Exact solution of the Ising model on group lattices of genus $g>1$

Tullio Regge and Riccardo Zecchina
Dipartimento di Fisica, Politecnico di Torino, I-10129 Torino, Italy

(Received 5 January 1996; accepted for publication 21 February 1996)

We discuss how to apply the dimer method to Ising models on group lattices having nontrivial topological genus g. We find that the use of group extension and the existence of both external and internal group isomorphisms greatly reduces the number of distinct Pfaffians and leads to explicit topological formulas for their sign and weight in the expansion of the partition function. The complete solution for the Ising model on the Klein lattice group $L(2,7)$ with $g=3$ is given. © *1996 American Institute of Physics.* [S0022-2488(96)04006-6]

I. INTRODUCTION

Among the known approaches to the exact evaluation of the $2D$ Ising partition function which have followed the celebrated Onsager solution,[1] the dimer method[2–4] fully exploits the combinatorial and group theoretical properties of the lattices by relating the partition function $\mathcal{Z}$ to the generating function $\mathcal{Z}_d$ of close-packed dimer configurations. Though the method is in principle independent from the dimensionality of the lattice, the corresponding analysis in three dimensions has never been developed, due to the difficulties in extending Kasteleyn's Theorem on lattice orientation. In this paper, we deal with the issue of generalizing the dimer approach to the case of non-Abelian $2D$ lattices of high topological genus which should in fact be equivalent to higher dimensional lattices. Indeed the $3D$ cubic lattice can be considered as a handlebody $2D$ lattice of genus $g=N/4$ where N is the number of sites of the lattice. This hints that a non vanishing ratio g/N may be related to an effective dimension $D>2$ of the lattice. The great difficulty of the problem suggests that a possible concrete way to analyze such lattices is to consider at first graphs possessing the largest possible symmetry group, and the best candidates appear to be the group graphs already well-known in the mathematical literature.[5–8] In this framework we may consider the $2D$ planar lattice with periodic boundary conditions as an example of Abelian lattice group (translational symmetry group) with genus $g=1$, whereas an example of finite non-Abelian lattice with $g=0$ is given by the fullerene-like lattice studied in Ref. 9.

The paper is organized as follows. In Sec. II we outline the basic ideas concerning application of the dimer method to group lattices. In Sec. III we define an extended lattice group H and relate it to the homology and cohomology groups (mod2) H_1, H^1 of the original lattice Λ, define the Grassmann algebra over the decorated lattice $\Lambda^{\#}$ and the Pfaffians as function on orbits of H^1. In Sec. IV we apply the results of Sec. III to discrete groups of particular interest such as the Klein group $L(2,7)$ (of order $N=168$ and genus $g=3$) and discuss the role of external automorphisms. In Sec. V we analyze in detail the orbits of H_1, H^1 under the action of H, define an invariant duality map $\varphi: H_1 \to H^1$ and auxiliary functions of relevant computational interest. Finally, in Sec. VI we construct explicitly the irreps of H, apply them to the harmonic analysis on $\Lambda^{\#}$ and derive the expansion for $\mathcal{Z}$. Few preliminary numerical results are also given.

II. GROUP LATTICES AS ISING LATTICES

We recall here key points of the dimer procedure which are specific to group lattices (see also Refs. 10) :

(1) A discrete group G is defined by a presentation given in terms of a set of p generators

0022-2488/96/37(6)/2796/19/$10.00

$A_k, k=1,\ldots,p$ and t relators $P_i, i=1,\ldots,t$. The P_i are words in the generators equivalent to the identity. Let $\mathscr{F}$ be the free group on the $A_k, k=1,\ldots,p$. Let $\mathscr{N}$ be the minimal normal subgroup of $\mathscr{F}$ containing all relators. Then by definition $G=\mathscr{F}/\mathscr{N}$.

(2) The Cayley lattice Λ for a group is defined by giving a map $L: G \to \mathbf{R}^3$ where $L(g) \in \mathbf{R}^3$ is the point of $\mathbf{R}^3$ corresponding to the group element $g \in G$. A bond of color k is then a line joining $L(g)$ to $L(A_k g)$. The genus g of Λ is that of the surface of minimal genus $S \subset \mathbf{R}^3$ on which Λ can be drawn. The Ising Hamiltonian is then defined as

$$E = -\sum_{h \in G} \sum_{k=1}^{p} J_k \sigma_h \sigma_{A_k h}, \tag{1}$$

where the $\{\sigma_h = \pm 1\}$ are the spin variables and $\{J_k\}$ the exchange interactions between connected spins.

(3) Each relator P_i is then represented on Λ as a closed circuit $\zeta(P_i)$ made of oriented colored bonds. If $\zeta(P_i)$ encloses a simply connected region (tile) on S then P_i is called local relator. If S has genus $g=0$ then all relators are local. Of particular interest are models where g is large.

(4) The group lattice Λ is interesting on its own but cannot be related directly to the partition function of an Ising model and to do this we must consider[4] a decorated lattice $\Lambda^{\#}$. This amounts to replace each site of coordination q $(q>2)$ of the original lattice by a sublattice containing $3(q-2)$ points and $4q-9$ decorating bonds. The Ising partition function is then related to the dimer covering generating function on the decorated lattice.

(5) In order to compute the generating function we orient $\Lambda^{\#}$ according to the Kasteleyn prescription by assigning arrows to each bond inherited from Λ in such a way that for any closed circuit ℓ on $\Lambda^{\#}$, the number of bonds of ℓ oriented clockwise is of opposite parity to the number of sites enclosed by ℓ. For the decorating bonds see Ref. 4 or Sec. V.

(6) The Kasteleyn rules define completely the orientation for lattices of genus $g=0$, whereas for lattices of higher genus we have to deal with further sign fixing for loops which are not homologically trivial, i.e., not the boundary of a union of tiles. The assignment of arrows to $\Lambda^{\#}$ (or Λ) is not invariant under the action of G but rather under an extension H of G closely related to the homology H_1 and cohomology H^1 groups of Λ.

(7) The dimer covering generating function of the lattice can be expressed as a weighted sum of Pfaffians $Pf(\phi)$, where $\phi \in H^1$ and with sign given explicitly by the H-invariant function $\theta(\zeta), \zeta \in H_1$ defined in Sec. V. Harmonic analysis on H allows us to factorize Pfaffians into determinants of lesser order and external automorphisms induce identifications between Pfaffians.

III. THE EXTENDED LATTICE GROUP

In this section we first discuss the group extension H of G. Next we show that H partitions the homology H_1 and the cohomology H^1 groups of Λ into nonintersecting orbits characterized in terms of sign functionals. Their role in the expansion of the dimer generating function is then analyzed.

A. The groups H, H_1 and H^1

The extended lattice group H can be obtained from G by replacing the relators P_i with new relators containing the following elements:

(**i**) If $P_i, P_j \in G$ are local, then $P_i P_j^{-1}, P_i^2, P_i A_k P_i^{-1} A_k^{-1}$ are relators in H;

(**ii**) For generic relators $P_i, P_j \in G$ then $P_i^2, P_j^2, P_i P_j P_i^{-1} P_j^{-1}$ are relators in H.

We can write then $P_j = Q$ $(Q^2 = 1)$ for all local relators P_j, with $A_k Q = Q A_k$, i.e. Q is a central element that we call central signature. Putting $Z_i = P_i Q$ the nonlocal relators will be written as $Z_i^2, Z_i Z_j Z_i^{-1} Z_j^{-1}$ where in general $A_k Z_i \neq Z_i A_k$. The $\{Z_i\}$ generate an Abelian normal subgroup $HZ \subset H$. Particular examples of this extension will be discussed further on.

Nontrivial loops form a chain group $C_1(\Lambda^{\#}, \mathbf{Z_2})$. The equivalence classes of $C_1(\Lambda^{\#}, \mathbf{Z}_2)$ modulo boundaries form the homology group $H_1(\Lambda^{\#}, \mathbf{Z}_2)$. The class of multiplicative functionals on $H_1(\Lambda^{\#}, \mathbf{Z}_2)$ with values ± 1 are then the elements of the cohomology group $H^1(\Lambda^{\#}, \mathbf{Z}_2)$. Notice that $H^1(\Lambda^{\#}, \mathbf{Z}_2) \sim H^1(\Lambda, \mathbf{Z}_2)$ and $H_1(\Lambda^{\#}, \mathbf{Z}_2) \sim H_1(\Lambda, \mathbf{Z}_2)$ and therefore we denote them briefly by the symbols H^1, H_1 respectively. When dealing with elements of HZ, H_1 we may use addition instead of the product as composition rule. We write $g \sim g'$ if $g, g' \in H$ define the same site on Λ.

H_1 is isomorphic to HZ. To see it consider the closed chain ℓ on Λ as defined by the sequence $g_0 = g, g_p = h_p g_{p-1}, p = 1, \ldots, n$ with $h_{n+p} = h_p$. $\zeta(\ell)$ is then defined as

$$\zeta(\ell) = g_0^{-1} h_n h_{n-1} \cdots h_1 g_0 = g_p^{-1} h_{p-1} h_{p-2} \cdots h_1 h_n h_{n-1} \cdots h_{p+1} g_p . \tag{2}$$

Starting from g_0 we move n steps across bonds in Λ and each bond defines an element $h_i \in H$, where $h_i = A_k^{\pm 1}$, A_k being a generator of H. If $g_n \sim g_0$, ℓ is closed, $\zeta(\ell) \in HZ$ does not depend on the choice of g_0 on ℓ and defines a map $\zeta: C_1(\Lambda, \mathbf{Z}_2) \to HZ$. Adding a boundary ℓ_0 to ℓ (i.e., adding the boundary of a union of tiles on the lattice) amounts to replace a sequence of bonds $h_{i_1}, \ldots, h_{i_n}$ by an equivalent one obtained by using local relators only, therefore $\zeta(\ell + \ell_0) = \zeta(\ell)$ and ζ induces the map $\kappa: H_1 \to HZ$. Given inversely an element $\zeta \in HZ$, expressed in terms of relators as $\zeta = h_n \cdots h_1$, a corresponding closed chain $\ell(\zeta) \in C_1(\Lambda, \mathbf{Z}_2)$, and therefore a cycle in $H_1(\Lambda, \mathbf{Z}_2)$, is given by a sequence of g_i, $i = 0, \ldots, n$, with $g_0 = \mathbf{1}$ and $h_i g_{i-1} = g_i$. Also if $\zeta = h_n \cdots h_1, \zeta' = h_{m+n} \cdots h_{1+n} \in HZ$ and $g_n \sim g_{m+n} \sim \mathbf{1}$ the chain $\ell(\zeta + \zeta') = \ell(\zeta) + \ell(\zeta') \in C_1(\Lambda, \mathbf{Z}_2)$ defined by $g_0 = \mathbf{1}$ and $h_i g_{i-1} = g_i, i = 1 \cdots m+n$ corresponds to the element $\zeta + \zeta' \in HZ$. Hence κ is a group isomorphism.

Right multiplication on Λ by an element $h \in H$ translates the group lattice and if we replace g_i with $g_i h$ in ℓ we obtain a closed path ℓ_h which is the right translation of ℓ by h and a corresponding element $\zeta(\ell_h) = h^{-1} \ell h$ which defines the action of H on $\ell \in HZ$. In this way H acts naturally on $\Lambda^{\#}$, H_1 and H^1 and partitions H^1, H_1 into nonintersecting orbits. The use of orbits greatly simplifies the computation of $\mathcal{Z}$.

B. Sign functionals and lattice orientation

We assign an orientation to $\Lambda^{\#}$ according to the Kasteleyn rules and to each site $h \in H$ a Grassmann variable $a(h)$, with an anticommuting wedge product $a(h) \wedge a(h') = -a(h) \wedge a(h')$. Reversing the arrows on all bonds sharing the same site i corresponds to the change $a(h) \to -a(h)$.

Let ℓ given by (2). Each h_i is of the form $A_{k_i}^{p_i}$ where $p_i = \pm 1$ determines the orientation of the arrow in the bond. Closing ℓ means that we must identify $a(g_0)$ and $a(g_n)$ as

$$a(g_0) = p_n a(g_n). \tag{3}$$

We define then

$$\eta(\zeta(\ell)) = -\prod_{i=1}^{n} p_i . \tag{4}$$

If ζ is trivial then $\eta(\zeta) = 1$. All $\eta(\zeta)$ defined in this way, hereafter called sign functionals, are characterized by a particular recursion relation which can be proved as follows. Following Ref. 4

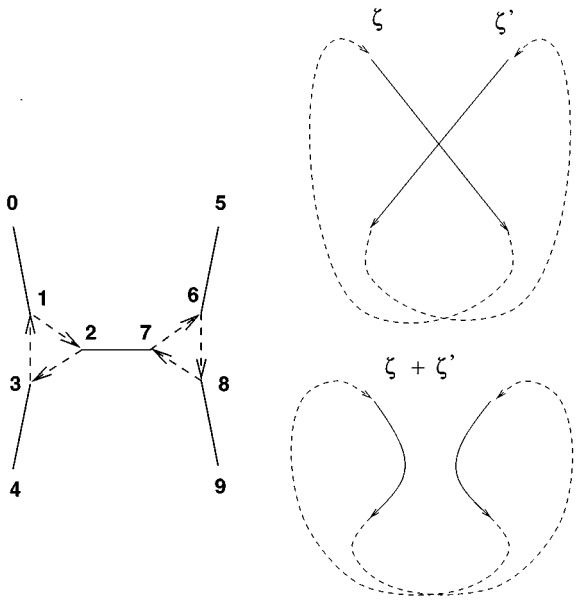

FIG. 1. Intersection between ℓ and ℓ' and schematic representation of ζ,ζ' and $\zeta+\zeta'$ (or ℓ,ℓ' and ℓ'').

we introduce a reference dimer configuration $\mathscr{C}_0$ on $\Lambda^{\#}$ consisting of all bonds of $\Lambda^{\#}$ inherited from Λ. By definition, any other dimer configuration $\mathscr{C}$ when superposed on $\mathscr{C}_0$ generates transition cycles $\zeta \in H_1$. In this proof we use transition cycles only. We consider representative chains $\ell,\ell',\ell'' \in C_1(\Lambda\#,\mathbf{Z}_2)$ of the pair of intersecting cycles ζ,ζ' and of the cycle $\zeta+\zeta'$ as in Fig. 1. Chains ℓ,ℓ' run over the sequence of sites P_i, $i=0,1,2,7,8,9$ and $i=5,6,7,2,3,4$ respectively, while ℓ'' runs over $i=0,1,3,4$ and $i=5,6,8,9$ but not $i=2,7$. We denote with B_{ij} the bonds joining P_i,P_j and with $n(\ell)$ the number of anticlockwise arrows on ℓ. The key point is that bonds B_{12},B_{13} are not contained in the intersection of ζ and $\zeta+\zeta'$ and thus $B_{12},B_{13}\notin\mathscr{C}_0$ whereas $B_{01}\in\mathscr{C}_0$. Similarly $B_{34},B_{27},B_{56},B_{89}\in\mathscr{C}_0$. By orienting $\Lambda^{\#}$ according to the Kasteleyn rules and counting arrows we see that $n(\ell'')\equiv n(\ell)+n(\ell')+1(\mathrm{mod}2)$. The general case where B_{ij} are replaced by sequences of bonds corresponds to the addition of boundaries to ℓ,ℓ',ℓ'' and leads to the same formula. Hence $n(\ell)$ is a function in H_1 and $\eta(\zeta+\zeta')=-\eta(\zeta)\eta(\zeta')$ if ζ,ζ' intersect and $\eta(\zeta+\zeta')=\eta(\zeta)\eta(\zeta')$ otherwise , i.e.,

$$\eta(\zeta+\zeta')=\eta(\zeta)\eta(\zeta')(-1)^{\Omega(\zeta,\zeta')}, \tag{5}$$

where $\Omega(\zeta,\zeta')=0,1$ is the intersection number (mod2) of ζ,ζ'. Given a sign functional $\eta(\zeta)$ then $\phi(\zeta)\eta(\zeta)$, $\phi\in H^1$, is another sign functional and so is the H-invariant function $\theta(\zeta),\zeta\in H_1$ defined in Sec. V.

C. Pfaffians and dimer covering generating function

Consider now the form

$$f=\frac{1}{2}\sum_{h,h'\in\Lambda^{\#}} x_{hh'}a(h)\wedge a(h'), \tag{6}$$

where $x_{hh'}=0$ if h and h' are not connected in $\Lambda^{\#}$ (neighbors). The factor $\frac{1}{2}$ is inserted in order to avoid double counting, the activity is given by $x_b=x_{hh'}=-x_{h'h}=\coth(\beta J_{hh'})$ if the bond b is oriented with the arrow from h to h', β is the inverse temperature and $J_{hh'}$ the exchange

interaction between spins (J_k in the previous notation) which depends only on the color k of the bond. Under the stated conditions decorating bonds have $x_{hh'}=1$. For the sole purpose of safe handling of signs we assume initially $x_b>0$. All arrows on $\Lambda^{\#}$ and all signs in (6) are then fixed by the sign functional η. The Pfaffian $Pf(\eta)$ is defined by

$$f^{M/2}=2^M M! Pf(\eta) a(1)\wedge a(2)\wedge\cdots\wedge a(M), \tag{7}$$

where $M=3(q-2)N$, N is the order of the group (or lattice size) and q is the lattice coordination. From (7) one derives the well-known relation

$$Pf(\eta)^2=Det(X(\eta)), \tag{8}$$

where $X(\eta)$ is the $M\times M$ matrix of elements x_{ij}. In general $Pf(\eta)$ is multilinear function of the x_b considered as independent variables. The partition function $\mathcal{Z}$ is then given by

$$\mathcal{Z}=\mathcal{Z}_d\, 2^N\prod_a \sinh(\beta J_a)^{1/2}, \tag{9}$$

where a runs on all the oriented bonds of the undecorated group lattice and

$$\mathcal{Z}_d=2^{-g}\sum_\eta s_\eta Pf(\eta), \quad s_\eta=\pm 1. \tag{10}$$

To each dimer configuration $\mathcal{C}$ we associate the contribution of $\mathcal{C}$ to $Pf(\eta)$, a monomial $M(\mathcal{C})=\Pi_b x_b$ where b runs over all oriented bonds of $\mathcal{C}$. Because of our conventions $M(\mathcal{C})$ has sign $\eta(\zeta)$ where ζ is the superposition of $\mathcal{C}$ and $\mathcal{C}_0$. In general ζ is the sum of nonintersecting cycles $\zeta=\Sigma_i\zeta_i$ so that $\eta(\zeta)=\Pi_i\eta(\zeta_i)$. The signs s_η must then be chosen in such a way as to set equal to 1 in (10) the coefficient of all $M(\mathcal{C})$ appearing in $\mathcal{Z}_d$. Once this is done in Sec. V the x_b can be given any sign.

IV. 2*D* ISING LATTICE AND THE *L*(2,7) LATTICE GROUP

The above group extension procedure can be naturally applied to a wide class of lattice groups. Here we discuss two examples: the Abelian $2D$ Ising lattice (of genus $g=1$) and the $L(2,7)$ Klein group. The latter is non-Abelian and of genus $g=3$, and its analysis should hopefully be of interest in the analysis of more general structures of dimension $D>2$.

A. 2*D* Ising lattice

The Onsager solution for the $2D$ Ising lattice made use of a rectangular $n\times m$ lattice with sites labelled by $i=1,\ldots,n$ and $j=1,\ldots,m$ (n even). In this lattice we identify opposite sides, giving it a toroidal ($g=1$) topology and turning in a group lattice G_{nm}. This last property makes it possible to apply harmonic analysis, i.e., Fourier transform methods, which eventually lead to the final formula. The group G_{nm} of the lattice is defined by the presentation

$$ST=TS, \quad S^n=\mathbf{1}, \quad T^m=\mathbf{1}, \tag{11}$$

for all integers n,m. However in order to satisfy the Kasteleyn rules we must use a central extension H_{nm} of (11) defined by

$$ST=QTS, \quad S^n=Z_1, \quad T^m=Z_2,$$

$$Q^2=Z_1^2=Z_2^2=1, \quad QZ_1=Z_1Q, \quad QZ_2=Z_2Q, \quad Z_1Z_2=Z_2Z_1. \tag{12}$$

Sites are labeled by elements $h\in H_{nm}$ with the condition

$$a(hQ) = -a(h). \tag{13}$$

The H_{nm} lattice is actually a covering of the G_{nm} lattice with corresponding variables $a(h)$ identified by the above condition which embodies the Kasteleyn rules.

Besides this condition we must set

$$a(hZ_1) = \epsilon_1 a(h), \quad a(hZ_2) = \epsilon_2 a(h), \tag{14}$$

where ϵ_1 and ϵ_2 take the values ± 1 in all the possible combinations. These correspond to the $2^{2g}=4$ possible choices of $\phi \in H^1$. It is tempting but misleading to label spin sites on the lattice by elements in G_{nm}. In this case the orientation would no longer be invariant under G_{nm}, a clear sign that the true symmetry is that of the extended group H_{nm}.

B. Non-Abelian group lattices of genus $g>1$

We examine now other types of symmetries which require non-central group extensions and which are of interest for models in $D>2$. The natural further step is provided by a vast array of discrete groups many of which are discussed in detail in the literature (see Refs. 5–8). Of particular interest are the Klein groups $L(2,p)$, where p is prime. The non-Abelian group of genus $g=0$ (the fullerene lattice) studied in Ref. 9 corresponds to $p=5$. The next interesting example which is at the same time non-Abelian and has a nontrivial topology is given by the lattice group $L(2,7)$ (also called $T(2,3,7)$ in the context of hyperbolic tessellations). The $L(2,7)$ group , briefly called G, has order 168 and is defined by the presentation

$$U^7 = \mathbf{1}, \quad V^2 = \mathbf{1}, \quad (UV)^3 = \mathbf{1}, \quad (VU^3)^4 = \mathbf{1}. \tag{15}$$

The analysis of a lattice possessing this kind of symmetry is one of the chief results of this paper which hopefully opens the way to the investigation of more general and interesting structures. The group lattice given by (15) has genus $g=3$ (produced by the nonlocal relator $(VU^3)^4$) and can be tessellated by 24 heptagons and 56 hexagons, for a total of 168 bonds of type U and 84 bonds of type V (see Ref. 11, pp. 539–549, for more details on the lattice).

The group G_{nm} given by (11) is Abelian and has a nontrivial genus $g=1$. On a lattice of genus g we expect that the Kasteleyn rule determines the orientation up to $2g$ signs with a total of 2^{2g} configurations. Each close path on the lattice Λ can be considered as an element of the homology group H_1 and an assignment of all remaining signs as an element of the cohomology group H^1. It is therefore sufficient to assign signs on a suitable basis of $2g$ elements of H_1. In the toroidal case this was done by giving ϵ_1, ϵ_2. In fact Z_1, Z_2 are central in the group G_{nm}.

The group G, as defined by (15), is non-Abelian and has a nontrivial genus, in particular the Z_i are no longer central elements and we deal with the discussed noncentral extension H of G defined by

$$U^7 = Q, \quad V^2 = Q, \quad (UV)^3 = Q, \quad W \equiv Q(VU^3)^4 = Z(\mathbf{1}), \tag{16}$$

and additional relators which can be expressed in term of the auxiliary elements

$$Z(h) = h^{-1} W h, \quad h \in H, \tag{17}$$

characterized by

$$Z(h_1)Z(h_2) = Z(h_2)Z(h_1), \quad (Z(h))^2 = 1, \quad \forall h_1, h_2, h \in H. \tag{18}$$

The $Z(h)$ are not all independent and can be expressed in terms of the subset of $2g=6$ elements

$$Z_n \equiv Z(U^n) = U^{-n} Z(\mathbf{1}) U^n. \tag{19}$$

Clearly $Z_n = Z_{n,(\mathrm{mod}7)}$ and $Z_0 = Z(\mathbf{1}) = Z_7$. The following identities equivalent under (18)

$$Z_5 Z_1 Z_4 Z_0 Z_3 Z_6 Z_2 = \mathbf{1}, \quad Z_1 Z_3 Z_5 Z_0 Z_2 Z_4 Z_6 = \mathbf{1}, \tag{20}$$

reduces to 6 the number of independent elements Z_i and can be proved by repeated application of relators (16) but not of (18).

A generic $\zeta \in H_1$can be always written in the additive form $\Sigma_i n_i Z_i$ where $n_i = 0,1$. Because of $\Sigma_{i=0}^{6} Z_i = 0$ we can always choose the n_i in such a way as to have $\Sigma_i n_i = 0$ or 1. All elements $Z(h), h \in H$, can be obtained by repeated conjugation of the Z_n by U and V. Conjugation by U is trivial, i.e. $U^{-1} Z_n U = Z_{n+1}$. Conjugation by V is less obvious. By using (16) and not (18) we find that

$$V^{-1} Z_0 V = Z_4, \quad V^{-1} Z_1 V = Z_3^{-1} Z_0^{-1}, \quad V^{-1} Z_2 V = Z_4^{-1} Z_2^{-1} Z_0^{-1},$$

$$V^{-1} Z_3 V = Z_4^{-1} Z_1^{-1}, \quad V^{-1} Z_4 V = Z_0, \quad V^{-1} Z_5 V = Z_5^{-1}, \quad V^{-1} Z_6 V = Z_6^{-1}, \tag{21}$$

which can be further simplified by using (18). In the additive form (21) and (19) can be written in full generality as

$$h^{-1} Z_i h = \sum_{k=0}^{6} P_{ik}(h) Z_k, \quad h \in H, \tag{22}$$

where $P(h)$is a representation mod 2 of H.

Moreover the group H has an external automorphism ν given by

$$\nu(V) = V^{-1} = -V, \quad \nu(U) = U^{-1}, \quad \nu(Z_p) = Z_{4-p}^{-1} = Z_{4-p}. \tag{23}$$

V. ORBITS OF HOMOLOGY AND COHOMOLOGY GROUPS

As anticipated, the analysis of orbits and of external automorphisms plays a central role in the computation of $\mathcal{Z}_d$. We thus give here the explicit construction of such orbits in H_1 and H_1, together with their duality map.

A functional $\phi \in H^1$ can be defined by the equivalent conditions:

$$a(gZ_i) = \epsilon_i a(g), \phi(Z_i) = \varepsilon_i, \quad i = 0, \ldots, 6; \quad \prod_{i=0}^{6} \epsilon_i = 1, \tag{24}$$

ϕ is then identified by $(\epsilon_0, \ldots, \epsilon_6)$. Let $\zeta \in H_1$ and let $h^{-1}\zeta h$ be the translated cycle. Then the translated functional ϕ_h is defined by

$$\phi_h(h^{-1}\zeta h) = \phi(\zeta). \tag{25}$$

We have then

$$\phi_U(U^{-1} Z_i U) = \phi(Z_i) = \epsilon_i = \phi_U(Z_{i+1}), \tag{26}$$

and hence

$$\phi_U(Z_i) = \epsilon_{i-1}, \quad \phi_{U_{-1}}(Z_i) = \epsilon_{i+1}. \tag{27}$$

Similarly we find

$$\phi_V(V^{-1} Z_0 V) = \phi(Z_0) = \epsilon_0 = \phi_V(Z_4), \tag{28}$$

and

$$\phi_V(Z_0)=\epsilon_4,\quad \phi_V(Z_3)=\epsilon_1\epsilon_4,\quad \phi_V(Z_2)=\epsilon_0\epsilon_4\epsilon_2,$$
$$\phi_V(Z_1)=\epsilon_3\epsilon_0,\quad \phi_V(Z_5)=\epsilon_5,\quad \phi_V(Z_6)=\epsilon_6. \tag{29}$$

There are $2^{2g}=64$ ($g=3$ denoting the genus of Λ) different elements in H^1 which fall in 5 different orbits containing 1,7,7,21,28 elements. We list these orbits with only one signature out of each cyclically permuted septet:

$$A:(1,1,1,1,1,1,1)\quad \text{(trivial)},$$
$$B:(1,1,-1,1,-1,-1,-1),$$
$$C:(-1,-1,-1,1,-1,1,1),$$
$$D:(-1,-1,-1,1,-1,-1,-1),(-1,-1,1,1,1,-1,-1),(1,1,-1,1,-1,1,1),$$
$$E:(-1,1,-1,1,-1,1,-1),(1,-1,-1,1,-1,-1,1),(-1,1,1,1,1,1,-1),(1,-1,1,1,1,-1,1). \tag{30}$$

The orbits B,C are mapped into each other by the action of ν. This proves incidentally that ν is external. We also list in similar fashion the dual orbits in H_1:

$$A:(0,0,0,0,0,0,0)\quad \text{(trivial)},$$
$$B:(1,1,0,0,1,0,1),$$
$$C:(1,0,1,0,0,1,1),$$
$$D:(0,0,1,0,1,0,0),(0,1,1,0,1,1,0),(0,1,0,0,0,1,0),$$
$$E:(1,0,0,0,0,0,1),(1,1,1,0,1,1,1),(1,1,0,0,0,1,1),(1,0,1,0,1,0,1), \tag{31}$$

as it can be checked by using (28)–(29).

For generic elements $\zeta,\zeta' \in H_1$ we use the additive form:

$$\zeta=\sum_{i=0}^{6} n_i Z_i,\quad \zeta'=\sum_{i=0}^{6} m_i Z_i, \tag{32}$$

and define the intersection number (mod2)

$$\tau(\zeta,\zeta')=\tau(\zeta',\zeta)=(-1)^{\Omega(\zeta,\zeta')}. \tag{33}$$

Ω is the $\mathbf{Z}_2$ valued form of Eq. (5) explicitly given by

$$\Omega(\zeta,\zeta')=\sum_{i,k=0}^{6} \chi(i-k)n_i m_k \tag{34}$$

with $\chi(i)=1$ if $i\equiv 1,2,5,6 \pmod 7$ and $\chi(i)=0$ otherwise, as it can be verified on the graph $\Lambda^{\#}$. $\tau(\zeta,\zeta')$ is invariant under conjugations by H, see (21), and is multiplicative, i.e.,

$$\tau(\zeta,\zeta'+\zeta'')=\tau(\zeta,\zeta')\tau(\zeta,\zeta''). \tag{35}$$

We define also

$$\theta(\zeta)=(-1)^{\frac{1}{2}\sum_{i,k=0}^{6}\chi(i-k)n_i n_k}, \tag{36}$$

so that $\theta(Z_i)=\theta(\mathbf{1})=1$ and $\theta(\zeta)$ is a sign functional as η in (5):

$$\theta(\zeta+\zeta')=\theta(\zeta)\theta(\zeta')\tau(\zeta,\zeta'). \tag{37}$$

All these definitions can be extended naturally to a wide class of lattice groups.

Then let

$$m_i=\sum_{k=0}^{6}\chi(i-k)n_k \tag{38}$$

and define the duality map $\varphi, H_1\to H^1$:

$$\varphi\left(\sum_{i=0}^{6} n_i Z_i\right)=((-1)^{m_0},\ldots,(-1)^{m_6}). \tag{39}$$

The 2^{2g} elements of H_1, H^1 are labeled as ζ_I, ϕ_I, where $\varphi(\zeta_I)=\phi_I$, by an index $I=1,\ldots,2^{2g}$ with ζ_1, ϕ_1 the trivial elements and sorted in such a way that in (31),(30) φ maps corresponding orbits in H_1, H^1. Clearly then $\phi_I(\zeta_K)=\tau(\zeta_I,\zeta_K)$. We set $\eta_I(\zeta)=\phi_I(\zeta)\theta(\zeta)$, $s_I=s_{\eta_I}$ so that we may label Pfaffians equally well with elements $\phi\in H^1$ and rewrite (10) as

$$\mathcal{Z}_d=2^{-g}\sum_I s_I Pf(\phi_I). \tag{40}$$

The importance of orbits should be clear once we realize that in (40) for elements ϕ_I, ϕ_J in the same orbit we have $Pf(\phi_I)=Pf(\phi_J)$. In this way the effective number of different terms in $\mathcal{Z}_d$ reduces to the number of orbits in H^1.

Further reductions arise from external automorphisms. When omitted, as in (40), we assume summation ranges on I,K to be $1\cdots 2^{2g}$. Since φ commutes with the group operations it maps orbits in H_1 into dual orbits in H^1 and we use the same label $A\cdots E$ for pairs of dual orbits. Moreover the $2^{2g}\times 2^{2g}$ matrix $\Phi=\Phi^T$ of elements $\Phi_{KI}=2^{-g}\tau(\zeta_I,\zeta_K)$ is orthogonal. First of all we have

$$\sum_I \Phi_{KI}^2=2^{-2g}\sum_I 1=1. \tag{41}$$

Next we have

$$\begin{aligned} p(K,K')=\sum_I \Phi_{KI}\Phi_{K'I}&=2^{-2g}\sum_I \phi_K(\zeta_I)\phi_{K'}(\zeta_I)\\ &=2^{-2g}\sum_I \phi_K(\zeta_I+\xi)\phi_{K'}(\zeta_I+\xi)\\ &=2^{-2g}\sum_I \phi_K(\zeta_I)\phi_{K'}(\zeta_I)\phi_K(\xi)\phi_{K'}(\xi)\\ &=p(K,K')\phi_K(\xi)\phi_{K'}(\xi) \end{aligned} \tag{42}$$

therefore $p(K,K')=0$ if $\exists\xi$: $\phi_K(\xi)\phi_{K'}(\xi)\neq 1$. But if $\forall\xi$: $\phi_K(\xi)\phi_{K'}(\xi)=1$ then $K=K'$ therefore $p(K,K')=0$ if $K\neq K'$. This proves that Φ is orthogonal and that $\Phi=\Phi^{-1}$.

We conclude this section with some rather technical formulas whose rôle will be crucial in what follows (Sec. VIII).

The sum $\Sigma_K\theta(\zeta_K)$ can be readily evaluated by using a standard basis for H_1 given by $X_i, Y_i, i=1\cdots g$ such that

$$\theta\left(\sum_i^g (p_iX_i+q_iY_i)\right)=(-1)^{\sum_{i=1}^g p_iq_i}, \tag{43}$$

where, for instance,

$$X_1=Z_0,\quad Y_1=Z_1,\quad X_2=Z_1+Z_5,\quad Y_2=Z_0+Z_2+Z_5,\quad X_3=Z_0+Z_3, Y_3=Z_1+Z_3+Z_6. \tag{44}$$

In this form $\Sigma_K\theta(\zeta_K)$ factors into g independent and equal sums each yielding a factor 2 and hence $\Sigma_K\theta(\zeta_K)=2^g$.

Furthermore,

$$2^{-g}\sum_K \tau(\zeta_I,\zeta_K)\theta(\zeta_K)=2^{-g}\theta(\zeta_I)\sum_K \theta(\zeta_K+\zeta_I)=\theta(\zeta_I) \tag{45}$$

since $\zeta_K+\zeta_I$ runs over the whole group H_1 taking every element once just as ζ_K and therefore $\Sigma_K\theta(\zeta_K+\zeta_I)=\Sigma_K\theta(\zeta_K)=2^g$.

VI. IRREPS OF *H*

The group H has $168\times 64=10752$ elements and in order to perform harmonic analysis and obtain partial block diagonalization of $X(\phi)$ and of Pfaffians we must find the unitary irreducible representations (irreps) of H.

The trivial functional (1,1,1,1,1,1) must be dealt with separately and requires the construction of the irreps of the factor group H_0 of H and central extension of G defined by

$$U^7=Q,\quad V^2=Q,\quad (UV)^3=Q,\quad (VU^3)^4=Q \tag{46}$$

(i.e., $Z_i=\mathbf{1}$) of order $168\times 2=336$. Therefore we have the relators

$$a(gZ_i)=a(g),\quad a(gQ)=-a(g). \tag{47}$$

Because of (47), only a subset of the unitary irreps of H_0 is actually used in the harmonic analysis. In order to see it let us write such irreps as $D^J_{\alpha\beta}(g)$ with J a convenient label and $\alpha,\beta=1,\ldots,d_J$ where d_J is the dimension of the irrep . The matrix elements satisfy the orthogonality relations:

$$\sum_{g\in H_0} D^J_{\alpha\beta}(g)^* D^{J'}_{\alpha'\beta'}(g)=\delta^{JJ'}\delta_{\alpha\alpha'}\delta_{\beta\beta'}. \tag{48}$$

Let us define

$$a^J_{\alpha\beta}=\sum_{g\in H_0} a(g)D^J_{\alpha\beta}(g). \tag{49}$$

Applying (49) to (47) we get

$$\sum_{g\in H_0} a(gQ)D^J_{\alpha\beta}(g) = -a^J_{\alpha\gamma} = a^J_{\alpha\gamma}D^J_{\gamma\beta}(Q). \tag{50}$$

But Q is a central element and $Q^2=\mathbf{1}$. Therefore by Schur lemma $D^J_{\gamma\beta}(Q)$ must be proportional to the identity, i.e.,

$$D^J_{\gamma\beta}(Q)=\kappa\delta_{\gamma\beta}, \quad \kappa=\pm 1, \tag{51}$$

therefore from (50)

$$\kappa a^J_{\alpha\gamma} = -a^J_{\alpha\gamma}, \tag{52}$$

i.e., $\kappa=-1$. It follows that only irreps having $\kappa=-1$ actually contribute to the Fourier expansion of $a(g)$. Those irreps which are also irreps of the original group G (i.e., those with $\kappa=1$) are absent from the expansion. There are only 5 irreps of H_0 with $\kappa=-1$ of dimension 4,4,6,6,8, satisfying separately the Burnside condition $4^2+4^2+6^2+6^2+8^2=168$. The detailed form is listed in Appendix A. The matrix elements of these irreps are polynomials in $K=\exp(i\pi/7)$ with $K^7=-1$. By abuse of language we may write

$$Q=-1, \quad U^7=-1, \quad V^2=-1, \quad (UV)^3=-1, \quad (VU^3)^4=-1, \tag{53}$$

instead of (46).

As for the remaining irreps of H the most convenient way is to obtain them as induced representations on the cosets of the subgroup L of H generated by

$$V, \quad U^{-1}VU^2, \quad U^{-6}VU^3, \quad U^{-4}VU^4, \quad U^{-5}VU^5, \tag{54}$$

as well as the cosets of the group $\nu(L)$ generated by

$$V^{-1}, \quad UV^{-1}U^{-2}, \quad U^6V^{-1}U^{-3}, \quad U^4V^{-1}U^{-4}, \quad U^5V^{-1}U^{-5}. \tag{55}$$

All generators and their inverses are of the form $U^{a(b)}VU^b, b=0,\ldots,6$. Let us briefly set $v=V$ and $t=U^{-1}VU^2$; we find then

$$\begin{gathered} U^{-6}VU^3=vt, \quad U^{-4}VU^4=Z_1(tv)^2=(tv)^2Z_4, \\ U^{-5}VU^5=vt(vt^{-1})^2Z_1=Z_2Z_6vt(vt^{-1})^2, \\ (vt)^4=QZ_3, \quad (tv)^4=QZ_1Z_4. \end{gathered} \tag{56}$$

It can be verified that $\{v,t,Z_i,Q\}$ generate the whole subgroup L. Let suppose that a representation $\lambda: L\to \mathrm{Hom}(\mathscr{S})$ is given on a linear space $\mathscr{S}$ of dimension n. Then λ can be extended to the induced representation μ: $H\to$ Hom$(\mathscr{H})$ where $\mathscr{H}\oplus_{p=0}^{6}\mathscr{S}_p$ and $\mathscr{S}_p$ are isomorphic to $\mathscr{S}$. Let ψ_i be a basis on $\mathscr{S}$, $\psi_{i,p}$ a basis on $\mathscr{S}_p$ and $\psi_{i,p+7}=-\psi_{i,p}$. The action of U on $\mathscr{H}$ is then defined by

$$U\psi_{i,p}=\psi_{i,p+1}, \tag{57}$$

hence $U^7=-1$. Moreover we set

$$w\psi_{i,0}=\psi_{k,p}\lambda_{k,i}(w), \quad w\in L. \tag{58}$$

From (56)–(58) derive the representation of V on $\mathscr{H}$ as follows:

$$V\psi_{i,b}=VU^b\psi_{i,0}=U^{a(b)}U^{-a(b)}VU^b\psi_{i,0}=U^{a(b)}\psi_{k,0}\lambda(U^{-a(b)}VU^b)_{k,i}$$
$$=\psi_{k,a(b)}\lambda(U^{-a(b)}VU^b)_{k,i}. \tag{59}$$

Since b can take all values $0,\ldots,6$ we deduce the complete representation of V on $\mathscr{H}$. The problem reduces now to that of finding a suitable representation of L on $\mathscr{L}$. Should we set $Q=Z_i=\mathbf{1}$, L becomes the octahedral group $T(2,3,4)$ of order 24. We are interested in irreps of L in which all $\lambda(Z_i)$ are diagonal and $\lambda(Z_i^2)=\mathbf{1}$. Each $\lambda(Z_i)$ is then a diagonal block matrix. In fact we have

$$Z_0\psi_{i,p}=Z_0U^p\psi_{i,0}=U^pZ_p\psi_{i,0}=U^p\lambda(Z_p)\psi_{i,0}=\lambda(Z_p)\psi_{i,p}. \tag{60}$$

It is then clear that $\mu(Z_s)$ is the diagonal matrix with entries $\lambda(Z_s)$, $\lambda(Z_{s+1}),\ldots,\lambda(Z_{s+6})$, where $\lambda(Z_s)$ has n eigenvalues $\xi_{i,s}=\pm1, i=1,\ldots,n, s=0,\ldots,6$. It follows also that each vector $\psi_{i,p}$ has eigenvalues

$$Z_s\psi_{i,p}=\xi_{i,s+p}\psi_{i,p}, \tag{61}$$

which define the element $\Xi\in H^1$:

$$\Xi=(\xi_{i,p},\xi_{i,p+1},\ldots,\xi_{i,p+6}). \tag{62}$$

For the group $\nu(L)$ the corresponding formulae are obtained by setting $v'=V^{-1}, t'=UV^{-1}U^{-2}$. We have then

$$U^6V^{-1}U^{-3}=v't', \quad U^4V^{-1}U^{-4}=Z_3(t'v')^2=(t'v')^2Z_0, \tag{63}$$

$$(v't')^4=QZ_0^{-1}, \quad (t'v')^4=QZ_0^{-1}Z_3^{-1}. \tag{64}$$

If an irrep of H contains a signature Ξ it contains also the whole orbit including its cyclical permutations. Nontrivial functionals have 7 distinct cyclical permutation of any Ξ corresponding to $p=0,\ldots,6$ in (62). The irrep μ of H generated by λ has dimension $7n$ and as many signatures. If it contains different orbits then is reducible. Therefore irreps can be grouped in disjoint subsets characterized by orbits. Irreps belonging to orbits A,D,E can be obtained either from L or $\nu(L)$ whereas B and C can be obtained only from L and $\nu(L)$ respectively. We list in Appendix B the explicit representations λ of the group L corresponding to each orbit by giving $\lambda(v),\lambda(t)$ and $\lambda(Z_1)$. In this way we obtain the irreps of the orbits A,B,D,E. Irreps of orbit C can be obtained by applying ν to irreps of B. Clearly orbits may appear in some irreps with multiplicities $m=1,2,4$ where n/m is the number of inequivalent signatures under cyclical permutations contained in the orbit. The method applied to orbits A yields representations which reduce into the irreps already discussed. The dimensions of the irreps satisfy a separate Burnside condition

$$\sum_{J\in O} d_J^2=n(O)N, \tag{65}$$

where $n(O)$ is the number of signatures belonging to a given orbit O.

VII. THE DECORATED LATTICE AND THE PARTITION FUNCTION

We need now a more explicit description of the decorated lattice $\Lambda^{\#}$ along lines already discussed in Ref. 9. Each element $h\in H$ identifies uniquely a site of Λ which we also label with h, being intended that $hQ\sim hZ_i\sim Z_ih$ identify the same site of Λ. h is connected to other 3 sites $Vh,Uh,U^{-1}h$ and is replaced in $\Lambda^{\#}$ by 3 sites h_a,h_b,h_c to which we associate Grasmann variables $a(h),b(h),c(h)$. The original oriented bonds $h\to Vh, h\to Uh$ are replaced by oriented

bonds $h_a \to Vh_a, h_b \to Uh_c$ (with exchange interaction J_V, J_U respectively) together with the additional decorating bonds $h_a \to h_c, h_c \to h_b, h_b \to h_a$. For each Pfaffian we need boundary conditions of the kind discussed above:

$$a(hZ_i) = \epsilon_i a(h), \quad a(Qh) = a(hQ) = -a(h) \tag{66}$$

and the corresponding conditions obtained by replacing a with b,c. Under these assumptions the 2-form (6) can be rewritten explicitly as

$$f = \sum_{h \in \Lambda} \left(a(h) \wedge c(h) + c(h) \wedge b(h) + b(h) \wedge a(h) + \frac{y}{2} a(h) \wedge a(Vh) + x b(h) \wedge c(Uh) \right), \tag{67}$$

where $y = \coth(\beta J_V)$, $x = \coth(\beta J_U)$.

Harmonic analysis on Λ can be performed by recalling the Fourier components of $a(h), b(h), c(h)$ given by $a(h) = \Sigma^J_{\alpha\beta} D^J_{\alpha\beta}(h)^* a^J_{\alpha\beta}$, etc. To this purpose we consider the matrices $\mathbf{a}^J, \mathbf{b}^J, \mathbf{c}^J$ of elements $a^J_{\alpha\beta}, b^J_{\alpha\beta}, c^J_{\alpha\beta}$ where $\alpha, \beta = 1 \cdots d_J$. By using the orthonormality relations (48) satisfied by the matrices $D^J_{\alpha\beta}(h)$ we rewrite $f = \Sigma_J f^J$ where

$$f^J = Tr \left(\mathbf{a}^{J\dagger} \wedge \mathbf{c}^J + \mathbf{c}^{J\dagger} \wedge \mathbf{b}^J + \mathbf{b}^{J\dagger} \wedge \mathbf{a}^J + \frac{y}{2} \mathbf{a}^{J\dagger} \wedge D^J(V) \mathbf{a}^J + x \mathbf{b}^{J\dagger} \wedge D^J(U) \mathbf{c}^J \right) \tag{68}$$

and $J^\dagger$ labels the complex conjugate irrep of J. The key point is that different pairs $J, J^\dagger$ lead to disjoint sets of Grassman variables, moreover $f^J + f^{J\dagger}$ separates into the sum of partial forms $\Sigma_\alpha (f^J)_{\alpha\alpha}$ + c.c. Therefore the final Pfaffian is the product of d_J partial (and identical) Pfaffians, which must be computed explicitly by use of (8). Once this is done we must determine the coefficients s_I appearing in (40). Since all the s_I and Pfaffians $Pf(\phi_I)$ sharing the same orbit O of ϕ_I are equal we can set $S_O = n(O) s_I, Pf(\phi_I) = pf(O), \forall \phi_I \in O$ and (40) reduces to

$$\mathcal{Z}_d = 2^{-g} \sum_O S_O pf(O). \tag{69}$$

The sign in $Pf(\phi_I)$ of a term associated with the path ζ is given by $\eta_I(\zeta) = \tau(\zeta_I, \zeta) \theta(\zeta)$. The s_I must be chosen in such a way as to set the final coefficient of ζ_K in the expansion (40):

$$2^{-g} \sum_I s_I \tau(\zeta_I, \zeta_K) \theta(\zeta_K) \tag{70}$$

equal to 1. Taking into account(45) we see that the condition

$$\forall I: 2^{-g} \sum_I s_I \tau(\zeta_I, \zeta_K) = \sum_I s_I \Phi_{IK} = \theta(\zeta_K) \tag{71}$$

has the simple solution

$$s_I = \theta(\zeta_I), \tag{72}$$

and thus $S_A = 1, S_B = S_C = 7, S_D = 21, S_E = -28$ and $S_A + S_B + S_C + S_D + S_E = 8 = 2^g$.

VIII. PFAFFIANS AND HARMONIC ANALYSIS ON THE LATTICE

The boundary conditions (66) on the Grassmann variables $a(h),b(h),c(h)$ imply strong restrictions on the Fourier components $a^J_{\alpha\beta},b^J_{\alpha\beta},c^J_{\alpha\beta}$ similar to those already derived for Q. Consider now $Pf(\phi)$ where $\phi=(\epsilon_0,\epsilon_1,\epsilon_2,\epsilon_3,\epsilon_4,\epsilon_5,\epsilon_6)$. From (66) we get

$$\sum_{h\in H} a(hZ_i)D^J_{\alpha\beta}(h)=\epsilon_i a^J_{\alpha\gamma}=a^J_{\alpha\gamma}D^J_{\gamma\beta}(Z_i). \tag{73}$$

In all the explicit representation of H listed in the Appendix B the matrices $D^J_{\gamma\beta}(Z_i)$ are diagonal and

$$D^J_{\gamma\beta}(Z_i)=\epsilon^J_i(\gamma)\,\delta_{\gamma\beta}. \tag{74}$$

Clearly $a^J_{\alpha\gamma},b^J_{\alpha\gamma},c^J_{\alpha\gamma}=0$ unless $\epsilon^J_i(\gamma)=\epsilon_i, i=0,\ldots,6$. The orbit O of ϕ identifies a subset of irreps and in (68) only a rectangular submatrix of $\mathbf{a}^J,\mathbf{b}^J,\mathbf{c}^J$ of dimension $d_J\times d_J/n(O)$ survives where d_J is the dimension of the irrep and $d_J/n(O)$the number of times a given signature in O appears in the irrep. The total number of surviving components of $a^J_{\alpha\gamma}$ among all irreps is in any case equal to the order N of the group G, i.e., 168.

Each $\mathbf{a}^J,\mathbf{b}^J,\mathbf{c}^J$ is therefore partitioned into $d_J/n(O)$ rectangular submatrices labeled by the signatures in O. Only one of these matrices needs to be used because they all yield the same final expression for the Pfaffian. Since in (68) all partial forms $f_{J\alpha}$ yield identical Pfaffians we may consider just one contribution and drop the index α. In this case the square of the partial Pfaffian can be written as the determinant of the block matrix Δ_J

$$\Delta_J=\begin{bmatrix} yD^J(V) & \mathbf{1} & -\mathbf{1} \\ -\mathbf{1} & 0 & \mathbf{1}-xD^J(U) \\ \mathbf{1} & -\mathbf{1}+xD^J(U^{-1}) & 0 \end{bmatrix}. \tag{75}$$

Notice that $\Delta_J^\dagger=-\Delta_J$. Upon multiplication of the last group of columns by $(\mathbf{1}-xD^J(U))^{-1}$ and the last group of rows by $(\mathbf{1}-xD^J(U^{-1}))^{-1}$ we find, as in Ref. 9,

$$Det(\Delta_J)=Det[y(\mathbf{1}-xD^J(U))D^J(V)(\mathbf{1}-xD^J(U^{-1}))+x(D^J(U)-D^J(U^{-1}))] \tag{76}$$

and therefore the effective dimension of the final determinant reduces to d_J. The dimer generating function $\mathcal{Z}_d$ is then

$$\mathcal{Z}_d=2^{-g}\sum_O S_O pf(O)=2^{-g}\sum_O S_O\prod_{J\in O} Pf_J^{d_J/n(O)}. \tag{77}$$

The degree of Pf_J in x,y is $d_J,d_J/2$ and therefore the total degree of $pf(O)$ in x is $\Sigma_{J\in O}d_J^2/n(O)=N$ because of the Burnside condition and half as much for y. Not all $Det(\Delta_J)$ are distinct, besides $Det(\Delta_J)=Det(\Delta_{J^\dagger})$ the external automorphism ν maps $pf(B)$into $pf(C)$and vice versa thus $pf(C)=pf(B)$. The number of independent Pfaffians is therefore further reduced to four $(64\to5\to4)$ by the existence of external automorphisms.

If $d_J/n(O)$ is odd the sign of $Pf_J=\pm\sqrt{Det(\Delta_J)}$ must be fixed unambiguously by computing it for instance in the limit $\beta\to0$. $\mathcal{Z}_d$ becomes then a polynomial in x,y of degree $N,N/2$.[12] In Fig. 2 we give the plot of the specific heat corresponding to a ferromagnetic choice of the exchange interactions, $(J_U=J_V=1)$. The specific heat presents a very sharp peak which prefigures the transition form and ordered ferromagnetic phase to a disordered paramagnetic one. When J_U,J_V have different signs or are both antiferromagnetic (i.e., negative) the model is totally frustrated and

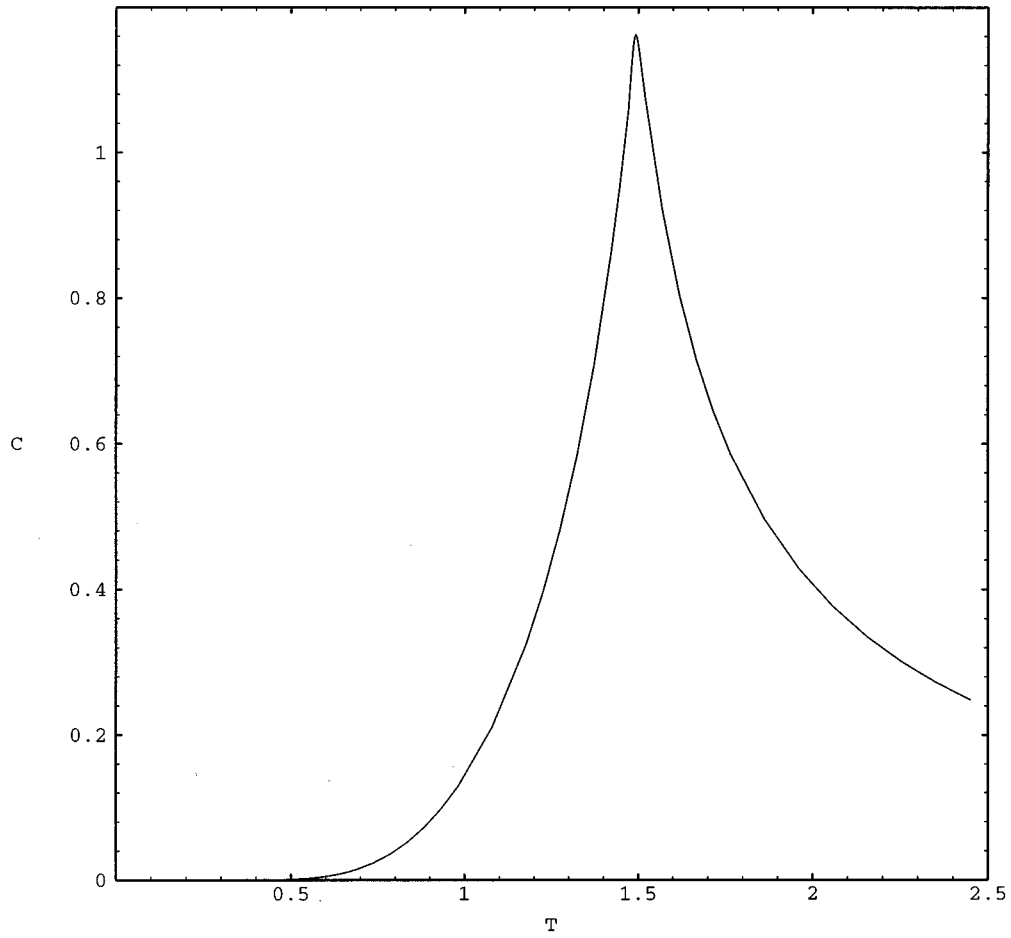

FIG. 2. Specific heat versus temperature for $J_U=J_V=1$.

the specific heat becomes smoother. Moreover, different finite values ($>\log\ 2/N$) of the ground state entropy are found, signaling an exponential degeneracy of the ground state.

IX. CONCLUSIONS

In this paper we have developed a formalism capable of dealing efficiently with Ising models defined on group lattices of nontrivial genus g. In particular we have applied the method to the Ising model on the Klein group $L(2,7)$ having $g=3$ and $N=168$. We found that the computation of the partition function $\mathcal{Z}$ is greatly simplified by use of symmetries of an extended group, both internal and external to the group, which reduce the number of and provide explicit formulas and topological interpretation for the sign and weight of Pfaffians in the expansion of $\mathcal{Z}$. We plan to apply this method to other lattices where N is large and g is comparable to N.

Note added in proof. A recent paper, to appear in Funct. Am. Appl. by N. P. Dolbilin, Yu. M. Zinoviev, A. S. Mishchenko, M. A. Slitan'ko, and M. I. Shtoprin contains results that partially overlap with ours.

APPENDIX A

Fermionic irreps of H_0 :

$$U^{(1)}=\mathrm{diag}(-1,K,-K^2,-K^4),\quad U^{(2)}=(U^{(1)})^*,$$

$$U^{(3)}=\mathrm{diag}(K,-K^2,-K^4,-K^6,K^5,K^3),\quad U^{(4)}=(U^{(3)})^*,$$

$$U^{(5)}=\mathrm{diag}(K,-K^2,-K^4,-1,-K^6,K^5,K^3,-1).$$

$$V^{(1)}=\frac{2i}{\sqrt{7}}\begin{pmatrix} \frac{1}{2} & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{2}} & c_1 & c_3 & c_2 \\ \frac{1}{\sqrt{2}} & c_3 & c_2 & c_1 \\ \frac{1}{\sqrt{2}} & c_2 & c_1 & c_3 \end{pmatrix}, \tag{A1}$$

with $c_k=\cos(2k\pi/7)$, $k=1,2,3$. $V^{(2)}=(V^{(1)})^*$.

$$V^{(3)}=\frac{2i}{7}\begin{pmatrix} \mathbf{A} & \mathbf{B} \\ \mathbf{B} & -\mathbf{A} \end{pmatrix},$$

where

$$\mathbf{A}=\begin{pmatrix} s_2-\sqrt{2}s_3 & s_1-\sqrt{2}s_2 & s_3-\sqrt{2}s_1 \\ s_1-\sqrt{2}s_2 & s_3-\sqrt{2}s_1 & s_2-\sqrt{2}s_3 \\ s_3-\sqrt{2}s_1 & s_2-\sqrt{2}s_3 & s_1-\sqrt{2}s_2 \end{pmatrix},$$

$$\mathbf{B}=r\begin{pmatrix} s_3+(\sqrt{2}-1)s_1 & s_2+(\sqrt{2}-1)s_3 & s_1+(\sqrt{2}-1)s_2 \\ s_2+(\sqrt{2}-1)s_3 & s_1+(\sqrt{2}-1s_2 & s_3+(\sqrt{2}-1)s_1 \\ s_1+\sqrt{2}-1s_2 & s_3+(\sqrt{2}-1)s_1 & s_2+(\sqrt{2}-1)s_3 \end{pmatrix},$$

with $s_1=\sin(\pi/7)$, $s_2=-\sin(2\pi/7)$, $s_3=-\sin(4\pi/7)$ and $r=\sqrt{2+\sqrt{2}}$.

Finally $V^{(4)}=(V^{(3)})^*$ and

$$V^{(5)}=\frac{i}{7}\begin{pmatrix} \mathbf{C} & \mathbf{D} \\ \mathbf{D} & -\mathbf{C} \end{pmatrix},$$

where

$$\mathbf{C}=\begin{pmatrix} s_1+s_2 & s_1+s_3 & s_2+s_3 & \sqrt{\frac{3}{2}}(s_2-s_1) \\ s_1+s_3 & s_2+s_3 & s_1+s_2 & \sqrt{\frac{3}{2}}(s_1-s_3) \\ s_2+s_3 & s_1+s_2 & s_1+s_3 & \sqrt{\frac{3}{2}}(s_3-s_2) \\ \sqrt{\frac{3}{2}}(s_2-s_1) & \sqrt{\frac{3}{2}}(s_1-s_3) & \sqrt{\frac{3}{2}}(s_3-s_1) & \frac{1}{2}(s_1-2s_2+s_3) \end{pmatrix},$$

and

$$\mathbf{D}=2\sqrt{3}\begin{pmatrix} s_2 & s_1 & s_3 & \frac{1}{\sqrt{2}}(s_1-s_2) \\ s_1 & s_3 & s_2 & \frac{1}{\sqrt{2}}(s_3-s_1) \\ s_3 & s_2 & s_1 & \frac{1}{\sqrt{2}}(s_2-s_3) \\ \frac{1}{\sqrt{2}}(s_1-s_2) & \frac{1}{\sqrt{2}}(s_3-s_1) & \frac{1}{\sqrt{2}}(s_2-s_3) & \frac{1}{2}(s_1-s_3) \end{pmatrix}.$$

All these irreps are changed into equivalent and conjugate expressions by replacing K with $-K^2$.

APPENDIX B

Putting $\lambda(x)=x_O$ for the representations λ belonging to the orbit O we have Case B:

$$v_B=\begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}, \quad t_B=\begin{pmatrix} \frac{(1+i\sqrt{2})}{2} & -\frac{1}{2} \\ \frac{1}{2} & \frac{(1-i\sqrt{2})}{2} \end{pmatrix}, \quad Z_{1,B}=\mathbf{I}_2\ ;$$

Case C: $v_C=v_B^{-1}$, $t_C=t_B^{-1}$, $Z_{1,C}=Z_{1,B}$;
Case D:

$$v_D^{(1)}=\frac{1}{\sqrt{2}}\begin{pmatrix} 0 & 0 & -1 & 1 & 0 & 0 \\ 0 & 0 & -1 & -1 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 & 0 \\ -1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -i & -i \\ 0 & 0 & 0 & 0 & -i & i \end{pmatrix}, \quad t_D^{(1)}=\frac{1}{\sqrt{2}}\begin{pmatrix} 0 & 0 & \sqrt{2} & 0 & 0 & 0 \\ 0 & 0 & 0 & \sqrt{2} & 0 & 0 \\ 0 & 0 & 0 & 0 & -i & -i \\ 0 & 0 & 0 & 0 & -i & i \\ -i & -i & 0 & 0 & 0 & 0 \\ -i & i & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$Z_{1,D}^{(1)}=\mathrm{diag}(1,1,1,1,-1,-1),$$

$$v_D^{(2)}=(v_D^{(1)})^*, \quad t_D^{(2)}=(t_D^{(1)})^*, \quad Z_{1,D}^{(2)}=Z_{1,D}^{(1)};$$

Case E :

$$v_E^{(1)}=\begin{pmatrix} 0 & 0 & -i & 0 \\ 0 & -i & 0 & 0 \\ -i & 0 & 0 & 0 \\ 0 & 0 & 0 & -i \end{pmatrix}, \quad t_E^{(1)}=\begin{pmatrix} -1 & 0 & 0 & 0 \\ 0 & 0 & -i & 0 \\ 0 & 0 & 0 & 1 \\ 0 & -i & 0 & 0 \end{pmatrix},$$

$$Z_{1,E}^{(1)}=\mathrm{diag}(1,-1,1,-1), \quad v_E^{(2)}=(v_E^{(1)})^*, \quad t_E^{(2)}=(t_E^{(1)})^*, \quad Z_{1,E}^{(2)}=-Z_{1,E}^{(1)},$$

$$v_E^{(3)}=\begin{pmatrix} 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & i & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -i & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & i & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -i \end{pmatrix},$$

$$t_E^{(3)}=\begin{pmatrix} \frac{1}{2} & \frac{-\sqrt{3}}{2} & 0 & 0 & 0 & 0 & 0 & 0 \\ \frac{\sqrt{3}}{2} & \frac{1}{2} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \frac{-1}{2} & \frac{-\sqrt{3}}{2} \\ 0 & 0 & 0 & 0 & 0 & 0 & \frac{-\sqrt{3}}{2} & \frac{1}{2} \\ 0 & 0 & \frac{1}{2} & \frac{\sqrt{3}}{2} & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{\sqrt{3}}{2} & \frac{-1}{2} & 0 & 0 & 0 & 0 \end{pmatrix},$$

$$Z_{1,E}^{(3)}=\mathrm{diag}(-1,-1,1,1,-1,-1,1,1).$$

The free streaming operator T is considered in a convex three dimensional region V, with diffusive multiplying boundary conditions. Some mathematical properties of T are examined by writing the particle density as an infinite series which takes into account successive reflections on ∂V, and by introducing an operator which in some sense annihilates the multiplying effect of ∂V. © *1996 American Institute of Physics.* [S0022-2488(96)01205-3]

I. INTRODUCTION

The basic mathematical properties of the streaming operator $T=-v\Omega\cdot\nabla$ usually are a first step in the study of abstract evolution problems in linear and nonlinear particle transport theory. In particular, whether or not T with suitable boundary conditions is the generator of a strongly continuous semigroup $\{\exp(tT),\ t\geqslant 0\}$ is a crucial question.[1] The behavior of $\|\exp(tT)\|$ as $t\to+\infty$ is also of interest because it leads to the asymptotic behavior of the total number of particles.

In this paper, we shall study the free streaming operator in a convex region $V\subset\mathbf{R}^3$, bounded by the closed C^1 surface ∂V, under the assumption that the following diffusive *multiplying* boundary condition holds

$$|\Omega\cdot\mathbf{n}(\mathbf{y})|f(\mathbf{y},\Omega)=\int_{\Omega'\cdot\mathbf{n}(\mathbf{y})>0}\alpha(\Omega,\Omega',\mathbf{y})\Omega'\cdot\mathbf{n}(\mathbf{y})f(\mathbf{y},\Omega')d\Omega',\quad \mathbf{y}\in\partial V,\quad \Omega\cdot\mathbf{n}(\mathbf{y})<0. \tag{1}$$

In relation (1), $f(\mathbf{y},\Omega)$ is the density of particles which are at $\mathbf{y}\in\partial V$ and have velocity $\mathbf{v}=v\Omega$, and $\mathbf{n}(\mathbf{y})$ is the (outward directed) normal unit vector at $\mathbf{y}$.

Furthermore, $\alpha(\Omega,\Omega',\mathbf{y})$ is a surface reflection kernel such that

$$\int_{\Omega\cdot\mathbf{n}(\mathbf{y})<0}\alpha(\Omega,\Omega',\mathbf{y})d\Omega=\alpha_0(\mathbf{y})>1\quad \text{at a.e.}\quad \mathbf{y}\in\partial V, \tag{2}$$

$$\alpha(\Omega,\Omega',\mathbf{y})=0\ \text{ if }\ 0\leqslant\Omega\cdot\mathbf{n}(\mathbf{y})<\epsilon_0\quad \text{at a.e.}\quad \mathbf{y}\in\partial V, \tag{3}$$

where ϵ_0 is an assigned positive number, with $\epsilon_0\ll 1$.

Relations (1) and (2) imply that particles, which impinge on ∂V at $\mathbf{y}$ with velocity $\mathbf{v}=v\Omega'$ $(\Omega'\cdot\mathbf{n}(\mathbf{y})>0)$, are reflected with velocity $\mathbf{v}=v\Omega$ $(\Omega\cdot\mathbf{n}(\mathbf{y})<0)$ and their number is multiplied by a factor larger than one. Such a multiplication phenomenon leads to some difficulties when one has to evaluate the norm of the evolution operator $\exp(tT)$. As it is shown in what follows, this difficulty may be overcome by introducing a suitable annihilation operator B.

Assumption (3) means that particles impinging on ∂V at $\mathbf{y}$ with velocity $\mathbf{v}$, such that the angle between $\mathbf{v}$ and $\mathbf{n}(\mathbf{y})$ is close to a right angle, are not reflected by ∂V. Hence, this (mainly technical)

condition cuts off the possibility of having two successive reflections at $\mathbf{y}$ and $\mathbf{y}'$ with $|\mathbf{y}-\mathbf{y}'|$ small. In any case, the number of this kind of reflections per unit time would be small compared with the total number of reflections at $\mathbf{y}\in\partial V$.

We finally remark that evolution problems with multiplying boundary conditions are certainly of mathematical interest.[2] However, they are also of physical interest because they may arise in connection with electron transport in photomultipliers, in algae or bacteria population problems, in neutron transport (in this case, ∂V may be the surface that bounds a moderator). The procedures that follow can also be used if multiplication is a volume phenomenon (i.e., if it occurs within V), such as in the case of neutron transport in a fissionable material.

II. THE SUCCESSIVE REFLECTION METHOD

In order to overcome the difficulties caused by the particle multiplication phenomenon on ∂V, we write the particle density $f(\mathbf{x},\Omega)$ as follows

$$f(\mathbf{x},\Omega)=\sum_{j=0}^{\infty} f_j(\mathbf{x},\Omega), \tag{4}$$

where $f_j(\mathbf{x},\Omega)$ is the density of the particles which ''remember'' just j reflections on the boundary surface ∂V. To explain the definition of f_j, we shall call ''mother'' a particle just before undergoing a reflection and ''daughters'' the particles generated by such a reflection. Assume that the daughters ''remember'' both the reflection during which they were generated and all the reflection events remembered by their mother. Then, f_j is composed of all particles which remember just j reflections.

According to definition (4) we introduce the Banach space X

$$X=\left\{ f: f=\begin{pmatrix} f_0 \\ f_1 \\ f_2 \\ \vdots \end{pmatrix}, \quad f_j\in L^1(V\times S), \quad \sum_{j=0}^{\infty} \|f_j\|_1<\infty \right\},$$

$$\|f\|=\sum_{j=0}^{\infty} \|f_j\|_1, \quad \|f_j\|_1=\int_V d\mathbf{x}\int_S |f_j(\mathbf{x},\Omega)|\,d\Omega, \tag{5}$$

and define the free streaming operator as follows

$$Tf=-v\begin{pmatrix} \Omega\cdot\nabla f_0 \\ \Omega\cdot\nabla f_1 \\ \Omega\cdot\nabla f_2 \\ \vdots \end{pmatrix},$$

$$D(T)=\{f: f\in X; Tf\in X; f \text{ satisfies the boundary conditions (7)}\} \tag{6}$$

$$|\Omega\cdot\mathbf{n}(\mathbf{y})|f_j(\mathbf{y},\Omega)=\int_{\Omega'\cdot\mathbf{n}(\mathbf{y})>0}\alpha(\Omega,\Omega',\mathbf{y})\Omega'\cdot\mathbf{n}(\mathbf{y})f_{j-1}(\mathbf{y},\Omega')d\Omega',$$

$$\mathbf{y}\in\partial V, \quad \Omega\cdot\mathbf{n}(\mathbf{y})<0, \quad j=0,1,2,\ldots\ . \tag{7}$$

In (5), S is the spherical surface of radius one, whereas $f_{-1}\equiv 0$ in the first of (7). Note that the boundary condition (7) shows that a reflection event changes f_{j-1} into f_j.

By using definitions (5), (6), and (7), we can write the abstract version of the free streaming problem in V:

$$\frac{d}{dt}u(t)=Tu(t), \quad t>0; \quad u(0)=u_0\in D(T)\cap X^+, \tag{8}$$

where $u(t)=u(\mathbf{x},\Omega;t)$ is now a function from $[0,+\infty)$ into the space X, $(d/dt)u$ is a strong derivative, and u_0 is an assigned initial particle distribution belonging to $D(T)$ and to the positive cone X^+.[3–5] We observe that (8) is in fact a system of infinite partial differential equations, coupled only because of the boundary conditions (7). In other words, (8) may be put into the form

$$\frac{d}{dt}u_j(t)=-v\Omega\cdot\nabla u_j, \quad t>0; \quad u_j(0)=u_{j0}\in X_1^+, \quad j=0,1,2,\ldots, \tag{9}$$

where the u_j's must satisfy (7) and be such that $-v\Omega\cdot\nabla u_j\in X_1=L^1(V\times S)$.

Equation (8) or system (9) are the mathematical formulation of the successive reflection method. Such a method has some similarity to the multiple collision technique[6] if multiplication occurs within V.

III. THE SEMIGROUP GENERATED BY *T*

To show that T is the generator of the strongly continuous semigroup $\{\exp(tT),\ t\geqslant 0\}$, we consider the equation

$$(zI-T)f=g, \tag{10}$$

where z is a positive constant, g is a given element of X, and the unknown must be sought in $D(T)$.

The solution $f\in D(T)$ of (10) has the form

$$f_j(\mathbf{x},\Omega)=\frac{1}{v}C_j(\mathbf{y},\Omega)\exp\left(-\frac{z}{v}s_0(\mathbf{x},\Omega)\right)+\frac{1}{v}\int_0^{s_0(\mathbf{x},\Omega)}\exp\left(-\frac{zs}{v}\right)g_j(\mathbf{x}-s\Omega,\Omega)ds, \tag{11}$$

where, given $\mathbf{x}$ and Ω, $s_0(\mathbf{x},\Omega)$ is such that $\mathbf{y}=\mathbf{x}-s_0(\mathbf{x},\Omega)\Omega\in\partial V$.

The constants $C_j(\mathbf{y},\Omega)$ can be evaluated by using the boundary condition (7) and assumption (3):

$$\begin{aligned}|\Omega\cdot\mathbf{n}(\mathbf{y})|C_j(\mathbf{y},\Omega)=&\int_{\Omega'\cdot\mathbf{n}(\mathbf{y})>\epsilon_0}d\Omega'\alpha(\Omega,\Omega',\mathbf{y})\Omega'\cdot\mathbf{n}(\mathbf{y})\left\{C_{j-1}(\mathbf{y}',\Omega')\exp\left(-\frac{z}{v}s_0(\mathbf{y},\Omega')\right)\right.\\&\left.+\int_0^{s_0(\mathbf{y},\Omega')}\exp\left(-\frac{zs}{v}\right)g_{j-1}(\mathbf{y}-s\Omega',\Omega')ds\right\},\\&\mathbf{y}\in\partial V, \quad \Omega\cdot n(\mathbf{y})<0, \quad j=0,1,2,\ldots,\end{aligned} \tag{12}$$

where $\mathbf{y}'=\mathbf{y}-s_0(\mathbf{y},\Omega')\Omega'\in\partial V$ and $C_{-1}\equiv 0$.

At any fixed $\mathbf{y}\in\partial V$, it follows from (12) and (2)

$$\begin{aligned}\int_{\Omega\cdot\mathbf{n}(\mathbf{y})<0}|\Omega\cdot\mathbf{n}(\mathbf{y})\|C_j(\mathbf{y},\Omega)|d\Omega\leqslant&\chi\exp\left(-\frac{z}{v}\delta\right)\int_{\Omega'\cdot\mathbf{n}(\mathbf{y})>0}\Omega'\cdot\mathbf{n}(\mathbf{y})|C_{j-1}(\mathbf{y}',\Omega')|d\Omega'\\&+\chi\int_{\Omega'\cdot\mathbf{n}(\mathbf{y})>0}d\Omega'\Omega'\cdot\mathbf{n}(\mathbf{y})\int_0^{s_0(\mathbf{y},\Omega')}|g_{j-1}(\mathbf{y}-s\Omega',\Omega')|ds,\end{aligned}$$

where

$$\chi=\sup\{\alpha_0(\mathbf{y}) \quad \mathbf{y}\in\partial V\}\geqslant 1, \quad \delta=\inf_{\mathbf{y}\in\partial V}\{\inf_{\Omega\cdot\mathbf{n}(\mathbf{y})\geqslant\epsilon_0}[s_0(\mathbf{y},\Omega)]\}>0 \tag{13}$$

(for example, if ∂V is a sphere of radius r, then $\delta=2r\epsilon_0$).

Integration over ∂V gives

$$\|C_j\|_b\leqslant\chi\,\exp\left(-\frac{z}{v}\,\delta\right)\|C_{j-1}\|_b+\chi\int_{\partial V}d\sigma_y\int_{\Omega'\cdot\mathbf{n}(\mathbf{y})>0}d\Omega'\,\Omega'\cdot\mathbf{n}(\mathbf{y})$$
$$\times\int_0^{s_0(\mathbf{y},\Omega')}|g_{j-1}(\mathbf{y}-s\Omega',\Omega')|ds, \tag{14}$$

where

$$\|\varphi\|_b=\int_{\partial V}d\sigma_y\int_{\Omega\cdot\mathbf{n}(\mathbf{y})<0}|\varphi(\mathbf{y},\Omega)|d\Omega,$$

and where we took into account that $\Omega'\cdot\mathbf{n}(\mathbf{y})d\sigma_y=|\Omega'\cdot\mathbf{n}(\mathbf{y}')|d\sigma_{y'}$. The second term on the right hand side of (45) can be written as follows:

$$\chi\int_S d\Omega'\int_{\partial V+(\Omega')}d\sigma_y\Omega'\cdot\mathbf{n}(\mathbf{y})\int_0^{s_0(\mathbf{y},\Omega')}|g_{j-1}(\mathbf{y}-s\Omega',\Omega')|ds$$
$$=\chi\int_S d\Omega'\int_V|g_{j-1}(\mathbf{x}',\Omega')|d\mathbf{x}'=\chi\|g_{j-1}\|_1,$$

where, $\mathbf{x}'=\mathbf{y}-s\Omega'$ and where, for each given Ω', $\partial V^+(\Omega')=\{\mathbf{y}:\mathbf{y}\in\partial V,\boldsymbol{\Omega}'\cdot\mathbf{n}(\mathbf{y})>0\}$.

Hence, (14) becomes

$$\|C_j\|_b\leqslant\chi\,\exp\left(-\frac{z}{v}\,\delta\right)\|C_{j-1}\|_b+\chi\|g_{j-1}\|_1, \tag{15}$$

and so:

$$\sum_{j=0}^{\infty}\|C_j\|_b\leqslant\eta(z)\|g\|, \tag{16}$$

where

$$\eta(z)=\frac{\chi}{1-\chi\,\exp(-(z/v)\,\delta)}, \tag{17}$$

provided that $\chi\exp(-(z/v)\,\delta)<1$, i.e., $z>z_0=(v/\delta)\ln\chi$.

On the other hand, we have from (11)

$$\|f_j\|_1\leqslant\frac{1}{v}\int_S d\Omega\int_V d\mathbf{x}\left\{|C_j(\mathbf{y},\Omega)|\exp\left(-\frac{z}{v}\,s_0(\mathbf{x},\Omega)\right)+\int_0^{s_0(\mathbf{x},\Omega)}\exp\left(-\frac{zs}{v}\right)|g_j(\mathbf{x}-s\Omega,\Omega)|ds\right\}.$$

By taking into account that $d\mathbf{x}=|\Omega\cdot\mathbf{n}(\mathbf{y})|d\sigma_y d\rho$ with $\Omega\cdot\mathbf{n}(\mathbf{y})<0$ for each fixed Ω, we obtain

$$\|f_j\|_1 \leqslant \frac{1}{v}\int_S d\Omega\Bigg\{\int_{\partial V^-(\Omega)} d\sigma_y |\Omega\cdot\mathbf{n}(\mathbf{y})\|C_j(\mathbf{y},\Omega)| \times \int_0^{s_0(\mathbf{y},-\Omega)} \exp\left(-\frac{z\rho}{v}\right)d\rho + \int_{\partial V^-(\Omega)} d\sigma_y|\Omega\cdot\mathbf{n}(\mathbf{y})| \times \int_0^{s_0(\mathbf{y},-\Omega)} d\rho\int_0^{\rho}\exp\left(z\,\frac{s'-\rho}{v}\right)|g_j(\mathbf{y}+s'\Omega,\Omega)|ds'\Bigg\},$$

where $\partial V^-(\Omega)=\{\mathbf{y}:\mathbf{y}\in\partial V,\ \Omega\cdot\mathbf{n}(\mathbf{y})<0\}$. Thus, we finally have

$$\|f_j\|_1 \leqslant \frac{1}{z}\{\|C_j\|_b+\|g_j\|_1\}, \tag{18}$$

and consequently

$$\|f\| \leqslant \frac{\eta(z)+1}{z}\|g\|, \quad z>z_0=\frac{v}{\delta}\ln\chi, \tag{19}$$

where we have used inequality (16).

We can summarize the preceding results as follows.

Lemma 1: Equation (10) has a unique solution $f=(zI-T)^{-1}g\in D(T)\forall g\in X$, provided that $z>z_0=(v/\delta)\ln\chi$. Moreover, $\|(zI-T)^{-1}\|\leqslant[\eta(z)+1]/z$ and $(zI-T)^{-1}[X^+]\subset X^+$.

Let now $g\in X^+$ and assume that $z>z_0$. Then, $f\in X^+$, $|f|=f$, and integration over S and V of the i-th component of (10) gives

$$z\|f_j\|_1+v\int_S d\Omega\int_V \Omega\cdot\nabla f_j(\mathbf{x},\Omega)d\mathbf{x}=\|g_j\|_1. \tag{20}$$

On the other hand, we have by using divergence theorem and condition (7)

$$\begin{aligned}\int_S d\Omega\Omega\cdot\int_V\nabla f_j(\mathbf{x},\Omega)d\mathbf{x} &= \int_S d\Omega\Omega\cdot\int_{\partial V} n(\mathbf{y})f_j(\mathbf{y},\Omega)d\sigma_y\\ &= \int_{\partial V}d\sigma_y\int_{\Omega\cdot\mathbf{n}(\mathbf{y})>0}\Omega\cdot\mathbf{n}(\mathbf{y})f_j(\mathbf{y},\Omega)d\Omega\\ &\quad -\int_{\partial V}d\sigma_y\int_{\Omega\cdot\mathbf{n}(\mathbf{y})<0}|\Omega\cdot\mathbf{n}(\mathbf{y})|f_j(\mathbf{y},\Omega)d\Omega\\ &= \int_{\partial V}d\sigma_y\int_{\Omega\cdot\mathbf{n}(\mathbf{y})>0}\Omega\cdot\mathbf{n}(\mathbf{y})f_j(\mathbf{y},\Omega)d\Omega\\ &\quad -\int_{\partial V}d\sigma_y\alpha_0(\mathbf{y})\int_{\Omega'\cdot\mathbf{n}(\mathbf{y})>0}\Omega'\cdot\mathbf{n}(\mathbf{y})f_{j-1}(\mathbf{y},\Omega')d\Omega'.\end{aligned}$$

Hence, (20) becomes

$$z\|f_j\|_1+v\int_{\partial V}d\sigma_y\int_{\Omega\cdot\mathbf{n}(\mathbf{y})>0}\Omega\cdot\mathbf{n}(\mathbf{y})f_j(\mathbf{y},\Omega)d\Omega$$

$$-v\int_{\partial V}d\sigma_y\alpha_0(\mathbf{y})\int_{\Omega'\cdot\mathbf{n}(\mathbf{y})>0}\Omega'\cdot\mathbf{n}(\mathbf{y})f_{j-1}(\mathbf{y},\Omega')d\Omega'=\|g_j\|_1.$$

As a consequence, we obtain

$$z\|f\|-v\int_{\partial V}d\sigma_y(\alpha_0(\mathbf{y})-1)\int_{\Omega\cdot\mathbf{n}(\mathbf{y})>0}\Omega\cdot\mathbf{n}(\mathbf{y})\sum_{j=0}^{\infty}f_j(\mathbf{y},\Omega)d\Omega=\|g\|.$$

Since $f=(zI-T)^{-1}g\in X^+$, we conclude that the resolvent operator satisfies the inequality

$$\|(zI-T)^{-1}g\|\geqslant\frac{\|g\|}{z},\quad z>z_0,\quad g\in X^+. \tag{21}$$

Note that $D(T)$ is dense in X; hence Lemma 1, inequality (20) and some results proved in Ref. 7 lead to the following theorem.

Theorem 1: $T\in\mathcal{G}(M,z_0;X)$, i.e., T is the infinitesimal generator of the strongly continuous semigroup $\{\exp(tT),\ t\geqslant 0\}$, such that $\|\exp(tT)\|\leqslant M\exp(z_0t)$, $\forall t\geqslant 0$. Moreover, $\exp(tT)[X^+]\subset[X^+]$, $\forall t\geqslant 0$.

We remark that, in Ref. 7, it is only shown that a suitable constant M exists, but no indication is given on how to evaluate it. This justifies the introduction of the ''annihilation'' operator B in the following section.

IV. THE ANNIHILATION OPERATOR

Due to Theorem 1, the unique strong solution of problem (8) has the form

$$u(t)=\exp(tT)u_0,\quad t\geqslant 0,\quad u_0\in D(T)\cap X^+, \tag{22}$$

and $u(t)\in D(T)\cap X^+$, $\forall t\geqslant 0$. Since $T\in\mathcal{G}(M,z_0;X)$, (22) gives

$$\|u(t)\|=\int_S d\Omega\int_V u(\mathbf{x},\Omega;t)d\mathbf{x}\leqslant M\ \exp(z_0t)\int_S d\Omega\int_V u_0(\mathbf{x},\Omega)d\mathbf{x}, \tag{23}$$

which is an upper bound for the total number of particles within V at time t. Note that inequality (23) depends on M, whose value is not easy to evaluate. On the other hand, the factor $\exp(z_0t)$ with $z_0=(v/\delta)\ln\chi$ has an interesting physical meaning. In fact, the ratio δ/v is the minimum time interval between two successive reflections on ∂V, whereas χ is the maximum multiplication factor. Hence, an upper bound for $\|u(t)\|$ can be obtained by assuming that all particles undergo their first collision at a time very close to $t=0$, the second at $t=\delta/v$, the third at $t=2\delta/v$,..., and that they are multiplied by χ each time. Then, the total number of particles at time t would be $\|u_0\|\chi\chi^{t/(\delta/v)}=\chi\exp((v/\delta)t\ln\chi)\|u_0\|=\chi\exp(z_0t)\|u_0\|$ because $1+tv/\delta$ is the number of reflection events during $[0,t]$.

In order to overcome the difficulty due to the constant M, we introduce the linear bounded operator

$$B\begin{pmatrix} 1 & 0 & 0 & \cdots \\ 0 & \chi^{-1} & 0 & \cdots \\ 0 & 0 & \chi^{-2} & \cdots \\ \cdots & \cdots & \cdots & \cdots \end{pmatrix}, \quad D(B)=X \tag{24}$$

which is such that $B[X^+]\subset[X^+]$, $\|B\|=1$.

Assume now that $f\in D(T)$ and let $g=Bf$; then, $\Omega\cdot\nabla f_j\in X_1$ and f_j satisfies condition (7). Moreover, $g_j=f_j/\chi^j$ and so $\Omega\cdot\nabla g_j\in X_1$ and g_j satisfies the boundary condition

$$|\Omega\cdot\mathbf{n}(\mathbf{y})|g_j(\mathbf{y},\Omega)=\int_{\Omega'\cdot\mathbf{n}(\mathbf{y})>0}\hat{\alpha}(\Omega,\Omega',\mathbf{y})\Omega'\cdot\mathbf{n}(\mathbf{y})g_{j-1}(\mathbf{y},\Omega')d\Omega',$$

$$\mathbf{y}\in\partial V, \quad \Omega\cdot\mathbf{n}(\mathbf{y})<0, \quad j=0,1,2,\ldots, \tag{25}$$

where $\hat{\alpha}(\Omega,\Omega',\mathbf{y})=\alpha(\Omega,\Omega',\mathbf{y})/\chi$.

Condition (25) suggests to define a new streaming operator $\hat{T}$ as follows

$$\hat{T}g=-v\begin{pmatrix} \Omega\cdot\nabla g_0 \\ \Omega\cdot\nabla g_1 \\ \Omega\cdot\nabla g_2 \\ \vdots \end{pmatrix}, \tag{26a}$$

$$D(\hat{T})=B[D(T)]=\{g:g\in X;\hat{T}g\in X;g \text{ satisfies the boundary conditions (25)}\}. \tag{26b}$$

Since

$$\hat{\alpha}_0(\mathbf{y})=\int_{\Omega\cdot\mathbf{n}(\mathbf{y})<0}\hat{\alpha}(\Omega,\Omega',\mathbf{y})d\Omega=\alpha_0(\mathbf{y})/\chi\leqslant 1,$$

$$\hat{\chi}=\sup\{\hat{\alpha}(\mathbf{y}),\mathbf{y}\in\partial V\}=1,$$

Theorem 2 can be proved by using procedures similar to those of Sec. 2 (with $\hat{\alpha}_0$ and $\hat{\chi}=1$ instead of α_0 and χ). We remark that (20) and (25) lead to the relation

$$z\|f\|-v\int_{\partial V}d\sigma_y(\hat{\alpha}_0(\mathbf{y})-1)\int_{\Omega\cdot\mathbf{n}(\mathbf{y})>0}\Omega\cdot\mathbf{n}(\mathbf{y})\sum_{j=0}^{\infty}f_j(\mathbf{y},\Omega)d\Omega=\|g\|,$$

where $f=(zI-\hat{T})^{-1}g$ and $\hat{\alpha}_0(\mathbf{y})\leqslant 1$. Hence, we have

$$\|(zI-\hat{T})^{-1}g\|\leqslant\frac{\|g\|}{z}, \quad \forall z>\hat{z}_0=\frac{v}{\delta}\ln\hat{\chi}=0. \tag{27}$$

Furthermore, $D(\hat{T})$ is dense in X, and so (27) leads to the following theorem.

Theorem 2: $\hat{T}\in\mathcal{G}(1,0;X)$ i.e., $\hat{T}$ is the infinitesimal generator of the strongly continuous semigroup $\{\exp(t\hat{T}),\ t\geqslant 0\}$, such that $\|\exp(t\hat{T})\|\leqslant 1$, $\forall t\geqslant 0$. Moreover, $\exp(t\hat{T})[X^+]\subset[X^+]$, $\forall t\geqslant 0$.

We also observe that the following commutation property holds

$$BTf=\hat{T}Bf, \quad \forall f\in D(T). \tag{28}$$

In fact, $Bf\in B[D(T)]=D(\hat{T})\forall f\in D(T)$ and $\hat{T}Bf$ exists and belongs to X. Furthermore, given any $j=0,1,2,...$, we have

$$(BTf)_j=(Tf)_j/\chi^j=(-v\Omega\cdot\nabla f_j)/\chi^j,$$

$$(\hat{T}Bf)_j=-v\Omega\cdot\nabla(Bf)_j=(-v\Omega\cdot\nabla f_j/\chi^j),$$

and (28) is proved.

Consider now the following modified evolution problem

$$\frac{d}{dt}w(t)=\hat{T}w(t),\quad t>0;\quad w(0)=w_0\in D(\hat{T}),\tag{29}$$

whose unique strong solution has the form

$$w(t)=\exp(t\hat{T})w_0,\quad t\geqslant 0.\tag{30}$$

By applying the bounded operator B to both sides of equation (8), we have

$$\frac{d}{dt}Bu(t)=BTu(t),\quad t>0,\quad Bu(0)=Bu_0,$$

i.e.,

$$\frac{d}{dt}[Bu(t)]=\hat{T}[Bu(t)],\quad t>0;\quad [Bu(0)]=Bu_0,\tag{31}$$

where we used (28) and the relation $B(du/dt)=(dBu/dt)$, that holds because $B\in\mathscr{B}(X)$[3].

Comparison of (29) with (31) shows that $w(t)=Bu(t)$, provided that $w_0=Bu_0$. Hence, we have

$$\|Bu(t)\|=\|w(t)\|\leqslant\|w_0\|=\|Bu_0\|,\quad \forall t\geqslant 0,\tag{32}$$

because of (30) and Theorem 2.

Inequality (32) shows that $Bu(t)$ has the norm bounded by the norm of its initial value Bu_0. Note that $(Bu(t))_j=u_j(t)/\chi^j$, i.e., the j-th component of $Bu(t)$ is the density of particles, which remember j reflections, divided by χ^j (which in some sense, annihilates the multiplying effect of the j reflections). Moreover, we may obviously take $(Bu_0)_j=0\forall j=1,2,...$ and $(Bu_0)_0=u_{00}\in X_1^+$, with $u_{00}(\mathbf{y},\Omega)=0\forall\mathbf{y}\in\partial V$, where u_{00} is the particle density at $t=0$ (under the assumption that at $t=0$, no particle has yet undergone any reflection). Then, (32) reads as follows

$$\sum_{j=0}^{\infty}\chi^{-j}\int_S d\Omega\int_V u_j(\mathbf{x},\Omega;t)d\mathbf{x}\leqslant\int_S d\Omega\int_V u_{00}(\mathbf{x},\Omega)d\mathbf{x}.\tag{33}$$

V. CONCLUDING REMARKS

We can summarize the preceding results as follows.

Theorem 3: If T is defined by (6) and $\hat{T}$ by (26), then $T\in\mathscr{G}(M,z_0;X)$,$\hat{T}\in\mathscr{G}(1,0;X)$ and relation (28) holds. Moreover, the (positive) semigroups generated by T and $\hat{T}$ are such that

$$B\exp(tT)u_0=\exp(t\hat{T})Bu_0,\quad t\geqslant 0,\quad u_0\in D(T),\tag{34}$$

where B is defined by (24). Since $D(T)$ is dense in X, (34) may be extended to the whole X.

Relation (34) is of mathematical and physical interest because it shows that an evolution problem with particle multiplication may be studied by means of a suitable modified problem without multiplication. Furthermore, (34) leads to the definition of B-bounded semigroups.[8]

Inequality (33) indicates that

$$\int_S d\Omega \int_V u_j(\mathbf{x},\Omega;t)d\mathbf{x} \leqslant \chi^j \int_S d\Omega \int_V u_{00}(\mathbf{x},\Omega)d\mathbf{x}, \quad j=0,1,2,\ldots,$$

because $u \in X^+$ and so all the terms of the infinite series are non-negative. Finally, let $\overline{s_0}=\sup\{s_0(\mathbf{x},\Omega),\mathbf{x}\in V,\Omega\in S\}$ be the diameter of V. Then if $t>n\overline{s_0}/v$, $u_j \equiv 0 \forall j=0,1,2,\ldots,n-1$ and (33) becomes

$$\sum_{j=n}^{\infty} \chi^{-(j-n)} \int_S d\Omega \int_V u_j(\mathbf{x},\Omega;t)d\mathbf{x} \leqslant \chi^n \int_S d\Omega \int_V u_{00}(\mathbf{x},\Omega)d\mathbf{x}.$$

Nonlinear discrete systems with nonanalytic dispersion relations

M. Boiti,[a] J. Leon, and F. Pempinelli[a]
Physique Mathématique et Théorique, CNRS-URA 768, 34095 Montpellier, Cedex 05, France

(Received 1 November 1995; accepted for publication 8 February 1996)

A discrete system of coupled waves (with nonanalytic dispersion relation) is derived in the context of the spectral transform theory for the Ablowitz–Ladik spectral problem (discrete version of the Zakharov–Shabat system). This 3-wave evolution problem is a discrete version of the *stimulated Raman scattering* equations, and it is shown to be solvable for arbitrary boundary value of the two *radiation fields* and initial value of the *medium state*. The spectral transform is constructed on the basis of the $\bar{\partial}$-approach. © *1996 American Institute of Physics.*

I. INTRODUCTION

This paper relates the study of the following discrete coupled system for the three fields $A_1(\theta,n,t)$, $A_2(\theta,n,t)$ and $q(n,t)$

$$\begin{aligned} &A_1(\theta,n,t)-A_1(\theta,n-1,t)=e^{-in\theta}q(n,t)A_2(\theta,n,t),\\ &A_2(\theta,n,t)-A_2(\theta,n-1,t)=-e^{in\theta}\overline{q(n,t)}A_1(\theta,n,t),\\ &q_t(n,t)=\frac{\rho(n,t)}{2\pi}\int_{-\pi}^{+\pi}d\theta e^{in\theta}(A_1*A_2)(\theta,n,t), \end{aligned} \tag{1}$$

where $\theta\in[-\pi,+\pi]$, $n\in\mathbf{Z}$ and $t\in\mathbf{R}^+$. The interaction term here above is defined as the *coupling* factor

$$(A_1*A_2)(\theta,n,t)=g(\theta,t)A_1(\theta,n-1,t)\overline{A_2}(\theta,n,t)+\overline{g(}\theta,t)A_1(\theta,n,t)\overline{A_2}(\theta,n-1,t), \tag{2}$$

where $g(\theta,t)$ is an arbitrary function in $L^2([-\pi,+\pi])$ (which could also be time dependent), and where the *energy ratio* $\rho(n,t)$ at the site n (it will be shown that this quantity is actually θ -independent) is defined as

$$\rho(n,t)=\frac{|I_1(\theta,t)|^2+|I_2(\theta,t)|^2}{|A_1(\theta,n,t)|^2+|A_2(\theta,n,t)|^2} \tag{3}$$

for the following definition of the boundary values $I_1(\theta,t)$ and $I_2(\theta,t)$ (input data)

$$I_1=\lim_{n\to+\infty}A_1(\theta,n,t),\qquad I_2=\lim_{n\to+\infty}A_2(\theta,n,t). \tag{4}$$

One of the main results is the proof that the system (1) with data (*initial-boundary value problem*)

$$q(n,0),\qquad I_1(\theta,t),\qquad I_2(\theta,t) \tag{5}$$

[a]Permanent address: Dipartmento di Fisica, Università di Lecce, I-73100 LECCE.

0022-2488/96/37(6)/2824/27/$10.00

is integrable. In particular this work provides the first instance of an integrable nonlinear discrete system with *nonanalytic dispersion relation*.

An interesting limit of the above equation arises when the arbitrary distribution $g(\theta)$ goes to a Dirac delta function, for instance $\delta(\theta)$. Then the system reads (now $A_j(n,t)$ denotes $A_j(\theta,n,t)|_{\theta=0}$)

$$A_1(n,t)-A_1(n-1,t)=q(n,t)A_2(n,t),$$

$$A_2(n,t)-A_2(n-1,t)=-\overline{q(}n,t)A_1(n,t), \tag{6}$$

$$q_t(n,t)=\rho(n,t)[A_1(n-1,t)\overline{A_2}(n,t)+A_1(n,t)\overline{A_2}(n-1,t)],$$

and it is called the *sharp line limit* of (1). Although a definite physical application of such an equation does not exist by now, it still can be understood in the following way. A_1 and A_2 are the two envelopes of some high frequency (HF) oscillations (say at frequency ω_1 and ω_2) which interact resonantly on each site n with a medium constituted of oscillators of envelope $q(n)$ and frequency $\Omega=\omega_1-\omega_2$, with a coupling intensity proportional to the relative amount $\rho(n)$ of the *total HF energy* which has reached the site n. Then the physical data are the input values $A_{1,2}(\theta,n,t)$ at $n=\infty$ of the HF external excitations, and the initial state of the medium oscillators.

The method used to build and solve (1) is the *inverse spectral* (or *scattering*) *transform* (IST) well known also as the *nonlinear Fourier transform*.[1] Indeed the method, in its principle, works like a Fourier transform. It associates to the field, solution of a nonlinear evolution equation, its *spectral transform* which evolves linearly. Then the field at time t is reconstructed from the spectral transform at time t by solving the *inverse spectral problem*. This method has been widely studied and extended to various interesting nonlinear evolution problems. We are particularly interested in three types of extension which will be used all three together.

The first extension involved here is the use of *discrete* spectral problems to solve discrete (in space) nonlinear evolution equations. Famous instances of integrable discrete systems are the Toda lattice[2] and a special discrete version of the nonlinear Schrödinger equation which has been proposed and integrated by Ablowitz and Ladik by using a discrete version of the Zakharov–Shabat spectral problem.[3] This so called Ablowitz–Ladik spectral problem and the related nonlinear differential–difference equations with polynomial dispersion relations have been extensively studied (see Refs. 4–17). Recently a different version of the discrete Zakharov–Shabat system has been proposed in order to keep the canonical Poisson structure of the continuous case.[18]

The second domain considered here concerns the extension of the spectral transform to the case of *nonanalytic dispersion relations*.[19,20] The first instance of such an integrable system is the self-induced transparency (SIT) equations of McCall–Hahn[21] which was shown to possess a Lax pair in Ref. 22 was given a N-soliton solution in Ref. 23 and later studied and completely solved in Ref. 24. These systems generically describe wave–wave interactions for which some boundary value are prescribed. These boundary values are strongly dependent on the physical problem under consideration. For instance the problem of superfluorescence in two-level media results in the same equation as SIT but with different boundary values and consequently quite different generic properties resulting mainly from a linear but *nonhomogeneous* evolution of the spectral transform.[25]

The third extension used is the generalization of the solution of an evolution equation with a nonanalytic dispersion relation to the case of *arbitrary boundary values*.[26] In this case, the evolution of the spectral transform can be not only nonhomogeneous but also *nonlinear* and still has interesting physical application. In particular the problem of stimulated Raman scattering of a high energy long laser pulse in a gas has been solved by this technique.[27,28]

The paper is organized as follows. In Sec. II we summarize the method of solution of the system (1) and provide there only the resulting formulae.

In Sec. III the principal Lax operator or, more precisely, the associated spectral problem (a special reduction of the Ablowitz–Ladik spectral problem) is used to define the spectral data (or nonlinear Fourier transform). This is done by selecting the basic set of Jost solutions and then proving that they obey a Riemann–Hilbert problem in the spectral parameter.

The inverse spectral problem is then solved in Sec. IV by means of the $\bar{\partial}$-formulation of the spectral problem, which means that the *potentials* are reconstructed from the *spectral data*. There the compatible *reductions* are also considered, which will allow in particular to obtain simpler integrable equations with an easier interpretation.

Section V is devoted to the formulation of the inverse spectral transform on the basis of the $\overline{\partial}$-problem. More precisely, having previously shown that the spectral problem (for the principal Lax operator) leads naturally to a ∂-problem, we prove here the reverse statement. This is useful in the following for considering the ∂-problem itself as the starting tool.

The general discrete integrable system with nonanalytic dispersion relations is then constructed by requiring a time evolution of the spectral transform with a *nonanalytic* dispersion law and a *nonhomogeneous* term.

These results are used in Sec. VI to prove that indeed the system (1) with the arbitrary boundary values (4) is solvable. That means that we obtain the time evolution of the spectral data in terms of the boundary values and the spectral transform of the initial datum $q(n,0)$. An interesting case corresponds to the growth of the field $q(n,t)$ on an initial medium at rest, that is for $q(n,0)\equiv 0$. The method furnishes in such a case the explicit output values of the HF fields $A_1(\theta,n,t)$ and $A_2(\theta,n,t)$ for $n=-\infty$.

II. SOLUTION OF THE SYSTEM. A SUMMARY

The general method to generate solutions of (1) is sketched hereafter. The starting point is the *spectral transform* of the initial datum $q(n,0)$, namely, the set of two scalar functions α and β defined on the unit circle, a sequence of N discrete points k_j outside the unit disc to each of which are associated N complex constants C_j. This set is given at $t=0$ as

$$\alpha(\zeta,0), \qquad \beta(\zeta,0), \qquad \zeta=e^{i\theta}; \qquad C_j(0), \qquad k_j, \qquad |k_j|>1, \qquad j=1,\ldots,N. \tag{7}$$

In the language of the scattering theory, α is called the *reflection coefficient*, β the *transmission coefficient*, N the number of *bound states* k_j, and C_j the related *normalization coefficients*. The effective construction of these data from $q(n,0)$ is displayed in Sec. III, but here we just consider that the set (7) is given and we show how to build from it a solution of (1). It is worth mentioning that in the linear limit case of *small* $q(x,0)$, $\alpha(\zeta,0)$ becomes the Fourier transform of q (with parameter 2ζ), $\beta(\zeta,0)$ become 1 and all the C_j's vanish (no discrete spectrum, or else no solitons in the linear limit).

The first step is to construct the *spectral transform* at time t by solving

$$\partial_t\alpha=\alpha\frac{g+\overline{g}}{2}(|I_1(\theta,t)|^2-|I_2(\theta,t)|^2)-(g+\overline{g})\overline{I_1}I_2 \tag{8}$$

$$-\alpha\frac{1}{2\pi i}P\oint_{\mathscr{C}}\frac{d\zeta'}{\zeta'-\zeta}(g+\overline{g})(|I_1|^2-|I_2|^2) \tag{9}$$

$$+\alpha\frac{1}{2\pi i}\oint_{\mathscr{C}}\frac{d\zeta'}{\zeta'}(g|I_1|^2-\overline{g}|I_2|^2), \tag{10}$$

$$\partial_t k_j=0, \tag{11}$$

$$\partial_t C_j(t) = -C_j(t)\frac{1}{2\pi i}P\oint_{\mathscr{C}}\frac{d\zeta'}{\zeta'-k_j}(g+\overline{g})(|I_1|^2-|I_2|^2) \tag{12}$$

$$+C_j(t)\frac{1}{2\pi i}\oint_{\mathscr{C}}\frac{d\zeta'}{\zeta'}(g|I_1|^2-\overline{g}|I_2|^2). \tag{13}$$

Unlike in the continuum case, the transmission coefficient $\beta(\zeta,t)$ cannot be computed directly from $\alpha(\zeta,t)$ and it becomes necessary to solve the equation

$$\beta(\zeta,t)^{-1}\partial_t\beta(\zeta,t) = -\frac{1}{2}\frac{\partial_t|\alpha|^2}{1+|\alpha|^2}+\frac{1}{2i\pi}P\oint_{\mathscr{C}}\frac{\zeta}{\zeta'}\frac{d\zeta'}{\zeta'-\zeta}\frac{\partial_t|\alpha|^2}{1+|\alpha|^2}. \tag{14}$$

In the integrals here, P denotes the Cauchy principal value and $\mathscr{C}$ the unit circle in the complex plane.

Although not elementary, in the case when I_1 and I_2 are given independently of α and β the above system of equations is *linear* and can in principle be explicitly solved as soon as the *initial data* (7) and the boundary values (4) are known. Before going further, it is already worth remarking that if the quantity I_1I_2 does not vanish, then the evolution for the reflection coefficient $\alpha(\zeta,t)$ has a nonhomogeneous term. Consequently the solution can grow on the *initial vacuum* $q(n,0)=0$ which has the spectral transform

$$\alpha(\zeta,0)=0, \qquad \beta(\zeta,0)=1; \quad N=0. \tag{15}$$

The second step consists in solving the following system of linear integral equations for the unknowns $\phi_i(k,n,t)$ for $|k|<1$

$$\begin{pmatrix}\phi_1(k)\\ \phi_2(k)\end{pmatrix} = \begin{pmatrix}1\\0\end{pmatrix}+\frac{1}{2i\pi}\oint_{\mathscr{C}}\frac{d\zeta'}{\zeta'-k}\frac{k}{\zeta'}(\zeta')^{-n}\alpha(\zeta')\begin{pmatrix}-\overline{\phi_2}(\zeta')\\ \overline{\phi_1}(\zeta')\end{pmatrix}$$
$$+\sum_{j=1}^{N}\frac{C_j}{k_j-k}\frac{k}{k_j}(k_j)^{-n}\begin{pmatrix}-\overline{\phi_2}(1/\overline{k_j})\\ \overline{\phi_1}(1/\overline{k_j})\end{pmatrix}. \tag{16}$$

The solution of (1) then reads (last step) for $\zeta=e^{i\theta}$

$$\begin{pmatrix}A_1\\ A_2\end{pmatrix} = I_1\begin{pmatrix}\phi_1(\zeta)\\ \zeta^n\phi_2(\zeta)\end{pmatrix}+I_2\begin{pmatrix}-\zeta^{-n}{}_2(\zeta)\\ \overline{\phi}_1(\zeta)\end{pmatrix}, \tag{17}$$

$$q(n+1,t) = -\overline{\phi}_2^{(-1)}(n,t), \tag{18}$$

with $\phi_2^{(-1)}$ the coefficient of k^{-1} in the Laurent expansion of the solution $\phi_2(k,n,t)$. This achieves the solution of the nonlinear system (1) with the arbitrary boundary values (4) as a sequence of *linear* operations.

An interesting information here is the output values (vs the input values) of the fields A_j (values for $n\to-\infty$) which will be proved to be

$$\begin{pmatrix}A_1\\ A_2\end{pmatrix}\xrightarrow[n\to-\infty]{}\frac{1}{1+|\alpha|^2}\begin{pmatrix}I_1\beta+I_2\overline{\alpha\beta}\\ -I_1\alpha\overline{\beta}+I_2\overline{\beta}\end{pmatrix} \tag{19}$$

for the input

$$\begin{pmatrix} A_1 \\ A_2 \end{pmatrix} \xrightarrow[n\to+\infty]{} \begin{pmatrix} I_1 \\ I_2 \end{pmatrix} \tag{20}$$

(note the necessity to compute not only the reflection coefficient α at time t but also the transmission coefficient β). This result, besides having a physical interest, has the nice property of being *explicit*. Indeed it does not require solving the integral equations (16). Actually, when the system (1) is viewed as describing the interaction of radiation components A_j with matter, the relevant (measured) physical information is the output values of the radiation components.

Now we can compute the ratio $\rho(-\infty,t)$ of transmitted *photon number*, defined in (3), as

$$\rho(n,t) \xrightarrow[n\to-\infty]{} \frac{1+|\alpha|^2}{|\beta|^2}, \tag{21}$$

while we have obviously

$$\rho(n,t) \xrightarrow[n\to+\infty]{} 1. \tag{22}$$

This is unlike in the continuous case for which we would find $\rho(-\infty,t)=1$, and results effectively from the discrete nature of (1). Indeed a direct calculation leads to the following *total photon number* nonconservation

$$|A_1(\zeta,n-1)|^2+|A_2(\zeta,n-1)|^2=(1+|q(n)|^2)(|A_1(\zeta,n)|^2+|A_2(\zeta,n)|^2). \tag{23}$$

As a consequence we obtain from (3) and the above relation

$$\rho^{-1}(n,t)=\prod_{i=n+1}^{\infty}(1+|q(i,t)|^2) \tag{24}$$

which proves in particular that the energy ratio $\rho(n,t)$ indeed does not depend on the variable θ.

III. THE SPECTRAL PROBLEM

In the case of the discrete variable, a spectral problem is understood as a difference equation for some unknown $\mu(n)$, which involves explicitly an external parameter, the *spectral parameter*, and a set of given n-dependent coefficients, the *potentials*. Solving a spectral problem results in defining the set of *spectral data* (functions of the parameter k) in such a way that they are in bijection with the set of potentials (in some given class of functions). We shall work here in the space of 2×2 matrices and adopt an equivalent form of the reduced Ablowitz–Ladik spectral problem used in Ref. 3 to integrate the discrete nonlinear Schrödinger equation. In our case we are able to write the spectral transform as a ∂-problem for the matrix $\mu(k,n)$, which results in a simple formulation of the inverse problem together with a very convenient tool for building and solving nonlinear evolutions, in particular those with nonanalytic dispersion relations and boundary value data.

A. Equation and Jost solutions

Let us consider the discrete spectral problem

$$\mu(k,n+1)-\Lambda^{-1}\mu(k,n)\Lambda=Q(n+1)\mu(k,n+1), \tag{25}$$

with the following definitions

$$\Lambda(k)=\begin{pmatrix} 1/z & 0 \\ 0 & z \end{pmatrix}, \qquad z^2=k, \qquad Q(n)=\begin{pmatrix} 0 & q(n) \\ r(n) & 0 \end{pmatrix}, \tag{26}$$

where k is the spectral parameter which belongs to the domain $\mathscr{D}=\mathbf{C}-\{0,\infty\}$. Up to a change of $n\to -n$, $k\to 1/k$ and a rescaling by convenient powers of z of the matrix elements of μ it is just the special reduction of the Ablowitz–Ladik spectral problem associated to the integrable discrete nonlinear Schrödinger equation. The solution of (25) possesses the property

$$\det\{\mu(k,n-1)\}=\det\{\mu(k,n)\}[1-r(n)q(n)]. \tag{27}$$

The solution of this spectral problem goes through the construction of some well chosen solutions (the Jost solutions) out of some particular asymptotic behaviors. These solutions are denoted by $\mu^{\pm}$ and are defined by the following discrete integral equations

$$\begin{pmatrix} \mu_{11}^{-}(k,n) \\ \mu_{21}^{-}(k,n) \end{pmatrix}=\begin{pmatrix} 1 \\ 0 \end{pmatrix}+\begin{pmatrix} -\sum_{i=n+1}^{+\infty} q(i)\mu_{21}^{-}(k,i) \\ \sum_{i=-\infty}^{n} k^{i-n}r(i)\mu_{11}^{-}(k,i) \end{pmatrix}, \tag{28}$$

$$\begin{pmatrix} \mu_{11}^{+}(k,n) \\ \mu_{21}^{+}(k,n) \end{pmatrix}=\begin{pmatrix} 1 \\ 0 \end{pmatrix}+\begin{pmatrix} -\sum_{i=n+1}^{+\infty} q(i)\mu_{21}^{+}(k,i) \\ -\sum_{i=n+1}^{+\infty} k^{i-n}r(i)\mu_{11}^{+}(k,i) \end{pmatrix}, \tag{29}$$

$$\begin{pmatrix} \mu_{12}^{-}(k,n) \\ \mu_{22}^{-}(k,n) \end{pmatrix}=\begin{pmatrix} 0 \\ 1 \end{pmatrix}+\begin{pmatrix} -\sum_{i=n+1}^{+\infty} k^{n-i}q(i)\mu_{22}^{-}(k,i) \\ -\sum_{i=n+1}^{+\infty} r(i)\mu_{12}^{-}(k,i) \end{pmatrix}, \tag{30}$$

$$\begin{pmatrix} \mu_{12}^{+}(k,n) \\ \mu_{22}^{+}(k,n) \end{pmatrix}=\begin{pmatrix} 0 \\ 1 \end{pmatrix}+\begin{pmatrix} \sum_{i=-\infty}^{n} k^{n-i}q(i)\mu_{22}^{+}(k,i) \\ -\sum_{i=n+1}^{+\infty} r(i)\mu_{12}^{+}(k,i) \end{pmatrix}. \tag{31}$$

We will make use also of the notation

$$\mu_1^{\pm}=\begin{pmatrix} \mu_{11}^{\pm} \\ \mu_{21}^{\pm} \end{pmatrix}, \qquad \mu_2^{\pm}=\begin{pmatrix} \mu_{12}^{\pm} \\ \mu_{22}^{\pm} \end{pmatrix}. \tag{32}$$

The above integral equations allow us to obtain, for some given class of potentials, the analytical properties of the solutions in the domain $\mathscr{D}$ of the complex k-plane, for all n. The function $\mu_1^{+}(k,n)$ is holomorphic inside the unit circle, the function $\mu_2^{-}(k,n)$ is holomorphic outside the unit circle, the function $\mu_1^{-}(k,n)$ is meromorphic outside the unit circle where it has a finite number N^{-} of simple poles k_j^{-}, the function $\mu_2^{+}(k,n)$ is meromorphic inside the unit circle where it has a finite number N^{+} of simple poles k_j^{+}. Moreover the two solutions $\mu^{\pm}$ are continuous on the unit circle.

B. Riemann–Hilbert problem and spectral data

The method to obtain from the integral equations defining $\mu^{\pm}$ the related Riemann–Hilbert problem is standard. We proceed through direct computation of the difference of the two column vectors μ_1^+ and μ_1^- and obtain the integral equation for this difference. It obeys the same equation as the quantity $-\alpha^-(k)k^{-n}\mu_2^-(k,n)$ (the quantity α^- is defined below) and, based on the uniqueness of the solution of such equations, we conclude

$$\mu_1^+(k,n)-\mu_1^-(k,n)=-\alpha^-(k)k^{-n}\mu_2^-(k,n), \qquad |k|=1. \tag{33}$$

The same approach is applied to $\mu_2^{\pm}$ and we get

$$\mu_2^+(k,n)-\mu_2^-(k,n)=\alpha^+(k)k^{n}\mu_1^+(k,n), \qquad |k|=1, \tag{34}$$

where the *reflection coefficients* $\alpha^-(k)$ and $\alpha^+(k)$ are defined (still for $|k|=1$) as

$$\alpha^-(k)=\sum_{-\infty}^{+\infty} k^i r(i)\mu_{11}^-(k,i), \qquad \alpha^+(k)=\sum_{-\infty}^{+\infty} k^{-i} q(i)\mu_{22}^+(k,i). \tag{35}$$

For future use we define also

$$\beta^-(k)=1-\sum_{-\infty}^{+\infty} q(i)\mu_{21}^-(k,i), \qquad \beta^+(k)=1-\sum_{-\infty}^{+\infty} r(i)\mu_{12}^+(k,i) \tag{36}$$

which are called the *transmission coefficients*. Note that, due to the analytical properties of μ_{21}^- (resp. μ_{12}^+), $\beta^-(k)$ can be continued analytically in $|k|\geqslant 1$ (resp. $\beta^+(k)$ in $|k|\leqslant 1$). Actually the vectors μ_1^- and μ_2^+ have poles where the transmission coefficients $\beta^{\pm}(k)$ have poles and we derive from the integral equations (after multiplication by $k-k_j^{\pm}$ and limit $k\to k_j^{\pm}$)

$$\operatorname*{Res}_{k_j^-}\{\mu_1^-(k,n)\}=\begin{pmatrix}0\\1\end{pmatrix}(k_j^-)^{-n}C_j^- +\begin{pmatrix} -\displaystyle\sum_{i=n+1}^{+\infty} q(i)\operatorname*{Res}_{k_j^-}\{\mu_{21}^-(k,i)\} \\ -\displaystyle\sum_{i=n+1}^{+\infty} (k_j^-)^{i-n} r(i)\operatorname*{Res}_{k_j^-}\{\mu_{11}^-(k,i)\}\end{pmatrix}, \tag{37}$$

$$\operatorname*{Res}_{k_j^+}\{\mu_2^+(k,n)\}=\begin{pmatrix}1\\0\end{pmatrix}(k_j^+)^{n}C_j^+ +\begin{pmatrix} -\displaystyle\sum_{i=n+1}^{+\infty} (k_j^+)^{n-i} q(i)\operatorname*{Res}_{k_j^+}\{\mu_{22}^+(k,i)\} \\ -\displaystyle\sum_{i=n+1}^{+\infty} r(i)\operatorname*{Res}_{k_j^+}\{\mu_{12}^+(k,i)\}\end{pmatrix} \tag{38}$$

with the following definitions of the $C_j^{\pm}$'s

$$C_j^-=\sum_{i=-\infty}^{+\infty} (k_j^-)^i r(i)\operatorname*{Res}_{k_j^-}\{\mu_{11}^-(k,i)\}, \tag{39}$$

$$C_j^+=\sum_{i=-\infty}^{+\infty} (k_j^+)^{-i} q(i)\operatorname*{Res}_{k_j^+}\{\mu_{22}^+(k,i)\} \tag{40}$$

which are called the *normalization coefficients*.

Since the vectors μ_1^+ and μ_2^- are holomorphic, we can write down their integral equations evaluated respectively in k_j^+ and k_j^- and compare them to the above integral equations for the residues. We obtain

$$\operatorname*{Res}_{k_j^-}\{\mu_1^-(k,n)\}=(k_j^-)^{-n}C_j^-\mu_2^-(k_j^-,n), \tag{41}$$

$$\operatorname*{Res}_{k_j^+}\{\mu_2^+(k,n)\}=(k_j^+)^{n}C_j^+\mu_1^+(k_j^+,n). \tag{42}$$

Finally the Riemann–Hilbert problem (33) and (34) is completed by the behaviors of the solution $\mu^{\pm}$ on the boundaries $|k|=0$ and $|k|=\infty$ of $\mathscr{D}$, which read

$$\mu_1^+(k,n)\xrightarrow[k\to 0]{}\begin{pmatrix}1\\0\end{pmatrix},\qquad \mu_2^-(k,n)\xrightarrow[k\to\infty]{}\begin{pmatrix}0\\1\end{pmatrix}. \tag{43}$$

The vectorial Riemann–Hilbert problem (33), (34) with singular points given by (41), (42) and the boundary behaviors (43) constitutes a closed problem which will be solved in the next section.

The behaviors of $\mu_1^-(k,n)$ at large k and of $\mu_2^+(k,n)$ at small k will be useful for the following and we define

$$\mu_{11}^-(k,n)\xrightarrow[k\to\infty]{} f(n). \tag{44}$$

Then

$$\mu_{21}^-(k,n)\xrightarrow[k\to\infty]{} r(n)f(n) \tag{45}$$

and one easily gets that $f(n)$ satisfies the integral equation

$$f(n)=1-\sum_{n+1}^{+\infty} q(i)r(i)f(i), \tag{46}$$

the solution of which is

$$f(n)=\prod_{n+1}^{+\infty}[1-q(i)r(i)]. \tag{47}$$

The same computation holds for $\mu_2^+(k,n)$ and we have finally

$$\mu^-(k,n)\xrightarrow[k\to\infty]{}\begin{pmatrix}f(n) & 0\\ r(n)f(n) & 1\end{pmatrix}, \tag{48}$$

$$\mu^+(k,n)\xrightarrow[k\to\infty]{}\begin{pmatrix}1 & q(n)f(n)\\ 0 & f(n)\end{pmatrix}. \tag{49}$$

It can be shown easily by using (33) and (34) that the determinant of the matrix $\mu(k,n)$ is analytic in the whole domain $\mathscr{D}$. Hence it follows from the Liouville theorem and the boundary values (48), (49) that

$$\det\{\mu(k,n)\}=f(n). \tag{50}$$

Note that, within the reduction $r=-\overline{q},\ f(n)=\rho(n)^{-1}$ as given by (24).

C. Asymptotic behaviors and unitarity relation

By taking the limit at large n directly on the integral equations, the functions $\mu^{\pm}$ obey for $|k|=1$

$$\mu^{-}(k,n)\xrightarrow[n\to+\infty]{}\begin{pmatrix}1 & 0\\ k^{-n}\alpha^{-}(k) & 1\end{pmatrix}, \tag{51}$$

$$\mu^{-}(k,n)\xrightarrow[n\to-\infty]{}\begin{pmatrix}\beta^{-}(k) & -k^{n}\hat{\alpha}^{-}(k)\\ 0 & \hat{\beta}^{-}(k)\end{pmatrix}, \tag{52}$$

$$\mu^{+}(k,n)\xrightarrow[n\to+\infty]{}\begin{pmatrix}1 & k^{n}\alpha^{+}(k)\\ 0 & 1\end{pmatrix}, \tag{53}$$

$$\mu^{+}(k,n)\xrightarrow[n\to-\infty]{}\begin{pmatrix}\hat{\beta}^{+}(k) & 0\\ -k^{-n}\hat{\alpha}^{+}(k) & \beta^{+}(k)\end{pmatrix}, \tag{54}$$

where the following *alternative scattering data* are defined as

$$\hat{\alpha}^{-}(k)=\sum_{-\infty}^{+\infty}k^{-i}q(i)\mu_{22}^{-}(k,i),\qquad \hat{\alpha}^{+}(k)=\sum_{-\infty}^{+\infty}k^{i}r(i)\mu_{11}^{+}(k,i), \tag{55}$$

$$\hat{\beta}^{-}(k)=1-\sum_{-\infty}^{+\infty}r(i)\mu_{12}^{-}(k,i),\qquad \hat{\beta}^{+}(k)=1-\sum_{-\infty}^{+\infty}q(i)\mu_{21}^{+}(k,i). \tag{56}$$

The quantities $\hat{\alpha}^{\pm}$ are also called the reflection coefficients *to the left* (referring to the limit $n\to-\infty$) when $\alpha^{\pm}$ are the reflection coefficients *to the right*.

It is easy to prove the following relations

$$\hat{\alpha}^{-}=\frac{\alpha^{+}\beta^{-}}{1-\alpha^{-}\alpha^{+}},\qquad \hat{\alpha}^{+}=\frac{\alpha^{-}\beta^{+}}{1-\alpha^{-}\alpha^{+}}, \tag{57}$$

$$\hat{\beta}^{-}=\frac{\beta^{+}}{1-\alpha^{-}\alpha^{+}},\qquad \hat{\beta}^{+}=\frac{\beta^{-}}{1-\alpha^{-}\alpha^{+}}. \tag{58}$$

Indeed, by using the Riemann–Hilbert problems (33) and (34) for μ (still for $|k|=1$) we have

$$\hat{\alpha}^{-}=\sum_{-\infty}^{+\infty}k^{-i}q(i)\mu_{22}^{+}(k,i)-\alpha^{+}\sum_{-\infty}^{+\infty}q(i)\mu_{21}^{+}(k,i)$$

$$=\alpha^{+}\left(1-\sum_{-\infty}^{+\infty}q(i)\mu_{21}^{+}(k,i)\right)=\alpha^{+}\hat{\beta}^{+}, \tag{59}$$

$$\hat{\beta}^+ = 1 - \sum_{-\infty}^{+\infty} q(i)\mu_{21}^-(k,i) + \alpha^- \sum_{-\infty}^{+\infty} k^{-i} q(i)\mu_{22}^-(k,i)$$

$$= \beta^- + \alpha^- \hat{\alpha}^-, \tag{60}$$

and so on for the other relations.

Now from (27) the determinant of $\mu(k,n)$ as $n \to -\infty$ can be computed and, by using the behaviors of $\mu(k,n)$, it leads to the relation

$$\beta^- \beta^+ = (1 - \alpha^- \alpha^+) \prod_{-\infty}^{+\infty} [1 - r(i)q(i)] \tag{61}$$

which is called the *unitarity relation*.

D. Reduction

A *reduction* denotes a simple (possibly algebraic) relation between the potentials (here $r(n)$ and $q(n)$) for which one can derive the counterpart relations for the spectral data. In other word a reduction is a relation which conserves the bijection between potentials and spectral data.

In the case

$$r(n) = -\overline{q(n)} \quad \Leftrightarrow \quad \overline{Q(n)} = \sigma_2 Q(n) \sigma_2, \tag{62}$$

it is easy to check that the function

$$\nu(k,n) = \sigma_2 \overline{\mu}(1/\overline{k},n)\sigma_2, \qquad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \tag{63}$$

obeys the same equation as $\mu(k,n)$. To compare them it is enough to consider their behaviors as $n \to \pm\infty$. Since

$$\sigma_2 \overline{\mu}^-(1/\overline{k},n)\sigma_2 \xrightarrow[n \to +\infty]{} \begin{pmatrix} 1 & -k^n \overline{\alpha^-}(1/\overline{k}) \\ 0 & 1 \end{pmatrix}, \tag{64}$$

we conclude that

$$\sigma_2 \overline{\mu}^-(1/\overline{k},n)\sigma_2 = \mu^+(k,n), \tag{65}$$

$$\overline{\alpha}^-(1/\overline{k}) = -\alpha^+(k). \tag{66}$$

The same calculation at $n \to -\infty$ gives

$$\overline{\beta}^-(1/\overline{k}) = \beta^+(k), \tag{67}$$

and also that the alternative scattering data obey similar relations.

For the discrete spectrum, the relation (65) implies

$$\operatorname*{Res}_{k_j^+} \{\mu_2^+(k,i)\} = \operatorname*{Res}_{k_j^+} \begin{pmatrix} -\overline{\mu_{21}}(1/\overline{k},i) \\ \overline{\mu_{11}}(1/\overline{k},i) \end{pmatrix}. \tag{68}$$

Using the basic relations

$$\operatorname*{Res}_{k_0}\{f(1/\overline{k})\}=-(\overline{k_0})^2\operatorname*{Res}_{1/\overline{k_0}}\{f(k)\},\quad \operatorname*{Res}_{k_0}\{\overline{g(k)}\}=\overline{\operatorname*{Res}_{k_0}\{g(k)\}},\tag{69}$$

the equation (68) becomes

$$\operatorname*{Res}_{k_j^+}\{\mu_2^+(k,i)\}=-(\overline{k}_j^+)^2\overline{\operatorname*{Res}_{1/\overline{k}_j^+}\begin{pmatrix}-\overline{\mu_{21}^-}(k,i)\\ \overline{\mu_{11}^-}(k,i)\end{pmatrix}}.\tag{70}$$

This last equation holds if

$$N^+=N^-,\qquad k_j^+=\frac{1}{\overline{k_j^-}}\tag{71}$$

for which it reads

$$\operatorname*{Res}_{k_j^+}\{\mu_2^+(k,i)\}=-(\overline{k}_j^+)^2\overline{\operatorname*{Res}_{k_j^-}\begin{pmatrix}-\overline{\mu_{21}^-}(k,i)\\ \mu_{11}^-(k,i)\end{pmatrix}}.\tag{72}$$

The above relation together with (65) and (71) then implies

$$\frac{C_j^+}{k_j^+}=\frac{\overline{C_j^-}}{\overline{k_j^-}}.\tag{73}$$

In the case of the reduction (62) we will use the following simplified notations (already used in Sec. II)

$$\alpha=\alpha^-,\qquad \beta=\beta^-,\qquad C_j=C_j^-,\qquad k_j=k_j^-,\qquad N=N^+=N^-.\tag{74}$$

In order to not over complicate this paper, we do not consider the other reduction $r=\overline{q}$ for which similar results can be easily obtained, but which corresponds to a spectral problem without discrete spectrum.

Last, it is useful for the following to rewrite the asymptotic boundary behaviors (51)–(54) within the reduction (and with the above notations) and for $|\zeta|=1$ as

$$\begin{pmatrix}\beta & \zeta^n\overline{\alpha}\gamma\\ 0 & \overline{\gamma}\end{pmatrix}\underset{n\to-\infty}{\longleftarrow}\mu^-(\zeta,n)\xrightarrow[n\to+\infty]{}\begin{pmatrix}1 & 0\\ \zeta^{-n}\alpha & 1\end{pmatrix},\tag{75}$$

$$\begin{pmatrix}\gamma & 0\\ -\zeta^{-n}\alpha\overline{\gamma} & \overline{\beta}\end{pmatrix}\underset{n\to-\infty}{\longleftarrow}\mu^+(\zeta,n)\xrightarrow[n\to+\infty]{}\begin{pmatrix}1 & -\zeta^n\overline{\alpha}\\ 0 & 1\end{pmatrix},\tag{76}$$

$$\gamma=\frac{\beta}{1+|\alpha|^2}.\tag{77}$$

Similarly, the unitarity relation (61) together with the definition (47) reads

$$|\beta|^2=(1+|\alpha|^2)f(-\infty).\tag{78}$$

IV. THE INVERSE SPECTRAL PROBLEM

The *inverse spectral problem* consists in reconstructing the potentials $q(n)$ and $r(n)$ from the spectral data

$$\alpha^{\pm}(k), \qquad \beta^{\pm}(k), \qquad |k|=1;$$

$$C_j^{\pm}, \qquad k_j^{\pm}, \qquad |k_j^{+}|<1, \qquad j=1,\ldots,N^{+}, \qquad |k_j^{-}|>1, \qquad j=1,\ldots,N^{-}. \tag{79}$$

A simple way of doing this is to reformulate the analytical properties of the matrix $\mu(k,n)$ in the domain $\mathscr{D}$ as a $\bar{\partial}$-problem.

A. Inverse problem as a $\bar{\partial}$-problem

Indeed, the set of fundamental relations (33), (34), (41) and (42), which contain all the information about the analytical properties of $\mu(k,n)$, can be summarized in the formula

$$\frac{\partial}{\partial \bar{k}}\mu(k,n)=\mu(k,n)R(k,n), \qquad k\in\mathscr{D}, \tag{80}$$

where the *spectral transform* contains all the information and reads

$$R(k,n)=\begin{pmatrix} 0 & \alpha^{+}(k)\,\delta^{+}(k,1) \\ -\alpha^{-}(k)\,\delta^{-}(k,1) & 0 \end{pmatrix}\begin{pmatrix} k^{-n} & 0 \\ 0 & k^{n} \end{pmatrix} -2i\pi\begin{pmatrix} 0 & \sum_{j=1}^{N^{+}} C_j^{+}\,\delta(k-k_j^{+}) \\ \sum_{j=1}^{N^{-}} C_j^{-}\,\delta(k-k_j^{-}) & 0 \end{pmatrix}\begin{pmatrix} k^{-n} & 0 \\ 0 & k^{n} \end{pmatrix}. \tag{81}$$

The distributions $\delta^{\pm}(k,1)$ are defined in the Appendix and the distribution $\delta(k)$ is normalized by requiring that $\int\int dk \wedge dk\,\delta(k)=1$. Using the method and tools described in the Appendix, and for the behaviors

$$\mu_1(k,n) \xrightarrow[k\to 0]{} \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \qquad \mu_2(k,n) \xrightarrow[k\to\infty]{} \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \tag{82}$$

we have the following solution of this $\bar{\partial}$-problem

$$\mu(k,n)=1+\frac{1}{2i\pi}\iint_{\mathscr{D}}\frac{d\lambda\wedge d\bar{\lambda}}{\lambda-k}\mu(\lambda,n)R(\lambda,n)\begin{pmatrix} k/\lambda & 0 \\ 0 & 1 \end{pmatrix}. \tag{83}$$

Due to the particular structure (81) of $R(k)$, the above matrix valued equation has actually to be understood as two vectorial integral equations, for $\mu_1^{+}(k,n)$ and for $\mu_2^{-}(k,n)$. As will be seen hereafter, the knowledge of these two vectors is sufficient for completely solving the problem.

B. Reconstruction of the potentials

The potentials are obtained from the asymptotic expansion of the Jost solutions μ_2^{-} and μ_1^{+} of (25) via the formulae

$$q(n+1)=-\mu_{12}^{-(-1)}(n), \qquad r(n+1)=-\mu_{21}^{+(1)}(n), \tag{84}$$

where $\mu_{12}^{-(-1)}(n)$ is the coefficient of k^{-1} in the Laurent expansion for $k\to\infty$ of $\mu_{12}^{-}(k,n)$, and $\mu_{21}^{+(1)}(n)$ the coefficient of k in the Taylor expansion for $k\to 0$ of $\mu_{21}^{+}(k,n)$. In particular from (83) we get

$$r(n+1)=\frac{1}{2i\pi}\oint_{\mathscr{C}} d\zeta\alpha^{-}(\zeta)\zeta^{-n-2}\mu_{22}^{-}(\zeta,n)-\sum_{j=1}^{N^{-}} C_j^{-}(k_j^{-})^{-n-2}\mu_{22}^{-}(k_j^{-},n), \tag{85}$$

$$q(n+1)=\frac{1}{2i\pi}\oint_{\mathscr{C}} d\zeta\alpha^{+}(\zeta)\zeta^{n}\mu_{11}^{+}(\zeta,n)+\sum_{j=1}^{N^{+}} C_j^{+}(k_j^{+})^{n}\mu_{11}^{+}(k_j^{+},n). \tag{86}$$

One could easily check that the potentials given by (86) and (85) do obey the reduction (62) when $\mu(k,n)$ obeys (65), $\alpha(k)$ obeys (66), $C_j^{\pm}$ obeys (73) and $k_j^{\pm}$ obeys (71).

Finally the transmission coefficients $\beta^{-}(k)$ and $\beta^{+}(k)$ are computed from their definitions (36), where the entries $\mu_{21}^{-}(k,n)$ and $\mu_{12}^{+}(k,n)$ are obtained from the solution μ_1^{+} and μ_2^{-} by using the explicit relations (33), (34). Equivalently one can use the relations (58) and the behaviors (52) and (54) to get ($|\zeta|=1$)

$$\beta^{+}(\zeta)=[1-\alpha^{+}\alpha^{-}]\lim_{n\to-\infty}\mu_{22}^{-}(\zeta,n), \tag{87}$$

$$\beta^{-}(\zeta)=[1-\alpha^{+}\alpha^{-}]\lim_{n\to-\infty}\mu_{11}^{+}(\zeta,n). \tag{88}$$

Remark: From the other components of μ_1^{+} and μ_2^{-} we obtain in (25) the following relations

$$\mu_{22}^{-(-1)}(n)=\sum_{n+1}^{\infty} r(i)q(i+1), \qquad \mu_{11}^{+(1)}(n)=\sum_{n+1}^{\infty} r(i+1)q(i). \tag{89}$$

V. THE METHOD OF THE $\bar{\partial}$-PROBLEM

We have shown in the preceding sections that the spectral problem (25) can be mapped to the ∂-problem (80), namely,

$$\frac{\partial}{\partial k}\mu(k)=\mu(k)R(k), \qquad k\in\mathscr{D}, \tag{90}$$

with the boundary behaviors (82). The solution of such a boundary value problem in the complex plane solves the Cauchy–Green integral equation

$$\mu(k)=1+\frac{1}{2i\pi}\iint_{\mathscr{D}}\frac{d\lambda\wedge d\bar{\lambda}}{\lambda-k}\mu(\lambda)R(\lambda)\begin{pmatrix} k/\lambda & 0\\ 0 & 1\end{pmatrix}. \tag{91}$$

The purpose of the following is to show that the above integral equation, for the unknown μ and the datum R, can be taken as the *starting tool*. More precisely we shall show how a parametric dependence of R (on an integer n and on a real t) induces the spectral problem (25) and a nonlinear evolution equation.

A. The principal spectral problem

We restrict this study to off-diagonal matrices $R(k)$ and consider the integral equation (91) as the given tool. If $R(k)$ depends now on an external integer n, the solution $\mu(k,n)$ solves then the ∂-problem (90) with the behaviors

$$\mu(k,n) \xrightarrow[k\to\infty]{} \begin{pmatrix} 1 & g(n) \\ 0 & f(n) \end{pmatrix} + k\mu^{(1)}(n) + \cdots, \tag{92}$$

$$\mu(k,n) \xrightarrow[k\to\infty]{} \begin{pmatrix} f'(n) & 0 \\ h(n) & 1 \end{pmatrix} + \frac{1}{k}\mu^{(-1)}(n) + \cdots, \tag{93}$$

where the functions f, f', g and h have to be evaluated. The determinant of $\mu(k,n)$ is analytic in $\mathscr{D}$ as indeed the off-diagonal structure of $R(k,n)$ implies

$$\frac{\partial}{\partial k}\det\{\mu(k,n)\} = 0, \tag{94}$$

and from the above behavior the Liouville theorem implies

$$\det\{\mu(k,n)\} = f(n) = f'(n). \tag{95}$$

We chose now the following explicit dependence of $R(k,n)$ on the discrete variable n

$$R(k,n+1) = \Lambda(k)^{-1} R(k,n) \Lambda(k), \tag{96}$$

with $\Lambda(k)$ defined in (26). The basic fundamental property which allows us to derive from the choice (96) a *difference* equation for μ in the variable n is the following

$$\frac{\partial}{\partial k} H(k,n) = 0, \qquad H(k,n) = \mu(k,n+1)\Lambda(k)^{-1}\mu(k,n)^{-1}\Lambda(k). \tag{97}$$

The above function $H(k,n)$ can then be reconstructed from its behaviors on the boundary of $\mathscr{D}$ ($k=\infty$ and $k=0$) which read from (92) and (93)

$$H(k,n) \xrightarrow[k\to\infty]{} \frac{1}{f(n)} \begin{pmatrix} f(n) - g(n+1)\mu_{21}^{(1)}(n) & g(n+1) \\ -f(n+1)\mu_{21}^{(1)}(n) & f(n+1) \end{pmatrix}, \tag{98}$$

$$H(k,n) \xrightarrow[k\to\infty]{} \frac{1}{f(n)} \begin{pmatrix} f(n+1) & -f(n+1)\mu_{12}^{(-1)}(n) \\ h(n+1) & f(n) - h(n+1)\mu_{12}^{(-1)}(n) \end{pmatrix}. \tag{99}$$

Since $H(k,n)$ is analytic, these two behaviors are equal, which implies the following four equations

$$\begin{gathered} f(n+1) = f(n) - g(n+1)\mu_{21}^{(1)}(n), \quad f(n+1) = f(n) - h(n+1)\mu_{12}^{(-1)}(n), \\ g(n+1) = -f(n+1)\mu_{12}^{(-1)}(n), \quad h(n+1) = -f(n+1)\mu_{21}^{(1)}(n), \end{gathered} \tag{100}$$

which are solved by first *defining* the *potentials* as

$$q(n+1) = -\mu_{12}^{(-1)}(n), \qquad r(n+1) = -\mu_{21}^{(1)}(n), \tag{101}$$

and hence

$$g(n) = q(n)f(n), \qquad h(n) = r(n)f(n), \tag{102}$$

with the recursion relation for $f(n)$

$$f(n)=f(n+1)[1-r(n+1)q(n+1)] \tag{103}$$

of which the solution is indeed given by (47).

Finally, the solution of the ∂-problem (97) reads

$$H(k,n)=\frac{1}{1-r(n+1)q(n+1)}\begin{pmatrix}1 & q(n+1)\\ r(n+1) & 1\end{pmatrix} \tag{104}$$

which can be written with (97) as the *discrete spectral problem*

$$\mu(k,n+1)\Lambda(k)^{-1}\mu(k,n)^{-1}\Lambda(k)=[1-Q(n+1)]^{-1}, \tag{105}$$

where

$$Q(n)=\begin{pmatrix}0 & q(n)\\ r(n) & 0\end{pmatrix}. \tag{106}$$

It is convenient for the following to define the quantity

$$U(n)=[1-Q(n+1)]^{-1} \tag{107}$$

such that the equation for $\mu(k,n)$ reads

$$\mu(k,n+1)=U(n)\Lambda(k)^{-1}\mu(k,n)\Lambda(k) \tag{108}$$

which is precisely the spectral problem (25).

B. Nonanalytic dispersion relations. A theorem

We consider now that $R(k,n)$ depends also on an external real t and address the problem of computing the expression of the time dependence of the solution μ of (91). The result can be stated as a theorem.

Theorem: *When the spectral transform $R(k,n,t)$ evolves according to*

$$R_t(k,n,t)=[R(k,n,t),\Omega(k,t)]+M(k,n,t), \tag{109}$$

where

$$M(k,n+1,t)=\Lambda(k)^{-1}M(k,n,t)\Lambda(k), \qquad [\Lambda(k),\Omega(k,t)]=0, \tag{110}$$

and where $\Omega(k,t)$ is the nonanalytic dispersion relation

$$\Omega(k,t)=\frac{1}{2i\pi}\iint_{\mathscr{D}}\frac{d\lambda\wedge d\bar{\lambda}}{\lambda-k}\frac{\partial\Omega(\lambda,t)}{\partial\bar{\lambda}}\begin{pmatrix}k/\lambda & 0\\ 0 & 1\end{pmatrix} \tag{111}$$

the potential Q obeys the following evolution

$$Q_t(n+1,t)=\left[\sigma_3,\frac{1}{2i\pi}\iint_{\mathscr{D}}\frac{d\lambda\wedge d\bar{\lambda}}{2\lambda}T(\lambda,n,t)\right], \tag{112}$$

where

$$T(k,n,t)=\Lambda(k)^{-1}\mu(k,n,t)\left\{M(k,n,t)-\frac{\partial\Omega(k,t)}{\partial\overline{k}}\right\}\Lambda(k)\mu^{-1}(k,n+1,t). \tag{113}$$

This theorem is proved hereafter.

1. The auxiliary spectral problem

Let us define the matrix

$$V(k,n,t)=\{\mu_t(k,n,t)-\mu(k,n,t)\Omega(k,t)\}\mu^{-1}(k,n,t), \tag{114}$$

and compute its $\overline{\partial}$-derivative which, from (80), (109) and (110), obeys

$$\frac{\partial V(k,n,t)}{\partial\overline{k}}=\mu(k,n,t)\left\{M(k,n,t)-\frac{\partial\Omega(k,t)}{\partial\overline{k}}\right\}\mu^{-1}(k,n,t). \tag{115}$$

To solve the above $\overline{\partial}$-problem we need the behaviors of V_1 as $k\to 0$ and V_2 as $k\to\infty$. Since

$$\mu(k,n,t)\xrightarrow[k\to 0]{}\begin{pmatrix}1 & q(n,t)f(n,t)\\ 0 & f(n,t)\end{pmatrix}+k\mu^{(1)}(n,t)+\cdots, \tag{116}$$

$$\mu(k,n,t)\xrightarrow[k\to\infty]{}\begin{pmatrix}f(n,t) & 0\\ r(n,t)f(n,t) & 1\end{pmatrix}+\frac{1}{k}\mu^{(-1)}(n,t)+\cdots, \tag{117}$$

it is easy to obtain, thanks also to the choice (111) (it would not be so in the case of a regular dispersion relation)

$$V_1(k,n,t)\xrightarrow[k\to 0]{}\begin{pmatrix}0\\ 0\end{pmatrix},\quad V_2(k,n,t)\xrightarrow[k\to\infty]{}\begin{pmatrix}0\\ 0\end{pmatrix}. \tag{118}$$

Consequently the solution reads

$$V(k,n,t)=\frac{1}{2i\pi}\iint_{\mathscr{D}}\frac{d\lambda\wedge d\overline{\lambda}}{\lambda-k}S(\lambda,n,t)\begin{pmatrix}k/\lambda & 0\\ 0 & 1\end{pmatrix}, \tag{119}$$

where we have defined

$$S(k,n,t)=\mu(k,n,t)\left\{M(k,n,t)-\frac{\partial\Omega(k,t)}{\partial\overline{k}}\right\}\mu^{-1}(k,n,t). \tag{120}$$

Now, with the above value of V, the definition (114) can be written as the *auxiliary spectral problem*

$$\mu_t(k,n,t)=V(k,n,t)\mu(k,n,t)+\mu(k,n,t)\Omega(k,t). \tag{121}$$

2. Fundamental property of V(k,n,t)

For simplicity of notations, we omit from now on the variable t. By direct computation the matrix S obeys the equation

$$S(k,n+1)U(n)=U(n)\Lambda(k)^{-1}S(k,n)\Lambda(k). \tag{122}$$

The next step consists in seeking an analogous property for $V(k,n)$, by computing the quantities $U(n)^{-1}V(k,n+1)$ on one side and $\Lambda(k)^{-1}V(k,n)\Lambda(k)U(n)^{-1}$ on the other side. Using

$$\Lambda(\lambda)^{-1}S(\lambda,n)\Lambda(\lambda)U(n)^{-1}\begin{pmatrix} k/\lambda & 0 \\ 0 & 1 \end{pmatrix}-\Lambda(k)^{-1}S(\lambda,n)\begin{pmatrix} k/\lambda & 0 \\ 0 & 1 \end{pmatrix}\Lambda(k)U(n)^{-1}$$

$$=\frac{\lambda-k}{\lambda}\begin{pmatrix} 0 & -q(n+1)s_{11}(\lambda,n)+\lambda s_{12}(\lambda,n) \\ r(n+1)s_{22}(\lambda,n)-(1/\lambda)s_{21}(\lambda,n) & 0 \end{pmatrix},$$

we obtain finally the required property of $V(k,n)$

$$U(n)^{-1}V(k,n+1)-\Lambda(k)^{-1}V(k,n)\Lambda(k)U(n)^{-1}=P(n), \tag{123}$$

$$P(n)=\frac{1}{2i\pi}\iint_{\mathscr{D}}\frac{d\lambda\wedge d\bar{\lambda}}{2\lambda}[\sigma_3,T(\lambda,n)], \tag{124}$$

$$T(k,n)=\Lambda(k)^{-1}S(k,n)\Lambda(k)U(n)^{-1}=U(n)^{-1}S(k,n+1). \tag{125}$$

We have used here above (122) to rewrite T in a more convenient form, and finally from the definition (120) of $S(k,n)$ and the spectral problem (25) it reads

$$T(k,n)=\Lambda(k)^{-1}\mu(k,n)\left\{M(k,n)-\frac{\partial\Omega(k)}{\partial\bar{k}}\right\}\Lambda(k)\mu^{-1}(k,n+1). \tag{126}$$

Note that the matrix $T(k,n)$ obeys a property similar to $S(k,n)$ since it can be checked directly that

$$U(n-1)T(k,n-1)=\Lambda(k)T(k,n)U(n)\Lambda(k)^{-1}. \tag{127}$$

3. The evolution equation

The nonlinear evolution of $Q(n,t)$ is now obtained in the usual way by requiring the compatibility between (108) and (121) which reads

$$\frac{\partial}{\partial t}\mu(k,n+1,t)=\frac{\partial}{\partial t}\{U(n)\Lambda(k)^{-1}\mu(k,n)\Lambda(k)\}$$

$$=V(k,n+1,t)\mu(k,n+1,t)+\mu(k,n+1,t)\Omega(k,t). \tag{128}$$

By means of (123) it is then easy to obtain the equation

$$U_t(n)=U(n)P(n)U(n), \tag{129}$$

which readily gives the evolution (112) since $U(n)=[1-Q(n+1)]^{-1}$. This ends the proof of the theorem.

C. Reduction

If we consider the reduction $r(n)=-\overline{q(n)}$ the matrices

$$\Omega(k,t)=\begin{pmatrix} \omega_1(k,t) & 0 \\ 0 & \omega_2(k,t) \end{pmatrix}, \tag{130}$$

$$M(k,n,t)=\begin{pmatrix} 0 & m_2(k,t) \\ m_1(k,t) & 0 \end{pmatrix}\begin{pmatrix} k^{-n} & 0 \\ 0 & k^n \end{pmatrix} \tag{131}$$

must be compatible with the preservation of the structure of $R(n)$ in the time evolution equation (109). We choose, therefore, ω_1 and ω_2 analytic inside and outside the unite circle with limit values on the two sides of the circle satisfying the symmetry properties ($\zeta=e^{i\theta}$)

$$\omega_1^-(\zeta,t)=\overline{\omega_2^+}(\zeta,t), \quad \omega_2^-(\zeta,t)=\overline{\omega_1^+}(\zeta,t), \tag{132}$$

and we choose m_1 and m_2 as

$$\begin{aligned} m_1(k,t)&=m^-(k,t)\,\delta^-(k,1)\equiv m(\zeta,t)\,\delta^-(k,1),\\ m_2(k,t)&=m^+(k,t)\,\delta^+(k,1)\equiv \overline{m(\zeta,t)}\,\delta^+(k,1), \end{aligned} \tag{133}$$

where

$$\zeta=\frac{k}{|k|}$$

and $m(\zeta,t)$ is a given *function* defined on the circle $|k|=1$. Note that the discontinuity of ω_1

$$p(\zeta,t)\equiv\omega_1^+(\zeta,t)-\omega_1^-(\zeta,t) \tag{134}$$

is related to the discontinuity of ω_2 by the formula

$$\omega_2^+(\zeta,t)-\omega_2^-(\zeta,t)=-\overline{p(\zeta,t)}. \tag{135}$$

The analytic properties of ω_1 and ω_2 are summarized by the formulae ($\zeta=k/|k|$)

$$\frac{\partial\omega_1}{\partial\bar{k}}=p(\zeta)\,\delta(k,1), \tag{136}$$

$$\frac{\partial\omega_2}{\partial\bar{k}}=-\overline{p(\zeta)}\,\delta(k,1), \tag{137}$$

where the distribution $\delta(k,1)$ is defined in the Appendix. Requiring that $\omega_1\to 0$ for $k\to 0$ and $\omega_2\to 0$ for $k\to\infty$, $\Omega(k)$ is defined by the following Cauchy–Green formula

$$\Omega(k)=\frac{1}{2\pi i}\oint_{\mathscr{C}}\frac{d\zeta}{\zeta-k}\begin{pmatrix} p(\zeta,t) & 0 \\ 0 & -\overline{p(\zeta,t)} \end{pmatrix}\begin{pmatrix} k/\zeta & 0 \\ 0 & 1 \end{pmatrix}. \tag{138}$$

It results that

$$\omega_1(k)=\overline{\omega_2(1/\bar{k})} \tag{139}$$

in agreement with the conditions on the boundaries (132).

It can be shown that with the choices indicated in (132) and (133) the evolution equation (112) is compatible with the reduction $r=-\bar{q}$. This evolution reads

$$q_t(n+1,t)=\frac{1}{2\pi}\,\frac{1}{f(n+1,t)}\int_{-\pi}^{+\pi}d\theta\;\gamma(\theta,n,t), \tag{140}$$

where

$$\gamma(\theta,n)=-\omega_1^-(\zeta)\mu_{11}^-(\zeta,n)\mu_{12}^-(\zeta,n+1)+\omega_1^+(\zeta)\mu_{11}^+(\zeta,n)\mu_{12}^+(\zeta,n+1)$$
$$+\omega_2^-(\zeta)\zeta\mu_{12}^-(\zeta,n)\mu_{11}^-(\zeta,n+1)-\omega_2^+(\zeta)\zeta\mu_{12}^+(\zeta,n)\mu_{11}^+(\zeta,n+1)+\alpha(\zeta)(\omega_1^-(\zeta)$$
$$-\omega_2^-(\zeta))\zeta^{-n}\mu_{12}^-(\zeta,n)\mu_{12}^-(\zeta,n+1)+\overline{\alpha}(\zeta)(\omega_1^+(\zeta)-\omega_2^+(\zeta))\zeta^{n+1}\mu_{11}^+(\zeta,n)\mu_{11}^+(\zeta,n+1)$$
$$-m(\zeta)\zeta^{-n}\mu_{12}^-(\zeta,n)\mu_{12}^-(\zeta,n+1)+\overline{m(\zeta)}\zeta^{n+1}\mu_{11}^+(\zeta,n)\mu_{11}^+(\zeta,n+1) \tag{141}$$

with $\zeta=e^{i\theta}$ (remember that $\alpha\equiv\alpha^-$ and $\alpha^+(\zeta)=-\overline{\alpha(\zeta)}$). Note that in computing $T(\lambda,n)$ in (112) the term containing $\Omega(k,t)$ must be written as follows

$$\Lambda^{-1}\mu(n)\frac{\partial\Omega}{\partial k}\Lambda\mu^{-1}(n+1)=\frac{\partial}{\partial k}(\Lambda^{-1}\mu(n)\Omega\Lambda\mu^{-1}(n+1))$$
$$-\Lambda^{-1}\mu(n)[R(n),\Omega]\Lambda\mu^{-1}(n+1) \tag{142}$$

which is a well defined local formulation of a $\bar{\partial}$ -problem for a sectionally holomorphic function.

It is convenient, by using equations (33) and (34), to rewrite (141) in terms of μ_1^+ and μ_2^-

$$\gamma(\theta,n)=p(\zeta)\mu_{11}^+(\zeta,n)\mu_{12}^-(\zeta,n+1)+\overline{p(\zeta)}\zeta\mu_{12}^-(\zeta,n)\mu_{11}^+(\zeta,n+1)$$
$$-m(\zeta)\zeta^{-n}\mu_{12}^-(\zeta,n)\mu_{12}^-(\zeta,n+1)+\overline{m(\zeta)}\zeta^{n+1}\mu_{11}^+(\zeta,n)\mu_{11}^+(\zeta,n+1) \tag{143}$$

which shows explicitly that the evolution equation depends only on the discontinuity of $\Omega(k)$ on the unit circle.

VI. INTEGRABLE DISCRETE INITIAL-BOUNDARY VALUE PROBLEM

By using the tools previously developed we prove now that the nonlinear system (1) is integrable when it is related to the initial boundary value (5). We rewrite hereafter this system in the variable $\zeta=e^{i\theta}$ and with the relation (24) as

$$q_t(n,t)\prod_{i=n+1}^{\infty}(1+|q(i,t)|^2)=\frac{1}{2\pi}\int_{-\pi}^{+\pi}d\theta\, e^{in\theta}(A_1*A_2)(\zeta,n,t), \tag{144}$$

$$A_1(\zeta,n,t)-A_1(\zeta,n-1,t)=\zeta^{-n}q(n,t)A_2(\zeta,n,t), \tag{145}$$

$$A_2(\zeta,n,t)-A_2(\zeta,n-1,t)=-\zeta^n\overline{q(n,t)}A_1(\zeta,n,t), \tag{146}$$

where the interaction term is defined as

$$(A_1*A_2)(\zeta,n,t)=g(\theta,t)A_1(\zeta,n-1,t)\overline{A_2}(\zeta,n,t)+\overline{g(\theta,t)}A_1(\zeta,n,t)\overline{A_2}(\zeta,n-1,t). \tag{147}$$

Theorem: *With the datum of the initial value* $q(n,0)$ *and the following arbitrary boundary values as* $n\to+\infty$

$$A_1(\zeta,n,t)\to I_1(\zeta,t),\qquad A_2(\zeta,n,t)\to I_2(\zeta,t), \tag{148}$$

the above system is solvable by the spectral transform method.

A. Proof of integrability

The proof is performed by showing that the evolution (144) can actually be written under the form (140). This then gives a unique definition of the functions $m(k)$ and $\omega(k)+\overline{\omega(}k)$ for which the two equations (140) and (144) are *identical*. Hence the evolution (109) of the spectral transform $R(k,t)$ is uniquely given via (132) and (133).

The first useful property is that *the following 5 vectors*

$$\begin{pmatrix} A_1(\zeta,n) \\ \zeta^{-n}A_2(\zeta,n) \end{pmatrix}, \qquad \begin{pmatrix} \mu_{11}^{\pm}(\zeta,n) \\ \mu_{21}^{\pm}(\zeta,n) \end{pmatrix}, \qquad \zeta^{-n}\begin{pmatrix} \mu_{12}^{\pm}(\zeta,n) \\ \mu_{22}^{\pm}(\zeta,n) \end{pmatrix}, \tag{149}$$

solve the equation (146). Then, by comparison of their asymptotic behaviors as $n\to+\infty$ given in (148) and in (53)–(52), we get

$$\begin{pmatrix} A_1(\zeta,n) \\ \zeta^{-n}A_2(\zeta,n) \end{pmatrix} = I_1(\zeta)\begin{pmatrix} \mu_{11}^{+}(\zeta,n) \\ \mu_{21}^{+}(\zeta,n) \end{pmatrix} + I_2(\zeta)\zeta^{-n}\begin{pmatrix} \mu_{12}^{-}(\zeta,n) \\ \mu_{22}^{-}(\zeta,n) \end{pmatrix}. \tag{150}$$

Next, to compute the product $(A_1*A_2)(\zeta,n)$ we make use of the Riemann–Hilbert relations

$$\mu_1^-(\zeta,n)-\mu_1^+(\zeta,n)=\alpha^-(\zeta)\zeta^{-n}\mu_2^-(\zeta,n), \tag{151}$$

$$\mu_2^-(\zeta,n)-\mu_2^+(\zeta,n)=-\alpha^+(\zeta)\zeta^{n}\mu_1^+(\zeta,n), \tag{152}$$

and rewrite it in terms only of μ_1^+ and μ_2^-

$$\begin{aligned}\zeta^{n+1}&(A_1*A_2)(\zeta,n+1)\\ &=-[g|I_1|^2-\overline{g|}I_2|^2]\mu_{11}^+(n)\mu_{12}^-(n+1)-[\overline{g|}I_1|^2-g|I_2|^2]\zeta\mu_{12}^-(n)\mu_{11}^+(n+1)\\ &\quad-(g+\overline{g)}\overline{I_1}I_2\zeta^{-n}\mu_{12}^-(n)\mu_{12}^-(n+1)+(g+\overline{g)}I_1\overline{I_2}\zeta^{n+1}\mu_{11}^+(n)\mu_{11}^+(n+1).\end{aligned} \tag{153}$$

Then, thanks to the expression (47), the two equations (140) and (144) are *identical* if and only if

$$p(\zeta,t)=-g(\theta,t)|I_1(\theta,t)|^2+\overline{g(}\theta,t)|I_2(\theta,t)|^2, \tag{154}$$

$$m(\zeta,t)=(g(\theta,t)+\overline{g(}\theta,t))\overline{I_1(}\theta,t)I_2(\theta,t). \tag{155}$$

Finally the theorem is proved and it remains to compute the evolution of the spectral transform.

B. Evolution of the spectral transform

1. Evolution of $\alpha(\zeta,t)$

The time evolution of $R(k,n,t)$ is given by (109) with M and Ω defined in (133) and in (138). Taking into account the structure (81) of $R(k,n,t)$ we have

$$\partial_t\alpha(\zeta,t)=[\omega_1^-(\zeta,t)-\omega_2^-(\zeta,t)]\alpha(\zeta,t)-m(\zeta,t), \tag{156}$$

$$\partial_t k_j=0, \qquad \partial_t C_j(t)=[\omega_1(k_j,t)-\omega_2(k_j,t)]C_j(t), \tag{157}$$

where from (138) and the Sokhotski–Plemelj formula we have

$$\omega_1^-(\zeta,t)-\omega_2^-(\zeta,t)=-\frac{1}{2}p(\zeta,t)-\frac{1}{2}\overline{p(\zeta,t)}+\frac{1}{2\pi i}P\oint_{\mathscr{C}}\frac{d\zeta'}{\zeta'-\zeta}p(\zeta',t)\frac{\zeta}{\zeta'}$$

$$+\frac{1}{2\pi i}P\oint_{\mathscr{C}}\frac{d\zeta'}{\zeta'-\zeta}\overline{p(\zeta',t)}, \tag{158}$$

$$\omega_1(k_j,t)-\omega_2(k_j,t)=\frac{1}{2\pi i}\oint_{\mathscr{C}}\frac{d\zeta'}{\zeta'-k_j}p(\zeta',t)\frac{k_j}{\zeta'}$$

$$+\frac{1}{2\pi i}\oint_{\mathscr{C}}\frac{d\zeta'}{\zeta'-k_j}\overline{p(\zeta',t)}, \tag{159}$$

and the functions $p(\zeta,t)$ and $m(\zeta,t)$ are given in (154) and (155).

As a result the evolution equation of α and C_j can be written

$$\partial_t\alpha=\alpha\frac{g+\overline{g}}{2}(|I_1(\theta,t)|^2-|I_2(\theta,t)|^2)-(g+\overline{g})\overline{I_1}I_2$$

$$-\alpha\frac{1}{2\pi i}P\oint_{\mathscr{C}}\frac{d\zeta'}{\zeta'-\zeta}(g+\overline{g})(|I_1|^2-|I_2|^2)$$

$$+\alpha\frac{1}{2\pi i}\oint_{\mathscr{C}}\frac{d\zeta'}{\zeta'}(g|I_1|^2-\overline{g}|I_2|^2), \tag{160}$$

$$\partial_t C_j(t)=-C_j(t)\frac{1}{2\pi i}P\oint_{\mathscr{C}}\frac{d\zeta'}{\zeta'-k_j}(g+\overline{g})(|I_1|^2-|I_2|^2)$$

$$+C_j(t)\frac{1}{2\pi i}\oint_{\mathscr{C}}\frac{d\zeta'}{\zeta'}(g|I_1|^2-\overline{g}|I_2|^2). \tag{161}$$

2. Evolution of $\beta(\zeta,t)$

The definition (58) allows us to obtain readily

$$\frac{\hat{\beta}_t^+}{\hat{\beta}^+}-\frac{\beta_t}{\beta}=-\frac{(|\alpha|^2)_t}{1+|\alpha|^2}, \tag{162}$$

which actually can be understood as a Riemann–Hilbert problem on the unit circle. Its solution reads

$$|k|>1:\quad \frac{\hat{\beta}_t^+}{\hat{\beta}^+}=\frac{\partial}{\partial t}\left(\frac{|\beta|^2}{1+|\alpha|^2}\right)\frac{1+|\alpha|^2}{|\beta|^2}-\frac{1}{2\pi i}\oint_{\mathscr{C}}\frac{d\zeta'}{\zeta'-k}\frac{(|\alpha(\zeta')|^2)_t}{1+|\alpha(\zeta')|^2}, \tag{163}$$

$$|k|<1:\quad \frac{\beta_t}{\beta}=-\frac{1}{2\pi i}\oint_{\mathscr{C}}\frac{d\zeta'}{\zeta'-k}\frac{k}{\zeta'}\frac{(|\alpha(\zeta')|^2)_t}{1+|\alpha(\zeta')|^2}. \tag{164}$$

Hence, writing the above equation for $k=\zeta(1-0)$, we get the evolution (14).

C. Evolution of the spectral transform from the Lax pair

For completeness, we rederive hereafter the preceding formula (evolution of α and β, in the absence of bound states for simplicity), by using the traditional approach for which the starting tool is the Lax pair (25), (121). The method consists simply in evaluating the asymptotic boundary values as $n\to\pm\infty$ on the auxiliary spectral problem (121), in which (forget for a while the (n,t)-dependence)

$$V(k)=\frac{1}{2i\pi}\iint_{\mathscr{D}}\frac{d\lambda\wedge d\bar{\lambda}}{\lambda-k}\mu(\lambda)\left(M(\lambda)-\frac{\partial\Omega(\lambda)}{\partial\bar{\lambda}}\right)\mu^{-1}(\lambda)\begin{pmatrix}k/\lambda & 0\\ 0 & 1\end{pmatrix}. \tag{165}$$

By using the identity (142), the equation (121) can be more conveniently written as

$$\mu_t(k,n,t)=X(k,n,t)\mu(k,n,t), \tag{166}$$

where

$$X(k)=\frac{1}{2i\pi}\iint_{\mathscr{D}}\frac{d\lambda\wedge d\bar{\lambda}}{\lambda-k}\mu(\lambda,n,t)(M(\lambda)+[R(\lambda),\Omega(\lambda)])\mu^{-1}(\lambda)\begin{pmatrix}k/\lambda & 0\\ 0 & 1\end{pmatrix}. \tag{167}$$

By inserting in the above equation the explicit forms of $R(k,n,t)$ given in (81) with (66) and no bound states, of $\Omega(k,t)$ given in (138), and of $M(k,n,t)$ given in (131) with (133), we get finally

$$X(k,n,t)=\frac{1}{2i\pi}\oint\frac{d\zeta'}{\zeta'-k}\frac{1}{f(n)}\chi(\zeta',n,t)\begin{pmatrix}k/\zeta' & 0\\ 0 & 1\end{pmatrix}, \tag{168}$$

with the following definition

$$\chi(\zeta)=\zeta^n[\overline{m}+(\omega_1^+-\omega_2^+)\overline{\alpha}]\begin{pmatrix}-\mu_{11}^+\mu_{21}^+ & (\mu_{11}^+)^2\\ -(\mu_{21}^+)^2 & \mu_{11}^+\mu_{21}^+\end{pmatrix}$$

$$+\zeta^{-n}[m-(\omega_1^--\omega_2^-)\alpha]\begin{pmatrix}\mu_{12}^-\mu_{22}^- & -(\mu_{12}^-)^2\\ (\mu_{22}^-)^2 & -\mu_{12}^-\mu_{22}^-\end{pmatrix}. \tag{169}$$

The main tool is now the asymptotic boundary behaviors (75) and (76) of $\mu^{\pm}$ which allows us to obtain, by taking the limit as $n\to+\infty$ of $\zeta^n\partial_t\mu_{21}^-(\zeta,n,t)$, the relations

$$\alpha_t(k)=-\frac{1}{2}[m-(\omega_1^--\omega_2^-)\alpha](k)+\lim_{n\to\infty}\frac{1}{2\pi i}P\oint\frac{d\zeta}{\zeta-k}\left(\frac{k}{\zeta}\right)^{n+1}[m-(\omega_1^--\omega_2^-)\alpha](\zeta),$$

$$0=-\frac{1}{2}[\overline{m}+(\omega_1^+-\omega_2^+)\overline{\alpha}](k)+\lim_{n\to\infty}\frac{1}{2\pi i}P\oint\frac{d\zeta}{\zeta-k}\left(\frac{\zeta}{k}\right)^{n}[\overline{m}+(\omega_1^+-\omega_2^+)\overline{\alpha}](\zeta).$$

Consequently, with the formula (see Appendix)

$$\lim_{n\to\infty}\frac{1}{2\pi i}P\oint\frac{d\zeta}{\zeta-k}\left(\frac{k}{\zeta}\right)^{n}\Phi(\zeta)=-\frac{1}{2}\Phi(k),\qquad |k|=1, \tag{170}$$

the preceding relations result precisely in the required evolution (156).

In the same way, by taking the limit as $n\to-\infty$ of $\partial_t\mu_{11}^-(\zeta,n,t)$, we readily obtain the required evolution (14) of the transmission coefficient $\beta(\zeta,t)$ (note that there, one should use also the unitarity relation (78)).

D. Time evolution of $f(n)$

It could be useful to have also explicitly the time evolution of the quantity $f(n)$. From (50) we have

$$f_t(n)=f(n)\ \mathrm{tr}\{\mu_t(k,n)\mu^{-1}(k,n)\} \tag{171}$$

and then using the auxiliary spectral problem (171)

$$f_t(n)=f(n)\ \mathrm{tr}\{X(k,n)\}. \tag{172}$$

From the expression (173) we obtain that the trace of $X(k,n)$ is k-independent and reads

$$\mathrm{tr}\{X(k,n)\}=\frac{1}{f(n)}\frac{1}{2i\pi}\oint\frac{d\zeta}{\zeta}\{\zeta^n\overline{m}\mu_{11}^+\mu_{21}^+-\zeta^{-n}m\mu_{12}^-\mu_{22}^-+(p+\overline{p})\mu_{12}^-\mu_{21}^+ -(\omega_1^+-\omega_2^+)\mu_{12}^+\mu_{21}^++(\omega_1^--\omega_2^-)\mu_{12}^-\mu_{21}^-. \tag{173}$$

Due to the analyticity of the function

$$\frac{1}{k}(\omega_1(k)-\omega_2(k))\mu_{12}(k)\mu_{21}(k)$$

inside and outside of the circle the last two terms in the r.h.s. vanish and we obtain for the evolution equation of $f(n)$

$$f_t(n)=\int_{-\pi}^{+\pi}d\theta\{\zeta^n\overline{m}\mu_{11}^+\mu_{21}^+-\zeta^{-n}m\mu_{12}^-\mu_{22}^-+(p+\overline{p})\mu_{12}^-\mu_{21}^+\}. \tag{174}$$

This result can also be expressed in terms of the physical quantities A_j and I_j by inverting (150) to get on the unit circle

$$\mu_{11}^+=\overline{\mu}_{22}^-=\frac{A_1\overline{I_1}+\overline{A_2}I_2}{|I_1|^2+|I_1|^2},$$

$$\mu_{21}^+=-\overline{\mu}_{12}^-=-\zeta^{-n}\frac{\overline{A_1}I_2-A_2\overline{I_1}}{|I_1|^2+|I_1|^2}$$

and then by inserting these formulae and those for $p+\overline{p}$ and m in (154) and (155) into (179). We obtain finally

$$f_t(n)=\frac{1}{2\pi}\int_{-\pi}^{\pi}d\vartheta(g+\overline{g})\frac{|I_1|^2|A_2|^2-|I_2|^2|A_1|^2}{|I_1|^2+|I_2|^2}. \tag{175}$$

Note that $f(n)$ is conserved if g is pure imaginary.

APPENDIX: MATHEMATICAL TOOLS

1. Basic distributions

The distributions $\delta^{\pm}(\lambda,1)$ and $\delta(\lambda,1)$ have support on the circle $\mathscr{C}$ of radius 1 in the complex λ-plane and are defined by the following formulae

$$\iint_{\mathscr{D}} d\lambda\wedge d\bar{\lambda}\,\delta^{\pm}(\lambda,1)f(\lambda)=\oint_{\mathscr{C}} d\zeta\; f((1\mp 0)\zeta), \tag{A1}$$

$$\iint_{\mathscr{D}} d\lambda\wedge d\bar{\lambda}\,\delta(\lambda,1)f(\lambda)=\oint_{\mathscr{C}} d\zeta\; f(\zeta), \tag{A2}$$

or, equivalently, by

$$\iint_{\mathscr{D}} d\lambda\wedge d\bar{\lambda}\,\delta^{\pm}(\lambda,1)f(\lambda)=i\int_{-\pi}^{\pi} d\theta\; e^{i\theta}f((1\mp 0)e^{i\theta}), \tag{A3}$$

$$\iint_{\mathscr{D}} d\lambda\wedge d\bar{\lambda}\,\delta(\lambda,1)f(\lambda)=i\int_{-\pi}^{\pi} d\theta\; e^{i\theta}f(e^{i\theta}). \tag{A4}$$

Note that the distributions $\delta^{\pm}(\lambda,1)$ can operate on functions which have defined left or right limit on $\mathscr{C}$, while the distribution $\delta(\lambda,1)$ can operate on functions continuous on $\mathscr{C}$ or with support on $\mathscr{C}$.

By complex conjugation of the equation (A3) and by the change of variable $\theta\to-\theta$, we obtain

$$\iint_{\mathscr{D}} d\lambda\wedge d\bar{\lambda}\;\overline{\delta^{\pm}(\lambda,1)}f(\lambda)=i\int_{-\pi}^{\pi} d\theta\; e^{i\theta}f((1\mp 0)e^{-i\theta}). \tag{A5}$$

Next, by means of the change of variable $\lambda\to 1/\lambda$ (remember that the domain $\mathscr{D}$ does not contain the point $\lambda=0$) and $\theta\to-\theta$, we obtain

$$\iint_{\mathscr{D}} d\lambda\wedge d\bar{\lambda}\,\delta^{\pm}\left(\frac{1}{\lambda},1\right)f(\lambda)=i\int_{-\pi}^{\pi} d\theta\; e^{i\theta}f((1\pm 0)e^{-i\theta}), \tag{A6}$$

and consequently

$$\delta^{\pm}\left(\frac{1}{\lambda},1\right)=\overline{\delta^{\mp}(\lambda,1)}. \tag{A7}$$

Now, through the change of variable $\lambda\to\bar{\lambda}$, we obtain

$$\iint_{\mathscr{D}} d\lambda\wedge d\bar{\lambda}\,\delta^{\pm}(\bar{\lambda},1)f(\lambda)=i\int_{-\pi}^{\pi} d\theta\; e^{i\theta}f((1\mp 0)e^{-i\theta}) \tag{A8}$$

which implies the second symmetry property

$$\delta^{\pm}(\bar{\lambda},1)=\overline{\delta^{\pm}(\lambda,1)}. \tag{A9}$$

These two relation naturally leads to

$$\delta^+(\lambda,1)=\delta^-\left(\frac{1}{\lambda},1\right). \tag{A10}$$

Similar symmetry properties can be obtained for $\delta(\lambda,1)$.

2. The generalized $\bar{\partial}$-formula

Let $F^+ \in C^1(\overline{D^+})$ where D^+ is the open disk of radius 1 centered in the origin and $F^- \in C^1(\mathscr{C}D^+)$, let F^+ and F^- satisfy the Hölder condition on the circle $\mathscr{C}$ of radius 1 and let F^- vanish at large z. Then by noting $F(z)$ the function defined as $F^+(z)$ for $z \in D^+$ and as $F^-(z)$ for $z \in D^- \equiv \mathscr{C}\overline{D^+}$ we have

$$F(z)=\frac{1}{2\pi i}\oint_{\mathscr{C}}\frac{F^+(\zeta)-F^-(\zeta)}{\zeta-z}d\zeta+\frac{1}{2\pi i}\iint_{D^+}\frac{\partial F/\partial\bar{\lambda}}{\lambda-z}d\lambda\wedge d\bar{\lambda}+\frac{1}{2\pi i}\iint_{D^-}\frac{\partial F/\partial\bar{\lambda}}{\lambda-z}d\lambda\wedge d\bar{\lambda}, \tag{A11}$$

where the circle $\mathscr{C}$ is anticlockwise oriented.

If we define the $\bar{\partial}$–derivative of a function $F(z)$ discontinuous on $\mathscr{C}$ as follows

$$\frac{\partial F}{\partial\bar{z}}=(F^+(\zeta)-F^-(\zeta))\,\delta(z,1)+\phi_{D^+}(z)\frac{\partial F}{\partial\bar{z}}+\phi_{D^-}(z)\frac{\partial F}{\partial\bar{z}} \qquad \zeta=\frac{z}{|z|}, \tag{A12}$$

where $\phi_A(z)=1$ for $z \in A$ and $\phi_A(z)=0$ for $z \notin A$ the generalized $\bar{\partial}$–formula (191) can be rewritten as

$$F(z)=\frac{1}{2\pi i}\iint_{\overline{D^+\cup D^-}}\frac{\partial F/\partial\bar{\lambda}}{\lambda-z}d\lambda\wedge d\bar{\lambda}. \tag{A13}$$

Formula (A1) can be considered as the local formulation of the generalized Cauchy–Green formula (A1).

Subtracting formula (A1) at $z=a$ we obtain

$$\begin{aligned}F(z)=F(a)&+\frac{1}{2\pi i}\int_{\mathscr{C}}\frac{F^+(\zeta)-F^-(\zeta)}{\zeta-z}\left(\frac{z-a}{\zeta-a}\right)d\zeta+\frac{1}{2\pi i}\iint_{D^+_{a,0}}\frac{\partial F/\partial\bar{\lambda}}{\lambda-z}\left(\frac{z-a}{\lambda-a}\right)d\lambda\wedge d\bar{\lambda}\\&+\frac{1}{2\pi i}\iint_{D^-}\frac{\partial F/\partial\bar{\lambda}}{\lambda-z}\left(\frac{z-a}{\lambda-a}\right)d\lambda\wedge d\bar{\lambda}\end{aligned} \tag{A14}$$

if $a \in D^+$ and an analogous formula if $a \in D^-$. The second integral on the right hand side is obtained first by computing it on the set $D_{a,\epsilon}=\{\lambda:\lambda \in D,|\lambda-a|>\epsilon\}$ and then by taking the limit $\epsilon\to 0$. Note that the formula remains valid also if $F(z)$ is going to a constant different from 0 for $z\to\infty$.

If for $z\to\infty$ $F(z)\to F(\infty)$ we can apply (A1) to $F(z)-F(\infty)$ getting

$$\begin{aligned}F(z)=F(\infty)&+\frac{1}{2\pi i}\int_{\mathscr{C}}\frac{F^+(\zeta)-F^-(\zeta)}{\zeta-z}d\zeta+\frac{1}{2\pi i}\iint_{D^+}\frac{\partial F/\partial\bar{\lambda}}{\lambda-z}d\lambda\wedge d\bar{\lambda}\\&+\frac{1}{2\pi i}\iint_{D^-}\frac{\partial F/\partial\bar{\lambda}}{\lambda-z}d\lambda\wedge d\bar{\lambda}.\end{aligned} \tag{A15}$$

Finally let us note that the Sokhotski-Plemelj formula on the circle reads

$$\oint_{\mathscr{C}} \frac{d\zeta'}{\zeta'-(1\mp 0)\zeta} f(\zeta') = \pm i\pi f(\zeta) + P \oint_{\mathscr{C}} \frac{d\zeta'}{\zeta'-\zeta} f(\zeta'), \qquad |\zeta| = 1, \tag{A16}$$

where $P\oint$ denote the Cauchy principal value integral.

3. Limits of integrals

Let us prove that

$$\lim_{n\to\infty} \frac{1}{2\pi i} P \oint \frac{d\zeta}{\zeta-k} \left(\frac{k}{\zeta}\right)^n \Phi(\zeta) = -\frac{1}{2}\Phi(k), \qquad |k| = 1. \tag{A17}$$

Under the following successive changes of variables

$$\zeta = e^{i\vartheta}, \qquad k = e^{i\varphi}, \qquad \alpha = \vartheta - \varphi, \qquad x = n\alpha, \tag{A18}$$

we derive

$$\frac{1}{2\pi i} P \oint \frac{d\zeta}{\zeta-k} \left(\frac{k}{\zeta}\right)^n \Phi(\zeta) = \frac{1}{4\pi i} P \int_{-(\pi+\varphi)n}^{(\pi-\varphi)n} dx \frac{e^{-ix}}{n \sin(x/2n)} e^{ix/2n} \Phi(e^{i(x/n+\varphi)}) \tag{A19}$$

and taking the limit, for $-\pi < \varphi < \pi$,

$$\begin{aligned} \lim_{n\to\infty} \frac{1}{2\pi i} P \oint \frac{d\zeta}{\zeta-k} \left(\frac{k}{\zeta}\right)^n \Phi(\zeta) &= \frac{1}{2\pi i} P \int_{-\infty}^{\infty} dx \frac{e^{-ix}}{x} \Phi(e^{i\varphi}) \\ &= -\frac{1}{2\pi} \int_{-\infty}^{\infty} dx \frac{\sin x}{x} \Phi(e^{i\varphi}) = -\frac{1}{2}\Phi(e^{i\varphi}). \end{aligned}$$

Multi-Hamiltonian structures for a class of degenerate completely integrable systems

Peter Bueken[a)]

(Received 24 February 1995; accepted for publication 22 February 1996)

In this paper, a class of degenerate (i.e., associated to a degenerate Poisson structure) completely integrable systems is studied which generalizes the so-called odd and even master systems introduced and studied by Mumford and by Vanhaecke. It is shown that all these completely integrable systems, called the generalized master systems, admit a multi-Hamiltonian formulation, and a systematic construction of this multi-Hamiltonian structure is described. © *1996 American Institute of Physics.* [S0022-2488(96)01406-5]

I. INTRODUCTION

A dynamical system is said to be *bi-Hamiltonian* if it can be written in Hamiltonian form with respect to two different Poisson structures $\{\cdot,\cdot\}_1$ and $\{\cdot,\cdot\}_2$, i.e.,

$$\dot{x}=\{x,H_1\}_1=\{x,H_2\}_2,$$

for some functions $H_1,H_2\in C^\infty(M)$, under the additional assumption that the Poisson brackets $\{\cdot,\cdot\}_1$ and $\{\cdot,\cdot\}_2$ are *compatible*, i.e., their sum is also a Poisson bracket. The existence of bi-Hamiltonian structures was first observed by Magri[1] in the case of the Korteweg–de Vries equation, and it was remarked by the same author (see, e.g., Ref. 2) that the existence of a bi-Hamiltonian structure for a mechanical system is closely related to the complete integrability of the system. In view of this remark, the study of bi-Hamiltonian structures for finite-dimensional Hamiltonian systems has received considerable interest in the recent literature. It turns out that, in contrast to the nondegenerate case (where it was shown in Refs. 3–5 that there exists only a limited number of completely integrable bi-Hamiltonian systems), many degenerate completely integrable systems admit a bi-Hamiltonian structure (see, e.g., Ref. 6), and a number of techniques for constructing these structures (e.g., R-matrices,[7] master symmetries,[8] and reductions of infinite-dimensional systems[9,10]) were discovered.

In Ref. 11, Mumford introduced a completely integrable system on the space $\mathbf{R}^{3g+1}$, whose (complexified) invariant manifolds can be completed (by adjoining a divisor) into the Jacobian of a hyperelliptic curve of genus g, given by an equation

$$y^2=f(x),\quad f(x)=x^{2g+1}+h_1x^{2g}+\cdots+h_{2g+1}, \tag{1}$$

where h_i are the values of certain constants of motion H_i of the completely integrable system. The construction of these completely integrable systems was later adapted to the case where

$$f(x)=x^{2g+2}+h_1x^{2g}+\cdots+h_{2g+1} \tag{2}$$

by Vanhaecke,[6] who also made a detailed study of the systems associated to (1) and (2), which he called the (*odd* and *even*) *master systems*, and who constructed a multi-Hamiltonian formulation for these systems (in the two-dimensional case).

[a)]Present address: University of Aberdeen, Department of Mathematical Sciences, Edward Wright Building, Dunbar Street, Aberdeen AB9 2TY, UK; Electronic mail address: peterb@maths.abdn.ac.uk

In Ref. 12, Vanhaecke constructs, starting from an arbitrary nonzero polynomial $\varphi(x,y)\in\mathbf{R}[x,y]$, a Poisson bracket $\{\cdot,\cdot\}^{\varphi}$ on $\mathbf{R}^{2d}$. Taking the product of this Poisson manifold with a trivial Poisson manifold $(\mathbf{R}^{k+1},\{\cdot,\cdot\}_0)$ (with standard coordinates $c_0,\ldots,c_k$), one obtains a Poisson bracket $\{\cdot,\cdot\}_0^{\varphi}$ on $\mathbf{R}^{2d+k+1}$ which has the functions $c_0,\ldots,c_k$ as Casimir functions. Considering a deformation family of polynomials of the form

$$F(x,y,c)=F(x,y)-x^d c(x),\quad c(x)=c_0x^k+\cdots+c_k,$$

where $F(x,y)$ is a polynomial depending explicitly on y, it turns out that the coefficients $H_1,\ldots,H_d$ of the polynomial

$$H(\lambda)=H_1\lambda^{d-1}+\cdots+H_d=(F(\lambda,v(\lambda))-\lambda^d c(\lambda))\bmod u(\lambda)$$

are in involution with respect to the Poisson bracket $\{\cdot,\cdot\}_0^{\varphi}$ (for every polynomial φ), and hence determine a completely integrable system on the Poisson manifold $(\mathbf{R}^{2d+k+1},\{\cdot,\cdot\}_0^{\varphi})$.

In the special case where $\varphi=1$, $d=k=g$, and

$$F(x,y)=y^2+x^{2g+1}\quad\text{or}\quad F(x,y)=y^2+x^{2g+2},$$

these completely integrable systems turn out to be the odd and even master systems, and all systems $(\mathbf{R}^{2d+k+1},\{\cdot,\cdot\}_0^{\varphi},H_1)$ constructed above will therefore be called *generalized master systems*.

The aim of this paper is to construct a multi-Hamiltonian formulation for the generalized master systems. To do this, we start by constructing, for each $0<i\leqslant k+1$, a new Poisson bracket $\{\cdot,\cdot\}_i^{x^i\varphi}$. Next, we show that the Hamiltonian vector fields of the generalized master system $(\mathbf{R}^{2d+k+1},\{\cdot,\cdot\}_0^{\varphi},H_1)$ can be written in Hamiltonian form with respect to this new Poisson bracket. Finally, we prove that the Poisson brackets $\{\cdot,\cdot\}_i^{x^i\varphi}$, $i=0,\ldots,k+1$, are compatible.

The paper is organized as follows. In Sec. II, we collect some preliminary material concerning bi-Hamiltonian structures and completely integrable systems, and we fix some notation which will be used in the rest of the paper. In Sec. III, we briefly describe the (two-dimensional) odd master system and its multi-Hamiltonian structure. In Sec. IV we review the results from Ref. 12 and we introduce the generalized master systems, and in Sec. V we describe the multi-Hamiltonian structure for these generalized master systems.

II. PRELIMINARIES

A *Poisson manifold* $(M,\{\cdot,\cdot\})$ is a smooth manifold M, endowed with an antisymmetric $\mathbf{R}$-bilinear mapping

$$\{\cdot,\cdot\}:C^{\infty}(M)\times C^{\infty}(M)\to C^{\infty}(M),$$

called a *Poisson bracket*, which is a derivation in both of its arguments, and which satisfies the *Jacobi identity*

$$\{\{f,g\},h\}+\{\{g,h\},f\}+\{\{h,f\},g\}=0$$

for all $f,g,h\in C^{\infty}(M)$. Two functions $f,g\in C^{\infty}(M)$ are said to *Poisson commute*, or to be *in involution*, if $\{f,g\}=0$, and a function f which Poisson commutes with *all* functions $g\in C^{\infty}(M)$ is called a *Casimir function*. As the Poisson bracket $\{\cdot,\cdot\}$ is a derivation in its arguments, every function $f\in C^{\infty}(M)$ determines a vector field X_f on M, given by

$$X_f(g)=\{g,f\}$$

for all $g \in C^\infty(M)$. If $H \in C^\infty(M)$ generates a nonzero vector field (i.e., H is not a Casimir function), H is said to be a *Hamiltonian*, X_H its *Hamiltonian vector field*, and the triple $(M,\{\cdot,\cdot\},H)$ is called a *Hamiltonian system*.

Let $(M,\{\cdot,\cdot\})$ be a Poisson manifold of dimension n which admits k (independent) Casimir functions (i.e., it is of rank $2d=n-k$). A Hamiltonian system $(M,\{\cdot,\cdot\},H)$ on this Poisson manifold is said to be *completely integrable* if (apart from the Casimir functions $C_1,\ldots,C_k$) it admits d independent first integrals (sometimes called the *Hamiltonians* of the system) $H_1=H,H_2,\ldots,H_d$, which are in involution with respect to the Poisson bracket $\{\cdot,\cdot\}$.

Two Poisson brackets $\{\cdot,\cdot\}_1$ and $\{\cdot,\cdot\}_2$ on a manifold M are said to be *compatible* if their sum is again a Poisson bracket, and a set of Poisson brackets are said to be compatible if they are pairwise compatible. Finally, a Hamiltonian system $(M,\{\cdot,\cdot\}_1,H_1)$ is said to be *multi-Hamiltonian* if its Hamiltonian vector field can be written in Hamiltonian form with respect to a set of *compatible* Poisson brackets, i.e.,

$$X_{H_1}=\{\cdot,H_1\}_1=\{\cdot,H_2\}_2=\cdots=\{\cdot,H_n\}_n$$

for some functions $H_2,\ldots,H_n \in C^\infty(M)$.

In the rest of this paper, we will use the following notational conventions. Let $u(x)=x^d+u_1x^{d-1}+\cdots+u_d$ be a polynomial of degree d such that $u_d\neq 0$, and let α be an integer. Then any polynomial $P(x)$ can be decomposed, in a unique way, as $P(x)=Q(x)u(x)+x^\alpha R(x)$, where $\deg R(x)<d$, and we will denote

$$Q(x)=\left[\frac{P(x)}{u(x)}\right]_\alpha, \quad x^\alpha R(x)=P(x)\bmod_\alpha u(x).$$

In the case where $\alpha=0$ we will, in analogy with the notation in Ref. 12, denote

$$P(x)\bmod_0 u(x)=P(x)\bmod u(x), \quad \left[\frac{P(x)}{u(x)}\right]_0=\left[\frac{P(x)}{u(x)}\right]_+,$$

and we have the following.

Lemma 1: Let i be an integer, $P(x)$ be an arbitrary polynomial, and $u(x)=x^d+u_1x^{d-1}+\cdots+u_d$ be a polynomial such that $u_d\neq 0$. Then

$$(x^iP(x))\bmod_i u(x)=x^i(P(x)\bmod u(x)).$$

Proof: If $P(x)=u(x)Q(x)+R(x)$, where $\deg R(x)<\deg u(x)$, then

$$x^iP(x)=u(x)x^iQ(x)+x^iR(x),$$

and the result follows immediately.

III. MULTI-HAMILTONIAN FORMULATION FOR THE ODD MASTER SYSTEM

In Ref. 11, Mumford constructs a completely integrable system on the space $\mathbf{R}^{3g+1}$, whose (complexified) invariant manifolds can be completed into the Jacobian of a hyperelliptic curve of genus g. In the case where $g=2$, this completely integrable system is determined by the vector field

$$X=\begin{cases}\dot{u}_1=2v_1,\\ \dot{u}_2=2v_2,\\ \dot{v}_1=w_2-u_2-u_1w_1+u_1^2,\\ \dot{v}_2=w_3-w_1u_2+u_1u_2,\\ \dot{w}_1=-2v_1,\\ \dot{w}_2=-2v_2-2v_1w_1+2v_1u_1,\\ \dot{w}_3=2u_1v_2-2v_2w_1,\end{cases} \tag{3}$$

and a straightforward computation yields that the functions

$$H_1=-u_1-w_1,\quad H_2=-u_2-u_1w_1-w_2,$$

$$H_3=v_1^2-u_2w_1-u_1w_2-w_3,\quad H_4=2v_1v_2-u_2w_2-u_1w_3,\quad H_5=v_2^2-u_2w_3,$$

are first integrals of this dynamical system.

In Ref. 6 Vanhaecke shows that this system admits a multi-Hamiltonian structure, which is constructed as follows. The Poisson structure $\{\cdot,\cdot\}_1$, given with respect to the coordinates (u,v,w) by

$$\begin{pmatrix} 0 & 0 & 0 & 1 & 0 & 0 & 0\\ 0 & 0 & 1 & u_1 & 0 & 0 & 2v_1\\ 0 & -1 & 0 & 0 & 0 & 1 & w_1-u_1\\ -1 & -u_1 & 0 & 0 & 1 & w_1 & w_2-u_2\\ 0 & 0 & 0 & -1 & 0 & 0 & 0\\ 0 & 0 & -1 & -w_1 & 0 & 0 & -2v_1\\ 0 & -2v_1 & u_1-w_1 & u_2-w_2 & 0 & 2v_1 & 0 \end{pmatrix},$$

has the functions H_1, H_2, and H_3 as Casimir functions, and $X=\{\cdot,H_4\}_1$, showing that the system is Hamiltonian with respect to the Poisson structure $\{\cdot,\cdot\}_1$. Further, the Poisson bracket $\{\cdot,\cdot\}_2$, given by

$$\begin{pmatrix} 0 & 0 & 1 & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & -u_2 & 0 & 0 & -2v_2\\ -1 & 0 & 0 & 0 & 1 & w_1-u_1 & 0\\ 0 & u_2 & 0 & 0 & 0 & -u_2 & -w_3\\ 0 & 0 & -1 & 0 & 0 & 0 & 0\\ 0 & 0 & u_1-w_1 & u_2 & 0 & 0 & 2v_2\\ 0 & 2v_2 & 0 & w_3 & 0 & -2v_2 & 0 \end{pmatrix},$$

has the functions H_1, H_2, and H_5 as Casimir functions, and $X=\{\cdot,H_3\}_2$, showing the Hamiltonian form of (3) with respect to this second bracket. A similar computation yields that the Poisson bracket $\{\cdot,\cdot\}_3$, given by

$$\begin{pmatrix} 0 & 0 & -u_1 & -u_2 & 0 & -2v_1 & -2v_2 \\ 0 & 0 & -u_2 & 0 & 0 & -2v_2 & 0 \\ u_1 & u_2 & 0 & 0 & -u_1 & -w_2 & -w_3 \\ u_2 & 0 & 0 & 0 & -u_2 & -w_3 & 0 \\ 0 & 0 & u_1 & u_2 & 0 & 2v_1 & 2v_2 \\ 2v_1 & 2v_2 & w_2 & w_3 & -2v_1 & 0 & 0 \\ 2v_2 & 0 & w_3 & 0 & -2v_2 & 0 & 0 \end{pmatrix},$$

has H_1, H_4, and H_5 as Casimir functions and that (3) can be written in Hamiltonian form with respect to this new bracket (with Hamiltonian H_2), and that the Poisson bracket $\{\cdot,\cdot\}_4$, given by

$$\begin{pmatrix} A & B \\ -{}^tB & C \end{pmatrix},$$

where

$$A=\begin{pmatrix} 0 & 0 & u_1^2-u_2 & u_1u_2 \\ 0 & 0 & u_1u_2 & u_2^2 \\ -u_1^2+u_2 & -u_1u_2 & 0 & 0 \\ -u_1u_2 & -u_2^2 & 0 & 0 \end{pmatrix}, \quad B=\begin{pmatrix} -2v_1 & 2u_1v_1-2v_2 & 2v_2u_1 \\ -2v_2 & 2u_2v_1 & 2v_2u_2 \\ -w_2+w_1u_1 & -w_3+u_1w_2 & u_1w_3 \\ -w_3+w_1u_2 & u_2w_2 & u_2w_3 \end{pmatrix},$$

and

$$C=\begin{pmatrix} 0 & -2v_1w_1 & -2v_2w_1 \\ 2v_1w_1 & 0 & 2v_1w_3-2v_2w_2 \\ 2v_2w_1 & 2v_2w_2-2v_1w_3 & 0 \end{pmatrix},$$

has H_3, H_4, and H_5 as Casimir functions, while the vector field (3) can be written in Hamiltonian form with respect to this bracket (with Hamiltonian H_1). Finally, it was shown in Ref. 6 that the Poisson brackets introduced in this section are compatible, proving that the odd master system is multi-Hamiltonian.

IV. GENERALIZED MASTER SYSTEMS

It was shown in Ref. 12 that one can associate, to an arbitrary (nonzero) polynomial $\varphi(x,y)$, a Poisson bracket $\{\cdot,\cdot\}^{\varphi}$ on the space $\mathbf{R}^{2d}$ and that, moreover, every polynomial $F(x,y)$ (depending explicitly on y) determines a completely integrable system on the Poisson manifold $(\mathbf{R}^{2d},\{\cdot,\cdot\}^{\varphi})$ (for any φ). We start this section by reviewing this construction. To this purpose, we consider the space $\mathbf{R}^{2d}$ as the space of pairs of polynomials

$$u(\lambda)=\lambda^d+u_1\lambda^{d-1}+\cdots+u_d,$$

$$v(\lambda)=v_1\lambda^{d-1}+\cdots+v_d,$$

i.e., the coefficients of the polynomials u,v serve as coordinates on $\mathbf{R}^{2d}$, and we write, e.g.,

$$\{u(\lambda),v_j\}=\sum_{i=1}^{d}\{u_i,v_j\}\lambda^{d-i}.$$

The following result gives explicit expressions for a family of Poisson brackets, indexed by the space of (nonzero) polynomials in two variables:

Proposition 2: Let $\varphi(x,y)$ be a nonzero polynomial in $\mathbf{R}[x,\ y]$. Then the bracket $\{\cdot,\cdot\}^{\varphi}$, given in terms of the coordinates u_i, v_i by

$$\{u_i,u_j\}^{\varphi}=\{v_i,v_j\}^{\varphi}=0,$$

$$\{u(\lambda),v_j\}^{\varphi}=\{u_j,v(\lambda)\}^{\varphi}=\varphi(\lambda,v(\lambda))\left[\frac{u(\lambda)}{\lambda^{d+1-j}}\right]_{+} \bmod u(\lambda), \tag{4}$$

$i,j=1,\ldots,d$, defines a (polynomial) Poisson structure on the space $\mathbf{R}^{2d}$. Moreover, all these Poisson brackets $\{\cdot,\cdot\}^{\varphi}$ are compatible.

The next step is the construction, for every Poisson bracket given by (4), of a collection of completely integrable systems on $\mathbf{R}^{2d}$. This is the purpose of the following proposition.

Proposition 3: Let $F(x,y)\in\mathbf{R}[x,\ y]\backslash\mathbf{R}[x]$. Then the coefficients $H_1,\ldots,H_d$ of the polynomial

$$H(\lambda)=H_1\lambda^{d-1}+\cdots+H_d=F(\lambda,v(\lambda)) \bmod u(\lambda)$$

define, for any nonzero polynomial $\varphi(x,y)$, a completely integrable system on the Poisson manifold $(\mathbf{R}^{2d},\{\cdot,\cdot\}^{\varphi})$.

Next, we consider the space $\mathbf{R}^{k+1}$ with standard coordinates $(c_0,\ldots,c_k)$, and we define a (trivial) Poisson bracket $\{\cdot,\cdot\}_0$ on this space by putting $\{f,g\}_0=0$ for all $f,g\in C^{\infty}(\mathbf{R}^{k+1})$. Considering the space $\mathbf{R}^{2d+k+1}$ as the product of the Poisson manifolds $(\mathbf{R}^{2d},\{\cdot,\cdot\}^{\varphi})$ and $(\mathbf{R}^{k+1},\{\cdot,\cdot\}_0)$, we obtain a (product) Poisson structure $\{\cdot,\cdot\}_0^{\varphi}$ on $\mathbf{R}^{2d+k+1}$, which has the coordinate functions $c_0,\ldots,c_k$ as Casimir functions. Denoting by $F(x,y,c_0,\ldots,c_k)$ a deformation family of polynomials (i.e., a family of polynomials depending on the parameters $c_0,\ldots,c_k$), it is easily seen that Proposition 3 immediately implies the following.

Proposition 4: The coefficients $H_1,\ldots,H_d$ of the polynomial

$$H(\lambda)=F(\lambda,v(\lambda),c_0,\ldots,c_k) \bmod u(\lambda)$$

are in involution with respect to the Poisson bracket $\{\cdot,\cdot\}_0^{\varphi}$, and hence determine a completely integrable Hamiltonian system $(\mathbf{R}^{2d+k+1},\{\cdot,\cdot\}_0^{\varphi},H_1)$, on the degenerate Poisson manifold $(\mathbf{R}^{2d+k+1},\{\cdot,\cdot\}_0^{\varphi})$.

The explicit expressions for the Hamiltonian vector fields of this system are given by the following.

Proposition 5: The Hamiltonian vector fields $X_{H_i}=\{\ \cdot\ ,H_i\}_0^{\varphi}, i=1,\ldots,d$, of the completely integrable system $(\mathbf{R}^{2d+k+1},\{\cdot,\cdot\}_0^{\varphi},H_1)$, are given by (the coefficients in μ^{d-i} of)

$$X_{H(\mu)}u_a=\frac{\partial F}{\partial y}(\mu,v(\mu),c)\{u_a,v(\mu)\}^{\varphi} \bmod u(\mu),$$

$$X_{H(\mu)}v_a=\left[\frac{F(\mu,v(\mu),c)}{u(\mu)}\right]_{+}\{u_a,v(\mu)\}^{\varphi} \bmod u(\mu),$$

$$X_{H(\mu)}c_b=0, \tag{5}$$

for all $a=1,\ldots,d$, and $b=0,\ldots,k$.

Remark 1: Putting $d=k=2$ and $\varphi(x,y)=1$, and letting $F(x,y,c)$ denote the special deformation family

$$F(x,y,c)=y^2+x^5-x^2c(x),\quad c(x)=c_0x^2+c_1x+c_2,$$

the construction described in this section yields a completely integrable system whose Hamiltonian vector field $\{\cdot,H_1\}_0^\varphi$ is given by

$$\dot{u}_1=2v_1, \quad \dot{u}_2=2v_2, \quad \dot{v}_1=2c_0u_1-c_1+3u_1^2-2u_2,$$

$$\dot{v}_2=c_0(2u_2-u_1^2)+c_1u_1-c_2-u_1^3+4u_1u_2+v_1^2,$$

$$\dot{c}_1=0, \quad \dot{c}_2=0, \quad \dot{c}_3=0.$$

Defining the functions (w_1,w_2,w_3) by

$$\lambda^3+w_1\lambda^2+w_2\lambda+w_3=\left[\frac{F(\lambda,v(\lambda))-\lambda^2c(\lambda)}{u(\lambda)}\right]_+,$$

we see that these differential equations determine the odd master system (3) and that, moreover, the Poisson structure $\{\cdot,\cdot\}_0^1$ and the invariants c_0,c_1,c_2,H_1,H_2 are exactly the Poisson structure $\{\cdot,\cdot\}_1$ and the invariants $H_1,\ldots,H_5$ described in Sec. III. In what follows, the completely integrable systems associated to a special deformation family of polynomials of the form

$$F(x,y,c)=F(x,y)-x^dc(x),$$

will therefore be called *generalized master systems.*

V. MULTI-HAMILTONIAN FORMULATION FOR THE GENERALIZED MASTER SYSTEMS

The aim of this section is to construct a multi-Hamiltonian formulation for the generalized master systems $(\mathbf{R}^{2d+k+1},\{\cdot,\cdot\}_0^\varphi,H_1)$ introduced in Sec. IV. To this purpose, let φ be a nonzero polynomial, $F(x,y,c)=F(x,y)-x^dc(x)$ be a deformation family of polynomials as above, and denote by

$$G(\lambda)=\lambda^dc(\lambda)+H(\lambda)=c_0\lambda^{d+k}+\cdots+c_k\lambda^d+H_1\lambda^{d-1}+\cdots+H_d$$

the polynomial whose coefficients are given by the Casimir functions of the Poisson bracket $\{\cdot,\cdot\}_0^\varphi$ and the first integrals $H_1,\ldots,H_d$ of the generalized master system $(\mathbf{R}^{2d+k+1},\{\cdot,\cdot\}_0^\varphi,H_1)$ associated to φ and F. Choosing any integer $0<i\leqslant k+1$, we can write the polynomial $G(\lambda)$ in the form

$$G(\lambda)=f_0\lambda^{d+k}+\cdots+f_{k-i}\lambda^{d+i}+\lambda^i(g_1\lambda^{d-1}+\cdots+g_d)+f_{k-i+1}\lambda^{i-1}+\cdots+f_k, \tag{6}$$

and, inspired by the choice of the Casimir functions of the different Poisson structures for the odd master system (Sec. III and Remark 1), we now construct a new Poisson bracket $\{\cdot,\cdot\}_i^\varphi$ which has the functions $f_0,\ldots,f_k$ as Casimir functions.

To do this, we start by remarking that

$$G(\lambda)=F(\lambda,v(\lambda))\text{mod } u(\lambda)+u(\lambda)\left[\frac{\lambda^dc(\lambda)}{u(\lambda)}\right]_+. \tag{7}$$

On the other hand, denoting

$$f(\lambda)=f_0\lambda^{d+k}+\cdots+f_{k-i}\lambda^{d+i}+f_{k-i+1}\lambda^{i-1}+\cdots f_k,$$

$$g(\lambda)=g_1\lambda^{d-1}+\cdots+g_d,$$

(6) takes the form

$$G(\lambda)=f(\lambda)+\lambda^i g(\lambda), \tag{8}$$

and comparing (7) and (8) we obtain

$$\left[\frac{\lambda^d c(\lambda)}{u(\lambda)}\right]_+=\left[\frac{f(\lambda)-(F(\lambda,v(\lambda))\text{mod } u(\lambda))}{u(\lambda)}\right]_i,$$

which yields

$$c(\lambda)=\left[\frac{u(\lambda)}{\lambda^d}\left[\frac{f(\lambda)-(F(\lambda,v(\lambda))\text{mod } u(\lambda))}{u(\lambda)}\right]_i\right]_+.$$

The right-hand side of this equation is defined on the subspace $u_d\neq 0$. As a consequence, the mapping

$$\phi:\mathbf{R}^{2d+k+1}\to\mathbf{R}^{2d+k+1}:(u,v,c)\mapsto(u,v,f(u,v,c))$$

is bijective on $M=\mathbf{R}^{2d+k+1}\backslash\{u_d=0\}$, and we can define a new Poisson bracket $\{\cdot,\cdot\}_i^\varphi$ on M by

$$\{f,g\}_i^\varphi=\{f\circ\phi^{-1},g\circ\phi^{-1}\}_0^\varphi\circ\phi.$$

This Poisson bracket has the functions $f_i=c_i\circ\phi$, $i=0,\ldots,k$, as Casimir functions and, moreover, it is easily seen that

$$\{u_i,u_j\}_i^\varphi=\{u_i,u_j\}_0^\varphi,\quad \{u_i,v_j\}_i^\varphi=\{u_i,v_j\}_0^\varphi,\quad \{v_i,v_j\}_i^\varphi=\{v_i,v_j\}_0^\varphi, \tag{9}$$

for all $i,j=1,\ldots,d$.

Our next step is to show that the Hamiltonian vector fields (5) of the generalized master system $(\mathbf{R}^{2d+k+1},\{\cdot,\cdot\}_0^\varphi,H_1)$ can be written in Hamiltonian form with respect to the Poisson brackets $\{\cdot,\cdot\}_i^{x^i\varphi}$, $i=1,\ldots,k+1$, the Hamiltonians being given by the remaining coefficients $g_1,\ldots,g_d$ of the polynomial $G(\lambda)$. To this purpose, we need the following two lemmas.

Lemma 6: The functions $c_0,\ldots,c_k,H_1,\ldots,H_d$ are in involution with respect to the Poisson bracket $\{\cdot,\cdot\}_i^\varphi$.

Proof: For the sake of simplicity, we use matrix notations in the proof of this theorem. In particular, we denote

$$\mathbf{u}=(u_1,\ldots,u_d,v_1,\ldots,v_d),\quad c=(c_0,\ldots,c_k),$$

$$f=(f_0,\ldots,f_k),\quad h=(H_1,\ldots,H_d).$$

For all $A,B\in\{\mathbf{u},f,c,h\}$, we denote by $\{A,B\}$ the matrix whose entries are given by $\{A_i,B_j\}$, and for all $A\in\{f,h\}$ and all $B\in\{\mathbf{u},c\}$, we write the Jacobian matrix of the functions A_i with respect to the coordinates B_j as A_B.

As the functions $c_0,\ldots,c_k$ are Casimir functions of the Poisson bracket $\{\cdot,\cdot\}_0^\varphi$, the Poisson matrix [with respect to the coordinates $(\mathbf{u},c)$] of the bracket $\{\cdot,\cdot\}_0^\varphi$ is of the form

$$\begin{pmatrix} A & 0\\ 0 & 0\end{pmatrix},$$

where A is the (skew-symmetric) $(2d\times 2d)$ matrix given by $\{\mathbf{u},\mathbf{u}\}^\varphi$.

Next, we compute the Poisson matrix of the bracket $\{\cdot,\cdot\}_i^\varphi$ with respect to the coordinates $(\mathbf{u},c)$. It follows immediately from (9) that this Poisson matrix is of the form

$$\begin{pmatrix} A & B \\ -{}^tB & C \end{pmatrix},$$

and taking into account that the functions f_i, $i=0,\ldots,k$, are Casimir functions of the bracket $\{\cdot,\cdot\}_i^\varphi$, we obtain that

$$\begin{pmatrix} A & B \\ -{}^tB & C \end{pmatrix}\begin{pmatrix} f_{\mathbf{u}} \\ f_c \end{pmatrix}=0,$$

which, together with the fact that $\det f_c\neq 0$ on M, yields that

$$B=-Af_{\mathbf{u}}f_c^{-1},\quad C={}^tf_c^{-1\,t}f_{\mathbf{u}}Af_{\mathbf{u}}f_c^{-1}.$$

The functions f_i are first integrals of the generalized master system $(\mathbf{R}^{2d+k+1},\{\cdot,\cdot\}_0^\varphi,H_1)$. Hence, they Poisson commute with respect to the bracket $\{\cdot,\cdot\}_0^\varphi$, implying that

$$\{f,f\}_0^\varphi={}^tf_{\mathbf{u}}Af_{\mathbf{u}}=0,$$

and consequently

$$C=0.$$

Summarizing, the Poisson matrix of the bracket $\{\cdot,\cdot\}_i^\varphi$ is of the form

$$\begin{pmatrix} A & -Af_{\mathbf{u}}f_c^{-1} \\ -{}^tf_c^{-1\,t}f_{\mathbf{u}}A & 0 \end{pmatrix},$$

and we see that

$$\{h,h\}_i^\varphi=({}^th_{\mathbf{u}}\,{}^th_c)\begin{pmatrix} A & -Af_{\mathbf{u}}f_c^{-1} \\ -{}^tf_c^{-1\,t}f_{\mathbf{u}}A & 0 \end{pmatrix}\begin{pmatrix} h_{\mathbf{u}} \\ h_c \end{pmatrix}=\{h,h\}_0^\varphi-{}^th_c\;{}^tf_c^{-1}\{f,h\}_0^\varphi-\{h,f\}_0^\varphi f_c^{-1}h_c=0.$$

Analogous computations yield that $\{c,h\}_i^\varphi=0$ and $\{c,c\}_i^\varphi=0$, which concludes the proof of the lemma.

Lemma 7: Let $\varphi(x,y)$, $F(x,y,c)$, and i be as above. Then

$$\{u_a,v(\mu)\}^{x^i\varphi}\bmod_i u(\mu)=\mu^i\{u_a,v(\mu)\}^\varphi,$$

for all $a=1,\ldots,d$.

Proof: A straightforward computation using (4) and Lemma 1 yields

$$\begin{aligned}\{u_a,v(\mu)\}^{x^i\varphi}\bmod_i u(\mu)&=\left(\mu^i\varphi(\mu,v(\mu))\left[\frac{u(\mu)}{\mu^{d+1-a}}\right]_+\bmod u(\mu)\right)\bmod_i u(\mu)\\&=\left(\mu^i\varphi(\mu,v(\mu))\left[\frac{u(\mu)}{\mu^{d+1-a}}\right]_+\right)\bmod_i u(\mu)\\&=\mu^i\left(\varphi(\mu,v(\mu))\left[\frac{u(\mu)}{\mu^{d+1-a}}\right]_+\bmod u(\mu)\right)=\mu^i\{u_a,v(\mu)\}^\varphi.\end{aligned}$$

We are now ready to prove the following theorem.

Theorem 8: Let $\varphi(x,y)$, $F(x,y,c)$, i, and $G(\lambda)$ be as above. Then we have, for all $a=1,\ldots,d$, that

$$\{\cdot,H_a\}_0^\varphi=\{\cdot,g_a\}_i^{x^i\varphi}.$$

Proof: As the functions $f_0,\ldots,f_n$ are Casimir functions of the Poisson bracket $\{\cdot,\cdot\}_i^{x^i\varphi}$, (6) yields

$$\{\cdot,G(\mu)\}_i^{x^i\varphi}=\mu^i(\{\cdot,g_1\}_i^{x^i\varphi}\mu^{d-1}+\cdots+\{\cdot,g_d\}_i^{x^i\varphi}). \tag{10}$$

On the other hand, we can rewrite $G(\mu)$ as

$$G(\mu)=F(\mu,v(\mu))-u(\mu)\left[\frac{F(\mu,v(\mu))-\mu^d c(\mu)}{u(\mu)}\right]_+,$$

which implies that

$$\{\cdot,G(\mu)\}_i^{x^i\varphi}=\{\cdot,v(\mu)\}_i^{x^i\varphi}\frac{\partial F}{\partial y}(\mu,v(\mu))-\{\cdot,u(\mu)\}_i^{x^i\varphi}\left[\frac{F(\mu,v(\mu))-\mu^d c(\mu)}{u(\mu)}\right]_+$$
$$-u(\mu)\left\{\cdot,\left[\frac{F(\mu,v(\mu))-\mu^d c(\mu)}{u(\mu)}\right]_+\right\}_i^{x^i\varphi}. \tag{11}$$

Comparing (10) and (11), we see that

$$\mu^i(\{\cdot,g_1\}_i^{x^i\varphi}\mu^{d-1}+\cdots+\{\cdot,g_d\}_i^{x^i\varphi})$$
$$=\left(\{\cdot,v(\mu)\}_i^{x^i\varphi}\frac{\partial F}{\partial y}(\mu,v(\mu))-\{\cdot,u(\mu)\}_i^{x^i\varphi}\left[\frac{F(\mu,v(\mu))-\mu^d c(\mu)}{u(\mu)}\right]_+\right)\mathrm{mod}_i\ u(\mu). \tag{12}$$

It follows immediately from (4) and (12) that, for all $b=1,\ldots,d$,

$$\mu^i(\{u_b,g_1\}_i^{x^i\varphi}\mu^{d-1}+\cdots+\{u_b,g_d\}_i^{x^i\varphi})=\left(\{u_b,v(\mu)\}^{x^i\varphi}\frac{\partial F}{\partial y}(\mu,v(\mu))\right)\mathrm{mod}_i\ u(\mu),$$

and Lemmas 1 and 7 then yield that

$$\mu^i(\{u_b,g_1\}_i^{x^i\varphi}\mu^{d-1}+\cdots+\{u_b,g_d\}_i^{x^i\varphi})=\mu^i\left(\{u_b,v(\mu)\}^\varphi\frac{\partial F}{\partial y}(\mu,v(\mu))\right)\mathrm{mod}\ u(\mu),$$

which, together with Proposition 5, implies that, for $a,b=1,\ldots,d$,

$$\{u_b,g_a\}_i^{x^i\varphi}=\{u_b,H_a\}_0^\varphi.$$

In a similar way, one proves that, for $a,b=1,\ldots,d$,

$$\{v_b,g_a\}_i^{x^i\varphi}=\{v_b,H_a\}_0^\varphi,$$

and we see from Lemma 6 that, for $b=0,\ldots,k$ and $a=1,\ldots,d$,

$$\{c_b,g_a\}_i^{x^i\varphi}=0=\{c_b,H_a\}_0^\varphi,$$

which concludes the proof of the theorem.

Finally, we show that the Poisson brackets $\{\cdot,\cdot\}_i^{x^i\varphi}, i=0,\ldots,k+1$, are compatible. To this purpose, it suffices to prove the following.

Theorem 9: Let φ be an arbitrary polynomial, and suppose that α and i are integers such that $\alpha+i\leqslant k+1$. Then the Poisson brackets $\{\cdot,\cdot\}_\alpha^\varphi$ and $\{\cdot,\cdot\}_{\alpha+i}^{x^i\varphi}$ are compatible.

