The perennial formalism is applied to the real, massive Klein–Gordon field on a globally-hyperbolic background space–time with compact Cauchy hypersurfaces. The parametrized form of this system is taken over from the accompanying paper. Two different algebras $\mathscr{S}_{\rm can}$ and $\mathscr{S}_{\rm loc}$ of elementary perennials are constructed. The elements of $\mathscr{S}_{\rm can}$ correspond to the usual creation and annihilation operators for particle modes of the quantum field theory, whereas those of $\mathscr{S}_{\rm loc}$ are the smeared fields. Both are shown to have the structure of a Heisenberg algebra, and the corresponding Heisenberg groups are described. Time evolution is constructed using transversal surfaces and time shifts in the phase space. Important roles are played by the transversal surfaces associated with embeddings of the Cauchy hypersurface in the space–time, and by the time shifts that are generated by space–time isometries. The automorphisms of the algebras generated by this particular type of time shift are calculated explicitly. The construction of the quantum theory using the perennial formalism is shown to be equivalent to the Segal quantization of a Weyl system if the time shift automorphisms of the algebra $\mathscr{S}_{\rm can}$ are used. In this way, the absence of any timelike Killing vector field in the background space–time leads naturally to the ''problem of time'' for quantum field theory on a background space–time. Within the perennial formalism, this problem is formally identical to the problem of time for any parametrized system, including general relativity itself. Two existing strategies—the ''scattering'' approach, and the ''algebraic'' approach—for dealing with this problem in quantum field theory on a background space–time are translated into the language of the perennial formalism in the hope that this may give some insight into how the general problem can be solved. The non-unitary time evolution typical of the Hawking effect is shown to be due to global properties of the corresponding phase space: specifically, the time shifts map a global transversal surface to a non-global one. Thus, the existence of this effect is closely related to the global time problem. [S0022-2488(96)02707-7]

I. INTRODUCTION

In the canonical approach to quantum gravity, much emphasis is placed on three particular issues: the conceptual problems that arise in the interpretation of the theory, especially the problem of time; the role of the space–time diffeomorphism group; and the construction of non-perturbative quantization methods (for reviews, see Refs. 1–3). The Dirac method of imposing

operator constraints on the allowed state vectors (which, in the case of gravity, leads to the Wheeler-DeWitt equation) has become particularly popular because of its manifest relation to the idea of invariance under the action of space–time diffeomorphisms.

However, diffeomorphism invariance can also be secured by adopting a method in which only ''gauge-invariant'' objects are quantized; Dirac himself laid the foundations[4] for a powerful approach of this sort. A generalization of the Dirac method to include all finite-dimensional, first-class parametrized systems was presented by Hájíček.[5] The resulting theory, which combines the group-theoretic[6] and algebraic[7] methods of quantization with that of Dirac, is called the ''perennial formalism,'' following the terminology introduced by Kuchař in his analysis[8] of the problem of observables in canonical quantum gravity. The key idea of this method is to find an algebra of phase-space functions whose Poisson brackets with all the first-class constraints vanish; such functions are therefore constant on the phase-space orbits of the (function) group generated by the constraints. Furthermore, this algebra is required to be large enough to generate all gauge-invariant functions in an appropriate sense. Quantization of the system then consists in finding irreducible self-adjoint representations of this algebra of ''physical observables'' or, essentially equivalently, finding irreducible, unitary representations of the associated ''canonical'' group.

In the present article we develop the perennial formalism in the context of a field system, namely a linear, massive scalar field propagating on a fixed, globally-hyperbolic space–time with compact Cauchy hypersurfaces.

Various motivations lie behind such a study. To begin with, infinite-dimensional systems are qualitatively different from finite-dimensional ones, and it is an important—and mathematically non-trivial—challenge to see how the perennial formalism can be extended to this case. We shall show how the scalar field theory can be rewritten in such a way as to become a simple example of a system with perennials. However, quantum field theory in a fixed background has been much studied in the past using standard methods, and hence it provides a useful model for exploring the perennial formalism for an infinite-dimensional system. As we shall see, new problems *do* appear, the most important of which concerns the choice of the operator representation for the group/algebra generated by the perennials.

In the standard approach to quantum field theory on a background space–time, the normal way of addressing the problem of operator representation makes extensive use of the classical time evolution of the system. Thus the time evolution and associated Hamiltonian are considerably more important for infinite-dimensional systems than they are in the finite-dimensional case. Specifically, if there is no timelike isometry group, then the physical representation for the quantum system is not determined and—at the same time—the time evolution and Hamiltonian of the classical system are not well-defined (by the perennial formalism). Such a lack of a Hamiltonian was identified in Ref. 5 as the general form taken by the problem of time within the perennial formalism. However, studies of quantum field theory on a background space–time have produced several possible strategies for dealing with this problem, and one can hope that some of these ideas may be applicable to other situations, especially if a common language—in our case, that of the perennial formalism—has been developed.

The perennial formalism enables us to reformulate the dynamics of a scalar field in a background space–time in terms of properties of the system's phase space. In this reformulation, an important role is played by the idea of a *transversal surface*, defined in general for a system with a gauge group as a submanifold in the phase space that cuts orbits of the gauge group transversally; the *domain* of a transversal surface is the set of points in the constraint submanifold that can be joined to the transversal surface by the orbits of the constraints; see Ref. 5. Global problems may arise: for example, there may not exist any global transversal surface (i.e., one whose domain is the whole constraint surface); or there might be a symmetry transformation that maps a global transversal surface onto a transversal surface that is not global. Indeed, we shall show that the latter situation arises in the particular case of a space–time with a black hole. This leads to an information loss in which the quantum evolution associated with the symmetry sends pure states

to mixed states (the Hawking effect). A situation with somewhat similar features can occur if a system has no global transversal surfaces (the so-called ''global'' time problem); in particular, an analogous non-unitarity is exhibited by the quantum time evolution. Toy models exhibiting such behavior were studied in Refs. 9 and 10. Thus, the ideas developed in the present article may be of use in finding a physical interpretation in general situations in which the global time problem arises.

Another motivation for our present work is that our understanding of quantum field theory on a fixed background might itself profit from the use of the language of perennials. For example, the symmetries and transversal surfaces that have been employed in the past in studies of such quantum field theories are of a very special nature: namely, transformations of phase space that are generated in a particular way by space–time transformations, and surfaces associated with space–time hypersurfaces. The perennial formalism permits more general types of symmetry and transversal surface, and suggests how these can be found. The question then is if these symmetries can be utilized in the quantum theory, and—if not—why not.

The plan of the paper is as follows. In section II, we summarize the results of the companion work[11] where the dynamics and the symplectic geometry of the parametrized scalar field was cast into the standard form of a first-class parametrized system so that the perennial formalism can be applied. In section III, two different kinds of perennials are constructed and each of them is shown to form an algebra of elementary perennials, both of which are versions of the infinite Heisenberg algebra. We show that each isometry of the background space–time defines a map of the phase space that is a symmetry. We calculate the action of these symmetries on the elementary perennials and find that they define automorphisms of the algebras. Then we show how the theory of time evolution as described in Ref. 5 can be applied to the present case.

In the final section we show how the group and algebraic quantization that is performed as the next step reduces to the familiar problem of finding a physically appropriate representation of the Weyl group. We briefly summarize the relevant results of the theory of Weyl systems in connection with quantum field theory on a background space–time, and we show that our quantization method leads to a quantum theory that is equivalent to the usual one. Finally, we discuss the problem of time in a quantum field theory in a fixed background. We study a ''scattering approach'' to quantization that makes use of an isolated symmetry that is defined on only a small subset of the phase space. In the context of the perennial formalism, such a generalized symmetry is sufficient to define a time evolution. We show that the resulting quantum evolution is nonunitary if the symmetry does not preserve the domains of the transversal surfaces involved in the construction, and we apply the results to the Hawking effect. We also briefly describe the ''algebraic approach'' to quantization in which the states are defined as functionals on the algebras of perennials.

II. STRUCTURE OF THE EXTENDED PHASE SPACE

In this section, we shall summarize the results of the companion work[11] so that the present paper becomes self-contained. For more details, one should consult.[11]

We work with a curved background space–time $(\mathscr{M},g)$ and assume that it is C^∞ and globally hyperbolic; the Cauchy surface Σ is assumed to be compact. The real scalar field ϕ satisfies the Klein–Gordon equation

$$|\det g|^{-1/2}\partial_\mu(|\det g|^{1/2}g^{\mu\nu}\partial_\nu\phi)+m^2\phi=0. \tag{1}$$

Consider a C^∞ embedding $X:\Sigma\to\mathscr{M}$ that is spacelike with respect to the metric g. Let $\mathscr{E}$ denote the space of all such embeddings. Each embedding X determines a positive-definite metric γ_X on Σ and a unit normal vector field n_X to $X(\Sigma)$ in $\mathscr{M}$. The embedding X also defines a Cauchy datum for the field ϕ along the hypersurface $X(\Sigma)$. This is a pair (φ,π) of fields on Σ, where the scalar φ and the density (of weight $w=1$) π are defined by

$$\varphi(x) := \phi(X(x)), \tag{2}$$

$$\pi(x) := (\det\ \gamma)^{1/2}[X(x)]n^{\mu}(X(x))\partial_{\mu}\phi(X(x)). \tag{3}$$

The space of all C^{∞} Cauchy data will be denoted by Γ_{ϕ}—a linear space that can be equipped with a Sobolev structure (for details, see Ref. 11). The dynamical equation (1) defines a mapping between Cauchy data corresponding to different embeddings. Specifically, let X and X' be two arbitrary spacelike embeddings and let $(\varphi,\pi) \in \Gamma_{\phi}$. Then there is a unique solution ϕ of Eq. (1) whose Cauchy datum at $X(\Sigma)$ is (φ,π), and this induces a well-defined Cauchy datum (φ',π') on $X'(\Sigma)$. Thus we get a map $(\varphi,\pi)\rightarrow(\varphi',\pi')$, which we denote by $\rho_{XX'}$. One can show that $\rho_{XX'}$ is an automorphism of the Sobolev space Γ_{ϕ}.

The space Γ_{ϕ} is the phase space of the (non-constrained) scalar field ϕ on the curved background $(\mathscr{M},g)$. If we extend this space by adding all spacelike embeddings X and their conjugate momenta P, and if we impose suitable constraints, we obtain a constrained system that is dynamically equivalent to the original one. The points of the resulting extended phase space Γ are collections of fields, $x\mapsto(\varphi(x),\pi(x),X(x),P(x))$ on Σ. These fields can be characterized by their transformation properties with respect to a pair of local charts

$$(U,h)\ \text{of}\ \Sigma \quad \text{and} \quad (\overline{V,h})\ \text{of}\ \mathscr{M} \tag{4}$$

(where $X(U)\cap\overline{V} \neq \emptyset$). In particular, $P_{\mu}(x)$ is a covector with respect to the transformation of (V,h) on $\mathscr{M}$ and a quadruple of scalar densities with respect to the transformation of (U,h) on Σ. Quantities of this type were called ''e-tensor densities'' by Kuchař.[12]

The phase space Γ can be given a structure of an infinite-dimensional differentiable manifold with tangent and cotangent vectors described as follows. Consider a curve $\lambda\rightarrow(\varphi_{\lambda},\pi_{\lambda},X_{\lambda},P_{\lambda})$ whose tangent vector components $(\Phi,\Pi,V,W)\equiv(\dot{\varphi}_{\lambda},\dot{\pi}_{\lambda},\dot{X}_{\lambda},\dot{P}_{\lambda})$ can be calculated by differentiating with respect to λ the coordinate representatives associated with the pair of charts (4). The fields $\Phi(x)$, $\Pi(x)$, $V(x)$ and $W(x)$ are again characterized by their transformation properties: the first three are e-tensors, but the fourth transforms in a more complicated way (see Ref. 11). The space $T_{(\varphi,\pi,X,P)}\Gamma$ of all such vectors can be given the C^{∞} structure of a Fréchet space. A cotangent vector at a point (φ,π,X,P) of Γ will be a quadruple $(A_{\varphi},A_{\pi},A,B)$ of fields on Σ such that the pairing

$$\langle(A_{\varphi},A_{\pi},A,B),(\Phi,\Pi,V,W)\rangle := \int_{\Sigma} d^3x(A_{\varphi}\Phi + A_{\pi}\Pi + A_{\mu}V^{\mu} + B^{\mu}W_{\mu}) \tag{5}$$

with vectors from $T_{(\varphi,\pi,X,P)}\Gamma$ gives a coordinate independent number. This requirement determines the transformation properties of the fields $(A_{\varphi},A_{\pi},A,B)$.

One can show that $(A_{\pi},-A_{\varphi},B,-A)$ transforms as a tangent vector. Thus, there is a map $J:T^{*}_{(\varphi,\pi,X,P)}\Gamma\rightarrow T_{(\varphi,\pi,X,P)}\Gamma$ given by $J(A_{\varphi},A_{\pi},A_X,A_P) := (A_{\pi},-A_{\varphi},A_P,-A_X)$. The C^{∞} structure of the space $T^{*}_{(\varphi,\pi,X,P)}\Gamma$ can be chosen in such a way that J is an isomorphism. Using this isomorphism, a symplectic structure Ω on Γ can be defined as follows. If v_1 and v_2 are two vectors in $T_{(\varphi,\pi,X,P)}\Gamma$ then

$$\Omega(v_1,v_2) := -\langle J^{-1}v_1,v_2\rangle. \tag{6}$$

It follows at once that (i) $\Omega(v_1,v_2) = -\Omega(v_2,v_1)$; (ii) Ω is weakly non-degenerate (see Ref. 13); and (iii) Ω is not only closed but also exact.

As Ω is only a weak symplectic form, not every differentiable function on Γ will have an associated Hamiltonian vector field. The class of functions that do can be characterized as follows. If $F:\Gamma\rightarrow\mathbb{R}$, we say that F has a *gradient* if the following two conditions are satisfied:

(1) the Fréchet derivative, $DF|_{(\varphi,\pi,X,P)}:T_{(\varphi,\pi,X,P)}\Gamma\rightarrow\mathbb{R}$ is a bounded linear map;

(2) there exists $\mathrm{grad}F \in T^*_{(\varphi,\pi,X,P)}\Gamma$ such that $\langle \mathrm{grad}F, v\rangle = \mathrm{D}F|_{(\varphi,\pi,X,P)}(v)$ for all $v \in T_{(\varphi,\pi,X,P)}\Gamma$.

The quantity $\mathrm{grad}F$ is calculated from DF as usual by integration by parts (if F contains derivatives). The ''components'' of this gradient will be denoted by the collection of functions $(\mathrm{grad}_\varphi F, \mathrm{grad}_\pi F, (\mathrm{grad}_X F)_\mu, (\mathrm{grad}_P F)^\nu)$.

For a differentiable function with a gradient, we can define the associated ''Hamiltonian vector field.'' Specifically, if F is such a function, then $\xi_F \in T_{(\varphi,\pi,X,P)}\Gamma$ is defined by the relation $\langle \mathrm{grad}F, v\rangle = \Omega(v, \xi_F)$, for all $v \in T_{(\varphi,\pi,X,P)}\Gamma$. Hence, because of Eq. (6), we see that $\langle \mathrm{grad}F, v\rangle = \langle J^{-1}\xi_F, v\rangle$ for all v, and so $\xi_F = J(\mathrm{grad}F)$. Finally, the Poisson bracket of a pair of differentiable functions F and G is defined as $\{F,G\} := -\Omega(\xi_F, \xi_G)$, and we see immediately that

$$\{F,G\} = \langle \mathrm{grad}F, \xi_G\rangle. \tag{7}$$

This Poisson bracket is antisymmetric and, since Ω is closed, it satisfies the Jacobi identity.

The constraints that must be imposed on the extended phase space Γ are

$$\mathscr{H}_\mu = P_\mu + \mathscr{H}^\phi_\mu, \tag{8}$$

$$\mathscr{H}^\phi_\mu = -\mathscr{H}^\phi_\perp n_\mu + \mathscr{H}^\phi_k X^k_\mu, \tag{9}$$

where $\mathscr{H}^\phi_\perp = \frac{1}{2}(\det\ \gamma)^{1/2}[(\pi^2/\det\ \gamma) + \gamma^{kl}\varphi_{,k}\varphi_{,l} + m^2\varphi^2]$, and $\mathscr{H}^\phi_k = \pi\varphi_{,k}$. One can show that the constraint set $\tilde{\Gamma}$ defined by $\mathscr{H}_\mu = 0$ is a smooth submanifold in a neighborhood of any of its points. Moreover, $\tilde{\Gamma} = \tilde{C}(\Gamma_\phi \times \mathscr{E})$, where $\tilde{C}: \Gamma_\phi \times \mathscr{E} \to \Gamma$ is defined by $\tilde{C}(\varphi,\pi,X) := (\varphi,\pi,X, -\mathscr{H}^\phi(\varphi,\pi,X))$. We shall often refer to $\tilde{\Gamma}$ as $\Gamma_\phi \times \mathscr{E}$.

If we smear $\mathscr{H}_\mu$ to get $\mathscr{H}_N := \int_\Sigma d^3x N^\mu(x)\mathscr{H}_\mu(x)$, where $N \in T_X\mathscr{E}$ [i.e., $N(x) \in T_{X(x)}\mathscr{M}$], we obtain a differentiable function with a gradient. Such a function defines a Hamiltonian vector field, and one can proceed in complete analogy with the theory of finite-dimensional systems. For example, let ϕ satisfy the Klein–Gordon equation (1) on $\mathscr{M}$. Then for each curve $\lambda \mapsto X_\lambda$ with the tangent vector field N on $\mathscr{E}$, the initial data $(\varphi_\lambda, \pi_\lambda)$ for ϕ on $X_\lambda(\Sigma)$ satisfy the evolution equation

$$(\dot{\varphi}, \dot{\pi}, \dot{X}, \dot{P}) = J(\mathrm{grad}\mathscr{H}_N). \tag{10}$$

Thus the Hamiltonian vector fields $J(\mathrm{grad}\mathscr{H}_N)$ of the functions $\mathscr{H}_N$ are tangential to $\tilde{\Gamma}$, and the system is first class according to the definition given in Ref. 5. The pull-back of the vector field (10) to $\Gamma_\phi \times \mathscr{E}$ is given by

$$\dot{\varphi} = \mathrm{grad}_\pi \mathscr{H}_N, \tag{11}$$

$$\dot{\pi} = -\mathrm{grad}_\varphi \mathscr{H}_N, \tag{12}$$

$$\dot{X} = N. \tag{13}$$

Let us denote the space of longitudinal vectors at $(\varphi,\pi,X) \in \Gamma_\phi \times \mathscr{E}$ by $\Xi_{(\varphi,\pi,X)}$, i.e.,

$$\Xi_{(\varphi,\pi,X)} := \{(\Phi,\Pi,V) \in T_{(\varphi,\pi,X)}\tilde{\Gamma} \,|\, \Phi = \mathrm{grad}_\pi \mathscr{H}_N, \Pi = -\mathrm{grad}_\varphi \mathscr{H}_N, V = N \in T_X\mathscr{E}\}. \tag{14}$$

The space $\Xi_{(\varphi,\pi,X)}$ is a closed subspace of $T_{(\varphi,\pi,X)}\tilde{\Gamma}$. Moreover, there is a submanifold of $\tilde{\Gamma}$ whose tangent space coincides with $\Xi_{(\varphi,\pi,X)}$ at each point of the submanifold. Let us denote the maximal submanifold of this kind passing through a point $(\varphi,\pi,X) \in \tilde{\Gamma}$ by $\gamma_{(\varphi,\pi,X)}$. This subset $\gamma_{(\varphi,\pi,X)}$ is called a ''c-orbit through (φ,π,X),'' in complete analogy with the situation for a finite-dimensional system.

Finally, the pull-back $\tilde{\Omega}$ of the form Ω to $\tilde{\Gamma}$ is given by the formula

$$\tilde{\Omega}((\Phi_1,\Pi_1,V_1),(\Phi_2,\Pi_2,V_2))$$

$$= \int_\Sigma d^3x[(\Pi_1 + \mathrm{grad}_{\varphi'}\mathscr{H}_{V_1})(\Phi_2 - \mathrm{grad}_{\pi'}\mathscr{H}_{V_2})$$

$$-(\Pi_2 + \mathrm{grad}_{\varphi'}\mathscr{H}_{V_2})(\Phi_1 - \mathrm{grad}_{\pi'}\mathscr{H}_{V_1})]. \tag{15}$$

Clearly, $\tilde{\Omega}$ is a presymplectic form and $\Xi_{(\varphi,\pi,X)}$ is its singular subspace.

III. PERENNIALS, SYMMETRIES AND TIME EVOLUTION

In section II we showed that the geometrical structure of the phase space, constraint submanifold and the c-orbits of our infinite-dimensional system are all analogous to those of the corresponding objects in a finite-dimensional system as studied, for example, in Ref. 5. The application of the perennial formalism is now straightforward.

A crucial role in the perennial formalism is played by quantities that are reparametrization and gauge invariant. In particular, a *perennial* is defined as a function $o:\Gamma\to\mathbb{R}$ that is constant along the c-orbits; or, equivalently,

$$\{o,H_N\}|_{\tilde{\Gamma}} = 0, \text{ for all } N. \tag{16}$$

In most physical applications of a field theory, one deals with a restricted class of functions on the phase space—the so-called ''local functionals.'' Each local functional has the form $\int_\Sigma d^3x F(x)$, where the value of $F(x)$ at $x \in \Sigma$ is a polynomial function of values of the fields and their x-derivatives taken at the same point. It is easy to show that (i) all local functionals possess gradients; (ii) the Poisson bracket of two local functionals is again a local functional, so that multiple Poisson brackets are well-defined; and (iii) they satisfy the Jacobi identity. Since the smeared constraint $\mathscr{H}_N$ is itself a local functional it follows that the set of all local functionals that are perennials forms a Poisson algebra $\mathscr{P}_{\mathrm{lf}}$.

Let us now construct a particular class of local functional perennials for the case of scalar field theory on a background space–time. The idea is to associate a perennial o_ϕ with each maximal solution ϕ of the classical field equations. Specifically, let (ξ,η,X,P) be an arbitrary point of Γ and let (φ,π) be the Cauchy datum of ϕ at X. Then o_ϕ is defined by

$$o_\phi(\xi,\eta,X,P) := \int_\Sigma d^3x(\varphi\eta - \xi\pi). \tag{17}$$

The main task is to show that o_ϕ is constant along c-orbits.

Let $\gamma_{(\xi,\eta,X)}$ be a c-orbit and let ψ be the associated maximal classical solution, i.e., (ξ,η) is the Cauchy datum of ψ on $X(\Sigma)$. Let $(\xi',\eta',X',P') \in \gamma_{(\xi,\eta,X)}$ be an arbitrary point on the c-orbit. Then

$$o_\phi(\xi',\eta',X',P') = \int_\Sigma d^3x(\varphi'\eta' - \xi'\pi'), \tag{18}$$

where (φ',π') and (ξ',η') are the Cauchy data of ϕ and ψ respectively at X'. Using Eqs. (2) and (3), we can rewrite this as

$$o_\phi(\xi',\eta',X',P') = \int_\Sigma d^3x(\det\,\gamma')^{1/2}n'^{\mu}(\phi\psi_{,\mu} - \psi\phi_{,\mu})_{X'(\Sigma)}, \tag{19}$$

where γ' is the induced metric on $X'(\Sigma)$, and n'^{μ} is the unit normal vector to $X'(\Sigma)$. However, the integral on the right hand side is just the familiar ''Klein–Gordon inner product'' $(\phi,\psi)_{\mathrm{KG}}$ of the two solutions ϕ and ψ, and this is well-known to be independent of the Cauchy surface $X'(\Sigma)$. Hence o_ϕ is constant, as claimed.

The perennial o_ϕ has the following properties.

(1) Suppose that o_ϕ is constant along the whole of the constraint set $\tilde{\Gamma}$. Then ϕ must have the same Klein–Gordon product with any other solution, which is only possible if $\phi=0$.

(2) Let ϕ and ψ be two maximal solutions with corresponding perennials o_ϕ and o_ψ. Then the definition (17) implies immediately that

$$o_\phi + o_\psi = o_{\phi+\psi}, \tag{20}$$

$$r o_\phi = o_{r\phi} \text{ for all } r \in \mathbb{R}, \tag{21}$$

where the linearity of the field equation (1) guarantees that the solutions $\phi+\psi$ and $r\phi$ are again maximal.

(3) The Poisson bracket of o_ϕ and o_ψ can be obtained from Eq. (7). To calculate it we need the gradients, and using Eqs. (11) and (12) we obtain

$$\langle \mathrm{grad}\, o_\phi|_{(\xi,\eta,X,P)}, (\Phi,\Pi,V,W)\rangle$$

$$= \int_\Sigma d^3x [\varphi\Pi - \pi\Phi + \xi \mathrm{grad}_\varphi H_V|_{(\varphi,\pi,X,P)} + \eta \mathrm{grad}_\pi H_V|_{(\varphi,\pi,X,P)}]. \tag{22}$$

Thus,

$$\mathrm{grad}_\varphi o_\phi|_{(\xi,\eta,X,P)} = -\pi,$$

$$\mathrm{grad}_\pi o_\phi|_{(\xi,\eta,X,P)} = \varphi,$$

$$\mathrm{grad}_P o_\phi|_{(\xi,\eta,X,P)} = 0,$$

where (φ,π) is the Cauchy datum of ϕ at X. It follows that

$$J(\mathrm{grad} o_\phi) = (\varphi,\pi,0,A), \tag{23}$$

where A_μ are functions of ξ, η, X, P and ϕ. Then

$$\{o_\phi, o_\psi\}(\xi,\eta,X,P) = \int_\Sigma d^3x (\det\,\gamma)^{1/2} n^\mu (\phi\psi_{,\mu} - \psi\phi_{,\mu})_{X(\Sigma)} = (\phi,\psi)_{\mathrm{KG}}, \tag{24}$$

where γ and n^μ are the induced metric and unit normal vector at $X(\Sigma)$. Thus the Poisson bracket is independent of (ξ,η,X,P) and is hence a constant real function on the phase space Γ.

(4) Let ϕ and ψ be two different maximal solutions representing two different orbits γ_ϕ and γ_ψ. Then there is a third solution, χ, such that $(\chi,\phi-\psi)_{\mathrm{KG}} \neq 0$, and hence o_χ has different values at γ_ϕ and γ_ψ.

Let $\mathcal{S}_\phi$ denote the set of perennials of the form o_ϕ where ϕ runs over the set of all C^∞ solutions to the field equations. Then, because of the second property above, $\mathcal{S}_\phi$ is a linear space. Let $\mathcal{R}\cong\mathbb{R}$ denote the set of the constant real functions on Γ, and consider the linear space $\mathcal{S}_{\mathrm{can}} := \mathcal{S}_\phi \oplus \mathcal{R}$. This space $\mathcal{S}_{\mathrm{can}}$ is closed with respect to Poisson bracket operations because of the third property above. Moreover, $\mathcal{S}_{\mathrm{can}} \subset \mathcal{P}_{\mathrm{lf}}$. Thus $\mathcal{S}_{\mathrm{can}}$ is a Lie subalgebra of $\mathcal{P}_{\mathrm{lf}}$. According to the fourth property above, it separates the c-orbits in $\tilde{\Gamma}$. It follows that $\mathcal{S}_{\mathrm{can}}$ can play the role of an ''algebra of elementary perennials'' for our system—the basic ingredient in the ''algebraic

method of quantization'' in which the quantum theory is associated with a self-adjoint representation of $\mathscr{S}_{\text{can}}$ on a Hilbert space (see Ref. 5). The relations (20), (21) and (24) imply that $\mathscr{S}_{\text{can}}$ is an infinite-dimensional Heisenberg algebra. Specifically, as a linear space it is a direct sum of $\mathscr{R}$ and the space $\mathscr{S}_\phi$ that is equipped with the (weakly) non-degenerate skew-symmetric form $(\cdot,\cdot)_{\text{KG}}$; the Lie bracket is then defined by

$$[(\phi_1,r_1),(\phi_2,r_2)]:=(0,(\phi_1,\phi_2)_{\text{KG}}). \tag{25}$$

The corresponding Lie group is the so-called ''Heisenberg group'' $\mathscr{G}_{\text{can}}$ defined on $\mathscr{S}_\phi\times\mathbb{R}$ by the group law

$$(\phi_1,r_1)\cdot(\phi_2,r_2):=\left(\phi_1+\phi_2,r_1+r_2+\frac{1}{2}(\phi_1,\phi_2)_{\text{KG}}\right). \tag{26}$$

The action of $\mathscr{G}_{\text{can}}$ on Γ can be deduced from the action of its generators o_ϕ given by Eq. (17): namely, the point (ξ,η,X,P) maps to $(\xi+\varphi,\eta+\pi,X,P')$, where (φ,π) is the initial datum of ϕ at $X(\Sigma)$ and P' is a function of ξ,η,X,P, and ϕ such that $(\xi+\varphi,\eta+\pi,X,P')\in\widetilde{\Gamma}$ if $(\xi,\eta,X,P)\in\widetilde{\Gamma}$. The action is not faithful since the subgroup $(0,\mathbb{R})$ acts trivially, and hence the group $\mathscr{G}_{\text{can}}$ is a central extension of a group of symmetries on Γ (see Ref. 6). Thus $\mathscr{G}_{\text{can}}$ satisfies all the conditions for a so-called ''first-class canonical group'' whose irreducible, unitary representations can be associated with a quantization of the system.[6]

There is an alternative choice for the algebra of elementary perennials in which the perennials are associated with ''smeared fields;'' as such, they form the basis for a different (but ultimately equivalent) quantization of the scalar field. The construction goes as follows. Let $D(\mathscr{M})$ be the space of C^∞ test functions with compact support on the space–time $\mathscr{M}$, let $f\in D(\mathscr{M})$ and $(\varphi,\pi,X,P)\in\Gamma$. Then there is a unique maximal classical solution ϕ with the Cauchy datum (φ,π) at $X(\Sigma)$, and we define the perennial $\kappa_f:\Gamma\to\mathbb{R}$ by the equation

$$\kappa_f(\varphi,\pi,X,P):=\int_{\mathscr{M}} d^4y|\det g|^{1/2}\phi f. \tag{27}$$

Note that κ_f does not depend on P, and it is a perennial because the same classical solution leads to the same value of κ_f. Let us list some important properties of this type of perennial.

(1) Clearly, κ_f can be constant along $\widetilde{\Gamma}$ only if $f=0$, and then $\kappa_f=0$.

(2) Let f and f' be two elements of $D(\mathscr{M})$ with corresponding perennials κ_f and $\kappa_{f'}$. Then the definition (27) implies immediately that

$$\kappa_f+\kappa_{f'}=\kappa_{f+f'},$$

$$r\kappa_f=\kappa_{rf}\text{ for all }r\in\mathbb{R}.$$

(3) We can find an explicit expression for κ_f if we use the Cauchy propagator $G(x,y)$ for Eq. (1) [$G(x,y)$ is sometimes known as the ''Pauli–Jordan function'']. The existence and uniqueness of such a propagator for space–times of the type with which we are dealing was shown by Choquet-Bruhat.[14] The basic properties of the Cauchy propagator (for example, see Ref. 15) are (i) $G(x,y)=-G^r(x,y)+G^a(x,y)$, where G^r and G^a are respectively the retarded and advanced propagators; (ii) $G(x,y)$ is real and skew-symmetric in x and y; and (iii) $G(x,y)$ satisfies the identity

$$\phi(x)=(G(x,\cdot),\phi(\cdot))_{\text{KG}}, \tag{28}$$

where $\phi(x)$ is any C^∞ solution to Eq. (1). From Eq. (28), it follows immediately that

$$(G(x,\cdot),G(\cdot,y))_{\mathrm{KG}}=G(x,y). \tag{29}$$

If the Klein–Gordon product on the right hand side of Eq. (28) is written out along Σ, we obtain an expression for the solution ϕ at any point $y \in \mathscr{M}$ in terms of its Cauchy data at $X(\Sigma)$. Substituting for $\phi(y)$ in Eq. (27) from Eq. (28) then gives the desired formula:

$$\kappa_f=-\int_\Sigma d^3x(\det\ \gamma)^{1/2}n^\mu \frac{\partial G(f,y)}{\partial y^\mu}|_{X(x)}\varphi(x)+\int_\Sigma d^3xG(f,X(x))\pi(x), \tag{30}$$

where

$$G(f,x):=\int_{\mathscr{M}} d^4y|\det g|^{1/2}f(y)G(y,x). \tag{31}$$

Thus, κ_f belongs to the class of local functionals.

(4) We have the relation $\{\kappa_f,\kappa_{f'}\}=-G(f,f')$, whose derivation is simple: read off the gradient of κ_f from the formula (30), insert it in Eq. (7), and use the identity (29).

The smeared perennials generate a Lie algebra, which we denote by $\mathscr{S}_{\mathrm{loc}}$. Properties (2) and (4) above imply that $\mathscr{S}_{\mathrm{loc}}$ is a Heisenberg algebra on $D(\mathscr{M})\times\mathbb{R}$ with the skew-symmetric form $-G(f,f')$. The corresponding Heisenberg group $\mathscr{G}_{\mathrm{loc}}$ can be used as a first-class canonical group for the system.

The next important step is to consider the role played by symmetries, where—in complete analogy with the finite-dimensional case (see Ref. 5)—a symmetry is defined as a symplectic diffeomorphism of Γ that preserves the constraint surface $\tilde{\Gamma}$. In particular, it can be shown that each symmetry maps c-orbits onto c-orbits.

We shall describe a particular class of symmetries that play an important role in the study of quantum field theory on a curved space–time. Any isometry $\vartheta:\mathscr{M}\to\mathscr{M}$ defines a map $\theta:\Gamma\to\Gamma$ as follows. Let $(\varphi,\pi,X,P) \in \Gamma$ be arbitrary and set $X':=\vartheta\circ X$. Since ϑ is an isometry, the embedding X' is spacelike, and hence a Cauchy surface for $\mathscr{M}$. The fields φ, π and P are e-tensor densities at $X \in \mathscr{E}$, and so can be considered as $\mathscr{M}$-tensors at points in $X(\Sigma)$ [note that $\varphi(x)$ and $\pi(x)$ are scalars, and $P(x)$ is a covector]. Set $(\varphi',\pi',P'):=(\vartheta^{*-1}\varphi,\vartheta^{*-1}\pi,\vartheta^{*-1}P)$, where ϑ^* is the usual pull-back of differential forms on $\mathscr{M}$. Finally, define $\theta(\varphi,\pi,X,P):=(\varphi',\pi',X',P')$.

A simple way of showing that θ is a symmetry is to use the ϑ-shifted chart. Each pair of local charts of the type $(U,h),(V,h)$ in Eq. (4) can be ''shifted'' by ϑ to become the chart (U,h) on Σ and the chart $(\vartheta(V),h\circ\vartheta^{-1})$ on $\mathscr{M}$. The functions that represent (φ',π',X',P') in the shifted charts coincide numerically with those that represent (φ,π,X,P) in the original charts. Moreover, the metric $g'_{\mu\nu}$ in $\vartheta(V)$ coincides with $g_{\mu\nu}$ in $\vartheta(V)$. Thus, if (φ,π,X,P) satisfies the constraints, then (φ',π',X',P') will also do so. Furthermore, any curve $\lambda\mapsto(\varphi_\lambda,\pi_\lambda,X_\lambda,P_\lambda)$ on Γ defines a curve $\lambda\mapsto\theta(\varphi_\lambda,\pi_\lambda,X_\lambda,P_\lambda)$ that has the same form in the respective coordinate systems. Thus the tangent vectors of these two curves must have the same components. It follows that θ is differentiable and—moreover—symplectic since the values of the symplectic form at (φ,π,X,P) and at (φ',π',X',P') must coincide numerically in the respective coordinate systems. Hence θ is a symmetry.

Let us list some of the important properties of θ.

(1) The restriction $\tilde{\theta}:\Gamma_\phi\times\mathscr{E}\to\Gamma_\phi\times\mathscr{E}$ of θ to $\tilde{\Gamma}$, is given by

$$\tilde{\theta}(\varphi,\pi,X)=(\varphi,\pi,\vartheta\circ X). \tag{32}$$

This follows immediately from the idea of a shifted chart and the fact that φ and π are scalar fields. Thus we obtain the same Cauchy datum at the shifted Cauchy surface.

(2) Let ϕ be a global solution of the field equation, with a Cauchy datum in the Sobolev space Γ_ϕ. Then $\phi\circ\vartheta^{-1}$ is again such a solution since ϑ is an isometry. If ϕ has the Cauchy datum (φ,π) at X, then $\phi\circ\vartheta^{-1}$ has the datum (φ,π) at $\vartheta\circ X$. It follows that the map $\rho_{XX'}$ defined earlier satisfies $\rho_{\theta\circ X\theta\circ X'}(\varphi,\pi)=\rho_{XX'}(\varphi,\pi)$.

(3) The definition of θ implies immediately that it maps c-orbits onto c-orbits. In particular, if γ_ϕ is an orbit corresponding to a maximal solution ϕ, then $\theta(\gamma_\phi)=\gamma_{\phi\circ\vartheta^{-1}}$.

(4) Let o_ϕ be a perennial in $\mathscr{S}_{\rm can}$. The θ-shifted perennial $s_\vartheta(o_\phi)$ was defined in Ref. 5 as $s_\vartheta(o_\phi):=o_\phi\circ\theta^{-1}$. Then we have the relation

$$s_\vartheta(o_\phi)=o_{\phi\circ\vartheta^{-1}}. \tag{33}$$

Indeed, $o_\phi(\theta^{-1}(\xi,\eta,X,P))=o_\phi(\xi,\eta,X',P')=\int_\Sigma d^3x(\varphi'\eta-\pi'\xi)$ where (φ',π') is the Cauchy datum of ϕ at $X'=\vartheta^{-1}\circ X$. However, (φ',π') is also the Cauchy datum of $\phi\circ\vartheta^{-1}$ at X. Thus, $o_\phi(\theta^{-1}(\xi,\eta,X,P))=o_{\phi\circ\vartheta^{-1}}(\xi,\eta,X,P)$, and this is equivalent to Eq. (33). A straightforward calculation gives the θ-shift for $\mathscr{S}_{\rm loc}$ as $s_\vartheta(\kappa_f)=\kappa_{f\circ\vartheta^{-1}}$.

The relation in Eq. (33) implies that s_ϑ is an automorphism of the algebra $\mathscr{S}_{\rm can}$ since the map $\phi\mapsto\phi\circ\vartheta^{-1}$ is a linear transformation of solutions that preserves the Klein–Gordon product, and the constant functions on Γ are left invariant by s_ϑ. Similarly, s_ϑ is an automorphism of the algebra $\mathscr{S}_{\rm loc}$ because the map $f\to f\circ\vartheta$ is linear and preserves the quadratic form $G(\cdot,\cdot)$. In fact, s_ϑ induces a transformation of perennials from $\mathscr{S}_{\rm can}$ that is directly related to the Bogoliubov transformations that arise in the study of quantum field theory on a curved background. Indeed, if we choose a complex orthonormal basis $\{\phi_m,\phi_m^*\}$ for the space of solutions (for example, see Ref. 15), then the coefficients $\{a_m,a_m^*\}$ of the expansion of any solution ϕ in terms of this basis have the form of our perennials: namely $a_m=(\phi_m^*,\phi)_{\rm KG}$. The transformation s_ϑ of perennials thus defines new coefficients a_m, and the expansion of these in terms of the old ones is what is normally called a ''Bogoliubov transformation.''

Let us observe that the perennial formalism allows a more general type of symmetry that is not necessarily associated with transformations of space–time. For example, the group $\mathscr{G}_{\rm can}$ is a group of such symmetries. This raises the interesting question of whether other symmetries that are not associated with space–time transformations can be found, and—if so—if they can be helpful in the study of quantum field theory on a curved background.

Finally, let us construct the time evolution of the system. In the finite-dimensional case, such a construction is based on a transversal surface Γ_0 and a one-dimensional symmetry group $\{h(t)\}$ that moves Γ_0 (see Ref. 5). A transversal surface Γ_0 is defined to be a smooth submanifold of $\widetilde{\Gamma}$ that (i) intersects each c-orbit γ in at most one point $p=\Gamma_0\cap\gamma$; and (ii) has the property that each such intersection is transversal, i.e., $T_p\Gamma_0\cap T_p\gamma=\{0\}$, where 0 is the zero vector. A transversal surface is said to be ''global'' if it intersects each c-orbit. All these definitions can be extended without change to the infinite-dimensional case.

Similarly, the projections of perennials and of symmetries can be defined as for finite-dimensional systems. Thus, let $i_0:\Gamma_0\to\Gamma$ be the submanifold injection, and let $\pi_0:\widetilde{\Gamma}\to\Gamma_0$ be the projection that is defined by $\pi_0(p):=\gamma_p\cap\Gamma_0$, where γ_p is the c-orbit through the point $p\in\widetilde{\Gamma}$. If o is a perennial, then its projection $o_0:\Gamma_0\to R$ is defined by

$$o_0:=i_0^*o=o\circ i_0=o|_{\Gamma_0}. \tag{34}$$

If $\psi:\Gamma\to\Gamma$ is a symmetry, then $a_0(\psi):\Gamma_0\to\Gamma_0$ is defined by

$$a_0(\psi):=\pi_0\circ\psi|_{\Gamma_0}. \tag{35}$$

One can easily show that i_0^* is a Poisson algebra isomorphism, and that $a_0(\psi)$ is a symmetry of Γ_0.

We shall use a special type of transversal surface that is associated with embeddings as follows. For any spacelike embedding $X:\Sigma\to\mathscr{M}$, define the subset $\Gamma_X\subset\widetilde{\Gamma}$ by

$$\Gamma_X:=\{(\varphi,\pi,X)\in\widetilde{\Gamma}|(\varphi,\pi)\in\Gamma_\phi\}. \tag{36}$$

In the following steps we shall show that Γ_X is a transversal surface.

(1) The subset Γ_X can be considered as the image of the map $i_X:\Gamma_\phi\to\Gamma$ defined by $i_X(\varphi,\pi):=(\varphi,\pi,X,P)$ where P is given by Eq. (9). Note that $\mathrm{D}i_X|_{(\varphi,\pi)}$ is given by

$$\mathrm{D}i_X|_{(\varphi,\pi)}(\Phi,\Pi,V,W)=(\Phi,\Pi,0,W)\in T_{\widetilde{C}(\varphi,\pi,X)}\widetilde{\Gamma}, \tag{37}$$

and hence the linear map $\mathrm{D}i_X|_{(\varphi,\pi)}$ is injective and splits as

$$T_{\widetilde{C}(\varphi,\pi,X)}\widetilde{\Gamma}=\{(\Phi,\Pi,0,W)|(\Phi,\Pi)\in T_{(\varphi,\pi)}\Gamma_\phi, W=-\mathrm{D}H^\phi(\Phi,\Pi,0)\}$$

$$\times\{(0,0,V,W)|V\in H_0^s, W=-\mathrm{D}H^\phi(0,0,V)\}. \tag{38}$$

Hence, Γ_X is a smooth submanifold of Γ.

(2) Any tangent vector to Γ_X at $(\varphi,\pi,X)\in\Gamma_\phi\times\mathscr{E}$ has the form $(\Phi,\Pi,0)$, where $(\Phi,\Pi)\in T_{(\varphi,\pi)}\Gamma_\phi\simeq\Gamma_\phi$. The tangent space to $\gamma_{(\varphi,\pi,X)}$ at (φ,π,X) is the space $\Xi_{(\varphi,\pi,X)}$ given by Eq. (14), and the only vector (Φ,Π,V) in $\Xi_{(\varphi,\pi,X)}$ with $V=0$ is the zero vector. Thus the condition for transversality is satisfied.

(3) Any c-orbit γ_ϕ intersects Γ_X, and the point of intersection is (φ,π,X), where (φ,π) is the (unique) Cauchy datum of ϕ at X. Thus Γ_X is a global transversal surface.

Note that the injection i_X gives Γ_X the structure of a linear (Fréchet) space. Hence we can identify $T_{(\varphi,\pi)}\Gamma_X$ with Γ_X itself.

The pull-back Ω_X of $\widetilde{\Omega}$ by $i_X|_{\widetilde{\Gamma}}$ can easily be calculated from Eq. (15) as

$$\Omega_X((\Phi_1,\Pi_1),(\Phi_2,\Pi_2))=\int_\Sigma d^3x(\Phi_2\Pi_1-\Phi_1\Pi_2). \tag{39}$$

This is a constant, weakly nondegenerate form on $T_{(\varphi,\pi)}\Gamma_\phi\times T_{(\varphi,\pi)}\Gamma_\phi$ that can be identified with the following one on $\Gamma_\phi\times\Gamma_\phi$:

$$\Omega_X((\varphi_1,\pi_1),(\varphi_2,\pi_2))=\int_\Sigma d^3x(\pi_1\varphi_2-\varphi_1\pi_2). \tag{40}$$

This form can be used to equip Γ_ϕ with the structure of a linear, weak-symplectic space.

Note that the perennial formalism allows for more general transversal surfaces that are not necessarily associated with surfaces in space–time. An intriguing—and open—question is if an explicit example of such a surface can be found and, if so, if it can be used to construct a quantum field theory on a generic space–time with no timelike Killing vectors (see later).

Let us suppose next that there is a one-dimensional group of isometries $\vartheta(t)$ in the space–time $\mathscr{M}$ such that, for all t, $\vartheta(t)(X(\Sigma))\neq X(\Sigma)$ and $\vartheta(t)$ is generated by an everywhere timelike Killing vector in $\mathscr{M}$. The corresponding one-dimensional group $\{\theta(t)\}$ of symmetries of Γ, together with the transversal surface Γ_X, form a basis for the construction of an ''auxiliary rest frame'' with ''time levels'' given by $\Gamma_t:=\theta(t)\Gamma_X$ and ''rest trajectories'' given by θ-orbits $\{\theta(t)p\}$, $p\in\Gamma_0$. Any c-orbit γ defines a curve, $t\mapsto\eta_\gamma(t):=\Gamma_t\cap\gamma$, and the motion with respect to the auxiliary rest frame can be defined in a complete analogy to the finite-dimensional case by comparing the curve $\eta_\gamma(t)$ with the rest trajectories $\theta(t)p$. ''The same measurement at different

times'' can again be defined as the set of time-shifted perennials $o \to o_t := s_{\vartheta(t)} o$, and the construction of the classical Schroedinger or Heisenberg pictures by means of the projection to Γ_0 is straightforward (for details see Ref. 5).

However, note that the procedure described here differs in one respect from that described in Ref. 5. Namely, the symmetry group $\{\theta(t)\}$ we have chosen to generate the time evolution is *not* a subgroup of the first-class canonical group $\mathcal{G}_{\rm can}$ or $\mathcal{G}_{\rm loc}$. Thus, the construction of the quantum mechanical time evolution as given in Ref. 5 has to be generalized. This will be done in the next section.

IV. QUANTUM THEORY

In this section, the construction of the quantum theory described in Ref. 5 for finite-dimensional systems will be extended to the scalar field on a fixed background. The construction uses a representation of the first-class canonical group $\mathcal{G}$ by unitary operators $R(g)$, $g \in \mathcal{G}$, on a Hilbert space $\mathcal{K}$. The generators of $\mathcal{G}$—the elements of the Lie algebra $\mathcal{S}$—are represented by self-adjoint operators on $\mathcal{K}$. Then the automorphism $s_{\vartheta(t)}$ of the algebra $\mathcal{S}$ defines an automorphism $\hat{s}_{\vartheta(t)}$ of the corresponding operator algebra by the commutative diagram:

$$\begin{array}{ccc} \mathcal{S} & \overset{s_{\vartheta(t)}}{\rightarrow} & \mathcal{S} \\ \downarrow R & & \downarrow R \\ R(\mathcal{S}) & \overset{\hat{s}_{\vartheta(t)}}{\rightarrow} & R(\mathcal{S}). \end{array} \tag{41}$$

We arrive at a unitary evolution if we can implement the automorphism $\hat{s}_{\vartheta(t)}$ by a unitary map $U(t): \mathcal{K} \to \mathcal{K}$; that is, $\hat{s}_{\vartheta(t)}(\hat{O}) = U^{-1}(t) \hat{O} U(t)$.

The classical constructions in the previous sections—in particular, the choice of the algebras of elementary perennials—were performed in such a way that the rules of the algebraic or group-theoretical approaches to quantization as described above lead directly to well-known approaches to the quantization of a scalar field on a fixed space–time background. In particular, $\mathcal{S}_{\rm can}$ leads to the Segal theory (for example, see Refs. 16 and 17).

Let us concentrate on $\mathcal{S}_{\rm can}$. As was explained in the previous section, $\mathcal{S}_{\rm can}$ is an infinite-dimensional version of the Heisenberg algebra, and it determines an abstract infinite-dimensional Heisenberg group $\mathcal{G}_{\rm can}$ (in fact, a ''nuclear group,'' see Ref. 18) that is a central extension of the corresponding symmetry group of the phase space Γ and which acts transitively on the c-orbits. The group $\mathcal{G}_{\rm can}$, together with a unitary representation (which must satisfy certain additional conditions in order to guarantee the existence of ''quantum observables;'' see Ref. 16) is called a ''Weyl system'' in the literature. If we apply the theory of Weyl systems to the present case, we can draw the following conclusions:

(1) The group-theoretical approach to the quantization of an infinite-dimensional system differs significantly from the finite-dimensional case in the following respects. As a rule, a finite-dimensional Lie group has only relatively few representations—indeed, the Heisenberg group of n dimensions has just one (up to unitary equivalence) for any n. Many finite-dimensional canonical groups arise naturally as semi-direct products in which the ''non-Abelian'' factor is sufficiently large that there are only a few inequivalent orbits in the dual of the abelian factor (see Ref. 6). However, an infinite-dimensional Heisenberg group has a huge number of non-equivalent representations. Many of these have no obvious physical application, while others have a meaning in relation to external parameters. For example, in quantum field theory at a finite temperature each value of the temperature is associated with a particular representation (and non-zero temperature representations are not even irreducible).

(2) The most difficult part of the construction of a linear quantum field theory is therefore the choice of a ''physical'' representation. In the Segal theory, the key object on which such a choice is based is the time evolution automorphism $s_{\vartheta(t)}$ of the Heisenberg algebra $\mathscr{S}_{\rm can}$. For example, a cyclic state (generating the representation by a Gel'fand–Neumark–Segal construction) might be selected using the Kubo–Martin–Schwinger condition with $\hat{s}_{\vartheta(t)}$. Another approach based on $s_{\vartheta(t)}$ is described in Ref. 17.

Thus a new problem arises here, analogous perhaps to the ''Hilbert space problem'' of Kuchař's classification[3] of different aspects of the problem of time in canonical quantum gravity. In fact, quantum field theory in a curved background has a time problem of its own: most interesting background space–times do not possess a one-dimensional group of timelike isometries $\vartheta(t)$ (i.e., there is no time-like Killing vector), so that $s_{\vartheta(t)}$ is not available. However, several methods have been developed for (at least, partly) bypassing this problem and thereby enabling a number of interesting questions to be addressed. These methods are not as mathematically rigorous as those based on a timelike Killing vector but, nevertheless, they may give some hints about the problem of time in the full theory of canonical quantum gravity. We shall consider two different strategies that we shall call the ''scattering approach'' and the ''algebraic approach'' to quantization. Let us describe how they can be applied in the context of the perennial formalism.

A. Scattering approach

The scattering approach to quantization is based on an isolated symmetry whose domain is a small subset of the phase space Γ. Let us consider first an (idealized) example in which $(\mathscr{M},g)$ is a space–time that satisfies the conditions of section II and which contains open subsets U' and U'' with the following properties:

(1) Both U' and U'' are locally stationary: i.e., there are local flows $\vartheta'(t,X)$ and $\vartheta''(t,X)$ generated by timelike Killing generators that are defined everywhere on U' and U'' respectively.

(2) Both U' and U'' contain Cauchy hypersurfaces: i.e., there are spacelike embeddings X' and X'' such that $X'(\Sigma)\subset U'$ and $X''(\Sigma)\subset U''$.

(3) There is an isometry $\vartheta: U'\to U''$ such that $X''=\vartheta\circ X'$.

Finally, let $\mathscr{S}_{\rm can}$ denote the algebra of elementary perennials as discussed in section III.

The local flows ϑ' and ϑ'' may not induce global symmetries of Γ, but they will define perennials h' and h'' in some neighborhood of $\Gamma_{X'}$ and $\Gamma_{X''}$ that correspond to the generators of ϑ' and ϑ'' respectively. These perennials can be used to construct representations $(R',\mathscr{K}')$ and $(R'',\mathscr{K}'')$ of $\mathscr{S}_{\rm can}$ such that $-h'$ and $-h''$ are represented by positive, self-adjoint operators $\hat{H}'$ and $\hat{H}''$ (see, e.g. Ref. 19). Following the procedure described in Ref. 9, one could now try to implement the map $\rho_{X'X''}:\Gamma_{X'}\to\Gamma_{X''}$, which is a symplectic diffeomorphism (see section II), by a unitary map $U(\rho):\mathscr{K}'\to\mathscr{K}''$. This would leave us with only one Hilbert space (a ''pasting'' of $\mathscr{K}'$ and $\mathscr{K}''$).

However, the literature on the quantum theory of a scalar field has proceeded in a different direction than can be related to the Heisenberg picture in the perennial formalism, as described in Ref. 5. The first observation is that the discrete isometry ϑ induces a symmetry θ that is defined in some neighborhood of $\Gamma_{X'}$ in Γ; in turn, θ determines a well-defined automorphism $s_\vartheta:\ \mathscr{S}_{\rm can}\to\mathscr{S}_{\rm can}$ of the space of perennials. Indeed, for this it is sufficient that θ maps a globally transversal surface $\Gamma_{X'}$ onto another such $\Gamma_{X''}$. The θ-shifted perennials are then completely determined by their values on $\Gamma_{X''}$, and these are given by the θ-maps of the restrictions of the original perennials to $\Gamma_{X'}$. Note that θ is not a symmetry in the sense of Ref. 5 (it is not globally defined); we shall refer to such a map as a ''time shift.''

The next step is to define the map $\hat{s}'_\vartheta: R'(\mathscr{S}_{\rm can})\to R'(\mathscr{S}_{\rm can})$ by the obvious analogue of the commutative diagram (41), and then to see whether or not it can be implemented by a unitary map $U(\vartheta):\mathscr{K}'\to\mathscr{K}'$. If the Cauchy hypersurface is compact, this is always possible.[20] Thus one can again work with just a single Hilbert space. The interpretation of the various mathematical objects

is then that $R'(\mathscr{S}_{\rm can})$ contains the Heisenberg observables at the ''time'' $\Gamma_{X'}$; $R'(s_\vartheta(\mathscr{S}_{\rm can}))$ contains those at the ''time'' $\Gamma_{X''}$; the elements of $\mathscr{K}'$ are the Heisenberg states; and $U(\vartheta)$ is the unitary scattering matrix.

If $U(\vartheta)$ does *not* exist, a Heisenberg-picture dynamics can still be used to calculate the expectation values of time-shifted operators that are well-defined in certain states. For example, in this way one can calculate the number of particles within a given finite energy range and a finite volume that are created from the vacuum of $\mathscr{K}'$ in the region between $X'(\Sigma)$ and $X''(\Sigma)$, even though the *total* number of created particles diverges.

Note that the scattering approach will work even if there is only the ''rudiments'' of a symmetry, but it will give only information on what comes ''out'' if we let something go ''in''; what happens ''inside'' remains quite undetermined.

B. The Hawking effect

An example of the scattering approach is the calculation of the Hawking effect.[19] In this section, we shall reformulate this calculation in terms of the perennial formalism. Our motivation is *not* to present a new and conceptually better derivation of the effect but rather to use this model of the scalar field on a black-hole background to suggest a possible meaning of a time shift that does not preserve the domains of transversal surfaces.

In a general system, a transversal surface Γ_X will not be global (i.e., it will not cut *all* the c-orbits transversally), and the time shift that is available will not preserve the domains of these surfaces [the domain $\mathscr{D}(\Gamma_1)$ of a transversal surface Γ_1 is the subset of $\widetilde{\Gamma}$ such that the c-orbit through any point of $\mathscr{D}(\Gamma_1)$ intersects Γ_1; see Ref. 5].

For example, the toy models studied in Refs. 9 and 10 do not possess global transversal surfaces, but there are some that are almost global in the sense that the closure of the domain contains the whole constraint surface $\widetilde{\Gamma}$. The results of Ref. 9 suggest that there is no difference between global and almost global surfaces as far as the quantum theory is considered. In Ref. 10, two almost global surfaces Γ_1 and Γ_2 were chosen, each with two components, $\Gamma_1^\pm$ and $\Gamma_2^\pm$ respectively, giving a total of four, closed transversal surfaces. There is a discrete symmetry θ that maps Γ_1^+ onto Γ_2^+, but $\mathscr{D}(\Gamma_1^+) \neq \mathscr{D}(\Gamma_2^+)$. The Hilbert spaces $\mathscr{K}_1$ and $\mathscr{K}_2$ corresponding to the transversal surfaces Γ_1^+ and Γ_2^+ were constructed, and a unitary map $U(\vartheta):\mathscr{K}_1\to\mathscr{K}_2$ of these Hilbert spaces was found that corresponds to the classical map θ. However, the pasting map $\rho:\Gamma_1^+\to\Gamma_2^+$ is defined (by the c-orbits; see Ref. 9) only between some proper subsets of Γ_1^+ and Γ_2^+; the corresponding map $U(\rho)$ is defined only on a proper subspace $\mathscr{K}_{12}\subset\mathscr{K}_1$, and $\mathscr{K}_{21}=U(\rho)\mathscr{K}_{12}$ is a proper subset of $\mathscr{K}_2$. Although the map $U(\rho):\mathscr{K}_{12}\to\mathscr{K}_{21}$ itself is unitary, the corresponding time evolution operator $U(\rho)\circ U^{-1}(\vartheta):\mathscr{K}_1\to\mathscr{K}_1$ is defined only on the subspace $\mathscr{K}_{12}$ and so it is not a unitary operator on $\mathscr{K}_1$. This leads to a time evolution that can change the norms of states, the only physical interpretation of which is that the system can be ''lost'' or ''found'' during the time evolution—this can in fact happen already in the classical theory of this (bizarre) system.

A similar situation can arise in the context of quantum field theory on a curved background. Suppose first that there is a Cauchy surface Σ that consists of two components Σ_1 and Σ_2, so that $\Sigma=\Sigma_1\cup\Sigma_2$. Then both Σ_1 and Σ_2 are closed surfaces in $\mathscr{M}$, and the space Γ_ϕ of Cauchy data on Σ splits into the direct sum of $\Gamma_{\phi 1}$ and $\Gamma_{\phi 2}$, where

$$\Gamma_{\phi i}=\{(\varphi,\pi)\in\Gamma_\phi|\,\mathrm{supp}(\varphi,\pi)\subset\Sigma_i\}, \tag{42}$$

$i=1,2$. Both $\Gamma_{\phi 1}$ and $\Gamma_{\phi 2}$ are Fréchet spaces, and $\Gamma_\phi=\Gamma_{\phi 1}\otimes\Gamma_{\phi 2}$. For a given spacelike embedding $X:\Sigma_1\cup\Sigma_2\to\mathscr{M}$, a pair of transversal surfaces Γ_{Xi}, $i=1,2$, can be defined by

$$\Gamma_{Xi}:=\{(\varphi,\pi,X)\in\widetilde{\Gamma}|\,\mathrm{supp}(\varphi,\pi)\subset\Sigma_i\}. \tag{43}$$

The proof that Γ_{Xi} is transversal is analogous to that for Γ_X in section III, with the relation Eq. (38) being replaced by

$$T_{\tilde{C}(\varphi,\pi,X)}\tilde{\Gamma}=\{(\Phi,\Pi,0,W)|(\Phi,\Pi)\in\Gamma_{\phi 1},W=-\mathrm{D}H^{\phi}(\Phi,\Pi,0)\}$$
$$\times\{(\Phi,\Pi,0,W)|(\Phi,\Pi)\in\Gamma_{\phi 2},W=-\mathrm{D}H^{\phi}(\Phi,\Pi,0)\}$$
$$\times\{(0,0,V,W)|V\in T_X\mathscr{E},W=-\mathrm{D}H^{\phi}(0,0,V)\}. \tag{44}$$

Of course, the surface Γ_{X1} is not even almost globally-transversal: we have the relation $\Gamma_X=\Gamma_{X1}\times\Gamma_{X2}$, and only Γ_X is a global transversal surface.

The Poisson algebra $\mathscr{P}$ of perennials contains ideals $\mathscr{P}_1$ and $\mathscr{P}_2$ of perennials associated with the transversal surfaces Γ_{X1} and Γ_{X2}, where

$$\mathscr{P}_i:=\{o\in\mathscr{P}|\text{supp } o\subset\mathscr{D}(\Gamma_{Xi})\}. \tag{45}$$

These ideals $\mathscr{P}_1$ and $\mathscr{P}_2$ generate $\mathscr{P}$. Similarly, the Lie algebra of elementary perennials $\mathscr{S}$ contains two ideals $\mathscr{S}_1$ and $\mathscr{S}_2$ defined by analogous equations, and $\mathscr{S}=\mathscr{S}_1\oplus\mathscr{S}_2$ is a Lie algebra decomposition. Indeed, each function $o\in\mathscr{S}$ has a restriction o_X to Γ_X, and there are unique $o_{X1}\in\mathscr{S}_1$ and $o_{X2}\in\mathscr{S}_2$ such that $o_X=o_{X1}+o_{X2}$. Observe that o_{Xi} vanishes at Γ_{Xi}, so that we have $\{o_{X1},o_{X2}\}=0$ as desired.

Suppose that the physical representations of the algebras $\mathscr{S}$, $\mathscr{S}_1$ and $\mathscr{S}_2$ on Hilbert spaces $\mathscr{K}$, $\mathscr{K}_1$ and $\mathscr{K}_2$ respectively have the property $\mathscr{K}=\mathscr{K}_1\otimes_s\mathscr{K}_2$, where $\otimes_s$ denotes the symmetrized tensor product. Let $|a\rangle$ be an arbitrary element of $\mathscr{K}$. Then it is well-known that there is a density operator $\hat{a}_1$ in $\mathscr{K}_1$ such that

$$\langle a|\hat{o}_1|a\rangle=\mathrm{tr}(\hat{a}_1\hat{o}_1),\quad \text{for } all\ \hat{o}_1\in L(\mathscr{K}_1) \tag{46}$$

(for example, see Ref. 19). Suppose finally that there is an isometry $\vartheta:X'(\Sigma)\to X(\Sigma_1)$, where $X'(\Sigma)$ is a Cauchy hypersurface and $X(\Sigma_1)$ is defined as above. The corresponding time shift $\theta:\Gamma_{X'}\to\Gamma_{X1}$ maps a global transversal surface onto a non-global one. Let us define s_ϑ by

$$s_\vartheta o|_{\Gamma_{X1}}=o\circ\theta^{-1},$$

$$s_\vartheta o|_{\Gamma_{X2}}=0\quad \text{for all } o\in\mathscr{S}.$$

We see immediately that $s_\vartheta(\mathscr{S})=\mathscr{S}_1$.

Now we can apply the Heisenberg picture method as described in subsection IV A. The elements of $\mathscr{K}$ are considered as Heisenberg states, and the algebra $R(\mathscr{S})$ contains the Heisenberg observables at the ''time'' $\Gamma_{X'}$ and $R(\mathscr{S}_1)$ contains those at the ''time'' Γ_{X1}. The result is that the time-evolution operator $\hat{s}_\vartheta$ maps the algebra $R(\mathscr{S})$ onto its own proper subalgebra $R(\mathscr{S}_1)$ so that the representation R of $\mathscr{S}_1$ is not irreducible, and a Heisenberg state $|a\rangle$ that is pure with respect to the algebra $R(\mathscr{S})$ is a mixed state $\hat{a}_1$ with respect to the time shifted algebra $R(\mathscr{S}_1)$.

An example in which ϑ maps a global transversal surface onto a non-global one is the Hawking radiation produced by the spherically-symmetric, asymptotically flat space–time associated with a collapsing star (see Ref. 19) (actually, it is a limiting case of the procedure above; moreover, the assumption must be made that the theory in Ref. 11 can be generalized to an asymptotically-flat spacetime). In this example, the scalar field is chosen to have a vanishing mass-parameter m, and hence the dynamics is determined completely by the conformal structure of the space–time $(\mathscr{M},g)$. The past and future null infinities $\mathscr{T}^+$ and $\mathscr{T}^-$ are null hypersurfaces in the conformal completion, $\mathscr{M}$, of $\mathscr{M}$. The hypersurfaces $\mathscr{T}^-$ and $\mathscr{T}^+\cup\mathscr{H}$ are Cauchy hypersurfaces for a zero rest mass field, where $\mathscr{H}$ is the event horizon in $\mathscr{M}$ (see Ref. 21). They can be considered as limits of time-like Cauchy hypersurfaces. Both $\mathscr{H}$ and $\mathscr{T}^+$ are closed hypersurfaces

in $\bar{\mathscr{M}}$. Note that Σ and $X_\pm$ can be chosen such that $X_-(\Sigma)=\mathscr{I}^-$ and $X_+(\Sigma)=\mathscr{I}^+$. The maps ϑ, ϑ_+ and ϑ_- which were (effectively) used in Ref. 19 can be described by means of the Eddington-Finkelstein coordinates (u,r,α,β) and (v,r,α,β) in some neighborhoods of $\mathscr{I}^-$ and $\mathscr{I}^+$ as follows: ϑ_- is defined by $(v,\infty,\alpha,\beta)\to(v+t,\infty,\alpha,\beta)$, ϑ_+ by $(u,\infty,\alpha,\beta)\to(u+t,\infty,\alpha,\beta)$, and ϑ by $u(v,\alpha,\beta)=v$, $r=\infty$, $dr\to -dr$, $\alpha(v,\alpha,\beta)=\alpha$, and $\beta(v,\alpha,\beta)=\beta$ (in-coming modes are mapped into out-going ones). This time shift ϑ is not uniquely determined because u and v are defined up to an additive constant, but most of the physically interesting results do not depend on the choice made. In this situation, the considerations above are applicable, and the result is again a non-unitary evolution that sends pure states into mixed states. This time, the normalization of states is preserved: some information is lost, but the system itself is not.

C. Algebraic approach

Hilbert spaces play a less direct role in this approach in which the basic objects are elements of some algebra of local observables on which states are defined as linear functionals. One can reformulate the algebraic approach in terms of the perennial formalism using the algebra of the smeared fields, $\mathscr{S}_{\rm loc}$. We shall not go into detail here, but just sketch the main ideas.

The local observables are polynomials in the smeared field operators

$$\hat{\kappa}_f, \quad \hat{\kappa}_f\hat{\kappa}_h, \ldots, \tag{47}$$

as well as the regularized stress-energy tensor components $\hat{T}^{\mu\nu}(p)$ at arbitrary points p of the space–time $\mathscr{M}$. The stress-energy tensor has an immediate physical interpretation whereas the smeared field operators play only an auxiliary role.

The states are defined as certain linear functionals on the above algebra, with the value of such a state σ on an operator $\hat{o}$ having the physical meaning of the expected value. Attention is restricted to so-called ''quasifree Hadamard states,'' whose value on any polynomial of the smeared fields is determined by its value on the following second-order polynomial

$$G_\sigma(f,h)=\sigma(\hat{\kappa}_f\hat{\kappa}_h+\hat{\kappa}_h\hat{\kappa}_f). \tag{48}$$

The bilinear form $G_\sigma(f,h)$ has a kernel $G_\sigma(y_1,y_2)$, so that

$$G_\sigma(f,h)=\int_{\mathscr{M}} \mathrm{d}^4y_1\,\mathrm{d}^4y_2 G_\sigma(y_1,y_2)f(y_1)h(y_2), \tag{49}$$

which satisfies the field equation in each argument y_1 and y_2. This leads to the crucial observation that the state can be ''calculated'' by solving the wave equation. For a Hadamard state, the short-distance behavior of $G_\sigma(y_1,y_2)$ as $y_1\to y_2$ is such that the expected value in the state σ of the stress-energy tensor is well-defined and can be calculated from $G_\sigma(y_1,y_2)$.

The quasifree Hadamard states do not form a Hilbert space: neither a scalar product—nor a linear combination—of a pair of them is well-defined. However, to obtain a physical interpretation of such a state it is only necessary to calculate the expected value of the stress-energy tensor, and this is feasible. For more details see Ref. 22.

V. CONCLUSIONS

We have found an intriguing result: canonical quantization of a system can lead to a non-unitary time evolution. The result has been derived by a careful analysis of global properties of the physical phase space: an aspect that has been rather neglected heretofore. However, more work is

necessary to understand the relations between the global properties and the time evolution in some generality. Also, the physical interpretation of the time evolution in parametrized systems needs to be developed further.

In the course of our calculations we have seen that the central commandment of the perennial formalism—to work only with perennials—is in reality not too restrictive since almost everything can be viewed as a perennial. In particular, the usual particle variables of the quantum field theory—for example, creation and annihilation operators—can be considered as perennials ($\mathscr{I}_{\rm can}$), as can the more local, smeared fields in $\mathscr{I}_{\rm loc}$.

However, these and other insights gained in our article have only a relative value in so far as their derivation exploited two special features of our model—the linearity of the field equations, and the existence of a background space–time. A question left for future research is if these structures can be replaced with something that will work in more complicated cases.

Separation of the massless field equations for arbitrary spin in the Robertson–Walker space–time

Antonio Zecca
Dipartimento di Fisica dell' Universita' and INFN, Sezione di Milano, Via Celoria 16, I-20133 Milano, Italia

(Received 14 July 1995; accepted for publication 14 March 1996)

The massless spin 2 free-field equation is studied in the Robertson–Walker space–time via the Newman–Penrose formalism and separated by using a Chandrasekhar–Teukolski method. The resulting temporal and angular equations are explicitly integrated. The radial equations are solved in the flat universe case. The closed universe case shows, in principle, the existence of a discrete spectrum of the energy of the massless particles. In the general case of spin greater than 2 the massless field equations are shown to be separable by induction. The separated equations admit the same recurrence structure and analog interpretation properties of the spin 2 and less than 2 cases. © *1996 American Institute of Physics.* [S0022-2488(96)00307-6]

I. INTRODUCTION

After the pioneer paper by Newman and Penrose[1] the spinor formalism represents the natural tool to formulate in general relativity the (massless and massive) field equations. In this context the massless free-field equation for a field of spin $s=\frac{1}{2}(n+1)$ can be written[2]

$$\nabla_{AA'}\phi^{A}_{A_1A_2\cdots A_n}=0, \quad \phi_{AA_1A_2\ldots A_n}=\phi_{(AA_1A_2\ldots A_n)}. \tag{1}$$

The equations (1) are consistent in a curved space–time for $n=0$ (Weyl's equation) and $n=1$ (homogeneous Maxwell equations).[2] For $n>1$, they are consistent only if the space–time is conformally flat[2–5] (Inconsistencies arise already in Minkowski space–time for $s>1$ in the case of electromagnetic interaction[6]). To overcome these difficulties in arbitrary curved space–time, alternative formulations have been proposed in terms of symmetrized field equations stronger than Eq. (1).[7–9]

In the case of conformally flat space–time the equation (1) can be solved in a general way for arbitrary spin.[2]

In this paper we propose an alternative general solution in the case of the (conformally flat) Robertson–Walker geometry.[2] The solution is obtained by separating Eq. (1) for arbitrary spin. The proof of the result is done by induction over n in the context of the Newman–Penrose formalism.

We first completely solve the case $s=2$ by a separation method already applied to the $s=\frac{1}{2}$ and $s=1$ cases[10,11] and that is similar to the Chandrasekhar–Teukolski method employed to solve the Dirac equation in the Kerr metric.[12] The time and angular equations relative to this case are integrated in the flat, closed, and open universe. The radial equations, which are explicitly integrated in case of flat space–time, imply a restriction on the minimum possible eigenvalue of the angular equations. In the case of a closed universe, the structures of the radial equations suggest that the energy of the massless particles takes purely discrete values, a compatibility problem, however, being open.

The induction is then completed by taking into account the recursive separated structure of the angular and radial equations of the case $s=2$. A central role in the proof is played by the special structure that the spin coefficients take in the null tetrad frame that has been employed to perform the calculations.

II. THE MASSLESS SPIN 2 EQUATIONS

We now develop the field equation (1) by the Newman–Penrose formalism in the case of a spin 2 field. Since the field is represented by a symmetric spinor, its independent components can be characterized by setting

$$\phi_h \equiv \phi_{AA_1A_2A_3} \Leftrightarrow A+A_1+A_2+A_3=h, \quad h=0,1,2,3,4. \tag{2}$$

With this simplified notation we now develop the content of Eq. (1) by applying the Newman–Penrose formalism.[1] By using the expressions of the covariant spinorial derivatives in terms of the generalized Dirac matrices, $\nabla_{\mathbf{AX}'} = \sigma^a_{\mathbf{AX}'}\nabla_a$, by expressing the covariant derivatives by means of the tabulated spin coefficients[2,12] and with the usual identification $D\equiv\partial_{00'}$, $\delta\equiv\partial_{01'}$, $\delta^*\equiv\partial_{10'}$, $\Delta\equiv\partial_{11'}$ relative to the directional derivatives, we get from Eq. (1)

$$(D-2\epsilon-4\rho)\phi_1-(\delta^*+\pi-4\alpha)\phi_0+3\kappa\phi_2=0, \tag{3.1}$$

$$(D-3\rho)\phi_2-(\delta^*+2\pi-2\alpha)\phi_1+2\kappa\phi_3+\lambda\phi_0=0, \tag{3.2}$$

$$(D-2\epsilon-2\rho)\phi_3-(\delta^*+3\pi)\phi_2+\kappa\phi_4+2\lambda\phi_1=0, \tag{3.3}$$

$$(D+4\epsilon-\rho)\phi_4-(\delta^*+4\pi+2\alpha)\phi_3+3\lambda\phi_2=0, \tag{3.4}$$

$$(\Delta+\mu-4\gamma)\phi_0-(\delta-4\tau-2\beta)\phi_1-3\sigma\phi_2=0, \tag{3.5}$$

$$(\Delta+2\mu-2\gamma)\phi_1-(\delta-3\tau)\phi_2-2\sigma\phi_3-\nu\phi_0=0, \tag{3.6}$$

$$(\Delta+3\mu)\phi_2-(\delta+2\beta-2\tau)\phi_3-2\nu\phi_1-\sigma\phi_4=0, \tag{3.7}$$

$$(\Delta+4\mu+2\gamma)\phi_3-(\delta+4\beta-\tau)\phi_4+3\nu\phi_2=0, \tag{3.8}$$

that are the massless spin 2 equations. It is a standard result that these equations are formally identical with the Bianchi identities in vacuum.[13] We have written down eight equations because for any one of the equations (3.2), (3.3), (3.6), and (3.7) we obtain also, by the above procedure, two replicas of them.

III. SPIN 2 IN THE ROBERTSON–WALKER GEOMETRY

The object is now to separate Eqs. (3) in the Robertson–Walker space–time whose metric is given by

$$ds^2=dt^2-R^2(t)\left[\frac{dr^2}{1-ar^2}+r^2(d\theta^2+\sin^2\theta\, d\varphi^2)\right], \quad a=0,\pm1. \tag{4}$$

In connection with the Newman–Penrose formalism we choose the null tetrad frame $\{l^i,n^i,m^i,m^{\star i}\}$, whose associated directional derivatives are given by

$$\begin{aligned} D&\equiv l^i\partial_i=(\partial_t+R^{-1}\sqrt{1-ar^2}\partial_r)/\sqrt{2},\\ \Delta&\equiv n^i\partial_i=(\partial_t-R^{-1}\sqrt{1-ar^2}\partial_r)/\sqrt{2},\\ \delta&\equiv m^i\partial_i=(\partial_\theta+i\ \csc\ \theta\partial_\phi)/(\sqrt{2}rR),\\ \delta^*&\equiv m^{*i}\partial_i=(\partial_\theta-i\ \csc\ \theta\partial_\phi)/(\sqrt{2}rR), \end{aligned} \tag{5}$$

to which there correspond the nonzero spin coefficients[10]

$$\begin{aligned}\rho&=-(r\dot{R}+\sqrt{1-ar^2})/(\sqrt{2}rR),\\ \mu&=(r\dot{R}-\sqrt{1-ar^2})/(\sqrt{2}rR),\\ \beta&=-\alpha=\cot\,\theta/(2\sqrt{2}rR),\\ \epsilon&=-\gamma=\dot{R}/(2\sqrt{2}R).\end{aligned}\tag{6}$$

Owing to the symmetry of the metric, the φ dependence in Eqs. (3) can be separated, by the substitution $\phi_h\rightarrow\phi_h\exp(im\varphi)$, $m=0,\pm1,\pm2,\pm3,\ldots$. By using the above results and by setting

$$\phi_h(r,\theta,\varphi,t)=\exp(im\varphi)\,\phi_h(r,t)S_h(\theta),\quad h=0,1,2,3,4,\quad m=0,\pm1,\pm2,\ldots,\tag{7}$$

in Eqs. (3), the φ dependence factors out and the θ dependence can be separated to obtain

$$\frac{rR\sqrt{2}}{\phi_0}(D-2\epsilon-4\rho)\phi_1=\frac{1}{S_1}L_2^-S_0=\lambda_0,\tag{8.1}$$

$$\frac{rR\sqrt{2}}{\phi_1}(D-3\rho)\phi_2=\frac{1}{S_2}L_1^-S_1=\lambda_1,\tag{8.2}$$

$$\frac{rR\sqrt{2}}{\phi_2}(D+2\epsilon-2\rho)\phi_3=\frac{1}{S_3}L_0^-S_2=\lambda_2,\tag{8.3}$$

$$\frac{rR\sqrt{2}}{\phi_3}(D+4\epsilon-\rho)\phi_4=\frac{1}{S_4}L_{-1}^-S_3=\lambda_3,\tag{8.4}$$

$$\frac{rR\sqrt{2}}{\phi_1}(\Delta+\mu-4\gamma)\phi_0=\frac{1}{S_0}L_{-1}^+S_1=\lambda_4,\tag{8.5}$$

$$\frac{rR\sqrt{2}}{\phi_2}(\Delta+2\mu-2\gamma)\phi_1=\frac{1}{S_1}L_0^+S_2=\lambda_5,\tag{8.6}$$

$$\frac{rR\sqrt{2}}{\phi_3}(\Delta+3\mu)\phi_2=\frac{1}{S_2}L_1^+S_3=\lambda_6,\tag{8.7}$$

$$\frac{rR\sqrt{2}}{\phi_4}(\Delta+4\mu+2\gamma)\phi_3=\frac{1}{S_3}L_2^+S_4=\lambda_7,\tag{8.8}$$

λ_i, $i=0,1,\ldots,7$, being the corresponding separation constants and where use has been made of the definition

$$L_n^{\pm}=\partial_\theta\mp m\,\csc\,\theta+n\,\cot\,\theta.\tag{9}$$

By further setting

$$\phi_h(r,t)=\psi_h(r)T(t),\quad h=0,1,2,3,4,\tag{10}$$

also the r,t dependence can be separated in Eqs. (8) to obtain

$$ik=\sqrt{1-ar^2}\,\frac{\psi_1'}{\psi_1}+\frac{4}{r}\,\sqrt{1-ar^2}-\frac{\lambda_0}{r}\,\frac{\psi_0}{\psi_1}, \tag{11.1}$$

$$ik=\sqrt{1-ar^2}\,\frac{\psi_2'}{\psi_2}+\frac{3}{r}\,\sqrt{1-ar^2}-\frac{\lambda_1}{r}\,\frac{\psi_1}{\psi_2}, \tag{11.2}$$

$$ik=\sqrt{1-ar^2}\,\frac{\psi_3'}{\psi_3}+\frac{2}{r}\,\sqrt{1-ar^2}-\frac{\lambda_2}{r}\,\frac{\psi_2}{\psi_3}, \tag{11.3}$$

$$ik=\sqrt{1-ar^2}\,\frac{\psi_4'}{\psi_4}+\frac{1}{r}\,\sqrt{1-ar^2}-\frac{\lambda_3}{r}\,\frac{\psi_3}{\psi_4}, \tag{11.4}$$

$$ik=-\sqrt{1-ar^2}\,\frac{\psi_0'}{\psi_0}-\frac{1}{r}\,\sqrt{1-ar^2}-\frac{\lambda_4}{r}\,\frac{\psi_1}{\psi_0}, \tag{11.5}$$

$$ik=-\sqrt{1-ar^2}\,\frac{\psi_1'}{\psi_1}-\frac{2}{r}\,\sqrt{1-ar^2}-\frac{\lambda_5}{r}\,\frac{\psi_2}{\psi_1}, \tag{11.6}$$

$$ik=-\sqrt{1-ar^2}\,\frac{\psi_2'}{\psi_2}-\frac{3}{r}\,\sqrt{1-ar^2}-\frac{\lambda_6}{r}\,\frac{\psi_3}{\psi_2}, \tag{11.7}$$

$$ik=-\sqrt{1-ar^2}\,\frac{\psi_3'}{\psi_3}-\frac{4}{r}\,\sqrt{1-ar^2}-\frac{\lambda_7}{r}\,\frac{\psi_4}{\psi_3}, \tag{11.8}$$

$$ik=-R\,\frac{\dot{T}}{T}-3\dot{R}, \tag{11.9}$$

where ik is the separation constant, k being assumed to be a real number as a consequence of the physical interpretation that will be given later on.

The time dependence can be obtained by integrating Eq. (11.9) to obtain

$$T(t)=T(0)\,\frac{R^3(0)}{R^3(t)}\,\exp\left[-ik\int_0^t\frac{dt'}{R(t')}\right]. \tag{12}$$

The result clearly depends on the assumed cosmological background.

IV. THE ANGULAR EQUATIONS

From the first-order angular equations (8) one derives 14 second-order equations: 8 of them are in only one of the functions S_0,S_1,S_2,S_3,S_4, 2 of them are in the pair S_0,S_2, 2 are in the pair S_1,S_3, and 2 are in the pair S_2,S_4. However, by taking into account the identities

$$L_2^-L_{-1}^+=L_0^+L_1^-+2, \tag{13.1}$$

$$L_1^-L_0^+=L_1^+L_0^-, \tag{13.2}$$

$$L_2^+L_{-1}^-=L_0^-L_1^++2, \tag{13.3}$$

and by assuming the separation constants satisfy the relations

$$\lambda_0\lambda_4=\lambda_1\lambda_5+2, \tag{14.1}$$

$$\lambda_1\lambda_5=\lambda_2\lambda_6, \tag{14.2}$$

$$\lambda_2\lambda_6=\lambda_3\lambda_7-2, \tag{14.3}$$

one is left with only five independent equations

$$L^+_{-1}L^-_2S_0=\lambda_0\lambda_4S_0, \tag{15.1}$$

$$L^-_2L^+_{-1}S_1=\lambda_0\lambda_4S_1, \tag{15.2}$$

$$L^-_1L^+_0S_2=(\lambda_0\lambda_4-2)S_2, \tag{15.3}$$

$$L^+_2L^-_{-1}S_3=\lambda_0\lambda_4S_3, \tag{15.4}$$

$$L^-_{-1}L^+_2S_4=\lambda_0\lambda_4S_4. \tag{15.5}$$

The remaining equations are automatically satisfied by the solutions of Eqs. (15). For what concerns Eqs. (15) we are looking for solutions that are regular in $\theta=0$ and $\theta=\pi$. Since Eqs. (15.4) and (15.5) can be obtained, respectively, from Eqs. (15.2) and (15.1) by the substitution $m\rightarrow -m$, we can reduce ourselves to the study of Eqs. (15.1)–(15.3). By setting

$$\lambda_0\lambda_4=-\lambda^2 \tag{16}$$

and by taking into account Eq. (13.2), one can check that the equations (15.3) and (15.2) coincide directly with two of the angular equations of the spin 1 case, once the substitution $\lambda^2+2\rightarrow\lambda^2$ is performed.[11] Therefore, the solutions of Eq. (15.3) are

$$S_1(\theta)=(1-\xi^2)^{|m|/2}P^m_{l_1}(\xi), \quad \xi=\cos\,\theta, \tag{17}$$

corresponding to $\lambda^2+2=l_1(l_1+1)$ with $l_1=|m|,|m|+1,|m|+2,\ldots$.

The solutions of Eq. (15.2), expressed in terms of the Jacobi polynomials[14] for $m\geqslant 1$, $m\leqslant -1$, $m=0$, respectively, are

$$S_1(\theta)=(1-\cos\,\theta)^{(m-1)/2}(1+\cos\,\theta)^{(m+1)/2}P^{(m+1,m-1)}_{l_1-m}(\cos\,\theta), \tag{18.1}$$

$$S_1(\theta)=(1+\cos\,\theta)^{(|m|-1)/2}(1-\cos\,\theta)^{(|m|+1)/2}P^{(|m|-1,|m|+1)}_{l_1-|m|}(\cos\,\theta), \tag{18.2}$$

$$S_1(\theta)=\sin\,\theta P^{(1,1)}_{l_1+2}(\cos\,\theta), \tag{18.3}$$

corresponding to $\lambda^2+2=l_1(l_1+1)$ in every case with $l_1=|m|,|m|+1,|m|+2,\ldots$, for $|m|\geqslant 1$ and $l_1=1,2,3,\ldots$, for $m=0$.

The solutions of Eq. (15.1) require some elaboration. By using the definition (9) and then by setting $\xi=\cos\,\theta$ it becomes

$$S_0''+\frac{2\xi}{\xi^2-1}S_0'+\frac{(\lambda^2+2)(1-\xi^2)-m^2-4-4m\xi}{(1-\xi^2)^2}S_0=0. \tag{19}$$

If now $m\geqslant 2$, by setting

$$S_0=(1-\xi)^{(m+2)/2}(1+\xi)^{(m-2)/2}f(\xi), \quad \xi=\cos\,\theta, \tag{20}$$

in (20) and then $\xi=2x-1$ in the resulting equation, one finds for f the equation

$$x(1-x)f''+[m-1-2x(m+1)]f'-[m(m+1)-(\lambda^2+2)]f=0, \tag{21}$$

whose acceptable solutions, in terms of the Jacobi polynomials, are

$$\begin{gathered} S_0(\theta)=(1-\xi)^{(m+2)/2}(1+\xi)^{(m-2)/2}P_{l_0-m}^{(m-2,m+2)}(\xi), \quad m\geqslant 2, \\ \lambda^2+2=l_0(l_0+1), \quad l_0=m,m+1,m+2,\ldots . \end{gathered} \tag{22.1}$$

The case $m\leqslant -2$ can be obtained from the case $m\geqslant 2$ by the substitution $\xi\to-\xi$, $m\to -m$, so that

$$\begin{gathered} S_0(\theta)=(1+\xi)^{(|m|+2)/2}(1-\xi)^{(|m|-2)/2}P_{l_0-|m|}^{(|m|+2,|m|-2)}(\xi), \quad m\leqslant -2, \\ \lambda^2+2=l_0(l_0+1), \quad l_0=|m|,|m|+1,|m|+2,\ldots . \end{gathered} \tag{22.2}$$

By a similar procedure we have for $m=1,-1,0$, respectively,

$$S_0(\theta)=(1-\xi)^{3/2}(1+\xi)^{1/2}P_{l_0-2}^{(1,3)}(\xi), \tag{22.3}$$

$$S_0(\theta)=(1+\xi)^{3/2}(1-\xi)^{1/2}P_{l_0-2}^{(3,1)}(\xi), \tag{22.4}$$

$$S_0(\theta)=(1-\xi)^{2}P_{l_0-2}^{(2,2)}(\xi), \quad \xi=\cos\,\theta, \tag{22.5}$$

all corresponding to $\lambda^2+2=l_0(l_0+1)$ with $l_0=2,3,4,\ldots$.

By comparing all the results of the angular equations one finds that the common eigenvalue have the form $\lambda^2+2=l(l+1)$ with $l=2,3,4,\ldots$.

V. THE RADIAL EQUATIONS

To simplify the study of the radial equations we introduce the operators

$$A_b=\sqrt{1-ar^2}\,\frac{d}{dr}+\frac{b}{r}\,\sqrt{1-ar^2}-ik, \quad k,b\in R. \tag{23}$$

They satisfy, among others, the identities

$$A_2 r A_3^{\star}=A_2^{\star} r A_3, \tag{24.1}$$

$$r A_3 r A_2^{\star}=r A_1^{\star} r A_4+2. \tag{24.2}$$

Accordingly, the radial equations (11) can be compactly written

$$r A_4\psi_1=\lambda_0\psi_0, \quad r A_1^{\star}\psi_0=-\lambda_4\psi_1, \tag{25.1}$$

$$r A_3\psi_2=\lambda_1\psi_1, \quad r A_2^{\star}\psi_1=-\lambda_5\psi_2, \tag{25.2}$$

$$r A_2\psi_3=\lambda_2\psi_2, \quad r A_3^{\star}\psi_2=-\lambda_6\psi_3, \tag{25.3}$$

$$r A_1^{\star}\psi_4=\lambda_3\psi_3, \quad r A_4^{\star}\psi_3=-\lambda_7\psi_4. \tag{25.4}$$

Also here one obtains 14 second-order equations for the radial functions ψ_h, $h=0,1,2,3,4$, that can be shown to be compatible by using the assumptions (14) and the identities (24). By this procedure one is left with the following five independent equations:

$$rA_4 rA_1^\star \psi_0 = \lambda^2 \psi_0, \tag{26.1}$$

$$rA_1^\star rA_4 \psi_1 = \lambda^2 \psi_1, \tag{26.2}$$

$$rA_2 rA_3^\star \psi_2 = (\lambda^2+2)\psi_2, \tag{26.3}$$

$$rA_1 rA_4^\star \psi_3 = \lambda^2 \psi_3, \tag{26.4}$$

$$rA_4^\star rA_1 \psi_4 = \lambda^2 \psi_4. \tag{26.5}$$

The solutions of these equations must satisfy also the condition

$$\psi_h(0)=0, \quad h=0,1,2,3,4, \tag{27}$$

as a consequence of the very structure of the radial equations. The number of equations to solve is reduced by remarking that if ψ_0 and ψ_1 satisfy Eqs. (26.1) and (26.2), then $\psi_0^\star$ and $\psi_1^\star$ satisfy Eqs. (26.5) and (26.4), respectively.

By using the definitions (23), Eqs. (26.1), (26.2), (26.3) become, respectively,

$$r(1-ar^2)\psi_0'' + (6-7ar^2)\psi_0' + \left[r(k^2-5a) + \frac{4-\lambda^2}{4} + 4ik\sqrt{1-ar^2} \right]\psi_0 = 0, \tag{28.1}$$

$$r(1-ar^2)\psi_1'' + (6-7ar^2)\psi_1' + \left[r(k^2-8a) + \frac{4-\lambda^2}{r} + 2ik\sqrt{1-ar^2} \right]\psi_1 = 0, \tag{28.2}$$

$$r(1-ar^2)\psi_2'' + (6-7ar^2)\psi_2' + \left[r(k^2-9a) + \frac{4-\lambda^2}{r} \right]\psi_2 = 0, \quad a=0,\pm 1. \tag{28.3}$$

Near $r=0$ the acceptable solutions of the Fuchs class equations (28) have the behavior

$$\psi_d(r) = r^{(\sqrt{4\lambda^2+9}-5)/2} f_d(r,k^2), \quad d=0,1,2, \tag{29}$$

f_d being a regular function in $r=0$. Therefore, as a consequence of (27), the eigenvalues of the angular equations are $\lambda^2+2=l(l+1)$ with now $l\geqslant 3$.

We are able to solve Eqs. (28) only in the flat universe case. By inserting

$$\psi_d(r) = r^{(\sqrt{4\lambda^2+9}-5)/2} e^{ikr} Z_d(r), \quad d=0,1,2, \tag{30}$$

in Eqs. (28) with $a=0$ and then by setting $\xi=-2ikr$, one finds for Z_d the confluent hypergeometric equation[14]

$$\xi Z_d'' + (1+\sqrt{4\lambda^2+9}-\xi)Z_d' - \tfrac{1}{2}[\sqrt{4\lambda^2+9}+5(1-d)]Z_d = 0, \tag{31}$$

whose solution $Z_d = \phi(\frac{1}{2}\sqrt{4\lambda^2+9} + \frac{5}{2}(1-d); 1+\sqrt{4\lambda^2+9}; r)$, $d=0,1,2$, corresponds to the acceptable ψ_d satisfying Eq. (27).

Finally we remark that as a consequence of Eq. (11) (λ_i and k being independent constants), we have also the constraints to be imposed to the wave functions

$$\psi_h(1)=0, \quad h=0,1,2,3,4. \tag{32}$$

Therefore $f_d(1,k^2)=0$ for $d=0,1,2$, and hence there is the possible existence of a discrete spectrum of values of k^2 that is common to the three cases. It is an open problem whether this is indeed possible and what are such values.

VI. GENERALIZATION TO ARBITRARY SPIN

We now show that the results of the previous sections relative to $s=2$ can be extended to hold for arbitrary spin $s>2$. By generalizing the procedure of Sec. II the general equation (1) can be developed to give

$$\partial_{AA'}\phi^{A}_{A_1A_2\cdots A_n}+\phi^{X}_{A_1A_2\cdots A_n}\Gamma^{A}_{AA'X}-\phi^{A}_{XA_2\cdots A_n}\Gamma^{X}_{AA'A_1}-\phi^{A}_{A_1\cdots XA_n}\Gamma^{X}_{AA'A_{n-1}}-\phi^{A}_{A_1\cdots A_{n-1}X}\Gamma^{X}_{AA'A_n}=0. \tag{33}$$

Let now the indexes $A_1A_2\cdots A_{n-1}$ be taken fixed, denote by ϕ_h the obvious generalization of Eq. (2), and let h be so chosen that $h=A_1+A_2+\cdots+A_{n-1}$.

Suppose $A_n=0$. Then the equation (33) contains in principle $\phi_h,\phi_{h+1},\phi_{h-1}$ [corresponding to the order $(n-1)$] plus four terms originating from

$$-\phi^{A}_{A_1\cdots A_{n-1}X}\Gamma_{AA'0}{}^{X}, \tag{34}$$

which are of the form $\phi_h\Gamma_{1A'0}{}^{0},\phi_{h+1}\Gamma_{0A'0}{}^{0},\phi_{h+1}\Gamma_{1A'0}{}^{1},\phi_{h+2}\Gamma_{0A'0}{}^{1}$.
However, $\Gamma_{0A'0}{}^{1}=0$ because it corresponds to the spin coefficients[2] κ and σ that are zero in our scheme [see Eq. (6)]. Therefore the term (34) introduces no new function with respect to the case $n-1$. Since ϕ_{h-1} is not present in the case $n=3$ [see Eqs. (3), where $\kappa=\lambda=\pi=\tau=\sigma=\nu=0$], by induction it is not present even in the equation (33) which therefore contains only ϕ_h,ϕ_{h+1}. Moreover one can check that the surviving terms originating from (34) are such that $\rho,\mu,\epsilon,D,\Delta$ are associated to one of the functions ϕ_h,ϕ_{h+1} while $\alpha,\beta,\delta,\delta^{\star}$ to the other.

Suppose now $A_n=1$. By the same argument of the case $A_n=0$ the term (34) add terms containing only ϕ_{h+1},ϕ_{h+2} to those relative to the order $(n-1)$ that are now $\phi_h,\phi_{h+1},\phi_{h+2}$. By induction, the term ϕ_h is not present because it is not present in the case $n=3$ [see again Eq. (3)]. Also here the association of the spin coefficients with the directional derivatives is the same of the case $A_n=0$.

By induction, the equations (33) have therefore the recursive structure of Eqs. (3), each equation containing only two functions.

The equations (33) are therefore not only separable, but, by applying by induction the procedure of the previous sections, they are such that the corresponding angular, radial, and time equations can be written down as the natural generalization of Eqs. (8) and (11).

The recursive structure of the equations resulting from (33) holds also to the cases $s=\frac{1}{2}$ and $s=1$ that have been previously studied.[10,11]

VII. CONCLUDING REMARKS

In the previous sections the constants λ^2 and k have been introduced by the separation procedure.

The constant λ^2 is directly connected, for $s=2$, to the eigenvalues of the angular equations [see (18) and (22)]. After the generalization of Sec. VI, the same interpretation holds for the other values of the spin.

In connection with the result (12) we interpret k^2 as the energy of the (massless) particles, even if the radial equations do not have the explicit form of a Schrödinger-like eigenvalue problem as it directly happens for $s=\frac{1}{2}$ (Ref. 10) and for the Dirac equation in the Kerr geometry.[12] The given interpretation can be extended to the arbitrary spin case because the time equation that generalizes Eq. (11.9) implies a solution with always the same exponential factor of Eq. (12).

According to this interpretation, the closed universe case implies discrete levels for the energy of the particle. The determination of the energy levels is in general difficult, the difficulty increasing with increasing spin because there are problems of mathematical compatibility already evident for $s=2$ as remarked in Sec. V. The simple case relative to $s=\frac{1}{2}$ has been studied and gives energy levels whose values are, however, very far from the present experimental sensitivity.[10]

Since also the (massive) Dirac equation shows the existence of discrete energy levels,[15] such a property seems to be a characteristic feature of the closed universe case of the standard cosmology.

ACKNOWLEDGMENT

It is a pleasure to thank the Referee for useful suggestions.

A quantum analog of the $\mathcal{Z}$ algebra

A. Hamid Bougourzi and Luc Vinet
Centre de Recherches Mathématiques, Université de Montréal, C.P. 6128-A, Montréal, Quebec H3C 3J7, Canada

(Received 2 August 1995; accepted for publication 19 February 1996)

We define a natural quantum analog for the $\mathcal{Z}$ algebra, and which we refer to as the $\mathcal{Z}_q$ algebra, by modding out the Heisenberg algebra from the quantum affine algebra $U_q(\widehat{sl(2)})$ with level k. We discuss the representation theory of this $\mathcal{Z}_q$ algebra. In particular, we exhibit its reduction to a group algebra, and to a tensor product of a group algebra with a quantum Clifford algebra when $k=1$, and $k=2$, and thus we recover the explicit constructions of $U_q(\widehat{sl(2)})$-standard modules as achieved by Frenkel–Jing and Bernard, respectively. Moreover, for arbitrary nonzero level k, we show that the explicit basis for the simplest $\mathcal{Z}$-generalized Verma module as constructed by Lepowsky and Primc is also a basis for its corresponding $\mathcal{Z}_q$-module, i.e., it is invariant under the q-deformation for generic q. We expect this $\mathcal{Z}_q$ algebra [associated with $U_q(\widehat{sl(2)})$ at level k] to play the role of a dynamical symmetry in the off-critical Z_k statistical models. © *1996 American Institute of Physics.* [S0022-2488(96)01506-X]

I. INTRODUCTION

One of the major recent developments in the field of integrable models has been the realization by the Kyoto school[1,2] of the important role played by non-Abelian and dynamical symmetries in the resolution of integrable systems. Prior to this and besides conformal field theory, the main approach in the analysis of integrable models has been based on Abelian symmetries together with the Bethe *ansatz*. However, this approach, despite its success of being more systematic in handling the spectra of most integrable systems, has its limitations as far as concrete computations of physical quantities are concerned such as form factors and correlation functions. The reason is that the latter quantities are based on scalar products of the eigenvectors of the Hamiltonians or transfer matrices of the systems; however, the eigenspaces in the physically interesting thermodynamic limit are infinite-dimensional, and hence it is not easy to define their structures, and much less the scalar products on them. However, since some non-Abelian infinite-dimensional algebras have well-defined scalar products on their infinite-dimensional modules, then if we succeed in establishing that the Hamiltonian or the transfer matrix of an integrable system commutes with one of these algebras, we automatically know not only its eigenspaces, which are the modules of this algebra, but also the scalar product on them. We might even describe the local operators and the creation and annihilation operators of the eigenvectors in terms of some operators related to this algebra, such as the intertwiners of its modules, and hence we might be able to compute exactly the form factors and correlation functions. In fact, this is precisely the program that has been behind the enormous success in the resolution of conformal field theories, and more recently in the resolution of the XXZ quantum spin chain model (which is equivalent to the six-vertex classical model) in the antiferromagnetic regime by the Kyoto school. We should, however, mention Ref. 3 where another approach to the calculation of correlation functions is developed.

It is then an interesting program to build as many infinite-dimensional algebras as possible, hoping that one of them turns out to be a non-Abelian or a dynamical symmetry of an integrable model, and vice versa. The main point of this paper is precisely to define a new infinite-dimensional algebra, which, as explained in the next paragraph, should be the dynamical symmetry of the off-critical Z_k models.

0022-2488/96/37(7)/3548/20/$10.00

It is known that the $\widehat{\mathrm{sl}(2)}$ affine Lie algebra is a dynamical symmetry in conformal field theory (the continuum critical limit of the XXX model)[4] and a non-Abelian symmetry of the antiferromagnetic (off-critical) XXX model.[2] Moreover, its deformation, the $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$ algebra, is also a non-Abelian symmetry of the antiferromagnetic (off critical) XXZ model. It is also known that the critical Z_k models, such as the Ising model ($k=2$) and the Potts model ($k=3$), have as a dynamical symmetry the parafermionic algebra,[5] which is ironically related to the $\mathcal{Z}$ algebra.[6] The latter algebra, in turn, is obtained from the quotient of the $\widehat{\mathrm{sl}(2)}$ algebra with level k by its Heisenberg subalgebra.

From all the above known results, it is therefore natural to consider a similar construction for a quantum analogue of the $\mathcal{Z}$ algebra, denoted by $\mathcal{Z}_q$, from the $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$ algebra, and to expect it to play the same role of a dynamical symmetry for the off-critical Z_k models. In fact, such a program is already and implicitly implemented in the simplest case of the off-critical Ising model ($k=2$), where the $\mathcal{Z}_q$ algebra (to be precise, the corresponding quantum parafermionic algebra) reduces simply to a quantum Clifford algebra.[7]

This paper is organized as follows: in Sec. II, we recall basic definitions about the $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$ quantum affine algebra, using the formal variable approach. In Sec. III, we gradually introduce the $\mathcal{Z}_q$ algebra by modding out the Heisenberg subalgebra from $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$ with level k. We derive two defining relations, called ''the quantum generalized commutation relations,'' for this algebra, as well as the relations between its elements and those of $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$. In Sec. IV, we discuss the reduction of $\mathcal{Z}_q$ in the simpler cases $k=1$ and $k=2$ to a group algebra $\mathbb{C}[Q]$, with Q being the root lattice of the sl(2) Lie algebra,[8] and to a tensor product of $\mathbb{C}[Q]$ with a quantum deformation of a Clifford algebra,[9] respectively. In Sec. V, we provide one of the main new results of this paper: an explicit construction of the basis of the simplest $\mathcal{Z}_q$ modules, and hence $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$ modules, for arbitrary nonzero level k. These are the so-called generalized Verma modules.[10,11] We show that the spanning vectors of the basis of a generalized Verma module, as constructed in the ''classical'' $\mathcal{Z}$ algebra case in Refs. 11 and 12, do still form a basis for a $\mathcal{Z}_q$-generalized Verma module. In Sec. VI, we give more quantum generalized commutation relations satisfied by polynomials of $\mathcal{Z}_q$ elements and discuss their potential applications. Finally, Sec. VII is devoted to our conclusions.

II. THE $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$ QUANTUM AFFINE ALGEBRA

The $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$ affine algebra is a unital associative algebra with elements $\{e_{\pm\alpha_i},\ k_i^{\pm},\ q^{\pm d};\ i=0,1\}$ and defining relations in the homogeneous gradation[13,14]

$$
\begin{gathered}
[k_i,\ k_j]=0, \quad k_i k_i^{-1}=k_i^{-1}k_i=1,\\
q^{-d}q^{d}=q^{d}q^{-d}=1,\\
q^{d}k_i q^{-d}=k_i, \quad q^{d}e_{\pm\alpha_i}q^{-d}=q^{\pm\delta_{i0}}e_{\pm\alpha_i},\\
k_i e_{\pm\alpha_j}k_i^{-1}=q^{\pm(\alpha_i,\alpha_j)}e_{\pm\alpha_j},\\
[e_{\alpha_i},\ e_{-\alpha_j}]=\delta_{ij}\,\frac{k_i-k_i^{-1}}{q-q^{-1}},\\
(e_{\pm\alpha_i})^3 e_{\pm\alpha_j}-[3](e_{\pm\alpha_i})^2 e_{\pm\alpha_j}e_{\pm\alpha_i}+[3]e_{\pm\alpha_i}e_{\pm\alpha_j}(e_{\pm\alpha_i})^2-e_{\pm\alpha_j}(e_{\pm\alpha_i})^3=0,
\end{gathered}
\tag{1}
$$

where $[x]=(q^x-q^{-x})/(q-q^{-1})$, $q=e^{t/2}$ is a complex number called a deformation parameter, and $\{\alpha_i, i=0,1\}$ is the set of positive simple roots of $\widehat{\mathrm{sl}(2)}$ affine Lie algebra with the invariant symmetric bilinear form $(\alpha_i,\alpha_j)=a_{i,j}$ (see Sec. IV). Here $a_{i,i}=2$ and $a_{i,1-i}=-2$, $i=0,1$ are the elements of the $\widehat{\mathrm{sl}(2)}$ affine Cartan matrix. Note that the special element $\gamma=k_0k_1$ is in the center of $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$ and acts as q^k on its highest weight representations, with k referred to as the level. We also refer to the above elements generating $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$ as the Chevalley generators.

The Chevalley generators are associated with the simple roots only. One would like to describe the commutation relations of all the elements associated with the infinite-dimensional set of roots $\{\pm\alpha+n\delta; n\in\mathbb{Z}\}\cup\{n\delta; n\in\mathbb{Z}\backslash 0\}\}$, with $\alpha=\alpha_1$ and $\delta=\alpha_0+\alpha_1$, and where the Serre relation [i.e., the last relation in (1)] becomes redundant. Drinfeld succeeded in finding such a set of generators, which we refer to as the Drinfeld generators.[15] This set is $\{x_u^{\pm}, \alpha_m, K^{\pm 1}, q^{\pm d}, \gamma^{\pm 1/2}; n\in\mathbb{Z}, m\in\mathbb{Z}^*=\mathbb{Z}\backslash 0\}\}$ with defining relations

$$\gamma^{1/2}\gamma^{-1/2}=\gamma^{-1/2}\gamma^{1/2}=1, \quad [\gamma^{\pm 1/2}, y]=0, \quad \forall y\in \mathrm{U}_q(\widehat{\mathrm{sl}(2)}), \tag{2}$$

$$KK^{-1}=K^{-1}K=1, \tag{3}$$

$$K_{\alpha_n}K^{-1}=\alpha_n, \tag{4}$$

$$Kx_n^{\pm}K^{-1}=q^{\pm 2}x_n^{\pm}, \tag{5}$$

$$q^dq^{-d}=q^{-d}q^d=1, \quad Kq^{\pm d}K^{-1}=q^{\pm d}, \tag{6}$$

$$q^dx_n^{\pm}q^{-d}=q^nx_n^{\pm}, \tag{7}$$

$$q^d\alpha_nq^{-d}=q^n\alpha_n, \tag{8}$$

$$[\alpha_n, \alpha_m]=\frac{(q^{2n}-q^{-2n})(\gamma^n-\gamma^{-n})}{nt^2}\,\delta_{n+m,0}, \tag{9}$$

$$[\alpha_n, x_m^{\pm}]=\pm\,\frac{\gamma^{\mp|n|/2}(q^{2n}-q^{-2n})}{nt}\,x_{n+m}^{\pm}, \tag{10}$$

$$[x_n^+, x_m^-]=\frac{\gamma^{(n-m)/2}\Psi_{n+m}-\gamma^{(m-n)/2}\Phi_{n+m}}{q-q^{-1}}, \tag{11}$$

$$x_{n+1}^{\pm}x_m^{\pm}-q^{\pm 2}x_m^{\pm}x_{n+1}^{\pm}=q^{\pm 2}x_n^{\pm}x_{m+1}^{\pm}-x_{m+1}^{\pm}x_n^{\pm}, \tag{12}$$

where Ψ_n and Φ_n are given by the mode expansions of the fields $\Psi(z)$ and $\Phi(z)$, which are themselves defined by

$$\begin{aligned}\Psi(z)&=\sum_{n\geqslant 0}\Psi_nz^{-n}=K\,\exp\left\{t\sum_{n>0}\alpha_nz^{-n}\right\},\\ \Phi(z)&=\sum_{n\leqslant 0}\Phi_nz^{-n}=K^{-1}\,\exp\left\{-t\sum_{n<0}\alpha_nz^{-n}\right\}.\end{aligned} \tag{13}$$

Here z is a formal variable and

$$K=\Psi_0=\Phi_0^{-1}\equiv q^{\alpha_0}, \tag{14}$$

where we mean identification by the symbol $\equiv$.

The isomorphism ρ between $U_q(\widehat{sl(2)})$ with the Chevalley generators and $U_q(\widehat{sl(2)})$ with the Drinfeld generators is given explicitly by

$$\begin{gathered}\rho: k_0 \to \gamma K^{-1}, \quad \rho: k_1 \to K, \\ \rho: e_{\pm\alpha_1} \to x_0^{\pm}, \quad \rho: e_{\alpha_0} \to x_1^{-} K^{-1}, \quad \rho: e_{-\alpha_0} \to K x_{-1}^{+}.\end{gathered} \tag{15}$$

For later purposes we will use the formal variable approach[16] (instead of the usual operator product expansion method) to reexpress the algebra as a quantum current algebra with elements $\{\Psi(z), \Phi(z), x^{\pm}(z), \gamma^{\pm 1/2}, q^{\pm d}\}$, where[8]

$$x^{\pm}(z) = \sum_{n \in \mathbb{Z}} x_n^{\pm} z^{-n}, \tag{16}$$

and with defining relations

$$\gamma^{1/2}\gamma^{-1/2} = \gamma^{-1/2}\gamma^{1/2} = 1, \quad [\gamma^{\pm 1/2}, y] = 0, \quad \forall y \in U_q(\widehat{sl(2)}), \tag{17}$$

$$[\Psi(z), \Psi(w)] = 0, \tag{18}$$

$$[\Phi(z), \Phi(w)] = 0, \tag{19}$$

$$\Psi(z)\Phi(w) = g(wz^{-1}\gamma) g(wz^{-1}\gamma^{-1})^{-1} \Phi(w)\Psi(z), \tag{20}$$

$$\Psi(z) x^{\epsilon}(w) = g(wz^{-1}\gamma^{-\epsilon/2})^{-\epsilon} x^{\epsilon}(w)\Psi(z), \tag{21}$$

$$\Phi(z) x^{\epsilon}(w) = g(zw^{-1}\gamma^{-\epsilon/2})^{\epsilon} x^{\epsilon}(w)\Phi(z), \tag{22}$$

$$[x^{\epsilon}(z), x^{-\epsilon}(w)] = \epsilon \frac{\delta(zw^{-1}\gamma^{-\epsilon})\Psi(w\gamma^{\epsilon/2}) - \delta(zw^{-1}\gamma^{\epsilon})\Phi(z\gamma^{\epsilon/2})}{q - q^{-1}}, \tag{23}$$

$$(z - wq^{2\epsilon}) x^{\epsilon}(z) x^{\epsilon}(w) = (zq^{2\epsilon} - w) x^{\epsilon}(w) x^{\epsilon}(z), \tag{24}$$

$$q^d x^{\epsilon}(z) = x^{\epsilon}(zq^{-1}) q^d, \tag{25}$$

$$q^d \Psi(z) = \Psi(zq^{-1}) q^d, \tag{26}$$

$$q^d \Phi(z) = \Phi(zq^{-1}) q^d. \tag{27}$$

Here $\epsilon = \pm 1$ and $g(z)$ is meant to be the following formal power series in z:

$$g(z) = \sum_{n \in \mathbb{Z}_+} c_n z^n, \tag{28}$$

where the coefficients c_n, $n \in \mathbb{Z}_+$ are determined from the Taylor expansion of the function

$$f(\xi) = \frac{q^2\xi - 1}{\xi - q^2} = \sum_{n \in \mathbb{Z}_+} c_n z^n \tag{29}$$

at $\xi = 0$.[8] In the above relations we have also introduced the δ-function $\delta(z)$ which is defined as the formal Laurent series

$$\delta(z)=\sum_{n\in\mathbb{Z}} z^n, \tag{30}$$

and which plays a key role in the formal calculus approach (see Ref. 16 for its properties).

The three relations (25), (26) and (27) translate the fact that $x_n^{\pm}$, Ψ_n, and Φ_n are homogeneous of the same degree n.

III. THE $\mathcal{Z}_q$ ALGEBRA

It is well known that the Heisenberg subalgebra of $\widehat{\mathrm{sl}(2)}$ plays a crucial role in the construction of vertex operators and highest weight representations. One would like to extend this role to the quantum case. Note that in the sequel, the unit element and $q^{\pm d}$ are meant to be in all the (sub)algebras defined below, so we will not consider them unless stated otherwise. Let $\mathrm{U}_q(\hat{h})$ be the quantum analog of the enveloping Heisenberg algebra, referred to as q-Heisenberg algebra. It is a subalgebra of $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$ generated by $\{\alpha_n,\ \gamma^{\pm 1/2},\ n\in\mathbb{Z}^*\}$ with relations

$$[\alpha_n,\ \gamma^{\pm 1/2}]=0,\quad \gamma^{1/2}\gamma^{-1/2}=\gamma^{-1/2}\gamma^{1/2}=1, \tag{31}$$

$$[\alpha_n,\ \alpha_m]=\delta_{n+m,0}\,\frac{(q^{2n}-q^{-2n})(\gamma^n-\gamma^{-n})}{2nt^2}. \tag{32}$$

Let $\mathrm{U}_q(\hat{h}^+)$ and $\mathrm{U}_q(\hat{h}^{-1})$ denote the commutative subalgebras of $\mathrm{U}_q(\hat{h})$ generated by $\{\alpha_n,\ \gamma^{\pm 1/2};\ n>0\}$ and $\{\alpha_n,\ n<0\}$, respectively. By the Poincaré–Birkhoff–Witt theorem for, $\mathrm{U}_q(\hat{h})$, we have

$$\mathrm{U}_q(\hat{h})=\mathrm{U}_q(\hat{h}^+)\mathrm{U}_q(\hat{h}^-), \tag{33}$$

and, consequently, the following induced $\hat{h}$-module,

$$I(q^k)=\mathrm{U}_q(\hat{h})\otimes_{\mathrm{U}_q(\hat{h}^+)}\mathbb{C}[q^k], \tag{34}$$

is irreducible (for $k\neq 0$ which is understood in the sequel) and isomorphic to $\mathrm{U}_q(\hat{h}^-)$ and hence to the symmetric algebra $\mathrm{S}(\hat{h}^-)$.[8] In this formula, $\mathbb{C}[q^k]$ denotes the field of complex numbers considered as the one-dimensional $\mathrm{U}_q(\hat{h}^+)$-module and on which γ acts as multiplication by q^k, and α_n, $n>0$ acts trivially. This means that $\mathrm{S}(\hat{h}^-)$ is a canonical $\mathrm{U}_q(\hat{h})$-module on which γ acts as multiplication by q^k, α_n $(n<0)$ acts as a creation (multiplication) operator, and α_n $(n>0)$ acts as an (derivation) annihilation operator satisfying the relation (32). The latter actions are given by

$$\gamma^{\pm 1}: x\to q^{\pm k}x,$$

$$\alpha_n: x\to \alpha_n x,\quad n<0,\quad \alpha_n: x\to[\alpha_n,\ x],\quad n>0, \tag{35}$$

where x is any element in $S(\hat{h}^-)$. Moreover, the action of $q^{\pm d}$ on $S(\hat{h}^-)$ is defined by

$$q^{\pm d}: x\to q^{\pm d}xq^{\mp d}. \tag{36}$$

The action of α_0 and hence the action of $\Psi_0 = q^{\alpha_0}$ (and Φ_0) on $S(\hat{h}^-)$ will be defined later.

Now we would like to show that the highest weight modules of the whole quantum affine algebra $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$ must be constructed as tensor products of the form $S(\hat{h}^-)\otimes W$. Here W are certain vector spaces to be defined later and which are trivial as $\mathrm{U}_q(\hat{h})$-module. *La raison d'être* of W stems from the fact that $S(\hat{h}^-)$ is only a $\mathrm{U}_q(\hat{h})$-module and in general cannot be upgraded to a $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$-module, which is especially true here since we are considering $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$ in the homogeneous gradation. Therefore, we have to ''correct'' $S(\hat{h}^-)$ by tensoring it with additional

new spaces which do not overlap with it, so that the resulting tensor product remains as a $U_q(\hat{h})$-module. Of course, this correction will be performed by considering a minimum number of extra spaces.

It is well known in the case of affine algebras that these constructions can be achieved by means of vertex operators. The most famous vertex construction of the quantum affine algebras is the Frenkel–Jing one, which is, however, valid only for the simply laced algebras and with the central element γ acting as q (i.e., $k=1$) on their highest weight modules.[8] In this case, which will be recovered explicitly later for $U_q(\widehat{sl(2)})$ when we set $k=1$ in our general construction, it turns out that W is identified with a group algebra associated with the weight lattice of the Lie algebra corresponding to the quantum affine algebra in question. If $k=2$, W is identified with a tensor product of a group algebra and an exterior (Clifford) algebra. Such a construction has been achieved in the case of $U_q(so(2n+1))$ with level 1 by Bernard.[9] For $k>2$ it was shown in Ref. 17 that one needs to introduce, besides the group algebra, a certain quantum parafermionic algebra (though the representation theory was not discussed there).

Although we are concerned with $U_q(\widehat{sl(2)})$ for $k>1$, the form of the vertex operators used by Frenkel and Jing for $k=1$ led us to introduce the following vertex operators:

$$S_{\epsilon}^{\pm}(z)=\exp\left\{\pm\epsilon t\sum_{n>0}\frac{\alpha_{\pm n}}{q^{nk}-q^{-nk}}\,q^{-\epsilon nk/2}z^{\mp n}\right\},\quad \epsilon=\pm, \tag{37}$$

which are viewed as formal Laurent series in z with coefficients acting on $S(\hat{h}^{-})$. Using (32) and the usual formal rule

$$e^A e^B=e^B e^A e^{[A,B]}\quad \text{if } [A,[A,B]]=[B,[A,B]]=0, \tag{38}$$

for some operators A and B, we find

$$\begin{aligned} S_{\epsilon}^{+}(z)S_{\epsilon'}^{-}(w)&=\frac{(q^{k-2-(\epsilon+\epsilon')k/2}wz^{-1};q^{2k})_{\infty}^{\epsilon\epsilon'}}{(q^{k+2-(\epsilon+\epsilon')k/2}wz^{-1};q^{2k})_{\infty}^{\epsilon\epsilon'}}\,S_{\epsilon'}^{-}(w)S_{\epsilon}^{+}(z),\\ S_{\epsilon}^{\pm}(z)S_{\epsilon'}^{\pm}(w)&=S_{\epsilon'}^{\pm}(w)S_{\epsilon}^{\pm}(z), \end{aligned} \tag{39}$$

where as usual $(x;y)_{\infty}$ means

$$(x;y)_{\infty}=\prod_{n=0}^{\infty}(1-xy^n). \tag{40}$$

Each factor $(1-\omega z^{-1}q^{x})^{-1}$ in (39) is understood as the formal power series $\Sigma_{n\geqslant 0}w^n z^{-n}q^{xn}$. Moreover, using (32) and the formal rule

$$[A,e^B]=[A,B]e^B,\quad \text{if } [B,[A,B]]=0, \tag{41}$$

for some operators A and B, we obtain

$$\begin{aligned} &[\alpha_n,S_{\epsilon}^{+}(z)]=0,\quad [\alpha_{-n}S_{\epsilon}^{+}(z)]=-\frac{\epsilon q^{-\epsilon nk/2}z^{-n}(q^{2n}-q^{-2n})}{nt}\,S_{\epsilon}^{+}(z),\\ &[\alpha_{-n},S_{\epsilon}^{-}(z)]=0,\quad [\alpha_n,S_{\epsilon}^{-}(z)]=-\frac{eq^{-\epsilon nk/2}z^{n}(q^{2n}-q^{-2n})}{nt}\,S_{\epsilon}^{-}(z), \end{aligned} \tag{42}$$

where $n>0$ and $\epsilon=\pm$. For future purposes let us note here that one can easily show that the commutation relations (21) and (22) are equivalent to

$$[\alpha_n, x^{\epsilon}(z)]=\frac{\epsilon q^{-\epsilon|n|k/2} z^n (q^{2n}-q^{-2n})}{nt}\, x^{\epsilon}(z), \quad \epsilon=\pm; \quad n\in\mathbb{Z}\backslash\{0\}. \tag{43}$$

Let us now define the main new objects of this paper, which we refer to as the ''$\mathcal{Z}_q$ operators $\mathcal{Z}_n^{\epsilon}$,'' as the Laurent modes in

$$\mathcal{Z}^{\epsilon}(z)=\sum_{n\in\mathbb{Z}} \mathcal{Z}_n^{\epsilon} z^{-n}, \tag{44}$$

where

$$\mathcal{Z}^{\epsilon}(z)=S_{\epsilon}^{-}(z)x^{\epsilon}(z)S_{\epsilon}^{+}(z). \tag{45}$$

These operators $\mathcal{Z}_n^{\epsilon}$ are the quantum analogs of the (classical, $q=1$) $\mathcal{Z}$ operators that have been extensively studied in the literature (see, for example, Ref. 12). By abuse of terminology, we refer also to the ''currents $\mathcal{Z}^{\epsilon}(z)$'' as $\mathcal{Z}_q$ operators, but strictly speaking they are the generating functions of the latter operators. Let us denote by $\mathcal{Z}_q$ the algebra generated by $\{\Psi_0,\Phi_0,\mathcal{Z}_n^{\epsilon};n\in\mathbb{Z}\}$. The defining relations of this algebra, which we refer to as ''the quantum generalized commutation relations,'' will be given shortly below.

The space W on which this algebra acts nontrivially is the necessary space to be tensored with $S(\hat{h}^-)$ such that $S(\hat{h}^-)\otimes W$ is a $U_q(\widehat{\mathrm{sl}(2)})$-module. Therefore W will be defined if we know all the properties of the $\mathcal{Z}_q$ operators, that is, their relations with $U_q(\widehat{\mathrm{sl}(2)})$ itself and their algebra.

By definition, the relation between $\mathcal{Z}_q$ operators is given through their generating functions by (45). Next, it can easily be checked that the relations (42) and (43) imply that they commute with the quantum Heisenberg algebra $U_q(\hat{h})$, i.e.,

$$[\alpha_n,\ \mathcal{Z}^{\epsilon}(z)]=0, \quad n\in\mathbb{Z}\backslash\{0\}, \quad [\gamma^{\pm 1/2},\mathcal{Z}^{\epsilon}(z)]=0, \quad \epsilon=\pm. \tag{46}$$

This is a very important result, which is, in fact, the main motivation behind the particular choice for the forms of $S_{\epsilon'}^{\epsilon}(z)$ as given by (37). This is because the symmetric algebra $S(\hat{h}^-)$ realizes already the quantum Heisenberg subalgebra $U_q(\hat{h})$ and since the $\mathcal{Z}_q$ operators commute with $U_q(\hat{h})$, we can define then the actions of $U(\hat{h})$ and $\mathcal{Z}_q$ as follows on $S(\hat{h}^-)\otimes W$:

$$x: u\otimes v\to xu\otimes v, \quad y: u\otimes v\to u\otimes yv, \tag{47}$$

where $x\in U_q(\hat{h})$, $y\in\mathcal{Z}_q$, $u\in S(\hat{h}^-)$, and $v\in W$. From the Laurent expansion in zw^{-1} of both sides of (21) and (22), we obtain the relation

$$\Psi_0 x^{\epsilon}(w)=q^{2\epsilon}x^{\epsilon}(w)\Psi_0, \tag{48}$$

which, because of (5), amounts to

$$\Psi_0\mathcal{Z}^{\epsilon}(w)=q^{2\epsilon}\mathcal{Z}^{\epsilon}(w)\Psi_0. \tag{49}$$

Combining this relation with (46) and

$$\begin{aligned}\Psi(z)&=\Psi_0 S_{\epsilon}^{+}(zq^{-3\epsilon k/2})S_{-\epsilon}^{+}(zq^{3\epsilon k/2}),\\ \Phi(z)&=\Phi_0 S_{\epsilon}^{-}(zq^{3\epsilon k/2})S_{-\epsilon}^{-}(zq^{-3\epsilon k/2}), \quad \epsilon=\pm,\end{aligned} \tag{50}$$

we arrive finally at

$$\begin{aligned}\Psi_n \mathscr{Z}^{\epsilon}(w) &= q^{2\epsilon}\mathscr{Z}^{\epsilon}(w)\Psi_n, \quad n\geqslant 0,\\ \Phi_n \mathscr{Z}^{\epsilon}(w) &= q^{-2\epsilon}\mathscr{Z}^{\epsilon}(w)\Phi_n, \quad n\leqslant 0.\end{aligned} \tag{51}$$

In the sequel, however, we will only consider the relations (46) and (49) but not (51) since the latter is an immediate consequence of the former and (50).

Clearly, the action of the generating functions $x^{\epsilon}(z)$ on $S(\hat{h}^-)\otimes W\otimes\mathbb{C}[z, z^{-1}]$ decomposes then as

$$x^{\epsilon}(z)=S^-_{-\epsilon}(zq^{-\epsilon k})S^+_{-\epsilon}(zq^{\epsilon k})\otimes\mathscr{Z}^{\epsilon}(z), \quad \epsilon=\pm, \tag{52}$$

where we have used

$$(S^{\pm}_{\epsilon}(z))^{-1}=S^{\pm}_{-}(zq^{\pm\epsilon k}), \quad \epsilon=\pm, \tag{53}$$

and (42) to express $x_{\epsilon}(z)$ in terms of $\mathscr{Z}^{\epsilon}(z)$. We now define the actions of $q^{\pm d}$ and $\gamma^{\pm 1}$ on $S(\hat{h}^-)\otimes W$ as

$$q^{\pm d}: u\otimes v\to q^{\pm d}u\otimes q^{\pm d}v, \quad \gamma^{\pm 1}: u\otimes v\to q^{\pm k}u\otimes v, \tag{54}$$

where $u\in S(\hat{h}^-)$ and $v\in W$. The relation between $\mathscr{Z}^{\epsilon}(z)$ and $q^{\pm d}$, which reads as

$$q^d\mathscr{Z}^{\epsilon}(z)=\mathscr{Z}^{\epsilon}(zq^{-1})q^d, \tag{55}$$

can easily be derived from (25) and

$$q^d S^{\epsilon}_{\epsilon'}(z)=S^{\epsilon}_{\epsilon'}(zq^{-1})q^d, \tag{56}$$

which, in turn, can be obtained from (38). Relation (55) means that the $\mathscr{Z}_q$ algebra is graded [it inherits the gradation of $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$] and that the $\mathscr{Z}_q$ operators $\mathscr{Z}^{\epsilon}_n$ are homogeneous of degree n.

Let us now turn to the derivation of the defining relations [besides (14) and (49)] of the $\mathscr{Z}_q$ algebra, that is, the quantum generalized commutation relations. They simply follow from the substitution of $x^{\epsilon}(z)$ as given by (52) in (23) and (24). We find

$$\begin{aligned}&\frac{(q^{k+2}wz^{-1};q^{2k})_{\infty}}{(q^{k-2}wz^{-1};q^{2k})_{\infty}}\,\mathscr{Z}^{\epsilon}(z)\mathscr{Z}(-\epsilon|w)-\frac{(q^{k+2}zw^{-1};q^{2k})_{\infty}}{(q^{k-2}zw^{-1};q^{2k})_{\infty}}\,\mathscr{Z}^{-\epsilon}(w)\mathscr{Z}^{\epsilon}(z)\\ &\quad=\frac{\epsilon}{q-q^{-1}}\,(\Psi_0\delta(zw^{-1}q^{-\epsilon k})-\Phi_0\delta(zw^{-1}q^{\epsilon k}))\\ &\quad=\frac{1}{q-q^{-1}}\,(q^{\epsilon\alpha_0}\delta(zw^{-1}q^{-k})-q^{-\epsilon\alpha_0}\delta(zw^{-1}q^{k})),\end{aligned} \tag{57}$$

$$\begin{aligned}&(z-q^{2\epsilon}w)\,\frac{(q^{k-2-k\epsilon}wz^{-1};q^{2k})_{\infty}}{(q^{k+2-k\epsilon}wz^{-1};q^{2k})_{\infty}}\,\mathscr{Z}^{\epsilon}(z)\mathscr{Z}^{\epsilon}(w)\\ &\quad=(q^{2\epsilon}z-w)\,\frac{(q^{k-2-k\epsilon}zw^{-1};q^{2k})_{\infty}}{(q^{k+2-k\epsilon}zw^{-1};q^{2k})_{\infty}}\,\mathscr{Z}^{\epsilon}(w)\mathscr{Z}^{\epsilon}(z).\end{aligned} \tag{58}$$

In summary, in addition to the latter quantum generalized commutation relations, the $\mathscr{Z}_q$ fields $\mathscr{Z}^{\epsilon}(z)$ must satisfy the following relations with the elements of $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$ when they act on the W part of the tensor product $S(\hat{h}^-)\otimes W$:

$$[\alpha_n, \mathscr{Z}^{\epsilon}(z)]=0, \quad n\in\mathbb{Z}\backslash\{0\}, \tag{59}$$

$$\Psi_0\mathscr{Z}^{\epsilon}(z)=q^{2\epsilon}\mathscr{Z}^{\epsilon}(z)\Psi_0, \tag{60}$$

$$x^{\epsilon}(z)=S^{-}_{-\epsilon}(zq^{-\epsilon k})S^{+}_{-\epsilon}(zq^{\epsilon k})\otimes\mathscr{Z}^{\epsilon}(z), \tag{61}$$

$$q^d\mathscr{Z}^{\epsilon}(z)=\mathscr{Z}^{\epsilon}(zq^{-1})q^d, \tag{62}$$

$$[\gamma^{\pm},\mathscr{Z}^{\epsilon}(z)]=0. \tag{63}$$

All these relations will be useful in the explicit construction of the space W from the operators $\mathscr{Z}^{\epsilon}_n$. This is illustrated in Sec. IV.

IV. EXPLICIT CONSTRUCTIONS OF SOME $U_q(\widehat{sl(2)})$-STANDARD MODULES

Let us briefly recall the definition of some $U_q(\widehat{sl(2)})$-modules.[2,11,18] For this, we still need some notions from $\widehat{sl(2)}$ affine algebra, which is generated by $\{e_i,f_i,h_i,d;i=0,1\}$. We define on its Cartan subalgebra $\hat{h}=\mathbb{C}h_0+\mathbb{C}h_1+\mathbb{C}d$ an invariant symmetric bilinear form $(\ ,\ )$ by

$$(h_i,h_i)=2, \quad (h_i,h_{1-i})=-2, \quad (h_i,d)=\delta_{i,0}, \quad (d,d)=0, \quad i=0,1. \tag{64}$$

Let $\hat{h}^*=\mathbb{C}\Lambda_0+\mathbb{C}\Lambda_1+\mathbb{C}\delta=\mathbb{C}\alpha_0+\mathbb{C}\alpha_1+\mathbb{C}\Lambda_0$ be the dual space to h with

$$\langle\Lambda_i,h_j\rangle=\delta_{i,j}, \quad \langle\delta,d\rangle=1, \quad \langle\Lambda_i,d\rangle=0, \quad \langle\delta,h_i\rangle=0, \tag{65}$$

where

$$\langle\ ,\ \rangle:\hat{h}^*\otimes\hat{h}\to\mathbb{C} \tag{66}$$

is the natural pairing, the vectors Λ_i are the fundamental weights, α_i are the positive roots, and $\delta=\alpha_0+\alpha_1$ is the null root. One can induce a symmetric bilinear form $(\ ,\ )$ on $\hat{h}^*$ by

$$\begin{aligned}&(\Lambda_i,\Lambda_j)=\tfrac{1}{2}\delta_{i,1}\delta_{j,1}, \quad (\Lambda_i,\delta)=1, \quad (\delta,\delta)=0, \quad (\alpha_i,\alpha_i)=2,\\ &(\alpha_i,\alpha_{1-i})=2, \quad (\alpha_i,\Lambda_0)=\delta_{i,0}, \quad (\Lambda_0,\Lambda_0)=0, \quad i,j=0,1.\end{aligned} \tag{67}$$

The weights $\lambda\in\hat{h}^*$ such that

$$\lambda=n_0\Lambda_0+n_1\Lambda_1, \quad n_0,n_1\in\mathbb{N}\backslash\{0\}, \tag{68}$$

are called regular dominant integral weights, and $n_0+n_1=k$ is the level that we have introduced previously.

As defined in Sec. II the algebra $U_q(\widehat{sl(2)})$ is generated by $\{e_i, f_i, K^{\pm1}, \gamma^{\pm1}, q^{\pm d}, i=0,1\}$. Let V be a $U_q(\widehat{sl(2)})$-module and $\mu\in\hat{h}$, the subspace $V_\mu\subset V$ defined by

$$V_\mu=\{v\in V/K^{\pm1}v=q^{\pm\langle\mu,h_1\rangle}v, \quad \gamma^{\pm1}v=q^{\pm k}v, \quad q^{\pm d}v=q^{\pm\langle\mu,d\rangle}v\}, \tag{69}$$

is called a μ-weight space, and any $v\in V_\mu$ is referred to as a μ-weight vector. The module V becomes a weight module if it is the direct sum of its weight spaces. A $U_q(\widehat{sl(2)})$ highest weight vector v_λ in V is a λ-weight vector which satisfies the additional condition

$$e_iv_\lambda=0, \quad i=0,1. \tag{70}$$

The space V is called a $U_q(\widehat{sl(2)})$ highest weight module if it generated from a λ highest weight vector v_λ. In this case, v_λ is unique (up to a multiplication by a scalar), and hence we label V by the weight λ as $V(\lambda)$. The $U_q(\widehat{sl(2)})$-module $V(\lambda)$ is called standard if it is generated from a highest weight vector v_λ with a dominant integral weight λ and such that

$$f_i^{\langle \lambda, h_i\rangle+1} v_\lambda = 0, \quad i=0,1, \tag{71}$$

in which case it is irreducible.

Let us now address the explicit constructions of the standard modules in the cases $k=1$ and $k=2$. As explained previously, we should address only the explicit constructions of the space W in terms of the $\mathcal{Z}_q$ operators since the $S(\hat{h}^-)$ part is already constructed in terms of polynomials of α_n. Consequently, in the sequel we will mainly concentrate on the W part of the $U_q(\widehat{sl(2)})$-modules.

Case I: $k=1$.[8] In this case, the relations (58)–(63) satisfied by the $\mathcal{Z}_q$ operators $\mathcal{Z}^\epsilon(z)$ simplify significantly and reduce to the following relations:

$$\begin{aligned}
&\frac{\mathcal{Z}^\epsilon(z)\mathcal{Z}^{-\epsilon}(w)}{(1-q^{-1}wz^{-1})(1-qwz^{-1})} - \frac{\mathcal{Z}^{-\epsilon}(w)\mathcal{Z}^\epsilon(z)}{(1-q^{-1}zw^{-1})(1-qzw^{-1})} \\
&\quad = \frac{\epsilon}{q-q^{-1}}\left(\Psi_0 \delta(zw^{-1}q^{-\epsilon}) - \Phi_0 \delta(zw^{-1}q^{\epsilon})\right) \\
&\quad = \frac{1}{q-q^{-1}}\left(q^{\epsilon\alpha(0)}\delta(zw^{-1}q^{-1}) - q^{-\epsilon\alpha(0)}\delta(zw^{-1}q)\right),
\end{aligned} \tag{72}$$

$$w^2 \mathcal{Z}^\epsilon(z)\mathcal{Z}^\epsilon(w) = z^2 \mathcal{Z}^\epsilon(w)\mathcal{Z}^\epsilon(z), \tag{73}$$

$$[\alpha_n,\ \mathcal{Z}^\epsilon(z)] = 0, \quad n \in \mathbb{Z}\backslash\{0\}, \tag{74}$$

$$\Psi_0 \mathcal{Z}^\epsilon(z) = q^{2\epsilon}\mathcal{Z}^\epsilon(z)\Psi_0, \tag{75}$$

$$\Phi_0 \mathcal{Z}^\epsilon(z) = q^{-2\epsilon}\mathcal{Z}^\epsilon(z)\Phi_0, \tag{76}$$

$$x^\epsilon(z) = S^-_{-\epsilon}(zq^{-\epsilon k})S^+_{-\epsilon}(zq^{\epsilon k}) \otimes \mathcal{Z}^\epsilon(z), \tag{77}$$

$$q^d \mathcal{Z}^\epsilon(z) = \mathcal{Z}^\epsilon(zq^{-1})q^d, \tag{78}$$

$$[\gamma^\pm,\ \mathcal{Z}^\epsilon(z)] = 0. \tag{79}$$

It can easily be checked that these equations are solved by

$$\mathcal{Z}^\epsilon(z) = e^{\epsilon\alpha} z^{\epsilon\alpha_0 + (1/2)(\alpha,\alpha)} = e^{\epsilon\alpha} z^{\epsilon\alpha_0 + 1}, \quad \epsilon = \pm, \tag{80}$$

where α is the sl(2) positive simple root and $e^\alpha \in \mathbb{C}[P]$. Here $P = Q \cup (Q + \alpha/2)$ and Q are the sl(2) weight and root lattices, while $\mathbb{C}[P]$ and $\mathbb{C}[Q]$ are the corresponding Abelian group algebras, respectively. The elements z^{α_0} and q^d act on $\mathbb{C}[P]$ as

$$z^{\alpha_0} e^\beta = z^{(\alpha,\beta)} e^\beta z^{\alpha_0}, \quad q^d e^\beta = e^\beta q^d q^{-\beta_0 - (\beta,\beta)/2}, \quad \beta \in P. \tag{81}$$

As a conclusion, $x^\epsilon(z)$ acts on $S(\hat{h}^-)\otimes\mathbb{C}[P]$ as $S^-_{-\epsilon}(zq^{-\epsilon})S^+_{-\epsilon}(zq^{\epsilon}) \otimes e^{\epsilon\alpha} z^{\epsilon\alpha_0+1}$ and is single valued. Moreover, the subspaces $S(\hat{h}^-)\otimes\mathbb{C}[Q]$ and $S(\hat{h}^-)\otimes e^{\alpha/2}\mathbb{C}[Q]$, whose direct sum is

$S(\hat{h}^-)\otimes\mathbb{C}[P]$, are invariant and irreducible. They are, in fact, isomorphic to the standard (basic) modules $V(\Lambda_0)$ and $V(\Lambda_1)$ with highest weight vectors realized as $1\otimes 1$ and $1\otimes e^{\alpha/2}$, respectively.

Case II: $k=2$.[9] In this case, the relations (58)–(63) satisfied by the $\mathcal{Z}_q$ operators reduce to

$$\frac{\mathcal{Z}^{\epsilon}(z)\mathcal{Z}^{-\epsilon}(w)}{1-wz^{-1}}-\frac{\mathcal{Z}^{-\epsilon}(w)\mathcal{Z}^{\epsilon}(z)}{1-zw^{-1}}=\frac{\epsilon}{q-q^{-1}}\left(\Psi_0\delta(zw^{-1}q^{-2\epsilon})-\Phi_0\delta(zw^{-1}q^{2\epsilon})\right)$$

$$=\frac{1}{q-q^{-1}}\left(q^{\epsilon\alpha_0}\delta(zw^{-1}q^{-2})-q^{-\epsilon\alpha_0}\delta(zw^{-1}q^{2})\right), \quad (82)$$

$$(z-wq^{2\epsilon})(1-wz^{-1}q^{-2\epsilon})\mathcal{Z}^{\epsilon}(z)\mathcal{Z}^{\epsilon}(w)=(zq^{2\epsilon}-w)(1-zw^{-1}q^{-2\epsilon})\mathcal{Z}^{\epsilon}(w)\mathcal{Z}^{\epsilon}(z), \quad (83)$$

$$[\alpha_n,\ \mathcal{Z}^{\epsilon}(z)]=0, \quad n\in\mathbb{Z}\backslash\{0\}, \quad (84)$$

$$\Psi_0\mathcal{Z}^{\epsilon}(z)=q^{2\epsilon}\mathcal{Z}^{\epsilon}(z)\Psi_0, \quad (85)$$

$$\Phi_0\mathcal{Z}^{\epsilon}(z)=q^{-2\epsilon}\mathcal{Z}^{\epsilon}(z)\Phi_0, \quad (86)$$

$$x_{\epsilon}(z)=S^{-}_{-\epsilon}(zq^{-2\epsilon})S^{+}_{-\epsilon}(zq^{2\epsilon})\otimes\mathcal{Z}^{\epsilon}(z), \quad (87)$$

$$q^d\mathcal{Z}^{\epsilon}(z)=\mathcal{Z}^{\epsilon}(zq^{-1})q^d, \quad (88)$$

$$[\gamma^{\pm},\ \mathcal{Z}^{\epsilon}(z)]=0. \quad (89)$$

Let the operator z^{α_0} act on $\mathbb{C}[P]$ and $\mathbb{C}[Q]$ as in the case $k=1$ and q^d act as

$$q^d e^{\beta}=e^{\beta}q^d q^{-\beta_0/2-(\beta,\beta)/4}, \quad \beta\in P. \quad (90)$$

The above equations are then satisfied by

$$\mathcal{Z}^{\epsilon}(z)=e^{\epsilon\alpha}z^{\epsilon\alpha_0/2+(1/4)(\alpha,\alpha)}\psi(z)=e^{\epsilon\alpha}z^{\epsilon\alpha_0/2+1/2}\psi(z), \quad \epsilon=\pm, \quad (91)$$

where

$$\{\psi(z),\psi(w)\}=\delta(zw^{-1}q^{-2})+\delta(zw^{-1}q^{2}),$$

$$\text{if } z^{\alpha_0/2}\in\mathrm{End}(e^{\alpha/2}\mathbb{C}[Q]\otimes\mathbb{C}[z,\ z^{-1}]), \quad (92)$$

$$\{\psi(z),\psi(w)\}=(zw^{-1})^{1/2}(q^{-1}\delta(zw^{-1}q^{-2})+q\,\delta(zw^{-1}q^{2})),$$

$$\text{if } z^{\alpha_0/2}\in\mathrm{End}(\mathbb{C}[Q])\otimes\mathbb{C}[z,\ z^{-1}]. \quad (93)$$

Relation (92) means that the fermion field $\psi(z)$ has the Laurent expansion

$$\psi(z)=\sum_{n\in\mathbb{Z}}\psi_n z^{-n}. \quad (94)$$

Substituting this expansion back in (92) and comparing the coefficients of powers of zw^{-1}, we obtain the following anticommutation relations for the modes ψ_n:

$$\{\psi_n,\psi_m\}=(q^{2n}+q^{-2n})\,\delta_{n+m,0}, \quad \text{if } z^{\alpha_0/2}\in\mathrm{End}(e^{\alpha/2}\mathbb{C}[Q]\otimes\mathbb{C}[z,\ z^{-1}]). \quad (95)$$

This is the usual Rammond (R) sector for the modes ψ_n, $n\in\mathbb{Z}$. Similarly (93) enforces the following expansion:

$$\psi(z)=\sum_{r\in\mathbb{Z}+1/2}\psi_r z^{-r}. \tag{96}$$

As in the (R) sector, relation (93) leads to the following anticommutation relations for the modes ψ_n:

$$\{\psi_r,\psi_s\}=(q^{2r}+q^{-2r})\,\delta_{r+s,0},\quad \text{if } z^{\alpha_0/2}\in \mathrm{End}(\mathbb{C}[Q]\otimes\mathbb{C}[z,z^{-1}]). \tag{97}$$

This is the familiar Neuveu–Schwarz (NS) sector for the modes ψ_r. The Clifford algebra with the anticommutation relations (95) and (97) first appeared in the work of Bernard on the explicit construction of $U_q(so(2n+1))$-standard modules with level $k=1$.[9] Then, it was used in Refs. 18 and 19 for the calculation of the N-point correlation functions for the spin-1 XXZ model.

Let $T^{\mathrm{R}}(T^{\mathrm{NS}})$, $T^{\mathrm{R}}_{\mathrm{even}}(T^{\mathrm{NS}}_{\mathrm{even}})$, $T^{\mathrm{R}}_{\mathrm{odd}}(T^{\mathrm{NS}}_{\mathrm{odd}})$ be the Fock space spanned by the modes $\{\psi_n, n<0\}$ ($\{\psi_r, r<0\}$), a subspace of $T^{\mathrm{R}}(T^{\mathrm{NS}})$ spanned by an even number of modes $\psi_n(\psi_r)$, and a subspace of $T^{\mathrm{R}}(T^{\mathrm{NS}})$ spanned by an odd number of modes $\psi_n(\psi_r)$, respectively. Note that in the (R) sector the zero mode ψ_0 acts trivially on T^{R}, and so to make its action nontrivial we extend the Fock space T^{R} by $\mathbb{C}^2$, with basis $\{v_+=\binom{1}{0}, v_-=\binom{0}{1}\}$ such that $\psi_n(n\neq 0)$ and ψ_0 act as $\psi_n\otimes 1$ and $1\otimes\left(\begin{smallmatrix}0&1\\1&0\end{smallmatrix}\right)$ on $T^{\mathrm{R}}\otimes\mathbb{C}^2$, respectively. Putting all the pieces together, we conclude that $x^{\epsilon}(z)$ acts as

$$x^{\epsilon}(z)=S^{-}_{-\epsilon}(zq^{-2\epsilon})S^{+}_{-\epsilon}(zq^{2\epsilon})\otimes\psi(z)\otimes e^{\epsilon\alpha}z^{\epsilon\alpha_0/2+1/2} \tag{98}$$

on the space $S(\hat{h}^-)\otimes(T^{\mathrm{R}}\otimes\mathbb{C}^2)\otimes e^{\alpha/2}\mathbb{C}[Q]$ in the (R) sector, and on the space $S(\hat{h}^-)\otimes(T^{\mathrm{NS}})\otimes\mathbb{C}[Q]$ in the (NS) sector. Moreover, the $U_q(\widehat{sl(2)})$-standard modules $V(2\Lambda_0)$, $V(2\Lambda_1)$, and $V(\Lambda_0+\Lambda_1)$ are isomorphic to the following subspaces of the latter spaces

$$\begin{aligned}
V(2\Lambda_0)&\sim S(\hat{h}^-)\otimes T^{\mathrm{NS}}_{\mathrm{even}}\otimes\mathbb{C}[2Q]\oplus S(\hat{h}^-)\otimes T^{\mathrm{NS}}_{\mathrm{odd}}\otimes e^{\alpha}\mathbb{C}[2Q],\\
V(2\Lambda_1)&\sim S(\hat{h}^-)\otimes T^{\mathrm{NS}}_{\mathrm{even}}\otimes e^{\alpha}\mathbb{C}[2Q]\oplus S(\hat{h}^-)\otimes T^{\mathrm{NS}}_{\mathrm{odd}}\otimes\mathbb{C}[2Q],\\
V(\Lambda_0+\Lambda_1)&\sim S(\hat{h}^-)\otimes(T^{\mathrm{R}}_{\mathrm{even}}\otimes v_+\oplus T^{\mathrm{R}}_{\mathrm{odd}}\otimes v_-)\otimes e^{\alpha/2}\mathbb{C}[2Q]\oplus S(\hat{h}^-)\otimes(T^{\mathrm{R}}_{\mathrm{odd}}\otimes v_+\oplus T^{\mathrm{R}}_{\mathrm{even}}\otimes v_-)\\
&\quad\otimes e^{3\alpha/2}\mathbb{C}[2Q],
\end{aligned} \tag{99}$$

and their respective highest weight vectors are given by

$$\begin{aligned}
v_{2\Lambda_0}&=1\otimes 1\otimes 1,\\
v_{2\Lambda_1}&=1\otimes 1\otimes e^{\alpha},\\
v_{\Lambda_0+\Lambda_1}&=1\otimes 1\otimes v_+\otimes e^{\alpha/2}.
\end{aligned} \tag{100}$$

V. CONSTRUCTION OF A $U_q(\widehat{sl(2)})$-GENERALIZED MODULE

Let $U_q(sl(2))$ be a subalgebra of $U_q(\widehat{sl(2)})$ generated by $\{e_1,f_1,K^{\pm 1}\}$ and let $M=\mathbb{C}v_0$ be the trivial one-dimensional $U_q(sl(2))$ weight module. We also introduce $U_q(\widehat{sl(2)})_{\geqslant 0}$, $U_q(\widehat{sl(2)})_{>0}$, and $U_q(\widehat{sl(2)})_{<0}$ as three subalgebras $U_q(\widehat{sl(2)})$ generated by all elements with non-negative, positive, and negative degrees with respect to q^d, respectively. We equip M with a $U_q(\widehat{sl(2)})_{\geqslant 0}$-module structure by

$$q^{\pm d}v_0=q^{\pm a}v_0,\quad a\in\mathbb{C},$$

$$\gamma^{\pm 1} v_0 = q^{\pm k} v_0, \tag{101}$$

$$x v_0 = 0, \quad \forall x \in \mathrm{U}_q(\widehat{\mathrm{sl}(2)})_{>0}.$$

Here a is scalar, which can be set to 0 without loss of generality. From M, we induce the following $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$-module:

$$G(M) = \mathrm{U}_q(\widehat{\mathrm{sl}(2)}) \otimes_{\mathrm{U}_q(\widehat{\mathrm{sl}(2)})_{\geqslant 0}} M, \tag{102}$$

which is called a generalized Verma module.[10,11] In fact, since M is a one-dimensional $\mathrm{U}_q(\mathrm{sl}(2))$-module, $G(M)$ is the simplest example of a $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$-generalized Verma module. Slightly more complicated examples of generalized Verma modules can be constructed from higher-dimensional M modules. We define the module $W(M)$ through the following isomorphism of $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$-modules:

$$G(M) \simeq \mathrm{U}_q(\widehat{\mathrm{sl}(2)})_{<0} \otimes_{\mathbb{C}} M \simeq S(\hat{h}^-) \otimes_{\mathbb{C}} W(M). \tag{103}$$

Both modules $G(M)$ and $W(M)$ are q^d weight modules with weight space decompositions:

$$G(M) = \oplus_{n \leqslant 0} G(M)_n,$$

$$W(M) = \oplus_{n \leqslant 0} W(M)_n. \tag{104}$$

From the work of Lusztig,[20] we know that for generic q the dimensions of weight spaces of $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$-modules are the same as those of the weight spaces of the $\widehat{\mathrm{sl}(2)}$-modules. The characters $\chi(G(M))$ and $\chi(W(M))$ of $G(M)$ and $W(M)$ have been computed in the $\widehat{\mathrm{sl}(2)}$ case in Refs. 6 and 11 and are given by

$$\begin{aligned} \chi(G(M)) &= \sum_{n \geqslant 0} \dim(G(M)_n) p^n = \frac{1}{\Pi_{n>0}(1-p^n)^3}, \\ \chi(W(M)) &= \sum_{n \geqslant 0} \dim(W(M)_n) p^n = \frac{1}{\Pi_{n>0}(1-p^n)^2}, \end{aligned} \tag{105}$$

where $p \in \mathbb{C}^*$ is a formal variable. The second character will allow us to prove the linear independence of a particular set of vectors constructed from the $\mathcal{Z}_q$ operators $\mathcal{Z}_n^{\epsilon}$ and which span $W(M)$. This means that the latter set of vectors is a basis for $W(M)$.

Here, we will not untwist the $\mathcal{Z}_q$ algebra into a tensor product of a group algebra and a new algebra, which is parafermionic in nature and has been partially described in Ref. 17. We will rather construct the $W(M)$ module in terms of the $\mathcal{Z}_q$ operators themselves. This will be sufficient to find an explicit realization of the $\mathrm{U}_q(\widehat{\mathrm{sl}(2)})$-generalized Verma module $G(M) = S(\hat{h}^-) \otimes W(M)$ since the $S(\hat{h}^-)$ is already constructed in terms of symmetric polynomials of α_n. To this end, we first define

$$\mathcal{Z}(\epsilon, \epsilon' | z, w) = f(\epsilon, \epsilon' | wz^{-1}) \mathcal{Z}^{\epsilon}(z) \mathcal{Z}^{\epsilon'}(w), \tag{106}$$

$$f(\epsilon, \epsilon' | z) = \frac{(q^{-(\epsilon+\epsilon')k/2+k-2} z; q^{2k})_{\infty}^{\epsilon\epsilon'}}{(q^{-(\epsilon+\epsilon')k/2+k+2} z; q^{2k})_{\infty}^{\epsilon\epsilon'}}. \tag{107}$$

Next, following some ideas in Ref. 6 in the case of $\widehat{\mathrm{sl}(2)}$ algebra, and which have been well summarized in Ref. 21 in the case of the elliptic algebra, we introduce the following formal Laurent and power series:

$$\mathcal{Z}(\epsilon,\epsilon'|z,w)=\sum_{n_1,n_2\in\mathbb{Z}}\mathcal{Z}(\epsilon,\epsilon'|n_1,n_2)z^{-n_1}w^{-n_2}, \tag{108}$$

$$\mathcal{Z}^{\epsilon}(z)=\sum_{n\in\mathbb{Z}}\mathcal{Z}_n^{\epsilon}z^{-n}, \tag{109}$$

$$f(\epsilon,\epsilon'|z)=\frac{1}{\Sigma_{n\geqslant 0}\tilde{a}_n^{\epsilon,\epsilon'}z^n}=\sum_{n\geqslant 0}a_n^{\epsilon,\epsilon'}z^n. \tag{110}$$

Relation (107) and (110) imply that

$$\begin{gathered}a_0^{\epsilon,\epsilon'}=\tilde{a}_0^{\epsilon,\epsilon'}=1,\\ \Sigma_{n\geqslant 0}\tilde{a}_n^{\epsilon,\epsilon'}a_{m-n}^{\epsilon,\epsilon'}=\delta_{m,0},\quad m\geqslant 0,\\ a_n^{\epsilon,\epsilon'}=\tilde{a}_n^{\epsilon,\epsilon'}=0,\quad n<0.\end{gathered} \tag{111}$$

Substituting the above expansions back in (106), and comparing the coefficients of the powers of wz^{-1}, we obtain

$$\mathcal{Z}_{n_1}^{\epsilon}\mathcal{Z}_{n_2}^{\epsilon'}=\sum_{n\geqslant 0}\tilde{a}_n^{\epsilon,\epsilon'}\mathcal{Z}(\epsilon,\epsilon'|n_1-n,n_2+n), \tag{112}$$

$$\mathcal{Z}(\epsilon,\epsilon'|n_1,n_2)=\sum_{n\geqslant 0}a_n^{\epsilon,\epsilon'}\mathcal{Z}_{n_1-n}^{\epsilon}\mathcal{Z}_{n_2+n}^{\epsilon'}. \tag{113}$$

Furthermore, substituting the latter expansions in the quantum generalized relations (57) and (58) and using (113), we arrive at

$$\mathcal{Z}(\epsilon,-\epsilon|n_1,n_2)=\mathcal{Z}(-\epsilon,\epsilon|n_2,n_1)+Y(\epsilon|n_1)\delta_{n_1+n_2,0}, \tag{114}$$

$$\mathcal{Z}(\epsilon,\epsilon|n_1,n_2)=q^{2\epsilon}\mathcal{Z}(\epsilon,\epsilon|n_1-1,n_2+1)+q^{2\epsilon}\mathcal{Z}(\epsilon,\epsilon|n_2,n_1)-\mathcal{Z}(\epsilon,\epsilon|n_2+1,n_1-1), \tag{115}$$

respectively, and where

$$Y(\epsilon|n)=\frac{1}{q-q^{-1}}\,(q^{kn+\epsilon\alpha_0}-q^{-kn-\epsilon\alpha_0}). \tag{116}$$

Relations (114) and (115) are useful in the normal ordering of products of $\mathcal{Z}_q$ operators by moving any operator $\mathcal{Z}_{n_1}^{\epsilon}$ with $n_1>n_2$ to the right of $\mathcal{Z}_{n_2}^{\epsilon'}$, and the operator $\mathcal{Z}_n^{+}$ to the right of $\mathcal{Z}_n^{-}$. To see this, let us examine the normal ordering of $\mathcal{Z}_{n_1}^{\epsilon}\mathcal{Z}_{n_2}^{\epsilon'}$ in the following three nontrivial cases:

A. $n_1 > n_2$, $\epsilon = -\epsilon'$

Using (112) and (114), we obtain

$$\mathcal{Z}^{\epsilon}_{n_1}\mathcal{Z}^{-\epsilon}_{n_2} = \sum_{n\geqslant 0} \tilde{a}^{\epsilon,-\epsilon}_{n}\mathcal{Z}(\epsilon,-\epsilon|n_1-n,n_2+n) = \sum_{0\leqslant n\leqslant (n_1-n_2-x)/2} \tilde{a}^{\epsilon,-\epsilon}_{n}\mathcal{Z}(-\epsilon,\epsilon|n_2+n,n_1-n)$$
$$+ \sum_{0\leqslant (n_1-n_2-x)/2<n} \tilde{a}^{\epsilon,-\epsilon}_{n}\mathcal{Z}(\epsilon,-\epsilon|n_1-n,n_2+n)$$
$$+ \sum_{0\leqslant n\leqslant (n_1-n_2-x)/2} \tilde{a}^{\epsilon,-\epsilon}_{n} Y(\epsilon|n_1)\,\delta_{n_1+n_2,0}\,, \tag{117}$$

where x is equal to 0 or 1 depending on whether n_1-n_2 is even or odd, respectively. It is therefore clear from the latter relation and (113) that the product $\mathcal{Z}^{\epsilon}_{n_1}\mathcal{Z}^{-\epsilon}_{n_2}$ with $n_1>n_2$ can be normal ordered.

B. $n_1 = n_2$, $\epsilon = -\epsilon' = +$

Like the previous case, we have

$$\mathcal{Z}^{+}_{n_1}\mathcal{Z}^{-}_{n_1} = \sum_{h\geqslant 0} \tilde{a}^{+,-}_{n}\mathcal{Z}(+,-|n_1-n,n_1+n),$$
$$= \mathcal{Z}(-,+|n_1,n_1) + Y(+|0)\,\delta_{n_1,0}$$
$$+ \sum_{n>0} \tilde{a}^{+,-}_{n}\mathcal{Z}(-\epsilon,\epsilon|n_1-n,n_1+n). \tag{118}$$

The same argument as in case A holds, and hence the product $\mathcal{Z}^{+}_{n_1}\mathcal{Z}^{-}_{n_1}$ can be normal ordered as well.

C. $n_1 > n_2$, $\epsilon = \epsilon'$

This case is less straightforward. First, (112) implies that

$$\mathcal{Z}^{\epsilon}_{n_1}\mathcal{Z}^{\epsilon}_{n_2} = \sum_{n\geqslant 0} \tilde{a}^{\epsilon,\epsilon}_{n}\mathcal{Z}(\epsilon,\epsilon|n_1-n,n_2+n), \tag{119}$$

which according to (113) means that the product $\mathcal{Z}^{\epsilon}_{n_1}\mathcal{Z}^{\epsilon}_{n_2}$ can be normal ordered if we can normal order also any operator $\mathcal{Z}(\epsilon,\epsilon|n_1,n_2)$ with $n_1>n_2$ by writing it as a linear combination of operators $\mathcal{Z}(\epsilon,\epsilon|m_1,m_2)$ with $m_1\leqslant m_2$. Relation (115) allows indeed this second type of normal ordering. The reason is that repeated use of this relation leads to

$$\mathcal{Z}(\epsilon,\epsilon|n_1+2p,n_1) = q^{2\epsilon}\mathcal{Z}(\epsilon,\epsilon|n_1,n_1+2p) + q^{2(p-1)\epsilon}(q^{2\epsilon}-1)\mathcal{Z}(\epsilon,\epsilon|n_1+p,n_1+p)$$
$$+ \sum_{n=1}^{p-1} q^{2(n-1)\epsilon}(q^{4\epsilon}-1)\mathcal{Z}(\epsilon,\epsilon|n_1+n,n_1+2p-n), \quad p>0,$$
$$\mathcal{Z}(\epsilon,\epsilon|n_1+2p+1,n_1) = q^{2\epsilon}\mathcal{Z}(\epsilon,\epsilon|n_1,n_1+2p+1) + \sum_{n=1}^{p} q^{2(n-1)\epsilon}(q^{4\epsilon}-1)$$
$$\times \mathcal{Z}(\epsilon,\epsilon|n_1+n,n_1+2p+1-n), \quad p>0, \tag{120}$$

where all the operators $\mathcal{Z}(\epsilon,\epsilon|m_1,m_2)$ on the right-hand sides of the above equations have $m_1 \leqslant m_2$. Consequently, the product $\mathcal{Z}^{\epsilon}_{n_1}\mathcal{Z}^{\epsilon}_{n_2}$ with $n_1 > n_2$ can also be normal ordered.

Since $x^{\epsilon}(z)$ acts as $S^{-}_{-\epsilon}(zq^{-2\epsilon})S^{+}_{-\epsilon}(zq^{2\epsilon})\otimes\mathcal{Z}^{\epsilon}(z)$ on $S(\hat{h}^{-})\otimes W(M)\otimes\mathbb{C}[z, z^{-1}]$, it is clear that $W(M)$ is spanned by the vectors in the set

$$\{\mathcal{Z}^{\epsilon_1}_{n_1}\cdots\mathcal{Z}^{\epsilon_s}_{n_s}v_0, \quad \epsilon_i=\pm, \quad n_i<0, \quad i=1,\ldots,s; \quad s>0\}. \tag{121}$$

The condition $n_i<0$ guarantees that the above vectors have negative degrees as they should (otherwise they are null) since $S(h^{-})\otimes W(M)$ is a graded $U_q(\widehat{sl(2)})$-highest weight module. Because of the normal ordering of the $\mathcal{Z}^{\epsilon}_{n}$ operators discussed above, the above spanning set for $W(G)$ can be reduced further to the smaller set

$$H=\{\mathcal{Z}^{\epsilon_1}_{n_1}\cdots\mathcal{Z}^{\epsilon_s}_{n_s}v_0, \quad \epsilon_i=\pm, \quad n_i\leqslant n_{i+1}; \quad \epsilon_i\leqslant\epsilon_{i+1} \quad \text{if} \quad n_i=n_{i+1}, \quad i=1,\ldots,s; \quad s>0\}, \tag{122}$$

where the order $-<+$ is meant. It can easily be seen that the set H is a basis for $W(M)$ since its character coincides with the one of $W(G)$ as given by (105). Therefore, we have an explicit construction of the $U_q(\widehat{sl(2)})$-generalized Verma module $G(M)$ with nonzero level k.

VI. RELATIONS IN THE $\mathcal{Z}_q$ ENVELOPING ALGEBRA

In this section, we extend the quantum generalized commutation relations (57) and (58) to relations satisfied by arbitrary polynomials of $\mathcal{Z}^{\epsilon}(z)$. For this purpose let us consider the following operators:

$$\mathcal{Z}(\epsilon_1,\ldots,\epsilon_s|z_1,\ldots,z_s)=S^{-}_{\epsilon_1}(z_1)\cdots S^{-}_{\epsilon_s}(z_s)x^{\epsilon_1}(z_1)\cdots x^{\epsilon_s}(z_s)S^{+}_{\epsilon_1}(z_1)\cdots S^{+}_{\epsilon_s}(z_s), \quad s>0, \tag{123}$$

which are a generalization of (45). They are expressed in terms of the operators $\mathcal{Z}^{\epsilon}(z)$ introduced in (45) as

$$Z(\epsilon_1,\ldots,\epsilon_s|z_1,\ldots,z_s)=\prod_{1\leqslant i<j\leqslant s}\frac{(q^{-(\epsilon_i+\epsilon_j)k/2+k-2}z_jz_i^{-1};q^{2k})^{\epsilon_i\epsilon_j}_{\infty}}{(q^{-(\epsilon_i+\epsilon_j)k/2+k+2}z_jz_i^{-1}q^{2k})^{\epsilon_i\epsilon_j}_{\infty}}\,\mathcal{Z}^{\epsilon_1}(z_1)\mathcal{Z}^{\epsilon_1}(z_2)\cdots\mathcal{Z}^{\epsilon_s}(z_s) \tag{124}$$

$$=\prod_{2\leqslant i\leqslant s}\frac{(q^{-(\epsilon_1+\epsilon_i)k/2+k-2}z_iz_1^{-1};q^{2k})^{\epsilon_1\epsilon_s}_{\infty}}{(q^{-(\epsilon_1+\epsilon_i)k/2+k+2}z_iz_1^{-1};q^{2k})^{\epsilon_1\epsilon_i}_{\infty}}\,\mathcal{Z}^{\epsilon_1}(z_1)\mathcal{Z}(\epsilon_2,\ldots\epsilon_s|z_2,\ldots,z_s). \tag{125}$$

The above relations can easily be derived from

$$S^{+}_{\epsilon}(z_1)x^{\epsilon'}(z_2)=\frac{(q^{-(\epsilon+\epsilon')k/2+k+2}z_2z_1^{-1};q^{2k})^{\epsilon\epsilon'}_{\infty}}{(q^{-(\epsilon+\epsilon')k/2+k-2}z_2z_1^{-1};q^{2k})^{\epsilon\epsilon'}_{\infty}}\,x^{\epsilon'}(z_2)S^{+}_{\epsilon}(z_1), \tag{126}$$

$$S^{-}_{\epsilon}(z_1)x^{\epsilon'}(z_2)=\frac{(q^{-(\epsilon+\epsilon')k/2+k-2}z_1z_2^{-1};q^{2k})^{\epsilon\epsilon'}_{\infty}}{(q^{-(\epsilon+\epsilon')k/2+k+2}z_1z_2^{-1};q^{2k})^{\epsilon\epsilon'}_{\infty}}\,x^{\epsilon'}(z_2)S^{-}_{\epsilon}(z_1). \tag{127}$$

Relations (46) and (124) imply that the operators $Z(\epsilon_1,\ldots,\epsilon_s|z_1,\ldots,z_s)$ commute also with $U_q(\hat{h})$.

Let us now derive the first type of the quantum generalized commutation relations in the $\mathcal{Z}_q$ enveloping algebra, which is valid only if $\epsilon_r=-\epsilon_{r+1}$:

$$
\begin{aligned}
&\mathscr{Z}(\epsilon_1,\ldots,\epsilon_r,\epsilon_{r+1},\ldots,\epsilon_s|z_1,\ldots,z_r,z_{r+1},\ldots,z_s)-\mathscr{Z}(\epsilon_1,\ldots,\epsilon_{r+1},\epsilon_r,\ldots,\epsilon_s|z_1,\ldots,z_{r+1},z_r,\ldots,z_s)\\
&\quad=S^-_{\epsilon_1}(z_1)\cdots S^-_{\epsilon_s}(z_s)x^{\epsilon_1}(z_1)\cdots x^{\epsilon_{r-1}}(z_{r-1})\\
&\qquad\times[x^{\epsilon_r}(z_r),x^{\epsilon_{r+1}}(z_{r+1})]x^{\epsilon_{r+2}}(z_{r+2})\cdots x^{\epsilon_s}(z_s)S^+_{\epsilon_1}(z_1)\cdots S^+_{\epsilon_s}(z_s)\\
&\quad=\frac{\epsilon_r}{q-q^{-1}}\,S^-_{\epsilon_1}(z_1)\cdots S^-_{\epsilon_s}(z_s)x^{\epsilon_1}(z_1)\cdots x^{\epsilon_{r-1}}(z_{r-1})(\Psi(z_{r+1}q^{\epsilon_r k/2})\,\delta(z_r z_{r+1}^{-1}q^{-\epsilon_r k})\\
&\qquad-\Phi(z_r q^{\epsilon_r k/2})\,\delta(z_r z_{r+1}^{-1}q^{\epsilon_r k}))x^{\epsilon_{r+2}}(z_{r+2})\cdots x^{\epsilon_s}(z_s)S^+_{\epsilon_1}(z_1)\cdots S^+_{\epsilon_s}(z_s)\\
&\quad=\frac{\epsilon_r}{q-q^{-1}}\,\mathscr{Z}(\epsilon_1,\ldots\hat{\epsilon}_r,\hat{\epsilon_{r+1}}\cdots\epsilon_s|z_1,\ldots,\hat{z}_r,\hat{z_{r+1}},\ldots,z_s)\\
&\qquad+\left\{\Psi_0\,\delta(z_r z_{r+1}^{-1}q^{-\epsilon_r k})q^{2\Sigma_{i>r+1}\epsilon_i}\prod_{i>r+1}\left(\frac{1-q^{-2-(\epsilon_i+\epsilon_r)k/2}z_i z_{r+1}^{-1}}{1-q^{2-(\epsilon_i+\epsilon_r)k/2}z_i z_{r+1}^{-1}-1}\right)^{\epsilon_i}\right.\\
&\qquad\left.-\Phi_0\,\delta(z_r z_{r+1}^{-1}q^{\epsilon_r k})q^{-2\Sigma_{i>r+1}\epsilon_i}\prod_{i<r}\left(\frac{1-q^{-2-(\epsilon_i+\epsilon_r)k/2}z_{r+1}z_i^{-1}-1}{q^{2-(\epsilon_i+\epsilon_r)k/2}z_{r+1}z_i^{-1}-1}\right)^{\epsilon_i}\right\},\\
&\qquad\epsilon_r=\epsilon_{r+1},
\end{aligned}
\tag{128}
$$

where we have used (48), (50), (53), and (127). Above, we have also introduced the notation

$$
\mathscr{Z}(\epsilon_1,\ldots,\hat{\epsilon}_r,\hat{\epsilon_{r+1}},\ldots,\epsilon_s|z_1,\ldots,\hat{z}_r,\hat{z_{r+1}},\ldots,z_s)=S^-xS^+,
\tag{129}
$$

with

$$
\begin{aligned}
S^\pm&=S^\pm_{\epsilon_1}(z_1)\cdots S^\pm_{\epsilon_{r-1}}(z_{r-1})S^\pm_{\epsilon_{r+2}}(z_{r+2})\cdots S^\pm_{\epsilon_s}(z_s),\\
x&=x^{\epsilon_1}(z_1)\cdots x^{\epsilon_{r-1}}(z_{r-1})x^{\epsilon_{r+2}}(z_{r+2})\cdots x^{\epsilon_s}(z_s),
\end{aligned}
\tag{130}
$$

and where the hat on $\hat{\epsilon}$ means that the symbol ϵ is omitted.

Using the formal power series

$$
\begin{aligned}
&\left(\frac{1-a}{1-b}\right)^{\epsilon}=(1-a^{(1+\epsilon)/2}b^{(1-\epsilon)/2})\sum_{n\geqslant 0}a^{n(1-\epsilon)/2}b^{n(1+\epsilon)/2},\\
&\prod_{i=1}^{s}(1-z_i z^{-1}q^{a_i})=\sum_{j_1,\ldots,j_i=0,1}(-1)^{\Sigma_{i=1}^s j_i}q^{\Sigma_{i=1}^s a_i}z_1^{j_1}\cdots z_s^{j_s}z^{-\Sigma_{i=1}^s j_i},
\end{aligned}
\tag{131}
$$

we can expand the products in (128) as

$$
\begin{aligned}
&\prod_{i>r+1}\left(\frac{1-q^{-2-(\epsilon_i+\epsilon_r)k/2}z_i z_{r+1}^{-1}}{1-q^{2-(\epsilon_i+\epsilon_r)k/2}z_i z_{r+1}^{-1}-1}\right)^{\epsilon_i}\\
&\quad=\sum_{j_{r+2},\ldots,j_s=0,1}\ \sum_{m_{r+2}\geqslant j_{r+2},\ldots,m_s\geqslant j_s}(-1)^{\Sigma_{i>r+1}j_i}q^{\Sigma_{i>r+1}m_i(2\epsilon_i-(\epsilon_i+\epsilon_r)k/2)-4\epsilon_i j_i}\\
&\qquad\times z_{r+1}^{-\Sigma_{i>r+1}m_i}z_{r+2}^{m_{r+2}}\cdots z_s^{m_s},
\end{aligned}
\tag{132}
$$

and

$$\prod_{i<r}\left(\frac{1-q^{-2-(\epsilon_i+\epsilon_r)k/2}z_{r+1}z_i^{-1}-1}{q^{2-(\epsilon_i+\epsilon_r)k/2}z_{r+1}z_i^{-1}-1}\right)^{\epsilon_i}$$
$$=\sum_{j_1,\ldots,j_{r-1}=0,1}\ \sum_{m_1\geqslant j_1,\ldots,m_{r-1}\geqslant j_{r-1}}(-1)^{\Sigma_{i<r}j_i}q^{\Sigma_{i<r}m_i(2\epsilon_i-(\epsilon_i+\epsilon_r)k/2)-4\epsilon_i j_i}z_1^{-m_1}\cdots$$
$$\times z_{r-1}^{-m_{r-1}}z_{r+1}^{\Sigma_{i<r}m_i}. \tag{133}$$

Substituting these expansions in (128) and taking into account the formal Laurent expansions

$$\mathcal{Z}(\epsilon_1,\ldots,\epsilon_s|z_1,\ldots,z_s)=\sum_{n_1,\ldots,n_s\in Z}\mathcal{Z}(\epsilon_1,\ldots,\epsilon_s|n_1,\ldots,n_s)z_1^{-n_1}\cdots z_s^{-n_s},$$
$$\mathcal{Z}(\epsilon_1,\ldots\hat{\epsilon}_r,\hat{\epsilon_{r+1}},\ldots,\epsilon_s|z_1,\ldots,\hat{z}_r,\hat{z_{r+1}},\ldots z_s) \tag{134}$$
$$=\sum_{n_1,\ldots,n_{r-1},n_{r+2},\ldots,n_s\in Z}\mathcal{Z}(\epsilon_1,\ldots,\hat{\epsilon}_r,\hat{\epsilon_{r+1}},\ldots,\epsilon_s|n_1,\ldots,\hat{n}_r,\hat{n_{r+1}},\ldots,n_s)$$
$$\times z_1^{-n_1}\cdots z_{r-1}^{-n_{r-1}}z_{r+2}^{-n_{r+2}}\cdots z_s^{-n_s},$$

we obtain the first quantum generalized commutation relation satisfied by the Laurent modes:

$$\mathcal{Z}(\epsilon_1,\ldots,\epsilon_r,\epsilon_{r+1},\ldots,\epsilon_s|n_1,\ldots,n_r,n_{r+1},\ldots,n_s)$$
$$-\mathcal{Z}(\epsilon_1,\ldots,\epsilon_{r+1},\epsilon_r,\ldots,\epsilon_s|n_1,\ldots,n_{r+1},n_r,\ldots,n_s)$$
$$=\frac{\epsilon_r}{q-q^{-1}}\left(\sum_{j_{r+2},\ldots,j_s=0,1}\ \sum_{m_{r+2}\geqslant j_{r+2},\ldots,m_s\geqslant j_s}\delta_{n_r+n_{r+1},\Sigma_{i>r+1}m_i}(-1)^{\Sigma_{i>r+1}j_i}\right.$$
$$\left.\times q^{n_r\epsilon_r k+\Sigma_{i>r+1}m_i(2\epsilon_i-(\epsilon_i+\epsilon_r)k/2)+2\epsilon_i(1-2j_i)}\right)$$
$$\times\mathcal{Z}(\epsilon_1,\ldots,\hat{\epsilon}_r,\hat{\epsilon_{r+1}},\ldots,\epsilon_s|n_1,\ldots,n_{r-1},\hat{n}_r,\hat{n_{r+1}},n_{r+2}+m_{r+2},\ldots,n_s+m_s)\Psi_0$$
$$-\sum_{j_1,\ldots,j_{r-1}=0,1}\ \sum_{m_1\geqslant j_1,\ldots,m_{r-1}\geqslant j_{r-1}}\delta_{n_r+n_{r+1},-\Sigma_{i<r}m_i}$$
$$\times(-1)^{\Sigma_{i<r}j_i}q^{-n_r\epsilon_r k-2\Sigma_{i>r+1}\epsilon_i+\Sigma_{i<r}m_i(2\epsilon_i-(\epsilon_i+\epsilon_r)k/2)-4\epsilon_i j_i}\mathcal{Z}(\epsilon_1,\ldots,\hat{\epsilon}_r,\hat{\epsilon_{r+1}},\ldots,\epsilon_s|n_1$$
$$+m_1,\ldots,n_{r-1}+m_{r-1},\hat{n}_r,\hat{n_{r+1}},n_{r+2},\ldots,n_s)\Phi_0,\quad \epsilon_r=-\epsilon_{r+1}. \tag{135}$$

We remark that in the above formula the following relations are meant:

$$\delta_{n_r+n_{r+1},\Sigma_{i>r+1}m_i}=\delta_{n_r+n_{r+1},0},\quad \text{if } r=1,$$
$$\delta_{n_r+n_{r+1},-\Sigma_{i<r}m_i}=\delta_{n_r+n_{r+1},0},\quad \text{if } r=s-1. \tag{136}$$

The second type of quantum generalized commutation relations in the $\mathcal{Z}_q$ enveloping algebra is derived in the case $\epsilon_r=\epsilon_{r+1}$ as follows:

$$
\begin{aligned}
&(z_r - z_{r+1}q^{2\epsilon_r})\mathscr{Z}(\epsilon_1,\ldots,\epsilon_r,\epsilon_{r+1},\ldots,\epsilon_s|z_1,\ldots,z_r,z_{r+1},\ldots,z_s)\\
&\quad-(z_r q^{2\epsilon_r} - z_{r+1})\mathscr{Z}(\epsilon_1,\ldots,\epsilon_{r+1},\epsilon_r,\ldots,\epsilon_s|z_1,\ldots,z_{r+1},z_r,\ldots,z_s)\\
&\quad=S^-_{\epsilon_1}(z_1)\cdots S^-_{\epsilon_s}(z_s)X_{\epsilon_1}(z_1)\cdots X_{\epsilon_{r-1}}(z_{r-1})((z_r - z_{r+1}q^{2\epsilon_r})X_{\epsilon_r}(z_r)X_{\epsilon_{r+1}}(z_{r+1})\\
&\qquad-(z_r q^{2\epsilon_r} - z_{r+1})X_{\epsilon_{r+1}}(z_{r+1})X_{\epsilon_r}(z_r))X_{\epsilon_{r+2}}(z_{r+2})\cdots X_{\epsilon_s}(z_s)S^+_{\epsilon_1}(z_1)\cdots S^+_{\epsilon_1}(z_s)\\
&\quad=0,\quad \epsilon_r=\epsilon_{r+1}.
\end{aligned}
\tag{137}
$$

Substituting the Laurent expansion (134) in this relation we obtain this second quantum generalized commutation relation satisfied by the Laurent modes

$$
\begin{aligned}
&\mathscr{Z}(\epsilon_1,\ldots,\epsilon_r,\epsilon_{r+1},\ldots,\epsilon_s|n_1,\ldots,n_{r-1},1+n_r,n_{r+1},\ldots,n_s)\\
&\quad-q^{2\epsilon_r}\mathscr{Z}(\epsilon_1,\ldots,\epsilon_{r+1},\epsilon_r,\ldots,\epsilon_s|n_1,\ldots,n_{r-1},n_{r+1},1+n_r,\ldots,n_s)\\
&\quad=q^{2\epsilon_r}\mathscr{Z}(\epsilon_1,\ldots,\epsilon_r,\epsilon_{r+1},\ldots,\epsilon_s|n_1,\ldots,n_{r-1},n_r,1+n_{r+1},\ldots,n_s)\\
&\qquad-\mathscr{Z}(\epsilon_1,\ldots,\epsilon_{r+1},\epsilon_r,\ldots,\epsilon_s|n_1,\ldots,n_{r-1},1+n_{r+1},n_r,\ldots,n_s),\quad \text{if } \epsilon_r=\epsilon_{r+1}.
\end{aligned}
\tag{138}
$$

Although the first quantum generalized commutation relation looks completely different from its classical analog due to the appearance of various sums over the indices j_i and m_i instead of a single sum over a single index in the classical case,[12] we have checked that in the limit $q\to 1$ this quantum generalized commutation relation does indeed reduce to its classical analog, which in our notation reads simply as follows:

$$
\begin{aligned}
&\mathscr{Z}(\epsilon_1,\ldots,\epsilon_r,\epsilon_{r+1},\ldots,\epsilon_s|n_1,\ldots,n_r,n_{r+1},\ldots,n_s)\\
&\quad-\mathscr{Z}(\epsilon_1,\ldots,\epsilon_{r+1},\epsilon_r,\ldots,\epsilon_s|n_1,\ldots,n_{r+1},n_r,\ldots,n_s)\\
&\quad=(n_r k+2\epsilon_r(\epsilon_{r+2}+\cdots+\epsilon_s)+\epsilon_r h)\\
&\qquad\times\mathscr{Z}(\epsilon_1,\ldots,\hat{\epsilon}_r,\hat{\epsilon_{r+1}},\ldots,\epsilon_s|n_1,\ldots,n_{r-1},\hat{n}_r,\hat{n_{r+1}},n_{r+2},\ldots,n_s),\\
&\qquad\text{if } n_r+n_{r+1}=0,\quad \epsilon_r=-\epsilon_{r+1},\\
&\quad=2\epsilon_r\sum_{i>r+1}\epsilon_i\mathscr{Z}(\epsilon_1,\ldots,\hat{\epsilon}_r,\hat{\epsilon_{r+1}},\epsilon_s|n_1,\ldots,n_{r-1},\hat{n}_r,\hat{n_{r+1}},n_{r+2},\ldots,n_i+n_r+n_{r+1},\ldots,n_s),\\
&\qquad\text{if } n_r+n_{r+1}>0,\quad \epsilon_r=-\epsilon_{r+1},\\
&\quad=-2\epsilon_r\sum_{i<r}\epsilon_i\mathscr{Z}(\epsilon_1,\ldots,\hat{\epsilon}_r,\hat{\epsilon_{r+1}},\ldots,\epsilon_s|n_1,\ldots,n_i+n_r+n_{r+1},\ldots,n_{r-1},\hat{n}_r,\hat{n_{r+1}},n_{r+2},\ldots,n_s),\\
&\qquad\text{if } n_r+n_{r+1}<0,\quad \epsilon_r=-\epsilon_{r+1}.
\end{aligned}
\tag{139}
$$

The classical analog of the second quantum generalized commutation relation is simpler and is given by

$$
\begin{aligned}
&\mathscr{Z}(\epsilon_1,\ldots,\epsilon_r,\epsilon_{r+1},\ldots,\epsilon_s|n_1,\ldots,n_r,n_{r+1},\ldots,n_s)\\
&\qquad-\mathscr{Z}(\epsilon_1,\ldots,\epsilon_{r+1},\epsilon_r,\ldots,\epsilon_s|n_1,\ldots,n_{r+1},n_r,\ldots,n_s)=0,\quad \text{if } \epsilon_r=\epsilon_{r+1}.
\end{aligned}
\tag{140}
$$

In the case $q=1$, the above formulas were used in Refs. 11 and 12 to construct bases for Verma modules and standard modules. We think that their explicit dependence on q might allow for the crystallization of these modules (i.e., $q\to 0$), and also for their treatment when q is a root of unity.

Moreover, since from the physical point of view, one is rather interested in the computation of traces and matrix elements of the intertwiners between the standard modules, a concrete realization of these modules in terms of the Z_q might be very useful for this purpose. Although it is not yet known how to achieve this program even when $q=1$, we think that the above formulas are a starting point in this direction, especially when $q=0$ where one expects some simplifications compared to $q=1$.

VII. CONCLUSIONS

In this paper, we have introduced a natural quantum analog of the Z_q algebra with arbitrary level k. In the special cases $k=1$ and $k=2$, our Z_q algebra simplifies considerably and reduces to the well-known results. Moreover, as a new example of a Z_q module, that is, with $k>2$, we provide an explicit construction of the basis for a generalized Verma module. One would like to diagonalize the off-critical Z_k statistical models by the elements of the quantum parafermionic algebra, which is obtained from the quotient of the Z_q algebra by its subalgebra $\mathbb{C}[Q]$, in the same way that the off-critical Ising model has been diagonalized by the quantum Clifford algebra (i.e., the special case $k=2$ of the quantum parafermionic algebra).[7]

Two parameter deformation of Grassmann matrix group and supergroup

Salih Çelik
Mimar Sinan University, Department of Mathematics, 80690 Besiktas, Istanbul, Turkey

(Received 7 November 1995; accepted for publication 11 March 1996)

The two parameter quantum deformations of 2×2 Grassmann matrices, Gr(2), and supermatrices, Gr(1|1), are presented. Gr(2) whose matrix elements are all Grassmannian variables is called the superdual of the general linear group GL(2), and Gr(1|1) whose diagonal matrix elements are Grassmannian variables is called the superdual of the supergroup GL(1|1) whose nondiagonal elements are Grassmannian. Noncentral dual superdeterminant for Grassmann supermatrices belonging to $\mathrm{Gr}_{p,q}(1|1)$ is constructed. As with the 2×2 quantum matrices, the relations satisfied by the matrix elements of the Grassmann matrices and supermatrices are expressed in terms of an $\hat{R}$ matrix. The properties of the nth power of a Grassmann supermatrix are given as an Appendix. © *1996 American Institute of Physics.*

I. INTRODUCTION

Quantum groups are a generalization of the concept of groups. More precisely, a quantum group is a deformation of a group that, for particular values of the deformation parameter, coincides with the group. The theory and applications of quantum groups have attracted a lot of attention among mathematicians and physicists. The main physical motivation for quantum groups is that when nonlinear physical systems which are classically completely integrable are quantized, the classical symmetry group should be replaced by the corresponding quantum group.[1] On the other hand, most of the difficulties involving the divergences of quantum field theories which lie at the heart of all interactions require supersymmetry and thus the introduction of supergroups.[2] The algebraic structure underlying quantum groups extends the theory of the supergroups.[3–8] In Ref. 9, the q analog, $\mathrm{Gr}_q(1|1)$, of the dual supermatrices Gr(1|1) is presented. $\mathrm{Gr}_q(1|1)$ is the superdual of the quantum group $\mathrm{GL}_q(1|1)$ and the properties of the quantum dual supermatrices are discussed. In this paper we present a two parameter deformation, $\mathrm{Gr}_{p,q}(2)$ and $\mathrm{Gr}_{p,q}(1|1)$, of the Grassmann matrices and supermatrices, respectively and give an $\hat{R}$ matrix for this deformation.

We will say that Grassmann matrices are the dual matrices in GL(2) and Grassmann supermatrices are the dual supermatrices in GL(1|1). To study the two parameter extension of the Grassmann matrices and supermatrices, we follow the approach of Manin[3] in Sec. II. In the following section we get an $\hat{R}$ matrix which gives the relations between the matrix elements of a dual matrix in GL(1|1). The properties of the nth power of a dual supermatrix which are more compact than the single deformation parameter case are given in Appendix.

II. THE QUANTUM GRASSMANN MATRIX GROUP $\mathrm{Gr}_{p,q}(2)$

Before discussing the two parameter deformation of the dual matrices in the general linear group GL(2), we give some notations and useful formulas.

A. Notations

Consider 2×2 matrices with Grassmannian entries. We will say that such matrices form the Grassmann matrix group and denote it by Gr(2). Explicitly, a Grassmannian 2×2 matrix $\hat{A}$ is of the form

0022-2488/96/37(7)/3568/8/$10.00

$$\hat{A}=\begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix}, \tag{2.1}$$

where all entries are Grassmannian.

Since the matrix elements of $\hat{A}$ are all Grassmannian, for the conventional tensor products

$$\hat{A}_1=\hat{A}\otimes I \quad \text{and} \quad \hat{A}_2=I\otimes\hat{A}, \tag{2.2}$$

one can write (no-grading)

$$(\hat{A}_1)^{ij}{}_{kl}=\hat{A}^i{}_k\delta^j{}_l, \tag{2.3a}$$

$$(\hat{A}_2)^{ij}{}_{kl}=\delta^i{}_k\hat{A}^j{}_l \tag{2.3b}$$

where δ denotes the Kronecker delta.

B. Two parameter deformation of Gr(2)

The one parameter deformation of Grassmann matrices was given by Corrigan *et al.*[4] In this section, we will give a two parameter deformation of Grassmann matrices, i.e., of Gr(2). Let $R_p[2|0]$ be a quantum vector space which is two dimensional. The coordinates of a vector $V=(x,y)^T\in R_p[2|0]$ satisfy the bilinear product relation

$$xy-pyx=0. \tag{2.4}$$

We consider a dual quantum vector space $R_q[0|2]$, the generators of which are Grassmannian. The coordinates of a (dual) vector $\hat{V}=(\xi,\eta)^T\in R_q[0|2]$ satisfy the relations

$$\xi^2=0=\eta^2, \quad \eta\xi+q\xi\eta=0 \tag{2.5}$$

as introduced in Ref. 3.

Now we want to define a two parameter deformation of the algebra of functions on the Grassmann matrix group Gr(2) as an associative algebra with unit, generated by the generators α, β, γ, and δ. For this, we consider linear transformations $\hat{A}$ with the following properties:

$$\hat{A}:R_p[2|0]\to R_q[0|2], \tag{2.6a}$$

$$\hat{A}:R_q[0|2]\to R_p[2|0]. \tag{2.6b}$$

We assume that the matrix elements of $\hat{A}$ commute with the coordinates of $R_p[2|0]$ and anti-commute with the coordinates of $R_q[0|2]$. Then the endomorphisms in (2.6) impose the following (p,q)-anti-commutation relations among the matrix elements of $\hat{A}$:

$$\begin{gathered}\alpha\beta+p^{-1}\beta\alpha=0, \quad \alpha\gamma+q^{-1}\gamma\alpha=0,\\ \gamma\delta+p^{-1}\delta\gamma=0, \quad \beta\delta+q^{-1}\delta\beta=0,\\ \alpha\delta+\delta\alpha=0, \quad \alpha^2=\beta^2=\gamma^2=\delta^2=0,\\ \beta\gamma+pq^{-1}\gamma\beta=(p-q^{-1})\delta\alpha,\end{gathered} \tag{2.7}$$

where p and q are nonzero complex numbers and $pq\pm1\neq0$.

Since the entries of $\hat{A}$ are all Grassmannian, a proper inverse cannot exist. However, the left and right inverses of $\hat{A}$ can be constructed. Let

$$\Delta_L=\beta\gamma+q^{-1}\delta\alpha, \tag{2.8a}$$

$$\Delta_R=\gamma\beta-p^{-1}\alpha\delta. \tag{2.8b}$$

Then at least the formally, the left and right inverses of $\hat{A}$ become

$$\hat{A}_L^{-1}=\begin{pmatrix} q^{-1}\delta & \beta \\ -pq^{-1}\gamma & -p\alpha \end{pmatrix}, \tag{2.9}$$

$$\hat{A}_R^{-1}=\begin{pmatrix} -q\delta & \beta \\ -qp^{-1}\gamma & p^{-1}\delta \end{pmatrix}. \tag{2.10}$$

Indeed, it is easy to show that

$$\hat{A}_L^{-1}\hat{A}=\Delta_L I, \tag{2.11a}$$

$$\hat{A}\hat{A}_R^{-1}=\Delta_R I, \tag{2.11b}$$

where I is the 2×2 unit matrix. In this case, Δ_L may be considered as a left quantum (dual) determinant and Δ_R as a right quantum (dual) determinant. Note that, one can write

$$\Delta_L\hat{A}_R^{-1}=\hat{A}_L^{-1}\Delta_R \tag{2.12}$$

using (2.8)–(2.10) and associativity of the algebra (2.7).

The algebra (2.7) is associative under multiplication and the relations in (2.7) may be also expressed in a tensor product form

$$\hat{R}(1)\hat{A}_1\hat{A}_2=-\hat{A}_2\hat{A}_1\hat{R}(1), \tag{2.13}$$

where

$$\hat{R}(x)=(p+q^{-1})\sum_i e^i{}_i\otimes e^i{}_i+2x\sum_{i\neq j}(pq^{-1})^{i-1}e^i{}_i\otimes e^j{}_j+(p-q^{-1})\left(\sum_{i>j}-\sum_{i<j}\right)e^i{}_j\otimes e^j{}_i. \tag{2.14}$$

Here the elements of the matrix $e^k{}_l$ are

$$(e^k{}_l)^i{}_j=\delta^i{}_k\delta^j{}_l. \tag{2.15}$$

The explicit form of $\hat{R}(x)$ is

$$\hat{R}(x)=\begin{pmatrix} p+q^{-1} & 0 & 0 & 0 \\ 0 & 2x & q^{-1}-p & 0 \\ 0 & p-q^{-1} & 2xpq^{-1} & 0 \\ 0 & 0 & 0 & p+q^{-1} \end{pmatrix}. \tag{2.16}$$

In terms of the matrix elements Eq. (2.13) is of the form

$$\hat{R}^{ij}{}_{kl}\hat{A}^k{}_m\hat{A}^l{}_n=-\hat{A}^j{}_l\hat{A}^i{}_k\hat{R}^{kl}{}_{mn}. \tag{2.17}$$

Finally, we note that the algebra (2.7) and the $\hat{R}$ matrix in (2.16) with $p=q$ and $x=-1$ was given in Ref. 4 (Sec. III).

III. TWO PARAMETER DEFORMATION OF THE GRASSMANN MATRIX SUPERGROUP

In this section, we consider 2×2 supermatrices whose diagonal elements are Grassmannian. We remark that the supergroup GL(1|1) whose nondiagonal elements are Grassmannian is (p,q) deformed in Refs. 7 and 8. We will say that such supermatrices form the Grassmann supermatrix group and denote it by Gr(1|1). Explicitly, a Grassmann 2×2 supermatrix $\hat{\mathscr{A}}$ is of the form

$$\hat{\mathscr{A}}=\begin{pmatrix}\alpha & b\\ c & \delta\end{pmatrix} \tag{3.1}$$

with two odd (greek letters) and two even (latin letters) matrix elements. Even matrix elements commute with everything and odd matrix elements anti-commute among themselves.

We begin with Manin's approach.[3] To do this, we consider the endomorphisms of a two-dimensional quantum superplane and its dual, denoted by $R_p[1|1]$ and $R_q^*[1|1]$, respectively.

$$U=\begin{pmatrix}x\\ \xi\end{pmatrix}\in R_p[1|1]\Leftrightarrow x\xi-p\xi x=0,\quad \xi^2=0, \tag{3.2}$$

and its dual

$$\hat{U}=\begin{pmatrix}\eta\\ y\end{pmatrix}\in R_q^*[1|1]\Leftrightarrow \eta^2=0,\quad \eta y-q^{-1}y\eta=0. \tag{3.3}$$

Suppose that the matrix elements of $\hat{\mathscr{A}}$ (anti-)commute with the coordinates of $R_p[1|1]$ and $R_q^*[1|1]$. Then, the endomorphisms

$$\hat{\mathscr{A}}:\quad R_p[1|1]\rightarrow R_q^*[1|1], \tag{3.4a}$$

$$\hat{\mathscr{A}}:\quad R_q^*[1|1]\rightarrow R_p[1|1] \tag{3.4b}$$

impose the following bilinear product relations among the generators of $\hat{\mathscr{A}}$:

$$\alpha b=p^{-1}b\alpha,\quad \alpha c=q^{-1}c\alpha, \tag{3.5a}$$

$$\delta b=p^{-1}b\delta,\quad \delta c=q^{-1}c\delta, \tag{3.5b}$$

$$\alpha\delta+\delta\alpha=0,\quad \alpha^2=0=\delta^2, \tag{3.5c}$$

$$bc=pq^{-1}cb+(p-q^{-1})\delta\alpha \tag{3.5d}$$

where p and q are nonzero complex numbers and $pq\pm1\neq0$. These relations may be considered as a two parameter deformation of a Grassmann superalgebra on four elements (α,b,c,δ) where α and δ are Grassmannian elements. This deformed algebra denoted by $\mathrm{Gr}_{p,q}(1|1)$. For $p=q$, one obtains the one parameter deformation of the generators of $\hat{\mathscr{A}}$ that was given in Ref. 9.

The inverse of $\hat{\mathscr{A}}$ can be found as in Ref. 9 and it is of the form

$$\hat{\mathscr{A}}^{-1}=\begin{pmatrix}-c^{-1}\delta b^{-1} & c^{-1}+c^{-1}\delta b^{-1}\alpha c^{-1}\\ b^{-1}+b^{-1}\alpha c^{-1}\delta b^{-1} & -b^{-1}\alpha c^{-1}\end{pmatrix} \tag{3.6}$$

provided that b and c are invertible. It is easy to verify that this is the proper right and left inverse of $\hat{\mathscr{A}}$, i.e.,

$$\hat{\mathscr{A}}\hat{\mathscr{A}}^{-1}=I=\hat{\mathscr{A}}^{-1}\hat{\mathscr{A}}.$$

Let

$$\hat{\mathscr{A}}^{-1}=\begin{pmatrix}\alpha' & b'\\ c' & \delta'\end{pmatrix}.$$

Then, the matrix elements of $\hat{\mathscr{A}}^{-1}$ satisfy the following relations

$$\begin{gathered}\alpha' b'=pb'\alpha', \quad \alpha' c'=qc'\alpha',\\ \delta' b'=pb'\delta', \quad \delta' c'=qc'\delta',\\ \alpha'\delta'+\delta'\alpha'=0, \quad \alpha'^2=0=\delta'^2,\\ b'c'=qp^{-1}c'b'+(q-p^{-1})\delta'\alpha'.\end{gathered} \tag{3.7}$$

Therefore, the matrix elements of $\hat{\mathscr{A}}^{-1}$ satisfy the (p^{-1},q^{-1})-commutation relations while the matrix elements of $\hat{\mathscr{A}}$ satisfy the (p,q)-commutation relations.

The quantum (dual) superdeterminant of $\hat{\mathscr{A}}$ is defined as

$$s\hat{D}_{p,q}(\hat{\mathscr{A}})=\hat{D}=c^{-1}b-c^{-1}\alpha c^{-1}\delta=pq^{-1}(bc^{-1}-\alpha c^{-1}\delta c^{-1}), \tag{3.8}$$

which for $p=q$ is the same as $s\hat{D}_q(\hat{\mathscr{A}})$ in Ref. 9. The factor pq^{-1} in (3.8) appeared because of the relation (3.5d). Note that the second equality in (3.8) is obtained by using the relation

$$bc^{-1}=qp^{-1}c^{-1}b-(q-p^{-1})c^{-1}\delta\alpha c^{-1}, \tag{3.9}$$

which in turn is obtained from Eq. (3.5d).

In general $\hat{D}$, the quantum (dual) superdeterminant of $\hat{\mathscr{A}}$, is not central but obeys the following commutation relations

$$\begin{gathered}\hat{D}\alpha=pq^{-1}\alpha\hat{D}, \quad \hat{D}\delta=pq^{-1}\delta\hat{D},\\ \hat{D}b=pq^{-1}b\hat{D}, \quad \hat{D}c=pq^{-1}c\hat{D}.\end{gathered} \tag{3.10}$$

It is interesting that the quantum (dual) superdeterminant $\hat{D}$ is not central while the quantum superdeterminant of a matrix $\mathrm{GL}_{p,q}(1|1)$ is 7. However, it becomes central for $p=q$ as noted down in Ref. 9.

Before passing to the next section, we remark that the interesting point in the construction of (3.6) is the fact that the dual superdeterminant $\hat{D}$ is not necessarily central.

IV. THE $\hat{R}$ MATRIX

In this section, we give an $\hat{R}$ matrix to obtain the relations (3.5). The algebra (3.5) is associative under multiplication and the relation (3.5) may be expressed in terms of a graded $\hat{R}$-matrix condition, as with the quantum supermatrix. To this end, we use the tensoring convention

$$(\hat{\mathscr{A}}_1)^{ij}{}_{kl}=(\hat{\mathscr{A}}\otimes I)^{ij}{}_{kl}=(-1)^{k(j+l)}\hat{\mathscr{A}}^i{}_k\delta^j{}_l=\hat{\mathscr{A}}^i{}_k\delta^j{}_l, \tag{4.1a}$$

$$(\hat{\mathscr{A}}_2)^{ij}{}_{kl}=(I\otimes\hat{\mathscr{A}})^{ij}{}_{kl}=(-1)^{i(j+l)}\hat{\mathscr{A}}^j{}_l\delta^i{}_k. \tag{4.1b}$$

The explicit form of $\hat{\mathscr{A}}_1$ and $\hat{\mathscr{A}}_2$ is

$$\hat{\mathscr{A}}_1=\begin{pmatrix} \alpha & 0 & b & 0 \\ 0 & \alpha & 0 & b \\ c & 0 & \delta & 0 \\ 0 & c & 0 & \delta \end{pmatrix}, \tag{4.2a}$$

$$\hat{\mathscr{A}}_2=\begin{pmatrix} -\alpha & -b & 0 & 0 \\ -c & -\delta & 0 & 0 \\ 0 & 0 & -\alpha & b \\ 0 & 0 & c & -\delta \end{pmatrix}. \tag{4.2b}$$

Then the associative algebra (3.5) is equivalent to equation

$$\hat{R}(-1).\hat{\mathscr{A}}_1.\hat{\mathscr{A}}_2=-\hat{\mathscr{A}}_2.\hat{\mathscr{A}}_1\hat{R}(-1), \tag{4.3}$$

where

$$\hat{R}(-1)=\begin{pmatrix} p+q^{-1} & 0 & 0 & 0 \\ 0 & -2 & q^{-1}-p & 0 \\ 0 & p-q^{-1} & -2pq^{-1} & 0 \\ 0 & 0 & 0 & p+q^{-1} \end{pmatrix}. \tag{4.4}$$

This $\hat{R}(-1)$ matrix obtained from (2.14) with $x=-1$. Here a 4×4 matrix in the form (4.2a) is labeled in the following way

$$M=\begin{pmatrix} M^{11}{}_{11} & M^{11}{}_{12} & M^{11}{}_{21} & M^{11}{}_{22} \\ M^{12}{}_{11} & M^{12}{}_{12} & M^{12}{}_{21} & M^{12}{}_{22} \\ M^{21}{}_{11} & M^{21}{}_{12} & M^{21}{}_{21} & M^{21}{}_{22} \\ M^{22}{}_{11} & M^{22}{}_{12} & M^{22}{}_{21} & M^{22}{}_{22} \end{pmatrix} \tag{4.5}$$

similar to Ref. 6.

We have given the (p,q)-commutation relations which satisfied by the matrix elements of a Grassmannian matrix and a Grassmannian supermatrix, i.e., we made a two parameter deformation of the Grassmann matrix group Gr(2) and the supermatrix group Gr(1|1). We obtained the Grassmannian quantum superdeterminant of a Grassmannian quantum supermatrix (p,q)-deformed case. However, it reduces to the case discussed in Ref. 9 for $p=q$. We have given an $\hat{R}$ matrix which by use of a tensor product gives the (p,q)-commutation relations between the matrix elements of a Grassmannian supermatrix.

APPENDIX: THE PROPERTIES OF THE *n*th POWER OF GRASSMANN SUPERMATRICES

Here we will discuss the properties of the nth power of a Grassmann supermatrix. First we note that the product of two Grassmann supermatrices is not a Grassmann supermatrix, i.e., the matrix elements of a product $M=\hat{M}\hat{M}'$ do not satisfy (3.5). However, $\hat{M}\hat{M}'\in \mathrm{GL}_{p,q}(1|1)$ if $\hat{M}$ and

$\hat{M}'$ are two Grassmann supermatrices and (b,c) $((\alpha,\delta))$ pairwise commute (anti-commute) with (b',c') $((\alpha',\delta'))$. So, we must consider the matrix elements of $\hat{M}^n$ with respect to even and odd values of n. Let the $(2n-1)$th power of $\hat{M}\in \mathrm{Gr}_{p,q}(1|1)$ be

$$\hat{M}^{2n-1}=\begin{pmatrix} A_{2n-1} & B_{2n-1} \\ C_{2n-1} & D_{2n-1} \end{pmatrix}, \quad n\geqslant 1. \tag{A1}$$

After some algebra, one obtains

$$\begin{aligned} A_{2n-1}&=\{\langle n\rangle_{pq}\alpha+p\langle n-1\rangle_{pq}\delta\}(bc)^{n-1},\\ B_{2n-1}&=\{bc+p\langle n-1\rangle_{p^2q^2}\alpha\delta\}(bc)^{n-2}b,\\ C_{2n-1}&=\{cb+q\langle n-1\rangle_{p^2q^2}\delta\alpha\}(cb)^{n-2}c,\\ D_{2n-1}&=\{\langle n\rangle_{pq}\delta+q\langle n-1\rangle_{pq}\alpha\}(cb)^{n-1}, \end{aligned} \tag{A2}$$

where

$$\langle N\rangle_{pq}=\frac{1-p^Nq^N}{1-pq}. \tag{A3}$$

Now it is easy to show the following relations are satisfied:

$$\begin{aligned} A_{2n-1}B_{2n-1}&=p^{-(2n-1)}B_{2n-1}A_{2n-1},\\ A_{2n-1}C_{2n-1}&=p^{-(2n-1)}C_{2n-1}A_{2n-1},\\ D_{2n-1}B_{2n-1}&=q^{-(2n-1)}B_{2n-1}D_{2n-1},\\ D_{2n-1}C_{2n-1}&=q^{-(2n-1)}C_{2n-1}D_{2n-1},\\ A_{2n-1}D_{2n-1}+D_{2n-1}A_{2n-1}&=0,\\ A_{2n-1}^2=0&=D_{2n-1}^2,\\ B_{2n-1}C_{2n-1}&=p^{2n-1}q^{-(2n-1)}C_{2n-1}B_{2n-1}+(p^{2n-1}-q^{-(2n-1)})A_{2n-1}D_{2n-1}. \end{aligned} \tag{A4}$$

Thus, $\hat{M}^{2n-1}$ is a Grassmann supermatrix with deformation parameters p^{2n-1} and q^{2n-1}, i.e., $\hat{M}^{2n-1}\in \mathrm{Gr}_{p^{2n-1},q^{2n-1}}(1|1)$.

Similarly, if we write the matrix $\hat{M}^{2n}$, the $(2n)$th power of $\hat{M}\in \mathrm{Gr}_{p,q}(1|1)$, as

$$\hat{M}^{2n}=\begin{pmatrix} A_{2n} & B_{2n} \\ C_{2n} & D_{2n} \end{pmatrix}, \quad n\geqslant 1 \tag{A5}$$

where

$$\begin{aligned} A_{2n}&=\left\{bc+p\,\frac{1-pq}{1+pq}\,\langle n\rangle_{pq}\langle n-1\rangle_{pq}\alpha\delta\right\}(bc)^{n-1},\\ B_{2n}&=\langle n\rangle_{pq}\{\alpha+p\,\delta\}(bc)^{n-1}b,\\ C_{2n}&=\langle n\rangle_{pq}\{\delta+q\,\alpha\}(cb)^{n-1}c, \end{aligned}$$

$$D_{2n}=\left\{cb+q\,\frac{1-pq}{1+pq}\,\langle n\rangle_{pq}\langle n-1\rangle_{pq}\delta\alpha\right\}(cb)^{n-1}, \tag{A6}$$

then the elements of $\hat{M}^{2n}$ obey the following relations

$$A_{2n}B_{2n}=q^{2n}B_{2n}A_{2n}, \quad A_{2n}C_{2n}=p^{2n}C_{2n}A_{2n},$$

$$D_{2n}B_{2n}=q^{2n}B_{2n}D_{2n}, \quad D_{2n}C_{2n}=p^{2n}C_{2n}D_{2n},$$

$$B_{2n}C_{2n}+p^{n}q^{-n}C_{2n}B_{2n}=0,$$

$$B_{2n}^{2}=0=C_{2n}^{2},$$

$$A_{2n}D_{2n}-D_{2n}A_{2n}=(p^{2n}-q^{-2n})C_{2n}B_{2n}. \tag{A7}$$

Thus the matrix $\hat{M}^{2n}$ is a supermatrix in the form of

$$T=\begin{pmatrix}\alpha & \beta\\ \gamma & d\end{pmatrix} \tag{A8}$$

with the deformation parameters p^{2n} and q^{2n}. Such supermatrices T form the supergroup GL(1|1) whose deformation was given in Refs. 7 and 8. The nth power of such a supermatrix and the relations between the matrix elements of T^n can be found in Ref. 10 (Sec. 3).

Algebraic proof of the symmetric space theorem

C. Daboul
Mathematisches Seminar der Universität Hamburg, Bundesstr.55, D-20146 Hamburg, Germany

(Received 11 October 1995; accepted for publication 28 November 1995)

I give a relatively elementary proof of the symmetric space theorem, due to Goddard, Nahm and Olive [Phys. Lett. B **160**, 111–116 (1985)]. Unlike their original proof, which involves the quark-model construction, I only use elementary algebraic techniques. © *1996 American Institute of Physics.*
[S0022-2488(96)00206-X]

I. INTRODUCTION

In 1985 Goddard, Nahm and Olive[1] proved an interesting theorem, which has been called the symmetric space theorem. It relates the vanishing of certain coset Virasoro algebras to the existence of symmetric spaces. This has further interesting mathematical consequences in representation theory of affine Kac–Moody algebras, since the vanishing of the coset Virasoro algebra is the condition for finite reducibility of representations of affine algebras restricted to certain affine subalgebras.

The original proof by the above authors involved the use of physical concepts, such as quarks. The purpose of the present paper is to state and prove the symmetric space theorem, by using purely algebraic concepts. In particular, I shall carry out the proof following an idea used by Witt,[2] thereby using only elementary algebraic transformations.

In section II I introduce relevant definitions and notations. In section III I first prove three auxiliary lemmas and two corollaries, then state and prove the theorem.

II. DEFINITIONS AND NOTATIONS

A. Affine algebras

The *affine Kac–Moody algebra*, affine algebra for short,

$$\tilde{\mathcal{G}}(\mathfrak{g}) = (\mathbb{C}[t,t^{-1}] \otimes_{\mathbb{C}} \mathfrak{g}) \oplus \mathbb{C}\mathcal{K}, \tag{1}$$

associated to an underlying simple Lie algebra $\mathfrak{g}$ is defined by the following commutation relations:

$$[t^m \otimes x, t^n \otimes y] = t^{m+n} \otimes [x,y] + m\,\delta_{m,-n}(x|y)\mathcal{K}, \tag{2}$$

where $\mathcal{K}$ spans the center of $\tilde{\mathcal{G}}(\mathfrak{g})$ and is called the central term, and $(.|.)$ is the *normalized invariant form* on $\mathfrak{g}$. The term invariant means that

$$([x,y]|z) = (x|[y,z]), \quad \forall x,y,z \in \mathfrak{g}. \tag{3}$$

It is well known (see for example Ref. 3), that two invariant symmetric bilinear forms on a simple Lie algebra differ only by a scalar factor. The normalized invariant form, which will be used henceforth, is defined such that the highest root has length $\sqrt{2}$.

The affine algebra for an underlying Abelian algebra $\mathfrak{g}$ can be defined similarly, by (1) and (2). However, for Abelian $\mathfrak{g}$ any nondegenerate symmetric form $(.|.)$ is invariant. In contrast to the case of a simple algebra, such a form cannot be further determined by algebraic constraints derived from the Lie algebra structure. In this article Abelian algebras will almost always appear

0022-2488/96/37(7)/3576/11/$10.00

as subalgebras of the simple algebra $so(n)$. Therefore, there will be a natural choice of $(.|.)$, namely the restriction of the normalized invariant form of $so(n)$ to $\mathfrak{g}$. In the definitions, where an Abelian algebra is not given as a subalgebra of $so(n)$, $(.|.)$ may be any fixed nondegenerate symmetric form.

When the central element $\mathscr{K}$ of the affine algebra $\widetilde{\mathscr{L}}(\mathfrak{g})$ acts as a scalar k id in a representation, then k is called the *level of this representation.*

For a reductive Lie algebra,

$$\mathfrak{u}=\mathfrak{u}_0\oplus\mathfrak{u}_1\oplus\ldots\oplus\mathfrak{u}_S, \tag{4}$$

with center $\mathfrak{u}_0$ and simple ideals $\mathfrak{u}_1,\ldots,\mathfrak{u}_S$, the affine algebra $\widetilde{\mathscr{L}}(\mathfrak{u})$ is the direct sum of the affine algebras associated to the ideals $\mathfrak{u}_0,\ldots,\mathfrak{u}_S$:

$$\widetilde{\mathscr{L}}(\mathfrak{u})=\bigoplus_{s=0}^{S}\widetilde{\mathscr{L}}(\mathfrak{u}_s)=\bigoplus_{s=0}^{S}((\mathbb{C}[t,t^{-1}]\otimes\mathfrak{u}_s)\oplus\mathbb{C}\mathscr{K}_s). \tag{5}$$

The affine algebra associated to a finite-dimensional reductive Lie algebra $\mathfrak{u}$ is thus a S-dimensional central extension of the *loop algebra* $\mathbb{C}[t,t^{-1}]\otimes\mathfrak{u}$ *associated to* $\mathfrak{u}$. (In the case of an underlying semi-simple Lie algebra the affine algebra is indeed the universal central extension of the loop algebra.) The loop algebra can be identified with the Lie algebra of polynomial maps of S^1 into $\mathfrak{u}$.

B. The Virasoro algebra and the Sugawara construction

The *Virasoro algebra,*

$$\mathrm{Vir}=\bigoplus_{n\in\mathbb{Z}}\mathbb{C}d_n\oplus\mathbb{C}c,$$

is defined by the following commutation relations:

$$\begin{aligned}&[c,d_n]=0,\\ &[d_m,d_n]=(m-n)d_{m+n}+\delta_{m,-n}\frac{m^3-m}{12}c,\quad \forall m,n\in\mathbb{Z}.\end{aligned} \tag{6}$$

Let $\mathfrak{g}$ be a simple Lie algebra. Let $\{u_i\}$ and $\{u^i\}$ be dual bases of $\mathfrak{g}$. The *quadratic Casimir operator* is the following element of the universal enveloping algebra $\mathfrak{U}(\mathfrak{g})$ of $\mathfrak{g}$:

$$\Omega=\sum_{i=1}^{\dim\mathfrak{g}}u_iu^i. \tag{7}$$

Ω commutes with any element of $\mathfrak{g}$, therefore, by the Schur lemma it acts as a scalar, denoted by ω_ρ, on any irreducible representation ρ of $\mathfrak{g}$. Given a representation of the affine algebra $\widetilde{\mathscr{L}}(\mathfrak{g})$ of level $k\neq-1/2\omega_{ad}$, where ω_{ad} denotes the scalar value of the quadratic Casimir operator in the adjoint representation, one can construct a representation of Vir by using the following *Sugawara operators* (cf. Ref. 4), where the notation $x^{(n)}\equiv t^n\otimes x$ is used:

$$L_0 := \frac{1}{(2k+\omega_{ad})}\left(\sum_i u_i u^i + 2\sum_{n=1}^{\infty}\sum_i u_i^{(-n)} u^{i(n)}\right),$$
$$L_n := \frac{1}{(2k+\omega_{ad})}\sum_{m\in\mathbb{Z}}\sum_i u_i^{(-m)} u^{i(m+n)}, \quad \forall n\in\mathbb{Z}\backslash\{0\}. \tag{8}$$

The operators L_n obey the commutation relations (6), where the central element of the Virasoro algebra takes the scalar value

$$c = \frac{2k\ \dim\ \mathfrak{g}}{2k+\omega_{ad}}. \tag{9}$$

For an underlying abelian algebra the same equations hold with $\omega_{ad}=0$. In this case (9) yields $c=\dim\ \mathfrak{g}$. The Sugawara operators L_m and the elements $x^{(n)}$ of the affine algebra obey the following commutation relations:

$$[L_m, x^{(n)}] = -n x^{(m+n)}, \quad \forall m,n\in\mathbb{Z}, x\in\mathfrak{g}. \tag{10}$$

For a reductive Lie algebra as in (4), the Sugawara operators corresponding to $\tilde{\mathscr{Z}}(\mathfrak{u})$ in a representation of levels $k_s \neq -1/2\omega_{ad_s}$, are given by

$$L_n^{\mathfrak{u}} := \sum_{s=0}^{S} L_n^{\mathfrak{u}_s},$$

where $L_n^{\mathfrak{u}_s}$ is the Sugawara operator for the individual ideal $\mathfrak{u}_s$. The $L_n^{\mathfrak{u}_s}$ provide a representation of the Virasoro algebra with central value

$$c_{\mathfrak{u}} = \sum_{s=0}^{S} \frac{2k_s\ \dim\ \mathfrak{u}_s}{2k_s+\omega_{ad_s}}. \tag{11}$$

Again, the $L_n^{\mathfrak{u}}$ satisfy a commutation relation similar to (10), where $x\in\mathfrak{u}$.

C. The coset construction

Let U be a compact Lie subgroup of the orthogonal group $SO(n)$. Then the complexified Lie algebra of U is a reductive algebra $\mathfrak{u}$ as in (4), which is a subalgebra of the orthogonal algebra $so(n)$.

The inclusion of $\mathfrak{u}$ in $so(n)$ gives rise to a homomorphism of the associated affine algebras:

$$\tilde{\mathscr{Z}}(\mathfrak{u}) = \bigoplus_{s=0}^{S}((\mathbb{C}[t,t^{-1}]\otimes\mathfrak{u}_s)\oplus\mathbb{C}\mathscr{K}_s) \to \tilde{\mathscr{Z}}(so(n)) = (\mathbb{C}[t,t^{-1}]\otimes so(n))\oplus\mathbb{C}\mathscr{K}. \tag{12}$$

The obvious inclusion homomorphism of the loop algebras is lifted consistently to a homomorphism of the affine algebras in (12) by letting

$$\mathscr{K}_s \mapsto j_s\mathscr{K}, \quad \text{for } s=0,\ldots,S, \tag{13}$$

where for the simple ideals $\mathfrak{u}_s$, $s\geq 1$, the factor j_s is the *Dynkin index*, which is defined as the ratio of the normalized invariant form $(.|.)_{so(n)}$ on $so(n)$ (restricted to $\mathfrak{u}_s$) and the normalized invariant form $(.|.)_s$ on $\mathfrak{u}_s$, i.e.

$$(x|y)_{so(n)} = j_s(x|y)_s, \quad \forall x,y\in\mathfrak{u}_s. \tag{14}$$

For $s=0$ we choose $(.|.)_0$ to be the restriction of $(.|.)_{so(n)}$ to $\mathfrak{u}_0$. Then, by letting $j_0=1$, equation (14) holds also for $s=0$.

In this situation the Sugawara construction can be applied to both $so(n)$ and $\mathfrak{u}$ to obtain Sugawara operators $L_n^{so(n)}$ and $L_n^{\mathfrak{u}}$ which are different in general and form representations of Vir. We can calculate their central values by using (9) and (11). We get

$$c_{so(n)}=\frac{k_{so(n)}n(n-1)}{2k_{so(n)}+2n-4} \tag{15}$$

and

$$c_{\mathfrak{u}}=\sum_{s=0}^{S}\frac{2k_{so(n)}j_s\dim\,\mathfrak{u}_s}{2k_{so(n)}j_s+\omega_{ad_s}}, \tag{16}$$

respectively. In (15) I substituted $\dim(so(n))=n(n-1)/2$ and

$$\omega_{ad_{so(n)}}=2n-4. \tag{17}$$

[The expression (17) can be computed, for example, by using the relation $\omega_{ad}=2\check{h}$, where $\check{h}$ is the *dual Coxeter number*. A table of dual Coxeter numbers can be found in Ref. 4.] In (16) I used $k_s=j_sk_{so(n)}$, which follows from (13).

By (10) we have

$$[L_l^{so(n)},x^{(m)}]=-mx^{(m+l)},\quad \forall l,m\in\mathbb{Z},\quad x\in so(n). \tag{18}$$

$$[L_l^{\mathfrak{u}},x^{(m)}]=-mx^{(m+l)},\quad \forall l,m\in\mathbb{Z},\quad x\in\mathfrak{u}. \tag{19}$$

Therefore, the difference operators,

$$K_l:=L_l^{so(n)}-L_l^{\mathfrak{u}},$$

commute with each $x^{(m)}\in\widetilde{\mathscr{G}}(\mathfrak{u})$ individually,

$$[K_l,x^{(m)}]=0,\quad \forall l,m\in\mathbb{Z},\quad x\in\mathfrak{u}, \tag{20}$$

and consequently, by (8), with the corresponding Sugawara operator,

$$[K_l,L_m^{\mathfrak{u}}]=0,\quad \forall l,m\in\mathbb{Z}. \tag{21}$$

It follows that

$$[K_l,K_m]=[L_l^{so(n)},L_m^{so(n)}]-[L_l^{\mathfrak{u}},L_m^{\mathfrak{u}}],\quad \forall l,m\in\mathbb{Z}. \tag{22}$$

We deduce that the K_m, like the $L_m^{so(n)}$ and the $L_m^{\mathfrak{u}}$, define a representation of Vir, whose central charge is equal to the difference of the Sugawara values,

$$c_K=c_{so(n)}-c_{\mathfrak{u}}=\frac{k_{so(n)}n(n-1)}{2k_{so(n)}+2n-4}-\sum_{s=0}^{S}\frac{2k_{so(n)}j_s\ \dim\,\mathfrak{u}_s}{2k_{so(n)}j_s+\omega_{ad_s}}. \tag{23}$$

The above construction of representations of the Virasoro algebra is called the *coset construction.* It was introduced by Goddard and Olive in Ref. 5. It can be applied similarly for any simple (or even reductive) Lie algebra $\mathfrak{g}$ instead of $so(n)$ and a reductive subalgebra $\mathfrak{u}\subseteq\mathfrak{g}$, but in this article I shall only consider the case $\mathfrak{g}=so(n)$.

An important property of all the above constructions is that they preserve the unitarity of the involved representations, i.e., a unitary representation of the affine algebra $\tilde{\mathscr{L}}(so(n))$, induces a unitary representation of its subalgebra $\tilde{\mathscr{L}}(\mathfrak{u})$. Then by the Sugawara construction applied to the unitary representations of $\tilde{\mathscr{L}}(\mathfrak{u})$ and $\tilde{\mathscr{L}}(so(n))$ we get two different unitary representations of Vir. Finally, the resulting coset representation of Vir is again unitary.

The Virasoro algebra has no nontrivial unitary representations with zero central charge, so that the coset Virasoro algebra vanishes iff $c_K=0$. Furthermore, as was first shown in Ref. 5, the representation of $\tilde{\mathscr{L}}(\mathfrak{u})$ induced by a unitary highest weight representation of $\tilde{\mathscr{L}}(so(n))$ is finitely reducible, if and only if the coset Virasoro algebra vanishes.

It can be shown that $c_K=0$ is only possible for level 1 representations of $\tilde{\mathscr{L}}(so(n))$ (see, e.g., Ref. 6). In this case (23) reduces to

$$c_K=\frac{n}{2}-\sum_{s=0}^{S}\frac{2j_s \dim \mathfrak{u}_s}{2j_s+\omega_{ad_s}}, \quad \text{for } k_{so(n)}=1. \tag{24}$$

D. Indices of representations

The *index* κ_ρ *of a representation* ρ of a simple Lie algebra is defined as the ratio between the trace form of the representation and the normalized invariant form on the algebra, i.e.,

$$Tr(\rho(x)\rho(y))=\kappa_\rho(x|y). \tag{25}$$

For a simple Lie algebra $\mathfrak{g}$ or an Abelian subalgebra of a simple Lie algebra in an n-dimensional representation ρ of $\mathfrak{g}$, on which the Casimir operator is a scalar multiple of the identity, $\rho(\Omega)=\omega_\rho \mathrm{id}_n$ one gets by using (7) and (25):

$$\kappa_\rho \dim \mathfrak{g}=\omega_\rho n. \tag{26}$$

In particular, if ρ is the adjoint representation of a simple Lie algebra, then (26) yields for its index,

$$\kappa_{ad}=\omega_{ad}. \tag{27}$$

This equation also holds (trivially) for an Abelian Lie algebra, since in this case $\kappa_{ad}=\omega_{ad}=0$.

It can be shown that the index of the natural representation of $so(n)$ [i.e., the representation of $so(n)$ by antisymmetric $n\times n$-matrices] is 2 (see, e.g., Ref. 6). Let $\mathfrak{u}$ be a reductive subalgebra of $so(n)$ as in subsection II C. Then the index κ_{ρ_s} of the representation ρ_s of the ideal $\mathfrak{u}_s$ obtained by restricting the natural representation of $so(n)$ to $\mathfrak{u}_s$ is determined by

$$Tr(\rho_s(x)\rho_s(y))=2(x|y)_{so(n)}=2j_s(x|y)_s, \quad \forall x,y\in\mathfrak{u}_s,$$

i.e.

$$\kappa_{\rho_s}=2j_s. \tag{28}$$

Note that with our choice of $(.|.)_0$ the definition of the index makes sense also for the Abelian subalgebra $\mathfrak{u}_0$ in the representation ρ_0 and we get $\kappa_0=2$.

E. Infinitesimal symmetric spaces

Let $\mathfrak{g}$ be a semi-simple Lie algebra and let σ be an *involution* of $\mathfrak{g}$, i.e. an automorphism of $\mathfrak{g}$ of order 2: $\sigma^2=\mathrm{id}$. Let

$$\mathfrak{g}=\mathfrak{g}_0\oplus\mathfrak{g}_1$$

be the decomposition of $\mathfrak{g}$ into eigenspaces of σ,

$$\mathfrak{g}_0=\{x\in\mathfrak{g}|\sigma(x)=x\},\quad \mathfrak{g}_1=\{x\in\mathfrak{g}|\sigma(x)=-x\},$$

then $\mathfrak{g}/\mathfrak{g}_0\cong\mathfrak{g}_1$ is called an *infinitesimal symmetric space.*

Under the above conditions the following relations hold:

$$[\mathfrak{g}_0,\mathfrak{g}_0]\subseteq\mathfrak{g}_0,\quad [\mathfrak{g}_0,\mathfrak{g}_1]\subseteq\mathfrak{g}_1,\quad [\mathfrak{g}_1,\mathfrak{g}_1]\subseteq\mathfrak{g}_0. \tag{29}$$

This means that the Lie algebra $\mathfrak{g}$ is $\mathbb{Z}/2\mathbb{Z}$-graded. On the other hand, given a $\mathbb{Z}/2\mathbb{Z}$-gradation on $\mathfrak{g}$ [i.e., a decomposition $\mathfrak{g}=\mathfrak{g}_0\oplus\mathfrak{g}_1$ such that (29) holds], then an involution σ of $\mathfrak{g}$ is defined by letting $\sigma(x)=x$ for all $x\in\mathfrak{g}_0$ and $\sigma(x)=-x$ for all $x\in\mathfrak{g}_1$. Thus the infinitesimal symmetric spaces can equivalently be defined by (29).

Since the Killing form is invariant under automorphisms, we have

$$Tr(ad(x)ad(y))=Tr(ad(\sigma(x))ad(\sigma(y)))=-Tr(ad(x)ad(y)),\quad \forall x\in\mathfrak{g}_0,y\in\mathfrak{g}_1. \tag{30}$$

Thus $\mathfrak{g}_0$ and $\mathfrak{g}_1$ are orthogonal with respect to the Killing form on $\mathfrak{g}$ and the restriction of the Killing form to $\mathfrak{g}_0$, respectively, to $\mathfrak{g}_1$ is nondegenerate.

The list of all symmetric spaces is due to Cartan. A derivation based on Kac's classification of finite order automorphisms of semisimple Lie algebras can be found in Ref. 7; cf. also Ref. 1.

F. The underlying real representation of an orthogonal representation

A complex representation of a compact Lie group U is called *orthogonal* if there exists a nondegenerate symmetric bilinear form $(.|.)$ on the representation space $\mathfrak{p}$, such that

$$(g(x)|g(y))=(x|y),\quad \forall g\in U,x,y\in\mathfrak{p}, \tag{31}$$

i.e. the form is *invariant* under U. By choosing an orthonormal base of $\mathfrak{p}$ with respect to $(.|.)$ we get a matrix representation of U by orthogonal matrices. If U is connected and the orthogonal representation is faithful, this gives an embedding of U in $SO(n)$.

On the Lie algebra level the invariance property is the following:

$$(u(x)|y)=-(x|u(y)),\quad \forall u\in\mathfrak{u},\quad x,y\in\mathfrak{p}, \tag{32}$$

for example (3) is equivalent to this equation in the special case of the adjoint representation. Since the Killing form is invariant under the adjoint action and since it is nondegenerate for a semisimple Lie algebra, the adjoint representation of a semisimple Lie algebra $\mathfrak{g}$ is an orthogonal representation.

In the case of a $\mathbb{Z}/2\mathbb{Z}$-graded Lie algebra, the representation of $\mathfrak{g}_0$ on $\mathfrak{g}_1$ is an orthogonal representation, the restriction of the Killing form to $\mathfrak{g}_1$ being an invariant form.

It is well known (see, e.g., Ref. 8, Prop. (6.4)), that every complex orthogonal representation of a compact Lie group U is the complexification of a real representation of U. This means that there exists a real subspace $\mathfrak{p}^{\mathbb{R}}$ of $\mathfrak{p}$, invariant under the group action $[U(\mathfrak{p}^{\mathbb{R}})\subseteq\mathfrak{p}^{\mathbb{R}}]$, such that

$$\mathfrak{p}=\mathfrak{p}^{\mathbb{R}}\oplus i\mathfrak{p}^{\mathbb{R}}$$

as a real vector space, (i.e., each element of $p\in\mathfrak{p}$ can be uniquely decomposed as $p=x+iy$ with $x,y\in\mathfrak{p}^{\mathbb{R}}$) and such that

$$u(x+iy)=u(x)+iu(y),\quad \forall u\in U,\quad x,y\in\mathfrak{p}^{\mathbb{R}}.$$

Although $\mathfrak{p}^{\mathbb{R}}$ is in general not uniquely determined as a real subspace of $\mathfrak{p}$, its isomorphic type as a real U-module is uniquely determined by the isomorphic type of the complex U-module $\mathfrak{p}$, since $\mathfrak{p}$ is isomorphic to $\mathfrak{p}^{\mathbb{R}} \oplus \mathfrak{p}^{\mathbb{R}}$ as a real U-module.

III. THE SYMMETRIC SPACE THEOREM

The following assumptions and notations shall be valid for the whole section: Let U be a compact Lie group and let the reductive Lie algebra $\mathfrak{u} = \mathfrak{u}_0 \oplus \mathfrak{u}_1 \oplus \ldots \oplus \mathfrak{u}_S$ with center $\mathfrak{u}_0$ and simple ideals $\mathfrak{u}_1, \ldots, \mathfrak{u}_S$ be the complexification of the Lie algebra of U. Let $\{u^i\}_{i=1,\ldots,\dim \mathfrak{u}}$ be a base for $\mathfrak{u}$ consisting of anti-Hermitian elements, which is the union of bases $\{u^i\}_{i \in I_s}$ for the ideals $\mathfrak{u}_s$ such that $(u^i | u^j) = -\delta_{ij}$ for $i, j \in I_s$. (This is possible since on the real subalgebra of anti-Hermitian elements the normalized invariant form is negative definite.) For $i \in \{1, \ldots, \dim \mathfrak{u}\}$ let $s(i)$ denote the index of the ideal, which contains the element u^i, $u^i \in \mathfrak{u}_{s(i)}$, such that $0 \leqslant s(i) \leqslant S$.

Before stating the theorem I shall prove three lemmas, which will be needed for its proof, but can also be useful by themselves.

Lemma 1: The following equation holds in the universal enveloping algebra $\mathfrak{U}(\mathfrak{u})$ *and thus in any representation of* $\mathfrak{u}$*:*

$$2 \sum_{i \in I_s} u^i u^j u^i = -2\Omega_s u^j + \delta_{s(j),s} \omega_{ad_s} u^j, \quad \text{for } 0 \leqslant s \leqslant S, \quad 1 \leqslant j \leqslant \dim \mathfrak{u}, \tag{33}$$

where Ω_s *denotes the quadratic Casimir operator of the ideal* $\mathfrak{u}_s$.

Proof: The quadratic Casimir operator of $\mathfrak{u}_s$ can be written as

$$\Omega_s = -\sum_{i \in I_s} (u^i)^2.$$

Applying $ad_{\mathfrak{u}}(\Omega_s)$ to u^j gives $\omega_{ad_s} u^j$, if $u^j \in \mathfrak{u}_s$ and 0 otherwise, since $[u^i, u^j] = 0$ for $s(i) \neq s(j)$. Therefore,

$$\begin{aligned} ad_{\mathfrak{u}}(\Omega_s) u^j = \delta_{s(j)s} \omega_{ad_s} u^j &= -\sum_{i \in I_s} ad(u^i)^2 (u^j) \\ &= -\sum_{i \in I_s} [u^i [u^i, u^j]] \\ &= -\sum_{i \in I_s} (u^i (u^i u^j - u^j u^i) - (u^i u^j - u^j u^i) u^i) \\ &= -\sum_{i \in I_s} ((u^i)^2 u^j - u^i u^j u^i - u^i u^j u^i + u^j (u^i)^2) \\ &= 2\Omega_s u^j + 2 \sum_{i \in I_s} u^i u^j u^i, \end{aligned}$$

where we used that Ω_s commutes with u^j. □

Applying (33) again to u^j and summing over j, we immediately get the following corollary.

Corollary 1: *The sum of the elements* $(u^i u^j)^2$ *lies in the center of* $\mathfrak{U}(u)$ *and is given in terms of the quadratic Casimir operators as follows:*

$$2 \sum_{i \in I_s} \sum_{j \in I_t} (u^i u^j)^2 = (2\Omega_t - \delta_{st} \omega_{ad_s}) \Omega_s, \quad \text{for } 0 \leqslant s, t \leqslant S. \tag{34}$$

By taking the trace of equation (34) we immediately get the following corollary, which will be used in the proof of the next lemma.

Corollary 2: *In any n-dimensional matrix representation of* $\mathfrak{u}$, *such that the operators* u^i *are represented by matrices* M^i *and such that the quadratic Casimir operator* Ω_s *of the ideal* $\mathfrak{u}_s$ *acts as a scalar* $\omega_s id_n$ *for* $s=0,\ldots,S$, *the following identity holds:*

$$2\sum_{i\in I_s}\sum_{j\in I_t} Tr((M^iM^j)^2)=(2\omega_t-\delta_{st}\omega_{ad_s})\omega_s n, \quad \text{for } 0\leqslant s,t\leqslant S. \tag{35}$$

The following further assumptions and notations shall again be valid in the sequel.

Let $\mathfrak{p}$ be a faithful n-dimensional orthogonal complex representation of the compact group U. This defines an embedding of U into $SO(n)$ and we shall thus view U as a subgroup of $SO(n)$. Let $\{p_\alpha\}_{\alpha=1,\ldots,n}$ be an orthonormal base of $\mathfrak{p}^{\mathbb{R}}$. Let the application of the operators u^i on the basis p_α be described by the real antisymmetric matrices M^i, as follows:

$$u^i(p_\alpha)=\sum_{\gamma=1}^{n} M^i_{\gamma\alpha}p_\gamma. \tag{36}$$

Furthermore let y_s denote the index of the representation of $\mathfrak{u}_s$ on $\mathfrak{u}\oplus\mathfrak{p}$.

To evaluate y_s we note that (a) the index of a direct sum of representations is the sum of the indices of the direct summands and (b) the index of the adjoint action of $\mathfrak{u}_s$ on $\mathfrak{u}$ is ω_{ad_s}, because of (27), and since the adjoint action of $\mathfrak{u}_s$ on the sum of the $\mathfrak{u}_t$ with $t\neq s$ is trivial. Denoting the index of the representation of the ideal $\mathfrak{u}_s$ on $\mathfrak{p}$ by κ_s (instead of κ_{ρ_s}), we get

$$y_s=\omega_{ad_s}+\kappa_s=\omega_{ad_s}+2j_s. \tag{37}$$

It follows that $y_s>0$ for $s=0,\ldots,S$.

We assume that the underlying real representation $\mathfrak{p}^{\mathbb{R}}$ of $\mathfrak{p}$ is irreducible. This holds, for example, if $\mathfrak{p}$ is itself irreducible, but $\mathfrak{p}$ can also decompose as $\mathfrak{p}\cong\mathfrak{q}\oplus\mathfrak{q}^*$, where $\mathfrak{q}$ is some irreducible complex representation, such that $\mathfrak{q}\ncong\mathfrak{q}^*$. [The theorem also holds when $\mathfrak{p}^{\mathbb{R}}$ is reducible, and it can be derived from the irreducible case (see, e.g., Ref. 6).]

It can be shown that under the assumption that $\mathfrak{p}^{\mathbb{R}}$ is irreducible as a U-module, the Casimir operators Ω_s act as real positive scalars on $\mathfrak{p}$, although $\mathfrak{p}$ is not irreducible as a module over $\mathfrak{u}_s$,

$$\rho(\Omega_s)=\omega_s \mathrm{id}_n, \quad \text{with } \omega_s>0. \tag{38}$$

Therefore, (26) and (35) hold in this situation.

Lemma 2: *Let V be a level one representation space of the affine algebra* $\tilde{\mathfrak{L}}(so(n))$. *Let* $c_{\mathfrak{u}}$ *denote the central element of the Virasoro algebra constructed from* $\tilde{\mathfrak{L}}(\mathfrak{u})$ *by the Sugawara construction on V and let* c_K *denote the central element of the coset Virasoro algebra on V. Furthermore, let*

$$J_{\alpha\beta\gamma\delta}:=\sum_{s=0}^{S}\frac{1}{y_s}\sum_{i\in I_s}(M^i_{\gamma\beta}M^i_{\delta\alpha}+M^i_{\beta\alpha}M^i_{\delta\gamma}+M^i_{\alpha\gamma}M^i_{\delta\beta}), \tag{39}$$

where M is defined in (36), then the following identity holds:

$$\sum_{\alpha\beta\gamma\delta}(J_{\alpha\beta\gamma\delta})^2=\frac{6}{n}c_{\mathfrak{u}}c_K. \tag{40}$$

Proof: First let us bring c_K and $c_{\mathfrak{u}}$ in the form that is most adequate to the following calculations. Substituting (28) in (24) we get

$$c_K=\frac{n}{2}-\sum_{s=0}^{S}\frac{\kappa_s \dim \mathfrak{u}_s}{\kappa_s+\omega_{ad_s}} \overset{(26)(37)}{=} \frac{n}{2}-\sum_{s=0}^{S}\frac{n\omega_s}{y_s}. \tag{41}$$

For $c_{\mathfrak{u}}$ alone we have

$$c_{\mathfrak{u}}=\sum_{s=0}^{S}\frac{n\omega_s}{y_s}>0. \tag{42}$$

The sums

$$J^i_{\alpha\beta\gamma\delta}:=M^i_{\gamma\beta}M^i_{\delta\alpha}+M^i_{\beta\alpha}M^i_{\delta\gamma}+M^i_{\alpha\gamma}M^i_{\delta\beta}, \tag{43}$$

are invariant under cyclic permutation of the indices α,β,γ: $J^i_{\alpha\beta\gamma\delta}=J^i_{\gamma\alpha\beta\delta}=J^i_{\beta\gamma\alpha\delta}$, so that

$$\begin{aligned}\frac{1}{3}\sum_{\alpha,\beta,\gamma,\delta}J^i_{\alpha\beta\gamma\delta}J^i_{\alpha\beta\gamma\delta}&=\sum_{\alpha,\beta,\gamma,\delta}J^i_{\alpha\beta\gamma\delta}M^j_{\gamma\beta}M^j_{\delta\alpha}\\&=\sum_{\alpha,\beta,\gamma,\delta}(M^i_{\gamma\beta}M^i_{\delta\alpha}+M^i_{\beta\alpha}M^i_{\delta\gamma}+M^i_{\alpha\gamma}M^i_{\delta\beta})M^j_{\gamma\beta}M^j_{\delta\alpha}\\&=(Tr(M^iM^j))^2-2Tr((M^iM^j)^2)\\&=\delta_{ij}\kappa^2_{s(i)}-2Tr((M^iM^j)^2),\end{aligned} \tag{44}$$

where κ_s is the index of the representation of $\mathfrak{u}_s$ on $\mathfrak{p}$. For the third equality I used the antisymmetry of the matrices M^i. Using (44) we get

$$\begin{aligned}\frac{1}{3}\sum_{\alpha,\beta,\gamma,\delta}(J_{\alpha\beta\gamma\delta})^2&=\frac{1}{3}\sum_{s,t=0}^{S}\frac{1}{y_sy_t}\sum_{i\in I_s,j\in I_t}\sum_{\alpha,\beta,\gamma,\delta}J^i_{\alpha\beta\gamma\delta}J^j_{\alpha\beta\gamma\delta}\\&\overset{(44)}{=}\sum_{s=0}^{S}\frac{\kappa_s^2\dim\mathfrak{u}_s}{y_s^2}-\sum_{s,t=0}^{S}\frac{2}{y_sy_t}\sum_{i\in I_s,j\in I_t}Tr((M^iM^j)^2)\\&\overset{(26)(35)}{=}\sum_{s=0}^{S}\left(\frac{\kappa_s\omega_sn}{y_s^2}-\sum_{t=0}^{S}\frac{(2\omega_t-\delta_{st}\omega_{ad_s})\omega_sn}{y_sy_t}\right)\\&\overset{(37)}{=}\sum_{s=0}^{S}\frac{\omega_sn}{y_s}\left(\frac{\kappa_s+\omega_{ad_s}}{y_s}-\sum_{t=0}^{S}\frac{2\omega_t}{y_t}\right)\\&=\left(\sum_{s=0}^{S}\frac{\omega_sn}{y_s}\right)\left(1-\sum_{t=0}^{S}\frac{2\omega_t}{y_t}\right)\\&\overset{(41)}{=}c_{\mathfrak{u}}\cdot\frac{2c_K}{n}.\end{aligned}$$

□

The following lemma was shown in Ref. 1.

Lemma 3: Suppose that $\mathfrak{g}\equiv\mathfrak{u}\oplus\mathfrak{p}$ *forms a* $\mathbb{Z}/2\mathbb{Z}$*-graded algebra, as in (29) with* $\mathfrak{g}_0=\mathfrak{u}$ *and* $\mathfrak{g}_1=\mathfrak{p}$*, which is related to the given orthogonal* $\mathfrak{u}$*-module-structure on* $\mathfrak{u}\oplus\mathfrak{p}$ *as follows.*

• *The Killing form of* $\mathfrak{g}$ *coincides on* $\mathfrak{p}\times\mathfrak{p}$ *with the given orthogonal inner product, i.e.,* $Tr(ad_{\mathfrak{g}}(p_\alpha)ad_{\mathfrak{g}}(p_\beta))=\delta_{\alpha,\beta}$, $\forall 1\leqslant\alpha,\beta\leqslant n$.

• *The restriction of the adjoint representation of* $\mathfrak{g}$ to $\mathfrak{u}$ *coincides with the given* $\mathfrak{u}$*-module structure of* $\mathfrak{u}\oplus\mathfrak{p}$*, i.e.,*

$$[u^i,u^j+p_\alpha]_{\mathfrak{g}}=[u^i,u^j]_{\mathfrak{u}}+u^i(p_\alpha)=[u^i,u^j]_{\mathfrak{u}}+\sum_\gamma M^i_{\gamma\alpha}p_\gamma,\quad \forall 1\leqslant i,j\leqslant \dim\,\mathfrak{u},\quad 1\leqslant\alpha\leqslant n, \tag{45}$$

where $[.,.]_{\mathfrak{g}}$ *and* $[.,.]_{\mathfrak{u}}$ *denote the Lie products on* $\mathfrak{g}$ and $\mathfrak{u}$, *respectively. Then the Lie product on* $\mathfrak{p}$ *is given by*

$$[p_\alpha,p_\beta]_{\mathfrak{g}}=\sum_{i=1}^{\dim\,\mathfrak{u}}\frac{1}{y_{s(i)}}M^i_{\alpha\beta}u^i. \tag{46}$$

Proof: The invariance (3) of the Killing form means that

$$Tr(ad(u^i)ad([p_\alpha,p_\beta]))=Tr(ad([u^i,p_\alpha])ad(p_\beta)). \tag{47}$$

Since $[\mathfrak{g}_1,\mathfrak{g}_1]\subseteq\mathfrak{g}_0$ by assumption, we must have $[p_\alpha,p_\beta]=\sum_{j=1}^{\dim\,\mathfrak{u}}X^j_{\alpha\beta}u^j$, where the $X^j_{\alpha\beta}$ are some constants, such that $X^j_{\alpha\beta}=-X^j_{\beta\alpha}$. These constants can be determined by equating the l.h.s. of (47),

$$\sum_{j=1}^{\dim\,\mathfrak{u}}X^j_{\alpha\beta}Tr(ad(u^i)ad(u^j))=\sum_{j=1}^{\dim\,\mathfrak{u}}-X^j_{\alpha\beta}y_{s(i)}\delta_{ij}=-X^i_{\alpha\beta}y_{s(i)},$$

with the r.h.s. of (47),

$$Tr(ad([u^i,p_\alpha])ad(p_\beta))=\sum_{\gamma=1}^{n}M^i_{\gamma\alpha}Tr(ad(p_\gamma)ad(p_\beta))=\sum_{\gamma=1}^{n}M^i_{\gamma\alpha}\delta_{\gamma\beta}=M^i_{\beta\alpha}.$$

It follows that

$$X^i_{\alpha\beta}=-\frac{1}{y_{s(i)}}M^i_{\beta\alpha}=\frac{1}{y_{s(i)}}M^i_{\alpha\beta}. \qquad \square$$

Symmetric Space Theorem (Goddard, Nahm, Olive): *Let U be a compact Lie group with a faithful n-dimensional orthogonal representation on* $\mathfrak{p}$. *Consider the Lie algebra* $\mathfrak{u}$ *of U as a subalgebra of so(n) with the inclusion of* $\mathfrak{u}$ *in so(n) induced by the representation on* $\mathfrak{p}$. *Let* c_K *denote the central element of the coset Virasoro algebra on a level one representation space of* $\widetilde{\mathscr{L}}(so(n))$.

Then c_K vanishes if and only if $\mathfrak{g}\equiv\mathfrak{u}\oplus\mathfrak{p}$ carries the structure of a $\mathbb{Z}/2\mathbb{Z}$-graded Lie algebra with $\mathfrak{g}_0=\mathfrak{u}$ and $\mathfrak{g}_1=\mathfrak{p}$, which is related to the given orthogonal $\mathfrak{u}$-module-structure on $\mathfrak{u}\oplus\mathfrak{p}$ as in Lemma 3.

Proof: The conditions of the theorem, in view of Lemma 3, leave no freedom in defining the Lie product $[.,.]_{\mathfrak{g}}$, if it exists: This is because these conditions already uniquely determine a bilinear antisymmetric product on $\mathfrak{g}=\mathfrak{u}\oplus\mathfrak{p}$, as follows:

$$[u^i,u^j]_{\mathfrak{g}}=[u^i,u^j]_{\mathfrak{u}},$$

$$[u^i,p_\alpha]_{\mathfrak{g}}=\sum_{\gamma=1}^{n}M^i_{\gamma\alpha}p_\gamma=-[p_\alpha,u^i]_{\mathfrak{g}},$$

$$[p_\alpha,p_\beta]_{\mathfrak{g}}=\sum_{i=1}^{\dim\,\mathfrak{u}}\frac{1}{y_{s(i)}}M^i_{\alpha\beta}u^i$$

(cf. Lemma 3). Therefore, the proof of the theorem boils down to showing, that c_K vanishes if and only if this bilinear antisymmetric product on $\mathfrak{g}$ obeys the Jacobi identity.

It can easily be shown from the assumptions that the Jacobi identity holds for any three elements, if at least one of them lies in $\mathfrak{u}$. Therefore, $\mathfrak{g}$ is a Lie algebra iff the Jacobi identity holds on its $\mathfrak{p}$ part, i.e., iff

$$0=[p_\alpha,[p_\beta,p_\gamma]]+[p_\gamma,[p_\alpha,p_\beta]]+[p_\beta,[p_\gamma,p_\alpha]]=\sum_{\delta=1}^{n} J_{\alpha\beta\gamma\delta}p_\delta, \quad \forall\,\alpha,\beta,\gamma, \tag{48}$$

where we used the equation

$$[p_\alpha,[p_\beta,p_\gamma]]=\sum_{\delta=1}^{n}\left(\sum_{i=1}^{\dim \mathfrak{u}} \frac{M^i_{\gamma\beta}M^i_{\delta\alpha}}{y_{s(i)}}\right)p_\delta,$$

which follows from Lemma 3.

Thus, the Jacobi identity (48) is equivalent to the condition

$$J_{\alpha\beta\gamma\delta}=0, \quad \forall\,\alpha,\beta,\gamma,\delta. \tag{49}$$

But since the M^i are real, the $J_{\alpha\beta\gamma\delta}$ are also real. Therefore, each individual $J_{\alpha\beta\gamma\delta}$ vanishes if and only if the sum of the squares $(J_{\alpha\beta\gamma\delta})^2$ on the l.h.s. of (40) vanishes. But since by Lemma 2 this sum is equal to $(6/n)c_{\mathfrak{u}}c_K$ and $c_{\mathfrak{u}}$ is always positive, it follows that (49) is equivalent to the vanishing of c_K:

$$c_K=0, \quad \text{iff } J_{\alpha\beta\gamma\delta}=0, \quad \forall\,\alpha,\beta,\gamma,\delta. \tag{50}$$

□

The equivalence (50) was shown in Ref. 5 using the quark model construction. This result and the observation that (49) is equivalent to a Jacobi identity led to the symmetric space theorem.[1]

(Received 28 September 1995; accepted for publication 3 January 1996)

The main result in this paper is the character formula for arbitrary irreducible highest weight modules of $\mathscr{W}$ algebras. The key ingredient is the functor provided by quantum Hamiltonian reduction, which constructs the $\mathscr{W}$ algebras from affine Kac–Moody (KM) algebras and in a similar fashion $\mathscr{W}$ modules from KM modules. Assuming certain properties of this functor, the $\mathscr{W}$ characters are subsequently derived from the Kazhdan–Lusztig conjecture for KM algebras. The result can be formulated in terms of a double coset of the Weyl group of the KM algebra: the Hasse diagrams give the embedding diagrams of the Verma modules and the Kazhdan–Lusztig polynomials give the multiplicities in the characters. © *1996 American Institute of Physics.* [S0022-2488(96)00607-X]

I. INTRODUCTION

The $\mathscr{W}$ algebras were introduced more than a decade ago as (higher spin) extensions of the Virasoro algebra in the context of two-dimensional conformal field theory.[1] Analogous to the Virasoro algebra, one expects that the representation theory of $\mathscr{W}$ algebras plays a crucial role in applications such as in conformal field theories with $\mathscr{W}$ symmetry, and in theories where the $\mathscr{W}$ symmetry is gauged ($\mathscr{W}$ strings and $\mathscr{W}$ gravity) (see Refs. 2 and 3 for reviews). For these applications, the relevant representations are highest weight modules. A basic goal is therefore to describe the irreducible modules, and more specifically to compute their characters.

There exists a general approach to find the irreducible characters from the characters of Verma modules. Any Verma module $M(x)$ can be decomposed into irreducible highest weight modules $L(y)$ (local composition series). This gives rise to character formulas of the form

$$\mathrm{ch}\ M(x)=\sum_y m_{xy}\ \mathrm{ch}\ L(y), \tag{1}$$

where m is a matrix whose entries m_{xy} count the number of times that $L(y)$ appears in the decomposition of $M(x)$. Doing this for all $M(x)$ such that m can be inverted gives

$$\mathrm{ch}\ L(x)=\sum_y m^{-1}_{xy}\ \mathrm{ch}\ M(y). \tag{2}$$

The characters of Verma modules are in general easy to compute, hence the computation of the characters of the irreducible modules boils down to determining the multiplicities m_{xy}.

This general program has been applied successfully to the Virasoro algebra.[4] The key ingredient there is that every submodule of a Verma module is a sum of Verma modules. Since there is at most one embedding between Verma modules, this implies that the multiplicities m_{xy} are 0 or 1, and the irreducible characters follow directly from the embedding pattern of the Verma modules. These embedding patterns are completely classified, and, consequently for the Virasoro algebra, the characters of *all* irreducible highest weight modules are known.

For $\mathscr{W}$ algebras the submodule structure of Verma modules is much more complicated: in general submodules are not sums of Verma modules. Therefore the embedding patterns of the Verma modules do not determine the irreducible characters. This is directly related to the occurrence of multiplicities $m_{xy}>1$.

There are, of course, also other approaches. For instance, for the $\mathscr{W}_N$ minimal models, the irreducible character $\mathrm{ch}\,L(x)$ (for x inside the Kac table) has been determined directly, using free-field methods.[5] In terms of the multiplicities this amounts to having computed a single row of m^{-1}. It does not appear to be possible to apply these methods to compute the other rows, which is necessary to determine the characters of all irreducible highest weight modules (i.e., also for x outside or on the boundary of the Kac table). In a way, the results of Ref. 5 for $\mathscr{W}_N$ algebras amount to having the $\mathscr{W}$ analog of the Weyl–Kac character formula for affine Kac–Moody (KM) algebras.

For affine KM algebras the characters are known beyond the Weyl–Kac character formula. For $k+h^\vee\neq 0$ the program described above has been fully completed. The result can be summarized as follows:

(i) The weights y appearing in the decomposition (1) are determined by a subgroup of the affine Weyl group, and the associated Bruhat ordering [the Kac–Kazhdan (KK) condition[6]].

(ii) The multiplicities m_{xy} are given in terms of the Kazhdan–Lusztig polynomials associated to the affine Weyl group [the Kazhdan–Lusztig (KL) conjecture[7,8]].

The main ingredient in the proof of (i) is the Jantzen filtration, whereas (ii) has been proven using the intersection cohomology of Schubert varieties (only for integral weights; for other weights it is still a conjecture). Neither of these concepts seems to have been worked out for $\mathscr{W}$ algebras.

It is now interesting to note that $\mathscr{W}$ algebras and KM algebras are intimately related. In particular, a large class of $\mathscr{W}$ algebras can be obtained from affine KM algebras by (quantum) Hamiltonian reduction, where one imposes certain constraints on the KM generators (see Ref. 9 for a review). In this way a $\mathscr{W}$ algebra can be constructed for every embedding of sl_2 into the simple Lie algebra underlying the affine KM algebra.[10] The quantum construction naturally allows for a Becchi–Rouet–Stora–Tyutin (BRST) formulation, in which the $\mathscr{W}$ algebra arises as the BRST cohomology of a complex involving the KM algebra.[11–13] Of course, given an sl_2 embedding, one can also compute the cohomology of a KM module. By construction, the result will be a module of the corresponding $\mathscr{W}$ algebra. Thus, one obtains in a natural way a functor from KM modules to $\mathscr{W}$ modules. The action of this ''reduction functor'' is, in general, hard to compute. In Ref. 12, the action on (resolutions of) admissible KM modules was computed for principal sl_2 embeddings, assuming certain properties of the reduction functor. This way the characters of the W_N minimal models are recovered.

The main new idea in this paper is to apply the reduction functor to ''arbitrary'' KM modules, to find the analogs of the general results (i) and (ii) for $\mathscr{W}$ algebras. The result is a natural generalization of the KL conjecture to $\mathscr{W}$ algebras associated to arbitrary sl_2 embeddings. We show how this ''KL conjecture for $\mathscr{W}$ algebras'' can be derived from the KL conjecture for KM algebras, assuming similar properties as in Ref. 12 of the reduction functor. These assumptions are motivated by the results[14] for finite $\mathscr{W}$ algebras. The upshot is that *all* irreducible characters for such $\mathscr{W}$ algebras are thereby determined. We verified the conjecture for a nontrivial set of $\mathscr{W}_3$ modules.

The setup of this paper is as follows. In Sec. II, we review the representation theory and KL conjectures of affine KM algebras, including a discussion of the translation functor that serves as a helpful analogy with the reduction functor. Then in Sec. III, after some remarks on the representation theory of general $\mathscr{W}$ algebras, we present the main result of this paper in Sec. III C, the KL conjecture for $\mathscr{W}$ algebras. We also give an idea of how it can be derived using the reduction

functor. Several applications of the conjecture are discussed in Sec. IV. Properties of Coxeter groups and their KL polynomials are given in the Appendix.

II. THE KAZHDAN–LUSZTIG CONJECTURES FOR AFFINE KAC–MOODY ALGEBRAS

We first present a collection of results concerning affine KM algebras and their highest weight modules, leading to the KL conjectures. Virtually everything stated here can be found somewhere in the mathematical literature on the subject, or can be concluded directly from it. We have avoided a rigorous presentation, but instead focussed on the line of thought, and made clear what is well established and what is conjectured. For background and explanations on KM algebras and the structure of the highest weight modules we refer to Refs. 15 and 16, and for Weyl groups and KL polynomials to Ref. 17.

A. Composition series and character formulas

Let g be an affine KM algebra, and fix a triangular decomposition $g=n_+\oplus h\oplus n_-$ in positive root generators, Cartan subalgebra (CSA), and negative root generators. A singular vector v_λ is an eigenvector of the generators of the Cartan subalgebra h with weight $\lambda\in h^*$, and is annihilated by the positive root generators. A highest weight module is a module that is generated from a singular vector, the highest weight vector, by the action of the negative root generators. There are two important examples of highest weight modules. The first is the Verma module $M(\lambda)$, which is uniquely defined by the property that it is generated freely from v_λ. The second is the quotient of $M(\lambda)$ by its maximal proper submodule, which gives the unique irreducible highest weight module $L(\lambda)$.

Highest weight modules themselves are special examples of modules in the so-called category $\mathscr{O}$.[8,18] In general this category consists of modules V which have a weight space decomposition

$$V=\oplus_{\mu\leqslant\lambda}V_\mu, \tag{3}$$

where the μs satisfy $\mu\leqslant\lambda$ for λ in some finite subset of h^* (recall that $\mu\leqslant\lambda$ iff $\lambda-\mu$ is on the positive root lattice Q_+ of g) and $\dim V_\mu<\infty$. The category $\mathscr{O}$ contains highest weight modules, tensor products, submodules, quotients, etc.

For every module V in $\mathscr{O}$, one can define a (formal) character $\mathrm{ch}\,V$,

$$\mathrm{ch}\,V=\sum_\mu \dim V_\mu e^\mu, \tag{4}$$

where the formal exponentials satisfy $e^\lambda e^\mu=e^{\lambda+\mu}$ and $e^0=1$. The character of the Verma module $M(\lambda)$ is given by

$$\mathrm{ch}\,M(\lambda)=e^\lambda\sum_{\gamma\in Q_+}P(\gamma)e^{-\gamma}=e^\lambda\prod_{\alpha\in\Delta_+}(1-e^{-\alpha})^{-\dim g_\alpha}, \tag{5}$$

where g_α is the root space of root α, Δ_+ is the set of positive roots, and $P(\gamma)$ is the (generalized) Kostant partition function. One of the central problems of representation theory is to find the characters of the irreducible highest weight modules $L(\lambda)$. The strategy is to relate these to the explicit characters of Verma modules (5). This is possible due to the following general structure theorem, which also illustrates that $\mathscr{O}$ is natural in the context of highest weight modules [in particular, the $L(\lambda)$s are the only irreducibles in $\mathscr{O}$]. Every module V in the category $\mathscr{O}$ has a local composition series at any weight λ of V. A local composition series for V at λ is a sequence of submodules of V, $V=V_0\supset V_1\supset\cdots\supset V_{n-1}\supset V_n=0$, such that either $V_i/V_{i+1}\cong L(\mu)$ for some $\mu\geqslant\lambda$, or $(V_i/V_{i+1})_\mu=0$ for all $\mu\geqslant\lambda$. One denotes by $[V:L(\mu)]$ the number of times that $L(\mu)$ appears in the local composition series of V at λ. It is called the multiplicity of $L(\mu)$ in V. It is independent of the particular sequence of submodules one chooses. We stress that $[V:L(\mu)]$ does

not count the number of singular vectors at weight μ in V: the statement that $V_i/V_{i+1}\cong L(\mu)$ only requires that there is a vector v_μ which is singular in the quotient V_i/V_{i+1} but not necessarily singular in V_i, let alone V. A vector that is singular in a quotient of submodules is called primitive, and the corresponding weight is called a primitive weight. Obviously, a singular vector is also primitive, but it is important to realize that there are also other types of primitive vectors. We also stress that the multiplicities $[M:L]$ can be larger than 1, contrary to what was initially thought based on the known trivial multiplicities of the simple Lie algebras $\overline{g} = \overline{\mathrm{sl}}_2, \overline{\mathrm{sl}}_3$ and the affine KM algebra $g=\mathrm{sl}_2$.

At the level of characters, the local composition series implies that (4) is given by a sum over the irreducible characters: $\mathrm{ch}\, V=\Sigma_\mu [V:L(\mu)]\mathrm{ch}\, L(\mu)$, where the sum runs over the weights of V (of course, only the primitive weights give a nonvanishing contribution). This applies in particular to Verma modules, leading to

$$\mathrm{ch}\, M(\lambda)=\sum_{\mu\leqslant\lambda} [M(\lambda):L(\mu)]\mathrm{ch}\, L(\mu). \tag{6}$$

Note that the composition series starts with $[M(\lambda):L(\lambda)]=1$, since $\dim M(\lambda)_\lambda=1$. Ordering the set of weights $\mu\leqslant\lambda$ as $\lambda=\mu_0, \mu_1, \mu_2,...$, such that $j\geqslant i$ whenever $\mu_j\leqslant\mu_i$, one has the following set of equations:

$$\mathrm{ch}\, M(\mu_i)=\sum_{\mu_j\leqslant\mu_i} [M(\mu_i):L(\mu_j)]\mathrm{ch}\, L(\mu_j).$$

The matrix $[M(\mu_i):L(\mu_j)]$, called the Jantzen matrix (for λ), is upper triangular with ones on the main diagonal. Therefore, it can be inverted. Denoting the inverse matrix elements by $(L(\mu_i):M(\mu_j))$ (which are possibly negative integers), one finds

$$\mathrm{ch}\, L(\mu_i)=\sum_{\mu_j\leqslant\mu_i} (L(\mu_i):M(\mu_j))\mathrm{ch}\, M(\mu_j).$$

In conclusion, from (6) one finds the character formula

$$\mathrm{ch}\, L(\lambda)=\sum_{\mu\leqslant\lambda} (L(\lambda):M(\mu))\mathrm{ch}\, M(\mu). \tag{7}$$

Here $\mathrm{ch}\, M(\mu)$ is given through (5). Computing $\mathrm{ch}\, L(\lambda)$ boils down to computing the numbers $(L(\lambda):M(\mu))$ for all $\mu\leqslant\lambda$ or, equivalently, the Jantzen matrix $[M(\mu_i):L(\mu_j)]$ for λ.

B. The Kac–Kazhdan conditions

The first step in determining the multiplicities $[M(\lambda):L(\mu)]$ is to find all pairs λ,μ such that $[M(\lambda):L(\mu)]\neq 0$. The general solution to this problem has been given by Kac and Kazhdan,[6] using the generalized Casimir of g and the Jantzen filtration of Verma modules.[15] For the purposes of this paper it is sufficient to consider only weights λ with $\langle\lambda+\rho,\delta\rangle=k+h^\vee\neq 0$. In that case the result of Ref. 6 can be rephrased in terms of properties of the affine Weyl group.[19]

The affine Weyl group W is a Coxeter group, generated by the simple reflections s_i where $s_i(\lambda)=\lambda-\langle\lambda,\alpha_i^\vee\rangle\alpha_i$ are the reflections in the simple roots α_i of g. Arbitrary elements $w\in W$ correspond to expressions $w = s_{i_1}s_{i_2}\cdots s_{i_k}$. The minimal number of simple reflections needed to generate w is called the length $\ell(w)$ of w. An expression of minimal length is called reduced. If $w,w'\in W$ are two reduced expressions, then we denote $w<w'$ if the reduced expression for w can be obtained by dropping simple reflections from a reduced expression for w'. The resulting relation $w\leqslant w'$ is a partial ordering of W, called the Bruhat ordering.

An important ingredient in what follows is the subgroup $W_\lambda \subset W$: it is the group generated by reflections $r_{\hat{\alpha}}$ with $\hat{\alpha} \in \Delta^{re}_{\lambda,+} = \{\alpha \in \Delta^{re}_+ | \langle \lambda+\rho, \alpha^\vee \rangle \in \mathbf{Z}\}$. Clearly, only if λ is integral, $W_\lambda = W$ (recall that $\rho \in h^*$ satisfies $\langle \rho, \alpha_i^\vee \rangle = 1$), otherwise W_λ will be a proper subgroup of W (which for affine W may be isomorphic to W). It can be shown that W_λ is again a Weyl group; it is generated by simple reflections $\hat{s}_i = r_{\hat{\alpha}_i}$ (simple in W_λ) where $\hat{\alpha}_i$ are the simple roots of the rootsystem $\Delta^{re}_{\lambda,+}$. The length function on W_λ is denoted $\ell_\lambda(w)$. Obviously, the relation between λ and W_λ is many-to-one; for instance, $W_\lambda = W_{\lambda+\mu}$ for arbitrary integral weight μ. In fact, up to isomorphisms, there is only a finite number of W_λ.[20]

The groups W_λ organize the nonvanishing multiplicities in the following way: the primitive weights of $M(\lambda)$ are on the shifted Weyl orbit $W_\lambda.\lambda$, where

$$w.\lambda \equiv w(\lambda+\rho) - \rho, \tag{8}$$

and vice versa. Only the lower weights (with respect to Bruhat ordering) on the orbit are primitive weights of $M(\lambda)$. In the remainder of this section we describe this in more detail.

First consider $k + h^\vee > 0$. Then every orbit $W_\mu.\mu$ has precisely one maximal element λ, the dominant weight, such that $w.\lambda \leqslant \lambda$ for all $w \in W_\mu$. Using (8) it is easy to see that such a dominant weight λ is characterized by

$$\langle \lambda+\rho, \hat{\alpha}_i^\vee \rangle \geqslant 0. \tag{9}$$

Clearly, there is a one-to-one correspondence between dominant weights λ and orbits $W_\lambda.\lambda$. There may not be a one-to-one correspondence between elements of W_λ and the weights on the orbit $W_\lambda.\lambda$. This happens precisely if there is a subgroup W^0_λ of W_λ which leaves λ invariant. Here W^0_λ is a finite parabolic subgroup of W_λ, generated by the simple reflections $r_{\hat{\alpha}_i}$ with $\hat{\alpha}_i$ satisfying $\langle \lambda+\rho, \hat{\alpha}_i^\vee \rangle = 0$. A dominant weight is called regular if W^0_λ is trivial, and it is called singular otherwise. Thus, weights on the orbit $W_\lambda.\lambda$ of a dominant weight are in one-to-one correspondence with elements of the coset

$$W_\lambda / W^0_\lambda, \tag{10}$$

i.e., any weight μ can be written uniquely as $\mu = w.\lambda$ with λ dominant and $w \in W_\lambda / W^0_\lambda$. This coset will be crucial in what follows: in particular *the multiplicities depend on* λ *only through the coset* W_λ / W^0_λ!

Denote $M_w = M(w.\lambda)$ and $L_w = L(w.\lambda)$. Then the Kac–Kazhdan condition for $k + h^\vee > 0$ can be described as follows:

$$[M_w : L_{w'}] \neq 0 \quad \text{iff} \quad w \leqslant w' \ \text{ with } \ w, w' \in W_\lambda / W^0_\lambda. \tag{11}$$

Here, the ordering on the coset W_λ / W^0_λ is induced from the Bruhat ordering on W_λ:

$$w \leqslant w' \ \text{ with } \ w, w' \in W_\lambda / W^0_\lambda \quad \text{iff} \quad \underline{w} \leqslant \underline{w}' \ \text{ with } \ \underline{w}, \underline{w}' \in W_\lambda. \tag{12}$$

[Here $\underline{w}$ is the minimal coset representative of w in the coset, defined through $\ell(\underline{ws}) > \ell(\underline{w})$ for all $s \in W^0_\lambda$. Of course we could also have chosen the maximal representatives $\overline{w}$ which have $\ell(\overline{ws}) < \ell(\overline{w})$ for all $s \in W^0_\lambda$.]

For the character formulas (6) and (7) the Kac–Kazhdan result implies the following. First of all, the sum over the weight space in (6) reduces to a sum over $w' \in W_\lambda / W^0_\lambda$:

$$\mathrm{ch}\, M_w = \sum_{w' \geqslant w} [M_w : L_{w'}] \mathrm{ch}\, L_{w'}. \tag{13}$$

Second, using transitivity of the Bruhat order this can be inverted

$$\mathrm{ch}\, L_w = \sum_{w' \geqslant w} (L_w : M_{w'})\, \mathrm{ch}\, M_{w'}\,. \tag{14}$$

Unlike the sum in (13) not all terms in this sum have to be nonvanishing.

For weights with $k+h^\vee<0$, the result can be rephrased analogously. We note that weights with $k+h^\vee<0$ are the image of weights with $k+h^\vee>0$ under the shifted inversion

$$\sigma.\lambda = -\lambda - 2\rho. \tag{15}$$

Clearly, $W_{\sigma.\lambda} = W_\lambda$, so σ is also a one-to-one map between the orbits on either side (orbits always belong to one side only as W leaves $k+h^\vee$ invariant). Since σ reverses the order of weights, every orbit now will have a minimal weight, called antidominant, which is of the form $\sigma.\lambda$ with λ dominant. In terms of these antidominant weights one has the analog of (11) describing the full KK condition for $k+h^\vee<0$:

$$[M_w : L_{w'}] \neq 0 \quad \text{iff} \quad w \geqslant w' \quad \text{with} \quad w, w' \in W_\lambda / W_\lambda^0. \tag{16}$$

Thus one finds the same character formulas (13) and (14), but with the sum over $w' \leqslant w$.

C. Embeddings of Verma modules

In the previous section we have discussed the role of the cosets W_λ / W_λ^0 in finding the primitive weights of a Verma module $M(\lambda)$. In this section we discuss how the same cosets also describe the embeddings between Verma modules.

This is based on the property of KM Verma modules that at every primitive weight there is at least one singular vector.[6] Since a singular vector v_μ in a Verma module $M(\lambda)$ gives rise to a homomorphism $M(\mu) \hookrightarrow M(\lambda)$ (embedding) between Verma modules, this statement implies that there is a homomorphism iff the multiplicity $[M(\lambda):L(\mu)]$ is nonvanishing. Hence

$$M_{w'} \hookrightarrow M_w \quad \text{iff} \quad w \leqslant w' \quad \text{with} \quad w, w' \in W_\lambda / W_\lambda^0. \tag{17}$$

In other words: the diagram representing the embeddings of the Verma modules is given by the Hasse diagram of the coset W_λ / W_λ^0: the vertices of this diagram are the elements of the coset and the links between the vertices connect the adjacent elements (two coset elements x,y are called adjacent if there is no third coset element z such that $x<z<y$). Since one can classify the Hasse diagrams, this gives a classification of embedding diagrams.

In fact, if $k+h^\vee \neq 0$, the relation between embeddings and the Hasse diagram is even stronger, because in that case there is at most one singular vector at every primitive weight. This implies that the homomorphism $M(\mu) \hookrightarrow M(\lambda)$ is unique, or

$$\dim \mathrm{Hom}(M(\mu), M(\lambda)) \leqslant 1. \tag{18}$$

This can be argued as follows. If there is a sequence $M(\mu_1) \hookrightarrow M(\mu_2) \hookrightarrow M(\mu_3)$ of homomorphisms, the embedding property implies that

$$\dim \mathrm{Hom}(M(\mu_1), M(\mu_3)) \geqslant \dim \mathrm{Hom}(M(\mu_2), M(\mu_3)). \tag{19}$$

For $k+h^\vee<0$, any Verma module contains always a lowest primitive weight (the antidominant weight). At this weight, there is precisely one singular vector (because any two embedded Verma modules necessarily overlap). This immediately implies (18).

For $k+h^\vee>0$, there is no lowest primitive weight. In that case (18) follows from the result for $k+h^\vee<0$ through the ''reflection principle'' of semi-infinite homology,[21]

$$\mathrm{Hom}(M(\mu), M(\lambda)) \simeq \mathrm{Hom}(M(\sigma.\lambda), M(\sigma \cdot \mu)). \tag{20}$$

D. Jantzen's translation functor

In this section we discuss how the multiplicities for *arbitrary* dominant weights follow from the multiplicities for *regular* dominant weights. The idea is to use Jantzen's translation functor[8,15] to map modules with regular weights (trivial W_λ^0) to modules with singular weights (nontrivial W_λ^0). The reason for highlighting this ingredient here is the striking similarity between this derivation and the derivation of $\mathscr{W}$ multiplicities from KM multiplicities using the reduction functor in Sec. III B.

Let λ' be a singular dominant weight, and let λ be a regular dominant weight such that $\lambda-\lambda'$ is an integral weight. Clearly, $W_\lambda = W_{\lambda'}$, but W_λ^0 is trivial whereas $W_{\lambda'}^0$ is not. The tensorproduct with the irreducible module associated with $\lambda'-\lambda$ gives rise to an exact functor[8,15,22] (the translation functor) that maps

$$M(w.\lambda) \overset{t}{\mapsto} M(w.\lambda'). \tag{21}$$

To obtain the action of the translation functor on irreducible modules, observe that for Verma modules $M(w'.\lambda) \hookrightarrow M(w.\lambda)$ with w,w' in the same coset, the functor maps the quotient $M(w.\lambda)/M(w'.\lambda)$ [which contains $L(w.\lambda')$] to zero, so it immediately follows that

$$L(w.\lambda) \overset{t}{\mapsto} L(w.\lambda')\,\delta_{\overline{w},w}\,. \tag{22}$$

(Here $\overline{w}$ is the maximal representative of w in the coset $W_\lambda / W_{\lambda'}^0$.) The maps (21) and (22) determine the multiplicities for singular weights from the multiplicities of the regular weights:

$$[M(w.\lambda'):L(w'.\lambda')] = [M(\overline{w}.\lambda):L(\overline{w'}.\lambda)]. \tag{23}$$

Another useful application of the translation functor is the computation of the character of the irreducible module L_e for regular dominant weights λ (without having to determine the full Jantzen matrix). For such weights namely, the sum in (14) runs over all the elements of W_λ. Applying (21) and (22) to it for a translation chosen such that $W_{\lambda'}^0$ contains just one reflection gives that the coefficients are given by $\varepsilon_w = (-1)^{l_\lambda(w)}$,[22] hence

$$\text{ch}\, L_e = \sum_{w \in W_\lambda} \varepsilon_w\, \text{ch}\, M_w\,. \tag{24}$$

This is the generalization of the Weyl–Kac formula[16] to arbitrary regular dominant weights. The same trick cannot be applied to obtain arbitrary characters (i.e., ch L_w or for λ singular). It is this particular character formula (for admissible λ) that forms the starting point of Ref. 12 for generalization to $\mathscr{W}$ algebras.

E. The KL conjectures

Now we are ready to describe the final step, i.e., to give the Kahdan–Lusztig formula for the multiplicities. In Ref. 7, Kazhdan and Lusztig defined for an arbitrary Coxeter group W a set of polynomials $P_{x,y}(q)$, labelled by pairs of elements x,y in W, and depending on a single variable q. For details and properties about the definition of these polynomials, see the Appendix. Important for us is that they can be computed explicitly from a recursion relation [see (A18)]

$$P_{x,ys} = q^{1-c} P_{xs,y} + q^c P_{x,y} - q \sum_{\substack{x \leqslant z < y \\ zs < z}} P_{x,z} P_{z,y}\,. \tag{25}$$

The simple reflection s is chosen such that $y<ys$, such that the polynomials $P_{x,y}$ are expressed in terms of polynomials $P_{x',y'}$ with $l(y')<l(y)$.

Similarly, one defines a set of inverse polynomials $Q_{x,y}(q)$ through

$$\sum_{x\leqslant z\leqslant w} P_{x,z}(q)Q_{z,y}(q)\epsilon_z\epsilon_y=\delta_{x,y}\,, \tag{26}$$

which can also be computed directly from a recursion relation [see (A18)]

$$Q_{x,ys}=cQ_{xs,y}+(-q)^cQ_{x,y}+cq\sum_{\substack{x<z\leqslant y\\ zs>z}}\mathcal{P}_{x,z}Q_{z,y}\,. \tag{27}$$

Analogously, one may also associate KL polynomials P^I,Q^I to a coset W/W_I for W_I a parabolic subgroup of W. If W_I is finite, these are related to the KL polynomials on W as follows:

$$P^I_{x,y}=P_{\underline{x},y},\quad Q^I_{x,y}=Q_{x,y}. \tag{28}$$

Here $\underline{z}$ and $\overline{z}$ are the minimal and maximal representatives of z in the coset $[z]$. In general, the polynomials P^I and Q^I are not each other's inverse. The inverse polynomials of P^I, Q^I are denoted $\widetilde{Q}^I$, $\widetilde{P}^I$; they are defined through

$$\sum_{x\leqslant z\leqslant y}\widetilde{Q}^I_{x,z}P^I_{z,y}=\sum_{x\leqslant z\leqslant y}Q^I_{x,z}\widetilde{P}^I_{z,y}=\delta_{x,y}\,. \tag{29}$$

They can also be expressed in terms of the polynomials on W:

$$\widetilde{P}^I_{x,y}=\sum_{z\in[x]}P_{z,y}\epsilon_z\epsilon_y,\quad \widetilde{Q}^I_{x,y}=\sum_{z\in[y]}Q_{\overline{x},z}\epsilon_{\overline{x}}\epsilon_z\,. \tag{30}$$

The KL conjectures relate the multiplicities in the character formulas to the value of these polynomials at $q=1$. Let λ be a dominant weight with coset W_λ/W^0_λ, $P_{w,w'}$ be the KL polynomials for W_λ, and $Q_{w,w'}$ be the associated inverse KL polynomials. Then the multiplicities are given by[7,8,15,23]

$$\begin{aligned} &k+h^\vee>0:\quad [M_w:L_{w'}]=P^I_{w,w'}(1),\quad (L_w:M_{w'})=\widetilde{Q}^I_{w,w'}(1)\\ &k+h^\vee<0:\quad [M_w:L_{w'}]=Q^I_{w',w}(1),\quad (L_w:M_{w'})=\widetilde{P}^I_{w',w}(1)\end{aligned}, \tag{31}$$

(the superscript I refers to the subgroup W^0_λ). These conjectures have been proven for integral weights, in Ref. 24 for $k+h^\vee>0$, and Ref. 25 for $k+h^\vee<0$. It is inconceivable that the conjectures for $k+h^\vee>0$ are related to the conjecture for $k+h^\vee<0$ through the semi-infinite cohomology of affine KM algebras.

The conjectures naturally fit in a circle of ideas generally referred to as Kazhdan–Lusztig theory. This theory interrelates many different problems, such as the classification of primitive ideals in enveloping algebras, the computation of the multiplicities in composition series, and the intersection cohomology of Schubert varieties (see Ref. 26 for an overview). It applies in particular to simple Lie algebras, affine KM algebras, and quantum groups. In Sec. III we show that it also applies to $\mathscr{W}$ algebras.

III. THE KL CONJECTURES FOR $\mathscr{W}$ ALGEBRAS

Compared to the situation for affine Kac–Moody algebras, relatively little is known about the representation theory of $\mathscr{W}$ algebras. The fact that a classification of such algebras is still lacking

makes it harder to give a general approach to this problem. We claim, however, that for the class of $\mathscr{W}$ algebras obtained through Hamiltonian reduction of affine KM algebras, the analog of most results described in Sec. II exists. In particular, we formulate the KL conjecture for such $\mathscr{W}$ algebras.

A. Some generalities on $\mathscr{W}$ algebras and modules

Let us first consider a general $\mathscr{W}$ algebra, generated by the modes of a finite set of quasiprimary fields (for a precise definition see Ref. 2). The $\mathscr{W}$ algebra will have a CSA h, i.e., a maximal Abelian subalgebra of the zero modes. Unlike for KM algebras, the adjoint action of h on the generators of the $\mathscr{W}$ algebra is, in general, not diagonalizable (e.g., the zero-mode W_0 of the spin three field of $\mathscr{W}_3$); therefore the ''triangular'' decomposition of $\mathscr{W}=\mathscr{W}_+\oplus h\oplus\mathscr{W}_-$, in positive root generators, Cartan subalgebra, and negative root generators is given with respect to a subalgebra $h'\subset h$:

$$\mathscr{W}=\oplus_{a'}\mathscr{W}_{-a'}\oplus h\oplus_{a'}\mathscr{W}_{a'}, \tag{32}$$

where a' runs over the set of positive roots Δ'_+. By assumption $\mathscr{W}_{-a'}\cong\mathscr{W}_{a'}$ as vector spaces, paired by an involutive map $\sigma:\mathscr{W}_{-a'}\to\mathscr{W}_{a'}$.

The setup of representation theory is similar to that of affine KM algebras, in the following sense. A singular vector v_a is an eigenvector of the generators of h with weight $a\in h^*$, and v_a is annihilated by all positive root generators. A highest weight module V is generated from v_a by the action of the negative root generators. Similarly, one introduces a category $\mathscr{O}$, which consists of modules V which have a weight space decomposition into a direct sum of weight spaces of the subalgebra h',

$$V=\oplus_{b'\leqslant a'}V_{b'}, \tag{33}$$

where the sum is over weights b' satisfying $b'\leqslant a'$ for a' in some finite subset of h'^*, and $\dim V_{b'}<\infty$ (note that $b'\leqslant a'$ iff $a'-b'$ is on the positive root lattice Q'_+ of h').

The category $\mathscr{O}$ again contains Verma modules $M(a)$, irreducible quotients $L(a)$, submodules, etc. (but no tensor products as, in general, the tensor product of two $\mathscr{W}$ modules is not a $\mathscr{W}$ module).

For every module V in $\mathscr{O}$ one can define a (formal) character ch V,

$$\mathrm{ch}\ V=\sum_{b'}\dim V_{b'}e^{b'}. \tag{34}$$

The Verma module $M(a)$ has character formula

$$\mathrm{ch}\ M(a)=e^{a'}\sum_{b'\in Q'_+}P(b')e^{-b'}=e^{a'}\prod_{b'\in\Delta'_+}(1-e^{-b'})^{-\dim\mathscr{W}_{b'}}, \tag{35}$$

where $P(b')$ is some generalized Kostant partition function.

The finite dimensionality of the weight spaces $V_{b'}$ implies that the action of the generators of the CSA h outside h' is reasonably well behaved: every weight space $V_{b'}$ can be decomposed into a finite number of Jordan blocks U_b,

$$V_{b'}=\oplus_b U_b. \tag{36}$$

This implies that one can make local composition series in $\mathscr{O}$, where the irreducible quotients are again the highest weight modules $L(b)$, occurring with multiplicities $[V:L(b)]$. This leads to

character formulas ch $V=\Sigma_b[V:L(b)]$ch $L(b)$, where of course b can only appear in the sum if b' is a weight of V. This applies in particular to a Verma module $M(a)$, leading to

$$\text{ch } M(a)=\sum_{b'\leqslant a'}[M(a):L(b)]\text{ch } L(b), \tag{37}$$

where clearly $[M(a):L(a)]=1$. Once again, this character formula can be inverted, such that the characters of irreducible modules can be expressed in characters of Verma modules

$$\text{ch } L(a)=\sum_{b'\leqslant a'}(L(a):M(b))\text{ch } M(b). \tag{38}$$

To conclude: also for $\mathscr{W}$ algebras, the general strategy to find character formulas is to compute the multiplicities $[M(a):L(b)]$. This is what we will do in the next section.

B. $\mathscr{W}$ modules from sl_2 reductions

A large class of $\mathscr{W}$ algebras can be obtained through a procedure of (quantum) Hamiltonian reduction of affine KM algebras.[9] A particularly nice set of reductions are those related to sl_2 embeddings.[10] For every sl_2 embedding into the simple Lie algebra underlying the untwisted affine KM algebra, one can define a BRST complex such that the associated cohomology is nonvanishing only in the zeroth term. This cohomology is a $\mathscr{W}$ algebra.[11–13]

Similarly, on the level of the representation theory, the cohomology of a complex associated to a KM module gives a $\mathscr{W}$ module. This defines a functor from the category of KM modules to the category of $\mathscr{W}$ modules. We assume the following properties of this reduction functor:[12,14] (1) the cohomology of the BRST complex associated to the KM module is nonvanishing only in the zeroth term, (2) KM Verma modules $M(\lambda)$ are mapped to $\mathscr{W}$ Verma modules $M(a(\lambda))$, and (3) a local composition series of a KM Verma module is mapped to a local composition series of the corresponding $\mathscr{W}$ Verma module.

From these assumptions it immediately follows that, when acting on KM irreducible modules, the reduction functor maps

$$L(\lambda)\to L(a(\lambda)) \quad \text{or} \quad L(\lambda)\to 0. \tag{39}$$

If one knows which $L(\lambda)$ have vanishing or nonvanishing cohomology, then the multiplicities of $\mathscr{W}$ Verma modules are determined. The main result of this paper is an explicit formula for these multiplicities, in terms of KL polynomials associated to a double coset which is completely fixed by the reduction data. Note that the reduction only gives rise to a $\mathscr{W}$ algebra for $k+h^\vee\neq 0$, i.e., precisely those weights for which the KM multiplicities are given by the KL conjecture. This implies that one has the complete KL conjecture for this class of $\mathscr{W}$ algebras, so that the characters of all irreducible highest weight $\mathscr{W}$ modules are known.

Let us explain how this should work. Associated to the particular sl_2-reduction is a regular subalgebra g_r of the finite-dimensional simple Lie algebra $\overline{g}$ underlying the affine Kac–Moody algebra g.[14] The sl_2 subalgebra is principally embedded into g_r. This embedding determines a set of constraints which can be chosen in such a way that they involve only positive roots. This is necessary to get nonvanishing cohomology from KM Verma modules. In explicit examples it is possible to verify that this cohomology is given by a Verma module of the corresponding $\mathscr{W}$ algebra.[12,14] We assume that this holds in general. From the results of Ref. 14 we expect that the parametrization $a(\lambda)$ of the $\mathscr{W}$ weight is invariant under the shifted action of the Weyl group W^r of g_r (which is a finite parabolic subgroup of W). More precisely,

$$a(w.\lambda)=a(\lambda) \quad \text{iff} \quad w\in W^r, \tag{40}$$

so there is a one-to-one correspondence between the $\mathscr{W}$ weights and the invariants of the Weyl group W^r. Using this parametrization we will from now on denote Verma modules and irreducible modules for the $\mathscr{W}$ algebra by $M^r(\lambda)$ and $L^r(\lambda)$ with λ a weight of g. Up to W^r invariance, the labelling by g weights fixes the $\mathscr{W}$ weights uniquely.

Let λ be a dominant weight. From the existence of the composition series it follows that the set of primitive weights in a $\mathscr{W}$ Verma module $M^r(\lambda)$ is contained in the orbit of the double coset

$$W^r_\lambda \backslash W_\lambda / W^0_\lambda, \tag{41}$$

where $W^r_\lambda = W^r \cap W_\lambda$. From the embedding property (17) of KM Verma modules it now follows that for each weight on this orbit there is an embedding of $\mathscr{W}$ Verma modules, thus there is a one-to-one correspondence between primitive weights and weights on the orbit of the double coset (41).

It is instructive to note the analogy with the translation functor discussed in Sec. II D: the translation functor maps regular KM Verma modules $M(\lambda)$ to arbitrary KM Verma modules $M(\lambda')$, such that the relevant cosets W_λ are mapped to $W_{\lambda'}/W^0_{\lambda'}$. Similarly, the reduction functor maps arbitrary KM Verma modules $M(\lambda)$ to arbitrary $\mathscr{W}$ Verma modules $M^r(\lambda)$, such that the relevant cosets W_λ/W^0_λ are mapped to $W^r_\lambda \backslash W_\lambda / W^0_\lambda$. Indeed, the derivation of the $\mathscr{W}$ multiplicities from KM multiplicities from this point on goes completely analogous to the derivation in Sec. II D.

The irreducible $\mathscr{W}$ module $L^r(\mu)$ may arise only as the cohomology of the KM modules $L(w.\mu)$ with $w \in W^r$. Obviously, the cohomology of the associated KM Verma modules $M(w.\mu)$ are identical. Therefore, the cohomology of $L(\mu)$ must vanish when there is a $w \in W^r_\mu$ such that $M(w.\mu) \subset M(\mu)$ with $w.\mu \neq \mu$. On every W^r_μ orbit of μ, only the lowest weight contributes therefore.

It follows that the reduction functor maps

$$M_w \to M^r_w, \quad L_w \to L^r_w \delta_{w,\overline{w}}, \tag{42}$$

where again $M^r_w = M^r(w.\lambda)$, $L^r_w = L^r(w.\lambda)$, and $\overline{w}$ is the maximal representative of w in the double coset (41).

Thus we observe that again the way to associate KL polynomials with the double coset (41) is to take maximal representatives.

