o=\psi^i\}. \end{cases}$$

Let

$$\lambda_0:=\begin{cases} -\lambda^*, & \text{if } \|H\|\leqslant 1, \\ -\lambda^*+\dfrac{1}{2a}\operatorname{Log}(\|H\|), & \text{if } \|H\|>1, \end{cases}$$

where

$$\lambda^*=-\lim_{|\xi|\to 0}\inf\sigma(\xi).$$

For $\operatorname{Re}\lambda>\lambda_0$, $\lambda\in\rho(T_H)$ and the resolvent of T_H are given by

$$(\lambda-T_H)^{-1}=\sum_{n\geqslant 0}B_\lambda H(M_\lambda H)^n G_\lambda+C_\lambda,$$

where B_λ, C_λ, G_λ, and M_λ are linear bounded operators. For the details, see Ref. 21. Note that C_λ is nothing but $(\lambda-T_0)^{-1}$, so we have

$$(\lambda-T_H)^{-1}-(\lambda-T_0)^{-1}=Q_\lambda,$$

where $Q_\lambda=\Sigma_{n\geqslant 0}B_\lambda H(M_\lambda H)^n G_\lambda$.

Theorem 4.1: *Let H be a bounded boundary operator. If H is weakly compact, then*

$$\sigma_{\text{ess}}(T_H)=\sigma_{\text{ess}}(T_0).$$

◇

Proof: The weak compactness of H implies that of Q_λ on X. In view of Theorem 3.2, we have $\sigma_w(T_H)=\sigma_w(T_0)$. Now, the result follows from Theorem 3.1. Q.E.D.

Remark 4.1: It should be noted that Theorem 4.1 shows not only that the result of Ref. 6, Theorem 4.1, remains valid for $p=1$ but also the hypothesis on the boundary operator H may be weakened. ◇

Remark 4.2: Let $\widetilde{H}$ be the boundary operator defined by

$$\begin{cases} \widetilde{H}: X^0 \to X^i, \\ u \to \widetilde{H}u, \\ \widetilde{H}u = \begin{pmatrix} H_{11} & 0 \\ H_{21} & 0 \end{pmatrix} \begin{pmatrix} u_1 \\ u_2 \end{pmatrix}, \end{cases}$$

where

$$\begin{cases} H_{11}: X_1^0 \to X_1^i, \\ u(-a,\xi) \to u(-a,\xi), \end{cases}$$

and H_{21} is an arbitrary operator of $\mathscr{L}(X_1^o, X_2^i)$. In spite of the fact that $\widetilde{H}$ is not compact, it has shown in Ref. 6, Proposition 4.1, that $\sigma_{\text{ess}}(T_{\widetilde{H}}) = \sigma_{\text{ess}}(T_0)$. Since H_{11} and H_{22} are not weakly compact, the operator $\widetilde{H}$ is not weakly compact either. So, by a similar reasoning to that in the proof of Ref. 6, Proposition 4.1, we get $\sigma_{\text{ess}}(T_{\widetilde{H}}) = \sigma_{\text{ess}}(T_0)$. This shows that the result of Theorem 4.1 is not optimal. ◇

Next we consider the transport operator $A_H := T_H + K$, where K is a bounded partially integral operator on X defined by

$$\begin{cases} K: X \to X, \\ \psi \to \displaystyle\int_{-1}^{1} \kappa(\xi,\xi')\psi(x,\xi')d\xi'. \end{cases}$$

The scattering kernel $\kappa: (-1,1)\times(-1,1) \to \mathbf{R}$ is assumed to be measurable.

Definition 4.1: A bounded operator K, defined as above, is said to be regular if its restriction to $L_1([-1,1],d\xi)$ is compact. ◇

Remark 4.3: Note that the fact that K is regular does not imply the compactness of K on X. To see this, suppose that $\kappa(\xi,\xi') = f(\xi)g(\xi')$ where $f \in L_1([-1,1],d\xi)$, $g \in L^{\infty}([-1,1],d\xi)$. Thus K is regular because it is of rank one on $L_1([-1,1],d\xi)$ but it is not compact on X because its spectrum $\sigma(K) = \overline{\{f(\xi), -1 \leqslant \xi \leqslant 1\}}$ is not necessary discrete. ◇

Let $\lambda \in \rho(T_H)$ be such that $r_\sigma[(\lambda - T_H)^{-1}K] < 1$ [$r_\sigma(.)$ denotes the spectral radius]. Then $\lambda \in \rho(A_H)$ and

$$(\lambda - A_H)^{-1} - (\lambda - T_H)^{-1} = \sum_{n \geqslant 1} [(\lambda - T_H)^{-1}K]^n (\lambda - T_H)^{-1}. \tag{4.1}$$

By using Eq. (4.1), Theorems 3.1 and 3.2, and Ref. 21, Theorem 2.1, we have the following.

Theorem 4.2: *Let H be a bounded boundary operator. Assume that the collision operator K is regular on X. Then*

$$\sigma_{\text{ess}}(A_H) = \sigma_{\text{ess}}(T_H). \quad \diamond$$

Theorems 4.1 and 4.2 and Ref. 6, Theorem 3.1, imply the following:

Corollary 4.1: Let H be a bounded boudary operator. If K is regular on X and H is weakly compact, then

$$\sigma_{\text{ess}}(A_H)=\{\lambda\in\mathbf{C}\ \ such\ \ that\ \ \text{Re}\ \lambda\leqslant-\lambda^*\}.$$ ◇

Remark 4.4: Theorems 4.2 and 4.3 and Corollary 4.1 generalize the results of Ref. 6 to the case $p=1$ and give positive answers to the problems indicated therein. ◇

We close this section by discussing briefly the essential spectrum of the multidimensional neutron transport equation. To this purpose, consider the neutron transport operator

$$A_0\psi(x,v)=-v\ \frac{\partial\psi}{\partial x}\ (x,v)-\sigma(v)\psi(x,v)+\int_V\kappa(v,v')\psi(x,v')dv'=T_0\psi+K\psi,$$

where T_0 is the streaming operator and K denotes the integral part of A_0 (the collision operator), $(x,v)\in D\times V$, where the configuration space D is an open and bounded subset of R^N, $N\geqslant 1$. The velocity space V is an arbitrary open subset of R^N. The unbounded operator A_0 (i.e., $H=0$) is studied in the Banach space $L_1(D\times V)$. Its domain is

$$D(A_0)=D(T_0)=\left\{\psi\in L_1(D\times V)\text{such that}\ v\ \frac{\partial\psi}{\partial x}\in L_1(D\times V),\quad \psi_{|\Gamma_-}=0\right\},$$

where $\Gamma_-=\{(x,v)\in\partial D\times V$ such that v is ingoing at $x\in\partial D\}$.

It is well known that

$$\sigma(T_0)=\{\lambda\in\mathbf{C}\ \ such\ \ that\ \ \text{Re}\ \lambda\leqslant-\lambda^*\}$$

(see, for instance, Ref. 22, Corollary 12.11, p. 272). More precisely we have

$$\sigma_{\text{ess}}(T_0)=\sigma C(T_0)=\{\lambda\in\mathbf{C}\ \ such\ \ that\ \ \text{Re}\ \lambda\leqslant-\lambda^*\}$$

(see Ref. 6, p. 6211).

The existence of the eigenvalues of T_0+K in the half-plane $\{\lambda\in\mathbf{C}/\text{Re}\ \lambda>-\lambda^*\}$ is related to the compactness of some iterate of $(\lambda-T_0)^{-1}K$ (see Ref. 22, Chap. 12). Unfortunately, this does not prevent the appearance of holes, included in the resolvent set of A_0, in the region $\{\lambda\in\mathbf{C}$ such that $\text{Re}\ \lambda\leqslant-\lambda^*\}$. However, if K is compact on $L_1(V)$, then $(\lambda-T_0)^{-1}K$ is weakly compact on $L_1(D\times V)$ (see Ref. 15, Lemma 2.1) and consequently we have the following result.

Theorem 4.3: *Suppose that K is compact on $L_1(V,dv)$. Then*

$$\sigma_{\text{ess}}(A_0)=\{\lambda\in\mathbf{C}\ \ such\ \ that\ \ \text{Re}\ \lambda\leqslant-\lambda^*\}.$$

◇

Proof: Let λ be such that $\text{Re}\ \lambda>s(A_0)$ (the spectral bound of A_0). Then we may write

$$(\lambda-A_0)^{-1}-(\lambda-T_0)^{-1}=\sum_{n\geqslant 1}\ [(\lambda-T_0)^{-1}K]^n(\lambda-T_0)^{-1}.$$

The hypothesis on K together with Ref. 15, Lemma 2.1, implies the weak compactness of

$$\sum_{n\geqslant 1}\ [(\lambda-T_0)^{-1}K]^n(\lambda-T_0)^{-1}.$$

Now the result follows from Theorems 3.1 and 3.2. Q.E.D.

(Received 20 February 1996; accepted for publication 4 June 1996)

We show that the action of the special conformal transformations of the usual (undeformed) conformal group is the $q\to 1$ scaling limit of the braided adjoint action or R-commutator of q-Minkowski space on itself. We also describe the q-deformed conformal algebra in R-matrix form and its quasi-$*$ structure. © *1996 American Institute of Physics.* [S0022-2488(96)03611-0]

I. INTRODUCTION

It is a standard geometrical fact that the action of the momentum generators of the Poincaré algebra in physics is determined by the additive group structure of space–time, by differentiation as an infinitesimal addition. In this note we provide a novel geometrical picture of the special conformal transformations c_i similarly in terms of the structure of space–time itself. Namely, we show that they act as the $q\to 1$ limit of the braided adjoint action by which any braided group acts upon itself. In the case of q-deformed space–time,[1] this is the R-commutator

$$c_i\cdot(x_{i_1}\cdots x_{i_n})=\frac{x_{i_1}\cdots x_{i_n}x_i-x_{a_1}x_{j_1}\cdots x_{j_n}\mathbf{R}^{j_1}{}_{i_1}{}^{a_1}{}_{a_2}\mathbf{R}^{j_2}{}_{i_2}{}^{a_2}{}_{a_3}\cdots\mathbf{R}^{j_n}{}_{i_n}{}^{a_n}{}_{i}}{q-q^{-1}},$$

where the x_i are the noncommuting space–time-coordinates with braid statistics controlled by the appropriate Yang–Baxter matrix $\mathbf{R}^{i}{}_{j}{}^{k}{}_{l}$. We take the limit $q\to 1$. The formula also works for $q\neq 1$ and extends the q-Poincaré action in Ref. 2 to an action of the q-deformed conformal algebra.

We believe that this result is interesting as an application of q-deformation techniques to classical geometry: the picture which it provides is rather simpler than the usual picture of the c_i in terms of conjugation under conformal inversion of space-time translation, but is only possible when $q\neq 1$. One may work with the c_i in our $q\neq 1$ setting and afterwards set $q=1$. The result adds weight to the idea that q-deformed geometry is conceptually simpler and more regular than classical geometry, with certain notions unified in ways that are singular when $q=1$.

In a previous paper[3] we showed that the braided adjoint action with respect to the *multiplicative* braided group structure[4] of q-Minkowski space (as Hermitian 2×2 matrices being multiplied) corresponds in a $q\to 1$ scaling limit to the internal symmetry Lie algebra $su(2)\times u(1)$. Our result now is for the *additive* braided group structure due to Meyer.[5] It appears that both adjoint actions have important scaling limits as $q\to 1$.

We note that while a lot of effort has been expended in q-deforming geometrical structures, in particular in the author's ''braided groups approach'' [1,4,6] (which included specific proposals[7] in a general and systematic R-matrix form), this program has been stuck in recent years due to the following ''dilaton problem:'' when one tries to q-deform the q-Poincaré group one finds quite generally[2] that, for the types of deformations of interest, one must include a scale generator as well. The purely Poincaré sector in this family does not close as a Hopf algebra. A related problem is that even after this extension, it does not seem possible to obtain a Hopf $*$-algebra (i.e., to define

[a)]Royal Society University Research Fellow and Fellow of Pembroke College, Cambridge.

complex conjugation of the generators) in any conventional sense. Moreover, the extended q-Poincaré Hopf algebra is not in general quasitriangular, i.e., not a strict quantum group in the sense of Drinfeld.[8]

Here we solve these three problems as follows. First, we propose to embrace the dilaton generator and q-deform the entire conformal algebra. This algebra is isomorphic to the standard Drinfeld–Jimbo deformation $U_q(so(4,2))$ or a cocycle twisting of it, but obtained now as an example of a new R-matrix construction. We use the categorical double-bosonization theory developed recently in Ref. 9. From a physical point of view, this focus on the conformal algebra limits our theories at first to massless ones. This is not, however, an unreasonable starting point, especially if we are interested in fundamental theories where observed particles are essentially massless compared to the Planck mass scale. Second, we show that the natural $*$-structure on the q-conformal algebra for real q makes it into a *quasi-*$*$ Hopf algebra in the sense recently introduced in Ref. 10 for the Poincaré case. There is also a quasitriangular structure. This work provides a first step towards the development of a q-twistor theory based on the properties of q-Minkowski space and the q-conformal algebra.

For quantum groups and braided groups, we adopt the conventions and notation in Refs. 11 and 12. Briefly, a quantum group H has a coproduct $\Delta: H\to H\otimes H$ which is a homomorphism to the usual tensor product. By contrast, a braided group B has a map $\underline{\Delta}: B\to B\underline{\otimes}B$ which is a homomorphism to a braided or noncommuting tensor product. This concept and many examples have been introduced by the author.[4] In physical terms, the elements of B enjoy braid statistics. When discussing quasitriangular structures, we will require formal power series in a deformation parameter in the usual way. All other constructions are algebraic.

Although we emphasize the construction in Proposition 2.1 below as a q-conformal algebra, we can also choose R from other standard families such as su_n. Then the construction takes us up one in the family, i.e., it allows the construction of quantum groups by induction.[9] Or we can choose nonstandard R and obtain altogether new quantum groups. Also, it has been pointed out to us that there are some superficial similarities between some of the relations in Proposition 2.1 and some of the relations independently proposed for a Hopf algebra construction in Ref. 13. The two constructions are, however, not at all the same.

II. q-CONFORMAL ALGEBRA

In this preliminary section we define a quasitriangular Hopf algebra which we call the conformal algebra associated to regular R-matrix data. When R is the so_n R-matrix, one obtains $U_q(so_{n+2})$. The construction is a specific example of a left-module version of a recent abstract construction in Ref. 9. This is explained further in the Appendix; here we describe only the resulting algebra. In fact, the construction of the dilaton-extended q-Poincaré algebra in R-matrix form has already been obtained (by the author) in Refs. 2 and 10. We use exactly the results and conventions developed for this, extending it now by the special conformal transformations.

Thus, let $\mathbf{R},\mathbf{R}'\in M_n\otimes M_n$ be invertible matrices obeying the conditions in Ref. 2 for the construction of a linear (momentum) braided group $V(\mathbf{R}',\mathbf{R})$ and its associated extended q-Poincaré algebra, which we denote $P(\mathbf{R}',\mathbf{R})$. The momentum sector has generators p^i and relations and braid statistics[2]

$$\mathbf{p}_1\mathbf{p}_2=\mathbf{R}'\mathbf{p}_2\mathbf{p}_1,\quad \mathbf{p}_1'\mathbf{p}_2=\mathbf{R}\mathbf{p}_2\mathbf{p}_1', \tag{1}$$

while $\mathbf{p}'$ denotes the generators of the second copy. We use a standard compact notation where suffices denote tensor contraction positions. The braided coproduct $\Delta\mathbf{p}=\mathbf{p}\otimes 1+1\otimes\mathbf{p}\equiv\mathbf{p}+\mathbf{p}'$ is called a *braided coaddition*. The braided antipode is $\underline{S}\mathbf{p}=-\mathbf{p}$. The rotation sector has matrix generators $l^{\pm i}{}_j$ and the usual relations[14]

$$\mathbf{l}_1^{\pm}\mathbf{l}_2^{\pm}\mathbf{R}=\mathbf{R}\mathbf{l}_2^{\pm}\mathbf{l}_1^{\pm},\quad \mathbf{l}_1^{+}\mathbf{l}_2^{-}\mathbf{R}=\mathbf{R}\mathbf{l}_2^{-}\mathbf{l}_1^{+}. \tag{2}$$

We also require other relations beyond these quadratic ones, such that the $\mathbf{l}^{\pm}$ with matrix coproduct $\Delta\mathbf{l}^{\pm}=\mathbf{l}^{\pm}\otimes\mathbf{l}^{\pm}$ define a quasitriangular Hopf algebra under which (1) and (5) remain covariant. For the so_n R-matrix the $\mathbf{l}^{\pm}$ generate $U_q(so_n)$ in the FRT form.[14] Our construction is not limited to this case, however. The dilatation sector is an additional generator ς with coproduct $\Delta\varsigma=\varsigma\otimes\varsigma$. The q-Poincaré algebra is generated by these subalgebras, with the cross relations[2]

$$\mathbf{l}_1^+\mathbf{p}_2=\lambda^{-1}\mathbf{R}_{21}^{-1}\mathbf{p}_2\mathbf{l}_1^+,\quad \mathbf{l}_1^-\mathbf{p}_2=\lambda\mathbf{R}\mathbf{p}_2\mathbf{l}_1^-,\quad \varsigma\mathbf{p}=\lambda^{-1}\mathbf{p}\varsigma,\quad [\mathbf{l}^{\pm},\,\varsigma]=0, \tag{3}$$

where λ is the *quantum group normalization constant*[2] appearing in the fundamental representation $\rho(\mathbf{l}^+)=\lambda\mathbf{R}$, $\rho(\mathbf{l}^-)=\lambda^{-1}\mathbf{R}_{21}^{-1}$ of the rotation sector. The braided coproduct and antipode of the $\mathbf{p}$ generators do not appear directly in the extended q-Poincaré algebra (which is an ordinary Hopf algebra), but in the bosonized form

$$\Delta\mathbf{p}=\mathbf{p}\otimes 1+\varsigma\mathbf{l}^-\otimes\mathbf{p},\quad S\mathbf{p}=-(S\mathbf{l}^-)\varsigma^{-1}\mathbf{p}. \tag{4}$$

To this construction, we add now the special conformal transformations as the linear braided group $V\check{}(\mathbf{R}',\mathbf{R})^{\mathrm{op}}$ with generators c_i and relations and braid statistics

$$\mathbf{c}_2\mathbf{c}_1=\mathbf{c}_1\mathbf{c}_2\mathbf{R}',\quad \mathbf{c}_2'\mathbf{c}_1=\mathbf{c}_1\mathbf{c}_2'\mathbf{R}. \tag{5}$$

There is a linear braided coproduct $\underline{\Delta}\mathbf{c}=\mathbf{c}+\mathbf{c}'$.

Proposition 2.1: The extended q-Poincaré algebra (1)–(4) has a further extension by generators c_i obeying

$$\mathbf{c}_2\mathbf{c}_1=\mathbf{c}_1\mathbf{c}_2\mathbf{R}',\quad \mathbf{l}_1^+\mathbf{c}_2=\lambda\mathbf{c}_2\mathbf{l}_1^+\mathbf{R}_{21},\quad \mathbf{l}_1^-\mathbf{c}_2=\lambda^{-1}\mathbf{c}_2\mathbf{l}_1^-\mathbf{R}^{-1},$$

$$\varsigma\mathbf{c}=\lambda\mathbf{c}\varsigma,\quad [\mathbf{p},\,\mathbf{c}]=\frac{\mathbf{l}^+\varsigma^{-1}-\mathbf{l}^-\varsigma}{q-q^{-1}},\quad \Delta\mathbf{c}=\mathbf{c}\otimes\mathbf{l}^+\varsigma^{-1}+\mathbf{l}\otimes\mathbf{c},\quad S\mathbf{c}=-\mathbf{c}\varsigma S\mathbf{l}^+,$$

where it is assumed that $\mathbf{R}$ *depends on a parameter q such that* $\mathbf{R}_{21}\mathbf{R}=\mathrm{id}+O(q-q^{-1})$. *We call this the q-conformal algebra* $C(\mathbf{R}',\mathbf{R})$ *associated to our R-matrix data.*

Proof: An abstract derivation is in the Appendix, but a direct proof is also possible. Indeed, it is clear that $\mathbf{c}$, $\mathbf{l}^{\pm}$, and ς generate a ''conjugate'' Hopf algebra to the extended q-Poincaré one: their relations are analogous under a symmetry. Hence it suffices to verify that the coproduct is compatible with the cross relations. Thus,

$$\begin{aligned}[\Delta p^i,\,\Delta c_j]&=[p^i,\,c_a]\otimes l^{+a}{}_j\varsigma^{-1}+\varsigma l^{-i}{}_a\otimes[p^a,\,c_j]+\varsigma l^{-i}{}_a c_b\otimes p^a l^{+b}{}_j\varsigma^{-1}-c_b\varsigma l^{-i}{}_a\otimes l^{+b}{}_j\varsigma^{-1}p^a\\
&=[p^i,\,c_a]\otimes l^{+a}{}_j\varsigma^{-1}+\varsigma l^{-i}{}_a\otimes[p^a,\,c_j]+\varsigma c_d l^{-i}{}_c\mathbf{R}^{-1c}{}_a{}^d{}_b\otimes p^a l^{+b}{}_j\varsigma^{-1}\\
&\quad -c_b\varsigma l^{-i}{}_a\otimes l^{+b}{}_j\varsigma^{-1}p^a\\
&=\frac{l^{+i}{}_a\varsigma^{-1}\otimes l^{+a}{}_j\varsigma^{-1}-l^{-i}{}_a\varsigma\otimes l^{-a}{}_j\varsigma}{q-q^{-1}}\\
&=\Delta\,\frac{l^{+i}{}_j\varsigma^{-1}-l^{-i}{}_j\varsigma}{q-q^{-1}}=\Delta[p^i,\,c_j]\end{aligned}$$

as required. We used the stated $\mathbf{c},\mathbf{l}^-$ and $\mathbf{p},\mathbf{l}^+$ relations for the second and third equalities, as well as the $[\mathbf{p},\mathbf{c}]$ relations for the latter.

Note that the $q-q^{-1}$ factor ensures that our algebra has a reasonable limit as $q\to 1$ but is not needed for the Hopf algebra structure itself (any factor will do for this). □

In a setting where $q=e^{t/2}$, there is typically a quasitriangular structure $\mathscr{R}_L$ for the Lorentz/rotation sector as a formal power series in t. In this setting, we have the following.

Proposition 2.2: The q-conformal Hopf algebra above is quasitriangular, with

$$\mathscr{R}=\mathscr{R}_L\lambda^{-\xi\otimes\xi}\exp(\mathbf{c}|\mathbf{p})^{-1}, \tag{6}$$

where $\mathscr{R}_L$ *is the q-Lorentz quantum group quasitriangular structure,* $\varsigma=\lambda^{\xi}$ *and* $\exp(\mathbf{c}|\mathbf{p})\in V^{\vee}\otimes V$ *is the* braided exponential *or canonical element associated with the braided group duality pairing between V and* $V^{\vee}$ *as linear braided groups.*

Proof: This follows from the general construction[9] underlying the above proposition; see the Appendix. To verify it directly, one may use the bicharacter property of the braided exponentials under the braided coproduct,[15] with the corresponding properties with respect to the bosonized coproduct. □

The braided exponential $\exp(\mathbf{c}|\mathbf{p})$ here is a $\mathbf{p}$-eigenfunction or plane wave in the copy of q-space–time generated by the c_i (and likewise a plane wave in the copy generated by p^i).

III. QUASI $*$-STRUCTURE ON THE CONFORMAL GENERATORS

So far, we have considered the complexified picture. We now consider $*$-structures on our algebras. The specification of the $*$-structure in the momentum sector determines which linear combinations are 'real' in the sense of being invariant under $*$. This determines which representations are unitary (such elements should be Hermitian) and also determines, when there is a quantum metric, whether it is of Euclidean, Minkowski, or another type according to the form of its restriction to such elements. The $*$-structures for the extended q-Poincaré group have already been-analyzed in Ref. 10, and we extend this now to the q-conformal case. We recall from Ref. 10 that one needs the notion of a quasi-$*$ Hopf algebra $\mathscr{H}$. This is a Hopf algebra over $\mathbb{C}$ which is a $*$-algebra, and an invertible element $\mathscr{S}\in\mathscr{H}\otimes\mathscr{H}$ such that

$$(*\otimes*)\circ\Delta\circ*=\mathscr{S}^{-1}(\tau\circ\Delta\ )\mathscr{S},\ \ (\Delta\otimes\mathrm{id})\mathscr{S}=\mathscr{S}_{13}\mathscr{S}_{23},\ \ (\mathrm{id}\otimes\Delta)\mathscr{S}=\mathscr{S}_{13}\mathscr{S}_{12},\ \ \mathscr{S}^{*\otimes*}=\mathscr{S}_{21}, \tag{7}$$

where τ denotes transposition. One can show that $\mathscr{S}$ obeys the quantum Yang–Baxter equations or QYBE (but we do not denote it here by $\mathscr{R}$, to avoid confusion with the quasitriangular structure also present). To have such a structure in our R-matrix setting we suppose that the R-matrix in the preceding section is of one of the two real types in Ref. 16. We also suppose a quantum metric η compatible with $\mathbf{R}$ (see Ref. 1) and of corresponding reality type:

$$\overline{\mathbf{R}^{i\ k}_{\ j\ l}}=\begin{cases}\mathbf{R}^{l\ j}_{\ k\ i} & \text{Real Type I,}\\ \mathbf{R}^{j\ \bar{i}}_{\ l\ \bar{k}} & \text{Real Type II,}\end{cases}\qquad \overline{\eta_{ij}}=\begin{cases}\eta^{ji} & \text{Real Type I,}\\ \eta_{\bar{j}\,\bar{i}} & \text{Real Type II,}\end{cases} \tag{8}$$

where η^{ij} is the transposed inverse of η_{ij} and $\bar{i}$ is an involution on the indices assumed in the type II case. We assume $\lambda^*=\lambda$ as well. These reality conditions hold for the standard choices of $\mathbf{R}$, when their parameter q is real.

The extended q-Poincaré algebra has the quasi-$*$-structure[10]

$$p^{i*}=\begin{cases}\eta_{i\bar{a}}p^a & \text{Real Type I,}\\ p^{\bar{i}} & \text{Real Type II,}\end{cases}\qquad l^{\pm i}{}_j{}^*=\begin{cases}\eta_{ib}l^{\mp b}{}_a\eta^{ja} & \text{Real Type I,}\\ l^{\mp\bar{i}}{}_{\bar{j}} & \text{Real Type II,}\end{cases}$$

$$\varsigma^*=\varsigma^{-1},\quad \mathscr{S}=\mathscr{R}_L\lambda^{-\xi\otimes\xi}, \tag{9}$$

where $\mathscr{R}_L\lambda^{-\xi\otimes\xi}$ is the dilaton-extended q-Lorentz quasitriangular structure and $\varsigma=\lambda^{\xi}$. Note that the real type II case used in Ref. 10 was chosen such that on the Lorentz generators in function-algebra form it appears as $t^i{}_j{}^*=t^{\bar{i}}{}_{\bar{j}}$, which corresponds to $l^{\pm i}{}_j{}^*=S^2l^{\mp\bar{i}}{}_{\bar{j}}$. We can equivalently put the S^2 automorphism on the function algebra side as $t^i{}_j{}^*=S^2t^{\bar{i}}{}_{\bar{j}}$, as we prefer now.

Proposition 3.1: The quasi-∗ structure (9) extends to one on the q-conformal algebra in Proposition 2.1, with

$$c_i{}^* = \begin{cases} c_a \eta^{ia}, & \text{Real Type I,} \\ c_{\bar{i}}, & \text{Real Type II.} \end{cases}$$

Moreover,

$$(*\otimes *)\circ\Delta\circ * = \exp(\mathbf{c}|\mathbf{p})^{-1}(\Delta\ )\exp(\mathbf{c}|\mathbf{p})$$

holds for the coproduct on any element of the q-conformal algebra.

Proof: The proof of compatibility of this ∗ with the $\mathbf{c},\mathbf{l}^{\pm}$ relations is similar to that for $\mathbf{p},\mathbf{l}^{\pm}$. Explicitly, in the type I case,

$$\begin{aligned}(\lambda c_b l^{+i}{}_a \mathbf{R}^b{}_k{}^a{}_j)^* &= \lambda \mathbf{R}^j{}_a{}^k{}_b \eta^{bd}\eta_{ic} l^{-c}{}_e \eta^{ae} c_d = \lambda \mathbf{R}^j{}_a{}^k{}_b \eta^{bd}\eta_{ic}\eta^{ae}\lambda^{-1} c_g l^{-c}{}_f \mathbf{R}^{-1 f}{}_e{}^g{}_d \\ &= c_a \eta^{ka}\eta_{ic} l^{-c}{}_d \eta^{jd} = (l^{+i}{}_j c_k)^*,\end{aligned}$$

using invariance of R under conjugation by $\eta\otimes\eta$. In addition, we have

$$[p^i,\ c_j]^* = [c_j{}^*,\ p^{i*}] = [c_a \eta^{ja}, p^b \eta_{ib}] = -\eta^{ja}\eta_{ib}\left(\frac{l^{+b}{}_a \mathfrak{s}^{-1} - l^{-b}{}_a \mathfrak{s}}{q-q^{-1}}\right) = \left(\frac{l^{+i}{}_j \mathfrak{s}^{-1} - l^{-i}{}_j \mathfrak{s}}{q-q^{-1}}\right)^*,$$

as required. Hence we have a ∗-algebra in this case. In the type II case, the calculation is

$$(\lambda c_b l^{+i}{}_a \mathbf{R}^b{}_k{}^a{}_j)^* = \lambda l^{-\bar{i}}{}_{\bar{a}} c_{\bar{b}} \mathbf{R}^{\bar{a}}{}_j{}^{\bar{b}}{}_{\bar{k}} = c_{\bar{k}} l^{-\bar{i}}{}_{\bar{j}} = (l^{+i}{}_j c_k)^*,$$

$$[p^i,\ c_j]^* = [c_{\bar{j}},\ p^{\bar{i}}] = -\left(\frac{l^{+\bar{i}}{}_{\bar{j}} \mathfrak{s}^{-1} - l^{-\bar{i}}{}_{\bar{j}} \mathfrak{s}}{q-q^{-1}}\right) = \left(\frac{l^{+i}{}_j \mathfrak{s}^{-1} - l^{-i}{}_j \mathfrak{s}}{q-q^{-1}}\right)^*.$$

In either case, the sub-Hopf algebra generated by $\mathfrak{s},\mathbf{c},\mathbf{l}^{\pm}$ forms a quasi-∗ Hopf algebra with the same cocycle $\mathcal{J} = \mathcal{R}_L \lambda^{-\xi\otimes\xi}$, by analogous arguments to the proof for the extended q-Poincaré algebra in Ref. 10. Combining (7) with Proposition 2.2 gives the form of $(*\otimes *)\circ\Delta\circ *$ stated. □

Although the q-conformal algebra with the above ∗-operation is not a Hopf ∗-algebra in the usual sense, we see that Δ fails to be a ∗-algebra map only up to conjugation by the plane wave $\exp(\mathbf{c}|\mathbf{p})$. More precisely, to every quasi-∗ Hopf algebra the conjugate coproduct $\Delta = (*\otimes *)\circ\Delta\circ *$ also provides a quasi-∗ Hopf algebra structure, in general different from Δ. In our case, this comes out as

$$\overline{\Delta\mathbf{c}} = \mathbf{c}\otimes\mathbf{l}^{-}\mathfrak{s} + 1\otimes\mathbf{c} \tag{10}$$

for either the real type I or type II ∗-structures above (similarly for $\overline{\Delta\mathbf{p}}$ in Ref. 10); Proposition 3.1 tells us that this Δ and the coproduct Δ in Proposition 2.1 are conjugate by $\exp(\mathbf{c}|\mathbf{p})$.

IV. SPINORIAL FORMULATION

An important class of examples of our data $\mathbf{R}',\mathbf{R}$ is provided by a ''spinorial'' construction starting from a smaller Yang–Baxter matrix $R\in M_s\otimes M_s$, where $n=s^2$. We require this to be q-Hecke in the sense $(PR-q)(PR+q^{-1})=0$, where P is the permutation matrix. The extended q-Poincaré algebra in this setting has been given in Ref. 10, while the momentum sector or q-space–time itself is from Refs. 4, 5, and 17 and reviewed in Ref. 1 or 11, Ch. 10. We include now the q-conformal algebra in this spinorial approach. In fact, the construction has two versions which are strictly ''gauge equivalent'' in a certain algebraic sense. These are the ''Euclidean'' and ''Minkowski'' gauges of the same construction, introduced in Ref. 17 and 4 and 5, respectively.

The Euclidean gauge construction is[17]

$$\mathbf{R}'^{i}{}_{j}{}^{k}{}_{l}=R^{-1}{}^{l_0}{}_{k_0}{}^{j_0}{}_{i_0}R^{i_1}{}_{j_1}{}^{k_1}{}_{l_1},\quad \mathbf{R}^{i}{}_{j}{}^{k}{}_{l}=R^{j_0}{}_{i_0}{}^{l_0}{}_{k_0}R^{i_1}{}_{j_1}{}^{k_1}{}_{l_1} \tag{11}$$

and is equivalent for R the standard su_2 R-matrix to taking for $\mathbf{R}$ the standard so_4 R-matrix. Of course, the construction is more general and can be used just as well to define nonstandard space–times by taking other nonstandard R. We write $i=i_0i_1$, $j=j_0j_1$, etc., as multi-indices.

We also write $p^i = p^{i_1}{}_{i_0}$. Then the relations (1) in the momentum sector (which will also be the relations of q-space–time) become[17]

$$R_{21}\mathbf{p}_1\mathbf{p}_2=\mathbf{p}_2\mathbf{p}_1R. \tag{12}$$

More nontrivially, we replace the vectorial q-Lorentz algebra generated by $l^{\pm i}{}_j$ by a spinorial version generated by two sets of generators $l^{\pm i_0}{}_{j_0}$ and $m^{\pm i_1}{}_{j_1}$ obeying relations like (2) with respect to R. For R the su_2 R-matrix, the momentum and space–time sectors are isomorphic to the quantum matrices $M_q(2)$, and the Lorentz/rotation sector is $U_q(su_2)\otimes U_q(su_2)$. The natural $*$-structure in this gauge is the unitary type one which corresponds to $SU_q(2)$ as a q-deformed three-sphere in $M_q(2)$. The dilation sector is generated by ς as before, commuting with $\mathbf{l}^{\pm},\mathbf{m}^{\pm}$. The cross-relations between these various sectors and the coproducts are obtained in Ref. 10. In the present (slightly different) conventions they come out as

$$\mathbf{p}_1\mathbf{l}_2^{+}=\lambda^{-1/2}R^{-1}\mathbf{l}_2^{+}\mathbf{p}_1,\quad \mathbf{p}_1\mathbf{l}_2^{-}=\lambda^{1/2}R_{21}\mathbf{l}_2^{+}\mathbf{p}_1,\quad \mathbf{p}_1\mathbf{m}_2^{+}=\lambda^{1/2}R\mathbf{m}_2^{+}\mathbf{p}_1,\quad \mathbf{p}_1\mathbf{m}_2^{-}=\lambda^{-1/2}R_{21}^{-1}\mathbf{m}_2^{-}\mathbf{p}_1,$$

$$\varsigma\mathbf{p}=\lambda^{-1}\mathbf{p}\varsigma,\quad \Delta\mathbf{p}=\mathbf{p}\otimes 1+\varsigma S^{-1}(S\mathbf{m}^{-}(\ )\mathbf{l}^{-})\otimes\mathbf{p},\quad \epsilon(\mathbf{p})=0, \tag{13}$$

where the space is for the matrix indices of $\mathbf{p}$ to be inserted.

To this spinorial extended q-Poincaré algebra, we add the special conformal transformations $c_i = c^{i_0}{}_{i_1}$. Note that the assignment is transposed relative to the assignment for p^i.

Proposition 4.1: In the Euclidean gauge, the spinorial extended q-Poincaré algebra in Ref. 10 *has a further extension by a matrix of generators* $\mathbf{c}$ *obeying*

$$R\mathbf{c}_1\mathbf{c}_2=\mathbf{c}_2\mathbf{c}_1R_{21},\quad \mathbf{l}_1^{+}\mathbf{c}_2=\lambda^{-1/2}\mathbf{c}_2\mathbf{l}_1^{+}R^{-1},\quad \mathbf{l}_1^{-}\mathbf{c}_2=\lambda^{1/2}\mathbf{c}_2\mathbf{l}_1^{-}R_{21},$$

$$\mathbf{m}_1^{+}\mathbf{c}_2=\lambda^{1/2}\mathbf{c}_2\mathbf{m}_1^{+}R,\quad \mathbf{m}_1^{-}\mathbf{c}_2=\lambda^{-1/2}\mathbf{c}_2\mathbf{m}_1^{-}R_{21}^{-1},\quad \varsigma\mathbf{c}=\lambda\mathbf{c}\varsigma,$$

$$[p^{i_1}{}_{i_0},\, c^{j_0}{}_{j_1}]=\frac{\varsigma^{-1}(S^{-1}l^{+j_0}{}_{i_0})m^{+i_1}{}_{j_1}-\varsigma(S^{-1}l^{-j_0}{}_{i_0})m^{-i_1}{}_{j_1}}{q-q^{-1}},$$

$$\Delta\mathbf{c}=\mathbf{c}\otimes\varsigma^{-1}(S^{-1}\mathbf{l}^{+})(\ )\mathbf{m}^{+}+1\otimes\mathbf{c},\quad \epsilon(\mathbf{c})=0,$$

and forming a quasitriangular Hopf algebra. This is the spinorial q-conformal algebra in the Euclidean gauge.

Proof: The $\mathbf{c}$, $\mathbf{l}^{\pm}$, $\mathbf{m}^{\pm}$, ς relations are obtained along the same lines as in Ref. 10 via double-bosonization. They are consistent with Proposition 2.1 using (11) and the ansatz $l^{\pm i}{}_j = (S^{-1}l^{\pm j_0}{}_{i_0})m^{\pm i_1}{}_{j_1}$. The $\mathbf{c}$, $\mathbf{p}$ relations and the coproduct follow at once from this form of $l^{\pm i}{}_j$. We note that if we use the (slightly different) identification $\eta_{ia}p^a = p^{i_0}{}_{i_1}$ used in Ref. 10, and the expression $\eta_{ij} = \epsilon^{i_0j_0}\epsilon_{i_1j_1}$ in terms of the spinor metric associated to R, then the $[p^i,c_j]$ relations come out as

$$[p^{i_0}{}_{i_1},c^{j_0}{}_{j_1}]=\frac{\varsigma^{-1}l^{+i_0}{}_{a_0}\epsilon^{a_0j_0}\epsilon_{a_1i_1}m^{+a_1}{}_{j_1}-\varsigma l^{-i_0}{}_{a_0}\epsilon^{a_0j_0}\epsilon_{a_1i_1}m^{-a_1}{}_{j_1}}{q-q^{-1}}. \tag{14}$$

The spinor metric also converts the $*$-structure in Sec. III into a matrix form. □

The Minkowski gauge for the same construction is[4,5]

$$\mathbf{R}'^{i}{}_{j}{}^{k}{}_{l}=R^{-1}{}^{d}{}_{k_0}{}^{j_0}{}_{a}R^{k_1}{}_{b}{}^{a}{}_{i_0}R^{i_1}{}_{c}{}^{b}{}_{l_1}\widetilde{R}^{c}{}_{j_1}{}^{l_0}{}_{d},\quad \mathbf{R}^{i}{}_{j}{}^{k}{}_{l}=R^{j_0}{}_{a}{}^{d}{}_{k_0}R^{k_1}{}_{b}{}^{a}{}_{i_0}R^{i_1}{}_{c}{}^{b}{}_{l_1}\widetilde{R}^{c}{}_{j_1}{}^{l_0}{}_{d}. \tag{15}$$

The momentum or space–time sector in this case has the braided matrix relations[4]

$$R_{21}\mathbf{p}_1R\mathbf{p}_2=\mathbf{p}_2R_{21}\mathbf{p}_1R, \tag{16}$$

where $\eta_{ia}p^a = p^{i_0}{}_{i_1}$, and yields the braided matrices $BM_q(2)$ for the standard su_2 R-matrix. The natural space–time $*$-structure in this case is a Hermitian one, justifying the name for this gauge. [The unit sphere here is actually isomorphic to $U_q(su_2)$ as a $*$-algebra when $q\neq 1$.] The Lorentz sector in this standard case is $U_q(su_2)\blacktriangleright\!\!\blacktriangleleft U_q(su_2)$ (with a more complicated coproduct than in the Euclidean gauge).

The Euclidean gauge for q-space–time was introduced in Ref. 17 precisely as gauge equivalent to the Minkowski gauge (which was found first). At the Lorentz algebra level the gauges are related by twisting by a quantum cocycle (see Ref. 2, Sec. 4, in a dual form). This was extended to the level of the extended q-Poincaré algebra in Ref. 10, using the same cocycle viewed in the bigger algebra. The cocycle is $\chi=\mathscr{R}_{23}^{-1}$ where $\mathscr{R}$ is the quasitriangular structure of $U_q(su_2)$ in the standard example.

Proposition 4.2: The same quantum cocycle χ viewed in the spinorial form of the q-conformal algebra twists its structure from the Euclidean to the Minkowski gauge.

Proof: This is true for the sub-Hopf algebra generated by $\mathbf{c},\mathbf{l}^{\pm},\varsigma$ by analogous arguments to those for the extended q-Poincaré algebra. Since the coproduct is entirely defined by its restriction to either of these two sub-Hopf algebras, we conclude the same twisting result for the entire q-conformal algebra. □

In view of this, we will not give the structure in detail in the Minkowski gauge: the structure of the spinorial form of the extended q-Poincaré algebra is given in Ref. 10. To this, we add the special conformal transformations in the form $R_{21}\mathbf{c}_1R\mathbf{c}_2=\mathbf{c}_2R_{21}\mathbf{c}_1R$, where $c_i = c^{i_1}{}_{i_0}$ and $\overline{R^{i}{}_{j}{}^{k}{}_{l}}=R^{l}{}_{k}{}^{j}{}_{i}$. The cross relations with $\mathbf{l}^{\pm}$ are similar to those between $\mathbf{p}$ and $\mathbf{l}^{\pm}$ in Ref. 10.

V. CONFORMAL TRANSFORMATIONS OF SPACE–TIME

So far, we have called our quasitriangular Hopf algebra $C(\mathbf{R}',\mathbf{R})$ the q-conformal one because of its structural form, which is analogous to that of the conformal Lie algebra. We are now ready to justify the terminology in geometrical terms, i.e., by its action on q-space–time. For the latter, we take the linear braided group $V^{\check{}}(\mathbf{R}',\mathbf{R})$ with generators x_i and relations and braid statistics

$$\mathbf{x}_1\mathbf{x}_2=\mathbf{x}_2\mathbf{x}_1\mathbf{R}',\quad \mathbf{x}_1'\mathbf{x}_2=\mathbf{x}_2\mathbf{x}_1'\mathbf{R}. \tag{17}$$

There is a linear coproduct $\underline{\Delta}\mathbf{x}=\mathbf{x}+\mathbf{x}'$ and a $*$-structure

$$x_i^*=\begin{cases} x_a\eta^{ia}, & \text{Real Type I,}\\ x_{\bar{i}}, & \text{Real Type II,}\end{cases}$$

which we take of the same form as for $\mathbf{c}$ in Sec. III.

From the theory of braided groups, it is known[2] that the extended q-Poincaré algebra acts covariantly on q-space–time by q-rotations (via the fundamental representation defined by $\mathbf{R}$) and braided-differentiation for the momentum sector[2,10]

$$\mathbf{l}_1^{+}\triangleright\mathbf{x}_2=\mathbf{x}_2\lambda\mathbf{R}_{21},\quad \mathbf{l}_1^{-}\triangleright\mathbf{x}_2=\mathbf{x}_2\lambda^{-1}\mathbf{R}^{-1},\quad p^i\triangleright x_j=-\delta^i{}_j,\quad \varsigma\triangleright x_i=\lambda x_i. \tag{18}$$

To this, we add the following.