Proof: To simplify the notation, we denote $\{\cdot,\cdot\}_1=\{\cdot,\cdot\}_\alpha^\varphi$ and $\{\cdot,\cdot\}_2=\{\cdot,\cdot\}_{\alpha+i}^{x^i\varphi}$. Further, we write the polynomial $G(\lambda)$ as

$$G(\lambda)=H_0\lambda^{d+k}+\cdots+H_{d+k},$$

and we denote by

$$\{\cdot,\cdot\}=\{\cdot,\cdot\}_1+\{\cdot,\cdot\}_2$$

the sum of the two brackets.

To prove the compatibility of $\{\cdot,\cdot\}_1$ and $\{\cdot,\cdot\}_2$, it suffices to prove the Jacobi identity

$$\{\{f,g\},h\}+\{\{g,h\},f\}+\{\{h,f\},g\}=0 \tag{13}$$

for all functions $f,g,h\in\{u_1,\ldots,u_d,v_1,\ldots,v_d,H_0,\ldots,H_{d+k}\}$. Using the fact that $\{\cdot,\cdot\}_1$ and $\{\cdot,\cdot\}_2$ are Poisson brackets and hence satisfy the Jacobi identity, (13) reduces to the ''mixed Jacobi identity''

$$\{\{f,g\}_2,h\}_1+\{\{g,h\}_2,f\}_1+\{\{h,f\}_2,g\}_1+\{\{f,g\}_1,h\}_2+\{\{g,h\}_1,f\}_2+\{\{h,f\}_1,g\}_2=0. \tag{14}$$

From Proposition 2 we know that $\{\cdot,\cdot\}^\varphi$ and $\{\cdot,\cdot\}^{x^i\varphi}$ are compatible. Hence, (14) holds if $f,g,h\in\{u_1,\ldots,u_d,v_1,\ldots,v_d\}$, and we only have to prove (14) in the case where at least one function (say, h) belongs to $\{H_0,\ldots,H_{d+k}\}$. As Theorem 8 implies that, for all $i=0,\ldots,d+k$, we have

$$\{\cdot,H_i\}_2=\{\cdot,H_j\}_1,\quad \{\cdot,H_i\}_1=\{\cdot,H_k\}_2,$$

for some j and k, we see that

$$\begin{aligned}&\{\{f,g\}_2,H_i\}_1+\{\{g,H_i\}_2,f\}_1+\{\{H_i,f\}_2,g\}_1+\{\{f,g\}_1,H_i\}_2+\{\{g,H_i\}_1,f\}_2+\{\{H_i,f\}_1,g\}_2\\&\quad=\{\{f,g\}_2,H_k\}_2+\{\{g,H_j\}_1,f\}_1+\{\{H_j,f\}_1,g\}_1+\{\{f,g\}_1,H_j\}_1+\{\{g,H_k\}_2,f\}_2\\&\qquad+\{\{H_k,f\}_2,g\}_2=0,\end{aligned}$$

as $\{\cdot,\cdot\}_1$ and $\{\cdot,\cdot\}_2$ satisfy the Jacobi identity.

A completely integrable Hamiltonian system

F. Calogero[a] and J.-P. Françoise
Université de Paris VI, UFR 920, 4 Pl. Jussieu tour 46, 5ième étage, 75252 Paris, France

(Received 13 June 1995; accepted for publication 14 February 1996)

The dynamical system characterized by the Hamiltonian $H(\boldsymbol{q},\boldsymbol{p}) = \Sigma_{j,k=1}^{n}\, p_j p_k f(q_j - q_k)$ with $f(x)=\lambda+\mu\,\cos(\nu x)+\mu'\,\sin(\nu|x|)$ is completely integrable. Here n is an arbitrary positive integer and λ,μ,μ',ν are 4 arbitrary constants (λ and μ real, μ' and ν both real or both imaginary). © *1996 American Institute of Physics.* [S0022-2488(96)02805-8]

I. INTRODUCTION

It has been recently pointed out that the dynamical system characterized by the Hamiltonian

$$H(\boldsymbol{q},\boldsymbol{p})=\sum_{j,k=1}^{n}\, p_j p_k\, \exp(-|q_j-q_k|) \tag{1.1}$$

is completely integrable.[1] (Actually in Ref. 1 it was shown that the evolution of the coordinates $q_j(t)$ entailed by the Hamiltonian (1.1) coincides with the motion of the solitons of an integrable PDE,[2,1] which features ''peaked'' solitons whose position can be precisely defined. Thereby a Lax pair representation for these equations of motion was found, and n independent integrals of motion exhibited. Although it was not proven that these n integrals are in involution, these results suggested quite convincingly that the Hamiltonian (1.1) is integrable; as it is now demonstrated, see below.)

Motivated by this remarkable discovery, one of us investigated the integrability of the Hamiltonian

$$H(\boldsymbol{q},\boldsymbol{p})=\sum_{j,k=1}^{n}\, p_j p_k f(q_j-q_k), \tag{1.2}$$

and found[3] that this system is integrable (indeed, explicitly solvable) if

$$f(x)=\lambda+\mu\,\cos(\nu x). \tag{1.3}$$

The purpose and scope of this paper is to point out that the Hamiltonian (1.2) is completely integrable also in the more general case

$$f(x)=\lambda+\mu\,\cos(\nu x)+\mu'\,\sin(\nu|x|), \tag{1.4}$$

with λ,μ,μ',ν being 4 arbitrary constants. (To keep H real, we assume hereafter that λ and μ are real, μ' and ν both real or both imaginary). Of course special cases of the Hamiltonian (1.2) with (1.4) are the Hamiltonian (1.1) (corresponding to $\lambda=0$, $\mu=1$, $\mu'=\mathrm{i}$, $\nu=\mathrm{i}$), as well as the Hamiltonian (1.2) with (1.3) or with

$$f(x)=\alpha+\beta|x|+\gamma x^2, \tag{1.5}$$

[a]Visiting professor. (Permanent position: Professor of Theoretical Physics, University of Rome I ''La Sapienza,'' Rome, Italy; on leave while serving as Secretary General, Pugwash Conferences on Science and World Affairs, Geneva, London, Rome.)

α, β, and γ being 3 arbitrary (real) constants (this corresponds to $\lambda = \alpha + 2\gamma/\epsilon^2$, $\mu = -2\gamma/\epsilon^2$, $\mu' = \beta/\epsilon$, $\nu = \epsilon$, $\epsilon \to 0$).

In Sec. II we show that the equations of motion entailed by the Hamiltonian (1.2) with (1.4) can be put in ''Lax pair'' form, and we thereby obtain n constants of motion for this system.

In Sec. III we prove that these n constants of motion are in involution; this entails the complete (''Liouville'') integrability of the Hamiltonian (1.2) with (1.4).

In Sec. IV we indicate how the problem can be reformulated via a convenient canonical transformation.

These findings suggest several avenues of additional research, which are outlined in Sec. V.

We end this introductory section with a remark on Arnol'd–Liouville integrability (with thanks to an anonymous referee for raising this issue).

A Hamiltonian system is termed *integrable in Liouville sense* if there exists n (n = number of degrees of freedom) globally defined constants of motion generically independent and in involution (one of them is of course the Hamiltonian itself).

If the n constants of motion in involution are of class C^1, and some other conditions hold, the Arnol'd–Liouville theorem affirms the global existence of torii on which the flow generated by the Hamiltonian (or by any one of the constants of motion) is *linear* (''actions-angles'' representation of the motion).

But the Hamiltonian (1.2) with (1.4) is not of class C^1, nor are the other $n-1$ constants of motion in involution of class C^1 (see below). Neither are they analytic. Indeed these features constitute perhaps the most remarkable characteristic of this model.

Hence the classical Arnol'd–Liouville theorem is not applicable to the Hamiltonian (1.2) with (1.4). Of course the existence of an integrable model of this type (neither C^1 nor analytic) underlies the interest of investigating extensions of the Arnol'd–Liouville theorem to include such systems.

II. LAX PAIR AND CONSTANTS OF MOTION

It was pointed out in Ref. 3 that the equations of motion entailed by (1.2), namely,

$$\dot{q}_j = 2\sum_{k=1}^{n} p_k f(q_j - q_k), \tag{2.1a}$$

$$\dot{p}_j = -2p_j \sum_{k=1}^{n} p_k f'(q_j - q_k), \tag{2.1b}$$

correspond to the $(n\times n)$-matrix Lax equation

$$\dot{\mathbf{L}} = [\mathbf{L}, \mathbf{A}] \tag{2.2}$$

provided the two $(n\times n)$-matrices $\mathbf{L}$ and $\mathbf{A}$ have the form

$$L_{jk} = (p_j p_k)^{1/2} \alpha(q_j - q_k), \tag{2.3}$$

$$A_{jk} = (p_j p_k)^{1/2} \gamma(q_j - q_k), \tag{2.4}$$

and the two (*a priori* arbitrary) functions $\alpha(x)$, $\gamma(x)$, together with the even function $f(x)$,

$$f(x) = f(-x), \tag{2.5}$$

satisfy the functional equation

$$2\alpha'(x+y)[f(x)-f(y)] - \alpha(x+y)[f'(x)-f'(y)] = \alpha(x)\gamma(y) - \alpha(y)\gamma(x). \tag{2.6}$$

[The ansatz (2.4) is actually less general than Eq. (4.9) of Ref. 3, and correspondingly this functional equation (2.6) is a special case of Eq. (3.4) of Ref. 3; but it is adequate for our present purposes.]

The first main result of this paper is to exhibit two functions, $\alpha(x)$ and $\gamma(x)$, that satisfy this functional equation, together with the function $f(x)$ given by (1.4). They read

$$\alpha(x)=(\Delta+\mu)^{1/2}\cos(\nu x/2)+(\Delta-\mu)^{1/2}\sin(\nu|x|/2), \tag{2.7}$$

$$\gamma(x)=\nu\mu'\ \mathrm{sign}(x)\{\cos(\nu x/2)-[\Delta+\mu)/(\Delta-\mu)]^{1/2}\sin(\nu|x|/2)\}, \tag{2.8}$$

with

$$\Delta^2=\mu^2+\mu'^2,\quad \Delta>0. \tag{2.9}$$

Several remarks are now in order.

Remark 2.1: The verification that these expressions of $\alpha(x)$ and $\gamma(x)$, together with the expression (1.4) of $f(x)$, satisfy the functional equation (2.6), requires an elementary if tedious computation, which must cover the three cases: (i) $x>0$, $y>0$; (ii) $x>0$, $y<0$, $x+y>0$; (iii) $x>0$, $y<0$, $x+y<0$ [all other possible cases are then automatically covered due to the obvious invariance of (2.6) under the interchange of x and y, as well as under the simultaneous change of sign of x and y if $\alpha(x)$ and $f(x)$ are even functions and $\gamma(x)$ is odd, as it is indeed implied by (1.4), (2.7), and (2.8)].

Remark 2.2: The expression (2.8) of $\gamma(x)$ could be generalized by adding to it $a\,\alpha(x)$, with a any arbitrary constant, since such an addition clearly does not affect the functional equation (2.6).

Remark 2.3: Both $f(x)$, see (1.4), and $\gamma(x)$, see (2.8), can be neatly related to $\alpha(x)$, see (2.7):

$$f(x)=\lambda-\Delta+\alpha^2(x), \tag{2.10}$$

$$\gamma(x)=2\mu'(\Delta-\mu)^{1/2}\alpha'(x). \tag{2.11}$$

Remark 2.4: The functional equation (2.6) can be rewritten as follows:

$$\alpha^2(x+y)\left[\frac{\partial}{\partial x}+\frac{\partial}{\partial y}\right]\{[f(x)-f(y)]/\alpha(x+y)\}=-\alpha(x)\gamma(y)+\alpha(y)\gamma(x). \tag{2.12}$$

Moreover, if one makes the assumption

$$\gamma(x)=c\,\alpha'(x), \tag{2.13}$$

which is *a priori* arbitrary, but *a posteriori* correct [in our case; see (2.11)], then the right-hand side of (2.12) can also be conveniently rewritten:

$$-\alpha(x)\gamma(y)+\alpha(y)\gamma(x)=c\left[\frac{\partial}{\partial x}-\frac{\partial}{\partial y}\right][\alpha(x)\alpha(y)] \tag{2.14a}$$

$$=c\,\alpha^2(y)\left[\frac{\partial}{\partial x}+\frac{\partial}{\partial y}\right][\alpha(x)/\alpha(y)] \tag{2.14b}$$

$$=-c\,\alpha^2(x)\left[\frac{\partial}{\partial x}+\frac{\partial}{\partial y}\right][\alpha(y)/\alpha(x)], \tag{2.14c}$$

entailing various possible reformulations of the functional equation (2.6) with (2.13), such as

$$\left[\frac{\partial}{\partial x}+\frac{\partial}{\partial y}\right]\{[f(x)-f(y)]/\alpha(x+y)\}=c\left[\frac{\partial}{\partial x}-\frac{\partial}{\partial y}\right][\alpha(x)\alpha(y)/\alpha^2(x+y)]. \tag{2.15}$$

Remark 2.5: In the special case $\mu'=0$ the function $f(x)$ takes of course the form (1.3), while $\alpha(x)$ and $\gamma(x)$ become

$$\alpha(x)=(2\mu)^{1/2}\cos(\nu x/2), \tag{2.16a}$$

$$\gamma(x)=-2\mu\nu\sin(\nu|x|/2). \tag{2.16b}$$

This is a different solution of the functional equation (2.6) than that given in Ref. 2, which reads instead (up to a convenient redefinition of the multiplicative constant)

$$\alpha(x)=(2\mu)^{1/2}\sin(\nu x/2), \tag{2.17a}$$

$$\gamma(x)=0. \tag{2.17b}$$

Note that in this case the matrix $\mathbf{L}$ is time-independent [see (2.2), (2.4), and (2.17b)]. It is of course trivial to verify that both these solutions, (2.16) and (2.17), satisfy (2.6) with (1.3).

Let us conclude this section by recalling that the possibility to rewrite the equations of motion (2.1) with (1.4) in the Lax pair form (2.2) [with (2.3)–(2.4) and (2.7)–(2.9)] yields n constants of motion, in the guise of the n eigenvalues of the Lax matrix (1.3), or equivalently of its n symmetrical invariants (the n coefficients of the polynomial $\det[\mathbf{L}-x\mathbf{I}]$, or of the traces of $\mathbf{L}^m$ with $m=1,2,\ldots,n$. We focus in the following on these latter quantities:

$$T_m=m^{-1}\,\mathrm{trace}[\mathbf{L}^m], \quad m=1,2,\ldots,n. \tag{2.18}$$

Note that (2.3), with (2.7) and (2.10), implies the relations

$$T_1=(\Delta+\mu)^{1/2}P, \tag{2.19}$$

$$T_2=(1/2)[H+(\Delta-\lambda)P^2], \tag{2.20}$$

with

$$P=\sum_{j=1}^{n}p_j \tag{2.21}$$

and H defined by (1.2).

In the special case $\mu'=0$ the matrix $\mathbf{L}$ is separable of rank 2 [see (2.3) with (2.16a)] and it therefore possesses only 2 nontrivial eigenvalues (all the others vanish); hence all T_m's with $m>2$ can be expressed in terms of T_1 and T_2. In this special case, however, there exists an alternative Lax matrix, which has the property that not only its eigenvalues, but indeed each of its $n(n-1)/2$ matrix elements, are constants of motion [see the *Remark 2.5* above; this Lax matrix is antisymmetrical, see (2.3) and (2.17a)]. Of course, for $n>3$, not all these constants of motion are independent; but there exist appropriate linear combinations of them (or rather of their squares), which provide *n independent* constants of motion *in involution*.[3] This implies the complete (''Liouville'') integrability of (1.2) with (1.3); a result which is however hardly interesting, since in this special case the time evolution of the Hamiltonian system can be exhibited in explicit form in terms of elementary functions (hence this system is not only *completely integrable*; it is *explicitly solvable*).[3]

Hereafter we focus on the general case with $\mu'\neq 0$. Then the Lax matrix [see (2.3) with (2.7) and (2.9)] is not separable, hence the quantities T_m, see (2.18), generally do provide *n indepen-*

dent integrals of motion. To demonstrate that this system is completely integrable it must moreover be shown that these n constants of motion are *in involution*. This is the second main result of this paper. The next section is devoted to its proof.

III. PROOF OF INVOLUTIVITY

Our task is to prove that the Poisson brackets,

$$\{T_m, T_{m'}\} = \sum_{i=1}^{n} \left[\left(\frac{\partial T_m}{\partial q_i} \right) \left(\frac{\partial T_{m'}}{\partial p_i} \right) - \left(\frac{\partial T_m}{\partial p_i} \right) \left(\frac{\partial T_{m'}}{\partial q_i} \right) \right], \tag{3.1}$$

vanish:

$$\{T_m, T_{m'}\} = 0; \quad m, m' = 1,2,\ldots,n. \tag{3.2}$$

For $m=1$ (or $m'=1$) this result is trivial; hereafter we assume $m>1$ (and $m'>1$).

The definition (2.18) implies the following formulas:

$$\frac{\partial T_m}{\partial q_i} = \sum_{i_1 \cdots i_m = 1}^{n} \left(\frac{\partial L_{i_1 i_2}}{\partial q_i} \right) L_{i_2 i_3} \cdots L_{i_m i_1}, \tag{3.3a}$$

$$\frac{\partial T_m}{\partial p_i} = \sum_{i_1 \cdots i_m = 1}^{n} \left(\frac{\partial L_{i_1 i_2}}{\partial p_i} \right) L_{i_2 i_3} \cdots L_{i_m i_1}. \tag{3.3b}$$

The definition (2.3) implies the following formulas:

$$\frac{\partial L_{jk}}{\partial q_i} = (p_j p_k)^{1/2} (\delta_{ij} - \delta_{ik}) \alpha'(q_j - q_k), \tag{3.4a}$$

$$\frac{\partial L_{jk}}{\partial p_i} = (1/2)(p_j p_k)^{1/2} (\delta_{ij} + \delta_{ik}) \alpha(q_j - q_k)/p_i. \tag{3.4b}$$

Hence, after a little algebra,

$$\begin{aligned} \{T_m, T_{m'}\} = (1/2) \sum_{i_1 \cdots i_m i'_1 \cdots i'_{m'} = 1}^{n} & ((1 \cdots m 1' \cdots m'))(23) \\ & \times (34) \cdots (m1)(2'3')(3'4') \cdots (m'1') \\ & \times \{\delta_{i_1 i'_1} [(12)'(1'2') - (1'2')'(12)]/p_{i_1} + (1 \leftrightarrow 2) \\ & + (1' \leftrightarrow 2') + (1 \leftrightarrow 2, 1' \leftrightarrow 2')\}. \end{aligned} \tag{3.5}$$

Here, we have introduced the convenient notations

$$((1 \cdots m 1' \cdots m')) \equiv p_{i_1} \cdots p_{i_m} p_{i'_1} \cdots p_{i'_{m'}}, \tag{3.6}$$

$$(12) \equiv \alpha(q_{i_1} - q_{i_2}), \quad (1'2') \equiv \alpha(q_{i'_1} - q_{i'_2}) \quad \text{and so on,} \tag{3.7a}$$

$$(12)' \equiv \alpha'(q_{i_1} - q_{i_2}), \quad (1'2')' \equiv \alpha'(q_{i'_1} - q_{i'_2}) \quad \text{and so on.} \tag{3.7b}$$

The notation $(1\leftrightarrow 2)$ indicates of course the exchange of the (summation) indices i_1, i_2; likewise $(1'\leftrightarrow 2')$ indicates the exchange of i'_1, i'_2.

Clearly the product $((1\cdots m1'\cdots m'))$ is invariant under any exchange of summation indices. Moreover the product $(23)(34)\cdots(m1)$ is invariant under the transformation $(1\leftrightarrow 2, m\leftrightarrow 3, m-1\leftrightarrow 4,...)$ [due to the evenness of $\alpha(x)=\alpha(-x)$, see (2.7), which implies $(12)=(21)$ and so on, see (3.7a)]. Likewise the product $(2'3')(3'4')\cdots(m'1')$ is invariant under the transformation $(1'\leftrightarrow 2', m\leftrightarrow 3', m'-1\leftrightarrow 4',...)$. Hence

$$\{T_m,_{m'}\}=2\sum_{i_1\cdots i_m i'_2\cdots i'_{m'}=1}^{n}((1\cdots m2'\cdots m'))(23)(34)\cdots(m1)(1m')$$
$$\times(m'm'-1)\cdots(3'2')[(12)'(12')-(12')'(12)]. \tag{3.8}$$

Note that the transition from (3.5) to (3.8) has involved two steps: the elimination of the 3 additional terms inside the curly bracket in the r.h.s. of (3.5) [compensated by the replacement of (1/2) by 2 in front of the sum], and then the sum over the index i'_1 (using the Kronecker $\delta_{i_1 i'_1}$).

Let us now consider the transformation $(2'\leftrightarrow 2,\ 3'\leftrightarrow 3,...,1\leftrightarrow h,...)$, under which the product $(23)(34)\cdots(m1)(1m')(m'm'-1)\cdots(3'2')$ is clearly invariant [as well, of course, as $(1\cdots m2'\cdots m')$]; incidentally, it would be easy to identify h, or more precisely the corresponding summation index i_h (which might or might not be a primed index), but this is not needed in the following. Hence,

$$\{T_m,T_{m'}\}=\sum_{i_1\cdots i_m i'_2\cdots i'_{m'}=1}^{n}((1\cdots m2'\cdots m'))(23)(34)\cdots(m1)(1m')(m'm'-1)\cdots(3'2')$$
$$\times[(12)'(12')-(12')'(12)+(h2')'(h2)-(h2)'(h2')]. \tag{3.9}$$

We now use the remarkable ''functional'' equality

$$(12)'(12')-(12')'(12)+(h2')'(h2)-(h2)'(h2')$$
$$=(\nu/2)(\Delta-\mu)^{1/2}(22')[s_{12}+s_{2h}+s_{h2'}+s_{2'1}], \tag{3.10}$$

which is proven below. Here we have introduced the convenient notation

$$s_{12}\equiv\mathrm{sign}(q_{i_1}-q_{i_2}), s_{h2'}\equiv\mathrm{sign}(q_{i_h}-q_{i'_2}) \text{ and so on.} \tag{3.11}$$

Note that this definition entails oddness of s_{12} under exchange of its two indices, $s_{12}=-s_{21}$, and likewise, of course, $s_{2h}=-s_{h2}$, $s_{h2'}=-s_{2'h}$, $s_{2'1}=-s_{12'}$.

Using (3.10) we get from (3.9)

$$\{T_m,T_{m'}\}=\sum_{i_1\cdots i_m i'_2\cdots i'_{m'}=1}^{n}S_{i_1\cdots i_m i'_2\cdots i'_{m'}}[s_{12}+s_{2h}+s_{h2'}+s_{2'1}], \tag{3.12a}$$

$$S_{i_1\cdots i_m i'_2\cdots i'_{m'}}=(\nu/2)(\Delta-\mu)^{1/2}((1\cdots m2'\cdots m'))(23)(34)\cdots(m1)(1m')$$
$$\times(m'm'-1)\cdots(3'2')(2'2). \tag{3.12b}$$

Note that $S_{i_1\cdots i_m i'_2\cdots i'_{m'}}$ depends cyclically on all $m+m'-1$ indices $i_1,...,\ i_m,\ i'_2,...,\ i'_{m'}$. Hence there clearly exists a transformation which interchanges any two chosen indices, and, in a suitable manner, all other indices pairwise (except one of two which might be

left unchanged, namely, get transformed into themselves), and leaves S invariant (it is actually easy to identify such a transformation; for instance, if the chosen pair are 1 and 2, the appropriate transformation is $(1\leftrightarrow 2, m'\leftrightarrow 2', m'-1\leftrightarrow 3', \ldots, m\leftrightarrow 3, m-1\leftrightarrow 4, \ldots)$. But s_{12} changes sign under any transformation that exchanges 1 and 2 (namely, the summation indices i_1 and i_2); likewise s_{2h} changes sign under any transformation that exchanges 2 and h, and so on for $s_{h2'}$ and $s_{2'1}$. It is thus shown that the sum in the r.h.s. of (3.12a) vanishes, and this implies (3.2.) Q.E.D.

There remains to prove the functional equation (3.10), namely, [see (3.7)]

$$\alpha'(q_1-q_2)\alpha(q_1-q_3)-\alpha'(q_1-q_3)\alpha(q_1-q_2)+\alpha'(q_0-q_3)\alpha(q_0-q_2)-\alpha'(q_0-q_2)\alpha(q_0-q_3)=(\nu/2)(\Delta-\mu)^{1/2}\alpha(q_2-q_3)[s_{12}+s_{20}+s_{03}+s_{31}], \tag{3.13}$$

where, for notational convenience, we have set $q_{i_1}=q_1$, $q_{i_2}=q_2$, $q_{i_h}=q_0$, $q_{i'_2}=q_3$ and of course $s_{jk}\equiv \mathrm{sign}(q_j-q_k)$. It is now a matter of trivial algebra to verify this formula, using the definition (2.7) of $\alpha(x)$, namely,

$$\alpha(q_j-q_k)=(\Delta+\mu)^{1/2}\cos[\nu(q_j-q_k)/2]+(\Delta-\mu)^{1/2}s_{jk}\sin[\nu(q_j-q_k)/2], \tag{3.14}$$

as well as the identity

$$s_{12}s_{13}+s_{23}s_{21}+s_{31}s_{32}=1, \tag{3.15}$$

whose validity is easily checked by considering all possible orderings of q_1, q_2, and q_3.

Note that these results clearly imply the following:

Proposition 3.1: Let the (nxn)-matrix $\mathbf{L}(\mathbf{q},\mathbf{p})$ be defined by (2.3), with $\alpha(x)$ *a priori* arbitrary except for the requirement that it be even, $\alpha(x)=\alpha(-x)$. Then the n quantities T_m defined by (2.18) are in involution [see (3.1,2)], provided $\alpha(x)$ satisfies the following functional equation:

$$\alpha'(x)\alpha(x+y+z)-\alpha'(x+y+z)\alpha(x)+\alpha'(y)\alpha(z)+\alpha'(z)\alpha(y)=\alpha(y+z)[\beta_1(x)+\beta_2(y)+\beta_3(z)+\beta_4(x+y+z)], \tag{3.16}$$

where the 4 functions $\beta_s(x)$ are also *a priori* arbitrary except for the requirement that they be all odd, $\beta_s(-x)=-\beta_s(x)$, $s=1,2,3,4$.

This functional equation is of course inferred from (3.13) via the positions $x=q_1-q_2$, $y=q_2-q_0$, $z=q_0-q_3$, implying $x+y+z=q_1-q_3$, $x+y=q_1-q_0$.

IV. A CANONICAL TRANSFORMATION

In this section we introduce new canonical coordinates x_j, y_j via the transformation

$$x_j=(2\mathrm{i}p_j/\nu)^{1/2}\exp(-\mathrm{i}\nu q_j/2), \tag{4.1a}$$

$$y_j=(2\mathrm{i}p_j/\nu)^{1/2}\exp(\mathrm{i}\nu q_j/2), \tag{4.1b}$$

$$p_j=(2\mathrm{i})^{-1}\nu x_j y_j, \tag{4.2a}$$

$$q_j=\nu^{-1}\arctan[\mathrm{i}(y_j{}^2-x_j{}^2)/(y_j{}^2+x_j{}^2)]. \tag{4.2b}$$

It is easy to check that this transformation is canonical:

$$\{x_j,y_k\}=\delta_{jk}. \tag{4.3}$$

In the new canonical variables the total momentum P, see (2.21), and the Hamiltonian H, see (1.2) with (1.4), read as follows:

$$P=(2\mathrm{i})^{-1}\sum_{j=1}^{n} x_j y_j ,$$

$$H=\lambda P^2-(\nu^2/8)\sum_{j,k=1}^{n}[\mu(x_j{}^2y_k{}^2+x_k{}^2y_j{}^2)-\mathrm{i}\mu' s_{jk}(x_j{}^2y_k{}^2-x_k{}^2y_j{}^2)], \tag{4.4}$$

where we are of course using the convenient notation

$$s_{jk}\equiv\mathrm{sign}(q_j-q_k). \tag{4.5}$$

Note the extreme simplicity of this Hamiltonian in the $\mu'=0$ case, when it takes the separable form

$$H=\lambda P^2-(\nu^2\mu/4)XY, \tag{4.6}$$

$$X=\sum_{j=1}^{n} x_j{}^2, \tag{4.7a}$$

$$Y=\sum_{j=1}^{n} y_j{}^2. \tag{4.7b}$$

This simplicity allows to solve in completely explicit form the equations of motion entailed by this Hamiltonian, which read

$$\dot{x}_j=-\mathrm{i}\lambda\nu P x_j-(1/2)\nu^2\mu X y_j , \tag{4.8a}$$

$$\dot{y}_j=\mathrm{i}\lambda\nu P y_j+(1/2)\nu^2\mu Y x_j , \tag{4.8b}$$

and which imply

$$\dot{P}=0, \tag{4.9}$$

$$\dot{X}=-2\mathrm{i}\nu(\lambda+\mu)PX, \tag{4.10a}$$

$$\dot{Y}=2\mathrm{i}\nu(\lambda+\mu)PY. \tag{4.10b}$$

This is left as an exercise for the diligent reader, who may thereby reobtain the results of Ref. 3.

Let us end this section by reporting (for the general case with $\mu'\neq 0$) the expressions, in the new canonical variables, of the matrices **L** and **A**:

$$L_{jk}=(\nu/4)[-\mathrm{i}(\Delta+\mu)^{1/2}(x_j y_k+x_k y_j)+(\Delta-\mu)^{1/2}s_{jk}(x_j y_k-x_k y_j)], \tag{4.11}$$

$$A_{jk}=(\nu^2\mu'/4)[-\mathrm{i}s_{jk}(x_j y_k+x_k y_j)-[(\Delta+\mu)/(\Delta-\mu)]^{1/2}(x_j y_k-x_k y_j)]. \tag{4.12}$$

V. OUTLOOK

In this final section we outline directions of research which are suggested by these findings.

There is the task to utilize them in order to explore the behavior of the dynamical system characterized by the Hamiltonian (1.2) with (1.4). While we do not expect an explicit solution to be obtainable in the general case with $\mu'\neq 0$, it should be possible to exploit the integrability of the system to evince much information on its behavior, in both cases: μ' and ν real, μ' and ν imaginary. A related problem arises from the ''geometrical'' interpretation naturally associated to

a Hamiltonian of type (1.2), which may be viewed as representing the kinetic energy of a particle moving on an n-dimensional manifold, whose metric is characterized via the function $f(x)$. This question may be enriched by performing canonical (or other) transformations before seeking a geometrical interpretation. In this connection we note that, in the special case $\mu'=0$, the Hamiltonian (4.4) includes the description of geodesic motion on the sphere.[4]

Several other questions are suggested by our findings. There exists an integrable nonlinear PDE whose solitons move according to the Hamiltonian (1.1);[1] is this also true in the general case [(1.2) with (1.4), $\mu'\neq 0$]? In the special case $\mu'=0$ there exists a quantized version of the Hamiltonian (1.2) with (1.3) which can be rather fully solved;[5] is this also true in the general case [(1.2) with (1.4), $\mu'\neq 0$]?

And what about possible (integrable) generalizations? For instance, one of us (F.C.) found that the Hamiltonian (1.2) with (1.3) remains solvable after addition of a term H',

$$H'(\mathbf{q},\mathbf{p})=c\sum_{j,k=1}^{n}(p_j-p_k)\sin[\nu(q_j-q_k)]. \tag{5.1}$$

It is likely that integrable generalizations of (1.2) with (1.4) also exist, corresponding to ''other root systems'' [if one associates (1.2) with the root system A_n], or obtainable via ''duplications,''[6] or involving the addition to the Hamiltonian of ''one-body terms,'' or including ''internal degrees of freedom'' (matrix models), or amounting to ''discretizations'' of the space variables (lattice models) or of the time variable (mappings). And what about complex or multidimensional extensions?

It is moreover evident that, for all models invariant under the translation $q_j\rightarrow q_j+q_0$, for which P is therefore a constant of the motion, the term P^2 in the Hamiltonian can rather trivially be replaced by a largely arbitrary function $F(P)$, without causing other than cosmetic changes. On the other hand it is rather clear[3] that the Hamiltonian

$$H=\lambda P^2+\sum_{j,k=1}^{n}p_jp_k[\mu_1\cos(\nu q_j)\cos(\nu q_k)+\mu_2\sin(\nu q_j)\sin(\nu q_k)] \tag{5.2}$$

is solvable in terms of elliptic functions.[7] Note that this model is not invariant under the translation $q_j\rightarrow q_j+q_0$, except in the special case $\mu_1=\mu_2=\mu$, when it reduces to (1.2) with (1.3).

And we end with the still extant, and most interesting, question: which is the most general function $f(x)$ such that the Hamiltonian (1.2) is integrable?

Supertraces on the algebras of observables of the rational Calogero model with harmonic potential

S. E. Konstein and M. A. Vasiliev
I. E. Tamm Department of Theoretical Physics, P. N. Lebedev Physical Institute, 117924 Leninsky Prospect 53, Moscow, Russia

(Received 25 September 1995; accepted for publication 7 December 1995)

We define a complete set of supertraces on the algebra $SH_N(\nu)$, the algebra of observables of the N-body rational Calogero model with harmonic interaction. This result extends the previously known results for the simplest cases of $N=1$ and $N=2$ to arbitrary N. It is shown that $SH_N(\nu)$ admits $q(N)$ independent supertraces, where $q(N)$ is a number of partitions of N into a sum of odd positive integers, so that $q(N)>1$ for $N\geqslant 3$. Some consequences of the existence of several independent supertraces of $SH_N(\nu)$ are discussed, such as the existence of ideals in associated W_∞-type Lie superalgebras. © *1996 American Institute of Physics.*

I. INTRODUCTION

In this paper we investigate some properties of the associative algebras that were shown in Refs. 1–3 to underlie the rational Calogero model[4] and were denoted as $SH_N(\nu)$ in Ref. 5. Algebra $SH_N(\nu)$ is the associative algebra of polynomials constructed from arbitrary elements σ of the symmetric group S_N and the generating elements a_i^α obeying the following relations:

$$\sigma a_i^\alpha = a_{\sigma(i)}^\alpha \sigma, \tag{1}$$

$$[a_i^\alpha, a_j^\beta] = \epsilon^{\alpha\beta} A_{ij}, \tag{2}$$

where $i,j=1,\ldots,N$, $\alpha,\beta=0,1$, $\epsilon^{\alpha\beta}=-\epsilon^{\beta\alpha}$, $\epsilon^{01}=1$, and

$$A_{ij}=\delta_{ij}+\nu\widetilde{A}_{ij}, \quad \widetilde{A}_{ij}=\delta_{ij}\sum_{l=1}^{N} K_{il}-K_{ij}. \tag{3}$$

Here $K_{ij}\in S_N$ with $i,j=1,\ldots,N$, $i\neq j$, are the elementary permutations $i\leftrightarrow j$ satisfying the relations

$$K_{ij}=K_{ji}, \quad K_{ij}K_{ij}=1, \quad K_{ij}K_{jl}=K_{jl}K_{li}=K_{li}K_{ij},$$

for $i\neq j\neq l\neq i$ and

$$K_{ij}K_{kl}=K_{kl}K_{ij},$$

if i,j,k,l are pairwise different. Note that in this paper repeated Latin indices $i,j,k,\ldots$, do not imply summation.

The defining relations (1)–(3) are consistent. In particular, the Jacobi identities,

$$[a_i^\alpha,[\alpha_j^\beta,a_k^\gamma]]+[a_j^\beta[a_k^\gamma,a_i^\alpha]]+[a_k^\gamma,[a_i^\alpha,a_j^\beta]]=0, \tag{4}$$

are satisfied.

An important property of $SH_N(\nu)$ that allows one to solve the Calogero model[4] is that this algebra possesses inner sl_2 automorphisms with the generators

0022-2488/96/37(6)/2872/20/$10.00

$$T^{\alpha\beta}=\frac{1}{2}\sum_{i=1}^{N}(a_i^\alpha a_i^\beta+a_i^\beta a_i^\alpha), \tag{5}$$

$$[T^{\alpha\beta},T^{\gamma\delta}]=\epsilon^{\alpha\gamma}T^{\beta\delta}+\epsilon^{\alpha\delta}T^{\beta\gamma}+\epsilon^{\beta\gamma}T^{\alpha\delta}+\epsilon^{\beta\delta}T^{\alpha\gamma}, \tag{6}$$

which act on the generating elements a_i^α as on sl_2 vectors,

$$[T^{\alpha\beta},a_i^\gamma]=\epsilon^{\alpha\gamma}a_i^\beta+\epsilon^{\beta\gamma}a_i^\alpha. \tag{7}$$

The Calogero Hamiltonian is identified with the Cartan element T^{01} which, according to (7), induces Z gradation of $SH_N(\nu)$. The latter property allows one[2] to construct wave functions via the standard Fock procedure with the Fock vacuum $|0\rangle$, such that $a_i^0|0\rangle=0$. Thus, the elements a_i^α serve as generalized oscillators underlying the Calogero problem. The concrete realization of these oscillators in terms of Dunkl differential-difference operators[6] was presented in Refs. 1 and 2.

These properties characterize the algebra $SH_N(\nu)$ as a natural generalization of the Heisenberg–Weyl algebra, the associative algebra of harmonic oscillators. Since the Lie algebra of quantum operators in the harmonic oscillator problem can be identified with the $W_{1+\infty}$ algebra,[7] the Lie (super)algebras constructed from $SH_N(\nu)$ with the aid of supercommutators give rise to a class of the $W_{1+\infty}$-type algebras, which have been denoted as $W_{N,\infty}(\nu)$ in Ref. 8, where it was shown that all these algebras contain the Virasoro algebra as a subalgebra. The latter observation indicates that the algebras $SH_N(\nu)$ and $W_{N,\infty}(\nu)$ can be related to conformal models as well as to other classes of models in the range from the quantum Hall effect[9] to higher-spin gauge theories[10] and KP hierarchy[11] where W_∞-type algebras prove to be important. An additional argument in favor of the relationship of $SH_N(\nu)$ to the quantum Hall effect is due to the known fact that the Calogero model can be interpreted as a one-dimensional reduction of the full anyonic problem.[12,3]

For lower values of N, a nature of $SH_N(\nu)$ is rather well understood. $SH_1(\nu)$ is the ordinary Heisenberg–Weyl algebra (since ν dependence is artificial in this case we will use the notation SH_1). Properties of this algebra are very well studied (see, e.g., Ref. 13). Note that since the center of mass coordinates $1/N\Sigma_{i=1}^N a_i^\alpha$ decouple from everything else in the defining relations (1)–(3), the associative algebra $SH_N(\nu)$ has the structure $SH_N(\nu)=SH_1\otimes SH_N'(\nu)$ where, by definition, $SH_N'(\nu)$ is the algebra of elements depending only on the relative coordinates $a_i^\alpha-a_j^\alpha$.

The properties of $SH_2'(\nu)$ are well studied too.[14] The algebra $SH_2'(\nu)$ is defined by the relations

$$[a^\alpha,a^\beta]=\epsilon^{\alpha\beta}(1+2\nu K), \tag{8}$$

where K is the only nontrivial element of S_2, while a^α are the relative motion oscillators. For the particular case of $\nu=0$, one recovers the algebra SH_1 in the sector of the K independent elements.

In Ref. 14 it was shown that $SH_2'(\nu)$ admits a unique supertrace operation defined by the simple formula

$$\mathrm{str}(1)=1,\quad \mathrm{str}(K)=-2\nu,\quad \mathrm{str}(W)=\mathrm{str}(WK)=0, \tag{9}$$

for any polynomial $W\in SH_2'$ of the form

$$W=\sum_{n=1}^{\infty}W_{\alpha_1\cdots\alpha_n}a^{\alpha_1}\cdots a^{\alpha_n}, \tag{10}$$

with arbitrary totally symmetric multispinors $W_{\alpha_1\cdots\alpha_n}$. For the particular case of $\nu=0$ one recovers the supertrace on SH_1.

Furthermore, it was shown in Ref. 14 by explicit evaluation of the invariant bilinear form $B(x,y)\overset{\text{def}}{=}\mathrm{str}(xy)$ that for $\nu=l+(1/2)$ (l is any integer) $SH_2'(\nu)$ reduces to finite-dimensional matrix algebras up to some infinite-dimensional ideals $\mathscr{I}$ that decouple from everything under the supertrace operation (9), i.e., $\mathrm{str}(xy)=0$, $\forall x\in\mathscr{I}$.

In Ref. 15 it was then observed that $SH_2'(\nu)$ is isomorphic to the factor of the enveloping algebra $U(\mathrm{osp}(1;2))$ of osp(1;2) over its ideal generated by the quadratic Casimir operator C_2 by factoring out all elements of the form $(C_2-c_2)U(\mathrm{osp}(1;2))$, where $c_2=\frac{1}{16}(4\nu^2-1)$ is an arbitrary constant. In its turn this observation clarified the origin of the ideals of $SH_2'(\nu)$ at $\nu=l+\frac{1}{2}$ as corresponding to the finite-dimensional representations of osp(1;2).

Although the algebra $SH_N(\nu)$ is getting interesting applications for any N, until now understanding of its algebraic properties for $N>2$ is far from being satisfactory. In particular, there is no interpretation of $SH_N(\nu)$ in terms of enveloping algebras of finite-dimensional superalgebras, and nothing is known about ideals of $SH_N(\nu)$ which information is very important in applications.

In this paper we analyze the existence of the invariant supertrace operation on $SH_N(\nu)$ i.e., such a complex-valued linear function $\mathrm{str}(f)$ on $SH_N(\nu)$ that

$$\mathrm{str}([f,g\})=0,\quad \forall f,g\in SH_N(\nu), \tag{11}$$

with the convention that

$$[f,g\}=fg-(-1)^{\pi(f)\pi(g)}gf, \tag{12}$$

where the parity π in $SH_N(\nu)$ is defined as follows:

$$\pi(a_i^\alpha)=1,\quad \pi(K_{ij})=0. \tag{13}$$

Let us note that an attempt to define differently graded traces like, e.g., an ordinary trace ($\pi\equiv 0$) unlikely leads to interesting results.

Knowledge of the supertrace operations on $SH_N(\nu)$ is useful in various respects. One of the most important applications of the supertrace is that it gives rise to n-linear invariant forms,

$$\mathrm{str}(a_1a_2\cdots a_n), \tag{14}$$

that allows one to work with the algebra essentially in the same way as with the ordinary finite-dimensional matrix algebras, and, for example, construct Lagrangians when working with dynamical theories based on $SH_N(\nu)$. Another useful property is that since null vectors of any invariant bilinear form span a both-side ideal of the algebra, this gives a powerful device for investigating ideals that decouple from everything under the supertrace operation as it occurs in $SH_2(\nu)$ for half-integer ν. It is also worth mentioning that having an explicit form of the trilinear form in one or another basis is practically equivalent to defining a star-product law in the algebra.

An important motivation for the analysis of the supertraces of $SH_N(\nu)$ is due to its deep relationship with the analysis of the representations of this algebra, which in its turn gets applications to the analysis of the wave functions of the Calogero model. For example, given representation of $SH_N(\nu)$, one can speculate that it induces some supertrace on this algebra as (appropriately regularized) supertrace of (infinite) representation matrices. When the corresponding bilinear form degenerates this would imply that the representation becomes reducible.

As we show, the situation for $SH_N(\nu)$ is very interesting, since starting from $N=3$ it admits more than one independent supertrace in contrast to the cases of $N=1$ and $N=2$. This fact is in agreement with the results of Ref. 5, where it was shown that there exist many inequivalent lowest-weight-type representations of $SH_N(\nu)$ for higher N (these representations are classified

according to the representations of S_N). Another important consequence of this phenomenon is that the Lie superalgebras $W_{N,\infty}(\nu)$ are not simple, while appropriate, their simple subalgebras possess nontrivial outer automorphisms.

The paper is organized as follows. In Sec. II we analyze consequences of S_N and sl_2 automorphisms of $SH_N(\nu)$. In Sec. III we discuss general properties of the supertraces and consequences of the existence of several independent supertraces. In Sec. IV we study the restrictions on supertraces of the group algebra of S_N considered as a subalgebra of $SH_N(\nu)$, which follow from the defining relations of $SH_N(\nu)$. These restrictions are called ground level conditions (GLC). They play a fundamental role in the problem, since, as we show in Sec. V, every solution of GLC admits a unique extension to some supertrace on $SH_N(\nu)$. In Appendix A it is shown that the number of independent supertraces on $SH_N(\nu)$ equals the number of partitions of N into a sum of odd positive integers. Some technical details of the proof of Sec. V are collected in Appendices B and C.

II. FINITE-DIMENSIONAL GROUPS OF AUTOMORPHISMS

The group algebra of S_N is the finite-dimensional subalgebra of $SH_N(\nu)$. The elements $\sigma\in S_N$ induce inner automorphisms of $SH_N(\nu)$. It is well known that any $\sigma\in S_N$ can be expanded into a product of pairwise commuting cycles,

$$\sigma=c_1c_2c_3\cdots c_t, \tag{15}$$

where $c_\mathfrak{m}$, $\mathfrak{m}=1,...,t$, are cyclic permutations acting on distinct subsets of values of indices i. For example, a cycle that acts on the first s indices as $1\to2\to\cdots\to s\to1$ has the form

$$c=K_{12}K_{23}\cdots K_{(s-1)s}. \tag{16}$$

We use the notation $|c|$ for the length of the cycle c. For the cycle (16), $|c|=s$. We take a convention that the cycles of unit length are associated with all values of i such that $\sigma(i)=i$, so that the relation $\Sigma_\mathfrak{m}|c_\mathfrak{m}|=N$ is true.

Given permutation $\sigma\in S_N$, we introduce a new set of basis elements $\mathfrak{B}_\sigma=\{b^I\}$ instead of $\{a_i^\alpha\}$ in the following way. For every cycle $c_\mathfrak{m}$ in the decomposition (15) ($\mathfrak{m}=1,...,t$), let us fix some index $l_\mathfrak{m}$, which belongs to the subset associated with the cycle $c_\mathfrak{m}$. The basis elements $b^\alpha_{\mathfrak{m}j}$, $j=1,...,|c_\mathfrak{m}|$, which realize one-dimensional representations of the commutative cyclic group generated by $c_\mathfrak{m}$, have the form

$$b^\alpha_{\mathfrak{m}j}=\frac{1}{\sqrt{|c_\mathfrak{m}|}}\sum_{k=1}^{|c_\mathfrak{m}|}(\lambda_\mathfrak{m})^{jk}a^\alpha_{l(\mathfrak{m},k)}, \tag{17}$$

where $l(\mathfrak{m},k)=c_\mathfrak{m}^{-k}(l_\mathfrak{m})$ and

$$\lambda_\mathfrak{m}=\exp(2\pi i/|c_\mathfrak{m}|). \tag{18}$$

From the definition (17), it follows that

$$c_\mathfrak{m}b^\alpha_{\mathfrak{m}j}=(\lambda_\mathfrak{m})^jb^\alpha_{\mathfrak{m}j}c_\mathfrak{m}, \tag{19}$$

$$c_\mathfrak{m}b^\alpha_{\mathfrak{n}j}=b^\alpha_{\mathfrak{n}j}c_\mathfrak{m}, \quad \text{for } \mathfrak{n}\neq\mathfrak{m}, \tag{20}$$

and therefore

$$\sigma b^\alpha_{\mathfrak{m}j}=(\lambda_\mathfrak{m})^jb^\alpha_{\mathfrak{m}j}\sigma. \tag{21}$$

In what follows, instead of writing $b^\alpha_{\mathfrak{m}j}$ we use the notation b^I with the label I accounting for the full information about the index α, the index $\mathfrak{m}$ enumerating cycles in (15), and the index j, which enumerates various elements $b^\alpha_{\mathfrak{m}j}$ related to the cycle $c_\mathfrak{m}$, i.e., $I(I=1,\ldots,2N)$ enumerates all possible triples $\{\alpha,\mathfrak{m},j\}$. We denote the index α, the cycle and the eigenvalue in (19) corresponding to some fixed index I as $\alpha(I)$, $c(I)$, and $\lambda_I=(\lambda_\mathfrak{m})^j$, respectively. The notation $\sigma(I)=\sigma_0$ implies that $b^\alpha_I \in \mathfrak{B}_{\sigma_0}$. $\mathfrak{B}_\mathbf{1}$ is the original basis of the generating elements a^α_i (here $\mathbf{1}$ is the unit permutation).

Let $\mathfrak{M}(\sigma)$ be the matrix that maps $\mathfrak{B}_\mathbf{1}\to\mathfrak{B}_\sigma$ in accordance with (17),

$$b^I=\sum_{i,\alpha}\mathfrak{M}^I_{i\alpha}(\sigma)a^\alpha_i. \tag{22}$$

Obviously this mapping is invertible. Using the matrix notations one can rewrite (21) as

$$\sigma b^I\sigma^{-1}=\sum_{J=1}^{2N}\Lambda^I_J(\sigma)b^J,\quad \forall b^I\in\mathfrak{B}_\sigma, \tag{23}$$

where $\Lambda^J_I(\sigma)=\delta^J_I\lambda_I$.

Every polynomial in $SH_N(\nu)$ can be expanded into a sum of monomials of the form

$$b^{I_1}b^{I_2}\cdots b^{I_s}\sigma, \tag{24}$$

where all $\sigma(I_k)=\sigma$. Every monomial of this form realizes some one-dimensional representation of the Abelian group generated by all cycles $c_\mathfrak{m}$ in the decomposition (15).

The commutation relations for the generating elements b^I follow from (2) and (3):

$$[b^I,b^J]=F^{IJ}=\mathscr{C}^{IJ}+\nu f^{IJ}, \tag{25}$$

where

$$\mathscr{C}^{IJ}=\epsilon^{\alpha(I)\alpha(J)}\delta_{c(I)c(J)}\delta_{\lambda_I\lambda_J^{-1}} \tag{26}$$

and

$$f^{IJ}=\sum_{i,j,\alpha,\beta}\mathfrak{M}^I_{i\alpha}(\sigma)\mathfrak{M}^J_{j\beta}(\sigma)\epsilon^{\alpha\beta}\widetilde{A}_{ij}. \tag{27}$$

The indices I,J are raised and lowered with the aid of the symplectic form $\mathscr{C}^{IJ}$

$$\mu^I=\sum_J\mathscr{C}^{IJ}\mu_J,\quad \mu_I=\sum_J\mu^J\mathscr{C}_{JI};\quad \sum_M\mathscr{C}_{IM}\mathscr{C}^{MJ}=-\delta^J_I. \tag{28}$$

Note that the elements b^I are normalized in (17) in such a way that the ν-independent part in (25) has the form (26).

Another important finite-dimensional algebra of inner automorphisms of $SH_N(\nu)$ is the sl_2 algebra that acts on the indices α. It is spanned by the S_N-invariant second-order polynomials (5). Evidently, $SH_N(\nu)$ decomposes into the infinite direct sum of only finite-dimensional irreducible representations of this sl_2 spanned by various homogeneous polynomials (24).

From the defining relations (1)–(3), it follows that $SH_N(\nu)$ is Z_2 graded with respect to the automorphism

$$f(a^\alpha_j)=-a^\alpha_j,\quad f(K_{ij})=K_{ij}, \tag{29}$$

which gives rise to the parity π (13). In applications to higher-spin models, this automorphism distinguishes between bosons and fermions.

The algebra $SH_N(\nu)$ admits the antiautomorphism ρ,

$$\rho(a_k^\alpha)=ia_k^\alpha, \quad \rho(K_{ij})=K_{ij}, \tag{30}$$

which leaves invariant the basic relations (1)–(3), provided that an order of operators is reversed according to the defining property of antiautomorphisms: $\rho(AB)=\rho(B)\rho(A)$. From (15), (16), and (21) it follows that

$$\rho(\sigma)=\sigma^{-1}, \quad \rho(b^I)=ib^J, \tag{31}$$

where J is related to I in such a way that $\alpha(J)=\alpha(I)$, $\sigma(J)=(\sigma(I))^{-1}$, $c(J)=(c(I))^{-1}$, and $\lambda_J=\lambda_I^{-1}$. Note that in higher-spin theories the counterpart of ρ distinguishes between odd and even spins.[16]

III. GENERAL PROPERTIES OF SUPERTRACE

In this section we summarize some general properties to be respected by any supertrace in $SH_N(\nu)$.

Let A be an arbitrary associative Z_2-graded algebra with the parity function $\pi(x)=0$ or 1. Suppose that A admits some supertrace operations str_p, where the label p enumerates different nontrivial supertraces. We call a supertrace str even (odd) if $\mathrm{str}(x)=0$, $\forall x\in A$ such that $\pi(x)=1(0)$. Let T_A be a linear space of supertraces on A. We say that $\dim T_A$ is the number of supertraces on A.

Given parity-preserving (anti) automorphism τ and supertrace operation str on A, $\mathrm{str}(\tau(x))$ is some supertrace as well. For inner automorphisms τ, $(\tau(x)=pxp^{-1}$, $\pi(p)=0)$, it follows from the defining property of the supertrace that $\mathrm{str}(\tau(x))=\mathrm{str}(x)$. Thus, T_A forms a representation of the factor group of the parity preserving automorphisms and antiautomorphisms of A over the normal subgroup of the inner automorphisms of A. Applying this fact to the original parity automorphism $(-1)^\pi$, one concludes that T_A can always be decomposed into a direct sum of subspaces of even and odd supertraces, $T_A=T_A^0\oplus T_A^1$ and that $T_A^1=0$ if the parity automorphism is inner.

In the sequel we only consider the case where $\dim T_A<\infty$ and there are no nontrivial odd supertraces. Let $A=A_1\otimes A_2$ with the associative algebras A_1 and A_2 endowed with some even supertrace operations t_1 and t_2, respectively. The supertrace on A can be defined by setting $\mathrm{str}(a_1\otimes a_2)=t_1(a_1)t_2(a_2)$, $\forall a_1\in A_1$, $\forall a_2\in A_2$. As a result, one concludes that $T_A=T_{A_1}\otimes T_{A_2}$. In the case of $SH_N(\nu)$, one thus can always separate out a contribution of the center of mass coordinates as an overall factor (SH_1 admits the unique supertrace).

If A is finite dimensional then the existence of two different supertraces indicates that A admits nontrivial both-side ideals. Actually, consider the bilinear form $B(f,g)=\alpha_1\,\mathrm{str}_1(fg)+\alpha_2\,\mathrm{str}_2(fg)$ with arbitrary parameters α_1, $\alpha_2\in\mathbb{C}$ and elements $f,g\in A$. The determinant of this bilinear form is some polynomial of α_1 and α_2. Therefore it vanishes for certain ratios α_1/α_2 or α_2/α_1 according to the central theorem of algebra. Thus, for these values of the parameters the bilinear form B degenerates and admits nontrivial null vectors x, $B(x,g)=0$, $\forall g\in A$. It is easy to see that the linear space $\mathcal{I}$ of all null vectors x is some both-side ideal of A. For infinite-dimensional algebras the existence of several supertraces does not necessarily imply the existence of ideals. As mentioned in the Introduction, the existence of several supertrace operations may be related to the existence of inequivalent representations. Also, it is worth mentioning that for the case of infinite-dimensional algebras and representations under investigation, it can be difficult to use the standard (i.e., matrixwise) definition of the supertrace. In this situation the formal definition of the supertraces on the algebra we implement in this paper is the only rigorous one.

Let l_A be the Lie superalgebra that is isomorphic to A as a linear space and is endowed with the product law (12). It contains the subalgebra $sl_A \in l_A$ spanned by elements g, such that $\mathrm{str}_p(g)=0$ for all p. Evidently sl_A forms the ideal of l_A. The factor algebra $t_A=l_A/sl_A$ is a commutative Lie algebra isomorphic to T_A^* as a linear space. Elements of t_A different from the unit element of A (which exist if $\dim T_A>1$) can induce outer automorphisms of sl_A. Let us note that it is this sl_A Lie superalgebra that usually has physical applications. For the case of $SH_N(\nu)$ under consideration, the algebra $l_{SH_N(\nu)}$ is identified with the algebra $W_{N,\infty}(\nu)$ introduced in Ref. 8. We therefore conclude that these algebras are not simple for $N>2$ because it is shown below that $SH_N(\nu)$ admits several supertraces for $N>2$. Instead, one can consider the algebras $sW_{N,\infty}(\nu)$.

Let l_A contain some subalgebra $\mathscr{L}$ such that A decomposes into a direct sum of irreducible representations of $\mathscr{L}$ with respect to the adjoint action of $\mathscr{L}$ on A via supercommutators. Then, only trivial representations of $\mathscr{L}$ can contribute to any supertrace on A. Actually, consider some nontrivial irreducible representation R of $\mathscr{L}$. Any $r \in R$ can be represented as

$$r=\sum_j [l_j, r_j\}, \quad l_j \in \mathscr{L}, \quad r_j \in R, \tag{32}$$

since elements of the form (32) span the invariant subspace in R. From (11) it follows then that $\mathrm{str}(r)=0$, $\forall r \in R$.

From the definition of the supertrace, it follows that

$$\mathrm{str}(a_1 a_2)+\mathrm{str}(a_2 a_1)=0, \tag{33}$$

for arbitrary odd elements a_1 and a_2 of A. A simple consequence of this relation is that

$$\mathrm{str}(a_1 a_2 \cdots a_n + a_2 \cdots a_n a_1 + \cdots + a_n a_1 \cdots a_{n-1})=0 \tag{34}$$

is true for an arbitrary even n if all a_i are some odd elements of A. Since we assume that the supertrace is even, (34) is true for any n. This simple property turns out to be practically useful because, when odd generating elements are subject to some commutation relations with the right-hand sides expressed via even generating elements like in (2), it often allows one to reduce evaluation of the supertrace of a degree-n polynomial of a_i to supertraces of lower degree polynomials.

Another useful property is that in order to show that the characteristic property of the supertrace (11) is true for any $x,g \in A$, it suffices to show this for a particular case where x is arbitrary while g is an arbitrary generating element of some fixed system of generating elements. Then (11) for general x and g will follow from the properties that A is associative and str is linear. For the particular case of $SH_N(\nu)$, this means that it is enough to set either $g=a_i^\alpha$ or $g=K_{ij}$.

Let us now turn to some specific properties of $SH_N(\nu)$ as a particular realization of A.

By identifying $\mathscr{L}$ with sl_2 (5) and taking into account that $SH_N(\nu)$ decomposes into a direct sum of irreducible finite-dimensional representations of sl_2, one arrives at the following.

Lemma 1: str(x) can be different from zero only when x is sl_2 singlet, i.e. $[T^{\alpha\beta}, x]=0$.

Corollary: Any supertrace on $SH_N(\nu)$ is even.

Analogously one deduces consequences of the S_N symmetry. In particular, one proves the following.

Lemma 2: Given $c \in S_N$ such that $cF=\mu Fc$ for some element F and any constant $\mu \neq 1$, str$(F)=0$. Given monomial $F = b^{I_1} b^{I_2} \cdots b^{I_s} \sigma$ with $b^{I_k} \in \mathfrak{B}_\sigma$ and a cycle c_0 in the decomposition (15) of σ, one concludes that str$(F)=0$ if $\Pi_{k:c(I_k)=c_0} \lambda_{I_k} \neq 1$, where λ_{I_k} are the eigenvalues (21) of b^{I_k}.

IV. GROUND LEVEL CONDITIONS

Let us analyze restrictions on a form of $\mathrm{str}(a), a \in S_N$, which follow from the defining relations of $SH_N(\nu)$.

First, we describe supertraces on the group algebra of S_N. Let some permutation σ decompose into n_1 cycles of length 1, n_2 cycles of length 2,... and n_N cycles of length N. The non-negative integers n_k satisfy the relation

$$\sum_{k=1}^{N} k n_k = N \tag{35}$$

and fix σ up to some conjugation $\sigma \to \tau\sigma\tau^{-1}$, $\tau \in S_N$. Thus

$$\mathrm{str}(\sigma) = \varphi(n_1, n_2, \ldots, n_N), \tag{36}$$

where $\sigma(n_1, n_2, \ldots, n_N)$ is an arbitrary function. Obviously the linear space of invariant functions on S_N [i.e., such that $f(\tau\sigma\tau^{-1}) = f(\sigma)$] coincides with the linear space of supertraces on the group algebra of S_N. Therefore, the dimension of the linear space of supertraces is equal to the number $p(N)$ of independent solutions of (35), the number of conjugacy classes of S_N. One can introduce the generating function for $p(N)$ as $P(q) = \Sigma_{n=0}^{\infty} p(n) q^n = \Pi_{k=1}^{\infty} 1/(1-q^k)$. The properties of this generating function and of the quantities $p(N)$ are discussed in detail, e.g., in Ref. 17.

According to the general argument of the previous section, the existence of several independent traces implies that the group algebra of S_N must have some ideals. Indeed, it can be shown to decompose into a direct sum of matrix algebras Mat_n.

Since the group algebra of S_N is embedded into $SH_N(\nu)$, some additional restrictions on the functions $\varphi(n_1, n_2, \ldots, n_N)$ follow from (11) and the defining relations (2)–(3) of $SH_N(\nu)$. Actually, consider some elements b^I such that $\lambda_I = -1$. Then, one finds from (11) and (21) that $\mathrm{str}(b^I b^J \sigma) = -\mathrm{str}(b^J \sigma b^I) = \mathrm{str}(b^J b^I \sigma)$, and therefore

$$\mathrm{str}([b^I, b^J]\sigma) = 0. \tag{37}$$

Since these conditions restrict supertraces of degree-0 polynomials of a_i^α, we call them ground level conditions (GLC). Thus, for every permutation σ and any even integer $2k$ such that there exists some cycle c of length $|c| = 2k$ in the decomposition (15), we have GLC (37) with b^I such that $c(I) = c$. Note, however, that if $\lambda_J \neq -1$ or $c(J) \neq c(I)$, then the relation $\mathrm{str}([b^I, b^J]\sigma) = 0$ is trivially satisfied as a consequence of *Lemma 2*.

It is convenient to rewrite GLC in the following form:

$$\mathrm{str}(c_0\sigma_0) = -\mathrm{str}(([b_{0k}^0, b_{0k}^1] - 1)c_0\sigma_0), \tag{38}$$

where c_0 is any cycle of even length $2k$ in the decomposition of the permutation $\sigma = c_0\sigma_0$ and b_{0k}^α is the corresponding variable (17) with $(\lambda_0)^k = -1$, i.e., $c_0 b_{0k}^\alpha = -b_{0k}^\alpha c_0$, $\sigma_0 b_{0k}^\alpha = b_{0k}^\alpha \sigma_0$ and $\lambda_0 = \exp(2\pi i/|c_0|)$.

To work out the explicit form of the restrictions on the functions $\varphi(n_1, n_2, \ldots, n_N)$ that follow from GLC, one has to use the following simple facts from the theory of the symmetric group.

Lemma 3: Let c_1 and c_2 be two distinct cycles in the decomposition (15). Let indices i_1 and i_2 belong to the subsets of indices associated with the cycles c_1 and c_2, respectively. Then the permutation $c = c_1 c_2 K_{i_1 i_2}$ is a cycle of length $|c| = |c_1| + |c_2|$.

Lemma 4: Given cyclic permutation $c \in S_N$, let $i \neq j$ be two indices such that $c^k(i) = j$, where k is some positive integer, $k < |c|$. Then $cK_{ij} = c_1 c_2$, where $c_{1,2}$ are some noncoinciding mutually commuting cycles such that $|c_1| = k$ and $|c_2| = |c| - k$.

Using the definition (17), the commutation relations (1)–(3) and *Lemmas 3* and *4*, one reduces GLC to the following system of equations:

$$n_{2k}\varphi(n_1,\dots,n_{2k},\dots,n_N) = -\nu n_{2k}\Bigg(2\sum_{s\neq k,s=1}^{2k-1} O_s\varphi(n_1,\dots,n_s+1,\dots,n_{2k-s}+1,\dots,n_{2k}-1;\dots,n_N)$$
$$+2O_k\varphi(n_1,\dots,n_k+2,\dots,n_{2k}-1,\dots,n_N)$$
$$+\sum_{s\neq 2k;s=1}^{N} sn_s\varphi(n_1,\dots,n_s-1,\dots,n_{2k}-1,\dots,n_{2k+s}+1,\dots,n_N)$$
$$+2k(n_{2k}-1)\varphi(n_1,\dots,n_{2k}-2,\dots,n_{4k}+1,\dots,n_N)\Bigg), \tag{39}$$

where $O_k=0$ for k even and $O_k=1$ for k odd.

Let us note that by virtue of the substitution

$$\varphi(n_1,\dots,n_N)=\nu^{E(\sigma)}\tilde{\varphi}(n_1,\dots,n_N), \tag{40}$$

where $E(\sigma)$ is the number of cycles of even length in the decomposition of σ (15), i.e.

$$E(\sigma)=n_2+n_4+\cdots, \tag{41}$$

one can get rid of the explicit dependence of ν from GLC (39). As a result, there are two distinguishing cases, $\nu=0$ and $\nu\neq 0$.

For lower N the conditions (39) take the form

$$\varphi(0,1)+2\nu\varphi(2,0)=0 \tag{42}$$

for $N=2$ [cf. (9)],

$$\varphi(1,1,0)+2\nu\varphi(3,0,0)+\nu\varphi(0,0,1)=0, \tag{43}$$

for $N=3$ and

$$\varphi(2,1,0,0)+2\nu\varphi(4,0,0,0)+2\nu\varphi(1,0,1,0)=0,$$

$$\varphi(0,2,0,0)+2\nu\varphi(2,1,0,0)+2\nu\varphi(0,0,0,1)=0,$$

$$\varphi(0,0,0,1)+4\nu\varphi(1,0,1,0)=0,$$

for $N=4$. As a result one finds 1-parametric families of solutions for $N=1$ and $N=2$ and 2-parametric families of solutions for $N=3$ and $N=4$.

Let G_N be the number of independent solutions of (39). As we show in the next section $G_N=\dim T_{SH_N(\nu)}$ for all ν. In other words, all other conditions on the supertrace do not impose any restrictions on the functions $\varphi(n_1,\dots,n_N)$ but merely express supertraces of higher-order polynomials of a_i^α in terms of $\varphi(n_1,\dots,n_N)$.

In the Appendix A we prove the following.

Theorem 1: *$G_N=q(N)$, where $q(N)$ is a number of partitions of N into a sum of odd positive integers, i.e. the number of the solutions of the equation $\Sigma_{k=0}^{\infty}(2k+1)n_k=N$ for non-negative integers n_i.*

One can guess this result from the particular case of $\nu=0$, where GLC tell us that $\varphi(n_1,\dots,n_N)$ can be nonvanishing (and arbitrary) only when all $n_{2k}=0$. Interestingly enough, G_N remains the same for $\nu\neq 0$.

V. SUPERTRACE FOR GENERAL ELEMENTS

In this section we prove the following.

Theorem 2: $\dim T_{SH_N(\nu)} = G_N$, *where* G_N *is the number of independent solutions of the ground level conditions (39).*

The proof of the *Theorem 2* will be given in a constructive way by virtue of the following double induction procedure.

(i) Assuming that GLC are true and $\mathrm{str}\{b^I, P_p(a)\sigma\} = 0$, $\forall P_p(a)$, σ and I provided that $b^I \in \mathfrak{B}_\sigma$ and

$$\lambda(I) \neq -1; \quad p \leqslant k,$$

or

$$\lambda(I) = -1, \quad E(\sigma) \leqslant l, \quad p \leqslant k,$$

or

$$\lambda(I) = -1; \quad p \leqslant k-2,$$

where $P_p(a)$ is an arbitrary degree p polynomial of a_i^α (p is odd) and $E(\sigma)$ is the number of cycles of even length in the decomposition (15) of σ, one proves that there exists such a unique extension of the supertrace that the same is true for $l \to l+1$.

(ii) Assuming that $\mathrm{str}\{b^I, P_p(a)\sigma\} = 0$, $\forall P_p(a)$, σ and b^I, such that $\sigma(I) = \sigma$, $p \leqslant k$ one proves that there exists such a unique extension of the supertrace that the assumption (i) is true for $k \to k+2$ and $l = 0$.

As a result this inductive procedure extends uniquely any solution of GLC to some supertrace on the whole $SH_N(\nu)$. [Let us remind ourselves that the supertrace of any odd element of $SH_N(\nu)$ is trivially zero by sl_2 invariance].

The inductive proof of *Theorem 2* is based on the S_N covariance of the whole setting and the following important lemma.

Lemma 5: Given permutation σ, *which has* $E(\sigma)$ *cycles of even length in the decomposition (15), the quantity* $f^{IJ}\sigma$ *for* $\sigma(I) = \sigma(J) = \sigma$ *and* $\lambda_I = \lambda_J = -1$ *can be uniquely expanded as* $f^{IJ}\sigma = \Sigma_q \alpha_q \sigma_q$, *where* α_q *are some coefficients and* $E(\sigma_q) = E(\sigma) - 1, \forall q$.

Lemma 5 is a simple consequence of the particular form of the structure coefficients f^{IJ} (27) and *Lemmas 3* and *4*. The proof is straightforward. Let us stress that it is *Lemma 5* that accounts for the specific properties of the algebra $SH_N(\nu)$ in the analysis of this section.

In practice, it is convenient to work with the exponential generating functions

$$\Psi_\sigma(\mu) = \mathrm{str}(e^S \sigma), \quad S = \sum_{L=1}^{2N} (\mu_L b^L), \tag{44}$$

where σ is some fixed element of S_N, $b^L \in \mathfrak{B}_\sigma$, and $\mu_L \in \mathbb{C}$ are independent parameters. By differentiating over μ_L, one can obtain an arbitrary polynomial of b^L in front of σ. The exponential form of the generating functions implies that these polynomials are Weyl ordered. In these terms the induction on a degree of polynomials is equivalent to the induction on a degree of homogeneity in μ of the power series expansions of $\Psi_\sigma(\mu)$.

As a consequence of the general properties discussed in the preceding sections, the generating function $\Psi_\sigma(\mu)$ must be invariant under the S_N similarity transformations,

$$\Psi_{\tau\sigma\tau^{-1}}(\mu) = \Psi_\sigma(\tilde{\mu}), \tag{45}$$

where the S_N transformed parameters are of the form

$$\tilde{\mu}_I = \sum_J \left(\mathfrak{M}(\tau\sigma\tau^{-1})\mathfrak{M}^{-1}(\tau)\Lambda^{-1}(\tau)\mathfrak{M}(\tau)\mathfrak{M}^{-1}(\sigma)\right)_I^J \mu_J, \tag{46}$$

and matrices $\mathfrak{M}(\sigma)$ and $\Lambda(\sigma)$ are defined in (22) and (23).

In accordance with the general argument of Sec. III, the necessary and sufficient conditions for the existence of even supertrace are the S_N-covariance conditions (45) and the condition that

$$\mathrm{str}\{b^L, (\exp S)\sigma\} = 0, \quad \text{for any } \sigma \quad \text{and} \quad L. \tag{47}$$

To transform (47) to an appropriate form, let us use the following two general relations, which are true for arbitrary operators X and Y and the parameter $\mu \in \mathbb{C}$:

$$X \exp(Y+\mu X) = \frac{\partial}{\partial \mu} \exp(Y+\mu X) + \int t_2 \exp(t_1(Y+\mu X))[X,Y]\exp(t_2(Y+\mu X))D^1t, \tag{48}$$

$$\exp(Y+\mu X)X = \frac{\partial}{\partial \mu} \exp(Y+\mu X) - \int t_1 \exp(t_1(Y+\mu X))[X,Y]\exp(t_2(Y+\mu X))D^1t, \tag{49}$$

with the convention that

$$D^{n-1}t = \delta(t_1+\cdots+t_n-1)\,\theta(t_1)\cdots\theta(t_n)dt_1\cdots dt_n. \tag{50}$$

The relations (48) and (49) can be derived with the aid of the partial integration (e.g., over t_1) and the following formula:

$$\frac{\partial}{\partial \mu} \exp(Y+\mu X) = \int \exp(t_1(Y+\mu X))X \exp(t_2(Y+\mu X))D^1t, \tag{51}$$

which can be proven by expanding in a power series. The well-known formula

$$[X, \exp(Y)] = \int \exp(t_1 Y)[X,Y]\exp(t_2 Y)D^1t, \tag{52}$$

is a consequence of (48) and (49).

With the aid of (48), (49), and (21), one rewrites (47) as

$$(1+\lambda_L)\frac{\partial}{\partial \mu_L}\Psi_\sigma(\mu) = \int (\lambda_L t_1 - t_2)\mathrm{str}(\exp(t_1 S)[b^L, S]\exp(t_2 S)\sigma)D^1t. \tag{53}$$

This condition should be true for any σ and L and plays the central role in the analysis of this section.

There are two essentially distinguishing cases, $\lambda_L \neq -1$ and $\lambda_L = -1$. In the latter case, the equation (53) takes the form

$$0 = \int \mathrm{str}(\exp(t_1 S)[b^L, S]\exp(t_2 S)\sigma)D^1t, \quad \lambda_L = -1. \tag{54}$$

In Appendix B we show by induction that the equations (53) and (54) are consistent in the following sense:

$$(1+\lambda_K)\frac{\partial}{\partial\mu_K}\int(\lambda_L t_1-t_2)\mathrm{str}(\exp(t_1S)[b^L,S]\exp(t_2S)\sigma)D^1t-(L\leftrightarrow K)=0,$$

$$\lambda_L\neq-1,\quad \lambda_K\neq-1 \tag{55}$$

and

$$(1+\lambda_K)\frac{\partial}{\partial\mu_K}\int\mathrm{str}(\exp(t_1S)[b^L,S]\exp(t_2S)\sigma)D^1t=0,\quad \lambda_L=-1. \tag{56}$$

Note that this part of the proof is quite general and does not depend on a concrete form of the commutation relations of a_i^α in (2).

By expanding the exponential e^S in (44) into power series in μ_K (equivalently b^K) one concludes that the equation (53) uniquely reconstructs the supertrace of monomials containing b^K with $\lambda_K\neq-1$ (from now on called regular polynomials) via supertraces of some lower-order polynomials. The consistency conditions (55) and (56) then guarantee that (53) does not impose any additional conditions on the supertraces of lower degree polynomials and allow one to represent the generating function in the form

$$\Psi_\sigma=\Phi_\sigma(\mu)+\sum_{L:\lambda_L\neq-1}\int_0^1\frac{\mu_L\,d\tau}{1+\lambda_L}\int D^1t(\lambda_L t_1-t_2)\mathrm{str}(e^{t_1(\tau S''+S')}[b^L,(\tau S''+S')]e^{t_2(\tau S''+S')}\sigma), \tag{57}$$

where we have introduced the generating functions Φ_σ for the supertrace of special polynomials, i.e. the polynomials depending only on b^L with $\lambda_L=-1$,

$$\Phi_\sigma(\mu)\overset{\text{def}}{=}\mathrm{str}(e^{S'}\sigma)=\Psi_\sigma(\mu)|_{(\mu_I=0,\quad\forall I:\lambda_I\neq-1)} \tag{58}$$

and

$$S'=\sum_{L:b^L\in\mathfrak{B}_\sigma,\lambda_L=-1}(\mu_L b^L);\quad S''=S-S'. \tag{59}$$

The relation (57) successively expresses the supertrace of higher-order regular polynomials via the supertraces of lower-order polynomials.

One can see that the arguments above prove effectively the inductive hypotheses (i) and (ii) for the particular case where either the polynomials $P_p(a)$ are regular and/or $\lambda_I\neq-1$. Note that for this case the induction on the number of cycles of even length (i) is trivial: one simply proves that a power of polynomial can be increased by 2.

Let us now turn to the less trivial case of the special polynomials:

$$\mathrm{str}\{b^I,(\exp S')\sigma\}=0,\quad \lambda_I=-1. \tag{60}$$

Consider the part of $\mathrm{str}\{b^I,(\exp S')\sigma\}$, which is of order k in μ, and suppose that $E(\sigma)=l+1$. According to (54), the conditions (60) give

$$0=\int\mathrm{str}(\exp(t_1S')[b^I,S'']\exp(t_2S')\sigma)D^1t. \tag{61}$$

Substituting $[b^I,S']=\mu^I+\nu\Sigma_M f^{IM}\mu_M$, where the quantities f^{IJ} and μ^I are defined in (25)–(28), one can rewrite the equation (61) in the form

$$\mu^I\Phi_\sigma(\mu)=-\nu\int \mathrm{str}\Big(\exp(t_1S')\sum_M f^{IM}\mu_M\,\exp(t_2S')\sigma\Big)D^1t. \tag{62}$$

Now we use the inductive hypothesis (i). The right-hand side of (62) is a supertrace of at most a degree $k-1$ polynomial of a_i^α in the sector of degree k polynomials in μ. Therefore one can use the inductive hypothesis (i) to obtain

$$\int \mathrm{str}\Big(\exp(t_1S')\sum_M f^{IM}\mu_M\,\exp(t_2S')\sigma\Big)D^1t=\int \mathrm{str}\Big(\exp(t_2S')\exp(t_1S')\sum_M f^{IM}\mu_M\sigma\Big)D^1t,$$

where we made use of the simple fact that $\mathrm{str}(S'F\sigma)=-\mathrm{str}(F\sigma S')=\mathrm{str}(FS'\sigma)$ due to the definition of S'.

As a result, the inductive hypothesis allows one to transform (60) to the following form:

$$X^I\equiv\mu^I\Phi_\sigma(\mu)+\nu\,\mathrm{str}\Big(\exp(S')\sum_M f^{IM}\mu_M\sigma\Big)=0. \tag{63}$$

By differentiating this equation with respect to μ_J, one obtains, after symmetrization,

$$\frac{\partial}{\partial\mu_J}(\mu^I\Phi_\sigma(\mu))+(I\leftrightarrow J)=-\nu\int \mathrm{str}\Big(e^{t_1S'}b^Je^{t_2S'}\sum_M f^{IM}\mu_M\sigma\Big)D^1t+(I\leftrightarrow J). \tag{64}$$

An important point is that the system of equations (64) is equivalent to the original equations (63), except for the ground level part $\Phi_\sigma(0)$. This can be easily seen from the simple fact that the general solution of the system of equations $(\partial/\partial\mu_J)X^I(\mu)+(\partial/\partial\mu_I)X^J(\mu)=0$ for entire functions $X^I(\mu)$ is of the form $X^I(\mu)=X^I(0)+\Sigma_J c^{IJ}\mu_J$, where $X^I(0)$ and $c^{JI}=-c^{IJ}$ are some constants. The part of (63) linear in μ is, however, equivalent to the ground level conditions analyzed in the previous section. Thus (64) contains all information additional to (39). For this reason we will, from now on, analyze the equation (64).

Using again the inductive hypothesis we move b^1 to the left and to the right with equal weights to get

$$\begin{aligned}\frac{\partial}{\partial\mu_J}\mu^I\Phi_\sigma(\mu)+(I\leftrightarrow J)=&-\frac{\nu}{2}\sum_M \mathrm{str}(\exp(S')\{b^J,f^{IM}\}\mu_M\sigma)\\&-\frac{\nu}{2}\int\sum_{L,M}(t_1-t_2)\mathrm{str}(\exp(t_1S')F^{JL}\mu_L\,\exp(t_2S')f^{IM}\mu_M\sigma)\\&\times D^1t+(I\leftrightarrow J).\end{aligned} \tag{65}$$

The last term on the right-hand side of this expression can be shown to vanish under the supertrace operation due to the factor of (t_1-t_2), so that one is left with the equation

$$L^{IJ}\Phi_\sigma(\mu)=-\frac{\nu}{2}R^{IJ}(\mu), \tag{66}$$

where

$$R^{IJ}(\mu)=\sum_M \mathrm{str}(\exp(S')\{b^J,f^{IM}\}\mu_M\sigma)+(I\leftrightarrow J) \tag{67}$$

and

$$L^{IJ}=\frac{\partial}{\partial\mu_J}\mu^I+\frac{\partial}{\partial\mu_I}\mu^J. \tag{68}$$

The differential operators L^{IJ} satisfy the standard $sp(2E(\sigma))$ commutation relations

$$[L^{IJ},L^{KL}]=-(\mathscr{C}^{IK}L^{JL}+\mathscr{C}^{IL}L^{JK}+\mathscr{C}^{JK}L^{IL}+\mathscr{C}^{JL}L^{IK}). \tag{69}$$

We show by induction in Appendix C that this algegra is consistent with the right-hand side of the basic relation (66), i.e. that

$$[L^{IJ},R^{KL}]-[L^{KL},R^{IJ}]=-(\mathscr{C}^{IK}R^{JL}+\mathscr{C}^{JL}R^{IK}+\mathscr{C}^{JK}R^{IL}+\mathscr{C}^{IL}R^{JK}). \tag{70}$$

Generally, these consistency conditions guarantee that the equations (66) express $\Phi_\sigma(\mu)$ in terms of R^{IJ} in the following way:

$$\Phi_\sigma(\mu)=\Phi_\sigma(0)+\frac{\nu}{8E(\sigma)}\sum_{I,J=1}^{2E(\sigma)}\int_0^1\frac{dt}{t}\,(1-t^{2E(\sigma)})(L_{IJ}R^{IJ})(t\mu), \tag{71}$$

provided that

$$R^{IJ}(0)=0. \tag{72}$$

The latter condition must hold for the consistency of (66), since its left-hand side vanishes at $\mu_I=0$. In the formula (71) it guarantees that the integral on t converges. In the case under consideration the property (72) is indeed true as a consequence of the definition (67).

Taking into account *Lemma 5* and the explicit form of R^{IJ} (67), one concludes that the equation (71) expresses uniquely the supertrace of special polynomials via the supertraces of polynomials of lower degrees or via the supertraces of special polynomials of the same degree with a lower number of cycles of even length, provided that the μ-independent term $\Phi_\sigma(0)$ is an arbitrary solution of GLC. This completes the proof of *Theorem 2*.

Comment 1: The formulas (57) and (71) can be effectively used in practical calculations of supertraces of particular elements of $SH_N(\nu)$.

Comment 2: Any supertrace on $SH_N(\nu)$ is determined unambiguously in terms of its values on the group algebra of S_N.

Corollary: Any supertrace on $SH_N(\nu)$ is ρ invariant, $\mathrm{str}(\rho(x))=\mathrm{str}(x)$, $\forall x\in SH_N(\nu)$, for the antiautomorphism ρ (30).

This is true, due to *Comment 2*, because σ and $\sigma^{-1}=\rho(\sigma)$ belong to the same conjugacy class of S_N so that $\mathrm{str}(\rho(\sigma))=\mathrm{str}(\sigma)$.

VI. CONCLUSIONS

In this paper we have shown that the algebras $SH_N(\nu)$ can be endowed with $q(N)$-independent supertrace operations, where $q(N)$ is the number of partitions of N into a sum of odd positive integers. We hope to apply the supertraces constructed in this paper to the analysis of the invariant forms of $SH_N(\nu)$. Although a definition of the supertraces on $SH_N(\nu)$ behaves regularly with the parameter ν [in particular, the number of supertraces $q(N)$ is ν independent], one can expect that this is not the case for the related bilinear forms, which can degenerate for some special values of ν, thus giving rise to ideals of $SH_N(\nu)$ as it happens[14] for the simplest case of $N=2$. The analysis of the structure of these ideals is a challenging problem important for various applications of $SH_N(\nu)$, including an analysis of its representations. We are going to study this problem for some lower values of $N>2$ in the future publication.

In conclusion, let us note that the method of the analysis of supertraces presented in this paper is rather general. Practically the only information of the specific structure of $SH_N(\nu)$ is that *Lemma 5* is true. Hopefully one can use the analogous methods for the analysis of supertraces of other associative algebras.

APPENDIX A: INDEPENDENCE G_N OF ν

For the case $\nu=0$ it was argued in Sec. IV that (39) possesses $q(N)$ independent solutions. Let us now consider the case $\nu\neq 0$. By induction on a number of cycles of even length $e=E(\sigma)$, we show that given σ with $E(\sigma)=e\geqslant 1$ there is only one independent equation on $\mathrm{str}(\sigma)$, provided that all equations (39) with $E(\sigma)=e'<e$ are resolved. In this proof we set $\nu=1$, which does not lead to the loss of generality due to the scaling property (40). The first step of the induction consists of the observation that there are no equations for the case $E(\sigma)=0$.

Let us consider the case where there are two equations (38) on $\mathrm{str}(\sigma)$ for some σ. This is only possible if $\sigma=c_1c_2\sigma'$, where c_1 and c_2 are some cycles in the decomposition of σ, such that $|c_1|=2k$, $|c_2|=2l$, and $k\neq l$. Note that $E(\sigma')=E(\sigma)-2=e-2$.

Without loss of generality, let us set

$$c_1=K_{12}K_{23}\cdots K_{(2k-1)2k}, \quad c_2=K_{(2k+1)(2k+2)}\cdots K_{(2k+2l-1)(2k+2l)}, \tag{A1}$$

$$b_1^\alpha=\frac{1}{\sqrt{2k}}\,(a_1^\alpha-a_2^\alpha+\cdots-a_{2k}^\alpha), \quad b_2^\alpha=\frac{1}{\sqrt{2l}}\,(a_{2k+1}^\alpha-a_{2k+1}^\alpha+\cdots-a_{2k+2l}^\alpha). \tag{A2}$$

Also, we introduce

$$c=K_{1(2k+1)}c_1c_2=K_{12}K_{23}\cdots K_{(2k+2l-1)(2k+2l)} \tag{A3}$$

and

$$b^\alpha=\frac{1}{\sqrt{2k+2l}}\,(\sqrt{2k}b_1^\alpha+\sqrt{2l}b_2^\alpha)=\frac{1}{\sqrt{2k+2l}}\,(a_1^\alpha-a_2^\alpha+\ldots-a_{2k+2l}^\alpha). \tag{A4}$$

The corresponding equations (38) take the form

$$\mathrm{str}(\sigma)=-\mathrm{str}(([b_1^0,b_1^1]-1)\sigma) \tag{A5}$$

and

$$\mathrm{str}(\sigma)=-\mathrm{str}(([b_2^0,b_2^1]-1)\sigma). \tag{A6}$$

Using the following simple identity that holds for any trace on S_N,

$$\mathrm{str}\left(\frac{1}{2k}\sum_{p=1}^{2k}\sum_{q=2k+1}^{2k+2l}K_{pq}\sigma\right)=2l\ \mathrm{str}(K_{1(2k+1)}\sigma),$$

one can rewrite the right-hand side of (A5) as

$$\mathrm{str}(([b_1^0,b_1^1]-1)\sigma)=\mathrm{str}\left(\left([b_1^0,b_1^1]-1-\frac{1}{2k}\sum_{p=1}^{2k}\sum_{q=2k+1}^{2k+2l}K_{pq}\right)\sigma\right)+2l\ \mathrm{str}(K_{1(2k+1)}\sigma). \tag{A7}$$

The direct analysis based on the commutation relations (2) and (3) then shows that the first term on the right-hand side of (A7) is the supertrace of a linear combination of permutations, which all contain the cycle c_2 in their decompositions. The second term is the supertrace of the permutation that contains the cycle c (A3) in its decomposition. It is easy to see that for each of these terms the number of cycles of even length is $E(\sigma)-1$. This allows us to apply the equation (38) to each of these terms due to the inductive hypothesis. We identify c_0 with c_2 and c, respectively, for the first and second terms on the right-hand side of (A7). As a result the equation (A5) turns out to be transformed to the form

$$\mathrm{str}(\sigma)=\mathrm{str}\left(([b_2^0,b_2^1]-1)\left([b_1^0,b_1^1]-1-\frac{1}{2k}\sum_{p=1}^{2k}\sum_{q=2k+1}^{2k+2l}K_{pq}\right)\sigma\right)$$
$$+\mathrm{str}(([b^0,b^1]-1)2lK_{1(2k+1)}\sigma). \tag{A8}$$

Analogously, one obtains for (A6),

$$\mathrm{str}(\sigma)=\mathrm{str}\left(([b_1^0,b_1^1]-1)\left([b_2^0,b_2^1]-1-\frac{1}{2l}\sum_{p=1}^{2k}\sum_{q=2k+1}^{2k+2l}K_{pq}\right)\sigma\right)$$
$$+\mathrm{str}(([b^0,b^1]-1)2kK_{1(2k+1)}\sigma) \tag{A9}$$

Let us prove that the difference of the right-hand sides of (A8) and (A9) vanishes. With the aid of the simple consequence of the S_N invariance,

$$\frac{1}{4kl}\,\mathrm{str}\left([b_i^0,b_i^1]\sum_{p=1}^{2k}\sum_{q=2k+1}^{2k+2l}K_{pq}\sigma\right)=\mathrm{str}([b_i^0,b_i^1]K_{1(2k+1)}\sigma),\quad i=1,2,$$

this difference can be transformed to the form

$$X=\mathrm{str}((2k[b_1^0,b_1^1]-2l[b_2^0,b_2^1])K_{1(2k+1)}\sigma), \tag{A10}$$

where we have taken into account that

$$\mathrm{str}([b^0,b^1]K_{1(2k+1)}\sigma)=0, \tag{A11}$$

as a consequence of the inductive hypothesis and GLC (37), and that

$$\mathrm{str}([([b_2^0,b_2^1]-1),([b_1^0,b_1^1]-1)]\sigma)=0, \tag{A12}$$

since each term in the commutator belongs to the group algebra of S_N and commutes with σ so that (A12) vanishes for any supertrace on the group algebra of S_N.

Using the relation $b_1^\alpha=1/\sqrt{2k}(\sqrt{2k+2l}b^\alpha-\sqrt{2l}b_2^\alpha)$ one transforms X to the form

$$X=2\,\mathrm{str}((k+l)[b^0,b^1]-\sqrt{l(k+l)}[b^0,b_2^1]-\sqrt{l(k+l)}[b_2^0,b^1])K_{1(2k+1)}\sigma). \tag{A13}$$

Due to the S_N invariance the second term on the right-hand side of (A13) can be rewritten as

$$
\begin{aligned}
&-2\sqrt{l(k+l)}\,\mathrm{str}([b^0,b_2^1]K_{1(2k+1)}\sigma)\\
&\quad=-\frac{\sqrt{l(k+l)}}{k+l}\sum_{p=1}^{2k+2l}\mathrm{str}(c^p[b^0,b_2^1]c^{-p}K_{1(2k+1)}\sigma)\\
&\quad=-\frac{\sqrt{l}}{\sqrt{k+l}}\,\mathrm{str}\left(\left[b^0,\sum_{p=1}^{2k+2l}(-1)^p c^p b_2^1 c^{-p}\right]K_{1(2k+1)}\sigma\right)\\
&\quad=-2l\ \mathrm{str}([b^0,b^1]K_{1(2k+1)}\sigma). \qquad \text{(A14)}
\end{aligned}
$$

Analogously, one can transform the third term on the right-hand side of (A13). Using again (A11), one concludes that $X=0$.

Thus, it is shown that the number of solutions of (39) is equal to the number of the conjugacy classes in S_N with $E(\sigma)=0$. This completes the proof of *Theorem 1*.

APPENDIX B: CONSISTENCY FOR $\lambda\neq-1$

Let us prove by induction that the equations (55) are true for any two $\mu_1\equiv\mu_{K_1}$ and $\mu_2\equiv\mu_{K_2}$, such that both $\lambda_1\equiv\lambda_{K_1}\neq-1$ and $\lambda_2\equiv\lambda_{K_2}\neq-1$. To implement induction one selects from (47) a part of order k in μ and observes that it contains the anticommutator of b^L with a degree k polynomial in b^M, while the part on the right-hand side of the differential version (53) of (47), which is of the same order in μ has the order $k-1$ as the polynomial of b^M. This happens because of the presence of the commutator $[b^L,S]$, which is a degree zero polynomial due to the basic relations (2) and (3). As a result, the inductive hypothesis allows one to use the properties of the supertrace, provided that the above commutator is always handled as the right-hand side of (2) (i.e., it is not allowed to represent it again as a difference of the second-order polynomials).

Direct differentiation with the aid of (51) gives

$$
\begin{aligned}
&(1+\lambda_2)\frac{\partial}{\partial\mu_2}\int(\lambda_1 t_1-t_2)\mathrm{str}(e^{t_1 S}[b^1,S]e^{t_2 S}\sigma)D^1t-(1\leftrightarrow2)\\
&\quad=\left(\int(1+\lambda_2)(\lambda_1 t_1-t_2)\mathrm{str}(e^{t_1 S}[b^1,b^2]e^{t_2 S}\sigma)D^1t-(1\leftrightarrow2)\right)\\
&\qquad+\left(\int(1+\lambda_2)(\lambda_1(t_1+t_2)-t_3)\mathrm{str}(e^{t_1 S}b^2e^{t_2 S}[b^1,S]e^{t_3 S})D^2t-(1\leftrightarrow2)\right)\\
&\qquad+\left(\int(1+\lambda_2)(\lambda_1 t_1-t_2-t_3)\mathrm{str}(e^{t_1 S}[b^1,S]e^{t_2 S}b^2e^{t_3 S}\sigma)D^2t-(1\leftrightarrow2)\right). \qquad \text{(B1)}
\end{aligned}
$$

We have to show that the right-hand side of (B1) vanishes. Let us first transform the second and the third terms on the right-hand side of (B1). The idea is to move the operators b^2 through the exponentials toward the commutator $[b^1,S]$ so that to use then Jacobi identities for the double commutators. This can be done in two different ways inside the supertrace so that one has to fix appropriate weight factors for each of these processes. The correct weights turn out to be

$$
D^2t(\lambda_1(t_1+t_2)-t_3)b^2\equiv D^2t(\lambda_1-t_3(1+\lambda_1))b^2=D^2t\left(\left(\frac{\lambda_1\lambda_2}{1+\lambda_2}-t_3(1+\lambda_1)\right)\overrightarrow{b^2}+\frac{\lambda_1}{1+\lambda_2}\overleftarrow{b^2}\right) \qquad \text{(B2)}
$$

and

$$D^2t(\lambda_1 t_1 - t_2 - t_3)b^2 \equiv D^2t((\lambda_1+1)t_1 - 1)b^2 = D^2t\left(\left(t_1(1+\lambda_1) - \frac{1}{1+\lambda_2}\right)\overleftarrow{b^2} - \frac{\lambda_2}{1+\lambda_2}\,\overrightarrow{b^2}\right) \tag{B3}$$

in the second and third terms on the right-hand side of (B1), respectively. Here the notations $\vec{A}$ and $\overleftarrow{A}$ imply that the operator A has to be moved from its position to the right and to the left, respectively. Using (52) along with the simple formula

$$\int \phi(t_3,\ldots,t_{n+1})D^n t = \int t_1\phi(t_2,\ldots,t_n)D^{n-1}t \tag{B4}$$

one finds that all terms that involve both $[b^1,S]$ and $[b^2,S]$ cancel pairwise after antisymmetrization $1\leftrightarrow 2$.

As a result, one is left with some terms involving double commutators, which by virtue of Jacobi identities and antisymmetrization all reduce to

$$\int (\lambda_1\lambda_2 t_1 + t_2 - t_1 t_2(1+\lambda_1)(1+\lambda_2))\,\mathrm{str}(\exp(t_1 S)[S,[b^1,b^2]]\exp(t_2 S)\sigma)D^1 t. \tag{B5}$$

Finally, one observes that this expression can be equivalently rewritten in the form

$$\int (\lambda_1\lambda_2 t_1 + t_2 - t_1 t_2(1+\lambda_1)(1+\lambda_2))\left(\frac{\partial}{\partial t_1} - \frac{\partial}{\partial t_2}\right)\mathrm{str}(\exp(t_1 S)[b^1,b^2]\exp(t_2 S)\sigma)D^1 t, \tag{B6}$$

and after integration by parts cancel the first term on the right-hand side of (B1). Thus it is shown that the equations (53) are mutually compatible for the case $\lambda_{1,2}\neq -1$.

Analogously one can show that the equations (53) are consistent with (54). Actually, let $\lambda_1 = -1$, $\lambda_2 \neq -1$. Let us prove that

$$\frac{\partial}{\partial \mu_2}\,\mathrm{str}([b^1,\exp(S)]\sigma) = 0, \tag{B7}$$

provided that the supertrace is well defined for the lower-order polynomials. The explicit differentiation gives

$$\begin{aligned}\frac{\partial}{\partial \mu_2}\,\mathrm{str}([b^1,\exp(S)]\sigma) &= \int \mathrm{str}([b^1,\exp(t_1 S)b^2\,\exp(t_2 S)]\sigma)D^1 t \\ &= (1+\lambda_2)^{-1}\,\mathrm{str}([b^1,(b^2\,\exp(S) + \lambda_2\,\exp(S)b^2)]\sigma) + \cdots,\end{aligned} \tag{B8}$$

where dots denote some terms of the form $\mathrm{str}([b^1,B]\sigma)$ involving further commutators inside B, which therefore amount to some lower-order polynomials and vanish by the inductive hypothesis. As a result, one finds

$$\begin{aligned}\frac{\partial}{\partial \mu_2}\,\mathrm{str}([b^1,\exp(S)]\sigma) &= (1+\lambda_2)^{-1}\,\mathrm{str}((b^2[b^1,\exp(S)] + \lambda_2[b^1,\exp(S)]b^2)\sigma) \\ &\quad + (1+\lambda_2)^{-1}\,\mathrm{str}(([b^1,b^2]\exp(S) + \lambda_2\,\exp(S)[b^1,b^2])\sigma),\end{aligned} \tag{B9}$$

which expression vanishes by the inductive hypothesis as well.

APPENDIX C: CONSISTENCY FOR $\lambda=-1$

In order to prove (70) we use the inductive hypothesis (i). In this appendix we use the convention that any upper or lower indices denoted by the same letter are automatically symmetrized, e.g. $F^{II}\stackrel{\text{def}}{=}1/2(F^{I_1I_2}+F^{I_2I_1})$. Let us write the identity

$$0=\sum_M \ \mathrm{str}([\exp(S')\{b^I,f^{IM}\}\mu_M,b^Jb^J]\sigma)-(I\leftrightarrow J), \tag{C1}$$

which holds due to *Lemma 5* for all terms of degree $k-1$ in μ with $E(\sigma)\leqslant l+1$ and for all lower-order polynomials in μ (one can always move f^{IJ} to σ, combining them into a combination of elements of S_N analyzed in *Lemma 5*).

The straightforward calculation of the commutator on the right-hand side of (C1) gives $0=X_1+X_2+X_3$, where

$$X_1=-\sum_{M,L}\int \mathrm{str}(\exp(t_1S')\{b^J,F^{JL}\}\mu_L\ \exp(t_2S')\{b^I,f^{IM}\}\mu_M\sigma)D^1t-(I\leftrightarrow J),$$

$$X_2=\sum_M \ \mathrm{str}(\exp(S')\{\{b^J,F^{IJ}\},f^{IM}\}\mu_M\sigma)-(I\leftrightarrow J), \tag{C2}$$

$$X_3=\sum_M \ \mathrm{str}(\exp(S')\{b^I,\{b^J,[f^{IM},b^J]\}\}\mu_M\sigma)-(I\leftrightarrow J).$$

The terms bilinear in f in X_1 cancel due to the antisymmetrization $(I\leftrightarrow J)$ and the inductive hypothesis (i). As a result, one can transform X_1 to the form

$$X_1=(-\tfrac{1}{2}[L^{JJ},R^{II}]+2\ \mathrm{str}(e^{S'}\{b^I,f^{IJ}\}\mu^J\sigma))-(I\leftrightarrow J). \tag{C3}$$

Substituting $F^{IJ}=\mathscr{C}^{IJ}+\nu f^{IJ}$ and $f^{IM}=\nu^{-1}([b^I,b^M]-\mathscr{C}^{IM})$, one transforms X_2 to the form

$$X_2=2\mathscr{C}^{IJ}R^{IJ}-2(\mathrm{str}(e^{S'}\{b^J,f^{IJ}\}\mu^I\sigma)-(I\leftrightarrow J))+Y, \tag{C4}$$

where

$$Y=\mathrm{str}(e^{S'}\{\{b^J,f^{IJ}\},[b^I,S']\}\sigma)-(I\leftrightarrow J). \tag{C5}$$

Using that

$$\mathrm{str}(\exp(S')[Pf^{IJ}Q,S']\sigma)=0, \tag{C6}$$

provided that the inductive hypothesis can be used, one transforms Y to the form

$$Y=\mathrm{str}(e^{S'}(-[f^{IJ},(b^IS'b^J+b^JS'b^I)]-b^I[f^{IJ},S']b^J-b^J[f^{IJ},S']b^I+[f^{IJ},\{b^I,b^J\}]S')\sigma). \tag{C7}$$

Let us rewrite X_3 in the form $X_3=X_3^s+X_3^q$, where

$$X_3^s=\frac{1}{2}\sum_M \ \mathrm{str}(e^{S'}(\{b^I,\{b^J,[f^{IM},b^J]\}\}+\{b^J,\{b^I,[f^{IM},b^J]\}\})\mu_M\sigma)-(I\leftrightarrow J),$$

$$X_3^a=\frac{1}{2}\sum_M \ \mathrm{str}(e^{S'}(\{b^I,\{b^J,[f^{IM},b^J]\}\}-\{b^J,\{b^I,[f^{IM},b^J]\}\})\mu_M\sigma)-(I\leftrightarrow J).$$

With the aid of the Jacobi identities $[f^{IM},b^J]-[f^{JM},b^I]=[f^{IJ},b^M]$, one expresses X_3^s in the form

$$X_3^s=\tfrac{1}{2}\,\mathrm{str}(e^{S'}(\{b^I,b^J\}[f^{IJ},S']+[f^{IJ},S']\{b^I,b^J\}+2b^I[f^{IJ},S']b^J+2b^J[f^{IJ},S']b^I)\sigma).$$

X_3^a can be transformed to the form

$$X_3^a=\frac{1}{2}\sum_M \ \mathrm{str}(e^{S'}[F^{IJ},[f^{IM},b^J]]\mu_M\sigma)-(I\leftrightarrow J). \tag{C8}$$

By virtue of the substitutions $F^{IJ}=\mathscr{C}^{IJ}+\nu f^{IJ}$ and $f^{IM}=\nu^{-1}([b^I,b^M]-\mathscr{C}^{IM})$ in (C8) one finds after simple transformations that $Y+X_3=0$. From (C3) and (C4) it follows then that the right-hand side of (C1) equals $1/2([L^{II},R^{JJ}]-[L^{JJ},R^{II}])+2\mathscr{C}^{IJ}R^{IJ}$. This completes the proof of the consistency conditions (70).

The nonsimultaneous nature of the Schwarzschild *R=0* singularity

Charles Hellaby[a)]
Department of Applied Mathematics, University of Cape Town, Rondebosch, 7700, South Africa

(Received 1 August 1995; accepted for publication 25 January 1996)

The relationship between the two well-behaved coordinate systems of Lemaître–Tolman–Novikov, and Kruskal–Szekeres–Penrose indicates that the Schwarzschild $R=0$ singularity is intrinsically nonsimultaneous. It follows that the simultaneous synchronous coordinates of Wald and Yip do not exist on the complete Schwarzschild manifold. In the process, the coordinate transformations between the Schwarzschild exterior model in its various common coordinate systems and the vacuum Lemaître–Tolman model (which includes Novikov coordinates and the closed Kantowski–Sachs model) is derived. It is also shown that, contrary to statements in the literature, the closed Kantowski–Sachs model is well-behaved limit of the Lemaître–Tolman model. © *1996 American Institute of Physics.* [S0022-2488(96)01605-9]

I. INTRODUCTION AND NOTATION

The spherically symmetric vacuum space–time is most commonly represented by the Kruskal–Szekeres and Penrose diagrams. The former represents the $R=0$ singularity as a right hyperbola, and the latter as a pair of parallel lines; the former shape implies a gradual emergence of the space–time from the past singularity, with the asymptotically flat regions appearing first and the neck appearing last, and the converse at the future singularity, whereas the latter suggests an instantaneous and simultaneous appearance or disappearance of the entire manifold. Although the $R=0$ surfaces are entirely spacelike, and although every point on, say, the past singularity is equivalent to every other point under T translations, this only establishes local equivalence. If white holes are generated by the big bang, and we can measure emerging signals, do there exist observers for whom it would look simultaneous, or at least homogeneous? The transformation between the causal coordinates of Kruskal–Szekeres and the geodesic coordinates of Lemaître–Tolman will show that $R=0$ is intrinsically nonsimultaneous.

The Schwarzschild[1] exterior metric is

$$ds^2=-\left(1-\frac{2M}{R}\right)dT^2+\frac{dR^2}{\left(1-\frac{2M}{R}\right)}+R^2\,d\Omega^2, \tag{1}$$

where

$$d\Omega^2=d\theta^2+\sin^2\theta\,d\phi^2. \tag{2}$$

The Schwarzschild to Kruskal–Szekeres[2,3] and Penrose[4–6] transformations are

$$U=\tan u=e^{(T+R)/4M}\sqrt{\frac{R}{2M}-1}, \tag{3}$$

0022-2488/96/37(6)/2892/14/$10.00

$$V=\tan v=-e^{(R-T)/4M}\sqrt{\frac{R}{2M}-1}, \tag{4}$$

where (U,V) and (u,v) are the Kruskal–Szekeres and Penrose coordinates, respectively. The resulting metrics are

$$ds^2=\frac{-32M^3}{Re^{R/2M}}dU\ dV+R^2\ d\Omega^2, \tag{5}$$

$$ds^2=\frac{-32M^3}{Re^{R/2M}}\frac{du\ dv}{\cos^2 u\ \cos^2 v}+R^2\ d\Omega^2, \tag{6}$$

where R is the solution of

$$e^{R/2M}\left(\frac{R}{2M}-1\right)=-UV=-\tan u\ \tan v. \tag{7}$$

The Lemaître–Tolman metric[7,8] represents spherically symmetric inhomogeneous dust in synchronous comoving coordinates,

$$ds^2=-dt^2+\frac{R'^2}{1+f}dr^2+R^2\ d\Omega^2, \tag{8}$$

where $'\equiv\partial/\partial r$, and $f=f(r)$ is an arbitrary function of coordinate radius that gives both the local spatial geometry, and the energy of the dust particles as a function of r. The areal radius $R=R(t,r)$ is the solution of

$$\dot{R}^2=\frac{2M}{R}+f, \tag{9}$$

where $\dot{}\equiv\partial/\partial t$, and the gravitational mass contained within a comoving sphere of radius r is $M=M(r)$. We will also need

$$\ddot{R}=-\frac{M}{R^2}, \tag{10}$$

$$2\dot{R}\dot{R}'=\frac{2M'}{R}-\frac{2MR'}{R^2}+f', \tag{11}$$

and the identity

$$R'=\left(\frac{M'}{M}-\frac{f'}{f}\right)R-\left[a'+\left(\frac{M'}{M}-\frac{3f'}{2f}\right)(t-a)\right]\dot{R}, \tag{12}$$

which holds for all f (See Refs. 9 and 10). The three (nontrivial) solutions are

elliptic—$f<0$:

$$R=\frac{M}{(-f)}(1-\cos\ \eta), \tag{13}$$

$$(\eta-\sin\ \eta)=\frac{(-f)^{3/2}(t-a)}{M}; \tag{14}$$

parabolic—$f=0$:

$$R=\left(\frac{9M(t-a)^2}{2}\right)^{1/3}; \tag{15}$$

hyperbolic—$f>0$:

$$R=\frac{M}{f}(\cosh\ \eta-1), \tag{16}$$

$$(\sinh\ \eta-\eta)=\frac{f^{3/2}(t-a)}{M}, \tag{17}$$

where $a=a(r)$ is a third arbitrary function that gives the time at which $R=0$—the big bang in cosmology, or the past singularity in vacuum.

The density is given by

$$8\pi\rho=\frac{2M'}{R^2R'}, \tag{18}$$

and since the pressure is zero, the dust particles (and therefore the constant r, θ, ϕ curves) follow geodesics of the space–time.

Obviously from (18) we have vacuum if M is a constant, and this must be equivalent to the Schwarzschild/Kruskal–Szekeres manifold, since it is spherically symmetric. In a previous paper—''P1''[11]—the vacuum Lemaître–Tolman models were discussed, and the wormhole topology of Kruskal–Szekeres was then extended to models that have nonvanishing density everywhere including the wormhole. In addition to constant M, complete coverage of the vacuum manifold requires that $f=-1$ at the narrowest part of the wormhole, where $R'=0$ permanently, and f must approach 0 or positive values as $r\to\infty$. The obvious choice for a, at least in models with $f\leqslant 0$ everywhere, is

$$a=-\frac{\pi M}{(-f)^{3/2}}, \tag{19}$$

since this makes the past and future singularities time symmetric. For models or regions where $f>0$, time symmetry is not possible, and this choice has no particular advantage. The set of all possible choices for $f(r)$ and $a(r)$ corresponds to all the possible families of radial geodesic coordinates for Schwarzschild, which have t as a global proper time along the geodesics. In other words the geodesics are orthogonal to the surfaces of constant proper time. A model where f goes from -1 to ∞ corresponds to the inner geodesics expanding and recollapsing from past to future singularities and the outer geodesics escaping to infinity, i^+ (or collapsing from infinity, i^-) (see Fig. 5 of P1 and below). To obtain Novikov's coordinates (Ref. 12, but see Ref. 13 or 14) for Schwarzschild from the Lemaître–Tolman form (see Fig. 4 of P1), we choose

$$M=\text{const}, \tag{20}$$

$$f=\frac{-1}{1+r^2}, \tag{21}$$

$$a=-\pi M(1+r^2)^{3/2}. \tag{22}$$

II. THE KANTOWSKI–SACHS LIMIT

It is usually stated[15,16] that the closed Kantowski–Sachs model[15] must be derived from the spherically symmetric field equations separately from the Lemaître–Tolman case. This is because $R=R(t)$ only in the former, but in the latter $R'=R'(t,r)\neq 0$. This is not true. We shall show that the Kantowski–Sachs model is a well-behaved limit of the Lemaître–Tolman model.

The closed Kantowski–Sachs metric, which describes a homogeneous, synchronous, comoving dust model, is

$$ds^2=-dt^2+X^2(t)dr^2+R^2(t)d\Omega^2, \tag{23}$$

where

$$t-t_0=\frac{A}{2}(\eta-\pi-\sin\ \eta), \tag{24}$$

$$R=\frac{A}{2}(1-\cos\ \eta), \tag{25}$$

$$X=E+\left(\frac{E}{2}(\pi-\eta)-B\right)\frac{\sin\ \eta}{(1-\cos\ \eta)}, \tag{26}$$

and the density is

$$8\pi\rho=\frac{4E}{A^2(1-\cos\ \eta)^2\left[E+\left(\frac{E}{2}(\pi-\eta)-B\right)\frac{\sin\ \eta}{(1-\cos\ \eta)}\right]}, \tag{27}$$

and A,E and B are constants. The η used here, which runs from 0 to 2π, is related to the one used by Kantowski and Sachs by

$$\eta_{\mathrm{KS}}=\frac{(\eta-\pi)}{2}, \tag{28}$$

and they also specified $E=0$ or 1, thus disallowing rescaling of the r coordinate. They identified the case $E=0$ as the region inside the horizon of the vacuum Schwarzschild model.

It is certainly true that R' must be zero everywhere, but this does not necessarily make the line element (8) degenerate, provided $\sqrt{1+f}$ also goes to zero, i.e., $f=-1$. It was first pointed out by Zel'dovich and Grishchuk[17] that many spatially closed Lemaître–Tolman model necessarily has points where $R(t=\mathrm{const},r)$ is a maximum and thus $R'=0$ there. Hellaby and Lake[10] further showed that, for either extremum to be a regular space–time point, $R'=0$ also requires $a'=0$, $f'=0$, and $M'=0$ at these points if shell crossings are to be avoided, as well as $f=-1$ if a surface layer is to be avoided. It turns out that there is no reason why these conditions cannot hold everywhere. So, let us set

$$\frac{R'}{\sqrt{1+f}}=X(t) \tag{29}$$

and then establish what extra conditions are required to reduce the evolution of (12) for the elliptic case, $f<0$, to that of (26). Substituting (13), (14), and (12) into (29) gives

$$\frac{R'}{\sqrt{1+f}} = \frac{1}{(1-\cos\,\eta)}\left[\frac{M}{(-f)\sqrt{1+f}}\left(\frac{M'}{M}-\frac{f'}{f}\right)(1-\cos\,\eta)^2 - \frac{M}{(-f)\sqrt{1+f}}\left(\frac{M'}{M}-\frac{3f'}{2f}\right)\sin\,\eta(\eta-\sin\,\eta) - \frac{a'\sqrt{-f}}{\sqrt{1+f}}\sin\,\eta\right]$$
$$= X(t) = \frac{1}{(1-\cos\,\eta)}\left[E(1-\cos\,\eta)+\left(\frac{E\pi}{2}-B\right)\sin\,\eta-\left(\frac{E}{2}\right)\eta\sin\,\eta\right]. \tag{30}$$

Identifying coefficients of $\cos^2\,\eta$ leads to

$$f' \to 0 \tag{31}$$

as expected, while identification of the remaining coefficients of $\eta\sin\,\eta$, $\sin\,\eta$, $\cos\,\eta$, and 1 yields

$$E = \frac{2M'}{(-f)\sqrt{1+f}}, \tag{32}$$

$$B = \frac{\pi M' + a'(-f)^{3/2}}{(-f)\sqrt{1+f}}. \tag{33}$$

To complete the transition of $R'/\sqrt{1+f}$ to a finite function of t only, we require M' and a' to also go to zero, so that E and B are finite,

$$M' = M_1\sqrt{1+f}, \tag{34}$$

$$\Rightarrow M = M_1\int \sqrt{1+f}\,dr + M_0, \tag{35}$$

$$a' = a_1\sqrt{1+f}, \tag{36}$$

$$\Rightarrow a = a_1\int \sqrt{1+f}\,dr + a_0, \tag{37}$$

$$f \to -1. \tag{38}$$

In summary, then, we choose the arbitrary Lemaître–Tolman functions of M and a to be as in (35) and (37), and then take the limit $f\to -1$ to arrive at the Kantowski–Sachs metric with

$$E = 2M_1, \tag{39}$$

$$B = \pi M_1 + a_1, \tag{40}$$

$$A = 2M_0, \tag{41}$$

$$t_0 = a_0 + \pi M_0. \tag{42}$$

In terms of the Lemaître–Tolman variables we then have

$$X = 2M_1 - (M_1\eta + a_1)\frac{\sin\,\eta}{(1-\cos\,\eta)}, \tag{43}$$

$$8\pi\rho=\frac{2M_1}{M_0^2(1-\cos\ \eta)^2X}. \tag{44}$$

Two specific examples of the function $f(r)$ with the appropriate limit are

$$f=-1+f_1\ \cos^2(r),\quad 0\leqslant f_1<1,\quad f_1\to 0, \tag{45}$$

$$f=\frac{-(1+f_2r^2)}{(1+f_3r^2)},\quad f_2\leqslant f_3,\quad f_2\to f_3 \tag{46}$$

III. DERIVING THE *(r,t)–(U,V)* TRANSFORMATION

It is convenient to find the transformation into Schwarzschild coordinates first. In order to transform the Schwarzschild metric to Lemaître–Tolman form, we write

$$T=T(t,r),\quad R=R(t,r). \tag{47}$$

Substituting the derivatives of the above into (1) and setting it equal to (8) results in

$$-\dot{T}^2\left(1-\frac{2M}{R}\right)+\frac{\dot{R}^2}{\left(1-\frac{2M}{R}\right)}=-1, \tag{48}$$

$$-2\dot{T}T'\left(1-\frac{2M}{R}\right)+\frac{2\dot{R}R'}{\left(1-\frac{2M}{R}\right)}=0, \tag{49}$$

$$-\left(1-\frac{2M}{R}\right)T'^2+\frac{R'^2}{\left(1-\frac{2M}{R}\right)}=\frac{R'^2}{1+f}. \tag{50}$$

Eliminating $\dot{T}$ and T' between these three equations leads to exactly the Lemaître–Tolman evolution equation (9), confirming that the vacuum Lemaître–Tolman model is just Schwarzschild in geodesic coordinates.

Substituting for $\dot{R}^2$ from (9) in (48) we find

$$\dot{T}=\frac{\sqrt{1+f}}{\left(1-\frac{2M}{R}\right)}, \tag{51}$$

and this in (49) gives

$$T'=\frac{R'\dot{R}}{\left(1-\frac{2M}{R}\right)\sqrt{1+f}}, \tag{52}$$

and one can check using (9)–(11) that both give the same $\dot{T}'$. Note, however, that if the mass is not held constant, $M=M(r)$, then these equations are not integrable. For regions where $f<0$, (51) may be transformed, by means of (13), the derivative of (14), and

$$\dot{T}=\frac{\partial T}{\partial\eta}\frac{\partial\eta}{\partial t} \tag{53}$$

into

$$\frac{\partial T}{\partial \eta}=\frac{M\sqrt{1+f}}{(-f)^{3/2}}\frac{(1-\cos\ \eta)^2}{(1-\cos\ \eta+2f)}, \tag{54}$$

which integrates with respect to η giving

$$T-J=\frac{M\sqrt{1+f}}{(-f)^{3/2}}[(\eta-\pi)(1-2f)-\sin\ \eta]$$
$$-2M\ln\left|\frac{1-(1+2f)\cos\ \eta+2\sqrt{(-f)(1+f)}\sin\eta}{1-\cos\ \eta+2f}\right| \tag{55}$$

where $J=J(r)$ is a function of integration (cf. Khuri,[18] and Misner, Thorne, and Wheeler[19]). Eliminating the parameter η once more with (13) and substituting from (9) converts this to

$$T-J=\frac{M\sqrt{1+f}(1-2f)}{(-f)^{3/2}}\cos^{-1}\left(1-\frac{(-f)R}{M}\right)-\frac{R\dot{R}\sqrt{1+f}}{(-f)}-2M\ \ln\left|\frac{(\dot{R}+\sqrt{1+f})^2}{\left(1-\frac{2M}{R}\right)}\right|, \tag{56}$$

and a very similar procedure for the case $f>0$ gives

$$T-J=-\frac{M\sqrt{1+f}(1-2f)}{f^{3/2}}\cosh^{-1}\left(1+\frac{fR}{M}\right)+\frac{R\dot{R}\sqrt{1+f}}{f}-2M\ \ln\left|\frac{(\dot{R}+\sqrt{1+f})^2}{\left(1-\frac{2M}{R}\right)}\right|. \tag{57}$$

Note that

$$\ln\left|\frac{(\dot{R}+\sqrt{1+f})^2}{\left(1-\frac{2M}{R}\right)}\right|=-\ln\left|\frac{(\dot{R}-\sqrt{1+f})^2}{\left(1-\frac{2M}{R}\right)}\right|.$$

A simpler version for $f=0$ gives

$$T-J=\sqrt{\frac{2R}{M}}\left(\frac{R+6M}{3}\right)-2M\ \ln\left|\frac{(\dot{R}+1)^2}{\left(1-\frac{2M}{R}\right)}\right|, \tag{58}$$

and one may verify, using Taylor expansions, that this is the $f\to 0$ limit of (56) and (57). Finally, substituting from (14) or (17) as appropriate converts (56) and (57) to

$$T-J=(1-2f)\sqrt{1+f}(t-a)+2R\dot{R}\sqrt{1+f}-2M\ \ln\left|\frac{(\dot{R}+\sqrt{1+f})^2}{\left(1-\frac{2M}{R}\right)}\right|, \tag{59}$$

which is valid for all values of f, and this is confirmed by straight differentiation of (59) with respect to t (holding r constant) to retrieve (51) again after applying (9) and (10).

It must now be checked that the solution also satisfies (52), which involves evaluating $J(r)$. Partial differentiation with respect to r and substitution from (9) and (11) leads to

$$T'-J'=\frac{1}{2\sqrt{1+f}R\dot{R}\left(1-\frac{2M}{R}\right)}\left\{f'\left[(1+2f)R\left(1-\frac{2M}{R}\right)(2R-3(t-a)\dot{R})\right]\right.$$
$$\left.+R'[4(1+f)(M+fR-2fM)]a'\left[2(1+f)(2f-1)R\dot{R}\left(1-\frac{2M}{R}\right)\right]\right\}. \tag{60}$$

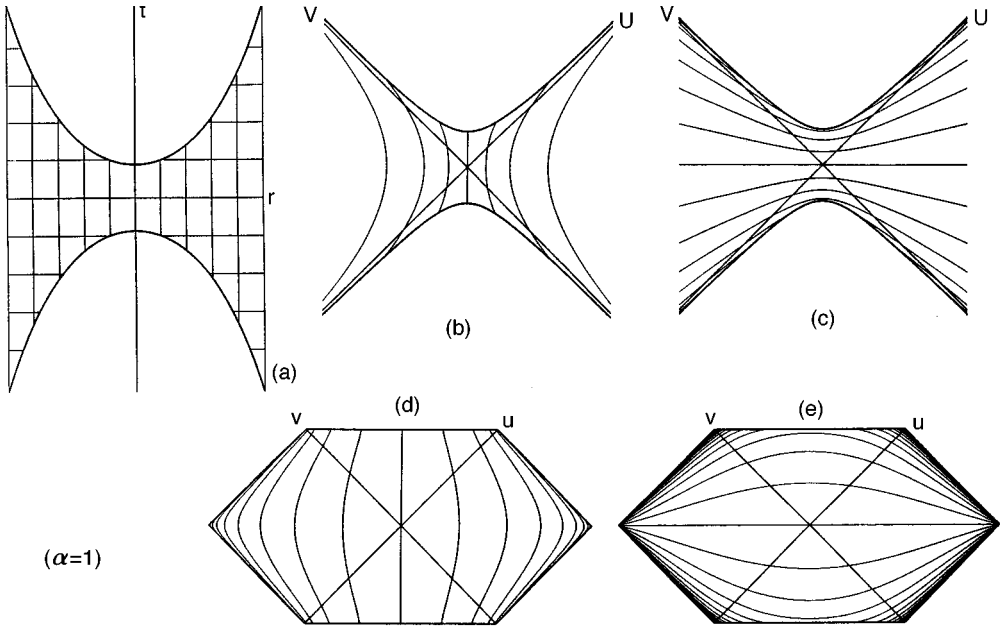

FIG. 1. The (a) Lemaître–Tolman, (b) and (c), Kruskal–Szekeres, and (d) and (e) Penrose diagrams, showing the constant t [(a), (b), and (d)] and constant r [(a), (c), and (e)] surfaces for Novikov coordinates.

Now (12) for constant M leads to

$$[3(t-a)\dot{R}-2R]f'=2fR'+2f\dot{R}a', \tag{61}$$

which may be used to eliminate f' in (60), yielding

$$T'-J'=\frac{\dot{R}R'}{\sqrt{1+f}\left(1-\frac{2M}{R}\right)}-\frac{a'}{\sqrt{1+f}}. \tag{62}$$

This clearly satisfies (52), once we have identified

$$J=\int\frac{a'dr}{\sqrt{1+f}}+J_0, \tag{63}$$

where J_0 is a constant.

The final transformation from vacuum Lemaître–Tolman to Schwarzschild coordinates then is

$$T=(1-2f)\sqrt{1+f}(t-a)+2R\dot{R}\sqrt{1+f}-2M\ \ln\left|\frac{(\dot{R}+\sqrt{1+f})^2}{\left(1-\frac{2M}{R}\right)}\right|+\int\frac{a'\ dr}{\sqrt{1+f}}+J_0, \tag{64}$$

combined with one of (13)+(14), (15), or (16)+(17), which cannot be made independent of the value of f. From (3) and (4) the vacuum Lemaître–Tolman to Kruskal–Szekeres transformation is

$$U=\sqrt{\frac{R}{2M}}(\sqrt{1+f}-\dot{R})\exp\left\{\frac{R+\sqrt{1+f}[(1-2f)(t-a)+2R\dot{R}]+J}{4M}\right\}, \tag{65}$$

$$V=-\sqrt{\frac{R}{2M}}(\sqrt{1+f}+\dot{R})\exp\left\{\frac{R-\sqrt{1+f}[(1-2f)(t-a)+2R\dot{R}]-J}{4M}\right\}. \tag{66}$$

Here $\dot{R}$ is just shorthand for $\sqrt{2M/R+f}$. A change in the value of the constant J_0 merely generates a constant translation of T and constant rescalings of U and V, so it may safely be set to zero. The transformations are illustrated in Fig. 1 for the Novikov choice of Lemaître–Tolman arbitrary functions.

IV. THE SHAPE OF THE *R=0* SINGULARITY

In Kruskal–Szekeres and Novikov coordinates the future singularity forms at the middle of the wormhole and succeeding shells collapse onto it at later times, the covers holding for the past singularity, whereas the Penrose diagram shows the past and future Schwarzschild singularities as simultaneous. In Lemaître–Tolman coordinates one is free to specify $a(r)$ and therefore can choose to make one, but not both, of the singularities simultaneous. We define the following family of Lemaître–Tolman arbitrary functions

$$M=\text{const}, \tag{67}$$

$$f=\frac{-1}{1+r^2}, \tag{68}$$

$$a=-\pi M\alpha(1+r^2)^{3/2}, \tag{69}$$

where the parameter α determines the degree of curvature of the past and future singularities—$\alpha=0$ makes the past singularity simultaneous at $t=0$, $\alpha=2$ makes the future singularity simultaneous at $t=0$, and $\alpha=1$ is the standard Novikov choice with the two singularities time symmetric about $t=0$. The corresponding transformations for various α values are shown in Fig. 2. It is apparent that, as the past singularity is brought closer and closer to being simultaneous, the geodesics crowd ever more tightly about $r=0,t=a$, and at $\alpha=0$ they all emerge from a single point on the past singularity, leaving large regions of the manifold uncharted by the coordinates. The envelope geodesic is obtained from the $r\to\infty$ limit with $a'=J=a=0$. In this limit the evolution is parabolic (15), and defining

$$y=\left(\frac{3t}{4M}\right)^{1/3} \tag{70}$$

gives the envelope in parametric form:

$$U=(y-1)\exp\left\{\frac{y^2}{2}+y\left(1+\frac{y^2}{3}\right)\right\}, \tag{71}$$

$$V=-(y+1)\exp\left\{\frac{y^2}{2}-y\left(1+\frac{y^2}{3}\right)\right\}. \tag{72}$$

The next model, defined by the choices

$$M=\text{const}, \tag{73}$$

$$f=-1+r^2, \tag{74}$$

$$a=0, \tag{75}$$

attempts to fill the uncovered regions with geodesics that escape to infinity, by extending f to positive values, but still keeping $a=0$. Although there is slightly greater coverage of the $U-V$ diagram, the curves still all start at the same $U-V$ event. The new envelope is given by the $f\to\infty$ limit of (65) and (66), holding R finite so that ($\cosh\eta-1\sim f$), i.e., $\eta\to\infty$ also. Replacing $\sqrt{1+f}$ with f gives

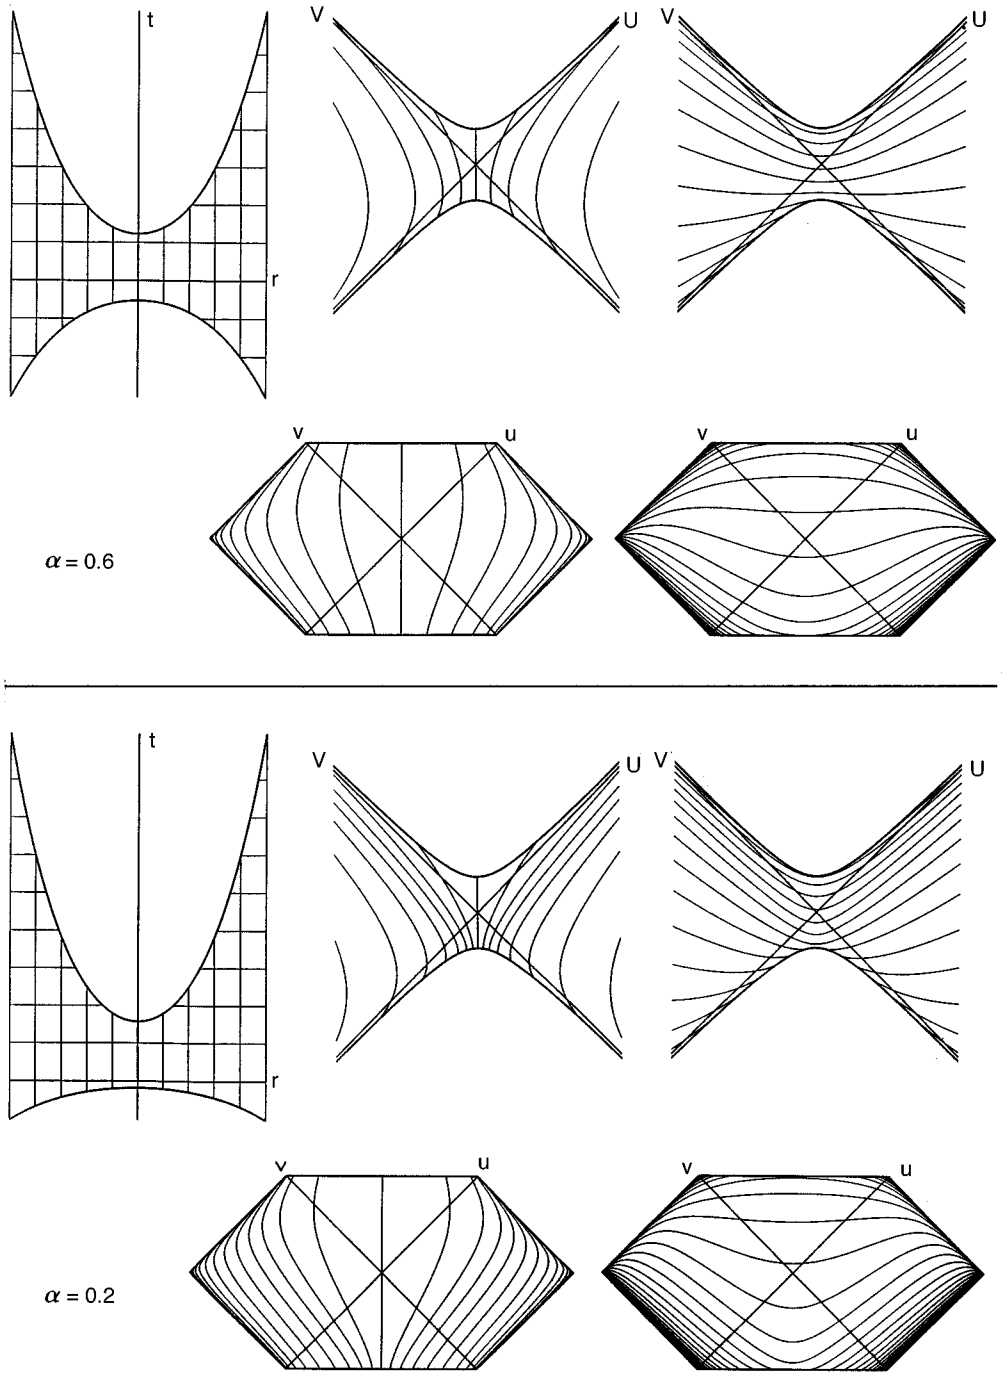

FIG. 2. The Lemaître–Tolman, Kruskal–Szekeres, and Penrose diagrams, showing the constant t and constant r surfaces for various values of α in the family of Lemaître–Tolman models given by the arbitrary functions (67)–(69).

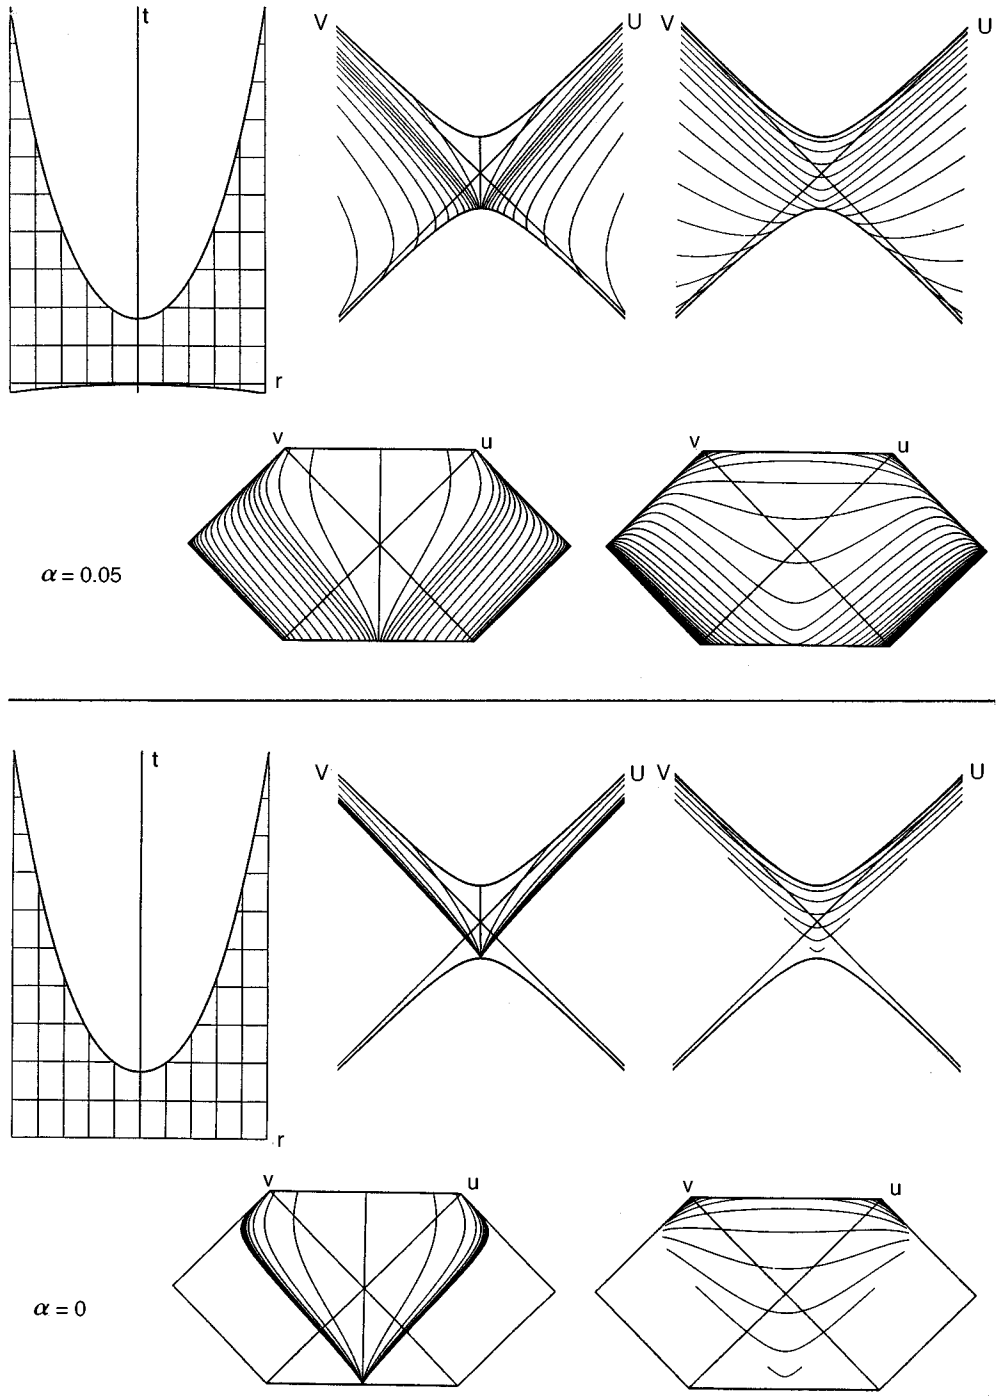

FIG. 2. (*Continued.*)

$$U=\left(\sqrt{\frac{\cosh\ \eta-1}{2}}-\sqrt{\frac{\cosh\ \eta+1}{2}}\right)\exp\left\{\frac{\cosh\ \eta-1}{4f}+\frac{\eta}{2}+\frac{J}{4M}\right\}, \tag{76}$$

$$V=-\left(\sqrt{\frac{\cosh\ \eta-1}{2}}+\sqrt{\frac{\cosh\ \eta+1}{2}}\right)\exp\left\{\frac{\cosh\ \eta-1}{4f}-\frac{\eta}{2}-\frac{J}{4M}\right\}, \tag{77}$$

so letting $a'=0=J$ and $\eta\to\infty$ gives

$$U \text{ undetermined}, \quad V=-1, \quad \text{or vice versa}, \tag{78}$$

which are the light rays emanating from $r=0$ on the past singularity, and reaching future null infinity.

In order to establish the same result in general, we take the $t\to a$, $R\to 0$, $\dot{R}\to\sqrt{2M/R}$ limit in the general expressions (65) and (66), arriving at

$$U\to -e^{J}, \quad V\to -e^{-J}, \tag{79}$$

which holds for arbitrary r, $f(r)$, and $a(r)$. Thus if $J\neq J(r)$, which is the case if $a'=0$ everywhere, then all constant r curves radiate from one $U-V$ point on the past singularity.

The one possibility we have not yet considered is the closed Kantowski–Sachs metric, which is well known to have R constant on all its constant t surfaces, so that both past and future singularities are simultaneous. Inserting the Kantowski–Sachs limit of the Lemaître–Tolman arbitrary functions into (64)–(66) gives

$$T=J_0+a_1 r-2M_0 \ln\left|\frac{\dot{R}^2}{\left(1-\frac{2M_0}{R}\right)}\right|, \tag{80}$$

$$U=-\dot{R}\sqrt{\frac{R}{2M_0}}\exp\left\{\frac{R+a_1 r+J_0}{4M_0}\right\}, \tag{81}$$

$$V=-\dot{R}=\sqrt{\frac{R}{2M_0}}\exp\left\{\frac{R-a_1 r-J_0}{4M_0}\right\}. \tag{82}$$

As expected, $t=\text{const}\to R=\text{const}$, and $r=\text{const}\to T=\text{const}$, so all coordinate geodesics pass through the neck (middle of the wormhole) at its moment of maximum expansion, and the metric is degenerate there, since there is a global shell crossing at that moment. Although these coordinates do cover the whole of the $R=0$ singularity and make it look simultaneous, they are not geodesically complete, and more importantly the coordinate geodesics are always in relative proper motion.

V. OBSERVER COORDINATES

In order to set up reasonable ''observer coordinates,'' which represent proper distance and time measurements, at least locally, we must start with a surface of simultaneity over a finite region, set up parallel timelike geodesics orthogonal to it, and then extend these geodesics a finite distance off the surface, using proper time along them for the fourth coordinate. Lemaître–Tolman coordinates already satisfy all but two of these requirements. A mere rescaling of the r coordinate,

$$\tilde{r}(r)=\int_0^r \frac{R'(t=\text{const},r)}{\sqrt{1+f}}\,dr \tag{83}$$

makes $\tilde{r}$ a local proper distance, and the coordinate geodesics are made parallel by requiring

$$\partial_t\sqrt{g_{rr}}=0\to\dot{R}'=0. \tag{84}$$

Inserting this and (12) into (11) and setting $M'=0$ for vacuum gives

$$a' = \frac{f'}{2Mf}(3M(t-a) - R^2\dot{R}), \tag{85}$$

which is always possible to satisfy *locally*, since the quantities in the brackets depend on a, f, and M but not directly on a' or f'. If $a'=0$ is required at some point, this in general requires $f'=0$, making it the locus of an extremum in the areal radius with $f=-1$.[10] Such a point necessarily occurs at one r value, and the corresponding geodesic is then a constant T curve, never quite emerging from the horizon. If, however, $a=$const is required, then $R'=0$ everywhere, and we have the $E=0=M_1$ closed Kantowski–Sachs model again, for which the coordinate geodesics cannot be made locally parallel away from $R=0$, since

$$\partial_t\sqrt{g_{rr}} = \dot{X} = \frac{2B}{A(1-\cos\,\eta)^2} = \frac{a_1}{M_0(1-\cos\,\eta)^2} \neq 0. \tag{86}$$

If both $E=0$ and $B=0$, then $X=0$, making the metric (23) degenerate.

VI. SIMULTANEOUS SYNCHRONOUS COORDINATES

Wald and Yip[20] considered conditions for the existence of simultaneous synchronous coordinates (SSCs) at spacelike singularities, as assumed in the Belinskii, Lifschitz, and Khalatnikov (BKL) approach to studying singularities (see Ref. 21). Wald and Yip's theorem 2 gives three conditions which allow one to find a Cauchy surface Σ such that Gaussian normal (i.e., synchronous) coordinates set up at Σ represent the singularity as simultaneous. In other words, the timelike geodesics of these coordinates all reach the singularity in the same proper time τ_Σ from Σ. Having set them up, the constant τ surfaces are a foliation that approaches the singularity as $\tau\to 0$. The conditions are, roughly speaking, (i) the (geodesic proper) time τ from Σ to the singularity (future causal boundary) is finite and nonzero; (ii) τ is a C^1 function throughout the future of $\Sigma(\mathrm{D}^+(\Sigma))$; (iii) every causal curve hits the singularity ($\tau\to 0$ along all causal curves).

We have shown that in the Schwarzschild/Kruskal–Szekeres manifold the following obtain

(a) Synchronous coordinates that cover the entire space–time manifold represent both future and past singularities as nonsimultaneous. Their $t=$const surfaces are Cauchy surfaces since $f\to 0$ or positive values as $r\to\infty$, thus covering the asymptotic regions, $R\to\infty$.

(b) Synchronous coordinates that make one or both singularities simultaneous do not cover the whole space–time. (Usually they do not even cover more than one $U-V$ point on the singularity that they make simultaneous.) Their $t=$const surfaces are not (complete) Cauchy surfaces.

(c) The nonexistence of SSCs for Schwarzschild black holes is due to the fact that the singularities, while entirely spacelike, are not all encompassing—they do not swallow all possible causal curves. The condition of Wald and Yip's theorem 2 that fails is condition (i), which requires τ_Σ (the maximum lifetime function of the Cauchy surface) to remain finite.

VII. CONCLUSION

We have found the transformation from the general vacuum Lemaître–Tolman model to Schwarzschild coordinates, and hence to Kruskal–Szekeres coordinates. Unfortunately this cannot be extended to nonempty Lemaître–Tolman models, since the system of partial differential equations (pdes) (51) and (52) are not integrable if M is not a constant. Similarly, equivalent expressions for $\dot{U}$ and U' are no longer integrable once $M=M(r)$, so the Lemaître–Tolman metric in double null coordinates cannot be expressed in the form (5)/(6), and probably contains nonzero coefficients of dU^2 and/or dV^2.

The vacuum Lemaître–Tolman model allows all possible families of radial geodesic coordinates to be set up, including those which generate observer coordinates in any given locality, as

well as those, such as the closed vacuum Kantowski–Sachs case, which never have a simultaneous surface on which the orthogonal timelike geodesics are parallel. Of course most arbitrary choices will have shell crossings, where the geodesics cross each other, at some time during their evolution, but this is only a coordinate problem in vacuum. Also there will be many choices that do not cover the full manifold, including all these that make $R=0$ simultaneous.

We have shown that it is impossible to find any reasonable set of ''observer coordinates,'' extended over a finite region of space–time, for which the Schwarzschild $R=0$ singularity is simultaneous. Furthermore, all possible global synchronous geodesic coordinates that cover the full spherically symmetric vacuum manifold represent $R=0$ as nonsimultaneous. Therefore we conclude that the Schwarzschild singularity is intrinsically nonsimultaneous, despite the appearance of the Penrose diagram. It would be interesting to determine whether this is a property of the spherically symmetric vacuum, or a property of the spatial topology. Nonempty Lemaître–Tolman models with the Kruskal–Szekeres topology were investigated in P1 where the horizons were shown to be split, and it has been shown[22] that the Lemaître–Tolman $R=0$ singularities are spacelike everywhere (unless a censorship violating singularity[23,24] is present, an impossibility in this topology which lacks an origin of spherical coordinates) but the detailed behavior of the light rays is not known.

Qualitative analysis of causal cosmological models

Vicenç Méndez and Josep Triginer
Departament de Física, Facultat de Ciències, edifici Cc,
Universitat Autònoma de Barcelona, E-08193 Bellaterra (Barcelona) Spain

(Received 9 November 1995; accepted for publication 12 February 1996)

The Einstein's field equations of Friedmann–Robertson–Walker universes filled with a dissipative fluid described by both the *truncated* and *non-truncated* causal transport equations are analyzed using techniques from dynamical systems theory. The equations of state, as well as the phase space, are different from those used in the recent literature. In the de Sitter expansion both the hydrodynamic approximation and the non-thermalizing condition can be fulfilled simultaneously. For $\Lambda=0$ these expansions turn out to be stable provided a certain parameter of the fluid is lower than 1/2. The more general case $\Lambda>0$ is studied in detail as well. © *1996 American Institute of Physics.* [S0022-2488(96)03205-6]

I. INTRODUCTION

Recently, isotropic spatially homogeneous viscous cosmological models have been investigated using the causal (truncated and nontruncated) Israel–Stewart theory of irreversible processes, to modelize the bulk viscous transport.[1–3] It is known that dissipative processes may play a crucial role in the evolution of relativistic fluids both in cosmology and in high-energy astrophysical phenomena. The most oftenly used theory to describe such irreversible processes has been long since the first-order non-causal Eckart's theory[4] which however suffers from serious pathologies and drawbacks, i.e., superluminal velocities and instabilities.[5,6] In the late sixties Müller[7] proposed a second order theory in which the entropy flow depended on the dissipative variables besides the equilibrium ones. Israel and Stewart[8,9] and Pavón *et al.*[10] developed a fully relativistic formulation on that basis, the so-called *extended* or *transient* thermodynamics (see Ref. 11 for a recent and comprehensive review of the state of the art).

Shortly after Israel's paper appeared, Belinskii *et al.*[12] applied it to a viscous cosmological fluid using the so-called *truncated* version, in which some divergence terms in the transport equations were neglected. Most of the papers dealing with viscous and/or heat conducting cosmological models make use of such a truncated transport equation without stating clearly what the implications of such a simplification may be. Recently, some effort has been invested in analyzing to what extent the neglecting of the divergence terms can be justified from a physical point of view.[3,13] As far as we know, Hiscock and Salmonson[14] were the first to raise this point in the cosmological context. These authors stressed the key importance of the usually neglected divergence terms when obtaining viscosity-driven inflationary solutions. However, it is now clear that to get realistic solutions to the Einstein's field equations, the role played by the equations of state relating the different thermodynamic quantities is crucial. Hence the claim in Ref. 14 applies only to a Boltzmann gas.[15] In fact, the difficulty in using the extended transport equations lies mainly in the occurrence of some additional unknown coefficients, whose explicit expressions must be obtained from techniques other than those coming from thermodynamics, either kinetic or fluctuation theory,[16] more than in their intrinsic complexity.

Few exact solutions have been found to the Einstein's field equations with a non-perfect fluid described by extended thermodynamics[17,18] (ET for short). However, they were obtained under severe restrictions on the values for the free parameters in the transport equations. Obviously, any further attempt to get a deeper insight on the possible behavior of the solutions must rely on an approximate analysis of the equations. In this paper, we apply qualitative analysis techniques to the study of causal viscous Friedmann–Robertson–Walker (FRW) models with and without a

0022-2488/96/37(6)/2906/14/$10.00

positive cosmological constant. It is organized as follows. In section II we state the basic equations governing the models and discuss the equations of state to be used. In section III we apply the truncated version of ET whereas in section IV a corresponding analysis is carried out using the *full* version. In both cases a null and a positive cosmological constant are considered in turn. In section V we explore their dynamical consequences, and finally in section VI we summarize the main conclusions of the paper.

II. BASIC EQUATIONS

We restrict ourselves to a FRW space-time filled with a bulk viscous fluid and a positive cosmological constant Λ. The stress-energy tensor is

$$T_{ab}=(\rho+p+\Pi)u_a u_b+(p+\Pi-\Lambda)g_{ab}, \tag{1}$$

where u_a is the four velocity, ρ the energy density, p the equilibrium pressure, Π the bulk viscous pressure. Einstein's field equations for the spatially flat case (the only one we adress in this paper) are

$$H^2=\frac{\kappa}{3}\rho+\frac{\Lambda}{3}, \quad 3(\dot{H}+H^2)=-\frac{\kappa}{2}(\rho+3P_{eff})+\Lambda, \tag{2}$$

where $H\equiv\dot{R}/R$ is the Hubble factor, $R(t)$ the cosmic scale factor of the Robertson–Walker metric, $P_{eff}=p+\Pi$ and $\kappa=8\pi G/c^4$. An overdot denotes differentiation respect to time t. We assume the fluid obeys equations of state of the form

$$\zeta=\alpha\rho^m, \quad p=(\gamma-1)\rho, \quad \tau=\frac{\zeta}{\rho}, \tag{3}$$

where α is a positive constant, and γ the adiabatic index lying in the range $1<\gamma<2$ as the sound velocity $v_s/c=\gamma-1$ in the fluid must be lower than the speed of light. $\tau(\geqslant 0)$ is the relaxation time for transient bulk viscous effects, i.e., the time the system takes in going back to equilibrium once the divergence of the four-velocity has been switched off. The causal evolution equation for bulk viscous pressure can be cast into the form[3]

$$\Pi+\tau\dot{\Pi}=-3\zeta H-\frac{b}{2}\tau\Pi\left(3H+\frac{\dot{\tau}}{\tau}-\frac{\dot{T}}{T}-\frac{\dot{\zeta}}{\zeta}\right), \tag{4}$$

where $b=0$ for the truncated theory and $b=1$ for the full one. Since a dissipative expansion is non-thermalizing, the relaxation time must exceed the expansion rate H^{-1}. This leads to

$$\tau^{-1}<H, \tag{5}$$

which is a condition that reduces the interval of values of γ for which the model holds. As we shall see this restriction may be violated in the truncated theory as well as in the full theory when an ideal gas equation of state is assumed. This conflict can be circumvented by resorting to the expression for the speed of the viscous signals $a\equiv v^2/c^2\sim\zeta/\tau\rho$, which roughly implies[3,13]

$$\tau=\frac{\zeta}{a\rho}, \qquad 0<a<1, \tag{6}$$

and using (6) instead of (3c).

Most of the stability analysis below will be carried out for the de Sitter solutions, $H=$ const. As the universe undergoes a de Sitter expansion it could be argued that the hydrodynamic de-

scription (absolutely needed in our study if the results are to hold) might break down. In order for the fluid approach remains valid the mean collision time t_{col} must be less (in fact much less) than the expansion rate, i.e., $t_{col}<H^{-1}$. From kinetic theory one has $t_{col}=1/n\sigma$ where n is the particle number density and σ the cross section for collisions. In general $\sigma(T)$ is an increasing function of the temperature whereas, for a FRW universe, $n \propto 1/R^3 (=e^{-3H_0 t}$ for a de Sitter universe). From equations (2a), (3a) and (6) the non-thermalizing condition (5) and the condition for the hydrodynamic approximation imply

$$\frac{e^{3H_0 t}}{n_0 \sigma} < H_0^{-1} < \frac{\alpha}{a}\left(\frac{3}{\kappa}\right)^{m-1} H_0^{2m-2}, \tag{7}$$

where n_0 is a positive but otherwise arbitrary integration constant. Later it will be shown that the second inequality in (7) can be fulfilled when suitable values for the arbitrary parameters are chosen. Moreover, the first inequality may hold for sufficiently early times (when the inflation era supposedly took place). As the temperature remains constant during this period the cross section σ can be taken approximately constant.[19]

Recently in performing the qualitative analysis of imperfect fluid cosmological models (see for instance Refs. 1,2,20,21) dimensionless equations of state were used in terms of the dimensionless variables x and y, defined as

$$x \equiv 3\rho/\Theta^2, \qquad y \equiv 9\Pi/\Theta^2. \tag{8}$$

The equations of state [Eq. (3.4a), (3.4b) in Ref. 20)]

$$p/\Theta^2 = p_0 x^l, \qquad \zeta/\Theta = \zeta_0 x^m, \tag{9}$$

with $\Theta(\equiv 3H)$ the expansion factor, coincide with (3a), (3b) only for $l=m=1/2$. Furthermore, for the spatially flat FRW metric with $\Lambda=0$, the case we are interested in, we have $x=1$. Then the bulk viscous coefficient ζ varies as Θ irrespective of m, which restricts (9) to just one case: $m=1/2$ in (3a). In this paper we shall consider only the *spatially flat* case ($k=0$) which allows us to take $(\dot{H},H)$ as suitable dynamical variables in the phase space. In this case it appears to be more natural, especially when the above comments are taking into account, to adopt the oftenly used equations of state (3) rather than (9) in order to be able to compare our results with those in the literature for $m=1/2$. Consequently, all the fixed points to be analyzed will correspond to either de Sitter or static spacetimes ($X \equiv \dot{H}=0$) the former being physically relevant in inflationary models. If one is interested in studying non-flat FRW models, the variables $(\dot{H},H)$ become no longer appropriate and an approach similar to that of Coley[20] should by adopted.

III. QUALITATIVE ANALYSIS USING THE TRUNCATED THEORY

From equations (2), (3) and the expression (6) for τ we find for the Hubble factor the equation

$$\ddot{H} + 3\gamma H\dot{H} + \frac{a}{\delta}\left(H^2 - \frac{\Lambda}{3}\right)^{1-m}\dot{H} + \frac{(3H^2-\Lambda)a}{2}\left[\frac{\gamma}{\delta}\left(H^2-\frac{\Lambda}{3}\right)^{1-m} - 3H\right] = 0, \tag{10}$$

where $\delta = \alpha(3/\kappa)^{m-1}$. Equation (10) can be recast into the form

$$\dot{H} = P(H,X), \quad \dot{X} = Q(H,X), \tag{11}$$

where

$$P(H,X) = X, \tag{12}$$

$$Q(H,X)=-3\gamma HX-\frac{a}{\delta}\left(H^2-\frac{\Lambda}{3}\right)^{1-m}X-\frac{(3H^2-\Lambda)a}{2}\left[\frac{\gamma}{\delta}\left(H^2-\frac{\Lambda}{3}\right)^{1-m}-3H\right]. \tag{13}$$

The qualitative analysis begins by linearizing the system (11) for small perturbations–where the linear theory holds. Then the Jacobian matrix

$$\mathbf{L}=\begin{pmatrix} P_H & P_X \\ Q_H & Q_X \end{pmatrix}, \text{ with } P_H\equiv\frac{\partial P}{\partial H}, \text{ etc.,} \tag{14}$$

can be constructed. The elements of this matrix must be evaluated at the equilibrium points (h_i,X_i) (de Sitter and static solutions) which are found by solving the system $P(h_i,X_i)=Q(h_i,X_i)=0$. After diagonalizing $\mathbf{L}$ and obtaining its eigenvalues we can decide about the type of fixed points and their stability.

The analysis of the system (12), (13) for the two cases with $\Lambda=0$ and $\Lambda>0$ will be carried out in turn.

i. $\Lambda=0$

- $m=1/2$

We have the trivial fixed point,

$$(0,0),$$

which corresponds to an unstable static model. However, this case does not make sense as, by Einstein's equation (2a), $\rho=0$. If γ and δ fulfill the restriction

$$\gamma/\delta=3, \tag{15}$$

there exists an infinity of fixed points $(h_0,0)$, where h_0 denotes an arbitrary positive real constant. In this case the fixed points are parallel stable straight lines.

- $m\neq 1/2$

In the intervals $0\leqslant m<1/2$, $1/2<m<2$ there are two fixed points,

$$(0,0), \qquad (h_0,0), \tag{16}$$

with

$$h_0=\left(\frac{3\delta}{\gamma}\right)^{1/(1-2m)}, \tag{17}$$

whereas for $m\geqslant 2$ there is only one fixed point $(h_0,0)$. The discussion for the point $(0,0)$ mimics that for $m=1/2$.

Let us define the auxiliar parameter,

$$\Sigma_1=\frac{1}{4a}\left(\gamma+\frac{a}{\gamma}\right)^2.$$

For $m<\frac{1}{2}-\Sigma_1$ the equilibrium point $(h_0,0)$ is an asymptotically stable focus, for $m=\frac{1}{2}-\Sigma_1$ it is an asymptotically stable degenerate node, whereas for $m>\frac{1}{2}-\Sigma_1$ two cases arise. If $\frac{1}{2}-\Sigma_1<m<\frac{1}{2}$, then the equilibrium point is an asymptotically stable node, whereas if $m>1/2$ it is a unstable saddle point.

In the paper by Pavón *et al.*[22] slightly different techniques were used to analyze the case $m=1/2$ and $a=1$. Their relevant parameter was our Σ_1 with $a=1$. Our results agree with those of the mentioned reference (see Sec. 3.1 of Ref. 22) providing a more accurate classification of the stability points.

ii. $\Lambda>0$

As we shall see, there are two fixed points: $(h_0^\Lambda,0)$ and $(h_1^\Lambda,0)$. From (10) it follows the equation for the fixed points,

$$(3h_i^2-\Lambda)\left[\frac{\gamma}{\delta}\left(h_i^2-\frac{\Lambda}{3}\right)^{1-m}-3h_i\right]=0, \tag{18}$$

which must be solved for different values of m. However, (18) has an obvious solution independent of m, $h_0^\Lambda=\sqrt{\Lambda/3}$, which can be shown to correspond to a saddle point. This solution will be ruled out however since it would imply that the energy density vanishes identically. The other solution h_1^Λ will be analyzed for $m=0,\frac{1}{2},1$, in turn.

● $m=0$

Setting to zero the big square parenthesis in (18) and solving the resulting equation, one obtains

$$h_1^\Lambda=\frac{3\delta}{2\gamma}+\frac{1}{2}\sqrt{\frac{9\delta^2}{\gamma^2}+\frac{4\Lambda}{3}}.$$

We define

$$\Sigma_1^\Lambda=\frac{2-2\Sigma_1}{2\Sigma_1-1}, \qquad \Lambda_0=\frac{27\delta^2}{\gamma^2}\frac{1+\Sigma_1^\Lambda}{(\Sigma_1^\Lambda)^2}.$$

For $\Lambda<\Lambda_0$ the fixed point $(h_1^\Lambda,0)$ is an asymptotically stable node. If $\Lambda=\Lambda_0$ the fixed point is an asymptotically stable degenerate node whereas for $\Lambda>\Lambda_0$ it is an asymptotically stable focus.

● $m=1/2$

Now h_1^Λ is given by

$$h_1^\Lambda=\sqrt{\frac{\Lambda/3}{1-9\delta^2/\gamma^2}}.$$

For $0<9\delta^2/\gamma^2<1$, $(h_1^\Lambda,0)$ is an asymptotically stable node whereas for $9\delta^2/\gamma^2>1$ the fixed point is an asymptotically stable focus for any $\Lambda>0$.

● $m=1$

Now $h_1^\Lambda=\gamma/3\delta$. For $\Lambda<\gamma^2/3\delta^2$ we have a saddle fixed point, whereas for $\gamma^2/3\delta^2<\Lambda<\Lambda_1$, where

$$\Lambda_1=\frac{\gamma^2}{3\delta^2}\Sigma_2^\Lambda>0, \text{ with } \Sigma_2^\Lambda=\frac{1}{2a}\left(\gamma+\frac{a}{\gamma}\right)^2+1,$$

the fixed point is an asymptotically stable node. For $\Lambda=\Lambda_1$, it is an asymptotically stable degenerate node whereas for $\Lambda>\Lambda_1$, it is an asymptotically stable focus.

IV. QUALITATIVE ANALYSIS USING THE FULL THEORY

Actually, a proper study of viscous phenomena in the frame of ET requires the use of the full equation (4) (i.e., $b=1$). The physical implications of neglecting the second term of (4) have been

analyzed in detail in Refs. 3,13. The use of (4) requires an explicit expression for the temperature T in terms of other variables such as ρ and/or n. So far (with the exception of Ref. 14) the expression adopted for T has been a power-law

$$T=\beta\rho^r, \tag{19}$$

where $r\geqslant 0$ and $\beta>0$ are constants, which is the simplest way to guarantee a positive heat capacity.[23] However, we shall see that standard thermodynamic relations restrict the range of r. Cãlvao *et al.*[24] found a general equation for the evolution of temperature when two equations of state,

$$\rho=\rho(T,n), \quad p=p(T,n), \tag{20}$$

are given. However, their equation was obtained in the context of matter creation where Π is reinterpreted as a non-equilibrium pressure associated to particle production. The same equation has been carefully analyzed in Ref. 13, it reads as

$$\frac{\dot{T}}{T}=-\Theta\left[\frac{(\partial p/\partial T)_n}{(\partial\rho/\partial T)_n}+\frac{\Pi}{T(\partial\rho/\partial T)_n}\right]. \tag{21}$$

Obviously, when the equations of state (20) are known the evolution of T is no longer free but fixed by (21). However, only in very few cases these equations are explicitly known, as for instance in the case of a radiation gas or an ideal gas.[25] Equation (19) generalizes in a simple way the Stefan–Boltzmann ($R=1/4$) equation which holds for a radiation-dominated fluid in equilibrium. Thus, in that case we get that both equations of state ρ and p (when a γ-law is used) have T as the only independent variable, i.e., $\partial\rho(p)/\partial T=d\rho(p)/dT$. A useful and interesting relation follows from considering the standard thermodynamic relation[26]

$$\left(\frac{\partial\rho}{\partial n}\right)_T=\frac{\rho+p}{n}-\frac{T}{n}\left(\frac{\partial p}{\partial T}\right)_n, \tag{22}$$

which, by virtue of (3b) and (19), yields

$$r=\frac{\gamma-1}{\gamma}\left(\Rightarrow 0<r<\frac{1}{2}\right), \tag{23}$$

i.e., r is no longer an independent parameter (we are indebted to Roy Maartens for pointing us out this restriction). It has been argued[2] that the inequality $r<1$ is reasonable from a physical point of view, since ultrarelativistic and cold non-relativistic matter have $r=1/4$ and $r\sim 2/3$, respectively.

However, an alternative equation can be used for T instead of (19). It is well-known that a relativistic ideal monoatomic gas is described by the two equations of state $p=nT$ and $\rho=3nT+m^2M$, where m is the mass of the particles and M the zeroth-order moment of the Maxwell–Boltzmann distribution function (we use units $k_B=1$, k_B being the Boltzmann constant). We see that the γ-law (γ constant) is *not* compatible with the equations of state of a monoatomic gas in *equilibrium* except for radiation ($m=0$). In that case we have $n\propto T^3$ and the two equations of state for p and ρ reduce to the Stefan–Boltzmann equation and the γ-law with $\gamma=4/3$.

In the remainder of this section the full viscous transport equation will be analyzed resorting to the two expressions for the temperature mentioned above: a power-law given by (19) and an ideal gas equation for p together with the γ-law defining ρ, i.e.

$$p=nT, \qquad \rho=\frac{nT}{\gamma-1}. \tag{24}$$

Note that now both T and n are independent variables and only in the equilibrium limit the particle number density depends exclusively on the temperature, $n=n(T)$ (see comments above). It must be stressed that the Stefan–Boltzmann equation together with an ideal gas equation of state (with $n \propto T^3$) implies $\Pi=0$. So we conclude that out of equilibrium we are forced to adopt one of the two possibilities: (i) a power-law for T with no dependence on n at all; (ii) an ideal gas equation of state for the pressure together a γ-law, with n an independent variable on the same footing as T. Both approaches will be considered in turn.

A. Potential law for the temperature

Using equations (2), (3), (6), (19) and (23) the equation governing the evolution of the Hubble factor reduces to

$$\ddot{H}+\frac{3}{2}[1+\gamma(1-r)]H\dot{H}+\frac{a}{\delta}\left(H^2-\frac{\Lambda}{3}\right)^{1-m}\dot{H}+\frac{(3H^2-\Lambda)a}{2}$$
$$\times\left[\frac{\gamma}{\delta}\left(H^2-\frac{\Lambda}{3}\right)^{1-m}-3\left(1-\frac{\gamma}{2}\right)H\right]-3(r+1)\frac{H\dot{H}^2}{3H^2-\Lambda}=0. \tag{25}$$

i. $\Lambda=0$

● $m=1/2$

As in Section III only the case with γ and δ fulfilling the restriction

$$\frac{\gamma}{\delta}=\frac{3}{2}(2-\gamma), \tag{26}$$

is physically meaningful. In such instance there exists an infinity of stable fixed points $(h_1,0)$, with h_1 an arbitrary positive real number. The phase portrait are parallel stable straight lines.

● $m\neq 1/2$

There are two fixed points, $(0,0)$ and $(h_1,0)$, in the interval $m \in [0,\frac{1}{2})\cup(\frac{1}{2},2)$, where

$$h_1=\left(\frac{3\delta(2-\gamma)}{2\gamma}\right)^{1/(1-2m)}. \tag{27}$$

For $m\geqslant 2$ only the $(h_1,0)$ fixed point occurs, which we analyze next as nothing new arises about the point $(0,0)$.

Let us define the parameter

$$\Sigma_2=\frac{[\gamma(2-a)+2a]^2}{8a\gamma^2(2-\gamma)}>0.$$

For $m<\frac{1}{2}-\Sigma_2$ the equilibrium point is an attractor in the phase space (asymptotically stable focus). For $\frac{1}{2}-\Sigma_2\leqslant m<\frac{1}{2}$ we have asymptotically stable nodes instead. Finally if $m>1/2$, the fixed point is a saddle.

ii. $\Lambda>0$

From Eq. (25) it follows the equation for the fixed points,

$$(3h_i^2-\Lambda)\left[\frac{\gamma}{\delta}\left(h_i^2-\frac{\Lambda}{3}\right)^{1-m}-3\left(1-\frac{\gamma}{2}\right)h_i\right]=0, \tag{28}$$

where, as in the truncated case, only the solutions vanishing the big square parentheses make sense from a physical point of view. Equation (28) will be solved only for three different values of m. In this case we must take into account the constraint (23).

- $m=0$

The fixed point is $(h_2^\Lambda,0)$ with

$$h_2^\Lambda=\frac{3\delta}{2\gamma}\left(1-\frac{\gamma}{2}\right)+\frac{1}{2}\sqrt{\frac{9\delta^2}{\gamma^2}\left(1-\frac{\gamma}{2}\right)^2+\frac{4\Lambda}{3}}.$$

Defining the two new parameters,

$$\Sigma_3^\Lambda=\frac{2(1-\gamma/2)}{1/a[1-a/2+a/\gamma]^2-2(1-\gamma/2)}-1.$$

and

$$\Lambda_2=\frac{27\delta^2}{\gamma^2}\left(1-\frac{\gamma}{2}\right)^2\frac{1+\Sigma_3^\Lambda}{(\Sigma_3^\Lambda)^2},$$

we see that for $\Lambda\leqslant\Lambda_2$ the fixed point is an asymptotically stable node, whereas for $\Lambda>\Lambda_2$ it is an asymptotically stable focus.

- $m=1/2$

The fixed point is

$$h_2^\Lambda=\sqrt{\frac{\Lambda/3}{1-(9\delta^2/\gamma^2)(1-\gamma/2)^2}},$$

so

$$\delta<\frac{2\gamma}{3(2-\gamma)}.$$

Let us introduce

$$\delta_0=\frac{2\gamma}{3(2-\gamma)}(1-\Sigma_2)^{1/2}.$$

For $\delta>\delta_0$, $(h_2^\Lambda,0)$ is found to be an asymptotically stable node, however if $\delta=\delta_0$ it is an asymptotically stable degenerate node, whereas for $\delta<\delta_0$ the fixed point is an asymptotically stable focus. In the radiation case—i.e. $\gamma=4/3$- $\delta_0<0$ and the fixed point is a stable node.

- $m=1$

In this case

$$h_2^\Lambda=\frac{\gamma}{3\delta(1-\gamma/2)}.$$

Let us define the parameter

$$\Lambda_3=\frac{\gamma^2(1+2\Sigma_2)}{3\delta^2(1-\gamma/2)^2}>0.$$

For $\Lambda > \Lambda_3$ the fixed point is an asymptotically stable focus, and for $\Lambda = \Lambda_3$ an asymptotically stable degenerate node.

Finally, when $\Lambda < \Lambda_3$ we can distinguish two subcases. Defining

$$\Lambda_3^* = \frac{\gamma^2}{3\delta^2(1-\gamma/2)^2},$$

we have a saddle point for

$$\Lambda < \Lambda_3^*,$$

and an asymptotically stable node for

$$\Lambda_3^* < \Lambda < \Lambda_3.$$

B. Ideal gas equation for the temperature

In this section we shall study the specific behavior of the equilibrium points, making use of the state equations (24). As neither particle production nor annilation occurs, n obeys the conservation equation

$$\dot{n} + 3Hn = 0, \tag{29}$$

which leads to $n \propto R^{-3}$. The expression for the temperature,

$$T = \frac{3}{\kappa}\frac{\gamma-1}{n_0} R^3 \left(H^2 - \frac{\Lambda}{3} \right), \tag{30}$$

where $n_0 > 0$ is a constant, follows easily. Using (2), (3a), (3b), (4), (6) and (30) we get the equation

$$\ddot{H} + \frac{a}{\delta}\left(H^2 - \frac{\Lambda}{3} \right)^{1-m} \dot{H} + \frac{(3H^2-\Lambda)a}{2}\left[\frac{\gamma}{\delta}\left(H^2 - \frac{\Lambda}{3} \right)^{1-m} - 3\left(1 - \frac{\gamma}{2} \right) H \right] - 6\frac{H\dot{H}^2}{3H^2-\Lambda} = 0, \tag{31}$$

i. $\Lambda = 0$

We have the same fixed points as in the truncated theory [see equation (17)].

In the case $m = 1/2$ the discussion runs along the same lines as that of the truncated theory. After linearizing the system and introducing the parameter

$$\Sigma_3 = \frac{a}{4\gamma^2},$$

the following will be discussed. For $m < \frac{1}{2} - \Sigma_3$ the eigenvalues are complex and the equilibrium point is an attractor (asymptotically stable focus). For $m = \frac{1}{2} - \Sigma_3$ there is a bifurcation point which is an asymptotically stable degenerate node. For $m > 1/2$ one has a saddle point. Finally, if $\frac{1}{2} - \Sigma_3 < m < 1/2$ the fixed point results an asymptotically stable node.

ii. $\Lambda > 0$

Now the fixed points $(h_2^\Lambda, 0)$ are again the same as in the full theory using a power law for the temperature.

- $m = 0$

For any $\Lambda > 0$ the fixed point is an asymptotically stable focus.

- $m=1/2$

Defining

$$\delta_1=\frac{\gamma}{3}\sqrt{1-\frac{1}{2\gamma^2}},$$

we note that if δ lies in the interval $0<\delta<\delta_1$ the fixed point is an asymptotically stable focus. If $\delta=\delta_1$ it is an asymptotically stable degenerate node, and if $\delta_1<\delta<\gamma/3$ an asymptotically stable node for any $\Lambda>0$.

- $m=1$

Let us define

$$\Lambda_4=\frac{\gamma^2}{3\delta^2}(1+2\Sigma_3).$$

If $\Lambda<\gamma/3\delta^2$ then the fixed point is a saddle point, but if $\gamma/3\delta^2<\Lambda<\Lambda_4$ it is an asymptotically stable node. For $\Lambda=\Lambda_4$ it is an asymptotically stable degenerate node, and for $\Lambda>\Lambda_4$ an asymptotically stable focus.

1. Non-thermalizing condition for dissipative de Sitter expansion

i. $\Lambda=0$

From (5) and (2) one finds

$$H^{1-2m}<\delta/a\,. \tag{32}$$

For the truncated and full theory using an ideal gas equation for T this condition reduces to $\gamma>3a$ by virtue of (17). On the other hand, as the velocity of the viscous pulses, as well as the speed of sound, cannot exceed the speed of light ($1<\gamma<2$) we obtain the restrictions on γ and a. If a lies in the range $0<a<\frac{1}{3}$, the two mentioned conditions amount to $1<\gamma<2$; whereas if $\frac{1}{3}<a<\frac{2}{3}$ these restrictions imply $3a<\gamma<2$. Finally, if $\frac{2}{3}<a<1$, no γ can fulfill both conditions.

For the full theory with a power law for temperature one obtains the restriction $\gamma>\gamma_c$ where

$$\gamma_c=\frac{6a}{3a+2}.$$

Two conditions must be fulfilled simultaneously by γ: $1<\gamma<2$ and $\gamma>\gamma_c$. For $0<a<\frac{2}{3}$, these restrictions imply $1<\gamma<2$ (since $\gamma_c<1$); whereas for $\frac{2}{3}<a<1$ one has $1<\gamma_c<\gamma<2$. So for $a<1$ the full theory with a power law for temperature always holds.

ii. $\Lambda>0$

Instead of (32) we now have

$$\frac{a}{\delta}\left(H^2-\frac{\Lambda}{3}\right)^{1-m}<H, \tag{33}$$

when a positive cosmological constant is present.

For the fixed point $(h_1^\Lambda,0)$ (that of the truncated theory) the restrictions for γ are the same that in the truncated case with $\Lambda=0$, whereas for the full theory the restriction (33), when applied to the point $(h_2^\Lambda,0)$, coincides with that of the full theory using a power law for the temperature with vanishing Λ.

V. DYNAMICAL CONSEQUENCES

In this section we study the dynamical implications of linearizing the equation for H. This linearization allows one to obtain an analytical solution for $R(t)$ near the equilibrium points. The matrix $\mathbf{L}$ is given by (14) and the system of differential equations to solve is

$$\begin{pmatrix} \dot{h} \\ \dot{X} \end{pmatrix} = \begin{pmatrix} P_H & P_X \\ Q_H & Q_X \end{pmatrix} \begin{pmatrix} h \\ X \end{pmatrix}, \tag{34}$$

where $h \equiv H - h_i$ and $\overline{X} \equiv X - X_i = X$ being $(h_i, X_i = 0)$ the fixed points. Equation (34) can be written as

$$\ddot{h} - Q_X \dot{h} - Q_H h = 0, \tag{35}$$

where in our model $P_H = 0$ and $P_X = 1$. The corresponding characteristic equation reads as

$$\lambda_{\pm} = \frac{Q_X \pm \sqrt{Q_X^2 + 4Q_H}}{2},$$

which coincides with the equation for the eigenvalues of $\mathbf{L}$. We perturb the system around the de Sitter solution for $t = 0$, i.e., $H(t=0) = h_i + \epsilon(0)$ and take $\dot{H}(t=0) = \dot{\epsilon}(0)$ as initial condition.

A. Saddle points and nodes

In the neighborhood of these points the discriminant Δ is positive and the eigenvalues $\lambda_{\pm}$ are real and different. For $det(\mathbf{L}) < 0$ one has a saddle point, and for $det(\mathbf{L}) > 0$ a node. The solution of (35) is

$$h = c_1 e^{\lambda_+ t} + c_2 e^{\lambda_- t},$$

with

$$c_1 = -\frac{\dot{\epsilon}(0) - \epsilon(0)\lambda_-}{\lambda_- - \lambda_+}, \quad c_2 = \frac{\dot{\epsilon}(0) - \epsilon(0)\lambda_+}{\lambda_- - \lambda_+}.$$

Upon integration, one has for the scale factor

$$R(t) \propto e^{h_i t} \exp\left[\frac{c_1}{\lambda_+} e^{\lambda_+ t} + \frac{c_2}{\lambda_-} e^{\lambda_- t}\right], \tag{36}$$

which shows superinflationary expansion if initial conditions are taken such that c_1, c_2 are positive. This type of evolution for $R(t)$ on time has been obtained previously in a different context.[27] In this case the fluid when submitted to a small perturbation, goes away from the equilibrium point expanding much more rapidly than the de Sitter's. In the case of nodes, and when $\lambda_+ + \lambda_- = Q_X$ is positive (negative), the node will be unstable (stable).

B. Attractors and repellors

We study here the behavior of the scale factor near a sink (an asymptotically stable attractor) and a source (an asympotically unstable repellor). The solutions of the characteristic equation are complex,

$$\lambda_{\pm} = \frac{Q_X \pm i\sqrt{|\Delta|}}{2},$$

where $\Delta = Q_X^2 + 4Q_H$. Then the solution of (35) is

$$h = c_1 e^{\frac{Q_X}{2}t} \sin \frac{\sqrt{|\Delta|}}{2}(t + c_2).$$

The integration constants can be determined through the initial conditions. They read as

$$c_2 = \frac{2}{\sqrt{|\Delta|}} \tan^{-1}\left[\frac{\epsilon(0)\sqrt{|\Delta|}}{2\dot{\epsilon}(0) - \epsilon(0)Q_x}\right]$$

and

$$c_1 = \frac{\epsilon(0)}{\sin\,(\sqrt{|\Delta|}/2)c_2}.$$

Integrating the equation for h, one follows that

$$R(t) \propto e^{h_i t} \exp\left[\frac{2c_1}{Q_x^2 + |\Delta|}\left(Q_x \sin\frac{\sqrt{|\Delta|}}{2}(t + c_2) - \sqrt{|\Delta|}\cos\frac{\sqrt{|\Delta|}}{2}(t + c_2)\right)\right]. \tag{37}$$

For $Q_X < 0$ we have an attractor (the scale factor undergoes an oscillatory approach to the de Sitter solution) and for $Q_X > 0$ it is a source, i.e., the scale factor deviates from the de Sitter solution.

C. Degenerate nodes

In this case $\Delta = 0$ and $\lambda_+ = \lambda_- = \lambda = Q_X/2$. The solution of (35) is

$$h = c_1 e^{\lambda t} + c_2 t e^{\lambda t}.$$

Because of the initial conditions the integration constants are

$$c_1 = \epsilon(0), \quad \text{and} \quad c_2 = \dot{\epsilon}(0) - \lambda\epsilon(0).$$

Integration of the expression for h leads to

$$R(t) \sim e^{h_i t} \exp\left[\frac{e^{\lambda t}}{\lambda}\left(\epsilon(0) + (\dot{\epsilon}(0) - \lambda\epsilon)\left(t - \frac{1}{\lambda}\right)\right)\right], \tag{38}$$

hence $R(t)$ approaches to or separates from the de Sitter solution depending on the sign of λ. The rate of evolution is faster than in the de Sitter case.

D. Energy conditions

The weak energy condition (WEC) states that $T_{ab}W^aW^b \geq 0$, where T_{ab} is the energy-momentum tensor given by (1) and W^a a generic timelike vector. In our model this condition reduces to

$$\rho + \Lambda \geq 0. \tag{39}$$

The dominant energy condition (DEC) imposes $T_{ab}W^aW^b \geq 0$ and $-T^{ab}W_a$ to be a non-spacelike vector which is equivalent to $T_{00} \geq |T_{ab}|$.[28] This conditions is fulfilled in our case solely if

$$-\rho \leq p + \Pi \leq \rho + 2\Lambda. \tag{40}$$

Finally, the strong energy condition (SEC) requires that $T_{ab}W^aW^b+\frac{1}{2}T^a_a\geqslant 0$ which amounts to

$$\rho-2\Lambda+3p+3\Pi\geqslant 0. \tag{41}$$

These conditions can be rewritten in terms of H and $\dot{H}$ as

$$\begin{aligned}&\text{WEC:}\quad H^2\geqslant 0,\\ &\text{SEC:}\quad H^2+\dot{H}\leqslant 0,\\ &\text{DEC:}\quad \dot{H}\leqslant 0\quad\text{and}\quad 3H^2+\dot{H}\geqslant 0.\end{aligned}$$

As occurs in the standard inflationary scenarios the de Sitter solutions with $\Lambda\geqslant 0$ satisfy the WEC and DEC but not SEC.

VI. CONCLUSIONS

We have carried out a detailed analysis on the stability of de Sitter and static cosmological models, both in the truncated and full theory for the viscous transport equation (with and without a cosmological constant). We have shown that the conditions for the hydrodynamic approach and the nonthermalizing condition in a de Sitter expansion can be fulfilled simultaneously for sufficiently early times. When *no* cosmological constant is considered the stability analysis for the de Sitter solutions leads to similar results in all the cases, i.e., the models are *unstable* only for $m>1/2$. It is remarkable that this result holds for both the truncated and the full version of ET. On the other hand, when a *positive* cosmological constant is included we see that the models can be stable for $m=1$ if Λ is bounded from below. It remains to be proved that this result holds for a generic $m>1/2$ other than 1.

We have stressed the fact that for a radiation gas a different thermodynamic approach exists, depending on whether the particle number density is taken as an independent variable or not. In the case of a power-law for the temperature it exists a relationship between γ and r.

(Received 18 December 1995; accepted for publication 29 February 1996)

Generic caustics in gravitational lensing occur locally either as folds or cusps. This paper rigorously proves that the total number of cusps, N_{cusps}, due to g point masses on a single plane having non-normalized external shear $\gamma>0$ and continuous matter with constant density σ_c, is bounded as follows: $0\leqslant N_{cusps}\leqslant 12g^2$. For vanishing shear $\gamma=0$ we obtain the result $0\leqslant N_{cusps}\leqslant 12g(g-1)$. Consequences of these bounds for the global geometry of caustics are discussed. It is also shown that if $\gamma\geqslant 0$ and σ_c is sufficiently large, then all cusps can be eliminated, that is, $N_{cusps}=0$. The paper also includes equations for calculating all the bi-caustics (i.e., curves yielding the positions of cusps during a one-parameter evolution) of a single point-mass lens with continuous matter and shear. The methods of the paper are based on a new approach to point-mass gravitational lensing using complex quantities and the theory of resultants. © *1996 American Institute of Physics.*

I. INTRODUCTION

This paper is part of a series of mathematical studies aimed at investigating the global properties of caustics in gravitational lensing. The global geometry of caustics produced by general multiplane gravitational lens systems has recently been studied by Petters.[1] The latter gave counting formulas for general cusps as well as cusps of the first and second kinds. Currently, however, very little is known concerning the range of possible values for the number of cusps. In this paper, we determine bounds on the number of cusps due to single plane point-mass lens systems with continuous matter and external shear. We add that the overall issue of counting cusps is not only of mathematical interest, but also physically relevant. For example, Wambsganss, Witt, and Schneider[2] have shown that for point-mass lens systems with low surface mass density as much as 40% of all magnification events in a light curve are due to point sources passing outside cusps.

II. BOUNDS ON NUMBER OF CUSPS

Let $\mathbf{x}_1,\ldots,\mathbf{x}_g$ be distinct points in the plane and let γ, σ_c, and $m_1,\ldots,m_g$ be non-negative real numbers. The map $\eta:\mathbf{R}^2-\{\mathbf{x}_1,\ldots,\mathbf{x}_g\}\to\mathbf{R}^2$ given by

$$\eta(\mathbf{x})=\mathbf{x}-\sum_{i=1}^{g} m_i\frac{\mathbf{x}-\mathbf{x}_i}{|\mathbf{x}-\mathbf{x}_i|^2}-\begin{pmatrix}\sigma_c-\gamma & 0\\ 0 & \sigma_c+\gamma\end{pmatrix}\mathbf{x}$$

is a single-plane *lensing map* due to point masses m_i on a plane with non-normalized shear γ acting along one of the coordinate axes, and continuous matter having constant density σ_c (in units of the critical density). This lens system is called *underfocused* (resp., *overfocused*) if $0\leqslant\sigma_c<1$ (resp., if $\sigma_c>1$).

The central result of the paper is the following theorem.

0022-2488/96/37(6)/2920/14/$10.00

Theorem 1: *Let N_{cusps} be the total number of cusps of η.*
(*i*) *If $\gamma=0$, then $0\leqslant N_{cusps}\leqslant 12g(g-1)$.*
(*ii*) *If $\gamma>0$, then $0\leqslant N_{cusps}\leqslant 12g^2$.*
(*iii*) *If $\gamma\geqslant 0$ and σ_c is sufficiently large, then $N_{cusps}=0$.*

The upper bounds in Theorem 1 apply to the sum of the maximum number of cusps for the under– and overfocused cases. A detailed discussion of this point is deferred to Section IV and the Appendix. Theorem 1 and its proof are also illustrated explicitly in the Appendix for the case of a single point mass with continuous matter and shear.

Theorem 1 can be used to obtain bounds on the total curvature of the caustics due to single plane point mass lens systems with continuous matter and shear. Recently, Petters[3] showed that the total curvature K_{tot} of the caustics due to these lens systems is given by:

$$K_{tot}=-2\pi g+\pi N_{cusps}.$$

By Theorem 1(i,ii) the total curvature is then bounded as follows:

$$-2\pi g\leqslant K_{tot}\leqslant\begin{cases}2\pi g(6g-1) & \text{if } \gamma>0\\ 2\pi g(6g-7) & \text{if } \gamma=0.\end{cases} \tag{1}$$

The upper bounds in Theorem 1 apply to the sum of the maximum number of cusps for the under– and overfocused cases. A discussion of this point is deferred to Section IV. In addition, Theorem 1 and its proof are illustrated explicitly in the Appendix for the case of a single point mass with continuous matter and shear.

Theorem 1(iii) yields that *for σ_c sufficiently large, all cusps of the lensing map η can be eliminated.* The general issue of cusp elimination for differentiable maps was investigated by Levine[4] in 1965 and later by Eliashberg,[5] culminating in the Levine–Eliashberg theorem: a locally stable map from a compact, oriented, boundaryless n-manifold M into the plane is homotopic to a locally stable map with 0 or 1 cusp depending on whether the Euler characteristic of M is even or not. However, this theorem cannot be directly applied in lensing because if one starts with a generic lensing map, there is no guarantee that each stage of the theorem's homotopy is a lensing map. An immediate consequence of cusp elimination is that *for σ_c sufficiently large, the caustics consist of g ovals (Petters[6]) and, hence, the high-tail magnification cross-section is determined only by folds.*

III. PROOF OF MAIN THEOREM

The proofs of Theorem 1(i-ii) and Theorem 1(iii) are given in Section III.B and Section III.A, respectively. Throughout the sequel, suppose that $\sigma_c\neq 1$ unless stated to the contrary.

A. Elimination of Cusps

Whitney's singularity theory yields explicit equations characterizing cusp points in terms of derivatives of η (e.g., Lu[7]). Unfortunately, these equations are very complicated and hence difficult to analyze in order to investigate cusp elimination or to determine upper bounds for N_{cusps}. On the other hand, the natural ''rational form'' of the lensing map makes it readily accessible to complex variable techniques. Thus, following Witt[8] we express $\eta(\mathbf{x})$ in complex form ($z=x+iy$, $\mathbf{x}_i=z_i$) as follows:

$$\zeta(z)=(1-\sigma_c)z+\gamma\overline{z}+\sum_{\ell=1}^{g}\frac{m_\ell}{\overline{z}_\ell-\overline{z}}.$$

Critical curves of η are determined by the vanishing of the Jacobian determinant of the complex lensing map $\zeta(z)$:

$$\det\ J(z,\overline{z})=\frac{\partial\zeta}{\partial z}\frac{\overline{\partial\zeta}}{\partial z}-\frac{\partial\zeta}{\partial\overline{z}}\frac{\overline{\partial\zeta}}{\partial\overline{z}}=0.$$

Since $\partial\zeta/\partial z$ is real and $a^2=w\overline{w}$ ($a\in\mathbf{R}$, $w\in\mathbf{C}$) implies $w=|a|e^{i\varphi}$, we see that the above equation is solved by

$$\frac{\partial\zeta}{\partial\overline{z}}=\left|\frac{\partial\zeta}{\partial z}\right|e^{i\varphi},\varphi\in[0,2\pi),$$

or, equivalently,

$$|1-\sigma_c|e^{i\varphi}=\gamma+\sum_{\ell=1}^{g}\frac{m_\ell}{(\overline{z_\ell}-\overline{z})^2}. \tag{2}$$

Equation (2) can be rewritten as follows:

$$F(\overline{z})\equiv\prod_{\ell=1}^{g}(\overline{z_\ell}-\overline{z})^2+\sum_{\ell=1}^{g}\left(\hat{m}_\ell\prod_{\substack{r=1\\r\neq\ell}}^{g}(\overline{z_r}-\overline{z})^2\right),$$

where

$$\hat{m}_\ell=\frac{m_\ell}{(|1-\sigma_c|e^{i\varphi}-\gamma)}.$$

Set

$$P(\overline{z})=\prod_{\ell=1}^{g}(\overline{z_\ell}-\overline{z})^2.$$

Since

$$\lim_{\sigma_c\to\infty}F(\overline{z})=P(\overline{z})$$

the coefficients of $F(\overline{z})$ approach those of $P(\overline{z})$ as $\sigma_c\to\infty$. Hence, in the latter limit the zeros of $F(\overline{z})$ are in one-to-one correspondence with the zeros of $P(\overline{z})$, where zeros are counted with multiplicity, and approach the double zeros $z_1,\ldots,z_g$ of $P(\overline{z})$. This follows from the fact that the zeros of a complex polynomial are continuous functions of the coefficients of the polynomial.[9]

For σ_c sufficiently large, the critical curves lie in small discs about each of the points $z_1,\ldots,z_g$. Consider any such disc, say, $D(z_j;r_j)$ with radius r_j and centered at z_j. The larger the value of σ_c, the smaller one can choose r_j. Now, write the lensing map as

$$\zeta(z)=(1-\sigma_c)z+\gamma\overline{z}+\frac{m_j}{\overline{z_j}-\overline{z}}+R(\overline{z}),$$

where

$$R(\overline{z})=\sum_{\substack{\ell=1\\\ell\neq j}}^{g}\frac{m_\ell}{\overline{z_i}-\overline{z}}$$

Restricting $\zeta(z)$ to $D(z_j;r_j)$ and making r_j sufficiently small, we can approximate $\zeta(z)$ arbitrarily close by

$$\zeta_j(z)=(1-\sigma_c)z+\gamma\overline{z}+\frac{m_j}{\overline{z_j}-\overline{z}}.$$

However, $\zeta_j(z)$ is the Chang–Refsdal lens of mass m_i at position z_j. Witt and Petters[10] have shown that for $\sigma_c>\sqrt{4/3}\gamma+1$ the Chang–Refsdal lens has a single simple closed caustic curve with no cusps, while cusps exist (and more than one caustic is possible) for $\sigma_c\leqslant\sqrt{4/3}\gamma+1$. Observe that the caustic of $\zeta_j(z)$ is stable[11] if $\sigma_c>\sqrt{4/3}\gamma+1$. Thus, for large enough σ_c the caustics of $\zeta(z)$ have no cusps and consist of g simple closed curves.

B. Upper Bounds

1. Resultants and Equations for Cusps

We now show that cusps generated by the lensing map η can be characterized as common solutions of two polynomial equations. Resultants are then used to give a necessary and sufficient condition for these common solutions. See Erdl and Schneider[12] for applications of resultants to the study of double point-mass lenses on distinct planes.

A point z is mapped by ζ to a cusp point if and only if $(z,\overline{z})$ satisfies both of the following equations:

$$\det J(z,\overline{z})=0 \quad \text{and} \quad H_\zeta(z,\overline{z})=0,$$

where $H_\zeta(z,\overline{z})$ is the (complex) tangential vector at the caustic. It is given by

$$H_\zeta(z,\overline{z})=\frac{\partial\zeta}{\partial z}H_z+\frac{\partial\zeta}{\partial\overline{z}}\overline{H_z},$$

where

$$H_z=2i\frac{\partial\,\det J}{\partial\overline{z}}=-2i\frac{\partial\overline{\zeta}}{\partial\overline{z}}\frac{\partial^2\zeta}{\partial\overline{z}^2}$$

is the (complex) tangential vector at the critical curve. The partial derivatives are given as follows:

$$\frac{\partial\zeta}{\partial z}=(1-\sigma_c);\quad \frac{\partial\zeta}{\partial\overline{z}}=\gamma+\sum_{\ell=1}^{g}\frac{m_\ell}{(\overline{z_\ell}-\overline{z})^2};\quad \frac{\partial^2\zeta}{\partial\overline{z}^2}=\sum_{\ell=1}^{g}\frac{2m_\ell}{(\overline{z_\ell}-\overline{z})^3}.$$

Now let us denote

$$p_{\zeta,1}(\overline{z})=\frac{\partial\zeta}{\partial\overline{z}}\prod_{\ell=1}^{g}(\overline{z_\ell}-\overline{z})^2=\gamma\prod_{\ell=1}^{g}(\overline{z_\ell}-\overline{z})^2+\sum_{\ell=1}^{g}m_\ell\prod_{\substack{r=1\\r\neq\ell}}^{g}(\overline{z_r}-\overline{z})^2$$

and

$$p_{\zeta,2}(\overline{z})=\frac{\partial^2\zeta}{\partial\overline{z}^2}\prod_{\ell=1}^{g}(\overline{z_\ell}-\overline{z})^4=\prod_{\ell=1}^{g}(\overline{z_\ell}-\overline{z})\left(\sum_{\ell=1}^{g}m_\ell\prod_{\substack{r=1\\r\neq\ell}}^{g}(\overline{z_r}-\overline{z})^3\right).$$

Direct computation shows that the equations $\det J(z,\overline{z})=0$ and $H_{\zeta}(z,\overline{z})=0$ are equivalent, respectively, to

$$P_J(z,\overline{z})\equiv(\det J)\prod_{\ell=1}^{g}(\overline{z_\ell}-\overline{z})^2(z_\ell-z)^2=\left\{(1-\sigma_c)^2\prod_{\ell=1}^{g}(\overline{z_\ell}-\overline{z})^2\right\}\prod_{\ell=1}^{g}(z_\ell-z)^2-p_{\zeta,1}(\overline{z})$$
$$\times\left\{\gamma\prod_{\ell=1}^{g}(z_\ell-z)^2+\sum_{\ell=1}^{g}m_\ell\prod_{\substack{r=1\\r\neq\ell}}^{g}(z_r-z)^2\right\}=0, \tag{3}$$

and

$$P_H(z,\overline{z})\equiv\frac{i}{4}H_{\zeta}(z,\overline{z})\prod_{\ell=1}^{g}(z_\ell-z)^3(\overline{z_\ell}-\overline{z})^4=(1-\sigma_c)p_{\zeta,2}(\overline{z})$$
$$\times\left\{\gamma\prod_{\ell=1}^{g}(z_\ell-z)^3+\prod_{\ell=1}^{g}(z_\ell-z)\sum_{\ell=1}^{g}m_\ell\prod_{\substack{r=1\\r\neq\ell}}^{g}(z_r-z)^2\right\}$$
$$-p_{\zeta,1}^2(\overline{z})\sum_{\ell=1}^{g}m_\ell\prod_{\substack{r=1\\r\neq\ell}}^{g}(z_r-z)^3=0. \tag{4}$$

Next, consider any two polynomials in x_1 and x_2:

$$p(x_1,x_2)=a_0(x_2)+a_1(x_2)x_1+\ldots+a_m(x_2)x_1^m$$

and

$$q(x_1,x_2)=b_0(x_2)+b_1(x_2)x_1+\ldots+b_n(x_2)x_1^n.$$

The x_1-Sylvester resultant of p and q is defined by

$$\mathrm{Res}(x_2)=\det(\mathbf{A}_{m+n}),$$

where

$$\mathbf{A}_{m+n}=\begin{bmatrix}
a_m & a_{m-1} & a_{m-2} & \cdot & \cdot & \cdot & a_0 & 0 & 0 & \cdot\cdot & 0\\
0 & a_m & a_{m-1} & \cdot & \cdot & \cdot & a_1 & a_0 & 0 & \cdot\cdot & 0\\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots\\
0 & \cdots & 0 & a_m & a_{m-1} & a_{m-2} & \cdot & \cdot & \cdot & a_1 & a_0\\
b_n & b_{n-1} & \cdot & \cdot & \cdot & b_0 & 0 & \cdot & \cdot & \cdot & 0\\
0 & b_n & b_{n-1} & \cdot & \cdot & \cdot & b_0 & \cdot & \cdot & \cdot & 0\\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots\\
0 & \cdot & \cdot & \cdot & 0 & b_n & b_{n-1} & \cdot & \cdot & \cdot & b_0
\end{bmatrix}. \tag{5}$$

Note that the exact location of the nth and mth columns relative to each other depends on the values of n and m. The matrix $\mathbf{A}_{m+n}$ is described explicitly as follows: The ℓth–row of $\mathbf{A}_{m+n}$, where $1\leqslant\ell\leqslant n$, consists of $\ell-1$ zeros, followed by $a_m,a_{m-1},\ldots,a_0$, and the remainder of the row filled with zeros. For $n+1\leqslant\ell\leqslant m+n$, the ℓth–row has $\ell-n-1$ zeros followed

by $b_n, b_{n-1}, \ldots, b_0$, and the remaining slots having zeros. Note that $\mathrm{Res}(x_2)$ is a polynomial in x_2. The Resultant Theorem (e.g., Abhyankar[13,14]) yields that β satisfies $\mathrm{Res}(\beta)=0$ if and only if either $a_m(\beta)=0=b_n(\beta)$, or, $p(\alpha,\beta)=0=q(\alpha,\beta)$ for some α.

Using Eqs. (3) and (4), we can express $P_J(z,\overline{z})$ and $P_H(z,\overline{z})$ as polynomials in z with coefficients that are polynomials in $\overline{z}$:

$$P_J(z)=a_0(\overline{z})+a_1(\overline{z})z+\cdots+a_{2g}(\overline{z})z^{2g}$$

and

$$P_H(z)=b_0(\overline{z})+b_1(\overline{z})z+\cdots+b_{3g}(\overline{z})z^{3g}.$$

Note that if $\gamma=0$, then $b_{3g}=b_{3g-1}=0$.

Notation: *In order to capture the cases* $\gamma=0$ *and* $\gamma>0$ *simultaneously, let* $n(\gamma)=3g-2$ *if* $\gamma=0$ *and let* $n(\gamma)=3g$ *if* $\gamma>0$.

Rewrite P_H as:

$$P_H(z)=b_0(\overline{z})+b_1(\overline{z})z+\cdots+b_{n(\gamma)}(\overline{z})z^{n(\gamma)}.$$

The z-Sylvester resultant of P_J and P_H is then given by

$$\mathrm{Res}(\overline{z})=\det[\mathbf{A}_{2g+n(\gamma)}].$$

By the Resultant Theorem, $\overline{z_0}$ satisfies $\mathrm{Res}(\overline{z_0})=0$ if and only if either

$$a_{2g}(\overline{z_0})=0=b_{n(\gamma)}(\overline{z_0}),$$

or,

$$P_J(z_0,\overline{z_0})=0=P_H(z_0,\overline{z_0}).$$

Consequently, the cusps of the lensing map η form a subset of the zeros of $\mathrm{Res}(\overline{z})$.

2. Upper bounds for the degree of Res ($\overline{z}$)

By the Resultant Theorem we have $N_{cusps}\leqslant \deg[\mathrm{Res}(\overline{z})]$. To find an upper bound for the degree of $\mathrm{Res}(\overline{z})$, first write

$$\begin{aligned}\mathrm{Res}(\overline{z})&=\sum W_{i_0\ldots i_{2g}j_0\ldots j_{n(\gamma)}}a_0^{i_0}\ldots a_{2g}^{i_{2g}}b_0^{j_0}\ldots b_{n(\gamma)}^{j_{n(\gamma)}}\\&\equiv \mathrm{Res}(a_0,\ldots,a_{2g},b_0,\ldots,b_{n(\gamma)}).\end{aligned}\tag{6}$$

This expresses the resultant as a polynomial in the variables $a_0,\ldots,a_{2g},b_0,\ldots,b_{n(\gamma)}$ with integer coefficients $W_{i_0\ldots i_{2g}j_0\ldots j_{n(\gamma)}}$. Using the fact[15] that the resultant is homogeneous of degree $n(\gamma)$ in the coefficients a_ℓ and degree $2g$ in b_ℓ, we get:

$$\mathrm{Res}(ta_0,\ldots,ta_{2g},\lambda b_0,\ldots,\lambda b_{n(\gamma)})=t^{n(\gamma)}\lambda^{2g}\,\mathrm{Res}(a_0,\ldots,a_{2g},b_0,\ldots,b_{n(\gamma)}).\tag{7}$$

Hence:

$$\deg[\,\mathrm{Res}(\overline{z})]\leqslant[n(\gamma)]r+(2g)s,$$

where r and s are, respectively, the largest of the degrees of the polynomials $a_\ell(\overline{z})$ and $b_\ell(\overline{z})$.

We now determine r and s for $\gamma>0$ and $\gamma=0$. The coefficients in curly brackets in Eq. (3) are all of degree $2g$ for $\gamma\geqslant 0$. The first curly bracketed coefficient in Eq. (4) is of degree $4g-3$ if $\gamma>0$; the coefficient vanishes for $\gamma=0$. The second curly bracketed coefficient is of degree $4g-3$ independent of the value of γ. When $\gamma>0$ the third curly bracketed coefficient is of degree $4g$ (it is of degree $4g-4$ for $\gamma=0$). Hence, if $\gamma=0$, then $r=2g$ and $s=4g-3$. If $\gamma>0$, we get $r=2g$ and $s=4g$. Thus,

$$N_{cusps}\leqslant \deg[\ \mathrm{Res}(\overline{z})]\leqslant [n(\gamma)]r+(2g)s=\begin{cases}14g^2 & \text{if } \gamma>0\\ 14g^2-10g & \text{if } \gamma=0.\end{cases} \tag{8}$$

Remark: Computations of the resultant for $g=2$ with Mathematica[16] yield a degree of $56=14(2)^2$ for $\gamma>0$ and 32 for $\gamma=0$. In the latter case, Eq. (8) predicts an upper bound of $14(2)^2-10(2)=36$ for the degree of the resultant. This overestimates the degree by 4 for $g=2$.

We now show that for $\gamma=0$ the result of Eq. (8) improves as follows:

$$N_{cusps}\leqslant \deg[\ \mathrm{Res}(\overline{z})]\leqslant 14g^2-12g, \text{ if } \gamma=0. \tag{9}$$

Note that for $g=2$, Eq. (9) yields $14(2)^2-12(2)=32$ (see Remark above). Closer inspection of the coefficients a_ℓ and b_ℓ of the polynomials P_J and P_H reveals the following structure:

$$a_\ell(\overline{z})=a_{\ell,1}(\overline{z})+p_{\zeta,1}(\overline{z})a_{\ell,2} \quad \text{and} \quad b_r(\overline{z})=b_{r,1}(\overline{z})+p^2_{\zeta,1}(\overline{z})b_{r,2},$$

where $\ell=0,\ldots,2g$ and $r=0,\ldots,n(\gamma)$. Note that $a_{\ell,2}$ and $b_{r,2}$ are complex constants. Equations (3) and (4) imply:

$$P_J(z_j,\overline{z})=\sum_{\ell=0}^{2g} a_\ell(\overline{z})z_j^\ell=-p_{\zeta,1}(\overline{z})m_j\prod_{\substack{\ell=1\\ \ell\neq j}}^{g}(z_\ell-z_j)^2$$

and

$$P_H(z_j,\overline{z})=\sum_{\ell=0}^{n(\gamma)} b_\ell(\overline{z})z_j^\ell=-p^2_{\zeta,1}(\overline{z})m_j\prod_{\substack{\ell=1\\ \ell\neq j}}^{g}(z_\ell-z_j)^3.$$

Since $p_{\zeta,1}(\overline{z})$ (resp., $p^2_{\zeta,1}(\overline{z})$) is not a factor of

$$\sum_{\ell=0}^{2g} a_{\ell,1}(\overline{z})z_j^\ell \quad \left(\text{resp.,}\sum_{\ell=0}^{n(\gamma)} b_{\ell,1}(\overline{z})z_j^\ell\right),$$

we get

$$\sum_{\ell=0}^{2g} a_{\ell,1}(\overline{z})z_j^\ell=0 \quad \text{and} \quad \sum_{\ell=0}^{n(\gamma)} b_{\ell,1}(\overline{z})z_j^\ell=0.$$

The Resultant Theorem implies that if two single-variable polynomials have a common root, then their resultant vanishes.[17] Thus, $\mathrm{Res}(a_{0,1}(\overline{z}),\ldots,a_{2g,1}(\overline{z});b_{0,1}(\overline{z}),\ldots,b_{n(\gamma),1}(\overline{z}))=0$.

Now, Eq. (6) implies:

$$\begin{aligned}&\mathrm{Res}(a_0(\overline{z}),\ldots,a_{2g}(\overline{z});b_0(\overline{z}),\ldots,b_{n(\gamma)}(\overline{z}))\\&=\mathrm{Res}(a_{0,1}(\overline{z}),\ldots,a_{2g,1}(\overline{z});b_{0,1}(\overline{z}),\ldots,b_{n(\gamma),1}(\overline{z}))+(\text{sum of terms each containing at least one factor with a }(\ell,2)\text{–index})\\&=(\text{sum of terms each containing at least one factor with a }(\ell,2)\text{–index}).\end{aligned}\tag{10}$$

In addition,

$$\max[\deg\{a_{\ell,1}(\overline{z}):\ell=0,\ldots,2g\}]=2g,$$

$$\max[\deg\{p_{\zeta,1}^2(\overline{z})b_{\ell,2}:\ell=0,\ldots,n(\gamma)\}]=4g-4\ \text{for}\ \gamma=0,$$

$$\max[\deg\{p_{\zeta,1}(\overline{z})a_{\ell,2}:\ell=0,\ldots,2g\}]=2g-2\ \text{for}\ \gamma=0,$$

and

$$\max[\deg\{b_{\ell,1}(\overline{z}):\ell=0,\ldots,n(\gamma)\}]=4g-3.$$

Hence, the maximum of the degrees of the terms in Eq. (10) coincides with the degree of one of the following terms:

$$a_{0,1}^{i_0}\cdots a_{2g,1}^{i_{2g}}(p_{\zeta,1}^2b_{0,2})^{j_0}\cdots(p_{\zeta,1}^2b_{n(\gamma),2})^{j_{n(\gamma)}},\tag{11}$$

$$(p_{\zeta,1}a_{0,2})^{i_0}\cdots(p_{\zeta,1}a_{2g,2})^{i_{2g}}b_{0,1}^{j_0}\cdots b_{n(\gamma),1}^{j_{n(\gamma)}},$$

and

$$(p_{\zeta,1}a_{0,2})^{i_0}\cdots(p_{\zeta,1}a_{2g,2})^{i_{2g}}(p_{\zeta,1}^2b_{0,2})^{j_0}\cdots(p_{\zeta,1}^2b_{n(\gamma),2})^{j_{n(\gamma)}}.$$

By Eq. (7) we get $i_0+\cdots+i_{2g}=n(\gamma)$ and $j_0+\cdots+j_{n(\gamma)}=2g$, where $n(\gamma)=3g-2$ since $\gamma=0$. Of the above listed terms, the one at Eq.(11) has the largest degree:

$$(2g)(3g-2)+(4g-4)(2g)=14g^2-12g.$$

This establishes Eq.(9).

3. The polynomial $p_{\zeta,1}^g(\bar{z})$ is a factor of Res $(\bar{z})$

We begin with the following lemma:

Lemma 2: Let $p(z)=a_0+a_1z+\cdots+a_mz^m$ and $q(z)=b_0+b_1z+\cdots+b_nz^n$ be polynomials over **C**. If $p(\alpha)=C_0C_1\neq 0$ and $q(\alpha)=C_0C_2\neq 0$, then:

$$\mathrm{Res}(a_0,\ldots,a_{2g};b_0,\ldots,b_{n(\gamma)})=C_0\ \mathrm{Res}(C_1,a_1,\ldots,a_{2g};C_2,b_1,\ldots,b_{n(\gamma)}).$$

Proof: First, note that

$$\begin{aligned}&\mathrm{Res}(a_0,a_1,\ldots,a_m;b_0,b_1,\ldots,b_n)\\&\quad=\mathrm{Res}\left(C_0C_1-\sum_{\ell=1}^{m}a_\ell\alpha^\ell,a_1,\ldots,a_m;C_0C_2-\sum_{\ell=1}^{n}b_\ell\alpha^\ell,b_1,\ldots,b_n\right).\end{aligned}$$

Since the last column of the resultant matrix of p and q contains a_0 and b_0 with zeros everywhere else (see Eq.(5)), we can expand the resultant in the coefficients a_0 and b_0. This yields:

$$\begin{aligned}&\mathrm{Res}(a_0,a_1,\ldots,a_m;b_0,b_1,\ldots,b_n)\\&\quad=\mathrm{Res}(C_0C_1,a_1,\ldots,a_m;C_0C_2,b_1,\ldots,b_n)\\&\qquad+\mathrm{Res}\left(-\sum_{\ell=1}^{m}a_\ell\alpha^\ell,a_1,\ldots,a_m;-\sum_{\ell=1}^{n}b_\ell\alpha^\ell,b_1,\ldots,b_n\right).\end{aligned}$$

The last Resultant vanishes because the polynomials

$$p_1(z)=\left(-\sum_{\ell=1}^{m}a_\ell\alpha^\ell\right)+a_1z+\cdots+a_mz^m$$

and

$$q_1(z)=\left(-\sum_{\ell=1}^{n}b_\ell\alpha^\ell\right)+b_1z+\cdots+b_nz^n$$

satisfy $p_1(\alpha)=q_1(\alpha)=0$. The lemma now follows since

$$\mathrm{Res}(C_0C_1,a_1,\ldots,a_m;C_0C_2,b_1,\ldots,b_n)=C_0\mathrm{Res}(C_0,a_1,\ldots,a_m;C_2,b_1,\ldots,b_n).$$

Q.E.D. Lemma

Applying Lemma 2 to P_J and P_H with $C_1=1$ yields that

$$C_0=-p_{\zeta,1}(\overline{z})m_j\prod_{\substack{\ell=1\\ \ell\neq j}}^{g}(z_\ell-z_j)^2$$

factorizes out of $\mathrm{Res}(a_0(\overline{z}),\ldots,a_{2g}(\overline{z});b_0(\overline{z}),\ldots,b_{n(\gamma)}(\overline{z}))$ for $j=1,\ldots,g$. Hence

$$(-1)^gp_{\zeta,1}^g(\overline{z})\prod_{j=1}^{g}m_j\prod_{\substack{\ell=1\\ \ell\neq j}}^{g}(z_\ell-z_j)^2$$

is a factor of the resultant.

4. Eliminating zeros of Res $(\bar{z})$ that do not map to cusps

By the Resultant Theorem not all the zeros of $\mathrm{Res}(\overline{z})=\mathrm{Res}(a_0(\overline{z}),\ldots,a_{2g}(\overline{z});b_0(\overline{z}),\ldots,b_{n(\gamma)}(\overline{z}))$ may correspond to cusps. On a critical curve with $\sigma_c\neq 1$, we have $|\partial\zeta/\partial\overline{z}|=|1-\sigma_c|\neq 0$. Consequently, the zeros of the polynomial $p_{\zeta,1}(\overline{z})=0$ cannot lie on a critical curve with $\sigma_c\neq 1$. This implies that the upper bound on the number of cusps reduces as follows:

$$N_{cusps}\leqslant\deg[\,\mathrm{Res}(\overline{z})]\leqslant\begin{cases}14g^2-(2g)g=12g^2 & \text{if } \gamma>0\\ 14g^2-12g-(2g-2)g=12g^2-10g & \text{if } \gamma=0.\end{cases}\tag{12}$$

There can also be common zeros of $a_{2g}(\overline{z})$ and $b_{n(\gamma)}(\overline{z})$ that are not cusp points. In fact, if $\gamma=0$, then

$$a_{2g}(\overline{z})=(1-\sigma_c)^2\prod_{\ell=1}^{g}(\overline{z_\ell}-\overline{z})^2,$$

$$a_{2g-1}(\overline{z})=(1-\sigma_c)^2\left[-2\sum_{\ell=1}^{g}z_\ell\right]\prod_{\ell=1}^{g}(\overline{z_\ell}-\overline{z})^2,$$

and

$$b_{3g-2}(\overline{z})=(1-\sigma_c)\prod_{\ell=1}^{g}(\overline{z_\ell}-\overline{z})\left(\sum_{\ell=1}^{g}m_\ell\prod_{\substack{r=1\\r\neq\ell}}^{g}(\overline{z_r}-\overline{z})^3\right).$$

The coefficients a_{2g}, a_{2g-1} and b_{3g-2} have a common factor. If we now consider the Sylvester matrix (see Eq.(5)) and expand its determinant by the first two columns, then:

$$\begin{aligned}\det[\mathbf{A}_{2g+3g-2}]&=a_{2g}\det[\mathbf{A}_{1,1}]+b_{3g-2}\det[\mathbf{A}_{3g-2,1}]\\&=a_{2g}\det[\mathbf{A}_{1,1}]+b_{3g-2}[a_{2g-1}\det[\mathbf{A}_{3g-2,1}(1,1)]\\&\quad+a_{2g}\det[\mathbf{A}_{3g-2,1}(2,1)]+b_{3g-2}\det[\mathbf{A}_{3g-2,1}(3g-3,1)]],\end{aligned}\tag{13}$$

where $\mathbf{A}_{i,j}$ is the submatrix of $\mathbf{A}_{2g+3g-2}$ obtained by removing the ith row and jth column. Here, $\mathbf{A}_{i,j}(r,s)$ is the submatrix of $\mathbf{A}_{i,j}$ obtained by removing the rth row and sth column. We observe that in the expansion of Eq. (13) the factor

$$(1-\sigma_c)^2\prod_{\ell=1}^{g}(\overline{z_\ell}-\overline{z})^2$$

must factorize out of the resultant for the case $\gamma=0$. Hence, $\overline{z_1},\ldots,\overline{z_g}$ yield double zeros of the resultant. But no $\overline{z_\ell}$ ($\ell=1,\ldots,g$) can be mapped to a cusp point because as $\overline{z}\to\overline{z_\ell}$ the lensing map satisfies $|\zeta(\overline{z})|\to\infty$. Thus, for $\gamma=0$ we can exclude an additional $2g$ zeros from $\mathrm{Res}(\overline{z})$. The latter and Eq. (12) imply:

$$N_{cusps}\leqslant\begin{cases}12g^2 & \text{if } \gamma>0\\ 12g(g-1) & \text{if } \gamma=0\end{cases}.\tag{14}$$

IV. DISCUSSION

A comparison of Eq.(14) with some special well-studied cases (cf. Witt and Petters[18]) reveals that our upper bounds seem much higher than the actual maximum number of cusps for certain special configurations. The reason for this lies in Eq. (2), the parametric representation of critical curves. Two configurations of caustics always occur, namely, the underfocusing case ($0\leqslant\sigma_c<1$) and overfocusing one ($\sigma_c>1$). These two configurations have the same critical curves due to the factor $|1-\sigma_c|$ in the parametric representation. Assuming the same position of the stars, all models with $\sigma_c=t$ and $\sigma_c=2-t$, where $0\leqslant t<1$, have identical critical curves. Since we only set upper bounds on the number of points on the critical curves that are mapped to cusps, Eq. (14) apply simultaneously to the under– and overfocused cases. It is not known *a priori* whether a point on a critical curve is mapped to a cusp for the under– or overfocused situation. Hence, *the results of Eq. (14) yield upper bounds on the sum of the maximum number of cusps for the under- and overfocused cases.*

Example: If $g=1$ and $\gamma>0$, we obtain exactly 4 cusps (see Fig. 2a) for the underfocused case with $0\leqslant\sigma_c<1-\gamma$ (see Fig. 1), and a maximum of 8 cusps (see Fig. 2c) for the overfocused case

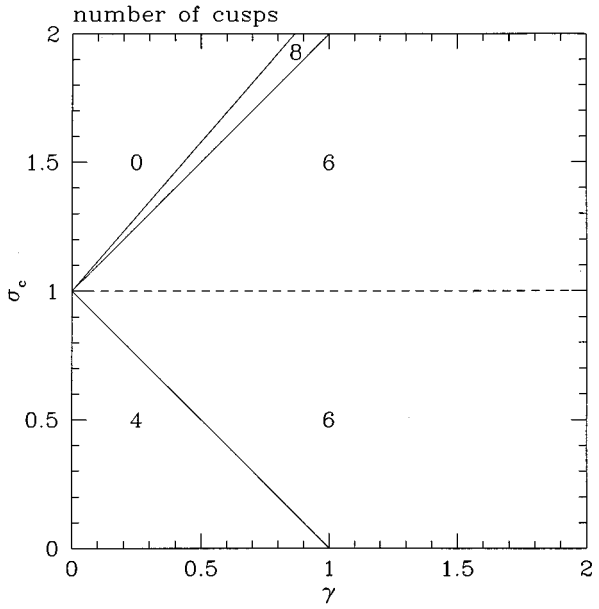

FIG. 1. Parameter space for the number of cusps for the one-point mass gravitational lens with shear γ and continuously distributed matter σ_c. The dashed line divides the under- and overfocused regions. The solid line below the dashed one is given by $\sigma_c = 1-\gamma$, while the line separating 8 and 6 cusps regions is $\sigma_c = 1+\gamma$. The boundary between the 0 and 8 cusps regions is $\sigma_c = 1+\sqrt{4/3}\gamma$.

with $1+\gamma < \sigma_c$ (cf. Witt and Petters[19]). For $1-\gamma < \sigma_c < 1+\gamma$ (note $\sigma_c \neq 1$) we get 6 cusps in the under– and overfocused cases (see Fig. 2b and 2d). The total sum agrees with our upper bound of 12: $4+8=12$ for $0 \leqslant \sigma_c < 1-\gamma$ ($\sigma_c > 1+\gamma$, respectively) and $6+6=12$ for $1-\gamma < \sigma_c < 1+\gamma$ (with $\sigma_c \neq 1$). The one-point mass lens with continuous matter and shear is detailed in the Appendix. We show that each zero z_0 of the resultant Res $(\overline{z})$ (see Eq. (A1)) is mapped by η in such a way that either $\eta(z_0)$ is a cusp for the underfocusing case, a cusp for the overfocusing case, or, is not a cusp point. For this reason, our upper bound on the number of cusps applies simultaneously to all three cases. In addition, we believe it is extremely difficult to separate cusps according to the under- and overfocused cases (see the Appendix), and, hence, to derive an upper bound for each such case. Therefore, it is not surprising that there are situations for which our upper bounds cannot be achieved. For instance, if $g=2$ and $\gamma=0$, then a maximum of 10 cusps occur for the separate cases of under– and overfocused lensing (Witt and Petters[20]). This yields a combined maximum of 20 cusps. But Eq.(14) predicts a combined maximum of 24.