To summarize, consider the $\mathscr{W}$ algebra associated with the regular subalgebra g_r. Let λ be a dominant weight, and let $w, w' \in W^r_\lambda \backslash W_\lambda / W^0_\lambda$. Denote the double coset of w by $[w]$, the minimal representatives by $\underline{w}$ and the maximal representative by $\overline{w}$, and define the following polynomials:

$$P^{IJ}_{w,w'} = P_{\overline{w},\overline{w'}}, \quad Q^{IJ}_{w,w'} = Q_{\underline{w},\underline{w}'}.$$
$$\widetilde{P}^{IJ}_{w,w'} = \sum_{x \in [w]} P_{x,\underline{w}'} \epsilon_x \epsilon_{\underline{w}'}, \quad \widetilde{Q}^{IJ}_{w,w'} = \sum_{x \in [w']} Q_{\overline{w},x} \epsilon_{\overline{w}} \epsilon_x. \tag{43}$$

Conjecture 1 (KL conjecture for $\mathscr{W}$ algebras): The multiplicities in Verma modules are given by the KL polynomials associated with the double coset (41):

$$\begin{aligned} k + h^\vee > 0: \quad & [M^r_w : L^r_{w'}] = P^{IJ}_{w,w'}(1), \quad (L^r_w : M^r_{w'}) = \widetilde{Q}^{IJ}_{w,w'}(1), \\ k + h^\vee < 0: \quad & [M^r_w : L^r_{w'}] = Q^{IJ}_{w',w}(1), \quad (L^r_w : M^r_{w'}) = \widetilde{P}^{IJ}_{w',w}(1). \end{aligned} \tag{44}$$

Hence the character formula for irreducible $\mathscr{W}$ modules is given by

TABLE I. Classification of embedding patterns of the Virasoro algebra.

Feigin–Fuchs	coset
I	trivial
$\mathrm{II}_{\pm}$	a_1
II^{0}	a_1/a_1
$\mathrm{III}_{\pm}$	$\hat{a}_1$
$\mathrm{III}^{0}_{\pm}$	$\hat{a}_1/a_1$
$\mathrm{III}^{00}_{\pm}$	$a_1\backslash\hat{a}_1/a_1$

$$k+h^\vee>0: \quad \mathrm{ch}\, L^r_w=\sum_{w'\geqslant w}\widetilde{Q}^{IJ}_{w,w'}(1)\mathrm{ch}\, M^r_{w'},$$
$$k+h^\vee<0: \quad \mathrm{ch}\, L^r_w=\sum_{w'\leqslant w}\widetilde{P}^{IJ}_{w',w}(1)\mathrm{ch}\, M^r_{w'}. \tag{45}$$

Conjecture 2: The embedding diagram of Verma modules corresponds to the Hasse diagram of the double coset (41):

$$\left.\begin{array}{ll} k+h^\vee>0: & M^r_{w'}\hookrightarrow M^r_w \\ k+h^\vee<0: & M^r_w\hookrightarrow M^r_{w'} \end{array}\right\} \quad \text{iff} \quad w\leqslant w' \quad \text{with} \quad w,w'\in W^r_\lambda\backslash W_\lambda/W^0_\lambda. \tag{46}$$

Moreover, we expect that also for $\mathscr{W}$ algebras there is just one singular vector at any given weight. The KL conjecture supports this as follows. For $k+h^\vee<0$, there is an antidominant weight, so here the proof is identical to the case discussed in Sec. II C. Barring a reflection principle for $\mathscr{W}$ algebras, a general proof for $k+h^\vee>0$ is lacking. However, in the examples we studied, the polynomials appear to have the property that at arbitrary length $l(w)$ one can always find a w such that polynomial $P_{e,w}=1$. This provides an upperbound for the number of singular vectors at that weight and, consequently, also at every primitive weight $w'.\lambda$ for any $w'\leqslant w$ [see (19)]. So we expect that also for $\mathscr{W}$ algebras, $\dim \mathrm{Hom}\,(M^r(\lambda), M^r(\mu))\leqslant 1$.

IV. EXAMPLES AND APPLICATIONS

In this section we discuss some examples that on the one hand provide evidence for the validity of the conjectures and, on the other, are an illustration of their effectiveness for actual computations. In particular, the (explicit) calculation of $\mathscr{W}$ characters for irreducible highest weight modules is now reduced to combinatorics on the Weyl group of g. For simplicity we restrict to $g=\mathrm{sl}_N$. If $\lambda=\Sigma_{i=0}^{l}\lambda_i\Lambda_i$ is a dominant weight (where Λ_i are the fundamental weights of $\mathrm{sl}_N, \langle\Lambda_i,\alpha_j^\vee\rangle=\delta_{ij}$), then the level $k=\Sigma_{i=0}^{l}\lambda_i$, P_+^k is the set of dominant integral weights of level k, and P_{++}^k are the regular weights in P_+^k. The finite part $\bar{\lambda}\in\bar{h}^*$ is $\bar{\lambda}=\Sigma_{i=1}^{l}\lambda_i\Lambda_i$ and finally $h^\vee=N$.

A. Comparison with known results

The first check is provided by the Virasoro algebra, which is the quantum Hamiltonian reduction of the affine KM algebra $g=\mathrm{sl}_2$. In that case, it is a straightforward exercise to show that the conjectures agree with the results of Feigin and Fuchs: (1) the embedding diagrams are classified by the double cosets of the reflection subgroups of the affine Weyl group $\hat{a}_1$ (see Table I) and 2 the multiplicities in the characters are given by the corresponding KL polynomials: $P_{x,y}=Q_{x,y}=1$ for all $x\leqslant y$.

TABLE II. Classification of $\mathscr{W}_3$ modules with W_λ isomorphic to $\hat{a}_2$.

W^r_λ	W^0_λ	t	Λ^+	Λ^-	c	h	w	Table

TABLE III. The KL polynomials $P_{x,y}$ for the Weyl group $\hat{a}_2$ of the affine KM algebra $g=\mathrm{sl}_3$, up to $l(y)=15$. To find $P_{x,y}$ for arbitrary pairs x,y [with $l(y)\leqslant 15$] use that (1) $P_{x,y}=0$ unless $x\leqslant y$, (2) $P_{x,y}=P_{x^{-1},y^{-1}}$, (3) $P_{x,y}=P_{\tau(x),\tau(y)}$ with τ an automorphism of the Dynkin diagram, (4) $P_{x,y}=P_{x',y}$ for $x\leqslant x'$ and $P_{x',y}(1)$ maximal, (5) if (1)–(4) do not apply, then $P_{x,y}=1$. So, given a pair x,y with $x\leqslant y$, one first fixes i,j,k and an order (i.e., reading from left-to-right or from right-to-left) such that y is in the table. Second, one searches for an x' (in the fixed order) in the table such that $x\leqslant x'$ and $P_{x',y}(1)$ is maximal; then $P_{x,y}=P_{x',y}$. If either of the two steps fail, then $P_{x,y}=1$.

$\ell(y)$	y	x	$P_{x,y}-1$	$\ell(y)$	y	x	$P_{x,y}-1$	$\ell(y)$	y	x	$P_{x,y}-1$

where $t=p/p'(p,p'$ relative prime integers), $\Lambda^+\in P^p_{++}$, $\Lambda^- \in P^{p'-1}_{++}$, and w is an arbitrary element of the Weyl group W of $\overline{g}$. The simple roots of $\Delta^{re}_{\lambda,+}$ are given by $\hat{\alpha}_i=w(\alpha_i)+\Lambda_i^-\delta$. Let $\hat{s}_i=r_{\hat{\alpha}_i}$. Then

(1) W_λ is generated by the simple reflections $\hat{s}_i$,
(2) W^0_λ is generated by the $\hat{s}_i$ for which $\Lambda_i^+=0$,
(3) W^r_λ is generated by the $\hat{s}_i$ for which $\Lambda_i^-=0$ and α_i is a simple root of g_r.

The $\mathscr{W}_N$ minimal models arise from dominant weights (47) which have trivial W^0_λ and W^r_λ, hence $\Lambda^+-\rho\in P^{p-N}_{++}$ and $\Lambda^- - \overline{\rho} \in P^{p'-N}_{++}$. The multiplicities $Q_{e,w}$ for these regular dominant weights are easily read off from the recursion relation (27) for $x=e$, since in that case $Q_{e,ys}=Q_{e,y}$ for all $sy>y$, so it follows that $Q_{e,w}=1$. This reproduces the character formulas of Refs. 5 and 12 for the $\mathscr{W}_N$ minimal models. Similarly, admissible modules for arbitrary $\mathscr{W}$ algebras can be obtained. As should be clear from above, the only difference will be in the domain of Λ^-.

New test cases for weights λ with $W_\lambda\cong W$ arise when one considers nontrivial subgroups W^0_λ and/or W^r_λ and nondominant highest weights. In the next section we will do this for the case of the $\mathscr{W}_3$ algebra.

B. Classification of $\mathscr{W}_3$ modules

The Zamolodchikov algebra $\mathscr{W}_3$ (Ref. 1) is the quantum Hamiltonian reduction of the affine KM algebra sl_3 with respect to the principal sl_2 subalgebra.[27] The W_3 weights are (h,w,c), the eigenvalues of the zero modes L_0W_0, and c, respectively. The parametrization of the $\mathscr{W}_3$ weights in terms of the sl_3 weight λ that follows from the BRST construction is

$$h=\frac{1}{2t}\,|\overline{\lambda}+\overline{\rho}|^2+\frac{c-2}{24},\quad w=\frac{1}{27t(t-1)}\,(\overline{\lambda}+\overline{\rho},\Lambda_1)(\overline{\lambda}+\overline{\rho},\Lambda_2)(\overline{\lambda}+\overline{\rho},\Lambda_1-\Lambda_2),\tag{48}$$

with $c=50-24t-24/t$ for $t=k+3$. The character of a $\mathscr{W}_3$ Verma module is given by $\mathrm{ch}\,M^r(\lambda)=q^h\eta(q)^2$ [note that if $t=1$, the parametrization (48) is singular, in that case one replaces $w\to(t-1)w$].

Up to isomorphism, there are two nontrivial parabolic subgroups of the affine Weyl group $\hat{a}_2$ of sl_3, namely $a_1\simeq Z_2$ and $a_2\simeq D_3$. This gives rise to nine inequivalent double cosets [we eliminated the invariance of the $\mathscr{W}_3$ weights under $(t,\lambda)\to(1/t,-\lambda/t)$, which interchanges W^0_λ and W^r_λ] (see Table II). For each of these double cosets, we computed the multiplicities $P^{IJ}_{w,w'}(1)$ (for the first 15 elements) from the KL polynomials $P_{w,w'}(q)$ of sl_3. Together with the KL polynomials $Q_{w,w'}(q)$ these are given in Tables III and IV.[28] Together with the associated Hasse diagrams, they are given in Tables V–XIII.

To check if the polynomials and Hasse diagrams correspond with multiplicities and embedding diagrams of $\mathscr{W}$ Verma modules, we subsequently calculated (parts of) the irreducible characters and embedding patterns directly on the Verma module.

This goes as follows. Starting from a highest weight vector v_a (eigenvector of L_0, W_0, c with eigenvalues h,w,c, and annihilated by the L_n, W_n for $n>0$) a basis $M(a)_{h+N}$ of the Verma

module at depth N is constructed. The rank of the innerproduct matrix (Shapovalov form) at depth N gives the dimension of the irreducible character at depth N, and the eigenvectors of W_0 in the kernel of L_1, L_2, and W_1 gives the singular vectors.

In practice, even at modest depth these calculations require much computer time: with the Mathematica routines we had available, the singular vectors could generically be determined up to depth 9, and the characters up to depth 6. To appreciate the effectiveness of the KL conjecture: applying Table III to the vacuum module for $c=0$ the characters are already determined beyond depth 200, where the Verma module has of the order of 10^{20} states. To verify the predictions of the conjectures, we selected a dominant weight with every coset such that the singular vectors in the associated Verma module occur at the lowest possible levels (see Table II). For every coset we computed the characters of the first 15 submodules, and reconstructed the embedding patterns. We found complete agreement with the KL conjecture.

C. Closed character formulas

The practical upshot of the KL conjectures is that characters of $\mathscr{W}$ algebras can be computed using only the combinatorics of double cosets of affine Weyl groups. In general, however, the word problem posed by the recursion relation (27) is too complicated to solve in closed form. Only in certain special cases, one does get a closed expression for character formulas, as in the case of the Virasoro algebra ($Q_{x,y}=1$ for $x\leqslant y$) and the $\mathscr{W}_N$ minimal models ($Q_{e,y}=1$). We end this section by discussing two more examples where a closed formula can be obtained: cosets of type $W\backslash W$ and of type $W\backslash W/W$.

1. The coset $\overline{W}\backslash W$

Consider a coset of the form $\overline{W}\backslash W$, with W the affine Weyl group and $\overline{W}$ the corresponding finite Weyl group. These cosets correspond to modules on the boundary of the Kac table (type III^0 of the Virasoro), where the characters are given by finite sums over Verma characters.

For the $\mathscr{W}_3$ algebra $W=\hat{a}_2$ and $W=a_2$. The KL polynomials $P^{IJ}_{x,y}$ and Hasse diagram of $a_2\backslash\hat{a}_2$ are given in Table IX. In that case it can be shown that there are two different character formulas, depending only on the length of $\underline{w}$ (the minimal representative of w in the coset). If the length $l(\underline{w})$ is odd, there are precisely two adjacent elements of $\underline{w}$ of length $l(\underline{w})+1$, of the form $\underline{w}.j$ and $\underline{w}.k$ (where j and k are distinct simple reflections). Let a_2 denote the a_2 generated by j and k. Then the character reads

$$\mathrm{ch}\, L(w.\lambda)=\sum_{x\in a_2}\epsilon_x\,\mathrm{ch}\, M(w.x.\lambda). \tag{49}$$

If the length $l(\underline{w})$ is even, there are at most three adjacent elements of $\underline{w}$ of length $l(\underline{w})+1$, and there is precisely one of the form $\underline{w}.i$ (for i a simple reflection). Then we find

$$\mathrm{ch}\, L(w.\lambda)=\sum_{x\in a_2}\epsilon_x(\mathrm{ch}\, M(w.i.x.i.\lambda)-\mathrm{ch}\, M(w.i.x.\lambda)), \tag{50}$$

where again the a_2 is generated by j,k (i,j,k are distinct simple reflections).

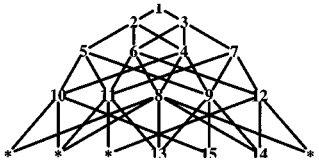
15	1232	·	·	·	·	·	·	·	·	·	·	·	·	·	·	1	(7,−7)



It appears that these two formulas are related to the generic decomposition patterns of Weyl modules, studied in Ref. 29. Similarly, there is 1 formula in the case of A_1, 4 different formulas for B_2, and 12 for G_2.

These character formulas apply in particular to the $(p,1)$ topological minimal models. The admissible weights (47) in that case are integral, hence $W_\lambda^r = W$. The regular integral weights

$$(\lambda+\rho,\alpha_i^\vee) \neq 0 \bmod p \tag{51}$$

are on the orbit of the coset $\overline{W}\backslash W$, with dominant weights $\lambda \in P_{++}^p$. For $\mathscr{W}_3$ therefore, provided $p \geqslant 3$, (49) and (50) give the character formulas for all the regular weights. We observe that (51) is exactly the condition for the physical states in $(p,1)$ topological minimal matter coupled to W-gravity.[30] An interesting open question is whether the nontrivial multiplicities indicate the presence of extra physical states.

The character formulas (49) and (50) apply in other cases as well, for instance (i) for regular integral weights on the boundary of the (p,p') Kac table, (ii) for weights with $W_\lambda^0 = W$ and W_λ^r trivial (interchanging left and right multiplication), and (iii) for the other $g = \mathrm{sl}_3$ related $\mathscr{W}$ algebras ($W_3^{(2)}$ and sl_3 itself).

2. The coset $\overline{W}\backslash W/\overline{W}$

Consider a coset of the form $\overline{W}\backslash W/\overline{W}$, with W an affine Weyl group and $\overline{W}$ a subgroup isomorphic to the finite Weyl group W. These cosets correspond to modules in a corner of the Kac table (type III^{00} of the Virasoro), where again the characters are given by finite sums over Verma characters, but in addition they are now grouped in $\overline{g}$ multiplets. Specifically, the multiplicities $P_{x,y}^{IJ}(1)$ are related to the dimension of weight spaces in finite-dimensional modules of the simple Lie algebra $\overline{g}$.[31] The correspondence is as follows. First consider the case where the embedding of the left and right subgroups is the same and given by W (depending on g there may be more ways to embed W in W). Since $W = W \cdot Q$ (semidirect product) and in Q there is a unique dominant element α on each W orbit, it follows that there is a one-to-one correspondence between coset elements $w \in W\backslash W/W$ and dominant roots $\overline{\alpha}_w \in P_+ \cap Q$. More generally, if the embeddings are chosen differently, this correspondence is between coset elements $w \in W\backslash W/W'$ and dominant weights $\lambda \in P_+ \cap Q + \Lambda_i$, where Λ_i is the fundamental weight that determines the embedding: W' is generated by the set of simple reflections s_j for $j \neq i$. Then the result of Ref. 31 states that

$$P_{w,w'}^{IJ}(1) = \dim L(\overline{\lambda}_{w'})_{\overline{\lambda}_w}, \tag{52}$$

where $L(\overline{\lambda})_{\overline{\mu}}$ is the weight space of weight $\overline{\mu}$ in the (finite dimensional) irreducible $\overline{g}$ module of highest weight λ.

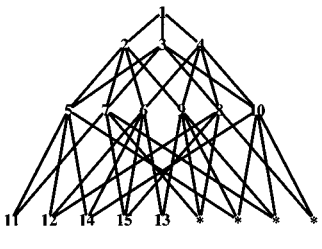
12	123	·	·	·	·	·	·	·	·	·	·	·	1	·	·	·	$(8,-22)$
13	131	·	·	·	·	·	·	·	·	·	·	·	·	1	·	·	$(6,-6)$
14	132	·	·	·	·	·	·	·	·	·	·	·	·	·	1	·	$(8,22)$
15	213	·	·	·	·	·	·	·	·	·	·	·	·	·	·	1	$(9,35)$



This result applies in particular to the $\mathscr{W}_N$ algebras with $c=\mathrm{rank}(\overline{g})$, i.e., with $k+h^\vee=1$. From (47) it follows that the dominant weight is determined by a level 1 weight, i.e., $\lambda+\rho=\Lambda_i$. Here $W^r_\lambda=W$ and $W^0_\lambda=W'$. Using the correspondence described above, to every primitive weight $\mu=w.\lambda$ one associates the dominant weight $\lambda_w=\overline{\mu}+\overline{\rho}$. Then the sum $w'\geqslant w$ can be rewritten as follows:

$$\mathrm{ch}\ M^r(\mu)=\sum_{\overline{\mu'}\geqslant\overline{\mu}}\dim L(\overline{\mu'}+\overline{\rho})_{\overline{\mu+\rho}}\,\mathrm{ch}\ L^r(\mu'). \tag{53}$$

Inverting this [using the basis transformation from Verma modules $M(\overline{\mu})$ to singlets $e^{\overline{\mu}}$] gives

$$\mathrm{ch}\ L^r(\mu)=\sum_{x\in W}\epsilon_x\ \mathrm{ch}\ M^r(\mu+\rho-x(\rho)). \tag{54}$$

This character formula was first proposed in Ref. 32, where it was obtained as a limit of the characters of the $\mathscr{W}_N$ minimal models.[5] The inverse formula (53) was obtained for $\mathscr{W}_3$ in Ref. 33, using an explicit construction of the singular vectors in the Fock space and comparison of the characters for each side. Again, this character formula applies more generally, in particular to the weights in a corner of the (p,p') Kac table [in that case one replaces $\rho\to p\rho$ everywhere on the rhs of (54)].

V. CONCLUDING REMARKS

In this paper we have formulated the KL conjecture for $\mathscr{W}$ algebras associated with arbitrary sl_2 reductions. The result can be described in terms of a double coset $W^r_\lambda\backslash W_\lambda/W^0_\lambda$: the Hasse diagram gives the embedding diagram of the Verma modules, and the KL polynomials give the multiplicities in the characters.

The conjectures also apply to finite $\mathscr{W}$ algebras, which are the Hamiltonian reduction of simple Lie algebras $\overline{g}$.[13] In that case one simply takes W to be the Weyl group W of $\overline{g}$. The character formulas for this class of algebras are given in Ref. 14 (for regular integral weights only) and the results agree completely.

We remark that the conjecture is also a useful tool to analyze the structure of the Verma modules in more detail. This is particularly important if one attempts to construct a resolution of the irreducible modules by Verma modules. The physical motivation for doing so is the application to $\mathscr{W}$ gravity/strings: it is much simpler to compute the (string) BRST cohomology on Verma modules than on irreducible modules. The problem is that it is not always possible to find a resolution by Verma modules. For instance, for the $\mathscr{W}_3$ string at $c=2$ it is found by explicit construction[33] that there is no resolution by Verma modules, but instead one is forced to introduce generalized Verma modules. This is directly linked to the existence of primitive vectors that are pseudo-singular rather than singular (they are not an eigenvector of W_0). For such an analysis it is convenient to have the data presented by the KL conjecture. This way, for instance, one can easily show that the character (50) of the $(p,1)$ topological minimal models for $\mathscr{W}_3$ cannot be reproduced by a resolution by (generalized) Verma modules. This is due to the occurrence of subsingular vectors.[14] It would be very interesting to know what type of modules are needed to build such a resolution, since these modules are going to carry the cohomology of the topological $\mathscr{W}_3$ string. Work on this is in progress.

APPENDIX

1. KL Polynomials on Coxeter groups

In this Appendix, we summarize the definition and some of the properties of KL polynomials $P_{x,y}$ for a Coxeter group W, (for details see Refs. 7 and 17). The starting point is the Hecke algebra $\mathscr{H}$ with generators T_y (one for each $y\in W$) and defining relations

$$T_x T_y = T_{xy} \quad \text{if } l(xy) = l(x) + l(y), \tag{A1}$$

$$(T_s + 1)(T_s - q) = 0 \quad \text{if } s \in S, \tag{A2}$$

where S is the set of simple reflections that generate W. The elements T_y are invertible in $\mathscr{H}$, and one can write

$$T_{y^{-1}}^{-1} = \sum_{x \leqslant y} \epsilon_x \epsilon_y R_{x,y}(q) q^{-l(y)} T_x, \tag{A3}$$

where $\epsilon_y = (-1)^{l(y)}$, and $R_{x,y}(q)$ is a polynomial in q of degree $l(y) - l(x)$ for $x \leqslant y$, uniquely defined by (A3). The map ι defined by

$$\iota(q) = q^{-1}, \quad \iota(T_y) = T_{y^{-1}}^{-1} \tag{A4}$$

is an automorphism of $\mathscr{H}$. The KL polynomials are associated with the invariants of ι. For any pair $x \leqslant y$ in W, there is a uniquely defined polynomial $P_{x,y}$ of degree $\leqslant (l(y) - l(x) - 1)/2$ if $x < y$, and $P_{x,x} = 1$, such that

$$C_y = \sum_{x \leqslant y} \epsilon_x \epsilon_y q^{l(y)/2 - l(x)} P_{x,y}(q^{-1}) T_x \tag{A5}$$

satisfies

$$\iota(C_y) = C_y \quad \text{for all } y \in W. \tag{A6}$$

Equivalently, the P-polynomials satisfy

$$q^{l(y)-l(x)} P_{x,y}(q^{-1}) = \sum_{x \leqslant z \leqslant y} R_{x,z} P_{z,y}(q) \quad \text{for all } x \leqslant y. \tag{A7}$$

From this, one can extract a recursion relation (expressing the polynomials $P_{x,y}$ in terms of the polynomials $P_{x',y'}$ with $y' < y$). Namely, for $ys > y$ one has[7]

$$P_{x,ys} = q^{1-c} P_{xs,y} + q^c P_{x,y} - q \sum_{\substack{x \leqslant z < y \\ zs < z}} P_{x,z} \not{P}_{z,y}. \tag{A8}$$

Here $c = 1$ if $xs < x$ and 0 otherwise, and $\not{P}_{z,y}$ is the term in $P_{z,y}$ of (maximal) degree $\frac{1}{2}(l(y) - l(z) - 1)$. The initial values of the recursion relation are $P_{x,e}(q) = \delta_{x,e}$. This implies in particular that $P_{x,y}(q) = 0$ unless $x \leqslant y$. From (A8) it also follows that $P_{x,y}(0) = 1$ if $x \leqslant y$. In the case of crystallographic Coxeter groups [which includes (affine) Weyl groups], the coefficients of $P_{x,y}$ give the dimensions of stalks of cohomology sheaves of the intersection cohomology complexes associated to Schubert varieties.[34] This implies, in particular, that these coefficients are non-negative integers.

Similarly, if $ys < y$ it can be shown that $C_y T_s = -C_y$, which implies that

$$P_{x,y} = P_{xs,y} \quad \text{for } x \leqslant y \text{ and } ys < y. \tag{A9}$$

For finite Coxeter groups (where there is a unique longest element w_0) it easily follows that

$$P_{x,w_0} = 1. \tag{A10}$$

2. Inverse KL polynomials on Coxeter groups

The KL polynomials $P_{y,w}$ form an upper triangular matrix with ones on the main diagonal, which naturally can be inverted. Thus, one can define for each $x \leqslant y$ in W a polynomial $Q_{x,y}$ such that

$$\sum_{x \leqslant z \leqslant y} \epsilon_x \epsilon_z P_{x,z} Q_{z,y} = \delta_{x,y} \quad \text{for all } x \leqslant y. \tag{A11}$$

It is clear that $Q_{x,x}(q)=1$ and that $Q_{x,y}(q)$ has degree $\leqslant (l(y)-l(x)-1)/2$ for $x<y$, and $\mathbb{Q}_{x,y}=\mathbb{P}_{x,y}$. It also follows that

$$q^{l(y)-l(x)} Q_{x,y}(q^{-1}) = \sum_{x \leqslant z \leqslant y} Q_{x,z} R_{z,y}(q) \quad \text{for all } x \leqslant y. \tag{A12}$$

The Q-polynomials are also associated to invariants of ι. Define elements S_x, D_x of $\mathscr{H}^*$ by

$$\langle S_x, \iota(T_y) \rangle = \langle D_x, C_y \rangle = \delta_{x,y^{-1}}, \tag{A13}$$

and let $\langle \iota(u), h \rangle = \iota(\langle u, \iota(h) \rangle)$. It follows that $\iota(D_x)=D_x$ and

$$D_x = \sum_{x \geqslant y} q^{l(x)/2-l(y)} Q_{x,y} S_y, \tag{A14}$$

with $Q_{x,y}$ the inverse polynomials (A11). From the right $\mathscr{H}$-action on $\mathscr{H}^*$ given by $\langle u \cdot h, h' \rangle = \langle u, hh' \rangle$ one can conclude that $D_x \cdot T_s = qD_x$ if $xs>x$. This implies

$$Q_{x,ys} = Q_{x,y} \quad \text{for } x \leqslant y \text{ and } xs>x. \tag{A15}$$

From this it easily follows that

$$Q_{e,y}=1 \quad \text{for all } y \in W. \tag{A16}$$

The analog of (A8) for the Q-polynomials is (for $xs<x$)

$$Q_{xs,y} = q^{1-c} Q_{x,ys} + q^c Q_{x,y} - q \sum_{\substack{x<z \leqslant y \\ zs>y}} \mathbb{Q}_{x,z} Q_{z,y}, \tag{A17}$$

with $c=1$ for $ys>y$ and $c=0$ for $ys<y$. In this form (A17) cannot be used to solve for the Q-polynomials (at least not in the case of infinite Coxeter groups). But, combining (A17) and (A15) for $ys>y$, one obtains a useful relation (expressing $Q_{z,w}$ in terms of $Q_{z',w'}$ with $w'<w$)

$$Q_{x,ys} = cQ_{xs,y} + (-q)^c Q_{x,y} + cq \sum_{\substack{x<z \leqslant y \\ zs>z}} \mathbb{Q}_{x,z} Q_{z,y}, \tag{A18}$$

with $c=1$ for $xs<x$ and $c=0$ for $xs>x$. In the case of (affine) Weyl groups the coefficients of $Q_{x,y}$ are again non-negative integers.

In the case of a finite Coxeter group, the KL polynomials P are related to the inverse polynomials Q through

$$Q_{x,y} = P_{w_0 y, w_0 x}. \tag{A19}$$

On the other hand, if the group is not finite, P and Q do not appear to be related in any such way.

3. KL polynomials on cosets

Similar as for ordinary Coxeter groups W, one can also construct KL polynomials on cosets W/W_I (or $W_I\backslash W$), where W_I is a parabolic subgroup of W.[35] In particular, one finds that again there are recursion relations for the associated polynomials $P^I_{x,y}$ and $Q^I_{x,y}$. If the subgroup W_I is finite (which is sufficient for our purposes), the polynomials P^I, Q^I and their inverses $\widetilde{Q}^I$, $\widetilde{P}^I$, defined through

$$\sum_{x\leqslant z\leqslant y} \widetilde{Q}^I_{x,z}P^I_{z,y}=\sum_{x\leqslant z\leqslant y} Q^I_{x,z}\widetilde{P}^I_{z,y}=\delta_{x,y}\,, \tag{A20}$$

can be expressed in terms of the KL polynomials of W:

$$\begin{aligned} &P^I_{x,y}=P_{\overline{x,y}}\,, \quad Q^I_{x,y}=Q_{\underline{x},\underline{y}},\\ &\widetilde{P}^I_{x,y}=\sum_{z\in[x]} P_{\underline{z},\underline{y}}\epsilon_z\epsilon_{\underline{y}}, \quad \widetilde{Q}^I_{x,y}=\sum_{z\in[y]} Q_{\overline{x},z}\epsilon_{\overline{x}}\epsilon_z\,. \end{aligned} \tag{A21}$$

Here $\underline{z}$ is the minimal and $\overline{z}$ is the maximal representative of the coset $[z]$ of z. (Note that this notation is slightly different from the notation used in Ref. 14.)

However, the cosets that play a role in this paper are two-sided cosets $W_I\backslash W/W_J$, with respect to parabolic subgroups W_I and W_J. There does not appear to be an abstract setup for double-sided cosets. In particular, the partial ordering on these cosets is more complicated than in the case of one-sided cosets (for example, the length of adjacent elements may differ by more than 1). So instead of defining KL polynomials through a recursion relation, we take (A21) as our starting point, i.e., we define

$$\begin{aligned} &P^{IJ}_{w,w'}=P_{\overline{w,w'}}\,, \quad Q^{IJ}_{w,w'}=Q_{\underline{w},\underline{w'}}\,,\\ &\widetilde{P}^{IJ}_{w,w'}=\sum_{x\in[w]} P_{x,\underline{w'}}\epsilon_x\epsilon_{\underline{w'}}\,, \quad \widetilde{Q}^{IJ}_{w,w'}=\sum_{x\in[w']} Q_{\overline{w},x}\epsilon_{\overline{w}}\epsilon_x\,, \end{aligned} \tag{A22}$$

where the polynomials $\widetilde{P}^{IJ}$, $\widetilde{Q}^{IJ}$ are again the inverse polynomials

$$\sum_{x\leqslant z\leqslant y} \widetilde{Q}^{IJ}_{x,z}P^{IJ}_{z,y}=\sum_{x\leqslant z\leqslant y} Q^{IJ}_{x,z}\widetilde{P}^{IJ}_{z,y}=\delta_{x,y}\,. \tag{A23}$$

A noncommutative Hopf structure on $\mathscr{C}^\infty$[SL(2,C)] as a quantum Lorentz group

Christiane Martin[a] and Mohamed Zouagui

(Received 14 August 1995; accepted for publication 26 February 1996)

We introduce a ''classical'' Fréchet Hopf algebra $\mathscr{A}$ containing the quantum deformation of the enveloping Lorentz algebra of Ogievestky and Wess *et al.* (as a dense Hopf subalgebra). We also show that $\mathscr{A}$ is isomorphic to a quasitriangular twisted topological tensor product Hopf algebra. By duality, we recover on the topological dual space of $\mathscr{A}$, the non-commutative algebra structure introduced by Podles and Woronowicz. Finally, this non-commutative product can be extended to $\mathscr{C}^\infty(SL(2,\mathbb{C}))$ which then becomes a topological Hopf algebra for its natural Fréchet topology. © *1996 American Institute of Physics.* [S0022-2488(96)02306-7]

I. INTRODUCTION

Quantum group theory[1] and the star-product approach to quantum mechanics[2] have a common basis: non-commutative deformations of a commutative algebra. This was made mathematically explicit in the results of Refs. 3–5: for example, every F.R.T. quantum group[6] (corresponding to a semi-simple real Lie group G) is realized as a subalgebra of $\mathscr{C}^\infty(G)$ endowed with a non-commutative product which is a deformation of the usual product of functions. Thus, the idea that the symmetry properties in Quantum Theory are described by a ''quantum group'' is very attractive: some of the failures of the constructive quantum field theory could be explained by the introduction of a ''quantum Poincaré group.''

A first step in such a program is the construction of a well-defined quantum Lorentz group (and its dual version). Taking into account the physical aim, this quantum Lorentz group must contain a Hopf subalgebra $SU_t(2)(q=e^t)$. Consequently, the Drinfeld–Jimbo deformation[1,7] of the enveloping algebra of the Lorentz Lie algebra is not appropriate.

A few years ago, Podles and Woronowiz,[8] Carow-Watamura *et al.*,[9] respectively, have introduced a quantum Lorentz group while a quantum Lorentz enveloping algebra was defined by Ogievestky *et al.*[10] Let us give a brief overview of each of these models.

- The P. W. model is the topological Hopf algebra of the continuous functions on the Lorentz quantum group. The latter is constructed by generators and relations from the fundamental representation of the Woronowicz model $SU_t(2)$ and its Pontryagin dual.
- The C. W. model is obtained from two copies of $SL_t(2)$ in its fundamental representation and a cross relation between the generators of each of them. It is the F.R.T. view.[6]
- The O. S. W. Z. model is a subalgebra of $\mathscr{U}_t(\mathfrak{sl}(2))\otimes\mathscr{U}_t(\mathfrak{sl}(2))(q=e^t)$ which carries an ad-hoc coproduct.

This raises several problems.

1. First, it is not proved that these models are some deformations (for the usual notion[11]) of the corresponding classical model. We only can assert that the quantum relations give the classical relations for $q\to 1$. Thus we cannot directly use the results of Drinfeld on quantum deformations nor those of Refs. 3 and 4.

[a]Electronic mail: cmartin@satie.u-bourgogne.fr

2. What relations do there exist between these three models: ''isomorphism,'' ''duality'' (the meaning of these words remaining to be precised)?

3. What is the structure of the O. S. W. Z. model (resp., C. W. model) with respect to the tensor product Hopf algebra $\mathscr{U}_t(\mathfrak{sl}(2))\otimes\mathscr{U}_t(\mathfrak{sl}(2))$ [resp., $SL_t(2)\otimes SL_t(2)$]?

Part of the answers to these questions was more or less given in Ref. 12, Majid asserts that the C. W. model is a double cross product of two copies of $SL_t(2)$; in Ref. 13, the authors obtain the Hopf structure of the O. S. W. Z. model, starting from the algebraic Hopf structure of the P. W. model. Let us remark that all these models are defined by generators and relations.

In this paper, we do not only answer the previous questions but we also realize the above mentioned model either as a classical topological algebra, or, as its topological dual vector space, endowed with various topological Hopf algebra structures. We are reminded that these classical topological models for ''quantum groups'' have been introduced in Refs. 3 and 4 and that one of its features is to define the q-deformed structure together with the classical structure on the same classical topological vector space.

To be more precise, we start with the O. S. W. Z. Hopf algebra,[10] or, more exactly, the Hopf algebra $\mathscr{U}_t\mathscr{L}$ generated by the basis of Schirrmacher and relations[14] (which is larger than the initial O. S. W. Z. model). We introduce a Fréchet topological algebra $\mathscr{A}$ by ''classical'' methods and its topological dual space $\mathscr{H}(G)$ where G is $SL(2,\mathbb{C})\times SL(2,\mathbb{C})$ (the classical algebra of coefficient functions on G for the holomorphic finite-dimensional representations) but we must take into account Problem 1. These topological models provide us the following results.

(i) The algebra $\mathscr{A}$ can be endowed with various topological Hopf structures so that the Hopf algebra $\mathscr{U}_t\mathscr{L}$ and the tensor product Hopf algebra $\mathscr{U}_t(\mathfrak{sl}(2))\otimes\mathscr{U}_t(\mathfrak{sl}(2))$ (including the classical cases $t=0$) are dense Hopf subalgebras of $\mathscr{A}$.

(ii) Denote by Δ_t (resp., δ_t) the coproduct of $\mathscr{U}_t\mathscr{L}$ [resp., $\mathscr{U}_t(\mathfrak{sl}(2))$] and by A_1 (resp., A_2) the topological model of $(\mathscr{U}_t(\mathfrak{sl}(2)),\delta_t)$ [resp., $(\mathscr{U}_t(\mathfrak{sl}(2)),\delta_t^{op})$] introduced in Ref. 3. We construct an element W of $A_2\hat{\otimes}A_1$ such that $(\mathscr{A},\Delta_t)$ is the twisting of the topological tensor product Hopf algebra $A_1\hat{\otimes}A_2$ by W. Thus $(\mathscr{A},\Delta_t)$ is isomorphic to a quasitriangular Hopf algebra: we give a quasitriangular R-matrix in $\mathscr{A}\hat{\otimes}\mathscr{A}$.

(iii) By duality, the coproduct Δ_t induces onto $\mathscr{H}(G)$ the non-commutative structure (noted $\star_t$) of the algebra introduced by Podles and Woronowicz.[8] The product $\star_t$ is given in term of the usual product of functions.

(iv) Dualizing the results of Point (ii), the Hopf algebra $(\mathscr{H}(G),\star_t)$ is isomorphic to the double cross product of two copies of $SL_t(2)$ with the same cross relations as defined in Ref. 12. We obtain the C. W. model.[9]

(v) The introduction of the real structure of Ref. 10 on $\mathscr{U}_t\mathscr{L}$ ($t\in\mathbb{R}$) is tantamount to considering the topological Hopf subalgebra $(\underline{H}(G_0),\star_t)$ of $(H(G),\star_t)$, where G_0 is a real Lie subgroup of G conjugate to the subgroup $\{(T,{}^tT^{-1}),T\in SL(2,\mathbb{C})\}$. We then prove from Ref. 5, $\mathscr{C}^{\infty}(G_0)$ with its natural Fréchet topology can be endowed with a topological Hopf algebra structure which is the extension of the Hopf structure defined by $\star_t$ on $\mathscr{H}(G_0)$.

In particular, Points (i), (iii) and (iv) answer Question 2 while Points (ii) and (iv) solve Question 3. Moreover, a unique topological classical model $(\mathscr{A},H(G))$ carries all q-deformed structures introduced by the previously mentioned authors. Finally, Point (v) completes the total parallelism between quantum group theory and the star-product approach to quantum mechanics. The paper is organized as follows.

In Section II we introduce some definitions and notations for the various Hopf algebras needed here and we recall some of their properties. Section III is devoted to the construction (up to equivalence) of all the finite-dimensional representations of the Hopf algebra $\mathscr{U}_t\mathscr{L}$: this classification is needed for the proof of Point (i). In Section IV, we construct the topological algebra $\mathscr{A}$ and we prove the results claimed in Points (i) and (ii). Section V deals with duality: The

topological dual space $\mathscr{H}(G)$ of $\mathscr{A}$ is introduced and the various properties of Points (iii), (iv) and (v) are obtained.

II. $\mathscr{U}_t(\mathfrak{sl}(2,\mathbb{C}))$ AND $\mathscr{U}_t(\mathfrak{so}(4))$: DEFINITIONS AND NOTATIONS

II.1. Let $\mathscr{L}$ be the complex Lie algebra of $\mathfrak{so}(3,1)$ or $\mathfrak{so}(4)$. $\mathscr{L}$ can be written as the direct sum of Lie algebras $\mathfrak{g}_1 \oplus \mathfrak{g}_2$ where the Lie algebra $(\mathfrak{g}_i)_{i=1,2}$ is isomorphic to $\mathfrak{sl}(2)$. A basis of $\mathfrak{g}_i$ is $\{Y_i, F_i, G_i\}$ with the relations.

$$[Y_i, F_i] = F_i, \quad [Y_i, G_i] = -G_i, \quad [F_i, G_i] = 2Y_i, \quad i = 1,2. \tag{1}$$

Let $\mathscr{U}\mathscr{L} = \mathscr{U}\mathfrak{g}_1 \otimes \mathscr{U}\mathfrak{g}_2$ be the enveloping algebra of $\mathscr{L}$. Its center is generated by the two elements:

$$Q_i = F_i G_i - Y_i + Y_i^2 = G_i F_i + Y_i + Y_i^2, \quad i = 1,2. \tag{2}$$

II.2. According to Refs. 10 and 14, we denote by $\mathscr{U}_t\mathscr{L}$ or $\mathscr{U}_t\mathfrak{sl}(2,\mathbb{C})$ the complex associative algebra ($q = e^t, q \in \mathbb{C}$) generated by $\{L_+, L_-, l, l^{-1}, K_1, K_2, k, \tilde{k}\}$ and the relations ($\lambda = q - q^{-1}$):

$$L_+ l = q l L_+, \quad L_- l = q^{-1} l L_-, \quad [L_+, L_-] = q^{-1}\lambda^{-1}(l^{-2} - l^2), \tag{3}$$

$$\begin{aligned} &kK_1 = qK_1 k, \quad \tilde{k}K_1 = q^{-1}K_1\tilde{k}, \quad kK_2 = qK_2 k, \quad \tilde{k}K_2 = q^{-1}K_2\tilde{k}, \\ &K_1K_2 = K_2K_1, \quad k\tilde{k} = \tilde{k}k - q\lambda^3 K_1K_2, \quad k\tilde{k} + q^2\lambda^2 K_1K_2 = 1, \end{aligned} \tag{4}$$

$$\begin{aligned} &kL_+ = q^{-1}L_+k + q^{-1}\lambda l^{-1}K_2, && kL_- = q^{-1}L_-k + q^{-1}\lambda l K_1, \\ &\tilde{k}L_+ = qL_+\tilde{k} - \lambda K_2 l, && \tilde{k}L_- = qL_-\tilde{k} - \lambda K_1 l^{-1}, \\ &kl = lk, && \tilde{k}l = l\tilde{k}, \\ &K_1L_+ = L_+K_1 - q^{-1}\lambda^{-1}(l^{-1}\tilde{k} - lk), && K_1L_- = L_-K_1, \\ &K_2L_+ = L_+K_2, && K_2L_- = L_-K_2 + q^{-1}\lambda(kl^{-1} - l\tilde{k}), \\ &K_1 l = q^{-1} l K_1, && K_2 l = q l K_2. \end{aligned} \tag{5}$$

Set $C = \frac{1}{2}(l + l^{-1}) \quad S = \lambda^{-1}(l - l^{-1}) \quad C' = \frac{1}{2}(k + \tilde{k}) \quad S' = \lambda^{-1}(k - \tilde{k})$.

Then $\{L_+, L_-, C, S, K_1, K_2, C', S'\}$ is a system of generators of $\mathscr{U}_t\mathscr{L}$ with relations [deduced from (3), (4), (5)] well defined for any q in $\mathbb{C}$. To simplify notations , we write here the elements of this last basis of $\mathscr{U}_t\mathscr{L}$ without subscript t.

If $\{L_{+,0}, L_{-,0}, C_0, S_0, K_{1,0}, K_{2,0}, C_0', S_0'\}$ denotes the basis of $\mathscr{U}_0\mathscr{L}$, set

$$\begin{aligned} &H_3 = -S_0C_0, \quad H_+ = C_0L_{+,0}, && H_- = C_0L_{-,0}, \\ &F_3 = iC_0'S_0', \quad F_+ = 2iK_{2,0}C_0' - iL_{+,0}C_0, && F_- = -2iK_{1,0}C_0' + iL_{-,0}C_0, \end{aligned} \tag{6}$$

and

$$\begin{aligned} &2Y_1 = H_3 - iF_3, && 2F_1 = H_+ - iF_+, \quad 2G_1 = H_- - iF_-, \\ &2Y_2 = -(H_3 + iF_3), && 2G_2 = H_+ + iF_+, \quad 2F_2 = H_- + iF_-, \end{aligned} \tag{7}$$

Then $\{Y_1, F_1, G_1, Y_2, F_2, G_2, C_0, C_0'\}$ is a system of generators of $\mathscr{U}_0\mathscr{L}$ where the six first elements generate the classical enveloping algebra $\mathscr{U}\mathscr{L}$ as defined in paragraph II.1., C_0 and C_0' commute with all the other ones and verify $C_0^2 = C'^2_0 = 1$. Then

$$\mathscr{U}_0\mathscr{L} = \mathscr{U}\mathscr{L} \otimes \frac{\mathbb{C}[X,Y]}{\langle X^2 - 1, Y^2 - 1\rangle}.$$

$\mathscr{U}_t\mathscr{L}$ has the two following central elements:

$$\begin{aligned} Q_1' &= qK_2L_- + \lambda^{-2}(q^{-1}kl^{-1} + q\tilde{k}l), \\ Q_2' &= qK_1L_+ + \lambda^{-2}(q^{-1}kl + q\tilde{k}l^{-1}). \end{aligned} \tag{8}$$

Remark II.2.1: The generators H_3, H_+, H_- (resp., F_3, F_+, F_-) defined by formulas (6) are the rotation generators (resp., boost generators) of $\mathscr{L}$ in the notations of Naimark (Ref. 15, p. 87, Sec. 2).

Moreover $\mathscr{U}_t\mathscr{L}$ has a Hopf algebra structure defined by Refs. 10 and 14:

- coproduct Δ_t,

$$\begin{aligned} &\Delta_t(l) = l\otimes l, \quad \Delta_t(L_+) = L_+\otimes l^{-1} + l\otimes L_+, \quad \Delta_t(L_-) = L_-\otimes l^{-1} + l\otimes L_-, \\ &\Delta_t(k) = k\otimes k - q\lambda^2 K_1\otimes K_2, \quad \Delta_t(\tilde{k}) = \tilde{k}\otimes\tilde{k} - q\lambda^2 K_2\otimes K_1, \\ &\Delta_t(K_1) = K_1\otimes\tilde{k} + k\otimes K_1, \quad \Delta_t(K_2) = K_2\otimes k + \tilde{k}\otimes K_2; \end{aligned} \tag{9}$$

- counit ε_t,

$$\begin{aligned} &\varepsilon_t(l) = \varepsilon_t(l^{-1}) = \varepsilon_t(k) = \varepsilon_t(\tilde{k}) = 1, \\ &\varepsilon_t(L_+) = \varepsilon_t(L_-) = \varepsilon_t(K_1) = \varepsilon_t(K_2) = 0; \end{aligned} \tag{10}$$

- antipode J_t,

$$\begin{aligned} &J_t(l) = l^{-1}, \quad J_t(l^{-1}) = l, \quad J_t(L_+) = -qL_+, \quad J_t(L_-) = -q^{-1}L_-, \\ &J_t(k) = \tilde{k}, \quad J_t(\tilde{k}) = k, \quad J_t(K_1) = -q^{-1}K_1, \quad J_t(K_2) = -qK_2. \end{aligned} \tag{11}$$

Introduce the algebra isomorphism φ of $\mathscr{U}_t\mathscr{L}$ into $\mathscr{U}_t\mathscr{L}$ as follows:

$$\varphi(l) = l^{-1}, \quad \varphi(k) = k, \quad \varphi(\tilde{k}) = \tilde{k}, \quad \varphi(K_1) = -qK_2, \quad \varphi(L_+) = -q^{-1}L_-; \tag{12}$$

and

$$\varphi\circ\varphi = id.$$

Thus, we have

$$\Delta_t\circ\varphi = (\varphi\otimes\varphi)\circ\tau\Delta_t, \quad (\varphi\circ J_t)^2 = 1, \quad \varepsilon_t\circ\varphi = \varepsilon_t,$$

where τ is the flip automorphism of $\mathscr{U}_t\mathscr{L}\otimes\mathscr{U}_t\mathscr{L}$ defined by $\tau(x\otimes y) = y\otimes x$.

Remark II.2.2: The q-Lorentz Hopf algebra as introduced in Ref. 10 can be seen as a Hopf subalgebra of the Hopf algebra $\mathscr{U}_t\mathscr{L}$. Actually, if $\{\tau_3, T_+, T_-, \tau_1, \sigma_2, S_1, T_2\}$ is a basis of Ref. 10, we have

$$\begin{aligned} &\tau_3 = l^4, \quad \tau_3^{-1} = (l^{-1})^4, \quad T_+ = q^{-1}L_+l, \quad T_- = q^2L_-l, \\ &\tau_1 = kl^{-1}, \quad \sigma_2 = \tilde{k}l, \quad S_1 = -qK_1l, \quad T_2 = K_2l^{-1}. \end{aligned}$$

II.3. We remark that $\mathscr{U}_t\mathscr{L}$ is not the usual quantum deformation of $\mathscr{U}\mathscr{L}$ as defined by Jimbo[7] from the Cartan matrix of $\mathscr{L}$. The Jimbo quantum deformation of the algebra $\mathscr{U}\mathscr{L}$ is the Hopf algebra $\mathscr{U}_t(\mathfrak{sl}(2))\otimes\mathscr{U}_t(\mathfrak{sl}(2))$ considered as the tensor product of two Hopf algebras. If m_t, δ_t, e_t, j_t are, respectively, the product, coproduct, counit, and antipode of $\mathscr{U}_t(\mathfrak{sl}(2))$, then the product m_t', coproduct Δ_t', counit ε_t' and antipode J_t' on $\mathscr{U}_t(\mathfrak{sl}(2))\otimes\mathscr{U}_t(\mathfrak{sl}(2))$ are

$$\begin{aligned}
&\Delta_t' = (I\otimes\tau\otimes I)\circ(\delta_t\otimes\delta_t),\\
&m_t' = (m_t\otimes m_t)\circ(I\otimes\tau\otimes I),\\
&\varepsilon_t' = e_t\otimes e_t,\\
&J_t' = j_t\otimes j_t .
\end{aligned} \tag{13}$$

A system of generators of $\mathcal{U}_t(\mathfrak{sl}(2))\otimes\mathcal{U}_t(\mathfrak{sl}(2))$ is $\{K_1', K_1'^{-1}, F_1', G_1', K_2', K_2'^{-1}, F_2', G_2'\}$ with the relations for $i=1,2$:

$$\begin{aligned}
&K_i'F_i' = qF_i'K_i', \quad K_i'G_i' = q^{-1}G_i'K_i',\\
&[F_i', G_i'] = \lambda^{-1}(K_i'^{2} - K_i'^{-2}),\\
&\Delta_t'(F_i') = F_i'\otimes K_i' + K_i'^{-1}\otimes F_i', \quad \Delta_t'(G_i') = G_i'\otimes K_i' + K_i'^{-1}\otimes G_i',\\
&\Delta_t'(K_i') = K_i'\otimes K_i' .
\end{aligned} \tag{14}$$

We also introduce the Hopf algebra $\mathcal{U}_t(\mathfrak{sl}(2))\otimes\mathcal{U}_t(\mathfrak{sl}(2))^{op}$ where $\mathcal{U}_t(\mathfrak{sl}(2))^{op}$ is the algebra $\mathcal{U}_t(\mathfrak{sl}(2))$ with the opposite Hopf structure $(\delta_t^{op},\ e_t,\ j_t^{-1})$. We set

$$\Delta_t'' = (I\otimes\tau\otimes I)\circ(\delta_t\otimes\delta_t^{op}), \quad J_t'' = j_t\otimes j_t^{-1} .$$

As $\mathcal{U}_t(\mathfrak{sl}(2))$ is a quasi-triangular Hopf algebra, the Hopf algebra $\mathcal{U}_t(\mathfrak{sl}(2))\otimes\mathcal{U}_t(\mathfrak{sl}(2))$ [resp., $\mathcal{U}_t(\mathfrak{sl}(2))\otimes\mathcal{U}_t(\mathfrak{sl}(2))^{op}$] also is quasi-triangular. Its universal R-matrix $\mathcal{R}'$ (resp., $\mathcal{R}''$) is given by

$$\mathcal{R}' = (1\otimes\tau\otimes 1)(R\otimes R), \quad \mathcal{R}'' = (1\otimes\tau\otimes 1)(R\otimes\tau R);$$

where R is the universal R-matrix of $\mathcal{U}_t(\mathfrak{sl}(2))$.

II.4 Let us introduce the following elements of $\mathcal{U}_t(\mathfrak{sl}(2))\otimes\mathcal{U}_t(\mathfrak{sl}(2))$:

$$\begin{aligned}
&l = K_1'^{-1}K_2', && l^{-1} = K_1'K_2'^{-1},\\
&k = K_1'K_2', && \tilde{k} = K_1'^{-1}K_2'^{-1} - q\lambda^2F_1'F_2',\\
&K_1 = K_1'F_2', && K_2 = K_2'F_1',\\
&L_+ = F_1'K_2'^{-1} + q^{-1}K_1'^{-1}G_2', && L_- = K_1'^{-1}F_2' + q^{-1}G_1'K_2'^{-1}.
\end{aligned}$$

Then, these elements verify Formulas (3), (4) and (5) so that the algebra $\mathcal{U}_t\mathcal{S}$ is a strict subalgebra of $\mathcal{U}_t(\mathfrak{sl}(2))\otimes\mathcal{U}_t(\mathfrak{sl}(2))$. In Section IV, we shall see that $\mathcal{U}_t\mathcal{S}$, $\mathcal{U}_t(\mathfrak{sl}(2))\otimes\mathcal{U}_t(\mathfrak{sl}(2))$ and the algebra introduced in Remark II.2.2 can be identified with dense subalgebras of the same topological algebra.

III. FINITE DIMENSIONAL REPRESENTATIONS OF $\mathcal{U}_t\mathcal{S}$ ($q^n\neq 1, \forall n\in\mathbf{N}$)

III.1. Let (m_0,p_0) be an element of $\mathbb{N}/2\times\mathbb{N}/2$ and let V_{m_0,p_0} be a $(2m_0+1)(2p_0+1)$ dimensional vector-space with a basis $\{f_{m,p,};m=0,1,\ldots,2m_0;p=0,1,\ldots,2p_0\}$. Let us introduce the operators defined on V_{m_0,p_0} by the formulas

$$
\begin{aligned}
&l f_{m,p} = \varepsilon_1 q^{m_0 - p_0 - m + p} f_{m,p},\\
&k f_{m,p} = \varepsilon_2 q^{-(m_0+p_0)+m+p} f_{m,p},\\
&\tilde{k} f_{m,p} = \varepsilon_2^{-1} q^{p_0+m_0-p-m} f_{m,p} - \varepsilon_2 q \lambda^2 [2m_0 - m][2p_0 - p] f_{m+1,p+1},\\
&L_+ f_{m,p} = \varepsilon_1 (q^{m_0-m-1}[p] f_{m,p-1} + q^{p_0-p}[2m_0 - m] f_{m+1,p}),\\
&L_- f_{m,p} = \varepsilon_1 (q^{p_0-p-1}[m] f_{m-1,p} + q^{m_0-m}[2p_0 - p] f_{m,p+1}),\\
&K_1 f_{m,p} = \varepsilon_2 q^{-m_0+m}[2p_0 - p] f_{m,p+1},\\
&K_2 f_{m,p} = \varepsilon_2 q^{-p_0+p}[2m_0 - m] f_{m+1,p},
\end{aligned}
\tag{15}
$$

where

$$
\varepsilon_1^2 = \varepsilon_2^2 = \pm 1, \quad [n] = \frac{q^n - q^{-n}}{q - q^{-1}}, \quad \forall n \in \mathbb{N}.
$$

Thus these operators on V_{m_0,p_0} verify the relations (3), (4), (5) of $\mathscr{U}_t\mathscr{L}$. Denote by $\rho^{m_0,p_0,\varepsilon_1,\varepsilon_2}$ the representation of $\mathscr{U}_t\mathscr{L}$ defined by Formulas (15) in the vector-space V_{m_0,p_0}.

Remark III.1.1: The representations $\rho^{m_0,p_0,\varepsilon_1,\varepsilon_2}$ with $\varepsilon_1^2 = \varepsilon_2^2 = -1$ have no limit for $q \to 1$.

III.2. Using (8) we have

$$
\begin{aligned}
&\rho^{m_0,p_0,\varepsilon_1,\varepsilon_2}(Q_1') = \varepsilon_1 \varepsilon_2^{-1} \left([m_0][m_0+1] + \frac{q + q^{-1}}{\lambda^2} \right),\\
&\rho^{m_0,p_0,\varepsilon_1,\varepsilon_2}(Q_2') = \varepsilon_1 \varepsilon_2 \left([p_0][p_0+1] + \frac{q + q^{-1}}{\lambda^2} \right).
\end{aligned}
\tag{16}
$$

Theorem III.2.1:

1. Every finite dimensional irreducible representation ρ of the complex algebra $\mathscr{U}_t\mathscr{L}$ in the vector-space V is equivalent to the representation $\rho^{m_0,p_0,\varepsilon_1,\varepsilon_2}$ in the $(2m_0+1)(2p_0+1)$ finite dimensional space $V_{m_0,p_0}, (m_0,p_0) \in \mathbb{N}/2 \times \mathbb{N}/2, \varepsilon_1^2 = \varepsilon_2^2 = \pm 1$.

2. Two representations $\rho^{m_0,p_0,\varepsilon_1,\varepsilon_2}$ and $\rho^{m_0',p_0',\varepsilon_1',\varepsilon_2'}$ of $\mathscr{U}_t\mathscr{L}$ are equivalent if and only if $m_0 = m_0', p_0 = p_0', \varepsilon_1 = \varepsilon_1', \varepsilon_2 = \varepsilon_2'$.

We must prove the two following Lemmas.

Lemma A: *There exists in V an eigenvector v of l and k with respective eigenvalues α and β. For such a vector, $\alpha\beta$ necessarily is different of zero.*

Proof: The relations $kl = lk$ and $ll^{-1} = 1$, the finite dimension of V imply the existence of v with α non zero. Suppose, for a contradiction, β equal to zero. We then prove

$k\tilde{k}^n v = (1 - q^{2n})\tilde{k}^{n-1} v$.

As q^n is different of 1 for any n, we obtain a contradiction with the finite dimension of V.

Lemma B: *We can choose v_0 as in Lemma A such that there exist two integers m_1 and p_1 with the property $\{K_2^m K_1^p v_0, m \in \{0,1,\cdots m_1\}, p \in \{0,1,\cdots p_1\}\}$ is a basis of V.*

Proof: (a) Let v be as in Lemma A. Thus $K_2^m K_1^p v ((m,p) \in \mathbb{N}^2)$ is zero or an eigenvector of l, k, lk^{-1}, lk with respective eigenvalues $\alpha q^{p-m}, \beta q^{p+m}, \beta\alpha^{-1} q^{2m}, \beta\alpha q^{2p}$ and $\alpha\beta$ non-zero.
We have the relations

$$
\begin{aligned}
&l(kl^{-1}L_- - K_1) = q(kl^{-1}L_- - K_1) l,\\
&k(kl^{-1}L_- - K_1) = q^{-1}(kl^{-1}L_+ - K_1) k,
\end{aligned}
\tag{17}
$$

$$\begin{aligned} l(klL_+ - K_2) &= q^{-1}(klL_+ - K_2)l, \\ k(klL_+ - K_2) &= q^{-1}(klL_+ - K_2)k. \end{aligned} \tag{18}$$

We define a subset of $\mathbb{Z}^2$ as follows:

$$P = \{(m,p) \in \mathbb{Z}^2 / \exists v_{m,p} \in V \text{ with } lv_{m,p} = \alpha q^{p-m} v_{m,p}, kv_{m,p} = \beta q^{p+m} v_{m,p}\}.$$

P contains $(0,0)$ and is finite. Set

$$m_0 = \inf\{m \in \mathbb{Z} / \exists p \in \mathbb{Z} \text{ with } (m,p) \in P\}, \quad p_0 = \inf\{p \in \mathbb{Z} \text{ with } (m_0,p) \in P\}.$$

We denote by v_0 a common eigenvector of l and k with the respective eigenvalues,

$$\alpha_0 = \alpha q^{p_0 - m_0} \quad \text{and} \quad \beta_0 = \beta q^{p_0 + m_0}.$$

Thus Formulas (17) and (18) imply

$$(kl^{-1}L_- - K_1)v_0 = 0 \quad \text{and} \quad (klL_+ - K_2)v_0 = 0\ . \tag{19}$$

Consider the subspace W of V generated by $\{K_2^m K_1^p v_0, (m,p) \in \mathbb{N} \text{ with } K_2^m K_1^p v_0 \neq 0\}$.

(b) We want to prove that W is V. The stability of W by l, l^{-1}, k, K_1, K_2 is evident. Using $\widetilde{k}k = 1 - \lambda^2 K_1 K_2$ and Lemma A, we deduce the stability of W by $\widetilde{k}$. Using Q_1' and Q_2' (8) which are represented by scalar operators on V, we deduce the stability of W by $K_2 L_-$ and $K_1 L_+$. The equality $l\widetilde{k}(kl^{-1}L_- v_0) = L_- v_0 - \lambda^2 K_1 (K_2 L_- v_0)$ together with (19) gives

$$L_- v_0 \in W.$$

A similar argument allows to conclude that $L_+ v_0$ is in W. The stability of W by L_+ and L_- results from relations (5). The irreducibility of the representation of $\mathscr{U}_t\mathscr{L}$ in V permits to assert that W is equal to V.

(c) Now we claim that

$$\{(m,p) \in \mathbb{N}^2 \text{ with } K_2^m K_1^p v_0 \neq 0\} = \{0,1,\cdots m_1\} \times \{0,1,\cdots p_1\},$$

where

$$m_1 = \sup\{m \in \mathbb{N} \text{ with } K_2^m v_0 \neq 0\}, \quad p_1 = \sup\{p \in \mathbb{N} \text{ with } K_1^p v_0 \neq 0\}.$$

Evidently, $K_2^m K_1^p v_0 = 0$ if $m > m_1$ or $p > p_1$. Now pick out an integer $m (m \leqslant m_1)$ and suppose there exists an integer $p' (1 \leqslant p' \leqslant p_1)$ such that $K_2^m K_1^{p'} v_0$ is zero and $K_2^m K_1^{p'-1} v_0$ is non-zero. From (17) we have

$$(kl^{-1}L_- - K_1)^m K_2^m K_1^{p'-1} v_0 = \mu K_1^{p'-1} v_0, \quad \mu \neq 0.$$

Applying K_1 we obtain $K_1^{p'} v_0 = 0$, in contradiction with the definition of p_1. Hence

$$\forall (m,p) \in \{0,1\cdots m_1\} \times \{0,1\cdots p_1\}, \quad K_1^m K_2^p v_0 \neq 0.$$

Lemma 2 is proved.

Proof of the theorem: Lemma 2 gives a basis of V and the action of $l, l^{-1}, K_1, K_2, k, \widetilde{k}$ on the elements of this basis, in a function of the two non-zero parameters α_0, β_0. From (19) we deduce easily $L_- v_0$ and $L_+ v_0$. The relations between L_-(resp., L_+) and K_1, L_-(resp., L_+) and K_2 give by induction the action of L_- and L_+ on the basis and the conditions

$$\alpha_0\beta_0^{-1}=\varepsilon q^{m_1},\quad \varepsilon^2=1(\text{ resp.},\ \alpha_0\beta_0=\varepsilon' q^{p_1},\quad \varepsilon'^2=1)$$

or

$$\alpha_0=\varepsilon_1 q^{(m_1-p_1)/2},\quad \beta_0=\varepsilon_2 q^{(-p_1-m_1)/2},\quad \varepsilon_1\varepsilon_2=\varepsilon',\quad \varepsilon_1\varepsilon_2^{-1}=\varepsilon.$$

Set for (m,p) in $\{0,1,\cdots m_1\}\times\{0,1,\cdots p_1\}$:

$$f_{m,p}=\varepsilon_2^{-p-m}\alpha_{mp}K_2^m K_1^p v_0\ ,$$

$$\alpha_{mp}=\frac{q^{(p_1 m+m_1 p)/2}-mp}{[m_1]\cdots[m_1-m+1][p]\cdots[p_1-p+1]}\ .$$

Then the action of $l,k,\tilde{k},K_1,K_2,L_+,L_-$ on the basis $\{f_{m,p}\}$ is given by formulas (15) where we have $2m_0=m_1$ and $2p_0=p_1$.
Part (b) of the theorem results from formulas (16) and from the spectrum of l and k in the representation $\rho^{m_0,p_0,\varepsilon_1,\varepsilon_2}$ (together with $q^n\neq 1,\forall n\in\mathbb{N}$).

We can introduce in $\mathscr{U}_t\mathscr{S}$ the following central elements:

$$Q_1(\varepsilon_1,\varepsilon_2)=Q_1'-\varepsilon_1\varepsilon_2^{-1}\lambda^{-2}(q+q^{-1}),$$
$$Q_2(\varepsilon_1,\varepsilon_2)=Q_2'-\varepsilon_1\varepsilon_2\lambda^{-2}(q+q^{-1}),$$
$$\text{with } \varepsilon_1^2=\varepsilon_2^2=\pm 1.$$

Theorem III.2.2: *Every finite dimensional representation of $\mathscr{U}_t\mathscr{S}$ is completely reducible.*
The proof is the same as for Theorem 1, Sec. IV, in Ref. 16

Corollary III.2.3: We have the following equivalences between representations of $\mathscr{U}_t\mathscr{S}$:

$$(a)\ \rho^{m_0,0,\varepsilon_1,\varepsilon_2}\otimes\rho^{0,p_0,\varepsilon_1',\varepsilon_2'}\circ\Delta_t=\rho^{m_0,p_0,\varepsilon_1\varepsilon_1',\varepsilon_2\varepsilon_2'},$$
$$(b)\ \rho^{0,p_0,\varepsilon_1',\varepsilon_2'}\otimes\rho^{m_0,0,\varepsilon_1,\varepsilon_2}\circ\Delta_t\simeq\rho^{m_0,p_0,\varepsilon_1\varepsilon_1',\varepsilon_2\varepsilon_2'},$$
$$(c)\ \rho^{m_0,0,\varepsilon_1,\varepsilon_2}\otimes\rho^{0,p_0,\varepsilon_1',\varepsilon_2'}\circ\tau\Delta_t\simeq\rho^{m_0,p_0,\varepsilon_1\varepsilon_1',\varepsilon_2\varepsilon_2'},$$
$$(d)\ \rho^{0,p_0,\varepsilon_1',\varepsilon_2'}\otimes\rho^{m_0,0,\varepsilon_1,\varepsilon_2}\circ\tau\Delta_t\simeq\rho^{m_0,p_0,\varepsilon_1\varepsilon_1',\varepsilon_2\varepsilon_2'},$$
$$(e)\ \rho^{m,p,\varepsilon_1,\varepsilon_2}\circ\varphi\simeq\rho^{p,m,\varepsilon_1^{-1},\varepsilon_2}.$$

Proof: For each case (a) to (d), it is easy to prove the irreducibility of the tensor product of the two considered representations of $\mathscr{U}_t\mathscr{S}$. Theorem III.2.1, together with the spectrum of the representants of Q_1, Q_2, l and k, gives the results. A direct calculation proves the equivalence of $\rho^{m,0,\varepsilon_1,\varepsilon_2}\circ\varphi$ and $\rho^{0,m,\varepsilon_1^{-1},\varepsilon_2}$. Then (e) is deduced from (a) and the property $\Delta_t\circ\varphi=(\varphi\otimes\varphi)\circ(\tau\Delta_t)$.

Corollary III.2.4: We have

$$\text{(a) } \rho^{m_0,p_0,\varepsilon_1,\varepsilon_2}\otimes\rho^{m_0',p_0',\varepsilon_1',\varepsilon_2'}\circ\Delta_t\simeq\bigoplus_{\substack{i=|m_0-m_0'|,\ldots,m_0+m_0'\\ j=|p_0-p_0'|,\ldots,p_0+p_0'}}\rho^{i,j,\varepsilon_1\varepsilon_1',\varepsilon_2\varepsilon_2'};$$

$$\text{(b) } \rho^{m_0,p_0,\varepsilon_1,\varepsilon_2}\otimes\rho^{m_0',p_0',\varepsilon_1'\varepsilon_2'}\circ\tau\Delta_t\simeq\bigoplus_{\substack{i=|m_0-m_0'|,\ldots,m_0+m_0'\\ j=|p_0-p_0'|,\ldots,p_0+p_0'}}\rho^{i,j,\varepsilon_1\varepsilon_1',\varepsilon_2\varepsilon_2'}.$$

IV. A COMMON MODEL FOR THE HOPF ALGEBRA $\mathcal{U}_t\mathcal{L}$ and $\mathcal{U}_t(\mathfrak{sl}(2))\otimes\mathcal{U}_t(\mathfrak{sl}(2))$ ($q^n\neq 1, \forall n\in\mathbb{N}$)

In this Section we construct a classical topological algebra $\mathcal{A}$ using the finite dimensional representations of the Lorentz Lie algebra. Then, the algebras $\mathcal{U}_t\mathcal{L}$ and $\mathcal{U}_t(sl(2))\otimes\mathcal{U}_t(sl(2))$ can be densely realized in $\mathcal{A}$ (Paragraph IV.1). Moreover, in Paragraph IV.2, the Hopf structures of $\mathcal{U}_t\mathcal{L}$ and $\mathcal{U}_t(sl(2))\otimes\mathcal{U}_t(sl(2))$ are extended onto the topological algebra $\mathcal{A}$ which then carries various topological Hopf structures. In particular Theorem IV.2.1 proves, the first Hopf structure on $\mathcal{A}$ is the twisting of the second one and consequently, it is quasi-triangular. Explicit formulas are given for the twisting element and the quasi-triangular R-matrix in $\mathcal{A}\hat{\otimes}\mathcal{A}$. As $\mathcal{U}_t\mathcal{L}$ is not a Drinfeld-Jimbo deformation, we need to prove Corollary IV.2.2 whose the result is basic for Paragraph V.3.

IV.1 The topological algebra $\mathcal{A}$

We use the results of Refs. 3 and 4. Consequently this common model is constructed from the set of finite dimensional irreducible representations of $\mathcal{U}\mathcal{L}=\mathcal{U}\mathfrak{g}_1\otimes\mathcal{U}\mathfrak{g}_2$ (paragraph II.1.). If (ρ_n, V_n) denotes the irreducible representation of $\mathfrak{sl}(2)$ of dimension $2n+1$, n in $\mathbb{N}/2$, each finite dimensional irreducible of $\mathcal{U}\mathcal{L}$ is equivalent to $(\rho_n\otimes\rho_p, V_n\otimes V_p),(n,p)$ in $\mathbb{N}/2\times\mathbb{N}/2$. To simplify, we denote

$$\rho_{n,p}=\rho_n\otimes\rho_p, \quad V_{n,p}=V_n\otimes V_p.$$

We introduce the Fréchet algebra $\mathcal{A}$ defined as follows:

(i) $\mathcal{A}=\Pi_{(n,p)\in\mathbb{N}/2\times\mathbb{N}/2}\mathcal{L}(V_n\otimes V_p)=\Pi_{(n,p)\in\mathbb{N}/2\times\mathbb{N}/2}\mathcal{L}(V_n)\otimes\mathcal{L}(V_p)$. $\mathcal{A}$ is endowed with the product topology.

(ii) If $a=(a_{n,p})$ and $b=(b_{n,p})$ are two elements of $\mathcal{A}$, then $a.b=(a_{n,p}b_{n,p})$.

(iii) Then, $\mathcal{A}$ is the projective tensor product $A_1\hat{\otimes}A_2$ where $A_i(i=1,2)$ is defined as in Ref. 3 (i.e., $A_1=\Pi_{n\in\mathbb{N}/2}\mathcal{L}(V_{n,0})$, [resp., $A_2=\Pi_{p\in\mathbb{N}/2}\mathcal{L}(V_{0,p})$] endowed with the product topology and the evident algebra structure).

Similarly to Ref. 3, we have the following properties:

i. $\mathcal{U}\mathcal{L}$ can be identified with a subalgebra of $\mathcal{A}$ via the injective morphism:

$u\in\mathcal{U}\mathcal{L}\rightarrow(\rho_{n,p}(u))_{(n,p)\in\mathbb{N}/2\times\mathbb{N}/2}\in\mathcal{A}$

ii. $\overline{\mathcal{U}\mathcal{L}}=\mathcal{A}$ (Jacobson density theorem).

iii. $\rho_{n,p}:\mathcal{U}\mathcal{L}\rightarrow\mathcal{L}(V_{n,p})$ is continuous and can be extended to a representation of $\mathcal{A}$, which we shall still denote $\rho_{n,p}$.

Now, let us introduce the following elements in $\mathcal{A}$:

$$\begin{aligned}
&\Lambda_1=(\Lambda_{1,n,p}), \quad \text{with } \Lambda_{1,n,p}=n\mathbb{1}_{V_n}\otimes\mathbb{1}_{V_p},\\
&\Lambda_2=(\Lambda_{2,n,p}), \quad \text{with } \Lambda_{2,n,p}=\mathbb{1}_{V_n}\otimes p\mathbb{1}_{v_p},\\
&C_1=(C_{1,n,p}), \quad \text{with } C_{1,n,p}=(-1)^{2n}\mathbb{1}_{V_n}\otimes\mathbb{1}_{V_p},\\
&C_2=(C_{2,n,p}), \quad \text{with } C_{2,n,p}=(-1)^{2p}\mathbb{1}_{V_n}\otimes\mathbb{1}_{V_p}.
\end{aligned} \tag{20}$$

Let us give the classical representation ρ_{n_0,p_0} of $\mathcal{U}\mathcal{L}$ on a standard basis $\{f_{n,p}, n=0,\ldots,2n_0, p=0,\ldots,2p_0\}$ of V_{n_0,p_0}:

$$\begin{aligned}
&Y_1f_{n,p}=(-n_0+n)f_{n,p}, \quad && Y_2f_{n,p}=(-p_0+p)f_{n,p},\\
&F_1f_{n,p}=(2n_0-n)f_{n+1,p}, \quad && F_2f_{n,p}=(2p_0-p)f_{n,p+1},\\
&G_1f_{n,p}=nf_{n-1,p}, && G_2f_{n,p}=pf_{n,p-1}.
\end{aligned} \tag{21}$$

Taking into account the identification of $\mathscr{U}\mathscr{L}$ as a subalgebra of $\mathscr{A}$, the following elements are well defined in the algebra $\mathscr{A}$:

$$
\begin{aligned}
&l = C_1 C_2 q^{(Y_2 - Y_1)}, \quad l^{-1} = C_1 C_2 q^{(Y_1 - Y_2)}, \\
&k = C_2 q^{(Y_2 + Y_1)}, \quad \tilde{k} = C_2 \left(q^{-(Y_1 + Y_2)} - \lambda^2 q \frac{[Y_1 - \Lambda_1 - 1][Y_2 - \Lambda_2 - 1]}{(Y_1 - \Lambda_1 - 1)(Y_2 - \Lambda_2 - 1)} F_1 F_2 \right), \\
&K_1 = C_2 q^{Y_1} \frac{[Y_2 - \Lambda_2 - 1]}{(Y_2 - \Lambda_2 - 1)} F_2, \quad K_2 = C_2 q^{Y_2} \frac{[Y_1 - \Lambda_1 - 1]}{(Y_1 - \Lambda_1 - 1)} F_1, \\
&L_- = C_1 C_2 \left(q^{-Y_2 - 1} \frac{[Y_1 + \Lambda_1 + 1]}{(Y_1 + \Lambda_1 + 1)} G_1 + q^{-Y_1} \frac{[Y_2 - \Lambda_2 - 1]}{(Y_2 - \Lambda_2 - 1)} F_2 \right), \\
&L_+ = C_1 C_2 \left(q^{-Y_1 - 1} \frac{[Y_2 + \Lambda_2 + 1]}{(Y_2 + \Lambda_2 + 1)} G_2 + q^{-Y_2} \frac{[Y_1 - \Lambda_1 - 1]}{(Y_1 - \Lambda_1 - 1)} F_1 \right),
\end{aligned}
\tag{22}
$$

$$
\begin{aligned}
&K_1' = C_1 q^{Y_1}, \quad K_1'^{-1} = C_1 q^{-Y_1}, \\
&F_1' = C_1 \frac{[Y_1 - \Lambda_1 - 1]}{(Y_1 - \Lambda_1 - 1)} F_1, \\
&G_1' = C_1 \frac{[Y_1 + \Lambda_1 + 1]}{(Y_1 + \Lambda_1 + 1)} G_1,
\end{aligned}
\tag{23a}
$$

$$
\begin{aligned}
&K_2' = C_2 q^{Y_2}, \quad K_2'^{-1} = C_2 q^{-Y_2}, \\
&F_2' = C_2 \frac{[Y_2 - \Lambda_2 - 1]}{(Y_2 - \Lambda_2 - 1)} F_2, \\
&G_2' = C_2 \frac{[Y_2 + \Lambda_2 + 1]}{(Y_2 + \Lambda_2 + 1)} G_2 \ .
\end{aligned}
\tag{23b}
$$

Denote by $\mathscr{A}_t$ (resp., $\mathscr{A}_t'$, $A_{1,t}$, $A_{2,t}$) the subalgebra of $\mathscr{A}$ generated by the elements of $\mathscr{A}$ defined by Formulas (22) [resp., (23a), (23b)]. Then, $\mathscr{A}_t'$ is the tensor product of algebras $A_{1,t} \otimes A_{2,t}$. From Ref. 3, $A_{1,t}$ (resp., $A_{2,t}$) is a dense subalgebra of A_1 (resp., A_2), which is isomorphic to $\mathscr{U}_t(\mathfrak{sl}(2))$.

We have

$$
\begin{aligned}
&l = K_1'^{-1} K_2', && l^{-1} = K_1' K_2'^{-1}, \\
&k = C_1 K_1' K_2', && \tilde{k} = C_1 (K_1'^{-1} K_2'^{-1} - q\lambda^2 F_1' F_2'), \\
&K_1 = C_1 K_1' F_2', && K_2 = C_1 K_2' F_1', \\
&L_+ = F_1' K_2'^{-1} + q^{-1} K_1'^{-1} G_2', && L_- = K_1'^{-1} F_2' + q^{-1} G_1' K_2'^{-1} \ .
\end{aligned}
\tag{24}
$$

Then we can claim the following.

Theorem IV.1.1: *$\mathscr{A}_t$ (resp., $\mathscr{A}_t'$) is a subalgebra of $\mathscr{A}$ isomorphic to $\mathscr{U}_t\mathscr{L}$* [resp., $\mathscr{U}_t(\mathfrak{sl}(2)) \otimes \mathscr{U}_t(\mathfrak{sl}(2))$]. Moreover we have $\mathscr{A}_t = \mathscr{A}$ (resp., $\mathscr{A}_t' = \mathscr{A}$).

Proof: Let X be one of the elements of $\mathscr{A}_t$ defined by Formulas (22). Then, we have $X = (\rho_{n,p}(X))$ and $\rho_{n,p}(X) = \rho^{n,p,(-1)^{2(n+p)},(-1)^{2p}}(X)$ where $\rho^{n,p,(-1)^{2(n+p)},(-1)^{2p}}(X)$ is defined by Formulas (15). Then the application $X \in \mathscr{A}_t \to X \in \mathscr{U}_t\mathscr{L}$ defines a morphism of $\mathscr{A}_t$ into $\mathscr{U}_t\mathscr{L}$. The injectivity of this morphism is deduced from the property that the set of representations of $U_t\mathscr{L}$, $\{\rho^{n,p,(-1)^{2n+2p},(-1)^{2p}}, (n,p) \in \mathbb{N}/2 \times \mathbb{N}/2\}$ is a complete set of representations of $\mathscr{U}_t\mathscr{L}$.

From now on, $\mathscr{U}_t\mathscr{L}$ can be identified with $\mathscr{A}_t$ and, consequently, $\rho^{n,p,(-1)^{2n+2p},(-1)^{2p}}$ with $\rho_{n,p}$ on $\mathscr{A}_t$. The density of $\mathscr{A}_t$ in $\mathscr{A}$ is given by the Jacobson density theorem applied to the $\mathscr{A}$-module $V=\Sigma_{(n,p)\in(\mathbb{N}/2)^2}V_{n,p}$ and to the semi-simple representation ρ of $\mathscr{A}_t, \rho=\Sigma_{(n,p)\in(\mathbb{N}/2)^2}\rho_{n,p}$.

The proof for $\mathscr{A}'_t$ is evident. We just have to remark that any finite-dimensional irreducible representation is equivalent to $\rho_n\otimes\rho_p$ and to use the results of Ref. 3 for $A_{i,t}(i=1,2)$.

Remark IV.1.2: (a) Part (e) of Corollary III.2.3, together with the density of $\mathscr{A}_t$ in $\mathscr{A}$ imply that the morphism φ defined on $\mathscr{A}_t$ [Formulas (12)] has a unique continuous extension on $\mathscr{A}$. We have

$$\begin{aligned}&\varphi(C_1)=C_1,\quad \varphi(C_2)=C_2,\\&\varphi(K'_1)=C_1C_2K'_2,\quad \varphi(F'_1)=-q^{-1}C_1C_2F'_2,\quad \varphi(G'_1)=-qC_1C_2G'_2\ .\end{aligned}\tag{25}$$

(b) The initial q-Lorentz algebra introduced in Ref. 10 (see Remark II.2.2) is a subalgebra of $\mathscr{A}$ which also is dense in $\mathscr{A}$.

IV.2 Various topological Hopf structures on $\mathscr{A}$

For that, we need to introduce $\mathscr{A}\hat{\otimes}\mathscr{A}$, the completion of $\mathscr{A}\otimes\mathscr{A}$ for the projective topology. Then

$$\mathscr{A}\hat{\otimes}\mathscr{A}=\prod_{\substack{(n,p)\\(n',p')\in(\mathbb{N}/2)^2}}\mathscr{L}(V_{np})\otimes\mathscr{L}(V_{n'p'})$$

Take into account Theorem IV.1.1, its consequences and Corollaries IV.2.3 and IV.2.4 and let us apply the methods of Refs. 3 and 4 to extend the Hopf structure $(\Delta_t,\varepsilon_t,J_t)$ [resp., $(\Delta'_t,\varepsilon'_t,J'_t)$ or $(\Delta''_t,\varepsilon'_t,J''_t)$] of $\mathscr{A}_t$ (resp., $\mathscr{A}'_t$) to $\mathscr{A}$. To be self contained we shall recall how this is done.

• The counit ε_t (resp., ε'_t) of $\mathscr{A}_t$ (resp., $\mathscr{A}'_t$) (equal to $\rho_{0,0}$) obviously extends to $\mathscr{A}$. The antipode J_t (resp., J'_t or J''_t) of $(\mathscr{A}_t,\ \Delta_t)$ [resp., $(\mathscr{A}'_t,\ \Delta'_t)$ or $(\mathscr{A}'_t,\ \Delta''_t)$] has a continuous extension to $\mathscr{A}$ given by (for J_t)

$$\forall a\in\mathscr{A},\quad (J_t(a))_{n,p}={}^t\hat{\rho}_{np}(a),\quad \forall(n,p)\in\mathbb{N}/2\times\mathbb{N}/2\ ,$$

where $\hat{\rho}_{np}(a)={}^t\rho_{np}\circ J_t(a)$ is the contragradient representation of $\rho_{n,p}$ of $\mathscr{A}$.

• The extension of Δ_t (resp., Δ'_t or Δ''_t) of $\mathscr{A}_t$ (resp., $\mathscr{A}'_t$) to $\mathscr{A}$ results from the existence of an element $\mathscr{P}(t)$ [resp., $\mathscr{P}'(t)$ or $\mathscr{P}''(t)$] of $\mathscr{A}\hat{\otimes}\mathscr{A}$ such that

$$\Delta_t=\mathscr{P}(t)\Delta_0\mathscr{P}(t)^{-1},\Delta'_t=\mathscr{P}'(t)\Delta_0\mathscr{P}'(t)^{-1},\Delta''_t=\mathscr{P}''(t)\Delta_0\mathscr{P}''(t)^{-1}.\tag{26}$$

The existence of $\mathscr{P}'(t)$ [resp., $\mathscr{P}''(t)$] (the Drinfeld twist) is proved in Ref. 17. In particular, denote by $P^{(i)}(t)$ the element of $(\mathscr{U}(\mathfrak{sl}(2))\otimes\mathscr{U}(\mathfrak{sl}(2)))[[t]]$ (Ref. 17) in the model $A_i(i=1,2)$ of Ref. 3 such that

$$\delta_t=P^{(i)}(t)\,\delta_0P^{(i)}(t)^{-1}\ .$$

Then we have

$$\mathscr{P}'(t)=P^{(1)}(t)_{1,3}P^{(2)}(t)_{2,4},\quad \mathscr{P}''(t)=P^{(1)}(t)_{1,3}P^{(2)}(t)_{4,2}\ .\tag{27}$$

Using Refs. 3 and 4, Theorem IV.1.1, Corollaries III.2.3 and III.2.4, $\mathcal{P}(t)$ can be constructed as follows:

$$(\rho_{n,p}\otimes\rho_{n',p'})\circ\Delta_t=\sum_{i=|n-n'|}^{n+n'}\sum_{j=|p-p'|}^{p+p'}\rho_{i,j}\ .$$

and

$$V_{n,p}\otimes V_{n',p'}=\sum_{i=|n-n'|}^{n+n'}\sum_{j=|p-p'|}^{p+p'}V_{i,j}(t)\ .$$

Then $\mathcal{P}_{(n,p),(n',p')}(t)$ is defined as the element of $\mathcal{L}(V_{np}\otimes V_{n'p'})$ which sends the basis of $V_{ij}(0)$ [Formulas (21)] onto the basis of $V_{i,j}(t)$ [Formulas (15)]. We have

$$(\rho_{n,p}\otimes\rho_{n',p'})\circ\Delta_t=(\Delta_t)_{(n,p),(n',p')}=\mathcal{P}_{(n,p),(n',p')}(t)\Delta_0(\mathcal{P}_{(n,p),(n',p')}(t))^{-1}\ .$$

Thus, Formulas (26) can be extended to $\mathcal{A}$ and provide an extension of Δ_t, (resp., Δ'_t, Δ''_t), still denoted by the same symbol. These extensions are continuous morphisms of $\mathcal{A}$ into $\mathcal{A}\hat{\otimes}\mathcal{A}$.

Now, in order to prove that the Hopf structure $(\mathcal{A},\ \Delta_t,\ \varepsilon_t,\ J_t)$ is a twisting of $(\mathcal{A},\ \Delta''_t,\ \varepsilon_t,\ J''_t)$, let us introduce the following element W of $A_2\hat{\otimes}A_1$:

$$W=e^{-2t(Y_2\otimes Y_1)}\sum_{i\in\mathbb{N}}\frac{\lambda^i}{[i]!}q^{i(3i+1)/2}F_2'^iK_2'^i\otimes F_1'^iK_1'^i\ . \tag{28}$$

Using Formulas (24), we remark that

$$W_{p,n}=\rho_{0,p}\otimes\rho_{n,0}(W)=\rho_{0,p}\otimes\rho_{n,0}(R_{21})\ , \tag{29}$$

where $R=R_{12}$ is the universal R-matrix of the Hopf subalgebra $\mathcal{U}_t(\mathfrak{sl}(2))$ of $\mathcal{U}_t(\mathcal{L})$ generated by $\{L_+,L_-,l,l^{-1}\}$. Recall that R is given by[18]

$$R=e^{2t(Y_1-Y_2\otimes Y_1-Y_2)}\sum_{i\in\mathbb{N}}\frac{\lambda^i}{[i]!}q^{i(3i+1)/2}L_+^il^{-i}\otimes L_-^il^i\ .$$

Formulas (29) implies the existence of W^{-1}. We have

$$(W^{-1})_{p,n}=(W_{p,n})^{-1}=\rho_{0,p}\otimes\rho_{n,0}(R_{21}^{-1})=\rho_{0,p}\otimes\rho_{n,0}[(J_t^{-1}\otimes id)R_{21}]=\rho_{0,p}\otimes\rho_{n,0}[(id\otimes J_t)R_{21}].$$

Theorem IV.2.1:

1. The Hopf algebra $(\mathcal{A},\ \Delta_t,\ \varepsilon_t,\ J_t)$ *is the twisting*[18] *of the Hopf algebra* $(\mathcal{A},\ \Delta''_t,\ \varepsilon'_t,\ J''_t)$ *by the element* $W_{23}=(1\otimes W\otimes 1)$ *of* $\mathcal{A}\hat{\otimes}\mathcal{A}$ *[W defined by Formula (28)].*

2. The Hopf algebra $(\mathcal{A},\ \Delta_t,\ \varepsilon_t,\ J_t)$ *has an R-matrix* $\mathcal{R}$ *given by*

$$\mathcal{R}=W_{41}R_{31}^{(1)-1}R_{42}^{(2)}W_{23}{}^{-1}, \tag{30}$$

where $R^{(i)}$ *is the universal R-matrix of* A_i $(i=1,2)$ *given in Ref. 18*

Sketch of the proof: Part 1 of the Theorem will be proved after having verified

$$\begin{aligned}\Delta_t&=W_{23}\Delta''_tW_{23}{}^{-1},\\ J_t&=W_{21}{}^{-1}(j_t\otimes j_t^{-1})W_{21},\end{aligned} \tag{31}$$

For that, we need to prove the following.

Lemma A:

$$1.\ \rho_{n,0}\otimes\rho_{0,p}\circ\Delta_t=\rho_{n,0}\otimes\rho_{0,p}\circ\Delta_t''=\rho_{np},\quad \forall(n,p)\in\mathbb{N}/2\times\mathbb{N}/2,$$
$$2.\ \rho_{n,0}\otimes\rho_{n',0}\circ\Delta_t=\rho_{n,0}\otimes\rho_{n',0}\circ\Delta_t'',\quad \forall(n,n')\in\mathbb{N}/2\times\mathbb{N}/2,$$
$$3.\ \rho_{0,p}\otimes\rho_{0,p'}\circ\Delta_t=\rho_{0,p}\otimes\rho_{0,p'}\circ\Delta_t'',\quad \forall(p,p')\in\mathbb{N}/2\times\mathbb{N}/2.$$

This lemma is easily obtained from Corollary III.2.3 (a) , Formulas (15) and (24).

Call τ_{np} the linear map of $V_n\otimes V_p$ into $V_p\otimes V_n$ which exchanges V_n and V_p.

Lemma B:

$$1.\ \rho_{0,p}\otimes\rho_{n,0}\circ\Delta_t''=\tau_{np}\rho_{np}\tau_{np}^{-1},\quad \forall(p,n)\in\mathbb{N}/2\times\mathbb{N}/2,$$
$$2.\ \rho_{0,p}\otimes\rho_{n,0}\circ\Delta_t=W_{p,n}(\rho_{0,p}\otimes\rho_{n,0}\circ\Delta_t'')W_{p,n}^{-1},\quad \forall(p,n)\in\mathbb{N}/2\times\mathbb{N}/2\ .$$

Proof: Theorem IV.1.1 and its consequences, together with Corollary III.2.3 (resp., the definition of Δ_t'') imply the equivalence of the representation $\rho_{0,p}\otimes\rho_{n,0}\circ\Delta_t$ (resp., $\rho_{0,p}\otimes\rho_{n,0}\circ\Delta_t''$) of $\mathcal{A}$ with the representation $\rho_{n,p}$ of $\mathcal{A}$. Now Lemma B (2) follows from a direct calculation on the basis of the dense subalgebra $\mathcal{U}_t\mathcal{L}$ of $\mathcal{A}$ and from the continuity of Δ_t and Δ_t'' on $\mathcal{A}$.

Now we want to prove the first identity of (31).

Lemma A (1) and Lemma B, with the coassociativity of Δ, imply

$$\rho_{n,p}\otimes\rho_{n',p'}\circ\Delta_t=(1\otimes W_{p,n'}\tau_{n',p}\otimes 1)[(\rho_{n,0}\otimes\rho_{n',0}\otimes\rho_{0,p}\otimes\rho_{0,p'})\circ(\Delta_t\otimes\Delta_t)\circ\Delta_t]$$
$$\times(1\otimes\tau_{n',p}{}^{-1}W_{p,n'}{}^{-1}\otimes 1).$$

Using Corollary III.2.4 (b) and Lemma A, we can replace Δ_t by Δ''_t in the right hand side of the previous equality. The first Formula of (31) now follows from Lemma B (1). We similarly prove the second identity of (31).

The previous result implies the existence of a R-matrix $\mathcal{R}$ for the Hopf algebra $(\mathcal{A},\Delta_t,\varepsilon_t, J_t)$ which verifies Formulas (30): here A_1 is endowed with the quasitriangular structure $(\tau R^{(1)})^{-1}$.

Theorem (IV.2.1), Formulas (27) and (28) together with the results of Ref. 17 $\{P^{(i)}(t)$ belongs to $(\mathcal{U}(\mathfrak{sl}(2))\otimes\mathcal{U}(\mathfrak{sl}(2)))[[t]]\}$ allow us to deduce

Corollary IV.2.2: *Let $\mathcal{P}(t)$ be the element of $\mathcal{A}\hat{\otimes}\mathcal{A}$ given by*

$$\mathcal{P}(t)=W_{23}\mathcal{P}''(t)=W_{23}P_{13}^{(1)}(t)P_{42}^{(2)}(t).$$

Then $\mathcal{P}(t)$ belongs to $[\mathcal{U}\mathcal{L}\otimes\mathcal{U}\mathcal{L}][[t]]$ [$\mathcal{U}\mathcal{L}$ defined in (1.1)] and verifies

$$\Delta(t)=\mathcal{P}(t)\Delta_0\mathcal{P}(t)^{-1}.$$

Now we consider the Hopf algebra (A_1,δ_t,e_t,j_t) and introduce the twisted topological tensor product Hopf algebra $A_1\hat{\otimes}_{\tau R^{(1)}}A_1$ which is the twisting[18] of the topological tensor product Hopf algebra $A_1\hat{\otimes}A_1$ by $(\tau R^{(1)})_{23}$. Moreover $A_1\hat{\otimes}_{\tau R^{(1)}}A_1$ has a quasitriangular structure given by Ref. 19:

$$\mathcal{R}_1=(\tau R^{(1)})_{41}(\tau R^{(1)})_{13}^{-1}R_{24}^{(1)}(\tau R^{(1)})_{23}^{-1}$$
$$=R_{14}^{(1)}(R^{(1)})_{31}^{-1}R_{24}^{(1)}(R^{(1)})_{32}^{-1}\ .$$

Call s the isomorphism of the Hopf algebra (A_1,δ_t) onto the Hopf algebra (A_2,δ_t^{op}) given by

$$X_1\in A_1\rightarrow s(X_1)=(S_p\rho_{p,0}(X_1)S_p^{-1})_{p\in\mathbb{N}/2}$$

$$S_p=\begin{pmatrix} 0 & \dots & \dots & 0 & q^{-2p} \\ \vdots & & & \iddots & 0 \\ \vdots & & \iddots & & \vdots \\ 0 & q^{-1} & & & \vdots \\ 1 & 0 & \dots & \dots & 0 \end{pmatrix}\ .$$

Set $\mathcal{S}=1\otimes s$.

Then, from Theorem IV.2.1, we can easily deduce the following.

Corollary IV.2.3: *$\mathcal{S}^{-1}$ realizes an isomorphism of the Hopf algebra $(\mathcal{A},\Delta_t,\varepsilon_t,J_t)$ onto the quasitriangular twisted tensor product Hopf algebra $A_1\hat{\otimes}_{\tau R^{(1)}}A_1$. Then $(\mathcal{A},\Delta_t,\varepsilon_t,J_t)$ has a quasitriangular structure given by $(\mathcal{S}\otimes\mathcal{S})(\mathcal{R}_1)$ which is equal to the R-matrix $\mathcal{R}$ [Formula (30)].*

Remark IV.2.4: The Hopf algebra $(\mathcal{A},\Delta_t,\varepsilon_t,J_t)$ has another quasitriangular *R*-matrix $\overline{\mathcal{R}}$ given by

$$\overline{\mathcal{R}}=W_{41}(R_{31}^{(1)})^{-1}(R_{24}{}^{(2)})^{-1}W_{23}{}^{-1}.$$

IV.3 $*$-structures on $(\mathcal{A},\Delta_t)$

In Refs. 10 and 14, the authors introduce a conjugate-linear map Φ on the Hopf algebra $\mathcal{U}_t\mathcal{L}$ (or $\mathcal{A}_t$) as follows :

$$\Phi(l)=l,\quad \Phi(k)=\tilde{k},\quad \Phi(\tilde{k})=k,\quad \Phi(K_1)=K_2,\quad \Phi(L_+)=L_-,$$

$$\Phi\circ\Phi=id.$$

After having chosen q real (equivalent to t real), Φ becomes an anti-involution of the algebra $\mathcal{A}_t$, which also is a morphism of the coalgebra structure. Then for t real, Formulas (11) and (12) permit us to prove that

$$\Phi=\overline{\varphi}\circ J_t|_{\mathcal{A}_t}\ , \tag{32}$$

where $\overline{\varphi}$ is the conjugate map of φ.

Taking into account Remark IV.1.2 (a) and the results of Section III. 2, Φ has a unique continuous extension on $\mathcal{A}$ (for t real), which is given by the preceding Formula. Thus, for t real, $(\mathcal{A},\Delta_t,\varepsilon_t,J_t,\varphi)$ is a *-Hopf algebra.

V. DUAL FORMALISM AND REAL STRUCTURES

In this section, we first construct the topological dual vector space of $\mathscr{A}$, $H(G)$ (G as defined in V.1) which coincides with the algebra of the coefficient functions on G (for the holomorphic finite-dimensional representations of G). In Sec. V.1 we also give the non-commutative Hopf algebra structure on $(H(G),\star_t)$ dual to the Hopf structure on $\mathscr{A}$ defined by $\mathscr{U}_t\mathscr{L}$: we obtain the non-commutative algebra structure of Podles-Woronowicz in term of the classical product of functions. Now, we introduce a *-structure on $(H(G),\star_t)$ which is equivalent to consider the Hopf subalgebra $(H(G_0),\star_t)$ (where G_0 is a real Lie subgroup of G isomorphic to $SL(2,\mathbb{C})$) (Sec. V.2). Then, the main result of this Section is to extend the Hopf structure of $(H(G_0),\star_t)$ to $\mathscr{C}^{\infty}(G_0)$ (which contains $H(G_0)$), endowed with its usual Fréchet topology. Such a result is proved in Ref. 5 for any real semi-simple Lie group G' and any deformation of the commutative algebra $H(G')$ which is inherited from a deformation of the coalgebra structure on the enveloping algebra of the Lie algebra of G'. In our case, the product $\star_t$ on $H(G_0)$ is inherited from the coproduct Δ_t on $\mathscr{A}$ with values in $\mathscr{A}\hat{\otimes}.\mathscr{A}$ and $\mathscr{A}\hat{\otimes}.\mathscr{A}$ strictly containing $(\mathscr{U}\mathscr{L}\otimes\mathscr{U}\mathscr{L})[[t]]$. Fortunately, the Formula $\Delta_t=\mathscr{P}(t)\Delta_0\mathscr{P}(t)^{-1}$ and Corollary IV.2.2. which asserts that $\mathscr{P}(t)$ belongs to $(\mathscr{U}\mathscr{L}\otimes\mathscr{U}\mathscr{L})[[t]]$, permits us to apply the result of Ref. 5 and to conclude (Sec. V.3).

V.1 Dual Hopf algebra of $(\mathscr{A},\Delta_t)$

Set

$$G=SL(2,\mathbb{C})\times SL(2,\mathbb{C}).$$

This group is imbedded in $\mathscr{A}$ by the following identification:

$$x=(T,\tilde{T})\in G\xrightarrow{i}a=(a_{n,p})_{(n,p)\in(\mathbb{N}/2)^2}\in\mathscr{A},$$

where

$$a_{n,p}=\rho_n(T)\otimes\rho_p(\tilde{T})=\rho_{n,p}(x).$$

i is an injective morphism. Using the same argument as for the density of $\mathscr{U}\mathscr{L}$ in $\mathscr{A}$ (Jacobson density Theorem), we get

$$\overline{\text{span } i(G)}=\mathscr{A}.$$

Let us consider the topological dual space $\mathscr{A}^{\star}$ of $\mathscr{A}$. $\mathscr{A}^{\star}$ can be identified with $\mathscr{H}(G)=\oplus_{(n,p)\in(\mathbb{N}/2)^2}\mathscr{L}(V_{n,p})$ (endowed by the inductive topology) as follows :

$$a=(a_{n,p})\in\mathscr{A},\quad b=\sum_{\text{finite}}b_{np}\in\mathscr{H},\quad \langle b|a\rangle=\sum_{\text{finite}}\text{Tr}(b_{np}a_{np})\ .$$

Then the density of G in $\mathscr{A}$ allows us to consider $\mathscr{H}(G)$ as an algebra of functions on G .

Using Corollary III.2.4, $\mathscr{H}(G)$ is exactly the algebra of functions on G generated by the coefficient functions, i.e.

$$\mathscr{H}(G)=\mathbb{C}[a,b,c,d,a',b',c',d']/\langle ad-bc=a'd'-b'c'=1\rangle,$$

where the element x of G is given by

$$x=(T,\tilde{T}),\quad \text{with } T=\begin{pmatrix}a & b\\ c & d\end{pmatrix}=\rho_{1/2,0}(x),\quad \tilde{T}=\begin{pmatrix}\tilde{a} & -\tilde{b}\\ -\tilde{c} & \tilde{d}\end{pmatrix}=\rho_{0,1/2}(x).$$

By duality, the results of Section IV give various topological Hopf structures on $\mathscr{H}$. The coproduct is always the mapping $h(x)\to h(x.y)$ if h is in $\mathscr{H}(G)$. But $\mathscr{H}(G)$ is endowed with different associative, non-commutative products. Denote by $\star_t$ (resp., $\star_t', \star_t''$) the product on $\mathscr{H}(G)$ induced by the coproduct Δ_t (resp., Δ_t', Δ_t'') of $\mathscr{A}$. Theorem IV.2.1 and Corollary IV.2.2 together with Formulas (26) and (27) allow us to express the products $\star_t, \star_t', \star_t''$ on $\mathscr{H}(G)$ in term of the classical product of functions.
Set $(.\otimes.)\circ\Delta_t=.\otimes_t.$ and $(.\otimes.)\circ\tau\Delta_t=.\otimes_t^{op}.$
We obtain

$$
\begin{aligned}
&\text{(a)}\quad T\underset{t}{\otimes}T=P^{(1)}_{1/2,\,1/2}(t)T\otimes_0 T(P^{(1)}_{1/2,\,1/2}(t))^{-1},\\
&\text{(b)}\quad T\underset{t}{\otimes}^{op}T=R^{(1)}_{1/2,\,1/2}(t)T\otimes_t T(R^{(1)}_{1/2,\,1/2}(t))^{-1},\\
&\text{(c)}\quad \widetilde{T}\underset{t}{\otimes}\widetilde{T}=\tau P^{(2)}_{1/2,\,1/2}(t)\widetilde{T}\otimes_0\widetilde{T}(\tau P^{(2)}_{1/2,\,1/2}(t))^{-1},\\
&\text{(d)}\quad \widetilde{T}\underset{t}{\otimes}^{op}\widetilde{T}=\tau R^{(2)}_{1/2,\,1/2}(t)\widetilde{T}\otimes_t\widetilde{T}(\tau R^{(2)}_{1/2,\,1/2}(t))^{-1};
\end{aligned}
\tag{33}
$$

$$
\begin{aligned}
&\text{(a)}\quad T\underset{t}{\otimes}\widetilde{T}=T\otimes_0\widetilde{T},\\
&\text{(b)}\quad \widetilde{T}\underset{t}{\otimes}T=\hat{R}_{(1/2,0),(0,1/2)}T\otimes_t\widetilde{T}(\hat{R}_{(1/2,0),(0,1/2)})^{-1},
\end{aligned}
\tag{34}
$$

or explicitly,

$$a^{\star 2}=a^2,\quad b^{\star 2}=b^2,\quad c^{\star 2}=c^2,\quad d^{\star 2}=d^2,$$

$$\widetilde{a}^{\,\star 2}=\widetilde{a}^{\,2},\quad \widetilde{b}^{\star 2}=\widetilde{b}^{\,2},\quad \widetilde{c}^{\,\star 2}=\widetilde{c}^{\,2},\quad \widetilde{d}^{\star 2}=\widetilde{d}^{\,2},$$

$$b\star_t a=qa\star_t b=q^{\frac{1}{2}}ab,\quad \widetilde{b}\star_t\widetilde{a}=q^{-1}\widetilde{a}\star_t\widetilde{b}=q^{\frac{-1}{2}}\widetilde{a}\widetilde{b},$$

$$c\star_t a=qa\star_t c=2q^{\frac{1}{2}}(q+q^{-1})^{-1}ac,\quad \widetilde{c}\star_t\widetilde{a}=q^{-1}\widetilde{a}\star_t\widetilde{c}=2q^{-\frac{1}{2}}(q+q^{-1})^{-1}\widetilde{a}\widetilde{c},$$

$$d\star_t b=qb\star_t d=2q^{\frac{1}{2}}(q+q^{-1})^{-1}bd,\quad \widetilde{d}\star_t\widetilde{b}=q^{-1}\widetilde{b}\star_t\widetilde{d}=2q^{\frac{-1}{2}}(q+q^{-1})^{-1}\widetilde{b}\widetilde{d},\tag{33$'$}$$

$$d\star_t c=qc\star_t d=2q^{\frac{1}{2}}cd,\quad \widetilde{d}\star_t\widetilde{c}=q^{-1}\widetilde{c}\star_t\widetilde{d}=2q^{\frac{-1}{2}}\widetilde{c}\widetilde{d},$$

$$c\star_t b=b\star_t c=2(q+q^{-1})^{-1}bc,\quad \widetilde{c}\star_t\widetilde{b}=\widetilde{b}\star_t\widetilde{c}=2(q+q^{-1})^{-1}\widetilde{b}\widetilde{c},$$

$$a\star_t d=ad-(q-q^{-1})(q+q^{-1})^{-1}bc,\quad \widetilde{a}\star_t\widetilde{d}=ad+(q-q^{-1})(q+q^{-1})^{-1}\widetilde{b}\widetilde{c},$$

$$d\star_t a=ad+(q-q^{-1})(q+q^{-1})^{-1}bc,\quad \widetilde{d}\star_t\widetilde{a}=ad-(q-q^{-1})(q+q^{-1})^{-1}\widetilde{b}\widetilde{c},$$

$$a\star_t\widetilde{a}=\widetilde{a}\star_t a+q\lambda\widetilde{c}\star_t c=a\widetilde{a},\quad a\star_t\widetilde{d}=\widetilde{d}\star_t a=a\widetilde{d},$$

$$b\star_t\widetilde{b}=\widetilde{b}\star_t b-q\lambda(\widetilde{a}\star_t a-d\star_t\widetilde{d})=b\widetilde{b},\quad b\star_t\widetilde{c}=\widetilde{c}\star_t b=b\widetilde{c},$$

$$c\star_t\widetilde{c}=\widetilde{c}\star_t c=c\widetilde{c},\quad c\star_t\widetilde{b}=\widetilde{b}\star_t c=c\widetilde{b},$$

$$d\star_t\tilde{d}=\tilde{d}\star_t d-q\lambda\tilde{c}\star_t c=d\tilde{d},\quad d\star_t\tilde{a}=\tilde{a}\star_t d=d\tilde{a},$$

$$c\star_t\tilde{a}=q^{-1}\tilde{a}\star_t c=\tilde{a}c,\quad a\star_t\tilde{c}=q^{-1}\tilde{c}\star_t a=\tilde{c}a,$$

$$c\star_t\tilde{d}=q\tilde{d}\star_t c=\tilde{d}c,\quad d\star_t\tilde{c}=q\tilde{c}\star_t d=\tilde{c}d, \tag{34'}$$

$$b\star_t\tilde{d}=q^{-1}\tilde{d}\star_t b-\lambda\tilde{c}\star_t a=b\tilde{d},\quad d\star_t\tilde{b}=q^{-1}\tilde{b}\star_t d-\lambda\tilde{a}\star_t c=d\tilde{b},$$

$$a\star_t\tilde{b}=q\tilde{b}\star_t a+q^2\lambda\tilde{d}\star_t c=a\tilde{b},\quad b\star_t\tilde{a}=q\tilde{a}\star_t b+q^2\lambda\tilde{c}\star_t d=b\tilde{a}.$$

Remark V.1.1 : We recognize in Formulas (33′) and (34′) the relations obtained by Podles and Woronowicz.[8]

Set

$$H=\mathbb{C}[a,b,c,d]/\langle ad-bc=1\rangle;\quad \tilde{H}=\mathbb{C}[\tilde{a},\tilde{b},\tilde{c},\tilde{d}]/\langle\tilde{a}\tilde{d}-\tilde{b}\tilde{c}=1\rangle\ .$$

From Theorem IV.2.1, the product $\star_t''$ (resp., $\star_t'$) coïncides with the product $\star_t$ (resp., $\star_t$) on H and with the product $\star_t$ (resp., $\star_{-t}$) on $\tilde{H}$.
The dual translation of Theorem IV.2.1 and Corollary IV.2.3 is the following one.

Proposition V.1.2:

(*a*) H and $\tilde{H}$ are two Hopf subalgebras of $(\mathscr{H}(G),\star_t')$ [which is isomorphic to $SL_t(2,\mathbb{C})$] and $(\mathscr{H}(G),\star_t')$ is $H\otimes\tilde{H}$ as the tensor product of Hopf algebras.

(*b*) H (resp., $\tilde{H}$) is a Hopf subalgebra of $(\mathscr{H}(G),\star_t)$ isomorphic to $SL_t(2)$ [resp., $SL_{-t}(2)$]. Moreover $(\mathscr{H}(G),\star_t)$ is isomorphic to the double cross product of two Hopf algebras $SL_t(2)$ as defined by Majid in Ref. 12.

Proof: Part (a) and the first affirmation of Part (b) summarize the above claimed properties. Using Corollary IV.2.3 and the injection of G in $\mathscr{A}$, Formula (34b) is equivalent by $\mathscr{S}$ to

$$\hat{R}_{(1/2,0),(1/2,0)}T\otimes_t s^{-1}(\tilde{T})=s^{-1}(\tilde{T})\otimes_t T\hat{R}_{(1/2,0),(1/2,0)}\ . \tag{35}$$

We recognize the Formula which is used for the definition of the q-Lorentz group in Ref. 12. Taking into account the results of Refs. 9 and 12, the Hopf algebra ${}^t\mathscr{S}^{-1}[\mathscr{H}(G)]$ is the double cross product of two Hopf algebras isomorphic to $SL_t(2)$ (or $H,\star_t$): Formula (35) gives the action of each of these algebras on the other one.

V.2 Real structure on $(\mathscr{H},\star_t)$ (for q real)

The anti-involution Φ of the algebras $\mathscr{A}$ [Formula (32)] defines by duality an anti-involution Φ^* of the algebra $(\mathscr{H}(G),\star_t)$:

$$\Phi^*={}^t(\Phi\circ J_t^{-1})={}^t\overline{\varphi}.$$

We have

$$\overline{\varphi(x)}=\begin{pmatrix}\begin{pmatrix}\overline{\tilde{a}} & q^{-1}\overline{\tilde{b}}\\ q\overline{\tilde{c}} & \overline{\tilde{d}}\end{pmatrix},\begin{pmatrix}\overline{a} & -q\overline{b}\\ -q^{-1}\overline{c} & \overline{d}\end{pmatrix}\end{pmatrix}.$$

A real structure on $\mathscr{H}$ is defined by

$$\Phi^*=J_t\ \Leftrightarrow\ \tilde{T}=\Gamma{}^t\overline{T^{-1}}\Gamma^{-1}, \tag{36}$$

where

$$\Gamma=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}.$$

Set $G_0=\{(T,\Gamma^t\overline{T^{-1}}\Gamma^{-1}),T\in SL(2,\mathbb{C})\}$.
G_0 is a subgroup of $SL(2,\mathbb{C})\times SL(2,\mathbb{C})$, isomorphic to the real Lie group $SL(2,\mathbb{C})$. Then the real form given by Formula (36) of the $*$-Hopf algebra $(\mathscr{H}(G),\star_t,\Phi^*)$ is $\mathscr{H}(G_0)$. We remark that $\{(T,\Gamma T\Gamma^{-1}),T\in SU(2)\}$ is a subgroup of G_0 isomorphic to $SU(2)$. Thus $\mathscr{H}(SU(2))$ [or $SU_t(2)$] is a Hopf subalgebra of $\mathscr{H}(G_0)$.

V.3 $\star$-product on $C^\infty(G_0)$

Let us introduce $C^\infty(G_0)$ with its usual Fréchet topology and its dual space $A(G_0)$ (the space of compactly supported distributions on G_0) with the strong dual topology. Thus $C^\infty(G_0)$ and $A(G_0)$ are topological Hopf algebras with dual Hopf structures. Moreover, $C^\infty(G_0)$ [resp., $A(G_0)$] contains $H(G_0)$ (resp., $\mathscr{U}\mathscr{L}$) as Hopf subalgebra and $A(G_0)$ is a subalgebra of $\mathscr{A}$. Now, as noticed at the beginning of Section V, the results of Corollary IV.2.2 allows us to apply Theorem IV.3 of Ref. 5. The latter one with Remark V.1.1 allows to assert the following.

Proposition V.3.1: *There exists a topological Hopf deformation of* $\mathscr{C}^\infty(G_0)$ [resp., $A(G_0)$] *which extends the topological Hopf deformation* $[\mathscr{H}(G_0),\star_t]$ *[resp., which is a restriction of the topological Hopf deformation* $(\mathscr{A},\Delta_t)$*]. Moreover, this product* $\star_t$ *induces on* $\mathscr{H}(G_0)$ *the noncommutative algebra structure introduced by Podles and Woronowicz.*[8]

To conclude, in this paper we show that the topological Hopf algebras $(\mathscr{C}^\infty(G_0),\star_t)$ and $(A(G_0),\Delta_t)$ are the good topological models for (respectively) $SL_t(2,\mathbb{C})$ and $\mathscr{U}_t\mathscr{L}$ in our approach to quantum group theory, which is based on deformation quantization.

Inclusion of gauge bosons in the tensor formulation of the Dirac theory

Frank Reifler and Randall Morris
Martin Marietta Corporation, GES, Bldg. 137-227, Moorestown, New Jersey 08057

(Received 27 April 1995; accepted for publication 8 March 1996)

A recent article characterized all classical tensor systems which admit Fermi quantization as those having unitary Lie–Poisson brackets. Examples include Euler's tensor equation for a rigid body and Dirac's bispinor equation in tensor form. It was further shown that the tensor form of Dirac's bispinor Lagrangian can be derived from a tetrad formulation of a Kaluza–Klein model, which unifies the Dirac and Einstein Lagrangians. Thus, fermions, like bosons, are represented as gauge fields in the tensor formulation of the Dirac theory. In this article boson gauge fields are added to the unified Dirac–Einstein Lagrangian by defining the gauge group of the Kaluza–Klein model to be a semi-direct product. It is shown that the semi-direct product structure uniquely prescribes the usual ''minimal coupling'' between bosons and fermions. © *1996 American Institute of Physics.*

I. INTRODUCTION

Ever since Dirac introduced his celebrated bispinor equation in 1928, there has been continued interest in its tensor formulation. Recently, Takahashi and Zhelnorovich investigated the tensor form of the Dirac Lagrangian.[1] Following this work, we showed that the tensor Dirac Lagrangian is equal to a constrained Yang–Mills Lagrangian in the limit of an infinitely large coupling constant.[2] We also showed that the tensor form of Dirac's partial differential bispinor equation is a classical Hamiltonian system with (noncanonical) unitary Lie–Poisson brackets.[3] Such Lie–Poisson brackets occur classically for systems with gauge symmetry such as Euler's equation for a rigid body.[4] Fermi quantization was derived for both the Dirac and Euler tensor equations by representing the classical Lie–Poisson brackets as commutators of Heisenberg operators.[3]

A belief that a 360° rotation alters the state of a fermion particle has for a long time supported the view in quantum field theory that fermions can be represented only by bispinor fields, and not by tensor fields. However, recent studies of particle localization show that 360° rotation of bispinor fields, whose energy spectrum is bounded from below, produces no observable effects.[2,5,6] Moreover, experiments designed to observe the rotation properties of bispinors, in fact, described the rotation properties of constrained tensor fields.[3]

More recently we showed that the tensor form of the Dirac Lagrangian and its constraint could be derived from a tetrad formulation of a Kaluza–Klein model which unifies the Dirac and Einstein Lagrangians. In this tetrad formulation, both the fermion field and the gravitational field arise from a tetrad of vector fields v_K, where $K=0,1,2,3$, and a complex scalar field ρ. We showed that the isometric modes of the tetrad propagate as fermions, whereas the self-adjoint modes propagate as gravitons.[7]

Introducing a tetrad to describe both fermion and gravitational fields addresses an important problem posed by current theories of fermion–graviton interaction. To define bispinor fields on a space–time, reference tetrad fields (or equivalent soldering forms) must be defined.[8,9] The implied dynamics of these reference fields have been, at best, partially modelled. We found that such tetrad fields themselves, used as dynamical variables, give rise to both fermions and gravitons.

In this article we introduce gauge bosons into the Kaluza–Klein model based on the constrained Yang–Mills formulation of the Dirac theory. In this formulation fermions are represented

0022-2488/96/37(7)/3630/11/$10.00

as constrained gauge potentials and bosons are represented as unconstrained gauge potentials. As discussed below, the two sets of gauge potentials are associated with a semi-direct product gauge group which precisely produces the usual coupling between bosons and fermions.

In the constrained Yang–Mills formulation of the Dirac theory, bispinor fields are mapped to $SL(2,R)\times U(1)$ gauge potentials F_α^K and a complex scalar field ρ which satisfy the orthogonal constraint[3,7]

$$F_\alpha^K F_{K\beta} = |\rho|^2 g_{\alpha\beta}, \tag{1.1}$$

where $g_{\alpha\beta}$ is the Minkowski space–time metric. The gauge index $K=0,1,2,3$ is contracted using a metric with Minkowski signature which will be denoted η_{JK} [note that the gauge group $SL(2,R)\times U(1)$ is a four-dimensional Lie group for which η_{JK} is an invariant metric]. The covariant derivative in the Yang–Mills formulation of the Dirac theory can be expanded symmetrically to include electromagnetic and chiral interactions by the addition of four $SL(2,R)\times U(1)$ unconstrained boson gauge potentials V_α^K which act on the four constrained fermion $SL(2,R)\times U(1)$ gauge potentials. This gives the gauge potentials V_α^K and F_α^K a hierarchical structure, whereby one set of gauge potentials acts on the second set, and not vice versa. This is precisely the hierarchical structure of gauge potentials associated with a gauge group which is a semi-direct product. Thus we show that the set of gauge potentials $\{F_\alpha^K, V_\alpha^K\}$ are associated with the semi-direct product gauge group $\Gamma = G_\varphi \times G$, where $G = SL(2,R)\times U(1)$ and φ denotes the adjoint action of G on G (see Sec. II). That is, in the tensor formulation the usual coupling between bosons and fermions results from the semi-direct product structure of the gauge group Γ.

As shown in Sec. II, the four boson gauge potentials V_α^K are also defined in the bispinor theory. The electromagnetic gauge potential V_α^0 and the chiral gauge potential V_α^3 correspond to a maximal compact subgroup $U(1)\times U(1)$ of $SL(2,R)\times U(1)$. The gauge potentials V_α^1 and V_α^2 correspond to noncompact one-parameter subgroups of $SL(2,R)\times U(1)$ which, acting on F_α^K or bispinor fields Ψ, mix positive and negative energy states. Thus only the compact gauge potentials V_α^0 and V_α^3 appear to be physical. Hence, as in the bispinor theory, we set V_α^1 and V_α^2 to zero by restricting the boson gauge group to a maximal compact subgroup of $SL(2,R)\times U(1)$.

The derivations presented in Sec. II suggest that the tensor formulation of the Dirac theory extends to more than one fermion flavor, and hence to further applications in particle physics. In Sec. II we show that the Dirac–Yang–Mills Lagrangian for the gauge group $SL(2,R)\times U(1)$ extends to the larger gauge group $SL(2,C)\times U(1)$, which contains the electroweak gauge group $SU(2)\times U(1)$ as a maximal compact subgroup. Application of the extended Lagrangian to electroweak theory is presently being considered.

In this paper we introduce two new notions which have application to Kaluza–Klein theories. First, we consider Kaluza–Klein theories for which the gauge group is a semi-direct product, which, as previously discussed, allows us to define boson gauge potentials which act on the fermion gauge potentials.

Second in the Kaluza–Klein formulation of the tensor Dirac theory, the fermion field, boson field, and the gravitational field are described by a scalar field ρ and a tetrad of vector fields v_K on a smooth manifold $M = X\times\Gamma$, where X is a space–time and $\Gamma = G_\varphi \times G$ is the semi-direct product gauge group defined previously. The tetrad v_K together with a (fixed) basis of right-invariant vector fields on Γ defines a metric, denoted as $\langle , \rangle$, and hence a volume form, denoted as dv, and also a curvature two-form, denoted as $R(,)$ on M (see Sec. III). The unified action, S, for the gravitational, boson, and fermion fields is given by

$$S = \int L\, dv, \tag{1.2}$$

where the unified Lagrangian, L, is (see Sec. III)

$$L=\frac{g}{16\pi\kappa_0}R[v]+\overline{v_K(\rho+m)}v^K(\rho+m)-\frac{1}{2}g^2|\rho|^4, \tag{1.3}$$

where κ_0 is Newton's gravitational constant, g is a coupling constant, and m is the fermion mass. In formula (1.3), we employ the sum of sectional curvatures restricted to the subspace spanned by the tetrad v_K:

$$R[v]=\sum_{J=0}^{3}\sum_{K=0}^{3}\langle R(v_J,v_K)v^J,v^K\rangle. \tag{1.4}$$

This both avoids unphysical terms such as the cosmic constant arising from the scalar curvature of Γ, and removes previously assumed restrictions on the gauge group, such as a bi-invariant metric.[10] Furthermore, by formulating the Kaluza–Klein Lagrangian (1.3) with the tetrad v_K, the constraint (1.1) is eliminated.

In Sec. II we include boson gauge fields in the derivation of the tensor form of the Dirac bispinor equation. Then in Sec. III we derive a Kaluza–Klein model based on the tensor Dirac theory. We express the usual equations for the gravitational field $g_{\alpha\beta}$, the electromagnetic and chiral fields V_α^K, and the Dirac bispinor field Ψ in terms of new variables (v_K,ρ), and thereby unify these fields within a simple conceptual framework at a classical level.

II. TENSOR FORM OF THE DIRAC BISPINOR LAGRANGIAN INCLUDING BOSON GAUGE POTENTIALS

In this section we include boson gauge potentials in the derivation of the tensor form of the Dirac bispinor Lagrangian. We will show that the tensor form of the Dirac Lagrangian unifies boson and fermion fields as gauge potentials belonging to a semi-direct product gauge group. We will further show that the semi-direct product structure of the gauge potentials produces the usual minimal coupling between boson and fermion fields. As in previous work,[3,7] the derivation exploits the SL(2,R)×U(1) gauge symmetry of Dirac's bispinor Lagrangian.

Consider the SL(2,R)×U(1) gauge transformations, acting on the bispinor field Ψ, with the infinitesimal generators τ_K for $K=0,1,2,3$ defined by

$$\begin{aligned}&\tau_0\Psi=-i\Psi, \quad \tau_1\Psi=i\Psi^C,\\ &\tau_2\Psi=\Psi^C, \quad \tau_3\Psi=i\gamma_5\Psi,\end{aligned} \tag{2.1}$$

where Ψ^C denotes the charge conjugate of Ψ and γ_5 is the fifth Dirac matrix.[6] Note that the action of SL(2,R)×U(1) on Ψ is *real* linear, whereas usually only complex linear gauge transformations of bispinors are considered. The infinitesimal gauge generators τ_0, τ_1, and τ_2 generate SL(2,R) and τ_3 generates U(1).

The SL(2,R)×U(1) gauge transformations generated by τ_K commute with Lorentz transformations.[6] From formula (2.1) the commutation relations of the gauge generators τ_K are given by

$$[\tau_0,\tau_1]=2\tau_2, \quad [\tau_0,\tau_2]=-2\tau_1, \quad [\tau_1,\tau_2]=-2\tau_0, \tag{2.2}$$

and τ_3 commutes with all the τ_K. Formula (2.2) can be written more compactly as

$$[\tau_J,\tau_K]=2f_{JK}^L\tau_L, \tag{2.3}$$

which defines the Lie algebra structure constants f_{JK}^L for the gauge group SL(2,R)×U(1).

From formula (2.2) the Minkowski metric η_{JK}, with diagonal elements $\{1,-1,-1,-1\}$ and zeros off the diagonal, is an invariant metric[11] for the gauge group $\mathrm{SL}(2,R)\times\mathrm{U}(1)$. Gauge indices $J,K,L=0,1,2,3$ will be raised and lowered using the Minkowski metric η_{JK}. As in formula (2.3), repeated gauge indices are to be summed.

We define the Yang–Mills covariant derivative $\hat{D}_\alpha$ acting on bispinor fields as follows:

$$\hat{D}_\alpha=\partial_\alpha+qV_\alpha^K\tau_K, \tag{2.4}$$

where $\alpha=0,1,2,3$ is a Lorentz index, ∂_α denote partial derivatives with respect to space–time coordinates, q is a Yang–Mills coupling constant, and V_α^K are boson gauge potentials associated with the gauge generators τ_K. Associated with the gauge potentials V_α^K is the Yang–Mills curvature tensor $V_{\alpha\beta}^K$ defined by the formula

$$[\hat{D}_\alpha,\hat{D}_\beta]=qV_{\alpha\beta}^K\tau_K. \tag{2.5}$$

From formulas (2.3) and (2.4) we obtain the explicit expression

$$V_{\alpha\beta}^L=\partial_\alpha V_\beta^L-\partial_\beta V_\alpha^L+2qf_{JK}^L V_\alpha^J V_\beta^K. \tag{2.6}$$

Dirac's bispinor Lagrangian, L_{D}, is given by

$$L_{\mathrm{D}}=\mathrm{Re}[i\overline{\Psi}\gamma^\alpha\hat{D}_\alpha\Psi-m_0 s]-\tfrac{1}{4}V_K^{\alpha\beta}V_{\alpha\beta}^K, \tag{2.7}$$

where s is the complex scalar field defined by

$$\mathrm{Re}[s]=\overline{\Psi}\Psi,\quad \mathrm{Im}[s]=i\overline{\Psi}\gamma_5\Psi, \tag{2.8}$$

where $\overline{\Psi}$ is the dual conjugate of the bispinor field Ψ, the γ^α are Dirac matrices,[6] and m_0 denotes the fermion mass. Lorentz indices α, $\beta=0,1,2,3$ are raised and lowered using the (Minkowski) space–time metric, which we will denote as $g_{\alpha\beta}$. Repeated Lorentz indices are to be summed.

Apart from the mass term, the Dirac Lagrangian (2.7) is invariant under the $\mathrm{SL}(2,R)\times\mathrm{U}(1)$ gauge transformations (2.1). From formula (2.8), s is invariant under $\mathrm{SL}(2,R)$ gauge transformations, and transforms as a complex scalar under the U(1) gauge transformations generated by τ_3. To make the Lagrangian (2.7) invariant for *all* $\mathrm{SL}(2,R)\times\mathrm{U}(1)$ gauge transformations, it suffices that m_0 transform like $\overline{s}$ (the complex conjugate of s). Since m_0 appears in the Lagrangian (2.7) without derivatives, the assumption that m_0 transforms like $\overline{s}$ under U(1) gauge transformations has no effect on the Dirac equation.

Expanding the covariant derivative $\hat{D}_\alpha$ in the Dirac Lagrangian (2.7), we obtain the following interaction term coupling the boson and fermion fields:

$$L_I=qV_\alpha^K j_K^\alpha, \tag{2.9}$$

where the fermion Noether currents j_K^α are defined by

$$j_K^\alpha=\mathrm{Re}[i\overline{\Psi}\gamma^\alpha\tau_K\Psi]. \tag{2.10}$$

The Noether currents (2.10) satisfy an orthogonal constraint known as a Fierz identity given by[1,3]

$$j_\alpha^K j_{K\beta}=|s|^2 g_{\alpha\beta}, \tag{2.11}$$

where, as previously stated, $g_{\alpha\beta}$ is the (Minkowski) space–time metric.

We then map a set of $\mathrm{SL}(2,R)\times\mathrm{U}(1)$ gauge potentials F_α^K and a complex scalar field ρ into (j_α^K,s) by setting

$$j^K_\alpha = 4|\rho|^2 F^K_\alpha, \quad s = 4|\rho|^2\overline{\rho.} \tag{2.12}$$

Note that by formulas (2.8), (2.10), and (2.12), the fields F^K_α transform as SL(2,R)×U(1) gauge potentials; whereas ρ is invariant under SL(2,R) gauge transformations, and transforms as a complex scalar under the U(1) gauge transformations generated by τ_3. For the fields (F^K_α,ρ), the Fierz identity (2.11) becomes the orthogonal constraint:

$$F^K_\alpha F_{K\beta} = |\rho|^2 g_{\alpha\beta}. \tag{2.13}$$

Note that the space–time metric $g_{\alpha\beta}$ has the same signature as the metric η_{JK}. The tetrad model presented in Sec. III will explicate both the constraint (2.13) and the equality of the metric signatures.

Now, consider (F^K_α, V^K_α) as gauge potentials for the gauge group Γ whose infinitesimal generators (S_K, T_K) satisfy the following semi-direct product commutation relations:[12]

$$[S_J,\ S_K] = f^L_{JK} S_L, \quad [T_J,\ S_K] = f^L_{JK} S_L, \quad [T_J,\ T_K] = f^L_{JK} T_L, \tag{2.14}$$

where f^L_{JK} are the previously defined SL(2,R)×U(1) structure constants.

We define the Yang–Mills covariant derivative for the semi-direct product gauge group Γ by

$$D_\alpha = \partial_\alpha + g F^K_\alpha S_K + 2q V^K_\alpha T_K, \tag{2.15}$$

where we set $T_K = \frac{1}{2}\tau_K$ [compare formulas (2.3) and (2.14)], g is a Yang–Mills coupling constant, and q is the previously defined coupling constant in formula (2.4). Note that the covariant derivative (2.15) can also be written as

$$D_\alpha = \hat{D}_\alpha + g F^K_\alpha S_K, \tag{2.16}$$

where we denote

$$\hat{D}_\alpha = \partial_\alpha + 2q V^K_\alpha T_K, \tag{2.17}$$

which often simplifies derivations. Formula (2.17) agrees with (2.4) since $T_K = \frac{1}{2}\tau_K$. No confusion results from using the same symbol, $\hat{D}_\alpha$, for the covariant derivative (2.17) acting on bispinor or tensor fields. Associated with the semi-direct product gauge potentials (F^K_α, V^K_α) is the Yang–Mills curvature tensor $(F^K_{\alpha\beta}, V^K_{\alpha\beta})$ defined by the formula

$$[D_\alpha,\ D_\beta] = g F^K_{\alpha\beta} S_K + 2q V^K_{\alpha\beta} T_K. \tag{2.18}$$

From formulas (2.14) and (2.15) we obtain the explicit expression

$$F^L_{\alpha\beta} = \hat{D}_\alpha F^L_\beta - \hat{D}_\beta F^L_\alpha + g f^L_{JK} F^J_\alpha F^K_\beta, \tag{2.19}$$

where we denote

$$\hat{D}_\alpha F^L_\beta = \partial_\alpha F^L_\beta + 2q f^L_{JK} V^J_\alpha F^K_\beta, \tag{2.20}$$

whereas $V^K_{\alpha\beta}$ is given as in formula (2.6).

Furthermore, we define the metric on the gauge group Γ to be the block matrix

$$\eta = (\eta_{ab}) = \begin{bmatrix} \eta_{JK} & 0 \\ 0 & -g\,\eta_{JK} \end{bmatrix}, \tag{2.21}$$

whose components we denote as η_{ab}. Let F^a_α and $F^a_{\alpha\beta}$ denote the components of (F^K_α, V^K_α) and $(F^K_{\alpha\beta}, V^K_{\alpha\beta})$, respectively. Furthermore, let the gauge indices a,b be raised and lowered using the metric η_{ab}. Then, with the orthogonal constraint (2.13), Dirac's equation is obtained from the following Yang–Mills Lagrangian, L_g, in the limit of an infinitely large Yang–Mills coupling constant g:

$$L_g = \tfrac{1}{4} F^{\alpha\beta}_a F^a_{\alpha\beta} + \overline{D_\alpha(\rho+m)} D^\alpha(\rho+m) - \tfrac{1}{2} g^2 |\rho|^4, \tag{2.22}$$

where $m_0 = \frac{1}{2} mg$ is the fermion mass, and, from formula (2.16),

$$D_\alpha(\rho+m) = \hat{D}_\alpha(\rho+m) + igF^3_\alpha(\rho+m), \tag{2.23}$$

where from formula (2.17)

$$\hat{D}_\alpha(\rho+m) = \partial_\alpha \rho + 2iqV^3_\alpha(\rho+m). \tag{2.24}$$

Recall that s and m_0, and hence ρ and m, transform as complex scalars under the U(1) gauge transformations generated by S_3 and T_3. [Note: The part of the Lagrangian (2.22) for the scalar field ρ is not unique. An alternative Lagrangian from which Dirac's bispinor Lagrangian can also be obtained was previously presented.[2,3] However, the Lagrangian (2.22) has unique additional properties discussed in Ref. 7.]

Note that the boson gauge potentials V^K_α occur in the Yang–Mills Lagrangian L_g via the minimal substitution of $\hat{D}_\alpha = \partial_\alpha + 2qV^K_\alpha T_K$ for ∂_α [see formulas (2.17), (2.19), (2.20), (2.23), and (2.24)]. This ''minimal coupling'' was shown by formulas (2.15) and (2.18) to be uniquely prescribed by the semi-direct product commutation relations (2.14). In the following theorem we derive the Dirac bispinor Lagrangian L_{D} from the Yang–Mills Lagrangian L_g, and thereby obtain the usual minimal coupling between boson gauge potentials V^K_α and bispinor fields Ψ.

Theorem 1: Dirac's bispinor Lagrangian (2.7) equals

$$L_{\mathrm{D}} = \lim_{g\to\infty} g^{-1} L_g. \tag{2.25}$$

Proof: The derivation is greatly simplified by embedding the F^K_α and V^K_α into SL(2,C)×U(1) gauge potentials A^K_α and W^K_α as follows:

$$\begin{gathered} A^0_\alpha = -F^3_\alpha, \quad W^0_\alpha = -V^3_\alpha, \quad A^1_\alpha = -iF^2_\alpha, \quad W^1_\alpha = -iV^2_\alpha, \\ A^2_\alpha = iF^1_\alpha, \quad W^2_\alpha = iV^1_\alpha, \quad A^3_\alpha = -F^0_\alpha, \quad W^3_\alpha = -V^0_\alpha, \end{gathered} \tag{2.26}$$

where now A^0_α and W^0_α are the U(1) gauge potentials, and $\mathbf{A}_\alpha = (A^1_\alpha, A^2_\alpha, A^3_\alpha)$ and $\mathbf{W}_\alpha = (W^1_\alpha, W^2_\alpha, W^3_\alpha)$ are complex SL(2,C) gauge potentials.[3] Substituting (2.26) into formula (2.22), L_g becomes

$$L_g = -\tfrac{1}{4}\,\mathrm{Re}[A^{\alpha\beta}_a A^a_{\alpha\beta}] + \overline{D_\alpha(\rho+m)} D^\alpha(\rho+m) - \tfrac{1}{2} g^2 |\rho|^4, \tag{2.27}$$

where $A^a_{\alpha\beta} = (A^K_{\alpha\beta}, W^K_{\alpha\beta})$ and

$$\begin{aligned} A^0_{\alpha\beta} &= \hat{D}_\alpha A^0_\beta - \hat{D}_\beta A^0_\alpha, \\ W^0_{\alpha\beta} &= \partial_\alpha W^0_\beta - \partial_\beta W^0_\alpha, \\ \mathbf{A}_{\alpha\beta} &= \hat{D}_\alpha \mathbf{A}_\beta - \hat{D}_\beta \mathbf{A}_\alpha - g\mathbf{A}_\alpha \times \mathbf{A}_\beta, \end{aligned} \tag{2.28}$$

$$\mathbf{W}_{\alpha\beta}=\partial_\alpha\mathbf{W}_\beta-\partial_\beta\mathbf{W}_\alpha-2q\mathbf{W}_\alpha\times\mathbf{W}_\beta,$$

$$D_\alpha(\rho+m)=\hat{D}_\alpha(\rho+m)+igA^0_\alpha(\rho+m),$$

where

$$\hat{D}_\alpha A^0_\beta=\partial_\alpha A^0_\beta,$$

$$\hat{D}_\alpha\mathbf{A}_\beta=\partial_\alpha\mathbf{A}_\beta-2q\mathbf{W}_\alpha\times\mathbf{A}_\beta, \tag{2.29}$$

$$\hat{D}_\alpha(\rho+m)=\partial_\alpha\rho+2iqW^0_\alpha(\rho+m).$$

The index a in formula (2.27) is contracted using the SL(2,C)×U(1) invariant metric η_{ab} defined just as in formula (2.21).

Furthermore, the orthogonal constraint (2.13) becomes

$$A^K_\alpha A_{K\beta}=-|\rho|^2 g_{\alpha\beta}. \tag{2.30}$$

With this constraint, a straightforward derivation using formulas (2.27) and (2.28) shows that formula (2.25) becomes

$$\lim_{g\to\infty} g^{-1}L_g=-\mathrm{Re}[(\hat{D}_\alpha\mathbf{A}_\beta)\cdot\mathbf{A}^\alpha\times\mathbf{A}^\beta+2i\overline{\rho A}^0_\alpha\hat{D}^\alpha\rho+4m_0|\rho|^2\overline{\rho}]-\tfrac{1}{4}V^{\alpha\beta}_K V^K_{\alpha\beta}. \tag{2.31}$$

Apart from the term $-\frac{1}{4}V^{\alpha\beta}_K V^K_{\alpha\beta}$ and the minimal substitution of $\hat{D}_\alpha$ for the partial derivatives, ∂_α, formula (2.31) is precisely the tensor form of the free Dirac bispinor Lagrangian.[1,3] By expanding $\hat{D}_\alpha$ in formula (2.31), and using formulas (2.12), (2.26), (2.29), and (2.30), we obtain the interaction term (2.9). Q.E.D.

Note that the embedding (2.26) is derived from embedding the gauge group SL(2,R)×U(1) as a subgroup of the gauge group SL(2,C)×U(1). Thus, the SL(2,C) gauge potentials $\mathbf{A}_\alpha$ and $\mathbf{W}_\alpha$ are restricted to an SL(2,R) subset of gauge potentials, which by formula (2.26) satisfy

$$\mathrm{Re}[A^1_\alpha]=\mathrm{Re}[A^2_\alpha]=\mathrm{Im}[A^3_\alpha]=0,$$

$$\mathrm{Re}[W^1_\alpha]=\mathrm{Re}[W^2_\alpha]=\mathrm{Im}[W^3_\alpha]=0. \tag{2.32}$$

The Euler–Lagrange equation for the Lagrangian (2.27) with the constraint (2.30), expressed using Lagrange multipliers, commutes with the restriction (2.32). Hence, the $\mathbf{A}_\alpha$ and $\mathbf{W}_\alpha$ can be used to denote either SL(2,C) or the subset of SL(2,R) gauge potentials. By regarding SL(2,R) as embedded in the complex analytic group SL(2,C), we are able to use familiar vector operations to express the Lie algebra structure constants, as, for example, the vector cross product in formulas (2.28) and (2.29), and the vector triple product in formula (2.31). The vector operations greatly simplify derivations.

Also, note from formula (2.1) that V^0_α is the electromagnetic gauge potential and V^3_α is the chiral gauge potential associated with the infinitesimal generators $\tau_0=-i$ and $\tau_3=i\gamma_5$, respectively. Here τ_0 and τ_3 generate a maximal compact U(1)×U(1) subgroup of SL(2,R)×U(1). The noncompact generators τ_1 and τ_2 by formula (2.1) mix positive and negative energy states. Thus, the associated boson gauge potentials V^1_α and V^2_α are unphysical, and hence must vanish for both the bispinor and tensor theories. Thus, the gauge group $\Gamma=G_\varphi\times K$, where G=SL(2,R)×U(1) and K=U(1)×U(1), and where φ denotes the adjoint representation[12] of K on G. This case is handled similarly to the case where $\Gamma=G_\varphi\times G$, which we considered previously, and is equivalent to setting V^1_α and V^2_α equal to zero in formulas (2.4) and (2.17).

III. UNIFICATION OF GRAVITONS, FERMIONS, AND BOSONS IN A TETRAD MODEL

In this section we add boson gauge potentials to the tetrad formulation of the Kaluza–Klein model, which previously contained only gravitational and fermion fields.[7] For simplicity, we will associate the boson gauge potentials V_α^K with the same gauge group $G=\mathrm{SL}(2,R)\times\mathrm{U}(1)$ as for the fermion gauge potentials F_α^K. However, this will not prevent us from restricting V_α^K to a compact subgroup of G, as discussed at the end of Sec. II.

Let X be a four-dimensional space–time, and let dx^α, with $\alpha=0,1,2,3$, denote local coordinate one-forms on an open chart $U\subset X$. The gravitational field, which here we denote as $\tilde{\gamma}$ on X, is expressed locally on U by

$$\tilde{\gamma}=g_{\alpha\beta}\,dx^\alpha\otimes dx^\beta. \tag{3.1}$$

The fermion and boson fields on X we denote as (F^K,ρ) and V^K, where F^K and V^K with $K=0,1,2,3$ are tetrads of one-forms, expressed locally on U by

$$F^K=F_\alpha^K\,dx^\alpha,\quad V^K=V_\alpha^K\,dx^\alpha, \tag{3.2}$$

and ρ is a complex scalar field. In this section we unify the gravitational field $\tilde{\gamma}$, the fermion field (F^K,ρ) and the boson field V^K by deriving the Einstein and Dirac–Yang–Mills Lagrangians from a tetrad formulation of a Kaluza–Klein model. The constraint (2.13) of the fermion field (F^K,ρ) will be shown to be a consequence of the tetrad model.

On the semi-direct product gauge group $\Gamma=G_\varphi\times G$ (see Sec. II) we fix two tetrads of right-invariant vector fields c_K and d_K with commutation relations given by [compare with formula (2.14)]:

$$[c_J,\,c_K]=\lambda f_{JK}^L c_L,\quad [d_J,\,c_K]=\hat{\lambda} f_{JK}^L c_L,\quad [d_J,\,d_K]=\hat{\lambda} f_{JK}^L d_L, \tag{3.3}$$

where f_{JK}^L are the previously defined $\mathrm{SL}(2,R)\times\mathrm{U}(1)$ structure constants, λ and $\hat{\lambda}$ are real scale factors given by

$$\lambda=g/\varepsilon,\quad \hat{\lambda}=2q/\varepsilon, \tag{3.4}$$

where g and q are the previously defined Yang–Mills coupling constants, and

$$\varepsilon=\sqrt{\frac{16\pi\kappa_0}{3g}}, \tag{3.5}$$

where κ_0 is Newton's gravitation constant. Since Γ is an eight-dimensional Lie group, the right-invariant vector fields $\{c_K,d_K\}$ span the Lie algebra of Γ. From formula (3.3), the vector fields $\{c_K,d_K\}$ are orthogonal with respect to the right-invariant metric η defined by

$$\eta=\eta_{JK}(\pi^J\otimes\pi^K-g\sigma^J\otimes\sigma^K), \tag{3.6}$$

where $\{\pi^K,\sigma^K\}$ are right-invariant one-forms on Γ dual to $\{c_K,d_K\}$ and η_{JK} has diagonal elements $\{1,-1,-1,-1\}$ and zeros off the diagonal. [Note that all Lie groups have right-invariant metrics, but only a restricted class of Lie groups have invariant (i.e., bi-invariant) metrics.[11] Note also that the metrics in this paper, such as the bi-invariant metric η_{JK} on $\mathrm{SL}(2,R)\times\mathrm{U}(1)$ which has a Minkowski signature, are not positive definite.]

On the space–time X, we assume the existence of a global nonsingular tetrad of smooth vector fields e_K. Let θ^K denote the tetrad of one forms on X dual to the vector fields e_K. Thus, on the Kaluza–Klein manifold $M=X\times\Gamma$, we can define the following tetrad of vector fields:

$$v_K=(e_K,\varepsilon|\rho|c_K,\varepsilon v_K^J d_J), \tag{3.7}$$

where now ρ is a complex scalar field on M, v_K^J are coefficients associated with the boson field [see formula (3.17)], and ε is the previously defined constant (3.5). We define the metric γ on M with respect to the basis $\{v_K, c_K, d_K\}$ to be

$$\gamma = \begin{bmatrix} \eta_{JK} & 0 \\ 0 & \eta_{ab} \end{bmatrix}, \tag{3.8}$$

where η_{ab} denote the components of the metric η defined in formula (3.6). We also denote the metric γ as $\langle , \rangle$. Thus, with respect to the metric $\langle , \rangle$, the tetrad v_K is orthonormal, and orthogonal to Γ.

The manifold $M = X \times \Gamma$ has a natural right action of Γ. For v_K to be right-invariant, it is necessary and sufficient that e_K, $|\rho|$, and v_K^J depend only on the space–time coordinates $x \in X$. Also, ρ is a complex U(1) scalar field. Specifically, in a local coordinate system (x^α, y^K, z^K) on M, ρ has the form

$$\rho = e^{i(\lambda y + \hat{\lambda} z)} \tilde{\rho}(x), \tag{3.9}$$

where $y = y^3$ and $z = z^3$ are the normal coordinates for the U(1) subgroups of Γ generated by c_3 and d_3 [see formula (3.3)].

Our goal in this section is to derive the Einstein and Dirac–Yang–Mills Lagrangians from the following Lagrangian for the fields (v_K, ρ):

$$L = \frac{g}{16\pi\kappa_0} R[v] + \overline{v_K(\rho + m)} v^K (\rho + m) - \frac{1}{2} g^2 |\rho|^4, \tag{3.10}$$

where the mass m is defined on M by

$$m = \frac{2m_0}{g} e^{i(\lambda y + \hat{\lambda} z)}, \tag{3.11}$$

and $R[v]$, at each point of M, is the sum of sectional curvatures over the four-dimensional subspace spanned by the orthonormal tetrad v_K, defined by

$$R[v] = \sum_{J=0}^{3} \sum_{K=0}^{3} \langle R(v_J, v_K) v^J, v^K \rangle, \tag{3.12}$$

where $R(\,,\,)$ is the curvature two-form[11] associated with the semi-Riemannian metric $\langle\,,\,\rangle$. We express the action for the fields (v_K, ρ) by

$$S = \int L \, dv, \tag{3.13}$$

where dv is the volume form on M associated with the metric $\langle\,,\,\rangle$.

We now show that the Lagrangian (3.10) equals the Hilbert–Einstein Lagrangian for the gravitational field plus the Dirac–Yang–Mills Lagrangian (2.22). The constraint (2.13) of the fermion gauge potentials will be shown to be a consequence of the tetrad v_K. Using a simplified notation, we can write v_K in formula (3.7) as

$$v_K = e_K + \varepsilon |\rho| c_K + \varepsilon v_K^J d_J, \tag{3.14}$$

where $e_K = (e_K, 0, 0)$, $c_K = (0, c_K, 0)$, and $d_K = (0, 0, d_K)$ on M, and similar notation for the dual one-forms θ^K, π^K, and σ^K induced on M.

From formula (3.14), the basis of one-forms on M dual to the basis of vector fields $\{v_K, c_K, d_K\}$ is given by $\{\theta^K, \omega^K, \mu^K\}$, where

$$\omega^K = \pi^K - \varepsilon|\rho|\,\theta^K, \quad \mu^K = \sigma^K - \varepsilon v_J^K \theta^J, \tag{3.15}$$

and the metric (3.8) is expressed by

$$\gamma = \eta_{JK}\theta^J \otimes \theta^K + \eta_{ab}\omega^a \otimes \omega^b, \tag{3.16}$$

where $\omega^a = (\omega^K, \mu^K)$.

Let us define with respect to the basis $\{\partial/\partial x^\alpha, c_K, d_K\}$ the following fields on $\mathrm{U}\times\Gamma$:

$$g_{\alpha\beta} = \eta_{JK}\theta_\alpha^J \theta_\beta^K, \quad F_\alpha^K = |\rho|\,\theta_\alpha^K, \quad V_\alpha^K = v_J^K \theta_\alpha^J. \tag{3.17}$$

By definition of θ^K and using formulas (3.15) and (3.17):

$$\theta^K = \theta_\alpha^K\, dx^\alpha, \quad \omega^K = \pi^K - \varepsilon F_\alpha^K\, dx^\alpha, \quad \mu^K = \sigma^K - \varepsilon V_\alpha^K\, dx^\alpha. \tag{3.18}$$

Moreover, writing $\pi^a = (\pi^K, \sigma^K)$ and $F_\alpha^a = (F_\alpha^K, V_\alpha^K)$, formula (3.18) can be expressed more simply by

$$\theta^K = \theta_\alpha^K\, dx^\alpha, \quad \omega^a = \pi^a - \varepsilon F_\alpha^a\, dx^\alpha. \tag{3.19}$$

On substituting formulas (3.17) and (3.19) into (3.16), the metric γ becomes

$$\gamma = \begin{bmatrix} g_{\alpha\beta} + \varepsilon^2 \eta_{ab} F_\alpha^a F_\beta^b & -\varepsilon F_\alpha^a \eta_{ab} \\ -\varepsilon\, \eta_{ab} F_\beta^b & \eta_{ab} \end{bmatrix}. \tag{3.20}$$

Thus, γ is precisely the Kaluza–Klein metric[10] for the gravitational field $g_{\alpha\beta}$ and the gauge potentials $F_\alpha^a = (F_\alpha^K, V_\alpha^K)$. Also, by formula (3.17),

$$\eta_{JK} F_\alpha^J F_\beta^K = |\rho|^2 g_{\alpha\beta}, \tag{3.21}$$

which is precisely the constraint (2.13). Furthermore, by formula (3.17), the gravitational metric $g_{\alpha\beta}$ has the same (Minkowski) signature as the invariant metric η_{JK} on $\mathrm{SL}(2,R)\times\mathrm{U}(1)$.

A straightforward derivation using the Kaluza–Klein metric γ in formula (3.20) shows that[7,10]

$$R[v] = \widetilde{R} + \tfrac{3}{4}\varepsilon^2 F_a^{\alpha\beta} F_{\alpha\beta}^a, \tag{3.22}$$

where $\widetilde{R}$ denotes the scalar curvature of X, and $F_{\alpha\beta}^a = (F_{\alpha\beta}^K, V_{\alpha\beta}^K)$ is defined as in formulas (2.6) and (2.19). We can now prove the following theorem:

Theorem 2: The total Lagrangian L given in formula (3.10) equals the Hilbert–Einstein Lagrangian for the gravitational field plus the Dirac–Yang–Mills Lagrangian L_g given in formula (2.22), and similarly for the action (3.13).

Proof: The theorem follows by substituting formula (3.22) into (3.10), and by noting from formula (3.8) that the volume form dv on M depends only on the one-forms θ^K. By expressing the gravitational field $g_{\alpha\beta}$, the fermion field (F_α^K, ρ), and the boson field V_α^K in terms of the new variables θ_α^K, ρ, and V_α^K as in formula (3.17), the constraint (2.13) is eliminated. Q.E.D.

(Note that the gravitational field $g_{\alpha\beta}$ and a bispinor field Ψ, which together have $10+8=18$ real components, are equivalent to θ_α^K and ρ, which also have $16+2=18$ real components.[7])

The following observations can be made about the proof of Theorem 2. First, the unphysical cosmic constant, which is the scalar curvature of the gauge group Γ occurring in the Lagrangian of the usual Kaluza–Klein model, does not occur in the Lagrangian (3.10) because in formula

(3.12) we restricted $R[v]$ to the tetrad v_K. Second, for the same reason, Theorem 2 does not require that the right-invariant metric η given in formula (3.6) be bi-invariant,[11] which, in the usual Kaluza–Klein model, places restrictions on the gauge group.[10]

Random perturbations of Markov processes on systems of contractive maps are considered. The existence of a unique invariant measure for the randomly perturbed process is proved under a very weak assumption on perturbations. In particular, the proof holds for the full class of translationally invariant perturbations. © *1996 American Institute of Physics.* [S0022-2488(96)00907-3]

The Markov operator $\mathscr{M}:\mathscr{P}(X)\to\mathscr{P}(X)$ defined by a set $\{w_i:X\to X\}$ of N Lipschitz maps in given by[1]

$$(\mathscr{M}\nu)(A)=\sum_{i=1}^{N} p_i\nu(w_i^{-1}A), \quad \text{for } A \text{ measurable}, \tag{1}$$

where $\mathscr{P}(X)$ denotes the set of normalized Borel measures on a compact space X, each w_i has Lipschitz constant $s_i<1$, and each p_i is non-negative and $\Sigma_{i=1}^{N}p_i=1$. The operator $\mathscr{M}$ formalizes the iteration dynamics on X given by choosing an i at random with probability p_i and then applying w_i. The dynamics on $\mathscr{P}(X)$ is deterministic with a unique invariant measure. Next, we consider random perturbations of the dynamics just defined. When any w_i is applied to a point x in X, in the presence of noise, the result is not necessarily $w_i(x)$. Instead, it only makes sense to give the probability $\mathscr{N}(A|w_i(x))$ for x to land in $A\subset X$ by the perturbed action of w_i, for each set A which belongs to the family $\mathscr{B}(X)$ of Borel measurable sets. In the noiseless limit $\mathscr{N}(\cdot|w_i(x))$ is a Dirac delta distribution located at $w_i(x)$. Therefore a random perturbation is a map $\mathscr{N}:\mathscr{B}(X)\times X\to[0,1]$. The effect of noise on measures is given by a map $\mathscr{S}:\mathscr{P}(X)\to\mathscr{P}(X)$, where $\mathscr{S}\nu$ is the measure onto which a given measure ν is taken by the perturbation, independent of the Markovian process $\mathscr{M}$. In terms of the pertubation $\mathscr{N}$, $\mathscr{S}$ is given by

$$\mathscr{S}\nu(A)=\int \mathscr{N}(A|\cdot)\,d\nu.$$

The function $\mathscr{N}(A|\cdot)$ is measurable for each $A\in\mathscr{B}(X)$. This condition is satisfied for the most commonly studied noises.

Under noise, the evolution is governed by the *perturbed Markov operator* $\mathscr{R}=(\mathscr{S}\circ\mathscr{M})$. In terms of the perturbation $\mathscr{N}$, the perturbed Markov operator $\mathscr{R}$ is

$$\mathscr{R}\nu(A)=\int \mathscr{N}(A|\cdot)\,d[\mathscr{M}\nu], \tag{2}$$

with operator $\mathscr{M}$ is defined in Eq. (1). Using in Eq. (2) the defining set of Lipschitz maps, $\{w_i\}$, the perturbed operator is written as

$$\mathscr{R}\nu(A)=\int \sum_{i=1}^{N} p_i \mathscr{N}(A|\cdot)\circ w_i d\nu. \tag{3}$$

The perturbed Markov operator $\mathscr{R}$ has a unique invariant measure if it is contractive in a suitable metric. We consider *Hutchinson* metric. Given any two measures $\mu,\ \nu\in\mathscr{P}(X)$, their distance $h(\mu,\nu)$ in the Hutchinson metric is given by $\min\{|\int f d\mu-\int f d\nu|: f\in\mathscr{F}\}$, where $\mathscr{F}$ is the set of real-valued functions on X with Lipschitz constant not bigger than one. Under a very weak assumption on $\mathscr{N}$, the following claim states that the perturbed operator $\mathscr{R}$ is contractive in the Hutchinson metric.

Lemma 1: Let a perturbation map $\mathscr{N}$ satisfy the inequality

$$\left|\int f d\mathscr{N}(\cdot|x)-\int f d\mathscr{N}(\cdot|y)\right|\leqslant d(x,y)$$

for each $x,\ y\in X$ and $f\in\mathscr{F}$. Then the perturbed Markov operator $\mathscr{R}$ is contractive in the Hutchinson metric for any Markov operator $\mathscr{M}$.

Proof: Let $\mu,\nu\in\mathscr{P}(X)$. From the form of $\mathscr{R}$ in Eq. (3) and the definition of the Hutchinson metric, we have

$$h(\mathscr{R}\mu,\mathscr{R}\nu)=\sup_{f\in\mathscr{F}}\left\{\left|\sum_{i=1}^{N} p_i\left(\int F_i\, d\mu-\int F_i\, d\nu\right)\right|\right\}\leqslant\sum_{i=1}^{N} p_i \sup_{g\in\mathscr{F}}\left\{\left|\int F_i\, d\mu-\int F_i\, d\nu\right|\right\}$$
$$=s\sum_{i=1}^{N} p_i \sup_{g\in\mathscr{F}}\left\{\left|\int \frac{1}{s}F_i\, d\mu-\int \frac{1}{s}F_i\, d\nu\right|\right\},$$

where $F_i: X\to R$ is defined by $F_i(x)=\int g d\mathscr{N}(\cdot|w_i(x))$, and $s=\max\{s_i\}$. By hypothesis, for all $g\in\mathscr{F}$ and all i, we have

$$\left|\frac{1}{s}\int g d\mathscr{N}(\cdot|w_i(x))-\frac{1}{s}\int g d\mathscr{N}(\cdot|w_i(y))\right|\leqslant\frac{1}{s}d(w_i(x),w_i(y))\leqslant\frac{1}{s}sd(x,y),$$

from which $(1/s)F_i\in\mathscr{F}$ for all i and each $g\in\mathscr{F}$. Therefore it follows that

$$h(\mathscr{R}\mu,\mathscr{R}\nu)\leqslant s\sum_{i=1}^{N} p_i h(\mu,\nu)=sh(\mu,\nu).$$

The most frequent kind of physical random perturbation is the homogeneous, or *translationally invariant*, noise. Let X be a compact subspace of a vector space [Hutchinson's function is a metric on $\mathscr{P}(X)$ only if X is compact]. A homogeneous perturbation $\mathscr{N}$ satisfies the condition $\mathscr{N}(A|x)=\mathscr{N}(A+(y-x)|y)$ for each $x,y\in X$ and each measurable A. Our claim is that the hypothesis of Lemma 1 holds for such a noise. Let $\{A_i\}$ be a partition of $\operatorname{supp}\mathscr{N}(\cdot|x)$, and let $x_i\in A_i$. The integral of any continuous function, and in particular of any $f\in\mathscr{F}$ with respect to the measure $\mathscr{N}(\cdot|x)$, can be approximated with an arbitrary degree of precision as $\Sigma_i\mathscr{N}(A_i|x)f(x_i)$ by making the diameter of the sets A_i sufficiently small. The same is true for the integral of f with respect to the measure $\mathscr{N}(\cdot|y)$, this time using the sets $B_i=A_i+(y-x)$ and the points $y_i=x_i+(y-x)$, and therefore the difference of the integrals of f with respect to $N(\cdot|x)$ and $N(\cdot|y)$ is arbitrarily close to $|\Sigma_i\mathscr{N}(A_i|x)f(x_i)-\Sigma_i\mathscr{N}(B_i|y)f(y_i)|$. Since $\mathscr{N}(A_i|x)=\mathscr{N}(B_i|y)$ for each i, this number is not bigger than $\Sigma_i\mathscr{N}(A_i|x)|f(y_i)-f(x_i)|$, and this cannot be bigger than $d(x,y)=|y-x|$ since $\Sigma_i\mathscr{N}(A_i|x)=1$ and each $|f(y_i)-f(x_i)|$ is not bigger than $|y_i-x_i|=|y-x|$ since $f\in\mathscr{F}$. Therefore we have proved the following.

Theorem 1: Let a Markov operator $\mathscr{M}$ be subjected to a translationally invariant random perturbation. Then the perturbed operator $\mathscr{R}$ is a contractive operator with a unique measure μ which satisfies $\mathscr{R}\mu=\mu$.

We remark that Theorem 1 is a very general result. The underlying space X is an arbitrary compact subset of a vector space; the mappings w_i are arbitrary contractive functions and the noise associated to each point is also arbitrary, provided that it is translationally invariant and that $\mathscr{N}(A|\cdot)$ is measurable for each $A\in\mathscr{B}(X)$. For instance, this measurability condition holds when X is contained in R^n and $\mathscr{N}(\cdot|x)$ defines a distribution function. In a related result, Garcia-Pelayo and Schieve[2] proved the existence of a unique invariant measure of a dynamical system subjected to external noise. Their treatment is restricted to R^n, the noise they study corresponds to a normal distribution centered in x for $\mathscr{N}(\cdot|x)$, and they only consider mappings w_i which are contractive affine transformations on X.

Comments on Hamiltonian structures for the *n*-dimensional Lotka–Volterra equations [J. Math. Phys. 36, 3520–3534 (1995)]

Laurent Cairó[a] and Marc R. Feix
MAPMO/URA CNRS 1803-Université d'Orléans, Department of Mathématiques, BP 6759, 45067, Orléans Cedex 2, France

(Received 4 October 1995; accepted for publication 2 April 1996)

In a recent paper, Plank presents results on first integrals for the Lotka–Volterra system (LVS) and their use as possible Hamiltonians. Since he was not acquainted with already published results, we feel that an embedding of his results in those of previous papers can clarify some of his statements. We concentrate our comments on the results presented in his paragraphs III and IV. © *1996 American Institute of Physics.* [S0022-2488(96)02207-4]

(A) 2d LVS. The idea of associating a Hamiltonian to a 2d ODE system was first introduced by Nutku[2] for the particular Lotka–Volterra system (LVS) studied by Volterra corresponding to the equations[1,1] (the two numbers refer respectively to the reference of the paper and the formula number) when $a_{11}=a_{22}=0$. A generalization was provided by Cairó and Feix[3] who showed that, if a system possess a first integral (invariant) I not depending explicitly on time, then I can be considered as Hamiltonian through a time rescaling. It must be pointed out that the relation given in theorem 3.1 (p. 3523) in order to allow the system to have a Hamiltonian structure is just the relation $R_{12}=0$ given in Ref. 4 to obtain invariant III (note that a and b are inverted in Refs. 1 and 4.

(B) First integrals for *n*-dimensional LVS. Plank mentioned four types of first integral on the top of p. 3525. (i) concerns the n-dimensional Volterra case (for $a_{ii}=0$), (ii) and (iii) are, respectively, invariant III and II of Cairó and Feix and (iv) is claimed to be new. In fact (iv) is a limiting case of invariant III. To fix ideas we look at the conditions of existence for Plank's first integral (iv) in the case $n=3$. These conditions are given at the bottom of p. 3531. The first one is $b_1=0$ for $B_0\neq 0$ (below we consider the case $B_0=0$). Let us take then $B_0=1$. Then from (iv) $B_2=a_{12}/b_2$ and $B_3=a_{13}/b_3$. Moreover, taking $i=k=2$ and $i=k=3$ in condition (iii) we obtain, respectively, $a_{12}=a_{22}$ and $a_{13}=a_{33}$. Using this result and taking for instance $i=2$, $k=3$, we obtain $a_{22}(a_{23}-a_{33})/b_2+a_{33}(a_{32}-a_{22})/b_3=0$, which is exactly our relation[4,26] $R_{23}=0$. On the other hand $b_1=0$ together with $a_{12}=a_{22}$ implies $R_{12}=0$ and $b_1=0$ and $a_{13}=a_{33}$ implies $R_{13}=0$. Consequently the conditions of existence of the first integral (iv) of Plank are a special case of those for invariant III of Cairó and Feix. Note that $B_0=0$ implies all b_i equal and we recover the invariant II conditions. One can easily prove that, indeed, invariant III takes the form given by the first integral (iv) of Plank. Moreover the conditions (i) to (iv) given at the bottom of p. 3527 are our conditions to obtain invariant III. In fact condition (iv) is automatically fulfilled if n is even. If n is odd, this condition is not necessary and actually the first integral is time-dependent through a factor e^{st}. Another point which needs further explanation is the expression of $K(x)$ and the conditions to be fulfilled given at the top of p. 3530. Conditions (i) are our conditions[4,17] and Plank's relation (ii) is identical to our relations.[4,19] Condition (iv) is automatically satisfied if n is odd and, if n is even, we do not need this condition if we introduce a factor e^{st} in the first integral. However, in that case we need a rescaling (see Ref. 5) both of the x_i and t of the form $x_i=e^{bt}\overline{x_i}$ and $\overline{dt}=e^{bt}dt$, where $b\equiv b_i$. So in all cases we can obtain a time-independent first integral

[a]Electronic mail: lcairo@univ-orleans.fr, marcfeix@univ-orleans.fr.

0022-2488/96/37(7)/3644/2/$10.00

without condition (iv). On the other hand Plank's condition (iii) is misleading. We have $n(n-1)/2$ equations and n unknowns. Since the system is homogeneous, we need $n(n-1)/2-n+1=(n-1)(n-2)/2$ relations between the a_{ij}. These relations appear in our paper.[4,15] where an explanation of this number of constraints is provided. The extension of the Hamiltonian formalism to systems of dimension greater than two possessing first integrals was also considered in Refs. 6–9.

In the right-hand side of Eq. (4.5) c_{kq} should be replaced by $c_{kq}p^{-(1/2)(N-3)}$. Since the quantities c_{kq} are defined throughout up to an arbitrary multiplicative constant c, it might appear that this change is irrelevant. This is not the case, because in the argument that follows Eq. (4.5) the fact that c_{kq} does not depend on p (in particular, on the sign of p) plays an essential role. Note that, *after this replacement*, c_{kq} is indeed independent of p, as it is clearly implied (for dimensional reasons) by (4.8), or rather by the identification of the right-hand-sides of (4.8) (of course with c_{kq} replaced by $c_{kq}p^{-(1/2)(N-3)}$) and (4.10), an identification which constitutes the defining property of the quantities c_{kq}. The rest of the proof following Eq. (4.5) proceeds then as given, with these consequential changes: In the right-hand-sides of (4.14), (4.10), and (4.8), A should be replaced by $A' \equiv A - \frac{1}{2}(N-3) = \frac{1}{2}N(N-1)(a+\frac{1}{2})$; likewise c_{kq} should be replaced by $c_{kq}p^{-(1/2)(N-3)}$ in the right-hand-sides of (4.5) and (4.8) (as already mentioned), as well as (4.9) and (4.18) (in this latter equation, one might then also wish to replace the newly inserted factor $p^{-(1/2)(N-3)}$ with $(\overline{p})^{-(1/2)(N-3)}$, as well as the first factor in the right-hand-side, $e^{-i\pi A}$, with $e^{-i\pi A'}$; since $\overline{p} = -p$, see (4.19), these latter changes are merely notational ones; but they are appropriate for the argument which is subsequently made).

Note that these adjustments do not affect the main conclusion, see Eq. (4.23). Moreover, they entail that the overall ''phase shift'' $\eta \equiv -iA' = -\frac{1}{2}N(N-1)i\pi(a+\frac{1}{2})$ can now be naturally interpreted as resulting from the addition of $\frac{1}{2}N(N-1)$ equal phase shifts due to as many two-body collisions (the ''factorization,'' or ''solitonic,'' property).

Surface-embeddability approach to the dynamics of the inhomogeneous Heisenberg spin chain

Radha Balakrishnan and Partha Guha[a)]
The Institute of Mathematical Sciences, Madras 600 113, India

(Received 18 August 1995; accepted for publication 25 March 1996)

The surface-embeddability approach of Lund and Regge is applied to the classical, inhomogeneous Heisenberg spin chain to study the class of inhomogeneity functions f for which the spin evolution equation and its gauge-equivalent generalized nonlinear Schrödinger equation (GNLSE) are exactly solvable. Writing the spin vector $\mathbf{S}(x,t)$ as $\partial_x\mathbf{r}$ and identifying $\mathbf{r}(x,t)$ with a position vector generating a surface, we show that the kinematic equation satisfied by $\mathbf{r}$ implies certain constraints on the admissible geometries of this surface. These constraints, together with the Gauss–Mainardi–Codazzi equations, enable us to express the coefficient of the second fundamental form as well as f in terms of the metric coefficients G and its derivatives, for arbitrary time-independent G. Explicit solutions for the GNLSE can also be found in terms of the same quantities. Of the admissible surfaces generated by $\mathbf{r}$, a special class that emerges naturally is that of surfaces of revolution: Explicit solutions for $\mathbf{r}$ and $\mathbf{S}$ are found and discussed for this class of surfaces. © *1996 American Institute of Physics.* [S0022-2488(96)01307-2]

I. INTRODUCTION

Over a decade ago, one of us proposed[1] a model Hamiltonian for the inhomogeneous Heisenberg spin chain and showed that the spin evolution equation in the continuum description is given by the nonlinear equation

$$\mathbf{S}_t=(f\mathbf{S}\times\mathbf{S}_x)_x, \quad \mathbf{S}^2=1, \tag{1.1}$$

where $\mathbf{S}$ denotes the spin vector, f is the site-dependent exchange interaction between spins, and the subscripts denote partial derivatives. Further, by using the moving space curve formalism,[2] it was shown[1] that Eq. (1.1) is gauge equivalent to a generalized nonlinear Schrödinger equation (GNLSE) of the form

$$iq_t+(fq)_{xx}+2q\left\{f|q|^2+\int_{-\infty}^{x}f_x|q|^2\,dx\right\}=0, \tag{1.2a}$$

where

$$q=\frac{\kappa}{2}\exp\int_{-\infty}^{x}\tau\,dx \tag{1.2b}$$

with the curvature κ and the torsion τ of the curve being given by

$$\kappa^2=(\mathbf{S}_x)^2; \quad \tau=\mathbf{S}.(\mathbf{S}_x\times\mathbf{S}_{xx})/\kappa^2. \tag{1.2c}$$

Equations (1.1) and (1.2a) have applications in fluid dynamics as well, where they appear in the study of the motion of an inhomogeneous vortex filament in an incompressible inviscid fluid.[3] The

[a)]Present address: Max Planck Institut für Mathematics, Gottfried Claren Str. 26, 53225 Bonn, Germany.

dynamics of the model and its higher dimensional analogs have attracted further attention in recent years.[4,5] For the homogeneous chain (corresponding to $f=$const), Eq. (1.2a) reduces[6] to the well-known completely integrable nonlinear Schrödinger equation[7] solvable by the (isospectral) inverse scattering transform (IST) method.[8] When f is a linear function of x, Eq. (1.2a) yields a slightly modified version of an integrable equation studied by Calogero and Degasperis,[9] and the IST in this case has been discussed by Lakshmanan and Bullough.[10] Here, the spectral parameter is a function of time. These are the only two classes of $f(x)$ for which the conventional IST method is directly applicable, and the corresponding GNLSEs are expected to pass the conventional integrability tests. All other $f(x)$ fall into a separate class, in the sense that the spectral parameter now becomes a function of both space and time.[1] Some years ago, Burtsev *et al.*[11] showed that if a nonlinear evolution equation has an associated spectral parameter with a certain prescribed functional form for its space–time dependence, it is possible to develop a conventional IST scheme to obtain strict soliton solutions. We note that the spin evolution of a chain with linear inhomogeneity belongs to this class. For certain other inhomogeneities, we have shown that if the space–time dependence of the spectral parameter has a separable product form, it becomes possible to use an approach[1] based on the Ablowitz–Kaup–Newell–Segur[8] formalism to analyze Eq. (1.2a) in terms of a transformed spatial variable to obtain localized solutions. However, more general questions such as integrability, strict solitons, etc., could not be addressed in this approach. Another point to be noted is that while knowing a solution $\mathbf{S}$ of Eq. (1.1) enables one to find the solution q of Eq. (1.2a) in a straightforward fashion by using Eqs. (1.2b) and (1.2c), the inverse procedure, i.e., the construction of $\mathbf{S}$ from q, is computationally not so easy. On the other hand, *if* q satisfies a completely integrable equation, the soliton-surfaces approach pioneered by Sym[12] can be adopted to construct $\mathbf{S}$, using the solution to the associated isospectral Lax pair system. This has been carried out for the homogeneous chain (the case $f=$const).[13] It is also possible to find soliton solutions for $\mathbf{S}$ by solving Eq. (1.1) directly, using the IST method,[14] for the homogeneous chain.

Recently, in a very interesting paper, Cieśliński, Sym, and Wesselius[5] have used some ideas from Sym's surface approach[12] to find exact solutions of Eq. (1.1) for several other inhomogeneity functions by a somewhat different route: Representing $\mathbf{S}$ as the spatial derivative of a vector $\mathbf{r}$, i.e., setting

$$\mathbf{S}=\mathbf{r}_x, \tag{1.3}$$

it is seen that the kinematic equation

$$\mathbf{r}_t=f(\mathbf{r}_x\times\mathbf{r}_{xx}), \quad \mathbf{r}_x^2=1, \tag{1.4}$$

for a vector $\mathbf{r}$ implies Eq. (1.1).

Assuming the surface generated by the position vector $\mathbf{r}(x,t)$ to be equipped with a metric of the geodesic form, they showed[5] that the Gauss–Mainardi–Codazzi (GMC) equations[15] for this surface can be cast in the same form as Eq. (1.2a), upon making appropriate identifications between q and f on the one hand and the coefficients of the first and second fundamental forms (i.e., the metric and the extrinsic curvature respectively) on the other. By specializing to surfaces of revolution, they demonstrated that the equations for the geodesics on the surface can be integrated explicitly for certain cases, and gave an algorithm for obtaining both f and the corresponding solution $\mathbf{S}$. Choosing the simplest geodesic coordinates on a surface of revolution ("parallels" and "meridians"), the solutions called "spins-on-meridians" could be found for a wide variety of time-independent, bounded, positive functions $f(x)$, i.e., inhomogeneous ferromagnetic couplings. However, for more general geodesic coordinates on surfaces of revolutions, the solutions turned out to correspond to time-dependent functions $f(x,t)$ which were either unbounded or negative in all typical examples. Both these characteristics are unphysical, and for the latter ($f<0$), an anti-

ferromagnetic coupling is implied, causing the nearest-neighbor spin vectors to be almost antiparallel for low energies, and therefore the continuum equation (1.1) is itself quite inappropriate to describe low-energy dynamics.

In view of what has been said above, we confine ourselves to the ferromagnetic case $f>0$ in this paper. Our geometric formulation differs form that of Cieśliński *et al.*[5] in the sense that although we also identify $\mathbf{r}(x,t)$ with a position vector that generates a surface, we do not compare the GMC equations to Eq. (1.2a), nor do we use the general equations of geodesics. We adopt the strategy suggested by Lund and Regge[16] in a different context, and regard the kinematic equation (1.4) as a *constraint* on the surface generated. Such a constraint is expected to permit only certain special geometries for the surface.[16] Indeed, for the model under investigation, the surface metric is shown to be *necessarily* of the geodesic form and, further, certain coefficients of the two fundamental forms get related through the function f. Using these results in the GMC equations, and *restricting* our discussion to the case of time-independent metrics, it becomes possible to "integrate" them. This enables us to find the expressions for L, M, and N (the coefficients of the second fundamental form) as well as the corresponding function f in terms of the metric coefficient G, its x derivatives, and two (arbitrary) integration constants. It is then demonstrated that the solution q of Eq. (1.2a) can also be written in terms of the above-mentioned quantities, by simply reexpressing the moving curve parameters κ and τ [appearing in Eq. (1.2b) and defined in Eq. (1.2c)] in terms of surface coefficients by using the Gauss–Weingaraten (GW) equations[15] for the surface. Thus we see that given an arbitrary metric coefficient, the explicit solution for q along with the corresponding f can be written down. This solution q is a *complex* function in general, and is interesting in its own right since it contains information[1] on the energy and momentum densities along the chain. Furthermore, on inspecting the expressions for L, M, and N obtained from the GMC equations, it is readily seen that they correspond to those of surfaces of revolution,[15] when one of the two integration constants referred to above vanishes. Also, $G^{1/2}$ plays the role of the generator of revolution, and the explicit solution of $\mathbf{r}(x,t)$ can be written down in this limiting case. In this limit, our expression for $f(x)$ reduces to the result obtained[5] in the geodesic approach, for the spins-on-meridian solutions. The corresponding solutions for q are necessarily *real*. For certain common surfaces of revolution like the torus and the catenoid, the solution $\mathbf{S}$ of Eq. (1.1) can be expressed solely as a functional of f that appears in the equation, essentially because the surface metric can be written down as a functional of the function f for these surfaces. Some illustrative examples are discussed at the end.

II. THE MODEL

We begin by briefly describing the physical system under consideration and outline the derivation of Eq. (1.1).

The inhomogeneous, isotropic Heisenberg spin chain is described by the following Hamiltonian:[1]

$$H=-\sum_i f_i \mathbf{S}_i \cdot \mathbf{S}_{i+1}. \tag{2.1}$$

Here f_i denotes a site-dependent nearest-neighbor interaction and $\mathbf{S}_i$ is the classical spin vector at site i; $(\mathbf{S}_i)^2=S^2=\text{const}$. A classical treatment for spins is justified from experimental results[17] for spins $S\geq\frac{3}{2}$. Hereafter, $\mathbf{S}_i^2$ is normalized to unity for convenience. For the conventional Heisenberg Hamiltonian, the exchange interaction which couples nearest-neighbor spins is a constant (say, f_0) everywhere along the chain. However, it is possible to fabricate systems in which (a) the distance between neighboring atoms varies along the chain so that the overlap of identical electronic wavefunctions (which is a measure of the exchange coupling f) varies as well, or (b) the atoms may be equally spaced, but the wavefunction may be made to change from site to site by the deliberate introduction of impurities or organic complexes in a controlled manner,[17] without

causing lattice distortions. The spin evolution equation for the system is found using $(d\mathbf{S}_i/dt)=\{H,\mathbf{S}_i\}$, where $\{,\}$ denotes the Poisson bracket, and the Cartesian spin-components S_i^α satisfy the angular momentum algebra $\{S_i^\alpha,S_j^\beta\}=\delta_{ij}\epsilon_{\alpha\beta\gamma}S_j^\gamma$. Using Eq. (2.1) for the Hamiltonian, we obtain[1]

$$\frac{d\mathbf{S}_i}{dt}=f_i(\mathbf{S}_i\times\mathbf{S}_{i+1})+f_{i-1}(\mathbf{S}_i\times\mathbf{S}_{i-1}). \tag{2.2}$$

A continuum version of Eq. (2.2) is suitable when $\mathbf{S}_i$ and f_i vary slowly over one lattice separation a. This would be a good description at low temperature for a ferromagnetic coupling, $f>0$. Hence we write $\mathbf{S}_i\to\mathbf{S}(x,t)$, $f_i\to f(x)$ and use Taylor expansions for $\mathbf{S}(x\pm a,t)$ and $f(x-a,t)$ to order a^2 to obtain

$$\mathbf{S}_t=f(\mathbf{S}\times\mathbf{S}_{xx})+f_x(\mathbf{S}\times\mathbf{S}_x), \tag{2.3}$$

on rescaling the time variable by a factor a^2. The two terms on the right-hand side can be combined easily to yield the spin evolution equation (1.1).

III. KINEMATIC RESTRICTIONS ON THE SURFACE GEOMETRY

Our starting point is the kinematic equation for $\mathbf{r}(x,t)$ given Eq. (1.4), which (as already stated) implies Eq. (1.1), when $\mathbf{r}_x=\mathbf{S}$. Let us identify $\mathbf{r}(x,t)$ with a position vector generating a smooth surface in E^3, with local coordinates x and t. Let the metric, i.e., the first fundamental form of this surface, be given by[15]

$$I=d\mathbf{r}^2=E\,dx^2+2F\,dxdt+G\,dt^2, \tag{3.1}$$

where by definition $E=\mathbf{r}_x^2$, $F=\mathbf{r}_x\cdot\mathbf{r}_t$ and $G=\mathbf{r}_t^2$. However, $\mathbf{S}^2=\mathbf{r}_x^2=1$ in the model and from Eq. (1.4) it is readily verified that $\mathbf{r}_x\cdot\mathbf{r}_t=0$. Therefore, $E=1$ and $F=0$, and the metric (3.1) is *necessarily* constrained to be of the geodesic form given below:

$$I=dx^2+G(x,t)dt^2. \tag{3.2}$$

The unit normal $\mathbf{n}$ to the surface is given by

$$\mathbf{n}=(\mathbf{r}_x\times\mathbf{r}_t)/G^{1/2}. \tag{3.3}$$

As usual, the extrinsic curvature (second fundamental form) is defined as

$$II=-d\mathbf{r}.d\mathbf{n}=L\,dx^2+2M\,dxdt+N\,dt^2, \tag{3.4}$$

where

$$L=\mathbf{r}_{xx}.\mathbf{n},\quad M=\mathbf{r}_{xt}.\mathbf{n},\quad\text{and}\quad N=\mathbf{r}_{tt}.\mathbf{n}. \tag{3.5}$$

As is well known in surface theory, the Gauss–Weingarten (GW) equations for surface can be written in terms of L,M,N and the usual Christoffel symbols Γ_{ij}^k.[15] For the metric given in Eq. (3.2), the latter reduce to

$$\begin{gathered}\Gamma_{11}^1=\Gamma_{11}^2=\Gamma_{12}^1=0;\\ \Gamma_{12}^2=\tfrac{1}{2}G_x/G,\quad \Gamma_{22}^1=-\tfrac{1}{2}G_x,\quad\text{and}\quad \Gamma_{22}^2=\tfrac{1}{2}G_t/G.\end{gathered} \tag{3.6}$$

Using these, the GW equations read

$$\mathbf{r}_{xx}=L\mathbf{n}, \tag{3.7a}$$

$$\mathbf{r}_{xt}=\tfrac{1}{2}(G_x/G)\mathbf{r}_t+M\mathbf{n}, \tag{3.7b}$$

$$\mathbf{r}_{tt}=-\tfrac{1}{2}G_x\mathbf{r}_x+\tfrac{1}{2}(G_t/G)\mathbf{r}_t+N\mathbf{n}, \tag{3.7c}$$

$$\mathbf{n}_x=-L\mathbf{r}_x-(M/G)\mathbf{r}_t, \tag{3.7d}$$

$$\mathbf{n}_t=-M\mathbf{r}_x-(N/G)\mathbf{r}_t. \tag{3.7e}$$

Further, for this surface it is easy to show that

$$(\mathbf{r}_x\times\mathbf{r}_{xx})=L(\mathbf{r}_x\times\mathbf{n})=(L/G^{1/2})\mathbf{r}_t, \tag{3.8}$$

where we have used Eq. (3.3) in Eq. (3.7a), along with $F=0$. Comparing this with the given equation (1.4), we get the constraint

$$f=-G^{1/2}/L, \tag{3.9}$$

for $L\neq 0$. In other words, given f, Eq. (1.4) can have a solution only if the coefficients G and L are related through f as in Eq. (3.9).

For coordinates with $E=1$ and $F=0$, the compatibility conditions $(\mathbf{r}_{xx})_t=(\mathbf{r}_{xt})_x$ and $(\mathbf{r}_{tt})_x=(\mathbf{r}_{xt})_t$ yield the following Gauss–Mainardi–Codazzi (GMC)[15] equations:

$$-(LN-M^2)/G=(\Gamma^2_{12})_x-(\Gamma^2_{11})_t+\Gamma^1_{12}\Gamma^2_{11}-\Gamma^1_{11}\Gamma^2_{12}+\Gamma^2_{12}\Gamma^2_{12}-\Gamma^2_{11}\Gamma^2_{22}, \tag{3.10a}$$

$$L_t-M_x=L\Gamma^1_{12}+M(\Gamma^2_{12}-\Gamma^1_{11})-N\Gamma^2_{11}, \tag{3.10b}$$

$$M_t-N_x=L\Gamma^1_{22}+M(\Gamma^2_{22}-\Gamma^1_{12})-N\Gamma^2_{12}. \tag{3.10c}$$

On using the expressions for Γ^k_{ij} given in Eq. (3.6), and the following definition for the Gaussian curvature K,

$$K=(LN-M^2)/G, \tag{3.11}$$

Eqs. (3.10) reduce to

$$-K=(G_x/2G)_x+(G_x/2G)^2, \tag{3.12a}$$

$$L_t-M_x=M(G_x/2G), \tag{3.12b}$$

$$M_t-N_x=-L(G_x/2)+M(G_t/2G)-N(G_x/2G). \tag{3.12c}$$

Now, the fundamental theorem of surfaces[15] states that if we can identify functions G, L, M and N which satisfy the Gauss equation [Eq. (3.12a)] and the Mainardi–Codazzi equations [Eqs. (3.12b) and (3.12c)], then there exists a surface $\mathbf{r}(x,t)$. In other words, an exact solution of Eq. (1.4) exists, provided, of course, if the additional constraint $f=-G^{1/2}/L$ is satisfied. [Further, the knowledge of these functions G, L, M, and N will also immediately enable us to find explicit solutions q of Eq. (1.2a), as will be demonstrated in Sec. V.]

Before concluding this section, we note that Eq. (3.12a) can be written in the more convenient form

$$(G^{1/2})_{xx}=-KG^{1/2}. \tag{3.13}$$

IV. EXPRESSIONS FOR L, M, AND N SATISFYING GMC EQUATIONS AND THE CORRESPONDING FORMULA FOR f

The task ahead of us is to determine the coefficients L, M, and N of the second fundamental form which satisfy the GMC equations (3.12) in a manner consistent with the given evolution. The most convenient starting point is the Gauss equation (3.13). It involves only x derivatives, suggesting the simplest nontrivial choice $G(x,t)=G(x)$. Further, if $f=f(x)$, then $L_t=0$, since $L=-G^{1/2}/f$ from Eq. (3.9). Thus Eq. (3.12b) yields $M_x=-MG_x/2G$, which (for a given G) has the solution

$$M=C_oG^{-1/2}, \tag{4.1}$$

where C_o is an arbitrary constant, taken to be independent of time. Hence $M_t=0$ on using $G_t=0$, and Eq. (3.12c) becomes

$$N_x-NG_x/2G=LG_x/2=-G^{1/2}G_x/2\,f, \tag{4.2}$$

where Eq. (3.9) has been used to express L in terms of G and f.

This has a solution

$$N=G^{1/2}\left\{C_1-\int \frac{G_x}{2f}\,dx\right\}, \tag{4.3}$$

where C_1 is a (time-independent) integration constant. However, we also have an expression for N arising from the definition of K given in Eq. (3.11), giving

$$N=(KG+M^2)/L=-f(KG+M^2)/G^{1/2}, \tag{4.4}$$

where we have used Eq. (3.9). Substituting for M from Eq. (4.1) yields

$$N=-fG^{1/2}(K+C_oG^{-2}). \tag{4.5}$$

Equating the expressions for N given in Eqs. (4.3) and (4.5) for consistency, we obtain

$$f(K+C_oG^{-2})=\left\{\int \frac{G_x}{2f}\,dx-C_1\right\}. \tag{4.6}$$

Interestingly, this equation can be solved for f in terms of $G^{1/2}$ as follows: Differentiating both sides of Eq. (4.6) gives

$$G_x=2f[f(K+C_oG^{-2})]_x. \tag{4.7}$$

Multiplying both sides of Eq. (4.7) by $(K+C_oG^{-2})$ and integrating with respect to x, we obtain

$$A_o+\int G_x(K+C_oG^{-2})dx=f^2(K+C_oG^{-2})^2, \tag{4.8}$$

where A_o is an arbitrary constant of integration. Equation (4.8) is solved for f to give

$$f=\pm(K+C_oG^{-2})^{-1}\left\{\int (K+C_oG^{-2})G_x\,dx+A_o\right\}^{1/2}, \tag{4.9}$$

where, from Eq. (3.13), $K=-(G^{1/2})_{xx}/G^{1/2}$. Another curious fact that emerges is that the integration in Eq. (4.9) can be carried out exactly, to give f as a function of $G^{1/2}$: To show this, define

$$G^{1/2}=\phi. \tag{4.10}$$

This yields $G=\phi^2$, $G_x=2\phi\phi_x$, and $K=-\phi_{xx}/\phi$. Substituting these in Eq. (4.9) and evaluating the integral we get the expression for the inhomogeneity function to be

$$f=\pm\phi\,\frac{(2A_o-\phi_x^2-C_o\phi^{-2})^{1/2}}{C_o\phi^{-3}-\phi_{xx}}. \tag{4.11}$$

On using this expression for f in Eqs. (3.9), (4.1), and (4.5) and setting $G=\phi^2$, we obtain the corresponding expressions for L, M, and N as

$$L=\frac{-\phi}{f}=\frac{\phi_{xx}-C_o\phi^{-3}}{(2A_o-\phi_x^2-C_o\phi^{-2})^{1/2}}, \tag{4.12}$$

$$M=C_o\phi^{-1}, \tag{4.13}$$

$$N=f(\phi_{xx}-C_o\phi^{-3})=-\phi(2A_o-\phi_x^2-C_o\phi^{-2})^{1/2}. \tag{4.14}$$

These clearly satisfy the GMC equations since they have been obtained by essentially integrating the equations. The point to be noted is that the quantities L,M,N as well as f depend on ϕ and its derivatives. Thus *given* an arbitrary function ϕ [with the provision that $(2A_o-\phi_x^2-C_o\phi^{-2})>0$] we can use Eqs. (4.11)–(4.14) to find the quantities explicitly. Combining this result with the fundamental theorem of surfaces discussed at the end of Sec. III, we conclude that for inhomogeneity functions f determined from Eq. (4.11) in this fashion, exact solutions $\mathbf{r}(x,t)$ of Eq. (1.4) exist. In addition, the solution q of Eq. (1.2a) corresponding to such functions can be explicitly found as will be shown in Sec. V. Explicit solutions of $\mathbf{r}$ can also be found for a special subclass of f. It can be verified that Eqs. (4.11)–(4.14) represent a special case (corresponding to a time-independent metric) of the formulas (29) in Ref. 5.

V. EXACT DYNAMICAL SOLUTIONS AND THEIR ASSOCIATED GEOMETRY

In this section, we show that the solution q for the GNLSE [Eq. (1.2a)] can be expressed in terms of the surface coefficients and can therefore be explicitly found for a given metric. Explicit solutions for $\mathbf{r}$ and $\mathbf{S}$ are written down in the case $G=G(x)$, $M=0$ corresponding to "spins on meridians" (Ref. 5).

A. Solutions for the GNLSE

As mentioned in the Introduction, the solution q of Eq. (1.2a) can be expressed in terms of the curvature κ and torsion τ, the parameters of a (moving) curve as $q=\frac{1}{2}\kappa\exp(i\int_{-\infty}^{x}\tau\,dx)$, where κ and τ are defined in Eq. (1.2c). Using these definitions together with the GW equations (3.7), we obtain

$$\kappa=(\mathbf{S}_x.\mathbf{S}_x)^{1/2}=(\mathbf{r}_{xx}.\mathbf{r}_{xx})=L; \tag{5.1}$$

τ can also be expressed in terms of the surface coefficients as follows:

$$\tau=\mathbf{S}.(\mathbf{S}_x\times\mathbf{S}_{xx})/\kappa^2=\mathbf{r}_x.(\mathbf{r}_{xx}\times\mathbf{r}_{xxx})/L^2. \tag{5.2}$$

However, from Eqs. (3.7a) and (3.7d),

$$\mathbf{r}_{xxx}=L_x\mathbf{n}+L\mathbf{n}_x=L_x\mathbf{n}-L^2\mathbf{r}_x-(LM/G)\mathbf{r}_t,$$

giving

$$(\mathbf{r}_{xx}\times\mathbf{r}_{xxx})=L^3(\mathbf{r}_x\times\mathbf{n})+(L^2M/G)(\mathbf{r}_t\times\mathbf{n}).$$

On using the definition of $\mathbf{n}$ given in Eq. (3.3), we obtain

$$(\mathbf{r}_{xx}\times\mathbf{r}_{xxx})=-(L^2/G^{1/2})(L\mathbf{r}_t-M\mathbf{r}_x). \tag{5.3}$$

Using Eq. (5.3) in (5.2) yields

$$\tau=M/G^{1/2}. \tag{5.4}$$

Substituting Eqs. (5.1) and (5.4) in Eq. (1.2b) gives the following solution for q in terms of L, M, and G:

$$q=\frac{1}{2}L\exp i\int MG^{-1/2}\,dx. \tag{5.5}$$

In Sec. IV we have shown that L and M are given by Eqs. (4.12) and (4.13), for $G=G(x)$. Substituting for them in Eq. (5.5) and setting $G^{-1/2}=\phi^{-1}$ leads to

$$q=\tfrac{1}{2}\frac{\phi_{xx}-C_o\phi^{-3}}{(2A_o-\phi_x^2-C_o\phi^{-2})^{1/2}\exp iC_o\int\phi^{-2}\,dx}. \tag{5.6}$$

Note that the torsion $\tau=C_0\phi^{-2}$ for this system. Summarizing, we have the following result: For any arbitrary ϕ [such that $(2A_0-\phi_x^2-C_o\phi^{-2})>0$], the inhomogeneity function f can be found from Eq. (4.11), and for that f, the corresponding solution q of Eq. (1.2a) is given in Eq. (5.6).

We parenthetically remark that Eq. (5.5) agrees with the result obtained by Sym and Wesselius.[4] However, their procedure involved showing essentially that when Eq. (5.5) is substituted into the GNLSE (1.2a) and real and imaginary terms are equated, GMC equations are obtained, on setting $f=\sqrt{G}/L$. We also note from Eq. (5.5) that while surfaces with $M=0$ pick out purely real solutions of (1.2a), those with $M\neq0$ correspond to complex solutions q.

The solution for q is physically interesting, since it has been shown[1] that the energy and momentum densities along the chain have the form $E(x,t)=2f|q|^2$ and $P(x,t)=4f^2|q|^2(\arg q)_x$. From Eqs. (4.1) and (5.5), we obtain the relation $E(x,t)=(2fG)^{-1}P(x,t)=(2f\phi^2)^{-1}P(x,t)$, where the general expression for f is given in Eq. (4.11). An interesting observation is that if the product (fG) is a constant, then the total (integrated) energy $\mathscr{E}=\int E(x,t)dx$ is proportional to the total momentum $\mathscr{P}=\int P(x,t)dx$, leading to the linear dispersion relation $\mathscr{E}\sim\mathscr{P}$. This is reminiscent of the dispersion relation for the basic excitations in other physical systems such as photons, linearized antiferromagnetic magnons in a *homogeneous* chain, etc. Unfortunately, the solutions for ϕ obtained by setting $f\sim\phi^{-2}$ in Eq. (4.11) are not expressible in terms of elementary functions, even if $C_o=0$. Nevertheless, the observation that $f(x)$ may be "tuned" to control the energy-momentum dispersion relation is of significance.

B. Solutions for r

In Sec. IV expressions for L, M, N, and f were obtained in terms of $\phi=G^{1/2}$ and two arbitrary constants C_o and A_o. Let us consider the two possible classes of surfaces corresponding to $M=0$ and $M\neq0$ one by one:

(i) $M=0$: From Eq. (4.13), we see that C_o must vanish when M vanishes. Using this, Eqs. (4.12) and (4.14) yield L and N respectively as

$$L=\phi_{xx}/(2A_o-\phi_x^2)^{1/2}\quad\text{and}\quad N=-\phi(2A_o-\phi_x^2)^{1/2}. \tag{5.7}$$

It is easily verified that these extrinsic curvature coefficients correspond to the following *surface of revolution*:

$$\mathbf{r}=\left(\int (2A_o-\phi_x^2)^{1/2}\,dx,\phi\cos t,\phi\sin t\right). \tag{5.8}$$

Thus ϕ plays the role of the generator of a surface of revolution. Further, since $\mathbf{r}_x^2=\mathbf{S}^2=1$, Eq. (5.8) leads to $2A_o=1$. By computing $\mathbf{r}_{xx}$ from Eq. (5.8), we find $L^2=(\mathbf{r}_{xx}.\mathbf{r}_{xx})=2A_o\phi_{xx}^2/(2A_o-\phi_x^2)$, which agrees with the expression for L given in (5.7), on setting $2A_o=1$. (The expression for N can be verified similarly).

Using this value of A_0 in Eq. (4.11) and setting $C_o=0$, we get

$$f=\pm\phi(1-\phi_x^2)^{1/2}/\phi_{xx}. \tag{5.9}$$

Note that this expression for f was also obtained by Cieśliński *et al.*[5] essentially by integrating the equations for geodesics on a surface of revolution. [See Eq. (37) of Ref. 5]. Thus we see that their result for spins on meridians corresponds to the limit $M=C_o=0$ of the expression for f given in Eq. (4.11), which we derived as the inhomogeneity function supporting an exact dynamical solution for a time-independent metric. From Eq. (5.6), $q=\frac{1}{2}\phi_{xx}/(2A_o-\phi_x^2)^{1/2}$.

(ii) $M\neq0$: This corresponds to $C_0\neq0$ [see Eq. (4.13)]. The construction of $\mathbf{r}$ corresponding to Eqs. (4.12)–(4.14) with $C_o\neq0$ is nontrivial and is an open problem. The solution of q for $C_o\neq0$ can be found from Eq. (5.6).

C. Solutions of S and illustrative examples

Returning to Eq. (5.9), many examples of $\phi(x)$ and the corresponding function $f(x)$ have been presented in Table I of Ref. 5 for which $\mathbf{r}$ and $\mathbf{S}$ can be found. In what follows, we study the problem from a different angle and present a discussion in terms of the Gaussian curvature K. Equation (3.13) for K can be written as

$$K=-\phi_{xx}/\phi. \tag{5.10}$$

Using this in Eq. (5.9) we obtain

$$Kf=(1-\phi_x^2)^{1/2}. \tag{5.11}$$

Substituting Eq. (5.11) in the expression for $\mathbf{r}$ given in Eq. (5.8) with $2A_o=1$ and computing $\mathbf{r}_x$ yields

$$\mathbf{S}=\mathbf{r}_x=((1-\phi_x^2)^{1/2},\phi_x\cos t,\phi_x\sin t)=(Kf,(1-K^2f^2)^{1/2}\cos t,(1-K^2f^2)^{1/2}\sin t). \tag{5.12}$$

Hence $\mathbf{S}$ is given as a functional of the product Kf.

Illustrative Examples: It is instructive to consider well-known surfaces of revolution as possible examples for finding $\mathbf{r}(x,t)$, keeping in mind the requirement that the corresponding inhomogeneity function should be positive definite (i.e., ferromagnetic) and bounded everywhere on the chain. Note that surfaces with $K=0$ [leading to $\phi_{xx}=0$—see Eq. (5.10)] must be excluded since f becomes unbounded. We give below three examples where the solution $\mathbf{S}$ of Eq. (1.1) can be written *solely* as a functional of f.

(i) *Torus*: $\mathbf{r}=(\sin x,(R+\cos x)\cos t,(R+\cos x)\sin t)$ gives $\phi=(R+\cos x)$, $f=\phi=G^{1/2}$, $K=(1-R\phi^{-1})=(1-Rf^{-1})$. Hence, using this K in Eq. (5.12),

$$\mathbf{S}=\mathbf{r}_x=((f-R),[1-(f-R)^2]^{1/2}\cos t,[1-(f-R)^2]^{1/2}\sin t).$$

(ii) *Sphere of radius* λ^{-1}: $\mathbf{r}=\lambda^{-1}(\sin\lambda x,\cos\lambda x\cos t,\cos\lambda x\sin t)$ gives $\phi=\cos\lambda x$, $f=\phi=G^{1/2}$, $K=1$. Note that $f=\cos\lambda x$ can be arranged to remain positive for $-L_0\leqslant x\leqslant L_0$, L_0 being the length of the chain, by choosing $\lambda=\pi/2L_0$. Thus

$$\mathbf{S}=(f,(1-f^2)^{1/2}\cos t,(1-f^2)^{1/2}\sin t).$$

(iii) *Catenoid:* $\mathbf{r}=(\sinh^{-1}x,(1+x^2)^{1/2}\cos t,(1+x^2)^{1/2}\sin t)$ gives $\phi=(1+x^2)^{1/2}$, $f=\phi^3=G^{3/2}$, $K=-\phi^{-4}=-f^{-4/3}$. Since $|x|<L_0$, f is bounded. Hence

$$\mathbf{S}=(-f^{-1/3},(1-f^{-2/3})^2\cos t,(1-f^{-2/3})^2\sin t).$$

Note that for these simple surfaces, $\mathbf{S}$ involves only f and no derivatives of f. This feature is obviously not true in general. As is clear from Eq. (5.12), if we choose the surface metric $G=\phi^2$ to be a functional of f (and its derivatives), $\mathbf{S}$ can also be expressed in terms of those quantities. This can be easily verified for the simple surfaces given above where ϕ is a functional of f. On the other hand, for example, consider a surface with the generator $\phi=\alpha\exp(-x^2)$, where $\alpha=$const. On using Eq. (5.9), we obtain $f=\pm[1-4x^2\exp(-2x^2)]^{1/2}/2(1-2x^2)=\pm[1-4(\ln\alpha-\ln\phi)\phi^2/\alpha^2]^{1/2}/2(1-\ln\alpha^2-\ln\phi^2)$ (f can remain positive by an appropriate choice of the length scale). Equation (5.10) yields $K=2(1-2x^2)=2(1-\ln\alpha^2-\ln\phi^2)$. Note that it is not possible to invert the expression for f to write ϕ as a simple functional of f, as was possible for the torus, etc. Therefore, for this example $\mathbf{S}$ cannot be written in terms of f, but only in terms of ϕ, since $Kf=[1-4(\ln\alpha\text{-}\ln\phi)\phi^2/\alpha^2]^{1/2}$ [see Eq. (5.9)].

It is interesting to investigate whether the completely integrable homogeneous chain with $f=f_0=$const (see the Introduction) has a class of special solutions of the surface of revolution class as well. A short calculation shows that, for this case, Eq. (5.9) can be solved to give special solutions for ϕ which are elliptic functions. On the other hand, for the other integrable example $f(x)=ax+b$, a and b being constants, Eq. (5.9) is a nonlinear ODE with x-dependent coefficients and its solution is nontrivial and the question remains open at present. However, it is pertinent to add that using the geodesic approach with cylindrical surfaces,[5] it is possible to obtain solutions for $\mathbf{r}$ for time-dependent functions $f(x,t)=a(t)x+b(t)$. However, as already mentioned there,[5] its physical interpretation as a model for a ferromagnet would present difficulties.

VI. CONCLUDING REMARKS

In this paper, we have used a surface-embeddability approach pioneered by Lund and Regge to analyze the nonlinear dynamics of an inhomogeneous ferromagnetic chain to find exact solutions of the spin evolution equation. Our approach is distinct from the existing one[5] which consists of calculating geodesics on surfaces of revolution. However, the surface considered in both the approaches is the same, viz, that generated by the position vector $\mathbf{r}(x,t)$ where $\mathbf{r}_x$ is the spin vector. We have given the formalism for surfaces with arbitrary time-independent metrics $G(x)$. Our emphasis has been on the determination of inhomogeneities $f(x)$ for which exact solutions of the dynamical system exist. In addition, the corresponding solutions for the GNLSE [Eq. (1.2a)] can be found explicitly for these inhomogeneities. Surfaces of revolution with simplest geodesic coordinates ("parallels" and "meridians") emerge as a subclass for which the corresponding solution for $\mathbf{r}$ can also be written down explicitly.

Extension of our procedure to include space–time-dependent metrics $G(x,t)$ and thereby enlarge the class of functions $f(x)$ amenable to exact solution in a consistent fashion would be of interest. However, since $G_t\neq0$ and $L=-G^{1/2}/f$, we have $L_t\neq0$ in this case. As a result, all the terms appearing in the GMC equations [Eqs. (3.12)] get retained, and the analysis for the determination of f becomes quite involved.

We calculate the Casimir energy of a two segment loop of string with one normal boundary point and one twisted boundary point. The energy is renormalized relative to the twisted uniform loop. The use of the twisted loop in simplifying untwisted loop calculations is discussed. © *1996 American Institute of Physics.* [S0022-2488(96)01908-1]

I. INTRODUCTION

Oscillating loops of cosmic strings have been suggested as a possible seed for galaxy formation in the early universe.[1] In these models, matter condenses about the oscillating string loops which radiate into the surrounding matter as they decay. String loops have been reviewed by Vilenkin[2] who discusses their radial oscillations and gives examples of the kinds of density fluctuations that could be seeded by decaying loops of various structures. In early models loops were created in a symmetry breaking phase transition[2] but more recently, Basu, Guth, and Vilenkin[3] have discussed spontaneous nucleation processes that create loops and other defects during the early universe inflationary period and the effects of these more persistent defects on galaxy seeding. A theory relating quantum fluctuations to the evolution of loops and other defects has been developed by Garriga and Vilenkin[4] and Basu and Vilenkin.[5]

Several kinds of radiation can be associated with an oscillating string, such as electromagnetic, gravitational or goldstone-boson emission. The importance of the latter type of radiation in galaxy formation models has been emphasized by Davis[6] and Vilenkin and Vachasspati.[7] Oscillations associated with strings have also been discussed by Rosenzweig and Srivastava[8] who consider the bulk vibrations associated with the Higgs field surrounding a string and point out that this contribution to the radiation emission might be dominant in string decay processes. They also point out an interesting aspect of twisted strings and string loops; one of the models discussed in this paper is a straight string threading a string loop and it is found that the interaction energy is absent when the configuration is twisted. Other complex loop arrangements are also possible.

One possibility for a more complex loop is a loop with segments. Davis,[6] for example, mentions that when formed a vortex loop could be made of many segments coming from previously casually disconnected regions so that oscillating segmented string loops could be considered. Pagels,[9] in a calculation of loop correlation functions, assumed that the initial loop in a loop decay process was segmented. There has also been considerable interest in the Casimir or zero point energy of oscillation segmented loops.[10–13] This particular aspect of loop behavior is interesting and important, given the possible importance of oscillating loops in galaxy formation processes and the role of fluctuations in the evolution of loop dynamics.[14] The segmented loop is also a relatively simple system on which to perform Casimir calculations and thus provides a useful testing ground for various renormalization methods. It may also be applicable to the vacuum states of two dimensional field theories.[10] The models so far discussed in the literature have had two building blocks, ϕ_i $(i=1,2)$ segments, each of a different density and tension but

0022-2488/96/37(8)/3662/13/$10.00

with the same wave speed $v=c$. The segments are joined alternatingly at points $x_{\bar{N}}$ to create segmented loops. The boundary condition is

$$\Phi_1(x_N)=\Phi_2(x_{\bar{N}}), \tag{1}$$

with a similar tension relation for the derivatives. $\bar{N}$ is the number of segments. In the literature, the energies for the segmented string have been renormalized by the energy of the uniform string joined to itself, a system with one boundary point. The boundary conditions at this point for the uniform string are analogous to (1).

In this paper, we will consider a string loop in which one of the boundary points, x_1, is twisted, where the fields obey the boundary conditions

$$\Phi_1(x_1)=-\Phi_2(x_1), \quad \Phi_1(x_{\bar{N}})=\Phi_2(x_{\bar{N}}) \quad \bar{N}\neq 1. \tag{2}$$

The tension relations for the derivatives at the boundary points are similar. For the uniform loop with one boundary point only, we are obviously creating a Möbius loop.

Twisted fields have been discussed generally by Isham.[15] In Minkowski space, DeWitt[16] has considered the Casimir energy of both twisted and untwisted scalar fields with a periodicity along the z-axis. Using cylindrical polar coordinates in Minkowski space, Ford[17] has treated the Casimir energy of a twisted string. Both DeWitt and Ford found the twisted scalar field to have a positive energy compared to a negative energy for the untwisted string. The twisted loop is an interesting problem because one can compare the energy to that of the untwisted loop to discover if it is energetically more favorable for a straight string to join in a simple or a twisted topology, because the differing loop topologies make Casimir energy comparisons quite valuable and because the twisted loop may offer a way of simplifying the untwisted string with a large number of segments.

The Casimir energy for the twisted uniform loop is calculated in the next section. A comparison is made to the untwisted uniform string. Twisted strings with two segments are discussed in the third part of the paper. The energies in these sections are renormalized using the Euler-MacLaurin sum formula and a cut off function. In the fourth section we compare this method to regularizing using point splitting and the generalized zeta function. It is potentially instructive to calculate the result by all three methods. There are many regularization methods, each with its advantages and problems. A comparison insures that a problem specific to one method has not influenced the result of the calculation. There are situations, usually involving a boundary, where the three methods do not agree and a study of the divergence behavior causing the disagreement can be insightful.[18] A comparison between the two segment twisted string and the four segment untwisted loop is discussed in the last section.

II. UNIFORM LOOPS

A. Twisted loop-anti periodic boundary condition

Let the field on the loop be described by both clockwise and counterclockwise moving waves,

$$\Phi(x)=\xi e^{i\omega x}+\eta e^{-i\omega x}. \tag{3}$$

The boundary conditions are

$$\Phi(x)=-\Phi(x+L), \quad \Phi'(x)=-\Phi'(x+L). \tag{4}$$

Using (3) and (4), the allowed frequencies are

$$\cos(\omega L)=-1, \quad \omega=\frac{2\pi}{L'}\left(n+\frac{1}{2}\right). \tag{5}$$

The energy associated with the zero point twisted string oscillations is found from the $\alpha \to 0$ limit of the sum with cutoff function

$$E_t = 2 \times \frac{1}{2} \sum_{n=0}^{\infty} \frac{2\pi}{L}\left(n+\frac{1}{2}\right)\exp\left(\frac{-2\pi\alpha(n+\frac{1}{2})}{L}\right). \tag{6}$$

Evaluating the sum using the Euler-McLaurin sum formula and taking the limit one finds

$$E_t = \frac{L}{2\pi\alpha^2} + \frac{\pi}{12L} + O(\alpha^2). \tag{7}$$

This could be compared to the energy for the untwisted uniform string given by Brevik and Nielsen,[10]

$$E_u = \frac{L}{2\pi\alpha^2} - \frac{\pi}{6L} + O(\alpha^2). \tag{8}$$

The first term in both Eqs. (7) and (8) can be identified as the energy of the string with no boundary.[19] Subtracting off the energy of the unbounded string one finds the renormalized energies,

$$E_{t,r} = \frac{\pi}{12L}, \quad E_{u,r} = -\frac{\pi}{6L}. \tag{9}$$

One sees that, relative to the unbounded string, the untwisted string represents the lower energy state. This is similar to the results of DeWitt[16] and Ford.[17]

B. Another boundary condition for the uniform string

More complex twists can be constructed using the boundary conditions

$$\begin{aligned} \Phi(x) &= \phi(x+L)\exp\left[\frac{2\pi i}{N}\right], \\ \Phi'(x) &= \Phi'(x+L)\exp\left[\frac{2\pi i}{N}\right], \end{aligned} \tag{10}$$

where N is the number of circuits needed to complete the field. $N=1$ is the uniform untwisted string, $N=2$ is the uniform twisted string treated in the previous section.

Applying the boundary conditions one finds that the allowed frequencies are given by

$$\cos\left(\omega L + \frac{2\pi}{N}\right) = 1, \tag{11}$$

$$\omega = \frac{2\pi}{L}\left(n+\frac{1}{N}\right). \tag{12}$$

The associated Casimir energy calculated with the sum formula and a cut off is

$$E_t - \frac{L}{2\pi\alpha^2} = \frac{2\pi}{L}\left(\frac{-1}{12} + \frac{1}{2N} - \frac{1}{2N^2}\right). \tag{13}$$

For integer N this is always greater than the untwisted string energy E_u given in (9). For $0<N<1$ the twisted uniform string energy can be less than that of the untwisted string.

III. THE TWO SEGMENT TWISTED STRING

A. Allowed frequencies

The two segment string has two scalar fields, one moving on each of the two kinds of string,

$$\Phi_1(x)=\xi_1 e^{i\omega x}+\eta_1 e^{-i\omega x},$$
$$\Phi_2(x)=\xi_2 e^{i\omega x}+\eta_2 e^{-i\omega x}. \tag{14}$$

We will take the twisted boundary point to be $x=0(L)$ and the normal boundary point to be $x=L_1$, where we allow for the possibility that the segments are of different lengths.

The boundary conditions on the fields gives

$$O(L):\xi_1 e^{0}+\eta_1 e^{-0}=\xi_2 e^{i\omega L}+\eta_2 e^{-i\omega L},$$
$$L_1:\xi_1 e^{i\omega L_1}+\eta_1 e^{-i\omega L_1}=\xi_2 e^{i\omega L_1}+\eta_2 e^{-i\omega L_1}. \tag{15}$$

The derivative conditions are

$$O(L):R(\xi_1 e^{0}-\eta_1 e^{-0})=\xi_2 e^{i\omega L}-\eta_2 e^{-i\omega L},$$
$$L_1:R(\xi_1 e^{i\omega L_1}-\eta_1 e^{-i\omega L_1})=\xi_2 e^{i\omega L_1}-\eta_2 e^{-i\omega L_1}, \tag{16}$$

where $R=T_1/T_2$, the ratio of the tensions in the two segments. Brevik and Nielsen[10] use x for this ratio.

From the coefficient determinent we can find the dispersion relation giving the allowed frequencies,

$$(1-R)^2\cos(\omega(L-2L_1))-(1+R)^2\cos(\omega L)-4R=0, \tag{17a}$$

which can be written as

$$(1-R)^2\cos(\omega(s-1)L_1)-(1+R)^2\cos(\omega(s+1)L_1)-4R=0. \tag{17b}$$

Another equivalent but useful form is

$$\sin(s\omega L_1)\sin(\omega L_1)=\frac{4R}{(1-R)^2}\cos^2\left(\frac{(s+1)\omega L_1}{2}\right), \tag{18}$$

where $s=L_2/L_1$, the ratio of the lengths of the two possible segments and $L=L_1+L_2$.

B. Some special cases

1. $R=1$ (equal tensions)

This is the same as the uniform twisted string treated in the second part of the paper.

2. $R=0$ ($T_2=\infty$ or $T_1=0$)

From the dispersion relation (18) we find

$$\omega_{n1}=\frac{\pi n_1}{L},\quad \omega_{n2}=\frac{\pi n_2}{L}. \tag{19}$$

This is the same result as for the $R=0$ untwisted string and has an identical Casimir energy.[10] Since we started with a twisted string, this is an interesting result but may be understood by realizing that the infinite T_2, implies infinite density since the wave speed is unity so that the second string blocks passage of the wave in the first string segment, effectively turning the boundary points of passage into points of reflection. The fact that the $R=0$ point is the same in both the twisted and untwisted loops may also identify this point as a common or double point between the two different loop topological phases. The zero tension limit has been discussed by Lindström.[20]

C. General energies and frequencies-odd *s*

1. The Casimir energy

The dispersion relation can be written as a polynomial in $\sin^{(s+1)}(\omega L_1)$. There will be $((s+1)/2)$ double branches, i.e., solutions to the equation for $\sin^2(\omega L_1)$. Each root is an allowed frequency. Each double branch has roots $\pi\beta_i$. There are $((s+1)/2)$ values of β_i. For each β_i the frequency spectrum is

$$\omega L_1=\begin{cases}\pi(\beta+n), \\ \pi(1-\beta+n),\end{cases} \quad 0\leqslant\beta\leqslant\tfrac{1}{2}. \tag{20}$$

There is no degeneracy to consider.

Using the Euler MacLaurin Sum formula with a cut off as in the uniform string case, the Casimir energy for a single β is

$$E(\beta)=\frac{L_1}{2\pi\alpha^2}-\frac{\pi}{2L_1}\left(\frac{\beta^2}{2}+\frac{(1-\beta)^2}{2}\right)+\frac{\pi}{6L_1}. \tag{21}$$

Summing over the $((s+1)/2)$ double branches we have

$$E=\frac{L}{2\pi\alpha^2}-\frac{\pi(s+1)}{4L}\sum_{i=1}^{(s+1)/2}(\beta_i^2+(1-\beta_i)^2)+\frac{\pi(s+1)^2}{12L}. \tag{22}$$

Once s is chosen, β can be determined from the dispersion relation (17) or (18) and numerical values for the energies found.

The energy in Eq. (22) is not yet renormalized. The prescription that we shall use is analogous to that used by Brevik and Nielsen for the untwisted string loop:

$$E_r=E \text{ (renormalized)}=E-E \text{ (uniform twisted loop)}. \tag{23}$$

Using this prescription and Eq. (22) we find the energy as

$$E_r=\frac{\pi(s^2+2s)}{12L}-\frac{\pi(s+1)}{4L}\sum_{i=1}^{(s+1)/2}(\beta_i^2+(1-\beta_i)^2). \tag{24}$$

We will now consider some special cases.

2. $s=1$ ($L_1=L_2$)

From the dispersion relation (18) we find one double branch for $s=1$,

$$\sin^2(\omega L_1)=\frac{4R}{(1+R)^2}. \tag{25}$$

TABLE I. Some energies for the twisted string loop renormalized to the unform twisted loop.

R	$E_r(s=1)$	$E_r(s=2)$	$E_r(s=3)$
0	$\frac{-\pi}{4L}$	$\frac{-\pi}{3.69L}$	$\frac{-\pi}{3.27L}$
$\frac{1}{2}$	$\frac{-\pi}{85.5L}$	$\frac{-\pi}{77.32L}$	$\frac{-\pi}{66.52L}$
1	0	0	0

The inverse sine of the square root of this equation for a given R is the single value of β for this case. From Eq. (23) the renormalized energy is

$$E_r=\frac{\pi}{4L}-\left(\frac{\pi}{2L}\right)(\beta^2+(1-\beta)^2). \tag{26}$$

Some values are tabulated in Table I.

3. $s=3$ ($L_2=3L_1$)

Using Eq. (19) again we find for the allowed frequencies,

$$\sin^4(\omega L_1)-\frac{3\sin^2(\omega L_1)(R+\frac{1}{3})(R+3)}{4(1+R)^2}+\frac{R}{(1+R)^2}=0. \tag{27}$$

There will be two values for β for each R. Some of the renormalized energies for $s=3$ are tabulated in Table I.

D. Casimir energies—even s

For even s we will use both Eqs. (17) and (18). We will first show that $\cos(\omega L_1)=-1$, $\omega L_1=\pi$, is a root for any even s.

From Eq. (18) we have

$$\sin(s\pi)\sin(\pi)=\left(\frac{4R}{(1-R)^2}\right)(1+\cos(\pi\langle s+1\rangle)),$$
$$1+\cos(\pi\langle s+1\rangle)=0. \tag{28}$$

So, for all even s, the polynomial has a degenerate root at $\omega L_1=\pi$.

The equation for the allowed frequencies is

$$(1-R)^2\cos(\omega L_1\langle s-1\rangle)-(1+R)^2\cos(\omega L_1\langle s+1\rangle)-4x=0,$$

with $1+\cos(\omega L_1)$ a factor. We will work out the $s=2$ case.

The allowed frequencies for $s=2$ are given in by

$$\cos^2(\omega L_1)-\cos(\omega L_1)+\frac{R}{(1+R)^2}=0 \quad \text{and} \quad \cos(\omega L_1)=-1. \tag{29}$$

Some values of the energy are tabulated in Table I.

IV. OTHER RENORMALIZATION METHODS

In the first part of the paper, the Casimir energies have been evaluated by considering the energy as a sum over possible modes of vibrations and using a limit of the Euler-MacLaurin sum formula with a cut-off function. There are several other regularization methods that could be applied to this problem.

A. Covariant point-splitting method-uniform twisted string

The result presented in Eq. (7) for the uniform twisted string can also be derived by the point-splitting method. This method is not only covariant but also cut-off independent.[21–23] To use this method the metric is assumed to be

$$ds^2=dt^2-(R_0)^2d\phi^2, \tag{30}$$

where R_0 is a constant and $\phi\epsilon[0,2\pi]$. This method, as in the previous one, begins with the possible modes of vibration. The wave equation in this metric is

$$D^{\mu}D_{\mu}\Phi(t,\phi)=0, \tag{31}$$

where D_{μ} is the covariant derivative operator for the metric (30).

As before the general solution is

$$\Phi_m(t,\phi)=Ae^{-i\omega_m t}\cos(m\phi), \quad \Phi_n(t,\phi)=Be^{-i\omega_n t}\sin(n\phi), \tag{32}$$

where A,B are constants and $\omega_m=m/R_0$, $\omega_n=n/R_0$. Now the time dependence is explicit and we use ϕ instead of x. Applying the antiperiodic boundary condition,

$$\Phi(t,\phi)=-\Phi(t,\phi+2\pi), \tag{33}$$

we obtain the eigenfunctions and eigenfrequencies, respectively, as

$$\Phi_n(t,\phi)=\frac{1}{\sqrt{\pi(2n+1)}}\exp(-i\omega_n t)\cos\left(\frac{(2n+1)\phi}{2}\right),$$
$$\omega_n=\frac{2n+1}{2R_0}, \quad n=0,1,2,3,\ldots, \tag{34}$$

and

$$\Phi_m(t,\phi)=\frac{1}{\sqrt{\pi(2n+1)}}e^{-i\omega_m t}\sin\left(\frac{(2m+1)}{2}\phi\right),$$
$$\omega_m=\frac{2m+1}{2R_0}, \quad m=0,1,2,\ldots . \tag{35}$$

The allowed frequencies are the same as in Eq. (5) with $L=2\phi R_0$. Rather than going directly to the energy as in the mode sum method, the modes are used to construct the Hadamard Green's function $G^{(1)}(x,x')$ which is written as[23]

$$G^{(1)}(x,x')=\frac{1}{2\pi}\ln\left[\frac{\cos(\Delta t/2R_0)+\cos(\delta)}{\cos(\Delta t/2R_0)-\cos(\delta)}\right], \tag{36}$$

where $\Delta t=t-t'$, and $\delta=(\phi-\phi')/2$. To renormalize this Green's function we express it as an image sum and write it as[24,25]

$$\frac{1}{2}G^{(1)}(x,x')=\frac{1}{4\pi}\sum_{n=-\infty}^{\infty}\ln\left[\frac{1}{(2n\pi+\delta)^2-(\Delta t/2R_0)^2}\right]+\frac{1}{4\pi}\ln\left[\cos\left(\frac{\Delta t}{2R_0}\right)+\cos(\delta)\right]$$
$$-\frac{1}{4\pi}\ln\left[\frac{1}{2}\right]-\frac{1}{\pi}\sum_{n=1}^{\infty}\ln\left[\frac{1}{2n\pi}\right]. \tag{37}$$

It is clear that the $n=0$ term corresponds to the infinite unbounded string result and hence the Casimir renormalization relative to the infinite string could be accomplished by dropping this term.[21] This is analogous to the energy renormalization of Eq. (9). Expressing the expectation value of the stress energy tensor as

$$\langle T_{\mu\nu}\rangle_r=\tfrac{1}{2}\operatorname*{Lim}_{x'\to x}(D_\mu D_{\nu'}-\tfrac{1}{2}g_{\mu\nu}D^\lambda D_\lambda)G_r^{(1)}(x,x'). \tag{38}$$

Using the covariant derivatives,

$$\operatorname*{Lim}_{x'\to x}\frac{1}{2}D_0D_{0'}G_r^{(1)}(x,x')=\frac{-1}{16\pi^3R_0^2}\sum_{n=1}^{\infty}\frac{1}{n^2}+\frac{1}{32\pi R_0^2},$$
$$\operatorname*{Lim}_{x'\to x}\frac{1}{2}D_\phi D_{\phi'}G_r^{(1)}(x,x')=\frac{-1}{16\pi^3}\sum_{n=1}^{\infty}\frac{1}{n^2}+\frac{1}{32\pi}, \tag{39}$$

we obtain

$$\langle T_0^0\rangle_r=\frac{1}{48\pi R_0^2},\quad \langle T_\phi^\phi\rangle_r=-\langle T_0^0\rangle_r. \tag{40}$$

The point splitting method will produce a density rather than an energy. Using this density the energy is

$$E_r=\frac{\pi}{12L}. \tag{41}$$

Equation (41) agrees with the results obtained with the sum formula and cut off, Eq. (9).

B. Regularization with the Zeta function

Another method that has been used to obtain the renormalized zero-point energies is Zeta function renormalization.[24–27] The use of Zeta function methods is interesting because the twisted string is such a simple example of the procedures. The history of Zeta function regularization applied to string loops has been reviewed by Elizalde.[27] The Zeta function method begins with a sum over an operator spectrum. We will use the Hurwitz Zeta function,[26]

$$\zeta(s^*,a)=\sum_{m=0}^{\infty}\frac{1}{(m+a)^{s^*}}, \tag{42}$$

with $\mathrm{Re}(s^*)>1$, $0<a\leq 1$. We use s^* rather than s to avoid confusion with the string length parameter.

One of the possible integral representations is

$$\zeta(s^*,a)=\frac{1}{\Gamma(s^*)}\int_0^\infty \frac{dt\, t^{(s^*-1)}e^{-at}}{1-e^{-t}}, \tag{43}$$

with $\mathrm{Re}(s^*)>1$ and $\mathrm{Re}(a)>0$. Transforming into a contour integral[26] we get

$$\zeta(s^*,a)=\frac{e^{-i\pi s^*}\Gamma(1-s^*)}{2\pi i}\oint \frac{dz\, z^{(s^*-1)}e^{-az}}{1-e^{-z}}. \tag{44}$$

This provides the analytic continuation of $\zeta(s^*,a)$ over the plane: It is regular everywhere except for a simple pole at $s^*=1$ with residue 1. In the special case where s^* is an negative integer $s^*=-m$, $m=0,1,2...$, we have

$$\zeta(-m,a)=\frac{-B_{m+1}(a)}{m+1}, \tag{45}$$

where $B_m(a)$ is the Bernoulli polynomial. The Zeta function method, just as in the mode sum method, starts with an expression for the energy as the sum over possible modes. The energy is given by Eq. (6) with $\alpha=0$, eliminating the cut off. That sum is clearly of the form (43) with $s^*=-1$. The Zeta function of interest is

$$\zeta(-1,a)=\frac{-a^2+a-\frac{1}{6}}{2}. \tag{46}$$

The Zeta function procedure regularizes the energy by assigning an analytically continued Zeta function to the energy sum.[23,27] It will be necessary to explicitly renormalize to the uniform twisted string energy at the end of the calculation. We now reconsider some of the cases considered in Sec. II using Zeta function regularization.

1. The uniform twisted string

From Eq. (5) we have $\omega_n=(2\pi/L)(n+1/2)$, $n=0,1,2,...$.
The Casimir energy is

$$E_t=2\times\frac{1}{2}\sum_{n=0}^{\infty}\frac{2\pi}{L}\left(n+\frac{1}{2}\right)=\frac{2\pi}{L}\zeta\left(-1,\frac{1}{2}\right)=\frac{\pi}{12L}, \tag{47}$$

where the factor 2 takes into account that the modes are degenerate. The simplicity of this procedure, compared to the more lengthly calculations associated with the mode sum/cut-off and point splitting methods is startling. Its very simplicity is, however, sometimes considered a drawback since the analytic continuation which removes the divergences somewhat hides the divergence behavior which could be of interest.

2. R=0

The $R=0$ case implies $T_1\to 0$ or $T_2\to\infty$.[20]
From Eq. (19) we get the allowed modes just as in the mode sum/cut-off method,

$$\omega_n=\begin{cases}\dfrac{n\pi}{L_1},\\ \dfrac{n\pi}{L_2},\end{cases}\quad n=0,1,2,\ldots\ . \tag{48}$$

The zero frequency mode is not of interest. The Casimir energy is

$$E_{1+2}=\frac{1}{2}\sum_{n=1}^{\infty}\ \frac{n\pi}{L_1}+\frac{n\pi}{L_2}. \tag{49}$$

Regularizing by the Riemann-Zeta function method we get

$$E_{1+2}=\left(\frac{\pi}{2L_1}+\frac{\pi}{2L_2}\right)\zeta(-1,1)=-\frac{\pi}{24}\left(\frac{1}{L_1}+\frac{1}{L_2}\right). \tag{50}$$

Using $s=L_2/L_1$ as before we can rewrite this equation as

$$E=\frac{-\pi}{24L}\left(s+\frac{1}{s}+2\right). \tag{51}$$

Renormalizing to the twisted string, using Eq. (23),

$$E_r=\frac{-\pi}{24L}\left(s+\frac{1}{s}+4\right). \tag{52}$$

This second renormalization must be included explicitly and is not performed by the Zeta function.

3. s an odd integer

Again, in agreement with the mode sum calculation we have from Eq. (20) the frequency spectrum

$$\omega L_1=\begin{cases}\pi(\beta+n),\\ \pi(1-\beta+n),\end{cases}$$

with $0\leqslant\beta\leqslant 1/2$, $n=0,1,2,\ldots$.

Just as in Eqs. (21) and (22) for the mode sum/cut-off method the Casimir energy for general β_i can be written as

$$E_{1+2}=\frac{\pi}{2L_1}\sum_{i=1}^{(s+1)/2}\ \zeta(-1,\beta_i)+\zeta(-1,1-\beta_i). \tag{53}$$

Using the special form for the Zeta function given in Eq. (46) we have

$$E_{1+2}=\frac{\pi(s+1)^2}{12L}-\frac{\pi(1+s)}{4L}\sum_{i=1}^{(s+1)/2}\ \beta_i^2+(1-\beta_i)^2 \tag{54}$$

or renormalizing to the uniform twisted string we have

$$E_r=E_{1+2}-E\ \text{(Uniform twisted string)},$$

$$E_r=\frac{\pi(s^2+2s)}{12L}-\frac{\pi(1+s)}{4L}\sum_{i=1}^{(s+1)/2}\beta_i^2+(1-\beta_i)^2. \tag{55}$$

V. RELATING THE TWISTED AND UNTWISTED STRING WITH $S=1$

One of the effects of once twisting the string with two segments is to compel the field to cross four string segments before returning to its initial condition. A uniform string with four segments also has this effect and the question arises of how the two cases are related.

A. The uniform string

First compare the uniform twisted string to the uniform untwisted string. Generalize the frequency conditions to allow the twisted and untwisted loops to have different radii. L_t will be the circumference of one loop of the twisted string and L_u will be the circumference of one loop of the untwisted string.

The frequency conditions are

$$\begin{aligned}&\text{twisted string: } \cos(\omega L_t)=-1,\\ &\text{untwisted string: } \cos(\omega L_u)=1.\end{aligned} \tag{56}$$

To make the strings similar one could clearly require that the path length traveled by a wave on each type of loop be the same,

$$2L_t=L_u. \tag{57}$$

Substituting into the frequency conditions one finds

$$\text{twisted string: } \cos\left(\frac{\omega L_u}{2}\right)=-1, \tag{58}$$

$$\text{untwisted string: } \cos\left(\frac{\omega L_u}{2}\right)=\pm 1. \tag{59}$$

The untwisted string contains the twisted string and the additional frequency $\omega L_u/2=2\pi,4\pi,\ldots$. For the uniform loops, there is no calculational advantage to treating one loop topology over the other but for higher numbers of segments, there is possibly a reduction in the dimensionality of the problem that needs to be solved for some of the parameter range. The next most complicated cases to compare are the two segment twisted string to the four segment untwisted string.

B. The two segment twisted string, the four segment untwisted string, $s=1$

The frequency conditions for the two segment twisted loop follows from Eq. (17b),

$$\cos\left(\frac{\omega L_u}{2}\right)=\frac{R^2-6R+1}{(1+R)^2}, \tag{60}$$

where we have made the same arguments about circumference and lengths as for the uniform string. The frequency condition for the four segment untwisted string was given in Ref. 13, Eq. (17).

$$-\frac{(1+R)^2}{8R^2}(3-10R+3R^2)+\frac{(1-R)^2}{2R^2}\cos\left(\frac{\omega L_u}{2}\right)-\frac{(1+R)^4}{8R^2}\cos(\omega L_u)=0. \tag{61}$$

The roots of this equation are

$$\cos\left(\frac{\omega L_u}{2}\right)=\frac{R^2-6R+1}{(1+R)^2} \quad \text{and} \quad +1. \tag{62}$$

Comparing (34) and (37) to (32) and (33) we see the same pattern. The untwisted string of 4 segments contains the twisted string plus a root of $+1$. Whether or not this pattern is more general is under investigation.

VI. CONCLUSIONS

We have calculated the energy of a uniform twisted loop of string and compared it to the uniform untwisted loop. We find that the untwisted loop has the lower energy for a pure antiperiodic boundary condition. More complex boundary conditions could reverse this.

The energy of a twisted two segmented loop was also calculated and, just as for the untwisted string, a non zero negative Casimir energy is observed. We found that the twisted and untwisted phases of the loop share a common point of their energy spectrum at zero tension. The double point in the energy spectrum of the twisted and untwisted loops may be important in loop dynamics. The loop tensions are part of the loop stress energy content and related to the behavior of the space time through the field equations. A process in which the loop tensions change with variations in the metric could create conditions for the loop phase transition to occur as either a one time transfer or as an oscillation between phases. A study of the behavior of the loop tension as a function of curvature is clearly an important question. It would be especially pertinent in the context of the types of radiation emitted by an oscillating loop and the question of loop stability. If loop stability is affected by the possibility of a phase transition or phase oscillation, this could have an effect on the galactic seeding process.[2,8,14]

A calculation involving loop tension and the curvature of the embedding cosmology opens up the possibility of a much more varied loop stress-energy structure. Cosmic string interiors with heat flow and vorticity,[28] and torsion[29] and spin density[30] have all been discussed in the literature. This larger array of possible stress-energy contents with both untwisted and twisted loop analogs might provide a richer loop thermodynamics with associated phases, such as spin-up/spin-down.[31] Casimir energy calculation on these more elaborate loops would be interesting. The existence of two accessible loop phases has suggested that more detailed calculations involving curvature would be valuable.

(Received 16 February 1996; accepted for publication 19 April 1996)

We formulate the q-Coulomb problem in configuration space with the aid of ladder operators for the radial wave function. The highest angular momentum state corresponding to the principal quantum number n is found to be the monomial r^{n-1} multiplied by a q-exponential. The states of lower angular momentum are q-associated Laguerre polynomials multiplied by the same q-exponential. The state functions all lie in the complex plane and may be interpreted in the standard way. The energy levels are again given by a Balmer formula with n replaced by the basic n. © *1996 American Institute of Physics.* [S0022-2488(96)03408-1]

I. INTRODUCTION

The q-Coulombic problem has been the subject of several studies which differ in the way the Coulombic symmetry is lifted.[1,2] The basic $O_3 \times O_3$ symmetry of this problem may be described in terms of the two vector integrals of the motion, $\mathbf{L}$, the angular momentum integral coming from the spherical symmetry and $\mathbf{A}$, the Lenz vector owing its existence to the k/r potential. The problem separates in spherical coordinates into an angular equation determining the eigenvalues of $\mathbf{L}^2$ and L_z and a radial equation parametrically dependent on $(L^2)'$ and determining the eigenvalues of the Hamiltonian H and $(\mathbf{A}^2)$, for which one finds

$$H' \equiv E \sim -\frac{1}{n^2},$$

$$(\mathbf{A}^2)' = m^2h^2 + 2mE((L^2)' + \hbar^2)),$$

where m is the mass. Here we discuss the q-derived problem by replacing the angular and the radial equations by their q-analogs.

II. THE ANGULAR AND RADIAL EQUATIONS (q=1)

The Hamiltonian for any spherically symmetric potential is

$$H = \frac{1}{2m}\left(\frac{1}{r}p_r^2 r + \frac{L^2}{r^2}\right) + V(r), \tag{2.1}$$

where

$$(r, p_r) = i\hbar. \tag{2.2}$$

The problem separates into an angular equation

[a)]e-mail: acadavid@galileo.csun.edu
[b)]e-mail finkelstein@physics.ucla.edu

$$L^2\Phi_{lm}(\theta,\phi)=l(l+1)\hbar^2\Phi_{lm}(\theta,\phi) \tag{2.3}$$

and a radial equation

$$\left[\frac{1}{2m}\left(\frac{1}{r}p_r^2 r\right)+\frac{l(l+1)\hbar^2}{r^2}+V(r)\right]R(r)=ER(r). \tag{2.4}$$

The solutions of (2.3) are spherical harmonics; and, if $V(r)$ is the Coulomb potential, the solutions of (2.4) are the associated Laguerre functions.

In dimensionless form the radial equation is

$$R''+\frac{2}{x}R'+\frac{2}{x}R-\frac{l(l+1)}{x^2}R=-\lambda R. \tag{2.5}$$

Set

$$\rho=xR \tag{2.6}$$

then

$$\rho''+\frac{2}{x}\rho-\frac{l(l+1)}{x^2}\rho=-\lambda\rho. \tag{2.7}$$

The eigenvalue, λ, as determined from the asymptotic form of this equation, is

$$\lambda=-\left(\frac{\rho''}{\rho}\right)_\infty. \tag{2.7}_\infty$$

We shall discuss the radial equation with the aid of the Infeld ladder method.[3,4] This procedure sometimes permits the factorization of the Sturm–Liouville operator into the product of a raising and a lowering operator.

Equation (2.7) may be so factored in either of the following ways:

$$H_l^- H_l^+ \cdot \rho_l^\lambda=\left(\lambda+\frac{1}{l^2}\right)\rho_l^\lambda, \tag{2.8a}$$

$$H_{l+1}^+ H_{l+1}^- \cdot \rho_l^\lambda=\left(\lambda+\frac{1}{(l+1)^2}\right)\rho_l^\lambda, \tag{2.8b}$$

where

$$H_l^\pm=\frac{l}{x}-\frac{1}{l}\pm\frac{d}{dx}. \tag{2.9}$$

It follows that

$$H_l^+ H_l^-(H_l^+\rho_l^\lambda)=\left(\lambda+\frac{1}{l^2}\right)(H_l^\pm\rho_l^\lambda), \tag{2.10a}$$

$$H_{l+1}^- H_{l+1}^+(H_{l+1}^-\rho_l^\lambda)=\left(\lambda+\frac{1}{(l+1)^2}\right)(H_{l+1}^-\rho_l^\lambda). \tag{2.10b}$$

By comparing (2.8a) with (2.10b) and (2.8b) with (2.10a) we see that, up to a normalization,

$$H^{-}_{l+1}\rho^{\lambda}_{l}=\rho^{\lambda}_{l+1} \tag{2.11a}$$

and

$$H^{+}_{l}\rho^{\lambda}_{l}=\rho^{\lambda}_{l-1}. \tag{2.11b}$$

Hence H^{-}_{l+1} and H^{+}_{l} are raising and lowering operators respectively. There is a highest state given by $\rho^{\lambda}_{\bar{l}}$ where $\bar{l}=l_{\max}$ and

$$H^{-}_{\bar{l}+1}\rho^{\lambda}_{\bar{l}}=0 \tag{2.12a}$$

or

$$\left(\frac{\bar{l}+1}{x}-\frac{1}{\bar{l}+1}-\frac{d}{dx}\right)\rho^{\lambda}_{\bar{l}}=0. \tag{2.12b}$$

The solution of (2.12) is

$$\rho^{\lambda}_{\bar{l}}=x^{\bar{l}+1}e^{-x/(\bar{l}+1)}. \tag{2.13}$$

When $\rho^{\lambda}_{\bar{l}}$ is substituted in (2.8b) we find

$$\lambda=-\frac{1}{(\bar{l}+1)^2}, \tag{2.14}$$

in agreement with $(2.7)_{\infty}$.

The energy levels are usually expressed in terms of a principal quantum number n:

$$\lambda=-\frac{1}{n^2}, \tag{2.15}$$

where

$$n=\bar{l}+1. \tag{2.16}$$

Then the radial wave function with maximum l and principal quantum number n is

$$\rho^{n}_{\bar{l}}=x^{n}e^{-x/n} \tag{2.17}$$

or

$$R^{n}_{\bar{l}}=x^{n-1}e^{-x/n}. \tag{2.18}$$

To find states belonging to the same n but with lower values of l one may apply the lowering operator H^{+}_{l}. For example we find the three top states (nonrenormalized):

$l=\bar{l}$: $$\rho^{n}_{\bar{l}}\sim x^{\bar{l}+1}e^{-x/n},$$

$$l=\bar{l}-1: \qquad \rho^n_{\bar{l}-1}\sim\left[x^{\bar{l}}-\frac{1}{\bar{l}(\bar{l}+1)}x^{\bar{l}+1}\right]e^{-x/n},$$

$$l=\bar{l}-2: \qquad \rho^n_{\bar{l}-2}\sim\left[(2\bar{l}-1)x^{\bar{l}-1}-\frac{2(2\bar{l}-1)}{(\bar{l}-1)(\bar{l}+1)}x^{\bar{l}}+\frac{2}{(\bar{l}-1)(\bar{l}+1)^2}x^{\bar{l}+1}\right]e^{-x/n}, \tag{2.19}$$

where the quantum numbers of the top state are $(n,\bar{l})$. Expressed in terms of associated Laguerre polynomials, one has

$$l=\bar{l}: \qquad \rho^n_{\bar{l}}\sim x^{\bar{l}+1}L^{2\bar{l}+1}_{2\bar{l}+1}\left(\frac{2x}{n}\right)e^{-x/n},$$

$$l=\bar{l}-1: \qquad \rho^n_{\bar{l}-1}\sim x^{\bar{l}}L^{2\bar{l}-1}_{2\bar{l}}\left(\frac{2x}{n}\right)e^{-x/n}, \tag{2.20}$$

$$l=\bar{l}-2: \qquad \rho^n_{\bar{l}-2}\sim x^{\bar{l}-1}L^{2\bar{l}-3}_{2\bar{l}-1}\left(\frac{2x}{n}\right)e^{-x/n},$$

where

$$L^{2l+1}_{n+l}(x)=-((n+l)!)^2\sum_{\lambda=0}^{n-\lambda-1}\frac{(-)^\lambda x^\lambda}{\lambda!(n-l-1-\lambda)!(2l+1+\lambda)!}. \tag{2.21}$$

III. THE DEFORMATION

A. The angular equation

Replace (2.3) by

$$L^2_q\Phi^q_{lm}(\theta,\phi)=\langle l\rangle\langle l+1\rangle\Phi^q_{lm}(\theta,\phi), \tag{3.1}$$

where L^2_q is the quadratic Casimir of $SU_q(2)$ and $\langle l\rangle$ is the basic number:

$$\langle l\rangle=\frac{q^l-1}{q-1}. \tag{3.2}$$

Here we have substituted the quadratic Casimir of $SU_q(2)$ for the quadratic Casimir of $SU(2)$ and therefore replaced $l(l+1)$ by $\langle l\rangle\langle l+1\rangle$. The eigensolutions of this equation, Φ^q_{lm}, the q-spherical harmonics, have been obtained by Rideau and Winternitz.[5]

B. The radial equation

We take over (2.2) as a q-commutator:

$$(r,p_r)_q=i\hbar, \tag{3.3}$$

where the conjugate momentum p_r becomes the difference operator

$$p_r=\frac{\hbar}{i}D^q_r \tag{3.4}$$

and

$$D_r^q f(r)=\frac{f(qr)-f(r)}{(q-1)r}. \tag{3.5}$$

We shall abbreviate D_r^q as D_r.

There are various possibilities for defining the q-radial problem. Here we shall adopt the q-modified raising and lowering Eq. (2.11) in dimensionless form, as follows:

$$H^-_{\langle l+1\rangle}\rho^\lambda_{\langle l\rangle}=\rho^\lambda_{\langle l+1\rangle}, \tag{3.6}$$

$$H^+_{\langle l\rangle}\rho^\lambda_{\langle l\rangle}=\rho^\lambda_{\langle l-1\rangle}, \tag{3.7}$$

where we have replaced l by $\langle l\rangle$, d/dx by D_x, and therefore $H_l^\pm$ by

$$H^\pm_{\langle l\rangle}=\frac{\langle l\rangle}{x}-\frac{1}{\langle l\rangle}\pm D_x. \tag{3.8}$$

We define the energy by

$$\lambda=-\left(\frac{D_x^2\rho}{\rho}\right)_\infty \tag{3.9}$$

as the natural extension of (2.7).

We take the view that (3.6)–(3.9) describe the full content of the q-radial problem, since (3.6), (3.7), and (3.9) imply (2.5) and $(2.7)_\infty$ in the limit $q=1$.

Since these modified equations do not lead to an acceptable Hamiltonian, the energy is fixed not by the eigenvalues of the Hamiltonian, but by the asymptotic form of the wave function via (3.9), or equivalently by poles of the corresponding amplitude in momentum space.

The highest state $(\bar{l})$ is now given by

$$H^-_{\langle \bar{l}+1\rangle}\rho^\lambda_{\langle l\rangle}=0 \tag{3.10}$$

or

$$\left(\frac{\langle \bar{l}+1\rangle}{x}-\frac{1}{\langle \bar{l}+1\rangle}-D_x\right)\rho^\lambda_{\langle l\rangle}=0. \tag{3.11}$$

The asymptotic form of this equation is

$$D_x\rho^\lambda_{\langle \bar{l}\rangle}=-\frac{1}{\langle \bar{l}+1\rangle}\,\rho^\lambda_{\langle \bar{l}\rangle}. \tag{3.12}$$

Also

$$(D_x)^2\rho^\lambda_{\langle \bar{l}\rangle}\to\frac{1}{\langle \bar{l}+1\rangle^2}\,\rho^\lambda_{\langle \bar{l}\rangle}. \tag{3.13}$$

By (3.9) and the preceding equation we have

$$\lambda=-\frac{1}{\langle \bar{l}+1\rangle^2} \tag{3.14a}$$

or the energy is

$$E(n,\bar{l})=-\frac{1}{\langle n\rangle^2};\quad n=\bar{l}+1. \tag{3.14b}$$

The asymptotic form of $\rho^{\lambda}_{\langle\bar{l}\rangle}$ is a solution of (3.12). We see that (3.12) is satisfied by

$$\rho^{\lambda}_{\langle\bar{l}\rangle}=\mathscr{E}_q\left(\frac{-x}{\langle n\rangle}\right), \tag{3.15}$$

where $\mathscr{E}_q$ is the q-exponential

$$\mathscr{E}_q(y)=\sum\frac{y^n}{\langle n\rangle!}. \tag{3.16}$$

Let the complete solution of (3.10) be

$$\rho^{\lambda}_{\langle\bar{l}\rangle}=f(x)\mathscr{E}_q\left(-\frac{x}{\langle n\rangle}\right). \tag{3.17}$$

By the q-Leibniz rule

$$D_xP^{\lambda}_{\langle n\rangle}=f(qx)\left(-\frac{1}{\langle n\rangle}\mathscr{E}_q\left(-\frac{x}{\langle n\rangle}\right)\right)+(D_xf(x))\mathscr{E}_q\left(-\frac{x}{\langle n\rangle}\right). \tag{3.18}$$

Then (3.10) becomes

$$\left(\frac{\langle n\rangle}{x}-\frac{1}{\langle n\rangle}\right)f(x)=-\frac{1}{\langle n\rangle}f(qx)+D_xf(x) \tag{3.19}$$

or

$$\left[(q-1)\langle n\rangle-\frac{(q-1)x}{\langle n\rangle}+1\right]f(x)=\left[1-\frac{(q-1)x}{\langle n\rangle}\right]f(qx). \tag{3.20}$$

If one sets $q=1$, (3.20) is simply an identity. To discuss this difference equation first convert it to a differential equation by differentiating with respect to q and then setting $q=1$. One finds

$$\langle n\rangle_1f(x)=xf'(x). \tag{3.21}$$

Therefore

$$f(x)=x^{\langle n\rangle_1} \tag{3.22}$$

$$=x^n. \tag{3.23}$$

By (3.17) and (3.23) one would have for the highest state,

$$\rho^{n}_{\langle\bar{l}\rangle}=x^n\mathscr{E}_q\left(-\frac{x}{\langle n\rangle}\right). \tag{3.24}$$

Equation (3.24) has the correct $q=1$ limit but does not satisfy the difference equation (3.20) from which it was derived. Therefore let us return to the difference equation and rewrite it in the following form:

$$f(x)=q^{-n}\left(\frac{1+ax}{1+q^{-n}ax}\right)f(qx); \quad a=\frac{1-q}{\langle n\rangle}, \tag{3.25}$$

$$=q^{-n}R(x)f(qx), \tag{3.26}$$

where

$$R(x)=\frac{1+ax}{1+aq^{-n}x}. \tag{3.27}$$

By $N-1$ iterations

$$f(x)=q^{-nN}\prod_{s=0}^{N-1} R(q^s x)f(q^N x) \tag{3.28}$$

and

$$f(x)=\prod_{0}^{\infty} R(q^s x)\lim_{N\to\infty} q^{-nN}f(q^N x). \tag{3.29}$$

Since $|q|<1$, $q^{-nN}\to\infty$. Therefore $f(q^N x)$ must vanish in this limit as is also indicated by (3.24). Then (3.28) suggests the ansatz

$$f(x)=x^n\phi(x) \tag{3.30}$$

so that by (3.29)

$$\phi(x)=\prod_{0}^{\infty} R(q^s x)\phi(0), \tag{3.31}$$

where

$$\prod_{0}^{\infty} R(q^s x)=\prod_{0}^{\infty}\frac{1+axq^s}{1+axq^{-n+s}} \tag{3.32a}$$

$$=\frac{(-ax|q)_\infty}{(-aq^{-n}x|q)_\infty}. \tag{3.32b}$$

Here

$$(x|q)_\infty=\prod_{0}^{\infty}(1-xq^s) \tag{3.33}$$

is the displaced factorial. Set

$$\phi(0)=1. \tag{3.34}$$

Then

$$f(x)=x^n\,\frac{(-ax|q)_\infty}{(-aq^{-n}x|q)_\infty} \tag{3.35}$$

and

$$\rho^n_{\langle n\rangle}(x)=x^n\,\frac{(-ax|q)_\infty}{(-aq^{-n}x|q)_\infty}\,\mathscr{E}_q\!\left(-\frac{x}{\langle n\rangle}\right) \tag{3.36}$$

or

$$R_{n\bar{l}}(x)=x^{n-1}\,\frac{(-ax|q)_\infty}{(-aq^{-n}x|q)_\infty}\,\mathscr{E}_q\!\left(-\frac{x}{\langle n\rangle}\right). \tag{3.37}$$

But[6]

$$(-ax|q)_\infty=\frac{1}{e_q(-ax)}=\frac{1}{e_q\!\left(-(1-q)\,\dfrac{x}{\langle n\rangle}\right)}=\frac{1}{\mathscr{E}_q\!\left(-\dfrac{x}{\langle n\rangle}\right)} \tag{3.38}$$

and

$$(-aq^{-n}x|q)_\infty=\frac{1}{\mathscr{E}_q\!\left(-\dfrac{q^{-n}x}{\langle n\rangle}\right)}. \tag{3.39}$$

Therefore

$$R_{n\bar{l}}(x)=x^{n-1}\mathscr{E}_q\!\left(-\frac{q^{-n}r}{\langle n\rangle}\right). \tag{3.40}$$

The remaining states are given by (3.7). For example, the three top states are

$$l=l:\quad \rho^n_{\bar{l}}\sim x^{\bar{l}+1}\mathscr{E}_q\!\left(-\frac{q^{-n}x}{\langle n\rangle}\right), \tag{3.41}$$

$$l=\bar{l}-1:\quad \rho^n_{\bar{l}-1}\sim\left(\rho^{\bar{l}}-\frac{x^{\bar{l}+1}}{\langle\bar{l}\rangle\langle\bar{l}+1\rangle}\right)\mathscr{E}_q\!\left(-\frac{q^{-n}x}{\langle n\rangle}\right), \tag{3.42}$$

$$\begin{aligned} l=\bar{l}-2:\quad \rho^n_{\bar{l}-2}\sim\Bigg\{&[\langle\bar{l}-1\rangle+\langle\bar{l}\rangle]x^{l-1}-\left[\frac{1}{\langle\bar{l}-1\rangle}+\frac{1}{\langle\bar{l}\rangle}+\frac{\langle\bar{l}-1\rangle}{\langle\bar{l}\rangle\langle\bar{l}+1\rangle}+\frac{q^{-1}}{\langle\bar{l}+1\rangle}\right]x^{\bar{l}}\\ &+\frac{1}{\langle\bar{l}\rangle\langle\bar{l}+1\rangle}\left(\frac{1}{\langle\bar{l}-1\rangle}+\frac{1}{\langle\bar{l}+1\rangle}\right)x^{\bar{l}+1}\Bigg\}\mathscr{E}_q\!\left(-\frac{q^{-n}x}{\langle n\rangle}\right). \end{aligned} \tag{3.43}$$

These are "q-Laguerre polynomials" which approach the usual Laguerre polynomials in the limit $q=1$.

The energy levels are given by (3.14). The Coulomb degeneracy is therefore not lifted in this version of the deformation.

IV. REMARKS

As already noted, the "q-deformation" is not a unique procedure. Reference 1 makes explicit use of the full $O(4)=O(3)\times O(3)$ undeformed symmetry since the integral equation of that paper lies in the $SU(2)$ group space which is carried into itself by the left and right motions (parameter groups) described by $O(3)\times O(3)$. Reference 2 is based on the q-deformation of $O(3)$. Since the quantum groups corresponding to $SU(2)$ and $O(3)$ are different, Refs. 1 and 2 describe different deformations. Furthermore, since both solutions lie in their respective algebras, they require a rule for their physical interpretation. In Ref. 7 such a rule is provided in terms of the Hilbert space defined by the algebra itself.

The totally different procedure followed here is based on rules such as the replacement of the radial commutator by the radial q-commutator, and further described in Sec. III of this paper. These rules are similar in spirit but formally weaker than the imposition of a quantum group. On the other hand, the wave functions here obtained have the clear advantage of lying in the complex plane as well as being simply related to the $q=1$ solutions from which they are derived. There is therefore no problem of physical interpretation such as we encounter in the other deformations of the Coulomb problem.

It is still possible to make canonical transformations including transformations which exchange the roles of x and p and transform probability amplitudes between configuration and momentum space. For example, the amplitude in r-space that we have obtained here may be q-Fourier transformed to momentum space, since the momentum operator is a q-derivative.[7]

There are in addition quite different canonical transformations, namely

$$\begin{pmatrix} r \\ p_r \end{pmatrix} = T_q \begin{pmatrix} R \\ P_R \end{pmatrix} \quad T_q \epsilon SU_q(2),$$

$$\begin{pmatrix} R \\ P_R \end{pmatrix} = T_{q^{-1}} \begin{pmatrix} r \\ p_r \end{pmatrix} \quad T_{q^{-1}} \epsilon SU_{q^{-1}}(2),$$

which preserve the q-commutator

$$(r,p_r)_q=(R,P_R)_q=i\hbar.$$

In previous work[7] we have restricted canonical transformations to either $SU_q(2)$ or $SU_{q^{-1}}(2)$. Then one can posit that one set of conjugate observables lies in a q- or q^{-1}-algebra while the other does not. If the state function turns out to lie in a q-algebra, the only invariant that could naturally be associated with a numerical probability of that state would be the Woronowicz integral over the algebra.

Cabled Wilson loops in BF theories

Alberto S. Cattaneo[a)]
Lyman Laboratory of Physics, Harvard University, Cambridge, Massachusetts 02138

(Received 8 February 1996; accepted for publication 29 April 1996)

A generating function for cabled Wilson loops in three-dimensional BF theories is defined, and a careful study of its behavior for vanishing cosmological constant is performed. This allows an exhaustive description of the unframed knot invariants coming from the pure BF theory based on SU(2), and, in particular, it proves a conjecture relating them to the Alexander–Conway polynomial. © *1996 American Institute of Physics.* [S0022-2488(96)00308-8]

I. INTRODUCTION

In Ref. 1, a relation was conjectured between the Alexander–Conway polynomial and the v.e.v. (*vacuum expectation value*) of a newly proposed observable for the TQFT (*topological quantum field theory*) known as BF theory[2] (or as "pure" BF theory, to distinguish it from its generalization "with a cosmological term"). The main purpose of this paper is to clarify that conjecture and to prove it in the case of SU(2), although in a slightly different form. To do so, however, we also perform a careful study of BF theories, both pure and with a cosmological term, introducing new observables that describe cabled Wilson loops.

The BF theories are interesting from both the mathematical and the physical points of view: They are TQFTs that, in principle, can be defined in any dimension (see Ref. 3 and references therein). They describe quantum gravity in three dimensions[4] and could be useful for the study of four-dimensional quantum gravity in the approach of Ref. 5. Moreover, they are related to Yang–Mills theories in the weak-coupling limit, where they could be used to describe a "topological phase"[6] (see also Ref. 7 for a related approach). Finally, hitherto only in the Abelian case, they have been used to study many-body systems.[8]

On the other side, the interest for the Alexander–Conway polynomial comes from the fact that it has always played a different role than the other knot invariants, being the only one that, hitherto, has been described by the methods of the traditional algebraic topology; yet it lacked a TQFT description (and Ref. 1 was an attempt to fill this gap).

Indeed, the Chern–Simons theory describes the knot invariants related to the q-deformation of a classical group G in terms of v.e.v.s of Wilson loops (i.e., traces of G-holonomies along the knots);[9] yet the $q=1$ case, i.e., the Alexander–Conway polynomial, does not correspond to any acceptable value of the Chern–Simons coupling constant k.

In the case of SU(2), an important improvement was given by the Melvin–Morton conjecture[10] (proved in Ref. 11), which states that the inverse of the Alexander–Conway polynomial appears in the $q-1$ expansion of the colored Jones function. Rozansky[12] was then able to prove the same result in the framework of the Chern–Simons theory; more precisely, he showed that the inverse of the Alexander–Conway polynomial is recovered by a saddle-point computation in the limit $k\to\infty$.

In Ref. 3, an equivalence between the v.e.v.s of the Chern–Simons theory and of the BF theory with cosmological constant $\kappa=1/(2k)$ was shown. The $k\to\infty$ limit (i.e., the $q=1$ case) is then simply described by removing the cosmological term, thus obtaining the pure BF theory.

In this paper we show that the trace in the fundamental representation of the pure-BF-theory observable (31), first introduced in Ref. 1, is related to the $\kappa\to 0$ limit of a newly proposed

observable, (22), for the BF theory with a cosmological term. In the framework of the Chern–Simons theory, this observable corresponds to the "exponential" of a holonomy; so its trace is the generating function for cabled Wilson loops, and the v.e.v. of this trace is the generating function for cabled knot invariants (as suggested by the results of Ref. 13).

Since the colored Jones functions are related to the cabled knot invariants, we are able to connect the $q-1$ expansion of the former to the pure-BF-theory knot invariant. By the Melvin–Morton conjecture, we conclude that the latter is related to the Alexander–Conway polynomial, the precise relation being (49). Our proof, however, can also go the other way; i.e., should one directly prove a relation between the pure BF theory and the Alexander–Conway polynomial, then we would have a further proof of the Melvin–Morton conjecture.

Our results are not limited to the trace in the fundamental representation of a particular observable for pure BF theory. In fact, we are able to prove that, in the standard framing, this observable is the most general one can consider (see Theorem 1 and Corollary 1). Moreover, we show how to compute the higher-representation knot invariants [see (34) and (35)], and also evaluate the limit as the dimension of the representation goes to infinity [see (37) and (40)]. Thus, we have a complete description of the unframed knot invariants coming from the pure BF theory based on SU(2) (see Theorem 2). The case of links has not been considered yet.

The paper is organized as follows: In Sec. II, we describe the colored Jones functions and introduce their generating function. In Sec. III, we recall the property of the BF theory with a cosmological term and define a generating function for cabled Wilson loops. In Sec. IV, we discuss the pure BF theory and prove Theorem 1 and Corollary 1. In Sec. V, we consider the limit for vanishing cosmological constant and prove Theorem 2. We conclude our work in Sec. VI, comparing our present results with those obtained perturbatively in Ref. 1. For the sake of clarity, we have put all the cumbersome computations into some appendices, to which we shall refer in the text.

II. THE COLORED JONES FUNCTION

The colored Jones function, $J_d(C;h)$, is defined in Ref. 10 as the invariant of the knot C obtained using the irreducible $SU(2)_q$-module ($q=e^h$) of dimension d. The main properties of its expansion as a rational power series (here and in the following, the notation of Ref. 11 is used),

$$J_d(C;h)=\sum_{m=0}^{\infty}\tilde{J}_m(C;d)h^m=d\sum_{j,m=0}^{\infty}b_{jm}(C)(d-1)^j h^m, \tag{1}$$

were stated in Ref. 10:

(i) The functions $\tilde{J}_m(C;d)$ are odd in d. This means that (the analytic continuation of) $J_d(C;h)$ itself is odd:

$$J_{-d}(C;h)=-J_d(C;h). \tag{2}$$

[This of course implies that the coefficients b_{jm} in (1) are not completely independent.]

(ii) These functions are actually polynomials of degree not exceeding $2m+1$.

(iii) In the hypothesis that *the standard framing for* C *is chosen*, the degree of $\tilde{J}_m$ cannot exceed $2m-1$.

In the same hypothesis of standard framing, two conjectures were also stated in Ref. 10:

(i) The degree of $\tilde{J}_m$ cannot actually exceed $m+1$, or in other words, $b_{..}$ in (1) is an upper triangular matrix,

$$b_{jm}(C)=0, \quad \text{if } j>m. \tag{3}$$

(ii) The diagonal elements of $b_{..}$ are related to the Alexander–Conway polynomial; viz., if one defines the Melvin–Morton function as

$$JJ(C;\hbar)=\sum_{m=0}^{\infty} b_{mm}(C)\hbar^m=\lim_{d\to\infty,h\to 0,dh=\hbar}\frac{J_d(C;h)}{d} \tag{4}$$

[the limit existing because of (3)], then

$$\hbar JJ(C;\hbar)=\frac{z}{\Delta(C;z)},\quad z=e^{\hbar/2}-e^{-\hbar/2}, \tag{5}$$

where $\Delta(C;z)$ is the Alexander–Conway polynomial with the normalization $\Delta(\bigcirc;z)=1$, where $\bigcirc$ is the unknot, and skein relation

$$\Delta(C_+;z)-\Delta(C_-;z)=z\Delta(C_0;z).$$

These two conjectures have been given a functional-integral proof by Rozansky.[12] In particular he proved that the Melvin–Morton function, (4), is related to the large-k limit of the Chern–Simons theory, so it can be computed in saddle-point approximation.

Eventually, Bar-Natan and Garoufalidis[11] gave a mathematical proof of (3) and (5) on the level of weight systems.

A. The generating function for colored Jones functions

In the following sections, the generating function

$$f(C;x,h)=\sum_{d=1}^{\infty}\frac{x^d}{d!}J_d(C;h), \tag{6}$$

with $x\in\mathbb{C}$, will be needed; so it is useful to anticipate here some of its properties. These are better clarified if one introduces $\tilde{f}$ defined by

$$f(C;x,h)=xe^x\tilde{f}(C;x,h). \tag{7}$$

In fact, the expansion of $\tilde{f}$ as a rational power series,

$$\tilde{f}(C;x,h)=\sum_{j,m=0}^{\infty}\tilde{b}_{jm}(C)x^jh^m, \tag{8}$$

shares the same properties as the expansion (1) of $J_d(C;h)$ (viz., see Appendix B). One can prove that

$$b\text{..}\ \text{upper triangular}\Leftrightarrow\tilde{b}\text{..upper triangular.} \tag{9}$$

Thus, (3) implies that $\tilde{b}$.. is actually an upper triangular matrix,

$$\tilde{b}_{jm}(C)=0,\quad \text{if } j>m, \tag{10}$$

and that $\tilde{f}$ has a well-defined limit for $|x|\to\infty$, $h\to 0$, and $xh=\hbar$ kept fixed. In Appendix B, it is shown that

$$\lim_{|x|\to\infty,h\to 0,xh=\hbar}\tilde{f}(C;x,h)=JJ(C;\hbar), \tag{11}$$

and that, in general, for any $n\geqslant 0$,

$$\lim_{|x|\to\infty,h\to 0,xh=\hbar}\left(x\frac{\partial}{\partial x}\right)^n \widetilde{f}(C;x,h)=\left(\hbar\frac{d}{d\hbar}\right)^n JJ(C;\hbar). \tag{12}$$

III. THE BF THEORY WITH A COSMOLOGICAL TERM

From the field-theoretical point of view, the colored Jones function is defined as the knot invariant obtained from the v.e.v. of a suitable observable, the Wilson loop, in the Chern–Simons theory[9] (actually, the general case of a compact simple Lie group is discussed there).

For the aims of this paper, however, it is more convenient to consider the formulation given in terms of the BF theory with a cosmological term, which is equivalent[3,14] to the previous one.

We will consider here only the case of a single knot C imbedded in S^3 and study its invariants associated to the group SU(2); viz., we consider the SU(2)-principal bundle $P\to S^3$, and define the action

$$\widetilde{S_{\mathrm{BF}}}(\kappa)=\frac{1}{2\pi}\int_{S^3}\mathrm{Tr}\left(B\wedge F+\frac{\kappa^2}{3}B\wedge B\wedge B\right), \tag{13}$$

where F is the curvature two-form of the connection A, B is a form in $\Omega^1(S^3,\mathrm{ad}\,P)$, and the parameter κ is called the *cosmological constant* (this name comes from the quantum-gravity interpretation of (13)[4]).

Then, given a knot C and a base point $x_0\in C$, we consider the observable

$$\Gamma(C,x_0;\kappa):=\mathrm{Hol}_{x_0}(A+\kappa B;C)=\sum_{n=0}^{\infty}\kappa^n\gamma_n(C,x_0), \tag{14}$$

where κ is the same cosmological constant as in (13), $\mathrm{Hol}_{x_0}(A+\kappa B;C)$ denotes the holonomy of the connection $A+\kappa B$ along the knot C with base point x_0, and the γs are functionals of A and B obtained by Taylor expanding the previous holonomy.

Notice that the holonomy of a connection A along a curve C, open or closed, can be written as

$$\mathrm{Hol}(A;C)=P\,\exp\left(\int_C A\right), \tag{15}$$

where P denotes path ordering. Thus, by (14) and (15), the γs turn out to be[3,14] iterated Chen integrals of the form

$$\gamma_n(C,x_0):=\oint_{(C;x_0)}\underbrace{\hat{B}\cdots\hat{B}}_{n\text{ times}}\mathrm{Hol}_{x_0}(A;C), \tag{16}$$

where the iterated integral $\int_a^b\omega_1\cdots\omega_2\cdots\omega_n$ of n one-forms $\{\omega_i\}_{i=1,\ldots,n}$ is given by the formula $\int_{a<x_1<\cdots<x_n<b}\omega_1(x_1)\wedge\omega_2(x_2)\wedge\cdots\wedge\omega_n(x_n)$. The su(2)-valued one-form $\hat{B}$ is defined as

$$\hat{B}(x):=\mathrm{Hol}_{x_0}^{x}B(x)[\mathrm{Hol}_{x_0}^{x}]^{-1}, \tag{17}$$

with the holonomies computed along the portions of the knot C going from the base point x_0 to the running points x.

The observable Γ in (14) is invariant under a gauge transformation of the connection $A-\kappa B$, while, under the gauge transformation

$$A+\kappa B\to g(A+\kappa B)g^{-1}+gdg^{-1}, \tag{18}$$

one has

$$\Gamma(C,x_0;\kappa)\to g(x_0)\Gamma(C,x_0;\kappa)g(x_0)^{-1}. \tag{19}$$

Thus, taking the trace of Γ gives a gauge invariant observable that is, moreover, independent of x_0. The knot invariant given by the v.e.v. of this observable, wrt the (normalized) Gibbs weight $\exp[iS_{\mathrm{BF}}(\kappa)]$, can be recognized by exploiting the relation with the Chern–Simons theory,[3] viz.,

$$J_d(C;h)=\langle \mathrm{Tr}_{(d-1)/2}\Gamma(C,x_0;\kappa)\rangle_{\mathrm{BF},\kappa}, \quad h=4\pi i\kappa, \tag{20}$$

where Tr_s is the trace in the irreducible representation of spin s. In this framework, (2) is an immediate consequence of (A8).

Notice, eventually, that the observable Γ can be decomposed into its even (Γ_0) and odd ($\kappa\Gamma_1$) parts,

$$\Gamma(C,x_0;\kappa)=\Gamma_0(C,x_0;\kappa)+\kappa\Gamma_1(C,x_0;\kappa), \tag{21}$$

and that both of them are good observables for the BF theory with a cosmological term.[14]

A. The BF-theory generating function

The behavior (19) of the observable Γ under a gauge transformation of the connection $A+\kappa B$ shows that all of the traces of powers of Γ are gauge invariant; so we can consider the knot invariants given by their v.e.v.s, or as will be clear in Sec. V, their generating function,

$$E(C;x,h)=\sum_{n=0}^{\infty}\frac{x^n}{n!}\langle \mathrm{Tr}_{1/2}\Gamma(C,x_0;\kappa)^n\rangle_{\mathrm{BF},\kappa}=\langle \mathrm{Tr}_{1/2}\exp[x\Gamma(C,x_0;\kappa)]\rangle_{\mathrm{BF},\kappa},$$

$$h=4\pi i\kappa, \tag{22}$$

with $x\in\mathbb{C}$. We consider only the fundamental representation here, for the discussion in Appendix A shows that considering any other representation does not give further content of information. Notice that the rightmost term in (22) is only formal since no addition is defined in the group. However, this notation usefully reminds us that E has the formal properties of an exponential. Notice that, since Γ is a holonomy, one has

$$\Gamma(C,x_0;\kappa)^n=\Gamma(nC,x_0;\kappa), \tag{23}$$

where by nC we denote the nth cabling of the knot C; thus, $E(C;x,h)$ is the *generating function for cabled knot invariants*. In the framework of the Chern–Simons theory, Γ is replaced by the holonomy of the connection A; thus, E can also be seen as the v.e.v. of *the generating function for cabled Wilson loops*.

By using the formulas in Appendix A, one can show that there is a simple relation with the generating function for colored Jones functions defined in (6). Actually by (A6), one can express $\mathrm{Tr}_{1/2}\Gamma^n$ in terms of the traces of Γ in the representations of spin $n/2$ and $n/2-1$. By (20), it then follows that

$$E(C;x,h)=\sum_{n=0}^{\infty}\frac{x^n}{n!}[J_{n+1}(C;h)-J_{n-1}(C;h)], \tag{24}$$

where, according to (A8), $J_1=1$, $J_0=0$, $J_{-1}=-1$.

By (6) and (24), and also noting that $E(C;0,h)=2$ and $\partial_x f(C;0,h)=J_1(C;h)=1$, one obtains

$$E(C;x,h)=1+\partial_x f(C;x,h)-\int_0^x d\xi\, f(C;\xi,h). \tag{25}$$

IV. THE PURE BF THEORY

The BF theory has the nice property that its limit for vanishing cosmological constant (corresponding to the $k\to\infty$ limit in the Chern–Simons theory) is still represented by a TQFT known as pure BF theory,[2,15] whose action reads

$$S_{\mathrm{BF}}=\frac{1}{2\pi}\int_{S^3}\mathrm{Tr}(B\wedge F). \tag{26}$$

It is immediately seen that S_{BF} is invariant under gauge transformations

$$A\to gAg^{-1}+gdg^{-1},\quad B\to gBg^{-1}, \tag{27}$$

as well as under B-transformations

$$A\to A,\quad B\to B+d_A\psi. \tag{28}$$

Here g is a map from S^3 to the group, while ψ is a form in $\Omega^0(S^3,\mathrm{ad}\,P)$. The action (26) is invariant under (28) owing to the Bianchi identity.

The good observables for the pure BF theory are of course obtained by $\Gamma_0(C,x_0;\kappa)$ and $\Gamma_1(C,x_0;\kappa)$, defined in (21), in the limit $\kappa\to 0$, and are simply given by $\gamma_0(C,x_0)$ and $\gamma_1(C,x_0)$ in (16); viz.,

$$\begin{aligned}\gamma_0(C,x_0)&=\mathrm{Hol}_{x_0}(A;C),\\ \gamma_1(C,x_0)&=\oint_{x\in(C,x_0)}\mathrm{Hol}_{x_0}^{x}B(x)\mathrm{Hol}_{x}^{x_0}.\end{aligned} \tag{29}$$

Under (27) and (28), they transform as

$$\gamma_i(C,x_0)\to g(x_0)\,\gamma_i(C,x_0)g(x_0)^{-1},\quad i=0,1, \tag{30}$$

provided we fix $\psi(x_0)=0$, which can always be done.[1]

Thus, we are led to consider the v.e.v.s of $\mathrm{Tr}_d\,\gamma_0$ and $\mathrm{Tr}_d\,\gamma_1$. They, however, are rather trivial, for they correspond, respectively, to $J_d(C;0)=d$ and $(d/dh)J_d(C;0)=0$.

From a field-theoretical point of view, the reason of this triviality is the following: In perturbative BF theory (on S^3), nonvanishing v.e.v.s contain a number n_A of fields A not exceeding the number n_B of fields B.[1] Therefore, after expanding the holonomies in (29) in powers of A, one sees that only the zeroth-order term $\mathrm{Tr}_{(d-1)/2}I=d$ (where I is the group identity) survives in the v.e.v. of $\mathrm{Tr}_{(d-1)/2}\gamma_0$; while, in the v.e.v. of $\mathrm{Tr}_{(d-1)/2}\gamma_1$, only the first-order term does [the zeroth-order term vanishing because it is the trace of an element of su(2)]. However, the latter v.e.v. (of the form $\langle\oint_C A\oint_C B\rangle_{\mathrm{BF},0}$) gives the self-linking number of the knot C that, by the hypothesis of standard framing, is zero. (If one uses a more general framing, the self-linking number is the only information one gets from these v.e.v.s.)

This is the reason why in Ref. 1 one looked for composite observables that contain a higher number n_B of fields B, and are invariant under (27) and (28). In particular, the generating function of the v.e.v.s of $\mathrm{Tr}_{(d-1)/2}(\gamma_1)^n$ was taken into account,

$$W_d(C;\lambda):=\sum_{n=0}^{\infty}\frac{\lambda^n}{n!}\langle \mathrm{Tr}_{(d-1)/2}\gamma_1(C,x_0)^n\rangle_{\mathrm{BF},0}=\langle \mathrm{Tr}_{(d-1)/2}\exp[\lambda\gamma_1(C,x_0)]\rangle_{\mathrm{BF},0}, \tag{31}$$

with $\lambda\in\mathbb{C}$. Again, as in (22), the rightmost term is only formal.

In Sec. V, we shall need (31) to study the limit $\kappa\to 0$ in (22), to which (31) is apparently related. However, there is a second, perhaps more natural, generating function to be considered, viz.,

$$\widetilde{W}_d(C;\lambda):=\langle \mathrm{Tr}_{(d-1)/2}\exp[\lambda\beta(C,x_0)]\rangle_{\mathrm{BF},0}, \tag{32}$$

where

$$\beta(C,x_0):=\gamma_1(C,x_0)\cdot\gamma_0(C,x_0)^{-1}=\oint_{C,x_0}\hat{B}\in\mathrm{su}(2). \tag{33}$$

Notice that the exponential in (32) is not formal, but it actually represents the exponential map from the algebra to the group.

The generating function $\widetilde{W}$ is particularly useful because it allows us to understand the meaning of the knot invariants related to higher-dimensional representations; indeed, by using (A7), one can easily prove that

$$\widetilde{W}_{2k}(C;\lambda)=\sum_{l=1}^{k}\widetilde{W}_2(C;(2l-1)\lambda), \tag{34}$$

$$\widetilde{W}_{2k+1}(C;\lambda)=1+\sum_{l=1}^{k}\widetilde{W}_2(C;2l\lambda). \tag{35}$$

Then, a formal resummation of the geometric sums appearing in (34) and (35) gives

$$\widetilde{W}_d(C;\lambda)=\begin{cases}\left\langle \mathrm{Tr}_{1/2}\dfrac{\exp[(d+1)\lambda\beta(C,x_0)]-1}{\exp[2\lambda\beta(C,x_0)]-1}\right\rangle_{\mathrm{BF},0} & \text{if } d \text{ is even,}\\ \left\langle \mathrm{Tr}_{1/2}\dfrac{\exp[(d+1)\lambda\beta(C,x_0)]-1}{\exp[2\lambda\beta(C,x_0)]-1}\right\rangle_{\mathrm{BF},0}+1 & \text{if } d \text{ is odd.}\end{cases} \tag{36}$$

These formulas show that the limit

$$\widetilde{WW}(C;\mu):=\lim_{d\to\infty,\lambda\to 0,d\lambda=\mu}\frac{\widetilde{W}_d(C;\lambda)}{d} \tag{37}$$

is well defined, and that

$$\widetilde{WW}(C;\mu)=\left\langle \mathrm{Tr}_{1/2}\frac{\exp[\mu\beta(C,x_0)]-1}{2\mu\beta(C,x_0)}\right\rangle_{\mathrm{BF},0}=\sum_{n=0}^{\infty}\frac{1}{2(n+1)!}\langle \mathrm{Tr}_{1/2}[\mu\beta(C,x_0)]^n\rangle_{\mathrm{BF},0}. \tag{38}$$

Thus, by (32) and (38), we obtain

$$\widetilde{W}_2(C;\lambda)=2\frac{d}{d\lambda}[\lambda\widetilde{WW}(C;\lambda)], \tag{39}$$

or equivalently,

$$\widetilde{WW}(C;\mu)=\frac{1}{\mu}\int_0^{\mu/2} dx\ \widetilde{W}_2(C;2x). \tag{40}$$

Notice that (34) and (35) are actually discretizations of the Riemann integral in (40) with $x=l\lambda$.

A more rigorous proof of the above results can be obtained by expanding $\widetilde{W}_2$ in powers of λ and using (34) and (35) to get the corresponding expansion of $\widetilde{W}_d$. Then one can use the asymptotic formula

$$\sum_{l=1}^{k} l^n \overset{k\to\infty}{\sim} \frac{k^{n+1}}{n+1}$$

to get the rightmost term in (38).

So far we have considered two different generating functions, viz., (31) and (32): in general, however, there are even more choices. Indeed, because of (30), a product of powers of γ_0 and γ_1 (in any order) is still an observable whose trace is invariant under (27) and (28).

To get rid of this arbitrariness in the definition of the generating function, we need the following.

Theorem 1: In pure BF theory, the knot invariant obtained by the v.e.v. of the trace of a function of $\gamma_0(C,x_0)$ and $\gamma_1(C,x_0)$ is equal to the knot invariant obtained by replacing $\gamma_0(C,x_0)$ with the identity of the group, *provided the standard framing is chosen.*

In Ref. 14, a proof of the theorem based on an explicit study of the Feynman integrals appearing in the evaluations of the v.e.v.s was given. Here, however, we give a simpler argument, based on the formal properties of the pure BF theory.

First of all we recall that, in the explicit evaluation of the v.e.v.s in BF theory, the choice of framing is done by evaluating all the holonomies in (29) on a companion knot C' obtained by C in terms of a "small," nonvanishing normal displacement.[1] Notice that the self-linking number of C is then, by definition, the linking number of C and C'.

The proof of the theorem, then, essentially relies on the fact that, if this linking number vanishes (standard framing), one can deform C' in γ_0 in such a way that it can be completely unlinked from C and, as such, shrunk to a point; so its holonomy, γ_0, becomes the identity.

This is possible since a knot C' appearing in γ_0 (not necessarily a framing for C) "does not see itself." In fact, a small deformation of the knot C' at a certain point x amounts to introducing curvature terms in x (remember that γ_0 is a holonomy). However, in pure BF theory, the curvature vanishes everywhere but on the knot C, along which γ_1 is evaluated. (We refer to Ref. 1 for the proof that, in an observable, A acts as a source for $d_A B$, while B acts as a source for the curvature F.) Therefore, C' can be deformed freely as far as this deformation does not intersect C; self-intersections of C' are allowed, however.

When such a self-intersection occurs, one can split C' into two closed curves C'_1 and C'_2; correspondingly, the holonomy $\gamma_0(C')$ can be written as $\gamma_0(C'_1)\cdot\gamma_0(C'_2)$,

To prove the theorem, one just has to repeat this procedure until C' is replaced by a collection of circles C'_1, all of which surround one single strand of C. Then one moves the C'_1s along C, and cuts and splices them together again to form a circle C''.

Since all these deformations do not affect the linking between C and C', the linking number of C and C'' is the same as the linking number of C and C'. If this linking number vanishes (standard framing), then the circle C'' and the knot C are unlinked, and C'' can be shrunk to a point. This concludes the proof of Theorem 1.

As a consequence of Theorem 1, we have the following.

Corollary 1: $W_d(C;\lambda)$ is the most general v.e.v. one can consider in pure BF theory if the standard framing is chosen.

Moreover, we can freely switch from W_d in (31) and $\widetilde{W}_d$ in (32). Thus, by (34) and (35), the higher-representation knot invariants W_d can be related to the fundamental-representation knot invariant W_2; besides, the limit

$$WW(C;\mu):=\lim_{d\to\infty,\lambda\to 0,d\lambda=\mu}\frac{W_d(C;\lambda)}{d}, \tag{41}$$

is well defined and, by (39),

$$W_2(C;\lambda)=2\frac{d}{d\lambda}[\lambda WW(C;\lambda)]. \tag{42}$$

We conclude this section with an important remark. Pure BF theory is known to be exact in saddle-point approximation[16] as far as the partition function is concerned. This result is a simple consequence of the fact that one can arbitrarily change the "Planck constant" in front of the action by simply rescaling the field B. Since the partition function (or the v.e.v. of an observable not containing B) is not affected by this rescaling, one can send the Planck constant to zero.

This, of course, cannot be done when one computes the v.e.v. of an observable containing B, as in (31) or (32). In this case one sees that the parameter λ actually plays the role of the Planck constant, and, of course, W_d is not independent of λ.

Notice, however, that WW corresponds to the limit $\lambda\to 0$, so it should be possible to compute it by using the saddle-point approximation. Then, by (42), it is possible to recover W_2—and hence, by (34) and (35), all the W_d's—from WW.

Thus, even if pure BF theory with B-dependent observables is *not* exact in saddle-point approximation, the saddle-point approximation turns out to be all that one needs.

V. TURNING OFF THE COSMOLOGICAL CONSTANT

In this section we want to show that, in the limit of vanishing cosmological constant, the BF-theory generating function (22) is related to both the pure-BF-theory generating function (31) and the Melvin–Morton function (4).

To establish the former relation, we first observe that, in order for the significant observable γ_1 to survive in the limit $\kappa\to 0$, we have to send $|x|\to\infty$ at the same time with the prescription that $x\kappa=\lambda$ be finite. If we work with the standard framing, by Theorem 1 the observable γ_0 can be replaced by the identity of the group; so (22) diverges as e^x; thus, we are led to consider

$$\widetilde{E}(C;x,h):=e^{-x}E(C;x,h). \tag{43}$$

By using the exponential representation of (22), we can write

$$\widetilde{E}(C;x,h)=\langle \mathrm{Tr}_{1/2}\exp\{x[\kappa\gamma_1(C,x_0)+O(\kappa^2)]\}\rangle_{\mathrm{BF},\kappa}$$

and get

$$\lim_{|x|\to\infty,h\to 0,xh=\hbar}\widetilde{E}(C;x,h)=W_2(C;\lambda),\quad \hbar=4\pi i\lambda. \tag{44}$$

In Appendix C, we give a more careful proof of (44).

Notice that the limit in (44) holds irrespectively of how x is sent to infinity in the complex plane. Therefore, if one sees $\widetilde{E}$ as a meromorphic function of x and $\hbar$, this implies that the regular part in x of $\widetilde{E}$ vanishes. Thus, $\widetilde{E}$, now rewritten in terms of x and h, does not contain more powers of x than of h. In other words, if $\widetilde{E}$ is expanded as a rational power series,

$$\tilde{E}(C;x,h)=\sum_{l,m=0}^{\infty}\epsilon_{lm}(C)x^l h^m, \tag{45}$$

then $\epsilon_{\cdot\cdot}$ is an upper triangular matrix,

$$\epsilon_{jm}(C)=0, \quad \text{if } j>m. \tag{46}$$

The relation between the BF-theory generating function and the Melvin–Morton function is obtained by exploiting (25) (see Appendix D for details). We arrive to the following conclusions:

$$\epsilon_{\cdot\cdot} \text{ uppper triangular} \Leftrightarrow b_{\cdot\cdot} \text{ upper triangular}, \tag{47}$$

and

$$\epsilon_{nn}(C)=2(1+n)b_{nn}(C), \tag{48}$$

where $\epsilon_{\cdot\cdot}$ and $b_{\cdot\cdot}$ are defined, respectively, in (45) and (1). Notice that (47) and (46) give a new proof of (3).

Since E is related to W_2 and to JJ in the same limit $\kappa\to 0$, we deduce that a relation exists between W_2 and JJ. Actually, by (1), (44), (45), and (48), we obtain

$$W_2(C;\lambda)=2\frac{d}{d\hbar}[\hbar JJ(C;\hbar)], \quad \hbar=4\pi i\lambda. \tag{49}$$

In order to recognize the knot invariant given by W_2, we can now resort to (5) and obtain

$$W_2(C;\lambda)=2\left[1+\left(\frac{z}{2}\right)^2\right]^{1/2}\frac{d}{dz}\frac{z}{\Delta(C;z)}, \quad z=2i\,\sin(2\pi\lambda), \tag{50}$$

and, in particular,

$$W_2(\bigcirc;\lambda)=2\left[1+\left(\frac{z}{2}\right)^2\right]^{1/2}, \quad z=2i\,\sin(2\pi\lambda), \tag{51}$$

where $\bigcirc$ is the unknot and we have chosen the normalization $\Delta(\bigcirc;z)=1$ (cfr. Sec. II). Thus, the normalized knot invariant

$$\langle C\rangle_2(\lambda):=\frac{W_2(C;\lambda)}{W_2(\bigcirc;\lambda)}, \tag{52}$$

defined in Ref. 1, satisfies

$$\langle C\rangle_2(\lambda)=\frac{d}{dz}\frac{z}{\Delta(C;z)}, \quad z=2i\,\sin(2\pi\lambda). \tag{53}$$

In conclusion, we have shown that W_2 is related to the first derivative of the inverse of the Alexander–Conway polynomial. By (34) and (35), W_d is given by a finite sum of W_2s, evaluated at different λs. Concerning the limit $d\to\infty$, we see that (42) and (49), together with the property $WW(C;0)=JJ(C;0)=1$, imply

$$WW(C;\lambda)=JJ(C;\hbar), \quad \hbar=4\pi i\lambda, \tag{54}$$

or, because of (5),

$$4\pi i\lambda WW(C;\lambda)=\frac{z}{\Delta(C;z)},\quad z=2i\,\sin(2\pi\lambda). \tag{55}$$

The above results, together with Corollary 1, prove the following.

Theorem 2: The set of the unframed knot invariants that can be obtained from the SU(2)-BF theory coincides with the set of the coefficients of (the inverse of) the Alexander–Conway polynomial.

In Ref. 1, the authors conjectured a relation between the Alexander–Conway polynomials and the pure BF theory based on second-order calculations in the perturbative expansion. Theorem 2 supersedes this conjecture and provides the correct relation.

VI. THE PERTURBATIVE EXPANSION OF W_d

In this section we want to compare the results we have proved in Sec. V with those obtained in Ref. 1 in the framework of "perturbative" BF theory.

By "perturbative" evaluation of (31), one means an expansion of $W_d(C;\lambda)$ (or of its generalization $W_{G,R}(C;\lambda)$, where G is a compact group and R a representation) in powers of λ,

$$W_{G,R}(C;\lambda)=\sum_{n=0}^{\infty} w_n(G,R;C)\lambda^n, \tag{56}$$

where the knot invariants $w_n(G,R;C)$ (actually, they are Vassiliev invariants[17]) are computed in terms of Feynman integrals.

The first property of the expansion (56) shown in Ref. 1 is that, owing to a symmetry of the corresponding Feynman integrals, odd-order terms vanish,

$$w_{2n+1}(G,R;C)=0. \tag{57}$$

Thus, W is an even function:

$$W_{G,R}(C;-\lambda)=W_{G,R}(C;\lambda). \tag{58}$$

In the case $G=\mathrm{SU}(2)$, by using (50), (34), and (35), we see that (58) is in accordance with the fact that the Alexander-Conway polynomial $\Delta(C;z)$—for a single knot C—is an even function of z.

A further computation done in Ref. 1, for the case $G=\mathrm{SU}(N)$, showed that, up to the second order, (56) reads

$$W_{G,R}(C;\lambda)=\dim R[1+(4\pi\lambda)^2c_2(R)c_v\rho(C)+O(\lambda^4)]. \tag{59}$$

where

(i) $\dim R$ and $c_2(R)$ are, respectively, the dimension and the quadratic Casimir of the representation R;
(ii) $c_v=N$ is the quadratic Casimir of the adjoint representation; and
(iii) $\rho(C)$ is the knot invariant studied in Refs. 18 and 19 in the framework of the Chern–Simons theory.

In Refs. 18 and 19, $\rho(C)$ was proved to be related to the second coefficient of the Alexander–Conway polynomial; viz., if one writes

$$\Delta(C;z)=\sum_{n=0}^{\infty} a_n(C)z^n,\quad a_0(C)=1,\quad a_1(C)=0 \tag{60}$$

(where only a finite number of coefficients are nonvanishing), then

$$\rho(C)=2a_2(C)+\rho(\bigcirc). \tag{61}$$

Moreover, a direct computation[18] shows that

$$\rho(\bigcirc)=-\tfrac{1}{12}. \tag{62}$$

Thus, one can write (59) as

$$W_{G,R}(C;\lambda)=\dim R\left[1+(4\pi\lambda)^2 2c_2(R)c_v\left(a_2(C)-\frac{1}{24}\right)+O(\lambda^4)\right]. \tag{63}$$

If we now expand (50) as

$$W_2(C;\lambda)=2[1+\tfrac{1}{8}z^2+O(z^4)][1-3a_2(C)z^2+O(z^4)]=2[1+3z^2(\tfrac{1}{24}-a_2(C))+O(z^4)],$$

$$z=4\pi i\lambda+O(\lambda^2),$$

we get a complete agreement with (63) in the case where $G=\mathrm{SU}(2)$ and the fundamental representation, R_2, is chosen; for, in this case, $c_v=2$ and $c_2(R_2)=\frac{3}{4}$.