Proposition 5.1: The q-conformal algebra in Proposition 2.1 acts covariantly on q-space–time by (18) and

$$\mathbf{c}_2 \triangleright \mathbf{x}_1 = \frac{\mathbf{x}_1\mathbf{x}_2 - \mathbf{x}_2\mathbf{x}_1\mathbf{R}}{q-q^{-1}}.$$

Proof: This follows from general theory in Ref. 9; the required action of $\mathbf{c}$ is derived in the Appendix. The direct proof that the $\mathbf{c}$, $\mathbf{l}^{\pm}$, ς relations are represented is similar to that for $\mathbf{p}$, $\mathbf{l}^{\pm}$, ς. For the $\mathbf{p}$, $\mathbf{c}$ relations we can check it easily at lowest order, as $(q-q^{-1})[p^i,c_j]\triangleright x_k = p^i\triangleright(x_k x_j - x_b x_a \mathbf{R}^a{}_k{}^b{}_j) + c_j \triangleright \delta^i{}_k = -\delta^i{}_k x_j - x_a \mathbf{R}^{-1}{}^i{}_j{}^a{}_k + \delta^i{}_b x_a \mathbf{R}^a{}_k{}^b{}_j + x_c \mathbf{R}^{-1}{}^i{}_a{}^c{}_b \mathbf{R}^a{}_k{}^b{}_j = (\varsigma^{-1} l^{+i}{}_j - \varsigma l^{-i}{}_j)\triangleright x_k$, where the outer two terms cancelled. We used the action of p^i on products $x_j x_k$ via the braided-Leibniz rule with R_{21}^{-1}.[10] One can proceed similarly for the higher order case, using the action of c_i on products obtained below. □

Note that both the action of p^i and c_i extend to products via a braided-Leibniz rule because they originate as braided module algebra structures (this is equivalent to the statement that the actions form a module-algebra structure with respect to the Hopf algebra coproducts.) In the case of p^i, the action on a general monomial comes out in terms of the braided-integer matrices with respect to $\mathbf{R}_{21}^{-1}$ (see Ref. 10). For the c_i we have:

Lemma 5.2: The action of c_i on a general product is

$$\mathbf{c}_n \triangleright \mathbf{x}_1\mathbf{x}_2\cdots\mathbf{x}_{n-1} = \mathbf{x}_1\mathbf{x}_2\cdots\mathbf{x}_n\left(\frac{1-(P\mathbf{R})_{12}(P\mathbf{R})_{23}\cdots(P\mathbf{R})_{n-1n}}{q-q^{-1}}\right),$$

where P is the permutation matrix.

Proof: We first compute the braided-Leibniz rule for c_i. As explained in the Appendix, its natural form is as a right-handed (braided) derivation $c_i\triangleright = \delta_i$ acting from the right. Then

$$(ab)\,\delta_i = a(b\,\delta_i) + a\Psi(b\otimes\delta_i),$$

where the braiding is the braiding for the covector braided group $V^{\vee}(\mathbf{R}',\mathbf{R})$, i.e., defined by $\mathbf{R}$. Hence

$$(\mathbf{x}_1\cdots\mathbf{x}_{n-1})\,\delta_n = \mathbf{x}_1\cdots\mathbf{x}_n\left(\frac{1-(P\mathbf{R})_{n-1n}}{q-q^{-1}}\right) + (\mathbf{x}_1\cdots\mathbf{x}_{n-2})\,\delta_{n-1}\mathbf{x}_n(P\mathbf{R})_{n-1n}.$$

The result then follows by induction. □

Another way to describe the action is in terms of the algebra structure of the corresponding semidirect product of space–time crossed by the q-conformal group. The cross relations between the extended q-Poincaré algebra and space–time is[10]

$$\mathbf{l}_1^+\mathbf{x}_2 = \mathbf{x}_2\lambda\mathbf{R}_{21}\mathbf{l}_1^+, \quad \mathbf{l}_1^-\mathbf{x}_2 = \mathbf{x}_2\lambda^{-1}\mathbf{R}^{-1}\mathbf{l}_1^-, \quad \mathbf{x}_2\mathbf{R}^{-1}\mathbf{p}_1 - \mathbf{p}_1\mathbf{x}_2 = \mathrm{id}, \quad \varsigma\mathbf{x} = \lambda\mathbf{x}\varsigma. \tag{19}$$

The $\mathbf{x},\mathbf{p}$ relations are the ''braided Heisenberg algebra'' in the present conventions. To this we now add the following.

Proposition 5.3: The q-conformal group acting as above and $\mathbf{x}$ acting by left multiplication on q-space–time form a representation of the algebra $V^{\vee}(\mathbf{R}',\mathbf{R})\bowtie C(\mathbf{R}',\mathbf{R})$ with the additional $\mathbf{c},\mathbf{x}$ cross relations

$$\left[\mathbf{c}_1 + \frac{\mathbf{x}_1\mathbf{l}_1^+\varsigma^{-1}}{q-q^{-1}}, \mathbf{x}_2\right] = 0.$$

Proof: We make a left-handed semidirect product using the coproduct in Proposition 2.1, the action of c_i above, and the already-known cross-relations (19). Thus

$$c_i x_j = (c_{i(1)} \triangleright x_j) c_{i(2)} = (c_a \triangleright x_j) \mathbf{l}^{+a}{}_i \mathbf{s}^{-1} + x_j c_i = \frac{x_j x_a - x_d x_c R^{c}{}_{j}{}^{d}{}_{a}}{q - q^{-1}} \, l^{+a}{}_i \mathbf{s}^{-1} + x_j c_i$$

$$= \frac{x_j x_a l^{+a}{}_i \mathbf{s}^{-1} - x_a l^{+a}{}_i \mathbf{s}^{-1} x_j}{q - q^{-1}} + x_j c_i ,$$

as stated. Because the action in Proposition 5.1 is covariant (q-space–time forms a module algebra under it), we know from the general theory of Hopf algebra cross products that these relations define an associative algebra structure on the tensor product vector space, and that the action on q-space–time extends to it with x_i acting by left-multiplication. □

We can also use the spinorial form of the q-conformal algebra. The action of the spinorial form of the extended q-Poincaré algebra is given in Ref. 10. To this, we add the following.

Proposition 5.4: The spinorial form of the q-conformal algebra in the Euclidean gauge acts as in Ref. 10 and

$$\mathbf{c}_2 \triangleright \mathbf{x}_1 = -\mathbf{x}_1 \mathbf{x}_2 P R.$$

Proof: We use the form of $\mathbf{R}$ in (11) in Proposition 5.1 and $R = R_{21}^{-1} + (q - q^{-1})P$ from the q-Hecke assumption in Sec. IV. Thus

$$(q - q^{-1}) c_j \triangleright x_i = x_i x_j - x_b x_a \mathbf{R}^{a}{}_{i}{}^{b}{}_{j} = x^{i_0}{}_{i_1} x^{j_0}{}_{j_1} - x^{b_0}{}_{b_1} x^{a_0}{}_{a_1} R^{-1 i_0}{}_{a_0}{}^{j_0}{}_{b_0} R^{a_1}{}_{i_1}{}^{b_1}{}_{j_1}$$

$$- (q - q)^{-1} x^{b_0}{}_{b_1} x^{a_0}{}_{a_1} \delta^{i_0}_{b_0} \delta^{j_0}_{a_0} R^{a_1}{}_{i_1}{}^{b_1}{}_{j_1}.$$

The first two terms then give zero due to the form of $\mathbf{R}'$ in (11) and the relations for the x_i. □

We are now in position to compute this action for our standard q-space–time.[1] The classical formula $c_j \triangleright x_i = \frac{1}{2} \eta_{ij} \mathbf{x} \cdot \mathbf{x} - x_i x_j$ would be

$$\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \triangleright \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} -a^2 & -ba & -ac & -bc \\ -ab & -b^2 & -ad & -bd \\ -ca & -da & -c^2 & -dc \\ -cb & -db & -cd & -d^2 \end{pmatrix}, \tag{20}$$

where

$$c = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}, \quad \mathbf{x} = \begin{pmatrix} a & b \\ c & d \end{pmatrix}, \text{ and } \quad \eta = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \\ 0 & -1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}$$

is the metric on complexified space–time in these spinor coordinates (different linear combinations are considered real space–time coordinates in the Minkowski and Euclidean cases).

Example 5.5: For the standard q-space–time in the Euclidean gauge, we have

$$\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \triangleright \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} -a^2 & -q^2 ab & -ca & -bc \\ -ba & -b^2 & -da & -db \\ -ac & -ad - (q - q^{-1}) bc & -c^2 & -qdc \\ -bc & -bd & -dc & -d^2 \end{pmatrix}.$$

This is a q-deformation of the usual action of the special conformal transformations on space–time.

Proof: This is computed easily from Proposition 5.4 with

$$R=\begin{pmatrix} q & 0 & 0 & 0 \\ 0 & 1 & q-q^{-1} & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & q \end{pmatrix},$$

which is the standard su_2 R-matrix in the q-Hecke normalization. The relations between the noncommutative spinor space–time coordinates in this case are given explicitly in Ref. 17. The quantum group normalization of the corresponding $\mathbf{R}$ is $\lambda=q^{-1}$. □

This justifies our proposal for $C(\mathbf{R}',\mathbf{R})$ as q-conformal group. Note that the metric does not play any direct role in our definition of the q-conformal group and its action on spacetime, i.e., our approach is a novel one even when $q=1$. It is remarkable therefore that it coincides for our standard example with the action (20) defined through a metric. The connection is quite general, however.

Lemma 5.6: If η is a quantum metric such that $\mathbf{x}\cdot\mathbf{x}=x_a x_b \eta^{ba}$ is central, then it is preserved by the q-conformal group up to scaling, in the sense

$$c_i\triangleright(\mathbf{x}\cdot\mathbf{x})^m=\left(\frac{1-\lambda^{-2m}}{q-q^{-1}}\right)x_i(\mathbf{x}\cdot\mathbf{x})^m,\quad \text{i.e.,}\quad c_i\triangleright f(\mathbf{x}\cdot\mathbf{x})=\left(\frac{1-\lambda^{-2}}{q-q^{-1}}\right)x_i\mathbf{x}\cdot\mathbf{x}(\partial_{\lambda^{-2}}f\,)(\mathbf{x}\cdot\mathbf{x}).$$

Proof: We compute $(q-q^{-1})c_i\triangleright(x_q x_b\eta^{ba})=x_a x_b x_i\eta^{ba}-x_c x_d x_e\mathbf{R}^{d}{}_{a}{}^{c}{}_{f}\mathbf{R}^{e}{}_{b}{}^{f}{}_{i}\eta^{ba}$ $=x_a x_b x_i\eta^{ba}-x_c x_d x_e\mathbf{R}^{d}{}_{a}{}^{c}{}_{f}\eta^{eb}\lambda^{-2}\mathbf{R}^{-1a}{}_{b}{}^{f}{}_{i}=\mathbf{x}\cdot\mathbf{x}x_i-\lambda^{-2}x_i\mathbf{x}\cdot\mathbf{x}$, using the covariance properties of the quantum metric. Under a further condition on the quantum metric (true in the main examples, see Ref. 1) one knows that $\mathbf{x}\cdot\mathbf{x}$ is also central. This gives the result for $m=1$. From the covariance properties of the quantum metric, we likewise compute the braiding $\mathbf{x}'\cdot\mathbf{x}'x_i=x'_a x'_b x_i\eta^{ba}$ $=x'_a x_d x'_c R^{c}{}_{b}{}^{d}{}_{i}\eta^{ba}=x'_a x_d x'_c\lambda^{-2}R^{-1a}{}_{b}{}^{d}{}_{i}\eta^{cb}=x_f x'_e x'_c R^{e}{}_{a}{}^{f}{}_{d}\lambda^{-2}R^{-1a}{}_{b}{}^{d}{}_{i}\eta^{cb}=\lambda^{-2}x_i\mathbf{x}'\cdot\mathbf{x}'$, i.e., $\Psi(\mathbf{x}\cdot\mathbf{x}\otimes x_i)=\lambda^{-2}\mathbf{x}_i\otimes\mathbf{x}\cdot\mathbf{x}$. The q-Leibniz rule for the action of c_i then implies $c_i\triangleright(\mathbf{x}\cdot\mathbf{x})^m=(\mathbf{x}\cdot\mathbf{x})^{m-1}x_i((1-\lambda^{-2})/(q-q^{-1}))\mathbf{x}\cdot\mathbf{x}+(c_i\triangleright(\mathbf{x}\cdot\mathbf{x})^{m-1})\mathbf{x}\cdot\mathbf{x}\lambda^{-2}$, which provides the general result by induction. We alternatively write this in terms of a λ^{-2}-deformed derivative defined in a usual way. □

Thus, our q-conformal group and its action do not *a priori* involve a metric, but when there is one, it is preserved in some sense. Instead, the structures and formulas which we normally associate with preservation up to scale of a metric are obtained from the braided adjoint action. For example, we see that the standard q-Gaussian g_η in the setting of Lemma 5.6, which is a λ^{-2}-exponential of $\mathbf{x}\cdot\mathbf{x}$, is preserved in the sense

$$c_i\triangleright g_\eta=-q^{-1}\left(\frac{1-\lambda^{-2}}{1-q^{-4}}\right)x_i(\mathbf{x}\cdot\mathbf{x})g_\eta,$$

in addition to its usual properties under the extended q-Poincaré algebra.

Finally, when a quasi-$*$ Hopf algebra acts covariantly on a $*$-algebra, its conjugate quasi-$*$ Hopf algebra acts with a conjugate action.[10] In the case of the extended q-Poincaré algebra it was shown that the action of $\mathbf{1}^{\pm},\varsigma$ on q-space–time is self-conjugate, while the conjugate action of the $\mathbf{p}$ generators is by braided-differentiation with $\mathbf{R}_{21}^{-1}$ replaced by $\mathbf{R}$.

Proposition 5.7: The conjugate action of the q-conformal algebra on q-space–time is

$$\mathbf{c}_2\overline{\triangleright}\mathbf{x}_1=\frac{\mathbf{x}_1\mathbf{x}_2-\mathbf{x}_2\mathbf{x}_1\mathbf{R}_{21}^{-1}}{q-q^{-1}}.$$

Moreover, $c_i \underline{\triangleright} \underline{S}(\ ) = \underline{S}(c_i \overline{\underline{\triangleright}}(\ ))$*, where* $\underline{S}$ *is the braided antipode or parity operator on q-space–time.*

Proof: The abstract treatment for the conjugate action of the special conformal generators is in the Appendix, from which one may compute the explicit form stated. In our R-matrix setting, a direct proof is as follows, using the $*$-structures in Sec. III for either the real type I or type II cases. In the type I case,

$$c_i \overline{\underline{\triangleright}} x_j = (Sc_a \eta^{ia} \underline{\triangleright} x_b \eta^{jb})^* = -(\eta^{ia} c_d \underline{\varsigma} Sl^{+d}{}_a \underline{\triangleright} x_b \eta^{jb})^* = -(\eta^{ia} c_d \underline{\triangleright} x_e R^{-1e}{}_b{}^d{}_a \eta^{jb})^*$$
$$= \left(\left(\frac{-x_e x_d + x_f x_g R^{g}{}_e{}^f{}_d}{q - q^{-1}} \right) \eta^{ia} R^{-1e}{}_b{}^d{}_a \eta^{jb} \right)^* = \frac{x_j x_i - x_a x_b R^{-1a}{}_i{}^b{}_j}{q - q^{-1}}$$

using the usual covariance properties of the quantum metric. In the type II case,

$$c_i \overline{\underline{\triangleright}} x_j = (Sc_i \underline{\triangleright} x_j)^* = -(c_a \underline{\varsigma} Sl^{+a}{}_i \underline{\triangleright} x_j)^* = -(c_a \underline{\triangleright} x_b R^{-1b}{}_j{}^a{}_i)^*$$
$$= \left(\left(\frac{-x_b x_a + x_d x_c R^{c}{}_b{}^d{}_a}{q - q^{-1}} \right) R^{-1b}{}_j{}^a{}_i \right)^*$$

which likewise computes to the stated formula.

For the result that the action and conjugate action are intertwined by $\underline{S}$, we have on the generators $\underline{S}(\mathbf{c}_2 \overline{\underline{\triangleright}} \mathbf{x}_1) = (q - q^{-1})^{-1} \underline{S}(\mathbf{x}_1 \mathbf{x}_2 - \mathbf{x}_2 \mathbf{x}_1 \mathbf{R}_{21}^{-1}) = (q - q^{-1})^{-1}((-\mathbf{x}_2)(-\mathbf{x}_1)\mathbf{R} - (-\mathbf{x}_1)(\mathbf{x}_2))$ $= \mathbf{c}_2 \underline{\triangleright} (-\mathbf{x}_1)$ using the braided-antimultiplicativity of the braided antipode $\underline{S}(\mathbf{x}) = -\mathbf{x}$. □

The same applies to the action on products of q-space–time generators: we use $\mathbf{R}_{21}^{-1}$ in place of $\mathbf{R}$ in Lemma 5.2. Thus the q-conformal group exhibits the same novel phenomenon demonstrated for the extended q-Poincaré algebra in Ref. 10 whereby $*$-conjugation is implemented in braided geometry by reversal of braid crossings. The equivalence of the action and conjugate action via the braided-parity operator also applies to all orders of products of q-space–time generators. This is the sense within braided geometry in which the operators c_i are ''anti-Hermitian.'' This also holds for the momentum p^i generators as the main result in Ref. 10.

The present work suggests the possibility of a systematic theory of massless spinning particles based on invariance under the q-conformal group. This will be attempted elsewhere. Classically, it requires the construction of fields with conformal weights defined as sections of certain vector bundles over compactified spacetime. In the q-deformed case one needs therefore nontrivial quantum homogeneous spaces and their associated bundles, for example along the lines in Ref. 18.

APPENDIX: ABSTRACT RESULTS

Most of the formulas for the q-conformal group in the text above have been given at the level of R-matrices and matrix relations. In principle, one also has to check a large number of nonquadratic relations, in particular associated with the $\mathbf{l}^{\pm}$ generators (they are not independent). These are needed to form a (quasitriangular) Hopf algebra in the Lorentz sector. Fortunately, such details are ensured by the abstract braided group and quantum group constructions underlying the R-matrix formulas. This is given for the extended q-Poincaré algebra in Ref. 10 and we extend this now for the q-conformal case. The basis for the latter is a recent construction[9] which associates to a braided group B in the category of H-modules (H is a quasitriangular Hopf algebra), a new quasitriangular Hopf algebra built from B, H, B^*, called the *double-bosonization* of B. Here we state without proof the relevant left-module version of the double-bosonization formulas (different right-module conventions are used in Ref. 9, for the purposes there). Then we study $*$-structures in this abstract setting, which is the new result of this Appendix.

Familiarity with abstract quantum group[11] and braided group[12] techniques is assumed. In particular, $\Delta h = h_{(1)} \otimes h_{(2)}$ denotes the coproduct of $h \in H$ and $\underline{\Delta} b = \underline{b_{(1)}} \otimes \underline{b_{(2)}}$ the braided coproduct of $b \in B$. Also, $\mathscr{R} = \mathscr{R}^{(1)} \otimes \mathscr{R}^{(2)}$ denotes the quasitriangular structure of $\overline{H}$, and $v = \mathscr{R}^{(1)} S \mathscr{R}^{(2)}$.

Let B be a braided group with invertible braided antipode in the braided category of left H-modules, dual to another braided group C. So $B = C^\star$. (In the infinite-dimensional case, we suppose a duality pairing ev: $B \otimes C \to k$ of braided groups.) The *double-bosonization* of B is the Hopf algebra $U(B)$ containing B, C^{op}, H as subalgebras and the cross relations, coproduct and antipode (cf. Ref. 9)

$$\begin{gathered} hb = (h_{(1)} \triangleright b) h_{(2)}, \quad hc = (h_{(2)} \triangleright c) h_{(1)}, \\ \underline{b_{(1)}} \mathscr{R}^{(2)} \underline{c_{(1)}} \mathrm{ev}(\mathscr{R}^{(1)} \triangleright \underline{b_{(2)}}, \underline{c_{(2)}}) = \mathrm{ev}(\underline{b_{(1)}}, \mathscr{R}^{(2)} \triangleright \underline{c_{(1)}}) \underline{c_{(2)}} \mathscr{R}^{(1)} \underline{b_{(2)}}, \\ \Delta b = \underline{b_{(1)}} \mathscr{R}^{(2)} \otimes \mathscr{R}^{(1)} \triangleright \underline{b_{(2)}}, \quad \Delta c = \mathscr{R}^{(2)} \triangleright \underline{c_{(1)}} \otimes \underline{c_{(2)}} \mathscr{R}^{(1)}, \\ Sb = (u \mathscr{R}^{(1)} \triangleright \underline{S} b) S \mathscr{R}^{(2)}, \quad Sc = \mathscr{R}^{-(1)} \underline{S}^{-1} (v^{-1} \mathscr{R}^{-(2)} \triangleright c), \end{gathered} \tag{21}$$

where $\triangleright$ denotes the action of H whereby B, C live in the braided category of H-modules. The pairing is assumed covariant, so $\mathrm{ev}(h \triangleright b, c) = \mathrm{ev}(b, (Sh) \triangleright c)$. The unit and counit are the trivial tensor product ones and H has its usual coproduct and antipode (it is a sub-Hopf algebra). Similar proofs to those in Ref. 9 show that this defines a Hopf algebra. The bosonization $B \bowtie H$ appears as a sub-Hopf algebra and a certain ''conjugate bosonization'' generated by C^{op}, H also appears as a sub-Hopf algebra.

When the pairing is nondegenerate, we have as a formal power series a canonical element $\exp = e_\alpha \otimes f^\alpha$ for the pairing, where $\{e_\alpha\}$ is a basis of C and $\{f^\alpha\}$ is a dual basis. Its inverse in the algebra $C^{\mathrm{op}} \otimes B$ is $\exp^{-1} = (\underline{S} e_\alpha \otimes f^\alpha)$ from the pairing axioms. In this case the double-bosonization is quasitriangular with

$$\mathscr{R}_{U(B)} = \mathscr{R}\, \exp^{-1}, \tag{22}$$

where we view $\mathscr{R}$ and exp in $U(B) \otimes U(B)$.

This describes the left-handed version of the formulas in Ref. 9. It underlies the formulas in Sec. II: we take H generated by $\mathbf{l}^{\pm}$, $\mathfrak{s}$ and B generated by $\mathbf{p}$. We take C generated by $\mathbf{c}$ which are dual to the $\mathbf{p}$ in the usual way except scaled so that $\mathrm{ev}(p^i, c_j) = (q - q^{-1})^{-1} \delta^i{}_j$. We then use the same methods as in Refs. 2 and 10 for the calculation of the extended q-Poincaré algebra as $B \bowtie H$. Similarly for the conjugate bosonization generated by H, C^{op}. The remaining cross relations are $[p^i, c_j] = \mathrm{ev}(p^i, c_a) \langle t^a{}_j g, \mathscr{R}^{(2)} \rangle \mathscr{R}^{(1)} - \mathscr{R}^{(2)} \langle S t^i{}_a g^{-1}, \mathscr{R}^{(1)} \rangle \mathrm{ev}(p^a, c_j)$ from (21) and the linear form of the braided coproducts on B, C. It is convenient to compute the action of $\mathscr{R}$ here on C as evaluation against the coaction of the matrix quantum group dual to H, with generators $\mathbf{t}, g$. We derive the formula in Proposition 2.1 in this way. The same method gives the spinorial formulas in Sec. IV.

Also given in Ref. 9 is a fundamental representation of $U(B)$. In our conventions it appears on C, making it into a left $U(B)$-module algebra as follows: first, B acts on C by the braided left coregular representation studied in Ref. 10, Sec. 2. Together with the given action $\triangleright$ of H on C, we have (Ref. 10, Cor. 2.2) a covariant action of $B \bowtie H$ on C (it defines the action of the extended q-Poincaré algebra on space–time). Second, C acts on itself by the right braided-adjoint action. This is given by the diagrams in Ref. 3 reflected in a mirror followed by reversal of braid crossings. We view this as a left action of C^{op} on itself (cf. Ref. 19). These actions fit together to give an action of $U(B)$ covariantly on C (i.e., respecting its product). Explicitly,

$$b \triangleright x = \mathrm{ev}(\underline{S}^{-1} b, \underline{x_{(1)^{\mathrm{op}}}}) \underline{x_{(2)^{\mathrm{op}}}}, \quad c \triangleright x = (\mathscr{R}^{(2)} \triangleright \underline{S} \underline{c_{(1)}}) (\mathscr{R}^{(1)} \triangleright x) \underline{c_{(2)}} \tag{23}$$

when acting on $x\in C$. Here $x_{\underline{(1)}^{\rm op}}\otimes x_{\underline{(2)}^{\rm op}}=\mathscr{R}^{-(1)}\triangleright x_{\underline{(2)}}\otimes\mathscr{R}^{-(2)}\triangleright x_{\underline{(1)}}$ is the opposite braided coproduct of C. This action underlies the formulas in Sec. V. The action of $p^i\in B$ is by braided differentiation as studied in Ref. 10. The action of $c_i\in C$ is computed as

$$c_i\triangleright x_j=(\mathscr{R}^{(2)}\triangleright \underline{S}c_i)x_a\langle\mathscr{R}^{(1)},t^a{}_jg\rangle+x_jc_i=x_jc_i-(\varsigma^{-1}Sl^{-a}{}_j\triangleright c_i)x_a=\frac{x_jx_i-x_ax_bR^b{}_j{}^a{}_i}{q-q^{-1}},$$

where $x_i\in C$ are the usual (not scaled) generators dual to p^i [so $c_i=(q-q^{-1})x_i$], and $\underline{S}x_i=-x_i$. This derives the action used in Sec. V.

Next we move on to new abstract considerations beyond.[9] We suppose that B,C are $*$-braided groups in the usual sense,[16] H is a real-quasitriangular Hopf $*$-algebra, and its action on B is unitary in the Hopf algebraic sense. Thus

$$(h\triangleright b)^*=(Sh)^*\triangleright b^*,\quad (h\triangleright c)^\star=(S(h^*))\triangleright c^\star. \tag{24}$$

As explained in Ref. 10, the second formula is dictated by the first one and braided group duality. We use $\bigstar$ to define the $*$-structure on $C^{\rm op}$ as the same antilinear map.

Proposition A.1: In this setting, the double bosonization $U(B)$ is a quasi-$*$ Hopf algebra with cocycle $\mathscr{R}$ viewed in $U(B)\otimes U(B)$. Moreover,

$$(*\otimes *)\circ\Delta\circ *=\exp^{-1}(\Delta\ )\exp$$

in $U(B)$.

Proof: It is proven in Ref. 10 that, in this setting, $B\bowtie H$ becomes a quasi-$*$ Hopf algebra with cocycle $\mathscr{R}$. By a similar calculation, we find that the conjugate bosonization generated by $C^{\rm op}$, H is also a quasi-$*$ Hopf algebra with the same cocycle $\mathscr{R}$. We verify that these $*$-structures are compatible with the cross-relations in (21). Applying $*$ to both sides:

$$\begin{aligned}(b_{\underline{(1)}}\mathscr{R}^{(2)}c_{\underline{(1)}})^*\overline{{\rm ev}(\mathscr{R}^{(1)}\triangleright b_{\underline{(2)}},c_{\underline{(2)}})}&=c_{\underline{(1)}}{}^*\mathscr{R}^{(2)*}b_{\underline{(1)}}{}^*{\rm ev}((\mathscr{R}^{(1)}\triangleright b_{\underline{(2)}})^*,c_{\underline{(2)}}{}^*)\\&=c^*{}_{\underline{(2)}}\mathscr{R}^{(1)}b^*{}_{\underline{(2)}}{\rm ev}(S^{-1}\mathscr{R}^{(2)}\triangleright b^*{}_{\underline{(1)}},c^*{}_{\underline{(1)}})\\&=c^*{}_{\underline{(2)}}\mathscr{R}^{(1)}b^*{}_{\underline{(2)}}{\rm ev}(b^*{}_{\underline{(1)}},\mathscr{R}^{(2)}\triangleright c^*{}_{\underline{(1)}})\\&={\rm ev}(\mathscr{R}^{(1)}\triangleright b^*{}_{\underline{(2)}},c^*{}_{\underline{(2)}})b^*{}_{\underline{(1)}}\mathscr{R}^{(2)}c^*{}_{\underline{(1)}}\\&={\rm ev}(b^*{}_{\underline{(2)}},S\mathscr{R}^{(1)}\triangleright c^*{}_{\underline{(2)}})b^*{}_{\underline{(1)}}\mathscr{R}^{(2)}c^*{}_{\underline{(1)}}\\&={\rm ev}(b_{\underline{(1)}}{}^*,(\mathscr{R}^{(2)}\triangleright c_{\underline{(1)}})^*)b_{\underline{(2)}}{}^*\mathscr{R}^{(1)*}c_{\underline{(2)}}{}^*\\&=\overline{{\rm ev}(b_{\underline{(1)}},\mathscr{R}^{(2)}\triangleright c_{\underline{(1)}})}(c_{\underline{(2)}}\mathscr{R}^{(1)}b_{\underline{(2)}})^*\end{aligned}$$

using $\overline{{\rm ev}(b\otimes c)}={\rm ev}(b^*,c^*)$, reality of $\mathscr{R}$ in the sense $\mathscr{R}^{*\otimes *}=\mathscr{R}_{21}$, our assumption (24), invariance of ev, and the cross-relations in (21) applied to b^*, c^*. This checks consistency of the relations under $*$ and implies that we have a $*$-algebra structure on $U(B)$. Since its two sub-Hopf algebras mentioned above are quasi-$*$ Hopf algebras with cocycle $\mathscr{R}$, it becomes a quasi-$*$ Hopf algebra as well, with the same cocycle.

Since $U(B)$ is also (in the nondegenerately paired case) quasitriangular via (22), we deduce that $(*\otimes *)\circ\Delta\circ *=\mathscr{R}^{-1}(\tau\circ\Delta\ )\mathscr{R}=\mathscr{R}^{-1}\mathscr{R}_{U(B)}(\Delta\ )\mathscr{R}_{U(B)}^{-1}\mathscr{R}=\exp^{-1}(\Delta\ )\exp$, as stated. □

We see from this proposition that the plane wave exp controls the extent that the double bosonization fails to be a Hopf $*$-algebra in the usual sense. This, in turn, expresses the sense in which the tensor product of unitaries fails to be unitary: they are unitary only up to a cocycle isomorphism expressed by the action of exp.

From the theory of quasi-$*$ Hopf algebras in Ref. 10, Lemma 4.7, it is known that if a quasi-$*$ Hopf algebra $\mathscr{H}$ acts covariantly on a $*$-algebra C by $\triangleright$, then the conjugate quasi-$*$ Hopf algebra [with coproduct $\overline{\Delta}=(*\otimes *)\circ\Delta\circ *$] acts covariantly on C by a conjugate action $\overline{\triangleright}$ defined by

$$h\overline{\triangleright}x=(S(h^*)\triangleright x^*)^* \tag{25}$$

for all $h\in\mathscr{H}$ and $x\in C$.

Theorem A.2: *The conjugate of the action of $U(B)$ as a quasi-$*$ Hopf algebra acting on C is $h\overline{\triangleright}x=h\triangleright x$ and $b\overline{\triangleright}x=\mathrm{ev}(b,x_{\underline{(1)}})x_{\underline{(2)}}$ as in* Ref. 10, *and*

$$c\overline{\triangleright}x=(\mathscr{R}^{-(1)}\triangleright\underline{S}^{-1}c_{\underline{(1)}^{\mathrm{op}}})(\mathscr{R}^{-(2)}\triangleright x)c_{\underline{(2)}^{\mathrm{op}}}.$$

Moreover, $(\ )\triangleright\underline{S}x=\underline{S}((\ )\overline{\triangleright}x)$, i.e., the action and conjugate action of $U(B)$ are intertwined by the braided antipode of C.

Proof: The conjugate actions of $h\in H$ and $b\in B$ are covered in the conjunction of Ref. 10, Cor. 2.4 and Prop. 4.8. To this we add now the conjugate of the action of $c\in C$. We compute

$$\begin{aligned}
c\overline{\triangleright}x&=(S(c^*)\triangleright x^*)^*=(\mathscr{R}^{-(1)}\triangleright((v^{-1}\mathscr{R}^{-(2)}\triangleright\underline{S}^{-1}c^*)\triangleright x^*))^*\\
&=S(\mathscr{R}^{-(1)}*)\triangleright((v^{-1}\mathscr{R}^{-(2)}\triangleright\underline{S}^{-1}c^*)\triangleright x^*)^*\\
&=S(\mathscr{R}^{-(1)}*)\triangleright((\mathscr{R}^{(2)}\triangleright\underline{S}(v^{-1}\mathscr{R}^{-(2)}\triangleright\underline{S}^{-1}c^*)_{\underline{(1)}})(\mathscr{R}^{(1)}\triangleright x^*)(v^{-1}\mathscr{R}^{-(2)}\triangleright\underline{S}^{-1}c^*)_{\underline{(2)}})^*\\
&=S(\mathscr{R}^{-(1)}*)\triangleright((v^{-1}\mathscr{R}^{-(2)}\triangleright\underline{S}^{-1}c^*)^*_{\underline{(1)}}(S(\mathscr{R}^{(1)}*)\triangleright x)\\
&\qquad\times(S(\mathscr{R}^{(2)}*)\triangleright\underline{S}(v^{-1}\mathscr{R}^{-(2)}\triangleright\underline{S}^{-1}c^*)^*_{\underline{(2)}}))\\
&=\mathscr{R}^{-(2)}\triangleright((u^{-1}\mathscr{R}^{-(1)}\triangleright\underline{S}^{-1}c)_{\underline{(1)}}(\mathscr{R}^{(2)}\triangleright x)(\mathscr{R}^{(1)}\triangleright\underline{S}(u^{-1}\mathscr{R}^{-(1)}\triangleright\underline{S}^{-1}c)_{\underline{(2)}}))\\
&=\mathscr{R}_2{}^{-(2)}\mathscr{R}_1{}^{-(2)}\triangleright((u^{-1}\mathscr{R}_1{}^{(2)}\mathscr{R}_2{}^{(1)}\mathscr{R}_1{}^{-(1)}\mathscr{R}^{-(1)}\triangleright\underline{S}^{-1}c_{\underline{(2)}})(\mathscr{R}^{(2)}\triangleright x)\\
&\qquad\times(\mathscr{R}^{(1)}u^{-1}\mathscr{R}_1{}^{(1)}\mathscr{R}_2{}^{(2)}\mathscr{R}_2{}^{-(1)}\mathscr{R}^{-(2)}\triangleright c_{\underline{(1)}})),
\end{aligned}$$

where we use the antipode of $U(B)$ from (21) and repeatedly use (24). For the fifth equality we use the axiom $c_{\underline{(1)}}{}^*\otimes c_{\underline{(2)}}{}^*=c^*{}_{\underline{(2)}}\otimes c^*{}_{\underline{(1)}}$ for $*$-braided groups. We then use the reality property of $\mathscr{R}$, which also implies that $v^{-1}{}^*=\overline{v}^{-1}$. Here $Sv^{-1}=u^{-1}=\mathscr{R}^{(2)}S^2\mathscr{R}^{(1)}$. For the last equality we use covariance of $\underline{\Delta}$ under the action of H [along with standard facts about quasitriangular Hopf algebras to compute Δu^{-1} and $(\Delta\otimes\mathrm{id})\mathscr{R}^{-1}$], and the braided anticomultiplicativity $\underline{\Delta}S^{-1}c=\mathscr{R}^{-(1)}\triangleright\underline{S}^{-1}c_{\underline{(2)}}\otimes\mathscr{R}^{-(2)}\triangleright\underline{S}^{-1}c_{\underline{(1)}}$ from Ref. 12. Numerical suffices on $\mathscr{R}$, $\mathscr{R}^{-1}$ are used to distinguish the various copies. The remaining steps are a tedious but straightforward computation: we use the QYBE for $\mathscr{R}$ to cancel some of the $\mathscr{R}$ factors. Then we compute the action of $\mathscr{R}_1{}^{-(2)}\mathscr{R}_2{}^{-(2)}$ on products using covariance, converting coproducts on $\mathscr{R}^{-1}$ into more copies of $\mathscr{R}^{-1}$. Using $u(\ )u^{-1}=S^2$ and $\mathscr{R}^{-(2)}u^{-1}\mathscr{R}^{-(1)}=1$, we can then cancel most of the $\mathscr{R}$, $\mathscr{R}^{-1}$ factors to obtain the result stated. Here $c_{\underline{(1)}^{\mathrm{op}}}\otimes c_{\underline{(2)}^{\mathrm{op}}}$ denotes the braided opposite coproduct of C as usual.

Next, we show that the action and conjugate action are intertwined by the braided antipode $\underline{S}$ of the copy of C in which we are acting. For the action of $h\in H$ this is covariance of the braided antipode. For $b\in B$ this is Ref. 10, Cor. 2.4. To this we now add

$$\underline{S}(c\overline{\triangleright x}) = (.\mathscr{R}^{(2)}\triangleright \underline{S}c_{\underline{(2)}^{\mathrm{op}}})(.\mathscr{R}^{(1)}\triangleright \underline{S}((.\mathscr{R}^{-(1)}\triangleright \underline{S}^{-1}c_{\underline{(1)}^{\mathrm{op}}})(.\mathscr{R}^{-(2)}\triangleright x)))$$
$$= (.\mathscr{R}_1{}^{(2)}.\mathscr{R}_2{}^{(2)}\triangleright \underline{S}c_{\underline{(2)}^{\mathrm{op}}})(.\mathscr{R}_1{}^{(1)}\triangleright \underline{S}x)(.\mathscr{R}_2{}^{(1)}\triangleright c_{\underline{(1)}^{\mathrm{op}}})$$
$$= (.\mathscr{R}^{(2)}\triangleright \underline{S}c_{\underline{(1)}})(.\mathscr{R}^{(1)}\triangleright \underline{S}x)c_{\underline{(2)}} = c\triangleright \underline{S}x$$

using braided-antimultiplicativity of $\underline{S}$ twice. This part of the proof can also be done diagrammatically. □

This therefore extends the abstract unitarity and quasi-$*$ considerations for bosonizations and the extended q-Poincaré algebra in Ref. 10 to double-bosonizations and the q-conformal algebra. It is used in Secs. III and V.

ACKNOWLEDGMENT

The algebra of q-pseudodifferential symbols and the q-$\mathbf{W}_{\mathrm{KP}}^{(n)}$ algebra

Javier Mas and Marcos Seco
Departamento de Física de Partículas Elementales, Universidad de Santiago, Santiago de Compostela, 15706, Spain

(Received 21 May 1996; accepted for publication 4 June 1996)

In this paper we continue with the program to explore the topography of the space of W-type algebras. In the present case, the starting point is the work of Khesin, Lyubashenko, and Roger on the algebra of q-deformed pseudodifferential symbols and their associated integrable hierarchies. The analysis goes on by studying the associated Hamiltonian structures for which compact expressions are found. The fundamental Poisson brackets yield q-deformations of $\mathbf{W}_{\mathrm{KP}}$ and related $\mathbf{W}$-type algebras which, in specific cases, coincide with the ones constructed by Frenkel and Reshetikhin. The construction underlies a continuous correspondence between the Hamiltonian structures of the Toda lattice and the KP hierarchies. © *1996 American Institute of Physics.* [S0022-2488(96)04011-X]

I. INTRODUCTION

The literature concerning the so-called **W** algebras increases as the belief that the *w* stands for ''wild.'' In fact they are wild objects in that they still resist all efforts to achieve a clear and unified understanding of their physical meaning or at least of their geometrical origin. On the other hand, the fascination about them stems from the way they underlie so many *a priori* disconnected physical and mathematical constructions: two-dimensional conformal field theory,[1] soliton systems,[2] vertex-operator and Kac–Moody algebras,[3] classical and quantum fluids,[4,5] 2-D quantum gravity,[6] generalized particle systems,[7] and many others.

On the way to taming the **W** algebras different proposals have been pursued. On one hand, in the last years some effort has been posed in setting up a classification program. It has been realized that a natural arena to handle this program is the phase space of integrable soliton systems, where very many of the known **W** algebras arise either as Poisson bracket algebras, or as symmetries of the evolution equations. On the other hand, searching for an interpretation of **W** algebras in physical terms, some simplifications have been produced, yielding somewhat simpler objects which still preserve many of the distinguishing features of **W** algebras. Among them, the presence of the Virasoro subalgebra plays a central role. Thus for example the ''dispersionless'' or ''classical'' limit, in which the operator ∂ is smoothly replaced by a commuting symbol ξ (Ref. 8), has shed some light about the geometry of classical **W**-morphisms in relation to ''area preserving diffeomorphisms'' [9] and Hamiltonian mechanics[10] (see also Ref. 11 for other interesting proposals).

Another interesting simplification should occur if we replaced the derivative ∂ by the q-derivative ∂_q. The q-derivative is in fact a difference operator, i.e., let F denote the ring of complex-valued polynomials in z and z^{-1} ($\mathbf{C}[z, z^{-1}]$) and $q \in \mathbf{C}$:

$$\partial_q f(z) \equiv \frac{f(qz)-f(z)}{z(q-1)},$$

where ∂ is recovered in the $\lim_{q\to 1}\partial_q = \partial$. Using ∂_q instead of ∂ provides a sort of short distance cutoff. For this reason it has been widely investigated in connection with the problem of regulating quantum field theories.[12] In the last years, a few works have been concerned with the issue of the

0022-2488/96/37(12)/6510/20/$10.00

q-deformed Virasoro and **W** algebras; in Refs. 13 and 14 we have listed the references we are aware of, where structures deserving such a name have been constructed. The generic approach in them exploits heavily the use of the q-affine algebras, q-vertex operators, and a q-deformed version of the Miura transformation. The connection of these algebras with integrable systems remained unclear, until the recent work of E. Frenkel.[15] In this paper it is claimed that the q-deformed W algebras constructed in Ref. 14 provide bi-Hamiltonian structures for a particular set of differential—q-difference integrable systems, which naturally deserve the name of q-deformed KdV hierarchies.

Our original motivation was to pursue the line of research developed in Ref. 16. In this work the central object of study was the Lie algebra of so-called q-pseudodifferential symbols ∂_q, its extensions and contractions, as well as the associated Lax systems. Actually, the q-deformed n-KdV integrable hierarchies defined there turn out to be the same as those in Ref. 15, albeit in a different basis. With respect to this work, ours is somewhat complementary in that we asked ourselves: first, what are the most general hierarchies that one could write in terms of Lax operators involving q-pseudodifferential symbols and, second, what are their Hamiltonian structures.[2] To perform the analysis, the unified framework described in Ref. 17 proved to be instrumental. As an output, a large class of q-deformations of classical W algebras are found, including those of $\mathbf{W}_{\mathrm{KP}}$, GD_n, or the centrally extended $W_{1+\infty}$. In specific cases we find agreement with the results of Ref. 15. We also comment on some obstruction found when trying to define a q-deformation of W_n.

This paper is organized as follows: for completeness, Secs. II and III are devoted to the introductory material. In the former, some basic notions about the algebra of q-pseudodifferential operators are included; the latter gives an overview of the r-matrix approach to integrable systems. In both sections we have followed closely the clear expositions of Refs. 16 and 17, respectively.

Section IV is a straightforward application of the machinery of Sec. III. The analysis is performed in a twisted basis T, which we refer to as the ''Toda lattice'' basis. In particular, three tri-Hamiltonian hierarchies of nonlinear differential-difference equations are found. The Poisson brackets are explicitly computed and agree in special cases with those found in Ref. 15. One of the advantages of the present formalism is the possibility of carrying out a transparent treatment of reductions. Some of them are investigated at the end of this section.

Section V is a reelaboration of the previous findings in the basis ∂_q introduced in Sec. I, and named q-KP basis after its direct relationship with the standard KP basis. The nonlinear infinite-dimensional algebra which we obtain and compute is connected with the $\mathbf{W}_{\mathrm{KP}}^{(n)}$ algebra[18] in the limit $q\to 1$; thereafter, we name it the q-$\mathbf{W}_{\mathrm{KP}}^{(n)}$ algebra. Reductions are treated at the end. Of utmost importance are the reductions of q-KP to q-KdV. We comment about the possibility of obtaining several q-deformations of the Virasoro algebra within the present formalism.

Finally, in Sec. VI we bring the logarithm of the q-differential symbol $\log \partial_q$ into the game. We do this by formally continuing the order n of the Lax operator to real values and taking afterwards a suitable limit $n\to 0$. The resulting algebra can be considered as a q-deformation of the centerful $W_{1+\infty}$ algebra.