Finally, the equations presented in Section III.B can be useful tools in the study of positions of cusps for the binary point-mass lens. Since there are already two binary events observed (Udalski *et al.*,[21] Alard, Mao and Guibert[22]), it is important to estimate the number of events that are passing close to cusps and to compute the corresponding cross section for the cusps (cf. Mao[23] and Schneider and Weiss[24]). This analysis is important because events passing outside a cusp of a binary lens can have a symmetrically shaped light curve, which is similar to events for a single point mass lens. Such cusp events can fake a single point mass event. This may lead to an underestimation of the fraction of binary or planetary systems in our galaxy (for an estimate about the expected fraction of binary events cf. Mao and Paczński[25]). Therefore, a careful analysis of the number or fraction of cusp-like events caused by binaries is needed. For such analysis we have to know the positions of the cusps in terms of the model parameters (e.g. mass of the star, separation of the binary etc.). The curves where cusps are located during a one-parameter evolution are called *bi-caustics* (see Petters[26]). For the case of the one-point mass lens with shear the bi-caustics (as a

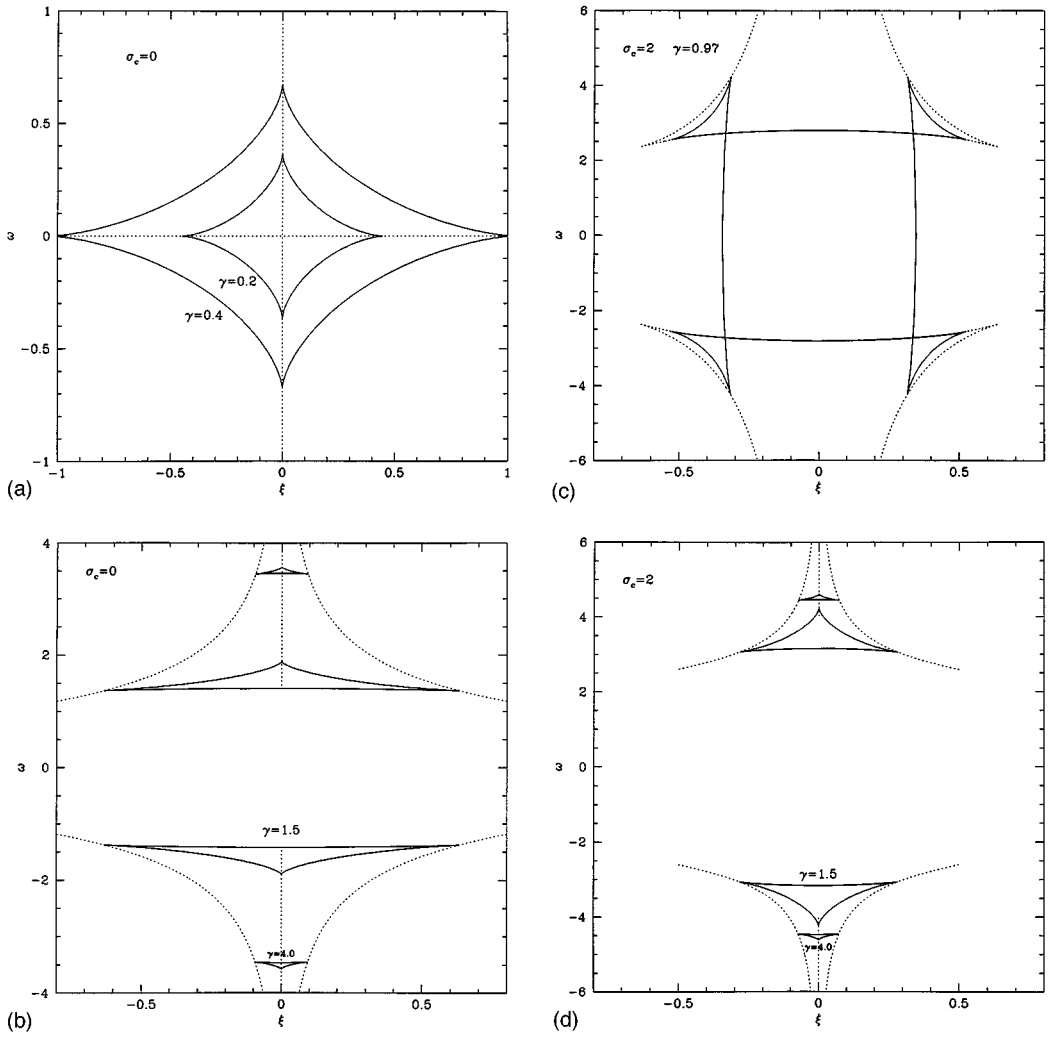

FIG. 2. Different caustics for the one point mass lens with different shears γ are shown. Each configuration corresponds to a parameter space in Fig. 1. The dotted lines indicate the bi-caustic curves where cusps may be located when γ is varied. The top (a) and (b) show the underfocused cases and the botton (c) and (d) show the overfocused cases. (Note that the case for 0 cusps is not shown in (c) but for $\gamma=\sqrt{3/4}$ the cusps merge at the point where the two bi-caustic curves merge. For smaller γ we obtain simply oval caustics.)

function of γ) are indicated as dotted lines in Fig. 2. Such curves can be evaluated with the tools presented here.

APPENDIX: ONE-POINT MASS LENS WITH CONTINUOUS MATTER AND SHEAR

In order to make Theorem 1 and its proof more transparent, we shall discuss the one-point mass lens with continuous matter $\sigma_c \geqslant 0$ and shear $\gamma > 0$. The lensing map is given by

$$\zeta(z)=(1-\sigma_c)z+\gamma\overline{z}-\frac{m}{\overline{z}},$$

where we set $m_1=m$ and $z_1=0$ for convenience. The derivatives of the lensing map are:

$$\frac{\partial\zeta}{\partial z}=(1-\sigma_c),\quad \frac{\partial\zeta}{\partial\overline{z}}=\gamma+\frac{m}{\overline{z}^2},\quad \frac{\partial^2\zeta}{\partial\overline{z}^2}=-\frac{2m}{\overline{z}^3}.$$

The points in the deflector plane that are mapped by ζ to cusps are the common solutions of

$$P_J(z,\overline{z})=[(1-\sigma_c)^2-\gamma^2)\overline{z}^2-\gamma m]z^2-m(m+\gamma\overline{z}^2)=0$$

and

$$P_H(z,\overline{z})=[(1-\sigma_c)\gamma m\overline{z}]z^3+[(1-\sigma_c)m^2\overline{z}]z-m(m+\gamma\overline{z}^2)^2=0.$$

Note that P_J is a polynomial of degree 2 in z, while P_H is of degree 3 in z. To solve these two polynomial equations simultaneously, we take the z-resultant of P_J and P_H in order to eliminate the z variable from the equations (see Section III.B(1)):

$$\begin{aligned}\mathrm{Res}(\overline{z})=&\gamma m^2[\overline{z}^4((1-\sigma_c)^2-\gamma^2)-2\gamma m\overline{z}^2-m^2][\overline{z}^2\gamma+m] \\ &\times[\overline{z}^8\gamma^2((1-\sigma_c)^2-\gamma^2)^2+\overline{z}^6\gamma m(3(1-\sigma_c)^4-7\gamma^2(1-\sigma_c)^2+4\gamma^4) \\ &+\overline{z}^4m^2(3(1-\sigma_c)^4-8\gamma^2(1-\sigma_c)^2+6\gamma^4)-\gamma m^3(3(1-\sigma_c)^2-4\gamma^2)\overline{z}^2+\gamma^2m^4].\end{aligned}\tag{A1}$$

The resultant polynomial is of degree 14. The two zeros of $p_{\zeta,1}(\overline{z})=\overline{z}^2\gamma+m$ cannot be mapped to cusps. At such zeros, the derivative $\partial\zeta/\partial\overline{z}$ vanishes, which is not allowed for points mapped to cusps (see Section III.B(4)). Hence, the under– and overfocused cases have a combined maximum of at most 12 cusps. Note that since the term $(1-\sigma_c)$ appears as a quadratic expression in Eq. (A1), the 12 zeros may be mapped to cusps for either the under– or overfocused case.

We emphasize that a zero $\overline{z}_0$ of the resultant cannot be mapped simultanously to a cusp for the under– and the overfocused cases. In fact, the tangential vector at the caustic is $H_\zeta=(1-t)H_z+(\partial\zeta/\partial\overline{z})\overline{H}_z$ for the case $\sigma_c=t$, and $H_\zeta=(t-1)H_z+(\partial\zeta/\partial\overline{z})\overline{H}_z$ for the case $\sigma_c=2-t$, where $0\leqslant t<1$ (see Section III.B(1)). Since $H_z,\overline{H}_z$, and $\partial\zeta/\partial\overline{z}$ are independent of t, both equations cannot vanish simultanously unless we require $H_z=0$. This can happen at a point z_0 on a critical curve only when $\partial^2\zeta/\partial\overline{z}^2=0$ at z_0. Such solutions z_0 are mapped by η to beak-to-beak singularities (Witt and Petters[27]), which result from the merger of two cusps. Thus, zeros of the resultant that may seem to map simultanously to cusps for the under– and the overfocused cases, are actually mapped to beak-to-beak singularities. The latter may be viewed as degenerate cusps.

The combined maximum of 12 cusps can readily be checked using Fig. 1. To each configuration (γ,σ_c) for the underfocused case $\sigma_c=t$, there exist a configuration for the overfocused case $\sigma_c=2-t$ with the same critical curve. The corresponding configuration is determined by reflecting about the dashed line. The sum of the number of cusps of both configurations cannot exceed 12 as is shown by Fig. 1. However, for some configurations the total sum is less than 12 which means that not all solutions of the resultant are necessarily mapped on a cusp. (We note that we have restricted ourselves to $\gamma>0$ and $\sigma_c>0$ because of physical reasons. However, in mathematical terms the values and Fig. 1 may also be expanded to negative values.)

For completeness we show that the polynomial of degree 8 in Eq. (A1) can be solved analytically as well when we split up the complex quantities $z=x+iy$ in real and imaginary parts. (Note that the polynomial of degree 4 can be readily solved.) The vanishing of the real and imaginary parts of Eq. (A1) yields solutions whose x-component satisfies

$$16\gamma^2[(1-\sigma_c)^2-\gamma^2]x^4+4\gamma m[3(1-\sigma_c)^2+2(1-\sigma_c)\gamma-4\gamma^2]x^2+3(1-\sigma_c)^2m^2=0 \quad \text{(A2)}$$

and y-component obeys

$$y^2=(2m+(1-\sigma_c+2\gamma)x^2)/(2\gamma-1+\sigma_c). \quad \text{(A3)}$$

We note that Eq. (A3) is directly obtained from the imaginary part of Eq. (A1), while we get Eq. (A2) after substituting (A3) into the real part of Eq. (A1). The solutions of (A2) and (A3) yield the eight positions in the deflector plane that might be mapped to cusps for the under- or overfocusing case.

Finally, Eqs. (A2) and (A3) can also be used to derive the so-called bi-caustic curves, which give the cusp locations. The off-axis cusps $\zeta_{cusp}=\xi_{cusp}+i\omega_{cusp}$ are given by

$$16\gamma^2[\gamma-(1-\sigma_c)]\xi_{cusp}^4+8\gamma^2m[8\gamma^2-9(1-\sigma_c)^2]\xi_{cusp}^2-27(1-\sigma_c)^4m^2[\gamma+(1-\sigma_c)]=0.$$

The equation for ω_{cusp} can be obtained by replacing ξ_{cusp} by ω_{cusp} and γ by $-\gamma$. The resulting bi-caustics relative to γ are indicated as dotted lines in Fig. 2. The bi-caustics equations are derived by eliminating x and y from the lens equation $(\xi-(1-\sigma_c)x-\gamma x)(x^2+y^2)+m=0$ with Eq.(A2) and Eq.(A3), via the resultant.

Abstract carrier space formalism for the irreducible tensor operators of compact quantum group algebras

J. F. Cornwell
School of Physics and Astronomy, University of St. Andrews, North Haugh, St. Andrews, Fife, KY16 9SS, Scotland, United Kingdom

(Received 18 October 1995; accepted for publication 22 January 1996)

Defining conditions for irreducible tensor operators associated with the unitary irreducible corepresentations of compact quantum group algebras are deduced within the framework of the abstract carrier space formalism. It is shown that there are *two* types of irreducible tensor operator, which may be called 'ordinary' and 'twisted'. The consistency of the definitions is demonstrated, and various consequences are deduced, including generalizations of the Wigner–Eckart theorem for both the ordinary and twisted operators. Examples of irreducible tensor operators for the standard deformation of the function algebra of the compact Lie group SU(2) are described to demonstrate the applicability of the new definitions. © *1996 American Institute of Physics.* [S0022-2488(96)03005-3]

I. INTRODUCTION

Most of the applications to physics of the theories of groups and Lie algebras depend on the Wigner–Eckart theorem, and so it is of great interest to see how this theorem generalizes to other algebraic structures. In a previous paper,[1] hereafter referred to as Paper I, a study of the definitions and properties of irreducible tensor operators for a *compact quantum group algebra* $\mathscr{A}$ was initiated by examining the case of the right regular and left regular coaction formalisms, and was extended to the case of operators associated with the corresponding quantum homogeneous spaces of $\mathscr{A}$. In the present paper this will be further extended to the case of operators acting in the abstract carrier spaces of irreducible corepresentations of $\mathscr{A}$.

The plan of the present paper is as follows. The remainder of this section will be devoted to putting the analysis that follows into context, first by reviewing briefly the situation for compact Lie groups, and then by indicating the background for the generalization of compact Lie groups to compact quantum group algebras. In the next section the most relevant properties of compact quantum group algebras will be summarized, particular attention being devoted to the essential role played by corepresentations. This summary is continued in Section III, where the two different types of tensor product of corepresentations and their associated Clebsch–Gordan coefficients are briefly discussed. The heart of the paper is reached in Section IV, where the irreducible tensor operators are defined and some of their immediate properties are deduced. In particular, it will be shown there that there are *two* types of irreducible tensor operators, which will be described as being *ordinary* and *twisted* respectively. The *motivations* for the definitions of Section IV are deliberately relegated to the Appendix in order to emphasize that the treatment given for the compact quantum group algebras in Sections IV and V are entirely self-contained. In Section V it is shown that there are *two* theorems of the Wigner–Eckart type, one for the 'ordinary' and one for the 'twisted' irreducible tensor operators. To illustrate the applicability of the new definitions of Section IV, examples of irreducible tensor operators for the standard deformation of the function algebra of the compact Lie group SU(2) are described in Section VI. Unless otherwise stated, the notations, definitions, and terminology are exactly the same as those given in Paper I, which also contains an account of the relationship of the present line of study to previous work on the applicability of the Wigner–Eckart theorem to quantum groups.

Because the space of functions defined on a compact Lie group $\mathscr{G}$ is a special example of a compact quantum group algebra, all the well-known results for compact Lie groups naturally

0022-2488/96/37(6)/2934/21/$10.00

reappear in this particular case. However, as the detailed analysis shows, the theory in the general situation is rather more subtle, and exhibits various complications. Nevertheless, the point of view of the present communication is best introduced by considering first the abstract carrier space formalism in this very well established and familiar context of a compact Lie group $\mathscr{G}$ (cf. Refs. 2, 3). Let V^p be a carrier space for a unitary irreducible representation $\mathbf{\Gamma}^p$ of $\mathscr{G}$, and let $\psi_1^p, \psi_2^p, \ldots, \psi_{d_p}^p$ be an ortho-normal basis for V^p. Define for each $T \in \mathscr{G}$ a linear operator $\Phi^p(T)$ that acts on V^p by the requirement that

$$\Phi^p(T)(\psi_n^p) = \sum_{m=1}^{d_p} \Gamma^p(T)_{mn} \psi_m^p \tag{1}$$

for all $T \in \mathscr{G}$ and all $n = 1,2,\ldots,d_p$. Let $\mathbf{\Gamma}^p$, $\mathbf{\Gamma}^q$, and $\mathbf{\Gamma}^r$ be any three unitary irreducible representations of $\mathscr{G}$. Then one can consider a set of irreducible tensor operators $Q_1^q, Q_2^q, \ldots, Q_{d_q}^q$ that each map V^p into V^r and which are such that

$$\Phi^r(T) Q_n^q \Phi^p(T)^{-1} = \sum_{m=1}^{d_q} \Gamma^q(T)_{mn} Q_m^q \tag{2}$$

for all $T \in \mathscr{G}$ and all $n = 1,2,\ldots,d_q$. In this case the Wigner–Eckart theorem deals with inner products $\langle , \rangle$ defined on V^r and states that the j,k, and ℓ dependence of $\langle \psi_\ell^r, Q_k^q(\psi_j^p) \rangle$ depends only on Clebsch–Gordan coefficients for the reduction of the tensor product $\mathbf{\Gamma}^p \otimes \mathbf{\Gamma}^q$ into its irreducible constituents $\mathbf{\Gamma}^r$.

In a minor extension of this formalism, one could introduce an inner product space V that is a direct sum of carrier spaces of certain unitary irreducible representations of $\mathscr{G}$ and which contains at least $V^p \oplus V^r$ (and which, in the extreme case, may contain one carrier space for every inequivalent irreducible representation of $\mathscr{G}$). Then, for each $T \in \mathscr{G}$ an operator $\Phi(T)$ can be defined which maps elements of V into V, and which acts as $\Phi^p(T)$ on V^p, as $\Phi^r(T)$ on V^r, and so on. The irreducible tensor operators are then required to each map V into V and to be such that $\Phi(T) Q_n^q \Phi(T)^{-1} = \Sigma_{m=1}^{d_q} \Gamma^q(T)_{mn} Q_m^q$ for all $T \in \mathscr{G}$ and all $n = 1,2,\ldots,d_q$. In this case the Wigner–Eckart theorem deals with inner products $\langle , \rangle$ defined on V, but is otherwise the same as above.

As emphasized in Paper I, one most important lesson that can be drawn from these simple group theoretical considerations concerns the *consistency* of the definitions of the basis vectors *and* of the irreducible tensor operators. As $\Phi^p(T)\Phi^p(T') = \Phi^p(TT')$ and $\mathbf{\Gamma}^p(T)\mathbf{\Gamma}^p(T') = \mathbf{\Gamma}^p(TT')$ for all $T, T' \in \mathscr{G}$, it follows that if (1) is valid for T and for T', then it is also valid for their product TT'. Similarly, and very significantly, by defining for each $T \in \mathscr{G}$ an operator $\Psi(T)$ by

$$\Psi(T)(Q) = \Phi^r(T) Q \Phi^p(T)^{-1} \tag{3}$$

for every operator Q that maps V^p into V^r, the definition (2) can be recast as

$$\Psi(T)(Q_n^q) = \sum_{m=1}^{d_q} \Gamma^q(T)_{mn} Q_m^q \tag{4}$$

for all $T \in \mathscr{G}$ and all $n = 1,2,\ldots,d_q$. As $\Psi(T)\Psi(T') = \Psi(TT')$ for all $T, T' \in \mathscr{G}$, it follows that if (4) is valid for T and for T', then it is also valid for their product TT'. Put another way, because of the similarity in form between (1) and (4), the *consistency* of the definition (2) of the irreducible tensor operators Q_n^q is ensured by the fact that they too form a basis for a carrier space, this time for $\mathbf{\Gamma}^q$. In the analysis that follows (cf. Section IV), essentially this argument will be used to

justify the definitions that will be given for the irreducible tensor operators of the compact quantum group algebras, the only essential difference being that the argument has to be cast in terms of *corepresentations* instead of representations.

As is well known, the set of functions defined on a Lie group $\mathscr{G}$ form a Hopf algebra, $\mathscr{A}$, and the dual $\mathscr{A}'$ of $\mathscr{A}$ is the universal enveloping algebra of the Lie algebra $\mathscr{L}$ of $\mathscr{G}$. Moreover, the structure of $\mathscr{G}$ can be encoded into the structure of $\mathscr{A}$, and, in particular, $\mathscr{A}$ is commutative. A 'deformation' (or 'quantization') of $\mathscr{A}'$ induces a corresponding deformation of $\mathscr{A}$, and will make $\mathscr{A}$ non-commutative as well as being non-cocommutative. Although most attention has been focused on the deformed Hopf algebras $\mathscr{A}'$, it has been demonstrated by the pioneering work of Woronowicz,[4–6] which itself has been refined and developed by Dijkhuizen and Koornwinder,[7–12] that it is of very great interest to produce a self-contained and direct study of generalizations of the Hopf algebras $\mathscr{A}$. This can be done by assuming that they have certain characteristic properties, and the resulting structures have been called *compact matrix pseudogroups* by Woronowicz,[4–6] and *compact quantum group algebras* by Dijkhuizen and Koornwinder.[7–12] It is these that provide the framework for the present paper, which, as intimated above, is devoted to the study of the irreducible tensor operators for compact quantum group algebras in the abstract carrier space formalism.

II. COREPRESENTATIONS OF COMPACT QUANTUM GROUP ALGEBRAS

It should be recalled (cf. Refs. 1, 7–12) that a *right* $\mathscr{A}$*-comodule* consists of a vector space V and a linear mapping π_V from V to $V\otimes\mathscr{A}$ such that

$$(\pi_V\otimes id)\circ\pi_V=(id\otimes\Delta)\circ\pi_V \tag{5}$$

and

$$((id\otimes\epsilon)\circ\pi_V)(v)=v\otimes 1_C \tag{6}$$

for all $v\in V$. The operation π_V is then said to be a *right coaction* and provides a *corepresentation* of $\mathscr{A}$ with carrier space V.

Of great importance are the finite-dimensional *irreducible* corepresentations, which, for a compact quantum group algebra $\mathscr{A}$, are assumed to form a *countable* set (up to equivalence). Moreover each such irreducible corepresentation is equivalent to a *unitary* corepresentation. Let π^p, for $p=1,2,\ldots$, denote the set of unitary irreducible corepresentations of $\mathscr{A}$ (one being chosen from every equivalence class), and let V^p be a carrier space of π^p, assumed to be of finite dimension d_p, with basis $v_1^p, v_2^p, \ldots, v_{d_p}^p$. Then there exists a uniquely determined set of elements π_{jk}^p of $\mathscr{A}$ (for $j,k=1,2,\ldots,d_p$), called the *matrix coefficients* of π^p, which are such that

$$\pi^p(v_j^p)=\sum_{k=1}^{d_p} v_k^p\otimes\pi_{kj}^p \tag{7}$$

for all $j=1,2,\ldots,d_p$. The requirements (5) and (6) then imply that

$$\Delta(\pi_{jk}^p)=\sum_{\ell=1}^{d_p}\pi_{j\ell}^p\otimes\pi_{\ell k}^p \tag{8}$$

and

$$\epsilon(\pi_{jk}^p)=\delta_{jk} \tag{9}$$

(for $j,k=1,2,\ldots,d_p$). The unitary requirement on π^p implies that

$$S(\pi^p_{jk}) = \pi^{p*}_{kj}, \tag{10}$$

$$\sum_{\ell=1}^{d_p} M(\pi^{p*}_{\ell j} \otimes \pi^p_{\ell k}) = \delta_{jk} 1_{\mathscr{A}}, \tag{11}$$

and

$$\sum_{\ell=1}^{d_p} M(\pi^p_{j\ell} \otimes \pi^{p*}_{k\ell}) = \delta_{jk} 1_{\mathscr{A}} \tag{12}$$

(for all $j,k=1,2,\ldots,d_p$). For a compact quantum group algebra $\mathscr{A}$ this set of matrix coefficients is assumed (cf. Refs. 1, 7–12) to form a basis for $\mathscr{A}$.

Let $\mathscr{P}^p_{ij}$ be a set of projection operators for V^p that are defined by

$$\mathscr{P}^{\,p}_{ij}(v^p_k) = \delta_{ik} v^p_j \tag{13}$$

for all $i,j,k=1,2,\ldots,d_p$. Let π^r be another unitary irreducible corepresentation of $\mathscr{A}$, and let $\mathscr{L}^{pr}$ be the set of linear operators that map elements of V^p into V^r. A basis for $\mathscr{L}^{pr}$ is provided by the set of operators $\mathscr{P}^{\,pr}_{ij}$ that are defined by

$$\mathscr{P}^{\,pr}_{ij}(v^p_k) = \delta_{ik} v^r_j \tag{14}$$

for all $i,k=1,2,\ldots,d_p$ and all $j=1,2,\ldots,d_r$. Then

$$\mathscr{P}^{\,r}_{mn} \circ \mathscr{P}^{\,pr}_{k\ell} \circ \mathscr{P}^{\,p}_{ij} = \delta_{kj}\delta_{m\ell}\mathscr{P}^{\,pr}_{in} \tag{15}$$

for all $i,j,k=1,2,\ldots,d_p$ and all $\ell,m,n=1,2,\ldots,d_r$. If Q is any element of $\mathscr{L}^{pr}$, then

$$Q(v^p_k) = \sum_{j=1}^{d_r} q_{jk} v^r_j \tag{16}$$

for all $k=1,2,\ldots,d_p$, where q_{jk} are the complex numbers that are defined by

$$q_{jk} = \langle v^r_j, Q(v^p_k) \rangle \tag{17}$$

for all $k=1,2,\ldots,d_p$ and all $j=1,2,\ldots,d_r$, $\langle,\rangle$ being the inner product of V^r. Moreover one can write

$$Q = \sum_{i=1}^{d_p} \sum_{j=1}^{d_r} q_{ji} \mathscr{P}^{\,pr}_{ij}. \tag{18}$$

III. TENSOR PRODUCTS AND CLEBSCH–GORDAN COEFFICIENTS

A. Ordinary and twisted tensor products

With the *ordinary tensor product* of two irreducible corepresentations π^p and π^q of $\mathscr{A}$ (with carrier spaces V^p and V^q respectively) being defined as the mapping $\pi^p \boxtimes \pi^q$ from $V^p \otimes V^q$ to $V^p \otimes V^q \otimes \mathscr{A}$ that is such that

$$\pi^p \boxtimes \pi^q = (id \otimes id \otimes M) \circ (id \otimes \sigma \otimes id) \circ (\pi^p \otimes \pi^q), \tag{19}$$

it is easily shown from (7) that the corresponding matrix coefficients are given by

$$(\pi^p \boxtimes \pi^q)_{st,jk} = M(\pi^p_{sj} \otimes \pi^q_{tk}) \tag{20}$$

for all $j,s = 1,2,\ldots,d_p$ and all $k,t = 1,2,\ldots,d_q$.

Similarly, with the *twisted tensor product* of π^p and π^q being defined as the mapping $\pi^p \widetilde{\boxtimes} \pi^q$ from $V^p \otimes V^q$ to $V^p \otimes V^q \otimes \mathscr{A}$ that is such that

$$\pi^p \widetilde{\boxtimes} \pi^q = (id \otimes id \otimes M) \circ (id \otimes id \otimes \sigma) \circ (id \otimes \sigma \otimes id) \circ (\pi^p \otimes \pi^q), \tag{21}$$

it is also easily shown from (7) that the corresponding matrix coefficients are given by

$$(\pi^p \widetilde{\boxtimes} \pi^q)_{st,jk} = M(\pi^q_{tk} \otimes \pi^p_{sj}) \tag{22}$$

for all $j,s = 1,2,\ldots,d_p$ and all $k,t = 1,2,\ldots,d_q$.

B. Clebsch–Gordan coefficients

Suppose that the ordinary tensor product $\pi^p \boxtimes \pi^q$ is reducible [and hence is completely reducible (cf. Refs. 1, 7–12)], and that n^r_{pq} is the number of times that the irreducible corepresentation π^r (or a corepresentation equivalent to it) appears in its reduction. If the carrier spaces V^p and V^q have basis elements $v^p_1, v^p_1, \ldots, v^p_{d_p}$ and $v^q_1, v^q_1, \ldots, v^q_{d_q}$ respectively, then the set of elements $v^p_j \otimes v^q_k$ form a basis for $V^p \otimes V^q$, the carrier space of $\pi^p \boxtimes \pi^q$, and consequently appropriate linear combinations form bases for all the irreducible corepresentations π^r that appear in the reduction of the tensor product. Let $w^{r,\alpha}_{\ell}$ be such a combination, so that

$$w^{r,\alpha}_{\ell} = \sum_{j=1}^{d_p} \sum_{k=1}^{d_q} \left(\begin{matrix} p & q \\ j & k \end{matrix} \middle| \begin{matrix} r & , & \alpha \\ \ell & & \end{matrix} \right) v^p_j \otimes v^q_k, \tag{23}$$

for $\ell = 1,2,\ldots,d_r$, and $\alpha = 1,2,\ldots,n^r_{pq}$, and

$$(\pi^p \boxtimes \pi^q)(w^{r,\alpha}_{\ell}) = \sum_{u=1}^{d_r} w^{r,\alpha}_u \otimes \pi^r_{ul}, \tag{24}$$

for $u = 1,2,\ldots,d_r$, and $\alpha = 1,2,\ldots,n^r_{pq}$. The inverse of (23) is

$$v^p_j \otimes v^q_k = \sum_r \sum_{\alpha=1}^{n^r_{pq}} \sum_{\ell=1}^{d_r} \left(\begin{matrix} r & , & \alpha \\ \ell & & \end{matrix} \middle| \begin{matrix} p & q \\ j & k \end{matrix} \right) w^{r,\alpha}_{\ell}, \tag{25}$$

for $j = 1,2,\ldots,d_p$ and $k = 1,2,\ldots,d_q$. The *Clebsch–Gordan coefficients* defined in (23) form the elements of a $d_p \times d_q$ matrix $\mathbf{C}$, while the inverse coefficients defined in (25) form the elements of $\mathbf{C}^{-1}$, where

$$\mathbf{C}^{-1}(\pi^p \boxtimes \pi^q)\mathbf{C} = \sum_r \oplus n^r_{pq} \pi^r. \tag{26}$$

This implies that

$$(\pi^p \boxtimes \pi^q)_{is,jt} = \sum_r \sum_{\alpha=1}^{n^r_{pq}} \sum_{\ell,u=1}^{d_r} \left(\begin{matrix} p & q \\ i & s \end{matrix} \middle| \begin{matrix} r & , & \alpha \\ u & & \end{matrix} \right) \pi^r_{u\ell} \left(\begin{matrix} r & , & \alpha \\ \ell & & \end{matrix} \middle| \begin{matrix} p & q \\ j & t \end{matrix} \right) \tag{27}$$

for $i,j = 1,2,\ldots,d_p$, and $s,t = 1,2,\ldots,d_q$.

Thus, by (20), the product of any two basis elements of $\mathscr{A}$ can be expressed in terms of Clebsch–Gordan coefficients, for

$$M(\pi^p_{ij}\otimes\pi^q_{st})=\sum_r\sum_{\alpha=1}^{n^r_{pq}}\sum_{\ell,u=1}^{d_r}\left(\begin{matrix}p & q & r & , & \alpha\\ i & s & u & & \end{matrix}\right)\pi^r_{u\ell}\left(\begin{matrix}r & , & \alpha & p & q\\ \ell & & & j & t\end{matrix}\right) \tag{28}$$

for $i,j=1,2,\ldots,d_p$, and $s,t=1,2,\ldots,d_q$. This is essentially the converse of the relation (I.137),[1] that is, of

$$\begin{aligned}h(\pi^r_{ul}{}^{*}\pi^q_{tk}\pi^p_{sj}) \quad = \quad & \sum_{\alpha=1}^{n^r_{qp}}\sum_{v=1}^{d_r}\left(\begin{matrix}r & , & \alpha & q & p\\ \ell & & & k & j\end{matrix}\right)\left(\begin{matrix}q & p & r & , & \alpha\\ t & s & v & & \end{matrix}\right)\\ & \times\{((\mathbf{F}^r)^{-1})_{vu}/tr((\mathbf{F}^r)^{-1})\}\end{aligned} \tag{29}$$

for all $j=1,2,\ldots,d_p$, $k=1,2,\ldots,d_q$, and $l=1,2,\ldots,d_r$. Here h is the Haar functional and $\mathbf{F}^r$ is a non-singular $d_r\times d_r$ matrix with the property that

$$\sum_{k=1}^{d_r}F^r_{jk}\pi^r_{k\ell}=\sum_{k=1}^{d_r}\pi^{r\ddagger}_{jk}F^r_{k\ell} \tag{30}$$

(for all $j,\ell=1,2,\ldots,d_r$), where $\pi^{r\ddagger}$ is the doubly contragredient partner of π^r.

IV. THE IRREDUCIBLE TENSOR OPERATORS

A. Introduction

Let π^p,π^q, and π^r be unitary irreducible right coactions of $\mathscr{A}$ of dimensions d_p, d_q, and d_r respectively, and with matrix coefficients π^p_{jk}, π^q_{jk}, and π^r_{jk} respectively. Let $\mathscr{L}^{pr}$ be the vector space of operators introduced in Section II. It will be shown that there exist two types of irreducible tensor operators that are members of $\mathscr{L}^{pr}$ and which belong to the corepresentation π^q. These will be denoted by Q^q_j and $\widetilde{Q}^q_j$ (for $j=1,2,\ldots,d_q$), and will be called *ordinary* and *twisted* irreducible tensor operators respectively. Naturally the two types of irreducible tensor operators coincide in the special case in which $\mathscr{A}$ is commutative.

It will also be shown that the definitions of both of these types of irreducible tensor operators are easily extended to the case in which V is a vector space that is a direct sum of carrier spaces of unitary irreducible corepresentations of $\mathscr{A}$ and which contains at least $V^p\oplus V^r$.

B. Definitions of irreducible tensor operators

1. Definition of the ordinary irreducible tensor operators Q^q_j

The *ordinary irreducible tensor operators* Q^q_j belonging to the unitary irreducible right coaction π^q of $\mathscr{A}$ are *defined* to be members of $\mathscr{L}^{pr}$ that satisfy the condition

$$((id\otimes M)\circ(\pi^r\otimes id)\circ(Q^q_j\otimes S)\circ\pi^p)(v^p)=\sum_{k=1}^{d_q}Q^q_k(v^p)\otimes\pi^q_{kj} \tag{31}$$

for all $v^p\in V^p$ and all $j=1,2,\ldots,d_q$. Clearly this definition involves *only* quantities defined for $\mathscr{A}$ and its coactions. Both sides (31) are members of $V^r\otimes\mathscr{A}$. [The motivation behind the definition (32) is explained in Section 2 of the Appendix.]

It will now be shown that (31) provides a *consistent* definition, in that it can be re-expressed by saying that the operators Q^q_j (for $j=1,2,\ldots,d_q$) form the basis of an irreducible subspace of

a carrier space for a certain right coaction of $\mathscr{A}$. This right coaction will be denoted by $\pi_{\mathscr{L}^{pr}}$, as its carrier space is $\mathscr{L}^{pr}$. The *definition* of $\pi_{\mathscr{L}^{pr}}$ is then that it is the mapping of $\pi_{\mathscr{L}^{pr}}$ into $\pi_{\mathscr{L}^{pr}}\otimes\mathscr{A}$ specified by

$$\pi_{\mathscr{L}^{pr}}(Q)=\sum_{i,j=1}^{d_p}\sum_{m,n=1}^{d_r}(q_{ni}\mathscr{P}^{pr}_{jm})\otimes M(\pi^{\ r}_{mn}\otimes S(\pi^{\ p}_{ij})), \tag{32}$$

for all $Q\in\mathscr{L}^{pr}$, where q_{ni} and $\mathscr{P}^{pr}_{jm}$ are defined in (17) and (14). [The motivation for the definition (33) is given in Section 2 of the Appendix.]

It is then quite easily shown that $\pi_{\mathscr{L}^{pr}}$ satisfies (5) and (6) (with π_V and V replaced by $\pi_{\mathscr{L}^{pr}}$ and $\mathscr{L}^{pr}$ respectively), and hence $\pi_{\mathscr{L}^{pr}}$ is indeed a right coaction with carrier space $\mathscr{L}^{pr}$. Moreover, it is easily demonstrated that

$$(\pi_{\mathscr{L}^{pr}}(Q))(v^p\otimes 1_{\mathscr{A}})=((id\otimes M)\circ(\pi^r\otimes id)\circ(Q\otimes S)\circ\pi^p)(v^p) \tag{33}$$

for all $v^p\in V^p$ and all $Q\in\mathscr{L}^{pr}$. Thus (31) and (33) imply that the definition (31) can be written equivalently as

$$\pi_{\mathscr{L}^{pr}}(Q^q_j)=\sum_{k=1}^{d_q}Q^q_k\otimes\pi^q_{kj} \tag{34}$$

(for all $j=1,2,\ldots,d_q$). Because (34) is similar in form to (7), and as $\pi_{\mathscr{L}^{pr}}$ is a right coaction with carrier space $\mathscr{L}^{pr}$, the consistency of the definition (31) is now ensured.

Now consider the situation in which V is a vector space that is a direct sum of carrier spaces of unitary irreducible corepresentations of $\mathscr{A}$ and which contains at least $V^p\oplus V^r$. Let π be the mapping of V into $V\otimes\mathscr{A}$ that coincides with π^p on V^p and with π^r on V^r, and which acts similarly on any other carrier spaces that might be contained in V. Then the generalization of (31) is clearly

$$((id\otimes M)\circ(\pi\otimes id)\circ(Q^q_j\otimes S)\circ\pi)(v)=\sum_{k=1}^{d_q}Q^q_k(v)\otimes\pi^q_{kj} \tag{35}$$

for all $v\in V$ and all $j=1,2,\ldots,d_q$. [The consistency of the definition (35) is an immediate consequence of the consistency of (31)].

2. Definition of the twisted irreducible tensor operators $\tilde{Q}^q_j$

The *twisted irreducible tensor operators* $\widetilde{Q}^q_j$ belonging to the unitary irreducible right coaction π^q of $\mathscr{A}$ are *defined* to be members of $\mathscr{L}^{pr}$ that satisfy the condition

$$((id\otimes M)\circ(id\otimes\sigma)\circ(\pi^r\otimes id)\circ(\widetilde{Q}^{qR}_j\otimes S^{-1})\circ\pi^p)(v^p)=\sum_{k=1}^{d_q}\widetilde{Q}^q_k(v^p)\otimes\pi^q_{kj} \tag{36}$$

for all $v^p\in V^p$ and all $j=1,2,\ldots,d_q$. This definition (36) differs from the corresponding definition (31) only in the replacement of M by $M\circ\sigma$ *and* S by S^{-1} (neither of which have any effect in the special case in which $\mathscr{A}$ is commutative). (See Section 2 of the Appendix for further discussion of this pair of substitutions. It should be recorded that Rittenberg and Scheunert[13] noted previously, in the context of what was essentially the abstract carrier space formalism of Section I as generalized to irreducible *representations* of the dual $\mathscr{A}'$, that these substitutions do produce another type of irreducible tensor operator, but they did not pursue this observation.)

The demonstration that (36) provides a *consistent* definition again involves showing that it can be re-expressed by saying that the operators $\widetilde{Q}_j^q$ (for $j=1,2,\ldots,d_q$) form the basis of an irreducible subspace of a carrier space for another right coaction $\widetilde{\pi}_{\mathscr{L}^{pr}}$ of $\mathscr{A}$. This right coaction is *defined* as the mapping of $\mathscr{L}^{pr}$ into $\mathscr{L}^{pr}\otimes\mathscr{A}$ specified by

$$\widetilde{\pi}_{\mathscr{L}^{pr}}(Q)=\sum_{i,j=1}^{d_p}\sum_{m,n=1}^{d_r}(q_{ni}\mathscr{P}^{pr}_{jm})\otimes M(S^{-1}(\pi^p_{ij}\otimes\pi^r_{mn})) \tag{37}$$

for all $Q\in\mathscr{L}^{pr}$. [The motivation for the definition (37) is given in Section 3 of the Appendix]. Then

$$(\widetilde{\pi}_{\mathscr{L}^{pr}}(Q))(v^p\otimes 1_{\mathscr{A}})=((id\otimes M)\circ(id\otimes\sigma)\circ(\pi^r\otimes id)\circ(Q\otimes S^{-1})\circ\pi^p)(v^p) \tag{38}$$

for all $v^p\in V^p$ and all $Q\in\mathscr{L}^{pr}$. Thus (37) and (39) imply that the definition (37) can be written equivalently as

$$\widetilde{\pi}_{\mathscr{L}^{pr}}(\widetilde{Q}_j^{qR})=\sum_{k=1}^{d_q}\widetilde{Q}_k^{qR}\otimes\pi^q_{kj} \tag{39}$$

(for all $j=1,2,\ldots,d_q$), which then ensures its consistency.

In the situation in which V is a vector space that is a direct sum of carrier spaces of unitary irreducible corepresentations of $\mathscr{A}$ and which contains at least $V^p\oplus V^r$, and with the mapping π from V into $V\otimes\mathscr{A}$ that is defined in the end of the previous subsubsection, the generalization of (36) is clearly

$$((id\otimes M)\circ(id\otimes\sigma)\circ(\pi\otimes id)\circ(\widetilde{Q}_j^{qR}\otimes S^{-1})\circ\pi)(v)=\sum_{k=1}^{d_q}\widetilde{Q}_k^q(v)\otimes\pi^q_{kj} \tag{40}$$

for all $v\in V$ and all $j=1,2,\ldots,d_q$. [Again, the consistency of the definition (40) is an immediate consequence of the consistency of (36)].

C. Properties of irreducible tensor operators

1. The identity operator as an irreducible tensor operator

Suppose that V is a vector space that is a direct sum of carrier spaces of unitary irreducible corepresentations of $\mathscr{A}$ and which contains at least $V^p\oplus V^r$, and that π is the mapping of V into $V\otimes\mathscr{A}$ that is defined in the previous subsection. Suppose that Q is the *identity operator* id of V [so that $Q(v)=v$ for all $v\in V$]. Then, on using (5) and (6), together with the Hopf algebra properties $M\circ(id\otimes S)\circ\Delta=u\circ\epsilon$ and $u(1_C)=1_{\mathscr{A}}$, it follows that

$$((id\otimes M)\circ(\pi\otimes id)\circ(id\otimes S)\circ\pi)(v)=v\otimes 1_{\mathscr{A}} \tag{41}$$

for all $v\in V$, which, by (35), leads to the conclusion that the identity operator id is an *ordinary* irreducible tensor operator for the one-dimensional *identity* corepresentation whose sole matrix coefficient is $1_{\mathscr{A}}$.

It is easily checked [using (40) in place of (35)], that id is also a *twisted* irreducible tensor operator for this identity corepresentation.

The same conclusions for identity operators follow directly from (31) and (36) in the special case in which $p=r$.

2. Two useful identities for the ordinary irreducible tensor operators Q_j^q and $\tilde{Q}_j^q$

If Q_k^q is an *ordinary* irreducible tensor operator belonging to the unitary irreducible corepresentation π^q of $\mathscr{A}$ (as defined in (31)), and v_j^p (for $j=1,2,\ldots,d_p$) provides a basis for the carrier space V^p of the unitary irreducible corepresentation π^p of $\mathscr{A}$, then

$$\pi^r(Q_k^q(v_j^p))=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}(Q_t^q(v_s^p))\otimes(M(\pi_{tk}^q\otimes\pi_{sj}^p)), \tag{42}$$

for all $j=1,2,\ldots,d_p$, and $k=1,2,\ldots,d_q$. By contrast, if $\tilde{Q}_k^q$ is a *twisted* irreducible tensor operator belonging π^q, then

$$\pi^r(\tilde{Q}_k^q(v_j^p))=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}(\tilde{Q}_t^q(v_s^p))\otimes(M(\pi_{sj}^p\otimes\pi_{tk}^q)), \tag{43}$$

for all $j=1,2,\ldots,d_p$ and $k=1,2,\ldots,d_q$. It should be noted that the factors in the second term of the right-hand side of (43) are interchanged relative to those of (42).

The proof of (42) is as follows. On applying (7) and the relation $S(\pi_{ks}^p)=\pi_{sk}^{p*}$, the left-hand side of (31) (with $v^p=v_s^p$) becomes

$$((id\otimes M)\circ(\pi^r\otimes id))\left(\sum_{k=1}^{d_p}(Q_j^q(v_k^p))\otimes\pi_{sk}^{p*}\right).$$

On multiplying from the right with $id\otimes\pi_{si}^p$, summing over s, and applying the relation $M(\pi_{sk}^{p*}\otimes\pi_{si}^p)=\delta_{ik}1_{\mathscr{A}}$, this reduces to $\pi^r(Q_i^q(v_j^p))$. However, multiplication of the right-hand side of (31) from the right with $id\otimes\pi_{si}^p$ and summing over s produces $\Sigma_{s=1}^{d_p}\Sigma_{t=1}^{d_q}(Q_t^q(v_s^p))\otimes(M(\pi_{tk}^q\otimes\pi_{sj}^p))$. The line of proof for (43) is similar.

3. Identification of the corepresentations $\pi_{\mathscr{L}^{pr}}$ and $\tilde{\pi}_{\mathscr{L}^{pr}}$ of $\mathscr{A}$

It is easily shown from the definition (33) of $\pi_{\mathscr{L}^{pr}}$ that

$$\pi_{\mathscr{L}^{pr}}(\mathscr{P}_{ij}^{pr})=\sum_{m=1}^{d_p}\sum_{n=1}^{d_r}\mathscr{P}_{mn}^{pr}\otimes(\pi^r\boxtimes\overline{\pi^p})_{nm,ji}, \tag{44}$$

where $\mathscr{P}_{ij}^{pr}$ are the operators defined in (14), and where $\overline{\pi^p}$ is the corepresentation of $\mathscr{A}$ that is *conjugate* to π^p, so that its matrix coefficients are given by $\overline{\pi}_{jk}^p=(\pi_{jk}^p)^*$. Then, by (20) and (22),

$$\pi_{\mathscr{D}^{pr}}(\mathscr{P}_{ij}^{pr})=\sum_{m=1}^{d_p}\sum_{n=1}^{d_r}\mathscr{P}_{mn}^{pr}\otimes(\overline{\pi^p}\tilde{\boxtimes}\pi^r)_{mn,ij}. \tag{45}$$

This shows that $\pi_{\mathscr{D}^{pr}}$ is actually the right coaction that is given by the *twisted* tensor product $\overline{\pi^p}\tilde{\boxtimes}\pi^r$, and that the operators $\mathscr{P}_{ij}^{pr}$ are the basis vectors of the carrier space $\mathscr{L}^{pr}$ of this coaction.

Taken with (34), this indicates that the irreducible tensor operators Q_j^q of the definition (31) exist only if π^q is contained in the reduction of $\overline{\pi^p}\tilde{\boxtimes}\pi^r$. As $\overline{\pi^p}\tilde{\boxtimes}\pi^r$ and $\pi^r\boxtimes\overline{\pi^p}$ are equivalent,[1] this implies that Q_j^q exists only if $n_{rp}^q>0$. But $n_{rp}^q=n_{qp}^r$ [cf. (I.125), Ref. 1], so Q_j^q exists only if $n_{qp}^r>0$. [These observations are confirmed by the explicit expressions for the irreducible tensor operators given in (47) below and by the Wigner–Eckart theorem of (50) below.]

Similarly, one can show from the definition (37) of $\tilde{\pi}_{\mathscr{D}^{pr}}$ that

$$\tilde{\pi}_{\mathscr{L}^{pr}}(\mathscr{P}^{\,pr}_{ij}) = \sum_{m=1}^{d_p} \sum_{n=1}^{d_r} \mathscr{P}^{\,pr}_{mn} \otimes (\overline{\pi^{p\ddagger}} \boxtimes \pi^r)_{mn,ij}\,, \tag{46}$$

where $\overline{\pi^{p\ddagger}}$ is the corepresentation of $\mathscr{A}$ that is *conjugate* to the corepresentation $\pi^{p\ddagger}$ that is itself *doubly contragredient* to π^p. This shows that $\tilde{\pi}_{\mathscr{L}^{pr}}$ is the right coaction that is given by the ordinary tensor product $\overline{\pi^{p\ddagger}} \boxtimes \pi^r$, and that the operators $\mathscr{P}^{\,pr}_{ij}$ are the basis vectors of the carrier space $\mathscr{L}^{\,pr}$ of this coaction.

Taken with (39), this shows that the twisted irreducible tensor operators $\tilde{Q}^q_j$ of the definition (36) exist only if π^q is contained in the reduction of $\overline{\pi^{p\ddagger}} \boxtimes \pi^r$. As $\overline{\pi^{p\ddagger}}$ and $\overline{\pi^p}$ are equivalent,[7–12] this implies that $\tilde{Q}^q_j$ exists only if $n^{\overline{q}}_{pr} > 0$. But $n^{\overline{q}}_{pr} = n^r_{pq}$ [cf. (I.125), Ref. 1], so $\tilde{Q}^q_j$ exists only if $n^r_{pq} > 0$. [These observations are confirmed by the explicit expressions for the twisted irreducible tensor operators given in (49) below and by the Wigner–Eckart theorem of (52) below].

4. Explicit expressions for the irreducible tensor operators

If $n^r_{qp} > 0$ there exist n^r_{qp} linearly independent *ordinary* irreducible tensor operators that satisfy (31). These are given by

$$Q^{q,\alpha}_j = \sum_{i=1}^{d_p} \sum_{\ell=1}^{d_r} \left(\begin{matrix} r & \overline{p} \\ \ell & i \end{matrix} \middle| \begin{matrix} q & , & \alpha \\ j & & \end{matrix} \right) \mathscr{P}^{\,pr}_{i\ell}\,, \tag{47}$$

for $\alpha = 1,2,\ldots,n^r_{qp}$ and $j = 1,2,\ldots,d_q$. Here the label $\overline{p}$ in the Clebsch–Gordan coefficients relates to the corepresentation $\overline{\pi^p}$ that is conjugate to π^p. As noted in the previous subsubsection, $n^{\overline{q}}_{rp} = n^r_{qp}$ [cf. (I.125)].

The proof of (47) is as follows. The analogue of (I.130) for the tensor product $\pi^r \boxtimes \overline{\pi^p}$ is

$$\sum_{\ell=1}^{d_r} \sum_{i=1}^{d_p} (\pi^r \boxtimes \overline{\pi^p})_{nm,\ell i} \left(\begin{matrix} r & \overline{p} \\ \ell & i \end{matrix} \middle| \begin{matrix} q & , & \alpha \\ j & & \end{matrix} \right) = \sum_{k=1}^{d_q} \left(\begin{matrix} r & \overline{p} \\ n & m \end{matrix} \middle| \begin{matrix} q & , & \alpha \\ k & & \end{matrix} \right) \pi^q_{kj} \tag{48}$$

for $m = 1,2,\ldots,d_p$, $j = 1,2,\ldots,d_q$, $n = 1,2,\ldots,d_r$, and $\alpha = 1,2,\ldots,n^r_{qp}$. However, by (32), (44), and (47),

$$\pi_{\mathscr{L}^{pr}}(Q^{q,\alpha}_j) = \sum_{i,m=1}^{d_p} \sum_{\ell,n=1}^{d_r} \left(\begin{matrix} r & \overline{p} \\ \ell & i \end{matrix} \middle| \begin{matrix} q & , & \alpha \\ j & & \end{matrix} \right) \mathscr{P}^{\,pr}_{mn} \otimes (\pi^r \boxtimes \overline{\pi^p})_{nm,\ell i}\,.$$

On applying (48) and (47), this reduces to

$$\pi_{\mathscr{L}^{pr}}(Q^{q,\alpha}_j) = \sum_{k=1}^{d_q} Q^{q,\alpha}_k \otimes \pi^q_{kj}$$

(for all $j = 1,2,\ldots,d_q$ and $\alpha = 1,2,\ldots,n^r_{qp}$). That is, the operators $Q^{q,\alpha}_j$ defined in (47) satisfy (35), which is equivalent to (32).

Similarly, if $n^r_{pq} > 0$ there exist n^r_{pq} linearly independent *twisted* irreducible tensor operators that satisfy (32). These are given by

$$\tilde{Q}^{q,\alpha}_j = \sum_{i=1}^{d_p} \sum_{\ell=1}^{d_r} \left(\begin{matrix} \overline{p^\ddagger} & r \\ i & \ell \end{matrix} \middle| \begin{matrix} q & , & \alpha \\ j & & \end{matrix} \right) \mathscr{P}^{\,pr}_{i\ell}\,, \tag{49}$$

for $\alpha=1,2,\ldots,n^r_{pq}$ and $j=1,2,\ldots,d_q$. Here the label $\overline{p^{\ddagger}}$ in the Clebsch–Gordan coefficients relates to the corepresentation $\overline{\pi^{p\ddagger}}$ that is conjugate to the corepresentation $\pi^{p\ddagger}$ that is itself doubly contragredient to π^p. It should be noted that $n^q_{p\overline{r}}=n^r_{pq}=n^q_{\overline{p^{\ddagger}}r}$ [c.f. (I.125)].

The proof of (49) is similar to that of (47), but uses the right coaction $\widetilde{\pi}_{\mathscr{D}^{pr}}$ in the place of $\pi_{\mathscr{D}^{pr}}$. Also needed is the relation

$$(\overline{\pi^{p\ddagger}})_{ij}=\sum_{k,\ell=1}^{d_p}\overline{F^p_{ik}}(\overline{\pi^p})_{k\ell}\overline{((\mathbf{F}^p)^{-1})_{\ell j}},$$

which follows from (30), and the corresponding relation

$$\left(\begin{matrix}\overline{p} & r\\ i & \ell\end{matrix}\middle|\begin{matrix}q & , & \alpha\\ j & & \end{matrix}\right)=\sum_{k=1}^{d_p}\overline{((\mathbf{F}^p)^{-1})_{ik}}\left(\begin{matrix}\overline{p^{\ddagger}} & r\\ k & \ell\end{matrix}\middle|\begin{matrix}q & , & \alpha\\ j & & \end{matrix}\right).$$

V. THEOREMS OF THE WIGNER–ECKART TYPE

If π^p, π^q, and π^r are unitary irreducible corepresentations of $\mathscr{A}$ of dimensions d_p, d_q, and d_r respectively, v^p_j and v^r_ℓ are basis vectors belonging to the carrier spaces V^p and V^r of π^p and π^r respectively, and Q^q_k is an *ordinary* irreducible tensor operator belonging to π^q [as defined in (31)], then

$$\langle v^r_\ell,Q^q_k(v^p_j)\rangle=\sum_{\alpha=1}^{n^r_{qp}}\left(\begin{matrix}r & , & \alpha\\ \ell & & \end{matrix}\middle|\begin{matrix}q & p\\ k & j\end{matrix}\right)(r|Q^q|p)_\alpha, \tag{50}$$

for all $j=1,2,\ldots,d_p$, all $k=1,2,\ldots,d_q$, and all $\ell=1,2,\ldots,d_r$. Here the *reduced matrix elements* $(r|Q^q|p)_\alpha$ are given by

$$(r|Q^q|p)_\alpha=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}\sum_{u,v=1}^{d_r}\langle v^r_u,Q^q_t(v^p_s)\rangle\left(\begin{matrix}q & p\\ t & s\end{matrix}\middle|\begin{matrix}r & , & \alpha\\ v & & \end{matrix}\right)\times\{((\mathbf{F}^r)^{-1})_{vu}/tr((\mathbf{F}^r)^{-1})\} \tag{51}$$

for $\alpha=1,2,\ldots,n^r_{qp}$, and $\langle,\rangle$ denotes the inner product of V^r. Here $\mathbf{F}^r$ is the matrix defined in (30).

On the other hand, if $\widetilde{Q}^q_k$ is a *twisted* irreducible tensor operator belonging to π^q [as defined in (36)], then

$$\langle v^r_\ell,\widetilde{Q}^q_k(v^p_j)\rangle=\sum_{\alpha=1}^{n^r_{pq}}\left(\begin{matrix}r & , & \alpha\\ \ell & & \end{matrix}\middle|\begin{matrix}p & q\\ j & k\end{matrix}\right)(r|\widetilde{Q}^q|p)_\alpha, \tag{52}$$

for all $j=1,2,\ldots,d_p$, all $k=1,2,\ldots,d_q$, and all $\ell=1,2,\ldots,d_r$, where the reduced matrix elements $(r|\widetilde{Q}^q|p)_\alpha$ are given by

$$(r|\widetilde{Q}^q|p)_\alpha=\sum_{s=1}^{d_p}\sum_{t=1}^{d_q}\sum_{u,v=1}^{d_r}\langle v^r_u,\widetilde{Q}^q_t(v^p_s)\rangle\left(\begin{matrix}p & q\\ s & t\end{matrix}\middle|\begin{matrix}r & , & \alpha\\ v & & \end{matrix}\right)\times\{((\mathbf{F}^r)^{-1})_{vu}/tr((\mathbf{F}^r)^{-1})\} \tag{53}$$

for $\alpha=1,2,\ldots,n^r_{pq}$.

The results (50) and (52) again exhibit the classic Wigner–Eckart theorem behavior, in that they show that the j, k, and ℓ dependences of the inner products $\langle v^r_\ell,Q^q_k(v^p_j)\rangle$ and

$\langle v^r_\ell, \widetilde{Q}^q_k(v^p_j)\rangle$ are determined only by Clebsch−Gordan coefficients, but it should be noted that in the general case in which $\mathscr{A}$ is non-commutative, the inner products for the *ordinary* and *twisted* irreducible tensor operators involve *different* sets of Clebsch−Gordan coefficients.

The proof of (50) is as follows. The condition for a corepresentation π_V of $\mathscr{A}$ to be unitary is that

$$\sum_{[v]} \langle w, v_{[1]},\rangle S(v_{[2]}) = \sum_{[w]} \langle w_{[1]}, v\rangle (w_{[2]})^* \tag{54}$$

for all $v, w \in V$, the carrier space of π_V, where

$$\pi_V(v) = \sum_{[v]} v_{[1]} \otimes v_{[2]}, \tag{55}$$

with $v_{[1]} \in V$ and $v_{[2]} \in \mathscr{A}$ [cf. (I.51)]. Thus with $v = Q^q_j(v^p_i)$ and $w = v^r_\ell$, (54), (55), (42), and (7) imply that

$$\sum_{s=1}^{d_p} \sum_{t=1}^{d_q} \langle v^r_\ell, Q^q_t(v^p_s)\rangle S(M(\pi^q_{tj} \otimes \pi^p_{si})) = \sum_{u=1}^{d_r} \langle v^r_u, Q^q_j(v^p_i)\rangle (\pi^r_{u\ell})^*. \tag{56}$$

But $(\pi^r_{u\ell})^* = S(\pi^r_{\ell u})$, so acting on both sides with S^{-1} (which is well defined for a compact quantum group algebra[7–12]), multiplying through from the left by $(\pi^r_{\ell k})^*$, summing over ℓ, and using the relation $\Sigma_\ell M((\pi^r_{\ell k})^* \otimes (\pi^r_{\ell u})) = \delta_{uk} 1_{\mathscr{A}}$, (56) reduces to

$$\sum_{\ell=1}^{d_r} \sum_{s=1}^{d_p} \sum_{t=1}^{d_q} \langle v^r_\ell, Q^q_t(v^p_s)\rangle ((\pi^r_{\ell k})^* \pi^q_{tj} \otimes \pi^p_{si}) = \langle v^r_k, Q^q_j(v^p_i)\rangle 1_{\mathscr{A}}. \tag{57}$$

On acting with the Haar functional h, and applying (29) and the relation $h(1_{\mathscr{A}}) = 1$, (50) follows immediately. The proof of (52) is similar.

VI. EXAMPLE: IRREDUCIBLE TENSOR OPERATORS FOR THE STANDARD DEFORMATION OF THE FUNCTION ALGEBRA OF THE COMPACT LIE GROUP SU(2)

It is particularly interesting to study the foregoing theory for the case in which $\mathscr{A}$ is the standard deformation of the function algebra of the compact Lie group SU(2),because both this Hopf algebra $\mathscr{A}$ and its dual $\mathscr{A}'$ have been very extensively investigated, the former in the language of 'compact matrix pseudogroups' and the latter as the deformation $U_q(sl(2))$ of the universal enveloping algebra $U(sl(2))$ of the simple Lie algebra $sl(2)$.

A. Structure of the standard deformation of the function algebra of the compact Lie group *SU*(2)

It is well known (cf. Ref. 14) that the irreducible representations of the deformation $U_q(sl(2))$ (for generic q) can be labelled by a single index j, which takes values $0, \frac{1}{2}, 1, \frac{3}{2}, \ldots$, the irreducible representation corresponding to j being $(2j+1)$-dimensional, with rows and columns that may be labeled by indices m' and m that take values $-j, -j+1, \ldots, j-1, j$, exactly as for the simple Lie algebra $sl(2)$. To each of these representations corresponds a *co*representation of the dual Hopf algebra $\mathscr{A}$. Consequently the labels for corepresentations of $\mathscr{A}$ will henceforth always be denoted by j (possibly with a prime or subscript attached) and the rows and columns of the corresponding matrix coefficients will be labelled by these indices m and m' (possibly with subscripts attached). (Although q was used in all the other sections of this paper to indicate an irreducible representation or corepresentation, in this section it will be employed to denote the standard deformation parameter.)

All of the irreducible corepresentations π^j (for $j=0,\frac{1}{2},1,\frac{3}{2},\ldots$) may be taken to be unitary, and their matrix coefficients $\pi^j_{m'm}$ form a basis for $\mathscr{A}$. Moreover *every* matrix coefficient $\pi^j_{m'm}$ for $j\geqslant 1$ can be written as a polynomial in the matrix coefficients of $\pi^{1/2}$, while $\pi^0_{00}=1_{\mathscr{A}}$. Let

$$\boldsymbol{\pi}^{1/2}=\begin{pmatrix} X & U \\ V & Y \end{pmatrix}, \tag{58}$$

where the entries are assumed to satisfy the relations

$$\begin{gathered} XU=q^{-1}UX, XV=q^{-1}VX, YU=qUY, YV=qVY, \\ UV=VU, XY-q^{-1}UV=1_{\mathscr{A}}, YX-qUV=1_{\mathscr{A}}. \end{gathered} \tag{59}$$

In the language of 'matrix pseudogroups' the matrix coefficients $\pi^j_{m'm}$ are called 'quantum d-functions' and are denoted by $d^j_{m'm}$. The work of Nomura[15] then implies that

$$\begin{aligned} \pi^j_{m'm}=q^{(m'-m)(2j-m'+m)/2}&\{[j+m']![j-m']![j+m]![j-m]!\} \\ &\times\sum_a \frac{q^{a(2j-m'+m-a)}X^{j+m-a}U^{m'-m+a}V^aY^{j-m'-a}}{[a]![j+m-a]![m'-m+a]![j-m'-a]!}, \end{aligned} \tag{60}$$

where $[n]=(q^n-q^{-n})/(q-q^{-1})$ and $[n]!=[n][n-1][n-2]\ldots[2][1]$, and where the sum over a is over all integers such that the expressions in the q-factorials are non-negative. (The present quantity q is actually $q^{1/2}$ in the notation of Nomura[15,16]). Then, for example

$$\boldsymbol{\pi}^1=\begin{pmatrix} X^2 & q^{1/2}[2]^{1/2}XU & U^2 \\ q^{1/2}[2]^{1/2}XV & XY+qUV & q^{1/2}[2]^{1/2}UY \\ V^2 & q^{1/2}[2]^{1/2}VY & Y^2 \end{pmatrix} \tag{61}$$

and

$$\boldsymbol{\pi}^{3/2}=\begin{pmatrix} X^3 & q[3]^{1/2}X^2U & q[3]^{1/2}XU^2 & U^3 \\ q[3]^{1/2}X^2V & X^2Y+q^2[2]XUV & q[2]XUY+q^2U^2V & q[3]^{1/2}U^2Y \\ q[3]^{1/2}XV^2 & q[2]XVY+q^2UV^2 & XY^2+q^2[2]UVY & q[3]^{1/2}UY^2 \\ V^3 & q[3]^{1/2}V^2Y & q[3]^{1/2}VY^2 & Y^3 \end{pmatrix}. \tag{62}$$

The product of any two matrix coefficients can (at least in principle) be deduced from the expressions.

An alternative way of getting the product of any two matrix coefficients is to invoke (28), for the Clebsch–Gordan coefficients are known for this $\mathscr{A}$. Indeed for this $\mathscr{A}$ the Clebsch–Gordan coefficients exhibit two simplifying features. First, the multiplicity is always just 1, so the index α in the Clebsch–Gordan coefficients of (23) may be omitted, and second, the Clebsch–Gordan coefficients can be taken to be purely real. As the Clebsch–Gordan series for $\pi^{j_1}\boxtimes\pi^{j_2}$ is the direct sum of π^j with $j=j_1+j_2, j_1+j_2-1,\ldots,|j_1-j_2|$, (28) reduces in this case to

$$M(\pi^{j_1}_{m_1'm_1}\otimes\pi^{j_2}_{m_2'm_2})=\sum_{j=|j_1-j_2|}^{j_1+j_2}\sum_{m',m=-j}^{j}\left(\begin{array}{cc|c} j_1 & j_2 & j \\ m_1' & m_2' & m' \end{array}\right)\left(\begin{array}{cc|c} j_1 & j_2 & j \\ m_1 & m_2 & m \end{array}\right)\pi^j_{m'm}. \tag{63}$$

Various equivalent expressions for the Clebsch–Gordan coefficients appear in the literature, but the most convenient for application here is that given by Nomura,[16] which, in the present notation, is

$$\left(\begin{array}{cc|c} j_1 & j_2 & j \\ m_1 & m_2 & m \end{array}\right)$$
$$= \Delta(j_1,j_2,j) q^{\{x(j_1)+x(j_2)-x(j)+2(j_1j_2+j_1m_2-j_2m_1)\}/2}$$
$$\times \{[j_1+m_1]![j_1-m_1]![j_2+m_2]![j_2-m_2]![j+m]![j-m]![2j+1]\}^{1/2}$$
$$\times \sum_a \frac{(-1)^a q^{-a(j_1+j_2+j+1)/2}}{[a]![j_1+j_2-j-a]![j_1-m_1-a]![j_2+m_2-a]![j-j_2+m_1+a]![j-j_1-m_2+a]!}, \tag{64}$$

where $\Delta(a,b,c)=\{[-a+b+c]![a-b+c]![a+b-c]!/[a+b+c+1]!\}^{1/2}$ and $x(a)=a(a+1)$, and where the sum over a is over all integers such that the expressions in the q-factorials are non-negative. In particular

$$\left(\begin{array}{cc|c} j+\frac{1}{2} & j & \frac{1}{2} \\ m+\frac{1}{2} & -m & \frac{1}{2} \end{array}\right) = (-1)^{j-m} q^{-j+\frac{1}{2}+\frac{3}{2}m} [j+m+1]^{1/2} \{[2][2j]!/[2j+2]!\}^{1/2} \tag{65}$$

and

$$\left(\begin{array}{cc|c} j+\frac{1}{2} & j & \frac{1}{2} \\ m-\frac{1}{2} & -m & -\frac{1}{2} \end{array}\right) = (-1)^{j-m} q^{\frac{1}{2}+\frac{3}{2}m} [j-m+1]^{1/2} \{[2][2j]!/[2j+2]!\}^{1/2}. \tag{66}$$

The action of the coproduct Δ and counit ϵ of $\mathscr{A}$ on the generators of $\mathscr{A}$ is given by

$$\Delta(X)=X\otimes X+U\otimes V, \quad \Delta(Y)=V\otimes U+Y\otimes Y,$$
$$\Delta(U)=X\otimes U+U\otimes Y, \quad \Delta(V)=V\otimes X+Y\otimes V,$$

and

$$\epsilon(X)=1, \epsilon(Y)=1, \quad \epsilon(U)=0, \epsilon(V)=0.$$

Moreover, the action of the star-operation * of $\mathscr{A}$ on the generators of $\mathscr{A}$ may be taken to be

$$X^*=Y, \quad Y^*=X, \quad U^*=-q^{-1}V, \quad V^*=-qU, \tag{67}$$

which implies[15] that its action on any matrix coefficient is given by

$$(\pi^j_{m'm})^* = (-1)^{m-m'} q^{m-m'} \pi^j_{-m',-m}. \tag{68}$$

As $S(\pi^j_{m'm})=(\pi^j_{mm'})^*$ [cf. (I.52), Ref. 1], it follows that

$$S(\pi^j_{m'm}) = (-1)^{-(m-m')} q^{-(m-m')} \pi^j_{-m,-m'}. \tag{69}$$

Thus

$$S^2(\pi^j_{m'm}) = q^{-2(m-m')} \pi^j_{m'm}. \tag{70}$$

As the matrix coefficients of the doubly contragredient corepresentation $\pi^{j\ddagger}$ are given by $(\pi^j_{m'm})^{\ddagger}=S^2\pi^j_{m'm}$ [cf. (I.57), Ref. 1], it follows that the $(2j+1)\times(2j+1)$ matrix of (30) (which appears in the expressions for the reduced matrix elements (51) and (53) of the Wigner–Eckart type theorems) is *diagonal* and that its elements are given by

$$F^j_{m'm}=\delta_{m'm}q^{-2(j-m)}. \tag{71}$$

B. Bosonic creation and annihilation operators as irreducible tensor operators

Let $b_1^\dagger, b_1$ and $b_2^\dagger, b_2$ be two pairs of 'deformed' bosonic creation and annihilation operators and N_1 and N_2 the associated number operators whose action on the infinite-dimensional Fock space spanned by the occupation number vectors $|n_i\rangle$ is given (cf. Refs. 17, 18) by

$$b_i^\dagger|n_i\rangle=[n_i+1]^{1/2}|n_i+1\rangle,$$

$$b_i|n_i\rangle=[n_i]^{1/2}|n_i-1\rangle, \quad N_i|n_i\rangle=n_i|n_i\rangle, \tag{72}$$

for $i=1,2$, where it is assumed that the vacuum state vectors $|0\rangle$ are such that $b_i|0\rangle=0$ for $i=1,2$. It is also assumed that every member of the set $\{b_1^\dagger, b_1, N_1\}$ commutes with every member of the set $\{b_2^\dagger, b_2, N_2\}$. In the deformed generalization of the Jordan–Schwinger realization of $sl(2)$ (cf. Refs. 17, 18), the basis vectors of the carrier spaces of the irreducible representations of $U_q(sl(2))$ are given by

$$v^j_m=|j+m, j-m\rangle, \tag{73}$$

and these, of course, are also the basis vectors of the carrier spaces of the irreducible *corepresentations* of $\mathscr{A}$.

Then

$$Q^{1/2}_{1/2}=b_1^\dagger q^{-(1/2)N_2}, \quad Q^{1/2}_{-1/2}=b_2^\dagger q^{(1/2)N_1}, \tag{74}$$

and

$$Q^{1/2}_{1/2}=qb_2q^{(1/2)N_1}, \quad Q^{1/2}_{-1/2}=-b_1q^{-(1/2)N_2}, \tag{75}$$

are two sets of pairs of *ordinary* irreducible tensor operators that belong to the 2-dimensional irreducible corepresentation $\pi^{1/2}$ of $\mathscr{A}$.

This will now be demonstrated for the *first* pair (74), starting from the definition (35), and taking V to be the direct sum of all the carrier spaces of all the irreducible corepresentations of $\mathscr{A}$ (with just one such irreducible corepresentation being included from each equivalence class). Define the right coaction π of $\mathscr{A}$ by

$$\pi(v^j_m)=\sum_{m'=-j}^{j} v^j_{m'}\otimes\pi^j_{m'm}, \tag{76}$$

for all $j=0,\frac{1}{2},1,\ldots$ and $m=j,j-1,\ldots,-j$. Then in this case (36) becomes

$$((id\otimes M)\circ(\pi\otimes id)\circ(Q^{1/2}_k\otimes S)\circ\pi)(v^j_m)=\sum_{\ell=-1/2}^{1/2} Q^{1/2}_\ell(v^j_m)\otimes\pi^{1/2}_{\ell k}, \tag{77}$$

for all $j=0,\frac{1}{2},1,\ldots$ and $m=j,j-1,\ldots,-j$. It will now be shown that this is indeed satisfied for $k=\frac{1}{2}$. (The proof for $k=-\frac{1}{2}$ is similar.) By (72), (69), (74), and (76), the left-hand side of (77) for $k=\frac{1}{2}$ is

$$\sum_{m''=-j-1}^{j}\sum_{m'=-j}^{j}[j+m'+1]^{1/2}q^{-(1/2)(j-m')-(m-m')}(-1)^{-(m-m')}$$
$$\times v^{j+(1/2)}_{m''+(1/2)}\otimes M(\pi^{j+(1/2)}_{m''+(1/2),m'+(1/2)}\otimes\pi^{j}_{-m,-m'}). \tag{78}$$

Similarly, by (72), (74), and (76), the right-hand side of (77) for $k=\frac{1}{2}$ is

$$[j+m+1]^{1/2}q^{-(1/2)(j-m)}v^{j+(1/2)}_{m+(1/2)}\otimes\pi^{1/2}_{1/2,1/2}+[j-m+1]^{1/2}q^{(1/2)(j+m)}v^{j+(1/2)}_{m-(1/2)}\otimes\pi^{1/2}_{-(1/2),(1/2)}, \tag{79}$$

so it remains to show that (78) reduces to (79). However, by (63) and (65), (78) reduces to

$$\sum_{m''=-j-1}^{j}\sum_{m'=-j}^{j}\sum_{j'=1/2}^{2j+(1/2)}\{[2][2j]!/[2j+2]!\}^{1/2}q^{((1/2)j-m-(1/2))}(-1)^{(j-m)}$$
$$\times\begin{pmatrix} j+\frac{1}{2} & j & \frac{1}{2}\\ m'+\frac{1}{2} & -m' & \frac{1}{2}\end{pmatrix}\begin{pmatrix} j+\frac{1}{2} & j & j'\\ m''+\frac{1}{2} & -m & m''+\frac{1}{2}-m\end{pmatrix}$$
$$\times\begin{pmatrix} j+\frac{1}{2} & j & j'\\ m'+\frac{1}{2} & -m' & \frac{1}{2}\end{pmatrix}v^{j+(1/2)}_{m''+(1/2)}\otimes\pi^{j'}_{m''+(1/2)-m,1/2}\,. \tag{80}$$

On invoking the Clebsch–Gordan orthogonality relation

$$\sum_{m'=-j}^{j}\begin{pmatrix} j+\frac{1}{2} & j & \frac{1}{2}\\ m'+\frac{1}{2} & -m' & \frac{1}{2}\end{pmatrix}\begin{pmatrix} j+\frac{1}{2} & j & j'\\ m'+\frac{1}{2} & -m' & \frac{1}{2}\end{pmatrix}=\begin{cases}1, & \text{if} \quad j'=\frac{1}{2}\\ 0, & \text{i} \quad \text{f}j'\neq\frac{1}{2}\end{cases}, \tag{81}$$

(80) [and hence (78)] reduces to

$$\sum_{m''=-j-1}^{j}\{[2][2j]!/[2j+2]!\}^{1/2}q^{((1/2)j-m-(1/2))}(-1)^{(j-m)}$$
$$\times\begin{pmatrix} j+\frac{1}{2} & j & \frac{1}{2}\\ m''+\frac{1}{2} & -m & m''+\frac{1}{2}-m\end{pmatrix}v^{j+(1/2)}_{m''+(1/2)}\otimes\pi^{j'}_{m''+1/2-m,1/2}. \tag{82}$$

However, the remaining Clebsch–Gordan coefficients are zero if $m''+\frac{1}{2}-m>\frac{1}{2}$, i.e. if $m''>m$, and are zero if $m''+\frac{1}{2}-m<-\frac{1}{2}$, i.e. if $m''<m-1$, so these Clebsch–Gordan coefficients are non-zero only for $m''=m,m-1$. Thus (82) [and hence (78)] becomes

$$\{[2][2j]!/[2j+2]!\}^{1/2}q^{(1/2j-m-1/2)}(-1)^{(j-m)}$$
$$\times\left\{\begin{pmatrix} j+\frac{1}{2} & j & \frac{1}{2}\\ m-\frac{1}{2} & -m & -\frac{1}{2}\end{pmatrix}v^{j+(1/2)}_{m-(1/2)}\otimes\pi^{1/2}_{-(1/2),1/2}+\begin{pmatrix} j+\frac{1}{2} & j & \frac{1}{2}\\ m+\frac{1}{2} & -m & \frac{1}{2}\end{pmatrix}v^{j+(1/2)}_{m+(1/2)}\otimes\pi^{1/2}_{1/2,1/2}\right\},$$

which, by (65) and (66), reduces to (79).

Similarly

$$\tilde{Q}^{1/2}_{1/2}=b_1^{\dagger}q^{(1/2)N_2},\quad \tilde{Q}^{1/2}_{-1/2}=b_2^{\dagger}q^{-(1/2)N_1}, \tag{83}$$

and

$$\tilde{Q}^{1/2}_{1/2}=q^{-1}b_2q^{-(1/2)N_1},\quad \tilde{Q}^{1/2}_{-1/2}=-b_1q^{(1/2)N_2}, \tag{84}$$

are two sets of pairs of *twisted* irreducible tensor operators belonging to the 2-dimensional irreducible corepresentation $\pi^{1/2}$ of $\mathscr{A}$. [This is easily deduced from (78) and (79), because in the special case of this algebra $\mathscr{A}$, (59) and (69) imply that the substitutions $M\rightarrow M\bigcirc\sigma$ and $S\rightarrow S^{-1}$ merely correspond to the replacement of q by q^{-1}].

It has been observed previously by Biedenharn and Tarlini[19] that (78) provide a pair of irreducible tensor operators for the 2-dimensional irreducible representation of $U_q(sl(2))$, their argument essentially using (A10) and the generalized Jordan-Schwinger realization of the generators of $U_q(sl(2))$, together with various identities involving the creation and annihilation operators. The object of the above analysis in this subsection is to give an explicit demonstration of the applicability of the *new* definitions (A10) and (A11) for $\mathscr{A}$, which, of course, apply not merely to this example but to *any* compact quantum group algebra.

APPENDIX: MOTIVATION FOR DEFINITIONS

1. Introduction

The purpose of this Appendix is to *motivate* the definitions that are given in the main body of the paper for the irreducible tensor operators. This will be done by considering the simple special case in which the Hopf algebra $\mathscr{A}$ is the set of functions defined on a *finite* group $\mathscr{G}$ of order g, so that the dual $\mathscr{A}'$ of $\mathscr{A}$ is the group algebra of $\mathscr{G}$. Of course, as $\mathscr{A}$ is commutative in this special case, the resulting expressions are to some extent ambiguous, in that in this special case M is indistinguishable from $M\circ\sigma$ and S is indistinguishable from S^{-1}. The demonstration of the correctness, consistency, and usefulness of the definitions that are actually employed for the *general* case are the subject matter of the self-contained arguments of the main body of this paper.

A summary of the basic facts concerning the relationship of $\mathscr{A}$ and $\mathscr{A}'$ may be found in the Introduction to the Appendix of Paper I.

B. Motivation for definitions of irreducible tensor operators

The starting point of the present argument is (2), which of course also applies to finite groups, and which may be rewritten as

$$\hat{\pi}'^r(x)Q^q_j\hat{\pi}'^p(x^{-1})=\sum_{k=1}^{d_q}\Gamma^q(x)_{kj}Q^q_k \tag{A1}$$

for all $x\in\mathscr{G}$ and all $j=1,2,\ldots,d_q$. Here the operators $\hat{\pi}'^p(x)$ are defined by

$$\hat{\pi}'^p(x)(v^p_j)=\sum_{k=1}^{d_p}\Gamma^p(x)_{kj}v^p_k, \tag{A2}$$

and are related to the corresponding left action π'^p of $\mathscr{A}'$ (a mapping of the carrier space V^p into $V^p\otimes\mathscr{A}'$) by the prescription

$$\hat{\pi}'^p(x)(v^p_j)=\pi'^p(x\otimes v^p_j). \tag{A3}$$

As here $S_{\mathscr{A}'}(x)=x^{-1}$ and $\Delta_{\mathscr{A}'}(x)=x\otimes x$, (A1) can be rewritten in purely Hopf algebraic terms (for $\mathscr{A}'$) as

$$(\pi'^{r}\circ(id\otimes Q_j^q)\circ(id\otimes\pi'^{p})\circ(id\otimes S_{\mathscr{A}'}\otimes id)\circ(\Delta_{\mathscr{A}'}\otimes id))(x\otimes v^p)=\sum_{k=1}^{d_q}\Gamma^q(x)_{kj}Q_k^q(v^p) \quad \text{(A4)}$$

for all $x\in\mathscr{A}'$, all $v^p\in V^p$, and all $j=1,2,\ldots,d_q$. [Here the $\Gamma^q(x)_{kj}$ are now matrix elements of the irreducible representation π'^q of the Hopf algebra $\mathscr{A}'$].

This condition can be recast entirely in terms of quantities defined for the Hopf algebra $\mathscr{A}$ in the following way. As noted in equation (I.214), the relationship between a right coaction π_V of $\mathscr{A}$ and the corresponding left action π'_V of $\mathscr{A}'$ (with the same carrier space V) is

$$\pi'_V(a'\otimes v)=(M_{V,C}\circ(id\otimes ev)\circ(\sigma\otimes id)\circ(id\otimes\pi_V))(a'\otimes v) \quad \text{(A5)}$$

for all $a'\in\mathscr{A}'$ and all $v\in V$, where the evaluation map ev (from $\mathscr{A}'\otimes\mathscr{A}$ to C) is defined [cf. (I.41)] by

$$ev(a'\otimes a)=\langle a',a\rangle \quad \text{(A6)}$$

for all $a'\in\mathscr{A}'$ and all $a\in\mathscr{A}$. On applying this twice (once with with $\pi'_V=\pi'^{r}$ and once with $\pi'_V=\pi'^{p}$), the left-hand side of (A4) becomes

$$(M_{V^r,C}\circ(id\otimes ev)\circ(\sigma\otimes id)\circ(id\otimes\pi^r)\circ(id\otimes Q_j^q)\circ(id\otimes\pi^p)\circ(id\otimes M_{V^p,C})$$

$$\circ(id\otimes id\otimes ev)\circ(id\otimes\sigma\otimes id)\circ(id\otimes S_{\mathscr{A}'}\otimes\pi^p)\circ(\Delta_{\mathscr{A}'}\otimes id)(x\otimes v^p). \quad \text{(A7)}$$

As (I.209) and (I.210) can be rewritten as

$$(M_C\circ(ev\otimes ev)\circ(id\otimes\sigma\otimes id)\circ(\Delta_{\mathscr{A}'}\otimes id))(a'\otimes a\otimes b)=(ev\circ(id\otimes M))(a'\otimes a\otimes b)$$

for all $a,b\in\mathscr{A}$ and all $a'\in\mathscr{A}'$, and

$$(ev\circ(S_{\mathscr{A}'}\otimes id))(a'\otimes a)=(ev\circ(id\otimes S))(a'\otimes a)$$

for all $a\in\mathscr{A}$ and all $a'\in\mathscr{A}'$, (96) can be re-expressed as

$$(M_{V^r,C}\circ(id\otimes ev)\circ(\sigma\otimes id)\circ(id\otimes id\otimes M)\circ(id\otimes\pi^r\otimes id)\circ(id\otimes Q_j^q\otimes S)\circ(id\otimes\pi^p))(x\otimes v^p). \quad \text{(A8)}$$

However, the right-hand side of (A4) can be rewritten using (I.217) as $\Sigma_{k=1}{}^{d_q}\langle x,\pi_{kj}^q\rangle Q_k^q(v^p)$, and hence as

$$\sum_{k=1}^{d_q}(M_{V^r,C}\circ(id\otimes ev)\circ(\sigma\otimes id)\circ(id\otimes Q_k^q\otimes id))(x\otimes v^p\otimes\pi_{kj}^q). \quad \text{(A9)}$$

On equating (A8) and (A9), as the first three terms are common to both expressions, they can be removed. The remaining terms act simply as the identity on the factor x, so on removing this now trivial effect on x, it follows that (A4) is equivalent to

$$((id\otimes M)\circ(\pi^r\otimes id)\circ(Q_j^q\otimes S)\circ\pi^p)(v^p)=\sum_{k=1}^{d_q}Q_k^q(v^p)\otimes\pi_{kj}^q$$

for all $v^p \in V^p$ and all $j=1,2,\ldots,d_q$. As this involves *only* quantities defined for $\mathscr{A}$, it provides the desired criterion (32).

Now consider the situation in which V is a vector space that is a direct sum of carrier spaces of unitary irreducible corepresentations of $\mathscr{A}$ and which contains at least $V^p \oplus V^r$. Let π be the mapping of V into $V\otimes\mathscr{A}$ that coincides with π^p on V^p and with π^r on V^r, and which acts similarly on any other carrier spaces that might be contained in V. Of course V is also is the direct sum of carrier spaces of unitary irreducible representations of $\mathscr{A}'$. Then the generalization of (A4) to this situation is

$$(\pi'\circ(id\otimes Q_j^q)\circ(id\otimes\pi')\circ(id\otimes S_{\mathscr{A}'}\otimes id)\circ(\Delta_{\mathscr{A}'}\otimes id))(x\otimes v)=\sum_{k=1}^{d_q}\Gamma^q(x)_{kj}Q_k^q(v) \quad \text{(A10)}$$

for all $x \in \mathscr{A}'$, all $v \in V$, and all $j=1,2,\ldots,d_q$. (Here π' is the mapping of $V\otimes\mathscr{A}'$ into V that coincides with π'^p on V^p and with π'^r on V^r, and which acts similarly on any other carrier spaces that might be contained in V.) The generalization of (31) to this situation is obviously

$$((id\otimes M)\circ(\pi\otimes id)\circ(Q_j^q\otimes S)\circ\pi)(v)=\sum_{k=1}^{d_q}Q_k^q(v)\otimes\pi_{kj}^q \quad \text{(A11)}$$

for all $v \in V$ and all $j=1,2,\ldots,d_q$.

Because M is indistinguishable from $M\circ\sigma$ and S is indistinguishable from S^{-1} in the situation being considered here, the above arguments would equally well apply with each of the following 3 substitutions:

(1) replace M by $M\circ\sigma$, but leave S unchanged;
(2) leave M unchanged, but replace S by S^{-1};
(3) replace M by $M\circ\sigma$ *and* replace S by S^{-1}.

However, in the general case in which $\mathscr{A}$ is non-commutative, the possibilities (1) and (2) are *excluded* because with them, and in the situation discussed in the previous paragraph, the identity operator would not be an irreducible tensor operator belonging to the identity corepresentation. With the substitution (3), (31) changes into (36), which is the defining condition for a *twisted* irreducible tensor operator $\widetilde{Q}_j^q$. (Of course the corresponding substitutions for $\mathscr{A}'$ are $\Delta_{\mathscr{A}'}\to\sigma\circ\Delta_{\mathscr{A}'}$ and $S_{\mathscr{A}'}\to(S'_{\mathscr{A}})^{-1}$, so that the analogues of (A4) and (A10) are

$$(\pi'^r\circ(id\otimes\widetilde{Q}_j^q)\circ(id\otimes\pi'^p)\circ(id\otimes(S'_{\mathscr{A}})^{-1}\otimes id)\circ(\sigma\otimes id)\circ(\Delta_{\mathscr{A}'}\otimes id))(x\otimes v^p)$$
$$=\sum_{k=1}^{d_q}\Gamma^q(x)_{kj}\widetilde{Q}_k^q(v^p) \quad \text{(A12)}$$

(for all $x \in \mathscr{A}'$, all $v^p \in V^p$, and all $j=1,2,\ldots,d_q$), and

$$(\pi'\circ(id\otimes\widetilde{Q}_j^q)\circ(id\otimes\pi')\circ(id\otimes(S'_{\mathscr{A}})^{-1}\otimes id)\circ(\sigma\otimes id)\circ(\Delta_{\mathscr{A}'}\otimes id))(x\otimes v)=\sum_{k=1}^{d_q}\Gamma^q(x)_{kj}\widetilde{Q}_k^q(v) \quad \text{(A13)}$$

(for all $x \in \mathscr{A}'$, all $v \in V$, and all $j=1,2,\ldots,d_q$).

It is worth noting that (A4), (A10), (A12), and (A13) provide the appropriate definitions for irreducible tensor operators not merely for the context in which they have been derived here (i.e. for the case in which $\mathscr{A}'$ is the group algebra of a finite group $\mathscr{G}$), but also for the case in which $\mathscr{A}'$ is the universal enveloping algebra $U(\mathscr{L})$ of a Lie algebra $\mathscr{L}$ (with $S_{\mathscr{A}'}(a)=-a$ and $\Delta_{\mathscr{A}'}(a)=a\otimes 1+1\otimes a$ for all $a(\mathscr{L})$, and for deformations of such universal enveloping algebras.

[Of course in the case $\mathscr{A}'=\mathscr{U}(\mathscr{L})$, the criteria (A4) and (A12) coincide and the criteria (A10) and (A13) also coincide, but this will not be true for deformations of $U(\mathscr{L})$].

3. Derivation of the right coactions $\pi_{\mathscr{L}^{pr}}$ and $\tilde{\pi}_{\mathscr{L}^{pr}}$

Consideration of (3) suggests that one first defines an operator $\pi'_{\mathscr{L}^{pr}}$ to be the mapping of $\mathscr{A}'\otimes\mathscr{L}^{pr}$ into $\mathscr{L}^{pr}$ that is given by

$$\pi'_{\mathscr{L}^{pr}}(x\otimes Q)=\hat{\pi}'^{r}(x)Q\hat{\pi}'^{p}(x^{-1}), \tag{A14}$$

where the operators $\hat{\pi}'^{p}(x)$ were defined (A2) [and the $\hat{\pi}'^{r}(x)$ are defined similarly], and where Q is any member of $\mathscr{L}^{pr}$. If $a^1,a^2,\ldots$ form a basis for $\mathscr{A}'$, (A14) can be re-expressed in purely Hopf algebra terms (with $x=a^k$) as

$$\begin{aligned}&\pi'_{\mathscr{L}^{pr}}(a^k\otimes Q)\\&\quad=(\hat{M}\circ(id\otimes\hat{M})\circ(\hat{\pi}'^{r}\otimes id\otimes\hat{\pi}'^{p})\circ(id\otimes\sigma)\circ(id\otimes S_{\mathscr{A}'}\otimes id)\circ(\Delta_{\mathscr{A}'}\otimes id))(a^k\otimes Q).\end{aligned} \tag{A15}$$

[Here the operator multiplication operation $\hat{M}$ is defined by $\hat{M}(Q\otimes Q')=Q\circ Q'$ for all $Q,Q'\in\mathscr{L}^{pr}$.] It is then easily demonstrated that $\pi'_{\mathscr{L}^{pr}}$ is a *left action* of $\mathscr{A}'$ with carrier space $\mathscr{L}^{pr}$.

After some algebra, it can be shown that (A15) can be rewritten in terms of components as

$$\pi'_{\mathscr{L}^{pr}}(a^k\otimes Q)=\sum_{i,j=1}^{d_p}\sum_{m,n=1}^{d_r}\langle a^k,M(\pi^{r}_{mn}\otimes S(\pi^{\ p}_{ij}))\rangle q_{ni}\mathscr{P}^{pr}_{jm}, \tag{A16}$$

where the operators $\mathscr{P}^{pr}_{bi}$ are defined in (14) and the matrix elements q_{ja} are defined in (17). The corresponding right coaction $\pi_{\mathscr{L}^{pr}}$ of $\mathscr{A}$ is then given [cf. (I.213)] by

$$\pi_{\mathscr{L}^{pr}}(Q)=\sum_k \pi'_{\mathscr{L}^{pr}}(a^k\otimes Q)\otimes a_k \tag{A17}$$

for all $Q\in\mathscr{L}^{pr}$, where $a_1,a_2,\ldots$ is the dual basis of $\mathscr{A}$. Thus, by (A16) and (A17),

$$\pi_{\mathscr{L}^{pr}}(Q)=\sum_{i,j=1}^{d_p}\sum_{m,n=1}^{d_r}(q_{ni}\mathscr{P}^{pr}_{jm})\otimes M(\pi^{\ r}_{mn}\otimes S(\pi^{\ p}_{ij})),$$

which is (32).

On replacing M by $M\circ\sigma$ and S by S^{-1}, the definition (32) changes into the definition (37) for $\tilde{\pi}_{\mathscr{L}^{pr}}$.

Quaternions and special relativity

Stefano De Leo[a)]
Università di Lecce, Dipartimento di Fisica, Instituto di Fisica Nucleare, Sezione di Lecce, Lecce, 73100, Italy

(Received 8 August 1995; accepted for publication 20 February 1996)

We reformulate Special Relativity by a quaternionic algebra on reals. Using *real linear quaternions*, we show that previous difficulties, concerning the appropriate transformations on the 3+1 space–time, may be overcome. This implies that a complexified quaternionic version of Special Relativity is a choice and not a necessity. © *1996 American Institute of Physics.* [S0022-2488(96)01106-1]

I. INTRODUCTION

''*The most remarkable formula in mathematics is:*

$$e^{i\theta}=\cos\ \theta+i\ \sin\ \theta. \tag{1}$$

This is our jewel. We may relate the geometry to the algebra by representing complex numbers in a plane

$$x+iy=re^{i\theta}.$$

This is the unification of algebra and geometry.''—Feynman.[1]

We know that a rotation of α-angle around the z axis, can be represented by $e^{i\alpha}$, in fact,

$$e^{i\alpha}(x+iy)=re^{i(\theta+\alpha)}.$$

In 1843, Hamilton in the attempt to generalize the complex field in order to describe the rotation in the three-dimensional space, discovered quaternions. Quaternions, as used in this paper, will always mean ''real quaternions''

$$q=a+ib+jc+kd,\quad a,b,c,d\in\mathscr{R}.$$

Today a rotation about an axis passing trough the origin and parallel to a given unitary vector $\mathbf{u}\equiv(u_x,u_y,u_z)$ by an angle α can be obtained taking the transformation

$$e^{(iu_x+ju_y+ku_z)\alpha/2}(ix+jy+kz)e^{-(iu_x+ju_y+ku_z)\alpha/2}. \tag{2}$$

Therefore, if we wish to represent rotations in the three-dimensional space and complete ''*the unification of algebra and geometry*,'' we need quaternions.

The quaternionic algebra has been expounded in a series of papers[2] and books[3] with particular reference to quantum mechanics; the reader may refer to these for further details. For convenience we repeat and develop the relevant points in the following section, where the terminology is also defined.

Nothing that U(1,q) is algebraically isomorphic to SU(2,c), the imaginary units i,j,k can be realized by means of the 2×2 Pauli matrices through

$$(i,j,k)\leftrightarrow(i\sigma_3,-i\sigma_2,-i\sigma_1)$$

a)Electronic mail address: deleos@le.infn.it

(this particular representation of the imaginary units i,j,k has been introduced in Ref. 4). So a quaternion q can be represented by a 2×2 complex matrix

$$q\leftrightarrow\mathcal{Q}=\begin{pmatrix} z_1 & -z_2^* \\ z_2 & z_1^* \end{pmatrix}, \tag{3}$$

where

$$z_1=a+ib, \quad z_2=c-id\in\mathcal{C}(1,i),$$

$$z_1^*=a-ib, \quad z_2^*=c+id.$$

It follows that a quaternion with unitary norm is identified by a unitary 2×2 matrix with unit determinant. This gives the correspondence between unitary quaternions $\mathrm{U}(1,q)$ and $\mathrm{Su}(2,c)$ [in a recent paper[5] the representation theory of the group $\mathrm{U}(1,q)$ has been discussed in detail]. Let us consider the transformation law of a spinor (two-dimensional representations of the rotation group)

$$\psi'=\mathcal{U}\psi, \tag{4}$$

where

$$\psi=\begin{pmatrix} z_1 \\ z_2 \end{pmatrix}, \quad \mathcal{U}\in\mathrm{SU}(2,c).$$

We can immediately verify that

$$\tilde{\psi}=\begin{pmatrix} -z_2 \\ z_1 \end{pmatrix}$$

transforms as follows,

$$\tilde{\psi}'=\mathcal{U}^*\tilde{\psi}, \tag{5}$$

so

$$\begin{pmatrix} z_1 & -z_2^* \\ z_2 & z_1^* \end{pmatrix}'=\mathcal{U}\begin{pmatrix} z_1 & -z_2^* \\ z_2 & z_1^* \end{pmatrix}$$

represents again the transformation law of a spinor.

Thanks to the identification (3) we can write the previous transformations by real quaternions as follows

$$q'=\mathcal{U}q,$$

with $q=z_1+jz_2$ and $\mathcal{U}$ quaternion with unitary norm $[N(\mathcal{U})=\mathcal{U}^+\mathcal{U}=1]$. Note that we do not need right operators to indicate the transformation law of a spinor.

Now we can obtain the transformation law of a three-dimensional vector $\mathbf{r}\equiv(x,y,z)$ by product of spinors; in fact, if we consider the purely imaginary quaternion

$$\omega=qiq^+=ix+jy+kz, \quad (i,j,k)^+\equiv-(i,j,k),$$

or the corresponding traceless 2×2 complex matrix

$$\Omega = \psi i \psi^{+} = \begin{pmatrix} ix & -y - iz \\ y - iz & -ix \end{pmatrix},$$

a rotation in the three-dimensional space can be written as follows:[6]

$$\omega' = \mathscr{U}\omega\mathscr{U}^{+} \quad \text{(quaternions)},$$

$$\Omega' = \mathscr{U}\Omega\mathscr{U}^{+} \quad (2\times 2 \text{ complex matrices}).$$

For infinitesimal transformations, $\mathscr{U}=1+\mathbf{Q}\cdot\boldsymbol{\theta}$, we find

$$\mathbf{Q}\cdot\mathbf{r}' = \mathbf{Q}\cdot\mathbf{r} + \mathbf{Q}\cdot\boldsymbol{\theta}\,\mathbf{Q}\cdot\mathbf{r} - \mathbf{Q}\cdot\mathbf{r}\mathbf{Q}\cdot\boldsymbol{\theta},$$

where

$$\mathbf{Q}\equiv(i,j,k), \quad \boldsymbol{\theta}\equiv(\alpha,\beta,\gamma).$$

If we rewrite the above mentioned transformation in the following form,

$$\mathbf{Q}\cdot\mathbf{r}' = [1 + \boldsymbol{\theta}\cdot(\mathbf{Q} - 1|\mathbf{Q})]\mathbf{Q}\cdot\mathbf{r}, \tag{6}$$

barred operators $\mathscr{O}|q$ act on quaternionic objects Φ as in $(\mathscr{O}|q)\Phi=\mathscr{O}\Phi q$.
We identify

$$\frac{i-1|i}{2}, \quad \frac{j-1|j}{2}, \quad \frac{k-1|k}{2},$$

as the generators for rotations in the three-dimensional space. The factor $\frac{1}{2}$ guarantees that our generators satisfy the usual algebra:

$$[A_m, A_n] = \epsilon_{mnp}A_p, \quad m,n,p = 1,2,3.$$

Up until now, we have considered only particular operations on quaternions. A quaternion q can also be multiplied by unitary quaternions $\mathscr{V}$ from the right. A possible transformation which preserves the norm is given by

$$q' = \mathscr{U}q\mathscr{V}, \quad (\mathscr{U}^{+}\mathscr{U} = \mathscr{V}^{+}\mathscr{V} = 1). \tag{7}$$

Since left and right multiplications commute, the group is locally isomorphic to SU(2)×SU(2), and so to O(4), the four-dimensional Euclidean rotation group.

As far as here we can recognize only particular real linear quaternions, namely,

$$1, \quad i, \quad j, \quad k, \quad 1|i, \quad 1|j, \quad 1|k.$$

Real linear and complex linear quaternion operators were first systematically discussed in the paper by Horwitz and Biedenharn.[7]

We have to hope of describing the Lorentz group if we use only previous objects. Analyzing the most general transformation on quaternions (see Sec. IV), we introduce new real linear quaternions which allow us to overcome the above difficulty and so obtain a quaternionic version of the Lorentz group, without the use of complexified quaternions. This result appears, to the best of our knowledge, for the first time in print.

First we briefly recall the standard way to rewrite special relativity by a quaternionic algebra on complex (see Sec. III).

In Sec. V, we present a quaternionic version of the special group SL(2,c), which is as well-known collected to the Lorentz group. Our conclusions are drawn in the final section.

II. QUATERNIONIC ALGEBRAS

A quaternionic algebra over a field $\mathscr{F}$ is a set

$$\mathscr{H}=\{\alpha+i\beta+j\gamma+k\delta|\,\alpha,\beta,\gamma,\delta\in\mathscr{F}\},$$

with multiplication operations defined by following rules for imaginary units i,j,k:

$$i^2=j^2=k^2=-1,\quad jk=-kj=i,\quad ki=-ik=j,\quad ij=-ji=k.$$

In our paper we will work with quaternionic algebras defined on reals and complex, so in this section we give a panoramic review of such algebras.

We start with a quaternionic algebra on reals

$$\mathscr{H}_R=\{\alpha+i\beta+j\gamma+k\delta|\,\alpha,\beta,\gamma,\delta\in\mathscr{R}\}.$$

We introduce the quaternion conjugation denoted by $^+$ and defined by

$$q^+=\alpha-i\beta-j\gamma-k\delta.$$

The previous definition implies

$$(\psi\varphi)^+=\varphi^+\psi^+,$$

for ψ, φ quaternionic functions. A conjugation operation which does not reverse the order of ψ, φ factors is given, for example, by

$$\tilde{q}=\alpha-i\beta+j\gamma-k\delta.$$

An important difference between quaternions and complexified quaternions, as remarked by Adler in his recent book[8] (pag. 8), is based on the concept of *division algebra*, which is a finite-dimensional algebra for which $a\neq0$, $b\neq0$ implies $ab\neq0$, in others words, which has no nonzero divisors of zero. A classical theorem[9] states that the only division algebras over the reals are algebras of dimension 1, 2, 4, and 8; the only associative algebras over the reals are $\mathscr{R}$, $\mathscr{C}$, and $\mathscr{H}_{\mathscr{R}}$;[10] the nonassociative division algebras include the octonions $\mathscr{O}$ (but there are others as well; see Ref. 11).

A simple example of a *nondivision* algebra is provided by the algebra of complexified quaternions

$$\mathscr{H}_{\mathscr{C}}=\{\alpha+i\beta+j\gamma+k\delta|\,\alpha,\beta,\gamma,\delta\in\mathscr{C}(1,\mathscr{I})\},$$

$$[\mathscr{I},\,i]=[\mathscr{I},\,j]=[\mathscr{I},\,k]=0.$$

In fact, since

$$(1+i\mathscr{I})(1-i\mathscr{I})=0,$$

there are nonzero divisors of zero.

For complexified quaternions we have different opportunities to define conjugation operations; we shall use the following terminology:

(1) The *complex* conjugate of $q_{\mathscr{C}}$ is

$$q_{\mathbb{C}}^{*}=\alpha^{*}+i\beta^{*}+j\gamma^{*}+k\delta^{*}.$$

Under this operation

$$(\mathscr{I},i,j,k)\rightarrow(-\mathscr{I},i,j,k)$$

and

$$(q_{\mathbb{C}}p_{\mathbb{C}})^{*}=q_{\mathbb{C}}^{*}p_{\mathbb{C}}^{*}.$$

(2) The *quaternion* conjugate of $q_{\mathbb{C}}$ is

$$q_{\mathbb{C}}^{\star}=\alpha-i\beta-j\gamma-k\delta.$$

Here

$$(\mathscr{I},i,j,k)\rightarrow(\mathscr{I},-i,-j,-k)$$

and

$$(q_{\mathbb{C}}p_{\mathbb{C}})^{\star}=p_{\mathbb{C}}^{\star}q_{\mathbb{C}}^{\star}.$$

(3) In the absence of standard terminology, we call that formed by combining these operations the *full* conjugate:

$$q_{\mathbb{C}}^{+}=\alpha^{*}-i\beta^{*}-j\gamma^{*}-k\delta^{*}.$$

Under this operation

$$(\mathscr{I},i,j,k)\rightarrow-(\mathscr{I},i,j,k)$$

and

$$(q_{\mathbb{C}}p_{\mathbb{C}})^{+}=p_{\mathbb{C}}^{+}q_{\mathbb{C}}^{+}.$$

Note that for real quaternions we have

$$q^{\star}\equiv q^{+}.$$

III. COMPLEXIFIED QUATERNIONS AND SPECIAL RELATIVITY

We begin this section by recalling a sentence of Anderson and Joshi[12] about the quaternionic reformulation of special relativity:

''There has been a long tradition of using quaternions for Special Relativity... The use of quaternions in special relativity, however, is not entirely straightforward. Since the field of quaternions is a four-dimensional Euclidean space, complex components for the quaternions are required for the 3+1 space–time of special relativity.''

In the following section, we will demonstrate that a reformulation of special relativity by a quaternionic algebra on reals is possible.

In the present section, we use complexified quaternions to reformulate special relativity (for further details the reader may consult the papers of Edmonds,[13] Gough,[14] Abonyi,[15] Gürsey,[16] and the book of Synge[17]).

A space–time point can be represented by complexified quaternions as follows:

$$\mathscr{X}=\mathscr{I}ct+ix+jy+kz. \tag{8}$$

The Lorentz invariant in this formalism is given by

$$\mathscr{X}^{*}.\mathscr{X}=(ct)^2-x^2-y^2-z^2. \tag{9}$$

If we consider the standard Lorentz transformation (boost $ct-x$)

$$ct'=\gamma(ct-\beta x),\quad x'=\gamma(x-\beta ct),\quad y'=y,\quad z'=z$$

and note that the first two equations may be rewritten as

$$ct'=ct\ \cosh\ \theta-x\ \sinh\ \theta,$$

$$x'=x\ \cosh\ \theta-ct\ \sinh\ \theta,$$

where $\cosh\ \theta=\gamma$ and $\sinh\ \theta=\beta\gamma$.

We can represent an infinitesimal transformation by

$$\mathscr{X}'=\mathscr{T}(ct-x\theta)+i(x-ct\theta)+jy+kz=\mathscr{X}+\mathscr{T}\frac{i+1|i}{2}\ \theta.\mathscr{X}.$$

We thus recognize, in the previous transformation, the generator

$$\mathscr{T}\frac{i+1|i}{2}.$$

It is now very simple to complete the translation. The set of generators of the Lorentz group is provided with

$$\text{boost}\ \ (ct,x)\quad \mathscr{T}\frac{i+1|i}{2},$$

$$\text{boost}\ \ (ct,y)\quad \mathscr{T}\frac{j+1|j}{2},$$

$$\text{boost}\ \ (ct,z)\quad \mathscr{T}\frac{k+1|k}{2},$$

$$\text{rotation around}\ \ x\quad \frac{i-1|i}{2},$$

$$\text{rotation around}\ \ y\quad \frac{j-1|j}{2},$$

$$\text{rotation around}\ \ z\quad \frac{k-1|k}{2}.$$

Therefore a general finite Lorentz transformation is given by

$$e^{\mathscr{T}(i\alpha_b+j\beta_b+k\gamma_b)+i\alpha_r+j\beta_r+k\gamma_r}(\mathscr{T}ct+ix+jy+kz)e^{\mathscr{T}(i\alpha_b+j\beta_b+k\gamma_b)-i\alpha_r-j\beta_r-k\gamma_r}.$$

The previous results can be elegantly summarized by the relation

$$\mathscr{X}'=\Lambda.\mathscr{X}\Lambda^{+},\quad \Lambda^{*}\Lambda=1, \tag{10}$$

where Λ is obviously a complexified quaternion. In this or a similar way many authors have reformulated special relativity with complex quaternions.

We remark that the complex component for the quaternions represent a choice and not a necessity.

IV. A NEW POSSIBILITY

We think that quaternions are the natural candidates to describe special relativity. It is simple to understand why: quaternions are characterized by four real numbers (whereas complexified quaternions by eight), thus we can collect these four real quantities with a point (ct,x,y,z) in the space–time. In quaternionic notation we have

$$\mathscr{X}=ct+ix+jy+kz. \tag{11}$$

In the first section we have introduced particular *real linear quaternions*, namely,

$$1, \quad \mathbf{Q}, \quad 1|\mathbf{Q},$$

where

$$\mathbf{Q}\equiv(i,j,k).$$

In order to write the most general real linear quaternions we must consider the following quantities:

$$\mathbf{Q}|i, \quad \mathbf{Q}|j, \quad \mathbf{Q}|k.$$

In fact, the most general transformation on quaternions is represented by

$$q+p|i+r|j+s|k, \tag{12}$$

with

$$q,p,r,s\in\mathscr{H}_{\mathscr{R}}.$$

New objects like

$$k|j, \quad j|k, \quad i|k, \quad k|i, \quad j|i, \quad i|j$$

will be essential to reformulate special relativity with real quaternions. They represent the wedges which permit us to overcome the difficulties which in the past did not allow a (real) quaternionic version of special relativity.

Returning to Lorentz transformations, let us start with the following infinitesimal transformation (boost $ct-x$):

$$\mathscr{X}'=ct-x\theta+i(x-ct\theta)+jy+kz=\mathscr{X}+\frac{k|j-j|k}{2}\,\theta\mathscr{X}.$$

We can immediately note that the generator which substitutes

$$\mathscr{I}\,\frac{i+1|i}{2}$$

is

$$\frac{k|j-j|k}{2}.$$

So we have the possibility of listing the generators of the Lorentz group without the need to work with complexified quaternions:

$$\text{boost } (ct,x) \quad \frac{k|j-j|k}{2},$$

$$\text{boost } (ct,y) \quad \frac{i|k-k|i}{2},$$

$$\text{boost } (ct,z) \quad \frac{j|i-i|j}{2},$$

$$\text{rotation around } x \quad \frac{i-1|i}{2},$$

$$\text{rotation around } y \quad \frac{j-1|j}{2},$$

$$\text{rotation around } z \quad \frac{k-1|k}{2}.$$

In Appendix A we explicitly prove that the action of previous generators leaves

$$\text{Re } \mathscr{Q}^2=(ct)^2-x^2-y^2-z^2 \tag{13}$$

invariant.

In Appendix B we will give an alternate but equivalent presentation of special relativity by a quaternionic algebra on reals. There we introduce a real linear quaternion g which substitutes the metric tensor $g^{\mu\nu}$.

V. A QUATERNIONIC VERSION OF THE COMPLEX GROUP SL(2)

In analogy to the connection between the rotation group O(3) to the special unitary group SU(2), there is a natural correspondence[18] between the Lorentz group O(3,1) and the special linear group SL(2). In fact, SL(2) is the universal covering group of O(3,1) in the same way that SU(2) is of O(3).

The aim of this Section is to give, by extending the consideration with which we collect the special unitary group SU(2) with unitary real quaternions (as shown in Sec. I), a quaternionic version of the special linear group SL(2). Once more the aim will be achieved with help of real linear quaternions.

A Lorentz spinor is a complex object which transforms under Lorentz transformations as

$$\psi'=\mathscr{A}\psi,$$

where $\mathscr{A}$ is a SL(2) matrix. When we restrict ourselves to the three-dimensional space and to rotations, this definition gives the usual Pauli spinors

$$\psi'=\mathscr{U}\psi,$$

where $\mathscr{U}$ is a SU(2) matrix.

Now we shall derive the generators of rotations and Lorentz boosts in the spinor representation by using real linear quaternions.

The action of generators of the special group SL(2),

$$\begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}, \quad \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & -i \\ -i & 0 \end{pmatrix}, \quad \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},$$

on the spinor

$$\psi = \begin{pmatrix} \xi \\ \eta \end{pmatrix}$$

can be represented by the action of real linear quaternions

$$i, \quad j, \quad k, \quad i|i, \quad j|i, \quad k|i$$

on the quaternion

$$q = \xi + j\,\eta.$$

In Sec. I we have obtained a three-dimensional vector (x,y,z) by product of Pauli spinors $q_{\mathscr{P}}$:

$$q_{\mathscr{P}}\, i q_{\mathscr{P}}^{+} = ix + jy + kz \quad (q'_{\mathscr{P}} = \mathscr{U} q_{\mathscr{P}}, \quad \mathscr{U}^{+}\mathscr{U} = 1).$$

Consequently, we have written its transformation law as follows:

$$(q_{\mathscr{P}}\, i q_{\mathscr{P}}^{+})' = \mathscr{U} q_{\mathscr{P}} i q_{\mathscr{P}}^{+} \mathscr{U}^{+}.$$

Now we start with a Lorentz spinor $q_{\mathscr{L}}$

$$q'_{\mathscr{L}} = \mathscr{A} q_{\mathscr{L}},$$

and construct a four-vector (ct,x,y,z) by-product of such spinors:

$$q_{\mathscr{L}}(1+i)q_{\mathscr{L}}^{+} = ct + ix + jy + kz.$$

The transformation law is then given by

$$(q_{\mathscr{L}}(1+i)q_{\mathscr{L}}^{+})' = (\mathscr{A} q_{\mathscr{L}})(1+i)(\mathscr{A} q_{\mathscr{L}})^{+}.$$

If we consider infinitesimal transformations

$$\mathscr{A} = 1 + \frac{\mathbf{Q}}{2} \cdot (\boldsymbol{\theta} + \boldsymbol{\zeta} | i),$$

with $\boldsymbol{\theta} \equiv (\alpha,\beta,\gamma)$ and $\boldsymbol{\zeta} \equiv (\tilde{\alpha},\tilde{\beta},\tilde{\gamma})$,
we have

$$\mathscr{T}' = \mathscr{T} + \frac{\alpha}{2}[i, \mathscr{T}] + \frac{\beta}{2}[j, \mathscr{T}] + \frac{\gamma}{2}[k, \mathscr{T}] + \frac{\tilde{\alpha}}{2}\{i, \tilde{\mathscr{T}}\} + \frac{\tilde{\beta}}{2}\{j, \tilde{\mathscr{T}}\} + \frac{\tilde{\gamma}}{2}\{k, \tilde{\mathscr{T}}\},$$

where

$$\mathscr{T}=q_{\mathscr{Z}}(1+i)q_{\mathscr{Z}}^{+}$$

and

$$\tilde{\mathscr{T}}=q_{\mathscr{Z}}i(1+i)q_{\mathscr{Z}}^{+}=\mathscr{T}-2q_{\mathscr{Z}}q_{\mathscr{Z}}^{+}.$$

In order to simplify next considerations we pose

$$\mathscr{T}=ix+jy+kz+ct=.\mathscr{T}_i+.\mathscr{T}_j+.\mathscr{T}_k+.\mathscr{T}_1,$$

$$\tilde{\mathscr{T}}=ix+jy+kz-ct=.\mathscr{T}_i+.\mathscr{T}_j+.\mathscr{T}_k-.\mathscr{T}_1,$$

so the standard Lorentz transformations are given by

$$.\mathscr{T}_1\to.\mathscr{T}_1+\tilde{\alpha}i.\mathscr{T}_i+\tilde{\beta}j.\mathscr{T}_j+\tilde{\gamma}k.\mathscr{T}_k,\quad .\mathscr{T}_i\to.\mathscr{T}_i-\tilde{\alpha}i.\mathscr{T}_1+\beta j.\mathscr{T}_k-\gamma k.\mathscr{T}_j,$$

$$.\mathscr{T}_j\to.\mathscr{T}_j-\tilde{\beta}j.\mathscr{T}_1-\alpha i.\mathscr{T}_k+\gamma k.\mathscr{T}_i,\quad .\mathscr{T}_k\to.\mathscr{T}_k-\tilde{\gamma}k.\mathscr{T}_1+\alpha i.\mathscr{T}_j-\beta j.\mathscr{T}_i.$$

In this way we obtain a quaternionic version of the special group SL(2) and demonstrate (in contrast with the opinion of Penrose)[6] that, if real linear quaternions appear, a ''trick'' similar to that one of rotations works to relate the full four-vector (ct,x,y,z) with real quaternions.

VI. CONCLUSIONS

The study of special relativity with a quaternionic algebra on reals has yielded a result of interest. While we cannot demonstrate in this paper that one number system (quaternions) is preferable to another (complexified quaternions), we have pointed out the advantages of using real linear quaternions which naturally appear when we work with a noncommutative number system, such as the quaternionic field. As seen in this paper these objects are very useful if we wish to rewrite special relativity by a quaternionic algebra on reals. The complexified quaternionic reformulation of special relativity is thus a choice and not a necessity. This affirmation is in contrast with the standard folklore (see, for example, Ref. 12).

Our principal aim in this work is to underline the potentialities of real linear quaternions. We wish to remember that many difficulties have been overcome thanks to these objects (which in our colorful language we have named generalized objects).[4]

To remark on their potentialities let us list the situations which have requested their use.

(i) The need of such objects naturally appears, for example, in the construction of quaternion group theory and tensor product group representations.[5] Also starting with only standard quaternions i,j,k in order to represent the generators of the group U(1,q), we find generalized quaternions when we analyze quaternionic tensor products.

$$\text{Spin } \frac{1}{2} \text{ generators: } \quad \frac{i}{2},\quad \frac{j}{2},\quad \frac{k}{2}.$$

$$\text{Spin } 1\oplus 0 \text{ generators: } \begin{pmatrix} \dfrac{i+1|i}{2} & 0 \\ 0 & \dfrac{i-1|i}{2} \end{pmatrix},\quad \begin{pmatrix} j & 1|i \\ 1|i & j \end{pmatrix},\quad \begin{pmatrix} k & -1 \\ 1 & k \end{pmatrix}.$$

(ii) If we desire to extend the isomorphism of SU(2,c) with U(1,q) to the group U(2,c), we must introduce the additional real linear quaternion ''$1|i$.'' In this way there exists at least one

version of quaternionic quantum mechanics in which a ''partial'' set of translations may be defined;[4] in fact, thanks to real linear operators, a translation between $2n\times 2n$ complex and $n\times n$ quaternionic matrices is possible.

(iii) In the work of Ref. 19 a quaternion version of the Dirac equation was derived in the form

$$\gamma_\mu \partial^\mu \psi i = m\psi,$$

where the γ_μ are two-by-two quaternionic matrices satisfying the Dirac condition

$$\{\gamma_\mu, \gamma_\nu\} = 2g_{\mu\nu}.$$

In Rotelli's formalism the momentum operator must be defined as

$$p^\mu = \partial^\mu |i,$$

which is also a generalized object.

(iv) In this paper, contrary to the common opinion, we have given a real quaternionic formulation of special relativity. In order to obtain that, we have introduced the following real linear quaternions:

$$\mathbf{Q}|i, \quad \mathbf{Q}|j, \quad \mathbf{Q}|k, \quad \mathbf{Q}\equiv(i,j,k).$$

A quaternionic version of the special group SL(2) has also been given.

We finally note that the process of generalization can be extended also to complexified quaternions. In a recent paper[20] we gave an elegant one-component formulation of the Dirac equation and, thanks to our generalization, we overcame previous difficulties concerning the doubling of solutions[12–14] in the complexified quaternionic Dirac equation.

In seeking a better understanding of the success of mathematical abstraction in physics and in particular of the wide applicability of quaternionic numbers in theories of physical phenomena, we found that generalized quaternions should *not* be undervalued. We think that there are good reasons to hope that these generalized structures provide new possibilities concerning physical applications of quaternions.

''The most powerful method of advance that can be suggested at present is to employ all the resources of pure mathematics in attempts to perfect and generalize the mathematical formalism that forms the existing basis of theoretical physics, and after each success in this direction, to try to interpret the new mathematical features in terms of physical entities...''—Dirac.[21]

APPENDIX A: QUATERNIONIC LORENTZ INVARIANT

In this Appendix we prove that the Lorentz invariant[8] is

$$\mathrm{Re}\ \mathscr{X}'^2 = \mathrm{Re}\ \mathscr{X}^2, \tag{A1}$$

where

$$\mathscr{X} = ct + ix + jy + kz.$$

Under an infinitesimal transformation, we have

$$\mathscr{X}' = \left(1 + \theta\,\frac{k|j - j|k}{2} + \alpha\,\frac{i-1|i}{2} + \cdots\right)\mathscr{X},$$

so, neglecting second-order terms,

$$\mathscr{X}'^2=\mathscr{X}^2+\frac{\theta}{2}\{\mathscr{X},k\mathscr{X}j-j\mathscr{X}k\}+\frac{\alpha}{2}\{\mathscr{X},i\mathscr{X}-\mathscr{X}i\}+\cdots .$$

Equation (14) is then satisfied since

$$\{\mathscr{X},i\mathscr{X}-\mathscr{X}i\}=(i-1|i)\mathscr{X}^2,$$

$$\{\mathscr{X},k\mathscr{X}j-j\mathscr{X}k\}=(1|j-j)\mathscr{X}k\mathscr{X}+(k-1|k)\mathscr{X}j\mathscr{X}$$

are purely imaginary quaternions.

Obviously we can derive the generators of the Lorentz group by starting from the infinitesimal transformation

$$\mathscr{X}'=\mathscr{X}+\mathscr{A}\mathscr{X}$$

and imposing that they satisfy the relation

$$\mathrm{Re}\{\mathscr{X},\mathscr{A}\mathscr{X}\}=0$$

$$(\mathrm{Re}\,\mathscr{X}'^2=\mathrm{Re}\,\mathscr{X}^2\Rightarrow\mathrm{Re}\{\mathscr{X},\mathscr{A}\mathscr{X}\}=0). \tag{A2}$$

With straightforward mathematical calculus we can find the generators requested. In order to simplify the following considerations let us pose

$$\mathscr{X}=a+ib+jc+kd,\quad \mathscr{A}=q_0+q_1|i+q_2|j+q_3|k$$

where $q_m=\alpha_m+i\beta_m+j\gamma_m+k\delta_m$ $(m=0,1,2,3)$ are real quaternions.

The only quantities which we must calculate are

$$\mathrm{Re}\{\mathscr{X},\mathscr{X}\},\quad \mathrm{Re}\{\mathscr{X},i\mathscr{X}i\},\quad \mathrm{Re}\{\mathscr{X},i\mathscr{X}\},\quad \mathrm{Re}\{\mathscr{X},k\mathscr{X}j\};$$

in fact, the other quantities can be obtained from previous ones, by simple manipulations:

$$\mathrm{Re}\{\mathscr{X},\mathscr{X}\}=2(+a^2-b^2-c^2-d^2),\quad \mathrm{Re}\{\mathscr{X},i\mathscr{X}i\}=2(-a^2+b^2-c^2-d^2),$$

$$\mathrm{Re}\{\mathscr{X},j\mathscr{X}j\}=2(-a^2-b^2+c^2-d^2),\quad \mathrm{Re}\{\mathscr{X},k\mathscr{X}k\}=2(-a^2-b^2-c^2+d^2),$$

$$\mathrm{Re}\{\mathscr{X},i\mathscr{X}\}=\mathrm{Re}\{\mathscr{X},\mathscr{X}i\}=-4ab,\quad \mathrm{Re}\{\mathscr{X},k\mathscr{X}j\}=\mathrm{Re}\{\mathscr{X},j\mathscr{X}k\}=4cd,$$

$$\mathrm{Re}\{\mathscr{X},j\mathscr{X}\}=\mathrm{Re}\{\mathscr{X},\mathscr{X}j\}=-4ac,\quad \mathrm{Re}\{\mathscr{X},j\mathscr{X}i\}=\mathrm{Re}\{\mathscr{X},i\mathscr{X}j\}=4bc,$$

$$\mathrm{Re}\{\mathscr{X},k\mathscr{X}\}=\mathrm{Re}\{\mathscr{X},\mathscr{X}k\}=-4ad,\quad \mathrm{Re}\{\mathscr{X},i\mathscr{X}k\}=\mathrm{Re}\{\mathscr{X},k\mathscr{X}i\}=4bd.$$

The previous relations imply the following conditions on the real parameters of the generator $\mathscr{A}$:

$$\alpha_0=0,\quad \beta_1=0,$$

$$\gamma_2=0,\quad \delta_3=0,$$

$$\beta_0=-\alpha_1=\alpha,\quad \gamma_0=-\alpha_2=\beta,$$

$$\delta_0=-\alpha_3=\gamma,\quad \delta_2=-\gamma_3=\theta,$$

$$\gamma_1=-\beta_2=\varphi,\quad \beta_3=-\delta_1=\eta.$$

We can immediately recognize the Lorentz generators given in Sec. IV.

APPENDIX B: QUATERNIONIC METRIC TENSOR

We introduce the usual four-vector x^μ by the following quaternion,

$$\mathscr{X}=x^0+ix^1+jx^2+kx^3,$$

and define a scalar product of two vectors $\mathscr{X}$, $\mathscr{Y}$ by

$$(\mathscr{X},g\mathscr{Y})_{\mathscr{R}}=\mathrm{Re}(\mathscr{X}^{+}g\mathscr{Y})=x^\mu g_{\mu\nu}y^\nu, \tag{B1}$$

where g is the generalized quaternion

$$-\tfrac{1}{2}(1+i|i+j|j+k|k).$$

We can define a real norm (or metric)

$$(\mathscr{X},g\mathscr{X})_{\mathscr{R}}=\mathrm{Re}(\mathscr{X}^{+}g\mathscr{X})=x^\mu g_{\mu\nu}x^\nu.$$

The vectors which transform under a Lorentz transformation $\mathscr{L}$ will be denoted by

$$\mathscr{X}'=\mathscr{L}\mathscr{X},$$

with $\mathscr{L}$ real linear operators [see Eq. (12)]. From the postulated invariance of the norm we can deduce the generators of Lorentz group.

If we consider infinitesimal transformations

$$\mathscr{L}=1+\mathscr{A},$$

we have

$$\mathrm{Re}(\mathscr{X}'^{+}g\mathscr{X}')=\mathrm{Re}(\mathscr{X}^{+}g\mathscr{X}+\mathscr{X}^{+}(\mathscr{A}^{+}g+g\mathscr{A})\mathscr{X})=\mathrm{Re}(\mathscr{X}^{+}g\mathscr{X}),$$

and therefore

$$\mathscr{A}^{+}g+g\mathscr{A}=0. \tag{B2}$$

Using real scalar products, given an operator

$$\mathscr{A}=q+p|i+r|j+s|k,\quad q,p,r,s\in\mathscr{H}_{\mathscr{R}},$$

we can write its Hermitian conjugate as follows:

$$\mathscr{A}^{+}=q^{+}-p^{+}|i-r^{+}|j-s^{+}|k.$$

Then Eq. (17) can be rewritten as

$$g\mathscr{A}+h.c.=0.$$

If we pose

$$g\mathscr{A}=B=\tilde{q}+\tilde{p}|i+\tilde{r}\,|j+\tilde{s}\,|k,$$

we obtain the following conditions on the operator B:

$$\mathrm{Re}\;\tilde{q}=\mathrm{Vec}\;\tilde{p}=\mathrm{Vec}\;\tilde{r}=\mathrm{Vec}\;\tilde{s}=0.$$

Noting that $\mathscr{A}=gB$ we can quickly write the generators of Lorentz group. We give explicitly an example

$$\mathscr{A}_1=g(1|i)=-\tfrac{1}{2}(-i+1|i+j|k-k|j),$$

$$\mathscr{A}_2=gi=-\tfrac{1}{2}(i-1|i+j|k-k|j),$$

$$\mathscr{A}=\mathscr{A}_1-\mathscr{A}_2=\frac{i-1|i}{2},\quad \tilde{\mathscr{A}}=\mathscr{A}_1+\mathscr{A}_2=\frac{k|j-j|k}{2}.$$

The solutions of a system of homogeneous first-order quasilinear evolution equations for which the propagation velocity depends only on the field value are characterized by their invariance under a particular type of flow. All simple wave solutions are shown to have this property. The local images of simple wave solutions are the integral curves of a system of ordinary differential equations on the field space. The model for barotropic compressible flow is an example of a system that has invariant solutions of higher rank. A solution of this system is invariant under the flow of the convective derivative if and only if it is divergence-free. The evolution of initial data is shown to be divergence-free if and only if its differential is nilpotent. © *1996 American Institute of Physics.* [S0022-2488(96)02006-3]

I. INTRODUCTION

In this paper we study systems of differential equations of the form

$$\frac{\partial u^\alpha}{\partial t}+\sum_{i=1}^{n}\sum_{\beta=1}^{q} A_\beta^{i\alpha}(u)\,\frac{\partial u^\beta}{\partial x^i}=0,\quad \alpha=1,\ldots,q. \tag{1.1}$$

in $p=n+1$ independent variables t, $x^1,\ldots,x^n$ and q dependent variables $u^1,\ldots,u^q$. We write (1.1) as a vector equation,

$$\frac{\partial u}{\partial t}+A^1(u)\,\frac{\partial u}{\partial x^1}+\cdots+A^n(u)\,\frac{\partial u}{\partial x^n}=0,$$

or simply

$$\left(\frac{\partial}{\partial t}+A(u)\cdot\,\frac{\partial}{\partial x}\right)u=0, \tag{1.2}$$

where $A^1,\ldots,A^n$ are $q\times q$ matrix functions. The equation (1.2) is a system of coupled homogeneous first-order quasilinear evolution equations, typical of those encountered in fluid dynamics.[1–3] A function $u(t,x)$ is a q-component field defined on an n-dimensional spatial domain parametrized by coordinates $x^1,\ldots,x^n$, evolving according to a time parameter t. The identification of a function $u(t,x)$ with its graph $\{(t,x,u(t,x))\}$ is a local correspondence between functions and p-dimensional submanifolds of $\mathbb{R}^p\times\mathbb{R}^q$ transverse to the projection onto $\mathbb{R}^p$. The equation (1.2) is a geometric condition on the tangent spaces of the submanifold. Its form is invariant under arbitrary change of field variables and affine change of space variables.

In this work all manifolds, functions, and transformations are C^∞ and all considerations are local. The equation (1.2) is autonomous and translation invariant, so we restrict our attention to solutions $u(t,x)$ defined on a neighborhood of the point $t=0$, $x=0$. The relevant initial value problem consists of solving (1.2) subject to initial data defined on an open subset of the hyper-

plane $t=0$. For sufficiently small initial data there exists a time interval $[0,T]$ in which a gradient catastrophe for the solution of (1.2) does not occur and the solution does not blow up.[4–6] This fact makes it possible to use the method of characteristics to solve the problems of propagation and nonlinear superposition of waves over the time interval $[0,T]$. Using this method, existence, uniqueness, and the continuous dependence of solutions on initial data have been proved by many authors.[7–9] However, the results thus far obtained are mainly limited to hyperbolic systems with two independent variables. In this case the solution was constructed in the entire domain, where its existence was expected.

Exhibiting generic solutions of (1.2) is practically impossible, except for the characteristic equations discussed in Sec. II. A characteristic equation is simply an invariance condition, and its general solution is easily described in the implicit form. This suggests that we look for invariant solutions of the general equation (1.2). We discuss this approach in Sec. III. In Sec. IV all rank 1 solutions of the general equation are shown to be invariant. The equations that model barotropic compressible flow are discussed in Sec. V, as an example of a system with higher rank invariant solutions.

II. CHARACTERISTIC EQUATIONS

The simplest equations (1.2) are those with scalar matrices. This is always the case if $q=1$. If $A^1=a^1I,\ldots,A^n=a^nI$, where I is the $q\times q$ identity matrix, then (1.2) is the *characteristic* equation,

$$\left(\frac{\partial}{\partial t}+a(u)\cdot\frac{\partial}{\partial x}\right)u=0, \tag{2.1}$$

of the vector field

$$V=\frac{\partial}{\partial t}+a(u)\cdot\frac{\partial}{\partial x}, \tag{2.2}$$

on the space $\{(t,x,u)\}$ of independent and dependent variables. A function $u(t,x)$ is a solution of (2.1) if and only if V is tangent to its graph $\{(t,x,u(t,x))\}$, i.e., if and only if its graph is locally invariant under the flow of V. The independent invariants,

$$x^1-a^1(u)t,\ldots,x^n-a^n(u)t,u^1,\ldots,u^q,$$

of V provide a complete local description of the invariant submanifolds. We find that the local solutions of (2.1) near $t=0$ are defined implicitly by the equations

$$u=f(x-a(u)t), \tag{2.3}$$

where $f:\mathbb{R}^n\to\mathbb{R}^q$ is an arbitrary locally defined function. The general solution (2.3) of the characteristic equation (2.1) is well known.[10] Note that for each function f there is a unique solution $u=u(t,x)$ of (2.3) defined near $t=0$ with $u(0,x)=f(x)$ on the domain of f. Thus the initial value problem for (2.1) has a unique solution. Geometrically, the solution manifold is foliated by the trajectories of V, i.e., by the characteristic lines $t\mapsto(t,x+a(u)t,u)$. In physical terms, the initial signal $f(x)$ propagates through space at constant velocity $dx/dt=a(f(x))$. Note that V is a trivial symmetry of its characteristic equation in that the flow of V carries any solution manifold of (2.1) into itself, by construction.

III. THE GENERAL PROBLEM

The equation (1.2) is less tractable when the matrices $A^1,\ldots,A^n$ are not scalar. We look for solutions that are invariant under a vector field (2.2), i.e., for solutions given implicitly by an equation (2.3). Geometrically, we want solution manifolds of (1.2) that are foliated by the char-

acteristic lines of a vector field with the special form (2.2). In physical terms, we want solutions of (1.2) for which the signal propagation velocity depends only on the field value. Analytically, we want solutions of the overdetermined system,

$$\left(\frac{\partial}{\partial t}+A(u)\cdot\frac{\partial}{\partial x}\right)u=0,\quad \left(\frac{\partial}{\partial t}+a(u)\cdot\frac{\partial}{\partial x}\right)u=0, \tag{3.1}$$

for some functions $a^1,\ldots,a^n$.

For arbitrary functions a there is no reason to expect that the system (3.1) has any nonconstant solutions, i.e., for an arbitrary vector field (2.2) there is no reason to expect that the original equation (1.2) has nonconstant V-invariant solutions. The problem is to find vector fields (2.2) that are compatible with the equation (1.2) in the sense that nonconstant V-invariant solutions exist. The invariance condition (2.1) imposes constraints on initial data so that its unique evolution along the flow of V will be a solution of (1.2). For example, if the components a of V are constant then V is a symmetry of (1.2), and the constraint on initial data is simply a classical symmetry reduction of (1.2). The resulting invariant solutions are unidirectional waves propagating at constant velocity a, independent of the field value. In general, there is no certainty that nonconstant solutions of this type exist. We are not even assured the existence of nonconstant stationary solutions of (1.2) (the case $a=0$), e.g., consider the case $n=1$ where A is nonsingular. If V is not a symmetry of (1.2) then the constraint on initial data obtained by adjoining all compatibility conditions of the overdetermined system (3.1) is called a weak symmetry reduction,[11–13] because V is a (trivial) symmetry of the entire system of evolution equations and compatibility conditions. We do not yet have a satisfactory understanding of the compatibility conditions in the general case.

The *rank* of a function $u(t,x)$ at a point of its domain is the rank of its differential there, as a linear map from $\mathbb{R}^p$ to $\mathbb{R}^q$. For example, the rank of the solution (2.3) of the characteristic equation (2.1) is equal to the rank of the initial data f, hence is at most equal to $\min(n,q)$ at each point of its domain. Note that invariance ensures that its rank is less than p. The rank of a function is generically constant, so we restrict ourselves to functions with constant rank. The local image of a function with constant rank m is an m-dimensional manifold: the local image of a rank 0 function is a point, the local image of a rank 1 function is a curve, the local image of a rank 2 function is a surface, etc. The rank 0 functions are trivial solutions of (1.2), invariant under any vector field (2.2). We show in Theorem 1 that any rank 1 solution of (1.2) is invariant under some vector field (2.2). At the other extreme, there are no invariant solutions with rank p. Of course, all solutions of a characteristic equation are invariant. The system of Sec. V is not characteristic, but nevertheless has invariant solutions of each possible rank.

IV. SIMPLE WAVES

Much of the study of the equation (1.2) has focused on rank 1 solutions, also called *simple wave* solutions.[2,14,15] The structure of higher rank solutions is considerably more subtle.

Theorem 1: Any rank 1 solution of the equation

$$\left(\frac{\partial}{\partial t}+A(u)\cdot\frac{\partial}{\partial x}\right)u=0, \tag{4.1}$$

is locally invariant under a vector field of the form

$$\frac{\partial}{\partial t}+a(u)\cdot\frac{\partial}{\partial x}. \tag{4.2}$$

Proof: If $u(t,x)$ is a rank 1 solution, then there are locally defined regular functions $r:\mathbb{R}^p\to\mathbb{R}$ and $g:\mathbb{R}\to\mathbb{R}^q$, such that $u(t,x)$ is locally equal to $g(r(t,x))$, and

$$\left(\left(\frac{\partial r}{\partial t}\,I+\frac{\partial r}{\partial x}\cdot A(g(r))\right)g'(r)\right)(t,x)=0. \tag{4.3}$$

There is a smooth $p\times q$ matrix function $B(u)$ on a neighborhood of the local image of g such that the rows of $B(g(r))$ are transpositions of the q-component column vectors,

$$g'(r),\quad A^1(g(r))g'(r),\ldots,A^n(g(r))g'(r).$$

The condition (4.3) is then

$$(Dr\ B(g(r)))(t,x)=0.$$

We use the coefficients of B to define vector fields

$$V_\alpha=b^0_\alpha(u)\,\frac{\partial}{\partial t}+b^i_\alpha(u)\,\frac{\partial}{\partial x^i},\quad \alpha=1,\ldots,q.$$

On the solution manifold $\mathscr{S}=\{(t,x,u(t,x))\}$, we have

$$\begin{aligned}V_\alpha u(t,x)&=\left(b^0_\alpha(g(r))\,\frac{\partial u}{\partial t}+b^i_\alpha(g(r))\,\frac{\partial u}{\partial x^i}\right)(t,x)\\&=\left(\left(b^0_\alpha(g(r))\,\frac{\partial r}{\partial t}+b^i_\alpha(g(r))\,\frac{\partial r}{\partial x^i}\right)g'(r)\right)(t,x)\\&=((Dr\ B(g(r)))_\alpha g'(r))(t,x)=0.\end{aligned}$$

This implies that $\mathscr{S}$ is invariant under the vector fields V. Note that $b^0_\alpha\neq 0$ for some α because $g^1(r)\neq 0$. $\mathscr{S}$ is also invariant under the vector field

$$\frac{\partial}{\partial t}+\left(\frac{b^i_\alpha}{b^0_\alpha}\right)(u)\,\frac{\partial}{\partial x^i}.$$

□

An arbitrary rank 1 function need not be invariant under any vector field of the form (4.2), hence need not be a solution of any equation of the form (4.1). Note also that a rank 1 solution of (4.1) may be invariant under more than one vector field (4.2). For a given equation (4.1) and vector field V of the form (4.2), define

$$\Delta(V)_u=\bigcup_{0\neq\lambda\in\mathbb{R}^n}\ker(\lambda\cdot A(u)-\lambda\cdot a(u)I),$$

for each u in the domain of A. For example, if (4.1) is a characteristic equation and $n\geqslant 2$ then $\Delta(V)_u=\mathbb{R}^q$ for any V. In general, $\Delta(V)_u$ is a union of lines in $T_u\mathbb{R}^q$, well defined with respect to arbitrary change of field variables and affine change of space variables. We interpret $\Delta(V)$ as a system of ordinary differential equations on the domain of A. The *integral curves* of $\Delta(V)$ are the one-dimensional submanifolds of this domain, which are tangent at each point to $\Delta(V)$. Thus a locally defined regular function $g:\mathbb{R}\to\mathbb{R}^q$ is a parametrization of an integral curve if and only if the linear system,

$$(\lambda\cdot A(g(r))-\lambda\cdot a(g(r))I)g'(r)=0, \tag{4.4}$$

has a nonzero solution λ for each value of r. An integral curve is *generic* if the rank of the system (4.4) is constant as r varies, in which case there are smooth vector functions $\lambda^1(r),\ldots,\lambda^l(r)$ that form a basis of solutions. This definition does not depend on the particular parametrization $g(r)$.

Theorem 2: If a rank 1 solution of the equation

$$\left(\frac{\partial}{\partial t}+A(u)\cdot\frac{\partial}{\partial x}\right)u=0,$$

is invariant under the vector field

$$V=\frac{\partial}{\partial t}+a(u)\cdot\frac{\partial}{\partial x};$$

then its local image is an integral curve of $\Delta(V)$. Conversely, a generic integral curve of $\Delta(V)$ is locally the image of a rank 1 V-invariant solution.

Proof: If $u(t,x)$ is a rank 1 solution then there are locally defined regular functions $r:\mathbb{R}^p\to\mathbb{R}$ and $g:\mathbb{R}\to\mathbb{R}^q$ such that $u(t,x)$ is locally equal to $g(r(t,x))$, and

$$\left(\left(\frac{\partial r}{\partial t}I+\frac{\partial r}{\partial x}\cdot A(g(r))\right)g'(r)\right)(t,x)=0. \tag{4.5}$$

If $u(t,x)$ is V-invariant then

$$\left(\frac{\partial r}{\partial t}+a(g(r))\cdot\frac{\partial r}{\partial x}\right)(t,x)=0. \tag{4.6}$$

Fix a point (t,x) in the domain of r, and define $\lambda=\partial r/\partial x(t,x)$. Then

$$\frac{\partial r}{\partial t}(t,x)=-\lambda\cdot a(g(r(t,x))),$$

by (4.6), so we have

$$((\lambda\cdot A(g(r))-\lambda\cdot a(g(r))I)g'(r))(t,x)=0,$$

by (4.5). Note that (4.5) implies $\lambda\neq 0$ because r and g are regular, hence

$$g'(r(t,x))\in\Delta(V)_{g(r(t,x))}.$$

This proves that the local image of $u(t,x)$ is an integral curve of $\Delta(V)$. The converse follows from Theorem 3. □

Theorem 3: Fix an equation,

$$\left(\frac{\partial}{\partial t}+A(u)\cdot\frac{\partial}{\partial x}\right)u=0; \tag{4.7}$$

a vector field,

$$V=\frac{\partial}{\partial t}+a(u)\cdot\frac{\partial}{\partial x};$$

and a generic integral curve of $\Delta(V)$ parametrized by a function $g(r)$. The rank 1 V-invariant solutions of (4.7) defined at $t=0$, $x=0$ that map into this curve are locally the functions $u(t,x)=g(r(t,x))$, where $r(t,x)$ is implicitly defined by an equation

$$r=\phi(\lambda^1(r)\cdot(x-a(g(r))t),\ldots,\lambda^l(r)\cdot(x-a(g(r))t)),$$

where ϕ is an arbitrary regular function of l variables defined on a neighborhood of $0\in\mathbb{R}^l$ such that $\phi(0)$ is in the domain of g, and where $\lambda^1(r),\ldots,\lambda^l(r)$ form a smooth basis of solutions of the linear system,

$$(\lambda\cdot A(g(r))-\lambda\cdot a(g(r))I)g'(r)=0.$$

Proof: Any rank 1 solution that maps into the curve is given locally by $g(r(t,x))$, where

$$\left(\left(\frac{\partial r}{\partial t}I+\frac{\partial r}{\partial x}\cdot A(g(r))\right)g'(r)\right)(t,x)=0.$$

We assume that r is defined at $t=0$, $x=0$. The solution is V-invariant if and only if

$$\frac{\partial r}{\partial t}(t,x)=-\left(a(g(r))\cdot\frac{\partial r}{\partial x}\right)(t,x). \tag{4.8}$$

Combining these conditions, we find that

$$\left(\left(\frac{\partial r}{\partial x}\cdot A(g(r))-\frac{\partial r}{\partial x}\cdot a(g(r))I\right)g'(r)\right)(t,x)=0.$$

Therefore $\partial r/\partial x$ is a linear combination of $\lambda^1(r),\ldots,\lambda^l(r)$ at each point (t,x). In conjunction with (4.8), this implies that $dr(t,x)$ is a linear combination of the covectors,

$$\lambda^j(r(t,x))\cdot(dx-a(g(r(t,x)))dt),\quad j=1,\ldots,l.$$

Hence at each point on the submanifold $\mathscr{S}=\{r=r(t,x)\}$ of the space $\{(t,x,r)\}$ the differential $d(r-r(t,x))$ is a linear combination of dr and $dr^1,\ldots,dr^l$, where

$$r^j(t,x,r)=\lambda^j(r)\cdot(x-a(g(r))t),\quad j=1,\ldots,l.$$

Therefore the differentials $dr,dr^1,\ldots,dr^l$ are dependent on $\mathscr{S}$, i.e., the functions $r,r^1,\ldots,r^l$ are dependent on $\mathscr{S}$, because $d(r-r(t,x))=0$ on $\mathscr{S}$. But the functions $r^1,\ldots,r^l$ are independent on $\mathscr{S}$, because $\lambda^1,\ldots,\lambda^l$ are independent. Hence we have

$$r=\phi(r^1,\ldots,r^l) \tag{4.9}$$

on a neighborhood of the point $r=r(0,0)$ on $\mathscr{S}$, for some function ϕ. The implicit function theorem provides a unique solution $r=r(t,x)$ of (4.9) on a neighborhood of $t=0$, $x=0$ for any function ϕ defined on a neighborhood of $0\in\mathbb{R}^l$, and r is regular at $t=0$, $x=0$ if and only if ϕ is regular at $0\in\mathbb{R}^l$. If $\phi(0)$ is in the domain of g, then $u(t,x)=g(r(t,x))$ is a rank 1 function defined at $t=0$, $x=0$ that maps into the given integral curve. Reversing the preceeding arguments proves that $u(t,x)$ is a V-invariant solution. □

The case of one space variable is well known.[1,2,4,15] The equation (4.1) is then simply

$$\frac{\partial u}{\partial t}+A(u)\frac{\partial u}{\partial x}=0, \tag{4.10}$$

where A is a single $q\times q$ matrix. Fix a vector field,

$$V=\frac{\partial}{\partial t}+a(u)\ \frac{\partial}{\partial x}.$$

The subspace

$$\Delta(V)_u=\ker(A(u)-a(u)I)$$

is nonzero if and only if $a(u)$ is a characteristic value of $A(u)$. The integral curves of $\Delta(V)$ are the characteristic curves of the matrix function $A(u)$ with characteristic value $a(u)$. The regular V-invariant solutions map into these curves, by Theorem 2. Any integral curve is generic, hence, is locally the image of a rank 1 solution, again by Theorem 2. If $g(r)$ is a parametrization of an integral curve then the rank 1 solutions defined at $t=0$, $x=0$ that map into this curve are locally the functions $u(t,x)=g(r(t,x))$, where $r(t,x)$ is implicitly defined by an equation,

$$r=\phi(x-a(g(r))t),$$

where ϕ is an arbitrary regular function of a single variable such that $\phi(0)$ is in the domain of g, by Theorem 3. Theorem 1 tells us that this accounts for all rank 1 solutions. The existence of rank 1 solutions of the equation (4.10) is thus related to the existence of characteristic curves of the matrix A. In the cases $n\geqslant 2$ the equation (4.4) is the relevant generalization of the characteristic equation of a single matrix, and the integral curves of $\Delta(V)$ for the various vector fields V are generalizations of the characteristic curves of a single matrix function.

V. BAROTROPIC FLOW

We now discuss a system that is not characteristic yet has invariant solutions of each possible rank. The equations

$$\left(\frac{\partial}{\partial t}+u\cdot\frac{\partial}{\partial x}\right)u=0,\quad \frac{\partial\rho}{\partial t}+\frac{\partial}{\partial x}\cdot(\rho u)=0,\quad \rho>0, \tag{5.1}$$

describe n-dimensional ideal compressible fluid flow at constant pressure with no external forces.[3] We assume that dissipative effects such as viscosity and thermal conductivity are negligible. There are $n+1$ independent variables $t,x^1,\ldots,x^n$ and $n+1$ dependent variables $u^1,\ldots,u^n,\rho$. The field variables u and ρ denote the velocity and density of the fluid, and the equations (5.1) represent conservation of momentum and of mass. Writing (5.1) in the form (1.2), we find that

$$A^1=\begin{pmatrix} u^1 & & & & \\ & u^1 & & & \\ \vdots & & \ddots & & \\ \rho & 0 & \cdots & 0 & u^1 \end{pmatrix},\ldots,A^n=\begin{pmatrix} u^n & & & & \\ & u^n & & & \\ \vdots & & \ddots & & \\ 0 & \cdots & 0 & \rho & u^n \end{pmatrix}.$$

We will solve the initial value problem for (5.1), and then characterize the solutions invariant under the convective derivative,

$$V=\frac{\partial}{\partial t}+u\cdot\frac{\partial}{\partial x}. \tag{5.2}$$

The overdetermined system (3.1) is equivalent to the equations

$$\left(\frac{\partial}{\partial t}+u\cdot\frac{\partial}{\partial x}\right)u=0,\quad \frac{\partial\rho}{\partial t}+\frac{\partial}{\partial x}\cdot(\rho u)=0,\quad \frac{\partial}{\partial x}\cdot u=0,\quad \rho>0,$$

so a solution of (5.1) is invariant under the vector field (5.2) if and only if its velocity field is divergence-free. It can be shown that (5.2) is not a symmetry of (5.1).

The change of coordinates,

$$\overline{t}=t,\quad \overline{x}=x-ut,\quad \overline{u}=u,\quad \overline{\rho}=\rho$$

transforms (5.1) to the system

$$\frac{\partial\overline{u}}{\partial\overline{t}}=0,\quad \frac{\partial\overline{\rho}}{\partial\overline{t}}+\overline{\rho}\,\mathrm{tr}\left(\left(I+\overline{t}\,\frac{\partial\overline{u}}{\partial\overline{x}}\right)^{-1}\frac{\partial\overline{u}}{\partial\overline{x}}\right)=0,\quad \overline{\rho}>0. \tag{5.3}$$

The general solution of the condition $\partial\overline{u}/\partial\overline{t}=0$ is $\overline{u}(\overline{t},\overline{x})=f(\overline{x})$, where $f:\mathbb{R}^n\to\mathbb{R}^n$ is an arbitrary locally defined function. Then

$$\mathrm{tr}\left(\left(I+\overline{t}\,\frac{\partial\overline{u}}{\partial\overline{x}}(\overline{t},\overline{x})\right)^{-1}\frac{\partial\overline{u}}{\partial\overline{x}}(\overline{t},\overline{x})\right)=\frac{\partial}{\partial\overline{t}}\ln(\det(I+\overline{t}\overline{D}f(\overline{x}))),$$

so the condition on $\overline{\rho}(\overline{t},\overline{x})$ is

$$\frac{\partial}{\partial\overline{t}}\ln(\overline{\rho}(\overline{t},\overline{x})\det(I+\overline{t}\overline{D}f(\overline{x})))=0,$$

which holds if and only if

$$\overline{\rho}(\overline{t},\overline{x})=g(\overline{x})/\det(I+\overline{t}\overline{D}f(\overline{x})),$$

for some positive locally defined function $g:\mathbb{R}^n\to\mathbb{R}$. Thus, the unique solution $u(t,x),\rho(t,x)$ of (5.1) with initial conditions,

$$u(0,x)=f(x),\quad \rho(0,x)=g(x),$$

is defined implicitly by the equations

$$u=f(x-ut),\quad \rho(t,x)=g(x-u(t,x)t)/\det(I+tDf(x-u(t,x)t)).$$

The initial data f and $g>0$ are arbitrary functions defined on the same open subset of $\mathbb{R}^n$. This solution is known for the cases $n=1,2$.[16,17]

Note that $V=\partial/\partial\overline{t}$, so the invariance conditions are $\partial\overline{u}/\partial\overline{t}=0$, $\partial\overline{\rho}/\partial\overline{t}=0$, with the general solution

$$\overline{u}(\overline{t},\overline{x})=f(\overline{x}),\quad \overline{\rho}(\overline{t},\overline{x})=g(\overline{x}). \tag{5.4}$$

Augmenting (5.3) with the invariance conditions gives us the system

$$\frac{\partial\overline{u}}{\partial\overline{t}}=0,\quad \frac{\partial\overline{\rho}}{\partial\overline{t}}=0,\quad \mathrm{tr}\left(\left(I+\overline{t}\,\frac{\partial\overline{u}}{\partial\overline{x}}\right)^{-1}\frac{\partial\overline{u}}{\partial\overline{x}}\right)=0,\quad \overline{\rho}>0,$$

with solution (5.4), where $g>0$ is arbitrary and

$$\frac{\partial}{\partial t}\det(I+\overline{tD}f(\overline{x}))=0,$$

or

$$\det(I+\overline{tD}f(\overline{x}))=1.$$

This holds if and only if the characteristic polynomial of Df is

$$\det(\epsilon I+Df\ )=\epsilon^n.$$

Hence the V-invariant solutions of (5.1) are defined implicitly by the equations

$$u=f(x-ut),\quad \rho(t,x)=g(x-u(t,x)t),$$

where the initial data f and $g>0$ are defined on the same open subset of $\mathbb{R}^n$ and Df is nilpotent. The requirement that Df be nilpotent is a constraint on the initial data, which ensures that its evolution along the flow of V is a solution of (5.1). In the case $n=1$ the invariant solutions are density waves,

$$u(t,x)=c,\quad \rho(t,x)=g(x-ct),$$

propagating at constant velocity. In the case $n=2$ the local invariant solutions are defined implicitly by the equations

$$u=\frac{\partial\phi}{\partial s}(x-ut,y-vt),\quad v=-\frac{\partial\phi}{\partial r}(x-ut,y-vt),$$

$$\rho(t,x)=g(x-u(t,x,y)t,y-v(t,x,y)t),$$

where ϕ and $g>0$ are defined on the same open subset of $\mathbb{R}^2$ and $\phi(r,s)$ satisfies the Monge–Ampere equation,

$$\left(\frac{\partial^2\phi}{\partial r\ \partial s}\right)^2=\frac{\partial^2\phi}{\partial r^2}\frac{\partial^2\phi}{\partial s^2}.$$

For arbitrary n we obtain explicit invariant solutions,

$$u(t,x)=(I+tC)^{-1}Cx,\quad \rho(t,x)=g((I+tC)^{-1}x),$$

where g is arbitrary and C is a constant $n\times n$ matrix with $C^n=0$. These solutions can have any rank from 0 to n.

ACKNOWLEDGMENTS

We thank Jacek Tafel for his suggestion that the invariant solutions considered here might be of interest. Several stimulating discussions with him helped to direct this research. See also Ref. 18. Two relativistic boson models in the Schrödinger picture in three space–time dimensions

E. Frochaux

(Received 7 December 1995; accepted for publication 24 January 1996)

A family of unitary representations of the Poincaré group is constructed, which describes two relativistic quantum bosons with weak interaction in three space–time dimensions. The mathematical formalism is the Schrödinger picture of quantum mechanics in the momentum space. The eigenvalue equation for the bound states is given and compared with the Schrödinger equation. © *1996 American Institute of Physics.* [S0022-2488(96)02706-5]

I. INTRODUCTION

Since the discovery of the Schrödinger equation in 1926, its relativistic generalization remains an open problem (see Ref. 1 for an overview of this question). In the present paper we propose a family of models for two relativistic quantum bosons with interaction in three space–time dimensions, in which the bound state equation (playing the role of a relativistic Schrödinger equation) agrees with what could be called an elementary (or naïve) relativistic generalization of the two-particle Schrödinger equation (with the kinetic term replaced by its relativistic counterpart and with a nonlocal interaction term). These models have been suggested by a new approach to the bound state problem in bosonic quantum field theory (QFT) in two space–time dimensions. The mathematical formalism is the Schrödinger picture of quantum mechanics (QM) in the momentum space, as in the standard representation of the two free boson models. More precisely, we start from such a free model and introduce an interaction by modifying the Hamiltonian and the Lorentz generators in such a way that the commutation rules of the Poincaré algebra remain satisfied. The interaction terms are constructed in terms of an ''interaction kernel,'' which can be chosen, in a center-of-mass frame, within a large class of functions. At the present state of this theory, however, the standard potential interaction used in QM cannot be obtained from this class.

Let us explain how this model has been found. In 1973 a rigorous mathematical construction for bosonic QFT models with weak coupling in two space–time dimensions has been obtained by Glimm, Jaffe, and Spencer[2] [the so-called weakly coupled $\mathscr{P}(\varphi)_2$ models]. Existence of bound states in some of these models have been established and the conditions for such states to occur completely specified (see Ref. 3 for a complete review of the question). Because of the mathematical construction of these models, other questions about the bound states than just their existence can be asked for. In particular, their eigenspaces can be investigated. A variational perturbation method has been established to construct an eigenvector by varying suitable combinations of zero-time vectors.[4] This construction has revealed the existence (at first perturbation orders) of stable subspaces under the Poincaré transformations, describing two particles with interaction, in the Schrödinger picture (because of the restriction to zero-time vectors) (Sec. III of Ref. 5). Such representations of the Poincaré group can be studied for themselves, without reference to QFT. We have obtained in Ref. 6 the complete set of such representations, in the weak-coupling regime, by a nonperturbative construction. They are given from an ''interaction kernel,'' which, in a center-of-mass frame, can be chosen arbitrarily. Such very simple models can be used to study in detail the phenomenology of quantum and relativistic particles at low energy, and in particular the bound state problem (high energy is without interest because particle creation does not occur). Moreover, the generalization to an arbitrary number of particles has been obtained[7] (so

the phenomena of particle creation could be introduced by taking suitable combinations of models with different particle numbers).

In the present article we are concerned with the generalization, for the two-particle case, to three space–time dimensions. The difficulty comes from the higher dimension of the Poincaré group (passing from 3 to 6) and from the number of commutation relations (passing from 3 to 15), which must hold simultaneously.

We consider first a two free boson representation of the Poincaré group in three space–time dimensions, acting on functions $f(\mathbf{p}_1,\mathbf{p}_2)$ of two momenta $(\mathbf{p}_1,\mathbf{p}_2)\in\mathbb{R}^2\times\mathbb{R}^2$. The infinitesimal generators are well known and given by unbounded self-adjoint operators satisfying the commutation rules of the Lie algebra of the Poincaré group. In this representation, the time variable does not appear explicitly, and this feature is what we call the ''Schrödinger picture.'' So we have the QM picture of a fixed state space, the time being a parameter introduced by the Hamiltonian evolution. Interaction is introduced by modifying the Hamiltonian and the Lorentz generators, in terms of an ''interaction kernel'' $h(\mathbf{P},\mathbf{Q},\mathbf{Q}')$ where $\mathbf{P}\in\mathbb{R}^2$ is the total momentum and $\mathbf{Q},\mathbf{Q}'\in\mathbb{R}^2$ are relative momenta. The Hilbert space of the representation is not changed. The commutation rules lead to several conditions on h, which reduce to a single equation, provided $h(\mathbf{P},\mathbf{Q},\mathbf{Q}')$ is a function of the norms $\|\mathbf{P}\|,\|\mathbf{Q}\|,\|\mathbf{Q}'\|$ only (this last requirement, which excludes the standard potential interactions of QM, cannot be removed at the present state of this theory). By the Banach fixed point theorem this equation can be completely solved in the weak-coupling regime. The solutions are parametrized by arbitrary functions of the relative momenta $c(\|\mathbf{Q}\|,\|\mathbf{Q}'\|)$, which are nothing else than the interaction kernel in a center-of-mass frame: $c(\|\mathbf{Q}\|,\|\mathbf{Q}'\|)=h(0,\mathbf{Q},\mathbf{Q}')$.

To investigate the physical content of these models, the asymptotic states have to be constructed, which assures that they really describe two-particle systems. Moreover, the equation for the bound states can be written down (consisting of the eigenvalue equation for the mass operator). This equation plays the role of a *relativistic Schrödinger equation*. It can be used to show the existence of bound states (for suitable functions c), which ensures that this theory is not trivial.

The connection between these models and QFT is not as simple as in two space–time dimensions, because of their particular interaction term and because in three space–time dimensions there are few available bosonic models in which bound states are known to exist. Such a connection could perhaps be obtained at a formal level, for theories admitting point interaction at first perturbation order.

Let us recall that the idea of modifying the free Poincaré representation in order to introduce interaction has been proposed in the 1940s by Dirac,[8] but for classical systems. By modifying only the Hamiltonian and the Lorentz generators he gets what he called an ''instant form dynamics.'' Dirac's conclusion was that it provides too complicated equations. In fact, what we have obtained is a set of solutions to these equations, in the quantum case and in three space–time dimensions, leading to explicit examples of such dynamics.

In Sec. II we recall the operators of the representation of the Poincaré group for two free bosons in the Schrödinger picture. The interaction is introduced by modifying some of these operators, by adding to them new terms obtained from an ''interaction operator'' $\mathcal{O}$. The commutation rules impose three conditions on $\mathcal{O}$, which, under a particular condition, reduce to a unique ''fundamental equation'' for the kernel of $\mathcal{O}$. In Sec. III we give the complete set of solutions of this equation, in the weak-coupling regime, by applying the Banach fixed point theorem. In Sec. IV we show that the operators we have obtained are really the infinitesimal generators of unitary, continuous representations of the Poincaré group, by applying a theorem by Fröhlich. In Sec. V the bound state equation is written down and compared with the two-body Schrödinger equation. The existence of a bound state is shown in an example. Finally, in Sec. VI we conclude by summing up what we have found: a family of two-particle models (by giving the construction of asymptotic states) with interaction having a (somewhat weak) link with (formal) QFT.

II. TWO-PARTICLE REPRESENTATIONS OF THE POINCARÉ ALGEBRA

The Lie algebra $\mathcal{G}$ of the Poincaré group $\mathcal{P}_+^\uparrow$ in three space–time dimensions is generated by the six operators H (Hamiltonian), $\mathbf{P}=(P_1,P_2)$ (momentum), J (angular momentum), and $\mathbf{L}=(L_1,L_2)$ (generators of the Lorentz transformations), satisfying the commutation rules

$$[P_1,P_2]=0, \quad [P_1,J]=-iP_2, \quad [P_2,J]=iP_1, \tag{1}$$

$$[P_j,H]=0, \quad [H,J]=0, \tag{2}$$

$$[P_j,L_k]=i\ \delta_{j,k}H, \quad [L_1,J]=-iL_2, \quad [L_2,J]=iL_1, \tag{3}$$

$$[H,L_j]=iP_j, \quad [L_1,L_2]=-iJ, \tag{4}$$

for all $1\leqslant j,\ k\leqslant 2$, where $\delta_{i,j}$ is the Kronecker tensor. This operator algebra admits two Casimir operators (i.e., operators that commute with all generators), the square mass operator M^2, and the Pauli–Lubanski operator E, given by

$$M^2:=H^2-P^2, \quad E:=-HJ+P_1L_2-P_2L_1. \tag{5}$$

The representation that describes one spinless particle of mass $m>0$, in the Schrödinger picture, is given by the following choice of operators:

$$\begin{gathered} P_j\phi(\mathbf{p})=p_j\phi(\mathbf{p}), \quad H\phi(\mathbf{p})=\omega(\mathbf{p})\phi(\mathbf{p}), \\ J\phi(\mathbf{p})=-i(p_1\partial_2-p_2\partial_1)\phi(\mathbf{p}), \quad L_j\phi(\mathbf{p})=-i\omega(\mathbf{p})\partial_j\phi(\mathbf{p}), \end{gathered} \tag{6}$$

for all $j\in\{1,2\}$, $\mathbf{p}=(p_1,p_2)\in\mathbb{R}^2$ and suitable functions $\phi:\mathbb{R}^2\to\mathbb{C}$, where we have put $\omega(\mathbf{p}):=\sqrt{\mathbf{p}^2+m^2}$. These operators define a representation of the algebra $\mathcal{G}$, which can be integrated to give an irreducible, unitary, and continuous representation of $\mathcal{P}_+^\uparrow$ in $L^2(\mathbb{R}^2,\sigma)$ (complex-valued functions), where σ is the measure $d\sigma(\mathbf{p}):=d\mathbf{p}[2\omega(\mathbf{p})]^{-1}$ (see Appendix A). In this representation the Casimir operators (5) are simply $M^2=m^2Id$ and $E=0$.

The representation that describes two identical bosons of mass $m>0$ without interaction, in the Schrödinger picture, is given by the symmetrical tensor product of two copies of the one-particle representation. By the properties of the tensor product we get a unitary continuous representation of $\mathcal{P}_+^\uparrow$ given by the generators

$$\begin{gathered} P_j\phi(\mathbf{p}_1,\mathbf{p}_2)=((\mathbf{p}_1)_j+(\mathbf{p}_2)_j)\phi(\mathbf{p}_1,\mathbf{p}_2), \\ H_0\phi(\mathbf{p}_1,\mathbf{p}_2)=(\omega(\mathbf{p}_1)+\omega(\mathbf{p}_2))\phi(\mathbf{p}_1,\mathbf{p}_2), \\ J\phi(\mathbf{p}_1,\mathbf{p}_2)=-i\left[\sum_{j=1}^{2}((\mathbf{p}_j)_1\partial_{(\mathbf{p}_j)_2}-(\mathbf{p}_j)_2\partial_{(\mathbf{p}_j)_1})\right]\phi(\mathbf{p}_1,\mathbf{p}_2), \\ L_{0,j}\phi(\mathbf{p}_1,\mathbf{p}_2)=-i(\omega(\mathbf{p}_1)\partial_{(\mathbf{p}_1)_j}+\omega(\mathbf{p}_2)\partial_{(\mathbf{p}_2)_j})\phi(\mathbf{p}_1,\mathbf{p}_2), \end{gathered} \tag{7}$$

for all $j\in\{1,2\}$, $(\mathbf{p}_1,\mathbf{p}_2)\in\mathbb{R}^4$ and suitable functions $\phi:\mathbb{R}^4\to\mathbb{C}$. The space of the representation is

$$\mathcal{H}:=L^2_{\mathrm{Sym}}(\mathbb{R}^2\times\mathbb{R}^2,\sigma_2) \tag{8}$$

[made of symmetrical functions $\phi(\mathbf{p}_1,\mathbf{p}_2)=\phi(\mathbf{p}_2,\mathbf{p}_1)$], where $\sigma_2:=\sigma\otimes\sigma$. It describes two particles without interaction (therefore we have put an index 0 to H_0 and $L_{0,j}$).

The Casimir operators are more complicated, given now by

$$M_0^2\phi(\mathbf{p}_1,\mathbf{p}_2)=[(\omega(\mathbf{p}_1)+\omega(\mathbf{p}_2))^2-(\mathbf{p}_1+\mathbf{p}_2)^2]\phi(\mathbf{p}_1,\mathbf{p}_2), \tag{9}$$

$$E_0\phi(\mathbf{p}_1,\mathbf{p}_2)=-i[\omega(\mathbf{p}_1)\mathbf{p}_2-\omega(\mathbf{p}_2)\mathbf{p}_1]\wedge\nabla_{\mathbf{p}_1-\mathbf{p}_2}\phi(\mathbf{p}_1,\mathbf{p}_2), \tag{10}$$

with the notation $(a_1,a_2)\wedge(b_1,b_2):=a_1b_2-a_2b_1$ for all $\mathbf{a},\mathbf{b}\in\mathbb{R}^2$ and $\nabla_{\mathbf{p}_1-\mathbf{p}_2}:=(\partial_{(\mathbf{p}_1)_1}-\partial_{(\mathbf{p}_2)_1},\partial_{(\mathbf{p}_1)_2}-\partial_{(\mathbf{p}_2)_2})$.

Now we want to modify these operators in order to introduce interaction. To remain in the Schrödinger picture we keep $\mathbf{P}$ and J unchanged and modify only H_0 and $\mathbf{L}_0$. Let $\mathscr{O}$ be a self-adjoint operator (the *interaction operator*) on which we only impose, for the moment, the formal commutation relations

$$[\mathscr{O},\mathbf{P}]=0,\quad [\mathscr{O},J]=0. \tag{11}$$

We define the interaction representation as follows:

$$\mathbf{P},J,\quad \text{as in (7)},\quad H:=H_0+\{\mathscr{O},H_0\},\quad L_j:=L_{0,j}+\{\mathscr{O},L_{0,j}\}, \tag{12}$$

for $j\in\{1,2\}$, where we have used the notation $\{A,B\}=AB+BA$. The Hilbert space of the representation is still given by (8). The particular form of the ''interaction terms'' of (12) together with the commutation rules (11) have the following nice consequence.

Lemma 1: The operators (12) satisfy formally the commutation rules (1), (2), and (3) of the algebra $\mathscr{G}$.

The proof is purely algebraic: (1) has not been changed; (2) is an immediate consequence of (11); (3) follows from a simple algebraic calculation (for more details, see Ref. 6 or 7). Note that (3) could be used to establish (12) once we impose the change of $L_{1,0}$ only. Until now, no condition on $\mathscr{O}$ except (11) was needed. But the last commutation rules (4) impose the following complicated equations:

$$0=[\{\mathscr{O},H_0\},L_{0,j}]+[H_0,\{\mathscr{O},L_{0,j}\}]+[\{\mathscr{O},H_0\},\{\mathscr{O},L_{0,j}\}], \tag{13}$$

$$0=[\{\mathscr{O},L_{0,1}\},L_{0,2}]+[L_{0,1},\{\mathscr{O},L_{0,2}\}]+[\{\mathscr{O},L_{0,1}\},\{\mathscr{O},L_{0,2}\}], \tag{14}$$

for all $j\in\{1,2\}$. This gives three equations for $\mathscr{O}$ of the same form (made of a linear term plus a bilinear term), which must hold simultaneously. We have now to find nontrivial solutions $\mathscr{O}\neq 0$ to this system.

In order to have a better physical understanding we make the change of variables $(\mathbf{p}_1,\mathbf{p}_2)\to(\mathbf{P},\mathbf{Q})$, given by

$$\begin{aligned}\mathbf{P}&:=\mathbf{p}_1+\mathbf{p}_2,\\ \mathbf{Q}&:=\frac{1}{2}(\mathbf{p}_1-\mathbf{p}_2)-\frac{1}{2}\mathbf{P}\frac{\omega(\mathbf{p}_1)-\omega(\mathbf{p}_2)}{M_0(\mathbf{p}_1,\mathbf{p}_2)+\omega(\mathbf{p}_1)+\omega(\mathbf{p}_2)},\end{aligned} \tag{15}$$

where $M_0(\mathbf{p},\mathbf{p}_2):=[(\omega(\mathbf{p}_1)+\omega(\mathbf{p}_2))^2-\mathbf{P}^2]^{1/2}$. The variable $\mathbf{P}$ is the total momentum while $\mathbf{Q}$ is the relative momentum, defined as the momentum in a center-of-mass frame [more precisely, $\mathbf{Q}$ is the transform of $\frac{1}{2}(\mathbf{p}_1-\mathbf{p}_2)$ under a Lorentz transformation leading to a center-of-mass frame; see Appendix B].

Under this change of variables the free representation (7) becomes

$$\begin{aligned}P_j\phi(\mathbf{P},\mathbf{Q})&=P_j\phi(\mathbf{P},\mathbf{Q}),\\ H_0\phi(\mathbf{P},\mathbf{Q})&=\Omega(\mathbf{P},\mathbf{Q})\phi(\mathbf{P},\mathbf{Q}),\end{aligned} \tag{16}$$

$$J\phi(\mathbf{P},\mathbf{Q}) = -i(P_1\partial_{P_2} - P_2\partial_{P_1} + J^{\mathbf{Q}})\phi(\mathbf{P},\mathbf{Q}),$$

$$L_{0,j}\phi(\mathbf{P},\mathbf{Q}) = -i(\Omega(\mathbf{P},\mathbf{Q})\partial_{P_j} + L^{\mathbf{Q}}_{0,j})\phi(\mathbf{P},\mathbf{Q}),$$

for all $j \in \{1,2\}$, where we have put

$$J^{\mathbf{Q}}\phi(\mathbf{P},\mathbf{Q}) := -i(Q_1\partial_{Q_2} - Q_2\partial_{Q_1})\phi(\mathbf{P},\mathbf{Q}),$$

$$L^{\mathbf{Q}}_{0,1}\phi(\mathbf{P},\mathbf{Q}) := \frac{P_2}{\Omega(\mathbf{P},\mathbf{Q}) + 2\omega(\mathbf{Q})}\, J^{\mathbf{Q}}\phi(\mathbf{P},\mathbf{Q}), \tag{17}$$

$$L^{\mathbf{Q}}_{0,2}\phi(\mathbf{P},\mathbf{Q}) := -\frac{P_1}{\Omega(\mathbf{P},\mathbf{Q}) + 2\omega(\mathbf{Q})}\, J^{\mathbf{Q}}\phi(\mathbf{P},\mathbf{Q}),$$

for all suitable functions ϕ, where $\Omega(\mathbf{P},\mathbf{Q}) = \sqrt{\mathbf{P}^2 + 4\omega(\mathbf{Q})^2}$ (see the calculation in Appendix B). As for (7), these operators define a representation of the algebra $\mathscr{G}$ that can be integrated to give a unitary and continuous representation of the Poincaré group $\mathscr{P}^{\uparrow}_{+}$, in the same function space (8), which can be written $\mathscr{H} = L^2_{Ev\cdot\mathbf{Q}}(\mathbb{R}^2 \times \mathbb{R}^2, \mu)$, made of functions even in $\mathbf{Q}$ [that is $\phi(\mathbf{P},\mathbf{Q}) = \phi(\mathbf{P}, -\mathbf{Q})$], where $d\mu(\mathbf{P},\mathbf{Q}) := d\sigma(\mathbf{Q})d\mathbf{P}\Omega(\mathbf{P},\mathbf{Q})^{-1}$ (see Appendix B). In these variables the Casimir operators (9), (10) concern only the $\mathbf{Q}$ variable,

$$M_0^2\phi(\mathbf{P},\mathbf{Q}) = 4\omega(\mathbf{Q})^2\phi(\mathbf{P},\mathbf{Q}), \tag{18}$$

$$E_0\phi(\mathbf{P},\mathbf{Q}) = 2\omega(\mathbf{Q})J^{\mathbf{Q}}\phi(\mathbf{P},\mathbf{Q}). \tag{19}$$

We call (17) the *relative terms* because without them [i.e., if we replace formally $J^{\mathbf{Q}}$ by 0 in (16)] we also get a representation of $\mathscr{G}$, which is nonequivalent to (7) (because with $E = 0$). Note that this particular representation is defined by the same formula as the one-particle representation (6), with $\mathbf{p}$ replaced by $\mathbf{P}$ and m replaced by $2\omega(\mathbf{Q})$. In the two space–time dimension case, the two free boson representation has such a property (Refs. 6 and 7). For this reason the relative terms (17) appear as the main difference between the two- and three-dimensional cases.

To find solutions to (13)–(14) we write $\mathscr{O}$ in the following general form:

$$\mathscr{O}\phi(\mathbf{P},\mathbf{Q}) := \int \frac{d\sigma(\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')}\, \phi(\mathbf{P},\mathbf{Q}')\, \frac{h(\mathbf{P},\mathbf{Q},\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}) + \Omega(\mathbf{P},\mathbf{Q}')}, \tag{20}$$

where $h(\mathbf{P},\mathbf{Q},\mathbf{Q}')$ is *a priori* a function of norms $\|\mathbf{P}\|,\|\mathbf{Q}\|,\|\mathbf{Q}'\|$ and of the scalar products $\mathbf{P}\cdot\mathbf{Q},\mathbf{P}\cdot\mathbf{Q}',\mathbf{Q}\cdot\mathbf{Q}'$ only, and satisfies the symmetry condition

$$h(\mathbf{P},\mathbf{Q},\mathbf{Q}') = h(\mathbf{P},\mathbf{Q}',\mathbf{Q})^*, \tag{21}$$

together with $h(\mathbf{P},\mathbf{Q},\mathbf{Q}') = h(\mathbf{P},\mathbf{Q},-\mathbf{Q}') = h(\mathbf{P},-\mathbf{Q},\mathbf{Q}')$, for all $\mathbf{P},\mathbf{Q},\mathbf{Q}' \in \mathbb{R}^2$, where the star * denotes the complex conjugation. Note that $\mathscr{O}$ is a symmetric operator that formally satisfies (11).

We establish in Appendix C that, if $h(\mathbf{P},\mathbf{Q},\mathbf{Q}')$ is a function of norms $\|\mathbf{P}\|,\|\mathbf{Q}\|,\|\mathbf{Q}'\|$ only, the three equations (13)–(14) reduce to a single nonlinear integro differential equation for h. With the differential operator D given by

$$Dh(\mathbf{P},\mathbf{Q},\mathbf{Q}') := \frac{\Omega(\mathbf{P},\mathbf{Q})\Omega(\mathbf{P},\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}) + \Omega(\mathbf{P},\mathbf{Q}')}\, \partial_{\|\mathbf{P}\|}h(\mathbf{P},\mathbf{Q},\mathbf{Q}'), \tag{22}$$

this equation can be written as follows:

$$0=2\,Dh(\mathbf{P},\mathbf{Q},\mathbf{Q}')+\int\frac{d\sigma(\mathbf{Q}'')}{\Omega(\mathbf{P},\mathbf{Q}'')^2}\left\{-\frac{\|\mathbf{P}\|}{\Omega(\mathbf{P},\mathbf{Q}'')}\,h(\mathbf{P},\mathbf{Q},\mathbf{Q}'')h(\mathbf{P},\mathbf{Q}'',\mathbf{Q}')\right.$$
$$\left.+Dh(\mathbf{P},\mathbf{Q},\mathbf{Q}'')h(\mathbf{P},\mathbf{Q}'',\mathbf{Q}')+h(\mathbf{P},\mathbf{Q},\mathbf{Q}'')Dh(\mathbf{P},\mathbf{Q}'',\mathbf{Q}')\right\}. \tag{23}$$

This is the fundamental equation that guarantees the relativistic structure of the theory. Let us sum up what we have found in the following statement.

Proposition 2: Let $h(\mathbf{P},\mathbf{Q},\mathbf{Q}')$ *be a function of* $\|\mathbf{P}\|,\|\mathbf{Q}\|,\|\mathbf{Q}'\|$ *only, which satisfies (21) and (23). Then the operators (12), with* $\mathscr{O}$ *given by (20), are symmetric and satisfy algebraically the commutation rules (1) to (4) of the algebra* $\mathscr{G}$.

III. EXISTENCE OF SOLUTIONS OF THE FUNDAMENTAL EQUATION

In this section we are concerned with the solutions to the equation (23).

Definition: Let $\mathscr{B}$ be the Banach space made of bounded, continuous functions $f:(\mathbb{R}_+)^3\to\mathbb{C}$, where $\mathbb{R}_+=[0,\infty)$, such that the following derivative $df(u,x,y):=r(u,x)r(u,y)[r(u,x)+r(u,y)]^{-1}\partial_u f(u,x,y)$ (with right derivation at $u=0$), where $r(u,v):=(u^2+4v^2+4m^2)^{1/2}$, exists and is also bounded and continuous, given the norm

$$|h|_{\mathscr{B}}:=\|h\|_\infty+\|dh\|_\infty. \tag{24}$$

The following result assures the existence of a large class of solutions of (23).

Proposition 3: There exists $0<K_1<\infty$ *such that, for all continuous bounded functions* $c:\mathbb{R}_+^2\to\mathbb{C}$ *satisfying* $\|c\|_\infty<K_1$, *there exists one and only one function* $f\in\mathscr{B}$ *satisfying*

(1) $|f|_{\mathscr{B}}<2K_1$,

(2) $f(0,x,y,)=c(x,y)$,

(3) $h(\mathbf{P},\mathbf{Q},\mathbf{Q}')=f(\|\mathbf{P}\|,\|\mathbf{Q}\|,\|\mathbf{Q}'\|)$ satisfies (23) for all $\mathbf{P},\mathbf{Q},\mathbf{Q}'\in\mathbb{R}^2$.

Moreover, h satisfies (21) if $c(x,y)=c(y,x)^*$.

Note that $h(\mathbf{P}=0,\mathbf{Q},\mathbf{Q}')=c(\|\mathbf{Q}\|,\|\mathbf{Q}'\|)$ is an arbitrary function, i.e. there is no restriction on the interaction kernel h for $\mathbf{P}=0$, that is in a center-of-mass frame. The proof is based on the Banach fixed point theorem. It gives not only existence and uniqueness, as stated in the Proposition, but also a formula for the solution h in terms of c.

Proof: Let us introduce a bilinear operator b,

$$b(f,g)(u,x,y):=\pi\int_0^u dv\left(\frac{1}{r(v,x)}+\frac{1}{r(v,y)}\right)\int_0^\infty\frac{z\,dz}{r(0,z)r(v,z)^2}\left\{-df(v,x,z)g(v,z,y)\right.$$
$$\left.-f(v,x,z)dg(v,z,y)+\frac{v}{r(v,z)}\,f(v,x,z)g(v,z,y)\right\}, \tag{25}$$

where $u,x,y\in\mathbb{R}_+$. By derivation of b (in the sense used in the definition of $\mathscr{B}$), one gets simply

$$db(f,g)(u,x,y)=\pi\int_0^\infty\frac{z\,dz}{r(0,z)r(u,z)^2}\left\{-df(u,x,z)g(u,z,y)-f(u,x,z)dg(u,z,y)\right.$$
$$\left.+\frac{u}{r(u,z)}\,f(u,x,z)g(u,z,y)\right\}. \tag{26}$$

The fundamental equation (23) can be written as $df-db(f,f)=0$, where $h(\mathbf{P},\mathbf{Q},\mathbf{Q}')=f(\|\mathbf{P}\|,\|\mathbf{Q}\|,\|\mathbf{Q}'\|)$. By integration, this equation becomes

$$f(u,x,y)=c(x,y)+b(f,f)(u,x,y):=A(f)(u,x,y), \tag{27}$$

where $c(x,y)$ is an arbitrary function (the integration ''constant''). This is a fixed point equation that can be solved by applying the Banach fixed point theorem (Ref. 9, Sec. 1.1) in the Banach space $\mathscr{B}$. From a standard analysis and a simple estimate, it follows that $b\colon \mathscr{B}\to\mathscr{B}$ and satisfies

$$|b(f,g)|_{\mathscr{B}} < K_1' |f|_{\mathscr{B}} |g|_{\mathscr{B}}, \tag{28}$$

where K_1' is the constant given by

$$K_1' = \pi \int_0^\infty \frac{2\,dv}{r(v,0)} \int_0^\infty \frac{z\,dz}{r(0,z)r(v,z)^2} + \pi \int_0^\infty \frac{z\,dz}{r(0,z)^3}.$$

Let us take $K_1 = (4K_1')^{-1}$ and $c(x,y) \in \mathscr{B}$ with $|c|_{\mathscr{B}} = \|c\|_\infty < K_1$. Then the operator $A(f)$ sends the ball $B(2K_1) := \{g \in \mathscr{B} \,|\, |g|_{\mathscr{B}} < 2K_1\}$ into itself and is a strict contraction on $B(2K_1)$ (see Ref. 6 or 7 for more details). In such a case, it follows from the Banach fixed point theorem that the equation $f = A(f)$ has one and only one solution in $B(2K_1)$, given by the limit of convergent sequence $f = \lim_{n\to\infty} A^n(0)$.

Let us suppose that c satisfies $c(x,y) = c(y,x)^*$. So does $A(0) = c$. If $g \in \mathscr{B}$ satisfies $g(u,x,y) = g(u,y,x)^*$, so does $b(g,g)$ and $A(g)$. By an induction argument it follows that $\lim_{n\to\infty} A^n(0)$ satisfies this symmetry, too. □

Remark 1: As previously mentioned, the proof gives a formula for the solution h in terms of c, given by a uniformly convergent sequence,

$$h(\mathbf{P},\mathbf{Q},\mathbf{Q}') = \lim_{n\to\infty} \mathscr{A}^n(0)(\mathbf{P},\mathbf{Q},\mathbf{Q}'), \tag{29}$$

for all $(\mathbf{P},\mathbf{Q},\mathbf{Q}') \in \mathbb{R}^6$, where

$$\mathscr{A}(g)(\mathbf{P},\mathbf{Q},\mathbf{Q}') := c(\|\mathbf{Q}\|,\|\mathbf{Q}'\|) + b(g,g)(\|\mathbf{P}\|,\|\mathbf{Q}\|,\|\mathbf{Q}'\|),$$

for all $g(\|\mathbf{P}\|,\|\mathbf{Q}\|,\|\mathbf{Q}'\|) \in \mathscr{B}$. The first terms of this sequence are

$$\mathscr{A}(0) = c, \quad \mathscr{A}^2(0) = \mathscr{A}(c) = c + b(c,c), \tag{30}$$

$$\mathscr{A}^3(0) = c + b(c,c) + b(b(c,c),c) + b(c,b(c,c)) + b(b(c,c),b(c,c)),$$

etc. The limit can be seen as a power series of c that converges uniformly. It is nonzero if $c \neq 0$ because it is continuous and satisfies $h(0,\mathbf{Q},\mathbf{Q}') = c(\|\mathbf{Q}\|,\|\mathbf{Q}'\|)$.

Remark 2: Proposition 3 ensures the existence of solutions only in a ball of a Banach space, that is, in the weak-coupling regime. However, the constant K_1 that limits the supremum of c can be taken of the order of m. A small calculation gives

$$K_1' = \frac{\pi}{4m}\left[\int_0^\infty \frac{u}{\cosh u}\,du + \frac{1}{2}\right] = \frac{1.8315\ldots}{m},$$

and thus $K_1 = m/7.3259\ldots$. In what follows we will take simply $K_1 = m/8$.

IV. UNITARY REPRESENTATIONS OF THE POINCARÉ GROUP

We have established the existence of a large class of operators $\mathscr{O}$ for which (12) gives rise to formal representations of the Lie algebra $\mathscr{G}$ (we call them formal because the problem of operator domains have not yet been considered). The natural question arises, under which conditions these

formal representations can be really defined and can be integrated to provide unitary and continuous representations of the Poincaré group. By imposing a new condition on c we can specify the domain of our operators.

Proposition 4: Let c: $\mathbb{R}_+^2 \to \mathbb{C}$ *satisfy* $c(x,y)=c(y,x)^*$ *and the hypothesis of Proposition 3 and, moreover,*

$$\sup_{(x,y)\in\mathbb{R}_+^2} |(x^2+m^2)^{3/4}(y^2+m^2)^{3/4}c(x,y)| < K_2, \tag{31}$$

for some $K_2>0$ *sufficiently small. Let* $h(\mathbf{P},\mathbf{Q},\mathbf{Q}')=f(\|\mathbf{P}\|,\|\mathbf{Q}\|,\|\mathbf{Q}'\|)$, *where* f *is the function deduced from* c *in Proposition 3. Then the following conditions are satisfied.*

(1) *The operators* H, $\mathbf{P}$, J, *and* $\mathbf{L}$ *are self-adjoint.*

(2) *The operator* $\Delta=m^{-2}(H^2+\mathbf{P}^2)+J^2+\mathbf{L}^2$ *is self-adjoint and there exists a dense domain* $\mathscr{D}$ *which is a common core for all operators* Δ, H, $\mathbf{P}$, J, *and* $\mathbf{L}$.

(3) *Let* A,B *be any pair of operators* H, P_1, P_2, J, L_1, L_2. *Then* A *is defined and symmetric on* $B\mathscr{D}$. *Moreover the commutation rules (1) to (4) hold on* $\mathscr{D}$.

This proposition gives a precise sense to our Lie algebra representations and to the commutation rules. Moreover, according to a theorem by Fröhlich[10] (see remark 2, after the proof), these conditions are sufficient to ensure the integrability of the algebra representations, leading, by the exponential map, to unitary, continuous representations of the universal cover of the Poincaré group. The interest of Fröhlich's theorem is that it does not require the domain $\mathscr{D}$ to be invariant under all operators, as in Nelson's classic theorem (Ref. 11, Theorem 5). The construction of a common invariant domain for operators as different as ours (multiplication, derivations, and kernel operators) is a difficult problem that has been achieved in the one-dimensional space case only at the price of strong conditions on c (in Ref. 6, c is a C^∞ fast decreasing function, which does not agree with the corresponding kernel in QFT). It is probable that with appropriate conditions on c, Nelson's theorem can also be used in the present case.

Proof: We proceed in three steps.

First step. We deduce from (31) two properties of h. Let $g\in\mathscr{B}$ such that $|g(u,x,y)|+|dg(u,x,y)|\leqslant k_1 s(x)^{-3/2}s(y)^{-3/2}$ for some $k_1\in(0,\infty)$ for all $(u,x,y,)\in\mathbb{R}_+^3$, where $s(t)=(t^2+m^2)^{1/2}$. By using this inequality in the integrals (25)–(26) and the methods leading to (28), we get

$$|b(g,g)(u,x,y)|+|db(g,g)(u,x,y)| \leqslant K_1' \frac{k_1^2}{m^3} \frac{1}{s(x)^{3/2}s(y)^{3/2}}.$$

Let c be a function satisfying the hypothesis of the proposition with K_2 small enough to have $4K_1'K_2/m^3 < 1$. Let us suppose that for some $n\in\mathbb{N}^*$ we know that $|A^n(0)(u,x,y)|+|dA^n(0)(u,x,y)|<C_n s(x)^{-3/2}s(y)^{-3/2}$ for some constant $C_n<2K_2$ and for all $(u,x,y)\in\mathbb{R}_+^3$ (this is true for $n=1$). Then

$$\begin{aligned}
&|A^{n+1}(0)(u,x,y)|+|dA^{n+1}(0)(u,x,y)| \\
&\quad = |c(x,y)+b(A^n(0),A^n(0))(u,x,y)| \\
&\qquad + |db(A^n(0),A^n(0))(u,x,y)| \\
&\quad \leqslant \left(K_2+K_1'\frac{C_n^2}{m^3}\right)\frac{1}{s(x)^{3/2}s(y)^{3/2}} = \frac{C_{n+1}}{s(x)^{3/2}s(y)^{3/2}},
\end{aligned}$$

with $C_{n+1} = K_2 + K_1'C_n^2/m^3 < 2K_2$. Thus, for such c all terms of the sequence $\{|A^n(0)(u,x,y)|+|dA^n(0)(u,x,y)|\}_{n=1}^\infty$ is bounded by $2K_2[s(x)s(y)]^{-3/2}$, and so are their limit. We have shown that for all $(\mathbf{P},\mathbf{Q},\mathbf{Q}')\in\mathbb{R}^6$,

$$\omega(\mathbf{Q})^{3/2}\omega(\mathbf{Q}')^{3/2}(|h(\mathbf{P},\mathbf{Q},\mathbf{Q}')|+|Dh(\mathbf{P},\mathbf{Q},\mathbf{Q}')|)<2K_2. \tag{32}$$

For the next step we also need to know that $\omega(\mathbf{Q})^{3/2}\omega(\mathbf{Q}')^{3/2}|\|\mathbf{P}\|\partial_{\|\mathbf{P}\|}\, Dh\|\mathbf{P}\|^{-1}|$ is bounded. Now $\|\mathbf{P}\|\partial_{\|\mathbf{P}\|}\, Dh\|\mathbf{P}\|^{-1} = \partial_{\|\mathbf{P}\|}\, Dh - \|\mathbf{P}\|^{-1}\, Dh$. A bound for the second term can be obtained from the equation (23) and the inequality (32), as follows. Let $g(\mathbf{P},\mathbf{Q},\mathbf{Q}')=\omega(\mathbf{Q})^{3/2}\omega(\mathbf{Q}')^{3/2}\|\mathbf{P}\|^{-1}\,\mathrm{Dh}(\mathbf{P},\mathbf{Q},\mathbf{Q}')$. From (23) we have

$$2g(\mathbf{P},\mathbf{Q},\mathbf{Q}')=\int \frac{d\mathbf{Q}''}{2\omega(\mathbf{Q}'')^4\Omega(\mathbf{P},\mathbf{Q}'')^3}\,\hat{h}(\mathbf{P},\mathbf{Q},\mathbf{Q}'')\hat{h}(\mathbf{P},\mathbf{Q}'',\mathbf{Q}')$$
$$-\int \frac{d\mathbf{Q}''}{2\omega(\mathbf{Q}'')^4\Omega(\mathbf{P},\mathbf{Q}'')^2}\,(g(\mathbf{P},\mathbf{Q},\mathbf{Q}'')\hat{h}(\mathbf{P},\mathbf{Q}'',\mathbf{Q}')+\hat{h}(\mathbf{P},\mathbf{Q},\mathbf{Q}'')g(\mathbf{P},\mathbf{Q}'',\mathbf{Q}')),$$

where $\hat{h}(\mathbf{P},\mathbf{Q},\mathbf{Q}'):=\omega(\mathbf{Q})^{3/2}\omega(\mathbf{Q}')^{3/2}h(\mathbf{P},\mathbf{Q},\mathbf{Q}')$ for all $(\mathbf{P},\mathbf{Q},\mathbf{Q}')\in\mathbb{R}^6$. From this relation and from (32) follows the estimate for the the sup-norm $\|g\|_\infty$:

$$2\|g\|_\infty<4K_2^2\int \frac{d\mathbf{Q}''}{16\omega(\mathbf{Q}'')^7}+\|g\|_\infty 4K_2\int \frac{d\mathbf{Q}''}{8\omega(\mathbf{Q}'')^6}.$$

Now $\int d\mathbf{Q}''\,\omega(\mathbf{Q}'')^{-6}<2m^{-4}$. Thus we obtain a bound for $\|g\|_\infty(2-K_2m^{-4})$. Now $2 - K_2m^{-4} > 2 - 1/(4mK_1') > 2 - \frac{1}{8}$ is positive, so we get a bound for $\|g\|_\infty$ (we have used the value of K_1' given in Remark 2, after the proof of Proposition 3).

The existence of $\partial_{\|\mathbf{P}\|}\, Dh$ is obtained as follows. In the sequence (29) the variable $\|\mathbf{P}\|$ appears only in the kernels $\Omega(\mathbf{P},\mathbf{Q})^{-1}$ or as the limit of integration on a variable u appearing only in such kernels or as a limit of integration, etc.. It follows that (29) is a sequence of analytic functions of $\|\mathbf{P}\|$ in a strip along the real axis. To study the convergence we replace u by $u+i\eta$ in the integrals (25) and (26), with $|\eta|$ small enough for the inequality (28) to be still satisfied (or for a smaller constant K_1' if necessary). Let us denote by b_η and db_η the bilinear operators on $\mathscr{B}$ we get, for suitable fixed η. The fixed-point equation (27), written for b_η, can be solved by the fixed-point theorem and leads to a sequence like (29), convergent in the same ball of $\mathscr{B}$. Because all the bounds are independent of η the convergence is also uniform wrt η. Thus, the limit $h(\mathbf{P},\mathbf{Q},\mathbf{Q}')$ is analytic for $\|\mathbf{P}\|$ in a neighborhood of the real axis, for all fixed $\mathbf{Q}$, $\mathbf{Q}'$.

To see that $\partial_{\|\mathbf{P}\|}\, Dh$ is bounded, we first note that Dh is also given by a convergent sequence like (29), where b is sometimes replaced by db. Let us write $b(g_1,g_2)=\int dz[\,\kappa_1^1 g_1 g_2 + \kappa_2^1\, dg_1 g_2+\kappa_3^1 g_1\, dg_2]$ and $db(g_1,g_2)=\int dz[\,\kappa_1^2 g_1 g_2+\kappa_2^2\, dg_1 g_2+\kappa_3^2 g_1\, dg_2]$, where the κ_i^j are functions of u,x,y,z, which are easily deduced from (25), (26). Let k_2 be a constant such that $\|\int dz[(\partial_u^n\kappa_1^j)g_1g_2+(\partial_u^n\kappa_2^j)dg_1g_2+(\partial_u^n\kappa_3^j)g_1\, dg_2\|_\infty<k_2|g_1|_{\mathscr{B}}|g_2|_{\mathscr{B}}$ for all $n\in\{0,1\}$ and $j\in\{1,2\}$. Let us consider the sequence for $\partial_{\|\mathbf{P}\|}\, Dh$ similar to (29) as a power series in c, as suggested by (30). The sum of n-order terms is bounded, in the sup norm, by $k_2K_1'^{n-2}n\mathscr{N}_n|c|_{\mathscr{B}}^n$ for all $n\in\mathbb{N}$, where $\mathscr{N}_n$ is the number of terms of order n in the limit of (30). This number can be calculated by applying the fixed point theorem to the trivial equation on $\mathbb{C}$: $x=k+x^2$, and from this explicit expression we get the estimate $\mathscr{N}_n<4^n$. This ensures the convergence of the series, in the sup norm, for all $|c|_{\mathscr{B}}<(4K_1')^{-1}$. Thus $\partial_{\|\mathbf{P}\|}\, Dh$ is bounded.

Let us introduce the function $\tilde{c}(\|\mathbf{Q}\|,\|\mathbf{Q}'\|)=m^{-3}\omega(\mathbf{Q})^{3/2}\omega(\mathbf{Q}')^{3/2}c(\|\mathbf{Q}\|,\|\mathbf{Q}'\|)$. From (31) and the condition on K_2 already used, it follows that $|\tilde{c}|_{\mathscr{B}}<(4K_1')^{-1}$, and so $\tilde{c}$ is an acceptable function. Now the series for $\partial_{\|\mathbf{P}\|}\, Dh(\mathbf{P},\mathbf{Q},\mathbf{Q}')$ can be bounded as follows: for all c we use $|c(\|\mathbf{Q}''\|,\|\mathbf{Q}'''\|)|\leq|\tilde{c}(\|\mathbf{Q}''\|,\|\mathbf{Q}'''\|)|$, except for the first and last factors, which we bound as follows: $|c(\|\mathbf{Q}\|,\|\mathbf{Q}''\|)|\leq\omega(\mathbf{Q})^{-3/2}|\tilde{c}(\|\mathbf{Q}\|,\|\mathbf{Q}''\|)|$, $|c(\|\mathbf{Q}''\|,\|\mathbf{Q}'\|)|\leq\omega(\mathbf{Q}')^{-3/2}|\tilde{c}(\|\mathbf{Q}''\|,\|\mathbf{Q}'\|)|$, respectively. We get an overall factor $\omega(\mathbf{Q})^{-3/2}\omega(\mathbf{Q}')^{-3/2}$ times a series that converges uniformly because each term can be bounded, as explained above. As a consequence of all these results the following estimate holds:

$$\omega(\mathbf{Q})^{3/2}\omega(\mathbf{Q}')^{3/2}|\|\mathbf{P}\|\partial_{\|\mathbf{P}\|}\, Dh(\mathbf{P},\mathbf{Q},\mathbf{Q}')\|\mathbf{P}\|^{-1}|<k_3, \tag{33}$$

for some $k_3 \in (0,\infty)$, for all $(\mathbf{P},\mathbf{Q},\mathbf{Q}') \in \mathbb{R}^6$.

Second step. We show that Δ is self-adjoint, using theorems by Nelson and Kato-Rellich. Because $\{\mathbf{P},H_0,J,\mathbf{L}_0\}$ are the infinitesimal generators of a unitary continuous representation of a Lie group (by Appendix A and the properties of the tensor product), it follows from a theorem by Nelson (see Ref. 11, Theorem 3) that all these operators and $\Delta_0 = m^{-2}(H_0^2+\mathbf{P}^2)+J^2+\mathbf{L}_0^2$ are self-adjoint and that there exists a domain $\mathscr{D}_0$ that is a common invariant domain and a common core for all of them. However, the largest common invariant domain is

$$\mathscr{D} = \{\phi \in \mathscr{H} | H_0^{n_1} P_1^{n_2} P_2^{n_3} J^{n_4} L_{0,1}^{n_5} L_{0,2}^{n_6} \Delta_0^{n_7} \phi \in \mathscr{H}, \quad \text{for all } n_1,\ldots,n_7 \in \mathbb{N}\}; \tag{34}$$

thus $\mathscr{D}$ is also a common core. By the Kato-Rellich theorem (Theorem X.12 of Ref. 12), Δ is essentially self-adjoint on $\mathscr{D}$ if

$$\|(\Delta-\Delta_0)\phi\| \leqslant k_4\|\Delta_0\phi\| + k_5\|\phi\|, \tag{35}$$

for all $\phi \in \mathscr{D}$, for some $0<k_4<1$ and $0<k_5<\infty$.

The bound (35) turns out to be a condition on the interaction terms of H and $\mathbf{L}$. To establish such a bound we need a general estimate of the norm of vectors like

$$\phi_\xi(\mathbf{P},\mathbf{Q}) := \int \frac{d\sigma(\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')}\, \phi(\mathbf{P},\mathbf{Q}')\xi(\mathbf{P},\mathbf{Q},\mathbf{Q}'),$$

for $\phi \in \mathscr{D}$ and a suitable kernel ξ. By using the Cauchy–Schwarz inequality and the Fubini theorem, as explained in detail in Ref. 6, we obtain

$$\|\phi_\xi\| \leqslant k_6\|\xi\|_{1/2,\infty}\|\phi\|, \tag{36}$$

where $k_6 := \sup \int d\sigma(\mathbf{Q})/(\Omega(\mathbf{P},\mathbf{Q})\omega(\mathbf{Q})) = \frac{1}{2}\int d\sigma(\mathbf{Q})\omega(\mathbf{Q})^{-2} = \pi/(2m)$ and

$$\|\xi\|_{\alpha,\infty} := \sup_{(\mathbf{P},\mathbf{Q},\mathbf{Q}') \in \mathbb{R}^6} \omega(\mathbf{Q})^\alpha \omega(\mathbf{Q}')^\alpha |\xi(\mathbf{P},\mathbf{Q},\mathbf{Q}')|, \tag{37}$$

for any $\alpha \in \mathbb{R}$. Now

$$\Delta - \Delta_0 = m^{-2}(H^2 - H_0^2) + \mathbf{L}^2 - \mathbf{L}_0^2.$$

For all $\phi \in \mathscr{D}$,

$$(H^2-H_0^2)\phi(\mathbf{P},\mathbf{Q}) = \int \frac{d\sigma(\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')}\, \phi(\mathbf{P},\mathbf{Q}')\Xi(\mathbf{P},\mathbf{Q},\mathbf{Q}'),$$

where

$$\Xi(\mathbf{P},\mathbf{Q},\mathbf{Q}') := (\Omega(\mathbf{P},\mathbf{Q})+\Omega(\mathbf{P},\mathbf{Q}'))h(\mathbf{P},\mathbf{Q},\mathbf{Q}') + \int \frac{d\sigma(\mathbf{Q}'')}{\Omega(\mathbf{P},\mathbf{Q}'')}\, h(\mathbf{P},\mathbf{Q}',\mathbf{Q}'')h(\mathbf{P},\mathbf{Q}'',\mathbf{Q}'). \tag{38}$$

By the following inequality: $\Omega(\mathbf{P},\mathbf{Q})+\Omega(\mathbf{P},\mathbf{Q}') \leqslant 2(\|\mathbf{P}\|+\omega(\mathbf{Q})+\omega(\mathbf{Q}')) \leqslant 2(\|\mathbf{P}\|+2\omega(\mathbf{Q})\omega(\mathbf{Q}')/m)$ and the estimate (36), we obtain

$$\|(H^2-H_0^2)\phi\| < 2k_6\|h\|_{1/2,\infty}\|(\|\mathbf{P}\|)\phi\| + \left[\frac{4k_6}{m}\|h\|_{3/2,\infty} + k_6^2\|h\|_{1/2,\infty}^2\right]\|\phi\|. \tag{39}$$

Because the coefficient of $\|\phi\|$ has not to be bounded, we omit to estimate it explicitly henceforth. Now let us put $\mathbf{L}_h := \mathbf{L} - \mathbf{L}_0$. We have to control the action of $\mathbf{L}^2 - \mathbf{L}_0^2 = \mathbf{L}_0 \cdot \mathbf{L}_h + \mathbf{L}_h \cdot \mathbf{L}_0 + \mathbf{L}_h^2$ on vectors $\phi \in \mathscr{D}$. Because $h(\mathbf{P},\mathbf{Q},\mathbf{Q})$ is only a function of the norms $\|\mathbf{P}\|,\|\mathbf{Q}\|,\|\mathbf{Q}\|$, we have $J^{\mathbf{Q}} h = J^{\mathbf{Q}'} h = 0$, and thus the terms $L_{0,j}^{\mathbf{Q}}$ of $L_{0,j}$ give no contribution. Thus, for the vector $\mathbf{L}_h \phi$, we find

$$\mathbf{L}_h \phi(\mathbf{P},\mathbf{Q}) = \int \frac{d\sigma(\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')} [\mathbf{L}_0 \phi(\mathbf{P},\mathbf{Q}')] \frac{h(\mathbf{P},\mathbf{Q},\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')} - i \int \frac{d\sigma(\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')} \phi(\mathbf{P},\mathbf{Q}') \times \left[\frac{\mathbf{P}}{\|\mathbf{P}\|} \frac{Dh(\mathbf{P},\mathbf{Q},\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')} - \frac{\mathbf{P}}{\Omega(\mathbf{P},\mathbf{Q}')^2} h(\mathbf{P},\mathbf{Q},\mathbf{Q}') \right], \tag{40}$$

for all $\phi \in \mathscr{D}$. Using the bound (36) we obtain

$$\|L_{h,j}\phi\| < \frac{k_6}{2m} \|h\|_{1/2,\infty} \|L_{0,j}\phi\| + \frac{k_6}{2m} \|(|h| + |Dh|)\|_{1/2,\infty} \|\phi\|, \tag{41}$$

for all $j \in \{1,2\}$. Replacing ϕ by $\mathbf{L}_0 \phi$ in (40) leads to the estimate

$$\|\mathbf{L}_h \cdot \mathbf{L}_0 \phi\| < \frac{k_6}{2m} \left\{ \|h\|_{1/2,\infty} \|\mathbf{L}_0^2 \phi\| + \|(|h| + |Dh|)\|_{1/2,\infty} \sum_{j=1}^{2} \|L_{0,j}\phi\| \right\}. \tag{42}$$

On the other hand, applying $\mathbf{L}_0$ to (40) gives

$$\begin{aligned} \mathbf{L}_0 \cdot \mathbf{L}_h \phi(\mathbf{P},\mathbf{Q}) = & \int \frac{d\sigma(\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')} \frac{\Omega(\mathbf{P},\mathbf{Q})}{\Omega(\mathbf{P},\mathbf{Q}')} [\mathbf{L}_0^2 \phi(\mathbf{P},\mathbf{Q}')] \frac{h(\mathbf{P},\mathbf{Q},\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')} \\ & - i \int \frac{d\sigma(\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')} \frac{\Omega(\mathbf{P},\mathbf{Q})}{\Omega(\mathbf{P},\mathbf{Q}')} [\mathbf{P} \cdot \mathbf{L}_0 \phi(\mathbf{P},\mathbf{Q}')] \\ & \times \left[-3 \frac{h(\mathbf{P},\mathbf{Q},\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')^2} + \left(\frac{2}{\Omega(\mathbf{P},\mathbf{Q}')} + \frac{1}{\Omega(\mathbf{P},\mathbf{Q})} \right) \frac{Dh(\mathbf{P},\mathbf{Q},\mathbf{Q}')}{\|\mathbf{P}\|} \right] \\ & - \Omega(\mathbf{P},\mathbf{Q}) \int d\sigma(\mathbf{Q}') \phi(\mathbf{P},\mathbf{Q}') (2 + \|\mathbf{P}\| \partial_{\|\mathbf{P}\|}) \\ & \times \left[\frac{Dh(\mathbf{P},\mathbf{Q},\mathbf{Q}')}{\|\mathbf{P}\| \Omega(\mathbf{P},\mathbf{Q}')^2} - \frac{h(\mathbf{P},\mathbf{Q},\mathbf{Q}')}{\Omega(P,q')^3} \right], \end{aligned}$$

for all $\phi \in \mathscr{D}$. We note in the last term the factor $\|\mathbf{P}\| \partial_{\|\mathbf{P}\|} Dh \|\mathbf{P}\|^{-1}$, the control of which requires the estimate (33). By $\Omega(\mathbf{P},\mathbf{Q})/\Omega(\mathbf{P},\mathbf{Q}') \leqslant (\omega(\mathbf{Q}) + \omega(\mathbf{Q}'))/m \leqslant 2\omega(\mathbf{Q})\omega(\mathbf{Q}')/m^2$, the inequality (36) and some trivial algebra, we obtain

$$\|\mathbf{L}_0 \cdot \mathbf{L}_h \phi\| \leqslant \frac{k_6}{m^3} \left(\|h\|_{3/2,\infty} \|\mathbf{L}_0^2 \phi\| + 3 \|(|h| + |Dh|)\|_{3/2,\infty} \sum_{i=1}^{2} \|L_{0,i}\phi\| \right) + k_7 \|\phi\|, \tag{43}$$

for some $k_7 \in (0,\infty)$ in which the constant k_3 of (33) is involved. By applying $\mathbf{L}_h$ to the expression (40) and by using (43) we get an estimate of the last term

$$\|\mathbf{L}_h^2\phi\| \leqslant \frac{k_6}{2m}\,\|(|h|+|Dh|)\|_{1/2,\infty}\left(\|\mathbf{L}_0\cdot\mathbf{L}_h\phi\|+\sum_{j=1}^{2}\|L_{h,j}\phi\|\right)$$
$$\leqslant \frac{k_6^2}{2m^6}\,(\|(|h|+|Dh|)\|_{3/2,\infty})^2\left(\|\mathbf{L}_0^2\phi\|+\frac{7}{2}\sum_{j=1}^{2}\|L_{0,j}\phi\|\right)+k_8\|\phi\|, \tag{44}$$

for some $k_8\in(0,\infty)$, where we have used $\|h\|_{1/2,\infty}\leqslant m^{-2}\|h\|_{3/2,\infty}$. More generally, from the definition (37) and the bound (32), it follows that

$$\|(|h|+|Dh|)\|_{1/2,\infty}\leqslant m^{-2}\|(|h|+|Dh|)\|_{3/2,\infty}<\frac{2K_2}{m^2}. \tag{45}$$

Finally, by collecting the estimates (39) and (42) to (45), we obtain

$$\|(\Delta-\Delta_0)\phi\|\leqslant 7(a+a^2)\left(\left\|\frac{\|\mathbf{P}\|}{m}\,\phi\right\|1+\sum_{j=1}^{2}\|L_{0,j}\phi\|\right)+(3a+2a^2)\|\mathbf{L}_0^2\phi\|+k_9\|\phi\|, \tag{46}$$

for some $k_9\in(0,\infty)$ and all $\phi\in\mathscr{D}$, where $a:=k_6K_2/m^3$. It remains to find a bound on $\|(\|P\|)\phi\|,\|L_{0,j}\phi\|,\|\mathbf{L}_0^2\phi\|$ of the type $k_{10}\|\Delta_0\phi\|+k_{11}\|\phi\|$ for constants k_{10} and k_{11}. Following Nelson (Ref. 11, proof of Lemma 6.1), we find

$$\left\|\frac{\|\mathbf{P}\|}{m}\,\phi\right\|+\sum_{j=1}^{2}\|L_{0,j}\phi\|\leqslant\sqrt{3}\left(\left\|\frac{\|\mathbf{P}\|}{m}\,\phi\right\|^2+\|\mathbf{L}_0\phi\|^2+\left\|\frac{H_0}{m}\,\phi\right\|^2+\|J\phi\|^2\right)^{1/2}$$
$$=\sqrt{3}(\phi,\Delta_0\phi)^{1/2}$$

$$<\sqrt{3}(\phi,(\tfrac{1}{2}\,\Delta_0^2+\Delta_0+\tfrac{1}{2})\phi)^{1/2}$$
$$=\sqrt{\tfrac{3}{2}}\|(\Delta_0+1)\phi\|\leqslant\sqrt{\tfrac{3}{2}}(\|\Delta_0\phi\|+\|\phi\|). \tag{47}$$

The bound on $\|\mathbf{L}_0^2\phi\|$ needs more development. Following Ref. 11 (proof of Lemma 6.1) again, we try to write $\Delta_0^2-(\mathbf{L}_0^2)^2$ as a sum of positive and negative operators. For that we use the commutation rules (1)–(4), which imply

$$\mathbf{P}^2\mathbf{L}^2+\mathbf{L}^2\mathbf{P}^2=\sum_{i,j=1}^{2}(P_iL_j^2P_i+L_iP_j^2L_i)-\mathbf{P}^2-4H^2,$$

$$H^2\mathbf{L}^2+\mathbf{L}^2H^2=H\mathbf{L}^2H+\mathbf{L}\cdot H^2\mathbf{L}-2\mathbf{P}^2-2H^2,$$

$$J^2\mathbf{L}^2+\mathbf{L}^2J^2=J\mathbf{L}^2J+\mathbf{L}\cdot J^2\mathbf{L}-\mathbf{L}^2,$$

$$J^2\mathbf{P}^2+\mathbf{P}^2J^2=J\mathbf{P}^2J+\mathbf{P}\cdot J^2\mathbf{P}-\mathbf{P}^2.$$

From these relations it follows that $\Delta_0^2-(\mathbf{L}_0^2)^2+m^{-2}(4\mathbf{P}^2+6H_0^2)+\mathbf{L}_0^2$ is a positive operator, and thus

$$(\mathbf{L}_0^2)^2 < \Delta_0^2 + m^{-2}(4\mathbf{P}^2 + 6H_0^2) + \mathbf{L}_0^2 < \Delta_0^2 + 6\Delta_0 + 9 = (\Delta_0 + 3)^2,$$

and finally $\|\mathbf{L}_0^2\phi\| < \|(\Delta_0+3)\phi\| \leqslant \|\Delta_0\phi\| + 3\|\phi\|$. By collecting all these results, the estimate (46) becomes

$$\|(\Delta - \Delta_0)\phi\| < (a + a^2)\left(3 + 7\sqrt{\frac{3}{2}}\right)\|\Delta_0\phi\| + k_{12}\|\phi\|,$$

for some constant $k_{12} \in (0,\infty)$ and all $\phi \in \mathscr{D}$. Let us compare this with the requirement (35). The necessary condition $k_4 := (a + a^2)(3 + 7\sqrt{3/2}) < 1$ is satisfied for $a \leqslant \pi/40$. Because $a = k_6 K_2/m^3 = \pi K_2/(2m^4)$ we get $K_2 \leqslant m^4/20$.