We can also compare the second-order expansion of (34) and (35) with (63) in the case where $G=\mathrm{SU}(2)$ and R_d is the irreducible representation of dimension d. This is done by noticing that one can compute the sums appearing in (34) and (35) as

$$\sum_{l=1}^{k}(2l-1)^2=\frac{1}{3}k(4k^2-1), \quad \sum_{l=1}^{k}l^2=\frac{2}{3}k(k+1)(2k+1).$$

Thus, one achieves complete agreement with (63) since

$$c_2(R_{2k})=\frac{(2k-1)(2k+1)}{4}, \tag{64}$$

$$c_2(R_{2k+1})=k(k+1). \tag{65}$$

By using (34) and (35), it is possible to see that—in agreement with the perturbative result of Ref. 1—the coefficients w_n in (56) are given by the product of a function depending only on the representation and a function depending only on the knot, viz.,

$$w_{2n}(\mathrm{SU}(2),R_d;C)=dg_{2n}(d)v_{2n}(C). \tag{66}$$

If we normalize $g_{2n}(2)=\frac{1}{2}$, then, by (34) and (35), we get an explicit formula for the gs:

$$g_{2n}(2k)=\frac{1}{2k}\sum_{l=1}^{k}(2l-1)^{2n}, \tag{67}$$

$$g_{2n}(2k+1)=\frac{1}{2k+1}\sum_{l=1}^{k}(2l)^{2n}. \tag{68}$$

By (64) and (65), we can also express the gs in terms of the quadratic Casimirs:

$$g_0=\tfrac{1}{2},\quad g_2=\tfrac{1}{3}c_2c_v,$$

$$g_4=\tfrac{1}{15}[6(c_2c_v)^2-c_2c_v^3],\quad g_6=\tfrac{1}{21}[12(c_2c_v)^3-6c_2^2c_v^4+c_2c_v^5], \tag{69}$$

$$\dots.$$

In general, the highest power of c_2 in g_{2n} is n.

In Ref. 1, it was conjectured that the *only* group factor to appear in g_{2n} was $(c_2c_v)^n$. From this conjecture, together with some field-theoretical arguments, it was concluded that, for some t,

$$\frac{W_{G,R}(C,\lambda)}{W_{G,R}(\bigcirc,\lambda)}=[\Delta(C;z)]^t,\quad z\propto\sqrt{c_2(R)c_v}\lambda+O(\lambda^3). \tag{70}$$

By (69), we see that the conjecture is wrong; by (49), we see that so is the conclusion (70).

It is, however, interesting to show that, if we retain only the terms $(c_2c_v)^n$ in (69), then the corresponding knot invariant is actually the (-1)-power of the Alexander–Conway polynomial. More precisely, we define the "truncated" coefficients

$$g_{2n}^{(\mathrm{tr})}(d)=[c_2(R_d)c_v]^n\gamma_{2n} \tag{71}$$

as the coefficients obtained by neglecting lower powers of $c_2(R_d)$ in (69), and the "truncated" knot invariant as

$$W_d^{(\mathrm{tr})}(C;\lambda):=\sum_{n=0}^{\infty} d\,g_{2n}^{(\mathrm{tr})}(d)v_{2n}(C)\lambda^{2n}. \tag{72}$$

Since $c_v=2$ and $c_2(R_d)\sim d^2/4$ as $d\to\infty$, the truncated coefficients $g_{2n}^{(\mathrm{tr})}(d)$ are the leading terms of the true coefficients $g_{2n}(d)$; thus, by (41) and (71),

$$WW(C;\lambda)=\sum_{n=0}^{\infty}\frac{\gamma_{2n}}{2^n}v_{2n}(C)\lambda^{2n}. \tag{73}$$

By comparing (73) with (72), we eventually get

$$W_d^{(\mathrm{tr})}(C;\lambda)=dWW(C;\sqrt{2c_2(R_d)c_v}\lambda); \tag{74}$$

thus, by (55), we see that

$$\frac{W_d^{(\mathrm{tr})}(C;\lambda)}{W_d^{(\mathrm{tr})}(\bigcirc;\lambda)}=\frac{1}{\Delta(C;z)},\quad z=2i\,\sin(2\pi\sqrt{2c_2(R_d)c_v}\lambda). \tag{75}$$

Thus, if the truncated knot invariants are used, (70) holds.

VII. CONCLUSIONS

In this paper we have discussed the unframed knot invariants coming from BF theories. Even if most of our results hold only for SU(2), we point out that Theorem 1 and Corollary 1, as well as the computation in Appendix C (with a slight abuse of notation), hold in general.

It would be interesting to generalize some of the other results to different groups and to consider links as well. However, the present case, i.e., knot observables in the theory based on SU(2), seems to be interesting enough to deserve further investigation.

Indeed, as we have noticed at the end of Sec. IV, it turns out that a saddle-point computation is enough to completely describe the pure BF theory. We defer to a forthcoming paper the related functional-integral computation.

Notice that this property of pure BF theory sets it at the boundary between TQFTs of Witten's and Schwarz's type: The former are twisted supersymmetric gauge theories (see, e.g., Ref. 20), whose main property—an effect of the twisted supersymmetry—is their independence of both the metric and the coupling constant, which makes them topological as well as exact in saddle-point approximation. The latter are topological gauge theories, as the Chern—Simons or the BF theories, whose dependence on the coupling constant is unavoidable. The pure BF theory formally belongs to the latter type, but, as the theories of the former type, is completely determined by its weak-coupling limit.

Moreover, as we have proved in Sec. V, the pure BF theory corresponds to the first diagonal in the (h,d) expansion of the colored Jones function. A description of the upper diagonals is still missing (see Ref. 21 for a first attempt); so it is natural to look for generalizations of the pure BF theory, i.e., for further variations of the Chern–Simons theory, that could correspond to these upper diagonals and, possibly, give them a better understanding (see Ref. 13 for a different approach). We are investigating along these lines.

ACKNOWLEDGMENTS

I thank A. Jaffe, T. Kerler, A. Leśniewski, M. Martellini, and M. Rinaldi for helpful conversations. I am especially thankful to P. Cotta-Ramusino for a number of very useful discussions and for constant advice.

APPENDIX A: SOME USEFUL IDENTITIES FOR THE CHARACTERS OF SU(2)

In this section we recall some properties of the group SU(2) that are necessary for this paper. In particular, we are interested in an identity relating $\mathrm{Tr}_{1/2}\, g^n$ to the traces of g in other representations, or, in other words, we want to give $\mathrm{Tr}_{1/2}\, g^n$ an expression in primitive characters,

$$\mathrm{Tr}_{1/2} g^n = \sum_{k=0}^{\infty} \phi_{nk} \chi_{k/2}(g), \tag{A1}$$

where

$$\chi_s(g) := \mathrm{Tr}_s g, \quad 2s \in \mathbf{Z}. \tag{A2}$$

Owing to the Peter–Weil Theorem, this can be done since $\mathrm{Tr}_{1/2}\, g^n$ depends only on the conjugacy class of g and belongs to $L^2(\mathrm{SU}(2),\mathbf{C})$. By a conjugacy transformation, one can always write g as

$$g = h e^{i\alpha R_3} h^{\dagger}, \tag{A3}$$

where R_3 is the (Hermitean) generator of the Cartan subalgebra. Noticing that the spectrum of R_3 in the representation of spin l is given by $\{-2l,-2(l-1),\ldots,2(l-1),2l\}$, one obtains

$$\mathrm{Tr}_{1/2} g^n = e^{in\alpha} + e^{-in\alpha}, \tag{A4}$$

and

$$\mathrm{Tr}_l\, g = e^{2il\alpha} + e^{2i(l-1)\alpha} + \cdots + e^{-2il\alpha} = \sum_{m=-l}^{l} e^{2im\alpha}, \tag{A5}$$

where the last sum is meant to be over integers or half-integers according to the fact that l is integer or half-integer. By (A4) and (A5), it immediately follows that, for $n \geqslant 2$,

$$\mathrm{Tr}_{1/2}\, g^n = \mathrm{Tr}_{n/2} g - \mathrm{Tr}_{n/2-1} g, \quad n \in \mathbf{Z}. \tag{A6}$$

By induction one can also prove that

$$\mathrm{Tr}_s\, g = \begin{cases} \sum_{l=1}^{s+1/2} \mathrm{Tr}_{1/2} g^{2l-1} & \text{if } s \text{ is half-integer,} \\ 1 + \sum_{l=1}^{s} \mathrm{Tr}_{1/2}\, g^{2l} & \text{if } s \text{ is integer.} \end{cases} \tag{A7}$$

Moreover, by (A7) and by the fact that

$$\mathrm{Tr}_{1/2} \exp(i\mathbf{a}\cdot\mathbf{R}) = 2\cos a,$$

with $\mathbf{a} \in \mathbb{R}^3$ and $\mathbf{R} = (R^1, R^2, R^3)$ the Pauli matrices, one also obtains

$$\mathrm{Tr}_s \exp(i\mathbf{a}\cdot\mathbf{R}) = \frac{\sin(da)}{\sin(a)}, \tag{A8}$$

where $d = 2s+1$ is the dimension of the representation of spin s.

Since, for a given g, $\mathrm{Tr}_{n/2} g$ is a map defined on the positive integers, its analytic continuation over the whole complex plane is uniquely defined and is actually given by (A8).

APPENDIX B: PROPERTIES OF THE GENERATING FUNCTION FOR COLORED JONES FUNCTIONS

In this section we explore the properties of the generating function for colored Jones functions defined in (6). By (1), we can write

$$f(C;x,h) = \sum_{d=1}^{\infty} \frac{x^d}{d!}\, d \sum_{j,m=0}^{\infty} b_{jm}(C)(d-1)^j h^m = x \sum_{j,m=0}^{\infty} B_j(x) b_{jm}(C) h^m, \tag{B1}$$

where

$$B_j(x) = \sum_{d=0}^{\infty} \frac{x^d}{d!}\, d^j = \left(\frac{\partial^j}{\partial \alpha^j}\right)\Bigg|_{\alpha=\log x} \sum_{d=0}^{\infty} \frac{e^{\alpha d}}{d!} = \left(\frac{\partial^j}{\partial \alpha^j}\right)\Bigg|_{\alpha=\log x} \exp(e^{\alpha}). \tag{B2}$$

By repeatedly applying Leibniz's rule, we obtain

$$B_j(x) = e^x P_j(x) = e^x [x^j + O(x^{j-1})], \tag{B3}$$

where $P_j(x)$ is a polynomial of degree j starting with x^j, viz.,

$$P_j(x) = \sum_{l=0}^{j} x^l c_{lj}, \quad c_{jj} = 1. \tag{B4}$$

Notice that (B4) implies that $c_{..}$ is an upper triangular matrix:

$$c_{lj}(C) = 0, \quad \text{if } l > j. \tag{B5}$$

The coefficients c_{lj} can easily be computed if we consider the following generating function,

$$B(\rho,x):=\sum_{j=0}^{\infty}\frac{\rho^j}{j!}B_j(x), \tag{B6}$$

which, by (B2), can be written as

$$B(\rho,x)=\exp e^{(\alpha+\rho)}|_{\alpha=\log x}=e^x\exp[x(e^\rho-1)]. \tag{B7}$$

Thus, by (B3), we obtain

$$P(\rho,x):=\sum_{j=0}^{\infty}\frac{\rho^j}{j!}P_j(x)=\sum_{n=0}^{\infty}\frac{x^n}{n!}(e^\rho-1)^n, \tag{B8}$$

while, by (B4), we have

$$P(\rho,x)=\sum_{n,j=0}^{\infty}x^n c_{nj}\frac{\rho^j}{j!}. \tag{B9}$$

By comparing the two different expansions of P in powers of ρ given by (B8) and (B9), we obtain eventually

$$c_{nj}=\frac{(-1)^n}{n!}\sum_{l=0}^{n}\binom{n}{l}(-1)^l l^j, \tag{B10}$$

where, by convention, $0^0=1$.

We want now to compute the coefficients $\tilde{b}_{\cdot\cdot}$ defined in (8). By (7), (B1), and (B3), we can write

$$\tilde{f}(C;x,h)=\sum_{j,m=0}^{\infty}P_j(x)b_{jm}(C)h^m; \tag{B11}$$

so by (8),

$$\tilde{b}_{nm}(C)=\sum_{j=0}^{\infty}c_{nj}b_{jm}(C). \tag{B12}$$

Since the matrices $\tilde{b}_{\cdot\cdot}$ and $b_{\cdot\cdot}$ are related by the matrix $c_{\cdot\cdot}$ that, by (B5), is upper triangular, we conclude that (9) holds. Moreover, if one knows that either $\tilde{b}_{\cdot\cdot}$ or $b_{\cdot\cdot}$ is upper triangular—and by (3) we know that this is true for the latter—then one has

$$\tilde{b}_{mm}(C)=b_{mm}(C). \tag{B13}$$

This implies that, in the limit considered in (11), we can write

$$\tilde{f}(C;x,h)=\sum_{m=0}^{\infty}\tilde{b}_{mm}(C)\hbar^m+O\left(\frac{\hbar}{x}\right)=\sum_{m=0}^{\infty}b_{mm}(C)\hbar^m+O\left(\frac{\hbar}{x}\right);$$

so by (4), (11) holds. In order to prove (12), we only have to notice that the operator $(x\partial/\partial x)^n$, when applied to x^j simply produces a factor j^n; so

$$\left(x\frac{\partial}{\partial x}\right)^n\tilde{f}(C;x,h)=\sum_{m=0}^{\infty}m^n\tilde{b}_{mm}(C)\hbar^m+O\left(\frac{\hbar}{x}\right)=\sum_{m=0}^{\infty}m^n b_{mm}(C)\hbar^m+O\left(\frac{\hbar}{x}\right).$$

By comparison with the effect of the operator $(\hbar d/d\hbar)^n$ on (4), we obtain (12).

APPENDIX C: FROM E TO W_2 AS $\kappa\to 0$

In this section we want to clarify the limit in (44). By (43), (22), and (14), we have

$$\widetilde{E}(C;x,h)=e^{-x}\sum_{n=0}^{\infty}\frac{x^n}{n!}\langle \mathrm{Tr}_{1/2}[\gamma_0(C,x_0)+\kappa\gamma_1(C,x_0)+O(\kappa^2)]^n\rangle_{\mathrm{BF},\kappa}, \tag{C1}$$

where $h=4\pi i\kappa$.

In Refs. 3 and 14, it is shown that, in an observable, the field B represents a source for $F+\kappa^2 B\wedge B$, while the field A is a source only for $d_A B$. Since a variation in the framing (i.e., the companion knot along which we integrate the field A) is still given by inserting a curvature term, we can repeat the steps of the proof of Theorem 1 and show that, if the standard framing is chosen, Γ_0 can be replaced by $I+O(\kappa^2)$, where I is the group identity. As a consequence, (C1) now reads

$$\widetilde{E}(C;x,h)=e^{-x}\sum_{n=0}^{\infty}\frac{x^n}{n!}\langle \mathrm{Tr}_{1/2}[I+\kappa\gamma_1(C,x_0)+O(\kappa^2)]^n\rangle_{\mathrm{BF},\kappa} \tag{C2}$$

By using Newton's binomial formula, one can easily prove that (C2) can also be written as

$$\widetilde{E}(C;x,h)=\sum_{n=0}^{\infty}\frac{x^n}{n!}\langle \mathrm{Tr}_{1/2}[\kappa\gamma_1(C,x_0)-O(\kappa^2)]^n\rangle_{\mathrm{BF},\kappa},$$

or, setting $\lambda=x\kappa$,

$$\widetilde{E}(C;x,h)=\sum_{n=0}^{\infty}\frac{\lambda^n}{n!}\langle \mathrm{Tr}_{1/2}[\gamma_1(C,x_0)+O(\kappa)]^n\rangle_{\mathrm{BF},\kappa}. \tag{C3}$$

Now, sending $\kappa\to 0$, with λ fixed, gives (44).

APPENDIX D: FROM E TO JJ AS $h\to 0$

In this section we consider the relation between the BF-theory generating function E and the Melvin–Morton function as the expansion parameter h is sent to zero.

The starting point is relation (25), which, by (7), can be rewritten in terms of $\widetilde{f}$. Actually, the second term on the rhs of (25) is easily seen to be

$$\partial_x f(C;x,h)=e^x(x+1)\widetilde{f}(C;x,h)+e^x x\partial_x\widetilde{f}(C;x,h), \tag{D1}$$

while the computation of the last term requires more work. First of all, it is useful to introduce the following notation:

$$I_n[g](x)=\int_0^x d\xi\, e^{\xi}g^{(n)}(\xi), \tag{D2}$$

where g is a generic analytic function and $g^{(n)}$ its nth derivative. By integrating by parts, one can prove the recursion rule

$$I_n[g](x)=e^x g^{(n)}(x)-g^{(n)}(0)-I_{n+1}[g](x), \tag{D3}$$

which implies that

$$I_0[g](x)=e^x\sum_{n=0}^{\infty}(-1)^n g^{(n)}(x)-\sum_{n=0}^{\infty}(-1)^n g^{(n)}(0). \tag{D4}$$

Now we set

$$g(x)=x\tilde{f}(C;x,h) \tag{D5}$$

(where C and h are supposed to be fixed), and note that, accordingly,

$$g^{(n)}(x)=n\partial_x^{n-1}\tilde{f}(C;x,h)+x\partial_x^n\tilde{f}(C;x,h). \tag{D6}$$

Then we use (D4) to compute the last term in (25) as

$$\int_0^x d\xi f(C;\xi,h)=e^x[(x-1)\tilde{f}(C;x,h)-x\partial_x\tilde{f}(C;x,h)+R(C;x,h)]+c(C;h), \tag{D7}$$

where

$$R(C;x,h)=\sum_{n=2}^{\infty}(-1)^n[n\partial_x^{n-1}\tilde{f}(C;x,h)+x\partial_x^n\tilde{f}(C;x,h)] \tag{D8}$$

and

$$c(C;h)=\sum_{n=0}^{\infty}(-1)^n(n+1)\partial_x^n\tilde{f}(C;0,h). \tag{D9}$$

Therefore, by (43), (25), (D1), and (D7), we obtain

$$\tilde{E}(C;x,h)=2[\tilde{f}(C;x,h)+x\partial_x\tilde{f}(C;x,h)]+R(C;x,h)+e^{-x}[1-c(C;h)]. \tag{D10}$$

We defer to the end of this section the proof that $c(C;h)=1$, cf. (D23); as a consequence of this fact, (D10) actually reads

$$\tilde{E}(C;x,h)=2[\tilde{f}(C;x,h)+x\partial_x\tilde{f}(C;x,h)]+R(C;x,h). \tag{D11}$$

Now we want to reexpress (D11) as a relation between the coefficients of the power series expansions of $\tilde{E}$ and $\tilde{f}$. Indeed, by (8), the terms in square brackets in (D11) can be written as

$$\sum_{n,l=0}^{\infty}(1+l)\tilde{b}_{lm}(C)x^l h^m,$$

while

$$R(C;x,h)=\sum_{n=2}^{\infty}\sum_{l,m=0}^{\infty}(-1)^n\frac{(n+l)!}{l!}\tilde{b}_{l+n-1,m}(C)x^l h^m. \tag{D12}$$

Therefore, by (45), we get eventually

$$\epsilon_{lm}(C)=\sum_{j=0}^{\infty}n_{lj}\tilde{b}_{jm}(C), \tag{D13}$$

with

$$n_{lj}=2(1-l)\delta_{lj}+\sum_{n=2}^{\infty}(-1)^n\frac{(n+l)!}{l!}\delta_{l+n-1,j} \tag{D14}$$

($\delta_{\cdot\cdot}$ being the Kronecker delta). Since $\eta_{\cdot\cdot}$ is an upper triangular matrix, by (D13) we have that

$$\epsilon_{\cdot\cdot}\text{ upper triangular}\Leftrightarrow\tilde{b}_{\cdot\cdot}\text{ upper triangular.} \tag{D15}$$

Finally, by (9), we conclude that (47) holds. Moreover, (D14) and (B13) imply (48).

We conclude this section by showing that the function $c(C;h)$, defined in (D9), is a constant equal to one.

We start by considering the expansion of c in powers of h. By (8), we obtain

$$c(C;h)=\sum_{n,m=0}^{\infty}(-1)^n(n+1)!\tilde{b}_{nm}(C)h^m=\sum_{j,m=0}^{\infty}D_jb_{jm}(C)h^m, \tag{D16}$$

where, by (B12),

$$D_j=\sum_{n=0}^{\infty}(-1)^n(n+1)!c_{nj}. \tag{D17}$$

Notice that, by (B5), (D17) is actually a finite sum. By (B10), we can also write

$$D_j=\sum_{n=0}^{\infty}\sum_{l=0}^{n}(n+1)\binom{n}{l}(-1)^ll^j. \tag{D18}$$

Let us consider now the generating function

$$D(p):=\sum_{j=0}^{\infty}\frac{p^j}{j!}D_j. \tag{D19}$$

By (D18), it follows that

$$D(\rho)=\sum_{n=0}^{\infty}(n+1)\sum_{l=0}^{n}\binom{n}{l}(-1)^le^{\rho l}=\sum_{n=0}^{\infty}(n+1)(1-e^{\rho})^n=e^{-2\rho}. \tag{D20}$$

By comparing the expansion of D in powers of ρ in (D19) with the expansion of $e^{-2\rho}$, we conclude that

$$D_j=(-2)^j. \tag{D21}$$

Thus, (D16) reads

$$c(C;h)=\sum_{j,m=0}^{\infty}b_{jm}(C)(-2)^jh^m=-J_{-1}(C;h), \tag{D22}$$

where the last identity follows from (1). However, by (2), we have

$$J_{-1}(C;h)=-J_1(C;h)=-1.$$

Therefore, we conclude that

$$c(C;h)=1. \tag{D23}$$

The KZ equation and the quantum-group difference equation in quantum self-dual Yang–Mills theory

Ling-Lie Chau and Itaru Yamanaka
Department of Physics, University of California, Davis, California 95616

(Received 29 September 1995; accepted for publication 15 November 1995)

From the time-independent current $\tilde{\mathcal{J}}(\bar{y},\bar{k})$ in the quantum self-dual Yang–Mills (SDYM) theory, we construct new group-valued quantum fields $\tilde{U}(\bar{y},\bar{k})$ and $\tilde{U}^{-1}(\bar{y},\bar{k})$ which satisfy a set of exchange algebras such that fields of $\tilde{\mathcal{J}}(\bar{y},\bar{k}) \sim \tilde{U}(\bar{y},\bar{k})\partial_{\bar{y}}\tilde{U}^{-1}(\bar{y},\bar{k})$ satisfy the original time-independent current algebra. For the correlation functions of the products of the $\tilde{U}(\bar{y},\bar{k})$ and $\tilde{U}^{-1}(\bar{y},\bar{k})$ fields defined in the invariant state constructed through the current $\tilde{\mathcal{J}}(\bar{y},\bar{k})$ we can derive the Knizhnik–Zamolodchikov (KZ) equations with an additional spatial dependence on $\bar{k}$. From the $\tilde{U}(\bar{y},\bar{k})$ and $\tilde{U}^{-1}(\bar{y},\bar{k})$ fields we construct the quantum-group generators, local, global and semi-local, and their algebraic relations. For the correlation functions of the products of the $\tilde{U}$ and $\tilde{U}^{-1}$ fields defined in the invariant state constructed through the semi-local quantum-group generators we obtain the quantum-group difference equations. We give the explicit solution to the two point function. © *1996 American Institute of Physics.* [S0022-2488(96)03207-0]

I. INTRODUCTION

One of the pressing problems in particle physics is to formulate four-dimensional (4-D) quantum field theory nonperturbatively and to find nonperturbative quantum-field-theoretical solutions to the Yang–Mills equations for strong interactions, as well as to quantum gravity. The path we have taken in this pursuit of nonperturbative results has been through the integrable-system method. The main important framework the integrable-system provides is the possibility of formulating the field theory in terms of group-valued local fields. This is a nontrivial starting point for 4-D gauge theory with nonvanishing curvatures. In this formulation the self-dual Yang–Mills (SDYM) theory is the simplest, yet important prototype to work out.[1]

In Ref. 2 we succeeded in formulating the quantum SDYM field theory in terms of the group-valued local quantum field $\tilde{J}$. We obtained the interaction Hamiltonian of the $\tilde{J}$ fields, derived the exchange algebras that the $\tilde{J}$ fields satisfy, showed that the the $\tilde{J}$ fields are bimodule quantum fields and the R matrix of the exchange algebras satisfies the Yang–Baxter relations so that the products of the $\tilde{J}$ fields satisfy associativity and we developed operator-product and normal-ordering procedure for the products of fields. From the $\tilde{J}$ fields, we constructed local currents and their algebras. We found that the one-spatial-dimension integrated currents and current algebras are actually time-independent, i.e. they commute with the interaction Hamiltonian. This is a striking new feature in this 4-D quantum field theory. In this paper we develop fully the implications of these time-independent currents. (Throughout the paper we use letters with a tilde to denote quantum operator fields.)

From the time-independent current $\tilde{\mathcal{J}}(\bar{y},\bar{k})$, we construct new group-valued quantum fields $\tilde{U}(\bar{y},\bar{k})$ and $\tilde{U}^{-1}(\bar{y},\bar{k})$ that satisfy a set of exchange algebras such that fields of $\tilde{\mathcal{J}}(\bar{y},\bar{k}) \sim \tilde{U}(\bar{y},\bar{k})\partial_{\bar{y}}\tilde{U}^{-1}(\bar{y},\bar{k})$ satisfy the original time-independent current algebra. For the correlation functions of the products of the $\tilde{U}(\bar{y},\bar{k})$ and $\tilde{U}^{-1}(\bar{y},\bar{k})$ fields defined in the invariant state constructed through the current $\tilde{\mathcal{J}}(\bar{y},\bar{k})$ we can derive the Knizhnik–Zamolodchikov (KZ) equations[3] with an additional spatial dependence on $\bar{k}$. We can obtain the n-point correlation functions of the $\tilde{U}(\bar{y},\bar{k})$ and $\tilde{U}^{-1}(\bar{y},\bar{k})$ fields; they are expressible in terms of the correlation functions of the quantum WZNW theory in two-dimensions (2-D) with coefficients being unknown functions of one of the additional spatial coordinates in 4-D.

From the $\tilde{U}(\bar{y},\bar{k})$ and $\tilde{U}^{-1}(\bar{y},\bar{k})$ fields we can also construct the quantum-group generators,

0022-2488/96/37(8)/3704/9/$10.00

local, global and semi-local, and their algebraic relations. For the correlation functions of the products of the $\tilde{U}$ and $\tilde{U}^{-1}$ fields defined in the invariant state constructed through the semi-local quantum-group generators, using the method given by Frenkel and Reshetikhin[4] we obtain the quantum-group difference equations. We give the explicit solution to the two point function.

With these results, we have exposed probably as much as possible the quantum integrability part of this 4-D interactive theory. As expected, the 4-D interactive theory is not, and should not be, as fully integrable as integrable systems in 2-D (for example, solutions to the KZ equation have unknown functions). However it is to important to find out the quantum-field-theoretical integrability properties of the theories which have many classical integrability properties. This work on the quantum SDYM has now prepared us to investigate fuller 4-D field theories.

II. THE QUANTUM SDYM SYSTEM: HAMILTONIAN, EXCHANGE ALGEBRAS, CRITICAL EXPONENTS, OPERATOR-PRODUCT EXPANSION, NORMAL ORDERING AND CURRENT ALGEBRA

First we briefly review the quantum self-dual Yang–Mills system as formulated in our previous paper.[2] It is characterized by a quantum field Hamiltonian,

$$\tilde{H}_{\rm int}=-\alpha\int d\bar{y}(2l)^2\Sigma_k\Sigma_{\bar{k}}\Big\{\mathrm{Tr}\Big\{(\partial_k\tilde{J})(\partial_{\bar{k}}\tilde{J}^{-1})+\int_0^1 d\rho\,\mathrm{Tr}\{(\partial_\rho\tilde{J})$$
$$\times[(\partial_{\bar{k}}\tilde{J}^{-1})(\partial_k\tilde{J})-(\partial_k\tilde{J}^{-1})(\partial_{\bar{k}}\tilde{J})](\tilde{J}^{-1})\}\Big\}, \tag{1}$$

where, in the case of sl(2), $\tilde{J}=\tilde{J}(y,\bar{y},k,\bar{k})$ is a 2×2 matrix with noncommuting operator-valued entries depending on the 4-D coordinates y, $\bar{y}$, k, $\bar{k}$; and y is the time. (Here we present the theory with z and $\bar{z}$ coordinates discretized: $z=ka$, $\bar{z}=\bar{k}a$, and $a\equiv 2l/N$ is the lattice size.)

The quantum $\tilde{J}$ fields satisfy the following exchange algebras:

$$\tilde{J}_1(y,\bar{y}_1,k_1,\bar{k}_1)\tilde{J}_{II}(y,\bar{y}_2,k_2,\bar{k}_2)=1_{I,II}\tilde{J}_{II}(y,\bar{y}_2,k_2,\bar{k}_2)\tilde{J}_I(y,\bar{y}_1,k_1,\bar{k}_1)R_{I,II}(q,y_1-\bar{y}_2), \tag{2a}$$

where

$$R_{I,II}(q,\bar{y}_1-\bar{y}_2)=P_{I,II}\{[q]^{\Delta_1\epsilon(\bar{y}_1-\bar{y}_2)}\mathscr{P}^q_{j_{12}=1}-[q]^{\Delta_0\epsilon(\bar{y}_1-\bar{y}_2)}\mathscr{P}^q_{j_{12}=0}\}, \tag{2b}$$

$$\epsilon(\bar{y}_1-\bar{y}_2)=-[\ln(\bar{y}_1-\bar{y}_2+i\epsilon)-\ln(\bar{y}_2-\bar{y}_1+i\epsilon)]/\pi i \tag{2c}$$

and

$$\epsilon(\bar{y}_1-\bar{y}_2)=\pm1, \quad \text{for } \bar{y}_1\gtrless\bar{y}_2; \tag{2d}$$

$$\epsilon(\bar{y}_1-\bar{y}_2)=0, \quad \text{for } \bar{y}_1=\bar{y}_2; \tag{2e}$$

$q\equiv e^{-[i\hbar/(2\alpha a^2)]\delta_{k_1k_2}\delta_{\bar{k}_1\bar{k}_2}}$, where α is the coefficient in front of the SDYM interaction Hamiltonian, Eq. (1); $\Delta_1=-1/2$ and $\Delta_0=3/2$ are the conformal dimensions; and the $\mathscr{P}^q_{j_{12}}$'s are the q-ed projection matrices projecting the two spin 1/2 states into $j_{12}=0$ or 1, satisfying $\mathscr{P}^q_{j_{12}}\mathscr{P}^q_{j'_{12}}=\mathscr{P}^q_{j_{12}}\delta_{j_{12}j'_{12}}$. In the more explicit expressions,

$$\mathscr{P}^q_{j_{12}=1}=\mathrm{diag}\left\{1,d\begin{pmatrix}q & 1\\ 1 & q^{-1}\end{pmatrix},1\right\}, \tag{2f}$$

where $d \equiv 1/(q+q^{-1})$. The q-ed singlet projection matrix is related to the triplet one by $\mathscr{P}^q_{j_{12}=0} = 1 - \mathscr{P}^q_{j_{12}=1}$. The matrix $P_{I,II}$ interchanges matrix in space I to II and visa versa, e.g., $P_{I,II}\tilde{J}_I(y,\bar{y}_1,k_1,\bar{k}_1)\tilde{J}_{II}(y,\bar{y}_2,k_2,\bar{k}_2) = \tilde{J}_{II}(y,\bar{y}_1,k_1,\bar{k}_1)\tilde{J}_I(y,\bar{y}_2,k_2,\bar{k}_2)P_{I,II}$, and its explicit representation is $P_{I,II} = 1/2 + 1/2\sum_{a=1}^{3}\sigma_I^a\sigma_{II}^a = \mathscr{P}_{j_{12}=1} - \mathscr{P}_{j_{12}=0}$; here the $\mathscr{P}_{j_{12}}$'s are the un-q-ed ordinary projection matrices, i.e., Eq. (2b) with $q=1$. Using another fact $1_{I,II} = \mathscr{P}_{j_{12}=1} + \mathscr{P}_{j_{12}=0}$, we can easily prove that at $\bar{y}_1 = \bar{y}_2$, exchange algebra Eq. (1) gives

$$\mathscr{P}_{j_{12}}\tilde{J}_I(y,\bar{y}_1,k_1,\bar{k}_1)\tilde{J}_{II}(y,\bar{y}_1,k_1,\bar{k}_1) = \tilde{J}_I(y,\bar{y}_1,k_1,\bar{k}_1)\tilde{J}_{II}(y,\bar{y}_1,k_1,\bar{k}_1)\mathscr{P}^q_{j_{12}}, \tag{2g}$$

where $j_{12}=0,1$. Equation (2c) implies $\mathscr{P}_{j_{12}}\tilde{J}_I(y,\bar{y}_1,k_1,\bar{k}_1)\tilde{J}_{II}(y,\bar{y}_1,k_1,\bar{k}_1)\mathscr{P}^q_{j'_{12}} = 0$, for $j_{12} \neq j'_{12}$. This and the later development of the quantum-group generators rely crucially on this interpretation of the R matrix at the coincidence point, Eq. (2c). We denote $R_{I,II}(q,\bar{y}_1-\bar{y}_2) = R_{I,II}(q,+)$, for $\bar{y}_1-\bar{y}_2>0$ and $R_{I,II}(q,\bar{y}_1-\bar{y}_2) = R_{I,II}(q,-)$, for $\bar{y}_1-\bar{y}_2<0$. Note that $[R_{I,II}(q,+)]^{-1} = R_{II,I}(q,-)$ and $[R_{I,II}(q,-)]^{-1} = R_{II,I}(q,+)$.

The expression for $\epsilon(\bar{y}_1-\bar{y}_2)$, Eq. (2a), indicates that the product $\tilde{J}_I(\bar{y}_1)\tilde{J}_{II}(\bar{y}_2)$ has singularity at $\bar{y}_1-\bar{y}_2=0$, with the specific critical exponents given by

$$\begin{aligned}&\mathscr{P}_{j_{12}}\tilde{J}_I(y,\bar{y}_1,k_1,\bar{k}_1)\tilde{J}_{II}(y,\bar{y}_2,k_1,\bar{k}_1)\mathscr{P}^q_{j'_{12}}\\ &\quad = (\bar{y}_1-\bar{y}_2)^{\Delta_{j_{12}}(\ln q)/\pi i}\{:\mathscr{P}_{j_{12}}\tilde{J}_I(y,\bar{y}_1,k_1,\bar{k}_1)\tilde{J}_{II}(y,\bar{y}_2,k_1,\bar{k}_1)\mathscr{P}^q_{j'_{12}}:\}.\end{aligned} \tag{3}$$

This also defines the normal-order products to be those in the curly brackets; their Taylor expansions give the operator-product expansions.

We then defined the $\tilde{J}^{-1}$ field by the following fixed-y-time equation

$$\tilde{J}(y,\bar{y},k,\bar{k})\tilde{J}^{-1}(y,\bar{y},k,\bar{k}) = 1 = \tilde{J}^{-1}(y,\bar{y},k,\bar{k})\tilde{J}(y,\bar{y},k,\bar{k}). \tag{4}$$

From Eqs. (4) and (2a), one can easily show that the $\tilde{J}^{-1}$ field satisfies the following fixed-y-time exchange algebras:

$$\tilde{J}_I^{-1}(y,\bar{y}_1,k_1,\bar{k}_1)\tilde{J}_{II}(y,\bar{y}_2,k_2,\bar{k}_2) = \tilde{J}_{II}(y,\bar{y}_2,k_2,\bar{k}_2)R^{-1}_{I,II}(q,\bar{y}_1-\bar{y}_2)\tilde{J}_I^{-1}(y,\bar{y}_1,k_1,\bar{k}_1), \tag{5a}$$

and

$$\tilde{J}_I^{-1}(y,\bar{y}_1,k_1,\bar{k}_1)\tilde{J}_{II}^{-1}(y,\bar{y}_2,k_2,\bar{k}_2) = R^{-1}_{I,II}(q,\bar{y}_1-\bar{y}_2)\tilde{J}_{II}^{-1}(y,\bar{y}_2,k_2,\bar{k}_2)\tilde{J}_I^{-1}(y,\bar{y}_1,k_1,\bar{k}_1). \tag{5b}$$

The construction of this $\tilde{J}^{-1}$ field is crucial for us to develop of the full content of the theory in terms of the group-valued fields.

From $\hat{H}_{\text{int}}$ and the exchange algebra Eq. (2a), we can calculate the equation of motion,

$$\partial_y(\tilde{J}\partial_{\bar{y}}\tilde{J}^{-1}) = \frac{\hbar}{i}[\tilde{H},\tilde{J}\partial_{\bar{y}}\tilde{J}^{-1}] = a^{-2}\partial_k(\tilde{J}\partial_{\bar{k}}\tilde{J}^{-1}). \tag{5c}$$

From fields $\tilde{J}$ and $\tilde{J}^{-1}$, we constructed the $\widehat{\text{sl}(2)}$ current,

$$\tilde{j}(y,\bar{y},k,\bar{k}) \equiv \kappa\tilde{J}\partial_{\bar{y}}\tilde{J}^{-1}(y,\bar{y},k,\bar{k}), \tag{6}$$

where $\kappa = \pi i/\ln(q)_{k_1=k_2,\bar{k}_1=\bar{k}_2} = -2\pi\alpha a^2/\hbar$. We then showed that the following equations can be easily derived from the exchange algebras, Eqs. (2a), (5a), and (5b):

$$[\tilde{j}_I(y,\bar{y}_1,k_1,\bar{k}_1),\tilde{j}_{II}(y,\bar{y}_2,k_2,\bar{k}_2)]=[M_{I,II},\tilde{j}_{II}(y,\bar{y}_2,k_2,\bar{k}_2)]2\pi i\delta(\bar{y}_1-\bar{y}_2)\delta_{k_1k_2}\delta_{\bar{k}_1\bar{k}_2}$$
$$+\kappa M_{I,II}2\pi i\delta'(\bar{y}_1-\bar{y}_2)\delta_{k_1k_2}\delta_{\bar{k}_1\bar{k}_2}, \tag{7}$$

$$[\tilde{j}_I(y,\bar{y}_1,k_1,\bar{k}_1),\tilde{J}_{II}(y,\bar{y}_2,k_2,\bar{k}_2)]=M_{I,II}\tilde{J}_{II}(\bar{y}_2,k_2,\bar{k}_2)2\pi i\delta(\bar{y}_1-\bar{y}_2)\delta_{k_1k_2}\delta_{\bar{k}_1\bar{k}_2}, \tag{8}$$

$$[\tilde{j}_I(y,\bar{y}_1,k_1,\bar{k}_1),\tilde{J}_{II}^{-1}(y,\bar{y}_2,k_2,\bar{k}_2)]=-\tilde{J}_{II}^{-1}(\bar{y}_2,k_2,\bar{k}_2)M_{I,II}2\pi i\delta(\bar{y}_1-\bar{y}_2)\delta_{k_1k_2}\delta_{\bar{k}_1\bar{k}_2}, \tag{9}$$

where $M_{I,II}\equiv P_{I,II}-1/2=1/2\Sigma_{a=1}^{3}\sigma_I^a\sigma_{II}^a$.

Equation (7) is the current algebra of the current $\tilde{j}$. Equation (8) indicates that the left side of $\tilde{J}$ forms the fundamental representation of the current $\tilde{j}$; Eq. (9) indicates that the right side of $\tilde{J}^{-1}$ forms the fundamental representation of the current $\tilde{j}$. These are fixed time relations. Since the current $\tilde{j}$ varies with time y, i.e., $[\tilde{j},\tilde{H}]\neq 0$.

As pointed out in Ref. 2 the k-summed (one-spatial-dimension-integrated) current

$$\tilde{\mathcal{J}}(\bar{y},\bar{k})\equiv\Sigma_k\tilde{j}(\bar{y},k,\bar{k}), \tag{10}$$

is constant in time y. It can be proven by directly calculating and showing $[\tilde{\mathcal{J}},\tilde{H}_{\text{int}}]=0$, or easily seen from integrating in z the equation of motion, Eq. (5c). That is why we do not put y dependence in $\tilde{\mathcal{J}}(\bar{y},\bar{k})$. The algebras become

$$[\tilde{\mathcal{J}}_I(\bar{y}_1,\bar{k}_1),\tilde{\mathcal{J}}_{II}(\bar{y}_2,\bar{k}_2)]=[M_{I,II},\tilde{\mathcal{J}}_{II}(\bar{y}_2,\bar{k}_2)]2\pi i\delta(\bar{y}_1-\bar{y}_2)\delta_{\bar{k}_1\bar{k}_2}$$
$$+\kappa' M_{I,II}2\pi i\delta'(\bar{y}_1-\bar{y}_2)\delta_{\bar{k}_1\bar{k}_2}, \tag{11}$$

$$[\tilde{\mathcal{J}}_I(\bar{y}_1,\bar{k}_1),\tilde{J}_{II}(\bar{y}_2,k_2,\bar{k}_2)]=M_{I,II}\tilde{J}_{II}(\bar{y}_2,k_2,\bar{k}_2)2\pi i\delta(\bar{y}_1-\bar{y}_2)\delta_{\bar{k}_1\bar{k}_2}, \tag{12}$$

$$[\tilde{\mathcal{J}}_I(\bar{y}_1,k_1),\tilde{J}_{II}^{-1}(\bar{y}_2,k_2,\bar{k}_2)]=-\tilde{J}_{II}^{-1}(\bar{y}_2,k_2,\bar{k}_2)M_{I,II}2\pi i\delta(\bar{y}_1-\bar{y}_2)\delta_{\bar{k}_1\bar{k}_2}, \tag{13}$$

which can be easily obtained from Eqs. (7), (8) and (9) by k-summation and the identification $\kappa'=\kappa N=\kappa 2l/a$. Note that $\Sigma_{k_1}\delta_{k_1k_2}=1$. Taking the trace of Eq. (11) onto σ_I^a and σ_{II}^b one can easily obtain the current algebra in terms of the Lie-components of the current $[\tilde{\mathcal{J}}^a(\bar{y}_1),\tilde{\mathcal{J}}^b(\bar{y}_2)]=i\epsilon^{abc}\tilde{\mathcal{J}}^c(\bar{y}_1)2\pi i\delta(\bar{y}_1-\bar{y}_2)\delta_{\bar{k}_1\bar{k}_2}+(\kappa'/2)\delta^{ab}2\pi i\delta'(\bar{y}_1-\bar{y}_2)\delta_{\bar{k}_1\bar{k}_2}$. The corresponding continuum equations can also be easily obtained.

III. KZ EQUATIONS FOR THE CORRELATION FUNCTIONS OF THE PRODUCTS OF THE NEW GROUP-VALUED LOCAL FIELDS $\tilde{U}(\bar{y},\bar{k})$ and $\tilde{U}^{-1}(\bar{y},\bar{k})$

Next we can construct new time-independent group-valued local fields $\tilde{U}(\bar{y},\bar{k})$ and $\tilde{U}^{-1}(\bar{y},\bar{k})$ such that

$$\tilde{\mathcal{J}}_I(\bar{y}_1,\bar{k}_1)=\kappa'\tilde{U}_I\partial_{\bar{y}_1}\tilde{U}_I^{-1}(\bar{y}_1,\bar{k}_1), \tag{14}$$

and the $\tilde{U}$ and $\tilde{U}^{-1}$ fields satisfy the following exchange algebras:

$$\tilde{U}_I(\bar{y}_1,\bar{k}_1)\tilde{U}_{II}(\bar{y}_2,\bar{k}_2)=\tilde{U}_{II}(\bar{y}_2,\bar{k}_2)\tilde{U}_I(\bar{y}_1,\bar{k}_1)R_{I,II}(q',\bar{y}_1-\bar{y}_2), \tag{15}$$

$$\tilde{U}_{II}^{-1}(\bar{y}_2,\bar{k}_2)\tilde{U}_I(\bar{y}_1,\bar{k}_1)=\tilde{U}_I(\bar{y}_1,\bar{k}_1)R_{I,II}(q',\bar{y}_1-\bar{y}_2)\tilde{U}_{II}^{-1}(\bar{y}_2,\bar{k}_2), \tag{16}$$

$$\tilde{U}_I^{-1}(\bar{y}_1,\bar{k}_1)\tilde{U}_{II}^{-1}(\bar{y}_2,\bar{k}_2)=R_{I,II}(q',\bar{y}_1-\bar{y}_2)\tilde{U}_{II}^{-1}(\bar{y}_2,\bar{k}_2)\tilde{U}_I^{-1}(\bar{y}_1,\bar{k}_1), \tag{17}$$

where $q' = e^{[-i\hbar/(2\alpha 2la)]\delta_{\bar{k}_1\bar{k}_2}} = (q^{1/N})_{k_1=k_2}$ and $\kappa' = \pi i/\ln(q')_{\bar{k}_1=\bar{k}_2}$. These exchange algebras guarantee the current algebra of $\tilde{\mathscr{T}}$, Eq. (11), and also gives the following algebra:

$$[\tilde{\mathscr{T}}_I(\bar{y}_1,\bar{k}_1),\tilde{U}_{II}(\bar{y}_2,\bar{k}_2)]=M_{I,II}\tilde{U}_{II}(\bar{y}_2,\bar{k}_2)2\pi i\,\delta(\bar{y}_1-\bar{y}_2)\,\delta_{\bar{k}_1\bar{k}_2}, \tag{18}$$

$$[\tilde{\mathscr{T}}_I(\bar{y}_1,\bar{k}_1),\ \tilde{U}_{II}^{-1}(\bar{y}_2,\bar{k}_2)]=-\tilde{U}_{II}^{-1}(\bar{y}_2,\bar{k}_2)M_{I,II}2\pi i\,\delta(\bar{y}_1-\bar{y}_2)\,\delta_{\bar{k}_1\bar{k}_2}. \tag{19}$$

From $2\pi i\,\delta(\bar{y}_1-\bar{y}_2) = 1/(\bar{y}_1-\bar{y}_2-i\epsilon)-1/(\bar{y}_1-\bar{y}_2+i\epsilon)$, the commutator equations, Eqs. (7) to (9), can be written out in the commonly used operator-product-expansion forms.

Let us make the decomposition [{]

$$\tilde{\mathscr{T}}(\bar{y}_1,\bar{k}_1)=\tilde{\mathscr{T}}^{+}(\bar{y}_1,\bar{k}_1)-\tilde{\mathscr{T}}^{-}(\bar{y}_1,\bar{k}_1), \tag{20}$$

with $\tilde{\mathscr{T}}^{\pm}$ satisfying the following algebras:

$$[\tilde{\mathscr{T}}_I^{\pm}(\bar{y}_1,\bar{k}_1),\tilde{\mathscr{T}}_{II}^{\pm}(\bar{y}_2;\bar{k}_2)]=\frac{1}{\bar{y}_1-\bar{y}_2+i\epsilon}[M_{I,II},(\tilde{\mathscr{T}}_I^{\pm}(\bar{y}_1,\bar{k}_1)+\tilde{\mathscr{T}}_{II}^{\pm}(\bar{y}_2,\bar{k}_2))]\delta_{\bar{k}_1\bar{k}_2}, \tag{21}$$

$$\begin{aligned}[\tilde{\mathscr{T}}_I^{+}(\bar{y}_1,\bar{k}_1),\tilde{\mathscr{T}}_{II}^{-}(\bar{y}_2,\bar{k}_2)]=&\frac{1}{\bar{y}_1-\bar{y}_2-i\epsilon}[M_{I,II}(\tilde{\mathscr{T}}_I^{+}(\bar{y}_1,\bar{k}_1)+\tilde{\mathscr{T}}_{II}^{-}(\bar{y}_2,\bar{k}_2))]\delta_{\bar{k}_1\bar{k}_2}\\ &-\frac{1}{(\bar{y}_1-\bar{y}_2+i\epsilon)^2}\kappa' M_{I,II}\delta_{\bar{k}_1\bar{k}_2},\end{aligned} \tag{22}$$

$$[\mathscr{T}_I^{\pm}(\bar{y}_1,\bar{k}_1),\tilde{U}_{II}(\bar{y}_2,\bar{k}_2)]=\frac{-1}{\bar{y}_1-\bar{y}_2\pm i\epsilon}M_{I,II}\tilde{U}_{II}(\bar{y}_2,\bar{k}_2)\delta_{\bar{k}_1\bar{k}_2}, \tag{23}$$

so that Eqs. (11), (18), and (19) are guaranteed.

Because of the singularities in the products of fields, we must prescribe the normal-ordering procedure and make consistency checks. The goal is to express $c\partial_{\bar{y}}\tilde{U}=:\tilde{\mathscr{T}}\tilde{U}:$, where c is a constant to be determined by the normal-order procedure and consistency. Following the procedure used in Ref. 4, we define the vacuum state $|0\rangle$ to be

$$\tilde{\mathscr{T}}^{-}(\bar{y},\bar{k})|0\rangle=0 \quad \text{and} \quad \langle 0|\tilde{\mathscr{T}}^{+}(\bar{y},\bar{k})=0. \tag{24}$$

After checking the consistency with all the above algebras, we find $c=(\kappa'+2)$ and obtain

$$(\kappa'+2)\partial_{\bar{y}}\tilde{U}_I(\bar{y},\bar{k})=-:\tilde{\mathscr{T}}_I(\bar{y},\bar{k})\tilde{U}_I(\bar{y},\bar{k}):\equiv-\tilde{\mathscr{T}}_I^{+}(\bar{y},\bar{k})\tilde{U}_I(\bar{y},\bar{k})+((\tilde{U}_I(\bar{y},\bar{k}))^T(\tilde{\mathscr{T}}_I(\bar{y},\bar{k}))^T)^T. \tag{25}$$

Then following the standard procedure, we obtain the KZ equation for the $\tilde{U}$ fields,

$$\left((\kappa'+2)\partial_{\bar{y}_j}+\sum_{j\neq k}\frac{M_{J,K}}{\bar{y}_j-\bar{y}_k}\,\delta_{\bar{k}_j\bar{k}_k}\right)\langle 0|\tilde{U}_I(\bar{y}_1,\bar{k}_1)\cdots\tilde{U}_N(\bar{y}_n,\bar{k}_n)|0\rangle=0. \tag{26}$$

Notice that taking away the $\bar{k}$ dependence, we recover the KZ equation of the quantum WZNW theory, Ref. 3.

The solutions of this SDYM KZ equation are expressible in terms of those of the WZNW KZ equation, $\langle 0|g_I(\bar{y}_1)\cdots g_N(\bar{y}n)|0)$, multiplied by unknown functions in $\bar{k}$. For example,

$$\langle 0|\tilde{U}_I(\bar{y}_1,\bar{k}_1)\tilde{U}_{II}(\bar{y}_2,\bar{k}_2)|0\rangle = C_2(\bar{k}_1)\langle 0|\tilde{g}_I(\bar{y}_1)\tilde{g}_{II}(\bar{y}_2)|0\rangle_{(\kappa'+2)}\delta_{\bar{k}_1\bar{k}_2} + C_{2I}(\bar{k}_1,\bar{k}_2)\langle 0|\tilde{g}_I(\bar{y}_1)|0\rangle_{(\kappa'+2)}\langle 0|\tilde{g}_{II}(\bar{y}_2)|0\rangle_{(\kappa'+2)}(1-\delta_{\bar{k}_1\bar{k}_2}), \tag{27}$$

$$\begin{aligned}\langle 0|\tilde{U}_I(\bar{y}_1,\bar{k}_1)\tilde{U}_{II}(\bar{y}_2,\bar{k}_2)\tilde{U}_{III}(\bar{y}_3,\bar{k}_3)|0\rangle &= C_3(\bar{k}_1)\langle 0|\tilde{g}_I(\bar{y}_1)\tilde{g}_{II}(\bar{y}_2)\tilde{g}_{III}(\bar{y}_3)|0\rangle_{(\kappa'+2)}\delta_{\bar{k}_1\bar{k}_2}\delta_{\bar{k}_1\bar{k}_3} \\ &+ \sum_{j\neq k\neq l}^{1\text{ to }3} C_{3j}(\bar{k}_k,\bar{k}_j)\langle 0|\tilde{g}_J(\bar{y}_j)|0\rangle_{(\kappa'+2)}\langle 0|\tilde{g}_K(\bar{y}_k)\tilde{g}_L(\bar{y}_l)|0\rangle_{(\kappa'+2)}\delta_{\bar{k}_k\bar{k}_l}(1-\delta_{\bar{k}_k\bar{k}_j}) \\ &+ C_{34}(\bar{k}_1,\bar{k}_2,\bar{k}_3)\langle 0|\tilde{g}_I(\bar{y}_1)|0\rangle_{(\kappa'+2)}\langle 0|\tilde{g}_{II}(\bar{y}_2)|0\rangle_{(\kappa'+2)}\langle 0|\tilde{g}_{III}(\bar{y}_3)|0\rangle_{(\kappa'+2)} \\ &\times(1-\delta_{\bar{k}_1\bar{k}_2})(1-\delta_{\bar{k}_1\bar{k}_3})(1-\delta_{\bar{k}_2\bar{k}_3}),\end{aligned} \tag{28}$$

$$\begin{aligned}\langle 0|\tilde{U}_I(\bar{y}_1,\bar{k}_1)U_{II}(\bar{y}_2,\bar{k}_2)U_{III}(\bar{y}_3,\bar{k}_3)U_{IV}(\bar{y}_4,\bar{k}_4)|0\rangle &= C_4(k_1)\langle 0|\tilde{g}_I(\bar{y}_1)\tilde{g}_{II}(\bar{y}_2)\tilde{g}_{III}(\bar{y}_3)\tilde{g}_{IV}(\bar{y}_4)|0\rangle_{(\kappa'+2)}\delta_{\bar{k}_1\bar{k}_2}\delta_{\bar{k}_2\bar{k}_3}\delta_{\bar{k}_3\bar{k}_4} \\ &+ \sum_{j\neq k\neq l\neq m}^{1\text{ to }4} C_{4j}(\bar{k}_k,\bar{k}_j)\langle 0|\tilde{g}_J(\bar{y}_j)|0\rangle_{(\kappa'+2)}\langle 0|\tilde{g}_K(\bar{y}_k)\tilde{g}_L(\bar{y}_l)\tilde{g}_M(\bar{y}_m)|0\rangle_{(\kappa'+2)} \\ &\times(1-\delta_{\bar{k}_j\bar{k}_k})\delta_{\bar{k}_l\bar{k}_k}\delta_{\bar{k}_m\bar{k}_k} + \sum_{j\neq k\neq l\neq m}^{1\text{ to }4} C_{41,jklm}(\bar{k}_j,\bar{k}_l)\langle 0|\tilde{g}_J(\bar{y}_j)(\tilde{g}_K)(\bar{y}_k)|0\rangle_{(\kappa'+2)} \\ &\times\langle 0|\tilde{g}_L(\bar{y}_l)\tilde{g}_M(\bar{y}_m)|0\rangle_{(\kappa'+2)}\delta_{\bar{k}_j\bar{k}_k}\delta_{\bar{k}_l\bar{k}_m}(1-\delta_{\bar{k}_j\bar{k}_l}) + \sum_{j\neq k\neq l\neq m}^{1\text{ to }4} C_{42,jklm}(\bar{k}_j,\bar{k}_k,\bar{k}_l) \\ &\times\langle 0|\tilde{g}_J(\bar{y}_j)|0\rangle_{(\kappa'+2)}\langle 0|\tilde{g}_K(\bar{y}_k)|0\rangle_{(\kappa'+2)}\langle 0|\tilde{g}_L(\bar{y}_l)\tilde{g}_M(\bar{y}_m)|0\rangle_{(\kappa'+2)} \\ &\times(1-\delta_{\bar{k}_j\bar{k}_l})\delta_{\bar{k}_l\bar{k}_m}(1-\delta_{\bar{k}_k\bar{k}_l})(1-\delta_{\bar{k}_j\bar{k}_k}) + C_{43}(\bar{k}_1,\bar{k}_2,\bar{k}_3,\bar{k}_4)\langle 0|\tilde{g}_I(\bar{y}_1)|0\rangle_{(\kappa'+2)} \\ &\times\langle 0|\tilde{g}_{II}(\bar{y}_2)|0\rangle_{(\kappa'+2)}\langle 0|\tilde{g}_{III}(\bar{y}_3)|0\rangle_{(\kappa'+2)}\langle 0|\tilde{g}_{IV}(\bar{y}_4)|0\rangle_{(\kappa'+2)}(1-\delta_{\bar{k}_1\bar{k}_2})(1-\delta_{\bar{k}_1\bar{k}_3}) \\ &\times(1-\delta_{\bar{k}_1\bar{k}_4})(1-\delta_{\bar{k}_2\bar{k}_3})(1-\delta_{\bar{k}_2\bar{k}_4})(1-\delta_{\bar{k}_3\bar{k}_4}).\end{aligned} \tag{29}$$

These are the nonperturbative y-time independent solutions of the correlation functions of the quantum CDYM theory. As expected, the 4-D theory has more freedom which is manifested in these unknown functions.

IV. QUANTUM-GROUP CURRENT $\tilde{\mathcal{J}}^q(\bar{y},\bar{k})$ AND $\bar{y}$-GLOBAL QUANTUM-GROUP GENERATORS $\tilde{G}(\bar{k})$

Similar to the construction of the current $\tilde{\mathcal{J}}$, Eq. (14), it is natural to construct the other current,

$$\tilde{\mathcal{J}}^q(\bar{y},\bar{k}) \equiv \kappa' \tilde{U}^{-1}(\bar{y},\bar{k})\partial_{\bar{y}}\tilde{U}(\bar{y},\bar{k}), \tag{30}$$

which we shall call the quantum-group current, since it has the quantum-group index on both sides.

We can work out the algebraic relations among its matrix elements and with the fields $\tilde{U}$ and $\tilde{U}^{-1}$, like Eqs. (11) to (13) for the $\tilde{\mathcal{J}}$. All of them have nice quantum-group interpretations. However, we find that $\tilde{\mathcal{J}}^q$ is not as useful a quantity as the current $\tilde{\mathcal{J}}$ in that it can not be used to develop its vacuum states and the corresponding differential equations as the current $\tilde{\mathcal{J}}$ was used to develop the KZ equations. On the other hand we find that the following group-valued quantities,

$\tilde{G}(\bar{k})$ and $\tilde{G}^{\Delta}(\bar{y},\bar{k})$, are the appropriate quantum-group generators for further development of the theory.

The $\bar{y}$-global quantum-group generator $\tilde{G}(\bar{k})$ is derived from the quantum-group current $\tilde{\mathcal{J}}^{q}$ of Eq. (30) by a path ordered integration,

$$\tilde{G}(\bar{k})=\vec{P}\ \exp\left(\int_{-\infty}^{\infty} d\bar{y}\tilde{U}^{-1}\partial_{\bar{y}}\tilde{U}(\bar{y},\bar{k})\right)=\tilde{U}^{-1}(\bar{y}=-\infty,\bar{k})\tilde{U}(\bar{y}=+\infty,\bar{k}). \tag{31}$$

Then, from the exchange algebras of the fields $\tilde{U}$ and $\tilde{U}^{-1}$, Eqs. (15) to (17), we can derive the algebraic relations among the matrix elements of $\tilde{G}(\bar{k})$ and with the fields $\tilde{U}$ and $\tilde{U}^{-1}$,

$$\{R_{\mathrm{II,I}}(q',+)\tilde{G}_{I}(\bar{k}_1)R_{\mathrm{I,II}}(q',+)\}\tilde{G}_{\mathrm{II}}(\bar{k}_2)=\tilde{G}_{\mathrm{II}}(\bar{k}_2)\{R_{\mathrm{II,I}}(q',+)\tilde{G}_{\mathrm{I}}(\bar{k}_1)R_{\mathrm{I,II}}(q',+)\}, \tag{32}$$

$$\tilde{G}_{\mathrm{I}}(\bar{k}_1)U_{\mathrm{II}}(\bar{y}_2,\bar{k}_2)=U_{\mathrm{II}}(\bar{y}_2,\bar{k}_2)\{R_{\mathrm{II,I}}(q',+)\tilde{G}_{\mathrm{I}}(\bar{k}_1)R_{\mathrm{I,II}}(q',+)\}, \tag{33}$$

$$U_{\mathrm{II}}^{-1}(\bar{y}_2,\bar{k}_2)\tilde{G}_{\mathrm{I}}(\bar{k}_1)=\{R_{\mathrm{II,I}}(q',+)\tilde{G}_{\mathrm{I}}(\bar{k}_1)R_{\mathrm{I,II}}(q',+)\}\tilde{U}_{\mathrm{II}}^{-1}(\bar{y}_2,\bar{k}_2), \tag{34}$$

where $R_{\mathrm{I,II}}(q',+)$ is the R-matrix with $\epsilon(\bar{y}_1-\bar{y}_2)=+1$ and the curley brackets are to guide the eyes to the proper grouping of matrices and operators. These three equations are the algebraic relations parallel to those of Eqs. (11), (18) and (19). Associativity of all these fields are true because the R matrix satisfies the Yang–Baxter relations.

The basic elements of the quantum-group generators $\{\tilde{e}_i(\bar{k});\ i=3 \text{ and } \pm\}$ are related to the components of the components of the matrix $\tilde{G}(\bar{k})$ by

$$\tilde{G}(\bar{k})\equiv\begin{pmatrix}1 & 0\\ (1-q^2)\tilde{e}_{+}(\bar{k}) & 1\end{pmatrix}\begin{pmatrix}q^{-\tilde{e}_3(k)} & 0\\ 0 & q^{\tilde{e}_3(\bar{k})}\end{pmatrix}\begin{pmatrix}1 & (q^{-1}-q)\tilde{e}_{-}(\bar{k})\\ 0 & 1\end{pmatrix}, \tag{35}$$

where the $\tilde{e}_{\pm}(\bar{k})$ and $q^{-\tilde{e}_3(\bar{k})}$ satisfy local quantum-groups algebras, which generalize those given in Ref. 5.

I. THE $\bar{y}$-SEMI-LOCAL QUANTUM-GROUP GENERATOR $\tilde{G}^{\Delta}(\bar{y},\bar{k})$

Changing the integration range in Eq. (31) to a semi-local region we obtain the $\bar{y}$-semilocal quantum-group generator $\tilde{G}^{\Delta}(\bar{y},\bar{k})$ quantum group generator:

$$\tilde{G}^{\Delta}(\bar{y},\bar{k})\equiv\vec{P}\ \exp\left(\int_{\bar{y}-\Delta}^{\bar{y}+\Delta} d\bar{y}'\,\tilde{U}^{-1}(\bar{y}',\bar{k})\partial_{\bar{y}'}\tilde{U}(\bar{y}',\bar{k})\right)=\tilde{U}^{-1}(\bar{y}-\Delta,\bar{k})\tilde{U}(\bar{y}+\Delta,\bar{k}). \tag{36}$$

we can easily show that $\tilde{G}^{\Delta}$ satisfies the following algebras:

$$\begin{aligned}&\{R_{I,II}^{-1}(q',\bar{y}_1-\bar{y}_2)\tilde{G}_{I}^{\Delta}(\bar{y}_1,\bar{k}_1)R_{I,II}(q',\bar{y}_1-\bar{y}_2+2\Delta)\}\tilde{G}_{II}^{\Delta}(\bar{y}_2,\bar{k}_2)\\ &\quad=\tilde{G}_{II}^{\Delta}(\bar{y}_2,\bar{k}_2)\{R_{I,II}^{-1}(q',\bar{y}_1-\bar{y}_2-2\Delta)\tilde{G}_{I}^{\Delta}(\bar{y}_1,\bar{k}_1)R_{I,II}(q',\bar{y}_1-\bar{y}_2)\},\end{aligned} \tag{37}$$

$$\tilde{G}_{I}^{\Delta}(\bar{y}_1,\bar{k}_1)\tilde{U}_{II}(\bar{y}_2,\bar{k}_2)=\tilde{U}_{II}(\bar{y}_2,\bar{k}_2)\{R_{I,II}^{-1}(q',\bar{y}_1-\bar{y}_2-\Delta)\tilde{G}_{I}^{\Delta}(\bar{y}_1,\bar{k}_1)R_{I,II}(q',\bar{y}_1-\bar{y}_2+\Delta)\}, \tag{38}$$

$$\tilde{U}_{II}^{-1}(\bar{y}_2,\bar{k}_2)\tilde{G}_{I}^{\Delta}(\bar{y}_1,\bar{k}_1)=\{R_{I,II}^{-1}(q',\bar{y}_1-\bar{y}_2-\Delta)\tilde{G}_{I}^{\Delta}(\bar{y}_1,\bar{k}_1)R_{I,II}(q',\bar{y}_1-\bar{y}_2+\Delta)\}\tilde{U}_{II}^{-1}(\bar{y}_2,\bar{k}_2). \tag{39}$$

We next split the semi-local generator into the annihilation and creation parts following a procedure similar to that used in Ref. 4,

$$\tilde{G}_{I}^{\Delta}(\bar{y},\bar{k})\equiv[G_{I}^{\Delta^{+}}(\bar{y},\bar{k})]^{-1}G_{I}^{\Delta^{-}}(\bar{y},\bar{k}), \tag{40}$$

and $G^{\Delta\pm}(\bar{y},\bar{k})$ satisfies the following exchange algebras:

$$R_{I,II}(q',\bar{y}_1-\bar{y}_2-\Delta)G_I^{\Delta\pm}(\bar{y}_1,\bar{k}_1)G_{II}^{\Delta\pm}(\bar{y}_2,\bar{k}_2)=G_{II}^{\Delta\pm}(\bar{y}_2,\bar{k}_2)G_I^{\Delta\pm}(\bar{y}_1,\bar{k}_1)R_{I,II}(q',\bar{y}_1-\bar{y}_2-\Delta), \tag{41}$$

$$R_{I,II}(q',\bar{y}_1-\bar{y}_2)G_I^{\Delta+}(\bar{y}_1,\bar{k}_1)G_{II}^{\Delta-}(\bar{y}_2,\bar{k}_2)=G_{II}^{\Delta-}(\bar{y}_2,\bar{k}_2)G_I^{\Delta+}(\bar{y}_1,\bar{k}_1)R_{I,II}(q',\bar{y}_1-\bar{y}_2-2\Delta), \tag{42}$$

$$\tilde{U}_I(\bar{y}_1,\bar{k}_1)G_{II}^{\Delta\pm}(\bar{y}_2,\bar{k}_2)=G_{II}^{\Delta\pm}(\bar{y}_2,\bar{k}_2)\tilde{U}_I(\bar{y}_1,\bar{k}_1)R_{I,II}(q',\bar{y}_1-\bar{y}_2\pm\Delta), \tag{43}$$

such that Eqs. (37) to (39) are true.

Notice that

$$\left[\sum_n \tilde{\mathscr{T}}(\bar{y}+n\Delta,\bar{k}),G^{\Delta}(\bar{y},\bar{k})\right]=0, \tag{44}$$

which manifests what we call the $\bar{k}$-local $\mathrm{sl}^{\Delta}(n)\otimes U^{1/\Delta}q[\mathrm{sl}(n)]$ symmetry of the theory. For $\Delta\to\infty$, Eq. (44) becomes $[\tilde{\mathscr{T}}(\bar{y},\bar{k}),\tilde{G}(\bar{k})]=0$, manifesting the $\bar{k}$-local $\widehat{\mathrm{sl}(n)}\otimes Uq[\mathrm{sl}(n)]$ symmetry of the theory. For $\Delta\to 0$, Eq. (44) becomes $[\tilde{Q}(\bar{k}),\tilde{\mathscr{T}}^q(\bar{y},\bar{k})]=0$, manifesting the $\bar{k}$-local $\mathrm{sl}(n)\otimes U_q^x[\mathrm{sl}(n)]$ symmetry of the theory.

VI. QUANTUM-GROUP DIFFERENCE EQUATION OF THE CORRELATION FUNCTIONS DEFINED IN THE $|0_q\rangle$-VACUUM

Using Eq. (40), let us rewrite Eq. (36) as

$$\tilde{U}(\bar{y}+\Delta,\bar{k})=\tilde{U}(\bar{y}-\Delta,\bar{k})\tilde{G}^{\Delta}(\bar{y},\bar{k})=\tilde{U}(\bar{y}-\Delta,\bar{k})[\tilde{G}^{\Delta+}(\bar{y},\bar{k})]^{-1}G^{\Delta-}(\bar{y},\bar{k}). \tag{45}$$

Now we want to move $(G^{\Delta+}(\bar{y},\bar{k}))^{-1}$ to the left of $\tilde{U}(\bar{y}-\Delta,\bar{k})$, since we shall consider the vacuum expectation values of the $\tilde{U}$ fields by the vacuum $|0_q\rangle$ defined by

$$G^{\Delta-}(\bar{y},\bar{k})|0_q\rangle=|0_q\rangle \quad \text{and} \quad \langle 0_q|G^{\Delta+}(\bar{y},\bar{k})=\langle 0_q|. \tag{46}$$

To achieve that feat we use Eq. (43), many matrix relations and finally reach

$$\tilde{U}(\bar{y}+\Delta,\bar{k})=(((G^{\Delta+}(\bar{y},\bar{k}))^{-1})^T\Upsilon\tilde{U}^T(\bar{y}-\Delta,\bar{k}))^TG^{\Delta-}(\bar{y},\bar{k}), \tag{47}$$

where the superscript T means matrix transposition, but the order of the operator stay the same; $\Upsilon\equiv(q'+q'^{-1})/(q'^2+q'^{-2})\times\mathrm{diag}(q',q'^{-1})$, which results from

$$\Upsilon_I=(Tr)_{II}(P_{I,II}(((R_{I,II}(q',0))^{T_I})^{-1})^{T_{II}}), \tag{48}$$

where the superscripts T_I and T_{II} indicate transposition of matrices in the tensor spaces I and II, respectively.

Using Eqs. (32) and (33), we obtain the difference equation for correlation function,

$$\begin{aligned}&\langle 0_q|\tilde{U}_I(\bar{y}_1,\bar{k}_1)\cdots\tilde{U}_L(\bar{y}_l+2\Delta,\bar{k}_l)\cdots\tilde{U}_N(\bar{y}_n,\bar{k}_n)|0_q\rangle\\&\quad=\langle 0_q|\tilde{U}_I(\bar{y}_1,\bar{k}_1)\cdots\tilde{U}_L(\bar{y}_l,\bar{k}_l)\cdots\tilde{U}_N(\bar{y}_n,\bar{k}_n)|0_q\rangle R_{L,L-1}(q',\bar{y}_l-\bar{y}_{l-1})\cdots\\&\qquad\times R_{L,I}(q',\bar{y}_l-\bar{y}_1)\Upsilon_L R_{L,N}(q',\bar{y}_l-\bar{y}_n+2\Delta)\cdots R_{L,L+1}(q',\bar{y}_l-\bar{y}_{l+1}+2\Delta).\end{aligned} \tag{49}$$

For the special case of "$+2\Delta$" being at $\bar{y}_n$, Eq. (49) simplifies to the following cyclic relation:

$$\langle 0_q|\tilde{U}_I(\bar{y}_1,\bar{k}_1)\cdots\tilde{U}_N(\bar{y}_n+2\Delta,\bar{k}_n)|0_q\rangle=\langle 0_q|\tilde{U}_N(\bar{y}_n,\bar{k}_n)\tilde{U}_I(\bar{y}_1,\bar{k}_1)\cdots\tilde{U}_{N-1}(\bar{y}_{n-1},\bar{k}_{n-1})|0_q\rangle\Upsilon_N. \tag{50}$$

For the two point function, Eq. (49) becomes

$$\langle 0_q|\tilde{U}_I(\bar{y}_1,\bar{k}_1)\tilde{U}_{II}(\bar{y}_2+2\Delta,\bar{k}_2)|0_q\rangle=\langle 0_q|\tilde{U}_I(\bar{y}_1,\bar{k}_1)\tilde{U}_{II}(\bar{y}_2,\bar{k}_2)|0_q\rangle R_{II,I}(q',\bar{y}_2-\bar{y}_1)\Upsilon_{II}. \tag{51}$$

Multiplying Eq. (51) from the right by $\mathscr{P}^{q'}_{j_{12}=0}$ and using the fact $\langle 0_q|\tilde{U}_I\tilde{U}_{II}|0_q\rangle\mathscr{P}^{q'}_{j_{12}=0}=\langle 0_q|\tilde{U}_I\tilde{U}_{II}|0_q\rangle$, which can be shown using the definition of $|0_q\rangle$ given by Eq. (46), whereby Eq. (51) becomes

$$\langle 0_q|\tilde{U}_I(\bar{y}_1,\bar{k}_1)\tilde{U}_{II}(\bar{y}_2+2\Delta,\bar{k}_2)|0_q\rangle=\langle 0_q|\tilde{U}_I(\bar{y}_1,\bar{k}_1)\tilde{U}_{II}(\bar{y}_2,\bar{k}_2)|0_q\rangle q'^{-\Delta_0\epsilon(\bar{y}_1-\bar{y}_2)}\frac{q'+q'^{-1}}{q'^2+q'^{-2}}, \tag{52}$$

where the last factor on the right is from $\mathscr{P}^{q'}_{j_{12}=0}R_{I,II}(\bar{y}_1-\bar{y}_2)\Upsilon_{II}\mathscr{P}^{q'}_{j_{12}=0}=\mathscr{P}^{q'}_{j_{12}=0}q'^{-\Delta_0\epsilon(\bar{y}_1-\bar{y}_2)}\times(b/a)$ with $b/a\equiv(q'+q'^{-1})/(q'^2+q'^{-2})=([2]_{q'})^2/[4]_{q'}$ and the fact that $\mathscr{P}^{q'}_{j_{12}=0}$ multiplying the vacuum expectation value becomes unit.

Its solution can be easily found and written in the following form:

$$\begin{aligned}&\langle 0_q|\tilde{U}_I(\bar{y}_1,\bar{k}_1)\tilde{U}_{II}(\bar{y}_2,\bar{k}_2)|0_q\rangle\\&=\delta_{\bar{k}_1,\bar{k}_2}A_0(\bar{k}_1)\exp\left\{-\left(\frac{\bar{y}_1-\bar{y}_2}{2\Delta}\right)\ln\left(\frac{q'+q'^{-1}}{q'^2+q'^{-2}}\right)\right.\\&\left.+\left[\left(\frac{|\bar{y}_1-\bar{y}_2|}{2\Delta}\right)+2\sum_{n=1}^{\infty}\theta\left(-\frac{|\bar{y}_1-\bar{y}_2|}{2\Delta}-n\right)\right]\ln(q'^{\Delta_0})\right\}+(1-\delta_{\bar{k}_1\bar{k}_2})A_1(\bar{k}_1,\bar{k}_2),\end{aligned} \tag{53}$$

where A_0 and A_1 are arbitrary functions; $\theta(x)=0,\frac{1}{2},1$ for $x<0,x=0,x>0$, respectively. This expression for the solution is continuous in the $\bar{y}_1-\bar{y}_2>0$ region. For expressing the solution in a function that is continuous the $\bar{y}_1-\bar{y}_2<0$ region, we replace $\Sigma_{n=1}^{\infty}\to\Sigma_{n=0}^{\infty}$ in the square bracket of the above equations.

The correspondence between the BV formalism and integration theory on supermanifolds is established. An explicit formula for the density on a Lagrangian surface in a superspace provided with an odd symplectic structure and a volume form is proposed. © *1996 American Institute of Physics.* [S0022-2488(96)02906-4]

I. INTRODUCTION

In their outstanding works,[1] Batalin and Vilkovisky proposed the most general method for quantizing arbitrary gauge field theories.

During the years it becomes clear that this scheme is very powerful for resolving ghost problems, and moreover it contains a rich geometrical structure. In the paper[2] Witten proposed a program for the construction of String Field Theory in the framework of the Batalin–Vilkovisky formalism (BV formalism) and noted the necessity of its geometrical investigation. The BV formalism indeed uses the geometry of the superspace provided with odd symplectic structure and the volume form. The properties of this geometry and its connection to the BV formalism was investigated, for example, in Refs. 3–6. Particularly in Ref. 5, Schwarz gives the detailed geometrical analysis of the BV formalism in terms of this geometry.

However, some specific aspects of the BV formalism are not completely clarified, such as the geometrical meaning of the initial conditions of the master action; the choice of the gauge fermion and the geometrical reasons for the extending the initial space of fields with ghosts and antighost fields.

In this work we try to analyze some of these questions. For this purpose we study the analogy between the BV scheme and the corresponding constructions in differential geometry.

From the geometrical point of view to the gauge symmetries correspond the vector fields on the space of the classical fields that preserve the action. The partition function, when gauge conditions are fixed, is the integral of a nonlocal density constructed by means of these vector fields over the surface that is defined by gauge conditions. This surface is embedded in the space of the classical fields.

The gauge independence means that this density have to be closed. To make this density local in the BV formalism one have to rise the density and the gauge fixing surface on the extended space: to the gauge fixing surface corresponds the Lagrangian manifold embedded in the phase space of the "fields" and "antifields" ("fields"=classical fields, ghosts), to the closed density corresponds the volume form on this manifold (the exponent of the BV master action), which obeys the BV master equation.[1,5,6]

In the second section we briefly recall the basic formulas of the BV formalism and in the

following[5] give the covariant explicit formula for the volume element on the Lagrangian manifold when it is given by arbitrary functions of the fields and antifields. This formula is related to the multilevel field–antifield formalism with the most general Lagrangian hypergauges.[7]

In the third section we briefly recall the basic constructions of the geometry of the superspace provided with an odd symplectic structure and volume form.[3,5,6] It is this geometry on which the BV formalism is based, and which development on the other hand was highly inspired by this formalism. In particular, we shortly describe the properties of the Δ operator arising in this geometry and the connection between the BV formalism and the Δ-operator nilpotency condition.

In the fourth section we consider the densities[8–11] (the general covariant objects that can be integrated over supersurfaces in the superspace). Following Refs. 9 and 11 we consider a special class of densities—pseudodifferential forms on which the exterior derivative can be defined correctly. Using Baranov–Schwarz (BS) transformations[9] we rise these forms to integration objects on the enlarged space and formulate the condition of closure of these forms in terms of the Δ operator.

In the fifth section, using BS transformations we study the relations between gauge symmetries in field theory and the closed pseudodifferential forms corresponding to the integrand for the partition function of the theory. We study the relations between the closure conditions and the BV master equation.

II. BV FORMALISM

In this section we recall the basic constructions of BV formalism:[1] the integral for the partition function and we rewrite this integral in the case where the Lagrangian manifold is given in a covariant way.

Let $S(\phi)$ be the action of theory with gauge symmetries $\{R^A_b(\phi)\}$:

$$R^A_b(\phi)\,\frac{\delta S(\phi)}{\delta \phi^A}=0. \tag{2.1}$$

We use de Witt condensed notations (index A runs over all the indices and the spatial coordinates of the fields ϕ). Let $\mathscr{E}$ be the space of the fields Φ^A and antifields Φ_{*A}, where $\Phi^A=(\phi^A,c^b,\nu_b,\dots)$ is the space of fields ϕ^A enlarged with the ghosts, Lagrangian multipliers for the constraints, etc., and Φ_{*A} has the parity opposite to Φ^A,

$$p(\Phi_{*A})=p(\Phi^A)+1. \tag{2.2}$$

In the space $\mathscr{E}$ one can define the symplectic structure by the odd Poisson bracket:

$$\{F,G\}=\frac{\delta F}{\delta \Phi^A}\frac{\delta G}{\delta \Phi_{*A}}+\frac{\delta F}{\delta \Phi_{*A}}\frac{\delta G}{\delta \Phi^A}\quad (\text{if } F \text{ is even}), \tag{2.3}$$

and the Δ_0 operator,

$$\Delta_0 F=\frac{\delta^2 F}{\delta \Phi_{*A}\,\delta \Phi^A}. \tag{2.4}$$

The master action $\mathscr{S}$ then can be uniquely defined by the equation

$$\Delta_0 e^{\mathscr{S}}=0\Leftrightarrow \Delta_0\mathscr{S}(\Phi^A,\Phi_{*A})+\tfrac{1}{2}\{\mathscr{S}(\Phi^A,\Phi_{*A}),\mathscr{S}(\Phi^A,\Phi_{*A})\}=0, \tag{2.5a}$$

and the initial conditions:

$$\mathscr{S}(\Phi^A,\Phi_{*A})=S(\phi)+c^b R^A_b\phi_{*A}+\cdots, \tag{2.5b}$$

where dots means terms containing ghosts and antifields of higher degrees.

If

$$[\mathbf{R}_a, \mathbf{R}_b] = t_{ab}^c \mathbf{R}_c + E_{ab}^{[AB]} \mathscr{F}_B,$$

where $\mathscr{F}_A$ are the equations of motion $[\mathscr{F}_A = \delta S(\phi)/\partial \phi^A]$, then

$$\mathscr{S}(\Phi^A, \Phi_{*A}) = S(\phi) + c^b R_b^A \phi_{*A} + \tfrac{1}{2} t_{ab}^c c^a c^b c_c^* + \tfrac{1}{2} c^a c^b E_{ab}^{CD} \phi_{*C} \phi_{*D} + \cdots . \tag{2.5c}$$

To the gauge conditions

$$f_b = 0, \tag{2.6}$$

corresponds the so-called "gauge fermion:"

$$\Psi = f_b \nu^b, \tag{2.7}$$

which defines the Lagrangian surface Λ in $\mathscr{E}$ by the equations

$$F_A(\Phi, \Phi_*) = 0, \tag{2.8}$$

where

$$F_A = \Phi_{*A} - \frac{\delta \Psi(\Phi)}{\delta \Phi^A} = 0 \tag{2.9}$$

(the surface embedded in the symplectic space is Lagrangian if it has half the dimension of space and the two-form defining the symplectic structure is equal to zero on it). The partition function Z is given by the integral of the master-action exponent over this Lagrangian surface Λ:

$$Z = \int e^{\mathscr{S}(\Phi_A, \Phi^{*A})} \delta\left(\Phi_{*A} - \frac{\delta \Psi(\Phi)}{\delta \Phi^A} \right) \mathscr{D}\Phi^* \, \mathscr{D}\Phi \tag{2.10}$$

(for details see Ref. 1).

The main statement of the BV formalism is that this integral does not depend on the choice of the Lagrangian surface Λ.

Before going into the geometrical analysis of the formula (2.10), we first rewrite it in a more covariant way if the functions F_A that define Λ by the equation (2.8) are arbitrary.

It is easy to see that the surface Λ defined by (2.8) is Lagrangian iff

$$\{F_A, F_B\}|_{F_A = 0} = 0. \tag{2.11}$$

Let us consider the integral:

$$\int e^{\mathscr{S}(\Phi_A, \Phi^{*A})} \sqrt{\mathrm{Ber} \frac{\delta(G^A, F_B)}{\delta(\Phi^A, \Phi_{*A})}} \sqrt{\mathrm{Ber}\{G^{\tilde{A}}, F_B\}} \delta(F) \mathscr{D}\Phi_* \, \mathscr{D}\Phi, \tag{2.12}$$

where G^A are arbitrary functions and $\tilde{A}$ has a parity reversed to A.

One can show that if the functions F_A define the Lagrangian manifold Λ (2.8), then this integral does not depend on the choice of the functions G^A, and it does not depend on the choice of the functions F_A defining Λ. On the other hand, in the case where the functions F_A have the form (2.9) and the functions G^A are equal to Φ^A, it evidently coincides with the BV integral (2.10) (for details see Ref. 12).

III. THE SURVEY OF BV FORMALISM GEOMETRY

The formulas (2.5)–(2.12) of the previous section have the following geometrical meaning (for details see Refs. 3,5,6 and also Ref. 13). In the superspace $E^{(n.n)}$ with the coordinates $z^A=(x^1,\ldots,x^n,\theta^1,\ldots,\theta^n)$, where x^i are even, θ^i odd coordinates one can consider the structure defined by the pair $(dv,\{,\})$, where dv is the volume form and $\{,\}$ the odd nondegenerated Poisson bracket corresponding to the odd symplectic structure. To the structure $(dv,\{,\})$ on $E^{(n.n)}$ corresponds the following geometrical constructions that constitutes the essence of BV formalism geometry.

We define a second-order differential operator on E (so-called Δ operator),

$$\Delta_{dv}f=\frac{1}{2}\operatorname{div}_{dv}\mathbf{D}_f\equiv\frac{1}{2}\frac{\mathscr{L}_{\mathbf{D}_f}dv}{dv}, \tag{3.1}$$

where $\mathbf{D}_f$ is the Hamiltonian vector field corresponding to the function f. This operator is typical for the odd symplectic geometry.[3]

Because of the Darboux theorem we can always choose (at least locally) coordinates $z^A=(x^1,\ldots,x^n,\theta^1,\ldots,\theta^n)$ (so-called Darboux coordinates) in which the symplectic structure and corresponding Poisson bracket take canonical expression:

$$\{f,g\}=\frac{\partial f}{\partial x^i}\frac{\partial g}{\partial\theta^i}+(-1)^{p(f)}\frac{\partial f}{\partial\theta^i}\frac{\partial g}{\partial x^i}. \tag{3.2}$$

If the volume form $dv=\rho(z)d^nx\,d^n\theta$ in Darboux coordinates, then

$$\Delta_{dv}f=\frac{1}{2\rho}(-1)^{p(A)}\frac{\partial}{\partial z^A}(\rho\{z^A,f\})=\frac{1}{2}\{\log\rho,f\}+\frac{\partial^2 f}{\partial x^i\,\partial\theta^i}, \tag{3.3}$$

where $p(A)$ is the parity of the coordinate z^A.

We say that the pair $(dv,\{,\})$ is canonical in the Darboux coordinates $z^A=(x^1,\ldots,x^n,\theta^1,\ldots,\theta^n)$ if $dv=1\cdot d^nx\,d^n\theta$. Then the Δ operator takes the canonical expression:

$$\Delta_0 f=\frac{\partial^2 f}{\partial x^i\,\partial\theta^i}. \tag{3.4}$$

If two Δ operators, Δ_{dv} and $\Delta_{d\tilde{v}}$, correspond to two structures with the different volume forms dv and $d\tilde{v}$ and the same symplectic structure, then it is easy to see using (3.3) that

$$\Delta_{d\tilde{v}}f=\Delta_{dv}f+\tfrac{1}{2}\{\log\lambda,f\}, \tag{3.5}$$

and

$$\Delta^2_{d\tilde{v}}f=\Delta^2_{dv}f+\{\lambda^{-1/2}\Delta_{dv}\lambda^{1/2},f\}, \tag{3.6}$$

where $d\tilde{v}=\lambda dv$.

For a given structure $(dv,\{,\})$ *the following statements are equivalent*:

(i) the operator Δ_{dv} is nilpotent,

$$\Delta^2_{dv}=0; \tag{3.7i}$$

(ii) the function $\rho(z)$ defining the volume form dv in Darboux coordinates obeys the equation

$$\Delta_0\sqrt{\rho}=0; \tag{3.7ii}$$

(iii) there exist Darboux coordinates in which the pair $(dv,\{,\})$ is canonical.

The (iii)⇒(i) is evident, the (i)⇔(ii) immediately follows from (3.6). The (i)⇒(iii) needs a more detailed analysis.

Remark: The structures $(dv,\{,\})$ for which these properties are obeyed are called SP structures.[5] One of us (O.M.K.) wants to note that in Ref. 3 where was first introduced the Δ operator related to the structure $(dv,\{,\})$ for an arbitrary volume form in superspace, the false statement was made that every $(dv,\{,\})$ structure is the SP structure.

The pair $(dv,\{,\})$ generates the invariant volume form dv_Λ on arbitrary Lagrangian manifolds Λ in E—"the square root of the volume form dv" in the following way:[5]

$$dv_\Lambda(e_1,\ldots,e_n)=\sqrt{dv(e_1,\ldots,e_n,f_1,\ldots,f_n)}, \tag{3.8}$$

where $\{e_i\}$ are the vectors tangent to Λ and $\{f_i\}$ are arbitrary vectors, such that

$$w(e_i,f_j)=\delta_{ij}$$

(w is a two-form, which defines the symplectic structure).

In these terms the BV formalism has the following geometrical meaning: We consider in the superspace $\mathcal{E}$ of the fields and antifields the pair $(dv,\{,\})$, where the volume form is defined by the master action:

$$\rho=e^{2\mathcal{S}}, \tag{3.9}$$

and $\{,\}$ is defined by (2.3). Then using (i), (ii), (iii), and comparing formulas (3.7) with formulas (2.3)–(2.5), we see that the master equation is nothing but the condition of nilpotency of the corresponding Δ operator. The partition function is nothing but the integral of the invariant volume form (3.8) on the Lagrangian surface Λ,[5] and Eq. (2.12) is the covariant expression for this volume form.

In the next section we will try to understand these statements from the point of view of integration theory on surfaces.

IV. INTEGRATION OVER SURFACES

In this section we present the basic objects of integration theory on supermanifolds: densities and dual densities.[9–11] We consider the special class of densities on which the exterior differential can be defined correctly—pseudodifferential forms.[8–11] Then we describe the Baranov–Schwarz (BS) representation of the pseudodifferential forms via the function on the superspace associated to the tangent bundle of initial space.[9] Considering the dual construction we show that the closure of the pseudodifferential form in the BS representation is formulated in terms of the Δ operator.

A. Densities

Let Ω be an arbitrary supersurface in the superspace E with coordinates z^a, given by a parametrization $z^a=z^a(\zeta^s)$. The function $L(z^a,\partial z^a/\partial\zeta^s)$ on E is called a density (covariant density), if it satisfies the condition[10]

$$L\left(z^a,\frac{\partial z^a}{\partial\zeta^{s'}}K_s^{s'}\right)=L\left(z^a,\frac{\partial z^a}{\partial\zeta^s}\right)\mathrm{Ber}\,K_s^{s'}, \tag{4.1}$$

where Ber is the superdeterminant of the matrix.

Then the following integral does not depend on the choice of the parametrization of the surface Ω:

$$\Phi_{\Omega}(L)=\int L\left(z^a(\zeta),\frac{\partial z^a(\zeta)}{\partial\zeta^s}\right)d\zeta, \tag{4.2}$$

and correctly defines the functional on the surface Ω corresponding to the density L.

In the bosonic case where there are not odd variables, one can see that if a density L is a linear function of the $\partial z^a(\zeta)/\partial\zeta^s$, then to L corresponds a differential form. The covariant density is closed if it satisfies identically the condition

$$\Phi_{\Omega+\delta\Omega}(L)=\Phi_{\Omega}(L), \tag{4.3}$$

for an arbitrary variation of an arbitrary surface Ω (up to boundary terms).

It is easy to see that

$$\Phi_{\Omega+\delta\Omega}(L)-\Phi_{\Omega}(L)=\mathcal{F}_a(z)\delta z^a, \tag{4.4}$$

where

$$\mathcal{F}_a(z)=\frac{\partial L}{\partial z^a}-(-1)^{p(a)p(s)}\frac{d}{d\zeta^s}\frac{\partial L}{\partial z^a_{,s}}, \tag{4.5}$$

are the left part of the Euler–Lagrange equations of the functional $\Phi(L)$.

B. How to define exterior derivative operator on the densities?

If d is the exterior derivative, then

$$\Phi_{\Omega+\delta\Omega}(L)-\Phi_{\Omega}(L)=\Phi_{\delta V}(dL)\ \ (\text{Stokes theorem}). \tag{4.6}$$

Equation (4.6) put strong restrictions on the class of densities on which the operator d is correctly defined.[11] Comparing (4.4), (4.5), and (4.6), we see that d is correctly defined if $\mathcal{F}_a(z)$ in (4.5) *do not contain the second derivatives of* ζ (for details see Ref. 11):

$$\frac{\partial^2 L}{\partial z^a_{,s}\,\partial z^b_{,t}}=-(-1)^{p(s)p(t)+(p(s)+p(t))p(b)}\frac{\partial^2 L}{\partial z^a_{,t}\,\partial z^b_{,s}}. \tag{4.7}$$

In this case dL defined by (4.6) does not depend on the second derivatives and

$$d^2=0. \tag{4.8}$$

The densities, which obey the conditions (4.7) are called pseudodifferential forms.

In the bosonic case from (4.7) follows that the density is a linear function of the variables $\partial z^a(\zeta)/\partial\zeta^s$, i.e. the exterior derivation can be defined only on the densities that correspond to the differential forms. In the supercase in general from (4.7) linearity conditions do not follow—the differential forms in the superspace are not in general integration objects over supersurfaces. It is the pseudodifferential forms that take their place as integration objects obeying Stokes theorem[8–11]).

To obtain the pseudodifferential forms, Baranov and Schwarz in Ref. 9 suggested the following procedure, which seems very natural in the spirit of a ghost technique:

Let STE be the superspace associated to the tangent bundle TE of the superspace E and (z^a,z^{*a}) its (local) coordinates. The coordinates z^{*a} transform from map to map like dz^a, and their parity is reversed: $p(z^{*a})=p(z^a)+1$. Then to an arbitrary function $W(z^a,z^{*a})$ on STE corresponds the density:

$$L_W = L\left(z^a, \frac{\partial z^a}{\partial \zeta^s}\right) = \int W\left(z^a, \frac{\partial z^a}{\partial \zeta^s}\,\nu^s\right) d\nu, \tag{4.9}$$

where ν^s has the reversed parity:

$$p(\nu^s) = p(\zeta^s) + 1. \tag{4.10}$$

It is easy to see using (4.10) that (4.9) obeys Eqs. (4.1) and (4.7) so that Eq. (4.9) indeed defines a density that is a pseudodifferential form. We say that the function W is the BS representation of the pseudodifferential form L_W.

A simple calculation shows that in the BS representation the exterior differentiation operator has the following expression:

$$\hat{d} = (-1)^{p(a)} z^{*a} \frac{\partial}{\partial z^a}, \quad (d(L_W) = L_{\hat{d}W}). \tag{4.11}$$

C. Dual densities

Consider now the dual constructions.

Let E be the superspace, and the volume form $dv = \rho(z)dz$ is defined on it.

Let Ω be an arbitrary supersurface in the superspace E with coordinates z^a, given not by the parametrization $z^a = z^a(\zeta^s)$ but by the equations

$$f^\alpha(z) = 0. \tag{4.12}$$

The function $\tilde{L} = \tilde{L}(z^a, \partial f^\alpha / \partial z^a)$ is called a D density (dual density) if it is satisfied to the condition

$$\tilde{L}\left(z^a, \frac{\partial f^\alpha(z)}{\partial z^a}\,\eta^\beta_\alpha\right) = \tilde{L}\left(z^a, \frac{\partial f^\alpha(z)}{\partial z^a}\right) \mathrm{Ber}\ \eta^\beta_\alpha. \tag{4.13}$$

Then the following integral does not depend on the choice of the equations (4.12) that define the surface Ω:

$$\Phi_\Omega(\tilde{L}) = \int \tilde{L}\left(z^a, \frac{\partial f^\alpha(z)}{\partial z^a}\right) \delta(f^\alpha(z)) dv, \tag{4.14}$$

and correctly defines the functional on the surface Ω corresponding to the D density $\tilde{L}$.

The D density $\tilde{L}$ corresponds to the density $L(\tilde{L} \to L)$ if for the arbitrary surface Ω the functionals (4.2) and (4.14) coincide (for details see Ref. 10).

[For example, the integrand in (2.12) is a D density that corresponds to the density (3.8).]

The D density is closed, if it satisfies the condition (4.3) (where we replace $\tilde{L} \to L$).

One can obtain the dual densities corresponding to pseudodifferential forms (such densities are called pseudointegral forms) by the procedure dual to the Baranov–Schwarz one.

Let ST^*E be the superspace associated to the cotangent bundle T^*E of the superspace E and (z^a, z^*_a) its (local) coordinates. The coordinates z^*_a transform from map to map like $\partial/\partial z^a$, and their parity is reversed: $p(z^*_a) = p(z^a) + 1$. Then to an arbitrary function $W(z^a, z^*_a)$ on ST^*E corresponds the D density—pseudointegral form:

$$\tilde{L}_W = \tilde{L}\left(z^a, \frac{\partial f^\alpha}{\partial z^a}\right) = \int W\left(z^a, \frac{\partial f^\alpha}{\partial z^a}\,\nu_\alpha\right) d\nu, \tag{4.15a}$$

where ν^α have the reversed parity like in (4.10):

$$p(\nu^\alpha)=p(f^\alpha)+1.$$

The functional (4.14) can be expressed in terms of the function W in the following way:

$$\Phi_\Omega(\widetilde{L})=\int \rho(z)W(z,z^*)\delta\left(z_a^*-\frac{\partial f^\alpha}{\partial z^a}\nu_\alpha\right)\delta(f^a)dz\ dz^*\ d\nu. \tag{4.15b}$$

A straightforward calculation shows that the operator of exterior differentiation $\widehat{\widetilde{d}}$ in the BS representation of the pseudointegral forms has the following expression:

$$\widehat{\widetilde{d}}=\frac{1}{\rho}\frac{\partial\rho}{\partial z^a}\frac{\partial}{\partial z_a^*}+\frac{\partial^2}{\partial z^a\ \partial z_a^*}. \tag{4.16}$$

(If $\widetilde{L}=\widetilde{L}_W\to L$ then $\widetilde{L}'=\widetilde{L}_{\widetilde{d}W}\to dL$.)

Comparing the equations (4.16) and (3.3), we see that on the superspace ST^*E it is natural to consider the structure $(d\hat{v},\{,\})$ (see Sec. III), where $\{,\}$ is the canonical odd symplectic structure on ST^*E generated by the relations

$$\{z^a,z_b\}=\{z^{*a},z_b^*\}=0,\quad \{z^a,z_b^*\}=(-1)^{p(a)}\delta_b^a, \tag{4.17}$$

and the volume form

$$d\hat{v}=\rho^2(z^1\cdots z^n)dz^1\cdots dz^n\ dz_1^*\cdots dz_n^*. \tag{4.18}$$

[One can note that (4.18) is in the accordance with (3.8). The space E with volume form $dv=\rho\ dz^1\cdots dz^n$ is evidently the Lagrangian surface in ST^*E with volume form (4.18)].

Comparing (4.16) and (3.3), we see that to the operator of the exterior differentiation corresponds the Δ operator:

$$\widehat{\widetilde{d}}=\Delta_{d\hat{v}} \tag{4.19a}$$

and the condition of closure of the dual density $\widetilde{L}_W$ in the BS representation is

$$\Delta_{d\hat{v}}W=0, \tag{4.19b}$$

where $d\hat{v}$ is defined by (4.18) and $\Delta_{d\hat{v}}$ by (3.3). This operator in this case is nilpotent because it corresponds to exterior differentiation operator. [Independently from (4.16) and (4.8), it follows from (4.18) and (3.7ii) or from (4.18) and (3.7iii) because $d\hat{v}$ "depends" on the half of the variables of the superspace ST^*E.]

V. THE CLOSED DENSITIES AND THE BV FORMALISM GEOMETRY

In this section we consider two examples of the previous constructions, comparing them with the constructions of Secs. II, III, IV. We check connections between the gauge symmetries of the theory, the densities that are integrand in the partition function after eliminating gauge degrees of freedom, and volume forms obeying the BV master equation.

Example 1: Let $R^a(z)(\partial/\partial z^a)$ be an even vector field on the superspace E with coordinates $(z^1,\ldots,z^n)$ and with volume form $dv=\rho(z)dz^1\cdots dz^n$. To this vector field corresponds the D density

$$\widetilde{L}=R^a(z^a)\frac{\partial f}{\partial z^a}. \tag{5.1}$$

One can define the functional on the surfaces of codimension (1.0) corresponding to the density (5.1):

$$\Phi_{\Omega}(\widetilde{L})=\int \widetilde{L}\left(z^a,\frac{\partial f(z)}{\partial z^a}\right)\delta(f(z))dv=\int R^a(z)\,\frac{\partial f(z)}{\partial z^a}\,\delta(f(z))dv, \tag{5.2}$$

where $f=0$ is the equation that defines the surface Ω (f is an even function). This functional is nothing but the well-known formula for the flux of the vector field through the surface Ω. It is evident that the density $\widetilde{L}$ in (5.1) is a pseudointegral form. To this density corresponds the function (4.15),

$$W=(-1)^{p(a)}R^a(z)z_a^*, \tag{5.3}$$

on ST^*E ($\widetilde{L}=\widetilde{L}_W$). The condition of closure of the density (5.1) is the Gauss formula:

$$\mathrm{div}_{dv}\,\mathbf{R}=\frac{1}{\rho}\,(-1)^a\,\frac{\partial(\rho R^a)}{\partial z^a}=0. \tag{5.4}$$

In BS representation it is [(4.18), (4.19)]

$$\Delta_{d\hat{v}}W=0 \quad [d\hat{v}=\rho^2(z)dz^1\cdots dz^n). \tag{5.5}$$

We can consider this example as a toy example of field theory.

Let a space E be the space of fields configurations ($z^a\to\varphi^a$) Let $R^a(z)(\partial/\partial z^a)$ be the "gauge" symmetry of the action $S(z)$ [compare with (2.1)]:

$$R^a(z)\,\frac{\partial S(z)}{\partial z^a}=0, \tag{5.6}$$

and this symmetry preserves the canonical volume form:

$$(-1)^{p(a)}\,\frac{\partial R^a}{\partial z^a}=0. \tag{5.7}$$

If we put

$$\rho=e^S, \tag{5.8}$$

then we see that the functional (5.2) corresponding to the density (5.1) constructed via the "gauge symmetry" $\mathbf{R}$ is the partition function of the theory with the action S after eliminating the "gauge" degrees of freedom corresponding to the symmetry $\mathbf{R}$. From (5.6)–(5.8) follow (5.4), (5.5); hence (5.1) is closed and (5.2) is "gauge" independent. Now we consider the more realistic example.

Example 2: Let

$$\left\{\mathbf{R}_\alpha=R^a_\alpha(z)\,\frac{\partial}{\partial z^a}\right\} \quad (\alpha=1,\ldots,m) \tag{5.9}$$

be the collection of the vector fields on the superspace E, with coordinates $(z^1,\ldots,z^n)$ and with volume form

$$dv=\rho(z)dz^1\cdots dz^n. \tag{5.10}$$

To (5.9) corresponds D density,

$$\widetilde{L}=\mathrm{Ber}\left(R^a_\alpha(z)\,\frac{\partial f^\beta}{\partial z^a}\right) \tag{5.11}$$

[the condition (4.13) is evidently satisfied]. One can consider the functional:

$$\Phi_\Omega(\widetilde{L})=\int \mathrm{Ber}\left(R^a_\alpha(z)\,\frac{\partial f^\beta}{\partial z^a}\right)\delta(f^\alpha)dv, \tag{5.12}$$

where Ω is the surface defined by the equations

$$f^\alpha=0.$$

[In the usual (not super)case, (5.12) can be considered as the flux of the polyvectorial field $\mathbf{R}_1\wedge\cdots\wedge\mathbf{R}_m$ through the surface Ω.]

One can see that $\widetilde{L}$ in (5.11) is the pseudointegral form $\widetilde{L}_W$, where W BS representation of this density can be defined by the following formal relation:

$$W=\int e^{c^\alpha R^a_\alpha(z)z^*_a}\,dc, \tag{5.13}$$

where we introduce additional variables (ghosts) c^α $[p(c^\alpha)=p(\nu^\alpha)]$. [(5.13) is correct if all the symmetries $\mathbf{R}_\alpha$ are even.]

Let the equations (5.6), (5.7) be satisfied for all $\mathbf{R}_\alpha$—these vector fields being the gauge symmetries of the theory with the action S. Again as in Example 1 we consider as volume form the exponent of the action (5.8). Is the density (5.11) closed in this case?

It is easy to see that

$$R^a(z)\,\frac{\partial S(z)}{\partial z^a}=0\Rightarrow[\mathbf{R}_\alpha,\mathbf{R}_\beta]=t^\gamma_{\alpha\beta}\mathbf{R}_c+E^{[ab]}_{\alpha\beta}\,\frac{\partial S(z)}{\partial z^b}. \tag{5.14}$$

To check the relation with the BV formalism, we consider instead superspace E the superspace E^e enlarged with the additional coordinates c^α. [The coordinates of E^e are $z^A=(z^a,c^\alpha)$.] The volume forms dv on E (5.10) and $d\hat{v}$ on ST^*E [see (4.18)] and the symplectic structure (4.17) are naturally prolongated on E^e and ST^*E^e.

Using (4.15a), (4.15b), and (5.13), we rewrite (5.12) as the integral over the space T^*SE^e:

$$\Phi_\Omega(\widetilde{L})=\int e^S e^{c^\alpha R^a_\alpha(z)z^*_a}\,dc\;\delta\left(z^*_a-\frac{\partial f^\alpha}{\partial z^a}\,\nu_\alpha\right)\delta(f^\alpha)dz\;dz^*\;dv \tag{5.15}$$

$$=\int e^S W^e(z^A,z^*_A)\,\delta\left(z^*_A-\frac{\partial f^\alpha}{\partial z^A}\,\nu_\alpha\right)\delta(f^\alpha)dz\;dz^*\;dv, \tag{5.16}$$

where

$$W^e(z^A,z^*_A)=e^{c^\alpha R^a_\alpha(z)z^*_a}, \tag{5.17}$$

is the BS representation of the pseudointegral form in ST^*E^e. Using (4.19), we can check its closure.

[(5.15), (5.16) is the partition function of the theory obtained after performing the Fadeev–Popov trick.]

Let

$$\Delta_{d\hat{v}} W^e = \Delta_{d\hat{v}} e^{c^\alpha R^a_\alpha(z) z^*_a} = 0, \tag{5.18}$$

be satisfied. The condition (5.18) means that not only the function W on ST^*E corresponds to the closed density on E [i.e., the partition function (5.15) is gauge invariant], but the function W^e on ST^*E^e corresponds to the closed density on E^e as well. In this case, from (3.6) and (3.7), it follows that the Δ operator corresponding to the volume form,

$$d\tilde{v} = (W^e)^2 \cdot d\hat{v}, \tag{5.19}$$

is nilpotent, as well as the Δ operator corresponding to the volume form (5.8). Now from (3.7) follows that the master action $\mathscr{S}$ related with $d\tilde{v}$ in the same way as S is related with dv in (5.8):

$$\mathscr{S} = S + c^\alpha R^a_\alpha z^*_a, \quad (\tilde{\rho} = e^{\mathscr{S}}), \tag{5.20}$$

obeys the master equation. So in the case where (5.18) holds, starting from gauge symmetries we constructed the closed density (5.12), (5.13), interpreting the volume form as the exponent of the action. The corresponding functional (5.12) is the partition function. Localizing this density in the space enlarged with the ghosts we came to the volume form (exponent of the master action) that obeys the master action.

In the general case the density (5.11) *is not closed* and the partition function (5.12), (5.16) is not gauge invariant.

Even in the case where the algebra of the symmetries is closed,

$$t^\gamma_{\alpha\beta} = \text{const} \quad \text{and} \quad E^{[ab]}_{\alpha\beta} \equiv 0, \tag{5.21}$$

the application of the Δ operator (4.19) to (5.17) and (5.13) give us

$$\Delta_{d\hat{v}} W^e = \Delta_{d\hat{v}} e^{c^\alpha R^a_\alpha(z) z^*_a}\, dc = \frac{1}{2}\, c^\alpha c^\beta \left(t^\gamma_{\alpha\beta} R^a_\gamma(z) + E^{[ab]}_{\alpha\beta} \frac{\partial S(z)}{\partial z^b} \right) z^*_a e^{c^\alpha R^a_\alpha(z) z^*_a}\, dc \tag{5.22}$$

and

$$\Delta_{d\hat{v}} W = \Delta_{d\hat{v}} \int e^{c^\alpha R^a_\alpha(z) z^*_a}\, dc = \int c^\alpha c^\beta \left(t^\gamma_{\alpha\beta} R^a_\gamma(z) + E^{[ab]}_{\alpha\beta} \frac{\partial S(z)}{\partial z^b} \right) z^*_a e^{c^\alpha R^a_\alpha(z) z^*_a}\, dc \tag{5.23}$$

In particular, it is easy to see from (5.22) that if the algebra of the symmetries is Abelian we come to (5.18).

If, for example, the symmetries are even and they form the closed unimodular algebra ($E^{[ab]}_{\alpha\beta} = 0$, $t^\gamma_{\alpha\beta} = \text{const}$ and $\Sigma_\alpha t^\alpha_{\alpha,\beta} = 0$), then the right-hand side of (5.23) is vanishing, so the function W corresponds to closed density in E (i.e., the partition function is gauge invariant). But the function W^e in (5.22) does not correspond to closed density in E^e. To close it in this case, one has to consider in the space ST^*E^e the function

$$W'^e(z^A, z^*_A) = e^{c^\alpha R^a_\alpha(z) z^*_a + (1/2) t^\gamma_{\alpha\beta} c^\alpha c^\beta c^*_\gamma},$$

which corresponds to a closed density in E^e. So the corresponding volume form and the master action,

$$\mathscr{S} = S + c^\alpha R^a_\alpha z^*_a + \tfrac{1}{2} t^\gamma_{\alpha\beta} c^\alpha c^\beta c^*_\gamma,$$

obey the master equation [compare with (2.5b)].

In the general case the density (5.11), (5.13) plays the role of initial conditions for constructing the closed density in enlarged space—i.e., the volume form (the exponent of the master action) obeying (3.7) (for details see Ref. 12).

BRST quantization of gauge theory in noncommutative geometry: Matrix derivative approach

Chang-Yeong Lee and Dae Sung Hwang
Department of Physics, Sejong University, Seoul 133-747, Korea

Yuval Ne'eman[a)]
Wolfson Distinguished Chair of Theoretical Physics, Raymond and Beverly Sackler Faculty of Exact Sciences, Tel Aviv University, Tel Aviv 69978, Israel

(Received 23 January 1996; accepted for publication 25 March 1996)

The Becchi–Rouet–Stora–Tyutin (BRST) quantization of a gauge theory in noncommutative geometry is carried out in the "matrix derivative" approach. BRST/anti-BRST transformation rules are obtained by applying the horizontality condition, in the superconnection formalism. A BRST/anti-BRST invariant quantum action is then constructed, using an adaptation of the method devised by Baulieu and Thierry-Mieg for the Yang–Mills case. The resulting quantum action turns out to be the same as that of a gauge theory in the 't Hooft gauge with spontaneously broken symmetry. Our result shows that only the even part of the supergroup acts as a gauge symmetry, while the odd part effectively provides a global symmetry. We treat the general formalism first, then work out the SU(2/1) and SU(2/2) cases explicitly. © *1996 American Institute of Physics.* [S0022-2488(96)02907-6]

I. INTRODUCTION

The Higgs mechanism makes it possible to give masses to gauge bosons, while preserving the gauge symmetry. In this construction, some of the original scalar particle fields "mutate" into the longitudinal components of the (now massive) gauge bosons. This fact may reflect the existence of an underlying structure, in which the gauge bosons and the original scalar particles belong to the same multiplet of a larger group. It is, therefore, natural to search for such a larger symmetry group and a suitable multiplet. As a matter of fact, this idea was implemented many years ago, using the supergroup SU(2/1);[1] it was also shown that this use of a supergroup could be extended to a large class of spontaneously broken symmetries.[2] More recently, the idea has further mathematically evolved within the *superconnection* construct.[3–6]

Another recent advance in mathematical physics has consisted[7] in Connes' *noncommutative geometry*. In this formalism, the Dirac K cycle on a star algebra acting on a Hilbert space, plays an important role, with possible applications to particle physics. Connes and Lott[8] then showed in particular that the *standard model* could be obtained in noncommutative geometry, as a gauge theory with a built-in spontaneous symmetry breakdown mechanism. The base space is the product of space–time by a set of two points (L, R), i.e., two disconnected $M_L \oplus M_R$. The gauge group is in both SU(2)×U(1), with different fiber representations. The scalar connection arises when parallel transport involves moving between the two manifolds (together with a matrix derivative) acting on the combined Hilbert spaces in the associated fiber. The Connes–Lott work has been further extended to GUT (grand unified theories),[9] to gravity,[10] and to supersymmetric theories.[11]

Soon after the work of Connes and Lott, Coquereaux and other workers[12,13] showed that the Connes–Lott approach is equivalent to a theory based on the superconnection concept,[5,14] rediscovering SU(2/1) in the process. The above joint embedding of the SU(2)×U(1) representation matrices for the lepton or quark $L \oplus R$ combined Hilbert spaces precisely reproduces the SU(2/1) matrices. In the Coquereaux *et al.*'s formulation, a Z_2 graded space of matrix-valued forms is

[a)]Also on leave from the Center for Particle Physics, University of Texas, Austin, Texas 78712.

constructed, with a generalized derivative; 0-form and 1-form fields together represent a superconnection. The generalized derivative consists of the usual Cartan exterior differential operator, raising the form degree by one unit and thus also changing its Grassmann grading (which we denote as "w grading," i.e., **d** has odd w grading) plus a graded *discrete* operator consisting in a (graded) commutator with a constant matrix and satisfying certain algebraic conditions (including odd grading in a supergroup's generating superalgebra, "g-odd" in our nomenclature). This graded commutator (or supercommutator) with a constant matrix is the *matrix derivative*.[13] We shall denote the Coquereaux *et al.* approach as *the matrix derivative* approach.

The equivalence between the Connes–Lott and Coquereaux *et al.* approaches has been stressed by Scheck and collaborators.[15] In both approaches, the 0-form scalar field is interpreted geometrically as an object interconnecting a two-sheeted world, whereas the 1-form field plays the usual role of a gauge field. The end product is equivalent to an extension of the internal supersymmetry method in its superconnection formulation, completing, as we shall see, its geometric generation of a spontaneous symmetry breakdown mode for a local gauge symmetry.

We have recently quantized the SU(2/1) electroweak theory in the superconnection formalism.[16] In the present paper we treat the quantization of the noncommutative geometry version of this "supergauge theory," by adjoining the matrix derivative approach to the superconnection formulation. Actually, this formulation goes beyond the internal supersymmetry method in one aspect, namely the emergence of the *negative squared mass* term for the scalar (Higgs) field from the geometry; in our previous treatment, most terms in the spontaneous symmetry breakdown Lagrangian emerged geometrically, namely (aside from the usual Yang–Mills term) the "free" Higgs field Lagrangian plus its interaction with the gauge bosons—and the quartic Higgs field potential; the exception, which had to be put in "by hand" (and thus also broke the symmetry explicitly) was this negative squared mass term, which is now provided by the matrix derivative.

We obtain the Becchi–Rouet–Stora–Tyutin (BRST)/anti-BRST transformation rules of the theory, applying our *horizontality* condition, extending Thierry-Mieg's ansatz.[6,17,18] We construct the quantum action by adapting the Baulieu/Thierry-Mieg method[19] for the Yang–Mills theory.

There are two important features deriving from our result. The first is the fact that we obtain the most appropriate gauge condition for a spontaneously broken gauge theory with scalar field, the 't Hooft gauge,[20,21] simply by adapting the method of Ref. 19, which would give the Landau gauge for the unbroken Yang–Mills theory, to the noncommutative geometry framework. The other relates to the physical content of a gauge theory in the noncommutative setting. Our quantization reveals that only the even part of the supergroup indeed acts as a gauge symmetry; the odd part simply produces a global symmetry. The resulting BRST transformation rules for the fields are thus the same as those of the spontaneously broken gauge theory with a Higgs mechanism, except that the scalar field transformation rule is changed by the addition of a constant shift (a vacuum shift), due to the action of the matrix derivative, thereby implementing geometrically the triggering of the spontaneous breakdown. Other fields are not affected by the appearance of the matrix derivative.

In Sec. II, we study the BRST quantization in the matrix derivative approach for the general case. In Sec. III, we treat the SU(2/1) gauge theory, effectively an algebraically constrained standard model SU(2)×U(1) gauge theory of the electroweak interaction. In Sec. IV, we consider an SU(2/2) gauge theory, which reduces to the spontaneously broken symmetry of an SU(2) ×SU(2) σ model. Section V contains a discussion and conclusions.

II. BRST/ANTI-BRST SYMMETRY AND QUANTUM ACTION

In the matrix derivative approach of a noncommutative geometrical gauge theory, the 0-form scalar field and 1-form gauge field together form a superconnection, with w-odd forms in the g-even part and w-even forms in the g-odd part of the supergroup. We write the superconnection $\mathscr{T}$ as

$$\mathcal{J}=\mathcal{J}_{\rm ev}+\mathcal{J}_{\rm od}=\begin{pmatrix}\omega_0 & 0\\ 0 & \omega_1\end{pmatrix}+\begin{pmatrix}0 & L_{01}\\ L_{10} & 0\end{pmatrix}. \tag{1}$$

The overall Z_2 grading is given by the sum of the supermatrix grading (Z_2 "g" grading) and the differential form grading (Z_2 "w" grading). The total grading of the superconnection is therefore odd, in this Z_2 graded space.[16] Multiplication in this superspace is given by[5,12]

$$(h\otimes W)\cdot(h'\otimes W')=(-1)^{|W||h'|}(hh')\otimes(WW'), \tag{2}$$

where W, W' are differential forms of fixed Grassmannian Z_2 w gradings $|W|$, $|W'|$, and h, h' are supermatrices of fixed Z_2 g grading $|h|$, $|h'|$. With this convention, we obtain the product rule for any two elements in our total Z_2 graded space, assuming A, B, C, D to be matrix-valued differential forms, which have fixed Z_2 w gradings of 0 or 1, depending on whether they are even or odd forms, respectively,[5,12]

$$\begin{pmatrix}A & B\\ C & D\end{pmatrix}\cdot\begin{pmatrix}A' & B'\\ C' & D'\end{pmatrix}=\begin{pmatrix}A\wedge A'+(-1)^{|B|}B\wedge C' & (-1)^{|A|}A\wedge B'+B\wedge D'\\ C\wedge A'+(-1)^{|D|}D\wedge C' & (-1)^{|C|}C\wedge B'+D\wedge D'\end{pmatrix}. \tag{3}$$

Once the superconnection is given, the supercurvature $\mathcal{F}_t$ is defined in the usual manner, with the generalized derivative $\mathbf{d}_t$, consisting of the usual 1-form differential operator $\mathbf{d}$ and the *matrix derivative* $\mathbf{d}_M$:[12,13]

$$\mathcal{F}_t=\mathbf{d}_t\mathcal{J}+\mathcal{J}\cdot\mathcal{J}, \tag{4}$$

$$\mathbf{d}_t=\mathbf{d}+\mathbf{d}_M, \tag{5}$$

$$\mathbf{d}=\begin{pmatrix}d & 0\\ 0 & d\end{pmatrix},\quad \text{where } d=1\otimes dx^\mu\frac{\partial}{\partial x^\mu}. \tag{6}$$

The matrix derivative is given by

$$\mathbf{d}_M=i[\,\eta,\quad]_\pm,\quad \text{where}\quad \eta=\begin{pmatrix}0 & \zeta\\ \bar{\zeta} & 0\end{pmatrix}. \tag{7}$$

Here ζ and $\bar{\zeta}$ are constant matrices of zero forms, satisfying

$$\bar{\zeta}\zeta=\zeta\bar{\zeta}\propto 1, \tag{8}$$

so that the matrix derivative satisfies the nilpotency condition, $\mathbf{d}_M^2=0$. Note that the total grading of the matrix derivative $\mathbf{d}_M$ is odd. Thus the matrix derivative is a supercommutator, i.e., it acts as a commutator for objects of even total grading and as an anticommutator for objects of odd total grading, where by "total," we mean the product of the gradings of "g" and "w."

We now write the classical action of the gauge theory in noncommutative geometry as

$$\mathcal{S}_{\rm cl}=-\frac{1}{4}\int \mathrm{Tr}\,\mathcal{F}_t^*\cdot\mathcal{F}_t, \tag{9}$$

where * denotes taking the Hermitian conjugate for supermatrices and taking the Hodge dual for differential forms. In order to find the BRST/anti-BRST transformation rules, we use the so-called *horizontality* condition,[3,17–19] which is another description of the Maurer–Cartan equation:

$$\tilde{\mathcal{F}}_t=\mathcal{F}_t, \tag{10}$$

where $\tilde{\mathscr{F}}_t$ is the supercurvature, defined in the extended space of the *doubled* fiber bundle,[16]

$$\tilde{\mathscr{F}}_t=\tilde{\mathbf{d}}_t\tilde{\mathscr{T}}+\tilde{\mathscr{T}}\cdot\tilde{\mathscr{T}}. \tag{11}$$

"Doubling" implies the extension of the base manifold through doubling the fiber, from $\{\mathscr{G}\}$ to $\{\mathscr{G}\}\otimes\{\mathscr{G}\}$, so that we have a gauge fiber coordinate y and its dual $\bar{y}$.[6,17–19] In this extended space, the generalized derivative and superconnection are given by

$$\tilde{\mathbf{d}}_t=\mathbf{d}_t+\mathbf{s}+\bar{\mathbf{s}}, \tag{12}$$

$$\tilde{\mathscr{T}}=\mathscr{T}+\mathscr{C}+\bar{\mathscr{C}}. \tag{13}$$

Here, $\mathbf{s}$ and $\bar{\mathbf{s}}$ are 1-form differential operators acting, respectively, on the coordinates of the fiber and of its dual:

$$\begin{aligned}\mathbf{s}&=\begin{pmatrix} s & 0\\ 0 & s\end{pmatrix},\quad \text{where } s=1\otimes dy^N\frac{\partial}{\partial y^N},\\ \bar{\mathbf{s}}&=\begin{pmatrix} \bar{s} & 0\\ 0 & \bar{s}\end{pmatrix},\quad \text{where } \bar{s}=1\otimes d\bar{y}^M\frac{\partial}{\partial \bar{y}^M}.\end{aligned} \tag{14}$$

C and $\bar{C}$ are obtained from $\mathscr{T}$ by replacing dx^μ by dy^N and $d\bar{y}^M$, and represent the ghost and antighost fields, respectively:

$$\begin{aligned}\mathscr{C}&=\begin{pmatrix} c_{0N}\,dy^N & 0\\ 0 & c_{1N}\,dy^N\end{pmatrix}\equiv\begin{pmatrix} c_0 & 0\\ 0 & c_1\end{pmatrix},\\ \bar{\mathscr{C}}&=\begin{pmatrix} \bar{c}_{0M}\,d\bar{y}^M & 0\\ 0 & \bar{c}_{1M}\,d\bar{y}^M\end{pmatrix}\equiv\begin{pmatrix} \bar{c}_0 & 0\\ 0 & \bar{c}_1\end{pmatrix}.\end{aligned} \tag{15}$$

After applying the horizontality condition we obtain the BRST/anti-BRST transformation rules:

$$\begin{aligned}(dy)^1{:}\,s\mathscr{T}&=-\mathbf{d}_t\mathscr{C}-\mathscr{T}\cdot\mathscr{C}-\mathscr{C}\cdot\mathscr{T},\\ (d\bar{y})^1{:}\,\bar{s}\mathscr{T}&=-\mathbf{d}_t\bar{\mathscr{C}}-\mathscr{T}\cdot\bar{\mathscr{C}}-\bar{\mathscr{C}}\cdot\mathscr{T},\\ (dy)^2{:}\,s\mathscr{C}&=-\mathscr{C}\cdot\mathscr{C},\\ (d\bar{y})^2{:}\,\bar{s}\bar{\mathscr{C}}&=-\bar{\mathscr{C}}\cdot\bar{\mathscr{C}},\\ (dy)^1(d\bar{y})^1{:}\,s\bar{\mathscr{C}}+\bar{s}\mathscr{C}+\mathscr{C}\cdot\bar{\mathscr{C}}+\bar{\mathscr{C}}\cdot\mathscr{C}&=0.\end{aligned} \tag{16}$$

By introducing an auxiliary field $\mathscr{E}$ such that

$$s\bar{\mathscr{C}}\equiv\mathscr{E},\quad i.e.,\quad \begin{pmatrix} s\bar{c}_0 & 0\\ 0 & s\bar{c}_1\end{pmatrix}\equiv\begin{pmatrix} b_0 & 0\\ 0 & b_1\end{pmatrix}, \tag{17}$$

we can fix the remaining BRST/anti-BRST transformation rules,

$$\overline{s}\mathscr{C}=-\mathscr{B}-\mathscr{C}\cdot\overline{\mathscr{C}}-\overline{\mathscr{C}}\cdot\mathscr{C},$$

$$s\mathscr{B}=0, \tag{18}$$

$$\overline{s}\mathscr{B}=-\overline{s}(\mathscr{C}\cdot\overline{\mathscr{C}}+\overline{\mathscr{C}}\cdot\mathscr{C})=-\overline{\mathscr{C}}\cdot\mathscr{B}+\mathscr{B}\cdot\overline{\mathscr{C}}.$$

One can easily check the nilpotency property of the BRST/anti-BRST transformations, $\mathbf{s}^2=\overline{\mathbf{s}}^2=0$, for the above transformation rules (16), (17), and (18).

Decomposing $\mathscr{T}$ into $\mathscr{T}_{\rm ev}+\mathscr{T}_{\rm od}$ as in (1), we can write the even and odd parts of the first two equations in (16) separately as follows, by noting that $\mathbf{d}$, $\mathbf{s}$, and $\overline{\mathbf{s}}$ are even matrices, whose entries are one-form differential operators.

$$\begin{aligned}
\text{Even part}\ :\quad & s\mathscr{T}_{\rm ev}=-\mathbf{d}\mathscr{C}-\mathscr{T}_{\rm ev}\cdot\mathscr{C}-\mathscr{C}\cdot\mathscr{T}_{\rm ev},\\
& \overline{s}\mathscr{T}_{\rm ev}=-\mathbf{d}\overline{\mathscr{C}}-\mathscr{T}_{\rm ev}\cdot\overline{\mathscr{C}}-\overline{\mathscr{C}}\cdot\mathscr{T}_{\rm ev},\\
\text{odd part}\ :\quad & s\mathscr{T}_{\rm od}=-\mathbf{d}_M\mathscr{C}-\mathscr{T}_{\rm od}\cdot\mathscr{C}-\mathscr{C}\cdot\mathscr{T}_{\rm od},\\
& \overline{s}\mathscr{T}_{\rm od}=-\mathbf{d}_M\overline{\mathscr{C}}-\mathscr{T}_{\rm od}\cdot\overline{\mathscr{C}}-\overline{\mathscr{C}}\cdot\mathscr{T}_{\rm od}.
\end{aligned} \tag{19}$$

Note that the even parts are the usual BRST/anti-BRST transformation rules of a one-form gauge field,[19] while the odd parts are those of a matter field, plus the additional terms caused by the matrix derivative. These additional terms represent a translation of the scalar field and correspond to the vacuum shift in the usual Higgs mechanism. The difference, however, is that this is a built-in property of a gauge theory in the noncommutative geometry setting, in contradistinction to the conventional Higgs construction. The system's "ordinary" gauge symmetry is thereby broken explicitly through that geometrical setting.

Adapting the Baulieu/Thierry-Mieg method for a BRST/anti-BRST invariant quantum action, which yields the Landau gauge for the usual Yang–Mills theory,[19] we write the quantum action as

$$\mathscr{S}_Q=-\frac{1}{4}\int \mathrm{Tr}\{\mathscr{F}_t^*\cdot\mathscr{F}_t-\mathbf{s}\overline{\mathbf{s}}(\mathscr{T}^*\cdot\mathscr{T})+\alpha\mathbf{s}(\overline{\mathscr{C}}^*\cdot\mathscr{B})\}, \tag{20}$$

where α is a parameter. Using the transformation rules (16), (17), (18), and (19), we obtain

$$\mathrm{Tr}\{\mathbf{s}\overline{\mathbf{s}}(\mathscr{T}_{\rm ev}^*\cdot\mathscr{T}_{\rm ev})\}=2\,\mathrm{Tr}\{(\mathscr{T}_{\rm ev})^*\cdot(\mathbf{d}\mathscr{B})+(\mathbf{d}\overline{\mathscr{C}})^*\cdot(\mathbf{d}\mathscr{C}+\mathscr{T}_{\rm ev}\cdot\mathscr{C}+\mathscr{C}\cdot\mathscr{T}_{\rm ev})\}, \tag{21}$$

$$\mathrm{Tr}\{\mathbf{s}\overline{\mathbf{s}}(\mathscr{T}_{\rm od}^*\cdot\mathscr{T}_{\rm od})\}=2\,\mathrm{Tr}\{(\mathscr{T}_{\rm od})^*\cdot(\mathbf{d}_M\mathscr{B})+(\mathbf{d}_M\overline{\mathscr{C}})^*\cdot(\mathbf{d}_M\mathscr{C}+\mathscr{T}_{\rm od}\cdot\mathscr{C}+\mathscr{C}\cdot\mathscr{T}_{\rm od})\}, \tag{22}$$

and

$$\mathrm{Tr}\{\alpha\mathbf{s}(\overline{\mathscr{C}}^*\cdot\mathscr{B})\}=\mathrm{Tr}\{\alpha\mathscr{B}^*\cdot\mathscr{B}\}. \tag{23}$$

Thus, the quantum action $\mathscr{S}_Q$ can be written as

$$\begin{aligned}
\mathscr{S}_Q=-\frac{1}{4}\int \mathrm{TR}\{&\mathscr{F}_t^*\cdot\mathscr{F}_t+\alpha\mathscr{B}^*\cdot\mathscr{B}-2(\mathscr{T}_{\rm ev})^*\cdot(\mathbf{d}\mathscr{B})-2(\mathbf{d}\overline{\mathscr{C}})^*\cdot(\mathbf{d}\mathscr{C}+\mathscr{T}_{\rm ev}\cdot\mathscr{C}+\mathscr{C}\cdot\mathscr{T}_{\rm ev})\\
&-2(\mathscr{T}_{\rm od})^*\cdot(\mathbf{d}_M\mathscr{B})-2(\mathbf{d}_M\overline{\mathscr{C}})^*\cdot(\mathbf{d}_M\mathscr{C}+\mathscr{T}_{\rm od}\cdot\mathscr{C}+\mathscr{C}\cdot\mathscr{T}_{\rm od})\}.
\end{aligned} \tag{24}$$

One can check that this quantum action is BRST/anti-BRST invariant.

In the above quantum action (24), the terms with the auxiliary field $\mathscr{B}$ are the gauge fixing terms and give rise to the 't Hooft gauge condition[20,21] as we shall see in the next two sections.

The first term is the classical action, and the remaining terms constitute the kinetic and interaction terms of the ghost fields. In the following two sections we calculate the quantum action (24) for the SU(2/1) and SU(2/2) cases explicitly.

III. BRST QUANTIZATION OF THE SU(2/1) CASE

The generators of SU(2/1) are the same as those of SU(3), namely, the conventional λ matrices, except for t_8, which is given by

$$t_8=\frac{1}{\sqrt{3}}\begin{pmatrix}-1&0&0\\0&-1&0\\0&0&-2\end{pmatrix}, \tag{25}$$

in order to satisfy $S\,\mathrm{Tr}(t_i)=0$. We write the SU(2/1) superconnection as

$$\begin{aligned}&\mathscr{T}=it_iJ_i \quad (i=1,2,\ldots,8)\\&=\mathscr{T}_{\mathrm{ev}}+\mathscr{T}_{\mathrm{od}}=i\begin{pmatrix}\tau_aW_a-\frac{1}{\sqrt{3}}B&0\\0&-\frac{2}{\sqrt{3}}B\end{pmatrix}+i\begin{pmatrix}0&\sqrt{2}\Phi\\\sqrt{2}\Phi^\dagger&0\end{pmatrix},\end{aligned} \tag{26}$$

where we identified the gauge and Higgs fields W_a, B, Φ, and $\Phi^\dagger$ with the components $W_a=J_a$ $(a=1,2,3)$, $B=J_8$, $\Phi=1/\sqrt{2}\binom{J_4-iJ_5}{J_6-iJ_7}$ and $\Phi^\dagger=1/\sqrt{2}\binom{J_4+iJ_5}{J_6+iJ_7}$.

We now introduce the ghost, antighost, and auxiliary fields, in the doubled-fiber bundle space,

$$\begin{aligned}&\mathscr{C}=i\begin{pmatrix}\tau_ac_a-\frac{1}{\sqrt{3}}c_8&0\\0&-\frac{2}{\sqrt{3}}c_8\end{pmatrix},\quad \bar{\mathscr{C}}=i\begin{pmatrix}\tau_a\bar{c}_a-\frac{1}{\sqrt{3}}\bar{c}_8&0\\0&-\frac{2}{\sqrt{3}}\bar{c}_8\end{pmatrix},\\&\mathscr{B}=i\begin{pmatrix}\tau_ab_a-\frac{1}{\sqrt{3}}b_8&0\\0&-\frac{2}{\sqrt{3}}b_8\end{pmatrix}\quad (a=1,2,3).\end{aligned} \tag{27}$$

In order to derive the BRST/anti-BRST transformation rules, we apply Eqs. (16)–(19) of the previous section. In calculating the SU(2/1) case, we encounter the following difficulty. With the 3×3 matrix representation, it is not possible to choose a constant matrix $\eta=\binom{0\ \ \xi}{\zeta\ \ 0}$ for the matrix derivative, satisfying the condition (8), $\bar{\zeta}\zeta=\zeta\bar{\zeta}\propto 1$, which is essential for the nilpotency of the matrix derivative. In order to resolve this difficulty, we first extend all 3×3 matrix representations of fields into 4×4 matrices, simply by adjoining a fourth row and a fourth column, with all components vanishing. We then choose the η matrix in this extended 4×4 matrix representation space, in which it does satisfy the nilpotency condition. This 4×4 η matrix, enables us to perform all calculations involving the η matrix, such as evaluating the supercurvature, etc. After this is done, we project back onto the 3×3 matrix representation space, simply discarding the fourth row and column. Note that this construction reflects the fact that the true fundamental representation of SU(2/1) is four dimensional,[3] reflecting the homomorphism with OSp(2/2) and fitting the internal

quantum numbers for quarks, i.e. $(u_R/u_L, d_L/d_R)$ where the order follows descending weak hypercharges (4/1,1/−2) [in units of (1/3)]. However, for integer charges, the upper state trivializes and disconnects (e.g., the ν_R), and we are left with the three-dimensional representation. As a matter of fact, the procedure we use here also corresponds to the *projective module* method of Connes and Lott.[8] We thus perform the actual calculation with

$$\zeta=\bar{\zeta}=\sqrt{2}k\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}, \quad k:\text{real},$$

and obtain the following BRST/anti-BRST transformation rules,

$$\begin{gathered}
sA_{II}=-dc_{II}-A_{II}c_{II}-c_{II}A_{II},\\
\bar{s}A_{II}=-d\bar{c}_{II}-A_{II}\bar{c}_{II}-\bar{c}_{II}A_{II},\\
sA_I=-dc_I, \quad \bar{s}A_I=-d\bar{c}_I,\\
s\Phi=-c_{II}(\Phi+\xi)-\frac{1}{\sqrt{3}}c_I(\Phi+\xi),\\
\bar{s}\Phi=-\bar{c}_{II}(\Phi+\xi)-\frac{1}{\sqrt{3}}\bar{c}_I(\Phi+\xi),\\
s\Phi^\dagger=(\Phi^\dagger+\xi^\dagger)c_{II}+\frac{1}{\sqrt{3}}(\Phi^\dagger+\xi^\dagger)c_I,\\
\bar{s}\Phi^\dagger=(\Phi^\dagger+\xi^\dagger)\bar{c}_{II}+\frac{1}{\sqrt{3}}(\Phi^\dagger+\xi^\dagger)\bar{c}_I,\\
sc_{II}=-c_{II}c_{II}, \quad \bar{s}\bar{c}_{II}=-\bar{c}_{II}\bar{c}_{II},\\
sc_I=\bar{s}\bar{c}_I=0,\\
s\bar{c}_{II}=b_{II}, \quad \bar{s}c_{II}=-b_{II}-c_{II}\bar{c}_{II}-\bar{c}_{II}c_{II},\\
sb_{II}=0, \quad \bar{s}b_{II}=-\bar{c}_{II}b_{II}+b_{II}\bar{c}_{II},\\
s\bar{c}_I=-\bar{s}c_I=b_I, \quad sb_I=\bar{s}b_I=0,
\end{gathered} \tag{28}$$

where

$$\begin{gathered}
A_{II}=i\tau_a W_a, \quad A_I=iB, \quad c_{II}=i\tau_a c_a, \quad c_I=ic_8,\\
\bar{c}_{II}=i\tau_a\bar{c}_a, \quad \bar{c}_I=i\bar{c}_8, \quad b_{II}=i\tau_a b_a \quad (a=1,2,3), \quad b_I=ib_8,\\
\xi=k\begin{pmatrix}0\\ 1\end{pmatrix}.
\end{gathered} \tag{29}$$

Note that the transformation rules of Φ and $\Phi^\dagger$ correspond to those of the Higgs fields with a shifted vacuum. For the supercurvature we obtain

$$\mathscr{F}_i=\begin{pmatrix} F_W-\frac{1}{\sqrt{3}}F_B-2(\Phi\Phi^\dagger+\xi\Phi^\dagger+\Phi\xi^\dagger) & -i\sqrt{2}\left(D\Phi+\left(i\vec{W}\cdot\vec{\tau}+\frac{i}{\sqrt{3}}B\right)\xi\right) \\ -i\sqrt{2}\left(D\Phi^\dagger-\xi^\dagger\left(i\vec{W}\cdot\vec{\tau}+\frac{i}{\sqrt{3}}B\right)\right) & -\frac{2}{\sqrt{3}}F_B-2(\Phi^\dagger\Phi+\xi^\dagger\Phi+\Phi^\dagger\xi) \end{pmatrix}, \tag{30}$$

where

$$F_W=\tfrac{1}{2}F_{W_{\mu\nu}}\,dx^\mu\wedge dx^\nu=d(i\vec{W}\cdot\vec{\tau})+(i\vec{W}\cdot\vec{\tau})(i\vec{W}\cdot\vec{\tau}),$$

$$F_B=\tfrac{1}{2}F_{B_{\mu\nu}}\,dx^\mu\wedge dx^\nu=d(iB),$$

$$\Phi=\begin{pmatrix}\phi^+\\ \phi^0\end{pmatrix}=\frac{1}{\sqrt{2}}\begin{pmatrix}\phi_3+i\phi_4\\ \phi_1+i\phi_2\end{pmatrix}=\frac{1}{\sqrt{2}}\begin{pmatrix}J_4-iJ_5\\ J_6-J_7\end{pmatrix}, \tag{31}$$

$$D\Phi=(D\Phi)_\mu\,dx^\mu=d\Phi+\left(i\vec{W}\cdot\vec{\tau}+\frac{i}{\sqrt{3}}B\right)\Phi,$$

$$D\Phi^\dagger=(D\Phi^\dagger)_\mu\,dx^\mu=d\Phi^\dagger-\Phi^\dagger\left(i\vec{W}\cdot\vec{\tau}+\frac{i}{\sqrt{3}}B\right).$$

We use $d^4x=dx^0\wedge dx^1\wedge dx^2\wedge dx^3$, $\epsilon_{0123}=1$, and adopt the convention of Ref. 22 for the dual of a differential form in n dimensions, required for (24),

$$*(dx^{i_1}\wedge dx^{i_2}\wedge\cdots\wedge dx^{i_p})=\frac{1}{(n-p)!}\,\epsilon^{i_1i_2\cdots i_p}{}_{i_{p+1}\cdots i_n}dx^{i_{p+1}}\wedge\cdots\wedge dx^{i_n}, \tag{32}$$

satisfying $**\omega_p=(-1)^{p(n-p)}\omega_p$ for a p-form ω_p.

Selecting the metric $g_{\mu\nu}=(-1,+1,+1,+1)$, the first term in (24), the classical action, is given by

$$\begin{aligned}\mathscr{L}_C=&\frac{1}{4}F_{Wa\mu\nu}F_{Wa}^{\mu\nu}+\frac{1}{4}F_{B\mu\nu}F_B^{\mu\nu}-\left(D\Phi^\dagger-\xi^\dagger\left(i\vec{W}\cdot\vec{\tau}+\frac{i}{\sqrt{3}}B\right)\right)_\mu\\ &\times\left(D\Phi+\left(i\vec{W}\cdot\vec{\tau}+\frac{i}{\sqrt{3}}B\right)\xi\right)^\mu-2((\Phi^\dagger+\xi^\dagger)(\Phi+\xi)-\xi^\dagger\xi)^2\\ =&\frac{1}{4}F_{Wa\mu\nu}F_{Wa}^{\mu\nu}+\frac{1}{4}F_{B\mu\nu}F_B^{\mu\nu}-\left(D\Phi^\dagger-ik\left(\sqrt{2}W_-,\frac{2}{\sqrt{3}}Z\right)\right)_\mu\\ &\times\left(D\Phi+ik\begin{pmatrix}\sqrt{2}W_+\\ \frac{2}{\sqrt{3}}Z\end{pmatrix}\right)^\mu-2(\Phi^\dagger\Phi+k(\phi^0-\bar{\phi}^0))^2,\end{aligned} \tag{33}$$

where $W_\pm^\mu=1/\sqrt{2}(W_1^\mu\mp iW_2^\mu)$, $Z^\mu=-(\sqrt{3}/2)W_3^\mu+(1/2)B^\mu$, $A^\mu=(1/2)W_3^\mu+(\sqrt{3}/2)B^\mu$.

In order to see the physical spectrum of the theory, we now write the above expression in the *unitary gauge*, which is given by $\Phi=\binom{0}{(1/\sqrt{2})\chi}$ with real χ.

$$\mathscr{L}_C^{UG}=\frac{1}{4}F_{Wa\mu\nu}F_{Wa}^{\mu\nu}+\frac{1}{4}F_{B\mu\nu}F_B^{\mu\nu}$$
$$\times-\left\{\frac{1}{2}\partial_\mu\chi\,\partial^\mu\chi+g^2W_{+\mu}W_-^\mu\left(\chi+\frac{\sqrt{2}k}{g}\right)^2+\frac{2}{3}g^2Z_\mu Z^\mu\left(\chi+\frac{\sqrt{2}k}{g}\right)^2\right\}$$
$$\times-\frac{1}{2}(g\chi^2+2\sqrt{2}k\chi)^2. \tag{34}$$

The coupling constant g is introduced by scaling the superconnection as $\mathscr{T}\to g\mathscr{T}$. In this unitary gauge we see that only one scalar field remains as a physical (and massive) Higgs field χ, whereas the other three scalars have been "mutated," now providing the longitudinal components of $W_\pm$ and Z. The masses of the massive particles are $M_\chi=2\sqrt{2}k$, $M_W=\sqrt{2}k$, $M_Z=(2\sqrt{2}/\sqrt{3})k$, and we see the relations $M_W^2/M_Z^2=3/4=\cos^2\theta_W$, $M_\chi=2M_W$. We shall return to the latter ratio M_χ/M_W in Sec. V, when discussing possible quantum corrections.

We now write the quantum Lagrangian of (24) as

$$\mathscr{L}_Q=\mathscr{L}_C+\mathscr{L}_1+\mathscr{L}_2, \tag{35}$$

where $\mathscr{L}_C$ is the classical Lagrangian, $\mathscr{L}_1$ stands for the ghost terms, and $\mathscr{L}_2$ for the gauge fixing terms. After some calculations, we obtain $\mathscr{L}_1$,

$$\mathscr{L}_1=\frac{1}{2}\,\mathrm{tr}\left[\partial_\mu\bar{c}_{II}\,D^\mu c_{II}+2\,\partial_\mu\bar{c}_I\,\partial^\mu c_I+\left\{\left(\bar{c}_{II}+\frac{1}{\sqrt{3}}\bar{c}_I\right)\xi(\Phi^\dagger+\xi^\dagger)\left(c_{II}+\frac{1}{\sqrt{3}}c_I\right)\right\}\right.$$
$$\left.+\left\{\xi^\dagger\left(\bar{c}_{II}+\frac{1}{\sqrt{3}}\bar{c}_I\right)\left(c_{II}+\frac{1}{\sqrt{3}}c_I\right)(\Phi+\xi)\right\}\right], \tag{36}$$

where $D^\mu c_{II}=\partial^\mu c_{II}+[A_{II}^\mu,c_{II}]$.

For $\mathscr{L}_2$, we obtain

$$\mathscr{L}_2=\frac{\alpha}{2}\left\{[(b_1)^2+(b_2)^2+(b_Z)^2+(b_A)^2]+\frac{2}{\alpha}\left[b_1(\partial_\mu W_1^\mu-\sqrt{2}k\phi_4)\right.\right.$$
$$\left.\left.+b_2(\partial_\mu W_2^\mu-\sqrt{2}k\phi_3)+b_Z\left(\partial_\mu Z^\mu-\frac{2\sqrt{2}}{\sqrt{3}}k\phi_2\right)+b_A(\partial_\mu A^\mu)\right]\right\}, \tag{37}$$

where $b_Z=-(\sqrt{3}/2)b_3+(1/2)b_8$, $b_A=(1/2)b_3+(\sqrt{3}/2)b_8$. After integrating out the auxiliary fields b_1,b_2,b_Z, and b_A, $\mathscr{L}_2$ becomes

$$\mathscr{L}_2=-\frac{1}{2\alpha}\left\{(\partial_\mu W_1^\mu-\sqrt{2}k\phi_4)^2+(\partial_\mu W_2^\mu-\sqrt{2}k\phi_3)^2+\left(\partial_\mu Z^\mu-\frac{2\sqrt{2}}{\sqrt{3}}k\phi_2\right)^2+(\partial_\mu A^\mu)^2\right\}. \tag{38}$$

This expression clearly shows that we obtain the gauge-fixed quantum Lagrangian of the 't Hooft gauge,[20,21] as we claimed in the previous section:

$$\partial_\mu W_1^\mu-M_W\phi_4=0,$$
$$\partial_\mu W_2^\mu-M_W\phi_3=0, \tag{39}$$

$$\partial_\mu Z^\mu - M_Z \phi_2 = 0,$$

$$\partial_\mu A^\mu = 0.$$

IV. BRST quantization of SU(2/2) case

We now calculate the SU(2/2) case. The generators of SU(2/2) are the same as those of SU(4), except for t_8 and t_{15}, which are replaced by

$$t_8 = \frac{1}{\sqrt{3}} \begin{pmatrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -2 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad t_{15} = \frac{1}{\sqrt{6}} \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 3 \end{pmatrix} \tag{40}$$

to conforming with the supertracelessness of the SU(2/2) generators. The superconnection for the SU(2/2) case can be written as

$$\mathcal{J} = i t_i J_i \quad (i = 1,2,\ldots,15) = \begin{pmatrix} A_L + \frac{1}{\sqrt{2}} B & i\Phi \\ i\Phi^\dagger & A_R + \frac{1}{\sqrt{2}} B \end{pmatrix}, \tag{41}$$

with one-forms in the even part and zero-forms in the odd part, given as

$$A_L = i\tau_a A_{La}, \quad A_R = i\tau_a A_{Ra}, \quad B = iIY, \quad \Phi = I\phi_0 + i\tau_a \phi_a, \tag{42}$$

where τ_a $(a=1,2,3)$ are Pauli matrices and I is 2×2 identity matrix. A_{La}, A_{Ra}, Y are real, whereas ϕ_0, ϕ_a are complex, the fields being assigned to the components of J's according to

$$A_{La} = J_a \quad (a=1,2,3), \quad A_{R_1} = J_{13}, \quad A_{R_2} = J_{14},$$

$$A_{R_3} = -\frac{1}{\sqrt{3}} (J_8 + \sqrt{2} J_{15}), \quad Y = -\frac{1}{\sqrt{3}} (\sqrt{2} J_8 - J_{15}),$$

$$\phi_0 = \frac{1}{2} [(J_4 - iJ_5) + (J_{11} - iJ_{12})], \quad \phi_1 = -\frac{i}{2} [(J_6 - iJ_7) + (J_9 - iJ_{10})],$$

$$\phi_2 = -\frac{1}{2} [(J_6 - iJ_7) - (J_9 - iJ_{10})], \quad \phi_3 = -\frac{i}{2} [(J_4 - iJ_5) - (J_{11} - iJ_{12})].$$

A_L and A_R are thus the SU(2) gauge fields, B is the U(1) gauge field, and Φ is the complex scalar field (with its four components).

We now introduce the ghost and antighost fields,

$$\mathcal{C} = \begin{pmatrix} c_L & 0 \\ 0 & c_R \end{pmatrix} + \begin{pmatrix} \frac{1}{\sqrt{2}} c_I & 0 \\ 0 & \frac{1}{\sqrt{2}} c_I \end{pmatrix}, \quad \bar{\mathcal{C}} = \begin{pmatrix} \bar{c}_L & 0 \\ 0 & \bar{c}_R \end{pmatrix} + \begin{pmatrix} \frac{1}{\sqrt{2}} \bar{c}_I & 0 \\ 0 & \frac{1}{\sqrt{2}} \bar{c}_I \end{pmatrix}. \tag{43}$$

where $c_L = i\tau_a c_{La}$, $c_R = i\tau_a c_{Ra}$ $(a=1,2,3)$, $c_I = iIc_{Ir}$, with real c_{La}, c_{Ra}, and c_{Ir} and similarly for $\bar{\mathscr{C}}$. $\{c_L, \bar{c}_L\}$ and $\{c_R, \bar{c}_R\}$ are the ghost and antighost fields for the SU(2) gauge fields A_L and A_R, respectively, and $\{c_I, \bar{c}_I\}$ are those of the U(1) gauge field B.

The BRST/anti-BRST transformation rules are obtained from (16)–(19). Choosing

$$\eta = \begin{pmatrix} 0 & \xi \\ \xi^\dagger & 0 \end{pmatrix}, \quad \text{where} \quad \xi = k\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad k;\ \text{real}, \tag{44}$$

we get

$$\begin{aligned}
sA_L &= -dc_L - A_L c_L - c_L A_L, \\
\bar{s}A_L &= -d\bar{c}_L - A_L \bar{c}_L - \bar{c}_L A_L, \\
sA_R &= -dc_R - A_R c_R - c_R A_R, \\
\bar{s}A_R &= -d\bar{c}_R - A_R \bar{c}_R - \bar{c}_R A_R, \\
sB &= -dc_I, \quad \bar{s}B = -d\bar{c}_I, \\
s\Phi &= (\Phi + \xi)c_R - c_L(\Phi + \xi), \\
\bar{s}\Phi &= (\Phi + \xi)\bar{c}_R - \bar{c}_L(\Phi + \xi), \\
s\Phi^\dagger &= (\Phi^\dagger + \xi^\dagger)c_L - c_R(\Phi^\dagger + \xi^\dagger), \\
\bar{s}\Phi^\dagger &= (\Phi^\dagger + \xi^\dagger)\bar{c}_L - \bar{c}_R(\Phi^\dagger + \xi^\dagger), \\
sc_L &= -c_L c_L, \quad \overline{sc}_L = -\bar{c}_L \bar{c}_L, \\
sc_R &= -c_R c_R, \quad \overline{sc}_R = -\bar{c}_R \bar{c}_R, \\
sc_I &= \overline{sc}_I = 0, \\
s\bar{c}_L &= b_L, \quad \bar{s}c_L = -b_L - c_L \bar{c}_L - \bar{c}_L c_L, \\
s\bar{c}_R &= b_R, \quad \bar{s}c_R = -b_R - c_R \bar{c}_R - \bar{c}_R c_R, \\
sb_L &= 0, \quad \bar{s}b_L = -\bar{c}_L + b_L + b_L \bar{c}_L, \\
sb_R &= 0, \quad \bar{s}b_R = -\bar{c}_R b_R + b_R \bar{c}_R, \\
s\bar{c}_I &= -\bar{s}c_I = b_I, \quad sb_I = \bar{s}b_I = 0.
\end{aligned} \tag{45}$$

We have introduced the auxiliary fields

$$\mathscr{B} = \begin{pmatrix} b_L & 0 \\ 0 & b_R \end{pmatrix} + \begin{pmatrix} \frac{1}{\sqrt{2}} b_I & 0 \\ 0 & \frac{1}{\sqrt{2}} b_I \end{pmatrix}$$

with $b_L=i\tau_a b_{La}$, $b_R=i\tau_a b_{Ra}$ $(a=1,2,3)$, and $b_I=iIb_{Ir}$, where b_{La}, b_{Ra}, and b_{Ir} are real. For the supercurvature, we obtain

$$\mathscr{F}_t=\begin{pmatrix} F_L+\frac{1}{\sqrt{2}}F_B-(\Phi\Phi^\dagger+\xi\Phi^\dagger+\Phi\xi^\dagger) & -i(D\Phi+A_L\xi-\xi A_R) \\ -i(D\Phi^\dagger-\xi^\dagger A_L+A_R\xi^\dagger) & F_R+\frac{1}{\sqrt{2}}F_B-(\Phi^\dagger\Phi+\xi^\dagger\Phi+\Phi^\dagger\xi) \end{pmatrix}, \tag{46}$$

where $F_L=dA_L+A_LA_L$, $F_R=dA_R+A_RA_R$, $F_B=dB$, $D\Phi=d\Phi+A_L\Phi-\Phi A_R$, $D\Phi^\dagger=d\Phi^\dagger-\Phi^\dagger A_L+A_R\Phi^\dagger$.

The classical Lagrangian, the first term in (24), is given by[23]

$$\begin{aligned}\mathscr{L}_C=\mathrm{tr}[&\tfrac{1}{4}F_{+\mu\nu}F_+^{\mu\nu}+\tfrac{1}{4}F_{-\mu\nu}F_-^{\mu\nu}+\tfrac{1}{8}F_{B\mu\nu}F_B^{\mu\nu}\\&-\tfrac{1}{2}(D\Phi^\dagger+2kA_-)_\mu(D\Phi-2kA_-)^\mu-\tfrac{1}{2}(\Phi^\dagger\Phi+k(\Phi+\Phi^\dagger))^2],\end{aligned} \tag{47}$$

where $A_\pm$ are, respectively, the vector and axial vector gauge fields, as defined by $A_\pm=(1/2)(\pm A_L+A_R)=i\tau_a A_{\pm a}$, and $F_+^{\mu\nu}=\partial^\mu A_+^\nu-\partial^\nu A_+^\mu+[A_+^\mu,A_+^\nu]+[A_-^\mu,A_-^\nu]$, $F_-^\mu=\partial^\mu A_-^\nu-\partial^\nu A_-^\mu+[A_+^\mu,A_-^\nu]+[A_-^\mu,A_+^\nu]$. The above expression tells us that the three axial vector gauge fields A_{-a} have acquired the mass $2k$, whereas the three vector gauge fields A_{+a} and the U(1) gauge field Y remain massless.

For the quantum Lagrangian $\mathscr{L}_Q$, we again write, as in (35),

$$\mathscr{L}_Q=\mathscr{L}_C+\mathscr{L}_1+\mathscr{L}_2.$$

The ghost part $\mathscr{L}_1$ is given by

$$\begin{aligned}\mathscr{L}_1=\tfrac{1}{2}\,\mathrm{tr}[&(\partial_\mu\bar{c}_L\,D^\mu c_L+\partial_\mu\bar{c}_R\,D^\mu c_R+\partial_\mu\bar{c}_L\,\partial^\mu c_I)-2k^2(\bar{c}_L-\bar{c}_R)(c_L-c_R)\\&+k(\{(\bar{c}_L-\bar{c}_R)c_R-c_L(\bar{c}_L-\bar{c}_R)\}\Phi^\dagger+\{c_R(\bar{c}_L-\bar{c}_R)-(\bar{c}_L-\bar{c}_R)c_L\}\Phi)],\end{aligned} \tag{48}$$

where $D^\mu c_L=\partial^\mu c_L+[A_L^\mu,c_L]$, $D^\mu c_R=\partial^\mu c_R+[A_R^\mu,c_R]$.

The gauge fixing part $\mathscr{L}_2$ is given by

$$\begin{aligned}\mathscr{L}_2=\alpha\Bigg\{&\left((b_{-a})^2+(b_{+a})^2+\frac{1}{2}(b_{Ir})^2\right)\\&+\frac{2}{\alpha}\left(b_{-a}(\partial_\mu A_{-a}^\mu-2k\varphi_a)+b_{+a}(\partial_\mu A_{+a}^\mu)+\frac{1}{2}b_{Ir}(\partial_\mu Y^\mu)\right)\Bigg\},\end{aligned} \tag{49}$$

where $b_\pm=(1/2)(\pm b_L+b_R)=i\tau_a b_{\pm a}$, $\varphi=(1/2)(\Phi-\Phi^\dagger)=\tau_a\varphi_a$. Integrating out the auxiliary fields $b_\pm$, $\mathscr{L}_2$ becomes

$$\mathscr{L}_2=-\frac{1}{\alpha}\left\{(\partial_\mu A_-^\mu-2k\varphi)^2+(\partial_\mu A_+^\mu)^2+\frac{1}{2}(\partial_\mu Y^\mu)^2\right\}. \tag{50}$$

This expression again displays the quantum Lagrangian in the 't Hooft gauge:

$$\partial_\mu A^\mu_{-a} - M_{A\_}\varphi_a = 0,$$

$$\partial_\mu A^\mu_{+a} = 0, \tag{51}$$

$$\partial_\mu Y^\mu = 0,$$

where $M_{A\_} = 2k$ is used. If we write Φ as $(\sigma + i\vec{\pi}\cdot\vec{\tau}) + i(\eta + \vec{\rho}\cdot\vec{\tau})$ with real $\sigma, \vec{\pi}, \eta, \vec{\rho}$ fields, then φ in $\mathcal{L}_2$ can be identified with $\vec{\pi}$. This is consistent with the fact that the $\vec{\pi}$ fields are gauged away and mutate into the longitudinal components of the axial vector fields $A\_$ in the unitary gauge. This is also related to the fact that the SU(2/2) case corresponds to the gauged SU(2)×SU(2) σ model.[23].

V. CONCLUSION

In the matrix derivative approach, derived from noncommutative geometrical gauge theory and adjoined to internal supersymmetry, in its superconnection version, the vector gauge fields and the scalar fields are combined together, constituting the superconnection. The two sets of fields are thus related as a supermultiplet from the very beginning. This provides for an elegant geometrical realization of the Higgs mechanism. The entire Lagrangian is geometrical, even including the negative mass term for the scalar field, needed to trigger the spontaneous symmetry breakdown for the (g-even) gauge subgroup. That symmetry-breaking quadratic term for the scalar field is provided by the matrix derivative, beyond the unification achieved by the supergroup by itself. Summarizing, the unification is complete, within the limitations set by the broken symmetry actual content. We return to these limitations in our last paragraph.

Another advantage of the formalism touches upon the quantum action, namely in the gauge in which it appears, as a result of the construction. This turns out to be the 't Hooft gauge, most convenient for a spontaneously broken symmetry with Higgs field and suitable for renormalization.[20,21] We obtained this action just by adapting the Baulieu/Thierry-Mieg method,[19] which would yield the Landau gauge for the unbroken Yang–Mills theory, to the matrix derivative approach.

For the calculation of the $\mathcal{F}_t^* \cdot \mathcal{F}_t$ term in the classical and some of the other parts of the quantum Lagrangian we have used the definition of (32) for the dual form. This definition gives the kinetic terms of both the vector and scalar fields automatically in their canonical form, also providing the relation $M_\chi = 2M_W$. Note that this is a classical relationship. Including a quantum correction might modify this result.[24] This mass ratio is also due to the fact that we have only one overall supergauge coupling constant g for the superconnection $\mathcal{F}$ in Sec. III, due to universality. Without the assumption of universality for the supergroup we would have independent couplings for fields corresponding to forms of different degrees—in our case the even and odd parts of the superconnection, i.e., two independent couplings. One might then obtain a different mass ratio for the Higgs and gauge bosons.[25]

Last, we note that only the even part of the supergroup is gauged in the sense of relativistic quantum field theory—even though the entire supergroup is used as a structure group for the theory and provides the geometrical framework for the quantization procedure, including the 't Hooft gauge. As a result, there is no guarantee of nonrenormalization of the theory's couplings beyond those of the g-even gauge subgroup.

A natural extension of coherent state path integrals

Masao Matsumoto[a)]
1-12-32 Kuzuha Asahi, Hirakata, Osaka 573, Japan

(Received 18 December 1995; accepted for publication 4 April 1996)

We develop the formulation of the path integrals via the coherent states based on general starting vectors. In this paper we treat the case of the ordinary canonical (Heisenberg-Weyl) coherent state. We find that an additional term appears in the action in the path integral expression. Geometric phases associated with the path integrals, including the possibilities of the experimental detection, are also discussed. © *1996 American Institute of Physics.* [S0022-2488(96)02908-8]

I. INTRODUCTION

The Feynman path integral, which is the space-time approach to quantum mechanics, provides us with the bird's-eye view by which we are able to grasp the evolution of the quantum systems globally.[1,2] Its mathematical grace and intuitive appeal have tempted quite a few to generalize the formalism to more wider cases,[2,3] such as phase space forms,[4,5] fermion systems,[5,6] spin systems[7,8] and fields (both Bose fields[5,9] and Fermi ones[5,6]).

Now let us concentrate our attention to the case of the phase space path integral, for this is not only the simplest, but also serves as a prototype in understanding the generalizations to other systems. There are two ways to obtain that path integral: in one we sum over all the histories on the phase space,[4] whereas the other performs the path integration via the states that are specified by the points on complex planes. The latter approach was pioneered by Klauder in the early sixties.[5] About that time Glauber considered the same quantum states in the context of quantum optics and called them "coherent states,"[10] whose origin dates back even to the middle of the twenties.[11]

Klauder tried to generalize such states and reached the concept of "continuous representations"[12] which gives the states that construct the paths on some manifolds. These states are called "coherent states (CS)" in a broad sense of the word. (In what follows the word "CS" is used as a plural as well as a singular.) It is by such coherent state path integrals (path integrals via CS) that the above generalizations in Refs. 3–9 are made. We can understand that the phase space manifolds on which the paths are defined are extended to the generalized ones with curvatures or even to the non-complex ones in the coherent state path integrals for other systems.

Especially the CS that Perelomov defined by the unitary irreducible representations of arbitrary Lie groups bring us a concrete and clear method to construct CS[13] and to carry out their path integration.[8] In this case the CS is determined by a point on the manifold of the coset space G/H that is related to the corresponding Lie group G and its certain isotropy subgroup H. [3,13]

As stated at the beginning, the method of path integrals is suitable for considering the problems in which the global structure of the quantum systems is important. The problem of geometric phases[14] is one of these, though it was first discussed in the formulation *à la* Schrödinger. In fact the celebrated Berry phase[15] turned out to be understood more deeply in the light of such formulation[16] and the extension to the general case[17] was also studied from the viewpoint of CS path integrals.[18]

In the present paper, following the development of the path integrals mentioned above, we try to let it take another step forward; we aim to generalize the method of coherent state path integrals by extending the canonical CS and apply it to the problems of geometric phases. The CS are

[a)]Electronic mail: matumoto@i.h.kyoto-u.ac.jp WWW: http://www.i.h.kyoto-u.ac.jp/~matumoto/

defined following the way of Perelomov. What is different from the conventional treatment is the choice of the starting vector; we take the generic one. Next we study various aspects of the CS: overcompleteness relation, the overlap of two coherent states, typical matrix elements and uncertainty relation. These are done in Sec. II. In Sec. III the path integration is performed via the CS obtained in Sec. II. We then proceed, in Sec. IV, to consider the problems of the geometric phases associated with the CS including some applications. Discussions on future problems are given in Sec. V. In the appendices we treat some deeper arguments about the matrix elements, the CS in the light of eigenvectors and alternative derivations of the action.

II. COHERENT STATES WITH GENERAL STARTING VECTORS

This section provides us with all the equipment for Sec. III. We revisit the canonical CS *à* la Perelomov[13] as well as its properties in a somewhat different manner from what has been given.

A. Construction of the coherent states

The canonical or Heisenberg-Weyl CS are constructed from the Lie algebra satisfying the following relation:

$$[\hat{q},\hat{p}]=i\hbar\ \mathbf{1},\ \ [\hat{q},\mathbf{1}]=[\hat{p},\mathbf{1}]=0. \tag{1}$$

By transforming the basis of the algebra to

$$\hat{a}=(2\hbar)^{-1/2}(\hat{q}+i\hat{p}),\ \ \hat{a}^{+}=(2\hbar)^{-1/2}(\hat{q}-i\hat{p}), \tag{2}$$

Eq. (1) can be put into a different form,

$$[\hat{a},\hat{a}^{+}]=\mathbf{1},\ \ [\hat{a},\mathbf{1}]=[\hat{a}^{+},\mathbf{1}]=0. \tag{3}$$

We define the canonical coherent state associated with the Lie algebra (1) or (3) by operating a unitary operator,

$$\hat{D}(\alpha)=e^{\alpha\hat{a}^{+}-\alpha^{*}\hat{a}}\quad(\alpha\text{: a complex parameter}), \tag{4}$$

on a starting vector $|\psi_0\rangle$. The vector is a fixed vector in the Hilbert space which, in the present case, is identical with the Fock space for Bosons.[13] In the conventional choice, it is taken as $|0\rangle$: the ground state of the boson number operator. According to the general theory of the CS,[13] however, we have much wider possibility in choosing a starting vector; and in fact it permits any fixed vector in the Fock space, which is represented uniquely as

$$|\psi_0\rangle=\sum_{n=0}^{\infty}c_n|n\rangle,\quad\text{with}\ \sum_{n=0}^{\infty}|c_n|^2=1, \tag{5}$$

in terms of a set of vectors $\{|n\rangle\}$. Here $|n\rangle$ is the eigenstate of the number operator fullfilling $\hat{a}^{+}\hat{a}|n\rangle=n|n\rangle$ and the $\{c_n\}$ denotes the coefficients of complex numbers. Therefore our CS $|\alpha\rangle$ takes the form of

$$|\alpha\rangle=\hat{D}(\alpha)|\psi_0\rangle=\sum_{n=0}^{\infty}c_n|\alpha,n\rangle,\quad\text{with}\ |\alpha,n\rangle\equiv e^{\alpha\hat{a}^{+}-\alpha^{*}\hat{a}}|n\rangle. \tag{6}$$

Perelomov has already discussed the above point and given some formulae. But it seems that there have been no concrete arguments on the general starting vector formulation of the CS, especially on the path integration, including its relation to the recent development of the geometric phases.

Some comments may serve for our understanding of Eq. (6). A general element of the Lie algebra (3) is given by $s\mathbf{1}+i(\alpha^*\hat{a}-\alpha\hat{a}^+)$, where s is a real number. And thus its corresponding Lie group is constructed by $T(s,\alpha)\equiv e^{i(s\mathbf{1}+i(\alpha^*\hat{a}-\alpha\hat{a}^+))}=e^{is}\hat{D}(\alpha)$, which is called the Heisenberg-Weyl group W_1. Since the operators $T(s,\alpha)$ act in the Fock space and form an irreducible unitary representation of W_1, the CS for W_1 is obtained by applying the operators $T(s,\alpha)$ on $|\psi_0\rangle$. Then we find that the CS is determined by one complex number α as Eq. (6), although an element g of W_1 is specified by one real as well as one complex parameters: $g=(s,\alpha)$. This happens because the isotropy subgroup of $|\psi_0\rangle$ is $H=\{h\}$, with $h=(s,0)$, which makes no difference to CS besides changing its phase factor. So we see that the CS is determined by a point on a complex plane of the α-variable which is nothing but the coset space W_1/H.

Now, with the aid of the well-known disentangling formula: $e^{\hat{A}+\hat{B}}=e^{\hat{A}}e^{\hat{B}}e^{-(1/2)[\hat{A},\hat{B}]}$, which holds for any two operators satisfying $[\hat{A},[\hat{A},\hat{B}]]=[\hat{B},[\hat{A},\hat{B}]]=0$,[19] Eq. (6) can be put into

$$|\alpha\rangle=e^{-(1/2)|\alpha|^2}e^{\alpha\hat{a}^+}e^{-\alpha^*\hat{a}}|\psi_0\rangle=e^{(1/2)|\alpha|^2}e^{-\alpha^*\hat{a}}e^{\alpha\hat{a}^+}|\psi_0\rangle. \tag{7}$$

Our CS is, of course, represented by a linear combination of the vectors $\{|m\rangle\}$ as

$$|\alpha\rangle=\sum_{n=0}^{\infty}c_n|\alpha,n\rangle, \tag{8a}$$

with

$$\begin{aligned}|\alpha,n\rangle&=\sum_{m=0}^{\infty}\langle m|\hat{D}(\alpha)|n\rangle|m\rangle\\&=e^{-(1/2)|\alpha|^2}\left(\sum_{m=0}^{n}\left(\frac{m!}{n!}\right)^{1/2}(-\alpha^*)^{n-m}L_m^{(n-m)}(|\alpha|^2)|m\rangle\right.\\&\left.+\sum_{m=n+1}^{\infty}\left(\frac{n!}{m!}\right)^{1/2}\alpha^{m-n}L_n^{(m-n)}(|\alpha|^2)|m\rangle\right).\end{aligned} \tag{8b}$$

Here $L_k^{(l)}(x)$ is the Laguerre polynomial defined as

$$L_k^{(l)}(x)\equiv\frac{e^x x^{-l}}{k!}\frac{d^k}{dx^k}(e^{-x}x^{k+l})=\sum_{r=0}^{k}\binom{k+l}{k-r}\frac{(-x)^r}{r!}, \tag{9}$$

and we have used the expression for the matrix elements $D_{mn}(\alpha)\equiv\langle m|\hat{D}(\alpha)|n\rangle$ which has been known in quantum electrodynamics.[20] When $|\alpha\rangle$ represents the state of the photon, the absolute square of $\langle m|\alpha\rangle=\Sigma_{n=0}^{\infty}c_nD_{mn}(\alpha)$ yields the probability of finding m photons in the state $|\alpha\rangle$, as in the case of usual CS.[21] The form of Eqs. (8) is valuable for later arguments. The state $|\alpha\rangle$ may be named "extended coherent state," yet we will call it just "our CS" or "the CS" in this paper, for it has been already included in the theory of CS.[3,13]

B. Resolution of unity

The most important property that the CS enjoy is the "overcompleteness relation" or "resolution of unity" which plays a central role in performing the path integration. The relation is so closely related to the irreducibility of the representation of groups that it actually follows from the latter as a natural result.[3,13] But here we take a more concrete method, which is a natural generalization of one used for the usual CS, to obtain this relation. It is expressed as

$$\frac{1}{\pi}\int |\alpha\rangle d^2\alpha\langle\alpha| = \mathbf{1}, \tag{10}$$

where $d^2\alpha \equiv d(\mathrm{Re}\ \alpha)\ d(\mathrm{Im}\ \alpha)$.

Proof. From Eqs. (8),

$$\langle\alpha| = \sum_{\tilde{n}=0}^{\infty}\sum_{\tilde{m}=0}^{\infty} c_{\tilde{n}}^{*} D_{\tilde{m}\tilde{n}}^{*}(\alpha)\langle\tilde{m}|. \tag{11}$$

Then, by using the polar coordinate $\alpha = re^{i\theta}$ in Eqs. (8) and (11), we obtain

$$\begin{aligned}\int |\alpha\rangle d^2\alpha\langle\alpha| = \sum_{n=0}^{\infty}\sum_{\tilde{n}=0}^{\infty} c_n c_{\tilde{n}}^{*} \Bigg[\int dr d\theta\, r e^{-r^2} \\ \times\Bigg(\sum_{m=0}^{n}\sum_{\tilde{m}=0}^{\tilde{n}} \left(\frac{m!\tilde{m}!}{n!\tilde{n}!}\right)^{1/2} (-1)^{(n-m)+(\tilde{n}-\tilde{m})}\, r^{(n-m)+(\tilde{n}-\tilde{m})}\, L_m^{(n-m)}(r^2) L_{\tilde{m}}^{(\tilde{n}-\tilde{m})}(r^2) \\ + \sum_{m=0}^{n}\sum_{\tilde{m}=\tilde{n}+1}^{\infty} \left(\frac{m!\tilde{n}!}{\tilde{m}!n!}\right)^{1/2} (-1)^{n-m}\, r^{(n-m)-(\tilde{n}-\tilde{m})}\, L_m^{(n-m)}(r^2) L_{\tilde{n}}^{(\tilde{m}-\tilde{n})}(r^2) \\ + \sum_{m=n+1}^{\infty}\sum_{\tilde{m}=0}^{\tilde{n}} \left(\frac{\tilde{m}!n!}{m!\tilde{n}!}\right)^{1/2} (-1)^{\tilde{n}-\tilde{m}}\, r^{(m-n)-(\tilde{m}-\tilde{n})}\, L_n^{(m-n)}(r^2) L_{\tilde{m}}^{(\tilde{n}-\tilde{m})}(r^2) \\ + \sum_{m=n+1}^{\infty}\sum_{\tilde{m}=\tilde{n}+1}^{\infty} \left(\frac{n!\tilde{n}!}{m!\tilde{m}!}\right)^{1/2} r^{(m-n)+(\tilde{m}-\tilde{n})}\, L_n^{(m-n)}(r^2) L_{\tilde{n}}^{(\tilde{m}-\tilde{n})}(r^2) \Bigg) \\ \times |m\rangle\langle\tilde{m}|\, e^{i((m-n)-(\tilde{m}-\tilde{n}))\theta} \Bigg].\end{aligned} \tag{12}$$

Hereafter we call the integral that includes the i-th term in the big parentheses the i-th integral. Let us consider the first integral. After integrating out the θ-variable, we are left with

$$\pi\sum_{n=0}^{\infty}\sum_{\tilde{n}=0}^{\infty} c_n c_{\tilde{n}}^{*} \left[\sum_{m=0}^{n}\sum_{\tilde{m}=0}^{n} \left(\frac{m!\tilde{m}!}{n!\tilde{n}!}\right)^{1/2} |m\rangle\langle\tilde{m}| \int_0^{\infty} ds\, e^{-s}\, s^{n-m}\, L_m^{(n-m)}(s) L_{\tilde{m}}^{(n-m)}(s) \right] \delta_{m-n,\tilde{m}-\tilde{n}}, \tag{13}$$

where $s \equiv r^2$. By the use of the orthogonality relation of the Laguerre polynomials,

$$\int_0^{\infty} du\, e^{-u} u^{\eta} L_k^{(\eta)}(u) L_{k'}^{(\eta)}(u) = \begin{cases} 0, & \text{for } k \neq k', \\ \dfrac{\Gamma(\eta+k+1)}{k!}, & \text{for } k = k', \end{cases} \tag{14}$$

which is valid for $\mathrm{Re}\ \eta > -1$, the first integral yields

$$\pi\sum_{n=0}^{\infty}\sum_{\tilde{n}=0}^{\infty} c_n c_{\tilde{n}}^{*} \left(\sum_{m=0}^{n}\sum_{\tilde{m}=0}^{n} \left(\frac{m!\tilde{m}!}{n!\tilde{n}!}\right)^{1/2} \frac{n!}{m!} \delta_{m-n,\tilde{m}-\tilde{n}}\, \delta_{m,\tilde{m}}\, |m\rangle\langle\tilde{m}| \right) = \pi\sum_{n=0}^{\infty} |c_n|^2 \left(\sum_{m=0}^{n} |m\rangle\langle m| \right). \tag{15}$$

Other integrals can be calculated just in the same manner. The fourth one gives $\pi\Sigma_{n=0}^{\infty}|c_n|^2(\Sigma_{m=n+1}^{\infty}|m\rangle\langle m|)$. For the second and the third ones we can find that the condition $m-n=\tilde{m}-\tilde{n}$ comming from θ-integration does not satisfy the summation restrictions on m and $\tilde{m}$. Thus these integrals vanish. So finally the result gives

$$\int |\alpha\rangle d^2\alpha\langle\alpha| = \pi\sum_{n=0}^{\infty}|c_n|^2\left(\sum_{m=0}^{\infty}|m\rangle\langle m|\right) = \pi\sum_{n=0}^{\infty}|c_n|^2\,\mathbf{1} = \pi\,\mathbf{1}, \tag{16}$$

which completes the proof. □

C. Overlap of two coherent states

The overlap of two coherent state $|\alpha\rangle=\Sigma_{n'}^{\infty}c_{n'}|\alpha,n'\rangle$ and $|\beta\rangle=\Sigma_{n}^{\infty}c_n|\beta,n\rangle$ is one of those important quantities which we employ for various calculations in the CS. It can be derived, with the help of Eqs. (6) and (8) together with the disentangling formula, as

$$\begin{aligned}\langle\alpha|\beta\rangle &= \sum_{n=0}^{\infty}\sum_{n'=0}^{\infty}c_nc_{n'}^{*}\,\langle n'|\hat{D}^{+}(\alpha)\hat{D}(\beta)|n\rangle \\ &= e^{(1/2)(\alpha^*\beta-\alpha\beta^*)}\sum_{n=0}^{\infty}\sum_{n'=0}^{\infty}c_nc_{n'}^{*}\,D_{n'n}(\beta-\alpha) \\ &= e^{-(1/2)(|\alpha|^2+|\beta|^2-2\alpha^*\beta)}\,G(\alpha,\alpha^*,\beta,\beta^*;\{c_n\}),\end{aligned} \tag{17}$$

where

$$\begin{aligned}G(\alpha,\alpha^*,\beta,\beta^*;\{c_n\}) \equiv \sum_{n=0}^{\infty}c_n\Bigg(&\sum_{n'=0}^{n}c_{n'}^{*}\left(\frac{n'!}{n!}\right)^{1/2}(-(\beta-\alpha)^*)^{n-n'}L_{n'}^{(n-n')}(|\beta-\alpha|^2) \\ &+\sum_{n'=n+1}^{\infty}c_{n'}^{*}\left(\frac{n!}{n'!}\right)^{1/2}(\beta-\alpha)^{n'-n}\,L_{n}^{(n'-n)}(|\beta-\alpha|^2)\Bigg).\end{aligned} \tag{18}$$

Especially putting $c_0=1$ and $c_n=0$ $(n\neq 0)$ yields $G(\alpha,\alpha^*,\beta,\beta^*;\{c_n\})=1$, which, since $L_0(x)\equiv 1$ for any x, brings us back to the conventional result of the overlap. Moreover, with $L_{n'}(0)=1$, it is easy to see that any state $|\alpha\rangle$ is normalized to unity, as conforms to our construction of the CS.

D. Typical matrix elements and uncertainty relation

Our next task is to calculate typical matrix elements that we encounter in later sections. For that purpose we find it useful to employ the following identities:

$$\hat{D}^{+}(\alpha)(\hat{a})^l\hat{D}(\alpha)=(\hat{a}+\alpha)^l \quad (l\text{: positive integer}) \tag{19}$$

and

$$\hat{D}^{+}(\alpha)(\hat{a}^{+}\hat{a})\hat{D}(\alpha)=\hat{a}^{+}\hat{a}-(\alpha\hat{a}^{+}-\alpha^*\hat{a})+|\alpha|^2. \tag{20}$$

The proofs are given by the straightforward application of the formula $e^{\hat{A}}\hat{B}e^{-\hat{A}}=\hat{B}+[\hat{A},\hat{B}]+(1/2!)[\hat{A},[\hat{A},\hat{B}]]+\cdots$.[19] From these relations one can easily obtain the valuable matrix elements between the CS,

$$\langle\alpha|(\hat{a})^l|\alpha\rangle=\alpha^l+\sum_{\substack{n=0\\ \text{with } n>n'}}^{\infty}\sum_{n'=0}^{\infty}c_n c_{n'}^{*}\binom{l}{n-n'}\left(\frac{n!}{n'!}\right)^{1/2}\alpha^{l-(n-n')}, \tag{21a}$$

$$\langle\alpha|(\hat{a}^{+})^l|\alpha\rangle=(\alpha^{*})^l+\sum_{\substack{n=0\\ \text{with } n>n'}}^{\infty}\sum_{n'=0}^{\infty}c_n^{*} c_{n'}\binom{l}{n-n'}\left(\frac{n!}{n'!}\right)^{1/2}(\alpha^{*})^{l-(n-n')}, \tag{21b}$$

and

$$\langle\alpha|\hat{a}^{+}\hat{a}|\alpha\rangle=\sum_{n=1}^{\infty}(n|c_n|^2-n^{1/2}(\alpha c_n^{*}c_{n-1}-\alpha^{*}c_n c_{n-1}^{*}))+|\alpha|^2. \tag{22}$$

Putting $c_0=1$ and $c_n=0(n\neq 0)$ in Eqs. (21)–(22) yields the conventional results.

We next describe the uncertainty relation that our CS fullfills. We show the case of $|\psi_0\rangle=|n\rangle$ here, which is sufficient for us to see what the situation looks like. Then $|\alpha\rangle=|\alpha,n\rangle$. From Eqs. (2) and (21), we obtain

$$\Delta q\Delta p=\frac{\hbar}{2}(2n+1). \tag{23}$$

Thus the fluctuation is enhanced through the factor n, just like in the case of a harmonic oscillator eigenfunction. It is obvious that the usual choice of $|\psi_0\rangle=|0\rangle$ gives the minimum uncertainty.[13] It can be readily seen that $\Delta q\Delta p\simeq O(N)$ holds for more generic cases, where $N=\max n$.

III. COHERENT STATE PATH INTEGRALS

In this section we will give the explicit path integral expression of the transition amplitude by means of the CS discussed in Sec. II. We invoke a well-known prescription for the coherent state path integrals[5,9,22] and especially follow Ref. 22. What we need is the propagator $K(\alpha_f,t_f;\alpha_i,t_i)$ which starts from $|\alpha_i\rangle$ at $t=t_i$, evolves under the effect of the Hamiltonian $\hat{H}(\hat{a}^{+},\hat{a};t)$ which is assumed to be a suitably-ordered function of $\hat{a}^{+}$ and $\hat{a}$, and ends up with $|\alpha_f\rangle$ at $t=t_f$:

$$K(\alpha_f,t_f;\alpha_i,t_i)\equiv\langle\alpha_f,t_f|\alpha_i,t_i\rangle=\langle\alpha_f|T\exp[-(i/\hbar)\textstyle\int_{t_i}^{t_f}dt\hat{H}(t)]|\alpha_i\rangle; \tag{24}$$

where T denotes the time-ordered product. By dividing the time interval into infinite numbers of an infinitesimal one ϵ and the successive use of the completeness relation (10), we obtain

$$K(\alpha_f,t_f;\alpha_i,t_i)=\lim_{N\to\infty}\left(\frac{1}{\pi}\right)^N\int d^2\alpha_1\cdots\int d^2\alpha_N\,\langle\alpha_f,t_f|\alpha_N,t_N\rangle\langle\alpha_N,t_N|\alpha_{N-1},t_{N-1}\rangle\cdots$$

$$\cdots\langle\alpha_j,t_j|\alpha_{j-1},t_{j-1}\rangle\cdots\langle\alpha_1,t_1|\alpha_i,t_i\rangle, \tag{25}$$

where $\epsilon=[(1/N+1)](t_f-t_i)$ and $t_j=t_i+j\epsilon$. So we only have to consider a propagator during an infinitesimal time interval, which gives

$$\begin{aligned}\langle\alpha_j,t_j|\alpha_{j-1},t_{j-1}\rangle&=\langle\alpha_j|T\exp[-(i/\hbar)\textstyle\int_{t_{j-1}}^{t_j}dt\hat{H}(t)]|\alpha_{j-1}\rangle\\&\simeq\langle\alpha_j|\left(1-\frac{i}{\hbar}\int_{t_{j-1}}^{t_j}dt\hat{H}(\hat{a}^+,\hat{a};t)\right)|\alpha_{j-1}\rangle\\&\simeq\langle\alpha_j|\alpha_{j-1}\rangle\left(1-\frac{i}{\hbar}\epsilon H(\alpha_j,\alpha_j^*,\alpha_{j-1},\alpha_{j-1}^*;t_{j-1})\right)\\&\simeq\exp\left[-\frac{1}{2}|\alpha_j|^2-\frac{1}{2}|\alpha_{j-1}|^2+\alpha_j^*\alpha_{j-1}+\ln G(\alpha_j,\alpha_j^*,\alpha_{j-1},\alpha_{j-1}^*;\{c_n\})\right.\\&\quad\left.-\frac{i}{\hbar}\epsilon H(\alpha_j,\alpha_j^*,\alpha_{j-1},\alpha_{j-1}^*;t_{j-1})\right]\\&\simeq\exp\left[-\frac{1}{2}|\alpha_j|^2-\frac{1}{2}|\alpha_{j-1}|^2+\alpha_j^*\alpha_{j-1}+\tilde{G}(\alpha_j,\alpha_j^*,\alpha_{j-1},\alpha_{j-1}^*;\{c_n\})\right.\\&\quad\left.-\frac{i}{\hbar}\epsilon H(\alpha_j,\alpha_j^*,\alpha_{j-1},\alpha_{j-1}^*;t_{j-1})\right],\end{aligned}\tag{26}$$

in which we have employed Eqs. (17)–(18). Here

$$H(\alpha'',\alpha''^*,\alpha',\alpha'^*;t)\equiv\frac{\langle\alpha''|\hat{H}(a^+,a;t)|\alpha'\rangle}{\langle\alpha''|\alpha'\rangle}\tag{27}$$

and

$$\tilde{G}(\alpha_j,\alpha_j^*,\alpha_{j-1},\alpha_{j-1}^*;\{c_n\})\equiv\sum_{n=1}^{\infty}n^{1/2}((\alpha_j^*-\alpha_{j-1}^*)c_nc_{n-1}^*-(\alpha_j-\alpha_{j-1})c_n^*c_{n-1}).\tag{28}$$

As can be seen from Appendix A, H is a function not only of $(\alpha'')^*$ and α', but also of α'' and $(\alpha')^*$. Care should be taken that in Eq. (26), only the terms with $n-n'=0,\pm1$ in G contribute to the infinitesimal propagator within the first order of ϵ. From (25) and (26),

$$\begin{aligned}K(\alpha_f,t_f;\alpha_i,t_i)=\lim_{N\to\infty}\left(\frac{1}{\pi}\right)^N\int d^2\alpha_1\cdots\int d^2\alpha_N\\\times\exp\left[\sum_{j=1}^{N+1}\left(-\frac{1}{2}|\alpha_j|^2-\frac{1}{2}|\alpha_{j-1}|^2+\alpha_j^*\alpha_{j-1}+\tilde{G}(\alpha_j,\alpha_j^*,\alpha_{j-1},\alpha_{j-1}^*;\{c_n\})\right.\right.\\\left.\left.-\frac{i}{\hbar}\epsilon H(\alpha_j,\alpha_j^*,\alpha_{j-1},\alpha_{j-1}^*;t_{j-1})\right)\right].\end{aligned}\tag{29}$$

The exponent in Eq. (29) becomes

$$\sum_{j=1}^{N+1}\left[-\frac{1}{2}\alpha_j^*\left(\frac{\alpha_j-\alpha_{j-1}}{\epsilon}\right)+\frac{1}{2}\alpha_{j-1}\left(\frac{\alpha_j^*-\alpha_{j-1}^*}{\epsilon}\right)+\frac{\tilde{G}(\alpha_j,\alpha_j^*,\alpha_{j-1},\alpha_{j-1}^*;\{c_n\})}{\epsilon}\right.$$

$$\left.-\frac{i}{\hbar}H(\alpha_j,\alpha_j^*,\alpha_{j-1},\alpha_{j-1}^*;t_{j-1})\right]\epsilon$$

$$\to\frac{i}{\hbar}\int_{t_i}^{t_f}dt\left[\frac{i\hbar}{2}((\alpha^*\dot{\alpha}-\dot{\alpha}^*\alpha)+A(\dot{\alpha},\dot{\alpha}^*;\{c_n\}))-H(\alpha^*,\alpha,t)\right]\quad(\text{as }\epsilon\to 0),\tag{30}$$

with

$$A(\dot{\alpha},\dot{\alpha}^*;\{c_n\})\equiv-2\lim_{\epsilon\to\infty}\frac{\tilde{G}(\alpha_j,\alpha_j^*,\alpha_{j-1},\alpha_{j-1}^*;\{c_n\})}{\epsilon}=2\sum_{n=1}^{\infty}n^{1/2}(\dot{\alpha}c_n^*c_{n-1}-\dot{\alpha}^*c_nc_{n-1}^*).\tag{31}$$

Then we finally find

$$K(\alpha_f,t_f;\alpha_i,t_i)=\int\mathcal{D}[\alpha(t)]\,e^{(i/\hbar)S[\alpha(t)]},\tag{32}$$

where

$$S[\alpha(t)]\equiv\int_{t_i}^{t_f}dt\left(\frac{i\hbar}{2}((\alpha^*\dot{\alpha}-\dot{\alpha}^*\alpha)+A(\dot{\alpha},\dot{\alpha}^*;\{c_n\}))-H(\alpha^*,\alpha,t)\right)\equiv\int_{t_i}^{t_f}L\,dt,\tag{33}$$

and we symbolized

$$\mathcal{D}[\alpha(t)]\equiv\lim_{N\to\infty}\left(\frac{1}{\pi}\right)^N\prod_{j=1}^{N}d^2\alpha_j.\tag{34}$$

The result (33) is different from the usual one associated with the starting vector $|\psi_0\rangle=|0\rangle$ in that it includes the A-term depending on the starting vector $|\psi_0\rangle$. However, even if the A-term vanishes, which occurs for example no neighboring $\{c_n\}$ exists for any c_n, we have to be careful that the content of the action is different generally due to the $|\psi_0\rangle$-dependence of $H(\alpha^*,\alpha,t)$ through the first term of Eq. (22).

What information does the semi-classical limit of our CS path integral give? In the situation where $\hbar\to 0$, the principal contribution in (32) comes from the path that satisfies $\delta S=0$, which requires the Euler-Lagrange equation for $L(\alpha,\dot{\alpha},\alpha^*,\dot{\alpha}^*;t)$. Then we obtain

$$i\hbar\dot{\alpha}=\frac{\partial H}{\partial\alpha^*},\quad -i\hbar\dot{\alpha}^*=\frac{\partial H}{\partial\alpha},\tag{35}$$

which is nothing but the canonical equation as in the conventional Heisenberg-Weyl CS. We see that since the A-term is expressed as a total derivative, it does not alter the Euler-Lagrange equation. The meaning of α, however, is quite different from the usual one. In our case α indicates the displacement *from the state* $|\psi_0\rangle$. Moreover Eq. (35) depends upon $|\psi_0\rangle$ through H via Eqs. (21)-(22) as mentioned earlier.

The extension of the present framework of path integral to the field theoretic case is straightforward; thus we omit it from the present paper. It can be performed in a manner described in Refs. 3 and 9. We merely have to be careful of the definition of the field CS: we have to use the direct product state, each of which is represented by Eq. (6).

IV. GEOMETRIC PHASES

A. Theory

Consider a cyclic change of our CS, whose initial and final states are expressed $|\alpha(0)\rangle$ and $|\alpha(T)\rangle$, respectively, under the effect of a Hamiltonian $\hat{H}$ during the time interval T. In the light of the formalism developed in Sec. III, the state vector accumulates the phase $\Phi(C)$ which amounts to[18]

$$\Phi(C)=\langle\alpha(0)|\alpha(T)\rangle=\exp\left[\frac{i}{\hbar}\sum_{\substack{\text{all the cyclic}\\ \text{paths } C}}(\Gamma(C)-\Delta(C))\right], \tag{36}$$

where

$$\Gamma(C)=\int_0^T\langle\alpha|i\hbar\frac{\partial}{\partial t}|\alpha\rangle dt=\int_0^T\frac{i\hbar}{2}(\alpha^*\dot{\alpha}-\dot{\alpha}^*\alpha)dt \tag{37}$$

and

$$\Delta(C)=\int_0^T H(\alpha^*,\alpha,t)dt. \tag{38}$$

We note that the effect of the A-term disappears in the case of the cyclic change of the CS as far as no restrictions are imposed on the region of the α-plane and hence it is simply-connected. We obtain from Eq. (37),

$$\Gamma(C)=\oint_C\langle\alpha|i\hbar\nabla_{\vec{\alpha}}|\alpha\rangle\cdot d\vec{\alpha}=\oint_C p dq, \tag{39}$$

where $\vec{\alpha}\equiv(\alpha,\alpha^*)$. Equation (39) shows that $\Gamma(C)$ depends only on the curve C on the α-plane, which is the same for the original geometric phases by Berry; [15] the equation also tells us that $\Gamma(C)$ is invariant under the canonical transformations.

In the present paper we are dealing with the canonical CS, however, $\Gamma(C)$ can be defined for any coherent states.[18] It is readily seen that we can define a line integral like $\Gamma(C)$ as long as the state we consider evolves as CS. What makes the CS develop as CS is the controlling the parameters by some successive continuous measurements. Although no mention of CS was made, such a point was described in a slightly different context.[23] In Ref. 18 the path is so chosen that it satisfies the variation principle in relation to the semiclassical approximation that plays a vital role in evaluating path integrals; and some developments of the CS geometric phases[24] including the application in this direction has been done.[25–27] Yet a such restriction is not inevitable. Especially when the Hamiltonain is at most bilinear in the generators of the Lie algebras in the canonical CS case and linear in SU(2)CS or SU(1,1)CS cases, however, the CS evolves as CS under the effect of the Hamiltonian and the resulting geometric phase agrees with one obtained by the variational path. Although it may look special at first sight, the above case covers the systems which are valuable in physics. And we will also take the case for example in the following discussion, for we want to compare the result with one obtained recently[27] and investigate the effect of our CS. We will see the result that is a direct extension of Ref. 27.

B. Simple application

Now we will give a more realistic argument by taking the following system as an example in which we choose a harmonic oscillator driven by an external force. The Hamiltonian is given by

$$\hat{H}=\tfrac{1}{2}(\hat{p}^2+\omega_0{}^2\hat{q}^2)+F(t)\hat{q}, \tag{40}$$

which can be written by means of boson creation and annihilation operators as

$$\hat{H}=\hbar\omega_0\hat{a}^+\hat{a}+f(t)\hat{a}^++f^*(t)\hat{a}. \tag{41}$$

We assume that the system is described by the CS $|\alpha,n\rangle$. Then, from Eq. (29), the propagator for the Hamiltonian of Eq. (41) gives

$$\begin{aligned}K(\alpha_f,t_f;\alpha_i,t_i)=&\lim_{N\to\infty}\left(\frac{1}{\pi}\right)^N\int d^2\alpha_1\cdots\int d^2\alpha_N\\&\times\exp\left[\sum_{j=1}^{N+1}\left(-\frac{1}{2}|\alpha_j|^2-\frac{1}{2}|\alpha_{j-1}|^2+\left(1-\frac{i}{\hbar}\epsilon\omega_0\right)\alpha_j^*\alpha_{j-1}-\frac{i}{\hbar}\epsilon f_j\alpha_j^*\right.\right.\\&\left.\left.+\frac{i}{\hbar}\epsilon f_{j-1}^*\alpha_{j-1}\right)\right],\end{aligned} \tag{42}$$

where we have applied Eqs. (A3) to two nearest states with the time interval ϵ. Equation (42) is the same as that for the usual CS under the same Hamiltonian (41). As mentioned earlier the direct evaluation of the Gaussian integral shows that the transition amplitude of the path obeying the variational condition is equal to the propagator.[1,2] Therefore it is enough to consider the variational path in this case.

The type of Hamiltonian in Eqs. (40) or (41) appears in the problems of detecting gravitational radiation[28] and quantum optics.[21,29] Here we shall take up the second one for example and discuss the possibility of finding the effect of the geometric phase. Consider a single mode electric field inside a cavity driven externally by a coherent driving field. If we neglect the cavity damping, we have the Hamiltonian:[29]

$$\hat{H}=\hbar\omega_0\hat{a}^+\hat{a}+i\hbar(\hat{a}^+E(t)e^{-i\omega t}-\hat{a}E^*(t)e^{i\omega t}). \tag{43}$$

The first term denotes the cavity mode Hamiltonian, where ω_0 means the fundamental cavity resonance and the second term gives the Hamiltonian for the coherent driving field respectively. $E(t)$ is the driving field amplitude, while ω is the driving frequency. If the cavity contains the medium with unharmonicity the term having $(\hat{a}^+)^2\hat{a}^2$ is added to the Hamiltonian,[29] but we neglect such an unharmonic effect hereafter. We also assume $E(t)=Ei$, with E: a positive real constant for brevity's sake.

It may be time for us to point out the role of the variable α in relation to quantum optics. We see, from Eqs. (21) that the matrix elements of $\hat{a}$ and $\hat{a}^+$ between our CS $|\alpha,n\rangle$ are identical with those for the usual CS. Consequently α is proportional to the complex amplitude of the classical electromagnetic field obtained as the solution of Maxwell equation, which can be shown in the same manner as that for the usual CS.[21]

Now we proceed to evaluate $\Gamma(C)$. With the aid of Eqs. (21)–(22),

$$H(\alpha,\alpha^*)=\hbar[\omega_0(|\alpha|^2+n)-2Er_0], \tag{44}$$

for the Hamiltonian Eq. (43). The variation equation, Eq. (35), reads as

$$\dot{\alpha}+i\omega_0\alpha=iEe^{-i\omega t}, \tag{45}$$

which, in the polar coordinate $\alpha=re^{i\theta}$, becomes

$$\dot{r}=E\sin(\theta+\omega t),\quad r(\dot{\theta}+\omega_0)=E\cos(\theta+\omega t). \tag{46}$$

These equations give a special cyclic solution with a period $T=2\pi/\omega$:

$$r=r_0,\quad \theta=-\omega t, \tag{47}$$

where the relation

$$r_0=\frac{E}{\omega_0-\omega} \tag{48}$$

holds. Equation (48) specifies the surface in the (E,ω,ω_0) space on which the phase Γ has the same value.[25-27] In the above argument, since we consider the cyclic path with the period T, we need not bother with the asymmetry of the solution of the variation equations in the general case.[7] The geometric phase Γ is evaluated from Eq. (37) as

$$\Gamma(C)=2\pi\hbar r_0^2. \tag{49}$$

On the other hand, from Eq. (38), the dynamical phase is calculated as

$$\Delta(C)=\frac{2\pi\hbar}{\omega}(\omega_0(r_0^2+n)-2Er_0). \tag{50}$$

We next turn to the detection of the phase $\Gamma(C)$ in experiments. The strategy invokes the inteference phenomena of two beams as in the previous cases.[25-27] We use the light beam prepared in the state $|n\rangle$ which is to be split into two parts. We assume that one part is suffered under the driving field E in Eq. (43), but the other is not and that these two parts are designed to come into reunion after a time interval of T. From Eq. (48) and Eq. (50), the vanishing of $\Delta(C)$ occurs when

$$\omega=\frac{\omega_0\sqrt{E^2-n\omega_0^2}}{E+\sqrt{E^2-n\omega_0^2}}. \tag{51}$$

The inteference pattern that gives the maximum intensity yields

$$2+2\cos\left(\frac{1}{\hbar}\Gamma(C)\right)=2+2\cos\left[2\pi\left(\frac{2E^2-n\omega_0^2+2E\sqrt{E^2-n\omega_0^2}}{\omega_0^2}\right)\right]. \tag{52}$$

Then n-dependence of $\Gamma(C)$ is as follows: the larger n, the smaller the magnitude of the phase $\Gamma(C)$, which causes the change of the interference pattern even for the same Hamiltonian. Putting $n=0$ recovers the result obtained by the usual CS. Thus the present result is a natural extension of one obtained before.[27]

V. DISCUSSION

We have tried to extend the realm of CS and their path integrals with success at least mathematically in the present paper. We also see that the formalism gives a new insight into the topological problems in quantum physics. Future problems are as follows.

First, the CS will play an important role in the problems where the quantum mechanical motions are closely related to the general n-th eigenstate of the harmonic oscillator; for example the problem of an electron moving under a strong magnetic field, which is related to the lowest Landau level and once treated by the CS method,[30] can be easily extended to the case of any field strength that is related to the general Landau level.

Second, the extension of the present path integral formalism to wider CS classes may be quite intriguing from the viewpoint of mathematical physics. Some works toward the direction will be treated in subsequent papers.

ACKNOWLEDGMENTS

The author extends his sincere thanks to the members of the mathematical information group at Kyoto University (Department of Fundamental Sciences, Faculty of Integrated Human Studies), especially to Professor T. Sakuragawa, for the help in typesetting the manuscript. He also expresses his deep appreciation to the members of Department of Physics at Ritsumeikan University for their warm hospitality where part of the present work has been performed.

APPENDIX A: MATRIX ELEMENTS AND THE GENERATING FUNCTION

This appendix is designed for the reference of the matrix elements in Sec. IV B. Here we demonstrate the simple case of $|\alpha\rangle=|\alpha,n\rangle$, which is sufficient for Sec. IV B; more general cases are obtained just in the same manner.

Consider the following function:

$$\begin{aligned} X(\mu,\mu^*)&\equiv\langle\alpha,n|e^{\mu\hat{a}^+}e^{-\mu^*\hat{a}}|\beta,n\rangle \\ &=e^{(1/2)|\mu|^2}\langle n|\hat{D}^+(\alpha)\hat{D}(\mu)\hat{D}(\beta)|n\rangle \\ &=e^{(1/2)[|\mu|^2+(\alpha^*+\beta^*)\mu-(\alpha+\beta)\mu^*+(\alpha^*\beta-\alpha\beta^*)]}\,D_{nn}(\mu-\alpha+\beta) \qquad \text{(A1)} \\ &=e^{\alpha^*\mu-\beta\mu^*}e^{-(1/2)(|\alpha|^2+|\beta|^2-2\alpha^*\beta)}\,L_n(|\mu-\alpha+\beta|^2), \end{aligned}$$

where we used the definition of D_{nn}, i.e. Eqs. (8), and the multiplication of $\hat{D}$. Clearly, $X(\mu,\mu^*)$ is the generating function[13] for the matrix elements:

$$\langle\alpha,n|(\hat{a}_+)^u(\hat{a})^v|\beta,n\rangle=\left(\frac{\partial}{\partial\mu}\right)^u\left(-\frac{\partial}{\partial\mu^*}\right)^v X(\mu,\mu^*)\bigg|_{\mu=0}. \qquad \text{(A2)}$$

For example,

$$\langle\alpha,n|\hat{a}|\beta,n\rangle=\beta\langle\alpha,n|\beta,n\rangle-e^{-(1/2)(|\alpha|^2+|\beta|^2-2\alpha^*\beta)}\sum_{r=1}^{\infty}(-1)^r\binom{n}{r}\frac{(\beta-\alpha)^r(\beta^*-\alpha^*)^{r-1}}{(r-1)!},$$

$$\langle\alpha,n|\hat{a}^+|\beta,n\rangle=\alpha^*\langle\alpha,n|\beta,n\rangle+e^{-(1/2)(|\alpha|^2+|\beta|^2-2\alpha^*\beta)}\sum_{r=1}^{\infty}(-1)^r\binom{n}{r}\frac{(\beta-\alpha)^{r-1}(\beta^*-\alpha^*)^r}{(r-1)!},$$

$$\begin{aligned} \langle\alpha,n|\hat{a}^+\hat{a}|\beta,n\rangle&=\alpha^*\beta\langle\alpha,n|\beta,n\rangle+(|\alpha|^2+|\beta|^2-2\alpha^*\beta) \\ &\quad\times\sum_{r=1}^{\infty}(-1)^r\binom{n}{r}\frac{|\beta-\alpha|^{2(r-1)}}{(r-1)!}-\sum_{r=1}^{\infty}(-1)^r\binom{n}{r}r\frac{|\beta-\alpha|^{2(r-1)}}{(r-1)!}. \qquad \text{(A3)} \end{aligned}$$

APPENDIX B: COHERENT STATES AS EIGENVECTORS

The original definition of the canonical CS $|\alpha)$ is the state which is the eigenstate of the boson annihilation operator $\hat{a}$ with an eigenvalue α: $\hat{a}|\alpha)=\alpha|\alpha)$. A question arises: are our CS the eigenstates of any operators? If so, what are they? For simplicity let us consider the case of $|\psi_0\rangle=|n\rangle$. We have two different answers to the problem.

The first approach starts by operating $\hat{D}(\alpha)$ on the relation $\hat{a}^+\hat{a}|n\rangle=n|n\rangle$. By Eq. (20), we obtain

$$(\hat{a}^+ + \alpha^*)(\hat{a}-\alpha)|\alpha,n\rangle = n|\alpha,n\rangle, \tag{B1}$$

which clearly gives us one of the possible answers.

We can look the problem from another point of view. From the defnition of the CS,

$$\hat{D}(\alpha)\hat{a}^{n+1}\hat{D}^+(\alpha)|\alpha,n\rangle = 0, \tag{B2}$$

which, together with Eq. (19), gives

$$(\hat{a}-\alpha)^{n+1}|\alpha,n\rangle = 0. \tag{B3}$$

Therefore our CS is the generalized eigenvector belonging to the generalized eigenspace which is well-known in the theory of linear algebra for the nilpotent groups.[31] It is obvious that taking $n=0$ brings us back to the relations that the usual CS fullfill both in Eq. (B1) and in Eq. (B3).

Moreover one can see that the latter argument holds also for the case of a general starting vector $|\psi_0\rangle$; we only have to replace n with N, where $N=\max n$.

APPENDIX C: ALTERNATIVE DERIVATIONS OF THE ACTION

There are alternative derivations that lead us to Eq. (32). In (26) we can write

$$\langle\alpha_j|\alpha_{j-1}\rangle \simeq \exp\left[-\langle\alpha_j|\frac{\partial}{\partial t}|\alpha_j\rangle\epsilon\right] \quad (\text{as } \epsilon\to 0). \tag{C1}$$

With the aid of (C1), one can easily obtain the same expression as Eq. (32) for the propagator except that the action is replaced by $\tilde{S}$, where

$$\tilde{S}[\alpha(t)] \equiv \int_{t_i}^{t_f} dt\left(\langle\alpha|i\hbar\frac{\partial}{\partial t}|\alpha\rangle - H(\alpha^*,\alpha,t)\right). \tag{C2}$$

But substituting Eq. (7) into the first term in the parentheses in Eq. (C2) gives

$$\langle\alpha|i\hbar\frac{\partial}{\partial t}|\alpha\rangle = \langle\alpha|i\hbar\left(\dot{\alpha}\frac{\partial}{\partial\alpha}+\dot{\alpha}^*\frac{\partial}{\partial\alpha^*}\right)|\alpha\rangle = \frac{i\hbar}{2}((\alpha^*\dot{\alpha}-\dot{\alpha}^*\alpha)+A(\dot{\alpha},\dot{\alpha}^*;\{c_n\})), \tag{C3}$$

where the use was made of Eqs. (21). The result reveals that $\tilde{S}=S$, which completes the proof. The formula of Eq. (C2) is not restricted to the canonical CS, but works well also for the general CS, though the derivation is somewhat formal as we have seen here.

We may also calculate the term $\langle\alpha|(\partial/\partial t)|\alpha\rangle$ with the aid of Eq. (17):

$$\langle\alpha|\frac{\partial}{\partial t}|\alpha\rangle = \langle\alpha|\frac{\partial}{\partial t}|\beta\rangle\Big|_{\alpha=\beta} = \left(\dot{\beta}\frac{\partial}{\partial\beta}+\dot{\beta}^*\frac{\partial}{\partial\beta^*}\right)\langle\alpha|\beta\rangle|_{\alpha=\beta}, \tag{C4}$$

which again results in Eq. (C3), hence in Eq. (33).

(Received 15 February 1996; accepted for publication 22 February 1996)

The Seiberg–Witten equations, when dimensionally reduced to $\mathbf{R}^2$, naturally yield the Liouville equation, whose solutions are parametrized by an arbitrary analytic function $g(z)$. The magnetic flux Φ is the integral of a singular Kaehler form involving $g(z)$; for an appropriate choice of $g(z)$, N coaxial or separated vortex configurations with $\Phi=2\pi N/e$ are obtained when the integral is regularized. The regularized connection in the $\mathbf{R}^1$ case coincides with the kink solution of φ^4 theory.
 [S0022-2488(96)01607-6]

The Seiberg–Witten equations[1] do not admit nonsingular solutions unless the curvature of the four-dimensional base manifold M happens to be negative over some regions of M. In particular, if $M=\mathbf{R}^4$, the Weitzenbock formula implies that the modulus squared of the spinor field ψ must either vanish everywhere, or exhibit singularities instead of local maxima.[2] There is also a global restriction on flat-space Seiberg–Witten solutions: Integrating the Weitzenbock formula, Witten[1] showed that all nontrivial flat solutions, including dimensionally reduced ones based on $\mathbf{R}^3$, $\mathbf{R}^2$, or $\mathbf{R}^1$, are all necessarily non-L^2.

Such singular, non-L^2 solutions, while probably not useful for Donaldson theory, may nevertheless be of physical interest. For example, Freund recently recognized that a singular $U(1)$ magnetic monopole field and an accompanying spinor, found earlier by Gürsey in a different setting, solve the $\mathbf{R}^3$-reduced Seiberg–Witten equations.[3] The monopole being the characteristic topological object in $\mathbf{R}^3$, one may inquire whether there are $\mathbf{R}^2$ and $\mathbf{R}^1$ Seiberg–Witten solutions corresponding to vortices and kinks, respectively. The chief purpose of the present note is to show that such solutions indeed exist. A novel aspect of the $\mathbf{R}^n$ $(n\leqslant 2)$ case is that the three coupled Seiberg–Witten equations (we should properly count $F=dA$ as one of the three) can be reduced to a single nonlinear one. This happens to be the Liouville equation,[4] which has recently been related to $N=2$ supersymmetric Seiberg–Witten theory in another context.[5]

We follow the conventions of Akbulut[6] in the choice of the Dirac γ-matrices

$$\gamma^1=\begin{pmatrix}\mathbf{0} & \mathbf{I}\\ -\mathbf{I} & \mathbf{0}\end{pmatrix},\quad \gamma^2=\begin{pmatrix}\mathbf{0} & i\sigma_3\\ i\sigma_3 & \mathbf{0}\end{pmatrix},$$
$$\gamma^3=\begin{pmatrix}\mathbf{0} & -i\sigma_2\\ -i\sigma_2 & \mathbf{0}\end{pmatrix},\quad \gamma^4=\begin{pmatrix}\mathbf{0} & -i\sigma_1\\ -i\sigma_1 & \mathbf{0}\end{pmatrix}, \tag{1}$$

and the self-dual Σ_{ij}

$$\Sigma_{12}=\frac{1}{4}\{[\gamma^1,\gamma^2]+[\gamma^3,\gamma^4]\}=\begin{pmatrix}i\sigma_3 & \mathbf{0}\\ \mathbf{0} & \mathbf{0}\end{pmatrix},$$

[a)]Permanent address: Physics Department, Boğaziçi University, 80815 Bebek-İstanbul, Turkey.

$$\Sigma_{13}=\frac{1}{4}\{[\gamma^1,\gamma^3]+[\gamma^4,\gamma^2]\}=\begin{pmatrix}-i\sigma_2 & \mathbf{0}\\ \mathbf{0} & \mathbf{0}\end{pmatrix}, \tag{2}$$

$$\Sigma_{23}=\frac{1}{4}\{[\gamma^1,\gamma^4]+[\gamma^2,\gamma^3]\}=\begin{pmatrix}-i\sigma_1 & \mathbf{0}\\ \mathbf{0} & \mathbf{0}\end{pmatrix}.$$

Taking a spinor $\psi^T=(a,b,0,0)$, a connection iA_μ, and its curvature $iF_{\mu\nu}=i(\partial_\mu A_\nu-\partial_\nu A_\mu)$, where $\mu,\nu=1,2,3,4$, the first of the Seiberg–Witten pair is nothing but the Dirac equation

$$\gamma^\mu(\partial_\mu+iA_\mu)\psi=0. \tag{3}$$

In the notation of Ref. 6, the second Seiberg–Witten equation becomes

$$\rho(iF_A^+)=\sigma(\psi), \tag{4}$$

where

$$\sigma(\psi)\equiv\begin{pmatrix}\dfrac{(|a|^2-|b|^2)}{2} & a\bar{b}\\ b\bar{a} & \dfrac{(|b|^2-|a|^2)}{2}\end{pmatrix} \tag{5}$$

and

$$\rho(iF_A^+)=\frac{i}{8}(F_{\mu\nu}+\tilde{F}_{\mu\nu})\cdot\Sigma_{\mu\nu}=\frac{i}{4}F_{\mu\nu}\Sigma_{\mu\nu}. \tag{6}$$

The vortex solutions in $\mathbf{R}^2$ follow from the *Ansatz*

$$A_\mu=(A_1,A_2,0,0), \tag{7}$$

$$\psi^T=(a,b,0,0), \tag{8}$$

where all quantities are assumed to depend only on x_1 and x_2. Putting (7) and (8) in (4), one finds two possibilities: either ($a\neq0$, $b=0$) or ($a=0$, $b\neq0$). Choosing the first, (4) reduces to

$$-F_{12}=-B_3=|a|^2, \tag{9}$$

while (3) yields

$$(-\partial_1+i\partial_2)a=(iA_1+A_2)a. \tag{10}$$

We now set

$$a=\alpha\ \exp(\omega_x+i\omega_y), \tag{11}$$

where α is a constant with the dimensions of inverse length as required by (4). This unusual dimension for the spinor field of course comes from the vacuum expectation value of the Higgs field in the twisted supersymmetric Yang–Mills theory underlying the Seiberg–Witten approach.[7] Dividing both sides of (10) by a, applying $(-\partial_1-i\partial_2)$, and separating real and imaginary parts, we find

$$(\partial_1^2+\partial_2^2)\omega_x=-B_3=\alpha^2\ \exp(2\omega_x) \tag{12}$$

and

$$(\partial_1^2+\partial_2^2)\omega_y=-(\partial_1 A_1+\partial_2 A_2). \tag{13}$$

In (12), we have also used (9). It is convenient to introduce the dimensionless coordinates $x=\alpha x_1$ and $y=\alpha x_2$ with $\alpha>0$ and to define $z(\bar{z})=x+(-)iy$. The equation (12) then becomes

$$4\partial_z\partial_{\bar{z}}\omega_x=\exp(2\omega_x). \tag{14}$$

This is, of course, the well-known Liouville equation. Using (10) and (11) we obtain

$$A_1=\alpha(\partial_y\omega_x-\partial_x\omega_y) \tag{15}$$

and

$$A_2=-\alpha(\partial_x\omega_x+\partial_y\omega_y), \tag{16}$$

which show that (13) is automatically satisfied. Equation (14) has the solution

$$\omega_x=\frac{1}{2}\ln\frac{4(dg/dz)(d\bar{g}/d\bar{z})}{(1-g\bar{g})^2}, \tag{17}$$

due to Liouville.[4] At this point, $g(z)$ is an arbitrary analytic function. Comparing (17) with (11), we see that

$$|a|=2\alpha\frac{|dg/dz|}{(1-g\bar{g})}, \tag{18}$$

which naturally suggests

$$\omega_y=\pm\arg\frac{dg}{dz}=\mp\arg\frac{d\bar{g}}{d\bar{z}}. \tag{19}$$

Note that this also makes ω_y harmonic and enforces $\nabla\cdot\mathbf{A}=0$ via (13). We finally take

$$a=2\alpha\frac{dg/dz}{(1-g\bar{g})}, \tag{20}$$

leading to

$$B_3=-\frac{4\alpha^2|dg/dz|^2}{(1-g\bar{g})^2}. \tag{21}$$

The $U(1)$ curvature is thus seen to be the Kaehler two-form

$$F=\frac{1}{e}F_{12}dx_1\wedge dx_2=\frac{i}{2e\alpha^2}F_{12}dz\wedge d\bar{z}=\frac{-2i}{e}\frac{dg\wedge d\bar{g}}{(1-g\bar{g})^2}, \tag{22}$$

where we have brought out the coupling constant e which was hidden in A_μ all along. We can also combine (15) and (16) into the one-form

$$A=\frac{i}{e}\left(\frac{\bar{g}dg}{(1-g\bar{g})}-\frac{gd\bar{g}}{(1-g\bar{g})}\right). \tag{23}$$

A number of remarks are in order:

(i) The singularity dictated by the Weitzenbock formula manifests itself in (20)–(23). The solutions are singular in the z plane along a curve defined by $g\bar{g}=1$. One can easily trace the minus in $(1-g\bar{g})$ to the relative plus sign between the two sides of the Liouville equation (14); introducing a relative minus sign in (14) changes all the $(1-g\bar{g})$ factors to $(1+g\bar{g})$ without affecting anything else.

(ii) Remarkably, (14) and (22) also arise in a twice dimensionally reduced Ansatz leading to vortexlike solutions of the self-dual Yang–Mills equations.[8] Since the $\mathbf{R}^4$ self-dual Yang–Mills (SDYM) system is conjectured to generate all integrable systems through various dimensional reductions, the appearance of (14) in both the SDYM and the Seiberg–Witten contexts may be regarded as an additional clue for similar integrability properties of the latter. Furthermore, putting $e^{w_x}=u$ in the Liouville equation (14) and performing a further dimensional reduction by demanding $u=u(|z|=r)$ results in the differential equation for the third Painlevé transcendent with $\gamma=1$, $\alpha=\beta=\delta=0$, in the notation of Ince.[9] Thus the Seiberg–Witten equations also exhibit a Painlevé property, considered an indication of integrability.[10]

(iii) In the SDYM case, passing from the $(++++)$ $\mathbf{R}^4$ to the twistor-based $(++--)$ $\mathbf{R}^{2,2}$ supplies the change in the relative sign in (14) converting the singular $(1-g\bar{g})^{-1}$ factor into $(1+g\bar{g})^{-1}$; the same obviously holds in our problem as well.

(iv) The curvature form (22) remains unchanged under $g\to 1/g$, just as it would under a gauge transformation. Indeed, this inversion of g precisely gives rise to the $U(1)$ gauge transformations

$$a\to a'=\frac{\bar{g}}{g}a \tag{24}$$

and

$$eA\to eA'=eA+id\ \ln\frac{g}{\bar{g}} \tag{25}$$

on the spinor field and the connection, respectively.

We now wish to restrict the choice of $g(z)$ by physical considerations. In Freund's case, $\int F$ gives the quantized magnetic charge; it would be natural to expect that $\int F\equiv\Phi$ is a quantized magnetic flux in $\mathbf{R}^2$ for an appropriate $g(z)$. This requires that we somehow "regularize" the singular integrand (22); happily, different approaches to making sense out of $\int F$ give the same result, as we shall see. Let us start by considering the $\mathbf{R}^{2,2}$ version of (22), which becomes the area of the Riemann sphere stereographically expressed onto the g plane:

$$\Phi=\int F=\frac{2i}{e}\int\frac{dg\wedge d\bar{g}}{(1+g\bar{g})^2}. \tag{26}$$

Note the overall sign change due to the change in the rhs of (14).

Trying $g=z^\nu$ for an axisymmetric solution centered at the origin, we find

$$\Phi=\frac{4\pi\nu}{e}\int_0^\infty\frac{(2\nu r^{2\nu-1})}{(1+r^{2\nu})^2}\,dr=\frac{4\pi\nu}{e}\int_1^\infty\frac{dw}{w^2}=\frac{4\pi\nu}{e}, \tag{27}$$

where we have put $w=1+r^{2\nu}$. We note that the gauge transformation (24) results in

$$a'=\bar{z}^\nu z^{-\nu}a=e^{-2i\nu\theta}a. \tag{28}$$

The single valuedness of a' at $\theta=2\pi$ allows the ν values

$$\nu=\tfrac{1}{2},1,\tfrac{3}{2},\ldots\ . \tag{29}$$

We need not consider $\nu\rightarrow-\nu$ as this only amounts to the gauge transformation $g\rightarrow 1/g$ mentioned earlier. Of the values in (29), it is the $\nu=\frac{1}{2}$ that corresponds to $2\pi/e$, i.e., the Nielsen–Olesen[11] unit of flux. Thus $g=z^{1/2}$ represents the basic single-vertex solution, while $g=z^{n/2}$ corresponds to a single vortex with n units of flux. It is now easy to verify that

$$g(z)=\prod_{k=1}^{n}(z-a_k)^{1/2} \tag{30}$$

describes n vortices centered at the locations $a_k=(a_{kx}+ia_{ky})$. To do this, we first switch to the compactified version of (23), which becomes

$$A=-\frac{i}{e}\left(\frac{\bar{g}dg}{(1+g\bar{g})}-\frac{gd\bar{g}}{(1+g\bar{g})}\right). \tag{31}$$

Next we use the $g(z)$ of (30) in

$$\Phi=\int_{\mathbf{R}^2}F=\int_{\partial\mathbf{R}^2}A, \tag{32}$$

where $\partial\mathbf{R}^2$ is a clockwise circle whose radius goes to infinity. Since $|g|\rightarrow|z^{n/2}|\gg 1$ on $\partial\mathbf{R}^2$, we obtain

$$\Phi=-\frac{i}{2e}\oint_{\partial\mathbf{R}^2}\left\{n\frac{dz}{z}-n\frac{d\bar{z}}{\bar{z}}\right\}=\frac{2n\pi}{e}. \tag{33}$$

The similarity of expression (30) to Weierstrassian functions suggests we might consider a doubly periodic solution on a two-dimensional lattice, with one vortex per unit lattice cell. Let us take ω_1 and ω_2 as the two basic lattice vectors, subject to the usual restriction $\mathrm{Im}(\omega_2/\omega_1)\neq 0$. For a pair of integers (n_1,n_2), $\omega=n_1\omega_1+n_2\omega_2$ is a point in the lattice. We can now choose for $g(z)$ the square root of the Weierstrassian quasi-periodic function $\sigma(z)$, i.e.,

$$g(z)=\sigma^{1/2}(z)=z^{1/2}\prod_{\omega\neq 0}\left(1-\frac{z}{\omega}\right)^{1/2}\exp\left(\frac{z^2}{4\omega^2}+\frac{z}{2\omega}\right). \tag{34}$$

The exponential factor is needed to ensure the convergence of the product.

Another method for defining the integral of the singular expression (22) is as follows. If we attempt to calculate Φ starting from (22), we obtain

$$\Phi=-\frac{4\pi\nu}{e}\int_0^\infty\frac{(2\nu r^{2\nu-1})}{(r^{2\nu}-1)^2}\,dr=-\frac{4\pi\nu}{e}\int_{-1}^\infty\frac{dw}{w^2},\quad w=r^{2\nu}-1, \tag{35}$$

instead of (27). Adopting Speer's analytic regularization,[12] we define

$$I(-1,\infty)=\int_{-1}^\infty\frac{dw}{w^2}=\left[\int_{-1}^\infty w^\lambda dw\right]_{\lambda=-2}=-1. \tag{36}$$

This is equivalent to writing $I(-1,\infty)=I(-\infty,\infty)-I(-\infty,-1)$ and throwing away the infinite "constant" $I(-\infty,\infty)$. Thus we get the same answer as in the compactified $\mathbf{R}^2$,[2] formulation.

Now let us return to Eq. (8) and ask what happens if we take $a=0$, $b\neq 0$. It is easy to check that one still ends up with the Liouville equation (14); the changes consist of $B_3\rightarrow-B_3$ and

$$b=2\alpha\frac{(d\bar{g}/d\bar{z})}{(1-g\bar{g})}. \tag{37}$$

Thus while it is not possible to change the direction of the magnetic field by $g\to 1/g$, antivortices can be obtained by $(a(g),0)\to(0,b(\bar{g}))$, $B_3\to -B_3$.

Finally, let us briefly examine the $n=1$ case. A possible *Ansatz* is

$$A_\mu=(0,0,0,A_4(x_1)) \tag{38}$$

and

$$\psi^T=(a(x_1),b(x_1),0,0). \tag{39}$$

The Seiberg–Witten equation (6) demands either $\psi^T=(a,a,0,0)$ or $\psi^T=(a,-a,0,0)$. Taking $a=\alpha\exp(\omega_x+i\omega_y)$ as before, these two cases yield

$$\partial_1(\omega_x+i\omega_y)=\pm A_4, \tag{40}$$

respectively. Thus in order for A_4 be real, ω_y can at most be a constant, which we may take to be zero. Then, using (3) we obtain

$$\partial_1^2\omega_x=\alpha^2\exp(2\omega_x). \tag{41}$$

Calling $\alpha x_1=x$ again, (41) is seen to be a y-independent version of the Liouville equation (12). While (41) may be integrated directly by elementary methods, it is simpler to read off the solution from (17) by picking a $g(z)$ such that the variable y disappears in ω_x. This happens only for $g(z)=\exp\kappa(z+x_0)$, κ and x_0 being constant real numbers [an imaginary constant added to x_0 cancels out along with the iy in (17)]. We may as well set $x_0=0$, which gives

$$\omega_x=\frac{1}{2}\ln\frac{4\kappa^2e^{2\kappa x}}{(1-e^{2\kappa x})^2}. \tag{42}$$

This results in

$$|a|=\frac{\alpha\kappa}{|\sinh\kappa x|}, \tag{43}$$

$$A_4=\pm\alpha\kappa\coth\kappa x, \tag{44}$$

and

$$E_1=\mp\frac{\alpha^2\kappa^2}{\sinh^2\kappa x}. \tag{45}$$

The expected singularity appears at $x=0$ in (42)–(45). In contrast, the nonsingular version obtained by $x_1\to ix_1$ has $(1+e^{2\kappa x})^{-2}$ in (42); in addition, cosh κx and sinh κx in (43)–(45) are now switched. Thus A_4 changes into $\pm\alpha\kappa\tanh\kappa x$, which is the well-known kink (antikink) solution of φ^4 theory.

In conclusion, we see that the dimensionally reduced Seiberg–Witten equations in $\mathbf{R}^n$ ($n=1,2,3$) yield a singular version of topological solitons characteristic of each n, the $n=3$ case being represented by Freund's monopole solution. The accompanying spinors are, of course, the new feature associated with these familiar solitons. The $n=2$ case indicates connections between integrable systems and the Seiberg–Witten equations. Finally, it should be interesting to look for

solutions of the Seiberg–Witten equations reduced to a two-dimensional manifold admitting negative local values for the scalar curvature and see how this affects the singularities.

(Received 16 October 1995; accepted for publication 21 February 1996)

Transformation bracket relating 2D harmonic oscillator product states with different sets of Jacobian coordinates is derived for systems composed of an arbitrary number of particles with arbitrary masses. The numerical diagonalization of the Hamiltonian of a three-electron quantum dot is given as an example to illustrate its applications. © *1996 American Institute of Physics.* [S0022-2488(96)00606-8]

I. INTRODUCTION

In recent years, mesoscopic physics is a rapidly developing field of research. Due to the advances of microfabrication technology in semiconductors, it is now possible to confine the 2D layer of electrons gas into dots of nanometer size,[1,2] where the motion of electrons in all the three dimensions are quantized. Experimentally, the number of electrons trapped in each dot ranges from one to several hundred and can be controlled very effectively by adjusting the gate voltages applied. Therefore quantum dots should be treated as disk-like atomic systems.

So far, quantum dots have been experimentally investigated by capacitance–voltage spectroscopy,[3] vertical tunneling,[4] in-plane transport,[5] as well as far-infrared spectroscopy in quantum dot arrays.[6] The accumulated data did not vary as smoothly as those predicted by Hartree-type calculations, but showed rich structures. Understanding of the data requires that the electron–electron interaction be treated exactly. The confinement potential is, of course, shape-dependent. To most of the quantum dots, harmonic oscillator potential is a good approximation.[7] The Slater determinants composed of single harmonic oscillator functions can thus be used as basis functions to diagonalize the Hamiltonian. The drawback of this formalism is that the trivial c.m. motion has been included. To separate the c.m. motion from the relative, a set of the c.m. and relative coordinates should be introduced to describe the system. However, the (anti-) symmetrization of harmonic basis with relative coordinates as variables is automatic in the case of two electrons[8] but a nontrivial matter for systems with $N>2$. In Ref. 9, Hawlyrak has proposed a scheme to construct the antisymmetric basis functions using Schwinger's coupled Boson representation.

In this paper we presented the transformation bracket relating product states of harmonic oscillator functions with different sets of Jacobian coordinates. This bracket can have many applications: first of all, since any particle permutation just transforms one set of Jacobi coordinates into another, properly symmetrized harmonic basis functions in coordinate space can be constructed with the bracket; second, the matrix elements of any pair of particle–particle interaction can be reduced to one single integral; finally, since the Jacobian coordinates are indispensable for describing the rearrangement scattering process, the bracket also plays a powerful tool for solving the problem of single electron tunneling through quantum dot on the exact quantum mechanical basis.[10]

The following section is devoted to deriving the transformation bracket for 2D harmonic oscillators. In the third section, we present an example to show how the transformation bracket can be applied to solve the quantum dot problems.

II. TRANSFORMATION BRACKET FOR 2D HARMONIC OSCILLATORS

Consider a system of N particles with coordinates $\mathbf{r}_i$, and masses m_i, moving independently in a 2D harmonic oscillator potential well with the frequency ω, the Hamiltonian reads

$$H=\sum_{i=1}^{N}\left(\frac{-\hbar^2}{2m_i}\nabla_{\mathbf{r}_i}^2+\frac{1}{2}m_i\omega^2 r_i^2\right). \tag{1}$$

A set of Jacobian coordinates for the system mean the components of a set of $(N-1)$ independent values $\{\boldsymbol{\xi}_j\}$ such that each vector represents the displacement of the c.m. of one subset of the N particles from the c.m. of another subset and such that no two such vectors connect with the same c.m. Associated with each Jacobian coordinate vector $\boldsymbol{\xi}_j, \mu_j$ will be the reduced mass of the pair of particle clusters the c.m. of which are joined by $\boldsymbol{\xi}_j$. Then the following relation is fulfilled

$$H=H_{cm}+H_r, \tag{2}$$

where

$$H_r=\sum_{j=1}^{N-1} h_j=\sum_{j=1}^{N-1}\left(\frac{-\hbar^2}{2\mu_j}\nabla_{\xi_j}^2+\frac{1}{2}\mu_1\omega^2\xi_j^2\right), \tag{3}$$

$$H_{cm}=\frac{-\hbar^2}{2M}\nabla_R^2+\frac{1}{2}M\omega^2R^2, \tag{4}$$

where M is the total mass, $M=\Sigma_{i=1}^{N}m_i$. $\mathbf{R}$ is the c.m. coordinate of the system, H_{cm} describes the c.m. motion, H_r describes the relative motion which we are mainly interested in. From Eqs. (2)–(4), we know that the c.m. motion is separable from the relative motion. This feature retains when particle–particle interactions are turned on. The c.m. motion is a harmonic oscillator and the relative motion is $(N-1)$ harmonic oscillators with the same frequency. Let us define a vector creator $\boldsymbol{\eta}$ by

$$\boldsymbol{\eta}=\sqrt{\frac{\mu\omega}{2\hbar}}\left(\frac{-\hbar}{\mu\omega}\nabla_{\xi}+\xi\right), \tag{5}$$

whose components η_x and η_y create quanta in the x,y oscillators, respectively. Then the Hamiltonian of an oscillator h and the angular momentum operator L_z in this representation are

$$h=\hbar\omega(\boldsymbol{\eta}\cdot\boldsymbol{\eta}^{+}+1), \tag{6}$$

$$L_z=-i\hbar\,\boldsymbol{\eta}\times\boldsymbol{\eta}^{+}, \tag{7}$$

where $\boldsymbol{\eta}^{+}$ is the Hermitian conjugation of $\boldsymbol{\eta}$. A 2D harmonic oscillator function with eigenenergy $(2n+|m|+1)\hbar m$ and angular momentum $m\hbar$ can, in the $\boldsymbol{\eta}$ representation, be written as

$$|nm\rangle=N_{nm}(\boldsymbol{\eta}\cdot\boldsymbol{\eta})^n(\eta_x+i\delta_m\eta_y)^{|m|}|0\rangle, \tag{8}$$

where $|0\rangle$ denotes the normalized ground state, N_{nm} is the normalization constant, δ_m is the sign of m given by

$$N_{nm}=\sqrt{\frac{1}{2^{2n+|m|}(|m|+n)!\cdot n!}}, \tag{9}$$

$$\delta_m=\begin{cases}+, & \text{if } m>0,\\ -, & \text{if } m\leqslant 0.\end{cases} \tag{10}$$

Thus for the relative motion of the N-particle system, we have

$$|K\rangle=\prod_{j=1}^{N-1}\{N_{n_jm_j}(\boldsymbol{\eta}_j\cdot\boldsymbol{\eta}_j)^{n_j}(\eta_{jx}+i\delta_{m_j}\eta_{jy})^{|m_j|}\}|0\rangle \tag{11}$$

and the corresponding eigenenergy $E_{[K]}$ and angular momentum $L_{z[K]}$ are given by

$$E_{[K]}=\hbar\omega\sum_{j=1}^{N-1}(2n_j+|m_j|+1), \tag{12}$$

$$L_{z[K]}=\hbar\sum_{j=1}^{N-1}m_j, \tag{13}$$

where $[K]$ denotes a set of $2(N-1)$ quantum numbers $(n_1,n_2,\ldots,n_{N-1};m_1,m_2,\ldots,m_{N-1})$.

Making use of the factorization

$$\boldsymbol{\eta}\cdot\boldsymbol{\eta}=(\eta_x-i\eta_y)(\eta_z+i\eta_y), \tag{14}$$

we can rewrite Eq. (11) into

$$|K\rangle=\prod_{j=1}^{N-1}\{N_{n_jm_j}(\eta_{jx}-\eta_{jy})^{\bar{n}_j}(\eta_{jx}+i\eta_{jy})^{\tilde{N}_j}\}|0\rangle \tag{15}$$

which will be more convenient for our following purpose, where

$$\bar{n}_j=\begin{cases}n_j, & \text{if } m_j>0,\\ n_j+|m_j|, & \text{if } m_j\leqslant 0,\end{cases}\quad \tilde{N}_j=\begin{cases}n_j+|m_j|, & \text{if } m_j>0,\\ n_j, & \text{if } m_j\leqslant 0.\end{cases} \tag{16}$$

For $N>2$ there are more than one set of Jacobian coordinates that can be assigned to the system. The different possible sets of Jacobian coordinates are related to each other by linear transformations

$$\sqrt{\mu_i^{(\alpha)}}\boldsymbol{\xi}_i^{(\alpha)}=\sum_{j=1}^{N-1}a_{ij}^{\alpha\beta}\sqrt{\mu_j^{(\beta)}}\boldsymbol{\xi}_i^{(\beta)}\quad (i=1,2,\ldots,N-1), \tag{17}$$

where all the $a_{ij}^{\alpha\beta}$ form an orthogonal matrix. Thus the Jacobian coordinates and the reduced masses and the creation-operators appearing in the above equations should be identified by superscripts $\alpha,\beta,\ldots,\gamma$, etc. Since such superscripts are absent from the terms on rhs of Eq. (1) and since they are superfluous to the c.m. quantities, Eqs. (2)–(4) imply that the following relation holds for any two sets of Jacobian coordinates for a given $N(>2)$-particle system

$$\sum_{j=1}^{N-1}\left\{\frac{-\hbar^2}{2\mu_j^{(\alpha)}}\nabla^2_{\boldsymbol{\xi}_j^{(\alpha)}}+\frac{1}{2}\mu_j^{(\alpha)}[\xi_j^{(\alpha)}]^2\right\}=\sum_{i=1}^{N-1}\left\{\frac{-\hbar^2}{2\mu_i^{(\beta)}}\nabla^2_{\boldsymbol{\xi}_i^{(\beta)}}+\frac{1}{2}\mu_i^{(\beta)}[\xi_i^{(\beta)}]^2\right\}. \tag{18}$$

Therefore an eigenstate in one set of Jacobian coordinates can be expanded by eigenstates of another set of Jacobian coordinates belonging to the same eigenvalues $E_{[K]}$ and $L_{z[K]}$

$$|K\rangle^{(\alpha)}=\sum_{[K']} B^{[K]}_{[K']}(N,\alpha\beta)|K'\rangle^{(\beta)}, \tag{19}$$

where $B^{[K]}_{[K']}(N,\alpha\beta)$ is the transformation bracket we are looking for.

With the definition of vector creator in Eq. (5), it can be easily verified that the creators associated with different sets of Jacobian coordinates are subjected to the following transformations

$$\boldsymbol{\eta}_i^{(\alpha)}=\sum_{j=1}^{N-1} a_{ij}^{\alpha\beta}\boldsymbol{\eta}_j^{(\beta)}. \tag{20}$$

Substituting Eq. (20) into Eq. (15) and expanding it in terms of the eigenstates in the β set, we obtain

$$\begin{aligned}|K\rangle^{(\alpha)}=&\sum_{\tilde{n}'_1\tilde{n}'_2\cdots\tilde{n}'_{N-1}}\ \sum_{\tilde{N}'_1\tilde{N}'_2\tilde{N}'_{N-1}}\prod_{j=1}^{N-1}\left(\frac{N_{n_jm_j}}{N_{n'_jm'_j}}\right)A^{\alpha\beta}(\tilde{n}_1,\tilde{n}_2,\ldots,\tilde{n}_{N-1};\tilde{n}'_1,\tilde{n}'_2,\ldots,\tilde{n}'_{N-1})\\&\cdot A^{\alpha\beta}(\tilde{N}_1,\tilde{N}_2,\ldots,\tilde{N}_{N-1};\tilde{N}'_1,\tilde{N}'_2,\ldots,\tilde{N}'_{N-1})\delta_{E_{[K]},E_{[K']}}\delta_{L_{z[K]},L_{z[K']}}\cdot\prod_{j=1}^{N-1}\{N_{n_jm_j}[\eta_{jx}^{(\beta)}\\&-\eta_{jy}^{(\beta)}]^{\tilde{n}'_j}[\eta_{jx}^{(\beta)}+i\eta_{jy}^{(\beta)}]^{\tilde{N}'_j}\}|0\rangle,\end{aligned} \tag{21}$$

where $A^{\alpha\beta}$ is defined by

$$\begin{aligned}A^{\alpha\beta}(\tilde{n}_1,\tilde{n}_2,\ldots,\tilde{n}_{N-1};\tilde{n}'_1,\tilde{n}'_2,\ldots,\tilde{n}'_{N-1})=&\sum_{r_1r_2\cdots r_{N-1}}\ \sum_{s_1s_2\cdots s_{N-1}}\cdots\sum_{t_1t_2\cdots t_{N-1}}\\&\cdot\prod_{i=1}^{N-1}\left\{\frac{\tilde{n}_i!(a_{i1}^{\alpha\beta})^{r_i}(a_{i2}^{\alpha\beta})^{s_i}\cdots(a_{iN-1}^{\alpha\beta})^{t_i}}{r_i!s_i!\cdots t_i!}\right\}.\end{aligned} \tag{22}$$

Summations in Eq. (22) are subjected to the conditions $\Sigma_{i=1}^{N-1}r_i=\tilde{n}'_1$, $\Sigma_{i=1}^{N-1}s_i=\tilde{n}'_2,\ldots,$ $\Sigma_{i=1}^{N-1}t_i=\tilde{n}'_{N-1}$, and $(r,s,\ldots,t)$ refers to $(N-1)$ different sets of variables.

Comparing Eq. (21) with Eqs. (15) and (19), we obtain the transformation bracket we are looking for

$$\begin{aligned}B^{[K]}_{[K']}(N,\alpha\beta)=&\prod_{j=1}^{N-1}\left\{\frac{N_{n_jm_j}}{N_{n'_jm'_j}}\right\}A^{\alpha\beta}(\tilde{n}_1,\tilde{n}_2,\ldots,\tilde{n}_{N-1};\tilde{n}'_2,\tilde{n}'_2,\ldots,\tilde{n}'_{N-1})\\&\times A^{\alpha\beta}(\tilde{N}_1,\tilde{N}_2,\ldots,\tilde{N}_{N-1};\tilde{N}'_1,\tilde{N}'_2,\ldots,\tilde{N}'_{N-1})\delta_{E_{[K]},E_{[K']}}\delta_{L_{z[K]},L_{z[K']}}.\end{aligned} \tag{23}$$

The relations between n_j, m_j and $\tilde{n}_j$, $\tilde{N}_j$ of Eq. (15) hold also for n'_j, m'_j and $\tilde{n}'_j$,$\tilde{N}'_j$.

In computing $B^{[K]}_{[K']}(N,\alpha\beta)$, it is helpful to take notice of the following properties

$$B^{[K]}_{[K']}(N,\alpha\beta)=B^{[K']}_{[K]}(N,\beta\alpha), \tag{24}$$

$$1=\sum_{[k']} B^{[K]}_{[K']}(N,\alpha\beta)\cdot B^{[K']}_{[K]}(N,\beta\alpha) \tag{25}$$

which can be derived directly from its definition.

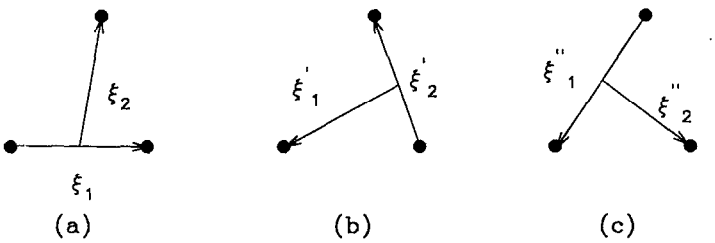

FIG. 1. Jacobian coordinates for three-body systems.

III. APPLICATIONS

Consider the motion of three electrons in a quantum dot with parabolic confinement $V(r_i)=1/2m^*\omega_0^2 r_i^2$, where m^* is the effective mass of electron. The three sets of Jacobian coordinates that can be assigned to the system are shown in Fig. 1. The linear transformation coefficients defined in Eq. (17) obviously fulfill, in this case, the following relations

$$a_{ij}^{\alpha\beta}=a_{ij}^{\beta\gamma}=a_{ij}^{\gamma\alpha} \tag{26}$$

with

$$(a_{ij}^{\alpha\beta})=\begin{pmatrix} -\frac{1}{2} & -\frac{\sqrt{3}}{2} \\ \frac{\sqrt{3}}{2} & -\frac{1}{2} \end{pmatrix}. \tag{27}$$

A. The Hamiltonian matrix elements between two harmonic states

The Hamiltonian describing the relative motion of three electrons can be written as

$$H_r=\frac{-\hbar^2}{2\mu_1^{(\alpha)}}\nabla^2_{\xi_1^{(\alpha)}}+\frac{-\hbar^2}{2\mu_2^{(\alpha)}}\nabla^2_{\xi_2^{(\alpha)}}+\sum_{i>j}u(r_{ij}) \tag{28}$$

with

$$u(r_{ij})=\frac{1}{6}m^*\omega_0^2 r_{ij}^2+\frac{e^2}{4\pi\epsilon r_{ij}}, \tag{29}$$

where the term proportional to r_{ij}^2 arises from the confinement. A noteworthy point is that there exists a minimum in u located at $r_{ij}=r_0\equiv(3e^2/4\pi\epsilon m^*\omega_0^2)^{1/3}$.

The Hamiltonian matrix elements $H_{[K],[K']}$ is then written as

$$\begin{aligned} H_{[K],[K']}&=\int[\phi_{n_1m_1}(\xi_1^{(\alpha)})\phi_{n_2m_2}(\xi_2^{(\alpha)})]H_r[\phi_{n_1'm_2'}(\xi_1^{(\alpha)})\phi_{n_2'm_2'}(\xi_2^{(\alpha)})]d\xi_1^{(\alpha)}d\xi_2^{(\alpha)} \\ &=H_0+H_a+H_b+H_c, \end{aligned} \tag{30}$$

where

$$H_0=(2n_1+2n_2+|m_1|+|m_2|+2)\hbar\omega\delta_{[K],[K']}, \tag{31}$$

$$H_a = U^{(m_1)}_{n_1,n_1'}\delta_{m_1,m_1'}\delta_{n_2,n_2'}\delta_{m_2,m_2'}, \tag{32}$$

$$H_b = \sum_{[K'']}\sum_{[K''']} B^{[K]}_{[K'']}(3,\alpha\beta)B^{[K']}_{[K''']}(3,\alpha\beta)U^{(m_1'')}_{n_1'',n_1'''}\delta_{m_1'',m_1'''}\delta_{n_2'',n_2'''}\delta_{m_2'',m_2'''}, \tag{33}$$

$$H_c = \sum_{[K'']}\sum_{[K''']} B^{[K]}_{[K'']}(3,\alpha\gamma)B^{[K]}_{[K''']}(3,\alpha\gamma)U^{(m_1'')}_{n_1'',n_1'''}\delta_{m_1'',m_1'''}\delta_{n_2'',n_2'''}\delta_{m_2'',m_2'''}, \tag{34}$$

$$U^{(m)}_{n,n'} = \int \phi_{nm}(\xi)u(\xi)\phi_{n'm}(\xi)d\xi. \tag{35}$$

The integrations in Eq. (35) can be carried out analytically.

B. Antisymmetrication of the basis functions

When dealing with the identical particle systems, the basis functions should have the permutation symmetry as is required. In the case of three-fermion system with total spin $S=3/2$, the antisymmetrized function $\phi_j(123)$ constructed from 2D harmonic states is of the following form

$$\begin{aligned}\phi_j(123) &= \frac{1}{6}(P_e - P_{12} - P_{13} - P_{23} + P_{123} + P_{132})[\phi_{n_1m_1}(\xi_1^{(\alpha)})\phi_{n_2m_2}(\xi_2^{(\alpha)})] \\ &= \frac{1}{3}\{[\phi_{n_1m_1}(\xi_1^{(\alpha)})\phi_{n_2m_2}(\xi_2^{(\alpha)})] + [\phi_{n_1m_1}(\xi_1^{(\beta)})\phi_{n_2m_2}(\xi_2^{(\beta)})] \\ &\quad + [\phi_{n_1m_1}(\xi_1^{(\gamma)})\phi_{n_2m_2}(\xi_2^{(\gamma)})]\} \\ &= \sum_{[K']}\frac{1}{3}\{\delta_{[K],[K']} + B^{[K]}_{[K']}(3,\beta\alpha) + B^{[K]}_{[K']}(3,\gamma\alpha)\}[\phi_{n_1'm_2'}(\xi_1^{(\alpha)})\phi_{n_2'm_2'}(\xi_2^{(\alpha)})].\end{aligned} \tag{36}$$

In the case of fermion system with $S=1/2$

$$\phi_j(123) = Q_0(123)\chi^0_{1/2} + Q_1(123)\chi^1_{1/2}, \tag{37}$$

where

$$\begin{aligned}Q_0(123) &= \frac{1}{6}(2P_e + 2P_{12} - P_{13} - P_{23} - P_{123} - P_{132})[\phi_{n_1m_1}(\xi_1^{(\alpha)})\phi_{n_2m_2}(\xi_2^{(\alpha)})] \\ &= \sum_{[K']}\frac{1}{3}[2\delta_{[K],[K']} - B^{[K]}_{[K']}(3,\beta\alpha) - B^{[K]}_{[K']}(3,\gamma\alpha)][\phi_{n_1'm_1'}(\xi_1^{(\alpha)})\phi_{n_2'm_2'}(\xi_2^{(\alpha)})],\end{aligned} \tag{38}$$

$$\begin{aligned}Q_1(123) &= \frac{\sqrt{3}}{6}(P_{13} - P_{23} + P_{123} - P_{132})[\phi_{n_1m_1}(\xi_1^{(\alpha)})\phi_{n_2m_2}(\xi_2^{(\alpha)})] \\ &= \sum_{[K']}\frac{\sqrt{3}}{3}[-B^{[K]}_{[K']}(3,\gamma\alpha) + B^{[K]}_{[K']}(3,\gamma\alpha)][\phi_{n_1'm_1'}(\xi_1^{(\alpha)})\phi_{n_2'm_2'}(\xi_2^{(\alpha)})],\end{aligned} \tag{39}$$

$$\chi^S_S = \{[\xi(1)\xi(2)]_s\xi(3)\}s. \tag{40}$$

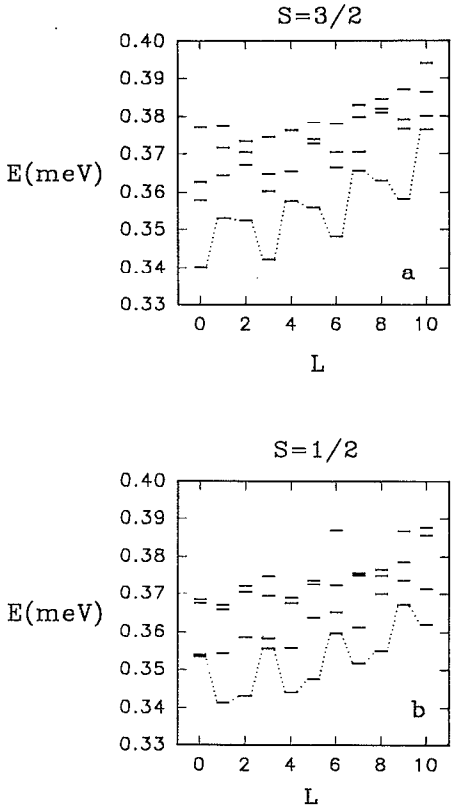

FIG. 2. Energy spectra of three electrons in a harmonic well with $\omega_0=0.01$ meV and without a magnetic field. The other parameters are taken appropriate for GaAs. The dotted lines are to guide the eyes to detect the magic numbers.

In the above equations, $\xi(i)$ is a spin state of the ith fermion, χ_S^s is the spin-part wave function with the total spin S, and with the spins of particles 1 and 2 coupled to s; Q_0 and Q_1 are the spatial parts, P_α denotes the permutation operator. A set of antisymmetrized functions $\{\phi_j(123)\}$ so obtained are, in general, linearly relevant, from which a set of orthonormalized basis functions can be constructed through the well known Schmidt procedure.

Before going to the details of the numerical results, let us discuss the implications of antisymmetrization on the geometric configurations. The minimum of total potential energy $U=\Sigma_{i>y}^3 u(r_{ij})$ is associated with an equilateral triangle (ET) with sidelength $r_{ij}=r_0$. The system should favor this configuration in order to minimize the averaged total potential energy. However, the antisymmetrization imposes restrictions on this pursuance. Let Φ_L be the spatial wave function with angular moment L and spin $S=3/2$. Since in the ET configuration a cyclic permutation of the three particles is equivalent to a rotation of $3\pi/2$, we have

$$P_{(123)}\Phi_L(ET)=R_{3\pi/2}\Phi_L(ET). \tag{41}$$

Thus we have

$$\Phi_L(ET)=e^{(i3\pi L/2)}\Phi_L(ET). \tag{42}$$

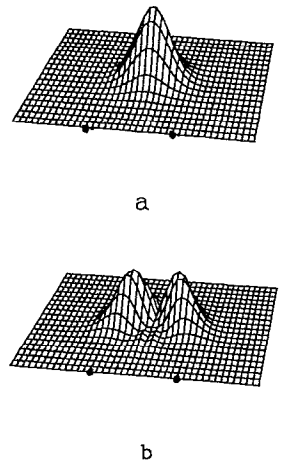

FIG. 3. Wave function distribution of the lowest state with (a) magic angular momentum; (b) non-magic angular momentum. The two dots on the front edge are positions of particles 1 and 2 with a separation r_0.

In other words, the most favorite ET component of the configurations will be completely prohibited in the $L \neq 3k$ ($k=integer$) states and this must lead to particularly high interacting energy. Similar arguments can be applied to the $S=1/2$ states. In contrast with $S=3/2$, the ET-prohibition will occur in the $L=3k$ states when $S=1/2$.

In Fig. 2, we presented the quantum spectra of three interacting electrons in a harmonic potential with a very small ω_0 ($=0.01$ meV) to emphasize the interaction. From the figure, one can see that the lowest state of a magic number of angular momentum (without ET-prohibition) is much lower than that of the adjacent non-magic numbers. In Fig. 3, we presented the wave function distributions of a magic-number state and a non-magic-number state for a comparison. In a magic-number state, the ET configuration is strongly pursued in order to minimize the potential energy while in the non-magic-number state the ET configuration is a node of the wave function demonstrating the ET-prohibition. The appearance of such a node increases both the kinetic and potential energies.

Experimentally, a vertical external magnetic field is applied. With the symmetric gauge, the Hamiltonian remains the same as Eq. (28) except for a replacement of $\omega_0 \rightarrow \sqrt{\omega_0^2+\omega_c^2/4}$ with the cyclotron frequency $\omega_c=eB/m^*$, and the additional Zeeman terms $(\omega_c L/2+g^*\mu_B B S_z)$. The Zeeman terms make states with larger L be even lower than states with smaller L when the magnetic field increases. From Fig. 2, it is easy to understand why the ground states occur only at the magic numbers of angular momentum.

Finally, we would like to emphasize that the appearance of magic numbers of angular momentum is completely due to the restrictions of geometric symmetry and permutational symmetry and has nothing to do with the details of the dynamic symmetries. With nonparabolic confinement, the c.m. motion is inseparable from the relative. For three electrons, the most favorite configuration continues to be the ET with its c.m. sitting on the minimum of the confinement and the magic numbers are of the same as discussed above.

Multiple condensate solutions for the Chern–Simons–Higgs theory

Gabriella Tarantello[a)]
Università di Roma "Tor Vergata," Via della Ricerca Scientifica, 00133-Roma, Italia

(Received 21 February 1996; accepted for publication 17 May 1996)

We study the existence of condensate solutions for the Chern-Simons-Higgs model with the choice of a potential field where both the symmetric and asymmetric vacua occur as ground states [see Hong, Kim, and Pac, Phys. Rev. Lett. **64**, 2230 (1990) and Jackiw and Weinberg, *ibid.* **64**, 2234 (1990)]. We show that if the Chern-Simons coupling parameter k is above a critical value, no such solutions can exist, while for $k>0$ below this critical value there exist at least *two* condensate solutions carrying the same quantized energy, as well as electric and magnetic charge. This multiplicity result accounts for the two vacua states present in the model. In fact, as $k\to 0^+$ it is shown that the two solutions found "bifurcate" from the asymmetric and symmetric vacuum states respectively. © *1996 American Institute of Physics.* [S0022-2488(96)03208-2]

I. INTRODUCTION

In recent years much attention has been devoted to the anyon model (see Refs. 1 and 2) and to the corresponding condensate (or multivortex) solutions which are believed relevant in several aspect of theoretical physics as, for instance, in high-temperature superconductivity. See Refs. 3–7.

Mathematically, the anyon model is a classical field theory defined on the (2+1)-Minkowski space, whose Lagrangean is characterized by the coupling of the scalar field, the Yang–Mills (or Maxwell) field and the Chern-Simons gauge field. It is the Chern-Simons term responsible for the presence of electrically and magnetically charged multivortices, known as anyons.

However in its full setting, the Euler–Lagrange equations relative to the anyon model take a complicated form, and so far a rigorous mathematical treatment of condensate solutions has been possible only for the reduced Abelian Chern–Simons–Higgs model where the Yang–Mills field is neglected. Such a reduction is justifiable at large distances and low energies where the Chern–Simons–Higgs term dominates the higher derivative Yang–Mills (or Maxwell) term.

For a special choice of the Higgs potential, where both symmetric and asymmetric vacua occur as ground states, Hong–Kim–Pac[8] and Jachiw–Weinberger[9] have observed that, in a full space settings, stationary vortex solutions for the Chern–Simons–Higgs model satisfy a set of Bogomolny-type selfdual equations similar to those obtained for the "classical" vortex theory, see Refs. 10–12

Thus, topological solutions carrying quantized electric and magnetic charge were obtained in Refs. 13 and 14, while non-topological solutions carrying fractal values of the charges were established in Refs. 15 and 16.

The same self-dual equations remain valid also under appropriate 't Hooft periodic boundary conditions, and were studied by Caffarelli and Yang in Ref. 17. They showed that, periodic multivortices (with assigned set of zeros for the Higgs scalar) exist, if and only if, the Chern-Simons coupling parameter is not too large with respect to the size of the periodic cell.

In this note, we complete the work of Caffarelli–Yang, and obtain that, to any assigned set of zeros for the Higgs scalar, there correspond (at least) two distinct solutions with the same quan-

[a)]E-mail: tarantello@mat.utovrm.it; Fax: 39-6-72594699.

tized energy as well as electric and magnetic charge. This feature is in contrast with the classical vortex theory (see Refs. 10, 11, and 12) where a solution to the self-dual equation is completely characterized by the set of zeros of its Higgs scalar. However, for the Chern–Simons–Higgs model such a multiplicity property should not be surprising since it accounts for each of the vacuum state present in the potential field. In fact, we show that the solutions found can be "ordered" according to their superconducting properties; and, as the Chern-Simons coupling parameter tends to zero, the most superconducting solution tends (in a suitable norm) to the asymmetric vacuum while the other solution converges to the symmetric vacuum.

We refer to Theorem 2.1 and 2.2 of the following section for the precise statements.

II. THE CHERN–SIMONS–HIGGS MODEL, CORRESPONDING EQUATIONS AND STATEMENT OF THE MAIN RESULTS

In this section we introduce the appropriate 't Hooft periodic boundary conditions (see Ref. 18) and derive the analytical set up for the study of periodic multivortices in the Chern–Simons–Higgs model.

For this purpose, we follow[17] and show that the selfdual equations of Refs. 8 and 9 remain valid in the periodic situations.

The convention of summing repeated upper and lower indices will be observed throughout.

We consider the (2+1)-Minkowski space $R^{2,1}$ with metric tensor given by diag $(1,-1,-1)$ which we use to raise or lower indices.

According to the Abelian Higgs theory (see Ref. 10), the gauge field A defines a connection over the principle bundle $R^{2,1}\times U(1)$:

$$A=-iA_\eta dx^\eta, \quad A_\eta=A_\eta(x)\in R, \quad x=(x_0,x_1,x_2), \quad \eta=0,1,2;$$

with corresponding covariant derivative $D_A=d-iA$.

The curvature of A defines the Yang–Mills (or Maxwell) potential F_A, and it is given by

$$F_A=\frac{-i}{2}F_{\alpha,\beta}dx^\alpha\wedge dx^\beta$$

with $F_{\alpha\beta}=\partial_\alpha A_\beta-\partial_\beta A_\alpha$, $\alpha,\beta=0,1,2$.

Thus, if $\phi=\phi(x)$ is the complex valued Higgs scalar (a section over the associated bundle $R^{2,1}\times C$) and we write

$$D_A\phi=D_\eta\phi dx^\eta \text{ with } D_\eta\phi=\partial_\eta\phi-iA_\eta\phi \quad \eta=0,1,2,$$

the Chern–Simons–Higgs Lagrangean action density is defined by

$$\mathscr{L}(A,\phi)=(D_\eta\phi)(\overline{D^\eta\phi})+\tfrac{1}{4}k\epsilon^{\alpha\beta\gamma}F_{\alpha\beta}A_\gamma-V(|\phi|),$$

where $V=V(|\phi|)$ is the ($U(1)$-invariant) Higgs potential, $k>0$ is the Chern–Simons coupling parameter and the Levi–Civita tensor $\epsilon^{\alpha\beta\gamma},\alpha,\beta,\gamma=0,1,2$; is fixed by $\epsilon^{012}=1$.

The Euler–Lagrange equations corresponding to $\mathscr{L}$ are given by

$$\begin{cases} \frac{1}{2}k\epsilon^{\alpha\beta\gamma}F_{\alpha\beta}=j^\alpha=i(\phi\overline{D^\alpha\phi}-\bar{\phi}D^\alpha\phi) \\ D_\eta(D^\eta\phi)=-\dfrac{\partial V}{\partial\bar{\phi}} \end{cases}, \tag{2.1}$$

where $j^\alpha=(\rho,\mathbf{j})$ is the conserved matter current density.

We seek a static configuration of (2.1) subject to appropriate boundary condition to be specified according to the gauge invariance of $\mathscr{L}$.

For this purpose, we follow Ref. 17 and, as in Refs. 8 and 9, we obtain a reduction of (2.1) to a more convenient set of Bogomolny-type selfdual equation by the choice of the Higgs potential:

$$V(\phi)=\frac{1}{k^2}|\phi|^2(1-|\phi|^2)^2. \tag{2.2}$$

In fact, in the time independent situation, the $\alpha=0$ component of (2.1) yields to the relation:

$$kF_{1,2}=\rho=-2A_0|\phi|^2 \tag{2.3}$$

from which we derive the following form for the corresponding static energy density:

$$\mathscr{E}(A,\phi)=|D_1\phi|^2+|D_2\phi|^2+\frac{k^2}{4}\frac{F_{1,2}^2}{|\phi|^2}+\frac{1}{k^2}|\phi|^2(1-|\phi|^2)^2.$$

To specify the appropriate periodic boundary conditions, we recall the gauge invariance of $\mathscr{L}$ under the transformation:

$$\phi\to e^{i\omega}\phi, \quad A_\alpha+\partial_\alpha\omega, \quad \alpha=0,1,2,$$

with $\omega=\omega(x)$ a smooth function. In the stationary situation, the function ω depends only on (x_1,x_2) so that the gauge invariance is expressed by the transformation:

$$\phi\to e^{i\omega}\phi, \quad A_0\to A_0, \quad A_j\to A_j+\partial_j\omega; \quad j=1,2.$$

Let Ω be a basic cell in R^2 generated by the two independent vectors $\mathbf{a}^1$ and $\mathbf{a}^2$. Namely,

$$\Omega=\{x=(x_1,x_2)\in R^2: x=s_1\mathbf{a}^1+s_2\mathbf{a}^2, \quad 0<s_j<1 \quad j=1,2\}$$

with boundary,

$$\partial\Omega=\Gamma^1\cup\Gamma^2\cup\{\mathbf{a}^1+\Gamma^2\}\cup\{\mathbf{a}^2+\Gamma^1\}\cup\{\mathbf{0},\mathbf{a}^1,\mathbf{a}^2,\mathbf{a}^1+\mathbf{a}^2\}$$

where

$$\Gamma^j=\{x\in R^2: x=s_j\mathbf{a}^j 0<s_j<1\}, \quad j=1,2.$$

In view of the given gauge invariance we require the following 't Hooft boundary condition[18] to be satisfied by a solution (ϕ, A) of (2.1) in Ω:

$$\begin{cases} e^{i\xi_k(x+\mathbf{a}^k)}\phi(x+\mathbf{a}^k)=e^{i\xi_k(x)}\phi(x) \\ A_0(x+\mathbf{a}^k)=A_0(x) \\ (A_j+\partial_j\xi_k)(x+\mathbf{a}^k)=(A_j+\partial_j\xi_k)(x) \quad j=1,2, \\ \forall x\in\Gamma^1\cup\Gamma^2\backslash\Gamma^k, \quad k=1,2 \end{cases} \tag{2.4}$$

where ξ_1 and ξ_2 are smooth functions defined in a neighborhood of $\Gamma^2\cup\{\mathbf{a}^1+\Gamma^2\}$ and $\Gamma^1\cup\{\mathbf{a}^2+\Gamma^1\}$ respectively.

To simplify notation, set $\xi_k(s_1,s_2)=\xi_k(s_1\mathbf{a}^1+s_2\mathbf{a}^2)$ with $0<s_k<1$, $k=1,2$. Since ϕ is a single valued complex function, its phase change around Ω can only be a multiple of 2π and from (2.4) we are lead to the condition:

$$\xi_1(1,1^-)-\xi_1(1,0^+)+\xi_1(0,0^+)-\xi_1(0,1^-)+\xi_2(0^+,1)-\xi_2(1^-,1)+\xi_2(1^-,0)-\xi_2(0^+,0)+2\pi N=0, \tag{2.5}$$

with N a suitable integer.

As a consequence, we obtain that both, the magnetic flux Φ and the electric charge Q are quantized on the domain cell Ω. In fact, from (2.4) and (2.5) it follows:

$$\Phi=\int_\Omega F_{1,2}=\int_{\partial\Omega} A_j dx^j=2\pi N, \tag{2.6}$$

while (2.3) gives

$$Q=\int_\Omega \rho=k\Phi=2\pi kN.$$

Thus, in analogy to the classical vortex theory (see Ref. 10) the integer N (known as the vortex number or flux) defines a homotopical invariant quantity as it counts the zeros of ϕ (according to their multiplicity) inside the periodic cell Ω.

At this point, following Ref. 17, we rewrite the energy density as follows:

$$\mathcal{E}(A,\phi)=\frac{1}{4}\left[\frac{k}{|\phi|}F_{1,2}+\frac{2}{k}|\phi|(|\phi|^2-1)\right]^2+|D_1\phi+iD_2\phi|^2+F_{1,2}+\mathrm{Im}\{\partial_j\epsilon_{j,k}\bar{\phi}D_k\phi\}$$

with $\epsilon_{j,k}=-\epsilon_{k,j}$, $j,k=1,2$, and $\epsilon^{1,2}=1$.

Since, by the boundary condition (2.4), we have: $\int_\Omega \partial_j\epsilon_{j,k}\bar{\phi}D_k\phi=0$, we obtain the following form for the energy functional:

$$E(A,\phi)=\int_\Omega \mathcal{E}=\int_\Omega \frac{1}{4}\left[\frac{k}{|\phi|}F_{1,2}+\frac{2}{k}|\phi|(|\phi|^2-1)\right]^2+\int_\Omega |D_1\phi+iD_2\phi|^2+\int_\Omega F_{1,2}\geq\int_\Omega F_{1,2}.$$

Thus, the minimizer of E over the homotopically invariant constraint:

$$\int_\Omega F_{1,2}=2\pi N$$

will have to satisfy the self-dual equation:

$$\begin{cases} D_1\phi+iD_2\phi=0 \\ F_{1,2}+\dfrac{2}{k^2}|\phi|^2(|\phi|^2-1)=0 \\ kF_{1,2}+2A_0|\phi|^2=0 \end{cases} \tag{2.7}$$

together with the boundary conditions (2.4) and (2.5).

By direct inspection, it is easy to check that, for V given by (2.2), every solution (A,ϕ) for $(2.7)_k$ satisfies the full set of second order equations (2.1).

Equations $(2.7)_k$ were first derived by Refs. 8 and 9 to hold in all of R^2, provided $|\phi|$ satisfies some appropriate decay assumptions. Periodic boundary conditions were treated by Caffarelli–Yang[17] (see also Ref. 4) and here we have essentially reported their arguments.

Concerning $(2.7)_k$ subject to the boundary conditions (2.4)–(2.5) we will establish an existence and multiplicity result whenever the zeros of ϕ are prescribed together with their multiplicity.

In Theorem 2.1 we complete the existence result of Caffarelli–Yang, [17] and use it to motivate the more interesting Theorem 2.2, where we obtain a multiplicity result.

Roughly speaking, Theorems 2.1 and 2.2 assert that from the limiting value $k=0$ and each of the vacuum state $|\phi|=1$ and $|\phi|=0$ it "bifurcates" a solution to $(2.7)_k$ $k>0$, subject to the boundary conditions (2.4) and with a prescribed set of zeros for the Higgs scalar.

By taking complex conjugate of ϕ and A if necessary, we can always assume that $N\geq 0$ in (2.5) and obtain the following:

Theorem 2.1 (Existence): Let $p_1,\ldots,p_m$ be given points in Ω and $n_1,\ldots,n_m$ positive integers such that $\Sigma_{j=1}^m n_j=N$. There exists a critical value $k_c \in (0,(1/2)\sqrt{|\Omega|/\pi N})$ of the coupling parameter such that, Eq. $(2.7)_k$ subject to the boundary condition (1.4)–(1.5) admits a solution (A,ϕ) for which $p_1,\ldots,p_m$ are the zeros for ϕ with multiplicity $n_1,\ldots,n_m$, if and only if $0<k\leq k_c$.

Furthermore, when $0<k\leq k_c$ then problem $(2.7)_k$ admits a solution (A_k,ϕ_k) which, in addition to the zero set property fixed above also satisfies:

(i) The energy, magnetic flux and electric change of (A_k,ϕ_k) are respectively given by,

$$E=2\pi N, \quad \Phi=2\pi N, \quad Q=2\pi kN. \tag{2.8}$$

(ii) The solution (A_k,ϕ_k) is the most superconducting (or "maximal") in the sense that the magnitude $|\phi_k|$ takes the largest possible values among all solutions to $(2.7)_k$ with the same zero set.

(iii) The map $k\to|\phi_k|0<k\leq k_c$ is strictly monotone increasing;
$|\phi_k|<1$ in Ω;
$|\phi_k|\to 1$ as $k\to 0^+$ pointwise, a.e. in Ω and in $W^{1,q}(\Omega)$, $1<q<2$.
$F_{1,2}^{(k)}=\partial_1 A_2^{(k)}-\partial_2 A_1^{(k)}\to 2\pi\Sigma_{j=1}^N \delta_{p_j}$ in the sense of measure as $k\to 0^+$, where each Dirac distribution δ_{p_j} is repeated according to the corresponding multiplicity n_j, $j=1,\ldots,m$.

Theorem 2.2 (Multiplicity): Let $p_1,\ldots,p_m\in\Omega$, $n_1,\ldots,n_m\in N$ $\Sigma_{j=1}^m n_j=N$ and k_c be as given in Theorem 2.1.

If $0<k<k_c$, then (beside the maximal solution (A_k,ϕ_k)) Eq. $(2.7)_k$ admits a second solution $(\tilde{A}_k,\tilde{\phi}_k)$ satisfying (2.4)–(2.5) and for which $p_1,\ldots,p_m$ are the zeros of $\tilde{\phi}_k$ with multiplicity $n_1,\ldots,n_m$ respectively.

The formulas (2.8) hold respectively for the energy, magnetic flux and electric charge relative to $(\tilde{A}_k,\tilde{\phi}_k)$ and $|\tilde{\phi}_k|<|\phi_k|$ in $\Omega\setminus\{p_1,\ldots,p_m\}$. Furthermore, if $N=1$ then, for every integer $q\geq 0$ we have

$$\|\tilde{\phi}_k\|_{C^q(\Omega)}\to 0 \quad \text{as} \quad k\to 0^+.$$

We believe that the last statement in Theorem 2.2 should hold without the restriction $N=1$. However, as well shall see in Sec. III, the condition $N=1$ is essential for our method to work and a completely different approach is needed in order to treat the case $N>1$.

Theorems 2.1 and 2.2 will be proved with the help of a further reduction of Eqs. $(2.7)_k$ to a semilinear elliptic problem. This is in the spirit of the work of Taubes (cf. Refs. 12, 11, and 10) on N-vortex solutions in R^2 relative to the Ginzburg-Landau equations in superconductivity. In this situation, an analogous set of selfdual equations were first derived by Bogomolny[19] for the special value of the parameter which distinguishes between type I and II superconductors. In view of Bogomolny's equations, Taubes observed that the Higgs scalar can admit only a discrete set of zeros with integer multiplicity. Furthermore, once that such zeros (and relative multiplicity) are prescribed, the N-vortex problem reduces (in a fixed gauge) to the single unknown $u=\ln(|\phi|^2)$, which, according to the self-dual equations, will have to satisfy a semilinear elliptic equation in R^2 together with appropriate decay conditions.

In Ref. 14, Wang showed that an analogous approach is possible for the self-dual equations $(2.7)_k$ and obtained a topological N-vortex solution in R^2 for each prescribed set of zeros of the Higgs scalar. Similarly, in the periodic situation, Caffarelli–Yang[17] obtained a condensate solutions by reducing the problem to the search of a solution for a semilinear elliptic equation on the two-dimensional torus.

We will use the same approach and exploit the variational structure of the reduced elliptic problem (on the 2-torus), to obtain two solutions which define, respectively, a local minimum and a mountain-pass critical point for the associated action functional. In case $N=1$, by means of this variational characterization of the solutions, we will be able to study their behavior as $k\to 0^+$. We will see that, while (as expected) the local minimum converges, in a suitable norm, to a solution of a singular elliptic equation (involving some Dirac's measures), the mountain-pass solution yields, at the limit, to a solution of a (more surprising) mean field-type equation, whose interest has emerged already in other contests. We are referring to Eq. (3) of Sec. III, and just mention that the corresponding Dirichlet problem (3)* is amply discussed in Refs. 20–22 in connection with the study of the statistical mechanics of point vortices as a possible approach to the understanding of 2D turbulence.

We now proceed to derive our semilinear elliptic problem. To this purpose, as in Refs. 11 and 12 we observe that the first of the equations in $(2.7)_k$ may be rewritten as:

$$2\bar{\partial}\phi - i\hat{A}\phi = 0 \tag{2.9}$$

where, $\hat{A}=A_1+iA_2$ and $\bar{\partial}=\frac{1}{2}(\partial_1+i\partial_2)$.

Hence, up to a nonvanishing multiple factor, ϕ is holomorphic and therefore it admits a finite number of zeros in Ω with integer multiplicity.

Furthermore, solving for $\hat{A}$ in (1.9) we have

$$\hat{A} = -2i\bar{\partial}\ln\phi. \tag{2.10}$$

Denote by $Z(\phi)=\{p_1,\ldots,p_N\}\subset\Omega$ the zeros of ϕ each repeated according to their multiplicity.

Setting $z=x_1+ix_2$ and $u(z)=\ln|\phi(z)|^2$, we can assume that ϕ takes the form:

$$\phi(z)=\exp\left(\frac{1}{2}u(z)+i\sum_{j=1}^{N}\arg(z-p_j)\right), \tag{2.11}$$

where the somewhat arbitrary choice on the imaginary part of ϕ merely reflects the gauge invariance of the equations.

In view of (2.10), from (2.11) we may recover the A_1 and A_2 components of the connection A by the formulas:

$$A_1 = -\mathrm{Re}(2i\bar{\partial}\ln\phi) \tag{2.12}$$

$$A_2 = -\mathrm{Im}(2i\bar{\partial}\ln\phi).$$

Contrary to what might seem, a straightforward calculation shows that A_j, $j=1,2$ defines a C^∞ function on Ω.

Consequently, the curvature component $F_{1,2}=\partial_1 A_2-\partial_2 A_1$ may be computed and by the last of the equations in $(2.7)_k$ we also recover the $\alpha=0$ component of A which is given by

$$A_0 = -\frac{kF_{1,2}}{2|\phi|^2} = -\frac{k}{2|\phi|^2}(\partial_1 A_2-\partial_2 A_1). \tag{2.13}$$

Thus, problem $(2.7)_k$ is reduced to the search of a periodic function u such that,

$$u(z)=n_k \ln |z-p_k|^2 \text{ as } z\to p_k \tag{2.14}$$

(n_k is the multiplicity of p_k), and

$$\Delta u=\frac{4}{k^2} e^u(e^u-1) \text{ in } \Omega\backslash Z(\phi), \tag{2.15}$$

where (2.15) is just a restatement of the second equation in $(2.7)_k$, since away from the zeros of ϕ, the function u is smooth and by means of (2.12) we derive: $F_{1,2}=-\frac{1}{2}\Delta u$ in $\Omega\backslash Z(\phi)$.

Putting together (2.14) and (2.15) we are reduced to finding a solution u on the (flat) 2-torus for the equation:

$$\Delta u=\frac{4}{k^2} e^u(e^u-1)+4\pi\sum_{j=1}^{N} \delta_{p_j} \tag{2.16}$$

with δ_p the Dirac distribution concentrated at the point p.

This task will be taken up in the following section.

Existence of solutions for (2.16)

We identify the doubly periodic cell Ω with the two-dimensional torus, $\Omega=R^2/Z\times Z$ and let $p_1,\ldots,p_N$ be fixed points in Ω, repeated according to their multiplicity. Denote by u_0 the unique solution for:

$$\begin{cases} \Delta u_0=-\dfrac{4\pi N}{|\Omega|}+4\pi\displaystyle\sum_{j=1}^{N} \delta_{p_j} \text{ on } \Omega \\ \displaystyle\int_\Omega u_0=0 \end{cases}, \tag{2.17}$$

(see Ref. 23). As well known, $u_0\in C^\infty(\Omega\backslash\{p_1,\ldots,p_N\})$ and if n_j is the multiplicity of p_j then u_0 behaves like: $\ln(|x-p_j|^{2n_j})$ as $x\to p_j$. In particular, $u_0\in W^{1,q}(\Omega)\forall 1<q<2$. If u is a solution to (2.16), then setting $\lambda=4/k^2$ and $u=u_0+v$ we have that v is smooth and it satisfies

$$\begin{cases} \Delta v=\lambda e^{u_0+v}(e^{u_0+v}-1)+\dfrac{4\pi N}{|\Omega|}. \\ v\in H^1(\Omega) \end{cases} \tag{2.18}_\lambda$$

Conversely, every solution v of $(2.18)_{\lambda=4/k^2}$ gives rise to the solution $u=u_0+v$ of (2.16).

Thus, our effort, in this section, will be on searching for solutions $(2.18)_\lambda$.

To this purpose, we observe that $(2.18)_\lambda$ admits a variational formulation in $H^1(\Omega)$. To see this, let us fix our notation so that, $\|\ \|_p$ denotes the norm in $L^p(\Omega)p\geq 1$, and $\|u\|=(\|\nabla u\|_2^2+\|u\|_2^2)^{1/2}$ defines the norm for the Sobolev space $H^1(\Omega)$.

The Moser–Trudinger inequality (cf. Ref. 24):

$$\forall\epsilon>0 \text{ there exists a constant } C(\epsilon)>0:$$

$$\int_\Omega e^v\leq C(\epsilon)\exp\left(\left(\frac{1}{16\pi}+\epsilon\right)\|\nabla v\|_2^2\right)\forall v\in H^1(\Omega), \quad \int_\Omega v=0 \tag{2.19}$$

and the fact that $e^{u_0}\in L^\infty(\Omega)$, imply that the functional:

$$I_\lambda(v)=\frac{1}{2}\|\nabla v\|_2^2+\frac{\lambda}{2}\int_\Omega (e^{u_0+v}-1)^2+\frac{4\pi N}{|\Omega|}\int_\Omega v, \quad v\in H^1(\Omega), \tag{2.20}$$

is well defined, and $I_\lambda \in C^1(H^1(\Omega))$.

Furthermore, every critical point of I_λ in $H^1(\Omega)$ defines a (weak) solution to $(2.18)_\lambda$. By means of variational methods we shall establish the following:

Theorem 2.3: There exists a value $\lambda_c > 16\pi N/|\Omega|$ such that,

(i) if $\lambda>\lambda_c$ then $(2.18)_\lambda$ admits, at least, two solutions $v_{1,\lambda}$ and $v_{2,\lambda}$ satisfying:
$$v_{1,\lambda}<v_{2,\lambda}<-u_0 \text{ a.e. in } \Omega;$$
(ii) if $\lambda=\lambda_c$ then $(2.18)_\lambda$ admits a solution v_* satisfying: $v_*<v_{2,\lambda}, \forall \lambda>\lambda_c$;
(iii) if $\lambda<\lambda_c$ then $(2.18)_\lambda$ admits no solutions.

In order to obtain Theorem 2.3 recall the following result due to Caffarelli–Yang.

Theorem 2.4 (Caffarelli-Yang[17]): There exists a critical value $\lambda_c \geq 16\pi N/|\Omega|$ such that for every $\lambda>\lambda_c$ problem $(2.18)_\lambda$ admits a maximal solution v_λ with $u_0+v_\lambda<0$ in Ω. While for $\lambda<\lambda_c$ problem $(2.18)_\lambda$ admits no solutions.

Remark 2.1: It follows from Ref. 17 (or (3.6) below) that if $(2.18)_\lambda$ admits a solution then necessarily $\lambda>16\pi N/|\Omega|$.

Remark 2.2: Although it is not explicitly mentioned in Ref. 17, it is clear that the maximal solutions v_λ are ordered with respect to λ. Namely, if $\lambda>\eta>\lambda_c$ then $v_\lambda>v_\eta$ in Ω. To see this, notice that v_η is a strict subsolution for $(2.18)_\lambda$, $\lambda>\eta$. In fact,

$$\Delta v_\eta = \eta e^{u_0+v_\eta}(e^{u_0+v_\eta}-1)+\frac{4\pi N}{|\Omega|}=\lambda e^{u_0+v_\eta}(e^{u_0+v_\eta}-1)+(\eta-\lambda)e^{u_0+v_\eta}(e^{u_0+v_\eta}-1)+\frac{4\pi N}{|\Omega|}$$
$$>\lambda e^{u_0+v_\eta}(e^{u_0+v_\eta}-1)+\frac{4\pi N}{|\Omega|}$$

a.e. in Ω; in fact, $u_0+v_\eta<0$ in Ω and therefore $(\eta-\lambda)e^{u_0+v_\eta}(e^{u_0+v_\eta}-1)>0$ in $\Omega\backslash\{p_1,\ldots,p_N\}$.

Thus, by the sub-supersolutions method and the maximality of v_λ it must result that necessarily, $v_\eta<v_\lambda$ in Ω.

This monotonicity property allows us to obtain a solution for $(2.18)_\lambda$ at $\lambda=\lambda_c$ as given by

$$v^*(x)=\inf_{\lambda>\lambda_c} v_\lambda(x), \quad x\in\Omega. \tag{2.21}$$

Lemma 2.1: The function v_* as given in (2.21) belongs to $H^1(\Omega)$ and it defines a solution for $(2.18)_{\lambda=\lambda_c}$, in particular $\lambda_c>16\pi N/|\Omega|$.

Proof: By definition, $v_\lambda \to v_*$ pointwise a.e. in Ω. We shall prove that, in fact, $v_\lambda \to v_*$ strongly in $H^1(\Omega)$, and this will suffice to obtain the desired conclusion. To this purpose, we show that if $\lambda_n \to \lambda_c$, then after passing to a subsequence if necessary, we have $\|v_{\lambda_n}-v_*\|\to 0$ as $n\to\infty$. Set $v_n=v_{\lambda_n}$ and write: $v_n=v_n'+c_n$ with $\int_\Omega v_n'=0$ and $c_n=1/|\Omega|\int_\Omega v_n$. Since $v_n<-u_0$ in Ω it follows that,

$$c_n<-\frac{1}{|\Omega|}\int_\Omega u_0=0. \tag{2.22}$$

Furthermore, from Eq. $(2.18)_{\lambda=\lambda_n}$, we also derive

$$\|\nabla v_n'\|_2^2=\lambda_n\int_\Omega e^{u_0+v_n}v_n'-\lambda_n\int_\Omega e^{2(u_0+v_n)}v_n'\leqslant\lambda_n\int_\Omega(e^{u_0+v_n}+e^{2(u_0+v_n)})|v_n'|$$

$$\leqslant 2\lambda_n\int_\Omega|v_n'|\leqslant 2\lambda_n c\|\nabla v_n'\|_2$$

for a suitable constant $c>0$. In other words,

$$\|v_n'\|\leqslant C,\quad \forall n\in N$$

hence, passing to a subsequence if necessary, we have that $v_n'\to v_*'$ weakly in $H^1(\Omega)$, strongly in $L^p(\Omega)$, $\forall p\geqslant 1$ and pointwise almost everywhere in Ω. By the compactness of the map:

$$H^1(\Omega)\to L^1(\Omega)$$

$$u\to\int_\Omega e^{\alpha u},\quad \alpha\in R\ \text{(see Ref. 23)}$$

we may also conclude that,

$$\int_\Omega e^{u_0+v_n'}\to\int_\Omega e^{u_0+v_*'},\quad \int_\Omega e^{2(u_0+v_n')}\to\int_\Omega e^{2(u_0+v_*')} \tag{2.23}$$

as $n\to\infty$.

On the other hand, by means of the Eq. $(2.18)_{\lambda=\lambda_n}$, we also have

$$e^{2c_n}\lambda_n\int_\Omega e^{2(u_0+v_n')}-e^{c_n}\lambda_n\int_\Omega e^{u_0+v_n'}+4\pi N=0$$

and consequently,

$$e^{c_n}=\frac{\displaystyle\int_\Omega e^{u_0+v_n'}\pm\sqrt{\left(\int_\Omega e^{u_0+v_n'}\right)^2-\frac{16\pi N}{\lambda_n}\int_\Omega e^{2(u_0+v_n')}}}{\displaystyle 2\int_\Omega e^{2(u_0+v_n')}}$$

$$=\frac{8\pi N}{\lambda_n}\frac{1}{\displaystyle\int_\Omega e^{u_0+v_n'}\mp\sqrt{\left(\int_\Omega e^{u_0+v_n'}\right)^2-\frac{16\pi N}{\lambda_n}\int_\Omega e^{2(u_0+v_*')}}}$$

$$\geqslant\frac{4\pi N}{\lambda_n}\frac{1}{\int_\Omega e^{u_0+v_n'}}\longrightarrow\frac{4\pi N}{\lambda_c}\frac{1}{\int_\Omega e^{u_0+v_*'}}\ \text{as}\ n\to+\infty;\ \text{(by (2.23))}.$$

Thus c_n is also bounded from below and (by passing to a subsequence if necessary) we can assume $c_n\to c_0$ as $n\to+\infty$.

In other words, $v_n\to v_*'+c_0$ weakly in $H^1(\Omega)$, strongly in $L^p(\Omega)p\geqslant 1$ and pointwise a.e. in Ω. So necessarily,

$$v_*=v_*'+c_0\in H^1(\Omega).$$

Furthermore, as v_n, $v_*<-u_0$ in Ω, it results:

$$0<\frac{e^{u_0+v_n}-e^{u_0+v_*}}{v_n-v_*}<1 \quad \text{in } \Omega$$

and consequently

$$\left|\int_\Omega (e^{u_0+v_n}-e^{u_0+v_*})\varphi\right| \leq \int_\Omega \left(\frac{e^{u_0+v_n}-e^{u_0+v_*}}{v_n-v_*}\right)|v_n-v_*||\varphi| \leq \|v_n-v_*\|_2\|\varphi\|_2 \to 0$$

$$\text{as } n\to+\infty, \quad \forall \varphi \in H^1(\Omega). \tag{2.24}$$

Hence, $\int_\Omega e^{u_0+v_n}\varphi \to \int_\Omega e^{u_0+v_*}\varphi$ and similarly, $\int_\Omega e^{2(u_0+v_n)}\varphi \to \int_\Omega e^{2(u_0+v_*)}\varphi$ as $n\to+\infty$, $\forall \varphi \in H^1(\Omega)$.

In other words, v_* satisfies $(2.18)_{\lambda=\lambda_c}$ and by taking $\varphi=v_n-v_*$ in (2.24) we also conclude:

$$\|\nabla(v_n-v_*)\|_2^2=\lambda_n\int_\Omega (e^{u_0+v_n}-e^{u_0+v_*})(v_n-v_*)-\lambda_n\int_\Omega (e^{2(u_0+v_n)}-e^{2(u_0+v_*)})(v_n-v_*)+o(1)$$

$$\leq 2\lambda_n\|v_n-v_*\|_2^2+o(1)\to 0, \text{ as } n\to+\infty.$$

Hence $v_n\to v_*$ strongly in $H^1(\Omega)$.

Finally, it follows from Ref. 6 or (3.6) below that if $(2.18)_\lambda$ admits a solution then necessarily $\lambda>16\pi N/|\Omega|$ and consequently $\lambda_c>16\pi N/|\Omega|$.

In virtue of lemma 2.1, we are able to identify a solution for $(2.18)_\lambda$ variationally as follows.

Lemma 2.2: For every $\lambda>\lambda_c$, problem $(2.1)_\lambda$ admits a solution which defines a local minimum for I_λ in $H^1(\Omega)$.

Proof: It is clear that the solution v_* of $(2.1)_{\lambda=\lambda_c}$ (as given by lemma 2.1) defines a strict subsolution for $(2.1)_\lambda$ for every $\lambda>\lambda_c$.

Set

$$\Lambda=\{v\in H^1(\Omega): v\geq v_* \text{ a.e. in } \Omega\}.$$

From the definition of the functional I_λ, (see (2.3)) we easily see that I_λ is weakly lower semicontinuous in $H^1(\Omega)$ and it is bounded from below and coercive on Λ.

Thus, I_λ achieves its infimum in Λ, and we denote it by w_λ.

Namely,

$$I_\lambda(w_\lambda)=\inf_\Lambda I_\lambda, \quad w_\lambda\in\Lambda.$$

Since, for every $\lambda>\lambda_c$, v_* is a strict subsolution for $(2.18)_\lambda$, we may conclude that w_λ is a critical point for I_λ in $H^1(\Omega)$ (hence a solution for $(2.18)_\lambda$). Although this is a well known fact, for completeness we have included a proof in the Appendix. Furthermore, by the maximum principle, we may also conclude that $w_\lambda>v_*$ on the compact 2-torus Ω.

This says that ω_λ is a local minimum for I_λ with respect to the $C^1(\Omega)$-topology. We prove in fact that w_λ is a local minimum also in $H^1(\Omega)$-topology.

To this purpose, we follow an argument of Brezis–Nirenberg[25] and argue by contradiction. Thus we suppose that, $\forall n\in N$

$$\inf_{\|v-w_\lambda\|\leq\frac{1}{n}} I_\lambda < I_\lambda(w_\lambda). \tag{2.25}$$

As above, we see that the infimum of (2.25) is achieved at a point $v_n\in H^1(\Omega)$ which satisfies:

(1) $-\Delta v_n+\lambda e^{u_0+v_n}(e^{u_0+v_n}-1)+4\pi N/|\Omega|=\eta_n(-\Delta(v_n-w_\lambda)+v_n-w_\lambda)$;
(2) $\|v_n-w_\lambda\|\leq 1/n$.

Clearly, $\eta_n\leq 0$ and, by the Sobolev embedding, $\|v_n-w_\lambda\|_p\to 0$ as $n\to+\infty$.

Consequently,

$$-\Delta(v_n-w_\lambda)=-\frac{|\eta_n|}{1+|\eta_n|}(v_n-w_\lambda)-\frac{\lambda}{1+|\eta_n|}(e^{2(u_0+v_n)}-e^{2(u_0+w_\lambda)})+\frac{\lambda}{1+|\eta_n|}(e^{u_0+v_n}-e^{u_0+w_\lambda}):=f_n \text{ in } \Omega.$$

$f_n\in L^p(\Omega)$ $\forall p>1$ and $\|f_n\|_p\leq C\|v_n-w_\lambda\|\leq C/n$, with $C=C(p,\lambda)$ a suitable constant independent of n.