II. THE ALGEBRA OF q-PSEUDODIFFERENTIAL OPERATORS

It will be useful to define the ''shift'' $\tau f(z)=f(qz)$, $\tau^{\beta} f(z)=f(q^{\beta}z)$, $\beta\in\mathbf{C}$. So, ∂_q is a q-derivative in the following sense:

$$\partial_q(fg)=\partial_q(f\,)g+\tau(f\,)\partial_q(g), \tag{2.1}$$

which can be proven by explicit computation. The actions of τ and ∂_q are not commutative but rather q-commutative, i.e., $\partial_q(\tau(f\,))=q\,\tau(\partial_q f\,)$

Definition 2.2: An algebra ΨDO_q of q-pseudodifferential operators is a vector space of formal series

$$\Psi DO_q=\left\{ A(x,\partial_q)=\sum_{-\infty}^{n} u_i(z)\partial_q^i \,\middle|\, u_i\in F \right\} \tag{2.3}$$

with respect to ∂_q. The multiplication law in ψDO_q is defined by the following rule: F is a subalgebra of ψDO_q and there are commutation relations ($u\in F$):

$$\begin{aligned} \partial_q u&=(\partial_q u)+\tau(u)\partial_q,\\ \partial_q^{-1}u&=\sum_{k\geqslant 0}(-1)^k q^{-k(k+1)/2}(\tau^{-k-1}(\partial_q^k u))\partial_q^{-k-1}. \end{aligned} \tag{2.4}$$

Each term of the product of two Laurent series in ∂_q is found by applying these rules a finite number of times. The formula (2.4) is built so that $\partial_q^{-1}\partial_q u=\partial_q\partial_q^{-1}u=u$. For $q=1$ these formulas recover the ''classical'' definition of multiplication law in the algebra of pseudodifferential operators ψDO.

The commutation rule for ∂_q^n (with any integer n) and $u(z)$ join these formulas in one

$$\partial_q^n u=\sum_{k\geqslant 0}\begin{bmatrix} n\\ k\end{bmatrix}_q(\tau^{n-k}(\partial_q^k u))\partial_q^{n-k}, \tag{2.5}$$

where we use the following notation for q-numbers and q-binomials.

$$(n)_q=\frac{q^n-1}{q-1},$$

$$\begin{bmatrix} m\\ k\end{bmatrix}_q=\frac{(m)_q(m-1)_q\cdots(m-k+1)_q}{(1)_q(2)_q\cdots(k)_q}.$$

The q-analog of the Leibnitz rule of multiplication of two q-pseudodifferential operators $A(x,\partial_q)$ and $B(x,\partial_q)$ can be written as the following operation on their symbols,

$$A(x,\partial_q)B(x,\partial_q)=\sum_{k\geqslant 0}\frac{1}{(k)_q!}\left(\frac{d^k}{d\partial_q^k}A\right)*(\partial_q^k B), \tag{2.6}$$

where for any complex value of α

$$\frac{d^k}{d\partial_q^k}(f\partial_q^\alpha)=(\alpha)_q(\alpha-1)_q\cdots(\alpha-k+1)_q f\partial_q^{\alpha-k}$$

and the $*$ multiplication of symbols obeys the following commutation rule for the generators:

$$f*\partial_q=f\partial_q,\quad \partial_q*f=\tau(f\ )\partial_q,\quad \partial_q^{-1}*f=\tau^{-1}(f\ )\partial_q^{-1}. \tag{2.7}$$

This follows by a straightforward verification of the formula (2.6) for the product $\partial_q^n u(z)$, which gives the same answer as (2.5).

Define the Lie algebra $\mathcal{G}_q$ as the set ΨDO_q of all q-pseudodifferential symbols equipped with the commutator bracket $[A,\ B]=AB-BA$.

With this setup in mind, it is straightforward to construct a q-deformed analog of the KP hierarchy. The phase space for this dynamical system is the set $\{L_q=\partial_q+u_1(z)+u_2(z)\partial_q^{-1}+u_3(z)\partial_q^{-2}+\cdots\}$, and the equations of motion adopt the familiar Lax form

$$\frac{dL_q}{dt_m}=[L_q,(L_q^m)_+]=[(L_q^m)_-,L_q]. \tag{2.8}$$

Notice that unlike in the differential case, the potential $u_1(z)$ has a nontrivial evolution. This is due to the fact that now the highest degree of the commutator of two q-pseudodifferential operators is the sum of their respective highest degrees, this being a consequence of the nonconmutativity of the multiplication of symbols as shown in (2.7).

III. *R*-MATRIX APPROACH TO INTEGRABLE SYSTEMS

We recall here the rudiments of r-matrix and refer the interested reader to the literature.[19] In this section we shall follow closely the clear introduction given in Ref. 17. A classical r-matrix on a Lie algebra g is a linear map $\mathscr{R}$: $g\to g$ such that the modified bracket

$$[a,\ b]_{\mathscr{R}}=[\mathscr{R}(a),\ b]+[a,\ \mathscr{R}(b)]$$

is a Lie bracket, thus providing a second Lie algebra structure on g. As was shown in Ref. 19, a sufficient condition for a linear map $\mathscr{R}$ to be an r-matrix is given by the so-called *modified Yang–Baxter* equation [m-YB(α) for short].

$$[\mathscr{R}(a),\ \mathscr{R}(b)]-\mathscr{R}([a,\ b]_{\mathscr{R}})=-\alpha[a,\ b], \tag{3.1}$$

where α is any real number. Now let us assume that in g there is an ad-invariant (under the natural Lie bracket [,] in g) inner product $\langle,\rangle$: $g\times g\to\mathbf{C}$ under which g can be identified with its dual g^*. Immediately we know of a natural Poisson structure that lives on $\mathbf{C}^\infty(g^*)$, namely the Lie–Poisson bracket arising from the modified Lie bracket $[,]_{\mathscr{R}}$:

$$\{f_1,f_2\}_1(L)\equiv\langle L,[\mathscr{R}df_1,\ df_2]+[df_1,\ \mathscr{R}df_2]\rangle, \tag{3.2}$$

evaluated at a point $L\in g=g^*$. This Poisson bracket, termed *linear* after its dependence on L, is the first of a series of other ''potential'' Poisson brackets:

$$\{f_1,f_2\}_2\equiv\langle L,[\mathscr{R}(Ldf_1+df_1L),\ df_2]+[df_1,\ \mathscr{R}(Ldf_2+df_2L)]\rangle, \tag{3.3}$$

$$\{f_1,f_2\}_3\equiv\langle L,[\mathscr{R}(Ldf_1L),\ df_2]+[df_1,\ \mathscr{R}(Ldf_2L)]\rangle. \tag{3.4}$$

Using ad-invariance of the inner product, and the definition of the adjoint r-matrix as $\langle\mathscr{R}(a),b\rangle=\langle a,\mathscr{R}^*(b)\rangle$, we may encode the above ''potential'' Poisson brackets in terms of the associated Poisson map J, defined by

$$\{f_1,f_2\}_s(L)=\langle J_L^{(s)}(df_1),df_2\rangle,\quad s=1,2,3, \tag{3.5}$$

as follows

$$\begin{aligned}
J_L^{(1)}(df\ )&=[L,\ \mathscr{R}(df\ )]+\mathscr{R}^*([L,\ df]),\\
J_L^{(2)}(df\ )&=[L,\ \mathscr{R}(Ldf+dfL)]+L\mathscr{R}^*([L,\ df])+\mathscr{R}^*([L,\ df])L,\\
J_L^{(3)}(df\ )&=[L,\ \mathscr{R}(LdfL)]+L\mathscr{R}^*([L,\ df])L.
\end{aligned} \tag{3.6}$$

Now the crucial question: for what $\mathscr{R}$ will the above maps define Hamiltonian maps? The findings of Refs. 17 and 20 specify the following.

(a) $J_L^{(1)}$ is Hamiltonian for any r-matrix $\mathscr{R}$ on g.

(b) $J_L^{(2)}$ is Hamiltonian if $\mathscr{R}$ and its skew-symmetric combination $\frac{1}{2}(\mathscr{R}-\mathscr{R}^*)$ *both* satisfy the m-YB(α) equation (3.1).
(c) $J_L^{(3)}$ is Hamiltonian if $\mathscr{R}$ is an r-matrix which satisfies m-YB(α) equation.

The three maps are related with one another by simple deformations

$$J_{L+\epsilon 1}^{(2)}=J_L^{(2)}+2\epsilon J_L^{(1)},$$

$$J_{L+\epsilon 1}^{(3)}=J_L^{(3)}+\epsilon J_L^{(2)}+\epsilon^2 J_L^{(1)},$$

where 1 is the generator of the center in g. This, by the way, shows the compatibility of the three ''would be'' Poisson structures.

The construction of integrable systems that are Hamiltonian with respect to the above brackets refers to the existence of a (possibly maximal) set of conserved functions in involution. Here, an important piece in the game is played by the set of Casimir (invariant) functions, i.e., those functions $C\in\mathbf{C}^\infty(g^*)$ satisfying $ad_L^*(C(L))=0$ or, equivalently,

$$ad_L(dC(L))=[L,\ dC(L)]=0.$$

If one has a chance to characterize the Casimir functions (in short, the centralizer of $L\in g$), then a short look at the form of $J^{(s)}$ in (3.6) reveals the following.

(i) The associated Hamiltonian flows adopt the Lax form

$$\frac{dL}{dt}=J_L^{(1)}(dC)=[L,\ \mathscr{R}(dC)],$$

$$\frac{dL}{dt}=J_L^{(2)}(dC)=[L,\ \mathscr{R}(2LdC)],$$

$$\frac{dL}{dt}=J_L^{(3)}(dC)=[L,\ \mathscr{R}(L^2dC)].$$

(ii) The Casimir functions are in involution. For example, when $s=1$

$$\{C_1,C_2\}_1=\langle[L,\ \mathscr{R}(dC_1)],dC_2\rangle=-\langle[L,\ dC_2],\mathscr{R}(dC_1)\rangle=0.$$

A particular (partial) solution is given by the traces of powers of L:

$$C_p(L)\equiv\frac{1}{k}\,\mathrm{Tr}(L^p),\quad dC_p(L)=L^{(k-1)},\quad p=1,2,\ldots\ .$$

For this particular set of functions, the Lax equations are tri-Hamiltonian

$$\frac{dL}{dt_p}\equiv[L,\ \mathscr{R}(L^p)]=J_L^{(1)}(dC_{p+1})=J_L^{(2)}(dC_p)=J_L^{(3)}(dC_{p-1}).$$

In some cases (n-KdV), p may be a fraction of the order of L.

The classification of solutions to (3.1) has been achieved partially. A class of them fall into the following characterization: if $g=g_+\oplus g_-$ is a decomposition into Lie subalgebras, denoting by P_+ (P_-) the projection of g_+ (resp. g_-) along g_- (resp. g_+), then $\mathscr{R}=\frac{1}{2}(P_+-P_-)$ satisfies the modified Yang–Baxter equation (3.1) with $\alpha=\frac{1}{4}$ since $[a,\ b]_{\mathscr{R}}$ is easily calculated to be $[a_+,\ b_+]-[a_-,\ b_-]$ in obvious notation.

We may give the particular form of (3.6) whenever adapted to the present situation (hereafter we shall obviate the dependence of $J_L^{(s)}$ on L, and write simply $J^{(s)}$):

$$
\begin{aligned}
J^{(1)}(df) &= [L,\ P_+ df] - P_-^*[L,\ df] = -[L,\ P_- df] + P_+^*[L,\ df], \\
J^{(2)}(df) &= [L,\ P_+(L df + df\, L)] - L(P_-^*[L,\ df]) - (P_-^*[L,\ df])L \\
&= -[L,\ P_-(L df + df\, L)] + L(P_+^*[L,\ df]) + (P_+^*[L,\ df])L, \\
J^{(3)}(df) &= [L,\ P_+(L df\, L)] - L(P_-^*[L,\ df])L = -[L,\ P_-(L df\, L)] + L(P_+^*[L,\ df])L.
\end{aligned}
\tag{3.7}
$$

Moreover, if g_+ and g_- are isotropic, then clearly $\mathscr{R}$ is skew-adjoint with respect to the inner product $\langle \mathscr{R}(a), b\rangle = \langle a, \mathscr{R}^*(b)\rangle$, i.e., $\mathscr{R}^* = -\mathscr{R}$. In this case $P_\pm^* = P_\mp$ and the three structures in (3.6) reduce to the following form ($X \equiv df$):

$$
\begin{aligned}
J_L^{(1)}(z) &= [L,\ X_+]_- - [L,\ X_-]_+, \\
J_L^{(2)}(z) &= L(XL)_+ - (LX)_+ L = -L(XL)_- + (LX)_- L, \\
J_L^{(3)}(z) &= [L,\ (LXL)_+]_- - L[L, X]_+ L.
\end{aligned}
\tag{3.8}
$$

IV. THE "TODA LATTICE" BASIS

Let us return to the q-deformation of the KP hierarchy that we showed in the introduction (2.8). Define, for $q \neq 1$,

$$
\begin{aligned}
T &= z(q-1)\partial_q + 1, \\
T^{-1} &= \frac{1}{z(q-1)\partial_q + 1} = \sum_{i=1}^{\infty} -\frac{(-q)^i}{(q-1)^i} z^{-i} \partial_q^{-i}.
\end{aligned}
\tag{4.1}
$$

Any element of ΨDO_q of the form (2.3) admits a similar expression in this "twisted" basis

$$
A = \sum_{-\infty}^{n} a_i(z)\partial_q^i = \sum_{-\infty}^{n} t_i(z) T^i. \tag{4.2}
$$

Hence we will be describing the same algebra $\mathscr{G}_q$ in this basis. The relevant composition law is the following, which can be proven by elementary manipulations: For any $f \in F$,

$$
Tf = \tau(f)T, \tag{4.3}
$$

in particular $Tz = qzT$. We will use the notation (Tf) to mean that T acts only on f, i.e., $(Tf) \equiv TfT^{-1} = \tau(f)$.

The algebraic approach to integrability relies heavily on the existence of an ad-invariant symmetric bilinear form. As a step in this direction, a linear functional $\int : f \in \mathbf{C}$ is defined satisfying $\int \tau(f) = \int f$ for all $f \in F$. In agreement with this requirement, we further specify that $\int z^n = \delta_{n,0}$. A particular realization of this definition is given by the usual Riemann integration over S^1 of the Fourier basis functions $z^n = e^{in\theta}$, where the action of τ is seen as a shift of $(-i \log q)$ in θ. Also $\delta(z) = \Sigma_{k \in \mathbf{Z}} z^k$.

Now, let $A = \Sigma_i a_i T^i \in \Psi DO_q$. We define the residue $\mathrm{res}_T : \Psi DO_q \to f$ by

$$
\mathrm{res}_T\left(\sum_i a_i T^i \right) = a_0
$$

and the trace Tr: $\Psi DO_q \to \mathbf{C}$ by

$$\mathrm{Tr}\ A = \int \mathrm{res}_T\ A$$

Lemma 4.4: The bilinear form $\langle , \rangle : \mathscr{G}_q \times \mathscr{G}_q \mathbf{C}$, *given by*

$$\langle A, B \rangle = \mathrm{Tr}\ AB = \int \mathrm{res}_T\ AB, \tag{4.5}$$

defines an ad-invariant bilinear symmetric inner product in $\mathscr{G}_q$

Proof: By direct computation and use of the defining ''shift'' invariance of $\int$ we find

$$\mathrm{Tr}\ AB = \int \mathrm{res}_T\ a_i T^i b_j T^j = \int a_i \tau^i(b_{-i}) = \int b_{-i} \tau^{-i}(a_i)$$

$$= \int \mathrm{res}_T\ b_j \tau^j(a_i) T^{j+1} = \int \mathrm{res}_T\ b_j T^j a_i T^i = \mathrm{Tr}\ BA.$$

■

We would like to stress that this bilinear product is the same (up to factors of q) as the one defined in Ref. 16, as we shall show in Sec. V. The previous lemma is fully equivalent to theorem 3.3 in that reference. With respect to this inner product, the adjoint of τ is $\tau^* = \tau^{-1}$, i.e., $(T^* f) = (T^{-1} f)$.

Let us investigate the possible splittings of the form $\mathscr{G}_q = \mathscr{G}_1 \oplus \mathscr{G}_2$, where $\mathscr{G}_1$ and $\mathscr{G}_2$ are Lie subalgebras. In view of the generic (graded) commutation relations

$$[t_i T^i,\ t_j T^j] = (t_i \tau^i(t_j) - t_j \tau^j(t_i)) T^{i+j},$$

we find only three possibilities as follows:

(1) $(\sigma = -1)$: $\mathscr{G}_q = \mathscr{G}_{\geqslant 0} \oplus \mathscr{G}_{\leqslant -1}$

$$\mathscr{G}_{\geqslant 0} \equiv \left\{ \sum_{i \geqslant 0} t_i(z) T^i \right\}; \quad \mathscr{G}_{\leqslant -1} \equiv \left\{ \sum_{i \leqslant -1} t_i(z) T^i \right\};$$

(2) $(\sigma = +1)$: $\mathscr{G}_q = \mathscr{G}_{\geqslant 1} \oplus \mathscr{G}_{\leqslant 0}$:

$$\mathscr{G}_{\geqslant 1} \equiv \left\{ \sum_{j \geqslant 1} t_j(z) T^j \right\}; \quad \mathscr{G}_{\leqslant 0} \equiv \left\{ \sum_{j \leqslant 0} t_j(z) T^j \right\};$$

(3) $(\sigma = 0)$: $\mathscr{G}_q = \mathscr{G}_{0+} \oplus \mathscr{G}_{0-}$

$$\mathscr{G}_{0+} \equiv \left\{ \sum_{k \geqslant 0} t_k(z) T^k,\ t_0 \in z\mathbf{C}[z] \right\};$$

$$\mathscr{G}_{0-} \equiv \left\{ \sum_{k \geqslant 0} t_k(z) T^k,\ t_0 \in z^{-1}\mathbf{C}[z^{-1}] \right\}.$$

Remark 4.6: As mentioned in Ref. 16, the interest of the last case comes from the fact that, relative to the inner product defined in (4.5), it is the only one where $\mathscr{G}_{0\pm}$ are isotropic. Hence $(\mathscr{G}, \mathscr{G}_{0+}, \mathscr{G}_{0-})$ is a Manin triple and $(\mathscr{G}, \mathscr{G}_{0-})$ a Lie double.

A. The fundamental Poisson brackets

In order to define the phase space where our dynamics will take place, let

$$L=\sum_{i=m}^{n} t_i(z)T^i, \tag{4.7}$$

where $n, m\in\mathbf{Z}$ and $n>m$. We regard any of these difference operators as ''points'' on a manifold $\mathscr{M}_T^{(n,m)}$. The dynamics is governed by differential—q-difference equations derived from the usual Lax system

$$\frac{dL}{dt_p}=[L,\ (L^p)_+]=[(L^p)_-,\ L], \tag{4.8}$$

which is manifestly consistent for L of the form given in (4.7). Here $\pm$ refers to any one of the $\sigma=0,\ \pm1$ splittings defined above.

In the case of $\sigma=-1$ with $(n,m)=(1,-\infty)$, this system is none other than the simplest version of the Toda lattice hierarchy involving one set of time parameters.[21,22] Indeed, in these works the Toda lattice hierarchy is formulated in terms of a Lax operator of the form

$$L=e^{\partial}+\sum_{n=0}^{\infty} u_{n+1}e^{-n\partial},$$

which involves the difference operator e^{∂} acting as $e^{n\partial}u_i(x)=u_i(x+n)e^{n\partial}$. The isomorphism between both formulations is made patent after identifying $u_i(x)$ with $t_i(z=q^x\zeta)$ where $\zeta\in\mathbf{C}$ is any fixed complex number.

Remark that only for $m=0$ and the splitting $\sigma=-1$, or $n=0$ and $\sigma=+1$, equations (4.8) are empty since in this case the commutator vanishes identically. The nontrivial flows may come then from fractional powers of L.[15,16] For example, let $n=N$ and $m=0$. Then

$$\frac{dL}{dt_p}=[L,\ (L^{p/N})_+]=[(L^{p/N})_-,\ L]$$

are nontrivial differential difference equations as long as p is not a multiple of N. An analogous way to characterize these flows is to consider an operator of the form $L\in\mathscr{M}_T^{1,-\infty}$ of the form $L=t_0T+t_1+t_2T^{-1}+...$, constrained to satisfy $L_-^N=0$.

On $\mathscr{M}_T^{(n,m)}$ the (linear) functionals of interest have the form $f_X(L)=\mathrm{Tr}\,LX$ with

$$X=\sum_{j=m}^{n} T^{-j}x_j(z).$$

Clearly f_X adopts the form of a Euclidean scalar product $f_X=\int\Sigma_{i=m}^{n}t_ix_i$. Defining the gradient $d:F\to\mathscr{G}_q$ by

$$\langle df,\delta L\rangle\equiv\frac{d}{d\epsilon}\,f_X(L+\epsilon\delta L)\bigg|_{\epsilon=0},$$

it turns out that $df_X(L)=X$.

We are interested in the fundamental Poisson brackets among the fields $t_i(z)$. Since the Poisson maps $J^{(s)}(df_X)$ are linear in $df_X=X$, we may expand

$$J^{(s)}(X)=\sum_{i=m}^{n}\sum_{j=m}^{n}(J_{ji}^{(s)}x_i)(z)T^j, \tag{4.9}$$

where $J_{ij}^{(s)}$ is some function of q-difference operators T. Plugging this back in (3.5) we obtain

$$\{f_X,f_Y\}=\int (J_{ij}x_j)y_i=\int x_i(J_{ji}^{*}y_j)=-\int x_i(J_{ij}y_j),$$

where the last equation follows from the antisymmetry $\{f_X,f_Y\}=-\{f_Y,f_X\}$, which implies that $J_{ji}^{*}=-J_{ij}$. Finally, comparing this expression with

$$\{f_X,f_Y\}_r=\int x_i(z)\int\{u_i(z),u_j(w)\}_s y_j(w)$$

shows that

$$\{u_i(z),u_j(w)\}_s=-(J_{ij}^{(s)}(z)\,\delta(z/w)), \tag{4.10}$$

where $\delta(z/w)=\Sigma_{j\in\mathbf{Z}}(z/w)^j$, and the operators J_{ij} act at z.

It is time to analyze in detail the potential Poisson structures on $\mathscr{M}_T^{(n,m)}$. We will do this by taking into consideration, case by case, the three possible splittings of $\mathscr{G}_q$: $\sigma=0,\pm1$. Notice that for all cases, the linear and cubic brackets in (3.2) and (3.4) define Poisson brackets, since $\mathscr{R}=\frac{1}{2}(P_+-P_-)$, with $P_\pm$ in each case the relevant projection operators, yields automatically an r-matrix obeying the m-YB($\frac{1}{4}$) equation (3.1). Therefore, further analysis is only required for the quadratic bracket.

1. ($\sigma=-1$): $\mathscr{G}_q=\mathscr{G}_{\geqslant 0}\oplus\mathscr{G}_{\leqslant -1}$

This splitting is, among the three, the most analogous to the one of the standard KP hierarchy. Notice, however, the important difference: now the subalgebra $\mathscr{G}_{\geqslant 0}$ is *not isotropic*, and in consequence the r-matrix is not anti-self-adjoint. Thus, whether the ''antisymmetric'' combination $\frac{1}{2}(\mathscr{R}-\mathscr{R}^*)$ satisfies the m-YB($\frac{1}{4}$) equation as well must be checked independently. In more concrete terms, let

$$\mathscr{R}=\tfrac{1}{2}(P_{\geqslant 0}-P_{\leqslant -1}).$$

In view of the definition of the inner product (4.5), $\mathscr{R}^*=\frac{1}{2}(P_{\leqslant 0}-P_{\geqslant 1})$, and therefore

$$\tfrac{1}{2}(\mathscr{R}-\mathscr{R}^*)=\tfrac{1}{2}(P_{\geqslant 1}-P_{\leqslant -1}). \tag{4.11}$$

It follows from an easy calculation that this linear map satisfies (3.1) with $\alpha=\frac{1}{4}$ as well. Hence all three brackets in (3.2) and (3.4) are Poisson brackets. Using the general formula (3.7) we may particularize to the present case and get ($X\equiv df$)

$$J^{(1)}(X)=[L,\,X_{\geqslant 0}]_{\leqslant 0}-[L,\,X_{\leqslant -1}]_{\geqslant 1}, \tag{4.12}$$

$$\begin{aligned}J^{(2)}(X)&=2L(XL)_{\geqslant 0}-2(LX)_{\geqslant 0}L+L\ \mathrm{res}_T([L,\,X])+\mathrm{res}_T([L,\,X])L\\&=-2L(XL)_{\leqslant -1}+2(LX)_{\leqslant -1}L+L\ \mathrm{res}_T([L,\,X])+\mathrm{res}_T([L,\,X])L,\end{aligned} \tag{4.13}$$

$$J^{(3)}(X)=[L,\,(LXL)_{\geqslant 0}]-L[L,\,X]_{\geqslant 1}L. \tag{4.14}$$

A word about consistency is needed. Concerning the *first structure* (4.12), in order that $J^{(1)}(X)$ describes a deformation of L we must demand that $n\geqslant 0$ and $1\geqslant m$ (in fact, for the particular case of $\mathscr{M}_T^{(n>0,0)}$ expression (4.12) appeared in Ref. 15). This may be seen from (4.12) written in the following form:

$$J^{(1)}(X)=[L_{\leqslant 0},\, X_{\geqslant 0}]_{\leqslant 0}-[L_{\geqslant 2},\, X_{\leqslant -1}]_{\geqslant 1}.$$

The first term on the right-hand side bounds the lowest order of $J^{(1)}(X)$ to be higher or equal to the lowest order of L. The second one bounds the highest order of the map to be strictly lower than the highest order of L. The constraints in n and m come from the projectors outside the commutators.

It is remarkable that for the *second structure* $J^{(2)}$ there is not such a restriction and $J(X)$ parametrizes a deformation of L for any (n,m).

The case of the cubic or *third structure* is more extreme. From (4.14) is evident that $\mathscr{M}_T^{(n,m)}$ is not an invariant subspace under the action of $J^{(3)}$, unless $(n,m)=(\infty,0)$, $(0,-\infty)$, or $(\infty,-\infty)$. For this reason we do not consider this algebra to be of much interest and we will not write down its explicit form. Hereafter we shall restrict our attention to the two other structures.

In terms of the fundamental Poisson brackets we obtain for $J^{(1)}$ the following difference operators $J_{ij}^{(1)}$:

$$J_{ij}^{(1)}=t_{i+j}T^i-T^{-j}t_{i+j}, \tag{4.15}$$

if either $i,j\geqslant 1$ with $n\geqslant i+j$ or, up to a sign, when $0\geqslant i,j$ with $i+j\geqslant m$. In all other cases $J_{ij}^{(1)}=0$. For the sake of comparison with similar results in the literature,[13–15] we may write down the Poisson brackets explicitly:

$$\{t_i(z),t_j(w)\}_1=-t_{i+j}(z)\,\delta\left(\frac{q^i z}{w}\right)+t_{i+j}(w)\,\delta\left(\frac{z}{q^j w}\right). \tag{4.16}$$

with the same set of restrictions upon the indices i,j. This expression exhibits the splitting of the linear Poisson bracket algebra in two graded subalgebras spanned by either positive or nonpositive values of i,j.

For $J_{ij}^{(2)}$ an analogous computation yields

$$J_{ij}^{(2)}=2\sum_{k=\max(m,i+j-n)}^{\min(n,i)}(t_kT^{k-j}t_{i+j-k}-t_{i+j-k}T^{i-k}t_k)+t_i(1+T^i)(1-T^{-j})t_j$$

or, again

$$\{t_i(z),t_j(w)\}_{(2)}=2\sum_{k=\max(m,i+j-n)}^{\min(n,i)}\left(t_{i+j-k}(z)t_k(w)\,\delta\left(\frac{q^{i-k}z}{w}\right)-t_k(z)t_{i+j-k}(w)\,\delta\left(\frac{z}{q^{j-k}w}\right)\right)$$
$$-t_i(z)t_j(w)\sum_{l\in\mathbf{Z}}\left(\frac{z}{w}\right)^l(1+q^i)(1-q^{-j})$$

2. ($\sigma=+1$): $\mathscr{G}_q=\mathscr{G}_{\geqslant 1}\oplus\mathscr{G}_{\leqslant 0}$

This situation is symmetric with respect to the one above. Notice that at the level of the algebra, this splitting transforms into the previous one upon the substitution $T\to T^{-1}$. Therefore, the formulas obtained from (4.12)–(4.14) can be adapted to the present case by a simple replacement $q\to q^{-1}$ and $m\leftrightarrow n$.

3. ($\sigma=0$): $\mathscr{G}_q=\mathscr{G}_{\mathbf{0}^+}\oplus\mathscr{G}_{\mathbf{0}^-}$

This is the standard case of a Lie bialgebra. The three maps in (3.8) automatically define Poisson brackets. The fundamental ones are a slight modification of the ones above, and involve an additional operator $\mathbf{p}_{\pm}$, which projects any element $f\in F$ into its Taylor and Laurent parts, respectively, i.e., $\mathbf{p}_+ z^m=z^m$ iff $m\geqslant 1$ and zero otherwise, and vice versa. Here $\mathbf{p}_+$ and $\mathbf{p}_-$ are mutually adjoint with respect to the inner product defined with $\int$ and commute with T.

As before, the linear structure is a direct sum of two subalgebras, spanned by the fields $t_0^+\equiv\mathbf{p}_+ t_0$ and $\{t_i,\ i=1,\ldots,n\}$ on one side, and $t_0^-\equiv\mathbf{p}_- t_0$ and $\{t_i,\ i=-1,-2,\ldots,m\}$ on the other. Therefore, as long as $i,j\geqslant 1$ but $n\geqslant i+j$,

$$J_{ij}^{(1)}=-(t_{i+j}T^i-T^{-j}t_{i+j}). \tag{4.17}$$

The same expression with opposite sign holds if $-1\geqslant i,j$ with $i+j\geqslant m$. Finally,

$$J_{0j}^{(1)}=\Theta(j-1)\mathbf{p}_+(T^{-j}-1)t_j-\Theta(-j-1)\mathbf{p}_-(T^{-j}-1)t_j \tag{4.18}$$

and $J_{i0}^{(1)}=-J_{0i}^{(1)*}$. In all other cases $J_{ij}=0$. In formula (4.18) Θ stands for the usual step function $\Theta(x)=1$ iff $x\geqslant 0$ and 0 otherwise. The quadratic brackets are computed along the same lines:

$$J_{ij}^{(2)}=2\sum_{k=\max(m,i+j-n)}^{\min(n,i)}(t_kT^{k-j}t_{i+j-k}-t_{i+j-k}T^{i-k}t_k)+2t_i(1-T^{i-j})\mathbf{p}_-t_j\,.$$

B. Some reductions

Let us focus on the $\sigma=-1$ splitting (the case $\sigma=+1$ follows a symmetric pattern). Remark that as far as the Lax equations are concerned, the field t_n is not dynamical. Let $\widetilde{\mathscr{M}}_T^{(n,m)}$ represent the submanifold of $\mathscr{M}_T^{(n,m)}$ defined by the constraint $t_n=1$ (or any constant). From $J^{(1)}$ in (4.12) we observe that, as long as $n\geqslant 1$, the highest positive order of $J^{(1)}$ is $n-1$ and therefore the Hamiltonian map is automatically tangent to the constraint submanifold. When $m=0$ this is also the case for a similar constraint on the lowest field $t_0=$constant; indeed (4.12) shows that in this case the contribution of $J^{(1)}(X)$ to order zero is $[L_0,\ X_0]=0$. In a few words, both constraints are first class, and the Poisson brackets are defined by simple restriction of (4.16).

For $J^{(2)}$, things are more involved. Notice in fact from the expression (4.13) that the highest order of $J^{(2)}(X)$ is n, i.e., the same as that of L. Therefore, in order to define Poisson brackets on $\widetilde{\mathscr{M}}_T^{(n,m)}$ we would follow the standard prescription for second class constraints due to Dirac. However, instead of plugging here the formula of the Dirac brackets, we will pause briefly to describe how they appear in our context. Given the projection map, such as $\mathscr{M}_T^{(n,m)}\to\widetilde{\mathscr{M}}_T^{(n,m)}$ that sets $t_n\to 1$, at each point L, the induced projection of vectors on the tangent subspace is unique. This is not so for one-forms. To see this notice that if we want to compute Poisson brackets of functions f,g on $\widetilde{\mathscr{M}}_T^{(n,m)}$ via (4.13), we first need to extend them to $\mathscr{M}_T^{(n,m)}$. This extension, being nonunique, renders the component $x_n=\delta f/\delta t_n$ in the gradient

$$df(L)=\sum_{k=m}^{n}T^{-k}x_k$$

undefined. Therefore some additional structure is required in order to specify the cotangent subspace. Since we have $J^{(2)}$ at hand, a map from one-forms to vectors, we may fix this ambiguity by demanding that the associated Hamiltonian vector fields be tangent to $\widetilde{\mathscr{M}}_T^{(n,m)}$. In other words, we fix x_n by the requirement that $J_2(df(L))$ should have no term of order n. This form of computing the algebra is fully equivalent to the Dirac bracket prescription as we show next.[23] The demand that $J(z)$ should stay tangent to the constraint manifold implies for $df(L)$ that

$$\sum_{j=m}^{n} J_{nj}x_j = 0$$

and this may be solved for $x_n = -\Sigma_{j=m}^{n-1} J_{nn}^{-1} J_{nj} x_j$. Plugging this back into (4.9) we have

$$J(z) = \sum_{i,j=m}^{n-1} (\tilde{J}_{ij} x_j) T^i,$$

where

$$\tilde{J}_{ij} = J_{ij} - J_{in} J_{nn}^{-1} J_{nj}, \quad i,j = 1,\ldots,n-1, \tag{4.19}$$

are the corresponding Dirac brackets on the constraint surface. For the explicitly reduced brackets we find a nonlocal expression as follows:

$$\tilde{J}_{ij}^{(2)} = 2 \sum_{k=\max(m,i+j-n)}^{\min(n,i)} (t_k T^{k-j} t_{i+j-k} - t_{i+j-k} T^{i-k} t_k) + 2 t_i \frac{(1-T^{i-n})(1-T^{-j})}{(1-T^{-n})} t_j. \tag{4.20}$$

Indeed, the interest in the reduction $t_n = 1$ stemmed from the fact that the Lax flows (4.8) stabilize this constraint. Likewise, if $m = 0$ the Lax equation for t_0 is trivial, hence we may want to set it also to a constant. However, in contrast to the previous case, the contribution of $J^{(2)}(X)$ to order zero is $2L_0(XL)_0 - 2(LX)_0 L_0 + 2L_0[L, X]_0 = 0$; in other words, for all j, $J_{0j}^{(2)}$ vanishes and therefore this constraint is first class and does not lead to any modification of the algebra. If we put $m = 0$, (4.20) is equivalent to formula (3.6) in Ref. 15.

V. THE q-KP BASIS

We recall that our main purpose is to construct a q-deformation of the algebra $\mathbf{W}_{\mathrm{KP}}$. For this reason it will be interesting to reformulate the findings of the previous section in terms of the basis ∂_q, i.e.,

$$\partial_q = \frac{1}{z(q-1)} (T-1). \tag{5.1}$$

Written in this basis, the limit $q \to 1$ should yield directly $\mathbf{W}_{\mathrm{KP}}^{(n)}$ in Ref. 18. We recall here the relevant formulas for the change of basis:

$$\begin{aligned} T &= z(q-1)\partial_q + 1, \\ T^{-1} &= \frac{1}{z(q-1)\partial_q + 1} \equiv -\sum_{i=1}^{\infty} \frac{(-q)^i}{(q-1)^i} z^{-i} \partial_q^{-i} \end{aligned} \tag{5.2}$$

These imply in particular that the phase space $\mathscr{M}_T^{(n,m)}$ will be coordinatized now by q-pseudodifferential operators L of the form

$$L = \sum_{j=-\infty}^{n} u_j(z) \partial_q^j, \tag{5.3}$$

$(m+n)$ being still the number of degrees of freedom. Yet the manifold of all q-pseudodifferential operators of the form (5.3), which we will denote by $\mathscr{M}_{\partial_q}^{(n)}$, is much bigger than $\mathscr{M}_T^{(n,m)}$. Rather, we have that the set of all these spaces $\{\mathscr{M}_T^{(n,m)}, m = 1,2,3,\ldots\}$ is dense in $\mathscr{M}_{\partial_q}^{(n)}$.

Notice that (5.2) involves a specific choice of the expansion point, namely around $\partial_q=\infty$. Other choices may lead to different W-algebras. In the q-KP basis we may grade $\mathscr{G}_q$ by the scaling dimension: if z has degree -1, ∂_q will have $+1$ and we may make L homogeneous of a certain degree, n, by further assignment of degree j to u_j. This gives us a chance to look for a q-deformation of the Virasoro algebra in the subalgebra spanned by the counterpart of the energy momentum tensor (the field u_2 in the context of the classical $\mathbf{W}_{\mathrm{KP}}$ algebra), which will be a particular x-dependent combination of various fields in the Toda basis (where the grading was a different one).

In order to study the Hamiltonian structures we have to redefine the residue and trace functionals in the new basis. The point is the following; let

$$L(T)_{\geqslant 0}=\sum_{i=0}^{n} t_i T^i=\sum_{i=0}^{n} u_i \partial_q^i=L(\partial_q)_{\geqslant 0},$$

where in each case the projection is performed with respect to the relevant basis. Making use of (5.1) we may write t_0 in terms of u_i:

$$t_0(u_i)=(-1)^m \frac{u_m}{z^m(q-1)^m}+(-1)^{m-1} \frac{u_{m-1}}{z^{m-1}(q-1)^{m-1}}+\cdots-\frac{u_1}{z(q-1)}+u_0. \tag{5.4}$$

If $L(T)\equiv t_i T^i$, $t_0=\mathrm{res}_T\, L(T)$. How can we manage to extract $t_0(u_i)$ out of $L(\partial_q)$ as given by the right-hand side of (5.4)? Notice that we may take advantage of the fact that the projections (in the respective basis) $(\ )_{\geqslant 0}$ and $(\ )_{\leqslant -1}$ commute with the change of basis $T\leftrightarrow\partial_q$, hence

$$(L(T))_0=(L(T)T^{-1})_{-1}=(L(T)_{\geqslant 0}T^{-1})_{-1}=\frac{z(q-1)}{q}\,(L(\partial_q)_{\geqslant 0}T^{-1}(\partial_q))_{-1}.$$

In the last expression $T^{-1}(\partial_q)$ stands for the second relation in (5.2). Thus

$$t_0(u_i)=\frac{z(q-1)}{q}\,\mathrm{res}_{\partial_q}(L(\partial_q)T^{-1}),$$

where we have introduced the symbol $\mathrm{res}_{\partial_q}\, a_i\partial_q^i \equiv a_{-1}$. Concerning the ad-invariant symmetric bilinear product, we find the same expression that was considered in Ref. 16 (modulo a constant factor)

$$\langle A,B\rangle=\langle B,A\rangle=\int \mathrm{res}_T\, AB=\frac{q-1}{q}\int z\,\mathrm{res}_{\partial_q}\, ABT^{-1}. \tag{5.5}$$

In this basis the natural integral functional is $\int_{-1}\equiv\int z$ which, in spite of not being scale invariant $\int_{-1}\tau(f\,)=q^{-1}\int_{-1} f$ satisfies the desirable property that $\int_{-1}(\partial_q f\,)=0$. With respect to the above inner product, the adjoints of τ and ∂_q are easy to compute, yielding

$$\tau^*=\frac{1}{q}\,\tau^{-1};\quad \partial_q^*=-\partial_q^*\tau^{-1}. \tag{5.6}$$

For later use we shall introduce the following compact notation:

$$\Omega(A)\equiv\frac{z(q-1)}{q}\,\mathrm{res}_{\partial_q}(A).$$

Next, we must characterize the three possible splittings of $\mathscr{G}_q(\sigma=0,\pm 1)$ in the ∂_q basis:

The untwisted basis is naturally adapted to the case $\sigma=-1$,

$$\mathscr{G}_{\geqslant 0}(T)=\mathscr{G}_{\geqslant 0}(\partial_q),\quad \mathscr{G}_{\leqslant -1}(T)=\mathscr{G}_{\leqslant -1}(\partial_q).$$

Here $\sigma=+1$ looks a little bit more contrived:

$$\mathscr{G}_{\leqslant 1}(T)=\widetilde{\mathscr{G}}_{\geqslant 0}(\partial_q)\equiv\left\{L=\sum_{j=0}^{m} u_j\partial_q^j \middle| \operatorname{res}_{\partial_q}(LT^{-1})=0\right\},$$

$$\mathscr{G}_{\leqslant 0}(T)=\mathscr{G}_{\leqslant 0}(\partial_q)=\left\{L=\sum_{j=-\infty}^{0} u_j\partial_q^j\right\}.$$

Last, the characterization of $\sigma=0$ in the untwisted basis makes this splitting very unnatural:

$$\mathscr{G}_{0^+}(\partial_q)\equiv\left\{L=\sum_{j=0}^{m} u_j\partial_q^j \middle| z\ \operatorname{res}_{\partial_q}(LT^{-1})\in z\mathbf{C}[z]\right\},$$

$$\mathscr{G}_{0^-}(\partial_q)\equiv\left\{L=\sum_{j=-\infty}^{0} u_j\partial_q^j \middle| u_0\in z^{-1}\mathbf{C}[z^{-1}]\right\}.$$

We want to consider again the Poisson maps (3.7). Now in order to compute the analog of (4.12)–(4.14) we have to say what the relevant projection operators are. From the form of the scalar product (5.5) it is clear that

$$\begin{aligned} &P_{\geqslant 0}L=L_{\geqslant 0},\quad P^*_{\geqslant 0}L=(LT^{-1})_{\leqslant -1}T,\\ &P_{\leqslant -1}L=L_{\leqslant -1},\quad P^*_{\leqslant -1}L=(LT^{-1})_{\geqslant 0}T. \end{aligned} \tag{5.7}$$

We may simplify these expressions, remembering that the projections $(\ )_{\geqslant 0}$ and $(\ )_{\leqslant -1}$ commute with the change of basis $T\leftrightarrow\partial_q$. So for $L=t_iT^i=u_j\partial_q^j$,

$$\begin{aligned} P^*_{\geqslant 0}L&=(L(\partial_q)T^{-1}(\partial_q))_{\leqslant -1}T=(L(T)T^{-1})_{\leqslant -1}T=(L(T))_{\leqslant 0}\\ &=(L(T))_{\leqslant -1}+t_0=(L(\partial_q))_{\leqslant -1}+\Omega(L), \end{aligned}$$

where we made use of (5.2). Similarly

$$\begin{aligned} P^*_{\leqslant -1}L&=(L(\partial_q)T^{-1})_{\geqslant 0}T=(L(T)T^{-1})_{\geqslant 0}T=L(T)_{\geqslant 1}T^{-1}T\\ &=L(T)_{\geqslant 0}-t_0=L(\partial_q)_{\geqslant 0}-\Omega(L). \end{aligned}$$

With these results the antisymmetric part of the r-matrix is

$$\tfrac{1}{2}(\mathscr{R}-\mathscr{R}^*)=\tfrac{1}{2}(P_{\geqslant 0}-P_{\leqslant -1}-\Omega)=\mathscr{R}-\tfrac{1}{2}\Omega. \tag{5.8}$$

It is not evident that this expression also satisfies the m-YB($\frac{1}{4}$) equation. However, an explicit computation shows that the only nonvanishing contribution to (3.1) has the form $\Omega([a_{\geqslant 0},\ b_{\geqslant 0}])$, which vanishes. An easy way to convince oneself of this fact is that when written in the T basis this is $\operatorname{res}_T[a(T)_{\geqslant 0},\ b(T)_{\leqslant 0}]=0$.

With all this information, it is now an easy exercise to find the explicit expressions for (3.7) as adapted to the present case. Let again $X\equiv df$:

$$J^{(1)}(X)=[L,\ X_{\geqslant 0}]_{\leqslant -1}-[L,\ X_{\leqslant -1}]_{\geqslant 0}+\Omega([L,\ X]), \tag{5.9}$$

$$J^{(2)}(X)=2L(XL)_{\geqslant 0}-2(LX)_{\geqslant 0}L+L\Omega([L,\,X])+\Omega([L,\,X])L$$
$$=-2L(XL)_{\leqslant -1}+2(LX)_{\leqslant -1}L+L\Omega([L,X])+\Omega([L,X])L, \tag{5.10}$$

$$J^{(3)}(X)=[L,\,(LXL)_{\geqslant 0}]-L[L,\,X]_{\geqslant 0}L+L\Omega([L,\,X])L. \tag{5.11}$$

Notice that as compared with the analogous expressions for the $\mathbf{W}_{\mathrm{KP}}$ algebra,[18] the ones above present additional terms which vanish in the limit $q\to 1$. However, these terms are not active whenever f is a Casimir function, and hence, in particular for the Lax–Hamiltonian flows.