Third step. We show the essential self-adjointness of H, $\mathbf{P}$, J, and $\mathbf{L}$ on $\mathscr{D}$ and establish the Conclusion 3). We already know that H_0, $\mathbf{P}$, J, and $\mathbf{L}_0$ are essentially self-adjoint on $\mathscr{D}$ (second step). Then H is also essentially self-adjoint on $\mathscr{D}$ because

$$(H - H_0)\phi(\mathbf{P},\mathbf{Q}) = \int \frac{d\sigma(\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')}\,\phi(\mathbf{P},\mathbf{Q}')h(\mathbf{P},\mathbf{Q},\mathbf{Q}') \tag{48}$$

is well defined for all $\phi \in \mathscr{H}$ [because of (36) and because, by (31), $\|h\|_{1/2,\infty} < K_2/(4m^2)$]. Note the bound on the operator norm: $\|H - H_0\|_{\mathrm{op}} \leqslant k_6\|h\|_{1/2,\infty}$. For $\mathbf{L}$ we consider the bound (41). From the Kato-Rellich theorem (Theorem X.12 of Ref. 12) it follows that $\mathbf{L}$ is essentially self-adjoint on $\mathscr{D}$, provided $k_6\|h\|_{1/2,\infty}/(2m) < 1$ (note that this condition leads to $\|H - H_0\|_{\mathrm{op}} < 2m$ and thus implies the positivity of H), which holds, because by (45): $k_6\|h\|_{1/2,\infty}/(2m) \leqslant K_2 k_6/m^3 = a$ and because $a \leqslant \pi/40$ (see the second step).

By using the methods of the second step it is easy (but tedious) to check that all products AB with $A \neq B$, where A,B are any pair of operators H, P_1, P_2, J, L_1, L_2, are well defined on $\mathscr{D}$ because of (32) and (33) (the second step of this proof concerned the squares A^2 and can be taken as examples). For more details see similar estimates in Ref. 7 in the one space dimension case. These calculations give clear, explicit expressions that make evident the symmetry property stated in the Conclusion 3), and on which the commutation rules, which already hold on an algebraical level by proposition 2, can be verified analytically. □

Remark 1: From the explicit estimate of the constants K_1 and K_2 given in the previous proof, it follows that the function

$$c(x,y) = \lambda(x^2 + m^2)^{-3/4}(y^2 + m^2)^{-3/4}, \tag{49}$$

for all $x,y \in \mathbb{R}_+$ and all $|\lambda| < m^4/20$, satisfies all the hypotheses of Propositions 3 and 4.

Remark 2: Let us explain how Proposition 4 leads to the integrability condition of Ref. 10. We first verify the hypothesis of the commutation theorem (Ref. 12, Theorem X.37) or (Ref. 10, Theorem 0′). By (2) the operator $N := \Delta + 1$ is essentially self-adjoint on the domain $\mathscr{D}$ given by (34). The first hypothesis follows then from Nelson's argument used to establish (47) (without the index 0). Now by (3) the following calculation makes sense on $\mathscr{D}$:

$$
\begin{aligned}
(H\phi,N\phi)-(N\phi,H\phi)&=(H\phi,\mathbf{L}^2\phi)-(\mathbf{L}\phi,H\phi)\\
&=\sum_{j=1}^{2}(L_jH\phi,L_j\phi)-(L_j\phi,L_jH\phi)\\
&=\sum_{j=1}^{2}(HL_j\phi,L_j\phi)+i(P_j\phi,L_j\phi)-(L_j\phi,HL_j\phi)+i(L_j\phi,P_j\phi)\\
&=i(\phi,(\mathbf{P}\cdot\mathbf{L}+\mathbf{L}\cdot\mathbf{P})\phi),
\end{aligned}
$$

where we have taken the case of H as an example. Now for all $\phi\in\mathscr{D}$:

$$
0\leqslant\|(m^{-1}P_j\pm L_j)\phi\|^2=(\phi,(m^{-1}P_j\pm L_j)^2\phi)=(\phi,(m^{-2}P_j^2+L_j^2)\phi))\pm m^{-1}(\phi,(P_jL_j+L_jP_j)\phi),
$$

for all $j\in\{1,2\}$, from which it follows

$$
m^{-1}|(\phi,(\mathbf{P}\cdot\mathbf{L}+\mathbf{L}\cdot\mathbf{P})\phi)|\leqslant(\phi,(m^{-2}\mathbf{P}^2+\mathbf{L}^2)\phi)<(\phi,N\phi),
$$

and then the hypotheses of the commutation theorem are satisfied. The integrability of our algebra representation follows then from Ref. 10, Corollary 4.

V. THE CASIMIR OPERATORS

We study the modification of the Casimir operators [defined by (5) and given in the two free particle representations by (18)–(19)] due to the introduction of interaction. From the operators of the interaction representation (12) and the commutation rules (11) for $\mathscr{O}$, it follows that the Pauli–Lubanski operator E takes the form

$$
E=E_0+\{\mathscr{O},E_0\},
$$

where E_0 is the Pauli–Lubanski operator of the free representation, given by (19). Now the condition that the kernel $h(\mathbf{P},\mathbf{Q},\mathbf{Q}')$ of the operator $\mathscr{O}$ depends only on the norms $\|\mathbf{P}\|,\|\mathbf{Q}\|,\|\mathbf{Q}'\|$ has the consequence that

$$
J^{\mathbf{Q}}\mathscr{O}=\mathscr{O}J^{\mathbf{Q}}=0, \tag{50}
$$

from which it follows that $E_0\mathscr{O}=\mathscr{O}E_0=0$, and thus

$$
E=E_0. \tag{51}
$$

Thus, the introduction of interaction has no effect on the Pauli–Lubanski operator. On the other hand, the square mass operator M^2 takes the form

$$
M^2\phi(\mathbf{P},\mathbf{Q})=4(\mathbf{Q}^2+m^2)\phi(\mathbf{P},\mathbf{Q})+\int\frac{d\sigma(\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')}\,\phi(\mathbf{P},\mathbf{Q}')\Xi(\mathbf{P},\mathbf{Q},\mathbf{Q}'), \tag{52}
$$

for all $\phi\in\mathscr{D}$, where the kernel Ξ is given by (38). Note that the spectrum of M_0^2, the square-mass operator of the two free particle representations, given by (18), is absolutely continuous, made of the complete interval $[4m^2,\infty)$. The introduction of interaction has the important effect that an isolated eigenvalue may occur.

Proposition 5: Let c: $\mathbb{R}_+^2\to\mathbb{C}$ *satisfying the hypothesis of Proposition 4 and* h *as there. Then the operator* M^2 *is self-adjoint. Moreover, let* c *be given by (49); then for all* $0>\lambda>-m^4/20$, M^2 *has an eigenvalue* $0<m_B^2<4m^2$, *and its spectrum is* $\{m_B^2\}\cup[4m^2,\infty)$.

Proof: Because H and $\mathbf{P}$ commute they admit a simultaneous spectral measure $dE(\rho,\mathbf{P})$, where $\rho>0$ is the spectral variable associated to H. In this representation M^2 becomes simply the multiplication operator by $\rho^2-\mathbf{P}^2$, and thus is self-adjoint. Moreover, the invariant subspaces are limited in the $(\rho,\mathbf{P})$ space by the half-hyperboloids $\{\rho = \sqrt{\mathbf{P}^2+K^2}\}$ with $K>0$, and so is the support of dE.

Let us consider the one-parameter group of operators $\{U_1(\gamma)\}_{\gamma\in\mathbb{R}}$ defined by

$$U_1(\gamma)\phi(\rho,\mathbf{P}) := \phi(\rho\ \cosh\ \gamma + P_1\ \sinh\ \gamma, P_1\ \cosh\ \gamma + \rho\ \sinh\ \gamma, P_2),$$

for all $\phi\in L^2(\mathbb{R}^3,dE)$ with compact support [note that $U_1(\gamma)$ is not necessarily $\exp(i\gamma L_1)$]. In the $(\rho,\mathbf{P})$ space, $U_1(\gamma)$ translates a point $(\rho_0,\mathbf{P}_0)$ on the hyperboloid $\{\rho=(\mathbf{P}^2+\rho_0^2-\mathbf{P}_0^2)^{1/2}\}$ restricted to the $P_2=P_{0,2}$ plane, from a ''hyperbolic angle'' γ. Obviously $U_1(\gamma)$ commutes with M^2. In the same way we define the one-parameter group $\{U_2(\gamma)\}_{\gamma\in\mathbb{R}}$, acting on the P_2 variable. Thus, by suitable applications of these groups we can reduce the study of the spectrum of M to a neighborhood of $\mathbf{P}=0$, that is to the restriction of M to the subspace,

$$\mathscr{H}_\epsilon := \text{closure}_{\mathscr{H}}\{\phi\in\mathscr{H}\,|\,\phi(\mathbf{P},\mathbf{Q})=0, \quad \text{for all } \|\mathbf{P}\|>\epsilon\}, \tag{53}$$

for arbitrary small $\epsilon>0$.

On the other hand, let us consider the operator $M_{\mathbf{P}}^2$ (i.e, for fixed $\mathbf{P}$), given by

$$M_p^2\varphi(\mathbf{Q}) := 4(\mathbf{Q}^2+m^2)\varphi(\mathbf{Q}) + \int d\sigma_{\mathbf{P}}(\mathbf{Q}')\varphi(\mathbf{Q}')\Xi(\mathbf{P},\mathbf{Q},\mathbf{Q}'), \tag{54}$$

for suitable φ in the space $\mathscr{H}_{\mathbf{P}}=L^2(\mathbb{R},d\sigma_{\mathbf{P}})$, where $d\sigma_{\mathbf{P}}(\mathbf{Q})=d\sigma(\mathbf{Q})\Omega(\mathbf{P},\mathbf{Q})^{-1}$. Here $\mathbf{P}\in\mathbb{R}^2$ is just a set of two parameters.

Let $H_{\mathbf{P}}$ be the restriction of H for fixed $\mathbf{P}$, as an operator on $\mathscr{H}_{\mathbf{P}}$. Because $M_{\mathbf{P}}^2 = H_{\mathbf{P}}^2 - \mathbf{P}^2$ the spectrum of $M_{\mathbf{P}}^2$ is easily deduced from the spectrum of $H_{\mathbf{P}}$. We write $H_{\mathbf{P}} = \Omega + H_{h,\mathbf{P}}$ where $H_{h,\mathbf{P}}\varphi(\mathbf{Q}) := \int d\sigma_{\mathbf{P}}(\mathbf{Q}')\varphi(\mathbf{Q}')h(\mathbf{P},\mathbf{Q},\mathbf{Q}')$ for all $\varphi\in\mathscr{H}_{\mathbf{P}}$. Because $\int|h(\mathbf{P},\mathbf{Q},\mathbf{Q}')|^2\,d\sigma_{\mathbf{P}}(\mathbf{Q})d\sigma_{\mathbf{P}}(\mathbf{Q}')$ is well defined [by (32)], $H_{h,\mathbf{P}}$ is compact. By the ''classical Weyl theorem'' (Ref. 13, Sec. XIII.4) the essential spectrum of $\mathscr{H}_{\mathbf{P}}$ is the same as of $\Omega(\mathbf{P},\mathbf{Q})$ (for fixed $\mathbf{P}$), that is the interval $[\Omega(\mathbf{P},\mathrm{O}),\infty)$. It may exist a finite number of eigenvalues in $(0,\Omega(\mathbf{P},0))$, with finite-dimensional eigenspaces. Moreover, $\mathbf{P}\to H_{h,\mathbf{P}}$ is an analytic family of compact operators in a $\mathbb{C}^2$ neighborhood of the real axis [because by giving a small imaginary value to $\mathbf{P}$ the integral $\int|h(\mathbf{P},\mathbf{Q},\mathbf{Q}')|^2\,d\sigma_{\mathbf{P}}(\mathbf{Q})d\sigma_{\mathbf{P}}(\mathbf{Q}')$ is still defined]. Thus $H_{\mathbf{P}}$ is an ''analytic family of type (A)'' and by Theorem XII.13 of Ref. 13 the eigenvalues, if there are any, are continuous functions of $\mathbf{P}$. Returning to the operator $M_{\mathbf{P}}^2 = H_{\mathbf{P}}^2 - \mathbf{P}^2$ we conclude that its spectrum is made of the interval $[4m^2,\infty)$ and of a finite number of possible eigenvalues in the interval $(0,4m^2)$, which are continuous with respect to $\mathbf{P}$.

Now let us consider the case where an eigenvalue exists. By the theory of Ref. 13, Sec. XIII.16, and more precisely by the point (d) of theorem XIII.85 of this reference, follows that the spectrum of M^2 restricted to the subspace $\mathscr{H}_\epsilon$ given by (53), has, in fact, a gap. By the geometrical form of the support of dE this property passes on to the operator M^2 itself.

Let us take now the functions c given by (49). Because the eigenvalues of $H_{\mathbf{P}}$ are continuous in $\mathbf{P}$, they are eigenvalues of H_0 for $\mathbf{P}=0$, that is, solutions of the equation

$$2\sqrt{\mathbf{Q}^2+m^2}\varphi(\mathbf{Q}) + \lambda\,\omega(\mathbf{Q})^{-3/2}\int \frac{d\mathbf{Q}'}{4(\mathbf{Q}'^2+m^2)}\,\varphi(\mathbf{Q}')\omega(\mathbf{Q}')^{-3/2} = m_B\varphi(\mathbf{Q}),$$

which admits one and only one eigenvalue $0<m_B<2m$, with eigenvector $\varphi(\mathbf{Q})=\omega(\mathbf{Q})^{-3/2}(2\omega(\mathbf{Q})-m_B)^{-1}$, where m_B is the unique solution of the implicit equation

$$1=-\lambda\int\frac{d\mathbf{Q}}{4(\mathbf{Q}^2+m^2)^{5/2}}\frac{1}{2\sqrt{\mathbf{Q}^2+m^2}-m_B},$$

for $0>\lambda>-m^4/20$. From the geometrical form of the support of dE, it follows that the spectrum of M^2 is made of only one isolated eigenvalue m_B^2 and of the continuous interval $[2m,\infty]$. □

Remark: The eigenvalue equation for M^2, given by (51), takes the form

$$m_B^2\phi(\mathbf{P},\mathbf{Q})=4(\mathbf{Q}^2+m^2)\phi(\mathbf{P},\mathbf{Q})+\int\frac{d\sigma(\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')}\phi(\mathbf{P},\mathbf{Q}')\Xi(\mathbf{P},\mathbf{Q},\mathbf{Q}'),\tag{55}$$

where Ξ is given by (38) and m_B is expected to lie in $(0,2m)$. (55) can be considered as a *relativistic Schrödinger equation* because it generates the discrete structure of the bound states. Note that, due to the variables (15), it has the same general form as the Schrödinger equation, but with two important differences: the interaction is nonlocal and depends on $\mathbf{P}$. Contrary to the nonrelativistic case, this dependence cannot be removed, unless a particular referential frame is chosen, a center-of-mass frame. In that case, i.e. for $\mathbf{P}=0$, (55) reduces to

$$(m_B^2-4m^2)\varphi(\mathbf{Q})=4\mathbf{Q}^2\varphi(\mathbf{Q})+\int\frac{d\sigma(\mathbf{Q}')}{2\omega(\mathbf{Q}')}\varphi(\mathbf{Q}')\Xi(0,\mathbf{Q},\mathbf{Q}'),\tag{56}$$

which, except for the nonlocal interaction, is a Schrödinger-like equation. Moreover, for $\mathbf{P}=0$ the operator M^2 is the square of H, so that the eigenvalue equation (56) can be written for H, and becomes

$$m_B\varphi(\mathbf{Q})=2\sqrt{\mathbf{Q}^2+m^2}\varphi(\mathbf{Q})+\int\frac{d\sigma(\mathbf{Q}')}{2\omega(\mathbf{Q}')}\varphi(\mathbf{Q}')c(\|\mathbf{Q}\|,\|\mathbf{Q}'\|),\tag{57}$$

where $c(\|\mathbf{Q}\|,\|\mathbf{Q}'\|)=h(0,\mathbf{Q},\mathbf{Q}')$ is a center-of-mass interaction kernel (which can be chosen arbitrarily). Note that (57) corresponds to some kind of elementary (or naïve) generalization of the Schrödinger equation to the relativistic case.

VI. CONCLUSION

Let us sum up what we have found. We have constructed a family of unitary, continuous representations of the Poincaré group in three space–time dimensions, as perturbations of the two free boson model. These perturbations are nontrivial, in the sense that isolated eigenvalues of the Casimir operator M may appear (but the Casimir operator E, the Pauli–Lubanski operator, remains unchanged). To affirm that we have really obtained models for two bosons with interaction, it remains to construct the asymptotic states. For that we only need to show the existence of the generalized wave operators (Ref. 14, Sec. XI.3). This can be obtained from Cook's method (Theorem XI.4 of Ref. 14), with $A=H$ and $B=H_0$, and from the further assumption that $c\in C^2(\mathbb{R}_+^2)$ (with right derivation at 0), with first and second derivatives also bounded [the example (49) satisfies these conditions]. Let us consider the functions

$$F(t,\mathbf{P},\mathbf{Q})=\int\frac{d\sigma(\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')}\phi(\mathbf{P},\mathbf{Q}')h(\mathbf{P},\mathbf{Q},\mathbf{Q}')e^{-it\Omega(\mathbf{P},\mathbf{Q}')},\tag{58}$$

for $\phi\in\mathscr{S}(\mathbb{R}^4)$ (the Schwartz space) satisfying $\phi(\mathbf{P},0,Q_2)=\partial_{Q_1}^{\nu}\phi(\mathbf{P},0,Q_2)=0$ for $\nu\in\{1,...,4\}$. Such vectors ϕ generate a dense subspace of $\mathscr{H}$. On the other hand, from the techniques of the first step of the proof of Proposition 4 [used to establish (33)] and from the new conditions on c, it follows that $h\in C^2(\mathbb{R}^6)$ with all derivatives bounded. Performing then two integrations by parts wrt Q_1' leads to

$$F(t,\mathbf{P},\mathbf{Q})=-\frac{1}{32t^2}\int d\mathbf{Q}'\ e^{-it\Omega(\mathbf{P},\mathbf{Q}')}\partial_{Q_1'}\left(\frac{\Omega(\mathbf{P},\mathbf{Q}')}{Q_1'}\,\partial_{Q_1'}\,\frac{\phi(\mathbf{P},\mathbf{Q}')h(\mathbf{P},\mathbf{Q},\mathbf{Q}')}{Q_1'\omega(\mathbf{Q}')}\right),$$

from which it follows that the function

$$t\mapsto\left[\int\frac{d\mathbf{P}\,d\sigma(\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')}\,|F(t,\mathbf{P},\mathbf{Q})|^2\right]^{1/2}=\|(H-H_0)e^{-itH_0}\phi\|, \tag{59}$$

is in $L^1([1,\infty))$, as required by Cook's method. In conclusion, provided c satisfies these new conditions, our models describe really two-particle systems.

However, the connection of these models with other physical theories, like QFT, is a difficult point. First, because of their particular interaction form, which by (50) can be formulated as follows: the image of the interaction operator $\mathscr{O}$ is contained in the subspace of states with vanishing relative angular momentum (the so-called ''s waves''). Second, because in three-dimensional space–time QFT there are few available bosonic models in which bound states are known to exist (see Ref. 3, Sec. IV). Following the example of the two space–time dimension case, we could find a connection for constant kernel c, with QFT models admitting point interaction (i.e., with a $\lambda\phi_3^4$ term in the Hamiltonian) at first perturbation orders. But these models are defined only for $\lambda\geqslant 0$, in which case bound states are absent. On the other hand, a constant c may satisfy the hypothesis of Proposition 3, but not of Proposition 4.

ACKNOWLEDGMENTS

I would like to thank Dr. Pierre Bader, Professor J.-J. Loeffel, Professor J. Fröhlich, and Professor W. O. Amrein for fruitful discussions and useful suggestions. I am also grateful to Professor G. Gallavotti and Professor S. V. Varadarajan for their interest in this work and for their encouragements.

APPENDIX A: ONE-PARTICLE REPRESENTATION

We show that the operators (6) are the infinitesimal generators of a unitary, continuous and irreducible representation of the universal covering of the Poincaré group $\mathscr{P}_+^\uparrow$. Such a representation is a good candidate for a theory describing a quantum relativistic spinless particle of mass $m>0$. To that purpose, and for the next appendix, we need the Lorentz transform $\Lambda_{\mathbf{v}}$ for an arbitrary velocity $\mathbf{v}\in\mathbb{R}^2$. It is given by a rotation (putting $\mathbf{v}$ parallel to the first axis) followed by a Lorentz boost (along this axis) and then by the inverse rotation. More precisely, if $\mathbf{v}=\|\mathbf{v}\|(\cos\alpha,\sin\alpha)$, we get

$$\Lambda_{\mathbf{v}}=\begin{pmatrix}1&0&0\\0&\cos\alpha&-\sin\alpha\\0&\sin\alpha&\cos\alpha\end{pmatrix}\begin{pmatrix}\gamma&\beta\gamma&0\\\beta\gamma&\gamma&0\\0&0&1\end{pmatrix}\begin{pmatrix}1&0&0\\0&\cos\alpha&\sin\alpha\\0&-\sin\alpha&\cos\alpha\end{pmatrix}$$

$$=\begin{pmatrix}\gamma&\beta_1\gamma&\beta_2\gamma\\\beta_1\gamma&1+\dfrac{\beta_1^2}{\beta^2}(\gamma-1)&\dfrac{\beta_1\beta_2}{\beta^2}(\gamma-1)\\\beta_2\gamma&\dfrac{\beta_1\beta_2}{\beta^2}(\gamma-1)&1+\dfrac{\beta_2^2}{\beta^2}(\gamma-1)\end{pmatrix},$$

where we have put $\boldsymbol{\beta}=(\beta_1,\beta_2)=\mathbf{v}/c$, c being the speed of light, $\beta=\|\boldsymbol{\beta}\|$, and $\gamma=(1-\beta^2)^{-1/2}$. By applying this transformation to a three-dimensional vector $(p^0,\mathbf{p})=(p^0,p_1,p_2)\in\mathbb{R}^3$, we get a more compact expression,

$$\Lambda_{\mathbf{v}}\begin{pmatrix} p^0 \\ \mathbf{p} \end{pmatrix} = \begin{pmatrix} \gamma(p^0 + \boldsymbol{\beta}\cdot\mathbf{p}) \\ \gamma\left(p^0 + \dfrac{\boldsymbol{\beta}\cdot\mathbf{p}}{\beta^2}\right)\boldsymbol{\beta} + \dfrac{\mathbf{p}\wedge\boldsymbol{\beta}}{\beta^2}\,\boldsymbol{\beta}^{\perp} \end{pmatrix}, \tag{A1}$$

where $\boldsymbol{\beta}\cdot\mathbf{p} := \beta_1 p_1 + \beta_2 p_2$, $\boldsymbol{\beta}^{\perp} := (\beta_2, -\beta_1)$, and $\mathbf{p}\wedge\boldsymbol{\beta} = \mathbf{p}\cdot\boldsymbol{\beta}^{\perp} = p_1\beta_2 - p_2\beta_1$. Let us take $c=1$ again. The Poincaré representation describing one particle of mass $m>0$ without spin is given by the following result.

Lemma 6: The operators (6) are the infinitesimal generators of a unitary, continuous and irreducible representation of the universal covering of the Poincaré group $\mathscr{P}_+^{\uparrow}$ in the space $L^2(\mathbb{R}^2,\sigma)$.

We recall that $d\sigma(\mathbf{p}) = d\mathbf{p}[2\omega(\mathbf{p})]^{-1}$, where $\omega(\mathbf{p}) = \sqrt{\mathbf{p}^2+m^2}$.

Proof: Let us consider the following transformations of functions $\phi\in L^2(\mathbb{R},\sigma)$:

$$(\boldsymbol{\xi},\tau,\alpha,\boldsymbol{\beta})\cdot\phi(\mathbf{p}) := e^{i(\boldsymbol{\xi}\cdot\mathbf{p}+\tau\omega(\mathbf{p}))}\phi(\lambda_{\boldsymbol{\beta}}\,R_{\alpha}\mathbf{p}), \tag{A2}$$

for all $\tau\in\mathbb{R}$, ξ, $\beta\in\mathbb{R}^2$, $\alpha\in[0,2\pi)$ and almost all $\mathbf{p}\in\mathbb{R}^2$, where R_{α} is the matrix of the rotation of $\mathbb{R}^2$ of angle α and $\lambda_{\boldsymbol{\beta}}\mathbf{p}$ is the ''spatial'' component of the Lorentz transform of $(\omega(\mathbf{p}),\mathbf{p})$ of speed $\boldsymbol{\beta}$, more precisely, from (A1):

$$\lambda_{\boldsymbol{\beta}}\mathbf{p} := \gamma\left(\omega(\mathbf{p}) + \frac{\boldsymbol{\beta}\cdot\mathbf{p}}{\beta^2}\right)\boldsymbol{\beta} + \frac{\mathbf{p}\wedge\boldsymbol{\beta}}{\beta^2}\,\boldsymbol{\beta}^{\perp}. \tag{A3}$$

We claim that these transformations define a unitary, continuous, and irreducible representation in $L^2(\mathbb{R}^2,\sigma)$ of the Poincaré group $\mathscr{P}_+^{\uparrow}$, the infinitesimal generators of which are given by (6).

The unitarity and the group law are easily seen by introducing a third variable p^0 together with a Dirac-delta function in the measure, that is, by replacing $L^2(\mathbb{R}^2,\sigma)$ by $L^2(\mathbb{R}^3,\Sigma)$, where $d\Sigma(p^0,p_1,p_2) = dp^0\,dp_1\,dp_2\,\delta(p^{02}-p_1^2-p_2^2-m^2)\,\theta(p^0)$, θ being the Heaviside function. Because of the Σ measure, a vector $\phi(p^0,p_1,p_2)$ is not distinguished from $\phi(\sqrt{p_1^2+p_2^2+m^2},p_1,p_2)$. The transformation (A2) becomes, after Fourier transformation,

$$(\boldsymbol{\xi},\tau,\alpha,\boldsymbol{\beta})\cdot\tilde{\phi}(t,\mathbf{x}) = \tilde{\phi}((\boldsymbol{\xi},\tau,\alpha,\boldsymbol{\beta})^{-1}\cdot(t,\mathbf{x}))$$

(where $\tilde{\phi}$ is the Fourier transform of ϕ) that is, given in terms of the ordinary Poincaré transformation on space–time. The group law is now obvious. The unitarity follows from the Poincaré invariance of the measure Σ.

The continuity of the representation is easily seen in $L^2(\mathbb{R}^2,\sigma)$, by standard analysis methods. The irreducibility is obtained as follows. Let ϕ be a continuous, nonzero function in $L^2(\mathbb{R}^2,\sigma)$. Let us show that the only vector orthogonal to $\{e^{i\boldsymbol{\xi}\cdot\mathbf{p}}\phi(\lambda_{\boldsymbol{\beta}}\mathbf{p})\,|\,\boldsymbol{\xi},\boldsymbol{\beta}\in\mathbb{R}^2\}$ is 0. By the Fourier theory,

$$\int_{\mathbb{R}^2} d\sigma(\mathbf{p})\,\psi(\mathbf{p})^* e^{i\boldsymbol{\xi}\cdot\mathbf{p}}\phi(\lambda_{\boldsymbol{\beta}}\mathbf{p}) = 0, \quad \text{for all } \boldsymbol{\xi}\in\mathbb{R}^2, \tag{A4}$$

implies that $\psi(\mathbf{p})=0$ for almost all $\mathbf{p}$, such that $\phi(\lambda_{\boldsymbol{\beta}}\mathbf{p})\neq 0$. Without loss of generality, we may assume that $\phi(0)\neq 0$. From (A3) follows that the vector $\boldsymbol{\beta} = -\mathbf{p}/\omega(\mathbf{p})$ satisfies $\lambda_{\boldsymbol{\beta}}\mathbf{p}=0$, for all $\mathbf{p}\in\mathbb{R}^2$. Thus, if moreover we impose that (A4) holds for all $\boldsymbol{\beta}\in\mathbb{R}^2$ we get $\psi=0$.

After an elementary calculation, the operators (6) turn out to be the infinitesimal generators of the representation (61). □

APPENDIX B: THE RELATIVE MOMENTUM

We explain the change of variable $(\mathbf{p}_1,\mathbf{p}_2)\to(\mathbf{P},\mathbf{Q})$ given in (15) and establish some useful formulas.

The meaning of $\mathbf{P}=\mathbf{p}_1+\mathbf{p}_2$, the total momentum, is clear. The notion of relative momentum is more subtle. Physically it must be related to the momentum of one of the particles in a center-of-mass frame.

Let $p_1=(\omega(\mathbf{p}_1),\mathbf{p}_1)$ and $p_2=(\omega(\mathbf{p}_2),\mathbf{p}_2)$ be the energy momenta of two free particles, of the same mass to simplify. We define first

$$P=(P^0,\mathbf{P})=p_1+p_2, \quad q=(q^0,\mathbf{q})=\tfrac{1}{2}(p_1-p_2).$$

Note the useful relation $\mathbf{P}\cdot\mathbf{q}=P^0q^0$. Let $\Lambda_{\boldsymbol{\beta}}$ be a Lorentz transformation such that $\Lambda_{\boldsymbol{\beta}}P=(M_0,\mathbf{0})$, where $M_0=[(P^0)^2-\mathbf{P}^2]^{1/2}$. Physically, $\Lambda_{\boldsymbol{\beta}}$ is associated with a change of referential frame, which put the two particles of momenta $\mathbf{p}_1,\mathbf{p}_2$ on one of their center-of-mass frames. Then we define the relative momentum $\mathbf{Q}$ as the spatial projection of $\Lambda_{\boldsymbol{\beta}}q$ [the relative momentum just defined (as the center-of-mass frame itself), is not unique because in its definition $\Lambda_{\boldsymbol{\beta}}$ could be followed by a fixed space rotation without consequence]. The calculation of a $\Lambda_{\boldsymbol{\beta}}$ i.e. of a $\boldsymbol{\beta}$, is obtained from (A3). The condition that the spatial component of $\Lambda_{\boldsymbol{\beta}}P$ vanishes gives

$$(1-\beta^2)^{-1/2}\left(P^0+\frac{\boldsymbol{\beta}\cdot\mathbf{P}}{\beta^2}\right)\boldsymbol{\beta}+\frac{\mathbf{P}\wedge\boldsymbol{\beta}}{\beta^2}\,\boldsymbol{\beta}^{\perp}=0.$$

If we choose the direction of $\boldsymbol{\beta}$ parallel to $\mathbf{P}$, we get the unique solution $\boldsymbol{\beta}=-\mathbf{P}/P^0$. After some calculation one gets $\Lambda_{-\mathbf{P}/P^0}q=(0,\mathbf{Q})$, where

$$\mathbf{Q}=\frac{q^0M_0}{\mathbf{P}^2}\,\mathbf{P}-\frac{\mathbf{q}\wedge\mathbf{P}}{\mathbf{P}^2}\,\mathbf{P}^{\perp}.$$

If we write it in the form $\mathbf{Q}=\mathbf{q}+\xi\mathbf{P}$, the calculation of $\mathbf{P}\cdot\mathbf{Q}$ leads to $\xi=-q^0[P^0+M_0]^{-1}$ and we finally get the formula (15).

Let us calculate the operators of the two free boson representation (7) in these variables, to establish (16). The norm $\|\mathbf{Q}\|$ is obtained by the initial definition of $\mathbf{Q}$ and the properties of the Lorentz transform, which gives $\mathbf{Q}^2=(q^0)^2-\mathbf{q}^2$. From the trivial identity $(P^0)^2-\mathbf{P}^2=4m^2+4[(q^0)^2-\mathbf{q}^2]$, it follows that $M_0=2\omega(\mathbf{Q})$, and then

$$P^0=\omega(\mathbf{p}_1)+\omega(\mathbf{p}_2)=M_0^2+\mathbf{P}^2=\sqrt{\mathbf{P}^2+4\mathbf{Q}^2+4m^2},$$

which is denoted by $\Omega(\mathbf{P},\mathbf{Q})$ in (16). The angular momentum J is easily obtained because a rotation of the system $\mathbf{p}_1,\mathbf{p}_2$ leads to the same rotation of $\mathbf{P},\mathbf{Q}$, which is an obvious consequence of the formula (15). The Lorentz generator $L_{0,1}$ is obtained as follows. Under an infinitesimal Lorentz transform of hyperbolic angle γ in the first direction (of unit vector $\mathbf{e}_1$), the fundamental quantities become

$$\mathbf{P}\to\mathbf{P}+\gamma P^0\mathbf{e}_1, \quad \mathbf{q}\to\mathbf{q}+\gamma q^0\mathbf{e}_1,$$

$$P^0\to P^0+\gamma P_1, \quad q^0\to q^0+\gamma q_1.$$

Under such a transformation, $\mathbf{Q}$ becomes

$$\mathbf{Q}\to\mathbf{q}+\gamma q^0\mathbf{e}_1-\frac{q^0+\gamma q_1}{M_0+P^0+\gamma P_1}\,(\mathbf{P}+\gamma P^0\mathbf{e}_1)\approx\mathbf{Q}+\gamma\,\frac{P_2}{M_0+P^0}\,\mathbf{Q}^{\perp},$$

where we have performed a first-order development. The formula for $L_{0,1}$ given in (16) is then easily deduced. $L_{0,2}$ is obtained in the same way.

The Jacobian of the transformation $(\mathbf{p}_1,\mathbf{p}_2)\to(\mathbf{P},\mathbf{Q})$ is calculated in two steps. First we perform the transformation $(\mathbf{p}_1,\mathbf{p}_2)\to(\mathbf{P},\mathbf{q})$, with Jacobian 1, and then the transformation $(\mathbf{P},\mathbf{q})\to(\mathbf{P},\mathbf{Q})$ with

Jacobian

$$\left| \det\begin{pmatrix} \frac{\partial Q_1}{\partial q_1} & \frac{\partial Q_1}{\partial q_2} \\ \frac{\partial Q_2}{\partial q_1} & \frac{\partial Q_2}{\partial q_2} \end{pmatrix} \right|^{-1} = \left[1 - \left(P_1 \frac{\partial}{\partial q_1} + P_2 \frac{\partial}{\partial q_2} \right) \frac{q^0}{M_0 + P^0} \right]^{-1},$$

which, after a long and tedious calculation, gives $4\omega(\mathbf{p}_1)\omega(\mathbf{p}_2)[M_0 P^0]^{-1}$. Thus, the measure σ_2 becomes $d\sigma_2(\mathbf{p}_1,\mathbf{p}_2) = d\mu(\mathbf{P},\mathbf{Q}) = d\mathbf{P}\, d\sigma(\mathbf{Q})\Omega(\mathbf{P},\mathbf{Q})^{-1}$.

APPENDIX C: THE FUNDAMENTAL EQUATION

The fundamental equation (23) is the condition on a kernel $h(\mathbf{P},\mathbf{Q},\mathbf{Q}')$, depending only on the norms $\|\mathbf{P}\|,\|\mathbf{Q}\|,\|\mathbf{Q}'\|$, for the relation (13) and (14) to hold. This norm dependence leads to (50) and thus to $L_{0,j}\mathscr{O} = L_{0,j}^{\mathbf{P}}\mathscr{O}$ and $\mathscr{O}L_{0,j} = \mathscr{O}L_{0,j}^{\mathbf{P}}$, where $L_{0,j}^{\mathbf{P}} := -i\Omega(\mathbf{P},\mathbf{Q})\partial_{P_j}$ for all $j \in \{1,2\}$.

Let us calculate the jth equation of (13). The linear part in $\mathscr{O}$ can be written as

$$A_j := [\{H_0,\mathscr{O}\},L_{0,j}] + [H_0,\{L_{0,j},\mathscr{O}\}] = 2(H_0\mathscr{O}L_{0,j} - L_{0,j}\mathscr{O}H_0 + iP_j\mathscr{O}),$$

where we have used $[H_0,L_{0,j}] = iP_j$ and the fact that P_j and $\mathscr{O}$ commute. By applying this operator to a vector $\phi \in \mathscr{D}$ [the domain given by (34)] we obtain, in obvious symbolic notation,

$$\begin{aligned} A_j\phi(\mathbf{P},\mathbf{Q}) &= -2i\Omega \int d\sigma(\mathbf{Q}')\, \frac{\partial_{P_j}\phi h}{\Omega+\Omega'} + 2i\Omega\partial_{P_j}\int d\sigma(\mathbf{Q}')\, \frac{\phi h}{\Omega+\Omega'} + 2iP_j \int \frac{d\sigma(\mathbf{Q}')}{\Omega'}\, \frac{\phi h}{\Omega+\Omega'} \\ &= 2i\int d\sigma(\mathbf{Q}')\phi\left(\Omega\partial_{P_j}\frac{h}{\Omega+\Omega'} + \frac{P_j}{\Omega'}\frac{h}{\Omega+\Omega'} \right) \\ &= 2i\int d\sigma(\mathbf{Q}')\phi(\mathbf{P},\mathbf{Q}')\, \frac{\Omega(\mathbf{P},\mathbf{Q})\partial_{P_j}(\mathbf{P},\mathbf{Q},\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}) + \Omega(\mathbf{P},\mathbf{Q}')}. \end{aligned}$$

To study the bilinear part, we rewrite (48) and (40):

$$\{H_0,\mathscr{O}\}\phi(\mathbf{P},\mathbf{Q}) = \int \frac{d\sigma(\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')}\, \phi(\mathbf{P},\mathbf{Q}')h(\mathbf{P},\mathbf{Q},\mathbf{Q}'),$$

$$\begin{aligned} \{L_{0,j}\mathscr{O}\}\phi(\mathbf{P},\mathbf{Q}) &= -i\int \frac{d\sigma(\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')}\, (\partial_{P_j}\phi(\mathbf{P},\mathbf{Q}'))h(\mathbf{P},\mathbf{Q},\mathbf{Q}) \\ &\quad -i\Omega(\mathbf{P},\mathbf{Q})\int d\sigma(\mathbf{Q}')\phi(\mathbf{P},\mathbf{Q}')\partial_{P_j}\frac{h(\mathbf{P},\mathbf{Q},\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')(\Omega(\mathbf{P},\mathbf{Q}) + \Omega(\mathbf{P},\mathbf{Q}'))} \end{aligned}$$

Thus, the bilinear part in $\mathscr{O}$ gives, in symbolic notation,

$$
\begin{aligned}
B_j\phi(\mathbf{P},\mathbf{Q}) :=& [\{H_0,\mathscr{O}\},\{L_0,\mathscr{O}\}]\phi(\mathbf{P},\mathbf{Q}) \\
=& \int \frac{d\sigma''}{\Omega''} h^{Q,Q''}\Bigg[-i\int \frac{d\sigma'}{\Omega'} (\partial_j\phi') h^{Q'',Q'} - i\Omega''\int d\sigma'\ \phi'\partial_j \frac{h^{Q'',Q'}}{\Omega'(\Omega''+\Omega')} \\
&+ i\partial_j \int \frac{d\sigma'}{\Omega'}\ \phi' h^{Q'',Q'}\Bigg] + i\Omega\int d\sigma''\left(\partial_j \frac{h^{Q,Q''}}{\Omega''(\Omega+\Omega'')}\right)\int \frac{dq'}{\Omega'}\ \phi' h^{Q'',Q'} \\
=& i\int d\sigma''\int d\sigma'\,\phi' \\
&\times\left(-h^{Q,Q''}\partial_j \frac{h^{Q''Q'}}{\Omega'(\Omega''+\Omega')} + \frac{h^{Q,Q''}}{\Omega''}\ \partial_j \frac{h^{Q'',Q'}}{\Omega'} + \frac{\Omega}{\Omega'}\left(\partial_j \frac{h^{Q,Q''}}{\Omega''(\Omega+\Omega'')}\right) h^{Q'',Q'}\right) \\
=& i\int \frac{d\sigma(\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')}\ \phi(\mathbf{P},\mathbf{Q}')\int \frac{d\sigma(\mathbf{Q}'')}{\Omega(\mathbf{P},\mathbf{Q}'')^2}\Bigg\{ -\frac{P_j}{\Omega(\mathbf{P},\mathbf{Q}'')}\ h(\mathbf{P},\mathbf{Q},\mathbf{Q}'')h(\mathbf{P},\mathbf{Q}'',\mathbf{Q}') \\
&+ \frac{\Omega(\mathbf{P},\mathbf{Q})\Omega(\mathbf{P},\mathbf{Q}'')\partial_{P_j}h(\mathbf{P},\mathbf{Q},\mathbf{Q}'')}{\Omega(\mathbf{P},\mathbf{Q})+\Omega(\mathbf{P},\mathbf{Q}'')}\ h(\mathbf{P},\mathbf{Q}'',\mathbf{Q}') \\
&+ h(\mathbf{P},\mathbf{Q},\mathbf{Q}'')\ \frac{\Omega(\mathbf{P},\mathbf{Q}'')\Omega(\mathbf{P},\mathbf{Q}')\partial_{P_j}h(\mathbf{P},\mathbf{Q}'',\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}'')+\Omega(\mathbf{P},\mathbf{Q}')}\Bigg\}.
\end{aligned}
$$

Because h depends on $\mathbf{P}$ only through $\|\mathbf{P}\|$ we can replace ∂_{P_j} everywhere by $P_j\|\mathbf{P}\|^{-1}\partial_{\|\mathbf{P}\|}$. The condition $A_j+B_j=0$, which must hold for all $\phi\in\mathscr{D}$, leads to the fundamental equation (23), for all $j\in\{1,2\}$.

The equation (14) is slightly more difficult. By using $J^{\mathbf{Q}}\mathscr{O}=0$ and by putting $J^{\mathbf{P}}:=J-J^{\mathbf{Q}}$, the linear part can be written in symbolic notations:

$$
\begin{aligned}
C\phi(\mathbf{P},\mathbf{Q}) :=& 2(L^{\mathbf{P}}_{0,1}\mathscr{O}L^{\mathbf{P}}_{0,2} - L^{\mathbf{P}}_{0,2}\mathscr{O}L^{\mathbf{P}}_{0,1} - i\mathscr{O}J^{\mathbf{P}})\phi(\mathbf{P},\mathbf{Q}) \\
=& -2\Omega\int d\sigma'[(\partial_2\phi')\partial_1 - (\partial_1\phi')\partial_2]\ \frac{h}{\Omega+\Omega'} \\
&-2\int \frac{d\sigma'}{\Omega'}\,[(P_1\partial_2 - P_2\partial_1)\phi']\ \frac{h}{\Omega+\Omega'} \\
=& -\frac{2i}{\|\mathbf{P}\|}\int \frac{d\sigma(\mathbf{Q}')}{\Omega(\mathbf{P},\mathbf{Q}')}\ (J^{\mathbf{P}}\phi(\mathbf{P},\mathbf{Q}'))Dh(\mathbf{P},\mathbf{Q},\mathbf{Q}').
\end{aligned}
$$

The bilinear part gives

$$
\begin{aligned}
D\phi(\mathbf{P},\mathbf{Q}) :=& \left(\frac{1}{2}\,(C\mathscr{O}+\mathscr{O}C) + L^{\mathbf{P}}_{0,1}\mathscr{O}^2L^{\mathbf{P}}_{0,2} - L^{\mathbf{P}}_{0,2}\mathscr{O}^2L^{\mathbf{P}}_{0,1} + i\mathscr{O}^2J^{\mathbf{P}}\right)\phi(\mathbf{P},\mathbf{Q}) \\
=& -\frac{i}{\|\mathbf{P}\|}\int \frac{d\sigma'}{\Omega'}\ J^{\mathbf{P}}\phi'\int \frac{d\sigma''}{\Omega''}\left(Dh^{\mathbf{Q},\mathbf{Q}''}\ \frac{h^{\mathbf{Q}'',\mathbf{Q}'}}{\Omega'+\Omega''} + \frac{h^{\mathbf{Q},\mathbf{Q}''}}{\Omega+\Omega''}\ Dh^{\mathbf{Q}'',\mathbf{Q}'}\right) \\
&\times(-i)^2\int \frac{d\sigma'}{\Omega'}\ \Omega\Omega'[(\partial_2\phi')\partial_1 - (\partial_1\phi')\partial_2]\int \frac{d\sigma''}{\Omega''}\ \frac{h^{\mathbf{Q},\mathbf{Q}''}}{\Omega+\Omega''}\ \frac{h^{\mathbf{Q}'',\mathbf{Q}'}}{\Omega'+\Omega''}
\end{aligned}
$$

$$+\int \frac{d\sigma'}{\Omega'}\,[(P_1\partial_2-P_2\partial_1)\phi']\int \frac{d\sigma''}{\Omega''}\,\frac{h^{\mathbf{Q},\mathbf{Q}''}}{\Omega+\Omega''}\,\frac{h^{\mathbf{Q}'',\mathbf{Q}'}}{\Omega'+\Omega''}$$

$$=-\frac{i}{\|\mathbf{P}\|}\int \frac{d\sigma'}{\Omega'}\,J^{\mathbf{P}}\phi'\int \frac{d\sigma''}{\Omega''^2}\,(Dh^{\mathbf{Q},\mathbf{Q}''}h^{\mathbf{Q}'',\mathbf{Q}'}+h^{\mathbf{Q},\mathbf{Q}''}Dh^{\mathbf{Q}'',\mathbf{Q}'})$$

$$+i\int \frac{d\sigma'}{\Omega'}\,J^{\mathbf{P}}\phi'\int \frac{d\sigma''}{\Omega''^3}\,h^{\mathbf{Q},\mathbf{Q}''}h^{\mathbf{Q}'',\mathbf{Q}'}.$$

The condition $C+D=0$, which must hold for all $J^{\mathbf{P}}\phi$, leads to the fundamental equation (23) again.

Scaling equations determining Haar-type wavelets are considered for three Pisot numbers $\beta=(1+\sqrt{5})/2,\ 1+\sqrt{2},\ 2+\sqrt{3}$ appearing as dilation factors in scale invariance of observed diffraction patterns of quasicrystals. Simple summation formulas for exponentials of the corresponding β integers are derived. © *1996 American Institute of Physics.* [S0022-2488(96)03006-X]

I. INTRODUCTION

Wavelets have found many applications in modern science.[1,2] They are useful in signal processing, numerical solution of differential equations, analysis of fractals, etc. From a quantum mechanical point of view wavelets represent coherent states of the affine groups defining bases of Hilbert spaces. A particular interest is paid to such bases built by discrete dilations and translations of one (or few) function(s). A self-consistent procedure (multiresolution analysis) of constructing the latter generating function has been developed for rational dilation factors β (see, e.g., Refs. 1–3 and references therein). Analysis of the irrational factor cases, both algebraic and transcendental ones, is one of the motivations of the present investigation. Although our consideration is far from complete, the summation formulas derived below may be useful in the description of some fractals and quasicrystals.

We shall consider three cases:

$$\beta=\frac{1+\sqrt{5}}{2}=2\cos\frac{2\pi}{10};$$

$$\beta=1+\sqrt{2}=1+2\cos\frac{2\pi}{8};$$

$$\beta=2+\sqrt{3}=2+2\cos\frac{2\pi}{12}. \tag{1}$$

Powers of these numbers appear as dilation factors in scale invariance of observed diffraction patterns of quasicrystalline alloys.[4] The numbers (1) are known to be unitary Pisot numbers. Let us give some necessary definitions. A number β is called an algebraic integer if it satisfies the equation

$$x^n+a_{n-1}x^{n-1}+\cdots+a_0=0, \tag{2}$$

where the coefficients a_k, $k=0,\ldots,n-1$ are integers. Note that the highest power of x appears in (2) with the coefficient 1. A solution of (2) β is called a Pisot, or a Pisot–Vijayaraghavan number if $\beta>1$ and all other roots of (2) have modulus less than 1 [it is assumed that all roots of (2) are

[a)]On leave from the Institute for Nuclear Research of the Russian Academy of Sciences, Moscow, Russia.

simple]. A Pisot number is called unitary if $|a_0|=1$. Ordinary integers are Pisot numbers but the rational numbers are not. An interesting property of Pisot numbers β is that the powers β^n are not uniformly distributed modulo 1 (more precisely, this sequence converges to 0 modulo 1). The Lebesgue measure of numbers with such a property is 0; astonishingly, it is not known whether fractional numbers belong to this set or not, i.e., in this respect they are more complicated than some irrational numbers. Pisot numbers form a closed set bounded from below and the lower bound $\beta_0 \approx 1.32$ is the real root of polynomial x^3-x-1.[5] Within this set lies the closed subset of totally real (i.e., all conjugated roots are real) Pisot numbers, which is bounded from below by the golden mean $(1+\sqrt{5})/2$. The existence of such bounds should have physical consequences in the sense that there should be some principal differences between the objects built by the scalings with the help of $\beta \geqslant \beta_0$ and $\beta < \beta_0$.

Let us briefly present the main wavelet construction formulas for the scaling factor equal to 2. The basic equation called the scaling equation (sometimes it is referred to as the refining equation),

$$\chi(x)=\sum_k c_k \chi(2x-k), \quad k \in \mathbf{Z}, \tag{3}$$

has compact support solutions when the number of nonzero coefficients in (3) is finite. The simplest representative of such systems appears from the equation

$$\chi(x)=\chi(2x)+\chi(2x-1), \tag{4}$$

determining the Haar scaling function

$$\chi(x)=\begin{cases} 1, & \text{for } x \in [0,1]; \\ 0, & \text{for } x \notin [0,1]. \end{cases} \tag{5}$$

An orthonormal basis of $L^2(\mathbf{R})$ is built from the wavelet function

$$h(x)=\sum_k (-1)^k c_{1-k} \chi(2x-k), \tag{6}$$

by discrete dilations and translations,

$$h_{j,k}(x)=2^{j/2} h(2^j x-k), \quad j,k \in \mathbf{Z}. \tag{7}$$

The scaling factor 2 in the given formulas plays the central role, the whole construction being based on the dyadic property $1/2^j = 1/2^{j+1} + 1/2^{j+1}$. However, the base of scaling 2 is too specific, in many cases dilations by arbitrary real numbers play an important role, e.g., such a situation takes place for the self-similar potentials discussed in Ref. 6, which are determined by the mixed differential and q-difference equations. It is expected that the wavelets provide a relevant tool for analysis of solutions of such equations. In the following sections we discuss how far one can go in the building of wavelets if the base of scaling is an irrational number.

II. GOLDEN MEAN SCALING FACTOR

Recently, a generalization of the Haar wavelet has been proposed in Ref. 7. It uses the τ-adic property of the ''golden mean'' number $\tau=(1+\sqrt{5})/2 \approx 1.62$:

$$\frac{1}{\tau^j}=\frac{1}{\tau^{j+1}}+\frac{1}{\tau^{j+2}} \quad \text{or} \quad \tau^2=\tau+1. \tag{8}$$

The number τ is the simplest irrational algebraic integer, by some properties it is quite close to the number 2. Equation (8) provides a subdivision of the unit interval into two parts $[0,1]=[0,1/\tau]\cup[1/\tau,1]$. The importance of scalings by τ and of the Fibonacci numbers associated with that in various domains of physics (and biology) is well known. It is especially relevant in geometrical studies of five-fold and ten-fold structures.

It is easy to see that the Haar scaling function (5) satisfies the equation

$$\chi(x)=\chi(\tau x)+\chi(\tau^2 x-\tau). \tag{9}$$

The τ wavelet of Haar[7] has the form

$$h^\tau(x)=\tau^{-1/2}\chi(\tau x)-\tau^{1/2}\chi(\tau^2 x-\tau). \tag{10}$$

An orthonormal basis of $L^2(\mathbf{R})$ is constructed in similarity with (7):

$$\{h^\tau_{j,b}(x),h^\tau_{j,-b-1}(x)\},\quad j\in\mathbf{Z},\quad b\in\tau\mathbf{Z}^+_\tau,$$

where

$$h^\tau_{j,b}(x)=\tau^{j/2}h^\tau(\tau^j x-b). \tag{11}$$

Here $\mathbf{Z}^+_\tau$ denotes the set of positive τ integers (including zero), i.e. real numbers that can be represented in the form

$$b=\sum_{l=0}^{j}\epsilon_l\tau^l,\quad \epsilon_l=\{0,1\},\quad \epsilon_l\epsilon_{l-1}=0. \tag{12}$$

The first τ integers are $0,1,\tau,\tau^2,\tau^2+1,\tau^3$, etc; they tile quasiperiodically positive real line by two tiles with respective lengths 1 and $1/\tau$, forming what is called the Fibonacci quasilattice. By $\tau\mathbf{Z}^+_\tau$ we denote the set of positive ''even'' τ integers b that do not have 1 as the last digit, i.e. $\epsilon_0(b)\neq 1$. Some additional information about the general β-numeration systems is given in the next section.

The Fourier transformation of (9) yields

$$\phi(\xi)=\frac{1}{\tau}\,\phi\left(\frac{\xi}{\tau}\right)+\frac{e^{-i\xi/\tau}}{\tau^2}\,\phi\left(\frac{\xi}{\tau^2}\right),\quad \phi(\xi)=\int_{-\infty}^{\infty}\chi(x)e^{-i\xi x}\,dx. \tag{13}$$

Fourier transform of the Haar scaling function is known explicitly,

$$\phi(\xi)=\int_0^1 e^{-i\xi x}\,dx=\frac{1-e^{-i\xi}}{i\xi}, \tag{14}$$

in particular, $\phi(0)=1$. Iterating relation (13) $N-1$ times one derives the equation (cf. with Ref. 8)

$$\phi(\xi)=\frac{F_{N+1}}{\tau^N}\,\phi\left(\frac{\xi}{\tau^N}\right)+\frac{F_N e^{-i\xi/\tau^N}}{\tau^{N+1}}\,\phi\left(\frac{\xi}{\tau^{N+1}}\right), \tag{15}$$

where the coefficients $F_N(\xi)$ satisfy the three-term recurrence relation

$$F_{N+2}(\xi)=F_{N+1}(\xi)+e^{-i\xi/\tau^N}F_N(\xi),\quad F_1=F_2=1. \tag{16}$$

Note that $F_N(0)$ coincide with the Fibonacci numbers.

Denote as $\{b_N\}$ the set of τ integers (12) that are strictly less than τ^N. From the general representation (12) one can deduce that $\{b_N\}=\{\tau b_{N-1}\}\cup\{1+\tau^2 b_{N-2}\}$. As a result, one can see that solution of the equation (16) is given by the following sum:

$$F_N(\xi)=\sum_{b\in\{b_{N-2}\}} e^{-i\xi b/\tau^{N-2}}. \tag{17}$$

The Fibonacci numbers $F_N(0)$ thus count the τ integers satisfying $0\leqslant b<\tau^{N-2}$. Since in the limit $N\to\infty$ one has $\phi(\xi/\tau^N)\to 1$, the relation (15) generates an interesting summation formula mentioned in Ref. 7,

$$e^{-i\xi/2}\frac{\sin\,\xi/2}{\xi/2}=\frac{1+\tau^2}{\tau^3}\lim_{N\to\infty}\frac{1}{\tau^N}\sum_{b\in\{b_N\}} e^{-i\xi b/\tau^N}. \tag{18}$$

A real part of the lhs of this equality is given by the function $\mathrm{sinc}\,\xi=\sin\xi/\xi$. Expanding both sides of the equation (18) into a Taylor series and equating coefficients in front of the powers of ξ, we get the following estimate of the growth of sums of powers of τ integers:

$$\sum_{0\leqslant b<\tau^N} b^n\to\frac{\tau^{N(n+1)+3}}{(n+1)(1+\tau^2)}. \tag{19}$$

For $n=1$ this may be compared with the sum of ordinary integers,

$$\sum_{0\leqslant k<2^N} k=2^{N-1}(2^N-1)\to 2^{2N-1}.$$

It would be interesting to find similar exact formulas for the sums (19). Repetition of the derivation of (18) for the standard scaling Eq. (4) results in the formula

$$e^{-i\xi/2}\frac{\sin\,\xi/2}{\xi/2}=\prod_{j=1}^{\infty}\left(\frac{1+e^{-i\xi/2^j}}{2}\right)=\lim_{N\to\infty}\frac{1}{2^N}\sum_{0\leqslant k<2^N} e^{-i\xi k/2^N}, \tag{20}$$

where the summation goes over the ordinary positive integers. In Fig. 1 we depict the function $\mathrm{sinc}\,\pi t$ versus the real parts of the rhs of (18) for $N=6$ ($\xi=\pi t$) and the rhs of (20) for $N=4$.

For arbitrary integer scaling factor p, the rhs of (20) is replaced by

$$\prod_{j=1}^{\infty}\left(\frac{1+e^{-i\xi/p^j}+\cdots+e^{-i\xi(p-1)/p^j}}{p}\right)=\lim_{N\to\infty}\frac{1}{p^N}\sum_{0\leqslant k<p^N} e^{-i\xi k/p^N}, \tag{21}$$

which follows from the evident identity $1=1/p+\cdots+1/p$ with p terms in the sum. However, it is not clear how to generalize this relation to the fractional scaling factors.

III. SUMMATION FORMULA FOR THE OCTONACCI NUMBER

Consider now another algebraic integer $\beta=1+\sqrt{2}\approx 2.41$, solution of the equation $\beta^2=2\beta+1$, which is sometimes called the octonacci number. This is the simplest unitary Pisot number in the extension ring $\mathbf{Z}[1,2\cos 2\pi/8]$ and such that $\mathbf{Z}[1,\beta]=\mathbf{Z}[1,2\cos 2\pi/8]$. Before considering properties of this specific number, we would like to describe briefly the general β-numeration algorithm.[9,10]

For a given real number $\beta>1$ any positive real number x can be represented in the form of series over β:

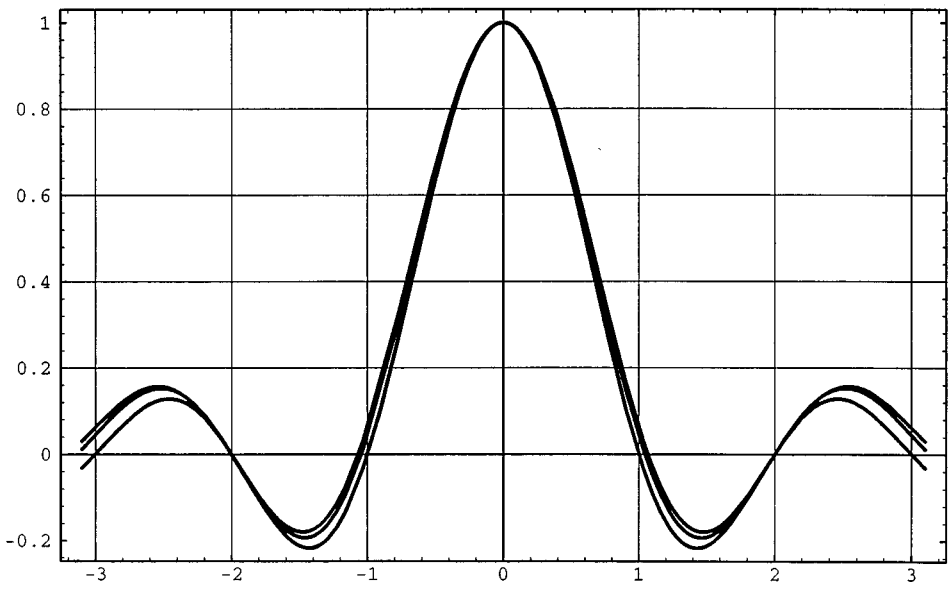

FIG. 1. The function sinc πt and real parts of the rhs of (18) for $N=6$ (the middle curve) and of the rhs of (19) for $N=4$ in appropriate units. The errors at $t=3$ are less than 5% of the maximum at $t=0$.

$$x=\sum_{l=-\infty}^{j} \epsilon_l \beta^l, \quad \epsilon_l=\{0,1,..,d\}, \tag{22}$$

where $d=\beta-1$ if β is an integer and otherwise $d=[\beta]$ the integer part of β. This representation, denoted symbolically as $x=\epsilon_j\cdots\epsilon_0.\epsilon_{-1}\cdots$, is unique if the digits ϵ_l are restricted in such a way that for any k one has $\Sigma_{l<k}\epsilon_l\beta^l<\beta^k$. For $\beta=\tau$ this means that there are no two successive digits equal to 1. When the expansion (22) contains only non-negative powers of β, x is said to be a β integer; β integers can be characterized by a finite algorithm only in special cases.

The above unique decomposition can be obtained by the so-called ''greedy'' algorithm. For any $x>0$ there is $k\in\mathbf{Z}$ such that $\beta^k\leqslant x<\beta^{k+1}$. Then put $\epsilon_k=[x/\beta^k]$ and $r_k=\{x/\beta^k\}$ (curled brackets $\{x\}$ denote the fractional part of x). Other digits ϵ_l, $l<k$ are determined recursively, $\epsilon_l=[\beta r_{l+1}]$, where $r_l=\{\beta r_{l+1}\}$. A simple characterization of the constraints upon digits uses the Rényi expansion of 1 denoted $d(1,\beta)=0.\epsilon_{-1}\cdots\epsilon_{-l}\cdots$ and obtained through the recursion $\epsilon_{-k-1}=[\beta T_\beta^k 1]$, where $T_\beta x\equiv(\beta x) \bmod 1$ for any $x\in[0,1]$.[9] For example, one has $d(1,\tau)=0.11$.

A number β is called a beta number if the corresponding Rényi expansion of 1 is eventually periodic [i.e., there exists an integer k such that for $l>k$ all digits ϵ_{-l} in $d(1,\beta)$ are obtained by periodic repetition of some finite set of digits]. For these numbers the notion of β integers is well defined in the sense that one can describe them by using a finite algorithm. An important fact is that any Pisot number is a beta number,[10] but there are beta numbers that are non-Pisot algebraic integers. Pisot numbers are important for building quasicrystals due to some additional properties (e.g., local inflationary properties) that we do not discuss here.

Returning to the octonacci number, we see that $\epsilon_l=\{0,1,2=[\beta]\}$, and in the corresponding β numeration the pairs $\{\epsilon_l,\epsilon_{l-1}\}$ are forbidden to be $\{2,1\}$ and $\{2,2\}$ since the Rényi expansion of 1 is $d(1,\beta)=0.21$. The first β integers are $0,1,2,\beta,\beta+1,\beta+2,2\beta,\beta^2,\ldots$. These numbers cover the real line quasiperiodically by two tiles with respective lengths 1 and $\beta-2=1/\beta$.

The equation satisfied by β determines a subdivision of the unit interval into three pieces such that the ratio of their lengths is equal to a power of β:

$$1=\frac{1}{\beta}+\frac{1}{\beta}+\frac{1}{\beta^2}. \tag{23}$$

This allows one to write a new equation for the Haar scaling function,

$$\chi(x)=\chi(\beta x)+\chi(\beta x-1)+\chi(\beta^2 x-2\beta), \tag{24}$$

Fourier transformation of which yields the following ''q-difference'' equation:

$$\phi(\xi)=\frac{1+e^{-i\xi/\beta}}{\beta}\,\phi\left(\frac{\xi}{\beta}\right)+\frac{e^{-i2\xi/\beta}}{\beta^2}\,\phi\left(\frac{\xi}{\beta^2}\right). \tag{25}$$

Iteration of this equation $N-1$ times results in

$$\phi(\xi)=\frac{G_{N+1}}{\beta^N}\,\phi\left(\frac{\xi}{\beta^N}\right)+\frac{e^{-i2\xi/\beta^N}G_N}{\beta^{N+1}}\,\phi\left(\frac{\xi}{\beta^{N+1}}\right), \tag{26}$$

where the coefficients $G_N(\xi)$ are determined from the recurrence relation

$$G_{N+2}=G_{N+1}(1+e^{-i\xi/\beta^{N+1}})+G_N e^{-i2\xi/\beta^N}, \quad G_0=0, \quad G_1=1. \tag{27}$$

In similarity with the previous case, solution of this recurrence is given by the sum

$$G_N(\xi)=\sum_{b\in\{b_N\}} e^{-i\xi b/\beta^{N-1}}, \tag{28}$$

where the summation goes over the set of β integers $\{b_N\}$ satisfying the constraints $0\leqslant b_N<\beta^N$ and $\epsilon_0(b_N)\neq 2$ (i.e., 2 is excluded as the last digit). The proof of (28) goes by induction. Indeed, $\{b_N\}$ can be split into three groups:

$$\{b_N\}=\{\beta b_{N-1}\}\cup\{1+\beta b_{N-1}\}\cup\{2\beta+\beta^2 b_{N-2}\}, \tag{29}$$

in self-explanatory notations. It is not difficult to see that (29) corresponds exactly to the rule of addition of exponentials in (27), (28). As a result, in the limit $N\to\infty$, one gets from (26) the summation formula

$$e^{-i\xi/2}\,\frac{\sin\,\xi/2}{\xi/2}=\frac{1+\beta^2}{\beta^2}\,\lim_{N\to\infty}\frac{1}{\beta^N}\sum_{b\in\{b_N\}} e^{-i\xi b/\beta^N}. \tag{30}$$

This formula differs from (18) and (20) by the presence of the constraint upon the last digit of β integers entering the sum. In Fig. 2 we depict $\mathrm{sinc}\,\pi t$ and the real part of the rhs of (30) for $N=3$ in the appropriate units. Analogously to (19), we can estimate from (30) the growth of the sum of powers of the β integers belonging to $\{b_N\}$,

$$\sum_{b\in\{b_N\}} b^n\to\frac{\beta^{N(n+1)+2}}{(n+1)(1+\beta^2)}.$$

Since we have a subdivision of $[0,1]$ into three intervals, there are two wavelet functions of the Haar type obtained by orthonormalization of $\chi(x)$, $\chi(\beta x)$, and $\chi(\beta x-1)$:

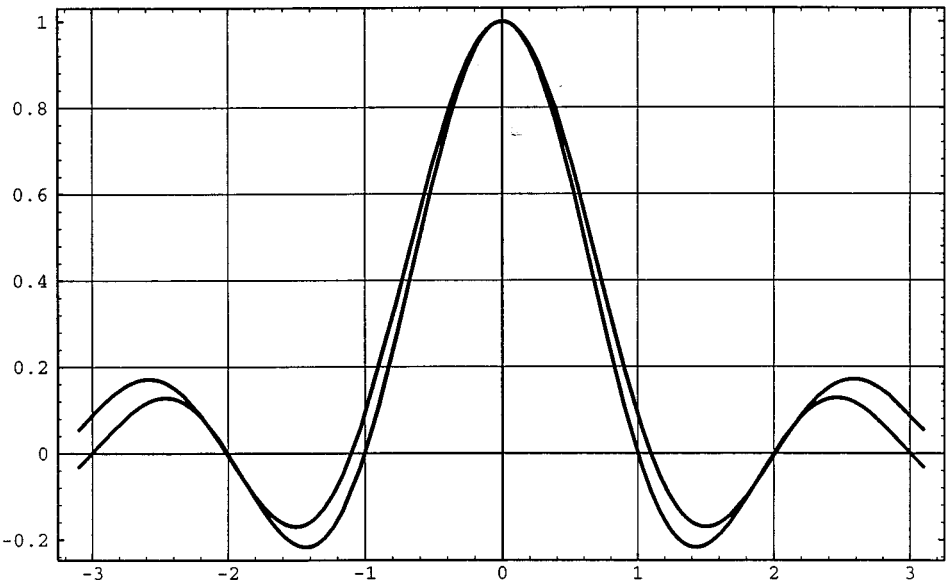

FIG. 2. The function sinc πt and the real part of the rhs of (30) for $N=3$. The approximation is less accurate than in Fig. 1.

$$h^{(1)}(x)=\sqrt{\beta-1}\,\chi(\beta x)-\frac{1}{\sqrt{\beta-1}}\,(\chi(\beta x-1)+\chi(\beta^2 x-2\beta)),$$
$$h^{(2)}(x)=\frac{1}{\sqrt{\beta-1}}\,(\chi(\beta x-1)-\beta\chi(\beta^2 x-2\beta)). \tag{31}$$

Splitting of the β integers into two sets, $\epsilon_0(b)\neq 2$ (''even'') and $\epsilon_0(b)=2$ (''odd'') appears naturally in the translations of (31) without overlaps. One can check that $h^{(l)}_{j,b}(x)=\beta^{j/2}h^{(l)}(\beta^j x-b)$ and $h^{(l)}_{j,-b-1}(x)$ define orthonormal vectors of $L^2(\mathbf{R})$, provided $\epsilon_0(b)\neq 2$. In order to prove that this sequence forms a basis of the Hilbert space, it is necessary to verify that it is dense that we do not pursue here.

IV. INFINITE PARTITION OF THE UNIT INTERVAL CASE

There are infinitely many algebraic integers for which one can derive summation formulas similar to (18) and (20). However, for some of these numbers subdivision of the unit interval contains infinitely many terms. For example, such a situation takes place for $\beta=2+\sqrt{3}\approx 3.73$, $\beta^2=4\beta-1$, when

$$1=\frac{3}{\beta}+2\sum_{j=2}^{\infty}\frac{1}{\beta^j},\quad \text{or}\quad d(1,\beta)=0.322\,222\ldots\,. \tag{32}$$

This β is the simplest unitary Pisot number in the extension ring $\mathbf{Z}[1,2\cos 2\pi/12]$, such that $\mathbf{Z}[1,\beta]=\mathbf{Z}[1,2\cos 2\pi/12]$. The β integers are defined similar to (12), with ϵ_l varying from 0 to $[\beta]=3$ and the constraint that between any two digits $\epsilon_l=3$ of the β numeration of arbitrary number, there should be at least one 0 or 1 (i.e., combinations {3,3}, {3,2,3}, etc. are forbidden). These numbers tile the positive real line by two tiles with respective lengths 1 and $\beta-3$; the first few β integers are $0,1,2,3,\beta,\beta+1,\beta+2,\beta+3,2\beta,\ldots$.

Using (32) one constructs a scaling equation for the characteristic function (5):

$$\chi(x)=\chi(\beta x)+\chi(\beta x-1)+\chi(\beta x-2)+\chi(\beta^2 x-3\beta)+\chi(\beta^2 x-3\beta-1)$$
$$+\sum_{k=3}^{\infty}\left[\chi(\beta^k x-3\beta^{k-1}-2\beta^{k-2}-\cdots-2\beta)+\chi(\beta^k x-3\beta^{k-1}-2\beta^{k-2}-\cdots-2\beta-1)\right], \tag{33}$$

or, after Fourier transformation,

$$\phi(\xi)=\frac{1}{\beta}\,(1+e^{-i\xi/\beta}+e^{-i\xi 2/\beta})\,\phi\left(\frac{\xi}{\beta}\right)+\frac{e^{-3i\xi/\beta}}{\beta^2}\,(1+e^{-i\xi/\beta^2})\,\phi\left(\frac{\xi}{\beta^2}\right)$$
$$+e^{-i\xi}\sum_{k=3}^{\infty}\frac{1}{\beta^k}\,(e^{-i\xi(1-\beta)/\beta^k}+e^{-i\xi(2-\beta)/\beta^k})\,\phi\left(\frac{\xi}{\beta^k}\right). \tag{34}$$

Let us write the result of successive iterations of this relation in the form

$$\phi(\xi)=\sum_{k=0}^{\infty}\frac{G_N^k(\xi)}{\beta^{N+k}}\,\phi\left(\frac{\xi}{\beta^{N+k}}\right), \tag{35}$$

where $N\geqslant 1$ and $G_1^k(\xi)$ are fixed in (34). Using the scaled form of (34) and substituting $\phi(\xi/\beta^N)$ into (35), we derive the following recurrence relation:

$$G_{N+1}^k(\xi)=G_N^0(\xi)G_1^k(\xi/\beta^N)+G_N^{k+1}(\xi). \tag{36}$$

For $k=0$ the first few steps of iteration of this relation allow us to see that $G_N^0(\xi)$ forms the pattern

$$G_N^0(\xi)=\sum_{b\in\{b_N\}}e^{-i\xi b/\beta^N}, \tag{37}$$

where $\{b_N\}$ are the β integers satisfying $0\leqslant b_N<\beta^N$, with the exception of those forming the left edge of tiles with length $\beta-3$. The latter means that $\epsilon_0(b_N)\neq 3$, but since we are dealing with the infinite partition of 1 there are other forbidden numbers as well. Namely, $3\beta+2$ and all other β integers having as the last digits the sequence {3,2,2,...} do not belong to $\{\beta_N\}$.

The summation formula we are interested in arises from (35) in the limit $N\to\infty$,

$$e^{-i\xi/2}\,\frac{\sin\,\xi/2}{\xi/2}=\lim_{N\to\infty}\sum_{k=0}^{\infty}\frac{G_N^k(\xi)}{\beta^{N+k}}. \tag{38}$$

For $N\to\infty$ the recursion (36) simplifies

$$G_{N+1}^0=3G_N^0+G_N^1,\quad G_{N+1}^k=2G_N^0+G_N^{k+1},\quad k\geqslant 1. \tag{39}$$

Since $G_N^0(\xi)$ is known (37), one may invert (39) in order to determine $G_N^k(\xi)$, $k>0$:

$$G_N^k=G_{N+k}^0-3G_{N+k-1}^0-2G_{N+k-2}^0-\cdots-2G_N^0,\quad k>0. \tag{40}$$

Substituting this formula into (38), we find the partial sum

$$S_l=\sum_{k=0}^{l}\lim_{N\to\infty}\frac{G_N^k(\xi)}{\beta^{N+k}}=\lim_{N\to\infty}\left(\frac{G_N^0}{\beta^N}\left(1-\frac{3}{\beta}-\frac{2}{\beta^2}-\cdots-\frac{2}{\beta^l}\right)+\frac{G_{N+1}^0}{\beta^{N+1}}\left(1-\frac{3}{\beta}-\frac{2}{\beta^2}-\cdots-\frac{2}{\beta^{l-1}}\right)\right.$$

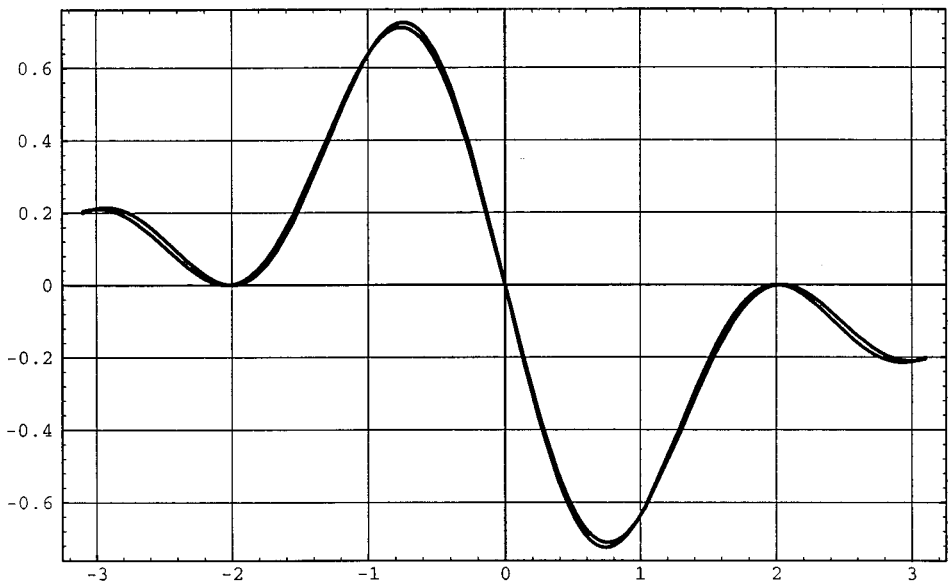

FIG. 3. The function $(\cos \pi t-1)/\pi t$ and the imaginary part of the rhs of (42) at $N=3$. Two curves almost coincide.

$$+\cdots+\frac{G^0_{N+l-1}}{\beta^{N+l-1}}\left(1-\frac{3}{\beta}\right)+\frac{G^0_{N+l}}{\beta^{N+l}}\Bigg)=\left(\frac{\beta+1}{\beta}-\frac{1}{\beta^l}\right)\lim_{N\to\infty}\frac{G^0_N(\xi)}{\beta^N}. \tag{41}$$

Taking the limit $l\to\infty$ in S_l, we find the summation formula

$$e^{-i\xi/2}\,\frac{\sin\,\xi/2}{\xi/2}=\frac{1+\beta}{\beta}\lim_{N\to\infty}\frac{1}{\beta^N}\sum_{b\in\{b_N\}}e^{-i\xi b/\beta^N}. \tag{42}$$

This formula looks similar to the previous ones, but its derivation is not rigorous because we did not verify that the recursion (36) corresponds indeed to the law of addition of exponents in (37) for arbitrary N. In Fig. 3 we depict imaginary parts of the lhs of (42) and the rhs for $N=3$ in the variable $t=\xi/\pi$ (the real part looks very close to the middle curve in Fig. 1). We are reminded that β integers from $\{b_N\}$ do not include left edges of the short $(\beta-3)$ tiles. It would be interesting to understand why for the golden mean number the sum (18) goes over all τ integers, whereas in the last two cases only the long tiles are relevant. If one takes inverse Fourier transforms of the derived summation formulas, one will find that the characteristic function of the unit interval can be approximated as a homogeneous sum of weighted Dirac delta functions located at the β-adic points and, again, it is not clear why one has to abandon some of these points for $\beta=1+\sqrt{2}$ and $2+\sqrt{3}$.

V. DISCUSSION OF THE MULTIRESOLUTION ANALYSIS

Wavelets are known to be related to iterative interpolation. In the case of interpolation of functions given on the lattice points $\mathbf{Z}$ the standard procedure consists in fixing the value of function on the dyadic (for the base 2), or, more generally, on the p-adic points of the real line. The rule of interpolation usually takes into account values of the function in several neighboring points (with some weights) in which the function was fixed at the previous steps of interpolation.[11] Due to the translational invariance the interpolation takes place homogeneously over the space. This is not so for the quasilattices.

Suppose that values of a function are fixed in the points of the Fibonacci quasiperiodic lattice Γ formed by the τ integers. Now there are two tiles with lengths 1 and $1/\tau$. The first step of subdivision process splits only the long tiles into two parts and the short tiles are left untouched. In this case the interpolation rule should be more involved than in the $\Gamma=\mathbf{Z}$ case, but the principle procedure remains the same.

Now let us discuss briefly a possible form of the multiresolution analysis associated with quasiperiodic tilings of a Euclidean space. Denote by Γ a set of points in $\mathbf{R}^n$ satisfying the Delaunay property. This means that (a) the distance between any two points of Γ is larger than a fixed real $r>0$, and (b) there exists a real number $R>0$ such that any ball of radius R contains at least one point from Γ. Such a set is said to form a quasilattice if it is equipped with additional properties (Meyer quasiaddition, local self-similarity,...). Assume that there exists an invertible matrix A whose eigenvalues have modulus larger than 1 and such that $A\Gamma\subset\Gamma$ for all points from Γ. A multiresolution analysis of the Hilbert space $L^2(\mathbf{R}^n)$ is a decomposition of it into a chain of subspaces V_j that satisfy the following set of conditions.

(1) $V_j\subset V_{j+1}$, $j\in\mathbf{Z}$.

(2) The closure of $\cup_{j\in\mathbf{Z}}V_j$ coincides with $L^2(\mathbf{R}^n)$.

(3) $\cap_{j\in\mathbf{Z}}V_j=\{0\}$.

(4) If $f(x)\in V_j$ then $f(Ax)\in V_{j+1}$ and $f(A^{-1}x)\in V_{j-1}$.

(5) There is a finite number of scaling functions $\chi^{(k)}(x)\in V_0$, $k=1,\ldots,K$, such that the set $\{\chi^{(k)}(x-\gamma),\ \gamma\in\Gamma\}$ is an orthonormal basis of V_0.

When Γ is a crystallographic lattice, e.g. $\mathbf{Z}^n$, and $K=1$, such definition is known to have nontrivial solutions for integer-valued matrices A.[12] In the one-dimensional space the above definition is valid for fractional dilation factors, but there are no compact support scaling functions in this case.[3] When β is irrational and $\Gamma=\mathbf{Z}$ only the $\sin c\, x$-type scaling functions are admissible.[3] For $K>1$ the scaling equation acquires a matrix form,[13] and the corresponding theory is referred to as a multiwavelet theory. The multidimensional multiwavelets were considered to some extent in Ref. 14.

Consider how scaling equations for Haar wavelets with an irrational scaling factor described earlier fit into the multiresolution scheme of $L^2(\mathbf{R})$. For $\beta=\tau$ the subspace V_0 is spanned by two functions[7] $\{\chi(x-b),\chi(x+b+1)\}$, with $b\in\tau\mathbf{Z}_\tau^+$ and $\{\chi(\tau x-b),\chi(\tau x+b+1)\}$ with $b\in\tau\mathbf{Z}_\tau^{+\mathrm{odd}}$ (a τ integer is odd if its last digit is 1, i.e. if it coincides with the left edge of a short tile). Despite the fact that the second scaling function is obtained from the first one by dilation, it is different from it, and this hints on the multiwavelets. Note however, that in the decomposition $V_1=V_0\oplus W_0$, the subspace W_0 is covered only by one wavelet function and the elements of W_0 have support only on the tiles of length 1. The latter means that the support of functions from W_j in the decomposition $V_{j+1}=V_j\oplus W_j$ never covers the whole line. This is an interesting property of the τ-multiresolution analysis—it subdivides only ''large'' tiles into the smaller ones.

Actually all three scaling equations considered by us can be represented in the 2×2 matrix form:

$$\chi^{(k)}(x)=\sum_{r=1}^{2}\sum_{m=0}^{[\beta]}c_m^{kr}\chi^{(r)}(\beta x-m), \tag{43}$$

where $\chi^{(1)}(x)=\chi(x)$, i.e. we indeed have multiwavelets. Note that only translations by integers are entering the sum in (43), but in the span of V_0 the functions $\chi^{(k)}(x)$ are translated by the β integers. For $\beta=\tau$ one has (unnormalized) $\chi^{(2)}(x)=\chi(\tau x)$ and

$$M(z)=\sum_{m=0}^{1}c_m z^m=\begin{pmatrix}1 & z\\ 1 & 0\end{pmatrix}. \tag{44}$$

For $\beta=1+\sqrt{2}$ one has $\chi^{(2)}(x)=\chi(\beta x)$ and

$$M(z)=\sum_{m=0}^{2} c_m z^m=\begin{pmatrix} 1+z & z^2 \\ 1 & 0 \end{pmatrix}. \tag{45}$$

A more interesting situation takes place for the infinite partition of 1 case, since the new scale intervenes the scene

$$\chi^{(2)}(x)=\chi\left(\frac{x}{\beta-3}\right),$$

so that

$$M(z)=\sum_{m=0}^{3} c_m z^m=\begin{pmatrix} 1+z+z^2 & z^3 \\ 1+z & z^2 \end{pmatrix}. \tag{46}$$

The choice $z=1$ in $M(z)$ corresponds to setting $\xi=0$ in the Fourier transform of the scaling equations. We remark that in all three cases $M(1)$ coincides with the matrix of substitutions of letters used in the construction of corresponding quasiperiodic tilings (for the Fibonacci case this is the celebrated $a\to ab$, $b\to a$ two letter algorithm). This observation should be relevant for building Haar-type wavelets for an arbitrary beta number.

The subdivision process in the octonacci number case is similar to the golden mean one—at each step only the long tiles are split into three pieces and the short ones are left untouched so that at any step of the subdivision only two types of tiles are present (also, it can be seen that the support of wavelets in W_j does not cover the whole line). In the $\beta=2+\sqrt{3}$ case the situation is different. As it is seen from the matrix form of the scaling equation, the long tiles are split into four pieces and the short ones into three, so that at each step of the subdivision one has again only two tiles with respective lengths $1/\beta^j$ and $(\beta-3)/\beta^j$. Such a picture of refining of the quasilattice may happen to be relevant for the quasicrystals growth process.

For completeness we give three Haar-type wavelets necessary for building an orthonormal basis of W_0 for $\beta=2+\sqrt{3}$:

$$h^{(1)}(x)=\sqrt{\beta-1}\,\chi(\beta x)-\frac{1}{\sqrt{\beta-1}}\,(\chi(x)-\chi(\beta x)),$$

$$h^{(2)}(x)=\sqrt{\frac{\beta(\beta-2)}{\beta-1}}\,\chi(\beta x-1)-\sqrt{\frac{\beta}{\beta+1}}\,(\chi(x)-\chi(\beta x)-\chi(\beta x-1)), \tag{47}$$

$$h^{(3)}(x)=\sqrt{\frac{2\beta}{\beta+1}}\left(\chi(\beta x-2)-\frac{\beta}{\beta-1}\,(\chi(x)-\chi(\beta x)-\chi(\beta x-1)-\chi(\beta x-2))\right).$$

In the splitting of length 1 tiles all three functions are appearing, whereas for the $(\beta-3)$ tiles only $h^{(2)}(x)$ and $h^{(3)}(x)$ are relevant, since their support is less than or equal to $\beta-3$.

With any beta number one can associate a tiling of the real line by a finite number of tiles. Therefore it is natural to expect that for an arbitrary beta-number scaling factor one will need only a finite number of Haar-type wavelets. If the dilation parameter is not a beta number (this does not necessarily mean that it is transcendental), probably there will always be an infinity of wavelets of compact support. Certainly this diminishes an economy reached by the discrete wavelets with respect to the continuous ones. For example, such a situation seems to take place for the fractional scaling factors since the Rényi expansion for them is not eventually periodic (this contradicts the intuition that fractional numbers are simple objects). Because the noncompact support wavelets

are less sensitive to the origin of the scaling factor, it may occur that there are finitely many discrete wavelets for some of the nonbeta number scaling factors (e.g., for some kind of fractions of beta numbers).

It should be stressed that in principle one can use a split of the unit interval into two subintervals with the help of arbitrary scaling factor $\beta>1$. This subdivision can be written tautologically as $1=1/\beta+1/\alpha$, $\alpha=\beta/(\beta-1)$. One may take the Fourier transform of the obvious equality $\chi(x)=\chi(\beta x)+\chi(\alpha x-\alpha/\beta)$ for the characteristic function $\chi(x)$ and iterate the resulting relation as we did it above. This would give a representation of the Fourier transform of $\chi(x)$ as an infinite sum of exponentials with arguments scaled by powers of β and α. However, the coefficients in front of these exponentials are not simple and the numbers entering the exponents are difficult to characterize. The importance of beta numbers, for any of which one can derive summation formulas similar to the discussed ones, stems from the fact that for them there is a finite algorithm for determining β integers following from the finite or eventually periodic form of the Rényi expansion of 1. Note that the scalings by arbitrary integer p lead to the infinite product representations of the sinc function, admitting a probabilistic interpretation. The summation formulas we have derived do not have a similar infinite product representation, but there should be some probabilistic meaning of them too.

The key difference between lattices and quasilattices is that the sum of two points of the lattice remains in the lattice, whereas for quasilattices $\{\gamma_1+\gamma_2\}\not\subset\Gamma$, $\gamma_{1,2}\in\Gamma$. Therefore for quasilattices one actually has the orthogonality relations with the larger number of points than those in Γ:

$$\int_{-\infty}^{\infty}\chi^{(j)}(x-\gamma_1)\chi^{(k)}(x-\gamma_2)dx=\delta_{\gamma_1,\gamma_2}\delta_{jk}=\delta_{0,\gamma_1-\gamma_2}\delta_{jk}, \tag{48}$$

which is valid, even if $\gamma_1-\gamma_2\notin\Gamma$. Note that there is a correlation between the indices j,k and $\gamma_{1,2}$ in (48). When β is a Pisot number the points of difference set either belong to Γ or they are close but not arbitrarily close to the quasilattice, i.e. the difference set obeys the Delaunay property[15] (such sets Γ are called Meyer sets). E.g., for $\beta=\tau$ its points either lie in Γ or they are obtained from Γ by adding $1/\tau$ or $1/\tau^2$.[16] Whether this requires further specification of the form of multiresolution analysis is not yet clear. However, most of the tools used for derivation of discrete wavelet bases from the multiresolution analysis disappear in the nonperiodic setting.

It is worth it to draw attention to the recent work,[14] where the crystallographic Coxeter groups were applied to the construction of wavelets. It is natural to expect that in the context of irrational scaling factors the higher-dimensional quasicrystallographic structures become relevant and, again, one may expect strong dependence of the multiresolution analyses on the nature of irrationality of the dilation parameter.

Moduli-space structure of knots with intersections

Norbert Grot[a] and Carlo Rovelli[b]
Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, Pennsylvania 15260

(Received 1 March 1996; accepted for publication 10 March 1996)

It is well known that knots are countable in ordinary knot theory. Recently, knots *with intersections* have raised a certain interest, and have been found to have physical applications. We point out that such knots—equivalence classes of loops in R^3 under diffeomorphisms—are not countable; rather, they exhibit a moduli-space structure. We characterize these spaces of moduli and study their dimension. We derive a lower bound (which we conjecture being actually attained) on the dimension of the (nondegenerate components) moduli spaces, as a function of the valence of the intersection. © *1996 American Institute of Physics.*

I. INTRODUCTION

At the end of his delicious booklet on catastrophe theory,[1] Arnold notices the following. Consider a set of n lines through the origin in the plane. Call two such sets equivalent if they can be mapped into each other by a linear transformation of the plane. The equivalence classes are discrete for $n=1,2,3$; but for $n=4$, a moment of reflection shows that the equivalence classes are parametrized by a continuous parameter. Precisely this phenomenon is at the root of the emergence of a rich moduli space structure in the spaces of knots with intersections.

Knots play an increasingly important role in various areas of mathematics and physics.[2–4] Classical knot theory[5] deals with knots without intersections, but recent applications of knot theory require knots *with intersections* to be considered as well.[6] For instance, quantum states of the gravitational field are labeled by knots with intersections in the loop representation approach to quantum gravity.[7,8] Knots can be defined in two ways: as equivalence classes of loops in R^3 under continuous deformations (ambient isotopy) of the image of the loop—''c knots;'' or as equivalence classes (of unparametrized loops) under invertible smooth transformations (diffeomorphisms) of R^3-''d knots.'' For the non-self-intersecting loops, the two definitions are equivalent, and there is no distinction between c knots and d knots. But the two definitions cease to be equivalent in the case with intersections. Intersecting d knots are different than intersecting c knots. The case of intersecting d knots is of particular interest in physics;[7] these knots display a remarkable novel phenomenon, which, to our knowledge, has been rarely noticed (the only mention to this phenomenon we could find in the literature is in Ref. 9): unlike ordinary knot spaces, the space $\mathcal{K}_d$ of the intersecting d knots is not countable.

The continuous dimensions of the space $\mathcal{K}_d$ come from the differential structure of the underlying manifold. The differential structure gives rise to a tangent space T_p at intersection points, loops define lines in T_p, and diffeomorphisms act linearly on T_p. Equivalence under diffeomorphisms imply equivalence under linear transformations of T_p. We are therefore precisely in the situation of Arnold's example—one dimension up. For a large enough number of lines, linear transformations of T_p fail to be able to align all the lines, and a moduli space structure emerge. Let us illustrate more in detail how this comes about by means of an example. Consider a smooth loop α in R^3, with a self-intersection point $p \in R^3$, and assume that α goes through p five times, so that it has five tangents $\mathbf{v}_1,...,\mathbf{v}_5$ at p (assume any three of the five are linearly indepen-

0022-2488/96/37(6)/3014/8/$10.00

dent). Let us denote by $K_c[\alpha]$ the c knot to which α belongs. Consider a loop β in the same c knot $K_c[\alpha]$. The loop β will have an intersection point as well, say q, and five tangents $\mathbf{w}_1,...,\mathbf{w}_5$ at q. In order for α and β to be in the same d knot, there must be a *diffeomorphism* $f:R^3\to R^3$ sending α into β. In particular, f maps p to q. The tangent map f^* maps the tangent space at p, T_p, to the tangent space at q, T_q, and it should align the tangents $\mathbf{v}_i$ $(i=1,...,5)$ to the tangents $\mathbf{w}_i$. But f^* is a *linear* map between three-dimensional spaces, given by the Jacobian matrix of f at p; it is a $GL(3)$ transformation depending on nine parameters. Since the directions of five vectors $\mathbf{v}_i$ depend on ten parameters, it is clear that generically no linear transformation exists that aligns five given vectors $\mathbf{v}_i$ to five given vectors $\mathbf{w}_i$. Generically, α and β will not belong to to the same d knot. There will be—at least—one continuous parameter λ—function of the angles between the five tangents—which is invariant under diffeomorphisms and distinguishes α from β. Actually, as we shall see, in this example there are two such parameters, λ_1 and λ_2; we will give them explicitly below. d knots are distinguished by such continuous parameters, and therefore fail to be countable. The space of all d knots in $K_c[\alpha]$ is a finite-dimensional space obtained by quotienting the infinite-dimensional space $K_c[\alpha]$ by the infinite-dimensional group Diff_{R^3}. Namely, it is a moduli space, coordinated by the two moduli, λ_1 and λ_2.

The same phenomenon repeats in the higher jets—namely for derivatives of the loops higher than the tangents—in a more intricate manner. Derivatives of order n transform under diffeomorphisms according to (nontrivial) transformation formulas that depend only on the derivatives of order $n-1$ (or lower) of the Jacobian matrix. Since the last have a finite number of components, a sufficiently high number of segments crossing one intersection will always give rise to new moduli. Thus, d knots are not countable and exhibit a very rich moduli space structure, coming from the jets of all orders.

In this paper, we make the above observation precise, we define the moduli spaces of intersecting d knots, and study their general structure and their dimension. We derive some general results on these dimensions. In particular, our main result is a formula for the dimension of the (generic components) of these spaces. We show that this formula gives a lower bound on the dimension of these spaces as a function of the valence of the intersection, and we conjecture that the formula gives indeed the correct dimension. Our original motivations came from quantum gravity, and we expect, in particular, that our results could be of interest for that field.

II. STRUCTURE OF THE INTERSECTING *d*-KNOT SPACE

By loop, we indicate here a smooth map α: $S_1\to M$ from the circle S_1 to a three-dimensional manifold M, which we assume for simplicity having the topology of R^3. We indicate loops by Greek letters $\alpha,\beta,...$, and denote the space of the loops in R^3 as $\mathscr{L}$. We consider two equivalence relations in $\mathscr{L}$. We say that α and β are c equivalent, and write $\alpha\sim_c\beta$ if there exist a smooth one-parameter family $c_t, t\in[0,1]$ of smooth, invertible maps from the image of α to R^3 such that $c_0\alpha=\alpha$ and $c_1\alpha=\beta$. Namely, if the image of α can be smoothly deformed to the image of β. This is clearly an equivalence relation; we call the corresponding equivalence classes in $\mathscr{L}$ c knots, and denote them as K_c. We denote the equivalence class to which α belongs as $K_c[\alpha]$ and the space of c knots as $\mathscr{K}_c$. Next we say that α and β are d equivalent, and we write $\alpha\sim_d\beta$, if there exist a diffeomorphism t of S_1 and a diffeomorphism f of M—connected to the identity—such that $\alpha=f\circ\beta\circ t$. This too is an equivalence relation. We call the corresponding d-equivalence classes in $\mathscr{L}$ d knots, and denote them as K_d. We denote the equivalence class to which α belongs as $K_d[\alpha]$, and the space of d knots as $\mathscr{K}_d$. Thus

$$\mathscr{K}_c=\frac{\mathscr{L}}{\sim_c},\quad \mathscr{K}_d=\frac{\mathscr{L}}{\sim_d}. \tag{1}$$

Our aim is to study the structure of $\mathscr{K}_d$. In particular, we want to investigate its continuous dimensions. d knots can be labeled by a set of discrete parameters k_j and continuous parameters

λ_j. We will use a Dirac-like notation $K_d=|k_j,\lambda_j\rangle$, suggested by the fact that d knots label quantum state of space–time in loop quantum gravity. We are interested in studying the appearance and the number of continuous parameters λ_j, namely the dimensions of the d-knot moduli spaces.

The space of the c knots $\mathscr{K}_c$ is countable. Since every diffeomorphism in the connected component of the identity induces a smooth deformation of the image of the loop, $\alpha\sim_d\beta$ implies $\alpha\sim_c\beta$, and therefore every d knot is contained inside a single c knot. Thus, we have a well-defined map $i:\mathscr{K}_d\to\mathscr{K}_c$ sending $K_d[\alpha]$ to $K_c[\alpha]$. As the example of the introduction shows, the map i is not injective: a c knot is formed, in general, by many d knots. We call $\mathscr{K}_d^{(K_c)}$ the inverse image of K_c under i, namely the set of the d knots that correspond to the c-knot K_c. The space $\mathscr{K}_d$ is thus the union of a countable number of components $\mathscr{K}_d^{(K_c)}$, one for every c knot K_c,

$$\mathscr{K}_d=\bigcup_{K_c\in\mathscr{K}_c}\mathscr{K}_d^{(K_c)}. \tag{2}$$

In other words, the first discrete parameter that characterizes a d-knot K_d is the c-knot K_c to which it belongs, and we can write $K_d=|K_c,\text{ other parameters}\rangle$.

Let us consider one of the components $K_d^{(K_c)}$. A continuous map cannot change the number of intersections I of a loop. Therefore this number is well defined for a c-knot K_c. Each intersection i is further characterized by the number N_i of times the loop crosses it, which we call the valence of the intersection, following the literature. Thus, a set of integers N_i, $i=1...I$—the valence of its intersections—is associated with every c knot. Imagine now that three segments cross at the intersection i, namely $N_i=3$. Imagine that the corresponding three tangents at the intersection are linearly dependent. A continuous transformation can alter this linear dependence, but a diffeomorphism cannot. Thus, the presence of linear dependency between tangents distinguishes the d knot. We denote an intersection of valence three with linearly dependent tangents as a degenerate intersection. Similarly, we denote an intersection of higher valence degenerate if at least one triple of its tangents is linearly dependent. As we shall better illustrate below, degeneracy of this kind—a relation between derivatives of the loop that cannot be removed by a diffeomorphism—may occur for higher than first derivatives of the loops as well. The information about the presence of degeneracy is discrete, and we represent it collectively by a discrete parameter k_i for every intersection i. We write $K_d=|K_c,k_i,\text{ other parameters}\rangle$ and denote the set of d knots in the same c knot and with the same degeneracies as $\mathscr{K}_d^{(K_c,k_i)}$. We shall write $k_i=0$, or just omit the k_i to indicate that the i intersection has no degeneracies.

This exhausts the discrete parameters that characterize d knots. The remaining parameters distinguishing d knots are continuous moduli parameters. Thus, the space of intersecting d knots $\mathscr{K}_d$ can be written as the union of a denumerable set of components $\mathscr{K}_d^{(K_c,k_i)}$ as

$$\mathscr{K}_d=\bigcup_{K_c\in\mathscr{K}_c}\bigcup_{k_i}\mathscr{K}_d^{(K_c,k_i)}, \tag{3}$$

where the spaces $\mathscr{K}_d^{(K_c,k_i)}$ are finite-dimensional moduli spaces, whose dimensions we are now going to study.

Let us consider one of these moduli spaces $\mathscr{K}_d^{(K_c,k_i)}$. A moment of reflection shows that each modulus is attached to one of the intersections, and that there is no relation between moduli of different intersections. As we will show below, the number of moduli that characterize a d knot at one intersection depends on the valence N_i of the intersection, and the possible presence of degeneracies described by k_i. Let $d(N_i,k_i)$ be the number of moduli that characterize an intersection i. Then, there will be $d(N_i,k_i)$ continuous parameters $\lambda_j^{(i)}$, $j=1...d(N_i,k_i)$ characterizing each intersection i. The d knot is then fully characterized by all these parameter for each of its intersections. Namely

$$K_d = |K_c, k_i, \lambda_{j_i}^{(i)}\rangle, \tag{4}$$

where $i = 1...I$ and $j_i = 1...d(N_i, k_i)$. In other words, the moduli space $\mathscr{K}_d^{(K_c, k_i)}$ is the Cartesian product of one moduli space per each intersection. We denote the moduli space of an intersection of valence N and (possible) degeneracy k, by $\mathscr{K}_{N,k}$. We thus have

$$\mathscr{K}_d = \bigcup_{K_c \in \mathscr{K}_c} \bigcup_{k_i} \otimes_{i \in K_c} \mathscr{K}_{N_i, k_i}. \tag{5}$$

It follows that it is sufficient to study intersections (of any valence N and with any degeneracy k) in order to fully determine the general structure of $\mathscr{K}_d$. Below, we will discuss the moduli space $\mathscr{K}_N = \mathscr{K}_{N,0}$ of the intersections of arbitrary valence, but with no degeneracy. The case with degeneracy $k \neq 0$ can be treated along similar lines.

III. THE MODULI SPACE $\mathscr{K}_N$

Let p be a nondegenerate intersection point of valence N (we drop the suffix i since we deal here with a single intersection) in a loop α. We denote by s (or $t, u, ...$) a coordinate on the circle S_1 and use coordinates x^a with $a = 1,2,3$ from an atlas of M. Thus p^a will be the coordinates of p and we write $\alpha: s \mapsto \alpha^a(s)$. There are N segments of α crossing p (the intersection between α and a sufficiently small M neighborhood of p); we denote them by $\alpha_i^a(s)$, where $i = 1...N$, and we call s_i the N points in S_1 defined by $\alpha(s_i) = p$. Similarly, we consider a second loop β in the same moduli space, namely in the same c knot and with the same degeneracies as α. Let q be its intersection point (corresponding to p) and $\beta_i^a(s)$ the coordinates of the segments crossing in q. The two loops are in the same d knot if there is a diffeomorphism of the three manifold $f: x^a \mapsto f^a(x)$ and a diffeomorphism of the circle $t: s \mapsto t(s)$, such that

$$f^a(\alpha(t(s))) = \beta^a(s). \tag{6}$$

If we Taylor expand this condition around the intersection point, for each of the N segments, we obtain

$$\begin{aligned}
&\beta^a(s_i) + \frac{d}{ds}\,\beta^a(s)\Big|_{s_i}(s - s_i) + \cdots + \frac{1}{n!}\,\frac{d^n}{ds^n}\,\beta^a(s)\Big|_{s_i}(s - s_i)^n + \cdots \\
&\quad = f^a(\alpha(t(s_i))) + \frac{d}{ds}\,f^a(\alpha(t(s)))\Big|_{s_i}(s - s_i) + \cdots \\
&\qquad + \frac{1}{n!}\,\frac{d^n}{ds^n}\,f^a(\alpha(t(s)))\Big|_{s_i}(s - s_i)^n + \cdots .
\end{aligned} \tag{7}$$

From here on, the following notation will be used (for the sake of tradition and brevity):

$$\begin{aligned}
&\dot{\alpha}_i^a = \frac{d}{ds}\,\alpha^a(s)\Big|_{s_i}, \quad \alpha_i^{(n)a} = \frac{d^n}{ds^n}\,\alpha^a(s)\Big|_{s_i}, \\
&f^a_{b_1 \ldots b_n} = \frac{\partial^n f^a}{\partial x^{b_1} \ldots, \partial x^{b_n}}\Big|_p, \quad t_i^{(n)} = \frac{d^n}{ds^n}\,t(s)\Big|_{s_i}.
\end{aligned} \tag{8}$$

We now consider each term of the expansion (7) separately. To zero order, we have

$$f^a(p)=q^a. \tag{9}$$

To first order

$$f^a_b\dot{\alpha}^b_i t^{(1)}_i=\dot{\beta}^a_i\,. \tag{10}$$

Indices are summed if repeated on different levels. To second order we have

$$f^a_{bc}\dot{\alpha}^b_i\dot{\alpha}^c_i(t^{(1)}_i)^2+f^a_b\dot{\alpha}^b_i t^{(2)}_i=-f^a_b\alpha^{(2)b}_i(t^{(1)}_i)^2+\beta^{(2)a}_i\,. \tag{11}$$

And, for any order $n\geqslant 2$,

$$f^a_{b_1\cdots b_n}\dot{\alpha}^{b_1}_i\cdots\dot{\alpha}^{b_n}_i(t^{(1)}_i)^n+f^a_b\alpha^{(n)b}_i(t^{(1)}_i)^n+f^a_b\dot{\alpha}^b_i t^{(n)}_i+F^a_i=\beta^{(n)a}_i\,, \tag{12}$$

or

$$f^a_{b_1\cdots b_n}\dot{\alpha}^{b_1}_i\cdots\dot{\alpha}^{b_n}_i(t^{(1)}_i)^n+f^a_b\dot{\alpha}^b_i t^{(n)}_i=\beta^{(n)a}_i-f^a_b\alpha^{(n)b}_i(t^{(1)}_i)^n-F^a_i\,, \tag{13}$$

where F^a_i is a function of the derivatives of f, α^a_i, and t of orders lower than n (namely of $f^a_{b_1\cdots b_k},\ldots;\alpha^{(k)a}_i,\ldots;t^{(k)}_i,\ldots$, with $k=1,\ldots,n-1$). Equation (7) is equivalent to the infinite system (9)–(13).

Now, the two loops α and β are d equivalent if this system can be solved for the functions f and t, namely for the infinite tower of variables $f^a_{b_1\cdots b_n},t^{(n)}_i$. Therefore, we may regard (9)–(13) as a system of equations for the unknowns $f^a_{b_1\cdots b_n},t^{(n)}_i$. If the system can be solved for every α and β, then all such loops are in the same d knot and there are no moduli. Namely, the moduli space has zero dimension. This is the case, for instance, if $N=2$ (the lowest valence intersection, formed by a single crossing). In fact, one can check in this case that for each order n the number of unknowns is larger than the number of equations, and the system can be solved. For higher valence intersections, however, the system cannot be solved for arbitrary α and β. This means that there are loops that are not in the same d knot, and we have a moduli space structure.

A moment of reflection shows that the dimension of the moduli space is equal to the number of (independent) equations that overdetermine the system. To clarify this point, imagine that the system is solvable for general α and β only if we leave, say, d (independent) equations out. By inserting f and t that solve the rest of the system into these equations we obtain d equations relating α and β. If we imagine that β is fixed, we obtain then d conditions on α, determining the set of α's d equivalent to β. Thus, this set has codimension d in the space of the α's. This means that a d knot has codimension d in the space of the loops in $\mathscr{K}_N$, and therefore that there is a d parameters space of d knots in $\mathscr{K}_N$. Namely $\mathscr{K}_N$ is d dimensional.

Our task is therefore to find—for every given N—the number of d of independent equations by which the system (9)–(13) is overdetermined. This may seem a hard task, given that the system has an infinite number of equations, but there is a key observation that simplifies the matter. First, observe that the system has a rather simple structure. As we increase the order n, at each new order there are only a finite number of new unknowns that appear. Indeed the unknowns $f^a_{b_1\cdots b_n}$ and $t^{(n)}_i$ appear only at order n or higher. We denote them as unknowns of order n. For instance, at order zero, the only unknowns are the three f^a. At order unity, we have the new unknowns f^a_b (nine of them) and $t^{(1)}_i$ (N of them), and so on. Now, at each other n, we have the same number $3N$ of equations in the system. But the number of unknowns increases rapidly, because the number of components of $f^a_{b_1\cdots b_n}$ increases with n. Indeed, $f^a_{b_1\cdots b_n}$ has $3\times I_n$ independent entries, where

$$I_n = \frac{(n+1)(n+2)}{2} \tag{14}$$

is the number of independent components in a completely symmetrized $3\times3\times\cdots\times3$ n-dimensional matrix. It is then easy to see that (for fixed N) the equations of sufficiently high order can always be solved. More precisely, for every N, there is a number m, which we determine below, such that all equations of order higher than m can always be solved, and we can safely forget them. This fact essentially reduces the system to a finite-dimensional system, making the problem treatable.

A. A gauge

One is now tempted to immediately proceed to determine the number of equations by which the system is overdetermined by naively counting equations and unknowns order by order, and subtracting. Unfortunately, there is a complication. At every order n, the actual number of unknowns is less than what a simple count would suggest, because of the particular structure of our equations. Consider first Eq. (10). The unknowns are the nine components of f^a_b and the N quantities $t^{(1)}_i$. However, if $f^a_b, t^{(1)}_i$ solve (10), so do

$$\tilde{f}^a_b = T f^a_b, \quad \tilde{t}^{(1)}_i = T^{-1} T^{(1)}_i, \tag{15}$$

for every nonvanishing T. Therefore, the overall scale T can never be determined by Eq. (10). In other words, Eq. (10) depends on only $(9+N-1)$ functions of the $(9+N)$ quantities $f^a_b, t^{(1)}_i$. The remaining one cannot be determined by this equation.

The same happens at higher orders. It is easy to verify that if $f^a_{b_1\cdots b_n}, t^{(n)}_i$ solve the equation of order n, so do

$$\tilde{f}^a_{b_1\cdots b_n} = f^a_{b_1\cdots b_n} + f^a_{(b_1} T_{b_2\cdots b_n)},$$

$$\tilde{t}^{(n)}_i = t^{(n)}_i - T_{a_1\cdots a_{n-1}} \dot{\alpha}^{a_1}_i \cdots \dot{\alpha}^{a_{n-1}}_i (t^{(1)}_i)^2, \tag{16}$$

for every symmetric tensor $T_{a_1\cdots a_{n-1}}$. This tensor has I_{n-1} components. We call this transformation the n-order gauge of the system. Because of the gauge, if we cut off the system at order n, we have indeed I_{n-1} less unknowns entering the system than what a naive counting would suggest. Are there other degeneracies beside the gauge we have just described? We suspect there are not, but we have not been able to prove this in general. Because of this incompleteness, we cannot claim that the number we compute below is in fact the dimension of the moduli space, but only that it is the dimension's lower bound.

B. Size of the space of solutions

Consider the order $n=0$, Eq. (9). We have three unknowns (f^a) and three equations there. The system is linear and can obviously always be solved. Consider next the order $n=1$, Eq. (10). There are $9+N$ unknowns, and $3N$ equations. But, because of the gauge described above, only $9+N-1$ unknowns can be determined by the equations. Generically, the system can be solved if the number of equations is less than or equal to the number of unknowns, namely if

$$3N \leqslant 9 + N - 1. \tag{17}$$

In this case, if $N\leqslant4$. A simple inspection of the equation confirms that for $N\leqslant4$ the three equations can indeed be solved, and thus they do not give rise to any continuous dimension (since we assumed an absence of degeneracies at the beginning of our analysis). What happens if $N=5$?

In this case we have 15 equations and 13 (independent) unknowns. Which means that the system is overdetermined by two equations. Again, inspection shows that this is indeed the case. Correspondingly, we expect to have at least a two-dimensional moduli space for $N=5$.

Let us study this $N=5$. At order 2 we have $3N=15$ equations and $3I_2+N-I_{2-1}+I_{1-1}=21$ unknowns, where the term I_{2-1} represents the number of irrelevant variables (the ones that cannot be solved for) because of the gauge of order 2, and the term I_{1-1} represents the gauge unknown of order 1 that becomes relevant (can be solved for) at order 2. We have more unknowns than equations and so we expect the system to be solvable. Indeed, it is solvable. The same happens for higher orders, and thus we can conclude that the only equations for which the system is overdetermined are the two of order 1. Thus, an intersection of valence 5 has a two-dimensional moduli space. In the next section, we will study this example in detail for illustration. Here let us continue the general analysis.

At any given order n, we have $3N$ equations and $3I_n+N-I_{n-1}+I_{n-2}$ new unknowns, where again the term I_{n-1} is for the gauge terms of order n (that are not being solved for at order n) and the term I_{n-2} is for the gauge terms of order $n-1$ (that can be solved for in order n as opposed to order $n-1$). Generically, the system can be solved if the number of equations is less than the number of unknowns:

$$3N \leqslant 3I_n+N-I_{n-1}+I_{n-2}, \tag{18}$$

which yields

$$N \leqslant \frac{3n^2+7n+6}{4}. \tag{19}$$

Solving this for n, we find that the system is solvable at any order $n>m(N)$, where

$$m(N) =: \mathrm{Int}^-\left(\frac{\sqrt{48N-23}-7}{6}\right), \tag{20}$$

where $\mathrm{Int}^-(x)$ is the largest integer smaller than x. Thus we can forget all equations of order larger than $m(N)$ in the system [(9)–(13)]. The remaining system is formed by the $3N\times m$ equations of order $n \leqslant m(N)$. (We do not count the three equations of order zero and the three unknowns f^a, which can always be found.) At each order n (less or equal to m), the number d_n of overdetermined equations is

$$d_n = \#\text{ equations} - \#\text{ unknowns} = 3N-(3I_n+N-I_{n-1}+I_{n-2}), \tag{21}$$

(where $I_0=I_{-1}=0$), and the total number of equations by which the system is overdetermined is

$$d=\sum_{n=1,m} d_n = \sum_{n=1,m} 2N-3I_n+I_{n-1}-I_{n-2} = 2mN+I_{n-1}-3\sum_{n=1,m} I_n. \tag{22}$$

Since we are under the assumption that the intersection is nondegenerate, there are no additional degeneracies in the linear system, and the d equations by which the system is overdetermined are independent. Thus d gives the lower bound on the dimension of the moduli space that we are searching. Performing the sum, we get

$$d(N)=(2N-5)m-\frac{5}{2}m^2-\frac{1}{2}m^3, \tag{23}$$

where m is a function of N, given in Eq. (20). Equation (23) is our main result. It gives (a lower bound on) the dimension of the moduli space of a single nondegenerate intersection of order N.

IV. AN EXAMPLE: $N=5$

Let us consider again the simplest nondegenerate case in which a moduli space appear, which is $N=5$. Thus, we have an intersection point p crossed by the loop α five times. From Eq. (20) we have $m=1$ and from Eq. (23) $d=2$, as anticipated. It is instructive to identify the two continuous degrees of freedom of the knot space. We will do this in two different ways. First, we give a geometrical construction of these two degrees of freedom, and then we give an explicit algebraic expression for the two moduli.

Let us fix an arbitrary coordinate chart in the neighborhood of p, and let $\dot\alpha_i^a$ for $i=1,2,3,4,5$ be the components of the five tangents of α at p. Let us (arbitrarily) pick three of these five tangents, say $\dot\alpha_k^a$ for $k=1,2,3$. The three vectors $\dot\alpha_k^a$ define a basis in the tangent space at p. Clearly the components of the other two tangents, $\dot\alpha_4^a$ and $\dot\alpha_5^a$ on this basis, are quantities that do not depend on the coordinate chosen, and are consequently invariant under diffeomorphisms. If we indicate by $(\dot\alpha^{-1})_a^k$ the 3×3 matrix inverse to the 3×3 matrix $\dot\alpha_k^a$, such components are given by

$$\beta_4^k=(\dot\alpha^1)_a^k\dot\alpha_4^a, \quad \beta_5^k=(\dot\alpha^1)_a^k\dot\alpha_5^a. \tag{24}$$

The quantities β_4^k and β_5^k are invariant under diffeomorphisms. They transform under a reparametrization of the loop as $\beta_4^k\mapsto t_4t_k^{-1}\beta_4^k$, where t_i are the five derivatives of the reparametrization in the intersection point. Assuming, for instance, that the components of β_4^k are positive, we can always choose these derivatives in such a way that, say, $\beta_4^k=(1,1,1)$. The length of the last vector, β_5^k, can be arbitrarily rescaled, by fixing t_5, but its direction is uniquely determined. This direction gives the two dimensions of the moduli space.

Notice that the sign of the components of β_4^k determine eight disconnected sectors of the moduli space, at the boundary of which are degenerate intersections. This is a general feature: the moduli spaces in general have disconnected components, separated by the degenerate cases.

Given the above discussion, it is not too hard to write the two moduli explicitly. This can be done, for instance, in the following manner:

$$\lambda_1=\frac{(\dot\alpha^{-1})_a^1\dot\alpha_4^a(\dot\alpha^{-1})_b^2\dot\alpha_5^b}{(\dot\alpha^{-1})_c^2\dot\alpha_4^c(\dot\alpha^{-1})_d^1\dot\alpha_5^d}, \quad \lambda_2=\frac{(\dot\alpha^{-1})_a^1\dot\alpha_4^a(\dot\alpha^{-1})_b^3\dot\alpha_5^b}{(\dot\alpha^{-1})_c^3\dot\alpha_4^c(\dot\alpha^{-1})_d^1\dot\alpha_5^d}. \tag{25}$$

It is easy to see that these two quantities are independent and are invariant under diffeomorphisms of the manifold and reparametrization of the loops.

ACKNOWLEDGMENTS

We thank Ted Newman for some suggestions. We are particularly indebted to Lee Smolin: the problem considered here emerged in a discussion with him. This work was partially supported by NFS Grant No. 5-39634.

The general framework of bicrossproduct Hopf algebras given by Majid is extended to Z_2-graded bicrossproduct Hopf superalgebras. As examples of bicrossproduct Hopf superalgebras we provide the graded algebras of functions on undeformed as well as κ-deformed $D=4$ Poincaré supergroups. © *1996 American Institute of Physics.* [S0022-2488(96)01806-3]

I. INTRODUCTION

The inhomogeneous groups G described by means of the semidirect product $G=H\ltimes A$ of a simple Lie group H and the Abelian group A are very important in physical applications (see, e.g., Ref. 1). The most important example is given by the $D=4$ Poincaré group $\mathscr{P}_4=\mathrm{SO}(3,1)\ltimes T^4$, where $H=\mathrm{SO}(3,1)$ is the Lorentz group and $A=T^4$ describes four Abelian translations. The Poincaré group as a semidirect product can be supersymmetrized in two ways.

(i) We keep the factor $H=\mathrm{SO}(3,1)$ unchanged but we replace the Abelian subgroup $A=T^4$ by its superextension $T^{4;4}$, with the $D=4$ superalgebra generators $(\overline{Q_{\dot\alpha}}=(Q_\alpha)^+)$,

$$\begin{gathered}\{Q_\alpha,\overline{Q_{\dot\beta}}\}=2(\sigma_\mu)_{\alpha\dot\beta}P^\mu,\quad \{Q_\alpha,Q_\beta\}=\{\overline{Q_{\dot\alpha}},\overline{Q_{\dot\beta}}\}=0,\\ [Q_\alpha,P_\mu]=[\overline{Q_{\dot\alpha}},P_\mu]=0,\quad [P_\mu,P_\nu]=0.\end{gathered}\tag{1.1}$$

The $D=4$ Poincaré group $\mathscr{P}_{4;1}$ can be written therefore as (see, e.g., Ref. 2)

$$\mathscr{P}_{4;1}=\mathrm{SO}(3,1)\ltimes T^{4;4},\tag{1.2}$$

where both factors in (1.2) are non-Abelian.

(ii) One can attach to the factor $H=\mathrm{SO}(3,1)$ only two complex supertranslations, e.g., generated by Q_α ($\alpha=1,2$). In such a way we introduce the graded Lorentz group SO(3,1;2) with the Lorentz generators $M_{\mu\nu}$ and two anticommuting odd generators Q_α, satisfying the relations

$$[M_{\mu\nu},Q_\alpha]=\frac{i}{2}(\sigma_{\mu\nu})_\alpha{}^\beta Q_\beta.\tag{1.3}$$

Denoting the graded Abelian group generated by generators $(P_\mu,\overline{Q_{\dot\alpha}})$ by $\overline{T_{4;2}}$, one can write

$$\mathscr{P}_{4;1}=\mathrm{SO}(3,1;2)\ltimes\overline{T_{4;2}}.\tag{1.4a}$$

In fact, there is still another possibility, obtained by substituting in SO(3,1;2) the generators Q_α by $Q_{\dot\alpha}(\mathrm{SO}(3,1;2)\to\overline{\mathrm{SO}(3,1;2)})$ and replacing in $T_{4;2}$ the generators $Q_{\dot\alpha}$ by $Q_\alpha(T_{4;2}\to T_{4;2})$. One gets

$$\mathscr{P}_{4;1}=\overline{\mathrm{SO}(3,1;2)}\ltimes T_{4;2}. \tag{1.4b}$$

The advantage of the semidirect products (1.4a)–(1.4b) is the preservation of the graded Abelian nature of the second factor. It appears that this graded Abelian structure will be preserved also after the κ deformation (compare with Ref. 9, where the four-momenta for κ-deformed Poincaré algebra commute).

The main result of this paper is the description of quantum κ deformation of $D=4$ Poincaré supergroup in the framework of bicrossproduct Hopf superalgebras. It appears that for the standard (''bosonic'') quantum groups the bicrossproduct Hopf algebra $H_1\triangleright\!\blacktriangleleft H_2$ provides an attractive proposal for the general framework of quantum deformations of the classical semidirect product of H_1 and H_2 supplemented by consistent coalgebra structure.[3–5] Indeed, recently it has been shown that the dual pair of κ-deformed Poincaré algebra[6,7] and κ-deformed Poincaré group[8] can be very well incorporated[9–11] into the bicrossproduct scheme (the general approach proposed recently by Podleś and Woronowicz[12] can be also put into the general bicrossproduct framework). Our aim here is to extend such a framework to the ''super'' case.

Our presentation contains two parts.

(i) It appears that the signature factors that enter into the defining properties of graded bicrossproduct Hopf algebras are not known in the literature, and appear in several formulas in a way that is far from obvious. In Sec. II we describe the general framework describing graded bicrossproduct Hopf algebras, extending to the super case results presented by Majid.[3–5]

(ii) In Sec. III we describe the $D=4$ κ-deformed Poincaré supergroup, presented first in Ref. 13, as the graded bicrossproduct Hopf algebra, i.e. we provide the example of our general scheme. In this description the graded Hopf algebra is the algebra of functions on a quantum supergroup with a graded set of generators.

It should be stressed that the bicrossproduct description of Hopf algebra, $H=H_1\triangleright\!\blacktriangleleft H_2$, implies the bicrossproduct structure of dual Hopf algebra, $\tilde H=\tilde H_2\triangleright\!\blacktriangleleft\tilde H_1$, where the ''tilde'' describes the dual object. Indeed, the first complete proof of duality between $D=4$ κ-Poincaré quantum algebra and $D=4$ κ-Poincaré quantum group was obtained in Ref. 11 after using the bicrossproduct form of both dual structures. In the present paper it is first demonstrated that the $D=4$ κ-Poincaré supergroup is an example of graded bicrossproduct Hopf algebra. Because the bicrossproduct structure of $D=4$ κ-Poincaré quantum superalgebra is already known,[14] we believe that it is only a technical matter to extend the proof given in Ref. 11 to the supersymmetrized case.

II. BICROSSPRODUCT HOPF ALGEBRAS

First, we shall recall the general definition of bicrossproduct Hopf algebra, due to Majid.[3–5] Let H_1, H_2 ($a\in H_1$, $h\in H_2$) are two Hopf algebras, with the coproducts $\Delta(a)=a_{(1)}\otimes a_{(2)}$, $\Delta(h)=h_{(1)}\otimes h_{(2)}$. We assume further that the following occurs.

(i) H_2 is a right H_1 module algebra, i.e., there exists an action α: $H_2\otimes H_1\to H_2$ denoted by

$$\alpha(a\otimes h)=a\triangleleft h, \tag{2.1}$$

defining the crossproduct $H_1\ltimes H_2$.

(ii) H_1 is a left H_2-comodule coalgebra, i.e. there exists a coaction β: $H_1\to H_2\otimes H_1$, such that

$$\beta(h)=h^{(1)}\otimes h^{(2)}, \tag{2.2}$$

where $h^{(1)}\in H_2$, $h^{(2)}\in H_1$, which defines the crossproduct $H_1\blacktriangleright\!\blacktriangleleft H_2$.

The following statement is valid.

Theorem 1: *(see Ref. 3, Theorem 3.3)*
The linear space $H_1 \otimes H_2$ is endowed with the Hopf algebra structure and defines the right–left bicrossproduct Hopf algebra $H_1 \triangleright\!\blacktriangleleft H_2$ if the action α and coaction β satisfy the following compatibility conditions:

$$\epsilon(a \triangleleft h) = \epsilon(a)\epsilon(h), \quad \beta(1) = 1 \otimes 1, \tag{2.3a}$$

$$\Delta(a \triangleleft h) = (a_{(1)} \triangleleft h_{(1)}) h_{(2)}{}^{(1)} \otimes a_{(2)} \triangleleft h_{(2)}{}^{(2)}, \tag{2.3b}$$

$$\beta(hg) = (h^{(1)} \triangleleft g_{(1)}) g_{(2)}{}^{(1)} \otimes h^{(2)} g_{(2)}{}^{(2)}, \tag{2.3c}$$

$$h_{(1)}{}^{(1)}(a \triangleleft h_{(2)}) \otimes h_{(1)}{}^{(2)} = (a \triangleleft h_{(1)}) h_{(2)}{}^{(1)} \otimes h_{(2)}{}^{(2)}. \tag{2.3d}$$

The multiplication structure in $H_1 \triangleright\!\blacktriangleleft H_2$ is defined by

$$(h \otimes a) \cdot (g \otimes b) = h g_{(1)} \otimes (a \triangleleft g_{(2)}) b, \tag{2.4}$$

and the comultiplication looks as follows:

$$\Delta(h \otimes a) = (h_{(1)} \otimes h_{(2)}{}^{(1)} a_{(1)}) \otimes (h_{(2)}{}^{(2)} \otimes a_{(2)}). \tag{2.5}$$

The antipode and the counit are given by the formulas

$$S(h \otimes a) = (1 \otimes S(h^{(1)} a)) \cdot (S(h^{(2)}) \otimes 1), \tag{2.6a}$$

$$\epsilon(h \otimes a) = \epsilon(h)\epsilon(a). \tag{2.6b}$$

The simplest examples of bicrossproduct Hopf algebras are the following.

(i) Semidirect product of simple Lie algebra and the Abelian algebra, e.g. $\mathscr{P}_4 = \mathrm{SO}(3,1) \triangleright\!\blacktriangleleft T^4$, considered a Hopf algebra with a primitive coproduct. In such a case ($M_{\mu\nu} \in \mathrm{SO}(3,1)$, $P_\mu \in T^4$),

$$\alpha(P_\mu \otimes M_{\rho\tau}) = P_\mu \triangleleft M_{\rho\tau} = [P_\mu, M_{\rho\tau}], \quad \beta(M_{\mu\nu}) = 1 \otimes M_{\mu\nu}. \tag{2.7}$$

(ii) If H_1 is commutative and H_2 is cocommutative, the bicrossproduct $H_1 \triangleright\!\blacktriangleleft H_2$ describes the Hopf algebra extension in the sense of Singer.[15]

(iii) The quantum κ deformation of $D=4$ Poincaré algebra $\mathscr{U}(so(3,1)) \triangleright\!\blacktriangleleft \mathscr{U}_\kappa(T^4)$[9,10] as well as the quantum κ deformation od $D=4$ Poincaré group $C(\mathrm{SO}(3,1)) \blacktriangleright\!\triangleleft C_\kappa(\widetilde{T}^4)$,[9–11] where $C(\mathrm{SO}(3,1))$ and $C_\kappa(\widetilde{T}^4)$ describe, respectively, the algebra of functions on the Lorentz group and the algebra of functions on the Abelian translation group [$C_\kappa(\widetilde{T}^4)$ is dual to $\mathscr{U}_\kappa(T^4)$].

III. Z_2-GRADED BICROSSPRODUCT HOPF SUPERALGEBRA

A. Z_2-graded Hopf superalgebras

Let us assume that $\mathscr{H}$ is a Z_2-graded algebra, i.e., as a vector space $\mathscr{H} = \mathscr{H}_0 \oplus \mathscr{H}_1$. We define the parity of an element $h \in \mathscr{H}$ as follows:

$$p(h) = 0, \quad \text{if } h \in \mathscr{H}_0; \quad p(h) = 1, \quad \text{if } h \in \mathscr{H}_1. \tag{3.1}$$

We introduce the tensor product of two Z_2-graded algebras $\mathscr{H} \otimes \mathscr{H}'$ as Z_2-graded algebra, with the following multiplication rule:

$$(h \otimes h') \cdot (g \otimes g') = (-1)^{p(h')p(g)} hg \otimes h'g', \tag{3.2}$$

where $h,g \in \mathscr{H}$ and $h',g' \in \mathscr{H}'$. Let us introduce the following definitions:[16–18]
Definition 1: The Hopf superalgebra $(\mathscr{H},\Delta,\epsilon,S)$ *is given by the following axioms*:

(i) $\mathscr{H}$ *is a* Z_2*-graded algebra.*

(ii) *The comultiplication map* Δ*:* $\mathscr{H}\to\mathscr{H}\otimes\mathscr{H}$ *is a homomorphism of* $\mathscr{H}$ *and is superassociative, i.e.*

$$(\Delta\otimes 1)\Delta(h)=(1\otimes\Delta)\Delta(h), \tag{3.3}$$

where the tensor product is defined by (3.2); besides $\Delta(1) = 1 \otimes 1$.

(iii) *The counit* ϵ *is linear map* $\mathscr{H}\to C$*, where*

$$\epsilon(hh')=\epsilon(h)\epsilon(h'), \quad (\epsilon\otimes 1)\Delta(h)=(1\otimes\epsilon)\Delta(h)=h. \tag{3.4}$$

(iv) *The antipode* S *is defined as linear antiisomorphism* $\mathscr{H}\to\mathscr{H}$ *with the property* $(m(h\otimes h')=h\cdot h')$

$$m\circ(S\otimes 1)\circ\Delta(h)=m\circ(1\otimes S)\circ\Delta(h)=\epsilon(h)\cdot 1. \tag{3.5}$$

If we introduce the graded flip operation:

$$\sigma(h\otimes h')=(-1)^{p(h)p(h')}h'\otimes h, \tag{3.6}$$

and the graded opposite coproduct,

$$\Delta'(h)=\sigma\circ\Delta(h), \tag{3.7}$$

we also obtain that

$$(S\otimes S)\Delta(h)=\Delta'(S(h)), \tag{3.8}$$

as well as

$$S(hh')=(-1)^{p(h)p(h')}S(h')S(h). \tag{3.9}$$

Remark 1: The Hopf superalgebra is a special case of anionic Hopf algebras, with Z_n grading, for the special case $n=2$.[19] The anionic algebras are the special case of braided Hopf algebras.[20–21]

Remark 2: The well-known examples of noncommutative and noncocommutative Hopf superalgebras are the quantum deformations of universal enveloping algebras of simple Lie superalgebras (see, e.g., Refs. 17–19), as well as the quantum-deformation of the algebra of functions on a simple Lie supergroups (see, e.g., Ref. 22).

B. Bicrossproduct Hopf superalgebras

Let us assume that $\mathscr{H}_1$, $\mathscr{H}_2$ are two Hopf superalgebras (we put $h,g,f \in \mathscr{H}_1$, $a,b,c \in \mathscr{H}_2$). We assume further the following.

(i) $\mathscr{H}_2$ is a right $\mathscr{H}_1$ module, with the action α [see (2.1)], satisfying the grading property

$$ab\triangleleft h=(-1)^{p(h_{(1)})p(b)}(a\triangleleft h_{(1)})(b\triangleleft h_{(2)}), \tag{3.10a}$$

$$a\triangleleft(hg)=(a\triangleleft h)\triangleleft g. \tag{3.10b}$$

(ii) $\mathscr{H}_1$ is a left $\mathscr{H}_2$-comodule cosuperalgebra with the action β [see (2.2)], satisfying $\beta(1)=1\otimes 1$ and the following properties:

$$(1\otimes\beta)\circ\beta=(\Delta\otimes 1)\circ\beta, \tag{3.11a}$$

$$(\epsilon\otimes 1)\circ\beta(h)=1_{\mathscr{H}_1}\otimes h, \tag{3.11b}$$

$$(1\otimes\Delta)\beta(h)=m_{12}\sigma_{23}(\beta\otimes\beta)\Delta. \tag{3.11c}$$

Theorem 2: *The linear Z_2-graded space (superspace) $\mathscr{H}_1\otimes\mathscr{H}_2$ is endowed with the Hopf superalgebra structure and defines the Z_2-graded bicrossproduct Hopf superalgebra $\mathscr{H}_1\bowtie\mathscr{H}_2$ with the following definitions of multiplication, comultiplication, counit and antipode,*

$$(h\otimes a)(g\otimes b)=(-1)^{p(a)p(g_{(1)})}hg_{(1)}\otimes(a\triangleleft g_{(2)})b, \tag{3.12}$$

$$\Delta(h\otimes a)=(-1)^{p(h_{(2)}{}^{(2)})p(a_{(1)})}h_{(1)}\otimes h_{(2)}{}^{(1)}a_{(1)}\otimes h_{(2)}{}^{(2)}\otimes a_{(1)}, \tag{3.13}$$

$$\epsilon(h\otimes a)=\epsilon(h)\cdot\epsilon(a), \tag{3.14}$$

$$S(h\otimes a)=(-1)^{p(h^{(2)})[p(h^{(1)})+p(a)]}(1\otimes S(h^{(1)}a))(S(h^{(2)})\otimes 1), \tag{3.15}$$

if the following compatibility conditions are satisfied [compare with (2.3a)–(2.3d)]:

$$\epsilon(a\triangleleft h)=\epsilon(a)\epsilon(h), \tag{3.16a}$$

$$\Delta(a\triangleleft h)(-1)^{p(a_{(2)})[p(h_{(1)})+p(h_{(2)}{}^{(1)})]}(a_{(1)}\triangleleft h_{(1)})h_{(2)}{}^{(1)}\otimes a_{(2)}\triangleleft h_{(2)}{}^{(2)}, \tag{3.16b}$$

$$\beta(hg)=(-1)^{p(h^{(2)})[p(g_{(1)})+p(g_{(2)}{}^{(1)})]}(h^{(1)}\triangleleft g_{(1)})g_{(2)}{}^{(1)}\otimes h^{(2)}g_{(2)}{}^{(2)}, \tag{3.16c}$$

$$h_{(1)}{}^{(1)}(a\triangleleft h_{(2)})\otimes h_{(1)}{}^{(2)}=(-1)^{p(a)p(h_{(2)}{}^{(1)})+p(h_{(1)})p(h_{(2)}{}^{(2)})}(a\triangleleft h_{(1)})h_{(2)}{}^{(1)}\otimes h_{(2)}{}^{(2)}. \tag{3.16d}$$

In the proof we check directly that with the definitions (3.12)–(3.15) and the properties (3.16a)–(3.16d) the axioms of the graded bicrossproduct $\mathscr{H}_1\bowtie\mathscr{H}_2$ being a Hopf superalgebra are satisfied. In particular, we have to check the associativity of the multiplication (3.12), i.e.

$$[(h\otimes a)(g\otimes b)](f\otimes c)=(h\otimes a)[(g\otimes b)(f\otimes c)], \tag{3.17}$$

the coassociativity of the coproduct (3.13) [see (3.3)] and, what is the most complicated part, the homomorphism property of the coproduct,

$$\Delta((h\otimes a)(g\otimes b))=\Delta(h\otimes a)\Delta(g\otimes b). \tag{3.18}$$

The graded bicrossproducts described in this section can be used for the description of quantum deformations of inhomogeneous supergroups.

IV. AN EXAMPLE: $D=4$ κ-DEFORMED POINCARÉ SUPERGROUP IN BICROSSPRODUCT FORM

The $D=4$ κ-deformed Poincaré supergroup has been obtained in Ref. 13 by quantization of the r-matrix Poisson bracket, with the following choice of the classical r matrix for $D=4$ Poincaré superalgebra (see also Ref. 23),

$$r=N_i\wedge P_i-\frac{i}{4}\,Q_\alpha\wedge\overline{Q_{\dot\alpha}}, \tag{4.1}$$

where $M_{\mu\nu}=(M_i,N_i)$ are Lorentz generators, P_μ describe the four-momenta and $Q_\alpha,\overline{Q_{\dot\alpha}}$ are four supercharges described by the doublet of Weyl 2-spinors. The Hopf superalgebra of the functions on $D=4$ κ-deformed Poincaré supergroup is described by the following relations (see Ref. 13).

(a) Algebra

(i) Lorentz sector $(A_\alpha^\beta,A_{\dot\alpha}^{\dot\beta})$ (we use the spinorial representation of the Lorentz generators, e.g. $L_i=\frac{1}{4}[(\sigma_i)_\alpha^\beta L_\beta^\alpha+(\overline{\sigma_i})_{\dot\alpha}^{\dot\beta}L_{\dot\beta}^{\dot\alpha}]$):

The Lorentz subgroup parameters are classical, i.e.

$$[A_\alpha^\beta,A_\gamma^\delta]=[A_\alpha^\beta,A_\gamma^{\dot\delta}]=[A_{\dot\alpha}^{\dot\beta},A_{\dot\gamma}^{\dot\beta}]=0. \tag{4.2}$$

(ii) Translations (X_μ) [we denote $\theta=\begin{pmatrix}\theta_1\\ \theta_2\end{pmatrix}$, $\overline{\theta}=\begin{pmatrix}\theta^{\dot1}\\ \theta^{\dot2}\end{pmatrix}$]:

$$[X^i,X^j]=\frac{i}{8\kappa}\,\theta^T\sigma^i(\mathbf{1}-(AA^+)^{-1})\sigma^j\overline{\theta}-\frac{i}{8\kappa}\,\theta^T\sigma^j(\mathbf{1}-(AA^+)^{-1})\sigma^i\overline{\theta}, \tag{4.3}$$

$$[X^0,X^j]=-\frac{i}{\kappa}\,X^j+\frac{i}{8\kappa}\,\theta^T[\sigma^j,(AA^+)^{-1}]\overline{\theta},$$

$$[A_\alpha^\beta,X^i]=\frac{1}{2\kappa}\,((A\sigma_n)_\alpha^\beta\Lambda_n^i(A)-(\sigma^i\cdot A)_\alpha^\beta), \tag{4.4}$$

$$[A_\alpha^\beta,X^0]=\frac{1}{2\kappa}\,(A\sigma_i)_\alpha^\beta\Lambda_i^0(A).$$

(iii) Supertranslations,

$$\{\theta^\alpha,\theta^\beta\}=\{\theta^{\dot\alpha},\theta^{\dot\beta}\}=0,\quad \{\theta^\alpha,\theta^{\dot\beta}\}=\frac{i}{2\kappa}\,(\mathbf{1}-(AA^+)^{-1})^{\dot\beta\alpha}, \tag{4.5}$$

$$\{X^i,\theta_\alpha\}=\frac{1}{4\kappa}\,(\theta^T\sigma^i)_\gamma(\mathbf{1}_2-(AA^+)^{-1})_\alpha^\gamma, \tag{4.6}$$

$$\{X^0,\theta_\alpha\}=-\frac{1}{4\kappa}\,\theta_\gamma^T(\mathbf{1}+(AA^+)^{-1})_\alpha^\gamma,\quad \{A_\alpha^\beta,\theta^\gamma\}=\{A_{\dot\alpha}^{\dot\beta},\theta^\gamma\}=0. \tag{4.7}$$

(b) Coalgebra,

$$\Delta(X_\mu)=X_\mu\otimes 1+\Lambda_\mu^\nu(A)\otimes X_\nu-\frac{i}{2}\,(A_\alpha^{-1\beta}\sigma_{\beta\dot\gamma}^\mu\theta^{\dot\gamma}\otimes\theta^\alpha+\theta^\alpha\sigma_{\alpha\dot\beta}^\mu A_{\dot\gamma}^{-1\beta}\otimes\theta^{\dot\gamma}),$$

$$\Delta(\theta_\alpha)=\theta_\alpha\otimes 1+(A^{-1})_\alpha^\beta\otimes\theta_\beta,\quad \Delta(A_\alpha^\beta)=A_\alpha^\gamma\otimes A_\gamma^\beta. \tag{4.8}$$

(c) Antipodes:

$$S(X^\mu)=-\Lambda_\nu^\mu(A^{-1})X^\nu,\quad S(A_\alpha^\beta)=(A^{-1})_\alpha^\beta,\quad S(\theta^\alpha)=-A_\beta^\gamma\theta^\beta. \tag{4.9}$$

In such a way, we have obtained the complete set of relations describing the κ deformation of $N=1$ Poincaré supergroup.

In order to put the Hopf superalgebra (4.2)–(4.9) in the bicrossproduct algebra form, we should introduce the complexified chiral superspace coordinates (see, e.g., Ref. 24) as follows:

$$z_\mu = x_\mu + \frac{i}{2}\,\theta_\alpha (\sigma_\mu)^{\alpha\dot\beta}\overline{\theta_{\dot\beta}}. \tag{4.10}$$

Let us introduce the following two κ-deformed Hopf superalgebras.

(i) The algebra of functions $C(z_\mu,\theta_\alpha)$ on κ-deformed chiral superspace (z_μ,θ_α), with the following Hopf superalgebra relations:

$$[z_i,z_j]=0, \quad [z_0,z_i]=-\frac{i}{\kappa}\,z_i,$$

$$[z_0,\theta_\alpha]=-\frac{i}{2\kappa}\,\theta_\alpha, \quad [z_i,\theta_\alpha]=0, \quad \{\theta_\alpha,\theta_\beta\}=0, \tag{4.11}$$

and

$$\Delta(z_\mu)=z_\mu\otimes 1+1\otimes z_\mu, \quad \Delta(\theta_\alpha)=\theta_\alpha\otimes 1+1\otimes\theta_\alpha. \tag{4.12}$$

(ii) The classical Hopf superalgebra of functions $C(A_{\alpha\beta},A_{\dot\gamma\beta},\overline{\theta_{\dot\alpha}})$ on the superextension of the classical Lorentz group, with the following defining relations:

$$[A_{\alpha\beta},A_{\gamma\delta}]=[A_{\alpha\beta},A_{\dot\gamma\dot\delta}]=[A_{\dot\alpha\dot\beta},A_{\dot\gamma\dot\delta}]=0,$$
$$[A_{\alpha\beta},\overline{\theta_{\dot\gamma}}]=[A_{\dot\alpha\dot\beta},\overline{\theta_{\dot\gamma}}]=0, \quad \{\overline{\theta_{\dot\alpha}},\overline{\theta_{\dot\beta}}\}=0, \tag{4.13}$$

and

$$\Delta(A_{\alpha\beta})=A_{\alpha\gamma}\otimes A_{\gamma\beta}, \quad \Delta(A_{\dot\alpha\dot\beta})=A_{\dot\alpha\dot\gamma}\otimes A_{\dot\gamma\dot\beta},$$
$$\Delta(\overline{\theta_{\dot\alpha}})=\overline{\theta_{\dot\alpha}}\otimes 1+(A_{\dot\alpha\dot\beta})^{-1}\otimes\overline{\theta_{\dot\beta}}. \tag{4.14}$$

One can prove the following statement.

Theorem 3: *The $D=4$ κ-deformed Poincaré supergroup can be described as the graded bicrossproduct Hopf superalgebra,*

$$C_\kappa(\mathscr{P}_{4;1})=C(z_\mu,\theta_\alpha)\triangleright\!\blacktriangleleft C(A_{\alpha\beta},A_{\dot\alpha\dot\beta},\overline{\theta_{\dot\alpha}}), \tag{4.15}$$

with the following definition of the action α:

$$\overline{\theta_{\dot\alpha}}\triangleleft z_i=-\frac{i}{2\kappa}\,[\mathbf{1}-(A^+A)^{-1}]_{\dot\alpha}{}^{\dot\beta}\overline{\theta_{\dot\beta}}, \quad \overline{\theta_{\dot\alpha}}\triangleleft z_0=-\frac{i}{2\kappa}\,(A^+A)_{\dot\alpha}{}^{\dot\beta}\overline{\theta_{\dot\beta}},$$

$$\overline{\theta_{\dot\alpha}}\triangleleft\theta_\beta=-\frac{i}{2\kappa}\,[\mathbf{1}-(AA^+)^{-1}]_{\dot\alpha\beta},$$

$$A_{\alpha\beta}\triangleleft z_i=\frac{1}{2\kappa}\,[(A\sigma_k)_{\alpha\beta}\Lambda_{ik}(A,\overline{A})-(\sigma_iA)_{\alpha\beta}],$$
$$\overline{A_{\dot\alpha\dot\beta}}\triangleleft z_i=\frac{1}{2\kappa}\,[(\sigma_i\overline{A})_{\dot\alpha\dot\beta}\Lambda_{lk}(A,\overline{A})-(\overline{A\sigma}_i)_{\dot\alpha\dot\beta}], \tag{4.16}$$

$$A_{\alpha\beta}\triangleleft z_0=\frac{1}{2\kappa}\,(A\sigma_i)_\alpha{}^\beta\Lambda_{i0}(A,\overline{A}), \quad \overline{A_{\dot\alpha\dot\beta}}\triangleleft z_0=\frac{1}{2\kappa}\,(\sigma_i\overline{A})_{\dot\alpha}{}^{\dot\beta}\Lambda_{i0}(A,\overline{A}),$$

$$\overline{A}_{\alpha\beta} \triangleleft \theta_\gamma = A_{\dot{\alpha}\dot{\beta}} \triangleleft \theta_\gamma = 0,$$

and coaction β,

$$\beta(z_\mu) = \Lambda_\mu{}^\nu (A, \overline{A}) \otimes z_\nu - i(A^{-1}\sigma_\mu)_{\alpha\dot{\beta}} \overline{\theta}_{\dot{\beta}} \otimes \theta_\alpha,$$

$$\beta(\theta_\alpha) = (A^{-1})_{\beta\alpha} \otimes \theta_\beta. \tag{4.17}$$

The proof is obtained by performing the transformation (4.10) of the superalgebra basis (4.2)–(4.9) and showing that the resulting Hopf superalgebra fits into the graded bicrossproduct superalgebra framework.

V. FINAL REMARKS

In this paper we give the not known in the literature general definition of graded bicrossproduct Hopf superalgebra and we provided as well an example. Such a scheme can be extended to the case of anionic groups[19] and braided groups.[20,21] To our knowledge only the crossproducts of braided cocommutative Hopf algebra with the quasitriangular Hopf algebras have been considered.[25] It is an interesting task to introduce the general braided bicrossproduct of braided Hopf algebras and provide some nontrivial examples.

(Received 9 February 1995; accepted for publication 11 October 1995)

The preliminary classification of $q_t = f(q, q_x, q_{xx}, q_{xxx})$ is given. The results are compared with Fokas's symmetry and Mikhailov–Shabat–Sokolov formal symmetry approaches. © *1996 American Institute of Physics.* [S0022-2488(96)01005-0]

I. INTRODUCTION

There are several methods[1] to examine the integrability of nonlinear partial differential equations, although in two dimensions most of these methods imply each other.[2] The existence of infinitely many conserved quantities is too strong. For example, Burger's equation has only one conservation law.[3] One can say that many integrable differential equations can be put into a bilinear form.[4] The converse, however, is not true, since a bilinear form can be constructed for equations that are not integrable. There are integrable equations like the Harry–Dym equation, which does not pass the Painlevé test.[5] Several authors[6,7] have considered the existence of bi-Hamiltonian formulation as the fundamental criteria to integrability.

Another approach to integrability is linearization technique.[8] If the linearized equation of a given differential equation supports an eigenvalue equation, then the given differential equation is integrable. The advantage of using this technique is the following: One member of the associated linear equation is known by virtue of the nonlinear partial differential equation itself. Unlike the Painlevé analysis, the given nonlinear equation can be of any form. We can classify nonlinear partial differential equations.

II. LINEARIZATION

We can describe the linearization method for evolutionary equations

$$q_t = f(q, q_x, q_{xx}, \ldots) \tag{1}$$

in the following way. First we linearize the given differential equation. In other words, we replace q (and its derivatives) in (1) by $q + \epsilon\Psi$ differentiate both sides of the resulting expression with respect to ϵ:

$$\Psi_t = D_f(\Psi), \tag{2}$$

where D_f is the Fréchet derivative.[3] The equation above can also be written as

$$\Psi_t = \sum_{i=0}^{N} f_i \Psi_i = \sum_{i=0}^{N} \frac{\partial f}{\partial q_i} \Psi_i, \tag{3}$$

where N is the order of differential equation, $q_0 = q$, $q_1 = q_x$, $q_2 = q_{xx}$, $\Psi_0 = \Psi$, $\Psi_1 = \Psi_x$, $\Psi_2 = \Psi_{xx}$, and so on. In the symmetry approach (2) is the main equation, Ψ is the symmetry of the differential equation, and it is a function of q_i.

The compatible eigenvalue equation is

$$H\Psi = 0, \tag{4}$$

[a)]Electronic mail address: satir@newton.physics.metu.edu.tr

0022-2488/96/37(6)/3050/12/$10.00

where H depends on q_i and a parameter k. If its order (highest derivative in H) is N, then (4) may be written as

$$\Psi_N=\sum_{i=0}^{N-1} A_i\Psi_i, \tag{5}$$

where $A_0,A_1,\ldots,A_{N-1}$ are functions of q_i and the parameter k. We assume the order of dependence of A_is on q_i in advance, similar to the symmetry approach. Compatibility condition of (5) and (2),

$$\Psi_{N,t}-\Psi_{t,N}=0, \tag{6}$$

using (2) gives

$$\sum_{i=0}^{N-1} \Psi_i W_i=0, \tag{7}$$

where W_is are functions of f_i, A_i, and their partial derivatives. Letting

$$W_i=0, \tag{8}$$

we obtain a system of differential equations among f_i, A_i, and their partial derivatives. Expanding A_is in terms of the parameter k will give

$$A_i=\sum_{j=0}^{N} A_{ij}k^j, \tag{9}$$

where A_{ij}s are functions of q_i. Now substituting (9) into (8) we obtain an overdetermined system of differential equations. Letting each coefficient of k^i vanish results in first (i) a set of algebraic equations among A_{ij} and f_i and, second (ii) a set of a system of differential equations. The solution of this system will determine the eigenvalue equation (5) which can be integrated to give

$$\Phi\Psi=k\Psi, \tag{10}$$

where Φ is the recursion operator.[9] Letting

$$\Psi=\sum k^n\Psi_n, \tag{11}$$

then one obtains

$$\Phi\Psi_n=\Psi_{n-1}. \tag{12}$$

Hence Φ is transforming a symmetry into another one. Suppose the given differential equation has Hamiltonian structure so that $\Psi=\Theta_1\gamma$, where Θ_1 is the Hamiltonian operator and γ is the conserved covariant. Then from (10) we obtain

$$(\Phi\Theta_1-k\Theta_1)\gamma=0. \tag{13}$$

Expanding $\gamma=\Sigma k^n\gamma_n$ we find

$$\Phi\Theta_1\gamma_n=\Theta_1\gamma_{n-1}. \tag{14}$$

Hence $\Phi\Theta_1$ is a candidate for the second Hamiltonian operator. In a sense the integrability in linearization is equivalent (for the scalar case) to the existence of a recursion operator which satisfies the eigenvalue equation. In this approach, the order of eigenvalue equation N, the order of dependence of A_is on the derivative of the dependent variable q, and the order of the spectral parameter are the key factors in the classification.[10]

Classification of integrable nonlinear differential equations started almost two decades ago.[11–13] So far the attempts for complete classification have been done for some evolutionary equations.[1,14,15] In this work, the preliminary classifications of $q_t=f(q,q_x,q_{xx})$ and $q_t=f(q,q_x,q_{xx},q_{xxx})$ are given and the results are compared with Olver–Fokas symmetry[3,12] and Mikhailov–Shabat–Sokolov (MSS)[14] formal symmetry approaches.

III. CLASSIFICATION OF $q_t=f(q,q_x,q_{xx})$

We consider differential equations of the following form:

$$q_t=f(q,q_x,q_{xx}). \tag{15}$$

The linearized form of the equation above can be given as

$$\Psi_t=\gamma\Psi_{xx}+\alpha\Psi_x+\beta\Psi, \tag{16}$$

where α,β,γ are functions of q,q_x,q_{xx}. We assume an eigenvalue equation having the same order as (15):

$$\Psi_{xx}=A\Psi_x+B\Psi. \tag{17}$$

With the expansion of A, B, and C as

$$A=A_0+A_1k+A_2k^2, \quad B=B_0+B_1k+B_2k^2, \tag{18}$$

here A_i and B_i $(i=0,1,2)$ are functions of q,q_x,q_{xx}. The highest power of k is related to the order of the given partial differential equation. [A different approach from Ref. 8 is used in this work. The order of the parameter (k) can take any integer value.] Compatibility of (16) and (17) give the following algebraic equations,

$$A_2=\frac{E_2}{\sqrt{\gamma}}, \quad A_1=\frac{E_1}{\sqrt{\gamma}}, \quad B_2=B_1\frac{E_2}{E_1}, \tag{19}$$

and evolution equations

$$\begin{aligned}A_{0,t}=&\alpha_{xx}+\alpha_xA_0+\gamma_{xx}A_0+2\gamma_xA_{0,x}+\gamma_xA_0^2+2\gamma_xB_0\\&+2\beta_x+A_{0,xx}\gamma+A_{0,x}\alpha+2A_{0,x}\gamma A_0+2B_{0,x}\gamma,\end{aligned} \tag{20}$$

$$\begin{aligned}B_{0,t}=&2\alpha_xB_0+\gamma_{xx}B_0+2\gamma_xB_{0,x}+\gamma_xA_0B_0+\beta_{xx}-\beta_xA_0\\&+2A_{0,x}\gamma B_0+B_{0,xx}\gamma+B_{0,x}\alpha,\end{aligned} \tag{21}$$

$$B_{1,t}=\frac{1}{\sqrt{\gamma}}\,(2\sqrt{\gamma}\alpha_xB_1+\sqrt{\gamma}\gamma_{xx}B_1+2\sqrt{\gamma}\gamma_xB_{1,x}+\sqrt{\gamma}\gamma_xA_0B_1 \tag{22}$$

$$-\beta_xE_1+2\gamma^{3/2}A_{0,x}B_1+\gamma^{3/2}B_{1,xx}+\gamma^{1/2}B_{1,x}), \tag{23}$$

$$\gamma_t = -\frac{1}{2E_1}(4\alpha_x \gamma E_1 + 2\gamma_{xx}\gamma E_1 - \gamma_x^2 \gamma E_1 + 8\gamma^{3/2}\gamma_x B_1 - 2\gamma_x \alpha E_1 + 4\gamma_x \gamma A_0 E_1 + 8A_{0,x}\gamma^2 E_1 + 8\gamma^{5/2} B_{1,x}). \tag{24}$$

A. Case (1)

The first type of integrable equation is given by the linearized equation

$$\Psi_t = \eta \Psi_{xx} - \left[\frac{2\eta r_q}{r} q_x - \frac{\eta_1}{E_1}\right]\Psi_x + \left[\frac{\eta(r_q^2 - r_{qq} r)}{r^2} q_x^2 - \frac{\eta_1 r_q}{\sqrt{\eta}}\right]\Psi, \tag{25}$$

with compatible eigenvalue equation

$$\Psi_{xx} = \left[-\frac{\sqrt{\eta} q_{xx}}{-\sqrt{\eta} q_x + E_1 r} + \frac{\sqrt{\eta} q_x^2 r_q}{r(-\sqrt{\eta} q_x + E_1 r)} + \frac{2E_1 r_q q_x}{-\sqrt{\eta} q_x + E_1 r} + \frac{E_1}{\sqrt{\eta}} k + \frac{E_2}{\sqrt{\eta}} k^2\right]\Psi_x + \left[\frac{E_1 r_q q_{xx}}{-\sqrt{\eta} q_x + E_1 r} + \frac{r_{qq} q_x^2}{r} - \frac{r_q^2 q_x^2}{r} - \frac{E_1 r_q^2 q_x^2}{r(-\sqrt{\eta} q_x + E_1 r)} - \frac{E_1(-\sqrt{\eta} q_{xx} + E_1 r_q q_x)}{-\sqrt{\eta} q_x + E_1 r} k - \frac{E_2(-\sqrt{\eta} q_{xx} + E_1 r_q q_x)}{-\sqrt{\eta} q_x + E_1 r} k^2\right]\Psi. \tag{26}$$

In linearization, the eigenvalue equation determines the recursion operator for the corresponding partial differential equation. Equation (26) can be integrated,

$$\Phi = D - \frac{r_q q_x}{r}, \tag{27}$$

to give the recursion operator. The integrable equation can be written as

$$q_t = \eta q_{xx} - \frac{\eta r_q q_x^2}{r} + \frac{\eta_1 q_x}{E_1} - \frac{\eta_1 r}{\sqrt{\eta}}, \tag{28}$$

where η, η_1, E_1, E_2 are constants and r is a function of q.

B. Case (2)

The second class can be given with linearized equation

$$\Psi_t = \eta \Psi_{xx} + \left[\frac{2\eta r_{qq}}{r_q} q_x + 2\eta r + \eta_1\right]\Psi_x + \left[\frac{\eta(r_{qqq} r_q - r_{qq}^2)}{r_q^2} q_x^2 + 2\eta r_q q_x\right]\Psi \tag{29}$$

and compatible eigenvalue equation

$$\Psi_{xx} = \left[\frac{q_{xx}}{q_x} - \frac{q_x r_{qq}}{r_q} - r + \frac{E_1}{\sqrt{\eta}} k + \frac{E_2}{\sqrt{\eta}} k^2\right]\Psi_x + \left[\frac{r q_{xx}}{q_x} - \frac{(r_{qqq} r_q - r_{qq}^2) q_x^2}{r_q^2} - 2 r_q q_x - \frac{E_1 q_{xx}}{\sqrt{\eta} q_x} k - \frac{E_2 q_{xx}}{\sqrt{\eta} q_x} k^2\right]\Psi. \tag{30}$$

The equation above can be integrated,

$$\Phi = D + \frac{r_{qq}q_x}{r_q} + r + q_x D^{-1} r_q, \tag{31}$$

where $(D^{-1}f)(x)=\int_{-\infty}^{x} f(\zeta)d\zeta$. The integrable equation can be written as

$$q_t = \eta q_{xx} + \frac{\eta r_{qq} q_x^2}{r_q} + (2\eta r + \eta_1) q_x. \tag{32}$$

Here η,η_1 are constants and r is a function of q. The equations (28) and (32) correspond to the integrable equations of Fokas,[12] Ibragimov–Shabat[11] and recursion operators (27) and (31) are obtained by the integration of the eigenvalue equations.

IV. CLASSIFICATION OF $q_t=f(q,q_x,q_{xx},q_{xxx})$

We consider differential equations of the general form

$$q_t = f(q,q_x,q_{xx},q_{xxx}). \tag{33}$$

The linearization of the equation above takes the following form:

$$\Psi_t = \alpha\Psi_{xxx} + \beta\Psi_{xx} + \gamma\Psi_x + \delta\Psi. \tag{34}$$

Here $\alpha,\beta,\gamma,\delta$ are functions of q,q_x,q_{xx},q_{xxx}. We consider an eigenvalue equation having the same order as (33),

$$\Psi_{xxx} = A\Psi_{xx} + B\Psi_x + C\Psi, \tag{35}$$

using the expansion of A, B, and C as

$$A = A_0 + A_1 k + A_2 k^2, \quad B = B_0 + B_1 k + B_2 k^2, \quad C = C_0 + C_1 k + C_2 k^2, \tag{36}$$

where A_i, B_i, and C_i are functions of $q,q_x,q_{xx},q_{xxx},q_{xxxx}$. The compatibility of (34) and (35) will give us for $q_t=f(q,q_x,q_{xx},q_{xxx})$ four classes:[14,15]

(1) $q_t = L_1 q_{xxx} + L_2$,
(2) $q_t = (L_1 q_{xxx} + L_2)^{-2} + L_3$,
(3) $q_t = (L_1 q_{xxx} + L_2)^{-1/2} + L_3$, and
(4) $q_t = (2L_1 q_{xxx} + L_2)(L_1 q_{xxx}^2 + L_2 q_{xxx} + L_3)^{-1/2} + L_4$,

where L_1, L_2, L_3, and L_4 are functions of q,q_x,q_{xx}.

A. Classification of $q_t=L_1q_{xxx}+L_2$

The classification will determine algebraic equations,

$$\begin{gathered} A_1=0, \quad A_2=0, \quad B_0=-\frac{2\gamma}{3\eta}, \quad B_1=E_1, \quad B_2=E_2, \\ C_0=-\frac{1}{3\eta}(\gamma_x - 2\gamma A_0 + 2\delta), \quad C_1=-E_1A_0, \quad C_2=-E_2A_0, \end{gathered} \tag{37}$$

and evolution equations as follows:

$$A_{0,t} = \gamma_x A_0 + \delta_x + A_{0,xxx}\eta + 3A_{0,xx}\eta A_0 + 3A_{0,x}^2\eta + A_{0,x}\gamma + 3A_{0,x}\eta A_0^2, \tag{38}$$

$$\gamma_t=\tfrac{1}{2}(2\gamma_{xxx}\eta-3\gamma_{xx}\eta A_0-3\gamma_x A_{0,x}\eta+2\gamma_x\gamma-3\delta_{xx}\eta+6\delta_x\eta A_0+6A_{0,x}\delta\eta), \tag{39}$$

$$\begin{aligned}\delta_t=\tfrac{1}{4}(&3\gamma_{xxx}\eta A_0-6\gamma_{xx}\eta A_0^2-3\gamma_x A_{0,xx}\eta-12\gamma_x A_{0,x}\eta A_0\\&+4\gamma_x\delta+\delta_{xxx}\eta-6\delta_{xx}\eta A_0+4\delta_x\gamma+12\delta_x\eta A_0^2+6A_{0,xx}\delta\eta+24A_{0,x}\delta\eta A_0),\end{aligned} \tag{40}$$

where η,E_1,E_2 are constants.

B. Case (1)

The linearized form of the first subclass is in the form

$$\Psi_t=\eta\Psi xxx+\left[\frac{\rho_1}{2}q_x^2+\rho\right]\Psi_x+\rho_q q_x\Psi \tag{41}$$

with compatible eigenvalue equation

$$\begin{aligned}\Psi xxx=&\frac{q_{xx}}{q_x}\Psi_{xx}+\left[-\frac{\rho_1}{3\eta}q_x^2-\frac{2\rho}{3\eta}+E_1k+E_2k^2\right]\Psi_x\\&+\left[-\frac{-2\rho q_{xx}+3\rho_q q_x^2}{3\eta q_x}-\frac{E_1q_{xx}}{q_x}k-\frac{E_2q_{xx}}{q_x}k^2\right]\Psi,\end{aligned} \tag{42}$$

where ρ_1 is constant and ρ is a function of q with the condition

$$\rho_{qqq}+\frac{4\rho_1}{3\eta}\rho_q=0. \tag{43}$$

The recursion operator can be obtained by integration:

$$\Phi=D^2+\frac{\rho}{3\eta}+\frac{\rho_1}{3\eta}q_x^2-\frac{\rho_1}{3\eta}q_xD^{-1}q_{xx}+\frac{q_x}{\eta}D^{-1}\rho_q. \tag{44}$$

The integrable equation is in the form

$$q_t=\eta q_{xxx}+\frac{\rho_1}{6}q_x^3+\rho q_x. \tag{45}$$

C. Case (2)

The second subclass is given by the linearized equation

$$\Psi_t=\eta\Psi xxx+\left[\frac{\epsilon_1}{2}q_x^2+\epsilon_1\epsilon_2q_x+\epsilon_3\right]\Psi_x, \tag{46}$$

with compatible eigenvalue equation

$$\begin{aligned}\Psi xxx=&\frac{q_{xx}}{q_x+\epsilon_2}\Psi_{xx}+\left[-\frac{\epsilon_1}{3\eta}q_x^2-\frac{2\epsilon_1\epsilon_2}{3\eta}q_x-\frac{2\epsilon_3}{3\eta}+E_1k+E_2k^2\right]\Psi_x\\&+\left[-\frac{(\epsilon_2^2\epsilon_1-2\epsilon_3)q_{xx}}{3\eta(q_x+\epsilon_2)}-\frac{E_1q_{xx}}{q_x+\epsilon_2}k-\frac{E_2q_{xx}}{q_x+\epsilon_2}k^2\right]\Psi,\end{aligned} \tag{47}$$

where $\epsilon_1,\epsilon_2,\epsilon_3$ are constants. The recursion operator can be obtained by integration

$$\Phi=D^2+\frac{2\epsilon_3}{3\eta}+\frac{\epsilon_1}{3\eta}q_x^2+\frac{2\epsilon_1\epsilon_2}{3\eta}q_x-\frac{\epsilon_1}{3\eta}(q_x+\epsilon_2)D^{-1}q_{xx}. \tag{48}$$

The integrable equation is in the form

$$q_t=\eta q_{xxx}+\frac{\epsilon_1}{6}q_x^3+\frac{\epsilon_1\epsilon_2}{2}q_x^2+\epsilon_3 q_x. \tag{49}$$

Equations (45) and (49) are classified by Fokas,[12] Ibragimov–Shabat,[11] and recursion operators (44) and (48) are obtained by the integration of the eigenvalue equations.

D. Case (3)

The eigenvalue equation is

$$\begin{aligned}\Psi_{xxx}=&\left[\frac{q_{xxx}+\lambda_1 q_{xx}+\lambda_2 q_x}{q_{xx}+\lambda_1 q_x+\lambda_2 q}-\lambda_3\right]\Psi_{xx}+\left[\frac{\lambda_3(q_{xxx}+\lambda_1 q_{xx}+\lambda_2 q_x)}{q_{xx}+\lambda_1 q_x+\lambda_2 q}-\lambda_4+\frac{E_1}{\lambda_5^{2/3}}k+\frac{E_2}{\lambda_5^{2/3}}k^2\right]\Psi_x\\&+\left[\frac{\lambda_4(q_{xxx}+\lambda_1 q_{xx}+\lambda_2 q_x)}{q_{xx}+\lambda_1 q_x+\lambda_2 q}-\frac{E_1(q_{xxx}+\lambda_1 q_{xx}+\lambda_2 q_x)}{\lambda_5^{2/3}(q_{xx}+\lambda_1 q_x+\lambda_2 q)}k-\frac{E_2(q_{xxx}+\lambda_1 q_{xx}+\lambda_2 q_x)}{\lambda_5^{2/3}(q_{xx}+\lambda_1 q_x+\lambda_2 q)}k^2\right]\Psi,\end{aligned} \tag{50}$$

and the linearized equation has the form

$$\Psi_t=\lambda_5\Psi_{xxx}+\tfrac{3}{2}\lambda_3\lambda_5\Psi_{xx}+\tfrac{3}{2}\lambda_4\lambda_5\Psi_x+\lambda_6\Psi. \tag{51}$$

The recursion operator is

$$\Phi=D^2+\lambda_3 D+\lambda_4. \tag{52}$$

The integrable equation is

$$q_t=\lambda_5 q_{xxx}+\tfrac{3}{2}\lambda_3\lambda_5 q_{xx}+\tfrac{3}{2}\lambda_4\lambda_5 q_x+\lambda_6 q, \tag{53}$$

where E_1, E_2, λ_1, λ_2, λ_3, λ_4, λ_5, and λ_6 are constants. Rabelo and Tanenblat also obtained linear equation using the classification method of pseudo-spherical surfaces with Gaussian curvature (-1).[16]

E. New integrable equation in the form $q_t=(L_1 q_{xxx}+L_2)^{-2}+L_3$

The classification will give the following algebraic equations,

$$\begin{aligned}A_1&=\frac{E_1}{\alpha^{1/3}},\\C_1&=-\tfrac{1}{3}(\alpha_x\alpha^{-4/3}E_1+\beta\alpha^{-4/3}E_1+3A_0\alpha^{-1/3}E_1-\alpha^{-2/3}E_2),\end{aligned} \tag{54}$$

and evolution equations

$$\alpha_t = -\frac{1}{9E_1\alpha}\,(27\alpha^{2/3}A_{0,x}E_2\alpha^2 + 18\alpha^{2/3}\beta_x E_2\alpha + 9\alpha^{2/3}\alpha_{xx}E_2\alpha - 6\alpha^{2/3}\alpha_x^2E_2 + 9\alpha^{2/3}\alpha_x E_2A_0\alpha$$

The linearized equation is given by

$$\Psi_t = \left[-\frac{8(2q_{xx}E_2 + 9q_xE_1V_1)^3E_2^6}{27(2q_{xxx}E_2^2 + 27q_{xx}E_2E_1V_1 + 81q_xE_1^2V_1^2)^3E_1^3}\right]\Psi_{xxx} + \left[\frac{4(2q_{xxx}E_2 + 9q_{xx}E_1V_1)(2q_{xx}E_2 + 9q_xE_1V_1)^2E_2^6}{9(2q_{xxx}E_2^2 + 27q_{xx}E_2E_1V_1 + 81q_xE_1^2V_1^2)^3E_1^3}\right]\Psi_{xx} + \frac{\left[\begin{array}{c}(2((8E_2^4 + 2187E_1^4V_1E_3)q_{xx}^2E_2^2 + 18(4E_2^4 + 729E_1^4V_1E_3)q_{xx}q_xE_2E_1V_1 \\ + 81(2E_2^4 + 243E_1^4V_1E_3)q_x^2E_1^2V_1^2)q_{xxx}E_2^2V_1 + 324(q_{xx}E_2 + 3q_xE_1V_1)q_{xxx}^2E_2^4E_1^3V_1E_3 \\ + 2187(q_{xx}E_2 + q_xE_1V_1)(2E_2^4 + 243E_1^4V_1E_3)q_x^2E_1^3V_1^4 + 3(40E_2^4 + 6561E_1^4V_1E_3) \\ \times q_{xx}^3E_2^3E_1V_1^2 + 81(16E_2^4 + 2187E_1^4V_1E_3)q_{xx}^2q_xE_2^2E_1^2V_1^3 + 8q_{xxx}^3E_2E_1^2E_3)\end{array}\right]}{(2q_{xxx}E_2^2 + 27q_{xx}E_2E_1V_1 + 81q_xE_1^2V_1^2)^3E_1^2} \times \Psi_x + U_1\Psi \tag{61}$$

and the eigenvalue equation is

$$\Psi_{xxx} = \left[\frac{(4q_{xxx}E_2^2 - 81q_xE_1^2V_1^2)}{(2(2q_{xx}E_2 + 9q_xE_1V_1)E_2)} - \frac{3E_1^2(2q_{xxx}E_2^2 + 27q_{xx}E_2E_1V_1 + 81q_xE_1^2V_1^2)}{2E_2^2(2q_{xx}E_2 + 9q_xE_1V_1)}k\right]\Psi_{xx} + \left[\frac{9(2q_{xxx}E_2 + 9q_{xx}E_1V_1)E_1V_1}{2(2q_{xx}E_2 + 9q_xE_1V_1)E_2} + \frac{\left[\begin{array}{c}-3(4q_{xxxx}q_{xx}E_2^3 + 18q_{xxxx}q_xE_2^2E_1V_1 - 8q_{xxx}^2E_2^3] \\ -90q_{xxx}q_{xx}E_2^2E_1V_1 - 81q_{xxx}q_xE_2E_1^2V_1^2 \\ -324q_{xx}^2E_2E_1^2V_1^2 - 729q_{xx}q_xE_13V_1^3)E_1^2\end{array}\right]}{2(2q_{xx}E_2 + 9q_xE_1V_1)^2E_2^2}k\right] \times \Psi_x. \tag{62}$$

The eigenvalue equation can be integrated:

$$D^2 + \frac{9E_1V_1}{2E_2}D = -k\frac{3E_1^2(2q_{xxx}E_2^2 + 27q_{xx}E_2E_1V_1 + 81q_xE_1^2V_1^2)}{2E_2^2(2q_{xx}E_2 + 9q_xE_1V_1)}D. \tag{63}$$

The new integrable equation is in the form

$$q_t=\frac{2E_2^4(2q_{xx}E_2+9q_xE_1V_1)^3}{27E_1^3(2q_{xxx}E_2^2+27q_{xx}E_2E_1V_1+81q_xE_1^2V_1^2)^2}+E_3q_x+U_1q, \tag{64}$$

where E_1, E_2, E_3, U_1, and V_1 are constants. The equation above is a new integrable equation which is included in the MSS classification.[14]

F. $q_t=(L_1q_{xxx}+L_2)^{-1/2}+L_3$

The leading order term gives the differential equation as

$$-3f_{q_{xxx},3}f_{q_{xxx}}+5(f_{q_{xxx},2})^2=0. \tag{65}$$

The solution to (65) is given by

$$q_t=(L_1q_{xxx}+L_2)^{-1/2}+L_3, \tag{66}$$

where L_1, L_2, and L_3 are functions of q,q_x,q_{xx}. The classification has not been finished yet due to computer limitations. One integrable equation in this class is given by eigenvalue equation

$$\Psi_{xxx}=\left[-D_1+\frac{E_1}{2^{1/2}E_2^{2/3}}(E_2q_{xxx}+E_2D_1q_x+E_2^{2/3}D_2)k\right]\Psi_x+\left[\frac{E_1E_2^{1/3}}{2^{1/3}}(q_{xxx}+D_1q_{xx})k\right]\Psi \tag{67}$$

and linearized equation

$$\Psi_t=-\frac{E_2}{(E_2q_{xxx}+E_2D_1q_x+E_2^{2/3}D_2)^{3/2}}\Psi_{xxx}-\frac{E_2D_1}{(E_2q_{xxx}+E_2D_1q_x+E_2^{2/3}D_2)^{3/2}}\Psi_x. \tag{68}$$

The eigenvalue equation (67) can be integrated to give the recursion operator

$$\Phi=D^2+D_1. \tag{69}$$

The integrable equation is given by

$$q_t=\frac{1}{(E_2q_{xxx}+E_2D_1q_x+E_2^{2/3}D_2)^{1/2}}+E_3q_x, \tag{70}$$

where E_1, E_2, E_3, D_1, and D_2 are constants. This integrable equation is included in S-integrable equations of Calogero.[17]

G. $q_t=(2L_1q_{xxx}+L_2)(L_1q_{xxx}^2+L_2q_{xxx}+L_3)^{-1/2}+L_4$

The differential equation coming from the leading order is

$$-3f_{q_{xxx},3}f_{q_{xxx}}+5(f_{q_{xxx},2})^2+3\frac{f_{q_{xxx},2}f_{q_{xxx}}}{q_{xxx}+K_1}=0, \tag{71}$$

where $K_1=K_1(q,q_x,q_{xx})$. The general solution is given by

$$q_t=(2L_1q_{xxx}+L_2)(L_1q_{xxx}^2+L_2q_{xxx}+L_3)^{-1/2}+L_4; \tag{72}$$

here L_1,L_2,L_3,L_4 are functions to be determined. The classification of the type of nonlinear partial differential equations above has not been finished yet due to present limitations in the computing system; we hope to have an extension of the system in the near future.

V. CONCLUSION AND COMPARISON

According to Fokas,[1] an integrable equation possess infinitely many generalized symmetries. Although there exist algorithmic ways of finding symmetries, it is better to use another approach. One can obtain one symmetry and using the recursion operator infinitely many symmetries can be generated. Therefore the first step in finding out the integrability of an equation is to find a Lie–Bäcklund symmetry. Apparently, there exists an intimate connection between linearization and Fokas' symmetry approach. The existence of generalized symmetry manifests itself in the existence of a Lie–Bäcklund operator. The existence of infinitely many symmetries is expressed by the existence of a recursion operator. There is also a close relationship[12] between a Lie–Bäcklund operator and a linearized equation. Because, if Fokas' admissible Lie–Bäcklund operator is applied on the evolution equation, we obtain the Fréchet derivative of the equation under consideration or linearized form of our equation. The recursion operator in linearization is obtained by the integration of the eigenvalue equation.

Let us briefly recall Olver's symmetry approach, linearization test, and Mikhailov–Shabat–Sokolov formal symmetry method:

Olver's symmetry test: The equation $u_t=f[u]$ is integrable if there exists infinitely many non-Lie point symmetries or, equivalently, one non-Lie point symmetry and a recursion operator. The recursion operator and time-independent part of the linearized equation form a Lax pair $\Phi_t+[\Phi,D_f]=0$.

Linearization test: The equation $u_t=f[u]$ is integrable if there exists an eigenvalue equation $H\Psi=0$ such that it is compatible with linearized equation $\Psi_t=D_f(\Psi)$. The compatibility condition is $H_t+[H,\ D_f]=0$.

Mikhailov–Shabat–Sokolov formal symmetry test: The equation $u_t=f[u]$ is integrable if there exists a pseudo-differential operator L such that $L_t+[L,\ D_f]=0$ holds up to sufficiently low orders.

In all three approaches the crucial point is the existence of the recursion operator. In MSS formal symmetry and Olver–Fokas symmetry approaches, to get a recursion operator is not as easy as in the linearization test. These methods are useful for classification purposes, because they can be applied to arbitrary equations (without polynomial restriction).

We must also mention that our classification is up to a change of variables. There are partial differential equations which are not included in the classification (IV.), but they can be obtained by a transformation.[17] [For example, Eq. (3.13) in Ref. 1 by extended hodograph transformation.] On the other hand, there are equations which appear in the same class, and are related to each other by a Miura-type transformation. Moreover, there may be other integrable equations that do not appear in the classification (IV.), because of a different eigenvalue problem.

The main idea in this work is to give a new definition of integrability. We conjecture that a partial differential equation is integrable if its linearized equation can support an eigenvalue equation. This definition implements a method to check whether a given partial differential equation is integrable. In addition, one can search an integrable subclass of a given class of partial differential equation. Linearization is also compared with Fokas's symmetry and Mikhailov–Shabat–Sokolov formal symmetry approaches.

ACKNOWLEDGMENT

I would like to thank M. Gürses for suggesting the problem, P. Tolun for her careful reading and comments on the manuscript, and the referee for constructive comments and suggestions.

A Rodriguez formula and integration measure for the quantum deformed Legendre functions

Jeffrey R. Schmidt
Department of Physics, University of Wisconsin–Parkside, Kenosha, Wisconsin 53141-2000

(Received 28 April 1995; accepted for publication 20 February 1996)

Quantum deformed analogs of the Legendre functions are constructed from shift operator representations of the quantum deformed orbital angular momentum operators. A Rodriguez formula is found as well as the measure used to orthonormalize the functions. © *1996 American Institute of Physics.*
[S0022-2488(96)00406-9]

I. INTRODUCTION

The representations of quantum deformed Lie algebras in terms of difference operators shows a rich variety of structure that can be traced to the nonuniqueness of the representations.[1] For example, recent work[2] on quantum su(2) has produced analytical realizations whose basis functions are rational rather than polynomial in nature. These functions do not conform simply to the standard classes of quantum deformed orthogonal polynomials but are interesting in their own right. The classical Legendre polynomials do have well known but not widely used rational forms. These do not appear naturally as eigenfunctions of differential operators in physics in the commonly used coordinate systems. In this paper we will show that the quantum deformed orbital angular momentum operators possess quantum analogs of these verions of the Legendre functions as their representation basis functions. From this knowledge a Rodriguez formula will be found and used to orthonormalize the functions.

II. AN OPERATOR REPRESENTATION OF $so(3)_q$

It is a simple matter to construct a difference operator representation of the angular momentum operators much in the spirit of Ref. 1. The product relations for the algebra are

$$[J_z, J_+]=J_+, \tag{1}$$

$$[J_z, J_-]=-J_-, \tag{2}$$

$$[J_+, J_-]=\frac{q^{2J_z}-q^{-2J_z}}{q-q^{-1}}. \tag{3}$$

In the hope that a realization in terms of operators acting on functions over the sphere S^2 can be found, we require that

$$J_z=\frac{1}{i}\frac{\partial}{\partial\phi}, \tag{4}$$

in which ϕ is the azimuthal angle on the sphere. The first two commutators essentially state that

$$J_+=e^{i\phi}o_+ \tag{5}$$

and

0022-2488/96/37(6)/3062/11/$10.00

$$J_- = e^{-i\phi} o_- , \tag{6}$$

in which the two operators o_+ and o_- have no ϕ dependence. For now we think of them as acting on a remaining variable x which must be a function of the polar angle θ. We define the deformation parameter q to be

$$q = e^s . \tag{7}$$

The remaining product (3) suggests the forms

$$J_+ = e^{i\phi}(A(x)e^{is\partial_\phi} + B(x)e^{-is\partial_\phi} + c(x)), \tag{8}$$

$$J_- = e^{-i\phi}(A^+(x)e^{is\partial_\phi} + B^+(x)e^{-is\partial_\phi} + c^+(x)), \tag{9}$$

in which for now $(+)$ does not necessarily mean adjoint. We further imagine that c and c^+ must contain difference operators that provide derivatives with respect to θ as q approaches 1, and so we define

$$c = ue^{is\partial_x}, \tag{10}$$

$$c^+ = u^+ e^{is\partial_x}. \tag{11}$$

Substitution into the products (1)–(3) gives six relations on the operators A, B, c, A^+, B^+, c^+ that seem to have only exponential solutions. A convenient set of solutions is

$$A = -B^+ = \frac{e^{-ix}}{q - q^{-1}}, \tag{12}$$

$$B = -A^+ = \frac{e^{ix}}{q - q^{-1}}, \tag{13}$$

$$u = -u^+ = -\frac{e^{ix} + e^{-ix}}{q - q^{-1}}. \tag{14}$$

This last choice of u is made to cancel terms of order s^{-1} as the limit q approaches 1. The limits of these operators as q goes to 1 do not agree with the standard orbital angular momentum operators and so we define

$$x = i \ln \tan \frac{\theta}{2}, \tag{15}$$

which gives the operators the correct undeformed limit. The full set of q-deformed angular momentum operators can now be displayed in terms of θ and ϕ:

$$J_z = \frac{1}{i}\frac{\partial}{\partial \phi}, \tag{16}$$

$$J_+ = \frac{e^{i\phi}}{q - q^{-1}}\left(\tan\frac{\theta}{2} e^{is\partial_\phi} + \cot\frac{\theta}{2} e^{-is\partial_\phi} - \frac{2}{\sin\theta} e^{s \sin\theta \partial_\theta}\right), \tag{17}$$

$$J_- = \frac{e^{-i\phi}}{q - q^{-1}}\left(-\cot\frac{\theta}{2} e^{is\partial_\phi} - \tan\frac{\theta}{2} e^{-is\partial_\phi} + \frac{2}{\sin\theta} e^{s \sin\theta \partial_\phi}\right). \tag{18}$$

These are in agreement with the results of Ref. 2.

III. HIGHEST WEIGHT EIGENFUNCTIONS

The highest weight eigenfunctions in the $2j+1$-dimensional subspace is the function annihilated by J_+:

$$(q^{-j}e^{-ix}+q^{j}e^{ix}-(e^{ix}+e^{-ix})e^{-is\partial_x})e^{ij\phi}\psi_{jj}=0. \tag{19}$$

This suggests the unusual form

$$\psi_{jj}=\frac{1}{\Sigma_n a_n e^{inx}}, \tag{20}$$

in which the coefficients have the recursion relation

$$a_{m+1}=-\frac{1-q^{j-m-1}}{1-q^{-(j+m+1)}}\,a_{m-1}. \tag{21}$$

This separates the solutions into even and odd cases; for example, in the even case the coefficients become

$$a_{2n}(q)=a_{-2n}(-q)=(-1)^n\prod_{m=0}^{n-1}\frac{1-q^{j-2m}}{1-q^{-(j+2m+2)}}, \tag{22}$$

and in both cases the q-binomial theorem allows the series solution to be expressed as

$$\psi_{jj}=\frac{e^{ij\phi}e^{ijx}}{\Pi_{m=1}^{j}(1+q^{2m}e^{2ix})}. \tag{23}$$

IV. THE q-LEGENDRE FUNCTIONS

The states annihilated by J_z would correspond to a q-analog of the Legendre functions. The most expedient way to build them is by solving the eigenvalue equation for the quadratic Casimir operator with the appropriate eigenvalue. The operator C_2 can be written as

$$\begin{aligned}(q-q^{-1})C_2=&(e^{ix}+e^{-ix})(q^{-1}e^{ix}+qe^{-ix})(q^{i\partial_x-i\partial_\phi}+q^{i\partial_x+i\partial_\phi}-q^{2i\partial_x})\\&-(q^{-1}e^{2ix}+qe^{-2ix}+2)\end{aligned} \tag{24}$$

and it has eigenvalues

$$\frac{(q^{j+1/2}-q^{-(j+1/2)})^2}{(q-q^{-1})^2}. \tag{25}$$

The issue of adjoint formation will be addressed in the section on the orthogonality of the eigenfunctions. Application of the Casimir operator to the sought-after function ψ_{j0} results in the equation

$$(2e^{is\partial_x}-e^{2is\partial_x})\psi_{j0}=\frac{q^{2j+1}+q^{-(2j+1)}+q^{-1}e^{2ix}+qe^{-2ix}}{(q^{-1}e^{2ix}+q+q^{-1}+qe^{-2ix})}\,\psi_{j0}. \tag{26}$$

Let $z=e^{ix}$ and extract the denominator from ψ_{j0} by defining

$$\psi_{j0}=\frac{f_j(z)}{\Pi_{n=1}^{j}(1+q^{2n}z^2)}, \tag{27}$$

and the result is that the numerator satisfies a difference equation

$$2(1+z^2)f_j(z)-(1+q^{2j}z^2)f_j(q^{-1}z)=(1+q^{-2j}z^2)f_j(qz), \tag{28}$$

which can be solved recursively for the series

$$f_j(z)=\sum_{m=0}^{j}(-1)^m\prod_{p=1}^{m}\left(\frac{q^{j-(p-1)}-q^{-(j-(p-1))}}{q^p-q^{-p}}\right)^2 z^{2m}. \tag{29}$$

The coefficients of z^{2m} are simply related to the Gaussian polynomials. Let

$$\binom{n}{m}_q=\frac{(q-q^{-1})(q^2-q^{-2})\cdots(q^n-q^{-n})}{(q-q^{-1})\cdots(q^m-q^{-m})(q-q^{-1})\cdots(q^{n-m}-q^{-(n-m)})}, \tag{30}$$

which reduces to the binomial coefficient as q goes to 1. Then our final expression for the q-Legendre function

$$\psi_{j0}=\frac{\Sigma_{m=0}^{j}(-1)^m\binom{j}{m}_q^2 z^{2m}}{\Pi_{m=1}^{j}(1+q^{2m}z^2)}, \tag{31}$$

is an obvious q-analog of a common rational expression for the Legendre functions

$$P_n(t)=\frac{\Sigma_{m=0}^{n}\binom{n}{m}^2 t^{2m}}{(1-t)^n}. \tag{32}$$

The substitution $x=(1+t)/(1-t)$ reduces this to the standard Legendre polynomial which can be shown by computing the generating function

$$2\pi\sum_{n=0}^{\infty}P_n(t)u^n=\int_0^{\infty}\sum_{n=0}^{\infty}\left(\frac{u(1+e^{i\theta}\sqrt{t})(1+e^{-i\theta}\sqrt{t})}{(1-t)}\right)^n d\theta=\frac{2\pi}{\sqrt{1-2u((1+t)/(1-t))+u^2}}. \tag{33}$$

In the classical case the Rodriguez formula is the equation

$$P_n=P_{n0}=(J_-)^nP_{nn}=\left[(1+t)^2\frac{d}{dt}\right]^n\left(\frac{t}{(1-t)^2}\right)^n, \tag{34}$$

in the rational representation, up to a normalization factor. The same route to a Rodriguez formula for the q-deformed functions can be followed. We define scale operators

$$d_+F(z)=F(qz), \tag{35}$$

$$d_-F(z)=F(q^{-1}z), \tag{36}$$

and the Jackson derivatives

$$\nabla_-F(z)=\frac{F(z)-F(q^{-1}z)}{z(1-q^{-1})}=\frac{1-d_-}{z(1-q^{-1})}F(z), \tag{37}$$

$$\nabla_+ F(z) = \frac{1-d_+}{z(1-q)} F(z), \tag{38}$$

change variables $z = e^{ix}$, and extract the ϕ dependence from ψ_{jm},

$$\psi_{jm} = e^{im\phi} g_{jm}(z). \tag{39}$$

The action of the lowering operators on the functions g_{jm} can be expressed as

$$g_{j(j-1)} = -z^{-1}[q^j(1+q^{-2j}z^2) - (1+z^2)d_-]g_{jj}, \tag{40}$$

$$g_{j(m-1)} = -z^{-1}[q^m(1+q^{-2m}z^2) - (1+z^2)d_-]g_{jm}. \tag{41}$$

The operator identity

$$\begin{aligned}(1-q^{-1})z^{-j}q^j(1+z^2)\cdots(1+q^{-2j}z^2)\nabla_- \frac{z^j F(z)}{(1+z^2)\cdots(1+q^{-2j+2}z^2)} \\ = z^{-1}[q^j(1+q^{-2j}z^2) - (1+z^2)d_-]F(z)\end{aligned} \tag{42}$$

allows us to write g_{j0} as the result of a q-power of an operator on g_{jj} by defining

$$D_m = q^m[-z^{-1}(1+q^{-2m}z^2)(1+q^{-2m+2}z^2)\nabla_-], \tag{43}$$

and by writing out repeated applications of J_- to g_{jj} we see cancellations of most of the binomials in the operator identity result in the compact expression

$$g_{j0} = D_1 D_2 \cdots D_j \left[\frac{z^j g_{jj}}{(1+z^2)\cdots(1+q^{-2j+2}z^2)}\right]. \tag{44}$$

This form will be particularly useful in the section in which the normalization integral is computed.

V. ORTHOGONALITY AND MEASURE

The functions g_{j0} are the q-Legendre functions but in an unnormalized state. They can be shown to be an orthogonal set with respect to a suitably chosen measure $\mu(z)$ on the positive z axis. Actual construction of the measure is simpler in the present case than in the examples of Refs. (3)–(5) because of the availability of the Rodriguez formula. The measure should be chosen if any ambiguity in its construction arises to have the expected classical limit as q approaches 1. The appropriate measure can be gotten quickly from the requirement that g_{00} be orthogonal to all g_{j0} for $j>0$. We write this condition as

$$\int_0^\infty \mu(z)(-z^{-1}(1+z^2)(1+q^{-2}z^2))\nabla_- \left[\frac{z^2 g_{j1}}{(1+z^2)(1+q^2z^2)}\right] dz = 0, \tag{45}$$

and now q-integrate by parts

$$\int_0^\infty \frac{z^2 g_{j1}}{(1+z^2)(1+q^2z^2)} \nabla_+ [q\mu(z)z^{-1}(1+z^2)(1+q^{-2}z^2)] dz = 0, \tag{46}$$

from which we see that

$$\mu(z)=\frac{z}{(1+z^2)(1+q^{-2}z^2)}, \tag{47}$$

up to a multiplicative factor. This does reduce to the correct classical limit. Now the orthogonality proof can proceed in the same way as in the classical case: express each function in terms of the Rodriguez formula and integrate by parts to move lowering operators from one function onto the other where they act as raising operators. This continues until a sufficient number act on the target function to annihilate it. An expedient would be a similar set of operator identities for the raising operator, such as the following:

$$g_{j1}=[(z+z^{-1})-(z+z^{-1})d_-]g_{j0}=(1+z^2)\nabla_- g_{j0}, \tag{48}$$

$$g_{j2}=[(zq+z^{-1}q^{-1})-(z+z^{-1})d_-]g_{j1}=q^{-1}z\nabla_- z^{-1}(1+q^2z^2)g_{j1}, \tag{49}$$

$$g_{j3}=[(zq^2+z^{-1}q^{-2})-(z+z^{-1})d_-]g_{j2}=\frac{q^{-2}z^2}{(1+q^2z^2)}\,(\nabla_- z^{-2}(1+q^2z^2)(1+q^4z^2))g_{j2}. \tag{50}$$

We now illustrate with an example, showing g_{20} and g_{10} are orthogonal. An operator O is interposed on the possibility that it may be needed and to facilitate simplification of the resulting expression:

$$\begin{aligned}&\int_0^\infty \mu(z)\left[qz^{-1}(1+z^2)(1+q^{-2}z^2)\nabla_- \frac{z}{(1+z^2)}\right]\\&\quad\times[q^2z^{-2}(1+z^2)(1+q^{-2}z^2)(1+q^{-4}z^2)\nabla_- \frac{z^2g_{22}}{(1+z^2)(1+q^2z^2)}]Og_{10}\,dz\\&\quad=-q\int_0^\infty\left[q^3z^{-1}(1+q^{-4}z^2)\nabla_- \frac{z^2g_{22}}{(1+z^2)(1+q^2z^2)}\right]\\&\qquad\times(1+q^{-2}z^2)\nabla_+ Og_{10}\,dz.\end{aligned} \tag{51}$$

If this process is to be the q-analog of the classical version, then we must have

$$(1+q^{-2}z^2)\nabla_+ Og_{10}=Og_{11}, \tag{52}$$

from which it is evident that the operator O decomposes into

$$O=d_-I, \tag{53}$$

in which the operator I transforms q into q^{-1} so that

$$(1+q^{-2}z^2)\nabla_+ d_-Ig_{10}=d_-I(1+z^2)\nabla_- g_{10}=d_-Ig_{11}. \tag{54}$$

Subsequent integrations by parts have the desired effect of raising d_-Ig_{11} past the point of no return:

$$\begin{aligned}&q^2\int_0^\infty q^3\,\frac{zg_{22}}{(1+z^2)(1+q^2z^2)}\,z\nabla_+ z^{-1}(1+q^{-4}z^2)d_-Ig_{11}dz\\&\quad=q^5\int_0^\infty\frac{zg_{22}}{(1+z^2)(1+q^2z^2)}\,d_-I[z\nabla_- z^{-1}(1+q^2z^2)g_{11}]dz=0,\end{aligned} \tag{55}$$

by the use of Eq. (49). The proof that the functions g_{j0} are orthogonal can now proceed as in the classical case along with a proof that J_+ and J_- are formal adjoints. First define the action of J_+ and J_- on g_{jm} in terms of the step operators

$$g_{j(m-1)}=J^m_{m-1}g_{jm}, \tag{56}$$

$$g_{j(m)}=J^{m-1}_{m}g_{j(m-1)}. \tag{57}$$

Now we develop by use of the operator identities

$$J^0_1=(1+z^2)\nabla_-, \tag{58}$$

$$J^1_2=q^1z\nabla_-z^{-1}(1+q^2z^2), \tag{59}$$

$$J^m_{m+1}=q^{-m}\frac{z^m}{(1+q^2z^2)\cdots(1+q^{2(m-1)}z^2)}\nabla_-z^{-m}(1+q^2z^2)\cdots(1+q^{2m}z^2), \tag{60}$$

$$J^1_0=qz^{-1}(1+z^2)(1+q^2z^2)\nabla_-\frac{z}{(1+z^2)}, \tag{61}$$

$$J^m_{m-1}=q^mz^{-m}(1+z^2)\cdots(1+q^{-2m}z^2)\nabla_-\frac{z^m}{(1+z^2)\cdots(1+q^{-2m+2}z^2)}, \tag{62}$$

a shorthand notation for the step operators.
Let

$$U_m=z^{-m}\prod_{n=1}^{m}(1+q^{2n}z^2), \tag{63}$$

$$V_m=z^{-m}\prod_{n=0}^{m}(1+q^{-2n}z^2), \tag{64}$$

with $U_0=1$ and $V_0=(1+z^2)$. Then the step operators can be written as

$$J^m_{m+1}=q^{-m}zU^{-1}_{m-1}\nabla_-U_m, \tag{65}$$

$$J^m_{m+1}=q^mV_m\nabla_-zV^{-1}_{m-1}. \tag{66}$$

The additional operator identity is trivial to prove:

$$d_-IV_m=q^mz^{-1}(1+z^2)(1+q^{-2}z^2)U_{m-1}d_-I. \tag{67}$$

Now apply this to $\Pi^j_1J^n_{n-1}$:

$$d_-I\prod_{n=2}^{j}J^n_{n-1}=z^{-1}(1+z^2)(1+q^{-2}z^2)\left[\prod_{n=2}^{j}(-q^{-n}U_{n-1}\nabla_+U^{-1}_{n-2})\right]\times\frac{z}{(1+z^2)(1+q^{-2}z^2)}d_-I. \tag{68}$$

Apply it to J^1_0:

$$d_-Iqz^{-1}(1+z^2)(1+q^{-2}z^2)\nabla_- \frac{z}{(1+z^2)}$$

$$=q^{-1}z^{-1}(1+z^2)(1+q^{-2}z^2)\nabla_+ \frac{z}{(1+q^{-2}z^2)}\, d_-I. \tag{69}$$

Put the two pieces together and use the definition of $\mu(z)$ to obtain

$$d_-I\prod_{n=1}^{j} J_{n-1}^n = q^{-1}\mu^{-1}(z)\prod_{n=2}^{j} (-q^{-n}U_{n-1}\nabla_+ zU_{n-2}^{-1})\mu(z)d_-I. \tag{70}$$

The factors in the product are precisely the transposes of the step-up operators and will be converted into J_{n+1}^n in turn upon integration by parts. In addition we have shown how to construct adjoints

$$\int_0^\infty \mu(z)F(z)d_-IJ_{m-1}^m G(z)dz = \int_0^\infty \mu(z)F(z)\mu^{-1}(z)q^{-m}U_{m-1}\nabla_+ zU_{m-2}^{-1}d_-IG(z)dz$$

$$=-\int_0^\infty U_{m-2}^{-1}z\nabla_- U_{m-1}q^{-m}F(z)\mu(z)d_-IG(z)dz$$

$$=\int_0^\infty \mu(z)J_m^{m-1}F(z)d_-IG(z)dz. \tag{71}$$

The proof of orthogonality is now obvious, partial integrations move lowering operators from g_{0j} onto g_{0k} and in the process makes them into raising operators. If $j>k$, this results in the annihilation of g_{0k}.

VI. THE NORMALIZATION INTEGRAL

The norm of g_{j0} can also be computed from the Rodriguez formula. Notice that the norm of g_{00} is well defined in the limit as q approaches 1 and $\mu(z)dz$ reduces correctly to $\sin\theta\, d\theta$ in that limit,

$$N_{00}=\int_0^\infty \frac{q^{-2}\, dy}{(1+y)(1+q^{-2}y)}=\frac{2\ln q}{(1-q^{-2})}. \tag{72}$$

We now demonstrate that

$$D_1D_2\cdots D_j \frac{z^{2j}}{\Pi_{n=1}^{2j}(1+q^{2n}z^2)}=q^{-j^2}\frac{(1-q^{-2})\cdots(1-q^{-2j})\Sigma_{n=0}^{j}(-1)^n(\begin{smallmatrix}j\\n\end{smallmatrix})_q{}^2 z^{2n}}{(1-q^{-1})\cdots(1-q^{-1})\Pi_{n=1}^{j}(1+q^{2n}z^2)}. \tag{73}$$

That this is true up to an overall multiplicative factor has already been established; now that factor is to be determined. The fastest path to this end is to notice that the numerator of the left-hand size of (73) always contains a term of order z^{2j}. The coefficient can be found by tracking its value with each application of a D_k operator with the result

$$q^{-j^2}\frac{(1-q^{-2})\cdots(1-q^{-2j})}{(1-q^{-1})\cdots(1-q^{-1})}, \tag{74}$$

as the coefficient of z^{2j}. The operators D_n to the right of d_-I in the expression

$$N_{jj}=\int_0^\infty \mu(z)\left[D_1\cdots D_j\left(\frac{z^j g_{jj}}{\Pi_0^{j-1}(1+q^{-2n}z^2)}\right)\right]d_-I\left[D_1\cdots D_j\left(\frac{z^j g_{jj}}{\Pi_0^{j-1}(1+q^{2n}z^2)}\right)\right]dz \quad (75)$$

are now passed through d_-I and moved by partial integration onto the first factor in the integral resulting in

$$N_{jj}=(-q)^j\int_0^\infty \mu(z)\left[D_{-j}\cdots D_{-1}D_1\cdots D_j\left(\frac{z^j g_{jj}}{\Pi_0^{j-1}(1+q^{-2n}z^2)}\right)\right]$$
$$\times d_-I\left[\left(\frac{z^j g_{jj}}{\Pi_0^{j-1}(1+q^{2n}z^2)}\right)\right]dz, \quad (76)$$

where

$$D_{-m}=q^{-m}z^{-1}(1+q^{2m-2}z^2)(1+q^{2m}z^2)\nabla_-. \quad (77)$$

The evaluation of the long string of D_{-k} operators on g_{j0} can be accomplished recursively by writing

$$g_{j0}=\frac{\Sigma_{n=0}^j A_n^{(0)}z^{2n}}{\Pi_{n=1}^j(1+q^{2n}z^2)}, \quad (78)$$

$$D_{-1}g_{j0}=\frac{\Sigma_{n=0}^j A_n^{(1)}z^{2n}}{\Pi_{n=2}^j(1+q^{2n}z^2)}, \quad (79)$$

$$\vdots$$

$$D_{-k}\cdots D_{-1}g_{j0}=\frac{\Sigma_{n=0}^j A_n^{(k)}z^{2n}}{\Pi_{n=k+1}^j(1+q^{2n}z^2)}. \quad (80)$$

Since the coefficients $A_m^{(0)}$ are already known, this recursive tower can be solved for

$$A_m^{(1)}=\frac{(-1)^m}{1-q^{-1}}\begin{pmatrix} j \\ m \end{pmatrix}_q^2 \frac{(1-q^{-2m})(1-q^{2j+2})}{(1-q^{2j+2-2m})}, \quad (81)$$

$$A_m^{(2)}=\frac{(-1)^m}{(1-q^{-1})^2}\begin{pmatrix} j \\ m \end{pmatrix}_q^2 \frac{(1-q^{-2m})(1-q^{2-2m})(1-q^{2j+2})(1-q^{2j+4})}{(1-q^{2j+2-2m})(1-q^{2j+4-2m})}, \quad (82)$$

$$\vdots.$$

The process terminates in

$$A_j^{(j-1)}=q^{-(j+2)(j-1)}\frac{(1-q^{2j})(1-q^{2j+2})\cdots(1-q^{4j-2})}{(1-q^2)(1-q^{-1})^{j-1}} \quad (83)$$

and

$$D_{-(j-1)}\cdots D_{-1}g_{j0}=A_j^{(j-1)}\frac{(1-z^2)}{(1+q^{2j}z^2)}. \quad (84)$$

The final expression for N_{jj} is

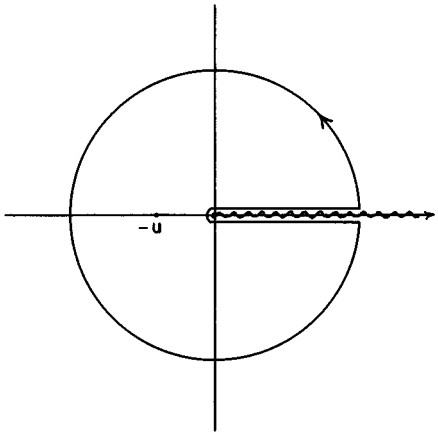

FIG. 1. Path of integration for (87).

$$N_{jj}=\frac{(1-q^{-2})\cdots(1-q^{-4j})}{(1-q^{-1})\cdots(1-q^{-1})}\int_0^\infty \frac{z^{2j+1}\,dz}{(1+q^{-2j}z^2)(1+q^{-2j+2}z^2)\cdots(1+q^{2j+2}z^2)}, \tag{85}$$

$$N_{jj}=2q^{2j(j+1)}\,\frac{(1-q^{-2})\cdots(1-q^{-4j})}{(1-q^{-1})\cdots(1-q^{-1})}\int_0^\infty \frac{y^j\,dy}{(1+y)\cdots(1+q^{4j+2}y)}. \tag{86}$$

This integral is of the form

$$I_{k,N}=\int_0^\infty \frac{y^{k-1}\,dy}{\Pi_{n=0}^N(u^n+y)}, \tag{87}$$

which can be evaluated by contour integration using the contour shown in the figure with branch cut extending to infinity, with result

$$I_{k,N}=\frac{2\pi i(-1)^{N+k-1}}{1-e^{2\pi ik}}\sum_{p=0}^{N}\frac{u^{-pN+p(p-1)/2+pk}(-1)^p}{(u)_p(u)_{N-p}}. \tag{88}$$

The sum can be performed using the q-binomial theorem

$$I_{k,N}=\frac{2\pi i}{1-e^{2\pi ik}}\,(-1)^{N+k-1}\,\frac{(u^{k-N})_N}{(u)_N}, \tag{89}$$

in which

$$(u)_N=(1-u)(1-u^2)\cdots(1-u^N). \tag{90}$$

For the case in which k is an integer, L'Hopital's rule gives

$$I_{k,N}=\frac{\ln u}{(1-u^N)\binom{N-1}{k-1}_u}. \tag{91}$$

The present usage of this integral has $u=q^{-2}$, $k=j+1$, and $N=2j+1$ with the conclusion that the functions

$$N_j D_1 \cdots D_j \left(\frac{z^{2j}}{\Pi_{n=1}^{2j}(1+q^{2n}z^2)} \right), \tag{92}$$

with

$$N_j = \sqrt{\frac{(1-q^{-2(2j+1)})(1-q^{-1})^{2j}}{2(1-q^{-2})^2 \cdots (1-q^{-2j})^2 \ln q^{-2}}}, \tag{93}$$

form an orthonormal set of rational functions on the positive ray that are q deformations of the rational form of the Legendre functions. The normalization coefficient N_j correctly reduces to

$$N_j = \frac{1}{2^j j!} \sqrt{\frac{2j+1}{2}}, \tag{94}$$

in the limit as q approaches 1.

It has recently been discovered [A. A. Ungar, Am. J. Phys. **59**, 824 (1991); **60**, 815 (1992)] that the set $\mathbb{R}_c^3=\{\mathbf{v}\in\mathbb{R}^3 : \|\mathbf{v}\|<c\}$ of all relativistically admissible velocities in Euclidean three-space $\mathbb{R}^3$, with a binary operation $\oplus$ given by relativistic velocity addition, forms a gyrogroup $(\mathbb{R}_c^3,\oplus)$. The gyrogroup $(\mathbb{R}_c^3,\oplus)$ reduces to the group $(\mathbb{R}^3,+)$ in the limit $c\to\infty$, $+$ being the prerelativistic velocity addition (that is, the ordinary vector addition in the Euclidean three-space $\mathbb{R}^3$). The binary operation $\oplus$ in $\mathbb{R}_c^3$ is *gyroassociative* and *gyrocommutative*, as opposed to the binary operation $+$ in $\mathbb{R}^3$ which is associative and commutative. In this article we extend the study of gyrogroups into that of Lorentz groups. In particular, we find that a gyrogroup must be equipped with a *cocycle form* in order to be extendible into a Lorentz group. We thus study gyrogroups that are equipped with a cocycle form, and their resulting Lorentz groups. Interestingly, the cocycle form needed for the extension of gyrogroups into Lorentz groups involves a *cocycle identity* which is known to be useful in various branches of mathematics [B. R. Ebanks and C. T. Ng, Aequat. Math. **46**, 76 (1993)]. © *1996 American Institute of Physics.* [S0022-2488(96)01606-6]

I. INTRODUCTION

The relevance of gyrogroup theory to the study of real and complex Lorentz groups has been demonstrated in Refs. 1–4. The use of the real $(1+3)$-dimensional Lorentz group in the special theory of relativity (STR) is well known; and a use of a complex Lorentz group in quantum mechanics is presented in Ref. 5. The Lorentz group of STR is parametrizable by (i) relativistically admissible velocities and (ii) orientations. The values of the orientation parameter form a group, SO(3), under rotation composition; and the values of the velocity parameter form a nongroup *gyrogroup*, $(\mathbb{R}_c^3, \oplus)$, under relativistic velocity addition $\oplus$. The gyrogroup operation $\oplus$ in $\mathbb{R}_c^3=\{\mathbf{v}\in\mathbb{R}^3 : \|\mathbf{v}\|<c\}$ turns out to be *gyrocommutative* and *gyroassociative*, as opposed to the prerelativistic velocity addition $+$ in $\mathbb{R}^3$ which is both commutative and associative.

The prefix *gyro-* that we extensively use stems from analogies shared with *Thomas gyration*. Thomas gyration, in turn, is an abstraction of the common Thomas precession of STR. Unfortunately, Thomas precession is commonly studied in STR as an isolated peculiarity. In this article, however, we will see that Thomas gyration plays a central role in STR and in its abstraction, giving rise to the gyrogroup concept. In fact, it is the notion of the gyrogroup that allows the abstraction of the Lorentz group acting on spacetime. It was found that the gyrogroup structure is closely related to that of the so-called *K loop*,[3] which was discovered in 1965 by Karzel,[4] and is extensively studied in some areas of geometry.[6]

In Sec. II we introduce the gyrogroup definition, as well as the definition of the *cocycle form* that a gyrogroup must possess in order to be extendible into a Lorentz group. It thus turns out that the study of gyrogroups equipped with a cocycle form is fruitful, giving rise to elegant identities and exposing previously unknown structure underlying Lorentz groups. Of particular interest is the special case of the real and complex relativistic gyrogroups and their cocycle forms, presented in Sec. III. In that section a nonstandard relativistic gyrogroup that results in a nonstandard Lorentz group is also presented.

J. Math. Phys. **37** (6), June 1996

The real and complex gyrogroups described in Sec. III are extended in Sec. IV into real and complex space–times. The action of abstract Lorentz transformations on these abstract space–times is then explored in Sec. V. The *gyrosemidirect product* presented in Sec. VI enables us in Sec. VII to study the abstract real and complex Lorentz transformation groups. In particular, we obtain Lorentz transformation composition laws that generalize the ones discovered in Refs. 7 and 8. Finally, group theoretical interpretation is presented in Sec. VIII.

Remarkably, although the cocycle identity is useful in several branches of mathematics,[9] the role it plays in the structure of the Lorentz group has gone unnoticed, along with the fact that the form $1+\mathbf{u}\cdot\mathbf{v}/c^2$ satisfies the cocycle identity in the relativistic gyrogroup $(\mathbb{R}^3_c,\oplus)$. The role played by the cocycle form in the abstract Lorentz group, described in this article, is indicated by the appearance of the relativistic cocycle form $1+\mathbf{u}\cdot\mathbf{v}/c^2$ in the expressions describing both the Lorentz transformation in STR and the relativistic velocity addition $\oplus$ in STR.

II. GYROGROUPS AND THEIR COCYCLE FORMS

Definition 2.1 (Groupoids and their automorphism groups): A groupoid $(S,+)$ is a nonempty set S with a binary operation $+$. An *automorphism* of the groupoid $(S,+)$ is a bijection of S that respects the binary operation $+$ in S. The set of all automorphisms of $(S,+)$ forms a group denoted by $\mathrm{Aut}(S,+)$.

Definition 2.2 (Gyrogroups): A groupoid $(P,+)$ is a gyrogroup if P contains an element, denoted by 0, such that

(G1) $\quad 0+x=x+0=x$

for any $x\in P$; and any element $x\in P$ has an inverse, denoted by $-x$, satisfying

(G2) $\quad -x+x=x+(-x)=0.$

Moreover, if for any x, $y\in P$ we define the map $\mathrm{gyr}[x;y]$ of P by the equation

$$\mathrm{gyr}[x;y]z=-(x+y)+(x+(y+z)),\quad z\in P,$$

then the following hold:

(G3)	$\mathrm{gyr}[x;y]\in\mathrm{Aut}(P,+)$,	gyroautomorphism,
(G4)	$x+y=\mathrm{gyr}[x;y](y+x)$,	gyrocommutative law,
(G5a)	$x+(y+z)=(x+y)+\mathrm{gyr}[x;y]z$,	right gyroassociative law,
(G5b)	$(x+y)+z=x+(y+\mathrm{gyr}[y;x]z)$,	left gyroassociative law,
(G6)	$\mathrm{gyr}[0;y]=I$,	identity gyroautomorphism,
(G7)	$\mathrm{gyr}[x+y;y]=\mathrm{gyr}[x;y]$,	loop property.

The gyroautomorphism $\mathrm{gyr}[x;y]$ of the gyrogroup $(P,+)$ is given in Definition 2.2 by its effect on any $z\in P$. Alternatively, if $L(a)$ denotes left gyrotranslation by a in $(P,+)$,

$$L(a)x=a+x$$

for all $a,x\in(P,+)$, then the inverse $L^{-1}(a)$ of $L(a)$ is $L^{-1}(a)=L(-a)$, and

$$\mathrm{gyr}[x;y]=L^{-1}(x+y)L(x)L(y). \tag{2.1}$$

In the particular case of the special-relativistic gyrogroup, the action of a gyroautomorphism $\mathrm{gyr}[x;y]$ is a rotation known as Thomas precession or *Thomas gyration*. Ambiguously, we say that the gyroautomorphisms $\mathrm{gyr}[x;y]$ are gyrations (or, rotations in the special relativistic case) of the gyrogroup P.

We will now present the definition and some properties of the cocycle form. In the sequel, these will prove useful in understanding the structure of Lorentz groups.

Definition 2.3 (The positive ray and the right-half complex plane): $\mathbb{R}$ and $\mathbb{C}$ denote, respectively, the real line and the complex plane. The *positive* ray is $\mathbb{R}^+=\{r\in\mathbb{R} : r>0\}$, and the *right-half complex plane* is $\mathbb{C}^+=\{z\in\mathbb{C} : \mathrm{Re}\, z>0\}$.