So, by elliptic estimates and the Sobolev embedding Theorem, for $p>2$ we derive that $v_n-w_\lambda\in C^{1,\alpha}(\Omega)$, $0<\alpha<1$ and $\|v_n-w_\lambda\|_{C^1(\Omega)}\to 0$ as $n\to+\infty$. But this is impossible, since w_λ is a local minimum for I_λ in the $C^1(\Omega)$ topology while $I_\lambda(v_n)=\inf_{\|v-w_\lambda\|\leq 1/n} I_\lambda<I_\lambda(w_\lambda)$.

From now on, we assume that the maximal solution v_λ (cf. Ref. 17) is the local minimum as defined by lemma 2.2 (if not, we would have already found our second solution); hence it satisfies:

$$\exists \rho_0>0: I_\lambda(v_\lambda)\leq I_\lambda(v) \quad \forall v: \|v-v_\lambda\|\leq\rho_0. \tag{2.26}$$

In order to find a second critical point, we observe that I_λ admits a "mountain-pass" structure (cf. Ref. 26). In fact, for $c>0$ we have

$$I_\lambda(v_\lambda-c)-I_\lambda(v_\lambda)=\frac{\lambda}{2}\int_\Omega[(e^{u_0+v_\lambda-c}-1)^2-(e^{u_0+v_\lambda}-1)^2]-2\pi Nc$$

$$\leq\lambda(1-e^{-c})\int_\Omega e^{u_0+v_\lambda}-2\pi Nc\to-\infty \text{ as } c\to+\infty. \tag{2.27}$$

In order to apply the minimax principle suitable to this situation we start by verifying a compactness property for I_λ as stated by the Palais–Smale (P.S.) condition.

Lemma 2.3: Every sequence $\{v_n\}\subset H^1(\Omega)$ satisfying:

(1) $I_\lambda(v_n)\to\alpha$ as $n\to+\infty$
(2) $\|I'_\lambda(v_n)\|\to 0$ as $n\to+\infty$

admits a convergent subsequence.

Proof: We have

$$\frac{1}{2}\|\nabla v_n\|_2^2+\frac{\lambda}{2}\int_\Omega(e^{u_0+v_n}-1)^2+\frac{4\pi N}{|\Omega|}\int_\Omega v_n=\alpha+o(1) \text{ as } n\to\infty \tag{2.28}$$

$$\left|\int_\Omega\nabla v_n\cdot\nabla\varphi+\lambda\int_\Omega e^{u_0+v_n}(e^{u_0+v_n}-1)\varphi+\frac{4\pi N}{|\Omega|}\int_\Omega\varphi\right|\leq\epsilon_n\|\varphi\|, \quad \epsilon_n\to 0 \tag{2.29}$$

as $n\to+\infty$, $\varphi\in H^1(\Omega)$.

By taking $\varphi=1$ in (2.29) we obtain

$$o(1)=\lambda\int_\Omega e^{u_0+v_n}(e^{u_0+v_n}-1)+4\pi N=\lambda\int_\Omega (e^{u_0+v_n}-1)^2+\lambda\int_\Omega e^{u_0+v_n}-\lambda|\Omega|+4\pi N$$

$$\geq\lambda\int_\Omega e^{u_0+v_n}-\lambda|\Omega|+4\pi N.$$

Consequently,

$$\int_\Omega e^{u_0+v_n}\leq|\Omega|-\frac{4\pi N}{\lambda}+o(1),\quad \text{as } n\to+\infty \tag{2.30}$$

and

$$\int_\Omega (e^{u_0+v_n}-1)^2\leq|\Omega|-\frac{4\pi N}{\lambda}+o(1)\ \text{ as } n\to+\infty, \tag{2.31}$$

which yields

$$\int_\Omega e^{2(u_0+v_n)}\leq 2\left(|\Omega|-\frac{4\pi N}{\lambda}\right)+o(1) \tag{2.32}$$

as $n\to+\infty$.

In particular, setting $c_n=1/|\Omega|\int_\Omega v_n$, from (2.28) and (2.31) we derive

$$\alpha+\frac{1}{2}(4\pi N-\lambda|\Omega|)+o(1)\leq\frac{\|\nabla v_n\|_2^2}{2}+4\pi N c_n\leq\alpha+o(1) \tag{2.33}$$

as $n\to+\infty$.

Decompose $v_n=v_n'+c_n$, $\int_\Omega v_n'=0$. By (2.29) with $\varphi=v_n'$ we have

$$\|\nabla v_n'\|_2^2+\lambda\int_\Omega e^{2(u_0+v_n)}v_n'-\lambda\int_\Omega e^{u_0+v_n}v_n'\leq\epsilon_n\|v_n'\|.$$

Consequently, by (2.32) and the fact that c_n is bounded above (see (2.33)) it follows:

$$\|\nabla v_n'\|_2^2+\lambda\int_\Omega e^{2(u_0+c_n)}(e^{2v_n'}-1)v_n'\leq-\lambda\int_\Omega e^{2(u_0+c_n)}v_n'+\epsilon_n\|v_n'\|+\lambda\left(\int_\Omega e^{2(u_0+v_n)}\right)^{1/2}\|v_n'\|_2$$

$$\leq C\|v_n'\|\ \text{ as } n\to+\infty, \tag{2.34}$$

for a suitable constant $C>0$.

Notice that, $(e^{2v_n'}-1)v_n'\geq 0$ a.e. in Ω, and therefore, from (2.17) we derive

$$\|v_n'\|\leq C,\quad \forall n\in N. \tag{2.35}$$

In turn, (2.35) together with (2.33) gives that $|c_n|$ is also uniformly bounded, and consequently, we have

$$\|v_n\|\leq C\quad \forall n\in N$$

for a suitable constant $C>0$.

Therefore, after passing to a subsequence (which we still denote by v_n), we may assume that,

$$v_n \rightharpoonup v \text{ weakly in } H^1(\Omega), \text{ strongly in } L^p(\Omega) p \geq 1$$

and pointwise a.e. in Ω.

In particular, $c_n \to (1/|\Omega|)\int_\Omega v = c$; and passing to the limit in (2.29) we obtain that v is a critical point for I_λ as it satisfies

$$\int_\Omega \nabla v \cdot \nabla \varphi + \lambda \int_\Omega e^{u_0+v}(e^{u_0+v}-1)\varphi + \frac{2\pi N}{|\Omega|}\int_\Omega \varphi = 0 \quad \forall \varphi \in H^1(\Omega). \tag{2.36}$$

Hence, by choosing $\varphi = v_n - v$ in (2.29) and (2.36), we conclude

$$\begin{aligned}\int_\Omega |\nabla(v_n - v)|^2 &= \lambda \int_\Omega (e^{u_0+v_n} - e^{u_0+v})(v_n - v) - \lambda \int_\Omega (e^{2(u_0+v_n)} - e^{2(u_0+v)})(v_n - v) + o(1) \\ &\leq \lambda \int_0^1 e^{tc_n+(1-t)c}\left(\int_\Omega e^{u_0+tv_n'+(1-t)v'}(v_n - v)^2 \right) dt + o(1) \\ &\leq C\|v_n - v\|_p^2 + o(1), \quad \text{as } n \to +\infty,\end{aligned}$$

for $p > 2$ and $C > 0$ a suitable constant independent of n. Therefore, $\|\nabla(v_n' - v')\| \to 0$ and in turn, $\|v_n - v\| \leq C(\|\nabla(v_n' - v')\|_2 + |c_n - c|) \to 0$ as $n \to +\infty$.

We are now ready to conclude.

The proof of Theorem 2.3: In view of lemma 2.1 and 2.2 and Caffarelli–Yang's result[17] we have that, problem $(2.18)_\lambda$ admits a solution if and only if $\lambda \geq \lambda_c > 16\pi N/|\Omega|$

Furthermore, for $\lambda > \lambda_c$, such a solution defines a local minimum for I_λ and, as already observed, it can be taken to coincide with the maximal solution v_λ for $(2.18)_\lambda$ (established by Caffarelli–Yang in Ref. 17). Therefore, (2.9) and (2.10) hold. In case v_λ is not a strict local minimum for I_λ then

$$\forall 0 < \rho < \rho_0, \quad \inf_{\|v - v_\lambda\| = \rho} I_\lambda = I_\lambda(v_\lambda) = \alpha_\lambda,$$

and, by an application of Ekeland's lemma (see Ref. 26, Corollary 1.6) we find a local minimum $v_\rho \in H^1(\Omega)$ such that $\|v_\rho - v_\lambda\| = \rho$, and $I_\lambda(v_\rho) = \alpha_\lambda$, $\forall \rho \in (0, \rho_0)$. Thus, in this situation, we obtain a one-parameter family of solutions for $(2.18)_\lambda$.

In case v_λ is a strict local minimum for I_λ (by the arguments of next section, we believe that this is always the case for $\lambda \to +\infty$) then there would exist $\rho_1 \in (0, \rho_0)$ such that

$$\inf_{\|v - v_\lambda\| = \rho_1} I_\lambda > I_\lambda(v_\lambda) = \alpha_\lambda \tag{2.37}$$

and in view of (2.27):

$$I_\lambda(v_\lambda - c_0) \leq I_\lambda(v_\lambda) - 1 < I_\lambda(v_\lambda)$$

for some $c_0 > \rho_1 > 0$ sufficiently large.

Let $\mathscr{P} = \{\gamma : [0,1] \to H^1(\Omega) \text{ continuous } \gamma(0) = v_\lambda,\ \gamma(1) = v_\lambda - c_0\}$ and set

$$\alpha = \inf_{\gamma \in \mathscr{P}} \sup_{t \in [0,1]} I_\lambda(\gamma(t)).$$

By (2.37) it results $\alpha > I_\lambda(v_\lambda) \geq \max\{I_\lambda(\gamma(0)), I_\lambda(\gamma(1))\}$ $\forall \gamma \in \mathscr{P}$. So by lemma 2.3, we see that I_λ satisfies all the hypothesis of the mountain-pass theorem of Ambrosetti–Rabinowitz[27] and we

conclude that α defines a critical value for I_λ. Since $\alpha > I_\lambda(v_\lambda)$, the corresponding critical point v yields to a second solution for $(2.18)_\lambda$. Clearly by the maximality of v_λ, it follows that $v < v_\lambda$ in Ω and the proof its completed.

III. ASYMPTOTIC BEHAVIOR FOR THE SOLUTIONS OF $(2.18)_\lambda$ AS $\lambda \to +\infty$

In this section, we would like to characterize the different nature of the solutions found in theorem 2.3, according to their behavior as $\lambda \to +\infty$.

In order to justify why a solution to $(2.18)_\lambda$ should admit a limit as $\lambda \to +\infty$, we start with the following *a priori* estimates.

Lemma 3.1: For every $q \in (1,2)$ there exists a constant $C = C(q) > 0$ (independent of λ and N) such that every solution v for $(2.18)_\lambda$ satisfies:

$$\|\nabla(u_0 + v)\|_q \leq C(4\pi N + \|\nabla u_0\|_q) \tag{3.1}$$

Proof: Let $p = q/(q-1) > 2$. Since $u_0 \in W^{1,q}(\Omega)$, the extremal problem:

$$\sup\left\{ \int_\Omega \nabla(v + u_0) \cdot \nabla \varphi, \varphi \in W^{1,p}(\Omega), \|\varphi\|_{W^{1,p}} = 1 \int_\Omega \varphi = 0 \right\} \tag{3.2}$$

achieves its supremum at some $\varphi_0 \in W^{1,p}(\Omega)$, $\int_\Omega \varphi_0 = 0$, $\|\varphi_0\|_{W^{1,p}} = 1$.

Take as test function φ in (3.2) the (normalized) unique solution for the problem:

$$\begin{cases} -\Delta \varphi = \operatorname{div}(|\nabla(v + u_0)|^{q-2} \nabla(v + u_0)) \text{ in } \Omega \\ \int_\Omega \varphi = 0 \end{cases}$$

Since $|\nabla(v + u_0)|^{q-2} \nabla(v + u_0) \in L^p(\Omega) p > 2$, by the Calderon–Zygmund inequality, we have

$$\|\nabla \varphi\|_p \leq c \|\nabla(v + u_0)\|_q^{q-1}$$

with suitable constant $c > 0$. Therefore,

$$c^{-1} \|\nabla(v + u_0)\|_q \leq \int_\Omega \nabla(v + u_0) \cdot \frac{\nabla \varphi}{\|\nabla \varphi\|_p} \leq \int_\Omega \nabla(v + u_0) \cdot \nabla \varphi_0 = -\int_\Omega \Delta v \varphi_0 + \int_\Omega \nabla u_0 \cdot \nabla \varphi_0$$

$$\leq \lambda \int_\Omega e^{u_0 + v}(1 - e^{u_0 + v}) \varphi_0 + \|\nabla u_0\|_q \|\nabla \varphi_0\|_p$$

$$\leq \|\varphi_0\|_\infty \lambda \int_\Omega e^{u_0 + v}(1 - e^{u_0 + v}) + C \|\nabla u_0\|_q ;$$

where we have used the fact that every solution of $(2.18)_\lambda$ satisfies $u_0 + v < 0$ on Ω, and therefore $1 - e^{u_0 + v} > 0$ on Ω.

On the other hand, as $p > 2$ by Sobolev embedding, we have that $\|\varphi_0\|_\infty \leq c \|\varphi_0\|_{W^{1,p}} = c$, while integrating $(2.18)_\lambda$ we have:

$$\lambda \int_\Omega e^{u_0 + v}(1 - e^{u_0 + v}) = 4\pi N. \tag{3.2'}$$

At this point, (3.1) follows immediately.

We begin by analyzing the behavior of the maximal solution v_λ as $\lambda \to +\infty$. Roughly speaking we show that v_λ "bifurcates from infinity" from the singular solution u_0.

More precisely we have the following.

Proposition 3.1: Let v_λ be the maximal solution for $(2.18)_\lambda \lambda > \lambda_c$. We have:

(i) $v_\lambda \to -u_0$ as $\lambda \to +\infty$ in $W^{1,q}(\Omega)\, 1<q<2$ and pointwise a.e. in Ω;

(ii) $\lambda e^{u_0+v_\lambda}(1-e^{u_0+v_\lambda}) \to 4\pi \Sigma_{j=1}^N \delta_{p_j}$ as $\lambda \to +\infty$, in the sense of measure.

Proof: Recall that v_λ is strictly monotone increasing in λ,

$$v_* < v_\lambda < -u_0 \text{ a.e. in } \Omega, \quad \forall \lambda > \lambda_c; \tag{3.3}$$

and

$$\int_\Omega e^{u_0+v_\lambda}(1-e^{u_0+v_\lambda}) = \frac{4\pi N}{\lambda}. \tag{3.4}$$

Set $\bar{v} = \sup_{\lambda>\lambda_c} v_\lambda(x), x \in \Omega$. We have that, $v_* < \bar{v} \leqslant -u_0$ a.e. in Ω and $v_\lambda \to \bar{v}$ pointwise a.e. in Ω, as $\lambda \to +\infty$.

By monotone (or dominated) convergence and (3.4) it follows that, as $\lambda \to +\infty$,

$$\int_\Omega e^{u_0+v_\lambda}(1-e^{u_0+v_\lambda}) \mapsto \int_\Omega e^{u_0+\bar{v}}(1-e^{u_0+\bar{v}}) = 0$$

and thus necessarily, $\bar{v} = -u_0$ a.e. in Ω.

Let $f_\lambda = \lambda e^{u_0+v_\lambda}(1-e^{u_0+v_\lambda}) \geqslant 0$. In view of (3.4) we have $\|f_\lambda\|_1 = 4\pi N$, therefore given any sequence $\lambda_n \to +\infty$, there exists a measure η on Ω such that (after passing to a subsequence if necessary) we have

$$\lambda_n e^{u_0+v_n}(1-e^{u_0+v_n}) \to \eta$$

in the sense of measure. Set $v_n = v_{\lambda_n}$, and let $\varphi \in C^\infty(\Omega)$ then:

$$\int_\Omega \lambda_n e^{u_0+v_n}(e^{u_0+v_n}-1)\varphi + \frac{4\pi N}{|\Omega|}\int_\Omega \varphi = \int_\Omega \Delta v_n \varphi = \int_\Omega v_n \Delta \varphi \overset{n\to+\infty}{\mapsto} \int_\Omega -u_0 \Delta \varphi$$

$$= -4\pi \sum_{j=1}^N \varphi(p_j) + \frac{4\pi N}{|\Omega|}\int_\Omega \varphi.$$

Consequently, $\eta = 4\pi \Sigma_{j=1}^N \delta_{p_j}$.

Since this holds for any sequence $\lambda_n \to +\infty$, we conclude, as $\lambda \to +\infty$ that,

$$\lambda e^{u_0+v_\lambda}(1-e^{u_0+v_\lambda}) \to 4\pi \sum_{j=1}^N \delta_{p_j};$$

in the sense of measure, and (ii) is established.

Next, fix $q \in (1,2)$ and let $p = q/(q-1) > 2$. For $\lambda_n \to +\infty$, and $v_n = v_{\lambda_n}$, let $\varphi_n \in W^{1,p}(\Omega)$, $\int_\Omega \varphi_n = 0$ and $\|\varphi_n\|_{W^{1,p}} = 1$ such that,

$$\int_\Omega \nabla(v_n+u_0)\cdot\nabla\varphi_n = \sup\left\{ \int_\Omega \nabla(v_n+u_0)\cdot\nabla\varphi, \int_\Omega \varphi = 0 \|\varphi\|_{W^{1,p}} = 1 \right\}.$$

As in lemma 3.1 it results,

$$c^{-1}\|\nabla(v_n+u_0)\|_q \leq \int_\Omega \nabla(v_n+u_0)\cdot\nabla\varphi_n \tag{3.5}$$

for a suitable constant $c>0$ (independent of n).

On the other hand, as $p>2$, we find a subsequence of $\{\varphi_n\}$ (which we still call φ_n) and $\varphi_0\in W^{1,p}(\Omega)$, $\int_\Omega\varphi_0=0$ such that, $\varphi_n\rightharpoonup\varphi_0$ weakly in $W^{1,p}(\Omega)$ and uniformly in Ω.

As a consequence we obtain:

$$\begin{aligned}
c^{-1}\|\nabla(v_n+u_0)\|_q &\leq \int_\Omega \nabla(v_n+u_0)\cdot\nabla\varphi_n = \int_\Omega \nabla v_n\cdot\nabla\varphi_n + \int_\Omega \nabla u_0\cdot\nabla\varphi_n \\
&= \int_\Omega \nabla v_n\cdot\nabla(\varphi_n-\varphi_0) + \int_\Omega \nabla v_n\cdot\nabla\varphi_0 + \int_\Omega \nabla u_0\cdot\nabla\varphi_n \\
&= \int_\Omega \lambda_n e^{u_0+v_n}(1-e^{u_0+v_n})(\varphi_n-\varphi_0) \\
&\quad - \frac{4\pi N}{|\Omega|}\int_\Omega(\varphi_n-\varphi_0) + \int_\Omega \lambda_n e^{u_0+v_n}(1-e^{u_0+v_n})\varphi_0 - 4\pi\sum_{j=1}^N \varphi_0(p_j)+o(1) \\
&\leq 4\pi N\|\varphi_n-\varphi_0\|_\infty + \int_\Omega \lambda_n e^{u_0+v_n}(1-e^{u_0+v_n})\varphi_0 - 4\pi\sum_{j=1}^N \varphi_0(p_j)+o(1) \\
&\to 0 \quad \text{as } n\to+\infty.
\end{aligned}$$

Since this holds for every sequence $\lambda_n\to+\infty$, we conclude that,

$$\|\nabla(u_0+v_\lambda)\|_q\to 0 \quad \text{as } \lambda\to+\infty.$$

On the other hand, by dominated convergence, we also have that $v_\lambda\to -u_0$ in $L^q(\Omega)$ and we derive the desired conclusion: $\|u_0+v_\lambda\|_{W^{1,q}}\to 0$, as $\lambda\to+\infty$.

We will exhibit a different behavior for the "mountain-pass" solution as $\lambda\to+\infty$ and $N=1$.

For this purpose we start by observing that every solution $v=v'+c$, $\int_\Omega v'=0$ for $(2.18)_\lambda$, $\lambda\geq\lambda_c$ satisfies:

$$e^{2c}\int_\Omega e^{2(u_0+v')} - e^c\int_\Omega e^{u_0+v'} + \frac{4\pi N}{\lambda} = 0,$$

hence necessarily,

$$\left(\int_\Omega e^{u_0+v'}\right)^2 - \frac{16\pi N}{\lambda}\int_\Omega e^{2(u_0+v')} \geq 0 \tag{3.6}$$

(which reaffirms the condition $\lambda_c\geq 16\pi N/|\Omega|$) and

$$e^c = \frac{\int_\Omega e^{u_0+v'} \pm \sqrt{(\int_\Omega e^{u_0+v'})^2 - (16\pi N/\lambda)\int_\Omega e^{2(u_0+v')}}}{2\int_\Omega e^{2(u_0+v')}}. \tag{3.7}$$

We show that, when $v=v_\lambda$ is the maximal solution for $(2.1)_\lambda$ and $\lambda\to+\infty$, then,

(i) the strict inequality must hold in (3.6);
(ii) the "plus" sign must be chosen in (3.7).

In fact, the monotonicity of the map: $\lambda \to v_\lambda$ guaranties that, $w_\lambda = \partial v_\lambda / \partial \lambda$ is well defined for almost every $\lambda > \lambda_c$. Furthermore $w_\lambda \geqslant 0$ a.e. in Ω and,

$$\langle I''_\lambda(v_\lambda) w_\lambda, \varphi \rangle = \int_\Omega e^{u_0+v_\lambda}(1-e^{u_0+v_\lambda})\varphi \quad \forall \varphi \in H^1(\Omega).$$

Since, $u_0 + v_\lambda < 0$ in Ω, this implies that $I''_\lambda(v_\lambda)$ is (strictly) positive definite for a.e. $\lambda > \lambda_c$. Hence, after a limiting process, we may conclude:

$$\langle I''_\lambda(v_\lambda)\varphi, \varphi \rangle \geqslant 0 \quad \forall \varphi \in H^1(\Omega). \tag{3.8}$$

Notice that (3.8) is obviously satisfied by the solution to $(2.18)_\lambda$ corresponding to the local minimum (see lemma 2.2) and therefore it should not be surprising since it is expected that the local minimum and maximal solution is one and the same.

Take $\varphi \equiv 1$ in the above inequality (3.8) to derive:

$$\lambda \int_\Omega e^{u_0+v_\lambda}(2e^{u_0+v_\lambda}-1) \geqslant 0.$$

On the other hand, by (3.7) we have:

$$\pm\lambda \sqrt{\left(\int_\Omega e^{u_0+v_\lambda}\right)^2 - \frac{16\pi N}{\lambda}\int_\Omega e^{2(u_0+v_\lambda)}} = \lambda \int_\Omega e^{u_0+v_\lambda}(2e^{u_0+v_\lambda}-1) \geqslant 0. \tag{3.9}$$

Now suppose that there exists a sequence $\lambda_n \to +\infty$ such that

$$\left(\int_\Omega e^{u_0+v'_n}\right)^2 = \frac{16\pi N}{\lambda_n}\int_\Omega e^{2(u_0+v'_n)}, \quad \forall n \in N$$

where $v_n = v_{\lambda_n} = v'_n + c_n$, $\int_\Omega v'_n = 0$. By (3.9) and Proposition 3.1 this yields the following contradiction,

$$0 = \int_\Omega (2e^{2(u_0+v_n)} - e^{u_0+v_n}) \mapsto |\Omega| \quad \text{as} \quad n \to +\infty.$$

In conclusion, there exists $\lambda_0 > 0$ such that, $\forall \lambda > \lambda_0$ (3.6) with $v = v_\lambda$ holds with a strict inequality and, in view of (3.9) the "plus" sign must be taken in (3.7).

Remark 3.1: Notice that conditions (i) and (ii) essentially characterize those solutions to $(2.18)_\lambda$ which correspond to local minima for I_λ.

Setting $v_\lambda = w'_\lambda + c_\lambda$ with $\int_\Omega w'_\lambda = 0$, we have,

$$e^{c_\lambda} = \frac{\int_\Omega e^{u_0+w'_\lambda} + \sqrt{(\int_\Omega e^{u_0+w'_\lambda})^2 - (16\pi N/\lambda)\int_\Omega e^{2(u_0+w'_\lambda)}}}{2\int_\Omega e^{2(u_0+w'_\lambda)}} > \frac{\int_\Omega e^{u_0+w'_\lambda}}{2\int_\Omega e^{2(u_0+w'_\lambda)}} \quad \text{as} \quad \lambda \to +\infty,$$

and we conclude that $c = c_\lambda$ defines a (strict) local minimum for the function

$$\psi(c) = I_\lambda(w'_\lambda + c), \quad c \in R.$$

Since v_λ is also a local minimum for I_λ with respect to all the other directions $v' \in H^1(\Omega)$, this suggests the definitions:

$$\mathcal{A}=\left\{w\in H^1(\Omega):\int_\Omega w=0,\left(\int_\Omega e^{u_0+w}\right)^2-\frac{16\pi N}{\lambda}\int_\Omega e^{2(u_0+w)}\geqslant 0\right\},$$

$$c_\pm(w)=\ln\left(\frac{\int_\Omega e^{u_0+w}\pm\sqrt{(\int_\Omega e^{u_0+w})^2-(16\pi N/\lambda)\int_\Omega e^{2(u_0+w)}}}{2\int_\Omega e^{2(u_0+w)}}\right)$$

$\forall w\in\mathcal{A}$, and alternatively characterize the local minimum for I_λ by the extremal problem:

$$\inf_{w\in\mathcal{A}}\min_{c\geqslant c_-(w)}I_\lambda(w+c)=\inf_{w\in\mathcal{A}}\left\{\int_\Omega\left[\frac{1}{2}|\nabla w|^2+\frac{\lambda}{2}(e^{u_0+w+c_+(w)}-1)^2\right]+4\pi c_+(w)\right\} \tag{3.10}$$

provided that the infimum in (3.10) is finite.

This point of view was adopted by Caffarelli–Yang in Ref. 17 where they show that, for $N=1$ and λ sufficiently large; (3.10) achieves its infimum at a solution of $(2.1)_\lambda$.

On the other hand, this approach also suggests to recast the "mountain pass" solution found above via an analogous minimax procedure which, as we shall see, turns out to be useful when studying the asymptotic behavior of such a solution for $\lambda\to+\infty$. To insure the boundedness from below of the appropriate minimization problem, as in Ref. 17, we shall treat the case $N=1$ (i.e. the vortices are periodically placed).

Proposition 3.2: Let $N=1$. There exists $\lambda_0\geqslant\lambda_c$ such that $\forall\lambda>\lambda_0$, the value

$$\beta_\lambda=\inf_{w\in\mathcal{A}}\max_{c\leqslant c_+(w)}I_\lambda(w+c)=\inf_{w\in\mathcal{A}}\left\{\int_\Omega\left[\frac{1}{2}|\nabla w|^2+\frac{\lambda}{2}(e^{u_0+w+c_-(w)}-1)^2\right]+4\pi c_-(w)\right\}$$

defines a critical value for I_λ in $H^1(\Omega)$.

Denoting with $\tilde{v}_\lambda=w_\lambda+c_\lambda\in H^1(\Omega)\int_\Omega w_\lambda=0$, the corresponding critical point we have

(1) $c_\lambda\mapsto-\infty$ as $\lambda\to+\infty$;
(2) there exists a constant $C>0$ (independent of λ) such that

$$\|w_\lambda\|\leqslant C,\quad\forall\lambda>\lambda_0.$$

Furthermore every sequence $\lambda_n\to+\infty$ admits a subsequence (still denoted by λ_n) such that, for $w_n=w_{\lambda_n}$, we have:

$$w_n\mapsto w_0\ \text{strongly in}\ H^1(\Omega),$$

and w_0 satisfies:

(3)
$$\begin{cases}-\Delta w_0=4\pi\left(\dfrac{e^{u_0+w_0}}{\int_\Omega e^{u_0+w_0}}-\dfrac{1}{|\Omega|}\right)\ \text{in}\ \Omega\\ \int_\Omega w_0=0,\quad w_0\in H^1(\Omega)\end{cases}.$$

Problem (3) is interesting in itself, and we will comment on it at the end of this section.

Proof: A direct calculation shows that,

$$\psi_\lambda(w):=\max_{c\leqslant c_+(w)}I_\lambda(w+c)=\frac{1}{2}\|\nabla w\|_2^2+\frac{\lambda}{2}\int_\Omega(e^{u_0+w+c_-(w)}-1)^2+4\pi c_-(w);\quad w\in\mathcal{A}.$$

As in Ref. 17, by means of Moser–Trudinger inequality (2.2) we show that ψ_λ is bounded from below in $\mathscr{A}$.

In fact, as $N=1$, then from the definition of $c_-(w)$, $w\in\mathscr{A}$ follows that,

$$e^{c_-(w)}=\frac{16\pi}{2\lambda}\frac{1}{\int_\Omega e^{u_0+w}+\sqrt{(\int_\Omega e^{u_0+w})^2-(16\pi/\lambda)\int_\Omega e^{2(u_0+w)}}}$$

from which we immediately derive the estimates:

$$\frac{4\pi}{\lambda}\frac{1}{\int_\Omega e^{u_0+w}}\leqslant e^{c_-(w)}\leqslant\frac{8\pi}{\lambda}\frac{1}{\int_\Omega e^{u_0+w}}, \tag{3.11}$$

and consequently,

$$\frac{\lambda}{2}\int_\Omega (e^{u_0+w+c_-(w)}-1)^2\geqslant\frac{\lambda}{2}|\Omega|-6\pi. \tag{3.12}$$

Furthermore, the first of the inequalities in (3.11) yields:

$$c_-(w)\geqslant\ln 4\pi-\ln\lambda-\ln\left(\int_\Omega e^{u_0+w}\right),$$

and, by Moser–Trudinger's inequality, for every $\epsilon>0$ and for every $q>1$, we have

$$\ln\left(\int_\Omega e^{u_0+w}\right)\leqslant\frac{1}{p}\ln\left(\int_\Omega e^{pu_0}\right)+q\left(\frac{1}{16\pi}+\epsilon\right)\|\nabla w\|_2^2+C(\epsilon) \tag{3.13}$$

with $1/p+1/q=1$ and $C(\epsilon)$ a suitable positive constant depending on $\epsilon>0$.

Consequently,

$$\psi_\lambda(w)\geqslant\left(\frac{1}{2}-\frac{q}{4}-4\pi q\epsilon\right)\|\nabla w\|_2^2+\frac{\lambda}{2}|\Omega|-4\pi\ln\lambda-C_\epsilon$$

with a suitable $C_\epsilon>0$ (independent of λ).

Therefore, for $q>1$ sufficiently close to 1 and $\epsilon>0$ sufficiently small we may conclude that the lower semicontinuous functional ψ_λ is bounded from below and coercive on $\mathscr{A}$.

Hence ψ_λ achieves its infimum on $\mathscr{A}$ and our next goal is to show that, as $\lambda\to+\infty$, such infimum lies on the interior of $\mathscr{A}$.

To this purpose, let $\lambda_0>0$ sufficiently large so that

$$\left(\int_\Omega e^{u_0}\right)^2-\frac{16\pi}{\lambda}\int_\Omega e^{2u_0}>0,\quad\forall\lambda\geqslant\lambda_0. \tag{3.14}$$

In other words, $w=0$ belongs to the interior of $\mathscr{A}$, $\forall\lambda\geqslant\lambda_0$.

Set

$$r_\lambda=\begin{cases}\inf\left\{\|\nabla w\|_2^2,\quad w\in\mathscr{A}:\left(\int_\Omega e^{u_0+w}\right)^2=\frac{16\pi}{\lambda}\int_\Omega e^{2(u_0+w)}\right\}\\ +\infty\quad\text{if }\partial\mathscr{A}\text{ is empty}\end{cases}. \tag{3.15}$$

Claim:

$$r_\lambda \to +\infty \quad \text{as} \quad \lambda \to +\infty. \tag{3.16}$$

To establish (3.16) we argue by contradiction and suppose that there exists $\lambda_n \to +\infty$, and $c > 0 : 0 \leq r_{\lambda_n} \leq c, \forall n \in N$.

For $\lambda = \lambda_n$, we have $\partial\mathcal{A}$ non-empty and the infimum in (3.15) is achieved at some $w_n \in H^1(\Omega) : \int_\Omega w_n = 0$ and $(\int_\Omega e^{u_0+w_n})^2 = (16\pi/\lambda_n)\int_\Omega e^{2(u_0+w_n)}$.

Since $\|\nabla w_n\|_2^2 \leq c \forall n \in N$, after passing to a subsequence if necessary, we can assume that $w_n \to w_0 \in H^1(\Omega)$ weakly in $H^1(\Omega)$ and $\int_\Omega e^{\alpha(u_0+w_n)} \mapsto \int_\Omega e^{\alpha(u_0+w_0)}$ with $\alpha = 1,2$. But this yields to a contradiction, since

$$0 = \left(\int_\Omega e^{u_0+w_n}\right)^2 - \frac{16\pi}{\lambda_n}\int_\Omega e^{2(u_0+w_n)} \mapsto \int_\Omega e^{u_0+w_0}$$

as $n \to +\infty$, and (3.16) is proved.

Suppose that $\partial\mathcal{A}$ is not empty and let $w \in \partial\mathcal{A}$, that is

$$\left(\int_\Omega e^{u_0+w}\right)^2 = \frac{16\pi}{\lambda}\int_\Omega e^{2(u_0+w)}. \tag{3.17}$$

In view of (3.17) we have

$$\begin{cases} c_-(w) = \ln 8\pi - \ln\lambda - \ln\int_\Omega e^{u_0+w}, \\ \int_\Omega e^{2(u_0+w+c_-(w))} = \frac{1}{2}\int_\Omega e^{u_0+w+c_-(w)} = \frac{4\pi}{\lambda}. \end{cases} \tag{3.18}$$

Thus

$$\begin{aligned} \psi_\lambda(w) &= \frac{1}{2}\|\nabla w\|_2^2 + \frac{\lambda}{2}\int_\Omega e^{2(u_0+w+c_-(w))} - \lambda\int_\Omega e^{u_0+w+c_-(w)} + \frac{\lambda}{2}|\Omega| + 4\pi c_-(w) \\ &= \frac{1}{2}\|\nabla w\|_2^2 - \frac{3\lambda}{4}e^{c_-(w)}\int_\Omega e^{u_0+w} + \frac{\lambda}{2}|\Omega| - 4\pi\ln\lambda - 4\pi\ln 8\pi - 4\pi\ln\left(\int_\Omega e^{u_0+w}\right) \\ &= \frac{1}{2}\|\nabla w\|_2^2 + \frac{\lambda}{2}|\Omega| - 4\pi\ln\lambda - 6\pi - 4\pi\ln 8\pi - 4\pi\ln\left(\int_\Omega e^{u_0+w}\right). \end{aligned}$$

By means of (3.13) with $q = 4/3$ and $\epsilon > 0$ sufficiently small, we may conclude that,

$$\psi_\lambda(w) \geq \frac{1}{8}\|\nabla w\|_2^2 + \frac{\lambda}{2}|\Omega| - 4\pi\ln\lambda - c, \quad \forall w \in \partial\mathcal{A}$$

with $c > 0$ a suitable constant independent of λ.

In other words, this proves that, if $\partial\mathcal{A}$ is non-empty, then:

$$\inf_{\partial\mathcal{A}}\psi_\lambda \geq \frac{1}{8}r_\lambda + \frac{\lambda}{2}|\Omega| - 4\pi\ln\lambda - c \tag{3.19}$$

for a suitable $c > 0$ (independent of λ).

On the other hand, if $\lambda \geq \lambda_0$, then by (3.14) we have that $w = 0$ belongs to the interior of $\mathcal{A}$. Setting $c_0 = c_-(w=0)$, and recalling,

$$\frac{4\pi}{\lambda\int_\Omega e^{u_0}} \leq e^{c_0} = \frac{\int_\Omega e^{u_0} - \sqrt{(\int_\Omega e^{u_0})^2 - (16\pi/\lambda)\int_\Omega e^{2u_0}}}{2\int_\Omega e^{2u_0}}$$

$$\leq \frac{8\pi}{\lambda\int_\Omega e^{u_0}}$$

we derive

$$\psi_\lambda(0) = \frac{\lambda}{2}\int_\Omega (e^{u_0+c_0}-1)^2 + 4\pi c_0 = \frac{\lambda}{2}\int_\Omega e^{2(u_0+c_0)} - \lambda\int_\Omega e^{u_0+c_0} + \frac{\lambda}{2}|\Omega| + 4\pi c_0$$

$$\leq -\frac{\lambda}{2}e^{c_0}\int_\Omega e^{u_0} + \frac{\lambda}{2}|\Omega| + 4\pi \ln\left(\frac{8\pi}{\int_\Omega e^{u_0}}\right) - 4\pi \ln\lambda$$

$$\leq \frac{\lambda}{2}|\Omega| - 4\pi \ln\lambda - 4\pi \ln\left(\frac{8\pi}{\int_\Omega e^{u_0}}\right) - 2\pi.$$

Thus, as $\lambda\to+\infty$ then $r_\lambda\to+\infty$ and by (3.19) we conclude

$$\inf_{\mathscr{A}}\psi_\lambda \leq \frac{\lambda}{2}|\Omega| - 4\pi \ln\lambda - 4\pi + 4\pi \ln\left(\frac{8\pi}{\int_\Omega e^{u_0}}\right) < \inf_{\partial\mathscr{A}}\psi_\lambda. \tag{3.20}$$

Therefore, for $\lambda>0$ sufficiently large, there exists $w_\lambda\in\mathscr{A}$ such that,

$$\left(\int_\Omega e^{u_0+w_\lambda}\right)^2 - \frac{16\pi}{\lambda}\int_\Omega e^{2(u_0+w_\lambda)} > 0 \tag{3.21}$$

and

$$\psi_\lambda(w_\lambda) = \inf_{\mathscr{A}}\psi_\lambda.$$

Set $\tilde{v}_\lambda = w_\lambda + c_-(w_\lambda)$, we show that it defines a critical point for I_λ and satisfies the required property (1) and (2).

To this purpose observe that from (3.21) follows that necessarily $c_-(w_\lambda) < c_+(w_\lambda)$, and therefore the property that:

$$I_\lambda(\tilde{v}_\lambda) = \max_{c\leq c_+(w_\lambda)} I_\lambda(w_\lambda + c)$$

suffices to guarantee,

$$\langle I'_\lambda(\tilde{v}_\lambda), \varphi = 1\rangle = \frac{d}{dc} I_\lambda(w_\lambda + c)|_{c=c_-(w_\lambda)} = 0. \tag{3.22}$$

On the other hand, if $\varphi\in H^1(\Omega)$ and $\int_\Omega\varphi=0$, then in view of (3.21) we can take $t>0$ sufficiently small and have that $w_\lambda + t\varphi\in\mathscr{A}$. Set $w_t = w_\lambda + t\varphi$ and let,

$$c_-(t) = \ln\left(\frac{\int_\Omega e^{u_0+w_t} - \sqrt{(\int_\Omega e^{u_0+w_t})^2 - (16\pi/\lambda)\int_\Omega e^{2(u_0+w_t)}}}{2\int_\Omega e^{2(u_0+w_t)}}\right).$$

Clearly, $c_-(t)\to c_-(w_\lambda)$ as $t\to 0^+$; and,

$$0 \leq \frac{1}{t}\left[I_\lambda(w_t + c_-(t)) - I_\lambda(w_\lambda + c_-(\lambda))\right] \leq \frac{1}{t}\left[I_\lambda(w_t + c_-(t)) - I_\lambda(w_\lambda + c_-(t))\right]$$

$$= \langle I'_\lambda(w_\lambda + c_-(t)), \varphi\rangle + o(1) \to \langle I'_\lambda(\tilde{v}_\lambda), \varphi\rangle \quad \text{as } t \to 0^+.$$

Replacing φ by $-\varphi$, we conclude $\langle I'_\lambda(\tilde{v}_\lambda), \varphi\rangle = 0$ $\forall \varphi \in H^1(\Omega)$, $\int_\Omega \varphi = 0$.

This, together with (3.22), readily implies that $\tilde{v}_\lambda$ is a critical point for I_λ, hence a solution for $(2.18)_\lambda$.

Set $c_\lambda = c_-(w_\lambda)$, from (3.11) it follows,

$$e^{c_\lambda} \leq \frac{8\pi}{\lambda} \frac{1}{\int_\Omega e^{u_0 + w_\lambda}} \leq \frac{8\pi}{\lambda |\Omega|}, \tag{3.23}$$

where we have used Jensen's inequality to obtain that $\int_\Omega e^{u_0 + w_\lambda} \geq |\Omega|$.

From (3.23) it follows immediately that $c_\lambda \to -\infty$ as $\lambda \to +\infty$, and (1) is established.

Finally, to establish (2) recall that:

$$4\pi \leq \lambda e^{c_\lambda} \int_\Omega e^{u_0 + w_\lambda} \leq 8\pi$$

(see (3.11)). Thus,

$$I_\lambda(\tilde{v}_\lambda) = \frac{1}{2}\|\nabla w_\lambda\|_2^2 + \frac{\lambda}{2}\int_\Omega e^{2(u_0 + \tilde{v}_\lambda)} - \lambda e^{c_\lambda} \int_\Omega e^{u_0 + w_\lambda} + \frac{\lambda}{2}|\Omega| + 4\pi c_\lambda$$

$$\geq \frac{1}{2}\|\nabla w_\lambda\|_2^2 - 6\pi + \frac{\lambda}{2}|\Omega| - 4\pi \ln \lambda + 4\pi \ln 4\pi - 4\pi \ln\left(\int_\Omega e^{u_0 + w_\lambda}\right).$$

So by (3.13) with $q = 4/3$ and $\epsilon > 0$ sufficiently small we may conclude:

$$\frac{1}{8}\|\nabla w_\lambda\|_2^2 + \frac{\lambda}{2}|\Omega| - 4\pi \ln \lambda - C_1 \leq I_\lambda(\tilde{v}_\lambda) \leq I_\lambda(c_-(0)) = \psi_\lambda(0) \leq + \frac{\lambda}{2}|\Omega| - 4\pi \ln \lambda + C_2$$

with C_1 and C_2 suitable positive constant independent of λ.

Consequently,

$$\|\nabla \tilde{v}_\lambda\|_2^2 = \|\nabla w_\lambda\|_2^2 \leq 8(C_1 + C_2) = C, \tag{3.24}$$

with $C > 0$ independent of λ and (ii) is proved.

Next, let $\lambda_n \to +\infty$, and set $w_n = w_{\lambda_n}$. In view of (3.24), we find a subsequence (which we still denote by w_n) and $w_0 \in H^1(\Omega)$, $\int_\Omega w_0 = 0$ such that, $w_n \to w_0$ weakly in $H^1(\Omega)$ and,

$$\int_\Omega e^{\alpha(u_0 + w_n)} \to \int_\Omega e^{\alpha(u_0 + w_0)} \quad \text{as } n \to +\infty, \quad \alpha = 1, 2.$$

Consequently, letting $c_n = c_-(w_n)$ we have

$$\lambda_n e^{c_n} = \frac{8\pi}{\int_\Omega e^{u_0 + w_n} + \sqrt{(\int_\Omega e^{u_0 + w_n})^2 - (16\pi/\lambda_n)\int_\Omega e^{2(u_0 + w_n)}}} \mapsto \frac{4\pi}{\int_\Omega e^{u_0 + w_0}}$$

as $n \to +\infty$; and

$$-\int_\Omega \nabla w_0\cdot\nabla\varphi=\lim_{n\to+\infty}\int_\Omega \nabla w_n\cdot\nabla\varphi=\lim_{n\to+\infty}\left[\lambda_n e^{c_n}\int_\Omega (e^{c_n}e^{u_0+w_n}-1)e^{u_0+w_n}\varphi+\frac{4\pi}{|\Omega|}\int_\Omega\varphi\right]$$

$$=-\frac{4\pi}{\int_\Omega e^{u_0+w_0}}\int_\Omega e^{u_0+w_0}\varphi+\frac{4\pi}{|\Omega|}\int_\Omega\varphi$$

$\forall\varphi\in H^1(\Omega)$.

So, w_0 is a solution for (3).

Finally, to show that $w_n\to w_0$ strongly in $H^1(\Omega)$ notice that,

$$\int_\Omega|\nabla(w_n-w_0)|^2=\lambda_n e^{c_n}\int_\Omega(1-e^{c_n}e^{u_0+w_n})e^{u_0+w_n}(w_n-w_0)-\frac{4\pi}{\int_\Omega e^{u_0+w_0}}\int_\Omega e^{u_0+w_0}(w_n-w_0)$$

$$=\lambda_n e^{c_n}\int_\Omega(e^{u_0+w_n}-e^{u_0+w_0})(w_n-w_0)-\lambda_n e^{2c_n}\left(\int_\Omega e^{2(u_0+w_n)}(w_n-w_0)\right)$$

$$+\left(\lambda_n e^{c_n}-\frac{4\pi}{\int_\Omega e^{u_0+w_0}}\right)\int_\Omega e^{u_0+w_0}(w_n-w_0)\mapsto 0,\quad \text{as } n\to+\infty.$$

Remark 3.2: In particular, Proposition 3.2 asserts that the limit point set Γ of $\{w_\lambda\}\subset C^\infty(\Omega)$ in the weak topology of $H^1(\Omega)$ defines the limit point set of $\{w_\lambda\}$ also in the strong topology of $H^1(\Omega)$. Since Γ is given by solution to (3), we have that $\Gamma\subset C^\infty(\Omega)$ and in fact, it defines the limit point set for $\{w_\lambda\}$ in any other relevant topology.

Corollary 3.1: Let $\tilde{v_\lambda}=w_\lambda+c_\lambda$ $\int_\Omega w_\lambda=0$ be the solution for $(2.18)_\lambda$ as given by Proposition 3.2. For every integer $k\geq 1$ there exists a constant $C=C(k)>0$ independent of λ such that,

$$\|w_\lambda\|_{C^k}\leq C. \tag{3.25}$$

Furthermore $\Gamma\subset C^\infty(\Omega)$ the limit point set of $\{w_\lambda\}$ in the weak topology of $H^1(\Omega)$ coincides with the limit point set of $\{w_\lambda\}$ in $C^k(\Omega)$ topology.

Proof: Recall that $w_\lambda\in H^1(\Omega)$ satisfies:

$$\begin{cases}-\Delta w_\lambda=\lambda e^{c_\lambda}e^{u_0+w_\lambda}(1-e^{u_0+w_\lambda+c_\lambda})-\dfrac{4\pi}{|\Omega|}:=f_\lambda & \text{on } Q\\ \int_\Omega w_\lambda=0\end{cases}$$

and

$$\lambda e^{c_\lambda}\leq\frac{8\pi}{|\Omega|}$$

(see (3.23)).

Therefore, the Moser–Trudinger inequality (2.2) together with (2) of Proposition 3.2 implies that, for every $p>1$ there exists a constant $C=C_p>0$ such that

$$\|e^{u_0+w_\lambda}\|_p\leq C\quad\forall\lambda.$$

Consequently, $\|f_\lambda\|_p\leq C_1$, $\forall\lambda$, and by elliptic L^p estimates and the Sobolev embedding, we may conclude that,

$$\|w_\lambda\|_{C^{1,\alpha}}\leq C_2$$

with $\alpha \in (0,1)$ and $C_2>0$ a suitable constant independent of λ.

Since $e^{u_0} \in C^\infty(\Gamma)$ we can iterate this procedure and by means of Schauder's estimates conclude that (3.25) holds with a suitable constant independent of λ.

Finally, if $\lambda_n \to +\infty$ and $w_n = w_{\lambda n} \rightharpoonup w_0 \in \Gamma$ weakly in $H^1(\Omega)$, then as in the proof of Proposition 3.2, we see that, $-\Delta(w_n - w_0) = h_n$ with $\|h_n\|_p \to 0$ as $n \to +\infty$ and $p>1$. Consequently, $\|w_n - w_0\|_{C^{1,\alpha}} \to 0$ as $n \to +\infty$ and $\alpha \in (0,1)$. Thus, a bootstrap argument yields $\|w_n - w_0\|_{C^{k,\alpha}} \to 0$ as $n \to +\infty$ and $k \in N$.

Final remarks

In particular. Proposition 3.2 yields the existence of a solution for problem (3). More generally, for the problem:

$$\begin{cases} -\Delta w = \eta \left(\dfrac{e^{u_0+w}}{\int_\Omega e^{u_0+w}} - \dfrac{1}{|\Omega|} \right) & \text{in } \Omega \\ \int_\Omega w = 0 \end{cases} \tag{3}_\eta$$

with $\eta \in (0,8\pi)$, this can be derived directly by minimizing the functional:

$$F(w) = \frac{1}{2} \|\nabla w\|_2^2 - \eta \ln \left(\int_\Omega e^{u_0+w} \right)$$

over the space

$$E = \left\{ w \in H^1(\Omega) : \int_\Omega w = 0 \right\}.$$

On the other hand, for $\eta \geqslant 8\pi$ it is not clear whether or not problem $(3)_\eta$ is solvable. Notice for instance that, the analogous problem, subject to Dirichlet boundary condition,

$$\begin{cases} -\Delta w = \eta \dfrac{e^w}{\int_\Omega e^w} & \text{on } \Omega \\ w = 0 & \text{on } \partial\Omega \end{cases} \tag{3}^*_\eta$$

is known to admit no solutions when Ω is a ball and $\eta \geqslant 8\pi$, see Ref. 28.

This suggest that our restriction to the case $N=1$ might be more serious than a mere technical limitation of our method, and the case $N>1$ might require a different approach all together.

Furthermore we believe that when $\eta \in (0,8\pi)$ the solution for $(3)_\eta$ is unique and $w_\lambda \to w_0$ as $\lambda \to +\infty$ (in any of the relevant norms) with w_0 the (unique!) solution to $(3)_{\eta=4\pi}$. So far however, uniqueness of $(3)_\eta$, $\eta \in (0,8\pi)$ remains an open problem supported by the fact that it has been established by Suzuki[28] for the analogous problem $(3)^*_\eta$ when $\eta \in (0,8\pi)$ and $\Omega \subset R^2$ is simply connected.

In concluding let us mention that problem $(3)^*_\eta$, has attracted much attention in view of its connection with the study of the statistical mechanics of point vortices in the mean field limit. In this contest, $(3)^*_\eta$ is commonly referred to, as the mean field equation and it has been discussed, for instance, in Refs. 20–22.

The proof of Theorems 2.1 and 2.2

At this point, Theorems 2.1 and 2.2 are easy consequence of Theorem 2.3, Propositions 3.1 and 3.2. In fact, by Theorem 2.3 the first part of Theorem 2.1 follows easily by taking $k_c = 2/\sqrt{\lambda_c} < \frac{1}{2}\sqrt{|\Omega|/\pi N}$.

Furthermore, for $0<k\leqslant k_c$, let $v_k = v_{\lambda=4/k^2}$ be the maximal solution for $(2.1)_{\lambda=4/k^2}$, then (A_k,ϕ_k) as defined by (2.11), (2.12), and (2.13) with $u=u_0+v_k$ defines a solution for $(2.7)_k$ satisfying (2.8). Since

$$|\phi_k|^2=e^{u_0+v_k}$$

we have that, ϕ_k vanishes exactly at $p_1,\ldots,p_m$ with multiplicity $n_1,\ldots,n_m$ respectively, $|\phi_k|$ satisfies the "maximality" property (ii), and the monotonicity property (iii)–*a.* of Theorem 2.1. In addition, since $v_k<-u_0$ in Ω, the estimate (iii)-*b*, also follows. Finally, by Proposition 3.1 we get that $|\phi_k|\to 1$ as $k\to 0^+$ pointwise a.e. in Ω and, by the monotone (or dominated) convergence theorem, in $L^p(\Omega)\forall p\geqslant 1$. On the other hand, for $1<q<2$, $\|\nabla|\phi_k|\|_q\leqslant\frac{1}{2}\|\nabla(u_0+v_k)\|_q\to 0$ as $k\to 0^+$, and we may conclude: $\||\phi_k|-1\|_{W^{1,q}}\to 0$ as $k\to 0$ and $1<q<2$. Finally, in virtue of (ii) of Proposition 3.1 and the second equation in $(2.7)_k$, we also derive the property (iii)—d. of Theorem 2.1.

Similarly the first part of Theorem 2.2 follows by taking $(\tilde{A}_k,\tilde{\phi}_k)$ as defined in (2.11), (2.12) and (2.13) with $u = u_0 + v_{1,\lambda=4/k^2}$ and $v_{1,\lambda}$ as given by Theorem 2.3. While for $N=1$, we may take $u = u_0 + \tilde{v}_{\lambda=4/k^2}$ for $k>0$ small and $\tilde{v}_\lambda$ as given by Proposition 3.2. In this situation,

$$|\tilde{\phi}_k|^2=e^{u_0+w_k+c_k}=Ue^{w_k+c_k}$$

with $U=e^{u_0}$ smooth, $w_k = w_{\lambda=4/k^2}$ and $c_k = c_{\lambda=4/k^2}\to -\infty$ as $k\to 0^+$. Thus, by Corollary 3.1 we conclude that, for every integer $q\geqslant 0$ there exists a positive constant $C=C(q)$ independent of k such that,

$$\|\phi_k\|_{C^q}\leqslant Ce^{c_k}\to 0 \quad \text{as } k\to 0^+.$$

We conclude by mentioning that other interesting self-dual Chern–Simons theories are discussed in Ref. 29.

APPENDIX

In this appendix we would like to show that, the following property:

$$\int_\Omega \nabla v_*\cdot\nabla\varphi+\lambda e^{u_0+v_*}(e^{u_0+v_*}-1)\varphi+\frac{4\pi N}{|\Omega|}\varphi\leqslant 0$$

$$\forall\varphi\in H^1(\Omega),\quad \varphi\geqslant 0 \text{ a.e. in } \Omega \tag{A1}$$

implies that, if $v_0\in\Lambda=\{v\in H^1(\Omega): v\geqslant v_* \text{ a.e. in } \Omega\}$ satisfies:

$$I_\lambda(v_0)=\inf_\Lambda I_\lambda$$

then v_0 defines a critical point for I_λ in $H^1(\Omega)$.

To this purpose, let $\varphi\in H^1(\Omega)$, $t>0$ and define:

$$v_t=\max\{v_0+t\varphi,v_*\}\in\Lambda.$$

If v_+ and v_- denotes the positive and negative part of v respectively, then we may write,

$$v_t=v_0+t\varphi+w_t,\ \text{with } w_t=(v_0+t\varphi-v_*)_-\geqslant 0 \text{ a.e. in } \Omega.$$

We have

$$0 \leqslant \frac{1}{t}\,(I_\lambda(v_t)-I_\lambda(v_0)) = \frac{1}{2t}\,(\|\nabla(v_0+t\varphi+w_t)\|_2^2-\|\nabla v_0\|_2^2)+\frac{\lambda}{2t}\int_\Omega\{(e^{u_0+v_0+t\varphi+w_t}-1)^2$$

$$-(e^{u_0+v_0}-1)^2\}+\frac{4\pi N}{|\Omega|}\left(\int_\Omega\varphi+\frac{1}{t}\int_\Omega w_t\right)$$

$$=\frac{1}{2t}\,\|\nabla(t\varphi+w_t)\|_2^2+\int_\Omega\frac{\nabla v_0\cdot\nabla(t\varphi+w_t)}{t}$$

$$+\frac{\lambda}{t}\int_\Omega e^{u_0+v_0}(e^{u_0+v_0}-1)t\varphi$$

$$+\frac{\lambda}{2t}\int_\Omega\{(e^{u_0+v_t}-1)^2-(e^{u_0+v_0}-1)^2-2e^{u_0+v_0}(e^{u_0+v_0}-1)t\varphi\}$$

$$+\frac{4\pi N}{|\Omega|}\left(\int_\Omega+\frac{1}{t}\int_\Omega w_t\right).$$

Consequently,

$$\int_\Omega\nabla v_0\cdot\nabla\varphi+\lambda\int_\Omega e^{u_0+v_0}(e^{u_0+v_0}-1)\varphi+\frac{4\pi N}{|\Omega|}\int_\Omega\varphi$$

$$\geqslant-\frac{t}{2}\,\|\nabla\varphi\|_2^2-\int_\Omega\nabla\varphi\cdot\nabla w_t-\frac{1}{2t}\,\|\nabla w_t\|_2^2-\frac{1}{t}\int_\Omega\nabla v_0\cdot\nabla w_t-\frac{\lambda}{2t}\int_\Omega\{(e^{u_0+v_t}-1)^2$$

$$-(e^{u_0+v_0}-1)^2-2e^{u_0+v_0}(e^{u_0+v_0}-1)t\varphi\}-\frac{4\pi N}{|\Omega|}\frac{1}{t}\int_\Omega w_t$$

$$=O(t)+\frac{1}{t}\int_\Omega\nabla(-t\varphi-v_0+v_*)\cdot\nabla w_t-\frac{1}{t}\int_\Omega\nabla v_*\cdot\nabla w_t$$

$$+\frac{\lambda}{t}\int_\Omega e^{u_0+v_*}(e^{u_0+v_*}-1)w_t-\frac{4\pi N}{|\Omega|}\frac{1}{t}\int_\Omega w_t-\frac{1}{2t}\,\|\nabla w_t\|_2^2-\frac{\lambda}{2t}\int_\Omega\{(e^{u_0+v_0+t\varphi+w_t}-1)^2$$

$$-(e^{u_0+v_0}-1)^2-2e^{u_0+v_0}(e^{u_0+v_0}-1)(t\varphi+w_t)\}\frac{\lambda}{t}$$

$$\times\int_\Omega[e^{u_0+v_*}(e^{u_0+v_*}-1)-e^{u_0+v_0}(e^{u_0+v_0}-1)]w_t$$

$$\geqslant O(t)-\frac{\lambda}{2t}\int_0^1\left(\int_\Omega e^{u_0+v_0+s(t\varphi+w_t)}(2e^{u_0+v_0+s(t\varphi+w_t)}-1)(t\varphi+w_t)^2\right)ds$$

$$+\frac{\lambda}{t}\int_\Omega(e^{2(u_0+v_*)}-e^{2(u_0+v_0)})w_t$$

where the last inequality follows by (A1), the fact that $v_0 \geqslant v_*$ a.e. in Ω and

$$\int_\Omega \nabla(-t\varphi - v_0 + v_*)\nabla w_t = \|\nabla w_t\|_2^2.$$

Since,

$$|t\varphi + w_t| \leq t|\varphi| \quad t \in [0,1]$$

we estimate

$$\int_0^1 \int_\Omega e^{2(u_0+v_0+s(t\varphi+w_t))}(t\varphi+w_t)^2 \leq t^2 \int_\Omega e^{2(u_0+v_0+t|\varphi|)}\varphi^2 = O(t^2). \tag{A2}$$

Set,

$$\Omega_t = \{x \in \Omega : v_0(x) + t\varphi(x) - v_*(x) < 0\} \quad \text{and} \quad \Omega_0 = \{x \in \Omega : v_0(x) = v_*(x)\},$$

hence $|\Omega_t \backslash \Omega_0| \mapsto 0$ as $t \to 0^+$. Using (A2) we conclude

$$\int_\Omega \nabla v_0 \cdot \nabla\varphi + \lambda \int_\Omega e^{u_0+v_0}(e^{u_0+v_0}-1)\varphi + \frac{4\pi N}{|\Omega|}\int_\Omega \varphi$$

$$\geq O(t) + \frac{\lambda}{t}\int_{\Omega_t \backslash \Omega_0} (e^{2(u_0+v_*)} - e^{2(u_0+v_0)})(v_* - v_0 - t\varphi)$$

$$\geq -\lambda \int_{\Omega_t \backslash \Omega_0} (e^{2(u_0+v_*)} - e^{2(u_0+v_0)})\varphi + O(t) \to 0 \quad \text{as } t \to 0^+.$$

In other words, we have obtained $\langle I_\lambda'(v_0), \varphi\rangle \geq 0 \forall \varphi \in H^1(\Omega)$. Replacing φ with $-\varphi$ we obtain the reverse inequality and the desired conclusion.

Deriving the standard model from the simplest two-point K cycle

R. Wulkenhaar
Institut für Theoretische Physik, Universität Leipzig, Augustusplatz 10/11, D-04109 Leipzig, Germany

(Received 12 June 1995; accepted for publication 11 April 1996)

Basing on a differential algebra over the simplest two-point K cycle and graded Lie algebras of homomorphisms of finite projective modules, we derive the classical action of the standard model. This construction uses both the general framework of noncommutative geometry developed by Connes and ideas of the Mainz–Marseille approach to model building. We get a prediction of the Weinberg angle and constraints between the fermion masses and the masses of the W and Higgs bosons on tree level, which differ from the relations obtained by Kastler and Schücker for the quaternionic K cycle. © *1996 American Institute of Physics.*

I. INTRODUCTION

This paper is the continuation of two earlier papers (Refs. 1, 2) by Matthes, Rudolph, and Wulkenhaar. In the first of them we presented an analysis of the structure of the differential algebra $\Lambda^*_{\mathcal{A}}$ canonically associated to the K cycle $(\mathcal{A},h,D)$ over the simplest two-point algebra $\mathcal{A}=C^\infty(X)\otimes(\mathbb{C}\oplus\mathbb{C})$. In the second one we constructed for a given finite projective right $\mathcal{A}$ module with Hermitian structure $\mathcal{E}$ the graded Lie algebra $\mathcal{H}=\mathrm{Hom}_{\mathcal{A}}(\mathcal{E},\mathcal{E}\otimes_{\mathcal{A}}\Lambda^*_{\mathcal{A}})$ with natural derivation. We showed that a certain graded Lie subalgebra $\mathcal{H}_0$ of $\mathcal{H}$ provides a rigorous mathematical link between Connes' theory and the Mainz–Marseille model building scheme.

The K cycle mentioned above together with a finite projective module $\mathcal{E}=e\mathcal{A}^2$ was used by Connes in Refs. 3 and 4 and by Connes and Lott in Ref. 5 to derive the Salam–Weinberg model in a unified form. Within this scheme the above K cycle cannot be used to obtain the full standard model. That is why Connes and Lott proposed a K cycle over the algebra $C^\infty_{\mathbb{R}}(X)\otimes(\mathbb{C}\oplus\mathbb{H})$; see Refs. 5, 3 and 6. A detailed exposition of these ideas was presented by Kastler in Refs. 7 and 8; see Ref. 9 for an earlier version, and by Kastler and Schücker in Ref. 10. One obtains a prediction of the Weinberg angle and certain tree-level constraints between the masses of the fermions and the masses of the W,Z, and Higgs bosons (Refs. 10, 11), which we review at the end of this Introduction.

Another way of obtaining the standard model by noncommutative geometry is the Mainz–Marseille model (Refs. 12–14), which uses the graded Lie algebra $\Lambda^*(X)\otimes spl(2,1)$ of matrix-valued differential forms; also see Ref. 15. We have shown in Ref. 2 that the assumptions of this approach are natural within Connes' framework. For the present paper the construction of the fermionic sector of the standard model given in Ref. 13 is of particular interest. This construction makes use of the theory of representations of the graded Lie algebra $spl(2,1)$ in a finite-dimensional vector space.[15]

Our strategy is the following: In Sec. II we give a review of some results obtained in Refs. 1 and 2. In Sec. III we construct an isomorphism $\mathbf{i}$ of graded Lie algebras from $\mathcal{H}_0$, which we constructed in Ref. 2 within Connes' theory onto its image, for which the fermionic sector in Ref. 13 serves as a guiding line. Next, in Sec. IV, we give an embedding of a subspace of $\mathbf{i}(\mathcal{H}_0)$ into the algebra of bounded operators on the Hilbert space of fermions. This allows us to construct the

fermionic action (Sec. V), the electroweak sector of the bosonic action of the standard model (Sec. VI), and the chromodynamics sector (Sec. VII). After a Wick rotation to Minkowski space and a reparametrization this action coincides with the classical action of the standard model, where some free parameters of the standard model are fixed; see Sec. VIII.

Thus, our construction rests—as the construction of Connes, Lott, and Kastler—upon a K cycle. However, we take a K cycle over the algebra $\mathcal{A}=C^\infty(X)\otimes(\mathbb{C}\oplus\mathbb{C})$, while the above authors start with a K cycle over the much bigger algebras $C^\infty_{\mathbb{R}}(X)\otimes(\mathbb{C}\oplus\mathbb{H})$ and $C^\infty_{\mathbb{R}}(X)\otimes(\mathbb{C}\oplus M_3\mathbb{C})$. To compensate this difference we use two finite projective $\mathcal{A}$ modules as an additional input: one module for the electroweak sector and the other one for the chromodynamics sector. In the construction of Connes, Lott, and Kastler the module is identical with the algebra of their K cycle, so that in their version the calculus of finite projective modules is not necessary. In both versions the differential of the differential algebras associated to the K cycles are composed of the classical exterior differential and a matrix differential, which in both versions contains fermionic mass parameters. In the construction of Connes, Lott, and Kastler the just mentioned differential algebra is of primary importance for the physical model. In our version the differential algebra plays only an auxiliary role, namely for building the graded Lie algebra $\mathcal{H}_0$. Moreover, the Hilbert space of our K cycle is also auxiliary: we have to add our physical Hilbert space by hand.

As it was shown in Ref. 2 one can derive from $\mathcal{H}_0$ the graded Lie algebra $\Lambda^*(X)\otimes spl(2,1)$, which is the starting point for the construction of the standard model in the Mainz–Marseille approach. The essential difference between $\mathcal{H}_0$ and $\Lambda^*(X)\otimes spl(2,1)$ is that $\mathcal{H}_0$ carries the fermionic mass parameters of the differential algebra associated to the K cycle. It is these fermionic mass parameters that relate the masses of the fermions to the masses of the W,Z, and Higgs bosons in the model of Connes, Lott, and Kastler, as well as in our model. Since the fermionic mass parameters are absent in $\Lambda^*(X)\otimes spl(2,1)$, there is no relation between fermion masses and boson masses in the Mainz–Marseille model.

Both in our model and in the Mainz–Marseille approach one needs certain representations of the graded Lie algebras $\mathcal{H}_0$, respectively, $\Lambda^*(X)\otimes spl(2,1)$, which are generalizations of classical $spl(2,1)$ representations.[15] The representations of $\Lambda^*(X)\otimes spl(2,1)$ generalize reducible indecomposable representations of $spl(2,1)$, which give the possibility to describe mixing between fermion generations.[13] For our model we take generalizations of the simplest irreducible representations of $spl(2,1)$, because the fermion generations are intrinsically contained in $\mathcal{H}_0$. With these representations there enters a big number of additional parameters due to not canonically determined free normalization constants of $sl(2,\mathbb{C})\oplus gl(1,\mathbb{C})$—subrepresentations of $spl(2,1)$. In the Mainz–Marseille construction these parameters are fitted to the fermion masses and the Kobayashi–Maskawa matrix. In our model there is a subtle interplay between these normalization parameters and the intrinsic fermionic mass parameters of the differential calculus. In the final Lagrangian there occur only such combinations of these parameters that for the simplest scalar product there is effectively only one additional free parameter in our model compared with the simplest version of the model of Connes, Lott, and Kastler.

From our formulation of the standard model we get tree-level predictions for the Weinberg angle θ_W and the ratios m_W/m_t, m_H/m_W, and g_3/g_2. Here, m_t, m_H, and m_W are the masses of the top quark, the Higgs boson, and the W boson and g_3, g_2 the coupling constants of the strong and weak interactions, respectively. We list our predictions (Model III, with the parameters $x>0$ and ϑ_1, ϑ_2, ϑ_3, ϑ_4) in Table I and compare them with corresponding tree-level predictions of the following noncommutative geometrical formulations of the standard model:

Model I: The construction based on a K cycle over the algebras $C^\infty_{\mathbb{R}}(X)\otimes(\mathbb{C}\oplus\mathbb{H})$ and $C^\infty_{\mathbb{R}}(X)\otimes(\mathbb{C}\oplus M_3\mathbb{C})$ as presented by Kastler and Schücker in Ref. 10. The parameters are $R>-1$, $\alpha,\beta>0$.

Model II: The Mainz–Marseille model as presented in Refs. 13 and 14, predictions for the adjoint representation of $spl(2,1)$, and a general scalar product. The parameters are $r_0, r_1, r_2>0$.

TABLE I. Comparison of tree-level predictions for general scalar products.

	Model I	Model II	Model III
$\left(\frac{m_i}{m_W}\right)^2$	$R+4>3$	...	$\frac{6+2x}{4-(1-x\sin^2\vartheta_1\cos^2\vartheta_2)}>\frac{3}{2}$
$\left(\frac{m_H}{m_W}\right)^2$	$11+3R-\frac{8+2R}{7+R}>7$	$\frac{2r_0r_2}{r_1^2}$	$\frac{8(x+3)(5\cos^2\vartheta_1+3x\cos^2\vartheta_4\sin^4\vartheta_1)\cos^4\vartheta_2}{3(4-(1-x\sin^2\vartheta_1)\cos^2\vartheta_2)^2}$
$\sin^2\theta_W$	$\frac{8+2R}{15+3R+\frac{2}{3}\alpha+2\beta}<\frac{2}{3}$	$\frac{1}{4}$	$\frac{1}{4}<\frac{3}{4}\frac{3+x}{5+3x}<\frac{9}{20}$
$\left(\frac{g_3}{g_2}\right)^2$	$\frac{R+4}{2\alpha}$	...	$\frac{3+x}{4}>\frac{3}{4}$

In Model I there is enough freedom to reproduce the experimental values for m_W/m_i, $\sin^2\theta_W$, and g_3/g_2. Then m_H is uniquely determined. Also in Model III it is possible to reproduce the experimental values for m_W/m_i, g_3/g_2, and $\sin^2\theta_W\approx 0.25$. However, then there is only an upper limit for m_H in our model; see Sec. VIII. In Model II there is no relation between fermion and boson masses and between g_3 and g_2. Moreover, this model does not give a prediction for m_H. However, in contrast to the other two models one obtains an experimentally well-confirmed relation between the Cabibbo angle and the quark masses; Ref. 16.

For the simplest scalar products given by $R=0$, $\alpha=2$, $\beta=\frac{3}{2}$ in Model I, $r_0=r_1=r_2$ in Model II and $x=1$ in Model III one gets

TABLE II. Comparison of tree-level predictions for simplest scalar products.

	Model I	Model II	Model III
m_i/m_W	2		1.41...1.63
m_H/m_W	3.14	1.41	0...2.43
$\sin^2\theta_W$	0.414	0.25	0.375
g_3/g_2	1		1

Now, m_H is fixed in Model II. In Model III there is still only an upper limit for m_H, and the relation between m_i and m_W does not fit the experimental value as well as the corresponding relation in Model I does.

II. REVIEW OF EARLIER RESULTS

In this section we give a review of some results, which were obtained in Refs. 1 and 2 and that we need for what follows. For technical reasons let for the moment X be a compact four-dimensional Riemannian spin manifold. We denote by $L^2(X,S)$ the Hilbert space of square integrable sections of the spinor bundle over X, by F a finite-dimensional Hilbert space, by C the Clifford bundle of the cotangent space over X, and by C^k the set of those sections of C whose values at each point $x\in X$ belong to the subspace spanned by products of less than or equal k elements of T_x^*X of the same parity. The simplest two-point K cycle $(\mathcal{A},h,D)$ consists of the algebra $\mathcal{A}=C^\infty(X)\otimes(\mathbb{C}\oplus\mathbb{C})$ acting on the Hilbert space $h=L^2(X,S)\otimes(F\oplus F)$ and a generalized Dirac operator $D=(D^{\rm cl}\otimes{\rm id}_{F\oplus F})\oplus(\gamma^5\otimes\mathcal{M})$. Here, $D^{\rm cl}$ is the classical Dirac operator and γ^5 the grading operator on $L^2(X,S)$. Moreover, $\mathcal{M}=\left(\begin{smallmatrix}0 & M\\ M^* & 0\end{smallmatrix}\right)$, where M is an endomorphism of F.

Now we are going to specify the parameters. We take F and M as

$$F=\mathbb{C}^3\oplus\mathbb{C}^3, \quad M=\begin{pmatrix} -m_l & 0 \\ 0 & -m_q \end{pmatrix}, \tag{1}$$

where m_l and m_q are real diagonal 3×3 matrices with non-negative entries. In principle, we could take for m_l and m_q arbitrary complex 3×3 matrices, which can be written as $u_1\delta u_2$, with u_1,u_2 unitary and δ diagonal and positive. However, the unitary matrices u_1,u_2 can be absorbed by unitary transformations of the physical fields.

One shows that the algebra $\pi(\Omega^*)$ obtained from an involutive representation π of the universal differential algebra Ω^* over $\mathcal{A}$ has the structure

$$\pi(\Omega^*)=\bigoplus_{k=0}^{\infty}\pi(\Omega^k),$$

$$\pi(\Omega^k)=\begin{bmatrix} \bigoplus_{r=0}^{m} C^{k-2r}\otimes\mathbb{C}M_1^r; & \bigoplus_{r=0}^{m} C^{k-2r-1}\gamma^5\otimes\mathbb{C}M_2^r \\ \bigoplus_{r=0}^{m} C^{k-2r-1}\gamma^5\otimes\mathbb{C}M_3^r; & \bigoplus_{r=0}^{m} C^{k-2r}\otimes\mathbb{C}M_4^r \end{bmatrix}, \tag{2}$$

where

$$M_1^r:=(MM^*)^r, \quad M_2^r:=M(M^*M)^r, \quad M_3^r:=M^*(MM^*)^r, \quad M_4^r:=(M^*M)^r. \tag{3}$$

In particular, we can identify $\mathcal{A}$ with $\pi(\Omega^0)$. We denote by $(m+1)$ the number of linear independent elements $(MM^*)^r$. In our case M and M^* commute with each other and generically we have $m=6$. We define $L^n:=C^n/C^{n-2}$, $L^*:=\oplus_{k=0}^4 L^k$, and put $L^n=\{0\}$ for $n<0$. There is a graded algebra $\Lambda^*_{\not d}$ associated with $\pi(\Omega^*)$ defined as follows:

$$\Lambda^*_{\not d}:=\bigoplus_{k=0}^{\infty}\Lambda^k_{\not d}, \quad \Lambda^k_{\not d}\equiv\sigma_k\wedge\pi(\Omega^k):=\begin{cases}\pi(\Omega^k)/\pi(\Omega^{k-2}), & \text{for } k\geq2,\\ \pi(\Omega^k), & \text{for } k=0,1,\end{cases} \tag{4}$$

with multiplication

$$\Lambda^k_{\not d}\times\Lambda^n_{\not d}\ni(\lambda^k,\tilde{\lambda}^n)\to\lambda^k\tilde{\lambda}^n:=\sigma_{k+n}(\tau^k\tilde{\tau}^n)\in\Lambda^{k+n}_{\not d}, \tag{5}$$

where $\tau^k\in\pi(\Omega^k)$, $\tilde{\tau}^n\in\pi(\Omega^n)$, such that $\sigma_k(\tau^k)=\lambda^k$, $\sigma_k(\tilde{\tau}^n)=\tilde{\lambda}^n$. One can show that elements $\lambda^k\in\Lambda^k_{\not d}$ have the form

$$\lambda^k=\begin{pmatrix} \sum_{r=0}^{m}\alpha_1^{k-2r}\otimes\mathbb{C}M_1^r; & \sum_{r=0}^{m}\alpha_2^{k-2r-1}\gamma^5\otimes\mathbb{C}M_2^r \\ \sum_{r=0}^{m}\alpha_3^{k-2r-1}\gamma^5\otimes\mathbb{C}M_3^r; & \sum_{r=0}^{m}\alpha_4^{k-2r}\otimes\mathbb{C}M_4^r \end{pmatrix}, \quad \alpha_q^n\in L^n. \tag{6}$$

Let ι_k denote the isomorphism of L^k onto $\Lambda^k(X)$, where $\Lambda^k(X)$ is the space of complex-valued k forms on X. We define the following operations:

$$[\gamma^5\otimes_{\mathscr{A}}\mathscr{M},\lambda^k]_g:=(\gamma^5\otimes_{\mathscr{A}}\mathscr{M})\cdot\lambda^k-(-1)^k\lambda^k(\gamma^5\otimes_{\mathscr{A}}\mathscr{M}),$$

$$\mathbf{d}\alpha^k:=\iota_{k+1}^{-1}\circ d\circ\iota_k(\alpha^k),\quad \mathbf{d}^*:=\gamma^5\,\mathbf{d}\gamma^5, \tag{7}$$

$$\mathbf{D}\lambda^k:=pr_{k+1}\circ((\mathbf{d}-\mathbf{d}^*)\otimes\mathrm{id}_F\otimes\mathbf{1}_{2\times 2})(\lambda^k),$$

for $\alpha^k\in L^k$, $\lambda^k\in\Lambda^k{}_{\mathscr{A}}$, where pr_{k+1} denotes the projection from $\Lambda_{\mathscr{A}}^{k+1}\oplus\Lambda_{\mathscr{A}}^{k-1}$ onto $\Lambda_{\mathscr{A}}^{k+1}$. One shows that

$$\hat{d}:=\mathbf{D}-i[\gamma^5\otimes_{\mathscr{A}}\mathscr{M},\cdot]_g \tag{8}$$

is a graded differential on $\Lambda^*{}_{\mathscr{A}}$, and one can write down explicit multiplication and differential rules for elements of $\Lambda^*{}_{\mathscr{A}}$; see Ref. 1.

In Ref. 2 we considered finite projective right $\mathscr{A}$ modules with Hermitian structure $\mathscr{E}=e\mathscr{A}^p$, where $e\in\mathrm{End}_{\mathscr{A}}(\mathscr{E})$, fulfilling $e=e^2=e^*$. Let $\mathscr{H}^k:=\mathrm{Hom}_{\mathscr{A}}(\mathscr{E},\mathscr{E}\otimes_{\mathscr{A}}\Lambda^k{}_{\mathscr{A}})$ be the set of homomorphisms of the right $\mathscr{A}$ module $\mathscr{E}$ to the right $\mathscr{A}$ module $\mathscr{E}\otimes_{\mathscr{A}}\Lambda^k{}_{\mathscr{A}}$. Elements $\varrho^k\in\mathscr{H}^k$ can be identified with $p\times p$ matrices of elements of $\Lambda^k{}_{\mathscr{A}}$, fulfilling $e\varrho^k e=\varrho^k$:

$$\varrho^k=\begin{pmatrix}\varrho^k_{11}&\cdots&\varrho^k_{1j}&\cdots&\varrho^k_{1p}\\ \vdots&\ddots&\vdots&\ddots&\vdots\\ \varrho^k_{i1}&\cdots&\varrho^k_{ij}&\cdots&\varrho^k_{ip}\\ \vdots&\ddots&\vdots&\ddots&\vdots\\ \varrho^k_{p1}&\cdots&\varrho^k_{pj}&\cdots&\varrho^k_{pp}\end{pmatrix},\quad \rho^k_{ij}\in\Lambda^k{}_{\mathscr{A}},\quad i,j=1,\ldots,p. \tag{9}$$

The space $\mathscr{H}=\oplus_{k=0}^{\infty}\mathscr{H}^k$ is an algebra with multiplication given by the tensor product of the multiplication in $\Lambda^*{}_{\mathscr{A}}$ and multiplication of $p\times p$ matrices. On $\mathscr{H}$ we have a canonical derivation $\mathscr{D}$ given by

$$\mathscr{D}\varrho=e\hat{d}(\varrho)e,\quad \varrho\in\mathscr{H}, \tag{10}$$

where $\hat{d}$ means the componentwise action on matrix elements belonging to $\Lambda^*{}_{\mathscr{A}}$. With respect to the graded commutator,

$$[\varrho^k,\tilde{\varrho}^n]_g:=\varrho^k\cdot\tilde{\varrho}^n-(-1)^{kn}\tilde{\varrho}^n\varrho^k,\quad \varrho^k\in\mathscr{H}^k,\quad \tilde{\varrho}^n\in\mathscr{H}^n, \tag{11}$$

$\mathscr{H}$ is a graded Lie algebra with graded derivation $\mathscr{D}$.

We define on $\Lambda^*{}_{\mathscr{A}}$, see (6), a linear map $T_\Lambda:\Lambda^*{}_{\mathscr{A}}\to L^*$ by

$$T_\Lambda\left(\begin{pmatrix}\sum_{t=0}^{m}\alpha_1^{k-2t}\otimes M_1^t; & \sum_{t=0}^{m}\alpha_2^{k-2t-1}\gamma^5\otimes M_2^t\\ \sum_{t=0}^{m}\alpha_3^{k-2t-l}\gamma^5\otimes M_3^t; & \sum_{t=0}^{m}\alpha_4^{k-2t}\otimes M_4^t\end{pmatrix}\right):=\sum_{t=0}^{m}(\alpha_1^{k-2t}-\alpha_4^{k-2t}), \tag{12}$$

which can be interpreted as a generalized trace. We have proved in Ref. 2 that there exists a graded Lie subalgebra $\mathscr{H}_0$ of $\mathscr{H}$ defined by

$$\mathscr{H}_0=\bigotimes_{k=0}^{\infty}\mathscr{H}_0^k,\quad \mathscr{H}_0^k=\left\{\varrho^k\in\mathscr{H}^k,\sum_{i=1}^{p}T_\Lambda(\varrho_n^k)=0\right\} \tag{13}$$

[in the notation of (9)]. Moreover, $\mathscr{D}$ is a graded derivation on $\mathscr{H}_0$.

Any connection ∇ on $\mathscr{E}$ has the form

$$\nabla = e\hat{d} + \rho, \quad \rho = -\rho^* \in \mathscr{H}^1. \tag{14}$$

The situation found in physics suggests to consider special connections, namely such that $\rho \in \mathscr{H}^1_0$. This implies that the gauge group is restricted to

$$\mathscr{U} = \{u \in \mathrm{Aut}_{\mathscr{A}}(\mathscr{E}), \quad uu^* = u^*u = e, \quad u\,\mathbf{d}u^* \in \mathscr{H}^1_0\}, \tag{15}$$

see Ref. 2, where $\mathbf{d}u^*$ means the action of the differential $\mathbf{d}$ on the L^* component of $u^* \in \mathscr{U}$. Gauge transformations of the connection ∇ are given by $u\,\nabla u^*$.

III. AN ISOMORPHISM OF GRADED LIE ALGEBRAS

Here we fix the module $\mathscr{E}$ by taking $p=2$ and for the projector $e = \left(\begin{smallmatrix} e' & 0 \\ 0 & 1_{\mathscr{A}} \end{smallmatrix}\right)$, where $1_{\mathscr{A}} = \left(\begin{smallmatrix} 1\otimes \mathrm{id}_F & 0 \\ 0 & 1\otimes \mathrm{id}_F \end{smallmatrix}\right) \in \mathscr{A}$ is the identity of $\mathscr{A}$ and $e' = \left(\begin{smallmatrix} 1\otimes \mathrm{id}_F & 0 \\ 0 & 0 \end{smallmatrix}\right) \in \mathscr{A}$. Then from (6), (9), (12), (13) and the discussion in Ref. 2 we get that elements $\varrho^k \in \mathscr{H}^k_0$ have the form

$$\varrho^k = \sum_{r=0}^{m} \begin{pmatrix} \frac{1}{2}(\alpha_0^{k-2r} + \alpha_3^{k-2r}) \otimes M_1^r & 0 & \alpha_-^{k-2r} \otimes M_1^r & \alpha_4^{k-2r-1}\gamma^5 \otimes M_2^r \\ 0 & 0 & 0 & 0 \\ \alpha_+^{k-2r} \otimes M_1^r & 0 & \frac{1}{2}(\alpha_0^{k-2r} - \alpha_3^{k-2r}) \otimes M_1^r & \alpha_5^{k-2r-1}\gamma^5 \otimes M_2^r \\ \alpha_6^{k-2r-1}\gamma^5 \otimes M_3^r & 0 & \alpha_7^{k-2r-1}\gamma^5 \otimes M_3^r & \alpha_0^{k-2r} \otimes M_4^r \end{pmatrix} \tag{16}$$

where $\alpha_f^n \in L^n$, $f = 0,+,-,3,4,5,6,7$. Due to (1) and (3) we have $M_s^r \in M_3\mathbb{C} \otimes M_2\mathbb{C}$, which means $\varrho^k \in L^* \otimes M_4\mathbb{C} \otimes M_3\mathbb{C} \otimes M_2\mathbb{C}$. In (16) we considered ϱ^k as a 4×4 matrix with $L^* \otimes M_3\mathbb{C} \otimes M_2\mathbb{C}$-valued entries. Of course, ϱ^k can also be treated as a 2×2 matrix with $L^* \otimes M_4\mathbb{C} \otimes M_3\mathbb{C}$-valued entries. With regard to this view, ϱ^k has the form

$$\varrho^k = \begin{pmatrix} \varrho_l^k & 0 \\ 0 & \varrho_q^k \end{pmatrix},$$

$$\varrho_l^k = \sum_{r=0}^{m} \begin{pmatrix} \frac{1}{2}(\alpha_0^{k-2r} + \alpha_3^{k-2r}) \otimes l_1^r & 0 & \alpha_-^{k-2r} \otimes l_1^r & \alpha_4^{k-2r-1}\gamma^5 \otimes l_2^r \\ 0 & 0 & 0 & 0 \\ \alpha_+^{k-2r} \otimes l_1^r & 0 & \frac{1}{2}(\alpha_0^{k-2r} - \alpha_3^{k-2r}) \otimes l_1^r & \alpha_5^{k-2r-1}\gamma^5 \otimes l_2^r \\ \alpha_6^{k-2r-1}\gamma^5 \otimes l_3^r & 0 & \alpha_7^{k-2r-1}\gamma^5 \otimes l_3^r & \alpha_0^{k-2r} \otimes l_4^r \end{pmatrix},$$

$$\varrho_q^k = \sum_{r=0}^{m} \begin{pmatrix} \frac{1}{2}(\alpha_0^{k-2r} + \alpha_3^{k-2r}) \otimes q_1^r & 0 & \alpha_-^{k-2r} \otimes q_1^r & \alpha_4^{k-2r-1}\gamma^5 \otimes q_2^r \\ 0 & 0 & 0 & 0 \\ \alpha_4^{k-2r} \otimes q_1^r & 0 & \frac{1}{2}(\alpha_0^{k-2r} - \alpha_3^{k-2r}) \otimes q_1^r & \alpha_5^{k-2r-1}\gamma^5 \otimes q_2^r \\ \alpha_6^{k-2r-1}\gamma^5 \otimes q_3^r & 0 & \alpha_7^{k-2r-1}\gamma^5 \otimes q_3^r & \alpha_0^{k-2r} \otimes q_4^r \end{pmatrix}, \tag{17}$$

where

$$\begin{aligned} &l_1^r = (m_l m_l^*)^r, \quad l_2^r = -m_l(m_l^* m_l)^r, \quad l_3^r = -m_l^*(m_l m_l^*)^r, \quad l_4^r = (m_l^* m_l)^r, \\ &q_1^r = (m_q m_q^*)^r, \quad q_2^r = -m_q(m_q^* m_q)^r, \quad q_3^r = -m_q^*(m_q m_q^*)^r, \quad q_4^r = (m_q^* m_q)^r. \end{aligned} \tag{18}$$

We introduce an isomorphism $\mathbf{i}$ of graded Lie algebras, which generalizes certain representations Refs. 15, 13 of the graded Lie algebra $spl(2,1)$ to the graded Lie algebra $\mathscr{H}_0$:

$$\mathbf{i}(\varrho^k)=\begin{pmatrix}\mathbf{i}_l(\varrho_l^k) & 0\\ 0 & \mathbf{i}_q(\varrho_q^k)\otimes\mathbb{1}_{3\times3}\end{pmatrix}, \tag{19}$$

$$\mathbf{i}_l(\varrho_l^k)=\sum_{r=0}^{m}\begin{pmatrix}\frac{1}{2}(\alpha_0^{k-2}+\alpha_3^{k-2r})\otimes l_1^r & \alpha_-^{k-2r}\otimes l_1^r & \alpha_4^{k-2r-1}\gamma^5\otimes\epsilon l_2^r\\ \alpha_+^{k-2r}\otimes l_1^r & \frac{1}{2}(\alpha_0^{k-2r}-\alpha_3^{k-2r})\otimes l_1^r & \alpha_5^{k-2r-1}\gamma^5\otimes\epsilon l_2^r\\ \alpha_6^{k-2r-1}\gamma^5\otimes\epsilon^{-1}l_3^r & \alpha_7^{k-2r-1}\gamma^5\otimes\epsilon^{-1}l_3^r & \alpha_0^{k-2r}\otimes l_4^r\end{pmatrix}, \tag{20}$$

$$\mathbf{i}_q(\varrho_q^k)=\sum_{r=0}^{m}\begin{pmatrix}(\frac{1}{2}\alpha_3^{k-2r}-\frac{1}{6}\alpha_0^{k-2r})\otimes q_1^r & \alpha_-^{k-2r}\otimes q_1^r & \alpha_7^{k-2r-1}\gamma^5\otimes\beta\sqrt{\frac{2}{3}}\,q_2^r & \alpha_4^{k-2r-1}\gamma^5\otimes\sqrt{\frac{1}{3}}\,q_2^r\chi\gamma\\ \alpha_+^{k-2r}\otimes q_1^r & (-\frac{1}{2}\alpha_3^{k-2r}-\frac{1}{6}\alpha_0^{k-2r})\otimes q_1^r & -\alpha_6^{k-2r-1}\gamma^5\otimes\beta\sqrt{\frac{2}{3}}\,q_2^r & \alpha_5^{k-2r-1}\gamma^5\otimes\sqrt{\frac{1}{3}}\,q_2^r\chi\gamma\\ -\alpha_5^{k-2r-1}\gamma^5\otimes\beta^{-1}\sqrt{\frac{2}{3}}\,q_3^r & \alpha_4^{k-2r-1}\gamma^5\otimes\beta^{-1}\sqrt{\frac{2}{3}}\,q_3^r & -\frac{2}{3}\alpha_0^{k-2r}\otimes q_4^r & 0\\ \alpha_6^{k-2r-1}\gamma^5\otimes(\chi\gamma)^{-1}\sqrt{\frac{1}{3}}\,q_3^r & \alpha_7^{k-2r-1}\gamma^5\otimes(\chi\gamma)^{-1}\sqrt{\frac{1}{3}}\,q_3^r & 0 & \frac{1}{3}\alpha_0^{k-2r}\otimes\chi^{-1}q_4^r\chi\end{pmatrix}. \tag{21}$$

The isomorphism $\mathbf{i}$ fulfills $\mathbf{i}([\varrho^k,\tilde{\varrho}^n]_g)=\mathbf{i}(\varrho^k)\mathbf{i}(\tilde{\varrho}^n)-(-)^{kn}\mathbf{i}(\tilde{\varrho}^n)\mathbf{i}(\varrho^k)$, for $\varrho^k\in\mathscr{H}_0^k$ and $\tilde{\varrho}^n\in\mathscr{H}_0^n$, where the multiplication $\mathbf{i}(\varrho^k)\mathbf{i}(\tilde{\varrho}^n)$ is the natural combination of the multiplication $\wedge$ in L^* and matrix multiplication.

In the above formulas ϵ and β are invertible diagonal 3×3 matrices, which, therefore, commute with m_l, m_l^*, m_q, m_q^*. For the invertible 3×3 matrices γ and χ we have to demand $(\chi\gamma)^{-1}m_q^*m_q\chi\gamma=\chi^{-1}m_q^*m_q\chi$, which is achieved by taking $\chi\gamma\chi^{-1}$ diagonal. The matrix χ need not be unitary. In principle, we could in an analogous way introduce matrices such as χ in the third row and column in (20) and (21), too. However, this can be reabsorbed by unitary transformations of the physical fields. Thus, the freedom in the choice of the isomorphism $\mathbf{i}$, modulo unitary transformations, introduced a lot of additional free parameters in (20) and (21). But, we shall see at the end of Sec. V that all these parameters are (not uniquely) fixed by the physical model. The genuine free parameters are the six eigenvalues of M; see (1).

The motivation to consider just the isomorphism (20), (21) comes from our paper,[2] where we constructed a partial homomorphism of $\mathscr{H}_0$ onto $\Lambda^*(X)\otimes spl(2,1)$, and the paper,[13] where similar looking representations of $spl(2,1)$ were used to write down a fermionic Lagrangian for the standard model.

IV. BOUNDED OPERATORS ON THE HILBERT SPACE OF FERMIONS

Here we are going to associate to each $\mathbf{i}(\rho^k)\in\mathbf{i}(\mathscr{H}_0^k)$, $k=0,1,2$, a bounded operator on the Hilbert space,

$$H=H_l\oplus H_q,$$

$$H_l=L^2(X,S)\otimes\mathbb{C}^3\otimes\mathbb{C}^3,\quad H_q=L^2(X,S)\otimes(\mathbb{C}^4\oplus\mathbb{C}^4\oplus\mathbb{C}^4)\otimes\mathbb{C}^3. \tag{22}$$

First, because of $L^0 \equiv C^0$ and $L^1 \equiv C^1$ we can regard elements of $\mathbf{i}(\mathscr{H}_0^0)$ and $\mathbf{i}(\mathscr{H}_0^1)$ in a natural way as bounded operators on H, see (20) and (21), where the matrices l_s^r and q_s^r act on the last $\mathbb{C}^3$ components. Next, we associate to the local basis $[\gamma^\mu] \wedge [\gamma^\nu]$ in L^2 the operator $\mathbf{c}([\gamma^\mu] \wedge [\gamma^\nu]) := \gamma^\mu \cdot \gamma^\nu \in B(L^2(X,S))$, for $1 \leq \mu < \nu \leq 4$. By linear extension we obtain a vector space isomorphism $\mathbf{c}$ of L^2 onto its image. The isomorphism $\mathbf{c}$ induces the vector space isomorphism $\tilde{\mathbf{c}}\mathbf{i}(\mathscr{H}_0^2) \to \tilde{\mathbf{c}} \circ \mathbf{i}(\mathscr{H}_0^2)$, $\tilde{\mathbf{c}} \circ \mathbf{i}(\mathscr{H}_0^2) \subset B(H)$:

$$\tilde{\mathbf{c}} \circ \mathbf{i}(\varrho^2) := \begin{pmatrix} (\mathbf{c} \otimes \mathrm{id}_{\mathbb{C}^3 \otimes \mathbb{C}^3})(\mathbf{i}_l(\varrho_l^2)) & 0 \\ 0 & \{(\mathbf{c} \otimes \mathrm{id}_{\mathbb{C}^3 \otimes \mathbb{C}^3})(\mathbf{i}_q(\varrho_q^2))\} \otimes \mathbf{1}_{3\times 3} \end{pmatrix}. \tag{23}$$

for $\varrho^2 \in \mathscr{H}_0^2$. Next, we define a vector subspace $\tilde{\mathscr{T}}^2 \subset B(H)$ as

$$\tilde{\mathscr{T}}^2 = \Big\{ \sum_\alpha (\mathbf{i}(\varrho_\alpha^l) \cdot \mathbf{i}(\tilde{\varrho}^1{}_\alpha) + \mathbf{i}(\tilde{\varrho}^1{}_\alpha) \cdot \mathbf{i}(\varrho_\alpha^1)), \quad \varrho_\alpha^1, \tilde{\varrho}^1{}_\alpha \in \mathscr{H}_0^1, \text{ finite sum} \Big\}. \tag{24}$$

where $\cdot$ denotes the multiplication in $B(H)$, and put

$$\mathscr{T}^2 = \tilde{\mathbf{c}} \circ \mathbf{i}(\mathscr{H}_0^2) + \tilde{\mathscr{T}}^2. \tag{25}$$

One easily convinces oneself that another characterization of this space is

$$\mathscr{T}^2 = \tilde{\mathbf{c}} \circ \mathbf{i}(\mathscr{H}_0^2) \oplus \mathbf{i}(\mathscr{H}_0^0) \oplus \Delta,$$

$$\Delta = \{\mathbf{i}(\mathrm{diag}(\alpha_3^0, 0, -\alpha_3^0, 0) \otimes \mathrm{id}_F) \ \mathbf{i}(\mathrm{diag}(\tilde{\alpha}^0{}_3, 0, -\tilde{\alpha}^0{}_3, 0) \otimes \mathrm{id}_F) + \mathbf{i}(\mathrm{diag}(\alpha_0^0, 0, \alpha_0^0, 2\alpha_0^0) \otimes \mathrm{id}_F) \ \mathbf{i}(\mathrm{diag}(\tilde{\alpha}^0{}_0, 0, \tilde{\alpha}^0{}_0, 2\tilde{\alpha}^0{}_0) \otimes \mathrm{id}_F), \quad \alpha_3^0, \tilde{\alpha}^0{}_3, \alpha_0^0, \tilde{\alpha}^0{}_0 \in C^0\}. \tag{26}$$

Let $\mathbf{p}_2$ be the projection of $\mathscr{T}^2 = \tilde{\mathbf{c}} \circ \mathbf{i}(\mathscr{H}_0^2) \oplus \mathbf{i}(\mathscr{H}_0^0) \oplus \Delta$ onto its first component $\tilde{\mathbf{c}} \circ \mathbf{i}(\mathscr{H}_0^2)$. Then we have

$$\tilde{\mathbf{c}}^{-1} \circ \mathbf{p}_2(\mathbf{i}(\varrho^1) \cdot \mathbf{i}(\tilde{\varrho}^1) + \mathbf{i}(\tilde{\varrho}^1) \cdot \mathbf{i}(\tilde{\varrho}^1)) = \mathbf{i}([\varrho^1, \tilde{\varrho}^1]_g), \tag{27}$$

which is in some sense an analogy to (5).

On $B(H)$ there is a natural scalar product given by the Dixmier trace Tr_ω:

$$\langle b, \tilde{b} \rangle_{B(H)} = \mathrm{Tr}_\omega(b^* \tilde{b} |D|^{-4}), \quad b, \tilde{b} \in B(H), \tag{28}$$

where D is the generalized Dirac operator of the K cycle and * denotes the involution in $B(H)$. In the case considered here the Dixmier trace can be expressed by a combination of the usual trace over the matrix structure, including the trace in the Clifford algebra and integration over the manifold X:

$$\langle b, \tilde{b} \rangle_{B(H)} = \frac{1}{32\pi^2} \int_X v_g \ \mathrm{tr}(b^* \tilde{b}), \tag{29}$$

where v_g is the canonical volume form on X and the factor $1/32\pi^2$ is taken from Ref. 6. By restriction of the scalar product (28) to $\mathscr{T}^2 \subset B(H)$ we get a natural scalar product on $\mathscr{T}^2$. However, since elements of $\mathscr{T}^2$ are diagonal with respect to the splitting $H = H_l \oplus H_q$ in (22), we can take as a scalar product $\langle \ , \ \rangle_{\mathscr{T}^2}$ on $\mathscr{T}^2$ a convex linear combination of the partial traces in $B(H_l)$ and $B(H_q)$, in the same way as in Ref. 11:

$$\langle b, \tilde{b} \rangle_{\mathscr{T}^2} = \langle zb, \tilde{b} \rangle_{B(H)}, \quad z = \begin{pmatrix} x\mathbf{1}_{9\times 9} & 0 \\ 0 & \mathbf{1}_{36\times 36} \end{pmatrix}, \tag{30}$$

for $b,\tilde{b}\in\mathscr{T}^2$ and $0<x<\infty$.

The direct sum decomposition $\mathscr{T}^2=\tilde{\mathbf{c}}\circ\mathbf{i}(\mathscr{H}_0^2)\oplus\ker\mathbf{p}_2$ is not an orthogonal decomposition with respect to $\langle\ ,\ \rangle_{\mathscr{T}^2}$. Let $\mathbf{s}_2$ be the orthogonal projection from $\mathscr{T}^2$ onto the orthogonal complement of the subspace $\ker\mathbf{p}_2$ (after a completion with respect to the scalar product). Then we define the canonical embedding $\mathbf{e}:\mathscr{H}_0^2\to B(H)$ by

$$\mathbf{e}(\varrho^2)=\mathbf{s}_2\circ\tilde{\mathbf{c}}\circ\mathbf{i}(\varrho^2),\quad \varrho^2\in\mathscr{H}_0^2. \tag{31}$$

In the same way as in Ref. 1 one can show that $\mathbf{e}(\varrho^2)$ is given by (20) and (21) if we replace

$$\alpha_f^2\mapsto\mathbf{c}(\alpha_f^2),\quad f=0,+,-,3, \tag{32}$$

$$l_s^2\mapsto\tilde{l}_s^2:=l_s^2-\frac{\operatorname{tr} l_s^2}{3}\,1_{3\times3},\quad q_s^2\mapsto\tilde{q}_s^2:=q_s^2-\frac{\operatorname{tr} q_s^2}{3}\,1_{3\times3},\quad s=1,4. \tag{33}$$

Thus, the operators on H associated to $\mathbf{i}(\varrho^k)\in\mathbf{i}(\mathscr{H}_0^k)$, $k=0,1,2$, are $\mathbf{i}(\varrho^k)$ themselves for $k=0,1$ and $\mathbf{e}(\varrho^k)$ for $k=2$. Of course, this construction can be extended to $\mathbf{i}(\mathscr{H}_0^k)$, $k>2$, but we do not need this for model building.

V. THE FERMIONIC ACTION

The connection form ρ is a skew-adjoint element of $\mathscr{H}_0^1$; see. (14). Therefore, we have

$$\rho=\begin{pmatrix} (\frac{1}{2}A^3+\frac{1}{2}A^0)\otimes\mathrm{id}_F & 0 & A^-\otimes\mathrm{id}_F & -i\Phi^1\gamma^5\otimes M \\ 0 & 0 & 0 & 0 \\ A^+\otimes\mathrm{id}_F & 0 & (-\frac{1}{2}A^3+\frac{1}{2}A^0)\otimes\mathrm{id}_F & -i\Phi^2\gamma^5\otimes M \\ -i\bar{\Phi}^1\gamma^5\otimes M^* & 0 & -i\bar{\Phi}^2\gamma^5\otimes M^* & A^0\otimes\mathrm{id}_F \end{pmatrix}, \tag{34}$$

where $A^0=-(A^0)^*$, $A^3=-(A^3)^*$, $A^+=-(A^-)^*\in L^1$, and $\Phi^1,\Phi^2\in L^0$. Applying the isomorphism $\mathbf{i}$ and abbreviating $\mathbf{1}=1_{3\times3}$, we get from (18), (20), and (21),

$$\mathbf{i}_l(\rho_l)=\begin{pmatrix} (\frac{1}{2}A^3+\frac{1}{2}A^0)\otimes\mathbf{1} & A^-\otimes\mathbf{1} & i\Phi^1\gamma^5\otimes\epsilon m_l \\ A^+\otimes\mathbf{1} & (-\frac{1}{2}A^3+\frac{1}{2}A^0)\otimes\mathbf{1} & i\Phi^2\gamma^5\otimes\epsilon m_l \\ i\bar{\Phi}^1\gamma^5\otimes\epsilon^{-1}m_l^* & i\bar{\Phi}^2\gamma^5\otimes\epsilon^{-1}m_l^* & A^0\otimes\mathbf{1} \end{pmatrix}, \tag{35}$$

$$\mathbf{i}_q(\rho_q)=\begin{pmatrix} (\frac{1}{2}A^3-\frac{1}{6}A^0)\otimes\mathbf{1} & A^-\otimes\mathbf{1} & i\bar{\Phi}^2\gamma^5\otimes\sqrt{\frac{2}{3}}\beta m_q & i\Phi^1\gamma^5\otimes\sqrt{\frac{1}{3}}m_q\chi\gamma \\ A^+\otimes\mathbf{1} & (-\frac{1}{2}A^3-\frac{1}{6}A^{(0)})\otimes\mathbf{1} & -i\bar{\Phi}^1\gamma^5\otimes\sqrt{\frac{2}{3}}\beta m_4 & i\Phi^2\gamma^5\otimes\sqrt{\frac{1}{3}}m_q\chi\gamma \\ -i\Phi^2\gamma^5\otimes\sqrt{\frac{2}{3}}\beta^{-1}m_q^* & i\Phi^1\gamma^5\otimes\sqrt{\frac{2}{3}}\beta^{-1}m_q^* & -\frac{2}{3}A^0\otimes\mathbf{1} & 0 \\ i\bar{\Phi}^1\gamma^5\otimes\sqrt{\frac{1}{3}}(\chi\gamma)^{-1}m_q^* & i\bar{\Phi}^2\gamma^5\otimes\sqrt{\frac{1}{3}}(\chi\gamma)^{-1}m_q^* & 0 & \frac{1}{3}A^0\otimes\mathbf{1} \end{pmatrix}. \tag{36}$$

The connection ∇ can be extended to an operator $\nabla:\mathscr{E}\otimes_{\mathscr{A}}h\to\mathscr{E}\otimes_{\mathscr{A}}h$,

$$\begin{aligned}\nabla(\xi\otimes_{\mathcal{A}}\psi)&=(i\,\nabla\xi)\otimes_{\mathcal{A}}\psi+\xi\otimes_{\mathcal{A}}D\psi=e\{((D\otimes\mathbb{1}_{2\times2})\xi-\xi D)+i\rho\xi\}\otimes_{\mathcal{A}}\psi+\xi\otimes_{\mathcal{A}}D\psi\\&=(e(D\otimes\mathbb{1}_{2\times2})e+i\rho)(\xi\otimes_{\mathcal{A}}\psi)\\&=(D^{\mathrm{cl}}+\mu+i\rho)(\xi\otimes_{\mathcal{A}}\psi),\\ \mu&=e(\gamma^5\otimes\mathcal{M}\otimes\mathbb{1}_{2\times2})e,\end{aligned}\tag{37}$$

for $\xi\in\mathcal{E}$, $\psi\in h$; see Ref. 5. We have used $\hat{d}a=-i[D,a]$ for $a\in\mathcal{A}$, see Ref. 1, and $L^n\equiv C^n$ for $n=0,1$. We have $\mu\in\mathcal{M}_0^1$, hence we can apply the isomorphism $\mathbf{i}$, and we find

$$\mathbf{i}_l(\mu_l)=\begin{pmatrix}0&0&0\\0&0&-\gamma^5\otimes\epsilon m_l\\0&-\gamma^5\otimes\epsilon^{-1}m_l^*&0\end{pmatrix},$$

$$\mathbf{i}_q(\mu_q)=\begin{pmatrix}0&0&-\gamma^5\otimes\sqrt{\frac{2}{3}}\,\beta m_q&0\\0&0&0&-\gamma^5\otimes\sqrt{\frac{1}{3}}\,m_q\chi\gamma\\\gamma^5\otimes\sqrt{\frac{2}{3}}\beta^{-1}m_q^*&0&0&0\\0&-\gamma^5\otimes\sqrt{\frac{1}{3}}\,(\chi\gamma)^{-1}m_q^*&0&0\end{pmatrix}.\tag{38}$$

The situation found in nature demands to use a pseudo-Riemannian manifold X_M instead of the Riemannian manifold X. We are interested in the case that X_M is the Minkowski space. We convert the results obtained so far for the Euclidian manifold X by a Wick rotation to Minkowski space. If we denote by $L^2(X_M,S)$ the space of square integrable sections of the spinor bundle over X_M then instead of H, see (22), we have to take the space

$$H_M=\{L^2(X_M,S)\otimes\mathbb{C}^3\oplus\mathbb{C}^3\}\oplus\{L^2(X_M,S)\otimes(\mathbb{C}^4\oplus\mathbb{C}^4\oplus\mathbb{C}^4)\otimes\mathbb{C}^3\}.\tag{39}$$

On H_M we have the invariant product

$$\langle\Psi,\widetilde{\Psi}\rangle_{H_M}:=\int_{X_M}\upsilon_M\Psi^*\gamma^0\widetilde{\Psi},\quad\Psi,\widetilde{\Psi}\in H_M,\tag{40}$$

where υ_M is the canonical volume form on X_M. Due to (37) the natural fermionic action is

$$S_F=\tfrac{1}{2}\langle\Psi,(D^{\mathrm{cl}}+i(\mu+i\rho_M))\Psi\rangle_{H_M}+\mathrm{H.c.},\quad\Psi\in H_M,\tag{41}$$

where ρ_M is the connection form ρ rotated to Minkowski space and H.c. denotes the Hermitian conjugate of the preceding term. We take

$$\Psi=(\Psi_l,\Psi_q)^T,\quad\Psi_l=(\nu_L,e_L,e_R)^T,\quad\Psi_q=(u_L,d_L,u_R,d_R)^T,\tag{42}$$

where $e_L,\nu_L,e_R\in L^2(X_M,S)\otimes\mathbb{C}^3$ and $u_L,d_L,u_R,d_R\in L^2(X,S)\otimes\mathbb{C}^3\otimes\mathbb{C}^3$, with

$$(\gamma^5\otimes\mathrm{id})f_L=-f_L,\quad(\gamma^5\otimes\mathrm{id})f_R=f_R,\quad f=e,\upsilon,u,d.\tag{43}$$

We obtain, denoting the Wick rotated fields $A^{0,+,-,3}$ and $\Phi^{1,2}$ by the same symbols,

$$S_F=\int_{X_M}\upsilon_M(\mathcal{L}_l+\mathcal{L}_l'+\mathcal{L}_q+\mathcal{L}_q'),\tag{44}$$

$$\mathscr{L}_l=(\nu_L^*,e_L^*)\left\{\gamma^0\begin{pmatrix} D^{\rm cl}+i(\frac{1}{2}A^3+\frac{1}{2}A^0) & iA^- \\ iA^+ & D^{\rm cl}+i(-\frac{1}{2}A^3+\frac{1}{2}A^0)\end{pmatrix}\otimes\mathbb{1}\right\}\begin{pmatrix}\nu_L\\ e_L\end{pmatrix}$$
$$+e_R^*\{\gamma^0(D^{\rm cl}+iA^0)\otimes\mathbb{1}\}\epsilon_R,$$

$$\mathscr{L}_l'=-\left\{e_R^*\{\gamma^0(\bar\Phi^1;\bar\Phi^2+1)\otimes\tfrac{1}{2}(\epsilon^*-\epsilon^{-1})m_l^*\}\begin{pmatrix}\nu_L\\ e_L\end{pmatrix}+\text{H.c.}\right\},$$

$$\mathscr{L}_q=(u_L^*,d_L^*)\left\{\gamma^0\begin{pmatrix} D^{\rm cl}+i(\frac{1}{2}A^3-\frac{1}{6}A^0) & iA^- \\ iA^+ & D^{\rm cl}+i(-\frac{1}{2}A^3-\frac{1}{6}A^0)\end{pmatrix}\otimes\mathbb{1}_c\otimes\mathbb{1}\right\}\begin{pmatrix}u_L\\ d_L\end{pmatrix}$$
$$+u_R^*\{\gamma^0(D^{\rm cl}-\tfrac{2}{3}iA^0)\otimes\mathbb{1}_c\otimes\mathbb{1}\}u_R+d_R^*\{\gamma^0(D^{\rm cl}+\tfrac{1}{3}iA^0)\otimes\mathbb{1}_c\otimes\mathbb{1}\}d_R,$$

$$\mathscr{L}_q'=-\left\{u_R^*\{\gamma^0(\Phi^2+1;-\Phi^1)\otimes\mathbb{1}_c\otimes\tfrac{1}{2}\sqrt{\tfrac{2}{3}}(\beta^*+\beta^{-1})m_q^*\}\begin{pmatrix}u_L\\ d_L\end{pmatrix}+\text{H.c.}\right\}$$
$$-\left\{d_R^*\{\gamma^0(\bar\Phi^1;\bar\Phi^2+1)\otimes\mathbb{1}_c\otimes\tfrac{1}{2}\sqrt{\tfrac{1}{3}}(\chi\gamma)^*-(\chi\gamma)^{-1}m_q^*\}\begin{pmatrix}u_L\\ d_L\end{pmatrix}+\text{H.c.}\right\},$$

where $\mathbb{1}_c=\mathbb{1}_{3\times3}$ is the identity acting on the colour space of the quarks; see Sec. VII. Comparing this with the classical fermionic action,[17] we read off the mass matrices of the fermions,

$$m_e=\tfrac{1}{2}(\epsilon^*-\epsilon^{-1})m_l^*,\quad m_u=\tfrac{1}{2}\sqrt{\tfrac{2}{3}}(\beta^*+\beta^{-1})m_q^*,\quad m_d'=\tfrac{1}{2}\sqrt{\tfrac{1}{3}}((\chi\gamma)^*-(\chi\gamma)^{-1})m_q^*. \tag{45}$$

where $e\equiv(e,\mu,\tau)^T$, $u\equiv(u,c,t)^T$, $d\equiv(d,s,b)^T$. The matrices m_e,m_u are diagonal. We can assume that their diagonal matrix elements are positive, otherwise this is achieved by unitary transformations $e_R\mapsto u_e e_R$, $u_R\mapsto u_u u_R$ with diagonal unitary matrices u_e,u_u. However, the matrix m_d' is—in general—an arbitrary nondiagonal 3×3 matrix. There exist unitary matrices u_1,u_2, so that $m_d'=u_1 m_d u_2^*$ for a diagonal matrix m_d with positive diagonal matrix elements. The matrix u_1 can be absorbed by means of a unitary transformation $d_R\mapsto u_1 d_R$. But the matrix u_2^* cannot be absorbed by a unitary transformation $\binom{u_L}{d_L}\mapsto\left(\begin{smallmatrix}u_2 & 0\\ 0 & u_2\end{smallmatrix}\right)\binom{u_L}{d_L}$, because this would make the matrix m_u nondiagonal. All we can do are transformations $\binom{u_L}{d_L}\mapsto\left(\begin{smallmatrix}\delta_1 & 0\\ 0 & \delta_1\end{smallmatrix}\right)\binom{u_L}{d_L}$, $u_R\mapsto\delta_1 u_R$ and $d_R\mapsto\delta_2 d_R$ by diagonal unitary matrices δ_1,δ_2, so that m_u remains invariant and $u_2^*\mapsto\delta_1^* u_2^*\delta_2=:V$. The matrix V is the famous Kobayashi–Maskawa matrix, which for an appropriate choice of δ_1,δ_2 can be brought into the standard form parametrized by three rotation angles and one phase. Thus, we can rewrite $\mathscr{L}_l'$ and $\mathscr{L}_q'$ as

$$\mathscr{L}_l'=-\left\{e_R^*\{\gamma^0(\bar\Phi^1;\bar\Phi^2+1)\otimes m_e\}\begin{pmatrix}\nu_L\\ e_L\end{pmatrix}+\text{H.c.}\right\},$$

$$\mathscr{L}_q'=-\left\{u_R^*\{\gamma^0(\Phi^2+1;-\Phi^1)\otimes m_\mu\otimes\mathbb{1}_c\}\begin{pmatrix}u_L\\ d_L\end{pmatrix}+\text{H.c.}\right\}$$
$$-\left\{d_R^*\{\gamma^0(\bar\Phi^1;\bar\Phi^2+1)\otimes m_d V\otimes\mathbb{1}_c\}\begin{pmatrix}u_L\\ d_L\end{pmatrix}+\text{H.c.}\right\}. \tag{46}$$

Now we count the free parameters on which the physical masses in our model depend. We can regard (45) as equations for computing the fermion masses and the Kobayashi–Maskawa matrix for given 3×3 matrices $\beta,\gamma,\epsilon,\chi,m_l,m_q$. But if we take the point of view that the fermion masses

and the Kobayashi–Maskawa matrix (13 parameters) are given by experiment, and if we keep the diagonal positive matrices m_l and m_q as additional free parameters, then (45), with $m'_d = m_d V$, are equations to determine $\beta,\gamma,\epsilon,\chi$. This gives a system of quadratic equations for the matrix elements of $\beta,\gamma,\epsilon,\chi$. We take any of the (possibly complex) solutions of this system to fix the matrices $\beta,\gamma,\epsilon,\chi$. Then, there remain only the six free parameters in the diagonal of m_l and m_q.

We remark that the presented construction of the fermionic action of the standard model yields immediately the correct hypercharges of the fermions—namely the coefficients in front of $-\frac{1}{2}A^0$ in (35) and (36). This is possible because we use the isomorphism $\mathbf{i}$ of graded Lie algebras, which allows embeddings into the space of bounded operators on the fermionic Hilbert space different from the fundamental embedding. For matrix algebras there exist—besides the trivial representation—only the fundamental representation and, hence, only the fundamental embedding. Therefore, in the derivation of the standard model elaborated on by Kastler,[7] one must additionally consider the chromodynamics algebra and impose a generalized Poincaré duality condition (Refs. 3, 7) in order to obtain the correct hypercharges.

VI. THE BOSONIC ACTION

We recall[2] that the curvature θ of the connection ∇ is given by

$$\theta = \mathscr{D}\rho + \tfrac{1}{2}\{\rho,\rho\}_g + \theta_0 = \mathbf{D}\rho - i[\mu,\rho]_g + \tfrac{1}{2}[\rho,\rho]_g + \theta_0, \tag{47}$$

where

$$\theta_0 = e\hat{d}(e)\hat{d}(e)e = \mathrm{diag}(MM^*,0,0,0). \tag{48}$$

The problem is that $\theta_0 \notin \mathscr{H}_0$, so that it is not possible to apply the isomorphism $\mathbf{i}$. We propose to replace here the isomorphism $\mathbf{i}$ by a linear mapping $\mathbf{i}'$ defined as follows. Looking at (16) we see that θ_0 is given by putting $\alpha_3^0 = \alpha_0^0 = 1$ and all other $\alpha_f^{0,1,2} = 0$, and then projecting away the last row and column. Thus, to the element $\widetilde{\theta}_0 \in \mathscr{H}_0^2$ given by $\alpha_3^0 = \alpha_0^0 = 1$ we apply the isomorphism $\mathbf{i}$, giving $\mathbf{i}_l(\widetilde{\theta}_{0,l}) = \mathrm{diag}(1_1^1,0,1_4^1)$ and $\mathbf{i}_q(\widetilde{\theta}_{0,q}) = \mathrm{diag}(\frac{1}{3}q_1^1, -\frac{2}{3}q_4^1, -\frac{2}{3}q_4^1, \frac{1}{3}q_4^1)$; see (20) and (21). Now we apply a reasonable projection:

$$\mathbf{i}'_l(\theta_{0,l}) := \mathrm{diag}(1_1^1,0,0), \quad \mathbf{i}'_q(\theta_{0,q}) := \mathrm{diag}(\tfrac{1}{3}q_1^1, -\tfrac{2}{3}q_1^1, -\tfrac{2}{3}q_4^1, 0). \tag{49}$$

The choice $\mathbf{i}'_f(\theta_{0,l})$ is plausible, but I have no deeper explanation for $\mathbf{i}'_q(\theta_{0,q})$, except that we need this below. We recall that $l_1^1 = l_4^1 = m_l m_l^* \equiv |m_l|^2$ and $q_1^1 = q_4^1 = m_q m_q^* \equiv |m_q|^2$. Then, using (35), (36), and (38), the transported curvature is given by ($f \in \{l,q\}$)

$$\mathbf{i}_f(\theta_f) = \mathbf{D}(\mathbf{i}_f(\rho_f)) - i[\mathbf{i}_f(\mu_f),\mathbf{i}_f(\rho_f)]_g + \tfrac{1}{2}[\mathbf{i}_f(\rho_f),\mathbf{i}_f(\rho_f)]_g + \mathbf{i}'_f(\theta_{0,f}), \tag{50}$$

$$\mathbf{i}_l(\theta_l) = \begin{pmatrix} (\frac{1}{2}\,\mathbf{d}(A^3+A^0)+A^-\wedge A^+) & (\mathbf{d}A^- + A^3\wedge A^-)\otimes \mathbb{1} & i(\mathbf{d}\Phi^1 + \frac{1}{2}(A^3-A^0)\Phi^1 \\ \otimes \mathbb{1} - (|\Phi^1|^2-1)\otimes|m_l|^2 & -\Phi^1(\bar{\Phi}^2+1)\otimes|m_l|^2 & +A^-(\Phi^2+1))\gamma^5\otimes\epsilon m_l \\ (\mathbf{d}A^+ + A^+\wedge A^3)\otimes\mathbb{1} & (\mathbf{d}(A^0-A^3)+A^+\wedge A^-) & i(-\frac{1}{2}(A^3+A^0)(\Phi^2+1) \\ -(\Phi^2+1)\bar{\Phi}^1\otimes|m_l|^2 & \otimes\mathbb{1} - (|\Phi^2+1|^2-1)\otimes|m_l|^2 & +\mathbf{d}\Phi^2 + A^+\Phi^1)\gamma^5\otimes\epsilon m_l \\ i(\mathbf{d}\bar{\Phi}^1 - \frac{1}{2}\bar{\Phi}^1(A^3-A^0) & i(\frac{1}{2}(\bar{\Phi}^2+1)(A^3+A^0) & \mathbf{d}A^0\otimes\mathbb{1} - (|\Phi^1|^2 \\ -(\bar{\Phi}^2+1)A^+)\gamma^5\otimes\epsilon^{-1}m_l^* & +\mathbf{d}\bar{\Phi}^2 - \bar{\Phi}^1 A^-)\gamma^5\otimes\epsilon^{-1}m_l^* & +|\Phi^2+1|^2 - 1\otimes|m_l|^2 \end{pmatrix}.$$

$$i_q(\theta_q)=\begin{pmatrix}
\begin{array}{l}(\mathrm{d}(\frac{1}{2}A^3-\frac{1}{6}A^0)\\ +A^-\wedge A^+)\otimes 1\\ +(\frac{2}{3}|\Phi^2+1|^2-\frac{1}{3}\\ -\frac{1}{3}|\Phi^1|^2)\otimes|m_q|^2\end{array} & \begin{array}{l}(\mathrm{d}A^-+A^3\wedge A^-)\otimes 1\\ -\Phi^1(\bar\Phi^2+1)\\ \otimes|m_q|^2\end{array} & \begin{array}{l}i(d\bar\Phi^2-\bar\Phi^1A^-\\ +\frac{1}{2}(\bar\Phi^2+1)\\ \times(A^3+A^0))\gamma^5\\ \otimes\sqrt{\frac{2}{3}}\,\beta m_q\end{array} & \begin{array}{l}i(\mathrm{d}\Phi^1+\\ \frac{1}{2}(A^3-A^0)\Phi^1+\\ +A^-(\Phi^2+1))\gamma^5\\ \otimes\sqrt{\frac{1}{3}}\,m_q\chi\gamma\end{array} \\
\begin{array}{l}(\mathrm{d}A^++A^+\wedge A^3)\\ \otimes 1\\ -(\Phi^2+1)\bar\Phi^1\otimes|m_q|^2\end{array} & \begin{array}{l}(\mathrm{d}(-\frac{1}{2}A^3-\frac{1}{6}A^0)\\ +A^+\wedge A^-)\otimes 1\\ -(\frac{1}{3}|\Phi^2+1|^2+\frac{1}{3}\\ -\frac{2}{3}|\Phi^1|^2\otimes|m_q|^2\end{array} & \begin{array}{l}-i(\mathrm{d}\bar\Phi^1\\ -(\bar\Phi^2+1)A^+\\ -\frac{1}{2}\bar\Phi^1(A^3-A^0))\gamma^5\\ \otimes\sqrt{\frac{2}{3}}\,\beta m_q\end{array} & \begin{array}{l}i(\mathrm{d}\Phi^2+A^+\Phi^1\\ -\frac{1}{2}(A^3+A^0)\\ \times(\Phi^2+1))\gamma^5\\ \otimes\sqrt{\frac{1}{3}}\,m_q\chi\gamma\end{array} \\
\begin{array}{l}-i(\mathrm{d}\Phi^2+A^+\Phi^1\\ -\frac{1}{2}(A^3+A^0)\\ \times(\Phi^2+1))\gamma^5\\ \otimes\sqrt{\frac{2}{3}}\,\beta^{-1}m_q^*\end{array} & \begin{array}{l}i(\mathrm{d}\Phi^1\\ +A^-(\Phi^2+1)\\ +\frac{1}{2}(A^3-A^0)\Phi^1)\gamma^5\\ \otimes\sqrt{\frac{2}{3}}\,\beta^{-1}m_q^*\end{array} & \begin{array}{l}-\frac{2}{3}\,\mathrm{d}A^0\otimes 1\\ +\frac{2}{3}(|\Phi^1|^2\\ +|\Phi^2+1|^2-2)\\ \otimes|m_q|^2\end{array} & 0 \\
\begin{array}{l}i(\mathrm{d}\bar\Phi^1\\ -(\bar\Phi^2+1)A^+\\ -\frac{1}{2}\bar\Phi^1(A^3-A^0))\gamma^5\\ \otimes\sqrt{\frac{1}{3}}\,(\chi\gamma)^{-1}m_q^*\end{array} & \begin{array}{l}i(\mathrm{d}\bar\Phi^2-\bar\Phi^1A^-\\ +\frac{1}{2}(\bar\Phi^2+1)\\ \times(A^3+A^0))\gamma^5\\ \otimes\sqrt{\frac{1}{3}}\,(\chi\gamma)^{-1}m_q^*\end{array} & 0 & \begin{array}{l}\frac{1}{3}\,\mathrm{d}A^0\otimes 1\\ -\frac{1}{3}(|\Phi^1|^2\\ +|\Phi^2+1|^2-1)\\ \otimes\chi^{-1}|m_q|^2\chi\end{array}
\end{pmatrix}.$$

Now we take the embedding $\mathbf{e}$ of θ into $B(H)$, which means to perform the replacements (32) and (33) in the above matrices, see Sec. IV. We introduce the abbreviations $|m|^2=mm^*$, $|m|^4:=(mm^*)^2$, and $|m|^{-2}:=(mm^*)^{-1}$, for a 3×3 matrix m. Thus, we get the Euclidean bosonic action—for an appropriate choice of the constants—as

$$S_B=\frac{8\pi^2}{3(x+3)g_2^2}\,\mathrm{Tr}_\omega\{(z\mathbf{e}(\theta))^*\mathbf{e}(\theta)\}=\frac{1}{12(x+3)g_2^2}\int_X v_g\,\mathrm{tr}\{z(\mathbf{e}(\theta))^*\mathbf{e}(\theta)\}$$

$$=\int_X v_g(\mathscr{L}_2+\mathscr{L}_1+\mathscr{L}_0),$$

$$\mathscr{L}_2=-\frac{1}{2g_2^2}\,\delta^{\mu\kappa}\delta^{\nu\lambda}\left\{\mathrm{tr}(F_{\mu\nu}F_{\kappa\lambda})+\frac{9x+11}{6x+18}\,F'_{\mu\nu}F'_{\kappa\lambda}\right\},$$

$$F_{\mu\nu}=\begin{pmatrix}\frac{1}{2}\,\partial_{[\mu}A^3_{\nu]}+A^-_{[\mu}A^+_{\nu]} & \partial_{[\mu}A^-_{\nu]}+A^3_{[\mu}A^-_{\nu]}\\ \partial_{[\mu}A^+_{\nu]}+A^+_{[\mu}A^3_{\nu]} & -\frac{1}{2}\,\partial_{[\mu}A^3_{\nu]}-A^-_{[\mu}A^+_{\nu]}\end{pmatrix},\quad F'_{\mu\nu}=\partial_{[\mu}A_{\nu]},$$

$$\mathscr{L}_1=\frac{1}{3(x+3)g_2^2}\,\delta^{\mu\nu}\overline{(D_\mu\Phi^1)}D_\nu\Phi^1+\overline{(D_\mu(\Phi^2+1)}D_\nu(\Phi^2+1))$$

$$\times\mathrm{tr}\{\chi(|\epsilon|^2+|\epsilon|^{-2})|m_l|^2+(2|\beta|^2+2|\beta|^{-2}+|\chi\gamma|^2+|\chi\gamma|^{-2})|m_q|^2\},$$

$$\begin{pmatrix} D_\mu\Phi^1 \\ D_\mu(\Phi^2+1) \end{pmatrix} = \begin{pmatrix} \partial_\mu\Phi^1 \\ \partial_\mu\Phi^2 \end{pmatrix} + \begin{pmatrix} \frac{1}{2}(A^3_\mu - A^0_\mu) & A^-_\mu \\ A^+_\mu & -\frac{1}{2}(A^3_\mu + A^0_\mu) \end{pmatrix} \begin{pmatrix} \Phi^1 \\ \Phi^2+1 \end{pmatrix},$$

$$\mathscr{L}_0 = \frac{2}{3(x+3)g_2^2}(|\Phi^1|^2+|\Phi^2+1|^2-1)^2\left(x|\widetilde{m}_l|^4+\frac{5}{3}|\widetilde{m}_q|^4\right)+\frac{1}{(x+3)g_2^2}\,\mathrm{tr}\left(\frac{1}{3}x|\widetilde{m}_l|^4+|\widetilde{m}_q|^4\right), \tag{51}$$

with $X_{[\mu}Y_{\nu]} \equiv X_\mu Y_\nu - X_\nu Y_\mu$. We have used $\mathrm{tr}_C(1)=4$, $\mathrm{tr}_C(\gamma^{\mu'}\cdot\gamma^{\nu'})=4\delta^{\mu'\nu'}$ and $\mathrm{tr}_C(\gamma^\mu\cdot\gamma^\nu\cdot\gamma^\kappa\cdot\gamma^\lambda)=4(\delta^{\nu\kappa}\delta^{\mu\lambda}-\delta^{\mu\kappa}\delta^{\nu\lambda})$ for $\mu\neq\nu,\kappa\neq\lambda$, where tr_C denotes the trace in the space of sections of the Clifford bundle C. We remark that the part $\mathscr{L}_0$ of the Lagrangian would vanish if there was only one generation of fermions, because in this case a formula corresponding to (33) would give zero for $\widetilde{m}_l$ and $\widetilde{m}_q$. But manifestly there are three fermionic generations in nature. Next, we perform some reparametrizations. We put

$$A^3_\mu = ig_2W^3_\mu, \quad A^-_\mu = \frac{i}{2}g_2(W^1_\mu - iW^2_\mu), \quad A^+_\mu = \frac{i}{2}g_2(W^1_\mu + iW^2_\mu),$$

$$A^0_\mu = -\sqrt{\frac{3x+9}{9x+11}}\,ig_2W^0_\mu, \tag{52}$$

$$\Phi^{1,2} = \sqrt{\frac{3(x+3)g_2^2}{2\,\mathrm{tr}\{x(|\epsilon|^2+|\epsilon|^{-2})|m_l|^2+(2|\beta|^2+2|\beta|^{-2}+|\chi\gamma|^2+|\chi\gamma|^{-2})|m_q|^2\}}}\,\phi_{1,2}.$$

This gives (I.T.≡interaction terms, C.C.≡cosmological constant)

$$\mathscr{L}_2 = \frac{1}{4}\delta^{\mu\kappa}\delta^{\nu\lambda}\left\{\sum_{a=1}^{3}F^a_{\mu\nu}F^a_{\kappa\lambda}+F^0_{\mu\nu}F^a_{\kappa\lambda}\right\}, \tag{53}$$

$$\mathscr{L}_1 = \frac{1}{2}\delta^{\mu\nu}\left\{\sum_{j=1}^{2}(\partial_\mu\phi_j)(\partial_\nu\phi_j)+m_W^2(W^1_\mu W^1_\nu+W^2_\mu W^2_\nu)+m_Z^2Z_\mu Z_\nu\right\}+\text{I.T.}, \tag{54}$$

$$\mathscr{L}_0 = \tfrac{1}{2}m_H^2(\mathrm{Re}\ \phi_2)^2+\text{I.T.}+\text{C.C.}, \tag{55}$$

where

$$F^a_{\mu\nu} = \partial_{[\mu}W^a_{\nu]} - g_2\sum_{b,c=1}^{3}\epsilon^a_{bc}W^b_\mu W^c_\nu, \quad F^0_{\mu\nu} = \partial_{[\mu}W^0_{\nu]},$$

$$Z = \cos\,\theta_W W^3 - \sin\,\theta_W W^0,$$

$$P = \sin\,\theta_W W^3 + \cos\,\theta_W W^0,$$

$$\sin^2\,\theta_W = \frac{3}{4}\frac{3+x}{5+3x}, \tag{56}$$

$$m_W = \sqrt{\frac{1}{6(x+3)}}\{\chi(|\epsilon|^2+|\epsilon|^{-2})|m_l|^2+(2|\beta|^2+2|\beta|^{-2}+|\chi\gamma|^2+|\chi\gamma|^{-2})|m_q|^2\}, \tag{57}$$

$$m_z = m_W/\cos\,\theta_W,$$

$$m_H=\frac{2}{3m_W}\sqrt{\frac{1}{x+3}(3x|\tilde{m}_l|^4+5|\tilde{m}_q|^4)}. \tag{58}$$

We can transform this action to Minkowski space by a Wick rotation of the physical fields, replacing $\delta^{\mu\nu}\mapsto -g^{\mu\nu}$ and introducing a global minus sign in the action. Then this action coincides with the electroweak sector of the classical bosonic action of the standard model,[17] where the Weinberg angle θ_W and the masses m_W of the W boson and m_H of the Higgs boson are fixed; see (56), (57), and (58). Inserting the reparameterizations (52) into (44), we get precisely the electroweak sector of the fermionic action of the standard model.[17] According to Ref. 2, the gauge group associated to the module $\mathscr{E}$ discussed in the beginning of Sec. III is isomorphic to $C^\infty_{\mathrm{R}}(X_M)\otimes(SU(2)\times U(1))$, where $C^\infty_{\mathrm{R}}(X_M)$ denotes the algebra of real smooth functions on the Minkowski space. The action is by construction invariant under gauge transformations.

VII. THE CHROMODYNAMICS SECTOR

The chromodynamics sector can be obtained from the module $\mathscr{E}_c=e_c\mathscr{A}^3$, with $e_c=\mathrm{diag}(e',e',e')$. The analysis of this case[2] shows that

$$\mathscr{H}^k_{0,c}=\bigoplus_{i=0}^{m} L^{k-2r}\otimes sl(3,\mathbb{C})\otimes M^r_l, \tag{59}$$

after omitting the rows and columns consisting of zeros only. Thus, elements $\varrho^k\in\mathscr{H}^k_{0,c}$ are of the form $\varrho^k=\Sigma_{r=0}^m G^{k-2r}\otimes M^r_4$, where $G^{k-2r}\in L^{k-2r}\otimes sl(3,\mathbb{C})$. We split $\mathscr{H}^k_{0,c}$ into its l^r_1- and q^r_l part, we take the trivial representation $\mathbf{i}_{c,l}(\varrho^k_l)\equiv 0$ of the l^r_l part, and the fundamental representation (tensorized with $1_{4\times 4}$) of the q^r_l part:

$$\mathbf{i}_{c,q}(\varrho^k_q)=\sum_{r=0}^{m}\mathrm{diag}(G^{k-2r},G^{k-2r},G^{k-2r},G^{k-2r})\otimes q^r_l. \tag{60}$$

Obviously, elements $\mathbf{i}_c(\varrho^k)$ are bounded operators on H for $k=0,1$. In analogy to the procedure in Sec. IV we construct the space $\mathscr{T}^2_c\subset B(H)$, which turns out to be

$$\mathscr{T}^2_c=\tilde{\mathbf{c}}_c\circ\mathbf{i}_c(\mathscr{H}^2_{0,c})+\mathbf{i}_c(C^0\otimes gl(3,\mathbb{C})\otimes\mathrm{id}_F), \tag{61}$$

where $\tilde{\mathbf{c}}_c$ is defined in analogy to (23) and where we extended $\mathbf{i}_c|_{\mathscr{H}^0_{0,c}}$ naturally to $C^0\otimes gl(3,\mathbb{C})\otimes\mathrm{id}_F$.

From (59) we find for the chromodynamics connection form $\varrho_c=G\otimes\mathrm{id}_F$, $G=-G^*\in L^1\otimes su(3)$. After rotating to Minkowski space ($G\mapsto G_M$) we obtain the following contribution to the fermionic action:

$$\mathscr{L}_s=(u^*_L;d^*_L;u^*_R;d^*_R)\left\{\gamma^0\begin{pmatrix} iG_M & 0 & 0 & 0\\ 0 & iG_M & 0 & 0\\ 0 & 0 & iG_M & 0\\ 0 & 0 & 0 & iG_M\end{pmatrix}\otimes 1\right\}\begin{pmatrix} u_L\\ d_L\\ u_R\\ d_R\end{pmatrix}. \tag{62}$$

The curvature θ_c of the chromodynamics connection ∇_c is given by

$$\theta=\mathbf{d}\rho_c+\tfrac{1}{2}[\rho_c,\rho_c]_g+\theta_{0,c},\quad \theta_{0,c}=1_c\otimes M^1_1. \tag{63}$$

These equations follow from the discussion in Ref. 2. We put in local bases

$$G=\frac{i}{2}\,g_3 G^a_\mu \gamma^\mu\otimes\lambda_a\,, \tag{64}$$

where λ_a, $a=1,...,8$, are the Gell–Mann matrices, fulfilling $[\lambda_b,\lambda_c]=\Sigma_{a=1}^{8}2if^a_{bc}\lambda_a$, $f^a_{bc}\in\mathbb{R}$, and $\mathrm{tr}(\lambda_a\lambda_b)=2\delta_{ab}$. Denoting by $\mathbf{e}_c(\theta_c)$ the embedding of θ_c into $B(H)$, we obtain for the Euclidian bosonic action of the chromodynamics sector

$$S^0_B=\frac{8\pi^2}{3(3+x)g_2^2}\,\mathrm{Tr}_\omega\{z(\mathbf{e}_c(\theta_c))^*\mathbf{e}_c(\theta_c)\}=\int_X v_g\mathscr{L}_c\,,$$
$$\mathscr{L}_c=\frac{1}{4}\sum_{a=1}^{8}\delta^{\mu\kappa}\delta^{\nu\lambda}F^a_{c,\mu\nu}F^a_{c,\kappa\lambda}+\frac{1}{g_3^2}\,(|\widetilde{m}_q|^4), \tag{65}$$

$$F^a_{c,\mu\nu}=\partial_{[\mu}G^a_{\nu]}-g_3\sum_{b,c=1}^{8}f^a_{bc}G^b_\mu G^c_\nu\,,$$
$$(g_3/g_2)^2=(3+x)/4. \tag{66}$$

Rotation to Minkowski space ($G\mapsto G_M$, $\delta^{\mu\nu}\to-g^{\mu\nu}$, $v_g\to v_M$, and global minus sign) transforms the first term in $\mathscr{L}_c$ into the bosonic action of chromodynamics,[17] the second term in $\mathscr{L}_c$ contributes to the "cosmological constant." The relation (66) between the coupling constants g_3 and g_2 of the strong and weak interactions, respectively, should not be taken too seriously, because it can easily be changed by a different normalization of the chromodynamics action. But if we take everywhere the simplest scalar product given by $x=1$ then we get $g_3=g_2$ from this model (just as in Refs. 11 and 10 for the simplest scalar product). According to Ref. 2, the gauge group associated to the module $\mathscr{E}_c$ is isomorphic to $C^\infty_{\mathbb{R}}(X_M)\otimes SU(3)$.

VIII. REMARKS ON MASS RELATIONS

In this section we are going to discuss the mass relations (57) and (58). This will be done only for $\mathrm{tr}(|m_l|^2)\leqslant\mathrm{tr}(|m_q|^2)$, because lepton masses are small compared with the quark masses of the same generation so that the case $\mathrm{tr}(|m_l|^2)\leqslant\mathrm{tr}(|m_q|^2)$ is more natural than the case $\mathrm{tr}(|m_l|^2)>\mathrm{tr}(|m_q|^2)$; see (45). Hence, we put

$$\mathrm{tr}(|m_l|^2)=\sin^2\vartheta_1\;\mathrm{tr}(|m_q|^2).$$

From the second equation of (45) we obtain $\mathrm{tr}(|m_u|^2)\geqslant\frac{2}{3}\mathrm{tr}(|m_q|^2)$, so that we put

$$\mathrm{tr}(|m_q|^2)=\tfrac{3}{2}\cos^2\vartheta_2\;\mathrm{tr}(|m_u|^2)=\tfrac{3}{2}m_t^2\cos^2\vartheta_2\,.$$

Here and in the sequel we neglect the other fermion masses against the mass m_t of the top quark. Then we get for (57),

$$m_W=\sqrt{(2/(3+x))\;\mathrm{tr}\{x(\tfrac{1}{3}|m_e|^2+\tfrac{1}{6}|m_l|^2)+(|m_u|^2+|m_d|^2-\tfrac{1}{6}|m_q|^2)\}}$$
$$=\sqrt{(2/(3+x))\;(1-\tfrac{1}{4}(1-x\sin^2\vartheta_1)\cos^2\vartheta_2)}m_t<\sqrt{\tfrac{2}{3}}\,m_t\,. \tag{67}$$

For $m\in M_3\mathbb{C}$ we have $\mathrm{tr}(|\widetilde{m}|^4)\equiv\mathrm{tr}\{(|m|^2-\frac{1}{3}(\mathrm{tr}(|m|^2))1)^2\}\leqslant\frac{2}{3}(\mathrm{tr}(|m|^2))^2$: see (33). Therefore, we put

$$\mathrm{tr}(|\tilde{m}_q|^4)=\tfrac{2}{3}\cos^2\vartheta_3(\mathrm{tr}(|m_q|^2))^2=\tfrac{3}{2}m_l^4\cos^2\vartheta_3\cos^4\vartheta_2,$$

$$\mathrm{tr}(|\tilde{m}_t|^4)=\tfrac{2}{3}\cos^2\vartheta_4(\mathrm{tr}(|m_t|^2))^2=\tfrac{3}{2}m_l^4\cos^2\vartheta_4\cos^4\vartheta_2\sin^4\vartheta_1.$$

Now we find for (58),

$$m_H=\sqrt{\frac{20\cos^2\vartheta_3+12x\cos^2\vartheta_4\sin^4\vartheta_1}{12-3(1-x\sin^2\vartheta_1)\cos^2\vartheta_2}}\,m_t\cos^2\vartheta_2<2m_t. \tag{68}$$

The experimental values $m_W=80$ GeV and $m_t=174$ GeV can be reproduced in the case $x\sin^2\vartheta_1\ll 1$ by $x=6.5...9.6$, depending on ϑ_2'; see (67). Then, by choosing ϑ_2 and ϑ_3, we can adjust m_H to any value smaller than $\sqrt{\frac{20}{9}}m_t=259$ GeV; see (68). Moreover, we find for the Weinberg angle $\sin^2\theta_W=0.27...0.29$, see (56), and for the ratio of the coupling constants of the strong and weak interactions $(g_3/g_2)^2=2.3...3.9$; see (66). In the case $x\sin^2\vartheta_1\gg 4$ we can reproduce the m_W/m_t ratio for $\sin^2\vartheta\approx 1$ and $\cos^2\vartheta_2\approx 1$. By choosing ϑ_4 we can adjust m_H to any value smaller than $2m_t=346$ GeV. Moreover, in this case we have $\sin^2\theta_W=0.25$ and $g_3\gg g_2$. Hence, we have enough freedom to bring the tree-level predictions (67), (68), (56), and (66) of our model into agreement with experimental data. However, these "predictions" have only a heuristic value, because they do not survive the classical quantization procedure. But there seems to be only a weak scale dependence.[18]

The simplest scalar product is given by $x=1$. In this case we get

$$m_W=\sqrt{\tfrac{1}{2}(1-\tfrac{1}{4}\cos^2\vartheta_1\cos^2\vartheta_2)}m_t,\quad \sqrt{\tfrac{1}{2}}m_t<m_W<\sqrt{\tfrac{3}{8}}m_t,$$

$$m_H=\sqrt{\frac{20\cos^2\vartheta_1+12\cos^2\vartheta_4\sin^4\vartheta_1}{12-3\cos^2\vartheta_1\cos^2\vartheta_2}}\,m_t\cos^2\vartheta_2<\sqrt{\tfrac{8}{3}}\,m_t,$$

$$\sin^2\theta_W=\tfrac{3}{8},\quad g_3=g_2. \tag{69}$$

These mass relations differ from the relations $m_t=2m_W$ and $m_H=3.14m_W$ obtained by Kastler and Schücker in Refs. 11 and 10 for the quaternionic K cycle, together with the simplest scalar product. While the m_W/m_t ratio is approximately stable, we get for the m_H/m_t ratio only an upper limit. Thus, we see that in comparison to the simplest model by Connes, Lott, and Kastler we get within our simplest model effectively one additional parameter determining the m_H/m_t ratio.

This means that although we introduced plenty of free parameters during the construction, these parameters occur in the final Lagrangians in the case of the simplest scalar product only in such combinations that we end up with nine parameters for the fermion masses, four parameters of the Kobayashi–Maskawa matrix, one undetermined coupling constant, and one additional parameter, which determines the ratio between the masses of the Higgs boson and the top quark. For this last parameter we have only an upper limit. Therefore, our model is less predictive than the model by Connes, Lott, and Kastler.

To summarize, the purpose of this paper was to present a different construction of the classical action of the standard model, which uses the simplest possible (nonclassical) algebra and puts the complexity into the module. In noncommutative geometry a K cycle replaces the notion of a manifold and a finite projective module over the algebra of this K cycle the notion of a vector bundle over this manifold. Therefore, our approach (a K cycle together with two associated modules—one for the electroweak sector and the other one for the chromodynamics sector) corresponds to a classical manifold with two associated fiber bundles over that manifold—a principal fiber bundle with structure group $SU(2)\times U(1)$ for the electroweak sector and a principal fiber bundle with structure group $SU(3)$ for the chromodynamics sector.

Discrete Weyl–Heisenberg transforms

J. Zak
Department of Physics, Technion, Haifa 32000, Israel

(Received 21 April 1995; accepted for publication 21 March 1996)

The concepts of von Neumann lattices and tight frames are used for defining discrete quantum mechanical transforms in the phase plane. These transforms are obtained by finite shifts la and mb in the coordinate x and momentum p, respectively, of the Weyl–Heisenberg group, and they are called the discrete Weyl–Heisenberg transforms $\psi(la,mb)$. Here $ab=h/N$ with h the Planck constant, l and m integers, and N a positive integer. A construction is carried out of $\psi(la,mb)$ for a general Weyl–Heisenberg set by using the kq-representation, in which a useful formula is established for the frame operator. The construction is illustrated on an example of the ground state of a harmonic oscillator. It is shown that any physical quantity can be described by the discrete Weyl–Heisenberg transform. Connections are established between $\psi(la,mb)$, the Bargmann representation, and the Husimi distribution function. © *1996 American Institute of Physics.*
[S0022-2488(96)01708-2]

In the early 1930s von Neumann[1] introduced a complete set of coherent states on a lattice in the phase plane with a unit cell of area h, the Planck constant. These states, in addition to forming a complete set, have also the attractive property of being well localized both in coordinate x and momentum p around each point la,mb on the lattice where a and b are constants with $ab=h$, and $l,m=0,\pm1,\pm2,...$, on the lattice. In 1946 Gabor[2] defined a similar set of states in the plane of time t and frequency ν with a unit cell of area 1. It has the same localization property for t and ν as the von Neumann set has with respect to x and p. This is, in principle, the same set of states which can therefore be called the von-Neumann–Gabor set.

The completeness of the von-Neumann–Gabor set (VNG set) was proven only in the 1970s.[3–5] It has, however, turned out[3,5] that the VNG set is over-complete by exactly one state: It remains complete if one state is removed, but ceases to be complete when more than one state is removed. This is a very unusual peculiarity which is characteristic to the VNG sets. It turns out that because of this peculiarity, expansions in such sets do not have good convergence properties.[6] In recent years an important contribution was made by Daubechies, Grossmann, and Meyer[7] who introduced the concept of frames for discrete sets in phase plane with $ab\leqslant h$. These latter sets are called the Weyl–Heisenberg sets (WH set), while the name VNG set is reserved here for the case when $ab=h$. It was shown in Ref. 7 that expansions in frames have good convergence properties and, as a consequence of this, frames have recently acquired much interest in signal processing.[8] The interest in the WH states stems from the fact that they carry simultaneous information about the coordinate and momentum (or time and frequency). As is well known one cannot construct in quantum mechanics wavefunctions $\psi(x,p)$ that depend on both the coordinate x and the momentum p, because this would be in violation of the uncertainty principle. In view of this restriction on the wavefunction, the approach of phase space distributions depending on x and p has developed in quantum mechanics, the most famous among them being the Wigner function.[9] These distributions are quadratic in the wavefunction and they carry some information on the simultaneous probability density for x and p. It should also, in principle, be possible to construct wavefunctions that depend on partial information about both x and p. An example of such a possibility is the kq-representation[10] in which the information about x is carried by the quasicoordinate q and the information about p by the quasimomentum $\hbar k$. Here q and k in the wavefunction $C(k,q)$ vary in a unit cell of the VNG lattice with area 2π, and they tell us where inside this cell x and $p/\hbar$ are,

but do not say anything about the number of cell (l,m). An alternative possibility would result if the wavefunction depended on l and m, $\psi(l,m)$, telling us in which unit cell x and p are, but saying nothing about their location inside the cell. Such a wavefunction $\psi(l,m)$ should then be in some sense a Fourier transform of the kq-wave function $C(k,q)$. To our knowledge no such wavefunction $\psi(l,m)$ has as yet been constructed, and one can even wonder whether such a wavefunction exists.

In this paper we use the concept of frames in signal processing[7] in order to construct what we call the discrete Weyl–Heisenberg transform $\psi(la,mb)$. The points (la,mb) are on the WH-lattice with $l,m=0,\pm1,\pm2,\ldots$. It is shown that for some special sets this discrete representation is closely related to a discrete subset of the Senitsky–Glauber coherent states[11] $|\alpha\rangle$. In constructing $\psi(la,mb)$ much use will be made of the elegant and powerful notion of tight frames.[7] The latter are defined in the following way. One first defines a frame: the WH-set is a frame if the frame operator F,

$$A \leqslant F \equiv \sum_{l,m=-\infty}^{\infty} |g_{lm}\rangle\langle g_{lm}| \leqslant B, \tag{1}$$

is bounded by two positive constants A and B, $A \leqslant F \leqslant B$; A and B are called the frame bounds. Here $|g_{lm}\rangle$ is a state of the set assigned to the cell (la,mb) of the lattice and in what follows it will be assumed that $ab=h/N$ with $N=1,2,\ldots$. One obtains a tight frame when the frame operator F in Eq. (1) is a multiple of the unit operator:

$$F=\sum_{l,m} |g_{lm}\rangle\langle g_{lm}| = AI. \tag{2}$$

Here A is a positive constant. An explicit construction is presented in this paper for WH tight frames with $A=1$:

$$\sum_{l,m} |g_{lm}\rangle\langle g_{lm}| = I. \tag{3}$$

Frames that satisfy this equation are called tight frames with bound 1. In quantum mechanics an equation of the type of Eq. (3) is usually obtained for an orthonormal basis. In Eq. (3), however, the states $|g_{lm}\rangle$ are not orthogonal, and as is known for them to satisfy Eq. (3), they cannot be normalized to one.[7] A full quantum mechanical framework is derived in this paper for these WH sets $|g_{lm}\rangle$ by using Eq. (3). This includes expressions for any operators, for their expectation values, etc. In other words, we construct in this paper what we call the discrete Weyl–Heisenberg transform $\psi(la,mb)$. It should be pointed out that originally the VNG set was built on coherent states.[1,11] This was later extended to cover any state in the Hilbert space and, correspondingly, it was called the Weyl–Heisenberg set.[12] In this paper a definition is presented of a quantum mechanical transform for a general WH tight frame and as a particular example the set of coherent states is considered.

Given a state $|g\rangle$ in Hilbert space, a Weyl–Heisenberg discrete set is defined in the following way. One uses the destruction a and creation a^+ operators and the constants α and α^*,

$$a=\frac{1}{\lambda\sqrt{2}}\left(x+i\frac{\lambda^2}{\hbar}p\right),\quad a^+=\frac{1}{\lambda\sqrt{2}}\left(x-i\frac{\lambda^2}{\hbar}p\right),$$
$$\alpha=\frac{1}{\lambda\sqrt{2}}\left(\bar{x}+i\frac{\lambda^2}{\hbar}\bar{p}\right),\quad \alpha^*=\frac{1}{\lambda\sqrt{2}}\left(\bar{x}-i\frac{\lambda^2}{\hbar}\bar{p}\right), \tag{4}$$

for defining the shift operator,

$$D(\alpha)=\exp(\alpha a^+-\alpha^* a), \tag{5}$$

and correspondingly the WH set,

$$|g_{la,mb}\rangle=D[\alpha(la,mb)]|g\rangle. \tag{6}$$

The following notations are used in Eqs. (4)–(6): λ, $\bar{x}$, and $\bar{p}$ are arbitrary constants,

$$\alpha(la,mb)=\frac{1}{\lambda\sqrt{2}}\left(la+i\frac{\lambda^2}{\hbar}mb\right), \tag{7}$$

while the constants a and b satisfy the relation

$$ab=\frac{h}{N},\quad N=1,2,3,\ldots, \tag{8}$$

where $l,m=0,\pm1,\pm2,\ldots$. When $N=1$, the set in Eq. (6) is the VNG set. It was proven in Ref. 7 that the set in Eq. (6) is a frame for $N\geqslant 2$. It is also known[13] that if $|g_{la,mb}\rangle$ is a frame [see Eqs. (1) and (6)], then

$$\frac{1}{F^{1/2}}|g_{la,mb}\rangle \tag{9}$$

is a tight frame with bound 1, where F is the frame operator [see Eq. (1)]. We are now going to present an explicit construction of the tight frame as given in Eq. (9) by using the kq-representation.[10] The wavefunctions $\psi(x)$ and $C(k,q)$ in the x and in the kq-representations, respectively, are related in the following way:

$$C^{(d)}(k,q)=\left(\frac{d}{2\pi}\right)^{1/2}\sum_n \exp(iknd)\psi(q-nd),\quad \psi(x)=\left(\frac{d}{2\pi}\right)^{1/2}\int_{-\pi/d}^{\pi/d}C^{(d)}(x,k)dk, \tag{10}$$

where d is an arbitrary constant. The basic operators x and p in this representation are[10]

$$x=i\frac{\partial}{\partial k}+q,\quad p=-i\hbar\frac{\partial}{\partial q}. \tag{11}$$

The kq-wave function $C^{(d)}(k,q)$ satisfies the following boundary conditions:

$$\exp(-ikd)C^{(d)}(k,q+d)=C^{(d)}\left(k+\frac{2\pi}{d},q\right)=C^{(d)}(k,q). \tag{12}$$

In signal processing $C(k,q)$ is called the Zak transform.[14] Bearing in mind the boundary condition (12) it will be convenient to write the shift operator $D[\alpha(la,mb)]$ as a product of two shift operators by splitting $\alpha(la,mb)$ in the following way:

$$\alpha(la,mb)=\alpha\left(l_1 d,m_1\frac{2\pi}{d}\hbar\right)+\alpha\left(l_2\frac{d}{L},m_2\frac{2\pi}{MD}\hbar\right), \tag{13}$$

where the αs are defined in Eq. (7), and where the integers are as follows

$$l=l_1L+l_2,\quad m=m_1M+m_2,\quad LM=N,\quad d=La. \tag{14}$$

Here $l_1,m_1=0,\pm1,\pm2,\ldots$, $l_2=0,1,\ldots L-1$, and $m_2=0,1,\ldots M-1$.

The frame operator F [Eq. (1)] in the kq-representation for the Weyl–Heisenberg set is[7,15]

$$\begin{aligned}\langle k,q|F|k',q'\rangle=&\sum_{l_1,m_1;l_{2,2}}\exp\left[-il_1(k-k')d+im_1(q-q')\frac{2\pi}{d}\right]\\&\times\left[D\left[\alpha\left(l_2\frac{d}{L},m_2\frac{2\pi}{Md}\hbar\right)\right]g^{(d)}(k,q)\right]^{*}D\left[\alpha\left(l_2\frac{d}{L},m_2\frac{2\pi}{Md}\hbar\right)\right]g^{(d)}(k',q')\\=&2\pi\sum_{l_2m_2}\left|g^{(d)}\left(k-\frac{2\pi}{Md}m_2,q-\frac{d}{L}l_2\right)\right|^2\\&\times\sum_{l_1}\delta\left(k-k'-\frac{2\pi}{d}l_1\right)\sum_{m_1}\delta(q-q'-dm_1),\end{aligned} \tag{15}$$

where we used the Poisson summation formula for distributions:[16]

$$\sum_l\exp(ildk)=\frac{2\pi}{d}\sum_l\delta\left(k-\frac{2\pi}{d}l\right). \tag{16}$$

What Eq. (15) actually means is that in the kq-representation the frame operator $F(k,q)$ is just the multiplication operator[13,17]

$$F(k,q)=2\pi\sum_{m_2=1}^{M}\sum_{l_2=1}^{L}\left|g^{(d)}\left(k-\frac{2\pi}{Md}m_2,q-\frac{d}{L}l_2\right)\right|^2. \tag{17}$$

When the WH set $|g_{la,mb}\rangle$ is a frame, one can use Eqs. (9) and (17) for constructing a tight frame. This can be done in the following way. According to Eq. (9) we define a new window function

$$\phi^{(d)}(k,q)=\frac{g^{(d)}(k,q)}{F^{1/2}(k,q)}. \tag{18}$$

We then have

$$\phi^{(d)}_{la,mb}(k,q)=D[\alpha(la,mb)]\phi^{(d)}(k,q)=\frac{g^{(d)}_{la,mb}(k,q)}{F^{1/2}(k,q)}, \tag{19}$$

where $F(k,q)$ is given by Eq. (17). For the case $N=2$ and when $g^{(d)}(k,q)$ is the ground state of a harmonic oscillator, this construction was explicitly carried out by Daubechies, Jaffard, and Journe.[18]

Having defined a WH tight frame $|\phi_{la,mb}\rangle$ we use it for a convenient decomposition of the unit operator I:

$$\sum_{l,m}^{\cdot} |\phi_{la,mb}\rangle\langle\phi_{la,mb}| = I. \tag{20}$$

From here any state $|\psi\rangle$ can be expanded in the following way:

$$|\psi\rangle = \sum_{l,m} \langle\phi_{la,mb}|\psi\rangle|\phi_{la,mb}\rangle. \tag{21}$$

Equations (20) and (21) look very much the same as in the case when $|\phi_{la,mb}\rangle$ is an orthonormal basis. However, the WH set $|\phi_{la,mb}\rangle$ is highly overcomplete (for $N\geq 2$) and not orthogonal. As a consequence of the overcompleteness the expansion in the set $|\phi_{la,mb}\rangle$ can be carried out with many other collections of coefficients c_{lm}:

$$|\psi\rangle = \sum_{l,m} c_{lm}|\phi_{la,mb}\rangle. \tag{22}$$

There is, however, a very special feature that the expansion coefficients $\langle\phi_{la,mb}|\psi\rangle$ in Eq. (21) possess. From the identity resolution [Eq. (20)] it follows that

$$\langle\psi|\psi\rangle = \sum_{l,m} |\langle\phi_{la,mb}|\psi\rangle|^2. \tag{23}$$

The special feature of $\langle\phi_{la,mb}|\psi\rangle$ is that among all the collections of c_{lm} in Eq. (22) for a given $|\psi\rangle$, the $\langle\phi_{la,mb}|\psi\rangle$ lead to a "minimal solution" [8,15]

$$\langle\psi|\psi\rangle = \sum_{l,m} |\langle\phi_{la,mb}|\psi\rangle|^2 \leq \sum_{l,m} |c_{lm}|^2. \tag{24}$$

The equality sign is reached only when $c_{lm} = \langle\phi_{la,mb}|\psi\rangle|$.

Based on this special feature of the expansion coefficients $\langle\phi_{la,mb}|\psi\rangle|$ in Eq. (21) we define the quantum mechanical discrete Weyl–Heisenberg transform $\psi^{(\phi)}(la,mb)$ for the function ϕ [see Eq. (18)] in the following way:

$$\psi^{(\phi)}(la,mb) \equiv \langle\phi_{la,mb}|\psi\rangle|. \tag{25}$$

Here $\psi^{(\phi)}(la,mb)$ contains partial information about x (via la) and partial information about p (via mb) with the pair (la,mb) specifying the cell in the phase plane around which ϕ_{lm} is localized [Eq. (19)]. What is very satisfying about this definition of $\psi^{(\phi)}(la,mb)$ is that for a normalized state, $\langle\psi|\psi\rangle = 1$,

$$P(la,mb) = |\psi(la,mb)|^2 \tag{26}$$

can be interpreted as giving the probability to find x and p in the cell (l,m) in phase plane. This is so because from Eqs. (23) and (25) it follows that

$$\sum_{l,m} P(la,mb) = \sum_{l,m} |\psi(la,mb)|^2 = 1 \tag{27}$$

as is required from a probability distribution.

It is to be pointed out that despite satisfying the probability requirement in Eq. (27), the discrete Weyl–Heisenberg transform $\psi(la,mb)$ cannot be given the interpretation of a wavefunction in quantum mechanics. The main reason for this is that la and mb are not eigenvalues of

some commuting physical observables. The situation is very much like that with coherent states $|\alpha\rangle$, when $\langle\alpha|\psi\rangle$ gives some probability information of the distribution of x and p in the state $|\psi\rangle$, but it can nevertheless not be interpreted as a wavefunction.

Before showing how the transform $\psi(la,mb)$ can be used for representing operators and expectation values, let us first work out an example. As an important illustration of $\psi(la,mb)$ we give in what follows an explicit construction of it for the case when $|g\rangle$ is the ground state of a Harmonic oscillator:

$$\langle x|g_0\rangle=\left(\frac{1}{\pi\lambda^2}\right)^{1/4}\exp\left(-\frac{x^2}{2\lambda^2}\right). \tag{28}$$

In the kq-representation this function is[6] [see Eq. (10) above]

$$g_0^{(d)}(k,q)=\left(\frac{d}{2\pi^{3/2}\lambda}\right)^{1/2}\exp\left(-\frac{q^2}{2\lambda^2}\right)\theta_3\left(\frac{kd}{2}-i\,\frac{qd}{2\lambda^2}\,\middle|\,i\,\frac{d^2}{2\pi\lambda^2}\right), \tag{29}$$

where θ_3 is the Jacobi Theta function[19]

$$\theta_3(z|\tau)=\sum_n e^{2izn+i\pi\tau n^2}. \tag{30}$$

For constructing the tight WH frame [Eq. (19)] we have to find the frame operator $F(k,q)$ [Eq. (17)]. For this purpose one can use the known formulas from VNG lattices[20] for any kq-function $g^{(d)}(k,q)$:

$$2\pi|g^{(d)}(k,q)|^2=\sum_{m,n}(-1)^{mn}\langle q_{md,\hbar(2\pi/d)n}|g\rangle\exp\left(i\,\frac{2\pi}{d}\,qm-idkm\right). \tag{31}$$

By using this formula, the summation on l_2,m_2 in Eq. (17) gives the following result for the frame operator $F(k,q)$:

$$F(k,q)=N\sum_{m,n}(-1)^{mnN}\langle g_{mLd,nM(2\pi/d)\hbar}|g\rangle\exp\left(i\,\frac{2\pi}{d}\,qmL-ikdnM\right), \tag{32}$$

where $N=LM$ [Eq. (14)]. This is a useful expression for the frame operator $F(k,q)$ in the kq-representation for any $g^{(d)}(k,q)$. For the ground state of the harmonic oscillator [Eqs. (28) and (29)], the operator $F(k,q)$ becomes[20]

$$F_0(k,q)=N\sum_{m,n}(-1)^{mnN}\exp\left\{-\frac{d^2}{4\lambda^2}\left[(nM)^2+\left(\frac{2\pi\lambda^2}{d^2}\right)^2(mL)^2\right]\right\}\exp\left(i\,\frac{2\pi}{d}\,qmL-ikdnM\right). \tag{33}$$

This is a very simple formula which becomes even simpler for the symmetric case of

$$N=L^2=M^2\equiv S^2 \quad\text{and}\quad \frac{2\pi\lambda^2}{d^2}=1. \tag{34}$$

We then have

$$F_0^{(N)}(k,q)=N\sum_{m,n}(-1)^{mnN}\exp\left[-\frac{N\pi}{2}(m^2+n^2)\right]\exp\left(i\,\frac{2\pi}{d}\,qmS-ikdnS\right). \tag{35}$$

Thus, for $N=4$, $F_0^{(4)}(k,q)$ becomes [see Eq. (30)]

$$F_0^{(4)}(k,q)=4\theta_3\left(2\pi\frac{q}{d}\middle|2i\right)\theta_3(kd|2i). \tag{36}$$

The frame operators in Eqs. (35) and (36) are very smooth functions of the k and q variables and they have the very good feature that their bounds [see Eq. (1)] A and B are close to one another. Thus, already for $N=4$ [Eq. (36)] one can check by using numerical values for θ_3-functions[19] that

$$A=3.970, \quad B=4.030, \quad \frac{B-A}{B+A}=0.0074. \tag{37}$$

This ratio goes rapidly down for $N>4$. One can therefore assume to a good approximation that the frame operator $F_0^{(N)}(k,q)\approx N$ for $N\geq 4$. It follows that for the symmetric case [Eq. (34)] the tight frame $(\phi_0^{(d)})_{la,mb}(k,q)$ for the ground state of a harmonic oscillator differs from the frame $(g_0^{(d)})_{la,mb}(k,q)$ only by the constant factor $S(N=S^2)$,

$$(\phi_0^{(d)})_{la,mb}(k,q)=\frac{1}{S}(g_0^d)_{la,mb}(k,q), \tag{38}$$

where a and b are defined in Eqs. (7) and (8). Also in this approximation the frame operator $F_0^{(N)}\approx N$ gives the number of the WH set states in a unit cell of the VNG lattice. For the ground state of the harmonic oscillator, we actually return to the original von Neumann coherent states[1,11] and correspondingly we can use the notation [see Eq. (38)]

$$(\phi_0^{(d)})_{la,mb}(k,q)\approx\frac{1}{S}\langle k,q|\alpha(la,mb)\rangle, \tag{39}$$

where $|\alpha(la,mb)\rangle$ is a coherent state[11] with $\alpha(la,mb)\rangle$ given in Eq. (7). What should, however, be pointed out is that the WH set $|\alpha(la,mb)\rangle$ is a frame, while $(\phi_0^{(d)})_{la,mb}$ is, to a "good approximation," a tight frame.

Having the result in Eq. (39), it is easy to write down the discrete Weyl–Heisenberg transform $\psi^{(g_0)}(la,mb)$ for any state $|\psi\rangle$. The superscript g_0 indicates that the ground state of the harmonic oscillator was used [see Eq. (28)] for constructing the Weyl–Heisenberg set. We have

$$\psi^{(g_0)}(la,mb)\approx\frac{1}{S}\langle\alpha(la,mb)|\psi\rangle. \tag{40}$$

As is well know the bracket on the right-hand side of Eq. (40) can be written as follows:

$$\langle\alpha(la,mb)|\psi\rangle=\exp(-\tfrac{1}{2}|\alpha(la,mb)|^2)\psi[\alpha^*(la,mb)], \tag{41}$$

where $\psi(\alpha^*)$ for continuous α is an analytic function of α^* and it is known as the Bargmann representation[21] of $|\psi\rangle$. Thus for the nth harmonic oscillator state $|\psi_n\rangle$, Eq. (40) becomes

$$\psi_{(n)}^{(g_0)}(la,mb)\approx\frac{1}{S}\exp\left(-\frac{1}{2}|\alpha(la,mb)|^2\right)\frac{\alpha^{*n}(la,mb)}{\sqrt{n!}}. \tag{42}$$

The probability distribution for this state will correspondingly be [see Eq. (26)]

$$P_n^{(g_0)}(la,mb)=|\psi_n^{(g_0)}(la,mb)|^2\approx\frac{1}{N}\exp(-|\alpha(la,mb)|^2)\frac{|\alpha(la,mb)|^{2n}}{n!}$$
$$=\frac{1}{N}\exp\left[-\pi\left(\frac{l^2}{L^2}+\frac{m^2}{M^2}\right)\right]\frac{\pi^n(l^2/L^2+m^2/M^2)^n}{n!}, \tag{43}$$

where Eqs. (7), (8), and (34) were used. This is a simple function which can be interpreted as giving the probability of finding x and p in the cell $la,mb(ab=h/N)$ in the state $|\psi_n\rangle$.

Equation (40) gives an approximate relation between the discrete Weyl–Heisenberg transform $\psi(la,mb)$ and the Bargmann representation $\langle\alpha(la,mb)|\psi\rangle$ of the state $|\psi\rangle$.

In the case of coherent states, the continuous transform $\langle\alpha|\psi\rangle$ [Eq. (41)] was used by Husimi[22] to define a phase space distribution function $P_H(x,p)$ which carries his name and which is connected to the Wigner function in the following way:[22]

$$P_H(x,p)=\frac{1}{2\pi\hbar}\langle\alpha|\psi\rangle|^2=\int W_{g_0}(x-x',p-p')W_\psi(x',p'),dx'dp', \tag{44}$$

where g_0 is given in Eq. (28) and where the Wigner function for any $\psi(x)$ is[9]

$$W(x,p)=\frac{1}{2\pi\hbar}\int\exp\left(-\frac{i}{\hbar}pz\right)\psi^*\left(x-\frac{1}{2}z\right)\psi\left(x+\frac{1}{2}z\right)dz. \tag{45}$$

Following the definition in Eq. (44), one can consider $P(la,mb)$ in Eq. (26) as being an extension of the Husimi distribution to any WH tight frame with the window function of ϕ. In the particular case when ϕ corresponds to the ground state of a harmonic oscillator [Eq. (39)], the discrete Husimi distribution becomes [see Eqs. (40) and (44)]

$$P^{(g_0)}(la,mb)\approx\frac{1}{N}|\langle\alpha(la,mb)|\psi\rangle|^2=\frac{2\pi\hbar}{N}\int W_{g_0}(la-x',mb-p')W_\psi(x',p')dx'dp'. \tag{46}$$

When $|\psi\rangle$ is the nth harmonic oscillator state $|\psi_n\rangle$, the discrete Husimi distribution is given by Eq. (43). This completes the description of the illustrative example for the Weyl–Heisenberg tight frame built on the ground state of a harmonic oscillator. In summing up this example it should be pointed out that the discrete Weyl–Heisenberg transform $\psi^{(g_0)}(la,mb)$ can be easily used in view of its relation to the coherent state amplitude $\langle\alpha(la,mb)|\psi\rangle$ as given by Eq. (40).

We now show how the WH transform $\psi(la,mb)$ can be used in the general framework of quantum mechanics. For this we show how to represent any operator $\hat{O}$ by using this transform. Given a matrix element $\langle\psi_i|\hat{O}|\psi_j\rangle$ of the operator $\hat{O}$ between the states $|\psi_i\rangle$ and $|\psi_j\rangle$ one can use the unit operator decomposition formula [Eq. (20)] to find

$$\langle\psi_i|\hat{O}|\psi_j\rangle=\sum_{l,m,l',m'}\langle\psi_i||\phi_{la,mb}\rangle\langle\phi_{la,mb}|\hat{O}|\phi_{l'a,m'b}\rangle\langle\phi_{l'a,m'b}|\psi_j\rangle$$
$$=\sum_{l,m,l',m'}\psi_i^{(\phi)*}(la,mb)\langle\phi_{la,mb}|\hat{O}|\phi_{l'a,m'b}\rangle\psi_j^{(\phi)*}(l'a,m'b). \tag{47}$$

When $i=j$, this formula gives the expectation value of $\hat{O}$ in the state $|\psi_i\rangle$ expressed via the discrete Weyl–Heisenberg transform $\psi_i^{(\phi)}(la,mb)$ and the matrix elements $\langle\phi_{la,mb}|\hat{O}|\phi_{l'a,m'b}\rangle$. In the case when the WH tight frame is built on the ground state of the harmonic oscillator, one can use Eq. (39) and (40) in order to simplify the general expression in Eq. (47). We see therefore that any quantity in quantum mechanics is expressible via the discrete WH transform $\psi(la,mb)$.

In conclusion, in this paper a quantum mechanical transform is defined, called the discrete Weyl–Heisenberg transform, which carries simultaneous information of the coordinate and momentum in a given state $|\psi\rangle$. This information is extracted by forming a scalar product of $|\psi\rangle$ with a discrete Weyl–Heisenberg set $|\phi_{la,mb}\rangle$ in the phase plane, where la and mb give the coordinate x and the momentum p, respectively (l and m being integers). When $|\phi_{la,mb}\rangle$ is chosen to be a tight frame with bound 1, the $\psi(la,mb)=\langle\phi_{la,mb}|\psi\rangle$ is then the discrete Weyl–Heisenberg transform. The $\psi(la,mb)$ is reminiscent of the Bargmann representation in quantum mechanics[22] and the windowed Fourier transform in signal processing.[23] In the latter case the simultaneous information is about time and frequency.

(Received 22 January 1996; accepted for publication 21 March 1996)

In this paper a numerical method is developed to solve a one-dimensional inverse scattering problem associated with a pair of two coupled partial differential equations. These equations are for the Green functions that can be used for the optimization of electromagnetic energy within selected regions of a medium in which the propagation is taking place. The method is based upon constructing the Nth degree interpolation polynomial to approximate the Green functions and the phase velocity function using Legendre–Gauss–Lobatto collocation points. An example is given to demonstrate the accuracy of the developed method. © *1996 American Institute of Physics.* [S0022-2488(96)01907-X]

I. INTRODUCTION

Decomposition of the total electromagnetic field which is propagating through an inhomogeneous medium into two components traveling in opposite directions is referred to as wave splitting technique. This technique along with the invariant technique is applied to the solution of inverse problems. Wave splitting and invariant imbedding techniques are presented in Refs. 1–4. Two related methods of the Green functions based upon wave splitting are introduced in Refs. 5 and 6. In general, they are formulated in the form of an inverse problem and described by a set of linear coupled partial differential equations. This problem is also addressed in Refs. 7 and 8. It has been shown in Ref. 9 that the wave-splitting Green function approach to the one-dimensional electromagnetic inverse problem is a well-posed inverse problem.

In Ref. 5 an electromagnetic plane wave impinging normally on a one-dimensional dissipative medium is characterized by spatially varying permittivity and conductivity profiles. Furthermore, a technique that maximizes the electromagnetic energy within a specified region of the medium is introduced. This is accomplished through the application of the Green functions technique. This technique is distinctively different by contrast from the invariant imbedding method. It yields the fields inside the inhomogeneous medium where the boundary values of the Green functions are the scattering kernels for the physical scattering geometry. This connection provides an alternative and efficient approach to obtain the scattering kernels. It is utilized in Refs. 10 and 11 to produce such kernels and the Green functions for an oblique incidence on a plasma and a point source excitation of a half-space, respectively. The Green functions are used to represent a time-averaged electromagnetic energy in regions within a medium by a weakly continuous functional for the purpose of optimization of the electromagnetic energy as suggested in Ref. 12. A higher dimension of this Green functions technique is suggested in Ref. 6 for the application to the treatment of cancer cells in the human body without the destruction of the surrounding healthy tissue. A time domain inverse scattering problem is regarded in Ref. 6 for axially symmetric electromagnetic fields in a stratified slab. The axial symmetry of the field is promoted through a Hankel transform

0022-2488/96/37(8)/3824/9/$10.00

which results in a one-dimensional wave equation to which wave splitting is applied. The inverse scattering problem is formulated in the form of a pair of two coupled partial differential equations in which the Green functions are present where they are functions of time and displacement. In this paper the one-dimensional inverse problem for the case of nonconductive and dielectric stratified medium is considered. We are solving this inverse problem and generating the Green functions and the phase velocity from the knowledge of the reflection kernels. Our approach is based on a spectral collocation method (pseudospectral method[13]) in which we construct the Nth degree interpolating polynomials to approximate the Green functions and the phase velocity of the medium. These polynomials are defined through the use of Legendre–Gauss–Lobatto points as collocation points and Lagrange polynomials as trial functions.

The paper is organized as follows: In Sec. II we describe the basic formulation of the pseudospectral Legendre method required for our subsequent development. Section III is devoted to the formulation of the inverse scattering problem. In Sec. IV, the proposed method is used to approximate the Green functions and the phase velocity function. In Sec. V, we report our numerical finding and demonstrate the efficiency and the accuracy of the proposed numerical scheme.

II. PSEUDOSPECTRAL LEGENDRE METHOD

Let $L_N(t)$, $-1\leqslant t\leqslant 1$ denote the Legendre polynomial of order N, then the Legendre–Gauss–Lobatto nodes are defined in Ref. 13 by

$$t_0=-1, \quad t_N=1, \quad t_m \text{ are the zeros of } L'_N(t),$$
$$1\leqslant m\leqslant N-1, \tag{1}$$

where $L'_N(t)$ denotes the first derivative of $L_N(t)$. No explicit formula of the nodes in Eq. (1) is known, however, they can be computed numerically. Define the polynomial approximation of $F(t)$ by

$$F^N(t)=\sum_{l=0}^{N} b_l\phi_l(t), \tag{2}$$

where

$$\phi_h(t)=\frac{1}{N(N+1)L_N(t_h)}\cdot\frac{(t^2-1)L'_N}{(t-t_h)}, \quad h=0,1,\ldots,N, \tag{3}$$

are Lagrange polynomials of order h, with the property

$$\phi_h(t_j)=\delta_{hj}=\begin{cases}0 & \text{if } h\neq j\\ 1 & \text{if } h=j\end{cases} \tag{4}$$

therefore $F^N(t_h)=b_h$. For the accuracy of pseudospectral Legendre approximation and error at the collocation points refer to Ref. 13.

III. PROBLEM FORMULATION

The inverse scattering problem is formulated in Ref. 6 as a pair of two coupled partial differential equations as

$$\frac{\partial}{\partial z}\begin{bmatrix}G_{11}\\ G_{21}\end{bmatrix}=\frac{2}{c}\frac{\partial}{\partial t}\begin{bmatrix}0\\ G_{21}\end{bmatrix}+a^+(0,z)\begin{bmatrix}-(A+B)\\ B\end{bmatrix}$$

$$+\begin{bmatrix} -\frac{1}{2}(bc-c_z/c)-(A+B)* & -c_z/2c+B* \\ -c_z/2c+B* & \frac{1}{2}(bc+c_z/c)+(A-B)* \end{bmatrix}\cdot\begin{bmatrix} G_{11} \\ G_{21} \end{bmatrix}, \tag{5}$$

$$\frac{\partial}{\partial z}\begin{bmatrix} G_{22} \\ G_{12} \end{bmatrix}=-\frac{2}{c}\frac{\partial}{\partial t}\begin{bmatrix} 0 \\ G_{12} \end{bmatrix}+a^{-}(z,L)\begin{bmatrix} (A-B) \\ B \end{bmatrix}$$

$$+\begin{bmatrix} \frac{1}{2}(bc+c_z/c)+(A-B)* & -c_z/2c+B* \\ -c_z/2c+B* & -\frac{1}{2}(bc-c_z/c)-(A+B)* \end{bmatrix}\cdot\begin{bmatrix} G_{22} \\ G_{12} \end{bmatrix}. \tag{6}$$

z represents depth in the medium, t represents time, $G_{ij}(i,j=1,2)$ are the Green functions and the asterisk represents a convolution in time. The convolution in time of two functions $r(z,t)$ and $s(z,t)$ is

$$r(z,t)*s(z,t)=\int_0^t r(z,x)s(z,t-x)dx.$$

c is the phase velocity of the electromagnetic field in the medium and the function $b(z)$ is related to the conductivity of the medium, $\sigma(z)$, through the equation

$$b(z)=\sigma(z)\mu_0, \tag{7}$$

where μ_0 is the permeability in vacuum. Since we are considering the nonconductive case, the function $b(z)$ is zero. It is given in Ref. 6 that

$$A(z,t)=(a_1/c)\left[J_1(a_1t)\frac{e^{-b_1t}}{t}\right], \tag{8}$$

$$D(z,t)=c^2e^{-b_1t}\cos(a_1t), \tag{10}$$

$$C(z,t)=(c^2/a_1)\sin(a_1t)e^{-b_1t}. \tag{11}$$

$J_1(x)$ is the Bessel function of the first kind of order one and κ is the Hankel transform parameter

$$B(z,t)=(c_z/2c)\kappa^2C(z,t)+\tfrac{1}{2}c_1[D(z,t)-b_1C(z,t)]. \tag{9}$$

This medium is inhomogeneous, of a known thickness and bounded with two known homogeneous media. The parameters $b_1,a_1,c_1,a^{+}(0,z),a^{-}(z,L)$ are functions of the electromagnetic properties of the medium, they are given in Ref. 6. For the case considered in this paper $b_1=c_1=0$ and

$$a_1=c\kappa, \tag{12}$$

$$a^{+}(0,z)=\sqrt{c(z)/c(0)}, \tag{13}$$

$$a^{-}(z,L)=\sqrt{c(z)/c(L)}. \tag{14}$$

L is the thickness of the medium. Thus the region $0\leqslant z\leqslant L$ is inhomogeneous and the regions $z<0$ and $z>L$ are homogeneous. Initial and boundary conditions on the Green functions are

$$G_{12}(z,0)=-\tfrac{1}{4}a^{-}(z,L)c_z, \tag{15}$$

$$G_{21}(z,0)=\tfrac{1}{4}a^{+}(0,z)c_z, \tag{16}$$

$$G_{11}(0,t)=0, \tag{17}$$

$$G_{21}(L,t)=0, \quad t>0, \tag{18}$$

$$G_{22}(L,t)=0, \quad t>0, \tag{19}$$

$$G_{12}(0,t)=0, \quad t>0. \tag{20}$$

IV. APPLICATION OF LEGENDRE–GAUSS–LOBATTO METHOD TO APPROXIMATE THE GREEN-FUNCTIONS AND THE PHASE VELOCITY FUNCTION

In order to apply Legendre–Gauss–Lobatto nodes and solve the inverse scattering problem we introduce the following transformations:

$$z=\frac{L}{2}(1+\alpha), \tag{21}$$

$$t=\frac{T}{2}(1+\beta). \tag{22}$$

The values of α and β are in the interval $[-1,1]$. T is the duration of the reflection scattering kernels $R^{\pm}(0,L,t)$. These two kernels are related to the phase velocity and the Green functions as[6]

$$R^{+}(z,L,t)_{\substack{|z=0\\ t=0}}=\tfrac{1}{4}c_z|_{z=0}. \tag{23}$$

$$G_{21}(0,t)=R^{+}(0,L,t), \tag{24}$$

$$R^{-}(z,L,t)_{\substack{|z=0\\ t=0}}=-\tfrac{1}{4}c_z|_{z=L}, \tag{25}$$

$$G_{12}(L,t)=R^{-}(0,L,t). \tag{26}$$

In general, the inputs to this method are the reflection kernels $R^{\pm}(0,L,t)$ and no information on the transmission kernels $T^{\pm}(z,L,t)$ is required. However, for the case considered in this paper the input is $R^{+}(0,L,t)$. Define the approximation of the function $A(z,t)$ as

$$A^{N}(\alpha,\beta)=\sum_{i=0}^{N}\sum_{j=0}^{N}a_{ij}\phi_i(\alpha)\phi_j(\beta), \tag{27}$$

where the a's are the coefficients and the functions ϕ_i are given in Eq. (3). Similar definitions for the function $B(z,t)$ and the Green functions $G_{11}(z,t)$, $G_{21}(z,t)$, $G_{22}(z,t)$, and $G_{12}(z,t)$ are formulated with the coefficients b, γ, θ, ζ, and η, respectively. The phase velocity function, $c(z)$, is assumed continuously differentiable within the medium. We define its approximation as

$$c^{N}(\alpha)=\sum_{i=0}^{N}\lambda_i\phi_i(\alpha). \tag{28}$$

The differentiations of $G^{N}{}_{11}(\alpha,\beta)$ with respect to α and β are

$$G_{11}{}^{N}(\alpha,\beta)_{\alpha}=\sum_{i=0}^{N}\sum_{j=0}^{N}\gamma_{ij}\phi'_i(\alpha)\phi_j(\beta), \tag{29}$$

$$G_{11}{}^{N}(\alpha,\beta)_{\beta}=\sum_{i=0}^{N}\sum_{j=0}^{N}\gamma_{ij}\phi_i(\alpha)\phi'_j(\beta). \tag{30}$$

Equations similar to Eqs. (29) and (30) can be generated for the other Green functions. Considering the nonconductive case and applying the approximations of the functions A, B, c, G_{11}, G_{21} and the corresponding derivatives of the last two functions to the coupled partial differential equations in Eq. (5) we get

$$\begin{aligned}
&\frac{2}{L}\sum_{i=0}^{N}\sum_{j=0}^{N}\gamma_{ij}\phi'_i(\alpha)\phi_j(\beta)\\
&\quad=-\sqrt{\frac{\Sigma_{i=0}^{N}\lambda_i\phi_i(\alpha)}{\lambda_0}}\cdot\left\{\sum_{i=0}^{N}\sum_{j=0}^{N}a_{ij}\phi_i(\alpha)\phi_j(\beta)+\sum_{i=0}^{N}\sum_{j=0}^{N}b_{ij}\phi_i(\alpha)\phi_i(\beta)\right\}\\
&\qquad+\frac{1}{2}\frac{\Sigma_{i=0}^{N}\lambda_i\phi'_i(\alpha)}{\Sigma_{i=0}^{N}\lambda_i\phi_i(\alpha)}\cdot\sum_{i=0}^{N}\sum_{j=0}^{N}\gamma_{ij}\phi_i(\alpha)\phi_j(\beta)\\
&\qquad-\left\{\sum_{i=0}^{N}\sum_{j=0}^{N}a_{ij}\phi_i(\alpha)\phi_j(\beta)+\sum_{i=0}^{N}\sum_{j=0}^{N}b_{ij}\phi_i(\alpha)\phi_i(\beta)\right\}*\sum_{i=0}^{N}\sum_{j=0}^{N}\gamma_{ij}\phi_i(\alpha)\phi_j(\beta)\\
&\qquad-\frac{1}{2}\frac{\Sigma_{i=0}^{N}\lambda_i\phi'_i(\alpha)}{\Sigma_{i=0}^{N}\lambda_i\phi_i(\alpha)}\cdot\left[\sum_{i=0}^{N}\sum_{j=0}^{N}\theta_{ij}\phi_i(\alpha)\phi_j(\beta)\right]\\
&\qquad+\left\{\sum_{i=0}^{N}\sum_{j=0}^{N}b_{ij}\phi_i(\alpha)\phi_i(\beta)\right\}*\left[\sum_{i=0}^{N}\sum_{j=0}^{N}\theta_{ij}\phi_i(\alpha)\phi_j(\beta)\right]
\end{aligned} \tag{31}$$

and

$$\begin{aligned}
&\frac{2}{L}\sum_{i=0}^{N}\sum_{j=0}^{N}\theta_{ij}\phi'_i(\alpha)\phi_j(\beta)\\
&\quad=\frac{4}{T\cdot\Sigma_{i=0}^{N}\lambda_i\phi_i(\alpha)}\cdot\sum_{i=0}^{N}\sum_{j=0}^{N}\theta_{ij}\phi_i(\alpha)\phi'_j(\beta)+\sqrt{\frac{\Sigma_{i=0}^{N}\lambda_i\phi_i(\alpha)}{\lambda_0}}\\
&\qquad\times\sum_{i=0}^{N}\sum_{j=0}^{N}b_{ij}\phi_i(\alpha)\phi_i(\beta)-\frac{1}{2}\frac{\Sigma_{i=0}^{N}\lambda\ \ _i\phi'_i(\alpha)}{\Sigma_{i=0}^{N}\lambda_i\phi_i(\alpha)}\cdot\sum_{i=0}^{N}\sum_{j=0}^{N}\gamma_{ij}\phi_i(\alpha)\phi_j(\beta)\\
&\qquad+\sum_{i=0}^{N}\sum_{j=0}^{N}b_{ij}\phi_i(\alpha)\phi_i(\beta)*\sum_{i=0}^{N}\sum_{j=0}^{N}\gamma_{ij}\phi_i(\alpha)\phi_j(\beta)\\
&\qquad+\frac{1}{2}\frac{\Sigma_{i=0}^{N}\lambda_i\phi'_i(\alpha)}{\Sigma_{i=0}^{N}\lambda_i\phi_i(\alpha)}\sum_{i=0}^{N}\sum_{j=0}^{N}\theta_{ij}\phi_i(\alpha)\phi_j(\beta)+\left\{\sum_{i=0}^{N}\sum_{j=0}^{N}a_{ij}\phi_i(\alpha)\phi_i(\beta)\right.\\
&\qquad\left.-\sum_{i=0}^{N}\sum_{j=0}^{N}b_{ij}\phi_i(\alpha)\phi_i(\beta)\right\}*\left[\sum_{i=0}^{N}\sum_{j=0}^{N}\theta_{ij}\phi_i(\alpha)\phi_j(\beta)\right].
\end{aligned} \tag{32}$$

At the Legendre–Gauss–Lobatto nodes $\alpha=\alpha_n$ and $\beta=\beta_m$ Eqs. (31) and (32) reduce to

$$\frac{2}{L}\sum_{i=0}^{N}\gamma_{im}\phi'_i(\alpha_n)$$

$$=-\sqrt{\frac{\lambda_n}{\lambda_0}}\cdot\{a_{nm}+b_{nm}\}+\frac{1}{2}\frac{\Sigma_{i=0}^{N}\lambda_i\phi'_i(\alpha_n)}{\lambda_n}\cdot\gamma_{nm}-\frac{T}{2}(1+\beta_m)$$
$$\times\sum_{j=0}^{N}a_{nj}\sum_{q=0}^{N}\gamma_{nq}\int_{-1}^{1}\phi_j(u)\phi_q(u)du-\frac{T}{2}(1+\beta_m)$$
$$\times\sum_{j=0}^{N}b_{nj}\sum_{q=0}^{N}\gamma_{nq}\int_{-1}^{1}\phi_j(u)\phi_q(u)du-\frac{1}{2}\frac{\Sigma_{i=0}^{N}\lambda_i\phi'_i(\alpha_n)}{\lambda_n}\cdot\theta_{nm}+\frac{T}{2}(1+\beta_m)$$
$$\times\sum_{j=0}^{N}b_{nj}\sum_{q=0}^{N}\theta_{nq}\int_{-1}^{1}\phi_j(u)\phi_q(u)du, \tag{33}$$

and

$$\frac{2}{L}\sum_{i=0}^{N}\theta_{im}\phi'_i(\alpha_n)$$

$$=\frac{4}{T\cdot\lambda_n}\cdot\sum_{j=0}^{N}\theta_{nj}\phi'_j(\beta_m)+\sqrt{\frac{\lambda_n}{\lambda_0}}\cdot b_{nm}-\frac{1}{2}\frac{\Sigma_{i=0}^{N}\lambda_i\phi'_i(\alpha_n)}{\lambda_n}\cdot\gamma_{nm}+\frac{T}{2}(1+\beta_m)$$
$$\times\sum_{j=0}^{N}b_{nj}\sum_{q=0}^{N}\gamma_{nq}\int_{-1}^{1}\phi_j(u)\phi_q(u)du+\frac{1}{2}\frac{\Sigma_{i=0}^{N}\lambda_i\phi'_i(\alpha_n)}{\lambda_n}\cdot\theta_{nm}+\frac{T}{2}(1+\beta_m)$$
$$\times\sum_{j=0}^{N}a_{nj}\sum_{q=0}^{N}\theta_{nq}\int_{-1}^{1}\phi_j(u)\phi_q(u)du-\frac{T}{2}(1+\beta_m)$$
$$\times\sum_{j=0}^{N}b_{nj}\sum_{q=0}^{N}\theta_{nq}\int_{-1}^{1}\phi_j(u)\phi_q(u)du, \tag{34}$$

where

$$a_{hg}=\frac{\kappa}{\frac{T}{2}(1+\beta_g)}\cdot J_1\left[\lambda_h\kappa\frac{T}{2}(1+\beta_g)\right], \tag{35}$$

$$b_{hg}=\frac{\kappa}{\lambda_h}\sum_{i=0}^{N}\lambda_i\phi'_i(\alpha_h)\cdot\sin\left[\lambda_h\kappa\frac{T}{2}(1+\beta_g)\right]. \tag{36}$$

Applying Eqs. (16)–(18) and (23)–(25) along with

$$4R^{+}(-1,1,-1)=\sum_{i=0}^{N}\lambda_i\phi'_i(-1) \tag{37}$$

to Eqs. (33) and (34) a set of algebraic equations is generated. In this case the inverse scattering problem is solved where the number of the unknown coefficients λ_{ij}, θ_{ij}, and γ_{ij} is equal to that of the algebraic equations which is $2N^2+N+1$. The coupled partial differential equations given in

Eq. (6) are discretized in the same fashion, however, this time the components of the phase velocity at the collocation points are already known from the solution of Eq. (5). Consequently, the direct problem is solved and the remaining coefficients ζ_{ij} and η_{ij} are generated. As a result the Green functions along with components of the phase velocity function are available at the collocation points.

V. AN ILLUSTRATIVE EXAMPLE

We selected an inhomogeneous medium of a known permittivity profile. The medium was of thickness $L=0.1$ m and conductivity $\sigma(z)=0$, where z represents depth in the medium. Then we assumed that a known one sided, down-going electromagnetic wave was incident on the medium from the top. The reflected electromagnetic data at the interface $z=0$ was assumed to be of a finite period of time $T=0.1$ s. Using a specific value of the Hankel transform parameter $\kappa=0.1$ m^{-1} and the pseudospectral Legendre approach, we solved the direct problem which is in the form of partial differential equations in Ref. 6 for the reflection kernel $R^+(0,0.1,t;0.1)$. This reflection kernel was used as an input to the method presented in this paper to solve the inverse problem. Values of the Green functions and the phase velocity function at the collocation points with $N=9$ were generated. Approximate and exact values of the phase velocity at the collocation points are listed in Table I. To illustrate how the method reconstructs the phase velocity profile with noisy data, Gaussian noise with STD=0.05 was added to the reflection kernel $R^+(0,0.1,t;0.1)$. This corresponds to a signal to noise ratio of 5.4 as suggested in Ref. 14. The Green functions $G_{11}(z,t)$ and $G_{21}(z,t)$ that corresponds to the data with no noise are given in Figs. 1 and 2, respectively. Using the same value of the Hankel transform parameter $\kappa=0.1$ m^{-1}, we applied the pseudospec-

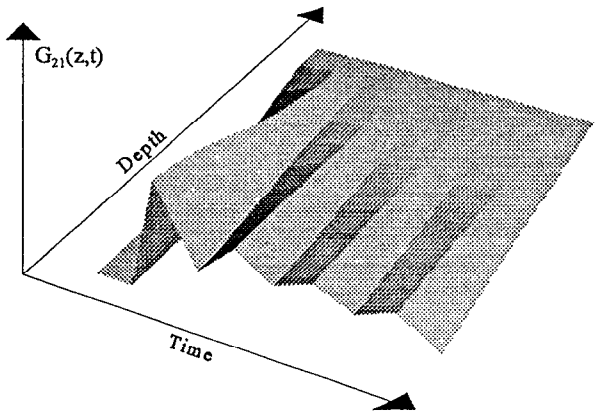

FIG. 2. The Green function $G_{21}(z,t)$.

tral Legendre approach and solved the partial differential equations given in Ref. 6 for the transmission kernels $T^{\pm}(z,L,t;\kappa)$ and then solved the set of equations of the Green functions which are also given in Ref. 6. These equations are relations between the Green functions, reflection kernels and the transmission kernels. The values of the Green functions generated by the method of this paper and those generated through the method of Ref. 6 were in close agreement. As a demonstration, the values of the function $G^9{}_{11}(\alpha,\beta)$ generated through both methods at the collocation points $\beta=-1$ and $\beta=0.165\ 28$ are given in Table II. These collocation points correspond to $t=0$ s and $t=0.058\ 26$ s, respectively. The CPU execution time in this example was 2 s on a Sun-Sparc Station II.

VI. CONCLUSION

An alternative scheme for solving a one-dimensional inverse problem for inhomogeneous nonconductive media is proposed in this paper. The method is based upon constructing the Nth degree interpolation polynomial to approximate the Green functions and the phase velocity function using Legendre–Gauss–Lobatto collocation points. The input to the scheme is the reflection kernel. From this input data, the scheme generates values of the Green functions and the phase velocity function at the collocation points through the solution of a set of algebraic equations. The rapid rate of convergence of pseudospectral Legendre approximations, see Ref. 13, and the Kronecker property that is presented in Eq. (4) makes the scheme very attractive.

(Received 2 June 1995; accepted for publication 26 January 1996)

We present a manifestly conformally invariant formulation of Maxwell equations on asymptotically flat space–times. It is shown how to construct regular self-dual and antiself-dual fields from suitable radiation data, and the general solution as a sum of fields with both types of duality. The basic variable in this formalism is a scalar field F defined as the phase of the parallel propagator (associated with the Maxwell potential) from interior points to future null infinity along null geodesics. Field equations equivalent to the source free Maxwell's equations are derived for F. A perturbative solution based on Huygens' principle is proposed. Exact solutions are found for H-spaces. The use of these results on gravitational lensing is discussed. © *1996 American Institute of Physics.* [S0022-2488(96)00507-5]

I. INTRODUCTION

The global behavior of electromagnetic radiation on curved space–times is used in astrophysics to study several interesting phenomena. In gravitational lensing one studies the global behavior of null geodesics in a gravitational field produced by sources with compact support. Several authors have also used parallel propagation of vectors on null geodesics to study the behavior of polarized light. Recently, a non-local formalism for general relativity (GR) was presented[1,2] where the fundamental variable contains all the information of the null geodesics of the given space–time, thus providing a useful tool to study electromagnetic radiation in the geometrical optics limit.

It has also been emphasized that when the wavelength of the radiation is of the same order of magnitude of the gravitational radius of an intervening compact object, diffraction effects have to be taken into account. That is, in this case one needs wave optics on a curved background. However, it is difficult to find global solutions of Maxwell's equations on a general space–time since a Green function for this problem is generally not available. In practice, one either tries to find a Green function perturbatively, or assumes a flat background except on a small region of interest, or considers space–times with high degrees of symmetry.

We present here a new formulation of Maxwell theory where the basic variable,

$$F \equiv \int_{\gamma} A_a dx^a, \tag{I.1}$$

a line integral of the Maxwell potential along a specific path γ, is a non-local object and where regularity of this variable is equivalent to regularity of the Maxwell field on a global scale. We derive field equations for this variable whose regular solutions automatically yield global solutions of the Maxwell's equations. Even the perturbed solutions of these non-local equations are, by construction, regular fields on a global scale. The formalism has another interesting feature, namely, the background geometry enters the field equations only through its conformal structure.[1,2] Thus, this non-local formulation of Maxwell theory is manifestly conformally invariant. It is also well adapted to discuss different global problems concerning electromagnetic radia-

tion. In the geometrical optics limit one recovers the description of the null geodesics via the non-local formulation of GR. In the full theory the formalism defines in a precise way Huygens or non-Huygens propagation of electromagnetic radiation on a curved background.

Before presenting technical details we briefly review some results already obtained using the basic variable in our formalism. In recent years this variable has received considerable attention not only for Maxwell Theory, but also for Yang–Mills Theory and General Relativity.[3–6] In 1975 Wu and Yang[7] suggested that the parallel propagator of a Maxwell potential A_a along a path γ,

$$\exp\left(-i\int_\gamma A_a dx^a\right)=\exp(-iF), \tag{I.2}$$

was better suited than the Maxwell field or potential to describe electromagnetism. [Note that our variable F is the phase of the propagator introduced in (I.2).]

In 1980 Sparling[8,9] obtained the field equations for the phase of the parallel propagator associated with a self-dual Maxwell field along null geodesics in Minkowski space. A brief description of his method follows.

Denoting by x points in the space–time, $(u,\zeta,\bar{\zeta})$ points in the future null boundary $\mathscr{I}^+$, the Sparling equation has the simple form

$$\eth F=-A_R(x,\zeta,\bar{\zeta}), \tag{I.3}$$

where F, the phase of the parallel propagator (I.2), is the line integral of the Maxwell potential along a null geodesic that begins at a point x and ends at null infinity intersecting the generator $(\zeta,\bar{\zeta})$ of $\mathscr{I}^+$; the "eth operator" $\eth$ is essentially $\partial/\partial\zeta$, and A_R, the "restricted" free data at $\mathscr{I}^+$, is obtained by evaluating the data $A(u,\zeta,\bar{\zeta})$ at the intersection of the future light cone of x with $\mathscr{I}^+$, the "light cone cut". In a general, asymptotically flat (in future null directions) space–time, the light cone cuts are 2-surfaces embedded in $\mathscr{I}^+$, described parametrically as

$$u=Z(x,\zeta,\bar{\zeta}). \tag{I.4}$$

In Minkowski space–time the Z function has a simple form in standard Lorentz coordinates x^a,

$$Z(x,\zeta,\bar{\zeta})=x^a l_a(\zeta,\bar{\zeta}), \tag{I.5}$$

where $l_a(\zeta,\bar{\zeta})$ spans the sphere of null covectors at x. Its explicit form in Minkowski coordinates is given in Appendix B.

Using the Green function of the eth operator one obtains the regular solution of (I.3) which, after a reconstruction procedure, yields the general solution of the self-dual Maxwell equations in Minkowski space.

Notice that in a similar way [starting from the complex conjugate of (I.3)] one obtains the field equations for the antiself-dual case. Furthermore, adding both solutions yields a general real Maxwell field satisfying the source free equations. Thus (I.3), a single equation for a scalar field, is equivalent to the full set of Maxwell equations on Minkowski space.

Is it possible to generalize the Sparling equation to curved space–times? Since one knows that, due to the linearity of the theory, self-dual data must produce a self-dual field, in principle it is possible to find a suitable generalization of Sparling's formalism for a "self-dual" parallel propagator on a curved space–time.

In this paper we present this generalization. We introduce the phase of the parallel propagator for a self-dual field associated with a special set of open curves, i.e., null geodesics that start at an interior point of the space–time and end at $\mathscr{I}^+$. We obtain the field equation for this propagator equivalent to the self-dual Maxwell's equations on curved space–times. This is a single equation on a complex non-local function where the free data enters as a source term.

The cut function Z (I.4) that describes the light cone cuts of $\mathscr{I}^+$ plays a fundamental role in our approach. As shown in Refs. 1 and 2, all the information about the conformal geometry of space–time is encoded in Z. Since Maxwell's equations are conformally invariant, the function Z contains precisely the needed information of the background space–time geometry. As a result we obtain a manifestly conformally invariant formulation of regular Maxwell's fields on space–times which are asymptotically flat at future null infinity.

In section II we review the geometrical meaning of Z, show its relationship to the underlying conformal metric and obtain some results that are used in the derivation of the field equation for our variable. In section III, we present the non-local variable F and give its kinematical relation with the Maxwell field. We derive field equations for F equivalent to the self-dual and antiself-dual Maxwell's equations and show how to recover a general Maxwell field from knowledge of F. A perturbative method for solving the field equation is presented and then used to show the non-Huygens nature of Maxwell fields propagating on curved space–times. A variation of this method to study fields on space–times which are small deviations from Minkowski space is suggested. In section IV the formalism is applied to obtain exact solutions in H spaces. The zeroth and first order solution to the field equation on small deviations from Minkowski space are also calculated. Section V contains a summary of the results and a brief discussion on the use of this formalism to approach the problems of scattering and gravitational lensing. In Appendix A we derive the equation for F in the general case (i.e., complex Maxwell fields without a definite duality), show the equivalence with the self-dual formulation and show how to recover the field strength and potential from F. Appendix B contains some review material on differential equations involving the eth operator and their Green functions, necessary for the article to be self-contained. Appendices C and D contain auxiliary calculations.

II. GEOMETRICAL PRELIMINARIES

A. The notion of duality

On the space–time (M, g_{ab}) a volume form ϵ_{abcd} is chosen satisfying the normalization condition

$$\epsilon_{abcd}\epsilon^{abcd} = -4!, \tag{II.1}$$

where, as usual, indices are raised using the inverse of the metric. Up to a sign (i.e., a choice of orientation), (II.1) singles out a unique volume form, which, together with the inverse of the metric, is used to construct the dual operator, a conformally invariant linear operator acting on 2-forms as

$$W_{ab} \to {}^*W_{ab} \equiv \tfrac{1}{2}\,\epsilon_{abcd} g^{ce} g^{df} W_{ef}. \tag{II.2}$$

From (II.1) and (II.2) it follows that ${}^{**}W_{ab} = -W_{ab}$, and so the possible eigenvalues of the dual operator are $\pm i$. A 2-form is called self-dual (SD) [antiself-dual (ASD)] if it is an eigenvector corresponding to the eigenvalue $i[-i]$. Under the inner product $g^{ac} g^{bd} W_{ab} Q_{cd}$ SD and ASD 2-forms are orthogonal to each other. It is important to note that every 2-form can be written as a sum of eigenvectors of the dual operator:

$$W_{ab} = W^+_{ab} + W^-_{ab}, \quad W^{\pm} \equiv \tfrac{1}{2}\,[W_{ab} \mp i {}^*W_{ab}]. \tag{II.3}$$

$W^+_{ab}[W^-_{ab}]$ is commonly referred to as "the SD [ASD] part of W_{ab}." This decomposition allows a compact form for (source free) Maxwell's equations, explicitly exhibiting their conformal invariance,

$$\partial_{[a} F^+_{bc]} = 0, \quad \partial_{[a} F^-_{bc]} = 0. \tag{II.4}$$

For real fields, the second equation is the complex conjugate of the first one, and Maxwell's equations reduce to a first order equation on a complex potential A_b^+,

$$\tfrac{1}{2}\,\epsilon_{ab}{}^{cd}\partial_{[c}A^+_{d]}=i\,\partial_{[a}A^+_{b]}, \tag{II.5}$$

instead of the usual second order equation on a real potential. It is clear from (II.4) and (II.3) that SD [ASD] closed 2-forms satisfy Maxwell's source free equations, and also that any solution of these equations is the sum of a SD closed 2-form and an ASD one. It follows that the problem of solving Maxwell's equations on (M,g_{ab}) amounts to finding SD and ASD closed 2-forms satisfying appropriate "initial conditions". The first step is to construct the dual operator (II.2), which, being conformally invariant, can be readily obtained from the Z function, as it is shown in the following subsection.

B. A non-local description of space–time

The theory of light cone cuts of null infinity[1,2] offers a completely different approach to general relativity. Instead of using a local field, the metric g_{ab}, to describe the geometry of the space–time, one introduces a non-local function that plays an equally important role, as it contains all the information of the conformal structure of space–time. In particular, it yields the null geodesics. A brief description of the kinematical features of this theory follows. The dynamics as well as other properties of this non-local variable are not presented here (in our formulation of Maxwell theory the background geometry is assumed fixed) but they can be found in (Refs. 1 and 2) and references therein.

Assume the space–time (M,g_{ab}) is asymptotically flat at future null infinity, $\mathscr{I}^+$. The intersection of the future null cone from $x^a\in M$ with $\mathscr{I}^+$ is a 2-surface called a light cone cut of null infinity. Introducing on $\mathscr{I}^+$ Bondi coordinates $(u,\zeta,\bar\zeta)$ this cut can be locally described as

$$u=Z(x^a,\zeta,\bar\zeta). \tag{II.6}$$

Assuming the smooth function Z is given, we introduce the following scalars:

$$u=Z(x^a,\zeta,\bar\zeta)\quad \omega=\eth\dot Z,\quad \bar\omega=\eth Z,\quad r=\eth\bar\eth Z, \tag{II.7}$$

where the $\eth$ (eth) and $\bar\eth$ (eth-bar) operators, defined in (B1) and (B2), are essentially partial derivatives with respect to ζ and $\bar\zeta$ respectively. For each $(\zeta,\bar\zeta)\in S^2$ the scalars (II.7) define a coordinate system. An alternative notation found in the literature is

$$(u,\omega,\bar\omega,r)=(\theta^0,\theta^+,\theta^-,\theta^1)=\theta^i,$$

with its gradient and dual vector basis denoted by $\theta^i{}_{,a}$, and θ^a_i, respectively. In past references, however, the following associated vector basis has been used:

$$\hat L^a=\theta^a_1,\quad \hat M^a=-\theta^a_{-1},\quad \hat{\bar M}^a=-\theta^a_+,\quad \hat N^a=\theta^a_0, \tag{II.8}$$

and we will keep the above convention in this work.

The coordinates (II.7) have an interesting geometrical interpretation: the points x^a satisfying $u=Z(x^a,\zeta,\bar\zeta)=$const. form the past light cone of $(u,\zeta,\bar\zeta)$ at $\mathscr{I}^+$, ω and $\bar\omega$ determine the direction angle of a geodesic on that cone and τ uniquely locates a point on that geodesic.[10,11] It follows that any null geodesic is characterized by the parameters $(u,\omega,\bar\omega,\zeta,\bar\zeta)$, and that the tangent at x to the affinely parametrized geodesic $[u=Z(x,\zeta,\bar\zeta),\ \omega=\eth Z(x,\zeta,\bar\zeta),\ \bar\omega=\bar\eth Z(x,\zeta,\bar\zeta);\zeta,\bar\zeta]$ is the null vector

$$Z^a(x,\zeta,\bar\zeta)\equiv g^{ab}Z_{,b}(x,\zeta,\bar\zeta). \tag{II.9}$$

By letting $(\zeta,\bar{\zeta})$ range over the sphere, this vector ranges over the -future- cone of null directions at x^a. Thus, the function Z determines the conformal structure of the space–time. As done in Ref. 1, we exploit the fact that Z depends smoothly on $(\zeta,\bar{\zeta})$ to obtain the components $g^{ij}(x,\zeta,\bar{\zeta})\equiv g^{ab}\theta^i_{,a}\theta^j_{,b}$ of the metric in the coordinate systems (II.7). The starting point is the fact that (II.9) is null, which immediately implies that

$$g^{00}=g^{ab}(x)\,\theta^0_{,a}\theta^0_{,b}=0. \tag{II.10}$$

Note that this result is true for any value of $(\zeta,\bar{\zeta})$. Thus, $\eth$ and $\bar{\eth}$ of (II.10) are also equal to zero. However, explicitly taking $\eth$ and $\bar{\eth}$ of (II.10) plus the fact that the metric does not depends on $(\zeta,\bar{\zeta})$ yields

$$\eth^{00}_g=2g^{ab}(x)\,\theta^0_{,a}\eth\theta^0_{,b}=2g^{0+}=0,\quad \bar{\eth}g^{00}=2g^{0-}=0. \tag{II.11}$$

Thus, we have obtained three (trivial) components of the conformal metric. As the above equations suggest, the metric components in this coordinate system are obtained by taking a sufficient number of $\eth$ and $\bar{\eth}$ derivatives of (II.10).

Taking $\eth\bar{\eth}$ of (II.10) we obtain

$$g^{-+}=-g^{01}. \tag{II.12}$$

Taking $\eth^2$ of (II.10) we get

$$g^{++}+g^{ab}Z_{,a}\Lambda_{,b}=0,$$

where $\Lambda\equiv\eth^2Z$. Assuming Λ is expressed in the θ^i coordinates as $\Lambda(\theta^i,\zeta,\bar{\zeta})$ one has $\Lambda_{,b}=\Lambda_{,i}\theta^i_{,b}$. Using the previous results we immediately obtain

$$g^{++}=-g^{01}\Lambda_{,r}. \tag{II.13}$$

We can continue this procedure until all the components (up to a choice of g^{01}) are obtained [1]. It is worth mentioning that knowledge of Λ determines all the non-trivial $g^{ij}(\theta^i,\zeta,\bar{\zeta})$. The final form of the metric is given by

$$g^{01}\begin{pmatrix} 0 & 0 & 0 & 1\\ 0 & -\Lambda_{,r} & -1 & h^{1+}\\ 0 & -1 & -\bar{\Lambda}_{,r} & h^{1-}\\ 1 & h^{1+} & h^{1-} & h^{11}\end{pmatrix}, \tag{II.14}$$

where the h^{1j} depend explicitly on Λ [1]. (In the derivation of our field equations, however, they will not be needed since we are only looking for the projection of the metric on the null surfaces $Z=$const).

Thus, in this approach the function Z serves a dual purpose: $\eth^2Z\equiv\Lambda$ determines the conformal metric and (II.7) are natural coordinates that allow simple expressions for many relevant tensor fields, as the metric itself. In the particular case $\Lambda=0$ we obtain conformal Minkowski space and, for each $(\zeta,\bar{\zeta})$, (II.7) becomes a null coordinate system (Appendix B). In general, θ^0 is a null coordinate, and simple expressions for both the null cone congruence from a point x^a and the geodesic deviation vectors of this congruence are obtained using the θ^i coordinates. Since these results will be used in following sections, we present them now. The detailed calculations can be found in Appendix C.

If we denote by $x^a(x_0^b,\zeta,\bar{\zeta},r)$ the parametric form of the null cone with apex at a point $x_0^b \in M$, $r = \eth\bar{\eth}Z(x^a,\zeta,\bar{\zeta}) - \eth\bar{\eth}Z(x_0^a,\zeta,\bar{\zeta})$ [refer to (C.1)–(C.3)], then a null geodesic on this cone is characterized by a fixed value of $(\zeta,\bar{\zeta})$ (a generator of $\mathscr{I}^+$). Neighboring rays around this fixed null geodesic, corresponding to different values of ζ, are described by the geodesic deviation vector $M^a \equiv \partial x^a$. As shown in Appendix C [see (C.6)], M^a can be written as

$$M^a \equiv (1+\zeta\bar{\zeta})\frac{\partial x^a(x_0,\zeta,\bar{\zeta},r)}{\partial\zeta} = (r-r_0)\hat{M}^a + (\Lambda-\Lambda_0)\hat{\bar{M}}^a - \eth(r-r_0)\hat{L}^a, \tag{II.15}$$

where the subindex 0 means that the corresponding scalar is evaluated at the apex x_0.

Finally, we present the explicit form of the dual of the light cone 2-surface element $\hat{L}_{[a}M_{b]}$ in our basis since this result is later used in the derivation of the field equations. We start by noting from (II.9), (II.14) and (II.8) that

$$\begin{aligned} Z^a &= g^{ab}u_{,b} = g^{01}\hat{L}^a, \\ g^{ab}\omega_{,b} &= g^{1+}\hat{L}^a + g^{01}\Lambda_{,r}\hat{\bar{M}}^a + g^{01}\hat{M}^a. \end{aligned} \tag{II.16}$$

The determinant of (II.14) yields the volume form

$$\epsilon = \frac{-i}{\sqrt{p}(g^{01})^2}\, du\wedge d\omega\wedge d\bar{\omega}\wedge dr, \quad p = 1-\Lambda_{,r}\bar{\Lambda}_{,r}, \tag{II.17}$$

which, together with (II.8), (II.2) and (II.16), gives

$$*\hat{L}_{[a}\hat{M}_{b]} = \frac{-i}{\sqrt{p}(g^{01})^2}\, u_{[,a}\omega_{,b]} = \frac{-i}{\sqrt{p}}[\hat{L}_{[a}\hat{M}_{b]} + \Lambda_{,r}\hat{L}_{[a}\hat{\bar{M}}_{b]}]. \tag{II.18}$$

(II.15) and (II.18) yield

$$*\hat{L}_{[a}M_{b]} = -i[\hat{L}_{[a}M_{b]} + 2\bar{f}\hat{L}_{[a}\hat{M}_{b]} + 2g\hat{L}_{[a}\hat{\bar{M}}_{b]}], \tag{II.19}$$

where

$$\begin{aligned} f &= \tfrac{1}{2}[(r-r_0)h - (1+h)(\bar{\Lambda}-\bar{L}_0)\Lambda_{,r}], \\ g &= \tfrac{1}{2}[(1+h)(r-r_0)\Lambda_{,r} - (2+h)(\Lambda-\Lambda_0)], \end{aligned} \tag{II.20}$$

and $h \equiv 1/\sqrt{p} - 1$. Alternatively, using (II.3),

$$\hat{L}_{[a}M^+_{b]} = -[\bar{f}\hat{L}_{[a}\hat{M}_{b]} + g\hat{L}_{[a}\hat{\bar{M}}_{b]}]. \tag{II.21}$$

Note that in the $\Lambda=0$ limit $\hat{L}_{[a}M_{b]}$ is ASD. Thus f and g represent the departure of $\hat{L}_{[a}M_{b]}$ from being an ASD 2-form.

III. A NON-LOCAL VARIABLE FOR MAXWELL FIELDS

A. Definitions and kinematical relations

Let A_a be a Maxwell potential whose projection to $\mathscr{I}^+$ has vanishing contraction with vectors tangent to the generators, $F_{ab} = 2\nabla_{[a}A_{b]}$ be its field strength. We define our basic variable F as

$$F(x,\zeta,\bar{\zeta})=-\int_x^\infty A_a Z^a ds=-\int_x^\infty A_a \hat{L}^a dr, \tag{III.1}$$

where the integral is taken along the null geodesic $l_x(\zeta,\bar{\zeta})$ that connects the point x with the generator $(\zeta,\bar{\zeta})$ of $\mathscr{I}^+$, s is an affine length and the second equality follows directly from (II.16). F is a non-local function on the space of null directions of space–time with a simple geometrical meaning: $G\equiv e^{iF}$ gives the parallel transport along $l_x(\zeta,\bar{\zeta})$ between x and the point at which $l_x(\zeta,\bar{\zeta})$ intersects $\mathscr{I}^+$. As A_a is a regular potential with a smooth extension to $\mathscr{I}^+$, the integrand of (III.1) behaves as s^{-2} when $s\to\infty$, thus giving a finite F. Conversely, if F is assumed to be regular, then the integrand "peels" appropriately.

We consider now the problem of obtaining A_a from a given regular F, i.e., inverting (III.1). This will be particularly important when we impose field equations on F since the potential A_a will then be a derived object. It follows from (III.1) and (II.9) that F satisfies

$$Z_{,a}(\nabla^a F-A^a(x))=0. \tag{III.2}$$

Taking a sufficient number of $\eth$ and $\bar{\eth}$ derivatives of (III.2) we obtain the components of $A^a(x)$ in the θ_i^a basis:

$$\begin{aligned} Z_{,b}(A^b-\nabla^b F)&=0,\\ \eth Z_{,b}(A^b-\nabla^b F)&=Z_{,b}\nabla^b \eth F,\\ \bar{\eth} Z_{,b}(A^b-\nabla^b F)&=Z_{,b}\nabla^b \bar{\eth} F,\\ \eth\bar{\eth} Z_{,b}(A^b-\nabla^b F)&=\bar{\eth} Z_{,b}\nabla^b \eth F+\eth Z_{,b}\nabla^b \bar{\eth} F+Z_{,b}\nabla^b \eth\bar{\eth} F, \end{aligned} \tag{III.3}$$

from where

$$A^a=\nabla^a F+(\theta_-^a \theta_{,b}^0+\theta_1^a\theta_{,b}^+)\nabla^b\bar{\eth}F+(\theta_+^a\theta_{,b}^0+\theta_1^a\theta_{,b}^-)\nabla^b\eth F+\theta_1^a\theta_{,b}^0\nabla^b\eth\bar{\eth}F. \tag{III.4}$$

Note that (III.4) naturally induces a gauge transformation giving a new potential,

$$A'_b=A_b-\nabla_b F.$$

Consider now the 2-surface $\Delta_x(\zeta,\bar{\zeta})$ swept by $l_x(\zeta,\bar{\zeta})$ as ζ moves in $[\zeta,\zeta+d\zeta]$ with $\bar{\zeta}$ fixed, denote by $\partial\Delta_x(\zeta,\bar{\zeta})$ its closed boundary constructed from two neighboring null geodesics $l_x(\zeta,\bar{\zeta})$ and $l_x(\zeta+d\zeta,\bar{\zeta})$, closed at $\mathscr{I}^+$ by the connecting vector $M^a d\zeta/P$. Using the phase of the holonomy operator,

$$\mathscr{H}=\int_{\partial\Delta_x(\zeta,\bar{\zeta})} A_a dx^a=\int_{\Delta_x(\zeta,\bar{\zeta})} F_{ab}dx^a dx^b, \tag{III.5}$$

one can find a useful relationship between F, the field strength F_{ab} and the free Maxwell data at $\mathscr{I}^+$.

We recall that source free Maxwell fields are uniquely determined by the data $(A(u,\zeta,\bar{\zeta}),\bar{A}(u,\zeta,\bar{\zeta}))$ on the "initial value" surface $\mathscr{I}^+$ [12]. These functions are defined by the following equations:

$$A(u,\zeta,\bar{\zeta})\equiv\lim_{\mathscr{I}^+} A_a M^a,\quad \bar{A}(u,\zeta,\bar{\zeta})\equiv\lim_{\mathscr{I}^+} A_a\bar{M}^a, \tag{III.6}$$

where the limit is taken along $l_x(\zeta,\bar{\zeta})$, x is any point satisfying $Z(x,\zeta,\bar{\zeta})=u$, and M^a and $\bar{M}^a$, given in (C.6) and c.c., are geodesic deviation vectors of the future null cone of x (see Appendix C). A and $\bar{A}$ are, respectively, associated to the SD and ASD parts of the field by the following equations (obtained from Ref. 13):

$$\lim_{\mathscr{I}^+} F^-_{ab}M^a\bar{M}^b=\eth\bar{A}, \quad \lim_{\mathscr{I}^+} F^+_{ab}M^a\bar{M}^b=-\bar{\eth}A. \tag{III.7}$$

Thus, $\bar{A}=0$ [$A=0$] for SD [ASD] fields. For real fields, $\bar{A}$ is the complex conjugate of A, the two degrees of freedom of the radiation fields are contained in a single complex function.

Defining the differential holonomy as

$$H(x,\zeta,\bar{\zeta})\equiv\int_x^\infty F_{ab}\hat{L}^aM^b dr, \tag{III.8}$$

i.e. $\mathscr{H}=Hd\zeta/P$, it follows directly from (III.5) and (III.6) that

$$\eth F(x,\zeta,\bar{\zeta})+A_R(x,\zeta,\bar{\zeta})=H(x,\zeta,\bar{\zeta}), \tag{III.9}$$

where the complex scalar $A_R(x,\zeta,\bar{\zeta})$ is the restriction of the free data $A(u,\zeta,\bar{\zeta})$ at $\mathscr{I}^+$ to the cut $u=Z(x,\zeta,\bar{\zeta})$, i.e.,

$$A_R(x,\zeta,\bar{\zeta})\equiv A(u=Z_1\zeta,\bar{\zeta}). \tag{III.10}$$

In an analogous way, using the holonomy phase $\bar{\mathscr{H}}$ around the loop $\partial\bar{\Delta}_x(\zeta,\bar{\zeta})$[$\Delta_x(\zeta,\bar{\zeta})$ being the 2-surface swept by $l_x(\zeta,\bar{\zeta})$ as $\bar{\zeta}$ moves in $[\bar{\zeta},\bar{\zeta}+d\bar{\zeta}]$ with ζ fixed] and defining

$$\bar{H}(x,\zeta,\bar{\zeta})\equiv\int_x^\infty F_{ab}\hat{L}^a\hat{M}^b dr, \tag{III.11}$$

one obtains

$$\bar{\eth}F(x,\zeta,\bar{\zeta})+\bar{A}_R(x,\zeta,\bar{\zeta})=\bar{H}(x,\zeta,\bar{\zeta}), \tag{III.12}$$

with $\bar{A}_R(x,\zeta,\bar{\zeta})$ the restriction of $\bar{A}(u,\zeta,\bar{\zeta})$ to the cut

$$\bar{A}_R(x,\zeta,\bar{\zeta})=\bar{A}(u=Z,\zeta,\bar{\zeta}) \tag{III.13}$$

(we will omit the subindex R from now on).

Equations (III.8) and (III.9) give $\eth F$ as a functional of the field strength F_{ab} and the free data $A(u,\zeta,\bar{\zeta})$. One can invert (III.8), using (III.9), to obtain F_{ab} in terms of $\eth F$ and c.c. This is done in Appendix A. The desired relationship is

$$\hat{\phi}\equiv F_{ab}(x)\hat{L}^a\hat{M}^b=\left[\frac{(\eth F)_{,r}-\Lambda_{,r}(\bar{\eth}F)_{,r}}{1-\Lambda_{,r}\bar{\Lambda}_{,r}}\right]_{,r}\equiv\hat{\Phi}[F] \quad \text{and c.c.} \tag{III.14}$$

Note that F_{ab} does not depend on $(\zeta,\bar{\zeta})$, whereas $\hat{L}^a\hat{M}^b$ does. Thus, evaluating (III.14) for different values of $(\zeta,\bar{\zeta})$ yields different components of $F_{ab}(x)$. Alternatively, we can take a sufficient number of $\eth$ and $\bar{\eth}$ derivatives of (III.14) [as was done in (III.3)] to obtain the components of F_{ab} in the $\theta^i_{,a}$ basis.

B. The field equations for F

We now want to find the equation satisfied by F when the field strength F_{ab} is a (closed) SD 2-form. The fact that F_{ab} is closed was already used in the definition of F and in eq. (III.9) as an application of the Stokes theorem.

A SD field satisfies

$$F_{ab}=F^{+}_{ab}. \tag{III.15}$$

Thus, integrating (III.15) on $\Delta_x(\zeta,\bar{\zeta})$ yields

$$H=\int_x^\infty F_{ab}\hat{L}^{[a}M^{b]}dr=\int_x^\infty F^{+}_{ab}(\hat{L}^{[a}M^{b]})dr=\int_x^\infty F^{ab}(\hat{L}_{[a}M_{b]})^{+}dr, \tag{III.16}$$

where the last equality follows from the vanishing contraction between SD and ASD 2-forms. Inserting (II.21) in (III.16) and using (III.9) and (III.14) yields the following integro-differential equation for F in the SD case (the + sign is used to indicate that the associated field is SD),

$$\eth F^{+}+A+\int_x^{My}(\bar{f}\hat{\Phi}[F^{+}]+g\hat{\bar{\Phi}}[F^{+}])dr=0. \tag{III.17}$$

Equation (III.17) is the desired generalization of the Sparling equation[8,9] to curved space-times.

A similar calculation yields the equation for F in the ASD case,

$$\bar{\eth}F^{-}+\bar{A}+\int_x^\infty(f\hat{\bar{\Phi}}[F^{-}]+\bar{g}\hat{\Phi}[F^{-}])dr=0. \tag{III.18}$$

A few remarks follow.

1. The kernel of the eth operator-acting on spin weight 0 functions- is the set of constant functions on the sphere (Appendix B). It then follows from (III.17) and (III.14) that the solutions of eq. (III.17) have the ambiguity of an arbitrary additive function $h(x)$. The origin of this term can be traced back to the definition of F.[14] If we integrate (III.17) using the Green function $G_{0,1'}(\zeta,\bar{\zeta};\zeta',\bar{\zeta}')$ for $\eth$ given in (B.8) (subindices indicate the spin weight for each variable), we obtain the following compact form for (III.17):

$$F-\mathscr{G}[F]=\mathscr{F}, \tag{III.19}$$

where

$$\mathscr{F}\equiv-\int_{S^2}G_{0,-1'}(\zeta,\bar{\zeta};\zeta',\bar{\zeta}')A_R(x,\zeta',\bar{\zeta}')dS' \tag{III.20}$$

and

$$\mathscr{G}[\cdot]\equiv-\int_{S^2}G_{0,-1'}(\zeta,\bar{\zeta};\zeta',\bar{\zeta}')\left(\int(\bar{f}\hat{\Phi}[\cdot]+g\hat{\bar{\Phi}}[\cdot])dr'\right)dS'. \tag{III.21}$$

In (III.21), the line integral is along $l_x(\zeta',\bar{\zeta}')$, and extends from x to $\mathscr{I}^+$. By omitting the term $h(x)$ on the r.h.s. of (III.19) we have selected the particular solution (i.e., chosen the gauge[14]) satisfying the condition $\int_{S^2}F(x,\zeta,\bar{\zeta})dS=0$. This follows from the fact that $\int_{S^2}G_{0,1'}(\zeta,\bar{\zeta};\zeta',\bar{\zeta}')dS=0$.[15] Analogous comments to this and the following remarks apply to the ASD case.

2. We know that there is a one to one correspondence between the free data $A(u,\zeta,\bar{\zeta})$ and the solution of the source free Maxwell's equations. Therefore it is appropriate to ask if the regular solutions to (III.19) uniquely correspond to a given $A(u,\zeta,\bar{\zeta})$. Although this issue is very involved due to the non-local nature of the equation, in those cases where a norm $\|\cdot\|$ can be defined on the linear space V of admissible functions $F(x,\zeta,\bar{\zeta})$, such that the linear operator $\mathcal{G}$ is continuous and has a norm less than 1 (meaning $\sup_V \|\mathcal{G}[F]\|/\|F\|<1$), the uniqueness of the solution of (III.19) is easily proved. In this case the operator $I-\mathcal{G}$ is known to be invertible, with its inverse given by the -convergent- power series,

$$[I-\mathcal{G}]^{-1}=I+\mathcal{G}+\mathcal{G}^2+\mathcal{G}^3+\dots . \tag{III.22}$$

The definition of $(V,\|\cdot\|)$ is a technically involved problem we defer for future work. Note however that, as $\mathcal{G}=0$ when $\Lambda=0$, any natural norm will satisfy the condition $\|\mathcal{G}\|<1$ when $\Lambda\simeq 0$ [this limit corresponds to a small deviation from -conformal- Minkowski space (Appendix B)].

From now on, we will assume that the linear operator $\mathcal{G}$ is such that (III.19) has a unique solution.

3. Although we have only proved that SD Maxwell's equations imply (III.19), the converse is also true. The equivalence of both sets of equations follows from the uniqueness of the solution of (III.19). A is the data for a unique SD Maxwell field F_{ab}. If B_a is the potential satisfying the conditions in Ref. 14 and

$$\int_{S^2}\left[\int_x^\infty B_a Z^a ds\right] dS=0,$$

then (III.1) constructed from B_a is a solution of (III.19) (remark 1). Now, F constructed in this way is *the only* solution of (III.19). It follows from remark 1 that, when applied to a solution of (III.17), (III.4) yields a potential $A_a(x)=B_a(x)+\nabla_a h(x)$ for the SD field $F_{ab}(x)$.

4. The equation satisfied by F in the general case is derived in Appendix A. It is shown that we can first solve for the SD and ASD parts and then add them up, i.e., if

$$F\equiv F^+ + F^-, \tag{III.23}$$

where F^+ and F^- are solutions of (III.17) and (III.18), respectively, then F yields -via (III.4) or (III.14)- a regular solution of the full source free-Maxwell's equations with "initial data" $(A,\bar{A})$ on the characteristic surface $\mathcal{I}^+$.

5. The function Z plays two distinct roles in the field equations (III.17), (III.18). It determines the restriction of the free data $A(\bar{A})$ to the cut $u=Z$ and it also enters the integral term via (II.20) and (III.14).

Two different perturbative methods to solve (III.17) may be suggested based on the information we have about Z:

(a) If the conformal geometry of the space–time is fully known (Z is given) we can construct the linear operator (III.21), and then apply (III.22) to solve (III.19),

$$F=[1-\mathcal{G}]^{-1}\mathcal{F}=[1+\mathcal{G}+\mathcal{G}^2+\mathcal{G}^3+\dots]\mathcal{F}. \tag{III.24}$$

Note that if F_n is the sum of the first n terms in (III.24) then

$$F=\lim_{n\to\infty} F_n, \quad F_{n+1}=\mathcal{G}[F_n]+\mathcal{F}, \tag{III.25}$$

an iterative process that could have been suggested directly from (III.19).

(b) If the space–time is a small deviation from -conformal- Minkowski space, then $\Lambda\simeq 0$ (Appendix B) and we can expand F around $\Lambda=0$. The expansion is obtained by rearranging

(III.24) guided by the observation that f only contains terms Λ^n with $n\geqslant 2$, g contains terms with $n\geqslant 1$ (II.20) and $\mathscr{G}$ contains terms $n\geqslant 1$ (III.21). Slightly modifying (III.25) by keeping track of the different powers of Λ we generate an iterative method to solve (III.17) in nearly Minkowskian backgrounds. The first two terms are explicitly calculated in part B of the following section.

6. The leading order term $\mathscr{F}(x,\zeta,\bar{\zeta})$ in the expansion series (III.24) represents the Huygens' part of the field, i.e., the contribution of A_R (the restriction of the data A to the light cone cut of x). It is clear that the other terms are non-Huygens. As an example, to calculate $\mathscr{G}\mathscr{F}$ at x we need to know $\mathscr{F}$ in the future cone of x [this follows from (III.21) and (III.14)]. From (III.20), the restriction of the data to the whole region of $\mathscr{I}^+$ enclosed by the light cone cut of x is needed, not only its value at the cut. A similar reasoning shows that to calculate all the other terms in (III.24) we only need the data in this region, as expected from general principles (the field at x can not affect its value out of the cut on $\mathscr{I}^+$). This shows that, on a general background, Maxwell fields do not obey the Huygens' principle. In the perturbation scheme (III.24) one assumes that the background geometry is such that the Huygens' part is dominant. The (finite) perturbation series will therefore be a good approximation to the solution whenever the support of the Green function for Maxwell's equations lies mainly on the characteristic surfaces.

IV. APPLICATIONS

A. Propagation of Maxwell fields on self-dual space–times

It is well known that SD and ASD Maxwell fields have zero stress-energy tensor and thus are solutions of the Einstein–Maxwell equations on a vacuum space–time. If the vacuum space–time is self-dual these solutions represent the (classical) interaction of photons with non-linear gravitatons.[16] Before proceeding further with our formalism, we present a brief review of the geometry of asymptotically flat self-dual space–times, the so called H-spaces. For a detailed account the reader is referred to Ref. 16.

Given an arbitrary null hypersurface whose intersection with $\mathscr{I}^+$ is described by the "cut" $u=Z(\zeta,\bar{\zeta})$, the condition for it to have asymptotically vanishing shear is that it satisfies the so called "good cut equation":[16]

$$\eth^2 Z=\sigma_B(Z,\zeta,\bar{\zeta}), \tag{IV.1}$$

where $\sigma_B(u,\zeta,\bar{\zeta})$ is the asymptotic shear associated with the Bondi cut $u=$constant. Note that (IV.1) is a non-linear second order p.d.e for a function Z on the sphere. Since σ_B is complex and Z real, in general eq. (IV.1) has no real solutions.

However, if we allow Z to be complex and if $\sigma_B(u,\zeta,\bar{\zeta})$ can be extended to a holomorphic function of *three independent complex variables* $(u,\zeta,\bar{\zeta})$, one can show that the good cut equation (IV.1) has a four-parameter family of (complex) solutions $Z(x,\zeta,\bar{\zeta})$. The space of solutions $\{Z(x,\zeta,\bar{\zeta}),x\in C^4\}$ is called H-space and can be given the structure of a complex manifold. One can also show that the function Z induces a holomorphic metric g_{ab} on H that satisfies the vacuum equations and has a self-dual Weyl tensor.[16]

Since σ_B represents (from the standard formulation of GR) outgoing gravitational waves, one has available a natural linear structure of superposition of incoming waves that yields a non-linear superposition of self-dual metrics [eq. (IV.1) is intrinsically non-linear]. Moreover, despite all the non-linearity of the theory, the scattering of self-dual gravitational waves is trivial. The solutions of (IV.1) are usually called "non-linear gravitons." Although self-dual solutions of Einstein's equations seem to be a mathematical device with no physical interest, they play a key role in the canonical approach to quantum gravity.[5]

To obtain the general solution of Maxwell's equations on H-spaces we will assume the Z function, which is obtained by solving (IV.1), is given and repeat the steps leading to (II.14). However, in this case the conformal factor is chosen as $g^{01}=1$.[16] From this condition and the fact that $\nabla_a\Lambda=(d\sigma/du)Z_a\equiv\sigma_B Z_a$ [see (IV.1)], we can readily write down the metric components g^{ij},

$$g^{ij}(x,\zeta,\bar{\zeta})=\begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \\ 0 & -1 & -\bar{\Lambda}_{,r} & g^{1-} \\ 1 & 0 & g^{1-} & g^{11} \end{pmatrix}, \tag{IV.2}$$

with

$$g^{1-}=-\tfrac{1}{2}\,\eth\bar{\Lambda}_{,r} \quad g^{11}=-2+\bar{\Lambda}_{,r}\dot{\sigma}-\tfrac{1}{2}\,\eth^2\bar{\Lambda}_{,r}. \tag{IV.3}$$

We also observe from (II.20) and (IV.1) that, for H-spaces,

$$f=\bar{f}=g=0, \quad \bar{g}=\tfrac{1}{2}\,[(r-r_0)\bar{\Lambda}_{,r}-2(\bar{\Lambda}-\bar{\Lambda}_0)], \tag{IV.4}$$

i.e., in H-spaces the SD part of $\hat{L}_{[a}M_{b]}$ vanishes. Therefore, for self-dual space–times (III.17) adopts the simple form

$$\eth F=-A(Z(x,\bar{\zeta},\bar{\zeta}),\zeta,\bar{\zeta}). \tag{IV.5}$$

The solution of eq. (IV.5) is

$$F(x,\zeta,\bar{\zeta})=-\int_{S^2}G_{0,-1'}(\zeta,\bar{\zeta};\zeta',\bar{\zeta}')A(Z(x,\zeta',\bar{\zeta}'),\zeta',\bar{\zeta}')dS'. \tag{IV.6}$$

Note from (IV.5) that two terms on the r.h.s. of (III.4) vanish. The remaining term is simplified by the explicit form of the metric, eq. (IV.2), giving

$$A_a(x)=2(\nabla^b\eth F)Z_{[a}\eth Z_{b]}+\nabla_a F. \tag{IV.7}$$

Introducing the normalized null tetrad $\{\mathscr{L}^a,\mathscr{M}^a,\bar{\mathscr{M}}^a,\mathscr{N}^a\}$, where

$$\begin{aligned} &\mathscr{L}_a=\nabla_a u, \quad \mathscr{M}_a=\nabla_a\omega, \quad \bar{\mathscr{M}}_a=\nabla_a\bar{\omega}+\tfrac{1}{4}\,(\eth\bar{\Lambda}_{,r})\nabla_a u-\tfrac{1}{2}\,\bar{\Lambda}_{,r}\nabla_a\omega, \\ &\mathscr{N}_a=\nabla_a u+\nabla_a r+(\tfrac{1}{4}\,\eth^2\bar{\Lambda}_{,r}-\tfrac{1}{2}\,\bar{\Lambda}_{,r}\dot{\sigma})\nabla_a u-\tfrac{1}{4}\,(\eth\bar{\Lambda}_{,r})\nabla_a\omega, \end{aligned} \tag{IV.8}$$

and performing the natural gauge transformation $A_a\to A_a-\nabla_a F$, we can rewrite (IV.7) in a more convenient form. The details are given in Appendix D. The final result is

$$A_a(x)=\frac{1}{4\pi}\int_{S^2}dS\dot{A}(Z(x,\zeta,\bar{\zeta}),\zeta,\bar{\zeta})\bar{\mathscr{M}}_a(x,\zeta,\bar{\zeta}), \tag{IV.9}$$

$$F_{ab}(x)=\frac{1}{2\pi}\int_{s^2}dS[\ddot{A}\mathscr{L}_{[a}\bar{\mathscr{M}}_{b]}+\dot{A}\nabla_{[a}\bar{\mathscr{M}}_{b]}], \tag{IV.10}$$

where $\dot{A}\equiv(\partial/\partial u)A$.

To check that F_{ab} satisfies the field equations, we only have to prove that it is a SD field. Since $\mathscr{L}_{[a}\bar{\mathscr{M}}_{b]}$ is, by construction, SD (IV.8), we should only show that $\nabla_{[a}\bar{\mathscr{M}}_{b]}$ is SD, that is, it has vanishing contraction with any ASD 2-form. In particular, if we introduce the ASD 2-form basis,

$$\mathscr{L}_{[a}\mathscr{M}_{b]}, \quad \mathscr{L}_{[a}\mathscr{N}_{b]}+\bar{\mathscr{M}}_{[a}\mathscr{M}_{b]}, \quad \bar{\mathscr{M}}_{[a}\mathscr{N}_{b]},$$

we should check that

$$\mathscr{L}^a \mathscr{M}^b \nabla_{[a} \bar{\mathscr{M}}_{b]} = (\mathscr{L}^a \mathscr{N}^b + \bar{\mathscr{M}}^a \mathscr{M}^b) \nabla_{[a} \bar{\mathscr{M}}_{b]} = \bar{\mathscr{M}}^a \mathscr{N}^b \nabla_{[a} \bar{\mathscr{M}}_{b]} = 0,$$

where

$$\nabla_{[a} \bar{\mathscr{M}}_{b]} = \mathscr{M}_{[a} \nabla_{b]} (\bar{\Lambda} \bar{\Lambda}_{,r}).$$

The first equality is immediate, whereas the second and third follow from the following relationships in H-space,[17]

$$\bar{\Lambda}_{,\bar{\omega}} = -\tfrac{1}{2} \eth \bar{\Lambda}_{,r}, \quad \bar{\Lambda}_{,\omega} = \tfrac{1}{2} \bar{\eth} \bar{\Lambda}_{,r},$$
$$\bar{\Lambda}_{,u} = \tfrac{1}{2} \bar{\Lambda}_{,r} - \tfrac{1}{4} \bar{\Lambda}_{,r}^2 \dot{\sigma}_B - \tfrac{1}{4} \bar{\eth} \eth \bar{\Lambda}_{,r} + \tfrac{1}{8} \bar{\Lambda}_{,r} \eth^2 \bar{\Lambda}_{,r} - \tfrac{1}{16} (\eth \bar{\Lambda}_{,r})^2. \tag{IV.11}$$

The solution to the ASD field equation (III.18) can be obtained following a similar approach to the one outlined above. In this case, however, the equations are more involved since the integral term in (III.18) is not trivial. (Note that the ASD fields are not just the complex conjugate of SD fields, as the underlying manifold is complex in this case.) There is an alternative approach based on the observation from (IV.8) that for each $(\zeta, \bar{\zeta}) \in S^2$, the 2-form,

$$\mathscr{L}_{[a} \bar{\mathscr{M}}_{b]} = \nabla_{[a} u \nabla_{b]} \omega \tag{IV.12}$$

is closed and ASD and thus, it is a particular solution of Maxwell equations.

If we multiply (IV.12) with *any* complex scalar function of $(u, \zeta, \bar{\zeta})$ and then integrate on the sphere we should obtain the general ASD field. Taking eqs. (IV.9) and (IV.10) as a reference, we make the following ansatz for the general solution of the ASD field equations:

$$A_a(x) = \frac{1}{4\pi} \int_{S^2} dS \dot{\bar{A}}(Z(x, \zeta, \bar{\zeta}), \zeta, \bar{\zeta}) \bar{\mathscr{M}}_a(x, \zeta, \bar{\zeta}), \tag{IV.13}$$

$$F_{ab}(x) = \frac{1}{2\pi} \int_{s^2} dS \ddot{\bar{A}} \mathscr{L}_{[a} \bar{\mathscr{M}}_{b]}. \tag{IV.14}$$

It only remains to check that $\bar{A}$ in (IV.13) is in fact the asymptotic value of the Maxwell connection, as had previously been defined. This is done in Appendix D.

As pointed out in Appendix B, the function (B.5) $Z^{(0)}(x, \zeta, \bar{\zeta})$ with $x \in C^4$ is the general regular solution of the good cut equation (IV.1) when $\sigma_B = 0$. This function describes the light cone cuts of complex Minkowski space–time. Complex Minkowski space–time is therefore a particular case of H space where (IV.10) and (IV.14) reduce to D'Adamard [18] solutions of Maxwell equations. Thus, (IV.10) and (IV.14) are the generalizations of D'Adamard formula to H spaces.

B. Small deviations from Minkowski space

When discussing the propagation of light on vacuum space–times, it is often a good approximation to consider the background geometry as a small deviation from Minkowski space. In those cases we can replace F by the first terms in the expansion $F = \Sigma_n F^{(n)}$ in powers of Λ, as Minkowski space is characterized by the equation $\Lambda = 0$. We will apply method b of remark 5 in section III to calculate the first two terms of this perturbative solution. This method is based on the facts that $\mathscr{S}$ in (III.24) contains no $\mathscr{O}(\Lambda^0)$ term and that Z is a linear functional of Λ,

$$Z=Z^{(0)}+\int_{S^2}G_{0,-2'}\Lambda dS'\equiv Z^{(0)}+Z^{(1)}. \tag{IV.15}$$

In (IV.15) $G_{0,-2'}$ is the Green function (B.9) for $\eth^2$ and $Z^{(0)}$ the general solution of the equation $\eth^2 Z=0$, given in inertial coordinates in (B.5).

Order 0

At $\mathcal{O}(\Lambda^0)$, $Z=Z^{(0)}$ (IV.15), $f=g=0$ (II.20) and (III.17) reduces to the Sparling equation (I.3), as expected. The solution is given by the first term in (III.24), with $\mathcal{F}$ calculated using $Z^{(0)}$. We can readily write down the field strength from (IV.10) and (B.7). This is just the D'Adamard formula,

$$F^{(0)}_{ab}(x)=\frac{1}{2\pi}\sum_{S^2}\ddot{A}(x^c l'_c,\zeta',\bar{\zeta}')l_{[a}(\zeta',\bar{\zeta}')\bar{m}_{b]}(\zeta',\bar{\zeta}')dS'. \tag{IV.16}$$

Order 1

As pointed out above, $\mathcal{G}$ in (III.24) contains no order zero term. Therefore, the first order expansion of F agrees with that of $(1+\mathcal{G})\mathcal{F}$. From (II.20) we obtain the first order approximations for f and g,

$$f=0,\quad g=\tfrac{1}{2}[(r-r_0)\Lambda_{,r}-2(\Lambda-\Lambda_0)]. \tag{IV.17}$$

Thus, the linear expansion of F is

$$F^{(0)}+F^{(1)}=-\int_{S^2}G_{0,-1'}\left[A(Z^{(0)},\zeta',\bar{\zeta}')+\dot{A}(Z^{(0)},\zeta',\bar{\zeta}')Z^{(1)}+\int_x^\infty g\hat{\phi}^{(0)}dr'\right]dS', \tag{IV.18}$$

with $\hat{\phi}^0=F^{(0)}_{ab}l^a\bar{m}^b$ and g in (IV.17).

Although in principle the Z function is assumed to be given, the background geometry is usually described in terms of the metric and its associated tensors. In those cases, the process of obtaining Z or Λ is involved (one must solve the geodesic deviation). However, it can be shown[2] that in the linear gravity approximation

$$\Lambda\simeq\sigma_B(Z^{(0)},\zeta,\bar{\zeta})-\int_r^\infty(r'-r)\Psi_0(Z^{(0)},\eth Z^{(0)},\bar{\eth}Z^{(0)},r',\zeta,\bar{\zeta})dr'. \tag{IV.19}$$

If the space–time is a small deviation from Minkowski space and if the Weyl tensor, rather than Z or Λ, is given, one can then use (IV.19) in (IV.15) and (IV.18) to obtain the linear gravity approximations of Z and F.

V. SUMMARY AND CONCLUSIONS

We have presented a manifestly conformally invariant formulation of Maxwell theory on asymptotically flat space–times. The field equations for our basic variable, the phase of the parallel propagator associated with self-dual (or antiself-dual) Maxwell fields, contain the free data $A(u,\zeta,\bar{\zeta})$ (or $\bar{A}$) at $\mathcal{I}^+$ as a source term and the solution of those equations is the generalization of D'Adamard's formula to curved space–times. A method to reconstruct the Maxwell field was given. In particular, adding a solution of (III.17) and its complex conjugate yields a real field that satisfies the source free Maxwell's equations. Since the free data has a well defined physical interpretation, namely, it represents incoming radiation, the solutions to the field equations represent the scattering of light due to the background curvature.

Exact solutions of the field equations were obtained when the background geometry was self-dual. A Huygens perturbation series was presented. The terms in the series can be given a physical interpretation. The zeroth order term represents a Huygens propagation on curved spaces. The first and higher order term yield the tails of the electromagnetic wave produced by the scattering of the field in the non-trivial geometry.

Since this formalism is specially adapted to discuss the evolution of electromagnetic radiation on a curved space–time we now address a few questions that can be answered without involved calculations or too many technical details.

We start with a question that was partially answered in Ref. 19; do SD or ASD Maxwell fields have trivial scattering in self-dual space–times? Since for H spaces σ_B is the same at $\mathscr{I}^+$ and $\mathscr{I}^-$, it follows from (IV.1) that cuts Z at $\mathscr{I}^+$ or at $\mathscr{I}^-$ are the same. Inserting this condition in (IV.10) and (IV.14) implies that the free data A at $\mathscr{I}^+$ or $\mathscr{I}^-$ are also the same. Thus, we conclude that electromagnetic radiation does not interact with self-dual gravitational waves.

A question that arises in the context of gravitational lensing is: does the curvature of space-time rotate the polarization vector of an electromagnetic wave? The difficulty with this question is that one should assign a meaning to the word "rotate" since it implies a comparison of vectors at different locations. An analogous, question is: can the curvature of space–time change the helicity on an electromagnetic wave?

To answer this question we first discuss the notion of helicity in our formalism. In Minkowski space one can show that self-dual Maxwell fields yield positive and negative helicity states via the positive or negative frequency decomposition of the free data $A(u,\zeta,\bar{\zeta})$ at $\mathscr{I}^+$.[20] Since asymptotically flat space–times share the same null boundary with Minkowski space, it is possible to define the notion of asymptotic helicity for the electromagnetic radiation. The Fourier transform of the data, $A(\omega,\zeta,\bar{\zeta})$, defines, for positive or negative frequencies ω, the corresponding asymptotic helicity states for the incoming radiation. The scattering of Maxwell fields is then studied by giving the initial data $A_{\mathscr{I}^-}$ at $\mathscr{I}^-$, solving the field equations in an entirely analogous way to what was done in section III, and then projecting the field to $\mathscr{I}^+$ as in (III.7) to obtain $A_{\mathscr{I}^+}$. By analyzing the frequency content of $A_{\mathscr{I}^+}$ we can determine whether or not helicity has been conserved. Our equations clearly suggest that helicity is not conserved.

The problem of scattering and its applications to gravitational lensing is currently being studied. A thorough discussion using this formalism will be presented in a following work.

We wish to thank Ted Newman, whose comments and suggestions led to important improvements in the completeness and presentation of this work. This research has been supported by CONICET and CONICOR.

APPENDIX A: THE FIELD EQUATION FOR THE F FUNCTION

We derive here an equation for F equivalent to the full set of source free Maxwell's equations. To do this consider the 3-volume V limited by (i) $\Delta_x(\zeta,\bar{\zeta})$, (ii) $\Delta_x(\zeta,\bar{\zeta}+d\bar{\zeta})$, (iii) $\bar{\Delta}_x(\zeta,\bar{\zeta})$, (iv) $\bar{\Delta}_x(\zeta+d\zeta,\bar{\zeta})$ and (v) the cap on $\mathscr{I}^+$; the corresponding surface elements being $\hat{L}^{[a}M^{b]}(x,\zeta,\bar{\zeta})(d\zeta dr/P)$, etc.[21] If the source free Maxwell's equations,

$$\partial^*_{[a}F_{bc]}=0,$$

are integrated in V we obtain (the i factor is put for later convenience)

$$0=\int_V i3!\partial^*_{[a}F_{bc]}dx^a dx^b dx^c=\int_{\partial V} i^*F_{bc}dx^b dx^c. \tag{A1}$$

The surface term is the sum of five integrals. As an example we calculate the surface integral over regions (i) and (ii):

$$\int_{(i)+(ii)} i^*F_{ab}dx^a dx^b = \frac{C(x,\zeta,\bar{\zeta})}{P(\zeta,\bar{\zeta})}\,d\zeta' - \frac{C(x,\zeta,\bar{\zeta}+d\bar{\zeta})}{P(\zeta,\bar{\zeta}+d\bar{\zeta})}\,d\zeta = -\bar{\delta}C\,\frac{d\zeta d\bar{\zeta}}{P^2}, \tag{A2}$$

where

$$C \equiv \int i^*F_{ab}\hat{L}^{[a}M^{b]}dr = \int F^{ab}i^*\hat{L}_{[a}M_{b]}ds. \tag{A3}$$

Analogously

$$\int_{(iii)+(iv)} i^*F_{ab} = -\delta\bar{C}\,\frac{d\zeta d\bar{\zeta}}{P^2}. \tag{A4}$$

Using (II.19), (A3) takes the following form:

$$C = H + 2\int (\bar{f}\hat{\phi} + g\hat{\bar{\phi}})dr \tag{A5}$$

From (A1), (A2) and (A4) we get

$$\bar{\delta}C + \delta\bar{C} + (i^*F_{ab}M^a\bar{M}^b)_{,\mathcal{I}^+} = 0. \tag{A6}$$

Using (A5), (III.7), (III.9) and (III.12), we can rewrite (A6) as

$$\delta\bar{\delta}F + \delta\bar{A} + \bar{\delta}A + \delta\int_{r_0}^{\infty}(f\hat{\bar{\phi}} + \bar{g}\hat{\phi})dr + \bar{\delta}\int_{r_0}^{\infty}(\bar{f}\hat{\phi} + g\hat{\bar{\phi}})dr = 0. \tag{A7}$$

Note that for SD [ASD] fields (A7) reduces to (III.17) [(III.18)].

We now show how to recover the Maxwell field F_{ab} from $F(x,\zeta,\bar{\zeta})$. Using eq. (C6) we can rewrite (III.3) as

$$H(x,\zeta,\bar{\zeta}) = \int_r^{\infty} F_{ab}(r')\hat{L}^a(r',\zeta,\bar{\zeta})[(r'-r)\hat{M}^b(r',\zeta,\bar{\zeta}) + (\Lambda(r',\zeta,\bar{\zeta}) - \Lambda(r,\zeta,\bar{\zeta}))\hat{\bar{M}}^b(r',\zeta,\bar{\zeta})]dr'. \tag{A8}$$

The integral is along $l_x(\zeta,\bar{\zeta})$, parametrized as in Appendix C, i.e., a point x' in the geodesic is given by $x' = x'(u,\omega,\bar{\omega},r';\zeta,\bar{\zeta})$. From (A8)

$$\hat{L}^a\nabla_a H = H_{,r} = -\int_r^{\infty}\hat{\phi}(r',\zeta,\bar{\zeta})dr' - \Lambda_{,r}\int_r^{\infty}\hat{\bar{\Phi}}(r',\zeta,\bar{\zeta})dr'.$$

Using this equation and its complex conjugate one can algebraically solve for $\int_r^{\infty}\hat{\phi}(r',\zeta,\bar{\zeta})dr'$. Taking one more radial derivative yields

$$\hat{\phi} = \left[\frac{(\delta F)_{,r} - \Lambda_{,r}(\bar{\delta}F)_{,r}}{1 - \Lambda_{,r}\bar{\Lambda}_{,r}}\right]_{,r} \equiv \hat{\Phi}[F] \quad \text{and c.c.}, \tag{A9}$$

i.e., eq. (III.14).

Putting together (A7) and (A9) we obtain the following integro-differential equation for F:

$$\eth\bar{\eth}F+\eth\left[\bar{A}+\int_{r_0}^{\infty}(f\hat{\Phi}[F]+\bar{g}\hat{\Phi}[F])dr\right]+\bar{\eth}\left[A+\int_{r_0}^{\infty}(\bar{f}\hat{\Phi}[F]+g\hat{\phi}[F])dr\right]=0. \tag{A10}$$

(A10) is our version of the source free Maxwell equations on curved spaces. It is not hard to see from (A10) that F is linear in the data $(A,\bar{A})$, from where it follows that we can first solve for the SD part of the field (by setting $\bar{A}=0$), and then add the solution for the ASD part ($A=0$), as in (III.23).

APPENDIX B: GREEN FUNCTIONS FOR THE ETH OPERATOR

The action of the eth operator on a spin weight s function f_s is given by[15]

$$g_{s+1}=\eth f_s\equiv P^{1-s}\frac{\partial}{\partial\zeta}(P^s f_s),\quad P\equiv 1+\zeta\bar{\zeta}. \tag{B1}$$

Similarly, the action of the eth-bar operator is

$$h_{s-1}=\bar{\eth}f_s\equiv P^{1+s}\frac{\partial}{\partial\bar{\zeta}}(P^{-s}f_s), \tag{B2}$$

therefore the commutator is

$$\bar{\eth}\eth-\eth\bar{\eth})f_s=2sf_s. \tag{B3}$$

From (B1), it follows that the only *regular* solution of the equation $\partial f_0=0$ is a constant. As the linear operator $\hat{\Phi}[\cdot]$ (III.14) acting on an S^2 constant gives zero, the solution F to the field equation (III.17) has the indeterminacy of an additive function of the space–time coordinates $f(x)$. As explained in remark 2 of Section III and in Ref. 14 this is a gauge term. Also from (B1), the general (regular) solution $Z^{(0)}$ of the "good cut equation" (IV.1) with $\sigma_B=0$,

$$\Lambda=\eth^2Z^{(0)}=0, \tag{B4}$$

is found to be a linear combination of 1, ζ/P, $\bar{\zeta}/P$ and $\zeta\bar{\zeta}/P$.[16] The choice of parametrization of the solution space gives a coordinate system for this H space (section IV). In particular, by choosing

$$Z^{(0)}(x,\zeta,\bar{\zeta})=x^a l_a(\zeta,\bar{\zeta}), \tag{B5}$$

$$l_a(\zeta,\bar{\zeta})=\frac{1}{\sqrt{2}P}(-1-\zeta\bar{\zeta},\zeta+\bar{\zeta},i(\bar{\zeta}-\zeta),-1+\zeta\bar{\zeta}), \tag{B6}$$

it is easily shown that this H space is (complex) Minkowski space–time (equivalently, $Z^{(0)}$ gives the family of space–times conformal to Minkowski space), and that x are inertial coordinates. This is proven by first obtaining the metric tensor (IV.2) and then transforming to the x coordinates using (II.7) and (B5). The result is $g^{ab}=\mathrm{diag}(-1,1,1,1,)$. Furthermore, the null tetrad (IV.8) is covariantly constant. In the x^a coordinates,

$$\mathscr{L}^a(x,\zeta,\bar{\zeta})=l^a(\zeta,\bar{\zeta})=g^{ab}l_a(\zeta,\bar{\zeta}),\quad \mathscr{M}^a(x,\zeta,\bar{\zeta})=\eth l^a(\zeta,\bar{\zeta})\equiv m^a(\zeta,\bar{\zeta}),$$

$$\bar{\mathscr{M}}^a(x,\zeta,\bar{\zeta})=\bar{\eth}l^a(\zeta,\bar{\zeta})\equiv\bar{m}^a(\zeta,\bar{\zeta}),\quad \mathscr{N}^a(x,\zeta,\bar{\zeta})=(1+\eth\bar{\eth})l^a(\zeta,\bar{\zeta})\equiv n^a(\zeta,\bar{\zeta}), \tag{B7}$$

where the usual notation for this tetrad in Minkowski space was introduced.

In a guide to construct Green functions for arbitrary combinations of ð and ð in terms of contractions of the tetrad (B7) is given. In particular, it is easy to verify from the information given there that

$$G_{0,-1'}(\zeta,\bar{\zeta};\zeta',\bar{\zeta},)\equiv\frac{1}{4\pi}\frac{l(\zeta,\bar{\zeta})\cdot\bar{m}(\zeta',\bar{\zeta}')}{l(\zeta,\bar{\zeta})\cdot l(\zeta',\bar{\zeta}')} \tag{B8}$$

is the Green function for the ð operator acting on spin-weight 0 functions. This function is used in the definition of $\mathscr{S}$ in the solution of the field equation (III.17)

Similarly, the Green function of $ð^2$ acting on spin-weight zero functions is

$$G_{0,-2'}(\zeta,\bar{\zeta};\zeta',\bar{\zeta},)\equiv\frac{1}{4\pi}\frac{(l\cdot\bar{m}')^2}{l\cdot l'}. \tag{B9}$$

This is used in (IV.15) to obtain $Z^{(1)}$.

APPENDIX C: GEODESIC DEVIATION VECTOR

Inverting (II.7) with $(\zeta,\bar{\zeta})$ fixed we get

$$x^a=x^a(u,\omega,\bar{\omega},r;\zeta,\bar{\zeta}). \tag{C1}$$

If $x\in l_{x_0}(\zeta,\bar{\zeta})$, the null geodesic with end points at x_0 and the $(\zeta,\bar{\zeta})$ generator of $\mathscr{I}^+$, then

$$u(x;\zeta,\bar{\zeta})=u(x_0,\zeta,\bar{\zeta}),\quad \omega(x,\zeta,\bar{\zeta})=\omega(x_0;\zeta,\bar{\zeta}),\quad \bar{\omega}(x,\zeta,\bar{\zeta})=\bar{\omega}(x_0;\zeta,\bar{\zeta}), \tag{C2}$$

as can be easily seen from (II.9), (II.10), (II.11) and the fact that $Z^a(x,\zeta,\bar{\zeta})$ is tangent to the geodesic at x. Thus, for $x\in C_{x_0}$, the future null cone of x_0, it follows from (C1) and (C2) that

$$x^a=x^a(u=Z(x_0;\zeta,\bar{\zeta}),\quad \omega=ðZ(x_0,\zeta,\bar{\zeta}),\quad \bar{\omega}=\bar{ð}Z(x_0;\zeta,\bar{\zeta}),\quad r+ðð Z(x_0,\zeta,\bar{\zeta});\zeta,\bar{\zeta}. \tag{C3}$$

In (C3), r has been redefined in order to obtain a coordinate system $(r,\zeta,\bar{\zeta})$ for C_{x_0}. The geodesic deviation vector $M^a\equiv ðx^a$ can be obtained from (C3) using (B1) and (B2),

$$P\frac{d}{d\zeta}x^a=\hat{N}^a\omega(x_0^b,\zeta,\bar{\zeta})-\hat{\bar{M}}^a[\Lambda(x_0^b,\zeta,\bar{\zeta})-\bar{\zeta}\omega]$$

$$-\hat{M}^a[r(x_0^b,\zeta,\bar{\zeta})+\bar{\zeta}\bar{\omega}]+\hat{L}^a ðr(x_0,\zeta,\bar{\zeta})+P\frac{\partial x^a}{\partial\zeta}. \tag{C4}$$

The last term in (C4) is the partial derivative of (C1) with respect to ζ. To calculate this derivative, we note from (II.7), (B1) and (B2) that, if x and $(\zeta,\bar{\zeta})$ moves in such a way that $u,\omega,\bar{\omega},r$ remain fixed, then

$$0=\delta u=\delta x^a\nabla_a u+\frac{\delta\zeta}{P}\omega,\quad 0=\delta\omega=\delta x^a\nabla_a\omega+\frac{\delta\zeta}{P}[\Lambda-\bar{\zeta}\omega],$$

$$0=\delta\bar{\omega}=\delta x^a\nabla_a\bar{\omega}+\frac{\delta\zeta}{P}[r+\bar{\zeta}\bar{\omega}],\quad 0=\delta r=\delta x^a\nabla_a r+\frac{\delta\zeta}{P}\bar{ð}r.$$

Using (B3) and the fact that $\nabla_a u,\nabla_a r,\nabla_a\omega,\nabla_a\bar{\omega}$ is the dual of the basis $\hat{N}^a,\hat{L}^a,-\hat{\bar{M}}^a,-\hat{M}^a$ we get

$$P\frac{\partial}{\partial\zeta}x^a=P\frac{\delta x^a}{\delta\zeta}=-\hat{L}^a\eth r+\hat{\bar{M}}^a[\Lambda-\bar{\zeta}\omega]+\hat{M}^a[r+\bar{\zeta}\bar{\omega}]-\omega\hat{N}^a. \tag{C5}$$

From (C4) and (C5) we obtain the following formula for the geodesic deviation vector:

$$M^a=P\frac{dx^a}{d\zeta}=(\Lambda-\Lambda_0)\hat{\bar{M}}^a(r-r_0)\hat{M}^a-\hat{L}^a\partial(r-r_0). \tag{C6}$$

APPENDIX D:

In this Appendix we complete the steps that lead to Eq. (IV.10) and we prove that in the ASD solution (IV.14), $\bar{A}$ is the data at $\mathscr{I}^+$ as had previously been defined.

Since the r.h.s of (IV.7) does not depend on $(\zeta,\bar{\zeta})$ one can perform an integration on the sphere without changing the result. Thus,

$$A_a(x)=2\frac{1}{4\pi}\int_{S^2}[(\nabla^b\bar{\eth}F)Z_{[a}\eth Z_{b]}]dS+\nabla_a\frac{1}{4\pi}\int_{S^2}F(x,\zeta,\bar{\zeta})dS. \tag{D1}$$

The last integral on the right vanishes if the -c.c. of-the solution (III.24) of (III.17) is chosen (see remark 1 in Section III). If not, it merely reduces to an unimportant gauge term that we will omit. Using (IV6) we can rewrite the above expression as

$$\begin{aligned}A_a(x)=-2\frac{1}{4\pi}\int_{S^2\times S^2}&dSdS'Z_{[a}(x,\zeta,\bar{\zeta})\eth Z_{b]}(x,\zeta,\bar{\zeta})\bar{\eth}G_{0,-1'}\\&\times(\zeta,\bar{\zeta};\zeta',\bar{\zeta}')\dot{A}(Z',\zeta',\bar{\zeta}')Z'^b,\end{aligned} \tag{D2}$$

where $\dot{A}(u,\zeta,\bar{\zeta})\equiv(\partial/\partial u)A(u,\zeta,\bar{\zeta})$. (B3) and $\eth(Z_{[a}\eth Z_{b]})=0$ [which follows from (IV.1)] yield

$$\eth\bar{\eth}(Z_{[a}\bar{\eth}Z_{b]})=\bar{\eth}\bar{\eth}(Z_{[a}\bar{\eth}Z_{b]})-2(Z_{[a}\eth Z_{b]})=-2Z_{[a}\eth Z_{b]},$$

which allows us to rewrite the dS integral in (D2) as

$$\begin{aligned}-2\int_{s^2}(\bar{\eth}G)Z_{[a}\bar{\eth}Z_{b]}dS&=\int_{S^2}(\bar{\eth}G_{0,-1'})\eth\bar{\eth}(Z_{[a}\eth Z_{b]})dS\\&=\int_{S^2}(\eth G_{0,-1'})\bar{\eth}^2(Z_{[a}\eth Z_{b]})dS\\&=\bar{\eth}'^2(Z'_{[a}\eth Z'_{b]}),\end{aligned} \tag{D3}$$

where we have used the fact that $G_{0,-1'}$ is the Green function of the $\eth$ operator. Inserting this result in (D2) gives

$$A_a(x)=\frac{1}{4\pi}\int_{S^2}dS'\dot{A}(Z',\zeta',\bar{\zeta}')Z'^b\bar{\eth}'^2(Z'_{[a}\eth' Z'_{b]}). \tag{D4}$$

Using (IV.2) the contraction can be calculated giving (IV.9).

We now show that the free data in (IV.13) is the asymptotic value of the connection at $\mathscr{I}^+$. From (III.18), the (restricted) free data is given by the following limit, taken along $l_{x_0}(\zeta,\bar{\zeta})$:

$$\bar{A}(x_0,\zeta,\bar{\zeta})=-\lim_{x\to\mathscr{I}^+}\bar{\eth}F(x,\zeta,\bar{\zeta}). \tag{D5}$$

If (III.1) is calculated using (IV.13) then

$$F(x,\zeta,\bar{\zeta})=\frac{1}{4\pi}\int_{S^2}dS'\int_{r(x,\zeta,\bar{\zeta})}^{\infty}dr'\mathring{A}(Z'(x'),\zeta',\bar{\zeta}')Z^b(x')\eth Z'_b(x'), \tag{D6}$$

where again the natural coordinates of section II are used and

$$x'=x'(u,\omega,\bar{\omega},r';\zeta,\bar{\zeta}),\quad u=Z(x;\zeta,\bar{\zeta}),\quad \omega=\eth Z(x;\zeta,\bar{\zeta}),\quad \bar{\omega}=\bar{\eth}Z(x;\zeta,\bar{\zeta}). \tag{D7}$$

Let us change coordinates and view a point x' in $l_x(\zeta,\bar{\zeta})$ as the intersection of $l_x(\zeta,\bar{\zeta})$ with the past cone of $(u,\zeta',\bar{\zeta}')$ at $\mathscr{I}^+$ [i.e., $(u,\zeta',\bar{\zeta}')$ is the point at which $l_{x'}(\zeta',\bar{\zeta}')$ intersects $\mathscr{I}^+$]. Keeping $(\zeta',\bar{\zeta}')$ fixed, u parametrizes $l_x(\zeta,\bar{\zeta})$, thus

$$x'=x'(x,\zeta,\bar{\zeta};u,\zeta',\bar{\zeta}'),\quad \frac{du}{dr'}=Z^c(x')Z'_c(x') \tag{D8}$$

and

$$\bar{\eth}F=\frac{1}{4\pi}\int_{S^2}dS'\int_{Z(x,\zeta',\bar{\zeta})}^{\infty}du\mathring{A}(u,\zeta',\bar{\zeta}')\bar{\eth}\left[\frac{Z^b(x')\eth' Z'_b(x')}{Z^c(x')Z'_c(x')}\right], \tag{D9}$$

where $\eth'$ is calculated without taking into account the $(\zeta',\bar{\zeta}')$ dependence of x' in (D7). Note that[22]

$$\bar{\eth}\left[\frac{Z^b(x')\bar{\partial}' Z'_b(x')}{Z^c(x')Z'_c(x')}\right]=\frac{\mathscr{L}^a(x')\,\bar{\mathscr{M}}^b(x')\mathscr{L}'_{[a}(x')\mathscr{M}'_{b]}(x')+\mathscr{O}(\bar{\Lambda},r)}{(\mathscr{L}^c(x')\mathscr{L}'_c(x'))^2}. \tag{D10}$$

Being $\mathscr{L}'_{[a}\mathscr{M}'_{b]}$ ASD and $\mathscr{L}_{[a}\bar{\mathscr{M}}_{b]}$ SD, their contraction is zero, so it is clear that in the $x\to\mathscr{I}^+$ limit (D10) will be zero in the $\zeta\neq\zeta'$ case, and a 0/0 indeterminacy if $\zeta=\zeta'$. Note that, if the H space is asymptotically flat, then $\lim_{\mathscr{I}^+}\bar{\Lambda}_{,r}(x,\zeta,\bar{\zeta})=0$, the limit taken along $l_x(\zeta,\bar{\zeta})$. To study the $\zeta\simeq\zeta'$ case, we express Z'_c as a second order Taylor expansion of Z_c around $(\zeta,\bar{\zeta})$. To do this, we obtain from (B.1) and (B.2) the relationship between $\eth Z_c,\bar{\eth}Z_c,\eth\bar{\eth}Z_c,\eth^2Z_c,\bar{\eth}^2Z_c$ and the first and second partial derivatives of Z_c, and then use (IV.1) and (IV.2). The result is

$$\begin{aligned}Z^cZ'_c&=\left[(\zeta-\zeta')(\bar{\zeta}-\bar{\zeta}')+\frac{1}{2}(\bar{\zeta}-\bar{\zeta}')^2\bar{\Lambda}_{,r}\right]/P^2+\mathscr{O}((\zeta-\zeta')^3)\\&=\left[(\zeta-\zeta')(\bar{\zeta}-\bar{\zeta}')+\frac{1}{2}(\bar{\zeta}-\bar{\zeta}')^2\bar{\Lambda}_{,r}\right]/[PP']+\mathscr{O}((\zeta-\zeta')^3)\\&=l\cdot l'+\frac{(\bar{\zeta}'-\bar{\zeta})^2}{2PP'}\bar{\Lambda}_{,r}+\mathscr{O}((\zeta-\zeta')^3),\end{aligned} \tag{D11}$$

where the notation of Appendix B has been used. In the $x\to\mathscr{I}^+$ limit, $\bar{\Lambda}_{,r}\to 0$. From (D11) and (B8),

$$-\lim_{x\to\mathscr{I}^+}\frac{1}{4\pi}\bar{\eth}\left[\frac{Z^b(x')\bar{\eth}' Z'_b(x')}{Z^c(x')Z'_c(x')}\right]=-\frac{1}{4\pi}\bar{\eth}\eth'\ln(l\cdot l')=\delta_{-1,1}(\zeta,\bar{\zeta};\zeta',\bar{\zeta}'). \tag{D12}$$

From (D9) and (D12),

$$-\lim_{x\to\mathscr{I}^+}\eth F(x,\zeta,\bar{\zeta})=-\int_{Z(x,\zeta,\bar{\zeta})}^{\infty}du\dot{\bar{A}}(u,\zeta,\bar{\zeta})=\bar{A}(Z(x_0,\zeta,\bar{\zeta}),\zeta,\bar{\zeta}), \tag{D13}$$

and so $\bar{A}$ in (IV.13) is the (restricted) free data, as we wanted to show.

[14] In (III.1) an admissible potential A_a must satisfy two conditions: (i) A_a has a smooth pull-back $\bar{A}_a$ to $\mathscr{I}^+$. (ii) $\bar{A}_a$ has vanishing contraction with vectors tangent to the generators of $\mathscr{I}^+$. A gauge transformation $A_a\to A'_a = A_a + \nabla_a h$ will yield another admissible potential A'_a whenever the pull-back $\bar{h}$ of h to $\mathscr{I}^+$ does not depend on u. However, as $\lim_{u\to\infty}A(u\zeta,\bar{\zeta})=0$ (and c.c.) (Ref. 12) we must have $\bar{h}=0$, which immediately gives $F'(x,\zeta,\bar{\zeta})=F(x,\zeta,\bar{\zeta})+h(x)$. This explains the appearance of an arbitrary additive function of x in the general solution of (III.17), which merely reflects the gauge freedom still remaining after the two above conditions have been imposed.

(Received 22 September 1995; accepted for publication 3 January 1996)

The invariant imbedding technique, via the solution of a Riccati-type equation, is modified to calculate the wave fields inside and scattered from a strongly (laterally and vertically) heterogenous, anisotropic inclusion, which may be large but remains compact. The factorization underlying this approach is carried out with respect to direction of average power flow rather than the more conventional factorization with respect to local direction of propagation. The solution of the operator Riccati equation is related to the Dirichlet-to-Neumann map. The formulation is robust in the sense that it can handle a rather extreme range of modal wave speeds, and allows continuous as well as discontinuous medium variations on different (wave) length scales. It also, inherently, takes care of critical-angle phenomena. The algorithm, based on the invariant imbedding approach, yields the internal fields for a full survey of sources and receivers simultaneously. The wave field solution in the inclusion is coupled to the external field via a boundary element approach.
 [S0022-2488(96)02607-2]

I. INTRODUCTION

In this article, we discuss a generalization of the invariant imbedding approach[1–4] to calculate the transmitted and backscattered wave fields from a strongly (laterally and vertically) heterogeneous, anisotropic inclusion. The inclusion, typically the size of a couple of wavelengths, defines a compact domain in which the system of coordinates is allowed to be curvilinear to accommodate for sharp as well as anomalous boundary conditions on hypersurfaces and interfaces in the configuration.

A directional decomposition of the wave field underlies the method of invariant imbedding. In the approach proposed in this article, the directional decomposition is carried out with respect to the direction of power flow averaged over a level hypersurface and a period in time, and as such differs from the one carried out with respect to the local propagation direction (Weston[5,6]). The separation into "up" and "down" no longer permits a separation into "left" and "right", here up/down is defined with respect to the local vertical direction, the direction of preference, normal to the hypersurfaces.

As in the standard invariant imbedding approach, we arrive at a Riccati-type equation, but here the standard "slab" has been deformed into a compact manifold. Our Riccati equation is an operator equation rather than an ordinary differential equation. Its solution has the interpretation of admittance operator, and bears close resemblance with the established Dirichlet-to-Neumann map in boundary value problems.[7–9] The internal field in the inclusion is decomposed into two families of "one-way" fundamental solutions.

The Dirichlet-to-Neumann map has been used in the analysis of several physical phenomena. These phenomena dominantly comprised elliptic equations, such as in electric conductivity and static elasticity. The Dirichlet-to-Neumann map appears to be particularly useful in inverse problems. Amongst the extensive literature on this subject is the work of Lee and Uhlmann,[7] who

[a)]Present address: Center for Wave Phenomena, Colorado School of Mines, Golden, CO 80401.

0022-2488/96/37(8)/3854/28/$10.00

derived a reconstruction procedure for anisotropic conductivities by boundary measurements; Nakamura and Uhlmann[8] established uniqueness for the inverse boundary value problems in static elasticity. Our aim is to employ the Dirichlet-to-Neumann map in hyperbolic, wave scattering problems. The feasibility of this has been established by Weston[6] and Fishman,[10] and earlier by Burridge[11] in crack propagation and wave diffraction, and has been further exploited in earthquake seismology.[12,13] The idea of introducing an operator that accounts for the most complicated part of the scattering process is much in the spirit of the T-matrix approach, be it that our approach decomposes the wave field rather than the medium into two constituents (see, e.g., Varadan and Varadan[14]).

The multidimensional invariant imbedding approach proposed in this article has certain advantages for the simulation of waves in complex media, since

(1) the medium can contain sharp and strong discontinuities over potentially many, closely spaced, curved interfaces,

(2) the medium can have a wide range of modal wave speeds,

(3) the medium can be generally anisotropic,

(4) it handles critical-angle phenomena and diffraction without any precaution.

The aim of the approach is to reach a generic accuracy similar to the one of the layer-matrix approach for the computation of the wave field in stratified media (see Kennett[15,16]). Further, invariant imbedding formulations are of theoretical importance to the method of stochastic averaging of wave fields propagating through media with strong small-scale (subwave length) fluctuations. Established proofs of pulse stabilization in the transmitted and backscattered fields in stratified media of such type rely on the structure and properties of the Riccati equation.[17]

The article is organized as follows. In Sec. II, the hyperbolic system on a compact manifold is introduced; Sec. III contains the associated representation theorems. In Sec. IV, the directional decomposition and the subsequent invariant imbedding formulation of the scattering problem to evaluate the internal field are discussed. To this end, an admittance operator is introduced. The existence of the continuation proposed depends on an up/down decomposition of the wave field representation with respect to direction of average power flow. The admittance satisfies a pseudo-differential operator Riccati equation. In Sec. V, the boundary-element method is employed to couple the solution inside the compact domain to the outside world, to evaluate the backscattered and transmitted fields. This hybrid approach is followed since the embedding (the outside world) is typically homogeneous or stratified and thus the embedding's wave field solution can be evaluated with simple methods. In Sec. VI, periodic boundary conditions in the directions transverse to the direction of preference are applied; the numerical aspects of solving the Riccati/one-way system of equations making use of pseudospectral techniques are discussed. To this end, the operator Riccati equation is transformed into an equation for the co-kernel of the admittance operator. Finally, the stability of the continuation is discussed.

II. THE BASIC EQUATIONS

In this section the symmetric hyperbolic system on a compact manifold is introduced. The system applies to wave motion in anisotropic fluid, and elastic and poroelastic media. The observable quantities will be represented by a general $2p\times 1$ field matrix $\mathbf{F}$, which is built from the components of vectors, v say, and tensors, σ say. We will apply the summation convention.

A. Fourier transformation and time averaging

Let t denote time and ω denote angular frequency. The one-sided Fourier transformation is employed to make use of the causality imposed on the wave motion. To show the notation, consider the contravariant vector v^i for which

$$v^i(x_m,\omega)=\int_{t\in\mathbb{R}_{\geqslant 0}} v^i(x_m,t)\exp(-i\omega t)dt. \tag{II.1}$$

Then

$$v^i(x_m,t)=\frac{1}{2\pi}\int_{\omega\in\mathbb{R}-i0} v^i(x_m,\omega)\exp(i\omega t)d\omega. \tag{II.2}$$

A "steady state" constituent is then represented by

$$\mathrm{Re}\{v^i(x_m,\omega)\exp(i\omega t)\}.$$

Let $\sigma_i{}^j$ be a mixed covariant/contravariant tensor, then

$$\mathrm{Re}\{v^i\exp(i\omega t)\}\mathrm{Re}\{\sigma_i{}^k\exp(i\omega t)\}=\tfrac{1}{4}[\bar{v}^i\sigma_i{}^k+v_i\bar{\sigma}_i{}^k]+\tfrac{1}{4}[v^i\sigma_i{}^k\exp(2i\omega t)+\bar{v}^i\bar{\sigma}_i{}^k\exp(-2i\omega t)]. \tag{II.3}$$

Taking the time average $\langle\cdots\rangle_T$ over a period, $T=2\pi/\omega$, of the latter expression then amounts to

$$-\langle\mathrm{Re}\{v^i\exp(i\omega t)\}\mathrm{Re}\{\sigma_i{}^k\exp(i\omega t)\}\rangle_T=-\tfrac{1}{2}\mathrm{Re}\{\bar{v}^i\sigma_i{}^k\}, \tag{II.4}$$

which upon identifying v^i with the (contravariant) particle velocity and $\sigma_i{}^k$ with the (covariant/contravariant) stress corresponds to the k component of the time-averaged (contravariant) elastodynamic Poynting vector. [In this framework, the strain tensor $\epsilon^i{}_j$ becomes mixed contravariant/covariant.]

B. Coordinate transformations and forms, and direction of preference

Let x_j denote global Cartesian coordinates in three-dimensional space. We employ curvilinear coordinates ξ_j on a manifold, standardly taken as contravariant, according to the transformation

$$x_j\rightarrow\xi_j, \tag{II.5}$$

with

$$x_\nu=\xi_\nu,\quad \nu=1,2\qquad \text{and } x_3=\mathrm{f}(\xi_\nu,\xi_3). \tag{II.6}$$

These coordinates parametrize curved hypersurfaces according to $\xi_3=$const. The function f is assumed to be single-valued and continuous; $\xi_3(x_1,x_2,x_3)$ is obtained via the implicit function theorem. Implicitly, a direction of preference has been introduced, viz., locally along the ξ_3-axis.

The spatial derivatives and forms transform as

$$\partial_{x_i}=\mathrm{u}_{ij}^{-1}\partial_{\xi_j},\quad dx_i=\mathrm{u}_{ji}d\xi_j, \tag{II.7}$$

employing the summation convention, in which the transformation matrices,

$$\mathrm{u}_{ij}=\frac{\partial x_j}{\partial\xi_i},\quad \mathrm{u}_{ij}^{-1}=\frac{\partial\xi_j}{\partial x_i},$$

are given by

$$\mathsf{u}=\begin{pmatrix} 1 & 0 & (\partial_{\xi_1}\mathsf{f}) \\ 0 & 1 & (\partial_{\xi_2}\mathsf{f}) \\ 0 & 0 & (\partial_{\xi_3}\mathsf{f}) \end{pmatrix}, \quad \mathsf{u}^{-1}=\begin{pmatrix} 1 & 0 & -\left(\dfrac{\partial_{\xi_1}\mathsf{f}}{\partial_{\xi_3}\mathsf{f}}\right) \\ 0 & 1 & -\left(\dfrac{\partial_{\xi_2}\mathsf{f}}{\partial_{\xi_3}\mathsf{f}}\right) \\ 0 & 0 & \left(\dfrac{1}{\partial_{\xi_3}\mathsf{f}}\right) \end{pmatrix}. \tag{II.8}$$

We have $\det(\mathsf{u}) = (\partial_{\xi_3}\mathsf{f})$, and assume that the Jacobian is regular. This condition can be somewhat relaxed, which will be discussed below. In curved space

$$D_\nu=\frac{i}{\omega}\,\partial_{\xi_\nu}, \quad \nu=1,2 \tag{II.9}$$

are referred to as the *local horizontal slowness operators.*

The metric tensor g_{ij}, associated with the coordinate transformation introduced above, is given by

$$\mathsf{g}_{ij}=\mathsf{u}_{ik}\mathsf{u}_{jl}\delta_{kl}, \quad \mathsf{g}^{ij}=\mathsf{g}_{ij}^{-1}=\mathsf{u}_{ki}^{-1}\mathsf{u}_{lj}^{-1}\delta^{kl};$$

thus

$$(\mathsf{g}_{ij})=\begin{pmatrix} 1+(\partial_{\xi_1}\mathsf{f})^2 & (\partial_{\xi_1}\mathsf{f})(\partial_{\xi_2}\mathsf{f}) & (\partial_{\xi_1}\mathsf{f})(\partial_{\xi_3}\mathsf{f}) \\ (\partial_{\xi_2}\mathsf{f})(\partial_{\xi_1}\mathsf{f}) & 1+(\partial_{\xi_2}\mathsf{f})^2 & (\partial_{\xi_2}\mathsf{f})(\partial_{\xi_3}\mathsf{f}) \\ (\partial_{\xi_3}\mathsf{f})(\partial_{\xi_1}\mathsf{f}) & (\partial_{\xi_3}\mathsf{f})(\partial_{\xi_2}\mathsf{f}) & (\partial_{\xi_3}\mathsf{f})^2 \end{pmatrix} \tag{II.10}$$

and

$$\mathsf{g}^{ij}=\begin{pmatrix} 1 & 0 & -\dfrac{\partial_{\xi_1}\mathsf{f}}{\partial_{\xi_3}\mathsf{f}} \\ 0 & 1 & -\left(\dfrac{\partial_{\xi_2}\mathsf{f}}{\partial_{\xi_3}\mathsf{f}}\right) \\ -\left(\dfrac{\partial_{\xi_1}\mathsf{f}}{\partial_{\xi_3}\mathsf{f}}\right) & -\left(\dfrac{\partial_{\xi_2}\mathsf{f}}{\partial_{\xi_3}\mathsf{f}}\right) & \dfrac{1+(\partial_{\xi_1}\mathsf{f})^2+(\partial_{\xi_2}\mathsf{f})^2}{(\partial_{\xi_3}\mathsf{f})^2} \end{pmatrix}. \tag{II.11}$$

The invariant volume form is then given by

$$dx_1dx_2dx_3=\sqrt{\det(\mathsf{g})}\;d\xi_1d\xi_2d\xi_3.$$

with

$$\det(\mathsf{g})=(\partial_{\xi_3}\mathsf{f})^2. \tag{II.12}$$

To identify the local vertical direction, we employ the vector n_i, normal to the surface ξ_3=const, given by

$$n_i=\sqrt{\mathsf{g}_{33}}\mathsf{u}_{i3}^{-1}=(\partial_{\xi_3}\mathsf{f})\mathsf{u}_{i3}^{-1}$$

or [from the gradient of $(x_3-\mathrm{f})$]

$$n_\nu=-\partial_{\xi_\nu}\mathrm{f},\quad n_3=1 \tag{II.13}$$

with

$$\|\mathbf{n}\|=\det(\mathsf{u})\|\mathsf{u}_{.3}^{-1}\|=[(\partial_{\xi_1}\mathrm{f})^2+(\partial_{\xi_2}\mathrm{f})^2+1]^{1/2}.$$

From Eqs. (II.8) and (II.13) it follows that Eq. (II.7) can be written explicitly in the form

$$\partial_{x_i}=\partial_{\xi_i}-\delta_{i3}\partial_{\xi_3}+\frac{1}{(\partial_{\xi_3}\mathrm{f})}\,n_i\partial_{\xi_3}. \tag{II.14}$$

A surface element $dA(\xi)$, locally normal to n_i and in a level surface of ξ_3, follows from the transformation

$$\frac{n_j\delta_{j3}}{\|\mathbf{n}\|}\,dA(\xi)=d\xi_1 d\xi_2=dx_1dx_2,$$

hence

$$dA(\xi)=\|\mathbf{n}\|d\xi_1d\xi_2. \tag{II.15}$$

A *stretched* normal component of a tensor is typically given by $\sigma_i{}^n=\sigma_i{}^k n_k$, the superscript n is reserved for this particular contraction. A factor $\|\mathbf{n}\|$ is thus absorbed in the normal vector and tensor components.

C. Transformation of field quantities

We will follow a covariant formulation of elasticity; see Fung.[18] For scalar quantities we apply the standard transformation rule

$$\rho'(\xi_m,\omega)=\rho(x_m,\omega). \tag{II.16}$$

For contravariant and covariant vectors v, and mixed co- and contravariant tensors σ, the transformations yield

$$v'_i(\xi_m,\omega)=\mathsf{u}_{ik}v_k(x_m,\omega),\qquad v_i(x_m,\omega)=\mathsf{u}^{-1}_{ik}v'_k(\xi_m,\omega),$$

$$v'^i(\xi_m,\omega)=\mathsf{u}^{-1}_{ki}v^k(x_m,\omega),\qquad v^i(x_m,\omega)=\mathsf{u}_{ki}v'^k(\xi_m,\omega),$$

$$\sigma'_i{}^j(\xi_m,\omega)=\mathsf{u}_{ik}\mathsf{u}^{-1}_{lj}\sigma_k{}^l(x_m,\omega),\quad \sigma_i{}^j(x_m,\omega)=\mathsf{u}^{-1}_{ik}\mathsf{u}_{lj}\sigma'_k{}^l(\xi_m,\omega),$$

where $v^k=v_k$, $v'^i=v'_k\mathsf{g}^{ki}$ and $\sigma'_i{}^j=\sigma'^{kj}\mathsf{g}_{ki}$. [The physical tensor components are given by $v'^i\sqrt{\mathsf{g}_{ii}}$ and $v'_i\sqrt{\mathsf{g}^{ii}}$, $\sigma'_i{}^j\sqrt{\mathsf{g}^{jj}/\mathsf{g}^{ii}}$ (no sums).] Note that $v^n=v^kn_k=\sqrt{\mathsf{g}_{33}}v'^3$. The covariant derivative D_j of a covariant vector follows as

$$\mathsf{D}_jv'_i=\partial_{\xi_j}v'_i-\Gamma^k_{ij}v'_k,\quad \partial_{x_j}v^i=\mathsf{u}^{-1}_{jl}\mathsf{u}^{-1}_{ip}\mathsf{D}_lv'_p; \tag{II.17}$$

the covariant derivative D_j of a contravariant vector follows as

$$\mathsf{D}_jv'^i=\partial_{\xi_j}v'^i+\Gamma^i_{jk}v'^k,\quad \partial_{x_j}v^i=\mathsf{u}^{-1}_{jl}\mathsf{u}_{pi}\mathsf{D}_lv'^p; \tag{II.18}$$

the covariant derivative of a mixed co- and contravariant tensor follows as

$$\mathsf{D}_k\sigma'_i{}^j=\partial_{\xi_k}\sigma'_i{}^j+\Gamma^j_{kl}\sigma'_i{}^l-\Gamma^l_{ik}\sigma'_l{}^j,\quad \partial_{x_k}\sigma_i{}^j=\mathsf{u}^{-1}_{kl}\mathsf{u}^{-1}_{ip}\mathsf{u}_{qj}\mathsf{D}_l\sigma'_p{}^q. \tag{II.19}$$

In our notation the Christoffel symbols are given by

$$\Gamma^i_{jk}=\mathsf{u}^{-1}_{li}\partial_{\xi_j}\mathsf{u}_{kl}=\tfrac{1}{2}\mathsf{g}^{il}[\partial_{\xi_j}\mathsf{g}_{kl}+\partial_{\xi_k}\mathsf{g}_{lj}-\partial_{\xi_l}\mathsf{g}_{jk}].$$

The physical equations of motion and the constitutive relations are obtained from their Cartesian form by replacing the vectors and tensors appropriately, and replacing the partial derivatives by their covariant counterparts.