In order to compute the algebra of fundamental Poisson brackets we have to describe the manifold and the class of functionals for which $J^{(i)}$, $i=1,2,3$, describe tangent maps. We will work on $\mathscr{M}_{\partial_q}^{(n)}$ whose points are parametrized as

$$L^{(n)}=\sum_{i=0}^{\infty} u_i\partial^{n-i}\quad (n\in\mathbf{Z}). \tag{5.12}$$

Accordingly, in order to define linear functionals of the form $f_X=\int_{-1}u_ix_i$ as $f_X=\int_{-1}\mathrm{res}_{\partial_q}LXT^{-1}$, our gradient one-forms will be q-pseudodifferential operators of the form

$$X\equiv df_X=\sum_{j=0}^{\infty}\partial_q^{j-n-1}Tx_j\,.$$

After a straightforward computation, we list the full set of fundamental brackets for $J^{(1)}$ as follows: first we have that for all j: $J_{00}^{(1)}=J_{0j}^{(1)}=J_{j0}^{(1)}=0$. If $i,j\geqslant n+1$,

$$J_{ij}^{(1)}=\sum_{k=0}^{i+j-n-1}\begin{bmatrix} i-n-1\\ k\end{bmatrix}_q q^{k(k+1)/2}\left(q^{n-i-1}(q-1)u_{i+j-n-k}(-\partial_q)^kx+\frac{1}{q}\,u_{i+j-n-k-1}(-\partial_q)^k\right)$$
$$\times T^{n-i}-\sum_{k=0}^{i+j-n}\begin{bmatrix} j-n\\ k\end{bmatrix}_q\frac{(q-1)}{q}\,T^{j-n-k}\partial_q^ku_{i+j-n-k}x$$
$$-\sum_{k=0}^{i+j-n-1}\begin{bmatrix} j-n-1\\ k\end{bmatrix}_q\frac{1}{q}\,T^{j-n-k-1}\partial_q^ku_{i+j-n-k-1}. \tag{5.13}$$

If, however, $1\leqslant i,j\leqslant n-1$, the same expression (5.13) is valid with the opposite sign.

Finally, when $j=n$,

$$J_{in}^{(1)}=\left\{\sum_{k=0}^{i-n-1}\left(\begin{bmatrix} i-n-1\\ k\end{bmatrix}_q q^{k(k+1)/2+n-i-1}(q-1)u_{i-k}(-\partial_q)^kxT^{n-i}\right)-\frac{1}{q}\,(q-1)xu_i\right\}$$
$$\times\Theta(i-(n+1))+\left\{-\sum_{k=0}^{i-1}\begin{bmatrix} i-n-1\\ k\end{bmatrix}_q q^{k(k+1)/2}\left(q^{n-i-1}(q-1)u_{i-k}(-\partial_q)^kx\right.\right.$$
$$\left.\left.+\frac{1}{q}\,u_{i-k-1}(-\partial_q)^k\right)+\frac{(q-1)}{q}\,xu_i+\sum_{k=0}^{i-1}\begin{bmatrix} -1\\ k\end{bmatrix}_q\frac{1}{q}\,T^{-k-1}\partial_q^ku_{i-k-1}\right\}$$
$$\times\Theta(n-i)+\frac{x(q-1)}{q}\left(u_n-\sum_{k=0}^{n}\begin{bmatrix} -1\\ k\end{bmatrix}_q T^{-k}\partial_q^ku_{n-k}\right)\delta_{i,n}\,. \tag{5.14}$$

The rest of the brackets can be computed making use of the identity $J_{ij}=-J_{ji}^{*}$ and (5.6).

Concerning reductions, as long as $n\geqslant 1$, the highest order of $J^{(1)}(X)$ is $n-1$ and thereafter its action is tangent to the submanifold defined by $u_0=$constant. Again this reduction is therefore first class. Two other consistent reductions of L are of the form $L=L_{\geqslant 0}$ with $J^{(1)}(X)=-[L_{\geqslant 0},\, X_{\leqslant -1}]_{\geqslant 0}+\Omega([L_{\geqslant 0},\, X_{\leqslant -1}])$ or $L=L_{\leqslant 0}$, in which case $J^{(1)}(X)=[L_{\leqslant 0},\, X_{\geqslant -1}]_{\leqslant -1}+\Omega([L_{\leqslant 0},\, X_{\geqslant -1}])$. The relevant explicit form of the Poisson brackets can be obtained in each case from (5.9) after suitably setting to zero the corresponding fields u_i and its duals x_i.

Written in this basis, the formula (5.13) exhibits a nested sequence of subalgebras $N=1,2,...$, spanned by $\{u_{n+N+k},\, k=0,1,2,...\}$. In the continuum limit $q\to 1$ these contract to the nested set truncations of the centerless $W_{1+\infty}$ algebra known as $W_{-N+\infty}$.[18]

For $J^{(2)}$ we have in turn

$$
\begin{aligned}
J^{(2)}_{ij}=&\,2\sum_{k=0}^{i-1}\sum_{l=0}^{k}\begin{bmatrix} l-k-1 \\ l \end{bmatrix}_q q^{(l-1)(k+1)}u_{j+k-l}\partial_q^l T^{-k}u_{i-k-1}\\
&-2\sum_{k=0}^{i-1}\sum_{l=0}^{j+k}\sum_{m=0}^{i-k-1}\begin{bmatrix} j-n-1 \\ l \end{bmatrix}_q\begin{bmatrix} n-m \\ i-k-m-1 \end{bmatrix}_q\\
&\times q^{(l-1)(l-j+n+1)+(i+l-k-m-2)(i-k-n-1)}u_m\partial_q^{i+l-k-m-1}T^{j+k-i-l+1}u_{j+k-l}\\
&+2\sum_{k=0}^{i}\sum_{l=0}^{k}\begin{bmatrix} l-k-1 \\ l \end{bmatrix}_q q^{(l-1)(k+1)}(q-1)xu_{j+k-l}\partial_q^l T^{-k}u_{i-k}\\
&-2\sum_{k=0}^{i}\sum_{l=0}^{j+k}\sum_{m=0}^{i-k}\begin{bmatrix} j-n-1 \\ l \end{bmatrix}_q\begin{bmatrix} n-m \\ i-k-m \end{bmatrix}_q q^{(l-1)(l-j+n+1)+(i+l-k-m-1)(i-k-n)}\\
&\times(q-1)xu_m\partial_q^{i+l-k-m}T^{j+k-i-l}u_{j+k-l}-(1-q^{-1})xu_iu_j\\
&+\sum_{k=0}^{i}\sum_{l=0}^{j}\begin{bmatrix} j-n-1 \\ l \end{bmatrix}_q\begin{bmatrix} n-k \\ i-k \end{bmatrix}_q q^{(l-1)(l-j+n+1)+(i+l-k-1)(i-n)}(q-1)xu_k\partial_q^{i+l-k}T^{j-i-l}u_{j-l}\\
&+\sum_{k=0}^{i-1}\sum_{l=0}^{j}\begin{bmatrix} j-n-1 \\ l \end{bmatrix}_q\begin{bmatrix} n-k \\ i-k-1 \end{bmatrix}_q q^{(l-1)(l-j+n+1)+(i+l-k-1)(i-n-1)}(q^{n-i+1}-1)\\
&\times u_k\partial_q^{i+l-k-1}T^{j-i-l+1}u_{j-l}+\sum_{k=0}^{i}\begin{bmatrix} n-k \\ i-k \end{bmatrix}_q q^{(i-k)(i-n)}(1-q^{-1})u_k\partial_q^{i-k}T^{n-i}xu_j\\
&-\sum_{k=0}^{j}\begin{bmatrix} j-n-1 \\ k \end{bmatrix}_q q^{(k-1)(k-j+n+1)}(q-1)xu_i\partial_q^k T^{j-k-n}u_{j-k}. \qquad (5.15)
\end{aligned}
$$

This expression reduces in the limit $q\to 1$ to the one of the W_{KP} algebra. Contrary to $J^{(1)}$,$J^{(2)}(X)$ does not stabilize the field u_0; i.e., from (5.10) we see that the highest order of $J^{(2)}(X)$ is the same as that of L. Therefore the constraint $u_0=1$ is second class. The same discussion that was developed in the T basis holds here *mutatis mutandi*. We will refrain from giving the explicit form of the reduced Poisson brackets, whose computation follows again the standard Dirac's recipe.

A. Reductions. Where is $q-W_n$?

Let us consider here the very important reductions of q-KP to q-KdV. The expressions in (5.9) and (5.10) are perfectly consistent when applied to purely q-differential operators $L=u_0\partial_q^n+u_1\partial_q^{n-1}+\cdots+u_n$. The related algebras are simply obtained by restricting the subindices of the fields appearing in (5.13)–(5.15) to take values in the range $i,j\in[0,\, n]$, and neglecting

all other fields. In a strict sense, these algebras should be considered as deformations of GD_n, the second Gelfand–Dickey bracket over the phase space of Lax operators of the form $L=\partial^n+u_1\partial^{n-1}+\cdots+u_n$. Hence we will name them $q-GD_n$ algebras.

An important point arises here: as compared with GD_n, $q-GD_n$ contain an additional generator u_0. In the limit $q\to 1$ this field decouples because $\lim_{q\to 1} J_{0j}=0$, $\forall j$ and we may set $u_0=1$. One could argue that in order to construct a true q-deformation of GD_n which involves exactly n generators we should first reduce $u_0=0$ via Dirac brackets. However, the projection involved in the reduction *is not a continuous* step and nothing guarantees that the resulting algebra will still recover the desired limit when $q\to 1$.

Let us give an example of this phenomenon by considering the simplest Lax operator $L=u_0\partial_q+u_1$. The Poisson brackets for u_0 and u_1 generate $q-GD_1$, whose brackets are given by

$$\begin{aligned} J_{00}^{(2)}&=\frac{q-1}{2q}\,u_0(T-T^{-1})zu_0,\\ J_{01}^{(2)}&=\frac{1}{2q}\,u_0(T-T^{-1})u_0,\\ J_{10}^{(2)}&=\frac{1}{2q}\,u_0(qT-q^{-1}T^{-1})u_0,\\ J_{11}^{(2)}&=\frac{1}{2zq(q-1)}\,u_0(T-T^{-1})u_0, \end{aligned} \tag{5.16}$$

which in the limit $q\to 1$ reproduce the free boson algebra GD_1 after u_0 is set to 1, i.e., $J_{11}^{(2)}\to\partial$, and $J_{0i}^{(2)}\to 0$. However, if we insisted in reducing $u_0=1$ before taking the limit, the Dirac formula gives us a vanishing answer for $\widetilde{J}_{11}^{(2)}$:

$$\begin{aligned} \widetilde{J}_{11}^{(2)}&=J_{11}^{(2)}-J_{10}^{(2)}(J_{00}^{(2)})^{-1}J_{01}^{(2)}\\ &=u_0\,\frac{1}{2q(q-1)}\left(\frac{1}{z}\,(T-T^{-1})-(qT-q^{-1}T^{-1})\,\frac{1}{z}\right)u_0=0. \end{aligned} \tag{5.17}$$

One cannot cure this result by multiplying the starting brackets by global factors of $(q-1)$, because the Dirac bracket is homogeneous under such rescalings. This vanishing result is also independent of any q-dependent redefinition of the field u_0.

We expect that a similar discussion applies to the classical W_n algebras although we do not have a general proof. These algebras arise as Hamiltonian reductions of GD_n where the generator u_1 is set to 0. The first generator, u_2, closes a linear subalgebra which is none other than the ubiquitous Virasoro algebra. It is in this sense that W_n algebras are sometimes defined as (nonlinear) extensions of the Virasoro algebra. A continuous q-deformation of W_n in $n-1$ fields $u_2,\ldots,u_n$ would present the same problems that we have exposed above in the case of GD_n. The naive procedure, of starting from $q-GD_n$ and reducing $u_0=1$ and $u_1=0$, may spoil the continuous correspondence with W_n in the limit $q\to 1$. We feel this is an important point that deserves further attention.

VI. ANALYTIC CONTINUATION

Notice that the expression for the algebra $q-\mathbf{W}_{\mathrm{KP}}^{(n)}$ as given in (5.15) admits analytic continuation to complex values of $n=\alpha\in\mathbf{C}$. This happens in contrast to the first structure, given in (5.13) and (5.14), where n appears explicitly in the limits of summatories. The best way to understand this is by implementing the analytic continuation right from the beginning. Actually the whole

formalism is susceptible of such a continuation along the lines advocated in Refs. 18 and 24. Hence $q-\mathbf{W}_{\mathrm{KP}}^{(\alpha)}$ describes a *two-parameter* family of nonlinear $\mathbf{W}_\infty$-type algebras.

There is an important technical question concerning the triviality of such deformation parameters, i.e., whether the algebras for different pairs (q,α) and (q',α') are isomorphic or not. At least in the continuum case $q=1$ we know positively that α represents a nontrivial deformation parameter.[25]

The second issue we intend to address in this concern is the possibility of connecting the linear and quadratic structures by a suitable contraction of the parameter α. In Ref. 18 the limit $\alpha\to 0$ was shown to yield an extension of the linear algebra $\mathbf{W}_{1+\infty}$ by means of the Khesin–Kravchenko cocycle.[26] This fact was also understood in Refs. 24 and 27 from a Poisson–Lie group theoretical point of view.

In more concrete terms, let us introduce a second parameter β and define $L^{(\alpha,\beta)}\in \mathscr{M}_{\partial_q}^{(\alpha)}$ such that

$$L^{(\alpha,\beta)}=\beta\partial_q^\alpha+\sum_{j=0}^{\infty} u_j(z)\partial_q^{\alpha-1}\equiv\beta\partial_q^\alpha+L^{(\alpha)}. \tag{6.1}$$

Correspondingly, the one-forms X will look as

$$X=\sum_{j=0}^{\infty}\partial_q^{j-\alpha-1}Tx_j\,.$$

We will be interested in the following ''scaling'' limit in which α tends to 0 and β to ∞ in such a way that $\alpha\beta=c$, a finite constant. It will be convenient to normalize $J^{(2)}$ in the following form:

$$J^{(2)}_{L^{(\alpha,\beta)}}(z)=\frac{1}{\beta}\{L^{(\alpha,\beta)}(XL^{(\alpha,\beta)})_{\geqslant 0}-(L^{(\alpha,\beta)}X)_{\geqslant 0}L^{(\alpha,\beta)}$$
$$+\tfrac{1}{2}\,L^{(\alpha,\beta)}\Omega([L^{(\alpha,\beta)},\,X])+\tfrac{1}{2}\,\Omega([L^{(\alpha,\beta)},\,X])L^{(\alpha,\beta)}\}.$$

Plugging (6.1) in this expression we may first gather all the terms quadratic in $\beta\partial_q^\alpha$:

$$\beta(\partial_q^\alpha(X\partial_q^\alpha)_{\geqslant 0}-(\partial_q^\alpha X)_{\geqslant 0}\partial_q^\alpha+\tfrac{1}{2}\partial_q^\alpha(\Omega[\partial_q^\alpha,\,X])+\tfrac{1}{2}\Omega([\partial_q^\alpha,\,X])\partial_q^\alpha).$$

Expanding $\partial_q^\alpha=1+\alpha\log\partial_q+O(\alpha^2)$ the surviving terms in the desired limit yield

$$c[\log\partial_q,\,X_{\geqslant 0}]-c[\log\partial_q,\,X]_{\geqslant 0}+c\Omega([\log\partial_q,\,X])=c[\log\partial_q,\,X_{\geqslant 0}]_{\leqslant -1}+c\Omega([\log\partial_q,\,X]).$$

In the linear terms the β dependence cancels out and we obtain

$$[L^{(0)},\,X_{\geqslant 0}]-[L^{(0)},\,X]_{\geqslant 0}+\Omega([L^{(\alpha)},\,X])=[L^{(0)},\,X_{\geqslant 0}]_{\leqslant -1}+\Omega([L^{(0)},tX]).$$

In summary, the limiting Hamiltonian structure yields

$$J_{1+\infty;q}(X)=[c\,\log\partial_q+L^{(0)},\,X_{\geqslant 0}]_{\leqslant -1}+\Omega([c\,\log\partial_q+L^{(0)},\,X]). \tag{6.2}$$

Consistency of $J(X)$ as a tangent map demands that L be of the form

$$L=\log\partial_q+u_0+\sum_{i=1}^{\infty}u_i\partial^{-i}.$$

The expression $\log\partial_q$ has to be understood as an outer automorphism of the Lie algebra of q-pseudodifferential symbols. Its action can be defined and computed as a limit:

$$[\log \partial_q,\ f\partial_q^p]=\lim_{\alpha\to 0}\frac{1}{\alpha}\,(\partial_q^{\alpha} f\partial_q^p\partial_q^{-\alpha}-f\partial_q^p)$$

$$=\log q f'\partial_q^p-\sum_{k\geqslant 1}\frac{\log q}{(q-1)}\begin{bmatrix}-1\\ k\end{bmatrix}_q q^k\tau^{-k}(\partial_q^k f\ )\partial_q^{p-k}.$$

The notation in (6.2) intends to make explicit that this algebra is a q-deformation of the centrally extended $W_{1+\infty}$ algebra. We will not write down explicitly the Poisson brackets here. They agree with the ones given in (5.13) and (5.14) with $n=0$ except for the central terms, which are the only ones that require corrections proportional to $\log q$.

VII. CONCLUSIONS AND OUTLOOK

The picture of an atlas of **W** algebras is slowly emerging. In this landscape, W_∞ algebras provide natural landmarks and, among them, the algebra $\mathbf{W}_{\mathrm{KP}}$ is a cornerstone. In Ref. 28 this algebra was shown to be related with a large amount of the known classical W-type algebras by continuous deformation or truncation. The main result of the present paper is that many of the points in that atlas admit yet another deformation, parametrized by q. Of particular importance are $q-\mathbf{W}_{\mathrm{KP}}^{(\alpha)}$, $q-GD_n$, and $q-W_{1+\infty}$.

It has been amusing to observe how many structures that worked fine for the algebra of pseudodifferential operators are robust enough to resist their implementation in the algebra of q-deformed pseudodifferential operators, as well. It certainly points out that perhaps other well-known results could be exported. To be more precise, we think about issues like the dressing transformation, the embedding of the Lie algebra of differential operators into W_n (Ref. 29), or the Kupershmidt–Wilson–Yu theorem.[30] In fact, concerning this last important theorem, a straightforward implementation of the proof given in Ref. 31 for a quadratic structure of the form (3.3) works fine in the case of an isotropic splitting. This requirement is only fulfilled in the present work for the splitting $\sigma=0$ and hence there is a q-deformed version of the Kupershmidt–Wilson–Yu theorem in this case. For $\sigma=\pm 1$ we have not been able to establish a similar result. In this respect we should mention that a proposal for a q-deformed Miura transformation has appeared in Ref. 14. Its connection to some peculiar way to factorize the Lax operator has been addressed in Ref. 15.

We should emphasize the existence of three consistent splittings ($\sigma=0,\pm 1$) for the algebra ΨDO_q. They all yield integrable Hamiltonian systems and thereafter **W**-type algebras. In Refs. 32 and 33 the m-KdV hierarchy was investigated in the scalar Lax formalism. It was recognized that this system is related to a nonstandard splitting of the algebra of ordinary ΨDO. Indeed $L=L_{\geqslant k}+L_{<k}$ yields consistent subalgebras for $k=0$, 1, and 2. It would be interesting to find out whether a possible q-deformation of these nonstandard splittings could be related to the cases $\sigma=0$ and $\sigma=+1$ in this paper.

The connection of the KP hierarchy with the Toda lattice hierarchy is a subject of recent interest which has received the attention of different groups.[22,34,35] We believe that our approach is substantially different from these and closer, at least in spirit, to the lattice deformation of Ref. 36. We expect that the powerful techniques that have been used in this paper can be implemented also in the context of the Calogero–Sutherland model, especially in the formulation that makes use of the exchange operators.[37]

ACKNOWLEDGMENTS

We are indebted to Boris Khesin for his useful comments and for bringing several references in Refs. 14 and 13 to our attention, and to E. Frenkel for clarification about his work. We also want to thank warmly Eduardo Ramos for his reading and comments on the manuscript. This work has been partially supported by the DGICYT under Contract No. PB/93-0344.

A calculus for SU(3) leading to an algebraic formula for the Clebsch–Gordan coefficients

J. S. Prakash[a] and H. S. Sharatchandra
The Institute of Mathematical Sciences, Madras-600 113, India

(Received 10 December 1993; accepted for publication 5 June 1996)

We develop a simple computational tool for SU(3) analogous to Bargmann's calculus for SU(2). Crucial new inputs are (i) explicit representation of the Gelfand–Zetlin basis in terms of polynomials in four variables and positive or negative integral powers of a fifth variable, (ii) an auxiliary Gaussian measure with respect to which the Gelfand–Zetlin states are orthogonal but not normalized, (iii) simple generating functions for generating all basis states and also all invariants. As an illustration of our techniques, an algebraic formula for the Clebsch–Gordan coefficients is obtained for the first time. This involves only Gaussian integrations. Thus SU(3) is made as accessible for computations as SU(2) is. © *1996 American Institute of Physics.* [S0022-2488(96)04309-5]

I. INTRODUCTION

Compact Lie groups have been extensively studied from different viewpoints.[1–12] In spite of this, there are gaps in our understanding which are keenly felt in specific applications. This has mostly to do with the absence of a viable scheme of general computations. For example, there is no algebraic formula for the Clebsch–Gordan coefficients of even the SU(3) group, despite extensive work by a generation of mathematical physicists. This is in contrast to the SU(2) group, where it seems that everything can be computed in more than one way. Somehow, every technique that works for SU(2) does not appear to have a simple generalization for other groups.

In this paper we develop techniques which provide a simple computation tool for SU(3). Our aim is to highlight the flexibility available for computations of various objects of interest in representation theory. In particular we obtain a closed formula for the Clebsch–Gordan coefficients of SU(3). With a couple of new inputs it might be possible to use our techniques for other groups also. We have borrowed ideas heavily from many earlier workers. We have made some conceptual and technical advances which together have enabled us to provide a simple tool.

We now give a summary of the earlier works, with specific reference to SU(3). An excellent summary of the situation up to 1971 is contained in the Appendix of the review by Smorodonskii and Shelepin.[13] Our summary is by no means complete and accurate.

In the SU(2)[13,14] case there are broadly three computational tools: (a) an infinitesimal approach; (b) a polynomial basis and generating invariants; and (c) use of the relationship with the symmetric group. Within each approach there have been many different ways[13,14] of deriving formulas for the Clebsch–Gordan coefficients. Almost every one of these variations has been tried for SU(3), but each has led to obstacles.

A major obstacle encountered in any approach is the outer multiplicity problem. In the decomposition into irreducible representations (IRs) of a Kronecker product of two IRs of SU(n), $n>3$, a given IR may appear more than once. These repeating IRs cannot be distinguished by the matrix-elements of the generators. We need to understand how the repeating IRs may be distinguished, labeled in a convenient and canonical way, and handled. Extensive efforts have been put into this problem. At least in the SU(3) case, the problem has been essentially resolved by many authors using diverse techniques and often without the knowledge of previous works. New Ca-

simirs (''Chiral Casimirs'') which distinguish between repeating IRs have been constructed.[15–17] Biedenharn and his collaborators have obtained a ''canonical resolution'' of the multiplicity problem.[18,19] An explicit formula for multiplicity has been obtained by Coleman[20] by analyzing the Littlewood–Richardson rule; by Jasselette[21,22] and Resnikoff[23] by applying the theory of invariants; and by O'Reilly[24] by a detailed and careful analysis of the Kronecker product. Anishetty *et al.*[25] recently reinterpreted these results to give the most explicit formula, analogous to the triangle rule for the addition of angular momenta in SU(2). The advantage of this formula is that the IRs in the Kronecker product are labeled by *free* integers which are subject only to additive constraints by the two IRs one started with. This therefore provides a ''natural labeling'' of the repeating IRs. Gadiyar and Sharatchandra[26] have recently solved the multiplicity problem for SU(n) for any n. This is done by obtaining an explicit algebraic solution of the Littlewood–Richardson rule in terms of free integers.

In the infinitesimal approach to SU(2), the Clebsch–Gordan coefficients are computed as follows. A recursion relation is obtained by considering the action of the Lie algebra on the direct product space. This does not work as it does for SU(3) and other groups. The Lie algebra does not provide a large enough number of recursion relations to be able to compute all Clebsch–Gordan coefficients. The reason is the multiplicity problem. Biedenharn and collaborators[27,28] have emphasized the need to define a basic set of irreducible tensor operators. The set they construct provides a ''canonical resolution'' of the multiplicity problem. For a review see Refs. 19, 29, and 30. Their ''pattern calculus'' provides a framework for computing the Clebsch–Gordan coefficients. There has been extensive formal work in this direction. It has led to significant concepts such as a global algebraic formulation of SU(3) tensor operator structure[27] and the denominator functions[28] which have wider ramifications.[31–35] In addition, this approach has been very useful for practical algorithms[36–38] and symbolic manipulation programs.[39] However the approach has not (yet!) led to an algebraic formula for the Clebsch–Gordan coefficients of SU(3).

The starting point of the second approach is the construction of a convenient *model space,* i.e., a concrete realization of (say, on a function space) the basis of every irreducible unitary representation of the group. In the case of SU(2), the simplest realization of the basis is as polynomials in two complex variables. This was known to Weyl[8] and was used by van der Waerden,[40] Cartan,[41] and Kramers.[42,43] It is related to the spinor representation of SO(3). Schwinger's[44] boson calculus is also related to this. This approach reached the peak in the work of Bargmann[54,42] where all computations in SU(2) are reduced to evaluation of Gaussian integrals. The computation of Clebsch–Gordan coefficients amounts to the construction of invariant polynomials. We will refer to this package of tools as the Bargmann calculus. We give a constructive analysis of this calculus in Sec. II. Though there are other model spaces for SU(2), e.g., the spherical harmonics, none provide as simple a computational tool.

There has been extensive work to generalize this second approach to other groups. Many model spaces have been constructed. Realization using polynomials[15,45,2,21,23,46,47] boson calculus[33,48,34] harmonic functions, i.e., functions on coset spaces.[55,49,50] Gelfand and collaborators[45] have obtained a differential equation which yields the measure with respect to which the Gelfand–Zetlin basis states are orthonormal. Jasselette,[21,22] Resnikoff,[23] and Karasev[46] have constructed invariant polynomials from which the Clebsch–Gordan coefficients may be obtained in principle. Resnikoff[23] made progress in using a Gaussian measure to extract the Clebsch–Gordan coefficients.

In spite of all this work, the situation is not comparable to the SU(2) case. Some of the coefficients[23,22,46] in the formula for the Clebsch–Gordan coefficients cannot be explicitly computed. The stumbling blocks in this approach which make it so much harder to handle SU(3) are the following. The realization of the basis functions in terms of polynomials is much more complicated. In fact all earlier realizations[15,47] are analogous to the harmonic polynomials (i.e., those which are annihilated by the Laplacian operators) obtained from the defining representation of SO(3) rather than to the monomials obtained from the spinor representation. Explicit construc-

tion of such basis vectors[15,48] and working with them is not easy. Moreover the measure with respect to which the basis is orthonormal is not known in a closed form.[45] Even were it known explicitly, the hope of computing with it appears remote. Invariant polynomials in the space of three IRs can be easily built.[21,23,46] However the invariant polynomial consistent with the three given IRs is not unique in general. The coefficients have to be fixed by demanding that they be expandable in terms of the constrained polynomials representing the basis vectors. Even this does not fix the invariant polynomial completely. This is a consequence of the multiplicity problem and requires a choice of basis to be made in the space of repeating IRs. After all this, there is no easy way of extracting the Clebsch–Gordan coeffients.[15,21–23,46]

In this paper we show how these stumbling blocks may all be overcome. We develop a calculus which is almost as simple as Bargmann's calculus. All computations are effectively reduced to Gaussian integrations.

The first simplification we have achieved is in the explicit realization[51] of the Gelfand–Zetlin basis vectors, free of constraints. We realized this in Sec. III. Our realization uses polynomials in four complex variables and positive or negative integral powers of a fifth variable. It is related to the functions on the cone $\vec{w}\cdot\vec{z}=0$ where $\vec{z}$ and $\vec{w}$ each are triplets of complex variables.[2,47] We choose a specific parametrization of the cone (i.e., eliminating w_3) and explicitly construct a Gelfand–Zetlin basis for the functions on the space. With our parametrization, we are using all polynomials and not just a subset as in earlier works.

Our realization is not as simple as the monomial basis for SU(2). However, in Sec. IV we use a generating function which generates all the (unnormalized) basis functions of every IR. This generating function is as simple as the ''principal vectors'' of Bargmann's calculus.[52,53]

At this stage of our formulation the normalizations of our basis vectors are not known. The normalization is to be determined by requiring that the representation matrix for each IR be unitary. It is always a headache to compute the normalization.[15,48] The great advantage of Bargmann's calculus is the Gaussian measure which permits explicit and easy computations. It is fortuitous that in the SU(2) case the measure with respect to which the Gelfand–Zetlin states are orthonormal is so simple. In order to retain this computability, we construct an auxiliary Gaussian measure with respect to which the Gelfand–Zetlin basis vectors are orthogonal but are not automatically normalized (Sec. V). In fact we use this measure to compute the normalization itself by requiring that the representation matrix in each IR be unitary (Sec. VI). This way we are killing two birds with one stone: To start with, the normalization and the measure are both unknown. A simple auxiliary measure is constructed and used to compute the normalization itself. The basis we use also leads to a simplification in the form of invariants in the direct product space of three IRs (Sec. VIII). This is a consequence of using the cone $\vec{w}\cdot\vec{z}=0$. The invariant polynomial corresponding to a choice of a repeating IR is now uniquely known and there are no unknown coefficients to be fixed separately (Sec. VIII). Therefore the Clebsch–Gordan coefficients (Sec. VII) can be obtained by simply expanding this polynomial in the basis vectors of each IR. We are assured that such an expansion exists because our basis spans all polynomials in contrast to the constrained polynomials of the earlier works.

In the SU(2) case, the Clebsch–Gordan coefficients are simply obtained by reading off the coefficients of the right monomial in the invariant polynomial. But our basis is more complicated. In order to obtain the coefficients in the expansion, we again use our auxiliary measure. We introduce a generating function for the invariant polynomials themselves (Sec. IX). This way all Clebsch–Gordan coefficients are being computed in one shot. Moreover, it is easier to do these computations than with each invariant polynomial individually. The Gaussian measure is used to find the inner product of the generating function for the basis vectors of the three IRs with the generating function for the invariant polynomials (Sec. X). There are terms in the exponent which are *apparently* cubic in this integration—a consequence of the ''multiplicity problem.'' Remarkably however, because of the specific measure we have chosen, the integrals can all be explicitly computed.

II. AN ANALYSIS OF BARGMANN'S TECHNIQUE FOR SU(2)

Bargmann[54] used an axiomatic approach in his analysis. This presumes many results known from other methods. In this section we give a constructive analysis of Bargmann's techniques for SU(2). This will set the stage for our techniques for SU(3), making it clear as to where new ideas are required. SU(2) is the group of simple unitary 2×2 matrices. Its action on $\mathscr{C}_2$, the two-dimensional complex Euclidean space, is given by

$$\begin{pmatrix} z_1 \\ z_2 \end{pmatrix} \to \mathscr{U} \begin{pmatrix} z_1 \\ z_2 \end{pmatrix} \tag{1}$$

where $\mathscr{U} \in \mathrm{SU}(2)$. The doublet of complex numbers (z_1, z_2) transforms as the irreducible representation (IR) $\underline{2}$ of SU(2). In particular, z_1 represents the spin ''up'' state and z_2, the spin ''down'' state. States of an arbitrarily high spin can be obtained from a large enough collection of spin 1/2 particles. In particular, states of spin J can be obtained from a system of $2J$ number of identical spin 1/2 particles, i.e., from $2J$ copies of $\mathscr{C}_2$. (The $2J$ boxes in the row of the Young table represent spin J). This corresponds to a realization of the IRs in the space of polynomials in z_1 and z_2: the monomial

$$z_1^m z_2^n \tag{2}$$

describes, up to a normalization, the basis states

$$|JM\rangle, \quad 2J = m+n, \quad 2M = m-n. \tag{3}$$

We notice that as m and n range independently over all non-negative integers, every basis state $|JM\rangle$ of every IR is realized uniquely. This means the following.

Consider the space $\mathscr{F}_2$ whose elements are, roughly speaking, polynomials in z_1 and z_2. In this space, every IR is realized, and moreover each IR is realized once only. Thus it is a model space (see Sec. I for the definition). In addition, the standard basis states [Eq. (3)] are simply realized as monomials. Thus this space is very convenient for calculations. There are further surprises to follow. The action of the group on any state is obtained in this model by transforming z_1 and z_2 in Eq. (2) as given by Eq. (1). To express this action on an arbitrary state, it is very convenient to work with the generating function,

$$\mathscr{Z}(a,b) = \exp(az_1 + bz_2). \tag{4}$$

Simply by extracting the coefficient of $a^m b^n$, an unnormalized basis state [Eq. (3)] can be extracted. This way, we are handling all states of all IRs in one shot. Moreover, the action of the group on the generating function is very simple:

$$\mathscr{U}: \mathscr{Z}(a,b) \to \mathscr{Z}((a,b)\mathscr{U}). \tag{5}$$

The normalizations of the basis states (within an IR) are obtained by demanding the unitarity of the representation matrices on the space. It is sufficient to use group elements close to the identity for this purpose. An SU(2) matrix close to identity may be represented as follows:

$$\mathscr{U} \simeq 1 + i(\epsilon_3 \sigma_3 + \epsilon_+ \sigma_+ + \epsilon_- \sigma_-), \tag{6}$$

where

$$\sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}; \quad \sigma_+ = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}; \quad \sigma_- = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} \tag{7}$$

(note that we are not using conventional normalization for the generators).

For unitarity, $\mathscr{U}^{\dagger}\mathscr{U}=1$, we require

$$\epsilon_{+}^{*}=\epsilon_{-}, \quad \epsilon_{3}^{*}=\epsilon_{3} \tag{8}$$

{det $\mathscr{U}=1$ is satisfied because the matrices [Eq. (7)] are traceless}. Using Eq. (6) in Eq. (5), we get the following representation for the generators on our model space,

$$\pi^{0}=a\,\frac{\partial}{\partial a}-b\,\frac{\partial}{\partial b}; \quad \pi^{-}=a\,\frac{\partial}{\partial b}; \quad \pi^{+}=b\,\frac{\partial}{\partial a}, \tag{9}$$

where the generators correspond to σ_3, σ_+, and σ_-, respectively. The notation we are using is motivated by the isospin triplet of pions. The requirement of unitarity of the representation matrix translates into the following condition on the generators:

$$(\pi^{0})^{*}=\pi^{0}, \quad (\pi^{+})^{*}=\pi^{-}, \tag{10}$$

where the asterisk stands for the adjoint. We write formally,

$$\mathscr{Z}(a,b)=\sum_{m,n} a^{m}b^{n}|m,n), \tag{11}$$

where

$$|m,n)=\frac{z_1^{m}z_2^{n}}{m!n!} \tag{12}$$

represent unnormalized basis states. The normalized basis

$$|J,M\rangle\equiv|m,n\rangle=N^{-1/2}(m,n)|mn), \quad 2J=m+n \quad 2M=m-n \tag{13}$$

are to be obtained by requiring,

$$\langle m'n'|T^{*}|mn\rangle=\langle mn|T|m'n'\rangle^{*} \tag{14}$$

for every generator T. Let

$$T|mn)=\sum_{m'n'} T(mn;m'n')|m'n'). \tag{15}$$

This action can be easily computed using the generating function [Eq. (4)] and the representation [Eq. (9)] of the generators. In terms of normalized states this means,

$$N^{1/2}(m,n)T|mn\rangle=\sum_{m'n'} T(mn;m'n')N^{1/2}(m',n')|m'n'\rangle. \tag{16}$$

Using orthonormality,

$$\langle m'n'|mn\rangle=\delta_{m'm}\delta_{n'n}, \tag{17}$$

we get

$$\langle m'n'|T|mn\rangle=T(mn;m'n')\,\frac{N^{1/2}(m',n')}{N^{1/2}(m,n)}. \tag{18}$$

Define $T^*(mn;m'n')$ for the generator T^*, analogously to Eq. (15). Condition (14) gives

$$\left|\frac{N(m,n)}{N(m'n')}\right| = \frac{T(mn;m'n')}{T^*(m'n';mn)}. \tag{19}$$

This way, the relative normalizations of basis states within an IR may be computed. For the present case,

$$\begin{aligned}
\pi^0 \sum a^m b^n|mn) &= \sum (m-n) a^m b^n|mn), \\
\pi^- \sum a^m b^n|mn) &= \sum a^{m+1} b^{n-1} n|mn), \\
\pi^+ \sum a^m b^n|mn) &= \sum a^{m-1} b^{n+1} m|mn).
\end{aligned} \tag{20}$$

Comparing like powers of a and b, we get,

$$\begin{aligned}
\pi^0(mn;mn) &= m-n, \\
\pi^-(mn;m-1,n+1) &= (n+1), \\
\pi^+(mn;m+1,n-1) &= (m+1).
\end{aligned} \tag{21}$$

Other matrix elements are zero. π^0 in Eq. (19) does not lead to any constraints on the normalizations. This is because it is diagonal in the chosen basis. However, using Eq. (19) for $\pi^{\pm}$, we get,

$$\left|\frac{N(m,n)}{N(m-1,n+1)}\right| = \frac{n+1}{m}. \tag{22}$$

We choose the solution,

$$N(m,n) = \frac{1}{m!n!}. \tag{23}$$

The solution is determined only up to (i) any function of the sum $m+n=2J$ and (ii) an arbitrary phase factor: (i) means that the relative normalization of states in different IRs is not fixed by our criterion. This is to be expected because unitarity of the representation matrix constrains relative normalizations of the basis states only within each IR. For any phase, unitarity is assured, and corresponds to a choice of the phases of the basis states.

Our orthonormalized basis states are represented by

$$|mn\rangle = \frac{z_1^m z_2^m}{\sqrt{m!}\sqrt{n!}}. \tag{24}$$

It would be easy to guess the measure with respect to which this basis is orthonormal. Define the inner product:

$$(f,g) = \int \frac{d^2z_1}{\pi}\frac{d^2z_2}{\pi} \exp(-\overline{z_1}z_1 - \overline{z_2}z_2)\overline{f(z_1,z_2)}g(z_1,z_2) \tag{25}$$

for functions in $\mathscr{F}_2$. The states [Eq. (24)] are orthonormal with respect to this measure. Note that the measure is invariant under the action of the group Eq. (1). We are led to a simple, Gaussian measure. As a consequence, it is easy to obtain a general formula for the Clebsch–Gordan coefficients. We now review this method.

Consider the direct product of two IRs, J_1 and J_2. This representation of the group is reducible in general. Consider its decomposition into various irreducible components:

$$|(J_1J_2)J_3M_3\rangle=\sum_{M_1,M_2} C^{J_1J_2J_3}_{M_1M_2M_3}|J_1M_1\rangle|J_2M_2\rangle. \tag{26}$$

The coefficients in the expansion are the Clebsch–Gordan coefficients. It is more convenient and symmetric to write this as follows. Given two IRs, J_1 and J_2, it is possible to form a nontrivial combination invariant under the group, only if $J_1=J_2$ and in this case,

$$\sum\ (-1)^{(J-M)}|J,M\rangle|J,-M\rangle=\text{invariant}. \tag{27}$$

As a consequence Eq. (26) may be reinterpreted as follows. Given three IRs, J_1, J_2 and J_3, try and form a (nontrivial) invariant combination

$$\sum_{M_1,M_2,M_3}\begin{pmatrix} J_1 & J_2 & J_3 \\ M_1 & M_2 & M_3\end{pmatrix}|J_1M_1\rangle|J_2M_2\rangle|J_3M_3\rangle. \tag{28}$$

The coefficients are the $3-j$ symbols.

Now represent the three IRs by homogeneous polynomials of degrees $2J_1,2J_2,2J_3$ in variables (z_1^1,z_2^1), (z_1^2,z_2^2), and (z_1^3,z_2^3), respectively. Then Eq. (28) corresponds to forming an invariant combination out of such polynomials. It is easy to do this. Invariant theory implies that any invariant polynomial in the six variables is a polynomial in the three independent invariants,

$$(z_1^1z_2^2-z_2^1z_1^2),\quad (z_1^2z_2^3-z_2^2z_1^3),\quad (z_1^3z_2^1-z_2^3z_1^1). \tag{29}$$

In order to satisfy our homogeneity requirements, we need non-negative integers N_1, N_2 and N_3 in

$$(z_1^1z_2^2-z_2^1z_1^2)^{N_3}(z_1^2z_2^3-z_2^2z_1^3)^{N_1}(z_1^3z_2^1-z_2^3z_1^1)^{N_2} \tag{30}$$

such that

$$2J_1=N_2+N_3,\quad 2J_2=N_3+N_1,\quad 2J_3=N_1+N_2. \tag{31}$$

For given J_1, J_2 and J_3, the only solution is

$$\begin{aligned} N_1&=J_2+J_3-J_1,\\ N_2&=J_3+J_1-J_2,\\ N_3&=J_1+J_2-J_3 \end{aligned} \tag{32}$$

if the right-hand sides are all non-negative. Thus if J_1, J_2, and J_3 satisfy the triangle condition, there is a unique invariant. Otherwise there is no nontrivial invariant. Thus the $3-j$ symbols are obtained (up to an overall normalization depending only on the total spins J_1, J_2, and J_3) by simply extracting in Eq. (30) the coefficients of the monomials [Eq. (24)] in the three sets of variables.

To obtain a formula for the $3-j$ symbols, we have to apply the binomial theorem, and extract the relevant powers of the monomials. We get (up to a normalization),

$$\sum_{p_a,q_a} \prod_{a=1}^{3} \frac{(-1)^{q_a}}{p_a! q_a!} \tag{33}$$

where the sum is over all nonnegative integers p_a, q_a satisfying the following matrix equation:

$$\begin{pmatrix} N_1 & N_2 & N_3 \\ m^1 & m^2 & m^3 \\ n^1 & n^2 & n^3 \end{pmatrix} = \begin{pmatrix} q_1+p_1 & q_2+p_2 & q_3+p_3 \\ q_2+p_3 & q_3+p_1 & q_1+p_2 \\ q_3+p_2 & q_1+p_3 & q_2+p_1 \end{pmatrix}. \tag{34}$$

III. A MODEL SPACE FOR SU(3)

Our first task is to construct a convenient model space for SU(3) (model space has been defined in Sec. I). It is not possible to get a model space as simple as the one for SU(2). But, we have constructed[47] a model space which is simple enough for obtaining general formulas. We provide an *ab initio* review of this construction in this section.

In the case of SU(2) all IRs could be constructed from the defining representation $\underline{2}$. This is no longer true for other semisimple groups. Consider a triplet (z_1, z_1, z_3) of complex numbers transforming as the defining representation $\underline{3}$ of SU(3). By considering polynomials in these complex variables we can only build totally symmetric tensors of SU(3). Such IRs are represented by Young's table with just our row. A general Young's table has two rows, some columns having two boxes and the rest having one box. In order to build a general IR, observe that an IR with one column of two rows corresponds to the $\underline{3^*}$ of SU(3). Therefore a general IR can be built using a direct product of $\underline{3^*}$s and $\underline{3}$s. Further, the tensors corresponding to the Young's table are symmetric in indices along each row. This means that it suffices to consider direct products which are totally symmetric in the $\underline{3^*}$s and in the $\underline{3}$s. Therefore, we may build a general IR in the space of polynomials in two triplets of complex numbers (z_1, z_2, z_3) and (w_1, w_2, w_3) transforming as $\underline{3}$ and $\underline{3}^*$ of SU(3), respectively. (All this is a heuristic explanation of a result proven in Refs. 1 and 2).