Definition 2.4R (A real cocycle form in a gyrogroup): A *real cocycle form* in a gyrogroup $(P,+)$ is a map

$$F : P\times P\to\mathbb{R}^+$$

possessing the following properties. For all $a,b,u,\nu,w\in P$,

(C1) $F(u,\nu+w)F(\nu,w)=F(\nu+u,w)F(u,\nu)$, cocycle identity,[9]

(C2) $F(u,\nu)=F(\mathrm{gyr}[a;b]u,\mathrm{gyr}[a;b]\nu)$, gyroinvariance, invariance under gyrations,

(C3R) $F(u,\nu)=F(\nu,u)$, symmetry,

(C4) $F(0,0)=1$, normalization condition.

If, in addition, F satisfies the condition

(C5) $F(-u,-\nu)=F(u,\nu)$, even cocycle form,

we say that F is *even*. The definition of a complex cocycle form is similar.

Definition 2.4C (Complex cocycle form in a gyrogroup): A *complex cocycle form* in a gyrogroup $(P,+)$ is a map

$$F : P\times P\to\mathbb{C}^+$$

possessing properties (C1)–(C4) of Definition 2.4R, but with property (C3R) replaced by the following property (C3C):

(C3C) $F(u,\nu)=\overline{F(\nu,u)}$, complex symmetry.

Clearly, if $F(u,\nu)$ is a complex cocycle form, then its modulus $|F(u,\nu)|$ is a real cocycle form.

Theorem 2.1: Let F be a real or complex cocycle form in a gyrogroup $(P,+)$. Then, for any $\nu,x\in P$,

(i) $F(0,\nu)=1$,

(ii) $F(\nu,-\nu)=F(\nu+x,-\nu)F(x,\nu)$,

(iii) $F(\nu,-\nu)$ is real, satisfying $F(\nu,-\nu)=F(-\nu,\nu)$.

Proof: The cocycle identity (C1) with $u=0$ and $\nu=-w$ gives

$$F(0,0)F(-w,w)=F(-w,w)F(0,-w)$$

implying, by means of (C4), that $F(0,-w)=1$ for any $w\in P$, thus verifying (i). Property (ii) follows from the cocycle identity (C1) with $u=x$ and $w=-\nu$, and from (i). The equality in (iii) follows from (i) and from (ii) with $x=-\nu$. If F is a complex cocycle form, then the reality of $F(\nu,-\nu)$ follows from (C3C).

Definition 2.5 (Gyrogroups with a cocycle form): A gyrogroup $(P,+)$ possessing a cocycle form F is denoted by $(P,+,F)$.

Definition 2.6 (The Lorentz factor γ): Let $(P,+,F)$ be a gyrogroup with a cocycle form F. For any $\nu\in P$, the Lorentz factor γ_ν is given by the equation

$$\gamma_\nu^{-2}=F(\nu,-\nu).$$

We will see in Sec. III that the relativistic gyrogroup possesses an even cocycle form, $S(\mathbf{u},\mathbf{v})$, such that its Lorentz factor $\gamma_{\mathbf{v}}$ [with $\gamma_{\mathbf{v}}^{-2}=S(\mathbf{v},-\mathbf{v})$] is the common Lorentz factor of STR.

Theorem 2.2R: Let $F(u,\nu)$ be an even real cocycle form in a gyrogroup $(P,+,F)$. Then

$$F(u,\nu)=\frac{\gamma_{u+\nu}}{\gamma_u\gamma_\nu} \tag{2.2}$$

for any $u,\nu\in P$.

Proof: By the cocycle identity

$$F(u+\nu,w)=\frac{F(\nu,u+w)F(u,w)}{F(\nu,u)}$$

with $w=-(u+\nu)$, noting that $u+w=-\nu$, we have

$$F(u+\nu,-(u+\nu))=\frac{F(\nu,-\nu)}{F(\nu,u)}\,F(u,-(u+\nu)). \tag{2.3}$$

By the identity (ii) in Theorem 2.1 with $x=u$, and by the symmetry of F, we have

$$F(\nu,-\nu)=F(\nu+u,-\nu)F(u,\nu)=F(\nu,u)F(\nu+u,-\nu),$$

implying

$$\frac{F(\nu,-\nu)}{F(\nu,u)}=F(\nu+u,-\nu). \tag{2.4}$$

Substituting (2.4) into (2.3) we have, by properties (C3R) and (C5) of the even real cocycle form $F(u,\nu)$,

$$\begin{aligned}F(u+\nu,-(u+\nu))&=F(\nu+u,-\nu)F(u,-(u+\nu))\\&=F(\nu+u,-\nu)F(u+\nu,-u)\\&=F(u+\nu,-u)F(\nu+u,-\nu).\end{aligned} \tag{2.5}$$

By two applications of identity (ii) in Theorem 2.1 (introducing $x=x_1$ in the first application and $x=x_2$ in the second application), with $x_1=\nu$ and $x_2=u$, and by (2.5) we have

$$\begin{aligned}F(u,-u)F(\nu,-\nu)&=F(u+x_1,-u)F(x_1,u)F(\nu+x_2,-\nu)F(x_2,\nu)\\&=F^2(u,\nu)F(u+\nu,-u)F(\nu+u,-\nu)\\&=F^2(u,\nu)F(u+\nu,-(u+\nu)).\end{aligned} \tag{2.6}$$

By Definition 2.6, the extreme left- and right-hand sides of Eq. (2.6) yield

$$\gamma_u^{-2}\gamma_\nu^{-2}=F^2(u,\nu)\,\gamma_{u+\nu}^{-2},$$

thus verifying Theorem 2.2R.

A generalization of Theorem 2.2R to any real cocycle form, not necessarily even, is given in Theorem 4.2. To demonstrate an application of Theorem 2.2R we verify the following.

Lemma 2.1R: Let $F(u,\nu)$ be an even real cocycle form in a gyrogroup $(P,+,F)$. Then F satisfies the identity

$$\frac{F(-(a+b),a+(b+\nu))F(a,b+\nu)F(b,\nu)}{F(a+b,-(a+b))F(a,b)}=1$$

for all $a,b,\nu\in P$.

Proof: By Theorem 2.2R, the identity in Lemma 2.1R can be written as

$$\frac{\gamma_\nu}{\gamma_{a+b}\gamma_{a+(b+\nu)}}\,\frac{\gamma_{a+(b+\nu)}}{\gamma_a\gamma_{b+\nu}}\,\frac{\gamma_{b+\nu}}{\gamma_b\gamma_\nu}\Big/\frac{1}{\gamma_{a+b}^2}\,\frac{\gamma_{a+b}}{\gamma_a\gamma_b}=1,$$

noting that

$$-(a+b)+\{a+(b+\nu)\}=\mathrm{gyr}[a;b]\nu,$$

so that

$$\gamma_{-(a+b)+(a+(b+\nu))}=\gamma_{\mathrm{gyr}[a;b]\nu}=\gamma_\nu,$$

thus completing the proof.

Lemma 2.1R and its proof were presented as an instructive demonstration of an application of Theorem 2.2R. However, the result of the Lemma can be extended to both real and complex cocycle forms which need not be even. We, therefore, present below a generalization of Lemma 2.1R.

Lemma 2.1: Let $F(u,\nu)$ be a real or complex cocycle form in a gyrogroup $(P,+,F)$. Then F satisfies the identity

$$\frac{F(-(a+b),a+(b+\nu))F(a,b+\nu)F(b,\nu)}{F(a+b,-(a+b))F(a,b)}=1 \tag{2.7}$$

for all $a,b,\nu\in P$.

Proof: By Theorem 2.1 (ii) we have

$$F(a+b,-(a+b))=F((a+b)+x,-(a+b))F(x,a+b)$$

for any $x\in P$. Hence, in particular, for $x=\mathrm{gyr}[a;b]\nu$, we have by (C2), (G5a), (G4), and (C3C) and by part (iii) of Theorem 2.1,

$$F(a+b,-(a+b))=F(a+(b+\nu),-(a+b))F(\nu,b+a)=F(-(a+b),a+(b+\nu))F(b+a,\nu). \tag{2.8}$$

Eliminating $F(b+a,\nu)$ between identity (2.8) and the cocycle identity

$$F(a,b+\nu)F(b,\nu)=F(b+a,\nu)F(a,b)$$

yields (2.7) as desired.

We will now present the complex counterpart of Theorem 2.2R.

Theorem 2.2C: Let $F(u,v)$ be an even complex cocycle form in a gyrogroup $(P,+,F)$. Then

$$|F(u,v)| = \frac{\gamma_{u+v}}{\gamma_u \gamma_v}$$

for any $u,v \in P$. Hence,

$$F(u,v) = \mathrm{tgyr}[u;v]\ \frac{\gamma_{u+v}}{\gamma_u \gamma_v},$$

where

$$\mathrm{tgyr}[u;v] = \frac{F(u,v)}{|F(u,v)|},$$

for any $u,v \in P$.

Proof: The complex conjugate of Eq. (2.3), noting that $F(v,-v)$ is real, takes the form

$$F(u+v,-(u+v)) = \frac{F(v,-v)}{\overline{F(v,u)}}\ \overline{F(u,-(u+v))}. \tag{2.9}$$

By the second identity in Theorem 2.1 with $x=u$, and by the complex symmetry of F, we have

$$F(v,-v) = F(v+u,-v)F(u,v) = \overline{F(v,u)}F(v+u,-v),$$

implying

$$\frac{F(v,-v)}{\overline{F(v,u)}} = F(v+u,-v). \tag{2.10}$$

Substituting (2.10) into (2.9) we have, by properties (C3C) and (C5) of the cocycle form $F(u,v)$,

$$\begin{aligned} F(u+v,-(u+v)) &= F(v+u,-v)\overline{F(u,-(u+v))} \\ &= F(v+u,-v)F(u+v,-u) \\ &= F(u+v,-u)F(v+u,-v). \end{aligned} \tag{2.11}$$

By the second identity in Theorem 2.1, with $x=v$ and $y=u$, and by (2.11) we have

$$\begin{aligned} F(u,-u)F(v,-v) &= F(u+x,-u)F(x,u)F(v+y,-v)F(y,v) \\ &= |F(u,v)|^2 F(u+v,-u)F(v+u,-v) \\ &= |F(u,v)|^2 F(u+v,-(u+v)). \end{aligned} \tag{2.12}$$

By Definition 2.6, the extreme left- and right-hand sides of Eq. (2.12) yield

$$\gamma_u^{-2}\gamma_v^{-2} = |F(u,v)|^2 \gamma_{u+v}^{-2},$$

thus verifying Theorem 2.2C.

Theorem 2.2C suggests the following.

Definition 2.7 (The time gyration): Let F be a complex cocycle form in a gyrogroup $(P, +, F)$. The *time gyrooperator* tgyr is a map

$$\text{tgyr} \ : \ P \times P \to \mathbb{C}_0^+ ,$$

where $\mathbb{C}_0^+ = \{z \in \mathbb{C} \ : \ |z| = 1, \ \text{Re}\, z > 0\}$, given by

$$\text{tgyr}[u; v] = \frac{F(u, v)}{|F(u, v)|} \tag{2.13}$$

for any $u, v \in P$. The $\text{tgyr}[u; v]$ are called *time gyrations*. They represent *rotations* of the complex plane $\mathbb{C}$.

The real counterpart of tgyr vanishes. If $F(u, v)$ is a real cocycle form in a gyrogroup $(P, +, F)$, then clearly $\text{tgyr}[u; v] = 1$ for any $u, v \in P$. Therefore, the extension from gyrogroups with a real cocycle form to gyrogroups with a complex cocycle form is not trivial; time gyration of a gyrogroup with a complex cocycle form has no real counterpart. As suggested by its term, tgyr possesses properties similar to those of gyr, as indicated in the following.

Theorem 2.3: The time gyration tgyr in a gyrogroup $(P, +, F)$ with a complex cocycle form satisfies the identities

(i) $\text{tgyr}^{-1}[u; v] = \text{tgyr}[v; u]$,

(ii) $\text{tgyr}[0; v] = 1$,

and it possesses the two loop properties

$$\text{tgyr}[u + v; v] = \text{tgyr}[u; v], \quad \text{left loop property (LLP)},$$

$$\text{tgyr}[u; v + u] = \text{tgyr}[u; v], \quad \text{right loop property (RLP)}.$$

Proof: (i) and (ii) follow immediately from the definition of tgyr, from property (C3C) of F, and from Theorem (2.1) (i). To verify the right loop property, let us substitute $w = u$ in the cocycle identity (C1), obtaining the identity

$$F(u; v + u)F(v, u) = F(v + u, u)F(u, v). \tag{2.14}$$

It follows from (2.14), by the complex symmetry property (C3C) of F, that the product $F(u, v + u)F(v, u)$ in $\mathbb{C}$ is real. Hence, the conjugate $\overline{F(v, u)} = F(u, v)$ of $F(v, u)$ is real proportional to $F(u, v + u)$, that is,

$$F(u, v) = rF(u, v + u) \tag{2.15}$$

for some positive real constant r. Dividing each side of (2.15) by its magnitude gives the right loop property (RLP). Taking the complex conjugate of each side of (2.15) one similarly verifies the left loop property (LLP). The proof of the theorem is thus complete.

III. THE REAL AND COMPLEX RELATIVISTIC GYROGROUPS AND THEIR COCYCLE FORMS

Definition 3.1 [Einstein gyrogroup; the standard relativistic gyrogroup $(V_c, \oplus)$]: Let $(V_\infty, +, \cdot)$ be a (real or complex) inner product space, and let

$$V_c = \{\mathbf{v} \in V_\infty \ : \ \|\mathbf{v}\| < c\} \tag{3.1}$$

be its open c ball; c being an arbitrary fixed positive constant. The inner product $\langle \mathbf{u},\mathbf{v}\rangle$ in V_∞ is denoted by $\mathbf{u}\cdot\mathbf{v}$ or $\mathbf{v}\cdot\mathbf{u}$ if V_∞ is real, and by $\mathbf{u}\cdot\overline{\mathbf{v}}$ or $\overline{\mathbf{v}}\cdot\mathbf{u}$ if V_∞ is complex (we make no attempt to define $\overline{\mathbf{v}}$ alone). To avoid unnecessary repetitions, if V_∞ is real then $\mathbf{u}\cdot\overline{\mathbf{v}}=\mathbf{u}\cdot\mathbf{v}$. Under this notation, the groupoid *induced* by the inner product space $(V_\infty,+,\cdot)$ is the pair $(V_c,\oplus)$ where the binary operation $\oplus$ in V_c is given by the abstract relativistic velocity addition

$$\mathbf{u}\oplus\mathbf{v}=\frac{1}{1+\overline{\mathbf{u}}\cdot\mathbf{v}/c^2}\left\{\mathbf{u}+\frac{1}{\gamma_u}\,\mathbf{v}+\frac{1}{c^2}\,\frac{\gamma_u}{1+\gamma_u}\,(\overline{\mathbf{u}}\cdot\mathbf{v})\mathbf{u}\right\},\quad \mathbf{u},\mathbf{v}\in V_c, \tag{3.2a}$$

γ_u being the well-known Lorentz factor of STR (written here for a possibly complex $\mathbf{u}$),

$$\gamma_u=\frac{1}{\sqrt{1-\overline{\mathbf{u}}\cdot\mathbf{u}/c^2}}. \tag{3.2b}$$

The use of the symbol γ_u in Eq. (3.2b) and in Definition 2.6 is not ambiguous, as indicated in Eqs. (3.6) and in a paragraph above these equations.

The groupoid $(V_c,\oplus)$ forms a gyrogroup known as the *(real or complex) relativistic gyrogroup*.[7] Following Ref. 13, it is also called Einstein gyrogroup.

Theorem 3.1 (A complex cocycle form in the complex relativistic gyrogroup): Let $(V_\infty,+,\cdot)$ be a complex inner product space, and let $(V_c,\oplus)$ be the gyrogroup induced on its open c ball V_c. Then the map

$$S\ :\ V_c\times V_c\to\mathbb{C}^+$$

given by the equation

$$S(\mathbf{u},\mathbf{v})=1+\frac{\overline{\mathbf{u}}\cdot\mathbf{v}}{c^2} \tag{3.3}$$

is an even complex cocycle form in the gyrogroup $(V_c,\oplus)$, giving rise to the triple $(V_c,\oplus,S)$ (defined in Definition 2.5).

Proof: We have to verify that $S(\mathbf{u},\mathbf{v})$ possesses properties (C1)–(C5) of the cocycle form. Invariance of $S(\mathbf{u},\mathbf{v})$ under gyrations is obvious; gyrations in the gyrogroup $(V_c,\oplus)$ are unitary transformations of V_c and of V_∞, under which the inner product $\cdot$ in V_∞ is invariant. This verifies (C2).

The validity of properties (C3)–(C5) for $S(\mathbf{u},\mathbf{v})$ is immediate. It remains to verify the cocycle identity (C1).

The binary operation $\oplus$ in the gyrogroup V_c is given by Eq. (3.2), which can be written as

$$\mathbf{u}\oplus\mathbf{v}=A_{\mathbf{u},\mathbf{v}}\mathbf{u}+B_{\mathbf{u},\mathbf{v}}\mathbf{v} \tag{3.4a}$$

with

$$A_{\mathbf{u},\mathbf{v}}=\frac{1}{1+(\overline{\mathbf{u}}\cdot\mathbf{v}/c^2)}\left(1+\frac{1}{c^2}\,\frac{\gamma_u}{1+\gamma_u}\,\overline{\mathbf{u}}\cdot\mathbf{v}\right)$$

and

$$B_{\mathbf{u},\mathbf{v}}=\frac{1}{1+(\overline{\mathbf{u}}\cdot\mathbf{v}/c^2)}\,\frac{1}{\gamma_u}. \tag{3.4b}$$

Hence,

$$\overline{\mathbf{u}\cdot(\mathbf{v}\oplus\mathbf{w})}=A_{\mathbf{v},\mathbf{w}}\overline{\mathbf{u}\cdot\mathbf{v}}+B_{\mathbf{v},\mathbf{w}}\overline{\mathbf{u}\cdot\mathbf{w}}=\frac{1}{1+(\overline{\mathbf{v}\cdot\mathbf{w}}/c^2)}\left\{\left(1+\frac{1}{c^2}\frac{\gamma_v}{1+\gamma_v}\overline{\mathbf{v}\cdot\mathbf{w}}\right)\overline{\mathbf{u}\cdot\mathbf{v}}+\frac{1}{\gamma_v}\overline{\mathbf{u}\cdot\mathbf{w}}\right\}$$

and

$$\overline{\mathbf{w}\cdot(\mathbf{v}\oplus\mathbf{u})}=A_{\mathbf{v},\mathbf{u}}\overline{\mathbf{v}\cdot\mathbf{w}}+B_{\mathbf{v},\mathbf{u}}\overline{\mathbf{u}\cdot\mathbf{w}}=\frac{1}{1+(\overline{\mathbf{u}\cdot\mathbf{v}}/c^2)}\left\{\left(1+\frac{1}{c^2}\frac{\gamma_v}{1+\gamma_v}\overline{\mathbf{u}\cdot\mathbf{v}}\right)\overline{\mathbf{v}\cdot\mathbf{w}}+\frac{1}{\gamma_v}\overline{\mathbf{u}\cdot\mathbf{w}}\right\}.$$

With the above definition of $S(\mathbf{u},\mathbf{v})$ we have (taking $c=1$ without loss of generality)

$$\begin{aligned}S(\mathbf{u},\mathbf{v}\oplus\mathbf{w})S(\mathbf{v},\mathbf{w})&=\{1+\overline{\mathbf{u}\cdot(\mathbf{v}\oplus\mathbf{w})}\}(1+\overline{\mathbf{v}\cdot\mathbf{w}})\\&=\left(1+\frac{1}{1+\overline{\mathbf{v}\cdot\mathbf{w}}}\left\{\left(1+\frac{\gamma_v}{1+\gamma_v}\overline{\mathbf{v}\cdot\mathbf{w}}\right)\overline{\mathbf{u}\cdot\mathbf{v}}+\frac{1}{\gamma_v}\overline{\mathbf{u}\cdot\mathbf{w}}\right\}\right)(1+\overline{\mathbf{v}\cdot\mathbf{w}})\\&=1+\overline{\mathbf{v}\cdot\mathbf{w}}+\left(1+\frac{\gamma_v}{1+\gamma_v}\overline{\mathbf{v}\cdot\mathbf{w}}\right)\overline{\mathbf{u}\cdot\mathbf{v}}+\frac{1}{\gamma_v}\overline{\mathbf{u}\cdot\mathbf{w}}\end{aligned}$$

and

$$\begin{aligned}S(\mathbf{v}\oplus\mathbf{u},\mathbf{w})S(\mathbf{u},\mathbf{v})&=\{1+\mathbf{w}\cdot\overline{(\mathbf{v}\oplus\mathbf{u})}\}(1+\overline{\mathbf{u}\cdot\mathbf{v}})\\&=\left(1+\frac{1}{1+\overline{\mathbf{u}\cdot\mathbf{v}}}\left\{\left(1+\frac{\gamma_v}{1+\gamma_v}\overline{\mathbf{u}\cdot\mathbf{v}}\right)\overline{\mathbf{v}\cdot\mathbf{w}}+\frac{1}{\gamma_v}\overline{\mathbf{u}\cdot\mathbf{w}}\right\}\right)(1+\overline{\mathbf{u}\cdot\mathbf{v}})\\&=1+\overline{\mathbf{u}\cdot\mathbf{v}}+\left(1+\frac{\gamma_v}{1+\gamma_v}\overline{\mathbf{u}\cdot\mathbf{v}}\right)\overline{\mathbf{v}\cdot\mathbf{w}}+\frac{1}{\gamma_v}\overline{\mathbf{u}\cdot\mathbf{w}},\end{aligned}$$

implying

$$S(\mathbf{u},\mathbf{v}\oplus\mathbf{w})S(\mathbf{v},\mathbf{w})=S(\mathbf{v}\oplus\mathbf{u},\mathbf{w})S(\mathbf{u},\mathbf{v}) \tag{3.5}$$

so that $S(\mathbf{u},\mathbf{v})$ satisfies the cocycle identity (C1) as desired. The proof of Theorem 3.1 is thus complete.

Clearly, Theorem 3.1 implicitly presents, as a special case, a real cocycle form in the real relativistic gyrogroup.

Theorem 3.1 associates the real and complex relativistic gyrogroups with respective real and complex cocycle forms S. Accordingly, we may denote the real and complex relativistic gyrogroups $(V_c,\oplus)$ by $(V_c,\oplus,S)$. Furthermore, following Definition 2.6 the relativistic even real form $S(\mathbf{v},\mathbf{u})$ induces a Lorentz factor $\gamma_{\mathbf{v}}$, $\gamma_{\mathbf{v}}^{-2}=S(\mathbf{v},-\mathbf{v})$. The factor $\gamma_{\mathbf{v}}$ turns out to be the well-known Lorentz factor of STR, Eq. (3.2b).

Due to the important role that the cocycle form $S(\mathbf{u},\mathbf{v})$ plays in the relativistic gyrogroup $(V_c,\oplus)$, it seems appropriate to express the binary operation $\oplus$ in V_c in terms of $S(\mathbf{u},\mathbf{v})$ rather than $\overline{\mathbf{u}\cdot\mathbf{v}}$. Equation (3.2) then takes the form

$$\mathbf{u}\oplus\mathbf{v}=\frac{1}{1+\gamma_u}\left(\gamma_u+\frac{1}{S(\mathbf{u},\mathbf{v})}\right)\mathbf{u}+\frac{1}{\gamma_u}\frac{1}{S(\mathbf{u},\mathbf{v})}\mathbf{v}, \tag{3.6a}$$

$$\gamma_u=\frac{1}{\sqrt{S(\mathbf{u},-\mathbf{u})}}, \tag{3.6b}$$

demonstrating the importance of the conditions $S(\mathbf{u},\mathbf{v})\neq 0$ and $S(\mathbf{u},-\mathbf{u})>0$ for all $\mathbf{u},\mathbf{v}\in V_c$.

Definition 3.2 [Möbius gyrogroup; the nonstandard relativistic gyrogroup $(V_c,\boxplus)$]: Let $(V_\infty,+,\cdot)$ be a real inner product space, and let V_c be its open c ball, c being an arbitrary fixed positive constant. The nonstandard binary operation in V_c, $\boxplus$, is given by the equation

$$\mathbf{u}\boxplus\mathbf{v}=\frac{1}{N^2(\mathbf{u},\mathbf{v})}\left\{\left(1+\frac{2}{c^2}\,\mathbf{u}\cdot\mathbf{v}+\frac{1}{c^2}\,\|\mathbf{v}\|^2\right)\mathbf{u}+\left(1-\frac{1}{c^2}\,\|\mathbf{u}\|^2\right)\mathbf{v}\right\} \tag{3.7a}$$

where $N^2(\mathbf{u},\mathbf{v})=(N(\mathbf{u},\mathbf{v}))^2$, N being the map

$$\mathrm{N}\ :\ \mathrm{V_c}\times\mathrm{V_c}\to\mathbb{R}^+$$

given by

$$N(\mathbf{u},\mathbf{v})=\sqrt{1+\frac{2}{c^2}\,\mathbf{u}\cdot\mathbf{v}+\frac{1}{c^4}\,\|\mathbf{u}\|^2\|\mathbf{v}\|^2}. \tag{3.8a}$$

The pair $(V_c,\boxplus)$ forms a gyrogroup[10,11] called the *nonstandard* relativistic gyrogroup induced by the real inner product space $(V_\infty,+,\cdot)$. Following Ref. 13, it is also called the Möbius gyrogroup.

Theorem 3.2: Let $(V_\infty,+,\cdot)$ be a real inner product space whose open c ball is V_c. Then $(V_c,\boxplus,F)$ is a gyrogroup with a real cocycle form, where $\boxplus$ and N are given by Eqs. (3.7a) and (3.8a).

Similarly to the proof of Theorem 3.1, the proof of Theorem 3.2 is lengthy but straightforward.

Remark: If we use the vector product notation

$$\mathbf{x}\times\mathbf{y}\times\mathbf{z}=-(\mathbf{y}\cdot\mathbf{z})\mathbf{x}+(\mathbf{x}\cdot\mathbf{z})\mathbf{y}$$

and

$$(\mathbf{x}\cdot\mathbf{y})^2=\|\mathbf{x}\|^2\|\mathbf{y}\|^2-(\mathbf{x}\cdot\mathbf{y})^2,$$

then Eqs. (3.7a) and (3.8a) take the elegant form

$$\mathbf{u}\boxplus\mathbf{v}=\frac{1+(1/c^2)\mathbf{u}\cdot\mathbf{v}-(1/c^2)(\mathbf{u}\times\mathbf{v})\times}{[1+(1/c^2)\mathbf{u}\cdot\mathbf{v}]^2+(1/c^4)(\mathbf{u}\times\mathbf{v})^2}\,(\mathbf{u}+\mathbf{v}) \tag{3.7b}$$

and

$$N(\mathbf{u},\mathbf{v})=\sqrt{[1+(1/c^2)\mathbf{u}\cdot\mathbf{v}]^2+(1/c^4)(\mathbf{u}\times\mathbf{v})^2}. \tag{3.8b}$$

The resulting space–time is the *expanding Minkowski space*, studied in Ref. 10.

Equation (3.7b), as opposed to Eq. (3.7a), is elegant in the sense that it exhibits the formal structure

$$\mathbf{u}\boxplus\mathbf{v}=\frac{A-B}{A^2+B^2}\,(\mathbf{u}+\mathbf{v}),$$

where A and B^2 are scalars, but B is an operator. The elegance of the binary operation $\boxplus$, as presented in Eq. (3.7b), stems from the fact that it is a generalized Möbius transformation.[11]

In a real inner product space V_∞ the standard and the nonstandard relativistic gyrogroups $(V_c,\oplus)$ and $(V_c,\boxplus)$ of Definitions 3.1 and 3.2 are isomorphic in the gyrogroup isomorphism sense introduced by You and Ungar.[12] In fact, the two binary operations $\oplus$ and $\boxplus$ in V_c, representing standard and nonstandard relativistic velocity addition, are related by the gyrogroup identity

$$\tfrac{1}{2}\odot(\mathbf{u}\oplus\mathbf{v})=\tfrac{1}{2}\odot\mathbf{u}\boxplus\tfrac{1}{2}\odot\mathbf{v} \tag{3.9}$$

in V_c.[12] In identity (3.9) the map $\frac{1}{2}\odot$ of V_c takes $\mathbf{u}\in V_c$ to its unique ''half'' $\frac{1}{2}\odot\mathbf{u}$ satisfying $\frac{1}{2}\odot\mathbf{u}\oplus\frac{1}{2}\odot\mathbf{u}=\mathbf{u}$, the inverse of which is the map $2\odot$ of V_c that takes $\mathbf{u}\in V_c$ to $2\odot\mathbf{u}=\mathbf{u}\oplus\mathbf{u}$.[13] It thus follows from (3.9) that $\boxplus$ is expressible in terms of $\oplus$ as

$$\mathbf{u}\boxplus\mathbf{v}=\tfrac{1}{2}\odot(2\odot\mathbf{u}\oplus 2\odot\mathbf{v}) \tag{3.10}$$

in V_c. Interestingly, when $V_\infty=\mathbb{R}^3$, the resulting standard and nonstandard Lorentz groups, studied in Ref. 10, are experimentally equivalent, as pointed out by Urbantke.[14] Their equivalence for abstract V_∞ is established in Ref. 12.

IV. REAL AND COMPLEX SPACE–TIMES

Definition 4.1: Let $(A\times B,\cdot)$ be a gyrogroup whose underlying set is the Cartesian product of two nonempty sets A and B. The gyro-operator gyr of the gyrogroup $(A\times B,\cdot)$ is *A central* if the gyration

$$\mathrm{gyr}[(a_1,b_1);(a_2,b_2)]$$

generated by (a_1,b_1) and (a_2,b_2) is independent of a_1, $a_2\in A$ for all (a_1,b_1), $(a_2,b_2)\in A\times B$. In other words,

$$\mathrm{gyr}[(a_1,b_1);(a_2,b_2)](a,b)=(a,\mathrm{gyr}_B[b_1;b_2]b) \tag{4.1}$$

for all $a\in A$ and $b\in B$ and some map

$$\mathrm{gyr}_B[b_1;b_2]:B\to B.$$

The map gyr_B is said to be the map of B induced by the A-central gyro-operator of the gyrogroup $(A\times B,\cdot)$.

Theorem 4.1: Let $(P,+)$ be a groupoid and let $(\mathbb{R}^+\times P,\cdot)$ be a groupoid of pairs whose groupoid operation $\cdot$ is related to the groupoid operation $+$ in P by the equation

$$(s,u)\cdot(t,\nu)=[F(u,\nu)st,u+\nu] \tag{4.2}$$

for some map

$$F\ :\ P\times P\to\mathbb{R}^+.$$

Then, the groupoid $(\mathbb{R}^+\times P,\cdot)$ is a gyrogroup with an $\mathbb{R}^+$-central gyro-operator if and only if the groupoid $(P,+)$ is a gyrogroup with a cocycle form, $(P,+,F)$, for which F is a real cocycle form.

Proof: Let $(P,+,F)$ be a gyrogroup equipped with the real cocycle form $F(u,\nu)$. We will show that the groupoid $(\mathbb{R}^+\times P,\cdot)$ is a gyrogroup whose gyro-operator is $\mathbb{R}^+$ central. (G1): The neutral element is (1,0); and (G2): The inverse is

$$(t,\nu)^{-1}=\left(\frac{1}{F(\nu,-\nu)t},-\nu\right). \tag{4.3}$$

It remains to show that the groupoid $(\mathbb{F}^+\times P,\cdot)$ possesses a gyro-operator gyr given by the equation

$$\mathrm{gyr}[(s,u);(t,\nu)]=L^{-1}[(s,u)\cdot(t,\nu)]L[(s,u)]L[(t,\nu)], \tag{4.4}$$

where $L[(t,\nu)]$ denotes left multiplication by (t,ν).

Let us therefore study the operator gyr in Eq. (4.4) by its effect on $(t,\nu)\in(\mathbb{F}^+\times P,\cdot)$, and show that it is indeed a gyro-operator of $(\mathbb{F}^+\times P,\cdot)$. We have, by Eq. (4.4),

$$\begin{aligned}
\mathrm{gyr}[(r,a);(s,b)](t,\nu) &= ((r,a)\cdot(s,b))^{-1}\cdot((r,a)\cdot((s,b)\cdot(t,\nu)))\\
&= (F(a,b)rs,a+b)^{-1}\cdot((r,a)\cdot((s,b)\cdot(t,\nu)))\\
&= \left(\frac{1}{F(a+b,-(a+b))F(a,b)rs},-(a+b)\right)\cdot((r,a)\cdot(F(b,\nu)st,b+\nu))\\
&= \left(\frac{1}{F(a+b,-(a+b))F(a,b)rs},-(a+b)\right)\\
&\quad\cdot(F(a,b+\nu)F(b,\nu)rst,a+(b+\nu))\\
&= \left(F(-(a+b),a+(b+\nu))\,\frac{F(a,b+\nu)F(b,\nu)rst}{F(a+b,-(a+b))F(a,b)rs},\right.\\
&\quad\left.-(a+b)+\{a+(b+\nu)\}\right)\\
&= (t,\mathrm{gyr}[a;b]\nu),
\end{aligned}\tag{4.5}$$

where in the last equality, (i) the equality between the first entry of pairs follows from Lemma 2.1, and (ii) the equality between the second entry of pairs follows from the definition of the gyro-operator gyr of the gyrogroup $(P,+)$ in Eq. (2.1). All the other equalities in the above chain of equations are obtained by pair multiplication, as defined in (4.2). Hence, we have the $\mathbb{R}^+$-central gyrooperator gyr of the groupoid $(\mathbb{R}^+\times P,\cdot)$ given by

$$\mathrm{gyr}[(r,a);(s,b)](t,\nu)=(t,\mathrm{gyr}[a;b]\nu)=\pi_2(\mathrm{gyr}[a;b])(t,\nu)=\mathrm{Gyr}[a;b](t,\nu),\tag{4.6}$$

where

$$\mathrm{Gyr}[a;b]=\pi_2\mathrm{gyr}[a;b])\tag{4.7}$$

with the map π_2 from operators B of P into operators $\pi_2(B)$ of $\mathbb{F}^+\times P$ given by the equation

$$\pi_2(B)(t,\nu)=(t,B\nu).\tag{4.8}$$

We should notice that gyr on the extreme left-hand side of Eq. (4.6) is the gyro-operator of $(\mathbb{R}^+\times P,\cdot)$, while gyr on the right-hand side of Eq. (4.7) is the gyro-operator of $(P,+)$, as clearly indicated by the arguments of gyr in these equations.

Equation (4.6) reveals a relation between the gyration $\mathrm{gyr}[a;b]$ of the gyrogroup $(P,+)$ and the operator $\mathrm{gyr}[(r,a);(s,b)]$ of the groupoid $(\mathbb{R}^+\times P,\cdot)$. We will show below that it readily follows (i) from this relation and (ii) from properties of the real cocycle form F that gyr possesses in $(\mathbb{R}^+\times P,\cdot)$ the gyrooperator properties (G3)–(G7). Hence, the groupoid $(\mathbb{R}^+\times P,\cdot)$ is indeed a gyrogroup, the gyrooperator of which is the $\mathbb{R}^+$-central gyro-operator Gyr (It is appropriate to interject here that, with one exception, all the gyro-operator properties are valid also when the cocycle form is complex. It is only the gyrocommutative law which fails when the cocycle form F is complex rather than real. Hence from the gyrogroup theoretic point of view a complex cocycle form gives rise to an interesting example of a *nongyrocommutative gyrogroup*, that is, a ''gyrogroup'' in which the gyrocommutativity axiom has been deleted.)

Let us now verify the validity of properties (G3)–(G7) in the groupoid $(\mathbb{R}^+\times P,\cdot)$. Using the abbreviation $g_{a,b}=\mathrm{gyr}[a;b]$ whenever convenient, we have (G3):

$$\begin{aligned}\mathrm{gyr}[(r,a);(s,b)]((t_1,\nu_1)\cdot(t_2,\nu_2)) &= \mathrm{gyr}[(r,a);(s,b)](F(\nu_1,\nu_2)t_1t_2,\nu_1+\nu_2)\\ &= (F(\nu_1,\nu_2)t_1t_2,\mathrm{gyr}[a;b](\nu_1+\nu_2))\\ &= (F(\nu_1,\nu_2)t_1t_2,g_{a,b}\nu_1+g_{a,b}\nu_2)\\ &= (F(g_{a,b}\nu_1,g_{a,b}\nu_2)t_1t_2,g_{a,b}\nu_1+g_{a,b}\nu_2)\\ &= (t_1,g_{a,b}\nu_1)\cdot(t_2,g_{a,b}\nu_2)\\ &= \mathrm{gyr}[(r,a);(s,b)](t_1,\nu_1)\cdot\mathrm{gyr}[(r,a);(s,b)](t_2,\nu_2).\end{aligned}$$

Hence $\mathrm{gyr}[(r,a);(s,b)]$ is an endomorphism of the groupoid $(\mathbb{R}^+\times P,\cdot)$, i.e., it is a map of the groupoid into itself respecting the binary operation. Moreover, $\mathrm{gyr}[(r,a);(s,b)]$ is invertible: for all $(t,\nu)\in\mathbb{R}^+\times P$ we have

$$\begin{aligned}\mathrm{gyr}[(r,a);(s,b)]\cdot\mathrm{gyr}[(s,b);(r,a)](t,\nu) &= \mathrm{gyr}[(r,a);(s,b)](t,\mathrm{gyr}[b;a]\nu)\\ &= (t,\mathrm{gyr}[a;b]\mathrm{gyr}[b;a]\nu)=(t,\nu).\end{aligned}$$

Hence $\mathrm{gyr}[(r,a);(s,b)]$ is an automorphism of the groupoid $(\mathbb{R}^+\times P,\cdot)$, thus verifying (G3). (G4): By the symmetry of $F(u,\nu)$,

$$\begin{aligned}\mathrm{gyr}[(r,a);(s,b)]((s,b)\cdot(r,a)) &= \mathrm{gyr}[(r,a);(s,b)](F(a,b)rs,b+a)\\ &= (F(a,b)rs,\mathrm{gyr}[a;b](b+a))\\ &= (F(a,b)rs,a+b)=(r,a)\cdot(s,b),\end{aligned}$$

thus verifying (G4).

(G5a):

$$\begin{aligned}(r,a)\cdot((s,b)\cdot(t,c)) &= (r,a)\cdot(F(b,c)st,b+c)\\ &= (F(a,b+c)F(b,c)rst,a+(b+c))\\ &= (F(b+a,c)F(a,b)rst,a+(b+c))\\ &= (F(a+b,g_{a,b}c)F(a,b)rst,(a+b)+g_{a,b}c)\\ &= (F(a,b)rs,a+b)\cdot(t,\ \mathrm{gyr}[a;b]c)\\ &= ((r,a)\cdot(s,b))\cdot\mathrm{gyr}[(r,a);(s,b)](t,c).\end{aligned}$$

(G5b):

$$\begin{aligned}((r,a)\cdot(s,b))\cdot(t,c) &= (F(a,b)rs,a+b)\cdot(t,c)\\ &= (F(a+b,c)F(a,b)rst,(a+b)+c)\\ &= (F(b+a,g_{b,a}c)F(a,b)rst,(a+b)+c)\\ &= (F(a,b+g_{b,a}c)F(b,g_{b,a}c)rst,a+(b+g_{b,a}c))\\ &= (r,a)\cdot(F(b,g_{b,a}c)st,b+g_{b,a}c)\\ &= (r,a)\cdot((s,b)\cdot(t,g_{b,a}c))=(r,a)\cdot((s,b)\cdot\mathrm{gyr}[(s,b);(r,a)](t,c));\end{aligned}$$

(G6):

$$\mathrm{gyr}[(1,0);(s,b)](t,c)=(t,\mathrm{gyr}[0;b]c)=(t,c),$$

so that $\mathrm{gyr}[(1,0);(s,b)]$ is the identity automorphism of $(\mathbb{R}^+\times P,\cdot)$, as required for (G6).

(G7):

$$\begin{aligned}\mathrm{gyr}[(r,a)\cdot(s,b);(s,b)](t,c) &= \mathrm{gyr}[F(a,b)rs,a+b);(s,b)](t,c)\\ &= (t,\mathrm{gyr}[a+b;b]c)\\ &= (t,\mathrm{gyr}[a;b]c)\\ &= \mathrm{gyr}[(r,a);(s,b)](t,c)\end{aligned}$$

for all $(t,c)\in\mathbb{R}^+\times P$, as required for (G7).

By establishing the validity of properties (G1)–(G7) for the groupoid $(\mathbb{R}^+\times P,\cdot)$, we have demonstrated that this groupoid is a gyrogroup.

Conversely, let assume that the groupoid $(\mathbb{R}^+\times P,\cdot)$ is a gyrogroup whose gyro-operator is $\mathbb{R}^+$ central. We will show that $(P,+,F)$ is a gyrogroup possessing the real cocycle form F.

Let the neutral element of the gyrogroup $(\mathbb{R}^+\times P,\cdot)$ be denoted by (1,0), and let the inverse of $(t,\nu)\in(\mathbb{R}^+\times P,\cdot)$ be denoted by $(T,-\nu)$ for some $T\in\mathbb{R}^+$. Then clearly the pair $(P,+)$ is a groupoid with a neutral element 0 and the inversion operation $-$.

To show that $(P,+,F)$ is a gyrogroup with F being its cocycle form, we have to establish the validity of properties (G1)–(G7) for the gyrogroup $(P,+)$, as well as the validity of properties (C1)–(C4) for its cocycle form F.

(G1): The neutral element of $(P,+)$ is 0.

(G2): The inverse of ν in $(P,+)$ is $-\nu$.

(C4): Since (1,0) is the neutral element of the product (4.2), we clearly have $F(0,\nu)=F(u,0)=1$ for any $u,\nu\in P$, and, in particular, $F(0,0)=1$.

The gyro-operator gyr of the gyrogroup $(\mathbb{R}^+\times P,\cdot)$ is given by Eq. (4.4), where the product $(s,u)\cdot(t,\nu)$ is given by Eq. (4.2). Hence, according to the fifth equality in the chain of equations (4.5), we have

$$\mathrm{gyr}[(r,a);(s,b)](t,\nu)=(G(a,b,\nu)t,\mathrm{gyr}[a;b]\nu), \tag{4.9}$$

where G is the map $G : P\times P\times P\to\mathbb{F}^+$ given by

$$G(a,b,\nu)=\frac{F(-(a+b),a+(b+\nu))F(a,b+\nu)F(b,\nu)}{F(a+b,-(a+b))F(a,b)}, \tag{4.10}$$

and where $\mathrm{gyr}[a;b]$ is the map of P given by

$$\mathrm{gyr}[a;b]=-(a+b)+\{a+(b+\nu)\}.$$

But the gyro-operator gyr of $(\mathbb{R}^+\times P,\cdot)$ in Eq. (4.9) is $\mathbb{R}^+$ central by assumption. Hence, it follows from Eq. (4.9) that $G(a,b,\nu)=1$, so that we have, by Eq. (4.10),

$$G(a,b,\nu)=\frac{F(-(a+b),a+(b+\nu))F(a,b+\nu)F(b,\nu)}{F(a+b,-(a+b))F(a,b)}=1, \tag{4.11}$$

and Eq. (4.9) can be written as

$$\mathrm{gyr}[(r,a);(s,b)](t,\nu)=(t,\mathrm{gyr}[a;b]\nu). \tag{4.12}$$

The gyrocommutative law in the gyrogroup $(\mathbb{F}^+\times P,\cdot)$ takes the form

$$(r,a)\cdot(s,b)=\mathrm{gyr}[(r,a);(s,b)]((s,b)\cdot(r,a)). \tag{4.13}$$

It can be written, by Eqs. (4.2) and (4.12), as

$$(F(a,b)rs,a+b)=\mathrm{gyr}[(r,a);(s,b)](F(b,a)rs,b+a)=(F(b,a)rs,\mathrm{gyr}[a;b](b+a)).$$

By equating each of the two entries of this equation we thus have (C3R): $F(a,b)=F(b,a)$ and (G4): $a+b=\mathrm{gyr}[a;b](b+a)$. *(G3):* $\mathrm{gyr}[a;b]$, *$a,b\in P$, is an automorphism of P.* To show this, we consider the following chain of equations. By means of Eqs. (4.12) and (4.2) we have

$$\begin{aligned}(F(\nu_1,\nu_2)t_1t_2,\mathrm{gyr}[a;b](\nu_1+\nu_2))&=\mathrm{gyr}[(r,a);(s,b)](F(\nu_1,\nu_2)t_1t_2,\nu_1+\nu_2)\\&=\mathrm{gyr}[(r,a);(s,b)]((t_1,\nu_1)\cdot(t_2,\nu_2))\\&=\mathrm{gyr}[(r,a);(s,b)](t_1,\nu_1)\cdot\mathrm{gyr}[(r,a);(s,b)](t_2,\nu_2)\\&=(t_1,\mathrm{gyr}[a;b]\nu_1)\cdot(t_2,\mathrm{gyr}[a;b]\nu_2)\\&=(F(\mathrm{gyr}[a;b]\nu_1,\mathrm{gyr}[a;b]\nu_2)t_1t_2,\mathrm{gyr}[a;b]\nu_1+\mathrm{gyr}[a;b]\nu_2),\end{aligned}$$

implying

$$\text{(C2):}\quad F(\nu_1,\nu_2)=F(\mathrm{gyr}[a;b]\nu_1,\mathrm{gyr}[a;b]\nu_2)$$

and

$$\mathrm{gyr}[a;b](\nu_1+\nu_2)=\mathrm{gyr}[a;b]\nu_1+\mathrm{gyr}[a;b]\nu_2. \tag{4.14}$$

Hence, by Eq. (4.14), $\mathrm{gyr}[a;b]$ is a homomorphism from P into itself for any $a,b\in P$. To verify that $\mathrm{gyr}[a;b]$ is an automorphism of P we will show that $\mathrm{gyr}[a;b]$ has an inverse, $\mathrm{gyr}^{-1}[a;b]=\mathrm{gyr}[b;a]$.

The inverse of the gyro-operator $\mathrm{gyr}[(r,a);(s,b)]$ is $\mathrm{gyr}[(s,b);(r,a)]$. Hence, by Eq. (4.12) we have

$$\begin{aligned}(t,\nu)&=\mathrm{gyr}[(r,a);(s,b)]\mathrm{gyr}[(s,b);(r,a)](t,\nu)\\&=\mathrm{gyr}[(r,a);(s,b)](t,\mathrm{gyr}[b;a]\nu)\\&=(t,\mathrm{gyr}[a;b]\mathrm{gyr}[b;a]\nu).\end{aligned}$$

Thus

$$\mathrm{gyr}[a;b]\mathrm{gyr}[b;a]=I \tag{4.15}$$

for any $a,b\in P$, I being the identity automorphism of P. It follows from Eq. (4.15) that the inverse of $\mathrm{gyr}[a;b]$ is $\mathrm{gyr}[b;a]$, as desired.

(G5a): Let us now establish the right gyroassociative law for $\mathrm{gyr}:P\times P\to\mathrm{Aut}(P,+)$. By the right gyroassociative law in the gyrogroup $(\mathbb{F}^+\times P,\cdot)$ and by Eqs. (4.2) and (4.12) we have

$$\begin{aligned}(F(u,\nu+w)F(\nu,w)rst,u+(\nu+w))&=(r,u)\cdot((s,\nu)\cdot(t,w))\\&=((r,u)\cdot(s,\nu))\cdot\mathrm{gyr}[(r,u);(s,\nu)](t,w)\\&=(F(u,\nu)rs,u+\nu)\cdot(t,\mathrm{gyr}[u;\nu]w)\\&=(F(u+\nu,\mathrm{gyr}[u;\nu]w)F(u,\nu)rst,u+\nu+\mathrm{gyr}[u;\nu]w),\end{aligned}$$

implying

$$F(u+\nu,\mathrm{gyr}[u;\nu]w)F(u,\nu)=F(u,\nu+w)F(\nu,w) \tag{4.16}$$

and

$$u+(\nu+w)=(u+\nu)+\mathrm{gyr}[u;\nu]w \tag{4.17}$$

for all $u,\nu,w\in P$. Equation (4.17) establishes the right gyroassociative law for gyr in $(P,+)$.

(G5b): We now wish to verify the left gyroassociative law for gyr:$P\times P\to\mathrm{Aut}(P,+)$. By the left gyroassociative law in the gyrogroup $(\mathbb{F}^+\times P,\cdot)$ and by Eqs. (4.2) and (4.12) we have

$$\begin{aligned}(F(u+\nu,w)F(u,\nu)rst,(u+\nu)+w)&=((r,u)\cdot(s,\nu)\cdot(t,w)\\&=(r,u)\cdot((s,\nu)\cdot\mathrm{gyr}[(s,\nu);(r,u)](t,w))\\&=(r,u)\cdot((s,\nu)\cdot(t,\mathrm{gyr}[\nu;u]w))\\&=(r,u)\cdot(F(\nu,\mathrm{gyr}[\nu;u]w)st,\nu+\mathrm{gyr}[\nu;u]w)\\&=(F(\nu,\mathrm{gyr}[\nu;u]w)F(u,\nu+\mathrm{gyr}[\nu;u]w)rst,u\\&\quad+(\nu+\mathrm{gyr}[\nu;u]w)),\end{aligned}$$

implying

$$F(\nu,\mathrm{gyr}[\nu;u]w)F(u,\nu+\mathrm{gyr}[\nu;u]w)=F(u+\nu,w)F(u,\nu) \tag{4.18}$$

and

$$(u+\nu)+w=u+(\nu+\mathrm{gyr}[\nu;u]w). \tag{4.19}$$

Equation (4.19) establishes the left gyroassociative law for gyr in $(P,+)$.

(G6): Since $\mathrm{gyr}[(s,u);(1,0)]=J$ is the identity automorphism of the gyrogroup $(\mathbb{F}^+\times P,\cdot)$, we have by Eq. (4.12)

$$(t,\nu)=\mathrm{gyr}[(r,a);(1,0)](t,\nu)=(t,\mathrm{gyr}[a;0]\nu)$$

implying

$$\mathrm{gyr}[a;0]\nu=\nu \tag{4.20}$$

for any $\nu\in P$. Hence

$$\mathrm{gyr}[a;0]=I, \tag{4.21}$$

I being the identity automorphism of P.

(G7): The (left) loop property (G7) for the gyrooperator gyr of the gyrogroup $(\mathbb{R}^+\times P,\cdot)$ takes the form

$$\mathrm{gyr}[(r,a)\cdot(s,b);(s,b)](t,\nu)=\mathrm{gyr}[(r,a);(s,b)](t,\nu)$$

for any $r,s,t\in\mathbb{F}^+$ and any $a,b,\nu\in P$. Hence by Eqs. (4.2) and (4.12) we have

$$\begin{aligned}(t,\mathrm{gyr}[a;b]\nu)&=\mathrm{gyr}[(r,a);(s,b)](t,\nu)\\&=\mathrm{gyr}[(r,a)\cdot(s,b);(s,b)](t,\nu)\\&=\mathrm{gyr}[(F(a,b)rs,a+b);(s,b)](t,\nu)\\&=(t,\mathrm{gyr}[a+b;b]\nu).\end{aligned}$$

Thus

$$\mathrm{gyr}[a+b;b]=\mathrm{gyr}[a;b] \tag{4.22}$$

for any $a,b,\nu\in P$. Equation (4.22) verifies (G7).

(C1): The cocycle identity follows from Eq. (4.16) and from (G4) and (C2):

$$\begin{aligned}F(u,\nu+w)F(\nu,w)&=F(u+\nu,\mathrm{gyr}[u;\nu]w)F(u,\nu)\\&=F(\mathrm{gyr}[u;\nu](\nu+u),\mathrm{gyr}[u;\nu]w)F(u,\nu)\\&=F(\nu+u,w)F(u,\nu),\end{aligned}$$

thus completing the proof of Theorem 4.1.

Definition 4.2 (Extended gyrogroups): The gyrogroup $(\mathbb{R}^+\times P,\cdot)$ of Theorem 4.1 is said to be the gyrogroup *over* a gyrogroup $(P,+,F)$, or the gyrogroup *extended* from a gyrogroup $(P,+,F)$.

Some properties of a real cocycle form F in a gyrogroup can be established by means of its extended gyrogroup. A real cocycle form F in a gyrogroup $(P,+,F)$ gives rise to its extended gyrogroup $(\mathbb{R}^+\times P,\cdot)$. The gyrogroup structure of the extended gyrogroup $(\mathbb{R}^+\times P,\cdot)$, in turn, reveals properties of F some of which are not easily detectable in $(P,+,F)$ itself. An example is provided by the proof of Theorem 4.2 below, a theorem that generalizes Theorem 2.2R.

Theorem 4.2: A real cocycle form F in a gyrogroup satisfies the identity

$$F(u,\nu)F(-u,-\nu)=\frac{F(u,-u)F(\nu,-\nu)}{F(u+\nu,-u-\nu)}=\frac{\gamma_{u+\nu}^2}{\gamma_u^2\gamma_\nu^2} \tag{4.23}$$

for all $u,\nu\in\mathbb{R}^+$.

Proof: In any gyrogroup $(G,+)$ we have [Ref. 15, Theorem 5.2]

$$-(a+b)=-a-b \tag{4.24}$$

for all $a,b\in G$. In the gyrogroup $(\mathbb{R}^+\times P,\cdot)$ extended from the gyrogroup $(P,+,F)$ with the real cocycle form F, Eq. (4.24) takes the form

$$(s,u)^{-1}\cdot(t,\nu)^{-1}=(F(u,\nu)st,u+\nu)^{-1}. \tag{4.25}$$

But, by Eqs. (4.3) and (4.2), we have

$$(s,u)^{-1}\cdot(t,\nu)^{-1}=\left(\frac{1}{F(u,-u)s},-u\right)\cdot\left(\frac{1}{F(\nu,-\nu)t},-\nu\right)=\left(\frac{F(-u,-\nu)}{F(u,-u)F(\nu,-\nu)st},-u-\nu\right) \tag{4.26}$$

and

$$(F(u,\nu)st,u+\nu)^{-1}=\left(\frac{1}{F(u+\nu,-u-\nu)F(u,\nu)st},-u-\nu\right). \tag{4.27}$$

Hence, by Eq. (4.25), the right-hand sides of Eqs. (4.26) and (4.27) are equal. From the equality of their first entries, we obtain the left identity in (4.23). The right identity in (4.23) follows from the definition of the factor γ in Definition 2.6. The proof is thus complete.

Clearly, if the real cocycle form F is even, then identity (4.23) specializes to (2.2).

V. REAL AND COMPLEX BOOSTS

In STR a boost is a pure Lorentz transformation; that is, a Lorentz transformation without rotation. The boosts discussed in this section result from abstraction of the relativistic boosts, and are restricted to the forward cone.

Definition 5.1 (Boosts of space–time): Let $(\mathbb{R}^+\times P,\cdot)$ be the gyrogroup extended from a gyrogroup $(P,+,F)$. Left multiplication of any $(t,\nu)\in(\mathbb{R}^+\times P,\cdot)$ by $B(u)=(\gamma_u,u)\in(\mathbb{R}^+\times P,\cdot)$ is called a *boost* of (t,ν) by $u\in P$. $B(u)$ is called a *boost of the space–time* $(\mathbb{R}^+\times P,\cdot)$, *parametrized by the gyrogroup* $(P,+)$. Thus

$$B(u)(t,\nu)=(\gamma_u,u)\cdot(t,\nu), \tag{5.1}$$

where the gyrogroup operation $\cdot$ in Eq. (5.1) is given by Eq. (4.2).

We will now show that the boosts of the space–time (forward cone) $(\mathbb{R}^+\times V_c,\oplus)$ parametrized by the relativistic gyrogroup $(V_c,\oplus,S)$ are the special relativistic Lorentz boosts (also known as *pure* Lorentz transformations, or Lorentz transformations *without rotation*).

Since the cocycle form S in the relativistic gyrogroup $(V_c,\oplus,S)$ is, by (3.3),

$$S(\mathbf{u},\mathbf{v})=1+\frac{\mathbf{u}\cdot\mathbf{v}}{c^2}, \tag{5.2}$$

multiplication in $(\mathbb{R}^+\times V_c,\oplus)$ takes the form

$$(r,\mathbf{u})\cdot(s,\mathbf{v})=\left(rs\left(1+\frac{\mathbf{u}\cdot\mathbf{v}}{c^2}\right),\mathbf{u}\oplus\mathbf{v}\right), \tag{5.3}$$

where no confusion should arise in the use of a dot to denote both a gyrogroup operation in a gyrogroup of pairs and an inner product in a vector space.

Let us introduce new notation in which we write the pair $(t,\mathbf{v})\in\mathbb{R}^+\times V_c$ as

$$(t,\mathbf{v})=\begin{pmatrix} t\\ \mathbf{v}t\end{pmatrix}=\begin{pmatrix} t\\ \mathbf{x}\end{pmatrix} \tag{5.4}$$

with $\mathbf{x}=\mathbf{v}t$. The right-hand side of Eq. (5.4) represents a forward time-like event.

Let $B(\mathbf{v})=(\gamma_\mathbf{v},\mathbf{v})$ be a boost of $(\mathbb{R}^+\times V_c,\oplus)$. Then the boost application to a space–time event $(t,\mathbf{v})\in(\mathbb{R}^+\times V_c,\oplus)$:

$$B(\mathbf{u})(t,\mathbf{v})=(\gamma_\mathbf{u},\mathbf{u})\cdot(t,\mathbf{v})=\left(\gamma_\mathbf{u}t\left(1+\frac{\mathbf{u}\cdot\mathbf{v}}{c^2}\right),\mathbf{u}\oplus\mathbf{v}\right),$$

takes the following form in the new notation:

$$B(\mathbf{u})\begin{pmatrix} t \\ \mathbf{x} \end{pmatrix} = \begin{pmatrix} \gamma_u t\left(1+\frac{1}{c^2}\,\mathbf{u}\cdot\mathbf{v}\right) \\ (\mathbf{u}\oplus\mathbf{v})\,\gamma_{\mathbf{u}} t\left(1+\frac{1}{c^2}\,\mathbf{u}\cdot\mathbf{v}\right) \end{pmatrix}$$

$$= \begin{pmatrix} \gamma_{\mathbf{u}}\left(t+\frac{1}{c^2}\,\mathbf{u}\cdot\mathbf{x}\right) \\ \frac{1}{1+\mathbf{u}\cdot\mathbf{v}/c^2}\left\{\mathbf{u}+\frac{1}{\gamma_u}\,\mathbf{v}+\frac{1}{c^2}\,\frac{\gamma_u}{1+\gamma_u}\,(\mathbf{u}\cdot\mathbf{v})\mathbf{u}\right\}\gamma_{\mathbf{u}} t\left(1+\frac{1}{c^2}\,\mathbf{u}\cdot\mathbf{v}\right) \end{pmatrix}$$

$$= \begin{pmatrix} \gamma_v\left(t+\frac{1}{c^2}\,\mathbf{u}\cdot\mathbf{x}\right) \\ \gamma_{\mathbf{u}}\mathbf{u}t+\mathbf{x}+\frac{1}{c^2}\,\frac{\gamma_u^2}{1+\gamma_u}\,(\mathbf{u}\cdot\mathbf{x})\mathbf{u} \end{pmatrix}. \tag{5.5}$$

This *real* boost application agrees with the *complex* boost application in Eq. (2.5) of Ref. 8.

Definition 5.2R (The norm of a real forward time-like space–time event): Let $(\mathbb{R}^+\times P,\cdot)$ be a space–time over the gyrogroup $(P,+,F)$ with a real cocycle form F, and let $(t,\nu)\in(\mathbb{R}^+\times P,\cdot)$ be an event. The norm $\|(t,\nu)\|$ of (t,ν) is given by

$$\|(t,\nu)\|^2 = t^2 F(\nu,-\nu).$$

Definition 5.2C (The norm of a complex forward time-like space–time event): Let $(\mathbb{C}^+\times P,\cdot)$ be a space–time over the gyrogroup $(P,+,F)$ with a complex cocycle form F, and let $(t,\nu)\in(\mathbb{C}^+\times P,\cdot)$ be an event. The norm $\|(t,\nu)\|$ of (t,ν) is given by

$$\|(t,\nu)\|^2 = |t|^2 F(\nu,-\nu).$$

Theorem 5.1R: Real boosts preserve the norm.

Proof: Let $(t',\nu')=B(u)(t,\nu)$. Then

$$(t',\nu')=B(u)(t,\nu)=(\gamma_u,u)\cdot(t,\nu)=(F(u,\nu)\,\gamma_u t, u+\nu)$$

and, hence,

$$\|(t',\nu')\|^2 = F^2(u,\nu)\,\gamma_u^2 t^2 F(u+\nu,-u-\nu)$$

$$= t^2\,\frac{\gamma_{u+\nu}^2}{\gamma_u^2\gamma_\nu^2}\,\gamma_u^2\,\frac{1}{\gamma_{u+\nu}^2} \qquad \text{(by Theorem 2.2R)}$$

$$= t^2\,\frac{1}{\gamma_\nu^2} = t^2 F(\nu,-\nu) = \|(t,\nu)\|^2.$$

Theorem 5.1C: Complex boosts preserve the norm.

Proof: Let $(t',\nu')=B(u)(t,\nu)$. Then,

$$(t',\nu')=B(u)(t,\nu)=(\gamma_u,u)\cdot(t,\nu)=(F(u,\nu)\,\gamma_u t, u+\nu)$$

and, hence,

$$\begin{aligned}\|(t',\nu')\|^2 &= |F^2(u,\nu)\gamma_u^2 t^2| F(u+\nu,-u-\nu)\\ &= |t|^2 \frac{\gamma_{u+\nu}^2}{\gamma_u^2\gamma_\nu^2}\,\gamma_u^2\,\frac{1}{\gamma_{u+\nu}^2} \qquad \text{(by Theorem 2.2C)}\\ &= |t|^2 \frac{1}{\gamma_\nu^2} = |t|^2 F(\nu,-\nu) = \|(t,\nu)\|^2.\end{aligned}$$

Theorem 5.2R: The real boost composition law is given by the equation

$$B(u)B(\nu) = B(u+\nu)\mathrm{Gyr}[u;\nu]. \tag{5.6}$$

Proof: Let $(\mathbb{R}^+\times P,\cdot)$ be the gyrogroup over a gyrogroup $(P,+,F)$ with a real cocycle form F. Then

$$\begin{aligned}B(u)B(\nu)(t,w) &= (\gamma_u,u)\cdot((\gamma_\nu,\nu)\cdot(t,w))\\ &= (\gamma_u,u)\cdot(F(\nu,w)\gamma_\nu t,\nu+w)\\ &= (F(u,\nu+w)F(\nu,w)\gamma_u\gamma_\nu t, u+(\nu+w))\\ &= (F(\nu+u,w)F(u,\nu)\gamma_u\gamma_\nu t,(u+\nu)+\mathrm{gyr}[u;\nu]w) \quad \text{[by (C1)]}\\ &= (F(\nu+u,w)\gamma_{u+\nu}t,(u+\nu)+\mathrm{gyr}[u;\nu]w) \qquad \text{(by Theorem 2.2.R)}\\ &= (F(\mathrm{gyr}[u;\nu](\nu+u),\ \mathrm{gyr}[u;\nu]w)\gamma_{u+\nu}t,(u+\nu)+\mathrm{gyr}[u;\nu]w)\\ &= (F(u+\nu,\ \mathrm{gyr}[u;\nu]w)\gamma_{u+\nu}t,(u+\nu)+\mathrm{gyr}[u;\nu]w)\\ &= (\gamma_{u+\nu},u+\nu)\cdot(t,\mathrm{gyr}[u;\nu]w)\\ &= (\gamma_{u+\nu},u+\nu)\cdot\mathrm{Gyr}[u;\nu](t,w)\\ &= B(u+\nu)\mathrm{Gyr}[u;\nu](t,w)\end{aligned}$$

for all $(t,w)\in(\mathbb{R}^+\times P,\cdot)$, as desired.

Similarly to the definition of π_2 in (4.8), we now define the map π_1 from transformations A of $\mathbb{C}$ into transformations $\pi_1(A)$ of $\mathbb{C}^+\times P$ by the equation

$$\pi_1(A)(t,\nu) = (At,\nu). \tag{5.7}$$

Similarly to Eq. (4.7), we define the map tGyr : $P\times P\to\mathrm{Aut}(\mathbb{C}^+\times P)$ by the equation

$$\mathrm{tGyr}[u;\nu] = \pi_1(\mathrm{tgyr}[u;\nu]). \tag{5.8}$$

Theorem 5.2C: The complex boost composition law is given by the equation

$$B(u)B(\nu) = B(u+\nu)\mathrm{tGyr}[u;\nu]\mathrm{Gyr}[u;\nu]. \tag{5.9}$$

Proof: Let $(\mathbb{C}^+\times P,\cdot)$ be a gyrogroup over $(P,+,F)$ with a complex cocycle form F.

We should remark here that the definition of $(\mathbb{C}^+\times P,\cdot)$ over $(P,+,F)$ for F complex is analogous to the definition of $(\mathbb{R}^+\times P,\cdot)$ over $(P,+,F)$ for real F in Definition 4.1. The resulting complex gyrogroup $(\mathbb{C}^+\times P,\cdot)$ satisfies all the gyrogroup axioms with one exception; it does not obey the gyrocommutative law. Thus, as opposed to the real gyrogroup $(\mathbb{R}^+\times P,\cdot)$ over $(P,+,F)$, its complex counterpart is a groupoid that may be called a nongyrocommutative gyrogroup.

Then we have

$$
\begin{aligned}
B(u)B(v)(t,w) &= (\gamma_u,u)\cdot((\gamma_v,v)\cdot(t,w)) \\
&= (\gamma_u,u)\cdot(F(v,w)\gamma_v t, v+w) \\
&= (F(u,v+w)F(v,w)\gamma_u\gamma_v t, u+(v+w)) \\
&= (F(v+u,w)F(u,v)\gamma_u\gamma_v t,(u+v)+\mathrm{gyr}[u;v]w) \quad [\text{by (C1)}] \\
&= (F(v+u,w)\gamma_{u+v}\,\mathrm{tgyr}[u;v]t,(u+v)+\mathrm{gyr}[u;v]w) \\
&\qquad\qquad (\text{by Theorem 2.2C}) \\
&= (F(\mathrm{gyr}[u;v](v+u),\mathrm{gyr}[u;v]w)\gamma_{u+v}\,\mathrm{tgyr}[u;v]t,(u+v)+\mathrm{gyr}[u;v]w) \\
&= (F(u+v,\ \mathrm{gyr}[u;v]w)\gamma_{u+v}\,\mathrm{tgyr}[u;v]t,(u+v)+\mathrm{gyr}[u;v]w) \\
&= (\gamma_{u+v},u+v)\cdot(\mathrm{tgyr}[u;v]t,\mathrm{gyr}[u;v]w) \\
&= (\gamma_{u+v},u+v)\cdot\mathrm{tGyr}[u;v]\mathrm{Gyr}[u;v](t,w) \\
&= B(u+v)\mathrm{tGyr}[u;v]\mathrm{Gyr}[u;v](t,w)
\end{aligned}
$$

for all $(t,w)\in(\mathbb{C}^+\times P,\cdot)$, as desired.

It is clear from Theorems 5.2R and 5.2C that the boost inverse to $B(u)$ is $B(-u)$. These theorems reveal an important distinction between real and complex boosts. While real boost compositions produce only space gyrations, complex boost compositions produce both space gyrations and time gyrations. As a result, in Sec. VII, real Lorentz transformations will be parametrized by two parameters, while complex Lorentz transformations will be parametrized by three parameters.

Definition 5.3 (Gyrogroup automorphisms): Let $(P,+,F)$ be a gyrogroup with a cocycle form. An *automorphism* A of $(P,+,F)$ is a bijection of P that respects $+$ and preserves F, that is, $A(a+b)=Aa+Ab$ and $F(Aa,Ab)=F(a,b)$ for any $a,b\in P$. The set of all automorphisms of $(P,+,F)$ forms a group denoted by $\mathrm{Aut}(P,+,F)$. Subgroups of $\mathrm{Aut}(P,+,F)$ containing all the gyrations $\mathrm{gyr}[a;b]$ of $P(a,b\in P)$ are denoted generically by $\mathrm{Aut}_0(P,+,F)$.

Theorem 5.3: Boosts ''commute'' with automorphisms according to the equation

$$\pi_2(A)B(u)=B(Au)\pi_2(A).$$

Proof: Let $\mathbb{F}^+$ denote either $\mathbb{R}^+$ or $\mathbb{C}^+$, let $(\mathbb{F}^+\times P,\cdot)$ be the real or complex space–time (forward cone) gyrogroup over a gyrogroup $(P,+,F)$ with a real or complex cocycle form F, and let $u\in P$ and $A\in\mathrm{Aut}(P,+,F)$. Then for any $(t,w)\in(\mathbb{F}^+\times P,\cdot)$ we have

$$
\begin{aligned}
\pi_2(A)B(u)(t,w) &= \pi_2(A)(\gamma_u,u)\cdot(t,w) \\
&= \pi_2(A)(F(u,w)\gamma_u t,u+w) \\
&= (F(u,w)\gamma_u t,A(u+w)) \\
&= (F(Au,Aw)\gamma_{Au}t,Au+Aw) \\
&= ((\gamma_{Au},Au)\cdot(t,Aw)) \\
&= B(Au)\pi_2(A)(t,w),
\end{aligned}
$$

and, hence, the result.

VI. THE GYROSEMIDIRECT PRODUCT GROUP

Definition 6.1 (The gyrosemidirect product): Let $(P,+)$ be a gyrogroup, the gyrooperator of which is denoted by gyr, and let $\mathrm{Aut}_0(P,+)$ be a subgroup of its automorphism group containing all its gyrations. The *gyrosemidirect product group*

$$(P,+)\times_g \mathrm{Aut}_0(P,+) \tag{6.1}$$

is a group of pairs $(a,A)\in P\times \mathrm{Aut}_0(P,+)$ with composition law given by

$$(a,A)(b,B)=(a+Ab,\mathrm{gyr}[a;Ab]AB). \tag{6.2}$$

It is anticipated in Definition 6.1 that the gyrosemidirect product (6.2) is a group operation in the Cartesian product $P\times\mathrm{Aut}_0(P,+)$ of a gyrogroup $P=(P,+)$ and an automorphism group. To show that this is indeed the case, we view any pair

$$(a,A)\in(P,+)\times_g\mathrm{Aut}_0(P,+) \tag{6.3}$$

as a bijection of P, given by

$$(a,A)x=a+Ax \tag{6.4}$$

for any $x\in P$. The inverse of the bijection (a,A) is clearly $(-A^{-1}a,A^{-1})$. The gyrosemidirect product (6.2) then emerges as a bijection composition and, hence, a group operation:

$$\begin{aligned}(a,A)(b,B)x&=(a,A)(b+Bx)\\&=a+A(b+Bx)\\&=a+(Ab+ABx)\\&=(a+Ab)+\mathrm{gyr}[a;Ab]ABx\\&=(a+Ab,\mathrm{gyr}[a;Ab]AB)x\end{aligned} \tag{6.5}$$

for all $x\in P$.

A slightly different gyrosemidirect product, that will be used with the complex Lorentz group, is the following.

Definition 6.2 (The complex gyrosemidirect product): Let $(P,+,F)$ be a gyrogroup with a complex cocycle form F, and let gyr and tgyr be its gyro-operator and its time gyro-operator, respectively. Moreover, let $\mathbb{C}_0$ be the group of all unimodular complex numbers. The *complex gyrosemidirect product*

$$(P,+,F)\times_g\{\mathbb{C}_0\times\mathrm{Aut}_0(P,+,F)\} \tag{6.6}$$

is a group of triples $(a,\alpha,A)\in P\times\mathbb{C}_0\times\mathrm{Aut}_0(P,+,F)$ with composition law given by

$$(a,\alpha,A)(b,\beta,B)=(a+Ab,\mathrm{tgyr}[a;Ab]\alpha\beta,\mathrm{gyr}[a;Ab]AB). \tag{6.7}$$

We are now in a position to present the real (complex) Lorentz transformation groups acting on the real (complex) space–time $(\mathbb{F}^+\times P,\cdot)$ over a gyrogroup $P=(P,+,F)$ with a real (complex) cocycle form F.

VII. ABSTRACT REAL AND COMPLEX LORENTZ TRANSFORMATION GROUPS

Our approach to the study of Lorentz groups by relativistic velocity spaces and the gyrogroups to which they give rise emphasizes analogies shared with Galilei relativity. These analogies are

partially summarized in the introductory section of Ref. 8. In particular, a $(1+n)$-dimensional Lorentz group in our approach appears as the gyrosemidirect product (see Sec. VI) of (i) a velocity gyrogroup and (ii) a rotation group. This is in full analogy with the $(1+n)$-dimensional Galilei group which is known to be the semidirect product of (i) a velocity group and (ii) a rotation group.

Our new approach became possible following the discovery in Ref. 1 of the symmetries concealed in Thomas precession, the abstraction of which is called Thomas gyration allowing us to introduce the prefix ''gyro.'' Following our approach to employ analogies shared with Galilean relativity and symmetries hidden in Thomas gyration, we treat the time coordinate on a different footing from the space coordinates, as we commonly do in Galilean relativity. Hence, in particular, the pair (t,ν) represents a (generalized) time–space as explained in Eq. (5.4), and should not be confused with the common energy-momentum space of STR. The pair (t,ν) represents a ''generalized'' or an ''abstract'' time–space in the sense that ν is an element of an abstract gyrogroup rather than a three-dimensional velocity.

Using techniques developed in the previous sections we generalize in this section results that were obtained in Refs. 7 and 8 for some special gyrogroups.

Definition 7.1R (The real Lorentz transformation): Let $(\mathbb{R}^+\times P,\cdot)$ be the space–time gyrogroup over a gyrogroup $(P,+,F)$ with a real cocycle form F, and let $\mathrm{Aut}_0(P,+,F)$ be a subgroup of $\mathrm{Aut}(P,+,F)$ containing all the gyroautomorphisms of P. For any $(u,U)\in(P,+,F)\times_g \mathrm{Aut}_0(P,+,F)$, the *real Lorentz transformation* $L\{u;U\}$ acting on the space–time $(\mathbb{R}^+\times P,\cdot)$ is given by

$$L\{u;U\}=B(u)\pi_2(U).$$

It follows from Definitions 5.1 and 6.1 that

$$\begin{aligned} L\{u;U\}(t,\nu)&=B(u)\pi_2(U)(t,\nu)\\ &=(\gamma_u,u)\cdot(t,U\nu)\\ &=(F(u,U\nu)\gamma_u t,u+U\nu) \end{aligned} \tag{7.1R}$$

for any $u\in(P,+,F)$, $U\in\mathrm{Aut}_0(P,+,F)$ and $(t,\nu)\in(\mathbb{R}^+\times P,\cdot)$.

Theorem 7.1R: Real Lorentz transformations preserve the norm.

Proof: By definition, the real Lorentz transformation

$$L\{u;U\}\ :\ (\mathbb{R}^+\times P,\cdot)\to(\mathbb{R}^+\times P,\cdot)$$

is given by a boost preceded by an automorphism,

$$L\{u;U\}=B(u)\pi_2(U).$$

Both $B(u)$ and $\pi_2(U)$ preserve the squared norm $\|(t,\nu)\|^2=t^2F(\nu,-\nu)$ in $(\mathbb{R}^+\times P,\cdot)$: $B(u)$ preserves the norm by Theorem 5.1R, and $\pi_2(U)$ preserves the norm, since it preserves the cocycle form $F(\nu,-\nu)$ by Definition 5.3. The proof is thus complete.

Theorem 7.2R (The real Lorentz transformation composition law):

The real Lorentz transformations of the space–time $(\mathbb{R}^+\times P,\cdot)$ over a gyrogroup $(P,+,F)$ with a real cocycle form, form a group with group operation given by

$$L\{u;U\}L\{\nu;V\}=L\{u+U\nu,\mathrm{gyr}[u;U\nu]UV\} \tag{7.2R}$$

for any $u,\nu\in P$ and $U,V\in\mathrm{Aut}(P,+,F)$.

Proof: Let $(\mathbb{R}^+\times P,\cdot)$ be a space–time gyrogroup over the gyrogroup $(P,+,F)$ with a real cocycle form F, and let $u,\nu\in P$ and $U,V\in\mathrm{Aut}(P,+,F)$. Then, the product of two successive real Lorentz transformations of $(\mathbb{R}^+\times P,\cdot)$ is

$$
\begin{aligned}
L\{u;U\}L\{\nu;V\} &= B(u)\pi_2(U)B(\nu)\pi_2(V) \\
&= B(u)B(U\nu)\pi_2(UV) && \text{(by Theorem 5.3)} \\
&= B(u+U\nu)\mathrm{Gyr}[u;U\nu]\pi_2(UV) && \text{(by Theorem 5.2R)} \\
&= B(u+U\nu)\pi_2(\mathrm{gyr}[u;U\nu]UV) \\
&= L\{u+U\nu);\mathrm{gyr}[u;U\nu]UV),
\end{aligned}
$$

as desired.

Theorem 7.2R presents the real Lorentz transformation composition law in terms of parameter composition, where the parameter composition is the gyrosemidirect product (6.2). Unlike its real counterpart, the complex Lorentz transformation involves three parameters.

Definition 7.1C (The complex Lorentz transformation):

Let $(\mathbb{C}^+\times P,\cdot)$ be the space–time gyrogroup over a gyrogroup $(P,+,F)$ with a complex cocycle form F, and let $\mathrm{Aut}_0(P,+,F)$ be a subgroup of $\mathrm{Aut}(P,+,F)$ containing all the gyroautomorphisms of P. For any $(u,\alpha,U)\in(P,+,F)\times_g\{\mathbb{C}_0\times\mathrm{Aut}_0(P,+,F)\}$, the *complex Lorentz transformation* $L\{u;\alpha;U\}$ acting on the space–time $(\mathbb{C}^+\times P,\cdot)$ is given by

$$L\{u;\alpha;U\}=B(u)\pi_1(\alpha)\pi_2(U).$$

It follows from Definitions 5.1 and 6.2 that

$$L\{u;\alpha;U\}(t,\nu)=B(u)\pi_1(\alpha)\pi_2(U)(t,\nu)=(\gamma_u,u)\cdot(\alpha t,U\nu)=(F(u,U\nu)\gamma_u\alpha t,u+U\nu) \tag{7.1C}$$

for any $u\in(P,+,F)$, $\alpha\in\mathbb{C}_0$, $U\in\mathrm{Aut}_0(P,+,F)$ and $(t,\nu)\in(\mathbb{C}^+\times P,\cdot)$.

Theorem 7.1C: Complex Lorentz transformations preserve the norm.

Proof: By definition, the complex Lorentz transformation

$$L\{u;\alpha;U\}\ :\ (\mathbb{C}^+\times P,\cdot)\to(\mathbb{C}^+\times P,\cdot)$$

is given by a boost preceded by two automorphisms of $(\mathbb{C}^+\times P,\cdot)$,

$$L\{u;\alpha;U\}=B(u)\pi_1(\alpha)\pi_2(U).$$

All $B(u)$, $\pi_1(\alpha)$ and $\pi_2(U)$ preserve the squared norm $\|(t,\nu)\|^2=|t|^2F(\nu,-\nu)$ in $(\mathbb{C}^+\times P,\cdot)$: $B(u)$ preserves the norm by Theorem 5.1C, $\pi_1(\alpha)$ preserves the norm since $\alpha\in\mathbb{C}_0$, and $\pi_2(U)$ preserves the norm since U preserves the cocycle form $F(\nu,-\nu)$ by Definition 5.3. The proof is thus complete.

Theorem 7.2C (The complex Lorentz transformation composition law): The complex Lorentz transformations of a complex space–time $(\mathbb{C}^+\times P,\cdot)$ over a gyrogroup $(P,+,F)$ form a group with group operation given by

$$L\{u;\alpha;U\}L\{\nu;\beta;V\}=L\{u+U\nu;\mathrm{tgyr}[u;U\nu]\alpha\beta;\mathrm{gyr}[u;U\nu]UV\} \tag{7.2C}$$

for any $u,\nu\in P$, $\alpha,\beta\in\mathbb{C}_0$, and $U,V\in\mathrm{Aut}(P,+,F)$.

Proof: Let $(\mathbb{C}^+\times P,\cdot)$ be the space–time gyrogroup over a gyrogroup $(P,+,F)$ with a complex cocycle form F, and let $u,\nu\in P$ and $U,V\in\mathrm{Aut}(P,+,F)$. Then, the product of two successive real Lorentz transformations of $(\mathbb{C}^+\times P,\cdot)$ is

$$
\begin{aligned}
L\{u;\alpha;U\}L\{\nu;\beta;V\} &= B(u)\pi_1(\alpha)\pi_2(U)B(\nu)\pi_1(\beta)\pi_2(V) \\
&= B(u)B(U\nu)\pi_1(\alpha\beta)\pi_2(UV) && \text{(by Theorem 5.3)} \\
&= B(u+U\nu)\mathrm{tGyr}[u;U\nu]\mathrm{Gyr}[u;U\nu]\pi_1(\alpha\beta)\pi_2(UV) && \text{(by Theorem 5.2C)} \\
&= B(u+U\nu)\pi_1(\mathrm{tgyr}[u;U\nu]\alpha\beta)\pi_2(\mathrm{gyr}[u;U\nu]UV \\
&= L\{u+U\nu;\mathrm{tgyr}[u;U\nu]\alpha\beta;\mathrm{gyr}[u;U\nu]UV\}
\end{aligned}
$$

as desired.

Theorem 7.2C presents the complex Lorentz transformation composition law in terms of parameter composition, where the parameter composition is the complex gyrosemidirect product (6.7). Unlike its real counterpart, the complex Lorentz transformation involves three parameters.

VIII. GROUP-THEORETICAL INTERPRETATION

The constructions used in this paper may be interpreted in terms of group theory. The group-theoretical interpretation is analogous in some ways to the useful interpretation of complex numbers $a+ib$ as 2×2 matrices

$$
\begin{pmatrix} a & -b \\ b & a \end{pmatrix}.
$$

Using this interpretation one may reduce complex analysis to matrix theory. For example, the square of the absolute value becomes the determinant, the real part is half the trace, and conjugation is matrix transposition. Of course, one does not normally view the complex numbers in this way since the matrix notation is excessively cumbersome for the purposes of complex analysis. By the same token, the gyrogroup approach, as presented in this article, is the most direct and convenient for computations in STR. In particular, the gyrogroup formalism stays very close to the familiar formalism of abelian groups. Thus the useful group-theoretical interpretation is of more purely mathematical interest.[16,17]

Specifically, our basic idea is to view the abstraction of the well-known relation

$$
\frac{(1-(u\oplus\nu))^2}{(1-u^2)(1-\nu^2)} = \frac{1}{(1+u\cdot\nu)^2}
$$

in STR, where $\oplus$ is the relativistic velocity addition (3.2), as a cocycle identity, Eq. (2.2); that is, the squared *coboundary* on the left is equal to the squared cocycle on the right. This identity is the fundamental relation used to extend the velocity addition law into a Lorentz transformation. In fact, this extension can be recast using the language of cohomologically trivial central extension of the Lorentz group. Furthermore, the present work may also have applications to areas of mathematical physics outside the foundations of special relativity, since it involves a new approach to polar decompositions and their relation to Grassmann varieties which occur frequently in various twistor constructions. As illustrative examples, we show below the relationship between our Theorems 4.1 and 2.2R and common group-theoretical considerations.

The gyrosemidirect product of Definition 6.1 shows how to embed a gyrogroup P into a group $G=P\times_g \mathrm{Aut}_0(P)$, a subgroup of the group $\widetilde{G}=P\times_g \mathrm{Aut}(P)$. The inversion map $J : P\to P$, $x\to -x$ is an automorphism of P, and conjugation by the element $(0, J)$ of $\widetilde{G}$ gives an involutory automorphism ϕ of G. Setting $P_0=\{(x, I)|x\in P\}$ and $K=\{(0, A)|A\in \mathrm{Aut}_0(P)\}$, one has $\phi(x,I)=(x,I)^{-1}$, $G=P_0K$, $P\cap K=\{(0, I)\}$, and P_0 is invariant under conjugation by elements of K. Moreover, elements of K are fixed by ϕ.

Conversely, consider a group G with an involutory automorphism ϕ. Suppose that $G=P_0K$ with $P_0\cap K=\{I\}$. Suppose that the elements of K are fixed points of ϕ. Suppose ϕ acts on P_0 by $\phi : P_0\to P_0;\ x\to x^{-1}$, and suppose that P_0 is invariant under conjugation by elements of K. Suppose x,y in P imply xyx in P_0, and suppose that $P_0\to P_0;\ x\to x^2$ is bijective, with two-sided inverse $x\to\sqrt{x}$. Then P becomes a gyrogroup $(P,+)$ under $x+y=\sqrt{x}y\sqrt{x}$. Indeed, for $xy=(x+y)k$, one has $\mathrm{gyr}[x;y]z=kzk^{-1}$.[17]

Now embed a gyrogroup P in a gyrosemidirect product group G, $G=PK$ as above. Since the inverse of a gyration is a gyration, the group generated by gyrations is just the set of products of gyrations. Thus the cocycle form $F : P\times P\to\mathbb{R}^+$ satisfying the gyroinvariance may be extended to a cocycle form on G by $F(\phi_1k_1,\phi_2k_2)=F(\phi_1,k_1\phi_2k_1^{-1})$. By the standard theory of central extensions for groups,[18] one obtains a central extension $\hat{G}$ of G by $\mathbb{R}^+$. The extension gyrogroup $(\mathbb{R}^+\times P,\cdot)$ of Theorem 4.1 may then be recovered from the extension group $\hat{G}$ as above. Conversely, if $(\mathbb{R}^+\times P,\cdot)$ is a gyrogroup, then $(P,+)$ is, too, by virtue of being a quotient. Theorem 2.2R corresponds to the case where the exact sequence

$$1\to\mathbb{R}^+\to\hat{G}\to G\to 1$$

splits.

Comment on: The Itzykson–Zuber integral for $U(m|n)$ [J. Math. Phys. 36, 3085–3093 (1995)]

Thomas Guhr[a)]
Max Planck Institut für Kernphysik, Postfach 103980, 69029 Heidelberg, Germany

(Received 20 July 1995; accepted for publication 25 January 1996)

[S0022-2488(96)01405-5]

In their recent work, Alfaro, Medina, and Urrutia evaluate the supersymmetric version of the Harish–Chandra–Itzykson–Zuber (HCIZ) integral[1,2] by generalizing the diffusion equation method of Itzykson and Zuber.[2] This integral is of considerable interest in quantum chaos and the theory of random matrices. In the case $n=m$, this integral was already calculated,[3] also by generalizing the diffusion equation method of Ref. 2. By using this integral, a new derivation of the correlation functions of the Gaussian unitary ensemble (GUE) was given which can be viewed as an irreducible integral representation.[3] For the discussion of transitions between ensembles, those integrals are the essential tool. By applying the ordinary HCIZ integral, Mehta and Pandey[4] calculated all correlations for the statistical model of gradually broken time reversal invariance. Employing the supersymmetric HCIZ integral, the correlations for the statistical model of a gradually broken quantum number were evaluated in Ref. 5.

After the angular integration over the unitary group, usually further integrations over the eigenvalues, i.e., the s-variables in Refs. 3 and 5 or the λ-variables in the work of Alfaro, Medina, and Urrutia, are required. Here, two important remarks are in order: First, all permutations in the determinant yield the same result because of the antisymmetry of the integration measure of the eigenvalues. This is why one needs only the trace term if further integrations are required.[3] Second, boundary contributions to the integral emerge which have no counterparts in the ordinary case. In Ref. 3, the most important one of those, the Efetov–Wegner term[6,7] was given. In the case of the group $U(1|1)$, a complete formula was constructed[8] using a very general theory developed by Rothstein.[9]

Obviously, the supersymmetric HCIZ has much to do with harmonic analysis in superspaces. For the group $U(1|1)$, graded or super spherical harmonics were derived[10] in which anticommuting indices formally play the role of an angular momentum. The corresponding representations in terms of graded or super Wigner functions were discussed in Ref. 11. In the general case $U(k_1|k_2)$, such representations involving anticommuting indices were constructed in Ref. 12 by generalizing the Gelfand–Tzetlin method to supersymmetry. These results have also been used in Ref. 12 to evaluate the supersymmetric HCIZ integral for $n\neq m$, including all permutation and exchange terms.

[S0022-2488(96)02205-X]

This note is to observe that the integral (B3) calculated in the Appendix B of Ref. 1 is not the supersymmetric IZ integral for the particular case $m=n$, but it rather corresponds to the expression that survives when the IZ integral is subsequently integrated over all the eigenvalues and after some symmetry properties are taken into account. Since some applications do not require a further integration over the eigenvalues, the difference between the two expressions is of basic importance.

The above remark is most easily illustrated with the standard IZ integral, in the case of ordinary $n\times n$ matrices. In this situation, the result given in Eq. (B3) of Ref. 1 would read

$$\int \exp\left(-\frac{1}{2t}\mathrm{tr}(\sigma-\rho)^2\right)d\mu(V)=A\frac{t^{n(n-1)/2}}{\Delta(R)\Delta(S)}\exp\left(-\frac{1}{2t}\mathrm{tr}(S-R)^2\right), \tag{1}$$

where $\Delta(R)$ denotes the Vandermonde determinant of the eigenvalues. The numerical constant A is independent of t and also of the eigenvalues. From the above expression we would conclude, according to Ref. 1, that the IZ integral is given by

$$\int \exp\left(\frac{1}{t}\mathrm{tr}(RVSV^{-1})\right)d\mu(V)=A\frac{t^{n(n-1)/2}}{\Delta(R)\Delta(S)}\exp\left(\frac{1}{t}\mathrm{tr}(RS)\right). \tag{2}$$

Nevertheless, we know from Ref. 2 that the correct answer for this integral is

$$\int \exp\left(\frac{1}{t}\mathrm{tr}(RVSV^{-1})\right)d\mu(V)=B\frac{t^{n(n-1)/2}}{\Delta(R)\Delta(S)}\det\left(\exp\frac{1}{t}r_i s_j\right). \tag{3}$$

The left-hand side of Eq. (2) corresponds only to the diagonal term in the expansion of the complete determinant which produces the correct answer in Eq. (3). Only under a further integration over all the eigenvalues, can the remaining n^2-1 terms reduce to the diagonal one. In other words, the result (1) is correct only under a symmetric integration over the eigenvalues

$$\int \exp\left(-\frac{1}{2t}\mathrm{tr}(\sigma-\rho)^2\right)d\mu(V)\Delta^2(R)d[R]=A\frac{t^{n(n-1)/2}}{\Delta(S)}\int \exp\left(-\frac{1}{2t}\mathrm{tr}(S-R)^2\right)\Delta(R)d[R]. \tag{4}$$

An analogous situation occurs in the supersymmetric case, when comparing the expression (B3) of Ref. 1 with the formula (9) of Ref. 3, in the case $m=n$.

Summarizing, even though the methods used by Guhr and the authors coincide, the results obtained are different in the same sense that the corresponding calculations of Ref. 2 and 4 are not equivalent to each other. Besides, nowhere in Ref. 1 can the expression for the supersymmetric IZ integral, given in Eq. (9) of Ref. 3, be found, even for the particular case $m=n$.

In relation to the interesting observation of Ref. 1 about the existence of Efetov–Wegner terms, we only observe that such terms will appear when the supersymmetric IZ integral is further integrated over the eigenvalues. They reflect the existence of singularities due to the contribution of the Berezinian, which need to be regularized. If the regulator chosen is not explicitly supersymmetric, the Efetov–Wegner terms will be needed to restore a supersymmetric result.

The Hodge–de Rham Laplacian on spheres acting on antisymmetric tensor fields is considered. Explicit expressions for the spectrum are derived in a quite direct way, confirming previous results. Associated functional determinants and the heat kernel expansion are evaluated. Using this method, new non-local counterterms in the quantum effective action are obtained, which can be expressed in terms of Betti numbers. © *1996 American Institute of Physics.* [S0022-2488(96)02507-8]

I. INTRODUCTION

Modern interest in antisymmetric tensor fields is connected with supergravity theories where these fields appear as members of a supermultiplet. Kaluza–Klein compactification of higher dimensional supergravities leads to backgrounds of the form $S^d \times R^4$, where S^d is the d-dimensional sphere. Quantum effects on such backgrounds were considered e.g. in Refs. 1,2. Some general mathematical statements about p-forms—very useful in this context—can be found in the monography by Gilkey.[3] Typically, the action for an antisymmetric tensor field B reads as

$$S = \int \sqrt{g} dx F_{ij\ldots k} F^{ij\ldots k}, \quad F = dB, \tag{1}$$

where d denotes external differentiation of forms. The action (1) for the p-form B^p is invariant under gauge transformations,

$$B^p \to B^p + dB^{p-1}. \tag{2}$$

All quantum corrections in a theory described by the action (1), including the contribution of ghosts, can be expressed in terms of determinants of the Hodge–de Rham Laplacian,

$$\Delta_{HdR} = -(d^*d + dd^*). \tag{3}$$

The spectrum of Δ_{HdR} is the same for p- and $(d\text{-}p)$-forms. Consequently, it is enough to evaluate the determinant of Δ_{HdR} for $p \leqslant d/2$. Due to the gauge invariance under the transformation (2) and to the factorization property,

$$\det_p(-\Delta_{HdR}) = \det_{pT}(-\Delta_{HdR}) \times \det_{(p-1)T}(-\Delta_{HdR}) \tag{4}$$

[a]Electronic mail: eli@zeta.ecm.ub.es
[b]Electronic mail: lygren@fm.unit.no

—where the subscript T means that the determinant is taken over the space of transversal forms—we can restrict our considerations to transversal p-forms. We will assume in all those expressions, as in (4), that zero modes (harmonic p-forms) are excluded from the determinants.

In Sec. II we will obtain the spectrum of the Hodge–de Rham Laplace operator on the unit sphere S^d, for any dimension d, acting on transversal p-forms. In Sec. III we will calculate explicitly the determinants for the sphere, and in Sec. IV the heat kernel coefficients. A complete list will be given up to $d=7$, a dimension that is important in the compactification of supersymmetric theories. Finally, a discussion on the transversal Laplacian and non-local counterterms will be provided in Sec. V. It is proven there that the heat kernel expansion for the Hodge–de Rham Laplacian on transversal p-forms contains a constant term, even in the case of odd-dimensional spaces. The new non-local counterterms in the quantum effective action will be expressed in terms of Betti numbers.

II. SPECTRUM OF THE LAPLACE OPERATOR

In this section we define the spectrum of the Laplace operator Δ_{HdR} on the unit sphere S^d acting on transversal p-forms. For $p=0,1$ this spectrum is well known[4]:

$$b_l^0=-l(l+d-1), \quad D_l^0=\frac{(2l+d-1)(l+d-2)!}{l!(d-1)!}, \quad l=0,1,2,\ldots,$$
$$b_l^1=-l(l+d-1)+2-d, \quad D_l^1=\frac{l(l+d-1)(2l+d-1)(l+d-3)!}{(d-2)!(l+1)!}, \quad l=1,2,3,\ldots, \tag{5}$$

where b_l^p denote the eigenvalues and D_l^p their degeneracies. For higher forms the spectrum of the Laplace operator on S^d can be obtained by using standard group theoretical techniques.[5–7]

For any homogeneous space G/H a field Φ_A belonging to an irreducible representation $D(H)$ can be expanded as[8]

$$\Phi_A(x)=V^{-\frac{1}{2}}\sum_{n,\zeta,q}\sqrt{\frac{d_n}{d_D}}D^{(n)}_{A\zeta,q}(g_x^{-1})\phi^{(n)}_{q,\zeta}, \tag{6}$$

where V is the volume of G/H and $d_D=$ dim $D(H)$. We sum over representations $D^{(n)}$ of G which give $D(H)$ after reduction to H. Here ζ labels the multiple components $D(H)$ in the branching $D^{(n)}\downarrow H$, $d_n=$ dim $D^{(n)}$. The matrix elements of $D^{(n)}$ have the following orthogonality property

$$\int_{G/H}dx\sqrt{g}D^{(n)*}_{A\zeta,q}(g_x^{-1})D^{(n')}_{A\xi,p}(g_x^{-1})=Vd_n^{-1}d_D\delta_{\zeta\xi}\delta_{pq}\delta_{nn'}. \tag{7}$$

Consider, for example, the case when $d=5$: $S^5=SO(6)/SO(5)$. The representations $D(H)=D(SO(5))$ describing antisymmetric tensors are just antisymmetric tensor powers of the vector representation of $SO(5)$:

$$p=0, \quad D(SO(5))=[0,0], \quad p=1, \quad D(SO(5))=[1,0],$$
$$p=2, \quad D(SO(5))=[1,1], \quad p=3, \quad D(SO(5))=[1,1]. \tag{8}$$

We label the representations by their Dynkin indices in square brackets. Notice that we use here the slightly non-standard definition of the Dynkin indices from the book by Barut and Raezka.[9] These indices are more convenient for the reduction of representations. Owing to duality, the representations in the last two lines of (8) are equivalent.

In order to construct the harmonic expansion (6) one must find all the representations of $SO(6)$ which give the representations (8) after reduction to $SO(5)$. For a given irreducible representation $[q_1,q_2]$ of $SO(5)$ with integer Dynkin indices q_1 and q_2, the representations $[m_1,m_2,m_3]$ of $SO(6)$ containing $[q_1,q_2]$ are defined by the conditions[9]

$$m_1 \geqslant q_1 \geqslant m_2 \geqslant q_2 \geqslant |m_3|, \tag{9}$$

where all m_A are integers and m_1 and m_2 are non-negative. Any representation satisfying the nonequality (9) contains the single representation $[q_1,q_2]$. Summation over ζ in (6) may be omitted. One can easily find all the representations of $SO(6)$ that are needed

$$\begin{gathered} p=0,\ D^{(l)}(SO(6))=[l,0,0],\ \ l=0,1,\ldots, \\ p=1,\quad D^{(l)}(SO(6))=[l,1,0],\ \ l=1,2,\ldots=[l,0,0], l=1,2,\ldots, \\ p=2,3,\quad D^{(l)}(SO(6))=[l,1,0],\ \ l=1,2,\ldots,=[l,1,1], l=1,2,\ldots,=[l,1,-1], l=1,2,\ldots\ . \end{gathered} \tag{10}$$

External differentiation maps transversal $p-1$ forms to longitudinal p-forms. This mapping can be traced back to the corresponding spherical harmonics. Hence, for the transversal forms only the following representations contribute to the harmonic expansion:

$$\begin{gathered} p=0,\quad D^{(l)}(SO(6))=[l,0,0], \\ p=1,\quad D^{(l)}(SO(6))=[l,1,0], \\ p=2,\quad D^{(l)}(SO(6))=[l,1,1],=[l,1,-1], \\ p=3,\quad D^{(l)}(SO(6))=[l,1,0], l=1,2,3,\ldots\ . \end{gathered} \tag{11}$$

The scalar mode with $l=0$ belongs to the kernel of the Laplace operator and should be regarded as a harmonic zero-form.

In the space of p-forms there are two main second-order differential operators, namely the Hodge–de Rham Laplacian, $-\Delta_{HdR}=dd^*+d^*d$, and the ordinary Laplacian, $\Delta=\nabla^i\nabla_i$. On the sphere S^d these two operators differ by a constant, namely

$$-\Delta_{HdR}=\Delta+p^2-dp. \tag{12}$$

In any homogeneous space G/H the Laplace operators can be expressed in terms of the quadratic Casimir operators of G and H:

$$\Delta=C_2(G)-C_2(H), -\Delta_{HdR}=C_2(G). \tag{13}$$

Using the harmonic expansion (11), (8), and standard expressions[9] for the Casimir operators in (13), we obtain the eigenvalues b_l^p of the Laplace operator Δ_{HdR} acting on transversal p-forms on S^5. The corresponding degeneracies D_l^p are equal to the dimensions of the representations of $SO(6)$.

$$\begin{gathered} b_l^2=-l(l+4)-4,\quad D_l^2=\frac{1}{2}l(l+1)(l+3)(l+4),\quad l=1,2,\ldots, \\ b_l^3=-l(l+4)-3,\quad D_l^3=\frac{1}{3}l(l+2)^2(l+4),\quad l=1,2,\ldots\ . \end{gathered} \tag{14}$$

For $p=0,1$ our result coincides with (5). Other spheres can be dealt with along the same lines. For $d=3$ we have:

$$b_l^2=-l(l+2), \quad D_l^2=(l+1)^2, \quad l=1,2,\ldots \ . \tag{15}$$

For $d=4$:

$$b_l^2=-l(l+3)-2, \quad D_l^2=\frac{1}{2}l(2l+3)(l+3), \quad l=1,2,\ldots \ . \tag{16}$$

For $d=6$:

$$b_l^2=b_l^3=-l(l+5)-6, \quad D_l^2=D_l^3=\frac{1}{12}l(l+1)(l+4)(l+5)(2l+5), \quad l=1,2,3,\ldots \ . \tag{17}$$

For $d=7$:

$$\begin{aligned} b_l^2&=-l(l+6)-8, \quad D_l^2=\frac{1}{24}l(l+1)(l+3)^2(l+5)(l+6), \\ b_l^3&=-l(l+6)-9, \quad D_l^3=\frac{1}{18}l(l+1)(l+2)(l+4)(l+5)(l+6), \quad l=1,2,3,\ldots \ . \end{aligned} \tag{18}$$

Owing to duality, the spectrum of Δ_{HdR} on transversal 4-forms on S^7 is the same as on longitudinal 3-forms. The latter one coincides with that on transversal 2-forms. Continuing in this way, one can define the spectrum for higher values of p. The remarkable property of equivalence of the spectra for $p=2$ and $p=3$ on S^6 holds only for transversal forms. In the above equations we have listed some spectra for $p>d/2$. They are useful in some applications not considered in this paper. For example, they are needed for the computation of the spectrum of the Laplacian on a ball.[10,7,11]

There is a general function for the eigenvalues and their multiplicities, which have been obtained above for some particular cases. It is the following:

$$\begin{aligned} D_l(d,p)&=\frac{(2l+d-1)(l+d-1)!}{p!(d-p-1)!(l-1)!(l+p)(l+d-p-1)}, \\ b_l(d,p)&=-l(l+d-1)-p(d-p-1). \end{aligned} \tag{19}$$

These equations can be obtained by means of lengthy but straightforward calculations repeating step by step the above derivation of the spectrum on S^5. All group theoretical techniques that are needed can be learned from Chaps. 9 and 10 of Ref. 9. Note that an explicit derivation for the case of the ordinary Laplacian had been carried out, e.g., in Ref. 5, and that previous results already existed in the mathematical literature.[12,13] Our method is similar to the one in the papers.[12,13] However, explicit expressions for the eigenvalues and degeneracies can be found in Ref. 5 only, where reduction of the harmonic polynomials from R^{d+1} was used. It is noticeable that a mistake in previous calculations was reported in Ref. 5, which shows that the computation is not trivial at all. It thus seems useful to present an alternative derivation of the spectrum, which turns out to be in complete agreement with Ref. 5 Note that the eigenvalues of the Laplace operator on transversal p-forms are denoted in Ref. 5 by ${}^{p+1}\lambda_k$, where $k=l-1=0,1,\ldots$.

III. CALCULATION OF THE DETERMINANTS FOR THE SPHERE

Here we are going to calculate the determinants corresponding to the Hodge–de Rham Laplacian on spheres of different dimensions, $d=2,3,4,5,6,7$, and for forms of different orders $p=1,2,3,4$. We shall make use of the formulas (see above)

$$\det(-\Delta_{HdR})^{(d)}=\det(-\Delta_{HdR})_{p^T}^{(d)}\times\det(-\Delta_{HdR})_{(p-1)^T}^{(d)}, \tag{20}$$

and employ the definition of determinant through the zeta function of the corresponding operator, that is

$$\det A=\exp(-\zeta_A'(0)). \tag{21}$$

Owing to the multiplicative property of the determinant—which is obviously fulfilled for the operators we are going to consider (see Ref. 14 for a discussion of more general cases)—at the level of the zeta functions the product in (20) transforms into a sum of the corresponding zeta functions (even before taking the derivative). We shall arrange our calculations according to this observation. The general methods employed in Refs. 15,16 will be used (see Ref. 17 for more references to these techniques). Related calculations have been carried out in Ref. 18.

Using the general formulas (19) for the spectrum and its degeneracy, one can write the expression of the zeta function corresponding to a p-form in any dimension d $(p\leqslant(d+1)/2)$, namely

$$\begin{aligned}\zeta_{-\Delta_{p^T}^{(d)}}(s)&=\sum_{l=1}^{\infty}D_l(d,p)[-b_l(d,p)]^{-s}\\&=\frac{1}{p!(d-p-1)!}\sum_{l=1}^{\infty}\frac{(2l+d-1)(l+d-1)!}{(l-1)!(l+p)(l+d-p-1)}\left[\left(l+\frac{d-1}{2}\right)^2-\left(p-\frac{d-1}{2}\right)^2\right]^{-s}.\end{aligned} \tag{22}$$

To continue, we notice that the degeneracy is a polynomial in l of order $d-1$, and we expand it in powers of $l+(d-1)/2$:

$$D_l(p,d)=\sum_{\alpha=0}^{d-1}e_\alpha(d,p)\left(l+\frac{d-1}{2}\right)^\alpha. \tag{23}$$

Formally, we can write

$$e_\alpha=\frac{1}{\alpha}\frac{d^\alpha}{dl^\alpha}D_l(p,d)|_{l=(1-d/2)}. \tag{24}$$

The sum over l can be evaluated easily, e.g.

$$\begin{aligned}\zeta_{-\Delta_{p^T}^{(d)}}(s)&=\sum_{\alpha=0}^{d-1}e_\alpha(d,p)\sum_{l=1}^{\infty}\left(l+\frac{d-1}{2}\right)^\alpha\left[\left(l+\frac{d-1}{2}\right)^2-\left(p-\frac{d-1}{2}\right)^2\right]^{-s}\\&=\sum_{\alpha=0}^{d-1}e_\alpha(d,p)\sum_{l=1}^{\infty}\left(l+\frac{d-1}{2}\right)^{\alpha-2s}[1-[p-(d-1)/2]^2[l+(d-1)/2]^2]^{-s}\\&=\frac{1}{\Gamma(s)}\sum_{\alpha=0}^{d-1}e_\alpha(d,p)\sum_{k=0}^{\infty}\frac{\Gamma(k+s)}{k!}\left(p-\frac{d-1}{2}\right)^{2k}\zeta_H\left(2s+2k-\alpha,\frac{d+1}{2}\right),\end{aligned} \tag{25}$$

where we have used the binomial expansion. Note that this expansion is absolutely convergent, since $[p-(d-1)/2]^2/[l+(d-1)/2]^2<1$ for $p\leqslant(d+1)/2$. The indetermined number 0^0 when $p=(d-1)/2$ is consistently defined to be one. Here $\zeta_H(s,\nu)$ is the Hurwitz zeta-function. For ν a natural number, this zeta-function can be directly related to the Riemann zeta-function through the formula[15–17]

$$\zeta_H(s,m)=\zeta_R(s)-\sum_{l=1}^{m} l^{-s}. \tag{26}$$

For ν a half-integer, we can correspondingly subtract terms from $\zeta_H(s,1/2)$, which is again related to the Riemann zeta-function,

$$\zeta_H(s,1/2)=(2^s-1)\zeta_R(s). \tag{27}$$

For d even, $e_\alpha=0$ for $\alpha=0,2,\ldots,d-2$, and for d odd, $e_\alpha=0$ for $\alpha=1,3,\ldots,d-2$. When we differentiate the zeta-function (25) we must distinguish between these two cases. For d odd, we get

$$\zeta'_{-\Delta_{pT}^{(d)}}(0)=\sum_{a=0}^{(d-1)/2} e_{2a}\left[2\zeta'_H\left(-2a,\frac{d+1}{2}\right)+\sum_{k=1}^{\infty}\frac{[p-(d-1)/2]^{2k}}{k}\zeta_H\left(2k-2a,\frac{d+1}{2}\right)\right]. \tag{28}$$

While for d even the expression is a bit more complicated since the Hurwitz zeta-function has a pole when its argument is one. Using the Laurent series expansion

$$\zeta_H(2s+1,\nu)=\frac{1}{2s}-\Psi(\nu)+\mathcal{O}(s), \tag{29}$$

we obtain, for d even,

$$\begin{aligned}\zeta'_{-\Delta_{pT}^{(d)}}(0)=\sum_{a=0}^{\frac{d}{2}-1} e_{2a+1}\Bigg[&2\zeta'_H\left(-2a-1,\frac{d+1}{2}\right)+\sum_{k=1}^{a}\frac{[p-(d-1)/2]^{2k}}{k}\zeta_H\left(2k-2a-1,\frac{d+1}{2}\right)\\&+\frac{(p-(d-1)/2)^{2a+2}}{a+1}\left(\frac{1}{2}\sum_{l=1}^{a} l^{-1}-\Psi\left(\frac{d+1}{2}\right)\right)\\&+\sum_{a+2}^{\infty}\frac{[p-(d-1)/2]^{2k}}{k}\zeta_H\left(2k-2a-1,\frac{d+1}{2}\right)\Bigg].\end{aligned} \tag{30}$$

Continuing in this way and substituting for the derivatives of the Riemann zeta function the values[19]

$$\begin{gathered}\zeta'(0)=-\frac{1}{2}\ln(2\pi),\zeta'(-1)=-0.1654211437,\zeta'(-2)=-0.0304484571,\\ \zeta'(-3)=0.0053785764,\zeta'(-4)=0.0079838115,\\ \zeta'(-5)=-0.0005729860,\zeta'(-6)=-0.0058997591,\ldots,\end{gathered} \tag{31}$$

we have obtained the following numerical results for the determinants:

$$\det(-\Delta_{HdR})_4^{(7)}=0.088786,\det(-\Delta_{HdR})_3^{(7)}=0.088786,\det(-\Delta_{HdR})_2^{(7)}=1.858601,$$

$$\det(-\Delta_{HdR})_1^{(7)}=0.775194,\det(-\Delta_{HdR})_3^{(6)}=7.103758,\det(-\Delta_{HdR})_2^{(6)}=1.726306,$$

$$\det(-\Delta_{HdR})_1^{(6)}=0.835544,\det(-\Delta_{HdR})_3^{(5)}=11.090330,\det(-\Delta_{HdR})_2^{(5)}=11.090330, \quad (32)$$

$$\det(-\Delta_{HdR})_1^{(5)}=0.581303,\det(-\Delta_{HdR})_2^{(4)}=0.128002,\det(-\Delta_{HdR})_1^{(4)}=0.621433,$$

$$\det(-\Delta_{HdR})_2^{(3)}=0.095528,\det(-\Delta_{HdR})_1^{(3)}=0.095528,\det(-\Delta_{HdR})_1^{(2)}=10.210016.$$

IV. CALCULATION OF THE HEAT KERNEL COEFFICIENTS

The heat-kernel coefficients B_k are given from the small$-t$ expansion of the heat kernel $K(t)$,

$$K(t)=(4\pi t)^{-d/2}\sum_{k=0,1/2,1,\ldots} B_k t^k. \quad (33)$$

When we consider a manifold without boundaries, as is the case for the sphere, the coefficients with a half-integer k vanish. There is a close connection between the coefficients for an operator and its zeta-function. This connection is given by the formulas

$$\mathrm{Res}\zeta(s)=\frac{B_{d/2-s}}{(4\pi)^{d/2}\Gamma(s)}, \quad (34)$$

at $s=m/2,(m-1)/2,\ldots,1/2;-(2l+1)/2$ for $l=0,1,2\ldots$, and

$$\zeta(-m)=(-1)^m m!\frac{B_{d/2+m}}{(4\pi)^{d/2}}, \quad (35)$$

for $m=0,1,2,\ldots$. These formulas constitute a very powerful approach to the determination of the heat kernel coefficients (see, for instance, Refs. 20,21 and the references therein). Again we consider separately the cases d odd and d even. When d is odd we only have to calculate the residues, since there are only integer coefficients. The residues matching integer coefficients are located at $s=d/2-m$, $m=0,1,2\ldots$. When $m\leqslant(d-1)/2$,

$$\mathrm{Res}\zeta_{-\Delta_{p^T}^{(d)}}\left(\frac{d}{2}-m\right)=\frac{1}{2}\sum_{a=(d-1)/2-m}^{(d-1)/2} e_{2a}\frac{\Gamma(1/2+a)}{\Gamma(d/2-m)(1-d)/2+m+a)!}\left(p-\frac{d-1}{2}\right)^{1-d+2m+2a}, \quad (36)$$

and when $m>(d-1)/2$,

$$\mathrm{Res}\zeta_{-\Delta_{p^T}^{(d)}}\left(\frac{d}{2}-m\right)=\frac{1}{2}\sum_{a=0}^{(d-1)/2} e_{2a}\frac{\Gamma(1/2+a)}{\Gamma\left(\frac{d}{2}-m\right)(1-d)/2+m+a)!}\left(p-\frac{d-1}{2}\right)^{1-d+2m+2a}. \quad (37)$$

For even dimension we must consider the point values at $s=-m$ and the residues at $s=d/2-l$, $l=0,1,\ldots,d/2-1.$,

$$\zeta_{-\Delta_{p^T}^{(d)}}(-m)=\sum_{a=0}^{d/2-1} e_{2a+1}\left[\sum_{k=0}^{m}\frac{(-1)^k m!}{(m-k)!k!}\left(p-\frac{d-1}{2}\right)^{2k}\zeta_H\left(2k-2a-1-2m,\frac{d+1}{2}\right)\right.$$
$$\left.+\frac{(-1)^m m!a!}{2(1+a+m)!}\left(p-\frac{d-1}{2}\right)^{2+2a+2m}\right], \tag{38}$$

and we get

$$\mathrm{Res}\zeta_{-\Delta_{p^T}^{(d)}}\left(\frac{d}{2}-l\right)=\frac{1}{2}\sum_{a=d/2-1-l}^{d/2-1} e_{2a+1}\frac{a!}{\Gamma\left(\frac{d}{2}-l\right)\left(1-\frac{d}{2}+l+a\right)!}\left(p-\frac{d-1}{2}\right)^{2-d+2a+2l}. \tag{39}$$

As the actual zeta-functions are sums of the zeta-functions for the transversal field, the heat kernel coefficients are also just sums of the corresponding coefficients for the transversal fields. Using the two equations (34) and (35) we immediately obtain the coefficients from the formulas given above.

For $d=7$, $p=4$ and $p=3$, we have

$$B_0=\frac{35\,\pi^4}{3},B_1=\frac{-175\,\pi^4}{3},B_2=\frac{2009\pi^4}{18},B_3=\frac{-553\,\pi^4}{6},B_4=\frac{159\,\pi^4}{8},B_5=\frac{167\pi^4}{24},$$
$$B_6=\frac{1289\pi^4}{720},B_7=\frac{613\pi^4}{1680},B_8=\frac{71\pi^4}{1152},B_9=\frac{461\pi^4}{51840},B_{10}=\frac{271\pi^4}{241920}. \tag{40}$$

For $d=7$, $p=2$:

$$B_0=7\,\pi^4,B_1=-21\,\pi^4,B_2=\frac{133\pi^4}{10},B_3=\frac{371\pi^4}{30},B_4=\frac{-229\pi^4}{40},B_5=\frac{-1213\pi^4}{120},$$
$$B_6=\frac{-2807\pi^4}{720},B_7=\frac{6483\pi^4}{2800},B_8=\frac{132847\pi^4}{28800}, \tag{41}$$
$$B_9=\frac{1050881\pi^4}{259200},B_{10}=\frac{3147083\pi^4}{1209600}.$$

For $d=7$, $p=1$:

$$B_0=\frac{7\,\pi^4}{3},B_1=\frac{7\,\pi^4}{3},B_2=\frac{-301\pi^4}{90},B_3=\frac{-203\pi^4}{30},B_4=\frac{-43\pi^4}{40},B_5=\frac{949\pi^4}{120},$$
$$B_6=\frac{6839\pi^4}{720},B_7=\frac{9823\pi^4}{8400},B_8=\frac{-282271\pi^4}{28800},B_9=\frac{-3734393\pi^4}{259200}, \tag{42}$$
$$B_{10}=\frac{-3734393\pi^4}{403200}.$$

For $d=6$, $p=3$:

$$B_0=\frac{64\,\pi^3}{3},B_1=\frac{-256\,\pi^3}{3},B_2=128\,\pi^3,B_3=\frac{-75008\pi^3}{945},B_4=\frac{1472\pi^3}{135},B_5=\frac{256\pi^3}{99},$$

$$B_6=\frac{373376\pi^3}{405405},B_7=\frac{40448\pi^3}{81081},B_8=\frac{1373248\pi^3}{3828825}, \tag{43}$$

$$B_9=\frac{167651072\pi^3}{535687425},B_{10}=\frac{65263383424\pi^3}{206239658625}.$$

For $d=6$, $p=2$:

$$B_0=16\,\pi^3,B_1=-48\,\pi^3,B_2=\frac{128\,\pi^3}{3},B_3=\frac{176\pi^3}{315},B_4=\frac{-48\,\pi^3}{5},B_5=\frac{-1360\pi^3}{297},$$

$$B_6=\frac{-171328\pi^3}{405405},B_7=\frac{80096\pi^3}{81081},B_8=\frac{37236464\pi^3}{34459425}, \tag{44}$$

,

$$B_9=\frac{52062832\pi^3}{59520825},B_{10}=\frac{2616564224\pi^3}{3618239625}.$$

For $d=6$, $p=1$:

$$B_0=\frac{32\,\pi^3}{5},B_1=0,B_2=\frac{-128\pi^3}{15},B_3=\frac{-1408\pi^3}{315},B_4=\frac{352\pi^3}{75},$$

$$B_5=\frac{11008\pi^3}{1485},B_6=\frac{5982208\pi^3}{2027025},B_7=\frac{-164096\pi^3}{57915}, \tag{45}$$

$$B_8=\frac{-952002848\pi^3}{172297125},B_9=\frac{-337870336\pi^3}{72747675},$$

$$B_{10}=\frac{-8650820224\pi^3}{4464061875}.$$

For $d=5$, $p=3$ and $p=2$:

$$B_0=10\,\pi^3,B_1=\frac{-80\,\pi^3}{3},B_2=\frac{70\,\pi^3}{3},B_3=\frac{-14\,\pi^3}{3},B_4=\frac{-29\pi^3}{18},B_5=\frac{-37\pi^3}{90},$$

$$B_6=-\frac{\pi^3}{12},B_7=\frac{-53\pi^3}{3780},B_8=\frac{-61\pi^3}{30240},B_9=\frac{-23\pi^3}{90720},B_{10}=\frac{-11\pi^3}{388800}. \tag{46}$$

For $d=5$, $p=1$:

$$B_0=5\,\pi^3,B_1=\frac{-10\,\pi^3}{3},B_2=\frac{-10\,\pi^3}{3},B_3=\frac{2\,\pi^3}{3},B_4=\frac{35\pi^3}{18},B_5=\frac{91\pi^3}{90},$$

$$B_6=\frac{-\pi^3}{12},B_7=\frac{-2101\pi^3}{3780},B_8=\frac{-3289\pi^3}{6048},B_9=\frac{-32791\pi^3}{90720},B_{10}=\frac{-104873\pi^3}{544320}. \tag{47}$$

For $d=4$, $p=2$:

$$B_0=16\,\pi^2, B_1=-32\,\pi^2, B_2=\frac{304\pi^2}{15}, B_3=\frac{-160\pi^2}{63}, B_4=\frac{-176\pi^2}{315}, B_5=\frac{-608\pi^2}{3465},$$
$$B_6=\frac{-11104\pi^2}{135135}, B_7=\frac{-448\pi^2}{8775}, B_8=\frac{-443504\pi^2}{11486475}, \tag{48}$$
$$B_9=\frac{-467045792\pi^2}{13749310575}, B_{10}=\frac{-2327539744\pi^2}{68746552875}.$$

For $d=4$, $p=1$:

$$B_0=\frac{32\,\pi^2}{3}, B_1=\frac{-32\,\pi^2}{3}, B_2=\frac{-32\pi^2}{45}, B_3=\frac{352\pi^2}{189}, B_4=\frac{928\pi^2}{945},$$
$$B_5=\frac{1952\pi^2}{10395}, B_6=\frac{-38848\pi^2}{405405}, B_7=\frac{-262336\pi^2}{2027025}, \tag{49}$$
$$B_8=\frac{-3454688\pi^2}{34459425}, B_9=\frac{-3024736672\pi^2}{41247931725}, B_{10}=\frac{-12244948288\pi^2}{206239658625}.$$

For $d=3$, $p=2$ and $p=1$:

$$B_0=6\,\pi^2, B_1=-6\,\pi^2, B_2=\pi^2, B_3=\frac{\pi^2}{3}, B_4=\frac{\pi^2}{12}, B_5=\frac{\pi^2}{60},$$
$$B_6=\frac{\pi^2}{360}, B_7=\frac{\pi^2}{2520}, B_8=\frac{\pi^2}{20160}, B_9=\frac{\pi^2}{181440}, B_{10}=\frac{\pi^2}{1814400}. \tag{50}$$

And for $d=2$, $p=1$:

$$B_0=8\,\pi, B_1=\frac{-16\,\pi}{3}, B_2=\frac{8\,\pi}{15}, B_3=\frac{32\,\pi}{315}, B_4=\frac{8\,\pi}{315}, B_5=\frac{32\,\pi}{3465},$$
$$B_6=\frac{3056\,\pi}{675675}, B_7=\frac{1856\,\pi}{675675}, B_8=\frac{22664\,\pi}{11486475}, B_9=\frac{4481632\,\pi}{2749862115}, B_{10}=\frac{104409808\,\pi}{68746552875}. \tag{51}$$

V. TRANSVERSAL LAPLACIAN AND NON-LOCAL COUNTERTERMS

In this section we see that the heat kernel expansion for the Hodge–de Rham Laplacian on transversal p-forms contains a constant term in odd–dimensional spaces. Call $\kappa(t)=\Sigma_{k=1}^{\infty}\exp(-tk^2)$. The asymptotic behavior of κ in the limit $t\to 0$ is $\kappa(t)=\frac{1}{2}(\sqrt{(\pi/t)}-1)$, where corrections are exponentially small and can be neglected in the computation of power-low asymptotics. The transversal heat kernel,

$$K(t;p,d)=\sum_{l=1}^{\infty} D_l(p,d)\exp[tb_l(p,d)], \tag{52}$$

on odd-dimensional spheres can be put in terms of κ using D_l and b_l of Sec. 2:

$$K(t;0,3)=-1-\kappa'(t),$$

$$K(t;1,3)=-2[\kappa'(t)+\kappa(t)],$$

$$K(t;0,5)=-1+\frac{1}{12}e^{4t}[\kappa''(t)+\kappa'(t)],$$

$$K(t;1,5)=1+\frac{1}{3}e^{t}[\kappa''(t)+4\kappa'(t)],$$

$$K(t;2,5)=\frac{1}{2}[\kappa''(t)+5\kappa'(t)+4\kappa(t)], \tag{53}$$

$$K(t;0,7)=-1-\frac{e^{9t}}{360}[\kappa'''(t)+5\kappa''(t)+4\kappa'(t)],$$

$$K(t;1,7)=1-\frac{e^{4t}}{60}[\kappa'''(t)+10\kappa''(t)+9\kappa'(t)],$$

$$K(t;2,7)=-1-\frac{e^{t}}{24}[\kappa'''(t)+13\kappa''(t)+36\kappa'(t)],$$

$$K(t;3,7)=-\frac{1}{18}[\kappa'''(t)+14\kappa''(t)+41\kappa'(t)+36\kappa(t)],$$

where the prime denotes differentiation. One can evaluate the coefficient $a_{d/2}$ before t^0 in the small-t expansion of $K(t;p,d)$. Derivatives of κ do not contribute and one obtains

$$a_{d/2}=(-1)^{p+1}. \tag{54}$$

At first sight this relation contradicts the general theory[22] of the heat kernel, which precludes integer powers of t on odd-dimensional manifolds without boundary. In fact, the relation (54) is well known and can be derived from general formulae.[22] Consider an odd-dimensional manifold M without boundary. The space of p-forms, Λ^p can be decomposed in a direct sum of eigenspaces of the Hodge–de Rham Laplacian:

$$\Lambda^p=\Lambda^{pT}\oplus\Lambda^{pL}\oplus H^p, \tag{55}$$

where Λ^T and Λ^L are transversal and longitudinal p-forms, respectively. H^p denotes the space of harmonic p-forms spanned by zero modes of the Hodge–de Rham Laplacian. The Laplace operator on *all* p-forms satisfies the whole set of requirements in Ref. 22 and, hence, the corresponding coefficient in front of t^0 in the heat kernel expansion should vanish. On the other hand, this coefficient is just the sum of the coefficients in front of t^0 for the same operator restricted to the spaces on the right hand side of (55). But this immediately gives

$$0=a^p_{d/2}+a^{p-1}_{d/2}+\beta_p, \tag{56}$$

where, as above, $a_{d/2}$ denotes the constant term in the heat kernel expansion for transversal p-forms. Here $\beta_p=$ dim H^p is the Betti number. For 0-forms we have

$$a^0_{d/2} = -\beta_0 . \tag{57}$$

The two equations (56) and (57) can be solved, giving

$$a^p_{d/2} = \sum_{q=0}^{p} (-1)^{p-q+1} \beta_q . \tag{58}$$

The relation (54) is a particular case of (58). What happens in odd dimensions is that the Betti numbers ''propagate'' up the chain leading to the formula (58).

Consider now the quantum path integral for an antisymmetric tensor field with the action (1). The partition function Z_p can be expressed in terms of the determinants of the Hodge–de Rham Laplacian on transversal forms[23,24]

$$Z_p = \prod_{q=0}^{p} \det{}_{qT}(-\Delta_{HdR})^{-(1/2)(-1)^{p-q}}. \tag{59}$$

To avoid possible ambiguities in treating the zero modes we suppose that $\beta_p = 0$. The ''total'' heat kernel for Z_p is an alternated sum of heat kernels for transversal forms. As the coefficient multiplying t^0 leads to a logarithmic divergence in the path integral, on an odd-dimensional manifold without boundary, we have that this divergence is proportional to

$$\sum_{q=0}^{p} (p-q+1)(-1)^{p-q+1} \beta_q . \tag{60}$$

Such divergence cannot be canceled by means of an integral of a local invariant constructed from the Riemann tensor and, hence, it requires a non–local counterterm. Some topological effects in quantum theories of antisymmetric tensor field were discussed in Ref. 24 These effects are, however, related to the Gauss–Bonnet term, which can be expressed in the function of local densities and vanishes for odd-dimensional spheres. In the context of three-dimensional Chern–Simons theory, Eq. (58) has been obtained in Ref. 25.

Proper time and path integral representations for the commutation function

S. P. Gavrilov[a] and D. M. Gitman[b]
Instituto de Física, Universidade de São Paulo, P.O. Box 66318, 05389-970 São Paulo, SP, Brasil

(Received 5 January 1996; accepted for publication 17 January 1996)

On the example of the quantized spinor field, interacting with arbitrary external electromagnetic field, the commutation function is studied. It is shown that a proper time representation is available in any dimensions. Using it, all the light cone singularities of the function are found explicitly, generalizing the Fock formula in four dimensions, and a path integral representation is constructed. © *1996 American Institute of Physics.* [S0022-2488(96)03806-6]

I. INTRODUCTION

It is known that the solution of quantum field theory problems involves as a rule different singular functions, e.g., commutation functions, Green functions, and so on. These functions are well studied for free fields (see, for example, Ref. 1). Problems appear when an interaction is presented. In particular, it is important to study singular functions in external backgrounds such as external fields and curved spaces and in arbitrary dimensions. The latter may be important for multidimensional version of field theories, which are considered now in relation with the unification of all the interactions. One ought to say that the commutation functions play an important role in QFT with external backgrounds. In contrast with the case without external backgrounds, the perturbation theory, which takes into account a background exactly, uses complicated (matrix) propagators. Such propagators contain as component parts, besides the causal and anticausal Green functions, the commutation functions as well.[2,3] Here, we present proper time and path integral representations for the commutation function and for some related functions in external fields. On the basis of the proper time representation we study, in particular, light cone singularities of the function in arbitrary dimensions. Traditionally QED is a testing ground where new procedures and methods are worked through, not infrequently creating new ideas and more profound understanding of the structure of QFT. That is why we consider here the case of QED with an arbitrary external electromagnetic field, bearing in mind that the results can be extend to other theories and backgrounds.

Fock for the first time[4] introduced an integral over the proper time to present the regular on the light cone part of the commutation function $S(x,x')$ (in $3+1$ dimensions) of the spinor fields, interacting with an external electromagnetic field $A_\mu(x)$,

$$S(x,x') = i[\psi(x), \overline{\psi}(x')]_+ , \tag{1}$$

where $\psi(x)$ and $\overline{\psi}(x')$ are the electron–positron field operators. This function obeys the Dirac equation

$$\begin{gathered}(\hat{\mathscr{P}}_\nu \gamma^\nu - m) S(x,x') = 0, \quad \hat{\mathscr{P}}_\nu = i\partial_\nu - g A_\nu(x), \\ [\gamma^\mu, \gamma^\nu]_+ = 2\eta^{\mu\nu}, \quad \eta^{\mu\nu} = \mathrm{diag}(1,-1,-1,-1),\end{gathered} \tag{2}$$

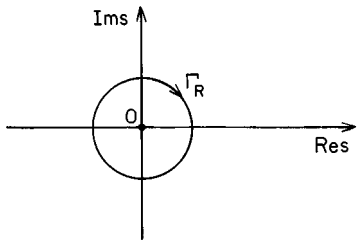

FIG. 1. Contour of integration for Δ_R function.

and the initial condition

$$S(x,x')|_{x_0=x_0'}=i\gamma^0\delta(\mathbf{x}-\mathbf{x}'). \tag{3}$$

The commutation function $S(x,x')$ is at the same time the propagation function of the Dirac equation, i.e., it connects solutions $\psi(x)$ of the equation in two different time instants,

$$\psi(x_0,\mathbf{x})=-i\int S(x,x')\gamma^0\psi(x_0',\mathbf{x}')d\mathbf{x}'. \tag{4}$$

Thus the Cauchy problem can be solved by means of the function. Squaring Eq. (2) one gets

$$S(x,x')=(\hat{\mathscr{P}}_\nu\gamma^\nu+m)\Delta(x,x'), \tag{5}$$

where the function $\Delta(x,x')$ obey the equation

$$[(\hat{\mathscr{P}}_\nu\gamma^\nu)^2-m^2]\Delta(x,x')=0, \tag{6}$$

and the initial conditions

$$\Delta(x,x')|_{x_0=x_0'}=0, \quad \partial_0\Delta(x,x')|_{x_0=x_0'}=\delta(\mathbf{x}-\mathbf{x}'). \tag{7}$$

Fock's solution of Eqs. (6) and (7) reads

$$\begin{gathered}\Delta(x,x')=\epsilon(x_0-x_0')\left[\Theta((x-x')^2)\Delta_R(x,x')+\frac{1}{2\pi}e^{ig\Lambda}\delta((x-x')^2)\right],\\ \epsilon(x_0-x_0')=\mathrm{sign}(x_0-x_0').\end{gathered} \tag{8}$$

The function Λ is the line integral of the potentials,

$$\Lambda=-\int_{x'}^{x}A_\mu(\tilde{x})d\tilde{x}^\mu; \tag{9}$$

$\Delta_R(x,x')$ is the Riemann function, which is presented by means of a proper time integral

$$\Delta_R(x,x')=\int_{\Gamma_R}f(x,x',s)ds \tag{10}$$

over the closed path Γ_R, (see Fig. 1) which is a clockwise circle around the point $s=0$ with a small enough radius, inside of which the function $f(x,x',s)$ has not any singularities besides the essential singularity $s=0$. The function $f(x,x',s)$ obeys the ''Schrödinger equation''

$$i\frac{d}{ds}f(x,x',s)=[m^2-(\hat{\mathscr{P}}_\nu\gamma^\nu)^2]f(x,x',s), \tag{11}$$

and the boundary condition

$$\lim_{s\to+0} f(x,x',s)=i\delta(x-x'). \tag{12}$$

One has to remark that the same function $f(x,x',s)$ appears in the Schwinger representation[5] for the causal Green function $S^c(x,x')$ (propagator) of the Dirac equation,

$$(\hat{\mathscr{P}}_\nu\gamma^\nu-m)S^c(x,x')=-\delta(x-x'). \tag{13}$$

Namely,

$$S^c(x,x')=(\hat{\mathscr{P}}_\nu\gamma^\nu+m)\int_0^\infty f(x,x',s)ds, \tag{14}$$

where at $s\to\infty$ one has to enter into the complex plane s, so that $\lim_{s\to\infty} f(x,x',s)=0$. Extension of the Schwinger representation to the curved space case was made by DeWitt[2] and then, developing his technics, to the gauge theory.[6]

The Schwinger representation for $S^c(x,x')$ and the Fock representation for $S(x,x')$ differ essentially in sense of possibilities of generalization. Thus the Schwinger representation retains its form for any space–time dimensionality d. Moreover, the inverse operator S^c can be easily presented via an exponent by means of the Schwinger proper time representation (super-proper time representation[7]), so that the path integral representations follows.[7,8] At the same time the Fock representation has the specific form (8) for $\Delta(x,x')$ in $d=3+1$. Besides, the form (8), which separates the light cone singular part from the regular one, does not give any leading consideration to write a path integral for the commutation function, similar to one for the propagator.

Below we propose a proper time representation for the commutation function, which has an universal form in any dimensions. Using it, we find explicitly all the light cone singularities of the commutation function in arbitrary dimensions, generalizing the Fock's formula (8). Moreover, such a representation allows one to write a path integral for the commutation function. In the conclusion we present similar representations for some other singular functions of the Dirac equation on the basis of the results obtained.

II. PROPER TIME REPRESENTATION FOR THE COMMUTATION FUNCTION

Here, we are going to write a proper time representation for the function $\Delta(x,x')$ from formula (5) in arbitrary space–time dimensions $d\geqslant 2$. To this end we need to find first the behavior of the function $f(x,x',s)$ at $s\to 0$. We will use Eqs. (11) and (12) in d-dimensions, where

$$[\gamma^\mu,\gamma^\nu]_+=2\eta^{\mu\nu},\quad \eta^{\mu\nu}=\mathrm{diag}\underbrace{(1,-1,\ldots,-1)}_{d}.$$

Similar to Schwinger[5] we present $f(x,x's)$ as a matrix element of an evolution operator $U(s)$,

$$\begin{aligned} f(x,x',s)&=i\langle x|U(s)|x'\rangle,\\ U(s)&=e^{-iHs},\quad H=m^2-(\Pi_\nu\gamma^\nu)^2, \end{aligned} \tag{15}$$

where $|x\rangle$ are eigenfunctions for some hermitian operators of coordinates X^μ, the corresponding canonically conjugate operators of momenta are P_μ, so that

$$X^\mu|x\rangle = x^\mu|x\rangle, \quad \langle x|x'\rangle = \delta(x-x'), \quad \int |x\rangle\langle x|dx = I,$$

$$[P_\mu, X^\nu]_- = -i\delta_\mu^\nu, \quad \langle x|P_\mu|x'\rangle = -i\partial_\mu\delta(x-x'), \tag{16}$$

$$\Pi_\mu = -P_\mu - gA_\mu(X), \quad [\Pi_\mu, \Pi_\nu]_- = -igF_{\mu\nu}(X), \quad F_{\mu\nu}(X) = \partial_\mu A_\nu(X) - \partial_\nu A_\mu(X).$$

The matrix element obeys the conditions

$$\left(i\frac{\partial}{\partial x^\mu} - gA_\mu(x)\right)\langle x|U(s)|x'\rangle = \langle x|\Pi_\mu U(s)|x'\rangle,$$

$$\left(-i\frac{\partial}{\partial x'^\mu} - gA_\mu(x')\right)\langle x|U(s)|x'\rangle = \langle x|U(s)\Pi_\mu|x'\rangle. \tag{17}$$

Introducing the operators

$$X^\mu(s) = U^{-1}(s)X^\mu U(s), \quad \gamma^\mu(s) = U^{-1}(s)\gamma^\mu U(s), \quad \Pi_\mu(s) = U^{-1}(s)\Pi_\mu U(s),$$

we come to the equations

$$\frac{d}{ds}X^\mu(s) = i[H, X^\mu(s)]_- = 2\Pi^\mu(s),$$

$$\frac{d}{ds}\gamma^\mu(s) = i[H, \gamma^\mu(s)]_-, \quad \frac{d}{ds}\Pi_\mu(s) = i[H, \Pi_\mu(s)]_-. \tag{18}$$

Using the decomposition in powers of s, one can get for H

$$H = -\frac{1}{4s}[X(s)X(s) - 2X(s)X(0) - X(0)X(0)] - i\frac{d}{2s} + O(1).$$

Then the solution of Eqs. (11), (12), and (17) has a form

$$f(x,x',s)|_{s\to 0} = f_0(x,x',s)[1+O(s)],$$

$$f_0(x,x',s) = \frac{1}{(4\pi s)^{d/2}}\exp\left\{-i\frac{\pi}{4}(d-4) + ig\Lambda - \frac{i}{4s}(x-x')^2\right\}, \tag{19}$$

where Λ is the d-dimensional line integral (9). Thus one can conclude that $f(x,x',s)$ has no singularities in a small enough neighborhood of the point $s=0$ (excluding this point). Based on this one can make a key observation in $3+1$ dimensions. Namely, let us consider the Fock representation (5) and (8) beyond the light cone $(x-x')^2 \neq 0$. In this case the relation holds

$$\Theta((x-x')^2)\int_{\Gamma_R} f(x,x',s)ds = \int_\Gamma f(x,x',s)ds, \tag{20}$$

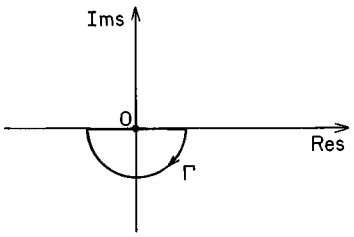

FIG. 2. Contour of integration for Δ function.

where Γ (see Fig. 2) is a contour, which connects the points $s=+0$ and $s=e^{-i\pi}0$, and passes in the lower part of complex plane s in a small enough neighborhood of the point $s=0$ so that Eq. (19) is still valid inside the contour Γ. Then the function $\Delta(x,x')$ can be written in $3+1$ dimensions at $(x-x')^2\neq 0$ in the following form:

$$\Delta(x,x')=\epsilon(x_0-x_0')\int_\Gamma f(x,x',s)ds. \tag{21}$$

It turns out that Eq. (21) is valid on the light cone as well and, moreover, in any dimensions. Below we are going to prove this statement.

First of all one can remark that Eq. (19) implies

$$\lim_{s\to e^{-i\pi_0}} f(x,x',s)=-i\delta(x-x'). \tag{22}$$

Together with Eqs. (11), (12), and (22) this allows one to verify that expression (21) obeys Eq. (6) at $x_0\neq x_0'$.

Now we have to study the behavior of function (21) at $x_0\to x_0'$. Using the representation (19) let us select all the light cone singularities in Eq. (21),

$$\Delta(x,x')=I_R(x,x')+\sum_{n=0}^{[d/2]-1} I^{(n)}(x,x'), \tag{23}$$

$$I_R(x,x')=\epsilon(x_0-x_0')\int_\Gamma f_R(x,x',s)ds, \tag{24}$$

$$f_R(x,x',s)=f(x,x',s)-\sum_{n=0}^{[d/2]-1} f^{(n)}(x,x',s),$$

$$I^{(n)}(x,x')=\epsilon(x_0-x_0')\int_\Gamma f^{(n)}(x,x',s)ds, \tag{25}$$

$$f^{(n)}(x,x',s)=\frac{1}{n!}\frac{d^n}{ds^n}\left[\frac{f(x,x',s)}{f_0(x,x',s)}\right]_{s=0} s^n f_0(x,x',s).$$

Here, $I_R(x,x')$ is a regular on the light cone function, which is zero at $(x-x')^2\leqslant 0$. All the singularities are concentrated in the functions $I^{(n)}(x,x')$. It is convenient to make a change of variables $t=s^{-1}$ in expression (25) to present the latter in the following form:

$$I^{(n)}(x,x')=\epsilon(x_0-x_0')a^{(n)}(x,x')\left(\frac{d}{d\tau}\right)^{[(d-2)/2]-n} Y(\tau-(\mathbf{x}-\mathbf{x}')^2)|_{\tau=(x_0-x_0')^2},$$
$$a^{(n)}(x,x')=\pi^{-[(d-1)/2]}e^{ig\Lambda}(4i)^{-n}\frac{1}{4n!}\frac{d^n}{ds^n}\left[\frac{f(x,x',s)}{f_0(x,x',s)}\right]_{s=0}, \tag{26}$$

where the function $Y(\tau-(\mathbf{x}-\mathbf{x}')^2)$ has different forms for even and for odd d. Namely, for even d,

$$Y(\tau-(\mathbf{x}-\mathbf{x}')^2)=Y_{\text{even}}(\tau-(\mathbf{x}-\mathbf{x}')^2)=2\Theta(\tau-(\mathbf{x}-\mathbf{x}')^2), \tag{27}$$

and for odd d,

$$Y(\tau-(\mathbf{x}-\mathbf{x}')^2)=Y_{\text{odd}}(\tau-(\mathbf{x}-\mathbf{x}')^2)$$
$$=e^{i(\pi/4)}\int_{e^{i\pi}\infty}^{\infty}(4\pi t)^{1/2}\exp\left\{-\frac{i}{4}[\tau-(\mathbf{x}-\mathbf{x}')^2]t\right\}dt. \tag{28}$$

Now one can see that for even d the function $I^{((d/2)-1)}(x,x')$ can be expressed via the Θ-function (27), whereas the rest functions $I^{(n)}(x,x')$ are concentrated on the light cone. Thus function (23) is zero for points, which cannot be causally connected, i.e., for $(x-x')^2<0$.

Consider the contribution of distributions (27) and (28) to an integral with some continuous functions on the coordinates $(\mathbf{x}-\mathbf{x}')$ in the case $(x_0-x_0')\to 0$. In this case the distributions are zero beyond the sphere of the radius $|x_0-x_0'|+0$, thus formula (27) can be written in the form

$$Y_{\text{even}}(\tau-(\mathbf{x}-\mathbf{x}')^2)=2V(\sqrt{\tau})\delta(\mathbf{x}-\mathbf{x}'), \tag{29}$$

where $V(r)$ is the volume of the $d-1$ sphere with the radius r,

$$V(r)=cr^{d-1},\quad c=\pi^{(d-1)/2}\Gamma^{-1}\left(\frac{d+1}{2}\right), \tag{30}$$

and $\Gamma(x)$ is the gamma-function. The least power of (x_0-x_0') in expression (23) comes from $I^{(0)}(x,x')$, the latter can be derived from Eqs. (26) and (29) and has the form $I^{(0)}(x,x')=e^{ig\Lambda}(x_0-x_0')\delta(\mathbf{x}-\mathbf{x}')$. In case $d\geqslant 4$, the next power of (x_0-x_0') comes from the function $I^{(1)}(x,x')\sim e^{ig\Lambda}(x_0-x_0')^3\delta(\mathbf{x}-\mathbf{x}')$. At $d=2$ the same power of (x_0-x_0') comes from the function $I_R(x,x')$ defined by Eq. (24). Thus we can write for any even d at $(x_0-x_0')\to 0$

$$\Delta(x,x')|_{x_0\to x_0'}=e^{ig\Lambda}[x_0-x_0'+O((x_0-x_0')^3)]\delta(\mathbf{x}-\mathbf{x}'). \tag{31}$$

One can see that Eq. (31) is a continuous function of the time (x_0-x_0') together with its first derivatives, and obeys Eq. (6) at $(x_0-x_0')\to 0$, and the initial conditions (7).

Expression (28) at $(x_0-x_0')\to 0$ (d is odd) can be presented in the form

$$Y_{\text{odd}}(\tau-(\mathbf{x}-\mathbf{x}')^2)=B(\tau)\delta(\mathbf{x}-\mathbf{x}'), \tag{32}$$

where

$$B(\tau)=\int_{V(r_0)}Y_{\text{odd}}(\tau-\mathbf{y}^2)d\mathbf{y}. \tag{33}$$

The integration in Eq. (33) is going over the volume of $d-1$ sphere with the radius $r_0=|x_0-x_0'|+0$. Integral (33) is reducing to one over the radius r only,

$$B(\tau)=(d-1)c\int_0^{r_0}Y_{\rm odd}(\tau-r^2)r^{d-2}\,dr, \tag{34}$$

where c was defined in Eq. (30) and we remember that $r_0>\tau$. The former can be calculated and presented in the form

$$B(\tau)=e^{i\pi d/4}\pi^{(d-2)/2}\int_{e^{i\pi}\infty}^{\infty}t^{-d/2}e^{-i\tau t}\,dt. \tag{35}$$

Similar to the even case the least power of (x_0-x_0') in Eq. (23) comes from the function $I^{(0)}(x,x')$. By means of Eqs. (32) and (35) the latter can be written as

$$I^{(0)}(x,x')=\epsilon(x_0-x_0')\,\delta(\mathbf{x}-\mathbf{x}')\,\frac{e^{i3\pi/4}e^{ig\Lambda}}{4\sqrt{\pi}}\int_{e^{i\pi}\infty}^{\infty}t^{-3/2}e^{-i(x_0-x_0')^2t}\,dt. \tag{36}$$

Using the representation

$$t^{-1/2}=e^{-i\pi/4}\frac{2}{\sqrt{\pi}}\left(\int_0^{\sqrt{(x_0-x_0')^2-0}}e^{iz^2t}\,dz+\int_{\sqrt{(x_0-x_0')^2+0}}^{\infty}e^{iz^2t}\,dz\right)$$

in Eq. (36) and changing the order of the integration over t and z, we get finally $I^{(0)}(x,x')=e^{ig\Lambda}(x_0-x_0')\,\delta(\mathbf{x}-\mathbf{x}')$. In the same manner one can verify that the next power of (x_0-x_0') at $d\geqslant 5$ comes from the function $I^{(1)}(x,x')\sim e^{ig\Lambda}(x_0-x_0')^3\delta(\mathbf{x}-\mathbf{x}')$. In the case $d=3$ the same power of (x_0-x_0') comes from function (24). That is why the same dependence Eq. (31) holds at any odd d.

Thus we have shown that function (21) obeys Eq. (6) and the initial conditions (7) in any dimensions d. Then the commutation function can be written in an universal form in any dimensions [by means of Eqs. (5) and (21)],

$$S(x,x')=\epsilon(x_0-x_0')(\hat{\mathscr{P}}_\nu\gamma^\nu+m)\int_\Gamma f(x,x',s)ds. \tag{37}$$

Here, we have used the initial conditions (7) to put $\epsilon(x_0-x_0')$ before the operator $\hat{\mathscr{P}}_\nu\gamma^\nu+m$.

It was already seen from Eqs. (23)–(28) that the representation (21) is convenient to select the light cone singularities. In case of even d one can also get d-dimensional generalization of the Fock representation. To this end let us write the function $I_R(x,x')$ from Eq. (24) by means of an integral over the closed path Γ_R, defined in Eq. (10),

$$I_R(x,x')=\epsilon(x_0-x_0')\Theta((x-x')^2)\int_{\Gamma_R}f_R(x,x',s)ds. \tag{38}$$

From $f_R(x,x',s)$ only the term $f^{(n)}(x,x',s)$ with $n=(d/2)-1$ gives nonzero contribution, namely,

$$\Theta((x-x')^2)\int_{\Gamma_R}f^{(d/2-1)}(x,x',s)ds=\int_\Gamma f^{(d/2-1)}(x,x',s)ds.$$

That allows one to rewrite Eq. (23) for even d in the form

$$\Delta(x,x')=\epsilon(x_0-x_0')\Bigg[\Theta((x-x')^2)\Delta_R(x,x')+\sum_{n=0}^{(d-4)/2} 2a^{(n)}(x,x')\left(\frac{d}{d\tau}\right)^{(d-4)/2-n}$$

$$\times\delta(\tau-(\mathbf{x}-\mathbf{x}')^2)\Big|_{\tau=(x_0-x_0')^2}\Bigg], \tag{39}$$

where $a^{(n)}(x,x')$ are defined in Eq. (26), and $\Delta_R(x,x')$ is d-dimensional Riemann function, defined by integral (10). At $d=4$ this expression coincides with the Fock's one (8).

The expression for the commutation function $i[\phi(x),\phi^\dagger(x')]_-$ of the scalar fields $\phi(x)$ and $\phi^\dagger(x')$ one can derive from representation (21) for the function $\Delta(x,x')$, putting formally all the γ-matrices to zero. We do not also see any difficulties to extend the results obtained to the curved space and gauge theories using the Schwinger–DeWitt technics.[2,6]

III. PATH INTEGRAL REPRESENTATION FOR THE COMMUTATION FUNCTION

Here, we are going to discuss a path integral representation for the commutation function at $d=4$. For our purpose, it is convenient to deal with the transformed by $\gamma^5=\gamma^0\gamma^1\gamma^2\gamma^3$ function $\widetilde{S}(x,x') = S(x,x')\gamma^5$, which obeys the properly transformed Dirac equation

$$(\hat{\mathscr{P}}_\nu\widetilde{\gamma}^\nu-m\gamma^5)\widetilde{S}(x,x')=0, \tag{40}$$

and the initial condition

$$\widetilde{S}(x,x')|_{x_0=x_0'}=-i\widetilde{\gamma}^0\delta(\mathbf{x}-\mathbf{x}'), \tag{41}$$

where $\hat{\mathscr{P}}_\nu=i\partial_\nu-gA_\nu(x)$, and $\widetilde{\gamma}^\nu=\gamma^5\gamma^\nu$. The matrices $\widetilde{\gamma}^\nu$ have the same commutation relations as initial ones γ^ν, $[\widetilde{\gamma}^\mu,\widetilde{\gamma}^\nu]_+=2\eta^{\mu\nu}$. For all the γ-matrices ($\widetilde{\gamma}^5=\gamma^5$) we have $[\widetilde{\gamma}^m,\widetilde{\gamma}^n]_+=2\eta^{mn}$, m, $n=\overline{0,3}$,5; $\eta^{mn}=\mathrm{diag}(1,-1,-1,-1,-1)$.

If one presents the function $\widetilde{S}(x,y)$ in the form

$$\widetilde{S}(x,x')=-(\hat{\mathscr{P}}_\nu\widetilde{\gamma}^\nu-m\gamma^5)\widetilde{\Delta}(x,x'), \tag{42}$$

then the function $\widetilde{\Delta}$ obeys the equation

$$(\hat{\mathscr{P}}_\nu\widetilde{\gamma}^\nu-m\gamma^5)^2\widetilde{\Delta}(x,x')=[(\hat{\mathscr{P}}_\nu\gamma^\nu)^2-m^2]\widetilde{\Delta}(x,x')=0. \tag{43}$$

One can remark that according to the definition and to Eqs. (6) and (7) there is a relation $\widetilde{\Delta}(x,x')=-\gamma^5\Delta(x,x')\gamma^5$, which allows on to conclude that the functions $\widetilde{\Delta}(x,x')$ and $\Delta(x,x')$ obey the same initial conditions. Because they obey also the same equation they coincide. Thus one can write, using the results obtained before Eq. (37),

$$\widetilde{S}(x,x')=-\epsilon(x_0-x_0')\int_\Gamma(\hat{\mathscr{P}}_\nu\widetilde{\gamma}^\nu-m\gamma^5)f(x,x',s)ds. \tag{44}$$

By means of the representation (15) for the function $f(x,x',s)$, where one can replace the operator $[(\Pi_\nu\gamma^\nu)^2-m^2]$ by one $(\Pi_\nu\widetilde{\gamma}^\nu-m\gamma^5)^2$, and introducing the operator $(\hat{\mathscr{P}}_\nu\widetilde{\gamma}^\nu-m\gamma^5)$ under the sign of the matrix element, we get

$$\widetilde{S}(x,x')=-i\epsilon(x_0-x_0')\int_\Gamma\langle x|(\Pi_\nu\widetilde{\gamma}^\nu-m\gamma^5)\exp\{i(\Pi_\nu\widetilde{\gamma}^\nu-m\gamma^5)^2\}|x'\rangle ds. \tag{45}$$

The operator $(\Pi_\nu\widetilde{\gamma}^\nu-m\gamma^5)$ can be presented via a Grassmannian integral,

$$(\Pi_\nu\tilde{\gamma}^\nu - m\gamma^5) = i\int e^{i\chi(\Pi_\nu\hat{\gamma}^\nu - m\gamma^5)}d\chi,$$

where χ is a Grassmann variable, which anticommutes with γ matrices by the definition. Here, and in what follows, integrals over Grassmann variables are understood as Berezin's integrals.[9] Thus the commutation function (45) takes the form

$$\tilde{S} = \tilde{S}(x_{\rm out}, x_{\rm in}) = \epsilon(x^0_{\rm out}, x^0_{\rm in}) \int_\Gamma ds \int \langle x_{\rm out}| e^{-i.\hat{\mathscr{H}}(s,\chi)} |x_{\rm in}\rangle d\chi, \tag{46}$$

where

$$\hat{\mathscr{H}}(s,\chi) = s\left(m^2 - \Pi^2 + \frac{ig}{2} F_{\alpha\beta}\tilde{\gamma}^\alpha\tilde{\gamma}^\beta\right) + (\Pi_\nu\tilde{\gamma}^\nu - m\tilde{\gamma}^5)\chi. \tag{47}$$

Now one can present the matrix element entering in expression (46) by means of a path integral. First, we write $\exp(-i.\hat{\mathscr{H}}) = (\exp(-i.\hat{\mathscr{H}}/N))^N$, and then insert $(N-1)$ resolutions of identity $\int |x\rangle\langle x| dx = I$ between all the operators $\exp(-i.\hat{\mathscr{H}}/N)$. Besides, we introduce N additional integrations over s and χ to transform then the ordinary integrals over these variables into the corresponding path-integrals,

$$\tilde{S} = \epsilon(x^0_{\rm out}, x^0_{\rm in}) \lim_{N\to\infty} \int_\Gamma ds_0 \int d\chi_0\, dx_1 \cdots dx_{N-1}\, ds_1 \cdots ds_N\, d\chi_1 \cdots d\chi_N$$

$$\times \prod_{k=1}^{N} \langle x_k| e^{-i.\hat{\mathscr{H}}(s_k,\chi_k)\Delta\tau} |x_{k-1}\rangle \delta(s_k - s_{k-1})\,\delta(\chi_k - \chi_{k-1}), \tag{48}$$

where $\Delta\tau = 1/N$, $x_0 = x_{\rm in}$, $x_N = x_{\rm out}$. Bearing in mind the limiting process, one can calculate the matrix elements from Eq. (48) approximately,

$$\langle x_k| e^{-i.\hat{\mathscr{H}}(s_k,\chi_k)\Delta\tau} |x_{k-1}\rangle \approx \langle x_k| 1 - i.\hat{\mathscr{H}}(s_k,\chi_k)\Delta\tau |x_{k-1}\rangle, \tag{49}$$

using the resolution of identity $\int |p\rangle\langle p| dp$, where

$$P_\mu|p\rangle = p_\mu|p\rangle, \quad \langle p|p'\rangle = \delta(p-p'), \quad \langle x|p\rangle = \frac{1}{(2\pi)^2} e^{ipx}.$$

In this connection it is important to notice that the operator $\hat{\mathscr{H}}(s_k,\chi_k)$ has originally the symmetric form in the operators $\hat{x}$ and $\hat{p}$. Indeed, the only one term in $\hat{\mathscr{H}}(s_k,\chi_k)$, which contains products of these operators is $[P_\alpha, A^\alpha(X)]_+$. One can verify that this is maximal symmetrized expression, which can be combined from entering operators (see remark in Ref. 10). Thus one can write $\hat{\mathscr{H}}(s,\chi) = \mathrm{Sym}_{(\hat{x},\hat{p})}\, \mathscr{H}(s,\chi,\hat{x},\hat{p})$, where $\mathscr{H}(s,\chi,x,p)$ is the Weyl symbol of the operator $\hat{\mathscr{H}}(s,\chi)$ in the sector of coordinates and momenta, $\mathscr{H}(s,\chi,x,p) = s(m^2 - \mathscr{P}^2 + ig/2F_{\alpha\beta}\tilde{\gamma}^\alpha\tilde{\gamma}^\beta) + (\mathscr{P}_\nu\tilde{\gamma}^\nu - m\gamma^5)\chi$, and $\mathscr{P}_\nu = -p_\nu - gA_\nu(x)$. That is a general statement,[11] which can be easily checked in that concrete case by direct calculations, that the matrix elements (49) are expressed in terms of the Weyl symbols in the middle point $\overline{x_k} = (x_k + x_{k-1})/2$. Taking all that into account, one can see that in the limiting process the matrix elements (49) can be replaced by the expressions

$$\int \frac{dp_k}{(2\pi)^4} \exp\left(i\left[p_k \frac{x_k - x_{k-1}}{\Delta\tau} - \mathscr{H}(s_k,\chi_k,\overline{x_k},p_k)\right]\right)\Delta\tau, \tag{50}$$

which are noncommutative due to the γ-matrix structure and are situated in Eq. (48) so that the numbers k increase from right to left. For the two δ-functions, accompanying each matrix element (49) in expression (48), we use the integral representations

$$\delta(s_k-s_{k-1})\,\delta(\chi_k-\chi_{k-1})=\frac{i}{2\pi}\int e^{i[\pi_k(s_k-s_{k-1})+\nu_k(\chi_k-\chi_{k-1})]}d\pi_k\,d\nu_k,$$

where ν_k are odd variables. Then we attribute formally to γ-matrices, entering into Eq. (50), index k, and then we attribute to all quantities the ''time'' τ_k, according the index k they have, $\tau_k=k\Delta\tau$, so that $\tau\in[0,1]$. Introducing the T-product, which acts on γ-matrices, it is possible to gather all the expressions, entering in Eq. (48), in one exponent and deal then with the γ-matrices like with odd variables. Thus we get for the right side of Eq. (48)

$$\widetilde{S}=\epsilon(x^0_{\rm out},x^0_{\rm in})T\int_\Gamma ds_0\int d\chi_0\int_{x_{\rm in}}^{x_{\rm out}}Dx\int Dp\int_{s_0}Ds\int_{\chi_0}D\chi\int D\pi\int D\nu$$
$$\times\exp\left\{i\int_0^1\left[s\left(\mathscr{P}^2-m^2-\frac{ig}{2}F_{\alpha\beta}\widetilde{\gamma}^\alpha\widetilde{\gamma}^\beta\right)+(m\gamma^5-\mathscr{P}_\nu\widetilde{\gamma}^\nu)\chi+p\dot{x}+\pi\dot{s}+\nu\dot{\chi}\right]d\tau\right\},\quad(51)$$

where x, p, s, π, are even and χ, ν are odd trajectories, obeying the boundary conditions $x(0)=x_{\rm in}$, $x(1)=x_{\rm out}$, $s(0)=s_0$, $\chi(0)=\chi_0$. The operation of T-ordering acts on the γ-matrices, which suppose formally to depend on time τ. Expression (51) can be reduced to

$$\widetilde{S}=\epsilon(x^0_{\rm out},x^0_{\rm in})\int_\Gamma ds_0\int d\chi_0\int_{x_{\rm in}}^{x_{\rm out}}Dx\int Dp\int_{s_0}Ds\int_{\chi_0}D\chi\int D\pi\int D\nu$$
$$\times\exp\left\{i\int_0^1\left[s\left(\mathscr{P}^2-m^2-\frac{ig}{2}F_{\alpha\beta}\frac{\delta_l}{\delta\rho_\alpha}\frac{\delta_l}{\delta\rho_\beta}\right)+\left(m\frac{\delta_l}{\delta\rho_5}-\mathscr{P}_\nu\frac{\delta_l}{\delta\rho_\nu}\right)\chi+p\dot{x}+\pi\dot{s}+\nu\dot{\chi}\right]d\tau\right\}$$
$$\times T\exp\int_0^1\rho_n(\tau)\widetilde{\gamma}^n\,d\tau\Big|_{\rho=0},$$

where five odd sources $\rho_n(\tau)$ are introduced, which anticommute with the γ-matrices by definition. One can present the quantity $T\exp\int_0^1\rho_n(\tau)\widetilde{\gamma}^n\,d\tau$ via a path integral over odd trajectories,[7]

$$T\exp\int_0^1\rho_n(\tau)\widetilde{\gamma}^n\,d\tau=\exp\left(i\widetilde{\gamma}^n\frac{\partial_l}{\partial\theta^n}\right)$$
$$\times\int_{\psi(0)+\psi(1)=\theta}\exp\left[\int_0^1(\psi_n\dot{\psi}^n-2i\rho_n\psi^n)d\tau+\psi_n(1)\psi^n(0)\right]\mathscr{D}\psi|_{\theta=0},$$

$$\mathscr{D}\psi=D\psi\left[\int_{\psi(0)+\psi(1)=0}D\psi\exp\left\{\int_0^1\psi_n\dot{\psi}^n\,d\tau\right\}\right]^{-1},\quad(52)$$

where θ^n are odd variables, anticommuting with γ-matrices, and $\psi^n(\tau)$ are odd trajectories of integration, obeying the boundary conditions, which are pointed out below the signs of integration. Using Eq. (52) we get the Hamiltonian path integral representation for the commutation function

$$\widetilde{S}=\epsilon(x^0_{\rm out},x^0_{\rm in})\exp\left(i\widetilde{\gamma}^n\frac{\partial_l}{\partial\theta^n}\right)\int_\Gamma ds_0\int d\chi_0\int_{s_0}Ds\int_{\chi_0}D\chi\int_{x_{\rm in}}^{x_{\rm out}}Dx\int Dp\int D\pi\int D\nu$$
$$\times\int_{\psi(0)+\psi(1)=\theta}\mathscr{D}\psi\,\exp\left\{i\int_0^1[s(\mathscr{P}^2-m^2+2igeF_{\alpha\beta}\psi^\alpha\psi^\beta)+2i(\mathscr{P}_\alpha\psi^\alpha-m\psi^5)\chi-i\psi_n\dot{\psi}^n\right.$$
$$\left.+p\dot{x}+\pi\dot{s}+\nu\dot{\chi}]d\tau+\psi_n(1)\psi^n(0)\right\}\Bigg|_{\theta=0}.$$

Integrating over momenta in the path integral, we get

$$\widetilde{S}=\epsilon(x^0_{\rm out},x^0_{\rm in})\exp\left(i\widetilde{\gamma}^n\frac{\partial_l}{\partial\theta^n}\right)\int_\Gamma de_0\int d\chi_0\;G(e_0,\chi_0,x^0_{\rm out},x^0_{\rm in}),\tag{53}$$

$$G(e_0,\chi_0,x^0_{\rm out},x^0_{\rm in})=\int_{e_0}De\int_{\chi_0}D\chi\int_{x_{\rm in}}^{x_{\rm out}}Dx\int D\pi\int D\nu\int_{\psi(0)+\psi(1)=\theta}\mathscr{D}\psi$$
$$\times M(e)\exp\left\{i\int_0^1\left[-\frac{\dot{x}^2}{2e}-\frac{e}{2}m^2-g\dot{x}A(x)+iegF_{\mu\nu}(x)\psi^\mu\psi^\nu\right.\right.$$
$$\left.\left.+i\left(\frac{\dot{x}_\mu\psi^\mu}{e}-m\psi^5\right)\chi-i\psi_n\dot{\psi}^n+\pi\dot{e}+\nu\dot{\chi}\right]d\tau+\psi_n(1)\psi^n(0)\right\}\Bigg|_{\theta=0},\tag{54}$$

where $M(e)$ is the integration measure,

$$M(e)=\int Dp\;\exp\left\{\frac{i}{2}\int_0^1 ep^2\,d\tau\right\}.\tag{55}$$

The exponent in integrand (54) can be considered as an effective and nondegenerate Lagrangian action of a spinning particle in an external field. It consists of two principal parts. The first one, which unites two summand with the derivatives of e and χ, can be treated as a gauge fixing term and corresponds to the gauge conditions $\dot{e}=\dot{\chi}=0$. The rest part of the effective action, in fact, coincides with the gauge invariant action[12] of a spinning particle. One can interpret the pair e_0, χ_0 in representation (53) as a super proper time.

Comparing the path integral representation (53) for the commutation function with one[7] for the Dirac propagator (causal Green function), one can remark that they are quite similar, one of the differences is in the contour of integration over s_0. Namely, the path integral representation for the Dirac propagator $\widetilde{S}^c$ (transformed by γ^5) reads

$$\widetilde{S}^c=\exp\left(i\widetilde{\gamma}^n\frac{\partial_l}{\partial\theta^n}\right)\int_\Gamma de_0\int d\chi_0\;G(e_0,\chi_0,x^0_{\rm out},x^0_{\rm in}),\tag{56}$$

where the function $G(e_0,\chi_0,x^0_{\rm out},x^0_{\rm in})$ has the same form (54). Thus in case of the commutation function the c-number component of the super proper time is complex in contrast with the case of the propagator.

IV. CONCLUSION

The results obtained for the commutation function allows one to get also similar proper time representation for some other singular functions. For example, it is easy to get for the retarded, $S^{\rm ret}(x,x')=\Theta(x_0-x_0')S(x,x')$, and advanced, $S^{\rm adv}(x,x')=-\Theta(x_0'-x_0)S(x,x')$, functions the following representations, in which one has to understand $\Theta(0)=1/2$:

$$S^{\rm ret}(x,x')=\Theta(x_0-x_0')(\hat{\mathscr{P}}_\nu\gamma^\nu+m)\int_\Gamma f(x,x',s)ds, \tag{57}$$

$$S^{\rm adv}(x,x')=\Theta(x_0'-x_0)(\hat{\mathscr{P}}_\nu\gamma^\nu+m)\int_\Gamma f(x,x',s)ds. \tag{58}$$

Combining the Schwinger representation (14) for the causal Green function and the representation (37) for the commutation function, one can get proper time representations for positive and negative frequency functions $S^{\mp}(x,x')$. Namely, let us define them via the Schwinger representation of the causal Green function,

$$S^{\mp}(x,x')=\pm S^c(x,x'),\quad \pm(x_0-x_0')>0. \tag{59}$$

Using the completeness relation

$$S(x,x')=S^-(x,x')+S^+(x,x'), \tag{60}$$

we get for any x,x'

$$S^{\mp}(x,x')=\Theta(\mp[x_0-x_0'])S(x,x')\pm S^c(x,x'). \tag{61}$$

In this connection one ought to remark that there is a problem with the causal Green function definition in case of an arbitrary external field. From the one hand, there exists the Feynman definition, based on the definition of the inverse operator to the Dirac equation by means of the prescription $m^2\to m^2-i\epsilon$. On the other hand, in the perturbation theory there appears a field theoretical definition of the propagator in the form

$$S^c(x,x')=i\langle 0|T\psi(x)\overline{\psi}(x')|0\rangle. \tag{62}$$

In the absence of the external field or in fields of special form, which do not violate the vacuum stability [then the operators of the spinor fields in Eq. (62) have to be taken in the Furry representation], it is possible to verify that the Feynman causal Green function and the propagator (14) coincide. In the same case one can establish that the former function can be defined via the Schwinger proper time representation. In external fields, which violate the vacuum stability (create pairs from the vacuum), the situation is not so clear. In this case does not exist an unique vacuum for all the time instances. One has to distinguish the initial $|0,\text{in}\rangle$ and final $|0,\text{out}\rangle$ vacua.[2,3,13] In virtue of that, one has also to use different kinds of propagators in the perturbation theory,

$$S^c(x,x')=i\,\frac{\langle 0,\text{out}|T\psi(x)\overline{\psi}(x')|0,\text{in}\rangle}{\langle 0,\text{out}|0,\text{in}\rangle}, \tag{63}$$

$$S^c_{\rm in}(x,x')=i\langle 0,\text{in}|T\psi(x)\overline{\psi}(x')|0,\text{in}\rangle, \tag{64}$$

and the positive and negative frequency commutation functions,

$$\begin{aligned} S^-(x,x')&=i\,\frac{\langle 0,\text{out}|\psi(x)\overline{\psi}(x')|0,\text{in}\rangle}{\langle 0,\text{out}|0,\text{in}\rangle},\\ S^+(x,x')&=i\,\frac{\langle 0,\text{out}|\overline{\psi}(x')\psi(x)|0,\text{in}\rangle}{\langle 0,\text{out}|0,\text{in}\rangle}. \end{aligned} \tag{65}$$

It was shown that in special cases of external fields, violating the vacuum stability, the Feynman causal Green function, presented by means of the Schwinger proper time integral, gives, namely, the propagator (63), whereas the propagator (64) demands a modification of the Schwinger contour in the proper time integration.[14] At the present time does not exist a proof of the equivalence between of the Feynman causal Green function and the propagator (63) for any external fields. Nevertheless, there is a strong believe that they are equivalent. If one excepts such an equivalence, then the positive and negative frequency commutation functions (65) have the representation (61) in arbitrary external fields.

We classify all $SL(2,\mathbb{R})$-covariant Poisson structures on the Lobachevsky plane with respect to all multiplicative Poisson structures on $SL(2,\mathbb{R})$ and describe quantizations for all these Poisson structures. © *1996 American Institute of Physics.* [S0022-2488(96)01507-1]

I. INTRODUCTION

A first step into the direction of a quantization of the notions of algebraic geometry (cf. Ref. 1) is the quantization of the three fundamental one-dimensional complex domains: the complex plane, the Riemannian sphere, and the complex upper half-plane. Quantum planes were considered in Ref. 2. Quantum Riemannian spheres are discussed in Refs. 3 and 4. A quantum upper half-plane appears first in Ref. 5 (for certain other quantizations of the upper half-plane, see also Remark 7). In this letter we consider the case of the quantum complex upper half-plane.

In the theory of quantum groups the classification of certain Poisson structures gives generally a good insight into the problem of the classification of quantum structures. At first we give the full solution of the classification problem in the classical limit [i.e., the description of all possible $SL(2,\mathbb{R})$-covariant Poisson structures for the upper half-plane with respect to the action of all possible multiplicative Poisson structures on $SL(2,\mathbb{R})$). Further, we describe classes of quantum structures, which reproduce all listed Poisson structures in the classical limit. We obtain two-parameter quantizations of the upper half-plane for every action of one of the quantum groups $SL_q(2,\mathbb{R})$, $SU_q(1,1)$, and $SL_h(2,\mathbb{R})$.

II. PRELIMINARIES

In this section we introduce the basic concepts (see also Refs. 5–7). Let (A,Δ,ϵ) be a Hopf algebra. A *left quantum space* (H,ϕ) is an algebra H along with an algebra homomorphism $\phi: H\to A\otimes H$ such that $(\Delta\otimes\mathrm{id})\phi=(\mathrm{id}\otimes\phi)\phi$ and $(\epsilon\otimes\mathrm{id})\phi=\mathrm{id}$. Two left quantum spaces (H_1,ϕ_1) and (H_2,ϕ_2) are *isomorphic* if there is an algebra isomorphism $h: H_1\to H_2$, such that $\phi_2\circ h=(\mathrm{id}\otimes h)\circ\phi_1$. Further consider commutative Hopf algebras and commutative quantum spaces. We say that the Poisson bracket $\{.,.\}$ on A is *multiplicative* if $\{\Delta(x),\Delta(y)\}_{A\otimes A}=\Delta(\{x,y\})$, where $A\otimes A$ carries the Poisson structure of the direct product. We call a Poisson bracket $\{.,.\}$ on H *covariant* if $\{\phi(x),\phi(y)\}_{A\otimes H}=\phi(\{x,y\})$, where $A\otimes H$ carries the direct product structure from A and H. We say that two multiplicative or covariant, respectively, Poisson brackets on A and, respectively, H are *equivalent* if they intertwine with an automorphism of A and, respectively, H.

III. THE CLASSICAL CASE

A. Poisson structures on SL(2,$\mathbb{R}$)

Let $A=\mathbb{R}[a,b,c,d]/(ad-bc-1)$ be the commutative unital algebra of polynomial functions in the coordinates of

$$\mathrm{SL}(2,\mathbb{R})=\left\{\left.\begin{pmatrix} a & b \\ c & d \end{pmatrix}\right| a,b,c,d\in\mathbb{R},\ \ ad-bd=1\right\}.$$

[a)]Electronic mail address: leitenb@husc.harvard.edu

Here A becomes a Hopf algebra with respect to the Hopf multiplication

$$\Delta\begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} a\otimes a + b\otimes c & a\otimes b + b\otimes d \\ c\otimes a + d\otimes c & c\otimes b + d\otimes d \end{pmatrix}$$

and the counit ϵ with

$$\epsilon\begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

Here A has the coinverse κ with

$$\kappa\begin{pmatrix} a & b \\ c & d \end{pmatrix} = \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}.$$

We consider three types of multiplicative Poisson algebras A_λ^A, A_λ^K, and A^N:
(1) $A_\lambda^A=(A,\{,\}_\lambda)$, $\lambda\in\mathbb{R}$, $\lambda\neq 0$, with

$$\{a,b\}_\lambda=\lambda ab,\quad \{a,c\}_\lambda=\lambda ac,\quad \{a,d\}_\lambda=2\lambda bc,$$

$$\{b,c\}_\lambda=0,\quad \{b,d\}_\lambda=\lambda bd,\quad \{c,d\}_\lambda=\lambda cd;$$

(2) $A_\lambda^K=(A,\{,\}_\lambda)$, $\lambda>0$, with

$$\{a,b\}_\lambda=\lambda(1-a^2-b^2),\quad \{a,c\}_\lambda=\lambda(a^2+c^2-1),\quad \{a,d\}_\lambda=\lambda(a-d)(b-c),$$

$$\{b,c\}_\lambda=\lambda(a+d)(b+c),\quad \{b,d\}_\lambda=\lambda(b^2+d^2-1),\qquad \{c,d\}_\lambda=\lambda(1-c^2-d^2);$$

and
(3) $A^N=(A,\{,\})$ with

$$\{a,b\}=(1-a^2),\quad \{a,c\}=c^2,\quad \{a,d\}=c(d-a),$$

$$\{b,c\}=c(d+a),\quad \{b,d\}=(d^2-1),\quad \{c,d\}=-c^2.$$

We shortly denote $A_\lambda^A(\lambda\in\mathbb{R},\ \lambda\neq 0)$, $A_\lambda^K(\lambda>0)$, and A^N by A_λ^I $(I=A,K,N)$.

Remark 1: The notation A_λ^I with $I=A,K,N$ is justified by the fact that the Poisson brackets of A_λ^A, A_λ^K, and A^N, respectively, vanish on the subgroups of the KAN-decomposition

$$G_A=\left\{\begin{pmatrix} e^x & 0 \\ 0 & e^{-x} \end{pmatrix}\middle|\, e\in\mathbb{R}\right\},$$

$$G_K=\left\{\begin{pmatrix} \cos x & \sin x \\ -\sin x & \cos x \end{pmatrix}\middle|\, x\in[0,2\pi)\right\},$$

and

$$G_N=\left\{\begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix}\middle|\, x\in\mathbb{R}\right\},$$

respectively.

Proposition 1: Every nontrivial multiplicative Poisson structure on A is equivalent to one of the structures $A_\lambda^A(\lambda\neq 0)$, $A_\lambda^K(\lambda>0)$, A^N. All these structures are nonequivalent.

Proof: We give a sketch proof. Set $g=\mathrm{sl}(2,\mathbb{R})$. Because $H^1(g,g\wedge g)=0$, every Poisson structure on $\mathrm{SL}(2,\mathbb{R})$ arises from a classical r-matrix, $r\in g\wedge g$, which satisfies the modified classical Yang–Baxter equation (MCYBE) $(\wedge_1^3 ad_x)C(r)=0$, $\forall x\in g$ with a certain element $C(r)\in g\wedge g\wedge g$ (cf. Ref. 6). Because $g=\mathrm{sl}(2,\mathbb{R})$ is a simple Lie algebra, the one-dimensional representation $\wedge_1^3 ad$ is trivial. That is, the MCYBE is satisfied for every $r\in g$.

To show that two structures are equivalent, it is enough to show that their r-matrices are connected by an automorphism of $\mathrm{sl}(2,\mathbb{R})$. All automorphisms are generated by inner automorphisms [i.e., the adjoint action of $\mathrm{SL}(2,\mathbb{R})$] and the automorphism α with

$$\alpha\begin{pmatrix} a & b \\ c & d \end{pmatrix}=\begin{pmatrix} a & -b \\ -c & d \end{pmatrix}.$$

Let

$$e_{-1}=\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix},\quad e_0=\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},\quad e_1=\begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$$

and $r=\alpha e_1\wedge e_{-1}+\beta e_0\wedge e_1+\gamma e_0\wedge e_{-1}$. Studying the adjoint action $\wedge_1^2 Ad$ of $\mathrm{SL}(2,\mathbb{R})$ and the action of α on $r\in g\wedge g$, we recognize that r is equivalent to one of the following elements:

$$r_\lambda^A=\lambda e_1\wedge e_{-1},\quad \lambda\in\mathbb{R},\lambda\neq 0,$$

$$r_\lambda^K=\lambda(e_0\wedge e_1+e_0\wedge e_{-1}),\quad \lambda>0,$$

$$r^N=e_0\wedge e_1.$$

All these elements are nonequivalent.

Because A consists of the matrix elements of the finite-dimensional representations $\rho:\mathrm{SL}(2,\mathbb{R})\to\mathbb{R}^n$, one can give the Poisson structures by the formula

$$\{l_1(\rho_1(g)v_1),l_2(\rho_2(g)v_2)\}=(l_1\otimes l_2)([(\rho_1\otimes\rho_2)(r_0),\rho_1(g)\otimes\rho_2(g)]v_1\otimes v_2)$$

[$v\in\mathbb{R}^d$, $l\in(\mathbb{R}^d)^*$, cf. Ref. 8]. The structures A_λ^A, A_λ^K, and A^N correspond to the above normal forms r_λ^A, r_λ^K, and r^N for r. □

B. Poisson structures on the upper half-plane

Further consider the subalgebra $H\subseteq A$ generated by the elements $A=a^2+b^2$, $B=ac+bd$, $D=c^2+d^2$ (cf. Ref. 5) and the left coaction $\phi=\Delta|_H:H\to A\otimes H$ with

$$\phi(A)=a^2\otimes A+b^2\otimes D+2ab\otimes B,$$

$$\phi(D)=c^2\otimes A+d^2\otimes D+2cd\otimes B,$$

$$\phi(B)=ac\otimes A+bd\otimes D+(ad+bc)\otimes B.$$

By the next Proposition we give a complete classification of all possible covariant Poisson structures on H with respect to A_λ^I.

Proposition 2: (1) All with respect to A_λ^I covariant Poisson structures are given by the one-parameter series:

(i) $H_{\lambda,\mu}^A$($\lambda\in\mathbb{R}$, $\lambda\neq 0$, $\mu\in\mathbb{R}$):

$$\{A,B\}=2\lambda A(B+\mu),\quad \{A,D\}=4\lambda B(B+\mu),\quad \{B,D\}=2\lambda D(B+\mu);$$

(ii) $H^K_{\lambda,\mu}(\lambda>0,\ \mu\in\mathbb{R})$:

$$\{A,B\}=2\lambda A(A+D+\mu),$$

$$\{A,D\}=4\lambda B(A+D+\mu),$$

$$\{B,D\}=2\lambda D(A+D+\mu);$$

(iii) $H^N_{\mu}(\mu\in\mathbb{R})$:

$$\{A,B\}=2A(D+\mu),\quad \{A,D\}=4B(D+\mu),\quad \{B,D\}=2D(D+\mu)$$

for $I=n$.

(2) Two Poission algebras H^I_{λ,μ_i} and H^I_{λ,μ_2} are equivalent if and only if $|\mu_1|=|\mu_2|$.

Proof: (1) All left invariant Poisson structures [i.e., $\phi(\{x,y\})=\{\phi(x),\phi(y)\}$, $\forall x,y\in H$, where $A\otimes H$ carries a Poisson structure which is the direct product of the zero structure on A and of the structure on H] are given by

$$\{A,B\}=2\mu A,\quad \{A,D\}=4\mu B,\quad \{B,D\}=2\mu D$$

($\mu\in\mathbb{R}$). We obtain the above formulas by the calculation for a fixed μ (for example, $\mu=0$) and from the fact that the difference of two left covariant structures is left invariant (cf. Ref. 7).

(2) The proof of the equivalence follows from the fact that (H,ϕ) has the unique automorphism $x\to -x,\forall x\in H$. □

The following Proposition shows that we can realize the Poisson algebras $H^I_{\lambda,\mu}$ as subalgebras of A^I_λ.

Consider subalgebras $H_{\alpha,\beta,\gamma}\subset A$ generated by elements $\overline{A},\overline{B},\overline{D}\in A$ with

$$\overline{A}:=\alpha a^2+\beta b^2+2\gamma ab,$$

$$\overline{B}:=\alpha ac+\beta bd+\gamma(ad+bc),$$

$$\overline{D}:=\alpha c^2+\beta d^2+2\gamma cd.$$

We have $H_{1,1,0}=H$, and the correspondence between A, B, D, and the overlined elements arranges an isomorphism $H_{\alpha,\beta,\gamma}\cong H$ (i.e., $\overline{AD}-\overline{B}^2=1$), if and only if $\alpha\beta-\gamma^2=1$.

Proposition 3: Let $\alpha\beta-\gamma^2=1$. Then $H_{\alpha,\beta,\gamma}$ is a Poisson subalgebra of A^I_λ and we have

$$\text{(i)}\quad H_{\alpha,\beta,\gamma}\cong H^A_{\lambda,-\gamma},$$

$$\text{(ii)}\quad H_{\alpha,\beta,\gamma}\cong H^K_{\lambda,-\alpha-\beta},\ \text{and}$$

$$\text{(iii)}\quad H_{\alpha,\beta,\gamma}\cong H^N_{\lambda,-\beta}.$$

Proof: The isomorphies can be verified by an explicit calculation.

Remark 2: The preceding Proposition admits the realization of all $H^I_{\lambda,\mu}$ by $H_{\alpha,\beta,\gamma}$ with real α,β,γ, except the cases H^N_0 and $H^K_{\lambda,\mu}$, $|\mu|<2$. For example, $H^A_{\lambda,\mu}\cong H_{1,1+\mu^2,\mu}$, $H^K_{\lambda,\mu}\cong H_{(\mu+\sqrt{\mu^2-4})/2,(\mu-\sqrt{\mu^2-4})/2,0}$ and $H^N_\mu\cong H_{-1/\mu,-\mu,0}$. In the other cases we have only complex realizations, for example, $H^K_{\lambda,\mu}\cong H_{(\mu+i\sqrt{4-\mu^2})/2,(\mu-i\sqrt{4-\mu^2})/2,0}$ and $H^N_0\cong H_{0,0,i}$. The realizations are not unique.

C. Geometric interpretation

There is an interpretation of the parameter μ in terms of fixed points z_0 of the upper half-plane.

Let $z\to(az+b)/(cz+d)$ be the usual action of $\mathrm{SL}(2,\mathbb{R})$ on the complex coordinate $z=+iy$, $y>0$, of the upper half-plane, i.e.,

$$x\to\frac{ac(x^2+y^2)+(ad+bc)x+bd}{c^2(x^2+y^2)+2cdx+d^2},$$

$$y\to\frac{y}{c^2(x^2+y^2)+2cdx+d^2}.$$

Further let G_{z_0} be the subgroup of $\mathrm{SL}(2,\mathbb{R})$, which fixes the point $z_0=x_0+iy_0$, $y_0>0$. It follows that the functions

$$x=x(a,b,c,d)=\frac{ac(x_0^2+y_0^2)+(ad+bc)x_0+bd}{c^2(x_0^2+y_0^2)+2cdx_0+d^2}$$

and

$$y=y(a,b,c,d)=\frac{y_0}{c^2(x_0^2+y_0^2)+2cdx_0+d^2}$$

are left G_{z_0}-invariant and can be identified with functions on $G_{z_0}G$. We recognize that $\overline{B}=xy^{-1}$, $\overline{D}=y^{-1}$ generate $H_{y_0+x_0^2/y_0,x_0/y_0,1/y_0}$ For the parameter μ we get the interpretation

$$\mu=\mathrm{ctg}(\arg(z_0))=\frac{\mathrm{Re}\ z_0}{\mathrm{Im}\ z_0},\quad \text{if } I=A,$$

$$\mu=-\frac{1+|z_0|^2}{\mathrm{Im}\ z_0},\quad \text{if } I=K,$$

$$\mu=-\frac{1}{\mathrm{Im}\ z_0},\quad \text{if } I=N.$$

We remark that $x,y\notin H=\mathbb{R}[\overline{A,B,D}]$ and $\overline{A,B,D}\notin H':=\mathbb{R}[x,y]$, but H and H' are dense subalgebras of the algebra of smooth functions on the upper half-plane (H and H' are dense on every compact subset). With respect to the xy coordinates the Poisson brackets have the form

$$\{x,y\}=-2\lambda(xy+\mu y^2)$$

if $I=A$,

$$\{x,y\}=-2\lambda(x^2y+y+y^3+\mu y^2)$$

if $I=K$, and

$$\{x,y\}=-2(y+\mu y^2)$$

if $I=N$.

IV. THE QUANTUM CASE

A. The quantum groups $\mathscr{A}_h^I$

First we recall the definition of the three known quantum deformations of SL(2,$\mathbb{R}$).

The Poisson algebras A_λ^I correspond to the quantum algebras $\mathscr{A}_h^A$ ($h\in\mathbb{R}$, $h\neq 2\pi n$, $n\in\mathbb{N}$), $\mathscr{A}_h^K$ ($h>0$), and $\mathscr{A}^N$. For all these algebras we write shortly $\mathscr{A}_h^I$ ($I=A,K,N$). The algebras $\mathscr{A}_h^I$ are generated by elements a,b,c,d and relations

$$ab=e^{\mathbf{i}h}ba,\quad ac=e^{\mathbf{i}h}ca,\quad bd=e^{\mathbf{i}h}db,$$

$$cd=e^{\mathbf{i}h}dc,\quad bc=cb,\quad ad-da=(e^{\mathbf{i}h}-e^{-\mathbf{i}h})bc,$$

$$ad-e^{\mathbf{i}h}bc=da-e^{\mathbf{i}h}cb=1,\quad h\neq 2\pi n,$$

for $I=A$;

$$ab-ba=\mathbf{i}h(1-a^2-b^2),\quad ac-ca=\mathbf{i}h(a^2+c^2-1),$$

$$bd-db=\mathbf{i}h(b^2+d^2-1),\quad cd-dc=\mathbf{i}h(1-c^2-d^2),$$

$$ad-da=\mathbf{i}h(ab+ba+ac+ca+bd+db+cd+dc),$$

$$bc-cb=\mathbf{i}h(ab+ba-ac-ca-bd-db+cd+dc),$$

$$ad+da-bc-cb=2+h(2-a^2-b^2-c^2-d^2),\quad h>0,$$

for $I=K$; and

$$ab-ba=\mathbf{i}(1-a^2),\quad ac-ca=\mathbf{i}c^2,\quad bd-db=\mathbf{i}(d^2-1),$$

$$cd-dc=-\mathbf{i}c^2,\quad ad-da=\mathbf{i}c(d-a),\quad bc-cb=\mathbf{i}(dc+ca),$$

$$ad-bc+\mathbf{i}ac=da-cb-\mathbf{i}ca=1$$

for $I=N$.

The algebras $\mathscr{A}_h^I$ become Hopf algebras with respect to the Hopf multiplication

$$\Delta\begin{pmatrix}a & b\\ c & d\end{pmatrix}=\begin{pmatrix}a\otimes a+b\otimes c & a\otimes b+b\otimes d\\ c\otimes a+d\otimes c & c\otimes b+d\otimes d\end{pmatrix}$$

and Hopf *-algebras with respect to the involution

$$a^*:=a,\quad b^*:=b,\quad c^*:=c,\quad d^*:=d.$$

The counit ϵ is given by

$$\epsilon\begin{pmatrix}a & b\\ c & d\end{pmatrix}=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}$$

and the coinverse κ is given by

$$\kappa\begin{pmatrix}a & b\\ c & d\end{pmatrix}=\begin{pmatrix}d & -q^{-1}b\\ -qc & a\end{pmatrix}$$

for $I=A$;

$$\kappa(a)=\frac{1}{4}\left(\left(2-\frac{2-2h^2}{1+h^2}\right)a+\left(2+\frac{2-2h^2}{1+h^2}\right)d-\frac{2h}{1+h^2}\,b-\frac{2h}{1+h^2}\,c\right),$$

$$\kappa(b)=\frac{1}{4}\left(\frac{2}{1+h^2}\,a-\frac{2}{1+h^2}\,d-\left(2+\frac{2-2h^2}{1+h^2}\right)b+\left(2-\frac{2-2h^2}{1+h^2}\right)c\right),$$

$$\kappa(c)=\frac{1}{4}\left(\frac{2}{1+h^2}\,a-\frac{2}{1+h^2}\,d+\left(2-\frac{2-2h^2}{1+h^2}\right)b-\left(2+\frac{2-2h^2}{1+h^2}\right)c\right),$$

$$\kappa(d)=\frac{1}{4}\left(\left(2+\frac{2-2h^2}{1+h^2}\right)a+\left(2-\frac{2-2h^2}{1+h^2}\right)d+\frac{2h}{1+h^2}\,b+\frac{2h}{1+h^2}\,c\right),$$

for $I=K$; and

$$\kappa\begin{pmatrix}a & b\\ c & d\end{pmatrix}=\begin{pmatrix}d+c & -b+(d-a+c)\\ -c & a-c\end{pmatrix}$$

for $I=N$.

Remark 3: $\mathscr{A}_h^K$ is equivalent to the quantum group $\mathrm{SU}_q(1,1)$, $q\in\mathbb{R}$, which is given by elements $\alpha,\alpha^*,\beta,\beta^*$ and relations

$$\alpha\beta=q\beta\alpha,\quad \alpha\beta^*=q\beta^*\alpha,$$

$$\beta\beta^*=\beta^*\beta,\quad \beta\alpha^*=q\alpha^*\beta,\quad \beta^*\alpha^*=q\alpha^*\beta^*,$$

$$\alpha\alpha^*-q^2\beta\beta^*=\alpha^*\alpha-\beta^*\beta=1.$$

The formulas of $\mathrm{SU}_q(1,1)$ and $\mathscr{A}_h^K$ are connected by the transformation of the deformation parameter $h=(1-q)/(1+q)$ and by the ''quantum Cayley transformation'' of the matrix elements

$$\alpha:=\tfrac{1}{2}(a+d+\mathbf{i}(b-c)),$$

$$\alpha^*=\tfrac{1}{2}(a+d+\mathbf{i}(-b+c)),$$

$$\beta:=\tfrac{1}{2}(a-d-\mathbf{i}(b+c)),$$

$$\beta^*=\tfrac{1}{2}(a-d+\mathbf{i}(b+c)).$$

Remark 4: Instead of $\mathscr{A}^N$ one considers Hopf *-algebras $\mathrm{SL}_h(2,\mathbb{R})$ $(h\neq 0)$, where the algebra structure is replaced by

$$ab-ba=\mathbf{i}h(1-a^2),\quad ac-ca=\mathbf{i}hc^2,\quad bd-db=\mathbf{i}h(d^2-1),$$

$$cd-dc=-\mathbf{i}hc^2,\quad ad-da=\mathbf{i}hc(d-a),\quad bc-cb=\mathbf{i}h(dc+ca),$$

$$ad-bc+\mathbf{i}hac=da-cb-\mathbf{i}hca=1.$$

(cf. Refs. 9 and 10). All these structures are equivalent to $\mathscr{A}^N$ by the Hopf *-algebra isomorphism $a\to a$, $b\to hb$, $c\to(1/h)c$, $d\to d$.

B. The quantum spaces ($\mathscr{H}^I_{h,k,d}$,ϕ)

1. The algebras $\mathscr{H}^I_{h,k,d}$

The Poisson algebras $H^I_{\lambda,\mu}$ correspond to the algebras $\mathscr{H}^a_{h,k,d}(h\neq 2\pi n)$, $\mathscr{H}^k_{h,k,d}$ $(h>0)$, $\mathscr{H}^n_{k,d}$, $k,d\in\mathbb{R}$. For all these algebras we write shortly $\mathscr{H}^I_{h,k,d}$.

We define the $\mathscr{H}^I_{h,k,d}$ as algebras which are generated by elements A,B,C,D and relations

$$C=e^{-\mathbf{i}h}B+k(1-e^{-\mathbf{i}h}),\quad AB=e^{2\mathbf{i}h}BA+k(1-e^{2\mathbf{i}h})A,$$

$$BD=e^{2\mathbf{i}h}DB+k(1-e^{2\mathbf{i}h})D,\quad AD-e^{2\mathbf{i}h}BC=d+k(1-e^{2\mathbf{i}h})B,$$

$$DA-e^{-2\mathbf{i}h}CB=d+k(1-e^{-2\mathbf{i}h})B,\quad h\neq 2\pi n$$

for $I=A$;

$$C=B-\mathbf{i}h(A+D+k),\quad AB-BA=\mathbf{i}h(2kA+2A^2+AD+BC),$$

$$BD-DB=\mathbf{i}h(2kD+2D^2+AD+CB),$$

$$AD-B^2=d+\mathbf{i}h(kB+AB+BD),$$

$$DA-C^2=d-\mathbf{i}h(kC+CA+DC),\quad h>0,$$

for $I=K$; and

$$C=B-\mathbf{i}(D+k),$$

$$AB-BA=2\mathbf{i}A(D+k)-2B(D+k),$$

$$BD-DB=2\mathbf{i}D(D+k),$$

$$AD-BC=d+2\mathbf{i}B(D+k),$$

$$DA-CB=d-2\mathbf{i}(D+k)C$$

for $I=N$.

The algebras $\mathscr{H}^I_{h,k,d}$ become *-algebras with respect to the involutions

$$A^*:=A,\quad D^*:=D,\quad B^*:=C=e^{-\mathbf{i}h}B+k(1-e^{-\mathbf{i}h}),\quad C^*:=B$$

for $I=A$;

$$A^*:=A,\quad D^*:=D,\quad B^*:=C=B-\mathbf{i}h(A+D+k),\quad C^*:=B$$

for $I=K$; and

$$A^*:=A,\quad D^*:=D,\quad B^*:=C=B-\mathbf{i}(D+k),\quad C^*:=B$$

for $I=N$.

Remark 5: Formally we recover the Poisson structures of Sec. III B in the limit $t\to\infty$, if we set $B=C$, $q=\lambda t$, $k=\mu$, $d=1$, and $\{x,y\}:=\lim(1/it)[x,y]$.

Next we show that we can realize the *-algebras $\mathscr{H}^I_{h,k,d}$ as *-subalgebras of $\mathscr{A}^I_h$. Let

$$\overline{A}:=\alpha a^2+\beta b^2+\gamma(ab+ba),$$

$$\overline{B}:=\alpha ac+\beta bd+\gamma(ad+bc),$$

$$\overline{C}:=\alpha ca+\beta db+\gamma(da+cb),$$

$$\overline{D}:=\alpha c^2+\beta d^2+\gamma(cd+dc).$$

Proposition 4: Let $\alpha,\ \beta,\ \gamma\in\mathbb{R}$, and $\overline{A,B,C,D}$ satisfy the relations of

(i) $\mathscr{H}^A_{h,\gamma,\alpha\beta-\gamma^2}$,
(ii) $\mathscr{H}^K_{h,-\alpha-\beta,\alpha\beta-\gamma^2}$, and
(iii) $\mathscr{H}^N_{h,-\beta,\alpha\beta-\gamma^2}$.

Proof: The proof can be given by an explicit calculation.

Remark 6: Proposition 4 admits the realization of all $\mathscr{H}^I_{h,k,d}$, with real α,β,γ without the cases $\mathscr{H}^K_{h,0,d}$, $|k|<2$, and $\mathscr{H}^N_{h,0,d}$, $d>0$. For example, $\mathscr{H}^A_{h,k,d}\cong\mathscr{H}_{\mathbf{1},d+k^2,k}$, $\mathscr{H}^K_{h,k,d}\cong\mathscr{H}_{(k+\sqrt{k^2-4})/2,(k-\sqrt{k^2-4})/2,0}$ and $\mathscr{H}^N_{h,k,d}\cong\mathscr{H}_{-d/k,-k,0}$. In other cases we have only complex realizations; for example, $H^K_{h,k,d}\cong H_{(k+i\sqrt{4-k^2})/2,(k-i\sqrt{4-k^2})/2,0}$ and $\mathscr{H}_{0,0,\mathbf{i}\backslash d}\cong\mathscr{H}^N_{h,0,d}$.

Remark 7: (1) The special case $\mathscr{H}_{\mathbf{1},\mathbf{1},0}\cong\mathscr{H}^A_{h,\mathbf{0},\mathbf{1}}$ was first mentioned in Ref. 5, p. 188.

(2) The formulas for $\mathscr{H}^A_{h,k,d}$ are similar those from Podles' sphere $C(X_{\mu,\lambda,\rho})$ (cf. Ref. 4). Both can be specified from the complex quantum space $\Xi_{q,\lambda,\rho}$ of $\mathrm{SL}_q(2,\mathbb{C})$ from Ref. 11 by fixing certain involutions.

(3) In Ref. 12 the quantum spaces $\mathscr{H}_{\alpha,\beta,0}\cong\mathscr{H}^A_{h,0,\alpha\beta}$, $\alpha,\beta\geqslant 0$, were considered.

(4) The quantum spaces $\mathscr{H}^K_{h,k,d}$ correspond to one-parameter series of quantum discs $C_{\mu,q}(\overline{U})$ in Ref. 13. Formally the correspondence is arranged by the quantum Cayley transformation (cf. Remark 3).

2. The coaction of $\mathscr{A}^I_h$ on $\mathscr{H}^I_{h,k,d}$

We will describe an coaction ϕ, i.e., a homomorphism $\phi:\mathscr{H}^I_{h,k,d}\to\mathscr{A}^I_h\otimes\mathscr{H}^I_{h,k,d}$ with $(\Delta\otimes\mathrm{id})\phi=(\mathrm{id}\otimes\phi)\phi$ and $(\epsilon\otimes\mathrm{id})\phi=\mathrm{id}$ such that we can call $(\mathscr{H}^I_{h,k,d},\phi)$ a quantum space with respect to $\mathscr{A}^I_h$.

According to Remark 6, consider $\mathscr{H}^I_{h,k,d}$ as a subalgebra of $\mathscr{A}^I_h$, i.e., we identify A,B,C,D with A,B,C,D. We obtain (independent from I,h,k,d)

$$\Delta(A)=a^2\otimes A+b^2\otimes D+ab\otimes B+ba\otimes C,$$

$$\Delta(D)=c^2\otimes A+d^2\otimes D+cd\otimes B+dc\otimes C,$$

$$\Delta(B)=ac\otimes A+bd\otimes D+ad\otimes B+bc\otimes C,$$

$$\Delta(C)=ca\otimes A+db\otimes D+cb\otimes B+da\otimes C.$$

That is, $\mathscr{H}^I_{h,k,d}$ is a left coideal of $\mathscr{A}^I_h$ and we have proven the following proposition.

Proposition 5: The homomorphism $\phi:\mathscr{H}^I_{h,k,d}\to\mathscr{A}^I_h\otimes\mathscr{H}^I_{h,k,d}:\phi:=\Delta|_{\mathscr{H}^I_{h,k,d}}$ defines a left coaction, that is, $(\mathscr{H}^I_{h,k,d},\phi)$ are left quantum spaces.

Remark 8: Every $\mathscr{H}^I_{h,k,d}$ is equivalent to one of the quantum spaces

$$\mathscr{H}^I_{h,k,\pm 1},\mathscr{H}^I_{h,k,0}$$

with $k\geqslant 0$.

Proof: We achieve $k\in[0,\infty)$ because of the automorphism $X\to -X$, $X\in\mathscr{H}^I_{h,k,d}$, and we achieve $d=0,\pm 1$ by the reparametrization $X\to(1/\sqrt{|d|})X$, $X\in\mathscr{H}^I_{h,k,d}$. ∎

(Received 6 September 1995; accepted for publication 22 March 1996)

Different regularizations are studied in localization of path integrals. We discuss the effect of the choice of regularization by evaluating the partition functions for the harmonic oscillator and the Weyl character for SU(2). In particular, we solve the Weyl shift problem that arises in path integral evaluation of the Weyl character by using the Atiyah–Patodi–Singer η-invariant and the Borel–Weil theory. © *1996 American Institute of Physics.* [S0022-2488(96)01107-3]

I. INTRODUCTION

Quantum localization is a generalization Duistermaat–Heckman theorem[1] to infinite dimensions. This theorem states that if the Hamiltonian H generates a global circle, or, more generally, a torus action in the phase space Γ, then the canonical partition function is given exactly by the saddle-point approximation around the critical points of H. Extensions to calculation of quantum mechanical partition functions using phase space path integrals have been represented in, e.g., Ref. 2.

We shall first consider basic ideas of localization. Then we shall carefully regularize the pertinent functional determinants arising from the path integrals. There is an ambiguity in choosing the regularization scheme because of the spectral asymmetry of first-order differential operators. Therefore, the result depends on the regularization as in the case of quantum mechanical anomalies.

Finally, we are going to apply our localization to the quantization of the simple harmonic oscillator and to the evaluation of the Weyl character of spin. We shall notice that different regularizations give different energy spectra for the harmonic oscillator. We also show that the continuum coherent state path integral yields directly the correct character for spin if we choose an appropriate regularization. In particular, we will consider the relation of character formulas to the Borel–Weil theory which constructs the irreducible representations of a Lie group as holomorphic functions. Using this theory we relate the character formulas to the equivariant index of the Dolbeault complex. The result is that the path integral yields directly the correct character without an explicit Weyl shift of the highest weight.

II. LOCALIZATION OF PHASE SPACE PATH INTEGRALS

We are interested in exact evaluation of phase space path integrals (partition functions) of the form

$$Z(T)=\int_{L\Gamma}\mathscr{D}xPf\|\omega_{ab}(x)\|\exp\left(i\int_0^T dt[\vartheta_a\dot{x}^a-H(x)]\right), \tag{1}$$

where $\{x^a\}$ are local coordinates in Γ, $Pf\|\omega_{ab}\|$ is the Liouville measure factor, ϑ_a is the symplectic potential, and $\omega_{ab}=\partial_a\vartheta_b-\partial_b\vartheta_a$. The integration is performed over the loop space $L\Gamma$ consisting of the phase space loops. The integrability condition[3] requires that

[a)]Electronic mail address: mauri@rhea.teorfys.uu.se

$$\int_\Sigma \omega = 2\pi n$$

for any two-cycle Σ in Γ so that the path integral is single valued. We introduce anticommuting variables ψ^a to write $Pf\|\omega_{ab}\|$ as a path integral:

$$Z(T) = \int \mathscr{D}x \mathscr{D}\psi \, \exp\left(i \int_0^T dt \left[\vartheta_a \dot{x}^a - H(x) + \frac{1}{2} \psi^a \omega_{ab} \psi^b \right] \right). \tag{2}$$

The boundary conditions are periodic also for the fermions, since they are a realization of the differentials of the bosonic coordinates.

We interpret the path integral (2) in terms of equivariant cohomology in $L\Gamma$. From the bosonic part of the action we obtain a Hamiltonian vector field in $L\Gamma$,

$$\chi_S^a = \dot{x}^a - \omega^{ab} \partial_b H,$$

whose zeroes define the Hamilton's equations. The equivariant exterior derivative in $L\Gamma$ is

$$d_S = d + \iota_S,$$

where ι_S denotes the contraction along the vector field χ_S. The square of d_S is the loop space Lie derivative

$$\mathscr{L}_S = d\iota_S + \iota_S d \sim \frac{d}{dt} - \mathscr{L}_H.$$

The action $S_B + S_F$ is supersymmetric under the infinitesimal loop space supersymmetry transformations that are parametrized by a gauge fermion $\delta\Psi$:

$$x^a \to x^a + \delta\Psi \, d_S x^a = x^a + \delta\Psi \, \psi^a, \qquad \psi^a \to \psi^a + \delta\Psi \, d_S \psi^a = \psi^a + \delta\Psi \, \chi_S^a. \tag{3}$$

This implies that the action is equivariantly closed:

$$d_S(S_B + S_F) = 0.$$

By an analog of Fradkin–Vilkovisky theorem[4] one can show that the path integral remains intact if we modify the action by $S \to S + d_S\Psi$, where Ψ satisfies the Lie derivative condition

$$d_S^2 \Psi = \mathscr{L}_S \Psi = 0. \tag{4}$$

In the limit $\lambda \to 0$ the path integral

$$Z_\lambda(T) = \int \mathscr{D}x^a \mathscr{D}\psi^a \, \exp\left(i \int_0^T dt \left[\vartheta_a \dot{x}^a - H(x^a) + \frac{1}{2} \psi^a \omega_{ab} \psi^b + \lambda d_S \Psi \right] \right) \tag{5}$$

reduces to (2) and $\lambda \to \infty$ gives localization.

To construct a gauge fermion Ψ we need a metric g in the phase space. The loop space Lie derivative condition (4) is satisfied if the metric g in Γ is invariant under the Hamiltonian action of H

$$\mathscr{L}_H g = 0, \tag{6}$$

which means that χ_H is a Killing vector field. This is a very restrictive condition for the Hamiltonian: it must generate a global U(1)-action in Γ. We can choose any metric which satisfies the condition (6) and average it over the group action.

We will consider the following selections for the gauge fermion:

$$\Psi_1 = \tfrac{1}{2} g_{ab} \dot{x}^a \psi^b$$

gives localization to the constant modes, which are points of the manifold;

$$\Psi_2 = \tfrac{1}{2} g_{ab} \chi_H^a \psi^b$$

to the zeroes of χ_H, which we assume to be nondegenerate and isolated; and

$$\Psi_3 = \tfrac{1}{2} g_{ab} \chi_S^a \psi^b$$

to the classical trajectories. For simplicity we use subscripts 1,2,3 in the actions and partition functions corresponding to the gauge fermions $\Psi_{1,2,3}$. The actions become

$$S_1 = \int_0^T dt \left[\left(\vartheta_a - \frac{\lambda}{2} g_{ab} \chi_H^b \right) \dot{x}^a - H + \frac{\lambda}{2} g_{ab} \dot{x}^a \dot{x}^b + \frac{\lambda}{2} \psi^a (g_{ab} \partial_t + \dot{x}^c g_{bd} \Gamma^d_{ac}) \psi^b + \frac{1}{2} \psi^a \omega_{ab} \psi^b \right],$$

$$S_2 = \int_0^T dt \left[\vartheta_a \dot{x}^a - H + \frac{\lambda}{2} g_{ab} \chi_H^a (\dot{x}^b - \chi_H^b) + \frac{\lambda}{2} \psi^a \partial_a (g_{cb} \chi_H^c) \psi^b + \frac{1}{2} \psi^a \omega_{ab} \psi^b \right],$$

$$S_3 = \int_0^T dt \left[\vartheta_a \dot{x}^a - H + \frac{\lambda}{2} g_{ab} \chi_S^a \chi_S^b + \frac{\lambda}{2} \psi^a \partial_a (g_{cb} \chi_S^c) \psi^b + \frac{1}{2} \psi^a \omega_{ab} \psi^b \right]. \tag{7}$$

To take the limit $\lambda \to \infty$ in path integrals we make the decomposition to constant modes x_0^a, ψ_0^a and to nonconstant modes x_t^a, ψ_t^a and scale the nonconstant modes by $1/\sqrt{\lambda}$:

$$x^a(t) = \psi_0^a + \frac{1}{\sqrt{\lambda}} x_t^a, \quad \psi^a(t) = \psi_0^a + \frac{1}{\sqrt{\lambda}} \psi_t^a. \tag{8}$$

The Jacobi determinant is unity. An expansion to a quadratic order around the constant modes and the limit $\lambda \to \infty$ gives a Gaussian path integral

$$Z_1 = \int dx_0^a d\psi_0^a \exp\left[-iT \left(H - \frac{1}{2} \psi_0^a \omega_{ab} \psi_0^b \right) \right] Z_{\mathrm{fl},1}(T), \tag{9}$$

where the fluctuation path integral $Z_{\mathrm{fl}}(T)$ is a product of fermionic and bosonic parts:

$$\begin{aligned} Z_{F,1} &= \int \prod_t d\psi_t^a \exp\left\{ -\frac{i}{2} \int_0^T dt \ \psi_t^a g_{ab} \partial_t \psi_t^b \right\}, \\ Z_{B,1} &= \int \prod_t dx_t^a \exp\left\{ \frac{i}{2} \int_0^T dt \ x_t^a [\mathscr{R}_{ab} \partial_t - g_{ab} \partial_t^2] x_t^b \right\}. \end{aligned} \tag{10}$$

Here

$$\mathscr{R}_{ab} = R_{ab} + \tilde{\Omega}_{ab}$$

is the equivariant curvature with R_{ab} the Riemannian curvature two-form and

$$\tilde{\Omega}_{ab}=\tfrac{1}{2}[\nabla_b(g_{ac}\chi_H^c)-\nabla_a(g_{bc}\chi_H^c)]$$

the momentum map[5] corresponding to χ_H, ∇ being the covariant derivative. Here H, ω, g and $\mathscr{R}$ are evaluated at the constant modes. The path integral Z_2 is given by a sum over the critical points $\{x_i\}$ of the Hamiltonian:

$$Z_2=\sum_{x_i}\frac{\exp[-iTH]}{\mathrm{Pf}\|\partial_a\chi_H^b\|}Z_{\mathrm{fl},2}(T). \tag{11}$$

Here $Z_{\mathrm{fl},2}$ is also a product of fermionic and bosonic parts:

$$Z_{F,2}(T)=\int\prod_t d\psi_t^a\,\exp\left\{\frac{i}{2}\int_0^T dt\;\psi_t^a\partial_a(g_{bc}\chi_H^c)\psi_t^b\right\},$$

$$Z_{B,2}(T)=\int\prod_t dx_t^a\,\exp\left\{\frac{i}{2}\int_0^T dt\;x_t^a\partial_a(g_{bc}\chi_H^c)(\delta_d^b\partial_t-\partial_d\chi_H^b)x_t^d\right\}. \tag{12}$$

Here g and χ_H are again evaluated at the constant modes. Finally, the path integral Z_3 reduces to a sum over the T-periodic classical trajectories

$$Z_3=\sum_{x_{cl}}\frac{1}{Pf\|\delta_b^a\partial_t-\partial_b\chi_H^a\|}\exp[iS_{cl}]. \tag{13}$$

In practice, it is usually a highly nontrivial problem to find the T-periodic classical trajectories of a dynamical system.[6]

III. REGULARIZATION OF FLUCTUATION PATH INTEGRALS

In the following all the path integrals and determinants are evaluated over periodic configurations for both the bosonic and fermionic degrees of freedom. The primes will denote that we exclude the constant modes. In real polarization the fluctuation parts in $Z_{1,2}$ become

$$Z_{\mathrm{fl},1}=\frac{1}{\sqrt{\mathrm{Det}'\|\delta_b^a\partial_t-\mathscr{R}_b^a\|}},\quad Z_{\mathrm{fl},2}=\frac{1}{\sqrt{\mathrm{Det}'\|\delta_b^a\partial_t-\partial_b\chi_H^a\|}}. \tag{14}$$

It is quite important to notice that in the reduced determinants one index is covariant and another contravariant.

In Kähler polarization the fluctuations parts are, using the additional symmetries of the metric and the Riemann curvature tensor,[7]

$$Z_{\mathrm{fl},1}=\frac{1}{\mathrm{Det}'\|\delta_a^b\partial_t-\mathscr{R}_a^b\|},\quad Z_{\mathrm{fl},2}=\frac{1}{\mathrm{Det}'\|\delta_a^b\partial_t-\partial_a\chi_H^b\|}. \tag{15}$$

These determinants are taken over the holomorphic indices. By this we mean the following: The relevant matrices can be block diagonalized

$$A=\mathrm{diag}(A_1,A_2,\ldots,A_N)$$

with blocks

$$A_k=\begin{pmatrix}a_k^+ & 0\\ 0 & a_k^-\end{pmatrix}\equiv\begin{pmatrix}a_k & 0\\ 0 & -a_k\end{pmatrix}.$$

The symbols a_k^+ and a_k^- denote the holomorphic and antiholomorphic eigenvalues of A, and we consider only the eigenvalues corresponding to the holomorphic indices to the determinant.

We have to choose a regularization scheme for the determinants. A standard method is to apply ζ- and η-functions. The ζ-function regularization does not directly apply to first-order operators because they have an infinite number of negative eigenvalues. To take them into account we define the η-function for the first-order operator B by

$$\eta_B(s)=\sum_{b_n\neq 0}\operatorname{sign}(b_n)|b_n|^{-s}+\dim\operatorname{Ker} B=\frac{1}{\Gamma((s+1)/s)}\int_0^\infty dt\ t^{(s-1)/2}\operatorname{Tr}[B\ \exp(-tB^2)].$$

Analytical continuation to $s=0$ gives the Atiyah–Patodi–Singer η-invariant[8] of B that measures the spectral asymmetry of B and specifies the phase of $\mathrm{Det}(B)$. The absolute value $|\mathrm{Det}(B)|$ is regularized using the formula

$$|\mathrm{Det}(B)|=+\sqrt{\mathrm{Det}(B^2)}=+\exp\left[-\frac{1}{2}\,\zeta'_{B^2}(0)\right].$$

In real polarization we have to evaluate the square root of a determinant of the antisymmetric operator $B=\partial_t-A$ where A is an antisymmetric matrix. In our case A is $\|\mathscr{P}_a^b\|$ or $\|\partial_a\chi_H^b\|$. By determining the spectrum of B and applying ζ-function regularization we obtain, up to an inessential numerical normalization, the result

$$\frac{1}{\sqrt{\mathrm{Det}'(\partial_t-A)}}=\prod_{n=1}^{N}\left|\frac{a_n/2}{\sin(a_nT/2)}\right|=\frac{1}{T^N}\,\hat{A}(TA), \tag{16}$$

where we have defined the function of the matrix X

$$\hat{A}(X)=\prod_n\ \frac{x_n/2}{\sin(x_n/2)},$$

where x_n are the skew-eigenvalues of X. The result is non-negative since the negative and positive skew-eigenvalues appear in pairs. Therefore there is no ambiguity with the spectral asymmetry.