If we want to allow kinks in the level surfaces, however, we should not differentiate factors $\partial_{\xi_\mu}\mathsf{f}$ with respect to ξ_ν any further. Then, we deviate from the covariant transformation rule, viz., by applying a straightforward change of coordinates,

$$\begin{aligned} v'^i(\xi_m,\omega)&=v^i(x_m,\omega),\\ \sigma'^{ij}(\xi_m,\omega)&=\sigma^{ij}(x_m,\omega), \end{aligned} \tag{II.20}$$

avoiding the introduction of the Christoffel symbols in the equations.

D. The hyperbolic system

We consider a generic symmetric hyperbolic system reduced to the form

$$\partial_{\xi_3}\mathbf{F}+i\omega\mathbf{A}(D_\nu,\partial_{\xi_k}\mathsf{f})\mathbf{F}=\mathbf{N}. \tag{II.21}$$

Here, $\mathbf{F}$ denotes the field matrix of physically observable quantities [e.g., $\mathbf{F}=(-p',v'^n)^T$ for fluid, $\mathbf{F}=(\sigma'^{in},v'^j)^T$ for solid, and $\mathbf{F}=(\sigma'^{in},-p,v'^j,w'^n)^T$ for poroelastic media where p denotes pressure and w infiltration velocity], $\mathbf{A}$ is a matrix of partial differential operators elliptic with parameters (yet to be determined) in (ξ_1,ξ_2)-space, and $\mathbf{N}$ is the matrix of notional sources. The dimension of $\mathbf{F}$ is $2p$ and can be smaller or greater than the dimension of the underlying manifold, 3 in our case. Using this, we introduce a generic *partitioning* of field quantities

$$\mathbf{F}=\begin{pmatrix}\mathbf{F}_1\\ \mathbf{F}_2\end{pmatrix},$$

such that the number of components of $\mathbf{F}_1$ and $\mathbf{F}_2$ are equal to p.

With respect to any partitioning, the system's matrix $\mathbf{A}$ satisfies the symplectic property

$$\mathbf{A}^T\mathbf{J}=-\mathbf{J}\mathbf{A}, \tag{II.22}$$

where a superscript T denotes the adjoint with respect to the real inner product in $[L^2(\mathbb{R}^2)]^{2p}$, and

$$\mathbf{J}=\begin{pmatrix}0 & \boldsymbol{I}\\ -\boldsymbol{I} & 0\end{pmatrix},\quad \text{but also set}\quad \mathbf{K}=\begin{pmatrix}0 & \boldsymbol{I}\\ \boldsymbol{I} & 0\end{pmatrix}$$

for the later analysis. Apart from the horizontal slowness operators, the system's matrix will contain the medium parameters, the normal $\mathbf{n}$ through tensor contractions, and the Jacobian $\det(\mathsf{u})$. An example is derived in App. A.

We are now in the position to formulate our scattering problem. We consider a compact inclusion in an infinite imbedding. The inclusion is irradiated by a point source located in the imbedding; the scattered field is observed in the embedding as well. The field inside the inclusion will be analyzed with an invariant imbedding approach.

III. REPRESENTATION THEOREMS

For the later analysis, we need the representation theorems for the solution of the hyperbolic system. We summarize these theorems in our coordinate system.

A. Reciprocity

Consider two physical states $(\mathbf{N}^a, \mathbf{F}^a)$ and $(\mathbf{N}^b, \mathbf{F}^b)$ in the same medium that both satisfy the system of equations (II.21), i.e.,

$$\partial_{\xi_3}\mathbf{F}^{a,b}+i\omega\mathbf{A}\mathbf{F}^{a,b}=\mathbf{N}^{a,b}.$$

Consider the interaction quantity (note that a factor $\|\mathbf{n}\|$ has been absorbed in $\mathbf{F}_1^{a,b}$)

$$\int_{\xi_\mu\in\mathbb{R}}(\mathbf{F}^a)^T(\xi_\mu,\xi_3)\mathbf{J}\mathbf{F}^b(\xi_\mu,\xi_3)d\xi_1d\xi_2,$$

in which the integral splits into real inner products in $[L^2(\mathbb{R}^2)]^p$. In the previous section, with respect to the full inner product, we have defined the adjoint of $\mathbf{A}$. Employ Eq. (II.21) to obtain

$$\begin{aligned}&\partial_{\xi_3}\int_{\xi_\mu\in\mathbb{R}}(\mathbf{F}^a)^T(\xi_\mu,\xi_3)\mathbf{J}\mathbf{F}^b(\xi_\mu,\xi_3)d\xi_1d\xi_2\\&\quad=-i\omega\int_{\xi_\mu\in\mathbb{R}}(\mathbf{F}^a)^T(\xi_\mu,\xi_3)[\mathbf{A}^T\mathbf{J}+\mathbf{J}\mathbf{A}]\mathbf{F}^b(\xi_\mu,\xi_3)d\xi_1d\xi_2\\&\qquad+\int_{\xi_\mu\in\mathbb{R}}[(\mathbf{N}^a)^T(\xi_\mu,\xi_3)\mathbf{J}\mathbf{F}^b(\xi_\mu,\xi_3)+(\mathbf{F}^a)^T(\xi_\mu,\xi_3)\mathbf{J}\mathbf{N}^b(\xi_\mu,\xi_3)]d\xi_1d\xi_2,\end{aligned}$$

which, given the symmetries (II.22), reduces to a reciprocity relation of the time-convolution type,

$$\begin{aligned}&\int_{\xi_3=\xi_3^0}^{\xi_3^1}\int_{\xi_\mu\in\mathbb{R}}[(\mathbf{N}^a)^T(\xi_\mu,\xi_3)\mathbf{J}\mathbf{F}^b(\xi_\mu,\xi_3)+(\mathbf{F}^a)^T(\xi_\mu,\xi_3)\mathbf{J}\mathbf{N}^b(\xi_\mu,\xi_3)]d\xi_1d\xi_2d\xi_3\\&\quad=\int_{\xi_\mu\in\mathbb{R}}(\mathbf{F}^a)^T(\xi_\mu,\xi_3^1)\mathbf{J}\mathbf{F}^b(\xi_\mu,\xi_3^1)d\xi_1d\xi_2-\int_{\xi_\mu\in\mathbb{R}}(\mathbf{F}^a)^T(\xi_\mu,\xi_3^0)\mathbf{J}\mathbf{F}^b(\xi_\mu,\xi_3^0)d\xi_1d\xi_2.\end{aligned}\tag{III.1}$$

Repeating the steps above for the interaction quantity

$$\int_{\xi_\mu\in\mathbb{R}}\overline{(\mathbf{F}^a)^T}(\xi_\mu,\xi_3)\mathbf{K}\mathbf{F}^b(\xi_\mu,\xi_3)d\xi_1d\xi_2,$$

where the overbar denotes complex conjugation, yields

$$\begin{aligned}&\partial_{\xi_3}\int_{\xi_\mu\in\mathbb{R}}\overline{(\mathbf{F}^a)^T}(\xi_\mu,\xi_3)\mathbf{K}\mathbf{F}^b(\xi_\mu,\xi_3)d\xi_1d\xi_2\\&\quad=-i\omega\int_{\xi_\mu\in\mathbb{R}}\overline{(\mathbf{F}^a)^T}(\xi_\mu,\xi_3)[-\overline{\mathbf{A}^T}\mathbf{K}+\mathbf{K}\mathbf{A}]\mathbf{F}^b(\xi_\mu,\xi_3)d\xi_1d\xi_2\\&\qquad+\int_{\xi_\mu\in\mathbb{R}}[\overline{(\mathbf{N}^a)^T}(\xi_\mu,\xi_3)\mathbf{K}\mathbf{F}^b(\xi_\mu,\xi_3)+\overline{(\mathbf{F}^a)^T}(\xi_\mu,\xi_3)\mathbf{K}\mathbf{N}^b(\xi_\mu,\xi_3)]d\xi_1d\xi_2,\end{aligned}$$

and a reciprocity relation of the time-correlation type follows as

$$\int_{\xi_3=\xi_3^0}^{\xi_3^1}\int_{\xi_\mu\in\mathbb{R}}[\overline{(\mathbf{N}^a)^T}(\xi_\mu,\xi_3)\mathbf{K}\mathbf{F}^b(\xi_\mu,\xi_3)+\overline{(\mathbf{F}^a)^T}(\xi_\mu,\xi_3)\mathbf{K}\mathbf{N}^b(\xi_\mu,\xi_3)]d\xi_1 d\xi_2 d\xi_3$$
$$=i\omega\int_{\xi_3=\xi_3^0}^{\xi_3^1}\int_{\xi_\mu\in\mathbb{R}}\overline{(\mathbf{F}^a)^T}(\xi_\mu,\xi_3)[\overline{\mathbf{A}^T}\mathbf{K}-\mathbf{K}\mathbf{A}]\mathbf{F}^b(\xi_\mu,\xi_3)d\xi_1 d\xi_2 d\xi_3$$
$$+\int_{\xi_\mu\in\mathbb{R}}\overline{(\mathbf{F}^a)^T}(\xi_\mu,\xi_3^1)\mathbf{K}\mathbf{F}^b(\xi_\mu,\xi_3^1)d\xi_1 d\xi_2-\int_{\xi_\mu\in\mathbb{R}}\overline{(\mathbf{F}^a)^T}(\xi_\mu,\xi_3^0)\mathbf{K}\mathbf{F}^b(\xi_\mu,\xi_3^0)d\xi_1 d\xi_2. \tag{III.2}$$

In nondissipative media, we have

$$\overline{\mathbf{A}^T}\mathbf{K}-\mathbf{K}\mathbf{A}=0.$$

B. The dissipative part of the complex energy balance

To derive the dissipative part of the complex energy balance associated with the hyperbolic system, set $b=a$ in Eq. (III.2); omit the state's superscript. Set $\overline{\cdot^T}=\cdot^\dagger$, then

$$-\int_{\xi_\mu\in\mathbb{R}}\mathbf{F}^\dagger(\xi_\mu,\xi_3^1)\mathbf{K}\mathbf{F}(\xi_\mu,\xi_3^1)d\xi_1 d\xi_2+\int_{\xi_\mu\in\mathbb{R}}\mathbf{F}^\dagger(\xi_\mu,\xi_3^0)\mathbf{K}\mathbf{F}(\xi_\mu,\xi_3^0)d\xi_1 d\xi_2$$
$$=i\omega\int_{\xi_3=\xi_3^0}^{\xi_3^1}\int_{\xi_\mu\in\mathbb{R}}\mathbf{F}^\dagger(\xi_\mu,\xi_3)[\mathbf{A}^\dagger\mathbf{K}-\mathbf{K}\mathbf{A}]\mathbf{F}(\xi_\mu,\xi_3)d\xi_1 d\xi_2 d\xi_3$$
$$-\int_{\xi_3=\xi_3^0}^{\xi_3^1}\int_{\xi_\mu\in\mathbb{R}}[\mathbf{N}^\dagger(\xi_\mu,\xi_3)\mathbf{K}\mathbf{F}(\xi_\mu,\xi_3)+\mathbf{F}^\dagger(\xi_\mu,\xi_3)\mathbf{K}\mathbf{N}(\xi_\mu,\xi_3)]d\xi_1 d\xi_2 d\xi_3. \tag{III.3}$$

This equation is completely real-valued. From its left-hand side we obtain the time-averaged normal component of the Poynting vector [cf. Eq. (II.4)]

$$4\langle S_n\rangle_T=-\mathbf{F}^\dagger\mathbf{K}\mathbf{F}=-2\,\mathrm{Re}\{\mathbf{F}_1^\dagger\mathbf{F}_2\}. \tag{III.4}$$

The time-averaged volumetric rate of energy input by external forces is given by

$$4\langle C_{src}\rangle_T=-[\mathbf{N}^\dagger\mathbf{K}\mathbf{F}+\mathbf{F}^\dagger\mathbf{K}\mathbf{N}]=-2\,\mathrm{Re}\{\mathbf{N}^\dagger\mathbf{K}\mathbf{F}\}. \tag{III.5}$$

The remaining term is interpreted as the dissipation potential,

$$4\langle D\rangle_T=-i\omega\mathbf{F}^\dagger[\mathbf{A}^\dagger\mathbf{K}-\mathbf{K}\mathbf{A}]\mathbf{F}=2\omega\,\mathrm{Im}\{\mathbf{F}^\dagger\mathbf{A}^\dagger\mathbf{K}\mathbf{F}\}. \tag{III.6}$$

For passive systems the operator $i\omega[\mathbf{K}\mathbf{A}-\mathbf{A}^\dagger\mathbf{K}]$ is positive. Note that the full complex energy balance follows upon considering the quantity

$$\int_{\xi_\mu\in\mathbb{R}}\mathbf{F}_1^\dagger(\xi_\mu,\xi_3)\mathbf{F}_2(\xi_\mu,\xi_3)d\xi_1 d\xi_2$$

and following the derivation of the reciprocity relation of the time-correlation type.

C. Representation theorem

Finally, we employ the reciprocity relation of the time-convolution type to derive a particular representation theorem, which will be of use for the field inside the inclusion. Define a Green's tensor $\mathbf{G}^I(\xi_\mu,\xi_3;\xi'_\nu,\xi'_3)$ through its notional sources,

$$\mathbf{N}^I=\begin{pmatrix} 0 \\ \boldsymbol{I}\delta(\xi_\mu-\xi'_\mu)\,\delta(\xi_3-\xi'_3)\end{pmatrix}.$$

Substituting this Green's tensor into Eq. (III.1) for state b yields the representation

$$\mathbf{F}_1^T(\xi'_\nu,\xi'_3)=-\int_{\xi_3=\xi_3^0}^{\xi_3^1}\int_{\xi_\mu\in\mathbb{R}}\mathbf{N}^T(\xi_\mu,\xi_3)\mathbf{J}\mathbf{G}^I(\xi_\mu,\xi_3)d\xi_1 d\xi_2 d\xi_3$$
$$+\int_{\xi_\mu\in\mathbb{R}}\mathbf{F}^T(\xi_\mu,\xi_3^1)\mathbf{J}\mathbf{G}^I(\xi_\mu,\xi_3^1)d\xi_1 d\xi_2-\int_{\xi_\mu\in\mathbb{R}}\mathbf{F}^T(\xi_\mu,\xi_3^0)\mathbf{J}\mathbf{G}^I(\xi_\mu,\xi_3^0)d\xi_1 d\xi_2 \tag{III.7}$$

if $\xi'_3\in(\xi_0^3,\xi_3^1)$. For the time being, we leave the boundary conditions for $\mathbf{G}^I$ free. If the system is dissipative, or the heterogenous domain is not compact (is extended to infinity through thin slabs centered on the level surface $x_3=0$), nonradiating boundary conditions of the "rigid" ($\mathbf{G}_2^I|_{\partial\mathscr{L}}=0$) or "normal-traction free" ($\mathbf{G}_1^I|_{\partial\mathscr{L}}=0$) types can be applied to arrive at Rayleigh-type integral representations.[19]

IV. INVARIANT IMBEDDING FORMULATION

In this section, we analyze the internal fields of the scattering problem. The configuration consists of a heterogeneous, compact domain $\mathscr{L}$, in which we have curvilinear coordinates (ξ_μ,ξ_3), imbedded in a homogeneous medium. Outside $\mathscr{L}$ the curvilinear coordinates transfer into the Cartesian coordinates (x_μ,x_3). The level surfaces $\xi_3=\xi_3^0,\xi_3^1$ bounding the heterogeneous domain, and the ones in between, are smoothly connected to the level surface $x_3=0$ outside this domain. Let the level surface $\xi_3=\xi_3^0$ represent the upper boundary $\partial\mathscr{L}^+$ of the heterogeneous domain, and let the level surface $\xi_3=\xi_3^1$ represent the lower boundary $\partial\mathscr{L}^-$; $\partial\mathscr{L}=\partial\mathscr{L}^+\cup\partial\mathscr{L}^-$. Inside $\mathscr{L}$ we assume that there are no sources, i.e., $\mathbf{N}=\mathbf{0}$.

A. Normalization

Given the partitioned wave field, we introduce a scaling matrix (multiplication) $\mathbf{Y}_0$ to be applied to the state vector $\mathbf{F}$, for two purposes:

(1) to balance the values of $\mathbf{F}_1$ and $\mathbf{F}_2$;
(2) to ensure that $\mathbf{A}$ becomes an elliptic operator with parameters which has a proper polyhomogeneous expansion of its symbol (de Hoop and de Hoop[20]); this expansion, as well as the one for the resolvent of $\mathbf{A}$, consists of increasingly smooth operators. We will not explicitly employ it in the further analysis.

The second issue is a condition necessary to ensure that the Dirichlet-to-Neumann map can be represented as a pseudo-differential operator. Thus, set

$$\mathbf{F}'=\mathbf{Y}_0\mathbf{F},\quad \mathbf{Y}_0=\begin{pmatrix} Y_0 & 0 \\ 0 & \boldsymbol{I}\end{pmatrix},\quad Y_0^T=Y_0. \tag{IV.1}$$

Then

$$\partial_3\mathbf{F}'+\omega\mathbf{A}'\mathbf{F}'=-\mathbf{X}\mathbf{F}'+\mathbf{N}' \tag{IV.2}$$

with

$$\mathbf{A}'=\mathbf{Y}_0\mathbf{A}\mathbf{Y}_0^{-1},\quad \mathbf{X}=\mathbf{Y}_0(\partial_3\mathbf{Y}_0^{-1}),\quad \mathbf{N}'=\mathbf{Y}_0\mathbf{N}. \tag{IV.3}$$

The parameters, η_0 say, are introduced in the operator $\mathbf{A}'$ upon replacing $(Y_0)_{ij}$ by $(\eta_0)_i(Y_0)_{ij}$ (no sums). The symplectic matrix in this normalization becomes

$$\mathbf{J}' = \mathbf{Y}_0^{-1}\mathbf{J}\mathbf{Y}_0^{-1} = \begin{pmatrix} 0 & Y_0^{-1} \\ -Y_0^{-1} & 0 \end{pmatrix}$$

so that

$$(\mathbf{A}')^T\mathbf{J}' = -\mathbf{J}'\mathbf{A}'. \tag{IV.4}$$

We will omit the primes in the further analysis.

B. Wave field decomposition

At any level surface in the inclusion, we seek a directional decomposition

$$\mathbf{F}_1 = \mathbf{F}_1^+ + \mathbf{F}_1^-, \tag{IV.5}$$

$$\mathbf{F}_2 = \mathbf{F}_2^+ + \mathbf{F}_2^- \quad \text{such that} \quad \mathbf{F}_2^\pm = \boldsymbol{Y}^\pm \mathbf{F}_1^\pm, \tag{IV.6}$$

and that the decomposed constituents satisfy Eq. (II.21) individually

$$\partial_3 \mathbf{F}_1^+ + i\omega(\mathbf{A}_{1,1} + \mathbf{A}_{1,2}\boldsymbol{Y}^+)\mathbf{F}_1^+ = 0, \tag{IV.7}$$

$$\partial_3 \mathbf{F}_1^- + i\omega(\mathbf{A}_{1,1} + \mathbf{A}_{1,2}\boldsymbol{Y}^-)\mathbf{F}_1^- = 0 \quad \text{in } \mathscr{D}. \tag{IV.8}$$

Here, $\boldsymbol{Y}^+$ and $\boldsymbol{Y}^-$ have the interpretation of *admittance operators* and are yet to be constructed; they will appear to be pseudodifferential operators of order 1. The admittance operator on a level surface defines a 2-form according to

$$\mathbf{F}_1^\pm \rightarrow \boldsymbol{Y}^\pm \mathbf{F}_1^\pm|_{\xi_3 = \text{const}}\, d\xi_1 d\xi_2,$$

which can be identified as the Dirichlet-to-Neumann map.[7] In the context of the "parameters," note that the transformation

$$\boldsymbol{Y}^\pm = (\boldsymbol{Y}^\pm)' Y_0$$

takes care of the normalization. It is important to note that $\mathbf{F}_1$ and $\boldsymbol{Y}$ are both continuous even at level surfaces across which the coefficients of the hyperbolic system jump by finite amounts.

We will now discuss the condition for such a wave field decomposition to exist. Apply the operator $\boldsymbol{Y}^-$ to both sides of Eq. (IV.5) and subtract the resulting equation from Eq. (IV.6). Then we obtain

$$\mathbf{F}_2 - \boldsymbol{Y}^-\mathbf{F}_1 = (\boldsymbol{Y}^+ - \boldsymbol{Y}^-)\mathbf{F}_1^+. \tag{IV.9}$$

Likewise, applying the operator $\boldsymbol{Y}^+$ to both sides of Eq. (IV.5) and subtracting Eq. (IV.6) from the resulting equation, leads to

$$\boldsymbol{Y}^+\mathbf{F}_1 - \mathbf{F}_2 = (\boldsymbol{Y}^+ - \boldsymbol{Y}^-)\mathbf{F}_1^-. \tag{IV.10}$$

If $(\boldsymbol{Y}^+ - \boldsymbol{Y}^-)$ would be invertible, Eqs. (IV.9) and (IV.10) would imply

$$\mathbf{F}_1^+ = (\boldsymbol{Y}^+ - \boldsymbol{Y}^-)^{-1}(\mathbf{F}_2 - \boldsymbol{Y}^-\mathbf{F}_1), \tag{IV.11}$$

$$\mathbf{F}_1^- = (\boldsymbol{Y}^+ - \boldsymbol{Y}^-)^{-1}(\boldsymbol{Y}^+\mathbf{F}_1 - \mathbf{F}_2). \tag{IV.12}$$

A sufficient condition for the inverse of $(\boldsymbol{Y}^+ - \boldsymbol{Y}^-)$ to exist is

$$(\boldsymbol{Y}^+ - \boldsymbol{Y}^-) + (\boldsymbol{Y}^+ - \boldsymbol{Y}^-)^\dagger \text{ is negative or positive}$$

implying that the spectrum of the operator $(\boldsymbol{Y}^+ - \boldsymbol{Y}^-)$ is bounded away from zero. This condition can be separated into two, physical, sufficient conditions, viz. the ones

$$\left.\begin{array}{ll} \boldsymbol{Y}^- + (\boldsymbol{Y}^+)^\dagger & \text{is a negative} \\ \boldsymbol{Y}^- + (\boldsymbol{Y}^-)^\dagger & \text{is a positive} \end{array}\right\} \text{ operator in each level surface.} \tag{IV.13}$$

This means that the Hermitean parts of the operators $\boldsymbol{Y}^\pm$ must be positive/negative. In the time-Laplace domain (see the next subsection), these conditions entail that the Hermitean parts are elliptic. We will loosely refer to them as ellipticity conditions, even in the frequency (ω) domain.

Let us continue with the latter existence conditions. They have the following interpretation. The power flow in the local $+\xi_3$-direction averaged over any level surface and a period [cf. Eq. (III.4)] is proportional to

$$-\int_{\xi_\mu \in \mathrm{R}} \mathbf{F}^\dagger \mathbf{K} \mathbf{F} d\xi_1 d\xi_2 = -2\int_{\xi_\mu \in \mathrm{R}} \mathrm{Re}\{\mathbf{F}_1^\dagger \mathbf{F}_2\} d\xi_1 d\xi_2 = -\int_{\xi_\mu \in \mathrm{R}} \mathbf{F}_1^\dagger (\boldsymbol{Y} + \boldsymbol{Y}^\dagger)\mathbf{F}_1 d\xi_1 d\xi_2,$$

for the $+$ and $-$ solutions. Hence, the sign of $(\boldsymbol{Y}+\boldsymbol{Y}^\dagger)$ determines the direction of average power flow: for the $\pm$-sign in the $\mp\xi_3$-direction. The ellipticity condition implies that there must be transport of energy through the domain under consideration. A somewhat paradoxal case arises if the wave constituent is (locally) propagating in one section of a level surface but (locally) evanescent in another section of the same level surface. However, since the sense of propagation is defined globally in each level surface, localized departures from the sense of propagation are possible. A more extreme possibility is the one where energy flow in one section of the level surface is opposite in direction to the overall flow. We find that the existence conditions enforce the directional decomposition.

In summary, the existence of our wave field decomposition depends on the existence of admittance operators with globally elliptic Hermitean parts, the signs of which are associated with the direction of average power flow. The energy balance provides the tool to reduce the conditions of global ellipticity to similar conditions on the bounding level surfaces $\partial\mathscr{D}$ of the heterogeneous, compact domain $\mathscr{D}$.

Upon integrating the dissipative part of the complex energy balance over a volume $\mathscr{D}_{[\xi_3^a,\xi_3^b]}$ that is bounded by two arbitrary level surfaces $\{\xi_3=\xi_3^a\}$ and $\{\xi_3=\xi_3^b\}$ $(\xi_3^b > \xi_3^a)$, we obtain

$$\int_{\xi_\mu \in \mathrm{R}} \langle \boldsymbol{S}_n \rangle_T|_{\xi_3=\xi_3^a} d\xi_1 d\xi_2 = \int_{\xi_\mu \in \mathrm{R}} \langle \boldsymbol{S}_n \rangle_T|_{\xi_3=\xi_3^b} d\xi_1 d\xi_2 + \int_{\xi_3=\xi_3^a}^{\xi_3^b} \int_{\xi_\mu \in \mathrm{R}} \langle \boldsymbol{D} \rangle_T d\xi_1 d\xi_2 d\xi_3,$$

having excluded the presence of external sources in the volume. For the sign of the component of the averaged Poynting vector normal to the level surface at $\xi_3=\xi_3^b$ to be positive, it is necessary that the sign of the latter component be positive at $\xi_3=\xi_3^a$. This observation holds if the $+\xi_3$-direction coincides with the direction of average power flow. Thus, imposing the condition of ellipticity with the negative sign at $\xi_3=\xi_3^1$ on $\boldsymbol{Y}^+$ guarantees its global proper behavior; similarly, for $\boldsymbol{Y}^-$ imposing the condition of ellipticity with the positive sign at $\xi_3=\xi_3^0$ guarantees that for $\xi_3 \geqslant \xi_3^0$ the $-\xi_3$-direction coincides with the direction of average power flow. The existence conditions obtain the form of constraints on the initial conditions and in fact correspond with radiation conditions.

C. The admittance operator

The admittance operator is a pseudodifferential operator of order 1. (For an overview of such operators, see Hörmander.[21]) In terms of an integral representation with Schwartz kernel $\mathscr{Y}$, we have

$$(\boldsymbol{Y}\mathbf{F}_1)(\xi_\mu,\xi_3)=\int_{\xi'_\nu\in\mathbb{R}}\mathscr{Y}(\xi_\mu,\xi'_\nu;\xi_3)\mathbf{F}_1(\xi'_\nu,\xi_3)d\xi'_1d\xi'_2. \tag{IV.14}$$

Given the plane-wave representation of the field quantities

$$\widetilde{\mathbf{F}}_1(\alpha_\nu,\xi_3)=\int_{\xi_\nu\in\mathbb{R}}\mathbf{F}_1(\xi_\nu,\xi_3)\exp(i\omega\alpha_\nu\xi_\nu)d\xi_1d\xi_2, \tag{IV.15}$$

we can relate the Schwartz kernel of the admittance operator to its left symbol, viz.,

$$\mathscr{Y}(\xi_\mu,\xi'_\nu;\xi_3)=\left(\frac{\omega}{2\pi}\right)^2\int_{\alpha_\nu\in\mathbb{R}}y(\xi_\mu,\alpha_\nu;\xi_3)\exp[i\omega\alpha_\nu(\xi'_\nu-\xi_\nu)]d\alpha_1d\alpha_2, \tag{IV.16}$$

which means that, schematically,

$$\boldsymbol{Y}\exp(-i\omega\alpha_\nu\xi_\nu)=y(\xi_\mu,\alpha_\nu;\xi_3)\exp(-i\omega\alpha_\nu\xi_\nu). \tag{IV.17}$$

In the horizontal Fourier domain, Eq. (IV.14) becomes

$$(\widetilde{\boldsymbol{Y}}\,\widetilde{\mathbf{F}}_1)(\alpha_\mu,\xi_3)=\left(\frac{\omega}{2\pi}\right)^2\int_{\alpha'_\nu\in\mathbb{R}}\tilde{y}(\alpha_\mu-\alpha'_\mu,\alpha'_\nu;\xi_3)\widetilde{\mathbf{F}}_1(\alpha'_\nu,\xi_3)d\alpha'_1d\alpha'_2, \tag{IV.18}$$

where the co-kernel $\tilde{y}$ is given by

$$\tilde{y}(\alpha_\mu,\alpha'_\nu;\xi_3)=\int_{\xi_\mu\in\mathbb{R}}y(\xi_\mu,\alpha'_\nu;\xi_3)\exp(i\omega\alpha_\mu\xi_\mu)d\xi_1d\xi_2. \tag{IV.19}$$

Co-kernels compose according to

$$\widetilde{ya}(\alpha_\mu,\alpha'_\nu;\xi_3)=\left(\frac{\omega}{2\pi}\right)^2\int_{\alpha''_\nu\in\mathbb{R}}\tilde{y}(\alpha_\mu-\alpha''_\mu,\alpha'_\nu+\alpha''_\nu;\xi_3)\tilde{a}(\alpha''_\mu,\alpha'_\nu;\xi_3)d\alpha''_1d\alpha''_2. \tag{IV.20}$$

Note that the locally vertical power flow averaged over a period in time and integrated over a level surface can be expressed in the co-kernel according to

$$-\tfrac{1}{2}\mathrm{Re}\int_{\alpha_\mu\in\mathbb{R}}\int_{\alpha'_\nu\in\mathbb{R}}\widetilde{\mathbf{F}}_1^\dagger(\alpha_\mu,\xi_3)\tilde{y}(\alpha_\mu-\alpha'_\mu,\alpha'_\nu;\xi_3)\widetilde{\mathbf{F}}_1(\alpha'_\nu,\xi_3)d\alpha'_1d\alpha'_2d\alpha_1d\alpha_2,$$

which can be written as a complex inner product. For the numerical representation a pseudospectral approach will be followed based on the horizontal Fourier and co-kernel representations.

The time-Laplace (s-) domain formulation follows from the analysis above upon substituting $s=i\omega$ and $\alpha^s_\nu=-i\alpha_\nu$; then $is\alpha^s_\nu\xi_\nu=i\omega\alpha_\nu\xi_\nu$.

D. The operator Riccati equation

Finally, we will derive the equation that $\boldsymbol{Y}^\pm$ must satisfy. To ensure that the decomposed constituents satisfy Eqs. (IV.7) and (IV.8), we will substitute Eq. (IV.11) into Eq. (IV.7). Note that

$$\partial_3[(\boldsymbol{Y}^+-\boldsymbol{Y}^-)^{-1}]=-(\boldsymbol{Y}^+-\boldsymbol{Y}^-)^{-1}[\partial_3(\boldsymbol{Y}^+-\boldsymbol{Y}^-)](\boldsymbol{Y}^+-\boldsymbol{Y}^-)^{-1}.$$

Upon differentiating Eq. (IV.11), we obtain

$$\partial_3\mathbf{F}_1^+=-(\boldsymbol{Y}^+-\boldsymbol{Y}^-)^{-1}\{[\partial_3(\boldsymbol{Y}^+-\boldsymbol{Y}^-)]\mathbf{F}_1^+-\partial_3\mathbf{F}_2+(\partial_3\boldsymbol{Y}^-)\mathbf{F}_1+\boldsymbol{Y}^-\partial_3\mathbf{F}_1\}. \tag{IV.21}$$

Substitute Eq. (II.21) into Eq. (IV.21) to arrive at

$$\begin{aligned}\partial_3\mathbf{F}_1^+=&-(\boldsymbol{Y}^+-\boldsymbol{Y}^-)^{-1}\{[\partial_3(\boldsymbol{Y}^+-\boldsymbol{Y}^-)]\mathbf{F}_1^+ +i\omega(\mathbf{A}_{2,1}\mathbf{F}_1+\mathbf{A}_{2,2}\mathbf{F}_2)\\ &+(\partial_3\boldsymbol{Y}^-)\mathbf{F}_1-i\omega\boldsymbol{Y}^-(\mathbf{A}_{1,1}\mathbf{F}_1+\mathbf{A}_{1,2}\mathbf{F}_2)\}.\end{aligned} \tag{IV.22}$$

At this point, substitute Eqs. (IV.5)–(IV.6) into Eq. (IV.22) and collect terms with $\mathbf{F}_1^+$ and $\mathbf{F}_1^-$. We obtain

$$\begin{aligned}\partial_3\mathbf{F}_1^+=&-(\boldsymbol{Y}^+-\boldsymbol{Y}^-)^{-1}\{[\partial_3\boldsymbol{Y}^+-i\omega\boldsymbol{Y}^+(\mathbf{A}_{1,1}+\mathbf{A}_{1,2}\boldsymbol{Y}^+)+i\omega(\boldsymbol{A}_{2,1}+\boldsymbol{A}_{2,2}\boldsymbol{Y}^+)]\boldsymbol{F}_1^+ +i\omega(\boldsymbol{Y}^+-\boldsymbol{Y}^-)\\ &(\mathbf{A}_{1,1}+\mathbf{A}_{1,2}\boldsymbol{Y}^+)\mathbf{F}_1^+ +[\partial_3\boldsymbol{Y}^--i\omega\boldsymbol{Y}^-(\mathbf{A}_{1,1}+\mathbf{A}_{1,2}\boldsymbol{Y}^-)+i\omega(\mathbf{A}_{2,1}+\mathbf{A}_{2,2}\boldsymbol{Y}^-)]\mathbf{F}_1^-\}.\end{aligned}$$

Thus, if $\boldsymbol{Y}^{\pm}$ satisfy the pseudodifferential operator equation

$$\partial_3\boldsymbol{Y}-i\omega\boldsymbol{Y}(\mathbf{A}_{1,1}+\mathbf{A}_{1,2}\boldsymbol{Y})+i\omega(\mathbf{A}_{2,1}+\mathbf{A}_{2,2}\boldsymbol{Y})=0, \tag{IV.23}$$

Eq. (IV.7) is satisfied. A similar reasoning holds for $\mathbf{F}_1^-$. Equation (IV.23) can be written in the form of a nonlinear Riccati equation

$$\partial_3\boldsymbol{Y}-i\omega(\boldsymbol{Y}\ \ -\boldsymbol{I})\mathbf{A}\begin{pmatrix}\boldsymbol{I}\\ \boldsymbol{Y}\end{pmatrix}=0. \tag{IV.24}$$

Supplemented by the linear one-way equation for $\mathbf{F}_1$,

$$\partial_3\mathbf{F}_1+i\omega(\mathbf{A}_{1,1}+\mathbf{A}_{1,2}\boldsymbol{Y})\mathbf{F}_1=0, \tag{IV.25}$$

the solution yields the + and − constituents, provided that the existence conditions at the boundary are satisfied. (In view of the symmetry properties of $\mathbf{A}$, $\boldsymbol{Y}^T$ satisfies the same equation as $\boldsymbol{Y}$.) The system of equations involves observable that are, in principle, continuous across surfaces with sharp discontinuities. It requires a solution via an evolution operator acting in the flow direction of the one-way equation coupled to a solution via an evolution operator of the Riccati equation acting in the opposite direction.

The system (IV.23)–(IV.25) reduces significantly if the underlying medium is locally up/down symmetric. Then the partitioning, in the covariant formulation, can be carried out in such a way that $\mathbf{A}_{1,1}=\mathbf{A}_{2,2}=0$. Equation (IV.25) reduces to the conventional one-way wave equation,

$$\partial_3\mathbf{F}_1+i\omega\mathbf{A}_{1,2}\boldsymbol{Y}\mathbf{F}_1=0,$$

while Eq. (IV.23) reduces to the form

$$\frac{i}{\omega}\,\partial_3\boldsymbol{Y}+\boldsymbol{Y}\mathbf{A}_{1,2}\boldsymbol{Y}-\mathbf{A}_{2,1}=0,$$

which is associated with the composition equation for the vertical slowness operators Γ identified as $\Gamma^{\pm}=\mathbf{A}_{1,2}\boldsymbol{Y}^{\pm}$; see de Hoop.[22] The vertical slowness operators are the generalized eigenvalues of the system matrix operator $\mathbf{A}$; we denote their left symbols as $\gamma^{\pm}$.

E. Fundamental solutions

To solve the system of equations (IV.23)–(IV.25) inside the heterogeneous, compact domain, we will follow a fundamental solutions approach (see, e.g., Krueger and Ochs).[23] In the process of constructing fundamental solutions, we will enforce the decomposition's existence conditions at the boundaries. The fundamental solutions are derived from the Green's tensors of the one-way equations, associated with point sources on one of the bounding level surfaces. The solution $(\boldsymbol{Y}^+,\mathbf{G}_1^+)$ yields downward directed energy flow ($\boldsymbol{Y}$ must be solved upward and $\mathbf{G}_1$ is solved downward) and the solution $(\boldsymbol{Y}^-,\mathbf{G}_1^-)$ yields upward directed energy flow ($\boldsymbol{Y}$ must be solved downward and $\mathbf{G}_1$ is solved upward). Here, $\mathbf{G}_1^+ = \mathbf{G}_1^+(\xi_\mu,\xi_3;\xi'_\nu,\xi_3^0)$ and $\mathbf{G}_1^- = \mathbf{G}_1^-(\xi_\mu,\xi_3;\xi'_\nu,\xi_3^1)$. Thus

$$\partial_3\mathbf{G}_1^+ + i\omega(\mathbf{A}_{1,1}+\mathbf{A}_{1,2}\boldsymbol{Y}^+)\mathbf{G}_1^+ = 0 \quad \text{for } \xi_3\in(\xi_3^0,\xi_3^1],$$
$$\mathbf{G}_1^+(\xi_\mu,\xi_3^0;\xi'_\nu,\xi_3^0) = \boldsymbol{I}\delta(\xi_\mu-\xi'_\mu) \quad \text{and} \quad \boldsymbol{Y}^+|_{\xi_3=\xi_3^1} = \boldsymbol{Y}^1; \tag{IV.26}$$

$$\partial_3\mathbf{G}_1^- + i\omega(\mathbf{A}_{1,1}+\mathbf{A}_{1,2}\boldsymbol{Y}^-)\mathbf{G}_1^- = 0 \quad \text{for } \xi_3\in[\xi_3^0,\xi_3^1),$$
$$\mathbf{G}_1^-(\xi_\mu,\xi_3^1;\xi'_\nu,\xi_3^1) = \boldsymbol{I}\delta(\xi_\mu-\xi'_\mu) \quad \text{and} \quad \boldsymbol{Y}^-|_{\xi_3=\xi_3^0} = \boldsymbol{Y}^0. \tag{IV.27}$$

To generate the fundamental solutions, we assume "appropriate" initial conditions $\boldsymbol{Y}^0$ for $\boldsymbol{Y}^-$ at the upper boundary and $\boldsymbol{Y}^1$ for $\boldsymbol{Y}^+$ at the lower boundary. Note that there is no unique choice of appropriate initial conditions, and hence a whole family of decompositions exists. However, the natural choice are the "radiation" conditions for the admittance symbols

$$y^1(\xi_\mu,\alpha_\nu) = ((a_{1,2})^{-1}\gamma^+)(\xi_\mu,\alpha_\nu), \quad y^0(\xi_\mu,\alpha_\nu) = ((a_{1,2})^{-1}\gamma^-)(\xi_\mu,\alpha_\nu), \tag{IV.28}$$

where $\gamma^\pm$ are the down/up local (principal) vertical slowness symbols in the embedding at the boundary $\partial\mathscr{D}$ of $\mathscr{D}$. This choice guarantees that the ellipticity conditions are satisfied, provided that the embedding is (slightly) dissipative; then purely evanescent modes do not occur.

However, in practice, simpler choices can be used, for example the vertically traveling components,

$$y^1(\xi_\mu,\alpha_\nu) = y^\downarrow(\xi_\mu) \equiv ((a_{1,2})^{-1}\gamma^+)(\xi_\mu,0),$$
$$y^0(\xi_\mu,\alpha_\nu) = y^\uparrow(\xi_\mu) \equiv ((a_{1,2})^{-1}\gamma^-)(\xi_\mu,0).$$

The implied initial values for $\mathbf{G}_2^\pm$ are essentially nonlocal in view of the definite power flow directions of the fundamental solutions:

$$\mathbf{G}_2^+(\xi_\mu,\xi_3;\xi'_\nu,\xi_3^0) = \mathscr{G}^+(\xi_\mu,\xi'_\nu;\xi_3) \quad \text{at } \xi_3=\xi_3^0$$

and

$$\mathbf{G}_2^-(\xi_\mu,\xi_3;\xi'_\nu,\xi_3^1) = \mathscr{G}^-(\xi_\mu,\xi'_\nu;\xi_3) \quad \text{at } \xi_3=\xi_3^1.$$

The internal field, i.e., the field inside the heterogeneous, compact inclusion, is finally written as

$$\mathbf{F}_1^{\text{int}} = \mathbf{F}_1^+ + \mathbf{F}_1^-,$$

$$\mathbf{F}_1^+(\xi_\mu,\xi_3) = \int_{\xi'_\nu\in\mathbb{R}} \mathbf{G}_1^+(\xi_\mu,\xi_3;\xi'_\nu,\xi_3^0)\boldsymbol{\alpha}^+(\xi'_\nu)d\xi'_1 d\xi'_2,$$

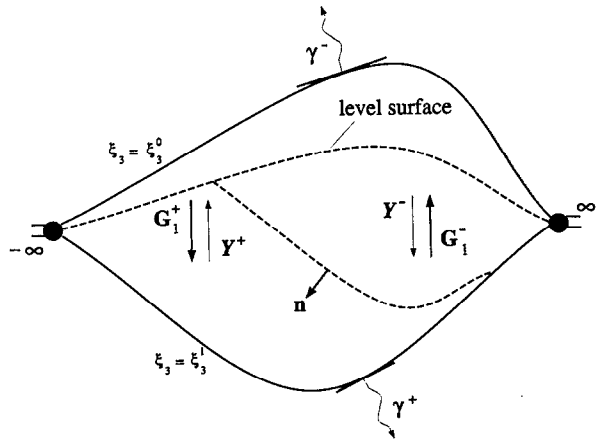

FIG. 1. The inclusion configuration.

$$\mathbf{F}_1^-(\xi_\mu,\xi_3)=\int_{\xi'_\nu\in\mathrm{R}}\mathbf{G}_1^-(\xi_\mu,\xi_3;\xi'_\nu,\xi_3^1)\boldsymbol{\alpha}^-(\xi'_\nu)d\xi'_1d\xi'_2, \tag{IV.29}$$

in which $\boldsymbol{\alpha}^+$ and $\boldsymbol{\alpha}^-$ are p-dimensional vectors in the bounding level surfaces. They equal the boundary values of the down- and upgoing constituents, viz.,

$$\boldsymbol{\alpha}^+(\xi_\mu)=\mathbf{F}_1^+(\xi_\mu,\xi_3^0) \quad \text{and} \quad \boldsymbol{\alpha}^-(\xi_\mu)=\mathbf{F}_1^-(\xi_\mu,\xi_3^1).$$

The respective 2-components of the two constituents on the boundary follow upon applying the Dirichlet-to-Neumann map with Schwartz kernel $\mathscr{Y}^+(\xi_\mu,\xi'_\nu;\xi_3^0)$ to $\mathbf{F}_1^+(\xi_\mu,\xi_3^0)$ to construct $\mathbf{F}_2^+(\xi_\mu,\xi_3^0)$ and applying the Dirichlet-to-Neumann map with Schwartz kernel $\mathscr{Y}^-(\xi_\mu,\xi'_\nu;\xi_3^1)$ to $\mathbf{F}_1^-(\xi_\mu,\xi_3^1)$ to construct $\mathbf{F}_2^-(\xi'_\nu,\xi_3^1)$. The entire construction is illustrated in Fig. 1. An alternative way of deriving a representation of the type Eq. (IV.29) is given in App. B.

The vectors $\boldsymbol{\alpha}^+$ and $\boldsymbol{\alpha}^-$ are determined by the values of the 1-component of the total field on the boundary $\partial\mathscr{D}^+\cup\partial\mathscr{D}^-$. The solvability of the resulting system of boundary integral equations determines whether the radiation conditions earlier employed are actually justified. To set up the latter system, one has to evaluate $\mathbf{G}_1^\pm$ for all values of $\xi'_j\in\partial\mathscr{D}^\pm$.

V. BACKSCATTERED AND TRANSMITTED FIELDS

In this section, the internal field solution is coupled to the external field solution to accomplish a representation for the backscattered ($x_3<0$) and transmitted ($x_3>0$) fields. To this end, the boundary-element method in accordance with Kupradze's Ansatz approach[24,25] is applied. First, we introduce the Green's tensor $\mathbf{H}$ in the imbedding, satisfying

$$\partial_{x_3}\mathbf{H}+i\omega\mathbf{A}(D_\nu)\mathbf{H}=\mathbf{N}^H \qquad \text{for} \quad x_j\in(\mathbb{R}^3\backslash\mathscr{D})\cup\partial\mathscr{D}, \tag{V.1}$$

with (unit body force) notional source

$$\mathbf{N}^H=\begin{pmatrix}I\delta(\xi_\mu-\xi'_\mu)\delta(\xi_3-\xi'_3)\\0\end{pmatrix}. \tag{V.2}$$

The medium of the embedding is assumed to be simple, i.e., typically homogeneous or planarly layered. Then a decomposition into "up" and "down" propagating constituents is readily carried out. Thus set

$$\mathbf{H}=\mathbf{H}^{+}+\mathbf{H}^{-},$$

$$\mathbf{H}^{+}\equiv 0 \quad \text{if } x_3<0 \quad \text{or } \xi_3<\xi_3^1,$$

$$\mathbf{H}^{-}\equiv 0 \quad \text{if } x_3>0 \quad \text{or } \xi_3>\xi_3^0. \tag{V.3}$$

The superscript + refers to the causal solution traveling in the positive x_3-direction and the superscript − refers to the causal solution traveling in the negative x_3-direction. Further, $\mathbf{H}_1$ denotes the "traction" Green's tensor due to a unit "body force," and $\mathbf{H}_2$ denotes the "particle velocity" Green's tensor due to a unit "body force."

Let $\partial\mathscr{S}_\infty^+$ denote the upper hemisphere at infinity in $\mathbb{R}^3$, and let $\partial\mathscr{S}_\infty^-$ denote the lower hemisphere at infinity. The section of the plane $\{x_3=0\}$ interconnecting $\partial\mathscr{D}$ with $\partial\mathscr{S}_\infty$ is denoted as $\partial\Xi$. Let the domains $\mathscr{V}^{\mp}$ be the ones bounded by $\partial\mathscr{V}^{\mp}=\partial\mathscr{D}^{\pm}\cup\partial\Xi\cup\partial\mathscr{S}_\infty^{\mp}$.

A. The boundary-element method

Write the external field in the form

$$\mathbf{F}^{\text{ext}}=\mathbf{F}^{\text{inc}}+\mathbf{F}^{\text{sc}}, \tag{V.4}$$

where $\mathbf{F}^{\text{inc}}$ denotes the irradiating or incident field which is typically excited by a source in the embedding, and $\mathbf{F}^{\text{sc}}$ denotes the scattered field; the scattered field satisfies the source-free hyperbolic system. The secondary sources associated with $\mathbf{F}^{\text{sc}}$ and the incident field in our scattering problem will be specified at the boundary $\partial\mathscr{D}$ of the compact domain, i.e., at $\xi_3=\xi_3^0$ and ξ_3^1 as well as at $\partial\Xi$ in the plane $\{x_3=0\}$ outside the domain. Then the external field is matched with the internal field on the boundary.

Any physical solution can be represented as a Kirchhoff boundary integral with kernel $\mathbf{H}_1^{\pm}$ outside the heterogeneous domain,

$$\mathbf{F}_1^{\text{sc}}=\mathbf{F}_1^{\text{sc},+}+\mathbf{F}_1^{\text{sc},-},$$

$$\mathbf{F}_1^{\text{sc},+}(\xi_\mu,\xi_3)=\int_{\xi'_\nu\in\mathbf{R}}\mathbf{H}_1^{+}(\xi_\mu,\xi_3;\xi'_\nu,\xi_3^1)\boldsymbol{\beta}^{+}(\xi'_\nu)d\xi'_1d\xi'_2 \quad \text{for } \xi\in\mathscr{V}^{+},$$

$$\mathbf{F}_1^{\text{sc},-}(\xi_\mu,\xi_3)=\int_{\xi'_\nu\in\mathbf{R}}\mathbf{H}_1^{-}(\xi_\mu,\xi_3;\xi'_\nu,\xi_3^0)\boldsymbol{\beta}^{-}(\xi'_\nu)d\xi'_1d\xi'_2 \quad \text{for } \xi\in\mathscr{V}^{-}, \tag{V.5}$$

where, according to Kupradze's Ansatz approach, $\boldsymbol{\beta}^{+}$ and $\boldsymbol{\beta}^{-}$ represent surface densities of force (dipoles). To remove the singularities arising from the kernels $\mathbf{H}_1^{+}$, the densities are shifted infinitesimally away from the bounding level surfaces; see Fig. 2. The representation for $\mathbf{F}_1^{\text{sc},\pm}$ follows upon applying the reciprocity theorem of the time-convolution type in the volume $\mathscr{V}^{\pm}$; see Fig. 2. The 2-components of the scattered field follow from the constitutive part of the hyperbolic equations as[24]

$$\mathbf{F}_2^{\text{sc},+}(\xi_\mu,\xi_3)=\tfrac{1}{2}\chi_{\partial\mathscr{V}^{-}}(\xi_3)\boldsymbol{\beta}^{+}(\xi_\mu)+\int_{\xi'_\nu\in\mathbf{R}}\mathbf{H}_2^{+}(\xi_\mu,\xi_3;\xi'_\nu,\xi_3^1)\boldsymbol{\beta}^{+}(\xi'_\nu)d\xi'_1d\xi'_2,$$

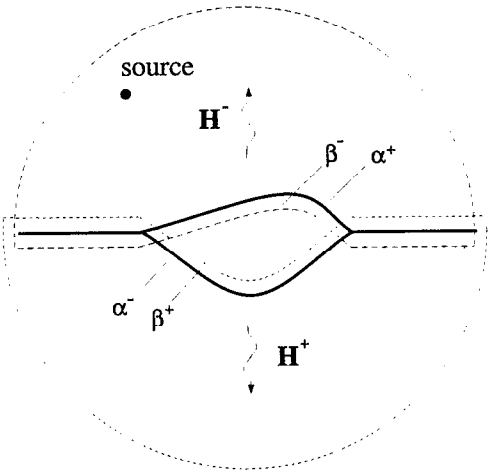

FIG. 2. The integral boundaries, limiting procedure.

$$\mathbf{F}_2^{\mathrm{sc},-}(\xi_\mu,\xi_3)=\tfrac{1}{2}\chi_{\partial\mathscr{L}^+}(\xi_3)\boldsymbol{\beta}^-(\xi_\mu)+\int_{\xi'_\nu\in\mathbb{R}}\mathbf{H}_2^-(\xi_\mu,\xi_3;\xi'_\nu,\xi_3^0)\boldsymbol{\beta}^-(\xi'_\nu)d\xi'_1d\xi'_2. \tag{V.6}$$

We have four unknown vector quantities and hence we need a system of four equations to solve the scattering problem. Expanding both components of the internal and external fields on the boundary, $\partial\mathscr{L}^+$ and $\partial\mathscr{L}^-$, yields the system of equations

$$\boldsymbol{\alpha}^+ + \int_{\xi'_\nu\in\mathbb{R}}\mathbf{G}_1^-(\cdot;\xi'_\nu,\xi_3^1)\boldsymbol{\alpha}^-(\xi'_\nu)d\xi'_1d\xi'_2\Big|_{\xi_3=\xi_3^0}$$

$$=\left[\mathbf{F}_1^{\mathrm{inc}}+\int_{\xi'_\nu\in\mathbb{R}}\mathbf{H}_1^-(\cdot;\xi'_\nu,\xi_3^0)\boldsymbol{\beta}^-(\xi'_\nu)d\xi'_1d\xi'_2\right]\Big|_{\xi_3=\xi_3^0}, \tag{V.7}$$

$$\int_{\xi'_\nu\in\mathbb{R}}\mathbf{G}_1^+(\cdot;\xi'_\nu,\xi_3^0)\boldsymbol{\alpha}^+(\xi'_\nu)d\xi'_1d\xi'_2\Big|_{\xi_3=\xi_3^1}+\boldsymbol{\alpha}^-$$

$$=\left[\mathbf{F}_1^{\mathrm{inc}}+\int_{\xi'_\nu\in\mathbb{R}}\mathbf{H}_1^+(\cdot;\xi'_\nu,\xi_3^1)\boldsymbol{\beta}^+(\xi'_\nu)d\xi'_1d\xi'_2\right]\Big|_{\xi_3=\xi_3^1}, \tag{V.8}$$

while

$$\mathbf{Y}^+\Big|_{\xi_3=\xi_3^0}\boldsymbol{\alpha}^+ + \mathbf{Y}^0\int_{\xi'_\nu\in\mathbb{R}}\mathbf{G}_1^-(\cdot;\xi'_\nu,\xi_3^1)\boldsymbol{\alpha}^-(\xi'_\nu)d\xi'_1d\xi'_2\Big|_{\xi_3=\xi_3^0}$$

$$=\tfrac{1}{2}\boldsymbol{\beta}^-+\left[\mathbf{F}_2^{\mathrm{inc}}+\int_{\xi'_\nu\in\mathbb{R}}\mathbf{H}_2^-(\cdot;\xi'_\nu,\xi_3^0)\boldsymbol{\beta}^-(\xi'_\nu)d\xi'_1d\xi'_2\right]\Big|_{\xi_3=\xi_3^0}, \tag{V.9}$$

$$\boldsymbol{Y}^1 \int_{\xi'_\nu \in \mathbb{R}} \mathbf{G}_1^+(\cdot;\xi'_\nu,\xi_3^0)\boldsymbol{\alpha}^+(\xi'_\nu)d\xi'_1 d\xi'_2 \Big|_{-\xi_3=\xi_3^1} + \boldsymbol{Y}^- \Big|_{\xi_3=\xi_3^1} \boldsymbol{\alpha}^-$$

$$= \tfrac{1}{2}\boldsymbol{\beta}^+ + \left[\mathbf{F}_2^{\mathrm{inc}} + \int_{\xi'_\nu \in \mathbb{R}} \mathbf{H}_2^+(\cdot;\xi'_\nu,\xi_3^1)\boldsymbol{\beta}^+(\xi'_\nu)d\xi'_1 d\xi'_2\right]\Big|_{\xi_3=\xi_3^1}; \tag{V.10}$$

in addition, on $\partial\Xi$ we get the boundary condition

$$0 = \int_{\xi'_\nu \in \mathbb{R}} \mathbf{H}_1^+(\cdot;\xi'_\nu,\xi_3^1)\boldsymbol{\beta}^+(\xi'_\nu)d\xi'_1 d\xi'_2 + \int_{\xi'_\nu \in \mathbb{R}} \mathbf{H}_1^-(\cdot;\xi'_\nu,\xi_3^0)\boldsymbol{\beta}^-(\xi'_\nu)d\xi'_1 d\xi'_2. \tag{V.11}$$

For all practical purposes, these boundary conditions are solved in the least-squares sense, in the horizontal Fourier domain. Note that the (constrained) freedom in the choice of $\boldsymbol{Y}^0$ and $\boldsymbol{Y}^1$ is explicit as well as implicitly present in $\mathbf{G}_1^-$ and $\mathbf{G}_1^+$.

VI. NUMERICAL ISSUES

The system of equations (IV.23)–(IV.25) can be solved along the lines of a pseudospectral/finite-difference scheme. In this section the most important details of such an approach will be discussed.

Double periodic boundary conditions are applied in the ξ-domain, along the level surfaces of ξ_3. This is preferably done on a hexagonal grid rather than our orthogonal one. The period in the ξ_ν-direction is denoted as Ξ_ν. Further, periodic boundary conditions are applied in t. A standard fast Fourier transform (FFT) representation is employed to obtain the wave field representation in time-frequency domain. A Fourier series is employed to represent the wave field as a function of the curvilinear transverse coordinates. The relevant sampling intervals in time and space are denoted as Δt, $\Delta\xi_\nu$, and $\Delta\xi_3 \equiv h$.

A. The periodic case, and discretization in the transverse directions

Consider the (ξ_ν, ξ_3) coordinate system. To reduce the stretch of the transient wave with the medium's wave speed along the horizontal or transverse directions, we apply a horizontal distance to travel-time transformation

$$\xi_1 \to \tau_1: \quad \tau_1(\xi_1) + \frac{T_1}{2} = \int_{\xi=-\Xi_1/2}^{\xi_1} V_{o,1}^{-1}(\xi)d\xi, \tag{VI.1}$$

where

$$V_{o,1}(\xi) \equiv \min_{\{\xi_2,\xi_3\}} \min_{\text{modes}} \min_{\text{directions}} V(\xi,\xi_2,\xi_3) \tag{VI.2}$$

with V denoting the modal phase velocity, being dependent on direction of propagation, and

$$T_1 \equiv \int_{\xi=-\Xi_1/2}^{\Xi_1/2} V_{o,1}^{-1}(\xi)d\xi. \tag{VI.3}$$

Then, $\tau_1(-\Xi_1/2) = -T_1/2$ and $\tau_1(\Xi_1/2) = T_1/2$. We have

$$\partial_{\xi_1} = V_{o,1}^{-1}(\xi_1)\partial_{\tau_1}. \tag{VI.4}$$

A similar transformation is carried out for ξ_2.

Consider the solution on the region $[-\Xi_1/2, \Xi_1/2]\times[-\Xi_2/2, \Xi_2/2]$ in a level surface of ξ_3 coordinated by $\{\xi_1,\xi_2\}$. Let us focus on the ξ_1-coordinate. We introduce the Fourier series basis functions

$$\psi_{k_1}(\tau_1)=\exp[-(2\pi i/T_1)k_1\tau_1], \tag{VI.5}$$

which define the wave number $\omega_1' = k_1(2\pi/T_1)$ [compare with $\omega\alpha_1$ in Eq. (IV.15)]. Then, for a general quantity f, we have

$$\tilde{f}_{k_1}=\langle f,\psi_{k_1}\rangle\equiv\frac{1}{T_1}\int_{\tau_1=-T_1/2}^{T_1/2} f(\tau_1)\overline{\psi_{k_1}(\tau_1)}d\tau_1, \tag{VI.6}$$

which is an integral over the one-dimensional torus $\mathscr{T}^1$, if

$$f(\tau_1)=\sum_{k_1=-\infty}^{\infty}\tilde{f}_{k_1}\psi_{k_1}(\tau_1). \tag{VI.7}$$

Note that the $\tilde{f}_{k_1}$ are implicitly functions of (τ_2,ξ_3), and satisfy $\Sigma_{k_1=-\infty}^{\infty}|\tilde{f}_{k_1}|^2(1+|k_1|^2)^r<\infty$ when f is restricted to the Sobolev space $H^r(\mathscr{T}^1)$. Note that the pseudo-differential operators, like the admittance operator, are continuous between appropriate Sobolev spaces.

Upon discretizing the integral in Eq. (VI.6), and truncating the summation in Eq. (VI.7), we arrive at the transform pair

$$\tilde{f}_{k_1}\simeq\frac{1}{N_1\Delta\tau_1}\sum_{l_1=-N_1/2}^{N_1/2-1} f(l_1\Delta\tau_1)\overline{\psi_{k_1}(l_1\Delta\tau_1)}\Delta\tau_1, \tag{VI.8}$$

$$f(l_1\Delta\tau_1)\simeq\sum_{k_1=-(M_1-1)/2}^{(M_1-1)/2}\tilde{f}_{k_1}\psi_{k_1}(l_1\Delta\tau_1) \tag{VI.9}$$

with

$$N_1\Delta\tau_1=T_1, \quad \text{hence} \quad \Delta\omega_1'\Delta\tau_1=\frac{2\pi}{N_1}. \tag{VI.10}$$

Note that for $M_1=N_1+1$ we obtain the well-known discrete Fourier transform (DFT) pair. However, here the values of N_1 and M_1 are left uncoupled, but assuming that N_1 is even and M_1 is odd. Due to the discretization Eq. (VI.8) of the integral in Eq. (VI.6), the field becomes also periodic in the k_1-domain with period N_1 and associated Nyquist horizontal wave number $\omega_{1,\mathrm{Nyq}}' = \pi/\Delta\tau_1$. In general, the horizontal wave number content (band width) of the wave field solution will be much less than this Nyquist value, which allows us to use $M_1\ll N_1$.

The co-kernel $\tilde{a}$ of the matrix operator $\mathbf{A}$ is of the form

$$\tilde{a}_{k_1-l_1,l_1}=\langle\psi_{k_1},\mathbf{A}\psi_{l_1}\rangle; \tag{VI.11}$$

for an element of the system's matrix of partial differential operators, we typically get

$$\begin{aligned}\langle\psi_{k_1},\partial_{\tau_1}(\rho(\tau_1,\xi_3)\partial_{\tau_1}\cdot)\psi_{l_1}\rangle&=(\widetilde{\partial_{\tau_1}\rho})_{k_1-l_i}(-il_1\Delta\omega_1')-\tilde{\rho}_{k_1-l_1}(-il_1\Delta\omega_1')^2\\&=(-ik_1\Delta\omega_1')(-il_1\Delta\omega_1')\tilde{\rho}_{k_1-l_1}.\end{aligned} \tag{VI.12}$$

Observe that upon imposing the periodic boundary conditions, the operators involved in the scattering problem will become compact.

Equations (IV.23)–(IV.25) are thus obtained in the discrete horizontal wave number domain; in fact, they have the form of a system of ordinary differential equations.

B. Discretization in the normal direction

For the discretization of the evolution equations we employ the fourth-order Runge–Kutta scheme. [We could have proposed any locally stable finite difference scheme.] We write Eqs. (IV.23)–(IV.25) in the generic co-kernel form

$$\partial_3 y + i\omega F(\xi_3, y) = 0, \tag{VI.13}$$

where we have suppressed the ξ_ν and ω dependence of F. The explicit fourth-order Runge–Kutta scheme is given by

$$y(\xi_3+h) = y(\xi_3) + \tfrac{1}{6}y_0 + \tfrac{1}{3}y_1 + \tfrac{1}{3}y_2 + \tfrac{1}{6}y_3 + O(h^5), \tag{VI.14}$$

where

$$y_0 = -i\omega h F(\xi_3, y(\xi_3)), \tag{VI.15}$$

$$y_1 = -i\omega h F(\xi_3 + \tfrac{1}{2}h, y(\xi_3) + \tfrac{1}{2}y_0), \tag{VI.16}$$

$$y_2 = -i\omega h F(\xi_3 + \tfrac{1}{2}h, y(\xi_3) + \tfrac{1}{2}y_1), \tag{VI.17}$$

$$y_3 = -i\omega h F(\xi_3, y(\xi_3) + y_2). \tag{VI.18}$$

To make this scheme quasi stable, the stepsize h is adapted in accordance with an eigenvalue analysis of $(\partial_y F)(\xi_3, y(\xi_3))$ over each range $\{\xi_3, \xi_3+h\}$ as it arises in the linearization of Eq. (VI.13).

To be more specific, consider a range $\{\xi_3^c, \xi_3^c + h\}$, say. Equation (IV.25) for $\mathbf{F}_1$is linear, hence

$$(\partial_y F)(\xi_3, y(\xi_3)) \to \mathbf{D} \equiv \mathbf{A}_{1,1} + \mathbf{A}_{1,2}\boldsymbol{Y}; \quad \mathbf{D}_c = \mathbf{D}|_{\xi_3 = \xi_3^c}. \tag{VI.19}$$

The linearization of Eq. (IV.23) follows from substituting

$$\boldsymbol{Y} = \boldsymbol{Y}_c + \boldsymbol{E} \quad \text{with} \quad \boldsymbol{Y}_c = \boldsymbol{Y}|_{\xi_3 = \xi_3^c};$$

omitting terms $O(\boldsymbol{E}^2)$ and using the symmetry properties of $\mathbf{A}$ then leads to the equation

$$\partial_3 \boldsymbol{E} - i\omega \{\boldsymbol{E}\mathbf{D}_c + \mathbf{D}_c^T \boldsymbol{E}\} \simeq (\partial_3 \boldsymbol{Y})_c, \tag{VI.20}$$

where

$$(\partial_3 \boldsymbol{Y})_c = i\omega \{\boldsymbol{Y}_c(\mathbf{A}_{1,1} + \mathbf{A}_{1,2}\boldsymbol{Y}_c) - (\mathbf{A}_{2,1} + \mathbf{A}_{2,2}\boldsymbol{Y}_c)\};$$

hence

$$(\partial_y F)(\xi_3, y(\xi_3))y \to -\{\boldsymbol{E}\mathbf{D} + \mathbf{D}^T\boldsymbol{E}\}. \tag{VI.21}$$

From the latter equation, in view of the equivalence in spectral properties of $\mathbf{D}$ and $\mathbf{D}^T$, it follows that the stability bound on h from the linearized Riccati equation for the admittance operator must be half the bound on h from the field equation based on Eq. (VI.19). However, since the equation

for the admittance operator must be solved prior to the one for the relevant field quantities, the Runge–Kutta scheme requires the sampling in ξ_3 of the admittance to be twice as dense as the one of the field anyway. [The material properties, in turn, have to be sampled four times as densely as the field.]

We will analyze the upper bound for h following from the field equation in more detail. Within the interval $\{\xi_3^c, \xi_3^c + h\}$, we assume the operator $\mathbf{A}$ to be slowly varying. Then, within this interval, we have [cf. Eq. (VI.19)]

$$\mathbf{D} = \mathbf{D}_c + \mathbf{A}_{1,2}\boldsymbol{E}. \tag{VI.22}$$

Using Eq. (VI.22), the norm of $\mathbf{D}$ can be estimated as

$$\|\mathbf{D}\| \leqslant \|\mathbf{D}_c\| + \|\mathbf{A}_{1,2}\boldsymbol{E}\|. \tag{VI.23}$$

The second norm on the right-hand side of Eq. (VI.23) can be estimated as

$$\|\mathbf{A}_{1,2}\boldsymbol{E}\| \leqslant h \, \|\delta_3 \boldsymbol{D}\|_{\max} \quad \text{with} \quad \|\delta_3 \mathbf{D}\|_{\max} \equiv \max_{\{\xi_3^c, \xi_3^c + h\}} \|\delta_3 \mathbf{D}\|$$

in which

$$\|\delta_3 \mathbf{D}\|_{\max} \sim \|(\partial_3 \mathbf{D})_c\| \simeq \|\mathbf{A}_{1,2}(\partial_3 \boldsymbol{E})_c\| \simeq \|\mathbf{A}_{1,2}(\partial_3 \boldsymbol{Y})_c\|$$

using Eq. (VI.20); here, δ_3 denotes the two-point difference operator. Substituting this result in Eq. (VI.23), we obtain

$$\|\mathbf{D}\| \leqslant \|\mathbf{D}_c\| + h \|\delta_3 \mathbf{D}\|_{\max}. \tag{VI.24}$$

Now, suppose we have the estimate

$$h\omega \, \|\mathbf{D}\| \leqslant \theta \tag{VI.25}$$

for some value of θ. Then the explicit Runge–Kutta scheme Eq. (VI.14) implies an upper bound δ for the amplication factor with

$$\delta = \frac{1}{720} \, \theta^5.$$

By choosing θ appropriately, the amplification can be reduced to any desired level. To arrive at an explicit bound, use Eq. (VI.24) in Eq. (VI.25)

$$h\omega \, (\|\mathbf{D}_c\| + h \|\delta_3 \mathbf{D}\|_{\max}) \leqslant \theta$$

to guarantee Eq. (VI.25). Upon analyzing the left-hand side of the latter inequality quadratic in $h\omega$, it is found that

$$h\omega \leqslant \frac{2\theta}{\|\mathbf{D}_c\| + \sqrt{\|\mathbf{D}_c\|^2 + 4\omega^{-1}\theta \|\delta_3 \mathbf{D}\|_{\max}}}. \tag{VI.26}$$

For practical purposes, we introduce a more conservative upper bound through

$$\sqrt{\|\mathbf{D}_c\|^2 + 4\omega^{-1}\theta \|\delta_3 \mathbf{D}\|_{\max}} \leqslant \|\mathbf{D}_c\| + 2\sqrt{\omega^{-1}\theta \|\delta_3 \mathbf{D}\|_{\max}},$$

which yields the approximation of Eq. (VI.26)

$$h\omega \leqslant \frac{\theta}{\|\mathbf{D}_c\| + \sqrt{\omega^{-1}\theta}\|\delta_3\mathbf{D}\|_{\max}}. \tag{VI.27}$$

Naturally, our sampling rate must be dependent on the frequency. The norms of the operators occurring in Eq. (VI.27) follow from (estimates of) the maximum eigenvalues of their respective co-kernel matrix representations.

A summary of the necessary steps in the numerical scheme is given in Appendix C.

VII. DISCUSSION

We have considered the Dirichlet-to-Neumann map or admittance operator at the boundary of a large inclusion, and analyzed the equations governing the continuation of this operator away from the boundary. Such a continuation required a directional decomposition of the (internal) wave field, viz., with respect to power flow averaged over a period in time and a level hypersurface in space, and the introduction of pseudodifferential operators. The continuation, essentially, followed from an invariant imbedding approach extended to higher dimensions. In the double periodic case, the latter approach reduced the continuation problem to solving a large system of ordinary differential equations; an explicit construction, based on the latter system, has been derived and its stability properties have been analyzed.

We envisage as a key application the analysis and computation of time-domain transient wave phenomena. This implied that we did not have to consider general frequencies, but only the ones relevant to carry out a proper inverse Fourier transform back to the time domain. In this respect, special care had to be taken to avoid possible resonances in the configuration.

The continuation of the admittance operator leads, in case the medium exhibits a local direction of preference, to an accurate method for the numerical simulation of waves. It suffers from only few limitations as far as the coefficients of the original hyperbolic system are concerned. Apart from conditions on proper sampling, it was assumed that the coefficients can only jump across hypersurfaces. Such surfaces, or interfaces, then determined the coordinates on the manifold as well as the local (normal) direction of preference. With those restrictions, general symmetric hyperbolic systems can be solved this way; the occurrence of anisotropy does not require special care.

The framework of continuation of the admittance operator has been designed to fill the gap between long wavelength and short wavelength theories, i.e., that scale where multiple scattering and mode interactions are the dominant phenomena of interest. In a scattering configuration as a whole, different scales may enter the direct problem; then the theory should only be applied locally. Since the admittance operator defines the Dirichlet-to-Neumann map, the framework discussed in this article opens the way for developing an inverse scattering theory from local boundary measurements.

ACKNOWLEDGMENTS

The second author (M. V. de H.) would like to thank Dr. L. Fishman for his interest in this work and his valuable comments. This research was supported in part by the Institute for Mathematics and its Applications, Minneapolis, MN, with funds provided by the National Science Foundation.

APPENDIX A: AN EXAMPLE—THE ANISOTROPIC FLUID

1. Covariant formulation

In the case of an anisotropic fluid, the hyperbolic system is given by

$$\mathrm{D}_k v^k = -i\omega\kappa^{-1}p \quad \text{with} \quad \mathrm{D}_k v^k = (\partial_{\xi_k} + \Gamma^j_{jk})v^k, \tag{A1}$$

$$-\mathsf{D}_{ip}=i\omega\rho_{ij}v^j \quad \text{with} \quad \mathsf{D}_{ip}=\partial_{\xi_i}p. \tag{A2}$$

We extract the locally normal component of the particle velocity,

$$v^n=n_jv^j, \tag{A3}$$

so that

$$v^i=V^i+v^n\frac{n^i}{\|\mathbf{n}\|^2} \quad \text{with} \quad V^i=\left(\delta^i{}_j-\frac{n^in_j}{\|\mathbf{n}\|^2}\right)v^j. \tag{A4}$$

Indeed, $V^n=0$. From Eq. (A2) we find that

$$-(\rho^{-1})^{jk}\mathsf{D}_kp=i\omega v^j. \tag{A5}$$

Set

$$\Sigma^{ij}\equiv(\rho^{-1})^{ij}, \quad \Sigma^j\equiv n_i(\rho^{-1})^{ij}.$$

Contracting Eq. (A5) with n_j yields

$$-\Sigma^k\mathsf{D}_kp=i\omega v^n,$$

hence

$$-\Sigma^\nu\mathsf{D}_\nu p-\Sigma^3\mathsf{D}_3p=i\omega v^n. \tag{A6}$$

On the other hand, contracting Eq. (A5) with $(\delta^i{}_j-n^in_j\|\mathbf{n}\|^{-2})$ yields

$$i\omega V^i=-\left(\delta^i{}_j-\frac{n^in_j}{\|\mathbf{n}\|^2}\right)(\rho^{-1})^{jk}\mathsf{D}_kp,$$

hence, upon substituting Eq. (A6),

$$i\omega\left(V^k+v^n\frac{n^k}{\|\mathbf{n}\|^2}\right)=(-\Sigma^{k\nu}+\Sigma^{k3}(\Sigma^3)^{-1}\Sigma^\nu)\mathsf{D}_\nu p+i\omega(\Sigma^3)^{-1}\Sigma^{k3}v^n. \tag{A7}$$

Now, substituting Eq. (A4) into Eq. (A1) yields

$$\mathsf{D}_3\left(V^3+v^n\frac{n^3}{\|\mathbf{n}\|^2}\right)+\mathsf{D}_\mu\left(V^\mu+v^n\frac{n^\mu}{\|\mathbf{n}\|^2}\right)=-i\omega\kappa^{-1}p.$$

In the covariant formulation, it follows that $\mathbf{n}$ must coincide with the unit vector in the ξ_3-direction. This implies that $v^n=v^3$, $V^3=0$, and $\Sigma^j=\Sigma^{3j}$. Eliminating V^μ with the aid of Eq. (A7) then amounts to

$$\mathsf{D}_\mu[(\Sigma^{33})^{-1}\Sigma^{\mu3}v^3]+\mathsf{D}_3v^3=\mathsf{D}_\mu\left[[-\Sigma^{\mu\nu}+\Sigma^{\mu3}(\Sigma^{33})^{-1}\Sigma^{3\nu}]\frac{i}{\omega}\mathsf{D}_\nu p\right]-i\omega\kappa^{-1}p. \tag{A8}$$

Hence, combining Eqs. (A6) and (A8) implies the covariant system's matrix operator

$$\mathbf{A}_C=\begin{pmatrix} -(\Sigma^{33})^{-1}\Sigma^{3\nu}\,\dfrac{i}{\omega}\,\partial_{\xi_\nu} & -(\Sigma^{33})^{-1} \\ \dfrac{i}{\omega}\,\mathsf{D}_\mu\left[(-\Sigma^{\mu\nu}+\Sigma^{\mu 3}(\Sigma^{33})^{-1}\Sigma^{3\nu})\,\dfrac{i}{\omega}\,\partial_{\xi_\nu}\cdot\right]-\kappa^{-1} & -\dfrac{i}{\omega}\,\mathsf{D}_\mu[\Sigma^{\mu 3}(\Sigma^{33})^{-1}\cdot] \end{pmatrix}; \tag{A9}$$

the Christoffel symbols appear in $\mathsf{D}_\mu = \partial_{\xi_\mu} + \Gamma^j_{j\mu}$. To arrive at the reduced system of the type (II.21), we have to add

$$\mathbf{A}_\Gamma=\begin{pmatrix} 0 & 0 \\ 0 & -\dfrac{i}{\omega}\,\Gamma^j_{j3} \end{pmatrix} \tag{A10}$$

to $\mathbf{A}_C$: $\mathbf{A}=\mathbf{A}_C+\mathbf{A}_\Gamma$. Note that monoclynic symmetry implies that $\Sigma^{3\nu}=\Sigma^{\mu 3}=0$; then $\mathbf{A}_C$ becomes a purely off-diagonal matrix operator.

2. Quasiscalar formulation

Consider Eq. (A2), but now in a Cartesian frame. Substituting Eq. (II.14) then leads to

$$-(\rho^{-1})_{jk}\left[\partial_{\xi_k}-\delta_{k3}\partial_{\xi_3}+\frac{1}{\sqrt{g_{33}}}\,n_k\partial_{\xi_3}\right]p=i\omega v_j, \tag{A11}$$

hence

$$-\left[(\rho^{-1})_{i\nu}\partial_{\xi_\nu}+\frac{(\rho^{-1})_{ij}n_j}{\sqrt{g_{33}}}\,\partial_{\xi_3}\right]p=i\omega v_i. \tag{A12}$$

Contract Eq. (A12) with n_i and set

$$\Sigma_{ij}\equiv(\rho^{-1})_{ij},\quad \Sigma_{n\nu}\equiv n_i(\rho^{-1})_{i\nu},\quad \Sigma_{in}\equiv(\rho^{-1})_{ij}n_j,\quad \Sigma_{nn}\equiv n_i(\rho^{-1})_{ij}n_j$$

then

$$-\Sigma_{n\nu}\partial_{\xi_\nu}p-\frac{\Sigma_{nn}}{\sqrt{g_{33}}}\,\partial_{\xi_3}p=i\omega v_n. \tag{A13}$$

Contract Eq. (A12) with $(\delta_{ki}-n_kn_i\|\mathbf{n}\|^{-2})$ to get

$$i\omega\left(V_k+v_n\frac{n_k}{\|\mathbf{n}\|^2}\right)=(-\Sigma_{k\nu}+\Sigma_{kn}\Sigma_{nn}^{-1}\Sigma_{n\nu})\partial_{\xi_\nu}p+i\omega\Sigma_{nn}^{-1}\Sigma_{kn}v_n. \tag{A14}$$

In the quasiscalar formulation, $\mathbf{n}$ is given by Eq. (II.13). Substituting Eqs. (II.14) and (A4) into Eq. (A1) now leads to ($n_3\equiv 1$)

$$\frac{1}{\sqrt{g_{33}}}\,\partial_{\xi_3}v_n+\left[\partial_{\xi_\mu}-\frac{1}{\sqrt{g_{33}}}\,(\partial_{\xi_3}n_\mu)\right]\left(V_\mu+v_n\frac{n_\mu}{\|\mathbf{n}\|^2}\right)=-i\omega\kappa^{-1}p.$$

Substituting Eq. (A13) into the latter equation yields

$$\sqrt{g_{33}}\partial_{\xi_\mu}-(\partial_{\xi_3}n_\mu)](\Sigma_{nn}^{-1}\Sigma_{\mu n}v_n)+\partial_{\xi_3}v_n$$

$$=[\sqrt{g_{33}}\partial_{\xi_\mu}-(\partial_{\xi_3}n_\mu)]\left[(-\Sigma_{\mu\nu}+\Sigma_{\mu n}\Sigma_{nn}^{-1}\Sigma_{n\nu})\frac{i}{\omega}\mu_{\xi_\nu}p\right]-i\omega\sqrt{g_{33}}\kappa^{-1}p. \tag{A15}$$

Using Eq. (II.13), we find that

$$[\sqrt{g_{33}}\partial_{\xi_\mu}-(\partial_{\xi_3}n_\mu)]\cdot=\partial_{\xi_\mu}[(\partial_{\xi_3}\mathrm{f})\cdot]=\partial_{\xi_\mu}[\sqrt{g_{33}}\cdot]. \tag{A16}$$

Then, combining Eqs. (A13) and (A15), the system's matrix operator follows as

$$\mathbf{A}=-\begin{pmatrix} \sqrt{g_{33}}\Sigma_{nn}^{-1}\Sigma_{n\nu}\frac{i}{\omega}\partial_{\xi_\nu} & \sqrt{g_{33}}\Sigma_{nn}^{-1} \\ \frac{i}{\omega}\partial_{\xi_\mu}\left[\sqrt{g_{33}}\widehat{\Sigma_{\mu\nu}}\frac{i}{\omega}\partial_{\xi_\nu}\cdot\right]+\sqrt{g_{33}}\kappa^{-1} & \frac{i}{\omega}\partial_{\xi_\mu}(\sqrt{g_{33}}\Sigma_{\mu n}\Sigma_{nn}^{-1}\cdot) \end{pmatrix}. \tag{A17}$$

with

$$\widehat{\Sigma_{\mu\nu}}\equiv\Sigma_{\mu\nu}-\Sigma_{\mu n}\Sigma_{nn}^{-1}\Sigma_{n\nu}. \tag{A18}$$

Note that, in general, the system's matrix is dense, even in the isotropic medium case; then we have

$$\Sigma_{ij}=\rho^{-1}\delta_{ij},\quad \Sigma_{n\nu}=\rho^{-1}n_\nu,\quad \Sigma_{in}=\rho^{-1}n_i,\quad \Sigma_{nn}=\rho^{-1}\|\mathbf{n}\|^2,$$

while

$$\widehat{\Sigma_{\mu\nu}}=\frac{1}{\rho}\left(\delta_{\mu\nu}-\frac{n_\mu n_\nu}{\|\mathbf{n}\|^2}\right).$$

APPENDIX B: EVOLUTION OF THE ADMITTANCE OPERATOR IN TERMS OF A GREEN'S TENSOR

1. Representation theorem

The starting point of this appendix is a representation theorem for $\mathbf{F}_2$ that follows from Eq. (III.1) upon substituting the Green's tensor $\mathbf{G}^{II}(\xi_\mu\xi_3,\xi'_\nu,\xi'_3)$ with notional sources

$$\mathbf{N}^{II}=\begin{pmatrix} I\delta(\xi_\mu-\xi'_\mu)\delta(\xi_3-\xi'_3) \\ 0 \end{pmatrix}.$$

Substituting this Green's tensor into Eq. (III.1) for state a yields the representation

$$\mathbf{F}_2(\xi'_\nu,\xi'_3)=-\int_{\xi_3=\xi_3^0}^{\xi_3^1}\int_{\xi_\mu\in\mathbb{R}}(\mathbf{G}^{II})^T(\xi_\mu,\xi_3)\mathbf{J}\mathbf{N}(\xi_\mu,\xi_3)d\xi_1d\xi_2d\xi_3$$

$$+\int_{\xi_\mu\in\mathbb{R}}(\mathbf{G}^{II})^T(\xi_\mu,\xi_3^1)\mathbf{J}\mathbf{F}(\xi_\mu,\xi_3^1)d\xi_1d\xi_2-\int_{\xi_\mu\in\mathbb{R}}(\mathbf{G}^{II})^T(\xi_\mu,\xi_3^0)\mathbf{J}\mathbf{F}(\xi_\mu,\xi_3^0)d\xi_1d\xi_2 \tag{B1}$$

if $\xi'_3\in(\xi_3^0,\xi_3^1)$. We will impose specific boundary conditions for the Green's tensor, viz., of the "normal-traction free" type,

$$\mathbf{G}_1^{II}|_{\partial\mathscr{V}}=0.$$

This boundary condition is nonradiating, implying that in the case of a nondissipative compact domain $\mathscr{D}$ the Green's tensor exists at the configuration's resonance frequencies only. By opening up the compact domain in $\mathbb{R}^3$ towards infinity along thin slabs centered on $x_3=0$, the configuration deforms into an open resonator; then $\mathbf{G}^{II}$ exists away from the resonance frequencies.

One of the reciprocity relations for such a Green's tensor follows as

$$(\mathbf{G}_2^{II})^T(\xi_\mu,\xi_3;\xi'_\nu,\xi'_3)=\mathbf{G}_2^{II}(\xi'_\nu,\xi'_3;\xi_\mu,\xi_3).$$

Using this relation and the nonradiating boundary condition in Eq. (B1) yields

$$\begin{aligned}\mathbf{F}_2(\xi'_\nu,\xi'_3)=&-\int_{\xi'_3=\xi_3^0}^{\xi_3^1}\int_{\xi_\mu\in\mathbb{R}}(\mathbf{G}^{II})^T(\xi_\mu,\xi_3;\xi'_\nu,\xi'_3)\mathbf{JN}(\xi_\mu,\xi_3)d\xi_1d\xi_2d\xi_3\\&-\int_{\xi_\mu\in\mathbb{R}}\mathbf{G}_2^{II}(\xi'_\nu,\xi'_3;\xi_\mu,\xi_3^1)\mathbf{F}_1(\xi_\mu,\xi_3^1)d\xi_1d\xi_2\\&+\int_{\xi_\mu\in\mathbb{R}}\mathbf{G}_2^{II}(\xi'_\nu,\xi'_3;\xi_\mu,\xi_3^0)\mathbf{F}_1(\xi_\mu,\xi_3^0)d\xi_1d\xi_2.\end{aligned}\tag{B2}$$

2. The evolution equations

Assume that $\mathbf{N}=\mathbf{0}$ in $\mathscr{D}_{[\xi_3^0,\xi_3^1]}$; then the volume integral on the right-hand side of Eq. (B2) vanishes and

$$\begin{aligned}\mathbf{F}_2(\xi'_\nu,\xi'_3)&=\mathbf{F}_2^0(\xi'_\nu,\xi'_3)+\mathbf{F}_2^1(\xi'_\nu,\xi'_3),\\\mathbf{F}_2^1(\xi'_\nu,\xi'_3)&=-\int_{\xi_\mu\in\mathbb{R}}\mathbf{G}_2^{II}(\xi'_\nu,\xi'_3;\xi_\mu,\xi_3^1)\mathbf{F}_1(\xi_\mu,\xi_3^1)d\xi_1d\xi_2,\\\mathbf{F}_2^0(\xi'_\nu,\xi'_3)&=\int_{\xi_\mu\in\mathbb{R}}\mathbf{G}_2^{II}(\xi'_\nu,\xi'_3;\xi_\mu,\xi_3^0)\mathbf{F}_1(\xi_\mu,\xi_3^0)d\xi_1d\xi_2,\end{aligned}\tag{B3}$$

for $\xi'_3\in(\xi_3^0,\xi_3^1)$. Apply representation (B3) in $\xi'_3=\xi_3^0$ and in $\xi'_3=\xi_3^0$. Set

$$\begin{aligned}(\mathbf{g}_2^{01}\mathbf{F}_1(.,\xi_3^1))(\xi'_\nu,\xi_3^0)&=\int_{\xi_\mu\in\mathbb{R}}\mathbf{G}_2^{II}(\xi'_\nu,\xi_3^0;\xi_\mu,\xi_3^1)\mathbf{F}_1(\xi_\mu,\xi_3^1)d\xi_1d\xi_2,\\(\mathbf{g}_2^{00}\mathbf{F}_1(\cdot,\xi_3^0))(\xi'_\nu,\xi_3^0)&=\int_{\xi_\mu\in\mathbb{R}}\mathbf{G}_2^{II}(\xi'_\nu,\xi_3^0;\xi_\mu,\xi_3^0)\mathbf{F}_1(\xi_\mu,\xi_3^0)d\xi_1d\xi_2,\\(\mathbf{g}_2^{11}\mathbf{F}_1(\cdot,\xi_3^1))(\xi'_\nu,\xi_3^1)&=\int_{\xi_\mu\in\mathbb{R}}\mathbf{G}_2^{II}(\xi'_\nu,\xi_3^1;\xi_\mu;\xi_3^1)\mathbf{F}_1(\xi_\mu,\xi_3^1)d\xi_1d\xi_2,\\(\mathbf{g}_2^{10}\mathbf{F}_1(\cdot,\xi_3^0))(\xi'_\nu,\xi_3^1)&=\int_{\xi_\mu\in\mathbb{R}}\mathbf{G}_2^{II}(\xi'_\nu,\xi_3^1;\xi_\mu,\xi_3^0)\mathbf{F}_1(\xi_\mu,\xi_3^0)d\xi_1d\xi_2.\end{aligned}\tag{B4}$$

Then

$$\begin{pmatrix}\mathbf{F}_2(\cdot,\xi_3^0)\\\mathbf{F}_2(\cdot,\xi_3^1)\end{pmatrix}=\begin{pmatrix}\mathbf{g}_2^{00}&-\mathbf{g}_2^{01}\\-\mathbf{g}_2^{10}&\mathbf{g}_2^{11}\end{pmatrix}\begin{pmatrix}\mathbf{F}_1(\cdot,\xi_3^0)\\\mathbf{F}_1(\cdot,\xi_3^1)\end{pmatrix}.\tag{B5}$$

Let the admittance operator be known at level surface $\xi_3=\xi_3^1$, i.e.,

$$\mathbf{F}_2(\cdot,\xi_3^1)=\boldsymbol{Y}^1\mathbf{F}_1(\cdot,\xi_3^1), \tag{B6}$$

where $\boldsymbol{Y}^1=\boldsymbol{Y}|_{\xi_3=\xi_3^1}$ as in the main text. Substituting Eq. (B6) into Eq. (B5) and solving the resulting operator equation yields the (forward) evolution equation for $\mathbf{F}_1$,

$$\mathbf{F}_1(\cdot,\xi_3^1)=-(\boldsymbol{Y}^1-\mathbf{g}_2^{11})^{-1}\mathbf{g}_2^{10}\mathbf{F}_1(\cdot,\xi_3^0), \tag{B7}$$

and the (backward) evolution equation for $\boldsymbol{Y}$

$$\boldsymbol{Y}^0=\mathbf{g}_2^{00}-\mathbf{g}_2^{01}(\boldsymbol{Y}^1-\mathbf{g}_2^{11})^{-1}\mathbf{g}_2^{10} \tag{B8}$$

upon identifying $\mathbf{F}_2(\cdot,\xi_3^0)=\boldsymbol{Y}^0\mathbf{F}_1(\cdot,\xi_3^0)$.

The existence of $(\boldsymbol{Y}^1-\mathbf{g}_2^{11})^{-1}$ needs to be further investigated. As in the main text, we will use a power flow argument. First, supplement representation (B3) with the 1-components

$$\begin{aligned}\mathbf{F}_1^1(\xi_\nu',\xi_3')&=-\int_{\xi_\mu\in\mathbb{R}}\mathbf{G}_1^{II}(\xi_\nu',\xi_3';\xi_\mu,\xi_3^1)\mathbf{F}_1(\xi_\mu,\xi_3^1)d\xi_1d\xi_2,\\ \mathbf{F}_1^0(\xi_\nu',\xi_3')&=\int_{\xi_\mu\in\mathbb{R}}\mathbf{G}_1^{II}(\xi_\nu',\xi_3';\xi_\mu,\xi_3^0)\mathbf{F}_1(\xi_\mu,\xi_3^0)d\xi_1d\xi_2.\end{aligned} \tag{B9}$$

Note that $\mathbf{F}^1$ and $\mathbf{F}^2$ independently satisfy the homogeneous hyperbolic system in $\mathscr{D}\backslash\partial\mathscr{D}$, with boundary values

$$\mathbf{F}_1^1(\cdot,\xi_3^0)=0,\quad \mathbf{F}_1^0(\cdot,\xi_3^0)=\mathbf{F}_1(\cdot,\xi_3^0), \tag{B10}$$

$$\mathbf{F}_1^1(\cdot,\xi_3^1)=\mathbf{F}_1(\cdot,\xi_3^1),\quad \mathbf{F}_1^0(\cdot,\xi_3^1)=0. \tag{B11}$$

From the fact that $\mathbf{F}_1^1(\cdot,\xi_3^0)=0$ it follows that the solution $\mathbf{F}^1$ does not allow any energy transport across the bounding level surface $\xi_3=\xi_3^0$. Then the physics constrains the averaged locally vertical component of the Poynting vector according to

$$0\geqslant-\int_{\xi_\mu\in\mathbb{R}}\tfrac{1}{2}\,\mathrm{Re}\{(\mathbf{F}_1^1)^\dagger\mathbf{F}_2^1\}(\xi_\mu,\xi_3^1)d\xi_1d\xi_2=-\tfrac{1}{2}\int_{\xi_\mu\in\mathbb{R}}(\mathbf{F}_1^1)^\dagger[\mathbf{g}_2^{11}+(\mathbf{g}_2^{11})^\dagger]\mathbf{F}_1^1(\xi_\mu,\xi_3^1)d\xi_1d\xi_2. \tag{B12}$$

Thus the Hermitian part of $\mathbf{g}_2^{11}$ is a negative or vanishing operator.

From the fact that $\mathbf{F}_1^0(\cdot,\xi_3^1)=0$ it follows that the solution $\mathbf{F}^0$ does not allow any energy transport across the bounding level surface $\xi_3=\xi_3^1$. Then the physics constrains the averaged locally vertical component of the Poynting vector according to

$$0\leqslant-\int_{\xi_\mu\in\mathbb{R}}\tfrac{1}{2}\,\mathrm{Re}\{(\mathbf{F}_1^0)^\dagger\mathbf{F}_2^0\}(\xi_\mu,\xi_3^0)d\xi_1d\xi_2=-\tfrac{1}{2}\int_{\xi_\mu\in\mathbb{R}}(\mathbf{F}_1^0)^\dagger[\mathbf{g}_2^{00}+(\mathbf{g}_2^{00})^\dagger]\mathbf{F}_1^0(\xi_\mu,\xi_3^0)d\xi_1d\xi_2. \tag{B13}$$

Thus the Hermitian part of $\mathbf{g}_2^{00}$ is a positive or vanishing operator.

In conclusion, $\boldsymbol{Y}^1$ is positive and $\mathbf{g}^{11}$ is negative or vanishing, which guarantees the existence of $(\boldsymbol{Y}^1-\mathbf{g}_2^{11})^{-1}$.

APPENDIX C: THE NUMERICAL SCHEME

For all frequencies calculate the fundamental solutions in inclusion: apply the radiation boundary conditions (IV.28), solve the Riccati equation for positive and negative directions (IV.23), reverse the order of both Riccati equation solutions, apply the point source boundary conditions (IV.26) and (IV.27), solve the one-way equation for negative and positive directions (IV.25) and save the fundamental solutions in the transverse wave number domain.

Calculate the boundary mapping: compose the wave number constituents of the fundamental solutions to give the fundamental solutions in the space domain (VI.7), combine the fundamental solutions with BEM for scattered fields in the embedding (IV.29), match the boundary conditions to calculate the kernel "matrices" mapping the incident field to the boundary source distribution and the weights of the fundamental solutions (IV.7)–(IV.10), and save these matrices.

Given the incident field: for all receivers in the inclusion obtain the weights of the fundamental solutions, for all receivers in the embedding obtain the boundary source distribution.

Evaluate the scattered field according to Eqs. (IV.29) and (V.6), which ends the frequency loop.

Multiply the total field with the source signature spectrum and inverse Fourier transform the result (II.2).

(Received 28 June 1995; accepted for publication 25 March 1996)

We examine some of the subtleties inherent in formulating a theory of spinors on a manifold with a smooth degenerate metric. We concentrate on the case where the metric is singular on a hypersurface that partitions the manifold into Lorentzian and Euclidean domains. We introduce the notion of a complex spinor fibration to make precise the meaning of continuity of a spinor field and give an expression for the components of a local spinor connection that is valid in the absence of a frame of local orthonormal vectors. These considerations enable one to construct a Dirac equation for the discussion of the behavior of spinors in the vicinity of the metric degeneracy. We conclude that the theory contains more freedom than the spacetime Dirac theory and we discuss some of the implications of this for the continuity of conserved currents. © *1996 American Institute of Physics.* [S0022-2488(96)01707-0]

I. INTRODUCTION

The interest in the influence of topology on physics is an old one. In recent times there has also been considerable debate on the influence of the geometrical structure of spacetime that may accompany a change in its overall topology. This has been partly motivated by the implications of the semi-classical theory of quantum gravity and partly by the interest in field theories on background spacetimes with interesting topologies. Further motivation arises from string theories in which string interactions arise from the topology of world sheets. In all these approaches fundamental assumptions about the signature of the spacetime metric are required. Such assumptions dictate the detailed behavior of both the causal structure of the theory and the selection rules for topology change. In the context of classical theory there are powerful constraints on the nature of such changes on manifolds with a global Lorentzian signature and a spinor structure.[1] To escape such constraints a number of authors have contemplated geometries in which the metric is allowed to become degenerate, particularly on hypersurfaces that partition the manifold into Lorentzian and Euclidean regions. Despite the obvious implications for causality there have been serious attempts to follow the consequences for physics associated with signature changing metrics. Despite the absence of a rigorous theory of second quantized fields on such a background, in Ref. 2 it was suggested that a quantized scalar field could exhibit spontaneous particle production even in the absence of gravitational curvature. This result relied on certain natural linear boundary conditions that were imposed on the scalar field at the hypersurface of signature change. Since there

is no continuous orthonormal coframe in the presence of metric degeneracy and the field equations are themselves dependent on the metric one must rely on a prescribed differential structure in order to define the necessary limits of the gradients of the scalar field in the vicinity of the metric degeneracy. In practice this means one can always rely on a local coordinate coframe to effect one's calculations. Furthermore the differentiability class of all tensor fields is defined with respect to the differentiability of their components in an arbitrary coordinate (co-)frame independent of any metric structure.

Since matter in flat Lorentzian spacetime is also described in terms of various representations of the Lorentzian SPIN group it is natural to try and extend these considerations to the behavior of spinor fields on manifolds with a degenerate metric. In particular one may wish to formulate a dynamical theory of spinor fields and deduce from their field equations a class of natural boundary conditions at the hypersurface of signature change. However a number of interesting problems then arise that have no counterpart in the theory of tensor fields. The most obvious is that the dimensionality of the real irreducible SPIN representations is signature dependent so that it becomes meaningless to try and match spinor fields belonging to representations with different dimensions. If one persists with the search for matching conditions one must in general consider complex representations.

In a smooth local basis of spinor fields one can define the differentiability class of the components of a spinor field. Such a basis is a basis for a module carrying representations of the SPIN group, which is a double cover of the $SO(p,q)$ group associated with the signature of the underlying metric on the manifold. Clearly this procedure will fail at the hypersurface where the signature changes, since the SPIN groups differ across the hypersurface. In order to define continuous spinor fields on a neighborhood crossing the hypersurface, alternatives to the traditional reliance on lifting orthonormal frames to spinor frames must be pursued. Of necessity one must expect some arbitrariness in defining the notion of a continuous spinor field in the presence of signature change.

It is natural to subject local spinor fields to the appropriate Dirac equation in regions where the metric is non-degenerate. In such regions the conventional Dirac operator can be defined in terms of a spinor covariant derivative that is designed to satisfy the natural Leibniz rules on products of tensors and spinors. In this manner it can be made compatible with the natural linear connection on tensors. A unique Levi-Civita tensor covariant derivative is determined completely by the metric tensor. When this metric is non-degenerate one can exploit the existence of local orthonormal frames to uniquely fix the spinor connection that determines the spinor covariant derivative. It is important to stress that it is only the *existence* of a class of orthonormal frames that is necessary to effect this determination, since it provides a reference frame for normalization. The SPIN connection so defined is then compatible with a SPIN invariant inner product on spinors. If one attempts to define a spinor connection in the absence of a class of orthonormal frames then one must recognize the inherent arbitrariness that cannot be removed by normalization. Since we are interested in subjecting our spinor fields to the appropriate Dirac equation in regions where the metric is regular we must accommodate this freedom in the spinor connection if we wish to discuss the matching of spinor solutions at the hypersurface of degeneracy.

Little attention has been devoted to the formulation of spinor fields on spaces with degenerate metrics. Romano[3] recognized that the choice of spinor equation was not straightforward. His analysis was restricted to the case of a discontinuous change of signature, whereas in this article we restrict ourselves instead to the case of continuous degenerate metrics. It is our purpose to examine the essential arbitrariness inherent in a formulation of spinor theory on manifolds with such metrics.

In section II we offer a definition of complex spinors in terms of a *spinor fibration* over a manifold. Although our construction relies on the representation theory of Clifford algebras, we have translated our arguments into the traditional language of γ matrices. The essential novelty is that these are matrix representations of a set of coordinate vector fields that constitute a frame in

the vicinity of the metric degeneracy. The representation structure is explicitly presented in terms of degenerate metrics in two and four dimensions.

Having defined the notion of spinor continuity in terms of a spinor fibration, we turn to the notion of the spinor covariant derivative in section III. We show how this can be determined to be both compatible with a SPIN invariant inner product and to commute with the complex structure ("charge conjugation"). In section IV we write down and solve the two dimensional Dirac equation written in terms of this spin connection, making explicit the dependence of the singularity structure of these solutions on both the spin metric and the metric on the underlying manifold. We conclude with a brief discussion of the $U(1)$ currents associated with these solutions and offer some speculations on alternative approaches.

II. SPINORS

In $n=2m$ dimensions we consider the manifold $M=\mathbb{R}^{2m}$ with metric

$$g=h(t)dt\otimes dt+\hat{g}_{ij}(\vec{x})dx^i\otimes dx^j \tag{1}$$

in a chart $(t,x^i)=(x^\mu)$, $i=1,\ \ldots,n-1$, where $\hat{g}$ is assumed to be positive definite. h is a smooth function which may have zeroes (at most countably many that are nowhere dense). However, we require that h changes sign at zeroes of h. None of the crucial steps of the development below rely on the topological triviality of this particular manifold. Although the discussion applies to complex spinors on any even dimensional manifold with signature change, we will pay particular attention to the cases $n=4$ and $n=2$.

Kossowski and Kriele have shown[4] under fairly general conditions that, at any zero of h where $\dot{h}\neq 0$, one can switch to coordinates (t',x^i) in a neighborhood of the zero such that $h(t)dt^2=t'dt'^2$. However, the precise nature of the signature change is not of importance within the scope of this article.

To define Dirac spinors on a manifold M of constant signature one usually[5] considers local irreducible representations $\boldsymbol{\gamma}$ of the complex Clifford algebra bundle

$$\mathcal{Cl}(M)=\cup_{p\in M}\mathcal{Cl}(T_pM,g_p), \tag{2}$$

i.e, $\boldsymbol{\gamma}$ is a fiber preserving homomorphism,

$$\boldsymbol{\gamma}:\pi^{-1}(U)\subset\mathcal{Cl}(M)\rightarrow M_k(\mathbb{C})\times U, \tag{3}$$

where $\pi:\mathcal{Cl}(M)\rightarrow M$ is the bundle projection, U is an open subset of M, and $M_k(\mathbb{C})$ is the set of complex $k\times k$ matrices ($k=2^m$). We will assume for now that $\boldsymbol{\gamma}$ is at least continuous. If the representation $\boldsymbol{\gamma}$ is also faithful, which is the case for even dimension of M, then $\boldsymbol{\gamma}$ is just a local trivialization of $\mathcal{Cl}(M)$. In particular, for vector fields X and Y, $\boldsymbol{\gamma}$ satisfies

$$\{\boldsymbol{\gamma}(X),\boldsymbol{\gamma}(Y)\}=2\,g(X,Y)\mathbf{1}. \tag{4}$$

With respect to a local coordinate chart $\boldsymbol{\gamma}$ is given by its components

$$\gamma_\mu:=\boldsymbol{\gamma}(\partial_\mu). \tag{5}$$

(Note that we use bold-faced $\boldsymbol{\gamma}$ for the representation map, and light-faced symbols for particular images under a representation. Both kinds of symbols may appear in a single expression, in which case a map defined by pointwise multiplication is described as in $[\gamma_\mu\boldsymbol{\gamma}](a)=\gamma_\mu[\boldsymbol{\gamma}(a)]$, $a\in\mathcal{Cl}(M)$.) With this definition we obtain the familiar relationship

$$\{\gamma_\mu,\gamma_\nu\}=2\,g_{\mu\nu}\mathbf{1}. \tag{6}$$

The Dirac spinor bundle $S(M)$ is a vector bundle carrying such a representation γ, i.e., there is a chart for $S(M)$ such that the Clifford action of $\mathcal{C}l(M)$ on $S(M)$ is given by multiplication of the γ-matrices with column spinors. If $\mathcal{C}l(M)$ transforms under a product of tensor representations of the orthogonal group and the Clifford action is covariant under this transformation, then $S(M)$ transforms under a spin representation of the orthogonal group.

Except for regions that contain zeroes of h it is straightforward to generalize these ideas to our signature changing spacetime M. The crucial question is how to link the spinor bundles across hypersurfaces of signature change. In the following exposition we will use the fact that the Clifford bundles are linked and lift this link to the spinor bundles. Specifically we will consider an algebra fibration which coincides with the Clifford bundles where the metric is non-degenerate and representations of this fibration which are continuous across a hypersurface of signature change. A detailed study of such representations suggests certain additional conditions which are sufficient to ensure the invariance of the resulting structure under appropriate changes of representations and/or coordinates. Since the group of transition functions is different for different signature we will adopt the term "fibration" for $\mathcal{C}l(M)$ and $S(M)$ instead of "bundle," but we will still refer to this object as the "Clifford" and "spinor" fibration, although we use these expressions in a non-traditional context.

The following example will illustrate some of the key issues we have to face.

A. An example in two dimensions

In $n=2$ dimensions we consider $M=\mathbb{R}^2$ with coordinates (t,x) and metric

$$g=h(t)dt\otimes dt+dx\otimes dx, \tag{7}$$

i.e., $\hat{g}=1$. Then the following γ-matrices:

$$\gamma_x=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix},\gamma_t=\begin{pmatrix}0 & 1\\ h(t) & 0\end{pmatrix}, \tag{8}$$

define a continuous representation γ on all of M which is faithful and irreducible for $h(t)\neq 0$. Note that γ_t is necessarily degenerate at zeroes of h, where the matrix algebra generated by these matrices actually reduces to upper-triangular matrices. Therefore, this representation is neither faithful nor irreducible at metric degeneracies. This behavior is generic because of an incompatibility of representations of degenerate and non-degenerate Clifford algebras: Since the Clifford algebra is no longer semi-simple for $h=0$, the dimension of an irreducible representation is smaller by a factor of two. The irreducible representation of the degenerate algebra is in fact just an irreducible representation of its non-degenerate "spatial" part, i.e., the part corresponding to the "spatial" γ_x. For the representation to remain faithful it would have to double its dimension in order to accommodate the whole nilpotent ideal generated by the degenerate direction. (Note that half of the algebra, namely the ideal generated by γ_t, is nilpotent of order 2 at the degeneracy.)

B. The general case

For a precise description of the behavior of a representation around a metric degeneracy we examine the behavior of $\gamma(\partial_\mu)|_p$ as p approaches a hypersurface $H=\{t=t_0\}$, where $h(t_0)=0$.

Observation 1: *If a continuous local representation γ satisfies Eq. (4) on an open set $U\subset M$ intersecting H and is faithful and irreducible on $U\backslash H$, then γ is a faithful representation of the "spatial subalgebra" $\mathcal{C}l^{sp}(M)$ generated by $\{\partial_i\}_{i=1,\ldots,n-1}$ on all of U. Furthermore, $\mathcal{C}l^{sp}(M)$ contains central orthogonal idempotents $P_\pm$ which effect a Pierce decomposition of $\mathcal{C}l(M)$ and a corresponding decomposition of γ. Given a particular form of $\gamma(P_\pm)$, this decomposition is reflected in a block structure of the matrix representation.*

From the previous example we infer that $\gamma(\partial_t)|_p$ becomes degenerate as $p \to H$. For the other coordinate vector fields this is not the case, since $\gamma(\partial_i)^2 = \mathbf{1}$ everywhere in U. This corresponds to the fact that the algebra generated by $\{\partial_i\}_{i=1,\ldots,n-1}$, which we call the "spatial subalgebra" $\mathcal{C}\ell^{sp}(M)$ remains non-degenerate on H, whence γ restricted to $\mathcal{C}\ell^{sp}(M)$ remains a faithful representation. Therefore, this spatial subalgebra does not "notice" the metric degeneracy and will provide the link that constrains the behavior of γ_t as we pass through H. $\mathcal{C}\ell^{sp}(M)$ contains central orthogonal idempotents,

$$P_\pm := \frac{1}{2}(1 \pm z), \tag{9}$$

where z is the normalized dual of the volume element of H, whence $z^2 = 1$, $P_\pm^2 = P_\pm$, and $P_\pm P_\mp = 0$. For example, $z = \partial_x$ for the metric given by Eq. (7), whereas $z = i\det\hat{g}^{-1/2}\partial_1 \wedge \partial_2 \wedge \partial_3$ in four dimensions with metric given by Eq. (1). The idempotents or projectors $P_\pm$ split $\mathcal{C}\ell^{sp}(M)$ into a direct sum of simple components,

$$\mathcal{C}\ell^{sp}(M) = \mathcal{C}\ell_+(M) \oplus \mathcal{C}\ell_-(M), \tag{10}$$

where

$$\mathcal{C}\ell_\pm(M) := P_\pm \mathcal{C}\ell(M) P_\pm . \tag{11}$$

Therefore γ induces inequivalent representations

$$\gamma_\pm := \gamma_\pm \gamma \gamma_\pm \tag{12}$$

of $\mathcal{C}\ell^{sp}(M)$, where

$$\gamma_\pm := \gamma(P_\pm). \tag{13}$$

So we get the following Pierce decomposition with respect to the idempotents $P_\pm$:

$$\begin{aligned}\mathcal{C}\ell(M) &= (P_+ + P_-)\mathcal{C}\ell(M)(P_+ + P_-) \\ &= P_+\mathcal{C}\ell(M)P_+ \oplus P_+\mathcal{C}\ell(M)P_- \oplus P_-\mathcal{C}\ell(M)P_+ \oplus P_-\mathcal{C}\ell(M)P_- \\ &= \mathcal{C}\ell_+(M) \oplus P_+\mathcal{C}\ell(M)P_- \oplus P_-\mathcal{C}\ell(M)P_+ \oplus \mathcal{C}\ell_-(M),\end{aligned} \tag{14}$$

which translates into representations

$$\gamma = \gamma_+\gamma\gamma_+ + \gamma_+\gamma\gamma_- + \gamma_-\gamma\gamma_+ + \gamma_-\gamma\gamma_- = \gamma_+ + \gamma_+\gamma\gamma_- + \gamma_-\gamma\gamma_+ + \gamma_- . \tag{15}$$

Since $\mathcal{C}\ell^{sp}(M)$ commutes with $P_\pm$ and

$$\mathcal{C}\ell(M) = \mathcal{C}\ell^{sp}(M) \oplus \mathcal{C}\ell^{sp}(M)\partial_t = \mathcal{C}\ell^{sp}(M) \oplus \partial_t\mathcal{C}\ell^{sp}(M), \tag{16}$$

the cross terms in Eq. (14) come from ∂_t:

$$P_\pm \mathcal{C}\ell(M) P_\mp = P_\pm(\mathcal{C}\ell^{sp}(M)\partial_t)P_\mp = \mathcal{C}\ell_\pm(M)\partial_t = P_\pm(\partial_t\mathcal{C}\ell^{sp}(M))P_\mp = \partial_t\mathcal{C}\ell_\mp(M). \tag{17}$$

[Note that $P_\pm\partial_t = \partial_t P_\mp$ and $P_\pm\mathcal{C}\ell^{sp}(M)P_\mp = 0$.] This can also be seen from the decomposition of γ_t:

$$\gamma_t = \gamma_+\gamma_t\gamma_- + \gamma_-\gamma_t\gamma_+ . \tag{18}$$

If $\gamma_\pm$ takes the form

$$\gamma_+=\begin{pmatrix}\mathbf{1} & \mathbf{0}\\ \mathbf{0} & \mathbf{0}\end{pmatrix},\quad \gamma_-=\begin{pmatrix}\mathbf{0} & \mathbf{0}\\ \mathbf{0} & \mathbf{1}\end{pmatrix}, \tag{19}$$

in terms of $2^{m-1}\times 2^{m-1}$ unit and zero matrices, which can always be achieved by an equivalence transformation pointwise on U (even on H), then the Pierce decomposition is reflected in a block structure of the matrix representation $\gamma(\mathcal{C}\ell(M))$. In particular, the induced representations $\gamma_\pm$ only have one non-zero block, namely in the upper left (lower right) corner. Denoting the non-zero blocks of the corresponding matrices by overlined symbols, for example,

$$\gamma_+(\mathcal{C}\ell_+(M))=\begin{pmatrix}\overline{\gamma_+(\mathcal{C}\ell_+(M))} & \mathbf{0}\\ \mathbf{0} & \mathbf{0}\end{pmatrix}, \tag{20}$$

we have the following block structure of $\gamma(\mathcal{C}\ell(M))$:

$$\begin{aligned}\gamma(\mathcal{C}\ell(M))&=\begin{pmatrix}\overline{\gamma_+(\mathcal{C}\ell_+(M))} & \overline{\gamma_+\gamma_t\gamma_-(\mathcal{C}\ell_-(M))}\\ \overline{\gamma_-\gamma_t\gamma_+(\mathcal{C}\ell_+(M))} & \overline{\gamma_-(\mathcal{C}\ell_-(M))}\end{pmatrix}\\ &=\begin{pmatrix}\overline{\gamma_+(\mathcal{C}\ell_+(M))} & \overline{\gamma_+(\mathcal{C}\ell_+(M))\gamma_t\gamma_-}\\ \overline{\gamma_-(\mathcal{C}\ell_-(M))\gamma_t\gamma_+} & \overline{\gamma_-(\mathcal{C}\ell_-(M))}\end{pmatrix}.\end{aligned} \tag{21}$$

[To arrive at this equation apply γ to Eq. (14) using Eqs. (12), (17), (19) and inserting projectors $P_\pm$ when appropriate.] This block structure helps us to understand what happens to a representation when we cross H. The blocks on the diagonal make up the spatial subalgebra and do not contain γ_t. Therefore, these blocks remain non-degenerate throughout U. The off-diagonal blocks show that γ_t intertwines γ_+ and γ_-.

Observation 2: *The inequivalent faithful representations $\gamma_\pm$ of $\mathcal{C}\ell^{sp}(M)$ have equivalent restrictions $\gamma_\pm^+$ to the even subalgebra $\mathcal{C}\ell^+(M)\subset\mathcal{C}\ell^{sp}(M)$. Furthermore, the restrictions $\gamma_\pm^+$ are intertwined by γ_t, which implies that for any $p\in H$, one of the off-diagonal blocks of $\gamma_t|_p$ in the previously discussed block structure vanishes and the other either vanishes or is regular. (The diagonal blocks are trivially zero.)*

Even though the representations $\gamma_\pm$ vanish on one of the simple components, $\gamma_\pm(\mathcal{C}\ell_\mp(M))=0$, they are equivalent when restricted to the even part $\mathcal{C}\ell^+(M)$ of $\mathcal{C}\ell^{sp}(M)$, which is a simple algebra isomorphic to $\mathcal{C}\ell_\pm(M)$. Applying $\gamma_i\gamma_t=-\gamma_t\gamma_i$ twice, we have $\gamma_i\gamma_j\gamma_t=+\gamma_t\gamma_i\gamma_j$, which implies that the restrictions $\gamma_\pm^+$ of $\gamma_\pm$ to $\mathcal{C}\ell^+(M)$ are intertwined by γ_t:

$$\gamma_\pm^+\gamma_t=\gamma_t\gamma_\mp^+. \tag{22}$$

In the block structure (21) the non-zero blocks $\overline{\gamma_\pm^+(\mathcal{C}\ell^+(M))}$ induce irreducible representations $\overline{\gamma_\pm^+}:\pi^{-1}(U)\cap\mathcal{C}\ell^+(M)\to M_{k/2}(\mathbb{C})\times U$. Since an intertwiner of two irreducible representations is determined up to a scale, with the intertwiner being non-singular unless the scale is zero, we see from the non-zero blocks associated with Eq. (22) that the two blocks of $\gamma_t=\gamma_+\gamma_t\gamma_-+\gamma_-\gamma_t\gamma_+$ are determined by Eq. (22) up to a scale. Since $(\gamma_\pm\gamma_t\gamma_\mp)\times(\gamma_\mp\gamma_t\gamma_\pm)=h(t)\gamma_\pm$, in fact, only a relative scale remains undetermined. Therefore at least one entire block of γ_t has to vanish for $h(t)\to 0$, so that we are left with a block triangular or block diagonal matrix algebra on H.

Even though we may not be able to achieve this block structure on all of U at the same time, this argument still shows that γ_t is determined up to a relative scale between $\gamma_+\gamma_t\gamma_-$ and $\gamma_-\gamma_t\gamma_+$ and that $\gamma(\mathcal{C}\ell(M))$ is isomorphic to a block triangular or block diagonal matrix algebra at each point of H.

Observation 3: *Two continuous local representations* $\gamma_{(r)}$, $r=1, 2$, *satisfying Eq. (4) on an open set* $U \subset M$ *intersecting* H *and faithful irreducible on* $U \backslash H$, *are equivalent if and only if the block structures of* $\gamma_{(r)}(\partial_t)|_H$ *agree. Furthermore, the intertwiner is guaranteed to be continuous across* H *if one block of* $\gamma_{(r)}(\partial_t)$ *stays regular.*

Given two overlapping local representations, we can use the same decomposition to show that it is a necessary condition that γ_t has the same behavior on H for both representations if they are related by a non-singular intertwiner. Conversely, if the behavior of γ_t is different for two local representations, the intertwiner necessarily becomes singular on H. Not only the agreement in block structure but its particular form on H is of importance. If both blocks of γ_t vanish, i.e., γ_t vanishes entirely for both overlapping local representations, their intertwiner may be discontinuous. If on the other hand only one block of γ_t vanishes then the intertwiner inherits the smoothness properties of the local representations, in particular it is at least continuous. In this case the non-zero block of γ_t serves as a link across H and no additional requirement of continuity of the intertwiner is needed to ensure that the gluing together of local representations is well-defined. Of course, the transition functions can be restricted to lie in the appropriate spin groups away from H, which requires the transition functions on H to continuously connect both spin groups.

C. Criteria for a spinor fibration

It can be shown that if γ is assumed to be not only C^1 away from H (this is required in order to define a spin connection as we will see in section IIIC) but also to have bounded partial derivatives on any bounded set, then exactly one of $\gamma_\pm \gamma_t \gamma_\mp$ vanishes on all of H and the other one does not. Therefore, a simple smoothness assumption gains the desired control over the block structure. Since the minor technical difference between requiring bounded partial derivatives on bounded sets and C^1, namely that the partial derivatives have limits on H, does not affect the continuity structure of the spinor fibration in question, we will use the more intuitive condition of continuous differentiability. Allowing the partial derivatives of γ to be locally unbounded relinquishes any control over the block structure, e.g., in the two dimensional example:

$$\gamma_x = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \gamma_t = \begin{cases} \begin{pmatrix} 0 & |h(t)|^{1/2}+x^2 \\ h(t)[|h(t)|^{1/2}+x^2]^{-1} & 0 \end{pmatrix}, & \text{for } x>0. \\ \begin{pmatrix} 0 & |h(t)|^{1/2} \\ h(t)|h(t)|^{-1/2} & 0 \end{pmatrix}, & \text{for } x \leqslant 0. \end{cases} \tag{23}$$

Piecing γ's like this one together we can get any behavior of γ_t on H we (do not) like.

These observations lead us to a set of criteria for local representations which ensure that they are related by C^1 equivalence transformations:

(i) γ is C^1 satisfying Eq. (4).

(ii) γ is faithful irreducible for $h(t) \neq 0$.

(iii) $\gamma_- \gamma_t \to 0$ for $h(t) \to 0$.

[Of course, the γ-matrices given by Eq. (8) satisfy these criteria.] Condition (iii) singles out one class of representations with a certain behavior for $h(t) \to 0$. Equally well, one could require

(iii′) $\gamma_+ \gamma_t \to 0$ for $h(t) \to 0$,

or even a mixture of both, fixing the behavior of the representation for each hypersurface of metric degeneracy separately. In this paper we focus on the issues arising from just one zero of h. In this case (iii′) is obtained from (iii) under a spatial inversion.

D. A possible generalization

We can relax the assumption of a metric of the form Eq. (1) if we assume the existence of a local frame of non-zero vector fields $\{X_\mu\}$ on any open set intersecting a hypersurface H of

signature change, such that $X_i \in T(H)$ satisfies $g(X_i,X_j)|_H=\delta_{ij}$ and $g(X_0,X_\mu)|_H=0$ and construct $\gamma(X_\mu)$ instead of $\gamma(\partial_\mu)$. The spatial subalgebra $\mathcal{Cl}^{sp}(M)$ of $\mathcal{Cl}(M)$ generated by $\{X_i\}$ coincides with the appropriate extension of $\mathcal{Cl}(H)=\cup_{p\in H}\mathcal{Cl}(T_pH,H^*g_p)$, which is really the only intrinsic structure in the vicinity of H. It is essential that the pullback metric H^*g_p be non-degenerate. It is then straightforward to retrace the steps we followed above and come to the same conclusions. Of course, the existence of a global fibration $S(M)$ will depend on the topology of M and possibly on the topology of hypersurfaces of metric degeneracy.

III. THE SPINOR COVARIANT DERIVATIVE

Having defined a spinor fibration $S(M)$ we have a notion of continuity of a spinor field. Namely, a spinor field is continuous if its component sections are continuous with respect to a bundle chart. In other words, given a set of γ-matrices satisfying appropriate conditions, a continuous spinor field is given by a column of continuous functions on which these γ-matrices act.

In order to write down a Dirac equation on M, we need a notion of covariant differentiation of a spinor field. However, given a linear connection on M, the spinor connection is not uniquely determined unless it is also required to be compatible with both a choice of spinor metric and a notion of charge conjugation. Furthermore, the traditional construction of a spinor connection relies on the existence of a non-degenerate metric. In the following we discuss these separate aspects in regions where the metric is manifestly non-degenerate. In section IV the interrelation between these different aspects will be examined in the vicinity of a hypersurface of signature change.

Authors of other literature on this subject usually work in orthonormal frames (see for example Ref. 6) with the notable exception of an early review[7] which also contains references to most of the original work and notes the scaling freedom in the spinor metric discussed below.

A. The spinor metric

In order to discuss the Dirac equation below we introduce the notion of a spinor metric. In particular, we adopt a Hermitian symmetric spin invariant bilinear form on Dirac spinors,

$$S(M)\times S(M)\to\mathfrak{F}(M),$$

$$\Psi,\Xi\mapsto(\Psi,\Xi)=\Psi^\dagger C\Xi, \tag{24}$$

where $\mathfrak{F}(M)$ denotes the space of functions on M and C is chosen to satisfy

$$C=C^\dagger, \tag{25}$$

$$C\gamma_\mu=-\gamma_\mu^\dagger C, \tag{26}$$

on M. The familiar Dirac adjoint is then given by

$$\bar{\Psi}=\Psi^\dagger C. \tag{27}$$

For our example, Eq. (8),

$$C_1=\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix}, \tag{28}$$

satisfies Eqs. (25) and (26). However, the spinor metric C is only determined up to a real scalar at each point of the manifold. Therefore $C_f=fC_1$ could equally well be chosen as a spinor metric, where $f=f^*\in\mathfrak{F}(M)$. Usually the spinor metric is required to be smooth and non-degenerate, which restricts f to be smooth and non-zero. This is one of the reasons why the choice of spinor metric does not usually appear in the standard discussion of the Dirac equation. The scaling function f is normalized to make the equation simple, i.e., C is chosen to be constant for constant

γ-matrices. (Note that the γ-matrices cannot be constant across a hypersurface of signature change.) The behavior of f where the spacetime metric is degenerate must be postulated separately, and it can not *a priori* be ruled out that f may be zero or singular there.

B. Charge conjugation

Charge conjugation can be defined as a map,

$$S(M)\to S(M),$$

$$\Psi\mapsto\Psi^c:=B^*\Psi^*, \tag{29}$$

where B satisfies

$$B\gamma_\mu=\gamma_\mu^* B, \tag{30}$$

$$B^*B=\pm\mathbf{1}=\beta\mathbf{1}. \tag{31}$$

These conditions determine B up to a phase which may vary over M. The sign in the second condition depends on the signature. $\beta=+1$ if there exists a real representation $\beta=-1$ otherwise. Defining the index ν of a metric to be the (signed) difference of the number of positive and negative eigenvalues of the metric, we note that

$$\beta=\begin{cases}+1, & \text{for } \nu\equiv 0,\ 2 \bmod 8,\\ -1, & \text{for } \nu\equiv 4,\ 6 \bmod 8.\end{cases} \tag{32}$$

Therefore, β changes sign and B is necessarily discontinuous if the signature changes from $(-+++)$, i.e., $\nu=2$, to $(++++)$, i.e., $\nu=4$, in four dimensions, while for the change of signature $(-+)\to(++)$ in two dimensions $\beta=1$ in both regions. Since β also determines the periodicity of the charge conjugation operation, namely

$$(\Psi^c)^c=\beta\Psi, \tag{33}$$

continuity of a spinor is only compatible with continuity of its charge conjugate if β is the same in Euclidean and Lorentzian regions. [This observation warrants an investigation of alternative spinor metrics and notions of charge conjugation for the opposite metrics, i.e., signature changing from $(+---)$ to $(----)$, in four dimensions. The reader is invited to pursue these technical aspects which lie outside the main thrust of this article. Note that the standard definitions for opposite Lorentzian metrics differ by signs in Eqs. (26) and (30). For completeness, one may also consider the inclusion of spinors with Grassmann-valued components or even non-standard versions of Eqs. (26) and (30).]

For our 2 dimensional example, we may take

$$B=e^{i\theta}\mathbf{1}, \tag{34}$$

where $\theta=\theta^*\in\mathfrak{F}(M)$.

C. The spinor connection

Given a spinor metric the spinor covariant derivative S_μ with respect to a vectorfield ∂_μ is given by

$$S_\mu=\partial_\mu+\Sigma_\mu, \tag{35}$$

where the spinor connection Σ_μ has to be determined such that the axioms for a spinor covariant derivative are satisfied:

$$S_\mu(a^\nu\gamma_\nu\Psi)=(\nabla_\mu a^\nu)\gamma_\nu\Psi+a^\nu\gamma_\nu(S_\mu\Psi), \tag{36}$$

$$\partial_\mu(\Psi,\Xi)=(S_\mu\Psi,\Xi)+(\Psi,S_\mu\Xi), \tag{37}$$

$$S_\mu(\Psi^c)=(S_\mu\Psi)^c. \tag{38}$$

$\nabla_\mu a^\nu:=a^\nu{}_{;\mu}:=\partial_\mu a^\nu+\Gamma^\nu{}_{\mu\rho}a^\rho$ denotes the components of the covariant derivative of the vector field given by a^ν, where $\Gamma_{\rho\mu\nu}$ are the spacetime connection coefficients, i.e., for the Levi-Civita connection $\Gamma_{\rho\mu\nu}=\frac{1}{2}(\partial_\mu g_{\nu\rho}+\partial_\nu g_{\mu\rho}-\partial_\rho g_{\mu\nu})$. These axioms ensure compatibility of covariant differentiation of tensors and spinors, Eq. (36), and compatibility of the spinor covariant derivative with the spinor metric and charge conjugation, Eqs. (37) and (38). Using the defining properties, Eqs. (35), (25), (26), (30), and (31), in Eqs. (36)–(38) we get the following conditions:

$$\partial_\mu\gamma_\nu-\Gamma^\rho{}_{\mu\nu}\gamma_\rho=[\gamma_\nu,\Sigma_\mu]=\gamma_\nu\Sigma_\mu-\Sigma_\mu\gamma_\nu, \tag{39}$$

$$C^{-1}\partial_\mu C=\Sigma_\mu+C^{-1}\Sigma_\mu^\dagger C, \tag{40}$$

$$B^{-1}\partial_\mu B=\Sigma_\mu-B^{-1}\Sigma_\mu^* B. \tag{41}$$

In order to give an explicit expression for Σ_μ we expand it in a basis of the Clifford algebra:

$$\Sigma_\mu=\sum_I \sigma_{\mu I}\gamma^I, \tag{42}$$

where the sum is taken over the set of ordered indices $\{(i_1,\ldots,i_p):1\leqslant i_1<\cdots<i_p\leqslant n,\ 0\leqslant p\leqslant n-1\}$, with $n=\dim M$, where also $\gamma^{(i_1\cdots i_p)}=\gamma^{i_1}\ldots\gamma^{i_p}$ and $\gamma^\emptyset=\mathbf{1}$ are understood. (Note that the superscript is the empty set $\emptyset$ *not* 0 in the last equation.) In particular $\{\gamma^I\}$ is a basis for the Clifford algebra in the representation γ.

We first solve for the components of Σ_μ using Eq. (39):

$$[\gamma_\nu,\Sigma_\mu]=\left[\gamma_\nu,\sum_I \sigma_{\mu I}\gamma^I\right]=2\sum_{\substack{\nu\notin I\\ |I|\text{odd}}}\sigma_{\mu I}\gamma_\nu\gamma^I+2\sum_{\substack{\nu\in I\\ |I|\text{even}}}\sigma_{\mu I}\gamma_\nu\gamma^I, \tag{43}$$

where $|I|$ denotes the length of the multi index. Thus all but the scalar part of Σ_μ is determined:

$$\sigma_{\mu I}=\frac{1}{2^{N+1}}\mathrm{tr}[\gamma_{I^r}\gamma^\nu(\partial_\mu\gamma_\nu-\Gamma^\rho{}_{\mu\nu}\gamma_\rho)]\quad(\text{no sum over }\nu), \tag{44}$$

where for given I one may choose any ν such that for $|I|$ even $\nu\in I$ while for $|I|$ odd $\nu\notin I$. (I^r denotes indices in reversed order, $N=2^{n/2}$.) For example, to calculate $\sigma_{\mu(0,1,2,3)}$ in four dimensions we may take any $\nu\in\{0,1,2,3\}$, the result is guaranteed to be the same.

We solve for the scalar part of Σ_μ using Eqs. (40) and (41):

$$\sigma_{\mu\emptyset}=\frac{1}{2^{N+1}}\mathrm{tr}(C^{-1}\partial_\mu C+B^{-1}\partial_\mu B). \tag{45}$$

Thus Σ_μ is completely determined. Eq. (45) is derived from the general conditions arising from Eqs. (40) and (41):

$$\mathrm{Re}\ \sigma_{\mu I}=\frac{1}{2^{N+1}}\mathrm{tr}(\gamma_{I^r}C^{-1}\partial_\mu C)\quad(|I|\ \text{even}), \tag{46}$$

$$\text{Im}\ \sigma_{\mu I}=\frac{1}{2^{N+1}i}\ \text{tr}(\gamma_{I'}B^{-1}\partial_\mu B). \tag{47}$$

Again these expressions are guaranteed to be real and compatible with Eq. (44). In some instances it may actually be more convenient to use these latter relationships to solve for various components of Σ_μ.

Applying Eqs. (44) and (45) to Eqs. (8), (25), (26), (30), and (31), we obtain for the spinor connection for our 2 dimensional example,

$$\Sigma_x=\frac{1}{2}f^{-1}\partial_x f+\frac{1}{2}i\partial_x\theta,$$

$$\Sigma_t=\frac{1}{2}f^{-1}\partial_t f+\frac{1}{2}i\partial_t\theta+\frac{1}{4}h^{-1}\partial_t h\,\gamma_x. \tag{48}$$

In the case of a local orthonormal frame $\{X_a\}$ with constant γ-matrices and constant matrices C and B, the familiar solution for Σ_a is purely a bivector

$$\Sigma_a=\frac{1}{4}\omega_{abc}\gamma^b\gamma^c, \tag{49}$$

where $\omega_{abc}=g(X_b,\nabla_{X_a}X_c)$ are the connection coefficients. (Note that the metric compatibility of the connection implies $\omega_{abc}=-\omega_{acb}$.)

IV. THE MASSLESS DIRAC EQUATION IN TWO DIMENSIONS

With the definition (35) of the spinor covariant derivative the massless Dirac equation in arbitrary dimensions takes the form

$$\not{S}\Psi\equiv\gamma^\mu S_\mu\Psi=0. \tag{50}$$

In two dimensions for the spinor connection (48) we obtain a family of equations depending on the two real functions f and θ:

$$\left[\gamma^\mu\left(\partial_\mu+\frac{1}{2}f^{-1}\partial_\mu f+\frac{1}{2}i\partial_\mu\theta\right)+\gamma^t\frac{1}{4}h^{-1}\partial_t h\,\gamma_x\right]\Psi=0. \tag{51}$$

A. Solution for the massless Dirac equation in two dimensions

We solve this equation for regions where it is regular. It is easy to check that Eq. (51) is equivalent to

$$\gamma^\mu[(f^{-1/2}e^{-1/2i\theta}D^{-1})\partial_\mu(f^{1/2}e^{1/2i\theta}D)]\Psi=0, \tag{52}$$

where the matrix D must satisfy

$$\partial_t D=D\frac{1}{4}h^{-1}\partial_t h\,\gamma_x, \tag{53}$$

$$\partial_x D=0. \tag{54}$$

Thus, up to an unimportant constant factor,

$$D=\frac{1}{2}[|h|^{1/4}(1+\gamma_x)+|h|^{-1/4}(1-\gamma_x)]=\begin{pmatrix}|h|^{1/4} & 0\\ 0 & |h|^{-1/4}\end{pmatrix}, \tag{55}$$

with

$$D^{-1}=\frac{1}{2}[|h|^{-1/4}(1+\gamma_x)+|h|^{1/4}(1-\gamma_x)]=\begin{pmatrix}|h|^{-1/4} & 0\\ 0 & |h|^{1/4}\end{pmatrix}. \tag{56}$$

The plane wave ansatz,

$$\Psi=(f^{-1/2}e^{-1/2i\theta}D^{-1})\psi_0 e^{-i(k_\tau\tau-k_x x)}, \tag{57}$$

where $\tau=\int\sqrt{|h(t)|}dt$, leads to

$$(-\gamma^t\sqrt{|h|}k_\tau+\gamma^x k_x)D^{-1}\psi_0=0. \tag{58}$$

For non-trivial solutions we need

$$\det(-\gamma^t\sqrt{|h|}k_\tau+\gamma^x k_x)=-k_x^2-h^{-1}|h|k_\tau^2=0, \tag{59}$$

which gives the dispersion relation

$$k_\tau=\begin{cases}\pm k_x, & \text{for } h<0,\\ \pm ik_x, & \text{for } h>0,\end{cases} \tag{60}$$

and corresponding solutions for ψ_0,

$$\psi_0=\begin{pmatrix}1\\ \mp 1\end{pmatrix}, \quad \text{for } h<0,\ k_\tau=\pm k_x, \tag{61}$$

$$\psi_0=\begin{pmatrix}1\\ \mp i\end{pmatrix}, \quad \text{for } h>0,\ k_\tau=\pm ik_x. \tag{62}$$

Thus the general solutions for regions where $h\neq 0$ and $f\neq 0$ are

$$\Psi_L=(f^{-1/2}e^{-(1/2)i\theta}D^{-1})\sum_{k>0}\left[\left(a_k^+e^{ikx}\begin{pmatrix}1\\ -1\end{pmatrix}+a_k^-e^{-ikx}\begin{pmatrix}1\\ 1\end{pmatrix}\right)e^{-ik\tau}\right.$$
$$\left.+\left(b_k^+e^{ikx}\begin{pmatrix}1\\ 1\end{pmatrix}+b_k^-e^{-ikx}\begin{pmatrix}1\\ -1\end{pmatrix}\right)e^{ik\tau}\right] \quad (h<0). \tag{63}$$

$$\Psi_E=|(f^{-1/2}e^{-(1/2)i\theta}D^{-1})\sum_{k>0}\left[\left(c_k^+e^{ikx}\begin{pmatrix}1\\ -i\end{pmatrix}+c_k^-e^{-ikx}\begin{pmatrix}1\\ i\end{pmatrix}\right)e^{k\tau}\right.$$
$$\left.+\left(d_k^+e^{ikx}\begin{pmatrix}1\\ i\end{pmatrix}+d_k^-e^{-ikx}\begin{pmatrix}1\\ -i\end{pmatrix}\right)e^{-k\tau}\right] \quad (h>0), \tag{64}$$

where $a_k^\pm$, $b_k^\pm$, $c_k^\pm$, and $d_k^\pm$ are arbitrary complex constants. (We omit the zero frequency solution.)

B. Asymptotic behavior and continuity of solutions

Assuming the Fourier sums above are convergent then the singularity structure of these solutions in the vicinity of the degeneracy is determined by $f^{-1/2}D^{-1}$:

$$\Psi_{L/E} \simeq \begin{pmatrix} O(f^{-1/2}|h|^{-1/4}) \\ O(f^{-1/2}|h|^{1/4}) \end{pmatrix}. \tag{65}$$

In particular, solutions are bounded if $f \simeq O(|h|^{-1/2})$. Thus one cannot have both bounded solutions and a bounded spinor metric at the degeneracy hypersurface. One possible choice is $f=|h|^{-1/2}$, in which case a continuous match of a Lorentzian and Euclidean solution would imply

$$a_k^+ + b_k^+ = c_k^+ + d_k^+ , \quad a_k^- + b_k^- = c_k^- + d_k^- , \tag{66}$$

where $\tau(t_0)=0$ is assumed. With this choice, requiring continuity does not induce a bijective map between Lorentzian and Euclidean solutions.

V. CURRENTS

There are two important currents that are locally conserved for solutions to the massless Dirac equation above. In regular domains the current

$$j_D^\mu[\Psi,\Xi] = \mathrm{Im}(\Psi, \gamma^\mu \Xi) \tag{67}$$

is conserved for solutions Ψ,Ξ:

$$\begin{aligned} \nabla_\mu(\Psi,\gamma^\mu\Xi) &= \partial_\mu(\Psi,\gamma^\mu\Xi) + \Gamma^\mu{}_{\mu\rho}(\Psi,\gamma^\rho\Xi) \\ &= (S_\mu\Psi,\gamma^\mu\Xi) + (\Psi, S_\mu(\gamma^\mu\Xi)) + \Gamma^\mu{}_{\mu\rho}(\Psi,\gamma^\rho\Xi) \\ &= -(\gamma^\mu S_\mu\Psi,\Xi) + (\Psi,\gamma^\mu S_\mu\Xi), \end{aligned} \tag{68}$$

using $[S_\mu,\gamma^\nu] = -\Gamma^\nu{}_{\mu\rho}\gamma^\rho$ and $(\Psi,\gamma^\mu\Xi) = -(\gamma^\mu\Psi,\Xi)$ which follow from the definitions and properties of the spinor covariant derivative and spinor metric (see section III). For a massless theory the axial vector current is also conserved,

$$j_A^\mu[\Psi,\Xi] = \mathrm{Re}(\Psi, \mathfrak{z}\gamma^\mu\Xi), \tag{69}$$

where $\mathfrak{z} = \sqrt{|h|}\gamma^t\gamma^x$, since

$$\nabla_\mu(\Psi,\mathfrak{z}\gamma^\mu\Xi) = (\gamma^\mu S_\mu\Psi,\mathfrak{z}\Xi) + (\Psi,\mathfrak{z}\gamma^\mu S_\mu\Xi). \tag{70}$$

Note that $\nabla\mathfrak{z}=0$, since the connection is metric compatible and $\mathfrak{z}$ is the metric dual of the metric volume element.

Given

$$\Psi = (f^{-1/2}e^{-1/2i\theta}D^{-1})\psi, \quad \Xi = (f^{-1/2}e^{-(1/2)i\theta}D^{-1})\xi, \tag{71}$$

which are defined piecewise on the non-degenerate parts of M, where they satisfy the massless Dirac equation, we obtain for the components of the Dirac current,

$$j_D^t[\Psi,\Xi] = -|h|^{-1/2}\mathrm{Re}\ \psi^\dagger \begin{pmatrix} 1 & 0 \\ 0 & -\mathrm{sgn}\ h \end{pmatrix}\xi, \quad j_D^x[\Psi,\Xi] = \mathrm{Re}\psi^\dagger \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\xi, \tag{72}$$

and for the components of the axial current

$$j^t_A[\Psi,\Xi]=h^{-1}|h|^{1/2}\mathrm{Im}\ \psi^\dagger\begin{pmatrix}0&1\\1&0\end{pmatrix}\xi,\ j^x_A[\Psi,\Xi]=\mathrm{Im}\ \psi^\dagger\begin{pmatrix}1&0\\0&-\mathrm{sgn}\ h\end{pmatrix}\xi. \tag{73}$$

The continuity of these currents depends on the assumptions made for the continuity of the spinor components. From our discussion above it is clear that this requires some assumptions about the behavior of the spinor metric in the vicinity of the signature change.

However some purely signature dependent effects can be seen by considering the coordinate independent contractions,

$$g_{\mu\nu}j^\mu_{D/A}[\Psi,\Xi]j^\nu_{D/A}[\Psi,\Xi]\simeq O(1), \tag{74}$$

which stay bounded near the hypersurface of signature change but contain terms which depend on sgn h. [Note that $\psi\simeq O(1)\simeq\xi$.] Thus the currents do not exhibit any divergences which depend on the choice of spinor metric or on h, although they can be seen to be discontinuous in general for any linear prescription relating spinor data across the hypersurface of signature change.

VI. CONCLUSION

We have drawn attention to some of the subtleties involved in discussing spinor fields in the presence of a smooth metric degeneracy. By insisting on interpolating smoothly (C^1) between the representations on either side of the degeneracy, we have been able to derive a number of interesting results. In particular, we have introduced the notion of a spinor fibration and used this to give a natural interpolation between the notions of a spinor on the two sides of the degeneracy. This enables one to discuss the concept of continuity of a spinor field in this context. Despite the absence of a continuous field of local orthonormal frames we have shown how a local massless Dirac equation can be constructed, albeit in terms of a class of spinor metrics equivalent up to local scalings and a phase freedom associated with charge conjugation. We have shown that the singularity structure of the solutions at metric degeneracies depends on the choice of spinor metric. An important conclusion of our work is that it is impossible to have both a continuous spinor metric and continuous solutions to the Dirac equation. Researchers studying spinor fields on manifolds with smooth degenerate metrics will be forced to make a choice. Furthermore, our formalism allows one to determine explicitly how various assumptions regarding the continuity of the spinor components affect the continuity of the Dirac current.

A dynamic theory of spinors on a degenerate background geometry may require a dynamical prescription to remove the freedom inherent in the construction of the spinor connection. One way to implement this idea would be to promote the scaling degree of freedom in the spinor metric to an independent scalar field and include this in the dynamical theory. A less radical suggestion might be to relinquish completely the irreducible spinor representations for matter by embedding a multiplet of spinor fields into a single Kähler field. The natural dynamics of such a multicomponent tensor field depends only on the metric structure of the manifold which is no longer required to sustain a spinor structure.

Relinquishing the assumption of a smooth interpolation of representations on either side of the metric degeneracy may lead to an alternative construction of a spinor fibration. However, it is unlikely to circumvent the discontinuity of the currents which was found to be purely an algebraic effect of the signature change.

For a nonequilibrium system characterized by its state space, by a dynamics defined by a transfer matrix and by a reference equilibrium dynamics given by a detailed-balance transfer matrix, we define various nonequilibrium concepts: relative entropy, dissipation during the relaxation to the stationary state, path entropy, cost for maintaining the system in a nonequilibrium state, fluctuation-dissipation theory, and finally a tree integral formula for the stationary state. © *1996 American Institute of Physics.* [S0022-2488(96)02808-3]

I. INTRODUCTION

For systems that are not in equilibrium, much of the general power of thermodynamics and statistical mechanics is lost. For chemical reactions, for fluids, for dynamic critical phenomena, or metastable states, and for many, many natural, social, and economic systems, specific methods have been developed to deal with time-dependent collective phenomena (see among many possible references [1–9]). The absence of overriding laws, such as the entropy-related variational principles of equilibrium statistical mechanics, has long been lamented, although there have been many attempts, for example to define generalizations of thermodynamic functions (see Refs. 1, 2, 6, and 10–12 for recent definitions). In the present paper we use a dynamical framework broad enough to cover most of the phenomena of interest and find that there *are* general statements that can be made. Of course, there is a kind of complementarity principle. The vast range of nonequilibrium phenomena in open systems precludes certain kinds of specific predictions and forces on us a level of abstraction that may limit usefulness.

The framework is the master equation. A state space and transition probabilities between states are given. This will not describe situations where quantum interference is important, but is nevertheless rather comprehensive—even finite memory effects can be included by enlarging the state space. In its various forms, for example, the Fokker–Planck equation, the master equation has already been used in many contexts. Our goal will be to seek general versions of the broadest kind of equilibrium information, things analogous to entropy inequalities, fluctuation-dissipation theorems, and the characterization of the steady state, when there is one.

Label the states x, $y \in X$ and the transition probabilities R_{xy}, defined as the (conditional) probability that the state of the system at time $t+\Delta t$ is x, given that it was y at time t. For most of the present paper, we take X and Δt finite. The stochastic matrix R is *not* assumed to satisfy detailed balance (for any vector) and indeed *it is this feature that is of greatest interest.* To avoid irrelevant mathematical complications, R is assumed to be irreducible.

For some of our results it would be easy to take continuum limits. Indeed in previous works (Refs. 13–15) we used the master equation approach advocated here to define a metastable state and in Ref. 16 to establish "self-organized criticality" (see Refs. 17 and 18) in a model system. These results were based on showing the disappearance of an energy gap, clearly going beyond the finite state context. Similarly, in Ref. 19 various critical properties in directed percolation derive

from the spectrum and eigenfunctions of the matrix R, in particular, its infinite size limit.

Within this framework there emerges the important general concept of *current*. By this we mean the flow of probability that can exist, even in the stationary state: $J_{xy}=R_{xy}\tilde{p}_y-R_{yx}\tilde{p}_x$, where $R\tilde{p}=\tilde{p}$. Currents, in particular current loops, which do not exist at equilibrium, are essential to anything one would consider *complex* as a dynamical system (see, e.g., Ref. 20 for different perspectives and Ref. 21 for other opinions). One must be careful here to distinguish currents in X from currents in an underlying physical coordinate space. For example, in this terminology, heat conduction with detailed balance is not complex, even though it is not in equilibrium. We shall discuss these matters in another publication.

The present paper is intended as an exposition of our general framework. In developing this framework we have had a number of examples in mind and in future publications we intend to exhibit these applications. However, because the present exposition is already rather lengthy, we will give only minimal indications of these examples. It is also clear that the wealth of potential applications will require tweaking of our framework. For example, directed percolation on finite systems generally has a trivial (absorbing) stationary state. By minor modification of the dynamics the interesting behavior of such systems can be studied with the present techniques (see, for example Ref. 22). However, in the present paper we do not focus on those issues.

Summary of results. A natural construct is the relative entropy $S(p|q)=-\Sigma_x p_x \log(p_x/q_x)$ of two distributions. For equilibrium theory this is already important [e.g., if q is the Gibbs state, $S(p|q)$ is essentially a thermodynamic potential] and it is also used extensively in information theory. It is easy to show (and well known) that

$$S(p|q)\leqslant S(Rp|Rp)\leqslant 0.$$

Much of this work focuses on the invariant state of R, which is called $\tilde{p}$. Thus $\tilde{p}=R\tilde{p}$. The analog of the entropy increase in equilibrium systems is the fact that $S(p|\tilde{p})$ can only increase as R is successively applied to p. In fact, we have a stronger statement: If δ is small and $p_\delta(x)\equiv\tilde{p}(x)\exp(\delta\varphi_1(x))$, then $S(p_\delta|\tilde{p})\sim-\delta^2\langle\varphi_1^2\rangle_{\tilde{p}}/2$. This allows bounds on the rate of approach to stationarity (i.e., $\tilde{p}$). Let ${}^tR$ be the transpose of R and $({}^tR)^*$ be its adjoint with respect to the inner product using $\tilde{p}$ as a weight. Let φ_1 be the eigenvector of ${}^tR({}^tR)^*$ with maximum eigenvalue $\mu_{\max}$, different from 1, then

$$S(Rp|\tilde{p})-S(p|\tilde{p})\geqslant\tfrac{1}{2}\langle\delta^2\varphi_1^2\rangle(1-\mu_{\max}).$$

This is a statement about dissipation and fluctuations, although in a moment we shall get to the usual form. In this context we are also able to get results on "excess work," a concept that has been used in the chemical literature.[10]

One question of great interest is, what does it "cost" to keep the system out of equilibrium? The matrix R can describe a system with temperature gradients, with sunlight, with wind, with currency exchange rate shifts. How can one associate a general cost? Given the broad nature of our goals, we preferred not to model the reservoirs that maintain R's imbalances. Rather, we assume that R is to be compared with a fiducial W, which is a transition matrix with an equilibrium state and detailed balance $[W_{xy}p_{\rm eq}(y)=W_{yx}p_{\rm eq}(x)]$. For example, if R describes Rayleigh–Benard flow, then W could represent a world uniformly at the temperature of the upper (or the colder) plate. The cost should then be what it takes to heat the lower plate. The choice of W is made by the observer and is partly conventional, depending on what the observer or designer intends to do with the R matrix. For example, in a Carnot cycle completed by a necessarily out-of-equilibrium engine, depending on whether the cycle is used to move a car or function as a refrigerator, W would be the thermal state at low or high temperature, respectively. However, within our general framework one is not committed to such a detailed point of view.

By considering a path entropy, we find it appropriate to define

$$\Delta_1\mathscr{I}(R,\tilde{p},W)=-\sum_{x,y} R_{xy}\tilde{p}(y)\log\left(\frac{R_{xy}}{W_{xy}}\right),$$

to be the dissipation per time step required to maintain the state $\tilde{p}$, against a tendency to relax to equilibrium. The following remarkable inequality emerges:

$$S(W\tilde{p}|p_{\rm eq})-S(\tilde{p}|p_{\rm eq})\leqslant 4\,\Delta_1\mathscr{I}(R,\tilde{p},W).$$

This inequality is proved for $\tilde{p}$ near equilibrium. It means that if we start with a certain stationary state and switch off the reservoirs defining R, so that $\tilde{p}$ starts to relax to the equilibrium $p_{\rm eq}$ by the W evolution, the dissipation per unit time is always less than four times the cost to maintain $\tilde{p}$, as defined by the path entropy.

To state a nonequilibrium fluctuation-dissipation theorem in a form similar to its usual equilibrium formulation, it is necessary to climb down from the grand generality adopted until this point. A distinction must be drawn between fast and slow variables—the motion of one dissipates while the others fluctuate. In the context of our master equation model we achieve this result. In fact, what we get is stronger than what is known in the equilibrium case. In particular, we have independent expressions for fluctuation and dissipation and the comparison of these expressions gives the fluctuation-dissipation statement, while traditional derivations do not give separate expressions for fluctuation and dissipation. Note that the state around which this generalized fluctuation dissipation theorem holds is *not* equilibrium but is the stationary state $\tilde{p}$. More precisely, let A be a slow variable of the system that is chosen to be a left eigenvector of the transfer matrix R whose eigenvalue is close to 1, and let p_α be a perturbation of the stationary state, such that $\langle A(0)\rangle_{p_\alpha}$ (average of A at time 0 in the state p_α) is given, then the dissipation is

$$\langle A(\Delta t)-A(0)\rangle\sim\langle A(0)\rangle_{p_\alpha}(\lambda-1),$$

while the fluctuation is

$$\langle(A(\Delta t)-A(0))\rangle\sim(\lambda-1)(-2\langle A^2\rangle_{p_\alpha})+O(\alpha).$$

The elimination of $\lambda-1$ then provides the analog of the fluctuation-dissipation relation in a nonequilibrium stationary state.

Finally, we state a generalization of the Onsager reciprocity relations for a general nonequilibrium system. The Onsager coefficients L_{kj} are not, in general, symmetric, but they are symmetric in the case of detailed balance dynamics.

In general, most of our statements (with the exception of the statements of Secs. II A and II B), hold for states near the stationary state, or for stationary states near an equilibrium state of reference (and an R matrix near a detailed balance matrix W). In our general framework, it is difficult to estimate how "near" one must be so that our statements remain valid. In particular, we do not discuss criticality (although everything we say is valid in this context too). Finally, we present a general expression for the stationary state of any stochastic matrix R. This is potentially important: for equilibrium theory, merely writing down the Gibbs state, $\exp(-\beta H)$, is a major step toward calculating various quantities. Our expression for the state is in terms of a sum over spanning trees built out of R and is reminiscent of a path integral formula; actually it is a "tree-integral formula." At the computational level this may turn out to be difficult to work with. (An Ising model with 5 spins has a 32×32 transition matrix. The number of spanning trees on 32 objects is about 10^{45}.) However, for formal manipulations it should be useful; for example, it could lead to an abstract definition of nonequilibrium phase transition.

II. DISSIPATION DURING THE RELAXATION TO THE STATIONARY STATE

In the following, X denotes a discrete space with points $x,y,\ldots$. We start by recalling elementary facts about probability distributions and their entropy on X.

A. Relative entropy of two probability distributions

Let p and q be two probability distributions on X. The relative entropy is defined to be

$$S(p|q)=-\sum_{x\in X} p(x)\log\frac{p(x)}{q(x)}.$$

By convention, $0\log 0=0$. It follows that

$$S(p|q)\leqslant 0. \tag{2.1}$$

The proof is immediate. We have

$$S(p|q)=-\sum p(x)\log\frac{p(x)}{q(x)}=-\sum q(x)L\left(\frac{p(x)}{q(x)}\right),$$

where $L(\xi)\equiv\xi\log\xi$. But $L'(\xi)=1+\log\xi$ and $L''\xi)=(1/\xi)\geqslant 0$, so L is convex. As a consequence, $L(\Sigma_x q(x)\alpha(x))\leqslant\Sigma q(x)L(\alpha(x))$, provided $\Sigma_x q(x)=1$. So

$$S(p|q)\leqslant -L\left(\sum_x q(x)\frac{p(x)}{q(x)}\right)=-L(1)=0.$$

Remark: If $\tilde{p}$ is an equilibrium distribution of the form $\tilde{p}(x)=\exp(-\beta E_x)/\mathcal{Z}$, the quantity S is (up to a sign) the corresponding thermodynamic potential. Specifically, $S(q|p)=\beta[\tilde{F}-F_q]$, where $\tilde{F}=-T\log\mathcal{Z}$ (the usual free energy) and $F_q=\langle E\rangle_q-T(-\Sigma q\log q)$.

B. Increase of the relative entropy

The result below, Eq. (2.2), is derived as in Ref. 23 but adapted to our notation.

We consider two distributions p_0,q_0 and a Markov chain on X, with transition matrix R_{xy} ($R_{xy}\equiv R_{x\leftarrow y}$ is the probability that starting from y, one has a transition $y\to x$ in unit time step). We call p_1, q_1 the probability distributions at time 1,

$$p_1(x)=\sum R_{xy}p_0(y),\quad q_1(x)=\sum R_{xy}q_0(y).$$

Then

$$S(p_0|q_0)\leqslant S(p_1|q_1). \tag{2.2}$$

Proof: Consider the states of the Markov chain at times 0 and 1, namely $\{x_0,x_1\}$. If the initial probability distribution is p_0, the joint law of $\{x_0,x_1\}$ is $P(x_0,x_1)=R_{x_1x_0}p_0(x_0)$, and if the initial probability distribution is q_0, the joint law of $\{x_0,x_1\}$ is $Q(x_0,x_1)=R_{x_1x_0}q_0(x_0)$. Then

$$S(P|Q)=-\sum_{x_0,x_1}P(x_0,x_1)\log\frac{P(x_0,x_1)}{Q(x_0,x_1)}=-\sum_{x_0,x_1}R_{x_1x_0}p_0(x_0)\log\frac{p_0(x_0)}{q_0(x_0)}=S(p_0|q_0).$$

Now, we compute $S(P|Q)$ in a different way. We can write P and Q by conditioning the past x_0 knowing the future x_1 in the following way:

$$P(x_0,x_1)=p_1(x_1)r_{x_1x_0}, \quad Q(x_0,x_1)=q_1(x_1)s_{x_1x_0},$$

where $p_1(x_1)$ [resp., $q_1(x_1)$] are the distribution probabilities of x_1, the initial distribution of x_0 being $p_0(x_0)$ [resp., $q_0(x_0)$], and where $r_{x_1x_0}$ is the distribution probability of x_0, knowing that the position at time 1 of the chain is x_1 [given the fact that the distribution of x_1 is $p_1(x_1)$], and, in the same manner, $s_{x_1x_0}$ is the distribution probability of x_0 knowing that at time 1 the position of the chain is x_1 [given the fact that the distribution of x_1 is $q_1(x_1)$].

Then the same computation proves that

$$S(P|Q)=S(p_1|q_1)+\sum_{x_1} p_1(x_1)S(r_{x_1,*}|s_{x_1,*}),$$

where

$$S(r_{x_1,*}|s_{x_1,*})=-\sum_{x_0} r_{x_1x_0}\log\frac{r_{x_1x_0}}{s_{x_1x_0}}\leqslant 0.$$

So we have

$$S(p_0|q_0)=S(P|Q)\leqslant S(p_1|q_1).$$

Remark: For $\tilde{p}=\exp(-\beta E_x)/\mathcal{Z}$, this shows that $F_q=\Sigma E_x q(x)-TS(q|1)$ can only decrease. (This F_q is the same as defined in our remark at the end of the previous section.)

C. Computation near the stationary state

Although Eq. (2.2) is known in the information theory context, the matter we now discuss appears more relevant to physical and chemical systems as such. To the extent that similar or weaker results are known, they arise in the statistical mechanics literature. As we proceed, we shall give references wherever appropriate. In any case the results we now derive are not contained in Ref. 23. We shall see that they are completely general and do not refer to any special feature of the physical or chemical systems we consider.

As above, our system is described by a state space X and its evolution can be represented by a stochastic matrix R_{xy} (which is the probability of a transition $y\to x$ in a unit time step Δt). We assume that R has a unique stationary state $\tilde{p}(x)$ satisfying

$$\tilde{p}(x)=\sum_y R_{xy}\tilde{p}(y). \tag{2.3}$$

Remark: Note that by virtue of (2.2), for any q,

$$S(Rq|\tilde{p})\geqslant S(q|\tilde{p}). \tag{2.4}$$

We consider a neighboring state $p_\delta(x)$, where δ is a small parameter, namely

$$p_\delta(x)\equiv\tilde{p}(x)\exp(\varphi(x,\delta)),$$

where

$$\varphi(x,\delta)\equiv\delta\varphi_1(x)+\delta^2\varphi_2(x)+\cdots.$$

Then, for small δ, it follows that

$$S(p_\delta|\tilde{p}) \sim -\frac{\delta^2}{2}\langle\varphi_1^2\rangle_{\tilde{p}}, \tag{2.5}$$

where $\langle\varphi_1^2\rangle_{\tilde{p}}$ is the mean square average of φ_1 in the state $\tilde{p}$,

$$\langle\varphi_1^2\rangle_{\tilde{p}} = \sum_x \tilde{p}(x)\varphi_1^2(x).$$

Proof: We start from the definition

$$S(p_\delta|\tilde{p}) = \sum p_\delta(x)\log\frac{p_\delta(x)}{\tilde{p}(x)}.$$

Then

$$\frac{\partial S}{\partial\delta} = -\sum \frac{\partial p_\delta(x)}{\partial\delta}\left(1+\log\frac{p_\delta(x)}{\tilde{p}(x)}\right),$$

$$\frac{\partial^2 S}{\partial\delta^2} = -\sum \frac{\partial^2 p_\delta(x)}{\partial\delta^2}\left(1+\log\frac{p_\delta(x)}{\tilde{p}(x)}\right) - \sum \frac{1}{p_\delta(x)}\left(\frac{\partial p_\delta(x)}{\partial\delta}\right)^2.$$

Now we have $\Sigma p_\delta(x)=1$. Therefore $\Sigma\partial p_\delta(x)/\partial\delta=0$ and $\Sigma\partial^2 p_\delta(x)/\partial\delta^2=0$. It follows that

$$S(p_\delta|\tilde{p}) \sim -\frac{\delta^2}{2}\sum_x \frac{1}{p_\delta(x)}\left(\frac{\partial p_\delta(x)}{\partial\delta}\right)^2\Bigg|_{\delta=0}.$$

But

$$\left.\frac{\partial p_\delta(x)}{\partial\delta}\right|_{\delta=0} = p_\delta(x)\varphi_1(x).$$

D. Variation of entropy near the stationary state

We again consider a state $p_\delta(x)$ near the stationary state, and for simplicity we drop the δ index. We note that

$$p(x) = \tilde{p}(x)\exp(\delta\varphi_1(x)+\delta^2\varphi_2(x)+\cdots).$$

We consider at time step Δt (one time step) the evolution of p, namely

$$p(x,\Delta t) = \sum_y R_{xy}p(y).$$

We know by Eq. (2.2) of Sec. II B that

$$S(p|\tilde{p}) \leqslant S(p(\cdot,\Delta t)|\tilde{p}),$$

but here we shall find the difference between these two entropies. We can write

$$p(x,\Delta t) = \tilde{p}(x)\exp(\delta\psi_1(x)+\delta^2\psi_2(x)+\cdots).$$

Now

$$\tilde{p}(x)\exp(\delta\psi_1(x)+\delta^2\psi_2(x)+\cdots)=\sum_y R_{xy}\tilde{p}(y)\exp(\delta\varphi_1(y)+\delta^2\varphi_2(y)+\cdots).$$

Comparing the terms of order δ, we find

$$\psi_1(x)=\frac{1}{\tilde{p}(x)}\sum_y R_{xy}\tilde{p}(y)\varphi_1(y), \tag{2.6}$$

or in vector notation,

$$\psi_1=\left(\operatorname{diag}\frac{1}{\tilde{p}}\right)R(\operatorname{diag}\tilde{p})\varphi_1. \tag{2.6'}$$

Then, in our context, we have

$$S(p(\cdot,\Delta t)|\tilde{p})-S(p|\tilde{p})\sim-\frac{1}{2}\left[\left\langle\left(\frac{1}{\operatorname{diag}\tilde{p}}R\ \operatorname{diag}\tilde{p}\ \delta\varphi_1\right)^2\right\rangle_{\tilde{p}}-\langle(\delta\varphi_1)^2\rangle_{\tilde{p}}\right]. \tag{2.7}$$

We shall study a lower bound for this quantity. To do this, we maximize the quantity

$$\max\left\langle\left(\frac{1}{\operatorname{diag}\tilde{p}}R\ \operatorname{diag}\tilde{p}\varphi_1\right)^2\right\rangle_{\tilde{p}},$$

subject to the conditions $\langle\varphi_1^2\rangle_{\tilde{p}}=1$ and $\langle\varphi_1\rangle_{\tilde{p}}=0$. [The last condition is a consequence of $\Sigma_x p_\delta(x)=1$, so that $\Sigma\varphi_1(x)\tilde{p}(x)=0$.]

To find this maximum, we introduce a Lagrange multiplier μ for the constraint $\langle\varphi_1^2\rangle_{\tilde{p}}=1$ and we assume that φ_1 has been found. Then, for any variation $\varphi_1+\epsilon_1$, we must have

$$\sum_x\tilde{p}(x)\left(\frac{1}{\operatorname{diag}\tilde{p}}R\ \operatorname{diag}\tilde{p}\varphi_1\right)_x\left(\frac{1}{\operatorname{diag}\tilde{p}}R\ \operatorname{diag}\tilde{p}\epsilon_1\right)_x-\mu\sum\tilde{p}(x)\epsilon_1(x)=0.$$

Rearranging, the factor of $\epsilon_1(x)$ must vanish identically, so that

$${}^tR\ \operatorname{diag}\left(\frac{1}{\tilde{p}}\right)R(\operatorname{diag}\tilde{p})\varphi_1=\mu\varphi_1. \tag{2.8}$$

Denote $M={}^tR$ (so $M_{xy}=R_{yx}$). We notice that the adjoint M^* of M for the scalar product,

$$(v|w)_{\tilde{p}}=\sum\tilde{p}(x)v(x)^*w(x), \tag{2.9}$$

is just

$$M^*=\operatorname{diag}\left(\frac{1}{\tilde{p}}\right)R\ \operatorname{diag}\tilde{p}, \tag{2.10}$$

and so Eq. (2.8) can be rewritten as

$$MM^*\varphi_1=\mu\varphi_1. \tag{2.11}$$

MM* is self-adjoint with respect to the scalar product $(\ |\ )_{\tilde{p}}$. Moreover, all its eigenvalues are obviously positive. Call $N=MM^*$. We show that all eigenvalues of N are less than 1. Let φ be eigenvector of eigenvalue μ,

$$\max_{y\in X}|N\varphi(y)|\leqslant\sum R_{xy}\frac{1}{\tilde{p}(x)}R_{xy}\tilde{p}(z)|\varphi(z)|\leqslant\max_{z}|\varphi(z)|\left(\sum_{x}R_{xy}\frac{1}{\tilde{p}(x)}\sum_{z}R_{xy}\tilde{p}(z)\right)$$

$$\leqslant\max|\varphi(z)|\left(\sum_{x}R_{xy}\frac{1}{\tilde{p}(x)}\tilde{p}(x)\right)=\max|\varphi(z)|,$$

but because of Eq. (2.11), $N\varphi=\mu\varphi$. We see that if $\varphi\not\equiv 0$, $\mu\leqslant 1$.

Obviously the matrix $N=MM^*$ has the eigenvalue 1 with trivial eigenvector $\{1\}$ because

$$\sum_{x,z}R_{xy}\frac{1}{\tilde{p}(x)}R_{xz}\tilde{p}(z)=1,\quad\text{for all } y.$$

Now in the variational problem above, we considered an eigenvector φ_1 that is orthogonal to the trivial eigenvector $\{1\}$ (because we imposed $\langle\varphi_1\rangle_{\tilde{p}}=0$). So, *we have proved that*

$$S(p(\cdot,\Delta t)|\tilde{p})-S(p|\tilde{p})\geqslant\tfrac{1}{2}\langle\delta^2\varphi_1^2\rangle_{\tilde{p}}(1-\mu_{\max}),\tag{2.12}$$

where $\mu_{\max}$ is the maximal eigenvalue of MM^* corresponding to an eigenvector φ_1 orthogonal to the trivial eigenvector $\{1\}$.

It remains to prove that $\mu_{\max}<1$. Suppose that $v(x)$ is an eigenvector of eigenvalue 1 but different from the trivial eigenvector $\{1\}$; thus $v(x)$ is orthogonal to $\{1\}$ for the scalar product $(\ |\ )_{\tilde{p}}$,

$$\sum\tilde{p}(x)v(x)=0.$$

We have

$$v(x)=\sum_{y,z}R_{yx}\frac{1}{\tilde{p}(y)}R_{yz}\tilde{p}v(z).$$

But $\tilde{p}(x)\neq 0$ for all x, so that at least one $v(x)$ must be negative. As a consequence, we obtain from the preceding inequality a strict inequality,

$$|v(x)|<\sum_{y,z}R_{yx}\frac{1}{\tilde{p}(y)}R_{yz}\tilde{p}(z)|v(z)|,$$

or finally

$$\max_{x\in X}|v(x)|<\max_{z\in X}|v(z)|,$$

which is a contradiction

Remark 1: All this assumes that $\tilde{p}(x)\neq 0$ for all x because we need to define $1/\tilde{p}(x)$ for all x. This is the case if R is irreducible. If R is reducible, one can sometimes introduce small matrix elements to make it irreducible while preserving its essential features, as in Ref. 22.

Remark 2: This "universal" inequality,

$$S(p(\cdot,\Delta(\cdot)|\tilde{p})-S(p(\cdot)|\tilde{p})\geq\tfrac{1}{2}\langle\delta^2\varphi_1^2\rangle_{\tilde{p}}(1-\mu_{\max})$$

is a kind of *fluctuation dissipation inequality* for nearby states, p, because the left side is the dissipation (in one time step) and the right side involves a fluctuation $\langle\delta^2\varphi_1^2\rangle$ of the relative free energy of p with respect to $\tilde{p}$ (and a factor that is $1-\mu_{\max}$).

Remark 3: If R satisfies detailed balance, then

$$M^*={}^tR$$

and

$$MM^*=({}^tR)^2.$$

In general, we see that the relevant operator is MM^* and not $M^2=({}^tR)^2$.

E. The notion of excess work

The notion of excess work has been introduced by Ross, Hunt, and Hunt[10] and we can give a meaning to it in our abstract setting.

We start from a stationary state $\tilde{p}(x)$ (and as usual the stochastic matrix, R). We can do two things.

(i) We force a variation of the state $\tilde{p}$ (by an external process) so that we have a displaced state $p(x)$,

$$p(x)=\tilde{p}(x)\exp(\delta\varphi_1(x)+\delta^2\varphi_2(x)+\cdots).$$

The relative cost in entropy for doing this is

$$S(p|\tilde{p})\sim-\frac{\delta^2}{2}\langle\varphi_1^2(x)\rangle_{\tilde{p}},$$

as we know from Eq. (2.5).

(ii) We start from a certain state q,

$$q(x)=\tilde{p}(x)\exp(\delta\psi_1(x)+\delta^2\psi_2(x)+\cdots),$$

and let it evolve in one time step Δt in such a way that the variation of free energy is exactly $\delta\varphi_1(x)$ (up to δ^2), so that we *want*

$$q(x,\Delta t)=\tilde{p}(x)\exp(\delta\psi_1(x)+\delta\varphi_1(x)+\cdots).$$

This implies

$$\tilde{p}(x)[\varphi_1(x)+\psi_1(x)]=\sum_y R_{xy}\tilde{p}(y)\psi_1(y). \tag{2.13}$$

The variation of entropy is then easily seen to be

$$S(q(\cdot,\Delta t)|\tilde{p})-S(q(\cdot)|\tilde{p})=-\frac{\delta^2}{2}(\langle\varphi_1^2\rangle_{\tilde{p}}+2(\psi_1|\varphi_1)_{\tilde{p}}),$$

with ψ_1 fixed by Eq. (2.13), or

$$\left[I-\operatorname{diag}\left(\frac{1}{\tilde{p}}\right)R\ \operatorname{diag}\tilde{p}\right]\psi_1\equiv-\varphi_1.$$

Alternatively,

$$\operatorname{diag}\tilde{p}(\varphi_1+\varphi_1)=R(\operatorname{diag}\tilde{p})\psi_1=-R(\operatorname{diag}\tilde{p})\left[I-\operatorname{diag}\left(\frac{1}{\tilde{p}}\right)R\ \operatorname{diag}\tilde{p}\right]^{-1}\varphi_1.$$

The excess work W_{exc} is given by (see Ref. 10)

$$\begin{aligned}
W_{\mathrm{exc}}&=S(q(\cdot,\Delta t)|\tilde{p})-S(q(\cdot)|\tilde{p})+S(p|\tilde{p})\\
&=-\delta^2\sum_x\tilde{p}(x)\varphi_1(x)(\varphi_1(x)+\psi_1(x))\\
&=-\delta^2\sum\varphi_1(x)(R(\operatorname{diag}\tilde{p})\psi_1)(x)\\
&=\delta^2\sum_x\left(\left[I-\left(\operatorname{diag}\frac{1}{\tilde{p}}\right)R(\operatorname{diag}\tilde{p})\right]\psi_1\right)_x((R\ \operatorname{diag}\tilde{p})\psi_1)_x\\
&=\delta^2\sum_x\tilde{p}(x)\psi_1(x)\left[({}^tR\psi_1)_x-\left({}^tR\ \operatorname{diag}\frac{1}{\tilde{p}}R\ \operatorname{diag}\tilde{p}\psi_1\right)_x\right]\\
&=\delta^2[(\psi_1|M\psi_1)-(\psi_1|MM^*\psi_1)],
\end{aligned}$$

where $M={}^tR$, $M^*=\operatorname{diag}(1/\tilde{p})R(\operatorname{diag}\tilde{p})$, and the scalar product has the weight $\tilde{p}$ as usual. One can rewrite this as

$$W_{\mathrm{exc}}=\delta^2\left[\left(\psi_1\left|\frac{M+M^*}{2}\psi_1\right.\right)-(\psi_1|MM^*\psi_1)\right]. \tag{2.14}$$

Notice that if R *satisfies detailed balance*, we have seen that

$$M^*=M={}^tR,$$

and so, because ${}^tR-({}^tR)^2\geqslant 0$, because ${}^tR$ has eigenvalue less than or equal to 1, we have

$$W_{\mathrm{exc}}=\delta^2[(\psi_1|({}^tR-({}^tR)^2)\psi_1)]\geqslant 0,$$

which is exactly Ross' result in our abstract context.

Remark: Ross *et al.* derive this result for the stochastic matrix corresponding to a master equation of a linear chemical system, in which case it is known that the master equation satisfies detailed balance. This is not the case for nonlinear chemical reactions. But we still have an expression for the excess work, in general.

Remark: For a stochastic matrix S that is self-adjoint with respect to a scalar product, it is clear that

$$(\psi|S\psi)\geqslant(\psi|S^2\psi).$$

Moreover, to prove that the excess work is positive, we would have to prove that $M+M^*-2MM^*$ is a positive matrix self-adjoint with respect to the scalar product $(\ |\ )_{\bar{p}}$.

III. PATH ENTROPIES AND DISSIPATION TO MAINTAIN THE STATIONARY STATE

To maintain a system in a nonequilibrium state against an equilibrated environment, it is necessary to dissipate energy. We introduce measures for the rate of dissipation of free energy.

A. Absolute path entropy

(a) Measure on a space of paths. Let X be our usual state space. A path up to time $T(T=n\ \Delta t)$ is a sequence $\gamma=\{x_0,x_1,\ldots,x_T\}$ of points in X. A path is then a sequence of transformations. For example, a Carnot cycle or a biochemical cycle will be realized by closed paths.

If p is an initial distribution, we define a probability measure $\mu^{(R,p)}(\gamma)$ on the space of paths by the formula

$$\mu^{(R,p)}(\gamma)=R_{x_Tx_{T-1}}R_{x_{T-1}x_{T-2}}\cdots R_{x_1x_0}p(x_0). \tag{3.1}$$

(b) We define an absolute entropy as

$$\sigma(T|R,p)=-\sum_{\gamma=\text{path up to } T}\mu^{(R,p)}(\gamma)\log\,\mu^{(R,p)}(\gamma)$$

$$=-\sum_{\gamma}\mu^{(R,p)}(\gamma)\left[\sum_{n=0}^{T-1}\log R_{x_{n+1}x_n}+\log p(x_0)\right].$$

As usual, we define recursively

$$(R^kp)(x)=\sum_y R_{xy}(R^{k-1}p)(y).$$

Then

$$\sum_{\gamma}\mu^{(R,p)}(\gamma)\log R_{x_{n+1}x_n}=\sum R_{x_Tx_{T-1}}\cdots R_{x_{n+1}x_n}\log R_{x_{n+1}x_n}(R^np)(x_n)$$

$$=\sum_{x_{n+1},x_n}R_{x_{n+1}x_n}\log R_{x_{n+1}x_n}(R^np)(x_n).$$

But

$$\sum_{x_{n+1}}R_{x_{n+1}x_n}(R^np)(x_n)=1.$$

Because $L(\xi)=\xi\log\xi$ is convex, we have

$$\sum_{x_{n+1},x_n} R_{x_{n+1}x_n}(R^n p)(x_n)\log R_{x_{n+1}x_n}$$

$$\geqslant \sum_{x_{n+1}} \left(\sum_{x_n} R_{x_{n+1}x_n}(R^n p)(x_n)\right)\log\left(\sum_{x_n} R_{x_{n+1}x_n}(R^n p)(x_n)\right)$$

$$= \sum_{x_{n+1}} (R^{n+1}p)(x_{n+1})\log(R^{n+1}p)(x_{n+1})$$

$$\equiv -S(R^{n+1}p) \quad \text{(absolute entropy of } R^{n+1}p\text{)}.$$

Finally,

$$\sigma(T|R,p)\leqslant \sum_{n=0}^{T} S(R^n p).$$

In particular, if $p=\tilde{p}$,

$$\sigma(T|R,\tilde{p})\leqslant (T+1)S(\tilde{p}).$$

B. Relative entropy on paths

The preceding concept involved the transition matrix R alone and, as such, did not measure the cost of the process R itself. Now, to quantify the extra dissipation needed to maintain a nonequilibrium state in a larger environment, we represent the action of this environment on our system by a stochastic matrix W satisfying the detailed balance. Namely, under the influence of W, the system X relaxes to an equilibrium state p_{eq} and we assume that for all x,y,

$$W_{yx}p_{\text{eq}}(x)=W_{xy}p_{\text{eq}}(y).$$

On the path space of X, we can consider the measure $\mu^{(R,p)}$, as well as the measures $\mu^{(W,q)}$, $\mu^{(W,p_{\text{eq}})}$.

The extra dissipation needed to maintain the R-dynamics in the larger equilibrium environment where action on the system is given by W is represented by the relative path entropy:

$$\mathscr{S}(T|(R,p),(W,q))=-\sum_{\text{path to } T} \mu^{(R,p)}(\gamma)\log\frac{\mu^{(R,p)}(\gamma)}{\mu^{(W,q)}(\gamma)}. \tag{3.2}$$

This can be rewritten using our basic quantity, $S(p|q)$, the relative entropy of Eq. (2.1),

$$\mathscr{S}(T|(R,p),(W,q))=S(p|q)-\sum_{\gamma=\text{path to } T} \mu^{(R,p)}(\gamma)\log\frac{R_{x_T x_{T-1}}\cdots R_{x_1 x_0}}{W_{x_T x_{T-1}}\cdots W_{x_1 x_0}}.$$

Analysis of $\mathscr{S}$. In the preceding equation, the second term is

$$\sum_{\gamma}\sum_{n=0}^{T-1} \mu^{(R,p)}(\gamma)\log\frac{R_{x_{n+1}x_n}}{W_{x_{n+1}x_n}}.$$

Now consider

$$\sum_{\gamma} \mu^{(R,p)}(\gamma)\log\frac{R_{x_{n+1}x_n}}{W_{x_{n+1}x_n}} = \sum_{x_{n+1},x_n} (R^n p)(x_n) R_{x_{n+1}x_n} \log\frac{R_{x_{n+1}x_n}}{W_{x_{n+1}x_n}}$$

$$= \sum_{x_n} (R^n p)(x_n) \sum_{x_{n+1}} W_{x_{n+1}x_n} \frac{R_{x_{n+1}x_n}}{W_{x_{n+1}x_n}} \log\frac{R_{x_{n+1}x_n}}{W_{x_{n+1}x_n}}. \tag{3.3}$$

Using the convexity of $\xi\log\xi$, this is

$$\geqslant \sum_{x_n} (R^n p)(x_n) \left(\sum_{x_{n+1}} W_{x_{n+1}x_n} \frac{R_{x_{n+1}x_n}}{W_{x_{n+1}x_n}} \right) \left(\log\left(\sum_{x_{n+1}} W_{x_{n+1}x_n} \frac{R_{x_{n+1}x_n}}{W_{x_{n+1}x_n}} \right) \right),$$

and so, this is positive or zero because $\Sigma_{x_{n+1}} R_{x_{n+1}x_n} = 1$. Let us define

$$\Delta_1 \mathcal{S}(R,q,W) = -\sum_{x,y} R_{xy} q(y) \log\frac{R_{xy}}{W_{x,y}}. \tag{3.4}$$

Then, from Eq. (3.3),

$$\mathcal{S}(T|(R,p),(W,q)) = S(p|q) + \sum_{t=0}^{T-1} \Delta_1 \mathcal{S}(R,R^t p,W), \tag{3.5}$$

and we have proved above that

$$\Delta_1 \mathcal{S}(R,q,W) \leqslant 0. \tag{3.6}$$

In particular,

$$\mathcal{S}(T|(R,p),(W,q)) \leqslant 0. \tag{3.7}$$

Note that *this is also decreasing with T*, i.e., *each increment* $\Delta_1 \mathcal{S}(R,R^t p,W) \leqslant 0$.

A Particular case: Take $p = \tilde{p}$, the stationary state, so that $R^t \tilde{p} = \tilde{p}$ for all t. Then $S(T|(R,\tilde{p}),(W,q)) = S(\tilde{p}|q) + T\,\Delta_1 S(R,\tilde{p},W)$. In this case, the fundamental quantity,

$$\Delta_1 \mathcal{S}(R,\tilde{p},W) = -\sum_{xy} R_{xy} \tilde{p}(y) \log\frac{R_{xy}}{W_{xy}} \tag{3.8}$$

is the *rate of dissipation per unit time step to maintain the stationary state* $\tilde{p}$ *(in the R-dynamics) against the W dynamics.*

We introduce

$$R_{xy} = W_{xy} e^{f_{xy}}. \tag{3.9}$$

Then

$$\Delta_1 \mathcal{S}(R,\tilde{p},W) = -\sum_{xy} R_{xy} \tilde{p}(y) f_{xy}. \tag{3.10}$$

Remark: If $f_{xy} = \varphi_x - \varphi_y$ then it is immediate that $\Delta_1 S(R,\tilde{p},W) = 0$. But in this case we would have

$$W_{xy} e^{\varphi_y} \tilde{p}(y) = \tilde{p}(x),$$

so that $e^{\varphi_y}\tilde{p}(y)$ would be the equilibrium state $p_{\rm eq}$ of W. But also $\Sigma_x R_{xy}=1$, so that $\Sigma_x W_{xy}e^{-\varphi_x} = e^{-\varphi_y}$. This implies that $\{e^{-\varphi_x}\}$ would be the left eigenvector of eigenvalue 1 of W and (in the absence of degeneracy) this would be a constant. Then $\tilde{p}$ would just be the equilibrium $p_{\rm eq}$ and $R=W$.

C. The minimal rate of dissipation of a given state

In this section, we start with a given $\tilde{p}$ (in a detailed balance dynamics W) and we want to build an R-dynamics for which $\tilde{p}$ is stationary but that minimizes the dissipation of energy with respect to an underlying detailed balance dynamics W. The rate of dissipation is $\Delta_1\mathscr{S}(R,\tilde{p},W)$. We define, as in Eq. (3.9),

$$R_{xy}=W_{xy}e^{f_{xy}},$$

and we want to minimize

$$|\Delta_1\mathscr{S}(R,\tilde{p},W)|=\sum_{xy} W_{xy}e^{f_{xy}}\tilde{p}(y)f_{xy},$$

subject to the conditions

(i) $\Sigma_x W_{xy}e^{f_{xy}} = 1$, for all y;

(ii) R preserves the stationary state $\tilde{p}$, or $\Sigma_y W_{xy}e^{f_{xy}}\tilde{p}(y) = \tilde{p}(x)$ for all x. We examine the effect of a variation δf_{xy} on $|\Delta_1\mathscr{S}(R,\tilde{p},W)|$,

$$\delta|\Delta_1\mathscr{S}(R,\tilde{p},W)|=\sum_{yx} W_{yx}\tilde{p}(x)\exp(f_{yx})(1+f_{yx})\,\delta f_{yx}. \tag{3.11}$$

The variations of the two constraints are

$$\delta\left(\sum_y W_{yx}\exp(f_{yx})-1\right)=\sum_y W_{yx}\exp(f_{yx})\,\delta f_{yx}, \tag{3.12}$$

$$\delta\left(\sum_y W_{yx}\exp(f_{yx})\tilde{p}(y)\right)=\sum_x W_{yx}\exp(f_{yx})\tilde{p}(x)\,\delta f_{yx}. \tag{3.13}$$

As usual, we introduce two Lagrange multipliers, λ_x for the constraints (3.12) and μ_y for the constraints (3.13), and write

$$0=\delta|\Delta_1\mathscr{S}(R,\tilde{p},W)|+\sum_x \lambda_x\delta\left(\sum_y W_{yx}\exp(f_{yx})-1\right)$$
$$+\sum_y \mu_y\delta\left(\sum_x W_{yx}\exp(f_{yx})\tilde{p}(x)-\tilde{p}(y)\right).$$

After rearrangement, this gives

$$0=\sum_{yx}\delta f_{yx}\exp(f_{yx})W_{yx}[\tilde{p}(x)(1+f_{yx})+\lambda_x+\mu_y\tilde{p}(x)].$$

If $W_{yx}=0$, we have no condition. But, if $W_{yx}\neq 0$ we obtain

$$f_{yx}=-\frac{\lambda_x}{\tilde{p}(x)}-\mu_y-1,$$

and then λ_x and μ_y are determined using the two constraints:

$$1=\sum_y W_{yx}\exp\left(-\frac{\lambda_x}{\tilde{p}(x)}\right)\exp(-\mu_y-1),$$

$$\tilde{p}(y)=\sum_x W_{yx}\exp\left(-\frac{\lambda_x}{\tilde{p}(x)}\right)\exp(-\mu_y-1)\tilde{p}(x).$$

Then, we see that $R_{yx}=0$ when $W_{yx}=0$ (this is our ansatz anyway), and

$$R_{yx}=W_{yx}\exp(\rho_y-\sigma_x), \tag{3.14}$$

when $W_{yx}\neq 0$, so that we can always use Eq. (3.14). Using (3.14), we can compute the rate of dissipation

$$|\Delta_1\mathcal{S}(R,\tilde{p},W)|=\sum_{y,x} W_{yx}\exp(f_{yx})f_{yx}\tilde{p}(x).$$

But

$$\sum_x W_{yx}e^{-\sigma_x}\tilde{p}(x)=e^{-\rho_y}\tilde{p}(y),\quad \sum_y W_{yx}e^{\rho_y}=e^{\sigma_x},$$

so that finally the minimal rate of dissipation is

$$|\Delta_1\mathcal{S}(R,\tilde{p},W)|=\sum_x \tilde{p}(x)(\rho_x-\sigma_x). \tag{3.15}$$

D. Analysis near equilibrium

In this section, we consider an equilibrium state p_{eq} with its detailed balance dynamics given by the matrix W. We further consider a nonequilibrium state $\tilde{p}$, which is close to p_{eq}, whose dynamics are given by a (non-detailed-balance) stochastic matrix R, close to W. We fix the notation as follows:

$$\tilde{p}(x)=p_{\mathrm{eq}}(x)\exp(\varphi(x,\delta))\equiv p_{\mathrm{eq}}(x)\exp(\delta\varphi_1(x)+\delta^2\varphi_2(x)+\cdots), \tag{3.16}$$

$$R_{xy}=W_{xy}\exp(f(x,y,\delta))\equiv W_{xy}\exp(\delta f_{xy}^{(1)}+\delta^2 f_{xy}^{(2)}+\cdots). \tag{3.17}$$

1. Identities satisfied by $f^{(1)}$ and φ_1

We differentiate the relation $\Sigma_y R_{yx}=1$ with respect to δ at $\delta=0$. This gives

$$\sum_y W_{yx}f_{yx}^{(1)}=0. \tag{3.18}$$

Similarly, the relation $\tilde{p}(x)=\Sigma_y R_{xy}\tilde{p}(y)$ is differentiated with respect to δ at $\delta=0$. This implies

$$p_{\mathrm{eq}}(x)\varphi_1(x)=\sum_y W_{xy}f_{yx}^{(1)}p_{\mathrm{eq}}(y)+\sum_y W_{xy}\varphi_1(y)p_{\mathrm{eq}}(y), \tag{3.19}$$

or using detailed balance,

$$W_{xy}p_{\rm eq}(y)=W_{yx}p_{\rm eq}(x),$$

$$\varphi_1(x)=\sum_y W_{yx}f^{(1)}_{yx}+\sum_y W_{yz}\varphi_1(y). \tag{3.20}$$

2. Variation of the entropy near the equilibrium state

Suppose that we start from the stationary state $\tilde{p}(x)$ and let it evolve spontaneously using the detailed balance dynamics W. We can compute in one time step Δt, the variation of relative entropy as in Sec. II D, except now $\tilde{p}\to p_{\rm eq}$ and $R\to W$. We obtain

$$S(\tilde{p}(\cdot,\Delta t)|p_{\rm eq})-S(\tilde{p}|p_{\rm eq})=\frac{\delta^2}{2}\left[\langle\varphi_1^2\rangle_{p_{\rm eq}}-\left\langle\left(\frac{1}{\text{diag } p_{\rm eq}}W\ \text{diag}\ p_{\rm eq}\varphi_1\right)^2\right\rangle_{p_{\rm eq}}\right].$$

But for detailed balance we have $((1/\text{diag}\, p_{\rm eq})W\ \text{diag}\, p_{\rm eq})_{xy}=(1/p_{\rm eq}(x))W_{xy}p_{\rm eq}(y)=W_{yx}$. Thus

$$S(\tilde{p}(\cdot,\Delta t)|p_{\rm eq})-S(\tilde{p}(\cdot)\cdot|p_{\rm eq})=\frac{\delta^2}{2}\left[\langle\varphi_1^2\rangle_{p_{\rm eq}}-\langle({}^tW\varphi_1)^2\rangle_{p_{\rm eq}}\right]. \tag{3.21}$$

3. Rate of dissipation

We now compute the rate of dissipation $|\Delta_1\mathscr{I}(\mathrm{R},\tilde{\mathrm{p}},\mathrm{W})|$. In Sec. III C, we obtained

$$|\Delta_1\mathscr{I}(R,\tilde{p},W)|=\sum_{xy}\ \exp(f(x,y,\delta))\tilde{p}(y)f(x,y,\delta),$$

which is evidently 0 for $\delta=0$ because $f(x,y,0)=0$. We expand this quantity in powers of δ up to second order. We write

$$\tilde{p}(x)=p_{\rm eq}(x)+\delta p_1(x)+O(\delta^2).$$

(We will not need the second order term in $\tilde{p}$.)

$$|\Delta_1\mathscr{I}(R,\tilde{p},W)|=\sum_{xy}W_{xy}\left\{1+\delta f^{(1)}_{xy}+\delta^2 f^{(2)}_{xy}+\frac{\delta^2}{2}(f^{(1)}_{xy})^2\right\}$$
$$\times\{p_{\rm eq}(y)+\delta p_1(y)\}\{\delta f^{(1)}_{xy}+\delta^2 f^2_{xy}\}+O(\delta^3).$$

The first-order term in δ is

$$\sum_y p_{\rm eq}(y)\sum_x W_{xy}f^{(1)}_{xy}.$$

But this is 0 because of relation (3.15) above,

$$\sum_x W_{xy}f^{(1)}_{xy}=0.$$

So we compute the second-order terms in δ; these are

$$\sum_{x,y} W_{xy} p_{\mathrm{eq}}(y)(f_{xy}^{(2)}+(f_{xy}^{(1)})^2)+\sum_{x,y} W_{xy} f_{xy}^{(1)} p_1(y).$$

But expanding $\Sigma_x R_{xy}=1$ up to second order gives

$$\sum_{x} W_{xy} f_{xy}^{(1)}=0 \quad \text{[relation (3.18) above]},$$

$$\sum_{x} W_{xy}\left(f_{xy}^{(2)}+\frac{1}{2}(f_{xy}^{(1)})^2\right)=0.$$

There remains only a single term, so that

$$|\Delta_1 \mathscr{S}(R,\tilde{p},W)|=\frac{\delta^2}{2}\sum_{x,y} W_{xy} p_{\mathrm{eq}}(y)(f_{xy}^{(1)})^2. \tag{3.22}$$

4. Minimal rate of dissipation

Starting from this last equation let us compute the minimal rate of dissipation, given $\tilde{p}$ and W. We thus have to minimize $|\Delta_1 \mathscr{S}(R,\tilde{p},W)|$ with respect to $f_{xy}^{(1)}$ under the conditions (3.18) and (3.20).

Introducing Lagrange multipliers λ_x, μ_y for (3.18) and (3.20), we see that

$$\sum_{x,y} W_{xy} p_{\mathrm{eq}}(y) f_{xy}^{(1)}\,(\delta f_{xy}^{(1)})+\sum_{x}\lambda_x\sum_{y} W_{yx}\,\delta f_{yx}^{(1)}+\sum_{x}\mu_x\sum_{y} W_{yx}\,\delta f_{xy}^{(1)}=0.$$

This implies that

$$W_{xy} p_{\mathrm{eq}}(y) f_{xy}^{(1)}+W_{xy}\lambda_y+\mu_x W_{yx}=0.$$

Using detailed balance, $W_{yx}=W_{xy}p_{\mathrm{eq}}(y)/p_{\mathrm{eq}}(x)$, we see that either

$$(1)\quad W_{xy}=0, \quad \text{or}$$

$$(2)\quad f_{xy}^{(1)}+\frac{\lambda_y}{p_{\mathrm{eq}}(y)}+\frac{\mu_x}{p_{\mathrm{eq}}(x)}=0,$$

which is exactly what we obtained above in a more general setting, namely

$$f_{xy}^{(1)}=\rho(x)-\sigma(y).$$

Let us assume that $f_{xy}^{(1)}$ has this form and determine σ and ρ using the constraints (3.18) and (3.20) above. This gives the following.

(1) For the constraint (3.18), $\Sigma_x W_{xy} f_{xy}^{(1)}=0$,

$$\sigma(x)=\sum_{y}\rho(y)W_{yx} \quad \text{or} \quad \sigma=\rho^t W. \tag{3.23}$$

(2) For the constraint (3.20), $\sigma_1(x)=\Sigma_y W_{yx} f_{xy}^{(1)}+\Sigma_y W_{yx}\varphi_1(y)$,

$$\varphi_1(x)=\sum_y W_{yx}(\rho(x)-\sigma(y))+\sum_y W_{yx}\varphi_1(y)$$

$$=\rho(x)-\sum_y \sigma(y)W_{yx}+\sum_y W_{yx}\varphi_1(y)$$

$$=(\rho(I-{}^tW)(I+{}^tW))_x+\sum_y W_{yx}\varphi_1(y).$$

This can be solved as

$$\varphi_1(I-{}^tW)=\rho(I+{}^tW)(I-{}^tW)$$

or

$$\varphi_1=\rho(I+{}^tW). \tag{3.24}$$

Now we can compute the minimal rate of dissipation (to maintain $\tilde{p}$ against the thermal detailed balance dynamics given by W),

$$|\Delta_1\mathscr{A}(R,\tilde{p},W)|=\frac{\delta^2}{2}\sum_{x,y} W_{xy}p_{\mathrm{eq}}(y)(f_{xy}^{(1)})^2=\frac{\delta^2}{2}\sum_{x,y} W_{xy}p_{\mathrm{eq}}(y)(\rho(x)-\sigma(y))^2.$$

Let us expand, using (3.23), $\sigma=\rho^tW$,

$$\sum_{x,y} W_{xy}(y)(\rho(x)-\sigma(y))^2$$

$$=\sum_{x,y} W_{xy}p_{\mathrm{eq}}(y)\rho(x)^2-2\sum_{x,yp} p_{\mathrm{eq}}(y)\rho(x)\sigma(y)+\sum_{x,y} W_{xy}p_{\mathrm{eq}}(y)\sigma(y)^2.$$

We consider the three terms above,

$$\sum_{x,y} W_{xy}p_{\mathrm{eq}}(y)\rho(x)^2=\sum_x p_{\mathrm{eq}}(x)\rho(x)^2-2\sum_{x,y} W_{xy}p_{\mathrm{eq}}(y)\rho(x)\sigma(y)$$

$$=-2\sum_y (\rho^tW)_y p_{\mathrm{eq}}(y)(\rho^tW)_y,$$

$$\sum_{x,y} W_{xy}p_{\mathrm{eq}}(y)\sigma(y)^2=\sum_y p_{\mathrm{eq}}(y)\sigma(y)^2=\sum_y p_{\mathrm{eq}}(y)((\rho^tW)_y),$$

so that

$$|\Delta_1\mathscr{A}(R,\tilde{p},W)|=\frac{\delta^2}{2}(\|\rho\|_{p_{\mathrm{eq}}}^2-\|\rho^tW\|_{p_{\mathrm{eq}}}^2). \tag{3.25}$$

5. Comparison of the rate of dissipation and the variation of S

We come back to relation (3.21), namely

$$S(\tilde{p}(\cdot,\Delta t)|p_{\mathrm{eq}})-S(\tilde{p}|p_{\mathrm{eq}})=\frac{\delta^2}{2}[\|\varphi_1\|_{p_{\mathrm{eq}}}^2-\|\varphi_1{}^tW\|_{p_{\mathrm{eq}}}^2]. \tag{3.26}$$

We see that this is similar to the relation (3.25) for the minimal rate of dissipation in the R-dynamics, except for the fact that $\varphi_1=\rho(I+{}^tW)$. [See the relation (3.24).]

We know that $\Sigma p_{\rm eq}(x)\varphi_1(x)=0$ so that φ_1 can be expanded in terms of the left eigenvectors of W with eigenvalues different from 1. Because of the (3.24), the same expansion is possible for ρ, and we therefore write

$$\rho=\sum c_n\theta_n^{(L)},$$

where $\theta_n^{(L)}$ are the left eigenvectors of W of eigenvalue less than 1.

Moreover, $\{\theta_n^{(L)}\}$ form an orthonormal basis for the equilibrium scalar product $p_{\rm eq}$ (because ${}^tW$ is self-adjoint for this scalar product due to detailed balance). It follows that

$$S(\tilde{p}(\cdot,\Delta t)|p_{\rm eq})-S(\tilde{p}(\cdot)|p_{\rm eq})=\frac{\delta^2}{2}\sum_n |c_n|^2|(1+\lambda_n)|^2(1-|\lambda_n^2|)$$

and

$$|\Delta_1\mathscr{S}(R,\tilde{p},W)|=\frac{\delta^2}{2}\sum_x |c_n|^2(1-|\lambda_n^2|).$$

Because $0\leqslant|\lambda_n|\leqslant 1$, we see that we always have

$$\tfrac{1}{4}[S(\tilde{p}(\cdot,\Delta t)|p_{\rm eq})-S(\tilde{p}(\cdot)|p_{\rm eq})]\leqslant|\Delta_1\mathscr{S}(R,\tilde{p},W)|. \tag{3.27}$$

The interpretation of this inequality is clear. If we start with the stationary state $\tilde{p}$ and switch off the R dynamics (so that $\tilde{p}$ starts to evolve by the detailed balance dynamics toward $p_{\rm eq}$), the dissipation is less than four times the cost to maintain $\tilde{p}$ using the dynamics in the larger environment (acting with W) on the system.

IV. FLUCTUATION AND DISSIPATION FOR SLOW VARIABLES

A. The macroscopic entropy

1. Fast and slow variables

Usually, a system with state space X is characterized by a small number of "slow" variables and by other "fast" variables. Such variables can be distinguished in terms of the eigenvalues of the master equation, i.e., in our case, in terms of the eigenvalues of the stochastic matrix R. Essentially, the slow variables are functions f on X, such that their set of values $\{f_x\}$ $(x\in X)$ can be decomposed on left eigenvectors of the matrix R associated with eigenvalues of R very close to 1 (but not equal to 1).

In this section, we shall assume that the system is characterized by only one slow variable $A_x(x\in X)$ taking values $a,a',\ldots$. We shall denote by u the other coordinates, so that a point x in X is identified with a couple (a,u), with $a=A(x)$.

2. Reduced description

At this point, it is customary to describe the system by the variable A alone. This is the reduced or macroscopic description, which is a coarse grained description of the full description by (a,u). We also must change the time scale, because in the time scale Δt (of the R dynamics), A does not evolve in an appreciable manner. So the relevant time scale becomes much longer, and the general idea is that, relative to this longer time scale, A varies but u readjusts itself instantaneously to its relative stationary distribution. This is the idea of all macroscopic descriptions (see Refs. 1, 6, and 7, among many references).

In our context, we can make this precise in the following way. We start as usual from a stationary state $\tilde{p}(x)$ and we define a reduced (or macroscopic) state $\tilde{P}$ by

$$\tilde{P}(x)=\sum_{\{x\in X|A(x)=a\}}\tilde{p}(x)=\sum_{u}\tilde{p}(x,u). \tag{4.1}$$

Following customary practice, we define a function $\Sigma(a)$ by the formula

$$\tilde{P}(a)=\exp(-\Sigma(a)) \tag{4.2}$$

(see, for example, Ref. 1, in the context of an equilibrium situation, and Refs. 2, 6, 10, and 24 for generalizations to nonequilibrium situations). Here $\Sigma(a)$ is a Lyapunov function for the reduced evolution of the A variable, as we shall see below.

In the case of equilibrium, $\Sigma(a)$ is the Einstein entropy. We shall assume now that the average of A in the stationary state is 0.

$$\langle A\rangle_{\tilde{p}}\equiv\sum A(x)\tilde{p}(x)=0. \tag{4.3}$$

3. Relation to the relative entropy

Let us assume that we have prepared the system in the state $\tilde{p}(x)$ (the stationary state for the R-dynamics), but that we observe in a particular sample of the system a certain fluctuation of A, so that A takes a value $a\neq 0$. Then, the probability distribution of the fast variables u, given the fact one observes the fluctuation a of A, is the conditional stationary probability distribution

$$\tilde{\pi}_a(u)=\frac{\tilde{p}(a,u)}{\tilde{P}(a)}, \tag{4.4}$$

and the quasistationary state is thus a state q_a,

$$q_a(x)\equiv\tilde{\pi}_a(u)\,\delta(A(x)-a). \tag{4.5}$$

It follows immediately that the relative entropy of q_a with respect to $\tilde{p}$, namely $S(q_a|\tilde{p})$ [see Eq. (1.1)], is in fact, $-\Sigma(a)$,

$$S(q_a|\tilde{p})=-\Sigma(a), \tag{4.6}$$

where $\Sigma(a)$ is defined as in Eq. (4.2). We calculate this as follows.

$$S(q_a|\tilde{p})=-\sum_{a}\tilde{\pi}_a(u)\,\delta(A(x)-a)\log\frac{\tilde{\pi}_a(u)}{\tilde{p}(a,u)}=-\log\frac{1}{\tilde{P}(a)}=-\Sigma(a).$$

This explains why $\Sigma(a)$ could be taken as a Lyapunov function for the evolution of a. If we wait an appropriate time, a would vary by a small quantity δa, while the fast u variables would recover their conditional stationary distribution. Our earlier assumption on time scales is precisely the assumption that such an appropriate time exists. Then the state q_a would become $q_{a+\delta a}$ by the R evolution, the variables u keeping their conditional stationary distribution. Under this circumstance,

$$S(q_{a+\delta a}|\tilde{p})-S(q_a|\tilde{p})\geq 0,$$

since $q_{a+\delta a}\approx Rq_a$ [cf. Eq. (2.4)]. This implies

$$\Sigma(a+\delta a)\leqslant\Sigma(a).$$

B. Fluctuation dissipation, in general

The usual near-equilibrium fluctuation dissipation theory is a formal consequence of the fact that a certain state p_{eq} is a stationary state of the W evolution: Writing the stationarity of the equilibrium state explicitly leads to an identity that can then be reinterpreted as a physical relation between fluctuation and dissipation (see Refs. 1, 6, 12, and 25 among many references). In the language of the previous section, if we are in a stationary state, and if we observe an actual fluctuation of A equal to a [this fluctuation has a probability $\widetilde{P}(a)$], then the dissipation induced by the reduction to 0 of this fluctuation is related in a natural way to this fluctuation (in a linear way), the proportionality coefficient being some given "transport" characteristic of the system (see Ref. 23).

We will show that it is possible to derive the fluctuation-dissipation theory in our context using the formalism of Sec. IV A. Moreover, our demonstration is not limited to near-equilibrium situations (and gives, in fact, a correction to it, as well as a finite-size effect correction).

There are various ways to derive fluctuation-dissipation theorems, each of which provides, in general, extra information, in particular about the transport or relaxation coefficients. Here we shall relate the "transport" coefficient to the eigenvalues of R. In our abstract context, we shall choose an analog of linear response theory (as presented, for example, in Ref. 25). We produce the fluctuation of the macroscopic variable A using an external force that modifies the stationary state $\widetilde{p}$.

C. Linear response theory: General computation

The general situation is as in Sec. IV A: we distinguish a variable $A(x)$ $(x\in X)$ and other variables u, so that $x=(a,u)$, where $a=A(x)$. Moreover, we have the stationary state $\widetilde{p}(x)$ with respect to the R dynamics as usual. We finally assume that A has average 0 in the stationary state [Eq. (4.3)].

1. The displaced state

We define, in analogy with the analysis of Sec. II B, a displaced state,

$$p_\alpha(x)=\frac{1}{Z_\alpha}\widetilde{p}(x)\exp(\alpha A(x)+\cdots), \tag{4.7}$$

where α is a small parameter and the ellipses represents higher-order terms in α. Then α can be viewed as a "conjugate field," αA being an extra energy (this field is imposed by an external source or observer on which the system does not react).

We have, because (by assumption) $\langle A(\,\cdot\,)\rangle_{\widetilde{p}}=0$,

$$Z_\alpha=\sum_x \widetilde{p}(x)\exp(\alpha A(x)+\cdots)=1+\frac{\alpha^2}{2}\langle A(x)^2\rangle_{\widetilde{p}}+\cdots,$$

so that one can suppress Z_α as being higher order in α, and write simply

$$p_\alpha(x)=\widetilde{p}(x)\exp(\alpha A(x)+\cdots). \tag{4.8}$$

Now, we have

$$\langle A\rangle_{p_\alpha}=\langle A\rangle_{\widetilde{p}}+\alpha\langle A^2\rangle_{\widetilde{p}}+\cdots,$$

so that for small α,

$$\langle A\rangle_{p_\alpha}=\alpha\langle A^2\rangle_{\tilde{p}}, \tag{4.9}$$

and $\langle A^2\rangle_{\tilde{p}}$ appears as usual to be the susceptibility for A.

2. Variation of the mean value

We start at time $t=0$ from the state $p_\alpha(x)$ given by (4.1). In one time step, the state becomes

$$p_\alpha(x,\Delta t)=\sum_y R_{xy}p_\alpha(y)=\sum_y R_{xy}\tilde{p}(y)\exp(\alpha A(y)),$$

and at time Δt,

$$\langle A(\Delta t)\rangle_{p_\alpha}=\sum_x A(x)p_\alpha(x,\Delta t).$$

Expanding

$$\langle A(\Delta t)\rangle_{p_\alpha}=\sum_{x,y} A(x)R_{xy}\tilde{p}(y)+\alpha\sum_{x,y} A(x)R_{xy}\tilde{p}(y)A(y)+\cdots .$$

The first term is 0 because this is $\Sigma_x A(x)\tilde{p}(x)$. Finally, we have, modulo terms of order α^2,

$$\langle A(\Delta t)-A(0)\rangle_{p_\alpha}=\alpha\sum_{x,y} A(x)(R_{xy}-\delta_{xy})A(y)\tilde{p}(y). \tag{4.10}$$

We can also eliminate α using Eq. (4.9) and get

$$\langle A(\Delta t)-A(0)\rangle_{p_\alpha}=\frac{\langle A\rangle_{p_\alpha}}{\langle A^2\rangle_{\tilde{p}}}\sum_{x,y} A(x)(R_{xy}-\delta_{xy})A(y)\tilde{p}(y). \tag{4.11}$$

3. Second moment

We now want to compute $\langle (A(\Delta t)-A(0))^2\rangle_{p_\alpha}$

(a) Computation of $\langle A(\Delta t)^2\rangle_{p_\alpha}$. This is, modulo terms in α^2,

$$\langle A(\Delta t)^2\rangle_{p_\alpha}=\sum_{x,y} A(x)^2R_{xy}\tilde{p}(y)\exp(\alpha A(y))=\langle A^2\rangle_{\tilde{p}}+\alpha\sum_{x,y} A(x)^2R_{xy}\tilde{p}(y)A(y). \tag{4.12}$$

(b) Computation of $\langle A^2\rangle_{p_\alpha}$. Again up to order α^2,

$$\langle A(0)^2\rangle_{p_\alpha}=\langle A^2\rangle_{\tilde{p}}+\alpha\langle A^3\rangle_{\tilde{p}}. \tag{4.13}$$

(c) Computation of $\langle A(\Delta t)A(0)\rangle_{p_\alpha}$

$$\begin{aligned}\langle A(\Delta t)A(0)\rangle_{p_\alpha}&=\sum_{x,y} A(x)R_{xy}A(y)\tilde{p}(y)\exp(\alpha A(y))\\&=\sum_{x,y} A(x)R_{xy}A(y)\tilde{p}(y)+\alpha\sum_{x,y} A(x)R_{xy}A(y)^2\tilde{p}(y).\end{aligned} \tag{4.14}$$

(d) Computation of $\langle (A(\Delta t)-A(0))^2\rangle_{p_\alpha}$ From Eqs. (4.12)–(4.14) we obtain, after rearrangement,

$$\langle (A(\Delta t)-A(0))^2\rangle_{p_\alpha}=-2\sum_{x,y} A(x)(R_{xy}-\delta_{xy})A(y)\tilde{p}(y)+\alpha\sum_{x,y}[A(x)^2A(y)(R_{xy}\tilde{p}(y) -R_{yx}\tilde{p}(x))-\tilde{p}(y)A(x)A(y)^2(R_{xy}-\delta_{xy})]. \tag{4.15}$$

We see that this term is again of order Δt because $R_{xy}-\delta_{xy}$ is of order Δt and because we can rewrite

$$R_{xy}\tilde{p}(y)-R_{yx}\tilde{p}(x)=(R_{xy}-\delta_{xy})\tilde{p}(y)-(R_{yx}-\delta_{yx})\tilde{p}(x).$$

D. The case of a left eigenvector of *R*

We shall now take for A a slow variable of the system, i.e., a variable that decays in one of the slowest possible modes. One way to do this is to choose for A a left eigenvector of the transfer matrix R with eigenvalue λ near 1 (but not exactly 1). (In fact, for our purposes the essential point is that the eigenvalue associated with A satisfy $1>\lambda\gg|\lambda'|$ for all other eigenvalues λ'. The closeness of λ to 1 is not used significantly.)

1. First moment

We assume for all $y\in X$, that

$$\lambda A_y=\sum_x A_x R_{xy}.$$

From Eq. (4.11) we obtain to first order in α,

$$\langle A(\Delta t)-A(0)\rangle_{p_\alpha}=\langle \dot{A}(0)\rangle_{p_\alpha}(\lambda-1). \tag{4.16}$$

2. Second moment

We obtain from Eq. (4.15),

$$\langle (A(\Delta t)-A(0))^2\rangle_{p_\alpha}=(\lambda-1)[-2\langle A^2\rangle_{\tilde{p}}-\alpha\langle A^3\rangle_{\tilde{p}}]+\alpha\sum_{x,y} A(x)^2A(y)(R_{xy}\tilde{p}(y)-R_{yx}\tilde{p}(x)). \tag{4.17}$$

3. The case of detailed balance

When R satisfies detailed balance, the second term on the right-hand side of Eq. (4.17) above vanishes identically and

$$\langle (A(\Delta t)-A(0))^2\rangle_{p_\alpha}=(1-\lambda)[-2\langle A^2\rangle_{\tilde{p}}+\alpha\langle A^3\rangle_{\tilde{p}}]. \tag{4.18}$$

Moreover, in this case, we can compute the rate of dissipation in one unit time step Δt starting from the state p_α and using the R dynamics. This is

$$S(p_\alpha(\cdot,\Delta t)|\tilde{p})-S(p_\alpha|\tilde{p})=\frac{\alpha^2}{2}\langle A^2\rangle_{\tilde{p}}(1-\lambda)(1+\lambda). \tag{4.19}$$

We saw the same result in Sec. II. To see the correspondence, take $\varphi_1=A$ and notice that $M=M^*={}^tR$, so that the μ eigenvalue of MM^* corresponding to $\varphi_1=A$ is $\mu=\lambda^2$.

4. Fluctuation dissipation

We return to the general (non-detailed-balance) case. If A is decaying slowly, $\lambda \approx 1$, and

$$S(p_\alpha(\cdot,\Delta t)|\bar{p}) - S(p_\alpha|\bar{p}) \sim \langle A^2\rangle_{\bar{p}}(1-\lambda). \tag{4.20}$$

Moreover, let us compare Eqs. (4.16) and (4.17) and let us assume that $\alpha\langle A^3\rangle_{\bar{p}} \approx 0$. Then eliminating $\lambda - 1$ from both equations, we obtain

$$\langle (A(\Delta t) - A(0))^2\rangle_{p_\alpha} = 2\langle A^2\rangle_{\bar{p}} \left| \frac{\langle A(\Delta t) - A(0)\rangle_{p_\alpha}}{\langle A(0)\rangle_{p_\alpha}} \right|. \tag{4.21}$$

This relation is, in our context, the analog of the standard fluctuation-dissipation theorem.

Example: The prototype of fluctuation-dissipation theory is obtained for a Langevin particle (of mass $m=1$) with the equation of motion

$$dx = v\ dt, \quad dv = -fv\ dt + dB(t),$$

where $dB(t)$ is the white noise force,

$$\langle dB(t)dB(s)\rangle = 2D\,\delta(t-s).$$

In the sense of our development, the "fast variables" are the sources of the noise. The variables x and v are "macroscopic" and "slow." The Fokker Planck equation is

$$L = \frac{\partial}{\partial v}\left(D\,\frac{\partial}{\partial v} + fv \right) - v\,\frac{\partial}{\partial x}.$$

This corresponds to a reduced operator (projected onto the slow variables) description of $I-R$ for the discrete time case. The space X consists of the configuration space (x,v) of the Langevin particle as well as the degrees of freedom that give rise to the white noise (that the Fokker–Planck equation absorbs into the diffusion coefficient). Take for A the function v. Then

$$L^* v = \left(D\,\frac{\partial^2}{\partial v^2} - fv\,\frac{\partial}{\partial v} + v\,\frac{\partial}{\partial x} \right) v = -fv,$$

and v is an eigenfunction of L^* with eigenvalue $-f$ (but not necessarily of the full operator that includes the sources of the noise). Now let us consider, instead of a state p_α, a state $\delta(v-v_0)$. Then

$$\langle v(\Delta t) - v_0\rangle_{\delta(v-v_0)} = \int (v-v_0)p(\Delta t, v|v_0)dv.$$

But

$$\begin{aligned} \lim_{\Delta t\to 0} \frac{\partial}{\partial \Delta t}\langle v(\Delta t) - v_0\rangle_{\delta(v-v_0)} &= \lim_{\Delta t\to 0} \int (v-v_0)L_v p(\Delta t, v|v_0)dv \\ &= \int L_v^*(v-v_0)\,\delta(v-v_0)dv \\ &= -fv_0. \end{aligned}$$

In the same way,

$$\lim_{\Delta t\to 0}\frac{\partial}{\partial \Delta t}\langle (v(\Delta t)-v(0))^2\rangle_{\delta(v-v_0)}=\int L_v^*(v-v_0)^2\delta(v-v_0)dv_0=2D.$$

Then our statement of the fluctuation-dissipation theorem [Eq. (4.21)] becomes

$$\lim_{\Delta t\to 0}\frac{\partial}{\partial \Delta t}\langle (v(\Delta t)-v(0))^2\rangle_{\delta(v-v_0)}$$

$$=2\langle v^2\rangle_{p_{\rm eq}}\left|\lim_{\Delta t\to 0} v\left(\frac{(\partial/\partial\Delta t)\langle v(\Delta t)-v_0\rangle_{\delta(v-v_0)}}{\langle v\rangle_{\delta(v-v_0)}}\right)\right|,$$

or

$$2D=2k_{\rm B}Tf,$$

which is the usual Einstein relation for $m=1$. So the relation (4.21) is the generalization of the standard fluctuation-dissipation theory in our context.

Remark: For initial conditions far from the stationary state, dissipation may be dominated by the friction coefficients, "f," irrespective of the fluctuations. As such, this way of calculating heat production, etc., will not involve the fluctuations. However, the validity of these mean field calculations (and use of f to derive heat production) does not contradict the fluctuation-dissipation theorem because it is a far from stationary-state situation.

5. The general case

In fact, Eqs. (4.16) and (4.17), even in the detailed balance case, are more precise than the fluctuation-dissipation theorem, because the fluctuation-dissipation theorem (in its usual statement) is the relation (4.21), relating these two quantities. In our case, we have separately derived each of the moments $\langle A(\Delta t)-A(0)\rangle_{p_\alpha}$ (the dissipation) and $\langle (A(\Delta t)-A(0))^2\rangle_{p_\alpha}$ (the fluctuation) *separately*, and related them to the spectrum of the transfer matrix.

Equation (4.16) [for $\langle A(\Delta t)-A(0)\rangle_{p_\alpha}$] is straightforward.

Equation (4.17) [for $\langle (A(\Delta t)-A(0))\rangle_{p_\alpha}$)] contains a correction Γ of cubic order in A and first order in α,

$$\Gamma\equiv\alpha\sum_{x,y}A(x)^2A(y)(R_{xy}\tilde{p}(y)-R_{yx}\tilde{p}(x)).$$

Notice, also, that if we are away from criticality, both Γ and $\langle A^3\rangle_{\tilde{p}}$ would be close to 0.

E. Summary

In a sense, the standard fluctuation-dissipation theorem is a tautology; namely, the assertion that the stationary state is a solution of the stationary equation (see Ref. 12). In our situation, we say more because we compute separately the fluctuation *and* the dissipation in terms of the spectrum of the transfer matrix and then deduce the relation between the fluctuation and dissipation by eliminating the eigenvalue of the transfer matrix. Still, at our level of abstraction, all these identities can only be tautological. (The physics enters in judging the suitability of the stochastic description and the time scale separation.)

We now summarize our results concerning the fluctuation-dissipation theorem. Let A be a slow variable of the system, so $AR=\lambda R$ for a λ close to 1; it follows that $\langle A\rangle_{\tilde{p}}=0$. Let

$$p_\alpha(x)=\tilde{p}(x)\exp(\alpha A(x)+O(\alpha^2)), \tag{4.22}$$

be a neighboring state of the stationary state $\tilde{p}$, so that

$$\langle A\rangle_{p_\alpha}=\alpha\langle A^2\rangle_{\tilde{p}}+O(\alpha^2). \tag{4.23}$$

Then we have the two relations [see Eqs. (4.16) and (4.17)]:
dissipation,

$$\langle A(\Delta t)-A(0)\rangle_{p_\alpha}=\langle A\rangle_{p_\alpha}(\lambda-1); \tag{4.24}$$

fluctuation,

$$\langle (A(\Delta t)-A(0))^2\rangle_{p_\alpha}=-2(\lambda-1)\langle A^2\rangle_{\tilde{p}}+O(\alpha A^3). \tag{4.25}$$

We thus obtain
fluctuation dissipation:

$$\langle (A(\Delta t)-A(0))^2\rangle_{p_\alpha}=\frac{2\langle A^2\rangle_{\tilde{p}}}{\langle A\rangle_{p_\alpha}}\langle A(\Delta t)-A(0)\rangle_{p_\alpha}. \tag{4.26}$$

In this form we have a statement relating changes in a variable as it returns to the steady state ("dissipation") to its spontaneous fluctuations in that steady state. The term "dissipation," suggesting energy flow, may not apply in all applications of this theorem. There will nonetheless be inequalities relating this "dissipation" to changes in the relative entropy that we have defined.

Another (inequivalent) statement is that if

$$p(x)=\tilde{p}(x)\exp(\delta\varphi_1(x)+\cdots),$$

then

$$S(p(\cdot,\Delta t)|\tilde{p})-S(p|\tilde{p})\geqslant\tfrac{1}{2}\langle\delta^2\varphi_1^2\rangle_{\tilde{p}}(1-\mu_{\max}), \tag{4.27}$$

where $\mu_{\max}$ is the maximal (non-1) eigenvalue of the matrix ${}^tR(1/\tilde{p})\,R$ diag $(\tilde{p})$ [see Eqs. (1.11)–(1.12)].

F. Generalization to the case of *n* slow variables

1. Entropy

Let us now assume that one can find n slow variables $A_1,\ldots,A_n$ for the R dynamics. Take these such that

$$\langle A_j\rangle_{\tilde{p}}=0, \quad \text{for all } j.$$

For given values $a_1,\ldots,a_n$, we define

$$\tilde{P}(a_1,\ldots,a_n)=\sum_{\{x\in X|A_j(x)=a_j \text{ for all } j\}}\tilde{p}(x),$$

and we define a function

$$\Sigma(a_1,\ldots,a_n)=-\log\tilde{P}(a_1,\ldots,a_n).$$

As before (Sec. IV A), we have

$$\Sigma(a_1,\ldots,a_n)=-S(q_a|\tilde{p}),$$

where

$$q_a(x)=\frac{\tilde{p}(a,u)}{\tilde{P}(a)}\prod_j \delta(A_j(x)-a_j),$$

and Σ will be a Lyapunov function for the evolution of $a_1,...,a_n$.

2. General linear response theory

We generalize the results of Secs. IV C and IV D. Call $\alpha\equiv(\alpha_1,...,\alpha_n)$, where α_j is a conjugate variable for A_j and define as in Sec. IV C,

$$p_\alpha(x)=\frac{1}{Z_\alpha}\tilde{p}(x)\exp\left(\sum_{i=1}^{n}\alpha_i A_i+O(\alpha^2)\right).$$

It is immediate that

$$\langle A_i\rangle_{p_\alpha}=\sum_{j=1}^{n}\alpha_j\langle A_iA_j\rangle_{\tilde{p}}+O(\alpha^2).$$

One also proves

$$\langle A_i(\Delta t)-A_i(0)\rangle_{p_\alpha}=\sum_{j=1}^{n}\alpha_j\sum_{x,y}A_i(x)(R_{xy}-\delta_{xy})\tilde{p}(y)A_j(y)+O(\alpha^2)$$

and

$$\begin{aligned}\langle (A_i(\Delta t)-A_i(0))(A_j(\Delta t)-A_j(0))\rangle_{p_\alpha}&\\ =-\sum_{x,y}A_i(x)((R_{xy}-\delta_{xy})\tilde{p}(y)+(R_{yx}-\delta_{yx})\tilde{p}(x))A_j(y)+\sum_{k=1}^{n}\alpha_k\sum_{x,y}[-\tfrac{1}{2}A_i(x)((R_{xy}&\\ -\delta_{xy})\tilde{p}(y)A_k(y)+(R_{yx}-\delta_{yx})\tilde{p}(x)A_k(x))A_j(y)+\tfrac{1}{2}A_i(x)(A_j(x)R_{xy}\tilde{p}(y)A_k(y)&\\ -A_j(y)R_{yx}\tilde{p}(x)A_k(x))+\tfrac{1}{2}A_j(x)(A_i(x)R_{xy}\tilde{p}(y)A_k(y)-A_i(y)R_{yx}\tilde{p}(x)A_k(x))]+O(\alpha^2).&\end{aligned}$$

3. Choice of A_i as eigenvectors

We now choose the A_i to be left eigenvectors of R,

$$\sum A_i(x)R_{xy}=\lambda_iA_i(y).$$

Then, modulo $O(\alpha^2)$,

$$\langle A_i(\Delta t)-A_i(0)\rangle_{p_\alpha}=(\lambda_i-1)\sum_k\alpha_k\langle A_iA_k\rangle_{\tilde{p}}=(\lambda_i-1)\langle A_i(0)\rangle_{p_\alpha},$$

and modulo $O(\alpha A^3)$ terms,

$$\langle (A_i(\Delta t)-A_i(0))(A_j(\Delta t)-A_j(0))\rangle_{p_\alpha}=-\langle A_iA_j\rangle_{\tilde{p}}(\lambda_i+\lambda_j-2).$$

We can eliminate the eigenvalues $\lambda_i - 1$ and obtain modulo $O(\alpha A^3)$ terms,

$$\langle (A_i(\Delta t) - A_i(0))(A_j(\Delta t) - A_j(0)) \rangle_{p_\alpha}$$
$$= -\langle A_i A_j \rangle_{\tilde{p}} \left(\frac{\langle A_i(\Delta t) - A_i(0) \rangle_{p_\alpha}}{\langle A_i(0) \rangle_{p_\alpha}} + \frac{\langle A_j(\Delta t) - A_j(0) \rangle_{p_\alpha}}{\langle A_j(0) \rangle_{p_\alpha}} \right),$$

which is the fluctuation-dissipation statement in our general context.

Remark: If $(R, \tilde{p})$ satisfies detailed balance, $\tilde{p}$ vanishes nowhere and A is a left eigenvector of R with eigenvalue λ, then $\tilde{p}(x)A(x)$ is a right eigenvector of R with eigenvalue λ. When applied to the above equations and use is made of the orthogonality of the left and right eigenvectors of R, this implies a diagonal susceptibility matrix. In effect this says that choosing left eigenvectors of R as the slow variables chooses the macroscopic variables to be in a form diagonalizing the susceptibility.

G. Onsager reciprocity relations for nonequilibrium states

We consider a stationary state $\tilde{p}$ for a stochastic matrix R, and we consider the observables $A_1, \ldots, A_n$ with

$$\langle A_i \rangle_{\tilde{p}} = 0.$$

As usual, we define $p_\alpha = \tilde{p} \exp(\Sigma \alpha_i A_i + \cdots)$, and it follows that

$$\langle A_i \rangle_{\tilde{p}} = \sum_j \langle A_i A_j \rangle_{\tilde{p}} \alpha_j \tag{4.28}$$

(up to powers of α^2). We have seen that the relative entropy is

$$S(p_\alpha | \tilde{p}) = -\sum_{k,l} \langle A_k A_l \rangle_p^{-1} \langle A_k \rangle_{p_\alpha} \langle A_l \rangle_{p_\alpha}, \tag{4.29}$$

so that the corresponding forces F_k are given by

$$F_k \equiv -\frac{\partial S(p_\alpha | \tilde{p})}{\partial \langle A_k \rangle_{p_\alpha}} = \sum_l \langle A_k A_l \rangle_p^{-1} \langle A_l \rangle_{p_\alpha} = \alpha_k. \tag{4.30}$$

Moreover, the current (in one time step Δt) for A_k is given by

$$J_k \equiv \langle A_k(\Delta t) - A_k(0) \rangle_{p_\alpha} = \sum_j \alpha_j \sum_{xy} A_k(x)(R_{xy} - \delta_{xy}) \tilde{p}(y) A_j(y). \tag{4.31}$$

We can then write

$$J_k = \sum_j L_{kj} \alpha_j = \sum_j L_{kj} F_j, \tag{4.32}$$

where

$$L_{kj} = \sum_{xy} A_k(x)(R_{xy} - \delta_{xy}) \tilde{p}(y) A_j(y). \tag{4.33}$$

In general, the matrix L_{kj} is not symmetric. However, when $(R,\tilde{p})$ satisfies detailed balance, $R_{xy}\tilde{p}(y)=R_{yx}\tilde{p}(x)$, one can immediately see that $L_{kj}=L_{jk}$. Thus, an *absence* of detailed balance in R is manifested at the macroscopic level.

V. A PATH SUMMATION FORMULA FOR THE STATIONARY STATE

A. Expression of the stationary state in term of determinants

We consider a general $N\times N$ matrix A. Let us suppose that λ_0 is a nondegenerate eigenvalue of A and consider the right eigenvector u and the left eigenvector v of A of eigenvalue λ_0, so that

$$Au=\lambda_0 u, \quad vA=\lambda_0 v.$$

We normalize u,v so that

$$\sum_{i=1}^{N} u_i v_i=1. \tag{5.1}$$

Moreover, call $M(\lambda)_{ij}$ the minor of the element (i,j) in the matrix $\lambda I-A$ and $C(\lambda)$ the characteristic polynomial of A. Then one has the following identity:

$$u_i v_j=\frac{(-1)^{i+j}M_{ji}(\lambda_0)}{dC(\lambda_0)/d\lambda}. \tag{5.2}$$

This identity is derived in Appendix A, but can also be found in Ref. 26.

We apply this formula to a stochastic matrix R and to its eigenvalue 1, which we assume nondegenerate. The right eigenvector is the stationary state $\tilde{p}_j$ and the left eigenvector is $v_i=1$ for all i. The normalization condition of Eq. (5.1) is the normalization of the stationary state. Then Eq. (5.2) reduces to

$$\tilde{p}_i=\frac{(-1)^{i+j}M_{ji}(1)}{dC(1)/d\lambda}. \tag{5.3}$$

In particular, it is convenient to set $i=j$ and arrive at

$$\tilde{p}_i=\frac{M_{ii}(1)}{dC(1)/d\lambda}.$$

Using the normalization condition, we deduce the following identity:

$$\frac{dC(1)}{d\lambda}=\sum_{i=1}^{N} M_{ii}(1) \tag{5.4}$$

(this is a kind of partition function formula) and

$$\tilde{p}_i=\frac{M_{ii}(1)}{\Sigma_{j=1}^{N}M_{jj}(1)}. \tag{5.5}$$

B. Tree summation formula for the stationary state

We shall now state and derive a "tree integral" formula for the stationary state from Eq. (5.5). This result has been independently discovered on several occasions (including by us); we will

include our derivation, since the result is not known in the physics literature and is of interest for our statistical mechanics application. See Refs. 27–29, which may also be consulted for some of our tree-theory terminology.

We consider a stochastic matrix R of size N. Consider also the set of states $\{1,\ldots,N\}$ and among these points, we mark one point, say j_0, which we call the root. We can define a spanning tree of root j_0 as an oriented tree of root j_0 (the orientation going from the leaves to the root), such that any state $1 \leqslant k \leqslant N$ is a vertex of the tree.

We call T_j such a tree. Now, any edge (k,l) of T_j such that (k,l) is oriented from k to l is labeled by R_{lk}. The weight of the tree T_j is defined by

$$W(T_j)=\prod_{(k,l)\in T_j} R_{lk}. \tag{5.6}$$

We have the following result:
The minor M_{ij} of $-1+R_{jj}$ in $-I+R$ (for an $N\times N$ stochastic matrix R) is given by

$$M_{jj}=(-1)^{N-1}\sum_{T_j} W(T_j), \tag{5.7}$$

where the sum is taken over all spanning trees T_j with root j, as defined above. We shall prove this result in Sec. V D, but we can immediately make a number of comments: (i) Apart from the overall $(-1)^{N-1}$, M_{jj} is given by a sum of positive terms. (ii) M_{jj} is homogeneous of degree $N-1$ with respect to the $\{R_{kl}\}$ (for $k\neq l$). (iii) In a given term, $W(T_j)$, for a fixed T_j, a given R_{kl} does not appear twice. Moreover, one cannot have within a particular $W(T_j)$ a product of the type $R_{ik}R_{lk}$, but one can have terms like $R_{ki}R_{kl}$. Finally, one cannot have closed loops like $R_{i_1i_2}R_{i_2i_1}$.

The proofs of these statements are a direct consequence of the definition of a tree and of the weight W associated with it.

(i) Is obvious.

(ii) Is a consequence of the fact that a spanning tree for a set of N points has $N-1$ edges.

(iii) It is obvious that a given R_{kl} appears at most once in a $W(T_j)$. Moreover, since $W(T_j)$ is constructed by taking the product of the R_{lk}, starting from the leaves and following the edges up to the root j, it is clear that one cannot have a term $R_{ik}R_{lk}$ (this would mean that the vertex k has two fathers in the tree), but one can have $R_{ni}R_{nl}$ (when i and l are sons of the same father n).

Finally, we see that Eq. (5.5) has a natural meaning when we use the calculation of M_{jj} given in Eq. (5.7). The stationary probability of the state j is obtained by summing over all oriented paths leading from various points of the state space to the point j, quantities that are, for each path, the product of the elements R_{nl} that one encounters along the oriented path. Moreover, these paths may have several irreducible components leading to j, and they contain no loop. This is why such an oriented reducible path leading to j, is, in fact, a tree with root j.

C. The case of detailed balance

Detailed balance means that for all i,j,

$$\frac{R_{ij}}{R_{ji}}=\frac{\tilde{p}_i}{\tilde{p}_j}. \tag{5.8}$$

In particular, this implies that for any closed cycle $c=(x_1,x_2,x_3,\ldots,x_k,x_1)$ we have

$$\frac{R_{x_1x_k}R_{x_kx_{k-1}}\cdots R_{x_2x_1}}{R_{x_1x_2}R_{x_2x_3}\cdots R_{x_kx_1}}=1, \tag{5.9}$$

or with obvious notation,

$$\frac{\Pi_C R}{\Pi_{C^{-1}}R}=1,$$

where C^{-1} denotes the reverse cycle. On the other hand, we have proved above

$$\frac{\tilde{p}_i}{\tilde{p}_j}=\frac{M_{ii}}{M_{jj}},$$

in the general case.

Let us now assume that Eq. (5.9) holds for any closed cycle and prove that detailed balance holds. To fix everything, take $i=1$, $j=2$ and consider a tree of the type T_1. In this tree, there is a certain (unique) oriented path $\gamma(T_1)$ leading from 2 to 1, and this path has a certain length, $|\gamma(T_1)|$. Then

$$W(T_1)=\left[\prod_{\gamma(T_1)} R\right]W(T_1|\gamma(T_1)),$$

where $W(T_1|\gamma(T_1))$ is the product of all the elements of R along the edges of T_1 that are not on $\gamma(T_1)$.

Now, the edges of T_1 that are not on $\gamma(T_1)$ form a collection of $N-1-|\gamma(T_1)|$ edges [because $W(T_1)$ has $N-1$ edges, as we have seen]. These edges form a disjoint union of oriented trees with roots on the path $\gamma(T_1)$ and with their other vertices outside $\gamma(T_1)$ (this union of disjoint trees is a "forest").

Conversely, given a directed path γ leading from 2 to 1, and a forest F of trees having their roots in γ and their other vertices outside γ and with a total number of edges $N-1-|\gamma|$, the union of γ and F is a spanning oriented tree with root 1. This means that one can write

$$M_{11}=\sum_{\gamma \text{ from 2 to 1}}\left(\prod_{\gamma} R\right)\Phi(\gamma), \tag{5.10}$$

where $\Phi(\gamma)$ is defined to be

$$\Phi(\gamma)=\sum_{F} W(F), \tag{5.11}$$

where the sum is taken over all the oriented forests F having $N-1-|\gamma|$ edges, their roots on γ, and their other vertices outside γ, and $W(F)$ is the product of the R on all edges of F. In the same way,

$$M_{22}=\sum_{\gamma' \text{ leading from 1 to 2}}\left(\prod_{\gamma'} R\right)\Phi(\gamma'). \tag{5.12}$$

Now, for any path from 2 to 1, γ, one can find the inverse path γ^{-1} from 1 to 2 so that Eq. (5.12) can be rewritten,

$$M_{22}=\sum_{\gamma \text{ leading from 2 to 1}}\left(\prod_{\gamma^{-1}} R\right)\Phi(\gamma^{-1}).$$

But it is clear that

$$\Phi(\gamma)=\Phi(\gamma^{-1}),$$

and moreover, because of Eq. (5.9),

$$\frac{\Pi_\gamma R}{\Pi_{\gamma^{-1}} R}=\frac{R_{12}}{R_{21}},$$

so that

$$M_{11}=M_{22}\frac{R_{12}}{R_{21}},$$

from which we deduce Eq. (5.8).

D. Proof of Eq. (5.7)

We shall prove something slightly more general. In the following, Latin indices run from 1 to N and Greek indices run from $\underline{1}$ to $\underline{p}$. We consider $b_{\alpha i}$ and a_{ij} $(i\neq j)$ to be positive numbers. (For emphasis, numerical values taken by Greek indices are underlined. We make this distinction because at a later stage we will need to deal with switches between one sort of index and the other.)

We define the following determinant:

$$D_N(b,a)=\det\begin{vmatrix} -\sum_{\alpha=1}^{p} b_{\alpha 1}-\sum_{i=2}^{N} a_{i1} & a_{12} & \cdots & a_{1N} \\ a_{21} & -\sum_{\alpha=1}^{p} b_{\alpha 2}-\sum_{\substack{i=1\\ i\neq 2}}^{N} a_{i2} & \cdots & a_{2N} \\ \vdots & & \vdots & \vdots \\ \vdots & & \vdots & \vdots \\ a_{N1} & a_{N2} & \cdots & -\sum_{\alpha=1}^{p} b_{\alpha N}-\sum_{i\neq N} a_{iN} \end{vmatrix}.$$

It is obvious that if all bs are zero, this determinant is zero because the sum of all lines is zero.

Moreover, $D_N(b,a)$ is a homogeneous function of degree N of the bs and the as. We now consider the set $\{\underline{1},...,\underline{p}\}\cup\{1,...,N\}$, and for each α we consider an oriented tree T_α with root α and with other vertices in $\{1,...,N\}$. To any oriented edge (k,l) or (n,α) of T_α, we associate the label a_{lk} or $b_{\alpha n}$. We define

$$W(T_\alpha)=\left(\prod_{(k,l)\in T_\alpha} a_{lk}\right)\left(\prod_{(n,\alpha)\in T_\alpha} b_{\alpha n}\right). \tag{5.14}$$

We call a spanning forest a union of disjoint trees $\{T_\alpha\}$ for $\alpha=\underline{1},...,\underline{p}$ as before, such that all other vertices $1\leq i\leq N$ belong to a tree T_α of the forest (and then to a unique one),

$$W(F)=\prod_{F=\{T_\alpha\}} W(T_\alpha), \tag{5.15}$$

with the convention that, if T_α contains no edge, $W(T_\alpha)=1$. In particular, a spanning forest has N edges.

The main result of this section is that

$$D_N(b,a)=(-1)^N\sum_F W(F), \tag{5.16}$$

where the sum is taken on all spanning forests, as defined before. The proof of this statement is by induction on N.

First, for $N=2$ we have

$$D_2(b,a)=\det\begin{vmatrix} -\sum_{\alpha=\underline{1}}^{p} b_{\alpha 1}-a_{21} & a_{12} \\ a_{21} & -\sum_{\alpha=\underline{1}}^{p} b_{\alpha 2}-a_{12} \end{vmatrix} = \sum_{\alpha,\beta=\underline{1}}^{p} b_{\alpha 1}b_{\beta 2}+\sum_{\alpha=\underline{1}}^{p} b_{a1}a_{12}+\sum_{\alpha=\underline{1}}^{p} b_{\alpha 2}a_{21},$$

which obviously has the structure of Eq. (5.16).

We now assume that the statement is true for all determinants of size less than N, and we consider D_N as defined by Eq. (5.13). It is clear that D_N is symmetric by permutation of the Latin indices. As we have seen, it is a polynomial in the $b_{\alpha j}$ of degree $\leqslant N$ without a constant term [because $D_N(0,a)=0$]. Moreover, it is clear that in a given monomial, one cannot have products $b_{\alpha j}b_{\beta j}$, $a_{ik}a_{jk}$, because they correspond to terms in the same column of $D_N(b,a)$.

By symmetry, we can consider only the terms containing $b_{\underline{1}1}$ as a factor. Such a term is obviously

$$-b_{\underline{1}1}\det\begin{vmatrix} -\sum_{\alpha=\underline{1}}^{p} b_{\alpha 2}-\sum_{\substack{i=1\\ i\neq 2}}^{N} a_{i2} & a_{23} & \cdots & a_{2N} \\ a_{32} & -\sum_{\alpha=\underline{1}}^{p} b_{\alpha 3}-\sum_{\substack{i=1\\ i\neq 3}}^{N} a_{i3} & \cdots & a_{3N} \\ \vdots & & \vdots & \vdots \\ \vdots & & \vdots & \vdots \\ a_{N2} & a_{N3} & \cdots & -\sum_{\alpha=\underline{1}}^{p} b_{\alpha N}-\sum_{i\neq N} a_{iN} \end{vmatrix}.$$

But the determinant multiplying $-b_{\underline{1}1}$ is a determinant of the type $D_{N-1}(b',a')$, where now the new greek indices vary in the new set:

$$\{\underline{1},\ldots,\underline{p},\underline{p+1}\}\equiv\{\underline{1},\ldots,\underline{p},1\}$$

(i.e., $\underline{p+1}$ is the old latin index 1), and the set $\{1,\ldots,N\}$ has been replaced by $\{2,\ldots,N\}$ and with the identifications

$$b'_{\alpha i}=b_{\alpha i},\quad \underline{1}\leqslant\alpha\leqslant\underline{p},\quad 2\leqslant i\leqslant N,$$

$$b'_{\underline{p+1},i}=a_{1,i},\quad 2\leqslant i\leqslant N,$$

$$a'_{ij}=a_{ij},\quad 2\leqslant i\neq j\leqslant N.$$

But now, $D_{N-1}(b',a')$ is a sum over all spanning forests F' (with $N-1$ edges) of the weight of these forests. Each forest F' is a union of trees $\{T'_\alpha\}$ with roots in $\{\underline{1},...,\underline{p},1\}$ and with other vertices in $\{2,...,N\}$ and

$$W(F')=\left[\prod_{\alpha=\underline{1}}^{\underline{p}} W(T'_\alpha)\right]W(T'_1).$$

It may happen that some trees have no edge. Then we rewrite

$$b_{\underline{1}1}W(F')=(b_{\underline{1}1}W(T'_1)W(T'_{\underline{1}}))\prod_{\alpha=\underline{2}}^{\underline{p}} W(T'_\alpha).$$

But this is exactly

$$b_{\underline{1}1}W(F')=\prod_{\alpha=\underline{1}}^{\underline{p}} W(T_\alpha),$$

with

$$\begin{aligned} T_\alpha &= T'_\alpha, \quad \text{for } \alpha=\underline{2},...,\underline{p}, \\ T_{\underline{1}} &= T'_{\underline{1}}\cup((1\underline{1})\cup T'_1), \end{aligned} \tag{5.17}$$

where $((\underline{1}1)\cup T_1)$ denotes a tree having as the root the point $\underline{1}$ and obtained by taking the edge $(1\underline{1})$ from 1 to $\underline{1}$ and attaching to it the tree T'_1 of root 1 (if it has some edge). Then

$$b_{\underline{1}1}W(F')=W(F),$$

where

$$F=\{T_{\underline{1}},T_{\underline{2}},...,T_{\underline{p}}\}.$$

Conversely, any spanning forest F that contains the oriented edge, $(1\underline{1})$, is obviously a union of disjoint trees $T_{\underline{1}},...,T_{\underline{p}}$ with $T_{\underline{1}}$ given as in Eq. (5.17), namely

$$T_{\underline{1}}=T'_{\underline{1}}\cup((1\underline{1})\cup T'_1),$$

with $T'_{\underline{1}}$ having its root in $\underline{1}$ and vertices in $\{2,...,N\}$ and T'_1 having its root in 1 and its vertices in $\{2,...,N\}$.

Thus, in $D_N(b,a)$ the terms containing $b_{\underline{1}1}$ are of the type $(-1)^N\Sigma_{1\underline{1}\in F}W(F)$. This proves Eq. (5.16).

Proof of Eq. (5.7) for M_{jj}: Eq. (5.7) is a particular case of Eq. (5.16). In this case, $p=1=j$, the $N-2$ indices $l\neq j$ correspond to the Latin indices, and the Greek index α can take only the value j. Finally $b_{\alpha l}=a_{jl}$ and for $l,k\neq j$, $a_{lk}=R_{lk}$.

In this case a spanning forest for $\{\underline{1}\}\cup\{1,...,N-2\}$ having its root at j and other indices at points $k\neq j$ is exactly a spanning tree with root at j.

APPENDIX: MATRIX FORMULAS

In this appendix, we derive the formulas of Sec. V A. We consider a matrix A and an eigenvalue λ_j of A. Call $\lambda_1,...,\lambda_p$ the other distinct eigenvalues. Then the matrix A can be decomposed in the Jordan normal form and we call E_{λ_j} the subspace associated with the eigenvalue λ_j in this decomposition. We call P_{λ_j} the projector on E_{λ_j} defined by

$$P_{\lambda_j}|_{E_{\lambda_j}}=I,$$
$$P_{\lambda_j}|_{E_{\lambda_l}}=0, \quad j\neq l. \tag{A1}$$

Take a contour γ_j in the complex plane surrounding λ_j once, but no λ_l for $l\neq j$. Then

$$P_{\lambda_j}=\frac{1}{2i\pi}\int_{\gamma_j}(z-A)^{-1}\,dz. \tag{A2}$$

Formula (A2) is obvious: take a vector u in the space E_{λ_l} for $l\neq j$. Then $(z-A)^{-1}u$ is holomorphic in a neighborhood of λ_j and

$$\int_{\gamma_j}(z-A)^{-1}u\,dz=0.$$

Now, if u is in the space E_{λ_j}, we can write on E_{λ_j},

$$A|_{E_{\lambda_j}}=(\text{diag}\,\lambda_j)+T,$$

where T is an upper triangular matrix. Then

$$(z-A)^{-1}|_{E_{\lambda_j}}=\text{diag}(z-\lambda_j)^{-1}+T',$$

where T' is another upper triangular matrix (depending holomorphically on z in a neighborhood of λ_j). Then

$$\frac{1}{2i\pi}\int_{\gamma_j}(z-A)^{-1}u\,dz=u,$$

so that the Cauchy integral on the right-hand side of (A2) is given exactly by (A1). In particular, since $(z-A)^{-1}_{nl}=(-1)^{n+l}[M_{ln}(z)/C(z)]$, we have, from (A2),

$$(P_{\lambda_j})_{nl}=(-1)^{n+l}\,\text{Residue}_{\lambda_j}\left(\frac{M_{ln}(z)}{C(z)}\right).$$

If λ_j is a simple eigenvalue, then E_{λ_j} is generated by the right eigenvector u and the projector is simply given by

$$(P_{\lambda_j})_{nl}=u_n^* v_l,$$

with the normalization condition of Eq. (5.1).

In the case of a stochastic matrix R, if we take, say M_{11}, it is easy to see that $M_{11}=(-1)^{l+1}M_{l1}$ directly (write down M_{11} explicitly, then replace row number l by the sum of all rows of M_{11} and use the stochastic property $\Sigma_{l=1}^{N}R_{ln}=1$). In general,

$$M_{nn}=(-1)^{n+l}M_{ln}.$$

But because $\det(I-R)=0$, we have

$$\sum_{j=1}^{N}(\delta_{lj}-R_{lj})(-1)^{j}M_{lj}=0, \quad l=1,\ldots,N,$$

which implies that the vector with components M_{jj} is an eigenvector of eigenvalue 1 of R.

Scattering matrix in external field problems

Edwin Langmann and Jouko Mickelsson
Theoretical Physics, Royal Institute of Technology, S-100 44 Stockholm, Sweden

(Received 3 January 1996; accepted for publication 28 March 1996)

We discuss several aspects of second quantized scattering operators $\hat{S}$ for fermions in external time-dependent fields. We derive our results on a general, abstract level having in mind as a main application potentials of the Yang-Mills type and in various dimensions. We present a new and powerful method for proving the existence of $\hat{S}$ which is also applicable to other situations like external gravitational fields. We also give two complementary derivations of the change of phase of the scattering matrix under generalized gauge transformations which can be used whenever our method of proving the existence of $\hat{S}$ applies. The first is based on a causality argument, i.e., $\hat{S}$ (including phase) is determined from a time evolution, and the second exploits the geometry of certain infinite-dimensional group extensions associated with the second quantization of one-particle operators. As a special case we obtain a Hamiltonian derivation of the axial fermion-Yang-Mills anomaly and the Schwinger terms related to it via the descent equations, which is on the same footing and traces them back to a common root. © *1996 American Institute of Physics.* [S0022-2488(96)03107-6]

I. INTRODUCTION

The main difficulty when quantizing fermions in higher than two space-time dimensions in background (gauge) fields is that the interaction term generically is too large to allow a naive application of the standard methods of canonical quantization. More precisely, if ϵ is the sign of the "free" Hamiltonian, then only those one-particle operators A are well-defined in the free Fock space which satisfy the condition that $[\epsilon, A]$ is of Hilbert-Schmidt type. For example, the minimal gauge interaction operator does not satisfy this condition when the space-time dimension is higher than 2. The same holds for gauge transformation operators which makes the implementation of these operators somewhat tricky.[1]

The one-particle time evolution operator can be constructed for example by the Dyson expansion provided that the potential is smooth and appropriate boundary conditions are satisfied. However, the time evolution cannot be quantized because of the remarks above. The asymptotic scattering operator S is better behaving. One can show that it satisfies the Hilbert-Schmidt condition. The existing proofs are rather involved.[2,3] In this article we give a conceptually simpler proof using the methods introduced earlier for the construction of the quantum gauge transformations and computation of commutator anomalies.[1] The method is based on the observation that the interaction Hamiltonians can be conjugated by unitary operators such that the resulting equivalent Hamiltonians satisfy the Hilbert-Schmidt condition with respect to fixed free Hamiltonian. Moreover, we give an effective method for an actual construction of such unitary conjugations, as a function of (time-dependent) background fields. This method is very general and does not use the specific properties of gauge interactions. In general, it applies to any bounded interactions such that its commutator with the absolute value of the free Hamiltonian does not have worse fall-off properties in the momentum space than the original operator. Gravitational background fields can be also treated using a somewhat modified form of the conjugation (Appendix A).

In sections III and IV we discuss the determination of the phase of the quantum scattering operator. It is shown that the phase is uniquely determined by causality (section III), or, alternatively, by the geometric structure of the central extension of the group of one-particle (renormalized) time evolution operators (section IV). Our treatment relies heavily on the theory of infinite-

J. Math. Phys. 37 (8), August 1996

dimensional linear groups. Some of the basic aspects of the theory of these groups in quantum field theory are recalled on the way; for further reading we recommend Refs. 4 and 5.

II. EXISTENCE OF QUANTUM SCATTERING OPERATORS

Consider a family of Hamiltonians of the form $H_A(t)=D_0+A(t)$ acting in a one-particle Hilbert space H where $t\mapsto A(t)$ is smooth and compactly supported ($t,t'\in\mathbb{R}$ here and in the following). We assume that D_0 is a self-adjoint operator and the $A(t)$ are bounded self-adjoint operators [so that the $D_0+A(t)$ are all self-adjoint for all t (Ref. 6)]. We study the time evolution equation

$$i\partial_t U_A(t,t')=H_A(t)U_A(t,t'),\quad U_A(t,t)=1. \tag{2.1}$$

Writing $V_A(t,t') = e^{itD_0}U_A(t,t')e^{-it'D_0}$ we obtain an equivalent equation

$$i\partial_t V_A(t,t')=h_A(t)V_A(t,t'),\quad V_A(t,t)=1 \tag{2.2}$$

where $h_A(t) = e^{itD_0}A(t)e^{-itD_0}$. Since $h_A(t)$ is bounded, this equation has a solution for all finite times given by the Dyson expansion

$$V_A(t,t')=\sum_{n=0}^{\infty} V_n(t,t'),\quad V_0(t,t')=1,\quad V_{n+1}(t,t')=-i\int_{t'}^{t} ds h_A(s)V_n(s,t') \tag{2.3}$$

[it is easy to see that this series converges absolutely in the operator norm $\|\cdot\|$ if one assumes $\int_{\mathbb{R}}dt\|A(t)\|<\infty$; see Appendix B 1].

Let $\epsilon=D_0/|D_0|$. (This is well-defined even if zero is in the spectrum of D_0 if we set $x/|x|=1$ and -1 for $x\geq 0$ and $x<0$, respectively, and use the spectral theorem of self-adjoint operators.[6])

The spectral decomposition $H=H_+\oplus H_-$ corresponding to the splitting of the spectrum of D_0 to positive and negative parts fixes an irreducible representation of the canonical anticommutation relations (CAR), uniquely defined up to unitary equivalence, in a Fock space $\mathcal{F}$ with a vacuum $|0\rangle$ which is annihilated by the elements $a^*(v_-)$ and $a(v_+)$, $v_\pm\in H_\pm$, of the CAR algebra

$$a^*(v)a(v')+a(v')a^*(v)=(v,v'), \tag{2.4}$$

and all the other anticommutators are equal to zero. Let $\{e_n\}_{n\in\mathbb{Z}}$ be an orthonormal basis in H such that $\{e_n\}_{n\geq 0}$ span H_+ and $\{e_n\}_{n<0}$ span H_-. Set $a_n=a(e_n)$ and $a_n^*=a^*(e_n)$. Fix the usual normal ordering for the products of creation and annihilation operators by: $a_n^*a_n:=-a_ma_n^*$ if $n=m<0$ and all the other products remain unchanged.

It is known that a bounded one-particle operator $X=(X_{nm})$ can be canonically quantized as

$$d\Gamma(X)=\sum X_{nm}:a_n^*a_m: \tag{2.5}$$

iff $[\epsilon,X]$ is of Hilbert-Schmidt type.[7,4] This quantization is such that $[d\Gamma(X),a^*(v)]=a^*(Xv)$ for all $v\in H$, and preserves the commutation relations of the Lie algebra of linear operators on H except for a complex valued cocycle ("Schwinger term"); see section III. Similarly, a unitary operator U on H can be second quantized to an operator $\Gamma(U)$ obeying $\Gamma(U)a^*(v)\Gamma(U)^{-1}=a^*(Uv)$ if and only if $[\epsilon,U]$ is of Hilbert-Schmidt type.[8,9]

If we have a time evolution with Hilbert-Schmidt $[\epsilon,A(t)]$ for all t, then it is easy to see that $[\epsilon,V_A(t,t')]$ is always of Hilbert-Schmidt type (if one assumes $\int_{\mathbb{R}}dt\|[\epsilon,A(t)]\|_2<\infty$ where $\|\cdot\|_2$ is the Hilbert-Schmidt norm; see Appendix B 1), and this trivially implies that the scattering operator

$$S_A = \lim_{t_f \to \infty} \lim_{t_i \to -\infty} V_A(t_f, t_i) \tag{2.6}$$

can be second quantized [note that due to our compactness assumption, $S_A = V_A(T, -T)$ for some $T < \infty$].

In many interesting situations $[\epsilon, A(t)]$ is not of Hilbert-Schmidt type, and $[\epsilon, V_A(t,t')]$ is not of Hilbert-Schmidt type either, and the canonical quantum operator $\Gamma(V_A(t,t'))$ does therefore not exist. Nevertheless the scattering operator can be still second quantized in many such cases. We will give proof below of a general, abstract result for this. As a motivation for our abstract setting, we first discuss a special case. We shall use some basic facts about pseudodifferential operators (PSDO):[10] see Appendix C for notation.

We assume that space-time is $M^n \times \mathbb{R}$ where M^n is a n-dimensional compact manifold with spin structure and $H = L^2(M^n) \oplus V$ where V is a vector space carrying the spin and color indices of the fermions. The following discussion applies also to noncompact situations like $M = \mathbb{R}^n$ but then one has to assume suitable fall-off properties of the interaction as $x \to \infty$. For example, in the case of a gauge interaction the requirement that the vector potential and all its derivatives fall off faster than $|x|^{-n/2}$ as $|x| \to \infty$ would be sufficient. Moreover, we assume that the free hamiltonian D_0 is a self-adjoint PSDO of order $\geqslant 1$.

We denote as B_2 the ideal of Hilbert-Schmidt operators in the algebra of bounded operators on H. In case D_0 has no mass gap in the spectrum around zero we interpret D_0^{-1} as $D_0(D_0^2 + \lambda)^{-1}$ for some $\lambda > 0$, and similarly for $|D_0|^{-1}$. We use this simplified notation since the precise value of λ is irrelevant (the essential regularizations concern the ultraviolet and λ is a harmless infrared regulator—if not evident to the reader, this will become clear in the following). Thus D_0^{-1} is always a bounded self-adjoint operator (its operator norm is $\leqslant 1/\sqrt{\lambda}$).

Denote as O_{-k} the PSDO's of order $\leqslant -k$ on a compact manifold M or in $\mathbb{R}^n$ with the asymptotic conditions discussed above, especially O_0 are bounded PSDO's. We assume that D_0 is a Dirac operator. We state the basic properties of these bounded PSDO's which we shall need in the proof of the main theorem (see Appendix C):

$$\begin{aligned} &\text{(i)} \quad O_0 \text{ is an algebra of bounded operators} \\ &\text{(ii)} \quad a \in O_0 \Rightarrow [|D_0|, a] \in O_0 \\ &\text{(iii)} \quad \exists p < \infty\colon \ |D_0|^{-p} a \in B_2 \quad \forall a \in O_0 . \end{aligned} \tag{2.7}$$

Since this is all we need in our proof, our result below applies to the set of all bounded operators $O_0^{(p)}$ with the properties (2.7): we regard $O_0^{(p)}$ as the abstract generalization of the PSDO's O_0. It can be defined as follows: $O_0^{(p)}$ is the algebra of all bounded operators a such that $a_{(n)} \equiv [|D_0|, a_{(n-1)}]$ $(a_{(0)} = a)$ is bounded and $|D_0|^{-p} a_{(n)}$ is of Hilbert-Schmidt type for all $n = 1, 2, \ldots$.

We shall show that S_A can be quantized whenever $A \in O_0^{(p)}$. The idea is to construct a time-dependent family of operators $T(A) = T_t(A)$ for a regularization on the one particle level,[1] i.e., consider the modified time evolution $T_t(A) U_A(t,t') T_{t'}(A)^{-1}$ which can be second quantized even if $U_A(t,t')$ cannot. It is easy to see that the latter is generated by the Hamiltonian $H'_A(t) = T_t(A) H_A(t) T_t(A)^{-1} - i[\partial_t T_t(A)] T_t(A)^{-1} = D_0 + A'(t)$ where

$$A'(t) = i[\partial_t T_t(A)] T_t(A)^{-1} - [D_0, T_t(A)] T_t(A)^{-1} + T_t(A) A(t) T_t(A)^{-1}. \tag{2.8}$$

Our strategy thus is to choose $T(A)$ in such a way that A' is better behaved than the original interaction A, i.e., that $[\epsilon, A'] \in B_2$. It is important to note that a conjugation $T_t(A)$, which becomes the identity as $|t| \to \infty$, does not alter the scattering matrix, $S_{A'} = S_A$.

All differentiations of operators etc., in the following are meant with respect to the operator norm.

Definition 2.9: Let D_0 be a self-adjoint operator and $O_0^{(p)}$ as above. We call an interaction A regular (*with respect* to D_0) if $A(t)$ and the derivatives $(\partial_t)^k A(t)$, $k=1,\ldots,p$, are in $O_0^{(p)}$ for all $t\in\mathbb{R}$ and some $p<\infty$. We denote the set of all such interactions (for fixed p) as $\mathscr{A}_p$.

Theorem 2.10: For all $p<\infty$ and interactions $A(t)\in\mathscr{A}_p$, there is a family of unitary operators $T_t(A)$ differentiable in t and such that the transformed time evolution $V_{A'}(t,t')$, A' Eq. (2.8), can be second quantized, $[\epsilon,V_{A'}(t,t')]\in B_2$ for all $t,t'\in\mathbb{R}$. Moreover $T(A)$ can be chosen local in time, i.e., $T_t(A)=1$ if $A(t)=0$ and $(\partial_t)^k A(t)=0$ for $k=1,\ldots,p$.

Corollary 2.11: For all regular interactions $A(t)$ compactly supported in t, the scattering operator S_A exists and can be second quantized, $[\epsilon,S_A]\in B_2$.

Proof of theorem: In this proof we write O_0 short for $O_0^{(p)}$, and we define

$$O_{-k}=\{a\in O_0\,|\,|D_0|^k a\in O_0\}.$$

Note that if $a\in O_{-k}$ then $|D_0|^{k'-l}a|D_0|^l\in O_0$ for all integers l and $k'=0,1,\ldots,k$. Below we consider maps $A:\mathbb{R}\to O_0$, $t\mapsto A(t)$ such that $[\epsilon,A]$ maps $\mathbb{R}$ to O_{-k}. We say that such a map is C^r if it is times differentiable with all derivatives $\partial_t^l A$ and $\partial_t^l[\epsilon,A]$ continuous maps $\mathbb{R}\to O_0$ and $\mathbb{R}\to O_{-k}$, respectively for $l=1,2,\ldots,r$.

We first prove the following key lemma providing the recipe for constructing $T(A)$.

Lemma 2.12: Let $A:\mathbb{R}\to O_0$ such that $[\epsilon,A]:\mathbb{R}\to O_{-k}$ be C^r with $r\geq 1$. Then $A'(t)$, defined by (2.8), with the unitary operator

$$T_t(A)=e^{\alpha(t)},\quad \alpha(t)=-\frac{1}{8}\left(|D_0|^{-1}[\epsilon,A(t)]+[\epsilon,A(t)]|D_0|^{-1}\right), \tag{2.13}$$

defines a map $A':\mathbb{R}\to O_0$ such that $[\epsilon,A']$ maps $\mathbb{R}$ into O_{-k-1} and is C^{r-1}.

Proof of lemma: We write $A'(t)=A_1'(t)+A_2'(t)$ where

$$A_1'=A+[D_0,\alpha]$$

are the leading terms in an expansion in powers of $|D_0|$, and

$$A_2'=-iT(A)^{-1}\partial_t(T(A)-1)+T(A)^{-1}[D_0,T(A)-\alpha-1]+T(A)^{-1}[A,T(A)-1]$$

is the rest. In the following we refer to maps $a:\mathbb{R}\to O_{-k}$ also as $a\in O_{-k}$, etc.

We first consider A_2'. We observe that

$$T(A)-1=\alpha T_1=T_1\alpha,\quad T(A)-1-\alpha=\alpha^2 T_2=T_2\alpha^2$$

where the operators $a=T(A)^{-1}$, $T_{1,2}$ and $\partial_t(T_1)$ all are bounded, and all these latter operators a are such that $ab,ba\in O_{-l}$, whenever $b\in O_{-l}$ for all $l=0,1,\ldots$. (intuitively this is quite obvious; the precise argument is somewhat technical and therefore deferred to Appendix B 2). Moreover, by assumption α and $\partial_t(\alpha)$ are in O_{-k-1}, and (2.7) and the definition of O_{-k} imply that αD_0 and $D_0\alpha$ are in O_{-k}; also for $A\in O_0$, $A\alpha$ and αA are in O_{-k-1}. We conclude that A_2' is in O_{-k-1}. By definition this implies $A_2'\in O_0$ and $[\epsilon,A_2']\in O_{-k-1}$.

$A_1'\in O_0$ follows from $\alpha\in O_{-k-1}$ as discussed above. The nontrivial part left to show is that $[\epsilon,A_1']\in O_{-k-1}$. This can be seen by the following calculation,

$$[\epsilon,A_1']=[\epsilon,A]-\frac{1}{8}[\epsilon,[D_0,|D_0|^{-1}[\epsilon,A(t)]+[\epsilon,A]|D_0|^{-1}]]$$

$$=\frac{1}{8}(8[\epsilon,A]-[\epsilon,\epsilon[\epsilon,A]-|D_0|^{-1}[\epsilon,A(t)]|D_0|\epsilon+\epsilon|D_0|[\epsilon,A(t)]|D_0|^{-1}-[\epsilon,A(T)]\epsilon])$$

$$=\frac{1}{8}(8[\epsilon,A]-4[\epsilon,A]-2|D_0|[\epsilon,A]|D_0|^{-1}-2|D_0|^{-1}[\epsilon,A]|D_0|)$$

$$=\frac{1}{4}(|D_0|^{-1}[|D_0|,[\epsilon,A]]-[|D_0|,[\epsilon,A]]|D_0|^{-1})$$

where we used $[\epsilon,A]=-\epsilon[\epsilon,A]\epsilon$ and $\epsilon D_0^{\pm 1}=D_0^{\pm 1}\epsilon=|D_0^{\pm 1}|$. Thus

$$[\epsilon,A_1']=\frac{1}{4}[|D_0|^{-1},[|D_0|,[\epsilon,A]]]$$

which is in O_{-k-1} by definition.

We gave the details of this calculation using D_0^{-1} for simplicity. If we replace D_0^{-1} by $D_0(D_0^2+\lambda)^{-1}$ a similar calculation leads to the same conclusion,

$$[\epsilon,A_1']=\frac{1}{4}[|D_0|(D_0^2+\lambda)^{-1},[|D_0|,[\epsilon,A]]]+\frac{1}{2}\lambda((D_0^2+\lambda)^{-1}[\epsilon,A]+[\epsilon,A](D_0^2+\lambda)^{-1}).$$

This proves our lemma.

We can apply this method successively: Starting from some interaction $A_0=A$ such that $[\epsilon,A]\in O_0$ we get a new interaction $A_1=A'$ using the conjugation $T(A)$, with $[\epsilon,A_1]\in O_{-1}$. We can then insert A_1 as an argument to $T(\cdot)$ and obtain a unitary operator $T(A_1)$. This defines again a new interaction $A_2=A_1'$ such that $[\epsilon,A_2]\in O_{-2}$. Continuing this way we obtain, after p steps, a unitary operator $T^{(p)}(A)=T(A_{p-1})\ldots T(A_0)$ such that the time evolution for the operator $T_t^{(p)}(A)U(t,t')T_{t'}^{(p)}(A)^{-1}$ is determined by an interaction A_p such that $[\epsilon,A_p(t)]\in O_{-p}$ for all t. For sufficiently big p the new interaction satisfies the Hilbert-Schmidt condition, and thus the corresponding scattering operator can be second quantized. Since $T_t^{(p)}(A)$ by construction is equal to the identity for times t where $A(t)$ and all its t-derivatives vanish, the latter scattering operator is equal to S_A. This implies Theorem 2.10.

Remark 1: As a particular case, our result gives the existence of the scattering operators for Dirac (or Weyl) fermions in external Yang-Mills fields, on a compact space manifold M^n or on $\mathbb{R}^n$ with sufficient fall-off properties for the vector potential as $|x|\to\infty$. Here our discussion above implies $p>n/2$, but for n odd one can show that actually $p=(n-1)/2$ is already sufficient, provided that $A(t)$ is $(n+1)/2$ differentiable in t (e.g., for $n=1$ no regularization is necessary). The latter follows from the following fact: if $A:\mathbb{R}\to O_0$ with $[\epsilon,A]:\mathbb{R}\to O_{-k}$ is C^1, then $[\epsilon,V(t,t')]\in O_{-k-1}$ for all t,t'.

To see this, consider $B(t)\equiv[\epsilon,h(t)]=[\epsilon,\epsilon^{iD_0t}A(t)\epsilon^{-iD_0t}]$ and observe that

$$\frac{d}{dt}B(t)=[\epsilon,[iD_0,h(t)]]+[\epsilon,\epsilon^{iD_0t}\dot{A}(t)\epsilon^{-iD_0t}]=2iD_0B(t)+i\epsilon[B,|D_0|]+\epsilon^{iD_0t}[\epsilon,\dot{A}(t)]\epsilon^{-iD_0t}$$

with $\dot{A}(t)=dA(t)/dt$, i.e.

$$B(t)\sim-\frac{i}{2}\frac{d}{dt}D_0^{-1}B(t)$$

where $\sim$ means "equal up to terms which obviously are in O_{-k-1}." [Note that at this point we require that $A(t)$ is C^1.] Inserting this in

$$[\epsilon, V_{n+1}(t,t')] = -i\int_{t'}^{t} ds\{B(s)V_n(s,t') + h(s)[\epsilon, V_n(s,t')]\}$$

following from Eq. (2.3), we obtain by induction (i.e., assuming $[\epsilon, V_{m\leqslant n}]\sim 0$: we use partial integration and (2.3)),

$$[\epsilon, V_{n+1}(t,t')]\sim -\frac{1}{2} D_0^{-1}B(s)V_n(s,t')\Big|_{s=t'}^{t} - i\int_{t'}^{t} ds\,\frac{1}{2} D_0^{-1}B(s)h(s)V_{n-1}(s,t')\sim 0$$

(since $B\in O_{-k}$, $V_n\in O_0$, and $D_0^{-1}a\sim 0$ for $a\in O_{-k}$).

Remark 2: We stress the Hilbert-Schmidt property of the scattering operator since only this is of primary interest for quantum field theory. However, our argument above shows that usually $[\epsilon, S_A]$ is much better behaved: e.g., in the fermion-Yang-Mills case it is in all Schatten classes B_q for $q>0$. (This follows from $O_{-k}\subset B_{(n+1)/k}$ in the case of PSDO and the possibility of choosing number p of regularization above arbitrarily large.)

Remark 3: Going through the proof above one can check that Theorem 2.10 can be slightly generalized: one can include in $O_0^{(p)}$ all bounded operators a such that $a_{(n)}$ is bounded and $|D_0|^{-p}a_{(n)}\in B_2$ for $n=1,2,\ldots,p$ (but not necessarily $n>p$).

III. PHASE OF QUANTUM SCATTERING OPERATOR: CAUSAL APPROACH

In the previous section we have shown that the one-particle scattering operator S satisfies the Hilbert-Schmidt condition for $[\epsilon, S]$ and therefore it can be promoted to a unitary operator $\hat{S}=\Gamma(S)$ in the Fock space $\mathscr{F}$. However, by this the operator $\hat{S}$ is uniquely defined only up to a phase. In this section we show that the regularization for the time evolution operators in the previous section fixes the phase in a natural causal manner.

We denote the group of unitary operators U on H with Hilbert-Schmidt $[\epsilon, U]$ as U_1. All $U\in U_1$ can be second quantized, and the second quantization $\Gamma(U)=\Gamma(U^{-1})^{-1}$ of $U\in U_1$ is unique up to a phase [=element in $U(1)$] which implies that for some local (near the unit element in U_1, e.g.) choice of of phases

$$\Gamma(U)\Gamma(V)=\chi(U,V)\Gamma(UV)\quad \forall U,V\in U_1, \tag{3.1}$$

where $\chi: U_1\times U_1\to U(1)$ is only defined locally (a derivation of an explicit, locally valid formula of χ is given in Ref. 11: in the second quantization setting see also Ref. 12). The latter is a nontrivial local 2-cocycle providing a central extension $\hat{U}_1$ of U_1 by $U(1)$. Similarly the (complexification of the) Lie algebra u_1 of U_1 contains all bounded operators X on H with Hilbert-Schmidt $[\epsilon, X]$ and its second quantization $u_1\ni X\to d\Gamma(X)=d\Gamma(X^*)^*$ gives a representation of a central extension $\hat{u}_1=u_1\oplus \mathbb{C}$ of u_1,

$$[d\Gamma(X), d\Gamma(Y)] = d\Gamma_1([X,Y]) + c_L(X,Y), \tag{3.2}$$

with a Lie algebra 2-cocycle[13]

$$c_L(X,Y)=\frac{1}{4}\,\mathrm{Tr}\,\epsilon[\epsilon,X][\epsilon,Y] \tag{3.3}$$

which is the infinitesimal version of the Lie group 2-cocycle χ above (Tr is the Hilbert space trace throughout the paper). It is possible to choose phases such that

$$\Gamma(e^{iX})=e^{id\Gamma(X)} \quad \forall X=X^* \text{ close to } 0\in u_1 \tag{3.4}$$

[the existence of the $e^{id\Gamma(X)}$ as a unitary operator follows from Stone's theorem[6] since $d\Gamma(X)$ is self-adjoint[4]]. This equation actually is true for all $X\in u_1$, but it fixes the phase of $\Gamma(U)$ for only $U\in U_1$ sufficiently close to the identity where local bijectivity of the exponential mapping is guaranteed. We will assume this phase convention in the following. Then (3.2) implies

$$\Gamma(e^{-i\delta sX}e^{-i\delta tY}e^{i\delta sX})=e^{\delta s\,\delta t c_L(X,Y)}\Gamma(e^{-i\delta sX})\Gamma(e^{-i\delta tY})\Gamma(e^{i\delta sX})+\mathcal{O}(\delta s^2,\delta t^2) \tag{3.5}$$

for all $X,Y\in u_1$ and sufficiently small $\delta s,\delta t\in\mathbb{R}$ [to see this, use (3.4) and expand both sides of this equation in powers of δs and δt].

We now consider a time evolution $V_A(t,t')=V(t,t')$ defined in eq. (2.2) with $h_A=h$: $\mathbb{R}\to u_1$ smooth and compactly supported. We first consider the simple case where $h(t)\in u_1$ so that $V(t,t')\in U_1$ for all $t,t'\in\mathbb{R}$. As shown in the last section, many interesting cases can be brought to this simplest situation using the conjugation by a family of operators $T(A)$ (we will discuss this in more detail further below).

We first note the essential group property of the time evolution.

$$V(t,t')V(t',t'')=V(t,t'') \quad \forall t,t',t''\in\mathbb{R}, \tag{3.6}$$

which follows from (2.2): it is this what we mean by causality. Somewhat parallel to our discussion, the use of the causality condition in the renormalization of a quantum field theory has been stressed by Scharf and his coworkers.[14]

To construct the second quantization of the scattering operator $S=S_A$ (2.6) including the phase, we first second quantize the time evolution. The naive guess $\Gamma(V(t,t'))$ for this is not right since this is not a time evolution: it does not obey an equation similar to (3.6) due to the Schwinger term χ in (3.1) which gives nontrivial contributions in general. One can, however, define $\hat{V}(t,t')=\lim_{N\to\infty}\hat{V}^{(N)}(t,t')$ with

$$\hat{V}^{(N)}(t,t')=\prod_{N\geq\nu\geq 1}\Gamma(V(t_\nu,t_{\nu-1})), \quad t_\nu=t'+\frac{(t-t')\nu}{N} \tag{3.7}$$

where $\Pi_{N\geq\nu\geq 1}F(t_\nu,t_{\nu-1})$ is the ordered product $F(t_N,t_{N-1})F(t_{N-1},t_{N-2})\ldots F(t_2,t_1)$ for any operator valued function F on $\mathbb{R}\times\mathbb{R}$. This is a time evolution by construction, and with (3.1)

$$\hat{V}(t,t')=\eta(t,t')\Gamma(V(t,t')), \tag{3.8a}$$

where η is a phase valued function on $\mathbb{R}\times\mathbb{R}$ which can be explicitly computed in terms of χ [for $V(t,t')$ in some neighborhood of the identity].[12] This allows us to calculate the scattering operator $\hat{S}=\hat{V}(T,-T)$ including phase as follows [here and in the following we assume that T is big enough so that $h(t)$ vanishes for $|t|>T/2$, say]: choose some partition $t_0=-T<t_1<\ldots<t_n=T$ of the time interval $[-T,T]$ such that all $V(t_i,t_{i-1})$ are in the neighborhood of the identity for which $\eta(t,t')$ is defined. Then

$$\hat{S}=\prod_{n\geq i\geq 1}\eta(t_i,t_{i-1})\Gamma(V(t_i,t_{i-1})) \tag{3.8b}$$

can be shown to be independent of which particular partition is chosen.

Remark 1: We note our formulas (3.8a) and (3.8b) still do not fix the phase of $\hat{S}$ completely since the function $\eta(t,t')$ is unique only up to

$$\eta(t,t')\mapsto\exp\left(-i\int_{t'}^{t}d\bar{t}E(\bar{t})\right)\eta(t,t') \tag{3.9}$$

with E a smooth real-valued function on $\mathbb{R}$. This is due to the ambiguity of the second quantization map $u_1 \ni X \to d\Gamma(X)$ which can be changed by smooth, linear functions $b: u_1 \mapsto \mathbb{C}$ with $b(X^*) = b(X)^*$. A shift $d\Gamma(X) \to d\Gamma(X) + b(X)$ changes (3.3) by a trivial 2-cocycle, $c_L(X,Y) \to c_L(X,Y) - b([X,Y])$, and this implies (3.9) with $E(t) = b(h(t))$.

Remark 2: Since $h(t) \in u_1$ for all t, the second quantized Hamiltonian $\hat{h}(t) = d\Gamma(h(t))$ (in the interaction picture) always exists, and it should be the generator of the second quantized time evolution $\hat{V}(t,t')$. Moreover, the ambiguity (3.9) of the phase of $\hat{V}(t,t')$ corresponds to a shift $\hat{h}(t) \to \hat{h}(t) + E(t)$ which physically amounts to a change of the zero-point energy. It would be difficult to construct $\hat{V}(t,t')$ directly from $\hat{h}(t)$ since the latter is unbounded which makes the existence of a Dyson series nontrivial. This technical problem is avoided in our approach above.

In the following we are interested in the change of the second quantized time evolution operator under transformations

$$V(t,t') \mapsto (g \cdot V)(t,t') \equiv g(t) V(t,t') g(t')^{-1}, \tag{3.10}$$

where g: $\mathbb{R} \mapsto U_1$, where $g(t)$ is assumed to be sufficiently smooth and such that $g(t) = 1$ for $|t| > T/2$. We will derive an explicit formula for the gauge anomaly of the time evolution,

$$\lambda(t,g) \equiv \Gamma(g(t))^{-1} \widehat{(g \cdot V)}(t,-T) \hat{V}(-T,t), \tag{3.11}$$

which is a phase factor according to our discussion above [since the r.h.s. is the second quantization of $g(t)^{-1}(g \cdot V)(t,-T) V(-T,t)$ equal to the identity]. In particular, $\lambda(g) \equiv \lambda(T,g)$ is the change of the quantum scattering operator $\hat{S}$ under the transformation g.

We first consider only infinitesimal gauge transformations $g(t) = e^{-i\delta s X(t)}$ for $\delta s \to 0$. We calculate $\lambda(t,g)$ as $\lim_{N\to\infty} \lambda^{(N)}$ where

$$\lambda^{(N)} = \Gamma(g(t))^{-1} \left\{ \prod_{N \geq \nu \geq 1} \Gamma(g(t_\nu) V(t_\nu, t_{\nu-1}) g(t_{\nu-1})^{-1}) \right\} \left\{ \prod_{1 \leq \nu \leq N} \Gamma(V(t_{\nu-1}, t_\nu)) \right\}$$

with $t_\nu = -T + (t+T)\nu/N$. Now (3.1) implies

$$\Gamma(g(t+\delta t) V(t+\delta t, t) g(t)^{-1}) = \lambda^{(t+\delta t, t)}(g) \Gamma(g(t+\delta t)) \Gamma(V(t+\delta t, t)) \Gamma(g(t))^{-1}$$

for some phase factors $\lambda^{(t+\delta t,t)}$, and we explicitly see that the various factors $\Gamma(g(t_\nu))$ and $\Gamma(g(t_{\nu-1}))^{-1}$ cancel each other leaving only phase factors. Using $V(t+\delta t, t) \simeq e^{-i\delta t h(t)}$, $g(t+\delta t) \simeq e^{-i\delta s X(t)}$ and (3.5), we get $\lambda^{(t+\delta t,t)}(g) \simeq e^{\delta s\, \delta t c_L(X(t), h(t))}$ ($\simeq$ means "equal up to irrelevant higher order terms in δs and δt"). Thus $\lambda^{(N)}$ is just the exponent of a Riemann sum, and in the limit $N \to \infty$.

$$\lambda(t, e^{-i\delta s X}) = \exp\left(\delta s \int_{-T}^{t} d\bar{t}\, c_L(X(\bar{t}), h(\bar{t})) \right) + \mathcal{O}(\delta s^2).$$

We now consider the case of finite gauge transformations $g(t)$ and introduce a homotopy $g_s(t)$, $0 \leq s \leq 1$, smoothly deforming it to the identity

$$g_1(t) = g(t) \quad \text{and} \quad g_0(t) = 1 \quad \forall t, \quad g_s(t) = 1 \quad \text{for } |t| > T/2. \tag{3.12}$$

To be specific, we first restrict ourselves to gauge transformations $g(t) = e^{-iX(t)}$ with $X(t) \in u_1$ for all t, and $g_s(t) = g(t) = e^{-isX(t)}$. We define $V_s(t,t') \equiv (g_s \cdot V)(t,t')$ and

$$\lambda_{s,s'} \equiv \Gamma(g_s(t))^{-1} \hat{V}_s(t,-T) \hat{V}_{s'}(-T,t) \Gamma(g_{s'}(t))$$

so that $\lambda(g)=\lambda_{1,0}$. We observe that these phases have the group property $\lambda_{s,s'}\lambda_{s',s''}=\lambda_{s,s''}$ for all $0\leq s,s',s''\leq 1$; thus we can evaluate $\lambda(g)$ as $\lim_{M\to\infty}\lambda_M$ where

$$\lambda_M=\prod_{M\geq\mu\geq 1}\lambda_{s_\mu,s_{\mu-1}},\quad s_\mu=\frac{\mu}{M}.$$

Now $\lambda_{s+\delta s,s}$ is the change of phase of $\hat{V}_s(T,-T)$ under an infinitesimal gauge transformation $g_{s+\delta s}(t)g_s(t)^{-1}\simeq e^{-i\delta s X_s(t)}$ and thus equal to $\exp[\delta s\int_{-T}^{t}d\bar{t}c_L(X_s(\bar{t}),h_s(\bar{t}))]$ with

$$h_s(t)=i\{\partial_t V_s(t)\}V_s(t)^{-1},\quad X_s(t)=i\{\partial_s V_s(t)\}V_s(t)^{-1},\quad V_s(t)=g_s(t)V(t,-T)\tag{3.13}$$

[we used $g_s(-T)=1$)]. Again λ_M becomes the exponential of a Riemann sum, and in the limit $M\to\infty$ we obtain

Theorem 3.14:

$$\lambda(t,g)=\exp\left(\int_0^1 ds\int_{-T}^{t}d\bar{t}c_L(X_s(\bar{t}),h_s(\bar{t}))\right).$$

Note that this result was derived for the special homotopy $g_s(t)=e^{-isX(t)}$, but our derivation can be immediately generalized to arbitrary gauge transformations $g(t)$ and homotopies $g_s(t)$ (sufficiently smooth in s and t) obeying (3.12). For $t\geq T$, $\lambda(t,g)=\lambda(g)$ (3.14) is then actually independent of the homotopy chosen [this follows from its definition (3.11) which does not depend on the homotopy]. For intermediate times $-T<t<T$ this is not true. The reason is that then the phase of the implementors $\Gamma(g(t))$ in (3.11) depends on the homotopy: our derivation above implies that this phase has to be chosen such that

$$\Gamma(g(t))=\lim_{M\to\infty}\prod_{M\geq\mu\geq 1}\Gamma(g_{s_\mu}(t)g_{s_{\mu-1}}(t)^{-1}),\quad s_\mu=\frac{\mu}{M},$$

and this coincides with our phase convention (3.4) only for homotopies $s\mapsto g_s(t)=e^{-isX(t)}$.

Remark 3: Our derivation of (3.14) above was given for one-parameter groups in U_1 for simplicity, but the result immediately generalizes to GL_1 which is the group of all (not only unitary) invertible operators U on H with Hilbert-Schmidt $[\epsilon,U]$: Eq. (3.14) remains true for $h(t)\in u_1$ not self-adjoint and $g(t)\in GL_1$. The technical problem for proving this more general result by the method above is that $\epsilon^{-i\delta t d\Gamma(X)}$ is unbounded if $d\Gamma(X)$ is not self-adjoint; thus one has to be careful with the domains of operators (the latter could, however, be handled by methods described in Ref. 15). Our alternative derivation of (3.14) in the next section is for GL_1 and bypasses such domain questions.

We consider now time evolutions generated by Hamiltonians $H_A(t)=D_0+A(t)$ with $A(t)\in\mathscr{A}$ [cf. definition (2.9)] and generalized gauge transformations

$$A(t)\to g\cdot A(t)=i(\partial_t g(t))g(t)^{-1}-[D_0,g(t)]g(t)^{-1}+g(t)A(t)g(t)^{-1}\tag{3.15}$$

so that $U_{g\cdot A}(t,t')=g(t)U_A(t,t')g(t')^{-1}$. We denote the group of all $g(t)$ which leave $\mathscr{A}$ invariant as $\mathscr{G}$. Note that $\mathscr{G}$ contains all $g(t)$ sufficiently smooth in t (i.e., C^{p+1}), which are unitary operators in O_0 for all t. We also introduce the Lie algebra $\mathrm{Lie}\mathscr{G}$ of $\mathscr{G}$. In the following, all A are in $\mathscr{A}$, all g,g',g'' in $\mathscr{G}$ and all $X,Y,Z\in\mathrm{Lie}\mathscr{G}$, except when stated otherwise. As before, we assume all these functions are trivial for $|t|>T/2$.

By Theorem 2.10, there exist appropriate regularization operators $T(A)$ and $T(g\cdot A)$ such that A' and $(g\cdot A)'$, defined in (2.8), all lead to time evolutions which can be second quantized, i.e., they are always in u_1. This also implies that the operators $T_t(g\cdot A)g(t)T_t(A)^{-1}=U_{g\cdot A}(t,-T)U_A(-T,t)$ all are in U_1, and thus

$$\Gamma_t(g;A)\equiv\Gamma(g'_A(t)),\quad g'_A(t)\equiv e^{itD_0}T_t(g\cdot A)g(t)T_t(A)^{-1}e^{-itD_0} \tag{3.16}$$

always exist. These unitary operators have the natural interpretation as implementors of the generalized gauge transformations g at fixed time t. They are local in time, i.e., only depend on g, A and t-derivatives thereof, at time t. We observe that they obey the relations

$$\Gamma(g';g\cdot A)\Gamma(g;A)=\chi(g',g;A)\Gamma(g'g;A), \tag{3.17a}$$

where we have dropped the common time argument t, with

$$\chi_t(g',g;A)=\chi((g')'_{g\cdot A}(t),g'_A(t)) \tag{3.17b}$$

defined locally [this follows from (3.1)]. Note that (3.17a) and associativity of the operator product imply the 2-cocycle relation

$$\chi(g'',g'g;A)\chi(g',g;A)=\chi(g'',g';g\cdot A)\chi(g''g',g;A). \tag{3.18}$$

Our construction above can now be used to calculate

$$\lambda(t,g;A)\equiv\Gamma_t(g;A)^{-1}\widehat{V_{(g,A)'}}(t,-T)\widehat{V_{A'}}(-T,t), \tag{3.19}$$

which we define as the change of the quantum time evolution $\widehat{V_{A'}}$ under the generalized gauge transformation g. We immediately get the formula

$$\lambda(t,g;A)=\exp\left(\int_0^1 ds\int_{-T}^{t}d\bar{t}\,c_L(\{\partial_s V_s(\bar{t})\}V_s(\bar{t})^{-1},\{\partial_t V_s(\bar{t})\}V_s(\bar{t})^{-1})\right) \tag{3.20a}$$

with

$$V_s(t)=e^{itD_0}T_t(g_s\cdot A)g_s(t)U_A(t,-T)e^{iTD_0} \tag{3.20b}$$

and $g_s(t)\in\mathcal{G}$ a homotopy interpolating between 1 and $g(t)$. Similarly as discussed above after Theorem 3.11, for $t\geq T$ (but in general not for intermediate times $-T<t<T$) this formula is independent of the homotopy $s\mapsto g_s(t)$ chosen.

We observe that these phases are connected with the Schwinger terms in (3.17b) via the relation

$$\lambda(t,g';g\cdot A)\lambda(t,g;A)\chi_t(g',g;A)=\lambda(t,g'g;A). \tag{3.21}$$

This follows from a simple calculation using the definition (3.19) and $(g'g)\cdot A=g'\cdot(g\cdot A)$,

$$\Gamma_t(g';g\cdot A)\lambda(t,g';g\cdot A)\Gamma_t(g;A)\lambda(t,g;A)$$

$$=\widehat{V_{(g'g\cdot A)'}}(t,-T)\widehat{V_{(g\cdot A)'}}(-T,t)\widehat{V_{(g\cdot A)'}}(t,-T)\widehat{V_{A'}}(-T,t)=\Gamma_t(g'g;A)\lambda(t,g'g;A),$$

and inserting (3.17a). According to our derivation, this equation is valid only locally [i.e., $g(t)$ and $g'(t)$ close to identity].

Especially for $t=T$, $\lambda(g;A)\equiv\lambda(T,g:A)$ is equal to the change of the quantum scattering matrix $\hat{S}_A$ under the transformation g, and Eq. (3.21) reduces to the 1-cocycle relation, $\lambda(g';g\cdot A)\lambda(g;A)=\lambda(g'g;A)$ [since $\chi(1,1;0)=1$]. The physical meaning of $\lambda(g;A)$ is as follows. We recall that the log of the vacuum expectation value of $\hat{S}_A$ is equal to the Minkowskian action of the fermions in the time dependent external field A, thus $\log\lambda(g;A)$ is the change of the

latter by the generalized time dependent gauge transformation $g(t)$. Especially for infinitesimal transformations $g(t)=1-i\delta s X(t)+\ldots$ it gives the generalized gauge anomaly $\mathrm{Anom}(X;A)=d/ds\ \log\lambda(e^{-isX};A)|_{s=0}$. We obtain

$$\mathrm{Anom}(X;A)=\int_{-T}^{T}dt\,\bar{\omega}^1(X(t),A(t)),\quad \bar{\omega}^1(X(t),A(t))=c_L(X'_A(t),h_{A'}(t)),\tag{3.22}$$

where $h_{A'}(t)=e^{itD_0}A'(t)e^{-itD_0}$ with A' given in Eq. (2.8), and

$$X'_A(t)\equiv e^{itD_0}[\{\mathscr{L}_X T_t(A)\}T_t(A)^{-1}-T_t(A)X(t)T_t(A)^{-1}]e^{-itD_0}\tag{3.23}$$

is in u_1 for all $A\in\mathscr{A}$ and $X\in\mathrm{Lie}\mathscr{G}$; we introduced the Lie derivative acting on functionals f on $\mathscr{A}$ as

$$\mathscr{L}_X f(A)=i\frac{d}{ds}f(e^{-isX}A)\bigg|_{s=0}.$$

Similarly, the infinitesimal version of (3.17a) and (3.17b) is[1]

$$[G(X;A),G(Y;A)]=G([X,Y];A)+S(X,Y;A)\tag{3.24a}$$

where $G(X;A)=\mathscr{L}_X+d\Gamma(X'_A)$ are implementors of infinitesimal gauge transformations and

$$S_t(X,Y;A)=c_L(X'_A(t),Y'_A(t)),\tag{3.24b}$$

a Schwinger term satisfying the 2-cocycle relation $\mathscr{L}_X S(Y,Z;A)+S(X,[Y,Z];A)+\mathrm{cycl.}=0$ [the latter is the infinitesimal version of (3.18) and also follows from the Jacobi identity].