IRs of SU(3) are conveniently labeled by two arbitrary non-negative integers (M,N) which stand for the number of columns with one box and two boxes, respectively. Such an IR can be realized using polynomials of degree M in the z's and N in the w's, i.e., polynomials built from the monomials,

$$z_1^{m_1} z_2^{m_2} z_3^{m_3} w_1^{n_1} w_2^{n_2} w_3^{n_3} \tag{35}$$

with

$$m_1+m_2+m_3=M, \quad n_1+n_2+n_3=N. \tag{36}$$

However, this space contains some other IRs (M',N') with $M'<M$ and $N'<N$. The reason is that it is possible to form an SU(3) invariant $\vec{w}\cdot\vec{z}$. This is again a major difference from the SU(2) case. A simple way to remove the unwanted IRs is to impose the constraint,

$$\vec{w}\cdot\vec{z}=0, \tag{37}$$

where

$$\vec{w}\cdot\vec{z}=w_1z_1+w_2z_2+w_3z_3 \tag{38}$$

(i.e., we are constraining our variables to a cone in C_6). The IR(M,N) is now uniquely realized in the subspace with constraints [Eq. (36)].

We are forced to contend with the constraint [Eq. (37)] in order to get a model space. We obtain an explicit and simple enough basis by simply eliminating w_3 (say), in favor of the other five variables

$$w_3 = -\frac{1}{z_3}(w_1 z_1 + w_2 z_2). \tag{39}$$

Thus our space is spanned by the monomials (allowing for negative powers of z_3),

$$z_1^{m_1} z_2^{m_2} w_z^{n_1} w_2^{n_2} (w_1 z_1 + w_2 z_2)^{n_3} z_3^{m_3 - n_3}. \tag{40}$$

In order to get an explicit realization of the Gelfand–Zetlin basis in this space, we proceed as follows. Note that (z_1, z_2) transforms as a $\underline{2}$ and (w_1, w_2) as a $\underline{2}^*$ (which is equivalent to $\underline{2}$) under the isospin SU(2) subgroup of SU(3). The combination $(w_1 z_1 + w_2 z_2)$ in Eq. (3.6) is an SU(2) singlet built of these two doublets. This suggests that it is useful to use the coupled basis for the isospin group. This is done as follows. The monomials $z_1^{m_1} z_2^{m_2}$ and $w_1^{n_1} w_2^{n_2}$ with

$$m_1 + m_2 = 2I', \quad n_1 + n_2 = 2I'' \tag{41}$$

span the IRs of (iso)spin I' and I'', respectively. Therefore the direct product of these two spaces is a direct sum of spaces with isospin $I' + I'', I' + I'' - 1, \ldots, |I' - I''|$, each isospin appearing just once. This decomposition can be performed explicitly by the following trick: Introduce an (external) doublet (p,q) transforming as a $\underline{2}^*$ of SU(2). Then the following combination is invariant under SU(2):

$$(p z_1 + q z_2)^R (p w_2 - q w_1)^S (w_1 z_1 + w_2 z_2)^T. \tag{42}$$

Now,

$$\frac{p^P q^Q}{\sqrt{P!}\sqrt{Q!}} \sim \left| I = \frac{P+Q}{2}, \quad I_3 = \frac{-P+Q}{2} \right\rangle \tag{43}$$

under SU(2) transformations. On using Eq. (1) this means that the coefficient of the monomial $p^P q^Q$ corresponds to the state,

$$|(I'I'')I\, I_3\rangle \tag{44}$$

of the coupled basis, where

$$\begin{aligned} R + S = P + Q = 2I, \quad S + T = n_1 + n_2 = 2I'', \\ T + R = m_1 + m_2 = 2I', \quad P - Q = 2I_3. \end{aligned} \tag{45}$$

This way, we are able to explicitly construct basis vectors of the coupled basis. By allowing for all non-negative integer values of P, Q, R, S, and T subject to the constraints of Eq. (45) we are simply making a change of basis from the basis [Eq. (41)]. We make this change of basis in the space spanned by (Eq. 40) (further constrained by Eq. (41). We get an equivalent basis (as coefficients of $p^P q^Q$) in,

$$(p z_1 + q z_2)^R (p w_2 - q w_1)^S (w_1 z_1 + w_2 z_2)^{T + n_3} z_3^{m_3 - n_3}. \tag{46}$$

In terms of the new parameters we have

$$R+T+m_3=M, \quad S+T+n_3=N. \tag{47}$$

We now notice that distinct values of m_3, n_3, and T such that $T+n_3$ and $T+m_3$ have the same values correspond to the same basis vector on the cone $\vec{w}\cdot\vec{z}=0$. This is the way that the repeating IRs in C_6 spanned by $(\vec{w},\vec{z})$ get identified on the five-(complex) dimensional cone $\vec{w}\cdot\vec{z}=0$. Redefine

$$T+m_3=U, \quad T+n_3=V, \tag{48}$$

where U and V are non-negative integers. In terms of these variables, Eq. (47) is

$$R+U=M, \quad S+V=N. \tag{49}$$

Also, from Eq. (44)

$$P+Q=R+S. \tag{50}$$

We started with freely ranging non-negative integers m_i and n_i, subject only to the constraints of Eq. (36). This translates to free non-negative integers P, Q, R, S, U, and V subject to the constraints of Eqs. (49) and (50).

We have finally arrived at the following explicit and convenient realization of the (unnormalized) Gelfand–Zetlin basis of an arbitrary IR of SU(3): Extract the coefficients of various monomials $p^P q^Q$ in

$$(pz_1+qz_2)^R(pw_2-qw_1)^S z_3^U w_3^V, \tag{51}$$

where w_3 is given by Eq. (39). We will denote the space spanned by these basis vectors by $\mathscr{S}(M,N)$.

In the quark model, the basis within each IR is labeled by the quantum numbers I (total isospin), I_3 (the third component of isospin), and Y (the hypercharge) (or equivalently strangeness). These are related to our labels $(PQRSUV)$ as follows:

$$2I=P+Q=R+S, \quad 2I_3=P-Q,$$

$$Y=\tfrac{1}{3}(M-N)+V-U\equiv\tfrac{2}{3}(N-M)-(S-R). \tag{52}$$

Our labels are better because allowed quantum numbers within each IR (M,N) can be read off easily: R takes all values from 0 to M. S takes all values from 0 to N. For a given R and S, Q takes all values from 0 to $R+S$.

IV. THE GENERATING FUNCTION

Our representation [Eq. (51)] of the basis vectors of the IRs of SU(3) is not as simple as the monomial basis of Bargmann for SU(3). We need to use specific polynomials. In spite of this it has enough features of the Bargmann's basis as to be useful for general calculations. We demonstrate this in the following sections.

The first important feature of our basis is the following. By allowing for all possible non-negative integral values for our labels $(PQRSUV)$ subject to the constraint [Eq. (50)], the basis for every IR is realized and moreover realized once only. Further there are homogeneity restrictions on the $\vec{z}$ and $\vec{w}$ variables. Even though we are forced to use polynomials instead of the

monomials for the basis, the polynomials needed can be obtained as the coefficients of a monomial $p^P q^Q$. As a consequence of all this a simple generating function can be used to easily and uniquely generate all unnormalized basis states.

$$\mathbf{g}(p,q,r,s,u,v)=\exp(r(pz_1+qz_2)+s(pw_2-qw_1)+uz_3+vw_3). \tag{53}$$

The coefficient of the *monomial*,

$$p^P q^Q r^R s^S u^U v^V, \tag{54}$$

generates the *unnormalized* Gelfand–Zetlin basis denoted by $|P,Q,R,S,U,V)$. Thus,

$$\mathbf{g}=\sum_{P,Q,R,S,U,V} p^P q^Q r^R s^S u^U v^V |PQRSUV). \tag{55}$$

Note that the constraint [Eq. (50)], $P+Q=R+S$, is automatically satisfied in the Taylor expansion of Eq. (53). We refer to the variables p, q, r, s, u, and v as the sources and collectively denote them by j. Similarly, we refer to the labels P,Q,R,S,U, and V as the quantum numbers and collectively denote them by E. By using the generating function [Eq. (53)] we have come even closer to the Bargmann's techniques for SU(2).

In order to calculate the normalizations of our unnormalized basis vectors, we have to first obtain (as in Sec. II) the representation of the generators as differential operators on $\mathscr{G}$. An infinitesimal SU(3) matrix may be parametrized as follows:

$$\begin{aligned}\mathscr{U}\sim 1+i(&\epsilon(\pi^0)\pi^0+\epsilon(\eta)\eta+\epsilon(\pi^+)\pi^+ +\epsilon(\pi^-)\pi^- \\ &+\epsilon(K^+)K^+ +\epsilon(K^-)K^- +\epsilon(K^0)K^0 +\epsilon(\overline{K^0})\overline{K^0}),\end{aligned} \tag{56}$$

where the (unnormalized) generators are

$$\pi^0=\begin{pmatrix}1&0&0\\0&-1&0\\0&0&0\end{pmatrix};\quad \eta=\begin{pmatrix}1&0&0\\0&1&0\\0&0&-2\end{pmatrix};\quad \pi^-=\begin{pmatrix}0&1&0\\0&0&0\\0&0&0\end{pmatrix},$$

$$\pi^+=\begin{pmatrix}0&0&0\\1&0&0\\0&0&0\end{pmatrix};\quad K^-=\begin{pmatrix}0&0&1\\0&0&0\\0&0&0\end{pmatrix};\quad K^+=\begin{pmatrix}0&0&0\\0&0&0\\1&0&0\end{pmatrix}, \tag{57}$$

$$K^0=\begin{pmatrix}0&0&0\\0&0&1\\0&0&0\end{pmatrix};\quad \overline{K^0}=\begin{pmatrix}0&0&0\\0&0&0\\0&1&0\end{pmatrix}.$$

For unitarity, we have

$$\begin{gathered}\epsilon(\pi^0)^*=\epsilon(\pi^0);\quad \epsilon(\eta)^*=\epsilon(\eta);\\ \epsilon(\pi^+)^*=\epsilon(\pi^-);\quad \epsilon(K^+)^*=\epsilon(K^-);\quad \epsilon(K^0)^*=\epsilon(\overline{K^0}).\end{gathered} \tag{58}$$

Under an SU(3) transformation,

$$\begin{pmatrix} z_1 \\ z_2 \\ z_3 \end{pmatrix} \to \mathscr{U} \begin{pmatrix} z_1 \\ z_2 \\ z_3 \end{pmatrix},$$

$$(w_1 \quad w_2 \quad w_3) \to (w_1 \quad w_2 \quad w_3)\mathscr{U}^+, \tag{59}$$

where $\mathscr{U} \in \mathrm{SU}(3)$. This transformation is true even when w_3 is eliminated in favor of the other variables since the constraint [Eq. (37)] is itself invariant under SU(3). In order to obtain the transformation of **g**, it is convenient to write the exponent in Eq. (53) as follows:

$$(r_p \quad r_q \quad u) \cdot \begin{pmatrix} z_1 \\ z_2 \\ z_3 \end{pmatrix} + (w_1 \quad w_2 \quad w_3) \cdot \begin{pmatrix} s_q \\ s_p \\ v \end{pmatrix}, \tag{60}$$

where

$$r_p = rp, \quad r_q = rq, \quad s_p = sp, \quad s_q = -sq. \tag{61}$$

It is convenient to regard r_p, r_q, s_p, and s_q as independent variables and not related by Eq. (61). Only at the end of the calculations we may set the values [Eq. (61)] and generate the required basis vectors. We will refer to this operation as ''*going on shell*.'' Thus we define the *generalized generating function*:

$$\mathscr{G}(r_p, r_q, u, s_q, s_p, v) = \exp\left((r_p \quad r_q \quad u) \begin{pmatrix} z_1 \\ z_2 \\ z_3 \end{pmatrix} + (w_1 \quad w_2 \quad w_3) \cdot \begin{pmatrix} s_q \\ s_p \\ v \end{pmatrix} \right). \tag{62}$$

Its transformation is

$$\mathscr{G}(r_p, r_q, u, s_q, s_p, v) \to \mathscr{G}\left((r_p \quad r_q \quad u)\mathscr{U}, \mathscr{U}^\dagger \begin{pmatrix} s_q \\ s_p \\ v \end{pmatrix} \right). \tag{63}$$

Substitute Eq. (56) and collect the coefficients of $\epsilon(\pi^+)$, etc., after using Eq. (58).

We get the following representation of the generators:

$$\hat{\pi}^0 = r_p \frac{\partial}{\partial r_p} - r_q \frac{\partial}{\partial r_q} - s_q \frac{\partial}{\partial s_q} + s_p \frac{\partial}{\partial s_p},$$

$$\hat{\pi}^- = r_p \frac{\partial}{\partial r_q} - s_p \frac{\partial}{\partial s_q}, \quad \hat{\pi}^+ = r_q \frac{\partial}{\partial r_p} - s_q \frac{\partial}{\partial s_p},$$

$$\hat{K}^- = r_p \frac{\partial}{\partial u} - v \frac{\partial}{\partial s_q}, \quad \hat{K}^+ = u \frac{\partial}{\partial r_p} - s_q \frac{\partial}{\partial v}, \tag{64}$$

$$\hat{K}^0 = r_q \frac{\partial}{\partial u} - v \frac{\partial}{\partial s_p}, \quad \overline{\hat{K}^0} = u \frac{\partial}{\partial r_q} - s_p \frac{\partial}{\partial v},$$

$$\hat{\eta} = r_p \frac{\partial}{\partial r_p} + r_q \frac{\partial}{\partial r_q} - 2u \frac{\partial}{\partial u} - s_p \frac{\partial}{\partial s_p} - s_q \frac{\partial}{\partial s_q} + 2v \frac{\partial}{\partial v}.$$

For $\hat{\pi}^0$, $\hat{\pi}^\pm$, and $\hat{\eta}$ we may use Eq. (61) and get the following expressions:

$$\hat{\pi}^0 = p\,\frac{\partial}{\partial p} - q\,\frac{\partial}{\partial q}, \quad \hat{\pi}^- = p\,\frac{\partial}{\partial q},$$
$$\hat{\pi}^+ = q\,\frac{\partial}{\partial p}, \quad \hat{\eta} = r\,\frac{\partial}{\partial r} - s\,\frac{\partial}{\partial s} - 2u\,\frac{\partial}{\partial u} + 2v\,\frac{\partial}{\partial v}. \tag{65}$$

However, in order to represent the other generators as differential operators, we need to regard r_p, r_q, s_p and s_q as independent variables. As a result we face the following problem. It is not easy to calculate the matrix elements,

$$(P'Q'R'S'U'V'|T|PQRSUV) \tag{66}$$

of these generators, which are needed to evaluate the normalizations (see Sec. II). Consider for example the action of $\hat{K}^-$ on $\mathbf{g}$:

$$\hat{K}^-\mathbf{g} = (rpz_3 - vw_1)\mathbf{g}. \tag{67}$$

We need to reexpress the effect of z_3 or w_1 multiplying a basis state [Eq. (51)] as a linear combination of such states. But this is not easy.

This is another stumbling block compared to the situation in SU(2). We devise the technique to overcome this problem in Sec. V.

V. AN AUXILIARY GAUSSIAN MEASURE

An important reason for the efficiency of Bargmann's techniques for SU(2) is the Gaussian measure, using calculations which can be performed explicitly and easily. It is obtained as the measure with respect to which the Gelfand–Zetlin vectors form an orthonormal set and the representation matrices are unitary. We have discussed this in Sec. II.

We have a model space using five complex variables $(z_1, z_2, z_3, w_1, w_2)$. The measure in this space with respect to which properly normalized basis vectors form an orthonormal set exists, in principle. Gelfand *et al.*[45] have obtained this measure as the solution of a differential equation in a related context. Unfortunately, this measure does not have the simplicity of the Gaussian measure for SU(2). It appears that using it as a calculational tool to obtain general formulas is quite remote. This is yet another stumbling block in extending the Bargmann techniques to SU(3).

We evade this problem in the following way. We construct an auxiliary measure which is amenable to computations by relaxing the condition that it gives correct *normalizations* of the Gelfand–Zetlin states. We only require that the basis states do form an *orthogonal* set with respect to the measure. This is in fact sufficient for calculations of formulas. The correct normalization of the basis states (which gives a unitary representation) is itself computed using the same measure.

Our condition on the measure may be expressed in terms of the generating function as follows. Define the inner product,

$$(\mathbf{g}', \mathbf{g}) = \int d\mu\, \exp\overline{(r'(p'z_1 + q'z_2) + s'(p'w_2 - q'w_1) + u'z_3 + v'w_3)}$$
$$\times \exp(r(pz_1 + qz_2) + s(pw_2 - qw_1) + (uz_3 + vw_3) \tag{68}$$

between generating functions for different sets of arguments. (The over line in the first exponential means complex conjugation of the expression under it.) The integration is over the variables $(z_1, z_2, z_3, w_1, w_2)$, w_3 being expressed in terms of these other variables. We want this inner product to be of the following type:

$$(\mathbf{g}', \mathbf{g}) = F(\overline{p'}p, \overline{q'}q, \overline{r'}r, \overline{s'}s, \overline{u'}u, \overline{v'}v), \tag{69}$$

where the function F has a Taylor expansion in its arguments about the origin with every coefficient positive definite. Such a form implies that the inner product is zero whenever the powers of the variables (p,q,r,s,u,v) do not match the powers of the corresponding variables (p',q',r',s',u',v'), i.e., Gelfand–Zetlin basis vectors are mutually orthogonal. Moreover the square of the norm given by the corresponding coefficient in the Taylor expansion is positive definite.

Our measure is closely related to Bargmann's. We have two doublets (z_1,z_2) and (w_1,w_2) of SU(2) and the coupled basis built using them. We know that coupled basis is obtained by a unitary transformation of the direct product basis. This means that Bargmann's measure for these two doublets ensures orthogonality of our SU(3) basis vectors in so far as the (z_1,z_2,w_1,w_2) variables are concerned. To be explicit we consider,

$$
\begin{aligned}
F=\int \frac{d^2z_1}{\pi}\frac{d^2z_2}{\pi}\frac{d^2w_1}{\pi}\frac{d^2w^2}{\pi}\exp(-\overline{z_1}z_1-\overline{z_2}z_2-\overline{w_1}w_1-\overline{w_2}w_2)\\
\times\exp\left(\overline{r'(p'z_1+q'z_2)+s'(p'w_2-q'w_1)-\frac{v'}{z_3}(z_1w_1+z_2w_2)+u'z_3}\right)\\
\times\exp\left(r(pz_1+qz_2)+s(pw_2-qw_1)-\frac{v}{z^3}(z_1w_1+z_2w_2)+uz_3\right). \qquad (70)
\end{aligned}
$$

This can be evaluated easily. Write the exponent as

$$
\begin{aligned}
&-(\overline{z_1}\ w_1)\begin{pmatrix}1 & \overline{\left(\frac{v'}{z_3}\right)}\\ \frac{v}{z_3} & 1\end{pmatrix}\begin{pmatrix}z_1\\ \overline{w_1}\end{pmatrix}-(\overline{z_2}\quad w_2)\begin{pmatrix}1 & \overline{\left(\frac{v'}{z_3}\right)}\\ \frac{v}{z_3} & 1\end{pmatrix}\begin{pmatrix}z_2\\ \overline{w_2}\end{pmatrix}+(rp-\overline{(s'q')})\begin{pmatrix}z_1\\ \overline{w_1}\end{pmatrix}\\
&+(\overline{z_1}\ w_1)\begin{pmatrix}\overline{r'p'}\\ -sq\end{pmatrix}+(rq\quad(\overline{s'p'}))\begin{pmatrix}z_2\\ \overline{w_2}\end{pmatrix}+(\overline{z_2}\quad w_2)\begin{pmatrix}\overline{(r'q')}\\ sp\end{pmatrix}+\overline{(u'z_3)}+uz_3. \qquad (71)
\end{aligned}
$$

Use the formula,

$$
\prod_{i=1}^{n}\int\frac{d^2z_i}{\pi}\exp(-\overline{z}^TXz+A^Tz+\overline{z}^T\overline{B})=(\det X)^{-1}\exp(A^TX^{-1}\overline{B}) \qquad (72)
$$

which is valid whenever the Hermitian part of X is positive definite. Here z is the column vector of the complex variables $(z_1,z_2,\ldots,z_n)$. We get,

$$
\begin{aligned}
F=\left(1-\frac{\overline{v'}v}{|z_3|^2}\right)^{-2}\exp\left[\left((1-\overline{v'}v/|z_3|^2)^{-1}\left((rp,-\overline{s'q'})\begin{pmatrix}1 & -\overline{v'}/\overline{z_3}\\ -v/z_3 & 1\end{pmatrix}\begin{pmatrix}\overline{r'p'}\\ -sq\end{pmatrix}\right.\right.\\
\left.\left.+(rq',\overline{s'p'})\begin{pmatrix}1 & -\overline{v'}/\overline{z_3}\\ -v/x_3 & 1\end{pmatrix}\begin{pmatrix}\overline{r'q'}\\ sp\end{pmatrix}\right)+\overline{u'z_3}+uz_3\right]. \qquad (73)
\end{aligned}
$$

Thus,

$$F=\left(1-\frac{\overline{v'}v}{|z_3|^2}\right)^{-2}\exp\left(\frac{(\overline{r'}r+\overline{s'}s)(\overline{p'}p+\overline{q'}q)}{(1-\overline{v'}v/|z_3|^2)}+\overline{u'z_3}+uz_3\right). \tag{74}$$

Note that this has the features [Eq. (69)] we required for the inner product, so far as the variables p, q, r, s, and v are concerned. This was to be expected, because the coupled basis constructed out of two doublets $(z_1 \quad z_2)$ and $(w_1 \quad w_2)$ is an orthogonal set with respect to Bargmann's measure.

We have to now propose a workable measure for integration over the z_3 variable. Note that $|z_3|^2$ appears in the denominators in Eq. (74). This suggests that it is best to set

$$z_3=\epsilon^{i\theta} \tag{75}$$

so that $|z_3|^2=1$. This means that our realization of the basis vectors is in terms of four complex variables z_1, z_2, w_1, w_2, and a phase variable $e^{i\theta}$. Setting the constraint [Eq: (75)] is no problem, because we have used only the variable z_3 and not $\overline{z_3}$ in our basis vectors. (See the Appendix for a more detailed discussion.) Our requirement on the measure for the θ variable is that (i) it is simple and (ii) we get a function of only the combination $\overline{u'}u$. From Eq. (74) we see that it is sufficient to average over θ. Thus the measure we use is

$$(\mathbf{g}',\mathbf{g})=\int_{-\pi}^{+\pi}\frac{d0}{2\pi}\int\frac{d^2z_1}{\pi}\frac{d^2z_2}{\pi}\frac{d^2w_1}{\pi}\frac{d^2w_2}{\pi}\,\overline{\mathbf{g}'}\mathbf{g}. \tag{76}$$

The inner product between two generating functions is

$$(\mathbf{g}',\mathbf{g})=(1-\overline{v'}v)^{-2}\left(\sum_{n=0}^{\infty}\frac{(\overline{u'}u)^n}{(n!)^2}\right)\exp[(1-\overline{v'}v)^{-1}(\overline{p'}p+\overline{q'}q)(\overline{r'}r+\overline{s'}s)]. \tag{77}$$

Notice that the coefficients of the Taylor expansion are all positive definite. This is a satisfactory inner product which we may use do to computations explicitly.

For our calculations, we need the inner product between any two generalized generating functions [Eq. (62)]. In place of Eq. (74), we get

$$\begin{aligned}(\mathscr{G}',\mathscr{G})=\int\frac{d\theta}{2\pi}(1-\overline{v'}v)^{-2}\exp\Bigg[&(1-\overline{v'}v)^{-1}(r_p \quad \overline{s'_q})\begin{pmatrix}1 & -\overline{v'}e^{i\theta}\\ -ve^{-i\theta} & 1\end{pmatrix}\begin{pmatrix}\overline{r'_p}\\ s_q\end{pmatrix}\\ &+\left((r_q \quad \overline{s'_p})\begin{pmatrix}1 & -\overline{v'}e^{+i\theta}\\ -ve^{-i\theta} & 1\end{pmatrix}\begin{pmatrix}\overline{r'_q}\\ s_p\end{pmatrix}+\overline{u'}e^{-i\theta}+ue^{i\theta}.\right.\end{aligned} \tag{78}$$

Therefore,

$$\begin{aligned}(\mathscr{G}',\mathscr{G})=&(1-\overline{v'}v)^{-2}\exp[(1-\overline{v'}v)^{-1}(\overline{r'_p}r_p+\overline{r'_q}r_q+\overline{s'_p}s_p+\overline{s'_q}s_q)]\\ &\times\left[\sum_{n=0}^{\infty}\frac{1}{(n!)^2}\left(\overline{u'}-v\,\frac{(\overline{r'_ps'_q}+\overline{r'_qs'_p})}{(1-\overline{v'}v)}\right)^n\left(u-\overline{v'}\,\frac{(r_ps_q+r_qs_p)}{(1-\overline{v'}v)}\right)^n\right].\end{aligned} \tag{79}$$

VI. CALCULATION OF THE NORMALIZATIONS

We now compute the normalization of our representation [Eq. (51)] of the (unnormalized) basis vectors. As discussed in Sec. II, this is obtained from the requirement that the representation matrix be unitary in each IR. Our technique differs from the one discussed in Sec. II in one crucial respect.

Let $|E)$ denote any unnormalized basis vector defined by the expansion [Eq. (55)]. E stands for the set of quantum numbers used in the basis. For any generator T let

$$T|E) = \sum_{E'} T(E,E')|E'). \tag{80}$$

We want to compute $N(E)$ defined by

$$|E) = N^{1/2}(E)|E\rangle, \tag{81}$$

where $|E\rangle$ denotes any Gelfand–Zetlin normalized basis vector:

$$\langle E'|E\rangle = \delta_{E'E}. \tag{82}$$

The representation matrix is unitary when the basis vectors $|E\rangle$ are used. $N(E)$ is obtained by the requirement,

$$\langle E'|T|E\rangle = \langle E|T^*|E'\rangle^* \tag{83}$$

for every generator T and for any normalized basis vectors $|E\rangle$ and $|E'\rangle$. We have from Eq. (80) and Eq. (81),

$$N^{1/2}(E)T|E\rangle = \sum_{E'} T(E,E')N^{1/2}(E')|E'\rangle \tag{84}$$

so that,

$$\langle E'|T|E\rangle = T(E,E')\,\frac{N^{1/2}(E')}{N^{1/2}(E)}. \tag{85}$$

Therefore, Eq. (83) gives

$$\left|\frac{N(E)}{N(E')}\right| = \frac{T(E,E')}{(T(E',E))^*}. \tag{86}$$

This means we need to evaluate $T(E,E')$, defined in Eq. (80). For this we use our ''auxiliary'' inner product given by Eq. (76). We denote this inner product between two vectors $|1)$ and $|2)$ by

$$(2\|1) \tag{87}$$

to distinguish it from the ''true'' inner product given by Eq. (82). The Gelfand–Zetlin normalized basis vectors $|E\rangle$ do form an orthogonal set but have a different norm with respect to the auxiliary inner product. Therefore,

$$(E'\|E) = \delta_{E'E}M(E), \tag{88}$$

where $M(E)$ is different from $N(E)$ in general. Using Eq. (88) in Eq. (80) we get

$$(E'\|(T|E)) = T(E,E')M(E'). \tag{89}$$

Therefore Eq. (86) gives

$$\left|\frac{N(E)}{N(E')}\right| = \frac{(E'\|T|E)}{(E\|T^*|E')^*}\,\frac{M(E)}{M(E')}. \tag{90}$$

Thus we can fix the normalization using an ''auxiliary'' inner product which allows explicit computation, even though it is not the ''true'' inner product.

$M(P,Q,R,S,U,V)$ can be read off as the coefficient of the monomial:

$$(\overline{p'}p)^P(\overline{q'}q)^Q(\overline{r'}r)^R(\overline{s'}s)^S(\overline{u'}u)^U(\overline{v'}v)^V$$

in Eq. (77).

We have

$$(\mathbf{g}',\mathbf{g})=\left(\sum_{2I=0}^{\infty}\frac{(\overline{p'}p+\overline{q'}q)^{2I}(\overline{r'}r+\overline{s'}s)^{2I}}{(2I)!(1-\overline{v'}v)^{2I+2}}\right)\left(\sum_{V=0}^{\infty}\frac{(\overline{u'}u)^U}{(U!)^2}\right). \tag{91}$$

Using

$$(x+y)^n=\sum_{m=0}^{n}{}^nC_m x^m y^{n-m} \tag{92}$$

and

$$\frac{1}{(1-x)^{m+1}}=\sum_{n=0}^{\infty}{}^{(n+m)}C_n x^n \tag{93}$$

we get

$$M(P,Q,R,S,U,V)=\frac{(V+2I+1)!}{P!Q!R!S!(U!)^2V!(2I+1)}. \tag{94}$$

We have used $2I=P+Q=R+S$.

We now apply the formula of Eq. (90) for each of our generators [Eq. (64)]. The generators $\hat{\pi}^0$ and $\hat{\eta}$ are diagonal in the chosen basis and therefore do not lead to any constraints on the relative normalizations of the basis vectors. Consider $\hat{\pi}^-$ as given by Eq. (65). We get

$$(\mathbf{g}',\hat{\pi}^-\mathbf{g})=p\,\frac{\partial}{\partial q}\,(\mathbf{g}',\mathbf{g})=p\overline{q'}\,\frac{(\overline{r'}r+\overline{s'}s)}{(1-\overline{v'}v)}\,(\mathbf{g}',\mathbf{g}) \tag{95}$$

on using Eq. (77). Extracting like powers of the monomials from both sides of Eq. (92), we get

$$(P,Q+1,R,S,U,V)\|\hat{\pi}^-|P+1,Q,R,S,U,V)=M_3(P,Q,R,S,U,V) \tag{96}$$

as the only nonzero auxiliary matrix element of $\hat{\pi}^-$. This is expected because $\hat{\pi}^-$ only lowers the I_3 value by 1 [see (Eq. (52)]. $M_3(P,Q,R,S,U,V)$ is listed in Table I. Similarly we get

$$(P+1,Q,R,S,U,V\|\hat{\pi}^+|P,Q+1,R,S,U,V)=M_3(P,Q,R,S,U,V). \tag{97}$$

Thus, in the present case,

$$(P,Q+1,R,S,U,V\|\hat{\pi}^-|P+1,Q,R,S,U,V)=(P+1,Q,R,S,U,V\|\hat{\pi}^+|P,Q+1,R,S,U,V) \tag{98}$$

since $M_3(P,Q,R,S,U,V)$ is real. Therefore the auxiliary normalization, also gives the Gelfand–Zetlin normalizations, is in this case:

$$\left|\frac{N(P+1,Q,R,S,U,V)}{N(P,Q+1,R,S,U,V)}\right|=\frac{M(P+1,Q,R,S,U,V)}{M(P,Q+1,R,S,U,V)}. \tag{99}$$

TABLE I. Normalization constants.

$M(P,Q,R,S,U,V)$	$\frac{\exp[(1-\overline{v}'v)^{-1}(\overline{p}'p+\overline{q}'q)(\overline{r}'r+\overline{s}'s)]}{(1-\overline{v}'v)^2}\sum_n \frac{(\overline{u}'u)^n}{(n!)^2}$	$\frac{(2I+1+V)!}{P!Q!R!S!U!V!}\frac{1}{U!(2I+1)}$
$M_1(P,Q,R,S,U,V)$	$\frac{\exp[(1-\overline{v}'v)^{-1}(\overline{p}'p+\overline{q}'q)(\overline{r}'r+\overline{s}'s)]}{(1-\overline{v}'v)^3}\sum_n \frac{(\overline{u}'u)^n}{(n!)^2}$	$\frac{(2I+2+V)!}{P!Q!R!S!U!V!}\frac{1}{U!(2I+1)(2I+2)}$
$M_2(P,Q,R,S,U,V)$	$\frac{\exp[(1-\overline{v}'v)^{-1}(\overline{p}'p+\overline{q}'q)(\overline{r}'r+\overline{s}'s)]}{(1-\overline{v}'v)^4}\sum_n \frac{(\overline{u}'u)^n}{(n!)^2}$	$\frac{(2I+3+V)!}{P!Q!R!S!U!V!}\frac{1}{U!(2I+1)(2I+2)(2I+3)}$
$M_3(P,Q,R,S,U,V)$	$\frac{\exp[(1-\overline{v}'v)^{-1}(\overline{p}'p+\overline{q}'q)(\overline{r}'r+\overline{s}'s)]}{(1-\overline{v}'v)^3}\times(\overline{r}'r+\overline{s}'s)\sum_n \frac{(\overline{u}'u)^n}{(n!)^2}$	Not needed
$M_4(P,Q,R,S,U,V)$	$\frac{\exp[(1-\overline{v}'v)^{-1}(\overline{p}'p+\overline{q}'q)(\overline{r}'r+\overline{s}'s)]}{(1-\overline{v}'v)^4}\times(\overline{p}'p+\overline{q}'q)(\overline{r}'r+\overline{s}'s)\sum_n \frac{(\overline{u}'u)^n}{(n!)^2}$	$\frac{(2I+2+V)!}{P!Q!R!S!U!V!}\frac{2I}{U!(2I+1)(2I+2)}$
$M_5(P,Q,R,S,U,V)$	$\frac{\exp[(1-\overline{v}'v)^{-1}(\overline{p}'p+\overline{q}'q)(\overline{r}'r+\overline{s}'s)]}{(1-\overline{v}'v)^2}\sum_n \frac{(\overline{u}'u)^n}{(n+1)!n!}$	$\frac{(2I+1+V)!}{P!Q!R!S!U!V!}\frac{1}{(U+1)!(2I+1)}$
$M_6(P,Q,R,S,U,V)$	$\frac{\exp[(1-\overline{v}'v)^{-1}(\overline{p}'p+\overline{q}'q)(\overline{r}'r+\overline{s}'s)]}{(1-\overline{v}'v)^3}\sum_n \frac{(\overline{u}'u)^n}{(n+1)!n!}$	$\frac{(2I+2+V)!}{P!Q!R!S!U!V!}\frac{1}{(U+1)!(2I+1)(2I+2)}$

The reason for this matching is that for the SU(2) subgroup we are using just the Bargmann measure. Using Table I we get,

$$\left|\frac{N(P+1,Q,R,S,U,V)}{N(P,Q+1,R,S,U,V)}\right|=\frac{Q+1}{P+1}, \tag{100}$$

exactly as in the SU(2) case (Sec. II). Thus the relative normalizations of basis vectors within an isospin multiplet are determined and are the same as in the SU(2) case:

$$N(P,Q,R,S,U,V)\sim\frac{1}{P!Q!}. \tag{101}$$

The dependence on the total isospin $P+Q=R+S$ as also on quantum numbers, R, S, U, and V are not determined at this stage.

We now compute the relative normalizations implied by $\hat{K}^{\pm}$. To calculate, $(\mathbf{g}',\hat{K}^{-}\mathbf{g})$ we use the generalized partition function:

$$(\mathbf{g}',\hat{K}^{-}\mathbf{g})=\left(r_p\frac{\partial}{\partial u}-v\frac{\partial}{\partial s_q}\right)(\mathscr{G}',\mathscr{G})\Big|, \tag{102}$$

where the vertical line at the end of this equation means that after applying a differential operator on $(\mathscr{G}',\mathscr{G})$, we need to set the values [Eq. (61)] for the sources. For instance,

$$(r_p s_q+r_q s_p)\big|=0;\quad (\overline{r_p}'\overline{s_q}'+\overline{r_q}'\overline{s_p}')\big|=0. \tag{103}$$

We get

$$(\mathbf{g}',\hat{K}^-\mathbf{g}) = \frac{1}{(1-\overline{v'}v)^2}\exp[(1-\overline{v'}v)^{-1}(\overline{p'}p+\overline{q'}q)(\overline{r'}r+\overline{s'}s)] \times\left[rp\sum_{n=0}^{\infty}\frac{\overline{u'}^{n+1}u^n}{(n+1)!n!}+\frac{v\overline{s'q'}}{(1-\overline{v'}v)}\sum_{n=0}^{\infty}\frac{\overline{u'}^n u^n}{(n!)^2}+\frac{v\overline{v'}rp}{(1-\overline{v'}v)}\sum_{n=0}^{\infty}\frac{\overline{u'}^{n+1}u^n}{(n+1)!n!}\right]. \tag{104}$$

Matching coefficients of like powers we get (Table I)

$$(P,Q,R,S,U+1,V\|\hat{K}^-|P+1,Q,R+1,S,U,V) = M_5(P,Q,R,S,U,V)+M_6(P,Q,R,S,U,V-1), \tag{105}$$

$$(P,Q+1,R,S+1,U,V\|\hat{K}^-|P,Q,R,S,U,V+1)=M_4(P,Q,R,S,U,V). \tag{106}$$

These nonzero matrix elements are as expected for $I=\frac{1}{2}$, $I_3=-\frac{1}{2}$, $Y=+1$ quantum numbers for $\hat{K}^-$. Similarly,

$$(P+1,Q,R+1,S,U,V)\|\hat{K}^+|P,Q,R,S,U+1,V)=M_4(P,Q,R,S,U,V), \tag{107}$$

$$(P,Q,R,S,U,V+1\|\hat{K}^+|P,Q+1,R,S+1,U,V) = M_6(P,Q,R,S,U-1,V)+2M_4(P,Q,R,S,U,V)+M_4(P,Q,R,S,U,V). \tag{108}$$

Using Eq. (91) we get the following constraints on relative normalizations from Eqs. (103)–(106):

$$\left|\frac{N(P+1,Q,R+1,S,U,V)}{N(P,Q,R,S,U+1,V)}\right|=(V+2I+2)\frac{(U+1)}{(P+1)(R+1)}\frac{(2I+1)}{(2I+2)}, \tag{109}$$

$$\left|\frac{N(P,Q+1,R,S+1,U,V)}{N(P,Q,R,S,U,V+1)}\right|=(U+2I+2)\frac{(V+1)}{(Q+1)(S+1)}\frac{(2I+1)}{(2I+2)}. \tag{110}$$

A solution for Eqs. (107) and (108) is

$$N(P,Q,R,S,U,V)=\frac{(U+2I+1)!(V+2I+1)!}{P!Q!R!S!U!V!(2I+1)}. \tag{111}$$

We now consider the nonuniqueness in this solution. The quantum numbers, Q, S, V, $P+U$, and $R+U$ do not change between the numerator and the denominator of Eq. (109). Therefore dependence of $N(P,Q,R,S,U,V)$ on these quantum numbers are not fixed by Eq. (109). However, Eq. (110) serves to fix the dependence on Q,S,V. Therefore the only ambiguity is in dependence of the combinations $P+U$ and $R+U$. We may hope that this ambiguity is removed by the constraints coming from the remaining generators $\hat{K}^0$ and $\hat{\bar{K}}^0$. The nonzero matrix elements of these generators in the unnormalized basis are:

$$(P,Q,R,S,U+1,V\|\hat{K}^0|P,Q+1,R+1,S,U,V) = M_5(P,Q,R,S,U,V)+M_6(P,Q,R,S,U,V-1), \tag{112}$$

$$(P+1,Q,R,S+1,U,V\|\hat{K}^0|P,Q,R,S,U,V+1)=-M_1(P,Q,R,S,U,V), \tag{113}$$

$$(P,Q+1,R+1,S,U,V\|\hat{K}^0|P,Q,R,S,U+1,V)=M_1(P,Q,R,S,U,V), \tag{114}$$

$$(P,Q,R,S,U,V+1)\|\hat{K}^0|P+1,Q,R,S+1,U,V)$$
$$=-M_6(P,Q,R,S,U-1,V)-2M_1(P,Q,R,S,U,V)-M_4(P,Q,R,S,U,V). \tag{115}$$

This gives the constraints,

$$\left|\frac{N(P,Q+1,R+1,S,U,V)}{N(P,Q,R,S,U+1,V)}\right|=(V+2I+2)\,\frac{(U+1)}{(Q+1)(R+1)}\,\frac{(2I+1)}{(2I+2)}, \tag{116}$$

$$\left|\frac{N(P+1,Q,R,S+1,U,V)}{N(P,Q,R,S,U,V+1)}\right|=(U+2I+2)\,\frac{(V+1)}{(P+1)(S+1)}\,\frac{(2I+1)}{(2I+2)}. \tag{117}$$

As expected, these constraints fix the dependence on $P+U$ and $R+U$. Thus the normalization factor of our unnormalized basis states is uniquely fixed by Eq. (111). It is worth noting that the matrix elements Eqs. (106), (108), and (114) are all equal and differ only in sign from Eq. (113). Similarly, Eqs. (105) and (112) are equal, whereas Eq. (108) only differs in sign from Eq. (115). As a consequence, there is a certain symmetry in the constraints [Eqs. (109), (110), (116), and (117) of the normalizations. (See Table I.) These relations between matrix elements with respect to auxiliary inner product between unnormalized basis states is a consequence of our choices of the inner product and basis states. They do not seem to have any group theoretic reason. Anyway we are only interested in matrix elements between normalized states.