Now we consider the determinants in Kähler polarization. It is sufficient to consider the determinant of a block. Earlier we noticed that the fluctuation path integrals reduce to the determinant of the operator $B=i\partial_t-a$. The functional Pfaffian in (13) is also similar to this determinant. To regularize

$$\mathrm{Det}'(B)=\prod_{n\neq 0}\left(\frac{2\pi n}{T}-a\right)$$

properly we have to take into account that B has an infinite number of negative eigenvalues. Thus there is a problem with the spectral asymmetry.

Therefore, we have to choose a regularization prescription which has a relation to quantum mechanical anomalies. In the regularization of the determinants it is not possible to maintain all the symmetries that are present in the classical theory. For example, Elitzur *et al.*[9] considered the corresponding fermionic problem with antiperiodic boundary conditions. They evaluated the quantum mechanical partition function for a Dirac fermion in an external gauge field $A(t)$ in $0+1$-dimensions,

$$Z(T)=\int \mathscr{D}\overline{\psi}\mathscr{D}\psi\ \exp\left[i\int_0^T dt\ \overline{\psi}(i\partial_t-a)\psi\right]=\mathrm{Det}(i\partial_t-a), \tag{17}$$

where, because of the gauge invariance of the action, only the constant mode a of $A(t)$ contributes. The classical action has both the invariance under large gauge transformations

$$a\to a+n2\pi/T,\quad \psi\to\psi, \tag{18}$$

and the charge conjugation invariance

$$a\leftrightarrow -a,\quad \psi\leftrightarrow -\overline{\psi}. \tag{19}$$

However, when regularizing the determinant one has to choose which symmetry one wants to maintain, which leads to a global anomaly. Here we have an analogous situation. It is not *a priori* clear what the result of the regularization should be, and there is a genuine ambiguity.

Since the zeroes of the determinant are at $aT=2\pi n$, the determinant must be proportional to

$$\frac{\sin(aT/2)}{a/2}.$$

The proportionality factor can be any function without zeroes, that is, the exponent function. The determinant is, therefore, up to an irrelevant constant,

$$\mathrm{Det}(i\partial_t-a)=\frac{\sin(aT/2)}{a/2}\exp(i\phi aT),$$

with a phase ϕ whose natural values turn out to be 0 and $\pm\frac{1}{2}$ since they yield the (anti)symmetries of the product under $a\leftrightarrow -a$ and $a\to a+2\pi n/T$. However, there is a minor subtlety: in our localization formulas the zero modes are absent and this destroys these symmetries. Nevertheless, we may still consider the residual symmetries. The choice $\phi=0$ corresponds to neglecting the spectral asymmetry and choosing the (anti)symmetry $a\to -a$ to be unbroken. In this regularization scheme the inverse determinant is simply

$$\frac{1}{\mathrm{Det}'(\partial_t-A)}=\frac{1}{T^N}\hat{A}(TA).$$

This is the result that usually appears in literature. However, there is another possibility. The values $\phi=\pm\frac{1}{2}$ correspond to maintaining the symmetry $a\to a+2\pi n/T$ and taking into account the spectral asymmetry by the Atiyah–Patodi–Singer η-invariant. This yields

$$\frac{1}{\mathrm{Det}'(\partial_t-A)}=\prod_{n=1}^{N}\frac{a_n/2}{\sin(a_nT/2)}\exp\left(\frac{ia_nT}{2}\right)=\frac{1}{T^N}\,\mathrm{Td}(TA), \tag{20}$$

where we have defined the following function of the matrix X:

$$\mathrm{Td}(X)=\prod_n\frac{x_n/2}{\sin(x_n/2)}\,e^{ix_n/2}.$$

We take only the eigenvalues corresponding to the holomorphic indices to the determinant.

Let us now write down the resulting localization formulas. The localization to constant modes yields the expression

$$Z_1(T)=\frac{1}{T^N}\int dx_0^a d\psi_0^a \ \mathrm{Ch}[-iT(H-\omega)]\begin{Bmatrix}\hat{A}(T\mathscr{R})\\ \mathrm{Td}(T\mathscr{R})\end{Bmatrix}. \tag{21}$$

We have defined equivariant generalizations[10] of the conventional characteristic classes known as equivariant $\hat{A}$ and Todd genus, and identified the exponential with the equivariant Chern class. When $H=0$ they reduce to the conventional characteristic classes and the result is a topological invariant. The localization to the critical points $\{x_i\}$ of the Hamiltonian gives the result

$$Z_2(T)=\frac{1}{T^N}\sum_{x_i}\ \frac{\exp(-iTH)}{\mathrm{Pf}(\partial\chi_H)}\begin{Bmatrix}\hat{A}(T\partial\chi_H)\\ \mathrm{Td}(T\partial\chi_H)\end{Bmatrix}. \tag{22}$$

We must use local coordinates in the evaluation of the determinants when localizing to the critical points of the Hamiltonian. Finally, the localization to T-periodic classical trajectories yields

$$Z^3(T)=\frac{1}{T^N}\sum_{x_{\mathrm{cl}}}\ \exp(iS_{\mathrm{cl}})\begin{Bmatrix}\hat{A}(T\partial\chi_H)\\ \mathrm{Td}(T\partial\chi_H)\end{Bmatrix}. \tag{23}$$

IV. HARMONIC OSCILLATOR

Now we show that the localization formulas yield the correct partition function for the harmonic oscillator in a flat phase space. The path integral for it is Gaussian and in principle there is no reason to apply localization to it. However, it is reasonable to check by some simple examples that our assumptions and derivations are valid. In particular, we will show that the choice of the metric in the phase space is not relevant, contrary to claims in literature.[11] It is also illustrative to consider the significance of the regularization schemes we have used.

In real polarization the Hamiltonian is $H=\frac{1}{2}(p^2+q^2)$ and the symplectic two-form is $dq\wedge dp$. The coherent state representation (Kähler polarization) requires some further investigation, since we have to fix an operator ordering prescription. In terms of creation and annihilation operators the normal and symmetric-ordered Hamiltonians are, respectively,

$$H_n=:\tfrac{1}{2}(a^\dagger a+aa^\dagger):=a^\dagger a,\quad H_s=a^\dagger a+\tfrac{1}{2}. \tag{24}$$

The symmetric-ordered Hamiltonian has an explicit zero point energy $E_0=\frac{1}{2}$.

To apply the localization formulas we must choose a metric in the phase space and calculate the equivariant curvature and the derivatives of the Hamiltonian vector field. If the Lie derivative condition $\mathscr{L}_H g=0$ is satisfied, we can start from an any smooth metric in the phase space and average it. So we may choose a constant metric

$$g=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}.$$

The nonzero components of the equivariant curvature are

$$\mathscr{R}^p_q=-\mathscr{R}^q_p=1.$$

The localization formula (21) yields the result

$$Z(T)=\int dpdqd\psi^q d\psi^p \exp\left[-iT\left(\frac{1}{2}p^2+\frac{1}{2}q^2-\psi^p\psi^q\right)\right]\frac{1}{2\sin(T/2)}$$
$$\sim\frac{1}{2\sin(T/2)}$$
$$=\sum_{n=0}^{\infty}\exp[i(n+1/2)T], \tag{25}$$

which is the correct partition function with the zero-point energy $E_0=\frac{1}{2}$.

Let us now digress slightly to discuss the result. In Ref. 11 Dykstra, Lykken, and Reiten analyzed this problem and they noticed a dependence on the metric. What they did not notice was that the index structure of the equivariant curvature is $\mathscr{R}_a^b$ and, therefore, it is invariant under global scalings of the metric. Furthermore, they used a metric which in polar coordinates near the origin behaves like

$$ds^2=dr^2+cr^2\,d\phi^2.$$

This is a metric on a cone, not on a plane when $c\neq 1$ and is not smooth, nor even continuous at the origin. Therefore it is not surprising that their energy levels depend on the parameter c, which represents the tip angle of the cone. From this we see that we cannot choose an arbitrary invariant metric, since it has to respect the topology of the phase space.

The localization to the critical points of the Hamiltonian (22) yields also the correct result. The only zero of χ_H is the origin of the phase space, which gives

$$Z(T)=\frac{1}{\mathrm{Pf}\begin{pmatrix}0&1\\-1&0\end{pmatrix}}\frac{1/2}{\sin(T/2)}=\frac{1}{2\sin(T/2)}.$$

If we want to apply the localization the classical trajectories, we must classify all the T-periodic classical trajectories. If $T\neq 2\pi n$, the problem reduces to the localization to the critical points of the Hamiltonian. However, if $T=2\pi n$, the zeroes of χ_S are not isolated and we have to use a degenerate version of the localization formula to the classical trajectories.[12]

We now consider the harmonic oscillator in the Kähler polarization. We will only discuss the localization formulas to constant modes. The reasoning is similar to other formulas. There are four cases to consider: the localizations with the $\hat{A}$ genus and Todd genus using two different orderings. We will only list the spectra we obtain. The use of $\hat{A}$ genus yields the spectra $E_n=n+\frac{1}{2}$ (normal ordering) and $E_n=n+1$ (symmetric ordering). The Todd genus gives the results $E_n=n$ (normal ordering) and $E_n=n+\frac{1}{2}$ (symmetric ordering). The first and fourth results have the correct zero-point energy. From this example we see that to get correct results from the path integral we do need some additional information other than the classical action and boundary conditions: we must choose a regularization scheme that gives physically correct results.

V. CHARACTER FOR SU(2)

We shall now use our localization formulas to derive the Kirillov and Weyl character formulas for Lie groups.[10] The character formula for SU(2) has been widely discussed in literature.[13–15] However, there has been some controversy about the Weyl shift problem: the path integral usually gives almost the correct character up to the substitution $j\to j+\frac{1}{2}$. We show that the coherent state path integral and the localization formulas with the Todd genus directly yield the correct character. In this calculation we use the continuum version of the coherent state path integral and show that this also yields the correct result, contrary to discussions in literature.[16]

To motivate the use of Todd genus we relate the character of a simple Lie group G in the highest weight representation λ to the index of the twisted Dolbeault complex on the coadjoint orbit O_f (Ref. 17) of the group. The Borel–Weil theory[14,18] constructs the irreducible representations of G as holomorphic sections of a line bundle L that is associated to a principal bundle $G \to G/T_G \sim O_f$, where T_G is the Cartan torus of G.[18] The holomorphic sections of this line bundle (coherent states) form the basis for the irreducible representation. The connection one-form on L is the symplectic potential

$$\vartheta = \frac{\partial F}{\partial z^k}\, dz^k - \frac{\partial F}{\partial \overline{z^k}} d\overline{z^k},$$

where F is the Kähler potential on O_f. It can be shown that the twisted Dolbeault operator $\overline{\partial_L} = \partial + \vartheta_{\overline{z}}$ annihilates the normalized coherent states $|z\rangle$ and therefore $|z\rangle \in H^{0,0}(O_f, L)$. If we can prove that all the other cohomology groups are trivial, e.g., by Lichnerowicz vanishing theorem,[10] we conclude that the dimension of the highest weight representation R_λ is $\dim H^{0,0}(O_f, L)$. Consequently, this is equal to the index of the twisted Dolbeault complex. The Riemann–Roch–Hirzebruch index theorem relates this analytical index to the topological invariant

$$\text{ind}\ \overline{\partial_L} = \dim\ R_\lambda = \int_{O_f} \text{Td}(O_f) \wedge \text{Ch}(L). \tag{26}$$

Indeed, we notice that the localization formula (21) with $H=0$ represents this index provided we use the Todd class. For SU(2) we obtain the known result for the dimension of the spin-j-representation

$$\dim\ R_j = \text{ind}\ \overline{\partial_L} = 2j+1.$$

This is the correct result without the explicit Weyl shift by the Weyl vector $\rho = \frac{1}{2}$.

We shall now use an equivariant version of the index theorem to derive the character formulas. The character of an element in the Cartan subalgebra is the partition function for the Hamiltonian H that represents it on O_f:

$$\chi(\beta) = \text{Str}\ \exp[-iTH]. \tag{27}$$

To make a relation to the Dolbeault index we write this as an equivariant index (character index, G-index, Lefschetz number).[10] One can show that the Laplacians $\overline{\partial_L^\dagger \partial_L}$ and $\overline{\partial_L \partial_L^\dagger}$ have equal nonzero eigenvalues. If all other comohomology classes except $H^{0,0}$ are trivial, as we presume, $\overline{\partial_L^\dagger}$ does not have zero modes. Consequently, we can write the trace as an equivariant index:

$$\begin{aligned} \text{ind}_H(\overline{\partial_L}, T) &\equiv \lim_{\beta\to\infty}\ \text{Tr}\ e^{-iTH}(e^{-\beta \overline{\partial_L^\dagger \partial_L}} - e^{-\beta \overline{\partial_L \partial_L^\dagger}}) \\ &= \lim_{\beta\to\infty}\ \text{Str}\ \exp[-iTH] \exp\left[-\beta \begin{pmatrix} \overline{\partial_L^\dagger \partial_L} & 0 \\ 0 & \overline{\partial_L \partial_L^\dagger} \end{pmatrix}\right]. \end{aligned} \tag{28}$$

Only the zero modes contribute to the trace. The expression is also independent of β. Therefore, in the limit $\beta \to 0$, all we are left with are the zero modes of ∂_L. Consequently, the equivariant index is equal to the character

$$\text{ind}_H(\overline{\partial_L}, T) = \text{Str}\ \exp[-iTH].$$

Thus, the character is the equivariant index of the twisted Dolbeault complex and therefore we choose the localization with the Todd class.

To derive the character formulas we apply standard methods to write $\mathrm{Str}\exp[-iTH]$ as a coherent state path integral of the form (2). Since we can choose an invariant metric on a coadjoint orbit[17] we can localize the path integral to classical trajectories, to constant modes, or to critical points of the Hamiltonian. The two latter cases yield the Kirillov character formula[19] ($2N$ is the dimension of the orbit)

$$\chi(T)=\frac{1}{T^N}\int_{O_f}\mathrm{Ch}[-iT(H-\omega)]\mathrm{Td}(T\mathscr{R}^+), \tag{29}$$

and the Weyl character formula

$$\chi(T)=\frac{1}{T^N}\sum_{z_i}\frac{\exp(-iTH)}{\det{}^+(\partial\chi_H)}\,\mathrm{Td}(T\partial\chi_H), \tag{30}$$

respectively. In (30) we have identified the Pfaffian in the real polarization with the determinant over the holomorphic eigenvalues of $\|\partial_a\chi_H^b\|$ and the summation is over the critical points of the Hamiltonian or equivalently the Weyl group.

As the only example we evaluate the character for SU(2). We write the character as a coherent state path integral over the coadjoint orbit $\mathrm{SU}(2)/U(1)\sim S^2$. We choose complex coordinates by introducing the stereographic projection from the south pole. The Kähler potential on the orbit with radius j is $F=j\log(1+z\bar{z})$ from which we obtain the metric and the symplectic one- and two-forms in the standard fashion. The integrability condition requires j to be a multiple of $\frac{1}{2}$: this is the topological quantization of spin. The canonical realization for $H=J_3$ is

$$J_3=-j\,\frac{1-z\bar{z}}{1+z\bar{z}}$$

and the path integral for the character becomes (2),

$$\chi_j(T)=\int\mathscr{D}z\mathscr{D}\bar{z}\mathscr{D}\psi\mathscr{D}\bar{\psi}\exp\left[ij\int_0^T dt\left(i\,\frac{\dot{z}\bar{z}-z\dot{\bar{z}}}{1+z\bar{z}}+\frac{1-z\bar{z}}{1+z\bar{z}}+\frac{2i\psi\bar{\psi}}{(1+z\bar{z})^2}\right)\right], \tag{31}$$

with periodic boundary conditions. The Lie derivative condition (6) is satisfied for $H=J_3$. This path integral is given exactly by the WKB approximation.[2,16] The relevant quantities in the Kirillov formula (29) are

$$H-\omega=j\,\frac{1-z\bar{z}-\psi\bar{\psi}}{1+z\bar{z}+\psi\bar{\psi}},\quad \mathscr{R}^+=R^++\Omega^+=\frac{1-z\bar{z}-\psi\bar{\psi}}{1+z\bar{z}+\psi\bar{\psi}}. \tag{32}$$

Now one can use the Parisi–Sourlas integration formula

$$\int dzd\bar{z}d\psi d\bar{\psi}F(z\bar{z}+\psi\bar{\psi})=\pi[F(\infty)-F(0)],$$

which gives

$$\chi_j(T)=\frac{\sin(j+1/2)T}{\sin(T/2)}=\sum_{m=-j}^{j}\exp[imT]. \tag{33}$$

This is exactly the correct result without an explicit Weyl shift. Also the Weyl formula (30) gives the correct result when we use local coordinate charts in the vicinity of the critical points. To get the correct north pole contribution we invert the coordinates $z \to 1/z$, $\overline{z} \to 1/\overline{z}$. This also yields the correct character (33):

$$\begin{aligned}\chi_j(T) &= \frac{\exp[-ijT]}{2\sin(T/2)}\exp[-iT/2] + \frac{\exp[-ijT(-1)]}{2\sin(-T/2)}\exp[iT/2] \\ &= \frac{\sin(j+1/2)T}{\sin(T/2)} \\ &= \sum_{m=-j}^{j} \exp[imT].\end{aligned}$$

On the other hand, using $\hat{A}$ genus we obtain the result

$$\chi_j(T) = \frac{\sin(jT)}{\sin(T/2)},$$

which is the correct result up to the Weyl shift $j \to j+1/2$. So we see that in the character formulas we have to use the Todd genus instead of $\hat{A}$ genus to directly get the correct result.

VI. CONCLUSIONS

We have considered phase space path integrals with the property that the Hamiltonian generates an isometry of the phase space. Using equivariant cohomology in the loop space we were able to reduce the path integrals to finite-dimensional integrals and sums. We also noticed that the results were not uniquely defined because of spectral asymmetry. The choice of regularization yielded equivariant $\hat{A}$ and Todd classes.

We applied localization to the harmonic oscillator and to the quantization of coadjoint orbits. We showed that localization produces correct results for these systems. In addition, we derived Kirillov and Weyl character formulas that produce correct characters for Lie groups without the Weyl shift. We demonstrated this explicitly by evaluating the character for SU(2). The explanation for the Weyl shift was the same as in the case of the Coxeter shift[20] in Chern–Simons theory, the η-invariant.

It would be interesting to apply our formalism to more complicated systems such as loop groups and field theories. Also, it seems possible to use localization and equivariant cohomology to study quantum integrability, generic supersymmetric theories, and problems in classical mechanics, as well.

One dimensional periodic Dirac Hamiltonians: Semiclassical and high-energy asymptotics for gaps

Gheorghe Nenciu and Radu Purice
Institute of Mathematics of the Romanian Academy, P.O. Box 1-764, RO-70700, Bucharest, Romania

(Received 1 June 1994; accepted for publication 30 November 1995)

In this article we consider a one-dimensional Dirac operator with a potential of Gevrey class α and study the semiclassical and high-energy asymptotics of the spectral gaps for a region of energies that in the Schrödinger case corresponds to unbounded motion. An exponential upper bound for the gap's widths as well as the asymptotic expansion of their positions are derived for both cases; the first two terms in the asymptotic expansions are explicitly written down for the scalar potential case. © *1996 American Institute of Physics.* [S0022-2488(96)02406-1]

I. INTRODUCTION

The asymptotics of the spectral gaps of the one-dimensional Schrödinger operators with periodic potentials, for both high-energy and semiclassical limits, is fairly well understood (for polynomial bounds on the error one can see Ref. 1, while for exponential bounds one can see Ref. 2, for an inverse scattering method, or Ref. 3 and references therein for WKB-type methods). The extension of this kind of results to more general systems of ordinary differential equations is far from being straightforward. In this paper we consider the problem of the high-energy asymptotics and of the semiclassical behavior of the spectral gaps for a general one-dimensional Dirac Hamiltonian with a periodic potential, as given by the formula (1). The class of potentials that we cover contains the Gevrey classes of any order α (in particular for $\alpha=1$ we recover the analytic case that is the one usually considered).

The method that we propose starts from the results in Ref. 4 about adiabatic expansions, that up to the end lead to a ''quantization rule'' precise enough to provide both the asymptotic expansion of the position of the spectral gaps, as well as the exponential decrease of their widths. Analogous results for the Schrödinger operator were written down, by using the same method, in the (partly unpublished) notes.[4] Let us notice that some of the results (e.g., the asymptotic expansion of the position of the gaps) seem to be new, even in the Schrödinger case (see, however, Ref. 1 for related results). Let us also point that the method we use allows us to extend some of the results below to more general systems of ordinary differential equations, e.g. to the linear Hamiltonian systems considered in Ref. 5. Our reason to restrict ourselves to the Dirac case were on the one hand to keep the length of the note to a reasonable level and on the other hand the fact the one-dimensional Dirac operator, apart from describing the physical three-dimensional situation when the periodic potential is actually constant along two spatial directions, appears also in other contexts. As an example, the so-called AKNS operator (recently studied in Ref. 6 by the inverse scattering method), which appeared[7,8] in connection with the ''generalized Fourier transform'' for nonlinear differential equations, is equivalent to a particular case of the Dirac Hamiltonian that we consider.

II. THE PROBLEM AND THE MAIN RESULTS

The one-dimensional Dirac Hamiltonian acting on $L^2(\mathbf{R};\mathbf{C}^2)$, has the following form:

$$H_{\mathrm{D}}(\hbar):=-i\hbar\sigma_1\partial+m\sigma_3+\mathbf{V}(s), \tag{1}$$

0022-2488/96/37(7)/3153/15/$10.00
J. Math. Phys. **37** (7), July 1996

where ∂ is the operator of derivation with respect to s on $\mathbf{R}$, $m \in \mathbf{R}_+$, σ_j for $j=1,2,3$ are the Pauli matrices:

$$\sigma_1=\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}; \quad \sigma_2=\begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}; \quad \sigma_3=\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},$$

and $\mathbf{V}(s)$ is a 2×2 Hermitian matrix-valued function. We assume that $\mathbf{V}(s)$ is C^∞ and periodic with period T:

$$\mathbf{V}(s+T)=\mathbf{V}(s). \tag{2}$$

Since the Pauli matrices are Hermitian and together with $\sigma_0=1$ they form a basis for the 2×2 Hermitian matrices one has

$$\mathbf{V}(s)=\sum_{j=0}^{3} V_j(s)\sigma_j, \tag{3}$$

where V_j are real C^∞ functions of period T. By Floquet theory one can show[9] that the spectrum $\sigma_{\mathrm{D}}(\hbar)$ of $H_{\mathrm{D}}(\hbar)$ has a ''band structure,'' a point $E \in \mathbf{R}$ being in $\sigma_{\mathrm{D}}(\hbar)$ if and only if the equation

$$H_{\mathrm{D}}(\hbar)f=Ef \tag{4}$$

admits a solution f that is uniformly bounded on $\mathbf{R}$. Multiplied by σ_1, (4) takes the form

$$i\hbar\ \partial f(s)=H_E(s)f(s); \quad H_E(s)=-im\sigma_2+\sigma_1\mathbf{V}(s)-E\sigma_1, \tag{5}$$

which is a linear ''evolution'' equation in $\mathbf{C}^2$, with a ''time'' dependent non-Hermitian generator $H_E(s)$. By the above discussion, if the ''motion'' generated by $H_E(s)$ is stable, then $E \in \sigma_{\mathrm{D}}(\hbar)$. We are thus led to study the stability of the ''motion'' generated by $H_E(s)$. For our method to work we need that

$$\sup_{s\in\mathbf{R}}\ \sup_{t\in\mathbf{R}} \|e^{itH_E(s)}\|<\infty. \tag{6}$$

Let

$$\lambda_{\pm}(s,E):=V_1(s)\pm\{(V_0(s)-E)^2-(m+V_3(s))^2-V_2(s)^2\}^{1/2} \tag{7}$$

be the eigenvalues of $H_E(s)$. Then (6) holds true for all $E \in \Sigma_d$, where

$$\Sigma_d:=\{E\in\mathbf{R}|\ \inf_{s\in\mathbf{R}}\{(V_0(s)-E)^2-(m+V_3(s))^2-V_2(s)^2\}\geqslant d\}, \tag{8}$$

where d is a strictly positive constant, since in this case $\lambda_{\pm}(s,E)$ are real and distinct.

In what follows we assume that $\mathbf{V}(s)$ belongs to the Gevrey class of order $\alpha\geqslant 1$. More exactly, we suppose the following.

Hypothesis V_α: There exist $M<\infty$ and $\alpha\geqslant 1$, such that

$$\sup_{s\in[0,T]} |\partial^k V_j(s)|\leqslant M^k(k!)^\alpha.$$

Remarks:

1. Since the functions V_j are bounded: $\Sigma_d\supset\mathbf{R}\backslash[-A,A]$ for sufficiently large A.

2. In the scalar case (8) reduces to

$$\Sigma_d=\{E\in\mathbf{R}|\ \inf_{s\in\mathbf{R}}\{(V_0(s)-E)^2-m^2\}\geqslant d\}.$$

Our results are summarized in the following.

Theorem: Suppose $\mathbf{V}(s)$ satisfies (2) and the hypothesis V_α. Let $\rho_{\mathrm{D}}(\hbar)$ be the resolvent set of $H_{\mathrm{D}}(\hbar)$.

A. (Semiclassical limit): There exists $\hbar_0>0$ depending upon M and d, such that for all $\hbar\in(0,\hbar_0]$ and all $E\in\Sigma_d$ there exist two real functions $\phi_\pm(s,\hbar,E)$, such that the following occurs.

(i) $\phi_\pm(s,\hbar,E)$ have asymptotic expansions in $\hbar$:

$$\phi_\pm(s,\hbar,E)\sim\hbar^{-1}\lambda_\pm(s,E)+\sum_{k=0}^{\infty}\hbar^k\phi_{\pm,k}(s,E).$$

More precisely, for any $n\in\mathbf{N}$ there exists $\hbar_n\in(0,\hbar_0]$ and a positive constant $C_{n,\hbar_n}$, depending only on n and $\hbar_n$ and such that for any $s\in[0,T]$ and any $\hbar\in(0,\hbar_n]$ one has the estimation

$$\left|\phi_\pm(s,\hbar,E)-\hbar^{-1}\lambda_\pm(s,E)-\sum_{k=0}^{n}\hbar^k\phi_{\pm,k}(s,E)\right|\leqslant C_{n,\hbar_1}\hbar^{n+1}.$$

(ii) If $K\subset\Sigma_d$ is a compact set and we denote

$$I(\hbar,E):=\int_0^T\{\phi_+(s,\hbar,E)-\phi_-(s,\hbar,E)\}ds,$$

$$\mathscr{E}(K;\hbar):=\{E\in K|\exists n\in\mathbf{Z}:I(\hbar,E)=2\pi n\},$$

then there exist constants $k_1<\infty$, $k_2>0$ depending only upon M and d, such that

$$\rho_{\mathrm{D}}(\hbar)\cap K\subset\{E\in K|\exists\widetilde{E}\in\mathscr{E}(K;\hbar):|E-\widetilde{E}|\leqslant k_1\ \exp(-k_2\hbar^{-1/\alpha})\}.$$

B. (High-energy limit): For sufficiently large E_0, there exist $n_0(E_0)$ and for any $n\geqslant n_0(E_0)$ there exist E_n, such that the following occurs.

(i) E_n have asymptotic expansions in n^{-1} of the form

$$E_n\sim\frac{\pi}{T}n+\sum_{k=0}^{\infty}F_{k+1}n^{-k}.$$

(ii) There exist constants $c_1<\infty$, $c_2>0$ depending only upon M and E_0, such that

$$\rho_{\mathrm{D}}(\hbar)\cap[E_0,\infty)\subset\{E\in[E_0,\infty)|\exists n\geqslant n_0:|E-E_n|\leqslant c_1\ \exp(-c_2n^{1/\alpha})\}.$$

Remarks:

(1) If $E_n(\hbar)$ are the solutions of the equation $I(\hbar,E)=2\pi n$, it follows from the proof of the theorem that $E_n(\hbar)-E_{n-1}(\hbar)$ is of order $\hbar$. Thus, for $\hbar\to0$ the gaps may accumulate, their separation diminishing like $\hbar$, but they shrink exponentially in $\hbar$.

(2) We would like to emphasize that our theorem does not provide a lower bound for the gap's width, so that some gaps may in fact be absent. A formula for the dominant term for the gap's width is much harder to obtain and not very much is known, even for the Schrödinger case (see Refs. 1, 3, 10, and references therein).

(3) The analog of the above theorem for the Schrödinger case was given in Ref. 4.

(4) From the results known for the Schrödinger case, one expects that the spectrum of $H_D(\hbar)$ contained in $\mathbf{R}\backslash\Sigma_0$ consists of energy bands that shrink exponentially as $\hbar\to 0$. The asymptotics of the first band has been obtained recently.[11]

(5) The functions $\phi_\pm(s,\hbar,E)$ and the constants F_k are easily computable for the case of the scalar potential ($V_1=V_2=V_3=0$), and the first three terms of the asymptotic expansions given in the above theorem are

$$\phi_{+,0}(s,E)=\phi_{-,0}(s,E)=0,$$

$$\phi_{+,1}(s,E)=\phi_{-,1}(s,E)=\frac{3}{8}\,m^2(\partial V_0(s))^2\{(V_0(s)-E)^2-m^2\}^{-5/2},$$

$$F_0=\pi/T \quad F_1=\frac{1}{T}\int_0^T V_0(s)ds, \quad F_2=-\frac{1}{2\pi}\int_0^T (3V_0(s)^2-m^2)ds.$$

One observes that the terms of order zero in the series of $\phi_\pm(s,\hbar,E)$, namely $\phi_{\pm,0}(s,E)$ (that are the leading terms of the Berry's phase) are zero. This is a general feature of the real Hamiltonians.

III. PROOF OF THE THEOREM

We give a detailed proof of part A of the theorem and we indicate the changes that one has to make in order to prove part B by a similar procedure. The proof combines the technique of quasi-invariant subspaces[4] for the time-dependent evolution (5) with methods from the theory of stability of motion for linear Hamiltonian systems.[12] For the sake of completeness we give in an Appendix the main definitions and results of Ref. 4 that we need. The proof is divided in a series of steps.

(1) Consider the Hamiltonian (1). As we already said, in view of (2) the Floquet theory[9] allows one to write a direct integral decomposition of $H_D(\hbar)$ and to show that $E\in\sigma_D(\hbar)$ if and only if (4) has a uniformly bounded solution on $\mathbf{R}$. The argument can be found in Ref. 9 in a rather abstract setting that covers our case.

(2) After multiplication with σ_1 (4) becomes [see (5)]

$$i\hbar\,\partial f(s)=H_E(s)f(s).$$

This equation can be viewed as an evolution equation for a classical system with a linear complex Hamiltonian. More precisely, if on $\mathbf{C}^2$ one considers the operator $J:=\sigma_1$ that satisfies

$$J=J^*=J^{-1},$$

and its associated nondegenerate, nondefinite scalar product:

$$\langle u,v\rangle:=(u,Jv), \tag{9}$$

with $(\cdot,\cdot)$ the usual scalar product on $\mathbf{C}^2$, one can verify that

$$H_E(s)=JH_E(s)^*J=:H_E(s)^\sharp, \tag{10}$$

which means that $H_E(s)$ is J Hermitian, i.e.

$$\langle u,H_E(s)v\rangle=\langle H_E(s)u,v\rangle.$$

As a consequence, if we denote by $U_\hbar(s,s_0;E)$ the evolution associated to (5):

$$i\hbar\,\partial_s U_\hbar(s,s_0;E)=H_E(s)U_\hbar(s,s_0;E); \quad U_\hbar(s_0,s_0;E)=\mathbf{1}, \tag{11}$$

then the following relation is verified:

$$U_\hbar(s,s_0;E)^\sharp U_\hbar(s,s_0;E)=\mathbf{1},$$

but due to the fact that the product $\langle\cdot,\cdot\rangle$ is not positive definite, this relation does not imply that $\|U_\hbar(s,s_0;E)\|\leqslant 1$, and our problem is precisely to find the values of E for which we have

$$\sup_{s\in\mathbf{R}}\|U_\hbar(s,s_0;E)\|=\infty. \tag{12}$$

(3) The condition $E\in\Sigma_d$ implies that $H_E(s)$ has two distinct real eigenvalues: $\lambda_\pm(s,E)$ given by (7). This implies that

$$H_E(s)=\sum_{\tau=\pm}\lambda_\tau(s,E)P_\tau(s,E), \tag{13}$$

where $P_\tau(s,E)$ are two projections in $\mathbf{C}^2$ satisfying the relations

$$P_\tau(s,E)^\sharp=P_\tau(s,E)=P_\tau(s,E)^2;\quad \sum_{\tau=\pm}P_\tau(s,E)=\mathbf{1},$$

$$P_+(s,E)P_-(s,E)=P_-(s,E)P_+(s,E)=0. \tag{14}$$

It follows that the associated eigenvectors satisfy the estimations

$$|\langle v_\tau(s),v_\tau(s)\rangle|\geqslant k(s)\|v_\tau(s)\|^2;\quad k(s)>0,$$

which, together with the fact that one can restrict s to the compact interval $[0,\ T]$, implies the existence of a strictly positive constant $k>0$, such that

$$|\langle v_\tau(s),v_\tau(s)\rangle|\geqslant k\|v_\tau(s)\|^2,\quad \forall s\in\mathbf{R},$$

i.e., the families of subspaces $P_\tau(s,E)\mathbf{C}^2$, $\tau=\pm$, are uniformly definite for $s\in\mathbf{R}$ (in the sense of Ref. 13). Indeed, let us fix $v_\pm\neq 0$ in $P_\pm(s,E)\mathbf{C}^2$ and suppose that $\langle v_-,v_-\rangle=0$. Any $v\in\mathbf{C}^2$ can be written as $v=\alpha v_-+\beta v_+$ and then $\langle v,v_-\rangle=0$, and since the product $\langle\cdot,\cdot\rangle$ is nondegenerate it follows that $v_-=0$. More precisely, let us observe that $\Sigma_d=\Sigma_d^+\cup\Sigma_d^-$, where

$$\Sigma_d^+:=[\sup_{s\in\mathbf{R}}\{V_0(s)+((V_3(s)+m)^2+V_2(s)+d)^{1/2}\},+\infty)\subset\mathbf{R},$$

$$\Sigma_d^-:=(-\infty,\inf_{s\in\mathbf{R}}\{V_0(s)-((V_3(s)+m)^2+V_2(s)+d)^{1/2}\}]\subset\mathbf{R},$$

and by some elementary algebra one can verify that $\langle v_+,v_+\rangle$ is positive for $E\in\Sigma_d^-$ and negative for $E\in\Sigma_d^+$, while $\langle v_-,v_-\rangle$ is positive for $E\in\Sigma_d^+$ and negative for $E\in\Sigma_d^-$.

(4) In order to apply the results from Ref. 4 taking $\hbar$ as the small parameter ϵ, one has to verify the ''gap'' and ''smoothness'' assumptions (see the hypothesis $\mathscr{H}_\alpha$ of the Appendix). The gap condition is evidently verified, since for $E\in\Sigma_d$

$$|\lambda_+(s,E)-\lambda_-(s,E)|\geqslant 2\sqrt{d}. \tag{15}$$

Let us now consider the smoothness condition. The condition $\mathscr{V}_\alpha$ implies directly that the family $H_E(s)$ satisfies for E in an arbitrary compact K:

$$\sup_{s\in[0,T]}\|\partial^k H_E(s)\|\leqslant N^k(k!)^\alpha, \tag{16}$$

where N depends only on M and the compact set K. The needed condition on the resolvent,

$$R_\hbar(s,E):=(H_E(s)-z)^{-1}, \tag{17}$$

follows from (16) and the following simple fact that can be proved by a slight modification of the argument in Ref. 14.

Lemma 1: Let f be a matrix-valued function with components of class $\mathbf{C}^\infty(\mathbf{R})$, satisfying: (i) f is of Gevrey class of order α, for some $\alpha\geqslant 1$, i.e. $\exists M\in\mathbf{R}_+$, such that

$$\sup_{s\in\mathbf{R}}\|\partial^k f(s)\|\leqslant M^k(k!)^\alpha,$$

(ii) $\exists\delta>0$, such that $|\det f(s)|\geqslant\delta$ for any $s\in\mathbf{R}$.

Then f is invertible for any $s\in\mathbf{R}$ and defines a function $\tilde{f}(s):=f(s)^{-1}$ that is also of the Gevrey class of order α, i.e. $\exists\tilde{M}\in\mathbf{R}_+$, such that

$$\sup_{s\in\mathbf{R}}\|\partial^k\tilde{f}(s)\|\leqslant\tilde{M}^k(k!)^\alpha.$$

(5) Following Ref. 4, for $\hbar$ small enough, one constructs (see the Appendix) for $\tau=\pm$ the J-orthogonal projections $P_{\tau,\hbar}(s,E)$ satisfying (14) with $P_\tau(s,E)$ replaced by $P_{\tau,\hbar}(s,E)$:

$$P_{\tau,\hbar}(s,E)\sim P_\tau(s,E)+\sum_{k=1}^{\infty}E_{\tau,k}(s,E)\hbar^k \tag{18}$$

(in the sense of an asymptotic series), and also satisfying the estimation

$$\|i\hbar\ \partial P_{\tau,\hbar}(s,E)-[H_E(s),P_{\tau,\hbar}(s,E)]\|\leqslant k_1\ \exp(-k_2\hbar^{-1/\alpha}), \tag{19}$$

where k_1,k_2 depend upon M,d, and K. In particular,

$$\lim_{\hbar\to 0}\|P_{\tau,\hbar}(s,E)-P_\tau(s,E)\|=0. \tag{20}$$

Moreover, from (20) and the fact that $P_\tau(s,E)\mathbf{C}^2$ are uniformly definite, it follows that $P_{\tau,\hbar}(s,E)\mathbf{C}^2$ are also uniformly definite, i.e., there exists $\kappa>0$, such that for all $v\in\mathbf{C}^2$,

$$|\langle P_{\tau,\hbar}(s,E)v,P_{\tau,\hbar}(s,E)v\rangle|\geqslant\kappa\|P_{\tau,\hbar}(s,E)v\|^2, \tag{21}$$

and the signs are the same as for $\langle P_\tau(s,E)v,P_\tau(s,E)v\rangle$. Notice also that due to the definitions given in the Appendix, $P_{\tau,\hbar}(s,E)$ are periodic functions of s with period T.

Consider $U^A_\hbar(s,s_0;E)$ associated to $P_{\tau,\hbar}(s,E)$, as given by Proposition A.5. In particular, it satisfies the intertwining property:

$$P_{\tau,\hbar}(s,E)=U^A_\hbar(s,s_0;E)P_{\tau,\hbar}(s_0,E)U^A_\hbar(s,s_0;E)^{-1}. \tag{22}$$

In spite of the fact that the operators $U^A_\hbar(s,s_0;E)$ are not unitary (they are J unitary), the intertwining property (22) allows us to control their norms. We remark first that from (21) it follows that there exist $c_1>0,c_2<\infty$ depending only upon κ, such that

$$c_1\|v\|^2\leqslant\sum_{\tau=\pm}|\langle P_{\tau,\hbar}(s,E)v,P_{\tau,\hbar}(s,E)v\rangle|\leqslant c_2\|v\|^2. \tag{23}$$

Using this relation and the J unitarity of the evolution, we can obtain an upper bound for the adiabatic evolution. In fact, for any $u \in \mathscr{H}$,

$$\|U_\hbar^A(s,s_0;E)u\|^2 \leqslant \frac{1}{c_1}\sum_{\tau=\pm}|\langle P_{\tau,\hbar}(s,E)U_\hbar^A(s,s_0;E)u, P_{\tau,\hbar}(s,E)U_\hbar^A(s,s_0;E)u\rangle|$$

$$= \frac{1}{c_1}\sum_{\tau=\pm}|\langle P_{\tau,\hbar}(s_0,E)v, P_{\tau,\hbar}(s_0,E)v\rangle| \leqslant \frac{c_2}{c_1}\|u\|^2, \tag{24}$$

so that we get the following estimation:

$$\|U_\hbar^A(s,s_0;E)\| \leqslant (c_2/c_1)^{1/2}, \tag{25}$$

where the constant c_2/c_1 does not depend on s and s_0, but only on d. A similar argument works for the inverse $U_\hbar^A(s,s_0;E)^{-1}$ so that the evolution $\{U_\hbar^A(s,s_0;E)\}_{s\in\mathbf{R}}$ is stable for any given $E \in \Sigma_d$ (with $d>0$).

(6) We want to estimate the difference between the two evolutions:

$$\{U_\hbar^A(s,s_0;E)\}_{s\in\mathbf{R}} \quad \text{and} \quad \{U_\hbar(s,s_0;E)\}_{s\in\mathbf{R}}.$$

Let us denote by $H_\hbar^A(s,E)$ the generator of the adiabatic evolution and let

$$B_\hbar(s,E) := H_E(s) - H_\hbar^A(s,E) \tag{26}$$

be the difference of the two generators. We consider the following factorization [(A17) in the Appendix]:

$$U_\hbar(s,s_0;E) = U_\hbar^A(s,s_0;E)\Omega_\hbar(s,s_0;E). \tag{27}$$

Using the results proved in Ref. 4 and reviewed in the Appendix, for each $s \in [0,T]$ one can find two constants $k(s)<\infty$ and $k_2(s)>0$, so that if we denote

$$\delta_\hbar(s) := k(s)\exp(-k_2(s)\hbar^{-1/\alpha}), \tag{28}$$

we have the estimation

$$\|B_\hbar(s,E)\| \leqslant \delta_\hbar(s), \quad \forall s \in \mathbf{R}. \tag{29}$$

By integration we obtain the following inequality:

$$\|\Omega_\hbar(s,s_0;E)-\mathbf{1}\| \leqslant \frac{1}{\hbar}\int_{s_0}^{s}\|U_\hbar^A(u,s_0;E)\|\|U_\hbar^A(u,s_0;E)^{-1}\|\|B_\hbar(u,E)\|du + \frac{1}{\hbar}\int_{s_0}^{s}\|U_\hbar^A(u,s_0;E)\|$$

$$\times\|U_\hbar^A(u,s_0;E)^{-1}\|\|B_\hbar(u,E)\|\|\Omega_\hbar(u,s_0;E)-\mathbf{1}\|du. \tag{30}$$

At this point we may use the following form of the Gronwall Lemma.

Lemma 2: Let $s_0 \in \mathbf{R}$ be fixed and $g,h \in L^\infty([s_0,\infty))$ be some positive functions with g nondecreasing on $[s_0,\infty)$. If $f \in L^\infty([s_0,\infty))$ satisfies

$$0 \leqslant f(t) \leqslant g(t) + \int_{s_0}^{t} h(s)f(s)ds$$

for almost all $t \in [s_0,\infty)$, then

$$f(t)\leqslant g(t)\exp\left(\int_{s_0}^{t} h(s)ds\right).$$

We obtain the following estimation:

$$\|\Omega_\hbar(s,s_0;E)-\mathbf{1}\|\leqslant\frac{c}{\hbar}\left(\int_{s_0}^{s}\delta_\hbar(u)du\right)\exp\left(\frac{c}{\hbar}\int_{s_0}^{s}\delta_\hbar(u)du\right). \tag{31}$$

(7) Due to the periodicity of $\mathbf{V}(s)$, we can study the stability of the evolution $\{U_\hbar(s,s_0;E)\}_{s\in\mathbf{R}}$ by looking only at the discrete evolution generated by the monodromy matrix:

$$M_\hbar(E):=U_\hbar(T,0;E). \tag{32}$$

Let us also define the adiabatic monodromy matrix:

$$M_\hbar^A(E):=U_\hbar^A(T,0;E) \tag{33}$$

and the factorization [similar to (27)]

$$M_\hbar(E)=M_\hbar^A(E)W_\hbar(E),\quad W_\hbar(E):=\Omega_\hbar(T,0;E), \tag{34}$$

so that

$$\|M_\hbar(E)-M_\hbar^A(E)\|\leqslant\frac{c}{\hbar}\left(\int_0^T\delta_\hbar(u)du\right)\exp\left(\frac{c}{\hbar}\int_0^T\delta_\hbar(u)du\right). \tag{35}$$

Due to the properties of $k(s)$ and $k_2(s)$ given in Ref. 4 and due to the fact that the interval $[0,T]$ is compact, there exist two positive constants $c_1<\infty$ and $c_2>0$ such that

$$\int_0^T\delta_\hbar(u)du\leqslant c_1\ \exp(-c_2\hbar^{-1/\alpha}). \tag{36}$$

In conclusion,

$$\|M_\hbar(E)-M_\hbar^A(E)\|\leqslant\frac{c}{\hbar}\exp(-c_2\hbar^{-1/\alpha}). \tag{37}$$

Moreover, the adiabatic evolution being stable [step (5)], it follows that it exists a finite constant c, such that

$$\|(M_\hbar^A(E))^n\|\leqslant c,\quad \forall n\in\mathbf{N}. \tag{38}$$

Let us now explicitly compute the eigenvalues of the adiabatic monodromy matrix. We choose a basis $\{v_\tau(E)\}_{\tau=\pm}$ in $\mathbf{C}^2$, such that $v_\tau(E)\in\mathscr{R}P_\tau(0,E)$ and

$$|\langle v_\tau(E),v_\tau(E)\rangle|=1,\quad \text{for } \tau=\pm.$$

We define the smooth (C^∞), periodic $\mathbf{C}^2$-valued functions:

$$v_\tau(s;E):=U_\hbar(s,0;E)v_\tau(E), \tag{39}$$

and we remark that they verify the relations

$$|\langle v_\tau(s;E),v_\tau(s;E)\rangle|=1,\quad \langle v_+(s;E),v_-(s;E)\rangle=0, \tag{40}$$

$$v_\tau(s;E) \in \mathscr{R}P_\tau(s,E), \quad \forall s \in \mathbf{R}. \tag{41}$$

For sufficiently small $\hbar$, we define the two $\mathbf{C}^2$-valued functions:

$$w_{\tau,\hbar}(s;E) := \left|\langle v_\tau(s;E), P_{\tau,\hbar}(s,E)v_\tau(s;E)\rangle\right|^{-1/2} P_{\tau,\hbar}(s,E)v_\tau(s;E), \tag{42}$$

that are periodic in s, and for fixed s and E take values in $\mathscr{R}P_{\tau,\hbar}(s,E)$. Taking into account that $U^A_\hbar$ is an intertwining family for the set of one-dimensional projections $\{P_{\tau,\hbar}(s,E)\}_{s\in\mathbf{R}}$ and making use of the differential equation satisfied by $\{U^A_\hbar(s,0;E)\}_{s\in\mathbf{R}}$, we can see that

$$U^A_\hbar(s,0;E)w_{\tau,\hbar}(s;E) = \exp\left(-i\int_0^s \phi_\tau(u,\hbar,E)du\right) w_{\tau,\hbar}(s;E), \tag{43}$$

where we have introduced the following functions:

$$\phi_\tau(u,\hbar,E) := \pm\frac{1}{\hbar}\langle w_{\tau,\hbar}(u;E), H^A_\hbar(u,E)w_{\tau,\hbar}(u;E)\rangle \mp i\left\langle w_{\tau,\hbar}(u;E), \frac{\partial}{\partial u} w_{\tau,\hbar}(u;E)\right\rangle. \tag{44}$$

These functions are real because of the evident identity:

$$\frac{\partial}{\partial u}\langle w_{\tau,\hbar}(u;E), w_{\tau,\hbar}(u;E)\rangle = 0,$$

and they are the functions appearing in part A of our theorem of Sec. I. The periodicity with respect to s implies the following form for the adiabatic monodromy matrix:

$$M^A_\hbar(E) = \exp(-i\Phi^+_n(E))P_{+,\hbar}(0,E) + \exp(-i\Phi^-_\hbar(E))P_{-,\hbar}(0,E), \tag{45}$$

$$\Phi^\tau_\hbar(E) := \int_0^T \phi_\tau(u,\hbar,E)du. \tag{46}$$

Thus $M^A_\hbar(E)$ has the eigenvalues $\mu^A_{\tau,\hbar}(E) \equiv \exp(-i\Phi^\tau_\hbar(E))$ and is evidently stable.

Let us remark here that due to the exponential estimation for the difference

$$B_\hbar(u,E) := H_E(u) - H^A_\hbar(u,E)$$

in deriving the asymptotic expansion for $\phi_\tau(u,\hbar,E)$, one can replace $H^A_\hbar(u,E)$ by $H_E(u)$. Now the asymptotic expansion for $\phi_\tau(u,\hbar,E)$ easily follows from that of the projections $P_{\tau,\hbar}(s,E)$ (theorem A.3 in the Appendix), and one can see that the leading term is $\hbar^{-1}\lambda_\tau(u,E)$.

(8) As remarked in the first step of our proof $E \in \sigma_{\mathrm{D}}(\hbar)$ if and only if Eq. (4) has a uniformly bounded solution on $\mathbf{R}$; thus, in order that $E \in K \subset \Sigma_d$ to belong to $\rho_{\mathrm{D}}(\hbar)$, it is necessary that the discrete evolution generated by $M_\hbar(E)$ should not be stable. The results of step (7) imply that the evolution generated by $M^A_\hbar(E)$ is stable for any $E \in \Sigma_d$. Moreover, for small $\hbar$, $M_\hbar(E)$ is very close to $M^A_\hbar(E)$ in the matrix norm. Observing that both $M_\hbar(E)$ and $M^A_\hbar(E)$ are J unitary, we make use of the following result:[12]

Lemma 3: Let M be a J-unitary matrix on $\mathbf{C}^2$ (with J unitary and self-adjoint), then its eigenvalues are symmetric with respect to the unit circle in $\mathbf{C}$.

Let $\{\mu_{\tau,\hbar}(E)\}_{\tau=\pm}$ be the two eigenvalues of $M_\hbar(E)$. We know that the eigenvalues of $M^A_\hbar(E)$ belong to the unit circle and let us suppose that

$$|\mu^A_{+,\hbar}(E) - \mu^A_{-,\hbar}(E)| = \epsilon_0 > 0. \tag{47}$$

Then for $\hbar$ small enough, we have

$$|\mu^A_{\tau,\hbar}(E)-\mu_{\tau,\hbar}(E)|\leqslant\|M^A_\hbar(E)-M_\hbar(E)\|\leqslant\frac{c}{\hbar}\exp(-c_2\hbar^{-1/\alpha})<\frac{\epsilon_0}{4}. \tag{48}$$

Using now Lemma 3, we conclude that the eigenvalues $\{\mu_{\tau,\hbar}(E)\}_{\tau=\pm}$ must also belong to the unit circle, the evolution generated by $M_\hbar(E)$ thus being stable. In conclusion, if (47) is true and $\hbar$ is sufficiently small, $E\in\sigma_{\mathrm{D}}(\hbar)$. Thus, in the limit $\hbar\to 0$, the necessary condition for E to belong to $\rho_{\mathrm{D}}(\hbar)$ is

$$\mu^A_{+,\hbar}(E)=\mu^A_{-,\hbar}(E). \tag{49}$$

Taking into account (45) and (46), condition (49) is precisely the condition

$$I(\hbar,E)=2\pi n,$$

defining the set $\mathscr{E}(\mathrm{K};\hbar)$ in the statement of part A of our theorem of Sec. I.

(9) In order to obtain the upper bound for the gap's width, we observe that for a small, fixed value of $\hbar$, we have

$$|\mu^A_{\tau,\hbar}(E)-\mu_{\tau,\hbar}(E)|\leqslant\frac{c}{\hbar}\exp(-c_2\hbar^{-1/\alpha}), \tag{50}$$

so that if

$$|\mu^A_{+,\hbar}(E)-\mu^A_{-,\hbar}(E)|\geqslant 2\frac{c}{\hbar}\exp(-c_2\hbar^{-1/\alpha}), \tag{51}$$

we conclude that the eigenvalues $\{\mu_{\tau,\hbar}(E)\}_{\tau=\pm}$ have to belong to the unit circle, so that $E\in\sigma_{\mathrm{D}}(\hbar)$. Hence, an upper bound for the gap's width can be derived from the condition

$$|\exp(-i\Phi^+_\hbar(E))-\exp(-i\Phi^-_\hbar(E))|\leqslant 2\frac{c}{\hbar}\exp(-c_2\hbar^{-1/\alpha}), \tag{52}$$

or equivalently

$$\left|\sin\left\{\int_0^T(\phi_+(u,\hbar,E)-\phi_-(u,\hbar,E))du\right\}\right|\leqslant\frac{c}{\hbar}\exp(-c_2\hbar^{-1/\alpha}). \tag{53}$$

As we explain in the Appendix, for fixed $\hbar$, the functions $\phi_\tau(u,\hbar,E)$ are differentiable with respect to E, their asymptotic series are differentiable term by term, and the derivatives of these series provide asymptotic expansions for the derivatives of $\phi_\tau(u,\hbar,E)$. The leading terms of these asymptotic expansions are $\hbar^{-1}\lambda_\tau(u,E)$ that has a nonzero derivative with respect to E, as one can easily see from the definition of $\lambda_\tau(u,E)$ in formula (7). The elementary inequality $|\sin x|\leqslant|x|$, $\forall x\in\mathbf{R}$, together with relation (53) imply the following upper bound for the gap's width:

$$|E-\widetilde{E}|\leqslant c_3\exp(-c_2\hbar^{-1/\alpha}),\quad \widetilde{E}\in\mathscr{E}(K), \tag{54}$$

for $\hbar$ small enough, as claimed in part A of our theorem in Sect. I.

(10) Concerning the second part of the theorem (the high-energy asymptotic expansion), we shall briefly comment on the changes one has to make in the above proof in order to get the desired conclusion. One has to fix $\hbar=1$ so that Eq. (5) becomes

$$i\,\partial f(s)=-im\sigma_2 f(s)+\sigma_1\mathbf{V}(s)f(s)-E\sigma_1 f(s). \tag{55}$$

By dividing with E, considering E large and denoting $\epsilon := E^{-1}$, we get the evolution equation:

$$i\epsilon\,\partial f(s) = -i\epsilon m\sigma_2 f(s) + \epsilon\sigma_1 \mathbf{V}(s) f(s) - \sigma_1 f(s) \equiv H_\epsilon(s) f(s). \tag{56}$$

In Ref. 4 it is observed that the general procedure elaborated for adiabatic expansions also works in the case when the generator $\{H(s)\}_{s\in\mathbf{R}}$ depends on the small parameter ϵ, as long as the generator $\{H_\epsilon(s)\}_{s\in\mathbf{R}}$, and all the derivatives of its resolvent are uniformly bounded for ϵ in a neighborhood of zero. The Hermitian nondefinite form $\langle\cdot,\cdot\rangle$ on $\mathbf{C}^2$ remains the same and one obtains two functions $\tilde{\phi}_\pm(s;\epsilon)$ given by a formula similar to (44). Then the same type of ''quantization rule'' is obtained and also similar asymptotic expansions.

Remark: We consider the scalar case $V_1(s) = V_2(s) = V_3(s) = 0$ and compute the first three terms of the asymptotic expansions for $\phi_\tau(u,\hbar,E)$ appearing in part A of the main theorem, and for the values E_n appearing in part B of the same theorem. Let us begin with $\phi_\tau(u,\hbar,E)$ and make use of the vector functions defined in step (7). We have

$$P_{\tau,\hbar}(s,E) = P_\tau(s,E) + \hbar E_{\tau,1}(s,E) + \hbar^2 E_{\tau,2}(s,E) + R, \tag{57}$$

with $\|R\| \leqslant c\hbar^3$ and c independent of s, $\hbar$, and E, but depending on the compact set $K \subset \Sigma_d$. We can easily see that

$$P_\tau(s,E) E_{\tau,1}(s,E) P_\tau(s,E) = 0, \tag{58}$$

$$P_\tau(s,E) E_{\tau,2}(s,E) P_\tau(s,E) = -P_\tau(s,E)[E_{\tau,1}(s,E)]^2 P_\tau(s,E). \tag{59}$$

Using these relations and the explicit formula for $E_{\tau,1}(s,E)$ [see (A6)], we obtain

$$E_{+,1}(s,E) = \frac{i}{\lambda_+ - \lambda_-}\{\langle \partial v_+, v_-\rangle |v_+\rangle\langle v_-| - \langle v_-, \partial v_+\rangle |v_-\rangle\langle v_+|\}, \tag{60}$$

$$\frac{1}{\hbar}\langle w_{\pm,\hbar}(u;E), H^A_\hbar(u,E) w_{\pm,\hbar}(u;E)\rangle = \pm\lambda_\pm(u,E)\frac{1}{\hbar} + \hbar\,\frac{|\langle \partial v_\pm(u,E), v_\mp\rangle|^2}{\lambda_+(u,E) - \lambda_-(u,E)}, \tag{61}$$

$$-i\left\langle w_{\tau,\hbar}(u;E),\ \frac{\partial}{\partial u} w_{\tau,\hbar}(u;E)\right\rangle = -i\left\langle v_\tau(u;E),\ \frac{\partial}{\partial u} v_\tau(u;E)\right\rangle + 2\hbar\,\frac{|\langle \partial v_\pm(u,E), v_\mp\rangle|^2}{\lambda_+(u,E) - \lambda_-(u,E)}. \tag{62}$$

In conclusion, we get

$$\phi_\pm(u,\hbar,E) = \lambda_\pm(u,E)\frac{1}{\hbar} \mp i\left\langle v_\tau(u;E),\ \frac{\partial}{\partial u} v_\tau(u;E)\right\rangle \pm 3\hbar\,\frac{|\langle \partial v_\pm(u,E), v_\mp\rangle|^2}{\lambda_+(u,E) - \lambda_-(u,E)} + r(\hbar^2). \tag{63}$$

With the leading term in the expansion being of order $\hbar^{-1}$, it is evident that the difference of two successive solutions E_n and E_{n+1} is of order $\hbar$. Now let us consider the scalar case and explicitly compute the first terms of the expansion. In this case

$$\lambda_\pm(u,E) = \pm\sqrt{(V_0(u) - E)^2 - m^2}, \tag{64}$$

$$v_\pm(u;E) = \sqrt{\frac{1}{2}}\begin{pmatrix} \dfrac{((V_0(u)-E)^2 - m^2)^{1/4}}{(V_0(u) - E + m)^{1/2}} \\ \\ \pm\dfrac{(V_0(u) - E + m)^{1/2}}{((V_0(u)-E)^2 - m^2)^{1/4}} \end{pmatrix}. \tag{65}$$

For the equation (56) by similar procedures, one obtains

$$\tilde{\lambda}_{\pm}(u,E)=\pm\sqrt{(\epsilon V_0(u)-1)^2-\epsilon^2 m^2}, \tag{66}$$

$$\tilde{v}_{\pm}(u;E)=\sqrt{\frac{1}{2}}\begin{pmatrix} \dfrac{((\epsilon V_0(u)-1)^2-\epsilon^2 m^2)^{1/4}}{(\epsilon V_0(u)-1+\epsilon m)^{1/2}} \\ \pm\dfrac{(\epsilon V_0(u)-1+\epsilon m)^{1/2}}{((\epsilon V_0(u)-1)^2-\epsilon^2 m^2)^{1/4}} \end{pmatrix}. \tag{67}$$

Introducing the relations (64), (65) into (63), we obtain the results given in remark 5 of Sec. I. Proceeding similarly with (66), (67) and solving for E up to order n^{-1}, we obtain the terms $F_k(s,E)$ for $k=0,1,2$.

APPENDIX A:

We gather here the main definitions and results from[4] that we have used in the proof of our main theorem of Sec. I. Suppose we are given a Hilbert space h with a sesquilinear Hermitian form $\langle\cdot,\cdot\rangle$ on it, defined by a Hermitian involution J on h. Let us consider a family of J-Hermitian operators $\{H(s)\}_{s\in\mathbf{R}}$ and the corresponding evolution equation:

$$i\epsilon\frac{\partial}{\partial s}U_\epsilon(s,s_0)=H(s)U_\epsilon(s,s_0), \tag{A1}$$

with a parameter $\epsilon\in[0,1)$. We are interested in the behavior of the solution $U_\epsilon(s,s_0)$ when $\epsilon\to 0$. Our procedure consists in considering ''quasi-invariant'' subspaces of $H(s)$ for ϵ small and to define a ''reduced evolution'' on these subspaces, that can be easily integrated. We denote

$$R_z(s):=(H(s)-z)^{-1}. \tag{A2}$$

$\mathscr{H}_\alpha$ *Hypothesis on* $H(s)$: For $s\in(a,b)\subset\mathbf{R}$, we consider a family of J-Hermitian operators $\{H(s)\}_{s\in(a,b)}$ satisfying the following.

(1.) For all $s\in(a,b)$, $H(s)$ has an isolated part of the spectrum $\sigma_0(s)$ such that

$$\sigma(s)=\sigma_0(s)\cup\sigma_1(s),\quad d(\sigma_0(s),\sigma_1(s)):=d(s)\geqslant d>0,$$

$$\operatorname{diam}(\sigma_0(s)):=D(s)\leqslant D<\infty.$$

(2.) Let $s\in(a,b)$ and let $\Gamma(s)$ be a contour enclosing $\sigma_0(s)$ in its interior and being at a distance $d(s)/2$ from $\sigma_0(s)$. We suppose there exists a neighborhood U of s, such that $\Gamma(s)\subset\rho(H(u))$ for $u\in U$ and there exists $\alpha\geqslant 1$ such that

$$\sup_{z\in\Gamma(s)}\left|\frac{\partial^k}{\partial s^k}R_z(s)\right|\leqslant b(s)c(s)^k(k!)^\alpha$$

for $k\in\mathbf{N}$, with $0\leqslant c(s),\ b(s)<\infty$.

We define the projection

$$P_0(s):=\frac{1}{2\pi i}\int_{\Gamma(s)}R_z(s)dz \tag{A3}$$

and build up some quasi-invariant associated subspaces and a corresponding reduced evolution. We denote

$$Q_0(s):=\mathbf{1}-P_0(s). \tag{A4}$$

Proposition A.1: Suppose that we are given a family $\{H(s)\}_{s\in(a,b)}$ of J-Hermitian operators on h, verifying the hypothesis $\mathscr{H}_\alpha$, and let P_0 be the projection given by (A3). Then the operators $\{E_j(s)\}_{j\in N}$ defined by

$$E_0(s):=P_0(s), \tag{A5}$$

$$E_j(s):=\sum_{m=1}^{j-1}E_m(s)E_{j-m}(s)-2P_0(s)\sum_{m=1}^{j-1}E_m(s)E_{j-m}(s)P_0(s)+\frac{1}{2\pi}\int_{\Gamma_{(s)}}R_z(s)$$
$$\times\{Q_0(s)\partial E_{j-1}(s)P_0(s)-P_0(s)\partial E_{j-1}(s)Q_0(s)\}R_z(s)dz \tag{A6}$$

are the unique solutions of the system of recurrent equations:

$$E_j(s)=\sum_{m=0}^{j}E_m(s)E_{j-m}(s), \tag{A7}$$

$$i\ \partial E_{j-1}(s)=[H(s),E_j(s)], \tag{A8}$$

and satisfy the estimations

$$\|E_j(s)\|\leqslant g(s)^j(j!)^\alpha, \tag{A9}$$

where $0\leqslant g(s)<\infty$ and $g(s)$ depends only on $c(s)$ and on the length of the contour $\Gamma(s)$.

We introduce the notation

$$N_\epsilon(s):=[(\epsilon g(s))^{-1/\alpha}]-1, \tag{A10}$$

where we have denoted by $[x]$ the entire part of x and we define

$$T_\epsilon(s):=\sum_{j=0}^{N_\epsilon(s)}\epsilon^jE_j(s). \tag{A11}$$

Proposition A.2: Suppose that we are given a family $\{H(s)\}_{s\in(a,b)}$ of J-Hermitian operators on h, verifying the hypothesis $\mathscr{H}_\alpha$, and let $T_\epsilon(s)$ be defined by (A11) and the family $\{E_j(s)\}_{j\in N}$ as given in Proposition A.1. Then we have that (i) for any $s\in(a,b)$, $\lim_{\epsilon\to0}\|T_\epsilon(s)-P_0(s)\|=0$; (ii) there exist two positive constants c_1 and c_2, such that

$$\|T_\epsilon(s)^2-T_\epsilon(s)\|\leqslant c_1b(s)\exp(-c_2(\epsilon g(s))^{-1/\alpha}).$$

Due to estimation (ii) of the above proposition, a procedure developed in Ref. 4 allows us to define the following projection:

$$P_\epsilon(s):=\frac{1}{2\pi i}\int_{\Gamma(s)}(T_\epsilon(s)-z)^{-1}\,dz, \tag{A12}$$

and its J-orthogonal projection: $Q_\epsilon(s):=\mathbf{1}-P_\epsilon(s)$.

Theorem A.3: Suppose that we are given a family $\{H(s)\}_{s\in(a,b)}$ of J-Hermitian operators on h, verifying the hypothesis $\mathscr{H}_\alpha$, then the following occurs.

(i) We have the asymptotic series $P_\epsilon(s)\sim\Sigma_{m=0}^{\infty}\epsilon^jE_j(s)$;

(ii) For any $s\in(a,b)$ there exist two positive constants $k_1(s)<\infty$ and $k_2(s)>0$, depending on $c(s)$ and the length of $\Gamma(s)$, such that

$$\|i\epsilon\,\partial P_\epsilon(s)-[H(s),P_\epsilon(s)]\|\leqslant b(s)k_1(s)\exp(-k_2(s)\epsilon^{-1/\alpha}).$$

Thus, we have obtained the quasi-invariant subspaces associated to the family $\{P_0(s)\}_{s\in(a,b)}$. Let us remark that the entire construction has been done pointwise, so that no integral over s is needed. We want to construct now an intertwining evolution for the family $\{P_\epsilon(s)\}_{s\in(a,b)}$, which, in addition, should have a J-Hermitian generator close to $H(s)$. As in Ref. 4 let us define

$$\begin{aligned}H^A_\epsilon(s):&=H(s)+(1-2P_\epsilon(s))\{i\epsilon\,\partial P_\epsilon(s)-[H(s),P_\epsilon(s)]\}\\&=P_\epsilon(s)H(s)P_\epsilon(s)+Q_\epsilon(s)H(s)Q_\epsilon(s)+(1-2P_\epsilon(s))(i\epsilon\,\partial P_\epsilon(s)),\end{aligned}\tag{A13}$$

$$B_\epsilon(s):=H(s)-H^A_\epsilon(s)\tag{A14}$$

and let $U^A_\epsilon(s,s_0)$ and $A_\epsilon(s,s_0)$ be the solutions of the following evolution equations:

$$i\epsilon\,\partial U^A_\epsilon(s,s_0)=H^A_\epsilon(s)U^A_\epsilon(s,s_0),\quad U^A_\epsilon(s_0,s_0)=\mathbf{1},\tag{A15}$$

$$\begin{gathered}i\,\partial A_\epsilon(s,s_0)=(1-2P_\epsilon(s))(i\epsilon\,\partial P_\epsilon(s))A_\epsilon(s,s_0),\\A_\epsilon(s_0,s_0)=\mathbf{1}.\end{gathered}\tag{A16}$$

Proposition A.4: The solution of the evolution equation (A16), which is called ''the parallel transport'' associated to the family $\{P_\epsilon(s)\}_{s\in(a,b)}$, is given by J-unitary operators and satisfies the relations

$$P_\epsilon(s)=A_\epsilon(s,s_0)P_\epsilon(s_0)A_\epsilon(s,s_0)^{-1},$$

$$P_\epsilon(s)(\partial A_\epsilon(s,s_0))P_\epsilon(s_0)=0.$$

Proposition A.5: The solution of the evolution equation (A15) is given by J-unitary operators, is an intertwining evolution for the family $\{P_\epsilon(s)\}_{s\in(a,b)}$, i.e.

$$P_\epsilon(s)=U^A_\epsilon(s,s_0)P_\epsilon(s_0)U^A_\epsilon(s,s_0)^{-1},$$

and we have the estimation

$$\|B_\epsilon(s)\|\leqslant b(s)k_1(s)\exp(-k_2(s)\epsilon^{-1/\alpha}),$$

with the same constants as in Theorem A.3.

If we define the factorization

$$U_\epsilon(s,s_0)=U^A_\epsilon(s,s_0)\Omega_\epsilon(s,s_0),\tag{A17}$$

one obtains for Ω_ϵ the following evolution equation:

$$\begin{gathered}i\epsilon\,\partial\Omega_\epsilon(s,s_0)=\{U^A_\epsilon(s,s_0)^{-1}B_\epsilon(s)U^A_\epsilon(s,s_0)\}\Omega_\epsilon(s,s_0),\\\Omega_\epsilon(s_0,s_0)=\mathbf{1}.\end{gathered}\tag{A18}$$

Propositions A.4 and A.5 imply that we can factorize $U^A_\epsilon(s,s_0)$ as the following product:

$$U^A_\epsilon(s,s_0)=A_\epsilon(s,s_0)U^r_\epsilon(s,s_0),\tag{A19}$$

where $\{U^r_\epsilon(s,s_0)\}_{s\in(a,b)}$ defines the ''reduced evolution'' on $P_\epsilon(s_0)h$ and satisfies the equation

$$[U^r_\epsilon(s,s_0),P_\epsilon(s_0)]=0. \tag{A20}$$

When $P_\epsilon(s_0)$ is of rank one, this evolution can be very easily integrated, and $U^r_\epsilon(s,s_0)$ is given by an operator of multiplication with a function $F_\epsilon(s,s_0)$.

Let us also remark that if $H(s)$ depends on a parameter E, taking values in some compact set and if one has uniform bounds on the E derivatives of all the s derivatives of the resolvent of $H(s)$ then all the procedures summarized in Theorem A.3 also work for the E derivatives of the projections $P_0(s;E)$. Thus, the asymptotic expansion for $P_\epsilon(s;E)$ can be differentiated term by term, and one obtains an asymptotic expansion for the E derivative of $P_\epsilon(s;E)$.

The contraction of the SU(1,1) discrete series of representations by means of coherent states

Jacques Renaud[a)]
Laboratoire de Physique Théorique et Mathématique, Université Paris VII, 2 place Jussieu F-75251 Paris Cedex 05, France

(Received 14 March 1995; accepted for publication 24 January 1996)

The group SU(1,1) is a deformation of the Poincaré group. This relationship is studied both at the classical level (coadjoint orbits) and at the quantum level (unitary representations). The contraction of the Lie algebras is written in such a way that the limit of coadjoint orbits, and hence of the classical mechanics, appears clearly. At the quantum level the representations are written on holomorphic functions Hilbert spaces and the contraction is realized by restricting these functions. It is shown that this restriction is a continuous operator. Moreover, using suitable coherent states, it is proved that the contraction extends to the representation of the whole enveloping algebras of the groups, hence it allows us to define the contraction of the quantum mechanics observables. © *1996 American Institute of Physics.* [S0022-2488(96)00106-5]

I. INTRODUCTION

It is well-known that the Lie algebra su(1,1) is a deformation of both the Lie algebra of the 1+1 Poincaré group $\mathcal{P}^{1,1}$ and the Lie algebra of the harmonic oscillator. In fact, writing

$$[X_0,X_1]=mc^2\kappa^2X_2,[X_2,X_0]=X_1/m,[X_2,X_1]=X_0/mc^2,$$

for su(1,1), one can see that the limit $\kappa\to 0$ gives the Poincaré Lie algebra and the limit $\kappa\to 0, c\to\infty, \kappa c=\omega$ gives the harmonic oscillator Lie algebra.[1] The contraction toward the harmonic oscillator has been studied in Ref. 2, we now study the contraction toward Poincaré group. Note that this contraction has another interpretation: The group SU(1,1) can be viewed as the relativity group of the anti-de Sitter space–time,[3] and the contraction is the zero curvature limit of a classical or quantum mechanics on a curved space–time. Both interpretations yield the same mathematical treatment that we now develop. This contraction has been studied by Refs. 4, 5 and 6, we shall follow the latter which constructs the contraction ''à la Dooley''[7] and obtains a deformation $\Pi_\kappa:\mathcal{P}^{1,1}\to\mathrm{SU}(1,1)$. If $\mathcal{B}_\kappa$ is the Hilbert space of the representation U of SU(1,1) and $\mathcal{H}$ the Hilbert space of the representation V of $\mathcal{P}^{1,1}$, one can define a precontraction map $i_\kappa:\mathcal{B}_\kappa\to\mathcal{H}$. The contraction is then realized formally by applying i_κ and, after that, by taking the limit $\kappa\to 0$. More precisely the essential result obtained in Ref. 6 is

$$\lim_{\kappa\to 0}\|i_\kappa U_{\Pi_\kappa(g)}i_\kappa^{-1}\psi-V_g\psi\|_{\mathcal{H}}=0, \tag{1}$$

where ψ belongs to a dense family in $\mathcal{H}$. The question of the continuity of the i_κ was not answered, we now give a positive answer. Moreover this construction was not satisfactory because the formula (1) is proved for ψ independent of κ. But the states of a relativistic harmonic oscillator are elements of $\mathcal{B}_\kappa$ and naturally depend on κ, hence it would be more natural to replace (1) by

$$\lim_{\kappa\to 0}\|i_\kappa U_{\Pi_\kappa(g)}\phi_\kappa-V_g i_\kappa\phi_\kappa\|_{\mathcal{H}}=0. \tag{2}$$

a) Electronic mail: renaud@ccr.jussieu.fr

0022-2488/96/37(7)/3168/12/$10.00

This formula cannot be true for any $\phi_\kappa \in \mathcal{B}_\kappa$, and we have to look for the states in $\mathcal{B}_\kappa$ which contract, it means the states for which $\lim_{\kappa\to 0} i_\kappa \phi_\kappa$ exists in some sense. Moreover the mathematical elements that are physically relevant are the observables and their mean values, that is the reason why we define the contraction of the representation of the Lie algebra and even of the representation of the enveloping algebra. However there is some difficulty in defining the limit of operators that do not live on the same space. We shall overcome this difficulty by using coherent states. The states on which the mean values of the observables of SU(1,1) are calculated are usually the eigenvectors of the Hamiltonian, written $|n\rangle$ or the Berezin coherent states[8] written $|z\rangle$. They both form quantum frames:[9]

$$\mathrm{Id}=\sum_n |n\rangle\langle n| \quad \text{and} \quad \mathrm{Id}=\int_{\mathcal{D}} |z\rangle\langle z| d\mu,$$

where the last integral is taken on the unit disk of the complex plane which carries the representation of SU(1,1), with the invariant measure. Unfortunately these states do not contract in the sense defined above. This is not surprising because the map i_κ is the restriction of the states to the vertical axis of the disk whereas the states $|n\rangle$ have a circular symmetry and the states $|z\rangle$ are concentrated on the point z, and the latter contracts in a weak sense only for z with real part equal to zero. The representation of SU(1,1) is square-integrable, hence for any $\psi_\kappa \in \mathcal{B}_\kappa$, the $U_g\psi_\kappa$ form a frame of $\mathcal{B}_\kappa$. The problem is to choose ψ_κ in a convenient way. The above remark on i_κ suggests that ψ_κ must be concentrated as near to the vertical axis of $\mathcal{D}$ as possible. Moreover the property for a state of minimizing the uncertainty relations is equivalent to being the eigenvector for some element of the representation of the complexified Lie algebra. This property should be preserved by the contraction and we shall see that this is the case as well. Hence we shall look for coherent states, minimizing the uncertainty relation, and whose shape[10] is as near to the vertical axis as possible. Such a state exists, and using the square integrability of the representation it allows us to construct a quantum frame that we shall use to define the contraction of quantum observables. *We shall prove that for* $\mathfrak{a}$ *in the* SU(1,1) *enveloping algebra the operator* $U(\mathfrak{a})$ *contracts to* $V(C(\mathfrak{a}))$ *where* $C(\mathfrak{a})$ *is the contraction of* $\mathfrak{a}$.

Dooley has suggested the use of the scheme of geometric quantization to study the contraction,[7] however the usual definition of the contractions is written with a rather arbitrary identification of the Lie algebras. This identification induces an identification of the dual spaces for which there is no convergence of the orbits. We develop below a new way to define contractions for which this disadvantage disappears: the coadjoint orbits do converge. With this definition the process of contraction becomes very clear at the classical mechanics level: Indeed *the coadjoint orbits are interpreted as phase spaces and the phase space of the first system tends to the phase space of the second system as the parameter tends to* 0.

II. THE GROUPS AND THEIR REPRESENTATIONS

The contraction of groups, or more precisely of Lie algebras, has been introduced by Inonü and Wigner,[11] and has been studied, for instance, in Refs. 12 and 7. We shall use a definition which is a little bit different:

Definition 2.1: Let $\mathfrak{g}_1=(V_1,[,]_1)$ *and* $\mathfrak{g}_2=(V_2,[,]_2)$ *be two Lie algebras. We say that* $\mathfrak{g}_2$ *is a contraction of* $\mathfrak{g}_1$ *when there exists a family* $\Phi_\kappa, \kappa \in \mathbb{R}^{+*}$ *of invertible linear maps from* V_2 *to* V_1 *such that*

$$\lim_{\kappa\to 0} \Phi_\kappa^{-1}[\Phi_\kappa x, \Phi_\kappa y]_1=[x,y]_2, \quad \forall x,y \in \mathfrak{g}_2.$$

One also says that $\mathfrak{g}_1$ is a deformation of $\mathfrak{g}_2$, the link between contractions and deformations is discussed in Ref. 13. In the papers previously cited, the spaces V_1 and V_2 are identified as vector spaces in a somehow arbitrary way, but the map Φ_κ furnishes another identification between these spaces, and we shall see that this is more natural. In fact, we choose a basis f_i of V_2, and note

c_{ij}^k the corresponding structure constants. Let be $f_i^\kappa=\Phi_\kappa(f_i)$ and let $c_{ij}^k(\kappa)$ be the corresponding structure constants in $\mathfrak{g}_1$. From $[f_i^\kappa,f_j^\kappa]_1=c_{ij}^k(\kappa)f_k^\kappa$ and from the above definition we get

$$c_{ij}^k=\lim_{\kappa\to 0}c_{ij}^k(\kappa). \tag{3}$$

We can identify the spaces $\mathfrak{g}_1$ and $\mathfrak{g}_2$ by means of the map Φ_κ, if this space is of finite dimension, the equality (3) implies that the endomorphism $\mathrm{ad}_{f_i^\kappa}$ tends to ad_{f_i} when $\kappa\to 0$, in the sense of the finite dimensional vector spaces natural topology. The identification of the Lie algebras allows an identification of the groups G_1 and G_2, at least in the vicinity of the identity, by means of the exponential map. The continuity of this map implies that the adjoint and coadjoint representations of G_1 converge toward the corresponding representations of G_2. Hence we have also the convergence of coadjoint orbits: *The contraction of the relativity groups implies the convergence of the whole classical mechanics of the first system toward the classical mechanics of the second system.* This was not the case in the usual definition of the contraction.

Here are some useful results on SU(1,1) and on the Poincaré group $\mathcal{P}^{1,1}$. The group SU(1,1) is the following set of matrices:

$$g=\begin{pmatrix}\alpha & \beta\\ \overline{\beta} & \overline{\alpha}\end{pmatrix},\quad |\alpha|^2-|\beta|^2=1. \tag{4}$$

The Lie algebra is three dimensional, here is a basis of this space:

$$e_0=\frac{1}{2}\begin{pmatrix}i & 0\\ 0 & -i\end{pmatrix},\quad e_1=-\frac{1}{2}\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix},\quad e_2=\frac{1}{2}\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix}.$$

The Poincaré group is the following set of matrices:

$$(a,\theta)=\begin{pmatrix}\cosh\theta & \sinh\theta & a^0\\ \sinh\theta & \cosh\theta & a^1\\ 0 & 0 & 1\end{pmatrix}.$$

The Lie algebra basis associated with this parameterization is written:

$$f_i=\frac{d}{da^i}(a,\theta)_{(a,\theta)=Id},i=0,1 \text{ and } f_2=\frac{d}{d\theta}(a,\theta)_{(a,\theta)=Id}.$$

We shall see now that the group SU(1,1) is a deformation of the Poincaré group, in fact we define:

$$\begin{array}{rccl}\Phi_\kappa: & p(1,1) & \to & \mathrm{su}(1,1),\\ & f_i & \mapsto & \kappa e_i,\quad i=0,1\\ & f_2 & \mapsto & e_2,\end{array}$$

and one can see that

$$\lim_{\kappa\to 0}\Phi_\kappa^{-1}[\Phi_\kappa f_i,\Phi_\kappa f_j]=[f_i,f_j].$$

This allows us to write the map which realizes the deformation

$$\begin{array}{rccc}\Pi_\kappa: & \mathcal{P}^{1,1} & \to & \mathrm{SU}(1,1)\\ & (a,\theta)=e^{a^0f_0+a^1f_1}e^{\theta f_2} & \mapsto & e^{\kappa(a^0e_0+a^1e_1)}e^{\theta e_2}.\end{array} \tag{5}$$

The SU(1,1) coadjoint orbit M_κ that we consider is defined by the equation

$$x_0^2-x_1^2-\kappa^2x_2^2=1, \quad x_0>0,$$

written in the dual basis $f_i^{\kappa *}$. This orbit is interpreted as the phase space of the system,[6] and using the above identification, it converges to M_0

$$x_0^2-x_1^2=1, \quad x_0>0,$$

when $\kappa\to 0$. The manifold M_0 is a coadjoint orbit of the Poincaré group and is interpreted as the phase space for a relativistic free particle on the two dimensional flat space–time. Then, following the argumentation of Ref. 6, one remarks that the curve C defined by

$$x_0^2-x_1^2=1, \quad x_2=0,$$

is a submanifold of all the M_κ, hence we shall write the quantum representation of the Poincaré group on a space of functions on C. This can be realized by means of a geometric quantization. Moreover the SU(1,1) representation corresponding to M_κ by geometric quantization can be more easily written on the unit disk of the plane, which is diffeomorphic to the orbits by means of a stereographic projection. By this projection, the curve C projects onto the imaginary axis of the disk and the precontraction will be realized by the restriction to this axis. More precisely, the SU(1,1) representations involved here are those of the discrete series. The Hilbert space is defined as follows:

$$\mathcal{B}_\kappa=\{f; f\in L^2(\mathcal{D},dP_\kappa); f \text{ holomorphic on } \mathcal{D}\},$$

where $\mathcal{D}=\{z\in\mathbb{C}; |z|<1\}$ and $dP_\kappa(z,\overline{z})=(2\kappa^{-1}-1)(1-z\overline{z})^{2\kappa^{-1}-2}dz\,d\overline{z}/\pi$ with $1/2<\kappa^{-1}\in\mathbb{N}/2$. The group representation is given by

$$U_g f(z)=(-\overline{\beta}z+\alpha)^{-2\kappa^{-1}} f\left(\frac{\overline{\alpha}z-\beta}{-\overline{\beta}z+\alpha}\right),$$

where g is as in (4). Note that this representation is defined on $\mathcal{D}$, which can be interpreted as the phase space, and the basis e_i of the Lie algebra can be used to define the three classical observables (see Ref. 2 for more details):

$$k_0=\frac{1+z\overline{z}}{1-z\overline{z}}, \quad k_1=i\frac{z-\overline{z}}{1-z\overline{z}}, \quad k_2=\frac{z+\overline{z}}{1-z\overline{z}}, \tag{6}$$

which are the classical version of the three quantum observables

$$K_i f=i\frac{d}{d\alpha}(U_{e^{\alpha e_i}}f)_{\alpha=0}.$$

We consider now the Poincaré group, the representation is defined on $L^2(]-1,1[;2dx/(1-x^2))=\mathcal{H}$ by

$$V_{(a,\theta)}f(x)=\exp\left(-i\frac{1+x^2}{1-x^2}a^0-i\frac{2x}{1-x^2}a^1\right)f\left(\frac{x\cosh(\theta/2)+\sinh(\theta/2)}{\cosh(\theta/2)+x\sinh(\theta/2)}\right).$$

This representation is equivalent to the usual Wigner one by the change of variable $x=p/(p_0+1)$. The observables corresponding to the basis f_i are given by

$$P_0=\frac{1+x^2}{1-x^2},\quad P_1=\frac{2x}{1-x^2},\quad P_2=i\frac{1-x^2}{2}\frac{d}{dx}. \tag{7}$$

Moreover the map Φ_κ allows us to define the contraction for the enveloping algebra in the following way. For E a vector space let TE be the tensor algebra of E, and for any algebra A, let

$$A[[\kappa]]=\oplus_{n\geqslant 0}(\kappa^n A)$$

be the set of formal power series with coefficients in A. This is an associative graded algebra. The map $T\Phi_\kappa: Tp(1,1)\to T\mathrm{su}(1,1)$ can be extended by linearity in

$$T_\kappa\Phi_\kappa: Tp(1,1)[[\kappa]]\to T\mathrm{su}(1,1)[[\kappa]],$$

which is injective and nonsurjective because of the definition of Φ_κ. Let E_κ be the image of $T_\kappa\Phi_\kappa$, this is the sub-algebra generated by the f_i^κ. One can see easily that we obtain the following commutative diagram:

$$\begin{array}{ccccc} Tsu(1,1)[[\kappa]] & \supset & E_\kappa & \xrightarrow{(T_\kappa\Phi_\kappa)^{-1}} & Tp(1,1)[[\kappa]] \\ \downarrow \pi_1 & & \downarrow \pi_2 & & \downarrow \pi_3 \\ \mathfrak{U}su(1,1)[[\kappa]] & \supset & \pi_1(E_\kappa) & \xrightarrow{C} & \mathfrak{U}p(1,1) \end{array}$$

where $\mathfrak{U}p(1,1)$ and $\mathfrak{U}\mathrm{su}(1,1)$ are the enveloping algebras, π_1 the natural projection, π_2 the restriction of π_1 and π_3 the projection composed with the operation $\kappa=0$. In fact one verifies easily that any element in the kernel of π_2 is also in the kernel of $\pi_3(T_\kappa\Phi_\kappa)^{-1}$, so there exists a linear application C which makes the diagramm commutative, C is the contraction map for the enveloping algebras.

Then one defines $K_i^\kappa=i(d/d\alpha)(U_{e^{\alpha f_i^\kappa}})_{\alpha=0}$. The representations U and V yield differential representations of the spaces in the previous diagram. We write again U and V for these differential representations. For any $\mathfrak{a}$ in $\pi_1(E_\kappa)$, the operator $U(\mathfrak{a})$ is of the form $P(K_0^\kappa,K_1^\kappa,K_2^\kappa,\kappa)$, where P is a polynomial. We shall see that this observable contracts in some sense toward $P(P_0,P_1,P_2,0)=V(C(\mathfrak{a}))$.

III. PRECONTRACTION

The precontraction is the following transformation. For $f\in\mathcal{B}_\kappa$ let

$$i_\kappa(f)(x)=(1-x^2)^{\kappa^{-1}}f(ix).$$

Then we have the following result.

Theorem 3.1: *The map i_κ is a continuous injection from $\mathcal{B}_\kappa$ to $\mathcal{H}$.*

Proof: The map i_κ is clearly injective, thanks to the analyticity of the elements of $\mathcal{B}_\kappa$. Let $f(z)=\Sigma_{n\geqslant 0}a_n z^n$ be in $\mathcal{B}_\kappa$, and let be

$$I=\|f\|^2_{\mathcal{B}_\kappa}=\sum_{n\geqslant 0}|a_n|^2\frac{\Gamma(2\kappa^{-1})\Gamma(n+1)}{\Gamma(2\kappa^{-1}+n)}:=\sum_{n\geqslant 0}b_n, \tag{8}$$

and

$$J=\|i_\kappa(f)\|^2_{\mathcal{H}}=2\int_{-1}^{1}|f(ix)|^2(1-x^2)^{2\kappa^{-1}-1}dx.$$

By a symmetry argument it will be enough to consider

$$J' := \int_0^1 |f(ix)|^2 (1-x^2)^{2\kappa^{-1}-1} dx.$$

Then

$$\begin{aligned} J' &= \lim_{\rho\to 1,\rho\leqslant 1} \int_0^\rho \sum_{n,m} a_n \overline{a_m} i^{n+m} (-1)^m x^{n+m} (1-x^2)^{2\kappa^{-1}-1} dx \\ &\leqslant \frac{1}{2}\sum_{n,m} |a_n||a_m| B\left(\frac{n+m+1}{2}, 2\kappa^{-1}\right) \\ &= \frac{1}{2}\sum_{p\geqslant 0} B\left(\frac{p+1}{2}, 2\kappa^{-1}\right) \sum_{n=0}^{p} |a_n||a_{n-p}| \\ &\leqslant \frac{1}{2}\sum_{p\geqslant 0} B\left(\frac{p+1}{2}, 2\kappa^{-1}\right) \sum_{n=0}^{p} |a_n|^2 \\ &= \frac{1}{2}\sum_{n\geqslant 0} |a_n|^2 \sum_{k\geqslant 1} B\left(\frac{n+k}{2}, 2\kappa^{-1}\right). \end{aligned}$$

Using the expression (8) and the identity $B(x,y)=\Gamma(x)\Gamma(y)/\Gamma(x+y)$, we obtain

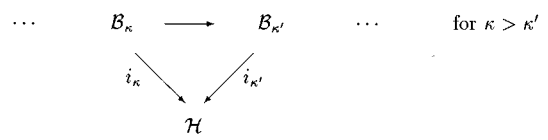
$$\begin{aligned} J' &\leqslant \frac{1}{2}\sum_{n\geqslant 0} b_n \frac{\Gamma(2\kappa^{-1}+n)}{\Gamma(n+1)\Gamma(2\kappa^{-1})} \sum_{k\geqslant 1} \frac{\Gamma((n+k)/2)\Gamma(2\kappa^{-1})}{\Gamma(2\kappa^{-1}+(n+k)/2)} \\ &= \frac{1}{2}\sum_{n\geqslant 0} b_n \frac{\Gamma(2\kappa^{-1}+n)}{\Gamma(n+1)} \sum_{p\geqslant n+1} \frac{1}{\Pi_{k=0}^{2\kappa^{-1}-1}\left(\frac{p}{2}+k\right)} \\ &\leqslant \frac{1}{2}\sum_{n\geqslant 0} b_n \frac{\Gamma(2\kappa^{-1}+n)}{\Gamma(n+1)} \int_{n+1}^{\infty} \frac{d\lambda}{((\lambda-1)/2)^{2\kappa^{-1}}} \\ &\leqslant \frac{(2\kappa^{-1})!\ 2^{2\kappa^{-1}-1}}{2\kappa^{-1}-1} I. \end{aligned}$$

This proves the theorem.

Remarks:

1. Let $\mathcal{C}_\kappa = i_\kappa(\mathcal{B}_\kappa)$. One can see easily that i_κ is injective and nonsurjective, moreover for $\kappa' < \kappa$ we have $\mathcal{B}_{\kappa'} \supset \mathcal{B}_\kappa$, hence $\mathcal{C}_{\kappa'} \supset \mathcal{C}_\kappa$ moreover $\mathcal{C}_1$ contains the functions $P(x)(1-x^2)$ where P is a polynomial which are dense in $\mathcal{H}$. This proves that $\mathcal{C}_\kappa$ is dense in $\mathcal{H}$ for any κ.

Hence we have the following commutative diagram:



The arrows represent continuous injections. In the contraction, a family of states ψ_κ covers the whole discrete series, but this will be written in $\mathcal{H}$ in which all the spaces $\mathcal{B}_\kappa$ are injected.

2. For $\kappa=1$ we obtain

Corollary 3.2: Let f be a holomorphic function on $\mathcal{D}$ which is square integrable for the Lebesgue measure on $\mathcal{D}$, then f is square integrable on any diameter of the disk, equipped with the measure $(1-r^2)dr$.

3. Let be $\mathcal{U}=\{f\in\mathcal{H}$; such that f can be analytically extended on $\mathcal{D}\}$ then $\cup_k\mathcal{C}_\kappa \neq \mathcal{U}$, this can be seen by considering the function $f(z)=e^{1/(1-z)}$.

The contraction of states is now defined in the following way:

Definition 3.3: A family of states $\psi_\kappa \in \mathcal{B}_\kappa$ contracts to $\psi \in \mathcal{H}$ iff $i_\kappa(\psi_\kappa)$ tends in some (possibly weak) sense to ψ.

IV. COHERENT STATES

In Ref. 2 we used the Berezin coherent states to study the contraction of SU(1,1) to the harmonic oscillator group. But these states cannot be used in the present contraction. In fact $i_\kappa(|z\rangle)$ has generally no limit when $\kappa\to 0$ except when $z=ia$ for $a\in\mathbb{R}$. In this case we have $\sqrt{(\pi\kappa)^{-1}}i_\kappa(|ia\rangle)\to\delta_a$ in a weak sense. This can be verified easily, let $\phi\in\mathcal{C}_0^\infty(]-1,1[)$, then we have

$$(\sqrt{(\pi\kappa)^{-1}}i_\kappa(|ia\rangle),\phi)_{\mathcal{H}}=\frac{\sqrt{\kappa^{-1}}}{\sqrt{\pi}}\int_{-1}^{1}\left(\frac{(1-x^2)(1-a^2)}{(1-ax)^2}\right)^{\kappa^{-1}}\phi(x)\frac{dx}{1-x^2}$$
$$=\frac{\sqrt{\kappa^{-1}}}{\sqrt{\pi}}\int_{-1}^{1}\left(1-\frac{(x-a)^2}{(1-ax)^2}\right)^{\kappa^{-1}}\phi(x)\frac{dx}{1-x^2}.$$

A straightforward calculation, using the dominated convergence theorem, proves that this expression tends to $\phi(a)$.

Turning to the coherent states, it is well-known that they have several definitions, which are not equivalent except for the Weyl group. One of them is to minimize the uncertainty relations for the group generators. In the case of SU(1,1), we can extract from the commutators the following uncertainty relation:

$$\frac{(\Delta K_1)(\Delta K_2)}{\langle K_0\rangle}\geqslant\frac{\kappa}{2},\tag{9}$$

where $(\Delta K_i)^2=\langle\psi|K_i^2|\psi\rangle-\langle\psi|K_i|\psi\rangle^2$ and $\langle K_0\rangle=\langle\psi|K_0|\psi\rangle$. One can see by an explicit calculation that the Berezin coherent states $|z\rangle$ do not minimize this relation (i.e., they do not realize the equality in (9)) except when $z=\overline{z}$. The Barut–Girardello coherent states[14] are defined as eigenvectors of the annihilator, they do minimize the relation but do not contract correctly. Following Nieto and Simmons,[10] we now look for states minimizing the uncertainty relations with a given ''shape.'' Suppose that a normalized state $|\psi_\alpha\rangle$ verifies

$$(AK_2+iK_1)|\psi_\alpha\rangle=\alpha|\psi_\alpha\rangle,\quad\text{where}\quad A\in\mathbb{R}_+\quad\text{and}\quad\alpha\in\mathbb{C},\tag{10}$$

then we have clearly $\alpha=A\langle K_2\rangle+i\langle K_1\rangle$ and calculating the square of the norm of (10), we obtain $A^2(\Delta K_2)^2+(\Delta K_1)^2=A\kappa\langle K_0\rangle$, and combined with (9) this gives $A\Delta K_2=\Delta K_1$, that is to say: $|\psi_\alpha\rangle$ has a given shape which does not depend on α. Moreover we have

$$\frac{(\Delta K_1)(\Delta K_2)}{\langle K_0\rangle}=\frac{\kappa}{2}.$$

The resolution of the equation (10) gives

for $A>1$

$$\psi_\alpha(z)=C_\alpha\left(z+i\sqrt{\frac{A+1}{A-1}}\right)^{-\kappa^{-1}+i\alpha(\kappa^{-1}/\sqrt{A^2-1})}\left(z-i\sqrt{\frac{A+1}{A-1}}\right)^{-\kappa^{-1}-i\alpha(\kappa^{-1}/\sqrt{A^2-1})}, \quad (11)$$

where C_α is a constant of normalization,

for $A=1$

$$\psi_\alpha(z)=C_\alpha e^{\kappa^{-1}\alpha z},$$

which are the Barut–Girardello coherent states,[14]

for $0<A<1$

$$\psi_\alpha(z)=C_\alpha\left(z+\sqrt{\frac{1+A}{1-A}}\right)^{-\kappa^{-1}+\alpha(\kappa^{-1}/\sqrt{A^2-1})}\left(z-\sqrt{\frac{1+A}{1-A}}\right)^{-\kappa^{-1}-\alpha(\kappa^{-1}/\sqrt{A^2-1})}.$$

Let us remark that the cases $A=0$ and $A=\infty$ give rise to solutions which are not square integrable. However, in view of the definition of the contraction, these states will have a good behavior during the contraction, only if they are concentrated in the vicinity of the vertical axis. This means that the classical observable k_2 (see(6)) must vanish in the limit $\kappa\to 0$. At the quantum level this means that $\Delta K_2\to 0$. Then it is natural to put $A=\kappa^{-1}$, and we define the state:

$$\psi_\kappa(z)=\left(z^2+\frac{1+\kappa}{1-\kappa}\right)^{-\kappa^{-1}},$$

obtained from (11) with $A=\kappa^{-1}$ and $\alpha=0$. The property of square integrability of the representation of SU(1,1) (Ref. 15) allows us to construct a quantum frame, i.e., a resolution of the identity in the following way. Let $\psi_{\kappa,g}=U_g\psi_\kappa$, we obtain

$$\mathrm{Id}=\int_{\mathrm{SU(1,1)}}|\psi_{\kappa,g}\rangle\langle\psi_{\kappa,g}|d\mu(g),$$

where $d\mu$ is the Haar measure on SU(1,1) conveniently normalized. The crucial point is the good behavior of these coherent states during the contraction.

V. CONVERGENCE RESULTS

We first need two lemmas:

Lemma 5.1: Let be $a\in\mathbb{R}$, $a>0$, $n_0\in\mathbb{N}$, $n>0$, $b\in\mathbb{R}$ *and A a non negative function defined for* $\kappa>0$ *such that* $0<\lim_{\kappa\to 0}A(\kappa)<\infty$, *and P a polynomial. Then for any* $x\in\,]-1,1[$ *and for* κ *small enough,*

$$P(x)\left(1+\frac{\kappa A(\kappa)}{1-x^2}\right)^{-a\kappa^{-1}+b+O(\kappa)}\frac{1}{(1-x^2)^{n_0}}\leqslant B(a,b,n_0), \quad (12)$$

where B does not depend on x nor on κ.

Proof: Even if it means changing a, it is sufficient to consider

$$\left(1+\frac{\kappa A(\kappa)}{1-x^2}\right)^{-a\kappa^{-1}}\frac{1}{(1-x^2)^{n_0}}.$$

Put $u=1/(1-x^2)\geqslant 1$, we have to prove that the function

$$\phi_\kappa(u)=n_0\ \log\ u-\frac{a}{\kappa}\log(1+\kappa A(\kappa)u),$$

is bounded uniformly in κ, for small enough κ. This is easily obtained by calculating the derivative of ϕ_κ, and proving that ϕ_κ has a maximum (depending on κ), with a finite limit when $\kappa\to 0$.

Definition 5.2: Let $\mathcal{A}$ be the set of functions on $]-1,1[$ which have the shape of the left hand side of (12).

Lemma 5.3: Let f_κ be in $\mathcal{H}$. Suppose that the family f_κ verify:

- $\lim_{\kappa\to 0} f_\kappa = f$ *almost everywhere on* $]-1,1[$,
- $f_\kappa(x)/(1-x^2)$ *is bounded on* $]-1,1[$, *uniformly in* κ,

then $f_\kappa\to f$ in the sense of the norm topology on $\mathcal{H}$.

Proof: From the second hypothesis, one can deduce that $|f_\kappa(x)|\leqslant M$ where M is a constant, hence we have $|f_\kappa(x)|^2/(1-x^2)\leqslant M^2$. As a consequence:

$$\frac{|f_\kappa(x)-f(x)|^2}{(1-x^2)}\leqslant\frac{|f_\kappa(x)|^2}{(1-x^2)}+2\frac{|f_\kappa(x)||f(x)|}{(1-x^2)}+\frac{|f(x)|^2}{(1-x^2)}\leqslant 4M^2.$$

Moreover $|f_\kappa(x)-f(x)|^2/(1-x^2)\to 0$ a.e. and by the dominated convergence theorem we obtain that

$$\int_{-1}^{1}\frac{|f_\kappa(x)-f(x)|^2}{(1-x^2)}dx\to 0.$$

Let

$$\tilde{\psi}_\kappa=i_\kappa\psi_\kappa\quad\text{and}\quad\tilde{\psi}_{\kappa,g}=i_\kappa\psi_{\kappa,\Pi_\kappa(g)}\quad\text{for } g\in\mathcal{P}^{1,1}.$$

One verifies easily that for any x: $\lim_{\kappa\to 0}\tilde{\psi}_\kappa(x)=e^{-2/(1-x^2)}=:\psi(x)$. Rewritten with the variable p on $L^2(\mathbb{R},dp/p_0)$ this state becomes $\psi(p)=Ce^{-p_0}$, called Gaussian probe in Ref. 9. This state stands out because, putting light velocity back and getting it to infinity, it becomes the ground state of the harmonic oscillator. We shall prove now that all the $\psi_{\kappa,g}=U_g(\psi_\kappa)$ contract in the sense of the norm. For this purpose, let us consider (a,θ) fixed in $\mathcal{P}^{1,1}$, then we have

$$\Pi_\kappa(a,\theta)=\begin{pmatrix}\alpha & \beta\\ \beta & \alpha\end{pmatrix}.$$

The coefficients can be calculated, using (5) and we obtain

$$\alpha=\alpha(\kappa)=\cosh\left(\frac{\theta}{2}\right)+\frac{i\kappa}{2}\left(a^0\cosh\left(\frac{\theta}{2}\right)-a^1\sinh\left(\frac{\theta}{2}\right)\right)+o(\kappa),$$

$$\beta=\beta(\kappa)=i\ \sinh\left(\frac{\theta}{2}\right)+\frac{\kappa}{2}\left(a^0\sinh\left(\frac{\theta}{2}\right)-a^1\cosh\left(\frac{\theta}{2}\right)\right)+o(\kappa).\tag{13}$$

Hence:

$$\tilde{\psi}_{\kappa,(a,\theta)}(x)=\left(1+\frac{2\kappa\left(x\sinh\left(\frac{\theta}{2}\right)+\cosh\left(\frac{\theta}{2}\right)\right)^2+i\kappa f(a,\theta,x)+P(a,\theta,x)o(\kappa)}{1-x^2}\right)^{-\kappa^{-1}},$$

where P is uniformly bounded with respect to x, that is to say $|P(a,\theta,x)|\leqslant M(a,\theta)$, and f is some function. One can easily verify that

$$\lim_{\kappa\to 0} i_\kappa U_{\Pi_\kappa(g)}\psi_\kappa(x)=V_g\psi(x)=:\psi_g(x) \quad \text{for any } x \text{ and for any } g \text{ in } \mathcal{P}^{1,1},$$

moreover,

$$|\tilde{\psi}_{\kappa,(a,\theta)}(x)|\leqslant\left(1+\frac{2\kappa(x\sinh(\theta/2)+\cosh(\theta/2))^2-|P(a,\theta,x)o(\kappa)|}{1-x^2}\right)^{-\kappa^{-1}}$$
$$\leqslant\left(1+\frac{2\kappa e^{-|\theta|}-M(a,\theta)o(\kappa)}{1-x^2}\right)^{-\kappa^{-1}}.$$

Then, using the first lemma we have $|\tilde{\psi}_{\kappa,(a\theta)}(x)|/(1-x^2)$ uniformly bounded in x and κ. Thanks to the second lemma we obtain:

Proposition 5.4: For a fixed (a,θ), $\lim_{\kappa\to 0} i_\kappa U_{\Pi_\kappa(a,\theta)}\psi_\kappa=V_{(a,\theta)}\psi$ in the sense of the norm topology on $\mathcal{H}$.

Note that this result generalizes (1) looking like (2). Now we are ready to state our definition of the contraction. Let A^κ be an observable on $\mathcal{B}_\kappa$, i.e., an essentially self adjoint operator whose domain contains the $\psi_{\kappa,g}$. Let

$$\tilde{A}^\kappa=i_\kappa A^\kappa i_\kappa^{-1}.$$

Here is the main definition.

Definition 5.5: Let A^κ be an observable on $\mathcal{B}_\kappa$, we say that A^κ contracts to an observable A on $\mathcal{H}$ iff

$$\lim_{\kappa\to 0}\langle\tilde{\psi}_{\kappa,g'}|\tilde{A}^\kappa|\tilde{\psi}_{\kappa,g}\rangle=\langle\psi_{g'}|A|\psi_g\rangle \forall g,g'\in\mathcal{P}^{1,1}.$$

The scalar product is the scalar product of $\mathcal{H}$.

We can now state the main result:

Theorem 5.6: *For any $\mathfrak{a}$ in $\pi_1(E_\kappa)$ and for any g,g' in $\mathcal{P}^{1,1}$ we have*

$$\lim_{\kappa\to 0}\langle\tilde{\psi}_{\kappa,g'}|\tilde{U}(\mathfrak{a})|\tilde{\psi}_{\kappa,g}\rangle=\langle\psi_{g'}|V(C(\mathfrak{a}))|\psi_g\rangle.$$

That is to say: Any polynomial expression in the K_i^κ contracts to the corresponding expression in the P_i.

Before proving this theorem, we need some intermediate results. The precontraction of the group generators gives the following results.

$$\tilde{K}_0^\kappa=\frac{1+x^2}{1-x^2}+\kappa x\frac{d}{dx},$$

$$\tilde{K}_1^\kappa=\frac{2x}{1-x^2}+\kappa\frac{1+x^2}{2}\frac{d}{dx},$$

$$\widetilde{K}_2^\kappa = i\frac{x^2-1}{2}\frac{d}{dx}.$$

Formally these formulas converge to (7), but we can obtain more. One can see easily that $\mathcal{A}$ (*cf.* definition 5.2) contains $\widetilde{\psi}_\kappa$ and moreover for any $f_\kappa \in \mathcal{A}$ which tends in norm to f for $\kappa \to 0$, one has $\widetilde{K}_i^\kappa f_\kappa \in \mathcal{A}$ and

$$\widetilde{K}_i^\kappa f_\kappa \overset{\mathcal{H}}{\to} P_i f.$$

As a consequence we have the following result:

Proposition 5.7: Let be $f_\kappa \in \mathcal{A}$ and P a polynomial, then $P(\widetilde{K}_0^\kappa, \widetilde{K}_1^\kappa, \widetilde{K}_2^\kappa) f_\kappa$ tends in the sense of the $\mathcal{H}$-norm to $P(P_0, P_1, P_2) f$ where f is the limit of f_κ.

Remark: A consequence of this proposition is that ψ minimizes the uncertainty relations:

$$\frac{(\Delta P_1)(\Delta P_2)}{\langle P_0 \rangle} \geqslant \frac{1}{2}.$$

In fact we have in $\mathcal{H}$,

$$(P_2 + iP_1)\psi = \lim_{\kappa\to 0}(\widetilde{K}_2^\kappa + i\widetilde{K}_1^\kappa)\widetilde{\psi}_\kappa = \lim_{\kappa\to 0} i_\kappa (K_2^\kappa + iK_1^\kappa)\psi_\kappa = 0.$$

Hence the property of minimizing the uncertainty relation is preserved by the contraction.

Now we consider the group action on $\mathcal{A}$, for any $f_\kappa \in \mathcal{A}$ we obtain

$$\widetilde{U}_g f_\kappa(x) = Z(x) f_\kappa\left(-i\frac{\overline{\alpha i}x - \beta}{-i\beta x + \alpha}\right),$$

where

$$Z(x) = (\alpha^2 + \beta^2)^{-\kappa^{-1}}\left(\frac{1-x^2}{1-2iFx-Ex^2}\right)^{\kappa^{-1}},$$

with

$$E = \frac{\overline{\alpha^2} + \overline{\beta^2}}{\alpha^2 + \beta^2} \quad \text{and} \quad F = \frac{\overline{\beta}\overline{\alpha} + \overline{\alpha}\overline{\beta}}{\alpha^2 + \beta^2}.$$

One can see easily that for any x, $\widetilde{U}_{\Pi_\kappa(a,\theta)} f_\kappa(x)$ tends to $V_{(a,\theta)} f(x)$, moreover one can show (Ref. 6) that Z is bounded by a constant which depends only on (a,θ). In view to obtaining the L^2-convergence, we have to control the second term, more precisely let

$$Y = \frac{1}{\left(1-\left(-i\left(\frac{\overline{\alpha i}x-\beta}{-i\beta x+\alpha}\right)\right)^2\right)^{n_0}}\left(1+\frac{\kappa A(\kappa)}{1-\left(-i\left(\frac{\overline{\alpha i}x-\beta}{-i\beta x+\alpha}\right)\right)^2}\right)^{-a\kappa^{-1}+b+O(\kappa)}.$$

Remark that, using (13) we obtain

$$\left(-i\left(\frac{\overline{\alpha i}x-\beta}{-i\beta x+\alpha}\right)\right)^2 = B + i\kappa C,$$

where $|B| < 1$ and for a^0, a^1, θ fixed, C is a bounded function of x and κ: $|C| \leqslant M$. Then

$$|Y| = \left(1 + \frac{(1-B)\kappa^{-1}+1}{((1-B)\kappa^{-1})^2 + C^2}\right)^{-\kappa^{-1}/2} \frac{\kappa^{-n_0}}{(((1-B)\kappa^{-1})^2 + C^2)^{n_0/2}}$$

$$\leqslant \left(1 + \frac{(1-B)\kappa^{-1}+1}{((1-B)\kappa^{-1})^2 + C^2}\right)^{-\kappa^{-1}/2} \kappa^{-n_0} \left(\frac{(1-B)\kappa^{-1}+1}{((1-B)\kappa^{-1})^2 + C^2}\right)^{n_0/2}.$$

And we can complete the demonstration as in the Lemma 5.1, verifying that $|Y|$ is bounded by a constant which depends only on (a,θ). Hence we have shown that

Proposition 5.8: $\forall (a,\theta) \in \mathcal{P}^{1,1}$ *and* $\forall f_\kappa \in \mathcal{A}$, $\widetilde{U}_{\Pi_\kappa(a,\theta)} f_\kappa$ *tends in the sense of the* $\mathcal{H}$*-norm to* $V_{(a,\theta)} f$ *where* f *is the* $\mathcal{H}$*-limit of* f_κ.

Turning to the demonstration of the Theorem 5.6, we remark that

$$P(\widetilde{K}_0^\kappa, \widetilde{K}_1^\kappa, \widetilde{K}_2^\kappa)\widetilde{\psi}_{\kappa,g} = \widetilde{U}_g \widetilde{U}_g^{-1} P(\widetilde{K}_0^\kappa, \widetilde{K}_1^\kappa, \widetilde{K}_2^\kappa)\widetilde{U}_g \widetilde{\psi}_\kappa = \widetilde{U}_g P(\tilde{\mathrm{a}}\mathrm{d}_g K_0^\kappa, \tilde{\mathrm{a}}\mathrm{d}_g K_1^\kappa, \tilde{\mathrm{a}}d_g K_2^\kappa)\widetilde{\psi}_\kappa .$$

We complete the demonstration, using the convergence of the structure constants and the above propositions.

VI. CONCLUSION

It was already known that SU(1,1) contracts to the Poincaré group. But in this paper we have proved that the classical and quantum mechanics described by this group contracts to the corresponding mechanics associated to the Poincaré group. This can be interpreted as the limit at null curvature of the anti-de Sitterian mechanics or as the limit of a relativistic harmonic oscillator to a free relativistic particle. We emphasize that this limit is not only for the representation but also for all the quantum observables. However this contraction is somehow singular, it is obtained by a restriction to a set of measure zero. Then it is not surprising that the frame $\psi_{\kappa,g}$ becomes at the limit a dense family which is no more a family of coherent states: it contains too many vectors. In fact $\psi \in D(P_0^{1/2})$ and one can deduce[9] that if $M = \mathcal{P}^{1,1}/e^{\mathbb{R}f_0}$ and if s is a Borelian section $M \to \mathcal{P}^{1,1}$, then the set of $V_{(s(z))}\psi$ where $z \in M$ is a frame of $\mathcal{H}$.

Quantum mechanics of charged particles in random electromagnetic fields

A. Truman and H. Z. Zhao
Department of Mathematics, University of Wales Swansea, Singleton Park, Swansea SA2 8PP, United Kingdom

(Received 23 October 1995; accepted for publication 20 February 1996)

In this paper we consider the $\hbar \to 0$ asymptotics for the solutions to stochastic Schrödinger equations for quantum mechanical particles in random electromagnetic fields in R^n. We obtain semi-classical expansions for their solutions up to any order in $L^2(R^n)$ a.s. by using a stochastic Hamilton Jacobi equation and a stochastic continuity equation. We conclude that as $\hbar \to 0$ the stochastic quantum mechanics with random electromagnetic fields tends to stochastic classical mechanics. © *1996 American Institute of Physics.* [S0022-2488(96)04306-X]

I. INTRODUCTION

In this paper we consider the $\hbar \to 0$ asymptotics of the solution to the following stochastic Schrödinger equation in R^n

$$\frac{i}{\hbar} dH \psi_t + d\psi_t = 0, \tag{1.1}$$

where the Hamiltonian for random electromagnetic fields is given by the following Stratonovich type differential

$$\begin{aligned} dH = &\left(\frac{1}{2} \{ -\hbar^2 \Delta + 2i\hbar b \cdot \nabla + i\hbar (\nabla \cdot b) + b^2 \} + V \right) dt \\ &+ \frac{1}{2} \sum_{r=1}^{m_1} [2i\hbar A^r \cdot \nabla + i\hbar (\nabla \cdot A^r) + 2(b \cdot A^r)] \circ dw_t^{1r} + \sum_{r=1}^{m_2} K^r \circ dw_t^{2r} \end{aligned} \tag{1.2}$$

and $w_t^{(k)} = (w_t^{k1}, w_t^{k2}, \cdot, w_t^{km_k})$ $(k = 1,2)$ is m_k-dimensional Brownian motion with $w_t^{k_i}$ independent Wiener processes on probability space $(\Omega, \mathcal{F}, P)$, b, A^r $(r = 1,2, \cdots, m_1)$ are C^2 vector fields in R^n and V, K^r $(r = 1,2, \cdots, m_2)$ are C^2 functions. Here we denote the inner product in R^n by $- \cdot -$ or sometimes $\langle -, - \rangle$, the corresponding Euclidean metric being $|-| = \sqrt{-, -} = \sqrt{\langle -, - \rangle}$. This random operator dH can be considered as the stochastic generalization of the Schrödinger operators in electromagnetic fields considered by many people, such as Simon,[1] Cycon *et al.*,[2] Elworthy, Truman and Watling,[3] and Cartier and DeWitt-Morette,[4] to name but a few. Heuristically we have to consider random Schrödinger operators like

$$\frac{1}{2} \left(i\hbar \nabla + b + \sum_{r=1}^{m_1} A^r \circ \frac{dw_t^{1r}}{dt} \right)^2 + V + \sum_{r=1}^{m_2} K^r \circ \frac{dw_t^{2r}}{dt},$$

which leads to (1.2) as $dw_t^{(1)} \circ dw_t^{(1)} = 0$ for Stratonovich type differentials. The random electromagnetic field in R^3 is given by $\nabla \times (b + \Sigma_{r=1}^{m_1} A^r \circ dw_t^{1r}/dt) = \text{curl } b + \Sigma_{r=1}^{m_1} \text{curl } A^r \circ dw_t^{1r}/dt$ and $\nabla^k (b^l + \Sigma_{r=1}^{m_1} A^{lr} \circ dw_t^{1r}/dt) - \nabla^l (b^k + \Sigma_{r=1}^{m_1} A^{kr} \circ dw_t^{1r}/dt)$ in the general case with the electric field given by $-\nabla (V + \Sigma_{r=1}^{m_2} K^r \circ dw_t^{2r}/dt)$. The sort of noise we consider is white noise in time distributed locally in different directions. Since it is known that before an earthquake there are

0022-2488/96/37(7)/3180/18/$10.00

random fluctuations in the Earth's local electromagnetic field, equation (1.1) is a useful model for earthquake predictions. Clearly there are also potential defence applications.

Inspired by Maslov's quasi-classical asymptotics of quantum mechanics (Maslov[5]), Truman,[6] Elworthy and Truman[7,8] developed the path-space Hamilton Jacobi theory in order to treat deterministic heat equations (or Schrödinger equations) to get quasi-classical expansions for their solutions. Elworthy and Truman[7] considered the Schrödinger equation

$$\frac{i}{\hbar}H\psi_t^\hbar + \frac{\partial}{\partial t}\psi_t^\hbar = 0 \tag{1.3}$$

with $H = -\frac{1}{2}\hbar^2\Delta + V = \frac{1}{2}(i\hbar\nabla)^2 + V$ and initial condition $\psi_0^\hbar(x) = T_0(x)\exp\{iS_0(x)/\hbar\}$ and proved if $T_0 \in C_0^\infty(R^n)$ and $S_0 \in C^\infty(R^n)$ then as $\hbar \to 0$

$$\psi_t^\hbar(-)\exp\{-iS(-,t)/\hbar\} \to T_0(\Phi_t^{-1}-)\phi^{\frac{1}{2}}(-,t) \tag{1.4}$$

in $L^2(R^n)$ where $\Phi_t : R^n \to R^n$ is defined by the following second order classical mechanical equation

$$\ddot{\Phi}_t = -\nabla V(\Phi_t), \Phi_0(x) = x, \dot{\Phi}_t(x) = \nabla S_0(x), \tag{1.5}$$

and under a no-caustics condition, Φ_t^{-1} is the inverse of Φ_t and

$$S(x,t) = \frac{1}{2}\int_0^t |\dot{\Phi}_s(\Phi_t^{-1}(x))|^2 ds + S_0(\Phi_t^{-1}(x)) - \int_0^t V(\Phi_s(\Phi_t^{-1}(x)))ds$$

and $\phi(x,t) = |\det(\partial/\partial x)\,\Phi_t^{-1}(x)|$. Elworthy, Truman and Watling [3] generalized the above result to Schrödinger equations in the presence of electromagnetic fields. The Hamilton Jacobi theory has been used successfully in the study of the Feynman–Kac integral in curved space in obtaining small time and small $\hbar$ asymptotics for solutions of diffusion heat equations and Schrödinger equations as well as the classical mechanical limit of the quantum partition function (Elworthy, Ndumu and Truman[9]). These techniques have been applied by Elworthy[10,11] to linear heat equations, by Elworthy, Truman and Zhao[12] to nonlinear generalized KPP equations in which we have proved that the travelling wave front is given by a Hamilton Jacobi function, and to many other problems. Truman and Zhao[13–15] and Kolokoltsov[16] independently developed stochastic Hamilton Jacobi theory to include the stochastic heat equations such as the Zakai equation of nonlinear filtering, and stochastic Schrödinger equations arising in quantum filtering (Belavkin[17]) and the stochastic evolution equation in Hudson and Parthasarathy[18] and random wave processes in Dawson and Papanicolaou.[19]

The challenging question is to develop the stochastic Hamilton Jacobi theory to treat equations such as (1.1) with dH defined by (1.2) in random electromagnetic fields. This question also arises in study of stochastic heat equations with random vector drifts. In this paper we tackle this problem. In section II we consider the stochastic Hamiltonian system and solve the Hamilton Jacobi equations under a no-caustic condition (Theorem 2.2)

$$dS_t(x) + \frac{1}{2}|\nabla S_t(x) - b(x,t)|^2 dt - \sum_{r=1}^{m_1} \langle A^r(x,t), \nabla S_t(x) - b(x,t)\rangle \circ dw_t^{1r} + V(x,t)dt$$
$$+ \sum_{r=1}^{m_2} K^r(x,t)dw_t^{2r} = 0. \tag{1.6}$$

and stochastic continuity equation (Lemma 2.3)

$$d\phi(x,t)+\operatorname{div}\left\{\phi(x,t)\left[(\nabla S(x,t)-b(x,t))dt-\sum_{r=1}^{m_1}A^r(x,t)\circ dw_t^{1r}\right]\right\}=0. \tag{1.7}$$

These give the desired cancellations of orders $i\hbar^{-1}$ and $(i\hbar)^0$ when we consider the stochastic Schrödinger equation (1.1) in section III. In fact we obtain the semi-classical expansions for the solution to equation (1.1) up to any order in $L^2(R^n)$ a.s. The corresponding question for the deterministic equation was considered by Elworthy, Truman and Watling.[3] Nevertheless the proof we give in this paper is simpler and more straightforward than that in the previous paper. As a simple consequence of above we conclude that in the limit as $\hbar\to 0$ the probability of the quantum mechanical charged particle in random electromagnetic fields being in the set A at time t equals the probability of the quantum mechanical particle being in the set $\Phi_t^{-1}A$ in time 0, i.e. $\lim_{\hbar\to 0}\widetilde{P}^{\hbar}(t,A)=\widetilde{P}(0,\Phi_t^{-1}A)$ where Φ_t is the classical stochastic Hamiltonian flow in configuration space, $\widetilde{P}$ being the quantum mechanical probability, A any Borel set in R^n. In this sense stochastic quantum mechanics associated with the stochastic Schrödinger equation converges to the stochastic classical mechanics of the corresponding stochastic Hamiltonian system as $\hbar\to 0$. Furthermore, our results give the asymptotic expansions of $\widetilde{P}^{\hbar}(t,A)$.

In section IV we prove a result that the random map $\Phi_s:R^n\to R^n$ is almost surely a diffeomorphism for $0\leqslant s\leqslant T(\omega)$ and such $T(\omega)>0$ exists almost surely i.e. for some positive time the no caustic condition is satisfied.

We can immediately apply the stochastic Hamilton Jacobi theory to stochastic heat equations and Burgers' equations with random drifts. For these results see Truman and Zhao.[20] For the Schrödinger equations, the no caustic condition avoids the complications of Maslov indices. When caustics do occur we expect the original analysis of Maslov could be generalized to this stochastic setting but we have not investigated this in any detail.

II. THE STOCHASTIC HAMILTON JACOBI EQUATIONS

In this section we consider the stochastic Hamilton Jacobi equation and the stochastic continuity equation. These are two basic equations in stochastic Hamilton Jacobi theory. Indeed in the next section we will give the semi-classical expansions for the solution of stochastic Schrödinger equation (1.1) by applying the stochastic Hamilton Jacobi theory where the stochastic Hamilton Jacobi equation and the stochastic continuity equation give the right cancellations as required.

For given C^2 vector fields b,A^r $(r=1,2,\cdots,m_1)$ in R^n and C^2 functions V,K^r $(r=1,2,\cdots,m_2)$, S_0 and m_k dimensional Brownian motion $w_s^{(k)}=(w_s^{k1},w_s^{k2},\cdots,w_s^{km_k})$ $(k=1,2)$ on the probability space $(\Omega,\mathcal{F},P)$, consider the following stochastic Hamiltonian system of Stratonovich type written in phase space

$$\begin{cases} d\Phi_s^k=v_s^k ds-\sum_{r=1}^{m_1}A^{kr}(\Phi_s,s)\circ dw_s^{1r}, \\ dv_s^k=-\nabla^k V(\Phi_s,s)ds-\sum_{r=1}^{m_2}\nabla^k K^r(\Phi_s,s)dw_s^{2r}-\dfrac{\partial}{\partial s}b_k(\Phi_s,s)ds \\ \qquad +(\nabla^k b_l(\Phi_s,s)-\nabla^l b_k(\Phi_s,s))\left(v_s^l ds-\sum_{r=1}^{m_1}A^{lr}(\Phi_s,s)\circ dw_s^{1r}\right) \\ \qquad +v_s^l\sum_{r=1}^{m_1}\nabla^k A^{lr}(\Phi_s,s)\circ dw_s^{1r}, \\ \qquad k=1,2,\cdots,n \end{cases} \tag{2.1}$$

with $\Phi_0(x)=x, v_0(x)=\nabla S_0(x)-b(x,0)$. Here we use usual summation convention over Latin indices.

Let $\widetilde{S}:[0,+\infty)\times R^n\times\Omega\to R$ be defined by the following non-anticipating Itô's stochastic integral

$$\widetilde{S}_t(y)=\frac{1}{2}\int_0^t|v_s(y)|^2ds+S_0(y)-\int_0^t V(\Phi_s(y),s)ds-\sum_{r=1}^{m_2}\int_0^t K^r(\Phi_s(y),s)dw_s^{2r}$$
$$+\int_0^t\langle b(\Phi_s(y),s),d\Phi_s(y)\rangle. \tag{2.2}$$

Lemma 2.1: *For any $t\geqslant 0$ and a.e. $\omega\in\Omega$,*

$$(\nabla_y\Phi_t(y))^*[v_t(y)+b(\Phi_t(y),t)]=\nabla_y\widetilde{S}_t(y) \tag{2.3}$$

and

$$d\widetilde{S}_t(y)=\frac{1}{2}|v_t(y)|^2dt-V(\Phi_t(y),t)dt-\sum_{r=1}^{m_2}K^r(\Phi_t(y),t)dw_t^{2r}+\langle b(\Phi_t(y),t),d\Phi_t(y)\rangle. \tag{2.4}$$

Here by $-^*$ we denote the transpose of $-$.

Proof: Differentiating $\widetilde{S}_t(y)$ with respect to y_j $(j=1,2,\cdots,n)$ we obtain

$$\nabla_{y_j}\widetilde{S}_t(y)=\int_0^t(\nabla_{y_j}v_s(y))^*v_s(y)ds+\nabla_{y_j}S_0(y)-\int_0^t(\nabla_{y_j}\Phi_s(y))^*\nabla V(\Phi_s(y),s)ds$$
$$-\sum_{r=1}^{m_2}\int_0^t(\nabla_{y_j}\Phi_s(y))^*\nabla K^r(\Phi_s(y),s)dw_s^{2r}+\int_0^t b^l(\Phi_s(y),s)d\nabla_{y_j}\Phi_s^l(y)$$
$$+\int_0^t\nabla^k b^l(\Phi_s(y),s)\nabla_{y_j}\Phi_s^k(y)d\Phi_s^l(y), \tag{2.5}$$

by using the summation convention. The first term in (2.5) can be calculated by using equation (2.1) and the integration by parts formula

$$\int_0^t v_s^k(y)\nabla_{y_j}v_s^k(y)ds=\int_0^t v_s^k(y)\left[d\nabla_{y_j}\Phi_s^k(y)+\sum_{r=1}^{m_1}\nabla^l A^{kr}(\Phi_s,s)\nabla_{y_j}\Phi_s^l(y)\circ dw_s^{1r}\right]$$
$$=v_t^k(y)\nabla_{y_j}\Phi_t^k(y)-v_0^k(y)\nabla_{y_j}\Phi_0^k(y)-\int_0^t\nabla_{y_j}\Phi_s^k(y)dv_s^k(y)$$
$$+\sum_{r=1}^{m_1}\int_0^t v_s^k(y)\nabla^l A^{kr}(\Phi_s,s)\nabla_{y_j}\Phi_s^l(y)\circ dw_s^{1r}$$
$$=v_t^k(y)\nabla_{y_j}\Phi_t^k(y)-v_0^k(y)\,\delta_j^k-\int_0^t\nabla_{y_j}\Phi_s^k(y)dv_s^k$$
$$+\sum_{r=1}^{m_1}\int_0^t v_s^l(y)\nabla^k A^{lr}(\Phi_s,s)\nabla_{y_j}\Phi_s^k(y)\circ dw_s^{1r},$$

by commuting the positions of k and l in the last term. It turns out from the cancellations due to equation (2.1) that (2.5) is

$$\nabla_{y_j}\widetilde{S}_t(y)=(\nabla_{y_j}\Phi_t(y))^* v_t(y)+b^j(y,0)-\int_0^t\nabla_{y_j}\Phi_s^k(y)\Big[v_s^l(y)(\nabla^k b_l(\Phi_s,s)-\nabla^l b_k(\Phi_s,s))ds$$
$$-\frac{\partial}{\partial s}b_k(\Phi_s,s)ds\Big]-\int_0^t\nabla_{y_j}\Phi_s^k(y)\sum_{r=1}^{m_1}A^{lr}(\Phi_s,s)(\nabla^l b^k(\Phi_s,s)-\nabla^k b^l(\Phi_s,s))\circ dw_s^{1r}$$
$$+\int_0^t b^k(\Phi_s(y),s)d\nabla_{y_j}\Phi_s^k(y)+\int_0^t\nabla^k b^l(\Phi_s(y),s)\nabla_{y_j}\Phi_s^k(y)d\Phi_s^l(y). \tag{2.6}$$

By the integration by parts formula again we have

$$\int_0^t b^k(\Phi_s(y),s)d\nabla_{y_j}\Phi_s^k(y)=b^k(\Phi_t(y),t)\nabla_{y_j}\Phi_t^k(y)-b^k(y,0)\,\delta_k^j-\int_0^t\nabla_{y_j}\Phi_s^k(y)$$
$$\times\Big(\nabla^l b^k(\Phi_s(y),s)d\Phi_s^l+\frac{\partial}{\partial s}b^k(\Phi_s,s)ds\Big). \tag{2.7}$$

Cancellations in (2.6) and (2.7) using equation (2.1) again finally lead to

$$\nabla_{y_j}\widetilde{S}_t(y)=\nabla_{y_j}\Phi_t^k(y)((v_t^k(y)+b^k(\Phi_t(y),t))),$$

which is (2.3) as required. We can prove (2.4) by direct differentiation easily. ■

We assume a *no-caustic condition*: there exists $T(\omega)>0$ a.s. such that for $0\leqslant s\leqslant T(\omega)$, $\Phi_s(\omega):R^n\to R^n$ is a diffeomorphism for a.e. $\omega\in\Omega$. In section IV we will prove this is true for $V,K^r\in C_0^\infty(R^n)$ and $b,A^r\in C_0^\infty(R^n,R^n)$. It is noteworthy here that the diffeomorphism property for the Hamiltonian system in configuration space is different from that in phase space. Actually in phase space, equation (2.1) is a multidimensional first order stochastic differential equation in which case the diffeomorphism property is covered by stochastic flow theory in Kunita[21] and Elworthy.[10] Unfortunately the diffeomorphism of $(\Phi_s,v_s):R^{2n}\to R^{2n}$ does not imply the diffeomorphism of $\Phi_s:R^n\to R^n$ in configuration space.

The following is the main result of this section. It gives the solution of the stochastic Hamilton Jacobi equation with random vector potentials under the no caustic condition.

Theorem 2.2: *With no caustic assumption for* $0\leqslant s\leqslant T(\omega)$ *we define* $S_t(\omega):R^n\to R^1$ *for a.e.* $\omega\in\Omega$ *and* $0\leqslant t\leqslant T(\omega)$ *by*

$$S_t(x)=\widetilde{S}_t(\Phi_t^{-1}(x)). \tag{2.8}$$

Then for a.e. $\omega\in\Omega$, $0\leqslant t\leqslant T(\omega)$ *and any* $x\in R^n$

$$\nabla S_t(x)=v_t(\Phi_t^{-1}(x))+b(x,t), \tag{2.9}$$

and $S_t(x)$ *satisfies the following stochastic Hamilton Jacobi equation:*

$$dS_t(x)+\frac{1}{2}|\nabla S_t(x)-b(x,t)|^2dt-\sum_{r=1}^{m_1}\langle A^r(x,t),\nabla S_t(x)-b(x,t)\rangle\circ dw_t^{1r}+V(x,t)dt$$
$$+\sum_{r=1}^{m_2}K^r(x,t)dw_t^{2r}=0. \tag{2.10}$$

Proof: Differentiating $S_t(x)$ with respect to x_k for $k \in \{1,2,\cdots,n\}$ and using (2.3)

$$\begin{aligned}\nabla_{x_k} S_t(x) &= \nabla^j \widetilde{S}_t(\Phi_t^{-1}(x)) \nabla_{x_k} \Phi_t^{-1}(x)_j \\ &= \nabla^j \Phi_t^l(\Phi_t^{-1}(x))(v_t^l(\Phi_t^{-1}(x)) + b^l(x,t)) \nabla_{x_k} \Phi_t^{-1}(x)_j \\ &= \nabla_{x_k} \Phi_t^l(\Phi_t^{-1}(x))(v_t^l(\Phi_t^{-1}(x)) + b^l(x,t)) \\ &= \delta_k^l (v_t^l(\Phi_t^{-1}(x)) + b^l(x,t)) = v_t^k(\Phi_t^{-1}(x)) + b^k(x,t),\end{aligned}$$

gives (2.9). It will be used often in the following form that

$$\nabla_x S_t(x) - b(x,t) = v_t(\Phi_t^{-1}(x)). \tag{2.11}$$

Differentiating $S_t(x)$ with respect to t and using (2.3), (2.4) and (2.11) we deduce that

$$\begin{aligned}dS_t(x) &= d\widetilde{S}_t(\Phi_t^{-1}(x)) + \nabla^j \widetilde{S}_t(\Phi_t^{-1}(x)) d\Phi_t^{-1}(x)_j \\ &= \frac{1}{2}|v_t(\Phi_t^{-1}(x))|^2 dt + \langle b(x,t), d\Phi_t(\Phi_t^{-1}(x))\rangle - V(x,t)dt - \sum_{r=1}^{m_2} K^r(x,t) dw_t^{2r} \\ &\quad + \nabla^j \Phi_t^l(\Phi_t^{-1}(x))(v_t^l(\Phi_t^{-1}(x)) + b^l(x,t)) d\Phi_t^{-1}(x)_j \\ &= \frac{1}{2}|\nabla S(x,t) - b(x,t)|^2 dt - V(x,t)dt - \sum_{r=1}^{m_2} K^r(x,t) dw_t^{2r} - d\Phi_t^l(\Phi_t^{-1}(x)) v_t^l(\Phi_t^{-1}(x)).\end{aligned} \tag{2.12}$$

This is from differentiating the identity $\Phi_t^l(\Phi_t^{-1}(x)) = x^l$ with respect to t to obtain $d\Phi_t^l(\Phi_t^{-1}(x)) + \nabla^j \Phi_t^l(\Phi_t^{-1}(x)) d\Phi_t^{-1}(x)_j = 0$. But from the Hamiltonian system (2.1) and the identity (2.11) the last term in (2.12) is

$$\begin{aligned}-\langle v_t(\Phi_t^{-1}(x)), d\Phi_t(\Phi_t^{-1}(x))\rangle &= -\left\langle v_t(\Phi_t^{-1}(x)), v_t(\Phi_t^{-1}(x))dt - \sum_{r=1}^{m_1} A^r(x,t) \circ dw_t^{1r} \right\rangle \\ &= -|\nabla S(x,t) - b(x,t)|^2 dt \\ &\quad + \sum_{r=1}^{m_1} \langle \nabla S(x,t) - b(x,t), A^r(x,t)\rangle \circ dw_t^{1r}.\end{aligned}$$

By replacing this formula in (2.12), we obtain the stochastic Hamilton Jacobi equation (2.10) as required. ■

Lemma 2.3: *Assume that Φ_t satisfies the no caustic condition for $0 \leqslant t \leqslant T(\omega)$ for a.e. $\omega \in \Omega$. Let $S(x,t)$ be defined as above and define $\phi(x,t) = |\det[\partial \Phi_t^{-1}(x)/\partial x]| > 0$. Then for $0 \leqslant t \leqslant T(\omega)$ for a.e. $\omega \in \Omega$ and any $x \in R^n$, $\phi(x,t)$ satisfies the following stochastic continuity equation:*

$$d\phi(x,t) + \operatorname{div}\left\{ \phi(x,t) \left[(\nabla S(x,t) - b(x,t))dt - \sum_{r=1}^{m_1} A^r(x,t) \circ dw_t^{1r} \right] \right\} = 0. \tag{2.13}$$

Proof: We make repeated use of the rule for differentiating determinants $|A|$ with respect to an external parameter u:

$$d_u|A| = \sum_{\alpha,\beta=1}^{n} \frac{\partial |A|}{\partial a_{\alpha\beta}} d_u a_{\alpha\beta} = \sum_{\alpha,\beta=1}^{n} A_{\alpha,\beta} d_u a_{\alpha\beta}, \tag{2.14}$$

where $|A| = \Sigma_{\beta=1}^{n} a_{\alpha\beta} A_{\alpha\beta}$, $A_{\alpha\beta}$ being a cofactor of $a_{\alpha\beta}$ in $|A|$. As we consider the Stratonovich type equation, (2.14) is still valid. Writing

$$\phi = \sum_{\beta=1}^{n} \frac{\partial (\Phi_t^{-1}(x))_\alpha}{\partial x^\beta} X_\beta^\alpha,$$

gives

$$d\phi(x,t) = \sum_{\alpha,\beta=1}^{n} d\frac{\partial (\Phi_t^{-1}(x))_\alpha}{\partial x^\beta} X_\beta^\alpha = \sum_{\alpha,\beta=1}^{n} \frac{\partial d(\Phi_t^{-1}(x))_\alpha}{\partial x^\beta} X_\beta^\alpha. \tag{2.15}$$

Now we consider the equation $\Phi_t^\alpha(\Phi_t^{-1}(x)) = x^\alpha$ and differentiate it with respect to t to give

$$\nabla_\beta \Phi_t^\alpha(\Phi_t^{-1}(x)) d\Phi_t^{-1}(x)^\beta + d\Phi_t^\alpha(\Phi_t^{-1}(x)) = 0. \tag{2.16}$$

But differentiating it with respect to $x^{\alpha'}$ gives

$$\nabla_\beta \Phi_t^\alpha(\Phi_t^{-1}(x)) \frac{\partial \Phi_t^{-1}(x)_\beta}{\partial x^{\alpha'}} = \delta_{\alpha'}^\alpha.$$

Hence we obtain from above

$$[\nabla_\beta \Phi_t^\alpha(\Phi_t^{-1}(x))]_{\alpha\beta}^{-1} = \left[\frac{\partial \Phi_t^{-1}(x)_\beta}{\partial x_0^\alpha}\right]_{\beta\alpha}$$

and so we deduce that

$$\frac{\partial (\Phi_t^{-1}(x))^{\beta'}}{\partial x_\alpha} \nabla_\beta \Phi_t^\alpha(\Phi_t^{-1}(x)) = \delta_\beta^{\beta'},$$

giving in (2.16)

$$d(\Phi_t^{-1}(x))^{\beta'} = -\frac{\partial (\Phi_t^{-1}(x))^{\beta'}}{\partial x^\alpha} d\Phi_t^\alpha(\Phi_t^{-1}(x)). \tag{2.17}$$

Now it turns out from (2.15) that

$$d\phi(x,t) = \sum_{\alpha,\beta=1}^{n} \frac{\partial}{\partial x^\beta}[X_\beta^\alpha d\Phi_t^{-1}(x)_\alpha] - \sum_{\alpha,\beta=1}^{n} \frac{\partial X_\beta^\alpha}{\partial x^\beta} d\Phi_t^{-1}(x)_\alpha.$$

The second term on the right hand side is zero as we now demonstrate. We differentiate the identity

$$\delta_\beta^k \phi = \sum_{\alpha=1}^{n} X_\beta^\alpha \frac{\partial \Phi_t^{-1}(x)_\alpha}{\partial x^k}, \quad \beta,k = 1,2,\cdots,n,$$

partially with respect to x^β and then sum over β to deduce that

$$\frac{\partial}{\partial x^k}\phi=\sum_{\beta=1}^{n}\frac{\partial}{\partial x^\beta}(\delta_\beta^k\phi)=\sum_{\alpha,\beta=1}^{n}X_\beta^\alpha\frac{\partial^2\Phi_t^{-1}(x)_\alpha}{\partial x^\beta\partial x^k}+\sum_{\alpha,\beta=1}^{n}\frac{\partial X_\beta^\alpha}{\partial x^\beta}\frac{\partial\Phi_t^{-1}(x)_\alpha}{\partial x^k}=\sum_{\alpha,\beta=1}^{n}X_\beta^\alpha\frac{\partial^2\Phi_t^{-1}(x)_\alpha}{\partial x^\beta\partial x^k}.$$

Therefore for any $k=1,2,\cdots,n$,

$$\sum_{\alpha,\beta=1}^{n}\frac{\partial X_\beta^\alpha}{\partial x^\beta}\frac{\partial\Phi_t^{-1}(x)_\alpha}{\partial x^k}=0.$$

Multiplying above by $d\Phi_t^k(\Phi_t^{-1}(x))$ and summing over k we have

$$-\sum_{\alpha,\beta=1}^{n}\frac{\partial X_\beta^\alpha}{\partial x^\beta}d\Phi_t^{-1}(x)_\alpha=0,$$

by using (2.17). It turns out from (2.17) again that

$$d\phi(x,t)=\sum_{\alpha,\beta=1}^{n}\frac{\partial}{\partial x^\beta}[X_\beta^\alpha d\Phi_t^{-1}(x)_\alpha]=-\sum_{\alpha,\beta,k=1}^{n}\frac{\partial}{\partial x^\beta}\left(\frac{\partial(\Phi_t^{-1}(x))^\alpha}{\partial x^k}d\Phi_t^k(\Phi_t^{-1}(x))X_\beta^\alpha\right).$$

This gives by using equation (1.1) again and (2.11)

$$\begin{aligned}d\phi(x,t)&=-\sum_{\beta,k=1}^{n}\frac{\partial}{\partial x^\beta}\{\delta_\beta^k\phi(x,t)d\Phi_t^k(\Phi_t^{-1}(x))\}\\&=-\sum_{k=1}^{n}\frac{\partial}{\partial x^k}\{\phi(x,t)d\Phi_t^k(\Phi_t^{-1}(x))\}\\&=-\sum_{k=1}^{n}\frac{\partial}{\partial x^k}\left\{\phi(x,t)\left[v^k(\Phi_t^{-1}(x))dt-\sum_{r=1}^{m_1}A^{kr}(x,t)\circ dw_t^{1r}\right]\right\}\\&=-\operatorname{div}\left\{\phi(x,t)\left[(\nabla S(x,t)-b(x,t))dt-\sum_{r=1}^{m_1}A^r(x,t)\circ dw_t^{1r}\right]\right\}.\end{aligned}$$

Finally we arrive at the result

$$d\phi(x,t)+\operatorname{div}\left\{\phi(x,t)\left[(\nabla S(x,t)-b(x,t))dt-\sum_{r=1}^{m_1}A^r(x,t)\circ dw_t^{1r}\right]\right\}=0,$$

as required. ■

III. STOCHASTIC SCHRÖDINGER EQUATIONS, PASSAGE FROM QUANTUM MECHANICS IN RANDOM ELECTROMAGNETIC FIELDS TO STOCHASTIC CLASSICAL MECHANICS

In this section we consider the Schrödinger equation (1.1) with dH defined by (1.2). This corresponds to situations when quantum particles are subject to random magnetic fields $(\nabla^k b^l-\nabla^l b^k)dt+\Sigma_{r=1}^{m_1}(\nabla^k A^{lr}-\nabla^l A^{kr})\circ dw_t^{1r}$ and random electric fields $-\nabla V dt-\Sigma_{r=1}^{m_2}\nabla K^r\circ dw_t^{2r}$. Here b,A^r $(r=1,2,\cdots,m_1)$ and V,K^r $(r=1,2,\cdots,m_2)$ and $w_t^{(1)},w_t^{(2)}$ are the same as in section I. The sort of noise in our model is white noise in time distributed locally about different points in different directions if $A^r\in C_0^\infty(R^1\times R^n,R^n)$ and $K^r\in C_0^\infty(R^1\times R^n)$. It is this case that physicists are interested in. It could also be a useful model in defence applications.

The following lemma is based on the stochastic Hamilton Jacobi equation and stochastic continuity equations.

Lemma 3.1: *Assume* b, A^r $(r=1,2,\cdots,m_1)$ *and* S_0, V, K^r $(r=1,2,\cdots,m_2)$ *and* $w_t^{(1)}, w_t^{(2)}$ *as above and the stochastic classical flow* Φ_t *defined by (2.1) satisfies the no caustic condition for* $0\leqslant t\leqslant T(\omega)$. *For any* $f\in C^\infty(R^1\times R^n)$ *and for* $0\leqslant t\leqslant T(\omega)$ *define* θ_t *for a.e.* $\omega\in\Omega$ *by*

$$\theta_t(x)=\exp\{iS(x,t)/\hbar\}\phi^{1/2}(x,t)f_t[\Phi_t^{-1}(x)], \tag{3.1}$$

where $S(x,t)$ *and* $\phi(x,t)$ *are defined as above, then* $||\theta_t||_{L^2(R^n)}=||f_t||_{L^2(R^n)}$ *almost surely and for* $0\leqslant t\leqslant T(\omega)$ *and a.e.* $\omega\in\Omega$,

$$\begin{aligned} d\theta_t(x)=&\left[\frac{1}{2}\phi^{-1}(x,t)d\phi(x,t)+i\hbar^{-1}dS(x,t)+f_t^{-1}[\Phi_t^{-1}(x)]df_t[\Phi_t^{-1}(x)]\right]\theta_t(x)\\ &-\exp\{iS(x,t)/\hbar\}\phi^{1/2}(x,t)\nabla_x f_t[\Phi_t^{-1}(x)]\cdot\Bigg((\nabla_x S(x,t)-b(x,t))dt\\ &-\sum_{r=1}^{m_1}A^r(x,t)\circ dw_t^{1r}\Bigg). \end{aligned} \tag{3.2}$$

However $\theta_t\in\mathscr{D}(dH)$ *(the domain of the operator dH), and*

$$\begin{aligned} \frac{idH}{\hbar}\theta_t(-)+d\theta_t(-)=&-\frac{1}{2}i\hbar\exp\{iS(-,t)/\hbar\}\Delta(\phi^{1/2}(-,t)f_t(\Phi_t^{-1}-))dt\\ &+\exp\{iS(-,t)/\hbar\}\phi^{1/2}(-,t)df_t(\Phi_t^{-1}-), \end{aligned} \tag{3.3}$$

where the quantum mechanical Hamiltonian in white noise electromagnetic fields is given by

$$\begin{aligned} dH=&\left(\frac{1}{2}\{-\hbar^2\Delta+2i\hbar b\cdot\nabla+i\hbar(\nabla\cdot b)+b^2\}+V\right)dt+\frac{1}{2}\sum_{r=1}^{m_1}[2i\hbar A^r\cdot\nabla+i\hbar(\nabla\cdot A^r)\\ &+2(b\cdot A^r)]\circ dw_t^{1r}+\sum_{r=1}^{m_2}K^r\circ dw_t^{2r} \end{aligned} \tag{3.4}$$

terms such as $b\cdot\nabla, \nabla\cdot b, b^2(=b\cdot b)$ *and* $A^r\cdot\nabla, \nabla\cdot A^r, b\cdot A^r$ *being multiplication operators.*

In particular for $f_t\equiv T_0\in C^\infty(R^n)$ *being independent of* t, $\theta_t(x)$ *is an approximate solution of stochastic Schrödinger equation in the sense that almost surely*

$$\frac{idH}{\hbar}\theta_t(-)+d\theta_t(-)=-\frac{1}{2}i\hbar\exp\{iS(-,t)/\hbar\}\Delta(\phi^{1/2}(-,t)T_0(\Phi_t^{-1}-))dt,$$

with initial condition $\theta_0(x)=\exp\{iS_0(x)/\hbar\}T_0(x)$, *for* $0\leqslant t\leqslant T(\omega)$.

Proof: The claim $||\theta_t||_{L^2(R^n)}=||f_t||_{L^2(R^n)}$ follows from changing variables in integral $\int_{R^n}|\theta_t(x)|^2dx$ from $x\to x_0=\Phi_t^{-1}(x)$ and the definition of ϕ. To get formula (3.2), firstly

$$\begin{aligned} d\theta_t(x)=&\left[\frac{1}{2}\phi^{-1}(x,t)d\phi(x,t)+i\hbar^{-1}dS(x,t)+f_t^{-1}[\Phi_t^{-1}(x)]df_t[\Phi_t^{-1}(x)]\right]\theta_t(x)\\ &+\exp\{iS(x,t)/\hbar\}\phi^{1/2}(x,t)Df_t[\Phi_t^{-1}(x)]\cdot d\Phi_t^{-1}(x). \end{aligned}$$

We obtain (3.2) by applying formula (2.17) for $d\Phi_t^{-1}(x)$ proved in section II, equations (2.1) and (2.9).

For (3.3), we use the following operator identity:

$$\begin{aligned}\Delta_x \exp\{iS(x,t)/\hbar\}\phi^{1/2}(x,t)-= &\exp\{iS(x,t)/\hbar\}\Delta_x(\phi^{1/2}(x,t)-)+i\hbar^{-1}\exp\{iS(x,t)/\hbar\}\phi^{1/2}(x,t)\\ &\times[\phi^{-1}(x,t)\nabla_x S(x,t)\cdot\nabla_x\phi(x,t)+\Delta_x S(x,t)+i\hbar^{-1}|\nabla_x S(x,t)|^2\\ &+2\nabla_x S(x,t)\cdot\nabla_x]-, \qquad (3.5)\end{aligned}$$

which is easy to prove and gives a rigorous identity when each side is applied to a suitable smooth function such as $f_t(\Phi_t^{-1}(x))$. From above, using

$$dH=(\tfrac{1}{2}\{-\hbar^2\Delta+2i\hbar b\cdot\nabla+i\hbar(\nabla\cdot b)+b^2\}+V)dt+\tfrac{1}{2}\sum_{r=1}^{m_1}[2i\hbar A^r\cdot\nabla+i\hbar(\nabla\cdot A^r)$$

$$+2(b\cdot A^r)]\circ dw_t^{1r}+\sum_{r=1}^{m_2}K^r\circ dw_t^{2r},$$

we obtain

$$\begin{aligned}\frac{idH}{\hbar}\theta_t(x)+d\theta_t(x)=&-\frac{1}{2}i\hbar\exp\{iS(x,t)/\hbar\}\Delta(\phi^{1/2}(x,t)f_t[\Phi_t^{-1}(x)])dt\\ &+\frac{1}{2}\exp\{iS(x,t)/\hbar\}\phi^{1/2}[\phi^{-1}(x,t)\nabla_x S(x,t)\cdot\nabla_x\phi(x,t)+\Delta_x S(x,t)\\ &+i\hbar^{-1}|\nabla_x S(x,t)|^2+2\nabla_x S(x,t)\cdot\nabla_x]f_t[\Phi_t^{-1}(x)]dt-(b\cdot\nabla)\\ &\times\{\exp\{iS(x,t)/\hbar\}\phi^{1/2}(x,t)f_t[\Phi_t^{-1}(x)]\}dt+i\hbar^{-1}\Big\{\frac{i\hbar}{2}\mathrm{div}\,b(x,t)+V\\ &+\frac{b^2}{2}(x,t)\Big\}\exp\{iS(x,t)/\hbar\}\phi^{1/2}(x,t)f_t[\Phi_t^{-1}(x)]dt-\sum_{r=1}^{m_1}(A^r\cdot\nabla)\\ &\times\{\exp\{iS(x,t)/\hbar\}\phi^{1/2}(x,t)f_t[\Phi_t^{-1}(x)]\}\circ dw_t^{1r}+i\hbar^{-1}\Big\{\sum_{r=1}^{m_1}\Big(\frac{i\hbar}{2}\mathrm{div}\,A^r(x,t)\\ &+(b(x,t)\cdot A^r(x,t))\Big)\circ dw_t^{1r}\\ &+\sum_{r=1}^{m_2}K^r(x,t)\circ dw_t^{2r}\Big\}\exp\{iS(x,t)/\hbar\}\phi^{1/2}(x,t)f_t[\Phi_t^{-1}(x)]\\ &+\Big[\frac{1}{2}\phi^{-1}(x,t)d\phi(x,t)+i\hbar^{-1}dS(x,t)+f_t^{-1}[\Phi_t^{-1}(x)]df_t[\Phi_t^{-1}(x)]\Big]\\ &\times\exp\{iS(x,t)/\hbar\}\phi^{1/2}(x,t)f_t[\Phi_t^{-1}(x)]-\exp\{iS(x,t)/\hbar\}\phi^{1/2}\nabla_x f_t[\Phi_t^{-1}(x)]\\ &\cdot\Big((\nabla S(x,t)-b(x,t))dt-\sum_{r=1}^{m_1}A^r(x,t)\circ dw_t^{1r}\Big) \qquad (3.6)\end{aligned}$$

all differentiations ∇ being with respect to x. Now we have

$$(b(x,t)\cdot\nabla)\{\exp\{iS(x,t)/\hbar\}\phi^{1/2}(x,t)f_t[\Phi_t^{-1}(x)]\}dt$$
$$=\exp\{iS(x,t)/\hbar\}\phi^{1/2}(x,t)(b(x,t)\cdot\nabla f_t[\Phi_t^{-1}(x)])dt+(b(x,t)\cdot\nabla)$$
$$\times\{\exp\{iS(x,t)/\hbar\}\phi^{1/2}\}(x,t)f_t[\Phi_t^{-1}(x)]dt$$

and

$$(b\cdot\nabla)\{\exp\{iS/\hbar\}\phi^{1/2}\}dt=\left[i\hbar^{-1}(b\cdot\nabla S)+\frac{1}{2}\phi^{-1}(b\cdot\nabla\phi)\right]\exp\{iS/\hbar\}\phi^{1/2}dt,$$

as well as

$$(A^r(x,t)\cdot\nabla)\{\exp\{iS(x,t)/\hbar\}\phi^{1/2}(x,t)f_t[\Phi_t^{-1}(x)]\}\circ dw_t^{1r}$$
$$=\exp\{iS(x,t)/\hbar\}\phi^{1/2}(x,t)(A^r(x,t)\cdot\nabla f_t[\Phi_t^{-1}(x)])\circ dw_t^{1r}+(A^r(x,t)\cdot\nabla)$$
$$\times\{\exp\{iS(x,t)/\hbar\}\phi^{1/2}\}(x,t)f_t[\Phi_t^{-1}(x)]\circ dw_t^{1r}$$

and

$$(A^r\cdot\nabla)\{\exp\{iS/\hbar\}\phi^{1/2}\}\circ dw_t^{1r}=\left[i\hbar^{-1}(A^r\cdot\nabla S)+\frac{1}{2}\phi^{-1}(A^r\cdot\nabla\phi)\right]\exp\{iS/\hbar\}\phi^{1/2}\circ dw_t^{1r}.$$

Now we consider potentially difficult term in $(i\hbar^{-1})$ in (3.6). This is easily computed to be

$$\left(\frac{1}{2}|\nabla S|^2-b\cdot\nabla S+V+\frac{b^2}{2}\right)dt-\sum_{r=1}^{m_1}A^r\cdot(\nabla S-b)\circ dw_t^{1r}+\sum_{r=1}^{m_1}K^r\circ dw_t^{2r}+dS$$
$$=\left(\frac{1}{2}|\nabla S-b|^2+V\right)dt-\sum_{r=1}^{m_1}A^r\cdot(\nabla S-b)\circ dw_t^{1r}+\sum_{r=1}^{m_2}K^r\circ dw_t^{1r}+dS=0 \tag{3.7}$$

from the stochastic Hamilton Jacobi equation.

Apart from the desired first term in (3.6), the remaining terms in $(i\hbar)^0$ are

$$\frac{1}{2}\exp\{iS/\hbar\}\phi^{1/2}f_t(\Phi_t^{-1}(x))\left[\phi^{-1}\left((\nabla S-b)dt-\sum_{r=1}^{m_1}A^r\circ dw_t^{1r}\right)\cdot\nabla\phi+\left((\Delta S-\operatorname{div}b)dt\right.\right.$$
$$\left.\left.-\sum_{r=1}^{m_1}\operatorname{div}A^r\circ dw_t^{1r}\right)+\phi^{-1}d\phi+2f_t^{-1}(\Phi_t^{-1}(x))df_t(\Phi_t^{-1}(x))\right]$$
$$=\exp\{iS/\hbar\}\phi^{1/2}df_t(\Phi_t^{-1}(x)), \tag{3.8}$$

since ϕ satisfies stochastic continuity equation (2.13). Hence we have proved (3.3). The rest of the lemma follows immediately. ■

In Lemma 3.1 we allow f to be a function of space and time t. The time dependence of f gives us an opportunity to push the approximate solution in the sense of Lemma 3.1 further, i.e., up to any order. The proof works by choosing the right f_t associated with each order and applying (3.3) in Lemma 3.1 such that we have the right cancellations in the summation. We have the following lemma.

Lemma 3.2: *Assume all the conditions in Lemma 3.1 and the same dH. For any* $T_0 \in C^\infty(R^n)$ *being independent of t, define*

$$T_0(-,t)=T_0[-], \tag{3.9}$$

and for $j=1,2,\cdots,m$ *for certain integer* $m\geqslant 0$, *a.e.* $\omega\in\Omega$ *and* $0\leqslant t\leqslant T(\omega)$,

$$T_j(y,t)=\int_0^t(\phi^{-1/2}(-,s)\Delta(\phi^{1/2}(-,s)T_{j-1}(\Phi_s^{-1}-,s)))\Phi_s(y)ds, \tag{3.10}$$

and

$$\theta_t^{(m)}(x)=\exp\{iS(x,t)/\hbar\}\phi^{1/2}(x,t)\sum_{j=0}^{m}\frac{1}{2^j}T_j(\Phi_t^{-1}(x),t)(i\hbar)^j. \tag{3.11}$$

Then $\theta_t^{(m)}\in\mathscr{D}(dH)$ *and* $\theta_t^{(m)}$ *is an approximate solution of the stochastic Schrödinger equation in the sense that*

$$\frac{idH}{\hbar}\theta_t^{(m)}(-)+d\theta_t^{(m)}(-)=-\frac{1}{2^{m+1}}(i\hbar)^{m+1}\exp\{iS(-,t)/\hbar\}\Delta(\phi^{1/2}(-,t)T_m(\Phi_t^{-1}-,t))dt, \tag{3.12}$$

with initial condition $\theta_0(x)=\exp\{iS_0(x)/\hbar\}T_0(x)$ *for a.e.* $\omega\in\Omega$ *and* $0\leqslant t\leqslant T(\omega)$.

Proof: Writing

$$g_j(x,t)=\frac{1}{2^j}\exp\{iS(x,t)/\hbar\}\phi^{1/2}(x,t)T_j(\Phi_t^{-1}(x),t)$$

and applying formula (3.3) in Lemma 3.1 to $g_j(x,t)$ where $f_t(-)=(1/2^j)\,T_j(-,t)$, we obtain

$$\frac{i}{\hbar}dHg_0(x,t)+dg_0(x,t)=-\frac{1}{2}i\hbar\exp\{iS(x,t)/\hbar\}\Delta(\phi^{1/2}(x,t)T_0(\Phi_t^{-1}(x),t))dt,$$

and for $j=1,2,\cdots,m$

$$\begin{aligned}\frac{i}{\hbar}dHg_j(x,t)+dg_j(x,t)=&-\frac{1}{2^{j+1}}i\hbar\exp\{iS(x,t)/\hbar\}\Delta(\phi^{1/2}(x,t)T_j(\Phi_t^{-1}(x),t))dt\\&+\frac{1}{2^j}\exp\{iS(x,t)/\hbar\}\Delta(\phi^{1/2}(x,t)T_{j-1}(\Phi_t^{-1}(x),t))dt.\end{aligned}$$

Therefore it follows obviously that

$$\begin{aligned}&\frac{i}{\hbar}dH\left(\sum_{j=0}^{m}g_j(x,t)(i\hbar)^j\right)+d\left(\sum_{j=0}^{m}g_j(x,t)(i\hbar)^j\right)\\&\quad=-i\hbar\sum_{j=0}^{m}\frac{1}{2^{j+1}}\exp\{iS(x,t)/\hbar\}\Delta(\phi^{1/2}(x,t)T_j(\Phi_t^{-1}(x),t))(i\hbar)^jdt\\&\qquad+\sum_{j=1}^{m}\frac{1}{2^j}\exp\{iS(x,t)/\hbar\}\Delta(\phi^{1/2}(x,t)T_{j-1}(\Phi_t^{-1}(x),t))(i\hbar)^jdt\\&\quad=-\sum_{j=0}^{m}\frac{1}{2^{j+1}}\exp\{iS(x,t)/\hbar\}\Delta(\phi^{1/2}(x,t)T_j(\Phi_t^{-1}(x),t))(i\hbar)^{j+1}dt\end{aligned}$$

$$+\sum_{j=1}^{m}\frac{1}{2^j}\exp\{iS(x,t)/\hbar\}\Delta(\phi^{1/2}(x,t)T_{j-1}(\Phi_t^{-1}(x),t))(i\hbar)^j dt$$

$$=-\frac{1}{2^{m+1}}(i\hbar)^{m+1}\exp\{iS(x,t)/\hbar\}\Delta(\phi^{1/2}(x,t)T_m(\Phi_t^{-1}(x),t))dt.$$

Therefore we have (3.12) as $\theta_t^{(m)}(x)=\Sigma_{j=0}^{m}g_j(x,t)(i\hbar)^j$. ■

Lemma 3.2 does not give us the approximate solution properly. In the following theorem we are going to pass the approximation in Lemma 3.2 to an approximation in $L^2(R^n)$ a.s.

Theorem 3.3: *Assume there exists a unique solution of* $\psi^\hbar(x,t)=\exp\{-i\int_0^t dH/\hbar\}\psi_0^\hbar(x)$ *in* $L^2(R^n,dn)$, *where*

$$dH=(\tfrac{1}{2}\{-\hbar^2\Delta+2i\hbar b\cdot\nabla+i\hbar(\nabla\cdot b)+b^2\}+V)dt$$
$$+\tfrac{1}{2}\sum_{r=1}^{m_1}[2i\hbar A^r\cdot\nabla+i\hbar(\nabla\cdot A^r)+2(b\cdot A^r)]\circ dw_t^{1r}+\sum_{r=1}^{m_2}K^r\circ dw_t^{2r},$$

with $A_t^r(r=1,2,\cdots,m_1), b\in C_0^\infty(R^n,R^n)$ *for any* $t\geqslant 0$, *and* $\psi_0^\hbar(x)=\exp\{iS_0(x)/\hbar\}T_0(x)$, $T_0\in C_0^\infty(R^n)$, S_0,T_0 *being independent of* $\hbar$. *Assume the stochastic flow* $\Phi_s:R^n\to R^n$ *defined by (2.1) satisfies the no caustic condition for* $0\leqslant s\leqslant T(\omega)$ *for a.e.* $\omega\in\Omega$. *Then for each* $t\in[0,T(\omega))$, *as* $\hbar\to 0$

$$\exp\{-iS(x,t)/\hbar\}\psi^\hbar(x,t)\to\phi^{1/2}(x,t)T_0(\Phi_t^{-1}(x)) \tag{3.13}$$

in $L^2(R^n)$ *uniformly in* t *almost surely, if* $\Delta(\phi^{1/2}(-,t)T_0(\Phi_t^{-1}(-))\in L^2(R^n)$ *and* $\int_0^t||\Delta(\phi^{1/2}(-,s)T_0(\Phi_s^{-1}(-))||_{L^2(R^n)}ds<\infty$ *almost surely. Here* $S(x,t)$ *is defined by (2.2) and (2.8) and* $\Phi_t^{-1}(x)$ *is the inverse of the stochastic flow* $\Phi_t:R^n\to R^n$ *and* $\phi(x,t)=|\det(\partial\Phi_t^{-1}(x)/\partial x)|$.

Furthermore, define

$$T_0(-,t)=T_0[-],$$

and for $j=1,2,\cdots,m$ *for certain integer* $m\geqslant 0$ *and* $0\leqslant t\leqslant T(\omega)$

$$T_j(-,t)=\int_0^t(\phi^{-1/2}(-,s)\Delta(\phi^{1/2}(-,s)T_{j-1}(\Phi_s^{-1}-,s)))\Phi(y)ds.$$

Then for a.e. $\omega\in\Omega$ *and* $0\leqslant t\leqslant T(\omega)$,

$$\psi_t^\hbar(x)=\exp\{iS(x,t)/\hbar\}\left[\phi^{1/2}(x,t)\sum_{j=0}^{m}\frac{1}{2^j}T_j(\Phi_t^{-1}(x),t)(i\hbar)^j+R_m(x,t)(i\hbar)^{m+1}\right], \tag{3.14}$$

and

$$||R_m(-,t)||_{L^2(R^n)}\leqslant\frac{1}{2^{m+1}}\int_0^t||\Delta(\phi^{1/2}(-,s)T_m(\Phi_s^{-1}-,s))||_{L^2(R^n)}ds, \tag{3.15}$$

if $\Delta(\phi^{1/2}(-,s)T_m(\Phi_s^{-1}(-),s))\in L^2(R^n)$ *for* $0\leqslant s\leqslant t$ *and*
$\int_0^t||\Delta(\phi^{1/2}(-,s)T_m(\Phi_s^{-1}(-),s))||_{L^2(R^n)}ds<\infty$ *almost surely.*

Proof: For the semi-classical expansion (3.14) and estimate (3.15) first note

$$\frac{idH}{\hbar}(\theta_t^{(m)}-\psi_t)+d(\theta_t^{(m)}-\psi_t)=-\frac{1}{2^{m+1}}(i\hbar)^{m+1}\exp\{iS(-,t)/\hbar\}\Delta(\phi^{1/2}(-,t)T_m(\Phi_t^{-1}-,t))dt,$$

from Lemma 3.2. Therefore by the definition of $L^2(R^n)$ norm

$$\begin{aligned}
d(\theta_t^{(m)}-\psi_t,\theta_t^{(m)}-\psi_t)_{L^2(R^n)}&=d\left(\int_{R^n}(\theta_t^{(m)}-\psi_t)(\overline{\theta_t^{(m)}}-\overline{\psi_t})dx\right)\\
&=\int_{R^n}((d(\theta_t^{(m)}-\psi_t))(\overline{\theta_t^{(m)}}-\overline{\psi_t})+(\theta_t^{(m)}-\psi_t)d(\overline{\theta_t^{(m)}}-\overline{\psi_t}))dx\\
&=\int_{R^n}\frac{i}{\hbar}-(\overline{\theta_t^{(m)}}-\overline{\psi_t})dH(\theta_t^{(m)}-\psi_t)+(\theta_t^{(m)}-\psi_t)\overline{dH}(\overline{\theta_t^{(m)}}-\overline{\psi_t}))\\
&\quad-\frac{1}{2^{m+1}}(i\hbar)^{m+1}\int_{R^n}\exp\{iS(x,t)/\hbar\}\Delta(\phi^{1/2}(x,t)T_m(\Phi_t^{-1}(x),t))\\
&\quad\times(\overline{\theta_t^{(m)}}-\overline{\psi_t})dxdt-\frac{1}{2^{m+1}}(-i\hbar)^{m+1}\int_{R^n}\exp\{-iS(x,t)/\hbar\}\\
&\quad\times\Delta(\phi^{1/2}(x,t)T_m(\Phi_t^{-1}(x),t))(\theta_t^{(m)}-\psi_t)dxdt.
\end{aligned}$$

Here by $\overline{\theta,\psi}$ we denote the complex conjugate of functions θ and ψ and by $\overline{dH}$ we denote the complex conjugate of operator dH. But

$$\begin{aligned}
&\int_{R^n}(-(\overline{\theta_t^{(m)}}-\overline{\psi_t})dH(\theta_t^{(m)}-\psi_t)+(\theta_t^{(m)}-\psi_t)\overline{dH}(\overline{\theta_t^{(m)}}-\overline{\psi_t}))\\
&\quad=\int_{R^n}\frac{1}{2}\{\hbar^2((\overline{\theta_t^{(m)}}-\overline{\psi_t})\Delta(\theta_t^{(m)}-\psi_t)-(\theta_t^{(m)}-\psi_t)\Delta(\overline{\theta_t^{(m)}}-\overline{\psi_t}))\}dxdt\\
&\qquad+\int_{R^n}i\hbar\left(bdt+\sum_{r=1}^{m_1}A^r\circ dw_t^{1r}\right)(-(\overline{\theta_t^{(m)}}-\overline{\psi_t})\nabla(\theta_t^{(m)}-\psi_t)-(\theta_t^{(m)}-\psi_t)\nabla(\overline{\theta_t^{(m)}}-\overline{\psi_t}))dx\\
&\qquad+\int_{R^n}i\hbar\left(\operatorname{div}bdt+\sum_{r=1}^{m_1}\operatorname{div}A^r\circ dw_t^{1r}\right)(-(\theta_t^{(m)}-\psi_t)(\overline{\theta_t^{(m)}}-\overline{\psi_t}))dx\\
&\quad=\frac{1}{2}\hbar^2\int_{R^n}\operatorname{div}((\overline{\theta_t^{(m)}}-\overline{\psi_t})\nabla(\theta_t^{(m)}-\psi_t)-(\theta_t^{(m)}-\psi_t)\nabla(\overline{\theta_t^{(m)}}-\overline{\psi_t}))dxdt\\
&\qquad-i\hbar\int_{R^n}\operatorname{div}\left(\left(bdt+\sum_{j=1}^{m_1}A^r\circ dw_t^{1r}\right)((\theta_t^{(m)}-\psi_t)(\overline{\theta_t^{(m)}}-\overline{\psi_t}))\right)dx=0,
\end{aligned}$$

by the Divergence Theorem.

Now by the Cauchy–Schwarz inequality we have

$$d(\theta_t^{(m)}-\psi_t,\theta_t^{(m)}-\psi_t)_{L^2(R^n)}=-\frac{1}{2^m}\int_{R^n}\Delta(\phi^{1/2}(x,t)T_m(\Phi_t^{-1}(x),t))\mathrm{Re}\{(i\hbar)^{m+1}\exp\{iS(x,t)/\hbar\}$$
$$\times(\overline{\theta_t^{(m)}}-\overline{\psi_t})\}dxdt$$
$$\leqslant\frac{1}{2^m}||\Delta(\phi^{1/2}(-,t)T_m(\Phi_t^{-1}(x),t))||_{L^2(R^n)}$$
$$\times||\mathrm{Re}\{(i\hbar)^{m+1}\exp\{iS(x,t)/\hbar\}(\overline{\theta_t^{(m)}}-\overline{\psi_t})\}||_{L^2(R^n)}dt$$
$$\leqslant\frac{1}{2^m}\hbar^{m+1}||\theta_t^{(m)}-\psi_t||_{L^2(R^n)}$$
$$\times||\Delta(\phi^{1/2}(x,t)T_m(\Phi_t^{-1}(x),t))||_{L^2(R^n)}dt.$$

Therefore solving the ordinary differential equation we have

$$||\theta_t^{(m)}-\psi_t||_{L^2(R^n)}\leqslant\frac{1}{2^{m+1}}\hbar^{m+1}\int_0^t||\Delta(\phi^{1/2}(-,s)T_m(\Phi_s^{-1}(-),s))||_{L^2(R^n)}ds.$$

Note the unitary property of the operator $\exp\{-iS(x,t)/\hbar\}$, therefore

$$||\exp\{-iS(x,t)/\hbar\}(\theta_t^{(m)}-\psi_t)||_{L^2(R^n)}\leqslant\frac{1}{2^{m+1}}\hbar^{m+1}\int_0^t||\Delta(\phi^{1/2}(-,s)T_m(\Phi_s^{-1}(-),s))||_{L^2(R^n)}ds.$$

This leads to the semi-classical expansion (3.14) and estimate (3.15). Claim (3.13) is only a special case of the result proved above. ■

Now let A be any measurable subset of the configuration space R^n and $\tilde{P}^\hbar(A,t)$ be the quantum probability that the quantum mechanical particle is in A at time t. Rewrite (3.14) in Theorem 3.3 to give

$$\psi_t^\hbar(x)=\exp\{iS(x,t)/\hbar\}\Bigg[\phi^{1/2}(x,t)\Bigg(\sum_{j=0}^{r_1}\frac{(-1)^j}{2^{2j}}T_{2j}(\Phi_t^{-1}(x),t)\hbar^{2j}$$
$$+i\sum_{j=0}^{r_2}\frac{(-1)^j}{2^{2j+1}}T_{2j+1}(\Phi_t^{-1}(x),t)\hbar^{2j+1}\Bigg)+R_m(x,t)(i\hbar)^{m+1}\Bigg]. \tag{3.16}$$

Here the integers r_1 and r_2 are defined by: $r_1=\max\{r:2r\leqslant m\}$ and $r_2=\max\{r:2r+1\leqslant m\}$.

According to Born's probabilistic interpretation:

$$\tilde{P}^\hbar(A,t)=\int_A|\psi_\hbar(x,t)|^2dx.$$

We now have an asymptotic expansion of $\tilde{P}^\hbar(A,t)$ as follows:

$$\tilde{P}^\hbar(A,t)=\sum_{j=0}^{m}P_{2j}\hbar^{2j}+\int_A|R_m(x,t)|^2dx\hbar^{2(m+1)}. \tag{3.17}$$

Here $\int_A|R_m(x,t)|^2dx$ is bounded and P_{2j} $(j=0,1,\cdots)$ are given below:

$$P_0(A,t)=\int_{\Phi_t^{-1}A}T_0^2(y,t)dy,$$

$$P_2(A,t)=\int_{\Phi_t^{-1}A}\left(\frac{1}{2^2}T_1^2(y,t)-\frac{1}{2}T_0(y,t)T_2(y,t)\right)dy,$$

$$P_4(A,t)=\int_{\Phi_t^{-1}A}\left(\frac{1}{2^4}T_2^2(y,t)+\frac{1}{2^3}T_0(y,t)T_4(y,t)-\frac{1}{2^3}T_1(y,t)T_3(y,t)\right)dy.$$

In the limit as $\hbar\to 0$ we have

$$\lim_{\hbar\to 0}\widetilde{P}^{\hbar}(A,t)=P_0=\int_{\Phi_t^{-1}A}|\psi_0(y)|^2dy=\widetilde{P}(\Phi_t^{-1}A,0),$$

Φ_t being the classical Hamiltonian flow associated with the stochastic system (2.1). Hence, in the limit as $\hbar\to 0$, the quantum mechanical system in the configuration space R^n, as determined by

$$\frac{idH}{\hbar}\psi_t+d\psi_t=0$$

in random electromagnetic fields can quantum mechanically arrive at only these points which are accessible to the corresponding stochastic classical system. In this sense, stochastic quantum mechanics tends to stochastic classical mechanics on R^n as $\hbar$ tends to zero. This is a simple consequence of the result in this paper.

Moreover, $\hbar^2T_1$ is the integral along the classical sample path of the Bohm's first quantum potential (see Holland[22]). This quantity has the dimensions of action i.e. the dimensions of $\hbar$. The first term in $\hbar^2P_2$ is the ratio of $(\hbar^2T_1)^2$ to $\hbar^2$. By the same token, $\hbar^4T_2T_0$ will have the dimensions of $(\text{action})^2$ i.e. yet again of $\hbar^2$, and the ratio of this quantity to $\hbar^2$ is what appears in $\hbar^2P_2$. We therefore see that the correction to the quantum probability for finding the particle in A at the time t are significant only when these ratios are nonnegligible.

When $A=R^n$, we can prove $P_2(R^n,t)=P_4(R^n,t)=\cdots=P_{2m}(R^n,t)=0$ by using the definition of P_{2j} and T_j. Therefore we have $P^{\hbar}(R^n,t)=P_0(R^n,t)=P^{\hbar}(R^n,0)$. This shows that the semiclassical expansion gives a normalized solution of stochastic Schrödinger equations. Detailed proofs of this and related results will be published in the future.

It is also interesting to note that in a classical inaccessible region A, $P_0(A,t)=0$. Therefore $T_0(-)=0$ almost everywhere in $\Phi_t^{-1}A$. It turns out that $\frac{1}{4}\hbar^2\int_{\Phi_t^{-1}}T_1^2(y,t)dy$ gives us (if the higher order terms are negligible) the probability of finding a quantum mechanical particle in the classical inaccessible region A.

The results in this paper also give the quantization of the stochastic Hamiltonian mechanics studied in Albeverio,[23] Albeverio, Hilbert and Zehnder,[24] and by McKean,[25] Markus and Weerasinghe.[26]

IV. NO CAUSTIC CONDITION

We end this paper by discussing the no-caustic condition. As we have pointed out in section II, the diffeomorphism property of the (stochastic) Hamiltonian system in configuration space is different from that for first order (stochastic) differential equations. The latter equations have been discussed by many people, in particular by Kunita[21] and Elworthy[10] for stochastic differential equations. The Lipschitz condition guarantees the stochastic flow property up to explosion time for first order stochastic differential equations. Unfortunately this is not true for the (stochastic) Hamiltonian system in configuration space. The simplest example is the harmonic oscillator studied in Elworthy, Truman and Zhao:[12] $\ddot{\Phi}_s=-\Phi_s,\Phi_0(x)=x,\dot{\Phi}_0(x)=x$. The solution is given by $\Phi_s(x)=x\cos s+x\sin s$. At $s=\frac{3}{4}\pi$, $\Phi_s(x)=0$, for any $x\in R^1$. That is to say $\Phi_{(3/4)\pi}$ is not a diffeomorphism and the caustic time is $s=\frac{3}{4}\pi$. Therefore a diffeomorphism theorem for (stochastic)

Hamiltonian system in configuration space is needed as clearly caustics are a common feature. In fact we have showed in Truman and Zhao[15] that it is caustics which lead to the random shock waves for inviscid stochastic Burgers' equations. Here we include a simple theorem guaranteeing the absence of caustics.

Theorem 4.1: *Assume* $A_t^r, b_t, (\partial/\partial t)\, b_t \in C_0^\infty(R^n,R^n)$, $V_t, K_t^r, S_0 \in C_0^\infty(R^n)$. *Then there exists* $T(\omega)>0$ *a.s. such that* $\Phi_t(\omega):R^n\to R^n$ *defined by (2.1), is a diffeomorphism for* $0\leqslant s\leqslant T(\omega)$ *for a.e.* $\omega\in\Omega$.

Proof: Integrating second equation of (2.1) we have

$$v_t^k=\nabla^k S_0(x)-b^k(x,0)+Z_t^k+\int_0^t(\nabla^k b_l(\Phi_s,s)-\nabla^l b_k(\Phi_s,s))v_s^l ds$$
$$+\int_0^t\sum_{r=1}^{m_1}\nabla^k A^{lr}(\Phi_s,s)v_s^l\circ dw_s^{1r},$$

where

$$Z_t^k=-\int_0^t\left(\nabla^k V(\Phi_s,s)ds-\sum_{r=1}^{m_2}\nabla^k K^r(\Phi_s,s)dw_s^{2r}-\frac{\partial}{\partial s}b_k(\Phi_s,s)ds\right)-\int_0^t(\nabla^k b_l(\Phi_s,s)$$
$$-\nabla^l b_k(\Phi_s,s))\sum_{r=1}^{m_1}A^{lr}(\Phi_s,s)\circ dw_s^{1r}.$$

For any $T^*>0$, Z_t^k $(k=1,2,\cdots,n)$ is bounded almost surely for any $0\leqslant t\leqslant T^*$. Therefore v_t^k $(k=1,2,\cdots,n)$ is bounded almost surely for any $0\leqslant t\leqslant T^*$. Differentiating (2.1) with respect to space variable x, we know $(\nabla_j\Phi_s^k,\nabla_j v_s^k)$ satisfies stochastic ordinary differential linear equations with $\nabla_j\Phi_0^k(x)=\delta_j^k,\nabla_j v_0^k(x)=\nabla_j(\nabla^k S_0(x)-b^k(x,0))$. Therefore for $0\leqslant t\leqslant T^*$, $(\nabla_j\Phi_s^k,\nabla_j v_s^k)$ are bounded almost surely. Therefore there exists $T(\omega)>0$ a.s. such that for $0\leqslant t\leqslant T(\omega)$ the matrix norm $||\int_0^t\nabla v_s ds-\Sigma_{r=1}^{m_1}\int_0^t(\nabla\Phi_s)^*\nabla A^r(\Phi_s,s)\circ dw_s^{1r}||<1$ a.s. But

$$\nabla\Phi_s=I+\int_0^t\nabla v_s ds-\sum_{r=1}^{m_1}\int_0^t(\nabla\Phi_s)^*\nabla A^r(\Phi_s,s)\circ dw_s^{1r}.$$

By the similar argument to the one in Elworthy and Truman[7] we know for $0\leqslant t\leqslant T(\omega)$, $\Phi_t(\omega)$ is nonsingular a.s. The diffeomorphism follows from the global inverse theorem. (See Ref. 7 for example). ■

Conditional symmetry and spectrum of the one-dimensional Schrödinger equation

R. Z. Zhdanov[a)]

Leibnitzstrasse 10, 38678 Clausthal-Zellerfeld, Germany

(Received 13 December 1995; accepted for publication 8 January 1996)

We develop an algebraic approach to studying the spectral properties of the stationary Schrödinger equation in one dimension based on its high-order conditional symmetries. This approach makes it possible to obtain in explicit form representations of the Schrödinger operator by $n\times n$ matrices for any $n\in\mathsf{N}$ and, thus, to reduce a spectral problem to a purely algebraic one of finding eigenvalues of constant $n\times n$ matrices. The connection to so-called quasiexactly solvable models is discussed. It is established, in particular, that the case, when conditional symmetries reduce to high-order Lie symmetries, corresponds to exactly solvable Schrödinger equations. A symmetry classification of Schrödinger equation admitting nontrivial high-order Lie symmetries is carried out, which yields a hierarchy of exactly solvable Schrödinger equations. Exact solutions of these are constructed in explicit form. Possible applications of the technique developed to multidimensional linear and one-dimensional nonlinear Schrödinger equations are briefly discussed.
 [S0022-2488(96)01807-5]

I. INTRODUCTION

Basic motivation for introducing conditional symmetries (the term ''conditional symmetry'' was suggested for the first time by Fushchych[1–3]), was a necessity to find a symmetry background of a quickly growing variety of exact solutions of nonlinear partial differential equations that could not be obtained within the framework of the classical Lie approach. An intensive search of such solutions was begun independently and almost simultaneously by Fushchych with collaborators (see, Refs. 4,5 and references therein), Clarkson and Kruskal (''the direct reduction method''[6]), Olver and Rosenau (''nonclassical reduction''[7]) and Winternitz and Levi.[8] A number of examples of nonlinear partial differential equations in two, three, and even four dimensions having nontrivial conditional symmetries is growing rapidly. In particular, it has been established by Fushchych, Zhdanov, and Revenko[9–13] that such fundamental equations of the modern quantum field theory as the four-dimensional nonlinear d'Alembert, Dirac, Levi–Leblond, Maxwell, and Yang-Mills equations possess *infinite* conditional symmetries, while their Lie symmetries are finite only.

On the other hand, much less attention is devoted to the study of conditional symmetries of linear differential equations (though the first example of conditional symmetry has been obtained by Bluman and Cole for the one-dimensional linear heat equation[14]). In view of the role played by conditional symmetries in the theory of nonlinear differential equations, one can expect that application of these to linear equations will also be rich in results. In the present paper we establish the rather unexpected (at least for the author) fact that conditional symmetries can be effectively applied to study spectral properties of the stationary Schrödinger equation,

$$\psi_{xx}=(\epsilon+V(x))\psi. \tag{1}$$

In particular, we will prove that it is conditional symmetry that is responsible for a phenom-

enon of so-called ''quasiexact solvability'' of some specific class of equations (1).[15–17] And what is more, the case when conditional symmetries are equivalent to Lie symmetries will be shown to yield exactly solvable Schrödinger equations.

All principal approaches to a construction of (quasi)exactly solvable models (apart from the specific ways of an implementation of these) are based on a possibility to construct a basis $u_1(x)$, $u_2(x),\ldots,u_n(x)$ of some invariant space $\mathscr{V}_n$ of the Schrödinger operator $S=\partial_x^2-V(x)$. This means that there should exist constant $n\times n$ matrix $\|\Lambda_{jk}\|$ such that the following conditions are fulfilled:

$$Su_j(x)\equiv(\partial_x^2-V(x))u_j(x)=\sum_{k=1}^{n}\Lambda_{jk}u_k(x),\quad j=1,2,\ldots,n. \tag{2}$$

Given such functions $u_j(x)$, a procedure for calculating the spectrum of the Schrödinger operator (or, more precisely, a part of the spectrum) is completely algebraic. Let $\mathbf{a}^j=(a_1^j,a_2^j,\ldots,a_n^j)$, $j=1,\ldots,m,m\leqslant n$ be a complete system of eigenvectors of the $n\times n$ matrix $\Lambda=\|\Lambda_{jk}\|_{j,k=1}^{n}$ and $\lambda_1,\ldots,\lambda_m$ be their eigenvalues, namely

$$\sum_{j=1}^{n}\Lambda_{jk}a_j^l=\lambda_l a_k^l,\quad l=1,2,\ldots,m. \tag{3}$$

Then, the function

$$\psi_k(x)=\sum_{j=1}^{n}a_j^k u_j(x) \tag{4}$$

is easily seen to satisfy the equation (1) with $\epsilon=\lambda_k$ under arbitrary $k=1,2,\ldots,m$.

Saying it another way, after being restricted to a linear space $\mathscr{V}_n$ with basis functions $u_1(x),u_2(x),\ldots,u_n(x)$ the Schrödinger operator becomes a matrix operator. Thus, a reduction of a differential operator to a matrix operator takes place. But such a procedure is quite a common routine in the theory of Lie symmetries of differential equations. Indeed, if we restrict a partial differential equation having N independent variables to a subset of its solutions invariant under a one-parameter subgroup of the Lie group admitted by the equation in question, then it is reduced to a partial differential equation with $N-1$ independent variables. Such a procedure is called symmetry reduction of differential equations (for more details, see, e.g., Refs. 4, 18, and 19). Taking $N=1$ (the case of an ordinary differential equation) we obtain as a reduced equation a differential equation with $N=0$, i.e. an algebraic equation!

One of the main aims of the present paper is to show that the idea of symmetry reduction, when formulated in an appropriate way, can be applied effectively to an algebraization of the problem of describing spectrum of the Schrödinger operator.

As mentioned above classical Lie symmetries of partial differential equation do not give all possible reductions. More general symmetries responsible for a possibility of reducing the order of differential equations are conditional symmetries. Roughly speaking, the necessary and sufficient condition providing a possibility to reduce a number of variables in a given partial differential equation is a requirement of conditional invariance (Ref. 20). It will be established that a similar situation takes place for the Schrödinger equation (1). Symmetries providing reducibility of differential equation (1) to a system of algebraic equations of the form (2) are exactly the high-order conditional symmetries introduced independently by Zhdanov and Fushchych[21,22] and Fokas and Liu[23] (also see Refs. 24–26).

It should be emphasized that considerations of the present paper are purely *algebraic*. The method of conditional symmetries making it possible to study spectral properties of the Schrödinger operator S gives no information about analytical properties of the corresponding eigenfunc-

tions. In each specific case such properties of the eigenfunctions obtained as square integrability, asymptotic behavior, singularities, etc. should be studied independently (see, e.g., Ref. 27). The reason is that this method (and group-theoretical, symmetry methods in general) exploits algebraic properties of the solution set of Eq. (1) (or its part) as a whole and, roughly speaking, is independent of analytical properties of specific solutions.

II. CONDITIONAL SYMMETRY OF THE SCHRÖDINGER EQUATION

Consider the nth-order differential operator,

$$Q=\sum_{j=0}^{n} q_j(x)\partial_x^j, \tag{5}$$

where $\partial_x^0=1$, $\partial_x^{j+1}=(d/dx)\partial_x^j$, and functions $q_j(x)$ are supposed to be independent of ϵ.

Following Refs. 28 and 29 we say that Eq. (1) is conditionally invariant with respect to the operator Q if the following operator identity holds:

$$[Q,\partial_x^2-(\epsilon+V(x))]=RQ+P(\partial_x^2-(\epsilon+V(x)). \tag{6}$$

Here $[Q_1,Q_2]\equiv Q_1Q_2-Q_2Q_1$, R, P are some first- and nth-order differential operators, correspondingly. The above operator equality should be understood in the following way: the differential operators on the left- and right-hand sides give the same result when acting on arbitrary $(n+2)$-times continuously differentiable function $f(x)$.

Provided R vanishes, condition (6) is nothing else but a criterion for Eq. (1) to be invariant with respect to the operator Q. In such a case, the operator Q is a generalized (high-order) Lie symmetry operator. But given a condition $R\neq 0$, the operator Q corresponds to high-order conditional symmetry of the Schrödinger equation (1).

It is easy to see that if an equation is conditionally invariant with respect to the operator Q, then it is conditionally invariant with respect to the operator $q(x)Q$ with an arbitrary sufficiently smooth function $q(x)$. Consequently, without loss of generality we can suppose that in (5) $q_n(x)=1$ and consider differential operators of the form

$$Q=\partial_x^n+\sum_{j=0}^{n-1} q_j(x)\partial_x^j. \tag{7}$$

As the coefficients of the operator Q do not depend on ϵ, equality (6) is only possible if $R=r(x)$ and $P=0$ with some sufficiently smooth function $r(x)$. Consequently, the condition (6) is rewritten to become

$$[Q,\partial_x^2-V(x)]=r(x)Q. \tag{8}$$

We call the Schrödinger operator *reducible* if there exist linearly independent functions $u_1(x),\ldots,u_n(x)$ and constants Λ_{jk} such that the conditions (2) are fulfilled. Let us note that this terminology is justified both from the point of view of the classical representation theory and of the symmetry analysis of differential equations. Indeed, conditions (2) mean that the representation space of the operator S contains an invariant subspace and, consequently, the representation is reducible. On the other hand, conditions (2) ensure the reduction of the differential equation (1) to a system of algebraic equations. We will prove an assertion that shows that this is not a simple coincidence but a fundamental fact having a natural symmetry interpretation.

Theorem 1: *The Schrödinger operator $S=\partial_x^2-V(x)$ is reducible if and only if there exists an nth-order differential operator Q of the form (5) such that Eq. (1) is conditionally invariant with respect to Q.*

Proof: The necessity. Let the operator $S=\partial_x^2-V(x)$ be reducible. Then, the conditions (2) hold. As functions $u_j(x)$ are linearly independent, they form a fundamental system of solutions of some nth-order linear ordinary differential equation.[30]

We recall that the fundamental system of solutions of an ordinary differential equation is a maximal set of its particular solutions such that any smooth solution can be represented as a linear combination of these. Provided the order of the ordinary differential equation in question is equal to n, any n linearly independent solutions of it form a fundamental system. Furthermore, having a fundamental system of solutions we can reconstruct the corresponding ordinary differential equation within a multiplication by a function $r(x)$. Consequently, if we fix the coefficient of the nth-order derivative to be equal to 1, then this equation is unique.

Thus, there exists the nth-order differential equation,

$$u^{(n)}(x)+\sum_{j=0}^{n-1}\widetilde{q}_j(x)u^{(j)}(x)=0, \tag{9}$$

such that the functions $u_j(x)$ form a fundamental system of its solutions.

We will prove that Eq. (1) is conditionally invariant with respect to the operator

$$\widetilde{Q}=\partial_x^n+\sum_{j=0}^{n-1}\widetilde{q}_j(x)\partial_x^j.$$

By force of relations (2) the following equalities hold:

$$[\widetilde{Q},\partial_x^2-V(x)]u_j(x)=\widetilde{Q}\{(\partial_x^2-V(x))u_j(x)\}-(\partial_x^2-V(x))\{\widetilde{Q}u_j(x)\}=\widetilde{Q}\left\{\sum_{k=1}^{n}\Lambda_{jk}u_k(x)\right\}=0,$$

for any $j=1,2,\ldots,n$.

Thus, the functions $u_j(x)$ satisfy an ordinary differential equation,

$$[\widetilde{Q},\partial_x^2-(\epsilon+V(x))]u(x)=0, \tag{10}$$

whose order is easily established to be equal to n. Consequently, its fundamental system of solutions consists of n functions. Hence, we conclude that the functions $u_j(x)$ form a fundamental system of solutions of (10). As an ordinary differential equation is determined by its fundamental system uniquely within a multiplication by a function $r(x)$, the relation holds,

$$[\widetilde{Q},\partial_x^2-(\epsilon+V(x))]=r(x)\widetilde{Q},$$

which is the same as what was to be proved.

The sufficiency. Let the Schrödinger equation (1) be conditionally invariant with respect to the operator (7), which means that the condition (8) is fulfilled. Consider an equation,

$$Qu(x)\equiv\left(\partial_x^n+\sum_{j=0}^{n-1}q_j(x)\partial_x^j\right)u(x)=0, \tag{11}$$

as an ordinary differential equation for a function $u(x)$. Clearly, its general solution is represented in the form

$$u(x)=\sum_{j=1}^{n}C_ju_j(x), \tag{12}$$

where C_j are arbitrary constants and $u_1(x),\ldots,u_n(x)$ is a fundamental system of solutions of nth-order ordinary differential equation (11).

From the condition (8) it follows that the Schrödinger operator $S=\partial_x^2-V(x)$ is a symmetry operator for the equation (11), i.e., it transforms each solution of Eq. (11) into another solution of the same equation. Consequently, for any $j=1,2,\ldots,n$ the function $\widetilde{u}_j(x)=(\partial_x^2-V(x))u_j(x)$ satisfy (11). But by definition the fundamental system of solutions of nth-order ordinary differential equation forms a maximal set of its linearly independent solutions, which means that any solution can be represented as a linear combination of functions $u_j(x)$. Thus, there exist such constants Λ_{jk} that functions $u_j(x)$ satisfy relations (2), whence it follows that the corresponding Schrödinger equation is reducible. The theorem is proved.

Note that the proof of theorem is, in fact, independent of the specific form of the Schrödinger operator $S=\partial_x^2-V(x)$. It is straightforward to generalize Theorem 1 to the case of an arbitrary Nth-order differential operator,

$$\widetilde{S}=\sum_{j=0}^{N} f_j(x)\partial_x^j. \tag{13}$$

We give the corresponding assertion without proof.

Theorem 2: *The operator $\widetilde{S}$ in (13) is reducible if and only if there exists nth-order differential operator Q of the form (5) such that equation $\widetilde{S}\psi(x)=0$ is conditionally invariant with respect to Q.*

To illustrate the above statement we consider two examples.

Example 1: Consider the harmonic oscillator Schrödinger equation,

$$\psi_{xx}=(\epsilon+x^2)\psi. \tag{14}$$

As a direct check shows the nth-order differential operator,

$$Q=(\partial_x-x)^n, \tag{15}$$

satisfies the following commutation relation:

$$[Q,\partial_x^2-(\epsilon+x^2)]=2nQ$$

(the easiest way to prove the above formula is to use the mathematical induction method).

Consequently, Eq. (14) is conditionally invariant with respect to the operator Q and we can apply Theorem 1. Integrating equation $Q\psi(x)=0$ yields a basis of the invariant space $\mathscr{V}_n$ of the Schrödinger operator $\partial_x^2-x^2$,

$$e^{-x^2/2},\quad xe^{-x^2/2},\quad x^2e^{-x^2/2},\ldots,x^{n-1}e^{-x^2/2}.$$

It is readily seen that the above functions satisfy relations (2) with $V(x)=x^2$. Calculating eigenvalues (λ_j) and eigenvectors ($\vec{a}^j$) of the corresponding matrix $\|\Lambda_{jk}\|$, we obtain exact solutions of the Schrödinger equation (14) with $\epsilon=\lambda_1,\ldots,\lambda_m$ in the form (4).

Example 2: Let us generalize the previous example as follows. We are looking for the Schrödinger equations (1) conditionally invariant with respect to the nth-order operator, which can be represented as a power of the first-order differential operator, i.e.

$$Q=(a(x)\partial_x+b(x))^{n+1}. \tag{16}$$

By an appropriate transformation of the dependent and independent variables,

$$z=F(x), \quad \varphi(z)=\exp\left(-\int G(x)dx\right)\psi(x),$$

we can transform the operator Q as follows:

$$\widetilde{Q}=\partial_z^{n+1}.$$

After rewriting the initial Schrödinger equation in the new variables $z,\varphi(z)$ we get

$$f(z)\varphi_{zz}+g(z)\varphi_z+(h(z)-\epsilon)\varphi=0,$$

where

$$f(z)=(F'(x))^2, \quad g(z)=F''(x)+2F'(x)G(x),$$

$$h(z)=-V(x)+G'(x)+G^2(x).$$

Commutation relations (8) now read as

$$[\partial_z^{n+1}, f(z)\partial_z^2+g(z)\partial_z+h(z)-\epsilon]=r(z)\partial_z^{n+1}. \tag{17}$$

Computing the commutator on the left-hand side (which is a simple exercise in differential calculus) and equating coefficients of the linearly independent operators ∂_z^j we conclude that the equation (17) is consistent if and only if the functions f,g,h are polynomials in z of the following form:

$$h(z)=A_0-n(B_2+(n-1)C_3)z+C_4(n-1)nz^2,$$

$$g(z)=B_0+B_1z+B_2z^2+2C_4(1-n)z^3,$$

$$f(z)=C_0+C_1z+C_2z^2+C_3z^3+C_4z^4,$$

where $A_0,B_0,B_1,\ldots,C_4$ are arbitrary constants.

Returning back to the initial variables $x,u(x)$ we get the necessary and sufficient conditions for the Schrödinger equation (1) to be conditionally invariant with respect to an operator belonging to the class (16),

$$-V+G'+G^2=A_0-n(B_2+(n-1)C_3)F+C_4(n-1)nF^2,$$

$$F''+2F'G=B_0+B_1F+B_2F^2+2C_4(1-n)F^3,$$

$$(F')^2=C_0+C_1F+C_2F^2+C_3F^3+C_4F^4,$$

whence we derive the form of the potential $V(x)$,

$$V(x)=\frac{v_0+v_1\omega+v_2\omega^2+v_3\omega^3+v_4\omega^4}{16(C_0+C_1\omega+C_2\omega^2+C_3\omega^3+C_4\omega^4)}, \tag{18}$$

$$v_0=4B_0^2-16A_0C_0+8B_1C_0-8B_0C_1+3C_1^2-8C_0C_2,$$

$$v_1=8B_0B_1+16B_2C_0(n+1)-16A_0C_1-16B_0C_2+4C_1C_2+16B_2C_0n+8C_0C_3(2n^2-2n-3),$$

$$v_2=4B_1^2+8B_0B_2+8B_2C_1(2n+1)-16A_0C_2-8B_1C_2+4C_2^2-24B_0C_3+2C_1C_3(8n^2-8n-3)$$
$$-16C_0C_4n(n+2),$$

$$v_3=8B_1B_2-16A_0C_3-16B_1C_3-16B_0C_4(n+1)+16B_2C_2n-16B_0C_4n-8C_1C_4(2n^2+2n-1)$$
$$+4C_2C_3(4n^2-4n+1),$$

$$v_4=4B_2^2+8B_2C_3(2n-1)-16A_0C_4-8B_1C_4(2n+1)+C_3^2(16n^2-16n+3)+8C_2C_4(1-2n^2),$$

and of the function $G(x)$,

$$G(x)=\frac{2B_0-C_1+2(B_1-C_2)\omega+(2B_2-3C_3)\omega^2-4C_4n\omega^3}{4\sqrt{C_0+C_1\omega+C_2\omega^2+C_3\omega^3+C_4\omega^4}}.$$

In the above formulas, $\omega(x)$ is an elliptic function determined by the quadrature

$$\int^{\omega(x)}\frac{d\tau}{\sqrt{C_0+C_1\tau+C_2\tau^2+C_3\tau^3+C_4\tau^4}}=x.$$

Furthermore, exact solutions of the Schrödinger equation with the potential (18) read as

$$\psi(x)=\exp\left(\int G(x)dx\right)\sum_{j=0}^{n}a_j\omega(x)^j,$$

where $\mathbf{a}=(a_0,a_1,\ldots,a_n)$ is an eigenvector of some $(n+1)\times(n+1)$ constant matrix whose entries are linear combinations of the parameters $A_0,B_0,B_1,\ldots,C_4$ (we omit the corresponding formulas).

Thus, we arrived at the nine-parameter family of quasiexactly solvable Schrödinger equations obtained by Turbiner and Shifman within the framework of their Lie algebraic approach[15,16] and by Ushveridze by means of a more general analytic approach. A detailed account of properties of the Schrödinger equation with potentials (18) can be found in the monograph.[17] We restrict ourselves to noting that if we choose in the above formulas $B_2=C_3=C_4=0$, then the potential $V(x)$ does not depend on n (the order of the operator Q) and, consequently, the corresponding Schrödinger equation is exactly solvable. Thus, the well-known six-parameter family of exactly solvable Schrödinger equations is obtained. In particular, choosing $C_1=C_2=C_3=C_4=0$, $C_0=1$ yields the harmonic oscillator Schrödinger equation (14).

Now let us pass from particular examples to the general case in order to examine which constraints are imposed on the coefficients of the operator (7) by the requirement of conditional invariance (8). In order to compute the commutator on the left-hand side of (8) we use the following identity:

$$[\partial_x^k,f(x)]=\sum_{j=0}^{k-1}C_k^jf^{(k-j)}(x)\partial_x^j,\quad k\in\mathbf{N},\tag{19}$$

where $C_k^j=k!(j!(k-j)!)^{-1}$ are binomial coefficients, which is established by the mathematical induction method with the help of the evident identity,

$$[\partial_x^{k+1},f(x)]\equiv\partial_x[\partial_x^k,f(x)]+f'(x)\partial_x^k.$$

Taking into account formula (19) we rewrite relation (8) as follows:

$$-\sum_{j=0}^{n-1} C_n^j V^{(n-j)} \partial_x^j - \sum_{i=1}^{n-1} \sum_{j=0}^{i-1} q_i C_i^j V^{(i-j)} \partial_x^j - \sum_{j=0}^{n-1} (2q_j' \partial_x + q_j'') \partial_x^j = r(x) \left(\partial_x^n + \sum_{j=0}^{n-1} q_j \partial_x^j \right).$$

Comparing the coefficients of ∂_x^n on the left- and right-hand sides of the above equation we conclude that $r(x) = -2q_{n-1}'$. Comparing the coefficients of the linearly independent operators $\partial_x, \partial_x^2, \ldots, \partial_x^{n-1}$, we arrive at the following system of nonlinear ordinary differential equations for the functions $q_0(x), q_1(x), \ldots, q_{n-1}(x), V(x)$:

$$2q_{j-1}' + q_j'' + C_n^j V^{(n-j)} + \sum_{i=j+1}^{n-1} q_i C_i^j V^{(i-j)} - 2q_{n-1}' q_j = 0, \tag{20}$$

where $j = 0,1,\ldots,n-1$ and by convention $q_{-1} \overset{\text{def}}{=} 0$, $q_n \overset{\text{def}}{=} 1$.

Thus, we have n equations for $n+1$ functions, which means that the system (20) is underdetermined. As an immediate consequence of this fact we conclude that *any* Schrödinger equation (1) is reducible. Indeed, fixing in an arbitrary way a function $V = V(x)$ yields a second-order system of n ordinary differential equations for n functions $q_0(x), q_1(x), \ldots, q_{n-1}(x)$. Each solution of such a system gives rise to an operator Q satisfying by construction condition (8). Consequently, the conditions of Theorem 1 can be fulfilled with any choice of the potential $V(x)$.

Let us demonstrate how the results obtained can be used to study the spectral properties of the Schrödinger equation. Remarkably, to this end we do not need an explicit form of solution of the system of nonlinear ordinary differential equations (20). It suffices to know initial values of the functions $q_j(x)$ and of their first derivatives $q_j'(x)$ at some point $x = x_0 \in \mathbf{R}$. We denote these as follows:

$$q_j(x_0) = A_{j+1}, \quad q_j'(x_0) = B_{j+1}, \quad j = 0,1,\ldots,n-1. \tag{21}$$

All the information about spectral properties of the Schrödinger operator restricted to an invariant space $\mathscr{V}_n$ with basis elements $u_1(x), u_2(x), \ldots, u_n(x)$ is contained in the matrix $\|\Lambda_{jk}\|$, which determines a transformation law (2) for the functions $u_j(x)$ with respect to the action of the Schrödinger operator S.

Let Q be a differential operator of the order n satisfying condition (8) with some choice of the function $V(x)$. Then, by force of Theorem 1, an invariant space $\mathscr{V}_n$ of the corresponding Schrödinger operator S is spanned by the fundamental system of solutions of the nth-order ordinary differential equation,

$$u^{(n)}(x) + \sum_{j=0}^{n-1} q_j(x) u^{(j)}(x) = 0. \tag{22}$$

We denote this system as $\{u_1(x), u_2(x), \ldots, u_n(x)\}$. As any n linearly independent solutions of Eq. (22) form a fundamental system of solutions, there is a freedom in the choice of the functions $u_j(x)$. We fix these by imposing initial conditions.

Let $\|L_{jk}\|$ be a constant nonsingular $n \times n$ matrix. Consider the following n Cauchy problems:

$$u_k^{(n)}(x)+\sum_{j=0}^{n-1} q_j(x)u_k^{(j)}(x)=0, \quad k=1,\ldots,n,$$
$$u_k^{(j-1)}(x_0)=L_{kj}, \quad k,j=1,\ldots,n. \tag{23}$$

It is well known from the general theory of linear differential equations that the above system has a unique solution, and what is more, this solution yields a fundamental system of solutions of Eq. (22).

Differentiating relations (2) $n-1$ times with respect to x and excluding the nth and the $(n+1)$th derivatives of the functions $u_j(x)$ with the help of Eqs. (23) we arrive at the following relations:

$$\sum_{k=1}^{n} \Lambda_{jk}u_k^{(i)}=u_j^{(i+2)}-\sum_{k=0}^{i} C_i^k V^{(i-k)}u_j^{(k)},$$
$$\sum_{k=1}^{n} \Lambda_{jk}u_k^{(n-2)}=-\sum_{k=0}^{n-1} q_k u_j^{(k)}-\sum_{k=0}^{n-2} C_{n-2}^k V^{(n-k-2)}u_j^{(k)}, \tag{24}$$
$$\sum_{k=1}^{n} \Lambda_{jk}u_k^{(n-1)}=\sum_{k=0}^{n-1} (q_{n-1}q_k-q_k'-q_{k-1}-C_{n-1}^k V^{(n-k-1)})u_j^{(k)},$$

where $j=1,\ldots,n$, $i=0,\ldots,n-3$ and as above $q_{-1}\overset{\text{def}}{=}0$.

Choosing $x=x_0$ in (24) yields

$$\sum_{k=1}^{n} \Lambda_{jk}L_{ki}=\sum_{k=1}^{n} L_{jk}R_{ki}, \quad j,i=1,\ldots,n,$$

where

$$R_{ki}=\delta_{ki+2}-C_{i-1}^{k-1}V^{(i-k)}(x_0), \quad i=1,\ldots,n-2,$$
$$R_{kn-1}=-A_k-C_{n-2}^{k-1}V^{(n-k-1)}(x_0), \tag{25}$$
$$R_{kn}=A_nA_k-B_k-A_{k-1}-C_{n-1}^{k-1}V^{(n-k)}(x_0).$$

In formulas (25), the index k runs from 1 to n, A_k, B_k are constants defined by (21), and δ_{kj} is the Kronecker symbol.

Rewriting the formulas obtained in the matrix form, we have $\Lambda L=LR$, where Λ, L, R are constant $n\times n$ matrices with entries $\Lambda_{jk}, L_{jk}, R_{jk}$, respectively. Hence, we derive the explicit form of the matrix Λ,

$$\Lambda=LRL^{-1}. \tag{26}$$

Thus we have proved the following assertion.

Theorem 3: *Let L be an arbitrary invertible $n\times n$ matrix, and $A_1,\ldots,A_n,B_1,\ldots,B_n$ be arbitrary constants. Then, for any choice of the function $V(x)$ there exist n functions $u_1(x),\ldots,u_n(x)$ such that the relations (2) hold, Λ_{jk} being the entries of the $n\times n$ matrix given by formulas (25), (26).*

The above theorem has as a consequence the following important assertion that describes a finite part of the spectrum of the Schödinger operator S.

Theorem 4: *Let* $\lambda_1,...,\lambda_m$ *be distinct eigenvalues of the matrix* $\|R_{jk}\|$ *determined by formulas (25). Then, for any choice of parameters* A_j, B_j *there exist linearly independent functions* $\psi_1(x),\ldots,\psi_m(x)$ *satisfying the Schrödinger equation (1) with* $\epsilon=\lambda_1$, $\epsilon=\lambda_2,...,$ $\epsilon=\lambda_m$ *correspondingly*.

The proof follows from Theorem 2 if one takes into account that the matrix Λ is similar to R and, consequently, has the same eigenvalues λ_1, $\lambda_2,...,\lambda_m$. The explicit form of the functions $\psi_1(x),\ldots,\psi_m(x)$ is given by the formula (4), where $\mathbf{a}^j=(a_1^j,a_2^j,\ldots,a_n^j)$, $j=1,\ldots,m$ are eigenvectors of the matrix Λ corresponding to the eigenvalues λ_1, $\lambda_2,...,\lambda_m$.

Thus, using the conditional symmetry approach we were able not only to calculate the spectrum of the Schrödinger operator $S=\partial_x^2-V(x)$ but also to construct in an explicit form a $2n$-parameter family of matrix representations of S.

As is seen from formulas (25), (26), there is a large freedom in choice of the matrix Λ. First, it depends on $2n$ arbitrary constants A_j, B_j, which fix a fundamental system of solutions of ordinary differential equation (22). Consequently, choosing specific constants A_j, B_j means fixing a representation space $\mathscr{V}_n$. Second, it contains an arbitrary constant $n\times n$ matrix L. The appearance of the matrix L in the definition of Λ reflects a freedom in choosing a basis of the representation space $\mathscr{V}_n$. Indeed, if $u_1(x),\ldots,u_n(x)$ is a basis of the space $\mathscr{V}_n$, then the functions $\Sigma_{k=1}^n L_{jk}u_k(x)$ also form a basis with an arbitrary invertible constant $n\times n$ matrix $\|L_{jk}\|$. That is why choosing a specific matrix L results in fixing a basis of the representation space $u_1(x,\ldots,u_n(x)$. This freedom can be used, in particular, to obtain an orthogonal basis for $\mathscr{V}_n$ (to this end one should apply the standard Gram–Schmidt orthogonalization procedure).

But representations of the Schrödinger operator in these bases are equivalent, which is readily seen from the formula (26).

Thus, it is established that *any* Schrödinger equation has n-dimensional invariant spaces $\mathscr{V}_n$ with arbitrary $n\in\mathbf{N}$. Furthermore, we have constructed the $2n$-parameter family of matrix representations of the corresponding Schrödinger operator in these spaces [the formulas (25), (26)]. But to obtain an explicit form of the basis of $\mathscr{V}_n$ we still have

•to integrate system of nonlinear ordinary differential equations (20), and

•to construct the general solution of the nth-order ordinary differential equation (22).

We will demonstrate that using a simple trick we may avoid the necessity to integrate Eq. (22). The said trick is based on the fact that we need not all solutions of (22), but only those that simultaneously satisfy the initial Schrödinger equation (1). This means that we have to solve the following overdetermined system of two ordinary differential equations:

$$\psi_{xx}=(\epsilon+V(x))\psi, \quad \psi^{(n)}(x)+\sum_{j=0}^{n-1} q_j(x)\psi^{(j)}(x)=0. \tag{27}$$

Using the first equation and its differential consequences up to the order $n-2$ we can exclude from the second equation all the derivatives of the function ψ of the order $j>1$ and rewrite system (27) in the following equivalent form:

$$\psi_{xx}=(\epsilon+V(x))\psi, \quad \left(\sum_{i=0}^{N} a_i(x)\epsilon^i\partial_x+\sum_{i=0}^{N} b_i(x)\epsilon^i\right)\psi=0, \tag{28}$$

where $N=[n/2], a_i(x), b_i(x)$ are linear combinations of the functions $q_j(x)$ with coefficients depending on $V(x)$ and its derivatives (and, consequently, independent of ϵ), and, furthermore, $a_N=1$ if $n=2N+1$ and $a_N=0, b_N=1$ if $n=2N$.

The compatibility condition for the above system reads as

$$\left(\frac{\Sigma_{i=0}^N b_i(x)\epsilon^i}{\Sigma_{i=0}^N a_i(x)\epsilon^i}\right)_x-\left(\frac{\Sigma_{i=0}^N b_i(x)\epsilon^i}{\Sigma_{i=0}^N a_i(x)\epsilon^i}\right)^2+V(x)+\epsilon=0. \tag{29}$$

As functions a_i, b_i are independent of ϵ, coefficients of the powers of ϵ should be independent of x. This requirement yields the following.

(1) $2N+1$ ordinary differential equations,

$$\sum_{i+j=k}(b_i'a_j-b_ia_j'-b_ib_j+Va_ia_j)+\sum_{i+j=k-1}a_ia_j=C_k, \tag{30}$$

where $k=0,1,\ldots,2N$, for $2N+2$ functions $a_0,\ldots,a_{N-1},b_0,\ldots,b_N,V$, provided $n=2N+1$; or

(2) $2N$ ordinary differential equations of the form (30), with k taking the values $0,1,\ldots,2N-1$ for $2N+1$ functions $a_0,\ldots,a_{N-1},b_0,\ldots,b_{N-1},V$, provided $n=2N$.

In (30), C_j are arbitrary constants.

Provided conditions (30) are fulfilled, the compatibility condition (29) reduces to an algebraic equation,

(1) under $n=2N+1$,

$$\epsilon^{2N+1}+\sum_{j=0}^{2N}C_j\epsilon^j=0; \tag{31}$$

(2) under $n=2N$,

$$\epsilon^{2N}+\sum_{j=0}^{2N-1}C_j\epsilon^j=0; \tag{32}$$

and the general solution of system (28) is given by the quadrature

$$\psi(x)=\exp\left\{-\int\left(\frac{\sum_{i=0}^{N}b_i(x)\epsilon^i}{\sum_{i=0}^{N}a_i(x)\epsilon^i}\right)dx\right\}. \tag{33}$$

It should be noted that Eqs. (31), (32) are nothing else but characteristic equations for the matrix R defined by (25). Their solutions $\lambda_1,\ldots,\lambda_m$ are eigenvalues and $\psi_1(x)=\psi(x)|_{\epsilon=\lambda_1},\ldots,\psi_m(x)=\psi(x)|_{\epsilon=\lambda_m}$ are eigenfunctions of the corresponding Schrödinger operator $S=\partial_x^2-V(x)$.

III. SYMMETRY AND EXACT SOLVABILITY

To the best of our knowledge, the first paper, where a systematic study of high-order Lie symmetries of the Schrödinger equations with nonvanishing potentials has been undertaken, is the one by Nikitin, Onufriychuk, and Fushchych.[31] In particular, for several one-dimensional exactly solvable models third-order symmetry operators were constructed. Furthermore, it was conjectured that exact integrability of the Schrödinger equation (1) is intimately connected with its symmetry properties. This conjecture has been confirmed in Ref. 24, where a number of exactly solvable potentials were obtained by means of third-order symmetries of (1) and, furthermore, a method for integrating the corresponding Schrödinger equations was suggested. Using a technique developed in the previous section we will demonstrate how to derive exact integrability of Eq. (1) from its symmetry properties in the class of arbitrary order symmetry operators.