Especially, if we consider the Yang-Mills case and infinitesimal chiral gauge transformations, $\mathrm{Anom}(X;A)$ is just the axial gauge anomaly and $S(X,Y;A)$ the Schwinger term appearing in the commutators of the chiral Gauss' law generators $G(X;A)$. We thus have obtained a Hamiltonian derivation of these two different manifestations of the gauge anomaly in a Hamiltonian framework which traces them back to a common root, i.e., the 2-cocycle c_L in (3.2).

It is interesting to consider also the infinitesimal version of Eq. (3.21) which can be written as

$$\delta\bar{\omega}^1+\partial_t S=0\tag{3.25}$$

where

$$(\delta\omega^1)(X,Y;A)=\mathscr{L}_X\omega^1(Y;A)-\mathscr{L}_Y\omega^1(X;A)-\omega^1([X;Y];A)$$

is defined on functions ω^1 on Lie $\mathscr{G}\times\mathscr{A}$. To interpret this equation, we recall that the above mentioned fermion-Yang-Mills anomalies are connected by descent equations:[16] the axial anomaly on a $n+1$ (even)-dimensional space-time manifold M^{n+1} is the integral of a $(n+1)$-(de Rham) form $\omega^1_{n+1}(X;A)$ over M^{n+1}; it depends on one infinitesimal gauge transformations X and the Yang-Mills field A. The corresponding Schwinger term is on n-dimensional space M^n and an integral of a n-form $\omega^1_n(X,Y;A)$ over M^n depending on two infinitesimal gauge transformations X, Y, and A. Embedding M^n in M^{n+1}, the descent equations are $\delta\omega^1_{n+1}+d\omega^2_n=0$ where δ is defined as above and d is the usual exterior differentiation of de Rham forms. Setting $M^{n+1}=M^n\times\mathbb{R}$ and $\bar{\omega}^1=\int_{M^n}\omega^1_{n+1}$ and $S=\int_{M^n}\omega^2_n$, one exactly obtains our Eq. (3.25). We thus have obtained an explicit field theory derivation of this descent equation for all odd dimensions n the Hamiltonian framework. We stress, however, that our equation (3.25) is not restricted to the Yang-Mills case but in fact is more general.

Remark 4: As just mentioned, fermion-Yang-Mills anomalies are local de Rham forms, whereas our formulas (3.22) for the axial anomaly and (3.24b) for the Schwinger term are not explicitly local in space. In the Yang-Mills case one can prove, however, that they cohomologous to local de Rham forms. General arguments and mathematical techniques for showing this by explicit calculations have been given recently.[1,17,18] Nevertheless it would be interesting to explicitly do this latter calculation for all dimensions. In this article we will only sketch the simplest case $n=1$ (end of next section).

In the next section we will give a different, more geometric approach to the phase of the scattering operator where the path independence of the anomaly becomes evident. Another important benefit in the geometric approach is that we can easily compute the cohomology class of the anomaly without going to the details of the renormalization $T(A)$.

IV. THE QUANTUM PHASE AND PARALLEL TRANSPORT

Let $\hat{G}$ be a central extension of a Lie group G by $\mathbb{C}^\times$. The Lie algebra $\hat{g}$ of $\hat{G}$ is a vector space direct sum $g\oplus\mathbb{C}$. Let π be the projection on the second summand and let $\theta=\mathbf{g}^{-1}d\mathbf{g}$ be the left Maurer-Cartan one-form. We can then define a complex valued one-form ϕ on $\hat{G}$ by $\phi=\pi(\theta)$. This is a connection form in the principal $\mathbb{C}^\times$ bundle $\hat{G}\to G$. Its curvature is a left invariant two-form on G given by $\omega(X,Y)=c(X,Y)$, where left invariant vector fields X,Y on G are identified as elements of the Lie algebra and c is the 2-cocycle on g defining the central extension

$$[(X,\lambda),(Y,\mu)]=([X,Y],c(X,Y)). \tag{4.1}$$

Recall that GL_1 is the group of invertible linear transformations $\mathbf{g}:H\to H$ such that $[\epsilon,\mathbf{g}]$ is of Hilbert-Schmidt type and U_1 its unitary subgroup. Let us apply the above remarks to $G=U_1$, and to the Lie algebra cocycle c_L (3.3) arising when promoting the one-particle operators to operators (2.5) in the fermionic Fock space, as discussed in the last section.

The central extension $\widehat{GL}_1$ is a nontrivial $\mathbb{C}^\times$ bundle over the base GL_1.[11] The elements of the group $\widehat{GL}_1$ (containing the unitary subgroup $\hat{U}_1$) can be thought of equivalence classes of pairs $(\mathbf{g},q)$, where $\mathbf{g}\in GL_1$ and $q:H_+\to H_+$ is an invertible operator such that $a-q$ is a trace-class operator,

$$\mathbf{g}=\begin{pmatrix} a & b \\ c & d \end{pmatrix}. \tag{4.2}$$

We have assumed that $\operatorname{ind} a=0$. If this is not the case, the subspace H_+ must be either enlarged or made smaller by a suitable finite-dimensional subspace in order to achieve $\operatorname{ind} a=0$. The equivalence relation is determined by $(\mathbf{g},q)\sim(\mathbf{g}',q')$ if $\mathbf{g}=\mathbf{g}'$ and $\det(q'q^{-1})=1$. Thus the fiber of the extension is $\mathbb{C}^\times$ and it is parameterized by (the nonexisting) determinant of q.

The product is defined simply $(\mathbf{g},q)(\mathbf{g}',q')=(\mathbf{g}\mathbf{g}',qq')$. Near the unit element in G we can define a local section $\mathbf{g}\mapsto(\mathbf{g},a)$.[11] Denoting

$$\mathbf{g}^{-1}=\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}$$

we can write the connection form as

$$\phi=\operatorname{Tr}[(\mathbf{g}^{-1}d\mathbf{g})a-q^{-1}dq]=\operatorname{Tr}[\alpha da+\beta dc-q^{-1}dq]. \tag{4.3}$$

The curvature of this connection at $\mathbf{g}=1$ is

$$\omega=-\operatorname{Tr}(d\beta d\gamma) \tag{4.4}$$

and is easily checked to agree with c_L in (3.3).

We compute the parallel transport determined by the connection in the range of the local section. Let $\mathbf{g}(t)$ be a path in GL_1, $-T\leqslant t\leqslant T$, with $\mathbf{g}(-T)=1$. The lift $(\mathbf{g}(t),q(t))$ is parallel if

$$0=\phi(g(t),q(t))(dg,dq)=\mathrm{Tr}[\alpha(t)a'(t)+\beta(t)c'(t)-q(t)^{-1}q'(t)].$$

Thus the parallel transport, relative to the trivialization $\mathbf{g}\mapsto(\mathbf{g},a)$, along the path $\mathbf{g}(t)$ in the base is accompanied with the multiplication by the complex number

$$\exp\left(-\int_{-T}^{T}\mathrm{Tr}[\{\alpha(t)-a(t)^{-1}\}a'(t)+\beta(t)c'(t)]dt\right) \tag{4.5}$$

in the fiber C.

Formally,

$$\mathrm{Tr}\, q^{-1}q'=\mathrm{Tr}[\alpha a'+\beta c']$$

and so

$$\det q(T)=\exp\int_{-T}^{T}\mathrm{Tr}\,[\alpha(t)a'(t)+\beta(t)c'(t)]dt$$

and also

$$\det a(T)=\exp\int_{-T}^{T}\mathrm{Tr}\, a(t)^{-1}a'(t)dt.$$

Individually, the traces in these two expressions do not converge, but put together the trace converges and gives

$$\det[a(T)q(T)^{-1}]=\exp\left\{\int_{-T}^{T}\mathrm{Tr}\,[(\alpha-a^{-1})a'+\beta c']dt\right\}. \tag{4.6}$$

Note that the exponent diverges outside of the domain of the local section, reflecting the fact that $\det a(T)=0$ outside of the domain.

We can now apply the above results to the "renormalized" one-particle time evolution operators $\mathbf{g}(t)=V_{A'}(t)=e^{itD_0}T_1(A)U_A(t,-T)e^{iTD_0}$. For all times t, these are elements of the group U_1. On the other hand, in the Fock representation of $\widehat{GL}_1$ these correspond to elements $\widehat{V_{A'}(t)}$ in the central extension $\hat{U}_1$. The phase of the quantum time evolution operator is then uniquely given by the parallel transport described above.

The Minkowskian effective action is by definition the vacuum expectation value of the quantum scattering operator $\hat{S}_A$. The vacuum is invariant under the free time evolution $\exp(itD_0)$ and taking into account the assumption that the interaction has essentially compact support in time, we can write

$$Z(A)=\langle 0|(V_{A'}(T),q(T))|0\rangle. \tag{4.7}$$

The vacuum expectation value is given by a simple formula,[11,19]

$$\langle 0|(\mathbf{g},q)|0\rangle=\det(aq^{-1}) \tag{4.8}$$

and therefore the parallel transport (4.5) (with respect to the given local trivialization) is equal the effective action $Z(A)$.

The above formalism can be applied for computing the gauge anomaly in the space-time formalism starting from the commutator anomaly (3.3). Let $g(t)\in\mathcal{G}$ be a time-dependent gauge transformation such that at $t=\pm T$ it is equal to the identity. The change in the phase of the effective action is now

$$\lambda(g;A)=\exp\left(\int_\gamma \phi\right)$$

where γ is the closed loop in U_1 obtained by first following backwards in time from T to $-T$ the time evolution $U_{A'}(t)$, following then the gauge transformed time evolution operators $g(t)U_{A'}(t)$ back from $-T$ to T. The parallel transport around a closed loop can be written as an integral of the curvature ω over a surface S enclosed by the loop γ. By construction, the gauge anomaly λ satisfies the 1-cocycle condition $\lambda(gg';A)=\lambda(g;g'.A)\lambda(g';A)$.

Joining $g(t)$ to the identity by a homotopy $g_s(t)$, $0\leqslant s\leqslant 1$, and writing $V_s(t)=g_s(t)U_{A'}(t)$ we get

$$\log\lambda(g;A)=\int_S dtdsc_L(\partial_s VV^{-1},\partial_s VV^{-1})=\frac{1}{4}\int dtds\,\mathrm{Tr}\,\epsilon[\epsilon,\partial_t,VV^{-1}][\epsilon,\partial_s VV^{-1}]. \quad (4.9)$$

This result agrees with (3.14). For infinitesimal gauge transformations $g_s(t)=1-isX(t)+\cdots$ we get axial anomaly (3.22) as discussed in the last section.

Let us complete the calculation for $1+1$ space-time dimensions in the case of chiral fermions in external Yang-Mills field. Now the chiral Hamiltonian on the circle S^1 acting on one-component spinors is $H(t)=-i\partial/\partial x-A_+$, where $A_+=A_0+A_1$ (0 and 1 are space–time indices). We now use that for $n=1$ one can choose $T_t(A)=1$ independent of A (see our remark 1 at the end of section II). Thus, applying (3.22) derived either from (3.20) or (4.9), we get

$$\mathrm{Anom}(X;A)=\frac{1}{4}\int_{-T}^{T}dt\,\mathrm{Tr}\,\epsilon[\epsilon,A_+][\epsilon,X(t)]=\frac{1}{2\pi i}\int_{-T}^{T}dt\int_{S^1}dx\ \mathrm{tr}\,A_+(t,x)\frac{\partial}{\partial x}X(t,x).$$

Here we have used the general formula

$$\frac{1}{4}\mathrm{Tr}\epsilon[\epsilon,X][\epsilon,Y]=\frac{1}{2}\mathrm{Tr}_C X[\epsilon,Y]=\frac{1}{2\pi i}\int_{S^1}dx\ \mathrm{tr}\,X\partial_x Y \quad (4.10)$$

valid for smooth multiplication operators X,Y on the unit circle; here we introduced the notation $\mathrm{Tr}_C(a)\equiv\frac{1}{2}\mathrm{Tr}(a+\epsilon a\epsilon)$ (conditional trace) which will be useful below. Up to a coboundary ($=a$ gauge variation of the local functional $\propto\int\mathrm{tr}\,A_+A_1$) this form of the anomaly is equal to the standard form of the two-dimensional chiral anomaly

$$\mathrm{Anom}(X;A)=\frac{1}{4\pi i}\int_{S^1\times\mathbb{R}}\mathrm{tr}\,A dX. \quad (4.11)$$

We finally note that this same equation also allows to calculate the Schwinger term (3.24b).

$$S(X,Y;A)=\frac{1}{2\pi i}\int_{S^1}\mathrm{tr}\,X dY \quad (4.12)$$

which actually is independent of A. This is the Kac-Moody cocycle and also the Schwinger term related to the axial anomaly (4.11) via the descent equations, as discussed at the end of the last section.

The cohomology class of the anomaly in dimensions $n+1>2$

The group GL_p consists of all bounded invertible operators (4.2) in $H=H_+\oplus H_-$ such that the off-diagonal blocks b,c are in the Schatten ideal B_{2p}. For any $p\geqslant 1$ the group GL_p contracts to the subgroup GL_1.[20] On the other hand, in GL_1 one can produce cohomologically equivalent cocycles $c_p\sim c_L$ such that c_p extends from GL_1 to GL_p. These are relevant for understanding the gauge group action in space-time dimension $n+1>2$. The static gauge transformations are elements of GL_p for $p>n/2$. For example, when $n=3$ the gauge group $\mathscr{G}_n=\mathrm{Map}\,(M^n,G)\subset GL_2$ and one has[21]

$$c_2(X,Y;f)=\frac{1}{8}\,\mathrm{Tr}_C[\epsilon,f]f^{-1}[[\epsilon,X],[\epsilon,Y]], \tag{4.13}$$

where $c_2(X,Y;f)$ is the value of a two-form on GL_2 at a point f to the directions of the left invariant vector fields (=Lie algebra elements) X,Y. This formula has been generalized for arbitrary p.[22,23]

In order to fix the cohomology class of the 1-cocycle $\lambda(g;A)$ it is sufficient to look how λ winds around the circle when a family $f(t,s)$ of time-dependent gauge transformations wraps around a closed surface S (parameterized by s,t) in the group $\mathscr{G}_n$ of static gauge transformations. This follows from the fact that the cohomology class of any two-form is determined by giving its integral over all closed 2-cycles. The winding number is given by the integral of the curvature c_L around the surface S in GL_1 defined by the family of gauge transformed renormalized evolution operators.

For any fixed potential A and a homotopy $f(t,s)$ of time-dependent gauge transformations we have a map $S=[-T,T]\times[0,1]\to GL_p$ given by $(t,s)\mapsto f(t,s)U(t)$, where $U(t)$ is the nonrenormalized time evolution operator determined by A. The renormalization $T(A)$ does not change the homology class of the surface S in $GL_1\subset GL_p$ since $T(A)$ is defined over a contractible parameter space. It follows that the integral over a closed surface S of the curvature on GL_1 is given by the integral of c_p of the nonrenormalized operators $f(t,s)U(t)$. Furthermore, the surface $(t,s)\mapsto f(t,s)U(t)$ contracts to $(t,s)\mapsto f(t,s)$. This follows from the fact that each component of U_p is simply connected and so $(t,s)\mapsto U(t)$ is contractible. Therefore, the final result for the anomaly around a closed surface is

$$\int_{f(t,s)} c_p=\int_{-T}^{T}dt\int_0^1 ds\,c_p(i(\partial_t f)f^{-1},i(\partial_t f)f^{-1}). \tag{4.14}$$

In the case $M=S^1$ $(p=1)$ this gives

$$\begin{aligned}-\frac{1}{2}\int_S dtds\ \mathrm{Tr}_C(\partial_t f)f^{-1}[\epsilon,(\partial_s f)f^{-1}]&=-\frac{1}{2\pi i}\int_{S\times S^1}dtdsdx\ \mathrm{tr}(\partial_t f)f^{-1}\partial_x((\partial_s f)f^{-1})\\&=\frac{1}{12\pi i}\int_{S\times S^1}\mathrm{tr}(f^{-1}df)^3,\end{aligned} \tag{4.15}$$

where we have used (4.10) in the first step and $\partial_x f^{-1}=-f^{-1}\partial_x(f)f^{-1}$ in the second step (the factor $1/6=1/3!$ is from antisymmetrization in the variables t,s,x which amounts to partial integrations).

In dimension $n=3$ $(p=2)$ a similar calculation gives

$$-\frac{1}{8}\int_S dtds\,\mathrm{Tr}_C[\epsilon,f]f^{-1}[[\epsilon,(\partial_t f)f^{-1}],[\epsilon,(\partial_s f)f^{-1}]]$$

$$=\frac{1}{24\pi^2}\int_S dtds\int_{\mathbb{R}^3} d^3x\,\epsilon^{ijk}\,\mathrm{tr}(\partial_i f)f^{-1}[(\partial_j(\partial_t f)f^{-1}),(\partial_k(\partial_s f)f^{-1})]$$

$$=\frac{1}{240\pi^2}\int_{S\times\mathbb{R}^3}\mathrm{tr}(f^{-1}df)^5 \tag{4.16}$$

where $\partial_i = \partial/\partial x_i$, ϵ^{ijk} is the antisymmetric tensor with $\epsilon^{123}=1$, and in the second step we again antisymmetrize in the variables t,s,x_1,x_2,x_3 which gives the combinatorial factor $1/10=3!2!/5!$. In the first step we used the three-dimensional analog of Eq. (4.10),[24]

$$\mathrm{Tr}_C(X_0[\epsilon,X_1][\epsilon,X_2][\epsilon,X_3])=-\frac{1}{3\pi^2}\int_{\mathbb{R}^3}\mathrm{tr}\,X_0dX_1dX_2dX_3\,. \tag{4.17}$$

Similar results can be derived for all $p>0$ using the results from Refs. 24 and 23. We note that $\int_{f(t,s)}c_p$ agrees with the integral of the two form over S in a gauge orbit obtained by the descent equations.[16] For example, in three space dimensions ($p=2$) this form is

$$\frac{i}{24\pi^2}\int_{\mathbb{R}^3}\mathrm{tr}\,A[dX,dY] \tag{4.18}$$

which is the commutator anomaly in three space dimensions[25,26] [by a similar calculation as above it is easy to see that replacing A, X, and Y by $i(df)f^{-1}$, $i(\partial_t f)f^{-1}$, and $i(\partial_s f)f^{-1}$ and integrating over S^2 also leads to Eq. (4.16)]. We finally note that these results can be understood on a more fundamental level using a generalization of the descent equations to noncommutative geometry[23] and the fact that the conditional trace Tr_C is indeed a generalization of integration of de Rham forms (which is the natural interpretation of Eqs. (4.10) and (4.17)[17,24]).

V. CONCLUSIONS

In section II we gave a new proof for the existence of the second quantized fermionic scattering operator in external Yang-Mills fields. The proof is valid also in a more abstract setting of generalized gauge interactions in the spirit of Connes's noncommutative geometry. In section III we derived a formula for the phase of the scattering operator and its gauge variation from the concept of causality by using the local 2-cocycle on the group GL_1. In section IV we gave an alternative geometric derivation using a connection on the global group extension $\widehat{GL}_1$. A constructive interpretation for the descent equations was given in the Hamiltonian framework, linking the anomaly of the Minkowskian effective action to the Schwinger terms. This is complementary to the standard approach which starts from the euclidean functional determinant.

The authors wish to thank S. N. M. Ruijsenaars for discussions and critical remarks on a first version of this paper. The authors also want to thank G. Marmo and P. Michor for inviting them to the Erwin Schödinger Institute where part of this work was done.

APPENDIX A: THE CASE OF AN EXTERNAL METRIC

Let $g=(g_{ij}(x,t))$ be a time-dependent metric tensor in $\mathbb{R}^n$. We assume that space and time has been foliated by a choice of the time coordinate such that the space coordinates $x_1,\ldots,x_n$ are orthogonal with respect to the time t, i.e., $g_{0i}=g_{i0}=0$ for $1\leqslant i\leqslant n$. The Weyl equation is written as

$$ig_{00}\partial_t\psi=\gamma^k h_{kj}(i\partial_j+\Gamma_j)\psi\simeq g_{00}D_h\psi \tag{A1}$$

where $h_{kj}(x)$ are the components of an oriented orthonormal basis in $(\mathbb{R}^n,g)$.

$$h_{kj}h_{mj}=g_{km}. \tag{A2}$$

The matrices Γ_j, are the components of the spin connection (defined by the Levi-Civita connection of g), taking values in the Lie algebra of the spin group Spin (n).

We assume that the deviation of the metric g from the euclidean metric has only compact support in space and time. Furthermore, $g(x,t)$ is assumed to be smooth. If the dimension $n=2N+1$ then the γ's are $2^N\times 2^N$ complex matrices with the property

$$\gamma^i\gamma^j+\gamma^j\gamma^i=2\delta_{ij}. \tag{A3}$$

The Lie algebra of Spin(n) is spanned by the commutators $[\gamma_i,\gamma_j]$. If $n=3$ the γ-matrices are just the 2×2 Pauli matrices which are also the generators of the spin group Spin(3)=SU(2).

The principal symbol of the Dirac Hamiltonian is $\gamma^k h_{kj}p_j$. The complete symbol is the sum of the principal symbol and of a symbol of order zero in the momenta.

Because for any given pair q,p of nonzero vectors there is a rotation R such that $q=Rp$, there exists an element $B(p,x)\in\mathrm{Spin}(n)$ such that

$$B\gamma^k p_k B^*=\lambda(x,p)\gamma^k h_{kj}p_j. \tag{A4}$$

Here the product is a matrix product, no momentum space differentiation is involved, and the scale factor λ is the ratio of the euclidean lengths of the vectors $p=\gamma^k p_k$ and $q=\gamma^k h_{kj}p_j$. Both λ and B are homogeneous functions of order zero in momenta.

At the first sight it appears that it is not possible to construct B as a continuous function of the h field, the apparent obstruction being the hairy ball theorem: For a given direction q one can always choose a rotation R_q such that $R_q\cdot p=q$, but R_q is not a continuous function of q when n is odd and at least equal to 3. However, here we can profit from the information encoded in the matrix h.

The set of all orthogonal transformations which takes p to $q=h\cdot p$ (up to a scale) form a fiber $P_{p,q}$ in a principal bundle P with base $X=GL_+(n,\mathbb{R})\times S^{n-1}$, consisting of the pairs $(h,p/|p|)$, and the fiber is isomorphic with $\mathrm{SO}(n-1)$; the '+' refers to matrices with positive determinant. The base contracts to $X'=\mathrm{SO}(n)\times S^{n-1}$ (by the Cartan decomposition). On the other hand, over X' the bundle P is trivial, the trivialization being given by $(h,p)\mapsto h$. Thus P is trivial. We choose a trivialization $(h,p)\mapsto R(h,p)$. We choose $B(h,p)\in\mathrm{Spin}(n)$ which projects down to $R\in\mathrm{SO}(n)$. There is a $\mathbb{Z}_2$ ambiguity in the choice which does not bother us since the transformation law for the Dirac operator is quadratic in B.

If we compute the left-hand side in (A4) with the complete star product instead of the matrix product, we generate symbols of order less than or equal to zero. Thus we have proven the following lemma:

Lemma. There is a function $B(h)$ of the basis h taking values in the group of invertible PSDO's of order zero such that $B^*\gamma^k h_{kj}p_j B$ differs from $\lambda(x,p)^{-1}\gamma^k p_k$ by an operator of order zero.

The unitarily equivalent Hamiltonian $B'=B^*D_hB$ has then the property that $[\epsilon,B^*D_hB]$ is a PSDO of order zero. One can now apply the recursive method in section 2 to obtain the renormalization operator $T=T(A)$ where now $A=B'-D_0$ and $D_0=\gamma^k p_k$. [The crucial step is the first application of Lemma 2.12: even though $A\in O_1$ (*i.e.*, $|D_0|^{-1}A\in O_0$) is unbounded, α Eq. (2.13) is O_{-1} and thus A' Eq. (2.8) is in O_0 (bounded). We also note that in this argument one never

considers the (ill defined) time evolution (Dyson series) Eq. (2.3) with the unbounded potential $A(t)$ but only the regularized one with a bounded potential.] This method applies as well to the case of combined background gauge and gravitational interactions.

APPENDIX B: ESTIMATES

(1) We consider here the Dyson series (2.3) solving the time evolution equation (2.2) with $h_A(t) = e^{itD_0}A(t)e^{-itD_0}$. If $A(t)$ is bounded for all t, one can easily prove by induction that

$$\|V_n(t,t')\| \leq \frac{1}{n!}\left(\int_{t'}^{t} dr\|A(r)\|\right)^n$$

which shows that (2.3) converges in the operator norm $\|\cdot\|$ for all $t,t' \in \mathbb{R}$.

Similarly, if $[\epsilon,A(t)]$ is of Hilbert-Schmidt type for all t, then the Hilbert-Schmidt norm of V_n can be estimated as

$$\|[\epsilon,V_n(t,t')]\|_2 \leq \int_{t'}^{t} dr\|[\epsilon,A(r)]\|_2 \frac{1}{(n-1)!}\left(\int_{t'}^{t} dr\|A(r)\|\right)^{n-1}$$

showing that $[\epsilon,V(t,t')]$ is also of Hilbert-Schmidt type.

(2) Here we prove the following result which was used in the proof of Lemma 2.12 in the main text (for notation see there): Let

$$f(x)=e^{-x}, \quad x^{-1}(e^x-1), \quad x^{-2}(e^x-1-x)$$

($x \in \mathbb{R}$). Then for all $\alpha=\alpha(t) \in O_0$ with $\alpha'=d\alpha/dt \in O_0$, the operators

$$a=f(\alpha), \quad \frac{d}{dt}f(\alpha)$$

all exist and

$$a_{(n)}=[|D_0|,a_{(n-1)}], \quad a_0=a$$

for $n=0,1,2,...$ all are bounded. Especially ab and ba are in O_{-l} for all $b \in O_{-l}$, $l=0,1,...$.

Proof: The functions $f(x)$ above all are analytic and have Taylor series with infinite radius of convergence,

$$f(x)=\sum_{\nu=0}^{\infty} c_\nu x^\nu, \quad \sum_{\nu=0}^{\infty} |c_\nu| x^\nu \equiv \tilde{f}(x),$$

thus

$$\|f(\alpha)_{(1)}\| = \|\sum_\nu c_\nu[|D_0|,\alpha^\nu]\| \leq \sum |c_\nu|\nu\|\alpha\|^{\nu-1}\|\alpha_{(1)}\| = \tilde{f}'(\|\alpha\|)\|\alpha_{(1)}\|,$$

and this argument can be easily extended to upper bound all $\|f(\alpha)_{(n)}\|$ by polynomials in $\tilde{f}^{(1\leq\nu\leq n)}(\|\alpha\|)$ (ν-th derivative) and $\|\alpha_{1\leq m\leq n}\|$. An efficient way to obtain these bounds is to use the generating functional for these repeated commutators,

$$e^{is|D_0|}\alpha e^{-is|D_0|} = \sum_{n=0}^{\infty} \frac{(is)^n}{n!}\alpha_{(n)},$$

i.e.

$$\|f(\alpha)_{(n)}\| = \left\| \frac{d^n}{d(is)^n} \epsilon^{is|D_0|} f(\alpha) \epsilon^{-is|D_0|} \right\|_{s=0}$$

$$= \left\| \frac{d^n}{d(is)^n} f(e^{is|D_0|} \alpha e^{-is|D_0|}) \right\|_{s=0} \leqslant \frac{d^n}{ds^n} \tilde{f}\left(\sum_{m=1}^{n} \frac{\|\alpha_{(m)}\| s^m}{m!} \right) \Bigg|_{s=0}.$$

Similarly,

$$F(\alpha,\alpha') \equiv \frac{d}{dt} f(\alpha) = \sum_{\nu=0}^{\infty} c_\nu \sum_{\mu=0}^{\nu-1} \alpha^{\nu-1-\mu} \alpha' \alpha^{\mu}$$

and

$$\|F(\alpha,\alpha')_{(n)}\| = \left\| \frac{d^n}{d(is)^n} F(e^{is|D_0|} \alpha e^{-is|D_0|}, e^{is|D_0|} \alpha' e^{-is|D_0|}) \right\|_{s=0}$$

$$\leqslant \frac{d^n}{ds^n} \tilde{f}'\left(\sum_{m=1}^{n} \frac{\alpha_{(m)}\| s^m}{m!} \right)\left(\sum_{m'=1}^{n} \frac{\|\alpha'_{(m')}\| s^{m'}}{m'!} \right) \Bigg|_{s=0}$$

which also is always finite by our assumption $\alpha,\alpha' \in O_0$.

If all repeated commutators $a_{(n)}$ of a with $|D_0|$ are bounded and $b \in O_{-l}$, then $ab, ba \in O_{-l}$ follows from the definition of O_{-l} and the ideal property of B_2.

APPENDIX C: PSEUDODIFFERTIAL OPERATORS (PSDO's)

To fix our notation we summarize here the basic definitions and facts about PSDO's.[10] A PSDO A on the Hilbert space $L^2(M^n) \oplus V$, with M^n a smooth manifold and V a finite-dimensional vector space, is given locally by its symbol $a(x,p) = \sigma(A)(x,p)$ which is a smooth matrix-$[gl(V,V)$-$]$ valued function of the local coordinates $x \in U \subset \mathbb{R}^n$ and momenta $p \in \mathbb{R}^n$.[10] The action of A on a section ψ with support in U is given as

$$(A\psi)(x) = \frac{1}{(2\pi)^{n/2}} \int a(x,p) \hat{\psi}(p) e^{-ip\cdot x} dp, \tag{C1}$$

where $\hat{\psi}$ is the Fourier transform of the function $\psi: U \to V$,

$$\hat{\psi}(p) = \frac{1}{(2\pi)^{n/2}} \int e^{ix\cdot p} \psi(x) dx. \tag{C2}$$

We shall consider the restricted class of PSDO's which admit an asymptotic expansion of the symbol as

$$a(x,p) \sim a_k(x,p) + a_{k-1}(x,p) + a_{k-2}(x,p) + \cdots,$$

where k is an integer and each a_j is a homogeneous matrix-valued function of the momenta, of order j, with $|a_j| \sim |p|^j$ as $\sqrt{p_1^2 + \ldots + p_n^2} = |p| \to \infty$. The order of such a PSDO is ord $a = k$.

The asymptotic expansion for the product of two PSDO's is given by the formula

$$a * b \sim \sum \frac{(-i)^{|m|}}{m!} [(\partial_p)^m a(x,p)][(\partial_x)^m b(x,p)], \tag{C3}$$

where the sum is over all sets of nonnegative integers $m=(m_1,\ldots,m_n)$, $|m|=m_1+\cdots+m_n$, $\partial_x^m = (\partial/\partial x_1)^{m_n}\cdots(\partial/\partial x_n)^{m_n}$, etc., and $m!=m_1!\cdots m_n!$.

The order of $a*b$ is equal to the sum of ord a+ord b since the leading term in $a*b$ is just the matrix product ab of the symbols.

The symbol of a massless Dirac operator D_A in an external vector potential A is $\gamma^k(p_k+A_k)$ where $\gamma_i\gamma_j+\gamma_j\gamma_i=g_{ij}$ are the Dirac gamma matrices and $g=(g_{ij})$ is the metric tensor. The symbol for the square D_A^2 is p^2+ lower order terms in p and therefore the symbol of $|D_A|$ is $|p|+$lower order terms. From this follows, using (C3), that the symbol of $[|D_A|,B]$ is $|p_k/|p|\partial/\partial x_k b(x,p)+$terms of order ord B for any PSDO B with symbol b. In particular, the order of $[|D_A|,B]$ is at most equal to the order of B.

On a compact manifold of dimension n a PSDO is of the trace class if its order is strictly less than $-n$ and it is of Hilbert-Schmidt type if the order is $<-n/2$. In $\mathbb{R}^n$ one has to assume in addition that the symbol is either compactly supported in x or at least the asymptotic behavior of the symbol and its derivatives at $|x|\to\infty$ is as $|x|^{-k}$, where $k>n$ in case of trace class operators and $k>n/2$ for Hilbert-Schmidt operators. In $\mathbb{R}^n$ the trace (when it exists) of a PSDO is simply given as

$$\mathrm{Tr}\, A=\frac{1}{(2\pi)^n}\int \mathrm{tr}\, a(x,p)dpdx. \tag{C4}$$

Quasi-exactly solvable potentials on the line and orthogonal polynomials

Federico Finkel, Artemio González-López, and Miguel A. Rodríguez
Departamento de Física Teórica II, Universidad Complutense, 28040 Madrid, Spain

(Received 21 March 1996; accepted for publication 15 April 1996)

In this paper we show that a quasi-exactly solvable (normalizable or periodic) one-dimensional Hamiltonian satisfying very mild conditions defines a family of weakly orthogonal polynomials which obey a three-term recursion relation. In particular, we prove that (normalizable) exactly solvable one-dimensional systems are characterized by the fact that their associated polynomials satisfy a two-term recursion relation. We study the properties of the family of weakly orthogonal polynomials defined by an arbitrary one-dimensional quasi-exactly solvable Hamiltonian, showing in particular that its associated Stieltjes measure is supported on a finite set. From this we deduce that the corresponding moment problem is determined, and that the kth moment grows like the kth power of a constant as k tends to infinity. We also show that the moments satisfy a constant coefficient linear difference equation, and that this property actually characterizes weakly orthogonal polynomial systems. © *1996 American Institute of Physics.* [S0022-2488(96)03108-8]

I. INTRODUCTION

In a recent paper,[1] Bender and Dunne introduced a remarkable family of orthogonal polynomials associated to the one-dimensional Hamiltonian

$$H=-\partial_x^2+\frac{(4s-1)(4s-3)}{4x^2}-(4s+4J-2)x^2+x^6, \tag{1}$$

where J is a positive integer and s is a real parameter. If $\psi_E(x)$ denotes an eigenfunction of H with energy E, the polynomials $P_k(E)$ in question are proportional to the coefficients in the expansion of $e^{x^4/4}x^{1/2-2s}\psi_E(x)$ in powers of x^2, namely

$$\psi_E(x)=e^{-x^4/4}x^{2s-1/2}\sum_{k=0}^{\infty}\frac{(-1)^k}{k!}\frac{P_k(E)}{\Gamma(k+2s)}\left(\frac{x^2}{4}\right)^k.$$

These polynomials are easily shown to satisfy a three-term recursion relation, from which it follows[2] that they are orthogonal with respect to a certain Stieltjes measure $d\omega(E)$ (ω being a function of bounded variation):

$$\int P_k(E)P_l(E)d\omega(E)=0, \quad k\neq l. \tag{2}$$

The form of the coefficients of the recursion relation satisfied by the polynomial system $\{P_k(E)\}_{k=0}^{\infty}$ implies that this system has several remarkable properties. First of all, the norm of the polynomials P_k with $k\geqslant J$ vanishes. Thus the polynomials P_k form what is called a *weakly orthogonal* polynomial system.[2] To be precise, we shall use from now on the term *orthogonal polynomial system* for a family of orthogonal polynomials $\{P_k(E)\}_{k=0}^{\infty}$ with $\deg P_k=k$ for all k, and such that the norm of P_k does not vanish for any k.

Second, each P_k with $k\geqslant J$ factors into the product of P_J and another polynomial, i.e.,

0022-2488/96/37(8)/3954/19/$10.00

$$P_{J+m}=P_J Q_m, \quad m\geq 0,$$

where Q_m has degree m. Finally, the J simple real zeros of P_J are eigenvalues of H whose corresponding eigenfunctions, being the product of the factor

$$\mu(x)=e^{-x^4/4}x^{2s-1/2}$$

times a polynomial in x^2, are square integrable. The existence of these exactly computable eigenfunctions and eigenvalues of H had been deduced before[3,4] from the fact that H is *quasi-exactly solvable*, meaning that it is an element of the enveloping algebra of a certain realization of $\mathfrak{sl}(2,\mathbb{R})$ in terms of first-order differential operators acting on a finite-dimensional subspace of the space of C^∞ functions (see the next section for more details). The above results strongly suggest[5] that there is a connection between quasi-exactly solvable Hamiltonians and certain families of weakly orthogonal polynomials. In this paper, we show in detail that this is indeed the case for all one-dimensional quasi-exactly solvable Hamiltonians, both normalizable and periodic, satisfying very general conditions.

The paper is organized as follows. Using the results on quasi-exact solvability reviewed in Sec. II, we explain in Sec. III how to construct the weakly orthogonal polynomial system associated to each of the normal forms of a one-dimensional quasi-exactly solvable Hamiltonian listed in Refs. 4 and 6. Like the polynomial system introduced in Ref. 1, this system always satisfies a three-term recursion relation, whose coefficients we explicitly compute. This allows us to prove that one-dimensional (normalizable) exactly solvable Hamiltonians are characterized by the fact that their associated polynomials satisfy a two-term recursion relation. In Sec. IV we show that the polynomials associated to an arbitrary one-dimensional quasi-exactly solvable Hamiltonian enjoy properties completely akin to those listed above for the Hamiltonian (1). We also study in this section the properties of the moment functional defined by the family of weakly orthogonal polynomials of a quasi-exactly solvable Hamiltonian, giving a rigorous proof of the fact that its associated Stieltjes measure is supported on a finite set,[5] so that the integral (2) reduces to a finite sum. From this we deduce that the associated (Hamburger or Stieltjes) moment problem is determined, and that the kth moment behaves like the kth power of a constant for large k, illustrating this statement with an explicit example for the Hamiltonian (1). We also show that the moments satisfy a constant coefficient linear difference equation, a property which in fact characterizes weakly orthogonal polynomial systems. The paper ends (Sec. V) with a brief review of these results, stressing the role played by weak orthogonality—as opposed to true orthogonality—in their derivation.

II. QUASI-EXACTLY SOLVABLE POTENTIALS

For the reader's convenience, we present in this section a summary of the major results in the theory of quasi-exactly solvable systems that we shall need in the sequel. A one-dimensional Schrödinger operator (or Hamiltonian) $H=-\partial_x^2+V(x)$ is *quasi-exactly solvable* if there exists a finite-dimensional Lie algebra of first-order differential operators

$$\mathfrak{g}=\mathrm{Span}\{\xi_a(x)\partial_x+\eta_a(x)\,|\,1\leq a\leq r\}\equiv\mathrm{Span}\{T_a(x)\,|\,1\leq a\leq r\}$$

such that

(i) $\mathfrak{g}$ leaves invariant a finite-dimensional module of smooth functions $\mathfrak{N}\subset C^\infty(\mathbb{R})$, i.e., $X\cdot f\in\mathfrak{N}$ for all $f\in\mathfrak{N}$ and all $X\in\mathfrak{g}$. In other words, $\mathfrak{g}$ admits a finite-dimensional representation in terms of smooth functions.

(ii) H is in the universal enveloping algebra of $\mathfrak{g}$, i.e., H can be expressed as a polynomial in the generators T_a, $1\leq a\leq r$, of $\mathfrak{g}$.

A Lie algebra of first-order differential operators satisfying (i) is called *quasi-exactly solvable*. A Hamiltonian H satisfying condition (ii) above for an arbitrary (not necessarily quasi-exactly solvable) Lie algebra $\mathfrak{g}$ is said to be *Lie algebraic*.

If H is quasi-exactly solvable, it follows that the restriction of H to $\mathfrak{N}$ is a finite-dimensional linear operator $\mathfrak{N}\to\mathfrak{N}$, and therefore the eigenfunctions of H lying in $\mathfrak{N}$ and their corresponding eigenvalues can be exactly computed by purely algebraic methods (diagonalizing a square matrix of order $\dim \mathfrak{N}$). We shall refer to these eigenfunctions of H lying in $\mathfrak{N}$ as its *algebraic eigenfunctions* (although, of course, they need not be algebraic functions in the technical sense of the word). The functions in $\mathfrak{N}$ need not *a priori* satisfy any boundary conditions (like square-integrability, periodicity, vanishing at the end points, etc.) coming from the physics of the problem, whose mathematical purpose is to guarantee that H is a self-adjoint operator. If they do, then the restriction of H to $\mathfrak{N}$ is self-adjoint, and therefore H has exactly $\dim \mathfrak{N}$ linearly independent algebraic eigenfunctions, whose corresponding $\dim \mathfrak{N}$ *real* eigenvalues (counting multiplicities) are exactly (i.e., algebraically) computable. We shall say in this case that the quasi-exactly solvable potential H (or the potential V) is *fully algebraic*. See Refs. 4 and 6 for an in-depth discussion of fully algebraic potentials under the boundary condition of square integrability on $\mathbb{R}$.

It can be shown (cf. Ref. 7) that a quasi-exactly solvable Schrödinger operator H can be expressed as a polynomial of degree at most two in the generators T_a, $1\leqslant a\leqslant r$, of $\mathfrak{g}$. Moreover, a well known theorem[3,8,7] asserts that every quasi-exactly solvable Lie algebra of first-order differential operators $\mathfrak{g}$ is related by a (local) change of variable

$$z=\zeta(x) \tag{3}$$

and a *gauge transformation* with gauge factor $\mu(z)>0$ to (a subalgebra of) one of the Lie algebras $\mathfrak{g}^n=\mathfrak{h}^n\oplus\mathbb{R}$, where $\mathfrak{h}^n=\mathrm{Span}\{J^n_-,J^n_0,J^n_+\}\approx\mathfrak{sl}(2,\mathbb{R})$,

$$J^n_-=\partial_z,\quad J^n_0=z\partial_z-\frac{n}{2},\quad J^n_+=z^2\partial_z-nz, \tag{4}$$

and n is a nonnegative integer. In other words, every element $X(x)\in\mathfrak{g}$ is of the form

$$X(x)=\mu(z)\cdot J(z)\cdot\left.\frac{1}{\mu(z)}\right|_{z=\zeta(x)},\quad J(z)\in\mathfrak{g}^n,$$

for some fixed n. This implies that the *gauge Hamiltonian*

$$H_{\text{gauge}}(z)=\left.\frac{1}{\mu(z)}\cdot H(x)\cdot\mu(z)\right|_{x=\zeta^{-1}(z)} \tag{5}$$

is also a polynomial of degree at most two in the generators J^n_ϵ, i.e., (dropping the explicit n dependence in the generators J^n_ϵ)

$$-H_{\text{gauge}}=\sum_{a,b}c_{ab}J_aJ_b+\sum_a c_aJ_a+c_*, \tag{6}$$

for some real constants c_*, c_a, and $c_{ab}=c_{ba}$ (the minus sign is for later convenience). The spectral problems of H and H_{gauge} are related in an obvious way: indeed, from (5) it follows that if $\chi(z)$ is an eigenfunction of H_{gauge} with eigenvalue E then

$$\psi(x)=\mu(z)\chi(z)|_{z=\zeta(x)} \tag{7}$$

will be an eigenfunction of H with the same eigenvalue (not taking into account the boundary conditions). Since the Lie algebra $\mathfrak{g}^n$ admits as invariant module the space $\mathscr{P}_n$ of real polynomials of degree at most n in z, if H is fully algebraic then H_{gauge} has $n+1$ linearly independent algebraic eigenfunctions lying in $\mathscr{P}_n$. Hence H has $n+1$ linearly independent algebraic eigenfunctions of the form (7), with $\chi \in \mathscr{P}_n$ a polynomial of degree at most n.

From (4) and (6) it follows[4] that the gauge Hamiltonian is of the form

$$-H_{\text{gauge}} = P(z)\partial_z^2 + \left\{ Q(z) - \frac{n-1}{2} P'(z) \right\} \partial_z + \left\{ R - \frac{n}{2} Q'(z) + \frac{n(n-1)}{12} P''(z) \right\}, \tag{8}$$

where P, Q, and R are polynomials of degrees 4, 2, and 0, respectively, given by

$$P(z) = c_{++}z^4 + 2c_{+0}z^3 + c_{00}z^2 + 2c_{0-}z + c_{--}, \tag{9}$$

$$Q(z) = c_+ z^2 + c_0 z + c_-, \tag{10}$$

$$R = \frac{n(n+2)}{12} c_{00} + c_*. \tag{11}$$

Note that, due to the Casimir relation

$$J_0^2 - \frac{1}{2}(J_+J_- + J_-J_+) = \frac{n}{4}(n+2),$$

we have set, without loss of generality, $c_{+-}=0$. There are also explicit formulas for the change of variables (3) and gauge factor $\mu(z)$ needed to put the differential operator (8) in Schrödinger form, cf. Ref. 4. Indeed, assuming that $P(z)>0$ on an interval I then for $z \in I$ we have

$$x = \zeta^{-1}(z) = \int^z \frac{dy}{\sqrt{P(y)}}, \quad \mu(z) = P(z)^{-n/4} \exp\left\{ \int^z \frac{Q(y)}{2P(y)}\, dy \right\} \tag{12}$$

and

$$V(x) = -R + \left. \frac{-n(n+2)(PP'' - \frac{3}{4}P'^2) - 3(n+1)(QP' - 2PQ') + 3Q^2}{12P} \right|_{z=\zeta(x)}, \tag{13}$$

where the primes denote derivatives with respect to z.

The canonical form (8) of the quasi-exactly solvable Hamiltonian H is not unique, since there is a residual symmetry group preserving the Lie algebra $\mathfrak{h}^n$, given by the adjoint action on $\mathfrak{h}^n$ of the Lie group of transformations generated by $\mathfrak{g}^n = \mathfrak{h}^n \oplus \mathbb{R}$. More precisely, the elements of $\mathfrak{g}^n$ are the infinitesimal generators of the standard GL(2,$\mathbb{R}$) action on the space $\mathscr{P}_n$, given by

$$p(z) \in \mathscr{P}_n \mapsto \hat{p}(w) = (\gamma w + \delta)^n p\left(\frac{\alpha w + \beta}{\gamma w + \delta} \right), \quad \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \in GL(2,\mathbb{R}). \tag{14}$$

We shall denote, as is customary, by ρ_n this (irreducible) multiplier representation of GL(2,$\mathbb{R}$) on $\mathscr{P}_n$. Note that the action (14) is just the composition of the projective transformation

$$z = \frac{\alpha w + \beta}{\gamma w + \delta}$$

and the gauge transformation with gauge factor $\mu(w)=(\gamma w+\delta)^n$. The adjoint action of $\mathrm{GL}(2,\mathbb{R})$ on $\mathfrak{h}^n$ induced by (14) is given by

$$J(z)\mapsto\hat{J}(w)=(\gamma w+\delta)^n\cdot J\left(\frac{\alpha w+\beta}{\gamma w+\delta}\right)\cdot(\gamma w+\delta)^{-n}. \tag{15}$$

A straightforward calculation[4] shows that the generators of $\mathfrak{h}^n$ transform under the representation $\rho_{2,-1}$—where $\rho_{n,i}=\rho_n\otimes\det^i$, $\det{:}A\mapsto\det A$ being the standard determinantal representation—independently of n. As a consequence of all this, the transformed differential operator

$$\hat{H}_{\text{gauge}}=(\gamma w+\delta)^n\cdot H_{\text{gauge}}\left(\frac{\alpha w+\beta}{\gamma w+\delta}\right)\cdot(\gamma w+\delta)^{-n} \tag{16}$$

is still of the form (8), with P, Q, and R replaced by appropriate polynomials $\hat{P}$, $\hat{Q}$, and $\hat{R}$ of respective degrees 4, 2, and 0. It can be shown, cf. Ref. 4, that $\hat{R}=R$ and

$$\hat{P}(w)=\frac{(\gamma w+\delta)^4}{\Delta^2}P\left(\frac{\alpha w+\beta}{\gamma w+\delta}\right),\quad \hat{Q}(w)=\frac{(\gamma w+\delta)^2}{\Delta}Q\left(\frac{\alpha w+\beta}{\gamma w+\delta}\right), \tag{17}$$

with

$$\Delta=\det\begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix}.$$

Hence the polynomials P, Q, and R determining the differential operator H_{gauge} transform under the representations $\rho_{4,-2}$, $\rho_{2,-1}$, and ρ_0 of $\mathrm{GL}(2,\mathbb{R})$. Furthermore, the algebraic eigenfunctions of H_{gauge} clearly transform under the representation ρ_n; indeed, if $\chi(z)$ is an eigenfunction of H_{gauge} with eigenvalue E then it follows from (16) that

$$\hat{\chi}(w)=(\gamma w+\delta)^n\cdot\chi\left(\frac{\alpha w+\beta}{\gamma w+\delta}\right) \tag{18}$$

is an eigenfunction of $\hat{H}_{\text{gauge}}$ with the same eigenvalue.

In Refs. 6 and 4, the form invariance of the differential operator H_{gauge} under the $\mathrm{GL}(2,\mathbb{R})$ action (16) described above was exploited to place H_{gauge} in canonical form. Indeed, it can be shown that there are ten inequivalent real normal forms for a (nonzero) fourth-degree polynomial P (Ref. 9) transforming under the representation $\rho_{4,-2}$ of $\mathrm{GL}(2,\mathbb{R})$, each of which leads to a canonical form for H_{gauge}. Of these ten canonical forms, five correspond to *normalizable* Hamiltonians, whose algebraic eigenfunctions are square integrable (provided the coefficients c_{ab} and c_a satisfy certain inequalities), and the remaining are associated to Hamiltonians with periodic potentials. The five normal forms associated to normalizable Hamiltonians, which are characterized by the fact that P has at least one multiple root on the real projective line $\mathbb{RP}$, are given by

$$\begin{aligned}&1.\ \nu(z^2+1),\\ &2.\ \nu(z^2-1),\\ &3.\ \nu z^2,\\ &4.\ z,\\ &5.\ 1,\end{aligned} \tag{19}$$

where $\nu>0$ is a real parameter. For example, the quasi-exactly solvable potential discussed in Ref. 1 corresponds to the fourth normalizable canonical form $P(z)=z$. The remaining normal forms, corresponding to periodic potentials, are

$$\begin{aligned} &6.\ \nu(1-z^2)(1-\kappa^2 z^2),\\ &7.\ \nu(1-z^2)(1-\kappa^2(1-z^2)),\\ &8.\ \nu(1+z^2)(1+(1-\kappa^2)z^2),\\ &9.\ \nu(1+z^2)^2,\\ &10.\ \nu(1-z^2), \end{aligned} \tag{20}$$

where $\nu>0$, $0<\kappa<1$.

III. THE RECURSION RELATION

Let $H=-\partial_x^2+V(x)$ be a quasi-exactly solvable Hamiltonian. From the previous section, we know that there is a change of variable (3) and gauge factor $\mu(z)>0$ such that $H(x)=\mu(z)\cdot H_{\text{gauge}}(z)\cdot[1/\mu(z)]\big|_{z=\zeta(x)}$, with H_{gauge} given by (6) (and $c_{+-}=0$). Furthermore, if H is fully algebraic then it has $n+1$ algebraic eigenfunctions of the form (7), with $\chi(z)\in\mathscr{P}_n$ an eigenfunction of H_{gauge}. Let $\chi_E(z)$ be an eigenfunction of H_{gauge} with eigenvalue E (not necessarily a polynomial in z). Writing

$$\chi_E(z)=\sum_{k=0}^{\infty} P_k(E)\chi_k(z), \tag{21}$$

where

$$\chi_k(z)=\frac{z^k}{k!},\quad k\geq 0,$$

and taking into account that

$$J_-\cdot\chi_k=\chi_{k-1},\quad J_0\cdot\chi_k=\left(k-\frac{n}{2}\right)\chi_k,\quad J_+\cdot\chi_k=(k-n)(k+1)\chi_{k+1}, \tag{22}$$

cf. (4), we easily find that the coefficients $P_k(E)$ satisfy the following five-term recursion relation:

$$\begin{aligned} -c_{--}P_{k+2}=&[(2k-n+1)c_{0-}+c_-]P_{k+1}+\left[E+c_*+c_0\left(k-\frac{n}{2}\right)+c_{00}\left(k-\frac{n}{2}\right)^2\right]P_k+k(k-1-n)\\ &\times[(2k-n-1)c_{+0}+c_+]P_{k-1}+k(k-1)(k-1-n)(k-2-n)c_{++}P_{k-2},\quad k\geq 0. \end{aligned} \tag{23}$$

If $c_{--}\neq 0$, the general solution of the recursion relation (23) depends on the two arbitrary functions $P_0(E)$ and $P_1(E)$. This simply reflects the fact that when $c_{--}\neq 0$ the leading coefficient $P(z)$ of H_{gauge} does not vanish at $z=0$ [cf. (9)]; thus, the differential equation $(H_{\text{gauge}}-E)\chi_E=0$ has a regular point at the origin, and therefore it admits two linearly independent solutions (21) analytic at 0. If $P_0(E)$ and $P_1(E)$ are chosen to be polynomials in E, then (23) implies that all the coefficients $P_k(E)$ are polynomials in E. However, the general recursion relation (23) suffers from two major drawbacks. In the first place, even if we choose $P_0(E)$ and $P_1(E)$ as polynomials of

degree 0 and 1 in E, respectively, (23) is incompatible with the desirable property that $P_k(E)$ be of degree k in E for all k, unless $c_{--}=0$. Second, even in this case (23) will be in general a four-term recursion relation, implying that the polynomials $P_k(E)$ may not be orthogonal with respect to any (nonzero) Stieltjes measure $d\omega(E)$. Indeed, it is well known,[2,10] that a necessary and sufficient condition for a family of polynomials $\{P_k\}_{k=0}^{\infty}$ (with deg $P_k=k$) to form an orthogonal polynomial system is that $P_k(E)$ satisfies a *three*-term recursion relation of the form

$$P_k=(A_kE+B_k)P_{k-1}+C_kP_{k-2}, \quad k\geq 1, \tag{24}$$

where the coefficients A_k, B_k, C_k are *independent* of E, $A_k\neq 0$, $C_1=0$, and $C_k\neq 0$ for $k>1$. If the coefficient C_k in (24) vanishes for some positive integer k, then this recursion relation only defines a *weakly* orthogonal polynomial system.[11] It is one of the main goals of this paper to show that both difficulties described above can always be overcome, provided (roughly speaking) that we expand the eigenfunction χ_E with respect to an appropriate variable. This will be achieved by using the nonuniqueness of H_{gauge}, due to the GL(2) symmetry described in the previous section, to place H_{gauge} in a suitable canonical form.

From the form of the recursion relation (23), it follows that both difficulties described above disappear if

$$c_{--}=c_{++}=0. \tag{25}$$

Indeed, if (25) holds then (23) reduces to the three-term recursion relation

$$-[(2k-n-1)c_{0-}+c_-]P_k=\left[E+c_*+c_0\left(k-\frac{n}{2}-1\right)+c_{00}\left(k-\frac{n}{2}-1\right)^2\right]P_{k-1}+(k-1)\times(k-2-n)[(2k-n-3)c_{+0}+c_+]P_{k-2}, \quad k\geq 1, \tag{26}$$

which uniquely determines all the functions $P_k(E)$ in terms of $P_0(E)$ provided that, for all positive integer values of k, the coefficient of the left-hand side of (26) does not vanish. If $P_0(E)$ is taken as a constant, for instance if $P_0(E)=1$, then (26) implies that $P_k(E)$ is a polynomial of degree k in E for all $k\geq 0$.

Let us see now that we can always arrange for (25) to be satisfied, by using the action (17) to transform $P(z)$ into a normal form $\hat{P}(w)$ for which (25) holds. Indeed, (25) simply states that the polynomial $P(z)$ vanishes at $z=0$ and $z=\infty$, when z is allowed to vary over the complex projective line $\mathbb{CP}$. Note that we need z to belong to the *complex* projective line at this stage so that P is guaranteed to have a root, which is essential for the argument that follows. Consequently, the GL(2,$\mathbb{R}$) action described in the previous section will be replaced in what follows by a GL(2,$\mathbb{C}$) action.

We can assume, first of all, that $P(z)$ is one of the normal forms listed in Eqs. (19) and (20). We must distinguish three cases, characterized by the position of the roots of P in the complex projective line. Indeed, either P has two different roots $z_1\neq z_2$ in $\mathbb{CP}$, or it has four coincident roots. In the first case, either one of the roots is at infinity, or both roots are finite.

A. Case 1: P has two different roots $z_1\neq z_2=\infty$

This case occurs when P is one of the first four normalizable canonical forms (19), or the fifth periodic canonical form (20). In this case, the translation $w=z-z_1$ transforms $P(z)$ into a polynomial $\hat{P}(w)$ vanishing at zero and infinity. In the original z coordinate, by (18) this amounts to replacing (21) by

$$\chi_E(z)=\sum_{k=0}^{\infty}P_k(E)\frac{(z-z_1)^k}{k!}. \tag{27}$$

In other words, we expand $\chi_E(z)$ as a power series around the point $z=z_1$, which is a singular point of the linear differential equation $(H_{\text{gauge}}-E)\chi_E=0$ (if z_1 is a simple root of P, z_1 is actually a regular singular point, whose indicial equation is easily seen to have 0 as a root). By (7), in the "physical" coordinate x (27) becomes

$$\psi_E(x)=\mu(\zeta(x))\sum_{k=0}^{\infty} P_k(E)\,\frac{(\zeta(x)-z_1)^k}{k!} \tag{28}$$

B. Case 2: P has two different finite roots $z_1 \neq z_2$

This is the case when P is one of the first four periodic normal forms (20). The projective transformation $w=(z-z_1)/(z-z_2)$ will again transform $P(z)$ into a polynomial $\hat{P}(w)$ vanishing at $w=0, \infty$. Going back to the original z coordinate, by (18) we just have to replace (21) by

$$\chi_E(z)=(z-z_2)^n\sum_{k=0}^{\infty}\frac{1}{k!}P_k(E)\left(\frac{z-z_1}{z-z_2}\right)^k, \tag{29}$$

apart from an inessential overall factor. In terms of the physical coordinate x, (29) can be written as

$$\psi_E(x)=\mu(\zeta(x))(\zeta(x)-z_2)^n\sum_{k=0}^{\infty}\frac{1}{k!}P_k(E)\left(\frac{\zeta(x)-z_1}{\zeta(x)-z_2}\right)^k. \tag{30}$$

C. Case 3: P has a quadruple root

This corresponds to the fifth normalizable canonical form, $P=1$, which has a quadruple root at infinity. Note that $P=1$ implies that the physical coordinate x can be taken as the canonical coordinate z. By (9), we have

$$c_{++}=c_{+0}=c_{00}=c_{0-}=0, \quad c_{--}=1.$$

Performing an additional translation, if necessary, we can also take without loss of generality $c_-=Q(0)=0$ (notice that P is constant, and therefore does not change under translations). Thus Eq. (23) reduces in this case to

$$-P_{k+2}=\left[E+c_*+c_0\left(k-\frac{n}{2}\right)\right]P_k+k(k-1-n)c_+P_{k-1}, \quad k\geq 0. \tag{31}$$

Since $P=1$ is the fifth normalizable case of Refs. 4 and 6, c_+ must vanish if we want H to be *normalizable*, i.e., the algebraic eigenfunctions of H to be square integrable. Therefore, in this case (31) reduces to

$$-P_{k+2}=\left[E+c_*+c_0\left(k-\frac{n}{2}\right)\right]P_k, \quad k\geq 0,$$

which is equivalent to two two-term recursion relations for the even and odd coefficients $P_j^0=P_{2j}$ and $P_j^1=P_{2j+1}$, namely

$$-P_{j+1}^{\epsilon}=\left[E+c_*+c_0\left(2j+\epsilon-\frac{n}{2}\right)\right]P_j^{\epsilon}, \quad j\geq 0; \quad \epsilon=0,1. \tag{32}$$

Note that in this case the potential is $V(x)=1/4c_0^2x^2-c_*$ (with $c_0<0$), cf. Ref. 4.

To complete the discussion of cases 1 and 2, we still have to deal with an important technical issue; namely, we must find under what conditions the coefficient of P_k in (26) never vanishes for positive integer values of k. Let $\hat{P}$ and $\hat{Q}$ be the transforms of P and Q under the projective transformation $z \mapsto w$ defined in the foregoing discussion of cases 1 and 2; note that, by construction, $\hat{P}(w)$ vanishes at $w=0, \infty$. The coefficient of interest can be expressed as

$$(2k-n-1)\hat{c}_{0-}+\hat{c}_{-}, \quad k \geq 1, \tag{33}$$

where

$$\hat{c}_{0-}=\tfrac{1}{2}\hat{P}'(0), \quad \hat{c}_{-}=\hat{Q}(0).$$

From (17) it easily follows that

$$\hat{c}_{0-}=\tfrac{1}{2}P'(z_1), \quad \hat{c}_{-}=Q(z_1), \tag{34}$$

for case 1 ($w=z-z_1$), and

$$\hat{c}_{0-}=\frac{P'(z_1)}{2(z_1-z_2)}, \quad \hat{c}_{-}=\frac{Q(z_1)}{z_1-z_2}, \tag{35}$$

for case 2 ($w=(z-z_1)/(z-z_2)$). We shall now distinguish three subcases:

1. Case i. z_1 is a simple real root of P

This case occurs when P is one of the canonical forms 2, 4, 6, 7, or 10. Note that in this case the mapping $z \mapsto w$ is real, and so are the coefficients $\hat{c}_{0-}$, $\hat{c}_{-}$. From (12) and (34)–(35) it is immediate to deduce the asymptotic formulas

$$x \underset{z \to z_1}{\sim} |z-z_1|^{1/2}, \quad \mu(z) \underset{z \to z_1}{\sim} |z-z_1|^{1/4(\hat{c}_{-}/c_{0-}-n)},$$

where we have dropped unessential constant multiplicative factors from the right-hand side, and have taken for convenience z_1 as the lower limit of the integral giving x in terms of z. We saw in the previous section that when H is fully algebraic it has $n+1$ linearly independent algebraic eigenfunctions of the form (7), where $\chi \in \mathscr{P}_n$. It follows that the polynomial factor $\chi(z)$ cannot vanish at the origin for all the algebraic eigenfunctions of H. Hence there is at least one algebraic eigenfunction of H whose asymptotic behavior at $x=0$ is given by

$$\psi(x) \underset{x \to 0}{\sim} |x|^{1/2(\hat{c}_{-}/\hat{c}_{0-}-n)}.$$

If *all* the algebraic eigenfunctions of H are regular at $x=0$, then we must have

$$\hat{c}_{-}/\hat{c}_{0-}-n \geq 0. \tag{36}$$

Since (33) can be written as

$$2\hat{c}_{0-}\left[\frac{1}{2}\left(\frac{\hat{c}_{-}}{\hat{c}_{0-}}-n\right)+\left(k-\frac{1}{2}\right)\right],$$

it follows from (36) that the coefficient (33) cannot vanish in this case.

2. Case ii. z_1 is a simple complex root of P

In this case P is either the first or the eighth canonical form. Since z_1 is not real, the mapping $z \mapsto w$ is not real either, and the above asymptotic argument is not valid (the eigenfunctions of H need not be regular outside the real axis). For the first canonical form (19), we can take $w=z-i$ and therefore

$$\hat{c}_{0-}=i\nu, \quad \hat{c}_{-}=c_{-}-c_{+}+ic_0$$

from (34). Hence the coefficient (33) does not vanish in this case provided that the following conditions are satisfied:

$$c_{-}\neq c_{+} \quad \text{or} \quad \frac{1}{2}\left(n+1-\frac{c_0}{\nu}\right)\neq 1,2,\ldots . \tag{37}$$

It is easily checked that the choice $w=z+i$ leads exactly to the same conditions. For the eighth canonical form, we can take $w=(z-i)/(z+i)$, and therefore, from (35),

$$\hat{c}_{0-}=\frac{1}{2}\nu\kappa^2, \quad \hat{c}_{-}=\frac{c_0}{2}+\frac{i}{2}(c_{+}-c_{-}).$$

Hence in this case the conditions for the coefficient (33) not to vanish are

$$c_{-}\neq c_{+} \quad \text{or} \quad \frac{1}{2}\left(n+1-\frac{c_0}{\nu\kappa^2}\right)\neq 1,2,\ldots . \tag{38}$$

It is straightforward to check that the choice $w=(z+i)/(z-i)$ yields the same conditions, while the other natural choice $w=(\sqrt{1-\kappa^2}z\mp i)/(\sqrt{1-\kappa^2}z\pm i)$ only has the effect of replacing the first condition (38) by $c_{+}\neq(1-\kappa^2)c_{-}$.

3. Case iii. z_1 is a multiple root of P

This case takes place when P is either the third or the ninth canonical form, and in both cases (33) reduces to $\hat{c}_{-}$. For the third canonical form (19), if $c_{-}\neq 0$ then we take $w=z$, and therefore $\hat{c}_{-}=c_{-}\neq 0$. If $c_{-}=0$, then $c_{+}\neq 0$ if all the algebraic eigenfunctions of H are square integrable (see Ref. 4). Hence, taking $w=1/z$, we get $\hat{P}(w)=\nu w^2$ and $\hat{Q}=-(c_{+}+c_0 w)$, so that $\hat{c}_{0-}=0$ and $\hat{c}_{-}=-c_{+}\neq 0$. Hence the coefficient (33) cannot vanish in this case. Finally, if P is the ninth canonical form (20) then $w=(z-i)/(z+i)$ and

$$\hat{c}_{-}=\frac{c_0}{2}+\frac{i}{2}(c_{+}-c_{-}).$$

Hence (33) will not vanish if

$$c_{+}\neq c_{-} \quad \text{or} \quad c_0\neq 0. \tag{39}$$

Note that when (39) does not hold V reduces to a constant potential:

$$V=\frac{c_{-}^2}{4\nu}-\frac{5}{12}n(n+2)-c_{*}.$$

In summary, the previous analysis shows that the critical coefficient (33) cannot vanish for any positive integer k provided that V is fully algebraic, that all its algebraic eigenfunctions are

regular [or square integrable, for the third normalizable canonical form (19)], and that conditions (37), (38), and (39) are satisfied when P is one of the normal forms 1, 8, or 9, respectively. If (33) does not vanish, defining new polynomials $\hat{P}_k$ by

$$P_k=\begin{cases}\dfrac{(-1)^k}{(2\hat{c}_{0-})^k}\dfrac{\hat{P}_k}{\Gamma\left(\dfrac{\hat{c}_-}{2\hat{c}_{0-}}+k-\dfrac{n}{2}+\dfrac{1}{2}\right)}, & \text{if } \hat{c}_{0-}\neq 0;\\ \dfrac{(-1)^k}{\hat{c}_-^k}\hat{P}_k, & \text{if } \hat{c}_{0-}=0\end{cases} \tag{40}$$

the recursion relation (26) can be written in the more standard form

$$\hat{P}_{k+1}=\left[E+c_*+\hat{c}_0\left(k-\frac{n}{2}\right)+\hat{c}_{00}\left(k-\frac{n}{2}\right)^2\right]\hat{P}_k-k(k-n-1)[\hat{c}_{+0}(2k-n-1)+\hat{c}_+]$$
$$\times[\hat{c}_{0-}(2k-n-1)+\hat{c}_-]\hat{P}_{k-1},\quad k\geq 0. \tag{41}$$

We have thus proved the main theorem in this section.

Theorem 1: Let V be a fully algebraic one-dimensional quasi-exactly solvable potential whose algebraic eigenfunctions are all regular [or normalizable, if V corresponds to the third or fifth canonical forms in (19)]. Assume, furthermore, that conditions (37), (38), or (39) are satisfied, if V is obtained from the first, eighth, or ninth canonical forms (19)–(20), respectively. Then V defines a family of weakly orthogonal polynomials $\{\hat{P}_k\}_{k=0}^{\infty}$ satisfying a three-term recursion relation (41) [or (32), if V corresponds to the fifth canonical form]. The polynomials $\hat{P}_k$ are defined by (40) and (28), if V is associated to one of the canonical forms 1–4 or 10, or by (40) and (30), if V corresponds to one of the normal forms 6–9. Finally, the potential V associated to the fifth canonical form defines two families of weakly orthogonal polynomials $P_j^0=P_{2j}$ and $P_j^1=P_{2j+1}$ through (28).

We shall say that a quasi-exactly solvable potential V is *exactly solvable* if it is independent of the "spin" parameter n. This implies that V has n algebraic eigenvalues and eigenfunctions for arbitrary $n\in\mathbb{N}$, so that we can algebraically compute an infinite number of eigenvalues of V (leaving aside the boundary conditions). All exactly solvable normalizable one-dimensional potentials have been classified; see Ref. 4 for a complete list. The quintessential example of exactly solvable one-dimensional potential is the harmonic oscillator potential, which corresponds to the fifth canonical form (19). We have seen in the previous section that in this case there are two families of orthogonal polynomials [the odd and even coefficients in (28)], each of which satisfies a two-term recursion relation (32). We shall now show that, as conjectured in Ref. 1, the latter property actually characterizes exactly solvable normalizable potentials:

Theorem 2: The weakly orthogonal polynomial system associated to an exactly solvable normalizable potential satisfies a two-term recursion relation.

Proof: The proof is a simple case-by-case analysis using the classification of exactly solvable normalizable potentials given in Ref. 4. Indeed, for the first normalizable canonical form $P(z)=\nu(z^2+1)$ we have $w=z\mp i$, and therefore $\hat{P}(w)=P(w\pm i)=\nu w(w\pm 2i)$, so that $\hat{c}_{+0}=0$. Since $\hat{Q}(w)=Q(w\pm i)$, we also have $\hat{c}_+=\hat{Q}''(0)/2=Q''(\pm i)/2=c_+$. But the exactly solvable potentials associated to this normal form are characterized by the vanishing of c_+, Ref. 4, so that $\hat{c}_+=\hat{c}_{+0}=0$, and (41) is a two-term recursion relation. Similarly, for the second normalizable canonical form, $P(z)=\nu(z^2-1)$ and, for instance, $w=z\mp 1$. Proceeding as before we obtain that $\hat{c}_{+0}=0$ and $\hat{c}_+=c_+$. Since exactly solvable potentials are again those satisfying the condition $c_+=0$, (41) reduces to a two-term recursion relation.

The third normalizable canonical form has $P(z)=\nu z^2$, and therefore $c_{+0}=c_{0-}=0$. The exactly solvable potentials are characterized by the vanishing of the coefficients c_+ or c_-, but not

both simultaneously. In the former case we can take $w=z$, while in the latter w is proportional to $1/z$ [see the foregoing discussion on the vanishing of the critical coefficient (33)]. In either case, the coefficient of P_{k-1} in (41) vanishes identically.

The fourth normalizable canonical form is given by $P(z)=z$, so that $w=z$ and $\hat{c}_{+0}=c_{+0}=0$, and its exactly solvable potentials are defined by the vanishing of the coefficient $c_+=\hat{c}_+=0$, so that (41) is two term. Finally, for the fifth normalizable canonical form $P(z)=1$ all normalizable potentials are automatically exactly solvable (they are translates of the harmonic oscillator), and we have already seen that its associated orthogonal polynomials satisfy the two-term recursion relations (32). Q.E.D.

IV. THE ORTHOGONAL POLYNOMIALS

We shall study in this section the properties of the family of weakly orthogonal polynomials associated to a quasi-exactly solvable one-dimensional Hamiltonian in the manner described in the previous section. Since, as we shall see, these properties can be established directly from the recursion relation (41) or (32), these polynomials have basically the same properties as those studied by Bender and Dunne in Ref. 1.

We have seen in the previous section that the polynomials $\hat{P}(E)$ defined by a quasi-exactly solvable one-dimensional Hamiltonian satisfy a three-term recursion relation of the form

$$\hat{P}_{k+1}=(E-b_k)\hat{P}_k-a_k\hat{P}_{k-1}, \quad k\geq 0, \tag{42}$$

with $a_0=0$ and

$$a_{n+1}=0. \tag{43}$$

For the fifth canonical form, the polynomials $(-1)^k P_k^0$ and $(-1)^k P_k^1$ also satisfy a recursion relation of the form (42), with $a_k=0$ for all $k\geq 0$. Note that the coefficients a_k, b_k in (42) are guaranteed to be real only for the canonical forms 2–7 and 10 (for which P has a real root). As remarked in the previous section, the vanishing of a_k for a positive integer value of k means that the polynomials $\hat{P}_k$ are only weakly orthogonal. In particular, many classical results, based on the fact that $a_k>0$ (or sometimes $a_k\geq 0$) for $k\geq 1$ cannot be applied in our case.

By Favard's theorem, Ref. 2, there is a *moment functional*, that is a linear functional $\mathscr{L}$ acting in the space $\mathbb{C}[E]$ of (complex) univariate polynomials, such that the polynomials $\hat{P}_k$ are orthogonal under $\mathscr{L}$:

$$\mathscr{L}(\hat{P}_k\hat{P}_l)=\gamma_k\delta_{kl}, \quad k,l\in\mathbb{N}. \tag{44}$$

The functional $\mathscr{L}$ is unique if we impose the normalization condition $\mathscr{L}(\hat{P}_0)=\mathscr{L}(1)=1$. It is also known (Boas's theorem[2]) that there is a (not necessarily unique) function of bounded variation ω such that

$$\mathscr{L}(p)=\int_{-\infty}^{\infty} p(E)\,d\omega(E) \tag{45}$$

for an arbitrary polynomial p. The coefficient $\gamma_k=\mathscr{L}(\hat{P}_k^2)$, which therefore plays the role of the square of the norm of $\hat{P}_k$, can be computed by multiplying (42) by $\hat{P}_{k-1}$ and taking $\mathscr{L}$ of both sides, obtaining

$$0=\gamma_k-a_k\gamma_{k-1}, \quad k\geq 1.$$

Taking into account that $\gamma_0=\mathscr{L}(1)=1$ we get

$$\gamma_k=\prod_{j=1}^{k} a_j, \quad k\geq 1. \tag{46}$$

In particular, from this formula follows one of the key properties of the weakly orthogonal polynomial system associated to a one-dimensional quasi-exactly solvable Hamiltonian. Namely, from (43) we have

$$\gamma_k=0, \quad k\geq n+1,$$

so that *all the polynomials* $\hat{P}_k$ *with* $k\geq n+1$ *have zero norm.* From this formula it also follows that the "squared norms" γ_k will be positive for $k\leq n$ if and only if $a_k>0$ for $1\leq k\leq n$. It can be shown by a straightforward computation that this is always the case when P is one of canonical forms 2–4 in (19), assuming that all the eigenfunctions of H are square integrable and that H is *not* exactly solvable. Note also that when H is normalizable [canonical forms 1–5 in (19)] and exactly solvable then $a_k=0$ for all $k\geq 0$. Hence the square norms of all the polynomials $\hat{P}_k$ vanish, from which it easily follows from (42) that $\mathscr{L}=\delta(E-b_0)$.

Other important properties of the polynomials $\hat{P}_k$ concern their zeros. Classically,[2] it can be shown that if $a_k>0$ for all $k\in\mathbb{N}$ then the zeros of the polynomials $\hat{P}_k$ satisfying a three-term recursion relation (42) are real and simple. In our case the condition $a_k>0$ for all $k\in\mathbb{N}$ can never hold on account of (43). However, if H is fully algebraic it can still be proved that all the zeros of $\hat{P}_{n+1}$ are real and simple. Indeed, by hypothesis H is self-adjoint on the space $\mathfrak{N}$ of functions of the form (7), with $\chi\in\mathscr{P}_n$. Hence H has $n+1$ linearly independent algebraic eigenfunctions lying in $\mathfrak{N}$, whose corresponding eigenvalues are real (by self-adjointness) and distinct (H being a one-dimensional Sturm–Liouville operator). Let us denote by $E_0<E_1<\ldots<E_n$ these $n+1$ real eigenvalues of H on $\mathfrak{N}$, and by $\psi_l(x)\equiv\psi_{E_l}(x)$ the eigenfunction corresponding to the eigenvalue E_l. Then (7) and either (28) or (30) imply that $P_k(E_l)=0$, or equivalently $\hat{P}_k(E_l)=0$, for $k\geq n+1$ and $0\leq l\leq n$. In particular, since $\hat{P}_{n+1}$ is of degree $n+1$ and all the eigenvalues E_l are different, it follows that

$$\hat{P}_{n+1}(E)=\prod_{l=0}^{n}(E-E_l), \tag{47}$$

where we have used (42) and the fact that $\hat{P}_0=1$. In other words, $\hat{P}_{n+1}$ *has* $n+1$ *simple real zeros at the* $n+1$ *algebraic eigenvalues of* H. Furthermore, from the fact that $\hat{P}_k$ vanishes at E_l for $k\geq n+1$ we conclude that there exist monic polynomials Q_k of degree k such that

$$\hat{P}_{k+n+1}=Q_k\hat{P}_{n+1}, \quad k\geq 0. \tag{48}$$

This is the so called *factorization property* of the polynomial system $\{\hat{P}_k\}_{k\in\mathbb{N}}$, cf. Ref. 1. Note that the vanishing of $\hat{P}_k(E_l)$ for all $k\geq n+1$ is consistent with the recursion relation on account of (43). In fact, when a_k is positive for $k\geq 1$ and b_k is real for $k\geq 0$, (47) follows directly from the recursion relation by Lemma 3, without using the fact that the polynomials $\hat{P}_k$ are associated to a fully algebraic quasi-exactly solvable one-dimensional Hamiltonian. The vanishing of $\hat{P}_k(E_l)$ for $k>n+1$ is then an immediate consequence of $\hat{P}_{n+1}(E_l)=0$, the recursion relation (42) and (43).

From the previous equation and (42) it follows that the polynomials Q_k also satisfy a three-term recursion, namely

$$Q_{k+1}=(E-b_{k+n+1})Q_k-a_{k+n+1}Q_{k-1}, \quad k\geq 0,$$

and are therefore orthogonal with respect to an appropriate moment functional $\mathscr{L}_Q$ (in general different from $\mathscr{L}$).

It was heuristically argued in Ref. 5 that

$$\mathscr{L}=\sum_{j=0}^{n}\omega_j\delta(E-E_j) \tag{49}$$

on $\mathbb{C}[E]$, where the coefficients ω_j are defined by

$$\sum_{l=0}^{n}\hat{P}_k(E_l)\omega_l=\delta_{k0},\quad k=0,1,\ldots,n. \tag{50}$$

Equivalently, the discrete Stieltjes measure $d\hat{\omega}(E)$ defined by the function

$$\hat{\omega}(E)=\sum_{j=0}^{n}\omega_j\theta(E-E_j), \tag{51}$$

where $\theta(t)$ is Heaviside's step function, satisfies (45). Note that the linear system (50) uniquely defines the $n+1$ constants ω_j, since by (27) or (29) its coefficient matrix is the matrix of the change of basis $\{c_k(z-z_1)^k/k!\}_{k=0}^n$ or $\{c_k(z-z_1)^k(z-z_2)^{n-k}/k!\}_{k=0}^n$ to $\{\chi_{E_l}\}_{l=0}^n$ in $\mathbb{C}\otimes\mathscr{P}_n$, c_k being the coefficient of $\hat{P}_k$ in (40). It is not difficult to show rigorously that (44) is satisfied. Indeed, by the uniqueness of $\mathscr{L}$ this is equivalent to showing that if $\mathscr{L}_0=\Sigma_{j=0}^n\omega_j\delta(E-E_j)$ then

$$\mathscr{L}_0(\hat{P}_k\hat{P}_l)=0,\quad k\neq l, \tag{52}$$

and that

$$\mathscr{L}_0(\hat{P}_0)=\mathscr{L}_0(1)=1,$$

since $\mathscr{L}(\hat{P}_k^2)$ and $\mathscr{L}_0(\hat{P}_k^2)$ must coincide if (52) holds due to the recursion relation (42) and (46). From the definition of ω_j we deduce that the last equation, together with (52) for $k=0$ and $l=1,\ldots,n$, are satisfied. Suppose now that (52) holds for $k=0,1,\ldots,K$ $(K\leqslant n-1)$ and $k<l\leqslant n$. Multiplying (42) by $\hat{P}_l$ and taking $\mathscr{L}_0$ of both sides we obtain

$$\mathscr{L}_0(\hat{P}_{K+1}\hat{P}_l)=\mathscr{L}_0((E-b_K)\hat{P}_K\hat{P}_l)-a_K\mathscr{L}_0(\hat{P}_{K-1}\hat{P}_l)=\mathscr{L}_0(E\hat{P}_K\hat{P}_l)$$

if $K+1<l\leqslant n$, by the induction hypothesis. But, using again (42),

$$\mathscr{L}_0(E\hat{P}_K\hat{P}_l)=\mathscr{L}_0(\hat{P}_K\cdot E\hat{P}_l)=\mathscr{L}_0(\hat{P}_K\hat{P}_{l+1})+b_l\mathscr{L}_0(\hat{P}_K\hat{P}_l)+a_l\mathscr{L}_0(\hat{P}_K\hat{P}_{l-1})=0,$$

by the induction hypothesis (since $l>K+1$ implies $l-1>K$). Hence (52) is true for $0\leqslant k,l\leqslant n$. Finally, (52) is trivially true when k or l are greater than n by the factorization property (48) and (47).

We shall next show that all the coefficients ω_j are positive if b_k is real for all $0\leqslant k\leqslant n$ and $a_k>0$ for $1\leqslant k\leqslant n$. [Several instances of this result were checked numerically in Ref. 5 for the orthogonal polynomials associated to the Hamiltonian (1).] The proof is based on the following simple lemma:

Lemma 3: If $a_k>0$ for $k=1,2,\ldots,n$ and b_k is real for $k=0,1,\ldots,n$ then $\mathscr{L}$ is positive-definite on $\mathscr{P}_{2n}$. In other words, if $p\in\mathscr{P}_{2n}$ is a real polynomial of degree at most $2n$, $p\neq 0$ and $p(E)\geqslant 0$ for all $E\in\mathbb{R}$ then $\mathscr{L}(p)>0$.

Proof: A polynomial $p\in\mathscr{P}_{2n}$ which is non-negative for all real values of E must be of the form q^2+r^2, where $q,r\in\mathscr{P}_n$ are real polynomials. Write $q=\Sigma_{k=0}^n q_k\hat{P}_k$; then all the coefficients q_k are real, since $\hat{P}_k$ is a real polynomial for $0\leqslant k\leqslant n$ by the hypotheses. Using the orthogonality of the polynomials $\hat{P}_k$ we obtain $\mathscr{L}(q^2)=\Sigma_{k=0}^n q_k^2\gamma_k$. Similarly, if $r=\Sigma_{k=0}^n p_k\hat{P}_k$ then $\mathscr{L}(r)=\Sigma_{k=0}^n r_k^2\gamma_k$, and $\mathscr{L}(p)=\Sigma_{k=0}^n(q_k^2+r_k^2)\gamma_k$. Since $\gamma_k>0$ for $k=0,1,\ldots,n$ by (46) and the

hypothesis on the coefficients a_k, it follows that $\mathscr{L}(p)\geq 0$, and $\mathscr{L}(p)=0$ if and only if $q_k=r_k=0$ for $k=0,1,\ldots,n$, that is if and only if $p=0$. Q.E.D.

Proposition 4: If $a_k>0$ for $k=1,2,\ldots,n$ and b_k is real for $k=0,1,\ldots,n$ then $\omega_k>0$ for all $k=0,1,\ldots n$.

Proof: Apply the previous lemma to the polynomials $\Pi_{0\leq j\neq k\leq n}(E-E_j)^2\in\mathscr{P}_{2n}$ for $k=0,1,\ldots n$. Q.E.D.

Note that the hypotheses of the previous proposition are satisfied when P is one of the canonical forms 2, 3, or 4, provided that all the eigenfunctions of H are square-integrable and that H is *not* exactly solvable. In particular, it is satisfied by the Hamiltonian (1).

The (Hamburger) *moment problem* for the moment functional (49) associated to the weakly orthogonal polynomials defined by a quasi-exactly solvable one-dimensional Hamiltonian consists in determining whether there is a *distribution function* (i.e., a nondecreasing function of bounded variation) ω such that $\mathscr{L}$ can be represented by (45) for an arbitrary polynomial p. We have already shown that this problem has a solution (51), since (51) is clearly nondecreasing and of bounded variation. We shall next show that this solution is unique (up to an additive constant), so that the moment problem associated to the weakly orthogonal polynomial system $\{\hat{P}_k\}_{k\in\mathbb{N}}$ is always determined.[12] Essentially, this is due to the fact that the *spectrum*

$$\sigma(\hat{\omega})=\{E\in\mathbb{R}:\hat{\omega}(E+\delta)-\hat{\omega}(E-\delta)>0,\forall\,\delta>0\}$$

of the distribution function (51) is the finite set $\{E_l\}_{l=0}^{n}$.[13] According to a well known result in the classical theory of orthogonal polynomials,[2] a distribution function ω defines a positive-definite functional on $\mathbb{C}[E]$ through integration with respect to the Stieltjes measure $d\omega(E)$ if and only if the spectrum of ω is infinite. Since $\mathscr{L}$ is not positive-definite ($\mathscr{L}(\hat{P}_{n+1}^2)=\gamma_{n+1}=0$), any solution ω of (45) must have a finite spectrum, and will thus be of the form

$$\omega(E)=\sum_{k=0}^{\tilde{n}}\tilde{\omega}_k\theta(E-\tilde{E}_k)+C$$

for some constant C, up to an immaterial redefinition of ω in $\sigma(\omega)$. If I is a compact interval containing $\sigma(\hat{\omega})\cup\sigma(\omega)$, then

$$\mathscr{L}(p)=\int_I p(E)d\hat{\omega}(E)=\int_I p(E)d\omega(E),\quad \forall p\in\mathbb{C}[E].$$

Since I is compact, a well known theorem (cf. Ref. 2) shows that $\hat{\omega}$ and ω differ by a constant at all points in which both $\hat{\omega}$ and ω are continuous. But this easily implies that $E_k=\tilde{E}_k$ and $\omega_k=\tilde{\omega}_k$ for $k=0,1,\ldots,n=\tilde{n}$, whence $\omega=\hat{\omega}+C$, as stated. Note that the same argument shows that the moment problem in any interval containing $[E_0,E_n]$ is determined; in particular, the (Stieltjes) moment problem in $[E_0,\infty)$ is also determined. In this respect, the weakly orthogonal polynomials associated to a quasi-exactly solvable one-dimensional Hamiltonian behave in exactly the same way as the classical orthogonal polynomials, whose moment problem is also determined.[2]

The *moments* of the moment functional $\mathscr{L}$ are by definition the numbers

$$\mu_k=\mathscr{L}(E^k)=\int_{-\infty}^{\infty}E^k\,d\hat{\omega}(E)=\sum_{l=0}^{n}\omega_l E_l^k,\quad k\in\mathbb{N}. \tag{53}$$

If the hypotheses of Proposition 4 hold, all the moments are real. From (53) we see that the module of the kth moment μ_k does not grow factorially as k tends to infinity, as argued in Ref. 1, but instead it diverges like the kth power of a constant.[14]

We shall next show that if the coefficient a_k satisfies the condition

$$a_k \neq 0, \quad 1 \leqslant k \leqslant n, \tag{54}$$

which guarantees that the polynomials $\hat{P}_k$ have nonzero norm for $k \leqslant n$, then *the moments* μ_k *with* $k \geqslant n+1$ *satisfy a constant coefficient difference equation of order* $n+1$. To this end, recall first of all that the bilinear form $\langle p,q\rangle = \mathscr{L}(pq)$ defined by $\mathscr{L}$ in $\mathbb{C}[E]$, when restricted to the subspace $\mathbb{C}\otimes\mathscr{P}_l$, is represented in the basis $\{E^k\}_{0\leqslant k\leqslant l}$ by the symmetric matrix $(\mu_{i+j})_{0\leqslant i,j\leqslant l}$, whose determinant we shall denote by Δ_l. On the other hand, the matrix of the bilinear form $\langle\cdot,\cdot\rangle$ in the basis $\{\hat{P}_k\}_{0\leqslant k\leqslant l}$ is clearly $\mathrm{diag}(1,\gamma_1,\ldots,\gamma_l)$; therefore, by (46) and the hypothesis on the coefficients a_k, we conclude that $\Delta_n \neq 0$ and

$$\Delta_k = 0, \quad k \geqslant n+1. \tag{55}$$

In particular, since $\Delta_n \neq 0$ but $\Delta_{n+1} = 0$, the last column of Δ_{n+1} must be a linear combination of the remaining columns, so that

$$\mu_k = \sum_{i=1}^{n+1} c_i \mu_{k-i}, \quad n+1 \leqslant k \leqslant 2(n+1), \tag{56}$$

for some (in general complex) constants $c_1,\ldots,c_{n+1}$. An easy induction argument using (55) then shows that the above relation is actually valid with the *same* constant coefficients c_i for all $k \geqslant n+1$, as claimed. In fact, it is not hard to see that c_i in (56) is minus the coefficient of E^{n+1-i} in $\hat{P}_{n+1}$. Indeed, write $\hat{P}_{n+1} = E^{n+1} - p_n$, with

$$p_n = \sum_{i=1}^{n+1} \tilde{c}_i E^{n+1-i},$$

and let $Q_k = E^k - q_{k-1}$, so that $q_{-1} = 0$ and $\deg q_{k-1} \leqslant k-1$ for $k \geqslant 1$. From (48) it follows that

$$\hat{P}_k = E^k - E^{k-n-1} p_n - q_{k-n-2} \hat{P}_{n+1}, \quad k \geqslant n+1,$$

which by (44) implies that

$$\mu_k = \mathscr{L}(E^k) = \mathscr{L}(E^{k-n-1} p_n) = \sum_{i=1}^{n+1} \tilde{c}_i \mu_{k-i}, \quad n+1 \leqslant k \leqslant 2(n+1).$$

Comparing with (56) and taking into account the linear independence of the columns of Δ_n we immediately obtain that $\tilde{c}_i = c_i$ for $i = 1,2,\ldots,n+1$, as stated.

Note that the fact that the moments satisfy a constant coefficient recursion relation (56) (with $k \geqslant n+1$) actually characterizes weakly orthogonal polynomial systems. Indeed, (56) simply expresses the fact that the $(n+2)$th column of Δ_l for $l \geqslant n+1$ is a linear combination of the first $n+1$ columns. Hence (56) implies (55), and since $\Delta_{n+1} = \prod_{j=1}^{n+1} \gamma_j$ this means that $\gamma_k = 0$ for some $k \leqslant n+1$, so that $a_k = 0$ for some $k \leqslant n+1$ by (46).

Consider, for example, the Hamiltonian (1) studied in Ref. 1, which corresponds to the fourth canonical form with

$$n = J-1, \quad c_+ = -16, \quad c_0 = c_* = 0, \quad c_- = 2s + \tfrac{1}{2}(n-1). \tag{57}$$

The coefficients of the corresponding recursion relation (42) are easily found to be

$$b_k = 0, \quad a_k = 16k(J-k)(k+2s-1), \quad k \geqslant 0. \tag{58}$$

Since we can take $s \geqslant 1/2$ without loss of generality, we see that $a_k > 0$ for $1 \leqslant k \leqslant n$, so that (54) is satisfied. Furthermore, since b_k vanishes for all $k \geqslant 0$ the polynomials $\hat{P}_k$ have parity $(-1)^k$, and

therefore all the odd moments vanish (the corresponding moment functional is said to be *symmetric*). For $J=3$ (that is, $n=2$), according to the foregoing observations we know that the moments satisfy a third-order recursion relation of the form (56), whose coefficients are minus the coefficients of E^2, E, and 1 in $\hat{P}_3$. From (42) (with $\hat{P}_0=1$) we obtain

$$\hat{P}_1=E, \quad \hat{P}_2=E^2-64s, \quad \hat{P}_3(E)=E^3-32(4s+1)E, \tag{59}$$

so that $c_1=c_3=0$—as expected, since the moment functional is symmetric—and $c_2=32(4s+1)$. Therefore the even moments satisfy the first-order recursion relation

$$\mu_{2j}=32(4s+1)\mu_{2j-2}, \quad j\geq 2, \tag{60}$$

and since $\mu_2=\gamma_1=a_1=64s$, from (60) we obtain

$$\mu_{2j}=32^{j-1}(4s+1)^{j-1}\cdot 64s, \quad j\geq 1. \tag{61}$$

Thus, in this case μ_{2j} has a pure power growth. The same result can be obtained using (53). Indeed, from (59) we have

$$E_0=-\lambda\equiv-\sqrt{32(4s+1)}, \quad E_1=0, \quad E_2=\lambda,$$

and therefore

$$\omega_0=\frac{s}{4s+1}, \quad \omega_1=\frac{2s+1}{4s+1}, \quad \omega_2=\omega_0$$

from (50) and (59). Thus

$$\mu_k=\frac{s}{4s+1}[(-\lambda)^k+\lambda^k],$$

which yields $\mu_{2j+1}=0$ for $j\geq 0$ and (61).

V. CONCLUSIONS

We have shown in this paper how every quasi-exactly solvable one-dimensional Hamiltonian satisfying conditions (37)–(39) defines a weakly orthogonal polynomial system $\{\hat{P}_k\}_{k=0}^{\infty}$ through the three-term recursion relation (41) (with initial condition $\hat{P}_0=1$). It is important, in this context, to emphasize the *weak* orthogonality of the polynomials $\hat{P}_k$, i.e., the fact that the norm of $\hat{P}_k$ may vanish—and in fact *does* vanish for $k\geq n+1$, n being the "spin" parameter present in the Hamiltonian. As explained in Sec. IV, this is an inevitable consequence of the vanishing of the coefficient of $\hat{P}_{k-1}$ in the recursion relation (41) for $k=n+1$, which is made possible by the fact that the parameter n is a non-negative integer. The latter fact, however, is an intrinsic property of one-dimensional quasi-exactly solvable (as opposed to merely Lie-algebraic) Hamiltonians; indeed, it is a key factor in the explanation of the partial integrability of a quasi-exactly solvable Hamiltonian outlined in Sec. II. To better illustrate this point, consider the Hamiltonian (1), which is Lie-algebraic for all real values of the parameter J. Indeed, H can be written in the form (5)–(6), with $\zeta(x)=x^2/4$, $\mu(z)=e^{-4z^2}z^{s-1/4}$, $c_{++}=c_{+0}=c_{00}=c_{+-}=c_{--}=0$, $c_{0-}=1/2$, and the remaining coefficients given by (57), where now n is to be regarded as an arbitrary real parameter. When n is not a non-negative integer, the generators (4) do not leave invariant any finite-dimensional polynomial module $\mathcal{P}_n$, so that H is in general nonintegrable—there is no special reason for H to have algebraically computable eigenfunctions of the form (7), with χ a polynomial. However, even when n is not a non-negative integer, the Lie-algebraic nature of H and

conditions (25) imply that the polynomials $\hat{P}_k$ defined by (7), (21), and (40) still satisfy a three-term recursion relation (42), with the coefficients given by (58). In other words, what makes H quasi-exactly solvable is not merely the fact that its associated polynomials satisfy a three-term recursion relation (42) (which implies their orthogonality with respect to some Stieltjes measure), but the fact that the coefficient a_k in this recursion relation vanishes for some positive integer value of k, so that the associated polynomials $\hat{P}_k$ can only be weakly orthogonal.

As we saw in Sec. IV, the Stieltjes measure with respect to which the polynomials $\hat{P}_k$ associated to a quasi-exactly solvable Hamiltonian H are orthogonal is supported in the set of algebraic eigenvalues of H, which is a finite set. For this reason, the polynomials $\hat{P}_k$ are *discrete polynomials*. Although the classical (Hermite, Legendre, Laguerre, Tchebycheff, etc.) polynomials of Mathematical Physics are orthogonal with respect to a continuous measure, discrete (Charlier, Hahn, Krawtchouk, Meixner, Tchebycheff, etc.) polynomials have also been studied in the mathematical literature of orthogonal polynomials, cf. Ref. 2. Note that a discrete polynomial system is truly—as opposed to weakly—orthogonal if and only if the supporting set of its Stieltjes measure is infinite. Some of the discrete polynomials cited above, like the Hahn, Krawtchouk, or discrete Tchebycheff polynomials, are in fact weakly orthogonal. In general, weakly orthogonal polynomials arise naturally, for instance, in the theory of approximate polynomial curve fitting.[15] More recently,[16] the study of second-order finite difference eigenvalue equations with infinitely many polynomial solutions has led to an interesting connection between a nonstandard finite-dimensional representation of $\mathfrak{sl}(2)$ and certain families of weakly orthogonal discrete polynomials (Hahn polynomials and analytically continued Hahn polynomials).

Let us stress, in closing, that the present paper deals only with one-dimensional quasi-exactly solvable Hamiltonians. It is an interesting open problem to generalize these results to quasi-exactly solvable multi-dimensional systems, a possibility already considered in Ref. 5, where a heuristic (but inconclusive, in our opinion) argument was advanced suggesting that all quasi-exactly solvable systems give rise to weakly orthogonal polynomials. In the two-dimensional case, at least, the classification of quasi-exactly solvable Lie algebras of first-order differential operators in two variables presented in Refs. 7 and 17 could be used as a starting point for an analysis along the present lines.

ACKNOWLEDGMENTS

It is a pleasure to thank M. A. Martín-Delgado, who pointed out to us Ref. 1, Gabriel Álvarez, for useful discussions regarding the theory of classical orthogonal polynomials, and Carlos Finkel, for providing several key references. The authors would also like to acknowledge the partial financial support of the DGICYT under Grant No. PB92-0197.

Constructive building of the Lax pair in the non-linear sigma model

Ariel O. García[a] and Roberto C. Trinchero[b]

(Received 14 November 1995; accepted for publication 25 March 1996)

A derivation of the Lax pair for the $(1+1)$-dimensional non-linear σ-model is described. Its main benefit is to have a clearer physical origin and to allow the study of a generalization to higher dimensions. © *1996 American Institute of Physics.* [S0022-2488(96)01007-9]

I. INTRODUCTION

It has been known for several years that the non-linear σ-model, in a two dimensional space–time, has a non-local conservation law[1] that can be cast as a non-local symmetry transformation.[2,3] This is usually shown to be true on the basis of the existence of a "Lax pair," a pair of linear differential equations depending on a spectral parameter, whose compatibility condition is exactly the field equation of the model. Exact integrability of the system follows, via the inverse scattering procedure.[4]

An infinite set of non-local conserved charges can be directly obtained from this Lax system, as in Ref. 1, or as in Ref. 2. In the former reference the authors prove that, with a careful selection of the boundary conditions, the variable of the Lax pair is time independent for spatial coordinate $x^1=+\infty$, given initial conditions at $x^1=-\infty$. Thus a Taylor expansion in the spectral parameter gives a series of non-local conserved charges. In the latter paper, the authors apply the transformation to the global (left, for instance) conserved current. This gives them a spectral parameter dependent conserved current, which upon Taylor expansion generates an infinite set of non-local currents, all of them conserved.

Although very well known and studied, in general and applied to this particular model, the Lax pair has a somewhat obscure physical origin. Also, there is no systematic way to find it in a given system. We hope to contribute a small step to solve these problems. We show here a way to get the Lax equation for the two dimensional σ-model, which somewhat clarifies its physical meaning. This way of proceeding also enables the study of a possible generalization to more dimensions.

We should stress here that a higher dimensional version of the non-local symmetry of this model is sensible. Actually the (4D Euclidean) self-dual gauge theory has this kind of symmetry transformation,[5] which is also related to several $(2+1)$ dimensional integrable systems.[6] Moreover, this symmetry and its associated Lax pair is also present in (at least) a subspace of the solution's manifold of a large class of models based on vacuum general relativity.[7,8]

Aside from its own interest, the non-local symmetry of this system is relevant in the Gribov problem. We must only realize that (classically) the vacuum sector of the Yang–Mills theory is exactly the n dimensional σ-model if we choose the Lorentz $(\partial\cdot A=0)$ gauge. So the existence of a continuous 1-parameter family of solutions of the non-linear σ-model tells us of a continuum of vacua in the non-Abelian gauge theories in the Lorentz gauge.

II. CONSTRUCTING THE LAX PAIR

Only to fix our notation, we enumerate first some standard results about this model. We write for the action

[a]Electronic mail: ariel@cab.cnea.edu.ar
[b]Also supported by CONICET. Electronic mail: trincher@cab.cnea.edu.ar

$$S=\int \mathrm{d}^d x \mathrm{Tr}[\partial_\mu(g^{-1})\partial^\mu g],$$

where g is a (G) group valued field over Minkowsky space–time M^d. We will consider here only a principal chiral field (group valued field), the symmetric space case will be addressed in Appendix **B**. This action has two global symmetries,

$$g(x)\mapsto Lg(x),$$

$$g(x)\mapsto g(x)R, \text{ with } L,R\in G \text{ and independent of } x\in M^d,$$

that tell us of the conservation of the (Noether) currents,

$$L_\mu \equiv g\partial_\mu g^{-1} \quad \text{and} \quad R_\mu \equiv g^{-1}\partial_\mu g,$$

which are related by $R_\mu = -g^{-1}L_\mu g$.

The equations of motion of this model can be written as[9]

$$\Box g+(\partial_\mu g\partial^\mu g^{-1})g\doteq 0, \tag{1}$$

or as

$$\partial\cdot L\doteq 0, \tag{2}$$

in terms of the left current, or equivalently $\partial\cdot R\doteq 0$ in terms of the right one. These currents obviously satisfy a "zero-curvature" condition,

$$\begin{aligned} F_{\mu\nu}(L)&\equiv\partial_\mu L_\nu-\partial_\nu L_\mu+[L_\mu,L_\nu]=0,\\ F_{\mu\nu}(R)&\equiv\partial_\mu R_\nu-\partial_\nu R_\mu+[R_\mu,R_\nu]=0. \end{aligned} \tag{3}$$

With this notation, the linear (when left-multiplied by U) equations,

$$U^{-1}\partial_\mu U=\frac{1}{2}[(1-\cosh(\lambda))L_\mu-\sinh(\lambda)\epsilon_{\mu\nu}L^\nu], \tag{4}$$

are called the Lax pair. λ is the spectral parameter and ϵ is the Levi-Civita tensor. The group valued field U should here be taken as the variable, for each given L. It is straightforward to verify that the compatibility condition $[\partial_\mu,\partial_\nu]U=0$ is satisfied for pure gauge L's with zero divergence. In this case a formal solution to Eq. (4) is given by

$$U(x)=U_o\mathrm{Pexp}\int \frac{1}{2}[(1-\cosh(\lambda))L_\mu-\sinh(\lambda)\epsilon_{\mu\nu}L^\nu]\mathrm{d}x^\mu,$$

where P is the path ordering operator (ordering from left to right), along a path from a fixed point to x. A completely analogous Lax pair can be constructed with the right current,

$$V^{-1}\partial_\mu V=\frac{1}{2}[(1-\cosh(\lambda))R_\mu-\sinh(\lambda)\epsilon_{\mu\nu}R^\nu]. \tag{5}$$

Bäklund transformations are at this point usually introduced.

We can in a sense reverse this argument, starting from a transformation $g\mapsto g'$ with

$$g'(x)=U(x)g(x)V^{-1}(x), \tag{6}$$

where U and V are some group valued fields. This is a pretty general form, but looking at the action we realize we can make it *a-priori* invariant asking for (6) to fulfill

$$\partial_\mu g' = \partial_\mu (U g V^{-1}) = U \Lambda_{\mu\nu} \partial^\nu g V^{-1}. \tag{7}$$

Here Λ is an undetermined Lorentz transformation,[10] $\Lambda_{\mu\nu}\Lambda^{\mu\sigma} = \delta^\sigma_\nu$. This obviously makes the action invariant, but what is not so trivial to fulfill is the consistency of condition (7), that is U and V such that this equation holds may not exist. Indeed in the $(1+1)$ dimensional case this condition is only solvable over the field equation solutions. Equation (7) can also be written as

$$U^{-1}\partial_\mu U - g V^{-1} \partial_\mu V g^{-1} = L_\mu - \Lambda_{\mu\nu} L^\nu, \tag{8}$$

and implies for L the transformation law

$$L'_\mu = U \Lambda_{\mu\nu} L^\nu U^{-1}. \tag{9}$$

We see that the Lax pairs (4) and (5) satisfy Eq. (8) in the $(1+1)$ dimensional case, because in this case any Lorentz transformation can be written as $\Lambda_{\mu\nu} = \cosh(\lambda)\eta_{\mu\nu} + \sinh(\lambda)\epsilon_{\mu\nu}$, η being the Minkowski metric. Anyway, Eq. (6) and Eq. (8) enable a testable path to generalization to higher dimensions.

We can obtain the Lax pair doing a series of infinitesimal transformations, with

$$\Lambda_{\mu\nu} = \eta_{\mu\nu} + \omega_{\mu\nu}, \quad |\omega_{\mu\nu}| \ll 1,$$

where $\omega_{\mu\nu}$ is an antisymmetric tensor. For just one transformation, we have

$$U = 1 + u + \mathcal{O}(\omega^2_{\mu\nu}), \quad V = 1 + v + \mathcal{O}(\omega^2_{\mu\nu}),$$

$$U^{-1}\partial_\mu U \simeq \partial_\mu u, \quad V^{-1}\partial_\mu V \simeq \partial_\mu v, \tag{10}$$

where we have taken U and V so as to preserve boundary conditions for g. That is, for the identity transformation we should have $g' = g$ so $U(\omega_{\mu\nu} = 0) = V(\omega_{\mu\nu} = 0) = 1$.

Therefore we have

$$\begin{aligned} L'_\mu &= g' \partial_\mu [g'^{-1}] = (1+u) g (1-v) \partial_\mu [(1+v) g^{-1} (1-u)] \\ &= L_\mu - \partial_\mu u + [u, L_\mu] + g \partial_\mu v g^{-1}. \end{aligned} \tag{11}$$

But Eq. (8) gives

$$\partial_\mu u = g \partial_\mu v g^{-1} - \omega_{\mu\nu} L^\nu, \tag{12}$$

up to first order in ω, so we get

$$L'_\mu = L_\mu + [u, L_\mu] + \omega_{\mu\nu} L^\nu + \mathcal{O}(\omega^2). \tag{13}$$

Calculating now the divergence of Eq. (13),

$$\begin{aligned} \partial \cdot L' &\doteq [\partial_\mu u, L^\mu] + \partial^\mu (\omega_{\mu\nu} L^\nu) \\ &= \left[\partial_\mu u + \frac{1}{2} \omega_{\mu\nu} L^\nu, L^\mu \right], \end{aligned} \tag{14}$$

where constancy of $\omega_{\mu\nu}$ was assumed and Eq. (3) was employed. If we impose $\partial \cdot L'$ to be zero [weakly, for all L verifying Eq. (2) and Eq. (3)], it is enough to take

$$\partial_\mu u + \frac{1}{2}\omega_{\mu\nu}L^\nu = \alpha L_\mu . \tag{15}$$

But for this equation to be consistent it should verify the condition[11]

$$[\partial_\mu, \partial_\nu]u = 0, \tag{16}$$

that is

$$\frac{1}{2}\omega_{\mu\sigma}\partial_\nu L^\sigma - \frac{1}{2}\omega_{\nu\sigma}\partial_\mu L^\sigma + \alpha(\partial_\mu L_\nu - \partial_\nu L_\mu) = 0. \tag{17}$$

If we now restrict ourselves to work in $1+1$ dimensions we can write $\omega_{\mu\nu} = \gamma\epsilon_{\mu\nu}$. So we obtain from Eq. (17)

$$\alpha(\partial_\mu L_\nu - \partial_\nu L_\mu) = 0, \tag{18}$$

because for $\mu \neq \nu$ it is $\epsilon_{\nu\sigma}\partial_\mu L^\sigma - \epsilon_{\mu\sigma}\partial_\nu L^\sigma = -\epsilon_{\mu\nu}\partial\cdot L \doteq 0$. We can then choose $\alpha = 0$, so

$$\partial_\mu u = -\frac{1}{2}\gamma\epsilon_{\mu\nu}L^\nu, \tag{19}$$

up to order γ. Renaming γ as γ_0, we can now iterate this procedure (obviously we must check consistency) doing a transformation of parameter γ_1 to obtain $g_{(2)}$, $L^\mu_{(2)}$ starting from $g_{(1)}$, $L^\mu_{(1)}$, etc. This can be summarized as shown below:

$$g, L \xrightarrow{\gamma_0, u_{(0)}} g_{(1)}, L_{(1)} \xrightarrow{\gamma_1, u_{(1)}} g_{(2)}, L_{(2)} \longrightarrow \cdots$$

Up to this point we have

$$\partial_\mu u_{(0)} = -\frac{1}{2}\gamma_0\epsilon_{\mu\nu}L^\nu_{(0)}, \tag{20a}$$

$$L^\mu_{(1)} = L^\mu_{(0)} + [u_{(0)}, L^\mu_{(0)}] + \gamma_0\epsilon^\mu{}_\nu L^\nu_{(0)} + \mathcal{O}(\gamma_0^2), \tag{20b}$$

and $v_{(0)}$ can be found from $\partial_\mu u_{(0)} = g_{(0)}\partial_\mu v_{(0)}[g_{(0)}]^{-1} - \gamma_0\epsilon_{\mu\nu}L^\nu_{(0)}$. We want to show first that this procedure can be iterated as many times as we want, and then we will show that this iteration leads us to a non-infinitesimal transformation, giving the usual Lax pair.

We started from a $L_{(0)}$ configuration with zero divergence and curvature and, because of integrability of Eq. (20a), $L_{(1)}$ given by Eq. (20b) is well defined. To restart the process $L_{(1)}$ should also have zero divergence and curvature. But, by construction $L_{(1)}$ has zero curvature up to leading order in γ_0, as it has been defined as $L^\mu_{(1)} = g_{(1)}\partial^\mu g^{-1}_{(1)}$, neglecting higher order terms. $L_{(1)}$ has also zero divergence, as $u_{(0)}$ was chosen for this purpose. Taking into account the discussion in Appendix **A** a well defined procedure for integrating the analog of Eq. (20a) for the second iteration can be given.

With exactly the same reasoning we see that for any n

$$\partial_\mu u_{(n)} = -\frac{1}{2}\gamma_n\epsilon_{\mu\nu}L^\nu_{(n)}, \tag{21a}$$

$$L^\mu_{(n+1)} = L^\mu_{(n)} + [u_{(n)}, L^\mu_{(n)}] + \gamma_n\epsilon^\mu{}_\nu L^\nu_{(n)}, \tag{21b}$$

provide us with

(I) a well defined $L^{\mu}_{(n+1)}$, because $[\partial_\mu,\partial_\nu]u_{(n)}=\frac{1}{2}\gamma_n\epsilon_{\mu\nu}\partial\cdot L_{(n)}$

(II) a zero divergence $L^{\mu}_{(n+1)}$, up to order γ_{n-1}

(III) a zero curvature $L^{\mu}_{(n+1)}$, up to order γ_n.

This can also be verified inductively. This way it is easier to see that

$$-[\partial_\mu,\partial_\nu]u_{(n)}=\frac{1}{2}\gamma_n\epsilon_{\mu\nu}\partial\cdot L_{(n)}=\gamma_n\mathcal{O}(\gamma_{n-2}^2,\ldots,\gamma_0^2),$$

$$-\partial\cdot L_{(n+1)}=\partial\cdot L_{(n)}+[u_{(n)},\partial\cdot L_{(n)}]-\gamma_n F_{01}(L_{(n)})=\mathcal{O}(\gamma_{n-1}^2,\ldots,\gamma_0^2),$$

$$\begin{aligned}-F_{\mu\nu}(L_{(n+1)})&=F_{\mu\nu}(L_{(n)})-\gamma_n\epsilon_{\mu\nu}\partial\cdot L_{(n)}+[u_{(n)},F_{\mu\nu}(L_{(n)})]\\&\quad+[\text{terms with }\gamma_n u_{(n)},\ \gamma_n^2,\ u_{(n)}^2,\text{ all are }\mathcal{O}(\gamma_n^2)]\\&=\mathcal{O}(\gamma_n^2,\ldots,\gamma_0^2).\end{aligned}$$

We now want to find $L^{\mu}_{(n)}$ and $g_{(n)}$ explicitly in terms of $L^{\mu}\equiv L^{\mu}_{(0)}$ and $g\equiv g_{(0)}$. Following Eq. (6) and Eq. (10), $g_{(n)}$ is given by

$$\begin{aligned}g_{(n+1)}&=(1+u_{(n)})g_{(n)}(1-v_{(n)})\\&=(1+u_{(n)})(1+u_{(n-1)})\ldots(1+u_{(0)})g_{(0)}(1-v_{(0)})\ldots(1-v_{(n)}).\end{aligned}$$

What we need is $U=$ (Limit of) $(1+u_{(n)})\ldots(1+u_{(0)})$, or considering the Lax pair we want to find, the equation satisfied by U: $U^{-1}\partial_\mu U=$ (something). For $n=0$ we have

$$\begin{aligned}U_0^{-1}\partial_\mu U_0&=(1-u_{(0)})\partial_\mu(1+u_{(0)})\\&=\partial_\mu u_{(0)}+\mathcal{O}(\gamma_0^2)=-\frac{1}{2}\gamma_0\epsilon_{\mu\nu}L^{\nu}_{(0)}.\end{aligned}$$

Writing $\Pi_{i=0}^{n}a_i$ for $a_0\ldots a_n$, and $\Pi_{i=n}^{0}a_i$ for $a_n\ldots a_0$ we get for an arbitrary n

$$\begin{aligned}U_n^{-1}\partial_\mu U_n&=\prod_{i=0}^{n}(1-u_{(i)})\partial_\mu\prod_{i=n}^{0}(1+u_{(i)})\\&=\sum_{j=0}^{n}\left[\prod_{i=0}^{j-1}(1-u_{(i)})\partial_\mu u_{(j)}\prod_{i=j-1}^{0}(1+u_{(i)})+\mathcal{O}(\gamma_n^2,\ldots,\gamma_j^2)\right].\end{aligned}$$

Here products $(1-u_{(i)})(1+u_{(i)})$, coming from the terms in U^{-1} and $\partial_\mu U$ respectively, cancel to first order in the parameter. If we now rewrite Eq. (21b) as

$$\begin{aligned}L^{\mu}_{(i)}&=L^{\mu}_{(i-1)}+[u_{(i-1)},L^{\mu}_{(i-1)}]+\gamma_{i-1}\epsilon^{\mu}{}_{\nu}L^{\nu}_{(i-1)}\\&=(1+u_{(i-1)})(\eta^{\mu}{}_{\nu}+\gamma_{i-1}\epsilon^{\mu}{}_{\nu})L^{\nu}_{(i-1)}(1-u_{(i-1)}),\end{aligned}\tag{22}$$

up to higher order terms, and we use Eq. (21a), we get

$$U_n^{-1}\partial_\mu U_n=\sum_{j=0}^{n}-\frac{1}{2}\gamma_j\epsilon_{\mu\nu_j}\left[\prod_{i=0}^{j-2}(1-u_{(i)})(\eta^{\nu_j}{}_{\nu_{j-1}}+\gamma_{j-1}\epsilon^{\nu_j}{}_{\nu_{j-1}})L_{(j-1)}^{\nu_{j-1}}\prod_{i=j-2}^{0}(1+u_{(i)})\right]$$
$$+\mathcal{O}(\gamma_n^2,\ldots,\gamma_0^2).$$

In this last equation factors $(1-u_{(j-1)})$ and $(1+u_{(j-1)})$ cancel at each side of the $L_{(j-1)}$. It is now easy to see that after employing Eq. (22) $(j-1)$ times more we obtain

$$U_n^{-1}\partial_\mu U_n=\sum_{j=0}^{n}-\frac{1}{2}\gamma_j\epsilon_{\mu\nu_j}(\eta^{\nu_j}{}_{\nu_{j-1}}+\gamma_{j-1}\epsilon^{\nu_j}{}_{\nu_{j-1}})\ldots(\eta^{\nu_1}{}_{\nu_0}+\gamma_0\epsilon^{\nu_1}{}_{\nu_0})L_{(0)}^{\nu_0}.$$

Expanding the sums and products, the final expression for this is

$$U_n^{-1}\partial^\mu U_n=-\frac{1}{2}\left(\sum\gamma+\sum_{\neq}\gamma\gamma\gamma+\ldots\right)\epsilon^\mu{}_\nu L_{(0)}^\nu-\frac{1}{2}\left(\sum_{\neq}\gamma\gamma+\ldots\right)L_{(0)}^\mu,$$

where all sums are with indices ranging from 0 to n, all indices are different within the sums and each term is included only once, i.e., $(\Sigma_{\neq}\gamma\gamma)$ means $(\Sigma_{i_1=0}^{n}\Sigma_{i_2>i_1}^{n}\gamma_{i_1}\gamma_{i_2})$, etc.

If we now fix all parameters γ_i to be equal, and define them as $\lambda/(n+1)$, we obtain

$$\sum\gamma=\sum_{i=0}^{n}\gamma_i=\lambda,$$

$$\sum_{\neq}\gamma\gamma=\sum_{i=0}^{n}\sum_{j>i}^{n}\gamma_i\gamma_j=\frac{\lambda^2}{(n+1)^2}\binom{N+1}{2}=\frac{\lambda^2}{2!}+\mathcal{O}\left(\frac{1}{n}\right),$$

$$\sum_{\neq}\gamma\gamma\gamma=\frac{1}{3!}\lambda^3+\mathcal{O}\left(\frac{1}{n}\right),$$

etc.,

whenever the order of the term is much lower than n. Therefore we get, in the large n limit, a Taylor series. Obviously this series adds up to

$$U^{-1}\partial^\mu U=\frac{1}{2}[(1-\cosh(\lambda))L^\mu-\sinh(\lambda)\epsilon^{\mu\nu}L_\nu],\tag{23}$$

that is what we had in Eq. (4).

III. DISCUSSION AND CONCLUSIONS

We have obtained the Lax pair for the non-linear σ-model in a mainly constructive way. It can now be given a physical significance, because it is the compatibility condition for the existence of a family of (non-linear/non-local) weak symmetry transformations for the model. The spectral parameter of such a family appears here as the parameter of a Lorentz transformation involved in the invariance of the action under the symmetry transformation. Built this way, it seems more realistic to think about its possible generalization to higher dimensions. Anyway, it is not an easy thing: for a $(2+1)$-dimensional space-time the construction breaks down at Eq. (18) because the first two terms of Eq. (17) do not cancel anymore, so α can not be chosen as zero to make Eq. (16) hold. One can try to restrict the symmetry to only a subset of the solutions' space, considering for instance only those fields g that are axially symmetric. Since we want to iterate the transformation

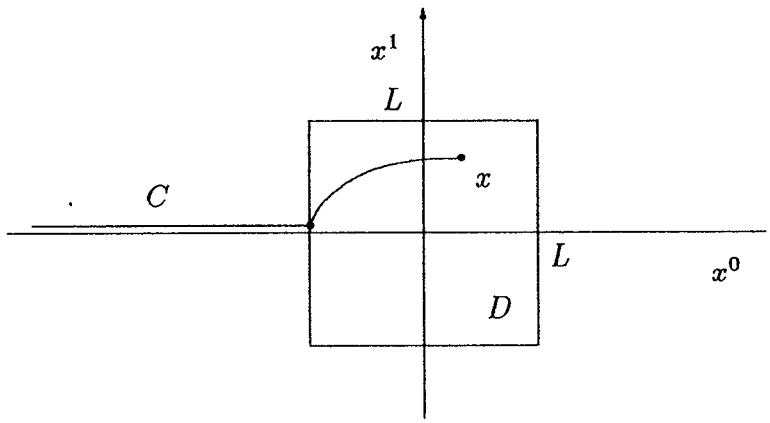

FIG. 1. Setup for integration of Eq. (21a).

in such a way that the new solution also has axial symmetry, the problem is that for physical consistency the $\omega_{\mu\nu}$ tensor of parameters should also be axially symmetric. This means that the (Cartesian) components $\omega_{\mu\nu}$ are position dependent. Therefore, if we want a non-trivial transformation, the second part of Eq. (14) must be modified with the addition of a term $L^\nu \partial^\mu \omega_{\mu\nu}$.

IV. ACKNOWLEDGMENT

We are greatly indebted to M. L. Bruschi for her comments and discussions.

APPENDIX A: PATH INDEPENDENCE

Note that being $[\partial_\mu, \partial_\nu] u_{(n)} = 0 + \mathcal{O}(\gamma_i^2)$ (i.e., not exactly zero in general) we still have a "small" path dependency in $u_{(n)}$. How can we deal with it?

We aim at obtaining a ("true") function $g'(x)$, starting from $g(x)$, making N steps of parameters $\gamma_0, \ldots, \gamma_{N-1}$, and finally taking the limit $N \to \infty$, with (for all i) $N\gamma_i = \lambda$, a non-infinitesimal quantity. However, before the limit procedure, the N-times iterated "function" $g_{(N)}(x)$ may be defined only on a bounded domain D_N of M^2. We can choose, for instance, a square region $|x^\mu| < L$, with $L^2 \sim 1/\max(\gamma_i)$. So for $x \in D_N$ we can find $u_{(i)}(x)$ from Eq. (21a) integrating over a path C, consisting of a fixed piece from $-\infty$ to some point on the boundary of D_N, and an arbitrary piece *inside* D_N to x (as shown in Fig. 1). Therefore, integrating over two different paths we get two different u's, with

$$|\Delta u_{(i)}| \sim |[\partial_0, \partial_1] u_{(i)}|\,|\text{ Area between paths}|$$

$$\leq |\gamma_i|\,|\partial \cdot L_{(i)}| L^2 \leq \frac{\gamma_i}{\max(\gamma_j)} \gamma_{i-2}^2,$$

and we obtain a "fixed" error for $g_{(N)}(x)$ whenever x is inside D_N, with a given $\lambda = N\gamma_i$.

APPENDIX B: SYMMETRIC SPACE CASE

Keeping the same action as in Section II but allowing the field g to vary only on a symmetric space we get what is called a symmetric space sigma model.

A symmetric space[12] is a homogeneous group G/H together with an involution i in G ($i^2 = 1$), where G is a connected Lie group and H is a closed subgroup of G consisting of (at least the unit component of) the set of fixed points of i. This involution selects in a natural way a

subalgebra $\mathfrak{h}$ and a subspace $\mathfrak{m}$ of the Lie algebra $\mathfrak{g}$ of G. These are the eigenspaces corresponding to eigenvalues ± 1 of the involution induced by i on the algebra $\mathfrak{g}$. Moreover, $\mathfrak{h}$ is exactly the Lie algebra of H, and together with $\mathfrak{m}$ they span $\mathfrak{g}$. It is easy to see that

$$[\mathfrak{h},\mathfrak{m}]\subset\mathfrak{m},$$

$$[\mathfrak{m},\mathfrak{m}]\subset\mathfrak{h},$$

and, $\mathfrak{h}$ being an algebra, $[\mathfrak{h},\mathfrak{h}]\subset\mathfrak{h}$. Let us call π the projector from $\mathfrak{g}$ onto $\mathfrak{h}$, having kernel $\mathfrak{m}$. This projector can be extended naturally to one acting over the whole tangent space of G, as

$$\pi(\partial g)=g\,\pi(g^{-1}\partial g).$$

We must also require this space to be a Riemannian symmetric space, i.e., the group $\mathrm{Ad}_g(H)$ of adjoint transformations on $\mathfrak{g}$ should be compact, for in this case we have an H-invariant scalar product $\langle\cdot,\cdot\rangle$ needed for defining the action.

This symmetric space model is equivalent[2] to a (G) group valued σ-model but with a modified action,

$$S=\int \mathrm{d}^dx\langle D_\mu g, D^\mu g\rangle,$$

where normal derivatives are replaced by covariant ones with a g dependent connection A_μ. Explicitly, we must take

$$\begin{aligned} D_\mu g &= \partial_\mu g - g\,\pi(g^{-1}\partial_\mu g)\\ &= (1-\pi)\partial_\mu g. \end{aligned}$$

We have now a left *G-global* and a right *H-gauge* symmetries. Currents are $L_\mu \equiv -D_\mu g g^{-1}$ and $R_\mu \equiv g^{-1}D_\mu g$, which are related by $R_\mu = -g^{-1}L_\mu g$ as before. L is conserved ($\partial\cdot L \doteq 0$) and R is covariantly conserved. Using that $[\mathfrak{m},\mathfrak{m}]\subset\mathfrak{h}$, one can check that these currents have zero curvature,

$$F_{\mu\nu}(L)\equiv\partial_\mu L_\nu-\partial_\nu L_\mu+f[L_\mu,L_\nu]=0,$$

$$F_{\mu\nu}(R)\equiv\partial_\mu R_\nu-\partial_\nu R_\mu+f[R_\mu,R_\nu]=0.$$

Here $f=2$, and it is kept explicitly to show the difference with the already treated $f=1$ case.

In this case we can generalize the Lax pair construction retaining Eq. (6), but replacing normal by covariant derivatives in Eq. (7):

$$D_\mu g' = D_\mu(UgV^{-1}) = U\Lambda_{\mu\nu}D^\nu g V^{-1}$$

(remember $D_\mu g'$ means employing g' also in the corresponding connection). This implies that Eq. (9) and its infinitesimal expression, Eq. (12), are unchanged. Eq. (8) should now be replaced by

$$\begin{aligned} V(\Lambda_{\mu\nu}R^\nu - R_\mu)V^{-1} = &-\pi(VR_\mu V^{-1})\\ &+(1-\pi)[VA_\mu V^{-1}-\partial_\mu VV^{-1}+Vg^{-1}U^{-1}\partial_\mu UgV^{-1}], \end{aligned}$$

which reduces to (8) in the $H=1$ case. This can be decomposed in two more useful equations, projecting over $\mathfrak{h}$ and $\mathfrak{m}$ with π and $(1-\pi)$, respectively. Doing so, we get

$$V\Lambda_{\mu\nu}R^{\nu}V^{-1}=(\text{ vertical}), \tag{24a}$$

$$A_{\mu}-V^{-1}\partial_{\mu}V+g^{-1}U^{-1}\partial_{\mu}Ug+(R_{\mu}-\Lambda_{\mu\nu}R^{\nu})=V^{-1}(\text{ horizontal})V. \tag{24b}$$

Instead of Eq. (14) we get

$$\partial\cdot L'=\left[\partial_{\mu}u+\frac{f}{2}\omega_{\mu\nu}L^{\nu},L^{\mu}\right],$$

with a constant $\omega_{\mu\nu}$. From now on we only have to take into account the coefficient f. This results in changing the 1/2 factor by $f/2$ in Eq. (19) and all subsequent formulas. As it should, in the symmetric space case the Lax pair for U loses the 1/2 factor, $U^{-1}\partial_{\mu}U=(1-\cosh(\lambda))L_{\mu}-\sinh(\lambda)\epsilon_{\mu\nu}L^{\nu}$, and the one for V becomes zero, or a purely horizontal contribution $((1-\pi)(V^{-1}\partial V)=0)$ that corresponds anyway to a gauge transformation. This can be seen from Eq. (24a) because being $\pi(R_{\mu})=0$ (vertical), V must be generated by a horizontal element of $\mathfrak{g}$.

[9] We will use $\doteq$ for weak equality, i.e., equality over field equations.
[10] Λ could in principle be point dependent but this implies Eq. (14) must have an extra term, $L^{\nu}\partial^{\mu}\omega_{\mu\nu}$, added to the commutator. Now (15) is not a solution of (14) anymore. We have not analyzed this case but, as mentioned in the conclusions, could be relevant in a higher-dimensional case.
[11] Note that $[\partial_{\mu},\partial_{\nu}]u=F_{\mu\nu}(U^{-1}\partial U)$ up to leading order in ω.

Integrable discretizations of the Bogoyavlensky lattices

Yuri B. Suris[a)]
Centre for Complex Systems and Visualization, University of Bremen, Postfach 330 440, 28334 Bremen, Germany

(Received 17 January 1996; accepted for publication 29 April 1996)

Discretizations of the Bogoyavlensky lattices are introduced, belonging to the same hierarchies as the continuous-time systems. The construction exemplifies the general scheme for integrable discretization of systems on Lie algebras with r-matrix Poisson brackets. An initial value problem for the difference equations is solved in terms of a factorization problem in a group. Interpolating Hamiltonian flows are found. © *1996 American Institute of Physics.* [S0022-2488(96)00908-5]

I. INTRODUCTION

The subject of integrable symplectic maps has received, in recent years, considerable attention. Given an integrable system of ordinary differential equations with such attributes as Lax pair, r-matrix, and so on, one would like to construct its difference approximation, desirably also with a (discrete-time analog of) Lax pair, r-matrix, etc. Recent years brought us several successful examples of such a construction.[1–10]

Recently, stimulated by the results of Refs. 6 and 7, there was formulated a general recipe for producing discretizations sharing the Lax matrix with the continuous-time system, so that the discrete-time system belongs to the *same* integrable hierarchy as the underlying continuous-time one.[8–10]

In the present paper we want to describe a new application of this scheme, to a class of integrable systems known as Bogoyavlensky lattices[11] (although some special cases were discovered earlier in Refs. 12 and 13). An r-matrix interpretation of these systems was given in Ref. 14. Some of the discrete time equations studied in the present paper appeared previously in the literature,[15] as certain reductions of the discrete KP equation in the bilinear form. They were derived also in Ref. 16 from an *ad hoc* ansatz for the Lax pair. Our approach is quite different and enables us to get these equations systematically, and, moreover, provides automatically the Hamiltonian formulation along with the interpolating Hamiltonian flows, as well as the solution in terms of matrix factorizations.

II. CONTINUOUS-TIME BOGOYAVLENSKY LATTICES

The Bogoyavlensky lattices were introduced in Ref. 11 as three families of integrable lattice systems depending on integer parameter $m \geqslant 1$ ($m>1$ for the third one):

$$\dot{a}_k = a_k\left(\sum_{j=1}^{m} a_{k+j} - \sum_{j=1}^{m} a_{k-j}\right), \tag{2.1}$$

$$\dot{a}_k = a_k\left(\prod_{j=1}^{m} a_{k+j} - \prod_{j=1}^{m} a_{k-j}\right), \tag{2.2}$$

$$\dot{a}_k = a_k\left(\prod_{j=0}^{m} a_{k+j}^{-1} - \prod_{j=0}^{m} a_{k-j}^{-1}\right) = \prod_{j=1}^{m} a_{k+j}^{-1} - \prod_{j=1}^{m} a_{k-j}^{-1}. \tag{2.3}$$

[a)]Electronic mail address:suris@mathematik.uni-bremen.de

0022-2488/96/37(8)/3982/15/$10.00

We shall call these systems lattice 1, lattice 2, and lattice 3, respectively.

The lattices 1 and 2 serve as generalizations of the famous Volterra lattice,

$$\dot{a}_k=a_k(a_{k+1}-a_{k-1}), \tag{2.4}$$

which is $m=1$ special case of both the systems (2.1) and (2.2). Certain generalizations of the Volterra lattice, including also lattice 1, were introduced independently (and earlier) by Narita;[12] some special case of the lattice 1 was found also by Itoh.[13]

The lattice 3 after the change of variables $a_k \mapsto a_k^{-1}$ and $t \mapsto -t$ turns into

$$\dot{a}_k=a_k^2\left(\prod_{j=1}^{m} a_{k+j}-\prod_{j=1}^{m} a_{k-j}\right), \tag{2.5}$$

which serves as a generalization of the so-called modified Volterra lattice, the $m=1$ particular case of (2.5):

$$\dot{a}_k=a_k^2(a_{k+1}-a_{k-1}). \tag{2.6}$$

All these systems may be considered on an infinite lattice (all the subscripts belong to $\mathbb{Z}$), and admit also periodic finite-dimensional reductions (all the subscripts belong to $\mathbb{Z}/N\mathbb{Z}$, where N is the number of particles). The lattices 1 and 2 admit also finite-dimensional versions with boundary conditions of the open-end type:

$$\text{for system (2.1):} \quad a_k=0 \quad \text{for } k\leqslant 0, \quad k\geqslant N-m+1;$$

$$\text{for system (2.2):} \quad a_k=0 \quad \text{for } k\leqslant 0, \quad k\geqslant N.$$

Bogoyavlensky has found also the Lax representations for these systems of the form

$$\dot{T}=[T, B], \tag{2.7}$$

where for the system (2.1)

$$T(a,\lambda)=\lambda^{-m}\sum a_k E_{k,k+m}+\lambda\sum E_{k+1,k}, \tag{2.8}$$

$$B(a,\lambda)=\sum (a_k+a_{k-1}+\cdots+a_{k-m})E_{k,k}+\lambda^{m+1}\sum E_{k+m+1,k}, \tag{2.9}$$

for the system (2.2)

$$T(a,\lambda)=\lambda^{-1}\sum a_k E_{k,k+1}+\lambda^{m}\sum E_{k+m,k}, \tag{2.10}$$

$$B(a,\lambda)=-\lambda^{-m-1}\sum a_k a_{k+1}\cdots a_{k+m}E_{k,k+m+1}, \tag{2.11}$$

and for the system (2.3)

$$T(a,\lambda)=\lambda^{-1}\sum a_k E_{k,k+1}+\lambda^{-m-1}\sum E_{k,k+m+1}, \tag{2.12}$$

$$B(a,\lambda)=\lambda^m\sum a_k^{-1}a_{k+1}^{-1}\cdots a_{k+m-1}^{-1}E_{k+m,k}, \tag{2.13}$$

Here for the infinite lattices all the subscripts belong to $\mathbb{Z}$, for the periodic case all the subscripts belong to $\mathbb{Z}/N\mathbb{Z}$, and for the open-end case all the subscripts belong to $1,\ldots,N$. Moreover, in the infinite-dimensional and open-end cases the dependence on the spectral parameter λ becomes inessential and may be suppressed by setting $\lambda=1$. Below we consider only finite lattices.

All the Bogoyavlensky lattices are Hamiltonian systems. More precisely, each system (2.1), (2.2), and (2.3) is Hamiltonian with respect to a certain quadratic Poisson bracket

$$\{a_k,a_j\}=\pi_{kj}a_ka_j, \tag{2.14}$$

with a skew-symmetric matrix (π_{kj}). The corresponding Hamiltonians are

$$H(a)=\frac{1}{(m+1)}\operatorname{tr}(T^{m+1})=\sum a_k \quad \text{for the systems (2.1)},$$

$$H(a)=\frac{1}{(m+1)}\operatorname{tr}(T^{m+1})=\sum a_ka_{k+1}\cdots a_{k+m-1} \quad \text{for the systems (2.2)},$$

$$H(a)=\frac{-1}{m}\operatorname{tr}(T^{-m})=\sum a_k^{-1}a_{k+1}^{-1}\cdots a_{k+m}^{-1} \quad \text{for the system (2.3)}.$$

The Poisson brackets (2.14), i.e., the matrices (π_{kj}), in the context of infinite systems were found for the lattice 1 in the original papers by Bogoyavlensky,[11] and for the lattices 2 and 3 in Ref. 17. For the finite lattices, where some subtleties come out, this was done systematically in Ref. 14.

III. DISCRETE TIME BOGOYAVLENSKY LATTICES

We present now equations of motion of some difference equations which can be considered as analogs and approximations to the Bogoyavlensky lattices for the case of the discrete time. The "Proposition k" ($k=1,2,3$) deals with the "discrete time Bogoyavlensky lattice k." We use tilde to denote the time shift, so that, for example, $\tilde{v}_k=v_k(t+h)$, if $v_k=v_k(t)$.

Proposition 1: The system of difference equations

$$\tilde{v}_k\prod_{j=1}^{m}(1+h\tilde{v}_{k-j})=v_k\prod_{j=1}^{m}(1+hv_{k+j}) \tag{3.1}$$

admits a Lax representation

$$\tilde{T}=L^{-1}TL$$

with the matrices

$$T(v,\lambda)=\lambda^{-m}\sum \alpha_kE_{k,k+m}+\lambda\sum E_{k+1,k}, \tag{3.2}$$

$$L(v,\lambda)=\sum \beta_kE_{k,k}+h\lambda^{m+1}\sum E_{k+m+1,k}, \tag{3.3}$$

where

$$a_k=v_k\prod_{j=1}^{m}(1+hv_{k-j}),\quad \beta_k=\prod_{j=0}^{m}(1+hv_{k-j}). \tag{3.4}$$

Proposition 2: The system of difference equations

$$\tilde{v}_k\left(1+h\prod_{j=1}^{m}\tilde{v}_{k-j}\right)=v_k\left(1+h\prod_{j=1}^{m}v_{k+j}\right) \tag{3.5}$$

admits a Lax representation

$$\tilde{T}=UTU^{-1}$$

with the matrices

$$T(v,\lambda)=\lambda^{-1}\sum a_kE_{k,k+1}+\lambda^m\sum E_{k+m,k}, \tag{3.6}$$

$$U(v,\lambda)=I+h\lambda^{-m-1}\sum \gamma_kE_{k,k+m+1}, \tag{3.7}$$

where

$$a_k=v_k\left(1+h\prod_{j=1}^{m}v_{k-j}\right),\quad \gamma_k=\prod_{j=0}^{m}v_{k+j}. \tag{3.8}$$

Proposition 3: The system of difference equations

$$\tilde{v}_k\left(1+h\prod_{j=0}^{m}\tilde{v}^{-1}_{k-j}\right)=v_k\left(1+h\prod_{j=0}^{m}v^{-1}_{k+j}\right) \tag{3.9}$$

admits a Lax representation

$$\tilde{T}=L^{-1}TL$$

with the Lax matrices

$$T(v,\lambda)=\lambda^{-1}\sum a_kE_{k,k+1}+\lambda^{-m-1}\sum E_{k,k+m+1}, \tag{3.10}$$

$$L(v,\lambda)=1+h\lambda^m\sum \alpha_kE_{k+m,k}, \tag{3.11}$$

where

$$a_k=v_k\left(1+h\prod_{j=0}^{m}v^{-1}_{k-j}\right),\quad \alpha_k=\prod_{j=0}^{m-1}v^{-1}_{k+j}. \tag{3.12}$$

Remark 1: Upon change of variables $v_k\mapsto v_k^{-1}$ and $h\mapsto -h$ the system (3.9) turns into

$$\tilde{v}_k\left(1-h\prod_{j=0}^{m}\tilde{v}_{k-j}\right)^{-1}=v_k\left(1-h\prod_{j=0}^{m}v_{k+j}\right)^{-1}, \tag{3.13}$$

which may be considered as a discrete time analog and approximation to (2.5).

Remark 2: The equation (3.1) was found in Ref. 15 as a certain reduction of the discrete KP equation in the bilinear form. The equations (3.1) and (3.5) for $m=1$ coincide, as they should (Volterra lattice). The Lax representation for this case with the matrices (3.6) and (3.7) was also given in Ref. 15, but without any hint on how it was obtained. After the present paper was submitted for publication, I became aware of Ref. 16, where equations (3.1), (3.5), and (3.9) are derived from an *ad hoc* ansatz for the Lax pair. (I thank V. Papageorgiou and F. W. Nijhoff for sending me their paper prior to publication.) However, our point of view and results concerning these equations are very different from those of Ref. 16.

In the above formulation the Propositions 1–3 may be easily checked by a direct computation, but their origin remains hidden. In the following sections we shall give a way to *derive* them systematically, which, as a by-product, will unvail an underlying invariant Poisson structure of these discrete systems, as well as a role of the auxiliary matrices L, U. This, in turn, will enable us to solve the initial value problems for our systems in terms of matrix factorizations and to find interpolating Hamiltonian flows. Our construction is just a particular case of a general one, applicable, in principle, to every system admitting an r-matrix interpretation. The key observation is that the Lax matrices (3.2), (3.6), and (3.10) of the discrete time systems formally coincide with the corresponding Lax matrices (2.8), (2.10), and (2.12) of the continuous time ones.

IV. ALGEBRAIC STRUCTURE OF BOGOYAVLENSKY LATTICES

In Ref. 14 we gave an r-matrix interpretation of the Bogoyavlensky lattices as simplest representatives of integrable hierarchies on associative algebras. The main results of Ref. 14 may be summarized as follows.

(1) For the *open-end case* (applies only to the lattices 1 and 2) we set $\mathbf{g}=\mathrm{gl}(N)$. To this algebra there corresponds a group $\mathbf{G}=\mathrm{GL}(N)$. As a linear space, $\mathbf{g}$ may be represented as a direct sum of two subspaces, which serve also as subalgebras: $\mathbf{g}=\mathbf{g}_+\oplus\mathbf{g}_-$. Here $\mathbf{g}_+$ ($\mathbf{g}_-$) is a space of all lower triangular (resp. strictly upper triangular) N by N matrices. The corresponding subgroups: $\mathbf{G}_+$ ($\mathbf{G}_-$) is a group of all nondegenerate lower triangular N by N matrices (resp. upper triangular N by N matrices with unities on the diagonal).

(2) For the *periodic case* (of all lattices 1, 2, and 3) $\mathbf{g}$ is a certain twisted loop algebra over $\mathrm{gl}(N)$, namely the algebra of formal semi-infinite Laurent series $T(\lambda)$ over $\mathrm{gl}(N)$, satisfying $\Omega T(\lambda)\Omega^{-1}=T(\omega\lambda)$, where $\Omega=\mathrm{diag}(1,\omega,\ldots,\omega^{N-1})$ and $\omega=\exp(2\pi i/N)$. The corresponding group is the twisted loop group $\mathbf{G}$ consisting of $\mathrm{GL}(N)$-valued functions $T(\lambda)$ of the complex parameter λ, regular in $\mathbb{C}P^1\{0,\infty\}$ and satisfying $\Omega T(\lambda)\Omega^{-1}=T(\omega\lambda)$. Again, as a linear space $\mathbf{g}=\mathbf{g}_+\oplus\mathbf{g}_-$, where for the lattices 1 and 2, $\mathbf{g}_+$ ($\mathbf{g}_-$) is a subspace and subalgebra consisting of $T(\lambda)$ containing only non-negative (resp. only negative) powers of λ, and the case of the lattice 3 differs in that, to which subalgebra do diagonal matrices belong: $\mathbf{g}_+$ contains only positive, and $\mathbf{g}_-$ only nonpositive powers of λ. For the lattices 1 and 2 the corresponding subgroups $\mathbf{G}_+$ and $\mathbf{G}_-$ consist of $T(\lambda)$ regular in the neighborhood of $\lambda=0$ (resp. regular in the neighborhood of $\lambda=\infty$ and taking the value I in $\lambda=\infty$). For the lattice 3 $\mathbf{G}_+$ is formed by $T(\lambda)$ regular in the neighborhood of $\lambda=0$ with $T(0)=I$, and $\mathbf{G}_-$ is formed by $T(\lambda)$ regular in the neighborhood of $\lambda=\infty$.

We shall need a notion of the gradient $\nabla\varphi(T)\in\mathbf{g}$ of a function $\varphi:\mathbf{g}\to\mathbb{C}$, defined in the open-end case by the relation

$$\mathrm{tr}(\nabla\varphi(T)X)=\frac{d}{d\varepsilon}\,\varphi(T+\varepsilon X)\bigg|_{\varepsilon=0}\qquad\forall X\in\mathbf{g};$$

in the periodic case "tr" should be replaced by "tr_0", the free term in the Laurent series for the trace.

For both the open-end and periodic cases every $T \in \mathbf{g}$ admits a unique decomposition $T = l(T) + u(T)$, where $l(T) \in \mathbf{g}_+$ and $u(T) \in \mathbf{g}_-$. Analogously, for both cases every $T \in \mathbf{G}$ from some neighborhood of the group unity admits a unique factorization $T = \mathscr{L}(T)\mathscr{U}(T)$, where $\mathscr{L}(T) \in \mathbf{G}_+$ and $\mathscr{U}(T) \in \mathbf{G}_-$.

There hold the following statements.

(a) For each system (2.1), (2.2), and (2.3) there exists a quadratic r-matrix Poisson bracket on $\mathbf{g}$ whose Dirac reduction to the corresponding set of matrices $\mathscr{P} = \{T(a,\lambda)\}$ from (2.8), (2.10), or (2.12), respectively, is given by (2.14).

(b) Let $\varphi: \mathbf{g} \to \mathbf{C}$ be an invariant function, so that $d\varphi(T) = T\nabla\varphi(T) = \nabla\varphi(T)T$ is covariant under conjugation. Then the Hamiltonian flow on $\mathbf{g}$ with the Hamiltonian function $\varphi(T^p)/p$ (here and below $p = m+1$ for the lattices 1 and 2, and $p = m$ for the lattice 3) is tangent to $\mathscr{P}$ and has the Lax form

$$\dot{T} = [T,\ l(d\varphi(T^p))] = -[T,\ u(d\varphi(T^p))]. \tag{4.1}$$

This flow admits the following solution in terms of the factorization problem

$$e^{td\varphi(T^p(0))} = \mathscr{L}(t)\mathscr{U}(t), \quad \mathscr{L}(t) \in \mathbf{G}_+, \quad \mathscr{U}(t) \in \mathbf{G}_-$$

(this problem has solutions at least for sufficiently small t):

$$T(t) = \mathscr{L}^{-1}(t)T(0)\mathscr{L}(t) = \mathscr{U}(t)T(0)\mathscr{U}^{-1}(t).$$

(c) Let $f: \mathbf{g} \to \mathbf{G}$ be a conjugation covariant function on $\mathbf{g}$. Then the difference equation

$$\tilde{T} = \mathscr{L}^{-1}(f(T^p))T\mathscr{L}(f(T^p)) = \mathscr{U}(f(T^p))T\mathscr{U}^{-1}(f(T^p)) \tag{4.2}$$

defines a Poisson map $\mathbf{g} \to \mathbf{g}$ which leaves $\mathscr{P}$ invariant, the restriction of this map on $\mathscr{P}$ being Poisson with respect to the reduced bracket (2.14). This difference equation admits the following solution in terms of the factorization problem

$$f^n(T^p(0)) = \mathscr{L}(nh)\mathscr{U}(nh), \quad \mathscr{L}(nh) \in \mathbf{G}_+, \quad \mathscr{U}(nh) \in \mathbf{G}_-$$

[this problem has solutions for a given n at least if $f(T(0))$ is sufficiently close to the group unity I]:

$$T(nh) = \mathscr{L}^{-1}(nh)T(0)\mathscr{L}(nh) = \mathscr{U}(nh)T(0)\mathscr{U}^{-1}(nh).$$

(d) The solutions of the difference equation (4.2) are interpolated by the flow (4.1) with the Hamiltonian function $\varphi(T^p)/p$, where $\varphi(T)$ is defined by

$$d\varphi(T) = h^{-1}\log(f(T)). \tag{4.3}$$

The statements (a) and (b) explain the Lax equation (2.7) with the matrices (2.8)–(2.13); as for the system (2.1) we have $B(a,\lambda) = l(T^{m+1}(a,\lambda))$, for the system (2.2) we have $B(a,\lambda) = -u(T^{m+1}(a,\lambda))$, and for the system (2.3) we have $B(a,\lambda) = l(T^{-m}(a,\lambda))$.

V. A DISCRETIZATION OF THE BOGOYAVLENSKY LATTICE 1

We get a correct perspective for the interpretation of the system (3.1) [as well as the systems (3.5) and (3.9)] if we take an "inverse" view-point. We consider the first equation in (3.4) as an implicit definition of the functions $v_k = v_k(a)$, rather then the expressions of a_k through v_j. In the open-end case the sequence of v_k's can be computed even explicitly, term by term, starting with

$v_k=a_k/(1+h\Sigma_{j=1}^{k-1}a_j)$ for $1\leqslant k\leqslant m+1$. In particular, for $m=1$, one has $v_k=a_k/(1+hv_{k-1})$, which implies a nice representation in form of a finite continued fraction:

$$v_k=\cfrac{a_k}{1+\cfrac{ha_{k-1}}{1+\ddots+\cfrac{ha_2}{1+ha_1}}}. \tag{5.1}$$

In the periodic case the existence of the functions $v_k=v_k(a)$, at least for h small enough, follows from the implicit functions theorem. Again, for $m=1$ we get an expression in the form of an infinite N-periodic continued fraction of the type (5.1).

The second equation in (3.4) may be rewritten as a recurrent relation for $\beta_k=\beta_k(a)$. In fact, we have $\beta_k-ha_k=\Pi_{j=1}^{m}(1+hv_{k-j})$, so that $a_k/(\beta_k-ha_k)=v_k$, and finally

$$\beta_k-ha_k=\prod_{j=1}^{m}\left(1+\frac{ha_{k-j}}{\beta_{k-j}-ha_{k-j}}\right). \tag{5.2}$$

Conversely, the last formula implies (3.4), if one sets $v_k=a_k/(\beta_k-ha_k)$.

The formula (5.2) may also serve for a successive computation of β_ks in the open-end case, and in the periodic case it uniquely defines a set of β_k-ha_k, $1\leqslant k\leqslant N$, via the implicit functions theorem. In both cases it is easy to see that

$$\beta_k=1+h\sum_{j=0}^{m}a_{k-j}+O(h^2). \tag{5.3}$$

Theorem 1: The quantities β_k defined by (5.2) serve as coefficients of the matrix

$$L=\mathscr{Z}(I+hT^{m+1})=\sum_k \beta_k E_{k,k}+h\lambda^{m+1}\sum_k E_{k+m+1,k}. \tag{5.4}$$

The discrete time Lax equation

$$\widetilde{T}=L^{-1}TL=\mathscr{Z}^{-1}(I+hT^{m+1})T\mathscr{Z}(I+hT^{m+1}). \tag{5.5}$$

with the Lax matrix (2.8) generates the following map on $\mathbb{R}^N\{a\}$, equivalent to (3.1):

$$\widetilde{a}_k=\frac{\beta_{k+m}}{\beta_k}a_k. \tag{5.6}$$

This map is Poisson with respect to the Poisson bracket (2.14) corresponding to the lattice 1, and is interpolated by the flow with the Hamiltonian function

$$\frac{1}{m+1}\operatorname{tr}\Phi(T^{m+1}),\quad \text{where}\quad \Phi(\xi)=h^{-1}\int_0^{\xi}\log(1+h\eta)\,\frac{d\eta}{\eta}. \tag{5.7}$$

Proof: The last two statements follow from the results formulated in the previous section, provided the first two statements are proved. Suppose for a moment that the $\mathscr{Z}$-factor of $I+hT^{m+1}$ has the form (5.4). Then the evolution equation (5.5), i.e., $L\widetilde{T}=TL$, is equivalent to

$$\beta_k\bar{a}_k=a_k\beta_{k+m},\quad h\tilde{a}_k+\beta_{k+m+1}=ha_{k+m+1}+\beta_{k+m}. \tag{5.8}$$

This in turn is equivalent to a combination of an evolution equation (5.6) with the condition of compatibility of two equations in (5.8):

$$\beta_k-ha_k=\frac{\beta_k}{\beta_{k+m}}(\beta_{k+m+1}-ha_{k+m+1}). \tag{5.9}$$

The last equation is equivalent to the fact that

$$\frac{\prod_{j=0}^{m}(\beta_{k+j}-ha_{k+j})}{\prod_{j=0}^{m-1}\beta_{k+j}}=\text{const}, \tag{5.10}$$

i.e., does not depend on k. We shall prove that the actual value of this constant is equal to 1, which is just equivalent to (5.2).

The inspection of the structure of the matrix T^{m+1} for T from (2.8) convinces us that the $\mathscr{L}$-factor of $I+hT^{m+1}$ has in fact the form (5.4), while the $\mathscr{U}$-factor has the form

$$U=\mathscr{U}(I+hT^{m+1})=I+h\sum_{j=1}^{m}\lambda^{-j(m+1)}\sum_k\gamma_k^{(j)}E_{k,k+j(m+1)}.$$

The quantities $\beta_k,\gamma_k^{(j)}$ are completely defined by the set of recurrent relations following from the definitions:

$$\beta_k+h^2\gamma_{k-m-1}^{(1)}=1+h\sum_{j=0}^{m}a_{k-j}, \tag{5.11}$$

$$\beta_k\gamma_k^{(j)}+h\gamma_{k-m-1}^{(j+1)}=\text{coef. by }\lambda^{-j(m+1)}E_{k,k+j(m+1)}\text{ in }T^{m+1},\quad 1\leq j\leq m-1;$$

$$\beta_k\gamma_k^{(m)}=\prod_{j=0}^{m}a_{k+jm}.$$

Now we are in a position to prove that the constant in (5.10) is equal to 1.

Indeed, in the open-end case it is enough to compute from (5.11) the first $m+1$ values of β_k, namely $\beta_k=1+h\Sigma_{j=1}^{k}a_j$, $1\leq k\leq m+1$, which implies $\Pi_{j=1}^{m+1}(\beta_j-ha_j)/\Pi_{j=1}^{m}\beta_j=1$.

In the periodic case we have found only a combinatoric proof based on tedious computations. For the sake of simplicity and in order to avoid complicated notations we present the corresponding argument only in the simplest cases $m=1,2$.

In the case $m=1$ the defining recurrent relations take the form

$$\beta_k+h^2\gamma_{k-2}^{(1)}=1+ha_k+ha_{k-1},\quad \beta_k\gamma_k^{(1)}=a_ka_{k+1}.$$

Excluding $\gamma_k^{(1)}$ from these relations, we obtain

$$1=\beta_{k+2}-ha_{k+2}-ha_{k+1}\frac{\beta_k-ha_k}{\beta_k}.$$

Replacing the fraction on the right-hand side through its expression following from (5.9) for $m=1$, we obtain

$$1=\frac{(\beta_{k+2}-ha_{k+2})(\beta_{k+1}-ha_{k+1})}{\beta_{k+1}},$$

which proves the theorem in the case $m=1$.

For $m=2$, the defining recurrent relations take the form

$$\beta_k+h^2\gamma^{(1)}_{k-3}=1+ha_k+ha_{k-1}+ha_{k-2},$$

$$\beta_k\gamma^{(1)}_k+h\gamma^{(2)}_{k-3}=a_ka_{k+2}+a_ka_{k+1}+a_{k-1}a_{k+1},\quad \beta_k\gamma^{(2)}_k=a_ka_{k+2}a_{k+4}.$$

Excluding from these relations $\gamma^{(j)}_k$, we obtain

$$1=\beta_{k+3}-ha_{k+3}-h(a_{k+2}+a_{k+1})\frac{\beta_k-ha_k}{\beta_k}+h^2a_{k+1}a_{k-1}\frac{\beta_{k-3}-ha_{k-3}}{\beta_k\beta_{k-3}}.$$

According to (5.9) for $m=2$, this is equivalent to

$$\begin{aligned}1&=\beta_{k+3}-ha_{k+3}-h(a_{k+2}+a_{k+1})\frac{\beta_{k+3}-ha_{k+3}}{\beta_{k+2}}+h^2a_{k+1}a_{k-1}\frac{\beta_{k+3}-ha_{k+3}}{\beta_{k+2}\beta_{k-1}}\\&=\frac{(\beta_{k+3}-ha_{k+3})(\beta_{k+2}-ha_{k+2})}{\beta_{k+2}}-ha_{k+1}\frac{(\beta_{k+3}-ha_{k+3})(\beta_{k-1}-ha_{k-1})}{\beta_{k+2}\beta_{k-1}}.\end{aligned}$$

Using in the last term once more (5.9) for $m=2$, we obtain

$$1=\frac{(\beta_{k+3}-ha_{k+3})(\beta_{k+2}-ha_{k+2})(\beta_{k+1}-ha_{k+1})}{\beta_{k+2}\beta_{k+1}},$$

which proves the theorem for $m=2$. The pattern of the proof for a general m may be seen from these two particular cases.

VI. A DISCRETIZATION OF THE BOGOYAVLENSKY LATTICE 2

For the lattice 2 we again consider the first equation in (3.8) as a definition of the functions $v_k=v_k(a)$. In the open-end case we can compute these functions successively, starting with $v_k=a_k(1+h\Sigma_{j=1}^{k-2}\Pi_{l=1}^{j}a_l)/(1+h\Sigma_{j=1}^{k-1}\Pi_{l=1}^{j}a_l)$ for $1\leqslant k\leqslant m+1$. In the periodic case the implicit functions theorem has to be invoked. In particular, for the case $m=1$ we obtain the same continued fractions expressions as in the previous section.

The second equation in (3.8) may be represented as a recurrent relation for $\gamma_k=\gamma_k(a)$. Indeed, we have $a_k-h\gamma_{k-m}=v_k$, so that

$$a_k-h\gamma_{k-m}=\frac{a_k}{1+h\prod_{j=1}^{m}(a_{k-j}-h\gamma_{k-m-j})}. \tag{6.1}$$

Conversely, the last formula implies (3.8), if one sets $v_k=a_k-h\gamma_{k-m}$.

In the open-end case the formula (6.1) serves as a basis for successive computation of γ_ks, and in the periodic case it uniquely defines, by the implicit function theorem, the quantities $a_{k+m}-h\gamma_k$, $1\leqslant k\leqslant N$. In both cases there holds the following asymptotic relation:

$$\gamma_k=\prod_{j=0}^{m}a_{k+j}(1+O(h)). \tag{6.2}$$

Theorem 2: The quantities γ_k defined by (6.1) serve as coefficients of the matrix

$$U=\mathscr{U}(I+hT^{m+1})=I+h\lambda^{-(m+1)}\sum_k \gamma_k E_{k,k+m+1}, \tag{6.3}$$

The discrete time Lax equation

$$\widetilde{T}=UTU^{-1}=\mathscr{U}(I+hT^{m+1})T\mathscr{U}^{-1}(I+hT^{m+1}) \tag{6.4}$$

with the Lax matrix (2.10) generates the following map on $\mathbb{R}^N\{a\}$, equivalent to (3.5):

$$\widetilde{a}_k=\frac{a_k-h\gamma_{k-m}}{a_{k+m+1}-h\gamma_{k+1}}a_{k+m+1}. \tag{6.5}$$

This map is Poisson with respect to the Poisson bracket (2.14) corresponding to the lattice 2, and is interpolated by the flow with the Hamiltonian function (5.7).

Proof: Again, it suffices to prove the first two statements. Assuming for a moment that the $\mathscr{U}$-factor of the the matrix $I+hT^{m+1}$ for T from (2.10) has the form (6.3), we see that the evolution equation (6.4), i.e., $\widetilde{T}U=UT$, is equivalent to

$$\widetilde{a}_k\gamma_{k+1}=\gamma_k a_{k+m+1}, \quad \widetilde{a}_k+h\gamma_{k-m}=a_k+h\gamma_k. \tag{6.6}$$

This in turn is equivalent to a combination of an evolution equation (6.5) with the condition of compatibility of two equations in (6.6):

$$a_k-h\gamma_{k-m}=\frac{\gamma_k}{\gamma_{k+1}}(a_{k+m+1}-h\gamma_{k+1}). \tag{6.7}$$

The last equation is equivalent to the fact that

$$\frac{1}{\gamma_k}\prod_{j=0}^{m}(a_{k+m-j}-h\gamma_{k-j})=\text{const}, \tag{6.8}$$

i.e., does not depend on k. We shall prove that the actual value of this constant is equal to 1, which is equivalent to (6.1).

This time the inspection convinces us that the $\mathscr{U}$-factor of the matrix $I+hT^{m+1}$ for T from (2.10) must indeed have the form (6.3), while the $\mathscr{L}$-factor must have the form

$$L=\mathscr{L}(I+hT^{m+1})=\sum_k \beta_k^{(0)}E_{k,k}+h\sum_{j=1}^{m}\lambda^{j(m+1)}\sum_k \beta_k^{(j)}E_{k+j(m+1),k},$$

where $\beta_k^{(m)}=1$, and other quantities $\gamma_k,\beta_k^{(j)}$ are completely defined by the recurrent relations following from the definitions:

$$\beta_k^{(0)}\gamma_k=\prod_{j=0}^{m}a_{k+j}, \tag{6.9}$$

$$\beta_k^{(0)}+h^2\beta_{k-m-1}^{(1)}\gamma_{k-m-1}=1+h\sum_{l=k-m}^{k}\prod_{j=0}^{m-1}a_{l+j}, \tag{6.10}$$

$\beta_k^{(j)}+h\beta_{k-m-1}^{(j+t)}\gamma_{k-m-1}=$coef. by $\lambda^{j(m+1)}E_{k+j(m+1),k}$ in T^{m+1}, $1\leqslant j\leqslant m-1$.

To prove that the constant in (6.8) is equal to 1, in the open-end case it is enough to compute from (6.9) and (6.10) the first $m+1$ values of γ_k, namely $\gamma_k=\Pi_{j=0}^{m}a_{k+j}/(1+h\Sigma_{l=1}^{k}\Pi a_{l+j})$, $1\leqslant k\leqslant m+1$, which implies $\Pi_{j=1}^{m+1}(a_{j+m}-h\gamma_j)/\gamma_{m+1}=1$.

In the periodic case we shall again give the proof only for $m=1,2$, leaving the tedious calculations for the general case to the reader. For $m=1$ the defining recurrences (6.9) and (6.10) take the form

$$\beta_k^{(0)}\gamma_k=a_ka_{k+1},\quad \beta_k^{(0)}+h^2\gamma_{k-2}=1+ha_k+ha_{k-1}.$$

Excluding from these relations $\beta_k^{(0)}$, we obtain

$$1=\frac{a_k}{\gamma_k}(a_{k+1}-h\gamma_k)-h(a_{k-1}-h\gamma_{k-2}).$$

Replacing the last term on the right-hand side through its expression following from (6.7) for $m=1$, we obtain

$$1=\frac{(a_{k+1}-h\gamma_k)(a_k-h\gamma_{k-1})}{\gamma_k},$$

which proves the theorem for $m=1$.

In the case $m=2$ the recurrent relations (6.9) and (6.10) take the form

$$\beta_k^{(0)}\gamma_k=a_ka_{k+1}a_{k+2},\quad \beta_k^{(0)}+h^2\beta_{k-3}^{(1)}\gamma_{k-3}=1+h(a_{k-2}a_{k-1}+a_{k-1}a_k+a_ka_{k+1}),$$

$$\beta_k^{(1)}+h\gamma_{k-3}=a_{k-1}+a_{k+1}+a_{k+3}.$$

Excluding $\beta_k^{(j)}$ from these relations, we obtain

$$1=\frac{a_ka_{k+1}}{\gamma_k}(a_{k+2}-h\gamma_k)-h(a_{k-2}+a_k)(a_{k-1}-h\gamma_{k-3})+h^2\gamma_{k-3}(a_{k-4}-h\gamma_{k-6}).$$

Using on the right-hand side repeatedly (6.7) for $m=2$, we can rewrite it as

$$1=\frac{a_ka_{k+1}}{\gamma_k}(a_{k+2}-h\gamma_k)-\frac{h(a_{k-2}+a_k)\gamma_{k-1}}{\gamma_k}(a_{k+2}-h\gamma_k)+\frac{h^2\gamma_{k-4}\gamma_{k-1}}{\gamma_k}(a_{k+2}-h\gamma_k)$$

$$=\frac{a_k}{\gamma_k}(a_{k+2}-h\gamma_k)(a_{k+1}-h\gamma_{k-1})-\frac{h\gamma_{k-1}}{\gamma_k}(a_{k+2}-h\gamma_k)(a_{k-2}-h\gamma_{k-4}).$$

Using in the last term once more (6.7) for $m=2$, we obtain

$$1=\frac{1}{\gamma_k}(a_{k+2}-h\gamma_k)(a_{k+1}-h\gamma_{k-1})(a_k-h\gamma_{k-2}),$$

which finishes the proof for $m=2$.

VII. A DISCRETIZATION OF THE BOGOYAVLENSKY LATTICE 3

For the lattice 3 we again define the functions $v_k=v_k(a)$ by means of the first equation in (3.12), which is justified by the implicit function theorem (as opposed to the lattices 1,2, this time an open-end reduction is not admissible, so that only the periodic case needs to be considered). In particular, for $m=1$ we have $v_k=a_k-h/v_{k-1}$, which leads to the expression in terms of an infinite N-periodic continued fraction:

$$v_k=a_k-\cfrac{h}{a_{k-1}-\ddots-\cfrac{h}{a_{k-N+1}-\cfrac{h}{v_k}}}.$$

The second equation in (3.8) implies $a_k-h\alpha_{k-m}=v_k$, and hence

$$\alpha_k=\prod_{j=0}^{m-1}\frac{1}{a_{k+j}-h\alpha_{k+j-m}}. \tag{7.1}$$

Conversely, the last formula implies (3.12), if one defines $v_k=a_k-h\alpha_{k-m}$.

The formula (7.1) defines, by the implicit function theorem, the set of quantities $\alpha_k, 1\leqslant k\leqslant N$, satisfying

$$\alpha_k=\prod_{j=0}^{m-1}a_{k+j}^{-1}(1+O(h)). \tag{7.2}$$

Theorem 3: The quantities α_k defined by (7.1) serve as coefficients of the matrix

$$L=\mathscr{L}(I+hT^{-m})=I+h\lambda^m\sum_k \alpha_k E_{k+m,k}. \tag{7.3}$$

The discrete time Lax equation

$$\widetilde{T}=L^{-1}TL=\mathscr{L}^{-1}(I+hT^{-m})T\mathscr{L}(I+hT^{-m}) \tag{7.4}$$

with the Lax matrix (2.12) generates the following map on $\mathbb{R}^N\{a\}$, equivalent to (3.9):

$$\widetilde{a}_k=\frac{a_k-h\alpha_{k-m}}{a_{k+m}-h\alpha_k}a_{k+m}. \tag{7.5}$$

This map is Poisson with respect to the Poisson bracket (2.14) corresponding to the lattice 3, and is interpolated by the flow with the Hamiltonian function

$$-\frac{1}{m}\operatorname{tr}\Phi(T^{-m}),\quad \text{where}\quad \Phi(\xi)=h^{-1}\int_0^{\xi}\log(1+h\eta)\frac{d\eta}{\eta}.$$

Proof: Again, it suffices to prove the first two statements. Assuming for a moment that the $\mathscr{L}$-factor of the matrix $I+hT^{-m}$ for T from (2.12) has the form (7.3), we see that the evolution equation (7.4), i.e., $L\widetilde{T}=TL$, is equivalent to

$$\alpha_k\widetilde{a}_k=a_{k+m}\alpha_{k+1},\quad \widetilde{a}_k+h\alpha_{k-m}=a_k+h\alpha_{k+1}. \tag{7.6}$$

This in turn is equivalent to a combination of an evolution equation (7.5) with the condition of compatibility of two equations in (7.6):

$$a_k-h\alpha_{k-m}=\frac{\alpha_{k+1}}{\alpha_k}(a_{k+m}-h\alpha_k). \tag{7.7}$$

The last equation is equivalent to the fact that

$$\alpha_k \prod_{j=0}^{m-1} (a_{k+j} - h\alpha_{k+k-m}) = \text{const}, \tag{7.8}$$

i.e., does not depend on k. We shall prove that the actual value of this constant is equal to 1, which is equivalent to (7.1).

To compute the $\mathscr{L}$-factor of the matrix $I+hT^{-m}$ for T from (2.12), we notice, first, that $T^{-1}=CD^{-1}$, where

$$C=\lambda\sum_k a_k^{-1}E_{k+1,k}, \quad D=I+\lambda^{-m}\sum_k a_{k+m}^{-1}E_{k,k+m}.$$

Further, notice that the $\mathscr{L}$-factor of any matrix is not changed under the right multiplication by the factor from $\mathbf{G}_-$. We multiply the matrix $I+hT^{-m}=I+(CD^{-1})^m$ from the right by $(DC^{-1})^m C^m$. To see that this matrix belongs to G_-, notice that it is equal to $DD_1\cdots D_{m-1}$, where $D_j=C^{-j}DC^j=I+\lambda^{-m}\Sigma d_k^{(j)}E_{k,k+m}\in\mathbf{G}_-$. For the further reference we give here an explicit formula

$$d_k^{(j)}=\prod_{l=0}^{j-1} a_{k+1}\prod_{l=0}^{j} a_{k+m+l}^{-1}.$$

So we obtain

$$\mathscr{L}(I+hT^{-m})=\mathscr{L}(DD_1\cdots D_{m-1}+hC^m),$$

and an inspection of this formula convinces us that this factor must indeed be of the form (7.3), while

$$\mathscr{U}(DD_1\cdots D_{m-1}+hC^m)=\sum_{j=0}^{m}\lambda^{-jm}\sum_k \beta_k^{(j)}E_{k,k+jm}.$$

Here the quantities $\alpha_k,\beta_k^{(j)}$ are completely defined by the recurrent relations following from the definitions:

$$\alpha_k\beta_k^{(0)}=\prod_{j=0}^{m-1} a_{k+j}^{-1}, \tag{7.9}$$

$$\beta_k^{(0)}+h\alpha_{k-m}\beta_{k-m}^{(1)}=1, \tag{7.10}$$

$\beta_k^{(j)}+h\alpha_{k-m}\beta_{k-m}^{(j+1)}=$coef. by $\lambda^{-jm}E_{k,k+jm}$ in $DD_1\cdots D_{m-1}$, $1\leq j\leq m$. (In the last equation for $j=m$ one must set $\beta_k^{(m+1)}=0$, which leads to $\beta_k^{(m)}=\Pi_{l=0}^{m-1}a_{k+m^2+l}^{-1}$.)

Again, we shall prove that the constant in (7.8) is equal to 1, only for the two simplest cases $m=1,2$, leaving the calculations for the general case to the reader.

For $m=1$ the defining recurrences (7.9) and (7.10) read

$$\alpha_k\beta_k^{(0)}=a_k^{-1}, \quad \beta_k^{(0)}+h\alpha_{k-1}\beta_{k-1}^{(1)}=1, \quad \beta_k^{(1)}=a_{k+1}^{-1}.$$

Excluding from these relations $\beta_k^{(0)},\beta_k^{(1)}$, we obtain

$$\frac{a_k^{-1}}{\alpha_k}=1-ha_k^{-1}\alpha_{k-1} \quad \text{or} \quad \frac{1}{\alpha_k}=a_k-h\alpha_{k-1},$$

which proves the theorem for $m=1$.

In the case $m=2$ the recurrent relations (7.9) and (7.10) take the form

$$\alpha_k\beta_k^{(0)}=a_k^{-1}a_{k+1}^{-1} \quad \beta_k^{(0)}+h\alpha_{k-2}\beta_{k-2}^{(1)}=1,$$

$$\beta_k^{(1)}+h\alpha_{k-2}\beta_{k-2}^{(2)}=a_{k+2}^{-1}+a_ka_{k+2}^{-1}a_{k+3}^{-1}, \quad \beta_k^{(2)}=a_{k+4}^{-1}a_{k+5}^{-1}.$$

Excluding $\beta_k^{(j)}$ from these relations, we obtain

$$\frac{a_k^{-1}a_{k+1}^{-1}}{\alpha_k}=1-h\alpha_{k-2}(a_k^{-1}+a_{k-2}a_k^{-1}a_{k+1}^{-1}-h\alpha_{k-4}a_k^{-1}a_{k+1}^{-1}),$$

or

$$\frac{1}{\alpha_k}=a_{k+1}(a_k-h\alpha_{k-2})-h\alpha_{k-2}(a_{k-2}-h\alpha_{k-4}).$$

Using in the last term on the right-hand side (7.7) for $m=2$, we can rewrite the last expression as

$$\frac{1}{\alpha_k}=a_{k+1}(a_k-h\alpha_{k-2})-h\alpha_{k-1}(a_k-h\alpha_{k-2})=(a_{k+1}-h\alpha_{k-1})(a_k-h\alpha_{k-2}).$$

This finishes the proof for $m=2$. Again, we hope that the pattern of the general proof is clear from these two simple cases. It would be highly desirable to find a less computational proof for the periodic case of all three lattices.

VIII. CONCLUSION

A new application of a general scheme for producing integrable discretizations for integrable Hamiltonian flows is described in the present paper. Advantages of this approach are rather obvious: it is, in principle, applicable in a standardized way to every system admitting an r-matrix formulation, at least with a constant r-matrix satisfying the modified Yang–Baxter equation. We shall demonstrate elsewhere that the discrete time systems from Refs. 6 and 7 with dynamical r-matrices may be also included into this framework. We hope also to report on numerous further applications of this approach in the future.

The drawback of this scheme is also obvious to any expert in this field. Namely, some of the most beautiful discretizations do not live on the same r-matrix orbits as their continuous time counterparts,[1,3–5] and there seems to exist no way of *a priori* identifying the correct orbit for nice discretizations. However, we hope that continuing to collect examples will someday bring some light to this intriguing problem.

(Received 7 March 1996; accepted for publication 10 May 1996)

The gravitational ionization of a Keplerian binary system via normally incident periodic gravitational radiation of definite helicity is discussed. The periodic orbits of the planar tidal equation are investigated on the basis of degenerate continuation theory. The relevance of the Kolmogorov-Arnold-Moser theory to the question of gravitational ionization is elucidated, and it is conjectured that the process of ionization is closely related to the Arnold diffusion of the perturbed system. © *1996 American Institute of Physics.* [S0022-2488(96)02208-6]

I. INTRODUCTION

In a recent paper,[1] we considered the long-term nonlinear perturbations of Keplerian orbits by incident gravitational waves of wavelengths much larger than the size of the system. In particular, we studied the periodic orbits of the perturbed system using the methods developed in Ref. 2. The existence of periodic orbits indicates the possibility of balance in the exchange of energy between the binary and the external radiation field. Thus gravitational ionization does not occur for such orbits. The issue of gravitational ionization is interesting as it involves the transport of energy by gravitational radiation and is analogous to the corresponding phenomenon that is well known in the electromagnetic context.

The theoretical investigation of the interaction of a binary system with the gravitational radiation field reveals subtle phenomena that are further studied in this paper. In particular, the absorption of gravitational radiation energy by the binary is not unidirectional in general. That is, the orbital energy of a binary immersed in a gravitational radiation field does not in general increase monotonically with time. On the other hand, the emission of gravitational radiation by the binary is expected to be accompanied by the monotonic decrease of the orbital energy of the system. In absorption, however, the incident wave can deposit energy into the orbit during one time interval and remove energy from the orbit during another time interval. A periodic orbit would result—even when the emission of the radiation by the binary is ignored—if after a certain time the net flow of energy between the incident wave and the binary is zero.

Let us imagine, for the sake of simplicity, that gravitational radiation is incident on a Newtonian binary system consisting of a massive body of mass M_0 at the origin of inertial coordinates and a particle of test mass $m_0 \ll M_0$ that revolves around it in the (x,y)-plane. The dynamical equation in this case is of the general form[3,4]

$$\frac{d^2x^i}{dt^2}+\frac{kx^i}{r^3}+\epsilon\mathscr{K}_{ij}(t)x^j=0, \tag{1}$$

where $k=G_0(M_0+m_0)$, ϵ, $0<\epsilon\ll 1$, is the perturbation parameter and $\epsilon\mathscr{K}_{ij}$ is the tidal matrix associated with the incident gravitational waves. Here $\mathscr{K}$ is symmetric and traceless, and is related to the gravitational perturbation of the Minkowski space-time by

$$\mathscr{K}_{ij}(t) = -\frac{1}{2}\frac{\partial^2 \chi_{ij}}{\partial t^2}(t,\mathbf{0}), \tag{2}$$

where $g_{\mu\nu} = \eta_{\mu\nu} + \epsilon\chi_{\mu\nu}$. Here we employ the transverse-traceless gauge for gravitational radiation, i.e. $\chi_{0\mu} = 0$, χ_{ij} is traceless and $\partial_j \chi_{ij} = 0$; moreover, χ_{ij} is a solution of the wave equation $\Box \chi_{ij} = 0$. Thus the gravitational radiation field can be expressed as a Fourier sum of monochromatic waves of frequency $\Omega_\star$ and wave vector $\mathbf{K}_\star$, $c|\mathbf{K}_\star| = \Omega_\star$,

$$\chi_{ij}(t,\mathbf{x}) = \mathrm{Re}\sum_{\mathbf{K}_\star} \hat{\chi}_{ij}(\mathbf{K}_\star)\exp(i\mathbf{K}_\star \cdot \mathbf{x} - i\Omega_\star t), \tag{3}$$

where $\hat{\chi}_{ij}$ is symmetric, traceless and $\hat{\chi}_{ij}K_\star^j = 0$. The summation in (3) extends over all waves with $2\pi c/\Omega_\star$ much larger than the average orbital radius. Equation (1) contains only the essential physics of the interaction of long-wavelength gravitational radiation with a Newtonian binary system; in fact, relativistic (i.e., post-Keplerian) effects in the binary are totally neglected. In particular, the emission of gravitational waves is ignored. The motivation for our treatment as well as its limitations is presented in detail in our recent work.[1]

The incident wave exchanges energy and angular momentum with the binary orbit but not linear momentum in the *quadrupole* approximation under consideration here.[1] This is in exact analogy with the electromagnetic problem of the interaction of an electromagnetic wave with an atom in the *dipole* approximation.

A simple linear perturbation treatment of (1) has revealed the possibility of the existence of resonances at $\Omega_\star = m\omega$, $m = 1,2,3, \ldots$, where ω is the Keplerian frequency of the unperturbed elliptical orbit. Moreover, in this analysis secular terms appear that lead to the breakdown of the linear theory over time.[4] Thus linear perturbation theory is inappropriate for the investigation of periodic orbits of the perturbed system, since a periodic orbit is expected to persist forever beyond a certain point in time.

In the first treatment of the nonlinear case,[1] we considered a single monochromatic plane wave of frequency $\Omega_\star$ that was normally incident on a Keplerian orbit of frequency ω. We found that in the generic case, certain orbits satisfying the resonance condition $\Omega_\star = m\omega$, $m = 1,2,3,\ldots$, could be continued to periodic orbits of the nonlinear system. The existence of periodic solutions of (1) demonstrates that ionization does not always occur; in fact, in a periodic orbit the energy exchange with the radiation field must be steady without any net flow. In addition, we found that for incident circularly polarized radiation of definite helicity the rotation of the inertial coordinates by frequency $\Omega_\star/2$ rendered the dynamical equations autonomous. The invariance of this autonomous system under time translation implies the existence of an energy integral in the rotating frame. In this case, the Kolmogorov-Arnold-Moser (KAM) theory implies that for sufficiently small ϵ ionization can never occur in this system regardless of the magnitude of $\Omega_\star/\omega$. To understand intuitively how this could come about, it should be pointed out that a binary system can gain or lose energy as it interacts with an incident gravitational wave. The situation in absorption is in contrast to the emission of gravitational waves by a binary. In the latter situation, the binary is expected to lose energy monotonically; in fact, this is consistent with the observed rate of inward spiraling of the Hulse-Taylor binary pulsar.[5,6] It follows that the reciprocity between emission and absorption of gravitational waves does not hold in general. This notion of reciprocity is valid in some other situations, however. For instance, a Keplerian ellipse of frequency ω emits gravitational radiation of frequency $m\omega$, $m = 1,2,3, \ldots$, which corresponds to the resonance condition for absorption.

Let us now consider a *general* periodic gravitational wave of period $2\pi/\Omega_\star$ that is normally incident on the binary system. The existence of certain periodic solutions of the perturbed system may be expected on general grounds. It would therefore be more interesting to investigate the interaction of circularly polarized gravitational radiation with the binary system and to determine

the stability of the resulting autonomous system under periodic perturbations. That is, a periodic wave may be expressed as a Fourier sum of components with frequencies $n\Omega_\star$, $n=1,2,3,\ldots$. For a single component of definite helicity, the transformation to the corresponding rotating frame would essentially remove the dependence of this perturbation upon time and for ϵ below a certain limit the orbit would remain forever bounded even though there is a steady flow of incident gravitational radiation energy in the inertial frame. However, the time-dependence of the other Fourier components would not disappear in the rotating frame, and we would like to study the influence of these components on the ionization of the system. Though we develop methods that are applicable to a general periodic perturbation, we restrict our attention to a tractable problem for the sake of simplicity.

In this paper, we consider a superposition of several harmonics in the perturbing function; clearly, the response of the system is not a superposition of the individual responses as a consequence of the intrinsic nonlinearity of the problem under consideration here. Specifically, we showed in Ref. 1 that for a normally incident circularly polarized monochromatic plane wave the motion is restricted to the (x,y)-plane and that a transformation to the uniformly rotating coordinate system in this plane with half the wave's frequency would result in an autonomous system for the equation of motion to which the KAM theory can be applied. It follows from the KAM theory that for sufficiently small ϵ the motion is confined and ionization does not occur. We wish to explore the sensitivity of this interesting result to the particular form of the incident wave. Therefore, we consider here a principal right circularly polarized wave of frequency $\Omega_\star=2\Omega$ that is slightly modified by the presence of similar components of frequencies Ω and 3Ω as follows:

$$\begin{aligned}\chi_{11}(t,\mathbf{0}) &= \cos 2\Omega t+2\delta[(\alpha-\beta)\cos\Omega t+\tfrac{1}{9}(\alpha+\beta)\cos 3\Omega t],\\ \chi_{12}(t,\mathbf{0}) &= \sin 2\Omega t+2\delta[(\alpha-\beta)\sin\Omega t+\tfrac{1}{9}(\alpha+\beta)\sin 3\Omega t],\end{aligned} \tag{4}$$

$\chi_{13}=\chi_{23}=\chi_{33}=0$. The other components of χ follow from the fact that χ is a symmetric traceless matrix. Here δ, $0<\delta\ll 1$, is a new perturbation parameter that determines the relative strength of the extra secondary components compared to the primary Fourier component of the normally incident radiation. Moreover, α and β are constant amplitudes of the order of unity, and the other numerical coefficients have been introduced for the sake of simplicity.

The plan of this paper is as follows: In Section II, we present the basic equations for a Hamiltonian description of the perturbed orbit in terms of Delaunay variables. Sections III–V are devoted to a development of degenerate continuation theory that is necessary for the identification of periodic orbits of the nonlinear problem via the methods and ideas that are originally due to Poincaré. The existence of periodic orbits, described in Section V, demonstrates that a state of equilibrium can be established between the wave and the binary such that ionization does not occur; in fact, the net flow of energy vanishes in this case. To apply the KAM theory to our problem, it is best to transform (1) to a uniformly rotating frame as in Section VI. It follows from the description of the nonlinear system in this reference frame that Arnold diffusion is expected for $\delta>0$, even for sufficiently small ϵ. Numerical experiments described in Section VII tend to corroborate the conjecture that gravitational ionization is tantamount to Arnold diffusion in this system. For background material, this paper relies heavily on our previous detailed treatment of the nonlinear problem for the case where the incident wave is essentially a simple monochromatic Fourier component;[1] however, we have attempted to present sufficient detail here in order to render the present paper essentially self-contained.

II. HAMILTONIAN DESCRIPTION IN DELAUNAY ELEMENTS

Using (1), (2) and (4), we can write the associated Hamiltonian for this system as the sum of the Kepler Hamiltonian and the quadrupole perturbation given by $\frac{1}{2}\epsilon\mathscr{K}_{ij}\,x^ix^j$. The motion is taken

to be in the (x,y)-plane, since the radiation is transverse and normally incident on the orbital plane; therefore, polar coordinates are convenient. Defining $\phi(t)$ and $\psi(t)$ as

$$\begin{aligned}\phi(t)&=\Omega^2\left\{\cos 2\Omega t+\frac{\delta}{2}[(\alpha-\beta)\cos\Omega t+(\alpha+\beta)\cos 3\Omega t]\right\},\\ \psi(t)&=\Omega^2\left\{\sin 2\Omega t+\frac{\delta}{2}[(\alpha-\beta)\sin\Omega t+(\alpha+\beta)\sin 3\Omega t]\right\},\end{aligned}\tag{5}$$

the Hamiltonian in polar coordinates may be written as

$$\mathscr{H}=\frac{1}{2}\left(p_r^2+\frac{p_\theta^2}{r^2}\right)-\frac{k}{r}+\epsilon r^2[\phi(t)\cos 2\theta+\psi(t)\sin 2\theta].\tag{6}$$

To express the Hamiltonian in a form particularly suitable for the analysis of orbital dynamics, we transform to the Delaunay elements (L,G,ℓ,g). To this end, consider the bounded motion of the test particle according to the Hamiltonian (6). At each instant of time, the particle can be described as belonging to an osculating Keplerian ellipse; that is, the perturbed motion passes through an infinite sequence of osculating ellipses in the course of time. Each such ellipse is described by the unperturbed Hamiltonian

$$H=\frac{1}{2}\left(p_r^2+\frac{p_\theta^2}{r^2}\right)-\frac{k}{r},$$

where we consider only bounded motions with $E=H(p_r,p_\theta,r,\theta)<0$. Let us now consider the canonical transformation from (p_r,p_θ,r,θ) to variables intrinsic to the ellipse. Thus we define action variables

$$L:=\left(\frac{-k^2}{2E}\right)^{1/2},\quad\text{and}\quad G:=p_\theta,$$

which correspond to an osculating Keplerian ellipse with semimajor axis a, $a=L^2/k$, and eccentricity e,

$$e=\left(1-\frac{G^2}{L^2}\right)^{1/2},$$

such that $0\leq e<1$. The equation of this ellipse is given by

$$r=a(1-e\cos\hat{u}),\quad\text{or}\quad r=a\frac{1-e^2}{1+e\cos\hat{v}},$$

where $\hat{u}$ is the eccentric anomaly and $\hat{v}$ is the true anomaly. The new canonical angle variables ℓ and g are then given by

$$\ell=\hat{u}-e\sin\hat{u},\quad g=\theta-\hat{v}.$$

In the following, we exclude $e=0$ and focus attention instead on noncircular elliptical orbits. The resulting Hamiltonian of the perturbed system in Delaunay variables is

$$\mathscr{H}=-\frac{k^2}{2L^2}+\epsilon[\mathscr{C}(L,G,\ell,g)\phi(t)+\mathscr{S}(L,G,\ell,g)\psi(t)],\tag{7}$$

where, in polar coordinates, $\mathscr{C}=r^2\cos 2\theta$ and $\mathscr{S}=r^2\sin 2\theta$. In Delaunay elements, $\mathscr{C}(L,G,\ell,g)$ and $\mathscr{S}(L,G,\ell,g)$ are given by

$$\begin{aligned}\mathscr{C}(L,G,\ell,g)&=\frac{5}{2}a^2e^2\cos 2g+a^2\sum_{\nu=1}^{\infty}\left(A_\nu(e)\cos 2g\cos\nu\ell-B_\nu(e)\sin 2g\sin\nu\ell\right),\\ \mathscr{S}(L,G,\ell,g)&=\frac{5}{2}a^2e^2\sin 2g+a^2\sum_{\nu=1}^{\infty}\left(A_\nu(e)\sin 2g\cos\nu\ell+B_\nu(e)\cos 2g\sin\nu\ell\right),\end{aligned}\tag{8}$$

where

$$\begin{aligned}A_\nu(e)&=\frac{4}{\nu^2e^2}\left(2\nu e(1-e^2)J_\nu'(\nu e)-(2-e^2)J_\nu(\nu e)\right),\\ B_\nu(e)&=-\frac{8}{\nu^2e^2}\sqrt{1-e^2}\left(eJ_\nu'(\nu e)-\nu(1-e^2)J_\nu(\nu e)\right).\end{aligned}\tag{9}$$

Here J_ν is the Bessel function of order ν, and a prime indicates the derivative of the function with respect to its argument. The dynamical equations are derived in the usual way from the Hamiltonian (7). Moreover, these equations are given in Delaunay elements by

$$\begin{aligned}\dot L&=-\epsilon\left(\frac{\partial\mathscr{C}(L,G,\ell,g)}{\partial\ell}\phi(t)+\frac{\partial\mathscr{S}(L,G,\ell,g)}{\partial\ell}\psi(t)\right),\\ \dot G&=-\epsilon\left(\frac{\partial\mathscr{C}(L,G,\ell,g)}{\partial g}\phi(t)+\frac{\partial\mathscr{S}(L,G,\ell,g)}{\partial g}\psi(t)\right),\\ \dot\ell&=\omega+\epsilon\left(\frac{\partial\mathscr{C}(L,G,\ell,g)}{\partial L}\phi(t)+\frac{\partial\mathscr{S}(L,G,\ell,g)}{\partial L}\psi(t)\right),\\ \dot g&=\epsilon\left(\frac{\partial\mathscr{C}(L,G,\ell,g)}{\partial G}\phi(t)+\frac{\partial\mathscr{S}(L,G,\ell,g)}{\partial G}\psi(t)\right),\end{aligned}\tag{10}$$

where ω is the Keplerian frequency of the binary given by $\omega^2=k/a^3$.

III. BIFURCATION FUNCTION

To establish the continuation (persistence) of periodic orbits of the Kepler problem to the system (10), we employ a method proposed in Ref. 2 and used in Ref. 1; we only state the main ideas here and the reader is referred to these references for details.

System (10) has the abstract form

$$\dot u=F(u)+\epsilon h(u,t),\tag{11}$$

where u is a coordinate on a manifold M that consists of a cross product of Euclidean spaces and tori, and the function h is periodic with period $2\pi/\Omega$ in its second argument. We consider solutions $t\mapsto u(t,\xi,\epsilon)$ of (11) with initial condition $u(0,\xi,\epsilon)=\xi$, $\xi\in M$, and define the mth order Poincaré map by $\mathscr{P}^m(\xi,\epsilon)=u(2\pi m/\Omega,\xi,\epsilon)$. Fixed points of this mth order Poincaré map correspond to periodic solutions of (11). Consider the unperturbed periodic solutions of (11) with $\epsilon=0$. These correspond to fixed points of the unperturbed mth order Poincaré map defined by $p^m(\xi)=\mathscr{P}^m(\xi,0)$. Let us now suppose that there is a submanifold $\mathscr{Z}\subset M$ that consists of fixed points of p^m, and $\zeta\in\mathscr{Z}$. If there is a continuous curve $\epsilon\mapsto\kappa(\epsilon)$ in M such that $\kappa(0)=\zeta$ and

$\mathcal{P}^m[\kappa(\epsilon),\epsilon]\equiv\kappa(\epsilon)$, i.e. for each fixed value of ϵ, $\kappa(\epsilon)$ is a fixed point of the mth order Poincaré map, then the unperturbed periodic orbit is continuable. The continuation is established by the method of Lyapunov-Schmidt reduction to the Implicit Function Theorem and requires that every vector in $T_\zeta M$ that is tangent to the submanifold $\mathcal{Z}$ be in the kernel of the infinitesimal displacement $\mathcal{D}(\zeta)=Dp^m(\zeta)-I$. This is equivalent to the requirement that for each $\zeta\in\mathcal{Z}$, the dimension of the kernel of the infinitesimal displacement at ζ be equal to the dimension of the manifold $\mathcal{Z}$. The manifold $\mathcal{Z}$ is called normally nondegenerate if it satisfies this condition.

Let $\mathcal{Z}$ be a normally nondegenerate submanifold of M with dimension q; then, the range of the infinitesimal displacement at each point of $\mathcal{Z}$ has codimension q. For each $\zeta\in\mathcal{Z}$, there is a vector complement $\hat{\mathcal{S}}(\zeta)$ to the range of the infinitesimal displacement of dimension q. We denote the projection of $T_\zeta M$ to $\hat{\mathcal{S}}(\zeta)$ by $\hat{s}(\zeta)$.

Let $\zeta\in\mathcal{Z}$ and consider the curve in the manifold M defined by $\epsilon\mapsto\mathcal{P}^m(\zeta,\epsilon)$; it passes through ζ at $\epsilon=0$ and its tangent vector at $\epsilon=0$ is in $T_\zeta M$. This tangent vector can be identified with the partial derivative $\mathcal{P}^m_\epsilon(\zeta,0)$. The bifurcation function $\mathcal{B}$ is defined to be the map from $\mathcal{Z}$ to the complement $\hat{\mathcal{S}}$ of the range of the infinitesimal displacement,

$$\mathcal{B}(\zeta)=\hat{s}(\zeta)\mathcal{P}^m_\epsilon(\zeta,0),$$

so that in local coordinates $\mathcal{B}:\mathbb{R}^q\to\mathbb{R}^q$. We define $\zeta\in\mathcal{Z}$ to be a simple zero of the bifurcation function if $\mathcal{B}(\zeta)=0$ and the derivative $D\mathcal{B}(\zeta)$ is invertible. The following continuation theorem is proved in Ref. 2.

Theorem: III.1: *Let $\mathcal{Z}$ denote a normally nondegenerate fixed point submanifold of M for the system (11). If $\zeta\in\mathcal{Z}$ is a simple zero of the corresponding bifurcation function, then the unperturbed periodic orbit of (11) with initial point ζ is continuable.*

To apply Theorem III.1 to the perturbed Kepler problem, we must compute the partial derivative $\mathcal{P}^m_\epsilon(\zeta,0)$ of the corresponding Poincaré map. For the system (10), the manifold M is the four dimensional Delaunay coordinate space and the Poincaré map is defined as the strobe with period $2\pi m/\Omega$ where Ω is the frequency of the perturbation. The partial derivative is obtained from the solution $t\mapsto W(t)$ of the second variational initial value problem

$$\dot{W}=DF(u(t,\zeta,0))W+h(u(t,\zeta,0),t),\quad W(0)=0.$$

In fact, we have $W(t)=u_\epsilon(t,\zeta,0)$ and

$$\mathcal{P}^m_\epsilon(\zeta,0)=W(2\pi m/\Omega).$$

We use Theorem III.1 to establish the existence of periodic orbits for the system (10). Of course, this will establish the existence of periodic orbits for our model system (1), which describes the perturbation of a Keplerian binary system by a multi-frequency periodic gravitational wave. We begin by identifying the normally nondegenerate fixed point submanifold of M mentioned in Theorem III.1. Recall that the frequency of the unperturbed periodic Keplerian orbit is $\omega=k^2/L^3$. The three-dimensional manifold

$$\mathcal{Z}^L:=\{(L,G,\ell,g):m\omega=n\Omega\},$$

where m and n are relatively prime positive integers, is a normally nondegenerate submanifold of M (cf. Ref. 1). Furthermore, the range of the infinitesimal displacement is complemented by the span of the vectors

$$\begin{pmatrix}1\\0\\0\\0\end{pmatrix},\begin{pmatrix}0\\1\\0\\0\end{pmatrix},\begin{pmatrix}0\\0\\0\\1\end{pmatrix}.$$

The bifurcation function associated with (10) is the projection of the partial derivative $\mathscr{P}^m_\epsilon(L,G,\ell,g,0)$ on the manifold $\mathscr{Z}^L$ onto the complement of the range of the infinitesimal displacement. To determine the bifurcation function, we solve the variational initial value problem

$$\dot{L}_\epsilon=-\frac{\partial\mathscr{C}}{\partial\ell}(L,G,\ell+\omega t,g)\phi(t)-\frac{\partial\mathscr{S}}{\partial\ell}(L,G,\ell+\omega t,g)\psi(t),$$

$$\dot{G}_\epsilon=-\frac{\partial\mathscr{C}}{\partial g}(L,G,\ell+\omega t,g)\phi(t)-\frac{\partial\mathscr{S}}{\partial g}(L,G,\ell+\omega t,g)\psi(t),$$

$$\dot{\ell}_\epsilon=-\frac{3k^2}{L^4}L_\epsilon+\frac{\partial\mathscr{C}}{\partial L}(L,G,\ell+\omega t,g)\phi(t)+\frac{\partial\mathscr{S}}{\partial L}(L,G,\ell+\omega t,g)\psi(t),$$

$$\dot{g}_\epsilon=\frac{\partial\mathscr{C}}{\partial G}(L,G,\ell+\omega t,g)\phi(t)+\frac{\partial\mathscr{S}}{\partial G}(L,G,\ell+\omega t,g)\psi(t),$$

with zero initial values; then, the solution evaluated at $t=m(2\pi/\Omega)$ is projected to the complement of the range of the infinitesimal displacement. It follows from a detailed analysis that one can set the initial value of time equal to zero, as we have done, with no loss in generality. The bifurcation function is thus given by

$$\mathscr{B}(G,\ell,g)=(B^L(G,\ell,g),B^G(G,\ell,g),B^g(G,\ell,g)),$$

where

$$B^L(G,\ell,g):=-\frac{\partial\mathscr{T}}{\partial\ell},\quad B^G(G,\ell,g):=-\frac{\partial\mathscr{T}}{\partial g},\quad B^g(G,\ell,g):=\frac{\partial\mathscr{T}}{\partial G},\tag{12}$$

and

$$\mathscr{T}:=\int_0^{2\pi m/\Omega}[\mathscr{C}(L,G,\ell+\omega t,g)\phi(t)+\mathscr{S}(L,G,\ell+\omega t,g)\psi(t)]dt.$$

To evaluate $\mathscr{T}$, we use the resonance relation $n\Omega=m\omega$ to change the variable of integration from t to $\hat{\sigma}=\Omega t/m+\ell/n$, then observe that the integrand of $\mathscr{T}$ is periodic with period 2π and substitute the Fourier series expansions for $\mathscr{C}$ and $\mathscr{S}$. After performing these steps, we obtain the following expression for $\mathscr{T}$ in case $n=1$:

$$\mathscr{T}=\pi ma^2\Omega\Big\{U_{2m}(e)\cos(2g+2m\ell)+\frac{\delta}{2}[(\alpha-\beta)U_m(e)\cos(2g+m\ell)$$
$$+(\alpha+\beta)U_{3m}(e)\cos(2g+3m\ell)]\Big\},\tag{13}$$

where

$$U_\nu(e)=A_\nu(e)+B_\nu(e).$$

If $n=2$ and m is odd, then

$$\mathcal{J}=\pi m a^2\Omega U_m(e)\cos(2g+m\ell);$$

while for $n=3$, if m is prime relative to 3, then

$$\mathcal{J}=\tfrac{1}{2}\pi m a^2\Omega\,\delta(\alpha+\beta)U_m(e)\cos(2g+m\ell).$$

It turns out that $\mathcal{J}=0$ for $n>3$, as expected.

We show in Ref. 1 that the bifurcation function does not have a simple zero for an incident monochromatic gravitational wave of definite helicity. The role of the secondary components of the wave is to resolve this issue for the bifurcation problem under consideration here. This is indeed the case for $n=1$ as demonstrated in the next section. However, for $n=2$ and $n=3$ simple zeros do not exist, and the consideration of these cases would require the calculation of the solutions of higher order variational initial value problems. On the other hand, higher order perturbing functions of order ϵ^2, etc., are neglected in the formulation of equation (1), which is the starting point of our analysis. It follows from this remark that the treatment of the cases $n=2$ and $n=3$ is beyond the scope of this work. Thus, we assume $n=1$ in the remainder of this section.

Substituting (13) into (12), we obtain the following explicit form for the bifurcation function $(n=1)$:

$$B^L(G,\ell,g)=2\pi m^2a^2\Omega\Big\{U_{2m}(e)\sin(2g+2m\ell)+\frac{\delta}{4}[(\alpha-\beta)U_m(e)\sin(2g+m\ell)$$
$$+3(\alpha+\beta)U_{3m}(e)\sin(2g+3m\ell)]\Big\},$$

$$B^G(G,\ell,g)=2\pi ma^2\Omega\Big\{U_{2m}(e)\sin(2g+2m\ell)+\frac{\delta}{2}[(\alpha-\beta)U_m(e)\sin(2g+m\ell)$$
$$+(\alpha+\beta)U_{3m}(e)\sin(2g+3m\ell)]\Big\},$$

$$B^g(G,\ell,g)=-\pi ma^2\Omega\left(\frac{G}{eL^2}\right)\Big\{U'_{2m}(e)\cos(2g+2m\ell)+\frac{\delta}{2}[(\alpha-\beta)U'_m(e)\cos(2g+m\ell)$$
$$+(\alpha+\beta)U'_{3m}(e)\cos(2g+3m\ell)]\Big\}, \tag{14}$$

where in the expression for B^g we have used the fact that the eccentricity e and the Delaunay element G are related by $G=\pm L\sqrt{1-e^2}$. We therefore make a change of variable from G to e and observe that the zeros and their multiplicities for the bifurcation function $\mathcal{B}$ are identical to those of the function

$$\mathcal{F}(e,\ell,g)=(F^L(e,\ell,g),F^G(e,\ell,g),F^g(e,\ell,g)),$$

where

FL(e,ℓ,g) = U2m(e)sin(2g+2mℓ) + δ4 [($\alpha-\beta$)Um(e)sin(2g+mℓ)

$$+3(\alpha+\beta)U_{3m}(e)\sin(2g+3m\ell)],$$

$$F^G(e,\ell,g)=U_{2m}(e)\sin(2g+2m\ell)+\frac{\delta}{2}[(\alpha-\beta)U_m(e)\sin(2g+m\ell)$$

$$+(\alpha+\beta)U_{3m}(e)\sin(2g+3m\ell)], \tag{15}$$

$$F^g(e,\ell,g)=U'_{2m}(e)\cos(2g+2m\ell)+\frac{\delta}{2}[(\alpha-\beta)U'_m(e)\cos(2g+m\ell)$$

$$+(\alpha+\beta)U'_{3m}(e)\cos(2g+3m\ell)].$$

To apply Theorem III.1, we must determine the simple zeros of the bifurcation function (14) or, equivalently, (15). We will show that simple zeros exist by a perturbation argument which is presented in the next section.

IV. ZEROS OF A DEGENERATE BIFURCATION FUNCTION

The bifurcation function (15) has the following abstract form:

$$\Delta(\mu,\hat{\epsilon})=\tau(\mu)+\hat{\epsilon}\varphi(\mu)=0, \quad \mu\in\mathbb{R}^3, \tag{16}$$

where the functions $\Delta:\mathbb{R}^3\times\mathbb{R}\mapsto\mathbb{R}^3$ and $\tau,\varphi:\mathbb{R}^3\mapsto\mathbb{R}^3$ are given in components by

$$\tau(\mu)=\begin{pmatrix}\tau_1(\mu)\\ \tau_2(\mu)\\ \tau_3(\mu)\end{pmatrix}, \quad \varphi(\mu)=\begin{pmatrix}\varphi_1(\mu)\\ \varphi_2(\mu)\\ \varphi_3(\mu)\end{pmatrix},$$

and where the first two components of τ are equal. In fact, we define $\hat{\tau}=\tau_1=\tau_2$.

Remark IV.1: *The fact that the bifurcation function has the abstract form (16) is not accidental. Every normally incident gravitational plane wave whose Fourier representation has as its dominant term a purely circularly polarized wave will result in a bifurcation function of the form (16) at resonance.*

We will determine the zero set for Δ in case $\hat{\epsilon}$ is sufficiently small.

Lemma IV.2: *Suppose Δ is defined by (16). If $\eta\in\mathbb{R}^3$ is such that $\tau(\eta)=0$ while the vectors* $\operatorname{grad}\hat{\tau}(\eta)$ *and* $\operatorname{grad}\tau_3(\eta)$ *are linearly independent, then there is a curve $s\mapsto\Gamma(s)$ in $\mathbb{R}^3$ such that $\Gamma(0)=\eta$, $\Gamma'(0)\neq 0$, and $\Delta(\Gamma(s),0)\equiv 0$. If such a curve exists and $s=0$ is a simple zero of the real-valued function $s\mapsto\varphi_2(\Gamma(s))-\varphi_1(\Gamma(s))$, then there is a curve $\hat{\epsilon}\mapsto\Upsilon(\hat{\epsilon})$ in $\mathbb{R}^3$ such that $\Upsilon(0)=\eta$ and $\Delta(\Upsilon(\hat{\epsilon}),\hat{\epsilon})\equiv 0$. Moreover, for each sufficiently small $\hat{\epsilon}\neq 0$, the point $\Upsilon(\hat{\epsilon})\in\mathbb{R}^3$ is a simple zero of the function $\mu\mapsto\Delta(\mu,\hat{\epsilon})$.*

Proof: The linearly independent vectors grad $\hat{\tau}(\eta)$ and grad $\tau_3(\eta)$ span a plane Q in $\mathbb{R}^3$. Let S denote one of the two possible rotation operators in space that preserves Q and rotates each vector in Q through $\pi/2$ radians. We note that S grad $\hat{\tau}(\eta)$ and S grad $\tau_3(\eta)$ are linearly independent vectors in Q. Also, we let v denote a vector in space such that the set $\{S \text{ grad } \hat{\tau}(\eta), S \text{ grad } \tau_3(\eta), v\}$ is linearly independent. This requirement is satisfied, for instance, if we choose v to be equal to the cross product of S $\operatorname{grad}\hat{\tau}(\eta)$ and S $\operatorname{grad}\tau_3(\eta)$.

The function $w:\mathbb{R}^3\mapsto\mathbb{R}^3$ defined by

$$(\mu_1,\mu_2,\mu_3)\mapsto\mu_1 S \text{ grad } \tau_3(\eta)+\mu_2 S \text{ grad } \hat{\tau}(\eta)+\mu_3 v+\eta$$

is invertible. We use it to define $\Theta:\mathbb{R}^3\to\mathbb{R}^2$ given by

$$\Theta(\mu_1,\mu_2,\mu_3)=(\hat{\tau}(w(\mu_1,\mu_2,\mu_3)),\tau_3(w(\mu_1,\mu_2,\mu_3)).$$

It follows that $\Theta(0)=0$. Moreover, the derivative of the transformation

$$(\mu_1,\mu_2)\mapsto(\hat{\tau}(w(\mu_1,\mu_2,0)),\tau_3(w(\mu_1,\mu_2,0))$$

at $(\mu_1,\mu_2)=(0,0)$ is given by the matrix

$$\begin{pmatrix} \text{grad } \hat{\tau}(\eta)\cdot S \text{ grad } \tau_3(\eta) & 0 \\ 0 & \text{grad } \tau_3(\eta)\cdot S \text{ grad } \hat{\tau}(\eta) \end{pmatrix} \tag{17}$$

that represents the partial derivative of Θ with respect to its first two arguments at the origin.

Using the linear independence of grad $\hat{\tau}(\eta)$ and grad $\tau_3(\eta)$, it is easy to see that the diagonal elements of the matrix (17) are both nonzero. Thus, by the Implicit Function Theorem, there is a unique curve $s\mapsto\sigma(s)$ in the (μ_1,μ_2)-plane such that $\sigma(0)=(0,0)$ and $\Theta(\sigma(s),s)\equiv 0$. The curve $\Gamma(s):=w(\sigma(s),s)$ is such that $\Gamma(0)=\eta$ and $\Delta(\Gamma(s),0)\equiv 0$. Moreover,

$$\Gamma'(0)=Dw(0)\begin{pmatrix}\sigma'(0)\\ 1\end{pmatrix}.$$

Since $Dw(0)$ is invertible and the vector $(\sigma'(0),1)\neq 0$, we have that $\Gamma'(0)\neq 0$. This proves the first assertion of the theorem.

Under the assumption that $s=0$ is a simple zero of the function $s\mapsto\varphi_2(\Gamma(s))-\varphi_1(\Gamma(s))$, we will use the Lyapunov-Schmidt reduction procedure to show that the corresponding point $\eta=\Gamma(0)$ in $\mathbb{R}^3$ is continuable as a zero of Δ. As $\Gamma'(0)\neq 0$, the image $\hat{\mathcal{Z}}$ of Γ is locally a one dimensional submanifold of $\mathbb{R}^3$. Moreover, $\hat{\mathcal{Z}}$ is normally nondegenerate in the sense that at each point $\hat{z}\in\hat{\mathcal{Z}}$ sufficiently close to η, the kernel $\hat{K}$ of $D\tau(\hat{z})$ is exactly the one dimensional tangent space of $\hat{\mathcal{Z}}$. In fact, since this tangent space is clearly in $\hat{K}$, it suffices to show that $\hat{K}$ is one dimensional. The derivative of τ is expressed in the standard vector notation by

$$D\tau(\hat{z})=\begin{pmatrix}\text{grad } \hat{\tau}(\hat{z})\\ \text{grad } \hat{\tau}(\hat{z})\\ \text{grad } \tau_3(\hat{z})\end{pmatrix}.$$

Since the vectors grad $\hat{\tau}(\hat{z})$ and grad $\tau_3(\hat{z})$ are linearly independent at $\hat{z}=\eta$, they will, by continuity, remain linearly independent in an open neighborhood of η. Thus, their span is two dimensional at each point of this neighborhood. In particular, for $\hat{z}$ in this neighborhood, it is clear (by matrix multiplication) that grad $\hat{\tau}(\hat{z})$ and grad $\tau_3(\hat{z})$ are not both in $\hat{K}$. This proves that $\hat{K}$ is one dimensional. It follows from the same Lyapunov-Schmidt reduction procedure that is used to prove Theorem III.1 (see Ref. 2) that if $\Pi(\hat{z})$ denotes a projection to the complement $\hat{\mathcal{Y}}$ of the range of $D\tau(\hat{z})$, then simple zeros of the map from $\hat{\mathcal{Z}}$ to $\mathbb{R}$ given by $\hat{z}\mapsto\Pi(\hat{z})\Delta_{\hat{\epsilon}}(\hat{z},0)$ are continuable. Thus, if η is such a simple zero, there is a curve $\hat{\epsilon}\mapsto\Upsilon(\hat{\epsilon})$ such that $\Upsilon(0)=\eta$ and $\Delta(\Upsilon(\hat{\epsilon}),\hat{\epsilon})\equiv 0$ as required in the lemma.

To construct such a projection into $\hat{\mathcal{Y}}$, it can be shown that, in fact, the range of $D\tau(\hat{z})$ is spanned by the transpositions of the vectors $(1,1,0)$ and $(0,0,1)$. To see this, it is sufficient to note that $D\tau(\hat{z})S$ grad $\hat{\tau}(\hat{z})$ is the transpose of a scalar multiple of $(0,0,1)$ while $D\tau(\hat{z})S$ grad $\tau_3(\hat{z})$ is a scalar multiple of the transpose of $(1,1,0)$. The transpose of the vector $(0,1,0)$ clearly spans a complement to the range that we will denote by $\hat{\mathcal{Y}}$. Thus, if $(\rho_1,\rho_2,\rho_3)\in\mathbb{R}^3$, the projection Π is easily computed and is given by $\Pi(\rho_1,\rho_2,\rho_3)=\rho_2-\rho_1$. Note that Π does not depend on the base point $\hat{z}\in\hat{\mathcal{Z}}$.

Using the projection Π and the definition of Δ, the Lyapunov-Schmidt reduced function $\hat{z}\mapsto\Pi(\hat{z})\Delta_{\hat{\epsilon}}(\hat{z},0)$ is given by $\hat{z}\mapsto\varphi_2(\hat{z})-\varphi_1(\hat{z})$ for $\hat{z}\in\hat{\mathcal{Z}}$. Thus, if, in the coordinates of $\hat{\mathcal{Z}}$, $s=0$ is a simple zero of $s\mapsto\varphi_2(\Gamma(s))-\varphi_1(\Gamma(s))$, then $\eta=\Gamma(0)$ is a continuable zero of Δ given by a curve Υ, as required in the statement of the lemma.

It remains to show that $\Upsilon(\hat{\epsilon})$, for sufficiently small $\hat{\epsilon}\neq 0$, is in fact a *simple* zero of the function $\mu\mapsto\Delta(\mu,\hat{\epsilon})$. To this end, it suffices to show that the matrix $D\Delta(\Upsilon(\hat{\epsilon}),\hat{\epsilon})$ does not have a zero eigenvalue. But, under the hypotheses of the lemma, the matrix $D\Delta(\eta,0)$ has a one dimensional kernel, namely the tangent space of $\hat{\mathcal{Z}}$. This means that $D\Delta(\eta,0)$ has exactly one zero eigenvalue. By the continuity of eigenvalues of matrices, there is a smooth family of eigenvalues $\lambda(\hat{\epsilon})$ such that $\lambda(0)=0$ and a corresponding smooth family of eigenvectors $V(\hat{\epsilon})$ such that $V(0)$ is a nonzero vector tangent to $\hat{\mathcal{Z}}$ with

$$D\Delta(\Upsilon(\hat{\epsilon}),\hat{\epsilon})V(\hat{\epsilon})=\lambda(\hat{\epsilon})V(\hat{\epsilon}).$$

It suffices to show that if $\hat{\epsilon}$ is positive and sufficiently small, then $\lambda(\hat{\epsilon})\neq 0$. By continuity, the remaining two eigenvalues of the matrix will be nonzero as well. The desired result follows as soon as we show that the derivative $\lambda'(0)\neq 0$. For this we have

$$D^2\Delta(\eta,0)(\Upsilon'(0),V(0))+D\Delta_{\hat{\epsilon}}(\eta,0)V(0)+D\Delta(\eta,0)V'(0)=\lambda'(0)V(0),$$

where D denotes differentiation with respect to the space variable $\mu\in\mathbb{R}^3$. After projection by Π into the complement of the range of $D\Delta(\eta,0)$,

$$\Pi D^2\Delta(\eta,0)(\Upsilon'(0),V(0))+\Pi D\Delta_{\hat{\epsilon}}(\eta,0)V(0)=\lambda'(0)\Pi V(0).$$

We claim that $\Pi D^2\Delta(\eta,0)(\Upsilon'(0),V(0))=0$. Once this claim is proved, the fact that $\lambda'(0)\neq 0$ would follow provided $\Pi D\Delta_{\hat{\epsilon}}(\eta,0)V(0)\neq 0$. The key point to note is that the projection operator, Π, is independent of the base point, i.e. the range of the projection operator is spanned by a constant basis vector independent of the base point. Thus since $\Delta_{\hat{\epsilon}}(\Gamma(s),0)=\varphi(\Gamma(s))$, we have

$$\frac{d}{ds}\Pi\varphi(\Gamma(s))|_{s=0}=\Pi D\varphi(\eta)\Gamma'(0)=\Pi D\Delta_{\hat{\epsilon}}(\eta,0)\Gamma'(0).$$

Since $\hat{\mathcal{Z}}$ is one dimensional, $\Gamma'(0)$ is just a scalar multiple of $V(0)$ and therefore if $\Pi D\varphi(\eta)\Gamma'(0)\neq 0$, then $\Pi D\Delta_{\hat{\epsilon}}(\eta,0)V(0)\neq 0$. By the definition of the components of φ and of the projection Π, we have

$$\frac{d}{ds}\Pi\varphi(\Gamma(s))|_{s=0}=\frac{d}{ds}[\varphi_2(\Gamma(s))-\varphi_1(\Gamma(s))]|_{s=0}.$$

Thus, if $s=0$ is a simple zero of $s\mapsto\varphi_2(\Gamma(s))-\varphi_1(\Gamma(s))$, then

$$\Pi D\Delta_{\hat{\epsilon}}(\eta,0)V(0)\neq 0,$$

as required.

To verify the claim, note that since Π projects to the complement of the range of $D\Delta(\eta,0)$ and since Π does not depend on the base point on $\hat{\mathcal{Z}}$, we have $\Pi D\Delta(\Gamma(\vartheta),0)\Upsilon'(\vartheta)\equiv 0$ for the real variable ϑ in the common domain of Γ and Υ. This implies that

$$0=\mathrm{d}\mathrm{d}\vartheta[\Pi D\Delta(\Gamma(\vartheta),0)\Upsilon\prime(\vartheta)]|\vartheta=0=\Pi D2\Delta(\eta,0)(\Gamma\prime(0),\Upsilon\prime(0))+\Pi D\Delta(\eta,0)\Upsilon\prime\prime(0)$$

$$= \hat{c}\Pi D^2\Delta(\eta,0)(V(0),\Upsilon'(0)),$$

where $\hat{c}V(0)=\Gamma'(0)$. Since $\hat{c}\neq 0$, the lemma is proved.

V. PERIODIC ORBITS

We now use Lemma IV.2 to prove that some of the zeros of the bifurcation function (15) are simple. We note that once this result is established, it will follow from Theorem III.1 that the corresponding bounded orbits of the Keplerian two-body system are continuable under perturbation by periodic gravitational waves.

If $\delta=0$, then the zeros of (15) are the union of the following one dimensional sets:

$$\begin{aligned}
\mathcal{Z}_1^+ &= \{(e,\ell,g): 2g+2m\ell=0, \quad U'_{2m}(e)=0\},\\
\mathcal{Z}_1^- &= \{(e,\ell,g): 2g+2m\ell=\pi, \quad U'_{2m}(e)=0\},\\
\mathcal{Z}_2^+ &= \left\{(e,\ell,g): 2g+2m\ell=\frac{\pi}{2}, \quad U_{2m}(e)=0\right\},\\
\mathcal{Z}_2^- &= \left\{(e,\ell,g): 2g+2m\ell=\frac{3\pi}{2}, \quad U_{2m}(e)=0\right\}.
\end{aligned} \tag{18}$$

We will show that the zeros in the sets $\mathcal{Z}_1^{\pm}$ and $\mathcal{Z}_2^{\pm}$ continue to simple zeros of the bifurcation function for sufficiently small $\delta\neq 0$. To conform with Lemma IV.2, we use (15) to identify the components of Δ as they appear in the lemma as follows:

$$\hat{\tau}(e,\ell,g) = U_{2m}(e)\sin(2g+2m\ell),$$

$$\tau_3(e,\ell,g) = U'_{2m}(e)\cos(2g+2m\ell),$$

$$\begin{aligned}
\varphi_1(e,\ell,g) = \tfrac{1}{4}[&(\alpha-\beta)U_m(e)\sin(2g+m\ell)\\
&+3(\alpha+\beta)U_{3m}(e)\sin(2g+3m\ell)],
\end{aligned}$$

$$\begin{aligned}
\varphi_2(e,\ell,g) = \tfrac{1}{2}[&(\alpha-\beta)U_m(e)\sin(2g+m\ell)\\
&+(\alpha+\beta)U_{3m}(e)\sin(2g+3m\ell)],
\end{aligned}$$

$$\begin{aligned}
\varphi_3(e,\ell,g) = \tfrac{1}{2}[&(\alpha-\beta)U'_m(e)\cos(2g+m\ell)\\
&+(\alpha+\beta)U'_{3m}(e)\cos(2g+3m\ell)].
\end{aligned}$$

Also, we note that δ in (15) plays the role of $\hat{\epsilon}$ in the lemma.

There are four cases to consider corresponding to the zero sets (18) of the unperturbed bifurcation function (14). We will consider the zero set $\mathcal{Z}_1^+$ for illustrative purposes, as the computational procedure is identical in all four cases. The set $\mathcal{Z}_1^+$ is just a line in $\mathbb{R}^3$, so here the curve Γ in the lemma can be taken to be a parametrization of this line starting at an appropriate point. By a direct calculation, the function $\varphi_2-\varphi_1$ on $\mathcal{Z}_1^+$ is given by

$$\tfrac{1}{4}[(\alpha-\beta)U_m(e)+(\alpha+\beta)U_{3m}(e)]\sin g.$$

The zeros of this function along $\mathscr{Z}_1^+$ are clearly simple provided the coefficient of $\sin g$ does not vanish at the value of the eccentricity determined by membership in $\mathscr{Z}_1^+$. The main result of this section is the following theorem.

Theorem V.1: *Consider the system (10) and suppose that (L,G,ℓ,g) is on an unperturbed $(m:n)$ resonant periodic solution with $n=1$, that is, $L^3=mk^2/\Omega$. If (e,ℓ,g) is in $\mathscr{Z}_1^+$ or $\mathscr{Z}_1^-$, respectively, (e,ℓ,g) is in $\mathscr{Z}_2^+$ or $\mathscr{Z}_2^-$, where e is the eccentricity of the corresponding Keplerian ellipse $(e^2=1-G^2/L^2)$ and if*

$$(\alpha-\beta)U_m(e)+(\alpha+\beta)U_{3m}(e)\neq 0,$$

respectively,

$$(\alpha-\beta)U_m(e)-(\alpha+\beta)U_{3m}(e)\neq 0,$$

then the Keplerian ellipse continues to a periodic orbit under the perturbation.

It remains to show that the sets $\{\mathscr{Z}_i^{\pm}\}$, $i=1,2$, are not empty. This fact will follow as soon as we show that both of the functions U_{2m} and U'_{2m} have zeros on the interval $0<e<1$.

Recall that $U_{2m}(e)=A_{2m}(e)+B_{2m}(e)$ and note that both A_{2m} and B_{2m} have removable singularities at $e=0$. Moreover, both have Taylor series at $e=0$ with leading terms given by

$$2(2m-1)\frac{m^{2m-2}}{(2m)!}e^{2(m-1)}.$$

In particular, if $m=1$, then $\lim_{e\to 0^+} U_2(e)=2$ and for $m>1$, the limit is zero, but $U_{2m}(e)>0$ for sufficiently small eccentricity. Also, $\lim_{e\to 1^-} U_{2m}=-J_{2m}(2m)/m^2$. By a standard property of the Bessel functions, $J_\nu(\nu)>0$; hence, $U_{2m}(1)<0$. This proves U_{2m} has at least one zero on the interval $0<e<1$. Numerical calculations suggest that this zero is unique.

A simple argument can be given to prove the existence of a zero in the case $m=1$ for the function U'_{2m}. In this case, the series expansion of U'_2 at $e=0$ is $-10e+O(e^2)$. Thus, $U'_2(e)<0$ for a small but positive eccentricity. The limit as $e\to 1^-$ is the same as

$$\lim_{e\to 1^-}\frac{2}{\sqrt{1-e^2}}J'_2(2).$$

By standard properties of the Bessel functions, $J_2(0)=0$ and $J_2>0$ on the interval $(0,\ j'_{2,1})$, where $j'_{2,1}$ is the first zero of J'_2. Hence, $J'_2>0$ on $(0,\ j'_{2,1})$. But, we also have $2<j'_{2,1}$. Thus, $J'_2(2)>0$ and $U'_2(e)\to\infty$ as $e\to 1^-$. This proves that $U'_2(e)$ has at least one zero on the interval $0<e<1$; moreover, numerical computations suggest that this zero is unique.

For $m\geq 2$, we will outline a proof that shows the function U'_{2m} has at least two zeros on the interval $0<e<1$. An asymptotic analysis shows that the function U'_{2m} is positive near the end points of the interval. The proof is completed by showing that U'_{2m} has a negative value within the interval. To this end, note that the function U'_{2m} has the form

$$U'_{2m}(e)=\gamma_1(m,e)J_{2m}(2me)+\gamma_2(m,e)J'_{2m}(2me),$$

where γ_1 and γ_2 are computed using (9). Moreover, by standard properties of the Bessel functions, both of the functions $e\mapsto J_{2m}(2me)$ and $e\mapsto J'_{2m}(2me)$ are positive for $0<e<1$. Let us define $\hat{e}:=(1-1/(4m^2))^{1/2}$, and observe that $0<\hat{e}<1$. A simple computation shows that

$$\gamma_1(m,\hat{e})<0,\quad \gamma_2(m,\hat{e})<0.$$

Hence, we have $U'_{2m}(\hat{e})<0$, as desired. Numerical computations suggest that the function U'_{2m} has exactly two zeros on the interval $0<e<1$.

It follows from these results that the resonant interaction of the incident multi-frequency gravitational wave of definite helicity with a Keplerian binary can result in orbits that are periodic with period $2\pi/\Omega$, where $\Omega=m\omega$, $m=1,2,3,\ldots$. It is conceivable that other periodic orbits may exist; however, our method can identify only those periodic orbits that are continuations of resonant Keplerian orbits of the unperturbed system.

VI. ROTATING FRAME

In a manner similar to that used by Hill in his treatment of the lunar theory,[7–9] we can view the dynamical system described by (6) in Cartesian coordinates rotating at half the principal frequency of the incident gravitational wave ($\Omega_*=2\Omega$). These coordinates—that we again represent by (x,y)—rotate with frequency $\frac{1}{2}\Omega_*=\Omega$ with respect to inertial coordinates; therefore, the equations of motion in these coordinates are given by

$$\begin{aligned}&\frac{d^2x}{dt^2}-2\Omega\frac{dy}{dt}-\Omega^2x+\frac{kx}{r^3}+2\epsilon\Omega^2[(1+\delta\alpha\cos\Omega t)x+(\delta\beta\sin\Omega t)y]=0,\\&\frac{d^2y}{dt^2}+2\Omega\frac{dx}{dt}-\Omega^2y+\frac{ky}{r^3}+2\epsilon\Omega^2[(\delta\beta\sin\Omega t)x-(1+\delta\alpha\cos\Omega t)y]=0.\end{aligned}\tag{19}$$

Let $X:=\dot{x}-\Omega y$ and $Y:=\dot{y}+\Omega x$ be the canonical momenta conjugate to x and y, respectively. Then (19) is equivalent to a Hamiltonian system with Hamiltonian

$$\begin{aligned}\mathscr{H}_R=&\frac{1}{2}(X^2+Y^2)+\Omega(yX-xY)-\frac{k}{r}\\&+\epsilon\Omega^2[(1+\delta\alpha\cos\Omega t)(x^2-y^2)+2(\delta\beta\sin\Omega t)xy].\end{aligned}\tag{20}$$

By identifying the momenta in polar rotating coordinates as $p_r=(xX+yY)/r$ and $p_\theta=xY-yX$, (20) in polar coordinates is given by

$$\begin{aligned}\mathscr{H}_R=&\frac{1}{2}\left(p_r^2+\frac{p_\theta^2}{r^2}\right)-\frac{k}{r}-\Omega p_\theta+\epsilon\Omega^2r^2[\cos 2\theta\\&+\delta(\alpha\cos 2\theta\cos\Omega t+\beta\sin 2\theta\sin\Omega t)],\end{aligned}\tag{21}$$

which in the corresponding Delaunay elements becomes

$$\begin{aligned}\mathscr{H}_R=&-\frac{k^2}{2L^2}-\Omega G+\epsilon\Omega^2\{\mathscr{C}(L,G,\ell,g)+\delta[\alpha\mathscr{C}(L,G,\ell,g)\cos\Omega t\\&+\beta\mathscr{S}(L,G,\ell,g)\sin\Omega t]\}.\end{aligned}\tag{22}$$

The Hamiltonian system given by (22) has periodic orbits with period $2\pi/\Omega$, where $\Omega=m\omega$, $m=1,2,\ldots$; this assertion can be demonstrated using results that have already been obtained in this paper. In fact, using the resonance assumption, periodic orbits exist in the inertial frame with period $2\pi/\Omega$ as shown in Section V. An orbit in the inertial frame, $t\mapsto(x_I(t),y_I(t))$, is represented in the rotating frame by

$$\begin{aligned}x_R(t)&=x_I(t)\cos\Omega t+y_I(t)\sin\Omega t,\\y_R(t)&=-x_I(t)\sin\Omega t+y_I(t)\cos\Omega t.\end{aligned}$$

It follows from these relations that if $x_I(t)$ and $y_I(t)$ are periodic with period $2\pi/\Omega$, then so are $x_R(t)$ and $y_R(t)$. Therefore, the orbits that are periodic in the inertial frame with period $2\pi/\Omega$ are observed to be periodic with period $2\pi/\Omega$ in the rotating frame. It is also possible to arrive at this conclusion by direct application of the methods developed in the previous sections.

To understand the physical structure of Hamiltonian (22), imagine right circularly polarized gravitational radiation of frequency 2Ω that is normally incident on the orbital plane. It follows from our previous work,[I] as well as equation (19), that in a reference frame rotating with frequency Ω the wave stands still. That is, observers at rest in the rotating frame do not perceive the variability associated with a wave so that in the absence of secondaries ($\delta=0$) the dynamical system (19) is autonomous. That an observer—by merely rotating about the propagation axis of the circularly polarized wave—could make the wave stand completely still would be a remarkable physical effect and deserves further discussion.

It is a fundamental consequence of Lorentz invariance that all basic radiation fields travel with speed c with respect to all *inertial* observers. This may be illustrated by an example: Let an inertial observer move with speed v_0 along the propagation axis of a monochromatic plane gravitational wave of frequency $\Omega_\star$. The frequency and the wave vector of the radiation as perceived by the moving observer are smaller than those measured by static inertial observers by a common Doppler factor of

$$\left(\frac{c-v_0}{c+v_0}\right)^{1/2}.$$

Mathematically, as $v_0\to c$ this ratio goes to zero and hence the frequency and wave vector of the radiation vanish so that the wave might appear to stand still. This limit is not physically allowed, however. No observer can move at the speed of light, although—theoretically—one can get arbitrarily close. Therefore, the wave can never stand still for an inertial observer. It has been shown[10] that according to the standard Einstein theory this is not the case for accelerated observers, i.e. an accelerated observer can indeed stand still with respect to a gravitational wave. The autonomous nature of the system (19) for $\delta=0$ provides an interesting illustration of this fact. That is, consider an observer at the center of a system of coordinates rotating with frequency Ω. The observer does not move, but the fact that it refers its observations to the axes that rotate with frequency Ω with respect to the inertial axes makes it a noninertial observer. Radiation of frequency $\Omega_\star$ is incident in the inertial frame along the axis of rotation. According to the noninertial observer, the frequency of the gravitational wave is $\Omega_\star'=\Omega_\star\mp 2\Omega$, where the upper sign refers to right circularly polarized (RCP) gravitational radiation and the lower sign refers to left circularly polarized (LCP) gravitational radiation. The first (second) case has helicity $+2$ (-2), so that $\Omega_\star'=\Omega_\star-\mathbf{h}\cdot\mathbf{\Omega}$, where $\mathbf{h}$ is the helicity of the gravitational radiation field; this is an example of the general phenomenon of helicity-rotation coupling. Now if $\Omega=\frac{1}{2}\Omega_\star$ for RCP gravitational waves or $\Omega=-\frac{1}{2}\Omega_\star$ for LCP gravitational waves, we find that $\Omega_\star'$ vanishes according to the noninertial observer (as well as any other observer at rest in the rotating frame anywhere along the z-axis) and the radiation field stands still. It has been shown in Ref. 1 that for a monochromatic gravitational wave with definite helicity and sufficiently small amplitude this observation concerning a rotating observer leads to the conclusion that a Keplerian system in the presence of this radiation can never ionize. *In principle, this absence of ionization could be considered an observable consequence of the physical possibility that a gravitational wave could stand completely still.*

Let us now consider the possibility of ionization of the binary system as a function of the parameter δ. The transformation to the rotating frame leaves the orbital radius unchanged; therefore, the ionization problem can be discussed equally well in the rotating frame. In fact, the problem becomes simpler since the principal component of the incident radiation field loses its time-dependence as in (22). Thus if $\delta=0$, the KAM theorem implies that for sufficiently small ϵ the perturbed trajectory is bounded since it is trapped between two dimensional invariant tori in

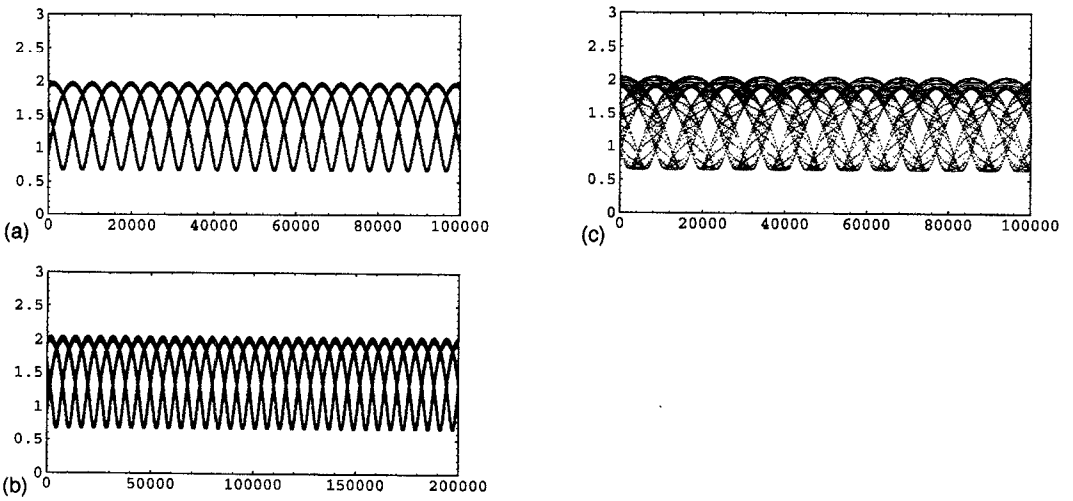

FIG. 1. Orbital radius versus time plots for the dynamical system given by Hamiltonian (6) with initial conditions $(p_r, p_\theta, r, \theta)$ equal to (0.5,1,1,0) and parameter values $\epsilon=0.001$, $\delta=0$, $\alpha=2.5$, $\beta=2$, $k=1$ and, from (a) to (c), $\Omega=2$, $\Omega=9\sqrt{3}/8$, $\Omega=1$.

the three dimensional energy surfaces. When $\delta\neq 0$, however, the two secondary components in the inertial frame both reduce to a perturbation of frequency Ω in the rotating frame; that is, the three Fourier components of the radiation field in the inertial frame are RCP waves with frequencies $\Omega_*=\Omega,2\Omega$ and 3Ω, while the tidal matrix in the rotating frame has frequencies given by $\Omega'_*=\Omega_*-2\Omega$, i.e. $-\Omega,0$ and Ω for the three components, respectively. The perturbation of frequency Ω in the rotating frame is expected to lead to Arnold diffusion[11,12] and hence ionization of the system. However, it has not been possible thus far to prove ionization for the system (22); therefore, we resort to numerical work in the following section.

VII. NUMERICAL EXPERIMENTS

In this section we illustrate—by means of numerical experiments—the conjecture that gravitational ionization and Arnold diffusion are closely related. The interpretation of the numerical results is simplified if we take the viewpoint of inertial observers and consider the perturbed motion given by Hamiltonian (6).

We have performed several numerical experiments to test the diffusion and ionization properties of the dynamical system that is represented by the Hamiltonian (6). The physical meaning of these numerical experiments is essentially the same as in our previous paper (cf. Figure 2 in Ref. 1): Let us choose two scales for the measurement of time and length that are arbitrary except that they are connected here by our choice of $k=1$. In these otherwise unspecified units, we have chosen an unperturbed ellipse of semimajor axis $a=4/3$ and eccentricity $e=1/2$ such that $g=-\pi/2$ and the Keplerian frequency is $\omega=3\sqrt{3}/8$. The ellipse is perturbed by the presence of periodic gravitational radiation and the orbital radius of the osculating ellipse is then plotted versus time in these units in Figures 1–4. These figures represent the results of our numerical experiments in which we have set the parameters of the external perturbation as follows:

$$\epsilon=0.001, \quad \alpha=2.5, \quad \beta=2,$$

and have changed δ in the range $0\leqslant\delta\leqslant 1$ and Ω in the range $1\leqslant\Omega\leqslant 2$. In each run, we set the initial conditions to be

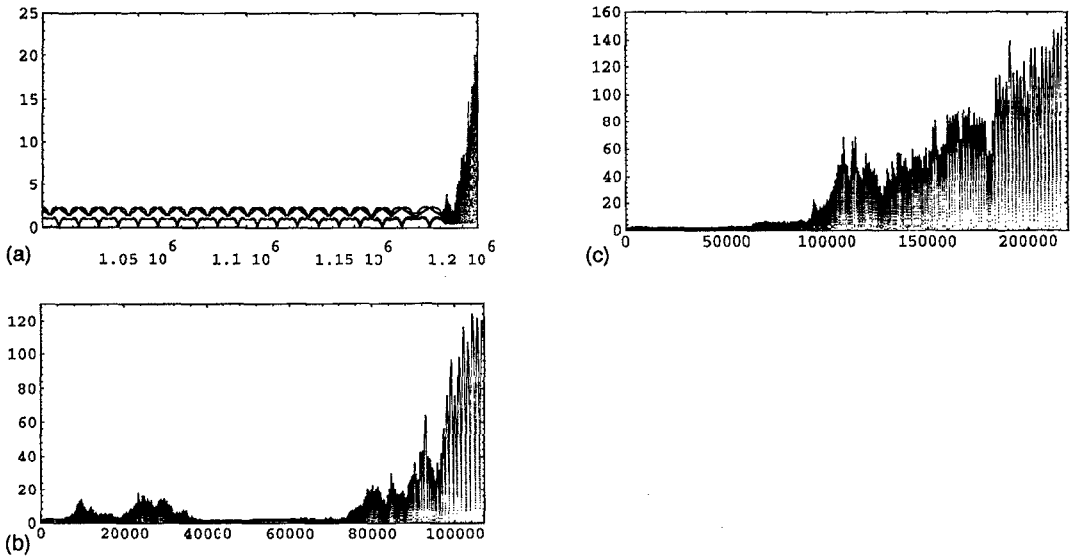

FIG. 2. Orbital radius versus time plots for the dynamical system given by the Hamiltonian (6) with initial conditions $(p_r, p_\theta, r, \theta)$ equal to (0.5,1,1,0) and parameter values $\epsilon = 0.001$, $\delta = 0.5$, $\alpha = 2.5$, $\beta = 2$, $k = 1$ and, from (a) to (c), $\Omega = 2$, $\Omega = 9\sqrt{3}/8$, $\Omega = 1$.

$$(p_r, p_\theta, r, \theta) = (0.5,1,1,0),$$

which correspond to the unperturbed ellipse described above. After integration over each time interval corresponding to one cycle of the perturbation, i.e. $2\pi/\Omega$, the corresponding elapsed time t and orbital radius are plotted. Clearly, for each value of t (abscissa) there is only one value of orbital radius r (ordinate); however, this is not discernible in some of the figures due to the way in which the plots have been prepared. The KAM theorem is illustrated in Figure 1, where the

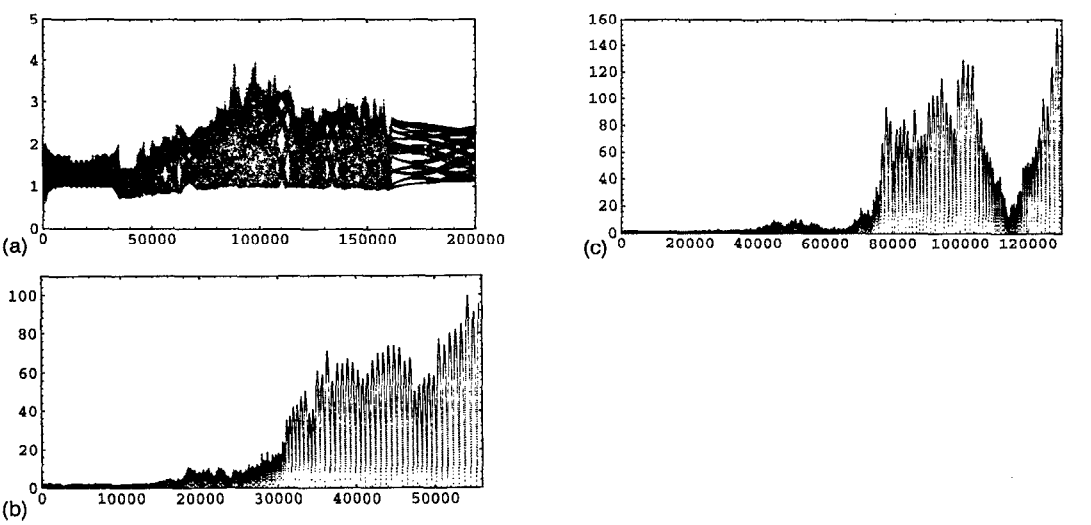

FIG. 3. Orbital radius versus time plots for the dynamical system given by the Hamiltonian (6) with initial conditions $(p_r, p_\theta, r, \theta)$ equal to (0.5,1,1,0) and parameter values $\epsilon = 0.001$, $\delta = 1$, $\alpha = 2.5$, $\beta = 2$, $k = 1$ and, from (a) to (c), $\Omega = 2$, $\Omega = 9\sqrt{3}/8$, $\Omega = 1$.

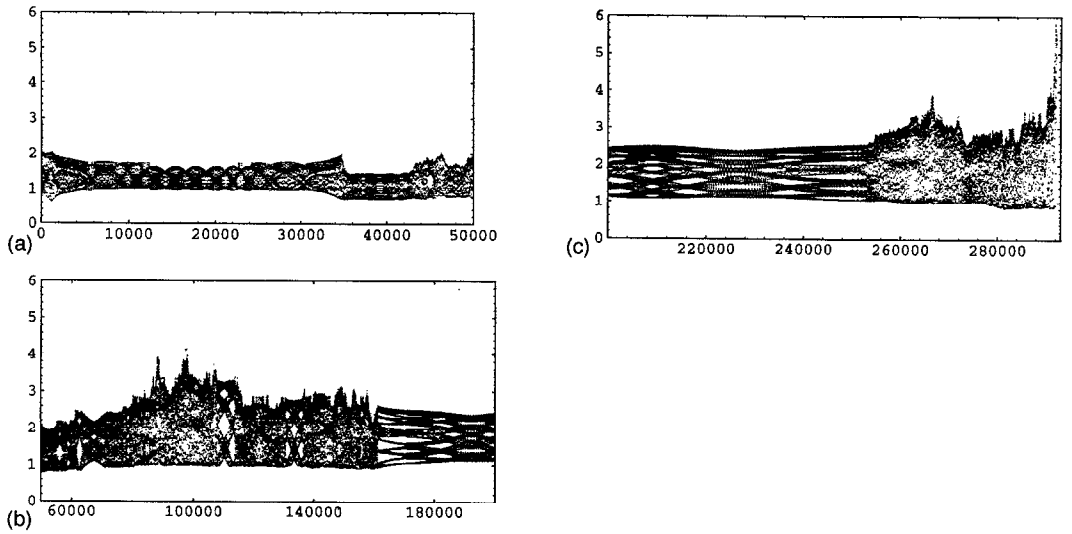

FIG. 4. Orbital radius versus time plots for the dynamical system given by the Hamiltonian (6) with initial conditions $(p_r, p_\theta, r, \theta)$ equal to (0.5,1,1,0) and parameter values $\epsilon=0.001$, $\delta=0.5$, $\alpha=2.5$, $\beta=2$, $k=1$, $\Omega=2$. This is an extended form of the plot presented in panel (a) of Figure 3.

value of r appears to oscillate between $\simeq a(1-e)=2/3$ and $\simeq a(1+e)=2$, thus indicating the complete absence of ionization. The possibility of ionization of the system is illustrated in Figures 2 and 3 for $\delta>0$, where the initial ellipse is near resonance in the first panel, on resonance in the middle panel and off resonance in the last panel. More precisely, the middle panel in either Figure 2 or Figure 3 corresponds to an exact third order resonance since $\Omega/\omega=3$, while the first panel illustrates the response of the ellipse to the external perturbation near resonance $\Omega/\omega\approx 3.08$; the last panel is off resonance with $\Omega/\omega\approx 1.54$. Additional calculations extending the integration time for the system depicted in the first panel of Figure 3 have been performed. These results suggest that a bursting behavior occurs in which the near resonance condition shown at the right end of this panel is followed by chaotic motion similar to that shown in the middle of this panel that in turn is followed by a period of near resonance. This recurrence of chaotic and near resonance behavior appears to continue for the extended interval of time studied as illustrated in Figure 4. Thus, this behavior is consistent with a type of chaotic behavior, called intermittent chaos, that has been studied for dissipative systems.[12] If the behavior suggested by these simulations is indeed present in the Hamiltonian system (6), then our result would be an example of *Hamiltonian intermittency*.

Imagine, for the sake of concreteness, a binary system consisting of an artificial satellite in an eccentric orbit about the Earth. Let the scales of length and time be R_0 and T_0, respectively; then, $R_0^3=kT_0^2$. Thus, if we take $R_0=10^9$ cm for the problem under consideration, it turns out that $T_0\approx 1.6\times 10^3$ s. The gravitational wave in our numerical experiments would then have a frequency of the order of $\Omega\approx 10^{-3}$ rad s^{-1}, corresponding approximately to 1.5×10^{-4} Hz as well as to a wavelength of 2×10^{14} cm, and an amplitude of the order of $\epsilon=10^{-3}$. Gravitational waves have not yet been directly observed; however, in a realistic situation the amplitude of the wave would be expected to be of the order of 10^{-20}.

Our numerical experiments are consistent with the expected behavior for a $2\frac{1}{2}$-degree of freedom Hamiltonian system. In fact, by introducing a fictitious action variable (cf. Sec. 6 in Ref. 1), our system is equivalent to an *autonomous* Hamiltonian system with *three* degrees of freedom. Each orbit of this new system is constrained to an energy manifold. However, whereas the two

dimensional KAM tori (if they exist for our choice of parameter values) separate each three dimensional energy manifold for the corresponding two-degree of freedom Hamiltonian system that we obtain with $\delta=0$, the three dimensional KAM tori, that may exist for the three-degree of freedom Hamiltonian system that we obtain with $\delta\neq 0$, do not separate space within the five dimensional energy manifolds. Of course, for sufficiently small choices of δ, there are orbits of the three-degree of freedom Hamiltonian system that remain bounded for all time; for example, the periodic orbits of Section V and the orbits confined to KAM tori. While the totality of bounded orbits in an energy manifold may be a set of positive measure, we expect that every open set of the five dimensional energy manifold contains an initial condition for a trajectory that will diffuse throughout the energy manifold. In fact, we expect this behavior for all $\delta>0$. On the other hand, as δ decreases toward zero, the time required to leave the vicinity of a KAM torus is expected to grow at an exponential rate. Figures 1–4 illustrate dynamical behavior that is characteristic of Arnold diffusion.[12]

APPENDIX: LATERALLY INCIDENT RADIATION

The purpose of this appendix is to point out that the main results of this paper still hold for a more general incident gravitational wave than that considered in (4).

In the general case of incident gravitational radiation on a binary system, the motion of the system away from the initial orbital plane (i.e., along the z-direction) also needs to be taken into account. It is necessary to mention here that *initial conditions* are generally ignored in our theoretical approach, which relies on the properties of the perturbed system once transients have died away and a "steady state" situation has been established. In this paper, we have limited our considerations to normally incident waves; in fact, the transversality of gravitational radiation makes it possible to set $z=0$ for normally incident waves. We wish to note here that essentially the same results can be obtained for a more general incident radiation field.

Consider, for instance, the superposition of a left circularly polarized (LCP) wave of frequency Ω traveling along the z-axis with a linearly polarized wave of frequency Ω traveling along the x-axis. Specifically, let χ_{ij} be of the form

$$\chi(t,\mathbf{0})=\begin{pmatrix} \cos\Omega t & -\sin\Omega t & 0 \\ -\sin\Omega t & 3\cos\Omega t & 0 \\ 0 & 0 & -4\cos\Omega t \end{pmatrix}, \tag{23}$$

up to a constant factor. It follows from (2) that the corresponding $\mathscr{K}$ is of the form

$$\mathscr{K}=\tfrac{1}{2}\Omega^2\chi(t,\mathbf{0}), \tag{24}$$

so that the equation of motion (1) along the z-direction is given by

$$\frac{d^2z}{dt^2}+\frac{kz}{r^3}-2\epsilon\Omega^2 z\cos\Omega t=0. \tag{25}$$

This equation is satisfied by $z=0$, which is consistent with the fact that the orbit is always in the (x,y)-plane. Therefore, to the incident radiation field in (4) one could add radiation fields of the type given by (23). Moreover, upon transformation to the rotating frame,

$$\mathscr{K}'=R^{-1}\mathscr{K}R=\frac{1}{2}\Omega^2\begin{pmatrix} \cos\Omega t & \sin\Omega t & 0 \\ \sin\Omega t & 3\cos\Omega t & 0 \\ 0 & 0 & -4\cos\Omega t \end{pmatrix}, \tag{26}$$

where

$$R=\begin{pmatrix} \cos \Omega t & -\sin \Omega t & 0 \\ \sin \Omega t & \cos \Omega t & 0 \\ 0 & 0 & 1 \end{pmatrix} \tag{27}$$

is the rotation matrix used in Section VII. It is remarkable that the tidal matrix $\mathscr{K}'$ in the rotating frame has the same frequency Ω as in the inertial frame; in fact, $\mathscr{K}'$ can be obtained from $\mathscr{K}$ simply by letting $\Omega \to -\Omega$.

A Riemannian generalization of a result of DeWitt concerning Ricci-flat Lorentz metrics

Olga Gil-Medrano[a)]
Departamento de Geometría y Topología, Universidad de Valencia, Valencia, Spain

(Received 13 November 1995; accepted for publication 22 February 1996)

For any given nonzero real number, α, and any curve from some open interval, I, into the space $\mathcal{M}$, of Riemannian metrics on a compact manifold M, a metric, $\tilde{g}$, on the manifold $I\times M$ can be constructed in a natural way; the metric is Riemannian for α positive and Lorentzian for α negative. The aim of this paper is to show that $\tilde{g}$ is an Einstein metric, with constant λ, if and only if the curve of metrics is a solution of a certain Lagrangian on $\mathcal{M}$ defined in terms of the DeWitt metric on $\mathcal{M}$, the total scalar curvature functional and the values α and λ. This result was obtained by DeWitt [Phys. Rev. **160**, 1113 (1967)], for the case where the dimension of M is three, α is negative and $\lambda=0$, in the context of a formulation of Einstein equations of evolution as a dynamical system. DeWitt metric is a member of a one parameter family of pseudometrics on $\mathcal{M}$; it is shown here that, no other such a metric can be used to describe the relationship of the $(n+1)$ geometry of $I\times M$ with the dynamics on $\mathcal{M}$, so a characterization of the DeWitt metric is obtained. © *1996 American Institute of Physics.* [S0022-2488(96)01207-8]

I. INTRODUCTION

Let $(N,\tilde{g})$ be a four-dimensional Lorentz manifold and let M be three-dimensional spacelike submanifold of N such that $\tilde{g}$ defines on M a one parameter family of Riemannian metrics, g_t. It is known that Einstein field equations in N, that is those describing the vanishing of the Ricci tensor of $\tilde{g}$, can be written as time evolution equations for the curve $t\to g_t$ in the manifold $\mathcal{M}$ of all Riemannian metrics on M. In Ref. 1, these equations are described as geodesic equations in $\mathcal{M}$, considered with a metric, which is now usually known as the DeWitt metric, and modified by a term due to the gravitational potential. More precisely, one of the results in Ref. 1, stated as in Ref. 2, reads as follows:

Theorem 1.1: *Let M be a compact, 3-dimensional manifold and let g_t, $t\in I=(-\varepsilon,\varepsilon)$, be a curve in the manifold of metrics $\mathcal{M}$. Let $(N,\tilde{g})$ be the Lorentz 4-manifold, where $N=I\times M$ and $\tilde{g}$ is defined in such a way that in an adapted coordinate system,*

$$\tilde{g}_{ij}(t,p)=(g_t)_{ij}(p);\quad \tilde{g}_{i0}\equiv 0;\quad \tilde{g}_{00}\equiv -1,$$

for each $i,j=1,2,3$. Then, $\tilde{g}$ is Ricci flat if and only if the curve g_t satisfies the second order differential equation,

$$g''=g'g^{-1}g'-\frac{1}{2}\mathrm{tr}(g^{-1}g')g'-\frac{1}{8}\langle g',g'\rangle_g^- g-2\rho_0(g)-\frac{1}{12}\tau(g)g,$$

together with the constraints $\delta_g(g'-\mathrm{tr}(g^{-1}g')g)=0$ and $\mathcal{H}(g,g'):=\frac{1}{2}\langle g',g'\rangle_g^- -2\tau(g)=0$. Here, $\rho_0(g)$, $\tau(g)$ and δ_g, represent the traceless part of the Ricci tensor, the scalar curvature and the divergence operator of the metric g and, $\langle,\rangle_g^-$ is the pointwise product that gives, by integration over M, the DeWitt metric G_g^-.

[a)]Electronic mail: gilo@uv.es

The second order equation is equivalent to the curve being a solution of the Lagrangian $L(g)=\frac{1}{2}G_g^-(g,g)+2S(g)$ and can be written as $g''=\Gamma^-(g,g')+2\mathrm{grad}^- S(g)$, where S is the total scalar curvature functional and Γ^- represents the Riemannian spray.

The purpose of this article is to give some generalizations of Theorem 1.1; namely we will prove that the assumption on the dimension of the manifold M is not necessary and also, that the conclusion is independent of the metric $\tilde{g}$ being Lorentzian. On the contrary, we will show that the DeWitt metric is the only metric, among those of a natural one parameter family of pseudometrics on $\mathcal{M}$, for which Einstein equations can be written in terms of its spray, gradients and divergences.

A Ricci flat metric is, in particular, an Einstein metric. Our last result is a generalization of Theorem 1.1 to this situation. We give the proof of the above mentioned results in Section IV.

Section II is concerned with the manifold of Riemannian metrics on a compact manifold and with the total scalar curvature functional, also known as gravitational potential. Although this material is fairly standard, we have included here a survey in order to establish the notation and to write the known results in the form in which they are going to be used in the sequel.

In Section III, we describe a one parameter family of weak pseudometrics, G^c, on the manifold $\mathcal{M}$; the usual L^2 metric and the DeWitt metric are among them. We use some results of Ref. 3 to obtain the explicit formulae for the Riemannian spray, gradients and divergences corresponding to each G^c.

II. PRELIMINARIES

Several topologies can be defined on sets of differentiable maps between manifolds, by using the adequate jet space; in this paper we will consider the C^∞-compact topology. With this topology, the space of smooth sections of a vector bundle over a manifold is a locally convex topological vector space; more precisely, it is a Fréchet space. Thus, it is possible to define manifolds modeled on these spaces of sections; the spaces themselves are manifolds with a single chart.

Many geometric structures on a manifold are defined to be one, or several, tensor fields satisfying certain conditions; so, each class of structures determines a subset of some space of tensor fields and, frequently, these subsets admit a structure of manifold modeled on spaces of sections.

Let M be a finite-dimensional, smooth manifold and for each nonnegative integers (r,s), let $\Gamma^\infty(T_{(r,s)}(M))$ be the space of r-times contravariant, s-times covariant, tensor fields on M. The C^∞-compact topology on it can be described in terms of a Riemannian metric on M, in a manner completely analogous to that used to define the same topology, on the space of smooth functions from an open domain of Euclidean space. It is only necessary to change the Euclidean norm, by the norm determined by the metric, and ordinary partial derivatives, by covariant derivatives with respect to its Levi-Civita connection. A detailed description can be seen in Ref. 4.

With exactly the same procedure, any other topology, of those usually defined on spaces of functions of Euclidean domains, can be extended to spaces of tensor fields. Among them, we can find the topologies associated either to Lebesgue or to Sobolev norms, which are obtained by integration of different powers of the norms of the tensor field or of its covariant derivatives. Nevertheless, if the manifold is not compact, the topology so defined depends upon the metric used for the definition and this fact has also a negative influence on the C^∞-compact topology; in fact, only for a compact manifold, spaces of sections, endowed with the C^∞-compact topology, are inverse limits of Hilbert spaces.

In what follows, we will assume that M is a compact manifold without boundary.

Let us denote by $S^2(M)$ the subspace of the symmetric elements of $\Gamma^\infty(T_{(0,2)}(M))$; it is easy to see that it is closed in the C^∞-compact topology and therefore it is a Fréchet space. Under the compactness assumption, the subset $\mathcal{M}\subset S^2(M)$, of positive definite elements, is open and then, it admits a Fréchet manifold structure modeled on $S^2(M)$. $\mathcal{M}$ is the manifolds of the metrics and it is a convex cone.

The diffeomorphism group of the manifold M, denoted by $\mathscr{D}$, is also a Fréchet manifold; its model is the space of vector fields on $\mathscr{M}$. $\mathscr{D}$ acts on each space of covariant tensor fields by pull-back.

For given $\varphi \in \mathscr{D}$, the map $\varphi:(M,\varphi^*g)\to(M,g)$ is, by definition, an isometry and so, any map of geometrical meaning, from $\mathscr{M}$ to a tensor field space, should be invariant by the action of $\mathscr{D}$. Examples of such maps, that we will use here, are the following.

– The Riemann curvature $R:\mathscr{M}\to\Gamma^\infty(T_{(0,4)}(M))$; it is given by $R(g)(X,Y,Z,W)=g(R_g(X,Y,Z),W)$ where $R_g(X,Y,Z)=-\nabla^g_X\nabla^g_Y Z+\nabla^g_Y\nabla^g_X Z+\nabla^g_{[X,Y]}Z$.

– The Ricci tensor $\rho:\mathscr{M}\to S^2(M)$; it is defined by $\rho(g)(X,Y)=\mathrm{tr}A^g_{X,Y}$ where $A^g_{X,Y}$ represents the (1,1)-tensor field given by $A^g_{X,Y}(Z)=R_g(X,Z,Y)$.

– The scalar curvature $\tau:\mathscr{M}\to C^\infty(M)$ given by $\tau(g)=\mathrm{tr}(g^{-1}\rho)$.

– The volume form $\mathrm{vol}:\mathscr{M}\to\Lambda^n(M)$, if $\mathscr{M}$ is oriented.

The scalar curvature is a particular case of what is called a natural Lagrangian; that is, a map $L:\mathscr{M}\to C^\infty(M)$ which is $\mathscr{D}$-invariant and that only depends on some k-th order jet of the metric.

Definition 2.1: A differentiable map $F:\mathscr{M}\to\mathbb{R}$ is said to be a Riemannian functional if and only if $F(\varphi^*g)=F(g)$ for all $(\varphi,g)\in\mathscr{D}\times\mathscr{M}$.

The condition on F defined above is equivalent to the map being constant on the $\mathscr{D}$-orbits.

Definition 2.2: Let $F:\mathscr{M}\to\mathbb{R}$ be a Riemannian functional; for a given $g\in\mathscr{M}$ let us denote by $T_gF:T_g\mathscr{M}\to\mathbb{R}$ the tangent map to F at g. A metric, g, is a critical point of F if and only if $\mathrm{Ker}(T_gF)=T_g\mathscr{M}$.

Definition 2.3: Let $L:\mathscr{M}\to C^\infty(M)$ be a, $\mathscr{D}$-invariant, smooth map. The Riemannian functional associated to L is defined as $F_L(g)=\int_M L(g)\mathrm{vol}(g)$ where $\mathrm{vol}(g)$ represents the volume element of g (a density on M unless M is oriented). In particular, F_τ is the total scalar curvature and will be denoted by S; if L is given by $L(g)\equiv 1$, then F_L is the volume functional.

The computations necessary to obtain the differential of maps related with the curvature operator have been done usually in local coordinates, and they are well known from a long time ago; in particular, those concerning total scalar curvature go back to Hilbert[5]. A good review of the known results is included in the corresponding chapter of Besse.[6]

The next statement contains several known results concerning the differential of the scalar curvature map. They are written in the form in which we are going to use them later.

Proposition 2.4

(1) $(T_g\mathrm{vol})(h)=\frac{1}{2}\mathrm{tr}(g^{-1}h)\mathrm{vol}(g)$,

(2) $(T_gF_L)(h)=\int_M((T_gL)(h)+\frac{1}{2}\langle L(g)g,h\rangle_g)\mathrm{vol}(g)$,

(3) $(T_g\tau)(h)=-\langle\rho(g),h\rangle_g+\Delta^g(\mathrm{tr}(g^{-1}h))+\delta_g\delta_g h$,

(4) $(T_gS)(h)=\int_M\langle-\rho(g)+\frac{1}{2}\tau(g)g,h\rangle_g\mathrm{vol}(g)$,

where δ_g is the divergence operator of the metric g, given by $\delta_g T=-\mathrm{tr}(g^{-1}\nabla^g T)$, and Δ^g is the Laplace operator, $\Delta^g T=-\mathrm{tr}(g^{-1}(\nabla^g)^2T)$. Here, $\langle,\rangle_g$ represents the usual pointwise product of tensor fields given by the metric which, for 2-covariant symmetric tensor fields, has the form $\langle k,h\rangle_g=\mathrm{tr}(g^{-1}kg^{-1}h)$.

The L^2 inner product on $S^2(M)$, obtained by integration of the usual pointwise product, gives rise to a Riemannian metric, G, on $\mathscr{M}$ by the formula

$$G_g(h,k)=\int_M\langle h,k\rangle_g\mathrm{vol}(g).$$

G is a symmetric, $\mathscr{D}$-invariant, bilinear form but it is a weak metric; in fact, the map, from $T_g\mathscr{M}$ into its dual, induced by G, is only injective and the topology, in $T_g\mathscr{M}$, defined by the G_g-norm is not the one obtained from the differentiable structure considered in $\mathscr{M}$.

Definition 2.5: Let $F:\mathscr{M}\to\mathbb{R}$ be a Riemannian functional. If there is a map $\mathrm{grad}F:\mathscr{M}\to S^2(M)$ *such that $G_g(\mathrm{grad}F(g),h)=(T_gF)(h)$, for each $g\in\mathscr{M}$ and each $h\in T_g\mathscr{M}$, this map is said to be the G-gradient of F.*

If F is such that its G-gradient exits then, a metric g is a critical point of F if and only if $\mathrm{grad}F(g)=0$.

From (4) of Proposition 2.4, the total scalar curvature admits a G-gradient, namely $\mathrm{grad}S(g)=-\rho(g)+\frac{1}{2}\tau(g)g$. For a manifold, of dimension $n\neq 2$, a metric is a critical point of S if and only if it is Ricci flat.

The next property, usually known as conservation laws, follows directly from the fact that, due to the $\mathscr{D}$-invariance of a Riemannian functional, its G-gradient must be, at each metric g, G_g-orthogonal to the orbit. The tangent space, at g, to the $\mathscr{D}$-orbit is the image of the elliptic differential operator $\delta_g^*:\Lambda^1(M)\to S^2(M)$ given by $\delta_g^*(\omega)=\mathrm{symm}(\nabla\omega)$; its formal G_g-adjoint is the divergence operator of g and then, the elements of $S^2(M)$ which are G_g-orthogonal to the orbit are just those of $\mathrm{Ker}\delta_g$.

Proposition 2.6: Let grad F *be the G-gradient of a Riemannian functional F; then, for each $g\in\mathscr{M}$ the tensor field* $\mathrm{grad}F(g)$ *has vanishing g-divergence.*

III. THE ONE PARAMETER FAMILY OF PSEUDOMETRICS, G^c ON $\mathscr{M}$

Each metric, g, determines an algebraic decomposition of the tangent space $T_g\mathscr{M}=S^2(M)$ as follows: $T_g\mathscr{M}=V_0(g)\oplus V_1(g)$ where, $V_0(g)=\{h\in T_g\mathscr{M};\mathrm{tr}(g^{-1}h)=0\}$ and $V_1(g)=C^\infty(M)g$; for an element $h\in S^2(M)$ we will represent by h_0 its traceless part, that is $h_0=h-(1/n)\ \mathrm{tr}(g^{-1}h)g$.

For each $c\in\mathbb{R}$, $c\neq 0$, a pointwise product is defined by the expression $\langle k,h\rangle_g^c=\mathrm{tr}(g^{-1}k_0g^{-1}h_0)+c\,\mathrm{tr}(g^{-1}k)\mathrm{tr}(g^{-1}h)$. We recover the usual pointwise product for $c=1/n$. By integration of the corresponding pointwise product, a weak pseudometric, G^c, is defined on $\mathscr{M}$; for $c>0$ it is in fact a metric.

In Ref. 7, Killing vector fields with respect to these pseudometrics have been studied. In Ref. 3 the pseudometrics G^c are extended to the space $\mathscr{B}$, of nondegenerate 2-times covariant tensor fields, and their Levi-Civita connection, geodesics, exponential mapping and curvature are calculated.

Proposition 3.1: Let $t\mapsto g(t)$ be a smooth curve in $\mathscr{M}$. It is a geodesic of the manifold $(\mathscr{M},G^c)$ if and only if

$$g''=g'g^{-1}g'-\frac{1}{2}\mathrm{tr}(g^{-1}g')g'+\frac{1}{4cn}\mathrm{tr}(g^{-1}g'g^{-1}g')g+\frac{cn-1}{4cn^2}\mathrm{tr}(g^{-1}g')^2g.$$

Therefore, the geodesic spray of G^c is given by

$$\Gamma^c(g,h)=hg^{-1}h-\frac{1}{2}\mathrm{tr}(g^{-1}h)h+\frac{1}{4cn}\langle h,h\rangle_g^c g.$$

Here g', g'', represent $(\partial/\partial t)g$ and $(\partial^2/\partial t^2)g$.

Proof: In Ref. 3 (Theorem 3.2) it is shown that the submanifold $\mathscr{M}$ of $\mathscr{B}$ is geodesically closed and then the geodesic equation is just the one appearing in 2.3 of Ref. 3. For the second assertion we have only to use the fact that $\Gamma^c(g,h)$ is the geodesic spray if and only if the geodesic equation is $g''=\Gamma^c(g,g')$, and the definition of $\langle,\rangle_g^c$. ■

Lemma 3.2: Let $F:\mathscr{M}\to\mathbb{R}$ be a Riemannian functional. Then, F admits G^c-gradient if and only if it admits G-gradient and both vector fields are related by

$$\mathrm{grad}^cF(g)=\mathrm{grad}F(g)-\frac{cn-1}{cn^2}\mathrm{tr}(g^{-1}\mathrm{grad}F(g))g.$$

Proof: By definition of the gradient,

$$G_g^c(\mathrm{grad}^c F(g),h)=(T_gF)(h)=G_g(\mathrm{grad}F(g),h).$$

Now, it is easy to see (Lemma 1.4 in Ref. 3) that the last member is equal to $G_g^c(\mathrm{grad}F(g)-[(cn-1)/cn^2](g^{-1}\mathrm{grad}F(g))g,h)$ from where the expression holds. ■

In the particular cases of the volume and total scalar curvature functionals, combining the above Lemma and formulae in Proposition 2.4 we obtain the following

Lemma 3.3:

(1) $\mathrm{grad}^c V(g)=(1/2cn)g$.

(2) $\mathrm{grad}^c S(g)=-\rho_0(g)+[(n-2)/2cn^2]\tau(g)g$.

For the G^c-gradient of a Riemannian functional, the same arguments used in 2.6 allow us to conclude that if δ_g^c represents the formal G^c-adjoint of the operator δ_g^* then, for every Riemannian functional F, we have $\delta_g^c(\mathrm{grad}^c F(g))=0$.

It is easy to see that the operator δ_g^c is given by $\delta_g^c(h)=\delta_g(h_0)-cd(\mathrm{tr}(g^{-1}h))$; in fact, using Lemma 1.4 of Ref. 3, we have

$$G_g^c(\delta_g^*(\omega),h)=G_g\left(\delta_g^*(\omega),h+\frac{cn-1}{n}\mathrm{tr}(g^{-1}h)g\right)=\left\langle \omega,\delta_g\left(h+\frac{cn-1}{n}\mathrm{tr}(g^{-1}h)g\right)\right\rangle_g,$$

for all $\omega\in\Lambda^1(M)$. Therefore $\delta_g^c(h)=\delta_g(h_0+c\,\mathrm{tr}(g^{-1}h)g)=\delta_g(h_0)-cd(\mathrm{tr}(g^{-1}h))$ and we have shown the following

Proposition 3.4: Let $\mathrm{grad}^c F$ *be the* G^c*-gradient of a Riemannian functional* F*; then, for each* $g\in\mathscr{M}$ *the tensor field* $(\mathrm{grad}^c F(g))_0+c\,\mathrm{tr}(g^{-1}(\mathrm{grad}^c F(g)))g$ *has vanishing* g*-divergence.*

Apart from the case $c=1/n$, the other distinguished member of the family of pseudometrics is the one corresponding to $c=(1-n)/n$; we will denote it by G^-. It is known as the DeWitt metric because it has been defined in Ref. 1, for the particular case $n=3$ and $c=-2/3$; for this case, the expression of the geodesic spray can be found there.

IV. RELATIONSHIP WITH THE $(n+1)$ GEOMETRY

In this section we study some generalizations of Theorem 1.1; let us start with a technical Lemma.

Lemma 4.1: Let g_t, $t\in I=(-\varepsilon,\varepsilon)$, *be a curve in the manifold* $\mathscr{M}$, *of metrics on* M, *and let* α *be a real number, different from* 0. *On the manifold* $N=I\times M$, *let us consider the pseudometric,* $\tilde{g}$, *defined in such a way that, in an adapted coordinate system, is given by*

$$\tilde{g}_{ij}(t,p)=(g_t)_{ij}(p);\quad \tilde{g}_{i0}\equiv 0;\quad \tilde{g}_{00}\equiv\alpha,$$

for each $i,j=1,\ldots,n$. *Then, Christoffel symbols of* $\tilde{g}$ *are given by*

$$\tilde{\Gamma}_{ij}^k(t,p)=(\Gamma^t)_{ij}^k(p),\quad \tilde{\Gamma}_{ij}^0(t,p)=\frac{-1}{2\alpha}(g_t')_{ij}(p),\quad \tilde{\Gamma}_{0j}^k(t,p)=\frac{1}{2}(g_t^{-1}g_t')_j^k(p),$$

$$\tilde{\Gamma}_{0j}^0(t,p)=\tilde{\Gamma}_{00}^k(t,p)=\tilde{\Gamma}_{00}^0(t,p)=0.$$

The components of the Ricci tensor are

$$\tilde{\rho}_{i0}(t,p)=\frac{-1}{2}\{(d\,\mathrm{tr}(g_t^{-1}g_t'))_i(p)+(\delta_t g_t')_i(p)\},$$

$$\tilde{\rho}_{00}(t,p)=\frac{-1}{2}\mathrm{tr}(g_t^{-1}g_t'')+\frac{1}{4}\mathrm{tr}(g_t^{-1}g_t'g_t^{-1}g_t'),$$

$$\widetilde{\rho}_{ij}(t,p)=\frac{-1}{2\alpha}(g_t'')_{ij}(p)+\frac{1}{2\alpha}(g_t'g_t^{-1}g_t')_{ij}(p)-\frac{1}{4\alpha}\mathrm{tr}(g_t^{-1}g_t')(g_t')_{ij}(p)+\rho_{ij}^t(p),$$

where, for simplicity, we have represented by $(\Gamma^t)_{ij}^k$, ρ_{ij}^t, δ_t, *the Christoffel symbols, the Ricci tensor and the divergence of* g_t, *respectively.*

Proof: Christoffel symbols are obtained by straightforward computation. Now, the components of Ricci tensor are given by

$$\widetilde{\rho}_{AB}=\sum_{C=0}^{n}\widetilde{R}_{ABC}^{C},$$

with

$$\widetilde{R}_{ABC}^{E}=(\widetilde{R}(\partial_B,\partial_C)\partial_A)^E=-\partial_B(\widetilde{\Gamma}_{CA}^E)+\partial_C(\widetilde{\Gamma}_{BA}^E)-\sum_{D=0}^{n}\widetilde{\Gamma}_{BD}^E\widetilde{\Gamma}_{CA}^D+\sum_{D=0}^{n}\widetilde{\Gamma}_{CD}^E\widetilde{\Gamma}_{BA}^D,$$

where $A,B,C,E\in\{0,1,\ldots,n\}$; see Ref. 8, p. 87.

The values of $\widetilde{\rho}_{ij}$ and $\widetilde{\rho}_{00}$ are obtained directly from the expressions above. It is easy to see that $\widetilde{R}_{i00}^0=0$ and then

$$\widetilde{\rho}_{i0}=\sum_{k=1}^{n}\widetilde{R}_{i0k}^{k}.$$

Therefore

$$\widetilde{\rho}_{i0}(t,p)=\frac{-1}{2}(d\mathrm{tr}(g_t^{-1}g_t'))_i(p)$$
$$+\frac{1}{2}\sum_k\left\{\partial_k(g_t^{-1}g_t')_i^k(p)-\sum_l(g_t^{-1}g_t')_k^l(\Gamma^t)_{il}^k(p)+\sum_l(g_t^{-1}g_t')_i^l(\Gamma^t)_{kl}^k(p)\right\}.$$

In order to finish the proof, we only need to show that for each metric g and each $h\in S^2(M)$,

$$\sum_k\left\{\partial_k(g^{-1}h)_i^k-\sum_l(g^{-1}h)_k^l\Gamma_{il}^k+\sum_l(g^{-1}h)_i^l\Gamma_{kl}^k\right\}=-(\delta_g(h))_i.$$

In fact

$$\sum_k\partial_k(g^{-1}h)_i^k=\sum_{k,l}g^{kl}\partial_k(h_{li})-\sum_{k,l,r,j}g^{kl}\partial_k(g_{lj})g^{jr}h_{ri},$$

and

$$\sum_{k,l}(g^{-1}h)_i^l\Gamma_{kl}^k=\frac{1}{2}\sum_{k,l,r,j}g^{lr}h_{ri}g^{kj}\partial_l(g_{jk}).$$

By adding the right-hand terms of both equalities we obtain

$$\sum_{k,l}g^{kl}\partial_k(h_{li})-\sum_{k,l,r}g^{kl}\Gamma_{lk}^r h_{ri},$$

and the result follows from the definition of the divergence. ■

Proposition 4.2: Let g_t, $\tilde{g}$, be as described in the previous Lemma. The first and second variations of the curve of metrics and the Ricci tensor of $\tilde{g}$ are related by

(1) $\tilde{\rho}_{i0}=-\frac{1}{2}(\delta_g^- g')_i$,

(2) $\tilde{\rho}_{00}=\alpha\mathrm{tr}(g^{-1}\tilde{\rho})-\alpha\tau-\frac{1}{4}\langle g',g'\rangle_g^c+\frac{n-1+cn}{4n}\mathrm{tr}(g^{-1}g')^2$,

(3) $$g''=-2\alpha\tilde{\rho}+\frac{n-2+2cn}{cn^2}(\alpha\mathrm{tr}(g^{-1}\tilde{\rho})-\tilde{\rho}_{00})g+\Gamma^c(g,g')-2\alpha\mathrm{grad}^c S(g)$$
$$-\frac{n-1+cn}{2cn^2}\left(\langle g',g'\rangle_g^c-\frac{n-2+2cn}{2}\mathrm{tr}(g^{-1}g')^2\right)g.$$

Proof: First equality is just the corresponding equality in Lemma 4.1, written in terms of the gradient operator associated to the DeWitt metric. For the second one we take the trace of g'' and then, we use the definition of $\langle,\rangle_g^c$.

Finally, the last equality can be obtained as follows: using Proposition 3.1, Lemma 3.3 and Lemma 4.1, it is easy to see that

$$g''=-2\alpha\tilde{\rho}+\Gamma^c(g,g')-2\alpha\mathrm{grad}^c S(g)+\left(\frac{n-2+2cn}{cn^2}\alpha\tau-\frac{1}{4cn}\langle g',g'\rangle_g^c\right)g.$$

To obtain the result we only need to change $\alpha\tau$ by its value obtained from (2). ■

Proposition 4.3: Let M be a compact, n-dimensional manifold and let g_t, $t\in I=(-\varepsilon,\varepsilon)$, be a curve in the manifold of metrics $\mathcal{M}$. Let $(N,\tilde{g})$ be the pseudoRiemannian $(n+1)$-manifold, where $N=I\times M$ and $\tilde{g}$ is defined in such a way that in an adapted chart,

$$\tilde{g}_{ij}(t,p)=(g_t)_{ij}(p);\quad \tilde{g}_{i0}\equiv 0;\quad \tilde{g}_{00}\equiv\alpha,$$

for each $i,j=1,\ldots,n$. Then $\tilde{g}$ is Ricci flat if and only if the curve satisfies the second order differential equation $g''=\Gamma^-(g,g')-2\alpha\mathrm{grad}^- S(g)$ together with the constraints $\delta_g^- g'=0$ and $\mathcal{H}(g,g'):=\frac{1}{2}\langle g',g'\rangle_g^- +2\alpha\tau(g)=0$.

Proof: Let us assume first that $\tilde{g}$ is Ricci flat. By (1) of 4.2, $\delta_g^- g'=0$ and if we take $c=[(1-n)/n]$ in (2), we also have the second constraint. The differential equation that the curve should satisfy comes from (3). The converse follows also immediately from the Proposition above. ■

Proposition 4.4: The DeWitt metric is the only metric, among those belonging to the one parameter family G^c, for which the above result holds. In fact if g_t, $t\in I=(-\varepsilon,\varepsilon)$, is a curve, in the manifold of metrics of a compact manifold, such that $\tilde{g}$ is Ricci flat and g_t satisfies

(1) $g''=\Gamma^c(g,g')-2\alpha\mathrm{grad}^c S(g)$ *and*

(2) $\frac{1}{2}\langle g',g'\rangle_g^c+2\alpha\tau(g)=0$,

for some $c\neq(1-n)/n$, then, $g_t=g_0$, for all t, and g_0 is Ricci flat.

Proof: Under the assumptions, equalities (2) and (3) of Proposition 4.2 become, respectively, $\mathrm{tr}(g^{-1}g')=0$ and $\langle g',g'\rangle_g^c-[(n-2+2cn)/2]\mathrm{tr}(g^{-1}g')^2=0$; so, $\mathrm{tr}(g^{-1}(g')_0 g^{-1}(g')_0)=0$ from where g' should vanish and the curve of metrics is constant to the initial value g_0. Now, from (1), the metric g_0 is a critical point of S and then it should be Ricci flat, provided the dimension of M is not 2. For a 2-dimensional manifold, a critical point of S has only $\rho_0=0$ and we have to use also (2) in order to conclude. ■

Proposition 4.5: Let g_t and $\tilde{g}$ be as described in Proposition 4.3. Then, the metric $\tilde{g}$ is Einstein with constant λ (i.e., $\tilde{\rho}=\lambda\tilde{g}$) if and only if the curve satisfies the second order differential

equation $g''=\Gamma^-(g,g')-2\alpha\operatorname{grad}^- S_\lambda(g)$ *together with the constraints* $\delta_g^- g'=0$ *and* $\mathscr{H}_\lambda(g,g'):=\frac{1}{2}\langle g',g'\rangle_g^- +2\alpha\tau^\lambda(g)=0$, where $\tau^\lambda(g)=\tau-\lambda(n-1)$ and $S_\lambda(g)=\int_M \tau^\lambda(g)\operatorname{vol}(g)$.

Proof: Let us assume first that $\tilde{\rho}=\lambda\tilde{g}$. By (1) of Proposition 4.2, $\delta_g^- g'=0$. If we take $c=(1-n)/n$ in (2), we have

$$\lambda\alpha=\lambda\alpha n-\alpha\tau-\frac{1}{4}\langle g',g'\rangle_g^-,$$

and so the second constraint. Now, equality (3) of Proposition 4.2 gives

$$g''=-\alpha\lambda g+\Gamma^-(g',g')-2\alpha\operatorname{grad}^- S(g);$$

the result follows from (1) of Lemma 3.3.

For the converse, equalities above imply that the components of the Ricci tensor of $\tilde{g}$ satisfy the following:

$$\tilde{\rho}_{00}=\alpha\operatorname{tr}(g^{-1}\tilde{\rho})-\lambda\alpha(n-1)$$

and

$$2\alpha\tilde{\rho}=\lambda\alpha g+\frac{1}{n-1}(\alpha\operatorname{tr}(g^{-1}\tilde{\rho})-\tilde{\rho}_{00})g.$$

As a consequence, $\tilde{\rho}=\lambda\tilde{g}$. ■

Conditions on the stability of the external space solutions in a higher-dimensional quadratic theory of gravity

K. Kleidis, H. Varvoglis, and D. B. Papadopoulos
Department of Physics, Section of Astrophysics, Astronomy and Mechanics, Aristotle University of Thessaloniki, GR-54006 Thessaloniki, Greece

(Received 23 October 1995; accepted for publication 23 April 1996)

By using Lyapounov's direct method we examine the conditions under which stable solutions to the field equations for the scale function of the external space may be derived in the context of a five-dimensional quadratic theory of gravity. We show that the time evolution of the distance, in a diagram $t-R$, between our solution to the field equations and a neighbouring one is determined, in the linear approximation, in terms of a second-order linear differential equation. Asking for bounded solutions of this equation we arrive at a stability criterion for the external scale function solutions, indicating that there exist three types of cosmological evolution of the visible universe which are linearly stable at all times. These are (i) the Milne model, (ii) the spatially flat Friedmann radiation solution, and (iii) the De Sitter inflationary solution. © *1996 American Institute of Physics.*

I. INTRODUCTION

The idea that the space–time may have more than four dimensions has been extensively studied, as an attractive way to unify all gauge interactions with gravity, in a *supergravity* scenario[1–3] and in *superstring* theories.[4] In a realistic higher-dimensional theory the extra dimensions are assumed to form, at present, a compact manifold (*internal space*) of very small size compared to that of the visible universe (*external space*),[5–8] leading to the problem of *compactification*.[8] It has been suggested that compactification of the extra space may be achieved in a natural way by adding a square curvature term, $\mathrm{R}_{\mu\nu\kappa\lambda}\mathrm{R}^{\mu\nu\kappa\lambda}$, in the action for the gravitational field.[9,10]

Gravitational Lagrangians containing quadratic terms of the curvature tensor have been studied classically in the search of inflationary solutions[11,12] and solutions free from cosmological singularities.[13–17] However, they attracted the interest of cosmologists only after it became clear that when gravity is extracted by the low energy approximation of superstrings, an additional $\mathrm{R}_{\mu\nu\kappa\lambda}\mathrm{R}^{\mu\nu\kappa\lambda}$ term arises in the gravitational action.[18,19]

The introduction of a quadratic combination into the gravitational action leads to differential equations of the fourth order with respect to the metric.[20,21] There is one particular combination of the quadratic curvature terms[22,23] which, in connection to the linear Einstein–Hilbert (EH) term, yields second-order differential equations. We refer to it as the Gauss–Bonnett (GB) combination, since in four dimensions it satisfies the relation

$$\frac{\delta}{\delta g_{\mu\nu}}\int(\mathrm{R}^2-4\mathrm{R}_{\mu\nu}\mathrm{R}^{\mu\nu}+\mathrm{R}_{\mu\nu\kappa\lambda}\mathrm{R}^{\mu\nu\kappa\lambda})\sqrt{-g}\,d^4x=0 \tag{1.1}$$

corresponding to the GB theorem.[24] Equation (1.1) implies that the addition of the GB combination to the EH Largangian will not affect the four-dimensional field equations. Therefore, the resulting theory differs from general relativity (GR) only if the space–time has more than four dimensions and, probably, yields a natural generalization of GR in higher-dimensional space–times.

In the present paper we examine the conditions under which stable solutions to the field equations for the scale function of the external space may be obtained, in the context of a five-dimensional GB cosmology. We use Lyapounov's method[25] to determine the stability conditions in terms of an *isochronous correspondence*[26] between the curve $R_0(t)$, obtained from our solution to the field equations, and another one, $R(t)$, corresponding to a neighboring set of initial conditions. The distance between these two curves, $\chi(t)$, at each time, is given by

$$\chi(t)=R(t)-R_0(t). \tag{1.2}$$

In Sec. II we derive the explicit form of the field equations for a quadratic theory in five dimensions. In Sec. III we consider the case of a pressureless internal space. Then the field equations *decouple* and the solution for the external scale function (representing the evolution of the ordinary universe) can be found independently of the corresponding internal one. We express the cosmological field equation for $R(t)$ in terms of $\chi(t)$ and show that, in the linear approximation, its evolution is determined by a second-order linear differential equation with time-dependent coefficients. In this case, we examine the conditions under which the origin $\chi=0$ is stable. By Eq. (1.2), the stability properties of $R_0(t)$ are the same as those of the zero solution.[27] On general grounds concerning the stability of linear systems[25–27] the solution $\chi=0$ is stable, provided that every solution of the linear equation for $\chi(t)$ is bounded. Accordingly we arrive at a criterion which guarantees the boundness of the solutions $\chi(t)$ and, therefore, the stability of the zero solution $\chi=0$ as well. Some cosmological implications of these results are finally discussed in Sec. IV.

II. THE FIELD EQUATIONS

In a recent paper[28] we have considered a five-dimensional model with a homogeneous and isotropic, three-dimensional external space and a bounded one-dimensional internal space. The space–time metric is of the form

$$ds^2=-dt^2+R^2(t)\left[\frac{dr^2}{1-kr^2}+r^2(d\theta^2+\sin^2\theta\, d\phi^2)\right]+S^2(t)(dx^5)^2, \tag{2.1}$$

where $\hbar=1=c$, $R(t)$ and $S(t)$ are the cosmic scale functions of the external and the internal spaces, respectively, and $k=-1, 0, +1$ is the curvature parameter of the external space. This model may be obtained through Hamilton's principle, where the gravitational part of the action is of the form

$$I_{GR}=\frac{1}{L_5}\int\sqrt{-g}\left[\frac{1}{2\kappa}\mathbb{R}+\alpha(\mathbb{R}^2-4\mathbb{R}_{\mu\nu}\mathbb{R}^{\mu\nu}+\mathbb{R}_{\mu\nu\kappa\lambda}\mathbb{R}^{\mu\nu\kappa\lambda})\right]d^5x. \tag{2.2}$$

In Eq. (2.2) Greek indices refer to the five-dimensional space–time, $\kappa=8\pi G$, α is a dimensionless constant and $L_5=2\pi R_5$ is a normalization constant,[29] corresponding to the *physical size* of the internal space, once it can be considered static.[20] As far as the matter content is concerned, we have considered an anisotropic perfect fluid source, having an energy-momentum tensor of the form $T_{\mu\nu}=\mathrm{diag}(\varrho, -p_3, -p_3, -p_3, -p_5)$, where p_3 and p_5 are the pressures of the fluid for the external and the internal space, respectively, and ϱ is the total mass energy density. The corresponding field equations, in connection to the conservation law $T^{\mu\nu}{}_{;\nu}=0$, are decomposed into three independent equations[28] involving $R(t)$, $S(t)$, ϱ, p_3, and p_5:

$$3\frac{\dot R}{R}\frac{\dot S}{S}+3\left[\left(\frac{\dot R}{R}\right)^2+\frac{k}{R^2}\right]+12\eta\left[\left(\frac{\dot R}{R}\right)^2+\frac{k}{R^2}\right]\frac{\dot R}{R}\frac{\dot S}{S}=8\pi G_5\varrho, \tag{2.3a}$$

$$3\frac{\ddot{R}}{R}+3\left[\left(\frac{\dot{R}}{R}\right)^2+\frac{k}{R^2}\right]+12\eta\left[\left(\frac{\dot{R}}{R}\right)^2+\frac{k}{R^2}\right]\frac{\ddot{R}}{R}=-8\pi G_5 p_5, \tag{2.3b}$$

$$\frac{d\varrho}{dt}+3\frac{\dot{R}}{R}p_3+\frac{\dot{S}}{S}p_5+\left(3\frac{\dot{R}}{R}+\frac{\dot{S}}{S}\right)\varrho=0, \tag{2.3c}$$

where an overdot denotes derivative with respect to time, $\eta=16\pi G\alpha$ is a constant of dimensions T^2, and $G_5=GL_5$ is the five-dimensional gravitational constant.[30] The system of Eqs. (2.3), together with the two equations of state for the matter content (one for each subspace[31]), determine completely the evolution of the five-dimensional cosmological model. Its solution will give us the unknown scale functions of the two subspaces, $R(t)$ and $S(t)$, as well as the time evolution of the matter-energy density, $\varrho(t)$. It corresponds to a Cauchy problem which has solution only if $R\neq 0$ and $S\neq 0$, $\forall t$. Cauchy's criterion[32] implies that, for a given set of initial conditions, the solution is unique, provided

$$1+4\eta W\neq 0, \quad \forall t, \tag{2.4}$$

where W stands for the combination[28]

$$W=\left(\frac{\dot{R}}{R}\right)^2+\frac{k}{R^2}=-\frac{1}{4\eta}\left[1\mp\sqrt{1-\left(\frac{R_m}{R}\right)^4}\right]. \tag{2.5}$$

In Eq. (2.5) R_m is the lowest bound of $R(t)$ for which we obtain physically acceptable solutions within the context of the quadratic theory under consideration.[28] Then, combination of Eqs. (2.4) and (2.5) indicates that $R(t)>R_m$, $\forall t$. For a monotonicaly increasing function $R(t)$, we have $R(t)>R_m$ when $t>t_m(t_m>0)$.

As in Ref. 28, we consider models of an already compactified internal space.[28,31,33] Compactification is a topological process of quantum origin, leading to the separation of the extra dimensions from the ordinary ones.[30] Therefore, we study only the process of contraction of the internal space, which may be understood by the classical equations of motion. Clearly, the contraction of the internal space presupposes the separation of the extra dimensions from the ordinary ones and starts immediately after compactification.

III. CONDITIONS ON THE STABILITY OF THE EXTERNAL SPACE SOLUTIONS

When the equations of state for the matter content in the two subspaces are determined, Eq. (2.3c) may be readily solved to give $\varrho(t)$ in terms of $R(t)$ and $S(t)$. Then, in order to determine the evolution of the five-dimensional model, one has to solve the self-consistent system of coupled Eqs. (2.3a) and (2.3b). As equation of state in the internal space, we choose $p_5=0$. It corresponds to an internal matter content in the form of dust, indicating the absence of motion along the extra dimension. This equation of state may represent successfully the later stages of the cosmological evolution in a five-dimensional theory of gravity, where the physical size of the internal space is very small.[33–35]

Now, the field equations (2.3a) and (2.3b) *decouple*. Each of them corresponds to a differential equation of only one scale function. Indeed, in this case Eq. (2.3b) has the first integral[28]

$$R^4\left[\left(\frac{\dot{R}}{R}\right)^2+\frac{k}{R^2}\right]+2\eta R^4\left[\left(\frac{\dot{R}}{R}\right)^2+\frac{k}{R^2}\right]^2=\text{const.} \tag{3.1}$$

Its solution will give the explicit time dependence of $R(t)$. Accordingly, Eq. (2.3a) becomes a differential equation of $S(t)$ with time-dependent coefficients, resulting in this form through the solution of Eq. (3.1).[32] Therefore, we end up with a problem involving the description of two

subspaces, where the evolution of each space obeys an ordinary differential field equation of time only. In this sense, the expansion of the visible universe, through Eq. (2.3b), does not depend on the evolution of the internal space. This result has a clear physical meaning:[28] The two subspaces are completely disjoint. This is not unexpected, since we have considered a cosmological model *after* the compactification process, which implies the separation of the extra dimensions from the ordinary ones. The external space will evolve according to Eq. (2.3b) independently on the time behavior of the internal one.

In this case, we examine the *stability* of the solutions of the self-consistent equation (2.3b) by using Lyapounov's direct method.[25] The solutions represent the time evolution of the visible universe and we would like to know under which conditions a stable solution at all times may be obtained, within the context of the quadratic theory under consideration. The question that arises now is, which solutions are considered stable at all times.