VII. THE 3-G SYMBOLS

In this section, we mostly review well-known material[1,2,15,48,23] in order to fix our notations and for logical continuity. In addition we emphasize the relation between the multiplicity in the Clebsch–Gordan series and the distinct invariants that can be constructed out of three IRs. Consider a compact group G. We denote the basis of states of unitary irreducible representations by

$$\left|\begin{matrix}\lambda\\ \alpha\end{matrix}\right\rangle, \tag{118}$$

where λ labels the IRs and α labels the basis for the IRs. For SU(3), for instance, we may use the ordered pair (M,N) for λ and (I,I_3,Y) for α. Consider the direct product of two IRs, λ and λ'. This can be completely reduced to the IRs of the group. In general, the same IR λ'' may appear more than once in the decomposition. Therefore we need extra labels for the IRs of the decomposition. We denote these additional labels collectively by k. (We discuss this in detail[25,26] for SU(3) in Sec. VIII). Thus we may write

$$\left|\begin{matrix}\lambda''\\ \alpha''\end{matrix}\right\rangle^k=\sum_{\alpha,\alpha'}\left|\begin{matrix}\lambda\\ \alpha\end{matrix}\right\rangle\left|\begin{matrix}\lambda'\\ \alpha'\end{matrix}\right\rangle\left\langle\begin{matrix}\lambda\lambda'\\ \alpha\alpha'\end{matrix}\right|\left.\begin{matrix}\lambda''\\ \alpha''\end{matrix}\right\rangle^k, \tag{119}$$

where $|{}^{\lambda''}_{\alpha''}\rangle^k$ are the basis vectors of the repeating IR λ'' and where the repetitions are labeled by k. The coefficients in this expansion,

$$\left\langle\begin{matrix}\lambda\lambda'\\ \alpha\alpha'\end{matrix}\right|\left.\begin{matrix}\lambda''\\ \alpha''\end{matrix}\right\rangle^k, \tag{120}$$

are the Wigner–Clebsch–Gordan coefficients of G. Equation (119) provides a unitary transformation from the basis of the IRs of the decomposition to the direct product basis. Inverse transformation may be written as

$$\left|\begin{matrix}\lambda\\ \alpha\end{matrix}\right\rangle\left|\begin{matrix}\lambda'\\ \alpha'\end{matrix}\right\rangle=\sum_{\alpha'',k}\left|\begin{matrix}\lambda''\\ \alpha''\end{matrix}\right\rangle^{k\,k}\left\langle\begin{matrix}\lambda''\\ \alpha''\end{matrix}\middle|\begin{matrix}\lambda\lambda'\\ \alpha\alpha'\end{matrix}\right\rangle. \tag{121}$$

We get

$$\sum_{\lambda'',k,\alpha''}\left\langle\begin{matrix}\lambda\lambda'\\ \alpha\alpha'\end{matrix}\middle|\begin{matrix}\lambda''\\ \alpha''\end{matrix}\right\rangle^{k\,k}\left\langle\begin{matrix}\lambda''\\ \alpha''\end{matrix}\middle|\begin{matrix}\lambda\lambda'\\ \beta\beta'\end{matrix}\right\rangle=\delta_{\alpha\beta}\delta_{\alpha'\beta'}, \tag{122}$$

$$\sum_{\alpha,\alpha'}{}^{k}\left\langle\begin{matrix}\lambda''\\ \alpha''\end{matrix}\middle|\begin{matrix}\lambda\lambda'\\ \alpha\alpha'\end{matrix}\right\rangle\left\langle\begin{matrix}\lambda\lambda'\\ \alpha\alpha'\end{matrix}\middle|\begin{matrix}\lambda'''\\ \alpha'''\end{matrix}\right\rangle^{k'}=\delta_{kk'}\delta_{\lambda''\lambda'''}\delta_{\alpha''\alpha'''}. \tag{123}$$

Let $D(g)^{\lambda}$ denote the unitary representation matrix of an element $g\in G$ in the IR λ. Thus under the group action,

$$g:\left|\begin{matrix}\lambda\\ \alpha\end{matrix}\right\rangle\rightarrow\sum_{\beta}D^{\lambda}_{\alpha\beta}(g)\left|\begin{matrix}\lambda\\ \beta\end{matrix}\right\rangle. \tag{124}$$

The matrices $\overline{D^{\lambda}}(g)$ whose elements are complex conjugates of $D^{\lambda}(g)$,

$$(\overline{D(g)})_{\alpha\beta}=(D^{\lambda}(g))^{*}_{\alpha\beta}, \tag{125}$$

also provide an irreducible representation of the group called the representation $\overline{\lambda}$ conjugate to λ. For SU(3), the IR (N,M) is the conjugate of (M,N). Define basis states

$$\left|\begin{matrix}\lambda\\ \alpha\end{matrix}\right\rangle_{c} \tag{126}$$

transforming like

$$g:\left|\begin{matrix}\lambda\\ \alpha\end{matrix}\right\rangle_{c}\rightarrow\sum_{\beta}(D(g)^{\lambda}_{\alpha\beta})^{*}\left|\begin{matrix}\lambda\\ \beta\end{matrix}\right\rangle_{c}. \tag{127}$$

This means

$$\begin{aligned}g:\sum_{\alpha}\left|\begin{matrix}\lambda\\ \alpha\end{matrix}\right\rangle\left|\begin{matrix}\lambda\\ \alpha\end{matrix}\right\rangle_{c}&\rightarrow\sum_{\alpha}\left(\sum_{\beta}(D(g))^{\lambda}_{\alpha\beta}\left|\begin{matrix}\lambda\\ \beta\end{matrix}\right\rangle\right)\left(\sum_{\gamma}(D(g)^{\lambda}_{\alpha\gamma})^{*}\left|\begin{matrix}\lambda\\ \gamma\end{matrix}\right\rangle_{c}\right)\\ &=\sum_{\beta,\gamma}(D^{\lambda\dagger}(g)D(g)^{\lambda})_{\gamma\beta}\left|\begin{matrix}\lambda\\ \beta\end{matrix}\right\rangle\left|\begin{matrix}\lambda\\ \gamma\end{matrix}\right\rangle_{c}=\sum_{\alpha}\left|\begin{matrix}\lambda\\ \alpha\end{matrix}\right\rangle\left|\begin{matrix}\lambda\\ \alpha\end{matrix}\right\rangle_{c}\end{aligned} \tag{128}$$

since $D(g)$ is unitary. Therefore

$$\frac{1}{\sqrt{d_{\lambda}}}\sum_{\alpha}\left|\begin{matrix}\lambda\\ \alpha\end{matrix}\right\rangle\left|\begin{matrix}\lambda\\ \alpha\end{matrix}\right\rangle_{c} \tag{129}$$

(where d_λ is the dimension of the IR λ) (i) is invariant under the group; (ii) is the unique invariant vector in the direct product space of λ and $\bar{\lambda}$ (since there is one, and only one singlet in the decomposition of the direct product of λ and $\bar{\lambda}$.); (iii) it has unit norm. Now $|^{\lambda''}_{\alpha''}\rangle^k$ in Eq. (119) transforms like the IR λ'' for every k. Therefore,

$$\frac{1}{\sqrt{d_\lambda}} \sum_{\alpha''} \left|\begin{matrix}\lambda'' \\ \alpha''\end{matrix}\right\rangle^k \left|\begin{matrix}\lambda'' \\ \alpha''\end{matrix}\right\rangle_c \tag{130}$$

is an invariant with unit norm for every k. Use this in Eq. (119). We get, in the direct product of three IRs, λ, λ' and λ'',

$$\frac{1}{\sqrt{d''_\lambda}} \sum_{\alpha,\alpha',\alpha''} \left\langle\begin{matrix}\lambda\lambda' \\ \alpha\alpha'\end{matrix}\middle|\begin{matrix}\lambda'' \\ \alpha''\end{matrix}\right\rangle^k \left|\begin{matrix}\lambda \\ \alpha\end{matrix}\right\rangle \left|\begin{matrix}\lambda' \\ \alpha'\end{matrix}\right\rangle \left|\begin{matrix}\lambda'' \\ \alpha''\end{matrix}\right\rangle_c \tag{131}$$

(i) is, for each k, an invariant of unit norm, (ii) are linearly independent vectors in the direct product space for various k's. (This is because $|^{\lambda''}_{\alpha''}\rangle^k$ in Eq. (119) are linearly independent for various k.) (iii) are the only invariant vectors in the direct product space of λ, λ' and λ''. This is because Eq. (129) are the only invariant vectors formed from $|^{\lambda''}_{\alpha''}\rangle^k$. We will rewrite Eq. (131) in the following way. Define the 3–G *symbols*,

$$\left[\begin{matrix}\lambda\lambda'\lambda'' \\ \alpha\alpha'\alpha''\end{matrix}\right]_k = \frac{1}{\sqrt{d_{\lambda''}}} \left\langle\begin{matrix}\lambda\lambda' \\ \alpha\alpha'\end{matrix}\middle|\begin{matrix}\lambda'' \\ \alpha''\end{matrix}\right\rangle^k_c . \tag{132}$$

Noting that

$$\left(\left|\begin{matrix}\lambda \\ \alpha\end{matrix}\right\rangle_c\right)_c = \left|\begin{matrix}\lambda \\ \alpha\end{matrix}\right\rangle, \tag{133}$$

we see that,

$$\sum_{\alpha,\alpha',\alpha''} \left[\begin{matrix}\lambda\lambda'\lambda'' \\ \alpha\alpha'\alpha''\end{matrix}\right]_k \left|\begin{matrix}\lambda \\ \alpha\end{matrix}\right\rangle \left|\begin{matrix}\lambda' \\ \alpha'\end{matrix}\right\rangle \left|\begin{matrix}\lambda'' \\ \alpha''\end{matrix}\right\rangle \tag{134}$$

give all linearly independent invariant vectors in the direct product space of three IRs λ, λ', and λ''. This gives the generalization of the definition [Eq. (28)] of $3j$ symbols. Thus the number of linearly independent invariant vectors and hence the 3–G symbols, are given by the outer multiplicity of λ'' in the direct product of λ and λ'. For SU(2) there is just one.

We now consider the normalization of the 3–G symbols. The basis vectors of all three IRs in Eq. (119) are orthonormal. Therefore we get

$$\sum_{\alpha\alpha'} \left\langle\begin{matrix}\lambda\lambda' \\ \alpha\alpha'\end{matrix}\middle|\begin{matrix}\lambda'' \\ \alpha''\end{matrix}\right\rangle^k \left\langle\begin{matrix}\lambda\lambda' \\ \alpha\alpha'\end{matrix}\middle|\begin{matrix}\lambda''' \\ \alpha'''\end{matrix}\right\rangle^{k'} = \delta_{kk'}\delta_{\lambda''\lambda'''}\delta_{\alpha''\alpha'''} . \tag{135}$$

For 3–G symbols, this gives [see Eq. (132)]

$$\sum_{\alpha\alpha'} \left[\begin{matrix}\lambda\lambda'\lambda'' \\ \alpha\alpha'\alpha''\end{matrix}\right]_k \left[\begin{matrix}\lambda\lambda'\lambda''' \\ \alpha\alpha'\alpha'''\end{matrix}\right]^*_{k'} = \frac{1}{d_{\lambda''}} \delta_{kk'}\delta_{\lambda''\lambda'''}\delta_{\alpha''\alpha'''} . \tag{136}$$

VIII. INVARIANTS IN THE SPACE $S(M^1N^1)\otimes S(M^2N^2)\otimes S(M^3N^3)$

The next step in obtaining a formula for the Clebsch–Gordan coefficients is to construct the invariants [Eq. (134)] using our realization of the basis vectors. This corresponds to Eq. (30) in the case of SU(2). However, the computation for SU(3) is more complicated for the following reasons.

(1) The variables (z_1,z_2,θ,w_1,w_2) that we use do not transform linearly under SU(3) in contrast to the variables (z_1,z_2) of the SU(2) case (see the Appendix).
(2) We can form more than one invariant in contrast to the SU(2) case.

To analyze the situation we first ignore the constraint $\vec{w}\cdot\vec{z}=0$. Consider three vector spaces, $\mathscr{P}(M^1,N^1)$, $\mathscr{P}(M^2N^2)$, and $\mathscr{P}(M^3N^3)$ built of polynomials in variables $(\vec{z}^1,\vec{w}^1)$, $(\vec{z}^2,\vec{w}^2)$, and $(\vec{z}^3,\vec{w}^3)$, respectively. $\mathscr{P}(M^a,N^a)$, $a=1$, 2, or 3 is the space of polynomials homogeneous of degree M in (z_1,z_2,z_3) and of degree N in (w_1,w_2,w_3), respectively. Invariant theory can be applied[15,21,23] to this situation. The result is that any invariant can be constructed out of the basic invariants,

$$\vec{z}^1\cdot\vec{w}^1,\quad \vec{z}^1\cdot\vec{w}^2,\quad \vec{z}^1\cdot\vec{w}^3,$$

$$\vec{z}^2\cdot\vec{w}^1,\quad \vec{z}^2\cdot\vec{w}^2,\quad \vec{z}^2\cdot\vec{w}^3,$$

$$\vec{z}^3\cdot\vec{w}^1,\quad \vec{z}^3\cdot\vec{w}^2,\quad \vec{z}^3\cdot\vec{w}^3, \tag{137}$$

$$\vec{z}^1\cdot\vec{z}^2\times\vec{z}^3,\quad \vec{w}^1\cdot\vec{w}^2\times\vec{w}^3. \tag{138}$$

Further, these invariants are not all independent, because

$$(\vec{z}^1\cdot\vec{z}^2\times\vec{z}^3)(\vec{w}_1\cdot\vec{w}^2\times\vec{w}^3)$$
$$=\begin{vmatrix} z_1^1 & z_2^1 & z_3^1\\ z_1^2 & z_2^2 & z_3^2\\ z_1^3 & z_2^3 & z_3^3\end{vmatrix}\times\begin{vmatrix} w_1^1 & w_1^2 & w_1^3\\ w_2^1 & w_2^2 & w_2^3\\ w_3^1 & w_3^2 & w_3^3\end{vmatrix}=\begin{vmatrix} \vec{z}^1\cdot\vec{w}^1 & \vec{z}^1\cdot\vec{w}^2 & \vec{z}^1\cdot\vec{w}^3\\ \vec{z}^2\cdot\vec{w}^1 & \vec{z}^2\cdot\vec{w}^2 & \vec{z}^2\cdot\vec{w}^3\\ \vec{z}^3\cdot\vec{w}^1 & \vec{z}^3\cdot\vec{w}^2 & \vec{z}^3\cdot\vec{w}^3\end{vmatrix}. \tag{139}$$

Thus we may remove either $\vec{z}^1\cdot\vec{z}^2\times\vec{z}^3$ or $\vec{w}^1\cdot\vec{w}^2\times\vec{w}^3$ from the list of basic invariants Eq. (137) and (138). Any invariant is a function of the remaining ten invariants. To decide which of the two invariants [Eq. (139)] is to be kept, note that we are interested in polynomials in the three sets of six variables. Therefore, we permit only positive integral powers of *either* $\vec{z}^1\cdot\vec{z}^2\times\vec{z}^3$ or $\vec{w}^1\cdot\vec{w}^2\times\vec{w}^3$ in addition to those of Eq. (137). This gives all independent invariant polynomials. We will not be repeating polynomials which are identical on using Eq. (139). This is because if we were to replace $\vec{z}^1\cdot\vec{z}^2\times\vec{z}^2$ in a polynomial by $\vec{w}^1\cdot\vec{w}^2\times\vec{w}^3$ using Eq. (139), the latter would be appearing in the denominator. Therefore it would not coincide with any linear combination of the other polynomials we have considered.

Thus a general invariant polynomial is a linear combination of the following invariants:

$$\mathscr{P}(N(1,1),N(1,2),N(1,3),N(2,1),N(2,2),N(2,3),N(3,1),N(3,2),N(3,3),L)$$
$$=(z^1\cdot w^1)^{N(1,1)}(z^1\cdot w^2)^{N(1,2)}(z^1\cdot z^3)^{N(1,3)}(z^2\cdot z^1)^{N(2,1)}(z^2\cdot w^2)^{N(2,2)}(z^2\cdot w^3)^{N(2,3)}$$
$$\times(\vec{z}^3\cdot\vec{w}^1)^{N(3,1)}(\vec{z}^3\cdot\vec{w}^2)^{N(3,2)}(\vec{z}^3\cdot\vec{w}^3)^{N(3,3)}((\vec{z}^1\cdot\vec{z}^2\times\vec{z}^3)^L \text{ or } (\vec{w}^1\cdot\vec{w}^2\times\vec{w}^3)^{-L}). \tag{140}$$

We have adopted the following notation. If L is a positive (likewise negative) integer, the invariant has the term $(z^1 \cdot z^2 \times z^3)^L$ [likewise $(w^1 \cdot w^2 \times w^3)^{-L}$]. This way, both possibilities are labeled by a single integer L taking both positive and negative values. The other labels, $N(a,b), a,b=1, 2,$ or 3 freely range over all non-negative integers.

The invariants in the space $\mathscr{F}(M^1,N^1)\otimes\mathscr{F}(M^2,N^2)\otimes\mathscr{F}(M^3,N^3)$ have to be built from a linear combination of those invariants [Eq. (140)] for which

$$\begin{aligned} &\sum_{b=1}^{3} N(a,b)+L\,\epsilon(L)=M^a, \\ &\sum_{b=1}^{3} N(b,a)+|L|\,\epsilon(-L)=N^a, \quad a=1,2,3. \end{aligned} \tag{141}$$

Here,

$$\begin{aligned} &\epsilon(L)=1, \quad L\geqslant 0, \\ &\epsilon(L)=-1, \quad L<0. \end{aligned} \tag{142}$$

For three given IRs, this gives six equations for ten unknowns $N(a,b)$ and L. Therefore, there are many independent invariants, in general.

In order to obtain the 3-SU(3) symbols (Sec. VII) we have to expand these invariants in terms of a realization of the SU(3) basis vectors as polynomials in $\vec{z}^a$ and $\vec{w}^a$. The analogous procedure for SU(2), discussed in Sec. II, is very simple because we have a simple monomial basis. All that is needed there is to collect coefficients in the Taylor's expansion. However in the SU(3) case the basis is more complicated. In the realization using six complex variables used in earlier works,[15,21–23] the basis spans only a subspace of the space of all polynomials. As a result, one is not even assured that a general invariant satisfying Eq. (139) can be expanded in the basis vectors. That it be so expandable imposes restrictions on the coefficients of the linear combinations of the basic invariants [Eq. (140)]. In fact each of the three IRs imposes one restriction on the linear combination. This effectively reduces the number of independent linear combinations that may be chosen. Any freedom that is left corresponds to the repeating IRs in the decomposition. We may hope that requiring the invariant polynomial to be an eigenstate of the chiral Casimir[15,23,17] uniquely determines the invariant polynomial corresponding to each of the repeating IRs in the decomposition.

In this way the 3-SU(3) symbols can be extracted—in principle. However, extracting an explicit formula for the symbols this way has not been possible. The closest has been a formula with some undetermined coefficients.[23] We are able to overcome all these hurdles here for the following reasons. (i) our basis is simpler, (ii) the relevant invariants are completely determined, (iii) we use our auxiliary measure to calculate the expansion coefficients, and (iv) we use a generating function for the basis states and also for the invariants. This way calculations for all IRs are being done in one shot. Moreover, all calculations effectively reduce to Gaussian integrations.

We now describe why the relevant invariants are completely determined in our basis.

We are using the five-(complex)-dimensional subspace $\vec{w}\cdot\vec{z}=0$ in our basis. This constraint is invariant under SU(3). Therefore, invariants in the larger six-dimensional space are also invariants when restricted to our subspace. However all invariants with nonzero $N(1,1)$, $N(2,2)$, and $N(3,3)$ vanish identically because in our basis

$$\vec{w}^a\cdot\vec{z}^a=0, \quad a=1,2,3. \tag{143}$$

Thus the basic invariants are only

$$I(N(1,2),N(2,3),N(3,1),N(2,1),N(3,2),N(1,3),L)$$

$$= (\vec{z}^1 \cdot \vec{w}^2)^{N(1,2)} (\vec{z}^2 \cdot \vec{w}^3)^{N(2,3)} (\vec{z}^3 \cdot \vec{w}^1)^{N(3,1)} (\vec{z}^2 \cdot \vec{w}^1)^{N(2,1)} (\vec{z}^3 \cdot \vec{w}^2)^{N(3,2)} (\vec{z}^1 \cdot \vec{w}^3)^{N(1,3)}$$
$$\times [(\vec{z}^1 \cdot \vec{z}^2 \times \vec{z}^3)^L \quad \text{or} \quad (\vec{w}^1 \cdot \vec{w}^2 \times \vec{w}^3)^{-|L|}]. \tag{144}$$

We now simply have

$$N(1,2)+N(1,3)+L\epsilon(L)=M^1, \quad N(2,3)+N(2,1)+L\epsilon(L)=M^2,$$
$$N(3,1)+N(3,2)+L\epsilon(L)=M^3, \quad N(2,1)+N(3,1)+|L|\epsilon(-L)=N^1, \tag{45}$$
$$N(3,2)+N(1,2)+|L|\epsilon(-L)=N^2, \quad N(1,3)+N(2,3)+|L|\epsilon(-L)=N^3.$$

Thus we are led to the same equations for multiplicity as obtained in Ref. 25 from other considerations.

Note that Eq. (142) implies

$$3L=\sum_{a=1}^{3} (M^a-N^a). \tag{146}$$

Thus L is completely determined by the three IRs chosen and is not an independent parameter. It counts the number of invariants formed using $\det(\mathscr{U})=1$ condition. It may be called the ''chirality number'' of the invariant.

As a result, when we consider three given IRs λ^1, λ^2, and λ^3, we have just six non-negative integers $N(a,b)$, $a \neq b$, constrained by five linearly independent equations [Eq. (145)]. Therefore, there can be more than one solution for the set $N(a,b)$. This corresponds to the multiplicity problem in the decomposition of the Kronecker product.

It is possible, in principle, that there are more invariants in our subspace which do not have an invariant extension into the larger space of $\vec{z}^a$ and $\vec{w}^a$ variables. We now argue that there are no further invariants constructed out of our basis vectors from three IRs. In Sec. III, we obtained our basis vectors from basis vectors in the space of $\vec{z}$ and $\vec{w}$ variables by retaining those which are distinct in our subspace. Now a basis for *all invariants* in the larger space are catalogued by Eq. (140). Therefore, by simply imposing the constraints [Eq. (142)] and retaining nontrivial and distinct invariants, we get all invariants for our case.

In earlier approaches one was not assured that an arbitrary linear combination of the basic invariants [Eq. (140)] could be expanded in the basis vectors of the three IRs. We do not have such a problem now. This is because our basis vectors form all polynomials in four variables z_1, z_2, w_1, and w_2 and all (positive or negative integral) powers of z_3. Thus, even the basic invariants. [Eq. (140)] with constraints [Eq. (142)] can be expanded in our basis. This means the following. We may simply regard each of basic invariants [Eq. (140)] as the (unnormalized) linearly independent invariant vectors in the direct product space of three IRs. For a given basic invariant [Eq. (140)], the three IRs of which it is composed are given by Eq. (144)].

Thus the $3-\mathrm{SU}(3)$ symbols are naturally labeled by the set of integers,

(1) $N(1,2)$, $N(2,3)$, $N(3,1)$, $N(2,1)$, $N(3,2)$, $N(1,3)$, L.
(2) $P^a, Q^a, R^a, S^a, U^a, V^a$, $a=1,2,3$.

In place of (2) we may use the quark-model labels,

(3) $M^a, N^a, I^a, I_3^a, Y^a$, $a=1,2,3$.

These labels are related by the constraints. These constraints may be displayed as follows:

$$\left[\begin{array}{cccccccc} & N(1,2) & & N(1,3) & & N(2,3) & & N(2,1) \\ N^2 & & M^1 & & N^3 & & M^2 & \\ & & U^1,R^1 & & V^3,S^3 & & U^2,R^2 & \\ & & P^1 & & P^3 & & P^2 & \end{array}\right.$$

$$\left.\begin{array}{cccccc} & N(3,1) & & N(3,2) & & \\ N^1 & & M^3 & & N^2 & \\ & V^1,S^1 & & U^3,R^3 & & V^2,S^2 \\ & Q^1 & & Q^3 & & Q^2 \end{array}\right]_L . \tag{147}$$

This is the analog of the $3-j$ symbol of SU(2) prescribed as an array of nine integers, [Eq. (34)]. As in that case, this array is highly redundant. This notation is nevertheless useful, because the allowed values can be easily read off. For convenience, we will adopt the following notation for the $3-$SU(3) symbols:

$$\left[\begin{array}{ccccccc} N(1,2) & N(2,3) & N(3,1) & L & N(1,3) & N(3,2) & N(2,1) \\ & M^1N^1 & & M^2N^2 & & M^3N^3 & \\ & I'I_3'Y' & & I^2I_3^2Y^2 & & I^3I_3^3Y^3 & \end{array}\right]. \tag{148}$$

IX. A GENERATING FUNCTION FOR THE INVARIANTS

Though our basis has simplified many aspects, it is still not simple enough to allow the expansion coefficients to be read off from the invariants [Eq. (145)]. In order to compute these coefficients we will use our auxiliary inner product. We will also use generating functions [Eq. (53)] for the basis states and also a generating function for the invariants. This simplifies the computations drastically. Moreover we are doing computations for all IRs in one shot.

Define the generating function for the invariants,

$$\begin{aligned} &\mathscr{I}_{\pm}(j_{12},j_{23},j_{31},j_{21},j_{32},j_{13},j_{\pm}) \\ &= \exp(j_{12}\vec{z}^1\cdot\vec{w}^2 + j_{23}\vec{z}^2\cdot\vec{w}^3 + j_{31}\vec{z}^3\cdot\vec{w}^1 + j_{21}\vec{z}^2\cdot\vec{w}^1 + j_{32}\vec{z}^3\cdot\vec{w}^2 + j_{13}\vec{z}^1\cdot\vec{w}^3 \\ &\quad + (j_+\vec{z}^1\cdot\vec{z}^2\times\vec{z}^3 \ \text{ or } \ j_-\vec{w}^1\cdot\vec{w}^2\times\vec{w}^3). \end{aligned} \tag{149}$$

By a Taylor expansion in the sources j we generate all basic invariants [Eq. (145)]. Note that we use *either* j_+ *or* j_- because we do not need both $z^1\cdot z^2\times z^3$ and $w^1\cdot w^2\times w^3$ together.

The exponent in Eq. (149) is linear in each of the variables separately. This is an important feature which allows explicit computations.

We may write

$$\begin{aligned} \mathscr{I}_{\pm} = &\sum_{N(1,2)\ldots,|L|} j_{12}^{N(1,2)} j_{23}^{N(2,3)} j_{31}^{N(3,1)} j_{21}^{N(2,1)} j_{32}^{N(3,2)} j_{13}^{N(1,3)} (j_{\pm})^{|L|} \\ &\times |N(1,2),N(2,3),N(3,1),N(2,1),N(3,2),N(1,3),\pm|L|). \end{aligned} \tag{150}$$

The kets on the right-hand side of Eq. (150) are the unnormalized invariant vectors [Eq. (134)] in the direct product of three IRs. For the corresponding normalized invariant vectors, we have

$$
\begin{aligned}
&|N(1,2),N(2,3),N(3,1),N(2,1),N(3,2),N(1,3),\pm|L|\rangle \\
&\quad\equiv n^{-1/2}(N(1,2),N(2,3),N(3,1),N(2,1),N(3,2),N(1,3),\pm|L|) \\
&\qquad\times|N(1,2)\ldots,\pm|L|) \qquad (151)\\
&\quad=\sum_{\{P^a,Q^a,R^a,S^a,U^a,V^a\}}\begin{bmatrix} N(1,2) & N(2,3) & N(3,1) & L & N(1,3) & N(3,2) & N(2,1)\\ & M^1N^1 & & M^2N^2 & & M^3N^3 & \\ & I^1I_3^1Y^1 & & I^2I_3^2Y^2 & & I^3I_3^3Y^3 & \end{bmatrix} \\
&\qquad\times|P^1,Q^1,R^1,S^1,U^1,V^1\rangle|P^2,Q^2,R^2,S^2,U^2,V^2\rangle|P^3,Q^3,R^3,S^3,U^3,V^3\rangle,
\end{aligned}
$$

where n is the normalization factor. We have used our labeling [Eq. (55)] for the basis vectors. The variables on the right-hand side of Eq. (151) are related by Eqs. (49), (50), and (52) for each $a=1,2,3$.

Consider the auxiliary inner product of $\mathscr{T}_\pm$ with $\mathbf{g}^1\mathbf{g}^2\mathbf{g}^3$ which is the product of the partition functions for basis vectors of the three IRs. Using Eq. (55) and noting from Eqs. (81) and (88)

$$
\begin{aligned}
&(P,Q,R,S,U,V\|P',Q',R',S',U',V'\rangle \\
&\quad=N^{-1/2}(P,Q,R,S,U,V)M(P,Q,R,S,U,V)\delta_{PP'}\delta_{QQ'}\delta_{RR'}\delta_{SS'}\delta_{UU'}\delta_{VV'}, \qquad (152)
\end{aligned}
$$

we get

$$
\begin{aligned}
&\int_\pm\equiv(\mathbf{g}^1\mathbf{g}^2\mathbf{g}^3,\mathscr{T}_\pm) \\
&\quad=\sum\prod_{a=1}^{3}(\overline{p^a}^{P^a}\overline{q^a}^{Q^a}\overline{r^a}^{R^a}\overline{s^a}^{S^a}\overline{u^a}^{U^a}\overline{v^a}^{V^a}N^{-1/2}(P^a,Q^a,R^a,S^a,U^a,V^a) \\
&\qquad\times M(P^a,Q^a,R^a,S^a,U^a,V^a))j_{12}^{N(1,2)}j_{23}^{N(2,3)}j_{31}^{N(3,1)}j_{21}^{N(2,1)}j_{32}^{N(3,2)}j_{13}^{N(1,3)} \\
&\qquad\times(j_\pm)^{|L|}n^{+1/2}(N(1,2),N(2,3),N(3,1),N(2,1),N(3,2),N(1,3),\pm L) \\
&\qquad\times\begin{bmatrix} N(1,2) & N(2,3) & N(3,1) & L & N(1,3) & N(3,2) & N(2,1)\\ & M^1N^1 & & M^2N^2 & & M^3N^3 & \\ & I^1I_3^1Y^1 & & I^2I_3^2Y^2 & & I^3I_3^3Y^3 & \end{bmatrix}. \qquad (153)
\end{aligned}
$$

Thus the $3-\mathrm{SU}(3)$ symbols can be computed by calculating $(\mathbf{g}_1\mathbf{g}_2\mathbf{g}_3,\ \mathscr{T}_\pm)$ with respect to the auxiliary inner product. The normalization n in Eq. (153) has to be evaluated separately, using Eq. (136).

X. EVALUATION OF $\int_+$

We now evaluated $\int_+$. We have,

$$
\int_\pm=\int d\mu^1\int d\mu^2\int d\mu^3\ \ \mathbf{g}^1\mathbf{g}^2\mathbf{g}^3.\mathscr{T}_\pm. \qquad (154)
$$

Here,

$$\int d\mu^a = \int_0^{2\pi} \frac{d\theta^a}{2\pi} \int \frac{d^2z_1^a}{\pi} \int \frac{d^2z_2^a}{\pi} \int \frac{d^2w_1^a}{\pi} \int \frac{d^2w_2^a}{\pi} \exp(-\overline{z_1^a} z_1^a - \overline{z_2^a} z_2^a - \overline{w_1^a} w_1^a - \overline{w_2^a} w_2^a), \tag{155}$$

$$\overline{\mathbf{g}^a} = \exp(\overline{r_p^a z_1^a + r_q^a z_2^a + s_q^a w_1^a + s_p^a w_2^a + u^a e^{i\theta^a} - v^a e^{-i\theta^a}(z_1^a w_1^a + z_2^a w_2^a)}), \quad a = 1,2,3. \tag{156}$$

In Eq. (156), it is sufficient to use the ''mass shell'' values [Eq. (61)] for the sources. Further, in $\mathscr{I}_{\pm}$ [see Eq. (149)], we have

$$\vec{z}^1 \cdot \vec{w}^2 = z_1^1 w_1^2 + z_2^1 w_2^2 - \exp(i\theta^1 - i\theta^2)(z_1^2 w_1^2 + z_2^2 w_2^2), \text{ etc.} \tag{157}$$

Also,

$$\vec{z}^1 \cdot \vec{z}^2 \times \vec{z}^3 = e^{i\theta^1}(z_1^2 z_2^3 - z_1^3 z_2^2) + (\text{cyclic}). \tag{158}$$

Note that all exponents in $\int_+$ are bilinear in $z_{1,2}^a$ and $w_{1,2}^a$ variables. Therefore these integrations can be explicitly done. The only term that could have caused problems is $\vec{z}^1 \cdot \vec{z}^2 \times z^3$ [Eq. (158)], which is related to the multiplicity problem and is apparently cubic. However, since $z_3^a = e^{i\theta^a}$, $a = 1,2,3$, this term is also bilinear. On the other hand, $\vec{w}^1 \cdot \vec{w}^2 \times \vec{w}^3$ appearing in $\int_-$ is not bilinear after elimination of w_3^a. We will handle this problem in Sec. XII.

The form of $\int_+$ suggests the following operations. First, dependence on θ^a, $a = 1,2,3$, can be completely transferred to the sources. Make a change of variables,

$$\begin{aligned} z_1^a &\to e^{i\theta^a} z_1^a; \quad & z_2^a &\to e^{i\theta^a} z_2^a, \\ \overline{z_1^a} &\to e^{-i\theta^a} \overline{z_1^a}; \quad & \overline{z_2^a} &\to e^{-i\theta^a} \overline{z_2^a}, \\ w_1^a &\to e^{-i\theta^a} w_1^a; \quad & w_2^a &\to e^{-i\theta^a} w_2^a, \\ \overline{w_1^a} &\to e^{-i\theta^a} \overline{w_1^a}; \quad & \overline{w_2^a} &\to e^{-i\theta^a} \overline{w_2^a} \end{aligned} \tag{159}$$

and the measure [Eq. (155)], remains unchanged. On the other hand,

$$\begin{aligned} \mathbf{g}^a \to \exp(&\overline{(r_p^a e^{i\theta^a}) z_1^a + (r_q^a e^{i\theta^a}) z_2^a + (s_q^a e^{-i\theta^a}) w_1^a + (s_p^a e^{-i\theta^a}) w_2^a} \\ &+ \overline{(u^a c^{i\theta^a}) - (v^a e^{-i\theta^a})(z_1^a w_1^a + z_2^a w_2^a)}). \end{aligned} \tag{160}$$

Also,

$$j_{12} \vec{z}^1 \cdot \vec{w}^2 \to j_{12} e^{i\theta^1 - i\theta^2}(z_1^1 w_1^2 + z_2^1 w_2^2 - z_1^2 w_1^2 - z_2^2 w_2^2) \tag{161}$$

with similar changes for $j_{23} \vec{z}^2 \cdot \vec{w}^3$, $j_{21} \vec{z}^2 \cdot \vec{w}^1$, etc. Lastly,

$$j_+ \vec{z}^1 \cdot \vec{z}^2 \times \vec{z}^3 \to j_+ e^{i\theta^1 + i\theta^2 + i\theta^3}((z_1^2 z_2^3 - z_1^3 z_2^2) + (\text{cyclic})). \tag{162}$$

This change of variables makes integration over θ^a, $a = 1,2,3$ very easy. Indeed, these integrations only implement one additive conservation law for each of the three IRs, since

$$\int_0^{2\pi} \frac{d\theta}{2\pi} e^{in\theta} = \delta_{n,0}. \tag{163}$$

The three kinds of charges for various sources as can be read off from Eq. (160)–(162) are displayed in Table II. In effect, each of (z_1^a, z_2^a, z_3^a) is given Q^a charge $+1$ and each of (w_1^a, w_2^a, w_3^a) has $Q^a = -1$.

TABLE II. $\overline{p^a}$, $\overline{q^a}$, $a=1,2,3$ do not carry any of these charges.

$Q^1=+1$	$\overline{s^1}$	$\overline{v^1}$	j_{12}	j_{13}	j_+
$Q^1=-1$	$\overline{r^1}$	$\overline{u^1}$	j_{21}	j_{31}	
$Q^2=+1$	$\overline{s^2}$	$\overline{v^2}$	j_{23}	j_{21}	j_+
$Q^2=-1$	$\overline{r^2}$	$\overline{u^2}$	j_{32}	j_{12}	
$Q^3=+1$	$\overline{s^3}$	$\overline{v^3}$	j_{31}	j_{32}	j_+
$Q^3=-1$	$\overline{r^3}$	$\overline{u^3}$	j_{13}	j_{23}	

The sources have the corresponding compensating charges. As a consequence, it is not necessary to explicitly do θ^a integrations. We may simply ignore the dependencies on θ^a. After integration over z^a and w^a variables, we only keep polynomial in sources each term of which is neutral with respect to Q^1, Q^2 and Q^3 charges.

From Table II and our definitions of quantum numbers, powers of the sources in the polynomials have to satisfy

$$\sum_{b\neq a} N(a,b)+L-\sum_{b\neq a} N(b,a)=R^a+U^a-S^a-V^a, \quad a=1,2,3. \tag{164}$$

From Eqs. (49) and (145), we notice that both sides of Eq. (164), are M^a-N^a. (see Table II.) Thus the θ integration is only implementing equality of M^a-N^a as calculated using the invariants [Eq. (145)] and the states [Eq. (49)]. However, we know that M and N evaluated in these two ways should each be separately equal. This stronger equality should be a consequence of integration over the z and w variables.

We now consider the integrations over the z and w variables. It is convenient to employ the following matrix notation:

$$Z_1=\begin{pmatrix} z_1^1 \\ z_1^2 \\ z_1^3 \end{pmatrix}, \quad \overline{Z_1}=\begin{pmatrix} \overline{z_1^1} \\ \overline{z_1^2} \\ \overline{z_1^3} \end{pmatrix}, \quad \overline{R_p}=\begin{pmatrix} \overline{r_p^1} \\ \overline{r_p^2} \\ \overline{r_p^3} \end{pmatrix} \tag{165}$$

with similar notations for $Z_2,\overline{Z_2},W_1,\overline{W_1},W_2,\overline{W_2},\overline{R_q},\overline{S_p},\overline{S_q}$. Further, define,

$$\overline{V}=\begin{pmatrix} \overline{v^1} & 0 & 0 \\ 0 & \overline{v^2} & 0 \\ 0 & 0 & \overline{v^3} \end{pmatrix}, \tag{166}$$

$$J=\begin{pmatrix} +j_{31}+j_{21} & -j_{12} & -j_{13} \\ -j_{21} & +j_{12}+j_{32} & -j_{23} \\ -j_{31} & -j_{32} & +j_{23}+j_{13} \end{pmatrix}, \tag{167}$$

$$A=\begin{pmatrix} 0 & 1 & -1 \\ -1 & 0 & 1 \\ 1 & -1 & 0 \end{pmatrix}. \tag{168}$$

In terms of these objects the integral we need is

$$\int \frac{d^2Z_1 d^2Z_2}{\pi^3\pi^3}\frac{d^2W_1 d^2W_2}{\pi^3\pi^3}\exp\Big(-\overline{Z}_1^T Z_1-\overline{Z}_2^T Z_2-\overline{W}_1^T W_1-\overline{W}_2^T W_2+\overline{Z}_1^T\overline{R_p}+\overline{Z}_2^T\overline{R_q}$$

$$+\overline{W}_1^T\overline{S_q}+\overline{W}_2^T\overline{S_p}-\overline{Z}_1^T\overline{VW_1}-\overline{Z}_2^T\overline{VW_2}-Z_1^T JW_1-Z_2^T JW_2+j_+Z_1^T AZ_2+\sum_{a=1}^{3}\overline{u^a}\Big), \tag{169}$$

where

$$\int \frac{d^2Z_1}{\pi^3}=\int\frac{d^2z_1^1}{\pi}\int\frac{d^2z_1^2}{\pi}\int\frac{d^2z_1^3}{\pi}, \tag{170}$$

etc. We now use Eq. (72) in the following order. Integrate over W_1 and W_2. We get,

$$\int \frac{d^2Z_1 d^2Z_2}{\pi^3\pi^3}\exp\Big(-\overline{Z}_1^T Z_1-\overline{Z}_2^T Z_2+\overline{Z}_1^T\overline{R_p}+\overline{Z}_2^T\overline{R_q}+Z_1^T J\overline{VZ_1}+Z_2^T J\overline{VZ_2}$$

$$-Z_1^T J\overline{S_q}-Z_2^T J\overline{S_p}+j_+Z_1^T AZ_2+\sum_{a=1}^{3}\overline{u^a}\Big). \tag{171}$$

Now integrating over Z_2, we get

$$\int \frac{d^2Z_1}{\pi^3}\det(1-\overline{VJ}^T)^{-1}\exp\Big(-\overline{Z}_1^T(1-\overline{VJ}^T)Z_1+\overline{Z}_1^T\overline{R_p}-\overline{S}_q^T J^T Z_1$$

$$-\overline{S}_p^T J^T(1-\overline{VJ}^T)^{-1}\overline{R_q}+j_+Z_1^T A(1-\overline{VJ}^T)^{-1}\overline{R_q}+\sum_{a=1}^{a}\overline{u^a}\Big). \tag{172}$$

Final integration over Z_1 gives

$$\det(1-\overline{VJ}^T)^{-2}\exp\Big(-\overline{S}_q^T J^T(1-\overline{VJ}^T)^{-1}\overline{R_p}-\overline{S}_p^T J^T(1-\overline{VJ}^T)^{-1}\overline{R_q}$$

$$+j_+\overline{R}_q^T(1-\overline{VJ}^T)^{T^{-1}}A^T(1-\overline{VJ}^T)^{-1}\overline{R_p}+\sum_{a=1}^{a}\overline{u^a}\Big). \tag{173}$$

We rewrite this as

$$\exp\Big(-\overline{R}_p^T BJ\overline{S_q}-\overline{R}_q^T BJ\overline{S_p}+j_+\overline{R}_p^T BAB^T\overline{R_q}+2\mathrm{tr}(\ln B)+\sum_{a=1}^{a}\overline{u^a}\Big), \tag{174}$$

where

$$B=(1-J\overline{V})^{-1}=\sum_{n=0}^{\infty}\frac{(J\overline{V})^n}{n!}. \tag{175}$$

XI. ALGEBRAIC FORMULA FOR 3-SU(3) COEFFICIENTS WHEN $L\geqslant 0$

To get 3-SU(3) symbols for a given set of three IRs, we have to expand Eq. (174) in powers of the various sources. On mass shell we have

$$-\overline{R_p^T}BJ\overline{S_q}-\overline{R_q^T}BJ\overline{S_p}=(\overline{r^1}(BJ)_{12}\overline{s^2}-\overline{r^2}(BJ)_{21}\overline{s^1})(\overline{p^1q^2}-\overline{q^1p^2})+\text{cyclic}. \tag{176}$$

Notice that we always have combinations such as $(\overline{p^1q^2}-\overline{q^1p^2})$ which are invariant under the (isospin) SU(2) transformations of the sources. This is to be expected because our measure is manifestly invariant under this subgroup. Note also that the diagonal terms of the matrix (BJ) do not appear on the right-hand side (this is because of the negative sign in $\overline{s_q^a}=-\overline{s^aq^a}$, $a=1,2,3$, etc.) This is again required by SU(2) invariance. With such diagonal terms we would get terms like $\overline{p^aq^a}$ which are not SU(2) invariant. We also have

$$\overline{R_p^T}BAB^T\overline{R_q}=\overline{r^1r^2}(\overline{p^1q^2}-\overline{q^1p^2})(BAB^T)_{12}+\text{cyclic}. \tag{177}$$

Again we get SU(2) invariant combinations. The reason now is the antisymmetry of the matrix A and hence of BAB^T.

Explicitly inverting the 3×3 matrix $(1-J\overline{V})$, we obtain quite simple expressions for the relevant matrix elements:

$$\begin{aligned}(BJ)_{12}&=\|B\|(-j_{12}+j_{12}(j_{23}+j_{13})\overline{v^3}+j_{13}\overline{v^3}j_{32}),\\ (BJ)_{21}&=\|B\|(-j_{21}+j_{21}(j_{23}+j_{13})\overline{v^3}+j_{23}\overline{v^3}j_{31})\end{aligned} \tag{178}$$

and corresponding cyclic expressions. Here,

$$\|B^{-1}\|=\det(1-J\overline{V})=1-((j_{31}+j_{21})\overline{v^1}+\text{cyclic})+((j_{31}j_{12}+j_{31}j_{32}+j_{21}j_{32})\overline{v^1}\overline{v^2}+\text{cyclic}). \tag{179}$$

Also notice that,

$$A_{ij}=\epsilon_{ijk}c_k, \tag{180}$$

where

$$\overline{c}=(c_k)=(1,1,1). \tag{181}$$

Therefore,

$$(BAB^T)_{il}=B_{ij}\epsilon_{jkm}c_mB_{lk}=\|B\|\epsilon_{iln}c_m(B^{-1})_{mn}. \tag{182}$$

Now,

$$c_m(B^{-1})_{mn}=\sum_{m=1}^{3}(1-J\overline{V})_{mn}=1 \quad \text{for each } n. \tag{183}$$

Thus,

$$(BAB^T)_{12}=(BAB^T)_{23}=(BAB^T)_{31}=\|B\|. \tag{184}$$

Now we have an explicit expression for $\int_+$:

$$\begin{aligned}\int_+ \sim\|B\|^2\ \exp[\|B\|\{&(\overline{u^1}+j_+\overline{r^1}\overline{r^2}-\overline{r^1}j_{12}\overline{s^2}+\overline{r^2}j_{21}\overline{s^1}+\overline{r^1}j_{12}\overline{s^2}(j_{23}+j_{13})\overline{v^3}\\ &-\overline{r^2}j_{21}\overline{s^1}(j_{23}+j_{13})\overline{v^3}+\overline{r^1}j_{13}\overline{v^3}j_{32}\overline{s^2}-\overline{r^2}j_{23}\overline{v^3}j_{31}\overline{s^1})(\overline{p^1q^2}-\overline{p^2q^1})+(\text{cyclic})\}],\end{aligned} \tag{185}$$

where $\sim$ means that we are supposed to keep only terms consistent with the conservation laws [Eq. (164)].

This form implies another conservation law. Note that j_{21} and j_{31} always appear with the $\overline{s^1}$ or $\overline{v^1}$. Therefore,

$$N(2,1)+N(3,1)=S^1+V^1, \tag{186}$$

which we expect because both sides equal N^1. We have similar equations for N^2 and N^3 also. Taken with Eq. (164), which are a consequence of θ^a, $a=1,2,3$ integrations, we get separate conservations of M^a and N^a $a=1,2,3$ as computed from the states and from the invariants.