The nth-order operator Q of the form (5) is a symmetry operator of Eq. (1) if the condition (2) is satisfied with $r(x)=0$. As coefficients of Q are independent of ϵ, equality (2) is only possible when $P\equiv 0$. Computing the commutator on the left-hand side of (2) with $r=0$, $P=0$, and equating to zero the coefficients of ∂_x^{n+1} and ∂_x^n, we conclude that $q_n(x)=\text{const}$, $q_{n-1}(x)=\text{const}$. Consequently, any nth-order symmetry operator admitted by the Schrödinger equation (1) can be represented in the form (5) with $q_n=C=\text{const}\neq 0$, $q_{n-1}=C_0=\text{const}$.

First, following Ref. 24 we will consider in more detail the third-order symmetry operators admitted by the Schrödinger equation (1). These are the lowest-order symmetry operators not equivalent to usual first-order Lie symmetries. The general form of a third-order symmetry operator is as follows (we choose $C=1$):

$$Q=\partial_x^3+C_0\partial_x^2+q_1(x)\partial_x+q_0(x), \tag{34}$$

where $q_0(x),q_1(x)$ are sufficiently smooth functions to be determined from the invariance condition (2) with $n=3$, $r=P=0$. A short computation yields the following expressions for the coefficients of the operator Q:

$$q_0(x)=C_2-C_0V(x)-\tfrac{3}{4}V'(x), \quad q_1(x)=C_1-\tfrac{3}{2}V(x),$$

where $V(x)$ is an arbitrary solution of the third-order nonlinear ordinary differential equation,

$$-4C_1V'+6VV'-V^{(3)}=0. \tag{35}$$

Integrating twice the above equation we arrive at the first-order ordinary differential equation integrable in elliptic functions,

$$C_4+2C_3V(x)+4C_1V(x)^2-2V(x)^3+V'(x)^2=0. \tag{36}$$

It was established in Ref. 24 that particular cases of almost all exactly solvable potentials that can be expressed in elementary functions, such as the trigonometric and hyperbolic Pöschel–Teller, Eckart, Kratzer potentials, potential well of finite and infinite depth, are obtained as solutions of the equation (36).

This fact implies an existence of an intimate connection between high-order Lie symmetries and exact solvability of the Schrödinger equations. In what follows we will show that this is not simply a conjecture but a fundamental fact, making it possible to classify exactly solvable models and to construct their exact solutions in an explicit form (see, also Refs. 24 and 25).

It is straightforward to check that if Q is a Lie symmetry of the Schrödinger equation (1), then $\widetilde{Q}=Q+P(\partial_x^2-V(x)-\epsilon)$, where P is an arbitrary differential operator, is also its Lie symmetry. Furthermore, systems of ordinary differential equations,

$$(\partial_x^2-V(x)-\epsilon)\psi(x)=0, \quad Q\psi(x)=0,$$

and

$$(\partial_x^2-V(x)-\epsilon)\psi(x)=0, \quad \widetilde{Q}\psi(x)=0,$$

are equivalent in a sense that they have the same solutions. Making use of these facts we can reduce the nth-order symmetry operator Q to a first-order symmetry operator, the coefficients of which are Nth-order polynomials in ϵ (we will preserve the same designation Q for the reduced operator),

$$Q=a(x,\epsilon)\partial_x+b(x,\epsilon)\equiv\left(\sum_{j=0}^{N}a_j(x)\epsilon^j\right)\partial_x+\sum_{j=0}^{N}b_j(x)\epsilon^j. \tag{37}$$

From the invariance condition for the reduced operator,

$$[\partial_x^2-V(x)-\epsilon,a(x,\epsilon)\partial_x+b(x,\epsilon)]=R(x,\epsilon)(\partial_x^2-V(x)-\epsilon),$$

we get a system of determining equations for the coefficients of Q,

$$a''(x,\epsilon)+2b'(x,\epsilon)=0,$$

$$b''(x,\epsilon)+a(x,\epsilon)V'(x)+2a'(x,\epsilon)(V(x)+\epsilon)=0,$$

where primes denote differentiation with respect to x.

Splitting the above equations by powers of ϵ with subsequent integrating yields

$$b_j(x)=-\frac{1}{2}a_j'(x)+B_j, \quad a_N(x)=A_N,$$
$$a_{j-1}(x)=\frac{1}{4}a_j''(x)-V(x)a_j(x)+\frac{1}{2}\int V'(x)a_j(x)dx+A_{j-1}. \tag{38}$$

In (38), A_{-1},A_j,B_j are arbitrary constants, $j=0,1,\ldots,N$, $a_{-1}(x)\overset{\text{def}}{=}0$.

Thus, the problem of describing nth-order symmetry operators of the Schrödinger equation is reduced to solving the recurrent relations,

$$a_{j-1}(x)=\frac{1}{4}a_j''(x)-V(x)a_j(x)+\frac{1}{2}\int V'(x)a_j(x)dx+A_{j-1}, \tag{39}$$

with $a_N(x)=A_N=\text{const}$, $a_{-1}(x)\overset{\text{def}}{=}0$, $j=N,N-1,\ldots,0$.

The first N relations ($j=N,N-1,\ldots,1$) are solved by subsequent integrations yielding the expressions for the functions $a_0(x),\ldots,a_{N-1}(x)$ via the function $V(x)$ and its derivatives. Substituting these results into the last equation ($j=0$) we arrive at the $2N$th-order nonlinear ordinary differential equation for the function $V(x)$. It will be shown that any solution of this equation gives rise to an exactly solvable Schrödinger equation (1).

To reveal the structure of the equation in question we introduce the new functions $U_0(x),U_1(x),\ldots$, by the following recurrence relation:

$$U_j(x)=XU_{j-1}(x)\equiv(\tfrac{1}{4}\partial_x^2-V(x)+\tfrac{1}{2}\partial_x^{-1}V'(x))U_{j-1}, \quad j=0,1,\ldots, \tag{40}$$

where ∂_x^{-1} denotes integration with respect to x and $U_{-1}(x)\overset{\text{def}}{=}1$.

Formally, a definition of functions $U_j(x)$ contains a quadrature but integrating relations (40) successively we can get rid of it for any $j=1,2,3,\ldots$. Below, we adduce expressions of the functions $U_j(x)$ for $j=0,1,2,3$,

$$U_0(x)=-\frac{1}{2}V(x), \quad U_1(x)=\frac{1}{2^3}(3V(x)^2-V''(x)),$$

$$U_2(x)=\frac{1}{2^5}(-10V(x)^3+5V'(x)^2+10V(x)V''(x)-V^{(4)}(x)),$$

$$U_3(x)=\frac{1}{2^7}(35V(x)^4-70V(x)V'(x)^2-70V(x)^2V''(x)+21V''(x)^2+28V'(x)V^{(3)}(x)$$
$$+14V(x)V^{(4)}(x)-V^{(6)}(x)).$$

Now we can solve the first N relations of (39) in terms of the functions $U_j(x)$,

$$a_{N-j}(x)=\sum_{k=0}^{j-1}A_{N-k}U_{j-k-1}(x)+A_{N-j}, \quad j=1,\ldots,N. \tag{41}$$

Inserting the above expressions into the last equation of (39), we get

$$A_{-1}+\sum_{k=0}^{N} A_{N-k}U_{N-k}(x)=0 \tag{42}$$

[when deriving the above equation we take into account that by convention $a_{-1}(x)=0$].

Equation (42) is the necessary and sufficient condition for the Schrödinger equation (1) to be invariant with respect to the first-order operator (37), whose coefficients are polynomials in ϵ of the order N. But it is easy to see that given a condition (42), Eq. (1) admits an operator of the form (37), whose coefficients are polynomials in ϵ of an arbitrary order $N'>N$.

Indeed, the invariance conditions for the operator,

$$Q=\left(\sum_{j=0}^{N'} a_j(x)\epsilon^j\right)\partial_x+\sum_{j=0}^{N'} b_j(x)\epsilon^j,$$

have the form (38) with $N=N'$. Coefficients $a_j(x)$ with $j=N',N'-1,\ldots,N'-N$ are given by formulas (41), where one should replace N by N', and the remaining coefficients by force of relation (42) read as

$$a_j(x)=\sum_{k=0}^{N-1}\tilde{A}_{jk}U_k(x)+A_j, \quad j=0,1,\ldots,N'-N-1,$$

where $A_0,\ldots,A_{N'-N-1}$ are arbitrary constants, $\tilde{A}_{jk}$ are constants expressed via $A_{N'-N},\ldots,A_{N'}$.

Substituting these results into the last ($j=0$) equation from (41) yields

$$A_{-1}+A_0U_0(x)+\sum_{k=0}^{N-1}\tilde{A}_{0k}U_{k+1}(x)=0,$$

whence we conclude that, provided $A_{-1}=A_0=0$, $\tilde{A}_{0k}=0$, $k=0,1,\ldots,N-1$, the invariance conditions are satisfied.

Thus, if Eq. (42) is fulfilled with some $N\in\mathbf{N}$, then the corresponding Schrödinger equation admits arbitrary-order Lie symmetries and, consequently, is exactly solvable.

A general solution of the Schrödinger equation invariant under the operator Q is given by (33). Substituting formula (33) into Eq. (1), where $V(x)$ is an arbitrary solution of (42), results in a $(2N+1)$th-order algebraic equation for ϵ. Its solutions $\epsilon=\lambda_1,\ldots,\epsilon=\lambda_m$ are eigenvalues of the Schrödinger operator. Corresponding eigenfunctions are obtained if we insert $\epsilon=\lambda_1,\ldots,\epsilon=\lambda_m$ into (33).

Summing up, we conclude that any solution $V(x)$ of (42) gives rise to an exactly solvable Schrödinger equation. In what follows it will be established that the more strong assertion holds. Namely, if $V(x)$ is a solution of (42) with some N, then the corresponding Schrödinger equation may have an *arbitrary* spectrum.

Theorem 5: *Let $V=V(x)$ be a solution of ordinary differential equation (42) with some fixed $N\in\mathbf{N}$. Then, the Schrödinger equation (1) is exactly solvable and, moreover, the Schrödinger operator $S=\partial_x^2-V(x)$ may have an arbitrarily prescribed spectrum.*

Proof: We will give the principal steps of the proof, omitting technical details. As the potential $V(x)$ satisfies Eq. (42), the corresponding Schrödinger equation admits a Lie symmetry of the form (37). Excluding from (37) the parameter ϵ we recover symmetry operator Q of the order $n=2N+1$ that commutes with the Schrödinger operator S. Next, we construct an operator $Q_1=Q+f(\epsilon)$, where $f(\epsilon)$ is an arbitrary smooth function. Evidently, Q_1 commutes with S and,

consequently, is a symmetry operator of the Schrödinger equation. This means that conditions of Theorem 1 are fulfilled and a fundamental system of solutions of the ordinary differential equation,

$$Q_1 u(x)=0$$

forms a basis of the invariant space $\mathscr{V}_n$ of the corresponding Schrödinger operator S. Representation of S in the space V_n is given by the formulas (25), (26), where $A_1=a+f(\epsilon)$ and parameters $a,A_2,\ldots,A_n,B_1,\ldots,B_N$ are independent of $f(\epsilon)$. Eigenvalues of the operator S are solutions of the characteristic equation for the matrix R having the entries (25), i.e. of the equation

$$\det\|R_{jk}-\epsilon\delta_{jk}\|=0.$$

It is not difficult to become convinced of that the above equation can be represented in the form

$$p_0(\epsilon)+p_1(\epsilon)f(\epsilon)+p_2(\epsilon)f(\epsilon)^2=0,$$

where p_0,p_1,p_2 are polynomials in ϵ of the order not higher than n.

Consequently, zeros of the function

$$F(\epsilon)=p_0(\epsilon)+p_1(\epsilon)f(\epsilon)+p_2(\epsilon)f(\epsilon)^2$$

are eigenvalues of the Schrödinger operator.

As $f(\epsilon)$ is arbitrary, the function $F(\epsilon)$ may have an arbitrarily prescribed set of zeros and, thus, a spectrum of the initial Schrödinger equation (1) may be arbitrary.

As an illustration, we will consider the simplest case when there exists such N_1 that $U_{N_1}(x)=0$. In such a case, the coefficients of the symmetry operator (37) with $N=kN_1$, $k\in\mathbf{N}$ are easily shown to be

$$a(x,\epsilon)=\left(\sum_{j=-1}^{N_1-1}U_j(x)\epsilon^{N_1-j-1}\right)\left(\sum_{j=0}^{k}A_j\epsilon^j\right),$$

$$b(x,\epsilon)=-\frac{1}{2}\left(\sum_{j=-1}^{N_1-1}U_j'(x)\epsilon^{N_1-j-1}\right)\left(\sum_{j=0}^{k}A_j\epsilon^j\right)+\left(\sum_{j=0}^{N}B_j\epsilon^j\right),$$

where $A_0,\ldots,A_k,B_0,\ldots,B_N$ are arbitrary constants.

Inserting this result into (41) and integrating we come to the following Ansatz for the function $\psi(x)$:

$$\psi(x)=\left(\sum_{j=-1}^{N_1-1}U_j(x)\epsilon^{N_1-j-1}\right)^{1/2}\exp\left\{-f(\epsilon)\int\frac{dx}{\sum_{j=-1}^{N_1-1}U_j(x)\epsilon^{N_1-j-1}}\right\},\tag{43}$$

where $f(\epsilon)=(\Sigma_{j=0}^{N}B_j\epsilon^j)(\Sigma_{j=0}^{k}A_j\epsilon^j)^{-1}$.

Substitution of the expression (43) into the initial equation after some manipulations gives the following algebraic equation:

$$\epsilon^{2N_1+1}+\sum_{j=0}^{N_1-1}\mathscr{I}_j\epsilon^j-f(\epsilon)^2=0,\tag{44}$$

where $\mathscr{I}_j$ are integrals of the ordinary differential equation $U_{N_1}(x)=0$ and, consequently, are constant on the set of its solutions.

Thus, for an arbitrary $N_1 \in \mathbf{N}$ any solution $V=V(x)$ of the ordinary differential equation $U_{N_1}(x) = 0$ gives rise to an exactly solvable Schrödinger equation. Eigenvalues of the Schrödinger operator S are the roots of the algebraic equation (44) and the eigenfunctions are of the form (43), where ϵ is an arbitrary solution of (44).

It is instructive to consider in more detail the above formulas for the case $N=N_1=1$. With this choice of N the formula (43) reads as

$$\psi(x)=(2\epsilon-V(x))^{1/2}\exp\left\{-2\,f(\epsilon)\left(\int\frac{dx}{2\epsilon-V(x)}\right)\right\}, \tag{45}$$

where $f(\epsilon)=(A_1\epsilon+A_0)(B_1\epsilon+B_0)^{-1}$ and the function $V(x)$ is a solution of the ordinary differential equation $U_1(x)=0$, i.e.

$$-3V(x)^2+V''(x)=0. \tag{46}$$

Inserting the Ansatz (45) into (1) yields the following equality:

$$-8\epsilon^3+\mathscr{I}_0+8f(\epsilon)^2=0, \tag{47}$$

where

$$\mathscr{I}_0=V(x)^3-\tfrac{1}{2}V'(x)^2$$

is the first integral of Eq. (46). Note that an alternative derivation of the formulas (45)–(47) has been obtained in Ref. 25.

Now let us make an important remark. It is readily seen from formulas (45)–(47) that the function $f(\epsilon)$ is not obliged to be a ratio of two first-order polynomials. It may be arbitrary. And what is more, eigenvalues of the Schrödinger operator are the zeros of the function $F(\epsilon)=-8\epsilon^3+\mathscr{I}_0+8f(\epsilon)^2$. Choosing an arbitrary function $f(\epsilon)$ in a proper way we can get the function $F(\epsilon)$ having arbitrary prescribed set of zeros. This means that the Schrödinger equation (1) with $V(x)$ satisfying (47) may have an arbitrary spectrum.

For example, if we choose $f=\sqrt{\epsilon^3-\mathscr{I}_0/8}$, then the function (45) is a solution of the Schrödinger equation under arbitrary ϵ (the case of a continuous spectrum). Next, if we choose $f=\sqrt{\epsilon^3-\mathscr{I}_0/8+\Sigma_{j=0}^{N}A_j\epsilon^j}$, then a finite discrete spectrum is obtained (eigenvalues are roots of the Nth-order polynomial). At last, choosing $f=\sqrt{\epsilon^3-\mathscr{I}_0/8+\sin\epsilon}$ yields an infinite discrete spectrum (eigenvalues are zeros of the $\sin\epsilon$).

Similar results are obtained for $N=N_1=2$,

$$\psi(x)=(8\epsilon^2-4\epsilon V(x)+3V(x)^2-V''(x))^{1/2}\exp\left\{-8f(\epsilon)\left(\int\frac{dx}{8\epsilon^2-4\epsilon V(x)+3V(x)^2-V''(x)}\right)\right\},$$

where $f(\epsilon)$ is an arbitrary function, $V(x)$ is a solution of the ordinary differential equation,

$$10V(x)^3-5V'(x)^2-10V(x)V''(x)+V^{(4)}(x)=0, \tag{48}$$

and ϵ is a solution of the equation,

$$-128\epsilon^5-2\epsilon\mathscr{I}_1+\mathscr{I}_0+128f(\epsilon)^2=0.$$

Here $\mathscr{I}_0$, $\mathscr{I}_1$ are integrals of Eq. (48) of the form

$$\mathscr{I}_0=5V(x)^4-10V(x)V'(x)^2-V''(x)^2+2V'(x)V^{(3)}(x),$$

$$\mathscr{I}_1=-\frac{\mathscr{I}_0V(x)}{2}+\frac{19V(x)^5}{2}-\frac{\mathscr{I}_0^2}{8V'(x)^2}-\frac{5\mathscr{I}_0V(x)^4}{4V'(x)^2}-\frac{25V(x)^8}{8V'(x)^2}+\frac{5V(x)^2V'(x)^2}{2}-10V(x)^3V''(x)$$
$$-V'(x)^2V''(x)+\frac{5V(x)V''(x)^2}{2}+\frac{\mathscr{I}_0V''(x)^2}{4V'(x)^2}+\frac{5V(x)^4V''(x)^2}{4V'(x)^2}-\frac{V''(x)^4}{8V'(x)^2}.$$

Generically, if $V(x)$ is a solution of the $2N$th-order ordinary differential equation $U_N(x)=0$, then the corresponding Schrödinger operator S may have an arbitrary spectrum. Eigenvalues of S are obtained by solving the algebraic equation (44) and its eigenfunctions by substituting the corresponding values for ϵ into (43).

We will finish this section with one more puzzling property of the exactly integrable models obtained. Let us denote the total derivatives of the functions $U_j(x)$ with respect to x as $W_j(x)$ and consider an infinite set of evolution equations for a function $u=u(t,x)$,

$$\frac{\partial u(t,x)}{\partial t}=F_j[u(t,x)],\quad j>1, \tag{49}$$

where the functions F_j are obtained from $W_j(x)$ by formal replacement of $V(x)$ with $u(t,x)$. Now we see that equations obtained in this way form the famous integrable KdV hierarchy. Taking, for example, $j=2$ yields the KdV equation,

$$\frac{\partial u(t,x)}{\partial t}=\frac{1}{2^3}\left(6u(t,x)\,\frac{\partial u(t,x)}{\partial x}-\frac{\partial^3u(t,x)}{\partial x^3}\right).$$

Furthermore, differentiating the relations (40) we obtain the recurrence relations determining $W_j(x)$,

$$W_{j+1}(x)=YW_j(x)\equiv(\tfrac{1}{4}\,\partial_x^2-V(x)-\tfrac{1}{2}\,V'(x)\partial_x^{-1})W_j(x),\quad j=0,1,\ldots,$$

with $W_0(x)=0$. The operator Y above is nothing else but the well-known recurrence operator for the KdV hierarchy.[32]

Next, if we formally replace $V(x)$ by $u(t,x)$ in $U_j(x)$ determined by the recurrence relations (40), then the densities of motion constants of the KdV equation are obtained, X being the recursion operator connecting these densities.

Equations of the form (42) are known in the literature as the stationary Lax–Novikov equations. Equations of the stationary KdV hierarchy are particular cases of Eqs. (42) with $A_1=\cdots=A_{N-1}=0$. We have proved that any solution $V=V(x)$ of the stationary Lax–Novikov hierarchy (42) yields an exactly solvable Schrödinger equation. The correspondence between solutions of stationary KdV hierarchy and exactly solvable Schrödinger equations with reflectionless potentials is known (see, e.g., the paper[33] and references therein). Moreover, it has been established that the Schrödinger operators with so chosen potentials may have an arbitrarily prescribed spectrum. But the fact that solutions of the stationary Lax–Novikov hierarchy (42) have the same property seems to be new.

IV. CONCLUSION

In view of numerous excellent papers and monographs (see, e.g., Ref. 17 and the literature cited therein) devoted to developing algebraic methods for the investigation of spectral properties of Eq. (1), it is, of course, not enough to say that the problem of describing part of the spectrum of the Schrödinger equation is equivalent to computing its conditional symmetries in order to

justify a necessity of introducing a new complicated structure. Our principal motivation for looking for a symmetry interpretation of the results obtained in this field is that it may open a possibility

- to study the spectrum of two- and three-dimensional Schrödinger equations;
- to investigate ''spectral properties'' of nonlinear Schrödinger equations; and
- to study spectral properties of matrix differential operators (say, of the Dirac operator), by purely algebraic means.

For instance, there are strong evidences that a necessary condition for a three-dimensional Schrödinger equation to be exactly solvable is an invariance with respect to a three-dimensional Lie algebra of high-order symmetry operators. We can guess that one of the necessary conditions of ''quasiexact solvability'' of the three-dimensional Schrödinger equations is a nontrivial conditional symmetry admitted. The simplest possibility to move in this direction is to combine the technique developed in the present paper with the method of separation of variables.[34] In our paper[35] we have classified potentials $V(x_1,x_2)$ such that the corresponding two-dimensional Schrödinger equation,

$$i\psi_t+\psi_{x_1x_1}+\psi_{x_2x_2}=V(x_1,x_2)\psi$$

can be separated into three ordinary differential equations. One of these is a first-order equation and can always be integrated by quadratures. Two other are exactly of the form (1) and can be solved within the framework of the approach described in Secs. II and III.

Furthermore, the method of conditional symmetries is applicable not only to linear partial differential equations but also to nonlinear ones.[21,22] Let, for example, the one-dimensional nonlinear Schrödinger equation,

$$\psi_{xx}=(\epsilon+V(x)+F(\psi,\psi^*,\psi_x,\psi_x^*))\psi \tag{50}$$

be conditionally invariant with respect to an nth-order Lie–Bäcklund operator,

$$Q=\eta(x,\psi,\psi',\ldots,\psi^{(n)})\partial_\psi+\cdots,$$

in the sense of Ref. 22. Then, using a technique similar to that developed in Sec. II we can construct an Ansatz for a function $\psi(x)$, which gives a solution of (50), provided the energy parameter ϵ satisfy some algebraic equation $G(\epsilon)=0$. Solutions of this equation can be interpreted as eigenvalues of the nonlinear Schrödinger operator ∂_x^2-V-F.

An interesting example is a family of nonlinear Schrödinger equations suggested by Doebner and Goldin.[36] Taking the polar decomposition,

$$\psi(t,x)=e^{r(t,x)+is(t,x)}, \tag{51}$$

and fixing the gauge $\nu_1=-1$, $\nu_2=0$ (this is always possible[37]), we can represent the Doebner–Goldin model in the following way:

$$\begin{gathered} r_t+s_{xx}+2r_xs_x=0,\\ s_t+2\mu_2r_{xx}+\mu_1s_{xx}+4(\mu_2+\mu_5)r_x^2+2(\mu_1+\mu_4)r_xs_x+\mu_3s_x^2+\mu_0V(x)=0, \end{gathered} \tag{52}$$

where $\mu_0,\ldots,\mu_5$ are model parameters.

If we impose on the solutions of (52) an additional condition $s_x=0$ (which picks out a subset of stationary solutions), then the system obtained is consistent if and only if the conditions,

$$r=r(x), \quad s=-\epsilon t, \quad \epsilon=\text{const}\in\mathbf{R}, \tag{53}$$

are fulfilled.

With this choice of functions r and s, system (52) reduces to a single equation,

$$-\epsilon+2\mu_2 r''+4(\mu_2+\mu_5)(r')^2+\mu_0 V(x)=0, \tag{54}$$

which is either linear ($\mu_2+\mu_5=0$) or can be linearized by the substitution

$$\varphi(x)=\exp\left\{\frac{\mu_2}{2(\mu_2+\mu_5)}\, r(x)\right\}, \tag{55}$$

to become

$$\varphi''=\left(\frac{\epsilon}{4(\mu_2+\mu_5)}-\frac{\mu_0}{4(\mu_2+\mu_5)}\, V(x)\right)\varphi. \tag{56}$$

As established in Sec. II, any equation of the form (56) possesses a nontrivial high-order conditional symmetry. Since the nonlinear equation (54) is equivalent to (56), it possesses high-order conditional symmetry as well. Thus, the initial Doebner–Goldin equation has a subset of solutions with nontrivial conditional symmetry, which can be effectively applied to construct finite or even infinite (if the conditional symmetry can be reduced to a high-order Lie symmetry) set of its exact solutions.

We hope that the reasonings above are convincing enough to motivate a further study of high-order conditional symmetries of linear and nonlinear Schrödinger equations in one, two, and three dimensions. It may be also very interesting to study classical and conditional symmetries of the stationary Dirac equation in the presence of nonvanishing electromagnetic field and to apply these to derive a spectrum of the Dirac operator. These problems are under investigation now and will be a topic of our future publications.

ACKNOWLEDGMENTS

The results of in the present paper were obtained by the author when he was staying at the Arnold–Sommerfeld Institute for Mathematical Physics, Technical University of Clausthal as the Alexander von Humboldt Research Fellow. The author wishes to thank the Director of the AS Institute, H.-D. Doebner, for hospitality. Special thanks are addressed to W. Fushchych and A. Nikitin for critical remarks and suggestions and also to A. Ushveridze, who introduced the author into the exciting world of quasiexactly solvable models. Furthermore, the author express his gratitude to P. Nattermann for critical reading of the manuscript and pointing out the possibility of linearization of the one-dimensional Doebner–Goldin model restricted to a subset of stationary solutions.

(Received 2 January 1996; accepted for publication 20 February 1996)

The recovery of the coefficient $H(x)$ in the one-dimensional generalized Schrödinger equation $d^2\psi/dx^2+k^2H(x)^2\psi=Q(x)\psi$, where $H(x)$ is a positive, piecewise continuous function with positive limits $H_\pm$ as $x\to\pm\infty$, is studied. The large-k asymptotics of the wave functions and the scattering coefficients are analyzed. A factorization formula is given expressing the total scattering matrix as a product of simpler scattering matrices. Using this factorization an algorithm is presented to obtain the discontinuities in $H(x)$ and $H'(x)/H(x)$ in terms of the large-k asymptotics of the reflection coefficient. When there are no bound states, it is shown that $H(x)$ is recovered from an appropriate set of scattering data by using the solution of a singular integral equation, and the unique solvability of this integral equation is established. An equivalent Marchenko integral equation is derived and is shown to be uniquely solvable; the unique recovery of $H(x)$ from the solution of this Marchenko equation is presented. Some explicit examples are given, illustrating the recovery of $H(x)$ from the solution of the singular integral equation and from that of the Marchenko equation. © *1996 American Institute of Physics.* [S0022-2488(96)02606-0]

I. INTRODUCTION

Consider the one-dimensional generalized Schrödinger equation,

$$\psi''(k,x)+k^2H(x)^2\psi(k,x)=Q(x)\psi(k,x), \quad x\in\mathbf{R}, \tag{1.1}$$

which describes the propagation of waves in a one-dimensional nonhomogeneous, nonabsorptive medium, where k^2 is energy, $1/H(x)$ is the wave speed, and $Q(x)$ is the restoring force density. The discontinuities of $H(x)$ correspond to abrupt changes in the properties of the medium in which the wave propagates. The prime denotes the derivative with respect to the spatial coordinate, and the coefficients $H(x)$ and $Q(x)$ are assumed to satisfy the following conditions:

(H1) $H(x)$ is strictly positive and piecewise continuous with jump discontinuities at x_n for $n=1,\ldots,N$, such that $x_1<\cdots<x_N$.
(H2) $H(x)\to H_\pm$ as $x\to\pm\infty$, where $H_\pm$ are positive constants.
(H3) $H-H_\pm\in L^1(\mathbf{R}^\pm)$, where $\mathbf{R}^-=(-\infty,0)$ and $\mathbf{R}^+=(0,+\infty)$.
(H4) H' is absolutely continuous on (x_n,x_{n+1}) and $2H''H-3(H')^2\in L^1_1(x_n,x_{n+1})$, for $n=0,\ldots,N$, where $x_0=-\infty$ and $x_{N+1}=+\infty$, and $L^1_\beta(I)$ denotes the space of measurable functions $f(x)$ on I, such that $\int_I dx\ (1+|x|)^\beta|f(x)|<+\infty$.
(H5) $Q(x)$ is real valued and belongs to $L^1_1(\mathbf{R})$.

The scattering solutions of (1.1) are those behaving like $e^{ikH_\pm x}$ or $e^{-ikH_\pm x}$ as $x\to\pm\infty$, and

0022-2488/96/37(7)/3218/28/$10.00

such solutions occur when $k^2>0$. Among the scattering solutions are the Jost solution from the left $f_l(k,x)$ and the Jost solution from the right $f_r(k,x)$ satisfying the boundary conditions

$$f_l(k,x)=\begin{cases} e^{ikH_+x}+o(1), & x\to+\infty, \\ \dfrac{1}{T_l(k)}\,e^{ikH_-x}+\dfrac{L(k)}{T_l(k)}\,e^{-ikH_-x}+o(1), & x\to-\infty, \end{cases}$$

$$f_r(k,x)=\begin{cases} \dfrac{1}{T_r(k)}\,e^{-ikH_+x}+\dfrac{R(k)}{T_r(k)}\,e^{ikH_+x}+o(1), & x\to+\infty, \\ e^{-ikH_-x}+o(1), & x\to-\infty, \end{cases}$$

where $T_l(k)$ and $T_r(k)$ are the transmission coefficients from the left and from the right, respectively, and $L(k)$ and $R(k)$ are the reflection coefficients from the left and from the right, respectively. For each fixed $x\in\mathbf{R}$, the Jost solutions have continuous extensions to the upper half complex plane $\mathbf{C}^+$, and they are analytic there.[1] The reduced transmission coefficient $\tau(k)$, the reduced reflection coefficients $\rho(k)$ from the right and $\check{\rho}(k)$ from the left, respectively, are defined as

$$\tau(k)=\sqrt{\frac{H_+}{H_-}}\,T_l(k)e^{ikA}=\sqrt{\frac{H_-}{H_+}}\,T_r(k)e^{ikA}, \tag{1.2}$$

$$\rho(k)=R(k)e^{2ikA_+}, \quad \check{\rho}(k)=L(k)e^{2ikA_-}, \tag{1.3}$$

where

$$A_\pm=\pm\int_0^{\pm\infty} ds[H_\pm-H(s)], \quad A=A_++A_-. \tag{1.4}$$

If $\tau(0)\neq0$, which is called the exceptional case, the Jost solutions $f_l(0,x)$ and $f_r(0,x)$ are linearly dependent. If $\tau(0)=0$, which is called the generic case, $f_l(0,x)$ and $f_r(0,x)$ are linearly independent, and in this case $\tau(k)$ vanishes linearly as $k\to0$. Usually these two cases need to be analyzed separately, and the small-k analysis of the scattering problem in the exceptional case requires tedious estimates. However, the fact[2] that an exceptional case can always be decomposed into two generic cases is expected to simplify the analysis of the scattering problem in the exceptional case.

In general, (1.1) may have bound states, i.e. nontrivial solutions belonging to $L^2(\mathbf{R},H(x)^2dx)$. Since the treatment of bound states requires many separate arguments, we do not consider them in this paper. Bound states were already studied in Ref. 1 and further results may appear in the future. Thus, we assume that (1.1) does not have any bound states. The number of bound states for (1.1) is equal[3] to the number of bound states for the Schrödinger equation,

$$\Phi''(k,x)+k^2\Phi(k,x)=Q(x)\Phi(k,x), \quad x\in\mathbf{R}, \tag{1.5}$$

and hence our assumption can be restated by saying that $Q(x)$ does not have any bound states.

The inverse scattering problem in which we are interested consists of the recovery of $H(x)$ in (1.1) from an appropriate set of scattering data. The analysis of the scattering problem in a discontinuous medium is the first step to analyze the inverse scattering problem, and we mention the relevant work[4–7] of Sabatier and his collaborators on the scattering in a discontinuous medium in one and three dimensions governed by $\{\alpha(x)^{-2}\nabla\cdot[\alpha(x)^2\nabla]+k^2-V(x)\}\phi(k,x)=0$. In Ref. 4 Sabatier estimated the large-k asymptotics of the scattering data and also briefly discussed the inverse scattering problem in such a medium. Various authors have studied inverse scattering problems for differential equations with discontinuous coefficients, as exemplified by Krueger's

work[8–10] and the bibliography of Ref. 1. Of more direct concern to us is the work by Sabatier[4] and Grinberg.[11,12] Grinberg, in the special (but still important) case $Q(x)=0$, developed a method to recover $H(x)$ using the solution of a singular integral equation; in this special case there are no bound states, the exceptional case occurs, and the norm of the associated singular integral operator is strictly less than unity so that the integral equation has a unique solution that can be obtained through iteration. The general case with nontrivial $Q(x)$ and with bound states was analyzed by a similar method in Ref. 1, and $H(x)$ was recovered from the solution of a singular integral equation under the assumption $Q\in L^1_{1+\alpha}(\mathbf{R})$ for some $\alpha\in(0,1]$. In Ref. 13 the scattering data leading to a unique solution of the inverse problem were specified.

In this paper, when there are no bound states, we develop a method to obtain $H(x)$ from the scattering data consisting of $Q(x)$, $\rho(k)$, and H_+. As already known,[13] H_+ must be omitted from the scattering data in the generic case, but in the exceptional case it needs to be specified in the scattering data in order to obtain $H(x)$ uniquely; this is also true in the method presented here. Note also that, in the scattering data, one can use $\measuredangle(k)$ instead of $\rho(k)$ and one can also use H_- instead of H_+. The method given here and the method of Ref. 1 have some similarities and differences. The method used here holds whenever $Q\in L^1_1(\mathbf{R})$, whereas in Ref. 1, for technical reasons, we needed $Q\in L^1_{1+\alpha}(\mathbf{R})$ for some $\alpha\in(0,1]$. In both methods a singular integral equation is formulated and from its solution $H(x)$ is recovered; however, in the present paper we exploit the large-k behavior of the reduced scattering coefficients, thus avoiding complications encountered in Ref. 1 as $k\to 0$. A crucial result here is Proposition 2.1, which strengthens the result of Theorem 2.4 in Ref. 1. From the solution at $k=0$ of the singular integral equation one finds $H(x)$ as the x-derivative of the solution $y(x)$ of a separable differential equation under the initial condition $y(0)=0$. Furthermore, when the reduced reflection coefficient $\rho(k)$ is an almost periodic function, the singular integral equation of the present paper becomes trivial, and so does the computation of $H(x)$; in Ref. 1, even this relatively simple case required extensive calculations.

When $H(x)$ and $H'(x)$ have no discontinuities, the large-k asymptotics of the reduced scattering coefficients defined in (1.2)–(1.3) are known to be of the form $\tau(k)-1=O(1/k)$, $\rho(k)=O(1/k)$, and $\measuredangle(k)=O(1/k)$. It is also known that each discontinuity of $H(x)$ contributes to the almost periodic part of the $O(1)$ terms in these asymptotics. We refer the reader to Refs. 1, 4, 11–13 for details. In this paper we show that the discontinuities in $H'(x)/H(x)$ are responsible for some of the $O(1/k)$ terms in these asymptotics; in fact, we develop an algorithm to recover the jumps in $H'(x)/H(x)$ from the large-k asymptotics of a reduced reflection coefficient.

This paper is organized as follows. In Sec. II we study the large-k asymptotics of the reduced scattering coefficients. In Sec. III we study the large-k asymptotics of certain wave functions defined in (3.1)–(3.2). In Sec. IV we present a factorization formula expressing the reduced scattering matrix as a matrix product of scattering matrices corresponding to potentials supported on a finite interval or on a half-line and those corresponding to discontinuities in $H(x)$ and $H'(x)/H(x)$. In Sec. V we present an algorithm to recover the discontinuities in $H(x)$ and $H'(x)/H(x)$ from the large-k asymptotics of the scattering data, thus generalizing the work of Ref. 13 regarding the discontinuities in $H(x)$. The results in Secs. II and III are used in Sec. VI in order to convert a key Riemann-Hilbert problem into a pair of uncoupled singular integral equations; in this section we also establish the unique solvability of these integral equations and show how to recover $H(x)$ from the solution of either singular integral equation. In Sec. VII we show that each singular integral equation can be converted into a Marchenko integral equation that is uniquely solvable, and we describe the recovery of $H(x)$ from the solution of a Marchenko equation. Hence, the inverse problem is solved by recovering $H(x)$ either by the method of Sec. VI or by that of Sec. VII. In Section VIII we present some examples illustrating the recovery of $H(x)$ using the solution of a singular integral equation and using the solution of a Marchenko equation; we also illustrate the algorithm of recovery of the discontinuities in $H'(x)/H(x)$.

II. SCATTERING COEFFICIENTS

In this section we analyze the large-k asymptotics of the reduced scattering coefficients defined in (1.2)–(1.3). Under the Liouville transformation

$$y=y(x)=\int_0^x ds\ H(s), \quad \psi(k,x)=\frac{1}{\sqrt{H(x)}}\,\phi(k,y), \tag{2.1}$$

the generalized Schrödinger equation (1.1) is transformed into

$$\frac{d^2\phi(k,y)}{dy^2}+k^2\phi(k,y)=V(y)\,\phi(k,y), \tag{2.2}$$

where

$$V(y(x))=\frac{H''(x)}{2H(x)^3}-\frac{3}{4}\,\frac{H'(x)^2}{H(x)^4}+\frac{Q(x)}{H(x)^2}. \tag{2.3}$$

Since $H(x)$ is assumed to have jump discontinuities at x_j for $j=1,\ldots,N$, the quantity $V(y)$ is undefined at $y_j=y(x_j)$. However, $V(y)$ is well defined in each of the intervals (y_j,y_{j+1}) for $j=0,\ldots,N$; thus, the Liouville transformation can be used on each interval (x_j,x_{j+1}) although it cannot be used on $\mathbf{R}$. Since $H(x)$ is strictly positive with positive limits as $x\to\pm\infty$, it follows that $y_0=y(x_0)=-\infty$ and $y_{N+1}=y(x_{N+1})=+\infty$. The constants q_j, defined by

$$q_j=\frac{H(x_j-0)}{H(x_j+0)}, \tag{2.4}$$

correspond to the relative jumps in the wave speed at the interfaces x_j, and y_j correspond to the times required for the wave to propagate from the fixed location $x=0$ to the interfaces x_j for $j=1,\ldots,N$.

Let $V_{j,j+1}(y)$ be the potential defined by

$$V_{j,j+1}(y)=\begin{cases} V(y), & y\in(y_j,y_{j+1}),\\ 0, & \text{elsewhere,}\end{cases} \tag{2.5}$$

where $V(y)$ is the quantity in (2.3). From (H4) it follows that $V_{j,j+1}\in L_1^1(\mathbf{R})$ for $j=0,\ldots,N$. Let $Y_{l;j,j+1}(k,y)$ and $Y_{r;j,j+1}(k,y)$ denote the Faddeev functions[1] from the left and from the right, respectively, associated with the potential $V_{j,j+1}(y)$. We have[1]

$$Y_{l;j,j+1}(k,y)=\begin{cases} \dfrac{1}{t_{j,j+1}(k)}\,[1+l_{j,j+1}(k)e^{-2iky}], & y\leqslant y_j, \quad j=1,\ldots,N, \quad k\in\overline{C^+},\\ \dfrac{1}{t_{0,1}(k)}\,[1+l_{0,1}(k)e^{-2iky}]+o(1), & y\to-\infty, \quad j=0, \quad k\in\mathbf{R},\end{cases} \tag{2.6}$$

$$Y_{r;j,j+1}(k,y)=\begin{cases} \dfrac{1}{t_{j,j+1}(k)}\,[1+r_{j,j+1}(k)e^{2iky}], & y\geqslant y_{j+1}, \quad j=0,\ldots,N-1, \quad k\in\overline{C^+},\\ \dfrac{1}{t_{N,N+1}(k)}\,[1+r_{N,N+1}(k)e^{2iky}]+o(1), & y\to+\infty, \quad j=N, \quad k\in\mathbf{R},\end{cases} \tag{2.7}$$

where $t_{j,j+1}(k)$, $r_{j,j+1}(k)$, and $l_{j,j+1}(k)$ denote the transmission coefficient and the reflection coefficients from the right and from the left, respectively, for the potential $V_{j,j+1}(y)$. Since $V_{j,j+1}\in L_1^1(\mathbf{R})$, it follows that for each fixed $y\in\mathbf{R}$ we have

$$Y_{l;j,j+1}(k,y)=1+O(1/k),\quad Y'_{l;j,j+1}(k,y)=o(1),\quad k\to\infty \text{ in } \overline{\mathbf{C}^+},\tag{2.8}$$

$$Y_{r;j,j+1}(k,y)=1+O(1/k),\quad Y'_{r;j,j+1}(k,y)=o(1),\quad k\to\infty \text{ in } \overline{\mathbf{C}^+}.\tag{2.9}$$

Using (2.1) it can be shown that the functions defined by

$$\eta_{j,j+1}(k,x)=\frac{1}{\sqrt{H(x)}}\,e^{iky}Y_{l;j,j+1}(k,y),\quad \xi_{j,j+1}(k,x)=\frac{1}{\sqrt{H(x)}}\,e^{-iky}Y_{r;j,j+1}(k,y),\tag{2.10}$$

are solutions of (1.1). Let us introduce the matrices

$$\Gamma_{j,j+1}(k,x)=\begin{bmatrix}\eta_{j,j+1}(k,x) & \xi_{j,j+1}(k,x)\\ \eta'_{j,j+1}(k,x) & \xi'_{j,j+1}(k,x)\end{bmatrix},\quad j=0,\ldots,N,\tag{2.11}$$

$$\mathcal{S}(k)=\prod_{n=1}^{N}\Gamma_{n-1,n}(k,x_n-0)^{-1}\Gamma_{n,n+1}(k,x_n+0).\tag{2.12}$$

It was shown in Ref. 1 that

$$\frac{1}{\tau(k)}=\frac{1}{t_{0,1}(k)}\,[1\ \ 0]\mathcal{S}(k)\begin{bmatrix}1\\0\end{bmatrix}=\frac{1}{t_{N,N+1}(k)}\,[0\ \ 1]\mathcal{S}(k)^{-1}\begin{bmatrix}0\\1\end{bmatrix},\tag{2.13}$$

$$\frac{\ell(k)}{\tau(k)}=\begin{bmatrix}\dfrac{l_{0,1}(k)}{t_{0,1}(k)} & 1\end{bmatrix}\mathcal{S}(k)\begin{bmatrix}1\\0\end{bmatrix},\tag{2.14}$$

$$\frac{\rho(k)}{\tau(k)}=\begin{bmatrix}1 & \dfrac{r_{N,N+1}(k)}{t_{N,N+1}(k)}\end{bmatrix}\mathcal{S}(k)^{-1}\begin{bmatrix}0\\1\end{bmatrix}.\tag{2.15}$$

Moreover,

$$\det\Gamma_{n,n+1}(k,x)=-\frac{2ik}{t_{n,n+1}(k)},\quad \det\mathcal{S}(k)=\frac{t_{0,1}(k)}{t_{N,N+1}(k)}.$$

Let

$$\alpha_n=\frac{1}{2}\left(\sqrt{q_n}+\frac{1}{\sqrt{q_n}}\right),\quad \beta_n=\frac{1}{2}\left(\sqrt{q_n}-\frac{1}{\sqrt{q_n}}\right),\tag{2.16}$$

$$E(k,x_n)=\begin{bmatrix}\alpha_n & \beta_n e^{-2iky_n}\\ \beta_n e^{2iky_n} & \alpha_n\end{bmatrix},\tag{2.17}$$

with q_n as in (2.4); let us also define $a(k)$ and $b(k)$ by

$$\begin{bmatrix}a(k) & b(k)\\ b(-k) & a(-k)\end{bmatrix}=\prod_{n=1}^{N}E(k,x_n).\tag{2.18}$$

Let AP^W (almost periodic functions with Wiener norm) stand for the algebra of all complex-valued functions $f(k)$ on $\mathbf{R}$ that are of the form $f(k)=\Sigma_{j=-\infty}^{\infty}f_j e^{ik\lambda_j}$, where $f_j\in\mathbf{C}$ and $\lambda_j\in\mathbf{R}$ for

all j and $\Sigma_j|f_j|<+\infty$. It is already known[1] that the functions $a(k)$, $b(k)$, $1/a(k)$, and $b(k)/a(k)$ belong to AP^W. In the next proposition we obtain the large-k asymptotics of the reduced scattering coefficients $\tau(k)$, $\rho(k)$, and $\ell(k)$.

Proposition 2.1: Under assumptions (H1)–(H5) we have

$$\tau(k)=\frac{1}{a(k)}+O\left(\frac{1}{k}\right), \quad k\to\infty \ \text{ in } \ \overline{\mathbf{C}^+}, \tag{2.19}$$

$$\rho(k)=-\frac{b(k)}{a(k)}+O\left(\frac{1}{k}\right), \quad k\to\pm\infty, \tag{2.20}$$

$$\ell(k)=\frac{b(-k)}{a(k)}+O\left(\frac{1}{k}\right), \quad k\to\pm\infty, \tag{2.21}$$

where $a(k)$ and $b(k)$ are the quantities defined in (2.18).

Proof: Using (2.8)–(2.10) we obtain

$$\Gamma_{n,n+1}(k,x_{n+1}-0)^{-1}\Gamma_{n+1,n+2}(k,x_{n+1}+0) = \begin{bmatrix} \alpha_{n+1}(1+O(1/k)) & \beta_{n+1}e^{-2iky_{n+1}}(1+O(1/k)) \\ \beta_{n+1}e^{2iky_{n+1}}(1+O(1/k)) & \alpha_{n+1}(1+O(1/k)) \end{bmatrix}, \quad k\to\infty \ \text{ in } \ \overline{\mathbf{C}^+}, \tag{2.22}$$

where α_n and β_n are the constants defined in (2.16). Furthermore, using (2.13)–(2.15) and the fact[14] that

$$t_{j,j+1}(k)=1+O(1/k), \quad k\to\infty \ \text{ in } \ \overline{\mathbf{C}^+},$$

$$r_{j,j+1}(k)=O(1/k), \quad l_{j,j+1}(k)=O(1/k), \quad k\to\pm\infty,$$

we obtain (2.19)–(2.21). ■

Proposition 2.1 is an improvement over Theorem 2.4 in Ref. 13, where the error terms in (2.19)–(2.21) were only shown to be $o(1)$. We refer the reader to Refs. 1 and 13 for various other properties of the reduced scattering coefficients.

III. ESTIMATES ON WAVE FUNCTIONS

In this section we analyze the large-k behavior of the scattering solutions of (2.2). As in (5.1)–(5.2) of Ref. 1, let us define the Faddeev functions $Z_l(k,y)$ and $Z_r(k,y)$, from the left and from the right, respectively, associated with (2.2):

$$Z_l(k,y)=\sqrt{\frac{H(x)}{H_+}}\,e^{-iky-ikA_+}f_l(k,x), \tag{3.1}$$

$$Z_r(k,y)=\sqrt{\frac{H(x)}{H_-}}\,e^{iky-ikA_-}f_r(k,x), \tag{3.2}$$

where y is the quantity defined in (2.1) and $A_\pm$ are the constants in (1.4). Note that $e^{iky}Z_l(k,y)$ and $e^{-iky}Z_r(k,y)$ are the Jost solutions from the left and from the right, respectively, of (2.2). In this section we analyze the large-k asymptotics of $Z_l(k,y)$ and $Z_r(k,y)$.

The next proposition shows that, for each fixed $y \in \mathbf{R}\backslash\{y_1,\ldots,y_N\}$, the Faddeev functions can be written as the sum of an almost periodic function and a continuous function, the latter vanishing as $k\to\infty$ in $\overline{\mathbf{C}^+}$.

Proposition 3.1: For each fixed $y \in \mathbf{R}\backslash\{y_1,\ldots,y_N\}$, we have

$$Z_l(k,y)=J_l(k,y)+O(1/k), \quad Z_r(k,y)=J_r(k,y)+O(1/k), \quad k\to\infty \ \text{ in } \ \overline{\mathbf{C}^+}, \tag{3.3}$$

where

$$J_l(k,y)=[1 \quad e^{-2iky}]\left(\prod_{n=j+1}^{N} E(k,x_n)\right)\begin{bmatrix}1\\0\end{bmatrix}, \quad y\in(y_j,y_{j+1}), \quad j=0,\ldots,N-1, \tag{3.4}$$

$$J_l(k,y)=1, \quad y\in(y_N,+\infty), \tag{3.5}$$

$$J_r(k,y)=1, \quad y\in(-\infty,y_1), \tag{3.6}$$

$$J_r(k,y)=[e^{2iky} \quad -1]\left(\prod_{n=j}^{1} E(k,x_n)\right)\begin{bmatrix}0\\-1\end{bmatrix}, \quad y\in(y_j,y_{j+1}), \quad j=1,\ldots,N, \tag{3.7}$$

with $E(k,x_n)$ defined in (2.17). The product notation in (3.7) means that n decreases from j to 1.

Proof: When $y\in(y_N,+\infty)$, from (3.13), (3.15), (3.21) of Ref. 1 and (2.10) and (3.1), we have

$$Z_l(k,y)=Y_{l;N,N+1}(k,y), \quad y\in(y_N,+\infty), \tag{3.8}$$

and hence $Z_l(k,y)=1+O(1/k)$ as $k\to\infty$ in $\overline{\mathbf{C}^+}$. Thus, we have (3.3) with $J_l(k,y)$ as in (3.5). Similarly, from (3.13), (3.15), (3.22) of Ref. 1 and (2.10) and (3.2), we get

$$Z_r(k,y)=Y_{r;0,1}(k,y), \quad y\in(-\infty,y_1), \tag{3.9}$$

and hence $Z_r(k,y)=1+O(1/k)$ as $k\to\infty$ in $\overline{\mathbf{C}^+}$. Thus, we have (3.3) with $J_r(k,y)$ as in (3.6).

When $y\in(y_j,y_{j+1})$ with $0\leqslant j\leqslant N-1$, from (3.25) of Ref. 1 and (3.1), we see that

$$\begin{aligned} Z_l(k,y)=&[1 \quad 0]\sqrt{H(x)}e^{-iky}\Gamma_{j,j+1}(k,x)\\ &\times\left(\prod_{n=j}^{N-1}\Gamma_{n,n+1}(k,x_{n+1}-0)^{-1}\Gamma_{n+1,n+2}(k,x_{n+1}+0)\right)\begin{bmatrix}1\\0\end{bmatrix}, \end{aligned}\tag{3.10}$$

where $\Gamma_{j,j+1}(k,x)$ is the matrix defined in (2.11). From (2.8)–(2.10) we have

$$[1 \quad 0]\sqrt{H(x)}e^{-iky}\Gamma_{j,j+1}(k,x)=[1+O(1/k) \quad e^{-2iky}(1+O(1/k))]. \tag{3.11}$$

Hence, using (2.22) and (3.11) in (3.10), we obtain

$$Z_l(k,y)=J_l(k,y)[1+O(1/k)], \quad k\to\infty \ \text{ in } \ \overline{\mathbf{C}^+}, \tag{3.12}$$

with $J_l(k,y)$ as in (3.4). Similarly, when $y\in(y_j,y_{j+1})$ with $1\leqslant j\leqslant N$, from (3.26) of Ref. 1 and (3.2), we see that

$$Z_r(k,y)=[1 \quad 0]\sqrt{H(x)}e^{iky}\Gamma_{j,j+1}(k,x)\left(\prod_{n=j}^{1}\Gamma_{n,n+1}(k,x_n+0)^{-1}\Gamma_{n+1,n+2}(k,x_n-0)\right)\begin{bmatrix}0\\1\end{bmatrix}. \tag{3.13}$$

From (2.8)–(2.10) we have

$$[1 \quad 0]\sqrt{H(x)}e^{iky}\Gamma_{j,j+1}(k,x)=[e^{2iky}(1+O(1/k)) \quad 1+O(1/k)]. \tag{3.14}$$

Using (2.22) and (3.14) in (3.13), we obtain

$$Z_r(k,y)=J_r(k,y)[1+O(1/k)], \quad k\to\infty \ \text{ in } \ \overline{\mathbf{C}^+}, \tag{3.15}$$

with $J_r(k,y)$ as in (3.7). Note that for each fixed $y\in\mathbf{R}\backslash\{y_1,\ldots,y_N\}$ the functions $J_l(k,y)$ and $J_r(k,y)$ are uniformly bounded in $\overline{\mathbf{C}^+}$, and hence we see that (3.12) and (3.15) imply (3.3). ■

Recall that the Hardy spaces $\mathbf{H}^p_\pm(\mathbf{R})$ are defined as the spaces of all functions $f(k)$ that are analytic in $k\in\mathbf{C}^\pm$ and satisfy $\sup_{\epsilon>0}\int_{-\infty}^{\infty}dk\ |f(k\pm i\epsilon)|^p<+\infty$.

Theorem 3.2: For each fixed $y\in\mathbf{R}\backslash\{y_1,\ldots,y_N\}$, the functions $Z_l(k,y)-J_l(k,y)$ and $Z_r(k,y)-J_r(k,y)$ belong to the Hardy space $\mathbf{H}^2_+(\mathbf{R})$.

Proof: It is proved in Theorem 2.1 of Ref. 1 that, for each fixed $x\in\mathbf{R}\backslash\{x_1,\ldots,x_N\}$, $f_l(k,x)$ and $f_r(k,x)$ are continuous functions of k in $\overline{\mathbf{C}^+}$ and analytic in $\mathbf{C}^+$; therefore, for each fixed $y\in\mathbf{R}\backslash\{y_1,\ldots,y_N\}$, the Faddeev functions $Z_l(k,y)$ and $Z_r(k,y)$ are continuous in $\overline{\mathbf{C}^+}$ and analytic in $\mathbf{C}^+$. From (3.4)–(3.7) we see that $J_l(k,y)$ and $J_r(k,y)$ are continuous in $\overline{\mathbf{C}^+}$ and analytic in $\mathbf{C}^+$. Hence, by Proposition 3.1 we can conclude that $Z_l(k,y)-J_l(k,y)$ and $Z_r(k,y)-J_r(k,y)$ belong to the Hardy space $\mathbf{H}^2_+(\mathbf{R})$. ■

Note that we can also conclude the analyticity in $\mathbf{C}^+$ and continuity in $\overline{\mathbf{C}^+}$ of $Z_l(k,y)$ and $Z_r(k,y)$ from (3.10) and (3.13), respectively, because the matrices there have these properties. At first the inverse matrices in (3.10) and (3.13) seem to have a $(1/k)$ singularity at $k=0$ in the exceptional case; however, if any $V_{n,n+1}(y)$ are exceptional potentials, we can divide each of those intervals (y_n,y_{n+1}) into two subintervals such that the fragments on the two subintervals are generic;[2] hence, even in the exceptional case, from (3.10) and (3.13), we can conclude that $Z_l(k,y)$ and $Z_r(k,y)$ are analytic in $\mathbf{C}^+$ and continuous in $\overline{\mathbf{C}^+}$.

Note that the matrix product $E(k,x_{j+1})\cdots E(k,x_N)$ in (3.4) can be explicitly evaluated in analogy to (2.28) of Ref. 13. Let us write

$$\prod_{n=j+1}^{N} E(k,x_n)=\begin{bmatrix} A_j(k) & B_j(k) \\ B_j(-k) & A_j(-k)\end{bmatrix},$$

where $A_j(k)$ and $B_j(k)$ will be explicitly evaluated. Thus, we can write (3.4)–(3.5) as

$$J_l(k,y)=[A_j(k)+e^{-2iky}B_j(-k)], \quad y\in(y_j,y_{j+1}), \tag{3.16}$$

with $A_N(k)=1$ and $B_N(k)=0$. Using induction, we can show that $A_j(k)$ and $e^{-2iky}B_j(-k)$ both are exponential polynomials having at most 2^{N-j} terms. All the coefficients in the exponential polynomials are real constants and all the exponentials are bounded by 1 in absolute value in $\overline{\mathbf{C}^+}$. For future reference, we list $A_j(k)$ and $B_j(k)$ for $j=N-1,\ N-2,\ N-3$.
If $j=N-1$,

$$A_{N-1}(k)=\alpha_N, \quad e^{2iky_N}B_{N-1}(k)=\beta_N.$$

If $j=N-2$,

$$A_{N-2}(k)=\alpha_{N-1}\alpha_N+\beta_{N-1}\beta_N e^{2ik(y_N-y_{N-1})},$$

$$e^{2iky_N}B_{N-2}(k)=\alpha_{N-1}\beta_N+\beta_{N-1}\alpha_N e^{2ik(y_N-y_{N-1})}.$$

If $j=N-3$,

$$A_{N-3}(k)=\alpha_{N-2}\alpha_{N-1}\alpha_N+\beta_{N-2}\beta_{N-1}\alpha_N e^{2ik(y_{N-1}-y_{N-2})}$$
$$+\alpha_{N-2}\beta_{N-1}\beta_N e^{2ik(y_N-y_{N-1})}+\beta_{N-2}\alpha_{N-1}\beta_N e^{2ik(y_N-y_{N-2})},$$

$$e^{2iky_N}B_{N-3}(k)=\alpha_{N-2}\alpha_{N-1}\beta_N+\beta_{N-2}\beta_{N-1}\beta_N e^{2ik(y_{N-1}-y_{N-2})}$$
$$+\alpha_{N-2}\beta_{N-1}\alpha_N e^{2ik(y_N-y_{N-1})}+\beta_{N-2}\alpha_{N-1}\alpha_N e^{2ik(y_N-y_{N-2})}.$$

We see that, for $j\leqslant N-1$, the term $e^{2iky_N}B_j(k)$ is obtained from $A_j(k)$ by interchanging β_N with α_N.

In a similar manner, using

$$E(k,x_j)^{-1}\cdots E(k,x_1)^{-1}=[E(k,x_1)\cdots E(k,x_j)]^{-1},$$

we can explicitly evaluate the matrix product $E(k,x_1)\cdots E(k,x_j)$ appearing in (3.7) in analogy to (2.28) of Ref. 13. Let us write

$$\prod_{n=1}^{j}E(k,x_n)=\begin{bmatrix}C_j(k) & D_j(k)\\ D_j(-k) & C_j(-k)\end{bmatrix},$$

where $C_j(k)$ and $D_j(k)$ will be explicitly evaluated. Thus, we can write (3.6)–(3.7) as

$$J_r(k,y)=[C_j(k)-e^{2iky}D_j(-k)],\quad y\in(y_j,y_{j+1}),\tag{3.17}$$

with $C_0(k)=1$ and $D_0(k)=0$. Using induction, we can show that $C_j(k)$ and $e^{2iky}D_j(-k)$ both are exponential polynomials having at most 2^j terms. All the coefficients in the exponential polynomials are real constants and all the exponentials are bounded by 1 in absolute value in $\overline{\mathbf{C}^+}$. For future reference, we list $C_j(k)$ and $D_j(k)$ for $j=1,\ 2,\ 3$.
If $j=1$,

$$C_1(k)=\alpha_1,\quad e^{2iky_1}D_1(k)=\beta_1.$$

If $j=2$,

$$C_2(k)=\alpha_1\alpha_2+\beta_1\beta_2e^{2ik(y_2-y_1)},\quad e^{2iky_2}D_2(k)=\alpha_1\beta_2+\beta_1\alpha_2e^{2ik(y_2-y_1)}.$$

If $j=3$,

$$C_3(k)=\alpha_1\alpha_2\alpha_3+\beta_1\beta_2\alpha_3e^{2ik(y_2-y_1)}+\alpha_1\beta_2\beta_3e^{2ik(y_3-y_2)}+\beta_1\alpha_2\beta_3e^{2ik(y_3-y_1)},$$

$$e^{2iky_3}D_3(k)=\alpha_1\alpha_2\beta_3+\beta_1\beta_2\beta_3e^{2ik(y_2-y_1)}+\alpha_1\beta_2\alpha_3e^{2ik(y_3-y_2)}+\beta_1\alpha_2\alpha_3e^{2ik(y_3-y_1)}.$$

We see that, for $j\geqslant 1$, the term $e^{2iky_j}D_j(k)$ is obtained from $C_j(k)$ by interchanging β_j with α_j.

IV. FACTORIZATION

In this section we generalize the factorization formula of Ref. 15 and show that the reduced scattering matrix corresponding to (1.1) can be expressed in terms of the scattering matrices corresponding to the potentials $V_{j,j+1}(y)$ defined in (2.5) and certain matrices associated with the discontinuities of $H(x)$ and $H'(x)/H(x)$. Using the scattering coefficients introduced in (2.6)–(2.7), let us define

$$\Lambda_{j,j+1}(k)=\begin{bmatrix} \dfrac{1}{t_{j,j+1}(k)} & -\dfrac{r_{j,j+1}(k)}{t_{j,j+1}(k)} \\ \dfrac{l_{j,j+1}(k)}{t_{j,j+1}(k)} & \dfrac{1}{t_{j,j+1}(-k)} \end{bmatrix}, \quad j=0,1,\ldots,N, \tag{4.1}$$

$$\Lambda(k)=\begin{bmatrix} \dfrac{1}{\tau(k)} & -\dfrac{\rho(k)}{\tau(k)} \\ \dfrac{\ell(k)}{\tau(k)} & \dfrac{1}{\tau(-k)} \end{bmatrix}, \tag{4.2}$$

$$F_j(k)=\begin{bmatrix} \alpha_j+\dfrac{\nu_j}{2ik} & \left(\beta_j+\dfrac{\nu_j}{2ik}\right)e^{-2iky_j} \\ \left(\beta_j-\dfrac{\nu_j}{2ik}\right)e^{2iky_j} & \alpha_j-\dfrac{\nu_j}{2ik} \end{bmatrix}, \quad j=1,\ldots,N, \tag{4.3}$$

where α_j and β_j are the constants defined in (2.16) and

$$\nu_j=\frac{1}{2\sqrt{H(x_j-0)H(x_j+0)}}\left[\frac{H'(x_j-0)}{H(x_j-0)}-\frac{H'(x_j+0)}{H(x_j+0)}\right]. \tag{4.4}$$

Note that $\nu_j=0$ if and only if $H'(x)/H(x)$ is continuous at x_j. Following Sabatier's terminology[4–7] we can refer to $F_j(k)$ as a ''hard scatterer'' and $\Lambda_{j,j+1}(k)$ as a ''soft scatterer.'' The following theorem shows how the matrices defined in (4.1)–(4.3) are related to one another.

Theorem 4.1: We have

$$\Lambda=\Lambda_{0,1}F_1\Lambda_{1,2}F_2\Lambda_{2,3}\cdots F_N\Lambda_{N,N+1}, \tag{4.5}$$

where Λ, $\Lambda_{j,j+1}$, and F_j are the matrices defined in (4.2), (4.1), and (4.3), respectively.

Proof: Note that we have $\Lambda_{j,j+1}=G_jD_j$, where we have defined

$$G_j=\begin{bmatrix} \dfrac{1}{t_{j,j+1}(k)} & 0 \\ \dfrac{l_{j,j+1}(k)}{t_{j,j+1}(k)} & 1 \end{bmatrix}, \quad D_j=\begin{bmatrix} 1 & -r_{j,j+1}(k) \\ 0 & t_{j,j+1}(k) \end{bmatrix}.$$

Using the displayed equation in Ref. 1 following (14.4), we can relate $\Lambda(k)$ and $\mathscr{G}(k)$ defined in (2.12) as $\Lambda=G_0\mathscr{G}D_N$. Inserting the identity matrices $G_jG_j^{-1}$ and $D_jD_j^{-1}$ in the appropriate places in (2.12), we obtain

$$\Lambda=G_0D_0\prod_{n=1}^{N}[D_{n-1}^{-1}\Gamma_{n-1,n}(k,x_n-0)^{-1}\Gamma_{n,n+1}(k,x_n+0)G_n^{-1}][G_nD_n]. \tag{4.6}$$

Using (2.11), it can be checked that

$$D_{n-1}^{-1}\Gamma_{n-1,n}(k,x_n-0)^{-1}\Gamma_{n,n+1}(k,x_n+0)G_n^{-1}=F_n, \tag{4.7}$$

where F_n are the matrices defined in (4.3). Thus, using (4.7) in (4.6), we get (4.5). ■

It is already known[13] that the function $H(x)$ given by

$$H(x)=\frac{h_{j,j+1}}{f_l(0,x)^2}, \quad x\in(x_j,x_{j+1}), \quad j=0,\ldots,N,$$

$$h_{N,N+1}=H_+; \quad h_{j-1,j}=q_j h_{j,j+1}, \quad j=0,\ldots,N,$$

corresponds to the scattering data $Q(x)$, $\rho(k)=-b(k)/a(k)$, and $\tau(k)=1/a(k)$; as seen from Proposition 2.1, the scattering coefficients in this case coincide with their asymptotic expressions as $k\to\pm\infty$. In this case, the matrix factorization given in (4.5) reduces to the factorization in (2.18). This is because in this case ν_j given in (4.4) vanishes, and hence the matrix $F_j(k)$ defined in (4.3) becomes equal to $E(k,x_j)$ defined in (2.17); in fact, $F_j(k)=E(k,x_j)$ if and only if $\nu_j=0$. Furthermore, in this case $V_{j,j+1}(y)=0$ and hence $\Lambda_{j,j+1}(k)=\mathbf{I}$; in fact, $\Lambda_{j,j+1}(k)=\mathbf{I}$ if and only if $V_{j,j+1}(y)=0$. In this case, we also have $Z_l(k,y)=J_l(k,y)$ and $Z_r(k,y)=J_r(k,y)$.

Now let us ask the following question. If we choose $V_{j,j+1}(y)=0$ for $j=0,1,\ldots,N$, but still allow $\nu_j\neq 0$, what is the corresponding $H(x)$? From the factorization formula (4.5), by letting $\Lambda_{j,j+1}(k)=\mathbf{I}$, we can explicitly evaluate the corresponding scattering matrix. In this case, the corresponding $H(x)$ is given by

$$\sqrt{H(x)}=\frac{1}{a_j f_l(0,x)+b_j f_r(0,x)}, \quad x\in(x_j,x_{j+1}), \quad j=0,\ldots,N, \tag{4.8}$$

$$a_N=\frac{1}{\sqrt{H_+}}, \quad b_N=0, \tag{4.9}$$

and a_j, b_j for $j=0,1,\ldots,N-1$, will be determined recursively by using the jumps in $H(x)$ and $H'(x)/H(x)$ according to (2.4) and (4.4), respectively. Using (4.8) in (2.4), we obtain

$$\frac{a_j f_l(0,x_j)+b_j f_r(0,x_j)}{a_{j-1} f_l(0,x_j)+b_{j-1} f_r(0,x_j)}=\sqrt{q_j}, \quad j=1,\ldots,N. \tag{4.10}$$

From (4.8) we have

$$\frac{H'(x)}{H(x)}=-2\,\frac{a_j f_l'(0,x)+b_j f_r'(0,x)}{a_j f_l(0,x)+b_j f_r(0,x)}, \tag{4.11}$$

and hence from (4.4) we get

$$\frac{a_{j-1} f_l'(0,x_j)+b_{j-1} f_r'(0,x_j)}{a_{j-1} f_l(0,x_j)+b_{j-1} f_r(0,x_j)}-\frac{a_j f_l'(0,x_j)+b_j f_r'(0,x_j)}{a_j f_l(0,x_j)+b_j f_r(0,x_j)}=-\nu_j\sqrt{H(x_j-0)H(x_j+0)}, \quad j=1,\ldots,N. \tag{4.12}$$

Solving the linear system (4.10) and (4.12) with unknowns a_{j-1} and b_{j-1} in terms of a_j and b_j and known quantities, and using (4.9), we obtain

$$a_{j-1}=\frac{a_j}{\sqrt{q_j}}+\frac{\nu_j f_r(0,x_j)\sqrt{H(x_j+0)}}{[f_l(0,x);f_r(0,x)]}, \quad j=1,\ldots,N; \quad a_N=\frac{1}{\sqrt{H_+}}, \tag{4.13}$$

$$b_{j-1}=\frac{b_j}{\sqrt{q_j}}-\frac{\nu_j f_l(0,x_j)\sqrt{H(x_j+0)}}{[f_l(0,x);f_r(0,x)]}, \quad j=1,\ldots,N; \quad b_N=0, \tag{4.14}$$

where $[f_l(0,x);f_r(0,x)]=f_l(0,x)f_r'(0,x)-f_l'(0,x)f_r(0,x)$ is the Wronskian, which is a constant completely determined by $Q(x)$ alone. We can also obtain the Jost solutions for (1.1) explicitly. In

this case, since $V_{j,j+1}(y)=0$, we have $Y_{l;j,j+1}(k,y)=1$ and $Y_{r;j,j+1}(k,y)=1$; thus, the matrix $\Gamma_{j,j+1}(k,x)$ defined in (2.11) is determined by using (2.10). Hence, using (3.8) and (3.10) the Faddeev function $Z_l(k,y)$ is determined, and using (3.9) and (3.13) the Faddeev function $Z_r(k,y)$ is determined. Then we obtain $f_l(k,x)$ and $f_r(k,x)$ as in (3.1)–(3.2).

Note that in the above procedure, in case $Q(x)$ is an exceptional potential, i.e., if $f_l(0,x)$ and $f_r(0,x)$ are linearly dependent, in (4.8)–(4.14) we need to replace $f_r(0,x)$ by a zero-energy solution of (1.5) linearly independent of $f_l(0,x)$, such as $\psi(x)=f_l(0,x)\int_0^x dy/f_l(0,y)^2$; with this choice of $\psi(x)$, we have $[f_l(0,x);\psi(x)]=1$. In the exceptional case, it turns out that although different choices for $\psi(x)$ lead to different coefficients a_j and b_j, the resulting $H(x)$ is independent of the choice of $\psi(x)$. Also note that, if $N=1$, it is necessary that the generic case occurs; however, for $N\geqslant 2$ the exceptional case may occur.

V. AN ALGORITHM TO RECOVER JUMPS IN $H'(x)/H(x)$

In Ref. 13 we described an algorithm to recover N, y_j, and q_j associated with the discontinuities of $H(x)$ in terms of the leading asymptotic behavior of the scattering data as $k\to\pm\infty$. In this section we will analyze the $O(1/k)$ terms in the scattering data and will describe an algorithm to recover the constants ν_j associated with the discontinuities of $H'(x)/H(x)$ from the almost periodic part of the $O(1/k)$ terms in the scattering data. The algorithm of Ref. 13 must be applied first to recover N, y_j, and q_j before the algorithm to recover ν_j is used. In order to use the algorithm, one also needs to know the value of $w_{N,N+1}$, where we have defined

$$w_{j,j+1}=\int_{y_j}^{y_{j+1}} dz\ V_{j,j+1}(z),$$

with $V_{j,j+1}(y)$ being the quantity defined in (2.5). The constant $w_{N,N+1}$ can be obtained from a reduced reflection coefficient in various ways without solving the entire inverse problem. For example, as we will see in Sec. VII, we have $w_{N,N+1}=2h_l(0+,y_N)$, where $h_l(t,y)$ is the solution of the Marchenko equation (7.7) that is uniquely solvable; hence the solution of (7.7) at the fixed point y_N gives us $w_{N,N+1}$.

Since $V_{j,j+1}\in L_1^1(\mathbf{R})$, the scattering coefficients associated with $V_{j,j+1}(y)$ satisfy[14]

$$\frac{1}{t_{j,j+1}(k)}=1+\frac{w_{j,j+1}}{2ik}+o\left(\frac{1}{k}\right),\quad k\to\pm\infty,$$

$$\frac{r_{j,j+1}(k)}{t_{j,j+1}(k)}=o\left(\frac{1}{k}\right),\quad \frac{l_{j,j+1}(k)}{t_{j,j+1}(k)}=o\left(\frac{1}{k}\right),\quad k\to\pm\infty,$$

and hence from (4.1) we have

$$\Lambda_{j,j+1}(k)=\mathbf{I}+\frac{w_{j,j+1}}{2ik}\,\mathbf{J}+o\left(\frac{1}{k}\right),\quad k\to\pm\infty,$$

where we have defined $\mathbf{J}=\mathrm{diag}(1,-1)$. Let us write (4.3) in the form

$$F_j=E_j+\frac{\nu_j}{2ik}\,U_j,$$

where E_j is the matrix $E(k,x_j)$ defined in (2.17) and

$$U_j=\begin{bmatrix} 1 & e^{-2iky_j} \\ -e^{2iky_j} & -1 \end{bmatrix}.$$

Thus, as $k\to\pm\infty$, from (4.5) we obtain $\Lambda=E_1E_2\cdots E_N+O(1/k)$ and

$$2ik[\Lambda-E_1E_2\cdots E_N]=w_{0,1}\mathbf{J}E_1E_2\cdots E_N+w_{1,2}E_1\mathbf{J}E_2\cdots E_N+\cdots+w_{N,N+1}E_1E_2\cdots E_N\mathbf{J}$$
$$+\nu_1U_1E_2\cdots E_N+\nu_2E_1U_2E_3\cdots E_N+\cdots+\nu_NE_1E_2\cdots E_{N-1}U_N+o(1). \tag{5.1}$$

Thus, from (2.18) and (4.2) we see that (5.1) allows us to express

$$2ik\left[\frac{1}{\tau(k)}-a(k)\right]=\Delta(k)+o(1),\quad k\to\pm\infty, \tag{5.2}$$

$$-2ik\left[\frac{\rho(k)}{\tau(k)}+b(k)\right]=\Omega(k)+o(1),\quad k\to\pm\infty, \tag{5.3}$$

where $\Delta(k)$ and $\Omega(k)$ are linear combinations of $w_{0,1},\ldots,w_{N,N+1}$ and $\nu_1,\ldots,\nu_N$ with almost periodic polynomials as coefficients.

Let us now explain how to compute ν_N. When $N=1$ we have

$$\Delta(k)=(w_{0,1}+w_{1,2})\alpha_1+\nu_1\equiv\Delta_1, \tag{5.4}$$

$$e^{2iky_1}\Omega(k)=(w_{0,1}-w_{1,2})\beta_1+\nu_1\equiv\Omega_1. \tag{5.5}$$

Multiplying (5.4) by β_1 and (5.5) by α_1, and subtracting the resulting equations, we obtain

$$\nu_1=\frac{1}{\alpha_1-\beta_1}[2w_{1,2}\alpha_1\beta_1+\alpha_1\Omega_1-\beta_1\Delta_1]. \tag{5.6}$$

When $N=2$, we have

$$\Delta(k)=\Delta_1+e^{2ik(y_2-y_1)}\Delta_2, \tag{5.7}$$

$$e^{2iky_2}\Omega(k)=\Omega_1+e^{2ik(y_2-y_1)}\Omega_2, \tag{5.8}$$

where we have defined

$$\Delta_1=(w_{0,1}+w_{1,2}+w_{2,3})\alpha_1\alpha_2+\nu_1\alpha_2+\nu_2\alpha_1, \tag{5.9}$$

$$\Omega_1=(w_{0,1}+w_{1,2}-w_{2,3})\alpha_1\beta_2+\nu_1\beta_2+\nu_2\alpha_1, \tag{5.10}$$

$$\Delta_2=(w_{0,1}-w_{1,2}+w_{2,3})\beta_1\beta_2+\nu_1\beta_2-\nu_2\beta_1,$$

$$\Omega_2=(w_{0,1}-w_{1,2}-w_{2,3})\beta_1\alpha_2+\nu_1\alpha_2-\nu_2\beta_1.$$

Multiplying (5.9) by β_2 and (5.10) by α_2 and subtracting the resulting equations, we obtain

$$\alpha_1(\beta_2-\alpha_2)\nu_2=-2w_{2,3}\alpha_1\alpha_2\beta_2+\beta_2\Delta_1-\alpha_2\Omega_1,$$

and hence

$$\nu_2=\frac{1}{\alpha_2-\beta_2}\left[2w_{2,3}\alpha_2\beta_2+\frac{\alpha_2\Omega_1-\beta_2\Delta_1}{\alpha_1}\right].$$

As can be seen from (5.4), (5.5), (5.7), and (5.8), and in general be proved by induction, the quantity $e^{2iky_N}\Omega(k)$ is obtained from $\Delta(k)$ by interchanging β_N with α_N and by changing the sign of $w_{N,N+1}$. It can also be shown that $\Delta(k)$ and $e^{2iky_N}\Omega(k)$ both are exponential polynomials having at most 2^{N-1} nonzero terms. To compute ν_N for arbitrary N, we let Δ_1 and Ω_1 denote the constant terms in the almost periodic polynomials $\Delta(k)$ and $e^{2iky_N}\Omega(k)$, respectively. From (5.1) we have

$$\Delta_1=\left(\sum_{j=0}^{N} w_{j,j+1}+\sum_{j=1}^{N}\frac{\nu_j}{\alpha_j}\right)\prod_{n=1}^{N}\alpha_n,$$

$$\Omega_1=\left(-2w_{N,N+1}\beta_N+\beta_N\sum_{j=0}^{N} w_{j,j+1}+\beta_N\sum_{j=1}^{N-1}\frac{\nu_j}{\alpha_j}+\nu_N\right)\prod_{n=1}^{N-1}\alpha_n.$$

Using

$$\beta_N\Delta_1-\alpha_N\Omega_1=2w_{N,N+1}\beta_N\prod_{j=1}^{N}\alpha_j+\nu_N(\beta_N-\alpha_N)\prod_{j=1}^{N-1}\alpha_j,$$

we get

$$\nu_N=\frac{1}{\alpha_N-\beta_N}\left[2w_{N,N+1}\alpha_N\beta_N+\frac{\alpha_N\Omega_1-\beta_N\Delta_1}{\Pi_{j=1}^{N-1}\alpha_j}\right].$$

After obtaining ν_N, we can recover ν_{N-1} as follows. The solution of the Marchenko equation in the interval $(y_N,+\infty)$ yields $V_{N,N+1}(y)$ by (7.9); thus also we have the matrix $\Lambda_{N,N+1}(k)$ defined in (4.1) because it is determined by the scattering matrix of the potential $V_{N,N+1}(y)$. Note that from the unitarity of the scattering matrix corresponding to the potential $V_{j,j+1}(y)$, we have $\det\Lambda_{j,j+1}(k)=1$. Using (2.16) it can be shown that $\det F_j(k)=1$. Thus, we can easily form the matrix $\Lambda\Lambda_{N,N+1}^{-1}F_N^{-1}$ and recover ν_{N-1} from this matrix, as we have recovered ν_N from the matrix Λ. Note that the reduced reflection coefficient from the right associated with the matrix $\Lambda\Lambda_{N,N+1}^{-1}F_N^{-1}$ is given by

$$\rho^{[N-1]}(k)=-\frac{[1\quad 0]\Lambda\Lambda_{N,N+1}^{-1}F_N^{-1}\begin{bmatrix}0\\1\end{bmatrix}}{[1\quad 0]\Lambda\Lambda_{N,N+1}^{-1}F_N^{-1}\begin{bmatrix}1\\0\end{bmatrix}}. \tag{5.11}$$

Once ν_{N-1} is obtained, we recursively get the remaining $\nu_{N-2},\ldots,\nu_1$.

VI. A SINGULAR INTEGRAL EQUATION

In this section, when there are no bound states, we formulate the singular integral equation (6.7) whose kernel and nonhomogeneous term are determined by the reduced reflection coefficient $\rho(k)$. We also show that (6.7) is uniquely solvable and its solution leads to the recovery of $H(x)$. In a similar manner, we formulate the singular integral equation (6.10) in terms of $\mathscr{l}(\mathrm{k})$ and prove its unique solvability and show that its solution also leads to the recovery of $H(x)$.

For each fixed $y\in\mathbf{R}\backslash\{y_1,\ldots,y_N\}$, from (5.11) of Ref. 1, we have

$$\begin{bmatrix}Z_l(-k,y)\\Z_r(-k,y)\end{bmatrix}=\begin{bmatrix}\tau(k) & -\rho(k)e^{2iky}\\-\mathscr{l}(k)e^{-2iky} & \tau(k)\end{bmatrix}\begin{bmatrix}Z_r(k,y)\\Z_l(k,y)\end{bmatrix},\quad k\in\mathbf{R}. \tag{6.1}$$

Using (2.19)–(2.21) and (3.3), we obtain

$$\begin{bmatrix} J_l(-k,y) \\ J_r(-k,y) \end{bmatrix} = \begin{bmatrix} \dfrac{1}{a(k)} & \dfrac{b(k)}{a(k)}\, e^{2iky} \\ -\dfrac{b(-k)}{a(k)}\, e^{-2iky} & \dfrac{1}{a(k)} \end{bmatrix} \begin{bmatrix} J_r(k,y) \\ J_l(k,y) \end{bmatrix}, \quad k \in \mathbf{R}. \tag{6.2}$$

Subtracting (6.2) from (6.1), we get

$$Z_l(-k,y) - J_l(-k,y) = \left[\tau(k) - \frac{1}{a(k)} \right] Z_r(k,y) + \frac{1}{a(k)} \left[Z_r(k,y) - J_r(k,y) \right] - \rho(k) e^{2iky} \left[Z_l(k,y) - J_l(k,y) \right] - \left[\rho(k) + \frac{b(k)}{a(k)} \right] e^{2iky} J_l(k,y), \tag{6.3}$$

$$Z_r(-k,y) - J_r(-k,y) = \left[\tau(k) - \frac{1}{a(k)} \right] Z_l(k,y) + \frac{1}{a(k)} \left[Z_l(k,y) - J_l(k,y) \right] - \ell(k) e^{-2iky} \left[Z_r(k,y) - J_r(k,y) \right] - \left[\ell(k) - \frac{b(-k)}{a(k)} \right] e^{-2iky} J_r(k,y). \tag{6.4}$$

Let us analyze (6.3). Using Propositions 2.1 and 3.1 and Theorem 3.2, for each fixed y, in the absence of bound states, of the four terms on the right-hand side, we see that the first two belong to the Hardy space $\mathbf{H}^2_+(\mathbf{R})$ and the last two belong to $L^2(\mathbf{R})$; the term on the left-hand side belongs to $\mathbf{H}^2_-(\mathbf{R})$. Let $\Pi_\pm$ denote the orthogonal projection operators from $L^2(\mathbf{R})$ onto $\mathbf{H}^2_\pm(\mathbf{R})$, i.e.

$$(\Pi_\pm f\,)(k) = \frac{\pm 1}{2\pi i} \int_{-\infty}^{\infty} \frac{ds}{s - k \mp i0}\, f(s).$$

Let us define

$$X_l(k,y) = Z_l(-k,y) - J_l(-k,y), \quad X_r(k,y) = Z_r(-k,y) - J_r(-k,y). \tag{6.5}$$

Applying the projection Π_- on both sides of (6.3), we obtain

$$X_l(\cdot\,,y) + \Pi_-(\rho e^{2i(\cdot)y} \mathscr{F} X_l(\cdot\,,y)) = -\Pi_- \left(\left[\rho + \frac{b}{a} \right] e^{2i(\cdot)y} J_l(\cdot\,,y) \right), \tag{6.6}$$

where $(\mathscr{F} f\,)(k) = f(-k)$. Note that (6.6) is a singular integral equation and can be written as

$$X_l(k,y) + (\mathscr{O}_l X_l)(k,y) = P_l(k,y), \quad k \in \mathbf{R}, \tag{6.7}$$

where we have defined

$$(\mathscr{O}_l X)(k) = \frac{1}{2\pi i} \int_{-\infty}^{\infty} \frac{ds}{s + k - i0}\, \rho(-s) e^{-2isy} X(s), \quad k \in \mathbf{R}, \tag{6.8}$$

$$P_l(k,y) = \frac{1}{2\pi i} \int_{-\infty}^{\infty} \frac{ds}{s - k + i0} \left[\rho(s) + \frac{b(s)}{a(s)} \right] e^{2isy} J_l(s,y). \tag{6.9}$$

Notice that the integral operator $\mathscr{O}_l$ defined in (6.8) is the same as the operator defined in (5.23) of Ref. 1. Comparing (5.21) of Ref. 1 and (6.7), we see that the kernels in these two integral equations differ by a minus sign. We also recall that the solution of the singular integral equation of Ref. 1 is given by $X_l(k,y) = [Z_l(-k,y) - Z_l(0,y)]/[k\sqrt{H(x)}]$, where $Z_l(k,y)$ is the quantity defined in (3.1), whereas the solution of the integral equation of this paper is given by (6.5). The factor $1/k$ in the expression for $X_l(k,y)$ used in Ref. 1 was introduced to ensure that $X_l(k,y)$ belongs to an appropriate Hardy space, namely to $\mathbf{H}_-^p(\mathbf{R})$ if $p<1/(1-\alpha)$. However, this factor, while providing the desired behavior as $k\to\infty$, introduced some complications at $k=0$. With the present definition (6.5) it is easy to show that $X_l(k,y)$ is continuous as $k\to 0$ in $\overline{\mathbf{C}^+}$ and $X_l(k,y)=O(1/k)$ as $k\to\infty$ in $\overline{\mathbf{C}^+}$, without imposing any stronger condition on $Q(x)$ than $Q\in L_1^1(\mathbf{R})$.

In a similar manner, in the absence of bound states, from (6.4) we obtain

$$X_r(\cdot,y)+\Pi_-(\mathscr{C}e^{-2i(\cdot)y}\mathscr{F}X_r(\cdot,y))=-\Pi_-\left(\left[\mathscr{C}-\frac{\mathscr{F}b}{a}\right]e^{-2i(\cdot)y}J_r(\cdot,y)\right),$$

which is equivalent to

$$X_r(k,y)+(\mathscr{O}_rX_r)(k,y)=P_r(k,y),\quad k\in\mathbf{R}, \tag{6.10}$$

where we have defined

$$(\mathscr{O}_rX)(k)=\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{ds}{s+k-i0}\,\mathscr{C}(-s)e^{2isy}X(s),\quad k\in\mathbf{R},$$

$$P_r(k,y)=\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{ds}{s-k+i0}\left[\mathscr{C}(s)-\frac{b(-s)}{a(s)}\right]e^{-2isy}J_r(s,y). \tag{6.11}$$

The solvability of (6.7) and (6.10) is analyzed in the next theorem.

Theorem 6.1: The singular integral equation (6.7) has a unique solution $X_l\in\mathbf{H}_-^2(\mathbf{R})$ for every nonhomogeneous term belonging to $\mathbf{H}_-^2(\mathbf{R})$, and the solution can be obtained through iteration. Similarly, (6.10) has a unique solution $X_r\in\mathbf{H}_-^2(\mathbf{R})$ for every nonhomogeneous term belonging to $\mathbf{H}_-^2(\mathbf{R})$ and the solution can be obtained through iteration.

Proof: The operator $\mathscr{O}_l$ defined in (6.8) is a strict contraction on $\mathbf{H}_-^2(\mathbf{R})$, which is proved in Theorem 7.1 of Ref. 1. Hence, (6.7) is uniquely solvable and its solution can be obtained through iteration. The proof for (6.10) is given in the same manner. ■

Next we will recover $H(x)$ from an appropriate set of scattering data. We will consider the generic and exceptional cases separately because the scattering data in these two cases are not the same.

Let us first consider the generic case; in this case an appropriate set of scattering data consists of $\{\rho(k),Q(x)\}$. We proceed as follows. Using the method of Ref. 16, from $\rho(k)$ we get $b(k)$ and $a(k)$; then from these we get N, $\{y_1,\ldots,y_N\}$, and $\{q_1,\ldots,q_N\}$ by using the method of Ref. 13. Hence, we have α_j and β_j for $j=1,\ldots,N$. Since $Q(x)$ is known, we also know the zero-energy Jost solutions of (1.5); these Jost solutions are identical to the zero-energy Jost solutions of (1.1). For example, we can get $f_l(0,x)$ by using (5.25) of Ref. 1. Next we obtain $J_l(k,y)$ using (3.4) and (3.5). Note that $J_l(k,y)$ is uniquely constructed from $\rho(k)$ because we already have y_j, α_j, and β_j for $j=1,\ldots,N$. From (3.1) and the fact that $H(x)=dy/dx$, we have

$$\frac{dy}{Z_l(0,y)^2}=H_+\,\frac{dx}{f_l(0,x)^2}. \tag{6.12}$$

Using $J_l(k,y)$ and $\rho(k)$ in (6.7), we obtain $X_l(k,y)$ uniquely. Then using (6.5), we write (6.12) in the form

$$\frac{dy}{[X_l(0,y)+J_l(0,y)]^2}=H_+\,\frac{dx}{f_l(0,x)^2}. \tag{6.13}$$

We get H_+ from (6.13) as

$$H_+=\frac{\int_{-\infty}^{0}dy/[X_l(0,y)+J_l(0,y)]^2}{\int_{-\infty}^{0}dx/f_l(0,x)^2}. \tag{6.14}$$

Note that both integrals in (6.14) converge because[17] in the generic case, $f_l(0,x)^2$ grows like x^2 as $x\to-\infty$ and $Z_l(0,y)^2$ grows like y^2 as $y\to-\infty$. Next, using a generalization of the method given in Theorem 5.1 of Ref. 13, we obtain $x_1,\ldots,x_N$. This is done as follows. If $N=1$ and $y_1=0$, then $x_1=0$. If $N=1$ and $y_1\neq0$, then we can proceed as in the case $N\geqslant2$. If $N\geqslant2$, then at least $N-1$ of the points $y_1,\ldots,y_N$ must be nonzero. If at least one of these is positive, we can pick the smallest of them, say y_p. Then x_p is uniquely determined by

$$\int_0^{y_p}\frac{dy}{[X_l(0,y)+J_l(0,y)]^2}=H_+\int_0^{x_p}\frac{dx}{f_l(0,x)^2}, \tag{6.15}$$

and we recursively determine $x_{p+1},\ldots,x_N$ using

$$\int_{y_p}^{y_{p+1}}\frac{dy}{[X_l(0,y)+J_l(0,y)]^2}=H_+\int_{x_p}^{x_{p+1}}\frac{dx}{f_l(0,x)^2}.$$

Similarly, we can determine $x_{p-1},x_{p-2},\ldots,x_1$. If all y_j are nonpositive, then we pick the one with the smallest absolute value that is nonzero (either y_N or y_{N-1}) and find the corresponding x_j by using the appropriate integral of the form (6.15). Having found each x_j corresponding to y_j, we obtain $y(x)$ by solving the first-order separable ordinary differential equation (6.13) with the initial condition $y(x_i)=y_i$. Having $y(x)$ in each interval (x_j,x_{j+1}), we get $H(x)=dy/dx$.

Now let us consider the exceptional case. In this case, we cannot use (6.14) to obtain H_+. In fact, for the unique recovery of $H(x)$ we need to include H_+ in the scattering data; otherwise, we get a one-parameter family of $H(x)$ corresponding to the set $\{\rho(k),Q(x)\}$. Thus, in the exceptional case, we recover $H(x)$ from the scattering data $\{\rho(k),H_+,Q(x)\}$ by the method outlined in the generic case.

Note that one can also recover $H(x)$ from the solution of the singular integral equation (6.10) using the scattering data $\{\mathscr{A}(k),Q(x)\}$ in the generic case and using $\{\mathscr{A}(k),Q(x),H_+\}$ in the exceptional case. One then needs to solve the analog of (6.12) given by

$$\frac{dy}{Z_r(0,y)^2}=H_-\,\frac{dx}{f_r(0,x)^2}, \tag{6.16}$$

with the condition $y(0)=0$. Note that from (6.5) we have $Z_r(0,y)=X_r(0,y)+J_r(0,y)$, and $f_r(0,x)$ is the zero-energy Jost solution from the right of (1.5) corresponding to $Q(x)$. The potential $Q(x)$ uniquely determines[14,18–20] $f_r(0,x)$, for example, by

$$f_r(0,x)=1+\int_{-\infty}^{x}dz\;(x-z)Q(z)f_r(0,z). \tag{6.17}$$

Once we obtain y as a function of x from (6.16), we recover $H(x)$ as

$$H(x)=H_- \frac{Z_r(0,y)^2}{f_r(0,x)^2}. \tag{6.18}$$

Note that, in the exceptional case, H_- can be expressed in terms of H_+ by using (5.29) of Ref. 1, namely,

$$H_-=H_+ \frac{1-\rho(0)}{1+\rho(0)} \left(\frac{1+R^{[0]}(0)}{T^{[0]}(0)} \right)^2, \tag{6.19}$$

where $R^{[0]}(k)$ and $T^{[0]}(k)$ are the reflection coefficient from the right and the transmission coefficient, respectively, associated with (1.5). Hence, in the exceptional case, one can use H_- in the scattering data instead of H_+ because of (6.19). Note also that in the exceptional case $f_l(0,x)$ and $f_r(0,x)$ are linearly dependent, and we have[17]

$$f_r(0,x)= \frac{1+R^{[0]}(0)}{T^{[0]}(0)} f_l(0,x). \tag{6.20}$$

Let $f_l^{[0]}(k,x)$ and $f_r^{[0]}(k,x)$ denote the Jost solutions of (1.5) from the left and from the right, respectively. In the generic case we have

$$f_r^{[0]}(k,x)=[f_l^{[0]}(k,x);f_r^{[0]}(k,x)]f_l^{[0]}(k,x) \int_{-\infty}^{x} \frac{dz}{f_l^{[0]}(k,z)^2}, \tag{6.21}$$

where the Wronskian $[f_l^{[0]}(k,x);f_r^{[0]}(k,x)]$ is equal to $-2ik/T^{[0]}(k)$. Hence, in the generic case from (6.21), after using the fact that $f_l^{[0]}(0,x)=f_l(0,x)$ and $f_r^{[0]}(0,x)=f_r(0,x)$, we have

$$f_r(0,x)= \left[\lim_{k\to 0} \frac{-2ik}{T^{[0]}(k)} \right] f_l(0,x) \int_{-\infty}^{x} \frac{dz}{f_l(0,z)^2}.$$

VII. MARCHENKO INTEGRAL EQUATION

In this section we show that the singular integral equation (6.7), with the use of the Fourier transform, can be transformed into the integral equation (7.7) generalizing the Marchenko integral equation[14,18–20] for the one-dimensional Schrödinger equation. We establish the unique solvability of (7.7) and describe how its solution leads to the recovery of $H(x)$.

Using (2.20) and the continuity of $\rho(k)$ and $b(k)/a(k)$, we see that $\rho+(b/a)\in L^p(\mathbf{R})$ for any $p\in(1,+\infty]$. We may then write

$$\rho(k)=-\frac{b(k)}{a(k)}+\int_{-\infty}^{\infty} dz\ e^{ikz}\varrho(z), \tag{7.1}$$

where $\varrho\in L^q(\mathbf{R})$ for $q\in[2,+\infty)$. The symmetry relation $F(-k)=\overline{F(k)}$ for $k\in\mathbf{R}$ valid for ρ, a, and b, implies that ϱ is real valued. Since b/a belongs to AP^W, we have $b(k)/a(k) = -\Sigma_s \gamma_s e^{ikb_s}$ where b_s are different real numbers and γ_s are real constants satisfying $\Sigma_s|\gamma_s|<+\infty$; thus we can write (7.1) in the form

$$\rho(k)=\sum_s \gamma_s e^{ikb_s}+\int_{-\infty}^{\infty} dz\ e^{ikz}\varrho(z). \tag{7.2}$$

Let us write (7.2) in the concise form

$$\rho(k)=\int_{-\infty}^{\infty} d\mu(t)\ e^{ikt}, \tag{7.3}$$

for a suitable real measure μ that is the sum of a discrete measure (with weights γ_s at the points b_s) and an absolutely continuous measure (with a Radon-Nikodym derivative ϱ). Let $\mathscr{F}$ denote the Fourier transform defined by

$$(\mathscr{F}g)(t)=\frac{1}{2\pi}\int_{-\infty}^{\infty} dk\ e^{ikt}g(k). \tag{7.4}$$

Since $X_l(\cdot,y)$ and $P_l(\cdot,y)$ appearing in (6.7) belong to $\mathbf{H}_-^2(\mathbf{R})$, their Fourier transforms are supported on the positive half-line; hence, we have

$$X_l(k,y)=\int_0^{\infty} dt\ e^{-ikt}h_l(t,y), \quad P_l(k,y)=\int_0^{\infty} dt\ e^{-ikt}h_{l0}(t,y), \tag{7.5}$$

where $h_l, h_{l0}\in L^q(\mathbf{R}^+)$ for any $q\in[2,+\infty)$. Furthermore, as seen from (3.16), $J_l(k,y)$ consists of a finite sum of exponential terms; hence we have $J_l(k,y)=\Sigma_s\omega_s(y)e^{ik\zeta_s(y)}$, where, in each interval (y_j,y_{j+1}), $\omega_s(y)$ is a constant and $\zeta_s(y)$ is either a constant or an affine function of y. Thus, from (6.9) we obtain

$$h_{l0}(t,y)=-\sum_s\ \omega_s(y)\varrho(-t-2y-\zeta_s(y)), \quad t\geqslant 0.$$

Now let us take the Fourier transform of both sides of (6.7). We have

$$h_l(\cdot,y)+(\mathscr{F}\mathscr{O}_l\mathscr{F}^{-1}h_l)(\cdot,y)=h_{l0}(\cdot,y). \tag{7.6}$$

Using (7.2) or (7.3) we can write (7.6) as the Marchenko-like integral equation

$$h_l(t,y)+\int_{-\infty}^{-(t+2y)} d\mu(z)\ h_l(-z-t-2y,y)=h_{l0}(t,y), \quad t\geqslant 0,$$

or equivalently

$$h_l(t,y)+\sum_{\{s:b_s<-t-2y\}}\gamma_s h_l(-t-2y-b_s,y)+\int_0^{\infty} ds\ \varrho(-s-t-2y)\ h_l(s,y)=h_{l0}(t,y), \quad t\geqslant 0. \tag{7.7}$$

We will call (7.7) a Marchenko equation. Note that when $N=0$, i.e. when $V(y)$ given in (2.3) is well defined for all $y\in\mathbf{R}$, the integral equation (7.7) reduces to

$$h_l(t,y)+\int_0^{\infty} ds\ \varrho(-s-t-2y)\ \ h_l(s,y)=-\varrho(-t-2y), \quad t\geqslant 0, \tag{7.8}$$

which is the Marchenko equation[14,18–20] for the ordinary Schrödinger equation. In a similar manner we can also obtain a Marchenko integral equation associated with the reflection coefficient ℓ(k), but we will not list it here. The next theorem shows that (7.7) is uniquely solvable.

Theorem 7.1: Equation (7.7) has a unique solution in $L^2(\mathbf{R}^+)$ for every nonhomogeneous term belonging to $L^2(\mathbf{R}^+)$, and the solution can be obtained through iteration.

Proof: The operator $\mathscr{O}_l$ in (7.6) is a strict contraction on $\mathbf{H}_-^2(\mathbf{R})$, as indicated in the proof of Theorem 6.1. Considering $L^2(\mathbf{R}^+)$ and $\mathbf{H}_-^2(\mathbf{R})$ as subspaces of $L^2(\mathbf{R})$, we see that $\sqrt{2\pi}\mathscr{F}$, where

$\mathscr{F}$ is the Fourier transformation defined in (7.4), is a unitary operator on $L^2(\mathbf{R})$ mapping $\mathbf{H}_-^2(\mathbf{R})$ onto $L^2(\mathbf{R}^+)$. Thus, the operator $\mathscr{F}\mathscr{O}_l\mathscr{F}^{-1}$ acting from $L^2(\mathbf{R}^+)$ into $L^2(\mathbf{R}^+)$ is a strict contraction. Hence, (7.7) is uniquely solvable and its solution can be obtained through iteration. ■

Let us now discuss the recovery of $H(x)$ from the solution of the Marchenko equation (7.7). Once $h_l(t,y)$ is obtained from (7.7), we can get $X_l(k,y)$ from (7.5) and recover $H(x)$ by repeating the procedure described in Sec. VI.

Let us also describe another way to recover $H(x)$. This is done in conjunction with the algorithm described in Sec. V, where N, y_j, q_j, are recovered first; recall that these are the parameters associated with the ''hard scatterers.'' Next we recover the quantities associated with the ''soft scatterers,'' namely we obtain $V_{j,j+1}(y)$. This is done recursively as follows. First we solve (7.7) only for $y>y_N$ and get $h_l(t,y)$ in the interval $(y_N,+\infty)$. Because of (3.8) we obtain[21]

$$V_{N,N+1}(y)=-2\,\frac{dh_l(0+,y)}{dy}, \quad y_N<y<+\infty, \tag{7.9}$$

$$Z_l(0,y)=1+\int_y^\infty dz\ (z-y)V_{N,N+1}(z)\ Z_l(0,z), \quad y_N<y<+\infty. \tag{7.10}$$

Then, as described in Sec. V, we form the new reduced reflection coefficient $\rho^{[N-1]}(k)$ defined in (5.11) and obtain $V_{N-1,N}(y)$ from the solution of the Marchenko equation corresponding to $\rho^{[N-1]}(k)$ by using the analog of (7.9). Continuing in this manner, we then recover $V_{j,j+1}(y)$ for $j=0,1,\ldots,N$. Then we obtain $Z_l(0,y)$ for $y\in\mathbf{R}\backslash\{y_1,\ldots,y_N\}$ as follows. From (3.1) we have

$$Z_l(k,y_j-0)=\sqrt{q_j}\ Z_l(k,y_j+0),$$

$$Z_l'(k,y_j-0)=\frac{Z_l'(k,y_j+0)}{\sqrt{q_j}}-2ik\left(\beta_j-\frac{\nu_j}{2ik}\right)Z_l(k,y_j+0),$$

as well as $Z_l(k,+\infty)=1$ and $Z_l'(k,+\infty)=0$. Hence, $Z_l(0,y)$ and $Z_l'(0,y)$ satisfy the following internal boundary conditions:

$$Z_l(0,y_j-0)=\sqrt{q_j}\ Z_l(0,y_j+0), \tag{7.11}$$

$$Z_l'(0,y_j-0)=\frac{Z_l'(0,y_j+0)}{\sqrt{q_j}}+\nu_j\ Z_l(0,y_j-0). \tag{7.12}$$

Thus, in each interval (y_j,y_{j+1}), we can uniquely obtain $Z_l(0,y)$ from $V_{j,j+1}(y)$ by using

$$Z_l(0,y)=(y-y_{j+1})Z_l'(0,y_{j+1}-0)+Z_l(0,y_{j+1}-0)+\int_y^{y_{j+1}}dz\ (z-y)V(z)\ Z_l(0,z). \tag{7.13}$$

Thus, using (7.10), (7.11)–(7.13) we obtain $Z_l(0,y)$ for $y\in\mathbf{R}\backslash\{y_1,\ldots,y_N\}$. Once we have $Z_l(0,y)$, we can recover $H(x)$ by using the procedure outlined starting with (6.12).

Note that although we assume that there are no bound states associated with (1.1), some of the $V_{j,j+1}(y)$ may have bound states. In terms of the factorization formula (4.5), this happens when the hard scatterers $F_j(k)$ in (4.5) overcome the bound states from the soft scatterers $\Lambda_{j,j+1}(k)$, resulting in no bound states for (1.1); in other words, the poles of $t_{j,j+1}(k)$ in $\mathbf{C}^+$ are canceled by the terms in $F_j(k)$, resulting in no poles in $\mathbf{C}^+$ for $\tau(k)$. The recovery of $V_{j,j+1}(y)$, even in the presence of bound states, is well understood;[22] since each $V_{j,j+1}(y)$ has support contained in a

half-line, the reflection coefficient $r_{j,j+1}(k)$ uniquely determines $V_{j,j+1}(y)$ without needing the bound state energies and the bound state norming constants; in fact, both the bound state energies and the norming constants are uniquely determined by $r_{j,j+1}(k)$ alone.

We can also obtain $H(x)$ by modifying the procedures described earlier. For example, using the reduced reflection coefficient from the left ℓ(k), the analog of (7.7) associated with ℓ(k) can be used to obtain $V_{j,j+1}(y)$ starting with the interval (y_0,y_1) and moving to the interval (y_1,y_2) and continuing in this manner. One can also solve the Marchenko equations associated with ℓ(k) and $\rho(k)$, respectively, simultaneously starting with the intervals (y_0,y_1) and (y_N,y_{N+1}), respectively, and moving to the intervals (y_1,y_2) and (y_{N-1},y_N), respectively, and continuing in this manner until all $V_{j,j+1}(y)$ are obtained. Then, using (7.11)–(7.13) one gets $Z_l(0,y)$ or $Z_r(0,y)$, from which $H(x)$ is obtained using (6.12) or (6.16).

VIII. EXAMPLES

In this section we illustrate the methods described in Secs. V–VII through explicitly solved examples. In Examples 8.1–8.3 we illustrate the recovery of $H(x)$ using the solution of the Marchenko integral equation (7.7). In Example 8.4 we illustrate the method of Sec. V to recover the discontinuities in $H'(x)/H(x)$. In Example 8.5 we illustrate the alternative procedure described in Sec. VII using (5.11). Finally, In Example 8.6 we illustrate the recovery of $H(x)$ in terms of the solutions of the singular integral equations (6.7) and (6.10).

Example 8.1: Let us demonstrate the Marchenko method of Sec. VII. As our scattering data, for a given $Q(x)$ with no bound states and a given H_+, let us use

$$\rho(k)=\epsilon\,\frac{k+i\alpha}{k+i\gamma}, \tag{8.1}$$

where ϵ, α, and γ are real constants satisfying $-1<\epsilon<1$, $\gamma>0$, and $\gamma^2>\alpha^2\epsilon^2$. It is straightforward but tedious to show that for $y\leqslant 0$ the denominator in (8.11) and (8.12) is nonzero if and only if $(\alpha+\beta)\epsilon\neq 0$. Thus, in this example, we assume $(\alpha+\beta)\epsilon\neq 0$ and postpone the case $(\alpha+\beta)\epsilon=0$ to Example 8.2. Using the method of Ref. 16 we construct $\tau(k)$ by solving the Wiener-Hopf factorization problem $\tau(k)\tau(-k)=1-|\rho(k)|^2$ for $k\in\mathbf{R}$, and we obtain

$$\tau(k)=\sqrt{1-\epsilon^2}\,\frac{k+i\beta}{k+i\gamma}, \tag{8.2}$$

where we have defined the positive constant

$$\beta=\sqrt{\frac{\gamma^2-\alpha^2\epsilon^2}{1-\epsilon^2}}. \tag{8.3}$$

It can be verified that $|\tau(k)|^2+|\rho(k)|^2=1$ and that $\tau(k)$ has no poles or zeros in $\mathbf{C}^+$. Since $\tau(0)\neq 0$, we are in the exceptional case. Using the method of Ref. 13, we obtain

$$N=1,\quad q_1=\frac{1-\epsilon}{1+\epsilon},\quad y_1=0,\quad a(k)=\frac{1}{\sqrt{1-\epsilon^2}},\quad b(k)=-\frac{\epsilon}{\sqrt{1-\epsilon^2}}. \tag{8.4}$$

From (3.16) we get

$$J_l(k,y)=\begin{cases}\dfrac{1-\epsilon e^{-2iky}}{\sqrt{1-\epsilon^2}}, & y<0,\\ 1, & y>0.\end{cases} \tag{8.5}$$

Thus, from (6.9) we obtain

$$P_l(k,y)=\begin{cases}\dfrac{i\epsilon}{k+i\gamma}\,(\alpha-\gamma)\sqrt{1-e^2}\,[e^{2\gamma y}-e^{2iky}], & y<0,\\ 0, & y>0.\end{cases} \tag{8.6}$$

Using (8.6) in (7.5) we have

$$h_{l0}(t,y)=\begin{cases}-\dfrac{\epsilon(\alpha-\gamma)}{\sqrt{1-\epsilon^2}}\,e^{\gamma(t+2y)}, & t>0, \quad t+2y<0,\\ 0, & t>0, \quad t+2y>0.\end{cases}$$

From (8.1) we see that we can write (7.2) as

$$\rho(k)=\epsilon+\int_{-\infty}^{\infty}dt\; e^{ikt}\varrho(t),$$

with

$$\varrho(t)=\begin{cases}0, & t<0\\ \epsilon(\alpha-\gamma)e^{-\gamma t}, & t>0,\end{cases} \tag{8.7}$$

and hence $\varrho(t)$ is supported only on $t\geqslant 0$. The Marchenko equation (7.7) has the following form:

$$h_l(t,y)=0, \quad t>0, \quad t+2y>0, \tag{8.8}$$

$$h_l(t,y)+\epsilon h_l(-t-2y,y)+\epsilon(\alpha-\gamma)e^{\gamma(t+2y)}\int_0^{-(t+2y)}ds\; e^{\gamma s}h_l(s,y)=-\frac{\epsilon(\alpha-\gamma)}{\sqrt{1-\epsilon^2}}\,e^{\gamma(t+2y)},$$

$$t>0, \quad t+2y<0. \tag{8.9}$$

Notice that from (8.8) we obtain $X_l(k,y)=0$ for $y>0$, and hence using (8.1) and (8.5), from (6.13) we conclude that

$$H(x)=\frac{H_+}{f_l(0,x)^2}, \quad y=H_+\int_0^x\frac{dz}{f_l(0,z)^2}, \quad x>0, \tag{8.10}$$

where $f_l(0,x)$ is the zero-energy Jost solution from the left associated with $Q(x)$. We can solve (8.9) exactly and obtain

$$h_l(t,y)=\frac{(\beta^2-\gamma^2)e^{\beta t}+\epsilon(\gamma-\beta)(\alpha+\beta)e^{-\beta(t+2y)}}{\sqrt{1-e^2}[(\alpha+\beta)\epsilon e^{-2\beta y}+\beta-\gamma]}, \quad t>0, \quad t+2y<0, \tag{8.11}$$

where β is the constant in (8.3) and the denominator does not vanish. Using (8.11) in (7.5), for $y<0$, we get

$$X_l(k,y)=\frac{(\beta+ik)(\beta^2-\gamma^2)[e^{2y(ik-\beta)}-1]+(\beta-ik)\epsilon(\gamma-\beta)(\alpha+\beta)e^{-2\beta y}[1-e^{2y(\beta+ik)}]}{(k^2+\beta^2)\sqrt{1-\epsilon^2}[(\alpha+\beta)\epsilon e^{-2\beta y}+\beta-\gamma]}. \tag{8.12}$$

Hence, using (8.5) and (8.12), we find

$$Z_l(0,y)=\sqrt{\frac{\gamma-\epsilon\alpha}{\gamma+\epsilon\alpha}}\,\frac{\epsilon(\alpha+\beta)e^{-2\beta y}+\gamma-\beta}{\epsilon(\alpha+\beta)e^{-2\beta y}-y+\beta}, \quad y<0. \tag{8.13}$$

Using (8.13) in (6.12), we obtain

$$\frac{\gamma+\epsilon\alpha}{\gamma-\epsilon\alpha}\left[y+\frac{2(\gamma-\beta)/\beta}{\epsilon(\alpha+\beta)+\gamma-\beta}-\frac{2(\gamma-\beta)/\beta}{\epsilon(\alpha+\beta)e^{-2\beta y}+\gamma-\beta}\right]=H_+\int_0^x\frac{dz}{f_l(0,z)^2}, \quad y<0, \tag{8.14}$$

$$H(x)=\frac{H_+}{f_l(0,x)^2}\,\frac{\gamma-\epsilon\alpha}{\gamma+\epsilon\alpha}\left[\frac{\epsilon(\alpha+\beta)e^{-2\beta y}+\gamma-\beta}{\epsilon(\alpha+\beta)e^{-2\beta y}-\gamma+\beta}\right]^2, \quad y<0, \tag{8.15}$$

where y in (8.15) is obtained in terms of x from (8.14).

Example 8.2: In this example we consider the same scattering data as in Example 8.1 but with the additional condition $(\alpha+\beta)\epsilon=0$, where β is the constant in (8.3). If $\epsilon=0$ then $\rho(k)=0$ and $\tau(k)=1$, and the Marchenko equation (7.7) gives us $h_l(t,y)=0$ for $t>0$ and $y\in\mathbf{R}$; thus, there are no discontinuities in $H(x)$ or $H'(x)/H(x)$, and we have

$$H(x)=\frac{H_+}{f_l(0,x)^2}, \quad x\in\mathbf{R}.$$

If $\beta=-\alpha$ but $\epsilon\neq0$, then $\gamma=\beta$; in this case we have

$$\rho(k)=\epsilon\,\frac{k-i\gamma}{k+i\gamma}, \quad \tau(k)=\sqrt{1-\epsilon^2}.$$

In this case, for $x>0$, (8.10) is still valid. When $x<0$, we proceed as follows. In the Marchenko equation (8.9), putting $\alpha=-\gamma$, we obtain

$$h_l(t,y)+\epsilon h_l(-t-2y,y)-2\gamma\epsilon e^{\gamma(t+2y)}\int_0^{-(t+2y)}ds\;e^{\gamma s}h_l(s,y)=\frac{2\epsilon\gamma}{\sqrt{1-\epsilon^2}}\,e^{\gamma(t+2y)},$$

$$t>0, \quad t+2y<0. \tag{8.16}$$

The solution of (8.16) is given by

$$h_l(t,y)=\frac{2\epsilon\gamma}{\sqrt{1-\epsilon^2}}\,\frac{e^{\gamma(t+2y)}}{1+\epsilon e^{2\gamma y}}, \quad t>0, \quad t+2y<0. \tag{8.17}$$

Using (6.5), (7.5), (8.5), (8.8), and (8.17), we obtain

$$Z_l(0,y)=\sqrt{\frac{1+\epsilon}{1-\epsilon}}\,\frac{1-\epsilon e^{2\gamma y}}{1+\epsilon e^{2\gamma y}}, \quad y<0. \tag{8.18}$$

Using (8.18) in (6.12), we obtain

$$\frac{1-\epsilon}{1+\epsilon}\left[y+\frac{2/\gamma}{1-\epsilon e^{2\gamma y}}-\frac{2/\gamma}{1-\epsilon}\right]=H_+\int_0^x\frac{dz}{f_l(0,z)^2}, \quad x<0, \tag{8.19}$$

$$H(x)=\frac{H_+}{f_l(0,x)^2}\,\frac{1+\epsilon}{1-\epsilon}\left(\frac{1-\epsilon e^{2\gamma y}}{1+\epsilon e^{2\gamma y}}\right)^2, \quad y<0, \tag{8.20}$$

where y in (8.20) is obtained in terms of x from (8.19).

Example 8.3: In this example, we consider the scattering data of Example 8.1 with $\gamma^2=\alpha^2\epsilon^2$. When $\gamma=\pm\alpha\epsilon$, we have $\beta=0$, and hence $\rho(k)=(\epsilon k\pm i\gamma)/(k+i\gamma)$. Since $\rho(0)=+1$ is not allowed (cf. Theorem 4.2 of Ref. 1), we cannot have $\gamma=+\alpha\epsilon$. Thus, the inverse scattering problem to be solved corresponds to the scattering data

$$\rho(k)=\frac{\epsilon k-i\gamma}{k+i\gamma}, \quad Q(x),$$

when there are no bound states. We have $\tau(k)=\sqrt{1-\epsilon^2}k/(k+i\gamma)$, and hence this corresponds to the generic case; thus H_+ cannot be specified arbitrarily in the scattering data, and it is determined as in (6.14). In this case, (8.8) still holds. Putting $\alpha=-\gamma/\epsilon$ in (8.9), we obtain

$$h_l(t,y)+\epsilon h_l(-t-2y,y)-\gamma(1+\epsilon)e^{\gamma(t+2y)}\int_0^{-(t+2y)} ds\; e^{\gamma s}h_l(s,y)=\frac{\gamma(1+\epsilon)}{\sqrt{1-\epsilon^2}}\,e^{\gamma(t+2y)},$$

$$t>0, \quad t+2y<0. \tag{8.21}$$

The solution of (8.21) is given by

$$h_l(t,y)=\frac{\gamma}{\sqrt{1-\epsilon^2}}, \quad t>0, \quad t+2y<0. \tag{8.22}$$

Using (7.5), (8.5), (8.8), and (8.22), we obtain

$$Z_l(0,y)=\frac{1-\epsilon-2\gamma y}{\sqrt{1-\epsilon^2}}, \quad y<0. \tag{8.23}$$

Using (8.23) in (6.12), we have

$$\frac{(1+\epsilon)y}{1-\epsilon-2\gamma y}=H_+\int_0^x\frac{dz}{f_l(0,z)^2}, \quad x<0. \tag{8.24}$$

Letting $x,y\to-\infty$ in (8.24), as in (6.14), we get

$$H_+=\frac{1+\epsilon}{2\gamma\int_{-\infty}^0 dz/f_l(0,z)^2}. \tag{8.25}$$

Thus, from (8.24) and (8.25) we find

$$y=\frac{1-\epsilon}{2\gamma}\,\frac{\int_0^x dz/f_l(0,z)^2}{\int_{-\infty}^x dz/f_l(0,z)^2}, \quad x<0,$$

$$H(x)=\frac{1-\epsilon}{2\gamma f_l(0,x)^2}\,\frac{\int_{-\infty}^0 dz/f_l(0,z)^2}{[\int_{-\infty}^x dz/f_l(0,z)^2]^2}, \quad x<0. \tag{8.26}$$

Alternatively, by using (6.21) we can write (8.26) as

$$H(x)=\frac{(1-\epsilon)[f_l^{[0]}(0,x);f_r^{[0]}(0,x)]^2}{2\gamma}\,\frac{\int_{-\infty}^{0} dz/f_l(0,z)^2}{f_r(0,x)^2},\quad x<0.$$

This expression agrees with that obtained in (6.51) of Example 6.2 in Ref. 1, but the method used here is simpler.

Example 8.4: In this example we describe how to obtain ν_j defined in (4.4) related to discontinuities in $H'(x)/H(x)$ using the method outlined in Sec. V. Let us use the scattering data of Example 8.1, and hence $\rho(k)$ is given by (8.1) and $\pi(k)$ is given by (8.2). We proceed as in Example 8.1 until (8.7); we then set up the Marchenko equation only for $y>0$, which, by (8.8), yields $h_l(t,y)=0$. At this point we can conclude that $V_{1,2}(y)=0$ and hence $w_{1,2}=0$. Using (5.2)–(5.5), we obtain

$$\Delta_1=\frac{2(\beta-\gamma)}{\sqrt{1-\epsilon^2}},\quad \Omega_1=\frac{2\epsilon(\alpha-\beta)}{\sqrt{1-\epsilon^2}}.$$

Thus, from (5.6) we get

$$\nu_1=\frac{2\epsilon(\alpha-\gamma)}{(1+\epsilon)\sqrt{1-\epsilon^2}}\,. \tag{8.27}$$

Hence, $H'(x)/H(x)$ is continuous at $x=0$ if and only if $\epsilon(\alpha-\gamma)=0$, i.e. if and only if $\rho(k)$ in (8.1) is a constant.

Example 8.5: In this example we illustrate the iterative method outlined in Sec. VII to recover $H(x)$, based on the matrix factorization in (4.5). Let us again use the scattering data of Example 8.1. We proceed as in Example 8.4 and get $H(x)$ given in (8.10) for $x>0$, $V_{1,2}(y)=0$, and ν_1 given in (8.27). Thus, we have $\Lambda_{1,2}=\mathbf{I}$ and

$$F_1(k)=\frac{1}{\sqrt{1-\epsilon^2}}\begin{bmatrix} 1+\dfrac{\epsilon(\alpha-\gamma)}{ik(1+\epsilon)} & -\epsilon+\dfrac{\epsilon(\alpha-\gamma)}{ik(1+\epsilon)} \\ -\epsilon-\dfrac{\epsilon(\alpha-\gamma)}{ik(1+\epsilon)} & 1-\dfrac{\epsilon(\alpha-\gamma)}{ik(1+\epsilon)} \end{bmatrix},$$

where $\Lambda_{j,j+1}(k)$ and $F_j(k)$ are the matrices defined in (4.1) and (4.3), respectively. From (4.1) and (4.5) we obtain $\Lambda_{0,1}(k)$. Note that, in this case, $\rho^{[0]}(k)$ defined in (5.11) and $r_{0,1}(k)$ corresponding to $V_{0,1}(y)$ coincide. We have

$$r_{0,1}(k)=\frac{-k_+k_-}{(k-k_+)(k-k_-)},\quad t_{0,1}(k)=\frac{k(k+i\beta)}{(k-k_+)(k-k_-)}, \tag{8.28}$$

where k_+ and k_- are the constants defined as

$$k_\pm=-\frac{i}{2}\,\frac{\gamma+\epsilon\alpha}{1+\epsilon}\,[1\pm\sqrt{1+E}],\quad E=\frac{4\epsilon(\gamma-\alpha)}{(1-\epsilon)(\gamma+\epsilon\alpha)}. \tag{8.29}$$

Next, we will solve the Marchenko equation (7.7) for $y<0$ with the input of (8.28) and (8.29). In fact, since there are no discontinuities associated with the reflection coefficient in (8.28), the Marchenko equation (7.7) reduces to (7.8). Note that the sign of E in (8.29) is the same as the sign

of $\epsilon(\gamma-\alpha)$. There are three cases to consider, namely $E=0$, $E<0$, and $E>0$. When $E=0$, i.e. when $\epsilon=0$ or $\alpha=\gamma$, we have $r_{0,1}(k)=0$, and hence $h_l(t,y)=0$. Thus $V_{0,1}(y)=0$, because in analogy to (7.9) we have

$$V_{0,1}(y)=-2\frac{dh_l(0+,y)}{dy}, \quad -\infty<y<0. \tag{8.30}$$

Thus $Y_{l;0,1}(k,y)=1$, and so $H(x)$ is given by (8.10) for all $x\in\mathbf{R}$. Next, we consider the case $E<0$. In this case both k_+ and k_- lie in $\mathbf{C}^-$, and hence using (8.28) in (7.1) we obtain

$$\varrho(t)=\begin{cases} 0, & t<0, \\ \dfrac{ik_+k_-}{k_+-k_-}[e^{-ik_+t}-e^{-ik_-t}], & t>0. \end{cases} \tag{8.31}$$

The solution of the Marchenko equation (7.8) with the integral kernel in (8.31) is given by

$$h_l(t,y)=\begin{cases} 0, & t>-2y, \\ \dfrac{k_+k_-}{\beta}\dfrac{(\beta+\gamma)[e^{\beta t}-e^{-2\beta y}]+\epsilon(\beta-\alpha)[1-e^{-\beta(t+2y)}]}{\epsilon(\beta-\alpha)+(\beta+\gamma)e^{-2\beta y}}, & t<-2y, \end{cases}$$

where β is the constant in (8.3). Again, using (8.30), we obtain

$$V_{0,1}(y)=\begin{cases} 0, & y>0, \\ -\dfrac{8\beta^2\epsilon(\beta-\alpha)(\beta+\gamma)e^{-2\beta y}}{[\epsilon(\beta-\alpha)+(\beta+\gamma)e^{-2\beta y}]^2}, & y<0. \end{cases} \tag{8.32}$$

Corresponding to $V_{0,1}(y)$ in (8.32), we have the zero-energy Jost solution from the right given by

$$Y_{r;0,1}(0,y)=\frac{-\epsilon(\beta-\alpha)+(\beta+\gamma)e^{-2\beta y}}{\epsilon(\beta-\alpha)+(\beta+\gamma)e^{-2\beta y}}, \quad y<0. \tag{8.33}$$

Using (3.9) we see that for $y<0$, $Z_r(0,y)$ is given by (8.33). Using (6.16)–(6.18) and (8.33) we obtain

$$y-\frac{2\epsilon(\beta-\alpha)/\beta}{\epsilon(\beta-\alpha)+\beta+\gamma}+\frac{2\epsilon(\beta-\alpha)/\beta}{\epsilon(\beta-\alpha)+(\beta+\gamma)e^{-2\beta y}}=H_-\int_0^x\frac{dz}{f_r(0,z)^2}, \quad x<0, \tag{8.34}$$

$$H(x)=\frac{H_-}{f_r(0,x)^2}\left[\frac{-\epsilon(\beta-\alpha)+(\beta+\gamma)e^{-2\beta y}}{\epsilon(\beta-\alpha)+(\beta+\gamma)e^{-2\beta y}}\right]^2, \quad x<0, \tag{8.35}$$

where y in (8.35) is obtained in terms of x from (8.34), and $f_r(0,x)$ is the zero-energy Jost solution from the right associated with $Q(x)$. Using (6.19) and (6.20), one can show that (8.34) and (8.35) are identical to (8.14) and (8.15), respectively. Finally, let us briefly consider the case where the constant E defined in (8.29) is positive. In this case, k_+ is in $\mathbf{C}^-$ and k_- is in $\mathbf{C}^+$. Thus, $V_{0,1}(y)$ has one bound state. However, since $V_{0,1}(y)$ is supported on a half-line, its bound state norming constant cannot be chosen arbitrarily and is determined by $r_{0,1}(k)$ alone.[22] Routine computations[21] lead us again to $H(x)$ as given in (8.14).

Example 8.6: In this example, we demonstrate the recovery of $H(x)$ by the method outlined in Sec. VI, namely by solving the singular integral equations (6.7) or (6.10). As our scattering data, let us use the same scattering data as in Example 8.1, with the same restrictions on the parameters ϵ, α, and γ. First, using the method of Ref. 13 we get the quantities given in (8.4). When $y>0$, we will solve (6.7); for this, using (3.16), we get $J_l(k,y)=1$ and from (6.9) we have

$P_l(k,y)=0$. Thus, the solution of (6.7) for $y>0$ is given by $X_l(k,y)=0$; hence from (6.13) we obtain $H(x)$ for $x>0$ as given in (8.10). Now let us consider the situation when $y<0$; in this case, it is easier to obtain ℓ(k) and solve (6.10). Using the method of Ref. 16 we construct $\tau(k)$ given in (8.2) and using $\ell(\mathrm{k})=-\rho(-\mathrm{k})\tau(\mathrm{k})/\tau(-\mathrm{k})$, we get

$$\ell(k)=-\epsilon\,\frac{k-i\alpha}{k+i\gamma}\,\frac{k+i\beta}{k-i\beta}. \tag{8.36}$$

Using (8.36) in (6.11), we obtain

$$P_r(k,y)=\frac{2i\epsilon\beta}{k-i\beta}\,\frac{\beta-\alpha}{\beta+\gamma}\,e^{2\beta y},\quad y<0. \tag{8.37}$$

Since $X_r(k,y)$ is analytic in $\mathbf{C}^-$, a contour integration along the boundary of $\mathbf{C}^-$ converts (6.10) into the algebraic equation,

$$X_r(k,y)-\frac{2i\epsilon\beta}{k-i\beta}\,\frac{\beta-\alpha}{\beta+\gamma}\,e^{2\beta y}X_r(-i\beta,y)=P_r(k,y),\quad y<0.$$

Using (8.37) and the analyticity requirement on $X_r(k,y)$ to evaluate $X_r(-i\beta,y)$, we get

$$X_r(k,y)=\frac{2i\epsilon\beta}{k-i\beta}\,\frac{\beta-\alpha}{\beta+\gamma}\,\frac{(\beta+\gamma)e^{2\beta y}}{\beta+\gamma+\epsilon(\beta-\alpha)e^{2\beta y}},\quad y<0. \tag{8.38}$$

From (3.17) we have $J_r(k,y)=1$ for $y<0$. Thus, using (6.5) and (8.38), we get

$$Z_r(0,y)=\frac{(\beta+\gamma)e^{-2\beta y}-\epsilon(\beta-\alpha)}{(\beta+\gamma)e^{-2\beta y}+\epsilon(\beta-\alpha)},\quad y<0.$$

Thus using (6.16) and (6.18)–(6.20), we obtain $H(x)$ given in (8.15).

Generalization of the Bremmer coupling series

Maarten V. de Hoop[a)]
Schlumberger Cambridge Research, High Cross, Madingley Road, Cambridge CB3 OEL, England

(Received 20 September 1995; accepted for publication 25 March 1996)

An operator formalism is developed to expand the acoustic wave field in a multi-dimensionally smoothly varying medium, generated by a source localized in space and time, into a sum of constituents each of which can be interpreted as a wave that has traveled up and down with respect to a direction of preference a definite number of times. This expansion is a generalization of the Bremmer coupling series. The condition of smoothness of the medium relates to the width of the signature of the source in the configuration. Both the existence and the convergence (in the weak sense) of the expansion are discussed. The operator calculus involved leads to a natural generalization of the concept of slowness surface to multi-dimensionally smoothly varying media. The operator associated with the corresponding generalized vertical slowness induces the full one-way wave operator in the type of media under consideration. In addition, a wavefield decomposition operator as well as an interaction operator that couples the decomposed constituents, are derived. [S0022-2488(96)01407-7]

I. INTRODUCTION

In recent years, there has been an increasing interest in the use of one-way ''parabolic'' approximations to the wave operator in the application of seismic modeling and migration-inversion techniques,[1–3] and in the application of long-range waveguiding problems in ocean acoustics[4–6] and integrated optics.[7,8] The parabolic approximation arises in the decomposition (or ''splitting'') of the acoustic wave field into constituents that travel ''up'' and ''down'' with respect to a given direction of preference, such that the two constituents satisfy coupled partial differential equations of a specific type. In this paper, we shall discuss the mathematical theory underlying this decomposition technique. The theory builds on the work of Seeley,[9,10] Hörmander,[11] and Duistermaat and Guilleman,[12] and is based on the calculus of pseudo-differential operators. The use of such operators, in particular in the field of underwater acoustics where it yields the factorization of the Helmholtz operator, has been noticed by Fishman and McCoy,[13–17] Fishman,[18,19] Fishman and Wales,[20] McCoy and Frazer,[21] and Weston.[22] The interaction of up- and downgoing constituents has been discussed by McCoy, Fishman, and Frazer.[23] Within the parabolic approximations, Corones[24] has put the interaction in the context of the Bremmer series.

The direction of preference, which is assigned to the ''vertical'' direction, arises from the medium's variations. In its exact form, the decomposition procedure transforms the scattering problem in n dimensions into a continuous family of $(n-1)$-dimensional problems, such that the remaining scattering phenomenon can be solved with the aid of a Neumann series in the relative vertical changes in the medium parameters. This series is a generalization to multi-dimensionally varying media of the Bremmer coupling series that has been used in one-dimensional scattering problems (for an example, see Ref. 25).

[a)]Present address: Center for Wave Phenomena, Colorado School of Mines, Golden, Colorado 80401–1887.

0022-2488/96/37(7)/3246/37/$10.00

The decomposition introduced applies to media which vary smoothly on the scale of the irradiating pulse, and generalizes the standard decomposition to media that are no longer translationally invariant in the ''horizontal'' directions. Owing to this generalization, more refined mathematical tools are required, such as the calculus of pseudo-differential operators. The up/down decomposition does not allow any further decomposition into horizontal, right/left, directions. Media, in which discontinuities in their physical properties occur, should be smoothed on the scale of the irradiating pulse with the aid of equivalent medium averaging prior to the decomposition. With regard to media with discontinuities, we mention the alternative, quasi-decomposition into up- and downgoing waves in the neighborhood of a ''rough'' interface separating two homogeneous half-spaces with the aid of the modified Rayleigh hypothesis.[26,27]

The key applications of the Bremmer series are (i) an efficient way of numerically solving a direct scattering problem, (ii) identification of multiple scattered wave constituents, and (iii) formulations of various inverse scattering procedures. Fast numerical schemes require sparse matrix representations of the kernel associated with the relevant integral or pseudo-differential part of the one-way wave operator in space domain. The properties of the kernel, however, are such that generic bases in which its representation becomes sparse do not exist. Parabolic-type approximations of the kernel's symbol, on the other hand, lead to possible sparsifications. The validity of such approximations has been discussed in previous papers.[2,3] They typically capture the precritical angle phenomena in the wave propagation. Beyond this regime, matrix representations for the exact cokernel, acting in horizontal slowness space, have to be considered. A list of references to the development and applications of parabolic theories can be found in Ref. 2. Approximations of a different nature and with a different range of validity result from the method of phase screens.[28] Other numerical procedures are based on constructing a spectral representation of the pseudo-differential part of the one-way wave operator and relate to normal-mode summation.

The solution of the direct scattering problem in the form of a Bremmer series allows one to identify or predict multiple scattered constituents in the configuration. Applying this process to physical measurements, however, requires some knowledge about the medium in which the experiment has been carried out. In fact, the Bremmer series yields an expansion of the acoustic wavefield in terms of the spatial derivatives of the medium properties, as opposed to an expansion in the medium's contrast with respect to a given embedding through a contrast-source integral representation. The leading term in the former expansion is a high-frequency (Rytov-like) approximation to the wavefield; in the latter expansion, the leading term is the (distorted) Born approximation in the embedding. It is noted that, once the former procedure has led to a construction of the Green's function in the embedding, the latter procedure can be applied to the contrast (possibly with discontinuities).

The Bremmer coupling series essentially recomposes the solutions of the system of coupled one-way wave equations into a two-way solution. As such, it connects the one-way wave formulation of scattering to the Dirichlet-to-Neumann map formulation (see also Refs. 29 and 30), and also yields a solution of the associated invariant imbedding equations. We note that the decomposition of the direct scattering problem is an integral part of the layer stripping approach to the inverse scattering problem (see, for example, Ref. 31 for the one-dimensional formulation and Ref. 32, for a multi-dimensional formulation). In fact, the Bremmer series representation allows one to link the asymptotic single-scattering approach (see, for example, Ref. 33 and 34) with the mentioned multiple-scattering approach.

The Bremmer coupling series becomes a powerful tool in those configurations in which the complexity of the medium is such that ray-theoretic approaches become intractable or the approximation by homogeneous horizontal layers breaks down.

The remainder of this paper is organized as follows. In Sec. II, the principle of directional decomposition is explained. In Sec. III, the decomposition problem is related to the solution of an elliptic problem in one dimension less than the original scattering problem. In Sec. IV, the original system of two-way wave equations is transformed into a system of coupled one-way wave equa-

tions. The one-way wave equations define a generalization of the concept of slowness surface, which is discussed in Sec. V. In Sec. VI, the fundamental properties of the Green's functions of the one-way equations are derived. These functions are used in Sec. VII to transform the system of one-way integro-differential equations into a system of integral equations, which is then solved in terms of a Neumann series expansion. Finally, presented in Sec. VIII is a series expansion for the generalized slowness surface that yields an explicit solution of the elliptic problem posed in Sec. III. Section IX concludes the paper.

We note that our analysis differs slightly from the standard mathematical treatment of factorizing differential operators, since in our case the $(n-1)$-dimensional (''horizontal'') space is not assumed to be compact. However, with regard to the numerical implementation of the theory, periodic boundary conditions may be imposed in the horizontal directions. The causal acoustic waves are well defined on $\mathscr{T}^{n-1}\times\mathbb{R}$, where $\mathscr{T}^{n-1}$ denotes the $(n-1)$-dimensional torus, for a finite time window.

II. DIRECTIONAL DECOMPOSITION OF THE ACOUSTIC SCATTERING PROCESS

In each subdomain of the configuration where the acoustic properties vary continuously with position, the acoustic wavefield satisfies the hyperbolic system of partial differential equations

$$\partial_k p+\rho\partial_t v_k=f_k, \tag{II.1}$$

$$\kappa\partial_t p+\partial_r v_r=q, \tag{II.2}$$

where p=acoustic pressure (Pa), v_r=particle velocity (m/s), ρ=volume density of mass (kg/m^3), κ=compressibility (Pa^{-1}), q=volume source density of injection rate (s^{-1}), f_k=volume source density of force (N/m^3), and $\{x_1,x_2,x_3\}$ are the right-handed, orthogonal, Cartesian coordinates, t is the time, and the subscript notation and the summation convention for Cartesian tensors are employed. We assume that the coefficients ρ and κ are smooth, i.e., infinitely differentiable functions of position, and time independent. Furthermore, we assume that these functions are constant outside a sphere of finite radius. This provision enables us to formulate the acoustic wave propagation, when necessary, as a scattering problem in a homogeneous embedding. The smoothness entails that the singularities of the wavefield (in particular the ones on the wavefront) arise from the ones in the signatures of the source distributions. Further, causality of the wave motion is enforced. This implies that if the sources that generate the wavefield are switched on at the instant $t=0$, the wavefield quantities satisfy the initial conditions

$$p(x_m,t)=0 \quad \text{for } t<0 \quad \text{and all} \quad x_m, \tag{II.3}$$

$$v_r(x_m,t)=0 \quad \text{for } t<0 \quad \text{and all} \quad x_m. \tag{II.4}$$

Due to the time invariance of the medium, the causality of the wave motion can also be taken into account by carrying out a one-sided Laplace transformation with respect to time and requiring that the transform-domain wave quantities are bounded functions of position in all space when the time Laplace-transform parameter s, which is in general complex, lies in the right half $\mathrm{Re}\{s\}>0$ of the complex s plane. The limiting case of sinusoidal oscillations of angular frequency $\omega\in\mathbb{R}$ is covered by considering the limiting case $s\to i\omega$, in which i is the imaginary unit, the limit being taken via $\mathrm{Re}\{s\}>0$. In view of Lerch's theorem,[35] however, it is sufficient to consider values with $\mathrm{Im}\{s\}=0$ and $s\geqslant s_0>0$; s_0 will be specified at several stages in the analysis.

To show the notation, we give the expression for the acoustic pressure,

$$\hat{p}(x_m,s)=\int_{t=0}^{\infty}\exp(-st)p(x_m,t)dt. \tag{II.5}$$

Under this transformation, assuming zero initial conditions, we have $\partial_t \rightarrow s$. The transformed system of first-order equations follows from Eqs. (II.1) and (II.2) as

$$\partial_k \hat{p} + s\rho \hat{v}_k = \hat{f}_k, \tag{II.6}$$

$$s\kappa \hat{p} + \partial_r \hat{v}_r = \hat{q}. \tag{II.7}$$

The change of the wavefield in space along a direction of preference can now be expressed in terms of the changes of the wavefield in the plane perpendicular to it. The direction of preference is taken along the x_3 axis (or ''vertical'' axis) and the remaining (''horizontal'') coordinates are denoted by x_μ, $\mu=1,2$. The procedure requires a separate handling of the horizontal components of the particle velocity. From Eqs. (II.6) and (II.7) we obtain

$$\hat{v}_\kappa = -\rho^{-1} s^{-1} (\partial_\kappa \hat{p} - \hat{f}_\kappa), \tag{II.8}$$

leaving, upon substitution, the matrix differential equation

$$(\partial_3 \delta_{I,J} + s\hat{A}_{I,J})\hat{F}_J = \hat{N}_I, \quad I,J \in \{1,2\}, \tag{II.9}$$

in which the elements of the acoustic field matrix are given by [in Eq. (II.7) $r=\nu$,3]

$$\hat{F}_1 = \hat{p}, \tag{II.10}$$

$$\hat{F}_2 = \hat{v}_3, \tag{II.11}$$

the elements of the acoustic system's operator matrix are given by

$$\hat{A}_{1,1} = \hat{A}_{2,2} = 0, \tag{II.12}$$

$$\hat{A}_{1,2} = \rho, \tag{II.13}$$

$$\hat{A}_{2,1} = -s^{-1} \partial_\nu (\rho^{-1} s^{-1} \partial_\nu) + \kappa, \tag{II.14}$$

and the elements of the notional source matrix by

$$\hat{N}_1 = \hat{f}_3, \tag{II.15}$$

$$\hat{N}_2 = -s^{-1} \partial_\nu (\rho^{-1} \hat{f}_\nu) + \hat{q}. \tag{II.16}$$

It is observed that the right-hand side of Eq. (II.8) and $\hat{A}_{I,J}$ contain spatial derivatives with respect to the horizontal coordinates only. Further, it is noted that $\hat{A}_{1,2}$ is a multiplicative operator, whereas $\hat{A}_{2,1}$ is a partial differential operator. Equation (II.9) is sometimes called the *two-way* wave equation (Ref. 36).

To be able to solve the scattering process along the vertical direction separately from the scattering process in the (family of) planes perpendicular to it, we decouple the two operators on the left-hand side of Eq. (II.9). This procedure will possibly lead to an additional source term on the right-hand side that accounts for the coupling. To achieve this, we shall construct an appropriate linear operator $\hat{L}_{I,J}$ with

$$\hat{F}_I = \hat{L}_{I,J} \hat{W}_J \tag{II.17}$$

that, with the aid of the commutation relation

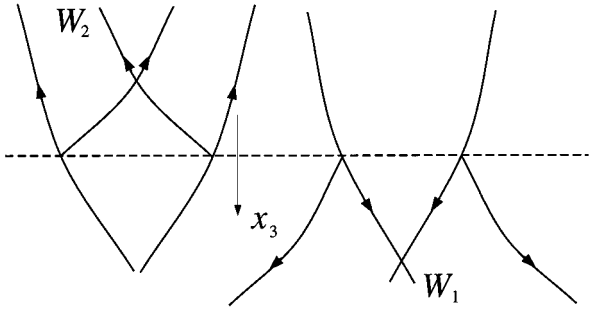

FIG. 1. Directional decomposition.

$$(\partial_3 \hat{L}_{I,J}) = [\partial_3, \hat{L}_{I,J}] \tag{II.18}$$

([.,.] denotes the commutator), transforms Eq. (II.9) into

$$\hat{L}_{I,J}(\partial_3 \delta_{J,M} + s\hat{\Lambda}_{J,M})\hat{W}_M = -(\partial_3 \hat{L}_{I,J})\hat{W}_J + \hat{N}_I, \tag{II.19}$$

so as to make $\hat{\Lambda}_{\mathrm{J,M}}$, satisfying

$$\hat{A}_{I,J}\hat{L}_{J,M} = \hat{L}_{I,J}\hat{\Lambda}_{J,M}, \tag{II.20}$$

a diagonal matrix of operators. We denote $\hat{L}_{I,J}$ as the composition operator and $\hat{W}_M$ as the wave matrix. The elements of the wave matrix represent the local weights of the down- and upgoing constituents (see also Fig. 1). The expression in parentheses on the left-hand side of Eq. (II.19) represents the two so-called *one-way* wave operators (Ref. 36). The first term on the right-hand side of Eq. (II.19) is representative for the scattering due to variations of the medium properties in the vertical direction. The scattering due to variations of the medium properties in the horizontal directions is contained in $\hat{\Lambda}_{\mathrm{J,M}}$ and, implicitly, in $\hat{L}_{I,J}$.

To investigate whether solutions $(\hat{L}_{I,J}, \hat{\Lambda}_{\mathrm{J,M}})$ of Eq. (II.20) exist, we introduce the column matrix, or generalized eigenvector, operators $\hat{L}_I^{(\pm)}$ according to

$$\hat{L}_I^{(+)} = \hat{L}_{I,1}, \tag{II.21}$$

$$\hat{L}_I^{(-)} = \hat{L}_{I,2}. \tag{II.22}$$

Upon writing the diagonal elements of $\hat{\Lambda}_{\mathrm{J,M}}$ as

$$\hat{\Lambda}_{1,1} = \hat{\Gamma}^{(+)}, \tag{II.23}$$

$$\hat{\Lambda}_{2,2} = \hat{\Gamma}^{(-)}, \tag{II.24}$$

Eq. (II.20) decomposes into the two systems of equations

$$\hat{A}_{I,J}\hat{L}_J^{(+)} = \hat{L}_I^{(+)}\hat{\Gamma}^{(+)}, \tag{II.25}$$

$$\hat{A}_{I,J}\hat{L}_J^{(-)} = \hat{L}_I^{(-)}\hat{\Gamma}^{(-)}. \tag{II.26}$$

By analogy with the case where the medium is translationally invariant in the horizontal directions, we shall denote $\hat{\Gamma}^{(\pm)}$ as the *vertical slowness* operators. Notice that the operators $\hat{L}_1^{(\pm)}$ compose the acoustic pressure and that the operators $\hat{L}_2^{(\pm)}$ compose the vertical particle velocity, whereas the elements of $\hat{W}_M$ may be physically ''nonobservable.''

Through mutual elimination, the equations for $\hat{L}_1^{(\pm)}$ and $\hat{L}_2^{(\pm)}$ can be decoupled as follows:

$$\hat{A}_{1,2}\hat{A}_{2,1}\hat{L}_1^{(\pm)}=\hat{L}_1^{(\pm)}\hat{\Gamma}^{(\pm)}\hat{\Gamma}^{(\pm)}, \tag{II.27}$$

$$\hat{A}_{2,1}\hat{A}_{1,2}\hat{L}_2^{(\pm)}=\hat{L}_2^{(\pm)}\hat{\Gamma}^{(\pm)}\hat{\Gamma}^{(\pm)}. \tag{II.28}$$

The partial differential operators on the left-hand sides, which are given by

$$\hat{A}_{2,1}\hat{A}_{1,2}=-s^{-1}\partial_\nu(\rho^{-1}s^{-1}\partial_\nu(\rho\ ))+\kappa\rho, \tag{II.29}$$

$$\hat{A}_{1,2}\hat{A}_{2,1}=-\rho s^{-1}\partial_\nu(\rho^{-1}s^{-1}\partial_\nu\ )+\rho\kappa, \tag{II.30}$$

are strongly elliptic in the horizontal plane $\mathbb{R}^2$ for each value of the vertical coordinate $x_3\in\mathbb{R}$ and all frequencies s under consideration; they differ from one another in case the volume density of mass does vary in the horizontal directions. To ensure that nontrivial solutions of Eqs. (II.27) and (II.28) exist, one equation must imply the other. To construct a formal solution, an Ansatz is introduced in the form of a commutation relation for one of the components $\hat{L}_J^{(\pm)}$ that restricts the freedom in the choice for the other component. Three choices will be considered.

A. Acoustic-pressure normalization analog

Our first Ansatz assumes that $\hat{L}_2^{(\pm)}$ can be chosen such that

$$[\hat{L}_2^{(\pm)},\hat{A}_{2,1}\hat{A}_{1,2}]=0. \tag{II.31}$$

In view of Eq. (II.28), the $\hat{\Gamma}^{(\pm)}$ must then satisfy

$$\hat{A}_{2,1}\hat{A}_{1,2}-\hat{\Gamma}^{(\pm)}\hat{\Gamma}^{(\pm)}=0. \tag{II.32}$$

The commutation relation for $\hat{L}_1^{(\pm)}$ follows as $[\hat{A}_{1,2}^{-1}\hat{L}_1^{(\pm)},\hat{A}_{2,1}\hat{A}_{1,2}]=0$ and a possible solution of Eqs. (II.25) and (II.26) is

$$\hat{L}_2^{(\pm)}=\hat{\Gamma}^{(\pm)},\quad \hat{L}_1^{(\pm)}=\hat{A}_{1,2}. \tag{II.33}$$

Since $\hat{L}_2^{(\pm)}$ as given by Eq. (II.33) satisfies Eq. (II.31), the Ansatz is justified. In view of the up/down symmetry, the solutions of Eq. (II.32) are written as

$$\hat{\Gamma}^{(+)}=-\hat{\Gamma}^{(-)}=\hat{\Gamma}=\hat{\mathrm{A}}^{1/2}, \tag{II.34}$$

where $\hat{\mathrm{A}}\equiv\hat{A}_{2,1}\hat{A}_{1,2}$. Thus, the composition operator becomes

$$\hat{L}=\begin{pmatrix}\hat{A}_{1,2} & \hat{A}_{1,2}\\ \hat{\Gamma} & -\hat{\Gamma}\end{pmatrix}. \tag{II.35}$$

In terms of the inverse vertical slowness operator, $\hat{\Gamma}^{-1}=\hat{\mathrm{A}}^{-1/2}$, the decomposition operator then follows as

$$\hat{L}^{-1}=\frac{1}{2}\begin{pmatrix}\hat{A}_{1,2}^{-1} & \hat{\Gamma}^{-1}\\ \hat{A}_{1,2}^{-1} & -\hat{\Gamma}^{-1}\end{pmatrix}. \tag{II.36}$$

In this normalization, the elements of the wave matrix correspond with pressures up to the action of $\hat{A}_{1,2}$; pressures are typically measured with hydrophones.

B. Vertical-particle-velocity normalization analog

A second Ansatz assumes that $\hat{L}_1^{(\pm)}$ can be chosen such that

$$[\hat{L}_1^{(\pm)},\hat{A}_{1,2}\hat{A}_{2,1}]=0. \tag{II.37}$$

Then, $\hat{\Gamma}^{(\pm)}$ must satisfy [cf. Eq. (II.27)]

$$\hat{A}_{1,2}\hat{A}_{2,1}-\hat{\Gamma}^{(\pm)}\hat{\Gamma}^{(\pm)}=0, \tag{II.38}$$

and a possible solution of Eqs. (II.25) and (II.26) is

$$\hat{L}_1^{(\pm)}=\hat{\Gamma}^{(\pm)},\quad \hat{L}_2^{(\pm)}=\hat{A}_{2,1}, \tag{II.39}$$

which satisfies the second Ansatz. The solutions of Eq. (II.38) are written as

$$\hat{\Gamma}^{(+)}=-\hat{\Gamma}^{(-)}=\hat{\Gamma}=\hat{\mathrm{A}}^{1/2}, \tag{II.40}$$

where $\hat{\mathrm{A}}\equiv\hat{A}_{1,2}\hat{A}_{2,1}$. Thus, the composition operator is given by

$$\hat{L}=\begin{pmatrix}\hat{\Gamma} & -\hat{\Gamma}\\ \hat{A}_{2,1} & \hat{A}_{2,1}\end{pmatrix}. \tag{II.41}$$

Now, the decomposition operator becomes

$$\hat{L}^{-1}=\frac{1}{2}\begin{pmatrix}\hat{\Gamma}^{-1} & \hat{\mathrm{A}}^{-1}\hat{A}_{1,2}\\ -\hat{\Gamma}^{-1} & \hat{\mathrm{A}}^{-1}\hat{A}_{1,2}\end{pmatrix}. \tag{II.42}$$

In this normalization, $\hat{A}_{2,1}$ acting on the elements of the wave matrix results in vertical particle velocities; particle velocities are typically measured with geophones.

C. Vertical-acoustic-power-flux normalization analog

It will appear to be advantageous to consider a third Ansatz, viz., the one arising from the acoustic-power-flux normalization. For this, the commutation relation

$$[\hat{A}_{1,2}^{-1/2}\hat{L}_1^{(\pm)},\ \hat{A}_{1,2}^{1/2}\hat{A}_{2,1}\hat{A}_{1,2}^{1/2}]=0 \tag{II.43}$$

is imposed on $\hat{L}_1^{(\pm)}$. Then the vertical slowness operators must satisfy the equation

$$\hat{A}_{1,2}^{1/2}\hat{A}_{2,1}\hat{A}_{1,2}^{1/2}-\hat{\Gamma}^{(\pm)}\hat{\Gamma}^{(\pm)}=0. \tag{II.44}$$

Note that the operator $\hat{\mathrm{A}}$,

$$\hat{\mathrm{A}}\equiv\hat{A}_{1,2}^{1/2}\hat{A}_{2,1}\hat{A}_{1,2}^{1/2}=-\rho^{1/2}s^{-1}\partial_\nu(\rho^{-1}s^{-1}\partial_\nu(\rho^{1/2}\,))+\kappa\rho, \tag{II.45}$$

is self-adjoint with respect to the standard real L^2 inner product in (almost all of) L^2. A possible solution of Eqs. (II.25) and (II.26) is now given by

$$\hat{L}_1^{(\pm)}=(\hat{A}_{1,2}/2)^{1/2}(\hat{\Gamma}^{(+)})^{-1/2},\quad \hat{L}_2^{(\pm)}=\pm(2\hat{A}_{1,2})^{-1/2}(\hat{\Gamma}^{(+)})^{1/2}. \tag{II.46}$$

The solutions of Eq. (II.44) are written as

$$\hat{\Gamma}^{(+)} = -\hat{\Gamma}^{(-)} = \hat{\Gamma} = \hat{A}^{1/2}. \tag{II.47}$$

Thus, the composition operator is given by

$$\hat{L} = \frac{1}{\sqrt{2}} \begin{pmatrix} \hat{A}_{1,2}^{1/2}\hat{\Gamma}^{-1/2} & \hat{A}_{1,2}^{1/2}\hat{\Gamma}^{-1/2} \\ \hat{A}_{1,2}^{-1/2}\hat{\Gamma}^{1/2} & -\hat{A}_{1,2}^{-1/2}\hat{\Gamma}^{1/2} \end{pmatrix}. \tag{II.48}$$

This composition operator $\hat{L}$: $(L^2)^2 \rightarrow (L^2)^2$ is normalized in the sense that [cf. Eq. (II.46)]

$$\hat{L}^T J \hat{L} = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix}, \tag{II.49}$$

with

$$J = \begin{pmatrix} 0 & I \\ I & 0 \end{pmatrix}. \tag{II.50}$$

This normalization establishes the connection with asymptotic ray theory in the vicinity of the wavefronts.

Using Eq. (II.48), we can map the pressure to the vertical particle velocity, viz.,

$$\hat{F}_2 = \hat{\boldsymbol{Y}}^{(+)}\hat{F}_1 \quad \text{if} \quad \hat{W}_2 = 0, \tag{II.51}$$

$$\hat{F}_2 = \hat{\boldsymbol{Y}}^{(-)}\hat{F}_1 \quad \text{if} \quad \hat{W}_1 = 0, \tag{II.52}$$

where

$$\pm\hat{\boldsymbol{Y}}^{(\pm)} = \hat{\boldsymbol{Y}} = \hat{A}_{1,2}^{-1/2}\hat{\Gamma}\hat{A}_{1,2}^{-1/2} \tag{II.53}$$

has the interpretation of *admittance* operator. The latter operator discriminates the decomposed constituents. Note that $\hat{F}_1^T\hat{F}_2$ represents the vertical component of the Poynting vector.

The decomposition operator becomes

$$\hat{L}^{-1} = \frac{1}{\sqrt{2}} \begin{pmatrix} \hat{\Gamma}^{1/2}\hat{A}_{1,2}^{-1/2} & \hat{\Gamma}^{-1/2}\hat{A}_{1,2}^{1/2} \\ \hat{\Gamma}^{1/2}\hat{A}_{1,2}^{-1/2} & -\hat{\Gamma}^{-1/2}\hat{A}_{1,2}^{1/2} \end{pmatrix}. \tag{II.54}$$

It is observed that all the operators involved can be directly constructed from $\hat{\mathrm{A}}^{-1/4}$, viz., $\hat{\Gamma}^{-1/2} = \hat{\mathrm{A}}^{-1/4}$, $\hat{\Gamma}^{1/2} = \hat{\mathrm{A}}(\hat{\mathrm{A}}^{-1/4})^3$, and $\hat{\Gamma} = \hat{\mathrm{A}}(\hat{\mathrm{A}}^{-1/4})^2$. All these powers of $\hat{\mathrm{A}}$ are self-adjoint in (almost all of) L^2 as well as positive definite, since it has been assumed that $\mathrm{Im}\{s\} = 0$ and $\mathrm{Re}\{s\} > 0$.

Apparently a whole class of composition operators $\hat{L}_{I,J}$, all leading to different representations of the scattering process in the horizontal space, exists. The final results for the acoustic pressure and the vertical particle velocity, however, will not depend on a particular choice: in terms of observables the decomposition yields

$$\hat{F}_I^{(+)} = \hat{L}_I^{(+)}(\hat{L}^{-1})_{1,J}\hat{F}_J, \tag{II.55}$$

$$\hat{F}_I^{(-)} = \hat{L}_I^{(-)}(\hat{L}^{-1})_{2,J}\hat{F}_J. \tag{II.56}$$

For practical applications, one adjusts the normalization to the sensors being used; it is quite common that only one of the two relevant field components is being measured.

At this point, it is emphasized that $\hat{\Gamma}^{(\pm)}$ are still unknown. It is noted that the key property we have used so far is that the diagonal of the system's operator matrix $\hat{A}$ vanishes. For the evaluation

of $\hat{\Gamma}^{(\pm)}$, and $\hat{L}_J^{(\pm)}$, we need to introduce (fractional) powers of an elliptic partial differential operator in $\mathbb{R}^2$ for each value of $x_3 \in \mathbb{R}$ [cf. Eq. (II.32), (II.38), or (II.44)]. How this can be done will be discussed in Sec. III. In this respect it is noted that only a proper definition of a negative (fractional) power is needed, since positive fractional powers are constructed from the negative ones through the application of the operator itself an appropriate number of times. For the time being, the vertical coordinate will play the role of parameter, which will be indicated by writing $\mathbb{R}^3=\mathbb{R}^2\times\mathbb{R}$. In this framework, the wavefield is viewed as a map of x_3 with values in a function space on $\mathbb{R}^2$.

III. THE DIMENSIONALLY REDUCED SCATTERING PROBLEM

In this section we will consider the acoustic-pressure normalization analog. All the other normalizations lead to similar results. Thus, consider the partial differential operator $\hat{\mathrm{A}}=\hat{\mathrm{A}}_{2,1}\hat{\mathrm{A}}_{1,2}$ on $\mathbb{R}^2$ [cf. Eq. (II.29)] which is *elliptic with a parameter* yet to be specified. The dependence on x_3 will be suppressed in this section.

In the following analysis it is assumed that the field matrix $\hat{F}_I$ and the wave matrix $\hat{W}_M$ are contained in proper spaces, which, in view of the smoothness of the medium, is controlled by the source distributions [cf. Eqs. (II.6) and (II.7)]. The elliptic operator is clearly well-defined on the space C_0^∞ of smooth functions with compact support in $\mathbb{R}^2$. It can be extended as a bounded operator $\hat{A}$: $H^r \to H^{r-2}$ for any real r (Ref. 37, Theorem 8.9). Here, H^r is a reserved symbol for the Sobolev spaces. [Whenever we write H^r, we mean $H^r(\mathbb{R}^2)$; otherwise, the underlying space will be specified.] The norm on H^r will be denoted as $\|.\|_r$, and the norm of an operator $H^r \to H^{r'}$ as $\|.\|_{r,r'}$. The norms are implicitly scaled with the time Laplace-transform parameter s; we postpone the discussion of this aspect to Sec. V. In particular, when $r=0$, we have an operator $\hat{\mathrm{A}}$: $\mathrm{L}^2 \to \mathrm{H}^{-2}$, which is bounded. On the other hand, note that $\hat{\mathrm{A}}$: $L^2 \to L^2$ is unbounded in general.

First, we shall discuss the existence and integral representations of powers of $\hat{\mathrm{A}}$. To this end, we need to analyze the properties of its *resolvent*. The construction of the resolvent is, essentially, the solution to the reduced scattering problem and will be dealt with in Sec. VIII.

A. Properties of the resolvent

Let λ be a complex variable. The resolvent $\hat{R}_\lambda$ of $\hat{\mathrm{A}}$ is defined as

$$\hat{R}_\lambda = (\hat{\mathrm{A}} - \lambda I)^{-1}: \; H^r \to H^{r+l}, \quad 0 \leqslant l \leqslant 2. \tag{III.1}$$

It exists for $\lambda \notin \sigma(\hat{\mathrm{A}})$, which defines the spectrum $\sigma(\hat{\mathrm{A}})$ of $\hat{\mathrm{A}}$. We refer to this spectrum as the *horizontal spectrum*. Whenever confusion would arise, the resolvent will be denoted as $\hat{R}_\lambda^{(\mathrm{A})}$ rather than $\hat{R}_\lambda$ to explicitly show its relation to the operator $\hat{\mathrm{A}}$.

First, to analyze the spectrum of $\hat{\mathrm{A}}$, we consider the case $r=l=0$. We have $\hat{A}$: $L^2 \to L^2$. In accordance with the structure of our horizontal partial differential operators, we introduce a family of inner products on L^2 with respect to $\hat{u}=\hat{u}(x_\mu, s)$ and $\hat{v}=\hat{v}(x_\mu, s)$ as

$$\langle \hat{u}, \hat{v} \rangle_{0_p} = \int_{x_\mu \in \mathbb{R}} \hat{u}^* \hat{v} \rho^p dx_1 dx_2, \tag{III.2}$$

where * denotes complex conjugate (note that for s real all the quantities are, however, real) and corresponding L^2-norms as

$$\|\hat{u}\|_{0_p}^2 = \langle \hat{u}, \hat{u} \rangle_{0_p} \tag{III.3}$$

with $-1 \leqslant p \leqslant 1$. For the acoustic-pressure normalization analog we take $p=1$. (For the vertical-particle-velocity normalization analog we take $p=-1$ and for the vertical-acoustic-power-flux normalization analog we take $p=0$. When $p=0$ the subscript will be omitted.) Using

$$\int_{x_\mu\in\mathbb{R}}[-s^{-1}\partial_\nu(\rho^{-1}s^{-1}\partial_\nu(\rho\hat{u}))]^*\ \hat{v}\rho dx_1dx_2$$

$$=-\int_{x_\mu\in\mathbb{R}}\rho^{-1}[-s^{-1}\partial_\nu(\rho\hat{u})]^*(s^*)^{-1}\partial_\nu(\rho\hat{v})dx_1dx_2$$

$$=\int_{x_\mu\in\mathbb{R}}\hat{u}^*[-(s^*)^{-1}\partial_\nu(\rho^{-1}(s^*)^{-1}\partial_\nu(\rho\hat{v}))]\ \rho dx_1dx_2, \tag{III.4}$$

it is found that $\hat{\mathrm{A}}$ is self-adjoint in L^2, i.e.,

$$\langle\hat{\mathrm{A}}\hat{u},\hat{v}\rangle_{0_1}=\langle\hat{u},\hat{\mathrm{A}}\hat{v}\rangle_{0_1}. \tag{III.5}$$

In the derivation of Eq. (III.4) it was used that the sum of contributions from the boundaries in the horizontal plane at infinity vanishes. In fact, the proof is obvious on C_0^∞; subsequently, use that C_0^∞ is dense in L^2. Note that the self-adjointness [cf. Eq. (III.5)] in combination with the unboundedness is not in contradiction with the Hellinger–Toeplitz theorem,[38] since it only holds for functions that satisfy boundary conditions associated with causal solutions to the spectral-domain acoustic equations.

From Eq. (III.4) it also follows that (here, we need the condition $\mathrm{Im}\{s\}=0$)

$$\langle\hat{\mathrm{A}}\hat{u},\hat{u}\rangle_{0_1}=\int_{x_\mu\in\mathbb{R}}\rho^{-1}|s^{-1}\partial_\nu(\rho\hat{u})|^2\ dx_1dx_2+\int_{x_\mu\in\mathbb{R}}\kappa\rho|\hat{u}|^2\ \rho dx_1dx_2, \tag{III.6}$$

so that

$$\langle\hat{\mathrm{A}}\hat{u},\hat{u}\rangle_{0_1}\geqslant\langle c^{-2}\rangle\langle\hat{u},\hat{u}\rangle_{0_1}, \tag{III.7}$$

in which

$$\langle c^{-2}\rangle=\inf_{x_\mu\in\mathbb{R}}\{\kappa\rho\}>0. \tag{III.8}$$

This shows that $\hat{\mathrm{A}}$ is positive and semi-bounded from below in $\|.\|_{0_1}$. Again, these properties trivially hold, e.g., on C_0^∞. Since by Cauchy–Schwarz' inequality

$$\|(\hat{\mathrm{A}}-\lambda I)\hat{u}\|_{0_1}\|\hat{u}\|_{0_1}\geqslant|\langle(\hat{\mathrm{A}}-\lambda I)\hat{u},\hat{u}\rangle_{0_1}|, \tag{III.9}$$

while [cf. Eq. (III.7)]

$$|\langle\hat{\mathrm{A}}\hat{u},\hat{u}\rangle_{0_1}-\lambda^*\langle\hat{u},\hat{u}\rangle_{0_1}|\geqslant[(\langle c^{-2}\rangle-\mathrm{Re}\{\lambda\})^2+(\mathrm{Im}\{\lambda\})^2]^{1/2}\langle\hat{u},\hat{u}\rangle_{0_1}=|\langle c^{-2}\rangle-\lambda|\langle\hat{u},\hat{u}\rangle_{0_1} \tag{III.10}$$

if $\mathrm{Re}\{\lambda\}\leqslant\langle c^{-2}\rangle$, we obtain

$$\|(\hat{\mathrm{A}}-\lambda I)\hat{u}\|_{0_1}\|\hat{u}\|_{0_1}\geqslant|\langle c^{-2}\rangle-\lambda|\|\hat{u}\|_{0_1}^2. \tag{III.11}$$

Hence, when $\lambda\notin\sigma(\hat{\mathrm{A}})$ and $\mathrm{Re}\{\lambda\}\leqslant\langle c^{-2}\rangle$, we arrive at the estimate

$$\|\hat{R}_\lambda\|_{0_1,0_1}\leqslant|\langle c^{-2}\rangle-\lambda|^{-1} \tag{III.12}$$

for the operator norm of the resolvent as an operator $L^2\to L^2$. When λ is large enough, this implies that there exists a constant $C_{0,0}$ such that

$$\|\hat{R}_\lambda\|_{0_1,0_1} \leqslant C_{0,0}/|\lambda|. \tag{III.13}$$

Now, let the inner product on H^r using Parseval's formula be defined through

$$\langle .,. \rangle_{r_p} = \langle (\hat{\Gamma}_0)^r ., (\hat{\Gamma}_0)^r . \rangle_{0_p} \quad \text{with} \quad \hat{\Gamma}_0 = [-s^{-2}\partial_\sigma \partial_\sigma + \langle c^{-2} \rangle]^{1/2}.$$

Thus, the inner product and the corresponding norm contain the parameter s. The estimate for the norm of $\hat{R}_\lambda$ can be generalized following Ref. 9, Theorem 1, Corollary 1, and is given in Sec. VIII:

$$\|\hat{R}_\lambda\|_{r,r+l} \leqslant C_{r,l}/|\lambda|^{1-l/2}, \quad 0 \leqslant l \leqslant 2, \tag{III.14}$$

when λ is large enough and lies in the sector $\Lambda = \Lambda_0 \cup \Lambda_{sp}$ of the complex plane, where Λ_0 is defined as $\pi/2 < |\arg(\lambda)| \leqslant \pi$ and Λ_{sp} is defined as $0 < |\arg(\lambda)| \leqslant \pi/2$.

From Eq. (III.7) ($r=0$) it also follows that the spectrum must be real and positive and bounded from below, i.e., when $\lambda \in \sigma(\hat{A})$,

$$\lambda \geqslant \langle c^{-2} \rangle; \tag{III.15}$$

the ''smoothness'' of the possible eigenfunctions is estimated in their appropriate Sobolev space H^r. The property that the spectrum is semibounded from below extends to $\hat{A}$ as an unbounded operator $H^r \to H^r$ also for $r \neq 0$ (see also Ref. 37, Theorem 13.31). We have to ensure that the spectrum is strictly positive in H^r for $r \neq 0$. Since the multiplication operator, arising from the multiplicative part, say $\hat{\phi}$, of the elliptic operator $\hat{A}$ satisfies $(\hat{\Gamma}_0)^r \hat{\phi} (\hat{\Gamma}_0)^{-r} = \hat{\phi} - [\hat{\phi}, (\hat{\Gamma}_0)^r](\hat{\Gamma}_0)^{-r}$ while $[\hat{\phi}, \hat{\Gamma}_0] = O(s^{-1})$ as $s \to \infty$, it is found that $\langle \hat{\phi}\hat{u}, \hat{u} \rangle_{r_p} \geqslant 0$ if the medium is sufficiently smooth or s is large enough and $\hat{\phi} \geqslant 0$. Anyway, the spectrum can be controlled by imposing constraints on the compressibility or on the topology of the underlying horizontal space. In general, the spectrum will consist of absolute continuous (branch cut), pure point and possibly singular continuous contributions. By requiring that $\kappa \to \infty$ as $|\chi_\mu| \to \infty$, or by applying periodic boundary conditions in the horizontal directions, the operator $\hat{A}$ becomes compact, and its spectrum becomes discrete.

It is observed that the estimate in Eq. (III.14) and the properties of $\hat{A}$ hold at each depth level x_3, provided that $\langle c^{-2} \rangle$ is a positive and bounded function of x_3. How to obtain, via a parametrix, the resolvent, which is a two-dimensional problem, will be discussed at the end of this paper.

Given the resolvent $\hat{R}_\lambda$ for $\lambda \notin \sigma(\hat{A})$, we then construct general powers of the differential operator $\hat{A}$, following a standard procedure from functional analysis. This will be discussed in the next subsections.

B. Negative fractional powers of the elliptic operator

Let the power λ^z of a complex variable λ with $z \in \mathbb{R}$ be defined as

$$\lambda^z = |\lambda|^z \exp[iz \arg(\lambda)], \tag{III.16}$$

with $\arg(\lambda) \in (-\pi, \pi)$. With this definition, the branch cut of λ^z is along the negative real axis. Let $\mathscr{B}$ be a contour of integration in the λ plane around the branch cut, counter-clockwise oriented, staying away a small but finite distance from the origin (the branch point), not intersecting the spectrum $\sigma(\hat{A})$, and going to infinity in the sector Λ_0. Then, for $z \in \mathbb{R}_{<0}$, the Dunford integral

$$\hat{A}_z = \frac{1}{2\pi i} \int_{\lambda \in \mathscr{B}} \lambda^z \hat{R}_\lambda \, d\lambda \tag{III.17}$$

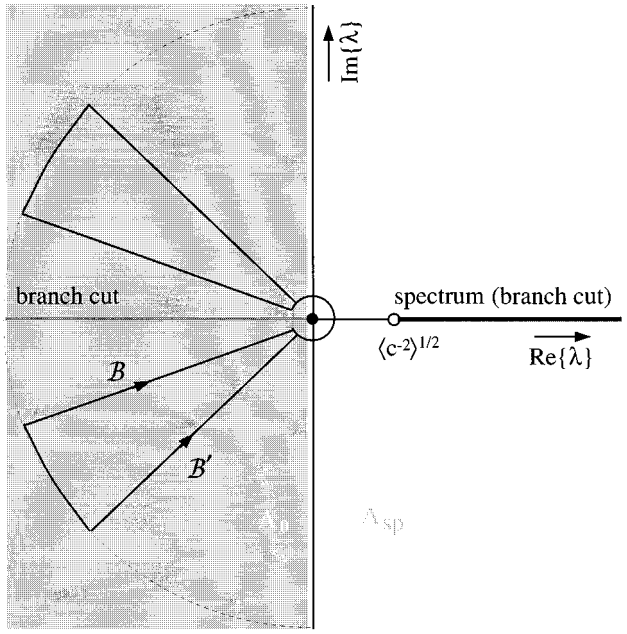

FIG. 2. Contours for the Dunford integral (Seeley's rays of minimal growth).

converges in the operator norm $\|.\|_{r,r-2z}$ on H^r (the proof relies on the symbol calculus of Secs. V and VIII for the parametrix of $\hat{A}-\lambda I$ for $\lambda\in\Lambda_0$ large, in combination with the knowledge about the spectrum $\sigma(\hat{A})$ near the origin). The integral satisfies the composition equation

$$\hat{A}_z\hat{A}_w=\hat{A}_{z+w} \tag{III.18}$$

for z, $w\in\mathbb{R}_{<0}$. To show this, consider another contour $\mathscr{B}'$ around the branch cut such that $\mathscr{B}$ is in between $\mathscr{B}'$ and the branch cut. The integral in Eq. (III.17) remains the same when the contour $\mathscr{B}$ is deformed into $\mathscr{B}'$ (see Fig. 2), since the contributions from the arcs connecting $\mathscr{B}$ and $\mathscr{B}'$ at infinity vanish. Using $\mathscr{B}'$ to evaluate $\hat{A}_z$ and $\mathscr{B}$ to evaluate $\hat{A}_w$, we get

$$\hat{A}_z\hat{A}_w=-\frac{1}{4\pi^2}\int_{\lambda\in\mathscr{B}'}\int_{\mu\in\mathscr{B}}\hat{R}_\lambda\hat{R}_\mu\lambda^z\mu^w\,d\lambda\,d\mu=-\frac{1}{4\pi^2}\int_{\lambda\in\mathscr{B}'}\int_{\mu\in\mathscr{B}}\frac{\lambda^z\mu^w}{\lambda-\mu}(\hat{R}_\lambda-\hat{R}_\mu)d\lambda\,d\mu, \tag{III.19}$$

in view of the Hilbert identity. Since for the first term we have owing to the theorem of residues

$$\int_{\lambda\in\mathscr{B}'}\left[\int_{\mu\in\mathscr{B}}\frac{\mu^w}{\lambda-\mu}\,d\mu\right]\lambda^z\hat{R}_\lambda\,d\lambda=2\pi i\int_{\lambda\in\mathscr{B}'}\lambda^{w+z}\hat{R}_\lambda\,d\lambda \tag{III.20}$$

and, upon changing the order of integration, for the second term

$$\int_{\mu\in\mathscr{B}}\left[\int_{\lambda\in\mathscr{B}'}\frac{\lambda^z}{\lambda-\mu}\,d\lambda\right]\mu^w\hat{R}_\mu\,d\mu=0, \tag{III.21}$$

in view of Cauchy's theorem, Eq. (III.19) reduces to

$$\hat{\mathrm{A}}_z\hat{\mathrm{A}}_w=\frac{1}{2\pi i}\int_{\lambda\in\mathscr{B}'}\lambda^{z+w}\hat{R}_\lambda\,d\lambda, \tag{III.22}$$

from which Eq. (III.18) is found.

C. The inverse operator

In the case $z=-1$, Eq. (III.17) implies

$$\hat{\mathrm{A}}_{-1}=\frac{1}{2\pi i}\int_{\lambda\in\mathscr{S}}\lambda^{-1}\hat{R}_\lambda\,d\lambda, \tag{III.23}$$

where $\mathscr{S}$ encircles the origin counter-clockwise (note that the contributions from the branch cut cancel). The spectrum of $\hat{\mathrm{A}}$ lies outside $\mathscr{S}$ in the λ plane. The change of variables $\mu=\lambda^{-1}$ leads to

$$\hat{\mathrm{A}}_{-1}=\frac{1}{2\pi i}\int_{\mu\in\mathscr{S}'}\mu\hat{R}_{\mu^{-1}}\mu^{-2}\,d\mu, \tag{III.24}$$

where $\mathscr{S}'$ denotes the contour in the μ plane corresponding to $\mathscr{S}$ in the λ plane, but also encircling the origin counter-clockwise. Notice that the spectrum of $\hat{\mathrm{A}}$ lies inside $\mathscr{S}'$ in the μ plane, hence $\hat{R}_{\mu^{-1}}$ is well defined on $\mathscr{S}'$. Since

$$\hat{R}_{\mu^{-1}}=\mu\hat{\mathrm{A}}^{-1}(\mu I-\hat{\mathrm{A}}^{-1})^{-1}, \tag{III.25}$$

certainly when $\mu\in\mathscr{S}'$, substitution in Eq. (III.24) yields

$$\hat{\mathrm{A}}_{-1}=\frac{1}{2\pi i}\,\hat{\mathrm{A}}^{-1}\int_{\mu\in\mathscr{S}'}\mu^{-1}(I-\mu^{-1}\hat{\mathrm{A}}^{-1})^{-1}\,d\mu. \tag{III.26}$$

Since the operator $\hat{\mathrm{A}}^{-1}$ must be bounded, $(I-\mu^{-1}\hat{\mathrm{A}}^{-1})^{-1}$ can be expanded in the Neumann series $(I-\mu^{-1}\hat{\mathrm{A}}^{-1})^{-1}=\Sigma_{n=0}^{\infty}\mu^{-n}\hat{\mathrm{A}}^{-n}$. In view of Cauchy's theorem, only the term $n=0$ in Eq. (III.26) contributes, from which it follows that

$$\hat{\mathrm{A}}_{-1}=\hat{\mathrm{A}}^{-1} \tag{III.27}$$

(see, e.g., Ref. 39, III Theorem 6.15). Equations (III.18) and (III.27) show that the operators $\hat{\mathrm{A}}_z$ behave like ordinary powers for negative values of z.

D. Non-negative fractional powers of the elliptic operator

With the aid of Eq. (III.17) a non-negative fractional power of $\hat{\mathrm{A}}$ can be readily introduced through

$$\hat{\mathrm{A}}^z=\hat{\mathrm{A}}^k\hat{\mathrm{A}}_{z-k}, \tag{III.28}$$

where k is an integer such that $k>z$. The resulting operators behave, again, like ordinary powers, i.e.,

$$\hat{\mathrm{A}}^z\hat{\mathrm{A}}^w=\hat{\mathrm{A}}^{z+w} \tag{III.29}$$

(note that $\hat{\mathrm{A}}$ and its resolvent commute).

In view of Eqs. (III.17), and (III.28) and (III.14), which are based on the results of Sec. VIII, it follows that $\hat{\mathrm{A}}^z$: $H^r\to H^{r-2z}$ is bounded for general r and for all $z\in\mathbb{R}$.

E. The Schrödinger problem

If $\hat{\mathrm{A}}$ is *compact* and self-adjoint, its eigenfunctions ψ and spectrum can be used to evaluate its negative fractional powers, viz., upon choosing the contour $\mathscr{B}$ in the Dunford integral equation (III.17) in Λ_{sp} around $\sigma(\hat{\mathrm{A}})$. Then, applying the theorem of residues leads to

$$\hat{\mathrm{A}}_z\psi_{[N]}=\frac{1}{2\pi i}\int_{\lambda\in\mathscr{B}}\lambda^z\hat{R}_\lambda\psi_{[N]}\,d\lambda=\frac{1}{2\pi i}\,\psi_{[N]}\int_{\lambda\in\mathscr{B}}\lambda^z(\lambda_{[N]}-\lambda)^{-1}\,d\lambda=\lambda^z_{[N]}\psi_{[N]}. \tag{III.30}$$

Expanding the components of the wave matrix into the eigenfunctions of $\hat{\mathrm{A}}$ leads to a diagonal representation of $\hat{\mathrm{A}}_z$, viz.,

$$\hat{\mathrm{A}}_z\hat{u}=\sum_{[N]}\lambda^z_{[N]}\hat{u}_{[N]}\psi_{[N]}\quad\text{with}\quad\hat{u}=\sum_{[N]}\hat{u}_{[N]}\psi_{[N]}. \tag{III.31}$$

Finding the horizontal spectrum and eigenfunctions, $\hat{\mathrm{A}}\psi=\lambda\psi$, is a Schrödinger problem in two dimensions; note that this spectrum may vary with x_3. The Dunford integral around the spectrum links the current methodology to the theory of waveguides in two dimensions, since $s^2\hat{\mathrm{A}}$ corresponds with a dimensionally reduced wave equation.

F. Vertical derivatives of powers of the elliptic operator

Consider, again, Eq. (II.19). We are now in a position to show that $(\partial_3\hat{L}_{I,J})$ exists. As before, it is sufficient to prove that the expression for $(\partial_3\hat{\mathrm{A}}_z)$ converges in operator norm when $z<0$. To this end, we consider the integral

$$\frac{1}{2\pi i}\int_{\lambda\in\mathscr{B}}\lambda^z\partial_3\hat{R}_\lambda\,d\lambda,$$

in which

$$\partial_3\hat{R}_\lambda=-\hat{R}_\lambda(\partial_3\hat{\mathrm{A}})\hat{R}_\lambda, \tag{III.32}$$

where ∂_3 in $(\partial_3\hat{\mathrm{A}})$ acts on the coefficients of $\hat{\mathrm{A}}$ only. In fact, $(\partial_3\hat{\mathrm{A}})$: $H^r\to H^r$ is a multiplication operator. Note that this operator is bounded, since the derivatives of the medium parameters are assumed to be continuous. Further, $\partial_3\hat{R}_\lambda$ vanishes in those regions where the medium properties are independent of x_3. The norm of $\partial_3\hat{R}_\lambda$ satisfies the estimate [cf. Eq. (III.14)]

$$\|\partial_3\hat{R}_\lambda\|_{r,r+l+m}\leqslant\|\hat{R}_\lambda\|_{r+l,r+l+m}\|(\partial_3\hat{\mathrm{A}})\|_{r+l,r+l}\|\hat{R}_\lambda\|_{r,r+l}\leqslant C_{r,l,m}/|\lambda|^{2-(l+m)/2} \tag{III.33}$$

for $0\leqslant l$, $m\leqslant 2$, and $\lambda\in\Lambda_0$ large. It then also follows that $(\partial_3\hat{\mathrm{A}}_z)$: $H^r\to H^{r-2(z-1)}$ exists and is bounded for $\mathrm{Re}\{z\}<0$ (the proof relies on the symbol expansions to be discussed in Sec. VIII). Now, use the relation

$$(\partial_3\hat{\mathrm{A}}^z)=(\partial_3\hat{\mathrm{A}}^k\hat{\mathrm{A}}_{z-k})=\sum_{q=0}^{k}\hat{\mathrm{A}}^q(\partial_3\hat{\mathrm{A}})\hat{\mathrm{A}}^{k-q}\hat{\mathrm{A}}_{z-k}+\hat{\mathrm{A}}^k(\partial_3\hat{\mathrm{A}}_{z-k})$$

to extend the result from $z<0$ to $z\geqslant 0$.

IV. THE SYSTEM OF ONE-WAY WAVE EQUATIONS IN THE TIME-LAPLACE-TRANSFORM DOMAIN

Next, we complete the directional decomposition procedure. Using any of the decomposition schemes, Eq. (II.19) transforms into

$$(\partial_3\delta_{I,M}+s\hat{\Lambda}_{I,M})\hat{W}_M=-(\hat{L}^{-1})_{I,M}(\partial_3\hat{L}_{M,K})\hat{W}_K+(\hat{L}^{-1})_{I,M}\hat{N}_M, \tag{IV.1}$$

which can be interpreted as a coupled system of one-way wave equations. The coupling between the components of $\hat{W}_M$ is apparent in the first sourcelike term on the right-hand side. In particular, we shall further investigate the decomposition operator associated with the vertical-power-flux normalization and given by Eq. (II.48). For this normalization, the coupling operator becomes

$$-\hat{L}^{-1}(\partial_3\hat{L})=\begin{pmatrix}\hat{T} & \hat{R}\\ \hat{R} & \hat{T}\end{pmatrix}, \tag{IV.2}$$

in which

$$\hat{T}=-\tfrac{1}{4}\hat{\Gamma}^{-1/2}[\hat{\Gamma},\,\hat{A}_{1,2}^{-1}(\partial_3\hat{A}_{1,2})]\hat{\Gamma}^{-1/2}-\tfrac{1}{2}[\hat{\Gamma}^{1/2},\,(\partial_3\hat{\Gamma}^{-1/2})], \tag{IV.3}$$

where we have used the property that $\hat{\Gamma}^{1/2}(\partial_3\hat{\Gamma}^{-1/2})=-(\partial_3\hat{\Gamma}^{1/2})\hat{\Gamma}^{-1/2}$, is the *transmission* operator that consists of commutators only, and

$$\begin{aligned}\hat{R}&=-\tfrac{1}{4}\hat{\Gamma}^{-1/2}([\hat{\Gamma},\,\hat{A}_{1,2}^{-1}(\partial_3\hat{A}_{1,2})]+2\hat{A}_{1,2}^{-1}(\partial_3\hat{A}_{1,2})\hat{\Gamma}-2(\partial_3\hat{\Gamma}))\hat{\Gamma}^{-1/2}\\&=-\tfrac{1}{4}\hat{\Gamma}^{-1/2}\{\hat{\Gamma},\hat{A}_{1,2}^{-1}(\partial_3\hat{A}_{1,2})\}\hat{\Gamma}^{-1/2}-\tfrac{1}{2}\{\hat{\Gamma}^{1/2},(\partial_3\hat{\Gamma}^{-1/2})\},\end{aligned} \tag{IV.4}$$

where {.,.} denotes the anticommutator, is the *reflection* operator. In the limit of a horizontally homogeneous medium (or as $s\to\infty$), the physical interpretation of Eq. (IV.1) simplifies since then $\hat{L}^{-1}(\partial_3\hat{L})$ becomes purely off-diagonal. In this case, therefore only counter-propagating constituents interact. This property reveals the consistency of the decomposition method with asymptotic ray theory.

The reflection and transmission operators are bounded and vanish, due to our initial assumption of a homogeneous, isotropic embedding, outside a closed interval along the x_3-direction. To show the boundedness, note that the multiplication operator,

$$\hat{A}_{1,2}^{-1}(\partial_3\hat{A}_{1,2}):\ H^s\to H^s\quad\text{with}\ \hat{A}_{1,2}^{-1}(\partial_3\hat{A}_{1,2})\in C_0^\infty, \tag{IV.5}$$

is bounded for all H^s. Further, $\hat{\Gamma}^{1/2}(\partial_3\hat{\Gamma}^{-1/2})=-(\partial_3\hat{\Gamma}^{1/2})\hat{\Gamma}^{-1/2}$: $H^r\to H^{r+l}$ with $0\leqslant l\leqslant 2$ are bounded. Thus, the norms of the reflection and transmission operators in $\mathbb{R}^2$ can be estimated as

$$\begin{aligned}\|\hat{T}\|_{r,r}\leqslant C_{r,1}^T\,[&\|\hat{\Gamma}^{-1/2}\|_{r-1/2,r}\|\hat{A}_{1,2}^{-1}(\partial_3\hat{A}_{1,2})\|_{r-1/2,r-1/2}\|\hat{\Gamma}^{1/2}\|_{r,r-1/2}\\&+\|\hat{\Gamma}^{1/2}\|_{r+1/2,r}\|\hat{A}_{1,2}^{-1}(\partial_3\hat{A}_{1,2})\|_{r+1/2,r+1/2}\|\hat{\Gamma}^{-1/2}\|_{r,r+1/2}]+C_{r,2}^T\,\|[\hat{\Gamma}^{1/2},(\partial_3\hat{\Gamma}^{-1/2})]\|_{r,r}\end{aligned} \tag{IV.6}$$

and

$$\begin{aligned}\|\hat{R}\|_{r,r}\leqslant C_{r,1}^R\,[&\|\hat{\Gamma}^{-1/2}\|_{r-1/2,r}\|\hat{A}_{1,2}^{-1}(\partial_3\hat{A}_{1,2})\|_{r-1/2,r-1/2}\|\hat{\Gamma}^{1/2}\|_{r,r-1/2}\\&+\|\hat{\Gamma}^{1/2}\|_{r+1/2,r}\|\hat{A}_{1,2}^{-1}(\partial_3\hat{A}_{1,2})\|_{r+1/2,r+1/2}\|\hat{\Gamma}^{-1/2}\|_{r,r+1/2}]+C_{r,2}^R\,\|\{\hat{\Gamma}^{1/2},(\partial_3\hat{\Gamma}^{-1/2})\}\|_{r,r}\end{aligned} \tag{IV.7}$$

uniformly in $s\geqslant s_0>0$.

So far we have replaced Eq. (II.9) by Eqs. (IV.1) and (II.17). Equation (IV.1) shows that at this stage the vertical derivative operator needs further analysis. To illustrate how the source distributions control the space to which the wave matrix belongs, suppose that $\hat{f}_k \in H^r$ and $\hat{q} \in H^{r-1}$. Then $\hat{N}_1 \in H^r$ and $\hat{N}_2 \in H^{r-1}$ [cf. Eqs. (II.15) and (II.16)]. In accordance with the matrix operator in Eq. (II.9), $\hat{F}_1 \in H^{r+1}$ and $\hat{F}_2 \in H^r$. Further, we have $\hat{A}_{1,2}$: $H^{r(+1)} \to H^{r(+1)}$, whereas $\hat{A}_{2,1}$: $H^{r+1} \to H^{r-1}$ [cf. Eqs. (II.12)–(II.14)]. In view of Eq. (II.48) we then arrive at $\hat{W}_M \in H^{r+1/2}$. In practice, we set $r = -\frac{1}{2}$.

A. Factorization of the "Helmholtz" operator

If we constrain our configuration to a vertically homogeneous (thin) slab, the directional decomposition implies a factorization of the Laplace-domain analog of the second-order wave equation. Using Eq. (II.40), we find that

$$(\partial_3 + s\hat{\Gamma}^{(+)})(\partial_3 + s\hat{\Gamma}^{(-)}) = \partial_3^2 - s^2\hat{\mathrm{A}}. \tag{IV.8}$$

Indeed, the pressure satisfies the equation [cf. Eq. (II.9)]

$$(\partial_3^2 - s^2\hat{A}_{1,2}\hat{A}_{2,1})\hat{F}_1 = \partial_3\hat{N}_1 - \hat{A}_{1,2}\ s\hat{N}_2. \tag{IV.9}$$

However, it is emphasized that the factorization does not hold in this form for vertically heterogeneous media.

V. THE GENERALIZED VERTICAL SLOWNESS

For the proofs of the basic results in Sec. III, for the evaluation of the resolvent $\hat{R}_\lambda^{(\mathrm{A})}$ and hence of $\hat{\Gamma}$ and $\hat{L}_{I,J}$, as well as in preparation of the evaluation (and the associated numerical implementation with respect to a Fourier basis) of the Green's functions belonging to the left-hand side of Eq. (IV.1), the calculus of pseudo-differential operators is employed. An overview of the pseudo-differential-operator calculus can be found in several textbooks.[11,40–42]

It is obvious that $\hat{\mathrm{A}}$: $H^r \to H^{r-2}$ can be interpreted as a pseudo-differential operator of order 2. The existence of the resolvent, via a parametrix, as a pseudo-differential operator has been shown by Seeley,[9] Section 6. As a consequence of this, the vertical slowness operator $\hat{\Gamma} = \hat{\mathrm{A}}^{1/2}$: $H^r \to H^{r-1}$ can be represented by a pseudo-differential operator of order 1.

A. General considerations

First, we present some rules for a general pseudo-differential operator $\hat{\Gamma}$: $H^r \to H^{r-d}$ of order d; later on, we will focus our attention on the particular case of the vertical slowness operator for which $d = 1$.

The Fourier transformation in the horizontal plane is defined as

$$\tilde{\hat{u}}(\alpha_\mu, x_3, s) = \int_{x_\mu \in \mathbb{R}} \hat{u}(x_m, s)\exp(is\alpha_\mu x_\mu)\,dx_1\,dx_2. \tag{V.1}$$

Here, $i\alpha_\mu$ are identified as the horizontal slownesses. Now, the Sobolev norm (with parameter s) on H^r is written as (in view of Plancherel's theorem)

$$\|\hat{u}\|_r^2 = \left(\frac{s}{2\pi}\right)^2 \int_{\alpha_\mu \in \mathbb{R}} [|\tilde{\hat{u}}(\alpha_\mu, x_3, s)|\ \ [(\langle c^{-2}\rangle + \alpha_\sigma\alpha_\sigma)^{1/2}]^r]^2\,d\alpha_1\,d\alpha_2. \tag{V.2}$$

In the space domain, $i\alpha_\lambda$ corresponds to the *horizontal slowness* operator

$$D_\lambda = -\frac{1}{s}\,\partial_\lambda. \tag{V.3}$$

Note that D_λ and the multiplication by x_κ do not commute, since

$$[x_\kappa,\, D_\lambda] = \frac{1}{s}\,\delta_{\kappa,\lambda}\,. \tag{V.4}$$

However, in the limit $s\to\infty$ the commutator vanishes. By letting the operator $\hat{\Gamma}$ act on a Fourier component $\exp(-is\alpha_\mu x_\mu)$ we introduce its left symbol $\hat{\gamma}(x_\kappa,\alpha_\lambda)$,

$$\hat{\Gamma}(x_\kappa,D_\lambda)\exp(-is\alpha_\mu x_\mu) = \hat{\gamma}(x_\kappa,\alpha_\lambda)\exp(-is\alpha_\mu x_\mu). \tag{V.5}$$

For a general test function $\hat{u}$ this implies

$$(\hat{\Gamma}(x_\kappa,D_\lambda)\hat{u})(x_\mu) = \int_{x'_\nu\in\mathbb{R}} \hat{\mathscr{C}}(x_\mu,x'_\nu)\hat{u}(x'_\nu)dx'_1dx'_2\,, \tag{V.6}$$

in which, with the use of Eq. (V.1),

$$\hat{\mathscr{C}}(x_\mu,x'_\nu) = \left(\frac{s}{2\pi}\right)^2 \int_{\alpha_\nu\in\mathbb{R}} \hat{\gamma}(x_\mu,\alpha_\nu)\exp[is\alpha_\nu(x'_\nu-x_\nu)]d\alpha_1d\alpha_2\,. \tag{V.7}$$

Here, $\hat{\mathscr{C}}$ is called the Schwartz kernel of the pseudo-differential operator $\hat{\Gamma}$. The left symbol and the Schwartz kernel are related through the Fourier transformation [cf. Eq. (V.7)]

$$\hat{\gamma}(x_\mu,\alpha_\lambda) = \int_{x'_\nu\in\mathbb{R}} \hat{\mathscr{C}}(x_\mu,x'_\nu)\exp[is(x_\lambda-x'_\lambda)\alpha_\lambda]dx'_1dx'_2\,. \tag{V.8}$$

In the horizontal space Fourier-transform domain Eq. (V.6) becomes

$$(\hat{\Gamma}\tilde{u})(\alpha_\mu) = \left(\frac{s}{2\pi}\right)^2 \int_{\alpha'_\nu\in\mathbb{R}} \tilde{\gamma}(\alpha_\mu-\alpha'_\mu,\alpha'_\nu)\tilde{u}(\alpha'_\nu)d\alpha'_1d\alpha'_2\,, \tag{V.9}$$

where $\tilde{\Gamma}$ is defined as

$$(\hat{\Gamma}\tilde{u})(\alpha_\mu) = \int_{x_\nu\in\mathbb{R}} \exp(is\alpha_\mu x_\mu)\hat{\Gamma}(x_\kappa,D_\lambda)\hat{u}(x_\nu)dx_1dx_2 \tag{V.10}$$

and $\tilde{\gamma}$ as

$$\tilde{\gamma}(\alpha_\mu,\alpha'_\nu) = \int_{x_\nu\in\mathbb{R}} \exp(is\alpha_\mu x_\mu)\,\hat{\gamma}(x_\mu,\alpha'_\nu)dx_1dx_2\,. \tag{V.11}$$

Equation (V.9) explicitly shows the interaction between the different Fourier components (see also Refs. 43–45). The quantity $\tilde{\gamma}$ is denoted as the *cokernel*[42] of $\hat{\Gamma}$. Its representation is useful for numerical computations.

The notation in Eq. (V.6) is justified by the fact that if $\hat{\gamma}$ would be a polynomial in α_λ, as is the case when $\hat{\Gamma}$ is a partial differential operator, then $\hat{\Gamma}$ would be obtained from $\hat{\gamma}$ by replacing $i\alpha_\lambda$ by D_λ put to the right of the coefficients. Still, we omit the dependencies of $\hat{\gamma}$ and $\hat{u}$ on x_3 and s for the time being. The integral in Eq. (V.6) converges with Eq. (V.7) even when $\hat{\gamma}$ becomes large, as long as $\hat{\gamma}$ oscillates more slowly than the exponential. The Schwartz kernel [cf. Eq. (V.7)] is a so-called oscillatory integral. To guarantee that the right-hand side of Eq. (V.7) exists as a distribution, the symbol $\hat{\gamma}$ must lie in a space $S^d(\mathbb{R}^2\times\mathbb{R}^2)$, d being a real number, which means that for all m_1,m_2,n_1,n_2 there exists a constant C_{m_1,m_2,n_1,n_2} such that (Ref. 11, Definition 18.1.1)

$$|(\partial_{\alpha_1}^{m_1}\partial_{\alpha_2}^{m_2}\partial_{x_1}^{n_1}\partial_{x_2}^{n_2}\hat{\gamma})(x_\kappa,\alpha_\lambda)| \leqslant C_{m_1,m_2,n_1,n_2}[(\langle c^{-2}\rangle+\alpha_\sigma\alpha_\sigma)^{1/2}]^{d-m_1-m_2} \tag{V.12}$$

for all $x_\kappa \in \mathbb{R}$, $\alpha_\lambda \in \mathbb{R}$. The constant C_{m_1,m_2,n_1,n_2} may depend on s but is $O(1)$ as $s\to\infty$. The number d is called the order of the space S^d. We write $S^{-\infty} = \cap_{d\in\mathbb{R}} S^d$. Under the condition Eq. (V.12) it follows that $\hat{\mathscr{C}}$ is a distribution of order $\leqslant k$ with $k>d+2$ (Ref. 46, Theorem 7.8.2 and Appendix A), while $\hat{\Gamma}$: $H^r\to H^{r-d}$ is continuous (Ref. 11, Theorem 18.1.13) and d is the so-called order of the operator; the corresponding operator norm associated with the Sobolev norm with parameter is $O(1)$ as $s\to\infty$ if the symbol is $O(1)$. Then the kernel is smooth outside the diagonal in $\mathbb{R}^2\times\mathbb{R}^2$. The space of pseudo-differential operators of which the left symbols are in S^d is denoted by Op S^d. It is observed that Op $S^{-\infty}$ is the space of operators the Schwartz kernels of which are in $C^\infty(\mathbb{R}^2\times\mathbb{R}^2)$. The expansions of symbols to be considered later on will all be mod $S^{-\infty}$.

B. The equation for the slowness surface

The left symbol $\hat{a}=\hat{a}(x_\mu,\alpha_\nu)$ of the normalized elliptic differential operator given in Eq. (II.45),

$$\begin{aligned}\hat{\mathrm{A}} &= -\rho^{1/2}s^{-1}\partial_\nu(\rho^{-1}s^{-1}\partial_\nu(\rho^{1/2}\,))+\kappa\rho \\ &= -s^{-2}\partial_\nu\partial_\nu+\kappa\rho+\tfrac{3}{4}\rho^{-2}s^{-2}(\partial_\nu\rho)^2-\tfrac{1}{2}\rho^{-1}s^{-2}(\partial_\nu\partial_\nu\rho),\end{aligned} \tag{V.13}$$

using Eq. (V.5), is obtained as

$$\hat{a}=\alpha_\nu\alpha_\nu+\kappa\rho+\tfrac{3}{4}\rho^{-2}s^{-2}(\partial_\nu\rho)^2-\tfrac{1}{2}\rho^{-1}s^{-2}(\partial_\nu\partial_\nu\rho). \tag{V.14}$$

The latter expression is real valued, while terms $O(s^{-1})$ do not occur. The symbol lies in S^2 (note that the third- and higher-order derivatives with respect to α_ν vanish and that the volume density of mass and the compressibility together with their derivatives are bounded functions of position in space). The corresponding Schwartz kernel is given by

$$\begin{aligned}\hat{\mathscr{C}}(x_\mu,x'_\mu) &= -s^{-2}\partial_\nu\partial_\nu\delta(x_\mu-x'_\mu) \\ &\quad +[\kappa\rho+\tfrac{1}{2}\rho^{-1}s^{-2}\{\tfrac{3}{2}\rho^{-1}(\partial_\nu\rho)^2-(\partial_\nu\partial_\nu\rho)\}](x_\mu)\,\delta(x_\mu-x'_\mu),\end{aligned} \tag{V.15}$$

with as its support $x_\mu = x'_\mu$, i.e., the diagonal in $\mathbb{R}^2\times\mathbb{R}^2$.

To transform the operator equation (II.44) into an equation for the corresponding left symbols, we consider the composition of two pseudo-differential operators. Representing the operators as in Eqs. (V.6) and (V.7), the composition rule for the respective left symbols is found (see the Appendix). Application of this rule yields the definition of the generalized slowness surface as the solutions $\hat{\gamma}^{(\pm)}\in S^1$ of [cf. Eq. (V.14)]

$$\begin{aligned}&-\left(\frac{s}{2\pi}\right)^2\int_{x'_\nu\in\mathbb{R}}\int_{\alpha'_\nu\in\mathbb{R}}\hat{\gamma}(x_\mu,\alpha'_\lambda)\exp[is(x_\sigma-x'_\sigma)(\alpha_\sigma-\alpha'_\sigma)]\,\hat{\gamma}(x'_\lambda,\alpha_\nu)\,d\alpha'_1 d\alpha'_2 dx'_1 dx'_2 \\ &+\alpha_\nu\alpha_\nu+\kappa\rho+\tfrac{3}{4}\rho^{-2}s^{-2}(\partial_\nu\rho)^2-\tfrac{1}{2}\rho^{-1}s^{-2}(\partial_\nu\partial_\nu\rho)=0.\end{aligned} \tag{V.16}$$

The branches are $\hat{\gamma}^{(\pm)}(x_\kappa,\alpha_\lambda)$ such that

$$\mathrm{Re}\{\hat{\gamma}^{(+)}(x_\mu,\alpha_\nu)\}\geqslant 0 \quad \text{and} \quad \mathrm{Re}\{\hat{\gamma}^{(-)}(x_\mu,\alpha_\nu)\}\leqslant 0.$$

Due to the isotropy (up/down symmetry) of the medium we have $\hat{\gamma}^{(+)}=-\hat{\gamma}^{(-)}$. Further, note that as $s\to\infty$ the composition of symbols tends to an ordinary multiplication. The solution of the

associated equation for the slowness surface yields the principal vertical slowness, which coincides pointwise with the vertical gradient of travel time along a characteristic.

So far, we had to assume that the medium properties (i.e., the coefficients in the elliptic operator) were smooth. This condition can be somewhat relaxed. Media, in which discontinuities in their physical properties occur, should be smoothed on the scale of the irradiating pulse width with the aid of equivalent medium averaging. To allow singularities in the medium and the volume source densities to coexist, however, requires a novel analysis of pseudo-differential operators.[47] Further, our analysis in the horizontal plane builds on the one on the torus; thus, we have chosen to use left symbols rather than Weyl symbols (Ref. 11, Sections 18.4 and 18.5) in this paper.

VI. THE GREEN'S FUNCTIONS OF THE ONE-WAY WAVE OPERATORS

We now subject the left-hand side of Eq. (IV.1) to a further investigation. In it, we recognize the operators

$$\partial_3+s\hat{\Gamma}^{(\pm)}\colon\ \mathscr{S}(\mathbb{R}_{\pm},H^r(\mathbb{R}^2))\rightarrow\mathscr{S}(\mathbb{R}_{\pm},H^{r-1}(\mathbb{R}^2)), \tag{VI.1}$$

where $\mathscr{S}(\mathbb{R}_{\pm},H^r(\mathbb{R}^2))$, denotes a Banach space of maps $\mathbb{R}_{\pm}\rightarrow H^r(\mathbb{R}^2)$. The operators in Eq. (VI.1) are the full one-way wave operators. A technical complication arises because the operators in Eq. (VI.1) cannot be identified as pseudo-differential operators $H^r(\mathbb{R}^2\times\mathbb{R})\rightarrow H^{r-1}(\mathbb{R}^2\times\mathbb{R})$ (see also Ref. 41).

To arrive at the coupled system of integral equations that is equivalent to Eq. (IV.1) and that can be solved in terms of a Neumann expansion, we have to invert the operator occurring on the left-hand side. The one-sided elementary kernels $\hat{\mathscr{G}}^{(\pm)}(x_\mu,x_3;x'_\nu,x'_3)$ associated with the operators

$$\hat{\mathrm{G}}^{(\pm)}=(\partial_3+s\hat{\Gamma}^{(\pm)})^{-1}\colon\ \mathscr{S}(\mathbb{R}_{\pm},H^r(\mathbb{R}^2))\rightarrow\mathscr{S}(\mathbb{R}_{\pm},H^r(\mathbb{R}^2))$$

in three-dimensional space are the so-called Green's functions. They satisfy the equations

$$\partial_3\hat{\mathscr{G}}^{(\pm)}+s\hat{\Gamma}^{(\pm)}\hat{\mathscr{G}}^{(\pm)}=\delta(x_\nu-x'_\nu)\,\delta(x_3-x'_3), \tag{VI.2}$$

together with the condition of causality.

We will consider the case $\hat{\mathrm{G}}=\hat{\mathrm{G}}^{(+)}$, $\hat{\mathscr{G}}=\hat{\mathscr{G}}^{(+)}$, and $\hat{\Gamma}=\hat{\Gamma}^{(+)}$ in detail. The operator $\hat{\mathrm{G}}$ acts on a test function $\hat{u}$ as

$$(\hat{\mathrm{G}}\hat{u})(x_\mu,x_3)=\int_{\zeta\in\mathbb{R}}\int_{x'_\nu\in\mathbb{R}}\hat{\mathscr{G}}(x_\mu,x_3;x'_\nu,\zeta)\hat{u}(x'_\nu,\zeta)dx'_1dx'_2d\zeta. \tag{VI.3}$$

Let us define the initial-value problem of determining the function $\hat{U}(x_\mu,x_3;\zeta)$ satisfying

$$(\partial_3+s\hat{\Gamma})\hat{U}=0\quad\text{for } x_3\geqslant\zeta,\quad \hat{U}(x_\mu,\zeta;\zeta)=\hat{u}(x_\mu,\zeta). \tag{VI.4}$$

Then it is observed that

$$(\hat{\mathrm{G}}\hat{u})(x_\mu,x_3)=\int_{\zeta=-\infty}^{x_3}\hat{U}(x_\mu,x_3;\zeta)d\zeta. \tag{VI.5}$$

A. Properties of the inverse one-way wave operator

Now, to estimate in a proper norm the operator $\hat{\mathrm{G}}$, let

$$\hat{\Gamma}=\hat{\mathrm{L}}+\hat{\mathrm{E}}, \tag{VI.6}$$

where

$$\hat{\mathrm{L}}=[-s^{-2}\partial_\sigma\partial_\sigma+c_L^{-2}]^{1/2} \tag{VI.7}$$

is an elliptic operator independent of x_3 (which can be identified as the vertical slowness operator of order 1 in a homogeneous medium with slowness c_L^{-1}) and where

$$\hat{\mathrm{E}}=\hat{\Gamma}-\hat{\mathrm{L}} \tag{VI.8}$$

is a pseudo-differential operator of order $\leqslant 0$. Note that [cf. Eq. (V.1) and below]

$$\|\hat{\mathrm{L}}\hat{u}\|_r\geqslant c_L^{-1}\|\hat{u}\|_r \tag{VI.9}$$

uniformly in s (and x_3). In this framework, our initial-value problem is written as

$$(\partial_3+s\hat{\mathrm{L}})\hat{U}=-s\hat{\mathrm{E}}\hat{U}\quad\text{for } x_3\geqslant x_3',\quad \hat{U}(x_\mu,x_3';x_3')=\hat{u}(x_\mu,x_3'). \tag{VI.10}$$

Thus, the causal or one-sided propagator $\hat{U}$ satisfies [cf. Eq. (VI.10)]

$$\hat{U}(x_3;x_3')=\exp[-s(x_3-x_3')\hat{\mathrm{L}}]\hat{U}(x_3';x_3')-s\int_{\zeta=x_3'}^{x_3}\exp[-s(x_3-\zeta)\hat{\mathrm{L}}]\ \hat{\mathrm{E}}(\zeta)\hat{U}(\zeta;x_3')d\zeta. \tag{VI.11}$$

Taking Sobolev norms on both sides yields on account of Eq. (VI.9)

$$\begin{aligned}\|\hat{U}(x_3;x_3')\|_r\leqslant&\exp[-s(x_3-x_3')c_L^{-1}]\|\hat{U}(x_3';x_3')\|_r\\&+s\int_{\zeta=x_3'}^{x_3}\exp[-s(x_3-\zeta)c_L^{-1}]\|\hat{\mathrm{E}}(\zeta)\|_{r,r}\|\hat{U}(\zeta;x_3')\|_r\,d\zeta.\end{aligned} \tag{VI.12}$$

Now, let

$$w(x_3)=\exp(sx_3c_L^{-1})\|\hat{U}(x_3;x_3')\|_r, \tag{VI.13}$$

then Eq. (VI.12) leads to

$$w(x_3)\leqslant w(x_3')+s\,\eta\int_{\zeta=x_3'}^{x_3}w(\zeta)d\zeta, \tag{VI.14}$$

where (note that $\hat{\mathrm{E}}$ must be bounded)

$$\eta(c_L^{-1})=\sup_{x_3\in\mathbb{R}}\|\hat{\mathrm{E}}(x_3)\|_{r,r}. \tag{VI.15}$$

(In view of the structure of $\hat{\Gamma}$ note that η depends on s but that an estimate can be given uniformly in s for values away from zero). Application of Gronwall's theorem (Ref. 48, p. 37) to Eq. (VI.14) yields

$$w(x_3)\leqslant w(x_3')\exp[s\,\eta\,(x_3-x_3')], \tag{VI.16}$$

for $x_3\geqslant x_3'$, so that upon using Eq. (VI.13) we have

$$\|\hat{U}(x_3;x_3')\|_r\leqslant\|\hat{U}(x_3';x_3')\|_r\exp[-s(x_3-x_3')(c_L^{-1}-\eta)] \tag{VI.17}$$

for $x_3 \geqslant x_3'$. To find a useful estimate for the norm of $\hat{\mathrm{G}}$, c_L^{-1} must be chosen such that $c_L^{-1} > \eta(c_L^{-1})$ uniformly in s for $s \geqslant s_0$. Let $\hat{e}$ denote the left symbol of $\hat{\mathrm{E}}$. An expansion for this symbol follows from Eq. (V.16) and the results of Sec. VIII:

$$\hat{e} = (\alpha_\nu \alpha_\nu + c^{-2})^{1/2} - (\alpha_\sigma \alpha_\sigma + c_L^{-2})^{1/2} + C^{(0)}, \tag{VI.18}$$

where $c^{-2} = \kappa\rho$, and $C^{(0)}$ is in S^d, $d \leqslant 0$ independent of c_L. Let

$$\mathsf{m} = \sup_{x_m \in \mathbb{R}^3} |c^{-1} - c_L^{-1}|. \tag{VI.19}$$

In a realistic medium, we can arrange the parameters such that there exists an estimate $\mathsf{m} \leqslant \mathsf{m}_0$ with m_0 independent of c_L. We have

$$|(\alpha_\nu \alpha_\nu + c^{-2})^{1/2} - (\alpha_\sigma \alpha_\sigma + c_L^{-2})^{1/2}| \leqslant \mathsf{m}.$$

Since $C^{(0)}$ is continuous, we find the estimate

$$|\hat{e}(x_m, \alpha_\lambda)| \leqslant \mathsf{m} + c^{(0)}. \tag{VI.20}$$

Further, we obtain

$$\partial_{\alpha_\mu} \hat{e} = \alpha_\mu \frac{(\alpha_\sigma \alpha_\sigma + c_L^{-2})^{1/2} - (\alpha_\nu \alpha_\nu + c^{-2})^{1/2}}{(\alpha_\nu \alpha_\nu + c^{-2})^{1/2} (\alpha_\sigma \alpha_\sigma + c_L^{-2})^{1/2}} + C^{(-1)}, \quad C^{(-1)} = \partial_{\alpha_\mu} C^{(0)}. \tag{VI.21}$$

Since $C^{(-1)} \in S^d$, $d \leqslant -1$, we find the estimate

$$|\partial_{\alpha_\mu} \hat{e}(x_m, \alpha_\lambda)| \leqslant (\mathsf{m} + c^{(-1)}) (\langle c^{-2} \rangle + \alpha_\sigma \alpha_\sigma)^{-1/2} \tag{VI.22}$$

with $c^{(-1)}$ independent of c_L. This way, we can continue to analyze estimates like Eq. (V.12) for $\hat{e}$ up to any order of differentiation. Let c_0 denote the supremum of all $c^{(d)}$ s; the calculus of symbols (and the proof of continuity of pseudo-differential operators[11]) then implies the estimate

$$\sup_{x_3 \in \mathbb{R}} \|\hat{\mathrm{E}}(x_3)\|_{r,r} \leqslant \beta \mathsf{m} + C_0, \quad C_0 = \beta c_0, \quad \beta > 1, \tag{VI.23}$$

where C_0 is independent of c_L. Now, choose c_L so that

$$c_L^{-1} > \beta \mathsf{m} + C_0 \geqslant \eta(c_L^{-1}) = \sup_{x_3 \in \mathbb{R}} \|\hat{\mathrm{E}}(x_3)\|_{r,r}. \tag{VI.24}$$

To be able to find a c_L^{-1}, C_0 must satisfy the inequalities [cf. Eq. (VI.24)]

$$0 < 2C_0 < -(\beta - 1) \sup_{x_m \in \mathbb{R}^3} c^{-1} + (\beta + 1) \inf_{x_m \in \mathbb{R}^3} c^{-1},$$

from which it follows that $\beta > 1$ must be chosen in accordance with the conditions

$$1 \leqslant \frac{\sup_{x_m \in \mathbb{R}^3} c^{-1}}{\inf_{x_m \in \mathbb{R}^3} c^{-1}} < \frac{\beta + 1}{\beta - 1}.$$

Let β_1 satisfy the conditions, and let $\beta=\beta_1+\beta_2$; then $\beta\,\mathsf{m}\leqslant\beta_1\mathsf{m}+\beta_2\mathsf{m}_0$, and $\beta\,\mathsf{m}_0$ can be absorbed in C_0 to recover an estimate of the type Eq. (VI.24). [In a horizontally homogeneous medium we find $\mathsf{m}(c_L^{-1}) = \sup_{x_3\in\mathbb{R}}|c^{-1} - c_L^{-1}|$, hence c_L^{-1} must be chosen in accordance with $c_L^{-1}>\beta(1+\beta)^{-1}\sup_{x_3\in\mathbb{R}}c^{-1}$.]

Now, take Sobolev norms on both sides of Eq. (VI.5):

$$\begin{aligned}\|(\hat{\mathrm{G}}\hat{u})(x_3)\|_r &\leqslant \int_{\zeta=-\infty}^{x_3} \|\hat{U}(x_3;\zeta)\|_r\, d\zeta \\ &\leqslant \int_{\zeta=-\infty}^{x_3} \exp[-s(x_3-\zeta)(c_L^{-1}-\eta)]\, \|\hat{U}(\zeta;\zeta)\|_r\, d\zeta \\ &= \int_{\zeta=-\infty}^{x_3} \exp[-s(x_3-\zeta)(c_L^{-1}-\eta)]\, \|\hat{u}(\zeta)\|_r\, d\zeta. \end{aligned} \tag{VI.25}$$

Apparently, a useful norm on $\mathscr{L}(\mathbb{R}_\pm, H^r(\mathbb{R}^2))$ for the wavefield in three-dimensional space is given by

$$\|\cdot\|_{r;3} = \sup_{x_3\in\mathbb{R}} \|\cdot\|_r . \tag{VI.26}$$

Then, from Eq. (VI.25) it follows that

$$\|\hat{\mathrm{G}}\|_{r;3,r;3} \leqslant \frac{1}{s(c_L^{-1}-\eta)}, \quad s\geqslant s_0 . \tag{VI.27}$$

This estimate has been made explicit for $r=0$ [cf. below Eq. (VI.17)]. Similar steps can be carried out upon replacing $(+)$ by $(-)$.