Let us denote by $R_0(t)$ the solution to Eq. (2.3b), whose stability is under consideration, and by $R(t)$ any other solution of it. Equation (2.3b), with the aid of Eq. (2.5), may be expressed in the form

$$\ddot{R}=-\frac{R}{4\eta}\left[1\mp\frac{1}{\sqrt{1-z}}\right], \tag{3.2}$$

where we have set $z=(R_m/R)$.[4] Clearly, by virtue of Eqs. (2.4) and (2.5), $z<1\forall t$. The distance, at each time, between the two corresponding curves $R(t)$ and $R_0(t)$ in a diagram $t-R$ is given by Eq. (1.2). We write Eq. (3.2) in terms of $\chi(t)$ and study its evolution in time. In this case, $\chi(t)$ actually represents a perturbation of the original solution, $R_0(t)$. We will examine the evolution of a small $\chi(t)$, since the question of stability is whether such small disturbances grow or not.[25–27]

We consider the linear stability of the resulting equation around the origin $\chi=0$, which corresponds to $R(t)=R_0(t),\forall t$.[25,27] If the zero solution $\chi=0$ is linearly stable, so is the evolution of the external space, since $R(t)$ remains *near* $R_0(t)$ at all times.[25,27,36] This is true only for smooth functions of time, i.e., functions for which $|\dot{R}(t)|<\infty,\forall t$. Equation (3.2), in linear terms of χ, may be written in the form[37]

$$\ddot{\chi}=-\frac{1}{4\eta}\chi\left[1\mp\frac{1-3z_0}{(1-z_0)^{3/2}}\right], \tag{3.3}$$

where $z_0=(R_m/R_0)$.[4] Since $R_0(t)$ is assumed known, Eq. (3.3) is a linear second-order differential equation for $\chi(t)$, with time-dependent coefficients. It is more convenient to write the function in the square brackets on the rhs of Eq. (3.3) in terms of a hypergeometric series, thus obtaining[38,39]

$$\ddot{\chi}=-\frac{1}{4\eta}\chi[1\mp{}_2F_1(\tfrac{1}{2},\tfrac{3}{4};-\tfrac{1}{4};z_0)]. \tag{3.4}$$

This is a choice to be justified by the subsequent analysis. We consider the case where η is positive ($\eta>0$) and we substitute $\xi=at$, where $a^2=(2\eta)^{-1}$. Then Eq. (3.4) can be cast into the form

$$\frac{d^2}{d\xi^2}\chi(\xi)+[1-\epsilon(\xi)]\chi(\xi)=0, \tag{3.5}$$

where

$$\epsilon(\xi)=\tfrac{1}{2}[1\pm{}_2F_1(\tfrac{1}{2},\tfrac{3}{4};-\tfrac{1}{4};z_0)]. \tag{3.6}$$

According to a general theorem on the stability property of linear systems,[25–27] the zero solution of Eq. (3.5) is stable for $\xi \geqslant \xi_{in}$ provided that every solution of this equation is *bounded*.[27] The constant value $\xi_{in}=at_{in}$ corresponds to the initial time, which, for every monotonically expanding solution $R_0(t)$, satisfies the condition[28] $t_{in}>t_m$.

By Eq. (1.2), the stability properties of $R_0(t)$ are the same as those of the zero solution of Eq. (3.5). Therefore, in order to determine the conditions under which a particular solution $R_0(t)$ is linearly stable at all times $t \geqslant t_{in}$, we have to investigate under which conditions Eq. (3.5) possesses bounded solutions inside the interval $[\xi_{in},\infty)$. Solutions of Eq. (3.5) exist[36,40] and can be put in the formal form[36]

$$\chi(\xi)=e^{i\xi}[1+h(\xi)]. \tag{3.7}$$

To guarantee the boundness of $\chi(\xi)$ we have to determine only the conditions under which $h(\xi)$ is finite, since the first term on the rhs of Eq. (3.7) is bounded for every $\xi \geqslant \xi_{in}$. Thus, the problem of determining the stability conditions of the external space solutions has now been reduced to the determination of the conditions under which the function $h(\xi)$ is bounded. To derive the functional form of $h(\xi)$, we combine Eqs. (3.5) and (3.7), obtaining

$$h''(\xi)+2ih'(\xi)-\varepsilon(\xi)h(\xi)=\varepsilon(\xi), \tag{3.8}$$

where a prime denotes differentiation with respect to ξ. Now, to solve this inhomogeneous differential equation for $h(\xi)$, we apply the method of *variation of parameters*.[36,38] The result may be written as an integral equation of Volterra's type[41]

$$h(\xi)=\frac{1}{2i}\int_{\xi_{in}}^{\xi}(1-e^{2i(\zeta-\xi)})\varepsilon(\zeta)[1+h(\zeta)]d\zeta. \tag{3.9}$$

Conversely, it can be verified by differentiation that any twice-differentiable solution of Eq. (3.9) satisfies Eq. (3.8). The general solution of Eq. (3.9) may be obtained in the form of a uniformly convergent series.[36] Accordingly, we define a sequence $h_s(\xi)$ $(s=0,1,2,...)$, with $h_0(\xi)=0$ and

$$h_s(\xi)=\frac{1}{2i}\int_{\xi_{in}}^{\xi}(1-e^{2i(\zeta-\xi)})\varepsilon(\zeta)[1+h_{s-1}(\zeta)]d\zeta \quad (s\geqslant 1), \tag{3.10}$$

where, in particular,

$$h_1(\xi)=\frac{1}{2i}\int_{\xi_{in}}^{\xi}(1-e^{2i(\zeta-\xi)})\varepsilon(\zeta)d\zeta. \tag{3.11}$$

Since $|1-e^{2i(\zeta-\xi)}|\leqslant 2$ we obtain $|h_1(\xi)|\leqslant\Psi(\xi)$, where

$$\Psi(\xi)=\int_{\xi_{in}}^{\xi}|\varepsilon(\zeta)|d\zeta \tag{3.12}$$

and the equality in Eq. (3.12) occurs when $\xi=\xi_{in}$. Then, by induction we find that the relation

$$|h_s(\xi)-h_{s-1}(\xi)|\leqslant\frac{\Psi^s(\xi)}{s!} \tag{3.13}$$

holds, for all s. Now, as long as $\Psi(\xi)$ is bounded, the series

$$h(\xi)=\sum_{s=0}^{\infty}[h_{s+1}(\xi)-h_s(\xi)] \tag{3.14}$$

satisfies the Weierstrass criterion and converges absolutely and uniformly.[36,39] Then, by summation of Eq. (3.14) and use of Eqs. (3.10) and (3.11), we verify that $h(\xi)$ satisfies the integral equation (3.9).

Therefore, Eq. (3.9) [and hence Eq. (3.8) also] admits bounded solutions, $h(\xi)$, such that

$$|h(\xi)|\leqslant e^{\Psi(\xi)}-1 \tag{3.15}$$

as results with the aid of Eq. (3.13). In this case, from Eq. (3.7) we obtain

$$|\chi(\xi)|\leqslant e^{\Psi(\xi)}. \tag{3.16}$$

Equation (3.16) indicates that a *bounded* function $\chi(\xi)$ exists for every $\xi\geqslant\xi_{in}$ if the integral $\Psi(\xi)$ converges in the corresponding time interval. Then, the origin $\chi=0$ is stable. The result guarantees the linear stability of the external space solutions, $R_0(t)$. To determine their stability properties at all times $t\geqslant t_{in}$, we need to investigate the conditions under which $\Psi(\xi)$ converges as $\xi\to\infty$:

$$\Psi=\int_{\xi_{in}}^{\infty}|\varepsilon(\xi)|d\xi<\infty. \tag{3.17}$$

According to the preceding analysis, Eq. (3.17) provides a criterion for the linear stability of the cosmological solutions $R_0(t)$ at all times, once the equation for the perturbation $\chi(t)$ is written in the form (3.5). The question that arises now is, under which conditions this criterion may be applied in our case, where Eq. (3.17) has the form

$$\Psi=\frac{1}{2}\int_{\xi_{in}}^{\infty}\left|1\pm{}_2F_1\left(\frac{1}{2},\frac{3}{4};-\frac{1}{4};z_0\right)\right|d\xi. \tag{3.18}$$

Having the minus sign on the rhs of Eq. (3.18), we obtain

$$\Psi=\frac{1}{2}\int_{\xi_{in}}^{\infty}\left[1-{}_2F_1\left(\frac{1}{2},\frac{3}{4};-\frac{1}{4};z_0\right)\right]d\xi \tag{3.19}$$

since the integrant in Eq. (3.19) is positive.[38,42] We normalize $R_0(\xi)$ as $R_N(\xi)=R_0(\xi)/R_m$ to obtain $z_0=1/R_N^4(\xi)$, where $R_N(\xi)$ simply measures $R_0(\xi)$ in units of R_m. Now, we expand the hypergeometric series involved, in terms of $R_N(\xi)$, to obtain

$$\Psi=\frac{2}{\sqrt{\pi}}\sum_{n=1}^{\infty}\left(n-\frac{1}{4}\right)\frac{\Gamma(n+\frac{1}{2})}{\Gamma(n+1)}\int_{\xi_{in}}^{\infty}\frac{1}{R_N^{4n}(\xi)}\,d\xi. \tag{3.20}$$

We will examine the stability of the monotonically increasing solutions for the external space, in connection to the cosmological observations at the present epoch. For this kind of cosmological evolution we have $\xi_{in}>\xi_m$ within the context of the quadratic theory under consideration.[28] In particular, we consider two different types of evolution.

(i) Power law solutions of the form

$$R_N(\xi)\sim\left(\frac{\xi}{\xi_m}\right)^{\lambda}. \tag{3.21}$$

Cosmological models of this form have been widely obtained in the context of the GB cosmology, either as exact solutions or as approximate ones.[16,20,28,33] Inserting Eq. (3.21) into (3.20), for $\lambda \neq \frac{1}{4}$, we obtain

$$\Psi = -\frac{2}{\sqrt{\pi}} \sum_{n=1}^{\infty} \frac{(4n-1)}{(4n\lambda-1)} \frac{\Gamma(n+\frac{1}{2})}{\Gamma(n+1)} \left(\frac{\xi_m}{\xi}\right)^{4n\lambda-1} \Bigg|_{\xi_{in}}^{\infty}. \tag{3.22}$$

As long as $\lambda > \frac{1}{4}$, the rhs of Eq. (3.22) is finite and positive. Indeed, in this case, Eq. (3.22) results in the infinite series form

$$\Psi = \frac{2}{\sqrt{\pi}} \sum_{n=1}^{\infty} \frac{(4n-1)}{(4n\lambda-1)} \frac{\Gamma(n+\frac{1}{2})}{\Gamma(n+1)} \left(\frac{\xi_m}{\xi_{in}}\right)^{4n\lambda-1}, \tag{3.23}$$

which, since $\xi_{in} > \xi_m$ converges absolutely. Therefore, the external space solutions of the form (3.21) with $\lambda > \frac{1}{4}$ satisfy the stability criterion (3.17) and, hence, they may be characterized as linearly stable at all times.

Some models of the form (3.21) have been obtained as solutions of Eq. (2.3b) for the external space, in the context of the five-dimensional GB cosmology under consideration.[28] These are (a) the Milne model ($\lambda=1$) in the zeroth-order approximation, for $k=-1$ and (b) the Friedmann radiation model ($\lambda=\frac{1}{2}$) in the first-order approximation for $k=0$. Both models have been obtained also as solutions in the EH cosmology. The fact that they result as solutions of the quadratic theory, as well, is very important, since, in this way, their linear stability is guaranteed through the criterion (3.17).

(ii) Exponential solutions of the form

$$R_N(\xi) \sim e^{\alpha\xi} \quad (\alpha > 0). \tag{3.24}$$

The models are linearly stable at all times, even after relaxing the condition $\xi_{in} > \xi_m$. Indeed, for every $\xi > 0$, integration of Eq. (3.20) gives

$$\Psi = \frac{2}{\sqrt{\pi}} \sum_{n=1}^{\infty} \frac{(4n-1)}{4n} \frac{\Gamma(n+\frac{1}{2})}{\Gamma(n+1)} e^{-4\alpha n \xi_{in}}, \tag{3.25}$$

which, since α, $\xi_{in} > 0$, converges absolutely. These models are obtained as solutions of the quadratic theory under consideration in the zeroth-order approximation,[28] for $k=0$. The result that they are linearly stable is in complete agreement with the fact that the De Sitter universe is an "*attractor*" of the GB cosmology.[11,12,30,43–46]

IV. DISCUSSION AND CONCLUSIONS

In the present paper we have examined under which conditions a stable solution for the external space (representing the evolution of the visible universe) may be obtained, in the context of a five-dimensional GB cosmology. We have considered $p_5=0$ in connection to cosmological models of an already compactified internal space; that is, we have studied only the process of contraction of the internal space, which may be understood by the classical equations of motion and starts immediately after compactification. In this case, the two subspaces are completely disjoint and the field equations decouple.

Since the two subspaces are disjoint, we have used Lyapounov's direct method[25–27] to find a criterion which guarantees the linear stability of the external space solutions. Investigation of the stability properties of the external space is very important, since it could lead to the determination of preferable solutions for the visible universe.

According to the theory of cosmological perturbations,[47] instabilities in the energy density may arise due to quantum phenomena at the Planck energy scale. These instabilities could affect the set of the initial conditions of a classical space-time, which emerges out of the Planck epoch, modifying its time evolution. In this case, we would like to know if the perturbed behavior of the visible universe differs from the unperturbed one by an acceptably small amount. If there exists a particular solution for which this is true, then every other physically acceptable solution, which may arise due to changes in the set of the initial conditions, will remain close to this particular one at all times. The changes in the initial conditions, it does not matter how, may be arbitrary and hence a stable model acts as an "*attractor.*" Now, if some special solution is the attractor for a wide range of initial conditions, such a solution is naturally realized asymptotically.[33]

Therefore, we have perturbed our original solution $R_0(t)$ by a small amount $\chi(t)$ and we have examined whether this perturbation grows in time or not. In linear terms, its time evolution is determined by the second-order linear differential equation (3.3). Now, if the zero solution, $\chi=0$, of this equation is stable, then every solution $R(t)$ remains "*near*" $R_0(t)$ at all times. The solution $\chi=0$ is stable, provided that every solution of Eq. (3.3) is bounded. It has been verified that the boundness of the solutions, at all times, is guaranteed by the convergence of the integral (3.17) as $t\to\infty$. Accordingly, Eq. (3.17) may be considered as a criterion which determines under which conditions stable solutions for the external space are possible or not.

Under some restrictions on the free parameters involved, this criterion is satisfied by three types of cosmological evolution obtained in the context of the quadratic theory under consideration: (i) the Milne universe, (ii) the Friedmann radiation model with $k=0$, and (iii) the inflationary De Sitter solution. Each of these models may arise as a natural candidate to describe the evolution of the visible space. Indeed, it has been found numerically that the De Sitter solution corresponds to an *attractor* of the GB cosmology,[43,46] while a similar result seems to hold also for the spatially flat Friedmann radiation solution.[48]

It is probable that, if one of these models determines the evolution of the ordinary space in a quadratic theory with $\eta>0$, every unpredictable instability[47] will affect only the dynamics of the one-dimensional internal space, leaving the external one unaltered. Consequently, to consider a quadratic higher-dimensional theory of gravity may be of great use in the theoretical establishment of the stability properties for the visible space and its observational characteristics, at least as regards some particular solutions.

Inhomogeneous Kasner-type cylindrically symmetric models in Kaluza–Klein space–time

L. K. Patel[a] and Naresh Dadhich[b]
Department of Mathematics and Applied Mathematics, University of Natal, Private Bag X10 Dalbridge 4014, South Africa

(Received 20 October 1995; accepted for publication 12 February 1996)

We consider a cylindrically symmetric metric separable in space and time variables having Kasnerian time dependence in the Kaluza–Klein space–time. We obtain perfect fluid models that admit the dimensional reduction yielding the usual four-dimensional space–time as the universe expands. The models are inhomogeneous and they have the Kasnerian vacuum solution as their matter-free limit. The five-dimensional Kasnerian vacuum solution goes over on dimensional reduction to the radiation Friedman–Robertson–Walker flat model. © *1996 American Institute of Physics.* [S0022-2488(96)00707-4]

I. INTRODUCTION

The consideration of cosmological models in higher dimensions has recently attracted the attention of many workers. The main motivation for this has been the early universe physics and cosmology. The extra dimensions are supposed to be relevant only at the scale of Planck length and as the universe expands the extra dimensions contract, leaving behind the observable four-dimensional (4–d) space–time. The work was initiated in this direction in the late 1980s.[1,2] To begin with, 5-d Kasnerian vacuum solutions were obtained[2] in which the extra fifth dimension shrank as the universe expanded.

In the early stages of evolution, it is expected that the universe will be inhomogeneous to allow for generic initial conditions and formation of large scale structures in the universe. This is why inhomogeneous solutions of Einstein equations have been considered by several authors.[3–10] Amongst them there exists a very interesting family of nonsingular cosmological models satisfying the strong energy condition $\rho+3p\geqslant 0$ with physically acceptable equations of state $\rho=3p$ and $\rho=p$.[8,9] Inhomogeneous cosmological models have also been considered in the 5-d Kaluza–Klein space–time.[11–15] Very recently Banerjee *et al.*[15] obtained the 5-d nonsingular solutions for stiff fluid and vacuum obtained by Dadhich *et al.*[9]

In this paper we wish to study the 5-d cylindrically symmetric cosmological models that have the Kasnerian time dependence[16] which reduce to the usual 4-d universe as the expansion proceeds. The time dependence in the metric will be given by powers of the cosmic time t and space dependence by powers of $(1+r^2)$. In the nonsingular metric,[8,9] the space dependence is given by $\cosh r$, which is equivalent to $(1+r^2)$. We shall thus obtain the 5-d Davidson-type[3] inhomogeneous cylindrical models.

In Sec. II we list the Ricci tensor for the general cylindrically symmetric metric and set up the field equations. The exact solutions of the equations with the above prescription for the metric are discussed in Secs. III and IV, followed by discussion.

II. THE METRIC AND THE FIELD EQUATIONS

We consider the five-dimensional cylindrically symmetric space–time given by the line element

$$ds^2=D^2dt^2-A^2dr^2-B^2dz^2-C^2d\varphi^2-E^2d\psi^2, \tag{2.1}$$

where A, B, C, D, and E are functions of the radial coordinate r and the time t. Here ψ is the extra dimension.

Introducing the pentad

$$\theta^1=Adr, \quad \theta^2=Bdz, \quad \theta^3=Cd\varphi, \quad \theta^4=Ed\psi, \quad \theta^5=Ddt, \tag{2.2}$$

we can express the metric (2.1) in the form

$$ds^2=(\theta^5)^2-(\theta^1)^2-(\theta^2)^2-(\theta^3)^2-(\theta^4)^2=g_{(ab)}\theta^a\theta^b. \tag{2.3}$$

Here and in what follows the bracketed indices denote pentad components. The surviving $R_{(ab)}$ for the metric (2.1) are listed below for ready reference:

$$R_{(15)}=\frac{1}{AD}\left[\frac{\dot{B}'}{B}+\frac{\dot{C}'}{C}+\frac{\dot{E}'}{E}-\frac{\dot{A}}{A}\left(\frac{B'}{B}+\frac{C'}{C}+\frac{E'}{E}\right)-\frac{D'}{D}\left(\frac{\dot{B}}{B}+\frac{\dot{C}}{C}+\frac{\dot{E}}{E}\right)\right], \tag{2.4}$$

$$R_{(11)}=\frac{1}{A^2}\left[\frac{B''}{B}+\frac{C''}{C}+\frac{D''}{D}+\frac{E''}{E}-\frac{A'}{A}\left(\frac{B'}{B}+\frac{C'}{C}+\frac{D'}{D}+\frac{E'}{E}\right)\right]$$
$$-\frac{1}{D^2}\left[\frac{\ddot{A}}{A}+\frac{\dot{A}}{A}\left(\frac{\dot{B}}{B}+\frac{\dot{C}}{C}+\frac{\dot{E}}{E}-\frac{\dot{D}}{D}\right)\right], \tag{2.5}$$

$$R_{(22)}=\frac{1}{A^2}\left[\frac{B''}{B}+\frac{B'}{B}\left(\frac{C'}{C}+\frac{D'}{D}+\frac{E'}{E}-\frac{A'}{A}\right)\right]-\frac{1}{D^2}\left[\frac{\ddot{B}}{B}+\frac{\dot{B}}{B}\left(\frac{\dot{A}}{A}+\frac{\dot{C}}{C}+\frac{\dot{E}}{E}-\frac{\dot{D}}{D}\right)\right], \tag{2.6}$$

$$R_{(33)}=\frac{1}{A^2}\left[\frac{C''}{C}+\frac{C'}{C}\left(\frac{B'}{B}+\frac{D'}{D}+\frac{E'}{E}-\frac{A'}{A}\right)\right]-\frac{1}{D^2}\left[\frac{\ddot{C}}{C}+\frac{\dot{C}}{C}\left(\frac{\dot{A}}{A}+\frac{\dot{B}}{B}+\frac{\dot{E}}{E}-\frac{\dot{D}}{D}\right)\right], \tag{2.7}$$

$$R_{(44)}=\frac{1}{A^2}\left[\frac{E''}{E}+\frac{E'}{E}\left(\frac{B'}{B}+\frac{D'}{D}+\frac{C'}{C}-\frac{A'}{A}\right)\right]-\frac{1}{D^2}\left[\frac{\ddot{E}}{E}+\frac{\dot{E}}{E}\left(\frac{\dot{A}}{A}+\frac{\dot{B}}{B}+\frac{\dot{C}}{C}-\frac{\dot{D}}{D}\right)\right], \tag{2.8}$$

$$R_{(55)}=\frac{1}{D^2}\left[\frac{\ddot{A}}{A}+\frac{\ddot{B}}{B}+\frac{\ddot{C}}{C}+\frac{\ddot{E}}{E}-\frac{\dot{D}}{D}\left(\frac{\dot{A}}{A}+\frac{\dot{B}}{B}+\frac{\dot{C}}{C}+\frac{\dot{E}}{E}\right)\right]-\frac{1}{A^2}\left[\frac{D''}{D}+\frac{D'}{D}\left(\frac{B'}{B}+\frac{C'}{C}+\frac{E'}{E}-\frac{A'}{A}\right)\right]. \tag{2.9}$$

Here and in what follows an overhead dash and a dot indicate differentiation with respect to r and t, respectively. Here ψ is taken in the form of a Kaluza–Klein (KK) parameter such that $0\leqslant\psi\leqslant 2\pi R_5$, where R_5 is the radius of KK circle.

We assume that the space–time is filled with a perfect fluid distribution described by

$$T_{ik}=(p+\rho)v_iv_k-pg_{ik}, \quad v_iv^i=1, \tag{2.10}$$

where ρ, p, and v^i stand for the energy density, the pressure, and the unit timelike flow vector, respectively.

The Einstein field equations are

$$R_{ik}-\tfrac{1}{2}Rg_{ik}=-8\pi T_{ik}, \tag{2.11}$$

and hence we write

$$R_{(ab)}=-8\pi[(p+\rho)v_{(a)}v_{(b)}-\tfrac{1}{3}(\rho-p)g_{(ab)}]. \tag{2.12}$$

We use comoving coordinates. Therefore we have

$$v_{(a)}=(0,0,0,0,1). \tag{2.13}$$

In view of (2.13), the field equations (2.12) give rise to the following relations:

$$R_{(15)}=0, \tag{2.14}$$

$$R_{(11)}=R_{(22)}=R_{(33)}=R_{(44)}, \tag{2.15}$$

$$8\pi\rho=-\tfrac{1}{2}[R_{(55)}+4R_{(22)}], \tag{2.16}$$

$$8\pi p=\tfrac{1}{2}[2R_{(22)}-R_{(55)}]. \tag{2.17}$$

III. PERFECT FLUID MODELS

As stated in the Introduction, we write for A, B, C, D, and E:

$$A=t^{\alpha}(1+r^2)^a,\quad B=t^{\beta}(1+r^2)^b,\quad C=rt^{\gamma}(1+r^2)^c,\quad D=(1+r^2)^d,\quad E=t^{\delta}(1+r^2)^e, \tag{3.1}$$

where a, b, c, d, e, α, β, γ, and δ are real constants. Time dependence in the function D is not included because such a dependence can always be removed by redefining the time coordinate.

Let us first consider the equation (2.14). Using (3.1) and (2.14) we obtain

$$\alpha=\gamma \tag{3.2}$$

and

$$\beta(b-d)+\delta(e-d)-\alpha(b+e+d)=0. \tag{3.3}$$

The equation $R_{(22)}=R_{(44)}$ of (2.15) implies

$$b=e \tag{3.4}$$

and

$$2\alpha+\beta+\delta=1. \tag{3.5}$$

On the other hand, $R_{(22)}=R_{(11)}$ of (2.15) leads to

$$a=3c+d \tag{3.6}$$

and

$$b+c+d+2c^2+4cd+4bc+2bd=0. \tag{3.7}$$

Lastly, the remaining equation $R_{(22)}=R_{(33)}$ of (2.15) leads to one more restriction,

$$(b-c)[2(b-c)-1]=0. \tag{3.8}$$

In view of (3.1), (2.16) and (2.17) determine ρ and p as

$$16\pi\rho=\frac{1}{D^2t^2}\left[1-(2\alpha^2+\beta^2+\delta^2)\right]-\frac{4(4b-d)}{A^2(1+r^2)^2}\left[1+2r^2(b-c)\right] \tag{3.9}$$

and

$$16\pi p=\frac{1}{D^2t^2}\left[1-(2\alpha^2+\beta^2+\delta^2)\right]+\frac{4(2b+d)}{A^2(1+r^2)^2}\left[1+2r^2(b-c)\right], \tag{3.10}$$

where A and D are given by (3.1).

The equation (3.8) gives rise to two separate cases: *case (i):* $b=c$ and *case (ii):* $b=c+\frac{1}{2}$. We now discuss them separately.

Case (i): $b=c$. In this case the constants a, c, d, e, and α can be expressed in terms of b. Using (3.2)–(3.7) we have

$$a=\frac{b(1+12b)}{1+6b},\quad c=b,\quad d=-\frac{2b(1+3b)}{(1+6b)},\quad e=b,\quad \alpha=\gamma=\frac{(1+4b)}{2(1+5b)}, \tag{3.11}$$

and

$$\beta+\delta+\frac{(1+4b)}{(1+5b)}=1. \tag{3.12}$$

The density ρ and the pressure p for this case are given by

$$16\pi\rho=\frac{1}{D^2t^2}\left\{1-(2\alpha^2+\beta^2+\delta^2)\right\}-\frac{24b(1+5b)}{(1+6b)A^2(1+r^2)^2} \tag{3.13}$$

and

$$16\pi p=\frac{1}{D^2t^2}\left\{1-(2\alpha^2+\beta^2+\delta^2)\right\}+\frac{24b^2}{(1+6b)A^2(1+r^2)^2}, \tag{3.14}$$

where

$$D=(1+r^2)^{-2b(1+3b)/(1+6b)},\quad A=t^{(1+4b)/2(1+5b)}(1+r^2)^{b(1+12b)/(1+6b)}. \tag{3.15}$$

The physical requirements $\rho\geq 0$ and $p\geq 0$ are satisfied if

$$-\frac{1}{6}<b\leq 0,\quad 2\alpha^2+\beta^2+\delta^2\leq 1. \tag{3.16}$$

Here ρ and p are decreasing functions of r and t and they tend to zero as r and/or t tend to infinity. The geometry of the five-dimensional cylindrical universe is described by the line element

$$\begin{aligned} ds^2=&(1+r^2)^{-4b(1+3b)/(1+6b)}dt^2-(1+r^2)^{2b(1+12b)/(1+6b)}t^{(1+4b)/(1+5b)}dr^2\\ &-(1+r^2)^{2b}[t^{2\beta}dz^2+r^2t^{(1+4b)/(1+5b)}d\varphi^2+t^{2\delta}d\psi^2], \end{aligned} \tag{3.17}$$

where β and δ are related by (3.12).

Case (ii): $b=c+\frac{1}{2}$. For this case we have

$$a=\frac{20b-24b^2-3}{2(1-6b)},\quad c=b-\frac{1}{2},\quad d=\frac{2b(3b-1)}{(1-6b)},\quad e=b,\quad \gamma=\alpha=\frac{(1-4b)}{2(1-5b)}, \tag{3.18}$$

$$\beta+\delta+\frac{(1-4b)}{(1-5b)}=1, \tag{3.19}$$

$$16\pi\rho=\frac{1}{D^2t^2}\{1-(2\alpha^2+\beta^2+\delta^2)\}-\frac{24b(1-5b)}{(1-6b)A^2(1+r^2)}, \tag{3.20}$$

and

$$16\pi p=\frac{1}{D^2t^2}\{1-(2\alpha^2+\beta^2+\delta^2)\}-\frac{24b^2}{(1-6b)A^2(1+r^2)}, \tag{3.21}$$

where

$$D=(1+r^2)^{2b(3b-1)/(1-6b)}, \quad A=(1+r^2)^{(20b-24b^2-3)/2(1-6b)}t^{(1-4b)/2(1-5b)}. \tag{3.22}$$

The physical requirements $\rho\geqslant 0$ and $p\geqslant 0$ give rise to the inequalities

$$0\leqslant b<\tfrac{1}{5}, \quad 2\alpha^2+\beta^2+\delta^2\leqslant 1. \tag{3.23}$$

The metric is given by

$$ds^2=(1+r^2)^{4b(3b-1)/(1-6b)}dt^2-(1+r^2)^{(20b-24b^2-3)/(1-6b)}t^{(1-4b)/(1-5b)}dr^2$$
$$-(1+r^2)^{2b}\left[t^{2\beta}dz^2+\frac{r^2}{(1+r^2)}t^{(1-4b)/(1-5b)}d\varphi^2+t^{2\delta}d\psi^2\right], \tag{3.24}$$

where β and δ are related by (3.19).

Note that one of the Kasnerian constraints $\alpha+\beta+\gamma+\delta=1$ is always satisfied in both the cases considered above. We, however, have two-parameter arbitrariness in choosing b and one of β and δ. This is quite interesting. For dimensional reduction $\delta<0$, which can always be so chosen. That is, all the models described by (3.1) will always permit the dimensional reduction.

IV. PARTICULAR CASES

Both the cases admit stiff fluid model for $b=0$. Then both the metrics (3.17) and (3.24) reduce to the same metric given by

$$ds^2=dt^2-tdr^2-t^{-2\delta}dz^2-r^2td\varphi^2-t^{2\delta}d\psi^2 \tag{4.1}$$

with

$$16\pi\rho=16\pi p=\frac{1}{2t^2}(1-4\delta^2)\geqslant o \quad \text{for } \frac{1}{4}\geqslant\delta^2. \tag{4.2}$$

The equality will give the Kasnerian vacuum solution. Here δ can be negative to permit the dimensional reduction.

It may be noted that the parameter b is the measure of inhomogeneity; whenever it vanishes then the model becomes homogeneous. Hence stiff fluid condition forces homogeneity.

Let us now consider the equation of state $\rho=kp$, $k>1$, for the perfect fluid.

First of all we must, in addition to $\alpha+\beta+\gamma+\delta=1$, have

$$\alpha^2+\beta^2+\gamma^2+\delta^2=1. \tag{4.3}$$

This means we have the exact Kasnerian time evolution. Equations (3.13) and (3.14) of the case (i) of Sec. III imply

$$b=-\frac{1}{k+5}, \tag{4.4}$$

where $k>1$. For the radiation universe $k=3$ and we shall have

$$e=c=b=-\tfrac{1}{8}, \quad a=\tfrac{1}{4}, \quad d=\tfrac{5}{8}, \quad \alpha=\gamma=\tfrac{2}{3}, \quad \beta=0, \quad \delta=-\tfrac{1}{3},$$

where values of β and δ can be interchanged. The density is given by

$$16\pi\rho=\tfrac{9}{2}(1+r^2)^{-5/2}t^{-4/3}, \tag{4.5}$$

which remains always positive and decreases with r and t. Since one of β and δ is always negative, the dimensional reduction is permitted.

In the case (ii) of Sec. III, the same considerations lead to $1>k>0$ and hence it is not physically admissible.

V. DISCUSSION

It can be easily verified that $R_{ik}v^iv^k=-(16\pi/3)(\rho+2p)\leq 0$, and hence the strong energy condition is always satisfied in our models. The expansion of the universe is $\theta=(tD)^{-1}$, which will tend to zero as $t\to\infty$. All the models admit the dimensional reduction as either δ or β is always negative. Note that our models are inhomogeneous.

The matter-free limit of the models, except the radiation model, yields the Kasnerian vacuum solution[2] given by

$$ds^2=dt^2-t(dr^2+r^2d\varphi^2+dz^2)-\frac{1}{t}\,d\psi^2, \tag{5.1}$$

which under dimensional reduction for large t reduces to the 4-d metric

$$ds^2=dt^2-t(dr^2+r^2d\varphi^2+dz^2). \tag{5.2}$$

This is the Friedman–Robertson–Walker (FRW) flat radiation universe with $\rho=3p$,

$$8\pi\rho=\frac{3}{4t^2}. \tag{5.3}$$

This is quite interesting that the 5-d vacuum solution goes over to the FRW radiation universe. It has been argued that 5-d vacuum solutions can on dimensional reduction represent matter field in four dimensions.[17]

It may also be noted that the stiff fluid condition requires $b=0$, which makes the model homogeneous. Hence the parameter b can be regarded as the measure of inhomogeneity.

There is one interesting static particular case of the general metric (2.1) which is the analog of the 4-d Levi–Civita vacuum solution. In here we have

$$A=B=r^a, \quad C=r^c, \quad D=r^d, \quad E=r^e, \tag{5.4}$$

where the constants a,c,d,e are constrained by

$$c+d+e=1, \quad c^2+d^2+e^2=1+2a. \tag{5.5}$$

The 5-d vacuum metric is given by

$$ds^2 = r^{2d}dt^2 - r^{2(d^2+e^2+de-d-e)}(dr^2+dz^2) - r^{2(1-d-e)}d\varphi^2 - r^{2e}d\psi^2, \tag{5.6}$$

where d and e are arbitrary constants. It will reduce to the Levi–Civita vacuum solution when ψ=constant and $e=0$. It can serve as the exterior vacuum solution for 5-d cylindrically symmetric static distributions.

Non-covariance of the generalized holonomies: Examples

Troy A. Schilling[a)]
Center for Gravitational Physics and Geometry,
Department of Physics, The Pennsylvania State University,
University Park, Pennsylvania 16802

(Received 21 November 1995; accepted for publication 5 April 1996)

A key aspect of a recent proposal for a *generalized loop representation* of quantum Yang–Mills theory and gravity is considered. Such a representation of the quantum theory has been expected to arise via consideration of a particular algebra of observables – given by the traces of the holonomies of *generalized loops*. We notice, however, a technical subtlety, which prevents us from reaching the conclusion that the generalized holonomies are covariant with respect to small gauge transformations. Further analysis is given which shows that they are *not* covariant with respect to small gauge transformations; their traces are *not* observables of the gauge theory. This result indicates what may be a serious complication to the use of generalized loops in physics, but does not affect the ordinary loop representation. © *1996 American Institute of Physics.* [S0022-2488(96)03607-9]

I. INTRODUCTION

There has recently been a variety of attempts to formulate gauge theories in terms of loops.[1,2] One of the key technical developments which suggests such a formulation of gauge theory is Giles' result[3] that, for $SU(N)$ theories, the information contained in the Wilson loops (i.e., the traces of all holonomies around closed curves) is sufficient for the reconstruction of the connection up to local gauge transformations. That is, the Wilson loops contain all of the gauge-invariant information about the connection. Since the Wilson loops separate points of the space of connections modulo gauge transformations, there is a sense in which any gauge-invariant function on the relevant space of connections (and hence any configuration observable of the gauge theory) may be expressed in terms of the Wilson loops. The (over-)completeness of these observables suggests that they be taken as the basic configuration observables in the quantization scheme.

This idea, along with Ashtekar's connection-dynamic formulation[4] of general relativity, provides the foundation of the Ashtekar–Rovelli–Smolin approach to quantum gravity. The duality between connections and loops[5] suggests the possibility of representing states by functions of loops. The idea of the loop representation was first introduced to gravity by Rovelli and Smolin,[6] and has resulted in a formalism with several attractive features. Most notable are the relationship between diffeomorphism invariance and knot theory, the combinatorial aspect of the formalism, and a sense in which discreteness emerges. For details of this approach to quantum gravity see Refs. 7 and 8.

Despite the merits of the loop-representation, subtle alternatives are also being explored. The problem of regularization of the Wilson loop operators suggests that one introduce a thickening, or framing, of the loops. A novel suggestion is presented by recent results of Di Bartolo, Gambini, and Griego.[9,10] The space of loops based at a fixed point forms a group,[11] but not a Lie group. In an attempt to "coordinatize" the group of based loops, the authors of Ref. 9 came upon a generalization of the notion of a loop. The result is an infinite-dimensional Lie group, which contains the group of (based) loops as a subgroup. The elements of this *extended loop group*[12] are (sequences of) distributional quantities, ordinary loops being the "most distributional" elements. There are also elements, however, which are "less distributional" than loops, objects that we may

think of as "smoothened loops." With regularization issues in mind, the existence of the smoothened loops is of obvious interest. An anticipated benefit of the use of generalized loops is the ability to apply familiar functional methods to the study of the (generalized) loop representation. Further, we will see that the extended loop group has the global structure of a vector space. Hence, integration on the generalized loop space is a fairly straight-forward matter. Integration techniques may supply a form of the inner-product which is inherent to the loop space.

For these reasons, one is motivated to examine the role of generalized loops in gauge theory. Recall that the idea of the loop representation is based on the Wilson loops. Since, as we will see, the generalized loops are defined via inspection of the functional form of the holonomies of ordinary loops, the holonomy formally extends to the extended loop group. It is through this extension of the holonomy that one can imagine the construction of a generalized loop representation. For such a formulation of quantum Yang–Mills theory or gravity to make sense, the generalized holonomies must be gauge-covariant with respect to (small) gauge transformations. At the very least, the traced holonomies should be gauge-invariant. The main result presented here is the fact that *the generalized holonomies are not covariant with respect to small gauge transformations*. Despite the beauty of the extended loop group, its use in gauge theory may therefore be limited.

In Sec. II, we review the construction of the extended loop group and discuss some useful properties of its elements. In Sec. III we focus on the generalized holonomies, with particular attention given to their transformation properties. Consideration of the Abelian case will suggest simple examples of non-covariance of the generalized $SU(2)$ holonomies. Two such examples are presented in Sec. IV. Finally, in Sec. V, we conclude with generalizations of the results and remarks concerning their relevance in physics.

II. GENERALIZED LOOPS

The purpose of this section is to recall the basic ideas regarding generalized loops (for details, see the original work[9]). After introducing the group of loops on an arbitrary connected manifold, consideration of the holonomies will suggest a generalization of the notion of loops. The set of these generalized loops—the extended loop group—forms an infinite-dimensional Lie group.

Fix a point p on an arbitrary connected manifold $\mathcal{M}$ and consider the space $\mathcal{C}_p$ of closed curves based at p. Elements of $\mathcal{C}_p$ are piecewise-smooth maps $C:I\to\mathcal{M}$ such that $C(0)=p=C(1)$, where I is the unit interval. Now, our main motivation for considering the space $\mathcal{C}_p$ is that the trace of the holonomy of a physical gauge field around any closed curve is gauge-invariant, i.e., an observable of the classical field theory. Since we are primarily concerned with the observables, we are not interested in the space $\mathcal{C}_p$ itself, but in a space of equivalence classes of elements of $\mathcal{C}_p$. For example, two closed curves which differ merely by reparametrization yield the same holonomies for an arbitrary smooth connection over $\mathcal{M}$. Gambini and Trias[11] provide an appropriate identification of elements of $\mathcal{C}_p$: Two closed curves $C,C'\in\mathcal{C}_p$ are deemed equivalent if $C\circ\bar{C}'$ is contractible *within itself* to the trivial curve $\iota(s)\equiv p$, where $\bar{C}'$ is the reversed path $\bar{C}'(s)=C'(1-s)$. With this equivalence relation on $\mathcal{C}_p$, it is easy to see that two closed curves which are equivalent give the same holonomies for any smooth connection over $\mathcal{M}$. Denote by $\mathcal{L}_p$ the space obtained by dividing $\mathcal{C}_p$ by this equivalence relation. The obvious composition of paths induces a *group operation* on the set $\mathcal{L}_p$, which we will call the *group of loops* based at p.

Next, consider a connection $\mathbf{A}$ on a principal bundle $P(\mathcal{M},G)$, where G is a compact, connected Lie group. For the sake of simplicity, we shall assume that P is trivial and view connections as Lie algebra-valued one-forms on $\mathcal{M}$. [Below, we will restrict attention to the case $G=SU(2)$, for which every bundle is trivial.] To an element $\gamma\in\mathcal{L}_p$ we may associate the holonomy, $U_A[\gamma]$, around any path C in the equivalence class defining γ. Expressed in terms of the fundamental representations of the gauge group G and its Lie algebra, the holonomy takes the form of the path-ordered exponential, which may be written explicitly as

$$U_A[\gamma]=P\exp\oint_C \mathbf{A}=\sum_{n=0}^{\infty}\int\cdots\int X_\gamma^{a_1\cdots a_n}(x_1,\ldots,x_n)\mathbf{A}_{a_1}(x_1)\cdots\mathbf{A}_{a_n}(x_n), \tag{1}$$

where

$$X_\gamma^{a_1\cdots a_n}(x_1,\ldots,x_n):=\oint_C dy^{a_1}\int_{y_1}^1 dy^{a_2}\cdots\int_{y_{n-1}}^1 dy^{a_n}\delta(x_1,y_1)\cdots\delta(x_n,y_n), \tag{2}$$

and the zeroth term in Eq. (1) is taken to be the identity. In Eq. (2) the index a_k is "attached" to the point x_k, and for each n, $X_\gamma^{a_1\cdots a_n}(x_1,\ldots,x_n)$ is an n-point distributional vector density of weight one in each argument x_k. As suggested by the subscript on the X's, these n-point distributions are independent of the particular path C chosen from the equivalence class determined by $\gamma\in\mathscr{L}_p$. It will be convenient to employ the notation

$$X_\gamma^{\mu_1\cdots\mu_n}:=X_\gamma^{a_1\cdots a_n}(x_1,\ldots,x_n), \tag{3}$$

where the index μ_k now represents the pair (a_k,x_k), and contraction of greek indices represents both contraction of the latin index and the integration over $\mathscr{M}$.

Thus, to every element $\gamma\in\mathscr{L}_p$ is associated a string,

$$X_\gamma:=(1,\ X_\gamma^{\mu_1},\ \ldots,\ X_\gamma^{\mu_1\cdots\mu_n},\ \ldots),$$

of multi-vector densities. As is observed in Ref. 9, if $\gamma,\eta\in\mathscr{L}_p$, the multi-densities corresponding to their product may be expressed as

$$X_{\gamma\circ\eta}^{\mu_1\cdots\mu_n}=\sum_{k=0}^{n} X_\gamma^{\mu_1\cdots\mu_k}X_\eta^{\mu_{k+1}\cdots\mu_n}, \tag{4}$$

with the convention that

$$X^{\mu_1\cdots\mu_0}:=1.$$

These strings of multi-densities satisfy two useful identities. Denote by X the string corresponding to an arbitrary loop in $\mathscr{L}_p$. The first identity reflects the ordering of points on the image of the loop;

$$X^{\underline{\mu_1\cdots\mu_k}\mu_{k+1}\cdots\mu_n}=X^{\mu_1\cdots\mu_k}X^{\mu_{k+1}\cdots\mu_n}, \tag{5}$$

where the left side is obtained by summing over all permutations of the μ_i which preserve the relative ordering of the first k indices and also the relative ordering of remaining $n-k$. For example,

$$X^{\underline{\mu_1\mu_2}\mu_3\mu_4}=X^{\mu_1\mu_2\mu_3\mu_4}+X^{\mu_1\mu_3\mu_2\mu_4}+X^{\mu_1\mu_3\mu_4\mu_2}+X^{\mu_3\mu_1\mu_2\mu_4}+X^{\mu_3\mu_1\mu_4\mu_2}+X^{\mu_3\mu_4\mu_1\mu_2}.$$

Next, since taking the divergence of a vector density requires no additional structure (e.g., a metric or derivative operator) on $\mathscr{M}$, it is natural to ask whether the divergence of an entry of X satisfies any useful property. The answer is in the affirmative;

$$\frac{\partial}{\partial x^{a_k}}X^{\mu_1\cdots\mu_n}=[\delta(x_k,x_{k-1})-\delta(x_k,x_{k+1})]X^{\mu_1\cdots\hat{\mu}_k\cdots\mu_n}, \tag{6}$$

where the caret over the μ_k is intended to indicate its absence, and the mixed notation on the left side should be transparent. By definition, x_0 and x_{n+1} are taken to be the base point, p. Thus the divergence of the rank-n entry of X is directly related to the rank-(n-1) entry.

The basic idea of Di Bartolo, Gambini, and Griego[9] is to consider the space of *all* objects satisfying these relations. To be precise, let $\mathscr{E}$ be the space of all sequences $(E^0, E^{\mu_1}, \ldots, E^{\mu_1\cdots\mu_n}, \ldots)$, where E^0 is a real number and $E^{\mu_1\cdots\mu_n}$ is a *distributional* vector-density in each index. $\mathscr{E}$ becomes an associative algebra when equipped with the product motivated by Eq. (4); given $E_1, E_2 \in \mathscr{E}$, we define

$$(E_1 \times E_2)^{\mu_1\cdots\mu_n} := \sum_{k=0}^{n} E_1^{\mu_1\cdots\mu_k} E_2^{\mu_{k+1}\cdots\mu_n}, \tag{7}$$

where $E^{\mu_1\cdots\mu_0} := E^0 \in \mathbb{R}$. The extended loop group (based at $p \in \mathscr{M}$) is defined to consist of those elements of $\mathscr{E}$ which satisfy the algebraic relation (5) and the differential relation (6) and for which the rank-zero entry is unity. This set, denoted by $\mathscr{X}_p$, is closed under the product defined above and every element is seen to have an inverse with respect to the identity element, $I := (1,0,0\ldots)$. $\mathscr{X}_p$ is then a group which contains $\mathscr{L}_p$ as a subgroup.

Next, $\mathscr{X}_p$ is an infinite-dimensional Lie group in the following sense. For any element $X \in \mathscr{X}_p$, the logarithm

$$\ln(X) := \sum_{m=1}^{\infty} \frac{(-)^{m+1}}{m} (X-I)^m$$

is a well-defined element of $\mathscr{E}$ (with vanishing rank-zero entry) which satisfies the differential relation given by Eq. (6) and the *homogeneous algebraic relation*

$$\ln(X)^{\underline{\mu_1\cdots\mu_k}\mu_{k+1}\cdots\mu_n} = 0, \quad \forall \quad 0 < k < n. \tag{8}$$

Let $\mathscr{F}_p$ consist of all elements of $\mathscr{E}$ which satisfy these two conditions and with vanishing rank-zero entry. One can show that if $F \in \mathscr{F}_p$ then $\exp(F) := \Sigma_{k=0}^{\infty} (1/k!)\, F^k$ is a well-defined element of $\mathscr{X}_p$. Further, for any element $X \in \mathscr{X}_p$ the logarithm $F = \ln X$ is the unique element of $\mathscr{F}_p$ for which $X = \exp(F)$. $\mathscr{F}_p$ is closed under the Lie bracket given by the commutator with respect to the associative product (7), defined on $\mathscr{E}$; this is the Lie bracket relevant to the group operation on $\mathscr{X}_p$. Thus, $\mathscr{F}_p$ is simply the Lie algebra corresponding to $\mathscr{X}_p$. Note also that $\mathscr{X}_p$ has the global structure of an infinite-dimensional vector space since there is a one-one correspondence between its elements and elements of its Lie algebra. In particular, we may unambiguously take the real power of any element in $\mathscr{X}_p$; $X^t := \exp(t \ln X)$.

One may then think of $\mathscr{X}_p$ as a "completion" of the group $\mathscr{L}_p$. Any generalized loop $X \in \mathscr{X}_p$ defines the one-parameter subgroup of $\mathscr{X}_p$, consisting of all real powers of X. Since generic elements of $\mathscr{X}_p$ are not easily described in terms of the geometry of the underlying manifold $\mathscr{M}$, it is most instructive to think of X^t in the group-theoretic sense.

Given a G-connection, one may consider the formal expression for the holonomy around an arbitrary extended loop,

$$U_A[X] := \sum_{n=0}^{\infty} X^{\mu_1\cdots\mu_n} \mathbf{A}_{\mu_1} \cdots \mathbf{A}_{\mu_n}. \tag{9}$$

There is no claim that the extended holonomies take values in the gauge group, or even that they converge. However, in Ref. 9 it is formally shown that $U_A[X_1 \times X_2] = U_A[X_1] U_A[X_2]$, where the right side is given by matrix multiplication in the fundamental representation. At least at the formal level, the holonomy extends to a homomorphism on $\mathscr{X}_p$. It is worth noticing one particular

situation in which the extended holonomies converge to elements of the gauge group. Suppose that $\mathbf{A}$ is an *Abelian* connection; i.e., $[\mathbf{A}(x),\mathbf{A}(y)]=0$. Then, using the algebraic relation (5), it is a simple matter to show that for any $X \in \mathscr{X}_p$,

$$U_A^{(n)}[X] := X^{\mu_1 \cdots \mu_n} \mathbf{A}_{\mu_1} \cdots \mathbf{A}_{\mu_n} = \frac{1}{n!}(X^\mu \mathbf{A}_\mu)^n. \tag{10}$$

So the extended holonomy corresponding to any Abelian connection is just given by the exponential of $X^\mu \mathbf{A}_\mu$. (This result depends only on the fact that the restriction of $\mathbf{A}$ to the support of X is Abelian.) If, for example, the support of $\mathbf{A}$ is also of compact closure, the holonomy is convergent and group-valued on all of $\mathscr{X}_p$. This result will be used extensively in what follows.

III. THE GENERALIZED HOLONOMIES

The construction of the extended loop group is elegant and of considerable interest from a purely mathematical point of view. However, the intention extends to physics as well. The idea is simply to generalize the formalism used in the ordinary loop representations of gauge theories, i.e., to consider the traces of the extended holonomies as observables for Yang-Mills theory and, perhaps more importantly, general relativity. In particular, an extended loop representation for quantum general relativity may be an especially useful setting for consideration of an inverse loop transform and the framing problem of knot invariants.[10,13]

With the intended application of the generalized loops in mind, it is natural to examine the behavior of the extended holonomies under gauge transformations. One often distinguishes between two types of gauge freedom. The gauge which is generated by the (first-class) constraints is *physical* gauge freedom, while that which is not is *symmetry*. The physical gauge freedom then corresponds to that generated by the infinitesimal gauge transformations. Thus, in order for the traces of the extended holonomies to give observables, it is necessary that they be invariant under small gauge transformations. This issue was considered in Ref. 9, but as is usual in pioneering work, a detailed analysis was sacrificed for the sake of progress in other directions.

Such an analysis is the purpose of this section. We will find that there is a technical subtlety which prevents us from accepting the naive conclusion that the extended holonomies are (formally) gauge covariant with respect to infinitesimal gauge transformations. In order to gain some insight about the transformations properties of the holonomies, we will then consider the Abelian case. In all that follows, we will restrict attention to the manifold $\mathscr{M} \approx \mathbb{R}^3$.

Recall that an infinitesimal gauge transformation is given by a map $\Lambda: \mathscr{M} \to \mathscr{L}G$, where $\mathscr{L}G$ is the Lie algebra of G. To first order in Λ, the gauge-transformed connection is given by

$$\mathbf{A}^\Lambda = \mathbf{A} + d\Lambda + [\mathbf{A},\Lambda].$$

Set

$$U_A^{(n)}[X] := X^{\mu_1 \cdots \mu_n} \mathbf{A}_{\mu_1} \cdots \mathbf{A}_{\mu_n},$$

as in Eq. (10), so that

$$U_A[X] = \sum_{n=0}^{\infty} U_A^{(n)}[X].$$

Using the differential relation (6) satisfied by the generalized loops, one may obtain the holonomy corresponding to the gauge-transformed connection;

$$U_{A^\Lambda}^{(n)}[X] = U_A^{(n)}[X] + [U_A^{(n-1)}[X],\Lambda(p)] + f_{(A,\Lambda)}^{(n)}[X] - f_{(A,\Lambda)}^{(n-1)}[X], \tag{11}$$

where

$$f^{(n)}_{(A,\Lambda)}[X]:=\sum_{k=1}^{n} X^{\mu_1\cdots\mu_n}\mathbf{A}_{\mu_1}\cdots\mathbf{A}_{\mu_{k-1}}[\mathbf{A},\Lambda]_{\mu_k}\mathbf{A}_{\mu_{k+1}}\cdots\mathbf{A}_{\mu_n}. \tag{12}$$

One is tempted to conclude from Eq. (11) that, since the $f^{(n)}$ cancel upon summation of the series for the transformed holonomy, all extended holonomies are formally gauge-covariant. However, let us proceed more carefully. Consider the partial sum,

$$\sum_{n=0}^{N} U^{(n)}_{A^\Lambda}[X]=\sum_{n=0}^{N} U^{(n)}_{A}[X]+\left[\sum_{n=0}^{N} U^{(n)}_{A}[X],\Lambda(p)\right]-[U^{(N)}_{A}[X],\Lambda(p)]+f^{(N)}_{(A,\Lambda)}[X]. \tag{13}$$

If we suppose that $U_A[X]$ converges, then $U^{(N)}_A[X]\to 0$ as $N\to\infty$ and the extended holonomy is covariant under infinitesimal gauge-transformations only if

$$f^{(N)}_{(A,\Lambda)}[X]\to 0, \quad \text{as} \quad N\to\infty. \tag{14}$$

Thus, gauge-covariance of the extended holonomies does not follow trivially from Eq. (11).

We are now faced with the problem of whether the notion of holonomy generalizes to the extended loop group. Although, by inspection of Eq. (12), the Abelian case is trivial, an example will lead the way to an understanding of the non-Abelian case. Therefore, let us consider $G=U(1)$. Let γ be the loop determined by the curve

$$C(s)=(\cos(2\pi s),\sin(2\pi s),0).$$

This loop determines an element $X_\gamma\in\mathscr{X}_p$, where the base point has been fixed as $p=(1,0,0)$. We will focus on the generalized holonomies of an arbitrary real power, X^t_γ, of this particular loop.

The generic $U(1)$-connection is of the form

$$\mathbf{A}(x)=-i\omega(x),$$

where ω is a real one-form on $\mathscr{M}$. To compute the holonomy of $\mathbf{A}$ around X^t_γ, we need only know the rank-1 entry of X^t_γ,

$$(X^t_\gamma)^\mu=tX^\mu_\gamma,$$

and that, with respect to the cylindrical coordinates z,r,θ,

$$X^\mu_\gamma=\frac{1}{r}\delta^1(r,1)\delta^1(z,0)\left(\frac{\partial}{\partial\theta}\right)^\mu.$$

By Eq. (10), the holonomy is then given by

$$U_A[X^t_\gamma]=\exp(tX^\mu\mathbf{A}_\mu)=\exp\left(-it\oint_\Gamma\omega\right), \tag{15}$$

where Γ is the unit circle in the x-y plane (the image of C). The holonomy of the gauge-transformed connection $\mathbf{A}^g=\mathbf{A}+g^{-1}\mathbf{d}g$ is

$$U_{Ag}[X^t_\gamma]=U_A[X^t_\gamma]\cdot\exp(-2\pi i t w_\gamma[g]), \tag{16}$$

where

$$w_\gamma[g] := \frac{i}{2\pi} \oint_\Gamma g^{-1} dg \in \mathbb{Z}. \tag{17}$$

Note that the pull-back of g to Γ is a map from the circle into $U(1)$ and that $w_\gamma[g]$ is simply the winding number of this map, i.e., the number of times g wraps $U(1)$ around Γ. Suppose g is a small gauge transformation. Then, by definition, there exists a homotopy g_λ (a smooth one-parameter family of gauge transformations, $\lambda \in [0,1]$) connecting $g = g_1$ to the trivial map $g_0 \equiv \mathbf{1}$. By pulling the homotopy back to Γ, one then obtains a one-parameter family of maps from the circle into $U(1)$. Since the winding number is integral, it must be the same for each g_λ. Hence, $w_\gamma[g] = w_\gamma[g_1] = w_\gamma[g_0] = 0$. We then see that the holonomy (15) is covariant with respect to small gauge transformations. Note that this was not a general proof of covariance of the $U(1)$-holonomies (the general proof is much simpler than what we have done above!). The above reasoning applies only to the arbitrary real power of the particular loop γ. The utility of our result, however, lies not in the conclusion, but in the methodology. The above ansatz, when applied to the case $G = SU(2)$, will suggest simple examples which show that the non-Abelian holonomies are *not* covariant with respect to small gauge.

IV. NON-COVARIANCE OF THE GENERALIZED HOLONOMIES

We can study the non-Abelian case, by "embedding" the above result into $SU(2)$. The idea in mind is to replace $U(1)$ by an Abelian subgroup of $SU(2)$. After making this idea more precise, natural examples of non-covariance will be presented. The first is, perhaps, the most natural; it involves the holonomy of the real power of an ordinary loop. For the second example, we will consider the holonomies of generalized loops which are "least distributional," in a sense to be explained below.

Let us consider an arbitrary Abelian subgroup of $SU(2)$. This subgroup is generated by an element, $\mathbf{T}$, of the Lie algebra, $\mathcal{L}SU(2)$. We may assume, without loss of generality, that $\mathbf{T}$ is normalized as

$$\mathrm{tr}(\mathbf{T}^2) = -2,$$

so that, for example,

$$\exp[r\mathbf{T}] = \exp[(r + 2\pi n)\mathbf{T}], \quad \forall \quad n \in \mathbb{Z}, \quad r \in \mathbb{R}. \tag{18}$$

Now suppose $\mathbf{A}$ is an $SU(2)$-connection which is proportional to $\mathbf{T}$; i.e.,

$$\mathbf{A} = \omega \mathbf{T}, \tag{19}$$

for some one-form ω. Suppose further that $g: \mathbb{R}^3 \to SU(2)$ is an $SU(2)$ gauge transformation whose restriction to Γ is contained in the $U(1)$-subgroup generated by $\mathbf{T}$. We can now mimic the discussion leading to Eq. (16) by making the replacement $-i \mapsto \mathbf{T}$. We obtain

$$U_{Ag}[X^t_\gamma] = U_A[X^t_\gamma] \cdot \exp(2\pi t v_\gamma[g]\mathbf{T}), \tag{20}$$

where v_γ is defined as

$$v_\gamma[g]\mathbf{T} := \frac{1}{2\pi} \oint_\Gamma g^{-1} \mathbf{d} g. \tag{21}$$

The meaning of v_γ is analogous to that of w_γ; it is simply the number of times g winds the $U(1)$-subgroup generated by $\mathbf{T}$ around the circle Γ. Of course, v_γ is only defined for such an Abelian gauge transformation.

For integral t, X_γ^t corresponds to an ordinary loop and the holonomy is covariant under all gauge transformations. But for the above holonomy to transform covariantly for all *real* t, $v_\gamma[g]$ must be trivial. Recall that in Sec. III it was the non-simple connectivity of $U(1)$ that prevented us from finding small gauge transformations with non-trivial winding number around Γ. $SU(2)$ is, of course, simply connected; hence, one may wonder whether there exist small gauge transformations with non-trivial v_γ. In fact, there do exist such gauge transformations. The task at hand is to produce an explicit expression for a small gauge transformation whose restriction to Γ lies is an Abelian subgroup of $SU(2)$, and which winds Γ non-trivially around this Abelian subgroup. Since the exponential factor in Eq. (21) is independent of the connection, we will then have shown that the generalized holonomies are not gauge covariant.

To this end, let us first focus on a convenient description of the manifold structure of $SU(2)$. The Lie algebra, $\mathcal{L}SU(2)$, of $SU(2)$ is a real, three-dimensional vector space with a natural (Killing–Cartan) inner-product, which, in the fundamental representation, takes the form[14]

$$(\mathbf{T}_1,\mathbf{T}_2) := -2\ \mathrm{tr}(\mathbf{T}_1\mathbf{T}_2). \tag{22}$$

Fix a basis $\{\tau_1,\tau_2,\tau_3\}$ for the Lie algebra, which is ortho-normal with respect to this inner-product. For any element $\mathbf{L} \in \mathcal{L}SU(2)$, $\exp \mathbf{L}$ may be uniquely written as[15]

$$\exp(\mathbf{L}) = a_0\mathbf{1} + 2[a_1\tau_1 + a_2\tau_2 + a_3\tau_3], \tag{23}$$

where $a_0^2+a_1^2+a_2^2+a_3^2=1$. While $a_0,\ldots,a_3$ may be written in terms of $\mathbf{L}$, we will not find their explicit form useful. Having chosen a basis $\{\tau_1,\tau_2,\tau_3\}$ for the Lie algebra, we then obtain an isomorphism of $SU(2)$ with the unit 3-sphere in $\mathbb{R}^4$. Of course, the identity $\mathbf{1}$ is represented by the point $(1,0,0,0)$. We will abuse notation and write $\exp(\mathbf{L}) = (a_0,a_1,a_2,a_3) = a_i\vec{e}_i$, where the a_i are those appearing in Eq. (23), and $\vec{e}_i$ form the obvious ortho-normal basis of $\mathbb{R}^4$. The algebra $\mathcal{L}SU(2)$ may be viewed as the tangent space to $SU(2)$ at the identity, and with the Lie algebra element, $\mathbf{L} = L^1\tau_1 + L^2\tau_2 + L^3\tau_3$, we may identify the vector $(0,L^1,L^2,L^3) \in \mathbb{R}^4$. The $U(1)$-subgroup generated by $\mathbf{L}$ is now simply represented by the great circle (through $\mathbf{1}$) whose tangent at the identity is proportional to $\mathbf{L}$. For example, $\exp(\alpha\tau_1) = (\cos(\alpha/2),\sin(\alpha/2),0,0)$.

We may now view a gauge transformation as a smooth map $g:\mathbb{R}^3 \to \mathbb{R}^4$ whose image is contained in the unit 3-sphere. Choose the basis $\{\tau_1,\tau_2,\tau_3\}$ so that the (arbitrary) algebra element considered above is given by $\mathbf{T} = 2\tau_1$ and let us look for a small gauge transformation g for which $g(\cos\theta,\sin\theta,0) = \exp(\theta\mathbf{T}) = (\cos\theta,\sin\theta,0,0)$. We will then have $v_\gamma[g] = 1$, and our goal will have been accomplished.

At this point, a brief digression will be quite instructive. Let us display a particular homotopy connecting the curve $h(\theta) = \exp(\theta\mathbf{T})$ to the trivial curve $\iota(\theta) \equiv \mathbf{1}$. This can be done geometrically, as follows. Consider the intersection of $SU(2)$ (the 3-sphere in $\mathbb{R}^4$) and the hyperplane $P^3 = \{\vec{a} \in \mathbb{R}^4 | a_3 = 0\}$. This is a 2-sphere in $\mathbb{R}^4$, which we will denote as S. Let $P^2(\alpha)$ be the 2-plane in P^3 consisting of points of the form $\vec{e}_0 + \vec{v}$ such that $\vec{v}\cdot\vec{n}(\alpha) = 0$, where $\vec{n}(\alpha) = \vec{e}_2\cos\alpha + \vec{e}_0\sin\alpha$. The intersection of S with $P^2(\alpha)$ is a circle of radius $r(\alpha) = \sin\alpha$, which may be parameterized as

$$h_\alpha(\theta) = \begin{pmatrix} 1-(1-\cos\theta)\sin^2\alpha \\ \sin\theta\sin\alpha \\ (1-\cos\theta)\sin\alpha\cos\alpha \\ 0 \end{pmatrix}, \tag{24}$$

for $\theta \in [0,2\pi]$. As α varies from 0 to π, these circles "foliate" the sphere S. Notice, in particular, that $h_0(\theta) \equiv \mathbf{1}$ and $h_{\pi/2}(\theta) = (\cos\theta,\sin\theta,0,0) = \exp(\theta\mathbf{T})$. Therefore, h_α provides the desired homotopy (see Fig. 1). This homotopy will play a very important role in the examples that follow.

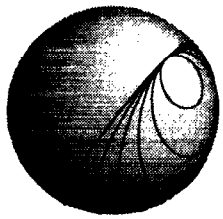

FIG. 1. A convenient homotopy connecting the trivial curve to the curve winding once around the $U(1)$-subgroup generated by $\mathbf{T}$. For each $0 \leq \alpha \leq \pi/2$, the image of h_α is a circle on the 2-sphere S, as shown for various values of the parameter α. As α decreases from $\pi/2$ to 0, h_α shrinks to a point (the identity element).

A. Example 1

We can now suggest the form of a gauge transformation $g:\mathbb{R}^3 \to SU(2)$ which is demonstrably small, whose restriction to the unit circle in the x-y plane lies in the Abelian subgroup generated by $\mathbf{T}$, and which winds this subgroup non-trivially around the unit circle. In order to satisfy generic boundary conditions at infinity, we will also demand that g be trivial outside of a compact region.

The desired gauge transformation may be obtained from a smooth assignment of the angle α to each pair of cylindrical coordinates r,z; i.e., we try

$$g(r\cos\theta, r\sin\theta, z) := h_{\alpha(r,z)}(\theta), \tag{25}$$

such that $\alpha(1,0) = \pi/2$. Any such gauge transformation is obviously small since the one-parameter family of gauge transformations,

$$g_\lambda(r\cos\theta, r\sin\theta, z) := h_{\lambda\alpha(r,z)}(\theta), \quad \lambda \in [0,1] \tag{26}$$

provides a homotopy connecting g to the trivial map.

It remains only to produce the assignment $\alpha(r,z)$. This may be accomplished by use of the smearing function,

$$\sigma_\Delta(x) := \begin{cases} e\cdot\exp\left(\dfrac{-\Delta^2}{\Delta^2 - x^2}\right) & : |x| \leq \Delta, \\ 0 & : |x| \geq \Delta. \end{cases} \tag{27}$$

σ_Δ is symmetric about $x=0$, at which it attains its maximum value $\sigma_\Delta(0)=1$. Most important, σ_Δ is an infinitely differentiable function, the support of which is compact. Putting $\alpha(r,z) := (\pi/2)\,\sigma_{1/2}(z)\sigma_{1/2}(r-1)$, we obtain

$$g(r\cos\theta, r\sin\theta, z) := h_{\pi/2\,\sigma_{1/2}(z)\sigma_{1/2}(r-1)}(\theta)$$

$$= \begin{pmatrix} 1-(1-\cos\theta)\sin^2\left[\dfrac{\pi}{2}\sigma_{1/2}(z)\sigma_{1/2}(r-1)\right] \\ \sin\theta\,\sin\left[\dfrac{\pi}{2}\sigma_{1/2}(z)\sigma_{1/2}(r-1)\right] \\ (1-\cos\theta)\sin\left[\dfrac{\pi}{2}\sigma_{1/2}(z)\sigma_{1/2}(r-1)\right]\cos\left[\dfrac{\pi}{2}\sigma_{1/2}(z)\sigma_{1/2}(r-1)\right] \\ 0 \end{pmatrix}. \tag{28}$$

Note that g is infinitely differentiable and is trivial outside a compact region. Further, since $\alpha_{1/2}(r=1,z=0)=\pi/2$, its restriction to the circle Γ is given by $g(\cos\theta,\sin\theta,0)=\exp(\theta\mathbf{T})$, as desired.

The purpose of this sub-section was the construction of this gauge-transformation. For any connection of the form written in Eq. (19), the holonomy "around" X^t_γ is *non-covariant*, according to Eq. (20). For example, choose

$$\mathbf{A}(r\cos\theta,r\sin\theta,z):=A\sigma_{1/2}(z)\sigma_{1/2}(r-1)\mathbf{T}d\theta,\quad A\in\mathbb{R} \tag{29}$$

(which also vanishes outside of a compact region). We then have

$$U_A[X^t_\gamma]=\exp[2\pi At\mathbf{T}], \tag{30}$$

and

$$U_{As}[X^t_\gamma]=\exp[2\pi At\mathbf{T}]\cdot\exp[2\pi t\mathbf{T}]. \tag{31}$$

This completes the first example.

B. Example 2

The above example involved what may be, from the Lie algebraic point of view, the most notable element of the extended loop group – the real power of an ordinary loop. The extended loop group also contains elements which seem radically different than ordinary loops, but which may be quite useful. These elements are, in a sense, "less distributional" than the ordinary loops. The differential relation (6) does not allow the existence of smooth extended loops, i.e., those for which all entries are smooth; they must be genuinely distributional. However, it is a trivial application of the results of Ref. 9 to show that given an arbitrary multi-vector density $Y^{\mu_1\cdots\mu_m}$ which is divergence-free in each index and satisfies the *homogeneous* algebraic relation (8), there exists an element $X\in\mathscr{X}_p$ such that $X^{\mu_1\cdots\mu_k}=0$, $\forall\, k<m$ and $X^{\mu_1\cdots\mu_m}=Y^{\mu_1\cdots\mu_m}$. In particular, we may choose $Y^{\mu_1\cdots\mu_m}$ to be *smooth*. The set of all extended loops whose first non-vanishing entry is smooth is a sub-Lie group of $\mathscr{X}_p$. One might think of these elements as "smoothened loops."

As was mentioned in the Introduction, the existence of the smoothened loops is a nice feature of $\mathscr{X}_p$. If X is as described above, then due to Eq. (6), $X^{\mu_1\cdots\mu_n}$ must be a genuine distribution for each $n>m$. Therefore, the hope of obtaining a gauge-invariant smearing of the connection by *smooth* functions is not borne out. Nonetheless, one might hope[10] that some light may be shed on the problem of regularization of the Wilson loop variables. Could it be that, by some mathematical miracle, the holonomies of smoothened loops do not suffer from the problem of non-covariance illustrated above? By "smearing out" the previous example, we will see that the answer to this question is, unfortunately, negative.

Recall that for Abelian connections, it is only the rank-one entry of X on which the holonomy $U_A[X]$ depends. Choose an element $X\in\mathscr{X}_p$ for which

$$X^\mu=\left(\frac{\partial}{\partial\theta}\right)^\mu\sigma_{1/2}(z)\sigma_{1/2}(r-1). \tag{32}$$

X^μ is a smooth vector density of compact support, which may be viewed as a smoothened version of the X^μ_γ considered above. Let $\mathbf{A}$ be as in the definition (29). A short calculation yields the holonomy

$$U_A[X]=\exp(X^\mu A_\mu)=\exp(2\pi A\, e^6\mathbf{T}). \tag{33}$$

In the spirit of the previous example, we construct a gauge transformation $\tilde{g}$ which commutes with **A**. The restriction of $\tilde{g}$ to the support of **A** must then take values in the Abelian subgroup generated by **T**. The idea is simply to replace the smearing function σ in Eq. (28). The function

$$t_\Delta(x) := \frac{2}{\Delta\, e^3}\int_{-\infty}^{x} dx'\,\sigma_\Delta(x') \tag{34}$$

is a smoothened step function. It vanishes for all $x \leqslant -\Delta$ and is unity for all $x \geqslant \Delta$. Of course, t_Δ is infinitely differentiable everywhere. Define

$$s_\Delta(x) := \begin{cases} t_\Delta(x+3\Delta) & : \quad x \leqslant 0, \\ 1 - t_\Delta(x-3\Delta) & : \quad x \geqslant 0. \end{cases} \tag{35}$$

This function is non-vanishing only for $|x| \leqslant 4\Delta$ and is constant on the interval $|x| \leqslant 2\Delta$, on which it assumes the value 1. Using $s_{1/4}$ in place of $\sigma_{1/2}$ in Eq. (28), one obtains the desired gauge transformation; put

$$\tilde{g}(r\cos\theta, r\sin\theta, z) := h_{\pi/2\, s_{1/4}(z) s_{1/4}(r-1)}(\theta)$$

$$= \begin{pmatrix} 1-(1-\cos\theta)\sin^2\left[\frac{\pi}{2} s_{1/4}(z) s_{1/4}(r-1)\right] \\ \sin\theta\,\sin\left[\frac{\pi}{2} s_{1/4}(z) s_{1/4}(r-1)\right] \\ \sin\left[\frac{\pi}{2} s_{1/4}(z) s_{1/4}(r-1)\right](1-\cos\theta)\cos\left[\frac{\pi}{2} s_{1/4}(z) s_{1/4}(r-1)\right] \\ 0 \end{pmatrix}. \tag{36}$$

On the support of X^μ, $\tilde{g}$ takes a very simple form; for $|z| \leqslant \frac{1}{2}$ and $|r-1| \leqslant \frac{1}{2}$, $\tilde{g}(r\cos\theta, r\sin\theta, z) = (\cos\theta, \sin\theta, 0, 0) = \exp(\theta \mathbf{T})$. One may then obtain

$$\int X^a \tilde{g}^{-1}(\mathbf{d}\tilde{g})_a = \frac{\pi\, e^3}{8}\mathbf{T}. \tag{37}$$

Finally,

$$U_{A\tilde{g}}[X] = U_A[X]\cdot\exp\left(\frac{\pi\, e^3}{8}\mathbf{T}\right). \tag{38}$$

The extended "holonomies" of the smoothened loops are not covariant with respect to small gauge transformations.

V. GENERALIZATIONS AND CONCLUSIONS

The extended loop group is a well-defined mathematical object. It is an infinite-dimensional group which encompasses the group of based loops on an arbitrary connected manifold, $\mathcal{M}$. (Note that we have used the term "Lie group" fairly loosely. For the sake of rigor, it should be shown that $\mathcal{X}_p$ admits a manifold structure with respect to which the group operations are continuous.) For applications to physics, however, one would also like to extend the concept of holonomy. In fact, the construction of the extended loop group was based on the functional form of the holonomy of ordinary loops. There is then the obvious candidate for a generalized holonomy. We

have found, however, that for the case $\mathcal{M} \approx \mathbb{R}^3$ this generalized holonomy is not covariant with respect to small gauge transformations. Its trace does not provide gauge-invariant functionals on the space of connections for an $SU(2)$ gauge theory on Minkowski space, for example.

In fact, the result is of a very general validity. Since any simple Lie group contains an $SU(2)$ subgroup, it extends to the non-Abelian case with such gauge groups – those which are typically relevant in physics. The result also applies to the case of gravity in terms of the Ashtekar variables. Further, although we restricted our attention to $\mathcal{M} \approx \mathbb{R}^3$, all of the mappings used in the first example are of compact support. We may then extend the result to an arbitrary manifold. (Note, however, that since the topology of $\mathbb{R}^3$ was used in a critical way in defining the smoothened loop group, the second example does not extend to manifolds of arbitrary topology; i.e., it is not clear that one can even define the smoothened loop group for the arbitrary case.)

From our point of view, the potential power of the extended loop group involves the use of the traced holonomies as a large class of observables for gauge theories. Our results then suggest a re-evaluation of the extended loop group as an arena for quantum gravity and Yang–Mills theory.

There are three alternatives worth consideration. First, the following question arises: What characterizes those generalized loops for which the holonomies are covariant? Perhaps consideration of this question would shed some light on the appropriate extension of the loop representation. Note however, that by Example 1, one will not have the continuous structure of a Lie group at one's disposal. Thus, techniques involving functional differentiation are not likely to be straight-forward in such a formulation. A second alternative, suggested by Di Bartolo, *et al.*, is to design a different extension of the holonomy which is covariant.[16] Alternatively, since observables of the theory are our primary concern, it may be most productive to focus on an extension of the concept of the Wilson loops. It may be the case, for example, that such an extension exists which does not manifest itself as the trace of a holonomy. Last, if some generalization of the ordinary loop representation is needed, it may turn out that the appropriate generalization is altogether different than that suggested by the existence of the extended loop group.

Perturbations of solutions of the Einstein–Maxwell equations with a null background electromagnetic field

G. F. Torres del Castillo
Departamento de Física Matemática, Instituto de Ciencias de la Universidad Autónoma de Puebla, 72000 Puebla, Pue., México

(Received 12 January 1996; accepted for publication 11 March 1996)

Expressions for the complete metric and vector potential perturbations of solutions of the Einstein–Maxwell equations with a null background electromagnetic field in terms of two complex scalar potentials are derived using Wald's method of adjoint operators. The perturbations of the Bell–Szekeres solution, in the regions prior to the collision of the plane-fronted waves, are obtained by this approach. We find that there exist nontrivial u-independent perturbations (where ∂_u defines the direction of propagation of the colliding wave) which, when the electromagnetic perturbation vanishes, are exact solutions of the Einstein–Maxwell equations. © *1996 American Institute of Physics.* [S0022-2488(96)00207-1]

I. INTRODUCTION

In the study of the perturbations of solutions of the Einstein equations by massless fields it is convenient to have expressions for the complete perturbations in terms of some few potentials, since this reduces the number of differential equations to solve and automatically gives the correct relative normalization for all the components of the perturbation. In the case of the algebraically special solutions of the Einstein vacuum field equations, the perturbations by massless fields of spin $\frac{1}{2}$ (neutrinos), 1 (electromagnetic field), $\frac{3}{2}$ (gravitinos), and 2 (gravitational perturbations) can be expressed in terms of a single scalar potential which obeys a second-order linear partial differential equation.[1–8]

When there is a background electromagnetic field, the electromagnetic perturbations are coupled to the gravitational perturbations. If the background electromagnetic field is non-null (algebraically general) and one of its principal null directions is geodetic and shearfree, the metric and vector potential perturbations can be expressed in terms of four scalar potentials that satisfy a system of four first-order partial differential equations.[9–12] While if the background electromagnetic field is null (algebraically special), the electromagnetic and gravitational perturbations can be expressed in terms of two scalar potentials that obey a system of two second-order partial differential equations.[13]

There are two systematic procedures to obtain the expressions of the perturbations in terms of potentials. One of them is based on the use of coordinates adapted to the totally null foliation of the space–times considered.[5,6,8,10,11,13,14] A second procedure, which is more elementary and involves shorter derivations, is Wald's method of adjoint operators, which is applicable when one can obtain decoupled equations from the perturbation equations.[3,4,7,9,12]

The aim of this paper is to give a derivation of the expressions for the complete perturbations of the solutions of the Einstein–Maxwell equations with a null background electromagnetic field in terms of two complex scalar potentials using Wald's method and the Newman–Penrose notation. The final expressions are equivalent to those obtained in Ref. 13, making use of the complex extension of the space–time and the spinor formalism. The usefulness of the formulas derived here is illustrated by considering the coupled perturbations of the Bell–Szekeres solution, which represents the collision of two plane electromagnetic waves, in the regions that contain the approaching waves (the electromagnetic field in the interaction region subsequent to the collision is algebraically general). These perturbations have been studied previously by Chandrasekhar and Xanthopoulos,[15] who solved directly the perturbation equations written in the Newman–Penrose

0022-2488/96/37(8)/4053/9/$10.00
J. Math. Phys. **37** (8), August 1996

notation. Our results differ from those of Ref. 15 in several aspects and we point out the origin of the discrepancies.

In Sec. II we obtain a decoupled system of two equations from the perturbation equations of a solution of the Einstein–Maxwell equations with a null background electromagnetic field which leads, making use of Wald's method, to the expressions for the complete metric and vector potential perturbations in terms of scalar potentials. In Sec. III, we find the perturbations of the Bell–Szekeres solution in those regions where the background electromagnetic field is null. Even though there is no proof that all perturbations of the solutions under consideration can be generated by the two scalar potentials employed here (see, however, Ref. 9), it has been shown,[5,6,16] by direct integration, that the general solution of the massless field equations of spin $\frac{1}{2}$, 1, and $\frac{3}{2}$ in an algebraically special space–time that admits a geodetic and shearfree null congruence can be expressed in terms of a single complex scalar potential that satisfies a second-order partial differential equation; hence, in the present case one expects that all the gravitational and electromagnetic perturbations can be expressed in terms of two complex potentials obeying a system of two second-order equations.

II. DECOUPLED EQUATIONS AND SCALAR POTENTIALS

Wald's method allows us to express the solution of a system of linear partial differential equations in terms of potentials. If $f_{\mu\nu\ldots}$ is an m-index tensor field that obeys a system of linear partial differential equations of the form

$$[\mathscr{E}(f_{\mu\nu\ldots})]_{\rho\sigma\ldots}=0, \tag{1}$$

where $\mathscr{E}$ is a linear differential operator that takes m-index tensor fields into n-index tensor fields, and if, by combining the equations in (1) and their derivatives, one is able to obtain a decoupled equation of the form

$$\mathscr{C}(\chi)=0, \tag{2}$$

where $\mathscr{C}$ is a linear differential operator that maps scalar fields into scalar fields and χ is a function made out (linearly) of $f_{\mu\nu\ldots}$ and its derivatives, then there exists a linear operator $\mathscr{T}$ such that $\chi=\mathscr{T}(f_{\mu\nu\ldots})$ and

$$\mathscr{C}\mathscr{T}=\mathscr{S}\mathscr{E}, \tag{3}$$

for some linear operator $\mathscr{S}$ which takes n-index tensor fields into scalar fields. By defining the adjoint, $\mathscr{E}^\dagger$, of $\mathscr{E}$ as that linear partial differential operator taking n-index tensor fields into m-index tensor fields such that

$$g^{\rho\sigma\cdots}[\mathscr{E}(f_{\mu\nu\ldots})]_{\rho\sigma\ldots}-[\mathscr{E}^\dagger(g^{\rho\sigma\cdots})]^{\mu\nu\cdots}f_{\mu\nu\ldots}=\nabla_\mu s^\mu, \tag{4}$$

where s^μ is some vector field, and similarly for the other operators, from Eq. (3) it follows that

$$\mathscr{E}^\dagger\mathscr{S}^\dagger=\mathscr{T}^\dagger\mathscr{C}^\dagger. \tag{5}$$

Therefore, if ψ is a scalar function satisfying $\mathscr{C}^\dagger(\psi)=0$, Eq.(5) implies that $t_{\mu\nu\ldots}=[\mathscr{S}^\dagger(\psi)]_{\mu\nu\ldots}$ satisfies the system of equations $\mathscr{E}^\dagger(t_{\mu\nu\ldots})=0$. Thus, if $\mathscr{E}$ is self-adjoint, $\mathscr{E}^\dagger=\mathscr{E}$ (as in the case of the source-free Maxwell equations for the vector potential and of the linearized Einstein vacuum field equations),[3] $\mathscr{S}^\dagger(\psi)$ is a solution of the original system, provided that the scalar potential ψ satisfies $\mathscr{C}^\dagger(\psi)=0$.

The linearized Einstein–Maxwell equations for the metric perturbations, $h_{\mu\nu}$, and the vector potential perturbations, b_μ, can be expressed in the form

$$\begin{bmatrix} \mathscr{E}_G & \mathscr{E}_{GE} \\ \mathscr{E}_{EG} & \mathscr{E}_E \end{bmatrix} \begin{bmatrix} (h_{\mu\nu}) \\ (b_\mu) \end{bmatrix} = 0, \tag{6}$$

where $\mathscr{E}_G$, $\mathscr{E}_{GE}$, $\mathscr{E}_{EG}$, and $\mathscr{E}_E$ are linear operators, and, when the background electromagnetic field is null, there exists a decoupled set of equations that follows from Eq. (6) which can also be written in matrix form [see Eqs. (21) below]. If the adjoint of an operator of the form

$$\begin{bmatrix} \mathscr{A}_{11} & \cdots & \mathscr{A}_{1s} \\ \vdots & & \\ \mathscr{A}_{r1} & \cdots & \mathscr{A}_{rs} \end{bmatrix},$$

where the $\mathscr{A}_{ij}$ are linear differential operators, is given by[12]

$$\begin{bmatrix} \mathscr{A}_{11} & \cdots & \mathscr{A}_{1s} \\ \vdots & & \\ \mathscr{A}_{r1} & \cdots & \mathscr{A}_{rs} \end{bmatrix}^\dagger = \begin{bmatrix} \mathscr{A}_{11}^\dagger & \cdots & \mathscr{A}_{r1}^\dagger \\ \vdots & & \\ \mathscr{A}_{1s}^\dagger & \cdots & \mathscr{A}_{rs}^\dagger \end{bmatrix}, \tag{7}$$

then, by multiplying one of the rows of Eq. (6) by an appropriate factor, the operator appearing in Eq. (6) is self-adjoint[9] and the conclusions of the preceding paragraph apply with χ and ψ being columns with several components. The adjoint operators can be readily obtained making use of Eq. (7), the properties $(\mathscr{A}\mathscr{B})^\dagger = \mathscr{B}^\dagger\mathscr{A}^\dagger$, $(\mathscr{A}+\mathscr{B})^\dagger = \mathscr{A}^\dagger + \mathscr{B}^\dagger$, and

$$\begin{aligned} &D^\dagger = -D - \varepsilon - \bar{\varepsilon} + \rho + \bar{\rho}, \quad \Delta^\dagger = -\Delta + \gamma + \bar{\gamma} - \mu - \bar{\mu}, \\ &\delta^\dagger = -\delta - \beta + \bar{\alpha} + \tau - \bar{\pi}, \quad \bar{\delta}^\dagger = -\bar{\delta} + \alpha - \bar{\beta} - \pi + \bar{\tau}. \end{aligned} \tag{8}$$

We shall consider a solution of the Einstein–Maxwell equations with a null background electromagnetic field and a possibly nonzero cosmological constant. Taking the tetrad vector l^μ along the (double) principal null direction of the background electromagnetic field, we have $\varphi_0 = 0 = \varphi_1$ and from the Maxwell equations it follows that $\kappa = 0 = \sigma$ (Mariot–Robinson theorem). Then, from the Goldberg–Sachs theorem one finds that $\Psi_0 = 0 = \Psi_1$. Denoting with a superscript B the first-order perturbed values of the corresponding quantities, from the Maxwell equations one obtains

$$(\bar{\delta} - 2\alpha + \pi)\varphi_0^B - (D - 2\rho)\varphi_1^B - \kappa^B \varphi_2 = 2\pi l^\mu j_\mu, \tag{9}$$

$$(\Delta - 2\gamma + \mu)\varphi_0^B - (\delta - 2\tau)\varphi_1^B - \sigma^B \varphi_2 = 2\pi m^\mu j_\mu, \tag{10}$$

where we have included a source for the electromagnetic perturbations, j_μ, in order to find an operator identity of the form (3) (cf. also Refs. 3, 7, 9, and 12).

Applying $(\delta - \beta - \bar{\alpha} - 2\tau + \bar{\pi})$ to Eq. (9) and $(D - \varepsilon + \bar{\varepsilon} - 2\rho - \bar{\rho})$ to Eq. (10) and subtracting, the terms with ψ_1^B cancel by virtue of the identity[17]

$$[D + (p-1)\varepsilon + \bar{\varepsilon} + q\rho - \bar{\rho}](\delta + p\beta + q\tau) = [\delta + (p-1)\beta - \bar{\alpha} + q\tau + \bar{\pi}](D + p\varepsilon + q\rho), \tag{11}$$

where p and q are arbitrary constants, which is a consequence of $\kappa = \sigma = \Psi_1 = 0$. Making use of the Maxwell equations

$$(D + 2\varepsilon - \rho)\varphi_2 = 0 = (\delta + 2\beta - \tau)\varphi_2 \tag{12}$$

and of the Ricci identity

$$(D-3\varepsilon+\bar{\varepsilon}-\rho-\bar{\rho})\sigma^B-(\delta-3\beta-\bar{\alpha}-\tau+\bar{\pi})\kappa^B=\Psi_0^B, \tag{13}$$

one finds that

$$\mathscr{O}_E(\varphi_0^B)-\varphi_2\Psi_0^B=2\pi[(D-\varepsilon+\bar{\varepsilon}-2\rho-\bar{\rho})(m^\mu j_\mu)-(\delta-\beta-\bar{\alpha}-2\tau+\bar{\pi})(l^\mu j_\mu)], \tag{14}$$

where

$$\mathscr{O}_E\equiv(D-\varepsilon+\bar{\varepsilon}-2\rho-\bar{\rho})(\Delta-2\gamma+\mu)-(\delta-\beta-\bar{\alpha}-2\tau+\bar{\pi})(\bar{\delta}-2\alpha+\pi). \tag{15}$$

Similarly, from the Bianchi identities one obtains

$$\begin{aligned}(\bar{\delta}-4\alpha+\pi)\Psi_0^B-(D-2\varepsilon-4\rho)\Psi_1^B-3\kappa^B\Psi_2\\ =4\pi[(\delta-2\beta-2\bar{\alpha}+\bar{\pi})l^\mu l^\nu T_{\mu\nu}-(D-2\varepsilon-2\bar{\rho})l^\mu m^\nu T_{\mu\nu}],\end{aligned} \tag{16}$$

$$\begin{aligned}(\Delta-4\gamma+\mu)\Psi_0^B-(\delta-2\beta-4\tau)\Psi_1^B-3\sigma^B\Psi_2+2(D-2\varepsilon+2\bar{\varepsilon}-\bar{\rho})\overline{\varphi_2}\varphi_0^B\\ =4\pi[(\delta-2\beta+2\bar{\pi})l^\mu m^\nu T_{\mu\nu}-\bar{\lambda}l^\mu l^\nu T_{\mu\nu}-(D-2\varepsilon+2\bar{\varepsilon}-\bar{\rho})m^\mu m^\nu T_{\mu\nu}],\end{aligned} \tag{17}$$

where we have included a source for the gravitational perturbations, $T_{\mu\nu}$ (in addition to the contribution coming from the electromagnetic perturbations), which will allow us to identify the operator $\mathscr{T}$, and we have made use of the Einstein field equations. Applying $(\delta-3\beta-\bar{\alpha}-4\tau+\bar{\pi})$ to Eq. (16) and $(D-3\varepsilon+\bar{\varepsilon}-4\rho-\bar{\rho})$ to Eq. (17), subtracting and using Eqs. (11)–(13) and the Bianchi identities $(D-3\rho)\Psi_2=0=(\delta-3\tau)\Psi_2$, it follows that

$$\begin{aligned}&\mathscr{O}_G(\Psi_0^B)+2\overline{\varphi_2}(D-3\varepsilon-\bar{\varepsilon}-4\rho)(D-2\varepsilon)\varphi_0^B\\ &=4\pi\{(D-3\varepsilon+\bar{\varepsilon}-4\rho-\bar{\rho})[(\delta-2\beta+2\bar{\pi})l^\mu m^\nu T_{\mu\nu}-(D-2\varepsilon+2\bar{\varepsilon}-\bar{\rho})\\ &\quad\times m^\mu m^\nu T_{\mu\nu}-\bar{\lambda}l^\mu l^\nu T_{\mu\nu}]+(\delta-3\beta-\bar{\alpha}-4\tau+\bar{\pi})\\ &\quad\times[(D-2\varepsilon-2\bar{\rho})l^\mu m^\nu T_{\mu\nu}-(\delta-2\beta-2\bar{\alpha}+\bar{\pi})l^\mu l^\nu T_{\mu\nu}]\},\end{aligned} \tag{18}$$

where

$$\mathscr{O}_G\equiv(D-3\varepsilon+\bar{\varepsilon}-4\rho-\bar{\rho})(\Delta-4\gamma+\mu)-(\delta-3\beta-\bar{\alpha}-4\tau+\bar{\pi})(\bar{\delta}-4\alpha+\pi)-3\Psi_2. \tag{19}$$

Thus, setting $j_\mu=0$, $T_{\mu\nu}=0$ in Eqs. (14) and (18), we find that the perturbation equations imply that φ_0^B and Ψ_0^B satisfy the equations

$$\begin{aligned}\mathscr{O}_E(\varphi_0^B)-\varphi_2\Psi_0^B=0,\\ \mathscr{O}_G(\Psi_0^B)+2\overline{\varphi_2}(D-3\varepsilon-\bar{\varepsilon}-4\rho)(D-2\varepsilon)\varphi_0^B=0.\end{aligned} \tag{20}$$

On the other hand, Eqs. (14) and (18) can be expressed in the form

$$\begin{bmatrix} \mathcal{O}_G & 2\overline{\varphi_2}(D-3\varepsilon-\bar{\varepsilon}-4\rho)(D-2\varepsilon) \\ -\varphi_2 & \mathcal{O}_E \end{bmatrix} \begin{bmatrix} \Psi_0^B \\ \varphi_0^B \end{bmatrix}$$

$$= 4\pi \begin{bmatrix} (D-3\varepsilon+\bar{\varepsilon}-4\rho-\bar{\rho})[(\delta-2\beta+2\bar{\pi})l^\mu m^\nu T_{\mu\nu}-(D-2\varepsilon+2\bar{\varepsilon}-\bar{\rho})m^\mu m^\nu T_{\mu\nu} \\ -\bar{\lambda}l^\mu l^\nu T_{\mu\nu}]+(\delta-3\beta-\bar{\alpha}-4\tau+\bar{\pi})[(D-2\varepsilon-2\bar{\rho})l^\mu m^\nu T_{\mu\nu} \\ -(\delta-2\beta-2\bar{\alpha}+\bar{\pi})l^\mu l^\nu T_{\mu\nu}] \\ \\ \frac{1}{2}[(D-\varepsilon+\bar{\varepsilon}-2\rho-\bar{\rho})m^\mu-(\delta-\beta-\bar{\alpha}-2\tau+\bar{\pi})l^\mu]j_\mu \end{bmatrix}, \quad (21)$$

which is an equation of the form (3), where the 2×2 matrix on the left-hand side corresponds to the operator $\mathcal{O}$,

$$\begin{bmatrix} \Psi_0^B \\ \varphi_0^B \end{bmatrix} = \mathcal{I} \begin{bmatrix} (h_{\mu\nu}) \\ (b_\mu) \end{bmatrix},$$

and the column on the right-hand side is, essentially,

$$\mathcal{S} \begin{bmatrix} (T_{\mu\nu}) \\ (j_\mu) \end{bmatrix}.$$

Making use of Eqs. (7), (8), and (12) one readily finds that

$$\mathcal{O}^\dagger = \begin{bmatrix} \mathcal{O}_G^\dagger & -\varphi_2 \\ 2\overline{\varphi_2}(D+3\varepsilon-\bar{\varepsilon}-\rho)(D+4\varepsilon+3\rho) & \mathcal{O}_E^\dagger \end{bmatrix},$$

where

$$\begin{aligned} \mathcal{O}_G^\dagger &\equiv (\Delta+3\gamma-\bar{\gamma}+\bar{\mu})(D+4\varepsilon+3\rho)-(\bar{\delta}+3\alpha+\bar{\beta}-\bar{\tau})(\delta+4\beta+3\tau)-3\Psi_2, \\ \mathcal{O}_E^\dagger &\equiv (\Delta+\gamma-\bar{\gamma}+\bar{\mu})(D+2\varepsilon+\rho)-(\bar{\delta}+\alpha+\bar{\beta}-\bar{\tau})(\delta+2\beta+\tau), \end{aligned} \quad (22)$$

and that the adjoints of the operators acting on $T_{\mu\nu}$ and j_μ on the right-hand side of Eq. (21) are (excluding the constant factor 4π)

$$\begin{aligned} &-l^\mu l^\nu[(\delta+3\beta+\bar{\alpha}-\tau)(\delta+4\beta+3\tau)-\bar{\lambda}(D+4\varepsilon+3\rho)]-m^\mu m^\nu(D+3\varepsilon-\bar{\varepsilon}-\rho)(D+4\varepsilon+3\rho) \\ &+l^{(\mu}m^{\nu)}[(D+3\varepsilon+\bar{\varepsilon}-\rho+\bar{\rho})(\delta+4\beta+3\tau)+(\delta+3\beta-\bar{\alpha}-\tau-\bar{\pi})(D+4\varepsilon+3\rho)], \\ &\frac{1}{2}[l^\mu(\delta+2\beta+\tau)-m^\mu(D+2\varepsilon+\rho)]. \end{aligned} \quad (23)$$

Hence, if the scalar potentials, ψ_G, ψ_E, satisfy the equation $\mathcal{O}^\dagger\begin{bmatrix}\psi_G \\ \psi_E\end{bmatrix} = 0$ i.e.,

$$\begin{aligned} &\mathcal{O}_G^\dagger(\psi_G)-\varphi_2\psi_E=0, \\ &2\overline{\varphi_2}(D+3\varepsilon-\bar{\varepsilon}-\rho)(D+4\varepsilon+3\rho)\psi_G+\mathcal{O}_E^\dagger(\psi_E)=0, \end{aligned} \quad (24)$$

then the metric and vector potential perturbations are obtained by applying the operators (23) on the two-component column formed by ψ_G and ψ_E. In order to find the correct relative normalization one can use the fact that the perturbations Ψ_0^B and φ_0^B generated by ψ_G and ψ_E must satisfy Eqs. (20) [see Eqs. (27) and (29) below]. Thus, we find for the *real* perturbations

$$h_{\mu\nu}=-2\{l_\mu l_\nu[(\delta+3\beta+\bar{\alpha}-\tau)(\delta+4\beta+3\tau)-\bar{\lambda}(D+4\varepsilon+3\rho)]$$
$$+m_\mu m_\nu(D+3\varepsilon-\bar{\varepsilon}-\rho)(D+4\varepsilon+3\rho)-l_{(\mu}m_{\nu)}[(D+3\varepsilon+\bar{\varepsilon}-\rho+\bar{\rho})(\delta+4\beta+3\tau)$$
$$+(\delta+3\beta-\bar{\alpha}-\tau-\bar{\pi})(D+4\varepsilon+3\rho)]\}\psi_G+\text{c.c.}, \tag{25}$$

$$b_\mu=\tfrac{1}{2}[l_\mu(\delta+2\beta+\tau)-m_\mu(D+2\varepsilon+\rho)]\psi_E+\text{c.c.} \tag{26}$$

Then, the components of the perturbed electromagnetic field are given by

$$\overline{\varphi_0^B}=\tfrac{1}{2}(D+\varepsilon-\bar{\varepsilon}-\rho)(D+2\varepsilon+\rho)\psi_E,$$

$$\overline{\varphi_1^B}=\tfrac{1}{4}[(D+\varepsilon+\bar{\varepsilon}-\rho+\bar{\rho})(\delta+2\beta+\tau)+(\delta+\beta-\bar{\alpha}-\tau-\bar{\pi})(D+2\varepsilon+\rho)]\psi_E,$$

$$\overline{\varphi_2^B}=\tfrac{1}{2}[(\delta+\beta+\bar{\alpha}-\tau)(\delta+2\beta+\tau)-\bar{\lambda}(D+2\varepsilon+\rho)]\psi_E+\varphi_2(D-\varepsilon+3\bar{\varepsilon}-\bar{\rho})(D+4\bar{\varepsilon}+3\bar{\rho})\overline{\psi_G}, \tag{27}$$

where we have made use of Eq. (24). The components of the perturbed Weyl spinor can be obtained from Eq. (25), making use of the formula

$$\Psi^B_{ACDE}=\tfrac{1}{2}\nabla^{R'}{}_{(A}\nabla^{S'}{}_{C}h_{DE)R'S'}. \tag{28}$$

In this manner, we find that

$$\overline{\Psi_0^B}=-(D+\varepsilon-3\bar{\varepsilon}-\rho)(D+2\varepsilon-2\bar{\varepsilon}-\rho)(D+3\varepsilon-\bar{\varepsilon}-\rho)(D+4\varepsilon+3\rho)\psi_G, \tag{29}$$

$$\overline{\Psi_4^B}=-[(\delta+\beta+3\bar{\alpha}-\tau)(\delta+2\beta+2\bar{\alpha}-\tau)-\bar{\lambda}(D+2\varepsilon+2\bar{\varepsilon}-\rho+2\bar{\rho})]$$
$$\times\{[(\delta+3\beta+\bar{\alpha}-\tau)(\delta+4\beta+3\tau)-\bar{\lambda}(D+4\varepsilon+3\rho)]\psi_G$$
$$+[(\bar{\delta}+\alpha+3\bar{\beta}-\bar{\tau})(\bar{\delta}+4\bar{\beta}+3\bar{\tau})-\lambda(D+4\bar{\varepsilon}+3\bar{\rho})]\overline{\Psi_G}\}$$
$$-[(\Delta-\gamma+3\bar{\gamma}+\mu)(\Delta-2\gamma+2\bar{\gamma}+\mu)+\nu(\delta-2\beta+2\bar{\alpha})$$
$$-\bar{\nu}(\bar{\delta}-2\alpha+2\bar{\beta}+\pi+2\bar{\tau})+((\delta+3\beta+\bar{\alpha}-\tau)\nu-\lambda\bar{\lambda})]$$
$$\times(D-\varepsilon+3\bar{\varepsilon}-\bar{\rho})(D+4\bar{\varepsilon}+3\bar{\rho})\overline{\psi_G}$$
$$+\tfrac{1}{2}[(\Delta-\gamma+3\bar{\gamma}+\mu)(\delta+2\bar{\alpha}-2\tau)+(\delta+\beta+3\bar{\alpha}-\tau)(\Delta+2\bar{\gamma}+2\mu)$$
$$-\bar{\nu}(D+2\bar{\varepsilon}-2\rho+2\bar{\rho})-\bar{\lambda}(\bar{\delta}+2\bar{\beta}+2\pi+2\bar{\tau})]$$
$$\times[(D+\varepsilon+3\bar{\varepsilon}+\rho-\bar{\rho})(\bar{\delta}+4\bar{\beta}+3\bar{\tau})+(\bar{\delta}-\alpha+3\bar{\beta}-\pi-\bar{\tau})(D+4\bar{\varepsilon}+3\bar{\rho})]\overline{\psi_G}$$
$$+[(\delta-\beta+3\bar{\alpha}-\bar{\pi})\bar{\lambda}][(D+3\varepsilon+\bar{\varepsilon}-\rho+\bar{\rho})(\delta+4\beta+3\tau)$$
$$+(\delta+3\beta-\bar{\alpha}-\tau-\bar{\pi})(D+4\varepsilon+3\rho)]\psi_G$$
$$-2\overline{\lambda\lambda}(D+3\varepsilon-\bar{\varepsilon}-\rho)(D+4\varepsilon+3\rho)\psi_G.$$

III. PERTURBATIONS OF THE BELL–SZEKERES SOLUTION

As shown in Ref. 15, the metric in each of the regions prior to the collision of the plane-fronted waves in the Bell–Szekeres solution can be specified by the null tetrad

$$D=-\frac{1}{\sqrt{2}}\,\partial_u,\quad \Delta=-\frac{1}{\sqrt{2}}\,(1-v^2)^{1/2}\partial_v,$$

$$\delta=\frac{1}{\sqrt{2}}\,(1-v^2)^{-1/2}(\partial_{x^1}-i\partial_{x^2}),\quad \bar{\delta}=\frac{1}{\sqrt{2}}\,(1-v^2)^{-1/2}(\partial_{x^1}+i\partial_{x^2}), \tag{30}$$

where u,v,x^1,x^2 are real coordinates. The only nonvanishing spin-coefficient is given by

$$\mu=\Delta\,\ln(1-v^2)^{1/2}, \tag{31}$$

the only nonvanishing component of the curvature is

$$\Phi_{22}=\tfrac{1}{2}, \tag{32}$$

and the electromagnetic field is given by

$$\varphi_0=0=\varphi_1,\quad \varphi_2=\tfrac{1}{2}. \tag{33}$$

Hence, the results of the preceding section can be applied to this solution with the null tetrad (30). Since u, x^1, and x^2 are ignorable coordinates, we seek solutions of Eqs. (24) of the form

$$\psi_E=f(v)e^{i(k_1x^1+k_2x^2+k_3u)},\quad \psi_G=g(v)e^{i(k_1x^1+k_2x^2+k_3u)}, \tag{34}$$

where k_1, k_2, and k_3 are constants. Substituting Eqs. (30), (31), (33), and (34) into Eqs. (24) one obtains the linear ordinary differential equations

$$ik_3\frac{d}{dv}\,[(1-v^2)^{1/2}g]+\frac{k_1^2+k_2^2}{1-v^2}\,g=f,$$

$$ik_3\frac{d}{dv}\,[(1-v^2)^{1/2}f]+\frac{k_1^2+k_2^2}{1-v^2}\,f=k_3^2g. \tag{35}$$

It can be easily verified that, if $k_3\neq0$, the most general solution of Eqs. (35) is given by[15]

$$f=(C_1v(1-v^2)^{-1/2}+C_2)\exp\left[i\,\frac{(k_1^2+k_2^2)}{k_3}\,v(1-v^2)^{-1/2}\right],$$

$$g=ik_3^{-1}(-C_2v(1-v^2)^{-1/2}+C_1)\exp\left[i\,\frac{(k_1^2+k_2^2)}{k_3}\,v(1-v^2)^{-1/2}\right], \tag{36}$$

where C_1 and C_2 are arbitrary constants (the case where k_3 vanishes will be treated below).

From Eqs. (27)–(31), (33), and (34) one obtains

$$\overline{\varphi_0^B}=-\tfrac{1}{4}k_3^2f(v)e^{i(k_1x^1+k_2x^2+k_3u)},\quad \overline{\varphi_1^B}=\frac{i(k_2+ik_1)}{k_3\sqrt{1-v^2}}\,\overline{\varphi_0^B},$$

$$\overline{\varphi_2^B}=-\frac{(k_2+ik_1)^2}{k_3^2(1-v^2)}\,\overline{\varphi_0^B}-\tfrac{1}{4}\overline{k_3^2g(v)e^{i(k_1x^1+k_2x^2+k_3u)}},$$

$$\overline{\Psi_0^B}=-\tfrac{1}{4}k_3^4 g(v)e^{i(k_1x^1+k_2x^2+k_3u)},\quad \overline{\Psi_1^B}=i\,\frac{(k_2+ik_1)}{k_3\sqrt{1-v^2}}\,\overline{\Psi_0^B},$$

$$\overline{\Psi_2^B}=-\frac{(k_2+ik_1)^2}{k_3^2(1-v^2)}\,\overline{\Psi_0^B},\quad \overline{\Psi_3^B}=-i\,\frac{(k_2+ik_1)^3}{k_3^3(1-v^2)^{3/2}}\,\overline{\Psi_0^B},\tag{37}$$

$$\overline{\Psi_4^B}=\frac{(k_2+ik_1)^4}{k_3^4(1-v^2)^2}\,\overline{\Psi_0^B}-\overline{\tfrac{1}{4}k_3^2 g(v)e^{i(k_1x^1+k_2x^2+k_3u)}},$$

where in the last equality we have made use of the fact that, in the present case, the terms containing $\overline{\psi_G}$ in Eq. (29) reduce to

$$\tfrac{1}{2}D^2\overline{\psi_G}\tag{38}$$

as a consequence of Eqs. (24).

The expressions for φ_2^B and Ψ_4^B given in Eqs. (37) (which are the only ones that contain $e^{i(k_1x^1+k_2x^2+k_3u)}$ and its complex conjugate) do not agree with the corresponding expressions obtained by Chandrasekhar and Xanthopoulos.[15] The error in Ref. 15 comes from the assumption that *all* the perturbed quantities have a dependence on x^1, x^2, and u of the form

$$e^{i(k_1x^1+k_2x^2+k_3u)}\tag{39}$$

even though some of the equations considered in that paper contain the perturbations of the electromagnetic field and of the conformal curvature and their complex conjugates [see, e.g., Eqs. (164) and (167) of Ref. 15].

It may be noticed that, in the approach followed here, the simultaneous presence of a factor (39) and its complex conjugate in some of the perturbed quantities arises naturally as a consequence of considering real metric and vector potential perturbations, despite the fact that the potentials ψ_E and ψ_G have a dependence on the ignorable coordinates of the form (39). [As pointed out in Ref. 18, the presence of the factor (39) and its complex conjugate in φ_2^B and Ψ_4^B means that there is a change in the polarization of the perturbations produced by their scattering from the background solution.] As noted in Ref. 15, the perturbations (37) diverge at $v=1$.

Now we shall consider the u-independent perturbations (which correspond to the case $k_3=0$). It is convenient to use in place of the real coordinates x^1 and x^2, the complex variable

$$z\equiv\frac{x^1+ix^2}{\sqrt{2}}\tag{40}$$

and its complex conjugate. Then, $\delta=(1-v^2)^{-1/2}\partial_z$ and $\overline{\delta}=(1-v^2)^{-1/2}\partial_{\bar{z}}$.

Assuming that the potentials ψ_G and ψ_E do not depend on u from Eqs. (24) it follows that

$$\psi_G=(1-v^2)^2[\bar{z}F(v,z)+G(v,z)],$$

$$\psi_E=-2(1-v^2)\partial_z F(v,z),\tag{41}$$

where $F(v,z)$ and $G(v,z)$ are arbitrary functions and the factors $(1-v^2)$ are introduced for convenience. {In these expressions for ψ_G and ψ_E we have excluded terms of the form $(1-v^2)^2[z\tilde{F}(v,\bar{z})+\tilde{G}(v,\bar{z})]$ and $-2(1-v^2)\partial_{\bar{z}}\tilde{F}(v,\bar{z})$, respectively, which yield trivial perturbations [see Eqs. (25) and (26)].} The metric and vector potential perturbations generated by (41) are

$$h_{\mu\nu}=-2(1-v^2)\{\bar{z}\partial_z^2F(v,z)+\partial_z^2G(v,z)+z\overline{\partial_z^2F(v,z)}+\overline{\partial_z^2G(v,z)}\}l_\mu l_\nu,$$
$$b_\mu=-\sqrt{1-v^2}[\partial_z^2F(v,z)+\overline{\partial_z^2F(v,z)}]l_\mu. \tag{42}$$

with $l_\mu dx^\mu=-\sqrt{2}(1-v^2)^{-1/2}\,dv$. And, according to Eqs. (27)–(29), the only nonvanishing components of the perturbed electromagnetic field and of the perturbed Weyl spinor are

$$\overline{\varphi_2^B}=-\partial_z^3F(v,z),\quad \overline{\Psi_4^B}=-\bar{z}\partial_z^4F(v,z)-\partial_z^4G(v,z). \tag{43}$$

Thus, contrary to the claim made in Ref. 15, there exist nontrivial u-independent perturbations which, moreover, need not diverge at $v=1$. Furthermore, if $\partial_z^3F=0$ (i.e., when the electromagnetic perturbations vanish), the metric perturbation (42) is not only a solution of the linearized Einstein–Maxwell equations, but it also corresponds to an *exact* solution of the Einstein–Maxwell equations. This result is analogous to Xanthopoulos theorem,[19] except that in the present case the background solution possesses an electromagnetic field (see also Ref. 20).

IV. CONCLUDING REMARKS

One of the advantages of finding the perturbations in terms of potentials is that one only has to find a consistent solution of the differential equations for the potentials, since the metric and vector potential perturbations are obtained by differentiating the potentials. It may be noticed, for instance, that in the study of the perturbations of the solution (31)–(33) presented in Ref. 15, after imposing some gauge conditions, at least 27 equations had to be considered.

Since we have found that there exist well-behaved perturbations in the region of the Bell–Szekeres solution that contain the approaching waves, it is interesting to find out whether these perturbations can be matched continuously with perturbations in the interaction region of the colliding waves (cf. Ref. 15).

Note added in proof: The term $\frac{1}{2}\Phi_{(AC'R'S'}h_{DE)R'S'}$ is missing in the right-hand side of Eq. (28), which only contributes to Ψ_4^B and cancels the second term in the right-hand side of the last equality in Eqs. (37).

Three-dimensional Riemannian manifolds with constant principal Ricci curvatures $\rho_1=\rho_2\neq\rho_3$

Peter Bueken[a)]
Katholieke Universiteit Leuven, Department of Mathematics, Celestijnenlaan 200B, B-3001 Heverlee, Leuven, Belgium

(Received 21 November 1995; accepted for publication 3 May 1996)

The main aim of this paper is the study of (nonhomogeneous) three-dimensional Riemannian manifolds with constant principal Ricci curvatures $\rho_1=\rho_2\neq\rho_3$. An error in a recent paper by McManus is pointed out and corrected, and it is shown that the techniques introduced by McManus provide a very simple method to obtain the complete local classification of these manifolds, which was first given by Kowalski.
 [S0022-2488(96)02008-7]

I. INTRODUCTION

A (pseudo-)Riemannian manifold (M,g) is said to be *curvature homogeneous*[1] if, for every pair of points $p,q\in M$, there exists a linear isometry $\varphi:T_pM\to T_qM$, such that, for all $X,Y,Z\in T_pM$,

$$\varphi R_{XY}Z=R_{\varphi X\varphi Y}\varphi Z,$$

where R denotes the Riemann curvature tensor of (M,g). It is easily seen that any (locally) homogeneous manifold is automatically curvature homogeneous, and in Ref. 1. Singer states the problem of constructing examples of nonhomogeneous curvature homogeneous spaces. This problem was studied extensively in both the Riemannian and Lorentzian case (see, e.g., Refs. 2–10), leading to the construction of a large number of explicit examples. For more information on the subject of curvature homogeneity and for a survey of known results, we refer to Refs. 11–14.

It is well known that the Riemann curvature tensor of a three-dimensional Riemannian manifold (M,g) is completely determined by its Ricci tensor and, as a consequence, a three-dimensional Riemannian manifold is curvature homogeneous if and only if it has constant *principal Ricci curvatures*, i.e., its Ricci tensor has constant eigenvalues. If all principal Ricci curvatures are equal (and constant), the manifold (M,g) is of constant curvature and hence locally homogeneous. In a number of recent papers (Refs. 5, 6, 15, and 16), the authors studied the problem of three-dimensional Riemannian manifolds with constant principal Ricci curvatures $\rho_1=\rho_2\neq\rho_3$. In Refs. 5 and 6, explicit examples of nonhomogeneous curvature homogeneous spaces with principal Ricci curvatures

$$\rho_1=\rho_2\neq\rho_3=0$$

were obtained by generalizing a construction of Sekigawa,[2] and it was later shown in Ref. 15 (see also Ref. 13) that these are the only examples of such manifolds. In Ref. 16, Kowalski gives a complete (local) classification of all three-dimensional Riemannian manifolds with constant principal Ricci curvatures $\rho_1=\rho_2\neq\rho_3(\neq0)$. He proves that, for any choice of constants $0\neq\alpha\neq\beta$, there exists a family of nonhomogeneous curvature homogeneous Riemannian manifolds (depending on two functions of one variable) whose associated principal Ricci curvatures are given by

0022-2488/96/37(8)/4062/14/$10.00

$$\rho_1=\rho_2=\beta, \quad \rho_3=\alpha, \tag{1}$$

and he constructs some explicit examples of such metrics. However, we remark that the techniques used in this paper are quite complicated, (e.g., the introduction of asymptotic foliations), and the computations involved in the proofs are of a rather complex nature.

In their study of space-times admitting shear-free, irrotational, geodesic time-like congruences, Coley and McManus (Refs. 17 and 18) were led to consider three-dimensional Riemannian manifolds with constant principal Ricci curvatures satisfying (1). Further, in Refs. 19 and 20, Bona and Coll studied the isometry groups of three-dimensional Riemannian metrics using the eigenvalues and eigenvectors of their Ricci tensor. In particular, they made a study of three-dimensional Riemannian manifolds satisfying (1) and admitting a three-dimensional or four-dimensional isometry group, which acts transitively. Motivated by these results, McManus[21] addresses, independently of the work of Kowalski, the problem of completely classifying these manifolds in the homogeneous and nonhomogeneous cases. Unfortunately, one of the main results (Theorem 2) stated in Ref. 21 (as well as Theorem 2 in Ref. 18) claims that a three-dimensional Riemannian manifold with constant principal Ricci curvatures $\rho_1=\rho_2\neq\rho_3$ is nonhomogeneous if and only if the simple principal Ricci curvature is zero and the shear of its principal Ricci direction is nonzero, leading to an obvious contradiction with the results of Ref. 16.

The first aim of this paper is to point out and correct the error made in Ref. 21. We will show that the techniques introduced by McManus can be applied to prove the (local) existence of a family of nonhomogeneous three-dimensional Riemannian manifolds with constant principal Ricci curvatures given by (1). We will then determine which of the metrics obtained in this way are isometric, thereby giving an alternative proof of the classification result from Ref. 16. It will turn out that the computations needed in this approach are much simpler than those used by Kowalski,[16] leading to a considerable simplification of the classification result, although up to this moment we were unable to find new examples of such spaces.

The paper is organized as follows. In Sec. II, we derive the differential equations that have to be satisfied by a Riemannian manifold with constant principal Ricci curvatures given by (1). We remark that many of the equations in this section have already been obtained in Refs. 19–21, but are collected here for easy reference. In Sec. III, we then investigate which of these manifolds are locally homogeneous. In Sec. IV we study the differential equations of Sec. II in more detail. Correcting the mistake in Ref. 21, we prove the (local) existence of nonhomogeneous Riemannian manifolds whose principal Ricci curvatures satisfy (1) for arbitrary constants α and β. Finally, in Sec. V we investigate the problem of determining which of these manifolds are isometric, thereby obtaining a new (and simpler) proof of the classification result in Ref. 16.

We end this section by remarking that the techniques used in the present paper can be adapted easily to the case where M is a three-dimensional Lorentzian manifold, leading to a similar classification of Lorentzian manifolds with constant principal Ricci curvatures given by (1). Again, this problem was studied before by McManus,[22] but, unfortunately, a similar mistake was made in this paper. In a forthcoming publication,[23] we will correct this error (as well as another one appearing in Ref. 22), and we will prove a classification result similar to the one given in the present paper.

II. THE BASIC DIFFERENTIAL EQUATIONS

We start this section by fixing some notations. In what follows, we denote by (M,g) a (smooth) three-dimensional Riemannian manifold and by ∇ the *Levi Civita connection* associated to g. Further, we define the *Riemann curvature tensor* R of (M,g) as the (1,3)-tensor field,

$$R_{XY}Z=\nabla_{[X,Y]}Z-\nabla_X\nabla_Y Z+\nabla_Y\nabla_X Z, \tag{2}$$

for all vector fields $X,Y,Z\in\mathfrak{X}(M)$. The *Ricci curvature tensor* ρ is defined (at the point $p\in M$) as the trace

$$\rho(X,Y)(p)=\sum_{i=1}^{3} g(R_{XE_i}Y,E_i)(p), \tag{3}$$

where $X,Y\in T_pM$ and $\{E_1,E_2,E_3\}$ is an orthonormal basis for T_pM, and the trace

$$\tau(p)=\sum_{i=1}^{3} \rho(E_i,E_i)(p),$$

is called the *scalar curvature* of (M,g) at p.

Let $\xi\in\mathfrak{X}(M)$ be a vector field of unit length, denote by η the metric dual of ξ, i.e., the one-form given, for all $X\in\mathfrak{X}(M)$, by

$$\eta(X)=g(X,\xi),$$

and by $h=g-\eta\otimes\eta$ the *projection tensor* associated to ξ. Then it is well known that there exists a *unique* decomposition

$$g(\nabla_X\xi,Y)=\sigma(X,Y)+\omega(X,Y)+\tfrac{1}{2}\theta h(X,Y)+g(\nabla_\xi\xi,Y)g(\xi,X), \tag{4}$$

where σ is a trace-free, symmetric (0,2)-tensor field and ω is an antisymmetric (0,2)-tensor field, such that, for all $X\in\mathfrak{X}(M)$,

$$\omega(X,\xi)=\sigma(X,\xi)=0.$$

The function

$$\theta=\sum_{i=1}^{3} g(\nabla_{E_i}\xi,E_i),$$

is said to be the *expansion* of ξ, and the (0,2)-tensor field σ (resp., ω) is called the *shear tensor* (resp., *twist tensor*) of ξ.

Now, let us suppose that (M,g) is a three-dimensional Riemannian manifold whose constant principal Ricci curvatures are given by (1). Then, locally, we can construct an orthonormal frame field $\{E_1,E_2,E_3\}$ consisting of principal Ricci directions, i.e., such that

$$\rho(E_1,E_1)=\rho(E_2,E_2)=\beta,\quad \rho(E_3,E_3)=\alpha,\quad \rho(E_i,E_j)=0,\quad \text{if } i\neq j. \tag{5}$$

Twice contracting the second Bianchi identity,

$$\nabla_{E_i}R_{E_jE_k}E_l+\nabla_{E_j}R_{E_kE_i}E_l+\nabla_{E_k}R_{E_iE_j}E_l=0,$$

we obtain the so-called three-dimensional second Bianchi identity,

$$E_i(\tau)-2\sum_{j=1}^{3}\nabla_{E_j}\rho(E_i,E_j)=0,\quad i\in\{1,2,3\}, \tag{6}$$

and taking into account that $\tau=2\beta+\alpha$ is constant along M, (6) is equivalent to

$$\sum_{j=1}^{3} g(\nabla_{E_j}E_i,E_j)\rho(E_j,E_j)+g(\nabla_{E_j}E_j,E_i)\rho(E_i,E_i)=0, \tag{7}$$

for all $i\in\{1,2,3\}$. Using the fact that $\alpha\neq\beta$, (7) yields that

$$g(\nabla_{E_3}E_3,E_1)=0,\quad g(\nabla_{E_3}E_3,E_2)=0,$$
$$g(\nabla_{E_1}E_3,E_1)+g(\nabla_{E_2}E_3,E_2)=0, \tag{8}$$

i.e., the simple principal Ricci direction E_3 is *geodesic* and *expansion-free*.[19–21]

At each point $p\in M$, the linear operator $\bar{\sigma}(p):T_pM\to T_pM$ associated to the shear tensor of E_3 is self-adjoint and trace-free, and $\bar{\sigma}E_3=0$. Hence, diagonalizing the operator $\bar{\sigma}$ at all points $p\in M$, we obtain a (local) orthonormal frame field $\{E_1,E_2,E_3\}$, consisting of principal Ricci directions [as in (5)] and such that the shear tensor of E_3 takes the form

$$\sigma(E_1,E_1)=-\sigma(E_2,E_2)=\sigma,\quad \sigma(E_1,E_2)=0,\quad \sigma(E_3,E_i)=0,\quad i\in\{1,2,3\}. \tag{9}$$

It follows from (4), (8), and (9) that, with respect to this local orthonormal frame field, the components of the Levi Civita connection of (M,g) are given by

$$\nabla_{E_1}E_1=-\theta_2E_2-\sigma E_3,\quad \nabla_{E_2}E_1=\theta_1E_2+\omega E_3,\quad \nabla_{E_3}E_1=kE_2,$$
$$\nabla_{E_1}E_2=\theta_2E_1-\omega E_3,\quad \nabla_{E_2}E_2=-\theta_1E_1+\sigma E_3,\quad \nabla_{E_3}E_2=-kE_1, \tag{10}$$
$$\nabla_{E_1}E_3=\sigma E_1+\omega E_2,\quad \nabla_{E_2}E_3=-\omega E_1-\sigma E_2,\quad \nabla_{E_3}E_3=0,$$

where we have denoted by $\omega=\omega(E_1,E_2)$ the only nonvanishing component of the twist tensor of E_3, and by $\theta_1=g(\nabla_{E_2}E_1,E_2)$ and $\theta_2=g(\nabla_{E_1}E_2,E_1)$ the expansions of E_1 and E_2. A straightforward computation using (2), (3), and (10) [or, alternatively, expressing the fact that, for all $X,Y\in\mathfrak{X}(M)$, $\rho(X,Y)=-[\nabla_X,\delta]Y-\operatorname{tr}\nabla Y\circ\nabla X$, where δ denotes the divergence operator] then yields that

$$\rho(E_1,E_1)=-\theta_2^2-\theta_1^2-2k\omega-E_1(\theta_1)-E_2(\theta_2)-E_3(\sigma),$$
$$\rho(E_2,E_2)=-\theta_2^2-\theta_1^2-2k\omega-E_1(\theta_1)-E_2(\theta_2)+E_3(\sigma),$$
$$\rho(E_3,E_3)=2(\omega^2-\sigma^2),$$
$$\rho(E_1,E_2)=-2k\sigma-E_3(\omega)=-2k\sigma+E_3(\omega), \tag{11}$$
$$\rho(E_1,E_3)=2\theta_1\sigma+E_1(\sigma)+E_2(\omega)=-(\omega-k)\theta_2+\sigma\theta_1+E_2(k)-E_3(\theta_1),$$
$$\rho(E_2,E_3)=-2\theta_2\sigma-E_1(\omega)-E_2(\sigma)=(\omega-k)\theta_1-\sigma\theta_2-E_1(k)-E_3(\theta_2).$$

From (11) and the fact that $\rho(E_1,E_2)=0$, it follows immediately that

$$k\sigma=0. \tag{12}$$

Let us suppose that $k\neq0$ at a point $p\in M$. Then there exists an open neighborhood U around p such that $k\neq0$ on U, and (12) implies that $\sigma=0$ on U. Consequently, the frame field $\{E_1,E_2,E_3\}$ is only determined up to a rotation of the vectors E_1 and E_2, i.e., we can replace it by a new frame field,

$$E_1'=\sin\varphi E_1+\cos\varphi E_2,\quad E_2'=-\cos\varphi E_1+\sin\varphi E_2,\quad E_3'=E_3.$$

In this new frame field, we have

$$\nabla_{E_3'}E_1' = -(E_3(\varphi)-k)E_2' = k'E_2',$$

and choosing the function $\varphi \in C^\infty(M)$ to be a solution of the differential equation

$$E_3(\varphi) = k,$$

we see that $k'=0$. As a consequence, we can always specify the (local) orthonormal frame field $\{E_1,E_2,E_3\}$ in such a way that $k=0$.

Expressing (5) using (11), we then obtain the equations

$$2(\omega^2-\sigma^2)=\alpha, \tag{13}$$

$$E_3(\omega)=E_3(\sigma)=0, \tag{14}$$

$$E_3(\theta_1)-\sigma\theta_1+\omega\theta_2=0, \tag{15}$$

$$E_3(\theta_2)-\omega\theta_1+\sigma\theta_2=0, \tag{16}$$

$$E_1(\sigma)+E_2(\omega)+2\theta_1\sigma=0, \tag{17}$$

$$E_1(\omega)+E_2(\sigma)+2\theta_2\sigma=0, \tag{18}$$

$$E_1(\theta_1)+E_2(\theta_2)+\theta_1^2+\theta_2^2+\beta=0. \tag{19}$$

It is easily seen from (10) that the Lie brackets of the orthonormal vectors E_1,E_2,E_3 are given by

$$[E_1,E_2]=\theta_2E_1-\theta_1E_2-2\omega E_3, \tag{20}$$

$$[E_1,E_3]=\sigma E_1+\omega E_2, \tag{21}$$

$$[E_2,E_3]=-\omega E_1-\sigma E_2. \tag{22}$$

Conversely, the Koszul formula,[24]

$$2g(\nabla_X Y,Z)=X(g(Y,Z))+Y(g(Z,X))-Z(g(X,Y))-g(X,[Y,Z])+g(Y,[Z,X])+g(Z,[X,Y]),$$

for all $X,Y,Z\in\mathfrak{X}(M)$, immediately shows that (20)–(22) imply (10).

Summarizing, we obtain the following.

Theorem 1: A three-dimensional Riemannian manifold (M,g) has constant principal Ricci curvatures given by (1) if and only if, in the neighborhood of each point $p\in M$, there exists an orthonormal frame field $\{E_1,E_2,E_3\}$ and functions ω, σ, θ_1, and θ_2, such that (13)–(22) hold.

Remark 1: It is easily seen that, replacing E_1 by $-E_1$ and E_3 by $-E_3$ if necessary, we can always choose the orthonormal frame field $\{E_1,E_2,E_3\}$ in such a way that $\sigma\geqslant 0$ and $\omega\geqslant 0$.

III. CURVATURE INVARIANTS AND HOMOGENEITY

As we have already mentioned in Sec. I, one of the main topics in the study of curvature homogeneous manifolds is the investigation of the existence of nonhomogeneous curvature homogeneous manifolds. It is therefore important to have a simple criterion to decide if a given curvature homogeneous manifold is locally homogeneous or not, and the aim of this section is to prove such a criterion for the case of three-dimensional Riemannian manifolds with constant principal Ricci curvatures $\rho_1=\rho_2\neq\rho_3$. To this purpose, let us assume that (M,g) is such a mani-

fold, and that the orthonormal frame field $\{E_1,E_2,E_3\}$ and the functions σ, ω, θ_1, and θ_2 are constructed as in Sec. II, i.e., they satisfy Eqs. (13)–(22). We are then able to prove the following.

Theorem 2: The curvature homogeneous Riemannian manifold (M,g) determined by (13)–(22) is (locally) homogeneous if and only if σ and ω are constant along M. Moreover, all locally homogeneous manifolds corresponding to given constants $\sigma,\omega,\alpha=2(\omega^2-\sigma^2)$ and β are locally isometric.

Proof: It was shown in Ref. 25 that a three-dimensional Riemannian manifold (M,g) with constant principal Ricci curvatures,

$$\rho_1=\rho_2=\beta\neq\alpha=\rho_3,$$

is locally homogeneous if and only if $\|\nabla\rho\|^2=\Sigma_{i,j,k=1}^{3}(\nabla_{E_i}\rho(E_j,E_k))^2$ is constant along M, and that the constants α, β, and $\|\nabla\rho\|^2$ give complete isometry invariants for (the universal covering manifold of) this manifold. From (5) and (10) we can easily compute that

$$\|\nabla\rho\|^2=4(\alpha-\beta)^2(\sigma^2+\omega^2),$$

which, together with (13), implies the required result. ■

IV. NONHOMOGENEOUS SOLUTIONS

We have shown in Theorem 1 that the necessary and sufficient condition for a three-dimensional Riemannian manifold to have constant principal Ricci curvatures as in (1) is the existence of a (local) orthonormal frame field $\{E_1,E_2,E_3\}$ and functions σ, ω, θ_1, and θ_2 satisfying (13)–(22). Moreover, we have seen in Sec. III that such a manifold is nonhomogeneous if and only if σ (and hence ω) is nonconstant along M. The aim of this section is to investigate the (local) existence of such nonhomogeneous manifolds. In Ref. 21, McManus claims that, if $\alpha\neq0$, the only solutions of the differential equations (13)–(22) are given by $\theta_1=\theta_2=\beta=0$, yielding that ω is constant along M and implying that no nonhomogeneous solutions exist. We will show that, if $\alpha\neq0$, the complete solution of the system of differential equations (13)–(22) is determined by (the solutions of) a system of two (partial) differential equations of second order, and we will prove the existence of solutions to these differential equations (for any choice of $\alpha\neq0$ and β), thereby pointing out and correcting the mistake made in Ref. 21. In the case where $\alpha=0$, we will determine the complete solution of the system of differential equations (13)–(22). It should be pointed out that a number of the expressions in this section were already obtained by McManus in Ref. 21, but are inserted here for easy reference.

We remark that, as M is supposed to be a nonhomogeneous manifold, the functions σ and ω are nonconstant and hence σ and ω are nonzero almost everywhere on M. For the sake of simplicity we will therefore, in what follows, restrict our attention to the generic points in M, i.e., the points p such that ω and σ are nonzero at p (and hence in a neighborhood U of p).

We start our computation by choosing a coordinate system (x,y',z') on a (possibly smaller) neighborhood U in M such that, for all points $p\in U$,

$$\frac{\partial}{\partial x}(p)=E_3(p),$$

and we write

$$E_1=a\frac{\partial}{\partial x}+b\frac{\partial}{\partial y'}+c\frac{\partial}{\partial z'},\quad E_2=d\frac{\partial}{\partial x}+e\frac{\partial}{\partial y'}+f\frac{\partial}{\partial z'}. \tag{23}$$

With respect to such a coordinate system, (14) implies that

$$\frac{\partial \sigma}{\partial x}=\frac{\partial \omega}{\partial x}=0, \tag{24}$$

while (15) and (16) take the form

$$\frac{\partial \theta_1}{\partial x}=\sigma\theta_1-\omega\theta_2, \quad \frac{\partial \theta_2}{\partial x}=\omega\theta_1-\sigma\theta_2, \tag{25}$$

and (21) and (22) yield that

$$\begin{aligned} &\frac{\partial a}{\partial x}=-\sigma a-\omega d, \quad \frac{\partial b}{\partial x}=-\sigma b-\omega e, \quad \frac{\partial c}{\partial x}=-\sigma c-\omega f, \\ &\frac{\partial d}{\partial x}=\omega a+\sigma d, \quad \frac{\partial e}{\partial x}=\omega b+\sigma e, \quad \frac{\partial f}{\partial x}=\omega c+\sigma f. \end{aligned} \tag{26}$$

Differentiating (25) with respect to x and using (13), (24), and (25), we see that

$$\frac{\partial^2 \theta_1}{\partial x^2}=-\frac{\alpha}{2}\theta_1.$$

Hence, the solution of the differential equations (25) depends on the sign of α, and in what follows we will therefore consider the cases $\alpha>0$, $\alpha<0$, and $\alpha=0$ separately.

Case I: $\alpha<0$.

In this case, putting $\lambda=\sqrt{-\alpha/2}$, (25) yields

$$\begin{aligned} \theta_1&=A(y',z')e^{\lambda x}+B(y',z')e^{-\lambda x}, \\ \theta_2&=-\frac{\lambda-\sigma}{\omega}Ae^{\lambda x}+\frac{\lambda+\sigma}{\omega}Be^{-\lambda x}, \end{aligned} \tag{27}$$

while (26) implies that

$$\begin{aligned} a&=a_1(y',z')e^{\lambda x}+a_2(y',z')e^{-\lambda x}, \\ b&=b_1(y',z')e^{\lambda x}+b_2(y',z')e^{-\lambda x}, \\ c&=c_1(y',z')e^{\lambda x}+c_2(y',z')e^{-\lambda x}, \\ d&=-\frac{\lambda+\sigma}{\omega}a_1e^{\lambda x}+\frac{\lambda-\sigma}{\omega}a_2e^{-\lambda x}, \\ e&=-\frac{\lambda+\sigma}{\omega}b_1e^{\lambda x}+\frac{\lambda-\sigma}{\omega}b_2e^{-\lambda x}, \\ f&=-\frac{\lambda+\sigma}{\omega}c_1e^{\lambda x}+\frac{\lambda-\sigma}{\omega}c_2e^{-\lambda x}. \end{aligned} \tag{28}$$

Now, let us suppose that (x,y,z) is a new coordinate system on U, such that

$$y=F(y',z'), \quad z=G(y',z').$$

With respect to this new coordinate system, the frame field $\{E_1,E_2,E_3\}$ can be written in the form

$$E_1=a\frac{\partial}{\partial x}+\left(b\frac{\partial F}{\partial y'}+c\frac{\partial F}{\partial z'}\right)\frac{\partial}{\partial y}+\left(b\frac{\partial G}{\partial y'}+c\frac{\partial G}{\partial z'}\right)\frac{\partial}{\partial z},$$

$$E_2=d\frac{\partial}{\partial x}+\left(e\frac{\partial F}{\partial y'}+f\frac{\partial F}{\partial z'}\right)\frac{\partial}{\partial y}+\left(e\frac{\partial G}{\partial y'}+f\frac{\partial G}{\partial z'}\right)\frac{\partial}{\partial z},$$

$$E_3=\frac{\partial}{\partial x},$$

and using (28) it is then easily seen that the functions F and G can be chosen in such a way that

$$b_2(y,z)=c_1(y,z)=0,\quad b_1(y,z)c_2(y,z)\neq 0.$$

Using (27) and (28) in (17), we find that

$$A=\frac{\lambda b_1}{2\sigma(\sigma-\lambda)}\frac{\partial\sigma}{\partial y},\quad B=-\frac{\lambda c_2}{2\sigma(\sigma+\lambda)}\frac{\partial\sigma}{\partial z},\tag{29}$$

and (18) is an immediate consequence of (29). A straightforward computation using (27), (28), and (29) then shows that (20) is equivalent to

$$-2\lambda^2a_2b_1+\lambda c_2b_1\frac{2\sigma-\lambda}{\sigma(\sigma-\lambda)}\frac{\partial\sigma}{\partial z}-2\lambda c_2\frac{\partial b_1}{\partial z}=0,\tag{30}$$

$$-2\lambda^2a_1c_2-\lambda c_2b_1\frac{2\sigma+\lambda}{\sigma(\sigma+\lambda)}\frac{\partial\sigma}{\partial y}+2\lambda b_1\frac{\partial c_2}{\partial y}=0,\tag{31}$$

$$b_1\frac{\partial a_2}{\partial y}-c_2\frac{\partial a_1}{\partial z}+\frac{c_2a_1}{b_1}\frac{\partial b_1}{\partial z}-\frac{a_2b_1}{c_2}\frac{\partial c_2}{\partial y}+\frac{\omega^2}{\lambda}=0.\tag{32}$$

Finally, solving a_1 and a_2 from (31) and (30) and substituting in (32) and (19), we obtain two partial differential equations of second order in σ and $\varphi=b_1c_2$:

$$\varphi\frac{\partial^2}{\partial y\,\partial z}\left(\ln\left(\frac{\sigma^2(\sigma^2-\lambda^2)}{\varphi^2}\right)\right)+2(\sigma^2-\lambda^2)=0,$$

$$-2\lambda^2\frac{\varphi}{\sigma}\frac{\partial^2\sigma}{\partial y\,\partial z}+2\lambda^2\varphi\frac{2\sigma^2-\lambda^2}{\sigma^2(\sigma^2-\lambda^2)}\frac{\partial\sigma}{\partial y}\frac{\partial\sigma}{\partial z}-\beta(\sigma^2-\lambda^2)=0.$$

A straightforward application of the Cauchy-Kowalewski theorem yields that, at least in the analytic case, there exists a family of solutions for Eqs. (13)–(22), depending on four functions of one variable (the initial conditions for the functions φ and σ), and one function of two variables (as $\varphi=b_1c_2$).

Case II: $\alpha>0$.

The computations in this case are very similar to those of Case I, although they turn out to be more complicated. We start by putting $\lambda=\sqrt{\alpha/2}$. Then (15) and (16) yield that

$$\theta_1=A(y,z)\cos\lambda x+B(y,z)\sin\lambda x,$$

$$\theta_2=\frac{\sigma A-\lambda B}{\omega}\cos\lambda x+\frac{\lambda A+\sigma B}{\omega}\sin\lambda x,$$

while (21) and (22) imply that

$$\begin{aligned}
a&=a_1(y,z)\cos\lambda x+a_2(y,z)\sin\lambda x,\\
b&=b_1(y,z)\cos\lambda x+b_2(y,z)\sin\lambda x,\\
c&=c_1(y,z)\cos\lambda x+c_2(y,z)\sin\lambda x,\\
d&=-\frac{\sigma a_1+\lambda a_2}{\omega}\cos\lambda x+\frac{\lambda a_1-\sigma a_2}{\omega}\sin\lambda x,\\
e&=-\frac{\sigma b_1+\lambda b_2}{\omega}\cos\lambda x+\frac{\lambda b_1-\sigma b_2}{\omega}\sin\lambda x,\\
f&=-\frac{\sigma c_1+\lambda c_2}{\omega}\cos\lambda x+\frac{\lambda c_1-\sigma c_2}{\omega}\sin\lambda x.
\end{aligned}\tag{33}$$

As in the previous case, we can choose a new coordinate system,

$$x,\quad y=F(y',z'),\quad z=G(y',z'),$$

such that

$$b_2(y,z)=c_1(y,z)=0,\quad b_1(y,z)c_2(y,z)\neq 0,$$

and Eq. (17) now yields that

$$A(y,z)=\frac{1}{2\omega\sigma}\left(b_1\sigma\frac{\partial\omega}{\partial y}-b_1\omega\frac{\partial\sigma}{\partial y}+c_2\lambda\frac{\partial\omega}{\partial z}\right),\tag{34}$$

$$B(y,z)=\frac{1}{2\omega\sigma}\left(c_2\sigma\frac{\partial\omega}{\partial z}-c_2\omega\frac{\partial\sigma}{\partial z}-b_1\lambda\frac{\partial\omega}{\partial y}\right),\tag{35}$$

while (18) is again an immediate consequence of (34) and (35).

As before, substituting these expressions in (20) yields that

$$-b_1c_2\frac{\partial(\sigma\omega)}{\partial z}-\lambda b_1^2\frac{\partial\omega}{\partial y}+2a_1b_1\lambda\omega\sigma+2\omega\sigma c_2\frac{\partial b_1}{\partial z}=0,$$

$$b_1c_2\frac{\partial(\sigma\omega)}{\partial y}-\lambda c_2^2\frac{\partial\omega}{\partial z}+2a_2c_2\lambda\omega\sigma-2\omega\sigma b_1\frac{\partial c_2}{\partial y}=0.$$

These equations can be solved for a_1 and a_2, and from (19) and (20) we obtain two partial differential equations of second order in σ and b_1 (depending on a free parameter c_2), which are of a rather complicated nature and will therefore be omitted. An argument similar to that in Case I then shows that, at least in the analytic case, there exists a family of solutions that depends on four functions of one variable (the initial conditions for the functions σ and b_1) and one function of two variables (namely c_2).

Case III: $\alpha=0$.

In this case, our choice of the vector fields E_1 and E_2 (see Remark 1) implies that $\sigma=\omega$. From (17), (18), and the fact that $\sigma\neq 0$, we then obtain that

$$\theta_1=\theta_2=\theta,$$

and denoting by $\{E_1',E_2',E_3'\}$ the new frame field (again consisting of principal Ricci directions) given by

$$E_1'=\frac{\sqrt{2}}{2}(E_1-E_2),\quad E_2'=\frac{\sqrt{2}}{2}(E_1+E_2),\quad E_3'=E_3,$$

Eqs. (13)–(22) can be written as

$$E_3'(\sigma)=E_3'(\theta)=0, \tag{36}$$

$$E_2'(\sigma)+\sqrt{2}\,\theta\sigma=0, \tag{37}$$

$$\sqrt{2}E_2'(\theta)+2\theta^2+\beta=0, \tag{38}$$

$$[E_1',E_2']=\sqrt{2}\,\theta E_1'-2\sigma E_3', \tag{39}$$

$$[E_1',E_3']=2\sigma E_2', \tag{40}$$

$$[E_2',E_3']=0. \tag{41}$$

From (41) we see that we can choose a coordinate system (x,y,z), such that

$$E_1'=a\frac{\partial}{\partial x}+b\frac{\partial}{\partial y}+c\frac{\partial}{\partial z},\quad E_2'=\frac{\partial}{\partial y},\quad E_3'=\frac{\partial}{\partial x}. \tag{42}$$

With respect to such a coordinate system, (36) implies that

$$\frac{\partial\sigma}{\partial x}=\frac{\partial\theta}{\partial x}=0,$$

while we obtain from (37) and (38) that

$$\sqrt{2}\frac{\partial\theta}{\partial y}+2\theta^2+\beta=0, \tag{43}$$

$$\frac{\partial\sigma}{\partial y}+\sqrt{2}\,\theta\sigma=0, \tag{44}$$

and (39) and (40) take the form

$$\begin{gathered}\frac{\partial a}{\partial x}=0,\quad \frac{\partial b}{\partial x}=-2\sigma,\quad \frac{\partial c}{\partial x}=0,\\ \frac{\partial a}{\partial y}=-\sqrt{2}\,\theta a+2\sigma,\quad \frac{\partial b}{\partial y}=-\sqrt{2}\,\theta b,\quad \frac{\partial c}{\partial y}=-\sqrt{2}\,\theta c.\end{gathered} \tag{45}$$

(1) $\beta>0$. In this case, the complete solution of (43) is given by

$$\theta=\sqrt{\frac{\beta}{2}}\tan(-\sqrt{\beta}y+f_1(z)).$$

Substituting this expression in (44), we then obtain that

$$\sigma=\frac{f_2(z)}{\cos(-\sqrt{\beta}y+f_1(z))},$$

and it follows from (45) that

$$a=\frac{2f_2(z)y+f_3(z)}{\cos(-\sqrt{\beta}y+f_1(z))},\quad b=\frac{-2f_2(z)x+f_4(z)}{\cos(-\sqrt{\beta}y+f_1(z))},\quad c=\frac{f_5(z)}{\cos(-\sqrt{\beta}y+f_1(z))},\tag{46}$$

completing the integration of (13)–(22).

(2) $\beta<0$. The complete solution of (43) is now given by

$$\theta=\sqrt{-\frac{\beta}{2}}\tanh(\sqrt{-\beta}y+f_1(z)).$$

Again substituting this expression in (44), we then obtain that

$$\sigma=\frac{f_2(z)}{\cosh(\sqrt{-\beta}y+f_1(z))},$$

and it follows from (45) that

$$a=\frac{2f_2(z)y+f_3(z)}{\cosh(\sqrt{-\beta}y+f_1(z))},\quad b=\frac{-2f_2(z)x+f_4(z)}{\cosh(\sqrt{-\beta}y+f_1(z))},\quad c=\frac{f_5(z)}{\cosh(\sqrt{-\beta}y+f_1(z))},\tag{47}$$

which concludes the integration of (13)–(22) in this case.

V. ISOMETRIC NONHOMOGENEOUS SOLUTIONS

In the previous section we have determined, for each choice of two constants $\alpha\neq\beta$, a family of nonhomogeneous Riemannian metrics whose principal Ricci curvatures are given by (1). This family of metrics depends (at least in the analytic case) on four functions of one variable and one function of two variables (if $\alpha\neq0$) or on five functions of one variable (if $\alpha=0$). In this section, we will investigate which of these metrics are locally isometric, thereby giving a new proof of the main results of Ref. 16.

Let (M,g) and (M',g') be (nonhomogeneous) three-dimensional Riemannian manifolds with constant principal Ricci curvatures $\alpha\neq\beta$, and let $\{E_1,E_2,E_3\}$ (resp., $\{E_1',E_2',E_3'\}$) be the (local) frame field along M (resp., M') consisting of principal Ricci directions constructed as in Sec. II. Then we have the following.

Theorem 3: The differentiable mapping $F:M\to M'$ is a (local) isometry if and only if

$$F_*E_1=\epsilon E_1',\quad F_*E_2=\epsilon E_2',\quad F_*E_3=E_3',$$

or

$$F_*E_1=\epsilon E_2',\quad F_*E_2=\epsilon E_1',\quad F_*E_3=-E_3',\quad \epsilon=\pm1.\tag{48}$$

Proof: First, if F is a local isometry of (M,g) and (M',g'), then it preserves (up to the sign) the simple principal Ricci direction E_3. As F also preserves the Levi Civita connection, it then preserves the shear tensor of E_3 and hence its eigendirections E_1 and E_2, and (48) follows from our choice of sign for σ and ω.

Conversely, if F satisfies (48), it maps a local orthonormal frame field along M into a local orthonormal frame field along M', proving that F is a local isometry. ■

Now, let us first assume that $\alpha<0$ and that the frame field $\{E_1,E_2,E_3\}$ is determined by (23) and (28). Then it is easily seen that the differentiable mapping $F:M\to M'$, given by

$$x'=x'(x,y,z), \quad y'=y'(x,y,z), \quad z'=z'(x,y,z),$$

satisfies (48) if and only if

$$x'=\pm x+f_1(y,z), \quad y'=f_2(y), \quad z'=f_3(z),$$

or

$$x'=\pm x+f_1(y,z), \quad y'=f_2(z), \quad z'=f_3(y).$$

Using a similar (but more complicated) argument in the case $\alpha>0$, we conclude that, in the case $\alpha\neq 0$, there is a family of isometries depending on two functions of one variable and one function of two variables.

In the case where $\alpha=0$, let us assume that the frame field is given by (42) and (46) [or (47)]. An argument similar to the one above then shows that the differentiable mapping $F:M\to M'$ satisfies (48) if and only if

$$x'=x+f_1(z), \quad y'=y+f_2(z), \quad z'=f_3(z)$$

(or a similar form for the other cases), and we conclude that, in this case, the family of isometries depends on three functions of one variable.

Comparing the family of solutions of the Eqs. (13)–(22) discovered in Sec. IV with the number of isometries for these metrics found in Sec. V, we obtain the following result from Ref. 16.

Theorem 4: Let $\alpha\neq\beta$ be constants. Then there exists a family of local nonhomogeneous Riemannian metrics, which are not (locally) isometric and whose constant principal Ricci curvatures satisfy (1), and this family depends on two arbitrary functions of one variable.

Remark 2: In the case $\alpha=0$, we know that the Riemannian metric g is completely determined by the orthonormal frame field $\{E_1,E_2,E_3\}$ given by (42) and (46) [or (47)]. Applying a suitable local isometry F of the form

$$x'=x+F_1(z), \quad y'=y+F_2(z), \quad z'=F_3(z),$$

we can map the frame field $\{E_1,E_2,E_3\}$ into the frame field

$$E_1'=a'\frac{\partial}{\partial x'}+b'\frac{\partial}{\partial y'}+c'\frac{\partial}{\partial z'}, \quad E_2'=\frac{\partial}{\partial y'}, \quad E_3'=\frac{\partial}{\partial x'},$$

where

$$a'=\frac{y'\varphi_2(z')}{\cos(-\sqrt{\beta}y'+\varphi_1(z'))},$$

$$b'=\frac{-x'\varphi_2(z')}{\cos(-\sqrt{\beta}y'+\varphi_1(z'))},$$

$$c' = \frac{\varphi_2(z')}{\cos(-\sqrt{\beta}y' + \varphi_1(z'))},$$

resp.,

$$a' = \frac{y'\varphi_2(z')}{\cosh(\sqrt{-\beta}y' + \varphi_1(z'))},$$

$$b' = \frac{-x'\varphi_2(z')}{\cosh(\sqrt{-\beta}y' + \varphi_1(z'))},$$

$$c' = \frac{\varphi_2(z')}{\cosh(\sqrt{-\beta}y' + \varphi_1(z'))},$$

showing that all these metrics are locally isometric to the Riemannian metrics of the form

$$g = \omega_1^2 + \omega_2^2 + \omega_3^2,$$

with

$$\omega_1 = (\mu_1(z')\cos(-\sqrt{\beta}y') + \mu_2(z')\sin(-\sqrt{\beta}y'))dz',$$

$$\omega_2 = dy' + x'dz', \quad \omega_3 = dx' - y'dz',$$

resp.,

$$\omega_1 = (\mu_1(z')\cosh(\sqrt{-\beta}y') + \mu_2(z')\sinh(\sqrt{-\beta}y'))dz',$$

$$\omega_2 = dy' + x'dz', \quad \omega_3 = dx' - y'dz',$$

which are exactly the metrics constructed in Ref. 6, the functions μ_1 and μ_2 being the two functions of one variable given by Theorem 4.

Summation of power series by continued exponentials

Carl M. Bender
Department of Physics, Washington University, St. Louis, Missouri 63130

Jade P. Vinson
Department of Mathematics, Washington University, St. Louis, Missouri 63130

(Received 5 June 1995; accepted for publication 14 February 1996)

It is proposed that a power series may be summed (analytically continued outside its radius of convergence) by converting it to a continued exponential, which is a structure of the form $a_0 \exp(a_1 z \exp(a_2 z \exp(a_3 z \exp(a_4 z \ldots))))$. The continued-exponential coefficients $\{a_i\}$ for a given function $f(z)$ are determined by equating the Taylor coefficients of the continued exponential with those of $f(z)$. (The coefficients $\{a_i\}$ have a combinatoric interpretation; the nth Taylor coefficient enumerates all $n+1$-vertex tree graphs whose vertex amplitudes are $\{a_i\}$.) Continued exponentials have remarkable convergence properties. When a power series has a nonzero radius of convergence, the corresponding continued exponential often converges in a heart-shaped region Ω, whose cusp is determined by the nearest zero or singularity of the function being approximated. The convergence region Ω contains and is much larger than the circle of convergence of the power series. Outside Ω, the complex plane is divided up into an elaborate patchwork of regions in which the continued exponential may either diverge or else approach an N-cycle, $N=2,3,4,\ldots$.

I. INTRODUCTION

A variety of mathematical techniques have been invented to accelerate the rate of convergence of a slowly convergent series and to assign a finite value to the sum of a divergent series. Such techniques are generally referred to as *summation methods*.[1] Summation methods are extremely useful to theoretical and mathematical physicists. The most powerful analytic tool for solving hard problems in theoretical physics is perturbation theory. However, perturbation series are notoriously badly behaved; they are either slowly convergent or, very often, they are divergent. Summation methods are crucial because they provide a way to recover useful physical information from perturbative calculations.

Consider a perturbation series in the form of a power series

$$\sum_{n=0}^{\infty} c_n z^n. \tag{1.1}$$

Here z is called the perturbation parameter and $\{c_n\}$ are the perturbation coefficients. One technique commonly used to improve the rate of convergence of such a series and/or to assign a meaningful sum to the series is called Padé summation.[2] To sum a formal power series using Padé summation one converts the series to a continued fraction. Continued-fraction coefficients are obtained by expanding the continued fraction as a power series, which is then identified term by term with the formal power series to be summed. A truncated continued fraction is a rational function; the rational functions obtained by successive truncation are called Padé approximants. Even if the perturbation series diverges, the Padé approximants often form a rapidly convergent sequence whose limiting value is physically meaningful.[3]

Recall that when a power series converges, its region of convergence is a disc in the complex plane. Generally, a summation method enlarges this region of convergence. For example, when one converts a power series representing a Stieltjes function [such as $\log(1+z)$] to a continued fraction, the sequence of Padé approximants converges in a cut plane that contains the disc.

In this paper we propose a new method for summing power series. The idea is to convert the series to a *continued exponential*, an infinite tower of exponentials of the form

$$a_0 \exp(a_1 z \exp(a_2 z \exp(a_3 z \exp(a_4 z \ldots)))). \tag{1.2}$$

This continued exponential is said to converge for a particular value of z if the sequence $E_0 \equiv a_0$, $E_1 \equiv a_0 \exp(a_1 z)$, $E_2 \equiv a_0 \exp(a_1 z \exp(a_2 z))$, ... converges.[4] We will see that continued exponentials often converge in a larger region than their associated Taylor series. When a continued exponential does not converge, the sequence $\{E_n\}$ may either grow out of bounds or it may approach a limit cycle. This limit cycle may be of finite length or it may even be infinite. [Later in this section we generalize the form of the continued exponential in Eq. (1.2) by replacing the structure $a_n z$ by $a_n z^{b_n}$. For example, to expand $\cos z$ as a continued exponential we take $b_n = 2$ for all $n \geq 1$.]

Having defined a continued exponential, we next consider some elementary operations that may be performed. For example, multiplying a continued exponential by a constant, or raising a continued exponential to a power are trivial. Unfortunately, most arithmetical operations, such as adding or multiplying two continued exponentials, are impossible.

It is straightforward to expand a continued exponential of the form $a_0 e^{a_1 z e^{a_2 z \cdots}}$ as a Taylor series. The first n terms of this Taylor series are obtained by truncating the continued exponential after the first n coefficients, expanding the finite tower as a Taylor series, and then retaining the first n terms of this Taylor series. The z^n term ($n>0$) of the Taylor series has 2^{n-1} contributions of the form $a_0 a_1^{j_1} \ldots a_k^{j_k}$ with $j_1 + \ldots + j_k = n$, where $j_i > 0$ for all i. Explicitly, the Taylor series is

$$a_0 + \sum_{n=1}^{\infty} \sum_{j_1 + \ldots + j_k = n} \frac{j_1^{j_2} j_2^{j_3} \cdots j_{k-1}^{j_k}}{j_1! j_2! j_3! \cdots j_k!} a_0 a_1^{j_1} \ldots a_k^{j_k} z^n. \tag{1.3}$$

To convert the power series in Eq. (1.1) to the continued exponential in Eq. (1.2) we expand the continued exponential as a Taylor series and set this series equal to the original power series. This gives an infinite sequence of equations that relate the Taylor coefficients $\{c_i\}$ to the continued-exponential coefficients $\{a_i\}$:

$$\begin{aligned}
c_0 &= a_0, \\
c_1 &= a_1 a_0, \\
c_2 &= a_0 a_1 a_2 + \tfrac{1}{2} a_0 a_1^2, \\
c_3 &= a_0 a_1 a_2 a_3 + \tfrac{1}{2} a_0 a_1 a_2^2 + a_0 a_1^2 a_2 + \tfrac{1}{6} a_0 a_1^3, \\
c_4 &= a_0 a_1 a_2 a_3 a_4 + \tfrac{1}{2} a_0 a_1 a_2 a_3^2 + a_0 a_1 a_2^2 a_3 + a_0 a_1^2 a_2 a_3 \\
&\quad + \tfrac{1}{6} a_0 a_1 a_2^3 + a_0 a_1^2 a_2^2 + \tfrac{1}{2} a_0 a_1^3 a_2 + \tfrac{1}{24} a_0 a_1^4,
\end{aligned} \tag{1.4}$$

and so on. These equations may be solved sequentially for the continued exponential coefficients:

$$a_0=c_0,$$

$$a_1=c_1/c_0,$$

$$a_2=\frac{2c_0c_2-c_1^2}{2c_0c_1}, \tag{1.5}$$

$$a_3=\frac{24c_0^2c_1c_3-12c_0^2c_2^2-12c_0c_1^2c_2+5c_1^4}{24c_0^2c_1c_2-12c_0c_1^3},$$

$$\begin{aligned}a_4=&(1152c_0^4c_1^2c_2c_4-576c_0^3c_1^4c_4-576c_0^4c_1^2c_3^2-576c_0^4c_1c_2^2c_3+576c_0^3c_1^3c_2c_3+48c_0^2c_1^5c_3\\&+240c_0^4c_2^4-480c_0^3c_1^2c_2^3+456c_0^2c_1^4c_2^2-264c_0c_1^6c_2+47c_1^8)/(1152c_0^4c_1^2c_2c_3-576c_0^3c_1^4c_3\\&-576c_0^4c_1c_2^3-288c_0^3c_1^3c_2^2+528c_0^2c_1^5c_2-120c_0c_1^7),\end{aligned}$$

and so on.

There is an *efficient* computational procedure for converting a formal power series to a continued exponential. This iterative procedure relies on taking logarithms and uses the first N terms of the power series as input. At each step we identify the leading term in the power series as the next term in the continued exponential. Then we normalize the power series by dividing by the first term and take its logarithm according to the formula

$$\log(1+x)=x-\tfrac{1}{2}x^2+\tfrac{1}{3}x^3-\ldots.$$

The result of this process is a continued exponential of a more general form: $a_0z^{b_0}e^{a_1z^{b_1}e^{a_2z^{b_2}\cdots}}$. In this representation the monomial $a_0z^{b_0}$ is the leading term of the power series. Note that the first N coefficients of the generalized continued exponential can be calculated (using MAPLE, Mathematica, or MACSYMA) in $O(N^4)$ time.[5]

There is only one example for which both the continued exponential coefficients and the Taylor series coefficients are known in closed form:

$$e^{ze^{ze^{ze^{z\cdots}}}}=\sum_{n=0}^{\infty}\frac{(n+1)^{n-1}}{n!}z^n. \tag{1.6}$$

For this example one can verify that $a_n=1$ and $c_n=(n+1)^{n-1}/n!$ satisfy Eqs. (1.4) and (1.5) and that the right side of Eq. (1.6) has the form in Eq. (1.3). The Taylor series on the right side of Eq. (1.6) converges in a disc of radius $1/e$ about the origin. However, as we will see, the continued exponential converges in a larger region whose shape is similar to that of a cardioid. The boundary of this heart-shaped region is given by the parametric equations $r=e^{-\cos t}$ and $\theta=t-\sin t$, where $0\leq\theta<2\pi$.

If the continued exponential coefficients a_n approach a constant, then the region of convergence is the heart-shaped region above, scaled by an appropriate factor. For example, when the Taylor series for $1/(1-z)$ about $z=0$ is converted to a continued exponential, the resulting coefficients satisfy $\lim_{n\to\infty}a_n=1/e$. In this case, the region of convergence is a cardioid with the cusp at $z=1$. This cardioid is larger than the region of convergence of the Taylor series, which is the unit disk.

In general, the boundary of the region of convergence of a continued exponential is determined by the zeros and the singularities of the function being represented. For example, the continued exponential representations for the functions $1-z$ and $1/(1-z)$ have the same region of convergence; in the former case the function has a zero at $z=1$ and in the latter case the function

has a pole at $z=1$. In either case the cusp of the cardioid is located at $z=1$. The function $\cos z$ vanishes at $z=\pm\pi/2$. The continued exponential representation of this function converges in a double cardioid with cusps at $z=\pm\pi/2$. The function $1/\cos/tz$ converges in the same double cardioid.

The most remarkable aspects of continued exponentials become apparent when they do *not* converge. Outside this region of convergence the continued exponential sequence E_0, E_1, $E_2, \ldots$ may either grow out of bounds (like the partial sums of a Taylor series outside the disc of convergence) or it may converge to a cycle of length N, $N=2, 3, 4, \ldots$, or even an infinite limit cycle. (By an *infinite limit cycle* we mean an infinite bounded sequence that does not approach a finite limit cycle.) The boundary of the region in which the sequence $\{E_n\}$ is unbounded appears fractal.

In comparison, the convergence properties of Taylor series are much simpler. A Taylor series converges (geometrically) inside its circle of convergence and diverges outside the circle of convergence. The only portion of the complex plane where a Taylor series may exhibit interesting convergence behavior, such as the nonuniform convergence typical of Fourier series, is *on* the circle of convergence. However, the circle of convergence is a one-dimensional object, a set of measure zero in the complex plane. Continued exponentials are thus much more elaborate than Taylor series.

This paper is organized as follows. In Sec. II we show that continued exponentials have a combinatoric interpretation; the coefficient of z^n in the Taylor series of $a_0 e^{a_1 z e^{a_2 z \cdots}}$ represents the sum of the amplitudes of tree graphs having $n+1$ vertices. In Sec. III we present a detailed discussion of the continued exponential Eq. (1.6), whose coefficients are all unity. We compare the convergence of this continued exponential with that of the continued fraction and Taylor series representations of this function. Section IV considers the continued exponential expansions of the polynomial $1-z$, the trigonometric functions $\sin z$ and $\cos z$, an Airy function, and the Stieltjes function whose formal power series is $\Sigma_{n=0}^{\infty}(-1)^n n! z^n$. Section V examines the continued exponential expansions of quadratic polynomials. Some concluding remarks are given in Sec. VI.

II. CONTINUED EXPONENTIALS AND TREE GRAPHS

Continued exponentials have a strong connection with combinatorics.[6] When a continued exponential is expanded as a Taylor series as in Eq. (1.3) the coefficient of z^n in this series counts all rooted tree graphs having $n+1$ vertices.

A tree graph is a graph having no closed loops. A rooted tree graph begins at a particular vertex called the root, with which we associate the weight a_0. Every other vertex is connected by a unique path to the root. If the length of this path is k we assign the weight a_k to the vertex: vertices connected to the root by one edge are weighted a_1, and so on. Each tree graph is assigned a symmetry number, which is defined as the reciprocal of the size of the automorphism group of the graph. The coefficient

$$\frac{j_1^{j_2} j_2^{j_3} \cdots j_{k-1}^{j_k}}{j_1! j_2! \cdots j_k!} a_0 a_1^{j_1} \cdots a_k^{j_k} \tag{2.1}$$

is the sum of the symmetry numbers of all rooted tree graphs having j_i vertices at a distance i from the root.

Because Eq. (2.1) is the summand in Eq. (1.3) continued exponentials enumerate tree graphs. The z^n term enumerates *all* rooted tree graphs with n+1 vertices, accounting for symmetry. To illustrate this graph counting, consider the z^5 term of the continued exponential $a_0 e^{a_1 z e^{a_2 z \cdots}}$:

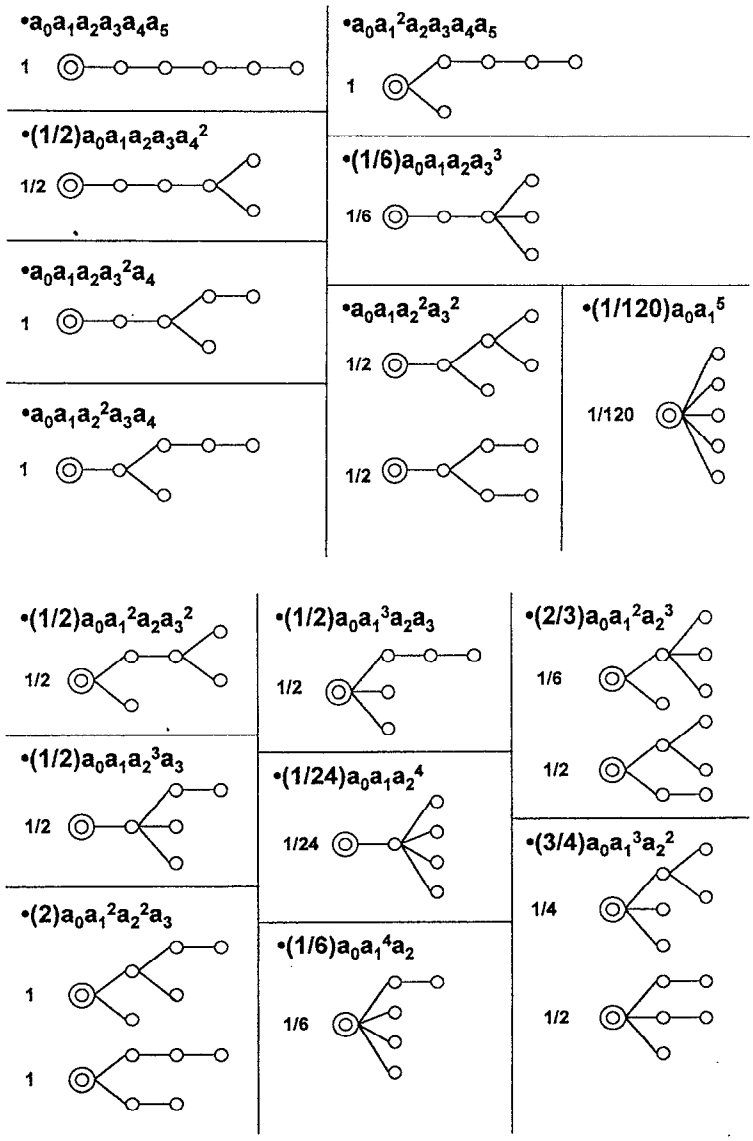

FIG. 1. Graphical representation of Eq. (2.2). Shown are all rooted tree graphs with six vertices a_i. Each vertex, indicated by a circle, lies at a distance i from the root, which is indicated by a double nested circle. The number adjacent to each graph is the symmetry number of that graph.

$$a_0a_1a_2a_3a_4a_5+\tfrac{1}{2}a_0a_1a_2a_3a_4^2+a_0a_1a_2a_3^2a_4+a_0a_1a_2^2a_3a_4+a_0a_1^2a_2a_3a_4+\tfrac{1}{6}a_0a_1a_2a_3^3$$
$$+a_0a_1a_2^2a_3^2+\tfrac{1}{2}a_0a_1^2a_2a_3^2+\tfrac{1}{2}a_0a_1^3a_2a_3+2a_0a_1^2a_2^2a_3+\tfrac{1}{2}a_0a1^3a_2a_3+\tfrac{1}{24}a_0a_1a_2^4+\tfrac{2}{3}a_0a_1^2a_2^3$$
$$+\tfrac{3}{4}a_0a_1^3a_2^2+\tfrac{1}{6}a_0a_1^4a_2+\tfrac{1}{120}a_0a_1^5. \tag{2.2}$$

This expression, which is the next in the sequence of coefficients given in Eq. (1.4), is a sum of terms of the form $a_0a_1^{j_1}\ldots a_k^{j_k}$ with $j_1+\ldots+j_k=5$, $j_i>0$. This term enumerates, according to symmetry number, all six-vertex rooted tree graphs with vertices a_j at a distance j from the root

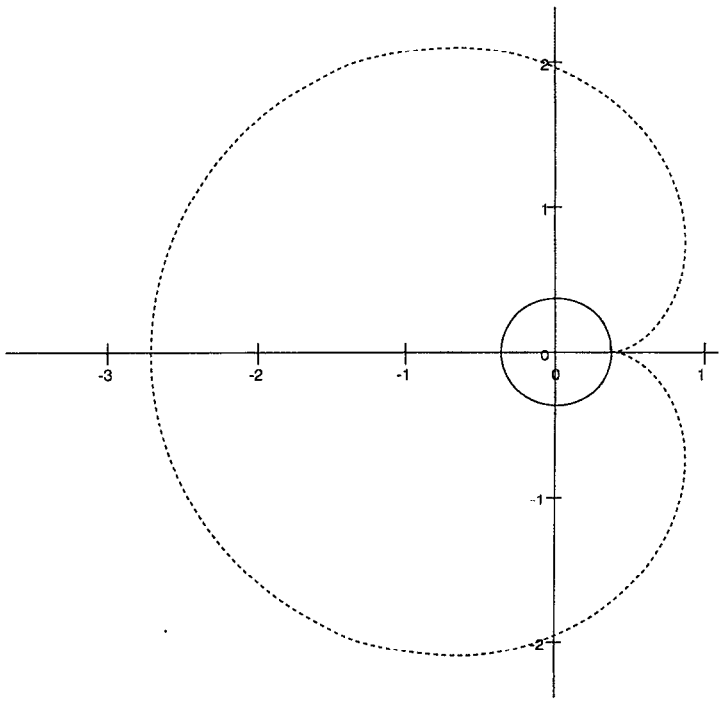

FIG. 2. The boundary (dashed line) of the region of convergence of the continued exponential whose coefficients are $a_n=1$. The shape of the boundary resembles that of a cardioid with a cusp located at $(1/e,0)$. We refer to this heart-shaped region as Ω. The boundary of Ω is given in implicit parametric form in Eq. (3.2). The solid line is the circle of convergence of the Taylor series representation of the same function.

of the tree (see Fig. 1). For example, the term $\frac{3}{4}a_0a_1^3a_2^2$ enumerates tree graphs with a root, three vertices at a distance 1 from the root, and 2 vertices at a distance 2 from the root. Up to isomorphism, there are two such graph trees. The first has 4 automorphisms, so its symmetry number is 1/4. The second tree has two automorphisms, so its symmetry number is 1/2. The sum of the symmetry numbers is $1/4+1/2=3/4$, the coefficient in the continued exponential expansion.

One can give another combinatoric interpretation of Eq. (1.3) as a composition theorem for the enumeration of certain subsets of symmetric semigroups and the corresponding sets of labeled functional digraphs.[7]

III. ILLUSTRATIVE EXAMPLE

Consider the differential equation initial-value problem

$$y'(z)=\frac{y^2}{1-zy},\quad y(0)=1. \tag{3.1}$$

The unique solution to this equation can be written in implicit form as $y=e^{zy}$. The solution to this functional equation that is analytic at $z=0$ has the Taylor series $\sum_{n=0}^{\infty}(n+1)^{n-1}z^n/n!$. The functional equation is also satisfied by the continued exponential $e^{ze^{ze^{z\cdots}}}$ in its region of convergence. For those values of z for which both the Taylor series and the continued exponential converge, they are equal. This equality is expressed formally by Eq. (1.6).

TABLE I. Comparison of convergence rates for the continued exponential, the continued fraction (Padé), and the Taylor series for the function $f(z)$, whose Taylor series is given in (3.1). Here we take $z=-0.2$, which lies inside the radius of convergence of the Taylor series. In the first column, the integer n represents the order of the approximation. Observe that while all three approximation schemes converge, the absolute errors (in parentheses) are significantly smaller for the continued fraction and the continued exponential. The exact value is $f(-0.2)=0.84457986749555\ldots$.

The Taylor series on the right side of Eq. (1.6) converges in a disc of radius $1/e$ about the origin. The convergence of the continued exponential is more complicated and has been investigated by Creutz and Sternheimer,[8–10] Baker and Rippon,[11–17] and others.[18–21] This continued exponential converges in a much larger region that contains the circle of convergence of the Taylor series. The boundary of the region of convergence of the continued exponential is similar in shape to that of a cardioid with a cusp located at $(1/e,0)$ (see Fig. 2). We will refer to this heart-shaped region as Ω. The boundary of Ω is given in implicit parametric form by

$$r=e^{-\cos t},$$
$$\theta=t-\sin t \quad (0\leqslant\theta<2\pi). \tag{3.2}$$

To derive Eq. (3.2) we argue as follows. In the complex plane, the continued exponential $e^{ze^{ze^{z\cdots}}}$ converges when the sequence $1, e^z, e^{ze^z}, \ldots$ converges. If it exists, the limit y_0 will be an attractive fixed point of the equation $y=e^{yz}$. Let $z=we^{-w}$. Then the fixed point y_0 is e^w. The multiplier of this fixed point (which determines whether it is attractive or repulsive) is w. Thus, the fixed point is attractive if and only if $|w|<1$. The region of convergence Ω is given by we^{-w} where $|w|<1$ and the boundary of Ω is given by $|w|=1$, which is equivalent to Eq. (3.2). The above argument shows that the rate of convergence at a point inside the cardioid is exponential.

It is instructive to compare numerically the convergence rates of the Taylor series and continued exponential in Eq. (1.6) and the continued fraction (Padé sequence) generated by the Taylor series. Tables I, II, and III list the first 12 terms in the continued exponential and continued fraction sequences and the first 12 partial sums of the Taylor series for three values of z: $z=-0.2$, $z=\frac{1}{2}i$, and $z=-1.5$. The point $z=-0.2$ lies inside the radius of convergence of the Taylor series. Observe that at this point the continued fraction and continued exponential converge far more rapidly than the Taylor series. The other two points lie inside the convergence region Ω but outside the radius of convergence of the Taylor series. For these two points the Padé converges more rapidly than the continued exponential but both the Padé and continued exponential provide a means of summing the Taylor series outside of its radius of convergence.

TABLE II. Same as in Table I, except that here we take $z=0.5i$, which lies outside the radius of convergence of the Taylor series. The continued exponential and continued fraction converge but the Taylor series diverges as n, the order of the approximation, increases. The exact value is $f(0.5i)=0.7852571487+0.3251992959i$.

Outside the convergence region Ω, the continued exponential sequence $E_0, E_1, E_2, \ldots$ behaves in a remarkable fashion. This sequence may either diverge (like the partial sums of a Taylor series outside the circle of convergence) or may it converge to a cycle of length N, $N=2, 3, 4, \ldots$. For example, the continued exponential $e^{ze^{ze^{z\cdots}}}$ converges to a two-cycle when $z=-9$. The first few terms in the sequence are 1, $e^{-9}=0.0001234$, $e^{-9e^{-9}}=0.99889$, $e^{-9e^{-9e^{-9}}}=0.0001246$, ...

Cycles of every integer length can be found outside the region of convergence. In Fig. 3 we display the regions in the complex-z plane for which the continued exponential sequence converges to an N-cycle. The boundary of the region in which the sequence $\{E_n\}$ is unbounded appears fractal.

Baker and Rippon have made other observations. The regions of convergence to a cycle are actually strips in the complex plane which extend infinitely far in the positive real direction. The

TABLE III. Same as in Table I, except that here we take $z=-1.5$, which lies outside the radius of convergence of the Taylor series. The continued exponential and continued fraction converge but the Taylor series diverges as n, the order of the approximation, increases.

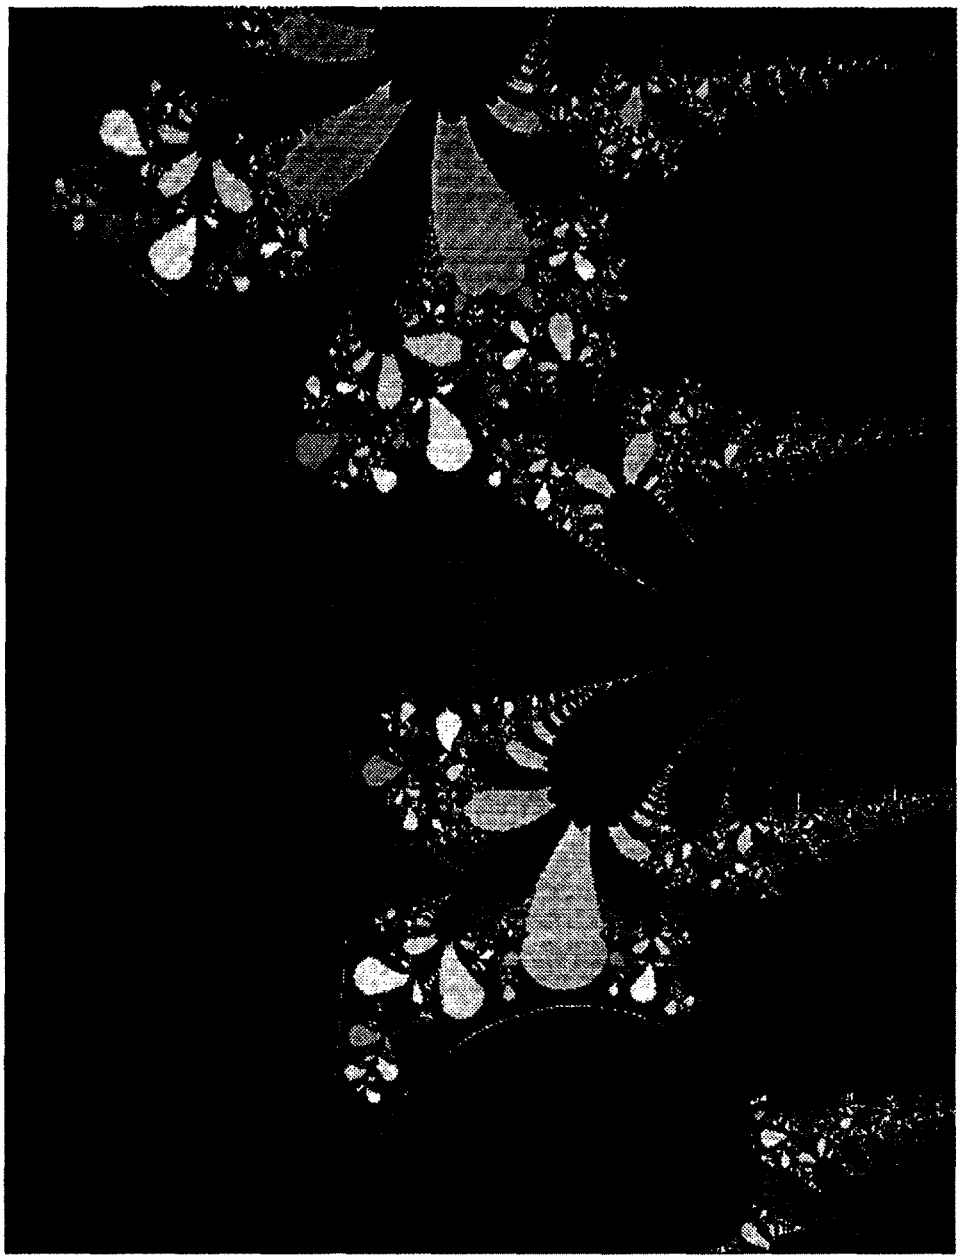

FIG. 3. Regions in the upper complex-z plane for which the continued exponential, whose coefficients are all 1, converges to an N-cycle. The regions in the lower-half plane are mirror images of those in the upper-half plane. Cycles of every integer length can be found outside the cardioid-shaped region of convergence Ω (purple). The boundary of the region (black) in which the sequence $\{E_n\}$ is unbounded appears fractal. Note that each region [except for Ω and the region of two-cycle (red)] is actually an infinitely long strip that becomes infinitely thin as it extends to $\mathrm{Re}(z)=\infty$. Each strip is artificially truncated by a crescent. The regions of three-cycles are magenta, four-cycles are green, five-cycles are yellow, six-cycles are blue, seven- through thirteen-cycles are various shades of pink.

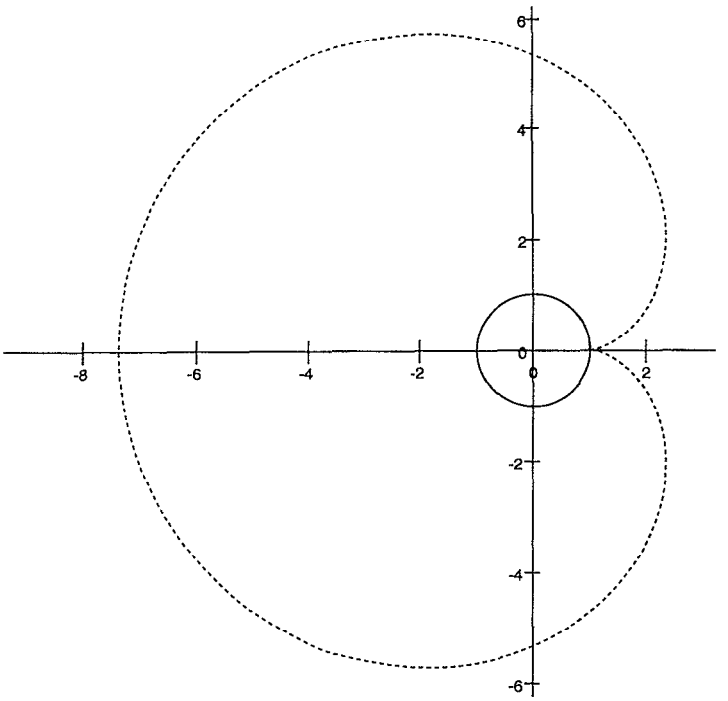

FIG. 4. Region of convergence (dashed line) of the continued exponential for the function $1/(1-z)$. The singularity at $z=1$ determines the location of the cusp. The solid line is the circle of convergence of the Taylor series for $1/(1-z)$.

ordering of these strips is well defined, and has interesting properties. For example, between every pair of adjacent n-strips is an infinite number of $(n+1)$-strips for $n>2$. Also, Baker and Rippon conjecture that the regions of convergence to a cycle are dense in the complex plane.

IV. ADDITIONAL EXAMPLES

In this section we consider a number of additional examples of continued exponentials.

A. The function $1/(1-z)$

Since the first finitely many coefficients a_i do not affect the convergence of a continued exponential, it is reasonable to suppose that if the coefficients a_i of the continued exponential $a_0 e^{a_1 z e^{a_2 z e^{a_3 z \cdots}}}$ approach a constant, then the region of convergence is the cardioid Ω scaled by an appropriate factor. An elementary example of a function for which the continued exponential coefficients approach a constant is $1/(1-z)$, whose Taylor series is $\Sigma_0^\infty z^n$. This Taylor series converges in a disc of radius 1. Its continued exponential coefficients are $a_0=1$, $a_1=1$, $a_2=\frac{1}{2}$, $a_3=\frac{5}{12}$, $a_4=\frac{47}{120}$, $a_5=\frac{12917}{33840}$, $a_6=\frac{329458703}{874222560}$, and so on. The coefficients a_i approach the limit $1/e\approx 0.36788$ monotonically. We have confirmed empirically that the region of convergence is $e\Omega$ (that is, the region Ω dilated by the factor e) (see Fig. 4). The cusp now lies at (1,0). This region is much larger than the region of convergence of the Taylor series. Note that the singularity at $z=1$ determines the location of the cusp of the cardioid.

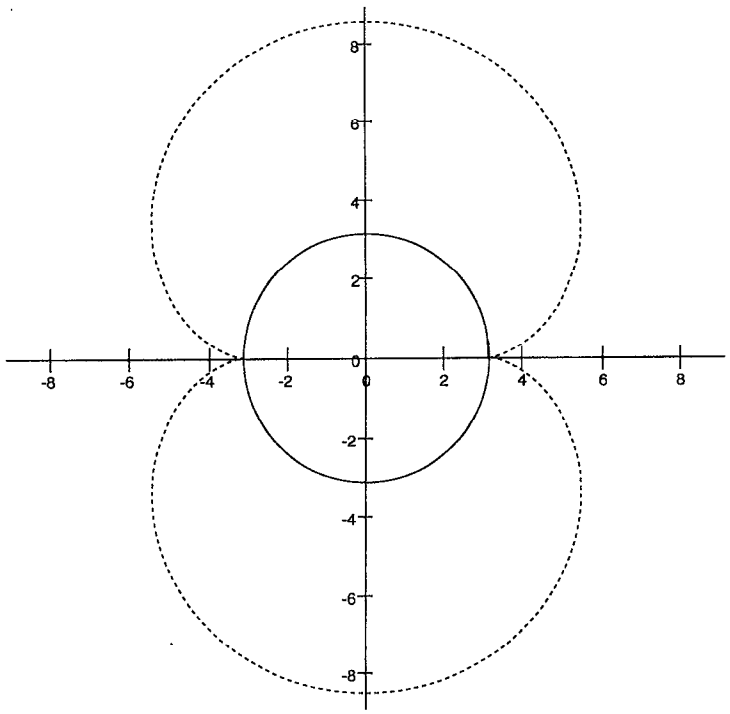

FIG. 5. Region of convergence (dashed line) of the continued exponential representing the function $z/\sin z$. Note that the region of convergence resembles a double cardioid. The cusps lie at $\pm\pi$, the nearest poles of the function. The solid line is the circle of convergence of the Taylor series for $z/\sin z$.

B. The function $z/(\sin z)$

Consider the function $z/(\sin z)$. Its Taylor series has a radius of convergence of π. By iteratively taking the logarithm of this Taylor series we find that its continued exponential is $a_0 e^{a_1 z^2 e^{a_2 z^2 e^{a_3 z^2 \cdots}}}$, where $a_0=1$, $a_1=\frac{1}{6}$, $a_2=\frac{1}{30}$, $a_3=\frac{59}{1260}$, $a_4=\frac{1219}{29736}$, $a_5=\frac{2300350279}{59809503600}$, and $\lim_{n\to\infty} a_n = 1/\pi^2 e \approx (0.037274)$. The sequence of continued exponential coefficients is monotone decreasing beginning with a_3. As in the previous example, the continued exponential converges when $z^2/\pi^2 e$ is inside the cardioid Ω, or equivalently, when z is in the double cardioid $\sqrt{\pi^2 e\Omega}$ shown in Fig. 5. This cardioid has cusps at $z=\pm\pi$, the location of the singularities of the function $z/(\sin z)$. The continued exponential converges in a much larger region than the Taylor series.

The continued exponential representation for the function $\sin z$ may be derived from that of $z/\sin z$:

$$\sin z = \frac{1}{a_0} z e^{-a_1 z^2 e^{a_2 z^2 e^{a_3 z^2 \cdots}}}.$$

Note that only the first two terms of this continued exponential differ from that of $z/(\sin z)$. The region of convergence of the continued exponential for the function $\sin z$ is the same double cardioid as that for the function $z/(\sin z)$. However, the Taylor series for the function $\sin z$ has an infinite radius of convergence. For the function $\sin z$ it is the zeros at $z=\pm\pi$ that determine the cusps of the cardioid.

Similarly, the continued exponentials for the functions $\cos z$ and $1/\cos z$ are identical except for the sign of a_1. Both continued exponentials have the same region of convergence, a double cardioid with cusps at $z=\pm\frac{1}{2}\pi$. These continued exponentials have the form

$$\cos z = a_0 e^{a_1 z^2 e^{a_2 z^2 e^{a_3 z^2 \cdots}}}$$

and

$$\frac{1}{\cos z} = \frac{1}{a_0} e^{-a_1 z^2 e^{a_2 z^2 e^{a_3 z^2 \cdots}}},$$

where $a_0=1$, $a_1=-\frac{1}{2}$, $a_2=\frac{1}{6}$, $a_3=\frac{11}{60}$, $a_4=\frac{4379}{27720}$, $a_5=\frac{7462435}{48554352}$, and so on. This sequence is monotone decreasing beginning with a_3 and it converges to the value $4/\pi^2 e$. Again, it is the zeros and/or singularities that determine the region of convergence of the continued exponential.

C. Continued exponential representation of an Airy function

The solution to the initial-value problem

$$y''(z)=zy(z), \quad y(0)=1, \; y'(0)=0,$$

can be expressed in terms of Airy functions $\mathrm{Ai}(x)$ and $\mathrm{Bi}(x)$:

$$y(z)=\pi[\mathrm{Bi}'(0)\mathrm{Ai}(z)-\mathrm{Ai}'(0)\mathrm{Bi}(z)].$$

This function has the Taylor series form

$$y(z)=\sum_{n=0}^{\infty}\frac{3^n\Gamma(n+1/3)}{(3n)!\Gamma(1/3)}z^{3n}.$$

If we convert this Taylor series to a continued exponential we obtain

$$y(z)=a_0 e^{a_1 z^3 e^{a_2 z^3 e^{a_3 z^3 \cdots}}},$$

where $a_0=1$, $a_1=\frac{1}{6}$, $a_2=-\frac{1}{20}$, $a_3=-\frac{7}{120}$, $a_4=-\frac{185}{3696}$, $a_5=-\frac{133817}{2772000}$, and so on.

To determine the region of convergence of the continued exponential we first observe that the continued exponential is a function of z^3. Thus, we expect the region of convergence to be a triple cardioid having three cusps. We find the location of the cusps by calculating that $\lim_{n\to\infty}a_n\approx -0.046939$; thus, the region of convergence consists of all z satisfying

$$-0.046939z^3\in\Omega.$$

This region of convergence is shown in Fig. 6. The cusps occur at the three zeros of $y(z)$ that are nearest to the origin. The locations of these zeros are given by the formula

$$z=-\left(\frac{1}{0.046939e}\right)^{1/3}\omega=-1.98635\omega,$$

where ω is a cube root of 1.

This example clearly demonstrates how the continued exponential accelerates the convergence of the Taylor series. Even though the radius of convergence of the Taylor series is infinite, the continued exponential converges faster than the Taylor series so long as z lies well inside the triple

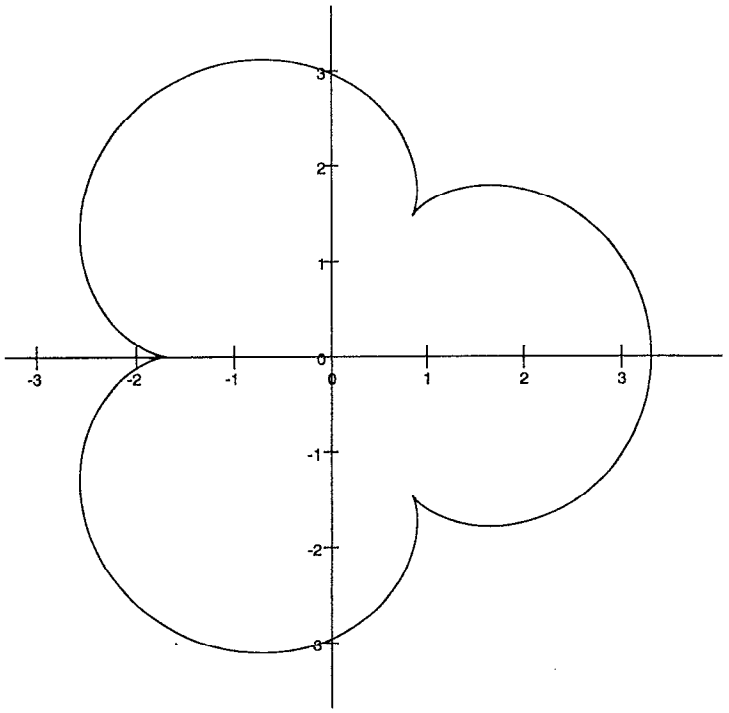

FIG. 6. Region of convergence of the continued exponential representing the Airy function $y(z)$ discussed in Sec. IV C. This triple cardioid has cusps at -1.98635ω, where ω is a cube root of 1. The cusps are located at the zeros of $y(z)$ that are nearest to the origin.

cardioid. For example, at $z=1$ a ten-term partial sum of Taylor series differs from the exact answer by a relative error of order 10^{-6} while a tenth-order continued exponential (constructed from the first ten terms in the Taylor series) has a relative error of order 10^{-14}. For a 15-term Taylor series, the relative error drops to 10^{-11} while that for a continued exponential drops to 10^{-21}.

D. Continued exponential representation of a Stieltjes function

Consider the Stieltjes function

$$f(z)=\int_0^\infty dt\frac{e^{-t}}{1+zt}. \tag{4.1}$$

The power series representation for this well known function is

$$f(z)\sim\sum_0^\infty (-1)^n n!z^n(|z|\to 0,\ \arg z<\pi).$$

This power series is divergent (it has a zero radius of convergence) but it is asymptotic to the function $f(z)$ as $z\to 0$ in the z plane cut along the negative real axis.

It is well known that the Padé sequence for this function converges for all z in the cut plane. What happens if we attempt to sum this series using a continued exponential? Converting Eq. (4.1) to a continued exponential gives

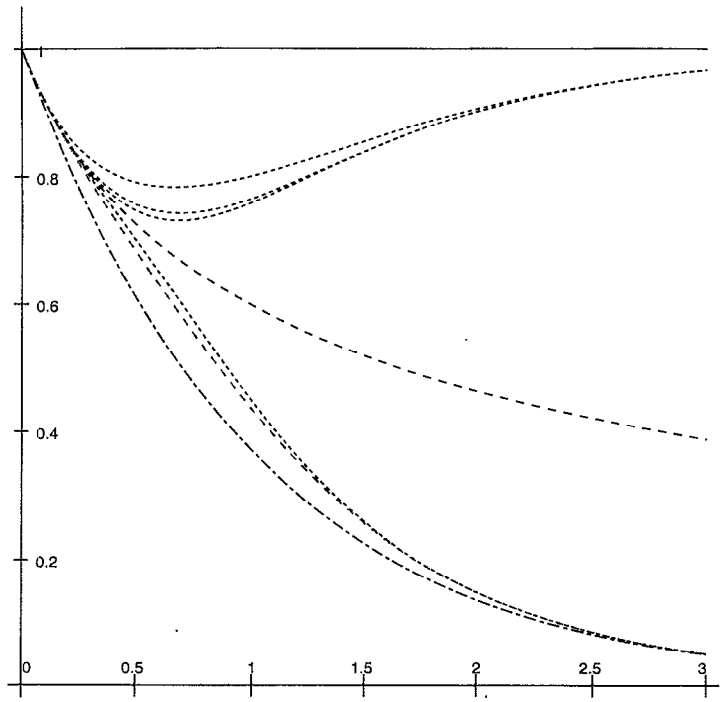

FIG. 7. Continued exponential approximants for the Stieltjes function $f(z)$ (solid line) discussed in Sec. IV D. When z is positive the continued exponential sequence (dashed lines) oscillates above and below $f(z)$ and converges to a cycle of length 2. For small values of z, this cycle is close to the exact value of $f(z)$. However, the continued exponential does *not* converge to $f(z)$.

$$f(z)=a_0 e^{a_1 z e^{a_2 z e^{a_3 z \cdots}}},$$

where $a_0=1$, $a_1=-1$, $a_2=-\frac{3}{2}$, $a_3=-\frac{77}{36}$, $a_4=-\frac{1405}{504}$, and so on. This continued exponential is different from those examined previously because the continued exponential coefficients grow with n rather than approaching a limit. In fact, $a_n \sim Cn$ as $n\to\infty$, where $C\approx -0.632$.

When z is positive the continued exponential sequence approaches a cycle of length 2 (see Fig. 7). For small values of z, this cycle is close to the exact value of $f(z)$ and oscillates above and below $f(z)$. However, the continued exponential does *not* converge to $f(z)$ and thus for this function it is not as useful as the Padé sequence. We do not know if it is possible to recover the exact value of $f(z)$ from the elements of the two-cycle; a calculational procedure, if one exists, would be more elaborate than an ordinary average or a geometric mean.

V. APPEARANCE OF CHAOTIC STRUCTURES

We have seen in Sec. IV that the cusp of the cardioid-shaped region of convergence of a continued exponential is located at the nearest zero or singularity of the function being represented. (We have also examined functions of the form $f(z^n)$, whose nearest zeros are arranged symmetrically around the origin at angles $2\pi/n$, where n is an integer. The convergence regions of such functions have n cusps.) In this section we briefly examine the extremely difficult problem of what happens when there is not just one but two nearest zeros (or singularities), which are not symmetrically arranged about the origin. An elementary function having this property is a quadratic polynomial of the form $(z-b+i)(z-b-i)$, where $b>0$.

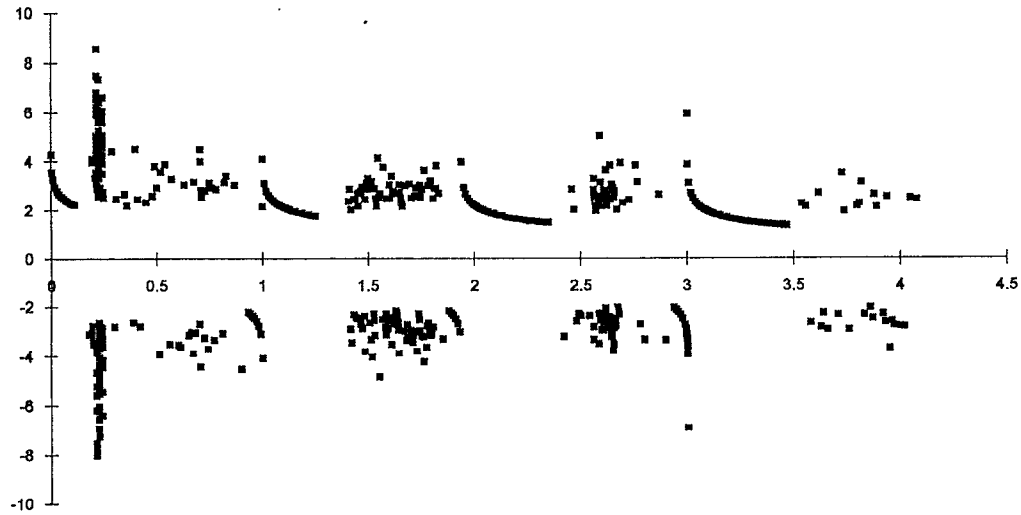

FIG. 8. A plot of the function $\mathrm{sgn}[f(b)][2+\log|f(b)|]$, $0 \leq b \leq 4.2$, where $f(b)$ is defined in Eq. (5.1). Observe that on the real line there are intervals where $f(b)$ appears meromorphic; that is, $f(b)$ is continuous except for simple poles. (One such interval is $2.9 \leq b \leq 3.5$.) These intervals are dispersed chaotically on the real line. Between pairs of intervals the function $f(b)$ appears noisy; however, on a finer scale we see that this noise is actually resolved into smaller subintervals where $f(b)$ is again meromorphic (see Fig. 9).

From our numerical studies (to order 100) of the function $(z-b+i)(z-b-i)$ it appears that the terms of the continued exponential representation often approach a constant, whose value depends on the parameter b. The continued exponential coefficients sometimes approach a limit monotonically, and sometimes sinusoidally. It is difficult to study this convergence because it tends to be very slow; we also find instances where the coefficients appear to converge slowly but then diverge.

Assuming that the coefficients a_n of the continued exponential converge for some values of b, the limit,

$$f(b) = \lim_{n \to \infty} a_n, \tag{5.1}$$

when it exists, is a function of the parameter b. The limiting function $f(b)$ depends chaotically upon b. We find that on the real line there are intervals where $f(b)$ is meromorphic; that is, $f(b)$ is continuous on the interval except for simple poles. These intervals are dispersed chaotically on the real line (see Figs. 8 and 9).

For each interval, the number of the coefficient following the last sign change is constant and will be called the convergence parameter of the interval. There may be several intervals with the same convergence parameter. We find that the length of an interval is roughly inversely related to the convergence parameter.

VI. CONCLUSIONS

We conclude this paper with several brief observations. First, it is clear from the examples we have presented that continued exponentials are a powerful and broadly applicable method for accelerating the convergence of a Taylor series inside its circle of convergence. Second, continued exponentials provide a means of analytically continuing a Taylor series to a much larger region

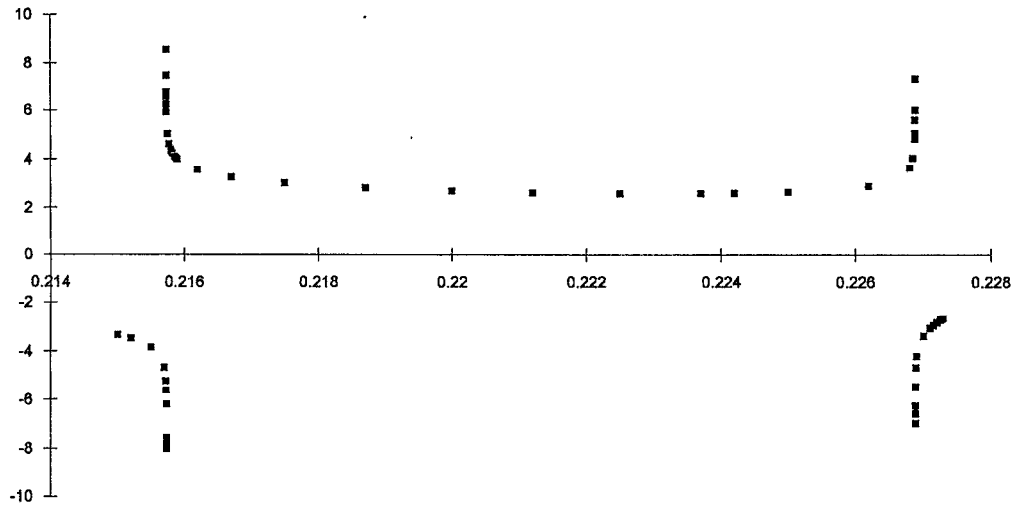

FIG. 9. Same as in Fig. 8 except that the domain is restricted to $0.215 \leq b \leq 0.228$.

than its circle of convergence so long as the function is zero free inside and near its circle of convergence. However, we do not yet know how to use continued exponentials to sum power series having a zero radius of convergence.

As we can see from the examples considered in this paper, the region of convergence of a continued exponential is determined by the zeros as well as by the singularities of the function being represented. This is true because a continued exponential approximates both a function and its reciprocal simultaneously. The function being approximated is zero-free in the region of convergence (except possibly for a zero at the origin). This observation may have some application in the study of complex variables; while it is often easy to locate the singularities of an analytic function it may be difficult to find the zeros. For example, finding the locations of the zeros of the Riemann zeta function is a well known, unsolved problem. Excluding the zeros away from $\mathrm{Re}(z)=1$ would be major progress in understanding the distribution of primes.

Finally, we remark that the theory of continued exponentials is intimately tied to the theory of chaos because it deals with iterated functions. We see chaotic structures emerge when we look at the cyclical convergence properties of a continued exponential outside the cardioid of convergence (see Fig. 3). Furthermore, we see chaotic behavior in such functions as $(z-b+i)(z-b-i)$ (Sec. V). The connection between chaos and continued exponentials deserves further study.

[4] To avoid possible notational ambiguities we point out that one evaluates a tower of exponentials by associating terms from the top down. For example, 2^{2^3} is evaluated as $2^{(2^3)}$, not $(2^2)^3$. An infinite tower of exponentials is evaluated as the limit of the sequence of finite truncations. Complex exponentiation is not well defined. For example, i^i can take

multiple values, depending on which value of $\log(i)$ is chosen. We avoid the ambiguity associated with evaluating $\beta_0^{\beta_1^{\beta_2 \cdots}}$ by considering instead continued exponentials of the form $\alpha_0 e^{\alpha_1 e^{\alpha_2 \cdots}}$.

[5] In exceptional cases, say for the function e^{z^2}, the generalized continued exponential terminates.

(Received 4 December 1995; accepted for publication 15 April 1996)

A finite-dimensional Lie algebra is called (symmetric) self-dual, if it possesses an invariant nondegenerate (symmetric) bilinear form. Symmetric self-dual Lie algebras have been studied by Medina and Revoy, who have proven a very useful theorem about their structure. In this paper we prove a refinement of their theorem that has wide applicability in conformal field theory, where symmetric self-dual Lie algebras start to play an important role due to the fact that they are precisely the Lie algebras that admit a Sugawara construction. We also prove a few corollaries that are important in conformal field theory. © *1996 American Institute of Physics.* [S0022-2488(96)03307-5]

I. INTRODUCTION AND MOTIVATION

For most physical applications, reductive Lie algebras are the most natural Lie algebras to consider. This is because they are the Lie algebras of the compact Lie groups, which have played a privileged role in physical theories. Reductive Lie algebras are completely classified, since they are direct products of Abelian and semisimple Lie algebras, and essentially everything is known about them and their representations, at least the finite-dimensional ones. However by any reasonable measure, reductive Lie algebras are rare; and comparatively little is known about their nonreductive counterparts. The Levi–Malcev theorem reduces the classification problem for general Lie algebras to that of semidirect products (i.e., split extensions) of semisimple and solvable Lie algebras; but already classifying solvable Lie algebras seems to be as hard as classifying Lie algebras in general: by brute force one can classify all Lie algebras of dimension $\leqslant 5$, and restricting oneself to solvable Lie algebras does not get one any further (although all nilpotent six-dimensional Lie algebras are known). Therefore in order to probe the space of Lie algebras one could hope to benefit by restricting oneself to a class of Lie algebras including the reductive Lie algebras but that are still special enough to allow for a classification. One property shared by all reductive Lie algebras is the existence of an invariant metric; that is, an invariant nondegenerate symmetric bilinear form. We will call Lie algebras possessing an invariant metric *symmetric self-dual* Lie algebras, and they compromise a nontrivial generalization of reductive Lie algebras. Although no classification exists to this date, there exists a structure theorem[1] that tells us in principle how to construct Lie algebras with an invariant metric starting from the reductive Lie algebras. In fact, reductive Lie algebras can be obtained from simple Lie algebras and the one-dimensional Lie algebra by the operation of direct sum. What Medina and Revoy found Ref. 1 is that all Lie algebras with an invariant metric can be obtained from the same ingredients provided that we introduce a new operation—the *double extension*—which generalizes the semidirect product in a nontrivial way.

The importance of symmetric self-dual Lie algebras in conformal field theory (and via CFT in

string theory) has to do with the following curious fact.[2,3] symmetric self-dual Lie algebras are precisely the Lie algebras for which a Sugawara construction exists. This fact may not appear so surprising if one assumes that the relation between the Sugawara construction and the WZW model persists in the nonreductive case: a WZW model needs for its definition a Lie group possessing a bi-invariant metric and this condition translates, at the level of the Lie algebra, into the statement that its Lie algebra should possess an invariant metric. Interestingly enough, the relation between the WZW model and the Sugawara construction does persist in the nonreductive case,[4] but the proof of this statement is not immediate and happens to necessitate detailed knowledge of the structure of symmetric self-dual Lie algebras, and, in particular, some refinements of the structure theorem in Ref. 1. The purpose of this paper is to collect those results on the structure of symmetric self-dual Lie algebras that were used in Ref. 4. Of necessity, those results are of a less physical nature than their applications, and we felt it inappropriate to include them together; hence the present paper.

This paper is organized as follows. In Sec. II we assemble some basic properties of symmetric self-dual Lie algebras and some properties of their ideals, which will be needed when we review the structure theorem of Medina and Revoy in Sec. III. In Sec. IV we define the double extension of a symmetric self-dual Lie algebra by a second Lie algebra and we work out some explicit formulas that we will need later. In Sec. V we discuss some examples of nonreductive self-dual Lie algebras. In Secs. VI and VII we prove some useful refinements and corollaries of the structure theorem. In Sec. VIII we comment briefly on the applications of this formalism to conformal field theory and string theory; and finally, in Sec. IV we mention some possible extensions and open problems. The paper also includes an appendix of a result on splittings of exact sequences involving Lie algebras. This result is used by Medina and Revoy, but we have not found a reference for it anywhere and we were forced to rederive it ourselves. We include it here for completeness.

II. BASIC PROPERTIES OF SYMMETRIC SELF-DUAL LIE ALGEBRAS

In this section we set up the notation and we introduce the necessary concepts about symmetric self-dual Lie algebras that we will need in the sequel.

Definition 2.1: Let $\mathscr{E}$ denote the class of pairs $(\mathfrak{g},\langle -,-\rangle)$, where $\mathfrak{g}$ is a finite-dimensional Lie algebra and $\langle -,-\rangle$ is a nondegenerate ad-invariant symmetric bilinear form on $\mathfrak{g}$. We shall call such a bilinear form simply an *invariant metric*, and we shall (tentatively) call an element of $\mathscr{E}$ a *symmetric self-dual* Lie algebra.

Remark 2.2: We should hasten to add that the nomenclature is by no means standard. French authors call these Lie algebras "orthogonal," whereas others call them "self-dual." The name "self-dual" presumably comes from the fact that the adjoint representation is equivalent to the coadjoint representation. But clearly for this to be the case, all that one requires is a nondegenerate invariant bilinear form on $\mathfrak{g}$, but not one that need be symmetric. After consulting with G. Zuckerman, who seems to have inspired "self-dual" in Ref. 5, we have chosen the compromise "symmetric self-dual," since it causes no confusion with the Lie algebras of the orthogonal Lie groups and does not preempt the term self-dual for their more general cousins. Nevertheless, since only symmetric self-dual Lie algebras will play a role in this paper, *we will use the term "self-dual" from now on to mean "symmetric self-dual" unless otherwise stated.*

Let us first mention some minor matters of notation. If a Lie algebra $\mathfrak{g}$ should decompose as a direct sum of *subspaces* A and B we will write $\mathfrak{g}=A\oplus B$. If moreover, the subspaces are *ideals*, so that the decomposition is one of Lie algebras, then we will write $\mathfrak{g}=A\times B$. It will prove convenient to introduce some nomenclature for particular subspaces of a self-dual Lie algebra depending on how the metric behaves on them.

Definition 2.3: Let $(\mathfrak{g},\langle -,-\rangle)$ be a self-dual Lie algebra. For any subspace $V\subset\mathfrak{g}$, let $V^{\perp}=\{w\in\mathfrak{g}|\langle w,v\rangle=0 \text{ for all } v\in V\}$. Notice that the operation $V\to V^{\perp}$ is involutive, so that $(V^{\perp})^{\perp}=V$. We say that

$$V \text{ is } \textit{isotropic} \Leftrightarrow V \subset V^{\perp},$$

$$V \text{ is } \textit{coisotropic} \Leftrightarrow V \supset V^{\perp},$$

$$V \text{ is } \textit{Lagrangian} \Leftrightarrow V = V^{\perp},$$

$$V \text{ is } \textit{degenerate} \Leftrightarrow V \cap V^{\perp} \neq 0,$$

$$V \text{ is } \textit{nondegenerate} \Leftrightarrow V \cap V^{\perp} = 0.$$

Let $(\mathfrak{g},\langle -,-\rangle)$ be a self-dual Lie algebra. We define the centralizer $Z_{\mathfrak{g}}(V)$ of a subspace $V \subset \mathfrak{g}$ as all those elements in the Lie algebra that commute with all elements of the subspace; that is $Z_{\mathfrak{g}}(V) \cong \{w \in \mathfrak{g} | [w,v]=0 \text{ for all } v \in V\}$. For a self-dual Lie algebra, centralizers and ideals are intimately linked, as the following lemma suggests.

Lemma 2.4: $I \subset \mathfrak{g}$ is an ideal if and only if $I^{\perp} \subset Z_{\mathfrak{g}}(I)$.

Proof: This follows immediately by the invariance of the metric. Indeed, $\langle [\mathfrak{g},I],I^{\perp}\rangle = \langle \mathfrak{g},[I,I^{\perp}]\rangle$, from where it follows that $[\mathfrak{g},I] \subset I^{\perp\perp} = I$ if and only if $[I,I^{\perp}]=0$.

The center of a self-dual Lie algebra can be also characterized very easily. In fact, the following occurs.

Lemma 2.5: Let $[\mathfrak{g},\mathfrak{g}]$ denote the first derived ideal and $Z(\mathfrak{g})$ be the center. Then $[\mathfrak{g},\mathfrak{g}]^{\perp} = Z(\mathfrak{g})$.

Proof: $x \in Z(\mathfrak{g}) \Leftrightarrow [x,y]=0, \forall y \Leftrightarrow \langle [x,y],z\rangle = 0, \forall y,z \Leftrightarrow \langle x,[y,z]\rangle = 0 \forall y,z \Leftrightarrow x \in |\mathfrak{g},\mathfrak{g}|^{\perp}$.

First of all, notice that if $I \subset \mathfrak{g}$ is an ideal, so is $I^{\perp}$. Recall that an ideal $I \subset \mathfrak{g}$ is minimal if it does not properly contain another nontrivial ideal $J \subset \mathfrak{g}$. In other words, if $I \subset \mathfrak{g}$ is a minimal ideal and if $J \subset \mathfrak{g}$ is another ideal with $J \subset I$, then either $J=0$ or $J=1$. Below we list some properties of minimal ideals that we shall need in the proof of the structure theorem or its refinements.

Proposition 2.6: Let $(\mathfrak{g},\langle -,-\rangle)$ be self-dual, and let $I \subset \mathfrak{g}$ be a minimal ideal. Then (1) If I is nondegenerate, then it is a factor, and hence simple or one dimensional; (2) if I is degenerate, then it is isotropic and Abelian; and (3) $I^{\perp}$ is a maximal ideal.

Proof: Let $I \in \mathfrak{g}$ be any ideal. Then so are $I^{\perp}$ and $I \cap I^{\perp} \subset I$, since the intersection of two ideals is an ideal. Since I is minimal, $I \cap I^{\perp}$ is either 0 or I.

(1) Let us take the first possibility: $I \cap I^{\perp}=0$. Definition 2.3 tells us that I is nondegenerate. Since both I and $I^{\perp}$ are ideals, $[I,I^{\perp}] \subset I$ and $[I,I^{\perp}] \subset I^{\perp}$; hence $[I,I^{\perp}] \subset I \cap I^{\perp}=0$. This means that $[I,I^{\perp}]=0$ and $\mathfrak{g}=I \times I^{\perp}$. Since I is a factor, any ideal of I is automatically an ideal of $\mathfrak{g}$. But by minimality, I cannot have any proper ideals, hence I is either simple or one-dimensional.

(2) The other possibility is that $I \cap I^{\perp}=I$, which means that I is degenerate. In fact, Definition 2.3 tells us that $I \subset I^{\perp}$ is isotropic. And by Lemma 2.4, $I \subsetneq I^{\perp} Z_{\mathfrak{g}}(I)$, whence it is Abelian.

(3) Finally, suppose that there exists a proper ideal J such that $I^{\perp} \subsetneq J$. Taking $^{\perp}$, we find $J^{\perp} \subsetneq I^{\perp\perp} = I$, which violates minimality. Hence $I^{\perp}$ is maximal. □

III. THE STRUCTURE THEOREM OF MEDINA AND REVOY

The class $\mathscr{C}$ of self-dual Lie algebras is closed under the operation of an orthogonal direct product; indeed, if $(\mathfrak{g}_1,\langle -,-\rangle_1)$ and $(\mathfrak{g}_2,\langle -,-\rangle_2)$ are two self-dual Lie algebras, so is $(\mathfrak{g}_1 \times \mathfrak{g}_2, \langle -,-\rangle_1 \oplus \langle -,-\rangle_2)$. We call a self-dual Lie algebra $(\mathfrak{g},\langle -,-\rangle)$ *indecomposable* if it cannot be written as such a direct product; and *decomposable* if it can. The following preliminary result on the structure of self-dual Lie algebras follows immediately from Proposition 2.6.

Corollary 3.1: Let $(\mathfrak{g},\langle -,-\rangle)$ be an indecomposable Lie algebra. Then exactly one of the following cases hold: (1) $\mathfrak{g}$ is simple (2); $\mathfrak{g}$ is one-dimensional; or (3) $\mathfrak{g}$ is not simple, $\dim \mathfrak{g}>1$, and every proper idal of $\mathfrak{g}$ is degenerate. □

It is clear that every self-dual Lie algebra is a product of objects of the types described above. Objects of types (1) and (2) are well known: they correspond to the direct product of a semisimple Lie algebra and an Abelian Lie algebra; that is, they are reductive. The class of objects of type (3) is more exotic. The following is the smallest such Lie algebra.

Example 3.2: Let $\mathfrak{g}$ be the four-dimensional Lie algebra with basis $\{h,e_\pm,g\}$ and Lie brackets

$$[h,e_\pm]=\pm e_\pm \quad \text{and} \quad [e_+,e_-]=g.$$

This Lie algebra is solvable but not nilpotent. For any scalars $\alpha\neq 0$ and β, the bilinear form

$$\langle e_+,e_-\rangle=\alpha, \quad \langle h,h\rangle=\beta, \quad \text{and} \quad \langle h,g\rangle=\alpha,$$

is invariant and nondegenerate. Hence it is a nonreductive self-dual Lie algebra. As shown in Ref. 6 the WZW model associated with this Lie algebra is an exact string background describing a gravitational wave. More nonreductive examples will be given in Sec. V.

In this section we will see that indecomposable self-dual Lie algebras of type (3) are easy to characterize. We shall do so in steps.

Let $(\mathfrak{d},\langle -,-\rangle)\in\mathscr{E}$ be indecomposable with $\mathfrak{d}$ not simple and with $\dim\mathfrak{d}>1$. We fix a proper minimal ideal $I\subset\mathfrak{d}$. By Corollary 3.1, it is degenerate and by Proposition 2.6 (2) it is isotropic and Abelian. By Lemma 2.4, I is a central ideal of $I^\perp$; whence $\mathfrak{g}=I^\perp/I$ is a Lie algebra. Moreover, since $I=I^{\perp\perp}$, $\mathfrak{g}$ inherits an invariant metric $\langle -,-\rangle_\mathfrak{g}$. In other words, we have proven the following lemma.

Lemma 3.3: We have an exact sequence

$$0\to I\to I^\perp\to\mathfrak{g}\to 0, \tag{3.4}$$

with $(\mathfrak{g},\langle -,-\rangle_\mathfrak{g})$ an object in $\mathscr{E}$.

It may seem overkill to use the language of exact sequences, but it turns out that it will be very useful and it will save us some time in the end. For the reader not familiar with this language, we simply recall that a sequence is exact whenever the kernel of any arrow is the image of the preceding one. In particular, the exactness of the above sequence simply says that $I\subset I^\perp$ is a Lie subalgebra (and an ideal since it is the kernel of a homomorphism) and that $\mathfrak{g}\cong I^\perp/I$ as Lie algebras. Moreover, since we are quotienting $I^\perp$ by its $^\perp$, the resulting quotient inherits a nondegenerate metric.

Before continuing, let us make the following notational remark. Below we will find it necessary to distinguish the Lie bracket and the inner product of the same pair of vectors when thought of as elements of different Lie algebraic structures on the same vector space. We will assume that when nothing is specified, the Lie bracket and the metric correspond to those in $\mathfrak{d}$.

Continuing with the argument, by Proposition 2.6 (3), $I^\perp$ is a maximal ideal of $\mathfrak{d}$; whence $\mathfrak{h}=\mathfrak{d}/I^\perp$ is a Lie algebra without proper ideals; that is, either $\mathfrak{h}$ is simple or one dimensional. It now follows that we can actually identify $\mathfrak{h}$ with a *subalgebra* of $\mathfrak{d}$. The proof of this lemma is much more technical than the proof of the structure theorem, and so we leave it to the Appendix. It is worth pointing out, however, that it is precisely this lemma that prevents the straightforward extension of the structure theorem to self-dual Lie superalgebras.

Lemma 3.5: The exact sequence

$$0\to I^\perp\to\mathfrak{d}\to\mathfrak{h}\to 0, \tag{3.6}$$

splits whenever $\mathfrak{h}$ is simple or one dimensional; that is, for such $\mathfrak{h}$, $\mathfrak{d}\cong\mathfrak{h}\ltimes I^\perp$.

In particular, $\mathfrak{d}=\mathfrak{h}\oplus I^\perp$, whence $V\equiv\mathfrak{h}\oplus I\subset\mathfrak{d}$ is a nondegenerate subspace of $\mathfrak{d}$. This implies that as vector spaces $\mathfrak{d}=V\oplus V^\perp$, and $I^\perp=V^\perp\oplus I$. The map $I^\perp\to\mathfrak{g}$ in (3.4) defines a vector space

isomorphism $\mathfrak{g}\cong V^\perp$. With some abuse of notation we will identify $\mathfrak{g}$ with $V^\perp\subset\mathfrak{0}$. In general, though, $V^\perp$ will fail to be a subalgebra. But all that happens is that it acquires a central extension. In fact, if $x,y,\in V^\perp$, then

$$[x,y]=[x,y]_{\mathfrak{g}}+\beta(x,y),$$

for some 2-cocycle $\beta:\wedge^2\mathfrak{g}\to I$, where, since $I\subset I^\perp$ is central, it becomes a trivial $\mathfrak{g}$ module. The cohomology class of this cocycle is the one defining the central extension (3.4).

Definition 3.7: Let $\mathfrak{g}$ be a self-dual Lie algebra. A linear map $D:\mathfrak{g}\to\mathfrak{g}$ is an *antisymmetric derivation* if D preserves both the Lie bracket and the invariant metric; that is, if

$$D([x,y])=[Dx,y]+[x,Dy] \quad \text{and} \quad \langle Dx,y\rangle=-\langle x,Dy\rangle.$$

Lemma 3.8: $\mathfrak{h}$ acts on $\mathfrak{g}$ via antisymmetric derivations.

Proof: We can define an action of $\mathfrak{h}$ on $\mathfrak{g}$ as follows. Take $x\in\mathfrak{g}$ and lift it to $V^\perp\subset\mathfrak{d}$. If $h\in\mathfrak{h}$, then we can define $h\cdot x=[h,x]$. *A priori*, this bracket is in $I^\perp=V^\perp\oplus I$. But we show that it is in fact in $V^\perp$. Indeed, let $h'\in\mathfrak{h}$ and compute $\langle h',[h,x]\rangle=\langle[h',h],x\rangle$. Since $[h',h]\in\mathfrak{h}\subset V$, the rhs is zero for all h'. Therefore $[h,x]\in\mathfrak{h}^\perp$. But nondegenary of V implies that $I\cap\mathfrak{h}^\perp=0$, whence $[h,x]\in V^\perp$. Since the bracket and metric of $\mathfrak{g}$ are induced from those of $\mathfrak{d}$, and $\mathfrak{h}\in\mathfrak{d}$ acts via (inner) antisymmetric derivations, it also acts on $\mathfrak{g}$ as antisymmetric derivations.

The action of $\mathfrak{h}$ on $\mathfrak{g}$ is intimately linked to the cocycle β characterizing the central extension (3.4). In fact, let $h\in\mathfrak{h}$ and $x,y\in\mathfrak{g}$. Lifting x and y back to $V^\perp\subset\mathfrak{d}$ we compute $\langle h\cdot x,y\rangle_{\mathfrak{g}}=\langle[h,x],y\rangle=\langle h,[x,y]\rangle=\langle h,[x,y]_{\mathfrak{g}}+\beta(x,y)\rangle$. But since $\mathfrak{h}$ is orthogonal to $V^\perp$, we find that

$$\langle h\cdot x,y\rangle_{\mathfrak{g}}=\langle h,\beta(x,y)\rangle. \tag{3.9}$$

Lemma 3.10: As $\mathfrak{h}$ modules, $I\cong\mathfrak{h}^*$.

Proof: Let $h\in\mathfrak{h}$ and $x\in I$. Since I is an ideal, $[h,x]\in I$, whence it is an $\mathfrak{h}$ module. Because $V=\mathfrak{h}\oplus I$ is nondegenerate and I is isotropic, we can identify I with $\mathfrak{h}^*$ as vector spaces: the isomorphism given by $I\ni x\to\langle x,-\rangle$ restricted to $\mathfrak{h}$. Now notice that for all $h'\in\mathfrak{h}$, $\langle[h,x],h'\rangle=-\langle x,[h,h']\rangle$, whence $I\cong\mathfrak{h}^*$ as $\mathfrak{h}$ modules. □

In summary, we have proven the following structure theorem.

Theorem 3.11: (Medina–Revoy[1]) Let$(\mathfrak{d},\langle-,-\rangle)$ be an indecomposable object in $\mathscr{C}$ such that $\mathfrak{d}$ is not simple nor one dimensional. Then $\mathfrak{d}$ is isomorphic to the Lie algebra with underlying vector space $\mathfrak{g}\oplus\mathfrak{h}\oplus\mathfrak{h}^*$, where (1) $\mathfrak{g}$ is the Lie algebra defined (3.4) and which inherits an invariant metric $\langle-,-\rangle_{\mathfrak{g}}$ by restricting $\langle-,-\rangle$; (2) $\mathfrak{h}$ is the Lie algebra defined by (3.6), which is either one dimensional or simple; (3) $\mathfrak{h}$ acts on $\mathfrak{g}$ via antisymmetric derivations: $(h,x)\to h\cdot x$ for $h\in\mathfrak{h}$ and $x\in\mathfrak{g}$; and (4) the Lie brackets are given for $x,x'\in\mathfrak{g}$, $h,h'\in\mathfrak{h}$ and $\alpha,\alpha'\in\mathfrak{h}^*$ by

$$[(x,h,\alpha),(x',h',\alpha')]=([x,x']_{\mathfrak{g}}+h\cdot x'-h'\cdot x,[h,h']_{\mathfrak{h}},\beta(x,x')+\mathrm{ad}_h^*\cdot\alpha'-\mathrm{ad}_h^*\cdot\alpha), \tag{3.12}$$

where $\beta:\wedge^2\mathfrak{g}\to\mathfrak{h}^*$ is given by (3.9). □

IV. DOUBLE EXTENSIONS

In this section we review the definition of a double extension, formalizing the results in the previous section on the structure of nonreductive indecomposable self-dual Lie algebras.

Definition 4.1: Given $(\mathfrak{g},\langle-,-\rangle_{\mathfrak{g}})\in\mathscr{C}$ and $\mathfrak{h}$ a Lie Algebra acting on $\mathfrak{g}$ via antisymmetric derivations, the Lie algebra $\mathfrak{d}$ defined on the vector space as $\mathfrak{g}\oplus\mathfrak{h}\oplus\mathfrak{h}^*$ by (3.12) and (3.9) is called the *double extension* of $\mathfrak{g}$ *by* $\mathfrak{h}$ and we denote it by $D(\mathfrak{g},\mathfrak{h})$.

Remark 4.2: Notice that the notation $D(\mathfrak{g},\mathfrak{h})$ is ambiguous on two counts. First of all, the data is not just $\mathfrak{g}$ but $(\mathfrak{g},\langle-,-\rangle_{\mathfrak{g}})$; and also not just $\mathfrak{h}$ but $\mathfrak{h}$ together with the action of $\mathfrak{h}$ on $\mathfrak{g}$ via antisymmetric derivations. Nevertheless, for the purposes of this paper, any ambiguity that might arise will be resolved contextually.

Provided that $\mathfrak{g}$ be self-dual, the double extension of $\mathfrak{g}$ by $\mathfrak{h}$ always carries an invariant metric. Indeed, if $\langle-,-\rangle_{\mathfrak{h}}$ is any invariant bilinear form on $\mathfrak{h}$, we define

$$\langle(x,h,\alpha),(x',h',\alpha')\rangle=\langle x,x'\rangle_{\mathfrak{g}}+\langle h,h'\rangle_{\mathfrak{h}}+\alpha(h')+\alpha'(h), \tag{4.3}$$

for all $x,x'\in\mathfrak{g},h,h'\in\mathfrak{h}$, and $\alpha,\alpha'\in\mathfrak{h}^*$. A routine calculation shows that this metric is invariant, whence $(\mathfrak{g},\langle-,-\rangle)$ is a self-dual Lie algebra.

Remark 4.4: It is worth pointing out that if the action of $\mathfrak{h}$ on $\mathfrak{g}$ is trivial, then the double extension is decomposable and isomorphic to $\mathfrak{g}\times(\mathfrak{h}\ltimes\mathfrak{h}^*)$. In particular, if $\mathfrak{g}=0$, then the double extension is $(\mathfrak{h}\ltimes\mathfrak{h}^*)$, which is the classical double of $\mathfrak{h}$ given the trivial bialgebra structure.[7]

It will be convenient later on to work with the explicit expression for the Lie brackets and for the invariant metric of a double extension. Hence we will now work out these expressions in a basis. We let $(\mathfrak{g},\langle-,-\rangle_{\mathfrak{g}})$ be a self-dual Lie algebra. Let the invariant metric have components $\Omega^{\mathfrak{g}}_{ij}$ relative to a fixed basis $\{G_i\}$. Also relative to this basis, we will let the Lie bracket in $\mathfrak{g}$ be given by $[G_i,G_j]_{\mathfrak{g}}=f_{ij}{}^kG_k$. We consider also a Lie bracket $\mathfrak{h}$, with basis $\{H_\alpha\}$, acting on $\mathfrak{g}$ via antisymmetric derivations,

$$H_\alpha\cdot G_i=f^j_{\alpha i}G_j,$$

and with Lie brackets given by $[H_\alpha,H_\beta]_{\mathfrak{h}}=f^\gamma_{\alpha\beta}H_\gamma$. Its dual $\mathfrak{h}^*$ has a canonical dual basis given by $\{H^\alpha\}$.

The double extension $\mathfrak{g}=D(\mathfrak{g},\mathfrak{h})$ will be then defined on the vector space $\mathfrak{g}\oplus\mathfrak{h}\oplus\mathfrak{h}^*$ by the following Lie brackets:

$$[G_i,G_j]=f^k_{ij}G_k+f_{ij\alpha}H^\alpha,\quad [H_\alpha,G_i]=f^j_{\alpha i}G_j,$$

$$[H_\alpha,H_\beta]=f^\gamma_{\alpha\beta}H_\gamma,\quad [H_\alpha,H^\beta]=-f^\beta_{\alpha\gamma}H^\gamma,$$

$$[H^\alpha,G_i]=[H^\alpha,H^\beta]=0,$$

where $f_{ij\alpha}=f^k_{\alpha i}\Omega^{\mathfrak{g}}_{kj}$. The above explicit expression makes manifest the fact mentioned in Remark 4.2 that $D(\mathfrak{g},\mathfrak{h})$ does not depend on $\mathfrak{g}$ and $\mathfrak{h}$ only through their Lie algebra structures, as the notation would suggest, but also on the action of $\mathfrak{h}$ and $\mathfrak{g}$ and on the metric of $\mathfrak{g}$.

The invariant metric on $D(\mathfrak{g},\mathfrak{h})$ is given by

$$\Omega^{\mathfrak{g}}_{ab}=H_a\begin{array}{c}\\ G_i\\ H_\alpha\\ H^\alpha\end{array}\begin{array}{c}\begin{array}{ccc}G_j & H_\beta & H^\beta\end{array}\\ \begin{pmatrix}\varphi^{\mathfrak{g}}_{ij} & 0 & 0\\ 0 & h_{\alpha\beta} & \delta_{\alpha\beta}\\ 0 & \delta^\alpha_\beta & 0\end{pmatrix}\end{array},$$

where $(h_{\alpha\beta})$ is an arbitrary (possibly degenerate) invariant bilinear from in $\mathfrak{h}$. We also record for future use the Killing form of the above double extension $\kappa^{\mathfrak{d}}$. This form will of course be degenerate, having the form

$$\begin{array}{r} \\ G_i \\ \kappa^{\mathfrak{d}}_{ab}=H_a \\ H^a \end{array} \begin{array}{c} \begin{array}{ccc} G_j & H_\beta & H^\beta \end{array} \\ \begin{pmatrix} \kappa^{\mathfrak{g}}_{ij} & \kappa^{\mathfrak{g}}_{i\beta} & 0 \\ \kappa^{\mathfrak{d}}_{\alpha j} & \kappa^{\mathfrak{d}}_{\alpha\beta} & 0 \\ 0 & 0 & 0 \end{pmatrix} \end{array},$$

where $\kappa^{\mathfrak{g}}$ is the Killing form of $\mathfrak{g}$ and where

$$\kappa^{\mathfrak{d}}_{i\alpha}=f^k_{ij}f^j_{\alpha k} \qquad \text{and} \qquad \kappa^{\mathfrak{d}}_{\alpha\beta}=f^j_{\alpha i}f^i_{\beta j}+2\kappa^{\mathfrak{h}}_{\alpha\beta}.$$

V. SOME NONREDUCTIVE EXAMPLES

Before going on to the main results of this paper, refining and extending the results described in the previous sections, let us pause to exhibit some examples of nonreductive indecomposable self-dual Lie algebras.

In Example 3.2 we saw the simplest such algebra: a four-dimensional solvable (but not nilpotent) Lie algebra. Over the complex numbers, it is the only such example in four dimensions. Viewed as a double extension, the algebra in Example 3.2 can be understood as $\mathfrak{D}(\mathfrak{b},\mathfrak{a})$, where $\mathfrak{a}$ is the one-dimensional Lie algebra and $\mathfrak{b}$ is a two-dimensional Abelian Lie algebra. Because $\mathfrak{b}$ is Abelian, all metrics are invariant, and over the complex numbers all metrics are equivalent, meaning that they can be transformed into one another by an automorphism of $\mathfrak{b}$. Over the reals, however, the signature of the metric is an invariant and we have two classes of metrics: the Euclidean and the Lorentzian.

We let $\mathfrak{a}_2$ denote the real self-dual Abelian Lie algebra with basis $\{e_1,e_2\}$ and with Euclidean metric $\langle e_i,e_j\rangle=\delta_{ij}$. Similarly, let $\mathfrak{a}_{1,1}$ denote the Lorentzian real form of the complex Lie algebra $\mathfrak{b}$. It has basis $\{e_1,e_2\}$ and Lorentzian metric $\langle e_1,e_1\rangle=-\langle e_2,e_2\rangle=1$. Since these Lie algebras are Abelian, any endomorphism is a derivation. The choice of metric dictates which are antisymmetric. For $\mathfrak{a}_2$ the Lie algebra of antisymmetric derivations is $so(2)$, whereas for $\mathfrak{a}_{1,1}$ it is $so(1,1)$. They are one-dimensional Abelian Lie algebras. We can now form the double extensions $\mathfrak{D}(\mathfrak{a}_2, so(2))$, and $\mathfrak{D}(\mathfrak{a}_{1,1}, so(1,1))$. These Lie algebras are self-dual, indecomposable, and nonreductive: in fact, they are solvable and not nilpotent. They are different real forms of the complex Lie algebra discussed in Example 3.2.

This interpretation allows us to generalize this example as follows[6,3]. Let $\mathbb{E}_{p,q}$ be the $(p+q)$-dimensional pseudo-Euclidean space with signature (p,q), and let $\mathfrak{a}_{p,q}$ denote the resulting self-dual Abelian Lie algebra. The Lie algebra of antisymmetric derivations is isomorphic to $so(p,q)$. We can form the double extension $\mathfrak{D}(\mathfrak{a}_{p,q}, so(p,q))$. This Lie algebra is self-dual, indecomposable, and nonreductive. It is not necessary to extend by the full Lie algebra of antisymmetric derivations to obtain an indecomposable double extension. Given a subalgebra $\mathfrak{h}\subset so(p,q)$ which acts effectively on $\mathbb{E}_{p,q}$, we can form $\mathfrak{D}(\mathfrak{a}_{p,q}, \mathfrak{h})$.

Other examples are known. In Ref. 9 some examples were obtained by Wigner contractions of semisimple Lie algebras, and this was further generalized in Ref. 3. Let $\mathfrak{g}$ be a semisimple Lie algebra and $\mathfrak{h}$ a subalgebra reductive in $\mathfrak{g}$ and such that there exists an $\mathfrak{h}$-invariant metric in $\mathfrak{g}$ relative to that $\mathfrak{g}$ splits as $\mathfrak{g}=\mathfrak{h}\oplus\mathfrak{h}^\perp$. This is true, for example, if $\mathfrak{g}$ is the Lie algebra of a compact Lie group and $\mathfrak{h}$ the Lie algebra of a (compact) Lie subgroup as in Ref. 9, or if both $\mathfrak{g}$ and $\mathfrak{h}$ are semisimple, among other cases. The models of Ref. 9 will be obtained as Wigner contractions of $\mathfrak{g}\times\mathfrak{h}$. Let $\mathfrak{e}=\mathfrak{h}^\perp$ denote the orthogonal complement of $\mathfrak{h}$ in $\mathfrak{g}$ relative to any $\mathfrak{h}$-invariant metric. Let us define subspaces $\mathfrak{h}_\pm\subset\mathfrak{h}\times\mathfrak{h}$ by $\mathfrak{h}_\pm=\{(h,\pm h)\in\mathfrak{h}\times\mathfrak{h}\}$. Choose bases $\{H^{(1)}_a\}$ and $\{H^{(2)}_a\}$ for the two copies of $\mathfrak{h}$, respectively, and $\{K_i\}$ for $\mathfrak{e}$. Then $\{H^\pm_a=H^{(1)}_a\pm H^{(2)}_a\}$ are bases for $\mathfrak{h}_\pm$, and the nonzero brackets of $\mathfrak{g}\times\mathfrak{h}$ are in this basis given by

$$[K_i,K_j]=f^k_{ij}K_k+\frac{1}{2}f^a_{ij}(H^+_\alpha+H^-_a), \quad [H^\pm_a,H^\pm_b]=f^c_{ab}H^+_c, \tag{5.1}$$

$$[H_a^{\pm},K_i]=f_{ai}^{j}K_j, \quad [H_a^{+},H_b^{-}]=f_{ab}^{c}H_c^{-},$$

where the f's are the structure constants of g in the chosen basis. To recover the structure of a double extension [compare with (3.12)], we would like that $[K_i,K_j]$ would not to close into H_a^{+}, and that $[H_a^{-},H_b^{-}]$ and $[H_a^{-},K_i]$ would vanish. The way out is to perform a contraction. To this effect, we define the following rescaled generators: $H_a^{+}(\epsilon)=\epsilon^{\Delta\pm}H_a^{+}$, and $K_i(\epsilon)=\epsilon^{\Delta}K_i$. Rewriting (5.1) in terms of the rescaled generators, we notice that we can get rid of the unwanted terms in the limit $\epsilon\to 0$ provided that we choose $\Delta_{+}=0$ and $\Delta_{-}=2\Delta>0$. Let us then choose these scaling dimensions, take the limit $\epsilon\to 0$, and introduce generators $X_i=K_i(0)$, $H_a=H_a^{+}(0)$, and $H^a=\frac{1}{2}g^{ab}H_b^{-}(0)$, where g^{ab} is the inverse of the $\mathfrak{h}$-invariant metric on $\mathfrak{h}$. With this notation and using the invariance of the metric, we find that the algebra becomes precisely (3.12), but with $f_{ij}^{k}=0$.

Notice that if we take $\mathfrak{g}$ to be any one of the de Sitter algebras for a space-time of signature (p,q)—that is, $\mathfrak{g}=so(p+1,q)$ or $\mathfrak{g}=so(p,q+1)$— and $\mathfrak{h}=so(p,q)$, then we recover precisely the examples described above.

All these examples share one property in common: they are double extensions $\mathfrak{D}(\mathfrak{a},\mathfrak{b})$, where $\mathfrak{a}$ is Abelian. Only one example is known of an indecomposable nonreductive self-dual Lie algebra that is the double extension of a non-Abelian Lie algebra. We refer the reader Ref. 10 for the details.

VI. SOME USEFUL REFINEMENTS

In this section we prove some refinements of Theorem 3.11 that have proven instrumental in the applications to Conformal Field Theory. We start by listing some conditions on $\mathfrak{g}$ under which any double extension $D(\mathfrak{g},\mathfrak{h})$ will fail to be indecomposable.

Remark 4.4 tells us that a double extension need not be indecomposable even if $\mathfrak{h}$ is taken to be simple or one dimensional; and one such example is when $\mathfrak{h}$ acts on $\mathfrak{g}$ via inner derivations, as we now see.

Proposition 6.1: If $\mathfrak{h}$ acts on $(\mathfrak{g},\langle-,-\rangle)\in\mathscr{E}$ via inner derivations, then $D(\mathfrak{g},\mathfrak{h})\cong\mathfrak{g}\times(\mathfrak{h}\ltimes\mathfrak{h}^{*})$.

Proof: Let $\varphi:\mathfrak{h}\to\mathfrak{g}$ be the homomorphism defining the action of $\mathfrak{h}$ on $\mathfrak{g}$. In other words, for $h\in\mathfrak{h}$ and $x\in\mathfrak{g}$, $h\cdot x=[\varphi(h),x]_{\mathfrak{g}}$. Let $\varphi^{\flat}:\mathfrak{h}\to\mathfrak{g}^{*}$ be the map sending $h\mapsto\langle\varphi(h),-\rangle_{\mathfrak{g}}$, and let $\varphi^{\sharp}:\mathfrak{g}\to\mathfrak{h}^{*}$ denote its transpose. Notice that because the metric of $\mathfrak{g}$ is $\mathfrak{h}$ invariant, these maps are actually intertwiners of the action of $\mathfrak{h}$; in particular, for $h\in\mathfrak{h}$ and $x\in\mathfrak{g}$, we have that

$$[h,\varphi^{\sharp}(x)]=\varphi^{\sharp}([\varphi(h),x]_{\mathfrak{g}}). \tag{6.2}$$

We can now define the following vector space automorphism Ψ of $\mathfrak{g}\oplus\mathfrak{h}\oplus\mathfrak{h}^{*}$:

$$\Psi(x,h,\alpha)=(x-\varphi^{\sharp}(x),h+\varphi(h),\alpha).$$

We claim that Ψ is a Lie algebra isomorphism $D(\mathfrak{g},\mathfrak{h})\xrightarrow{\cong}\mathfrak{g}\times(\mathfrak{h}\ltimes\mathfrak{h}^{*})$. Indeed, for $x,y\in\mathfrak{g}$, $\Psi([x,y])=\Psi([x,y]_{\mathfrak{g}}+\beta(x,y))=[x,y]_{\mathfrak{g}}-\varphi^{\sharp}([x,y]_{\mathfrak{g}})+\beta(x,y)$. But from (3.9) we have that $\beta(x,y)=\varphi^{\sharp}([x,y]_{\mathfrak{g}})$, whence $\Psi([x,y])=[\Psi(x),\Psi(y)]$. Second, we have that, on the one hand, for $h\in\mathfrak{h}$, $\Psi([h,x])=\Psi([\varphi(h),x]_{\mathfrak{g}})=[\varphi(h),x]_{\mathfrak{g}}-\varphi^{\sharp}([\varphi(h),x]_{\mathfrak{g}})$ and $[\Psi(h),\Psi(x)]=[h+\varphi(h),x-\varphi^{\sharp}(x)]=[\varphi(h),x]_{\mathfrak{g}}-[h,\varphi^{\sharp}(x)]$, on the other. But both of these expressions agree by virtue of (6.2). Similarly, $\Psi([h,h'])=[h,h']+\varphi([h,h'])$ agrees with $[\Psi(h),\Psi(h')]=[h+\varphi(h),h'+\varphi(h')]=[h,h']+[\varphi(h),\varphi(h')]$ for all $h'\in\mathfrak{h}$, since φ is a homomorphism of Lie algebras. The rest of the brackets are verified in a similar fashion. □

Remark 6.3: The invariant metric in $(\mathfrak{h}\ltimes\mathfrak{h}^{*})$ is now given by

$$\langle(h,\alpha),(h',\alpha')\rangle=\langle h,h'\rangle_{\mathfrak{h}}+\langle\varphi(h),\varphi(h')\rangle_{\mathfrak{g}}+\alpha(h')+\alpha'(h).$$

In other words, $\langle -,- \rangle_{\mathfrak{h}}$ receives a correction coming from the pull-back by φ to $\mathfrak{h}$ of the invariant metric in $\mathfrak{g}$; that is, $\langle -,- \rangle_{\mathfrak{h}} + \varphi^* \langle -,- \rangle$.

In particular, if all the antisymmetric derivations of $\mathfrak{g}$ are inner, then $\mathfrak{g}$ factors out of the double extension. This idea can be pursued further, but first a definition. Recall a (real) Lie algebra $\mathfrak{g}$ is *perfect* if $[\mathfrak{g},\mathfrak{g}]=\mathfrak{g}$ or, equivalently, if $H^1(\mathfrak{g};\mathbb{R})=0$. By analogy let us define the following.

Definition 6.4: We say that a (real) Lie algebra $\mathfrak{p}$ is *pluperfect* whenever $H^1(\mathfrak{p};\mathbb{R}) = H^2(\mathfrak{p};\mathbb{R})=0$. Notice that semisimple Lie algebras are pluperfect.

Theorem 6.5: The Lie algebra $\mathfrak{g}$ in Theorem 3.11 cannot have a pluperfect factor.

Proof: We will prove that if $\mathfrak{g}$ has a pluperfect factor, then its double extension is decomposable, in contradiction to the hypothesis of Theorem 3.11. Thus let $(\mathfrak{g},\langle -,- \rangle_{\mathfrak{g}})$ be an object in $\mathscr{C}$ such that $\mathfrak{g}=\mathfrak{p}\times\mathfrak{a}$ with $\mathfrak{p}$ pluperfect and $\mathfrak{a}$ arbitrary without pluperfect factors.

(1) $\mathfrak{p}$ and $\mathfrak{a}$ are orthogonal.

$\mathfrak{p}$ is, in particular, perfect, which together with the invariance of the metric implies that $\langle \mathfrak{p},\mathfrak{a} \rangle = \langle [\mathfrak{p},\mathfrak{p}],\mathfrak{a} \rangle = \langle \mathfrak{p},[\mathfrak{p},\mathfrak{a}] \rangle = 0$.

(2) Let $\mathrm{Der}_{\mathfrak{a}}$ stand for the antisymmetric derivations. Then $\mathrm{Der}_{\mathfrak{a}}\mathfrak{g}=\mathfrak{p}\times\mathrm{Der}_{\mathfrak{a}}\mathfrak{a}$.

Let $d \in \mathrm{Der}_{\mathfrak{a}}\mathfrak{g}$ be an antisymmetric derivation. If $x \in \mathfrak{g}$ we write $d(x)=d_1(x)+d_2(x)$, where $d_1(x) \in \mathfrak{p}$ and $d_2(x) \in \mathfrak{a}$. Let $s,s' \in \mathfrak{p}$. Since d is a derivation, we have $[d(s),s'] + [s,d(s')] = d([s,s'])$. Breaking it up into its components, we find that $[d_1(s),s'] + [s,d_1(s')] = d_2([s,s'])$ and that $d_2([s,s'])=0$. The former equation says that $d_1 \in \mathrm{Der}\,\mathfrak{p}$, whereas the latter says that d_2 annihilates $[\mathfrak{p},\mathfrak{p}]=\mathfrak{p}$. If $a \in \mathfrak{a}$ we have $[s,d(a)] + [d(s),a] = 0$. Breaking it up into components we find $[s,d_1(a)]=0$, which says the $d_1(a)$ is central in $\mathfrak{p}$. But since $[\mathfrak{p},\mathfrak{p}]=\mathfrak{p}$, Lemma 2.5 says that the center is trivial, whence $d_1(a)$ must vanish. If $a' \in \mathfrak{a}$, then $[d(a),a'] + [a,d(a')] = d([a,a'])$, which breaks up as $[d_2(a),a'] + [a,d_2(a')] = d_2([a,a'])$. This means that $d_2 \in \mathrm{Der}\,\mathfrak{a}$. Finally, the antisymmetry condition says that $d_2 \in \mathrm{Der}_{\mathfrak{a}}\mathfrak{a}$, whereas from $H^2(\mathfrak{p};\mathbb{R})=0$ it follows that all antisymmetric derivations of $\mathfrak{p}$ are inner: every antisymmetric derivation $D \in \mathrm{Der}_{\mathfrak{a}}\mathfrak{p}$ defines, a 2-cocycle by $\gamma(s,s')=\langle d(s),s' \rangle$, which is a coboundary $\gamma(s,s') = -\eta([s,s'])$ for some $\eta \in \mathfrak{p}^*$. But this means that there exists $s'' \in \mathfrak{p}$ such that $-\eta([s,s']) = \langle s'',[s,s'] \rangle = \langle [s'',s],s' \rangle$, whence $d(s)=[s'',s]$ is inner. Conversely, all inner derivations are antisymmetric, so that $d_1 \in ad\,\mathfrak{p}$.

In particular, since $\mathfrak{h}$ acts $\mathfrak{g}$ via inner derivations, there exists a Lie algebra (hence $\mathfrak{h}$ module) morphism $\varphi:\mathfrak{h}\to\mathfrak{p}$ such that for $h \in \mathfrak{h}$ and $s \in \mathfrak{p}$, $h \cdot s = [\varphi(h),s]_{\mathfrak{p}}$. Then the proof of Proposition 6.1 implies, *mutatis mutandis*, that $\mathfrak{p}$ factors out of the double extension.

In other words, the vector space automorphism Ψ of $\mathfrak{p}\oplus\mathfrak{a}\oplus\mathfrak{h}\oplus\mathfrak{h}^*$:

$$\Psi(s,a,h,\alpha) = (s-\varphi^\sharp(s),a,h+\varphi(h),\alpha)$$

defines a Lie algebra isomorphism $D(\mathfrak{p}\times\mathfrak{a},\mathfrak{h}) \xrightarrow{\simeq} \mathfrak{p}\times D(\mathfrak{a},\mathfrak{h})$. Furthermore, the invariant metric in $D(\mathfrak{a},\mathfrak{h})$ is now given by

$$\langle (a,h,\alpha),(a',h',\alpha') \rangle = \langle a,a' \rangle_{\mathfrak{a}} + \langle h,h' \rangle_{\mathfrak{h}} + \langle \varphi(h),\varphi(h') \rangle_{\mathfrak{p}} + \alpha(h') + \alpha'(h).$$

This concludes the proof of Theorem 6.5. □

As a corollary of Theorem 3.11 and Theorem 6.5 we have the following characterization of the class $\mathscr{C}$.

Corollary 6.6: The class $\mathscr{C}$ breaks up as $\mathscr{C}_S \times \mathscr{C}_N$, where $\mathscr{C}_S$ is the subclass of semisimple Lie algebras and $\mathscr{C}_N$ is the smallest class of real finite-dimensional Lie algebras containing the one-dimensional Lie algebra and closed under the operations of direct product and double extension by a simple or one-dimensional algebra. In particular, all objects in $\mathscr{C}_N$ are nonsemisimple. Moreover, the subclass $\mathscr{C}'_S \subset \mathscr{C}_N$ of solvable Lie algebras is the class generated by the one dimensional Lie algebra under the operations of direct product and double extension by the one-dimensional Lie algebra. □

VII. DEFORMING THE INVARIANT METRIC

Let $(\mathfrak{d},\Omega)$ be a self-dual Lie algebra. We would like to ask whether one can deform the metric Ω while retaining nondegeneracy. Rather than analyze this problem in its full generality, we will limit ourselves to the case of interest in Conformal Field Theory. Namely, we will deform Ω by a scalar multiple of the Killing form κ. Such shifts are the typical effect of quantum renormalization. Let t be a scalar (a real or complex number) and let g_t denote the bilinear form $g_t=\Omega-t\kappa$. Fix t once and for all and define $\mathfrak{d}^\perp$ to be the radical of g_t; that is, $\mathfrak{d}^\perp=\{v\in\mathfrak{d}|g_t(v,w)=0\forall w\in\mathfrak{d}\}$. Notice that $\mathfrak{d}^\perp\subset\mathfrak{d}$ is an ideal, since the bilinear form g_t is invariant. In particular, $\mathfrak{d}^\perp$ is a Lie algebra. We will prove the following result.

Theorem 7.1: If $(\mathfrak{d},\Omega)$ is an indecomposable self-dual Lie algebra, then $\mathfrak{d}^\perp=0$ unless $\mathfrak{d}$ is simple and $\Delta=t\kappa$, in which case $g_t=0$ and $\mathfrak{d}^\perp=\mathfrak{d}$.

Proof: Since $(\mathfrak{d},\Omega)$ is indecomposable, then by Theorem 3.11 it is either simple, one dimensional, or a double extension $D(\mathfrak{g},\mathfrak{h})$, where $\mathfrak{h}$ is simple or one dimensional. The theorem is clear for the first two cases, as we now show. If $\mathfrak{d}$ is one dimensional, then $\kappa=0$ and $\mathfrak{d}^\perp=0$; and similarly if $\mathfrak{d}$ is simple, then $\mathfrak{d}^\perp$, being an ideal, must be either 0 or $\mathfrak{d}$; the latter case corresponding to the case $g_t=0$, or equivalently $\Omega=t\kappa$. Therefore all we have left to tackle is the case where $\mathfrak{d}=D(\mathfrak{g},\mathfrak{h})$ is a double extension. The theorem will follow if we can prove that $\mathfrak{d}^\perp=0$ in this case.

We proceed by induction on the dimension of the Lie algebra. Suppose that the theorem is true for all indecomposable self-dual Lie algebras of dimension $\leqslant N$—the case $N=1$ being trivially satisfied—and let $\mathfrak{d}=D(\mathfrak{g},\mathfrak{h})$ be an indecomposable double extension of dimension $N+1$. [Actually we have not shown that there is no indecomposable self-dual Lie algebra in every dimension. So if there is no indecomposable $\mathfrak{d}=D(\mathfrak{g},\mathfrak{h})$ in dimenson $N+1$ then take one of the smallest dimension $>N$.] The theorem follows if we can prove that $\mathfrak{d}^\perp=0$. We now have the following lemma, whose proof we give below.

Lemma 7.2: Let $\mathfrak{d}=D(\mathfrak{g},\mathfrak{h})$ be a double extension, with $\mathfrak{g}$ and $\mathfrak{h}$ arbitrary. Then there is a Lie algebra isomorphism:

$$\mathfrak{d}^\perp=D(\mathfrak{g},\mathfrak{h})^\perp\cong\mathfrak{g}^\perp.$$

□

Using Lemma 7.2, we have that $\mathfrak{d}^\perp\cong\mathfrak{g}^\perp$. In general, $\mathfrak{g}$ need not be indecomposable, so write it as $\mathfrak{g}=\mathfrak{g}_1\times\cdots\times\mathfrak{g}_\kappa$, where each $\mathfrak{g}_i$ is indecomposable. Clearly, $\mathfrak{g}^\perp\cong\mathfrak{g}_1^\perp\times\cdots\times\mathfrak{g}_\kappa^\perp$. Since $\dim\mathfrak{g}_i<\dim\mathfrak{d}$ for each i, we can apply the induction hypothesis to deduce that $\mathfrak{g}_i^\perp$ will only be nonzero when $\mathfrak{g}_i$ is simple. But if $\mathfrak{g}$ would have a simple factor, Theorem 6.5 would imply that $\mathfrak{d}$ is decomposable, violating the hypothesis. Therefore $\mathfrak{g}^\perp=0$ and we can extend the induction hypothesis. □

Corollary 7.3: Let $(\mathfrak{d},\Omega)$ be any self-dual Lie algebra. Then (1) $\mathfrak{d}^\perp$ is semisimple; (2) $\mathfrak{d}$ decomposes into an orthogonal direct sum $\mathfrak{d}=\mathfrak{d}^\perp\times\mathfrak{d}_1$, where $\mathfrak{d}^\perp$ is semisimple, and $\mathfrak{d}_1^\perp=0$.

Proof: (1) is an immediate corollary. Since $\mathfrak{d}^\perp$ is a semisimple ideal, it is a factor; hence (2). Finally we prove the lemma. □

Proof (of Lemma 7.2): In the explicit basis introduced in Sec. IV, we let $v=v^jG_j+v^\alpha H_\alpha+v_\alpha H^\alpha$ belong to $\mathfrak{d}^\perp$ and let us see what this implies. The bilinear form defining $^\perp$ is $\Omega^{\mathfrak{d}}_{ab}-t\kappa^{\mathfrak{d}}_{ab}$, whose matrix is given by

$$\begin{array}{c} \\ G_i \\ H_\alpha \\ H^\alpha \end{array}\begin{array}{c} \begin{array}{ccc} G_j & H_\beta & H^\beta \end{array} \\ \begin{pmatrix} \Omega^{\mathfrak{g}}_{ij}-t\kappa^{\mathfrak{g}}_{ij} & -t\kappa^{\mathfrak{d}}_{i\beta} & 0 \\ -t\kappa^{\mathfrak{d}}_{\alpha j} & h_{\alpha\beta}-t\kappa^{\mathfrak{d}}_{\alpha\beta} & \delta_\alpha{}^\beta \\ 0 & \delta^\alpha{}_\beta & 0 \end{pmatrix} \end{array}.$$

Therefore, $v\in\mathfrak{d}^\perp$ implies that

$$(\Omega^{\mathfrak{d}}_{ab}-t\kappa^{\mathfrak{d}}_{ab})\begin{pmatrix} v^j \\ v^\beta \\ v_\beta \end{pmatrix}=\begin{pmatrix} (\Omega^{\mathfrak{g}}_{ij}-t\kappa^{\mathfrak{g}}_{ij})v^j-t\kappa^{\mathfrak{d}}_{i\beta}v^\beta \\ -t\kappa^{\mathfrak{d}}_{\alpha j}v^j+(h_{\alpha\beta}-t\kappa^{\mathfrak{d}}_{\alpha\beta})v^\beta+v_\alpha \\ v^\alpha \end{pmatrix}=0.$$

This in turn yields the equations $v^\alpha=0$, $v_\alpha = t\kappa^{\mathfrak{d}}_{\alpha j}v^j$, and

$$(\Omega^{\mathfrak{g}}_{ij}-t\kappa^{\mathfrak{g}}_{ij})v^j=0,$$

whence v^jG_j belongs to $\mathfrak{g}^\perp$. Conversely, any $v^jG_j\in\mathfrak{g}^\perp$ extends to a vector $v^jG_j + tv^j\kappa^{\mathfrak{d}}_{\alpha j}H^\alpha$, which by the above computation belongs to $\mathfrak{d}^\perp$. In summary, we have a vector space isomorphism $s:\mathfrak{g}^\perp\to\mathfrak{d}^\perp$, defined by $s(v^jG_j) = v^jG'_j$ where $G'_j = G_j + t\kappa^{\mathfrak{d}}_{\alpha j}H^\alpha$. We will not show that this is also an isomorphism of Lie algebras. Computing the brackets in $\mathfrak{d}$, we obtain

$$[s(G_i),s(G_j)]_{\mathfrak{d}}=[G'_i,G'_j]_{\mathfrak{d}}=f^k_{ij}G_k+f_{ij\alpha}H^\alpha=f^k_{ij}G^j_k+(f_{ij\alpha}-tf^k_{ij}\kappa^{\mathfrak{d}}_{k\alpha})H^\alpha. \tag{7.4}$$

Now notice that $f_{ija} = f^a_j\Omega^{\mathfrak{d}}_{a\alpha}$, that $f^k_{ij}\kappa^{\mathfrak{d}}_{k\alpha} = f^a_{ij}\kappa^{\mathfrak{d}}_{a\alpha}$; so that we rewrite (7.4) as

$$[G'_i,G'_j]_{\mathfrak{d}}=f^k_{ij}G'_k+f^a_{ij}(g^{\mathfrak{d}}_i)_{a\alpha}H^\alpha.$$

Using that $g^{\mathfrak{d}}_i$ is an invariant bilinear form, we arrive at

$$[G'_i,G'_j]_{\mathfrak{d}}=f^k_{ij}G'_k-f^a_{i\alpha}(g^{\mathfrak{d}}_t)_{aj}H^\alpha.$$

Finally, we notice that $f^a_{i\alpha}(g^{\mathfrak{d}}_t)_{aj} = f_{i\alpha}{}^k(g^{\mathfrak{d}}_t)_{kj}$ and that the restriction of $g^{\mathfrak{d}}_t$ to $\mathfrak{g}$ coincides with $g^{\mathfrak{g}}_t$, so that we end up with

$$[G'_i,G'_j]_{\mathfrak{d}}=f^k_{ij}G'_k-f_{i\alpha}{}^k(g^{\mathfrak{d}}_t)_{jk}H^\alpha,$$

which shows explicitly that if v^iG_i and w^jG_j are in $\mathfrak{g}^\perp$ then

$$[s(v^iG_i),s(w^jG_j)]_{\mathfrak{d}}=s([v^iG_i,w^jG_j]_{\mathfrak{g}},$$

so that s is a homomorphism. □

VIII. APPLICATIONS IN CONFORMAL FIELD THEORY

To conclude we would like to mention very briefly some of the applications of self-dual Lie algebras, and, in particular, of the results in this paper in conformal field theory. We will be brief and will limit ourselves mostly to directing the attention of the reader to the relevant literature.

Any conformally invariant two-dimensional σ model (of the right central charge) is a possible (bosonic) string background. Any such σ model is classically conformally invariant, but demanding that this persists upon quantitation imposes equations on the metric that need to be satisfied. Therefore in the process of satisfying these equations, the classical form of the metric gets "renormalized" and it is seldom the case that one can write down a nontrivial metric that exactly solves the equations—that is, an exact string background. In Ref. 6 Nappi and Witten constructed one such exact string background out of a WZW model with target space a four-dimensional solvable Lie group. The nonperturbative proof of the conformal invariance of the theory made use of a Sugawara construction built out of a nondegenerate metric on the Lie algebra. This fact prompted Mohammedi[2] to investigate the existence of a Sugawara construction on a given Lie algebra $\mathfrak{g}$. The conclusion of his analysis (see also Ref. 3) is that a Sugawara construction exists if and only if $\mathfrak{g}$ is self-dual. Self-dual Sugawara constructions have appeared also in the work of Lian[5] on finitely generated simple vertex operator algebras.

In Ref. 3 we analyzed the Sugawara constructions arising out of self-dual Lie algebras, with the motivation of answering the following question. All examples of nonsemisimple Sugawara constructions known at the time shared the property that the central charge was equal to the dimension of the Lie algebra. *Was this inevitable or could one construct CFTs with nonintegral values of the central charge?* The answer turns out to be negative—a fact we established in Ref. 3. More precisely, we used Corollary 6.6 (derived from a weaker version of Theorem 6.5) to deduce that the Sugawara central charge associated with any self-dual Lie algebra in the class $\mathscr{C}_N$ is integral and equal to the dimension of the Lie algebra. Hence any other value for the central charge has its origins in a Sugawara construction in the class $\mathscr{C}_S$. A detailed analysis of the self-dual Lie algebras in low dimension has been made by Kehagias, who classified the WZW models in (target) dimension $\leqslant 5$ and, in addition, all those six dimensional ones with nilpotent target group.[11] These limits are dictated by the present classification of arbitrary Lie algebras. More recently, we have studied the coset constructions arising out of self-dual Lie algebras[4] as well as settled some issues concerning the relation between the WZW model and the Sugawara construction, for which Theorem 7.1 proved instrumental. In Ref. 4 the reader may also find more references on nonreductive Sugawara constructions and (gauged) WZW models.

We conclude this brief survey of applications with a word on supersymmetry. It was proven Ref. 2 that the condition for the existence of an $N=1$ supersymmetric Sugawara construction on the $N=1$ affine Lie algebra $\hat{\mathfrak{g}}_{N=1}$ is also that $\mathfrak{g}$ be self-dual. This opens possibility of studying for which self-dual Lie algebras $\mathfrak{g}$, does the $N=1$ Sugawara construction $\hat{\mathfrak{g}}_{N=1}$ admit an $N=2$ extension. The conditions were found in Ref. 12 and reinterpreted in Ref. 13 in order to classify all those solvable six dimensional—that is, those with central charge $c=9$—self-dual Lie algebras admitting an $N=2$ construction. The conditions under which a pair of self-dual Lie algebras $(\mathfrak{h},\mathfrak{g})$ admits an $N=1$ and an $N=2$ coset construction have found Ref. 14, which can be thought of as a continuation of Ref. 4 and where further use is made of the results described in this paper.

IX. SOME OPEN PROBLEMS

We have seen that the results of Medina and Revoy, suitably refined and augmented, have a wide applicability in Conformal Field Theory. Certainly there still remains a lot to be learned from self-dual Lie algebras and, if we compare them with semisimple Lie algebras, very little is known about them indeed. At this stage a complete classification is hard to envision, but some more modest results would be welcome; for instance, the classification of all six-dimensional self-dual Lie algebras. An interesting open problem is the extension of these results to self-dual Lie superalgebras. As shown in Ref. 15 and in Ref. 4, self-dual Lie superalgebras also lead to Sugawara constructions. Motivated by this fact, one would like to have a structure theorem for such Lie superalgebras. If we study closely the results outlined in this paper, one sees that one can substitute Lie algebra for Lie superalgebra in many of the results and the statements and proofs still hold *mutatis mutandis*. (Statements like Corollary 6.6 would, of course, have to be modified, since not all simple Lie superalgebras are self-dual.) The only exception is Lemma 3.5, for which we have not been able to find a proof nor a counterexample. The notion of a double extension still works and allows one to construct self-dual Lie superalgebras, but without a superanalog of Lemma 3.5, nothing guarantees that this is the way to obtain them all.

Notice that although the results described in this paper hold for symmetric self-dual Lie algebras, one could have used an antisymmetric form for much of the discussion in this paper and many of the results would have remained unchanged. However, had we dropped any symmetry requirements whatsoever, the results would need severe modification. The determination of a structure theorem for these more general self-dual Lie algebras is an open problem—one we find intriguing and to which we may return elsewhere.

ACKNOWLEDGMENTS

We are grateful to the referee for a most careful reading of the manuscript and for constructive suggestions, in particular, a simplification in the proof of the Proposition in the Appendix. We feel that the paper has improved as a result of the refereeing process.

APPENDIX A: SPLIT EXTENSIONS OF SOME LIE ALGEBRAS

We now prove Lemma 3.5. More precisely we prove the following result, which implies Lemma 3.5.

Proposition A.1: If c is simple or one dimensional, every Lie algebra extension,

$$0\to\mathfrak{a}\to\mathfrak{b}\to\mathfrak{c}\to 0, \tag{A1}$$

splits.

Remark A.3: Before we proceed to the proof we mention that if $\mathfrak{a}$ were Abelian the result would follow immediately as a consequence of the second Whitehead lemma: $H^2(\mathfrak{c};\mathfrak{a})=0$. Similarly, if $\mathfrak{a}$ were solvable one could proceed by induction on the derived length of $\mathfrak{a}$. If, on the other hand, $\mathfrak{a}$ were semisimple, then $\mathfrak{b}$ would decompose as a direct product $\mathfrak{a}\times\mathfrak{c}$. However, we are interested in general $\mathfrak{a}$. This result should be standard but we have not found it in the literature.

Proof (of Proposition A.1): Let $0\to\mathfrak{r}\to\mathfrak{a}\to\mathfrak{l}\to 0$ be a Levi decomposition for $\mathfrak{a}$ with $\mathfrak{r}$ the radical and $\mathfrak{l}$ semisimple. Since $\mathfrak{r}$ is a characteristic ideal of $\mathfrak{a}$ and $\mathfrak{a}$ is an ideal of $\mathfrak{b}$, $\mathfrak{r}$ is an ideal of $\mathfrak{b}$. Let $\mathfrak{g}\equiv\mathfrak{b}/\mathfrak{r}$. Since $\mathfrak{l}\subset\mathfrak{a}$ is a subalgebra we have a map $\mathfrak{l}\to\mathfrak{g}$ induced by the composition of $\mathfrak{a}\to\mathfrak{b}\to\mathfrak{g}$. It is clear that this map is one to one and the image of $\mathfrak{l}$ in $\mathfrak{g}$ is an ideal. Define then $\mathfrak{h}\equiv\mathfrak{g}/\mathfrak{l}$. Since $\mathfrak{l}$ is semisimple, the sequence $0\to\mathfrak{l}\to\mathfrak{g}\to\mathfrak{h}\to 0$ splits, and we can identify $\mathfrak{h}$ with an ideal of $\mathfrak{g}$, so that $\mathfrak{g}=\mathfrak{h}\times\mathfrak{l}$. Indeed, notice that $\mathfrak{l}\cong\mathfrak{a}/\mathfrak{r}$ and that $\mathfrak{g}\cong\mathfrak{b}/\mathfrak{r}$, and this implies that $\mathfrak{h}\cong\mathfrak{g}/\mathfrak{l}=(\mathfrak{b}/\mathfrak{r})/(\mathfrak{a}/\mathfrak{r})\cong\mathfrak{b}/\mathfrak{a}\cong\mathfrak{c}$, whence $\mathfrak{g}=\mathfrak{l}\times\mathfrak{c}$.

The key observation is that the obstruction is now a linear map $\beta:\Lambda^2\mathfrak{c}\to\mathfrak{a}\cong\mathfrak{r}\oplus\mathfrak{l}$.

(1) Case: $\mathfrak{c}$ simple

If $\mathfrak{c}$ is simple, $\mathfrak{g}$ is semisimple, which imp,lies that $\mathfrak{r}$ is the radial of $\mathfrak{b}$. The splitting of (A1) then follows from the Levi–Malcev theorem.

(2) Case: $\mathfrak{c}$ one dimensional

The splitting of (A1) is equivalent to the splitting of

$$0\to\mathfrak{r}\to\mathfrak{b}\to\mathfrak{l}\times\mathfrak{c}\to 0. \tag{A2}$$

Since $\mathfrak{r}$ is solvable, we will prove this by induction on its derived length. If $\mathfrak{r}$ is Abelian, then the split follows as a result of the fact that

$$H^2(\mathfrak{l}\times\mathfrak{c},\mathfrak{r})=\bigoplus_{i=0}^{2}H^i(\mathfrak{l};\mathbb{R})\otimes H^{2-i}(\mathfrak{c};\mathfrak{r})=0.$$

We take as our induction hypothesis that the above sequence splits for every solvable algebra of derived length $<n$. We let $\mathfrak{r}$ have derived length n and consider the exact sequence

$$0\to\mathfrak{r}/[\mathfrak{r},\mathfrak{r}]\to\mathfrak{b}/[\mathfrak{r},\mathfrak{r}]\to\mathfrak{l}\times\mathfrak{c}\to 0.$$

It splits by the induction hypothesis since $\mathfrak{r}/[\mathfrak{r},\mathfrak{r}]$ is Abelian and has derived length zero. Let $s:\mathfrak{l}\times\mathfrak{c}\to\mathfrak{b}/[\mathfrak{r},\mathfrak{r}]$ denote the splitting map and let $s(\mathfrak{l}\times\mathfrak{c})=\mathfrak{p}/[\mathfrak{r},\mathfrak{r}]$, where the subalgebra $\mathfrak{p}\subset\mathfrak{b}$ is the preimage of $\mathfrak{l}\times\mathfrak{r}$. Now, the exact sequence,

$$0\to[\mathfrak{r},\mathfrak{r}]\to\mathfrak{p}\to\mathfrak{p}/[\mathfrak{r},\mathfrak{r}]\to 0,$$

splits by the induction hypothesis since the derived length of $[\mathfrak{r},\mathfrak{r}]$ is $n-1$. Let $z:\mathfrak{l}\times\mathfrak{c}\to\mathfrak{p}$ denote the splitting map. Then the composition $s\circ z:\mathfrak{l}\times\mathfrak{c}\to\mathfrak{p}/[\mathfrak{r},\mathfrak{r}]\to\mathfrak{p}\subset\mathfrak{b}$ is the desired splitting of (A2). □

(Received 13 November 1995; accepted for publication 11 March 1996)

We present an algebraic interpretation of the continuous q-Jacobi polynomials. They are shown to realize a basis for a representation space of a q deformation of the four-dimensional Euclidean algebra $e(4)$. A q analog of the expansion of an exponential in Jacobi polynomials is naturally obtained from this model. © *1996 American Institute of Physics.* [S0022-2488(96)03407-X]

I. INTRODUCTION

Most special functions of mathematical physics admit q analogs, namely deformations involving a parameter q. These q-special functions,[1,2] which share many common properties with their undeformed counterparts, have become a subject of very intense research since quantum groups and algebras were introduced. Most remarkably, just as Lie algebras provide a unifying framework for discussing special functions, quantum algebras furnish an equivalent setting for studying q-special functions. Indeed, q-orthogonal polynomials and q-special functions arise as basis vectors of quantum algebra representations or as matrix elements of q exponentials of generators in such representations (e.g. Refs. 3–12). Moreover, the algebraic interpretation leads naturally to generating relations, orthogonality properties, and additional formulas for these functions.

Most of the q polynomials encountered in these investigations were orthogonal with respect to a discrete measure. Still, many q polynomials are known to be orthogonal with respect to continuous measures,[1,2] and it is natural to look for their algebraic interpretation. These polynomials are all encompassed as special cases of the four-parameter family of Askey–Wilson polynomials $p_n(x;a,b,c,d,|q)$. It might thus seem more economical, at first sight, to obtain directly the algebraic interpretation of the Askey–Wilson polynomials and to extract therefrom the interpretation of the various polynomials as special cases. This, however, would be an extremely arduous undertaking, since the complexity of the quantum algebra associated with a family of q polynomials increases rapidly with their number of parameters. It is therefore more advisable to start from the bottom of the Askey–Wilson hierarchy, and to consider systematically cases of increasing complexity. Thus, after an initial study[13] dealing with Roger's continuous q-Hermite and continuous q-ultraspherical polynomials, which involve zero and one parameter, respectively, we tackled the one-parameter class of continuous big q-Hermite polynomials,[14] and showed how the q-oscillator algebra can be used to obtain relations between q-Hermite, big q-Hermite, Wall, and q-Laguerre polynomials.[15]

We pursue this approach here by showing that a q deformation of the four-dimensional Euclidean algebra $e(4)$ provides an algebraic interpretation of the two-parameter family of q-Jacobi polynomials $P_n^{(\alpha,\beta)}(x|q)$. The latter are defined in Sec. II, where certain preliminary results are also presented, while the realization of a q deformation of $e(4)$ is given in Sec. III. As illustration of the usefulness of the algebraic approach, we derive in Sec. IV a q analog[16] of the formula for the expansion of an exponential in Jacobi polynomials:

(1)

$$e^{irx}=e^{-ir}\sum_{n=0}^{\infty}\frac{(\alpha+\beta+1)_n}{(\alpha+\beta+1)_{2n}}(2ir)^n{}_1F_1\left(\begin{matrix}n+\beta+1\\2n+\alpha+\beta+2\end{matrix}\middle|2ir\right)P_n^{(\alpha,\beta)}(x),$$

$$-1<x<1. \tag{1.1}$$

We have not been able to find in the literature an algebraic derivation of (1.1). It will be briefly discussed in the Appendix; it essentially amounts to the $q\to 1^-$ limit of the construction given in the body of the paper.

II. DEFINITIONS AND PRELIMINARY RESULTS

We shall use standard notation for the q-shifted factorials $(a;q)_\alpha$,

$$(a;q)_\alpha=\frac{(a;q)_\infty}{(aq^\alpha;q)_\infty}, \tag{2.1a}$$

$$(a;q)_\infty=\prod_{k=0}^{\infty}(1-aq^k),\quad |q|<1, \tag{2.1b}$$

$$(a_1,a_2,\ldots,a_k;q)_\alpha=(a_1;q)_\alpha(a_2;q)_\alpha\cdots(a_k;q)_\alpha, \tag{2.1c}$$

as well as for the q-hypergeometric series ${}_r\phi_s$,

$$\begin{aligned}&{}_r\phi_s(a_1,a_2,\ldots,a_r;b_1,\ldots,b_s;q,z)\\&\quad={}_r\phi_s\left(\begin{matrix}a_1,a_2,\ldots,a_r\\b_1,\ldots,b_s\end{matrix}\middle|q;z\right)\\&\quad=\sum_{n=0}^{\infty}\frac{(a_1,\ldots,a_r;q)_n}{(q,b_1,\ldots,b_s;q)_n}[(-1)^nq^{n(n-1)/2}]^{1+s-r}z^n.\end{aligned} \tag{2.2}$$

Defining the Askey–Wilson polynomials,[1,2,17]

$$p_n(x;a,b,c,d|q)=(ab,ac,ad;q)_n a^{-n}\times{}_4\phi_3\left(\begin{matrix}q^{-n},abcdq^{n-1},ae^{i\theta},ae^{-i\theta}\\ab,ac,ad\end{matrix}\middle|q;q\right), \tag{2.3}$$

with

$$x=\cos\,\theta, \tag{2.4}$$

we can express the continuous q-Jacobi polynomials $P_n{}^{(\alpha,\beta)}(x|q)$ in the following manner:[1,2]

$$\begin{aligned}P_n^{(\alpha,\beta)}(x|q)=&\frac{q^{n(2\alpha+1)/4}}{(q,-q^{(\alpha+\beta+1)/2},-q^{(\alpha+\beta+2)/2};q)_n}\\&\times p_n(x;q^{(2\alpha+1)/4},q^{(2\alpha+3)/4},-q^{(2\beta+1)/4},-q^{(2\beta+3)/4}|q),\end{aligned} \tag{2.5}$$

This definition corresponds to the original normalization of Ref. 17. One also finds in the literature q-Jacobi polynomials $P_n{}^{(\alpha,\beta)}(x;q)$ with a different normalization, introduced in Ref. 18. These two types of q-Jacobi polynomials are connected by the quadratic transformation

$$P_n^{(\alpha,\beta)}(x;q)=\frac{(-q^{\alpha+\beta+1};q)_n}{(-q;q)_n}q^{-\alpha n}P_n^{(\alpha,\beta)}(x|q^2). \tag{2.6}$$

It is well known that the following two q analogs of the exponential function:[1]

$$e_q(z)=\sum_{n=0}^{\infty}\frac{1}{(q;q)_n}z^n=\frac{1}{(z;q)_\infty},$$
$$E_q(z)=\sum_{n=0}^{\infty}\frac{q^{n(n-1)/2}}{(q;q)_n}z^n=(-z;q)_\infty, \tag{2.7}$$

are eigenfunctions of the q-derivative operators D_z^+ and D_z^-, respectively, which are defined by

$$D_z^{\pm}=\frac{1}{z}(1-T_z^{\pm 1}). \tag{2.8}$$

The operator T_z is the q-shift operator, the powers of which act as follows on any function of z:

$$T_z^{\alpha}f(z)=f(q^{\alpha}z), \quad \alpha\in\mathbb{R}. \tag{2.9}$$

The q-derivative operators $D_z^{\pm}$, however, are not the appropriate ones for the study of the continuous q-orthogonal polynomials. Rather, one uses the divided difference operator[17,19]

$$\tau=\frac{1}{z-z^{-1}}(T_z^{1/2}-T_z^{-1/2}), \tag{2.10}$$

the eigenfunctions of which are a third q analog of the exponential function,[20]

$$\mathscr{E}_q(x;a,b)=\sum_{n=0}^{\infty}\frac{q^{n^2/4}}{(q;q)_n}(aq^{(1-n)/2}e^{i\theta};q)_n(aq^{(1-n)/2}e^{-i\theta};q)_n b^n. \tag{2.11}$$

One has, indeed,

$$\tau\mathscr{E}_q(x;a,b)=abq^{-1/4}\mathscr{E}_q(x;a,b). \tag{2.12}$$

In the following, we shall need not only the action of the divided difference operator τ on the q exponential $\mathscr{E}_q(x;-i,r)$, but also that of the operators,

$$\tilde{\tau}_q^*=q^{-1/2}\frac{1}{z-z^{-1}}\left(\frac{1}{z^2}T_z^{1/2}-z^2T_z^{-1/2}\right), \tag{2.13}$$

$$\tilde{\mu}_q=\frac{1}{z-z^{-1}}\left(-\frac{1}{z}T_z^{1/2}+zT_z^{-1/2}\right), \tag{2.14}$$

$\tilde{\tau}^*_{1/q}$ and $\tilde{\mu}_{1/q}$. The operators (2.13) and (2.14) are those to which the ladder operators τ^* and μ of Ref. 19 reduce when the four parameters in the Askey–Wilson polynomials vanish. We can express the action of these operators on $\mathscr{E}_q(x;-i,r)$ in the following manner:

$$\tilde{\tau}_q^*\mathscr{E}_q(x;-i,r)=i\frac{q^{1/4}}{r}\left[\left(1+\frac{r^2}{q^2}\right)T_r^{-1}-1\right]\mathscr{E}_q(x;-i,r), \tag{2.15a}$$

$$\tilde{\mu}_q\mathscr{E}_q(x;-i,r)=\frac{(-r^2/q;q^2)_\infty}{(-r^2;q^2)_\infty}T_r^{-1/2}\mathscr{E}_q(x;-i,r), \tag{2.15b}$$

$$\tilde{\tau}^{*}_{1/q}\mathscr{E}_q(x;-i,r)=-i\,\frac{q^{1/4}}{r}\,[(1+r^2q)T_r-1]\mathscr{E}_q(x;-i,r), \tag{2.15c}$$

and

$$\tilde{\mu}_{1/q}\mathscr{E}_q(x;-i,r)=\frac{(-r^2q;q^2)_\infty}{(-r^2q^2,q^2)_\infty}\,T_r^{1/2}\mathscr{E}_q(x;-i,r). \tag{2.15d}$$

The first two of these equations are most readily proved by expanding $\mathscr{E}_q(x;-i,r)$ on a basis of continuous q-Hermite polynomials $H_k(x|q)$,[13]

$$(-r^2;q^2)_\infty\mathscr{E}_q(x;-i,r)=\sum_{k=0}^{\infty}\frac{q^{k^2/4}}{(q;q)_k}\,(ir)^kH_k(x|q), \tag{2.16}$$

and exploiting the known action of $\tilde{\tau}^{*}_q$ and $\tilde{\mu}_q$ on the latter,[14]

$$\tilde{\tau}^{*}_qH_k(x|q)=-q^{-(k+1)/2}H_{k+1}(x|q),\quad \tilde{\mu}_qH_k(x|q)=q^{-k/2}H_k(x|q). \tag{2.17}$$

The last two equations are then a consequence of the following properties of the q exponentials:

$$E_q(x)=e_{1/q}(-x/q),\quad E_{1/q}(x)=e_q(-qx), \tag{2.18}$$

$$\mathscr{E}_{1/q}(x;a,b)=\mathscr{E}_q(x;1/a,-q^{1/2}a^2b). \tag{2.19}$$

III. A MODEL FOR q-DEFORMED $e(4)$

We will now construct a model for a q deformation of the Lie algebra $e(4)$, involving operators acting on functions of the three variables $x=(z+z^{-1})/2$, s, and t. The generators of the q-deformed algebra will involve four operators that are, essentially, the ladder operators introduced in Ref. 19, namely the divided difference operator τ, already defined in (2.10), as well as

$$\begin{aligned}\tau^{*}=\frac{q^{-1/2}}{z-z^{-1}}\Bigg[&\frac{1}{z^2}\,(1-q^{-1/4}zT_s^{1/2}T_t^{-1/2})(1-q^{1/4}zT_s^{1/2}T_t^{-1/2})(1+q^{-1/4}zT_s^{1/2}T_t^{1/2})\\&\times(1+q^{1/4}zT_s^{1/2}T_t^{1/2})T_z^{1/2}-z^2\left(1-\frac{q^{-1/4}}{z}\,T_s^{1/2}T_t^{-1/2}\right)\left(1-\frac{q^{1/4}}{z}\,T_s^{1/2}T_t^{-1/2}\right)\\&\times\left(1+\frac{q^{-1/4}}{z}\,T_s^{1/2}T_t^{1/2}\right)\left(1+\frac{q^{1/4}}{z}\,T_s^{1/2}T_t^{1/2}\right)T_z^{-1/2}\Bigg],\end{aligned} \tag{3.1}$$

$$\begin{aligned}\mu=\frac{1}{z-z^{-1}}\Bigg[&-\frac{1}{z}\,(1-q^{-1/4}zT_s^{1/2}T_t^{-1/2})(1-q^{1/4}zT_s^{1/2}T_t^{-1/2})T_z^{1/2}\\&+z\left(1-\frac{q^{-1/4}}{z}\,T_s^{1/2}T_t^{-1/2}\right)\left(1-\frac{q^{1/4}}{z}\,T_s^{1/2}T_t^{-1/2}\right)T_z^{-1/2}\Bigg],\end{aligned} \tag{3.2}$$

and

$$\begin{aligned}\mu^{*}=\frac{1}{z-z^{-1}}\Bigg[&-\frac{1}{z}\,(1+q^{-1/4}zT_s^{1/2}T_t^{1/2})(1+q^{1/4}zT_s^{1/2}T_t^{1/2})T_z^{1/2}\\&+z\left(1+\frac{q^{-1/4}}{z}\,T_s^{1/2}T_t^{1/2}\right)\left(1+\frac{q^{1/4}}{z}\,T_s^{1/2}T_t^{1/2}\right)T_z^{-1/2}\Bigg].\end{aligned} \tag{3.3}$$

Let us now define the following ten generators:

$$L_+ = \frac{1}{1-q}\, s\tau, \tag{3.4a}$$

$$L_- = \frac{1}{1-q}\,\frac{1}{s}\,\tau^*, \tag{3.4b}$$

$$L_0 = \frac{1}{1-q}\,(1-T_s^2), \tag{3.4c}$$

$$J_+ = \frac{q^{1/2}}{1-q}\, t\mu T_s^{-1/2}, \tag{3.4d}$$

$$J_- = \frac{1}{1-q}\,\frac{1}{t}\,\mu^* T_s^{-1/2}, \tag{3.4e}$$

$$K = T_t, \tag{3.4f}$$

$$P_+ = s^{1/2} t^{1/2}, \tag{3.4g}$$

$$P_- = \frac{q^{-1/2}}{s^{1/2} t^{1/2}}\,(1+q^{-1/4} z T_s^{1/2} T_t^{1/2})\left(1+\frac{q^{-1/4}}{z}\,T_s^{1/2} T_t^{1/2}\right) T_t^{1/2}, \tag{3.4h}$$

$$Q_+ = q^{-1/4}\,\frac{s^{1/2}}{t^{1/2}}\,\frac{1}{z-z^{-1}}\left[\left(1+\frac{q^{1/4}}{z}\,T_s^{1/2} T_t^{1/2}\right) T_z^{-1/2} - (1+q^{1/4} z T_s^{1/2} T_t^{1/2}) T_z^{1/2}\right] T_t^{1/2}, \tag{3.4i}$$

$$\begin{aligned} Q_- = -q^{-1/2}\,\frac{t^{1/2}}{s^{1/2}}\,\frac{1}{z-z^{-1}}\Bigg[&\frac{1}{z^2}\,(1-q^{-1/4} z T_s^{1/2} T_t^{-1/2})(1-q^{1/4} z T_s^{1/2} T_t^{-1/2})(1+q^{1/4} z T_s^{1/2} T_t^{1/2}) \\ &\times T_z^{1/2} - z^2\left(1-\frac{q^{-1/4}}{z}\,T_s^{1/2} T_t^{-1/2}\right)\left(1-\frac{q^{1/4}}{z}\,T_s^{1/2} T_t^{-1/2}\right)\left(1+\frac{q^{1/4}}{z}\,T_s^{1/2} T_t^{1/2}\right) T_z^{-1/2}\Bigg]. \end{aligned} \tag{3.4j}$$

To these we will add the operator

$$H = T_s, \tag{3.5}$$

which proves more convenient to use, occasionally, than L_0.

The ten operators we have just introduced can be shown to realize the q-algebra characterized by the following commutation relations:

$$\begin{aligned} &qL_+L_- - L_-L_+ = L_0, && [J_+, J_-] = \frac{K-K^{-1}}{q^{1/2}-q^{-1/2}}, \\ &q^{\mp 1} L_0 L_\pm - q^{\pm 1} L_\pm L_0 = \pm\frac{1+q}{q}\,L_\pm, && KJ_\pm = q^{\pm 1} J_\pm K, \\ &L_0 P_+ - qP_+ L_0 = P_+, && KP_+ = q^{1/2} P_+ K, \\ &[L_+, P_+] = 0, && q^{1/4} J_+ P_+ = P_+ J_+, \end{aligned}$$

$$
\begin{aligned}
&qP_+L_- - L_-P_+ = Q_-, && P_+J_- - q^{1/4}J_-P_+ = Q_+,\\
&P_-L_0 - qL_0P_- = P_-, && KP_- = q^{-1/2}P_-K,\\
&qL_+P_- - P_-L_+ = q^{-1/4}Q_+, && J_+P_- - q^{-1/4}P_-J_+ = Q_-K,\\
&[L_-, P_-] = 0, && q^{3/4}P_-J_- = J_-P_-,\\
&L_0Q_+ - qQ_+L_0 = Q_+, && KQ_+ = q^{-1/2}Q_+K,\\
&[L_+, Q_+] = 0, && Q_+J_+ - q^{1/4}J_+Q_+ = KP_+,\\
&L_-Q_+ - qQ_+L_- = q^{1/4}P_-, && J_-Q_+ = q^{3/4}Q_+J_-,\\
&Q_-L_0 - qL_0Q_- = Q_-, && KQ_- = q^{1/2}Q_-K,\\
&Q_-L_+ - qL_+Q_- = P_+, && q^{1/4}J_+Q_- = Q_-J_+,\\
&[L_-, Q_-] = 0, && J_-Q_- - q^{-1/4}Q_-J_- = P_-,
\end{aligned}
\tag{3.6}
$$

$$qP_+P_- - q^{1/4}P_-P_+ = -(1-q^{1/2})(1-KH)K^{1/2},$$

$$q^{3/4}P_+Q_+ - Q_+P_+ = (1-q)(1-q^{1/2})K^{1/2}L_+,$$

$$[P_+, Q_-] = q^{-3/4}(1-q)(1-q^{1/2})J_+HK^{1/2},$$

$$[Q_+, P_-] = q^{-7/4}(1-q)(1-q^{1/2})J_-HK^{3/2},$$

$$Q_-P_- - q^{-3/4}P_-Q_- = q^{-1}(1-q)(1-q^{1/2})L_-K^{1/2},$$

$$Q_+Q_- - q^{-1/4}Q_-Q_+ + qP_+P_- - q^{-3/4}P_-P_+$$

$$= (1-q)(1-q^{1/2})(q^{-1}L_-L_+ - qL_+L_-)K^{1/2}.$$

Moreover, the operators of the set $\{L_\pm, L_0\}$ commute with those of the set $\{J_\pm, K\}$. As will be shown in the Appendix, this q-deformed algebra reduces, in the $q \to 1^-$ limit, to the Lie algebra $e(4)$ of the Euclidean group in four dimensions $E(4)$. Thus, the ten operators (3.6) provide a model for a q deformation of the latter. Interestingly enough, the two sets $\{L_\pm, L_0\}$ and $\{J_\pm, K\}$ realize two different q deformations of the two $sl(2)$ subalgebras of $e(4)$.