We now change the right-hand side of Eq. (185) to a form which automatically gives the conservation law:

$$N(1,2)+N(1,3)+L=R^1+U^1 \tag{187}$$

and corresponding cyclic expressions. For this we remove $\exp(\Sigma_{a=1}^3 \overline{u^a})$ and insert $\overline{u^1},\overline{u^2},\overline{u^3}$ factors suitably in the other terms of the exponent and in $\|B\|$:

$$\begin{aligned}\int_+ \rightarrow \|\widetilde{B}\|^2 \exp[\|\widetilde{B}\|\{&((j_+\overline{r^1r^2u^3}-\overline{r^1}j_{12}\overline{s^2}+\overline{r^2}j_{21}\overline{s^1}+\overline{r^1}j_{12}\overline{s^2})(\overline{u^2}j_{23}\overline{v^3}+\overline{u^1}j_{13}\overline{v^3})\\ &-\overline{r^2}j_{21}\overline{s^1}(\overline{u^2}j_{23}\overline{v^3}+\overline{u^1}j_{13}\overline{v^3})+\overline{r^1}j_{13}\overline{v^3}\overline{u^3}j_{32}\overline{s^2}\\ &-\overline{r^2}j_{23}\overline{v^3}\overline{u^3}j_{31}\overline{s^1})(\overline{p^1q^2}-\overline{p^2q^1})\ +(\text{cyclic})\},\end{aligned} \tag{188}$$

where

$$\begin{aligned}\|\widetilde{B}\|=1-(&\overline{u^3}j_{31}\overline{v^1}+\overline{u^2}j_{21}\overline{v^1}+(\text{cyclic}))+(\overline{u^3}j_{31}\overline{v^1}\overline{u^1}j_{12}\overline{v^2}\\ &+\overline{u^3}j_{31}\overline{v^1}\overline{u^3}j_{32}\overline{v^2}+\overline{u^2}j_{21}\overline{v^1}\overline{u^3}j_{32}\overline{v^2}+(\text{cyclic})).\end{aligned} \tag{189}$$

Now j_{12} and j_{13} always appears with $\overline{r^1}$ or $\overline{u^1}$ except in the terms $\overline{r^1r^2u^3}+(\text{cyclic})$. The effect of these last terms is to provide monomials where the powers R^a+U^a, $a=1,2,3$ are equal. The net effect is to imply Eq. (187) and corresponding cyclic expressions where L is given by the sum of the powers of $\overline{r^1r^2u^3}$, $\overline{r^2r^3u^1}$ and $\overline{r^3r^1u^2}$. Thus the right-hand side of Eq. (188) automatically takes care of conservations laws, Eqs. (186) and (187) and corresponding cyclic expressions. It also gives $\int_+$ exactly except for the additional factor

$$\frac{1}{U^1!U^2!U^3!} \tag{190}$$

(coming from $\exp(\overline{u^1}+\overline{u^2}+\overline{u^3})$) to be associated with $(\overline{u^a})^{U^a}$, $a=1,2,3$.

We have to now expand the right-hand side of Eq. (188) in powers of the various monomials in the exponent and determinant. This is exactly analogous to the SU(2) case [Eq. (33)]. As in that case, we have to collect all the terms contributing to the monomial. For this we have first to adopt a notation for the powers of the monomials. This is presented in Table III.

We have deliberately adopted this notation for the powers because, the arguments in the symbols uniquely characterize the term being considered. Thus for example $l(123)$ is associated with $(j_+)(\overline{p^1r^1})(\overline{q^2r^2})(\overline{u^3})$. We have such variables associated with every permutation of (123) arising from the term $j_+\overline{r^1r^2u^3}(\overline{p^1q^2}-\overline{p^2q^1})+\text{cyclic}$ in the exponent in Eq. (188). In Table IV, we catalogue all allowed arguments in our variables of Table III. The advantage of our notation is

TABLE III. Definition of the variables $l(\cdots)$, ... , $g(\cdots)$.

Monomial	$j_+\overline{p^1q^2r^1r^2u^3}$	$\overline{p^2q^1r^1r^2u^3}$	$\overline{p^1q^2r^1}j_{12}\overline{s^2}$	$\overline{p^2q^1r^1}j_{12}\overline{s^2}$
Order used in label	$\overline{p^1q^2u^3}$	$\overline{p^2q^1u^3}$	$\overline{p^1q^2r^1s^2}$	$\overline{p^2q^1r^1s^2}$
Power	$l(123)$	$l(213)$	$k(1212)$	$k(2112)$

$\overline{p^1q^2r^2}j_{21}\overline{s^1}$	$\overline{p^1q^2r^1}j_{12}\overline{s^2u^2}j_{23}\overline{v^3}$	$\overline{p^1q^2r^1}j_{12}\overline{s^2u^1}j_{13}\overline{v^3}$	$\overline{p^1q^2r^1}j_{13}\overline{v^3u^3}j_{32}\overline{s^2}$
$\overline{p^1q^2r^2s^1}$	$\overline{p^1q^2r^1s^2u^2v^3}$	$\overline{p^1q^2r^1s^2u^1v^3}$	$\overline{p^1q^2r^1s^2u^3v^3}$
$k(1221)$	$m(121223)$	$m(121213)$	$n(12123)$

$\overline{u^3}j_{31}\overline{v^1}$	$\overline{u^2}j_{21}\overline{v^1}$	$\overline{u^3}j_{31}\overline{v^1u^1}j_{12}\overline{v^2}$	$\overline{u^2}j_{21}\overline{v^1u^1}j_{32}\overline{v^2}$	$\overline{u^3}j_{31}\overline{v^1u^3}j_{32}\overline{v^2}$
$\overline{u^3v^1}$	$\overline{u^2v^1}$	$\overline{u^3v^1u^1v^2}$	$\overline{u^3v^2u^2v^1}$	$\overline{u^3u^3v^2v^1}$
$e(31)$	$e(21)$	$f(3112)$	$f(3221)$	$g(321)$

that we can easily trace the terms that involve a given source j_{12}, $\overline{p^1}$, etc. Thus for example, we can write the conservation laws in a compact form as below. By collecting the powers of each source, we get

$$P^\alpha=\sum\ (l(\alpha--)+k(\alpha---)+m(\alpha------)+n(\alpha------));$$

$$Q^\alpha=\sum\ (l(-\alpha-)+k(-\alpha--)+m(-\alpha----)+n(-\alpha----));$$

$$R^\alpha=\sum\ (l(\alpha--)+l(-\alpha-)+k(--\alpha-)+m(--\alpha---)+n(--\alpha---));$$

$$S^\alpha=\sum\ (k(---\alpha)+m(---\alpha--)+n(---\alpha--));$$

TABLE IV. Permitted arguments of $l(\cdots)$, ... , $g(\cdots)$.

$\alpha,\beta,\gamma\cdots=1$, 2, or 3	
$l(\alpha\beta\gamma)$	$(\alpha\beta\gamma)$ is a permutation of (123)
$k(\alpha\beta\gamma\delta)$	$(\alpha\beta)$ is same or transpose of $(\gamma\delta)$
$m(\alpha\beta\gamma\delta\epsilon\phi)$	$(\gamma\delta\phi)$ is a permutation of (123); $(\alpha\beta)$ is same or transpose of $(\gamma\delta)$; ϕ is either γ or δ.
$n(\alpha\beta\gamma\delta\epsilon)$	$(\gamma\delta\epsilon)$ is a permutation of (123); $(\alpha\beta)$ is same or transpose of $(\gamma\delta)$.
$e(\alpha\beta)$: $\alpha\neq\beta$.	
$f(\alpha\beta\gamma\delta)$	$\beta=\gamma$ and $(\alpha\beta\delta)$ is a permutation of (123):
$g(\alpha\beta\gamma)$	$(\alpha\beta\gamma)$ only even permutation of (123)

$$U^\alpha=\sum\ (l(--\alpha)+m(----\alpha-)+n(-----\alpha-))+e(\alpha-)$$
$$+f(\alpha---)+f(--\alpha-)+2g(\alpha\beta\gamma));$$

$$V^\alpha=\sum\ (m(------\alpha)+n(-------\alpha))+e(-\alpha)+f(-\alpha--)$$
$$+f(---\alpha)+g(-\alpha-)+g(--\alpha));$$

$$L=\sum\ l(---);$$

$$N(\alpha,\beta)=\sum\ (k(--\alpha\beta)+m(--\alpha\beta--))+m(----\alpha\beta)+n(--\alpha\beta--)$$
$$+n(---\alpha\beta)+e(\alpha\beta)+f(\alpha\beta--)+f(--\alpha\beta)+g(\alpha\beta-)+g(\alpha-\beta));$$
(191)

Here we have used the following notation: Σ stands for summation over all allowed arguments in the blank spaces.

Note that Eqs. (190) and (191) express the non-negative integers, $P^\alpha,\ldots,V^\alpha$, $N(\alpha,\beta)$, and L, α, β=1,2, or 3 in terms of yet other non-negative integers of Table III. It is easy to see that the constraint $P^\alpha+Q^\alpha=R^\alpha+S^\alpha$ for the labels of each IR α=1,2, or 3 is satisfied. Also the constraints [Eqs. (186) and (187)] are satisfied as is seen from the positions of the labels and Table III.

We may read off various conservation laws in the 3-SU(3) symbols from Eq. (191):

$$\sum_{\alpha=1}^{3} P^\alpha=\sum_{\alpha=1}^{3} Q^\alpha.$$ (192)

This is valid because we are summing over all positions of α in the labels. This is simply a statement of the conservation of I_3.

Similarly,

$$\sum_{\alpha=1}^{3} U^\alpha=\sum_{\alpha=1}^{3} V^\alpha+L.$$ (193)

This implies conservation of hypercharge as seen by rewriting it as

$$\sum_{\alpha=1}^{3}\left(\frac{1}{3}(M^\alpha-N^\alpha)+V^\alpha-U^\alpha\right)=0.$$ (194)

When we expand the exponent in powers of each monomial, we collect a factor

$$\|\widetilde{B}\|^{1+h}$$ (195)

in Eq. (188). Here

$$-1+h=\sum\ (l()+k()+m()+n()).$$ (196)

Alternately, note that the number of $\|\tilde{B}\|$ factors is the sum of the number of s^α variables ($\alpha=1,2,3$) and the power of j_+, i.e.,

$$-1+h=L+S^1+S^2+S^3. \tag{197}$$

We may now apply the formula

$$\left(1-\sum_{k=1}^{K} x_k\right)^{-1-h}=\sum_{n_1,n_2=0}^{\infty} \frac{(h+\Sigma n_k)!}{h!\Pi_k(n_k!)}\prod_{k=1}^{K} x_k^{n_k} \tag{198}$$

to calculate coefficients of various monomials in Eq. (195) where $\|\tilde{B}\|$ is as in Eq. (188). This gives the coefficient of the monomials in the expansion of the RHS of Eq. (188) to be

$$\frac{1+\Sigma(l()+k()+m()+n()+e()+f()+g())!}{(1+\Sigma(l()+k()+m()+n()))!\Pi(l()!(k()!(m()!(n()!(e()!(f()!(g()!}$$
$$\times\exp[i\pi\Sigma_s(k()+n())+\Sigma_A m()+\Sigma(f()+g())]. \tag{199}$$

Here Σ and Π are over all possible arguments of the variables indicated. Σ_S (respectively Σ_A) correspond to summations over only those arguments ($\alpha\beta\gamma\delta\cdots$) such that $\alpha\beta$ is same as (respectively transposes of) $\gamma\delta$.

In order to get the coefficient of the monomial in $\int_+$, we have to multiply Eq. (199) by the factor Eq. (190). We may now extract the 3-SU(3) symbol from Eq. (153), by supplying factors of $N^{1/2}$ and M^{-1} as required. We get the 3-SU(3) symbol for $L\geqslant 0$,

$$\begin{bmatrix} N(1,2) & N(2,3) & N(3,1) & L & N(1,3) & N(3,2) & N(2,1) \\ & M^1N^1 & & M^2N^2 & & M^3N^3 & \\ & I^1I_3^1Y^1 & & I^2I_3^2Y^2 & & I^3I_3^3Y^3 & \end{bmatrix}$$
$$=n^{-1/2}(N(1,2),N(2,3),N(3,1),N(2,1),N(3,2),N(1,3),L)$$
$$\times\left[\prod_{\alpha=1}^{3}\frac{P^\alpha!Q^\alpha!R^\alpha!S^\alpha!U^\alpha!V^\alpha!(U^\alpha+2I^\alpha+1)!(2I^\alpha+1)}{(V^\alpha+2I^\alpha+1)!}\right]^{1/2}$$
$$\times\sum_{e,f,g,k,l,m,n}\frac{(1+\Sigma(e()+f()+g()+k()+l()+m()+n()))!}{(1+\Sigma(k()+l()+m()+n()))!\Pi(l()!\ldots n())!}$$
$$\times\exp[i\pi\Sigma_S(k()+n())+\Sigma_A m()+\Sigma(f()+g())]. \tag{200}$$

This is the exact analog of Eq. (33) of SU(2). The Clebsch–Gordan coefficients are presented as a sum over non-negative integers which satisfy conditions Eq. (191). (See Tables III and IV.)

XII. DISCUSSION

In our calculations for SU(3) we have ignored the questions involving the choice of phases until now. We will now make a careful analysis. With our definition [Eq. (55)] of the unnormalized basis vectors, note that the $\mathfrak{Z}^*$ is represented by $(-w_1,w_2,w_3)$ up to a normalization constant. Our computations of the relative normalization, Eqs. (109) and (110) fix only the magnitude of the normalizations. The phases may be chosen arbitrarily as discussed in Sec. II for the SU(2) case. Under a change of phases,

$$|E\rangle\rightarrow\exp(i\theta_E)|E\rangle, \tag{201}$$

the representation matrix changes as

$$(D(g))_{EE'} \to e^{i\theta_E}(D(g))_{EE'}e^{-i\theta_{E'}} \tag{202}$$

and remains unitary.

However one may want to make a choice of phases to rid the formulas of phases and relative signs if possible. For instance, we may choose the phase to have $\underline{3}^*$ be represented by $1/\sqrt{2}(w_1, w_2, w_3)$.

Fortunately our basis vectors [Eqs. (53)–(55)] have real coefficients even though they are represented by polynomials in complex variables. Similarly, our invariants [Eq. (140)] have real coefficients. Thus we are assured that the 3-SU(3) symbols are real as is checked in Eq. (200).

We now address the ambiguity in the phase of the Clebsch–Gordan coefficients. In the definition of Eq. (119), various coupled basis vectors $|\lambda''\alpha''>^k$, are required to transform as an IR(λ''). This fixes phases of all 3-SU(3) symbols except for an overall phase for each λ'' and k.

In previous sections we calculated 3-SU(3) symbols only for the $L \geqslant 0$ case. With our choice of regarding w_3 as a dependent variable, the relevant integrations could be explicitly computed in this case. We now show the 3-SU(3) symbols can be obtained for $L<0$ also.

In constructing the basis vectors, we could have as well chosen to eliminate z_3 instead of w_3. We could have done all computations with this basis. In this case, the integrations for 3-SU(3) symbols can be done explicitly for $L<0$ instead of $L>0$.

This is related to the invariance of the 3-SU(3) symbols under conjugation of the IRs involved. (It is possible that the invariance is only up to an additional phase factor as may happen if the phases of the basis states are not chosen carefully.) In our formalism this invariance may be seen as follows. Consider an expansion of an invariant [Eq. (140)] with $L \geqslant 0$ as a linear combination of the basis vectors of Eqs. (53)–(55). Now consider an interchange $\vec{z} \leftrightarrow \vec{w}$ in this expansion. The effect on the invariant is to change it to another invariant with

$$N(\alpha, \beta) \to N(\beta, \alpha), L \to -L. \tag{203}$$

This means

$$M^a \leftrightarrow N^a, \quad a = 1,2,3. \tag{204}$$

The effect of $\vec{z} \leftrightarrow \vec{w}$ on the generating functions [Eq. (53)] is equivalent to the following changes:

$$p^a \to -q^a, \quad q^a \to p^a, \quad r^a \to s^a, \quad s^a \to -r^a, \quad u^a \to v^a, \quad v^a \to u^a. \tag{205}$$

Thus the effect on the unnormalized basis states [Eq. (55)] is

$$|PQRSUV) \to (-1)^{Q+R}|QPSRVU). \tag{206}$$

In the usual notation,

$$M^a \leftrightarrow N^a, \quad I^a \to I^a, \quad I_3^a \to -I_3^a, \quad Y^a \to -Y^a \tag{207}$$

and in addition an additional phase factor $(-1)^{Q+R}$ is picked up.

In Eq. (188), note that the isospin dependence is always contained in the SU(2) invariant combination of sources, $(\overline{p^1 q^2} - \overline{p^2 q^1})$, etc. As a consequence, it is possible to extract isoscalar factors also.[3] However, we will not pursue this here. Equation (188) can be used, in principle, to extract Regge symmetries[62] of SU(3) Clebsch–Gordan coefficients. We do not attempt this here.

XIII. SUMMARY OF RESULTS

For easy accessibility we summarize our results in a self-contained way here.

(i) Labels for the basic vectors. Normalized basis vectors are denoted by $|M,N;P,Q,R,S,U,V\rangle$. All labels are non-negative integers. All IRs are uniquely labeled by (M,N). For a given IR (M,N), labels (P,Q,R,S,U,V) take all non-negative integral values subject to the constraints:

$$R+U=M, \quad S+V=N, \quad P+Q=R+S.$$

The allowed values can be read off easily: R takes all values from 0 to M, and S from 0 to N. For a given R and S, Q takes all values from 0 to $R+S$.

(ii) Explicit realization of the basis states. Consider the coefficient of the monomial

$$p^P q^Q r^R s^S u^U v^V$$

in

$$\exp(r(pz_1+qz_2)+s(pw_2-qw_1)+uz_3+vw_3).$$

Divide it by the normalization,

$$\left[\frac{(U+2I+1)!(V+2I+1)!}{P!Q!R!S!U!V!(2I+1)}\right]^{1/2}.$$

This then provides an explicit realization of the normalized basis state $|PQRSUV\rangle$.

(iii) Generating function for the invariants. All Clebsch–Gordan coefficients can be extracted from the following generating function of the invariants:

$$\mathcal{J}_{\pm}(j_{12},j_{23},j_{31},j_{21},j_{32},j_{13},j_{\pm}) = \exp(j_{12}\vec{z}^1\cdot\vec{w}^2+j_{23}\vec{z}^2\cdot\vec{w}^3+j_{31}\vec{z}^3\cdot\vec{w}^1+j_{21}\vec{z}^2\cdot\vec{w}^1+j_{32}\vec{z}^3\cdot\vec{w}^2 + j_{13}\vec{z}^1\cdot\vec{w}^3+(j_+\vec{z}^1\cdot\vec{z}^2\times\vec{z}^3 \text{ or } j_-\vec{w}^1\cdot\vec{w}^2\times\vec{w}^3)).$$

(iv) Multiplicity labels for the Clebsch–Gordan series. For three given IRs, $(M',N'),(M'',N''),(M''',N''')$, construct all solutions of

$$N(1,2)+N(1,3)+L\epsilon(L)=M^1, \quad N(2,3)+N(2,1)+L\epsilon(L)=M^2,$$

$$N(3,1)+N(3,2)+L\epsilon(L)=M^3, \quad N(2,1)+N(3,1)+|L|\epsilon(-L)=N^1,$$

$$N(3,2)+N(1,2)+|L|\epsilon(-L)=N^2, \quad N(1,3)+N(2,3)+|L|\epsilon(-L)=N^3,$$

$$3L=\sum_{a=1}^{3}(M^a-N^a),$$

where $N(a,b)$, $a\neq b$ are non-negative integers. They provide unambiguous labels for the Clebsch–Gordan series as follows.

For given two IRs (M,N) and (M',N'), construct all (M'',N'') for which $N(a,b)$, $a\neq b$ have non-negative integer solutions. Then the reversed pair (N'',M'') gives all IRs in the Clebsch–Gordan series. Multiplicity of solutions for one (M'',N'') provides the multiplicity of repeating IRs. Therefore $N(a,b)$ unambiguously provide the multiplicity labels.

(v) 3−SU(3) symbol. The $3-G$ symbols are related to the Clebsch–Gordan coefficients as in Eq. (132), and have more explicit symmetry than the latter. The 3−SU(3) symbol is represented by,

$$\begin{bmatrix} N(1,2) & N(1,3) & N(2,3) & N(2,1) & N(3,1) & N(3,2) & \\ N^2 & M^1 & N^3 & M^2 & N^1 & M^3 & N^2 \\ & U^1,R^1 & V^3,S^3 & U^2,R^2 & V^1,S^1 & U^3,R^3 & V^2,S^2 \\ & P^1 & P^3 & P^2 & Q^1 & Q^3 & Q^2 \end{bmatrix}_L .$$

Here the top row specifies the multiplicity labels: the second and third rows specify the usual complete set of labels for the basis states of the three IRs.

(vi) Generating function for the 3−SU(3) symbol for $L>0$. Extract coefficient of the monomial

$$j_{12}^{N(1,2)} j_{21}^{N(2,1)} j_{13}^{N(1,3)} j_{31}^{N(3,1)} j_{23}^{N(2,3)} j_{32}^{N(3,2)} j_{+}^{L} \prod_{\alpha=1}^{3} \overline{p}^{\alpha P^\alpha} \overline{q}^{\alpha Q^\alpha} \overline{r}^{\alpha R^\alpha} \overline{s}^{\alpha S^\alpha} \overline{u}^{\alpha U^\alpha} \overline{v}^{\alpha V^\alpha}$$

in

$$\int_{+} \to \|\tilde{B}\|^2 \exp[\|\tilde{B}\|((j_{+}\overline{r}^{1}\overline{r}^{2}\overline{u}^{3} - \overline{r}^{1} j_{12} \overline{s}^{2} + \overline{r}^{2} j_{21} \overline{s}^{1} + \overline{r}^{1} j_{12} \overline{s}^{2}(\overline{u}^{2} j_{23} \overline{v}^{3} + \overline{u}^{1} j_{13} \overline{v}^{3})$$
$$- \overline{r}^{2} j_{21} \overline{s}^{1}(\overline{u}^{2} j_{23} \overline{v}^{3} + \overline{u}^{1} j_{13} \overline{v}^{3}) + \overline{r}^{1} j_{13} \overline{v}^{3} \overline{u}^{3} j_{32} \overline{s}^{2} - \overline{r}^{2} j_{23} \overline{v}^{3} \overline{u}^{3} j_{31} \overline{s}^{1})$$
$$\times (\overline{p}^{1}\overline{q}^{2} - \overline{p}^{2}\overline{q}^{1}) + (\text{cyclic})]$$

Multiply by the factor

$$\prod_{\alpha=1}^{3} \left[\frac{P^\alpha! Q^\alpha! R^\alpha! R^\alpha! S^\alpha! U^\alpha! V^\alpha! (U^\alpha + 2I^\alpha + 1)! (2I^\alpha + 1)}{(V^\alpha + 2I^\alpha + 1)!} \right]^{1/2} .$$

This gives the 3−SU(3) symbol up to an overall normalization depending only on IRs involved.

(vii) Formula for 3−SU(3) symbol for $L>0$. We have obtained an explicit analog of the Bargmann's formula for the $3-j$ symbol of SU(2), [Eq. (33)]. This formula for 3−SU(3) symbols (for $L>0$) is presented in Eq. (187). The notation used for the summation variables is defined in Tables III and IV as explained in detail in Sec. XI.

(viii) Generating function and formula for 3−SU(3) symbol for $L<0$ case. These can be obtained from those for $L>0$ by making the changes indicated in Eqs. (203)–(207).

APPENDIX: GROUP ACTION ON THE VARIABLES

In Sec. V, we set $|z_3|=1$ in constructing the auxiliary measure. Thus the IRs are realized in the space of polynomials in z_1, z_2, w_1, w_2 and $e^{i\theta}$. We clarify here the manner in which the group acts on these variables.

The action of the group on $\vec{z}$ and $\vec{w}$ is given by,

$$\mathscr{U}: z_i \to \mathscr{U}_{ij} z_i \equiv z_i' , \quad w_i = \mathscr{U}_{ij}^{*} w_j \equiv w_i' . \tag{A1}$$

We have imposed the constraint, $\vec{w}\cdot\vec{z}=0$ and regarded (z_1,z_2,z_3,w_1,w_2) as independent variables. The action of the group on these variables is,

$$\mathscr{U}: (z_1,z_2,z_3,w_1,w_2) \to (z_1',z_2',z_3',w_1',w_2'), \tag{A2}$$

where the primed variables are defined in Eq. (A1).

Now let us take $|z_3|=1$ i.e., $z_3=e^{i\theta}$. However, under the action [Eq. (A)], $z_3\neq 0$ in general:

$$z_3' = |z_3'| \exp(i\theta') . \tag{A3}$$

Now define,

$$z_1''=\frac{z_1'}{|z_3'|},\quad z_2''=\frac{z_2'}{|z_3'|},\quad w_1''=\frac{w_1'}{|z_3'|},\quad w_2''=\frac{w_2'}{|z_3'|}. \tag{A4}$$

Then action of the group is defined by,

$$\mathscr{U}:(z_1,z_2,w_1,w_2,\theta)\rightarrow(z_1'',z_2'',w_1'',w_2'',\theta'). \tag{A5}$$

This action is nonlinear as seen from Eqs. (A1) and (A4). In spite of this it serves our purpose as a calculating tool. This realization is intimately related to the optimal boson calculus for SU(3).[51]

Also the action is ambiguous whenever $z_3'=0$, because θ' is then undefined. However, this does not pose a problem for us, because we use a generic situation in our calculations. $z_3'=0$ is a set of measure zero in our space of variables, (z_1,z_2,z_3,w_1,w_2).

Orbit–orbit branching rules between classical simple Lie algebras and maximal reductive subalgebras

M. Thoma and R. T. Sharp
Physics Department, McGill University, Montreal, Quebec, H3A 2T8, Canada

(Received 18 June 1996; accepted for publication 26 August 1996)

Complete orbit–orbit branching rules are found for the classical algebra–maximal reductive subalgebra pairs $A_{m+n+1}\supset A_m\oplus A_n\oplus u(1)$, $B_{m+1}\supset B_m\oplus u(1)$, $C_{m+1}\supset A_m\oplus u(1)$, $D_{m+1}\supset D_m\oplus u(1)$, and $D_{m+1}\supset A_m\oplus u(1)$. © *1996 American Institute of Physics.* [S0022-2488(96)02812-5]

I. INTRODUCTION

In a recent paper,[1] to be referred to as **I**, we found orbit–orbit branching rules for the classical algebra–subalgebra pairs $C_{m+n}\supset C_m\oplus C_n$, $B_{m+n}\supset D_m\oplus B_n$, $D_{m+n}\supset D_m\oplus D_n$. Our motivation here is similar, and we refer to **I** for an account of it.

We now consider the algebra–subalgebra pairs $A_{m+n+1}\supset A_m\oplus A_n\oplus u(1)$, $B_{m+1}\supset B_m\oplus u(1)$, $C_{m+1}\supset A_m\oplus u(1)$, $D_{m+1}\supset D_m\oplus u(1)$, $D_{m+1}\supset A_m\oplus u(1)$, in which the subalgebra contains the factor $u(1)$; this completes the cases in which the algebra is classical and the subalgebra is maximal and equal rank [we regard $u(1)$ as contributing 1 to the subalgebra rank]. As for the cases considered in **I**, explicit representation–representation branching rules for the present algebra–subalgebra pairs are not known for general values of m,n. Weyl sectors of algebra and subalgebra line up, i.e., each subalgebra sector contains only complete algebra sectors.

In recent publications[2,3] it is shown that for the cases under consideration (equal rank algebra–subalgebra pairs, with Weyl sectors lining up) the integrity basis (elementary Weyl orbits), in terms of which the subalgebra Weyl orbits (or, simply, orbits) contained in all algebra orbits may be expressed as stretched products (all orbit labels additive, i.e., each algebra and subalgebra label of the product orbit is equal to the sum of the corresponding labels of the factor orbits) consists entirely of the subalgebra orbits contained in the fundamental orbits of the algebra. We label an orbit by the components of its highest weight in a fundamental weights basis; a fundamental orbit is one which has a fundamental weight as its highest weight (one label is unity, the rest zero).

We use orthonormal vectors e_i for the most part as our basis in weight space rather than the more commonly used fundamental weights—it is easier then to recognize to which algebra orbit a subalgebra orbit belongs.

The $u(1)$ label, u, is centered so that its sum over all states of an algebra orbit vanishes, and its scale is such that the spacing between adjacent values in the same algebra orbit is unity. Unlike other orbit labels u can take negative and fractional values.

For each algebra–subalgebra pair we define a $u(1)$ fundamental weight ω_u. It is orthogonal to the other subalgebra fundamental weights (and roots) and points in the $u(1)$ direction. The presence of $u\omega_u$ in the weight of a state indicates that its $u(1)$ label is u.

The branching rules given in **I** for $B_{m+n}\supset D_m\oplus B_n$ and $D_{m+n}\supset D_m\oplus D_n$ are inapplicable for $m=1$, when D_m becomes $u(1)$; that is why $B_{m+1}\supset B_m\oplus u(1)$ and $D_{m+1}\supset D_m\oplus u(1)$ are treated here.

II. THE ALGEBRA–SUBALGEBRA PAIR $A_{m+n+1}\supset A_m\oplus A_n\oplus u(1)$

As basis vectors in weight space we use the $l+1$ ($l=m+n+1$) orthonormal vectors e_i, $i=1,\ldots,l+1$. The Weyl group is generated by the interchanges $e_i\leftrightarrow e_j$.

The simple roots of A_l are $\alpha_i=e_i-e_{i+1}$, $i=1,\ldots,l$. The fundamental weights ω_i are expressed in terms of the simple roots by the reciprocal of the Cartan matrix

0022-2488/96/37(12)/6570/12/$10.00

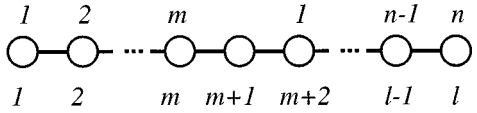

FIG. 1. The Dynkin–Coxeter diagram for $A_{m+n+1}\supset A_m\oplus A_n\oplus u(1)$. The numbers below the diagram label the simple roots of $A_l=A_{m+n+1}$. The first m above label those of A_m and the last n above label those of A_n. The direction unlabeled above corresponds to that of $u(1)$, orthogonal to the other $l-1=m+n$ simple roots of A_l.

$$\omega_i=\sum_{h=1}^{l}(C^{-1})_{ih}\alpha_h,\quad (i=1,\ldots,l); \tag{1}$$

in terms of the orthonormal basis we find

$$\omega_i=(l+1)^{-1}\left[(l-i+1)\sum_{h=1}^{i}e_h-i\sum_{h=i+1}^{l+1}e_h\right]. \tag{2}$$

α_i and ω_i are all orthogonal to $\Sigma_{h=1}^{l+1}e_h$ and hence lie in an $l=m+n+1$ dimensional weight space.

For any weight of the fundamental orbit $[i]$ according to Eq. (2) the number of e_h with coefficient $(l-i+1)/(l+1)$ is i and the number with coefficient $-i/(l+1)$ is $l-i+1$.

The simple roots of A_l, A_m, and A_n are shown in Fig. 1. In terms of the simple roots of A_l the simple roots α'_j of A_m and α''_k of A_n are $\alpha'_j=\alpha_j$, $j=1,\ldots,m$ and $\alpha''_k=\alpha_{m+k+1}$, $k=1,\ldots,n$. The fundamental weights ω'_j of A_m and ω''_k of A_n are

$$\begin{aligned}\omega'_j&=(m+1)^{-1}\left[(m-j+1)\sum_{h=1}^{j}e_h-j\sum_{h=j+1}^{m+1}e_h\right],\quad j=1,\ldots,m,\\ \omega''_k&=(n+1)^{-1}\left[(n-k+1)\sum_{h=m+2}^{m+k+1}e_h-k\sum_{h=m+k+2}^{l+1}e_h\right],\quad k=1,\ldots,n.\end{aligned} \tag{3}$$

The fundamental $u(1)$ weight is

$$\omega_u=(m+1)^{-1}\sum_{h=1}^{m+1}e_h-(n+1)^{-1}\sum_{h=m+2}^{l+1}e_h. \tag{4}$$

The algebra weight $[\lambda_1,\lambda_2,\ldots,\lambda_l]$ becomes, in the subalgebra basis, $[\lambda_1,\lambda_2,\ldots,\lambda_m;\lambda_{m+2},\lambda_{m+3},\ldots,\lambda_l;u]$, where

$$u=(l+1)^{-1}\left[(n+1)\sum_{i=1}^{m+1}i\lambda_i+(m+1)\sum_{j=1}^{n}(n-j+1)\lambda_{m+j+1}\right]. \tag{5}$$

The elementary $A_m\oplus A_n\oplus u(1)$ orbits are those contained in the fundamental A_l orbits $[i]$. A representative one, $[j;k]$, in $[i]$ has as the weight of its highest state $\omega'_j+\omega''_k+u\omega_u$, where

$$k=i-j, \tag{6}$$

$$u=(l+1)^{-1}[j(n+1)-k(m+1)]. \tag{7}$$

Thus

$$[i] \supset \sum_{j=\max(0,i-n-1)}^{\min(m+1,i)} [j;i-j]. \tag{8}$$

When $j=0$ or $m+1$ the point orbit of A_m is understood; similarly for the A_n orbit when $k=0$ or $n+1$. It may be checked that the weights $\omega'_j + \omega''_k + u\omega_u$ have i e's with coefficient $(l-i+1)/(l+1)$ and $l-i+1$ with coefficient $-i/(l+1)$ and therefore belong to the A_l orbit $[i]$; moreover the weights of $[j;k]$ exhaust those of $[i]$.

It remains to find the compatibility rules between pairs of elementary orbits. Consider the stretched product $[j;k]\cdot[j';k']$; it implies the orbit $[j,j';k,k']$ of $A_m \oplus A_n \oplus u(1)$ where the A_m orbit $[j,j']$ is that with labels $\lambda'_h = \delta_{hj} + \delta_{hj'}$ and similarly for the orbit $[k,k']$ of A_n. The pair $[j;k],[j';k']$ is compatible if and only if their stretched product belongs to the orbit $[i,i']$ of A_l, where $i=j+k$ and $i'=j'+k'$. We may suppose $i'>i$ (two elementary orbits in the same A_l orbit are known to be incompatible). We may also suppose $j'>j$ (otherwise interchange the roles of A_m and A_n). Now a weight of the A_l orbit $[i,i']$ has i e's with coefficient $(2l-i-i'+2)/(l+1)$, $i'-i$ with coefficient $(l-i-i'+1)/(l+1)$ and $l-i'+1$ with coefficient $-(i+i')/(l+1)$.

The A_m orbit $[j,j']$ has weight $\omega'_j + \omega'_{j'} + [(j+j')(l-m) - (k+k')(m+1)][(l+1)(m+1)]^{-1}\Sigma_{h=1}^{m+1} e_h$; we have included the part of the $u(1)$ weight component for which $h \leqslant m+1$. There are j e's with coefficient $(2l-i-i'+2)/(l+1)$, $j'-j$ with coefficient $(l-i-i'+1)/(l+1)$ and $m+1-j'$ with coefficient $-(i+i')/(l+1)$. Comparing this with the number of e's in the A_l orbit with each coefficient we conclude that in the A_n part of the weight there are k e's with coefficient $(2l-i-i'+2)/(l+1)$, $k'-k$ with coefficient $(l-i-i'+1)/(l+1)$ and $n-k'+1$ with coefficient $-(i+i')/(l+1)$. This is possible only if $k' \geqslant k$. So $[j;k]$ and $[j';k']$ are compatible if and only if $j' \geqslant j$ and $k' \geqslant k$ (recall $i'>i$). The compatibility condition is shown diagrammatically in Fig. 2. Two elementary orbits are incompatible if one lies above and to the right of the other.

So the orbit–orbit branching rules are complete. To get the $A_m \oplus A_n \oplus u(1)$ orbit content of the A_l orbit $[\lambda_1,\lambda_2,...,\lambda_l]$, choose a series of boxes $[j_i;k_i]$, one from each diagonal row $i=j_i+k_i$ for which $\lambda_i \neq 0$, such that each is compatible with the last preceding i (and therefore with all preceding i). Each such series contributes one subalgebra orbit $[\lambda'_1,\ldots,\lambda'_m;\lambda''_1,\ldots,\lambda''_n]$ with $\lambda'_h = \Sigma_i \lambda_i \delta_{hj_i}$, $\lambda''_h = \Sigma_i \lambda_i \delta_{hk_i}$ (the stretched product of the chosen mutually compatible orbits); the $u(1)$ labels are also additive. The same strategy can be used to get the subalgebra orbit content of an arbitrary algebra orbit for the algebra–subalgebra pairs considered in the next four sections; we will not repeat it for them.

III. THE ALGEBRA–SUBALGEBRA PAIR $B_{m+1} \supset B_m \oplus u(1)$

In this and the next three sections (III–VI), to save space, we state our results without detailed proofs; the proofs are very similar to those given in Sec. II for $A_{m+n+1} \supset A_m \oplus A_n \oplus u(1)$. The roots of B_l $(l=m+1)$ are $\pm e_i$, $i=1,\ldots,l$ and $\pm e_i \pm' e_j$, $i=1,\ldots,l-1$ and $j=i+1,\ldots,l$ where e_i, $i=1,\ldots,l$ are orthonormal vectors; the prime above is to indicate that the $\pm$ signs are independent. The Weyl group is generated by sign reversals $e_i \to -e_i$ and interchanges $e_i \leftrightarrow e_j$.

The simple roots of B_l are $\alpha_i = e_i - e_{i+1}$, $i=1,\ldots,l-1$ and $\alpha_l = e_l$. The fundamental weights are given by

$$\omega_i = \sum_{h=1}^{i} e_h, \quad i=1,\ldots,l-1, \quad \omega_l = \frac{1}{2}\sum_{h=1}^{l} e_h. \tag{9}$$

In any weight of the fundamental orbit $[i]$, $i=1,\ldots,l-1$, the number of e_h with coefficient ± 1 is i, the number with coefficient 0 is $l-i$; in the fundamental orbit $[l]$, all l e_h have coefficient $\pm\frac{1}{2}$.

The simple roots of B_l and B_m are shown in Fig. 3. The simple roots of B_m are $\alpha'_i = \alpha_{i+1}$.

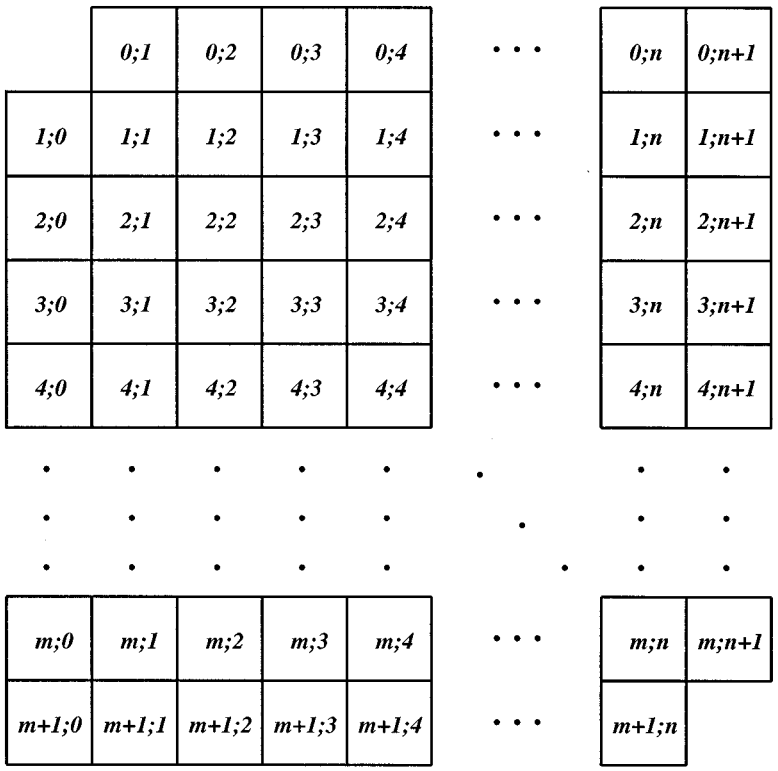

FIG. 2. The elementary $A_{m+n+1}\supset A_m\oplus A_n\oplus u(1)$ W orbits. The elementary orbit $[j;k]$ belongs to the $(j+k)$th fundamental orbit of A_{m+n+1}. Two elementary orbits are compatible only if one lies below and/or to the right of the other.

The fundamental weights of B_m are

$$\omega_i'=\sum_{h=2}^{i+1} e_h\,,\quad i=1,\ldots,m-1,$$

$$\omega_m'=\frac{1}{2}\sum_{h=2}^{l} e_h\,. \tag{10}$$

The fundamental $u(1)$ weight is

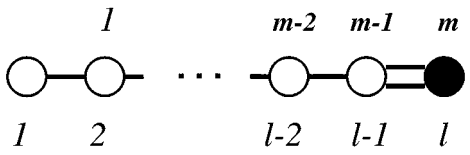

FIG. 3. The Dynkin–Coxeter diagram for $B_{m+1}\supset B_m\oplus u(1)$. The numbers below the diagram label the simple roots of $B_l=B_{m+1}$. Those above label those of B_m. The direction unlabeled above corresponds to that of $u(1)$, orthogonal to the simple roots and fundamental weights of B_m.

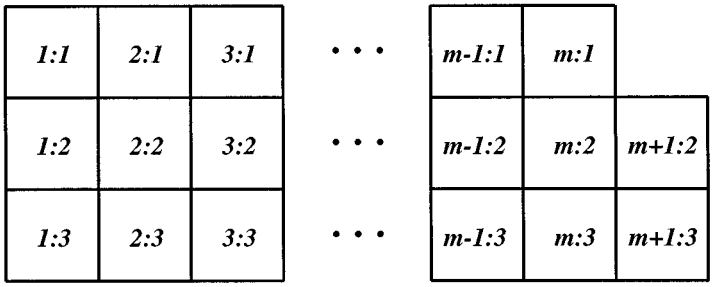

FIG. 4. The elementary subalgebra orbits for $B_{m+1}\supset B_m\oplus u(1)$. Those in the ith column belong to the ith fundamental orbit of $B_l=B_{m+1}$. One in the first row is compatible with all those to its right, in any row. One in the second or third row is compatible with one to its right only if they are in the same row.

$$\omega_u=e_1. \tag{11}$$

The algebra weight $[\lambda_1,\lambda_2,...,\lambda_l]$ becomes, in the subalgebra basis, $[\lambda_2,\lambda_3,...,\lambda_l;u]$ with

$$u=\sum_{h=1}^{l-1}\lambda_h+\frac{1}{2}\lambda_l. \tag{12}$$

The elementary $B_m\oplus u(1)$ orbits are those contained in the fundamental B_l orbits $[i]$. The first m orbits contain 3 elementary orbits each and the lth contains 2

$$\begin{gathered}[i]\supset[i{:}1]\oplus[i{:}2]\oplus[i{:}3],\quad i=1,\ldots,m,\\ [l]\supset[l{:}2]\oplus[l{:}3],\end{gathered} \tag{13}$$

where

$$\begin{gathered}[i{:}1]=[i;0],\quad i=1,\ldots,m-1,\quad [m{:}1]=[2m;0],\\ [i{:}2]=[i-1;1],\quad i=1,\ldots,m,\\ [i{:}3]=[i-1;-1],\quad i=1,\ldots,m,\\ [l{:}2]=[m;\tfrac{1}{2}],\quad [l{:}3]=[m;-\tfrac{1}{2}],\end{gathered} \tag{14}$$

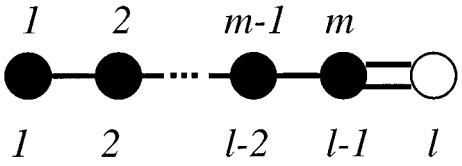

FIG. 5. The Dynkin–Coxeter diagram for $C_{m+1}\supset A_m\oplus u(1)$. The numbers below the diagram label the simple roots of $C_l=C_{m+1}$. Those above label those of A_m. The direction unlabeled above corresponds to that of $u(1)$, orthogonal to the simple roots and fundamental weights of A_m.

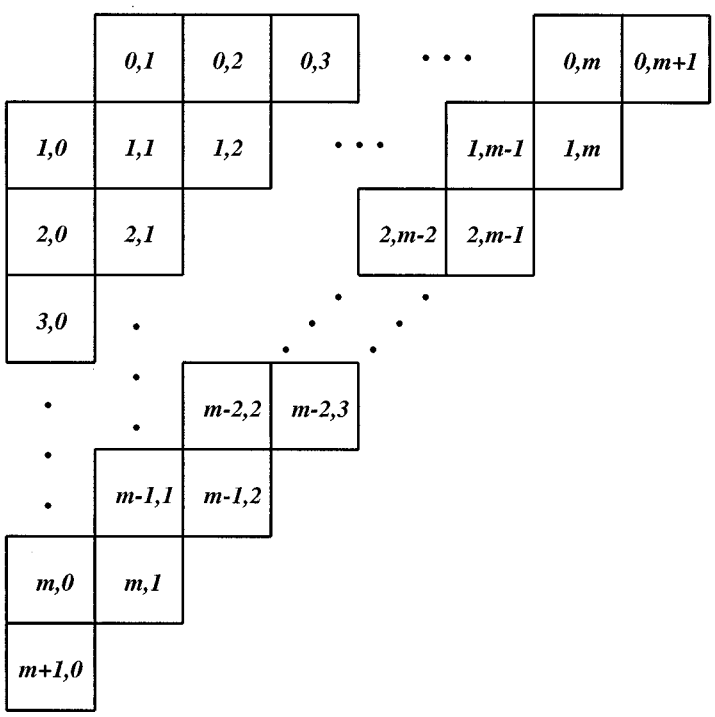

FIG. 6. The elementary $C_{m+1}\supset A_m\oplus u(1)$ orbits $[j,k]$. The orbit $[j,k]$ belongs to the ith$=(j+k)$th fundamental orbit of $C_l=C_{m+1}$. Two elementary orbits are incompatible if and only if one lies to the right and above the other.

The numbers i, $i-1$, m mean the corresponding B_m fundamental orbits; $2m$ means the B_m orbit whose mth label is 2, the others 0; $i-1$ means the point orbit when $i=1$. The symbol on the right of the semicolon is the $u(1)$ label of the orbit.

Two elementary orbits $[j{:}k]$ and $[j';k']$, with $j'>j$, are compatible if $k=1$, or if k and k' are equal; if $k\neq 1$ and $k'\neq k$ they are incompatible; see Fig. 4.

IV. THE ALGEBRA–SUBALGEBRA PAIR $C_{m+1}\supset A_m\oplus u(1)$

The roots of C_l $(l=m+1)$ are $\pm e_i$, $1\leqslant i\leqslant l$ and $\pm e_i\pm' e_j$, $1\leqslant i<j\leqslant l$, where e_i, e_j are orthonormal weight space vectors. Weyl reflections are generated by sign reversals $e_i\rightarrow -e_i$ and

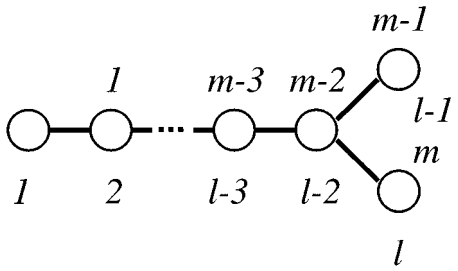

FIG. 7. The Dynkin–Coxeter diagram for $D_{m+1}\supset D_m\oplus u(1)$. The numbers below the diagram label the simple roots of D_l $(l=m+1)$. Those above label those of D_m. The direction unlabeled above corresponds to that of $u(1)$, orthogonal to the simple roots and fundamental weights of D_m.

interchanges $e_i \leftrightarrow e_j$. The simple roots are $\alpha_i = e_i - e_{i+1}$, $i = 1,\ldots,l-1$ and $\alpha_l = 2e_l$ (for simplicity we have multiplied them and the fundamental weights below by $\sqrt{2}$). In terms of the orthonormal basis the fundamental weights are

$$\omega_i = \sum_{h=1}^{i} e_h, \quad i = 1,\ldots,l. \tag{15}$$

Any weight of the fundamental orbit $[i]$, with highest weight ω_i, has i e's with coefficient ± 1, $l-i$ with coefficient 0.

The simple roots of C_l and A_m are shown in Fig. 5. Those of A_m are $\alpha'_i = \alpha_i$, $i = 1,\ldots,m$. The fundamental weights ω'_j of A_m are

$$\omega'_j = l^{-1}\left[(l-j)\sum_{h=1}^{j} e_h - j\sum_{h=j+1}^{l} e_h\right]. \tag{16}$$

The fundamental $u(1)$ weight is

$$\omega_u = 2l^{-1}\sum_{h=1}^{l} e_h. \tag{17}$$

The algebra weight $[\lambda_1,\ldots,\lambda_l]$ becomes, in the subalgebra basis, $[\lambda_1,\ldots,\lambda_{l-1};u]$ with

$$u = \frac{1}{2}\sum_{i=1}^{l} i\lambda_i. \tag{18}$$

The elementary $A_m \oplus u(1)$ orbits are the ones contained in the fundamental C_l orbits $[i]$. A representative one, $[j;k]$, in $[i]$ has as the weight of its highest state $\omega_j + \omega_{l-k} + u\omega_u$, where

$$k = i - j, \tag{19}$$

$$u = \tfrac{1}{2}(j-k). \tag{20}$$

Thus

$$[i] \supset \sum_{j=0}^{i} [j, i-j], \quad i = 1,\ldots,l. \tag{21}$$

The elementary orbit $[j,k]$, where $k = i-j$, has A_m orbit labels

$$\lambda_h = \delta_{hj} + \delta_{h,l-k}, \tag{22}$$

where δ_{hj} or $\delta_{h,l-k}$ is taken as zero when j or k, respectively, is 0 or l. The u label of the orbit $[j,k]$, suppressed in Eq. (21), is given by Eq. (20). When $i = l$, j and $l-k$ are equal and nonzero A_m orbit labels are all 2.

It can be shown that two elementary orbits $[j,k]$ and $[j',k']$ (we may suppose $i' = j' + k' > i = j + k$) are compatible if and only if $j' \geqslant j$ and $k' \geqslant k$ (only one of the $\geqslant$ signs can be $=$). The elementary orbits and their compatibility rules are shown graphically in Fig. 6.

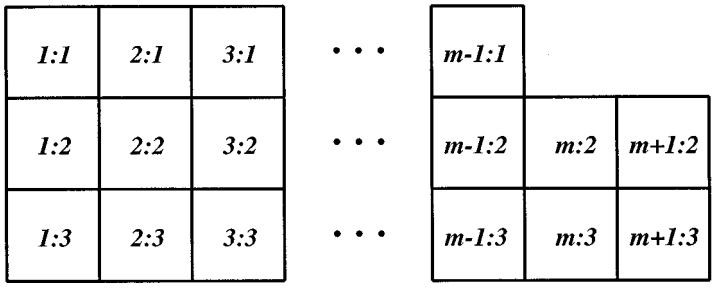

FIG. 8. The elementary subalgebra orbits for $B_{m+1}\supset B_m\oplus u(1)$. Those in the ith column belong to the ith fundamental B_l orbit, $l=m+1$. One in the first row is compatible with all those to its right, in any row. Each in rows 2 and 3 is compatible with those to its right in the same row, and both in the mth column are compatible with both in the $(m+1)$th column.

V. THE ALGEBRA–SUBALGEBRA PAIR $D_{m+1}\supset D_m\oplus u(1)$

The roots of D_l $(l=m+1)$ are $\pm e_i\pm' e_j$, $1\leqslant i<j\leqslant l$ where e_i, e_j are orthonormal weight space vectors. The Weyl group is generated by two sign reversals at a time $e_i\rightarrow -e_i$, $e_j\rightarrow -e_j$ and interchanges $e_i\leftrightarrow e_j$.

The simple roots are $\alpha_i=e_i-e_{i+1}$, $i=1,\ldots,l-1$, $\alpha_l=e_{l-1}+e_l$. The fundamental weights are

$$\omega_i=\sum_{h=1}^{i} e_h, \quad i=1,\ldots,l-2,$$

$$\omega_{l-1}=\frac{1}{2}\left[\sum_{h=1}^{l-1} e_h-e_l\right], \quad \omega_l=\frac{1}{2}\left[\sum_{h=1}^{l-1} e_h+e_l\right]. \tag{23}$$

Thus a weight of the orbit $[i]$, $i\leqslant l-2$, has i e_h with coefficient ± 1, the rest with coefficient 0; one of $[l-1]$ has an odd number with coefficient $-\frac{1}{2}$, the rest with coefficient $\frac{1}{2}$; one of $[l]$ has an even number with coefficient $-\frac{1}{2}$, the rest with coefficient $\frac{1}{2}$.

The simple roots of D_l and D_m are shown in Fig. 7. The simple roots of D_m are $\alpha_i'=\alpha_{i+1}$, $i=1,\ldots,m$. The fundamental weights of D_m are

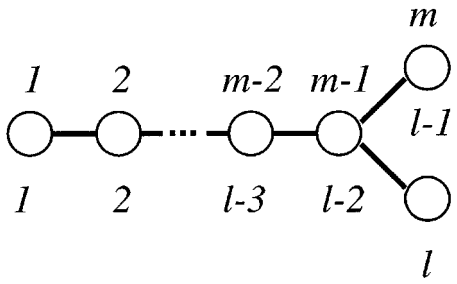

FIG. 9. The Dynkin–Coxeter diagram for $D_{m+1}\supset A_m\oplus u(1)$. The numbers below the nodes label the simple roots of D_l $(l=m+1)$. Those above label those of A_m. The direction unlabeled above corresponds to that of $u(1)$, orthogonal to the roots and fundamental weights of A_m.

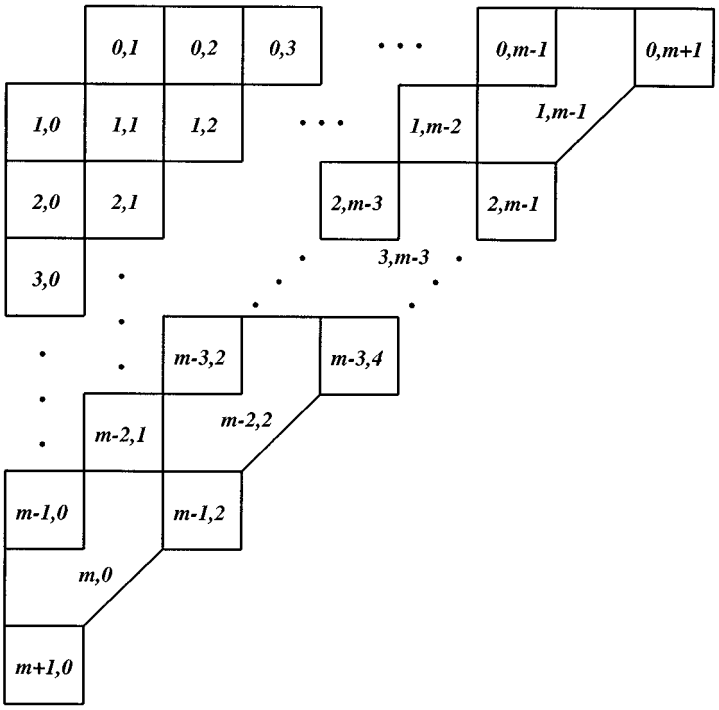

FIG. 10. The elementary $D_{m+1}\supset A_m\oplus u(1)$ orbits for $l=m+1$ even. Two orbits are compatible only if one is to the right of and/or below the other, or, in case one of them is in the diagonal row $l-1$, if either of its squares is to right of and/or below the other or to the left of and/or above the other.

$$\omega_i'=\sum_{h=2}^{i+1} e_h\,,\quad i=1,\ldots,m-2,$$
$$\omega_{m-1}'=\frac{1}{2}\left[\sum_{h=2}^{l-1} e_h-e_l\right],\quad \omega_m'=\frac{1}{2}\sum_{h=2}^{l} e_h\,. \tag{24}$$

The fundamental $u(1)$ weight is

$$\omega_u=e_1\,. \tag{25}$$

A D_l weight $[\lambda_1,\ldots,\lambda_l]$, in a $D_m\oplus u(1)$ basis, becomes $[\lambda_2,\lambda_3,\ldots,\lambda_l;u]$ with

$$u=\sum_{i=1}^{l-2}\lambda_i+\frac{1}{2}(\lambda_{l-1}+\lambda_l). \tag{26}$$

The elementary $D_m\oplus u(1)$ orbits are those contained in the fundamental D_l orbits $[i]$. The first $l-2$ orbits contain 3 elementary orbits each; the $(l-1)$th and lth each contains 2

$$[i]\supset[i{:}1]\oplus[i{:}2]\oplus[i{:}3],\quad i=1,\ldots,l-2,$$
$$[l-1]\supset[l-1{:}2]\oplus[l-1{:}3],\quad [l]\supset[l{:}2]\oplus[l{:}3], \tag{27}$$

where

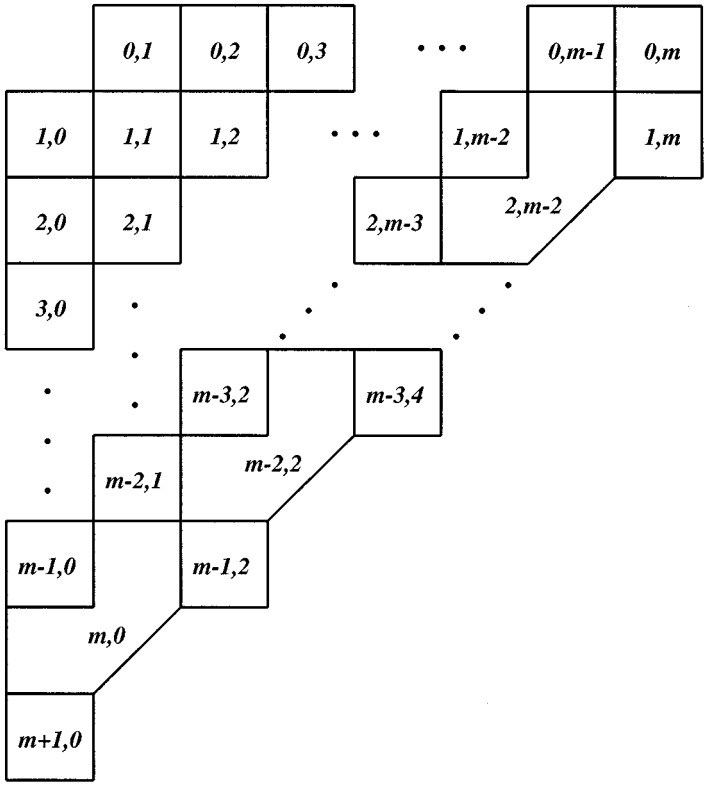

FIG. 11. The elementary $D_{m+1}\supset A_m\oplus u(1)$ orbits for $l=m+1$ odd. The compatibility condition for two orbits is the same as that in the caption of Fig. 10.

$$
\begin{gathered}
[i{:}1]=[i;0],\quad i=1,\ldots,l-3,\\
[l-2{:}1]=[m-1,m;0]\ \text{(the last two } D_m \text{ labels are 1, the rest 0)}\\
[i{:}2]=[i-1;1],\quad i=1,\ldots,l-2,\\
[i{:}3]=[i-1;-1],\quad i=1,\ldots,l-2,\\
[l-1{:}2]=[m-1;\tfrac{1}{2}],\quad [l-1{:}3]=[m;-\tfrac{1}{2}],\\
[l{:}2]=[m;\tfrac{1}{2}],\quad [l{:}3]=[m-1;-\tfrac{1}{2}].
\end{gathered}
\tag{28}
$$

The numbers $i,i-1,m,m-1$ mean the corresponding D_m fundamental orbits, i.e., the corresponding D_m orbit label is 1. The number to the right of the semicolon is the $u(1)$ label.

Two elementary orbits $[j{:}k]$ and $[j'{:}k']$, with $j'>j$, are compatible if $k=1$ or if k and k' are equal or if $j=m$ and $j'=m+1$; otherwise they are incompatible; see Fig. 8.

VI. THE ALGEBRA–SUBALGEBRA PAIR $D_{m+1}\supset A_m\oplus u(1)$

The roots and fundamental weights of D_l $(l=m+1)$ are of course the same as those given in the first paragraph of Sec. V.

The simple roots of D_l and A_m are shown in Fig. 9. The simple roots of A_m are $\alpha_i' = \alpha_i$, $i=l,\ldots,m$. The fundamental weights of A_m are

$$\omega_i' = (m+1)^{-1}\left[(m-i+1)\sum_{h=1}^{i} e_h - i\sum_{h=i+1}^{m+1} e_h\right]. \tag{29}$$

The fundamental $u(1)$ weight ω_u is

$$\omega_u = \frac{2}{l}\sum_{h=1}^{l} e_h . \tag{30}$$

The D_l weight $[\lambda_1,\ldots,\lambda_l]$ becomes, in the $A_m \oplus u(1)$ basis, $[\lambda_1,\ldots,\lambda_{l-1};u]$, with

$$u = \frac{1}{2}\sum_{i=1}^{l-2} i\lambda_i + \frac{l-2}{4}\lambda_{l-1} + \frac{l}{4}\lambda_l . \tag{31}$$

The elementary $A_m \oplus u(1)$ orbits are those contained in the fundamental D_l orbits $[i]$. We find

$$[i] \supset \sum_{j=0}^{i} [j,i-j], \quad i=1,\ldots l-2, \tag{32}$$

$$[i] \supset \sum_{j=0}^{[(1/2)\,i]} [i-2j,2j], \quad i=l-1,l. \tag{33}$$

In Eq. (32) the elementary orbit $[j,k]$, with $k=i-j$, is that with labels

$$\lambda_h = \delta_{hj} + \delta_{h,l-k}, \tag{34}$$

i.e., the nonzero (unit) labels are the jth and $(l-k)$th; if j (or k) is 0 or l the corresponding Kronecker δ in Eq. (34) is 0. The u label of the orbit $[j,k]$, suppressed in Eq. (32), is

$$u = \tfrac{1}{2}(j-k). \tag{35}$$

In Eq. (33) $[\frac{1}{2}i]$ means the integer part of $\frac{1}{2}i$, i.e., $\frac{1}{2}i$ or $\frac{1}{2}(i-1)$ according to whether i is even or odd. The elementary orbit $[i-2j,2j]$ is that with labels

$$\lambda_h = \delta_{h,i-2j}, \tag{36}$$

i.e., there is one nonzero (unit) label, the $(i-2j)$th; if $i-2j$ is 0 or l the Kronecker δ in Eq. (36) is 0 and we have the point or zero orbit of A_m. The u-label of $[i-2j,2j]$ is

$$u = \tfrac{1}{2}i - j - \tfrac{1}{4}l. \tag{37}$$

The elementary orbits and their compatibility rules are shown graphically in Figs. 10 and 11, for l even and odd, respectively.

For the $(l-1)$th fundamental orbit we associate with the elementary orbit $[m-2j,2j]$ also the labels $[m-2j-1,2j+1]$ (except when $m-2j=0$), so it is represented by two boxes in Figs. 10 and 11. Two elementary orbits $[j,k],[j',k']$ are incompatible if $j'>j$ and $k'<k$ or if $j'<j$ and $k'>k$. In case $j+k=m$ or $j'+k'=m$ these inequalities must hold for both versions of $[j,k]$ or $[j',k']$; see the caption of Fig. 10.

VII. CONCLUSIONS

This work concludes the computation of branching rules for Weyl orbits of classical Lie algebras and their maximal reductive regular subalgebras. Work on a similar problem for Kac–Moody algebras is in progress.

A version of Schur's lemma is proven that elucidates some issues raised by that paper. © *1996 American Institute of Physics.* [S0022-2488(96)03712-7]

I. PRELIMINARIES: PROJECTIVE REPRESENTATIONS OF INDIVIDUAL SYMMETRIES

In a paper[1] recently published in this journal, Adler mentions divergences between his approach and that taken by the present author[2] in connection with a then new proof[3,4] for Wigner's theorem (also see notes No. 5–7 for Bargmann's review[5] on the several proofs that appeared at the time). It seems worth pointing out that these divergences are not due, as Adler states, to a ''failure'' that ''can lead to erroneous conclusions,'' but rather to subtle shifts in the assumptions.

Let us first recall that in Refs. 2 and 3 a *symmetry* of an irreducible quaternionic quantum system is defined as an isomorphism μ of the canonically relatively orthocomplemented lattice $\mathscr{P}(\mathscr{H}_{\mathbf{H}})$ of all projectors of a Hilbert space $\mathscr{H}_{\mathbf{H}}$ on the field $\mathbf{H}$ of the real quaternions. To make things as unambiguous as is compatible with conciseness, we only mention here that the scalar product in $\mathscr{H}_{\mathbf{H}}$ is a positive definite sesquilinear form, linear in its first factor: $(q\phi,\psi)=q(\phi,\psi)$ and $(\phi,\psi)=(\psi,\phi)^*$, $\forall q\in\mathbf{H}$; $\phi,\psi\in\mathscr{H}_{\mathbf{H}}$; and that μ is an isomorphism of $\mathscr{P}(\mathscr{H}_{\mathbf{H}})$ exactly when it is a bijective map, such that

$$P\subset Q\Rightarrow\mu P\subset\mu Q;\quad (\mu P)^{\perp}=\mu(P^{\perp}),\quad \forall P,Q\in\mathscr{P}(\mathscr{H}_{\mathbf{H}}). \tag{1.1}$$

The interpretation of this formulation has its roots in the work of Birkhoff and von Neumann:[6] the elements of $\mathscr{P}$ are to be interpreted as the ''propositions'' (or ''questions'' or ''yes–no'' experiments) on the physical system considered. Hence (1.1) is the pragmatic requirement that *if Q is true whenever P is true, i.e. if P implies Q, then μP implies μQ; and the negation $(\mu P)^{\perp}$ of μP is the image through μ of the negation $P^{\perp}$ of P*.

As a consequence[3] of the first fundamental theorem of projective geometry,[7] every such μ is implemented by a bijective semilinear map of $\mathscr{H}_{\mathbf{H}}$ into itself:

$$\mu(P)=S^{-1}PS,\quad \forall P\in\mathscr{P}(\mathscr{H}_{\mathbf{H}}), \tag{1.2}$$

with

$$S(\phi+\psi)=S\phi+S\psi\quad\text{and}\quad S(q\phi)=q_S^{-1}qq_SS\phi,\forall q\in\mathbf{H};\quad \phi,\psi\in\mathscr{H}_{\mathbf{H}}. \tag{1.3}$$

Clearly, then, one can assume without loss of generality that there exists a bijective, *linear* map of $\mathscr{H}_{\mathbf{H}}$ onto itself, namely $S_0\equiv q_sS$, which implements the same symmetry:

$$S_0^{-1}PS_0=\mu(P)=S^{-1}PS,\quad \forall P\in\mathscr{P}(\mathscr{H}_{\mathbf{H}}). \tag{1.4}$$

Proposition 1 (A Quaternionic Schur's lemma): The bijective semilinear map S of $\mathscr{H}_{\mathbf{H}}$ which implements a symmetry μ of $\mathscr{P}(\mathscr{H}_{\mathbf{H}})$ is unique up to a multiplicative constant ω; i.e., if $S_k(k=1,2)$ are two bijective semilinear maps such that

$$S_1^{-1}PS_1=S_2^{-1}PS_2,\forall P\in\mathscr{P}(\mathscr{H}_{\mathbf{H}}); \tag{1.5}$$

0022-2488/96/37(12)/6582/4/$10.00

then

$$S_1 = \omega S_2, \quad \text{for some non-zero} \quad \omega \in \mathbf{H}. \tag{1.6}$$

As the proof of this result bears directly on the main issue of this paper, it is given with some details here.

Proof: Let $S \equiv S_1 S_2^{-1}$ and let $S_0 \equiv q_s S$ be the corresponding bijective, *linear* map [cf. (1.4)]. We have then

$$PS_0 = S_0 P, \quad \forall P \in \mathscr{P}(\mathscr{H}_{\mathbf{H}}). \tag{1.7}$$

For every $\psi \in \mathscr{H}_{\mathbf{H}}$ with $\|\psi\| = 1$, let P_ψ denote the projector

$$P_\psi : \phi \in \mathscr{H}_H \to (\phi, \psi)\psi \in \mathscr{H}_{\mathbf{H}}. \tag{1.8}$$

From (1.7) we have in particular for all ϕ and ψ on the unit sphere of $\mathscr{H}_{\mathbf{H}}$:

$$P_\psi S_0 \phi = S_0 P_\psi \phi, \tag{1.9}$$

which reads as (recall that S_0 is linear)

$$(S_0\phi, \psi)\psi = (\phi, \psi) S_0 \psi, \tag{1.10}$$

and thus in particular, for $\phi = \psi$:

$$S_0\phi = \omega_0(\phi)\phi, \quad \forall \phi \in \mathscr{H}_{\mathbf{H}} \quad \text{with} \quad \|\phi\| = 1. \tag{1.11}$$

The essence of Proposition 1 is to assert that any explicit dependence of ω on ϕ would not be compatible with the definition (1.1) of a symmetry. Indeed, we first notice that, whenever $(\phi, \psi) \neq 0$, (1.9) reads as

$$S_0\psi = \omega_0(\psi)\psi, \quad \text{with} \quad \omega_0(\psi) = (\phi, \psi)^{-1}\omega_0(\phi)(\phi, \psi). \tag{1.12}$$

Upon using the above argument again for $\chi = (\|\phi + \psi\|)^{-1}(\phi + \psi)$ whenever ϕ and ψ are linearly independent and not orthogonal, we have

$$\omega_0(\chi)\phi + \omega_0(\chi)\psi = (\|\phi + \psi\|) S_0 \chi = \omega_0(\phi)\phi + \omega_0(\psi)\psi, \tag{1.13}$$

i.e., upon using linear independence of ϕ and ψ,

$$\omega_0(\phi) = \omega_0(\psi). \tag{1.14}$$

For ϕ, ψ as above, and $q \in \mathbf{H}$ with $\|q\| = 1$, the previous argument, now with $\phi' = q\phi$, used instead of ϕ, gives

$$\omega_0(q\phi) = \omega_0(\psi), \tag{1.15}$$

i.e., together with (1.12) and (1.14),

$$q\omega_0(\phi)q^* = \omega_0(\phi), \quad \forall q \in \mathbf{H} \quad \text{with} \quad \|q\| = 1. \tag{1.16}$$

This implies that $\omega_0(\phi)$ is *real*.

Finally, when $(\phi, \psi) = 0$ let $\zeta = (1/\sqrt{2})(\phi + \psi)$ to get similarly

$$\omega_0(\phi) = \omega_0(\zeta) \quad \text{and} \quad \omega_0(\zeta) = \omega_0(\psi), \tag{1.17}$$

so that (1.14) holds again in this case. Hence, there is an ω_0 real, and *independent* of ϕ, such that

$$S_0\phi=\omega_0\phi, \quad \forall\,\phi\in\mathscr{H}_{\mathbf{H}} \quad \text{with } \|\phi\|=1. \tag{1.18}$$

Since ω_0 is real, we have

$$S_0\phi=\omega_0\phi, \quad \forall\,\phi\in\mathscr{H}_{\mathbf{H}}, \text{ i.e., } S_0=\omega_0 I. \tag{1.19}$$

Returning now to the first line of the proof, we see that (1.19) proves the proposition, namely

$$S_1=\omega S_2, \quad \text{with } \omega=q_S^{-1}\omega_0. \tag{1.20}$$

Remark: Without loss of generality, we can assume[2–4] that the transformations S implementing any symmetry μ are not only semilinear but counitary, i.e.,

$$(S\phi,S\psi)=q_S(\phi,\psi)q_S^{-1}, \quad \forall\,\phi,\psi\in\mathscr{H}_{\mathbf{H}}. \tag{1.21}$$

We can therefore require, without loss of generality, that the quaternion ω in the conclusion (1.6) is of norm 1.

II. THE ISSUE: PROJECTIVE REPRESENTATIONS OF SYMMETRY GROUPS

Having predicated our analysis (as Adler apparently did his) on the idea that the natural language in which to express the primary concepts of the theory of symmetries is *projective geometry*, we defined[2] a *projective representation* μ of a group G as a *group homomorphism*,

$$\mu: g\in G\mapsto\mu(g)\in \mathrm{Aut}\{\mathscr{P}(\mathscr{H}_{\mathbf{H}})\}, \tag{2.1}$$

where Aut $\{\mathscr{P}(\mathscr{H}_{\mathbf{H}})\}$ is the group of all bijective maps of $\mathscr{P}(\mathscr{H}_{\mathbf{H}})$ onto itself, satisfying (1.1). Since the theory of group representations on vector spaces is still (and certainly was in the 1930s) better developed than the corresponding theory for projective spaces, the interest of Wigner's theorem is to help reduce the study of the latter to that of the former. Specifically, we defined a *lifting* of a projective representation μ as a map

$$S: g\in G\mapsto S(g)\in \mathrm{Aut}\{\mathscr{H}_H)\}, \quad \text{with } S(g)^{-1}PS(g)=\mu P, \quad \forall\,P\in\mathscr{P}(\mathscr{H}_{\mathbf{H}})), \tag{2.2}$$

where Aut $\{\mathscr{H}_{\mathbf{H}})\}$ denotes the group of all bijective semilinear maps of $\mathscr{H}_{\mathbf{H}}$ onto itself. Note that, while the map S implements μ, this is not sufficient to ensure that the map S is itself a group homomorphism. Nevertheless, since for any pair g_1, g_2 of elements of G, $S(g_1)S(g_2)$ and $S(g_1g_2)$ implement the same symmetry, we have

$$[S(g_1)S(g_2)]^{-1}P[S(g_1)S(g_2)]=[S(g_1g_2)]^{-1}P[S(g_1g_2)], \quad \forall\,P\in\mathscr{P}(\mathscr{H}_{\mathbf{H}}). \tag{2.3}$$

Proposition 1 thus implies that there exists a nonzero quaternion $\omega(g_1,g_2)$ (which one can actually take to be of norm 1; see the remark at the end of Sec. I), such that

$$S(g_1)S(g_2)=\omega(g_1,g_2)S(g_1g_2). \tag{2.4}$$

Adler collapses these two definitions [projective representation, i.e. (2.1); and lifting i.e. (2.2)] into one, namely that

$$[S(g_1)S(g_2)]\phi=\omega(\phi;g_1,g_2))[S(g_1g_2)]\phi, \tag{2.5}$$

holds ''for one particular complete set of states.''

III. DISCUSSION

Adler emphasizes that one should allow for an actual dependence of ω on ϕ in (2.5); also see his book;[8] especially its Sec. 4.6 (his Ref. 4) that he cites to support his version, formula (2), of the above (2.5). Adler points out correctly that this requires restricting (2.5) to hold only on a particular set of vectors rather than on the whole unit sphere of $\mathscr{H}_{\mathbf{H}}$; indeed the latter would imply that one of the transformations $S(g_1)$, $S(g_2)$, or $S(g_1g_2)$ would not be semilinear, thus violating Wigner's theorem.

This is to say that the definitions (2.1–2.2) and (2.5) (with an explicit dependence on ϕ) are not compatible unconditionally; specifically, condition (2.5) holds only if condition (2.3) is violated in such a way that one cannot go past (1.11) in the proof of Proposition 1 (see Sec. I); hence, the weakening of condition (2.3) must be such as to exclude, in that proof, the consideration of pairs ψ, ϕ of (unit) vectors in $\mathscr{H}_{\mathbf{H}}$ that are not orthogonal. This then requires (i) that in (2.3) $\mathscr{P}(\mathscr{H}_{\mathbf{H}})$ be replaced by the atomic maximal Boolean orthocomplemented sublattice $\mathscr{P}_0$ of $\mathscr{P}(\mathscr{H}_{\mathbf{H}})$ corresponding to a complete orthonormal basis $\{\psi_n\}$ in $\mathscr{H}_{\mathbf{H}}$; and (ii) that the modified condition (2.3) holds only on pure states on $\mathscr{P}_0$; i.e., that ψ and ϕ run over the members of $\{\psi_n\}$.

For consistency reasons, one may then wish to pursue Adler's more general definition, involving only ''one particular complete set of states,'' into the actual premises of the theory, namely the axiomatic (i.e., physical) definition of a symmetry. One would then have to take into account the fact that the first fundamental theorem of projective geometry does not hold in such a weakened environment, invalidating thereby the usual arguments (Refs. 3–5, i.e., Adler's Refs. Nos. 1–3) that are intimately linked to the derivation and axiomatic implications of Wigner's representation of individual symmetries by semilinear transformations of the underlying Hilbert space.

Thus, we thought that what ultimately amounts to a subtle shift in assumptions—rather than to some erroneous deductions from accepted basic premises—deserved to be pinpointed, as it clarifies the genuine scope of the new horizons opened by Adler's generalization.

(Received 8 July 1996; accepted for publication 12 August 1996)

We discuss the differing definitions of complex and quaternionic projective group representations employed by us and by Emch. The definition of Emch (termed here a strong projective representation) is too restrictive to accommodate quaternionic Hilbert space embeddings of complex projective representations. Our definition (termed here a weak projective representation) encompasses such embeddings, and leads to a detailed theory of quaternionic, as well as complex, projective group representations. © *1996 American Institute of Physics.* [S0022-2488(96)03812-1]

I. PRELIMINARIES NOT INVOLVING GROUP STRUCTURE

Before turning to a discussion of what is an appropriate definition of a quaternionic projective group representation, we first address several issues that do not involve the notion of a *group* of symmetries. We follow throughout the Dirac notation used in our recent book,[1] in which linear operators in Hilbert space act on ket states from the left and on bra states from the right, as in $\mathcal{O}|f\rangle$ and $\langle f|\mathcal{O}$, while quaternionic scalars in Hilbert space act on ket states from the right and on bra states from the left, as in $|f\rangle\omega$ and $\omega\langle f|$.

We begin by recalling the statement (see Sec. 2.3 of Ref. 1) of the quaternionic extension of Wigner's theorem, which gives the Hilbert space representation of an individual symmetry in quantum mechanics. Physical states in quaternionic quantum mechanics are in one-to-one correspondence with unit rays of the form $|\mathbf{f}\rangle=\{|f\rangle\omega\}$, with $|f\rangle$ a unit normalized Hilbert space vector and ω a quaternionic phase of unit magnitude. A symmetry operation $\mathcal{S}$ is a mapping of the unit rays $|\mathbf{f}\rangle$ onto images $|\mathbf{f}'\rangle$, which preserves all transition probabilities,

$$\mathcal{S}|\mathbf{f}\rangle=|\mathbf{f}'\rangle, \quad |\langle\mathbf{f}'|\mathbf{g}'\rangle|=|\langle\mathbf{f}|\mathbf{g}\rangle|. \tag{1}$$

Wigner's theorem, as extended to quaternionic Hilbert space, asserts that by an appropriate $\mathcal{S}$-dependent choice of ray representatives for the states, the mapping $\mathcal{S}$ can always be represented (in Hilbert spaces of dimension greater than 2) by a unitary transformation $U_{\mathcal{S}}$ on the state vectors, so that

$$|f'\rangle=U_{\mathcal{S}}|f\rangle. \tag{2}$$

Conversely, any unitary transformation of the form of Eq. (2) clearly implies the preservation of transition probabilities, as in Eq. (1). When only one symmetry transformation is involved, the issue of projective representations does not enter, since Wigner's theorem asserts that this transformation can be given a unitary representation on appropriate ray representative states in Hilbert space. The issue of projective representations arises only when we are dealing with two (or more) symmetry transformations, in which case the ray representative choices which reduce the first symmetry transformation to unitary form may not be compatible with the ray representative choices which reduce a second symmetry transformation to unitary form. Thus we disagree with Emch's statement, in the semifinal paragraph of his Comment, that Wigner's theorem (which he notes is a form of the first fundamental theorem of projective geometry) may be dependent on the definition adopted for quaternionic projective group representations.

0022-2488/96/37(12)/6586/4/$10.00

In the first section of his Comment, Emch proves a Proposition stating that if an operator $\mathcal{O}$ commutes with all of the projectors $|f\rangle\langle f|$ of a quaternionic Hilbert space of dimension 2 or greater, then $\mathcal{O}$ must be a real multiple of the unit operator 1 in Hilbert space. When $\mathcal{O}$ is further restricted to be a unitary operator (as obtained from a symmetry transformation via the Wigner theorem), the real multiple is further restricted to be ± 1. Since we will refer to this result in the next section, let us give an alternative proof, based on the spectral representation of a general unitary operator U in quaternionic Hilbert space,

$$U=\sum_{\ell} |u_{\ell}\rangle e^{i\theta_{\ell}}\langle u_{\ell}|, \quad 0\leqslant\theta_{\ell}\leqslant\pi, \tag{3}$$

in which the sum over ℓ spans a complete set of orthonormal eigenstates of U. Let us focus on a two state subspace spanned by $|u_1\rangle$ and $|u_2\rangle$, and construct the projector $P=|\Phi\rangle\langle\Phi|$, with

$$|\Phi\rangle=|u_1\rangle+|u_2\rangle\omega, \quad \overline{\omega}=-\omega, \quad \omega=\omega_\alpha+j\omega_\beta, \quad \omega_\alpha\omega_\beta\neq 0, \tag{4}$$

where $\omega_{\alpha,\beta}$ are symplectic components lying in the complex subalgebra of the quaternions spanned by 1 and i. Then the projector P is given by

$$P=|u_1\rangle\langle u_1|+|u_2\rangle\langle u_2|+|u_2\rangle\omega\langle u_1|-|u_1\rangle\omega\langle u_2|, \tag{5a}$$

and the part of U lying in the $|u_{1,2}\rangle$ subspace is

$$U_{1,2}=|u_1\rangle e^{i\theta_1}\langle u_1|+|u_2\rangle e^{i\theta_2}\langle u_2|. \tag{5b}$$

The commutator of U and P is then given by

$$[U,P]=[U_{1,2},P]=|u_2\rangle(e^{i\theta_2}\omega-\omega e^{i\theta_1})\langle u_1|-|u_1\rangle(e^{i\theta_1}\omega-\omega e^{i\theta_2})\langle u_2|, \tag{6}$$

which vanishes only if $e^{i\theta_1}=e^{i\theta_2}$ (from equating to zero the coefficient of ω_α) and $e^{i\theta_1}=e^{-i\theta_2}$ (from equating to zero the coefficient of ω_β). Since $0\leqslant\theta_{1,2}\leqslant\pi$, this requires either $\theta_1=\theta_2=0$ or $\theta_1=\theta_2=\pi$. Repeating the argument for each dimension 2 subspace in turn, we learn that $U=\pm 1$. Note that in a complex Hilbert space, the analogous argument shows only that $e^{i\theta_1}=e^{i\theta_2}$, from which we conclude (again by repeating the argument for each dimension 2 subspace in turn) that $U=e^{i\theta}$, which commutes with all projectors because any complex number is a c-number in complex Hilbert space.

Clearly, the argument just given involves only elementary properties of the projectors in Hilbert space, and makes no reference to the notion of a group of symmetries. The same is true of the proposition given in Sec. I of Emch's Comment. Since Schur's lemma ordinarily describes the restrictions on an operator that commutes with the representation matrices of an irreducible group representation, and since the projectors in Hilbert space do not form a group (they are not invertible and the product of two different projectors is not a projector), it is a misnomer to describe Emch's Proposition, or the corollary given here, as a ''quaternionic Schur's lemma.'' In addition to disagreeing with Emch's terminology, we also disagree with his statement, in the second paragraph of Sec. III of his Comment, that the analysis leading to his Proposition is dependent on the definition adopted for quaternionic projective group representations; in fact, the notion of a group of symmetries does not enter into either his analysis, or the corollary for unitary matrices proved here.

II. HOW SHOULD ONE DEFINE QUATERNIONIC PROJECTIVE GROUP REPRESENTATIONS?

Let us now address the central question of how one should generalize to quaternionic Hilbert space the notion of a projective group representation. We begin by reviewing how projective

group representations arise in complex Hilbert space. Let $\mathscr{G}$ be a symmetry group composed of abstract elements a with group multiplication ab. By Wigner's theorem, each group element is represented, after an a-dependent choice of ray representatives, by a unitary operator U_a acting on the states of Hilbert space. In the simplest case, in which the U_a are said to form a vector representation, the U's obey a multiplication law isomorphic to that of the corresponding abstract group elements,

$$U_a U_b = U_{ab}\,. \tag{7}$$

However, when the complex rephasings of the states used in Wigner's theorem are taken into account, there exists the more general possibility that for any state $|f\rangle$, the states $U_a U_b|f\rangle$ and $U_{ab}|f\rangle$ are not equal, but rather differ from one another by a change of ray representative, i.e.,

$$U_a U_b|f\rangle = U_{ab}|f\rangle e^{i\phi(a,b;f)}. \tag{8}$$

Corresponding to Eq. (8), there are two possible definitions of a projective representation in complex Hilbert space

Definition (1): In a *weak* projective representation, the multiplication law of the U's obeys Eq. (8) on one complete set of states $\{|f\rangle\}$. This suffices, by superposition, to determine the multiplication law of the U's on all states.

Definiton (2): In a *strong* projective representation, the multiplication law of the U's obeys Eq. (8) on all states in Hilbert space. In this case, we can easily prove that the phases $\phi(a,b;f)$ are independent of the state label f. To see this, let us define $V_{ab} = U_{ab}^{-1} U_a U_b$; then Eq. (8) implies that

$$V_{ab}|f\rangle = |f\rangle e^{i\phi(a,b;f)}, \tag{9}$$

which immediately implies that V_{ab} commutes with the projector $|f\rangle\langle f|$, for all states $|f\rangle$ in Hilbert space. But invoking the complex Hilbert space specialization of the result of the preceding section, we learn that V_{ab} must be a c-number, $V_{ab} = e^{i\phi(a,b)}$. This is the customary definition of a projective representation in complex Hilbert space, and is well known to have nontrivial realizations.

Let us now turn to the question of how to define projective representations in quaternionic Hilbert space. Emch choses as his generalization the strong definition given above, which by the reasoning following Eq. (9), and the quaternionic result of Sec. I, implies that $V_{ab} = (-1)^{n_{a,b}}$, with $n_{a,b}$ an integer that can depend in general on a and b. In other words, *the only strong quaternionic projective representations are real projective representations*.

The problem with adopting the strong definition, however, is that it excludes from consideration as a quaternionic projective representation the embedding into quaternionic Hilbert space of a nontrivial complex projective representation realized on a complex Hilbert space. Thus potentially interesting structure is lost. To avoid this problem, Ref. 1 adopts as the quaternionic generalization of the notion of a projective representation the weak definition given above, which in quaternionic Hilbert space states that

$$U_a U_b|f\rangle = U_{ab}|f\rangle \omega_{a,b}\,, \quad |\omega_{a,b}| = 1 \tag{10}$$

for one particular complete set of states $\{|f\rangle\}$. As discussed in Ref. 1, Eq. (10) can also be rewritten in the operator form

$$U_a U_b = U_{ab}\Omega(a,b), \tag{11a}$$

with

$$\Omega(a,b)=\sum_f |f\rangle\omega(a,b;f)\langle f|. \tag{11b}$$

Since the operator Ω depends on the particular complete set of states on which the projective phases are given, a more complete notation (not employed in Ref. 1) would in fact be $\Omega(a,b;\{|f\rangle\})$. Using the result of an analysis[2] of the associativity condition for weak quaternionic projective representations, Tao and Millard[3] have recently given a beautiful complete structural classification theorem for weak quaternionic projective representations. The complex specialization of their Corollary 2, incidentally, states that in a complex Hilbert space, the weak definition of a projective representation implies the strong one.

Can the weak definition of a quaternionic projective representation be weakened even further, by using a *different* complete set of states $\{|f\rangle\}$ to specify the projective phases for each pair of group elements a and b?[4] In this case, the operator Ω takes the form $\Omega(a,b;\{|f\rangle\}_{a,b})$. However, since any unitary operator is diagonalizable on some complete set of states, this further weakening allows an arbitrary specification of Ω for each a,b, and any relationship of the unitary representation to the underlying group structure is lost.

III. DISCUSSION

We conclude that the difference between our analysis and that of Emch is traceable to what I have here termed the difference between a *strong* and a *weak* definition of projective representation. The strong definition is the customary one in complex Hilbert space, but it excludes potentially interesting structure when applied to quaternionic Hilbert space. Since the weak definition leads to a detailed theory[1–3] of projective group representations in quaternionic Hilbert space, and since it implies[3] the strong definition in complex Hilbert space, the weak definition is in fact the more appropriate one in both complex and quaternionic Hilbert spaces.

(1) Superscripts on q: throughout the paper, the first superscript on q is its space–time index while the second one, wherever it occurs, is its exponent.
For example, on p. 1714, Eq. (1.1) should read $\phi \equiv (q^1)^2 + (q^2)^2 + p_1^2 + p_2^2 - R^2 = 0$ and the exponent in Eq. (3.5) is $-[(q^1)^2 + (q^2)^2]/2$.
Other places where such double-superscripts should be resolved are:
p. 1717, Eq. (3.4) and
p. 1718, Eq. (3.11).
(2) In the second line on p. 1715, (θ', ϑ') should read (θ', φ').
(3) (Weil's) ''integrability'' (condition) should read (Weil's) ''integrality'' (condition) in the following:
p. 1716, last but two lines,
p. 1718, 7th line after Eq. (3.11),
p. 1719, Sec. IV, 5th line and
p. 1721, line preceding Eq. (A15).
(4) In the Appendix, subscripts on ∇:
Eq. (A7) should read $\hat{f} = -i\hbar\nabla_{X_f} + f$ and
Eq. (A8) should read $\nabla_{X_{m^s}} = 0$.