The module associated with our model has the basis vectors

$$F_n^{(\alpha,\beta)}(x,s,t) = s^{(\alpha+\beta)/2}P_n^{(\alpha,\beta)}(x|q)t^{(\beta-\alpha)/2}. \tag{3.7}$$

The action of the ten operators (3.6) on the latter can be shown to be the following:

$$L_+F_n^{(\alpha,\beta)} = -\frac{q^{-n+\alpha/2+3/4}(1-q^{n+\alpha+\beta+1})}{(1-q)(1+q^{(\alpha+\beta+1)/2})(1+q^{(\alpha+\beta+2)/2})}F_{n-1}^{(\alpha+1,\beta+1)}, \tag{3.8a}$$

$$L_-F_n^{(\alpha,\beta)} = -\frac{1}{q^{\alpha/2+1/4}}\frac{1-q^{n+1}}{1-q}(1+q^{(\alpha+\beta-1)/2})(1+q^{(\alpha+\beta)/2})F_{n+1}^{(\alpha-1,\beta-1)}, \tag{3.8b}$$

$$L_0 F_n^{(\alpha,\beta)} = \frac{1-q^{\alpha+\beta}}{1-q} F_n^{(\alpha,\beta)}, \tag{3.8c}$$

$$J_+ F_n^{(\alpha,\beta)} = \frac{q^{-(\alpha+\beta-2)/4}}{1-q} (1-q^{n+\alpha}) F_n^{(\alpha-1,\beta+1)}, \tag{3.8d}$$

$$J_- F_n^{(\alpha,\beta)} = \frac{q^{-n-(\alpha+\beta)/4}}{1-q} (1-q^{n+\beta}) F_n^{(\alpha+1,\beta-1)}, \tag{3.8e}$$

$$K F_n^{(\alpha,\beta)} = q^{(\beta-\alpha)/2} F_n^{(\alpha,\beta)}, \tag{3.8f}$$

$$P_+ F_n^{(\alpha,\beta)} = \frac{1}{(1+q^{(\alpha+\beta+1)/2})(1-q^{(2n+\alpha+\beta+1)/2})} \times [(1-q^{n+\alpha+\beta+1}) F_n^{(\alpha,\beta+1)} + q^{(\alpha+\beta+1)/2}(1-q^{n+\alpha}) F_{n-1}^{(\alpha,\beta+1)}], \tag{3.8g}$$

$$P_- F_n^{(\alpha,\beta)} = q^{-(\alpha+\beta)/4} \frac{1+q^{(\alpha+\beta)/2}}{q^{\alpha/2+1}} \frac{1}{(1-q^{(2n+\alpha+\beta+1)/2})} \times [q^{\beta}(1-q^{n+1}) F_{n+1}^{(\alpha,\beta-1)} + q^{(\alpha+\beta+1)/2}(1-q^{n+\beta}) F_n^{(\alpha,\beta-1)}], \tag{3.8h}$$

$$Q_+ F_n^{(\alpha,\beta)} = -\frac{q^{-(\alpha+\beta)/4}}{(1+q^{(\alpha+\beta+1)/2})(1-q^{(2n+\alpha+\beta+1)/2})} \times [q^{\beta}(1-q^{n+\alpha+\beta+1}) F_n^{(\alpha+1,\beta)} - q^{-n+(\alpha+\beta+1)/2}(1-q^{n+\beta}) F_{n-1}^{(\alpha+1,\beta)}], \tag{3.8i}$$

$$Q_- F_n^{(\alpha,\beta)} = \frac{1+q^{(\alpha+\beta)/2}}{q^{\alpha/2+1/4}} \frac{1}{(1-q^{(2n+\alpha+\beta+1)/2})} \times [(1-q^{n+1}) F_{n+1}^{(\alpha-1,\beta)} - q^{n+(\alpha+\beta+1)/2}(1-q^{n+\alpha}) F_n^{(\alpha-1,\beta)}]. \tag{3.8j}$$

IV. THE q-ANALOG OF THE EXPANSION OF A PLANE WAVE IN TERMS OF JACOBI POLYNOMIALS

In order to illustrate how some of the previous results may be applied to the theory of q-special functions, we will now derive algebraically a q analog of the expansion (1.1) of a plane wave in terms of Jacobi polynomials. As a starting point, we will let $\mathscr{E}_q(x;-i,r)$ act on the function $F_0^{(\alpha,\beta)}(x,s,t)$ and expand the result on the complete basis (3.7):

$$\mathscr{E}_q(x;-i,r) F_0^{(\alpha,\beta)}(x,s,t) = \sum_{n=0}^{\infty} W_n^{(\alpha,\beta)}(r) F_n^{(\alpha,\beta)}(x,s,t). \tag{4.1}$$

This expansion involves no summation over α and β, because the left-hand side is an eigenfunction of L_0 and K, which both commute with the q exponential. Therefore, the right-hand side also must be an eigenstate of these operators, with the same eigenvalues. We will extract from (4.1) the expansion we are looking for by exploiting the properties of the model we have built for q-deformed $e(4)$ in the previous section. Acting successively with L_+, L_-, and P_+ on both members of (4.1) will yield enough conditions on the coefficients $W_n^{(\alpha,\beta)}$ to make their complete determination possible.

The action of the operator L_+ on the left-hand side of (4.1) follows directly from its definition (3.4a), the definition (3.7) of $F_0^{(\alpha,\beta)}$ and Eq. (2.12),

$$L_+ \mathscr{E}_q(x;-i,r)F_0^{(\alpha,\beta)} = -\frac{irq^{-1/4}}{1-q}\,\mathscr{E}_q(x;-i,r)F_0^{(\alpha+1,\beta+1)}$$
$$= -\frac{irq^{-1/4}}{1-q}\sum_{n=0}^{\infty} W_n^{(\alpha+1,\beta+1)}F_n^{(\alpha+1,\beta+1)}, \tag{4.2}$$

while its action on the right-hand side is an immediate consequence of (3.8a),

$$L_+\sum_{n=0}^{\infty} W_n^{(\alpha,\beta)}F_n^{(\alpha,\beta)} = -\sum_{n=0}^{\infty}\frac{q^{-n+\alpha/2+3/4}(1-q^{n+\alpha+\beta+1})}{(1-q)(1+q^{(\alpha+\beta+1)/2})(1+q^{(\alpha+\beta+2)/2})}\,W_n^{(\alpha,\beta)}F_{n-1}^{(\alpha+1,\beta+1)}. \tag{4.3}$$

Comparing (4.2) and (4.3), we obtain a first condition on the coefficients $W_n^{(\alpha,\beta)}$;

$$W_{n-1}^{(\alpha+1,\beta+1)}(r) = -\frac{i}{r}\frac{q^{-n+\alpha/2+1}(1-q^{n+\alpha+\beta+1})}{(1+q^{(\alpha+\beta+1)/2})(1+q^{(\alpha+\beta+2)/2})}\,W_n^{(\alpha,\beta)}(r). \tag{4.4}$$

The action of L_- on the left-hand side of (4.1) is a less straightforward operation, since one must first know the result of acting with τ^* on $\mathscr{E}_q(x;-i;r)F_0^{(\alpha,\beta)}$. This can be determined by expressing τ^* in terms of the operators defined in (2.10), (2.13), and (2.14),

$$\tau^* F_n^{(\alpha,\beta)} = [\tilde{\tau}_q^* + q^{-3/4}(1+q^{1/2})(q^{\alpha/2}-q^{\beta/2})\tilde{\mu}_q + q^{-1/2}[q^\alpha + q^\beta - q^{(\alpha+\beta-1)/2}(1+q^{1/2})^2]\tau$$
$$+ q^{-3/4}(1+q^{1/2})q^{(\alpha+\beta)/2}(q^{\alpha/2}-q^{\beta/2})\tilde{\mu}_{1/q} - q^{\alpha+\beta-1}\tilde{\tau}_{1/q}^*]F_n^{(\alpha,\beta)}. \tag{4.5}$$

Using the relations (2.12) and (2.15), one then obtains

$$\tau^*\mathscr{E}_q(x;-i,r)F_0^{(\alpha,\beta)} = \tau_r^*(\alpha,\beta)\mathscr{E}_q(x;-i,r)F_0^{(\alpha,\beta)}, \tag{4.6}$$

where $\tau_r^*(\alpha,\beta)$ is an operator acting on the variable r instead of x:

$$\tau_r^*(\alpha,\beta) \equiv \left\{ i\frac{q^{1/4}}{r}\left[\left(1+\frac{r^2}{q^2}\right)T_r^{-1}-1\right] + q^{-3/4}(1+q^{1/2})(q^{\alpha/2}-q^{\beta/2})\frac{(-r^2/q;q^2)_\infty}{(-r^2;q^2)_\infty}\,T_r^{-1/2}\right.$$
$$- irq^{-3/4}[q^\alpha + q^\beta - q^{(\alpha+\beta-1)/2}(1+q^{1/2})^2] + q^{-3/4}(1+q^{1/2})q^{(\alpha+\beta)/2}$$
$$\left.\times(q^{\alpha/2}-q^{\beta/2})\frac{(-r^2q;q^2)_\infty}{(-r^2q^2;q^2)_\infty}\,T_r^{1/2} + i\frac{q^{1/4}}{r}\,q^{\alpha+\beta-1}[(1+r^2q)T_r - 1]\right\}. \tag{4.7}$$

Steps analogous to those leading to (4.2) and (4.3) finally yield, for the action of L_- on both members of (4.1),

$$\tau_r^*(\alpha,\beta)\sum_{n=0}^{\infty} W_n^{(\alpha-1,\beta-1)}(r)F_n^{(\alpha-1,\beta-1)}(x,s,t)$$
$$= -\frac{(1+q^{(\alpha+\beta-1)/2})(1+q^{(\alpha+\beta)/2})}{q^{\alpha/2+1/4}}\sum_{n=0}^{\infty}(1-q^{n+1})W_n^{(\alpha,\beta)}(r)$$
$$\times F_{n+1}^{(\alpha-1,\beta-1)}(x,s,t), \tag{4.8}$$

which entails the following conditions on the coefficients $W_n^{(\alpha,\beta)}$:

$$\tau_r^*(\alpha,\beta)W_0^{(\alpha-1,\beta-1)}(r)=0, \tag{4.9a}$$

$$\tau_r^*(\alpha,\beta)W_{n+1}^{(\alpha-1,\beta-1)}(r)=-\frac{(1-q^{n+1})}{q^{\alpha/2+1/4}}(1+q^{(\alpha+\beta-1)/2})(1+q^{(\alpha+\beta)/2})W_n^{(\alpha,\beta)}(r),$$

$$n\geqslant 0. \tag{4.9b}$$

Using (4.4), one can express $W_n^{(\alpha,\beta)}$ in terms of the $W_{n+1}^{(\alpha-1,\beta-1)}$, so that (4.9) can be rewritten as

$$\tau_r^*(\alpha+1,\beta+1)W_n^{(\alpha,\beta)}(r)=\frac{i}{r}q^{-n+1/4}(1-q^{n+\alpha+\beta+1})(1-q^n)W_n^{(\alpha,\beta)}(r). \tag{4.10}$$

Notice that this condition includes (4.9a), since the right-hand side vanishes for $n=0$. In terms of the variable $y=ir$, it becomes

$$\begin{aligned}\Bigg\{\Bigg[\left(1-\frac{y^2}{q^2}\right)T_y^{-1}-1\Bigg]&-y(1+q^{-1/2})(q^{\alpha/2}-q^{\beta/2})\frac{(y^2/q;q^2)_\infty}{(y^2;q^2)_\infty}T_y^{-1/2}\\&+y^2[q^\alpha+q^\beta-q^{(\alpha+\beta-1)/2}(1+q^{1/2})^2]+(1-q^{-n})(1-q^{n+\alpha+\beta+1})\\&-y(1+q^{1/2})q^{(\alpha+\beta+1)/2}(q^{\alpha/2}-q^{\beta/2})\frac{(y^2q;q^2)_\infty}{(y^2q^2;q^2)_\infty}T_y^{1/2}\\&+q^{\alpha+\beta+1}[(1-y^2q)T_y-1]\Bigg\}W_n^{(\alpha,\beta)}(y)=0.\end{aligned} \tag{4.11}$$

This q-difference equation determines the function $W_n^{(\alpha,\beta)}(y)$ up to a multiplicative constant. The first problem one meets when trying to solve it comes from the two terms involving ratios of infinite q-shifted factorials (which, incidentally, happen to disappear in the special case $\alpha=\beta$, where the continuous q-Jacobi polynomials reduce to continuous q-ultraspherical polynomials). Hopefully, one can eliminate these unwieldy ratios by assuming that $W_n^{(\alpha,\beta)}(y)$ itself contains a similar ratio such that it is reconstituted up to a simple multiplicative factor when acted upon by the operators involved in the various terms of the equation. Then, the common ratio of infinite q-shifted factorials can be factored out. Assuming that $W_n^{(\alpha,\beta)}(y)$ is of the form

$$W_n^{(\alpha,\beta)}(y)=C_n^{(\alpha,\beta)}\frac{(\sigma y^k q^l;q^m)_\infty}{(\rho y^\kappa q^\lambda;q^\mu)_\infty}w_n(y), \tag{4.12}$$

where $C_n^{(\alpha,\beta)}$ is a constant, one checks easily that this condition is realized only if the parameters of the ratio take the values $\sigma=\pm 1$, $\rho=-\sigma$, $k=\kappa=m=\mu=1$, $l=1/2$, and $\lambda=0$. Indeed,

$$\frac{(y^2/q;q^2)_\infty}{(y^2;q^2)_\infty}T_y^{-1/2}\frac{(\sigma y q^{1/2};q)_\infty}{(-\sigma y;q)_\infty}=(1-\sigma q^{-1/2}y)\frac{(\sigma y q^{1/2};q)_\infty}{(-\sigma y;q)_\infty}, \tag{4.13a}$$

$$\frac{(y^2q;q^2)_\infty}{(y^2q^2;q^2)_\infty}T_y^{1/2}\frac{(\sigma y q^{1/2};q)_\infty}{(-\sigma y;q)_\infty}=(1+\sigma y)\frac{(\sigma y q^{1/2};q)_\infty}{(-\sigma y;q)_\infty}, \tag{4.13b}$$

and the simpler operators T_y and T_y^{-1} act in an analogous fashion.

Equation (4.11) can be further simplified by making the substitution $q^{1/2}\to q$, to eliminate fractional powers of T_y, and, finally, by writing $w_n(y)=y^n\phi_n(y)$, so that

$$W_n^{(\alpha,\beta)}(y)=C_n^{(\alpha,\beta)}\frac{(\sigma y q^{1/2};q)_\infty}{(-\sigma y;q)_\infty}\,y^n\phi_n(y). \tag{4.14}$$

It then reduces to

$$\begin{aligned}&\{q^2(1-\sigma q^{-2}y)(1-\sigma q^{-1}y)T_y^{-2}-(1+q)(a-b)y(1-\sigma q^{-1}y)T_y^{-1}\\&+[(a-b)^2-abq^{-1}(1+q^2)]y^2-(1+q)ab(a-b)y(1+\sigma y)T_y\\&+a^2b^2(1+\sigma qy)(1+\sigma y)T_y^2-q^2-a^2b^2\}\phi_n(y)=0,\end{aligned} \tag{4.15}$$

with the notation

$$a=q^{n+\alpha+1},\quad b=q^{n+\beta+1}. \tag{4.16}$$

Amazingly enough, this equation can be factorized in the following manner:

$$\begin{aligned}&[ab(1+\sigma y)T_y-(a-b)y+q+ab+q(1-\sigma q^{-1}y)T_y^{-1}]\\&\times[ab(1+\sigma y)T_y-(a-b)y-q-ab+q(1-\sigma q^{-1}y)T_y^{-1}]\phi_n(y)=0.\end{aligned} \tag{4.17}$$

For $\sigma=1$, one recognizes in the second factor of (4.17), the equation

$$[(1-bT_y)(1+aT_y)-(1-abT_y)D_y^+]\phi(y)=0, \tag{4.18}$$

when multiplied from the left by $-yT_y^{-1}$. Thus, in order to find a solution of (4.17) in that case, it is enough to solve the much simpler equation (4.18). Solutions of the latter are known:[21] the regular one is the basic hypergeometric series ${}_2\phi_1(b,-a;ab;q,y)$. Therefore, up to a multiplicative constant, the solution of Eq. (4.11) is

$$W_n^{(\alpha,\beta)}(y)=C_n^{(\alpha,\beta)}\frac{(\sigma y q^{1/2};q)_\infty}{(-\sigma y;q)_\infty}\,y^n\,{}_2\phi_1\left(\begin{matrix}q^{(n+\beta+1)/2},-q^{(n+\alpha+1)/2}\\ q^{(2n+\alpha+\beta+2)/2}\end{matrix}\middle|\,q^{1/2};y\right), \tag{4.19}$$

for $\sigma=1$. When $\sigma=-1$, one falls back on the previous case by doing $y\to -y$ and $a\leftrightarrow b$ in (4.17). Using Heines's q analog of Euler's transformation formula,[1] one easily shows that performing these substitutions in (4.19) yields no new solution.

All that remains to be done, now, is to determine the multiplicative constants $C_n^{(\alpha,\beta)}$. A two-term recurrence relation for these quantities can be obtained by acting on both members of (4.1) with the operator P_+. Proceeding in the usual manner, one obtains a condition on the coefficients $W_n^{(\alpha,\beta)}$, which, once expressed in terms of the $C_n^{(\alpha,\beta)}$ through (4.19), reads

$$\begin{aligned}&C_n^{(\alpha,\beta+1)}\,{}_2\phi_1((qb)^{1/2},-a^{1/2};(qab)^{1/2};q^{1/2},y)\\&=\frac{1}{1+q^{(\alpha+\beta+1)/2}}\left\{\frac{1-q^{n+\alpha+\beta+1}}{1-q^{(2n+\alpha+\beta+1)/2}}\,C_n^{(\alpha,\beta)}\,{}_2\phi_1(b^{1/2},-a^{1/2};(ab)^{1/2};q^{1/2},y)\right.\\&\left.+\frac{q^{(\alpha+\beta+1)/2}(1-q^{n+\alpha+1})}{1-q^{(2n+\alpha+\beta+3)/2}}\,C_{n+1}^{(\alpha,\beta)}y\,{}_2\phi_1((qb)^{1/2},-(qa)^{1/2};q(ab)^{1/2};q^{1/2},y)\right\}.\end{aligned} \tag{4.20}$$

Now, it is a simple matter to prove the following three-term recurrence relation:

$$ {}_2\phi_1(bq,-a;abq;q,y)={}_2\phi_1(b,-a;ab;q,y)+\frac{b(1-a^2)}{(1-ab)(1-abq)}\,y\,{}_2\phi_1(bq,-aq;abq^2;q,y). \tag{4.21} $$

When used on the left-hand side of (4.20), the latter leads to a relation between two linearly independent functions ${}_2\phi_1$, which yields the following two conditions on the multiplicative coefficients $C_n^{(\alpha,\beta)}$:

$$ C_n^{(\alpha,\beta+1)}=\frac{1-q^{n+\alpha+\beta+1}}{(1+q^{(\alpha+\beta+1)/2})(1-q^{(2n+\alpha+\beta+1)/2})}\,C_n^{(\alpha,\beta)}, \tag{4.22a} $$

$$ \frac{q^{n/2}}{1-q^{(2n+\alpha+\beta+2)/2}}\,C_n^{(\alpha,\beta+1)}=\frac{q^{\alpha/2}}{1+q^{(\alpha+\beta+1)/2}}\,C_{n+1}^{(\alpha,\beta)}. \tag{4.22b} $$

Eliminating $C_n^{(\alpha,\beta+1)}$ from these equations, one obtains a two-term recurrence relation,

$$ C_{n+1}^{(\alpha,\beta)}=\frac{q^{(n-\alpha)/2}(1-q^{n+\alpha+\beta+1})}{(1-q^{(2n+\alpha+\beta+1)/2})(1-q^{(2n+\alpha+\beta+2)/2})}\,C_n^{(\alpha,\beta)}, \tag{4.23} $$

which is easily solved by iteration and determines $C_n^{(\alpha,\beta)}$ up to a multiplicative function of α and β, $C_0^{(\alpha,\beta)}$,

$$ C_n^{(\alpha,\beta)}=\frac{q^{n(n-2\alpha-1)/4}(q^{\alpha+\beta+1};q)_n}{(q^{(\alpha+\beta+1)/2},q^{(\alpha+\beta+2)/2};q)_n}\,C_0^{(\alpha,\beta)}. \tag{4.24} $$

It turns out that $C_0^{(\alpha,\beta)}$ is a constant independent of α and β. Indeed, for $n=0$ Eq. (4.22a) becomes

$$ C_0^{(\alpha,\beta+1)}=C_0^{(\alpha,\beta)}. \tag{4.25} $$

Besides, using Eq. (4.19), we can rewrite (4.4) in the following manner:

$$ C_{n+1}^{(\alpha,\beta)}=\frac{(1+q^{(\alpha+\beta+1)/2})(1+q^{(\alpha+\beta+2)/2})}{q^{-n+\alpha/2}(1-q^{n+\alpha+\beta+2})}\,C_n^{(\alpha+1,\beta+1)}. \tag{4.26} $$

Equating the right-hand sides of (4.23) and (4.26), and setting $n=0$, we obtain

$$ C_0^{(\alpha+1,\beta+1)}=C_0^{(\alpha,\beta)}. \tag{4.27} $$

The fact that $C_0^{(\alpha,\beta)}$ is a constant follows immediately from (4.25) and (4.27). Its value can be determined to be $C_0^{(\alpha,\beta)}=1$ by setting $r=0$ in (4.1) and (4.19).

Finally, setting $s=t=1$ in (4.1), we obtain the expansion of the q exponential in terms of continuous q-Jacobi polynomials,

$$ \mathscr{E}_q(x;-i,r)=\sum_{n=0}^{\infty} W_n^{(\alpha,\beta)}(r)P_n^{(\alpha,\beta)}(x|q), \tag{4.28a} $$

with

$$W_n^{(\alpha,\beta)}(r)=q^{n(n-2\alpha-1)/4}\frac{(q^{\alpha+\beta+1};q)_n}{(q^{(\alpha+\beta+1)/2},q^{(\alpha+\beta+2)/2};q)_n}(ir)^n\frac{(irq^{1/2};q)_\infty}{(-ir;q)_\infty}$$
$$\times{}_2\phi_1\left(\begin{matrix}q^{(n+\beta+1)/2},-q^{(n+\alpha+1)/2},\\ q^{(2n+\alpha+\beta+2)/2}\end{matrix}\middle|q^{1/2};ir\right). \tag{4.28b}$$

This q analog of the expansion (1.1) was first obtained in Ref. 16. We have derived it here in a purely algebraic manner.

In the special case $\alpha=\beta$, the continuous q-Jacobi polynomials $P_n^{(\alpha,\beta)}(x|q)$ reduce to continuous q-ultraspherical polynomials $C_n(x;q^m|q)$,[2]

$$P_n^{(\alpha,\alpha)}(x|q)=q^{n(2\alpha+1)/4}\frac{(q^{\alpha+1};q)_n}{(q^{2\alpha+1};q)_n}C_n(x;q^{\alpha+1/2}|q). \tag{4.29}$$

Setting $\alpha=\beta$ in Eqs. (4.28), defining $l=\alpha+1/2$, and using (4.29) as well as the relation[1]

$${}_2\phi_1\left(\begin{matrix}q^{(n+l+1/2)/2},-q^{(n+l+1/2)/2}\\ q^{n+l+1/2}\end{matrix}\middle|q^{1/2};ir\right)=(q;q)_{n+l}\frac{r^{-(n+l)}}{(ir;q^{1/2})_\infty}J_{n+l}^{(2)}(2r;q), \tag{4.30}$$

one obtains readily the q analog of the Fourier–Gegenbauer expansion,[13,20]

$$\mathscr{E}_q(x;-i,r)=\frac{r^{-l}}{(-r^2;q^2)_\infty}(q;q)_{l-1}\sum_{n=0}^{\infty}i^n q^{n^2/4}(1-q^{n+l})J_{n+l}^{(2)}(2r;q)C_n(x;q^l|q), \tag{4.31}$$

as a special case of the expansion (4.28).

APPENDIX: THE $q\to 1^-$ LIMIT

Before considering the $q\to 1^-$ limit of the model given in Sec. III, let us first recall the structure of the Lie algebra of Euclidean transformations in a four-dimensional space. The six rotation operators m_{ij} and the four translation operators p_i have the following commutation relations:

$$[m_{ij},m_{kl}]=\delta_{jk}m_{il}-\delta_{jl}m_{ik}-\delta_{ik}m_{jl}+\delta_{il}m_{jk}, \tag{A1}$$

$$[m_{ij},p_k]=\delta_{jk}p_i-\delta_{ik}p_j, \tag{A2}$$

$$[p_i,p_j]=0. \tag{A3}$$

In order to investigate the structure of this algebra, it proves useful to define the following linear combinations of the six m_{ij}'s:

$$l_1=\frac{i}{2}(m_{32}+m_{41}),\quad l_2=\frac{i}{2}(m_{13}+m_{42}),\quad l_3=\frac{i}{2}(m_{21}+m_{43}),$$
$$j_1=\frac{i}{2}(m_{32}-m_{41}),\quad j_2=\frac{i}{2}(m_{13}-m_{42}),\quad j_3=\frac{i}{2}(m_{21}-m_{43}). \tag{A4}$$

As a consequence of (A3), they obey the commutation relations

$$[l_\lambda, l_\mu] = \epsilon_{\lambda\mu\nu} l_\nu, \quad [j_\lambda, j_\mu] = \epsilon_{\lambda\mu\nu} j_\nu, \quad [l_\mu, j_\nu] = 0, \tag{A5}$$

where Greek indices take values from 1 to 3 only. This makes explicit that the $so(4)$ subalgebra of $e(4)$ is isomorphic to $so(3) \oplus so(3)$.

Finally, introducing the further definitions

$$\begin{aligned} l_\pm &= l_1 \pm i l_2, & l_0 &= 2 l_3, \\ j_\pm &= j_1 \pm i j_2, & j_0 &= 2 j_3, \\ p_\pm &= p_2 \pm i p_3, & q_\pm &= p_1 \pm i p_4, \end{aligned} \tag{A6}$$

we can write the Lie algebra of Euclidean transformations in a four-dimensional space in the following manner:

$$\begin{aligned} [l_+, l_-] &= l_0, & [j_+, j_-] &= j_0, \\ [l_0, l_\pm] &= \pm 2 l_\pm, & [j_0, j_\pm] &= \pm 2 j_\pm, \\ [l_0, p_\pm] &= \pm p_\pm, & [j_0, p_\pm] &= \pm p_\pm, \\ [l_\pm, p_\pm] &= 0, & [j_\pm, p_\pm] &= 0, \\ [l_\pm, p_\mp] &= \pm q_\pm, & [j_\pm, p_\mp] &= \pm q_\mp, \\ [l_0, q_\pm] &= \pm q_\pm, & [j_0, q_\pm] &= \mp q_\pm, \\ [l_\pm, q_\pm] &= 0, & [j_\pm, q_\mp] &= 0, \\ [l_\pm, q_\mp] &= \mp p_\pm, & [j_\pm, q_\pm] &= \mp p_\pm. \end{aligned} \tag{A7}$$

Moreover, the four translation operators $\{p_+, p_-, q_+, q_-\}$ all commute with each other.

Now, defining the operator J_0 through

$$K = q^{J_0/2}, \tag{A8}$$

one sees readily that the q-deformed algebra (3.6) reduces to the Lie algebra we have just written, when $q \to 1^-$, with

$$\lim_{q \to 1^-} L_\pm = l_\pm, \tag{A9}$$

and so on. Explicitly, the operators defined in (3.4), (A8) and (A9) then become

$$\begin{aligned} l_0 &= 2s \frac{\partial}{\partial s}, & j_0 &= 2t \frac{\partial}{\partial t}, \\ l_+ &= -\frac{s}{2} \frac{\partial}{\partial x}, & j_+ &= t\left[(x-1)\frac{\partial}{\partial x} + s\frac{\partial}{\partial s} - t\frac{\partial}{\partial t}\right], \\ l_- &= \frac{2}{s}\left[(1-x^2)\frac{\partial}{\partial x} - 2xs\frac{\partial}{\partial s} + 2t\frac{\partial}{\partial t}\right], & j_- &= \frac{1}{t}\left[(x+1)\frac{\partial}{\partial x} + s\frac{\partial}{\partial s} + t\frac{\partial}{\partial t}\right], \\ p_+ &= s^{1/2} t^{1/2}, & p_- &= 2 s^{-1/2} (x+1) t^{-1/2}, \end{aligned} \tag{A10}$$

$$q_+ = -s^{1/2}t^{-1/2}, \quad q_- = 2s^{-1/2}(x-1)t^{1/2},$$

while the basis vectors are now expressed[2] in terms of classical Jacobi polynomials,

$$f_n^{(\alpha,\beta)}(x,s,t) = \lim_{q\to 1^-} F_n^{(\alpha,\beta)}(x,s,t) = s^{(\alpha+\beta)/2} P_n^{(\alpha,\beta)}(x) t^{(\beta-\alpha)/2}. \tag{A11}$$

In this realization, the action of the generators on the basis vectors is the following:

$$\begin{aligned}
l_+ f_n^{(\alpha,\beta)} &= -\frac{n+\alpha+\beta+1}{4} f_{n-1}^{(\alpha+1,\beta+1)}, \quad j_+ f_n^{(\alpha,\beta)} = (n+\alpha) f_n^{(\alpha-1,\beta+1)}, \\
l_- f_n^{(\alpha,\beta)} &= -4(n+1) f_{n+1}^{(\alpha-1,\beta-1)}, \quad j_- f_n^{(\alpha,\beta)} = (n+\beta) f_n^{(\alpha+1,\beta-1)}, \\
l_0 f_n^{(\alpha,\beta)} &= (\alpha+\beta) f_n^{(\alpha,\beta)}, \quad j_0 f_n^{(\alpha,\beta)} = (\beta-\alpha) f_n^{(\alpha,\beta)}, \\
p_+ f_n^{(\alpha,\beta)} &= \frac{1}{2n+\alpha+\beta+1}\left[(n+\alpha+\beta+1) f_n^{(\alpha,\beta+1)} + (n+\alpha) f_{n-1}^{(\alpha,\beta+1)}\right], \\
q_+ f_n^{(\alpha,\beta)} &= -\frac{1}{2n+\alpha+\beta+1}\left[(n+\alpha+\beta+1) f_n^{(\alpha+1,\beta)} - (n+\beta) f_{n-1}^{(\alpha+1,\beta)}\right], \\
p_- f_n^{(\alpha,\beta)} &= \frac{4}{2n+\alpha+\beta+1}\left[(n+1) f_{n+1}^{(\alpha,\beta-1)} + (n+\beta) f_n^{(\alpha,\beta-1)}\right], \\
q_- f_n^{(\alpha,\beta)} &= \frac{4}{2n+\alpha+\beta+1}\left[(n+1) f_{n+1}^{(\alpha-1,\beta)} - (n+\alpha) f_n^{(\alpha-1,\beta)}\right],
\end{aligned} \tag{A12}$$

as can be seen by taking the limit $q\to 1^-$ in (3.8), or by applying directly the operators (A10) to the basis functions $f_n^{(\alpha,\beta)}(x,s,t)$.

The algebraic derivation of the expansion of an exponential in terms of Jacobi polynomials, Eq. (1.1), is also the $q\to 1^-$ limit of the derivation given in Sec. IV for the q analog of this expansion. Writing

$$e^{irx} f_0^{(\alpha,\beta)} = \sum_{n=0}^{\infty} w_n^{(\alpha,\beta)}(r) f_n^{(\alpha,\beta)}(x,s,t), \tag{A13}$$

one determines the coefficients $w_n^{(\alpha,\beta)}(r)$ by acting on (A12) with the generators l_+, l_-, and p_+. This yields, respectively, the following three relations:

$$w_{n-1}^{(\alpha+1,\beta+1)}(r) = -\frac{i}{r}\frac{n+\alpha+\beta+1}{2} w_n^{(\alpha,\beta)}(r), \tag{A14}$$

$$\left\{ ir\left(1+\frac{\partial^2}{\partial r^2}\right) + (\alpha+\beta) i \frac{\partial}{\partial r} + \beta - \alpha \right\} w_{n+1}^{(\alpha-1,\beta-1)}(r) = -2(n+1) w_n^{(\alpha,\beta)}(r), \tag{A15}$$

and

$$w_n^{(\alpha,\beta+1)}(r) = \frac{n+\alpha+\beta+1}{2n+\alpha+\beta+1} w_n^{(\alpha,\beta)}(r) + \frac{n+\alpha+1}{2n+\alpha+\beta+3} w_{n+1}^{(\alpha,\beta)}(r). \tag{A16}$$

The first two relations give

$$\left\{ir\left(1+\frac{\partial^2}{\partial r^2}\right)+(\alpha+\beta+2)i\,\frac{\partial}{\partial r}+\beta-\alpha\right\}w_n^{(\alpha,\beta)}(r)=\frac{i}{r}\,n(n+\alpha+\beta+1)w_n^{(\alpha,\beta)}(r), \quad \text{(A17)}$$

which is easily seen to have the solution

$$w_n^{(\alpha,\beta)}(r)=c_n^{(\alpha,\beta)}e^{-ir}(2ir)^n{}_1F_1\left(\begin{matrix}n+\beta+1\\2n+\alpha+\beta+2\end{matrix}\middle|2ir\right). \quad \text{(A18)}$$

Proceeding as in the previous section, one finds that, as a consequence of (A16), the multiplicative constant is

$$c_n^{(\alpha,\beta)}=\frac{(\alpha+\beta+1)_n}{(\alpha+\beta+1)_{2n}}. \quad \text{(A19)}$$

Some trigonometric sums arising in the perturbative study of integrable chiral Z_n quantum chains are directly evaluated. © *1996 American Institute of Physics.* [S0022-2488(96)01006-7]

I. INTRODUCTION AND RESULTS

In the study of chiral Potts model[1] and of the integrable chiral Z_n quantum chains,[2] the high- and low-temperature expansions of the free energy serve as generating functions for some classes of trigonometric sums. In a previous paper[3] we gave a method of evaluating directly trigonometric sums of the form

$$T_k(p)=\sum_{j=1}^{n-1}\frac{\sin^2(\pi jp/n)}{\sin^{2k+2}(\pi j/n)}, \tag{1.1}$$

$$U_k(p)=\sum_{j=1}^{n-1}\sum_{l=1}^{n-1}\frac{2(1-\omega^{jp})+2(1-\omega^{lp})-(1-\omega^{(j-l)p})}{(\sin(\pi j/n)\sin(\pi l/n))^{2k}}, \tag{1.2}$$

$$V_k(p)=\sum_{j=1}^{n-1}\sin^2\left(\frac{\pi jp}{n}\right)\sum_{l=1,l\neq j}^{n-1}\sum_{m=1,m\neq j}^{n-1}\left[\sin\left(\frac{\pi l}{n}\right)\sin\left(\frac{\pi(j-l)}{n}\right)\sin\left(\frac{\pi m}{n}\right)\sin\left(\frac{\pi(j-m)}{n}\right)\right]^{-k}, \tag{1.3}$$

$$W_k(p)=\sum_{j=1}^{n-1}\sin^2\left(\frac{\pi jp}{n}\right)\sum_{l=1,l\neq j}^{n-1}\sum_{m=1,m\neq l}^{n-1}\left[\sin\left(\frac{\pi j}{n}\right)\sin\left(\frac{\pi(j-l)}{n}\right)\sin\left(\frac{\pi(l-m)}{n}\right)\sin\left(\frac{\pi m}{n}\right)\right]^{-k}, \tag{1.4}$$

where n,k,p are all integers and the dependence on n is implicit in the definitions (1.1)–(1.4); we have set

$$\omega=\exp(2\pi i/n). \tag{1.5}$$

For this we needed the classical properties of polynomials and rational functions (the Appendix summarizes the results). This time we give a method of evaluating sums of the form

$$I(k,p)=\sum_{\substack{j_1,\ldots,j_k=1\\ j_r\neq j_{r+1}}}^{n-1}\left\{\sin\left(\frac{\pi j_1}{n}\right)\sin\frac{\pi}{n}(j_1-j_2)\cdots\sin\frac{\pi}{n}(j_{k-1}-j_k)\sin\left(\frac{\pi j_k}{n}\right)\right\}^{-p}, \tag{1.6}$$

or alternately sums

$$\bar{I}(k,p)=-(2i)^{(k+1)p}I(k,p), \tag{1.7}$$

[c)]Present address: Theory Division, Tata Institute of Fundamental Research, Homi Bhabha Road, Bombay 400 005, India.

0022-2488/96/37(8)/4150/6/$10.00

which may eventually be written as

$$\bar{I}(k,p)=\sum_{\substack{j_1,\ldots,j_k=1\\ j_r\neq j_{r+1}}}^{n-1}\left\{\frac{1}{1-\omega^{j_1}}\,\omega^{j_1}\,\frac{1}{\omega^{j_1}-\omega^{j_2}}\,\omega^{j_2}\cdots\frac{1}{\omega^{j_{k-1}}-\omega^{j_k}}\,\omega^{j_k}\,\frac{1}{\omega^{j_k}-1}\right\}^p. \tag{1.8}$$

Changing the summation indices j_r to $n-j_r$, one sees that $I(k,p)=0$ if $(k+1)p$ is odd; $\bar{I}(k,p)$ [or $I(k,p)$] will be expressed as a combination of sums of powers of a certain function $F(j,p)$:

$$\bar{I}(k,p)=\sum_{r=1}^{k+1}(-1)^{r+1}\sum_{\substack{l_1,\ldots,l_r;l_i\geqslant 2\\ l_1+\cdots+l_r=k+1}} G_{l_1}\cdots G_{l_r}, \tag{1.9}$$

$$G_l=\frac{1}{n}\sum_{j=0}^{n-1}[F(j,p)]^l. \tag{1.10}$$

Here $F(j,p)$ is a polynomial in j and n of degree p:

$$F(j,p)=(-1)^p\left[n\binom{j+p-1}{p-1}-\binom{j+p}{p}+\sum_{l=1}^{p}\binom{j+p}{p-l}t_l\right] \tag{1.11}$$

with

$$t_l=\sum_{q=1}^{n-1}(\omega^q-1)^{-l}, \tag{1.12}$$

a polynomial in n. The t_l can be calculated successively from the recurrence equation

$$t_l=c_1t_{l-1}-c_2t_{l-2}+\cdots+(-1)^lc_{l-1}t_1+(-1)^{l+1}lc_l, \tag{1.13}$$

with

$$c_j=(-1)^j\frac{1}{j+1}\binom{n-1}{j}. \tag{1.14}$$

II. $\bar{I}(k,p)$ AS A COMBINATION OF TRACES OF POWERS OF AN $n\times n$ MATRIX

Let us define the $n\times n$ matrix M_{ij}, $i,j=0,1,\ldots,n-1$, as

$$M_{ij}=\omega^{ip/2}(\omega^i-\omega^j)^{-p}\omega^{jp/2}=\frac{\omega^{(i-j)p/2}}{(\omega^{i-j}-1)^p},\quad \text{if } i\neq j, \tag{2.1}$$

$$M_{ii}=0. \tag{2.2}$$

This matrix is symmetric or antisymmetric according to whether p is even or odd. Then

$$\bar{I}(k,p)=\sum_{\substack{j_1,\ldots,j_k=1\\ j_r\neq j_{r+1}}}^{n-1}M_{0j_1}M_{j_1j_2}\cdots M_{j_{k-1}j_k}M_{j_k0}. \tag{2.3}$$

To put the index 0 on the same level as the other indices $1,2,\ldots,n-1$, we write Eq. (2.3) as

$$\bar{I}(k,p)=[M(I-P)M(I-P)M\cdots M(I-P)M]_{00}, \tag{2.4}$$

where I is the $n\times n$ unit matrix and the projector P is the $n\times n$ matrix all of whose elements are zero except the (1,1) element which is 1:

$$I=\begin{bmatrix}1&0&\cdots&0\\0&1&\cdots&0\\.&.&\cdots&.\\0&0&\cdots&1\end{bmatrix},\quad P=\begin{bmatrix}1&0&\cdots&0\\0&0&\cdots&0\\.&.&\cdots&.\\0&0&\cdots&0\end{bmatrix}. \tag{2.5}$$

Thus

$$\bar{I}(k,p)=\sum_{r=1}^{k+1}(-1)^{r+1}\prod_{l_1,\ldots,l_r}(M^{l_i})_{00},\quad l_1+\cdots+l_r=k+1, \tag{2.6}$$

where $(M^l)_{00}$ has the same structure as $\bar{I}(k,l)$ except that the summation over the intermediate indices now runs from 0 to $n-1$. As M_{ij} and hence $(M^k)_{ij}$ depend only on $i-j \bmod n$,

$$(M^l)_{00}=(M^l)_{jj},\quad j=1,2,\ldots,n-1. \tag{2.7}$$

Then we rewrite Eq. (2.6) as

$$\bar{I}(k,p)=\sum_{r=1}^{k+1}(-1)^{r+1}\prod_{l_1,\ldots,l_r}\left(\frac{1}{n}\operatorname{tr} M^{l_i}\right),\quad l_1+\cdots+l_r=k+1. \tag{2.8}$$

Setting

$$G_l=\frac{1}{n}\operatorname{tr} M^l, \tag{2.9}$$

one has, for example,

$$\bar{I}(1,p)=G_2, \tag{2.10}$$

$$\bar{I}(2,p)=G_3, \tag{2.11}$$

$$\bar{I}(3,p)=G_4-G_2^2, \tag{2.12}$$

$$\bar{I}(4,p)=G_5-2G_3G_2, \tag{2.13}$$

$$\bar{I}(5,p)=G_6-2G_4G_2-G_3^2+G_2^3, \tag{2.14}$$

etc.

III. DIAGONALIZATION OF *M*

Fortunately, the matrix M may be easily diagonalized with the obviously unitary matrix B:

$$B_{ij}=\frac{1}{\sqrt{n}}\omega^{i(j+p/2)},\quad i,j=0,1,\ldots,n-1. \tag{3.1}$$

We have

$$(B^{\dagger}MB)_{ij}=\frac{1}{n}\sum_{l,m=0}^{n-1}\omega^{-l(i+p/2)}\frac{\omega^{(l-m)p/2}}{(\omega^{l-m}-1)^{p}}\omega^{m(j+p/2)}(1-\delta_{lm}). \tag{3.2}$$

Setting $l-m=q$ as a new summation index, one has

$$(B^{\dagger}MB)_{ij}=\frac{1}{n}\sum_{m=0}^{n-1}\omega^{m(j-1)}\sum_{q=1}^{n-1}\frac{\omega^{-iq}}{(\omega^{q}-1)^{p}}=\delta_{ij}F(j,p), \tag{3.3}$$

where the quantities

$$\begin{aligned}F(j,p)&=\sum_{q=1}^{n-1}\frac{\omega^{-jq}}{(\omega^{q}-1)^{p}},\\&=\sum_{q=1}^{n-1}\frac{\omega^{q(j+p)}}{(1-\omega^{q})^{p}},\quad j=0,1,\ldots,n-1,\end{aligned} \tag{3.4}$$

are the eigenvalues of M. To get the second form in Eq. (3.4) one changes, for example, the summation index q to $n-q$. Note that

$$F(j,p)=(-1)^{p}F(n-p-j,p). \tag{3.5}$$

IV. CALCULATION OF THE EIGENVALUES

To compute $F(j,p)$, we use partial fractions

$$\frac{x^{j+p}}{(x-1)^{p}}=A(x)+\sum_{l=1}^{p}\frac{a_l}{(x-1)^{l}}, \tag{4.1}$$

where $A(x)$ is a polynomial of degree j and $a_1,\ldots,a_p$ are constants. Clearing the denominators, one has

$$x^{j+p}=(x-1)^{p}A(x)+\sum_{l=1}^{p}a_l(x-1)^{p-l}, \tag{4.2}$$

and a simple limiting procedure gives

$$a_l=\binom{j+p}{p-l},\quad l=1,2,\ldots,p, \tag{4.3}$$

$$A(1)=\binom{j+p}{p}. \tag{4.4}$$

We shall also need

$$A(0)=a_1-a_2+a_3-a_4+\cdots+(-1)^{p+1}a_p=\sum_{l=1}^{p}(-1)^{l+1}\binom{j+p}{p-l}=\binom{j+p-1}{p-1}. \tag{4.5}$$

The summation over the index q of the polynomial part of (4.1) is easily performed using a trick similar to that in Ref. 3: setting $A(x)=\Sigma_{s=0}^{j}\lambda_s x^{s}$, we have

$$\sum_{q=1}^{n-1} A(\omega^q)=\sum_{s=0}^{j}\lambda_s\sum_{q=1}^{n-1}\omega^{qs}=\sum_{s=0}^{j}\lambda_s(-1+n\delta_{s,0})=nA(0)-A(1). \tag{4.6}$$

As to the remaining polar part, it is rewritten as $\Sigma_{l=1}^{p}a_l t^l$ with

$$t_l=\sum_{q=1}^{n-1}(\omega^q-1)^{-l}. \tag{4.7}$$

Therefore,

$$F(j,p)=(-1)^p\left\{nA(0)-A(1)+\sum_{l=1}^{p}a_l t_l\right\}. \tag{4.8}$$

The $A(0)$, $A(1)$, and a_l are given by Eqs. (4.5), (4.4), and (4.3). The t_l are the power sums of the roots of the algebraic equation

$$(y+1)^n-y^n=0 \tag{4.9}$$

and can be computed readily (see Ref. 3). In particular, the t_l can be determined successively from the recurrence equation

$$t_l=c_1t_{l-1}-c_2t_{l-2}+c_3t_{l-3}-\cdots+(-1)^l c_{l-1}t_1+(-1)^{l+1}lc_l \tag{4.10}$$

with the elementary symmetric functions

$$c_j=(-1)^j\frac{1}{n}\binom{n}{j+1}=(-1)^j\frac{1}{j+1}\binom{n-1}{j}. \tag{4.11}$$

Thus

$$t_1=-\tfrac{1}{2}(n-1),$$

$$t_2=-\tfrac{1}{12}(n-1)(n-5),$$

$$t_3=\tfrac{1}{8}(n-1)(n-3),$$

$$t_4=\tfrac{1}{720}(n-1)(n^3+n^2-109n+251),$$

$$t_5=-\tfrac{1}{288}(n-1)(n^3+n^2-49n+95),$$

etc. We finally have

$$\frac{1}{n}\operatorname{tr} M^k=\frac{1}{n}\sum_{j=0}^{n-1}[F(j,p)]^k, \tag{4.12}$$

$$F(j,p)=(-1)^p\left[n\binom{j+p-1}{p-1}-\binom{j+p}{p}+\sum_{l=1}^{p}\binom{j+p}{p-l}t_l\right], \tag{4.13}$$

and t_l are given by Eqs. (4.10) and (4.11). For example,

$$F(j,1)=j-\tfrac{1}{2}(n-1), \tag{4.14}$$

$$F(j,2)=-\frac{1}{2}\left[\left(j-\frac{n-2}{2}\right)^2-\frac{1}{12}(n^2+2)\right], \tag{4.15}$$

$$F(j,3)=\frac{1}{6}\left(j-\frac{n-3}{2}\right)^3-\frac{1}{24}(n^2+3)\left(j-\frac{n-3}{2}\right), \tag{4.16}$$

$$F(j,4)=-\frac{1}{24}\left(j-\frac{n-4}{2}\right)^4+\frac{1}{48}(n^2+4)\left(j-\frac{n-4}{2}\right)^2-\frac{1}{5760}(7n^4+40n^2+88), \tag{4.17}$$

etc. Here $F(j,p)$ is a polynomial in $j-\frac{1}{2}(n-p)$ having the same parity as p, a simple consequence of the symmetry equation (3.5), and from the above expressions (4.14)–(4.17) it seems that the coefficients are even functions of n.

ACKNOWLEDGMENTS

M.L.M. is thankful to the Tata Institute of Fundamental Research, Bombay, for its hospitality. The authors are greatly indebted to Dr. Gilbert Mahoux for reading the manuscript and suggesting many changes to make it more readable.

APPENDIX: SUMMARY OF TRIGONOMETRIC SUMS

Summary of the trigonometric sums (1.1)–(1.4):

$$T_k(p)=p^2T_k-4\sum_{l=1}^{p}(p-l)T_{k-1}(l),$$

$$T_0(p)=p(n-p),$$

$$T_k\equiv T_k(1) \quad \text{are determined separately}$$

(see Ref. 3).

$$U_k(p)=(-1)^{k-1}2^{2k}T_{k-1}(p)T_k+2^{4k-2}T_{k-1}^2(p),$$

$$V_k(p)=4^k\sum_{l=0}^{k}(-1)^l\binom{k}{l}T_{2k-l-1}(p),$$

$$W_k(p)=-4^k\sum_{j=1}^{n-1}\frac{\sin^2(\pi jp/n)}{\sin^{2k}(\pi j/n)}\left\{2^kT_k+\left(1-\frac{3}{2\sin^2(\pi j/n)}\right)^k\right\}.$$

Thus $T_k(p)$ can be successively evaluated knowing T_k and then $U_k(p)$, $V_k(p)$, $W_k(p)$ can be evaluated successively.

Continuous wavelet transforms on the sphere

Matthias Holschneider[a)]
Centre de Physique Théorique, Unité Propre de Recherche 7061, CNRS, Luminy, Case 907 F-13288 Marseille, Cedex 9, France

(Received 6 September 1995; accepted for publication 2 April 1996)

In this very short paper we shall construct a continuous wavelet analysis based on dilations translations and rotations on the sphere. It is the analog of the construction proposed by Murenzi [in his thesis, 1990], on $\mathbb{R}^2$. At small scale we shall recover the Euclidian structure of the sphere. At large scale we obtain that the wavelet transform decays rapidly because the sphere is compact. © *1996 American Institute of Physics.* [S0022-2488(96)01408-9]

I. INTRODUCTION

Recently the construction of wavelets on the sphere has attracted attention in particular in view of applications to geophysical situations.[1] Some recent constructions of decompositions of unity on the sphere are Refs. 2–5. The first construction is based on group representations in the tangent bundle of the sphere. The second construction is mainly based on the Poisson or Heat semi-group. It also focuses on rotation invariant wavelets. The third construction is more of Weyl–Heisenberg type. The fourth construction is based on the Calderón reproducing formula. The construction we propose in this paper is different in that it constructs a family of wavelets in a more *ad hoc* way. At small scale we shall see that the sphere is flat and asymptotically our wavelet analysis tends to the usual wavelet analysis of functions on $\mathbb{R}^2$ based on dilations and rotations. A discretized version of continuous wavelet analysis on the sphere can, e.g., be found in Refs. 6 and 7.

II. THE ROTATION GROUP

We now want to decompose the Hilbert space $L^2(S^2)=L^2(S^2,d\Omega)$ of square integrable functions over the unit sphere S^2; that is, S^2 is the subset of all points x in three-dimensional Euclidean space with $|x|=1$. Here $d\Omega$ is the surface measure of the sphere. We sometimes use spherical coordinates (θ,ϕ), where θ are the latitudes and ϕ the longitudes. Thus $\theta=0$ corresponds to the north pole, that we occasionally denote by N. The south pole S corresponds to $\theta=\pi$. We denote by $\mathrm{SO}(n)$ the group of rotations of n-dimensional space. Then the two-sphere may be identified with the homogeneous space $\mathrm{SO}(3)/\mathrm{SO}(2)$. We therefore have natural left action $x\mapsto\xi\cdot x$ of $\xi\in\mathrm{SO}(3)$ on $x\in S^2$. It is given by the rotations of the sphere. We thus have an obvious unitary representations of $\mathrm{SO}(3)$ in $L^2(S^2)$ by means of

$$(U(\xi)s)(x)=s(x\cdot\xi^{-1}),\quad U(\xi)U(\xi')=U(\xi\xi').$$

A. Spherical harmonics

As is well known, the representation U is reducible. It splits into irreducible components

$$L^2(S^2)=\oplus W_l.$$

Each W_l is $2l+1$-dimensional. Consider the spherical harmonics Y_l^n, with $l=1,1,\ldots$, $n=-l,-l+1,\ldots,l$. The collection $\{Y_l^m|\ |m|\leqslant l\}$ is an ortho-normal basis of W_l. Thus they are an ortho-normal basis of $L^2(S^2)\ominus\mathbb{C}$. The complete collection $\{Y_l^m\}$ is an ortho-normal basis of $L^2(S^2)$.

a)E-mail address: hols@cpt.univ-mrs.fr

0022-2488/96/37(8)/4156/10/$10.00

In terms of the Y_l^m the representation U of SO(3) reads

$$\langle Y_l^m | U(\xi) | Y_{l'}^n \rangle = \delta_{l,l'} D_l^{m,n}(\xi),$$

where the $D^{m,n}$ are the Wiegner functions. For $n=0$ we explicitly have

$$\xi = x\phi \Rightarrow D_l^{m,0}(\xi) = Y_l^n(x). \tag{1}$$

That means $D^{m,0}(\xi)$ depends only on the coset $\xi/\mathrm{SO}(2)$ which can identify with a point in S^2.

It is natural to introduce the Fourier coefficients of $s \in L^2(S^2)$ via

$$\hat{s}(l,n) = \langle Y_l^n | s \rangle.$$

Then Plancherel's formula takes on the following form:

$$\int_{S^2} d\Omega(x) \overline{s}(x) r(x) = \sum_{l=0}^{\infty} \sum_{|m| \le l} \overline{\hat{s}(l,m)} \hat{r}(l,m).$$

III. MURENZI WAVELETS ON THE SPHERE

We now present the construction of directional wavelets over the sphere. The problem is that there is no "good" dilation operator on the sphere. This is intuitively clear, since, e.g., dilations along a geodesic around the north pole would create more and more singular functions at the south pole. We therefore will introduce the different scales in a more or less *ad hoc* way.

Let $g_a \in L^2(S^2, d\Omega)$ be a family of functions indexed by a parameter $a>0$. We usually suppose that $a \to g_a$ is Bochner integrable, but for all practical purposes one might suppose-at-least continuity $(a \mapsto g_a) \in C^0(\mathbf{R}_+, L^2(S^2))$.

We then define a wavelet transform of $s \in L^2(S^2, d\Omega)$ with respect to this family of functions as the following set of scalar products:

$$\mathscr{W}[\{g_a\}, s](\xi, a) = \langle U(\xi) g_a | s \rangle, \quad \xi \in \mathrm{SO}(3), \quad a \in \mathbf{R}_+ .$$

We sometimes also write $\mathscr{W}_{\{g_a\}} s$ and if no confusion is possible we simple write $\mathscr{W}_g s$. It is a function over the parameter half-space

$$\mathrm{H} = \mathrm{SO}(3) \times \mathbf{R}_+ .$$

Since the group SO(3) is compact, it is unimodular and hence it has an essentially unique invariant measure denoted by $d\Sigma$. We normalize it such that

$$\int_{\mathrm{SO}(3)} d\Sigma = 4\pi^2,$$

which is possible since SO(3) is compact.

The formal wavelet synthesis with respect to a family $h_a \in L^2(S^2, d\Omega)$ reads now

$$\mathscr{M}[\{h_a\}, T](x) = \int_0^{\infty} \frac{da}{a} \int_{\mathrm{SO}(3)} d\Sigma(\xi) T(\xi, a) (U(\xi) h_a)(x)$$

Again we simply write $\mathscr{M}_{\{h_a\}} r$ or simply $\mathscr{M}_h s$ if no confusion is possible.

Definition III.1: We say a family of functions $g_a \in C^{\infty}(S^2)$ is admissible if the following three conditions are met.

Condition 1 (energy conservation): There is a finite constant c_g, $0<|c_g|<\infty$, such that for all $s\in L^2(S^2)$ with $\int_{S^2} s = 0$ we have

$$\int_{\mathrm{H}} \frac{d\Sigma(\xi)\wedge da}{a} |\mathscr{W}[\{g_a\}, s](\xi,a)|^2 = c_g \int_{S^2} d\Omega(x)|s(x)|^2.$$

Condition 2 (large scale decay): For all $\alpha>0$, there is a finite constant c_α such that for $a>1$ we have

$$|\mathscr{W}[\{g_a\}, s](\xi,a)| \leq c_\alpha a^{-\alpha}.$$

Condition 3 (Euclidian limit): There is a function $g\in L^2(\mathbb{R}^2)$ such that the following limit holds pointwise almost everywhere:

$$\lim_{a\to 0} a^2 g_a(\Phi^{-1}(ax)) = g(x),$$

where $\Phi: S^2\setminus\{0,0-1\}\to\mathbb{R}^2$ is the stereographic projection of the sphere with the south pole removed onto the open two-dimensional plane.

Some comments are in order. Condition 1 says that the wavelet transform is a partial isometry. Condition 2 and 3 allow us to interpret a as a scale parameter: condition 2 says that there are now features at large scale. This is natural since the functions on the sphere live on a compact space. This also is similar to what can be observed on the circle (e.g., Ref. 8). Condition 3 finally tells us that at small scales, the earth is flat; that is, asymptotically a behaves like a dilation parameter as $a\to 0$. Clearly one might be interested in stronger convergence properties depending on the application. The reason why we still want to have at least at small scale a dilation-like behavior is simply the fact that local regularity analysis (e.g., pointwise Hölder continuity) is based on dilations being incorporated into wavelet analysis (e.g., Refs. 9 and 10).

In analogy with the case of wavelet analysis over $\mathbb{R}^2$ we also consider admissible pairs.

Definition III.2: We say that $\{g_a\}$ and $\{h_a\}$ are an admissible analysis reconstruction pair if they satisfy Condition 2 and Condition 3 and if, in addition, Condition 1 is replaced by the following.

Condition 4 (boundedness of wavelet transform): There is a constant c_g such that

$$\int_{\mathrm{H}} \frac{d\Sigma(\xi)\wedge da}{a} |\mathscr{W}[\{g_a\}, s](\xi,a)|^2 \leq c_g \int_{S^2} d\Omega(x)|s(x)|^2.$$

Condition 5 (boundedness of wavelet synthesis): There is a constant c_h such that

$$\int_{S^2} d\Omega(x)|\mathscr{M}_{\{h_a\}}T(x)|^2 \leq c_h \int_{\mathrm{H}} \frac{d\Sigma(\xi)\wedge da}{a} |T(\xi,a)|^2.$$

Condition 6 (inversion formula):

$$\mathscr{M}_{\{h_a\}}\mathscr{W}_{\{g_a\}} = \mathbb{1}.$$

We always have that $\mathscr{M}_{\{g_a\}}$ is the adjoint of $\mathscr{W}_{\{g_a\}}$ as can be formally seen by exchanging the integrals

$$\int_{S^2} d\Omega(x)\overline{(\mathscr{M}_{\{g_a\}})r(x)}s(x) = \int_{\mathrm{H}} \frac{d\Sigma(\xi)\wedge da}{a} r(\xi,a)\mathscr{W}_{\{g_a\}}s(\xi,a).$$

We now want to give sufficient conditions on g_a that ensure that $\{g_a\}$ is admissible.

Theorem III.1: Condition 1 (energy conservation) holds iff $\widehat{g_a}(l,m) = \langle Y_l^m | g_a \rangle_{L^2(S^2,d\Omega)}$ satisfies

$$c_g(l) = \frac{8\pi}{2l+1} \int_0^\infty \frac{da}{a} \sum_{|m|\leq l} |\widehat{g_a}(l,m)|^2 = c_g$$

with some c_g independent of l.

Proof: The proof is essentially the same as for standard wavelet analysis if we restrict ourselves to the invariant subspaces W_l. The general case follows by decomposition into irreducible components.

We come to the details. For fixed $r \in L^2(S^2,d\Omega)$ consider the operator

$$B[r]:s \mapsto \int_{SO(3)} d\Sigma(\xi) \langle U(\xi) r | s \rangle U(\xi) r.$$

It is a bounded operator from $L^2(S^2,d\Omega)$ into itself. In addition, since $d\Sigma$ is invariant under the group translations, it is easy to verify that

$$B[r]U(\xi) = U(\xi)B[r]$$

for all ξ. Thus we have have Schur's lemma, applied to each irreducible subspace W_l,

$$B[r] = \sum_{l=0}^{\infty} c_r(l) \Pi_l,$$

where the Π_l are the projectors on the invariant spaces W_l, and $c_r(l)$ are some constants. To compute the constants we note that the Wiegner functions $D_l^{m,m'}$ are known to satisfy at

$$\int_{SO(3)} d\Sigma(\xi) D_{l_1}^{m_1,m_1'}(\xi)^* D_{l_2}^{m_2,m_2'}(\xi) = \frac{8\pi}{2l_1+1} \delta_{l_1,l_2} \delta_{m_1,m_2} \delta_{m_1',m_2'}.$$

We may take $s = Y_l^0$ and hence

$$c_r(l) = \frac{8\pi}{2l+1} \sum_{|m|\leq l} |\hat{r}(l,m)|^2.$$

Now we have

$$\|\mathscr{W}_{\{g_a\}} s\|^2_{L^2(S^2,d\Omega)} = \int_0^\infty \frac{da}{a} \langle s | B[g_a] s \rangle.$$

Therefore, we have by the previous result

$$\|\mathscr{W}_{\{g_a\}} s\|^2_{L^2(S^2,d\Omega)} = \int_0^\infty \frac{da}{a} \sum_{l=1}^{\infty} c_{g_a}(l) \|\Pi_l s\|^2_{L^2(S^2,d\Omega)}.$$

Therefore conservation of energy holds for all s iff

$$\int_0^\infty \frac{da}{a} c_{g_a}(l) = c_g,$$

independent of l, which is precisely the statement of the theorem. □

Corollary III.1: Condition 4 (boundedness of transform) holds iff there is a constant $c<\infty$ such that $c_g(l)\leq c$. Condition 5 holds iff $c_h(l)\leq c$. Finally Condition 6 holds iff

$$\frac{8\pi}{2l+1}\int_0^\infty \frac{da}{a}\sum_{|m|\leq l}\overline{\widehat{g_a}(l,m)}\widehat{h_a}(l,m)=1.$$

Proof: The first statement is obvious. For the second we note that the wavelet synthesis is the adjoint of the wavelet analysis. Hence it has the same norm. For the last statement it is enough to consider the operator

$$B:s\mapsto\int_{SO(3)}d\Sigma(\xi)\langle U(\xi)g_a|s\rangle U(\xi)h_a$$

and to integrate over a as before. □

Corollary III.2: If g_a and h_a are an admissible analysis-reconstruction pair, then we have the following identity valid for s, $r\in L^2(S^2,d\Omega)$ and $\int s=\int r=0$:

$$\int_0^\infty\frac{da}{a}\int_{SO(3)}d\Sigma(\xi)\overline{\mathscr{W}[\{g_a\},s](\xi,a)}\mathscr{W}[\{h_a\},r](\xi,a)=c_{g,h}\int_{S^2}d\Omega(x)\overline{s(x)}r(x).$$

Proof: Indeed, we may write

$$\langle\mathscr{W}_{\{h_a\}}s|\mathscr{W}_{\{g_a\}}r\rangle_{L^2(SO(3)\times R_+)}=\langle s|\mathscr{M}_{\{h_a\}}\mathscr{W}_{\{g_a\}}r\rangle_{L^2(SO(3)\times R_+)}=\langle s|r\rangle_{L^2(S^2)}.$$

□

Condition 2, the large scale decay, is easy to meet.

Theorem III.2: Condition 2 (large scale decay) holds iff

$$\sum_{l=0}^\infty\sum_{|m|\leq l}|\widehat{g_a}(l,m)|^2\leq O(a^{-\infty}),\quad a\to\infty.$$

Proof: Use Parsevals equation on the sphere. □

As usual, the image is characterized by a reproducing kernel equation

Theorem III.3: Let $g_a,h_a\in L^2(S^2,d\Omega)$ be an analysis-reconstruction pair. Then $T\in$ immag $\mathscr{W}_{\{g_a\}}$ if and only if

$$T(\xi,a)=\int_H\frac{d\Sigma(\rho)\wedge da'}{a'}\Pi_{g,h}(\xi\cdot\rho^{-1},a,a')T(\rho,a'),$$

where

$$\Pi_{g_a,h_a}(\xi,a,a')=\mathscr{W}_{\{g_a\}}h_{a'}(\xi,a).$$

For arbitrary T the right-hand side defines a projector onto immag $\mathscr{W}_g$. In the case $g=h$, this projector is orthogonal.

Proof: This is a standard argument for partial isometries. We may suppose $c_{g,h}=1$. Consider $\Pi=\mathscr{W}_g\mathscr{M}_h$. We have

$$\Pi^2=\mathscr{W}_g(\mathscr{M}_h\mathscr{W}_g)\mathscr{M}_h=\mathscr{W}_g\mathscr{M}_h=\Pi.$$

Thus Π is a projector. Its range lies obviously in immag $\mathscr{W}_g$ and, since $T=\mathscr{W}_g s$ implies

$$\Pi T = \mathscr{W}_g(\mathscr{M}_h \mathscr{W}_g)s = \mathscr{W}_g s = T,$$

the other inclusion holds as well. In the case $g=h$, the operator is self-adjoint. The reproducing formula above follows now by exchanging the integrals in

$$T(\xi,a) = \int_{S^2} d\Omega(x) \int_{\mathrm{H}} \frac{d\Sigma(\rho)\wedge da'}{a'} \overline{U(\xi)g_a(x)} T(\rho,a') U(\rho) h_{a'}(x)$$

$$= \int_{\mathrm{H}} \frac{d\Sigma(\rho)\wedge da'}{a'} T(\rho,a') \langle U(\xi)g_a(x) | U(\rho)h_{a'}(x)\rangle_{L^2(S^2,d\Omega)}.$$

But now

$$\langle U(\xi)g_a(x) | U(\rho)h_a(x)\rangle = \langle U(\rho^{-1}\xi)g_a(x) | h_{a'}(x)\rangle = \mathscr{W}_g h_{a'}(\rho^{-1}\xi, a),$$

and the theorem is proved. □

IV. THE EUCLIDEAN LIMIT

The Euclidean limit is the most interesting constraint. Here we proceed as follows. Let $S_0(\mathbb{R}^2)$ be the subspace of the class of Schwartz of functions g for which all moments vanish ($\alpha \in \mathbb{N}^2$):

$$\int_{\mathbb{R}^2} d^2x\, x^\alpha g(x) = 0 \Leftrightarrow \hat{g}(k) = O(k^\infty) \quad (k \to 0).$$

We choose this context for convenience only. As the proofs will show, larger function spaces are possible. We now want to find an admissible family $g_a \in S_0(\mathbb{R}^2)$ that satisfies the Eucledian limit in the sense that we have pointwise

$$\lim_{a\to 0} a^2 g_a(a\theta,\phi) = g(\theta,\phi).$$

On the left-hand side we have local spherical coordinates, whereas on the right-hand side we have polar coordinates. That is we have written g as $g=g(r,\phi)$ with $r>0$ and $\phi \in [0, 2\pi)$. Note that for the case of pointwise convergence, any local coordinate system will produce equivalent results provided it agrees in first order at the north pole with the coordinate system given through stereographic projection. However, if one wants to consider topologies involving estimates of derivatives, the order of contact must be higher than first order. For the sake of simplicity we will only work out the case of pointwise convergence.

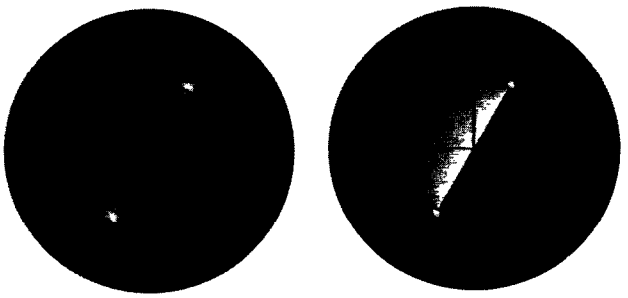

FIG. 1. The modulus and the phase at scale $a=4$.

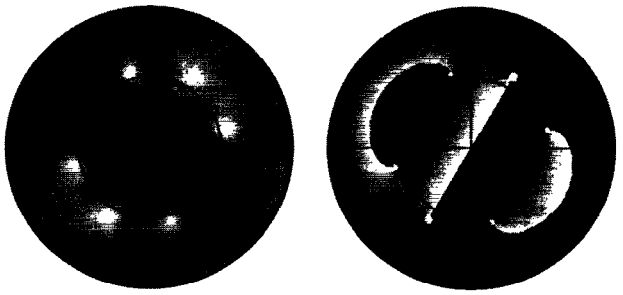

FIG. 2. The modulus and the phase at scale $a=2$.

We now come to the construction. Take the two-dimensional Fourier transform of g and write it in polar coordinates, $\hat{g}=\hat{g}(k,\phi)$. Decompose for each k into a Fourier series

$$\hat{g}(k,\varphi)=\frac{1}{2\pi}\sum_{n\in Z}\hat{\gamma}(k,n)e^{in\varphi},\quad \hat{\gamma}(r,n)=\int_0^{2\pi}d\varphi\ \hat{g}(k,\varphi)e^{-in\varphi}.$$

We first shall prove that the Euclidean limit holds for the following family of functions:

$$g_a=\sum_{l=0}^{\infty}\sum_{|m|\leqslant l}\widehat{g_a}(l,m)Y_l^m,\quad \widehat{g_a}(l,m)=\sqrt{l}\,\hat{\gamma}(al,m).$$

Later we modify this family slightly to make it admissible.

That the Euclidean limit holds can be observed numerically by looking at Figs. 1–5, where the scale of the Morlet wavelet changes from $a=2$ to $a=\frac{1}{4}$. The thick outermost circle corresponds to the south pole. The inner circle is the equator. The center of the picture is the north pole. In all figures we have fixed the rotation around the north pole to $2\pi/3$.

We come to the details. As we did before let us also write g in polar coordinates, $g=g(r,\phi)$, $r>0$, $\phi\in[0,2\pi)$, and let us introduce the Fourier coefficients with respect to ϕ:

$$g(r,\phi)=\frac{1}{2\pi}\sum_{n\in Z}\gamma(r,n)e^{in\phi},\quad \gamma(r,n)=\int_0^{2\pi}d\phi\ \hat{g}(r,\phi)e^{-in\phi}.$$

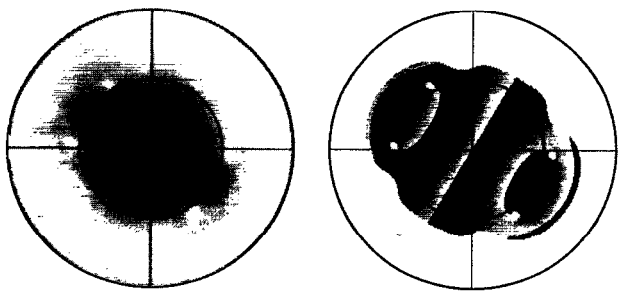

FIG. 3. The modulus and the phase at scale $a=1$.

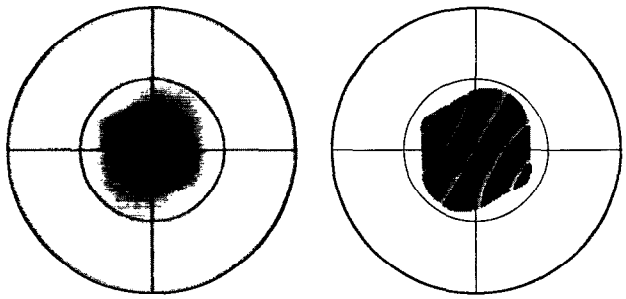

FIG. 4. The modulus and the phase at scale $a=\frac{1}{2}$.

Lemma IV.1: The following relation holds,

$$\hat{\gamma}(k,n)=\int_0^\infty r\,dr\;\gamma(r,n)J_n(kr).$$

where J_n is the nth-order Bessel function.

Proof: The Fourier transform of g reads in spherical coordinates $k>0$, $\phi\in[0,2\pi)$,

$$\begin{aligned}\hat{g}(k,\phi)&=\int_0^\infty r\,dr\int_0^{2\pi}d\varphi\;g(r,\varphi)e^{-ikr\cos(\phi-\varphi)}\\&=\frac{1}{2\pi}\sum_{n\in Z}\int_0^\infty r\,dr\int_0^{2\pi}d\varphi\;\gamma(r,n)e^{-i(kr\cos(\phi-\varphi)+n\varphi)}\\&=\frac{1}{2\pi}\sum_{n\in Z}e^{in\phi}\int_0^\infty r\,dr\int_0^{2\pi}d\varphi\;\gamma(r,n)e^{-i(kr\cos(\varphi)+n\varphi)}\\&=\frac{1}{2\pi}\sum_{n\in Z}\int_0^\infty r\,dr\;\gamma(r,n)J_n(kr)e^{in\phi}.\end{aligned}$$

Upon identifying the terms of both expressions, the expansion coefficients γ and $\hat{\gamma}$ are related as stated in the lemma.

Now the following limit is known to hold uniformly for $\theta\in I$, compact (see, e.g., Ref. 11):

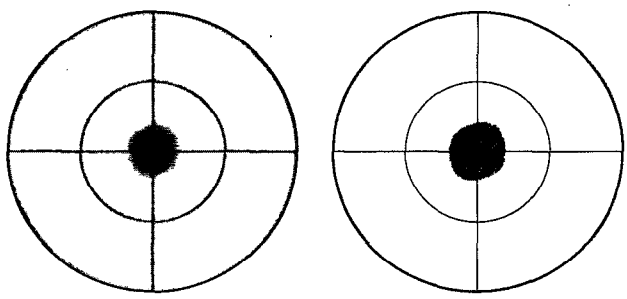

FIG. 5. The modulus and the phase at scale $a=\frac{1}{4}$.

$$\lim_{l\to\infty}\sqrt{\frac{2\pi}{l}}\,Y_l^m(\theta/l,\phi)=J_m(\theta)e^{im\phi}.$$

We now propose to look at the limit $a\to 0$ in

$$a^2\sum_{l=0}^{\infty}\sum_{|m|\le l}\hat{\gamma}(al,m)l^{-1/2}Y_l^m(a\theta,\phi).$$

Note that

$$\sum_{|m|\le l}|Y_l^m|^2=\frac{2l+1}{4\pi}.$$

Therefore, by Schwarz's inequality, discarding a term smaller than $a^2\epsilon$, we may suppose that g such that $\hat{g}$ is supported by a corona $c_1\le|k|\le c_2$. Now as a gets small, the l that contribute to the sum get large since al stays in $[c_1, c_2]$. We thus can use the above asymptotic for Y_l^m without changing the limit, and we obtain

$$a\sum_{l=0}^{\infty}\sum_{|m|\le l}(al)\hat{\gamma}(al,m)J_m(al\theta)e^{im\phi}.$$

As $a\to 0$, the sum over l may be replaced by a Riemann integral and we obtain as limit $(al\to r, a\to dr)$

$$\frac{1}{2\pi}\sum_{m\in\mathbb{Z}}\int_0^{\infty}r\,dr\,\hat{\gamma}(r,m)J_m(r\theta)e^{im\phi}.$$

By the Fourier inversion formula (Lemma IV.1) this equals $g(\theta,\phi)$ in polar coordinates.

V. AN ADMISSIBLE FAMILY

We now modify the family slightly to make it admissible. Consider again a function $g\in S_0(\mathbb{R}^2)$. Then let as before

$$\hat{\gamma}(k,m)=\int_0^{2\pi}d\phi\;\hat{g}(k,\phi)e^{-im\phi}$$

Now set

$$g_a=\sum_{l=0}^{\infty}\sum_{|m|\le l}\widehat{g_a}(k,m)Y_l^m$$

with

$$\widehat{g_a}(k,m)=\frac{\hat{\gamma}(al,m)}{\sqrt{\dfrac{8\pi^2}{2l+1}\displaystyle\int_0^{\infty}\frac{da'}{a'}\sum_{|m|\le l}|\hat{\gamma}(a',m)|^2}}.$$

Theorem V.1: The $\{g_a\}$ is an admissible family.

Proof: Clearly Conditions 1 and 2 are satisfied. To show that the Euclidian limit holds we note that by Parsevals equation we have for $l\to\infty$

$$\int_0^\infty \frac{da}{a} \sum_{|m|\leq l} \to \int_0^\infty \frac{da'}{a'} \int_0^{2\pi} |\hat{g}(a',\phi)|^2 = \int_{\mathbb{R}^2} \frac{d^2k}{|k|^2} |\hat{g}(k)|^2.$$

Note that the integral on the right-hand side is the admissibility condition of Murenzi.[1] It therefore follows that

$$\sqrt{l}\,\hat{\gamma}(al,m) \to \widehat{g_a}(l,m),$$

as it should.

(Received 30 October 1995; accepted for publication 31 January 1996)

A method to construct differential calculi on quantized universal enveloping algebras is discussed. These differential calculi are obtained by quantizing calculi on "classical" enveloping algebras provided with appropriate co-Poisson structures. The procedure is demonstrated by applying it to the standard quantizations of the Heisenberg algebra and the algebra $gl(2)$. © *1996 American Institute of Physics.* [S0022-2488(96)04206-5]

I. INTRODUCTION

Noncommutative differential geometry, currently a field of active research, deals with differential calculus on algebras which are generally noncommutative. There are a few basic principles to construct such a noncommutative theory. One can replace the commutative function algebra on a space by some noncommutative algebra and try to generalize the basic concepts of the traditional case to this more abstract situation. Then there is the approach, already standard in algebraic geometry, to encode the structure of the underlying space into the function algebra defined on the space, which in turn is deformed. This is the approach customary in quantum group theory. These ideas led Connes (see, e.g., Ref. 1) and his collaborators to create "noncommutative geometry." Here, the commutative function algebra is replaced by some noncommutative C^*-algebra.

In quantum group theory it was Woronowicz,[2] who first developed the theory of differential calculus on quantum groups, giving a very interesting example of noncommutative differential geometry. This rather abstract theory has been reformulated in more concrete terms by Wess and Zumino.[3] A substantial number of very interesting papers, proposing other approaches, elucidating various aspects, studying concrete examples or dealing with applications have been written since. See, e.g., Refs. 4–7.

In this paper we discuss a method to construct a differential calculus on a quantized universal enveloping algebra $U_h(\mathfrak{g})$ of a Lie algebra $\mathfrak{g}$. We follow the idea of Faddeev and his school[8] that all objects of a quantized theory should appear naturally as a result of quantization of appropriate Poisson structures. Accordingly, our starting point should be a differential calculus on $U(\mathfrak{g})$. These differential calculi are provided and studied in Ref. 9. Moreover, they turn out to be Hopf algebras and actually such a differential calculus turns out to be the universal enveloping algebra of a color Lie superalgebra, see Ref. 10. Consequently, our starting point is this enveloping algebra $U(L)$ equipped with an appropriate co-Poisson bracket δ. Its restriction to L, notation δ_L, defines a color Lie bisuperalgebra structure which may be obtained by extending the cocommutator $\delta_{\mathfrak{g}}$ of $\mathfrak{g}$.

The procedure is illustrated by two examples. We apply it to the standard quantizations of the enveloping algebra of the Heisenberg algebra and the algebra $gl(2)$.

Matrix quantum groups can be embedded as Hopf algebra in a quantization of the enveloping algebra of the dual Lie algebra, see Ref. 11. This indicates that our construction can be used to obtain differential calculi on quantum groups. Work on this is in progress; we will report on this in the near future.

II. THE QUANTIZATION METHOD

Let $\mathfrak{g}$ be a finite dimensional Lie algebra over the field of complex numbers C. We present a procedure to construct differential calculi on quantized universal enveloping algebras of $\mathfrak{g}$ by quantizing differential calculi on the classical universal enveloping algebra $U(\mathfrak{g})$. This method connects the following two concepts related to $U(\mathfrak{g})$: quantization and differential calculus. In the classical limit the inter-relation between these concepts is expressed by a compatibility condition between the cocommutator that determines the Lie bialgebra structure on $\mathfrak{g}$ and the differential d. In order to explain the origin of this compatibility condition we shortly recall some notions related to differential calculi and quantization.

A quantization of the Lie algebra $\mathfrak{g}$ is a Hopf algebra deformation $U_h(\mathfrak{g})$ of $U(\mathfrak{g})$. Usually, $U_h(\mathfrak{g})$ is called a quantized universal enveloping algebra. The map δ defined by

$$\delta(x)=\frac{\Delta_h(x)-\Delta_h^{\mathrm{op}}(x)}{h} \bmod h \qquad \delta: U(\mathfrak{g})\mapsto U(\mathfrak{g})\otimes U(\mathfrak{g}) \tag{2.1}$$

is a co-Poisson bracket on $U(\mathfrak{g})$. In this formula Δ_h represents the comultiplication of $U_h(\mathfrak{g})$ and Δ_h^{op} the opposite comultiplication given by $\Delta_h^{\mathrm{op}}=\sigma\circ\Delta_h$, where σ is the ordinary flip operator on the tensor product. The restriction of δ to $\mathfrak{g}$, which will be denoted by $\delta_{\mathfrak{g}}$, defines a Lie bialgebra $(\mathfrak{g},\delta_{\mathfrak{g}})$. This means that $\delta_{\mathfrak{g}}:\mathfrak{g}\mapsto\mathfrak{g}\otimes\mathfrak{g}$ is a 1-cocycle and $\delta_{\mathfrak{g}}^*:\mathfrak{g}^*\mapsto\mathfrak{g}^*\otimes\mathfrak{g}^*$ is a Lie bracket on $\mathfrak{g}^*$. The Lie bialgebra $(\mathfrak{g},\delta_{\mathfrak{g}})$ is called the classical limit of the quantization $U_h(\mathfrak{g})$ and $\delta_{\mathfrak{g}}$ is called the cocommutator. For more details on this we refer to Ref. 12.

A differential Hopf algebra (see, e.g., Ref. 13) is an N-graded Hopf algebra $\Omega=\Sigma_{p=0}^{\infty}\Omega^p$ equipped with a differential d. This operator d is a graded derivation of degree $+1$ with the property $d^2=0$. Furthermore it satisfies $(d\otimes id+\tau\otimes d)\circ\Delta=\Delta\circ d$ and $\epsilon\circ d=0$, where Δ denotes the comultiplication and ϵ the counit of Ω. The linear map $\tau:\Omega\to\Omega$ has degree zero and satisfies $\tau(a)=(-1)^p a$ for all $a\in\Omega^p$. A differential calculus on $U(g)$ is a differential Hopf algebra Ω with the additional properties $\Omega^0=U(\mathfrak{g})$ and Ω is generated by $\Omega^0\cup d(\Omega^0)$.

In Ref. 10 we showed that a differential calculus on $U(\mathfrak{g})$ of Poincaré–Birkhoff–Witt-type can be described as the universal enveloping algebra of a color Lie superalgebra L which is a natural extension of the Lie algebra $\mathfrak{g}$. For the sake of clarity, we recall the definition of color Lie superalgebra (see Ref. 14). Let G be an abelian semigroup and α a 2-cocycle on G with values in C*. An (α)-color Lie superalgebra is a G-graded algebra L with product $[,]$ satisfying

$$[x,y]=-\alpha(p,q)[y,x] \quad \text{and} \quad \alpha(p,r)[[x,y],z]+\alpha(q,p)[[y,z],x]+\alpha(r,q)[[z,x],y]=0$$

for all $x\in L^p, y\in L^q, z\in L^r$. As in the case of ordinary Lie algebras, one can define the universal enveloping algebra of a color Lie superalgebra and a corresponding Hopf algebraic structure on it. The structure of the above mentioned color Lie superalgebra L, which represents the differential calculus on $U(\mathfrak{g})$, is as follows. L is the N-graded algebra $L=\oplus_{p\in\mathrm{N}}L^p$, where $L^0=\mathfrak{g}=\langle x^1,x^2,\ldots,x^n\rangle$, $L^1=\langle\hat{x}^1,\hat{x}^2,..,\hat{x}^n\rangle$, and $L^p=0$ for all $p\geq 2$. The corresponding 2-cocycle α is given by

$$\alpha:\mathrm{N}\times\mathrm{N}\to\mathrm{C}^* \qquad \alpha(p,q)=(-1)^{pq}.$$

The Lie bracket of L is such that its restriction to L^0 is simply the Lie bracket of $\mathfrak{g}$ and the linear map $d:L\mapsto L$ given by $d(x_i)=\hat{x}_i$ and $d(\hat{x}_i)=0$ for all $1\leq i\leq n=\dim(\mathfrak{g})$ is a graded derivation of degree $+1$ on L. So the bracket of L is of the following form:

$$[x_i,x_j]=c_{ij}^k x_k; \quad [x_i,\hat{x}_j]=a_{ij}^k\hat{x}_k; \quad [\hat{x}_i,\hat{x}_j]=0.$$

We use the notation $\hat{x}_i$ to emphasize the fact that these elements have been formally introduced to represent the differentials of the elements x_i. The differential d on $\Omega=U(L)$ is defined as the unique graded derivation extending the operator d on L.

We come to the introduction of a differential calculus on $U_h(\mathfrak{g})$. According to the foregoing, a differential calculus on $U_h(\mathfrak{g})$ is a differential Hopf algebra Ω_h, with differential denoted by d_h, which is generated by $\Omega_h^0 \cup d_h(\Omega_h^0)$, where $\Omega_h^0=U_h(\mathfrak{g})$. On the other hand, as analog to the quantization procedure, it is natural that, by putting h equal to zero, Ω_h reduces to $U(L)$, where L is a color Lie superalgebra extension of $\mathfrak{g}$ of the form described above, and d_h reduces to the differential d of $U(L)$. This implies that (Ω_h, d_h) is a differential Hopf algebra deformation of $(U(L),d)$. We demand this deformation to be homogeneous of degree zero such that the N-grading of $U(L)$ induces the N-grading on $U_h(L)$. In particular $\Omega_h=U_h(L)$ is a Hopf algebra deformation of $U(L)$, or in other words a quantization of the color Lie superalgebra L. The classical limit of this quantization is a color Lie bisuperalgebra (L,δ_L) extending the Lie bialgebra $(\mathfrak{g},\delta_{\mathfrak{g}})$, which is the classical limit of $U_h(\mathfrak{g})$. This gives rise to the following commutative diagram:

$$\begin{array}{ccc} U_h(\mathfrak{g}) & \rightarrow & U_h(L) \\ \downarrow & & \downarrow \\ (g,\delta_{\mathfrak{g}}) & \rightarrow & (L,\delta_L) \end{array}$$

The vertical arrows denote the classical limit and the horizontal ones denote the canonical embeddings of (N-graded) Hopf algebras and color Lie bisuperalgebras.

We denote the comultiplication of $U_h(L)$ by Δ_h. From the definition of a differential Hopf algebra we know that $\Delta_h \circ d_h=(d_h)_{\otimes}\circ\Delta_h$ with $(d_h)_{\otimes}=d_h\otimes id+\tau\otimes d_h$. The co-Poisson bracket $\delta: U(L)\mapsto U(L)\otimes U(L)$ is defined as in the classical case described in formula (2.1), with the exception that, in the definition of Δ_h^{op} the operator σ denotes the graded flip operator, which is defined by

$$\sigma(x\otimes y)=(-1)^{pq}y\otimes x \quad \text{for all} \quad x\in U_h(L)^p, y\in U_h(L)^q.$$

One can easily verify that d_h has the property $\sigma\circ(d_h)_{\otimes}=(d_h)_{\otimes}\circ\sigma$. From this it follows that

$$\frac{\Delta_h-\Delta_h^{\mathrm{op}}}{h}\circ d_h=(d_h)_{\otimes}\circ\frac{\Delta_h-\Delta_h^{\mathrm{op}}}{h}$$

and for h equal to zero this reduces to

$$\delta\circ d=d_{\otimes}\circ\delta,$$

so the differential operator should commute with the co-Poisson bracket δ on $U(L)$. The restriction to L yields the following condition for the cocommutator δ_L:

$$\delta_L\circ d=d_{\otimes}\circ\delta_L. \tag{2.2}$$

To understand the meaning of this condition, let us assume we have a color Lie superalgebra L equipped with an operator d representing a differential calculus on $U(\mathfrak{g})$. Any Lie bialgebra $(\mathfrak{g},\delta_{\mathfrak{g}})$ gives rise to a unique extension $\delta_L: L\mapsto L\otimes L$ satisfying condition (2.2). We call the differential calculus on $U(\mathfrak{g})$ and the Lie bialgebra $(\mathfrak{g},\delta_{\mathfrak{g}})$ compatible if and only if (L,δ_L) is a color Lie bisuperalgebra. From the preceding reasoning we learn that this is a necessary condition in order to obtain a differential calculus on $U_h(\mathfrak{g})$ starting from the differential calculus on $U(\mathfrak{g})$ given by L. The examples we have studied so far seem to indicate that the condition is also sufficient.

Thus from the discussion above we can subtract the following procedure to construct a differential calculus on a quantized universal enveloping algebra.

(1) Construct a differential calculus on $U(\mathfrak{g})$.
(2) Compute a Lie bialgebra $(\mathfrak{g},\delta_{\mathfrak{g}})$ which is compatible with the constructed differential calculus.
(3) Quantize $(\mathfrak{g},\delta_{\mathfrak{g}})$, i.e., construct a quantized universal enveloping algebra $U_h(\mathfrak{g})$ with classical limit $(\mathfrak{g},\delta_{\mathfrak{g}})$.
(4) Quantize (L,δ_L) where δ_L is the unique extension of $\delta_{\mathfrak{g}}$ given by formula (2.2).

Note that in the last step one can fruitfully use that $U_h(L)$ is an extension of $U_h(\mathfrak{g})$ and that the differential d_h should respect the defining relations of $U_h(L)$. We will illustrate this in more detail in the examples.

Finally, we mention that there is a nice algebraic interpretation for the compatibility condition (2.2). The linear operator d on L is a graded derivation, this means that

$$d([x,y])=[d(x),y)]+(-1)^p[x,d(y)] \quad \text{for } x\in L^p, y\in L,$$

or equivalently $[,]\circ d_{\otimes}=d\circ[,]$, where $[,]$ denotes the Lie bracket of L. Analogously, the linear operator d^* is a graded derivation on L^* with Lie bracket δ_L^* if it satisfies $\delta_L^*\circ(d^*)_{\otimes}=d^*\circ\delta_L^*$. But this is equivalent to Eq. (2.2). So we can express the compatibility condition appropriately by saying that d should be a color Lie bisuperalgebra derivation on (L,δ_L).

III. THE HEISENBERG ALGEBRA

As first example, we will consider the Heisenberg algebra H. A basis of H is given by $\{p,q,c\}$ and the Lie product is given by

$$[p,q]=c; \quad [p,c]=0; \quad [q,c]=0.$$

A. The differential calculus on $U(H)$

In Ref. 9 we constructed all differential calculi $\Omega=\Sigma_{p=0}^{\infty}\Omega^p$ of Poincaré–Birkhoff–Witt-type on H. Here, $\Omega^0=U(H)$ and Ω^p denotes the space of p-forms; in particular $\Omega^1=d(\Omega^0)$. As we described in Sec. II, Ω is isomorphic to $U(L)$, where L is a color Lie superalgebra such that $L^0=H$ and $L^1=\hat{H}$. In particular, the differential calculus is completely determined by the map $\rho:H\to gl(\hat{H})$, which is in fact the commutator in L of elements from L_0 and L_1. (L_1 is a representation of L_0 using the commutator). As basis of $\hat{H}$ we will use $\{\hat{p},\hat{q},\hat{c}\}$, where $d(x)$ denotes the element $\hat{x}$. It turns out that the simplest and most elegant solution is described by

$$\rho(p)(q)=[p,\hat{q}]=\tfrac{1}{2}\hat{c}, \quad \rho(q)(p)=[q,\hat{p}]=-\tfrac{1}{2}\hat{c},$$

and all others equal to zero.

Summarizing we start with the quotient of the free N-graded associative algebra on the alphabet $\{p,q,c,\hat{p},\hat{q},\hat{c}\}$, where $\{p,q,c\}$ are homogeneous of degree 0 and $\{\hat{p},\hat{q},\hat{c}\}$ are homogeneous of degree 1, divided by the ideal I which is generated by the following homogeneous relations:

$$pq-qp=c; \quad pc-cp=0; \quad qc-cq=0$$

$$p\hat{p}=\hat{p}p; \quad p\hat{q}=\hat{q}p+\tfrac{1}{2}\hat{c}; \quad p\hat{c}=\hat{c}p$$

$$q\hat{p}=\hat{p}q-\tfrac{1}{2}\hat{c}; \quad q\hat{q}=\hat{q}q; \quad q\hat{c}=\hat{c}q$$

$$c\hat{p}=\hat{p}c; \quad c\hat{q}=\hat{q}c; \quad c\hat{c}=\hat{c}c$$

$$\hat{p}\hat{q}=-\hat{q}\hat{p}; \quad \hat{p}\hat{c}=-\hat{c}\hat{p}; \quad \hat{q}\hat{c}=-\hat{c}\hat{q}$$

$$\hat{p}\hat{p}=0; \quad \hat{q}\hat{q}=0; \quad \hat{c}\hat{c}=0.$$

The differential d is the unique graded derivation of degree $+1$ satisfying $d(p)=\hat{p}$, $d(q)=\hat{q}$, $d(c)=\hat{c}$ and $d(\hat{p})=0$, $d(\hat{q})=0$, $d(\hat{c})=0$.

B. The compatible cocommutator on H

Next we have to construct a Lie bialgebra structure on H, which is compatible with d. This is a matter of straight computation, which we performed using computer algebra. There is a unique solution, given by

$$\delta(c)=0; \quad \delta(p)=p\wedge c; \quad \delta(q)=q\wedge c;$$

and consequently the continuation to $\hat{H}=d(H)$, which is prescribed by $\delta(\hat{x})=(d\otimes id+\tau\otimes d)\circ\delta(x)$, yields

$$\delta(\hat{c})=0; \quad \delta(\hat{p})=\hat{p}\wedge c+p\wedge\hat{c}; \quad \delta(\hat{q})=\hat{q}\wedge c+q\wedge\hat{c}.$$

Note that the restriction of δ to H is a cocommutator of coboundary type with corresponding R-matrix

$$R=p\wedge q. \tag{3.1}$$

One can easily verify that δ itself is not of coboundary type.

C. Quantization of (H,δ)

In order to quantize the situation above, we note that the R-matrix (3.1) is the standard one. This suggests that we can take for $U_h(H)$ the standard quantization

$$\Delta_h(p)=p\otimes e^{hc}+1\otimes p; \quad \Delta_h(q)=q\otimes 1+e^{-hc}\otimes q; \quad \Delta_h(c)=c\otimes 1+1\otimes c$$

and the only relation in $U_h(H)$ that differs from the relations in $U(H)$ is

$$[p,q]=\frac{\sinh(hc)}{\sinh(h)}.$$

The unit and counit are unchanged. The antipode is rather easy to compute, from Ref. 12 we know that it exists. For example to calculate $S_h(p)$, we consider

$$0=\mu_h\circ(S_h\otimes id)\circ\Delta_h(p)=S_h(p)e^{hc}+p.$$

Hence we find

$$S_h(p)=-pe^{-hc}$$

and similarly

$$S_h(q)=-qe^{hc}; \quad S_h(c)=-c.$$

Although $U_h(H)$ is clearly not cocommutative, one can easily verify that the antipode still satisfies $S_h^2=Id$.

D. Quantization of (L,δ)

From here on we will use $\hat{x}$ to denote the element $d_h(x)$. Due to $\Delta_h\circ d_h=(d_h)_\otimes\circ\Delta_h$, we have $\Delta_h(\hat{c})=\hat{c}\otimes 1+1\otimes\hat{c}$ and

$$\Delta_h(\hat{p})=\hat{p}\otimes e^{hc}+p\otimes h\hat{c}e^{hc}+1\otimes\hat{p};\quad \Delta_h(\hat{q})=\hat{q}\otimes 1+e^{-hc}\otimes\hat{q}-h\hat{c}e^{-hc}\otimes q.$$

It remains to determine the new relations in Ω_h; since $\Delta_h(c)$ and $\Delta_h(\hat{c})$ are unchanged it is natural to require that only the relations $[p,\hat{q}]$, $[\hat{p},q]$, and $[\hat{p},\hat{q}]$ will change.

So, let us assume that $[p,\hat{q}]=\alpha_1$ and $[\hat{p},q]=\alpha_2$. From $[p,q]=[\sinh(hc)]/[\sinh(h)]$ it follows that

$$\alpha_1+\alpha_2=[p,\hat{q}]+[\hat{p},q]=d_h([p,q])=h\hat{c}\,\frac{\cosh(hc)}{\sinh(h)}. \tag{3.2}$$

Further we have

$$\Delta_h(\alpha_1)=\Delta_h(p\hat{q}-\hat{q}p)=(p\otimes e^{hc}+1\otimes p)(\hat{q}\otimes 1-h\hat{c}e^{-hc}\otimes q+e^{-hc}\otimes\hat{q})-(\hat{q}\otimes 1-h\hat{c}e^{-hc}\otimes q$$
$$+e^{-hc}\otimes\hat{q})(p\otimes e^{hc}+1\otimes p)=[p,\hat{q}]\otimes e^{hc}-h\hat{c}e^{-hc}\otimes[p,q]+e^{-hc}\otimes[p,\hat{q}]$$

so,

$$\Delta_h(\alpha_1)=\alpha_1\otimes e^{hc}-h\hat{c}e^{-hc}\otimes\frac{\sinh(hc)}{\sinh(h)}+e^{-hc}\otimes\alpha_1. \tag{3.3}$$

In the same way we find for α_2

$$\Delta_h(\alpha_2)=\alpha_2\otimes e^{hc}+\frac{\sinh(hc)}{\sinh(h)}\otimes h\hat{c}e^{-hc}+e^{-hc}\otimes\alpha_2. \tag{3.4}$$

Equations (3.2), (3.3), and (3.4) suggest to take

$$\alpha_i=\frac{\lambda_i e^{hc}+\mu_i e^{-hc}}{\sinh(h)}\,h\hat{c};\quad (i=1,2).$$

Substitution yields a unique solution

$$[p,\hat{q}]=h\hat{c}\,\frac{e^{-hc}}{2\sinh(h)};\quad [\hat{p},q]=h\hat{c}\,\frac{e^{hc}}{2\sinh(h)}. \tag{3.5}$$

This also dictates the relation between $\hat{p}$ and $\hat{q}$ by differentiation of Eq. (3.5)

$$\hat{p}\hat{q}=-\hat{q}\hat{p}.$$

Finally, from $S_h\circ d_h=d_h\circ S_h$ it follows that the extension of the antipode is given by

$$S_h(\hat{p})=-(\hat{p}-hp\hat{c})e^{-hc};\quad S_h(\hat{q})=-(\hat{q}+hq\hat{c})e^{hc};\quad S_h(\hat{c})=-\hat{c}.$$

It still satisfies $S_h^2=Id$. In order to compute the action of S_h on an arbitrary element of Ω_h, one can use linearity and the antialgebra-morphism property

$$S_h(ab)=(-1)^{rs}S_h(b)S_h(a);\quad (a\in\Omega^r,b\in\Omega^s).$$

E. Summary of results for *H*

For clearness' sake, we summarize the results of this section in the following theorem.

Theorem 1: *The standard quantization of the Heisenberg algebra H, given by*

$$[p,q]=\frac{\sinh(hc)}{\sinh(h)};\quad [p,c]=0;\quad [q,c]=0$$

and

$$\Delta_h(p)=p\otimes e^{hc}+1\otimes p;\quad \Delta_h(q)=q\otimes 1+e^{-hc}\otimes q;\quad \Delta_h(c)=c\otimes 1+1\otimes c$$
$$S_h(p)=-pe^{-hc};\quad S_h(q)=-qe^{hc};\quad S_h(c)=-c$$

admits a differential calculus d_h. If we denote $d_h(x)$ by $\hat{x}$ for all elements x in H, then $\hat{c}$ is primitive and

$$\Delta_h(\hat{p})=\hat{p}\otimes e^{hc}+p\otimes h\hat{c}e^{hc}+1\otimes\hat{p};\quad \Delta_h(\hat{q})=\hat{q}\otimes 1+e^{-hc}\otimes\hat{q}-h\hat{c}e^{-hc}\otimes q$$
$$S_h(\hat{p})=-(\hat{p}-hp\hat{c})e^{-hc};\quad S_h(\hat{q})=-(\hat{q}+hq\hat{c})e^{hc}.$$

The commutation between functions and forms is described by

$$[p,\hat{q}]=h\hat{c}\,\frac{e^{-hc}}{2\sinh(h)};\quad [q,\hat{p}]=-h\hat{c}\,\frac{e^{hc}}{2\sinh(h)}$$

and $[x,\hat{y}]=0$ for all other choices of elements x and y from $\{p,q,c\}$. Finally, the commutation of forms is determined by the relation $\hat{x}\hat{y}=-\hat{y}\hat{x}$ for all $x,y\in H$.

Finally, we remark that by an obvious and small modification the same result is obtained for the general $2n+1$-dimensional Heisenberg algebra with basis $\{p_i,q_i,c\}_{1\leqslant i\leqslant n}$ and Lie product given by

$$[p_i,q_j]=\delta_j^i c;\quad [p_i,c]=0;\quad [q_i,c]=0;\quad [p_i,p_j]=0;\quad [q_i,q_j]=0.$$

IV. THE ALGEBRA *gl*(2)

The next example that we consider is $gl(2)$. We will denote

$$E_+=E_{12};\quad E_-=E_{21};\quad H_+=E_{11};\quad H_-=E_{22}.$$

Hence in the enveloping algebra $U(gl(2))$, we have the following relations:

$$[H_+,H_-]=0;\quad [H_+,E_\pm]=\pm E_\pm;\quad [H_-,E_\pm]=\mp E_\pm;\quad [E_+,E_-]=H_+-H_-.$$

A. The differential calculus on *U*(*gl*(2))

On $U(gl(2))$ we can construct differential calculi of Poincaré–Birkhoff–Witt type; as said in the previous sections, these calculi are completely determined by an appropriate representation $\rho: gl(2)\to\widehat{gl(2)}$. For $gl(n)$ there is a natural solution, namely,

$$\rho(x)\hat{y}=\widehat{xy},$$

where xy denotes the product of x and y as $n\times n$ matrices. We will use this ρ in the sequel. Hence we can determine the differential calculus Ω. Apart from the relations above, it satisfies the following relations ($\hat{x}=d(x);\ x\in gl(2)$):

$$[H_\pm,\hat{E}_\pm]=\hat{E}_\pm;\quad [H_\pm,\hat{E}_\mp]=0;\quad [H_\pm,\hat{H}_\pm]=\hat{H}_\pm;\quad [H_\pm,\hat{H}_\mp]=0$$
$$[E_\pm,\hat{E}_\pm]=0;\quad [E_\pm,\hat{E}_\mp]=\hat{H}_\pm;\quad [E_\pm,\hat{H}_\pm]=0;\quad [E_\pm,\hat{H}_\mp]=\hat{E}_\pm.$$

Note the similar roles that H_+ and H_- play; hence the basis chosen (instead of H_+-H_- and H_++H_-) is very natural. One can note that the representation ρ is the direct sum of two 2-dimensional $gl(2)$-representations V_1 and V_2, where $V_1=\langle\hat{E}_+,\hat{H}_-\rangle$ and $V_2=\langle\hat{E}_-,\hat{H}_+\rangle$.

B. The compatible cocommutator on $gl(2)$

Again compatible Lie bialgebra structures can be computed. There is a unique solution if we demand the solution to be homogeneous of degree zero with respect to the natural grading on $gl(2)$ defined by $|H_\pm|=0$, $|E_\pm|=\pm 1$. This solution is given by

$$\delta(H_\pm)=0;\quad \delta(E_+)=E_+\wedge H_-;\quad \delta(E_-)=H_+\wedge E_-$$

which extends to L as

$$\delta(\hat{H}_\pm)=0;\quad \delta(\hat{E}_+)=\hat{E}_+\wedge H_-+E_+\wedge\hat{H}_-;\quad \delta(\hat{E}_-)=\hat{H}_+\wedge E_-+H_+\wedge\hat{E}_-.$$

As in the case of the Heisenberg algebra, δ itself is not of coboundary type. Its restriction to $gl(2)$ is coboundary, the corresponding R-matrix is given by $R=\frac{1}{2}(E_+\wedge E_-+H_+\wedge H_-)$.

C. Quantization of $(gl(2),\delta)$

The way of quantizing is similar as in the case of the Heisenberg algebra. Again $\delta(H_\pm)=0$ suggests to take

$$\Delta_h(H_\pm)=H_\pm\otimes 1+1\otimes H_\pm.$$

Similarly $\delta(E_+)=E_+\wedge H_-$ and $\delta(E_-)=H_+\wedge E_-$ suggest

$$\Delta_h(E_+)=E_+\otimes e^{hH_-}+1\otimes E_+;\quad \Delta_h(E_-)=E_-\otimes 1+e^{hH_+}\otimes E_-.$$

From this it follows that the antipode is given by

$$S_h(H_\pm)=-H_\pm;\quad S_h(E_+)=-E_+e^{-hH_-};\quad S_h(E_-)=-e^{-hH_+}E_-.$$

The commutation relation between E_+ and E_- has to be changed, all others in $gl(2)$ remain the same

$$[E_+,E_-]=\frac{e^{hH_+}-e^{hH_-}}{2\sinh(h)}.$$

D. Quantization of (L,δ)

Extending Δ_h to $\widehat{gl(2)}$ is straightforward, the only complication is that $[H_\pm,\hat{H}_\pm]=\hat{H}_\pm$. Due to this, we have

$$d_h(e^{hH_\pm})=\hat{H}_\pm e^{hH_\pm}(e^h-1).$$

So we find

$$\Delta_h(\hat{H}_\pm)=\hat{H}_\pm\otimes 1+1\otimes\hat{H}_\pm$$

and

$$\Delta_h(\hat{E}_+)=\hat{E}_+\otimes e^{hH_-}+E_+\otimes\hat{H}_-e^{hH_-}(e^h-1)+1\otimes\hat{E}_+;$$

$$\Delta_h(\hat{E}_-)=\hat{E}_-\otimes 1+\hat{H}_+e^{hH_+}(e^h-1)\otimes E_-+1\otimes\hat{E}_-.$$

Now we have to adjust the relations between $gl(2)$ and $\widehat{gl(2)}$, so that Δ_h becomes an algebra-morphism. One can check by direct calculation that we can take all commutators involving either $H_\pm$ or $\hat{H}_\pm$ unchanged. We will require that $[\hat{x},\hat{y}]=0$ remains unchanged for all $x,y\in gl(2)$. Hence our problem is to adjust the commutators $[E_\pm,\hat{E}_\pm]$ and $[E_\pm,\hat{E}_\mp]$.

Let us first consider $[E_+,\hat{E}_+]$. For this we consider $[\hat{E}_+,\hat{E}_+]=0$, so that $\hat{E}_+\hat{E}_+=0$. Applying Δ_h, we find

$$\Delta_h(\hat{E}_+)\Delta_h(\hat{E}_+)=\cdots=(-E_+\hat{E}_++e^h\hat{E}_+E_+)\otimes\hat{H}_-e^{2hH_-}(e^h-1)=0.$$

Here, we used that $e^{hH_-}\hat{H}_- = \hat{H}_-e^{hH_-}e^h$, since $[H_-,\hat{H}_-]=\hat{H}_-$. So this forces

$$E_+\hat{E}_+-e^h\hat{E}_+E_+=0.$$

Similarly we find

$$E_-\hat{E}_--e^h\hat{E}_-E_-=0.$$

One must check that these relations are compatible with Δ_h, i.e., that $\Delta_h(E_+\hat{E}_+-e^h\hat{E}_+E_+)=0$. This is indeed the case.

Finally, it remains to obtain $[E_\pm,\hat{E}_\mp]$. A tedious calculation shows that we can choose

$$[E_\pm,\hat{E}_\mp]=\frac{e^h-1}{2\sinh(h)}\hat{H}_\pm e^{hH_\pm}.$$

Finally, the antipode is not difficult to calculate. In fact we have $S_h(\hat{H}_\pm)=-\hat{H}_\pm$ and

$$S_h(\hat{E}_+)=-(\hat{E}_++E_+\hat{H}_-(e^{-h}-1))e^{-hH_-};$$

$$S_h(\hat{E}_-)=-e^{-hH_+}\hat{E}_--\hat{H}_+(e^{-h}-1)e^{-hH_+}E_-$$

as follows from the formula $S_h\circ d_h=d_h\circ S_h$. We remark that the square of the antipode on $U_h(gl(2))$ is given by

$$S_h^2(H_\pm)=H_\pm;\quad S_h^2(E_+)=e^{hH_-}E_+e^{-hH_-}=e^{-h}E_+\quad S_h^2(E_-)=e^{-hH_+}E_-e^{hH_+}=e^hE_-$$

and again due to the commutation of S_h and d_h also

$$S_h^2(\hat{H}_\pm)=\hat{H}_\pm;\quad S_h^2(\hat{E}_\pm)=e^{\mp h}\hat{E}_\pm.$$

Concluding we can say that we completed the quantization. The choice of Δ_h was quite natural, and led to deforming the commutation relations involving only $E_\pm$ and $\hat{E}_\pm$.

E. Summary of results for *gl*(2)

For clearness' sake, we summarize the results of this section in the following theorem.

Theorem 2: *The quantization of the algebra* $gl(2)$, *given by*

$$[H_+,H_-]=0;\quad [H_+,E_\pm]=\pm E_\pm;\quad [H_-,E_\pm]=\mp E_\pm;\quad [E_+,E_-]=\frac{e^{hH_+}-e^{hH_-}}{2\sinh(h)}$$

and

$$\Delta_h(H_\pm)=H_\pm\otimes 1+1\otimes H_\pm;$$

$$\Delta_h(E_+)=E_+\otimes e^{hH_-}+1\otimes E_+;\quad \Delta_h(E_-)=E_-\otimes 1+e^{hH_+}\otimes E_-$$

with corresponding antipode given by

$$S_h(H_\pm)=-H_\pm;\quad S_h(E_+)=-E_+e^{-hH_-};\quad S_h(E_-)=-e^{-hH_+}E_-$$

admits a differential calculus d_h. If we denote $d_h(x)$ by $\hat{x}$ for all elements x in $gl(2)$, then $\hat{H}_\pm$ is primitive and

$$\Delta_h(\hat{E}_+)=\hat{E}_+\otimes e^{hH_-}+E_+\otimes\hat{H}_-e^{hH_-}(e^h-1)+1\otimes\hat{E}_+;$$

$$\Delta_h(\hat{E}_-)=\hat{E}_-\otimes 1+\hat{H}_+e^{hH_+}(e^h-1)\otimes E_-+1\otimes\hat{E}_-;$$

$$S_h(\hat{E}_+)=-(\hat{E}_++E_+\hat{H}_-(e^{-h}-1))e^{-hH_-},\quad S_h(\hat{E}_-)=-e^{-hH_+}\hat{E}_--\hat{H}_+(e^{-h}-1)e^{-hH_+}E_-.$$

The commutation between functions and forms is described by

$$[H_\pm,\hat{E}_\pm]=\hat{E}_\pm;\quad [H_\pm,\hat{E}_\mp]=0;\quad [H_\pm,\hat{H}_\pm]=\hat{H}_\pm;\quad [H_\pm,\hat{H}_\mp]=0,$$

$$E_\pm\hat{E}_\pm-e^h\hat{E}_\pm E_\pm=0;\quad [E_\pm,\hat{E}_\mp]=\frac{e^h-1}{2\sinh(h)}\hat{H}_\pm e^{hH_\pm};\quad [E_\pm,\hat{H}_\pm]=0;\quad [E_\pm,\hat{H}_\mp]=\hat{E}_\pm.$$

Finally, the commutation of forms is determined by the relation $\hat{x}\hat{y}=-\hat{y}\hat{x}$ for all $x,y\in gl(2)$.

(Received 7 November 1995; accepted for publication 30 April 1996)

It is shown that the orthosymplectic Lie superalgebras osp $(m/2n)$ have a nonregular subalgebra osp$(1/2n)$. This implies that paraboson operators can be realized as elements of osp$(m/2n)$. The embedding osp$(2/2n) \supset$ osp$(1/2n)$, or, in a different notation, $C(n+1) \supset B(0,n)$, is studied in more detail. In particular, branching rules are determined for all typical and atypical irreducible representations of osp$(2/2n)$ with respect to the subalgebra osp$(1/2n)$. Finally, dimension and superdimension formulas are given for the Lie superalgebras under consideration. © *1996 American Institute of Physics.* [S0022-2488(96)01108-5]

I. INTRODUCTION

Lie superalgebras and their irreducible representations (simple modules) have been the subject of much attention in both the mathematical[1–4] and the physics[5–9] literature. However, even for the simplest family of basic classical Lie superalgebras, namely sl(m/n), a number of open problems remain with respect to understanding all finite-dimensional simple modules. The main reason is the existence of so-called *atypical* modules,[2,3] besides the *typical* modules which are well understood. For singly atypical modules (for which the highest weight Λ is atypical with respect to only one single odd root) of sl(m/n), a character formula has been constructed[10] and also the dimensions can be obtained.[11] For the remaining atypical modules, a number of conjectures have been formulated.[12–14]

The Lie superalgebras considered in this paper are the orthosymplectic superalgebras osp$(m/2n)$, and in particular those with $m=1$ and $m=2$. For osp$(1/2n)$, or $B(0,n)$ in Kac's notation, all representations are typical and thus a character formula is known for all of its finite-dimensional simple modules. An interesting feature of osp$(1/2n)$ is its relation with the so-called paraboson algebra, established by Palev.[15] We shall use this relation here in order to identify a nonregular osp$(1/2n)$ subalgebra in osp$(m/2n)$. The Lie superalgebra osp$(2/2n)$, or $C(n+1)$ in Kac's notation, does have both typical and atypical representations. However, the atypical modules are only singly atypical, and thus the techniques of Ref. 12 could be used to construct their characters.[16] Thus, also here a character formula is available for all finite-dimensional simple modules.

Little work has been done on branching rules for Lie superalgebras. The reason is quite obvious: all simple Lie superalgebras except for $B(0,n)$ have finite-dimensional indecomposable representations. Thus for a subalgebra pair of Lie superalgebras $G_1 \supset G_2$, the decomposition of a simple G_1 module with respect to G_2 is, in general, not completely reducible. The branching considered in this paper, $C(n+1) \supset B(0,n)$, does not have this disadvantage. Moreover, since the characters of all simple modules (both typical and atypical) of $C(n+1)$ are known, we can give a complete set of branching rules (Proposition 2). In particular, the branching rules shed some further light on the structure of atypical representations of $C(n+1)$.

The structure of the paper is as follows. In Sec. II we give the main definitions for osp$(m/2n)$.

In Sec. III we consider the nonregular embedding $\mathrm{osp}(m/2n)\supset\mathrm{osp}(1/2n)$, and as a byproduct gives a realization of n paraboson operators in $\mathrm{osp}(m/2n)$. In Sec. IV, the representation theory of $\mathrm{osp}(2/2n)=C(n+1)$ is recalled, and this is used in Sec. V to find the decomposition of simple $\mathrm{osp}(2/2n)$ modules with respect to its subalgebra $\mathrm{osp}(1/2n)$. Examples are given, and can be checked by counting dimensions and superdimensions. In a final section, (super)dimension formulas are given for $\mathrm{sp}(2n)$, $\mathrm{osp}(1/2n)$, and $\mathrm{osp}(2/2n)$. Some of these formulas are not new, but were never given in the partition notation for the highest weight. The dimension formula for atypical representations of $\mathrm{osp}(2/2n)$, however, is new; an alternative expression for this formula is constructed in the Appendix.

II. THE LIE SUPERALGEBRAS osp($m/2n$)

The general linear Lie superalgebra $G=\mathrm{gl}(m/n)$ with $m,n\in\mathbb{N}$ is defined[2,4] by

$$\mathrm{gl}(m/n)=\left\{x=\begin{pmatrix}A & B\\ C & D\end{pmatrix}\middle|\,A\in M_{m\times m},B\in M_{m\times n},C\in M_{n\times m},D\in M_{n\times n}\right\},\tag{1}$$

where $M_{p\times q}$ is the space of all $p\times q$ complex matrices. The even subspace $\mathrm{gl}(m/n)_{\bar{0}}$ has $B=0$ and $C=0$; the odd subspace $\mathrm{gl}(m/n)_{\bar{1}}$ has $A=0$ and $D=0$. The Lie superalgebra bracket is determined by

$$[a,b]=ab-(-1)^{\alpha\beta}ba,\quad \forall a\in G_\alpha \text{ and } \forall b\in G_\beta\quad(\alpha,\beta\in\{\bar{0},\bar{1}\}).\tag{2}$$

One defines the *supertrace* $\mathrm{str}(x)$ of $x=\left(\begin{smallmatrix}A & B\\ C & D\end{smallmatrix}\right)$ as[2,4] $\mathrm{str}(x)=\mathrm{tr}(A)-\mathrm{tr}(D)$, where tr is the ordinary trace. The *special linear Lie superalgebra* $\mathrm{sl}(m/n)$ is

$$\mathrm{sl}(m/n)=\{x\in\mathrm{gl}(m/n)\,|\,\mathrm{str}(x)=0\}.\tag{3}$$

Using the definition of *supertranspose* of $x=\left(\begin{smallmatrix}A & B\\ C & D\end{smallmatrix}\right)$,

$$x^T=\begin{pmatrix}A^t & -C^t\\ B^t & D^t\end{pmatrix},\tag{4}$$

with A^t the ordinary transpose of A, the orthosymplectic subalgebra $\mathrm{osp}(m/2n)$ of $\mathrm{sl}(m/2n)$ is defined[2,4] as

$$\mathrm{osp}(m/2n)=\left\{x=\begin{pmatrix}A & B\\ C & D\end{pmatrix}\in\mathrm{sl}(m/2n)\middle|\,x_\alpha^TJ+(-1)^\alpha Jx_\alpha=0,\quad\forall x_\alpha\in\mathrm{sl}(m/2n)_\alpha\ (\alpha=\bar{0},\bar{1})\right\},\tag{5}$$

where

$$J=\begin{pmatrix}I_m & & \\ & 0 & I_n\\ & -I_n & 0\end{pmatrix}\tag{6}$$

and I_q is the $q\times q$ identity matrix. In the notation of Kac,[2] $B(m,n)=\mathrm{osp}(2m+1/2n)$, $D(m,n)=\mathrm{osp}(2m/2n)$ for $m\neq1$ and $C(n+1)=\mathrm{osp}(2/2n)$.

III. THE NONREGULAR EMBEDDING osp($m/2n$)$\supset$osp(1/2n)

In this section the embedding osp$(m/2n)\supset$osp$(1/2n)$ $(m>1)$ will be established. This is a nonregular embedding, in the sense that the root vectors of osp$(1/2n)$ are not root vectors of osp$(m/2n)$ (see Ref. 2, or the following section, for the set of roots).

Let $E_{i,j}\in$gl$(m/2n)$ denote the matrix with entry 1 at position (i,j) and 0 elsewhere. The following matrices are odd elements of osp$(m/2n)$:

$$b_k^+=\sqrt{\frac{2}{m}}\sum_{i=1}^{m}(E_{i,m+n+k}+E_{m+k,i}), \tag{7}$$

$$b_k^-=\sqrt{\frac{2}{m}}\sum_{i=1}^{m}(E_{i,m+k}-E_{m+n+k,i}), \quad k=1,2,\ldots,n. \tag{8}$$

Proposition 1: The elements b_k^ξ satisfy the following relation:

$$[[b_i^\xi,b_j^\eta],b_k^\theta]=2\theta\delta_{j,k}\delta_{\theta,-\eta}b_i^\xi+2\theta\delta_{i,k}\delta_{\theta,-\xi}b_j^\eta \quad (i,j,k=1,2,\ldots,n;\xi,\eta,\theta=\pm). \tag{9}$$

Note that in (9) the inner bracket stands for an anticommutator, and the outer bracket for a commutator. Relation (9) is the defining equation for paraboson operators.[15,17,18] Thus the proposition claims that a set of n paraboson operators have a realization in osp$(m/2n)$.

The proof of (9) is by straightforward computation: for $(\xi,\eta,\theta)=(+,+,+)$ or $(-,-,-)$ the calculation is trivial; due to symmetry of the anticommutator the remaining cases to be checked are $(+,+,-)$, $(+,-,+)$, $(+,-,-)$, and $(-,-,+)$.

Next, a theorem of Palev[15] is used: the Lie superalgebra generated by $2n$ odd elements b_k^ξ satisfying the relations (9) is osp$(1/2n)$. Therefore it follows that osp$(m/2n)$ contains osp$(1/2n)$ as a (nonregular) subalgebra (algebra–subalgebra in the sense of Lie superalgebras).

IV. THE LIE SUPERALGEBRA $C(n+1)$=osp(2/2n) AND ITS REPRESENTATIONS

In this section, $G=C(n+1)=$osp$(2/2n)$. The Lie superalgebra G has a Cartan subalgebra H spanned by the diagonal matrices in (5) with $m=2$. The dual space H^* is described in the basis of forms ϵ and δ_j $(j=1,\ldots,n)$, where $\epsilon:x\to A_{1,1}$ and $\delta_j:x\to D_{jj}$ for $x=\left(\begin{smallmatrix}A&B\\C&D\end{smallmatrix}\right)$. Denote by Δ the set of all roots of G, by Δ_0 the set of even roots, and by Δ_1 the set of odd roots. We have[2,16]

$$\Delta_0=\{\delta_j-\delta_k(j\neq k),\pm(\delta_j+\delta_k),(1\leqslant j,k\leqslant n)\}, \tag{10}$$

$$\Delta_1=\{\epsilon\pm\delta_k,-\epsilon\pm\delta_k,(1\leqslant k\leqslant n)\}, \tag{11}$$

$$\Delta=\Delta_0\cup\Delta_1. \tag{12}$$

A set of simple roots $\{\alpha_0,\alpha_1,\ldots,\alpha_n\}$ of Δ may be chosen as follows:[2] $\alpha_0=\epsilon-\delta_1$, $\alpha_j=\delta_j-\delta_{j+1}(1\leqslant j\leqslant n-1)$, and $\alpha_n=2\delta_n$. This choice corresponds to the "distinguished basis."[3] The even and odd *positive* roots of G are then given by

$$\Delta_0^+=\{\delta_j-\delta_k(j<k),\delta_j+\delta_k\}, \quad \Delta_1^+=\{\epsilon\pm\delta_k\}. \tag{13}$$

The nondegenerate bilinear form $\langle|\rangle$ on H^* is determined by[16]

$$\langle\epsilon|\epsilon\rangle=1, \quad \langle\epsilon|\delta_j\rangle=0, \quad \text{and} \quad \langle\delta_j|\delta_k\rangle=-\delta_{jk}. \tag{14}$$

An element $\Lambda\in H^*$ with $\Lambda=\lambda_0\epsilon+\Sigma_{j=1}^n\lambda_j\delta_j$ can be written as $\Lambda=(\lambda_0;\lambda_1,\ldots,\lambda_n)$ in terms of its *components* in the $\epsilon\delta$-basis, or in terms of its *Dynkin labels* $\Lambda=[a_0;a_1,\ldots,a_n]$,

where

$$a_0=\lambda_0+\lambda_1, \quad a_k=\lambda_k-\lambda_{k+1} \quad (1\leqslant k\leqslant n-1), \quad \text{and } a_n=\lambda_n. \tag{15}$$

A weight $\Lambda\in H^*$ is *integral dominant* if all $a_i\in\mathbb{N}$ for $i=1,\ldots,n$. This implies that $\lambda_1\geqslant\lambda_2\geqslant\cdots$. Thus in terms of its components, an integral dominant weight is characterized by a complex number λ_0 and a *partition* $\lambda=(\lambda_1,\ldots,\lambda_n)$ consisting of at most n parts.

Kac[3] showed that every integral dominant weight Λ uniquely determines a simple finite-dimensional highest weight module $V(\Lambda)$, and vice versa that every simple finite-dimensional G-module is uniquely characterized by its integral dominant highest weight Λ. In order to describe the structure of such a simple module $V(\Lambda)$ by means of its character, we need to introduce a few more objects. The *Weyl group* W of G is defined to be the Weyl group of $G_{\bar{0}}$, so in this case it is just the Weyl group of the symplectic Lie algebra $\mathrm{sp}(2n)$. As usual, $\varepsilon(w)$ denotes the signature of $\omega\in W$. Further on, we denote $\rho=\rho_0-\rho_1$ with

$$\rho_0=\frac{1}{2}\sum_{\alpha\in\Delta_0^+}\alpha, \quad \rho_1=\frac{1}{2}\sum_{\beta\in\Delta_1^+}\beta, \tag{16}$$

or explicitly, $\rho_0=\Sigma_{k=1}^n(n+1-k)\delta_k$ and $\rho_1=n\epsilon$.

Kac[3] distinguished between *typical* and *atypical* modules: $V(\Lambda)$ and Λ are said to be typical if and only if $\langle\Lambda+\rho|\beta\rangle\neq 0$ for all $\beta\in\Delta_1^+$. Otherwise, $V(\Lambda)$ and Λ are said to be atypical. Explicitly, an integral dominant weight $\Lambda=(\lambda_0;\lambda)$ is typical if

$$\lambda_0\neq n\pm(\lambda_k+n+1-k) \quad (k=1,2,\ldots,n). \tag{17}$$

For a typical module $V(\Lambda)$, Kac proved the following character formula:[3]

$$\mathrm{ch}\ V(\Lambda)=L_0^{-1}\sum_{w\in W}\varepsilon(w)w\left(e^{\Lambda+\rho_0}\sum_{\beta\in\Delta_1^+}(1+e^{-\beta})\right), \tag{18}$$

where $L_0=\Pi_{\alpha\in\Delta_0^+}(e^{\alpha/2}-e^{-\alpha/2})$ and $e^\lambda(\lambda\in H^*)$ is the *formal exponential*.

For atypical modules of $C(n+1)$, the characters were determined in Ref. 16, where two alternative expressions were given. The one we shall use here is

$$\mathrm{ch}\ V(\Lambda)=L_0^{-1}\sum_{w\in W}\varepsilon(w)w\left(e^{\Lambda+\rho_0}\prod_{\substack{\beta\in\Delta_1^+\\ \langle\Lambda+\rho|\beta\rangle\neq 0}}(1+e^{-\beta})\right). \tag{19}$$

These character formulas contain all the information on the weight structure of the simple modules. Hence, to determine the decomposition of a G module with respect to a subalgebra of G, the character is in principle all that is needed.

V. THE BRANCHING $C(n+1)=\mathrm{osp}(2/2n)\supset\mathrm{osp}(1/2n)=B(0,n)$

The embedding $\mathrm{osp}(2/2n)\supset\mathrm{osp}(1/2n)$ was described in Sec. III. The two Lie superalgebras have almost the same even subalgebra: $\mathrm{osp}(2/2n)_{\bar{0}}=\mathbb{C}\oplus\mathrm{sp}(2n)$ and $\mathrm{osp}(1/2n)_{\bar{0}}=\mathrm{sp}(2n)$. They have the same Weyl group W, namely the Weyl group of $\mathrm{sp}(2n)$. And the weight space of $\mathrm{osp}(1/2n)$ can be identified with the subspace of H^* spanned by the δ_ks only. Thus for an $\mathrm{osp}(2/2n)$ module $V(\Lambda)$ reduced to $\mathrm{osp}(1/2n)$, the $\mathrm{osp}(1/2n)$ weights are determined by projecting the $\mathrm{osp}(2/2n)$ weights on this subspace, i.e., by putting the ϵ-component equal to 0. Since all finite-dimensional modules of $\mathrm{osp}(1/2n)$ are completely reducible [cf. Kac;[3] note that $\mathrm{osp}(1/2n)$ is

the only simple Lie superalgebra with this property], one simply has to decompose the character of this osp(1/2n) module into simple osp(1/2n) characters in order to obtain the decomposition of $V(\Lambda)$ into simple osp(1/2n) modules.

A simple osp(1/2n) module $V=V(\mu)$ is uniquely characterized by its highest weight $\mu=\Sigma_{j=1}^{n}\mu_j\delta_j=(\mu_1,\ldots,\mu_n)$, which is integral dominant, i.e., μ forms a partition. All $V(\mu)$ are typical, with their character given by

$$\text{ch } V(\mu)=L_0^{-1}\sum_{w\in W}\varepsilon(w)w\left(e^{\mu+\rho_0}\prod_{j=1}^{n}(1+e^{-\delta_j})\right); \tag{20}$$

herein, L_0, W, and ρ_0 are the same as in (18). The procedure to determine the decomposition of a simple osp(2/2n) module $V(\Lambda)$ into simple osp(1/2n) modules $V(\mu)$ is thus as follows: consider the character ch $V(\Lambda)$, substitute herein $\epsilon=0$, and rewrite the result as a sum of characters ch $V(\mu)$ of the type (20). This procedure can formally be executed for both typical and atypical representations of osp(2/2n). Without going into the details of the computation, we give the main result in Proposition 2. Before formulating this result, recall that a partition $\lambda=(\lambda_1,\lambda_2,\ldots)$ is conveniently represented[19] by its Young diagram F^λ consisting of left-adjusted rows of boxes of length λ_i. A diagram F^σ obtained from F^λ by adding or removing certain boxes is called *standard* if it still corresponds to a partition, i.e., if $\sigma_1\geqslant\sigma_2\geqslant\cdots$. For example, let

$F^{(3,2,2)}=$  . (21)

Adding one box in the second row yields a standard diagram; adding one box in the third row yields a nonstandard diagram.

Proposition 2: Let $\Lambda=(\lambda_0;\lambda)=(\lambda_0;\lambda_1,\lambda_2,\ldots,\lambda_n)\in H^*$ be integral dominant and $V(\Lambda)$ the simple osp(2/2n) module with highest weight Λ. Then the set of μs determining the decomposition of $V(\Lambda)$ into simple osp(1/2n) modules $V(\mu)$ is found as follows.

(a) If Λ is typical construct all standard diagrams F^μ obtained from F^λ by adding either no or else one box into each row of F^λ.

(b) If Λ is atypical with respect to $\epsilon-\delta_k$, i.e., $\lambda_0=-\lambda_k+k-1$, then construct all standard diagrams F^μ obtained from F^λ by adding no box in row k and by adding either no or else one box into each row different from k.

(c) If Λ is atypical with respect to $\epsilon+\delta_k$, i.e., $\lambda_0=\lambda_k-k+2n+1$, then construct all standard diagrams F^μ obtained from F^λ by adding one box in row k and by adding either no or else one box into each row different from k.

The proposition makes the distinction between typical and atypical modules very clear. To illustrate this, consider osp(2/6)$\supset$osp(1/6) for $V(\Lambda)$ with $\Lambda=(\lambda_0;3,2,2)$. For $\lambda_0\notin\{-3,-1,0,6,7,9\}$, $V(\Lambda)$ is typical and the decomposition is given by

$$\begin{aligned}(\lambda_0;3,2,2)&\rightarrow(3,2,2)\oplus(4,2,2)\oplus(3,3,2)\oplus(4,3,2)\oplus(3,3,3)\oplus(4,3,3),\\ 24192 &= 1386+4095+2310+9009+1386+6006,\\ 0 &= 54-135-70+231+30-110.\end{aligned}$$

If $\lambda_0=-1$, Λ is atypical with respect to $\epsilon-\delta_2$ and in this case the decomposition is

$$\begin{aligned}(-1;3,2,2)&\rightarrow(3,2,2)\oplus(4,2,2),\\ 5481 &= 1386+4095,\\ 81 &= -54+135.\end{aligned} \tag{22}$$

If $\lambda_0=6$, Λ is atypical with respect to $\epsilon+\delta_3$ and then the decomposition is given by

$$\begin{aligned}(6;3,2,2)&\rightarrow(3,3,3)\oplus(4,3,3),\\ 7392 &= 1386 + 6006,\\ 80 &= -30 + 110.\end{aligned}\tag{23}$$

Below the representation labels are given the dimensions ($\dim V = \dim V_{\bar{0}} + \dim V_{\bar{1}}$) and so-called superdimensions ($\mathrm{sdim}\, V = \dim V_{\bar{0}} - \dim V_{\bar{1}}$). Some but not all of these dimensions can be found in the tables of Thierry-Mieg.[20] In Sec. VI, we shall list the known dimension formulas for osp($m/2n$) ($m=0,1,2$) and give some new expressions.

VI. DIMENSION FORMULAS

Below we summarize the dimension and superdimension formulas for the simple modules of the Lie superalgebras treated in this paper, in an obvious notation. First we recall the dimension formula of the simple module with highest weight $\lambda=\sum_{i=1}^{n}\lambda_i\delta_i$ for the Lie algebra sp($2n$), taken from Ref. 21. Next are given the superdimension and dimension formula for osp($1/2n$); these can be deduced from Ref. 3 (up to some printing errors). From the same reference follow the dimension and superdimension of *typical* representations of osp($2/2n$) [here, the highest weight of the module is $\Lambda=(\lambda_0;\lambda)$, but λ_0 does not appear in the dimension formulas]:

$$\dim_{\mathrm{sp}(2n)}(\lambda)=\prod_{i=1}^{n}\frac{\lambda_i+n+1-i}{n+1-i}\prod_{1\leq i<j\leq n}\frac{(\lambda_i-\lambda_j+j-i)(\lambda_i+\lambda_j+2n+2-i-j)}{(j-i)(2n+2-i-j)};\tag{24}$$

$$\mathrm{sdim}_{\mathrm{osp}(1/2n)}(\lambda)=\prod_{1\leq i<j\leq n}\frac{(\lambda_i-\lambda_j+j-i)(\lambda_i+\lambda_j+2n+1-i-j)}{(j-i)(2n+1-i-j)};\tag{25}$$

$$\dim_{\mathrm{osp}(1/2n)}(\lambda)=\prod_{i=1}^{n}\frac{\lambda_i+n-i+\frac{1}{2}}{n-i+\frac{1}{2}}\,\mathrm{sdim}_{\mathrm{osp}(1/2n)}(\lambda);\tag{26}$$

$$\mathrm{sdim}^{\mathrm{typ}}_{\mathrm{osp}(2/2n)}(\lambda_0;\lambda)=0;\tag{27}$$

$$\dim{}^{\mathrm{typ}}_{\mathrm{osp}(2/2n)}(\lambda_0;\lambda)=2^{2n}\dim_{\mathrm{sp}(2n)}(\lambda).\tag{28}$$

What remains to be determined are formulas for the dimensions and superdimensions of *atypical* irreducible representations of osp($2/2n$). For the superdimension, a formula can be derived from equation (6.21) of Ref. 16:

$$\mathrm{sdim}^{\mathrm{atyp}:\epsilon\pm\delta_k}_{\mathrm{osp}(2/2n)}(\lambda_0;\lambda)=\dim_{\mathrm{sp}(2n-2)}(\lambda_1+1,\lambda_2+1,\ldots,\lambda_{k-1}+1,\lambda_{k+1},\lambda_{k+2},\ldots,\lambda_n).\tag{29}$$

Again, the notation should be obvious: $\mathrm{sdim}^{\mathrm{atyp}:\beta}_{\mathrm{osp}(2/2n)}(\lambda_0;\lambda)$ stands for the superdimension of a simple module with highest weight $\Lambda=(\lambda_0;\lambda)$ atypical with respect to a positive odd root β. The dimension formula for an atypical osp($2/2n$) module is more difficult to obtain. In fact, contrary to the dimension formulas given so far, it is not completely but only partially factorizable into monomials in the λ_i. A technique to obtain a dimension formula from a character formula of the type (19) was given by Kac and Wakimoto.[22] Following this technique leads in the present case to the following formulas:

$$\dim^{\text{atyp};\epsilon+\delta_k}_{\text{osp}(2/2n)}(\lambda_0;\lambda)=\frac{2^{2n-1}}{n!}\left(\prod_{i=1}^{n}\frac{(2i)!}{(n-i)!(n+i)!}\right)\prod_{\substack{i=1\\ i\neq k}}^{n}x_i\prod_{\substack{1\leq i<j\leq n\\ i,j\neq k}}(x_i-x_j)(x_i+x_j)$$
$$\times(-1)^{k-1}\sum_{j=0}^{2n-1}\sum_{l=0}^{j}(-1)^l 2^{-j}\binom{j}{l}(x_k-l)\prod_{\substack{i=1\\ i\neq k}}^{n}(x_k-l-x_i)(x_k-l+x_i), \tag{30}$$

where $x_i=\lambda_i+n+1-i$;

$$\dim^{\text{atyp};\epsilon-\delta_k}_{\text{osp}(2/2n)}(\lambda_0;\lambda)=\frac{2^{2n-1}}{n!}\left(\prod_{i=1}^{n}\frac{(2i)!}{(n-i)!(n+i)!}\right)\prod_{\substack{i=1\\ i\neq k}}^{n}x_i\prod_{\substack{1\leq i<j\leq n\\ i,j\neq k}}(x_i-x_j)(x_i+x_j)$$
$$\times(-1)^{k-1}\sum_{j=0}^{2n-1}\sum_{l=0}^{j}(-1)^l 2^{-j}\binom{j}{l}(x_k-l)\prod_{\substack{i=1\\ i\neq k}}^{n}(x_k-l-x_i)(x_k-l+x_i), \tag{31}$$

where $x_i=\lambda_i+n+1-i(i\neq k)$ and $x_k=\lambda_k+n-k$.

For example, consider osp(2/6) and representations that are atypical with respect to $\epsilon+\delta_3$; then (30) yields

$$\begin{aligned}\dim^{\text{atyp};\epsilon+\delta_3}_{\text{osp}(2/6)}(\lambda_0=\lambda_3+4;\lambda_1,\lambda_2,\lambda_3)=&\tfrac{1}{90}(\lambda_1+3)(\lambda_2+2)(\lambda_1-\lambda_2+1)(\lambda_1+\lambda_2+5)(2\lambda_3+3)\\ &\times(2\lambda_1^2\lambda_2^2-2\lambda_1^2\lambda_3^2-2\lambda_2^2\lambda_3^2+2\lambda_3^4+8\lambda_1^2\lambda_2+12\lambda_1\lambda_2^2\\ &-6\lambda_1^2\lambda_3-6\lambda_2^2\lambda_3-12\lambda_1\lambda_3^2-8\lambda_2\lambda_3^2+12\lambda_3^3+5\lambda_1^2\\ &+48\lambda_1\lambda_2+15\lambda_2^2-36\lambda_1\lambda_3-24\lambda_2\lambda_3-4\lambda_3^2\\ &+30\lambda_1+60\lambda_2-66\lambda_3+35).\end{aligned} \tag{32}$$

Using this formula, the dimension in (23) can be calculated. Note in (32) that the polynomial obtained from the sum over j and l part in (30), with the proper arguments, gives rise to one more factor, namely $(2\lambda_3+3)=(2x_3+1)$. All other examples we have worked through confirm this extra factor. This comes as no surprise. Indeed, the branching rule for an atypical representation (of type $\epsilon+\delta_k$, for example) determined in the previous section implies that all osp(1/2n) components of this representation have $(x_k+\frac{1}{2})$ as a factor for their dimensions, thus also the total osp(2/2n) dimension should have this factor. This means that the polynomial part (i.e., sum over j and l) in (30) or (31) can be rewritten in another form, giving this extra factor explicitly. Identifying this polynomial in (30) as $P_{n-1}(x_k;x_1,x_2,\ldots,x_{k-1},x_{k+1},\ldots,x_n)$, it is of the type

$$P_N(z;z_1,\ldots,z_N)=\sum_{j=0}^{2N+1}\sum_{l=0}^{j}(-1)^l\binom{j}{l}2^{-j}(z-l)\prod_{i=1}^{N}(z-l-z_i)(z-l+z_i), \tag{33}$$

and the presently obtained branching rule implies that this polynomial has a factor $(2z+1)$. After various combinatorial manipulations, the details of which are presented in the Appendix, we arrived indeed at the following expression:

$$P_N(z;z_1,\ldots,z_N)=(2z+1)\sum_{p=0}^{N}\left(\sum_{m=0}^{p}\alpha_{p,m}\prod_{q=2}^{m+1}(2z+q)\right)e_{N-p}. \tag{34}$$

Herein, e_r is the rth elementary symmetric function[19] in the variables $z^2-z_1^2,\ldots,z^2-z_N^2$, and an expression for the coefficient $\alpha_{p,m}$ is given by

$$\alpha_{p,m}=\sum_{j=0}^{2p+1}\sum_{a=0}^{j}\sum_{b=0}^{m}2^{-j-1}(-1)^{a+b}\frac{1}{(m+1)!}\binom{j}{a}\binom{m+1}{b+1}a^p(a+b+2)^p(2a+b+2). \tag{35}$$

In the last formula, 0^0 should be interpreted as 1.

APPENDIX: PROOF OF (34)

First, we prove two short lemmas.

Lemma 1: Let $f(z)$ and $g(z)$ be real polynomials in z with $g(z-\frac{1}{2})+g(z+\frac{1}{2})=f(z)$. If $f(-z)=-f(z)$, then also $g(-z)=-g(z)$.

Proof: Putting $z=0$, and using $f(0)=0$, yields $g(-1/2)=-g(1/2)$. Assume now $g(-k/2)=-g(k/2)$ for k an odd positive integer. Then,

$$g\left(\frac{k}{2}\right)+g\left(\frac{k}{2}+1\right)=f\left(\frac{k+1}{2}\right)=-f\left(-\frac{k+1}{2}\right)=-g\left(-\frac{k}{2}\right)-g\left(-\frac{k}{2}-1\right),$$

thus also $g(-k/2-1)=-g(k/2+1)$. By induction $g(-k/2)=-g(k/2)$ for all odd positive integers k. Since $g(z)$ is a polynomial, this can only happen when $g(-z)=-g(z)$.

The second lemma follows from numerical analysis results, and uses the translation operator $Ef(z)=f(z+1)$ and the forward difference operator $\Delta f(z)=f(z+1)-f(z)$; thus $\Delta=E-1$.

Lemma 2: Let $f(z)$ be a polynomial in z of degree n. Then

$$\sum_{k=0}^{j}(-1)^k\binom{j}{k}f(z+k)=0 \quad \text{for } j>n.$$

Proof: The sum can be written as

$$\sum_{k=0}^{j}(-1)^k\binom{j}{k}f(z+k)=\sum_{k=0}^{j}(-1)^k\binom{j}{k}E^kf(z)=(1-E)^jf(z)=(-\Delta)^jf(z),$$

and this is zero, since it is a classical result that $\Delta^j f(z)=0$ for $f(z)$ a polynomial with degree $n<j$.

Consider now (33); using

$$\prod_{i=1}^{N}(z-l-z_i)(z-l+z_i)=\prod_{i=1}^{n}(l^2-2zl+(z^2-z_i^2)),$$

and

$$\prod_{i=1}^{N}(x+x_i)=\sum_{n=0}^{N}x^n e_{N-n}(x_1,\ldots,x_N),$$

with e_r the rth elementary symmetric function, we see that

$$P_N(z;z_1,\ldots,z_N)=\sum_{n=0}^{N}p_n(z)e_{N-n}(z^2-z_1^2,\ldots,z^2-z_N^2),$$

with

$$p_n(z)=\sum_j \sum_l (-1)^l \binom{j}{l} 2^{-j}(z-l)l^n(l-2z)^n.$$

By Lemma 2, the sum over j runs from 0 to $2n+1$; the sum over l is restricted by the binomial coefficient. Next, we use

$$\begin{aligned}(z-l)l^n(l-2z)^n &= \sum_i \binom{n}{i} l^{2n-i}(-2z)^i(z-l)\\ &= -\frac{1}{2}\sum_i \binom{n}{i} l^{2n-i}(-2z)^{i+1} - \sum_i \binom{n}{i} l^{2n+1-i}(-2z)^i\\ &= -\frac{1}{2}\sum_i \binom{n}{i-1} l^{2n+1-i}(-2z)^i - \sum_i \binom{n}{i} l^{2n+1-i}(-2z)^i\\ &= -\frac{1}{2}\sum_i l^{2n+1-i}(-2z)^i\left\{\binom{n}{i-1}+2\binom{n}{i}\right\}\\ &= -\frac{1}{2}\sum_i l^{2n+1-i}(-2z)^i\left\{\binom{n}{i}+\binom{n+1}{i}\right\},\end{aligned}$$

so

$$p_n(z)=\sum_{i,j,l} (-1)^{l+1}\binom{j}{l}2^{-j-1}\left\{\binom{n}{i}+\binom{n+1}{i}\right\} l^{2n+1-i}(-2z)^i. \tag{A1}$$

In order to see that $p_n(z)$ has $2z+1$ as a divisor, and to rewrite the quotient in an appropriate form, we shall express all quantities in terms of the functions $w_m(z)$, where $w_0(z)=1$ and

$$w_m(z)=\prod_{q=1}^{m}(-2z-q).$$

Using the following formula from combinatorial analysis,

$$x^r=\sum_{m,k}\frac{(-1)^{m-k}}{m!}\binom{m}{k}k^r x(x-1)\cdots(x-m+1),$$

on $(-2z)^i=\Sigma_r\binom{i}{r}(-2z-1)^r$, yields

$$(-2z)^i=\sum_r\binom{i}{r}\sum_{m,k}\frac{(-1)^{m-k}}{m!}\binom{m}{k}k^r w_m(z)=\sum_{m,k}\frac{(-1)^{m-k}}{m!}\binom{m}{k}(k+1)^i w_m(z).$$

Putting this back in (A1) gives

$$p_n(z)=\sum_{m=0}^{2n+1}\beta_{n,m}w_m(z),$$

with

$$\beta_{n,m}=\sum_{i,j,l,k}(-1)^{l+1}\binom{j}{l}2^{-j-1}\left\{\binom{n}{i}+\binom{n+1}{i}\right\}l^{2n+1-i}\frac{(-1)^{m-k}}{m!}\binom{m}{k}(k+1)^i$$

$$=\sum_{j,l,k}\frac{(-1)^{l+m+k+1}}{m!}\binom{j}{l}\binom{m}{k}2^{-j-1}\sum_i\left\{\binom{n}{i}+\binom{n+1}{i}\right\}l^{2n+1-i}(k+1)^i$$

$$=\sum_{j,l,k}\frac{(-1)^{l+m+k+1}}{m!}\binom{j}{l}\binom{m}{k}2^{-j-1}\{l^n(l+k+1)^{n+1}+l^{n+1}(l+k+1)^n\}$$

$$=\sum_{j,l,k}\frac{(-1)^{l+m+k+1}}{m!}\binom{j}{l}\binom{m}{k}2^{-j-1}l^n(l+k+1)^n(2l+k+1).$$

This gives a proper form for the coefficients of $p_n(z)$ in terms of $w_m(z)$. It remains to be shown that the coefficient of $w_0(z)$ vanishes, or $\beta_{n,0}=0$ for all n, where

$$\beta_{n,0}=\sum_{j,l}(-1)^{l+1}\binom{j}{l}2^{-j-1}l^n(l+1)^n(2l+1).$$

Consider

$$t_n=\sum_{k=0}^{n}\binom{n}{k}4^{n-k}\beta_{n-k,0};$$

since this is a triangular system of the $\beta_{n-k,0}$ in terms of the t_n, all $\beta_{j,0}$ are zero if we prove that all t_n are zero for $n=0,1,2,\ldots$. For t_n, there comes the expression

$$t_n=\sum_{k,j,l}\binom{n}{k}4^{n-k}(-1)^{l+1}\binom{j}{l}2^{-j-1}(l^2+l)^{n-k}(2l+1)=\sum_{j,l}(-1)^{l+1}\binom{j}{l}2^{-j-1}(2l+1)^{2n+1}.$$

Consider

$$T_n(z)=\sum_j 2^{-j-1}\sum_l(-1)^{l+1}\binom{j}{l}(2z+2l+1)^{2n+1};$$

then $t_n=T_n(0)$, and with $f(z)=(2z+1)^{2n+1}$ we have (using the notation of Lemma 2)

$$T_n(z)=\sum_j 2^{-j-1}\sum_l(-1)^{l+1}\binom{j}{l}f(z+l)$$

$$=-\sum_j 2^{-j-1}(-1)^j\Delta^j f(z)$$

$$=-\frac{1}{2}\sum_j\left(-\frac{\Delta}{2}\right)^j f(z)$$

$$=-\frac{1}{2}\frac{1}{1+\Delta/2}f(z)$$

$$=\frac{-1}{1+E}f(z).$$

Hence $T_n(z)$ is the polynomial solution of $T_n(z+1)+T_n(z)=-(2z+1)^{2n+1}$. Replacing herein z by $z-1/2$ leads to $T_n(z+1/2)+T_n(z-1/2)=-(2z)^{2n+1}$; using Lemma 1 implies that $T_n(z)$ is an odd function of z, thus $t_n=T_n(0)=0$. Combining all results now leads to (34) and (35).

SU3 isoscalar factors

H. T. Williams
Department of Physics, Washington and Lee University, Lexington, Virginia 24450

(Received 19 September 1995; accepted for publication 30 April 1996)

A summary of the properties of the Wigner–Clebsch–Gordan coefficients and isoscalar factors for the group SU3 in the SU2⊗U1 decomposition is presented. The outer degeneracy problem is discussed in detail with a proof of a conjecture (Braunschweig's) which has been the basis of previous work on the SU3 coupling coefficients. Recursion relations obeyed by the SU3 isoscalar factors are produced, along with an algorithm which allows numerical determination of the factors from the recursion relations. The algorithm produces isoscalar factors which share all the symmetry properties under permutation of states and conjugation which are familiar from the SU2 case. The full set of symmetry properties for the SU3 Wigner–Clebsch–Gordan coefficients and isoscalar factors are displayed. © *1996 American Institute of Physics.* [S0022-2488(96)01208-X]

I. INTRODUCTION

The group SU3 continues to be useful in modeling symmetries observed in particle and nuclear physics. In the late 1950s application was found in classification of "elementary" hadrons, and in the description of rotational states of nonspherical nuclei. Its utility persists as the color symmetry of quantum chromodynamics, various models for collective nuclear motion, and elsewhere.

The Wigner–Clebsch–Gordan coefficients (WCG) are of particular interest. These can be defined as the expansion coefficients of a composite state of good SU3 quantum numbers in terms of direct products of two individual SU3 classified states, paralleling Wigner's original use of SU2 in the treatment of quantum angular momentum. The WCG can also be developed as the matrix elements of a set of tensor operators which have distinctive properties under the transformations of SU3. These two viewpoints on the WCG are formally identical, and their algebraic connection is expressed by the Wigner–Eckart Theorem. The SU3 case presents a complication that is absent in the SU2 recoupling problem—that of the *outer degeneracy*. The complete determination of WCGs in SU3 requires a criterion outside the SU3 group to completely classify composite states, and thus to fully define numerical values for the WCG. In *this* process, the two perspectives on the WCG mentioned above suggest quite different mechanisms.

Biedenharn and co-workers,[1–3] adopting the operator point of view, have developed a set of canonical SU3-labeled unit tensor operators, whose matrix elements become the "canonical WCGs." The canonical operators acquire SU3 labels by virtue of their behavior under the transformations of the group. As well, each produces a unique set of shifts, i.e., its action when operating on a state from a particular irreducible representations (irrep) produces states from a unique second irrep; and in cases of nontrivial outer degeneracy there is a distinct operator for each degeneracy index. The uniqueness of the operators, and thus their designation as canonical, comes from their null space properties. The *characteristic null space* of an operator is the union of all irreps which identically yield zero under the action of the operator. In the case of a tensor operator of degeneracy one, the null space is uniquely determined by the group properties of the operator and the state operated upon: for higher degeneracy the operators for distinct degeneracy labels are chosen to have a null space each larger than the previous and completely containing it.

Adopting the alternative viewpoint—the WCGs as coupling coefficients which give the amplitude for the joining of two SU3 states to a composite state of good SU3 quantum numbers—coefficients which exhibit symmetry under interchange of the two states being coupled are sug-

gested (a symmetry missing from the canonical coefficients).[4] The WCGs for those couplings which have degeneracy 1 possess this symmetry, and indeed all the symmetries under permutation of irreps of the familiar SU2 Clebsch–Gordan coefficients. It has been proven that such permutation symmetric WCGs for the SU3 case with degeneracy >1 exist[5–7] and examples of such SU3 WCGs have been developed.[8,9]

In the sections which follow, new results pertaining to the SU3 WCGs are presented which simplify evaluation of the WCGs, and which are independent of the particular scheme adopted for outer degeneracy resolution. In particular, a collection of recursion relations are defined for the isoscalar factors. An algorithm is presented which utilizes these recursion relations to generate a set of WCGs demonstrating all the Racah symmetries familiar from SU2. This algorithm has been used in a successful C language implementation.

II. DEFINITIONS AND NOTATION

A linear vector space which carries an irrep of SU3 is fully specified by two integers (p,q), henceforth referred to as the *irrep labels*. The dimension of the space is

$$d=(p+1)(q+1)(p+q+2)/2. \tag{1}$$

A complete set of d orthogonal vectors within the irrep can be labeled by three further integers (k,l,m), the *subspace labels*, which satisfy the *betweenness conditions*

$$p+q\geqslant k\geqslant q\geqslant l\geqslant 0; \quad k\geqslant m\geqslant l. \tag{2}$$

A fully specified member of the orthonormal spanning set for the irrep is denoted by the ket

$$|p,q;k,l,m\rangle.$$

The WCGs are the coefficients (C) of the expansion of a composite SU3 state ket in terms of products of SU3 kets,

$$|\mathscr{P};\kappa\rangle=\sum C^{[\mathscr{P}_1]\ \ [\mathscr{P}_2]\ \ [\mathscr{P}]}_{[\kappa_1]\ \ [\kappa_2]\ \ [\kappa]}\ |\mathscr{P}_1;\kappa_1\rangle|\mathscr{P}_2;\kappa_2\rangle, \tag{3}$$

where $\mathscr{P}$ is shorthand for the pair (p,q) and κ for the set (k,l,m); the sum extends over subspace labels of κ_1 and κ_2, and $n=0,1,...$ labels the outer degeneracy. The Wigner–Eckart Theorem relates the WCGs to matrix elements of operators $T^n_{p,q;k,l,m}$, which transform like tensors under the operations of SU3:

$$\langle p,q;k,l,m|T^n_{p_1,q_1;k_1,l_1,m_1}|p_2,q_2;k_2,l_2,m_2\rangle=C^{[\mathscr{P}_1]\ \ [\mathscr{P}_2]\ \ [\mathscr{P}]}_{[\kappa_1]\ \ [\kappa_2]\ \ [\kappa]}\langle p,q\|T^n_{p_1,q_1}\|p_2,q_2\rangle, \tag{4}$$

where

$$\langle p,q\|T^n_{p_1,q_1}\|p_2,q_2\rangle,$$

the *reduced matrix element*, is a complex number which depends only upon the three sets of irrep labels. (The unit tensor operators of the Biedenharn scheme are so named since each has a reduced matrix element of one.)

The ket labeling scheme described above represents the decomposition SU3⊃SU2⊗U1. The labels (k,l,m) are the quantum numbers of the SU2 subgroup, and are related to the isospin (I) and its z component (I_z) by

$$I=\frac{k-l}{2}, \tag{5}$$

$$I_z=m-\frac{k+l}{2}, \tag{6}$$

and the U1 subgroup with the hypercharge (Y) given by

$$Y=k+l-\tfrac{2}{3}(p+2q). \tag{7}$$

The WCG of Eq. (3) will vanish unless the subspace labels obey the relations

$$I_1+I_2\geqslant I,$$
$$|I_1-I_2|\leqslant I, \tag{8}$$

$$I_{1_z}+I_{2_z}=I_z, \tag{9}$$

$$Y_1+Y_2=Y. \tag{10}$$

This decomposition allows factoring of an SU2 Clebsch–Gordan coefficient from the SU3 WCG as follows:

$$C\begin{matrix}[\mathscr{P}_1] & \overset{n}{[\mathscr{P}_2]} & [\mathscr{P}] \\ [\kappa_1] & [\kappa_2] & [\kappa]\end{matrix}=C\begin{matrix}I_1 & I_2 & I \\ I_{1_z} & I_{2_z} & I_z\end{matrix}F^n(p,q,k,l;p_1,q_1,k_1,l_1;p_2,q_2,k_2,l_2), \tag{11}$$

where the factor F, which is independent of the m subspace labels, is called the *isoscalar factor* (ISF). In subsequent usage, when their values are obvious from the context, the p and q values will be suppressed in the notation for the ISF.

A particular set of subspace labels, $k=m=p+q$, $l=0$, will play an important role in the present consideration. This set, referred to as the *state of highest weight* (SHW) for a particular irrep, will be referred to by the replacement $(k=p+q,\ l=0,\ m=p+q)\rightarrow$SHW and likewise in the isoscalar factor by $(p,q,k=p+q,\ l=0)\rightarrow(p,q,\text{SHW})$.

III. OUTER DEGENERACY

The Clebsch–Gordan series for SU3,

$$(p_1,q_1)\otimes(p_2,q_2)=\sum_i \eta_i(p_i',q_i'), \tag{12}$$

indicates the number of distinct times (η_i) the irrep (p_i',q_i') appears in the outer product of irreps (p_1,q_1) and (p_2,q_2). The circumstance of $\eta_i>1$ is a feature of SU3 referred to as *outer degeneracy*, and the coefficients η_i will be referred to herein as the *degeneracy* of the coupling $(p_1,q_1)\otimes(p_2,q_2)\rightarrow(p_i',q_i')$.

The value of the degeneracy is a function of the six irrep labels and can be deduced from the betweenness conditions of Eq. (2) for each irrep, and the requirements of the SU2 and U1 subgroups, given in Eqs. (8)–(10). These latter requirements follow from the corresponding Clebsch–

Gordan series for SU2 (triangularity of three Euclidian vectors in two dimensions) and for U1 (scalar addition). Various ways of evaluating the degeneracy appear in the literature.[10,11] An equivalent expression for the degeneracy consistent with present notation is

$$\eta=\max(\eta'+1-\max(\gamma,\sigma),0),$$
$$\eta'=\min(p_1+\sigma,p_2+\sigma,q+\sigma,q_1+\gamma,q_2+\gamma,p+\gamma,2(\sigma+\gamma),p_1+q_1-\gamma-\sigma,p_2+q_2-\gamma-\sigma) \tag{13}$$

where $\gamma\equiv(p_1+p_2-p)/3$, and $\sigma\equiv(q_1+q_2-q)/3$.

This expression can be used to prove Braunschweig's conjecture which has been used by several authors[12–14] in work related to determination of WCGs for SU3. The conjecture suggests that the number of nonvanishing values of the WCG,

$$C^{\overset{n}{[\mathscr{P}_1]\quad[\mathscr{P}_2]\quad[\mathscr{P}]}}_{[\mathrm{SHW}]\quad[\kappa_2]\quad[\mathrm{SHW}]'} \tag{14}$$

is no less than the degeneracy of the irrep coupling. The value for the subspace label m_2 is fixed by Eq. (9) and l_2 is dependent upon k_2 through Eq. (10)

$$k_2+l_2=p_2+q_2-\gamma+\sigma, \tag{15}$$

so counting the number of nonvanishing WCGs of this type can be accomplished by determining the range of k_2 values. Upper and lower limits on k_2 come from the triangularity expressions of Eq. (8) combined with Eq. (15), producing

$$k_2\geq p_2+q_2-2\gamma-\sigma, \quad k_2\geq\gamma+2\sigma, \tag{16}$$
$$k_2\leq p+q+\gamma+2\sigma.$$

The betweenness relations for state 2 give further limits on $k_2(p_2+q_2\geq k_2\geq q_2)$ and on $l_2(q_2\geq l_2\geq 0)$, which when combined with Eq. (15) produce

$$k_2\geq\sigma-\gamma+p_2, \quad k_2\leq\sigma-\gamma+p_2+q_2. \tag{17}$$

The limits on k_2 are thus

$$\max(p_2+q_2-2\gamma-\sigma,\gamma+2\sigma,q_2,p_2+\sigma-\gamma)\leq k_2\leq\min(p_2+q_2+\sigma-\gamma,p_2+q_2,p+q+\gamma+2\sigma), \tag{18}$$

which implies that the total number of k_2 values producing nonvanishing WCGs in this case is given by

$$1+\min(\gamma+2\sigma,\sigma+2\gamma,p_2+q_2-\sigma-2\gamma,p_2+q_2-\gamma-2\sigma,q_2,q_2$$
$$+\gamma-\sigma,p_1+q_1,p+q,p+q-q_2+\gamma+2\sigma,p+q-p_2+2\gamma+\sigma). \tag{19}$$

A term-by-term comparison of this expression with that for the degeneracy [Eq. (13)] reveals that the number of k_2 values producing nonvanishing WCGs of the form of Eq. (14) is greater than or equal to the degeneracy. This inequality is sufficient for the uses of the previously cited references, and has been important in the development of the algorithm presented later in this paper.

IV. RECURSION RELATIONS

An efficient scheme for evaluation of the SU3 ISF *independent of the method chosen for resolution of outer degeneracy* involves use of recursion relations for these quantities, which can be derived using the group generators.[15] Explicit expressions for the generators depend upon a choice of signs of the matrix elements of the generators between elements of the fundamental three-dimensional representation: those given below follow the phase convention of de Swart.[16] The actions of these generators on the orthonormal kets previously defined are

$$\hat{T}_+|p,q;k,l,m\rangle=\sqrt{(k-m)(m-l+1)}|p,q;k,l,m+1\rangle, \tag{20}$$

$$\hat{T}_-|p,q;k,l,m\rangle=\sqrt{(k-m+1)(m-l)}|p,q;k,l,m-1\rangle, \tag{21}$$

$$\hat{V}_+|p,q;k,l,m\rangle=\sqrt{\frac{(k+2)(m-l+1)(k-q+1)(p+q-k)}{(k-l+1)(k-l+2)}}|p,q;k+1,l,m+1\rangle + \sqrt{\frac{(l+1)(k-m)(q-l)(p+q-l+1)}{(k-l)(k-l+1)}}|p,q;k,l+1,m+1\rangle, \tag{22}$$

$$\hat{V}_-|p,q;k,l,m\rangle=\sqrt{\frac{(k+1)(m-l)(k-q)(p+q-k+1)}{(k-l)(k-l+1)}}|p,q;k-1,l,m-1\rangle + \sqrt{\frac{l(k-m+1)(q-l+1)(p+q-l+2)}{(k-l+1)(k-l+2)}}|p,q;k,l-1,m-1\rangle, \tag{23}$$

$$\hat{U}_+|p,q;k,l,m\rangle=\sqrt{\frac{(k+2)(k-m+1)(k-q+1)(p+q-k)}{(k-l+1)(k-l+2)}}|p,q;k+1,l,m\rangle - \sqrt{\frac{(m-l)(l+1)(q-l)(p+q-l+1)}{(k-l)(k-l+1)}}|p,q;k,l+1,m\rangle, \tag{24}$$

$$\hat{U}_-|p,q;k,l,m\rangle=\sqrt{\frac{(k+1)(k-m)(k-q)(p+q-k+1)}{(k-l)(k-l+1)}}|p,q;k-1,l,m\rangle - \sqrt{\frac{l(m-l+1)(q-l+1)(p+q-l+2)}{(k-l+1)(k-l+2)}}|p,q;k,l-1,m\rangle. \tag{25}$$

Three diagonal operators indicate the values of the subspace labels for a ket:

$$\hat{T}_3|p,q;k,l,m\rangle=I_z|p,q;k,l,m\rangle, \tag{26}$$

$$\hat{Y}|p,q;k,l,m\rangle=Y|p,q;k,l,m\rangle, \tag{27}$$

$$\hat{T}^2|p,q;k,l,m\rangle=\tfrac{1}{2}(\hat{T}_+\hat{T}_-+\hat{T}_-\hat{T}_++2(\hat{T}_3)^2)|p,q;k,l,m\rangle=I(I+1)|p,q;k,l,m\rangle, \tag{28}$$

making use of the definitions of Eqs. (6) and (7). The operators $\hat{T}_+$ and $\hat{T}_-$ move up and down in the variable I_z, and thus have no effect on the ISF. The remaining four nondiagonal (ladder) operators form the basis of the derivation of the recursion relations.

Consider a composite state of highest weight:

$$|\mathscr{P};\mathrm{SHW}\rangle=\sum C^{[\mathscr{P}_1]\quad [\mathscr{P}_2]\quad [\mathscr{P}]}_{[\kappa_1]\quad [\kappa_2]\quad [\mathrm{SHW}]}\ |\mathscr{P}_1;\kappa_1\rangle|\mathscr{P}_2;\kappa_2\rangle. \tag{29}$$

The action of $\hat{V}_+$ on this ket must vanish since each of the two states it produces have $m=p+q+1$, which violates betweenness. Linearity of the generators (e.g., $\hat{V}_+=\hat{V}_{1+}+\hat{V}_{2+}$) implies from Eq. (29) that

$$\hat{V}_+|\mathscr{P};\mathrm{SHW}\rangle=0=\sum C^{[\mathscr{P}_1]\quad [\mathscr{P}_2]\quad [\mathscr{P}]}_{[\kappa_1]\quad [\kappa_2]\quad [\mathrm{SHW}]}\ (|\mathscr{P}_2;\kappa_2\rangle\hat{V}_{1+}|\mathscr{P}_1;\kappa_1\rangle + |\mathscr{P}_1;\kappa_1\rangle\hat{V}_{2+}|\mathscr{P}_2;\kappa_2\rangle). \tag{30}$$

Use of the defining equation for $\hat{V}_+$ [Eq. (22)] changes this expression into a summed four-term expression which must vanish. The orthogonality of any two SU3 kets with different subspace labels allows this sum to be transformed into a four-term recursion relation for the WCG:

$$\begin{aligned}
0=&\sqrt{\frac{(k_1+1)(m_1-l_1)(k_1-q_1)(p_1+q_1-k_1+1)}{(k_1-l_1)(k_1-l_1+1)}}\\
&\times C^{[\mathscr{P}_1]\quad [\mathscr{P}_2]\quad [\mathscr{P}]}_{[k_1-1,l_1,m_1-1]\quad [k_2,l_2,m_2]\quad [\mathrm{SHW}]}\\
&+\sqrt{\frac{(k_2+1)(k_2-q_2)(p_2+q_2-k_2+1)(m_2-l_2+1)}{(k_2-l_2)(k_2-l_2+1)}}\\
&\times C^{[\mathscr{P}_1]\quad [\mathscr{P}_2]\quad [\mathscr{P}]}_{[k_1,l_1,m_1]\quad [k_2-1,l_2,m_2-1]\quad [\mathrm{SHW}]}\\
&+\sqrt{\frac{l_1(q_1-l_1+1)(k_1-m_1+1)(p_1+q_1-l_1+2)}{(k_1-l_1+1)(k_1-l_1+2)}}\\
&\times C^{[\mathscr{P}_1]\quad [\mathscr{P}_2]\quad [\mathscr{P}]}_{[k_1,l_1-1,m_1-1]\quad [k_2,l_2,m_2]\quad [\mathrm{SHW}]}\\
&+\sqrt{\frac{l_2(k_2-m_2+1)(q_2-l_2+1)(p_2+q_2-l_2+2)}{(k_2-l_2+1)(k_2-l_2+2)}}\\
&\times C^{[\mathscr{P}_1]\quad [\mathscr{P}_2]\quad [\mathscr{P}]}_{[k_1,l_1,m_1]\quad [k_2,l_2-1,m_2-1]\quad [\mathrm{SHW}]}.
\end{aligned} \tag{31}$$

This should be valid for any set of projection quantum numbers, thus for $k_1=m_1$ which allows the replacement of the WCG in this expression by products of ISF and simple SU2 Clebsch–Gordan coefficients whose values can be expressed analytically.[17] The result of this replacement is a four-term recursion relation among the ISFs for coupling to a state of highest weight:

$$\begin{aligned}
0=&a_1F^n(\mathrm{SHW}:k_1-1,l_1;k_2,l_2)+a_2F^n(\mathrm{SHW}:k_1,l_1;k_2-1,l_2)-a_3F^n(\mathrm{SHW}:k_1,l_1-1;k_2,l_2)\\
&+a_4F^n(\mathrm{SHW}:k_1,l_1;k_2,l_2-1),
\end{aligned}$$

where

$$a_1=\sqrt{\frac{(k_1+1)(k_1-q_1)(p_1+q_1-k_1+1)(p+q+2I_1+2I_2+3)(p+q+2I_1-2I_2+1)}{I_1(2I_1+1)}},$$

$$a_2=\sqrt{\frac{(k_2+1)(k_2-q_2)(p_2+q_2-k_2+1)(p+q+2I_1+2I_2+3)(p+q-2I_1+2I_2+1)}{I_2(2I_2+1)}},$$

$$a_3=\sqrt{\frac{l_1(q_1-l_1+1)(p_1+q_1-l_1+2)(-p-q+2I_1+2I_2+1)(p+q-2I_1+2I_2+1)}{(2I_1+1)(I_1+1)}}, \tag{32}$$

$$a_4=\sqrt{\frac{l_2(q_2-l_2+1)(p_2+q_2-l_2+2)(-p-q+2I_1+2I_2+1)(p+q+2I_1-2I_2+1)}{(2I_2+1)(I_2+1)}}.$$

Similarly,

$$\hat{U}_{-1}|\mathscr{F};\mathrm{SHW}\rangle=0 \tag{33}$$

since the two kets produced by this operation both violate betweenness. By an analogous set of steps one derives a second, distinct recursion relation:

$$0=b_1F^n(\mathrm{SHW}:k_1+1,l_1;k_2,l_2)-b_2F^n(\mathrm{SHW}:k_1,l_1;k_2+1,l_2)+b_3F^n(\mathrm{SHW}:k_1,l_1+1;k_2,l_2)$$
$$+b_4F^n(\mathrm{SHW}:k_1,l_1;k_2,l_2+1),$$

where

$$b_1=\sqrt{\frac{(k_1+2)(k_1-q_1+1)(p_1+q_1-k_1)(-p-q+2I_1+2I_2+1)(p+q-2I_1+2I_2+1)}{(2I_1+1)(I_1+1)}},$$

$$b_2=\sqrt{\frac{(k_2+2)(k_2-q_2+1)(p_2+q_2-k_2)(-p-q+2I_1+2I_2+1)(p+q+2I_1-2I_2+1)}{(2I_2+1)(I_2+1)}},$$

$$b_3=\sqrt{\frac{(l_1+1)(q_1-l_1)(p_1+q_1-l_1+1)(p+q+2I_1+2I_2+3)(p+q+2I_1-2I_2+1)}{I_1(2I_1+1)}}, \tag{34}$$

$$b_4=\sqrt{\frac{(l_2+1)(q_2-l_2)(p_2+q_2-l_2+1)(p+q+2I_1+2I_2+3)(p+q-2I_1+2I_2+1)}{I_2(2I_2+1)}}.$$

One can "step down" from the ISFs for the coupled state of highest weight to ISFs for any other k,l values by use of two relations derived in an analogous fashion from the actions of the operators $\hat{V}_-$ and $\hat{U}_+$, respectively:

$$F^n(k,l:k_1,l_1;k_2,l_2)=\alpha(c_1F^n(k+1,l-1:k_1,l_1;k_2,l_2)+c_2F^n(k,l-1:k_1,l_1-1;k_2,l_2)$$
$$-c_3F^n(k,l-1:k_1,l_1;k_2-1,l_2)+c_4F^n(k,l-1:k_1,l_1;k_2,l_2-1), \tag{35}$$

where

$$\alpha=\frac{k-l+2}{\sqrt{2l(q-l+1)(p+q-l+2)}},$$

$$c_1=\sqrt{\frac{(k+2)(k-q+1)(p+q-k)(I_1+I_2-I)(-I_1+I_2+I+1)}{(I+1)^2(I_1+I_2+I+2)(I_1-I_2+I+1)}},$$

$$c_2=\sqrt{\frac{4I_1(q_1-l_1+1)(p_1+q_1-l_1+2)(2I_1+1)}{(2I_1+2)(2I_1+2I_2+2I+4)(2I_1-2I_2+2I+2)}},$$

$$c_3=\sqrt{\frac{(k_2+1)(k_2-q_2)(p_2+q_2-k_2+1)(I_1+I_2-I)}{I_2(2I_2+1)(I_1-I_2+I+1)}},$$

$$c_4=\sqrt{\frac{l_2(q_2-l_2+1)(p_2+q_2-l_2+2)(-I_1+I_2+I+1)}{(2I_2+1)(I_2+1)(I_1+I_2+I+2)}};$$

and

$$F^n(k,0:k_1,l_1;k_2,l_2)=\beta(d_1F^n(k+1,0:k_1+1,l_1;k_2,l_2)+d_2F^n(k+1,0:k_1,l_1;k_2+1,l_2)$$
$$+d_3F^n(k+1,0:k_1,l_1;k_2,l_2+1)), \tag{36}$$

where

$$\beta=\sqrt{\frac{(k+2)}{2(k-q+1)(p+q-k)}},$$

$$d_1=\sqrt{\frac{(k_1+2)(k_1-q_1+1)(p_1+q_1-k_1)(2I_1+1)}{(I_1+1)(I_1+I_2+I+2)(I_1-I_2+I+1)}},$$

$$d_2=\sqrt{\frac{(k_2+2)(k_2-q_2+1)(p_2+q_2-k_2)(-I_1+I_2+I+1)}{(2I_2+1)(I_2+1)(I_1+I_2+I+2)}},$$

$$d_3=\sqrt{\frac{(l_2+1)(q_2-l_2)(p_2+q_2-l_2+1)(I_1+I_2-I)}{I_2(2I_2+1)(I_1-I_2+I+1)}}.$$

The second of these two expressions is not the most such general relation which can be derived, but when used in combination with the first, it is sufficient to determine the value of any ISF for the given irrep coupling, once the values of the ISFs for k,l=SHW are known.

V. DETERMINING THE ISOSCALAR FACTORS

To move from the recursion relations to determination of the ISF, a sign convention and a resolution scheme for outer degeneracy must be chosen. For a given coupling,

$$(p_1,q_1)\otimes(p_2,q_2)\rightarrow(p,q),$$

the degeneracy is determined by Eq. (13). For cases of degeneracy $\eta=1$, the choice of sign of one of the nonvanishing ISFs for (k,l)=SHW is sufficient to determine all the others. In practice, one such ISF is set equal to 1; Eqs. (32) and (34) are used to generate all others from this one; and all are multiplied by a common factor to enforce the normalization condition

$$\sum_{k_1,l_1,k_2,l_2}(F(\mathrm{SHW}:k_1,l_1;k_2,l_2))^2=1. \tag{37}$$

Even in such simple cases, the particular ISF to initialize must be chosen as one which allows use of the recursion relations (32) and (34) to determine neighboring values, and a recursive path from the starting point to arbitrary ISFs must be deduced.

When the (k,l)=SHW ISFs are all known, Eq. (36) can be used to deduce all $k<p+q$, $l=0$ ISFs, and from them Eq. (35) implies all $l>0$ cases.

The most delicate problem is the determination of an algorithm which uniquely determines all ISFs in cases of outer degeneracy two or higher. Such an algorithm has been developed and implemented in C language codes for evaluation of arbitrary ISFs as floating point values, and as exact precision square roots of a ratio of integers.[18] The ISFs produced by this algorithm share all the symmetries under irrep exchange and conjugation with the familiar SU2 Clebsch–Gordan coefficients.

The logic of the algorithm can be made clearer through a change of variables. Of the four integers, k_1,l_1,k_2,l_2, used heretofore as parameters of the isoscalar factor for a coupling to a state of highest weight, only three are independent. The hypercharge conservation relation (10) implies

$$k_1+l_1+k_2+l_2=\tfrac{1}{3}(2(p_1+p_2)+4(q_1+q_2)+p-q).$$

Use of the definition

$$s\equiv k_1-l_1+k_2-l_2$$

allows the ISFs to be expressed as $F^n(\mathrm{SHW}{:}s,k_1,l_1)$. The degeneracy index $n=0,1,\ldots,\eta-1$ is necessary for couplings with degeneracy $\eta>1$. The algorithm works as follows:

(i) Make the following assignments for $0\leqslant n<\eta$, $0\leqslant n'<\eta$; $F^n(\mathrm{SHW}{:}s_{\max}-2n',k_{1\,\min},l_{1\,\min})=\delta_{n,n'}$, where δ is the Kroneker delta.

(ii) Using these assignments, the recursion relations (32) and (34) are adequate to determine all ISFs (with k,l=SHW) for $s_{\max}\geqslant s\geqslant s_{\max}-2(\eta-1)$.

(iii) The ISFs (with k,l=SHW) for remaining values of s can be determined without further assignments, evaluating each set of values for fixed s before moving to lower s. To move to a lower s value, the recursion relation reduces to only three terms either at $k_1=k_{1\,\max}$, $l_1=l_{1\,\min}$; or at $k_1=k_{1\,\min}$, $l_1=l_{1\,\max}$. This allows determination of one ISF for the new s value, which then allows the evaluation of all others at this s value using the full four-term recursion relation. This stepdown procedure fails in a small subset of cases, whereupon one must take advantage of permutation symmetry (discussed below) to move to the lower value of s.

(iv) The $F^0(\mathrm{SHW}{:}s,k_1,k_2)$ values, once normalized, are proper isoscalar factors. A linear combination of the F^0s and the F^1s, made orthogonal to F^0 and normalized, become proper $F^1(\mathrm{SHW}{:}s,k_1,k_2)$ values. Likewise, using the Gram–Schmidt orthogonalization procedure, each set of F^n with higher n is constructed from those with lower ns.

(v) Remaining ISFs for values of $k,l\neq$SHW can be determined in a straightforward way using the remaining recursion relations, (35) and (36).

In this description, $s_{\max}$ is the maximum value of s for which a nonvanishing ISF occurs for a coupling of fixed p, q, p_1, q_1, p_2, q_2 values: $k_{1\,\min}$, $l_{1\,\min}$, $k_{1\,\max}$, $l_{1\,\max}$ are the minimum and maximum values of the k_1 and l_1 variables for a particular value of s.

VI. SYMMETRIES OF THE ISOSCALAR FACTOR

The symmetries of the SU2 Clebsch–Gordan coefficient under permutation of irreps (j_i,m_i) and under conjugation $(j,m\rightarrow j,-m)$, known as the Racah symmetries, are well known and frequently utilized to simplify tabulations of coefficients and recoupling calculations. For SU3 couplings of degeneracy one, a complete set of Racah symmetries can be demonstrated. The

algorithm described in Sec. V extends these symmetries to couplings of arbitrary degeneracy, in contrast to some other degeneracy resolution schemes. Once the symmetries of the SU3 WCG are known, one can use the symmetry relations for the SU2 Clebsch–Gordan coefficients to deduce symmetry properties of the SU3 isoscalar factors.

Derivation of the symmetry relations for the SU3 WCG is straightforward, albeit tedious. If one applies the V_+ operator [Eq. (22)] to both sides of the defining expression for the WCG [Eq. (3)], the result is a linear expression involving six WCGs of various indices and corresponding coefficients which sum to zero. Under each of the transformations

(1) $(p_1,q_1;k_1,l_1,m_1)\leftrightarrow(p_2,q_2;k_2,l_2,m_2)$, referred to as $(1\leftrightarrow 2)$;
(2) $(p_1,q_1;k_1,l_1,m_1)\rightarrow(q,p;p+q-l,p+q-k,p+q-m)$ and $(p,q;k,l,m)\rightarrow(q1,p1;p1+q1-l1,p1+q1-k1,p1+q1-m1)$, referred to as $(1\leftrightarrow\bar{3})$; and
(3) $(p,q;k,l,m)\rightarrow(q,p;p+q-l,p+q-k,p+q-m)$ and similarly for the states p_1,q_1 and p_2,q_2, referred to as *conjugation*,

the coefficients in the six term expression of WCGs transform among one another in pairs, easily exhibiting the fact that the transformed WCGs (within a sign which depends on the k,l,m indices) obey the same six term recursion relations as the original WCGs.

The symmetry transformations can also involve a sign change which depends upon the p and q variables. This is fully dependent upon another sign convention which must be chosen in order to fully specify the WCGs and ISFs. Convenient choices are

$$C^{\,j_1\quad j_2\quad j}_{m_1=j_1\quad m_2=-j_2\quad >0},$$

the familiar Condon and Shortley phase convention,[19] and

$$F^n(\mathrm{SHW{:}SHW}_1;k_{2\,\max},l_{2\,\min})>0,$$

with the s value of the F chosen to be positive given as $s_{\max}-n$. To derive the p,q dependence of the phase under one of the symmetry transformations, begin with a SU3 WCG which is positive under this convention; apply the transformation; and determine the sign of the transformed WCG relative to that which is positive by convention among the transformed coefficients, using the recursion relations derived earlier. This sign, which will depend upon the six p,q values only, becomes part of the symmetry relation.

The absolute magnitude of the ratio of a WCG to its permuted version results from the normalization condition

$$\sum_{\kappa_1,\kappa_2}\left(C^{[\mathscr{P}_1]\quad [\mathscr{P}_2]\quad [\mathscr{P}]}_{[\kappa_1]\quad [\kappa_2]\quad [\kappa]}\right)^2=1. \tag{38}$$

It is straightforward to show that two of the transformations—$(1\leftrightarrow 2)$ and conjugation—produce no change in normalization and thus require no constant term; and the third—$(1\leftrightarrow\bar{3})$—requires a constant equal to the square root of the ratio of the dimension of the irreps $\mathscr{P}_1$ and $\mathscr{P}$.

When one considers couplings which have degeneracy greater than one, each set of distinct WCG's (labeled by the index n) has a unique element chosen as positive by convention. As a result, there is an additional phase contribution of $(-1)^n$ in each of the transformations considered here.

The resulting symmetry relations are as follows:

$$C\begin{matrix}[\mathscr{P}_1] & \overset{n}{[\mathscr{P}_2]} & [\mathscr{P}] \\ [\kappa_1] & [\kappa_2] & [\kappa]\end{matrix}=(-1)^{\gamma+\sigma+\max(\gamma,\sigma)+n}C\begin{matrix}[\mathscr{P}_2] & \overset{n}{[\mathscr{P}_1]} & [\mathscr{P}] \\ [\kappa_2] & [\kappa_1] & [\kappa]\end{matrix} \tag{39}$$

for the $(1\leftrightarrow 2)$ transformation;

$$C\begin{matrix}[\mathscr{P}_1] & \overset{n}{[\mathscr{P}_2]} & [\mathscr{P}] \\ [\kappa_1] & [\kappa_2] & [\kappa]\end{matrix}=(-1)^{m_2+n}\sqrt{\frac{(p+1)(q+1)(p+q+2)}{(p_1+1)(q_1+1)(p_1+q_1+2)}}C\begin{matrix}[\tilde{\mathscr{P}}] & \overset{n}{[\mathscr{P}_2]} & [\tilde{\mathscr{P}}_1] \\ [\tilde{\kappa}] & [\kappa_2] & [\tilde{\kappa}_1]\end{matrix} \tag{40}$$

for the $(1\leftrightarrow\bar{3})$ transformation (where $\tilde{\mathscr{P}}$ represents the ordered pair q,p and $\tilde{\kappa}$ represents $p+q-l$, $p+q-k$, $p+q-m$); and

$$C\begin{matrix}[\mathscr{P}_1] & \overset{n}{[\mathscr{P}_2]} & [\mathscr{P}] \\ [\kappa_1] & [\kappa_2] & [\kappa]\end{matrix}=(-1)^{\gamma+\sigma+\min(\gamma,\sigma)+n}C\begin{matrix}[\tilde{\mathscr{P}}_1] & \overset{n}{[\tilde{\mathscr{P}}_2]} & [\tilde{\mathscr{P}}] \\ [\tilde{\kappa}_1] & [\tilde{\kappa}_2] & [\tilde{\kappa}]\end{matrix} \tag{41}$$

for the conjugation transformation.

No additional information is given by repeating this procedure with the ladder operators $\hat{V}_-$ and $\hat{U}_+$ since they are related to the two operators already considered by Hermitian conjunction: similar treatment using $\hat{T}_+$ and $\hat{T}_-$ generate the symmetry relations for the SU2 Clebsch–Gordan coefficients.

Corresponding symmetry relations for the isoscalar factors follow from the above combined with the symmetry relations for the SU2 Clebsch–Gordan coefficients in the Condon and Shortley phase conventions. They are

$$F^n(\mathscr{P},\kappa:\mathscr{P}_1,\kappa_1;\mathscr{P}_2,\kappa_2)=(-1)^{\gamma+\sigma+\max(\gamma,\sigma)+n+l_1+l_2-l}F^n(\mathscr{P},\kappa:\mathscr{P}_2,\kappa_2;\mathscr{P}_1,\kappa_1) \tag{42}$$

for the $(1\leftrightarrow 2)$ transformation [here κ represents the pair (k,l)];

$$F^n(\mathscr{P},\kappa:\mathscr{P}_1,\kappa_1;\mathscr{P}_2,\kappa_2)=(-1)^{l_2+n}\sqrt{\frac{(p+1)(q+1)(p+q+2)(k_1-l_1+1)}{(p_1+1)(q_1+1)(p_1+q_1+2)(k-l+1)}}\times F^n(\tilde{\mathscr{P}}_1,\tilde{\kappa}_1:\tilde{\mathscr{P}},\tilde{\kappa};\mathscr{P}_2,\kappa_2) \tag{43}$$

for the $(1\leftrightarrow\bar{3})$ transformation; and

$$F^n(\mathscr{P},\kappa:\mathscr{P}_1,\kappa_1;\mathscr{P}_2,\kappa_2)=(-1)^{\gamma+\sigma+\min(\gamma,\sigma)+n+l_2+l_2-l}F^n(\tilde{\mathscr{P}},\tilde{\kappa}:\tilde{\mathscr{P}}_1,\tilde{\kappa}_1;\tilde{\mathscr{P}}_2,\tilde{\kappa}_2) \tag{44}$$

for the conjunction transformation.

The choice of a resolution procedure which yields symmetries such as these produces considerable simplifications in calculations of physical states, reduces the complexity of definitions of $6-j$ and $9-j$ type recoupling coefficients, and significantly shortens databases and printed tables of WCGs and ISFs.

ACKNOWLEDGMENTS

The author acknowledges with appreciation several useful discussions with L. C. Biedenharn regarding work described herein. M. Danos read an early version of this manuscript, suggesting several improvements. T. A. Kaeding's work in implementing the algorithm in explicit code has corrected several errors and helped refine the algorithm.

[S0022-2488(96)02508-X]

There are two main common errors in these papers.

1. The Greens function, used in Eq. (25) of the paper published in J. Math. Phys. **34**, 690–699 (1993) has to be multiplied by u/u' when applied to the inhomogenous term. The same expression is also used in the article, J. Math. Phys. **35**, 3043–3050 (1994). This modifies Eq. (28) of the first article as

$$g_1=\frac{1}{iu}\left(\frac{k_1x+k_2y}{x^2+y^2}+\frac{iR}{2}\log(x^2+y^2)\right)$$

and Eq. (26) of the second article as

$$f_1=\frac{2}{iu}\frac{k_y-k_2x}{x^2+y^2}+iR\tan^{-1}\frac{y}{x}.$$

The following expressions change accordingly.

The final expression which does not appear explicitly in these references reads

$$G_F^{(1)}=\frac{1}{32\pi}\frac{1}{(u-u')(v-v')}\left[\frac{\Theta(v)v-\Theta(v')v'}{(v-v')}\right]\left[\frac{\delta}{2}\log(x^2+y^2)-2\epsilon\tan^{-1}y/x\right]$$
$$+\left(\frac{\Theta(v)u'-\Theta(v')u}{(u-u')}\right)[\delta\log(x^2+y^2)-4\epsilon\tan^{-1}y/x]$$
$$+(\Theta(v)+\Theta(v'))\left[\frac{\delta}{4}\log(x^2+y^2)-2\epsilon\tan^{-1}y/x\right].$$

Here the terms proportional to δ give the result in the first paper and those proportional to ϵ give the result in the second paper. We could not find the finite part of these expressions as u goes to u' and v goes to v'.

2. The symmetrization of the final expression in the above mentioned articles is not correct. As seen in this expression upon proper symmetrization the Hadamard form for the Greens function is obtained, contrary to the claims made in these two articles.

Canonical commutation relations, the Weierstrass Zeta function, and infinite dimensional Hilbert space representations of the quantum group $U_q(\mathfrak{sl}_2)$

Asao Arai[a)]
Department of Mathematics, Hokkaido University, Sapporo 060, Japan

(Received 13 November 1995; accepted for publication 25 April 1996)

A two-dimensional quantum system of a charged particle interacting with a vector potential determined by the Weierstrass Zeta function is considered. The position and the physical momentum operators give a representation of the canonical commutation relations with two degrees of freedom. If the charge of the particle is not an integer (the case corresponding to the *Aharonov–Bohm effect*), then the representation is inequivalent to the Schrödinger representation. It is shown that the inequivalent representation induces infinite-dimensional Hilbert space representations of the quantum group $U_q(\mathfrak{sl}_2)$. Some properties of these representations of $U_q(\mathfrak{sl}_2)$ are investigated. © *1996 American Institute of Physics.*

I. INTRODUCTION

In a previous paper,[1] we considered a quantum system of a charged particle moving in the Euclidean plane $\mathbf{R}^2$ under the influence of a perpendicular magnetic field, which may be strongly singular at some fixed points $\mathbf{a}_1,...,\mathbf{a}_N$ in $\mathbf{R}^2$. If the magnetic field is concentrated on the discrete set $\{\mathbf{a}_n\}_{n=1}^N$ in the sense of distribution, then the position and the physical momentum operators give a representation of the canonical commutation relations (CCRs) (Heisenberg relations) with two degrees of freedom.

Here we recall some technical terms in the representation theory of CCR. A set $\{\mathscr{H},\mathscr{D},\{Q_j,P_j\}_{j=1}^d\}$ consisting of a Hilbert space $\mathscr{H}$, a dense subspace $\mathscr{D}$ of $\mathscr{H}$, and self-adjoint operators Q_j, P_j, $(j=1,\ldots,d)$ is called a representation of the CCR with d degrees of freedom if $\mathscr{D}\subset\cap_{j,k=1}^d[D(Q_jQ_k)\cap D(Q_jP_k)\cap D(P_kQ_j)\cap D(P_jP_k)]$ [$D(T)$ denotes the domain of operator T] and the CCR,

$$[Q_j,Q_k]=0,\quad [P_j,P_k]=0,\quad [Q_j,P_k]=i\delta_{jk},\quad j,k=1,\ldots,d,$$

hold on $\mathscr{D}$, where $[S,T]:=ST-TS$. Following Putnam,[2] we say that a set $\{Q_j,P_j\}_{j=1}^d$ of self-adjoint operators on a Hilbert space is a *Schrödinger d system* if it is unitarily equivalent to a direct sum of the Schrödinger representation of the CCR with d degrees of freedom. A representation $\{\mathscr{H},\mathscr{D},\{Q_j,P_j\}_{j=1}^d\}$ of CCR is called *equivalent* (resp., *inequivalent*) if $\{Q_j,P_j\}_{j=1}^d$ is (resp., not) a Schrödinger d system.

In Ref. 1 the following facts were shown: (i) the representation of CCR mentioned above is equivalent if and only if the magnetic flux is locally quantized (i.e., the magnetic flux at each point $\mathbf{a}_n$ $(n=1,\ldots,N)$ is an integer multiple of $2\pi/\alpha$, where α is the charge of the particle); (ii) the inequivalent representation appearing in the case where the magnetic flux is not locally quantized may be regarded as a mathematical form of the *Aharonov–Bohm effect*.[3] A geometric construction of a representation of CCR that is unitarily equivalent to the one given in Ref. 1 was considered by Kurose and Nakazato,[4] and more detailed properties of the representation were discussed.

[a)]Electronic mail: irai@math.hokudai.ac.jp

To investigate differences between the equivalent and the inequivalent representations of CCR in Ref. 1, an analysis has been made on Dirac–Weyl operators defined in terms of the physical momentum operator.[5] Moreover, the framework and results in Ref. 1 were extended to the case of a non-Abelian gauge theory.[6,7]

Recently Wiegmann and Zabrodin[8] considered a quantum system of a particle on a two-dimensional square lattice in a magnetic field and showed that magnetic translations on the lattice are related to finite-dimensional representations of the quantum group $U_q(\mathfrak{sl}_2)$. Inspired by their work, we investigate in this paper if there is any connection between the quantum system considered in Ref. 1 and representations of $U_q(\mathfrak{sl}_2)$. We shall show that, for a vector potential determined by the Weierstrass Zeta function, special elements of the unitary groups generated by the components of the physical momentum operator induce representations of $U_q(\mathfrak{sl}_2)$ on the Hilbert space $L^2(\mathbf{R}^2)$. This establishes a connection of a classical special function to $U_q(\mathfrak{sl}_2)$. A particular feature of the representations of $U_q(\mathfrak{sl}_2)$ given in this paper is that they have no finite-dimensional irreducible components.

The present paper is organized as follows. In Sec. II we consider a quantum system of a charged particle in $\mathbf{R}^2$ under the influence of a perpendicular magnetic field that may be singular at points in an *infinite lattice* [see (2.1)]. This is an extension of the framework of Ref. 1 to the case where the number of possible singular points of the magnetic field is infinite. Fundamental results in Ref. 1 continue to hold in the present case too with no significant modifications. As in the case of Ref. 1, the position operator and the physical momentum operator $\mathbf{P}=(P_1,P_2)$ of the particle give a representation of the CCR with two degrees of freedom if the magnetic field is concentrated on the infinite lattice. Spectral properties of the unitary operators generated by P_1 and P_2 are analyzed. Also, we show that, under some conditions for the vector potential of the magnetic field, P_1 and P_2 have permutation-reflection symmetries.

In Secs. III–V, we consider the special case where the vector potential $A=A_1\,dx+A_2\,dy$ (a 1-form) of the magnetic field is given by the Weierstrass Zeta function ζ in such a way that $\zeta=A_2+iA_1$ [see (3.2)–(3.4)]. We first show in Sec. III that, if the charge of the particle is not an integer, then special elements of the unitary groups generated by P_1 and P_2 give representations of the quantum plane. Unitary equivalences of these representations are discussed. As is shown in Ref. 8, a representation of the quantum plane with some additional properties induces representations of $U_q(\mathfrak{sl}_2)$. Applying this idea, we construct in Secs. IV and V representations of $U_q(\mathfrak{sl}_2)$ on $L^2(\mathbf{R}^2)$ and investigate some properties of them.

II. A CHARGED PARTICLE IN A MAGNETIC FIELD WITH POSSIBLE SINGULARITIES ON AN INFINITE LATTICE

A. Representation of CCR

We consider a quantum system of a charged particle with charge $\alpha\in\mathbf{R}\backslash\{0\}$ moving in the plane $\mathbf{R}^2=\{\mathbf{r}=(x,y)|x,y\in\mathbf{R}\}$ under the influence of a perpendicular magnetic field B that may be singular at points in the infinite lattice,

$$\mathbf{Z}^2_{\omega_1,\omega_2}:=\{\mathbf{\Omega}_{m,n}=(\omega_1 m,\omega_2 n)|m,n\in\mathbf{Z}\},\tag{2.1}$$

where ω_j, $j=1,2$, are positive constants and $\mathbf{Z}$ is the set of integers. A vector potential of the magnetic field B is given by a *continuously differentiable* real 1-form $A=A_1\,dx+A_2\,dy$ on the nonsimply connected domain

$$\mathbf{M}=\mathbf{R}^2\backslash\mathbf{Z}^2_{\omega_1,\omega_2},\tag{2.2}$$

such that

$$B=D_xA_2-D_yA_1,\tag{2.3}$$

in the distribution sense, where D_x and D_y are the generalized partial differential operators in the variables x and y, respectively. We say that A is *flat on* $\mathbf{M}$ if $B=0$ on $\mathbf{M}$, i.e., B is concentrated on $\mathbf{Z}^2_{\omega_1,\omega_2}$ (in the sense of distribution).

Throughout this paper we use a physical unit system such that $\hbar$ (the Planck constant divided by 2π)$=c$ (the light velocity)$=1$. Let (Q_1,Q_2) be the position operator of the particle, i.e., Q_1 and Q_2 are the maximal multiplication operators by x and y acting in the Hilbert space $L^2(\mathbf{M})\cong L^2(\mathbf{R}^2)$, respectively. The physical (kinetic) momentum operator $\mathbf{P}=(P_1,P_2)$ of the particle is defined by the operators

$$P_j=p_j-\alpha A_j, \quad j=1,2, \tag{2.4}$$

acting in $L^2(\mathbf{R}^2)$, where (p_1,p_2) is the momentum operator of the free particle:

$$p_1=-iD_x, \quad p_2=-iD_y. \tag{2.5}$$

We denote by $C_0^m(\mathbf{M})$ $(m=0,1,2,\ldots)$ the space of m times continuously differentiable functions on $\mathbf{M}$ with bounded support in $\mathbf{M}$. In the same way as in Ref. 1, we can prove the following fact.

Lemma 2.1:

(i) *Each P_j is essentially self-adjoint on $C_0^1(\mathbf{M})$. (We denote the closure of P_j by the same symbol.)*

(ii) *Suppose that A is flat on $\mathbf{M}$. Then $\{L^2(\mathbf{R}^2), C_0^2(\mathbf{M}), \{Q_j,P_j\}_{j=1}^2\}$ is a representation of the CCR with two degrees of freedom.*

The analysis of the representation $\{L^2(\mathbf{R}^2), C_0^2(\mathbf{M}), \{Q_j,P_j\}_{j=1}^2\}$ in Lemma 2.1 can be done in quite the same way as in the case where $\mathbf{Z}^2_{\omega_1,\omega_2}$ is replaced by a finite discrete set in $\mathbf{R}^2$ (see Refs. 1, 4, and 6). Hence, as for that, we describe only results needed later. Let

$$\mathbf{S}_1=\mathbf{R}\backslash\{m\omega_1\}_{m\in\mathbf{Z}}, \quad \mathbf{S}_2=\mathbf{R}\backslash\{n\omega_2\}_{n\in\mathbf{Z}}.$$

For $(x,y)\in\mathbf{R}\times\mathbf{S}_2$, we can define

$$U_1(x,y)=\exp\left(-i\alpha\int_0^x A_1(x',y)dx'\right). \tag{2.6}$$

Then U_1 defines a unique unitary operator as a multiplication operator on $L^2(\mathbf{R}^2)$. Similarly, the function

$$U_2(x,y)=\exp\left(-i\alpha\int_0^y A_2(x,y')dy'\right), \quad (x,y)\in\mathbf{S}_1\times\mathbf{R}, \tag{2.7}$$

defines a unique unitary operator as a multiplication operator on $L^2(\mathbf{R}^2)$. We then have *operator equalities*,

$$P_j=U_j^{-1}p_jU_j, \quad j=1,2. \tag{2.8}$$

It follows from these relations that, for all $t\in\mathbf{R}$, $\psi\in L^2(\mathbf{R})$, and for almost everywhere (a.e.) (x,y),

$$(e^{itP_1}\psi)(x,y)=\exp\left(-i\alpha\int_x^{x+t} A_1(x',y)dx'\right)\psi(x+t,y), \tag{2.9}$$

$$(e^{itP_2}\psi)(x,y)=\exp\left(-i\alpha\int_y^{y+t}A_2(x,y')dy'\right)\psi(x,y+t). \tag{2.10}$$

Let $C_\pm(x,y;s,t)$ $(x,y,s,t\in\mathbf{R})$ be hook-shaped paths from (x,y) to $(x+s,y+t)$ given by

$$C_-(x,y;s,t)=\{(x+\theta s,y)|0\leqslant\theta\leqslant 1\}\cup\{(x+s,y+\theta t)|0\leqslant\theta\leqslant 1\},$$

$$C_+(x,y;s,t)=\{(x,y+\theta t)|0\leqslant\theta\leqslant 1\}\cup\{(x+\theta s,y+t)|0\leqslant\theta\leqslant 1\},$$

and set

$$C(x,y;s,t)=C_+(x,y;s,t)^{-1}\circ C_-(x,y;s,t), \tag{2.11}$$

the rectangular path: $(x,y)\to(x+s,y)\to(x+s,y+t)\to(x,y+t)\to(x,y)$. For $s,t\in\mathbf{R}$, we set

$$\mathbf{S}_1^{(s)}=\mathbf{R}\backslash\{\omega_1 m,\omega_1 m-s|m\in\mathbf{Z}\},\quad \mathbf{S}_2^{(t)}=\mathbf{R}\backslash\{\omega_2 n,\omega_2 n-t|n\in\mathbf{Z}\}, \tag{2.12}$$

and define

$$\mathbf{M}_{s,t}=\mathbf{S}_1^{(s)}\times\mathbf{S}_2^{(t)},\quad s,t\in\mathbf{R}. \tag{2.13}$$

For each $s,t\in\mathbf{R}$, we can define a function $\Phi_{s,t}^A$ on $\mathbf{M}_{s,t}$ by

$$\Phi_{s,t}^A(x,y)=\int_{C(x,y;s,t)}A,\quad (x,y)\in\mathbf{M}_{s,t}, \tag{2.14}$$

which physically means the magnetic flux passing through the interior domain of the closed curve $C(x,y;s,t)$. Since $\mathbf{R}^2\backslash\mathbf{M}_{s,t}$ is a null set with respect to the two-dimensional Lebesgue measure, one can regard $\Phi_{s,t}^A$ as a real-valued function on $\mathbf{R}^2$, which is a.e. finite. Hence $\Phi_{s,t}^A$ defines a unique self-adjoint multiplication operator on $L^2(\mathbf{R}^2)$. We denote this operator by the same symbol. The following theorem gives commutation relations for the one parameter unitary groups generated by Q_j and P_j, $j=1,2$.

Theorem 2.2. (cf. Theorem 2.1 in Ref. 1): *For all* $s,t\in\mathbf{R}$,

$$e^{isQ_j}e^{itP_k}=e^{-ist\delta_{jk}}e^{itP_k}e^{isQ_j}, \tag{2.15}$$

$$e^{isP_1}e^{itP_2}=e^{-i\alpha\Phi_{s,t}^A}e^{itP_2}e^{isP_1}. \tag{2.16}$$

Following Ref. 1, we say that *the magnetic flux is locally quantized if, for all* $s,t\in\mathbf{R}$, $\Phi_{s,t}^A$ *is a* $2\pi\mathbf{Z}/\alpha$*-valued function on* $\mathbf{M}_{s,t}$.

Theorem 2.2 implies the following characterization of the representation $\{Q_j,P_j\}_{j=1}^2$ of CCR in the case where A is flat [Lemma 2.1(ii)].

Theorem 2.3: *Suppose that* A *is flat on* $\mathbf{M}$. *Then the representation* $\{Q_j,P_j\}_{j=1}^2$ *of CCR is equivalent if and only if the magnetic flux is locally quantized*.

Remark: (i) In the case where the magnetic flux is not locally quantized, formula (2.16) may be regarded as a mathematical form of the *Aharonov–Bohm effect*.[9] Thus the inequivalent representation of $\{Q_j,P_j\}_{j=1}^2$ corresponds to the Aharonov–Bohm effect.

(ii) In operator theory, two self-adjoint operators, S and T, on a Hilbert space are said to be *strongly commuting* if their spectral measures commute. It is well known that S and T are strongly commuting if and only if $e^{iaS}e^{ibT}=e^{ibT}e^{iaS}$ for all $a,b\in\mathbf{R}$ (Theorem VIII.13 in Ref. 10). It follows from this fact and (2.16) that P_1 and P_2 *are strongly commuting if and only if the magnetic flux is locally quantized*.

Let $\omega_0>0$ be a number such that, for all $(m,n),(m',n')\in\mathbf{Z}^2$ with $(m,n)\neq(m',n')$, $\{\mathbf{r}||\mathbf{r}-\mathbf{\Omega}_{m,n}|<\omega_0\}\cap\{\mathbf{r}||\mathbf{r}-\mathbf{\Omega}_{m',n'}|<\omega_0\}=\emptyset$. The following fact is easily proven.

Lemma 2.4: Suppose that A is flat. Let $0<\delta<\omega_0$. Then

$$\gamma_{m,n}(A):=\int_{|\mathbf{r}-\mathbf{\Omega}_{m,n}|=\delta}A \tag{2.17}$$

is independent of δ, where the orientation of the integral on the right-hand side (rhs) is taken to be anticlockwise. Moreover, for all $s,t\in\mathbf{R}$,

$$\Phi^A_{s,t}(x,y)=\epsilon(s)\epsilon(t)\sum_{\mathbf{\Omega}_{m,n}\in D(x,y;s,t)}\gamma_{m,n}(A),\quad (x,y)\in\mathbf{M}_{s,t},$$

where $D(x,y;s,t)$ is the interior domain of $C(x,y;s,t)$ and $\epsilon(t)$ is the sign function: $\epsilon(t)=1$ for $t\geqslant 0$; $\epsilon(t)=-1$ for $t<0$.

Theorem 2.3 and Lemma 2.4 imply the following fact.

Theorem 2.5: *Suppose that A is flat. Then the representation $\{Q_j,P_j\}_{j=1}^2$ of CCR is equivalent if and only if $\gamma_{m,n}(A)\in 2\pi\mathbf{Z}/\alpha$ for all $m,n\in\mathbf{Z}$.*

B. Spectral properties

For later use, we investigate spectral properties of some unitary operators. For a densely defined closed linear operator T on a Hilbert space, we denote by $\sigma(T)$ [resp., $\sigma_p(T)$] the spectrum (resp., point spectrum) of T. We set

$$\mathbb{T}=\{z\in\mathbf{C}||z|=1\}. \tag{2.18}$$

Lemma 2.6:

(i) *$\sigma(P_j)=\mathbf{R}$, $\sigma_p(P_j)=\emptyset$, $j=1,2$.*

(ii) *For all $t\in\mathbf{R}\backslash\{0\}$ and $j=1,2$, $\sigma(e^{itP_j})=\mathbb{T}$, $\sigma_p(e^{itP_j})=\emptyset$.*

Proof: (i) By (2.8), we have $\sigma(P_j)=\sigma(p_j)=\mathbf{R}$, $\sigma_p(P_j)=\sigma_p(p_j)=\emptyset$. (ii) This follows from part (i) and the spectral mapping theorem. ■

Lemma 2.7: For all $s,t\in\mathbf{R}\backslash\{0\}$,

$$\sigma_p(e^{isP_1}e^{itP_2})=\emptyset,\quad \sigma_p(e^{itP_2}e^{isP_1})=\emptyset. \tag{2.19}$$

Proof: It follows from (2.9) and (2.10) that, for all $s,t\in\mathbf{R}$,

$$e^{isP_1}e^{itP_2}=\exp\left(-i\alpha\int_{C_-(x,y;s,t)}A\right)e^{isp_1}e^{itp_2}, \tag{2.20}$$

$$e^{itP_2}e^{isP_1}=\exp\left(-i\alpha\int_{C_+(x,y;s,t)}A\right)e^{itp_2}e^{isp_1}. \tag{2.21}$$

Since $e^{isP_1}e^{itP_2}$ is unitary, we have $\sigma_p(e^{isP_1}e^{itP_2})\subset\mathbb{T}$. Suppose that there exists a vector $\psi\in L^2(\mathbf{R}^2)$ and a constant $\lambda\in\mathbb{T}$ such that $e^{isP_1}e^{itP_2}\psi=\lambda\psi$. Then, by (2.20), we have $\exp(e^{-i\alpha}\int_{C_-(x,y;s,t)}A)\psi(x+s,y+t)=\lambda\psi(x,y)$ a.e. (x,y). Hence $|\psi(x,y)|=|\psi(x+s,y+t)|$ a.e. (x,y), which, together with the fact $\psi\in L^2(\mathbf{R}^2)$, implies $\psi=0$. Thus the first formula of (2.19) follows. Similarly, using (2.21), we can prove the second one of (2.19). ■

Proposition 2.8: Consider the case where the magnetic flux is locally quantized. Then, for all $t,s\in\mathbf{R}\backslash\{0\}$,

$$\sigma(e^{isP_1}e^{itP_2})=\sigma(e^{itP_1}e^{isP_2})=\mathbb{T}.$$

Proof: Under the present assumption, P_1 and P_2 strongly commute [see Remark (ii) after Theorem 2.3]. Hence, by the two variable functional calculus, we see that sP_1+tP_2 is essentially self-adjoint and $e^{isP_1}e^{itP_2} = e^{itP_2}e^{isP_1} = e^{i(\overline{sP_1+tP_2})}$, where $\overline{sP_1+tP_2}$ is the closure of sP_1+tP_2. By the two variable functional calculus and Lemma 2.6(i), we have $\sigma(\overline{sP_1+tP_2}) = \mathbf{R}$. Thus, by the spectral mapping theorem, we obtain the desired result. ■

Remark: We have been unable to identify $\sigma(e^{isP_1}e^{itP_2})$ and $\sigma(e^{itP_2}e^{isP_1})$ in the case where the magnetic field is not locally quantized. It would be interesting to see if there appears any difference from the case where the magnetic field is locally quantized. In the case of Dirac–Weyl operators defined in terms of P_1 and P_2, such differences exist; see Ref. 5. We leave this problem as an open problem.

C. Permutation-reflection symmetry of the physical momentum operator

Let $R_j : L^2(\mathbf{R}^2) \to L^2(\mathbf{R}^2)$, $j=1,2$, be the unitary operators defined by

$$(R_1\psi)(x,y) = \psi(-y,x), \quad (R_2\psi)(x,y) = \psi(y,-x), \quad \psi \in L^2(\mathbf{R}^2). \tag{2.22}$$

Then it is easy to see that

$$R_1R_2 = R_2R_1 = I, \tag{2.23}$$

$$R_1p_1R_1^{-1} = -p_2, \quad R_1p_2R_1^{-1} = p_1, \tag{2.24}$$

$$R_2p_1R_2^{-1} = p_2, \quad R_2p_2R_2^{-1} = -p_1. \tag{2.25}$$

As usual, we denote by $z=x+iy$ the point in the complex plane $\mathbf{C}$ corresponding to $\mathbf{r}=(x,y)\in\mathbf{R}^2$. We set

$$\widetilde{A}(z) = A_2(x,y) + iA_1(x,y). \tag{2.26}$$

Proposition 2.9:
(i) *Suppose that*

$$\widetilde{A}(iz) = -i\widetilde{A}(z). \tag{2.27}$$

Then

$$R_1P_1R_1^{-1} = -P_2, \quad R_1P_2R_1^{-1} = P_1. \tag{2.28}$$

(ii) *Suppose that*

$$\widetilde{A}(iz) = i\widetilde{A}(-z). \tag{2.29}$$

Then

$$R_2P_1R_2^{-1} = P_2, \quad R_2P_2R_2^{-1} = -P_1. \tag{2.30}$$

Proof: (i) Condition (2.27) is equivalent to that

$$A_2(-y,x) = A_1(x,y), \quad A_1(-y,x) = -A_2(x,y).$$

Hence, for all $\psi \in C_0^1(\mathbf{M})$,

$$R_1P_1R_1^{-1}\psi = -P_2\psi, \quad R_1P_2R_1^{-1}\psi = P_1\psi. \tag{2.31}$$

Since R_1 leaves $C_0^1(\mathbf{M})$ invariant bijectively and P_j, $j=1,2$, are essentially self-adjoint on $C_0^1(\mathbf{M})$ [Lemma 2.1(i)], the vector equations in (2.31) extend to operator equalities (2.28).

(ii) Similar to part (i). ■

In Sec. III, we shall consider the case of a vector potential satisfying (2.27) and (2.29).

D. Small coupling limit

Finally we consider the small coupling limit $\alpha\to 0$ of P_j.

Lemma 2.10: For all $t\in\mathbf{R}$ and $j=1,2$,

$$\text{s-lim}_{\alpha\to 0}\ e^{itP_j}=e^{itp_j}, \tag{2.32}$$

where s-lim *denotes strong limit.*

Proof: For all $\psi\in C_0^1(\mathbf{M})$, we have $P_j\psi\to p_j\psi$ ($\alpha\to 0$). Note that $C_0^1(\mathbf{M})$ is a common core of P_j and p_j. Hence, by general convergence theorems [Theorem VIII.25 (a) and Theorem VIII.21 in Ref. 10], we obtain (2.32). ■

III. A VECTOR POTENTIAL GIVEN BY THE WEIERSTRASS ZETA FUNCTION AND REPRESENTATIONS OF THE QUANTUM PLANE

We now specialize the vector potential A. We set

$$\Omega_{m,n}=m\omega_1+in\omega_2,\quad m,n\in\mathbf{Z}. \tag{3.1}$$

Let $\zeta(z)$ ($z\in\mathbf{C}$) be the Weierstrass Zeta function with poles at $z=\Omega_{m,n}, m,n\in\mathbf{Z}$:

$$\zeta(z)=\frac{1}{z}+\sum_{(m,n)\in\mathbf{Z}^2\setminus\{(0,0)\}}\left(\frac{1}{z-\Omega_{m,n}}+\frac{1}{\Omega_{m,n}}+\frac{z}{\Omega_{m,n}^2}\right). \tag{3.2}$$

In what follows, we assume that the vector potential A is given by $A=A_1\,dx+A_2\,dy$ with

$$A_1(\mathbf{r})=\text{Im}\ \zeta(z),\quad A_2(\mathbf{r})=\text{Re}\ \zeta(z), \tag{3.3}$$

so that

$$\zeta(z)=A_2(\mathbf{r})+iA_1(\mathbf{r}). \tag{3.4}$$

Then, by the Cauchy–Riemann equation, A is flat on $\mathbf{M}$.

In the present case, the constant $\gamma_{m,n}(A)$ defined by (2.17) is computed as

$$\gamma_{m,n}(A)=2\pi, \tag{3.5}$$

independently of $(m,n)\in\mathbf{Z}^2$. Hence *the magnetic flux is locally quantized if and only if α is an integer*. Thus the local quantization of the magnetic flux is equivalent to the ''charge quantization.'' *The representation $\{Q_j,P_j\}_{j=1}^2$ of CCR in the present case is an inequivalent representation if and only if α is not an integer*.

Let

$$q_\alpha=e^{2\pi i\alpha}. \tag{3.6}$$

Lemma 3.1: For all $m,n\in\mathbf{Z}$,

$$e^{in\omega_2P_2}e^{im\omega_1P_1}=q_\alpha^{nm}e^{im\omega_1P_1}e^{in\omega_2P_2}. \tag{3.7}$$

Proof: For all $(x,y) \in \mathbf{M}_{\omega_1,\omega_2}$, $D(x,y;\omega_1,\omega_2)$ contains only one point in the lattice $\mathbf{Z}^2_{\omega_1,\omega_2}$. Hence, by Lemma 2.4 and (3.5), $\Phi^A_{\omega_1,\omega_2} = 2\pi$, a.e., which, together with (2.16), implies (3.7) with $m=n=1$. Using this relation repeatedly, we obtain (3.7) with $m,n \in \mathbf{N}\cup\{0\}$, whose adjoint gives (3.7) with $m,n<0$. Noting that e^{itP_j} $(t\in\mathbf{R})$ is invertible with $(e^{itP_j})^{-1} = e^{-itP_j}$, we obtain (3.7) with $m\geqslant 0, n<0$ or $m\leqslant 0, n>0$. ∎

Relation (3.7) naturally leads us to the *quantum plane*,[11] which is defined to be the algebra generated by two elements X,Y subject to the relation

$$qXY = YX,$$

with q a parameter.[12] We denote the quantum plane by $\mathbf{C}^2_q$.

For an algebra $\mathfrak{U}$, a set (π,V) of a complex vector space V and an algebraic homomorphism $\pi:\mathfrak{u}\to\mathrm{End}(V)$ is called a representation of $\mathfrak{U}$.

We denote by $\mathfrak{B}(L^2(\mathbf{R}^2))$ the $*$ algebra of bounded linear operators on $L^2(\mathbf{R}^2)$. The following theorem immediately follows from Lemma 3.1.

Theorem 3.2: *The following correspondence* $\pi_\alpha:\{X,Y\}\to\mathfrak{B}(L^2(\mathbf{R}^2))$ *defines a representation of* $\mathbf{C}^2_{q_\alpha}$ *on* $L^2(\mathbf{R}^2)$*:*

$$\pi_\alpha(X) = e^{i\omega_1 P_1}, \quad \pi_\alpha(Y) = e^{i\omega_2 P_2}. \tag{3.8}$$

It should be noted that, in the representation $(\pi_\alpha, L^2(\mathbf{R}^2))$, $\pi_\alpha(X)$ and $\pi_\alpha(Y)$ are unitary operators. Also, $q_\alpha \neq 1$ if and only if $\alpha \notin \mathbf{Z}$.

We have

$$\lim_{\alpha\to 0} q_\alpha = 1, \tag{3.9}$$

which means that the small coupling limit $\alpha\to 0$ corresponds to the ''classical limit'' of deformation by the parameter q_α.

The representation $(\pi_\alpha, L^2(\mathbf{R}^2))$ has a nontrivial classical limit.

Proposition 3.3:

$$\text{s-}\lim_{\alpha\to 0} \pi_\alpha(X) = e^{i\omega_1 p_1} \neq I, \quad \text{s-}\lim_{\alpha\to 0} \pi_\alpha(Y) = e^{i\omega_2 p_2} \neq I,$$

where I denotes the identity operator on $L^2(\mathbf{R}^2)$*.*

Proof: This follows from Lemma 2.10. ∎

For a subalgebra $\mathfrak{M}$ of $\mathfrak{B}(L^2(\mathbf{R}^2))$, we denote by $\mathfrak{M}'$ the commutant of $\mathfrak{M}$:

$$\mathfrak{M}' = \{T \in \mathfrak{B}(L^2(\mathbf{R}^2)) \mid TS = ST, S \in \mathfrak{M}\}. \tag{3.10}$$

Let $\mathfrak{E}_\alpha$ be the algebra generated by $\{e^{i\omega_1 P_1}, e^{i\omega_2 P_2}\}$:

$$\mathfrak{E}_\alpha = \pi_\alpha(\mathbf{C}^2_q\alpha).$$

Lemma 3.4: $e^{\pm 2\pi i Q_1/\omega_1}$, $e^{\pm 2\pi i Q_2/\omega_2} \in \mathfrak{E}'_\alpha$.

Proof: This follows from (2.15). ∎

By Lemma 3.1, we have

$$q_\alpha e^{-i\omega_2 P_2} e^{i\omega_1 P_1} = e^{i\omega_1 P_1} e^{-i\omega_2 P_2}, \quad q_\alpha e^{i\omega_2 P_2} e^{-i\omega_1 P_1} = e^{-i\omega_1 P_1} e^{i\omega_2 P_2}, \tag{3.11}$$

$$q_\alpha e^{-i\omega_1 P_1} e^{-i\omega_2 P_2} = e^{-i\omega_2 P_2} e^{-i\omega_1 P_1}. \tag{3.12}$$

Hence, each of $\{e^{-i\omega_2 P_2}, e^{i\omega_1 P_1}\}$, $\{e^{i\omega_2 P_2}, e^{-i\omega_1 P_1}\}$, and $\{e^{-\omega_1 P_1}, e^{-i\omega_2 P_2}\}$ gives a representation of $\mathbf{C}^2_{q_\alpha}$. We denote these representations by $(\pi_\alpha^{(j)}, L^2(\mathbf{R}^2))$, $j=1,2,3$, respectively.

Proposition 3.5: Suppose that

$$\omega_1 = \omega_2 . \tag{3.13}$$

Then, each representation $(\pi_\alpha^{(j)}, L^2(\mathbf{R}^2))$ *is unitarily equivalent to* $(\pi_\alpha, L^2(\mathbf{R}^2))$.

Proof: It is easy to check that, if (3.13) is satisfied, then (2.27) and (2.29) hold with $\widetilde{A}(z)$ replaced by $\zeta(z)$. Hence we have (2.28) and (2.30), which imply that, for all $t \in \mathbf{R}$,

$$R_1 e^{itP_1} R_1^{-1} = e^{-itP_2}, \quad R_1 e^{itP_2} R_1^{-1} = e^{itP_1}, \quad R_2 e^{itP_1} R_2^{-1} = e^{itP_2}, \quad R_2 e^{itP_2} R_2^{-1} = e^{itP_1}. \tag{3.14}$$

These relations give a unitary equivalence between $(\pi_\alpha, L^2(\mathbf{R}^2))$ and $(\pi_\alpha^{(j)}, L^2(\mathbf{R}^2))$ $(j=1,2)$. Moreover, (3.14) implies that

$$R_1^2 e^{itP_1} R_1^{-2} = e^{-itP_1}, \quad R_2^2 e^{itP_2} R_2^{-2} = e^{-itP_2}.$$

It is easy to see that $R_1^2 = R_2^2$. Thus, the unitary equivalence between $(\pi_\alpha, L^2(\mathbf{R}^2))$ and $(\pi_\alpha^{(3)}, L^2(\mathbf{R}^2))$ follows. ■

Remark: (i) In the case $\omega_1 \neq \omega_2$, we have been unable to clarify whether $(\pi_\alpha, L^2(\mathbf{R}^2))$, $(\pi_\alpha^{(j)}, L^2(\mathbf{R}^2))$, $j=1,2,3$, are unitarily equivalent to each other or not.

(ii) Relation (2.15) implies that

$$q_\alpha e^{2\pi i \alpha Q_j/\omega_j} e^{i\omega_j P_j} = e^{i\omega_j P_j} e^{2\pi i \alpha Q_j/\omega_j}, \quad j=1,2.$$

Hence, for each $j=1,2$ $\{e^{2\pi i \alpha Q_j/\omega_j}, e^{i\omega_j P_j}\}$ gives a representation of $\mathbf{C}^2_{q_\alpha}$. It is a problem to clarify whether these representations and the representations $(\pi_\alpha, L^2(\mathbf{R}^2))$, $(\pi_\alpha^{(j)}, L^2(\mathbf{R}^2))$, $j=1,2,3$, are unitarily equivalent to each other or not.

In this paper we concentrate our attention on the representation $(\pi_\alpha, L^2(\mathbf{R}^2))$. The methods developed in what follows apply also to the other representations of the quantum plane.

(iii) Consider the case where α is a rational number: $\alpha = p/r$ with $p \in \mathbf{Z}$ and $r \in \mathbf{Z}\backslash\{0\}$. Then $q_\alpha^r = 1$. It follows from (3.7) that, for all m, $n \in \mathbf{Z}$ with $mn = r$, $e^{im\omega_1 P_1}$ and $e^{in\omega_2 P_2}$ commute. But, if α is irrational, then $e^{im\omega_1 P_1}$ and $e^{in\omega_2 P_2}$ do not commute for all m, $n \in \mathbf{Z}\backslash\{0\}$.

IV. REPRESENTATION OF $U_q(\mathfrak{sl}_2)$ (I)

For a complex number $q \in \mathbf{C}\backslash\{0,1,-1\}$, the quantum group $U_q(\mathfrak{sl}_2)$ is defined to be the algebra generated by four elements E, F, K, K^{-1} subject to the following relations:[13]

$$KK^{-1} = K^{-1}K = 1,$$

$$KEK^{-1} = q^2 E, \quad KFK^{-1} = q^{-2} F,$$

$$[E,F] = \frac{K - K^{-1}}{q - q^{-1}}.$$

The Casimir element C of $U_q(\mathfrak{sl}_2)$ is defined by

$$C = \frac{qK - 2 + q^{-1}K^{-1}}{(q - q^{-1})^2} + FE. \tag{4.1}$$

Given a representation (π, V) of the quantum plane $\mathbf{C}^2_q$ such that $\pi(X)$ and $\pi(Y)$ are bijective, we can construct a representation of $U_q(\mathfrak{sl}_2)$.

Lemma 4.1 (cf. Ref. 8): *Let (π,V) be as above and $a,b,a',b' \in \mathbf{C}$ be constants satisfying*

$$abq = a'b'q^{-1} = -\frac{1}{(q-q^{-1})^2}. \tag{4.2}$$

Then the following correspondence Π:$\{E,F,K,K^{-1}\} \to \mathrm{End}(V)$ defines a representation of $U_q(\mathfrak{sl}_2)$:

$$\Pi(E) = \pi(X)(a\pi(X) + a'\pi(X)^{-1})\pi(Y)^{-1},$$

$$\Pi(F) = \pi(Y)(b\pi(X) + b'\pi(X)^{-1})\pi(X)^{-1},$$

$$\Pi(K) = \pi(X)^2, \quad \Pi(K^{-1}) = \pi(X)^{-2}.$$

In this representation, we have

$$\Pi(C) = a'b + ab' - \frac{2}{(q-q^{-1})^2}. \tag{4.3}$$

Proof: Direct computations. ∎

Remark: By (4.2), we can write $\Pi(C)$ as

$$\Pi(C) = (a' + aq)(b + b'q^{-1}).$$

In the rest of the paper, we assume that A_j, $j=1,2$, are given by (3.3) and

$$\alpha \notin \frac{\mathbf{Z}}{2}. \tag{4.4}$$

Hence $q_\alpha^2 \neq 1$.

Let a_α, a'_α, b_α, b'_α be constants satisfying

$$a_\alpha b_\alpha q_\alpha = a'_\alpha b'_\alpha q_\alpha^{-1} = -\frac{1}{(q_\alpha - q_\alpha^{-1})^2} = \frac{1}{4\sin^2 2\pi\alpha}. \tag{4.5}$$

By Lemma 4.1 and Theorem 3.2, we have the following theorem.

Theorem 4.2: *The following correspondence Π_α:$\{E,F,K,K^{-1}\} \to \mathfrak{B}(L^2(\mathbf{R}^2))$ defines a representation of $U_{q_\alpha}(\mathfrak{sl}_2)$ on $L^2(\mathbf{R}^2)$:*

$$\Pi_\alpha(E) = e^{i\omega_1 P_1}(a_\alpha e^{i\omega_1 P_1} + a'_\alpha e^{-i\omega_1 P_1})e^{-i\omega_2 P_2},$$

$$\Pi_\alpha(F) = e^{i\omega_2 P_2}(b_\alpha e^{i\omega_1 P_1} + b'_\alpha e^{-i\omega_1 P_1})e^{-i\omega_1 P_1},$$

$$\Pi_\alpha(K) = e^{2i\omega_1 P_1}, \quad \Pi_\alpha(K^{-1}) = e^{-2i\omega_1 P_1}.$$

We investigate basic properties of the representation $(\Pi_\alpha, L^2(\mathbf{R}^2))$.

Theorem 4.3: *The representation $(\Pi_\alpha, L^2(\mathbf{R}^2))$ has no weight vectors. In particular, there exists no nonzero finite-dimensional subspace W such that (Π_α, W) gives a representation of $U_{q_\alpha}(\mathfrak{sl}_2)$.*

Proof: A weight vector of weight $\lambda \in \mathbf{C}$ in the representation $(\Pi_\alpha, L^2(\mathbf{R}^2))$ is a nonzero vector ψ satisfying $\Pi_\alpha(K)\psi = q_\alpha^\lambda \psi$. Hence ψ is an eigenvector of $e^{2i\omega_1 P_1}$. But, by Lemma 2.6(ii), $e^{2i\omega_1 P_1}$ has no eigenvectors. The last assertion in Theorem 4.3 follows from the well-known fact that any nonzero finite-dimensional $U_q(\mathfrak{sl}_2)$-module contains a highest weight vector (Proposition VI.3.3 in Ref. 11). ∎

Let

$$\mathfrak{U}_\alpha = \Pi_\alpha(U_{q_\alpha}(\mathfrak{sl}_2)). \tag{4.6}$$

Theorem 4.4: *Suppose that* $a'_\alpha = \overline{b_\alpha}$, $b'_\alpha = \overline{a_\alpha}$ ($\overline{z}$ *denotes the complex conjugate of the complex number* z). *Then*

(i) $\mathfrak{U}_\alpha$ *is a* $*$ *subalgebra of* $\mathfrak{B}(L^2(\mathbf{R}^2))$.

(ii) *The representation* $(\Pi_\alpha, L^2(\mathbf{R}^2))$ *is completely reducible.*

Proof: (i) In the present assumption, we have

$$\Pi_\alpha(E)^* = \Pi_\alpha(F),$$

where T^* denotes the adjoint of operator T. It is obvious that $\Pi_\alpha(K)^* = \Pi_\alpha(K^{-1})$. Hence it follows that $\mathfrak{U}_\alpha$ is self-adjoint (i.e., $T \in \mathfrak{U}_\alpha \Rightarrow T^* \in \mathfrak{U}_\alpha$). Thus part (i) follows.

(ii) As in Lemma 3.4, we have

$$\{e^{\pm 2\pi i Q_j/\omega_j}\}_{j=1}^2 \subset \mathfrak{U}'_\alpha, \tag{4.7}$$

which implies that $\mathfrak{U}'_\alpha \neq \mathbf{C}I$. As proven in part (i), $\mathfrak{U}_\alpha$ is self-adjoint. Hence $\mathfrak{U}_\alpha$ is not irreducible (Proposition 2.3.8 in Ref. 14). Let W be any closed subspace of $L^2(\mathbf{R}^2)$, which is invariant under the action of $\mathfrak{U}_\alpha$. Since $\mathfrak{U}_\alpha$ is self-adjoint, it follows that $W^\perp$ [the orthogonal complement of W in $L^2(\mathbf{R}^2)$] is also invariant under the action of $\mathfrak{U}_\alpha$. Thus $(\Pi_\alpha, L^2(\mathbf{R}^2))$ is completely reducible. ■

For a subset $\mathfrak{M}$ of $\mathfrak{B}(L^2(\mathbf{R}^2))$, we denote by $\overline{\mathfrak{M}}$ the closure of $\mathfrak{M}$ with respect to the operator norm.

We denote by $\mathfrak{F}_\alpha$ the algebra generated by $e^{\pm 2i\omega_1 P_1}$, $e^{\pm i\omega_2 P_2}$, which is a $*$ subalgebra of $\mathfrak{B}(L^2(\mathbf{R}^2))$, so that $\overline{\mathfrak{F}_\alpha}$ is a C^* subalgebra.

Theorem 4.5: *Suppose that* $|a_\alpha| \neq |a'_\alpha|$, $|b_\alpha| \neq |b'_\alpha|$. *Then*

(i)

$$\overline{\mathfrak{F}_\alpha} = \overline{\mathfrak{U}_\alpha}. \tag{4.8}$$

(ii) $\overline{\mathfrak{U}_\alpha}$ *is completely reducible.*

Proof: (i) For simplicity, we set $a = a_\alpha$, $a' = a'_\alpha$, $b = b_\alpha$, $b' = b'_\alpha$. We have

$$\Pi_\alpha(E) = Se^{-i\omega_2 P_2}, \quad \Pi_\alpha(F) = e^{i\omega_2 P_2}T, \tag{4.9}$$

with

$$S = ae^{2i\omega_1 P_1} + a', \quad T = b + b'e^{-2i\omega_1 P_1}.$$

Hence it follows that $\mathfrak{U}_\alpha \subset \mathfrak{F}_\alpha$, implying

$$\overline{\mathfrak{U}_\alpha} \subset \overline{\mathfrak{F}_\alpha}. \tag{4.10}$$

To prove the converse inclusion relation, we express $e^{\pm i\omega_2 P_2}$ in terms of $\Pi_\alpha(E)$, $\Pi_\alpha(F)$, $\Pi_\alpha(K)$, and $\Pi_\alpha(K^{-1})$. We first consider the case $|a|/|a'| < 1$. We can write

$$S = a\Pi_\alpha(K) + a' = a'\left(1 + \frac{a}{a'}\,\Pi_\alpha(K)\right).$$

We have $\|a\Pi_\alpha(K)/a'\| = |a|/|a'| < 1$, where $\|L\|$ with operator $L \in \mathfrak{B}(L^2(\mathbf{R}^2))$ denotes the operator norm of L. Hence, S is bijective with

$$S^{-1}=\frac{1}{a'}\sum_{n=0}^{\infty}(-1)^n\left(\frac{a}{a'}\right)^n\Pi_\alpha(K)^n$$

in the operator norm topology. Therefore we obtain

$$e^{-i\omega_2 P_2}=S^{-1}\Pi_\alpha(E)\in\overline{\mathfrak{U}_\alpha}.$$

In the case $|a|/|a'|>1$, we write

$$S=a\Pi_\alpha(K)\left(1+\frac{a'}{a}\,\Pi_\alpha(K^{-1})\right).$$

Then, in the same way as in the preceding case, we can show that S is bijective with

$$S^{-1}=a^{-1}\sum_{n=0}^{\infty}(-1)^n\left(\frac{a'}{a}\right)^n\Pi_\alpha(K^{-1})^{n+1},$$

in the operator norm topology. Hence $e^{-i\omega_2 P_2}\in\overline{\mathfrak{U}_\alpha}$. Similarly, the second relation in (4.9) implies that $e^{i\omega_2 P_2}\in\overline{\mathfrak{U}_\alpha}$. Thus, $\overline{\mathfrak{F}_\alpha}\subset\overline{\mathfrak{U}_\alpha}$, which, together with (4.10), gives (4.8).

(ii) Relation (4.7) implies that

$$\{e^{\pm 2\pi i Q_j/\omega_j}\}_{j=1}^2\subset\overline{\mathfrak{U}'_\alpha}.$$

By the preceding result, $\overline{\mathfrak{U}_\alpha}$ is self-adjoint (in fact, a C^* subalgebra). Thus, by the same reasoning as in the proof of Theorem 4.4(ii), we obtain the desired result. ■

Remark: In the case $a_\alpha=\pm a'_\alpha$, S is injective, but not surjective [Lemma 2.6(ii)]. Hence S^{-1} is unbounded. The same applies to T in the case $b_\alpha=\pm b'_\alpha$.

For $(m,n)\in\mathbf{Z}^2$, we define a function $F_{m,n}(x,y)$ by

$$F_{m,n}(x,y)=\begin{cases}\exp\left(-i\alpha\displaystyle\int_{C_-(x,y;2m\omega_1,n\omega_2)}A\right); & (x,y)\in\mathbf{M}_{\omega_1,\omega_2},\\ 0; & (x,y)\notin\mathbf{M}_{\omega_1,\omega_2}.\end{cases}\tag{4.11}$$

For $\psi\in L^2(\mathbf{R}^2)$, we set

$$\psi_{m,n}(x,y)=\psi(x+2m\omega_1,y+n\omega_2),\quad (m,n)\in\mathbf{Z}^2.\tag{4.12}$$

Corollary 4.6: Suppose that $|a_\alpha|\neq|a'_\alpha|$, $|b_\alpha|\neq|b'_\alpha|$. Let W be any irreducible closed subspace of the representation $(\Pi_\alpha,L^2(\mathbf{R}^2))$. Then each nonzero vector $\psi\in W$ is cyclic and W is generated by vectors of the form $F_{m,n}\psi_{m,n}$, $(m,n)\in\mathbf{Z}^2$.

Proof: The first half is due to a general fact (Proposition 2.3.8 in Ref. 14). By Theorem 4.5(i), W is generated by vectors of the form

$$\phi_{m,n}=e^{2im\omega_1 P_1}e^{in\omega_2 P_2}\psi,\quad (m,n)\in\mathbf{Z}^2.$$

Using (2.20), we see that $\phi_{m,n}=F_{m,n}\psi_{m,n}$. ■

Corollary 4.6 clarifies the structure of any irreducible closed subspace W of the representation $(\Pi_\alpha,L^2(\mathbf{R}^2))$ in the case $|a_\alpha|\neq|a'_\alpha|$, $|b_\alpha|\neq|b'_\alpha|$. By Theorem 4.3, $\dim W=\infty$.

V. REPRESENTATION OF $U_q(\mathfrak{sl}_2)$ (II)

In this section, we construct representations of $U_q(\mathfrak{sl}_2)$ that are different from the one given in Sec. IV.

Lemma 5.1 (cf. Ref. 8): *Suppose that* $q \in \mathbf{C}\backslash\{0,1,-1\}$. *Let* (π,V) *be a representation of* $\mathbf{C}^2_{q^2}$ *[i.e.,* $q^2\pi(X)\pi(Y)=\pi(Y)\pi(X)$*] with the following properties.*

(i) $\pi(X)$ *and* $\pi(Y)$ *are bijective on* V.

(ii) *There exists a bijection* $Z \in \mathrm{End}(V)$ *such that* $Z^2=\pi(Y)^{-1}\pi(X)$.

Let $c_\pm$ and $d_\pm$ be constants satisfying

$$c_\pm d_\pm = \pm\frac{1}{(q-q^{-1})^2}. \tag{5.1}$$

Then the following correspondences $\Pi_\pm:\{E,F,K,K^{-1}\}\to\mathrm{End}\,(V)$ *define representations of* $U_q(\mathfrak{sl}_2)$*:*

$$\Pi_\pm(E)=c_\pm Z(\pi(X)^{-1}+\pi(Y)^{-1}),$$

$$\Pi_\pm(F)=d_\pm(\pi(X)+\pi(Y))Z^{-1},$$

$$\Pi_\pm(K)=\pm q^{-1}\pi(Y)^{-1}\pi(X),$$

$$\Pi_\pm(K^{-1})=\pm q\,\pi(X)^{-1}\pi(Y).$$

In these representations, we have

$$\Pi_\pm(C)=\pm\frac{(1+q^2)\pi(Y)^{-1}\pi(X)+(1+q^{-2})\pi(X)^{-1}\pi(Y)}{(q-q^{-1})^2}. \tag{5.2}$$

Proof: Direct computations. ■

To apply Lemma 5.1 with the representation $(\pi_\alpha, L^2(\mathbf{R}^2))$ of $\mathbf{C}^2_{q_\alpha}$ given in Theorem 3.2, we need the following lemma.

Lemma 5.2: Let U *be a unitary operator on a Hilbert space* $\mathscr{H}$. *Then there exists a unitary operator* T *on* $\mathscr{H}$ *such that*

$$T^2=U. \tag{5.3}$$

Proof: By the spectral theorem for unitary operators, there exists a unique resolution of identity $F(\theta)$ such that $F(0)=0$, $F(2\pi)=I$, and $U=\int_0^{2\pi}e^{i\theta}\,dF(\theta)$. Let $T=\int_0^{2\pi}e^{i\theta/2}\,dF(\theta)$. Then, by the functional calculus, T is unitary and (5.3) holds. ■

The operator $e^{-i\omega_2 P_2}e^{i\omega_1 P_1}$ is unitary on $L^2(\mathbf{R}^2)$. Hence, by Lemma 5.2, there exists a unitary operator Z_α on $L^2(\mathbf{R}^2)$ satisfying

$$Z_\alpha^2=e^{-i\omega_2 P_2}e^{i\omega_1 P_1}. \tag{5.4}$$

Let

$$q_\alpha^{1/2}:=e^{i\pi\alpha}. \tag{5.5}$$

Applying Lemma 5.1 with $\pi(X)=e^{i\omega_1 P_1}$, $\pi(Y)=e^{i\omega_2 P_2}$, we obtain the following theorem.

Theorem 5.3: *Let* $c_\pm(\alpha)$ *and* $d_\pm(\alpha)$ *be constants satisfying*

$$c_\pm(\alpha)d_\pm(\alpha)=\pm\frac{1}{(q_\alpha^{1/2}-q_\alpha^{-1/2})^2}=\mp\frac{1}{4\sin^2\pi\alpha}. \tag{5.6}$$

Then the following correspondences $\Pi_\alpha^\pm : \{E,F,K,K^{-1}\} \to \mathfrak{B}(L^2(\mathbf{R}^2))$ *define representations of* $U_q(\mathfrak{sl}_2)$ *with* $q = q_\alpha^{1/2}$:

$$\Pi_\alpha^\pm(E) = c_\pm(\alpha) Z_\alpha (e^{-i\omega_1 P_1} + e^{-i\omega_2 P_2}),$$

$$\Pi_\alpha^\pm(F) = d_\pm(\alpha)(e^{i\omega_1 P_1} + e^{i\omega_2 P_2}) Z_\alpha^{-1},$$

$$\Pi_\alpha^\pm(K) = \pm q_\alpha^{-1/2} e^{-i\omega_2 P_2} e^{i\omega_1 P_1},$$

$$\Pi_\alpha^\pm(K^{-1}) = \pm q_\alpha^{1/2} e^{-i\omega_1 P_1} e^{i\omega_2 P_2}.$$

In these representations, we have

$$\Pi_\alpha^\pm(C) = \pm \frac{(1+q_\alpha) e^{-i\omega_2 P_2} e^{i\omega_1 P_1} + (1+q_\alpha^{-1}) e^{-i\omega_1 P_1} e^{i\omega_2 P_2}}{(q_\alpha^{1/2} - q_\alpha^{-1/2})^2}. \tag{5.7}$$

By Lemma 2.7, we obtain the following theorem.

Theorem 5.4: *The representations* $(\Pi_\alpha^\pm, L^2(\mathbf{R}^2))$ *have no weight vectors. In particular, there exist no nonzero finite-dimensional subspaces* $W_\pm$, *such that* $(\Pi_\alpha^\pm, W_\pm)$ *give representations of* $U_{q_\alpha^{1/2}}(\mathfrak{sl}_2)$.

Let

$$\mathfrak{U}_\alpha^\pm = \Pi_\alpha^\pm(U_{q_\alpha^{1/2}}(\mathfrak{sl}_2)). \tag{5.8}$$

Theorem 5.5: *Let* $\overline{c_\pm(\alpha)} = d_\pm(\alpha)$. *Then*

(i) $\mathfrak{U}_\alpha^\pm$ *are* $*$ *subalgebras of* $\mathfrak{B}(L^2(\mathbf{R}^2))$.

(ii) $(\Pi_\alpha^\pm, L^2(\mathbf{R}^2))$ *are completely reducible.*

Proof: Under the assumption, $\mathfrak{U}_\alpha^\pm$ are self-adjoint, since we have

$$\Pi_\alpha^\pm(E)^* = \Pi_\alpha^\pm(F), \quad \Pi_\alpha^\pm(K)^* = \Pi_\alpha^\pm(K^{-1}).$$

Note that, if $T \in \mathfrak{B}(L^2(\mathbf{R}^2))$ commutes with $e^{-i\omega_2 P_2} e^{i\omega_1 P_1}$, then T commutes with Z_α. In particular, Z_α commutes with $e^{2\pi i Q_j/\omega_j}$, $j=1,2$. Hence $\{e^{2\pi i Q_j/\omega_j}\}_{j=1}^2 \subset \mathfrak{U}_\alpha^{\pm\prime}$. Thus, by the same reasoning as in the proof of Theorem 4.4, we obtain the desired result. ■

Note that $q_{2\alpha}^{1/2} = q_\alpha$. Hence $(\Pi_{2\alpha}^\pm, L^2(\mathbf{R}^2))$ are representations of $U_q(\mathfrak{sl}_2)$ with $q = q_\alpha$. It is natural to ask if these representations are equivalent to the representation $(\Pi_\alpha, L^2(\mathbf{R}^2))$ constructed in the preceding section.

Theorem 5.6: *The representations* $(\Pi_{2\alpha}^\pm, L^2(\mathbf{R}^2))$ *are not equivalent to* $(\Pi_\alpha, L^2(\mathbf{R}^2))$.

Proof: By (5.7), (2.20), and (2.21), we have, for all $\psi \in L^2(\mathbf{R}^2)$,

$$(\Pi_{2\alpha}^\pm(C)\psi)(x,y) = \pm \frac{1+q_\alpha^2}{(q_\alpha - q_\alpha^{-1})^2} \exp\left(-2i\alpha \int_{C_+(x,y;\omega_1,-\omega_2)} A \right) \psi(x+\omega_1, y-\omega_2)$$
$$\pm \frac{1+q_\alpha^{-2}}{(q_\alpha - q_\alpha^{-1})^2} \exp\left(-2i\alpha \int_{C_-(x,y;-\omega_1,\omega_2)} A \right) \psi(x-\omega_1, y+\omega_2), \quad \text{a.e.}$$

From this expression, it is seen that $\Pi_{2\alpha}^\pm(C)$ are not scalar multiples of the identity. [For example, consider a function $\psi \in L^2(\mathbf{R}^2)$, $\psi \neq 0$, with support in $S = (0,\omega_1) \times (0,\omega_2)$. Then the support of $\Pi_{2\alpha}^\pm(C)\psi$ is outside of S.] On the other hand, by (4.3), $\Pi_\alpha(C)$ is a scalar multiple of the identity. Thus, the desired result follows. ■

We can prove a more detailed fact on the inequivalence between $(\Pi^{\pm}_{2\alpha}, L^2(\mathbf{R}^2))$ and $(\Pi_\alpha, L^2(\mathbf{R}^2))$. For this purpose, we prepare a lemma. Let

$$h^{\pm}_\alpha(\lambda) = \pm \frac{(1+q_\alpha)\lambda + (1+q_\alpha^{-1})\overline{\lambda}}{(q_\alpha^{1/2} - q_\alpha^{-1/2})^2}, \quad \lambda \in \mathbf{C}. \tag{5.9}$$

Note that $h^{\pm}_\alpha$ are real valued.

Lemma 5.7:

(i)

$$\sigma(\Pi^{\pm}_\alpha(C)) = \{h^{\pm}_\alpha(\lambda) | \lambda \in \sigma(e^{-i\omega_2 P_2} e^{i\omega_1 P_1})\}. \tag{5.10}$$

In particular,

$$\sigma(\Pi^{\pm}_\alpha(C)) \subset [-R_\alpha, R_\alpha], \tag{5.11}$$

where

$$R_\alpha = \frac{2|1+q_\alpha|}{|q_\alpha^{1/2} - q_\alpha^{-1/2}|^2} = \frac{|\cos \pi\alpha|}{\sin^2 \pi\alpha}. \tag{5.12}$$

(ii)

$$\sigma_p(\Pi^{\pm}_\alpha(C)) = \emptyset. \tag{5.13}$$

Proof: (i) We first note that

$$U_\alpha := e^{-i\omega_2 P_2} e^{i\omega_1 P_1}$$

is unitary and $U_\alpha^{-1} = e^{-i\omega_1 P_1} e^{i\omega_2 P_2}$. We have

$$\Pi^{\pm}_\alpha(C) = \pm \frac{(1+q_\alpha)U_\alpha + (1+q_\alpha^{-1})U_\alpha^{-1}}{(q_\alpha^{1/2} - q_\alpha^{-1/2})^2}.$$

Relation (5.10) follows from this expression and the spectral mapping theorem for unitary operators. It is easy to see that there exists a constant $\delta_\alpha \in [0, 2\pi)$ such that

$$h^{\pm}_\alpha(e^{i\theta}) = \pm R_\alpha \cos(\theta + \delta_\alpha), \quad \theta \in \mathbf{R}. \tag{5.14}$$

Hence (5.11) follows.

(ii) Suppose that $\sigma_p(\Pi^{+}_\alpha(C)) \neq$ and $\lambda \in \sigma_p(\Pi^{+}_\alpha(C))$. Then, by (5.11), $-R_\alpha \leqslant \lambda \leqslant R_\alpha$ and there exists a nonzero vector $\psi \in L^2(\mathbf{R}^2)$ such that $\Pi^{+}_\alpha(C)\psi = \lambda\psi$. Let E be the spectral measure of U_α:

$$U_\alpha = \int_0^{2\pi} e^{i\theta}\, dE(\theta).$$

Then we have

$$0 = \|\Pi^{+}_\alpha(C)\psi - \lambda\psi\|^2 = \int_0^{2\pi} |h^{+}_\alpha(e^{i\theta}) - \lambda|^2 d\|E(\theta)\psi\|^2,$$

which implies that the support of the measure $\|E(\cdot)\psi\|^2$ is included in the set $\{\theta\in[0,2\pi]|h_\alpha^+(e^{i\theta})=\lambda\}$. By (5.14), the equation $h_\alpha^+(e^{i\theta})=\lambda$ has at most two solutions: $\theta_j\in[0,2\pi)$, $j=1,2$. This implies that one of $E(\{\theta_j\})\psi$ $(j=1,2)$ is not zero and an eigenvector of U_α with eigenvalue $e^{i\theta_j}$. But this contradicts Lemma 2.7. Thus $\sigma_p(\Pi_\alpha^+(C))$ must be empty. Similarly, we can prove $\sigma_p(\Pi_\alpha^-(C))=\emptyset$. ■

Theorem 5.8: *Let* (Π_α,W) *be any irreducible component of* $(\Pi_\alpha,L^2(\mathbf{R}^2))$ $(W\subset L^2(\mathbf{R}^2))$. *Then* (Π_α,W) *is not equivalent to any irreducible component of* $(\Pi_{2\alpha}^{\pm},L^2(\mathbf{R}^2))$.

Proof: By Lemma 5.7(ii), $\Pi_{2\alpha}^{\pm}(C)$ are not scalar multiples of the identity in any irreducible components of $(\Pi_{2\alpha}^+,L^2(\mathbf{R}^2))$. Thus, the desired result follows. ■

Remark: It is an open problem to clarify whether $(\Pi_\alpha^+,L^2(\mathbf{R}^2))$ is equivalent to $(\Pi_\alpha^-,L^2(\mathbf{R}^2))$ or not.

(Received 5 January 1996; accepted for publication 12 April 1996)

The problem of the existence of the thermodynamical limit of the algebraic dynamics for a class of spin systems is considered in the framework of a generalized algebraic approach in terms of a special class of quasi*-algebras, called CQ^*-algebras. Physical applications to (almost) mean-field models and to bubble models are discussed. © *1996 American Institute of Physics.*

I. INTRODUCTION

When working with spin systems it is not difficult to build up simple models for which the algebraic approach developed by Haag and Kastler[1] fails. In this approach, the observable algebra $\mathfrak{U}$ of the system is taken to be a quasilocal C^*-algebra. But already for reasonably simple interactions, e.g., for mean-field models, the thermodynamical limit of the local Heisenberg dynamics does not converge in the usual spin C^*-algebra $\mathfrak{U}_S$. One possible way to overcome this difficulty consists in weakening the Haag–Kastler axioms by assuming that the observable algebra of the system is a more general structure than a C^*-algebra. In Refs. 2, and 3, Lassner proposed to define on the algebra $\mathfrak{U}_0$ generated by all the local algebras $\mathfrak{U}_V$ a different topology (that he called *physical*), constructed *ad hoc* to allow the thermodynamical limit of the local Heisenberg dynamics to live in the completion of $\mathfrak{U}_0$ with respect to this topology.

In Ref. 4 we introduced a particular class of quasi*-algebras, called CQ^*-algebras, with the scope of providing an intermediate structure between a general quasi*-algebra and a C^*-algebra, which still allows a solution of the problems mentioned above. A CQ^*-algebra can be thought, roughly speaking, as the completion of a C^*-algebra with respect to a certain weaker norm.

In Ref. 4 we proved that, at least for certain representations of $\mathfrak{U}_0$, the thermodynamical limit can be found for the so-called *almost* mean-field models[5,6] in the CQ^*-algebra of operators, where the representations take their values.

In this paper we consider the same problem from a more general point of view (i.e., without specifying, as far as it is possible, the local Hamiltonian), and we investigate on the properties that a spin model should satisfy in order that the existence of the thermodynamical limit of the local dynamics can be obtained in the CQ^*-algebras framework (or at least in a quasi*-algebra, which is obtained as the projective limit of CQ^*-algebras).

In Sec. II we construct the spin CQ^*-algebra and study the derivation δ arising as the limit of the local derivations δ_V, for finite V, where $\delta_V(A)=[H_V,A]$, $A\in\mathfrak{U}$. The integration of the derivation δ is then discussed both in the purely algebraic setup and, under representations, making use of the so-called *effective Hamiltonians*.

In Sec. III, we exhibit examples of spin models satisfying the assumptions of Sec. II. In particular, we rediscuss in this different framework the almost mean-field models studied in Refs.

5 and 6 and some other models (bubble models) that are obtained by unitary transformations of the previous ones and have nevertheless a physical meaning on their own.

The basic definitions and properties of quasi*-algebras and of CQ^*-algebras are collected in the Appendix.

II. SPIN LATTICE SYSTEMS

Let V be a finite region of a d-dimensional lattice and $|V|$ the number of points in V. The local C^*-algebra $\mathfrak{U}_V$ is generated by the Pauli operators, $\sigma_p=(\sigma_p^1,\sigma_p^2,\sigma_p^3)$ and by the unit 2×2 matrix I_p at every point $p\in V$. The σ_p's are copies of the Pauli matrices,

$$\sigma^1=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\quad \sigma^2=\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix},\quad \sigma^3=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}.$$

$\mathfrak{U}_V$ is isomorphic to the C^*-algebra of all $2^{|V|}\times 2^{|V|}$ matrices on the $2^{|V|}$-dimensional complex Hilbert space $\mathscr{H}_V=\otimes_{p\in V}C_p^2$, where C_p^2 is the two-dimensional complex Hilbert space at p. If $V\subset V'$ and $A_V\in\mathfrak{U}_V$, then $A_V\to A_{V'}=A_V\otimes(\otimes_{p\in V'\setminus V}I_p)$ defines the natural imbedding of $\mathfrak{U}_V$ into $\mathfrak{U}_{V'}$.

Let $n=(n^1,n^2,n^3)$ be a unit vector in $\mathbb{R}^3$, and put

$$(\sigma\cdot n)=n^1\sigma^1+n^2\sigma^2+n^3\sigma^3.$$

Then, denoting as $Sp(\sigma\cdot n)$ the spectrum of $\sigma\cdot n$, we have

$$Sp(\sigma\cdot n)=\{1,-1\}.$$

Let $|n\rangle$ be a unit eigenvector associated with 1. Let $\{n\}=\{n_1,n_2,\ldots\}$ be an infinite sequence of unit vectors in $\mathbb{R}^3$ and $|\{n\}\rangle=\otimes_p|n_p\rangle$ the corresponding unit vector in the infinite tensor product, $\mathscr{H}_\infty=\otimes_p C_p^2$. We put

$$\mathfrak{U}_0=\bigcup_V \mathfrak{U}_V$$

and

$$\mathscr{D}_{\{n\}}^0=\mathfrak{U}_0|\{n\}\rangle,$$

and we denote the closure of $\mathscr{D}_{\{n\}}^0$ in $\mathscr{H}_\infty$ by $\mathscr{H}_{\{n\}}$. As we saw above, to any sequence $\{n\}$ of three-vectors it corresponds a state $|\{n\}\rangle$ of the system. Such a state defines a realization $\pi_{\{n\}}(\mathfrak{U}_0)$ in the Hilbert space $\mathscr{H}_{\{n\}}$. This representation is faithful, since the norm completion $\mathfrak{U}_S$ of $\mathfrak{U}_0$ is a simple C^*-algebra. To define it one starts with constructing a special basis for $\mathscr{H}_{\{n\}}$. This is obtained from the *ground* state $|\{n\}\rangle$ by *flipping* a finite number of spins.

Let $(n,n^{(1)},n^{(2)})$ be an orthonormal basis of $\mathbb{R}^3$. We put

$$n^{\pm}=\tfrac{1}{2}(n^{(1)}\pm in^{(2)})$$

and

$$|m,n\rangle=(\sigma\cdot n^-)^m|n\rangle\quad (m=0,1).$$

Then we have

$$(\sigma\cdot n)|m,n\rangle=(-1)^m|m,n\rangle\quad (m=0,1).$$

Thus the set $\{|\{m\},\{n\}\rangle = \otimes_p |m_p, n_p\rangle;\ m_p = 0,1,\ \Sigma_p m_p < \infty\}$ forms an orthonormal basis in $\mathscr{H}_{\{n\}}$.[7] In this space we define the unbounded self-adjoint operator M by

$$M|\{m\},\{n\}\rangle = \left(\sum_p m_p\right)|\{m\},\{n\}\rangle.$$

M counts the number of the flipped spins in $|\{m\},\{n\}\rangle$ with respect to the ground state $|\{n\}\rangle$. Of course M depends on $\{n\}$, but we will not explicitly indicate this fact whenever no confusion arises.

Next we consider the natural representation $\pi_{\{n\}}$ of $\mathfrak{U}_0$ into some class of operators in the Hilbert space $\mathscr{H}_{\{n\}}$. The representation $\pi_{\{n\}}$ is defined on the basis vectors $\{|\{m\},\{n\}\rangle\}$ by

$$\pi_{\{n\}}(\sigma_p^i)|\{m\},\{n\}\rangle = \sigma_p^i |m_p, n_p\rangle \otimes \left(\prod_{p' \neq p} \otimes |m_{p'}, n_{p'}\rangle\right) \quad (i = 1,2,3).$$

This definition is then extended in an obvious way to the whole space $\mathscr{H}_{\{n\}}$. It turns out that $\pi_{\{n\}}$ is a *bounded* representation of $\mathfrak{U}_0$ into $\mathscr{H}_{\{n\}}$.

But in view of the definition of a new topology on $\mathfrak{U}_0$, different from that induced by its C^*-norm, it is quite unconvenient to consider $\pi_{\{n\}}$ as a bounded representation of $\mathfrak{U}_0$ into $\mathscr{H}_{\{n\}}$. For this reason, we will consider more appropriate domains where the representation $\pi_{\{n\}}$ lives.

First we can put

$$\mathscr{D}_{\{n\}} = \bigcap_k \mathscr{D}(M^k).$$

Then very simple estimates show that $\pi_{\{n\}}(A)$ leaves $\mathscr{D}_{\{n\}}$ invariant, for any $A \in \mathfrak{U}_0$.[2] It turns out that $\pi_{\{n\}} : \mathfrak{U}_0 \to \mathscr{L}^\dagger(\mathscr{D}_{\{n\}})$.

With this choice one can follow the approach developed in Refs. 2, 5, and 6 and define a *physical topology* on $\mathfrak{U}_0$ as the weakest locally convex topology, such that each $\pi_{\{n\}}$ is continuous from $\mathfrak{U}_0$ into $\mathscr{L}^\dagger(\mathscr{D}_{\{n\}})$, this latter endowed with the so-called quasiuniform topology $\tau_{\{n\}}$.[2]

There is, however, a different and, in our opinion, simpler possible choice.

As seen above, the operator M is a number operator. Therefore, the operator e^M is a densely defined self-adjoint operator. Let $\mathscr{D}$ denote its domain. Then $\mathscr{D}$ can be made into a Hilbert space, denoted as $\mathscr{H}_M$, in a canonical way. The norm in $\mathscr{H}_M$ is given by

$$\|f\|_M = \|e^M f\|, \quad f \in \mathscr{H}_M.$$

Taking the conjugate dual $\mathscr{H}_{\overline{M}}$ of $\mathscr{H}_M$, with respect to the scalar product of $\mathscr{H}_{\{n\}}$, we get the triplet of Hilbert spaces,

$$\mathscr{H}_M \subset \mathscr{H}_{\{n\}} \subset \mathscr{H}_{\overline{M}}.$$

Now we can consider the CQ^*-algebra $(\mathscr{B}(\mathscr{H}_M, \mathscr{H}_{\overline{M}}), *, \mathscr{B}(\mathscr{H}_M), \flat)$ of bounded operators acting in the triplet (see the Appendix).

The norm of $\mathscr{B}(\mathscr{H}_M, \mathscr{H}_{\overline{M}})$ can be written in terms of the norm in $\mathscr{B}(\mathscr{H}_{\{n\}})$ by

$$\|X\|_{M,\overline{M}} = \|e^{-M} X e^{-M}\|, \quad X \in \mathscr{B}(\mathscr{H}_M, \mathscr{H}_{\overline{M}}).$$

Similarly, the norm in $\mathscr{B}(\mathscr{H}_M)$ becomes

$$\|X\|_M = \|e^M X e^{-M}\|, \quad X \in \mathscr{B}(\mathscr{H}_M).$$

Also in this case it is not difficult to prove that $\pi_{\{n\}}(A)$ maps $\mathscr{H}_M$ into itself, for each $A \in \mathfrak{U}_0$. Then if we look at $\pi_{\{n\}}(A)$ as a bounded operator in $\mathscr{H}_M$, we get, taking into account the fact that $\pi_{\{n\}}$ can be viewed as the restriction to $\mathfrak{U}_0$ of a *-representation of the simple C^*-algebra $\mathfrak{U}_S$,

$$\|\pi_{\{n\}}(A)\|_M = \|A\|, \quad \forall A \in \mathfrak{U}_0,$$

where the norm on the right-hand side is the C^*-norm of $\mathfrak{U}_0$.

On the other hand, the CQ^*-norm,

$$\|\pi_{\{n\}}(A)\|_{M,\overline{M}} = \|e^{-M}\pi_{\{n\}}(A)e^{-M}\|,$$

is, in general, different from $\|A\|$.

Of course, to each $\{n\}$ it corresponds a CQ^*-algebra of the kind discussed above. This algebraic setup could also be taken as a reasonable framework, where discussing problems like the existence of the thermodynamical limit of the local Heisenberg dynamics. The results would, however, depend on $\{n\}$ and hence on the representation $\pi_{\{n\}}$. This has been done, for instance, in Ref. 5, for the so-called *almost-mean-field* models. Nevertheless, in that case the dependence on the representation is not crucial at all, provided that the states $\{n\}$ are chosen in a suitable family of *relevant* states. We will come back to this point in the next section.

For general models, however, this dependence on the representation cannot be easily eliminated. For this reason it might be convenient to define a topology that takes into account the whole class $\mathscr{F}$ of states under consideration. This topology, which we call *weak physical topology* and denote by $\tau_{\mathscr{F}}$ is defined by the family of seminorms (we will explicitly write the dependence of M on $\{n\}$):

$$A \in \mathfrak{U}_0 \to \|e^{-M_{\{n\}}}\pi_{\{n\}}(A)e^{-M_{\{n\}}}\|, \quad \{n\} \in \mathscr{F}.$$

Of course, $\tau_{\mathscr{F}}$ is the weakest locally convex topology, such that each $\pi_{\{n\}}$ is continuous from $\mathfrak{U}_0$ into $(\mathscr{B}(\mathscr{H}_M,\mathscr{H}_{\overline{M}}),*,\mathscr{B}(\mathscr{H}_M),\flat)$. The completion of $\mathfrak{U}_0[\tau_{\mathscr{F}}]$ will be denoted with $\mathfrak{U}$. The new seminorms above will take the place of the seminorms $\|A\|^{f,k} = \max\{\|M^k A f(M)\|, \|f(M)AM^k\|\}$ introduced in Refs. 5 and 6 to deal with the thermodynamical limit, where f runs in a suitable set of functions. We prefer to use the topology $\tau_{\mathscr{F}}$ because it is directly linked to the family of CQ^*-algebras shown above (it is indeed the projective limit of the norms of that family), and it still allows a complete discussion of the questions arose. The following proposition is now obvious.

Lemma II.1: Let $\mathfrak{U}$ *denote the completion of* $\mathfrak{U}_0[\tau_{\mathscr{F}}]$. *Then* $(\mathfrak{U}[\tau_{\mathscr{F}}],\mathfrak{U}_0)$ *is a topological quasi* *-*algebra*.

A. The thermodynamical limit

The possibility of defining a topology $\tau_{\mathscr{F}}$ for a specific model relies on the particular form of the Hamiltonian and, of course, on the possibility of choosing a family $\mathscr{F}$ of *relevant* states.

To begin with, let H_V be the finite volume Hamiltonian of the system and put

$$\delta_V(A) = i[H_V, A], \quad A \in \mathfrak{U}_0$$

and

$$\delta_V^k(A) = i[H_V, A]_k, \quad A \in \mathfrak{U}_0,$$

where $[H_V, A]_1 = [H_V, A]$ and $[H_V, A]_k = [H_V, [H_V, A]_{k-1}]$.

Proposition II.2: Let the finite volume Hamiltonian H_V *of the system be a polynomial* $p_V(S_V^i, \sigma_k^j)$ *in the variables* S_V^i *with* $S_V^i \in \mathfrak{U}_0$, $i = 1,2,\ldots,N$ *and a continuous function of the* σ_k^j*'s.*

Assume that (i) $\forall A \in \mathfrak{U}_0$, $[H_V, A]$ *depends on V only through the* S_V^i*'s*; (ii) $\lim_{|V|\to\infty}(S_V^i)^n$ *exists in* $\mathfrak{U}[\tau_{\mathscr{T}}]$, $\forall n \in \mathbb{N}$, $i=1,2,\ldots,N$.
Then, for each $A \in \mathfrak{U}_0$ *and for any* $k \in \mathbb{N}$ *the limits*

$$\lim_{|V|\to\infty} \delta_V^k(A)$$

exist in $\mathfrak{U}[\tau_{\mathscr{T}}]$. *Setting* $\delta(A) = \tau_{\mathscr{T}} - \lim_{|V|\to\infty} \delta_V(A)$, $A \in \mathfrak{U}_0$, *then* δ *has the properties* (a) $\delta(A)^* = \delta(A)^*$, $\forall A \in \mathfrak{U}_0$; (b) $\delta(AB) = \delta(A)B + A\delta(B)$, $\forall A, B \in \mathfrak{U}_0$.

Proof: By induction on k, one can show that, as well as for $k=1$, $\delta_V^k(A)$ is a polynomial in $\vec{S}_V$ and does not depend explicitly on V. Therefore, by (ii)

$$\tau_{\mathscr{T}} - \lim_{|V|\to\infty} \delta_V^k(A) \equiv \delta^{(k)}(A)$$

exist in $\mathfrak{U}$, for each $A \in \mathfrak{U}_0$ and for any $k \in \mathbb{N}$. (The notation $\delta^{(k)}$ is used to stress the fact that the powers of δ are not well defined, in general.)

Of course, by the $\tau_{\mathscr{T}}$ continuity of the involution and by the separate continuity of the multiplication one has, for any $A, B \in \mathfrak{U}_0$,

$$\delta(A^*) = \tau_{\mathscr{T}} - \lim_{|V|\to\infty} \delta_V(A^*) = \tau_{\mathscr{T}} - \lim_{|V|\to\infty} \sigma_V(A)^* = \delta(A)^*$$

and

$$\delta(AB) = \tau_{\mathscr{T}} - \lim_{|V|\to\infty} \delta_V(AB) = \tau_{\mathscr{T}} - \lim_{|V|\to\infty} (\delta_V(A)B + A\delta_V(B)) = \delta(A)B + A\delta(B).$$

□

Example II.3: The assumption (i) of the above proposition seems to be very strong. In spite of this appearance, it is fulfilled by several interesting models such as the (almost) mean-field spin models considered Refs. 5 and 6. For the Heisenberg model, for instance, the local Hamiltonian has the form

$$H_V = \frac{J}{|V|^\gamma} \sum_{p,q \in V} \sum_{i=1}^{3} \sigma_p^i \sigma_q^i, \tag{2.1}$$

with $\frac{1}{2} < \gamma \leqslant 1$, and the operators S_V^i are defined as

$$S_V^i = \frac{1}{|V|^\gamma} \sum_{p \in V} \sigma_p^i, \quad i = 1,2,3.$$

In this case one can show that, if $A \in \mathfrak{U}_{V'}$, then all the repeated commutators $[H_V, A]_k$ depend on the means S_V^i and on operators belonging to $\mathfrak{U}_{V'}$.

Analogous conclusions are obtained even for non-mean-field models like, for instance, the one defined by the following Hamiltonian:

$$H_V = \sum_{p,q \in V} \sum_{i=1}^{3} J_{p,q} (\sigma_p^i - \overline{\sigma^i})(\sigma_q^i - \overline{\sigma^i}), \tag{2.2}$$

where $\overline{\sigma^i}$ is the ith component of a fixed three vector (times the unit matrix).[8] Here the relevant V-dependent variables are

$$S_V^i(q)=\sum_{p\in V} J_{p,q}(\sigma_p^i-\overline{\sigma^i}),\quad i=1,2,3;\quad p=1,2,\ldots,|V|.$$

Remark II.4: The linear map δ defined in Proposition II.2 may be regarded as a *-derivation of $\mathfrak{U}_0$ defined on the domain

$$D(\delta)=\{A\in\mathfrak{U}_0:\delta(A)\in\mathfrak{U}_0\},\tag{2.3}$$

which is, as is readily checked, a *-subalgebra of $\mathfrak{U}_0$. This is, however, an unnecessary limitation. As we have seen in Proposition II.2, δ is, indeed, everywhere defined in $\mathfrak{U}_0$ [and of course the products in (b) make sense in the quasi *-algebra $\mathfrak{U}$). So, it would be natural to consider it as a *-derivation of the quasi*-algebra $(\mathfrak{U},\mathfrak{U}_0)$ in the sense of Ref. 9. This is, however, not always possible since, in general, δ is not continuous from $\mathfrak{U}_0[\tau_{\mathscr{F}}]$ into $\mathfrak{U}[\tau_{\mathscr{F}}]$.

The derivations δ_V and δ describe, at an infinitesimal level, respectively, the finite and the infinite volume dynamics of the system. What is, in general, expected is that they are generators of one-parameter groups of automorphisms of the completion of $\mathfrak{U}_0$ in a suitably chosen topology. This is certainly true for δ_V, $|V|<\infty$, since

$$\alpha_V^t(A)=e^{iH_Vt}Ae^{-iH_Vt},\quad A\in\mathfrak{U}_0,$$

is well defined, because $H_V\in\mathfrak{U}_V$ (and so does e^{iH_Vt}). The local dynamics α_V^t can be extended to the whole spin C^*-algebra $\mathfrak{U}_S$ and, as a function of t, is a one-parameter group of *-automorphisms of $\mathfrak{U}_S$. Since δ_V is bounded in $\mathfrak{U}_0$, we also get

$$\alpha_V^t(A)=\sum_{k=0}^{\infty}\frac{(it)^k}{k!}\delta_V^k(A),\quad A\in\mathfrak{U}_0,$$

and we know that $\delta_V^k(A)$ is $\tau_{\mathscr{F}}$ convergent to what we called $\delta^{(k)}(A)$. The problem of finding the limit for $|V|\to\infty$ of $\alpha_V^t(A)$ is then solved if we can control in a reasonable way the behavior of $\|\pi_{\{n\}}(\delta_V^k(A))\|_{M,\overline{M}}$ when $|V|$ grows to infinity.

Many models allow, indeed, some useful estimate of the norm of $\delta_V^k(A)$. This is true, for instance, for all mean-field models whose Hamiltonian is a polynomial of the three components of the mean spin.[10]

Lemma II.5: Assume that the local Hamiltonian H_V of a spin model can be written in the form

$$H_V=|V|p(S_V^1,S_V^2,S_V^3),$$

where p is a polynomial and

$$S_V^i=\frac{1}{|V|}\sum_{p\in V}\sigma_p^i,\quad i=1,2,3.$$

Then there exist two constants C_1, $C_2>0$ such that

$$\|\pi_{\{n\}}(\delta_V^k(A))\|_{M,\overline{M}}\leqslant\frac{C_1}{q}\max(2,\|A\|)C_2^k|V'|^k(k-1)!,\quad \forall A\in\mathfrak{U}_{V'}.$$

The constant C_1 depends only on $\{n\}$, C_2 depends only on the degree and on the form of the polynomial p, and $q\geqslant 1$ is the degree of the polynomial p.

Proof: In Ref. 10 it has been proved that, under the same assumptions, there exists $C_2>0$ such that

$$\|\delta_V^k(A)\| \leqslant \frac{1}{q}\max(2,\|A\|)C_2^k|V'|^k(k-1)!, \quad \forall A \in \mathfrak{U}_{V'}.$$

The statement then follows from the fact that $\|\pi_{\{n\}}(X)\|_{M,\overline{M}} \leqslant \|\pi_{\{n\}}(I)\|_{M,\overline{M}}\|X\|$, for each $X \in \mathfrak{U}_0$ and choosing $C_1 = \|\pi_{\{n\}}(I)\|_{M,\overline{M}}$. □

Proposition II.6: In the hypotheses of Lemma II.5, for each $A \in \mathfrak{U}_0$ there exists a positive number r_A such that the local dynamics

$$\alpha_V^t(A) = e^{iH_V t}Ae^{-iH_V t}$$

converges in the topology $\tau_{\mathscr{T}}$, when $|V| \to \infty$, to a limit that we denote by $\alpha^t(A)$, for any t with $|t| < r_A$.

Proof: If $A \in \mathfrak{U}_0$, then $A \in \mathfrak{U}_{V'}$ for some V'. Making use of Lemma II.5 we get

$$\left\| \sum_{k=0}^{\infty} \frac{(it)^k}{k!}\pi_{\{n\}}(\delta_V^k(A)) \right\|_{M,\overline{M}} \leqslant \sum_{k=0}^{\infty} \frac{|t|^k}{k}\frac{C_1}{q}\max(2,\|A\|)C_2^k|V'|^k.$$

The series on the right-hand side has a radius of convergence $r_A = 1/C_2|V'|$. □

It is worth noticing that the path followed in Ref. 5 depends strictly on the form of H_V since those results were mostly obtained by direct estimates. In the perspective we are following now, i.e., trying to obtain results for certain classes of interactions rather than for a specific one, it is not useful therefore to follow that approach. A more general strategy, for mean spin models, based on abstract results on differential equations can be found in Ref. 11.

Another possible approach to the problem of the existence of the thermodynamical limit makes use of the possibility of defining an *effective Hamiltonian.*

We will indicate with the same symbol the representation $\pi_{\{n\}}$ and its continuous extension to $\mathfrak{U}$ (this extension exists by the definition itself of the topology).

Definition II.7: We say that the model admits an effective Hamiltonian if for each $\{n\} \in \mathscr{T}$ there exists a self-adjoint operator $H_{\text{eff}}^{\{n\}}$ in $\mathscr{H}_{\{n\}}$ with the property

$$\pi_{\{n\}}(\delta(A)) = i[H_{\text{eff}}^{\{n\}}, \pi_{\{n\}}(A)], \quad \forall A \in \mathfrak{U}_0.$$

This equation is understood in the following weak sense:

$$\langle \pi_{\{n\}}(\delta(A))\phi, \psi\rangle = i\{\langle \pi_{\{n\}}(A)\phi, H_{\text{eff}}^{\{n\}}\psi\rangle - \langle H_{\text{eff}}^{\{n\}}\phi, \pi_{\{n\}}(A^*)\psi\rangle\},$$

$$\forall \phi, \psi \in D(H_{\text{eff}}^{\{n\}}), \quad \forall A \in \mathfrak{U}_0.$$

Remark II.8: This definition says, in practice, that the derivation on $\pi_{\{n\}}(\mathfrak{U}_0)$,

$$\delta_{\{n\}}(\pi_{\{n\}}(A)) = \pi_{\{n\}}(\delta(A))$$

is spatial and the implementing operator is self-adjoint. As is known, both these conditions require quite strong assumptions to be fulfilled.

For instance, if the states $|\{n\}\rangle$ with $\{n\} \in \mathscr{T}$ satisfy the condition

$$\langle\{n\}|\pi_{\{n\}}(\delta(A))|\{n\}\rangle = 0, \quad \forall A \in \mathfrak{U}_0, \tag{2.4}$$

then, as is known (Ref. 12, Sec. 3.2.2), the effective Hamiltonians $H_{\text{eff}}^{\{n\}}$ exist as self-adjoint operators in $\mathscr{H}_{\{n\}}$.

Equation (2.4) is fulfilled, for instance, by the almost mean-field Ising model,[5] for a suitable choice of the family $\mathscr{T}$ of states. This will be discussed in the next section.

If the model admits an effective Hamiltonian, then one can consider the subset $\mathscr{D}$ of $D(\delta)$ consisting of all the *generalized analytic elements* of δ, i.e., $A\in\mathscr{D}$ iff

$$e^{iH_{\rm eff}^{\{n\}}t}\pi_{\{n\}}(A)e^{-iH_{\rm eff}^{\{n\}}t}=\sum_{k=0}^{\infty}\frac{(it)^k}{k!}\,\pi_{\{n\}}(\delta^{(k)}(A)),$$

where the series on the right-hand side is understood to converge with respect to $\|\ \|_{M_{\{n\}},\overline{M}_{\{n\}}}$.

Proposition II.9: Let $\mathscr{F}_0\subset\mathscr{F}$ be a set of states such that for each $\{n\}\in\mathscr{F}_0$, $M_{\{n\}}$ and $H_{\rm eff}^{\{n\}}$ commute strongly (i.e., their spectral families commute). Then, for each $A\in\mathscr{D}$, the series $\Sigma_{k=0}^{\infty}[(it)^k/k!](\delta^{(k)}(A))$ converges, with respect to the topology $\tau_{\mathscr{F}_0}$, to an element of $\mathfrak{U}$ that we call $\alpha_t(A)$. Moreover, α_t can be extended to the closure $\overline{\mathscr{D}}$ of $\mathscr{D}$ in $\mathfrak{U}[\tau_{\mathscr{F}_0}]$.
If $\overline{\mathscr{D}}=\mathfrak{U}$, then α_t is a one-parameter group of automorphisms of $\mathfrak{U}$.

Proof: For $A\in\mathscr{D}$, we get

$$\left\|\sum_{k=0}^{\infty}\frac{t^k}{k!}\,(\delta^{(k)}(\pi_{\{n\}}(A)))\right\|_{M_{\{n\}},\overline{M}_{\{n\}}}=\left\|e^{-M_{\{n\}}}\left(\sum_{k=0}^{\infty}\frac{t^k}{k!}\,\pi_{\{n\}}(\delta^{(k)}(A))\right)e^{-M_{\{n\}}}\right\|$$
$$=\|e^{-M_{\{n\}}}e^{iH_{\rm eff}^{\{n\}}t}\pi_{\{n\}}(A)e^{-iH_{\rm eff}^{\{n\}}t}e^{-M_{\{n\}}}\|=\|\pi_{\{n\}}(A)\|_{M_{\{n\}},\overline{M}_{\{n\}}}. \tag{2.5}$$

Thus, the series

$$\sum_{k=0}^{\infty}\frac{(it)^k}{k!}\,(\delta^{(k)}(A))$$

is $\tau_{\mathscr{F}_0}$ convergent and we define $\alpha_t(A)$ as its limit. Equation (2.5) also implies the continuity of α_t. Then α_t can be extended to $\overline{\mathscr{D}}$. If $\overline{\mathscr{D}}=\mathfrak{U}$, the group property can be easily derived, under representation, for $A\in\mathfrak{U}_0$, making use of the effective Hamiltonian and then by pullback of the faithful representation $\pi_{\{n\}}$. For an arbitrary element of $\mathscr{D}$, the statement follows by continuous extension. □

Remark II.10: As noticed above, there could be some difference between $\delta^{(k)}(A)=\tau_{\mathscr{F}}-\lim_{V\to\infty}\delta_V^k(A)$ and $\delta^k(A)$, since the latter might not be well defined for an arbitrary $A\in\mathfrak{U}_0$. However, even when $\delta^k(A)$ is well defined, for any k (think of the case of an everywhere defined δ), there is no reason for $\delta^{(k)}(A)$ and $\delta^k(A)$ to coincide, since, in general, the convergence of $\delta_V^k(A)$ is not uniform in V.

Even the algebraic dynamics α_t is not, in general, the $\tau_{\mathscr{F}}$ limit of α_V^t in spite of the fact that $\delta(A)=\tau_{\mathscr{F}}-\lim_{V\to\infty}\delta_V(A)$.

If the derivation $\delta_{\{n\}}$ is continuous, some information can be obtained without making reference to the effective Hamiltonians.

Proposition II.11: Assume that for each $\{n\}\in\mathscr{F}$ there exists $C_{\{n\}}>0$, such that

$$\|\pi_{\{n\}}(\delta(A))\|_{M,\overline{M}}\leqslant C_{\{n\}}\|\pi_{\{n\}}(A)\|_{M,\overline{M}},\quad\forall A\in\mathscr{D}, \tag{2.6}$$

where $\mathscr{D}$ is a dense-subalgebra of $\mathfrak{U}$. Then* (i) *δ has a unique extension to $\mathfrak{U}$*; (ii) *for each $A\in\mathscr{D}$, the series $\Sigma_{k=0}^{\infty}[(it)^k/k!](\delta^{(k)}(A))$ converges, with respect to the topology $\tau_{\mathscr{F}}$, to an element of $\mathfrak{U}$ that we call $\alpha_t(A)$*; (iii) *$\{\alpha_t\}_{t\in\mathbb{R}}$ is a one-parameter group of automorphisms of $\mathfrak{U}$.*

Proof: (i) The inequality (2.6) implies the $\tau_{\mathscr{F}}$ continuity of δ on $\mathscr{D}$. So there exists a unique continuous extension (which we denote with the same symbol) of δ to $\mathfrak{U}$ for which (2.6) still holds.

(ii) From (2.6) it follows also, by an induction argument, that

$$\|\pi_{\{n\}}(\delta^{(k)}(A))\|_{M,\overline{M}} \leqslant C_{\{n\}}^k \|\pi_{\{n\}}(A)\|_{M,\overline{M}}, \quad \forall A \in \mathfrak{U},$$

and so

$$\left\| \sum_{k=0}^{\infty} \frac{(it)^k}{k!} \pi_{\{n\}}(\delta^k(A)) \right\|_{M,\overline{M}} \leqslant \sum_{k=0}^{\infty} \frac{|t|^k}{k!} C_{\{n\}}^k \|\pi_{\{n\}}(A)\|_{M,\overline{M}} \quad , \forall A \in \mathfrak{U}.$$

The series on the left-hand side converges therefore in $\mathfrak{U}$ to an element that we call $\alpha_t(A)$.

(iii) follows from a simple standard calculation. □

We will now give another existence theorem for the dynamics in representation whose assumptions, indeed very strong, are satisfied by many models.

Proposition II.12: Let H_{eff} be such that for all $X \in \mathfrak{U}_0$ there exist two positive constants, $L_{X,\{n\}}$, M_X such that

$$\|[H_{\text{eff}}, \pi_{\{n\}}(X)]_k\|_{M_{\{n\}},\overline{M}_{\{n\}}} \leqslant M_X^k L_{X,\{n\}},$$

for all $k \in N$. Therefore the series $\Sigma_{k=0}^{\infty}[(it)^k/k!]\pi_{\{n\}}((\delta^{(k)}(X)))$ converges, with respect to the norm $\|\ \|_{M_{\{n\}},\overline{M}_{\{n\}}}$, to $e^{iH_{\text{eff}}t}\pi_{\{n\}}(X)e^{-iH_{\text{eff}}t}$, for each $\{n\} \in \mathscr{F}$. Therefore the series $\Sigma_{k=0}^{\infty}[(it)^k/k!](\delta^{(k)}(X))$ converges in $\mathfrak{U}[\tau_{\mathscr{F}}]$ to an element that we call $\alpha_t(X)$.

The proof is straightforward so that we will omit it. It is more interesting here to provide some examples satisfying the above hypotheses.

We consider first the almost mean-field Ising model. The effective Hamiltonian is given by $H_{\text{eff}}^{\mathscr{J}} = 2J\eta n_3 \Sigma_p[\pi_{\{n\}}(\sigma_p^3) - n_p^3]$. Let $A_k \equiv \sigma_{p_1}^{i_1} \cdots \sigma_{p_k}^{i_k}$ be an element of the basis of $\mathfrak{U}_0$. By a direct estimate we deduce that

$$\|[H_{\text{eff}}, \pi_{\{n\}}(A_k)]_l\|_{M_{\{n\}},\overline{M}_{\{n\}}} \leqslant C_{\{n\}}(4Jk)^l.$$

This inequality can be extended to a general element of $\mathfrak{U}_0$ simply using the linearity. Analogous estimates also hold for the almost mean-field Heisenberg model, for the van der Waals spin model,[13] and also for the (long-range) Ising model described by (2.2).

III. PHYSICAL APPLICATIONS

This section is devoted to discussing some explicit physical spin models that fit well in the framework discussed above. In particular, we will consider once more the almost mean-field spin models discussed in Refs. 5 and 6. After that we will also introduce more spin models, unitarily equivalent to these ones, which describes different physical situations.

A. (Almost) mean-field spin models

As before, the basic mathematical ingredient for the study of this model is the spin *-algebra $\mathfrak{U}_0$. Its norm completion, $\mathfrak{U}_S$, is not, as is known, rich enough for a comprehensive discussion of the thermodynamical limit of the algebraic dynamics.

The finite volume Hamiltonian that describes the Ising model is

$$H_V^{\mathscr{J}} = \frac{1}{|V|^{\gamma}} \sum_{i,j \in V} \sigma_i^3 \sigma_j^3, \tag{3.1}$$

while for the Heisenberg model

$$H_V^{\mathscr{H}} = \frac{1}{|V|^{\gamma}} \sum_{i,j \in V} \sum_{\alpha=1}^{3} \sigma_i^{\alpha} \sigma_j^{\alpha}. \tag{3.2}$$

For $\gamma=1$ these are typical mean-field models, extensively discussed in the literature.[7,2,11] The case $\gamma<1$ has been considered in Refs. 5 and 6.

The local Heisenberg equations of motion for both models are given by

$$\frac{d}{dt}\,\alpha_V^t(\sigma_p^i)=i[H_V,\alpha_V^t(\sigma_p^i)],\quad i=1,2,3, \tag{3.3}$$

whose solution can be easily computed as in Refs. 5 and 6.

As is known, the thermodynamical limit of $\alpha_V^t(A)$, $A\in\mathfrak{U}_0$ does not belong to $\mathfrak{U}_S$.

All the approaches suggested in the previous section, make reference to a family $\mathscr{F}$ of relevant states. For these models we choose

$$\mathscr{F}=\left\{\{n\}=\{n_1,n_2,n_3,\ldots\}:\lim_{|V|,\infty}\frac{1}{|V|^\gamma}\sum_{p\in V}n_p=\eta n,\quad |\eta|\leqslant 1\right\},$$

where n is a fixed unit vector in $\mathbb{R}^3$, which, for Ising models, has to be chosen, as well as the n_p's for large p, of the form $(0,0\pm 1)$. In the first approach, which is closer to that developed in Refs. 5 and 6, we will make use of the *weak physical topology* $\tau_{\mathscr{F}}$ defined in the previous section.

Of course, our aim is to make use of Proposition II.2. For this reason we need to find local observables S_V^i fulfilling the conditions given there. This role will be played by the ''almost'' mean spin operators. They do indeed converge, together with their powers, in the weak physical topology. This can be easily shown with analogous techniques as the ones used in Refs. 5 and 6. We prove in detail the convergence of

$$S_V^3\equiv\frac{1}{|V|^\gamma}\sum_{p\in V}\sigma_p^3, \tag{3.4}$$

for the ''almost'' Ising model in the $\tau_{\mathscr{F}}$ topology. Using the same notations as in the cited papers, and in particular by means of the spectral decomposition $M=\Sigma_{n=0}^{\infty}mP_m$, neglecting the n dependence in this formula, we have

$$\|\pi_{\{n\}}(S_V^3)-\eta n_3\|_{M_{\{n\}},\overline{M}_{\{n\}}}=\sum_{l,k=0}^{\infty}e^{-l}e^{-k}\|P_l(\pi_{\{n\}}(S_V^3)-\eta n_3)P_k\|,$$

and this last contribution can be estimated as in Ref. 5. We get, indeed,

$$\|\pi_{\{n\}}(S_V^3)-\eta n_3\|_{M_{\{n\}},\overline{M}_{\{n\}}}\leqslant\left|\frac{1}{|V|^\gamma}\sum_{p\in V}n_p^3-\eta n_3\right|\sum_l e^{-2l}+\frac{2}{|V|^\gamma}\sum_l e^{-2l+1}\to 0.$$

Moreover, even the powers converge in this topology, as is easily seen.

As far as the convergence of the algebraic dynamics α_V^t is concerned, it is also possible, and perhaps more convenient, to make use of the effective Hamiltonian H_{eff}. Both for the Ising and the Heisenberg models these effective Hamiltonian do really exist and allow us to treat both models in the same way. Indeed, at least for the Ising model, each state in the family $\mathscr{F}$ satisfies Eq. (2.4). For instance, if $A=\sigma_p^i$ then $\delta_V(A)=S_V^3(c_1\sigma_p^1+c_2\sigma_p^2)$ plus terms going to zero when $|V|\to\infty$, where c_1 and c_2 are complex numbers. If now $\{n\}\in\mathscr{F}$ it follows that for large p $\lim_{V\to\infty}\langle\{n\}|S_V^3(c_1\sigma_p^1+c_2\sigma_p^2)|\{n\}\rangle=0$. These effective Hamiltonians are given, for Ising and the Heisenberg models, respectively, by the two self-adjoint operators in $\mathscr{H}_{\{n\}}$:

$$H_{\text{eff}}^{\mathscr{I}}=2J\eta n_3\sum_p\left[\pi_{\{n\}}(\sigma_p^3)-n_p^3\right]$$

and

$$H_{\text{eff}}^{\mathscr{H}}=2J\eta\sum_p\ [\pi_{\{n\}}(\sigma_p)\cdot n-\epsilon_p].$$

Here n, n_p, and η are the quantities entering in the definition of the family $\mathscr{F}$, while ϵ_p is a sequence consisting of elements equal either to 1 or to -1, such that

$$\lim_{|V|\to\infty}\frac{1}{|V|^\gamma}\sum_{p\in V}\epsilon_p=\eta.$$

These sequences can be used to define a subset $\mathscr{F}_0$ of $\mathscr{F}$ just by considering, for a fixed three-vector n, the sequence $\{n_p\}$ where $n_p=\epsilon_p n$. The states in $\mathscr{F}_0$ are such that $H_{\text{eff}}^{\mathscr{H}}$ commutes with $M_{\{n\}}$; see Ref. 6. These effective Hamiltonians both satisfy the following condition:

$$[H_{\text{eff}},\pi_{\{n\}}(A)]=\pi_{\{n\}}(\lim_{|V|\to\infty}[H_V,A]),$$

for all $A\in\mathfrak{U}_0$. As in Ref. 6 we can therefore prove that the following equality holds true:

$$e^{iH_{\text{eff}}t}\pi_{\{n\}}(A)e^{-iH_{\text{eff}}t}=\sum_{k=0}^{\infty}\frac{(it)^k}{k!}\,\pi_{\{n\}}(\delta^{(k)}(A)),$$