B. Path integral representations

With the vertical slowness symbols following from the resolvent, which represents the scattering process in the horizontal directions, we can construct the Green's functions $\hat{\mathscr{G}}^{(\pm)}$ using a Hamiltonian path integral representation.[49–51]

First, it is observed that the vertical slowness operators at different levels of x_3 do not necessarily commute with one another due to the heterogeneity of the medium. Thus we arrive at a ''time''-ordered product integral representation (see, e.g., Ref. 50) of the one-sided propagators [cf. Eq. (VI.4)] associated with the one-way wave equations, where ''time'' refers to the vertical coordinate x_3,

$$\hat{U}^{(\pm)}(.,x_3;x_3') = \pm H(\mp[x_3'-x_3]) \left\{ \prod_{\zeta=x_3'}^{x_3} \exp[-s\hat{\Gamma}^{(\pm)}(.,\zeta)d\zeta] \right\} \hat{u}(.,x_3'). \tag{VI.28}$$

In this expression, the operator ordering is initiated by $\exp[-s\hat{\Gamma}(.,x_3')d\zeta]$ acting on $\hat{u}(.,x_3')$ followed by applying $\exp[-s\hat{\Gamma}(.,\zeta)\mathrm{d}\zeta]$ to the result, successively for increasing ζ.

If the medium in the interval $[x_3', x_3]$ were weakly varying in the vertical direction, the Trotter product formula can be applied to the product integral in Eq. (VI.28). This results in the Hamiltonian path integral representations for the Green's functions,

$$\hat{\mathscr{G}}^{(\pm)}(x_\nu,x_3;x_\mu',x_3') = \pm H(\mp[x_3'-x_3]) \int_P \mathscr{D}(x_\nu'',\alpha_\nu'')$$

$$\times\exp\left[-s\int_{\zeta=x_3'}^{x_3}d\zeta\{i\alpha_\sigma''(d_\zeta x_\sigma'')+\hat{\gamma}^{(\pm)}(x_\mu'',\zeta,\alpha_\nu'',s)\}\right], \tag{VI.29}$$

P being a set of paths $(x_\mu''(\zeta),\alpha_\nu''(\zeta))$ in (horizontal) phase space satisfying

$$x_\nu''(\zeta=x_3')=x_\nu', \quad x_\nu''(\zeta=x_3)=x_\nu. \tag{VI.30}$$

Omitting the Heaviside function in the expression for the $\hat{\mathscr{G}}^{(\pm)}$ yields the kernel $\hat{g}^{(\pm)}$ of the so-called *phase shift operator* (Ref. 52). A perturbative approximation of the latter operator based on the split-step Fourier transform is discussed in Ref. 53. In Eq. (VI.29) we have restricted ourselves to causal solutions, since the conditions $\mathrm{Re}\{\hat{\gamma}^{(+)}\}\geqslant 0$ and $\mathrm{Re}\{\hat{\gamma}^{(-)}\}\leqslant 0$ imply that $\hat{\mathscr{G}}^{(\pm)}$ remain bounded as $|x_3|\to\infty$.

The path integral in Eq. (VI.29) is to be interpreted as the lattice multiple integral

$$\begin{aligned}&\hat{\mathscr{G}}^{(\pm)}(x_\nu,x_3;x_\mu',x_3')\\&\quad=\pm H(\mp[x_3'-x_3])\lim_{N\to\infty}\int\prod_{i=1}^{N}\left(\frac{s}{2\pi}\right)^2 d^2\alpha_\nu^{(i)}\prod_{j=1}^{N-1}d^2x_\nu^{(j)}\\&\qquad\times\exp\left[-s\sum_{k=1}^{N}\{i\alpha_\sigma^{(k)}(x_\sigma^{(k)}-x_\sigma^{(k-1)})+\hat{\gamma}^{(\pm)}(x_\mu^{(k)},\zeta_k-\tfrac{1}{2}N^{-1}\Delta x_3,\alpha_\nu^{(k)},s)N^{-1}\Delta x_3\}\right]\end{aligned} \tag{VI.31}$$

with

$$x_\nu^{(0)}=x_\nu', \quad x_\nu^{(N)}=x_\nu, \tag{VI.32}$$

and

$$\Delta x_3=x_3-x_3'. \tag{VI.33}$$

Note that the function

$$\tau(x_\nu,x_\nu')=\sum_{k=1}^{N}\{i\alpha_\sigma^{(k)}(x_\sigma^{(k)}-x_\sigma^{(k-1)})+\hat{\gamma}^{(\pm)}(x_\mu^{(k)},\zeta_k-\tfrac{1}{2}N^{-1}\Delta x_3,\alpha_\nu^{(k)},s)N^{-1}\Delta x_3\}$$

can be associated with travel time along a path. All the integrations are taken over the interval $(-\infty,\infty)$, $N^{-1}\Delta x_3$ is the step size in ζ, and $(x_\mu^{(j)},\alpha_\nu^{(j)})$ are the coordinates of a path at the discrete values ζ_j of ζ as $j=1,\ldots,N$. If Δx_3 is sufficiently small, the path integral reduces to

$$\begin{aligned}\hat{\mathscr{G}}^{(\pm)}(x_\mu,x_3;x_\nu',x_3')\simeq\pm H(\mp[x_3'-x_3])\int\left(\frac{s}{2\pi}\right)^2 d\alpha_1''d\alpha_2''\\\times\exp[-s\{i\alpha_\sigma''(x_\sigma-x_\sigma')+\hat{\gamma}^{(\pm)}(x_\mu,x_3-\tfrac{1}{2}\Delta x_3,\alpha_\nu'',s)\Delta x_3\}].\end{aligned} \tag{VI.34}$$

In the analysis $\hat{\gamma}^{(\pm)}$ may be interpreted as (nonstandard square-root) Hamiltonians.

If the medium varies strongly in the vertical direction, the interval $[x_3',\ x_3]$ is divided up into thinner slabs, and the product integral is used to arrive at a composition of one-sided propagators through these slabs, for which the lattice multiple integrals are then substituted. The resulting

multiple integral is similar to the one in Eq. (VI.31). It is conjectured that the stationary-phase approximation of the path integral in Eq. (VI.29) leads to the leading term of the asymptotic ray expansion[54,55] including the KMAH index,[55] in the presence of caustics.

The expression in Eq. (VI.34) serves as the basis for numerical computations based on Fourier transformations. Rather than using this thin-slab propagator, quasi-Monte Carlo methods can be applied to numerically calculate the propagator over larger vertical distances. Also techniques from the theory of symplectic integrators (Ref. 56) may prove to be useful in the propagation over long distances.

C. The Schwartz kernel

The one-sided Green's function is directly related to the Schwartz kernel associated with the vertical slowness operator. Since [cf. Eqs. (VI.3) and (VI.29)]

$$\partial_3(\hat{\mathrm{G}}\hat{u})(x_\mu,x_3)-\hat{u}(x_\mu,x_3)=\int_{\zeta=-\infty}^{x_3}\int_{x'_\nu\in\mathbb{R}}\partial_3\hat{\mathscr{G}}(x_\mu,x_3;x'_\nu,\zeta)\hat{u}(x'_\nu,\zeta)dx'_1dx'_2d\zeta, \tag{VI.35}$$

while [cf. Eq. (VI.5)]

$$\partial_3(\hat{\mathrm{G}}\hat{u})(x_\mu,x_3)-\hat{u}(x_\mu,x_3)=\int_{\zeta=-\infty}^{x_3}\partial_3\hat{U}(x_\mu,x_3;\zeta)d\zeta$$

for all x_3, we have [cf. Eq. (VI.4)]

$$-s\hat{\Gamma}(.,.;x_3)\hat{U}(.,x_3;\zeta)=\int_{x'_\nu\in\mathbb{R}}\partial_3\hat{\mathscr{G}}(.,x_3;x'_\nu,\zeta)\hat{u}(x'_\nu,\zeta)dx'_1dx'_2. \tag{VI.36}$$

Upon taking the limit $\zeta\uparrow x_3$, we thus obtain

$$-s(\hat{\Gamma}(.,.;x_3)\hat{u})(x_\mu,x_3)=\int_{x'_\nu\in\mathbb{R}}\lim_{\zeta\uparrow x_3}\partial_3\hat{\mathscr{G}}(x_\mu,x_3;x'_\nu,\zeta)\hat{u}(x'_\nu,\zeta)dx'_1dx'_2 \tag{VI.37}$$

so that

$$\hat{\mathscr{C}}(x_\mu,x'_\nu;x_3)=\lim_{\zeta\uparrow x_3}-\frac{1}{s}\,\partial_3\hat{\mathscr{G}}(x_\mu,x_3;x'_\nu,\zeta). \tag{VI.38}$$

This expression implies that, in the special case of a homogeneous medium, the Schwartz kernel reduces to the vertical particle velocity ($\hat{F}_2$) response due to a vertical point-force source [$\hat{f}_3=\delta(x_\mu-x'_\mu)\,\delta(x_3-x'_3)$] at zero vertical offset.

VII. THE BREMMER COUPLING SERIES

The resolvents $\hat{R}^{(\mathrm{A})}_\lambda$ fully describe the scattering in the level surfaces of x_3. From these resolvents the left vertical slowness symbols have been derived, which in their turn are used in constructing the Green's functions introduced in Sec. VI. Employing the Green's functions of the one-way operators, we are now able to formulate the scattering process along the vertical direction in terms of a coupled system of integral equations.

To simplify the notation, we set

$$\hat{X}_1=(\hat{L}^{-1})_{1,M}\hat{N}_M,\quad \hat{X}_2=(\hat{L}^{-1})_{2,M}\hat{N}_M. \tag{VII.1}$$

Using Eq. (VII.1), we rewrite Eq. (IV.1) as [cf. Eqs. (IV.3) and (IV.4)]

$$\partial_3 \hat{W}_1 + s\hat{\Gamma}^{(+)}\hat{W}_1 = \hat{X}_1 + \hat{T}\hat{W}_1 + \hat{R}\hat{W}_2, \tag{VII.2}$$

$$\partial_3 \hat{W}_2 + s\hat{\Gamma}^{(-)}\hat{W}_2 = \hat{X}_2 + \hat{R}\hat{W}_1 + \hat{T}\hat{W}_2. \tag{VII.3}$$

To derive an integral representation for $\hat{W}_{1,2}$, we introduce the *adjoint* Green's functions $\hat{\mathscr{G}}_\alpha^{(\pm)}$ satisfying

$$\partial_3 \hat{\mathscr{G}}_a^{(\pm)} - s[\hat{\Gamma}^{(\pm)}]^T \hat{\mathscr{G}}_a^{(\pm)} = \delta(x_\nu - x'_\nu)\,\delta(x_3 - x'_3), \quad \text{with } [\hat{\Gamma}^{(\pm)}]^T = \hat{\Gamma}^{(\pm)} \tag{VII.4}$$

since $\hat{\Gamma}^{(\pm)}$ is self-adjoint in L^2. Note that

$$\hat{\mathscr{G}}_a^{(\pm)}(x'_\nu, \zeta; x_\mu, x_3) = -\hat{\mathscr{G}}^{(\pm)}(x_\mu, x_3; x'_\nu, \zeta). \tag{VII.5}$$

In fact, in view of the up/down symmetry of the medium, we also have

$$\hat{\mathscr{G}}_a^{(\pm)}(x'_\nu, \zeta; x_\mu, x_3) = \hat{\mathscr{G}}^{(\mp)}(x'_\nu, \zeta; x_\mu, x_3). \tag{VII.6}$$

[Equations (VII.5) and (VII.6) constitute reciprocity relations.] Combining Eq. (VII.4) for the adjoint Green's functions with (VII.2) and (VII.3), it is found that

$$\partial_3 \langle \hat{\mathscr{G}}_a^{(+)}, \hat{W}_1 \rangle_0 = \langle \hat{\mathscr{G}}_a^{(+)}, \hat{X}_1 + \hat{T}\hat{W}_1 + \hat{R}\hat{W}_2 \rangle_0 + \hat{W}_1(x'_\nu, x'_3)\,\delta(x_3 - x'_3), \tag{VII.7}$$

$$\partial_3 \langle \hat{\mathscr{G}}_a^{(-)}, \hat{W}_2 \rangle_0 = \langle \hat{\mathscr{G}}_a^{(-)}, \hat{X}_2 + \hat{R}\hat{W}_1 + \hat{T}\hat{W}_2 \rangle_0 + \hat{W}_2(x'_\nu, x'_3)\,\delta(x_3 - x'_3). \tag{VII.8}$$

Now, we have

$$\langle \hat{\mathscr{G}}_a^{(+)}(.,x_3;x'_\mu,x'_3), \hat{W}_1(.,x_3) \rangle_0 = 0 \tag{VII.9}$$

as $x_3 \to \infty$ since $\hat{\mathscr{G}}_a^{(+)} = 0$ when $x_3 > x'_3$ while in view of the assumption that in some upper half-space the fluid is homogeneous, $\hat{W}_1 = 0$ as $x_3 \to -\infty$ on the basis of causality. A similar reasoning leads to

$$\langle \hat{\mathscr{G}}_a^{(-)}(.,x_3;x'_\mu,x'_3), \hat{W}_2(.,x_3) \rangle_0 = 0 \tag{VII.10}$$

as $x_3 \to \pm\infty$. Integration of Eqs. (VII.7) and (VII.8) over all x_3 then yields a coupled system of integral equations which can be written in operator form as [cf. Eq. (VII.5)]

$$(\delta_{I,J} - \hat{\mathrm{K}}_{I,J})\hat{W}_J = \hat{W}_I^0, \tag{VII.11}$$

in which

$$\begin{pmatrix} \hat{W}_1^0 \\ \hat{W}_2^0 \end{pmatrix} = \begin{pmatrix} \hat{\mathrm{G}}^{(+)} & 0 \\ 0 & \hat{\mathrm{G}}^{(-)} \end{pmatrix} \begin{pmatrix} \hat{X}_1 \\ \hat{X}_2 \end{pmatrix}, \tag{VII.12}$$

i.e.,

$$\hat{W}_1^0(x_\mu, x_3) = \int_{\zeta=-\infty}^{x_3} \int_{x'_\nu \in \mathbb{R}} \hat{\mathscr{G}}^{(+)}(x_\mu, x_3; x'_\nu, \zeta)\hat{X}_1(x'_\nu, \zeta)\,dx'_1 dx'_2 d\zeta, \tag{VII.13}$$

$$\hat{W}_2^0(x_\mu, x_3) = \int_{\zeta=x_3}^{\infty} \int_{x'_\nu \in \mathbb{R}} \hat{\mathscr{G}}^{(-)}(x_\mu, x_3; x'_\nu, \zeta)\hat{X}_2(x'_\nu, \zeta)\,dx'_1 dx'_2 d\zeta \tag{VII.14}$$

denote the directly transmitted waves, and

$$\hat{\mathrm{K}}=\begin{pmatrix}\hat{\mathrm{G}}^{(+)} & 0\\ 0 & \hat{\mathrm{G}}^{(-)}\end{pmatrix}\begin{pmatrix}\hat{T} & \hat{R}\\ \hat{R} & \hat{T}\end{pmatrix} \tag{VII.15}$$

(note that the second matrix operator acts in the horizontal directions only, whereas the first matrix operator acts in the full space), i.e.,

$$(\hat{\mathrm{K}}_{1,1}\hat{W}_1)(x_\mu,x_3)=\int_{\zeta=-\infty}^{x_3}\int_{x'_\nu\in\mathbb{R}}\hat{\mathscr{G}}^{(+)}(x_\mu,x_3;x'_\nu,\zeta)(\hat{T}\hat{W}_1)(x'_\nu,\zeta)dx'_1dx'_2d\zeta, \tag{VII.16}$$

$$(\hat{\mathrm{K}}_{1,2}\hat{W}_2)(x_\mu,x_3)=\int_{\zeta=-\infty}^{x_3}\int_{x'_\nu\in\mathbb{R}}\hat{\mathscr{G}}^{(+)}(x_\mu,x_3;x'_\nu,\zeta)(\hat{R}\hat{W}_2)(x'_\nu,\zeta)dx'_1dx'_2d\zeta, \tag{VII.17}$$

$$(\hat{\mathrm{K}}_{2,1}\hat{W}_1)(x_\mu,x_3)=\int_{\zeta=x_3}^{\infty}\int_{x'_\nu\in\mathbb{R}}\hat{\mathscr{G}}^{(-)}(x_\mu,x_3;x'_\nu,\zeta)(\hat{R}\hat{W}_1)(x'_\nu,\zeta)dx'_1dx'_2d\zeta, \tag{VII.18}$$

$$(\hat{\mathrm{K}}_{2,2}\hat{W}_2)(x_\mu,x_3)=\int_{\zeta=x_3}^{\infty}\int_{x'_\nu\in\mathbb{R}}\hat{\mathscr{G}}^{(-)}(x_\mu,x_3;x'_\nu,\zeta)(\hat{T}\hat{W}_2)(x'_\nu,\zeta)dx'_1dx'_2d\zeta \tag{VII.19}$$

are representative for the multiple scattering formalism. Now, consider the operators $\hat{\mathrm{K}}_{I,J}$: $\mathscr{S}(\mathbb{R}_{\pm},H^0(\mathbb{R}^2))\to\mathscr{S}(\mathbb{R}_{\pm},H^0(\mathbb{R}^2))$. In the space of wave matrices we introduce the norm [cf. Eq. (VI.26)]

$$\|\hat{W}\|=\left(\sum_{J=1}^{2}\|\hat{W}_J\|^2_{0;3}\right)^{1/2}. \tag{VII.20}$$

Hence, $\|\hat{\mathrm{K}}\|^2\leqslant\Sigma_{I,J=1}^{2}\|\hat{\mathrm{K}}_{I,J}\|^2_{0;3,0;3}$. Using the norm estimates of the preceding sections, it is found that $\|\hat{\mathrm{K}}\|=O(s^{-1})$ as $s\to\infty$, which implies that the norm of $\hat{\mathrm{K}}$ is less than 1 when $s\geqslant s_0$, for s_0 sufficiently large. In that case a convergent Neumann expansion of Eq. (VII.11) yields its solution.

Thus, the solution of Eq. (VII.11),

$$\hat{W}=\hat{R}^{(\mathrm{K})}\hat{W}^0, \tag{VII.21}$$

is found in the form of a sum of generalized-ray-like constituents, the Bremmer series,[57] upon employing the Neumann expansion for the resolvent of $\hat{\mathrm{K}}$:

$$\hat{R}^{(\mathrm{K})}=(I-\hat{\mathrm{K}})^{-1}=\sum_{n=0}^{\infty}\hat{\mathrm{K}}^n. \tag{VII.22}$$

To emphasize that we have found the solution of the direct scattering problem as a summation over multiple scattered constituents, we write

$$\hat{W}=\sum_{n=0}^{\infty}\hat{W}^{(n)}\quad\text{with}\quad\hat{W}^{(n)}=\hat{\mathrm{K}}\hat{W}^{(n-1)}. \tag{VII.23}$$

Figure 3 illustrates the decomposition procedure and the interrelation between the different resolvents. The analog of the series in a horizontally shift invariant medium can be found, e.g., in Refs. 58 and 59.

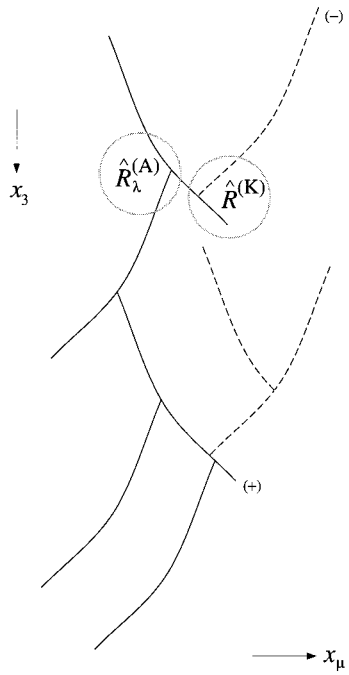

FIG. 3. The decomposition of the scattering process (the solid rays refer to one term in the series).

Upon substituting in $\hat{\mathrm{K}}$ the path integral representations for the Green's functions of Sec. VI, the recursion formula (VII.23) leads to path integral representations for all the constituents in the coupling series. Upon substituting for the transmission/reflection operators their Schwartz kernel representations, Eq. (VII.23) essentially composes path integrals at any level where interaction takes place. In particular, one finds a path integral representation for the leading order backscattered field, $\hat{W}^{(1)}$.

Finally, Eq. (II.17) must be employed to compose the acoustic field matrix per constituent [cf. Eq. (VII.21)], i.e., to obtain the observables. The uniqueness of the time-domain counterpart of this result for $s \geqslant s_0$ is guaranteed by Lerch's theorem (see Ref. 35). Note that the convergence of the series is guaranteed essentially in the time domain; the convergence criterium in the frequency or complex Laplace domain as described by Wing,[60] and earlier by Atkinson,[61] is different from ours. From the final representation of the acoustic field matrix, the associated representation for the Dirichlet-to-Neumann map can be obtained.[29]

VIII. ANALYSIS OF THE SYMBOLS

The scattering process in horizontal space is governed by a composition equation for the (unknown) resolvent of a (known) elliptic operator. Here, we shall discuss an asymptotic expansion for the left symbol of the resolvent belonging to $\hat{\mathrm{A}}$ introduced in Sec. III as the slowness vector becomes large to find the solution of the composition equation (V.16) as well as the other powers needed to transform Eq. (II.9) into Eq. (IV.1). Using the first few terms of the asymptotic expansion, a Neumann series is derived for the resolvent. The latter expansion is the counterpart in horizontal space of the Neumann expansion introduced in Sec. VII.

A natural decomposition of the left symbol of the partial differential operator $\hat{\mathrm{A}}$ is [cf. Eq. (V.14)]

$$\hat{a} = \hat{a}^{(\infty)} + \hat{a}^{(-2)}, \tag{VIII.1}$$

the first term being $O(1)$ and the second term being $O(s^{-2})$ as $s\to\infty$. We have

$$\hat{a}^{(\infty)}=\alpha_\nu\alpha_\nu+\check{c}^{-2}c_\infty^{-2},$$
$$\hat{a}^{(-2)}=\tfrac{3}{4}\rho^{-2}s^{-2}(\partial_\nu\rho)^2-\tfrac{1}{2}\rho^{-1}s^{-2}(\partial_\nu\partial_\nu\rho), \tag{VIII.2}$$

where

$$\check{c}^{-1}=(c/c_\infty)^{-1} \tag{VIII.3}$$

and

$$c^{-2}=\kappa\rho, \tag{VIII.4}$$

in which c_∞^{-1} is an appropriate parameter, introduced to enforce the correct asymptotic behavior. The differential equation for the symbol $\hat{r}_\lambda$ of the resolvent follows from the equation $(\hat{\mathrm{A}}-\lambda I)\hat{R}_\lambda=I$ as [cf. Eq. (VIII.2)]

$$(is^{-1}\partial_{x_\sigma}+\alpha_\sigma)^2\hat{r}_\lambda+(c^{-2}+\hat{a}^{(-2)}-\lambda)\hat{r}_\lambda-1=0. \tag{VIII.5}$$

This equation must be solved for $\hat{r}_\lambda\in S^{-2}$. The left symbols of the negative real powers then follow from [cf. Eq. (III.17)]

$$\hat{a}_z=\frac{1}{2\pi i}\int_{\mathscr{B}}\lambda^z\hat{r}_\lambda\,d\lambda. \tag{VIII.6}$$

The symbols of the positive real powers are obtained using the composition equation for left symbols repeatedly (see the Appendix).

A. The parametrix: asymptotic analysis

To carry out the asymptotic analysis, the symbol of the operator $\hat{\mathrm{A}}-\lambda I$ with parameter is written as

$$\hat{a}_\lambda=\hat{a}_{\lambda,2}+\hat{a}_{\lambda,0}, \tag{VIII.7}$$

where

$$\hat{a}_{\lambda,2}=\hat{a}^{(\infty)}-\lambda,\quad \hat{a}_{\lambda,0}=\hat{a}^{(-2)}. \tag{VIII.8}$$

The correct behavior of the symbol of the resolvent as λ and c_∞^{-1} become large is achieved by thinking of λ and c_∞^{-2} as the squares of the Fourier domain counterparts of two new independent variables. Actually, it is natural to treat the slowness of the medium as if it were a component of the slowness vector. This way, the term $-\lambda$ and the one linear in c_∞^{-2} are absorbed in the principal part of the symbol. It is noticed that $\hat{a}_{\lambda,2}$ is homogeneous of degree 2 in $(\alpha_\mu,\lambda^{1/2},c_\infty^{-1})$, i.e.,

$$\hat{a}_{t^2\lambda,2}(x_\mu,t\alpha_\nu,tc_\infty^{-1})=t^2\hat{a}_{\lambda,2}(x_\mu,\alpha_\nu,c_\infty^{-1}) \tag{VIII.9}$$

for $t>0$ such that $t^2\lambda\in\Lambda$, while $\hat{a}_{\lambda,0}$ is homogeneous of degree 0 in the same sense. Further, it follows that $\hat{a}_{\lambda,2}\neq 0$ for $\lambda\in\Lambda$ and $(\alpha_\sigma\alpha_\sigma)^{1/2}+|\lambda|^{1/2}+|c_\infty^{-1}|\neq 0$, where Λ is, again, the sector in the complex λ plane defined by $0<|\arg(\lambda)|\leqslant\pi$. Hence, the operator associated with $\hat{a}_\lambda$ is ''elliptic with parameters λ and c_∞^{-1},'' whereas the symbol itself is in $S^2_\Lambda(\mathbb{R}^2\times\mathbb{R}^2,\mathbb{R})$. The extension of this concept to anisotropic elastic media has been given by de Hoop and de Hoop.[62] In the following it is crucial to restrict λ to the sector Λ in the complex plane.

Consider the *parametrix* $\hat{B}_\lambda$, which is an approximation to the resolvent $\hat{R}_\lambda$ in the following sense. Let the symbol of the resolvent, too, be expanded in a sum of symbols $b_{\lambda,-2-j}$ which are homogeneous of degree $-2-j$ in $(\alpha_\mu,\lambda^{1/2},c_\infty^{-1})$; then this sum defines the parametrix, which resembles the resolvent up to an integral operator in Op $S^{-\infty}$ with an infinitely differentiable kernel (Ref. 63, p. 20). The successive terms in the series have increasingly smooth kernels. This way, a parametrix is constructed with the correct behavior as $|\lambda|\to\infty$ or $c_\infty^{-1}\to\infty$ (the latter corresponds to $s\to\infty$). Thus, the symbol of the parametrix is written as

$$\hat{b}_\lambda=\sum_{j=0}^{\infty}\hat{b}_{\lambda,-2-j}. \tag{VIII.10}$$

The terms $\hat{b}_{\lambda,-2-j}$, $j=0,1,...$, are determined as follows. Substitute the expansion Eq. (VIII.10) into Eq. (VIII.5) and collect terms of equal degrees. Then we arrive at

$$\begin{aligned}&\hat{a}_{\lambda,2}\hat{b}_{\lambda,-2}=1,\\ &\hat{a}_{\lambda,2}\hat{b}_{\lambda,-3}+2is^{-1}\alpha_\mu\partial_{x_\mu}\hat{b}_{\lambda,-2}=0,\\ &\hat{a}_{\lambda,2}\hat{b}_{\lambda,-2-j}+2is^{-1}\alpha_\mu\partial_{x_\mu}\hat{b}_{\lambda,-1-j}+[\hat{a}_{\lambda,0}-s^{-2}\partial_{x_\mu}\partial_{x_\mu}]\hat{b}_{\lambda,-j}=0,\quad j=2,3,\dots .\end{aligned} \tag{VIII.11}$$

It can be shown that the solutions must satisfy (following Ref. 9)

$$\begin{aligned}|(\partial_{\alpha_1}^{m_1}\partial_{\alpha_2}^{m_2}\partial_{x_1}^{n_1}\partial_{x_2}^{n_2}\hat{b}_{\lambda,-2-j})(x_\kappa,\alpha_\mu)|\le s^{-j}C_{m_1,m_2,n_1,n_2}&[(\langle c^{-2}\rangle+\alpha_\nu\alpha_\nu+c_\infty^{-2}+|\lambda|)^{1/2}]^{-2}\\ &\times[(\langle c^{-2}\rangle+\alpha_\sigma\alpha_\sigma)^{1/2}]^{-j-m_1-m_2}.\end{aligned} \tag{VIII.12}$$

For the asymptotic sum as following from Eq. (VIII.11), we have the estimate

$$\hat{b}_\lambda-\sum_{j=0}^{K-1}\hat{b}_{\lambda,-2-j}=O(|\alpha|^{-2-K})\quad\text{as }|\alpha|\to\infty \tag{VIII.13}$$

for $K=1,2,3,...$. Let $\hat{B}_{\lambda,-2-j}$ be the operator that corresponds to the symbol $\hat{b}_{\lambda,-2-j}$, and let

$$\hat{B}_\lambda^{(K)}=\sum_{j=0}^{K-1}\hat{B}_{\lambda,-2-j}. \tag{VIII.14}$$

From Eq. (VIII.12), using that for $l=0,1,2$ we have

$$[(\langle c^{-2}\rangle+\alpha_\nu\alpha_\nu+c_\infty^{-2}+|\lambda|)^{1/2}]^{-2}\le|\lambda|^{-1+l/2}\,[(\langle c^{-2}\rangle+\alpha_\nu\alpha_\nu+c_\infty^{-2})^{1/2}]^{-l}, \tag{VIII.15}$$

we obtain the estimate for $\hat{B}_\lambda^{(K)}$:

$$\|\hat{B}_\lambda^{(K)}\|_{r,r+l}\le C''_{r,l,K}/|\lambda|^{1-l/2} \tag{VIII.16}$$

with $l=0,1,2$ and $\lambda\in\Lambda$. With $\hat{B}_\lambda^{(K)}$ there is associated the truncated expansion of $\hat{A}$, viz., $\hat{A}^{(K)}=\Sigma_{j'=0}^{K-1}\hat{A}_{2-j'}$ (set $\hat{a}_2=\hat{a}^{(\infty)}$, $\hat{a}_0=\hat{a}^{(-2)}$, $\hat{a}_{j'}=0$ otherwise). In general, if $K\ge2$ we have $\hat{A}-\hat{A}^{(K)}\in\text{Op }S^0$, so that the latter difference is bounded and continuous as an operator $H^r\to H^r$; the same holds for $\hat{A}-\hat{A}^{(K)}$: $H^r\to H^{r+K-2}$. Using this and Eq. (VIII.16), it follows that for $K\ge2$

$$\|(\hat{A}-\lambda I)\hat{B}_\lambda^{(K)}-(\hat{A}^{(K)}-\lambda I)\hat{B}_\lambda^{(K)}\|_{r,r+l+K-2}\le C'_{r,l,K}/|\lambda|^{1-l/2}. \tag{VIII.17}$$

Using Eqs. (A15), (VIII.11), and (VIII.12), after some manipulations as in Refs. 9 and 10, we arrive at

$$\|I-(\hat{\mathrm{A}}-\lambda I)\hat{B}_{\lambda}^{(K)}\|_{r,r+l+K-2}\leqslant C_{r,l,K}/|\lambda|^{1-l/2} \tag{VIII.18}$$

with $l=0,1,2$ and $\lambda\in\Lambda$, whereas $C_{r,l,K}=O(s^{-K})$ as $s\to\infty$. Hence, for $K=2$, setting

$$\hat{C}_{\lambda}=I-(\hat{\mathrm{A}}-\lambda I)\hat{B}_{\lambda}^{(2)}, \tag{VIII.19}$$

we get for sufficiently large λ [cf. Eq. (VIII.18)]

$$\|\hat{C}_{\lambda}\|_{r,r}\leqslant\tfrac{1}{2}. \tag{VIII.20}$$

Thus, the resolvent follows as the convergent Neumann series

$$\hat{R}_{\lambda}=\hat{B}_{\lambda}^{(2)}\left(\sum_{n=0}^{\infty}\hat{C}_{\lambda}^{n}\right)\quad\text{for }\lambda\in\Lambda\text{ large.} \tag{VIII.21}$$

Now, using that

$$\sum_{n=0}^{\infty}\|\hat{C}_{\lambda}^{n}\|_{r+l,r+l}\leqslant 2, \tag{VIII.22}$$

in combination with Eq. (VIII.16), finally leads to the estimate in Eq. (III.14). Following Ref. 9 (Theorem 2), through the explicit evaluation of the symbols [cf. Eq. (VIII.6)] it can be shown that the integral in Eq. (III.17) defines a pseudo-differential operator of order $2z$.

Solving the system of equations (VIII.11) yields

$$\hat{b}_{\lambda,-2}=\hat{a}_{\lambda,2}^{-1}, \tag{VIII.23}$$

$$\hat{b}_{\lambda,-3}=2\alpha_{\mu}(is^{-1}\partial_{x_{\mu}}\hat{a}_{\lambda,2})\;\hat{a}_{\lambda,2}^{-3}, \tag{VIII.24}$$

while

$$\begin{aligned}\hat{b}_{\lambda,-4}=&-\hat{a}_{\lambda,0}\;\hat{a}_{\lambda,2}^{-2}-s^{-2}(\partial_{x_{\mu}}\partial_{x_{\mu}}\hat{a}_{\lambda,2})\;\hat{a}_{\lambda,2}^{-3}+[2s^{-2}(\partial_{x_{\mu}}\hat{a}_{\lambda,2})(\partial_{x_{\mu}}\hat{a}_{\lambda,2})\\&+4\alpha_{\mu}s^{-1}\alpha_{\nu}s^{-1}(\partial_{x_{\mu}}\partial_{x_{\nu}}\hat{a}_{\lambda,2})]\;\hat{a}_{\lambda,2}^{-4}-12(\alpha_{\mu}s^{-1}\partial_{x_{\mu}}\hat{a}_{\lambda,2})\\&\times(\alpha_{\nu}s^{-1}\partial_{x_{\nu}}\hat{a}_{\lambda,2})\;\hat{a}_{\lambda,2}^{-5}\end{aligned} \tag{VIII.25}$$

and so on.

It is observed that the Neumann series for the vertical scattering gives rise to a decomposition into constituents that have traveled up and down a definite number of times, while the Neumann series in Eq. (VIII.21) clearly does not separate the wavefield into constituents that travel from right to left or vice versa.

B. The vertical slowness

From a physical point of view, it is interesting to compare the contributions to the generalized slowness surface from the successive terms of the parametrix. For this, the integration over λ has to be carried out and the original elliptic operator has to be applied to the result. Using Eqs. (VIII.6), (VIII.23), and (VIII.24), we have

$$\hat{a}_{-1/2}(x_\mu,\alpha_\nu)=(c^{-2}+\alpha_\sigma\alpha_\sigma)^{-1/2}\,[1+\tfrac{3}{4}(c^{-2}+\alpha_\nu\alpha_\nu)^{-2}i\alpha_\mu s^{-1}(\partial_{x_\mu}c^{-2})+\cdots].$$

With this the left symbol for the vertical slowness becomes

$$\begin{aligned}\hat{\gamma}(x_\mu,\alpha_\nu)&=(is^{-1}\partial_{x_\sigma}+\alpha_\sigma)^2\hat{a}_{-1/2}+(c^{-2}+\hat{a}^{(-2)})\hat{a}_{-1/2}\\&=(c^{-2}+\alpha_\sigma\alpha_\sigma)^{1/2}\,[1+(c^{-2}+\alpha_\nu\alpha_\nu)^{-1}\hat{a}^{(-2)}+\tfrac{1}{2}(c^{-2}+\alpha_\nu\alpha_\nu)^{-2}\\&\quad\times\{-\tfrac{1}{2}i\alpha_\mu s^{-1}(\partial_{x_\mu}c^{-2})+s^{-2}(\partial_{x_\mu}\partial_{x_\mu}c^{-2})\}+\cdots].\end{aligned}\tag{VIII.26}$$

Note that this expansion is valid for real-valued α_μ; it is, however, nonuniform. In the complex radial horizontal slowness plane, a set of branch points, where the argument of the square root vanishes, has been introduced. Near the branch points the polyhomogeneous expansion does not behave properly, and a uniform expansion must be found. It is an open issue whether a parallel analytic continuation of the symbols into the complex radial horizontal slowness and complex Laplace planes exists and would be stable. However, in the angular frequency (ω) domain with $s=i\omega$ and $\alpha_\nu=-i\alpha_\nu^{(\omega)}$, $\omega\in\mathbb{R}$ and $\alpha_\nu^{(\omega)}\in\mathbb{R}$, a uniform expansion has been found by Fishman and Gautesen.[30]

Spectral theory (Sec. III) can also be employed to construct a convergent expansion for $\hat{a}_z$,

$$\hat{a}_z(x_\mu,\alpha_\nu)=\sum_{[N]}\frac{\lambda^z_{[N]}}{N_{[N]}}\,\psi_{[N]}(x_\mu)\int_{x'_\nu\in\mathbb{R}}\psi_{[N]}(x'_\nu)\exp[is(x_\sigma-x'_\sigma)\alpha_\sigma]dx'_1dx'_2\tag{VIII.27}$$

if

$$\int_{x_\mu\in\mathbb{R}}\psi_{[N]}(x_\mu)\,\psi_{[M]}(x_\mu)dx_1dx_2=N_{[N]}\delta_{[N],[M]}.\tag{VIII.28}$$

Upon taking $z=-\frac{1}{2}$ and composing the result with $\hat{a}$, the vertical slowness symbol is found, as before. The latter construction implies an explicit regularization of the vertical slowness operator. Numerical algorithms associated with a construction of this kind can be found in the literature on the Mode Expansion Method[64] (see also Ref. 65).

IX. DISCUSSION OF THE RESULTS

In this paper, we have generalized the Bremmer coupling series to configurations with multidimensionally varying media with properties that are up/down symmetric. The setup of the series required the introduction of the directional wavefield decomposition into, the one-way wave equations for, and the interaction of up/down constituents. The decomposition into ''up'' and ''down'' no longer permits a separation into ''left'' and ''right.'' The convergence of the series in space–time has been proved.

The solution of the direct scattering problem in smoothly varying media has been given in terms of two nested series expansions. Both expansions represent resolvents, one associated with the coupling of counter-propagating constituents, and the other associated with the evaluation of the generalized slowness surface and the (de)composition operators. For practical purposes, one hopes that just a few terms of both series suffice to describe the scattering phenomenon under investigation; particular numerical advantage is achieved when only a few frequencies are of physical importance. Smoothness of the medium is understood relative to the pulse width associated with the irradiating source.

The derivation of the generalized Bremmer coupling series implies two basically alternative numerical approaches: a spectral approach based upon the eigenfunctions of the elliptic operator,

and a phase space approach making direct use of the left symbols. The spectral approach is rigorous, but not as efficient as the phase space approach. The most straightforward way to develop a propagation algorithm of the first kind is based on a matrix representation of the elliptic operator on the torus in terms of a basis of pyramid-type functions (rather than a basis of eigenfunctions); this leads to a finite difference approximation of the partial differential operator. The matrix is then diagonalized with the aid of the Lanczos method[66] in which only the relevant eigenpairs are calculated and propagated. The remaining calculations make use of the diagonal form thus obtained.

The phase space approach lends itself for various different approximations to enhance its computational efficiency. Among those are the (rational) parabolic approximations and the phase-screen reduction of the vertical slowness symbol. The phase-screen approximation is only valid in relatively weakly heterogeneous media. In the rational approximation method, special care has to be taken to keep the associated, approximate vertical slowness operator self-adjoint; inherently, the distinction between the principal part of and the higher-order contributions to the vertical slowness symbol becomes obscure (see Ref. 67). The uniform expansion of Fishman and Gautesen[30] lends itself to a competing algorithm, and includes critical scattering-angle phenomena, unlike the rational approximation approach. We note that the generalized Bremmer coupling series as presented in this paper lends itself to understanding the limits of approximate one-way wave theories.

Several approaches exist for the transformation back to the time domain. A numerical inverse Laplace transform can be used under the assumption that we restrict our scattered field to a finite time window. It is emphasized that causility in this approach throughout the calculations is preserved. For a review of various algorithms we refer the reader to Ref. 68; pioneering work was carried out by Papoulis.[69] As a candidate, we mention the Stehfest algorithm.

ACKNOWLEDGMENTS

The author would like to thank Professor J. J. Duistermaat and Professor A. T. de Hoop for their interest in this work and their many valuable comments.

APPENDIX: THE CALCULUS OF PSEUDO-DIFFERENTIAL OPERATORS

1. The composition equation

In this subsection we consider the composition of two pseudo-differential operators, $\hat{\mathrm{B}}_3=\hat{\mathrm{B}}_1\hat{\mathrm{B}}_2$, say. Representing the operators as in Eqs. (V.6) and (V.7),

$$(\hat{\mathrm{B}}(x_\kappa,D_\lambda)\hat{u})(x_\mu)=\int_{x'_\nu\in\mathbb{R}}\hat{\mathscr{B}}(x_\mu,x'_\nu)\hat{u}(x'_\nu)dx'_1dx'_2, \tag{A1}$$

in which

$$\hat{\mathscr{B}}(x_\mu,x'_\nu)=\left(\frac{s}{2\pi}\right)^2\int_{\alpha_\nu\in\mathbb{R}}\hat{\beta}(x_\mu,\alpha_\nu)\exp[is\alpha_\nu(x'_\nu-x_\nu)]d\alpha_1d\alpha_2, \tag{A2}$$

a composition rule for the corresponding left symbols, $\hat{\beta}_1$, $\hat{\beta}_2$, and $\hat{\beta}_3$, is found. To begin with, the Schwartz kernels must satisfy the composition rule

$$\hat{\mathscr{B}}_3(x_\mu,x'_\nu)=\int_{x''_\nu\in\mathbb{R}}\hat{\mathscr{B}}_1(x_\mu,x''_\nu).\hat{\mathscr{B}}_2(x''_\nu,x'_\nu)dx''_1dx''_2. \tag{A3}$$

Hence,

$$\left(\frac{s}{2\pi}\right)^2\int_{\alpha_\nu\in\mathbb{R}}\hat{\beta}_3(x_\mu,\alpha_\nu)\exp[is\alpha_\sigma(x'_\sigma-x_\sigma)]d\alpha_1d\alpha_2=\int_{x''_\nu\in\mathbb{R}}\hat{\mathscr{B}}_1(x_\mu,x''_\nu).\hat{\mathscr{B}}_2(x''_\nu,x'_\nu)dx''_1dx''_2. \tag{A4}$$

Substituting in Eq. (A4) $u_\nu=x_\nu$ and $u_\nu=-(x'_\nu-x_\nu)$, we arrive at

$$\left(\frac{s}{2\pi}\right)^2\int_{\alpha_\nu\in\mathbb{R}}\hat{\beta}_3(u_\mu,\alpha_\nu)\exp(-is\alpha_\sigma v_\sigma)d\alpha_1d\alpha_2=\int_{x''_\nu\in\mathbb{R}}\hat{\mathscr{B}}_1(u_\mu,x''_\nu).\mathscr{B}_2(x''_\nu,u_\nu-v_\nu)dx''_1dx''_2. \tag{A5}$$

By inverse Fourier transformation it now follows that

$$\hat{\beta}_3(u_\mu,\alpha_\nu)=\int_{v_\nu\in\mathbb{R}}\int_{x''_\nu\in\mathbb{R}}\hat{\mathscr{B}}_1(u_\mu,x''_\nu).\hat{\mathscr{B}}_2(x''_\nu,u_\nu-v_\nu)\exp(is\alpha_\sigma v_\sigma)dx''_1dx''_2dv_1dv_2. \tag{A6}$$

Substituting Eq. (A2) twice yields

$$\begin{aligned}\hat{\beta}_3(u_\mu,\alpha_\nu)=\left(\frac{s}{2\pi}\right)^4&\int_{x''_\nu\in\mathbb{R}}\int_{\alpha'_\nu\in\mathbb{R}}\int_{\alpha''_\nu\in\mathbb{R}}\int_{v_\nu\in\mathbb{R}}\hat{\beta}_1(u_\mu,\alpha'_\nu)\hat{\beta}_2(x''_\nu,\alpha''_\nu)\\&\times\exp[is\{(\alpha_\sigma-\alpha''_\sigma)v_\sigma+(u_\sigma-x''_\sigma)(\alpha''_\sigma-\alpha'_\sigma)\}]\\&\times dv_1dv_2d\alpha''_1d\alpha''_2d\alpha'_1d\alpha'_2dx''_1dx''_2.\end{aligned} \tag{A7}$$

Upon performing four of the integrations, we arrive at ($u_\mu=x_\mu$)

$$\begin{aligned}\hat{\beta}_3(x_\kappa,\alpha_\lambda)=\left(\frac{s}{2\pi}\right)^2&\int_{x''_\nu\in\mathbb{R}}\int_{\alpha'_\nu\in\mathbb{R}}\hat{\beta}_1(x_\mu,\alpha'_\nu)\hat{\beta}_2(x''_\nu,\alpha_\nu)\\&\times\exp[is(x_\sigma-x''_\sigma)(\alpha_\sigma-\alpha'_\sigma)]d\alpha'_1d\alpha'_2dx''_1dx''_2.\end{aligned} \tag{A8}$$

This equation can also be written as a differential equation. To this end, we introduce the four-dimensional Fourier transformation in phase space

$$\tilde{\tilde{\beta}}(\xi_\mu,\eta_\nu)=\left(\frac{s}{2\pi}\right)^2\int_{x_\mu\in\mathbb{R}}\int_{\alpha_\nu\in\mathbb{R}}\hat{\beta}(x_\mu,\alpha_\nu)\exp[is(\xi_\kappa x_\kappa+\eta_\lambda\alpha_\lambda)]d\alpha_1d\alpha_2dx_1dx_2 \tag{A9}$$

and its inverse

$$\hat{\beta}(x_\mu,\alpha_\nu)=\left(\frac{s}{2\pi}\right)^2\int_{\xi_\mu\in\mathbb{R}}\int_{\eta_\nu\in\mathbb{R}}\tilde{\tilde{\beta}}(\xi_\mu,\eta_\nu)\exp[-is(\xi_\kappa x_\kappa+\eta_\lambda\alpha_\lambda)]d\eta_1d\eta_2d\xi_1d\xi_2. \tag{A10}$$

Using Eq. (A10), we have

$$\left(\frac{s}{2\pi}\right)^2\int_{x_\kappa\in\mathbb{R}}\int_{\alpha_\lambda\in\mathbb{R}}\hat{\beta}(x_\kappa,\alpha_\lambda)\exp(isx_\sigma\alpha_\sigma)d\alpha_1d\alpha_2dx_1dx_2$$

$$=\left(\frac{s}{2\pi}\right)^4\int_{\alpha_\lambda\in\mathbb{R}}\int_{x_\kappa\in\mathbb{R}}\int_{\xi_\kappa\in\mathbb{R}}\int_{\eta_\lambda\in\mathbb{R}}\tilde{\tilde{\beta}}(\xi_\kappa,\eta_\lambda)\exp[-is(\xi_\sigma x_\sigma+\eta_\sigma\alpha_\sigma$$

$$-x_\sigma\alpha_\sigma)]d\eta_1 d\eta_2 d\xi_1 d\xi_2 dx_1 dx_2 d\alpha_1 d\alpha_2$$

$$=\left(\frac{s}{2\pi}\right)^2\int_{\xi_\kappa\in\mathbb{R}}\int_{\eta_\lambda\in\mathbb{R}}\tilde{\tilde{\beta}}(\xi_\kappa,\eta_\lambda)\exp(-is\xi_\sigma\eta_\sigma)d\eta_1 d\eta_2 d\xi_1 d\xi_2$$

$$=\exp\left[\frac{i}{s}\,\partial_{\alpha_\sigma}\partial_{x_\sigma}\right]\hat{\beta}(x_\kappa,\alpha_\lambda)\big|_{(x_\kappa,\alpha_\lambda)=(0,0)}. \tag{A11}$$

Using this equality in Eq. (A8), it is found that

$$\hat{\beta}_3(x_\kappa,\alpha_\lambda)=\exp\left[\frac{i}{s}\,\partial_{\alpha'_\sigma}\partial_{x'_\sigma}\right]\hat{\beta}_1(x_\kappa,\alpha'_\nu)\hat{\beta}_2(x'_\mu,\alpha_\lambda)\Big|_{(x'_\kappa,\alpha'_\lambda)=(x_\kappa,\alpha_\lambda)}. \tag{A12}$$

The interpretation of the exponential operator follows upon analyzing

$$\hat{B}_3(x_\kappa,\alpha_\lambda,x'_\mu,\alpha'_\nu)=\exp\left[\frac{i}{s}\,\partial_{\alpha'_\sigma}\partial_{x'_\sigma}\right]\hat{\beta}_1(x_\kappa,\alpha'_\nu)\hat{\beta}_2(x'_\mu,\alpha_\lambda) \tag{A13}$$

introducing

$$\hat{\rho}_M(x_\kappa,\alpha_\lambda,x'_\mu,\alpha'_\nu)=\hat{B}_3(x_\kappa,\alpha_\lambda,x'_\mu,\alpha'_\nu)-\sum_{m=0}^{M-1}\frac{1}{m!}\left(\frac{i}{s}\right)^m(\partial_{\alpha'_\sigma}\partial_{x'_\sigma})^m\hat{\beta}_1(x_\kappa,\alpha'_\nu)\hat{\beta}_2(x'_\mu,\alpha_\lambda). \tag{A14}$$

Note that $\hat{\beta}_3(x_\kappa,\alpha_\lambda)=\hat{B}_3(x_\kappa,\alpha_\lambda,x_\kappa,\alpha_\lambda)$. Suppose that $\hat{\beta}_1$ lies in a space S^{s_1} and that $\hat{\beta}_2$ lies in a space S^{s_2}. Then the following estimate holds (see the proof of Theorem 18.1.8 in Ref. 11)

$$\begin{aligned}&|(\partial^{m_1}_{\alpha_1}\partial^{m_2}_{\alpha_2}\partial^{n_1}_{x_1}\partial^{n_2}_{x_2}\partial^{m'_1}_{\alpha'_1}\partial^{m'_2}_{\alpha'_2}\partial^{n'_1}_{x'_1}\partial^{n'_2}_{x'_2}\hat{\rho}_M)(x_\kappa,\alpha_\lambda,x'_\mu,\alpha'_\nu)|\\&\quad\leqslant C_{M,m_1,m_2,n_1,n_2,m'_1,m'_2,n'_1,n'_2}\,[(1+\alpha'_\rho\alpha'_\rho)^{1/2}]^{s_1-M-m'_1-m'_2}\\&\quad\quad\times[(1+\alpha_\sigma\alpha_\sigma)^{1/2}]^{s_2-m_1-m_2},\end{aligned} \tag{A15}$$

which implies that $\hat{\rho}_M(x_\mu,\alpha_\nu,x_\mu,\alpha_\nu)\in S^{s_1+s_2-M}$.

2. Continuity

We will review the proof of continuity of a pseudo-differential operator $\hat{\mathrm{B}}$: $H^r\to H^{r-d}$, given that its symbol $\hat{\beta}$ is contained in S^d. Let $\hat{\Gamma}$ be the pseudo-differential operator of order 1,

$$\hat{\Gamma}_0=[-D_\sigma\,D_\sigma+\langle c^{-2}\rangle]^{1/2}, \tag{A16}$$

which, by Fourier analysis, is trivially continuous as an operator $H^r\to H^{r-1}$. Then also

$$\hat{\Gamma}_0^d:\ H^r\to H^{r-d}\quad\text{continuous for}\quad d\in\mathbb{R}. \tag{A17}$$

Now, let $\hat{u}\in H^r$. Then $\hat{u}_0=\hat{\Gamma}_o^r\hat{u}\in L^2$; using the parametrix $\hat{\Gamma}_o^{-r}$ of $\hat{\Gamma}_o^r$, we can write

$$\hat{u}=\hat{\Gamma}_0^{-r}\hat{u}_0+\hat{v}_0 \quad \text{with } \hat{u}_0\in L^2 \text{ and } \hat{v}_0\in C^\infty.$$

The contribution from $\hat{v}_0$ is trivially dealt with. We obtain

$$\hat{\Gamma}_0^{r-d}\hat{\mathrm{B}}\hat{u}=\hat{\Gamma}_0^{r-d}\hat{\mathrm{B}}\hat{\Gamma}_0^{-r}\hat{u}_0. \tag{A18}$$

Hence, continuity of $\hat{\mathrm{B}}$ is proved, if

$$\hat{\mathrm{B}}_0\equiv\hat{\Gamma}_0^{r-d}\hat{\mathrm{B}}\hat{\Gamma}_0^{-r}:\ L^2\to L^2 \text{ continuous.} \tag{A19}$$

From the calculus of symbols, discussed in the preceding subsection, we find that the symbol $\hat{\beta}_0$ of the latter operator is contained in S^0.

Step 1: $\hat{\beta}\in S^{-n-1}$. Let $\mu=1,...,n$, and $\hat{\beta}\in S^{-n-1}$. Then

$$|\hat{\mathscr{B}}(x_\mu,x'_\nu)|\leqslant\left(\frac{s}{2\pi}\right)^2\int_{\alpha_\nu\in\mathbb{R}}|\hat{\beta}(x_\mu,\alpha_\nu)|^2 d\alpha_1\cdots d\alpha_n\leqslant C.$$

Note that

$$(x_\mu-x'_\mu)^{l_\mu}\hat{\mathscr{B}}(x_\mu,x'_\nu) \text{ corresponding with } i^{l_\mu}\partial_{\alpha_\mu}^{l_\mu}\hat{\beta}(x_\mu,\alpha_\nu)$$

must be bounded as well, hence

$$(1+[(x_\mu-x'_\mu)^2]^{1/2})^{n+1}\ |\hat{\mathscr{B}}(x_\mu,x'_\nu)|\leqslant C.$$

Schur's lemma states that if $\hat{\mathscr{B}}(x_\mu,x'_\nu)$ is continuous and

$$\sup_{x'_\nu}\int_{x_\mu\in\mathbb{R}}|\hat{\mathscr{B}}(x_\mu,x'_\nu)|dx_1\cdots dx_n\leqslant C \quad\text{and}\quad \sup_{x_\mu}\int_{x'_\nu\in\mathbb{R}}|\hat{\mathscr{B}}(x_\mu,x'_\nu)|dx'_1\cdots dx'_n\leqslant C, \tag{A20}$$

that then $\hat{\mathrm{B}}:L^2\to L^2$ is bounded with norm $\leqslant C$. (This is a consequence of Cauchy–Schwarz inequality.) Conditions (A20) are satisfied for $\hat{\beta}\in S^{-n-1}$.

Step 2: $\hat{\beta}\in S^m$, $m\leqslant -1$. Let $\hat{\beta}\in S^m$, $m\leqslant -1$. Let $\hat{\beta}^*\in S^m$ be the symbol of the adjoint operator $\hat{\mathrm{B}}^T$. Set $\hat{\mathrm{C}}\equiv\hat{\mathrm{B}}^T\hat{\mathrm{B}}$. Then

$$\|\hat{\mathrm{B}}\hat{u}\|^2\leqslant\|\hat{\mathrm{C}}\hat{u}\|\ \|\hat{u}\|.$$

Hence, if $\hat{\mathrm{C}}$ is continuous, then $\hat{\mathrm{B}}$ must be continuous. Let the symbol of $\hat{\mathrm{C}}$ be contained in S^{2m}. By induction, we find continuity for

$$m\leqslant-\frac{n+1}{2},\quad m\leqslant-\frac{1}{2}\frac{n+1}{2},\quad \ldots,\quad m\leqslant -1.$$

Step 3: $\hat{\beta}\in S^0$. Let $\hat{\beta}\in S^0$. Then there is an estimate

$$M>2\sup|\hat{\beta}(x_\mu,\alpha_\nu)|^2.$$

Set

$$\hat{\delta}(x_\mu,\alpha_\nu)\equiv[M-|\hat{\beta}(x_\mu,\alpha_\nu)|^2]^{1/2}\in S^0.$$

Since

$$M-|\hat{\beta}(x_\mu,\alpha_\nu)|^2\geqslant M/2,$$

the symbol $\hat{\delta}$ is well defined. Using the calculus of the previous subsection, form the operator $\hat{\mathrm{D}}^T\hat{\mathrm{D}}$; then

$$\hat{\mathrm{D}}^T\hat{\mathrm{D}}=M-\hat{\mathrm{B}}^T\hat{\mathrm{B}}+\hat{\mathrm{E}},\quad \hat{e}\in S^{-1}.$$

From this operator equality, we obtain

$$\|\hat{\mathrm{B}}\hat{u}\|^2\leqslant\|\hat{u}\|^2M+\langle\hat{\mathrm{E}}\hat{u},\hat{u}\rangle.$$

In the previous step we have shown that $\hat{\mathrm{E}}$ must be continuous ($\hat{e}\in S^{-1}$); hence $\hat{\mathrm{B}}$ must be continuous.

Diffuse tomography modulo Grassmann and Laplace

S. K. Patch[a)]
Institute for Mathematics and its Applications, 514 Vincent Hall, 206 Church Street S. E., Minneapolis, Minnesota 55455

(Received 7 April 1995; accepted for publication 5 December 1995)

Complicated and unphysical families of modified transition probabilities for the 4×4 diffuse tomographic problem are presented. Grassmann–Plücker identities and Laplace expansions of determinants are used to simplify the initial transition probabilities. Besides restoring self-consistency to the system, enforcing range conditions eliminates one-half of the parameters. © *1996 American Institute of Physics.* [S0022-2488(96)01705-5]

I. INTRODUCTION

Applications in medical imaging motivated efforts to invert two-and three-dimensional versions of the Redheffer *-product.[1–7] One possible application is monitoring the brains of neonates, which are unable to withstand repeated x-ray irradiation. Brain hemorrhage is the leading cause of death among premature infants. The goal is to detect cranial bleeds without overexposing the infant to harmful radiation.

Range conditions were studied in Refs. 8 and 9 for very general two- and three-dimensional systems. Because of these range conditions the inverse problem is underdetermined. In Ref. 10 a recursive algorithm was sketched for recovering a p-parameter family of solutions to the inverse problem in the plane where the difference between the amount of independent data and number of unknowns is p. The purpose of this paper is to fill in the details.

The first section of this paper includes an introduction to the forward problem and a description of its range conditions. Each recursive level of the inversion scheme presented in Ref. 10 consists of two parts. The first part divides a system into four subsystems and computes families of data sets for the subsystems from the original data set. Unfortunately, this process introduces too many parameters. The superfluous parameters must be eliminated from the subsystems' data sets. This is done in Secs. II and III for the first level of the recursive scheme by enforcing range conditions upon the subsystems' data sets. Sections I C and I D give insight into the difficulty of enforcing the various range conditions. Because of the combinatorial nature of the problem, several different matrix identities are helpful. Grassmann–Plücker identities are used to derive some of them in Sec. II A. The solutions presented in Sec. I D are presented modulo the matrix identities in Sec. II B. These solutions are functions of the data and 64 parameters. That the range conditions which are simplest to enforce imply that eight of the parameters are identically zero is shown in Sec. III A. The rest of the relatively easily enforceable conditions are studied in Secs. III B 1 and III B 2. The remaining conditions are more difficult to enforce (Sec. III C). Additional matrix identities are required to reduce these remaining conditions to palatable form (Secs. III C 2 and 3). In Section III C 4 it is shown that these identities form a complete set. Sections III B 2 and III C 4 are quite technical and may be omitted without losing sight of the main objective—recursive subdivision of a diffuse tomographic system.

A. Description of the model

Consider an $n\times n$ array of pixels in the plane. On each outer face there are two devices. One device shoots photons across the outside edge into the neighboring pixel; the other device detects photons as they leave the system. For each of the $4n$ outside edges $4n$ pieces of data are collected.

[a)]Electronic mail address: patch@ima.umn.edu

These data are stored as a $4n\times 4n$ transition matrix, Q. Within the system, photons travel either horizontally or vertically. Label the horizontal and vertical axes x_1 and x_2, respectively. A photon traveling parallel to the x_i axis in the positive direction moves with velocity x_i^+. Photons traveling in the opposite direction travel with velocity x_i^-. They do not interact and may be absorbed within a pixel. Photons move according to a Markov process.[11] The probabilities with which a photon moves to a neighboring pixel depend upon its previous, as well as present, location. In this two-step formulation the state space consists of locations. The state space may be redefined so that photons move according to a one-step Markov process. In the new state space a single state consists of the photon's location and direction of travel.

There are three different types of these Markov states: incoming, outgoing, and hidden. The probabilities with which photons move from one state to another are referred to as transition probabilities. For each pixel O and incident direction the sum of the absorption probability and the four possible transition probabilities must be identically one. The absorption probability is therefore neglected in the rest of this paper. Each pixel corresponds to 16 transition probabilities. For example, a photon which travels with velocity x_i^+ into pixel O and travels straight through pixel O does so with some probability, denoted by $x_i^+Ox_i^+$. The same photon travels to O's neighbor in the x_j^+ direction with probability $x_i^+Ox_j^+$. These probabilities are the nonzero entries of the Markov transition matrix M. M is sparse and may be written as a block matrix with nontrivial subblocks Pio, Pih, Pho, and Phh. Pio, for example, contains the probabilities with which photons in incoming states move directly to outgoing states. Pih contains the probabilities with which photons in incoming states move to hidden states. Pho and Phh are the transition matrices for photons starting in hidden states traveling to outgoing and hidden states, respectively. Pio and Phh are always square matrices.

B. Forward problem

The forward map takes $16n^2$ transition probabilities to the $4n\times 4n$ data matrix Q. The domain of the forward map lies in the unit cube in $\mathbb{R}^{16n^2}$ and is defined by

$$(x_i^{\pm}Ox_1^+ + x_i^{\pm}Ox_1^-) + (x_i^{\pm}Ox_2^+ + x_i^{\pm}Ox_2^-) \leqslant 1, \quad \pm = +,-, i = 1,2,$$

for each pixel O. Furthermore, none of these transition probabilities may be zero. Here Q_i^j represents the probability that a photon which enters the system at source i exits the system at detector j. Q provides no time-of-flight information. Because Q is a transition matrix, acceptable solutions lie in the unit cube in $\mathbb{R}^{16n^2}$ and satisfy

$$0 \leqslant \sum_{\lambda=1}^{4n} Q_i^{\lambda} \leqslant 1, \quad i = 1,2,\ldots,4n.$$

The forward map is given by the following matrix expression:

$$Q = Pio + Pih\sum_{n=0}^{\infty} Phh^n \;\; Pho = Pio + Pih(I - Phh)^{-1}Pho \tag{1}$$

C. Range conditions

Range conditions appear as rank-deficient submatrices of Q. Each of these rank-deficient submatrices represents travel from one ''side'' of the system to the other ''side.'' Let b be a (not necessarily straight) barrier of $\#b$ hidden states separating the ''sides.'' The Markovian nature of the system can be used to show that the corresponding submatrix is generically of rank $\#b$.[8] For the purposes of this paper it is only necessary to consider straight barriers.

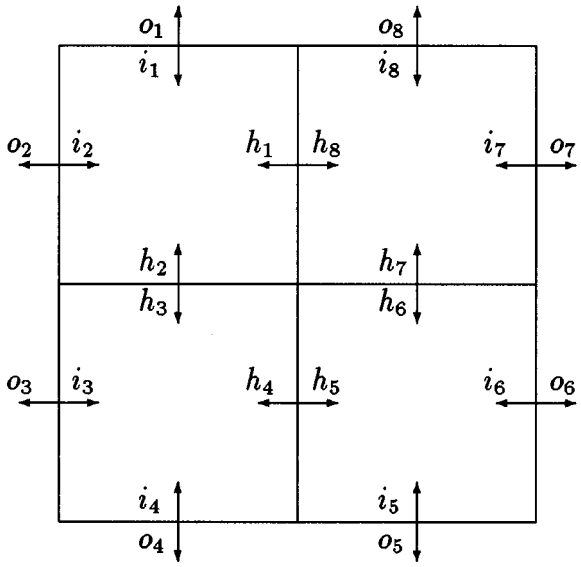

FIG. 1. Incoming, hidden, and outgoing states are labeled with is, hs, and os, respectively.

Notation: Let Q_r^c denote the submatrix of Q taken from rows **r** and columns **c**. Let dQ_r^c denote the determinant of this submatrix. Furthermore, let $a-b$ denote $a,a+1,\ldots,b$, where $a,b\in\mathbb{N}$.

For example, the data matrix for a 2×2 system has many rank-deficient submatrices. See Fig. 1. The 4×4 submatrix representing travel from left to right, Q_{1-4}^{5-8}, is generically rank two, as is Q_{5-8}^{1-4}. Similarly, the submatrices $Q_{3-6}^{1,2,7,8}$ and $Q_{1,2,7,8}^{3-6}$ are generically of rank two as well.

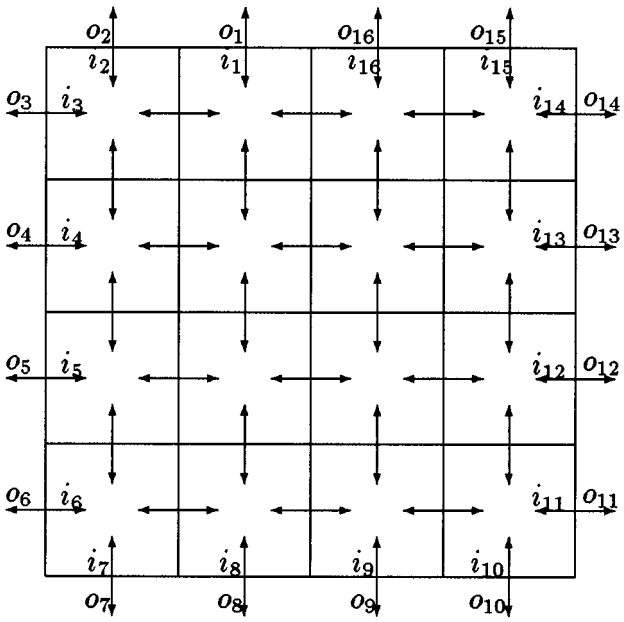

FIG. 2. A 4×4 system. The incoming and outgoing states are labeled; all unlabeled states are hidden states. There are 16 incoming and 16 outgoing states, but 48 hidden states.

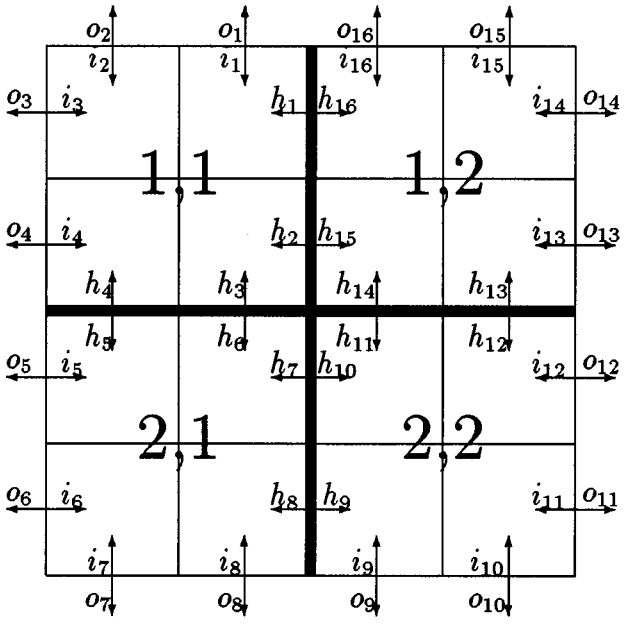

FIG. 3. Decomposition of a 4×4 system into four 2×2 subsystems. The thick lines separate the subsystems. The ''modified'' 4×4 system disregards individual pixels. Only the subsystems are relevant at the first level of this recursive procedure.

D. Modified transition matrices in terms of *A*

Although the final goal is to recover the microscopic transition probabilities for each pixel from boundary value data, the purpose of this section is more modest. A 32-parameter family of data sets for the subsystems shown in Fig. 3 are computed from the original data. Once the data sets for each of the subsystems are found, the 2×2 subsystems can be tackled in parallel.

The sparse block structures of Pio, Pho, Pih, and Phh were used in Ref. 10 to solve for nonzero blocks of Phh, Pio, and Pih in terms of $A \equiv Pho^{-1}$. This result is used here and requires the following.

Notation: $[M:N]$ denotes the concatenation of matrices M and N (where M and N have the same number of rows). Furthermore, let r_{a-b} denote any choice of one half of the natural numbers between a and b inclusive. ($b-a$ is always odd.) Finally, define $r_{\mathbf{l}} \equiv r_{1-8}$, $r_{\mathbf{b}} \equiv r_{5-12}$, $r_{\mathbf{r}} \equiv r_{9-16}$, and $r_{\mathbf{t}} \equiv r_{1-4,13-16}$, representing choices of rows from the left, bottom, right, and top of the system, respectively.

The following solutions will be used later to eliminate some of the A_i^js:

$$Phh_{1-4}^{5,6} = Pho_{1-4}^{1-4}(Q_{r_{\mathbf{r}}}^{1-4})^{-1} Q_{r_{\mathbf{r}}}^{5-8} A_{5-8}^{5,6}, \tag{2}$$

$$Phh_{1-4}^{15,16} = Pho_{1-4}^{1-4}(Q_{r_{\mathbf{b}}}^{1-4})^{-1} Q_{r_{\mathbf{b}}}^{13-16} A_{13-16}^{15,16}, \tag{3}$$

$$Pih_{1-4}^{5,6} = [Q_{1-4}^{5-8} - (Q_{1-4}^{1-4} - Pio_{1-4}^{1-4})(Q_{r_{\mathbf{r}}}^{1-4})^{-1} Q_{r_{\mathbf{r}}}^{5-8}] A_{5-8}^{5,6}, \tag{4}$$

$$Pih_{1-4}^{15,16} = [Q_{1-4}^{13-16} - (Q_{1-4}^{1-4} - Pio_{1-4}^{1-4})(Q_{r_{\mathbf{b}}}^{1-4})^{-1} Q_{r_{\mathbf{b}}}^{13-16}] A_{13-16}^{15,16}, \tag{5}$$

where

$$Pio_{1-4}^{1-4}=Q_{1-4}^{1-4}-[Q_{1-4}^{13-16}(Q_{r_{\mathbf{b}}}^{13-16})^{-1}Q_{r_{\mathbf{b}}}^{1-4}A_{1-4}^{1,2}:Q_{1-4}^{5-8}(Q_{r_{\mathbf{b}}}^{5-8})^{-1}Q_{r_{\mathbf{r}}}^{1-4}A_{1-4}^{3,4}]Pho_{1-4}^{1-4}. \quad (6)$$

Solutions for blocks within the same transition matrix have a common structure. Hidden–outgoing and hidden–hidden transitions can be expressed in terms of Q and A much more simply than incoming–outgoing and incoming–hidden transitions.

II. SIMPLIFYING THE SOLUTIONS

Although the above solutions are relatively compact, the solutions for Pio and Pih can be simplified. The Grassmann–Plücker identites found in classical algebraic geometry are used to derive matrix identities in the next section. The results are used to simplify the solutions for Pio and Pih in Sec. II B.

A. Matrix truisms

Since the inverse problem involves linear systems, it is not surprising that Grassmannians and the Grassmann–Plücker embedding come into play. The identities which embed Grassmannians $G(k,n)$ in $\mathbb{P}^{\binom{n}{k}-1}$ are derived below. A cursory explanation of the embedding can be found in Refs. 12 and 13. For a more thorough exposition see Refs. 14 and 15. Let Λ be any rectangular matrix with k rows and n columns where $k<n-1$ and $\Lambda=(a)_{ij}$. Let $I=(i_1,i_2,i_3,\ldots,i_{(k-1)})$ index $(k-1)$ distinct columns of Λ. Let $J=(j_1,j_2,j_3,\ldots,j_{(k+1)})$ index $(k+1)$ distinct columns of Λ. Then,

$$\sum_{\lambda=1}^{k+1}\pi_{(i_1,i_2,\ldots,i_{k-1},j_\lambda)}\pi_{(j_1,j_2,\ldots,j_{\lambda-1},j_{\lambda+1},\ldots,j_{k+1})}=0. \quad (7)$$

Equation (7) defines the Grassmann relations. Let $\alpha,\beta,\gamma,\eta,\kappa\in\mathbb{N}^k$. For any matrix Q, basic matrix properties imply

$$(Q_\alpha^\gamma)^{-1}Q_\alpha^\eta=\left(\frac{dQ_\alpha^{\gamma_1,\gamma_2,\ldots,\gamma_{i-1},\eta_j,\gamma_{i+1},\ldots,\gamma_n}}{dQ_\alpha^\gamma}\right)_{i,j}, \quad (8)$$

$$Q_\kappa^\gamma(Q_\alpha^\gamma)^{-1}Q_\alpha^\eta=Q_\kappa^\eta-\left(\frac{1}{dQ_\alpha^\gamma}\right)(dQ_{\kappa_i,\alpha}^{\eta_j,\gamma})_{i,j}. \quad (9)$$

The identity (8) combines with Grassmann-Plücker relations to imply

$$\begin{aligned}(dQ_{\kappa_i,\alpha}^{\gamma_k,\beta})_{i,k}(Q_\alpha^\gamma)^{-1}Q_\alpha^\eta&=(dQ_{\kappa_i,\alpha}^{\gamma_k,\beta})_{i,k}\left(\frac{dQ_\alpha^{\gamma_1,\gamma_2,\ldots,\gamma_{k-1},\eta_j,\gamma_{k+1},\ldots,\gamma_n}}{dQ_\alpha^\gamma}\right)_{k,j}\\&=\frac{-1}{dQ_\alpha^\gamma}\sum_{k=1}^{n}(-1)^k(dQ_{\kappa_i,\alpha}^{\gamma_k,\beta}dQ_\alpha^{\eta_j,\gamma_1,\gamma_2,\ldots,\gamma_{k-1},\gamma_{k+1},\ldots,\gamma_n})_{i,j}\\&=\left(dQ_{\kappa_i,\alpha}^{\eta_j,\beta}-\frac{dQ_\alpha^\beta}{dQ_\alpha^\gamma}dQ_{\kappa_i,\alpha}^{\eta_j,\gamma}\right)_{i,j}. \quad (10)\end{aligned}$$

These matrix identities can be used to simplify (4)–(6). Finally, note that

$$I=A_{1-4}^{1-4}Pho_{1-4}^{1-4}=A_{1-4}^{1,2}Pho_{1,2}^{1-4}+A_{1-4}^{3,4}Pho_{3,4}^{1-4}$$

because Pho is block diagonal and $A=Pho^{-1}$. This argument applies to other blocks on the diagonal.

B. Matrix solutions revisited

The solution for Pio_{1-4}^{1-4} can be simplified using (9) as follows:

$$
\begin{aligned}
Pio_{1-4}^{1-4} &= Q_{1-4}^{1-4} - \left[\left(Q_i^j - \frac{dQ_{i,r_5}^{j,13-16}}{dQ_{r_5}^{13-16}} \right)_{i,j} A_{1-4}^{1,2} : \left(Q_i^j - \frac{dQ_{i,r_9}^{j,5-8}}{dQ_{r_9}^{5-8}} \right)_{i,j} A_{1-4}^{3,4} \right] Pho_{1-4}^{1-4} \\
&= Q_{1-4}^{1-4} - [Q_{1-4}^{1-4} A_{1-4}^{1,2} : Q_{1-4}^{1-4} A_{1-4}^{3,4}] Pho_{1-4}^{1-4} \\
&\quad + \left[\left(\frac{dQ_{i,r_5}^{j,13-16}}{dQ_{r_5}^{13-16}} \right)_{i,j} A_{1-4}^{1,2} : \left(\frac{dQ_{i,r_9}^{j,5-8}}{dQ_{r_9}^{5-8}} \right)_{i,j} A_{1-4}^{3,4} \right] Pho_{1-4}^{1-4} \\
&= \left[\left(\frac{dQ_{i,r_5}^{j,13-16}}{dQ_{r_5}^{13-16}} \right)_{i,j} A_{1-4}^{1,2} : \left(\frac{dQ_{i,r_9}^{j,5-8}}{dQ_{r_9}^{5-8}} \right)_{i,j} A_{1-4}^{3,4} \right] Pho_{1-4}^{1-4} \\
&= \left(\frac{dQ_{i,r_5}^{j,13-16}}{dQ_{r_5}^{13-16}} \right)_{i,j} A_{1-4}^{1,2} Pho_{1,2}^{1-4} + \left(\frac{dQ_{i,r_9}^{j,5-8}}{dQ_{r_9}^{5-8}} \right)_{i,j} A_{1-4}^{3,4} Pho_{3,4}^{1-4} \\
&= \left(\frac{dQ_{i,r_5}^{j,13-16}}{dQ_{r_5}^{13-16}} - \frac{dQ_{i,r_9}^{j,5-8}}{dQ_{r_9}^{5-8}} \right)_{i,j} A_{1-4}^{1,2} Pho_{1,2}^{1-4} + \left(\frac{dQ_{i,r_9}^{j,5-8}}{dQ_{r_9}^{5-8}} \right)_{i,j} .
\end{aligned}
$$

Define the 4×4 matrices

$$
\mathbf{m} = \left(\frac{dQ_{i,r_5}^{j,13-16}}{dQ_{r_5}^{13-16}} - \frac{dQ_{i,r_9}^{j,5-8}}{dQ_{r_9}^{5-8}} \right)_{i,j} ,
$$

$$
\mathbf{M} = \mathbf{m}\, A_{1-4}^{1,2}\, Pho_{1,2}^{1-4} .
$$

Then the nonzero entries of Pio can be expressed (fairly) compactly, albeit nonuniquely:

$$
Pio_{1-4}^{1-4} = \mathbf{M} + \left(\frac{dQ_{i,r_9}^{j,5-8}}{dQ_{r_9}^{5-8}} \right)_{i,j} . \tag{11}
$$

Simpler solutions for Pio can be used to express Pih more succinctly. For instance, substituting the matrix identity (8) as well as (11) and

$$
\left(\frac{dQ_{i+12,5-8}^{j+12,9-12}}{dQ_{5-8}^{9-12}} \right)_{i,j} (Q_{5-8}^{13-16})^{-1} Q_{5-8}^{1-4} = \left(\frac{dQ_{i+12,5-8}^{j,9-12}}{dQ_{5-8}^{9-12}} - \frac{dQ_{i+12,5-8}^{j,13-16}}{dQ_{5-8}^{13-16}} \right)_{i,j} , \tag{12}
$$

$$
\left(\frac{dQ_{i+12,r_5}^{j+12,1-4}}{dQ_{r_5}^{1-4}} \right)_{i,j} (Q_{r_b}^{13-16})^{-1} Q_{r_b}^{1-4} = \left(\frac{dQ_{i+12,r_b}^{j,1-4}}{dQ_{r_b}^{1-4}} - \frac{dQ_{i+12,r_b}^{j,13-16}}{dQ_{r_b}^{13-16}} \right)_{i,j} \equiv - \left(\frac{dQ_{i+12,r_b}^{j,13-16}}{dQ_{r_b}^{13-16}} \right)_{i,j} \tag{13}
$$

into equations (4) and (5) yields

$$
Pih_{1-4}^{5,6} = \mathbf{M} (Q_{r_r}^{1-4})^{-1} Q_{r_r}^{5-8} A_{5-8}^{5,6} , \tag{14}
$$

$$Pih_{1-4}^{15,16}=\left[\left(\frac{dQ_{i,9-12}^{j+12,5-8}}{dQ_{9-12}^{5-8}}\right)_{i,j}+\mathbf{M}(Q_{9-12}^{1-4})^{-1}Q_{9-12}^{13-16}\right]A_{13-16}^{15,16}. \tag{15}$$

In (12) and (15) the choice of rows is dictated by the matrix identity (10). Similar computations give simple expressions for each block of Pio and Pih in terms of Q and the 64 nonzero entries of A.

III. REMOVING A_i^js

In this section range conditions are used to derive 32 independent conditions upon the A_i^js. The entries of Pho, Phh, Pio, and Pih are (almost) the data for each of the 2×2 subsystems. They do not obey the range conditions mentioned in Sec. I C, however. Range conditions for the 2×2 subsystems are zero-valued 3×3 minors of the subsystems' data sets. Enforcing these conditions yields polynomials in the A_i^js. These polynomials factor into products of several terms; the relevant term is always linear. Although there are many such conditions, only 32 of them are independent. Only half, therefore, of the parameters may be eliminated by virtue of range conditions upon the 2×2 subsystems.

Each of the four subsystems has an 8×8 data matrix. The data matrix for the 1,1 subsystem is shown below:

$$Q11=\begin{bmatrix} Pio_2^2 & Pio_2^3 & Pio_2^4 & Pih_2^5 & Pih_2^6 & Pih_2^{15} & Pih_2^{16} & Pio_2^1 \\ Pio_3^2 & Pio_3^3 & Pio_3^4 & Pih_3^5 & Pih_3^6 & Pih_3^{15} & Pih_3^{16} & Pio_3^1 \\ Pio_4^2 & Pio_4^3 & Pio_4^4 & Pih_4^5 & Pih_4^6 & Pih_4^{15} & Pih_4^{16} & Pio_4^1 \\ Pho_4^2 & Pho_4^3 & Pho_4^4 & Phh_4^5 & Phh_4^6 & Phh_4^{15} & Phh_4^{16} & Pho_4^1 \\ Pho_3^2 & Pho_3^3 & Pho_3^4 & Phh_3^5 & Phh_3^6 & Phh_3^{15} & Phh_3^{16} & Pho_3^1 \\ Pho_2^2 & Pho_2^3 & Pho_2^4 & Phh_2^5 & Phh_2^6 & Phh_2^{15} & Phh_2^{16} & Pho_2^1 \\ Pho_1^2 & Pho_1^3 & Pho_1^4 & Phh_1^5 & Phh_1^6 & Phh_1^{15} & Phh_1^{16} & Pho_1^1 \\ Pio_1^2 & Pio_1^3 & Pio_1^4 & Pih_1^5 & Pih_1^6 & Pih_1^{15} & Pih_1^{16} & Pio_1^1 \end{bmatrix}.$$

$Q11$ has four rank-deficient submatrices. They are 4×4 submatrices of rank two (or less). Two constraints are required to force a generic vector in $\mathbb{R}^4$ to lie in a given two-dimensional subspace. Four conditions are required, therefore, to force a generic 4×4 matrix to be of rank two. These conditions will be studied in order of increasing complexity. (Clearly, the conditions which involve variables from Pih are bound to be horrendous, so the are not considered until much later.) Eight of the conditions are identities of the form $A_i^j=0$. The rest reduce (at a generic point) to four term linear equations. Right–left, left–right, top–bottom, and bottom–top rank deficient submatrices are labeled as Qij_{rl}, Qij_{lr}, Qij_{tb}, and Qij_{bt}, where $i,j=1,2$. One such rank deficient submatrix whose entries are relatively simple expressions in A and Q is

$$Q11_{rl}=\begin{bmatrix} Q11_5^1 & Q11_5^2 & Q11_5^3 & Q11_5^4 \\ Q11_6^1 & Q11_6^2 & Q11_6^3 & Q11_6^4 \\ Q11_7^1 & Q11_7^2 & Q11_7^3 & Q11_7^4 \\ Q11_8^1 & Q11_8^2 & Q11_8^3 & Q11_8^4 \end{bmatrix}=\begin{bmatrix} Pho_3^2 & Pho_3^3 & Pho_3^4 & Phh_3^5 \\ Pho_2^2 & Pho_2^3 & Pho_2^4 & Phh_2^5 \\ Pho_1^2 & Pho_1^3 & Pho_1^4 & Phh_1^5 \\ Pio_1^2 & Pio_1^3 & Pio_1^4 & Pih_1^5 \end{bmatrix}.$$

Other relatively simple rank-deficient submatrices are the ''hidden–outgoing'' submatrices: $Q11_{bt}$, $Q12_{bt}$, $Q12_{lr}$, $Q21_{tb}$, $Q21_{rl}$, $Q22_{lr}$, and $Q22_{tb}$. The preponderance of their entries

represent hidden–outgoing transitions. Entries of ''incoming–hidden'' submatrices are predominantly incoming–hidden transitions. There are eight ''incoming–hidden'' submatrices: $Q11_{tb}$, $Q11_{lr}$, $Q21_{lr}$, $Q21_{bt}$, $Q22_{bt}$, $Q22_{rl}$, $Q12_{rl}$, and $Q12_{tb}$.

A. Identities

Since $Q11_{rl}$ is rank two, the determinant of any 3×3 minor is identically zero. Recall that A is a 16×16 block matrix, with 4×4 blocks on the diagonal. The upper left block of A is the inverse of the upper left block of Pho, and so

$$-A_4^1=\begin{vmatrix} Pho_1^2 & Pho_1^3 & Pho_1^4 \\ Pho_2^2 & Pho_2^3 & Pho_2^4 \\ Pho_3^2 & Pho_3^3 & Pho_3^4 \end{vmatrix} \Big/ dPho_{1-4}^{1-4}=\begin{vmatrix} Q11_5^1 & Q11_5^2 & Q11_5^3 \\ Q11_6^1 & Q11_6^2 & Q11_6^3 \\ Q11_7^1 & Q11_7^2 & Q11_7^3 \end{vmatrix} \Big/ dPho_{1-4}^{1-4}=0.$$

The same reasoning applies to $Q11_{bt}$ and shows that $A_1^4=0$. This argument also applies to the rank-deficient submatrices $Q21_{rl}$, $Q21_{tb}$, $Q12_{lr}$, $Q22_{tb}$, and $Q22_{lr}$ and yields the following identities:

$$A_1^4=0,\quad A_4^1=0,\quad A_5^8=0,\quad A_8^5=0,\quad A_9^{12}=0,\quad A_{12}^9=0,\quad A_{13}^{16}=0,\quad A_{16}^{13}=0. \tag{16}$$

B. ''Easy'' conditions

The rest of the equations used to removed parameters are linear in the A_i^js. The simplest result from forcing the other 3×3 minors of ''hidden–outgoing'' submatrices to be zero. In this section eight more conditions are derived by considering the 3×3 minors of ''hidden–outgoing'' submatrices whose entries are only hidden–outgoing and hidden–hidden transitions. Then it is shown that all other conditions upon the ''hidden–outgoing'' submatrices are redundant.

1. Hidden–outgoing and hidden–hidden conditions

Consider the 3×4 submatrix of $Q11_{rl}$:

$$\begin{bmatrix} Q11_5^1 & Q11_5^2 & Q11_5^3 & Q11_5^4 \\ Q11_6^1 & Q11_6^2 & Q11_6^3 & Q11_6^4 \\ Q11_7^1 & Q11_7^2 & Q11_7^3 & Q11_7^4 \end{bmatrix}=\begin{bmatrix} Pho_3^2 & Pho_3^3 & Pho_3^4 & Phh_3^5 \\ Pho_2^2 & Pho_2^3 & Pho_2^4 & Phh_2^5 \\ Pho_1^2 & Pho_1^3 & Pho_1^4 & Phh_1^5 \end{bmatrix}.$$

Since $Phh_{1-3}^5 = Pho_{1-3}^{1-4}(Q_{r_{\mathbf{r}}}^{1-4})^{-1}Q_{r_{\mathbf{r}}}^{5-8}A_{5-8}^5$, it helps to define

$$\mathbf{v}=(Q_{r_{\mathbf{r}}}^{1-4})^{-1}Q_{r_{\mathbf{r}}}^{5-8}A_{5-8}^5.$$

Then every 3×3 minor of

$$\begin{bmatrix} Pho_1^2 & Pho_1^3 & Pho_1^4 & \\ Pho_2^2 & Pho_2^3 & Pho_2^4 & Pho_{1-3}^{1-4}\mathbf{v} \\ Pho_3^2 & Pho_3^3 & Pho_3^4 & \end{bmatrix}$$

must be identically zero. Let $\{\alpha,\beta,\gamma\}=\{2,3,4\}$. Then

$$\begin{vmatrix} Pho_1^\alpha & Pho_1^\beta & \\ Pho_2^\alpha & Pho_2^\beta & Pho_{1-3}^{1-4}\mathbf{v} \\ Pho_3^\alpha & Pho_3^\beta & \end{vmatrix}=\begin{vmatrix} Pho_1^\alpha & Pho_1^\beta & Pho_1^1 \\ Pho_2^\alpha & Pho_2^\beta & Pho_2^1 \\ Pho_3^\alpha & Pho_3^\beta & Pho_3^1 \end{vmatrix} v_1+\begin{vmatrix} Pho_1^\alpha & Pho_1^\beta & Pho_1^\gamma \\ Pho_2^\alpha & Pho_2^\beta & Pho_2^\gamma \\ Pho_3^\alpha & Pho_3^\beta & Pho_3^\gamma \end{vmatrix} v_\gamma$$

$$= \pm A_4^{\gamma} v_1 / dA_{1-4}^{1-4} + \pm A_4^1 v_{\gamma} / dA_{1-4}^{1-4}$$
$$= \pm A_4^{\gamma} v_1 / dA_{1-4}^{1-4},$$

since $A_4^1 \equiv 0$. Furthermore, A_4^{γ} is generally nonzero, forcing $v_1 = 0$. The matrix identity (8) says that the first row of $(Q_{r_{\mathbf{r}}}^{1-4})^{-1} Q_{r_{\mathbf{r}}}^{5-8}$ equals $(dQ_{r_{\mathbf{r}}}^{j+4,2,3,4} / dQ_{r_{\mathbf{r}}}^{1-4})_{j=1,2,3,4}$ which implies

$$0 = \sum_{j=5}^{8} dQ_{r_{\mathbf{r}}}^{j,2,3,4} A_j^5 \equiv \sum_{j=5}^{7} dQ_{r_{\mathbf{r}}}^{j,2,3,4} A_j^5, \tag{17}$$

where the last equivalence holds by virtue of the fact that $A_8^5 \equiv 0$. The same reasoning applied to the other ''hidden–outgoing'' submatrices results in

$$0 = \sum_{j=1}^{3} dQ_{r_{\mathbf{b}}}^{j,14,15,16} A_j^1 = \sum_{j=2}^{4} dQ_{r_{\mathbf{r}}}^{j,5,6,7} A_j^4 = \sum_{j=6}^{8} dQ_{r_{\mathbf{t}}}^{j,9,10,11} A_j^8 = \sum_{j=9}^{11} dQ_{r_{\mathbf{t}}}^{j,6,7,8} A_j^9 = \sum_{j=10}^{12} dQ_{r_{\mathbf{l}}}^{j,13,14,15} A_j^{12}$$
$$= \sum_{j=13}^{15} dQ_{r_{\mathbf{l}}}^{j,10,11,12} As_j^{13} = \sum_{j=14}^{16} dQ_{r_{\mathbf{b}}}^{j,1,2,3} A_j^{16}. \tag{18}$$

2. Redundant hidden–outgoing conditions

In the previous section, a 3×4 submatrix of the 4×4 $Q11_{rl}$ was forced to be of rank two. This would not generally suffice to show that rank $Q11_{rl}=2$. In this section, however, it is shown that conditions (17) and (18) do in fact force rank $Q11_{rl}=2$. We start by checking that modulo (17) and (18) the first three columns of $Q11_{rl}$ are rank two. As mentioned in the Introduction, the reader may prefer to skip ahead to Sec. III C.

$$\begin{bmatrix} Q11_5^1 & Q11_5^2 & Q11_5^3 \\ Q11_6^1 & Q11_6^2 & Q11_6^3 \\ Q11_7^1 & Q11_7^2 & Q11_7^3 \\ Q11_8^1 & Q11_8^2 & Q11_8^3 \end{bmatrix} = \begin{bmatrix} Pho_3^2 & Pho_3^3 & Pho_3^4 \\ Pho_2^2 & Pho_2^3 & Pho_2^4 \\ Pho_1^2 & Pho_1^3 & Pho_1^4 \\ Pio_1^2 & Pio_1^3 & Pio_1^4 \end{bmatrix} = \begin{bmatrix} \begin{pmatrix} & & 1 \\ & 1 & \\ 1 & & \end{pmatrix} Pho_{1-3}^{2-4} \\ \mathbf{m}_1 A_{1-4}^{1,2} Pho_{1,2}^{1-4} + \mathbf{w} \end{bmatrix},$$

where

$$\mathbf{w} = \left(\frac{dQ_{i,r_{\mathbf{r}}}^{j,5-8}}{dQ_{r_{\mathbf{r}}}^{5-8}} \right)_{j=2,3,4} \quad \text{and} \quad \mathbf{m}_1 = \left(\frac{dQ_{1,r_{\mathbf{b}}}^{j,13-16}}{dQ_{r_{\mathbf{b}}}^{13-16}} - \frac{dQ_{1,r_{\mathbf{r}}}^{j,5-8}}{dQ_{r_{\mathbf{r}}}^{5-8}} \right)_{j,1,2,3,4}. \tag{19}$$

Then for $1 \leqslant \alpha < \beta \leqslant 3$,

$$0=\begin{vmatrix} Pho_{\alpha}^{2} & Pho_{\alpha}^{3} & Pho_{\alpha}^{4} \\ Pho_{\beta}^{2} & Pho_{\beta}^{3} & Pho_{\beta}^{4} \\ Pio_{1}^{2} & Pio_{1}^{3} & Pio_{1}^{4} \end{vmatrix}$$

$$=\left|\begin{bmatrix} \mathbf{e}_{\alpha} \\ \mathbf{e}_{\beta} \\ \mathbf{m}_{1}[A_{1-4}^{1,2}:0] \end{bmatrix} Pho_{1-3}^{2-4}\right| + \left|\begin{bmatrix} \mathbf{e}_{\alpha} \\ \mathbf{e}_{\beta} \end{bmatrix} Pho_{1-3}^{2-4} \\ \mathbf{w} \right|$$

$$=\left|\begin{matrix} \mathbf{e}_{\alpha} \\ \mathbf{e}_{\beta} \\ \mathbf{m}_{1}[A_{1-4}^{1,2}:0] \end{matrix}\right| |Pho_{1-3}^{2-4}| + \left|\begin{matrix} Pho_{\alpha,\beta}^{2-4} \\ \mathbf{w} \end{matrix}\right| = \mathbf{w}^{2} dPho_{\alpha,\beta}^{3,4} - \mathbf{w}^{3} dPho_{\alpha,\beta}^{2,4} + \mathbf{w}^{4} dPho_{\alpha,\beta}^{2,3}. \quad (20)$$

The last line follows from the fact that $|Pho_{1-3}^{2-4}| \equiv 0$. Since $A \equiv Pho^{-1}$, for $\{a,b,c,d\} = \{1,2,3,4\}$ and $\{\alpha,\beta,\gamma\} = \{1,2,3\}$, $dPho_{\alpha,\beta}^{a,b} = -1^{\alpha+\beta+a+b} dA_{c,d}^{\gamma,4} / dA_{1-4}^{1-4}$. Substituting this, (16), and (19) into (20) implies

$$0=\left|\begin{matrix} Pho_{\alpha,\beta}^{2-4} \\ \mathbf{w} \end{matrix}\right| = A_{1}^{\gamma}(A_{2}^{4} dQ_{1,r_{\mathbf{r}}}^{2,5-8} + A_{3}^{4} dQ_{1,r_{\mathbf{r}}}^{3,5-8} + A_{4}^{4} dQ_{1,r_{\mathbf{r}}}^{4,5-8}). \quad (21)$$

Generally $A_{1}^{\gamma} \neq 0$. The second term of (21) is really equivalent to the second equation in (18). Consider the Jacobian of both equations:

$$\begin{bmatrix} dQ_{1,r_{\mathbf{r}}}^{2,5-8} & dQ_{1,r_{\mathbf{r}}}^{3,5-8} & dQ_{1,r_{\mathbf{r}}}^{4,5-8} \\ dQ_{r_{\mathbf{r}}}^{2,5-7} & dQ_{r_{\mathbf{r}}}^{3,5-7} & dQ_{r_{\mathbf{r}}}^{4,5-7} \end{bmatrix}. \quad (22)$$

Let $j,k \in \{2,3,4\}$. Grassman relations imply

$$dQ_{1,r_{\mathbf{r}}}^{j,5-8} dQ_{r_{\mathbf{r}}}^{k,5-7} - dQ_{1,r_{\mathbf{r}}}^{k,5-8} dQ_{r_{\mathbf{r}}}^{j,5-7} = dQ_{r_{\mathbf{r}}}^{5-8} dQ_{1,r_{\mathbf{r}}}^{j,k,5-7} = 0. \quad (23)$$

The last equality follows because of range conditions. For any $j,k \in \{2,3,4\}$, $Q_{1,r_{\mathbf{r}}}^{j,k,5-7}$ represents travel across the barrier separating incoming states [1,8–16] from outgoing states [2–7]. This matrix is generally of rank four, so $dQ_{1,r_{\mathbf{r}}}^{j,k,5-7} \equiv 0$. Because of (23) the Jacobian (22) is rank one.

The only 3×3 minors of $Q11_{rl}$ which have not yet been shown to be zero by virtue of (17) and (18) are those which are functions in incoming–hidden transitions. For example,

$$\begin{vmatrix} Pho_{2}^{3} & Pho_{2}^{4} & Phh_{2}^{5} \\ Pho_{1}^{3} & Pho_{1}^{4} & Phh_{1}^{5} \\ Pio_{1}^{3} & Pio_{1}^{4} & Pih_{1}^{5} \end{vmatrix} \quad (24)$$

is an example of such a minor. Before showing that (24) is trivally zero we define **U** and **u** as follows:

$$\mathbf{U} \equiv (Q_{r_{\mathbf{r}}}^{1-4})^{-1} Q_{r_{\mathbf{r}}}^{5-8} A_{5-8}^{5} = \frac{1}{dQ_{r_{\mathbf{r}}}^{1-4}} \begin{bmatrix} dQ_{r_{\mathbf{r}}}^{2,3,4,5} & dQ_{r_{\mathbf{r}}}^{2,3,4,6} & dQ_{r_{\mathbf{r}}}^{2,3,4,7} \\ -dQ_{r_{\mathbf{r}}}^{1,3,4,5} & -dQ_{r_{\mathbf{r}}}^{1,3,4,6} & -dQ_{r_{\mathbf{r}}}^{1,3,4,7} \\ dQ_{r_{\mathbf{r}}}^{1,2,4,5} & dQ_{r_{\mathbf{r}}}^{1,2,4,6} & dQ_{r_{\mathbf{r}}}^{1,2,4,7} \\ -dQ_{r_{\mathbf{r}}}^{1,2,3,5} & -dQ_{r_{\mathbf{r}}}^{1,2,3,6} & -dQ_{r_{\mathbf{r}}}^{1,2,3,7} \end{bmatrix} A_{5-7}^{5} = \frac{1}{dQ_{r_{\mathbf{r}}}^{1-4}} \begin{bmatrix} 0 \\ \mathbf{u} \end{bmatrix},$$

where the first entry in the last equality is due to (17). Recall (19),

$$Phh^{5}_{1-2}=Pho^{1-4}_{1-2}(Q^{1-4}_{r_{\mathbf{r}}})^{-1}Q^{5-8}_{r_{\mathbf{r}}}A^{5}_{5-8}=\left(\frac{1}{dQ^{1-4}_{r_{\mathbf{r}}}}\right)Pho^{2-4}_{1-2}\mathbf{u},$$

$$Pih^{5}_{1}=\mathbf{M}_1(Q^{1-4}_{r_{\mathbf{r}}})^{-1}Q^{5-8}_{r_{\mathbf{r}}}A^{5}_{5-8}=\left(\frac{1}{dQ^{1-4}_{r_{\mathbf{r}}}}\right)\mathbf{m}_1A^{1,2}_{1-4}Pho^{2-4}_{1,2}\mathbf{u}, \tag{25}$$

$$Pio^{3,4}_{1}=\mathbf{M}^{3,4}_{1}+\mathbf{w}^{3,4}=\mathbf{m}_1A^{1,2}_{1-4}Pho^{3,4}_{1,2}+\mathbf{w}^{3,4}.$$

Furthermore, $\left|{}^{Pho^{2-4}_{1,2}}_{\mathbf{w}}\right| = 0$ because of the fact that (21) is equivalent to (18). Plugging this into (24) yields a 3×3 minor which is trivially zero because

$$\begin{aligned}
&\begin{vmatrix} Pho^{3,4}_{1,2} & : & Pho^{2-4}_{1,2}\mathbf{u} \\ \mathbf{m}_1A^{1,2}_{1-4}Pho^{3,4}_{1,2}+\mathbf{w}^{3,4} & : & \mathbf{m}_1A^{1,2}_{1-4}Pho^{2-4}_{1,2}\mathbf{u}\end{vmatrix} \\
&\quad=\begin{vmatrix} Pho^{3,4}_{1,2} & : & Pho^{2-4}_{1,2}\mathbf{u} \\ \mathbf{m}_1A^{1,2}_{1-4}Pho^{3,4}_{1,2} & : & \mathbf{m}_1A^{1,2}_{1-4}Pho^{2-4}_{1,2}\mathbf{u}\end{vmatrix}+\begin{vmatrix} Pho^{3,4}_{1,2} & : & Pho^{2-4}_{1,2}\mathbf{u} \\ \mathbf{w}^{3,4} & : & 0\end{vmatrix} \\
&\quad=\left|\begin{pmatrix} 1 & 0 \\ 0 & 1 \\ \mathbf{m}_1A^{1,2}_{1-4} & \end{pmatrix}Pho^{2-4}_{1,2}\begin{pmatrix} 0 & 0 & \mathbf{u}_1 \\ 1 & 0 & \mathbf{u}_2 \\ 0 & 1 & \mathbf{u}_3\end{pmatrix}\right|+\left|\begin{pmatrix} Pho^{2-4}_{1,2} \\ \mathbf{w}\end{pmatrix}\begin{pmatrix} 0 & 0 & \mathbf{u}_1 \\ 1 & 0 & \mathbf{u}_2 \\ 0 & 1 & \mathbf{u}_3\end{pmatrix}\right|=0.
\end{aligned}$$

The last line follows because of Eq. (21) and the fact that the determinant of a 3×2 matrix with a 2×3 matrix is zero. Therefore, forcing (24) to be zero yields no additional conditions upon the A^{j}_{i}s. Analogous computations hold for the rest of the range conditions upon $Q11_{rl}$, $Q11_{bt}$, $Q12_{bt}$, $Q12_{lr}$, $Q21_{tb}$, $Q21_{rl}$, $Q22_{lr}$, and $Q22_{tb}$. All of these conditions are equivalent to the identities (16)–(18), so only 16 of the possible 32 conditions are independent. In the next section, more conditions are found amongst the modified data for $Q11_{tb}$, $Q11_{lr}$, $Q21_{lr}$, $Q21_{bt}$, $Q22_{bt}$, $Q22_{rl}$, $Q12_{rl}$, and $Q12_{tb}$.

C. ''Hard'' conditions

Consider now the rank-deficient ''incoming–hidden'' submatrix

$$Q11_{tb}=\begin{bmatrix} Pih^{5}_{1} & Pih^{6}_{1} & Pih^{15}_{1} & Pio^{4}_{1} \\ Pih^{5}_{2} & Pih^{6}_{2} & Pih^{15}_{2} & Pio^{4}_{2} \\ Pih^{5}_{3} & Pih^{6}_{3} & Pih^{15}_{3} & Pih^{4}_{3} \\ Phh^{5}_{1} & Phh^{6}_{1} & Phh^{15}_{1} & Pho^{4}_{1}\end{bmatrix}. \tag{26}$$

In Sec. III C 1 range conditions upon $Q11_{tb}$ are derived. These conditions are simplified in Sec. III C 3. Finally, all other conditions upon the ''incoming–hidden'' submatrices are shown to be redundant in Sec. III C 4.

1. Derive ''hard'' conditions

In order to start with as few incoming–hidden transitions as possible, let $1\leqslant\alpha<\beta\leqslant3$ and consider the minor of (26) taken from rows $\alpha,\beta,4$ and columns 1,2,4:

$$\begin{vmatrix} \mathbf{M}_{\alpha,\beta}(Q_{r_{\mathbf{r}}}^{1-4})^{-1}Q_{r_{\mathbf{r}}}^{5-8}A_{5-8}^{5,6} & : & \mathbf{M}_{\alpha,\beta}e_4+\left(\dfrac{dQ_{i,r_{\mathbf{r}}}^{4-8}}{dQ_{r_{\mathbf{r}}}^{5-8}}\right)_{i,j} \\ Pho_1^{1-4}(Q_{r_{\mathbf{r}}}^{1-4})^{-1}Q_{r_{\mathbf{r}}}^{5-8}A_{5-8}^{5,6} & : & Pho_1^4 \end{vmatrix}. \tag{27}$$

Now define the 2×4 and 3×4 derivates and $\mathbf{m}$ and $\mathbf{N}$:

$$\mathbf{m}_{\alpha,\beta}\equiv\left(\begin{matrix} \dfrac{dQ_{\alpha,r_{\mathbf{b}}}^{j,13-16}}{dQ_{r_{\mathbf{b}}}^{13-16}}-\dfrac{dQ_{\alpha,r_{\mathbf{r}}}^{j,5-8}}{dQ_{r_{\mathbf{r}}}^{5-8}} \\ \dfrac{dQ_{\beta,r_{\mathbf{b}}}^{j,13-16}}{dQ_{r_{\mathbf{b}}}^{13-16}}-\dfrac{dQ_{\beta,r_{\mathbf{r}}}^{j,5-8}}{dQ_{r_{\mathbf{r}}}^{5-8}} \end{matrix}\right)_j, \quad \text{for } j\in\{1,2,3,4\}, \tag{28}$$

$$\mathbf{N}\equiv\begin{bmatrix} \mathbf{m}_{\alpha,\beta} & A_{1-4}^{1,2} \\ 1 & 0 \end{bmatrix}Pho_{1,2}^{1-4}, \tag{29}$$

and note that $\mathbf{N}$ is rank two. Substituting (28) and (29) into (27) yields the following form for the 3×3 determinants:

$$\begin{vmatrix} \mathbf{N}(Q_{r_{\mathbf{r}}}^{1-4})^{-1}Q_{r_{\mathbf{r}}}^{5-8}A_{5-8}^{5,6}:\mathbf{N}e_4+\dfrac{1}{dQ_{r\mathbf{r}}^{5-8}}\begin{pmatrix} dQ_{\alpha,r_{\mathbf{r}}}^{4-8} \\ dQ_{\beta,r_{\mathbf{r}}}^{4-8} \\ 0 \end{pmatrix} \end{vmatrix}$$

$$=\left|\mathbf{N}[(Q_{r_{\mathbf{r}}}^{1-4})^{-1}Q_{r_{\mathbf{r}}}^{5-8}A_{5-8}^{5,6}:e_4]\right|+\frac{1}{dQ_{r_{\mathbf{r}}}^{5-8}}\begin{vmatrix} \mathbf{N}(Q_{r_{\mathbf{r}}}^{1-4})^{-1}Q_{r_{\mathbf{r}}}^{5-8}A_{5-8}^{5,6}: & dQ_{\alpha,r_{\mathbf{r}}}^{4-8} \\ & dQ_{\beta,r_{\mathbf{r}}}^{4-8} \\ & 0 \end{vmatrix}$$

$$=\frac{1}{dQ_{r_{\mathbf{r}}}^{5-8}}\begin{vmatrix} \begin{bmatrix} \mathbf{m}_{\alpha,\beta} & : & A_{1-4}^{1,2} \\ 1 & : & 0 \end{bmatrix}Pho_{1,2}^{1-4}(Q_{r_{\mathbf{r}}}^{1-4})^{-1}Q_{r_{\mathbf{r}}}^{5-8}A_{5-8}^{5,6} & : & dQ_{\alpha,r_{\mathbf{r}}}^{4-8} \\ & & & & dQ_{\beta,r_{\mathbf{r}}}^{4-8} \\ & & & & 0 \end{vmatrix}$$

$$=\frac{1}{dQ_{r_{\mathbf{r}}}^{5-8}}\begin{vmatrix} \mathbf{m}_{\alpha,\beta} & A_{1-4}^{1,2} & \vdots & dQ_{\alpha,r_{\mathbf{r}}}^{4-8} \\ & & & dQ_{\beta,r_{\mathbf{r}}}^{4-8} \\ 1 & 0 & \vdots & 0 \end{vmatrix}\begin{vmatrix} Pho_{1,2}^{1-4}(Q_{r_{\mathbf{r}}}^{1-4})^{-1}Q_{r_{\mathbf{r}}}^{5-8}A_{5-8}^{5,6} & 0 \\ & 0 \\ 0 & 1 \end{vmatrix}$$

$$=C\left|\mathbf{m}_{\alpha,\beta}A_{1-4}^2:\begin{matrix} dQ_{\alpha,r_{\mathbf{r}}}^{4-8} \\ dQ_{\beta,r_{\mathbf{r}}}^{4-8} \end{matrix}\right|=C\sum_{j=1}^{4}\begin{vmatrix} \left(\dfrac{dQ_{\alpha,r_{\mathbf{b}}}^{j,13-16}}{dQ_{r_{\mathbf{b}}}^{13-16}}-\dfrac{dQ_{\alpha,r_{\mathbf{r}}}^{j,5-8}}{dQ_{r_{\mathbf{r}}}^{5-8}}\right) & dQ_{\alpha,r_{\mathbf{r}}}^{4-8} \\ \left(\dfrac{dQ_{\beta,r_{\mathbf{b}}}^{j,13-16}}{dQ_{r_{\mathbf{b}}}^{13-16}}-\dfrac{dQ_{\beta,r_{\mathbf{r}}}^{j,5-8}}{dQ_{r_{\mathbf{r}}}^{5-8}}\right) & dQ_{\beta,r_{\mathbf{r}}}^{4-8} \end{vmatrix}A_j^2$$

$$=\sum_{j=1}^{4}\left(\frac{1}{dQ_{r_{\mathbf{b}}}^{13-16}}(dQ_{\alpha,r_{\mathbf{b}}}^{j,13-16}dQ_{\beta,r_{\mathbf{r}}}^{4-8}-dQ_{\beta,r_{\mathbf{b}}}^{j,13-16}dQ_{\alpha,r_{\mathbf{r}}}^{4-8})-\frac{1}{dQ_{r_{\mathbf{r}}}^{5-8}}(dQ_{\alpha,r_{\mathbf{r}}}^{j,5-8}dQ_{\beta,r_{\mathbf{r}}}^{4-8}\right.$$

$$\left.-dQ_{\beta,r_{\mathbf{r}}}^{j,5-8}dQ_{\alpha,r_{\mathbf{r}}}^{4-8})\right)A_j^2$$

$$=\frac{C}{dQ_{r_{\mathbf{b}}}^{13-16}}\sum_{j=1}^{4}(dQ_{\alpha,r_{\mathbf{b}}}^{j,13-16}dQ_{\beta,r_{\mathbf{r}}}^{4-8}-dQ_{\beta,r_{\mathbf{b}}}^{j,13-16}dQ_{\alpha,r_{\mathbf{r}}}^{4-8}-dQ_{r_{\mathbf{b}}}^{13-16}dQ_{\alpha,\beta,r_{\mathbf{r}}}^{j,4-8})A_j^2, \tag{30}$$

where $C\equiv|\,Pho_{1,2}^{1-4}(Q_{r_{\mathbf{r}}}^{1-4})^{-1}Q_{r_{\mathbf{r}}}^{5-8}A_{5-8}^{5,6}|/dQ_{r_{\mathbf{r}}}^{5-8}$. The last equality holds because Grassman relations imply

$$dQ_{\alpha,r_{\mathbf{r}}}^{j,5-8}dQ_{\beta,r_{\mathbf{r}}}^{4-8}-dQ_{\beta,r_{\mathbf{r}}}^{j,5-8}dQ_{\alpha,r_{\mathbf{r}}}^{4-8}=dQ_{\alpha,\beta,r_{\mathbf{r}}}^{j,4-8}dQ_{r_{\mathbf{r}}}^{5-8}. \tag{31}$$

If $C\neq 0$, then forcing (27) to be zero gives three conditions upon the A_j^2s, since there are three ways to choose α,β in (30). The same argument applied to other ''incoming–outgoing'' submatrices yields similar conditions. These conditions are simplified in Sec. III C 3. However, first we must verify the following.

Claim: $C\neq 0$.

Proof: Define $\eta\equiv Pih(I-Phh)^{-1}$. Then $Q_{r_{\mathbf{r}}}^{1-4}=\eta_{r_{\mathbf{r}}}^{1-4}Pho_{1-4}^{1-4}$ and $Q_{r_{\mathbf{r}}}^{5-8}=\eta_{r_{\mathbf{r}}}^{5-8}Pho_{5-8}^{5-8}$. Since $A\equiv Pho^{-1}$,

$$C\equiv|Pho_{1,2}^{1-4}(Q_{r_{\mathbf{r}}}^{1-4})^{-1}Q_{r_{\mathbf{r}}}^{5-8}A_{5-8}^{5,6}|/dQ_{r_{\mathbf{r}}}^{5-8}$$

$$=\frac{1}{dQ_{r_{\mathbf{r}}}^{5-8}}\left|\begin{pmatrix}1&0&0&0\\0&1&0&0\end{pmatrix}(\eta_{r_{\mathbf{r}}}^{1-4})^{-1}\eta_{r_{\mathbf{r}}}^{5-8}\begin{pmatrix}1&0\\0&1\\0&0\\0&0\end{pmatrix}\right| \tag{32}$$

$$=-\begin{vmatrix}d\eta_{r_{\mathbf{r}}}^{2-5}&d\eta_{r_{\mathbf{r}}}^{2,3,4,6}\\d\eta_{r_{\mathbf{r}}}^{1,3,4,5}&d\eta_{r_{\mathbf{r}}}^{1,3,4,6}\end{vmatrix}\Big/(dQ_{r_{\mathbf{r}}}^{5-8}(d\eta_{r_{\mathbf{r}}}^{1-4})^2) \tag{33}$$

$$=d\eta_{r_{\mathbf{r}}}^{3-6}/(dQ_{r_{\mathbf{r}}}^{5-8}d\eta_{r_{\mathbf{r}}}^{1-4}). \tag{34}$$

Equation (32) follows from the definitions of $Q_{r_{\mathbf{r}}}^{1-4}$, $Q_{r_{\mathbf{r}}}^{5-8}$, and A in terms of η and Pho. Equation (8) implies (33), which combined with Grassmann relations yields (34). Since there is no barrier of less than four states separating incoming states 9, 10, 11, and 12 from hidden states 1, 2, 3, and 4, $d\eta_{r_{\mathbf{r}}}^{3-6}\neq 0$ in the generic case. □

2. More matrix identities

In the following section condition (30) is simplified using many matrix identities. First note that Grassmann relations imply

$$\begin{vmatrix}dQ_{14,15,5-8}^{i,9-13}&dQ_{14,15,5-8}^{j,9-13}\\dQ_{14,16,5-8}^{i,9-13}&dQ_{14,16,5-8}^{j,9-13}\end{vmatrix}=dQ_{14,5-8}^{9-13}dQ_{14-16,5-8}^{i,j,9-13} \tag{35}$$

and $dQ_{14-16,5-8}^{i,j,9-13}dQ_{15,16,5-8}^{k,9-13}-dQ_{14-16,5-8}^{i,k,9-13}dQ_{15,16,5-8}^{j,9-13}+dQ_{14-16,5-8}^{j,k,9-13}dQ_{15,16,5-8}^{i,9-13}=0$. Therefore,

$$\begin{vmatrix}dQ_{14,15,5-8}^{i,9-13}&dQ_{14,15,5-8}^{j,9-13}&dQ_{14,15,5-8}^{k,9-13}\\dQ_{14,16,5-8}^{i,9-13}&dQ_{14,16,5-8}^{j,9-13}&dQ_{14,16,5-8}^{k,9-13}\\dQ_{15,16,5-8}^{i,9-13}&dQ_{15,16,5-8}^{j,9-13}&dQ_{15,16,5-8}^{k,9-13}\end{vmatrix}$$

$$= dQ^{9-13}_{14,5-8}\left(dQ^{i,j,9-13}_{14-16,5-8}dQ^{k,9-13}_{15,16,5-8} - dQ^{i,k,9-13}_{14-16,5-8}dQ^{j,9-13}_{15,16,5-8} + dQ^{j,k,9-13}_{14-16,5-8}dQ^{i,9-13}_{15,16,5-8}\right)$$
$$\equiv 0. \tag{36}$$

Because Q^{9-16}_{1-8} is generically of rank four,

$$Q^{13-16}_{5-8} = Q^{9-12}_{5-8}(Q^{9-12}_{1-4})^{-1}Q^{13-16}_{1-4}. \tag{37}$$

This means that for $\alpha \in \{1,2,3,4\}$

$$\begin{aligned} dQ^{n,13-16}_{\alpha,5-8} &= \begin{vmatrix} Q^n_\alpha & \vdots & Q^{13-16}_\alpha \\ Q^n_{5-8} & \vdots & Q^{13-16}_{5-8} \end{vmatrix} = \begin{vmatrix} Q^n_\alpha & \vdots & Q^{13-16}_\alpha \\ Q^n_{5-8} & \vdots & Q^{9-12}_{5-8}(Q^{9-12}_{1-4})^{-1}Q^{13-16}_{1-4} \end{vmatrix} \\ &= \begin{vmatrix} Q^n_\alpha & \vdots & \mathbf{e}_\alpha \\ Q^n_{5-8} & \vdots & Q^{9-12}_{5-8}(Q^{9-12}_{1-4})^{-1} \end{vmatrix} \begin{vmatrix} 1 & \\ & Q^{13-16}_{1-4} \end{vmatrix} \\ &= \begin{vmatrix} Q^n_\alpha & \vdots & Q^{9-12}_\alpha \\ Q^n_{5-8} & \vdots & Q^{9-12}_{5-8} \end{vmatrix} \begin{vmatrix} 1 & \\ & (Q^{9-12}_{1-4})^{-1} \end{vmatrix} \begin{vmatrix} 1 & \\ & Q^{13-16}_{1-4} \end{vmatrix} \\ &= dQ^{n,9-12}_{\alpha,5-8}\frac{dQ^{13-16}_{1-4}}{dQ^{9-12}_{1-4}}. \end{aligned} \tag{38}$$

Similarly,

$$dQ^{n,4-8}_{\alpha,\beta,13-16} = dQ^{n,4,9-12}_{\alpha,\beta,13-16}\frac{dQ^{5-8}_{1-4}}{dQ^{9-12}_{1-4}} \quad \text{and} \quad dQ^{n,5-8}_{\alpha,13-16} = dQ^{n,9-12}_{\alpha,13-16}\frac{dQ^{5-8}_{1-4}}{dQ^{9-12}_{1-4}}. \tag{39}$$

Finally, Grassmann relations and range conditions combine with the above identities in the following:

$$\sum_{\sigma\in S_3}\frac{\operatorname{sgn}\sigma}{2}dQ^{\sigma_1,\sigma_2,9-13}_{14-16,5-8}dQ^{\sigma_3,13-16}_{\alpha,5-8}$$
$$= \frac{dQ^{13-16}_{1-4}}{dQ^{9-12}_{1-4}}\sum_{\sigma\in S_3}\frac{\operatorname{sgn}\sigma}{2}dQ^{\sigma_1,\sigma_2,9-13}_{14-16,5-8}dQ^{\sigma_3,9-12}_{\alpha,5-8} \tag{40}$$
$$= \frac{dQ^{13-16}_{1-4}}{dQ^{9-12}_{1-4}}\left(\pm dQ^{9-13}_{\alpha,5-8}dQ^{\sigma_1,\sigma_2,\sigma_3,9-12}_{14-16,5-8} + dQ^{9-12}_{5-8}dQ^{\sigma_1,\sigma_2,\sigma_3,9-13}_{\alpha,14-16,5-8}\right) \tag{41}$$
$$= \frac{dQ^{13-16}_{1-4}}{dQ^{9-12}_{1-4}}dQ^{9-12}_{5-8}dQ^{\sigma_1,\sigma_2,\sigma_3,9-13}_{\alpha,14-16,5-8} \tag{42}$$
$$= dQ^{13-16}_{5-8}dQ^{\sigma_1,\sigma_2,\sigma_3,9-13}_{\alpha,14-16,5-8}. \tag{43}$$

Equation (41) follows from (40) by Grassmann relations; (42) follows from (41) because consistency conditions force $dQ^{9-13}_{\alpha,5-8}\equiv 0$. Finally, (37) forces (43).

In the next section the following notation will also be used.

Notation: Define the matrix $\mathbf{C}$ with columns $\mathbf{c}^j$ and rows $\mathbf{c}_j$, i.e.,

$$\mathbf{C} = [\mathbf{c}^1 \quad \mathbf{c}^2 \quad \mathbf{c}^3 \quad \mathbf{c}^4] = \begin{bmatrix} \mathbf{c}_1 \\ \mathbf{c}_2 \end{bmatrix}.$$

3. Simplification of "hard" conditions

This section consists of a single

Claim: The conditions in (30) are equivalent to

$$0=\sum_{n=1}^{4} dQ^{n,9-13}_{\gamma,\delta,5-8}A_n^2 \quad \text{for } \gamma,\delta\in\{14,15,16\}. \tag{44}$$

Furthermore, Eqs. (30) and (44) constitute only two independent conditions upon the A_i^2s.

Proof: Due to (36), only two independent conditions upon the A_n^2s are given by (44). For convenience, consider (30) where $r_{\mathbf{b}}=5-8$ and $r_{\mathbf{r}}=13-16$. To finish the proof of this claim it is necessary to show that for $\alpha,\beta\in\{1,2,3\}$, the matrix $\mathbf{C}$

$$\mathbf{c}^j=\begin{pmatrix} dQ^{j,13-16}_{\alpha,5-8}dQ^{4-8}_{\beta,13-16}-dQ^{j,13-16}_{\beta,5-8}dQ^{4-8}_{\alpha,13-16}-dQ^{13-16}_{5-8}dQ^{j,4-8}_{\alpha,\beta,13-16} \\ dQ^{j,9-13}_{14,15,5-8} \\ dQ^{j,9-13}_{14,16,5-8} \end{pmatrix}_j \tag{45}$$

is also of rank two. Equations (35), (43), and (39) are combined to show that for $i,j,k\in\{1,2,3,4\}$ $|\mathbf{c}^i\ \ \mathbf{c}^j\ \ \mathbf{c}^k|=0$, forcing $\mathbf{C}$ to be rank two:

$$\begin{aligned}
\frac{|\mathbf{c}^i\ \ \mathbf{c}^j\ \ \mathbf{c}^k|}{dQ^{9-13}_{14,5-8}} &= ((dQ^{i,13-16}_{\alpha,5-8}dQ^{4-8}_{\beta,13-16}-dQ^{i,13-16}_{\beta,5-8}dQ^{4-8}_{\alpha,13-16}-dQ^{13-16}_{5-8}dQ^{i,4-8}_{\alpha,\beta,13-16})dQ^{j,k,9-13}_{14-16,5-8} \\
&\quad -(dQ^{j,13-16}_{\alpha,5-8}dQ^{4-8}_{\beta,13-16}-dQ^{j,13-16}_{\beta,5-8}dQ^{4-8}_{\alpha,13-16}-dQ^{13-16}_{5-8}dQ^{j,4-8}_{\alpha,\beta,13-16})dQ^{i,k,9-13}_{14-16,5-8} \\
&\quad +(dQ^{k,13-16}_{\alpha,5-8}dQ^{4-8}_{\beta,13-16}-dQ^{k,13-16}_{\beta,5-8}dQ^{4-8}_{\alpha,13-16}-dQ^{13-16}_{5-8}dQ^{k,4-8}_{\alpha,\beta,13-16})dQ^{i,j,9-13}_{14-16,5-8}) \\
&= \sum_{\sigma\in S_3(i,j,k)} \frac{\operatorname{sgn}\sigma}{2} dQ^{\sigma_1,\sigma_2,9-13}_{14-16,5-8}((dQ^{\sigma_3,13-16}_{\alpha,5-8}dQ^{4-8}_{\beta,13-16}-dQ^{\sigma_3,13-16}_{\beta,5-8}dQ^{4-8}_{\alpha,13-16}) \\
&\quad -dQ^{13-16}_{5-8}dQ^{\sigma_3,4-8}_{\alpha,\beta,13-16}) \qquad (46) \\
&= dQ^{13-16}_{5-8}\Bigg(dQ^{i,j,k,9-13}_{\alpha,14-16,5-8}dQ^{4-8}_{\beta,13-16}-dQ^{i,j,k,9-13}_{\beta,14-16,5-8}dQ^{4-8}_{\alpha,13-16} \\
&\quad -\sum_{\sigma\in S_3(i,j,k)} \frac{\operatorname{sgn}\sigma}{2} dQ^{\sigma_1,\sigma_2,9-13}_{14-16,5-8}dQ^{\sigma_3,4-8}_{\alpha,\beta,13-16}\Bigg) \qquad (47) \\
&= \frac{dQ^{13-16}_{5-8}dQ^{5-8}_{1-4}}{dQ^{9-12}_{1-4}}\Bigg(dQ^{i,j,k,9-13}_{\alpha,14-16,5-8}dQ^{4,9-12}_{\beta,13-16}-dQ^{i,j,k,9-13}_{\beta,14-16,5-8}dQ^{4,9-12}_{\alpha,13-16} \\
&\quad -\sum_{\sigma\in S_3(i,j,k)} \frac{\operatorname{sgn}\sigma}{2} dQ^{\sigma_1,\sigma_2,9-13}_{14-16,5-8}dQ^{\sigma_3,4,9-12}_{\alpha,\beta,13-16}\Bigg) \qquad (48) \\
&= \frac{dQ^{13-16}_{5-8}dQ^{5-8}_{1-4}}{dQ^{9-12}_{1-4}}(\pm dQ^{4,9-13}_{\alpha,\beta,13-16}\,dQ^{i,j,k,9-12}_{14-16,5-8}\pm dQ^{4,9-12}_{\alpha,\beta,14-16}\,dQ^{i,j,k,9-13}_{13-16,5-8}) \qquad (49) \\
&= 0. \qquad (50)
\end{aligned}$$

Equation (47) follows from (46) and (43). Equation (48) follows from (47), (38), and (39). Equation (49) is the result of another Grassmann relation. The last equation, (50), holds because consistency conditions force $dQ^{4,9-12}_{\alpha,\beta,13-16}=0=dQ^{4,9-13}_{\alpha,\beta,13-16}$. □

Similar calculations hold for $Q11_{lr}$, $Q21_{lr}$, $Q21_{bt}$, $Q22_{bt}$, $Q22_{rl}$, $Q12_{rl}$, and $Q12_{tb}$, yielding 16 independent conditions upon the A^j_is:

$$0=\sum_{n=1}^{4} dQ^{n,9-13}_{\alpha,\beta,5-8}A^2_n \quad \text{for } \alpha,\beta\in\{14,15,16\}, \tag{51}$$

$$0=\sum_{n=1}^{4} dQ^{n,8-12}_{\alpha,\beta,13-16}A^3_n \quad \text{for } \alpha,\beta\in\{5,6,7\}, \tag{52}$$

$$0=\sum_{n=5}^{8} dQ^{n,1,13-16}_{\alpha,\beta,9-12}A^6_n \quad \text{for } \alpha,\beta\in\{2,3,4\}, \tag{53}$$

$$0=\sum_{n=5}^{8} dQ^{n,12-6}_{\alpha,\beta,1-4}A^7_n \quad \text{for } \alpha,\beta\in\{9,10,11\}, \tag{54}$$

$$0=\sum_{n=9}^{12} dQ^{n,1-5}_{\alpha,\beta,13-16}A^{10}_n \quad \text{for } \alpha,\beta\in\{6,7,8\}, \tag{55}$$

$$0=\sum_{n=9}^{12} dQ^{n,1-4,16}_{\alpha,\beta,5-8}A^{11}_n \quad \text{for } \alpha,\beta\in\{13,14,15\}, \tag{56}$$

$$0=\sum_{n=13}^{16} dQ^{n,5-9}_{\alpha,\beta,1-4}A^{14}_n \quad \text{for } \alpha,\beta\in\{10,11,12\}, \tag{57}$$

$$0=\sum_{n=13}^{16} dQ^{n,4-8}_{\alpha,\beta,9-12}A^{15}_n \quad \text{for } \alpha,\beta\in\{1,2,3\}. \tag{58}$$

4. Redundant "hard" conditions

In the previous section two equations were derived which force the first, second, and fourth columns of $Q11_{tb}$ to be rank two. In this section conditions forcing the first three columns of $Q11_{tb}$ to be rank two are shown to be equivalent to conditions (51)–(58).

The reader is reminded that this section is quite technical and is included for the sake of completeness. Much of the notation of the previous section is retained. Here, however, $r_{\mathbf{b}}$ and $r_{\mathbf{r}}$ are fixed so that $r_{\mathbf{b}}\equiv 9-12\equiv r_{\mathbf{r}}$. For the sake of notation, define the 2×4 matrices $\mathbf{L}$ and $\mathbf{D}$:

$$\mathbf{L}^j\equiv\begin{pmatrix} dQ^{j+12,5-8}_{\alpha,r_{\mathbf{r}}} \\ dQ^{j+12,5-8}_{\beta,r_{\mathbf{r}}} \end{pmatrix} \quad \text{and} \quad \mathbf{D}\equiv\mathbf{m}_{\alpha,\beta}. \tag{59}$$

The minor taken from rows α, β, 4 and first three columns of $Q11_{tb}$ can be written as follows:

$$\begin{vmatrix} Pih^5_\alpha & Pih^6_\alpha & Pih^{15}_\alpha \\ Pih^5_\beta & Pih^6_\beta & Pih^{15}_\beta \\ Phh^5_1 & Phh^6_1 & Phh^{15}_1 \end{vmatrix}$$

$$
\begin{aligned}
&= \left| \mathbf{N}(Q^{1-4}_{9-12})^{-1} Q^{5-8}_{9-12} A^{5,6}_{5-8} \vdots \left(\mathbf{N}(Q^{1-4}_{9-12})^{-1} Q^{13-16}_{9-12} + \frac{1}{dQ^{5-8}_{9-12}} \begin{pmatrix} \mathbf{L} \\ 0 \end{pmatrix} \right) A^{15}_{13-16} \right| \\
&= |\mathbf{N}(Q^{1-4}_{9-12})^{-1} [Q^{5-8}_{9-12} A^{5,6}_{5-8} \vdots Q^{13-16}_{9-12} A^{15}_{13-16}]| + \frac{1}{dQ^{5-8}_{9-12}} \\
&\quad \times \left| \mathbf{N}(Q^{1-4}_{9-12})^{-1} Q^{5-8}_{9-12} A^{5,6}_{5-8} \vdots \begin{pmatrix} \mathbf{L} \\ 0 \end{pmatrix} A^{15}_{13-16} \right| \\
&= C \left| \begin{matrix} \mathbf{D} A^{1,2}_{1-4} \\ 1 \quad 0 \end{matrix} \vdots \begin{pmatrix} \mathbf{L} \\ 0 \end{pmatrix}_j A^{15}_{13-16} \right|, \quad \text{since } \mathbf{N} \text{ is rank two} \\
&= C |\mathbf{D} A^2_{1-4} \vdots \mathbf{L} A^{15}_{13-16}|. \qquad (60)
\end{aligned}
$$

At first blush this appears to be quadratic in A^j_is. Equation (30) can be used to factor the A^j_is out of (60). Now define the matrices **F** and **G** whose columns are

$$
\mathbf{f}^j \equiv \begin{pmatrix} dQ^{j,9-13}_{14,15,5-8} \\ dQ^{j,9-13}_{14,16,5-8} \end{pmatrix}, \quad \mathbf{g}^j \equiv \begin{pmatrix} dQ^{j+12,4-8}_{1,2,9-12} \\ dQ^{j+12,4-8}_{1,3,9-12} \end{pmatrix}.
$$

Then (51) and (58) imply

$$
0 = \mathbf{F} \begin{pmatrix} A^2_1 \\ A^2_2 \\ A^2_3 \\ A^2_4 \end{pmatrix} \quad \text{and} \quad 0 = \mathbf{G} \begin{pmatrix} A^{15}_{13} \\ A^{15}_{14} \\ A^{15}_{15} \\ A^{15}_{16} \end{pmatrix}
$$

or

$$
\begin{pmatrix} A^2_1 \\ A^2_2 \\ A^2_3 \\ A^2_4 \end{pmatrix} = \begin{pmatrix} -[\mathbf{f}^1 \ \mathbf{f}^2]^{-1} [\mathbf{f}^3 \ \mathbf{f}^4] \\ I \end{pmatrix} \begin{pmatrix} A^2_3 \\ A^2_4 \end{pmatrix} \quad \text{and} \quad \begin{pmatrix} A^{15}_{13} \\ A^{15}_{14} \\ A^{15}_{15} \\ A^{15}_{16} \end{pmatrix} = \begin{pmatrix} -[\mathbf{g}^1 \ \mathbf{g}^2]^{-1} [\mathbf{g}^3 \ \mathbf{g}^4] \\ I \end{pmatrix} \begin{pmatrix} A^{15}_{15} \\ A^{15}_{16} \end{pmatrix}. \qquad (61)
$$

Plugging (59) and (61) into (60) takes the previously found ''hard'' conditions into account and yields

$$
C \left| \mathbf{D} \begin{pmatrix} -[\mathbf{f}^1 \ \mathbf{f}^2]^{-1} [\mathbf{f}^3 \ \mathbf{f}^4] \\ I \end{pmatrix} \begin{pmatrix} A^2_3 \\ A^2_4 \end{pmatrix} \vdots \mathbf{L} \begin{pmatrix} -[\mathbf{g}^1 \ \mathbf{g}^2]^{-1} [\mathbf{g}^3 \ \mathbf{g}^4] \\ I \end{pmatrix} \begin{pmatrix} A^{15}_{15} \\ A^{15}_{16} \end{pmatrix} \right|. \qquad (62)
$$

Showing that (62) is zero requires several steps:

(1) Show that $\mathbf{D}\left(\begin{smallmatrix} -[\mathbf{f}^1 \ \mathbf{f}^2]^{-1}[\mathbf{f}^3 \ \mathbf{f}^4] \\ I \end{smallmatrix}\right)$ and $\mathbf{L}\left(\begin{smallmatrix} -[\mathbf{g}^1 \ \mathbf{g}^2]^{-1}[\mathbf{g}^3 \ \mathbf{g}^4] \\ I \end{smallmatrix}\right)$ are both rank one.
(2) Compute column vectors $\mathbf{c}, \overline{\mathbf{c}}$, such that $\mathbf{D}\left(\begin{smallmatrix} -[\mathbf{f}^1 \ \mathbf{f}^2]^{-1}[\mathbf{f}^3 \ \mathbf{f}^4] \\ I \end{smallmatrix}\right) = \mathbf{c}\mathbf{r}^T$ and $\mathbf{L}\left(\begin{smallmatrix} -[\mathbf{g}^1 \ \mathbf{g}^2]^{-1}[\mathbf{g}^3 \ \mathbf{g}^4] \\ I \end{smallmatrix}\right) = \overline{\mathbf{c}}\overline{\mathbf{r}^T}$ for some column vectors $\mathbf{r}$, and $\overline{\mathbf{r}}$.
(3) Check that $0 \equiv |\mathbf{c} : \overline{\mathbf{c}}|$.

Step One: The following identity for any 2×4 matrix **F** is helpful:

$$
[\mathbf{f}^1 \ \mathbf{f}^2]^{-1} [\mathbf{f}^3 \ \mathbf{f}^4] = \frac{1}{|\mathbf{f}^1 \ \mathbf{f}^2|} \begin{bmatrix} -|\mathbf{f}^2 \ \mathbf{f}^3| & |\mathbf{f}^2 \ \mathbf{f}^4| \\ |\mathbf{f}^1 \ \mathbf{f}^3| & -|\mathbf{f}^1 \ \mathbf{f}^4| \end{bmatrix}.
$$

Therefore,

$$\left|\mathbf{f}^1\ \mathbf{f}^2||\mathbf{d}^1\mathbf{d}^2|\right|-[\mathbf{f}^1\ \mathbf{f}^2|^{-1}[\mathbf{f}^3\ \mathbf{f}^4|+[\mathbf{d}^1\ \mathbf{d}^2|^{-1}[\mathbf{d}^3\ \mathbf{d}^4|\Bigg|$$

$$=|\mathbf{f}^1\ \mathbf{f}^2||\mathbf{d}^1\ \mathbf{d}^2|\begin{vmatrix} +\left(\left|\frac{\mathbf{f}^2\ \mathbf{f}^3}{\mathbf{f}^1\ \mathbf{f}^2}\right|-\left|\frac{\mathbf{d}^2\ \mathbf{d}^3}{\mathbf{d}^1\ \mathbf{d}^2}\right|\right) & -\left(\left|\frac{\mathbf{f}^2\ \mathbf{f}^4}{\mathbf{f}^1\ \mathbf{f}^2}\right|-\left|\frac{\mathbf{d}^2\ \mathbf{d}^4}{\mathbf{d}^1\ \mathbf{d}^2}\right|\right) \\ -\left(\left|\frac{\mathbf{f}^1\ \mathbf{f}^3}{\mathbf{f}^1\ \mathbf{f}^2}\right|-\left|\frac{\mathbf{d}^1\ \mathbf{d}^3}{\mathbf{d}^1\ \mathbf{d}^2}\right|\right) & +\left(\left|\frac{\mathbf{f}^1\ \mathbf{f}^4}{\mathbf{f}^1\ \mathbf{f}^2}\right|-\left|\frac{\mathbf{d}^1\ \mathbf{d}^4}{\mathbf{d}^1\ \mathbf{d}^2}\right|\right) \end{vmatrix} \tag{63}$$

$$=\frac{1}{|\mathbf{f}^1\ \mathbf{f}^2||\mathbf{d}^1\ \mathbf{d}^2|}\,((|\mathbf{f}^2\ \mathbf{f}^3||\mathbf{d}^1\ \mathbf{d}^2|-|\mathbf{f}^1\ \mathbf{f}^2||\mathbf{d}^2\ \mathbf{d}^3|)(|\mathbf{f}^1\ \mathbf{f}^4||\mathbf{d}^1\ \mathbf{d}^2|$$
$$-|\mathbf{f}^1\ \mathbf{f}^2||\mathbf{d}^1\ \mathbf{d}^4|)-(|\mathbf{f}^1\ \mathbf{f}^3||\mathbf{d}^1\ \mathbf{d}^2|-|\mathbf{f}^1\ \mathbf{f}^2||\mathbf{d}^1\ \mathbf{d}^3|)(|\mathbf{f}^2\ \mathbf{f}^4||\mathbf{d}^1\ \mathbf{d}^2|$$
$$-|\mathbf{f}^1\ \mathbf{f}^2||\mathbf{d}^2\ \mathbf{d}^4|))$$

$$=\frac{1}{|\mathbf{f}^1\ \mathbf{f}^2||\mathbf{d}^1\ \mathbf{d}^2|}\,(|\mathbf{d}^1\ \mathbf{d}^2|^2(|\mathbf{f}^1\ \mathbf{f}^4||\mathbf{f}^2\ \mathbf{f}^3|$$
$$-|\mathbf{f}^1\ \mathbf{f}^3||\mathbf{f}^2\ \mathbf{f}^4|)+|\mathbf{f}^1\ \mathbf{f}^2|^2(|\mathbf{d}^1\ \mathbf{d}^4||\mathbf{d}^2\ \mathbf{d}^3|-|\mathbf{d}^1\ \mathbf{d}^3||\mathbf{d}^2\ \mathbf{d}^4|)$$
$$+|\mathbf{d}^1\ \mathbf{d}^2||\mathbf{f}^1\ \mathbf{f}^2|(-|\mathbf{d}^1\ \mathbf{d}^4||\mathbf{f}^2\ \mathbf{f}^3|-|\mathbf{f}^1\ \mathbf{f}^4||\mathbf{d}^2\ \mathbf{d}^3|+|\mathbf{f}^1\ \mathbf{f}^3||\mathbf{d}^2\ \mathbf{d}^4|$$
$$+|\mathbf{d}^1\ \mathbf{d}^3||\mathbf{f}^2\ \mathbf{f}^4|)) \tag{64}$$

$$=\frac{1}{|\mathbf{f}^1\ \mathbf{f}^2||\mathbf{d}^1\ \mathbf{d}^2|}\,(-|\mathbf{d}^1\ \mathbf{d}^2|^2|\mathbf{f}^1\ \mathbf{f}^2||\mathbf{f}^3\ \mathbf{f}^4|-|\mathbf{f}^1\ \mathbf{f}^2|^2|\mathbf{d}^1\ \mathbf{d}^2||\mathbf{d}^3\ \mathbf{d}^4|$$
$$+|\mathbf{d}^1\ \mathbf{d}^2||\mathbf{f}^1\ \mathbf{f}^2|(-|\mathbf{d}^1\ \mathbf{d}^4||\mathbf{f}^2\ \mathbf{f}^3|-|\mathbf{f}^1\ \mathbf{f}^4||\mathbf{d}^2\ \mathbf{d}^3|+|\mathbf{f}^1\ \mathbf{f}^3||\mathbf{d}^2\ \mathbf{d}^4|$$
$$+|\mathbf{d}^1\ \mathbf{d}^3||\mathbf{f}^2\ \mathbf{f}^4|)) \tag{65}$$

$$=-(|\mathbf{d}^1\ \mathbf{d}^2||\mathbf{f}^3\ \mathbf{f}^4|-|\mathbf{d}^1\ \mathbf{d}^3||\mathbf{f}^2\ \mathbf{f}^4|+|\mathbf{d}^1\ \mathbf{d}^4||\mathbf{f}^2\ \mathbf{f}^3|+|\mathbf{d}^2\ \mathbf{d}^3||\mathbf{f}^1\ \mathbf{f}^4|$$
$$-|\mathbf{d}^2\ \mathbf{d}^4||\mathbf{f}^1\ \mathbf{f}^3|+|\mathbf{d}^3\ \mathbf{d}^4||\mathbf{f}^1\ \mathbf{f}^2|) \tag{66}$$

$$=-\left|\begin{matrix}\mathbf{D}\\ \mathbf{F}\end{matrix}\right| \tag{67}$$

$$=-\left|\begin{matrix}\mathbf{d}_1\\ \mathbf{d}_2\\ \mathbf{F}\end{matrix}\right|=\frac{1}{dQ_{5-8}^{13-16}dQ_{\alpha,13-16}^{4-8}}\left|\begin{matrix}\mathbf{d}_1\\ -dQ_{5-8}^{13-16}dQ_{\alpha,13-16}^{4-8}\,\mathbf{d}_2\\ \mathbf{F}\end{matrix}\right|$$

$$=\frac{1}{dQ_{5-8}^{13-16}dQ_{\alpha,13-16}^{4-8}}\left|\begin{matrix}\mathbf{d}_1\\ dQ_{5-8}^{13-16}(dQ_{\beta,13-16}^{4-8}\,\mathbf{d}_1-dQ_{\alpha,13-16}^{4-8}\mathbf{d}_2)\\ \mathbf{F}\end{matrix}\right|$$

$$=\frac{1}{dQ_{5-8}^{13-16}dQ_{\alpha,13-16}^{4-8}}\left|\begin{matrix}\mathbf{d}_1\\ \mathbf{C}\end{matrix}\right|=0 \tag{68}$$

so

$$\left|-[\mathbf{f}^1\ \mathbf{f}^2]^{-1}[\mathbf{f}^3\ \mathbf{f}^4]+[\mathbf{d}^1\ \mathbf{d}^2]^{-1}[\mathbf{d}^3\ \mathbf{d}^4]\right|=0$$

Line (65) follows from (64) by virtue of Grassmann relations; (66) is simply the Laplace expansion of (67).[16] In equation (68), $\mathbf{C}$ is the same rank two matrix defined in (45), so $|^{\mathbf{d}_1}_{\mathbf{C}}|$ is rank deficient. Now,

$$\begin{aligned}
&\left|\mathbf{D}\begin{pmatrix} -[\mathbf{f}^1\ \ \mathbf{f}^2]^{-1}[\mathbf{f}^3\ \ \mathbf{f}^4] \\ I \end{pmatrix}\right| \\
&\quad = |-[\mathbf{d}^1\ \ \mathbf{d}^2][\mathbf{f}^1\ \ \mathbf{f}^2]^{-1}[\mathbf{f}^3\ \ \mathbf{f}^4]+[\mathbf{d}^3\ \ \mathbf{d}^4]| \\
&\quad = |[\mathbf{d}^1\ \ \mathbf{d}^2](-[\mathbf{f}^1\ \ \mathbf{f}^2]^{-1}[\mathbf{f}^3\ \ \mathbf{f}^4]+[\mathbf{d}^1\ \ \mathbf{d}^2]^{-1}[\mathbf{d}^3\ \ \mathbf{d}^4])| \\
&\quad = |[\mathbf{d}^1\ \ \mathbf{d}^2]|\left|(-[\mathbf{f}^1\ \ \mathbf{f}^2]^{-1}[\mathbf{f}^3\ \ \mathbf{f}^4]+[\mathbf{d}^1\ \ \mathbf{d}^2]^{-1}[\mathbf{d}^3\ \ \mathbf{d}^4])\right| = 0
\end{aligned}$$

so

$$\mathbf{D}\begin{pmatrix} -[\mathbf{f}^1\ \ \mathbf{f}^2]^{-1}[\mathbf{f}^3\ \ \mathbf{f}^4] \\ I \end{pmatrix}$$

is rank one. A similar method works to show that

$$\mathbf{L}\begin{pmatrix} -[\mathbf{g}^1\ \ \mathbf{g}^2]^{-1}[\mathbf{g}^3\ \ \mathbf{g}^4] \\ I \end{pmatrix}$$

is also rank one. Recall (31) and the definition of $\mathbf{l}_\alpha$:

$$\mathbf{l}_\alpha = (dQ^{13,5-8}_{\alpha,9-12}\quad dQ^{14,5-8}_{\alpha,9-12}\quad dQ^{15,5-8}_{\alpha,9-12}\quad dQ^{16,5-8}_{\alpha,9-12}).$$

Furthermore, define

$$\mathbf{l}_{\alpha,\beta} = (dQ^{13,4-8}_{\alpha,\beta,9-12}\quad dQ^{14,4-8}_{\alpha,\beta,9-12}\quad dQ^{15,4-8}_{\alpha,\beta,9-12}\quad dQ^{16,4-8}_{\alpha,\beta,9-12})$$

and notice that

$$dQ^{4-8}_{\beta,9-12}\mathbf{l}_\alpha - dQ^{4-8}_{\alpha,9-12}\mathbf{l}_\beta = dQ^{5-8}_{9-12}\mathbf{l}_{\alpha\beta}.$$

The argument used to go from (63) to (67) and the fact that

$$\mathbf{L} = \begin{pmatrix} \mathbf{l}_\alpha \\ \mathbf{l}_\beta \end{pmatrix} \quad \text{and} \quad \mathbf{G} = \begin{pmatrix} \mathbf{l}_{1,2} \\ \mathbf{l}_{1,3} \end{pmatrix}$$

lead to the following:

$$\begin{aligned}
\left|\mathbf{L}\begin{pmatrix} -[\mathbf{g}^1\ \ \mathbf{g}^2]^{-1}[\mathbf{g}^3\ \ \mathbf{g}^4] \\ I \end{pmatrix}\right| &= |[\mathbf{l}^1\ \ \mathbf{l}^2]|\,|(-[\mathbf{g}^1\ \ \mathbf{g}^2]^{-1}[\mathbf{g}^3\ \ \mathbf{g}^4]+[\mathbf{l}^1\ \ \mathbf{l}^2]^{-1}[\mathbf{l}^3\ \ \mathbf{l}^4])| = |[\mathbf{l}^1\ \ \mathbf{l}^2]|\left|\begin{matrix}\mathbf{L}\\ \mathbf{G}\end{matrix}\right| \\
&= |[\mathbf{l}^1\ \ \mathbf{l}^2]|\begin{vmatrix} \mathbf{l}_\alpha \\ \mathbf{l}_\beta \\ \mathbf{l}_{1,2} \\ \mathbf{l}_{1,3} \end{vmatrix} = |[\mathbf{l}^1\ \ \mathbf{l}^2]|\begin{vmatrix} \mathbf{l}_\alpha \\ \mathbf{l}_\beta \\ dQ^{4-8}_{2,9-12}\mathbf{l}_1 - dQ^{4-8}_{1,9-12}\mathbf{l}_2 \\ dQ^{4-8}_{3,9-12}\mathbf{l}_1 - dQ^{4\times 8}_{1,9-12}\mathbf{l}_2 \end{vmatrix}
\end{aligned}$$

$$= |[\mathbf{l}^1 \ \ \mathbf{l}^2]| \left| \begin{pmatrix} & \mathbf{e}_\alpha & \\ & \mathbf{e}_\beta & \\ dQ^{4-8}_{2,9-12} & -dQ^{4-8}_{1,9-12} & 0 \\ dQ^{4-8}_{3,9-12} & 0 & -dQ^{4-8}_{1,9-12} \end{pmatrix} \begin{pmatrix} \mathbf{l}_1 \\ \mathbf{l}_2 \\ \mathbf{l}_3 \end{pmatrix} \right| = 0,$$

since the product of a 4×3 with a 3×4 matrix is a 4×4 rank-deficient matrix.

Step Two: Brute force suffices to find the column vector $\mathbf{c}$ where

$$\begin{aligned}
\mathbf{c}\mathbf{r}^T &= \mathbf{D}\begin{pmatrix} -[\mathbf{f}^1 \ \ \mathbf{f}^2]^{-1}[\mathbf{f}^3 \ \ \mathbf{f}^4] \\ I \end{pmatrix} \\
&= -[\mathbf{d}^1 \ \ \mathbf{d}^2][\mathbf{f}^1 \ \ \mathbf{f}^2]^{-1}[\mathbf{f}^3 \ \ \mathbf{f}^4] + [\mathbf{d}^3 \ \ \mathbf{d}^4] \\
&= -\frac{1}{|\mathbf{f}^1 \ \ \mathbf{f}^2|}[\mathbf{d}^1 \ \ \mathbf{d}^2]\begin{bmatrix} -|\mathbf{f}^2 \ \ \mathbf{f}^3| & -|\mathbf{f}^2 \ \ \mathbf{f}^4| \\ |\mathbf{f}^1 \ \ \mathbf{f}^3| & |\mathbf{f}^1 \ \ \mathbf{f}^4| \end{bmatrix} + [\mathbf{d}^3 \ \ \mathbf{d}^4] \\
&= -\frac{1}{|\mathbf{f}^1 \ \ \mathbf{f}^2|}[-|\mathbf{f}^2 \ \ \mathbf{f}^3|\mathbf{d}^1 + |\mathbf{f}^1 \ \ \mathbf{f}^3|\mathbf{d}^2 : -|\mathbf{f}^2 \ \ \mathbf{f}^4|\mathbf{d}^1 + |\mathbf{f}^1 \ \ \mathbf{f}^4|\mathbf{d}^2] + [\mathbf{d}^3 : \mathbf{d}^4] \\
&= \frac{1}{|\mathbf{f}^1 \mathbf{f}^2|}[(|\mathbf{f}^2 \ \ \mathbf{f}^3|\mathbf{d}^1 - |\mathbf{f}^1 \ \ \mathbf{f}^3|\mathbf{d}^2 + |\mathbf{f}^1 \ \ \mathbf{f}^2|\mathbf{d}^3) : (|\mathbf{f}^2 \ \ \mathbf{f}^4|\mathbf{d}^1 - |\mathbf{f}^1 \ \ \mathbf{f}^4|\mathbf{d}^2 + |\mathbf{f}^1 \ \ \mathbf{f}^2|\mathbf{d}^4)]
\end{aligned}$$

therefore set $\mathbf{c} \equiv [|\mathbf{f}^2 \ \mathbf{f}^3|\mathbf{d}^1 - |\mathbf{f}^1 \ \mathbf{f}^3|\mathbf{d}^2 + |\mathbf{f}^1 \ \mathbf{f}^2|\mathbf{d}^3]$. A similar calculation holds to show

$$\mathbf{L}\begin{pmatrix} -[\mathbf{g}^1 \ \ \mathbf{g}^2]^{-1}[\mathbf{g}^3 \ \ \mathbf{g}^4] \\ I \end{pmatrix} = \overline{\mathbf{c}\,\mathbf{r}^T} \quad \text{for} \quad \overline{\mathbf{c}} = [|\mathbf{g}^2 \ \ \mathbf{g}^3|\mathbf{l}^1 - |\mathbf{g}^1 \ \ \mathbf{g}^3|\mathbf{l}^2 + |\mathbf{g}^1 \ \ \mathbf{g}^2|\mathbf{l}^3].$$

Step Three: In order to show that (60) is trivially zero a few more identities are needed. Because Q^{1-8}_{9-16} is generically of rank four, $Q^{5-8}_{9-12} = Q^{1-4}_{9-12}(Q^{1-4}_{13-16})^{-1}Q^{5-8}_{13-16}$ and $dQ^{4-8}_{\alpha,9-12}$ can be expressed as a product of minors

$$\begin{aligned}
dQ^{4-8}_{\alpha,9-12} &= \begin{vmatrix} Q^4_\alpha & \vdots & Q^{5-8}_\alpha \\ Q^4_{9-12} & \vdots & Q^{5-8}_{9-12} \end{vmatrix} = \begin{vmatrix} Q^4_\alpha & \vdots & Q^{5-8}_\alpha \\ Q^4_{9-12} & \vdots & Q^{1-4}_{9-12}(Q^{1-4}_{13-16})^{-1}Q^{5-8}_{13-16} \end{vmatrix} \\
&= \begin{vmatrix} 1 & & \\ & Q^{1-4}_{9-12} & \end{vmatrix} \begin{vmatrix} Q^4_\alpha & \vdots & Q^{5-8}_\alpha \\ \mathbf{e}_4 & \vdots & (Q^{1-4}_{13-16})^{-1}Q^{5-8}_{13-16} \end{vmatrix} \\
&= \begin{vmatrix} 1 & & \\ & Q^{1-4}_{9-12} & \end{vmatrix} \begin{vmatrix} 1 & & \\ & (Q^{1-4}_{13-16})^{-1} & \end{vmatrix} \begin{vmatrix} Q^4_\alpha & \vdots & Q^{5-8}_\alpha \\ Q^4_{13-16} & \vdots & Q^{5-8}_{13-16} \end{vmatrix} \\
&= dQ^{4-8}_{\alpha,13-16}\frac{dQ^{1-4}_{9-12}}{dQ^{1-4}_{13-16}}.
\end{aligned} \tag{69}$$

The Grassmann relation

$$\sum_{\sigma\in S_3} \frac{\operatorname{sgn}\sigma}{2} dQ^{\sigma_1,\sigma_2,4-8}_{1-3,9-12} dQ^{\sigma_3,5-8}_{\alpha,9-12} = dQ^{\sigma_1,\sigma_2,\sigma_3,5-8}_{1-3,9-12} dQ^{4-8}_{\alpha,9-12},$$

as well as Grassmann relations for the minors

$$|\mathbf{f}^j \ \ \mathbf{f}^k| = dQ^{9-13}_{14,5-8} dQ^{j,k,9-13}_{14-16,5-8},$$

$$|\mathbf{g}^j \ \ \mathbf{g}^k| = dQ^{4-8}_{1,9-12} dQ^{j+12,k+12,4-8}_{1-3,9-12},$$

can be used to write $\overline{\mathbf{c}}$ fairly simply:

$$\begin{aligned}\overline{\mathbf{c}} &= \sum_{\sigma\in S_3} \frac{\operatorname{sgn}\sigma}{2} |\mathbf{g}^{\sigma_1} \ \mathbf{g}^{\sigma_2}| \mathbf{l}^{\sigma_3} \\ &= dQ^{4-8}_{1,9-12} \sum_{\sigma\in S_3(13,14,15)} \frac{\operatorname{sgn}\sigma}{2} dQ^{\sigma_1,\sigma_2,4-8}_{1-3,9-12} \begin{pmatrix} dQ^{\sigma_3,5-8}_{\alpha,9-12} \\ dQ^{\sigma_3,5-8}_{\beta,9-12} \end{pmatrix} \\ &= dQ^{4-8}_{1,9-12} dQ^{13,14,15,5-8}_{1-3,9-12} \begin{pmatrix} dQ^{4-8}_{\alpha,9-12} \\ dQ^{4-8}_{\beta,9-12} \end{pmatrix} = \tilde{\kappa} \begin{pmatrix} dQ^{4-8}_{\alpha,13-16} \\ dQ^{4-8}_{\beta,13-16} \end{pmatrix}.\end{aligned}$$

The last line follows from Eq. (69) for some $\overline{\kappa}\in\mathbb{R}$. Computing $\mathbf{c}$ is more complicated. First note that Eqs. (38) and (39) can be used to rewrite

$$\mathbf{d}^i \equiv \begin{pmatrix} \dfrac{dQ^{i,13-16}_{\alpha,5-8}}{dQ^{13-16}_{5-8}} - \dfrac{dQ^{i,5-8}_{\alpha,13-16}}{dQ^{5-8}_{13-16}} \\ \dfrac{dQ^{i,13-16}_{\beta,5-8}}{dQ^{13-16}_{5-8}} - \dfrac{dQ^{i,5-8}_{\beta,13-16}}{dQ^{5-8}_{13-16}} \end{pmatrix} = \begin{pmatrix} \dfrac{dQ^{i,9-12}_{\alpha,5-8}}{dQ^{9-12}_{5-8}} - \dfrac{dQ^{i,9-12}_{\alpha,13-16}}{dQ^{9-12}_{13-16}} \\ \dfrac{dQ^{i,9-12}_{\beta,5-8}}{dQ^{9-12}_{5-8}} - \dfrac{dQ^{i,9-12}_{\beta,13-16}}{dQ^{9-12}_{13-16}} \end{pmatrix} = \mathbf{d}^i_a - \mathbf{d}^i_b,$$

where

$$\mathbf{d}^i_a \equiv \frac{1}{dQ^{9-12}_{5-8}} \begin{pmatrix} dQ^{i,9-12}_{\alpha,5-8} \\ dQ^{i,9-12}_{\beta,5-8} \end{pmatrix} \quad \text{and} \quad \mathbf{d}^i_b \equiv \frac{1}{dQ^{9-12}_{13-16}} \begin{pmatrix} dQ^{i,9-12}_{\alpha,13-16} \\ dQ^{i,9-12}_{\beta,13-16} \end{pmatrix}.$$

A combination of Grassmann relations and range conditions are required now

$$\begin{aligned}\sum_{\sigma\in S_3} \frac{\operatorname{sgn}\sigma}{2} dQ^{\sigma_1,\sigma_2,9-13}_{14-16,5-8} dQ^{\sigma_3,9-12}_{\alpha,5-8} &= \pm dQ^{\sigma_1,\sigma_2,\sigma_3,9-12}_{14-16,5-8} dQ^{9-13}_{\alpha,5-8} + dQ^{\sigma_1,\sigma_2,\sigma_3,9-13}_{\alpha,14-16,5-8} dQ^{9-12}_{5-8} \\ &= dQ^{\sigma_1,\sigma_2,\sigma_3,9-13}_{\alpha,14-16,5-8} dQ^{9-12}_{5-8},\end{aligned}$$

since consistency conditions force $dQ^{9-13}_{\alpha,5-8} \equiv 0$. Another identity is useful:

$$\begin{aligned}\sum_{\sigma\in S_3} \frac{\operatorname{sgn}\sigma}{2} dQ^{\sigma_1,\sigma_2,9-13}_{14-16,5-8} dQ^{\sigma_3,9-12}_{\alpha,13-16} &= dQ^{9-12}_{13-16} \, dQ^{1-3,9-13}_{\alpha,14-16,5-8} + dQ^{9-13}_{\alpha,13-16} \, dQ^{1-3,9-12}_{14-16,5-8} \\ &\quad - dQ^{9-12}_{\alpha,14-16} \, dQ^{1-3,9-13}_{13-16,5-8}.\end{aligned}$$

Therefore,

$$\begin{aligned}\sum_{\sigma\in S_3} \frac{\operatorname{sgn}\sigma}{2} |\mathbf{f}^{\sigma_1} \mathbf{f}^{\sigma_2}| \mathbf{d}^{\sigma_3}_a &= \frac{dQ^{9-13}_{14,5-8}}{dQ^{9-12}_{5-8}} \sum_{\sigma\in S_3} \frac{\operatorname{sgn}\sigma}{2} dQ^{\sigma_1,\sigma_2,9-13}_{14-16,5-8} \begin{pmatrix} dQ^{\sigma_3,9-12}_{\alpha,5-8} \\ dQ^{\sigma_3,9-12}_{\beta,5-8} \end{pmatrix} \\ &= dQ^{9-13}_{14,5-8} \begin{pmatrix} dQ^{1-3,9-13}_{\alpha,14-16,5-8} \\ dQ^{1-3,9-13}_{\beta,14-16,5-8} \end{pmatrix} \qquad (70)\end{aligned}$$

and

$$\sum_{\sigma\in S_3}\frac{\operatorname{sgn}\sigma}{2}|\mathbf{f}^{\sigma_1}\ \mathbf{f}^{\sigma_2}|\mathbf{d}_b^{\sigma_3}=\frac{dQ^{9-13}_{14,5-8}}{dQ^{9-12}_{13-16}}\sum_{\sigma\in S_3}\frac{\operatorname{sgn}\sigma}{2}dQ^{\sigma_1,\sigma_2,9-13}_{14-16,5-8}\begin{pmatrix}dQ^{\sigma_3,9-12}_{\alpha,13-16}\\ dQ^{\sigma_3,9-12}_{\beta,13-16}\end{pmatrix}$$
$$=dQ^{9-13}_{14,5-8}\begin{pmatrix}dQ^{1-3,9-13}_{\alpha,14-16,5-8}\\ dQ^{1-3,9-13}_{\beta,14-16,5-8}\end{pmatrix}+\frac{dQ^{9-13}_{14,5-8}}{dQ^{9-12}_{13-16}}\left(dQ^{1-3,9-12}_{14-16,5-8}\begin{pmatrix}dQ^{9-13}_{\alpha,13-16}\\ dQ^{9-13}_{\beta,13-16}\end{pmatrix}\right.$$
$$\left.-dQ^{1-3,9-13}_{13-16,5-8}\begin{pmatrix}dQ^{9-12}_{\alpha,14-16}\\ dQ^{9-12}_{\beta,14-16}\end{pmatrix}\right).\tag{71}$$

Notice that thanks to range conditions

$$\begin{vmatrix}dQ^{9-13}_{\alpha,13-16} & dQ^{9-12}_{\alpha,14-16}\\ dQ^{9-13}_{\beta,13-16} & dQ^{9-12}_{\beta,14-16}\end{vmatrix}=\pm dQ^{9-13}_{\alpha,\beta,14-16}\,dQ^{9-12}_{13-16}=0,$$

which permits (71) to be written more simply. For some $\kappa,\hat{\kappa}\in\mathbb{R}$,

$$\sum_{\sigma\in S_3}\frac{\operatorname{sgn}\sigma}{2}|\mathbf{f}^{\sigma_1}\ \mathbf{f}^{\sigma_2}|\mathbf{d}_b^{\sigma_3}=dQ^{9-13}_{14,5-8}\begin{pmatrix}dQ^{1-3,9-13}_{\alpha,14-16,5-8}\\ dQ^{1-3,9-13}_{\beta,14-16,5-8}\end{pmatrix}+\hat{\kappa}\begin{pmatrix}dQ^{9-13}_{\alpha,13-16}\\ dQ^{9-13}_{\beta,13-16}\end{pmatrix}$$
$$=dQ^{9-13}_{14,5-8}\begin{pmatrix}dQ^{1-3,9-13}_{\alpha,14-16,5-8}\\ dQ^{1-3,9-13}_{\beta,14-16,5-8}\end{pmatrix}+\kappa\begin{pmatrix}dQ^{5-8,13}_{\alpha,13-16}\\ dQ^{5-8,13}_{\beta,13-16}\end{pmatrix}.\tag{72}$$

The last line follows from (39). Equations (70) and (72) imply

$$\mathbf{c}=\sum_{\sigma\in S_3}\frac{\operatorname{sgn}\sigma}{2}|\mathbf{f}^{\sigma_1}\ \mathbf{f}^{\sigma_2}|\mathbf{d}^{\sigma_3}=\sum_{\sigma\in S_3}\frac{\operatorname{sgn}\sigma}{2}|\mathbf{f}^{\sigma_1}\ \mathbf{f}^{\sigma_2}|(\mathbf{d}_a^{\sigma_3}-\mathbf{d}_b^{\sigma_3})=\kappa\begin{pmatrix}dQ^{5-8,13}_{\alpha,13-16}\\ dQ^{5-8,13}_{\beta,13-16}\end{pmatrix}.\tag{73}$$

The Grassmann relation

$$\begin{vmatrix}dQ^{5-8,13}_{\alpha,13-16} & dQ^{4-8}_{\alpha,13-16}\\ dQ^{5-8,13}_{\beta,13-16} & dQ^{4-8}_{\beta,13-16}\end{vmatrix}=\pm dQ^{4-8,13}_{\alpha,\beta,13-16}\,dQ^{5-8}_{13-16}$$

can be used to simplify

$$|\mathbf{c}\ \overline{\mathbf{c}}|=\hat{\kappa}\kappa\begin{vmatrix}dQ^{5-8,13}_{\alpha,13-16} & dQ^{4-8}_{\alpha,9-12}\\ dQ^{5-8,13}_{\beta,13-16} & dQ^{4-8}_{\beta,9-12}\end{vmatrix}=\pm\hat{\kappa}\kappa(dQ^{4-8,13}_{\alpha,\beta,13-16}\quad dQ^{5-8}_{13-16})=0.$$

The last equality follows from range conditions. Since $\alpha,\beta\in\{1,2,3\}$, rank $Q^{4-8,13}_{\alpha,\beta,14-16}\leqslant 4$. Therefore, rank $Q^{4-8,13}_{\alpha,\beta,13-16}\leqslant 5$, forcing $dQ^{4-8,13}_{\alpha,\beta,13-16}=0$. Finally, steps 1–3 imply

$$\begin{vmatrix}Pih^5_\alpha & Pih^6_\alpha & Pih^{15}_\alpha\\ Pih^5_\beta & Pih^6_\beta & Pih^{15}_\beta\\ Phh^5_1 & Phh^6_1 & Phh^{15}_1\end{vmatrix}=C|\mathbf{D}A^2_{1-4}:\mathbf{L}A^{15}_{13-16}|$$
$$=\left|\mathbf{D}\begin{pmatrix}-[\mathbf{f}^1\ \mathbf{f}^2]^{-1}[\mathbf{f}^3\ \mathbf{f}^4]\\ I\end{pmatrix}\begin{pmatrix}A^3_2\\ A^2_4\end{pmatrix}:\mathbf{L}\begin{pmatrix}-[\mathbf{g}^1\ \mathbf{g}^2]^{-1}[\mathbf{g}^3\ \mathbf{g}^4]\\ I\end{pmatrix}\begin{pmatrix}A^{15}_{15}\\ A^{15}_{16}\end{pmatrix}\right|$$
$$=\left|\mathbf{cr}^T\begin{pmatrix}A^2_3\\ A^2_4\end{pmatrix}:\overline{\mathbf{cr}}^T\begin{pmatrix}A^{15}_{15}\\ A^{15}_{16}\end{pmatrix}\right|\begin{vmatrix}Pih^5_\alpha & Pih^6_\alpha & Pih^{15}_\alpha\\ Pih^5_\beta & Pih^6_\beta & Pih^{15}_\beta\\ Phh^5_1 & Phh^6_1 & Phh^{15}_1\end{vmatrix}$$

$$= \left(\mathbf{r}^T \cdot \begin{pmatrix} A_3^2 \\ A_4^2 \end{pmatrix}\right) * \left(\overline{\mathbf{r}^T} \cdot \begin{pmatrix} A_{15}^{15} \\ A_{16}^{15} \end{pmatrix}\right) * |\mathbf{c}:\overline{\mathbf{c}}|$$

$$= 0.$$

Similar calculations hold to show that other minors of this ilk are trivially zero and force no additional conditions upon the A_i^js.

IV. CONCLUSION

Enforcing range conditions upon the solution of the ''modified problem,'' which subdivides a 4×4 system in to four subsystems, was done analytically in Sec. III. That it might prove computationally infeasible to eliminate excess parameters for larger systems has been one of the author's greatest fears for diffuse tomography. Some of the tricks used here carry over to larger systems. Others, however, do not. For example, the derivation of the condition (30) does not go through. The author's goal is to implement a recursive scheme which generates data for $n/2\times n/2$ subsystems from an $n\times n$ system's data set. In order to implement such a scheme a complete and computationally reasonable set of conditions analogous to (16)–(18) and (51)–(58) is required. Hopefully, they will be as succinct and linear as their counterparts for the 4×4 problem.

(Received 27 November 1995; accepted for publication 8 January 1996)

This paper shows that various models of electron transport in semiconductors that have been previously proposed in the literature can be connected one with each other by the diffusion approximation methodology. We first investigate the diffusion limit of the semiconductor Boltzmann equation towards the so-called ''spherical harmonic expansion model,'' under the assumption of dominant elastic scattering. Then, this model is again connected, either to the energy-transport model or to a ''periodic spherical harmonic expansion model'' through a diffusion approximation, respectively making electron–electron or phonon scattering large. We provide the mathematical background which makes the Hilbert expansions associated with these various diffusion limits rigorous. © *1996 American Institute of Physics.* [S0022-2488(96)01306-0]

I. INTRODUCTION

This paper is concerned first with a mathematical derivation of the spherical harmonic expansion model of semiconductors from the Boltzmann equation and, second, with the connections of this model to other previously derived macroscopic models (energy-transport, drift-diffusion, and periodic spherical harmonic expansion models). Indeed, the search for macroscopic models which provide reliable but not too computationally expensive descriptions of hot electron transport in semiconductors is an important issue for industry. This paper intends to clarify the relations between the various models of semi-classical electron-transport that are now available.

In this paper, the hierarchy between the various models is outlined, together with the macroscopic limit which links two successive steps of the hierarchy. Each macroscopic limit is associated with a particular choice of space and time scales which makes a specific collision mechanism dominant. Figure 1 provides an overview of this hierarchy. Each of the considered models appears in a box together with its abbreviation and the physical unknown it is concerned with. An arrow between two boxes indicates a macroscopic limit which connects the corresponding models. Solid lines indicate which macroscopic limits will be detailed in this paper. Dashed arrows have already been dealt with in previous papers and will not be considered. Along the arrow is mentioned the dominant scattering mechanism which is used in the corresponding macroscopic limit.

The drift–diffusion limit (arrow 1) has first been investigated in Ref. 1 and successively by many authors.[2–5] The mathematical theory has been given in Refs. 6 and 7 in the framework of model collision operators for which the scattering matrix is assumed to be smooth. This direct arrow from the Boltzmann equation (BE) to the drift-diffusion model (DD) is well understood and will not be investigated here.

More recently, a new model based on the diffusion approximation of the Boltzmann equation subject to dominant scattering by optical phonons of constant energy has been proposed,[8–10] (arrow 2). This new model will further be referred to as the ''periodic spherical harmonic expansion model'' (PSHE) because of its analogy with the (unperiodic) spherical harmonic expansion model (SHE). Mathematically rigorous approximation theorems are given in Refs. 8 and 9; part of the analysis relies on properties of the optical phonon collision operator which were proved in Refs. 11–13. This arrow 2 will not be further investigated here.

The energy-transport model (ET) consists of a system of diffusion equations for the electron density and temperature. This extended drift-diffusion model can also be viewed as a hydrodynamic model in which the inertia terms in the momentum transport equation are neglected[14–16]

0022-2488/96/37(7)/3306/28/$10.00

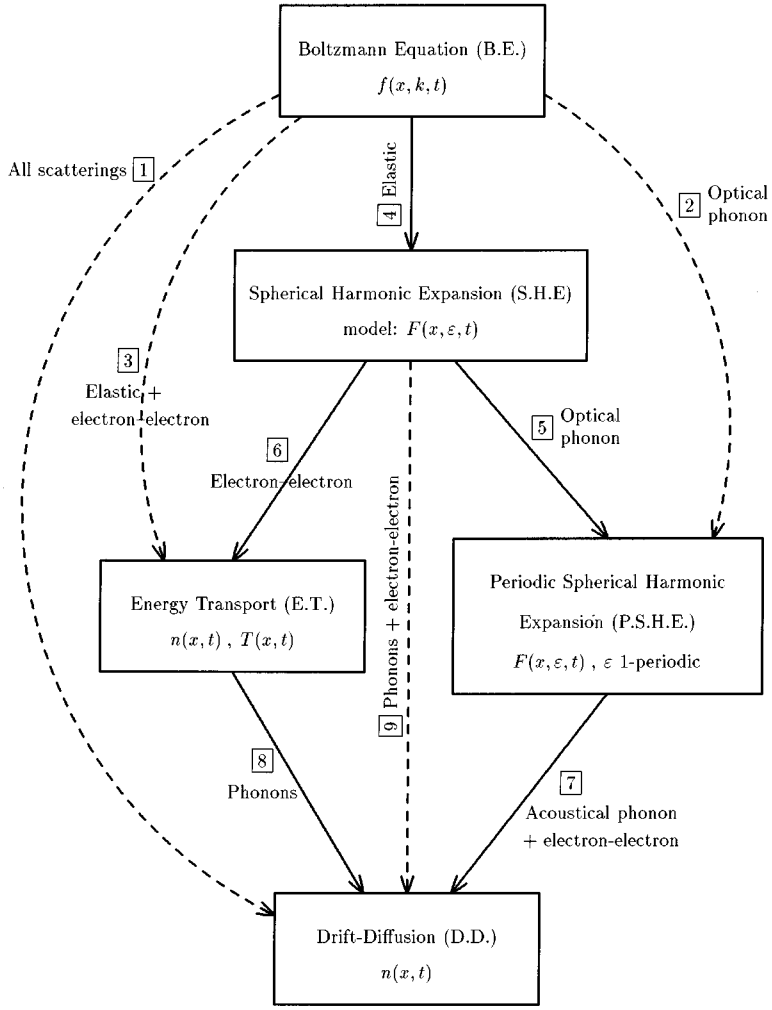

FIG. 1. The hierarchy of models.

(for the hydrodynamic model of semiconductors we refer the reader in particular to Refs. 17–19). The ET model first appeared in Refs. 20 and 21 and then has been widely used for numerical computations,[14,15,22,23] mostly with phenomenological transport coefficients. Its derivation from the Boltzmann equation may be found in Refs. 24 and 25. The dominant scatterings needed for this model to be valid are shown in Ref. 16 to be electron–electron and elastic collisions (arrow 3). Mathematically rigorous convergence results for this limit are in progress.[26] Again, this limit will not be further investigated in the present paper.

There are several drawbacks to the approaches of Ref. 10 (for the PSHE model) and of Ref. 16 (for the ET model). In neither case is the assumption on the dominant scattering realistic for hot electron transport. Indeed, the basic assumption of Ref. 10 is that the (constant) optical phonon energy is of order 1. However, at room temperature and for hot electrons this energy should rather be considered as small and both the impurity and phonon scatterings viewed (at leading order) as elastic. Also, in Ref. 16, the electron–electron collision operator is assumed of the same order of magnitude as the elastic operator, which is questionable. Therefore, in the present paper, we investigate the diffusion approximation of the Boltzmann equation subject to dominant elastic scattering, which yields the SHE model (arrow 4).

This question has first been investigated in Ref. 27. Another drawback of Refs. 10 and 16 is that the diffusion constants coming from these theories are not explicit. We shall see that both the PSHE model and the ET model can be obtained through relaxation limits of the SHE model (arrows 5 and 6) and that these limits yield more explicit expressions of the diffusion coefficients (even analytic in the most simple situations).

The SHE model first appeared in studies by Stratton.[20,21,28,29] Then, it was introduced as a numerical method in Refs. 30–37. The first derivation of this model from a diffusion approximation of the Boltzmann equation appears in Ref. 27 and we shall follow their approach. However, the analysis of Ref. 27 is restricted to isotropic scattering while that of Ref. 30 is restricted to spherically symmetric band diagrams. We shall derive the model in a general setting and show that it reduces to that of Refs. 27 and 30 under suitable assumptions. This more general approach applies particularly to III–V materials, for instance, for which the phonon collisions are highly anisotropic and the band diagrams not spherically symmetric. We shall also provide the necessary mathematical framework to make these analyses more rigorous. However, the proof of the convergence of the diffusion approximation will be deferred to future work.

The relaxation limits of the SHE model towards the PSHE model (arrow 5) and towards the ET model (arrow 6) will also be considered in detail. In Ref. 38, arrow 6 is investigated via a moment expansion method but needs phenomenological closure relations. In our ET model, the diffusion coefficients are the same as in Ref. 20. At variance, the investigation of arrow 5 is new and is proved directly via a coercivity estimate (contrary to Refs. 9 and 10 where the resolution of a recursion system is needed).

To be complete, the relaxation limits of both the PSHE model and the ET model towards the drift-diffusion (DD) model (arrows 7 and 8) will be outlined. Arrow 7 is treated by considering both acoustical phonon and electron–electron scattering. At variance, Ref. 10 treats such a limit by considering a second polar optical phonon scattering with an irrational phonon energy with respect to the first optical phonon energy. Finally the direct limit of the SHE model to the DD model (arrow 9) is not considered but would be rather straightforward. Note that the three limits (arrows 7–9) yield the same diffusion coefficient in the DD model and that its expression is different from what the direct limit from the Boltzmann equation (arrow 1) would give.

The paper is organized as follows: Sec. II is devoted to a presentation of the Boltzmann equation and of the appropriate scaling. Section III is concerned with the diffusion limit of the Boltzmann equation to the SHE model (arrow 4). In Sec. IV we deal with the relaxation limit of the SHE model to the ET model (arrow 6) and outline the relaxation limit of the latter to the DD model (arrow 8). In Sec. V, we perform a similar program going from the SHE model to the PSHE model and then to the DD model, via a sequence of relaxation limits (arrows 5 and 7).

II. THE BOLTZMANN EQUATION

The starting point is the Boltzmann equation for the electrons in the conduction band of the semiconductor. Let $f(x,k,t)$ be the distribution function depending on the position $x \in \mathbb{R}^3$, the wave vector $k \in B$, and the time $t \geqslant 0$. The Brillouin zone B is the elementary cell of the dual lattice L^* and is identified with the torus $\mathbb{R}^3/L^*$. Any function of k will thus be considered as L^* periodic.

The Boltzmann equation is written[25]

$$\frac{\partial f}{\partial t} + \frac{1}{\hbar}\,\nabla_k \varepsilon(k)\cdot\nabla_x f + \frac{q}{\hbar}\,\nabla_x V(x,t)\cdot\nabla_k f = Q_{\mathrm{ld}}(f) + Q_e(f), \tag{II.1}$$

where $\varepsilon: k \in B \mapsto \varepsilon(k) \in \mathbb{R}$ is the given energy band diagram, $V:(x,t) \in \mathbb{R}^3 \times [0,\infty) \mapsto \mathbb{R}$ is the electrostatic potential, q is the elementary charge, $\hbar$ is the reduced Planck constant, $Q_{\mathrm{ld}}(f)$ is the collision operator for lattice-defect collisions, and $Q_e(f)$ is the collision operator for electron–

electron collisions. The coupling of V to f through Poisson's equation need not be considered in the subsequent analysis. Therefore, $V(x,t)$ will be treated as a given function.

The main three classes of lattice-defects are impurities, acoustical phonons, and optical phonons:[39]

$$Q_{\rm ld}(f)=Q_{\rm imp}(f)+Q_{ac}(f)+Q_{\rm op}(f), \tag{II.2}$$

Because of the elastic character of impurity scattering, Pauli's exclusion terms in the gain and loss terms cancel and we obtain

$$Q_{\rm imp}(f)(k)=\int_B \Phi_{\rm imp}(x,k,k')\,\delta(\varepsilon'-\varepsilon)(f'-f)dk', \tag{II.3}$$

where $\varepsilon=\varepsilon(k)$, $\varepsilon'=\varepsilon(k')$, $f=f(k)$, $f'=f(k')$, δ is the delta measure, and $\Phi_{\rm imp}(x,k,k')=\Phi_{\rm imp}(x,k',k)$ is the impurity scattering matrix element. For optical phonons, we have

$$\begin{aligned} Q_{\rm op}(f)(k)=\int_B \Phi_{\rm op}(x,k,k')\{&[(N_{\rm op}+1)\delta(\varepsilon-\varepsilon'+\varepsilon_{\rm op})+N_{\rm op}\delta(\varepsilon-\varepsilon'-\varepsilon_{\rm op})]f'(1-f)\\ &-[(N_{\rm op}+1)\delta(\varepsilon'-\varepsilon+\varepsilon_{\rm op})+N_{\rm op}\delta(\varepsilon'-\varepsilon-\varepsilon_{\rm op})]f(1-f')\}dk', \end{aligned} \tag{II.4}$$

where $\Phi_{\rm op}(x,k,k')=\Phi_{\rm op}\,(x,k',k)$ is the matrix element, $\varepsilon_{\rm op}$ is the constant optical phonon energy, and $N_{\rm op}$ is optical phonon occupation number:

$$N_{\rm op}=(e^{\varepsilon_{\rm op}/k_{\rm B}T_L}-1)^{-1}$$

with $k_{\rm B}$ the Boltzmann constant and T_L the lattice temperature. The acoustical phonon collision operator is given by a similar expression (II.4) with the indices ''op'' replaced by ''ac.'' The only major difference between acoustical and optical scattering is that the acoustical phonon energy $\varepsilon_{\rm ac}=\varepsilon_{\rm ac}\,(k-k')$ is a nonconstant function of $k-k'$.

The electron–electron collision operator is given by[16,39]

$$\begin{aligned} Q_e(f)(k)=\int_{B^3}\Phi_e(k,k_1,k',k_1')\,\delta(\varepsilon'+\varepsilon_1'-\varepsilon-\varepsilon_1)\,\delta_p(k'+k_1'-k-k_1)\\ \times[f'f_1'(1-f)(1-f_1)-ff_1(1-f')(1-f_1')]dk_1dk'dk_1', \end{aligned} \tag{II.5}$$

where

$$\delta_p(k'+k_1'-k-k_1)=\sum_{g\,\epsilon L^*}\delta(k'+k_1'-k-k_1+g). \tag{II.6}$$

In (II.6), the terms with $g\neq 0$ account for umklapp processes and are necessary to preserve the periodic structure in k. Note that since the integral defining Q_e is taken on B^3, then only a finite number of terms of the sum in (II.6) need to be taken into account. The matrix element Φ_e is such that $\Phi_e(k,k_1,k',k_1')=\Phi_e(k_1,k,k',k_1')=\Phi_e(k',k_1',k,k_1)$. In all these operators, the normalizing factors $1/4\pi^3$ coming from the momentum density of states have been transferred to the ϕs and will be ignored in the remainder of the paper.

The Boltzmann equation (II.1) is scaled by introducing typical density and kinetic energy scales for electrons: n_0 is the typical density injected in the structure (which can be larger than the doping density if high injection effects are present) and ε_0 is the typical kinetic energy that the

electrons can gain in the structure ($\varepsilon_0 \approx qV_A$ if V_A is the applied bias). Let now k_0 be the typical norm of wave vectors k satisfying $\varepsilon(k)=\varepsilon_0$. The dimensionless parameter

$$\eta = \frac{4\pi^3 n_0}{k_0^3}$$

is the natural distribution function scale and measures the level of degeneracy of the electron gas. The velocity scale is given by $v_0=\varepsilon_0/\hbar k_0$ and the space scale x_0 is linked to the time scale t_0 through $x_0=v_0 t_0$. Finally the potential scale V_0 is connected to ε_0 by $qV_0=\varepsilon_0$ (i.e., $V_0 \approx V_A$).

Dimensionless parameters measuring the relative strength of the collision operators ν_{imp}, ν_{op}, ν_{ac}, ν_e, are given by

$$\nu_{\text{imp}} = \frac{\phi_{\text{imp},0} k_0^3}{\varepsilon_0} t_0, \quad \nu_e = \frac{\phi_{e,0} 4\pi^3 n_0 k_0^3}{\varepsilon_0} t_0,$$

where $\Phi_{\text{imp},0}$ and $\Phi_{e,0}$ are ''typical values'' of Φ_{imp} and Φ_e, and ν_{op} and ν_{ac} are given by similar expressions as ν_{imp} associated with ''typical values'' $\Phi_{\text{op},0}$ and $\Phi_{\text{ac},0}$. Here $\Phi_{\text{imp},0}$ is used to scale the matrix element Φ_{imp} in dimensionless form and similarly with the other scattering mechanisms.

Finally, let also $\varepsilon_{\text{ac},0}$ be the order of magnitude of the acoustical phonon energy and introduce the dimensionless parameters

$$\alpha^2 = \frac{\varepsilon_{\text{op}}}{\varepsilon_0}, \quad \beta^2 = \frac{\varepsilon_{\text{ac},0}}{\varepsilon_0}, \quad \gamma^2 = \frac{k_B T_L}{\varepsilon_0},$$

α^2 (resp. β^2) measures the typical energy gain or loss during an optical (resp. acoustical) phonon collision, while γ^2 quantifies how ''hot'' is the electron gas ($\gamma^2 \ll 1$ implies hot electron effects).

After scaling with the above units, the equations are written

$$\frac{\partial f}{\partial t} + \nabla_k \varepsilon(k) \cdot \nabla_x f + \nabla_x V \cdot \nabla_k f = \nu_{\text{imp}} Q_{\text{imp}}(f) + \nu_{\text{ac}} Q_{\text{ac}}^{\beta}(f) + \nu_{\text{op}} Q_{\text{op}}^{\alpha}(f) + \nu_e Q_e(f) \qquad \text{(II.7)}$$

with Q_{imp} given by (II.3) applied with the dimensionless quantities. Here $Q_{\text{op}}^{\alpha}(f)$ is obtained from (II.4) in the same manner, and by replacing ε_{op} by α^2, $(1-f)$ by $(1-\eta f)$, and $(1-f')$ by $(1-\eta f')$. To obtain $Q_{\text{ac}}^{\beta}(f)$ from (II.4), it is enough to replace Φ_{op} by the dimensionless form of Φ_{ac}, N_{op} by N_{ac}, ε_{op} by $\beta^2 \varepsilon_{\text{ac}}$, and $(1-f)$ by $(1-\eta f)$. This latter substitution is sufficient to yield the dimensionless form of $Q_e(f)$.

The equations are posed on a dilated Brillouin zone B/k_0. We recall that

$$N_{\text{op}} = (e^{\alpha^2/\gamma^2} - 1)^{-1}, \quad N_{\text{ac}} = (e^{\beta^2 \varepsilon_{\text{ac}}/\gamma^2} - 1)^{-1}.$$

We shall analyze the behavior of (II.7) at various time, length, and energy scales. First, we are interested in a high energy scale (i.e., for large applied biases) at which the relative energy gain or loss of electron energy during a phonon collision is very small. Therefore, we let, following Refs. 27 and 16,

$$\alpha^2 \ll 1, \quad \beta^2 \ll 1. \qquad \text{(II.8)}$$

Together with (II.8), we suppose that

$$\frac{\alpha^2}{\gamma^2} \approx \frac{\beta^2}{\gamma^2} = 0(1), \qquad \text{(II.9)}$$

which means that at the high energy scale, the acoustical phonon energy $\varepsilon_{ac,0}$, the optical phonon energy $\varepsilon_{op,0}$, and the lattice thermal energy $k_B T_L$ are all considered of the same order of magnitude, and very small compared with the electron energy ε_0. Of course, one knows that, physically, $\varepsilon_{ac,0}<K_B T_L<\varepsilon_{op,0}$,[39] but the differences in the magnitudes of these energies are only detectable on longer time scales. This point will be clarified in Secs. IV and V.

By expanding $Q^{\alpha}_{op}(f)$ and $Q^{\beta}_{ac}(f)$ in powers of α^2 and β^2 and using (II.8), we can write the global lattice-defect collision operator according to (see also Refs. 27 and 16):

$$Q_{ld}(f)=(\nu_{imp}+\nu_{ac}+\nu_{op})Q_0(f)+\beta^2\nu_{ac}Q^{\beta}_{ac,1}(f)+\alpha^2\nu_{op}Q^{\alpha}_{op,1}(f),$$

where $Q_0(f)$ is an elastic collision operator given by

$$\begin{aligned} Q_0(f)&=\int \Phi_0(x,k,k')\,\delta(\varepsilon'-\varepsilon)(f'-f)dk', \\ \Phi_0&=\Phi_{imp}+(2N_{op}+1)\Phi_{op}+(2N_{ac}+1)\Phi_{ac}, \end{aligned} \tag{II.10}$$

and $Q^{\beta}_{ac,1}$ (resp. $Q^{\alpha}_{op,1}$) is of order 1 when β (resp. α) tends to zero. We now choose the time scale to be such that $(\nu_{imp}+\nu_{ac}+\nu_{op})=1$. From (II.9), we let $\alpha^2=\beta^2$ and we assume that

$$\nu_e=0(\alpha^2), \quad \text{i.e.,}\ \nu_e=\alpha^2\overline{\nu_e},\ \ \overline{\nu_e}=0(1). \tag{II.11}$$

We define

$$Q^{\alpha}_1=\nu_{ac}Q^{\alpha}_{ac,1}(f)+\nu_{op}Q^{\alpha}_{op,1}(f)+\overline{\nu_e}Q_e(f)=0(1)\ \ \text{as}\ \ \alpha\to 0. \tag{II.12}$$

The final form of the scaled Boltzmann equation (II.7) is thus

$$\frac{\partial f}{\partial t}+\nabla_k\varepsilon(k)\cdot\nabla_x f+\nabla_x V(x,t)\cdot\nabla_k f=Q_0(f)+\alpha^2 Q^{\alpha}_1(f), \tag{II.13}$$

where $Q_0(f)$ is the elastic operator (II.10) and $Q^{\alpha}_1(f)$ is given by (II.12). The ordering between the collision operators is the same as in Ref. 27. In Ref. 16 electron–electron collisions are considered of order 1, instead of α^2, and are brought into the leading order collision operator. A precise discussion of the magnitude of $Q_e(f)$ compared with Q_0 is given in Refs. 28 and 29. It is shown that for large densities Q_0 and Q_e are of the same order of magnitude while at low densities Q_e is smaller than Q_0. The ordering displayed by (II.13) is then characteristic of a rather small density case.

III. FIRST MACROSCOPIC SCALE: THE "SPHERICAL" HARMONIC EXPANSION MODEL

A. Scaling

We are interested in the diffusion scaling for Eq. (II.13). Following Ref. 27 or 16, we let

$$x'=\alpha x, \quad t'=\alpha^2 t.$$

This leads to the following scaled version of (II.13):

$$\frac{\partial f^{\alpha}}{\partial t}+\frac{1}{\alpha}\,(\nabla_k\varepsilon\cdot\nabla_x f^{\alpha}+\nabla_x V\cdot\nabla_k f^{\alpha})=\frac{1}{\alpha^2}\,Q_0(f^{\alpha})+Q^{\alpha}_1(f^{\alpha}). \tag{III.1}$$

Inserting the Hilbert expansion of f^{α},

$$f^\alpha = f_0 + \alpha f_1 + \alpha^2 f_2 + \cdots ,$$

in (III.1), we find

$$Q_0(f_0) = 0, \tag{III.2}$$

$$Q_0(f_1) = \nabla_k \varepsilon \cdot \nabla_x f_0 + \nabla_x V \cdot \nabla_k f_0, \tag{III.3}$$

$$Q_0(f_2) = \frac{\partial f_0}{\partial t} + \nabla_k \varepsilon \cdot \nabla_x f_1 + \nabla_x V \cdot \nabla_k f_1 - Q_1^\alpha(f_0). \tag{III.4}$$

To solve these equations, we need to investigate the operator Q_0.

B. Properties of Q_0

We first recall the coarea formula:[40] for any C^1 function $\varepsilon: B \to \mathbb{R}$, and any test function $\psi \in C^0(B)$ [where $C^0(B)$ denotes the set of continuous functions on B], we have

$$\int_B \psi(k)\,dk = \int_{-\infty}^{+\infty} \left(\int_{\varepsilon^{-1}(e)} \psi(k)\, \frac{dS_e(k)}{|\nabla \varepsilon(k)|} \right) de, \tag{III.5}$$

where $dS_e(k)$ denotes the Euclidean surface element on the manifold $\varepsilon^{-1}(e)$. We shall denote $dN_e(k) = dS_e(k)/|\nabla \varepsilon(k)|$ and (III.5) will be formally written

$$\int_B \psi(k)\,dk = \int_{-\infty}^{+\infty} \left(\int_{\varepsilon} \psi(k)\, dN_\varepsilon(k) \right) d\varepsilon. \tag{III.6}$$

We let $N(e)$ be the density of states of energy e:

$$N(e) = \int_{\varepsilon^{-1}(e)} dN_e(k). \tag{III.7}$$

By duality, we have for any $\psi \in C^0(B)$

$$\int_B \psi(k)\, \delta(\varepsilon(k) - \varepsilon)\,dk = \int_\varepsilon \psi(k)\, dN_\varepsilon(k). \tag{III.8}$$

We now recall that

$$Q_0(f) = \int_B \phi_0(x,k,k')\, \delta(\varepsilon' - \varepsilon)(f' - f)\,dk',$$

and we note that

$$Q_0(\psi(\varepsilon) f) = \psi(\varepsilon) Q_0(f), \quad \forall \psi = \psi(\varepsilon), \ \forall f. \tag{III.9}$$

We introduce

$$Lf = Q_0\left(\frac{f}{N(\varepsilon(k))} \right) = \frac{1}{N(\varepsilon(k))}\, Q_0(f), \tag{III.10}$$

and we denote by L^2_N the weighted space

$$L_N^2=\left\{ f(k), \int_B f^2(k)N(\varepsilon(k))dk<+\infty \right\}.$$

We assume that $N(\varepsilon(k))\neq 0$ for k a.e. in B so that L_N^2 is a separable Hilbert space with the scalar product and norm

$$\langle f,g\rangle_N=\int_B f(k)g(k)N(\varepsilon(k))dk, \quad \|f\|_N^2=\langle f,f\rangle_N.$$

Proposition III.1: Assume $\exists C_1, C_2>0$, $C_1\leqslant\phi_0\leqslant C_2$. Then

(i) $-L$ is a self-adjoint bounded non-negative operator on L_N^2,
(ii) $\mathrm{Ker}\, L=\{f\in L_N^2 \text{ s.t.} \exists g\in L^2(\mathbb{R}),\ f(k)=g(\varepsilon(k))/N(\varepsilon(k))\}$,
(iii) $(\mathrm{Ker}\, L)^\perp=\{f\in L_N^2, \text{ s.t. } \int_\varepsilon f(k)dN_\varepsilon(k)=0, \text{ a.e.}\varepsilon\}$,
(iv) $\exists\mu>0$, $\langle -Lf,\ f\rangle_N\geqslant\mu\|f-Pf\|_N^2$, where Pf is the orthogonal projection on $\ker L$,
(v) $Pf(k)=1/N(\varepsilon)\int_\varepsilon f dN_\varepsilon(k)$ and $\forall\psi(\varepsilon)$, $P(\psi(\varepsilon)f)=\psi(\varepsilon)Pf$,
(vi) $R(L)=(\mathrm{Ker}\, L)^\perp$.

Here $\mathrm{Ker}\, L$ and $R(L)$ stand for the kernel and the range of the operator L.

Proof: (i) is easy using the boundedness of Φ_0 and the formula

$$\int \Phi_0(f)g dk=\langle Lf,g\rangle=-\frac{1}{2}\int\int_{B\times B}\Phi_0(x,k,k')\delta(\varepsilon'-\varepsilon)(f'-f)(g'-g)dk\ dk'. \tag{III.11}$$

(ii) and (iii) are obvious by the coarea formula. To prove (iv), we just have to prove that

$$\langle -Lf,f\rangle_N\geqslant\mu\|f\|_N^2, \quad \forall f\in(\mathrm{Ker}\, L)^\perp.$$

We have, with (III.11),

$$\begin{aligned}\langle -Lf,f\rangle_N&=\frac{1}{2}\int\int_{B\times B}\Phi_0(x,k,k')\delta(\varepsilon'-\varepsilon)|f'-f|^2\ dk\ dk'\\ &\geqslant C\int_{-\infty}^{+\infty}\int_{\varepsilon(k')=\varepsilon}\int_{\varepsilon(k)=\varepsilon}[|f(k)|^2\\ &\quad +|f(k')|^2-2f(k)f(k')]\cdot dN_\varepsilon(k)dN_\varepsilon(k')d\varepsilon.\end{aligned}$$

However, since $f\in(\mathrm{Ker}\, L)^\perp$,

$$\int_{\varepsilon(k')=\varepsilon}\int_{\varepsilon(k)=\varepsilon}f(k')f(k)dN_\varepsilon(k)dN_\varepsilon(k')=0$$

and therefore

$$\langle -Lf,f\rangle_N\geqslant C\int_0^{+\infty}\int_{\varepsilon(k')=\varepsilon}\int_{\varepsilon(k)=\varepsilon}(f(k)^2+f(k')^2)dN_\varepsilon(k)dN_\varepsilon(k')d\varepsilon\geqslant 2C\|f\|_N^2.$$

(v) is just a computation and (vi) is a direct consequence of (iv). ■

C. Resolution of the Hilbert expansion (3.2)–(3.4)

By Eq. (III.2) and proposition III.1 (ii), there exists a function $F(x,\varepsilon,t)$ such that

$$f_0(x,k,t)=F(x,\varepsilon(k),t). \tag{III.12}$$

Then, Eq. (III.3) is equivalently written

$$Lf_1=\frac{1}{N(\varepsilon(k))}\,\nabla_k\varepsilon(k)\left[\nabla_x F+\nabla_x V\,\frac{\partial F}{\partial\varepsilon}\right]. \tag{III.13}$$

Since $\nabla_x F+\nabla_x V\partial F/\partial\varepsilon$ only depends on k through $\varepsilon(k)$, it is clear that the right-hand side of (III.13) belongs to $(\mathrm{Ker}\,L)^{\perp}=R(L)$. Therefore, Eq. (III.13) is solvable in f_1. Moreover, we have the following obvious lemma, using (III.9).

Lemma III.2: Let $\boldsymbol{\lambda}(x,k)$ be the unique solution in $(\mathrm{Ker}\,L)^{\perp}$ of

$$-L(\boldsymbol{\lambda})=\frac{1}{N(\varepsilon(k))}\,\nabla_k\varepsilon. \tag{III.14}$$

Then the unique solution in $(\mathrm{Ker}\,L)^{\perp}$ of Eq. (III.13) is given by

$$f_1=-\boldsymbol{\lambda}(x,k)\cdot\left(\nabla_x F+\nabla_x V\,\frac{\partial F}{\partial\varepsilon}\right). \tag{III.15}$$

Remark III.3: $\boldsymbol{\lambda}$ depends on x through L because Φ_0 may depend on x. (In particular, the impurity scattering matrix element depends on the doping density). Here $\boldsymbol{\lambda}$ is a vector-valued function and Eq. (III.14) must be understood componentwise. Adding an element of $\ker L$ to f_1 would not modify the subsequent analysis. ■

Then, Eq. (III.4) can be written

$$Lf_2=\frac{1}{N(\varepsilon)}\left[\frac{\partial F}{\partial t}+\nabla_k\varepsilon\cdot\nabla_x f_1+\nabla_x V\cdot\nabla_k f_1-Q_1^{\alpha}(F)\right]. \tag{III.16}$$

By Proposition III.1 (vi) and (iii), the solvability condition for (III.16) is written

$$\int_{\varepsilon}\left[\frac{\partial F}{\partial t}+\nabla_k\varepsilon\cdot\nabla_x f_1+\nabla_x V\cdot\nabla_k f_1-Q_1^{\alpha}(F)\right]dN_{\varepsilon}(k)=0,\quad \text{a.e. } \varepsilon. \tag{III.17}$$

Setting

$$S^{\alpha}(F)=\int_{\varepsilon}Q_1^{\alpha}(F)\,dN_{\varepsilon}(k), \tag{III.18}$$

$$J(x,\varepsilon,t)=\int_{\varepsilon}\nabla_k\varepsilon\,f_1(x,k,t)\,dN_{\varepsilon}(k), \tag{III.19}$$

we find the following.

Theorem III.4: Let f_0 and f_1 be given by (III.12) and (III.15). Then, the solution f_2 of Eq. (III.4) exists if and only if $F\ (x,\varepsilon,t)$ satisfies

$$N(\varepsilon)\,\frac{\partial F}{\partial t}+\nabla_x\cdot J+\nabla_x V\cdot\,\frac{\partial J}{\partial\varepsilon}-S^{\alpha}(F)=0, \tag{III.20}$$

$$J(x,\varepsilon,t)=-D(x,\varepsilon)\left(\nabla_x F+\nabla_x V\,\frac{\partial F}{\partial\varepsilon}\right), \tag{III.21}$$

where

$$D(x,\varepsilon)=\int_{\varepsilon}\nabla_k\varepsilon\otimes\boldsymbol{\lambda}(x,k)\,dN_{\varepsilon}(k). \tag{III.22}$$

Proof: Equations (III.21) and (III.22) just come from (III.19) and (III.15). The first, second, and fourth terms of (III.20) obviously come from the corresponding terms in (III.17). For the third term, we proceed as in Ref. 10. We write, for any $\psi=\psi(\varepsilon)$,

$$\begin{aligned}\int_B \nabla_k f_1\psi(\varepsilon)\,dk &= -\int_B f_1\nabla_k\psi(\varepsilon)\,dk\\ &= -\int_B f_1\nabla_k\varepsilon\,\psi'(\varepsilon)\,dk\\ &= -\int_{\mathbb{R}}\psi'(\varepsilon)\left(\int_{\varepsilon} f_1\nabla_k\varepsilon\,dN_{\varepsilon}(k)\right)d\varepsilon\\ &= -\int_{\mathbb{R}}\psi'(\varepsilon)J(\varepsilon)\,d\varepsilon\\ &= \int_{\mathbb{R}}\psi(\varepsilon)J'(\varepsilon)\,d\varepsilon.\end{aligned}$$

It follows that

$$\int_{\varepsilon}\nabla_k f_1\,dN_{\varepsilon}(k)=\frac{\partial J}{\partial\varepsilon}.$$

■

Remark III.5: System (III.20) and (III.21) is in the form of Ref. 27 except for the expression of the diffusion matrix (see below). By the change of unknowns

$$F(x,\varepsilon,t)=G(x,\varepsilon-V(x,t),t),\quad J(x,\varepsilon,t)=I(x,\varepsilon-V(x,t),t),$$

system (III.20) and (III.21) is equivalent with

$$N(u+V(x,t))\left(\frac{\partial G}{\partial t}-\frac{\partial V}{\partial t}\,\frac{\partial G}{\partial u}\right)+\nabla_x\cdot I=S^{\alpha}(G), \tag{III.23}$$

$$I(x,t,u)=-D(x,u+V(x,t))\nabla_x G, \tag{III.24}$$

where u stands for the new variable $\varepsilon-V(x,t)$. System (III.23) and (III.24) is in the form of Ref. 30, except again for the expression of the diffusion matrix (see below). System (III.23) and (III.24) is a system of diffusion equations coupled by the transport term $N\,\partial V/\partial t\,\partial G/\partial u$ and by the collision operator S^{α}. In reference to Ref. 30, it will be called the ''spherical'' harmonic expansion model, the quotes indicating that, for arbitrary band diagrams, the expansion in no more ''spherical'' but rather on constant energy shells. ■

D. Properties of the diffusion matrix

Proposition III.6: $D(x,\varepsilon)$ is a symmetric non-negative 3×3 matrix. Moreover, $\exists C>0$ such that

$$D(x,\varepsilon)\geqslant \frac{C}{N(\varepsilon)} \int_{\varepsilon} \nabla_k\varepsilon\otimes\nabla_k\varepsilon \; dN_\varepsilon(k). \tag{III.25}$$

Remark III.7: The right-hand side of (III.25) is a symmetric non-negative 3×3 matrix which is degenerate at the critical points of ε. Estimate (III.25) is sharp as will further be shown by examples. ■

Proof: Let $\psi(\varepsilon)\in C^0(\mathbb{R})$. By definition (III.22) we have

$$\int_{\mathbb{R}} D_{ij}(\varepsilon)\psi(\varepsilon)d\varepsilon = \int_{\mathbb{R}}\left(\int_{\varepsilon}\partial_{k_i}\varepsilon\lambda_j \; dN_\varepsilon(k)\right)\psi(\varepsilon)d\varepsilon.$$

Then, by using the coarea formula and definition (III.14) of $\boldsymbol{\lambda}$, we have

$$\int_{\mathbb{R}} D_{ij}(\varepsilon)\psi(\varepsilon)d\varepsilon = -\int_B L(\lambda_i N(\varepsilon))\lambda_j\psi(\varepsilon)dk.$$

Now, using the self-adjointness of L and property (III.9),

$$\begin{aligned}
\int_{\mathbb{R}} D_{ij}(\varepsilon)\psi(\varepsilon)d\varepsilon &= -\int \lambda_i N(\varepsilon) L(\lambda_j\psi(\varepsilon))dk \\
&= -\int \lambda_i\psi(\varepsilon) L(\lambda_j N(\varepsilon))dk \\
&= \int \lambda_i\psi(\varepsilon)\partial_{k_j}\varepsilon \; dk \\
&= \int_{\mathbb{R}}\psi(\varepsilon)\left(\int_{\varepsilon}\lambda_i\partial_{k_j}\varepsilon dN_\varepsilon(k)\right)d\varepsilon \\
&= \int_{\mathbb{R}}\psi(\varepsilon)D_{ji}(\varepsilon)d\varepsilon,
\end{aligned}$$

which proves that $D_{ij}(\varepsilon)=D_{ji}(\varepsilon)$.

Now, we choose $\psi\in C^0(\mathbb{R})$, $\psi\geqslant0$, and we let $\xi=(\xi_1,\xi_2,\xi_3)\in\mathbb{R}^3$. Using Einstein's summation convention, we have

$$\begin{aligned}
\int_{\mathbb{R}}\psi(\varepsilon)D_{ij}(\varepsilon)\xi_i\xi_j \; d\varepsilon &= \int_{\mathbb{R}}\psi(\varepsilon)\left(\int_{\varepsilon}\partial_{k_i}\varepsilon\xi_i\lambda_j\xi_j \; dN_\varepsilon(k)\right)d\varepsilon \\
&= -\int_B L(\lambda_i\xi_i\sqrt{\psi(\varepsilon)})(\lambda_j\xi_j\sqrt{\psi(\varepsilon)})N(\varepsilon)dk.
\end{aligned}$$

Since $\lambda_i\xi_i\sqrt{\psi(\varepsilon)}\in(\mathrm{Ker}\ L)^\perp$, we have, by Proposition 3.1 (iv),

$$\int_{\mathbb{R}}\psi(\varepsilon)D_{ij}(\varepsilon)\xi_i\xi_j \; d\varepsilon \geqslant \mu\|\lambda_i\xi_i\sqrt{\psi(\varepsilon)}\|_N^2. \tag{III.26}$$

By the continuity of L, we deduce

$$\begin{aligned}\|\lambda_i\xi_i\sqrt{\psi(\varepsilon)}\|_N^2 &\geqslant C\|L(\lambda_i\xi_i)\sqrt{\psi(\varepsilon)}\|_N^2\\ &\geqslant C\|(1/N)\vec{\nabla}_k\varepsilon\cdot\boldsymbol{\xi}\sqrt{\psi(\varepsilon)}\|_N^2\\ &\geqslant C\int_{\mathbb{R}}\frac{\psi(\varepsilon)}{N(\varepsilon)}\left(\int_\varepsilon|\vec{\nabla}_k\varepsilon\cdot\boldsymbol{\xi}|^2dN_\varepsilon(k)\right)d\varepsilon.\end{aligned}\tag{III.27}$$

Inserting (III.26) in (III.27) leads to

$$\int_{\mathbb{R}}\psi(\varepsilon)(D_{ij}(\varepsilon)\xi_i\xi_j)d\varepsilon\geqslant C'\int_{\mathbb{R}}\psi(\varepsilon)\left(\frac{1}{N(\varepsilon)}\int_\varepsilon(\boldsymbol{\nabla}_k\varepsilon\otimes\boldsymbol{\nabla}_k\varepsilon)dN_\varepsilon(k)\right)_{ij}\xi_i\xi_j\,d\varepsilon$$

for all $\psi\in C^0(\mathbb{R})$, $\psi\geqslant 0$, which implies (III.25). ■

We now investigate simplifying assumptions which enable us to give more explicit expressions of $D(x,\varepsilon)$. First, we assume that $\Phi_0(x,k,k')=\Phi_0(x,\varepsilon(k))$ [we recall that Φ_0 needs only to be defined on the set $\varepsilon(k')=\varepsilon(k)$]. Then $Q_0(f)$ is equivalently written in the form of a relaxation operator:

$$Q_0(f)=-\frac{1}{\tau(x,\varepsilon)}\,(f-Pf)\tag{III.28}$$

with $\tau(x,\varepsilon)=(\Phi_0(x,\varepsilon)N(\varepsilon))^{-1}$ and P is the projection defined in Proposition 3.1 (v). Then, the solution of (III.10) can be written

$$\boldsymbol{\lambda}(x,k)=\tau(x,\varepsilon)\nabla_k\varepsilon\tag{III.29}$$

and can be referred to as the ''mean free path of particles of wave vector k.'' Therefore, we have

$$D(x,\varepsilon)=\tau(x,\varepsilon)\int_\varepsilon\vec{\nabla}_k\varepsilon\otimes\hat{\nabla}_k\varepsilon\;dN_\varepsilon(k).\tag{III.30}$$

This is the case explicitly treated in Ref. 27 and our results coincide. This case proves that estimate (III.25) is sharp, because it becomes an equality in the case of Ref. 27.

Another simplification is to consider a spherically symmetric band diagram (and therefore $B=\mathbb{R}^3$), together with Φ_0 being such that $\Phi_0(x,k,k')=\Phi_0(x,\varepsilon,(k/|k|)\cdot(k'/|k'|))$. In this case, the elastic collision operator is rotationally invariant. A relaxation time can be defined by (with S^2 being the unit sphere of $\mathbb{R}^3$)

$$\begin{aligned}\frac{1}{\tau(x,\varepsilon)}&=\frac{1}{4\pi}\left(\int_{S^2}\Phi_0(x,\varepsilon,\omega)(1-\omega_z)d\omega\right)N(\varepsilon),\\ N(\varepsilon)&=4\pi\sum_{\varepsilon(|k|)=\varepsilon}\frac{|k|^2}{|\varepsilon'(|k|)|}\end{aligned}\tag{III.31}$$

[we assume that for any $\varepsilon\in\mathbb{R}$, the set $\{|k|,\varepsilon(|k|)=\varepsilon\}$ is discrete.] Then a straightforward computation leads to

$$\boldsymbol{\lambda}(x,k)=\tau(x,\varepsilon)\varepsilon'(|k|)\mathbf{k}/|k|.\tag{III.32}$$

$$D(x,\varepsilon)=\frac{4\pi}{3}\,\tau(x,\varepsilon)\left(\sum_{\varepsilon(|k|)=\varepsilon}|\varepsilon'(|k|)|\;|k|^2\right)\mathrm{Id}\tag{III.33}$$

where Id is the identity matrix of $\mathbb{R}^3$. This expression can be further simplified if one assumes that ε is a strictly monotone (e.g., increasing) function of $|k|$. In such a case, the $\varepsilon(|k|)$ relation can be inverted, and, following Ref. 30, we can define a function γ such that

$$|k|^2=\gamma(\varepsilon).$$

All the functions of $|k|$ may be expressed as functions of ε, and we have

$$\varepsilon'(\varepsilon)=2\frac{\sqrt{\gamma(\varepsilon)}}{\gamma'(\varepsilon)},\quad N(\varepsilon)=2\pi\sqrt{\gamma(\varepsilon)}\gamma'(\varepsilon), \tag{III.34}$$

$$\boldsymbol{\lambda}(x,k)=\Lambda(x,\varepsilon)\mathbf{k}/|k|,\quad \Lambda(x,\varepsilon)=\tau(x,\varepsilon)\varepsilon'(\varepsilon), \tag{III.35}$$

and

$$D(x,\varepsilon)=\left(\frac{8\pi}{3}\,\tau(x,\varepsilon)\,\frac{\gamma(\varepsilon)^{3/2}}{\gamma'(\varepsilon)}\right)\ \mathrm{Id}=\frac{1}{3}\,(N(\varepsilon)\Lambda(x,\varepsilon)\varepsilon'(\varepsilon))\mathrm{Id}. \tag{III.36}$$

This is the case considered in Ref. 30 and our results coincide. Even more specifically, let us assume that $\Phi_0=\Phi_0(x)$ is independent of k, k', which is true for acoustical and nonpolar optical phonons. (Indeed, these are the main sources of scattering in Si at room temperature, since the impurity scattering can be neglected.) Let us also assume a parabolic band structure $\gamma(\varepsilon)=2m_*\varepsilon$ with m_* being the effective mass. Then, by (III.36),

$$D(x,\varepsilon)=\frac{2\varepsilon}{3\Phi_0(x)m_*}\,\mathrm{Id}. \tag{III.37}$$

IV. SECOND MACROSCOPIC SCALE DRIVEN BY ELECTRON–ELECTRON COLLISIONS: THE ENERGY-TRANSPORT MODEL

A. Scaling

The starting point is now the ''spherical'' harmonic expansion model (III.20) and (III.21). Going back to (II.12), the collision term $S^\alpha(f)$ is written

$$S^\alpha(F)=\frac{\nu_{\mathrm{ac}}}{\alpha^2}\,\mathrm{S}^\alpha_{\mathrm{ac}}(F)+\frac{\nu_{\mathrm{op}}}{\alpha^2}\,S^\alpha_{\mathrm{op}}(F)+\overline{\nu_e}S_e(F), \tag{IV.1}$$

where we have [because the elastic parts Q^0_{ac} and Q^0_{op} vanish on $F(\varepsilon)$]

$$S^\alpha_{\mathrm{ac}}(F)(\varepsilon)=\int_\varepsilon Q^\alpha_{\mathrm{ac}}(F)dN_\varepsilon(k),\quad S^\alpha_{\mathrm{op}}(F)(\varepsilon)=\int_\varepsilon Q^\alpha_{\mathrm{op}}(F)dN_\varepsilon(k), \tag{IV.2}$$

$$S_e(F)(\varepsilon)=\int_\varepsilon Q_e(F)dN_\varepsilon(k). \tag{IV.3}$$

We now assume that both phonon collision operators $\nu_{\mathrm{ac}}/\alpha^2S^\alpha_{\mathrm{ac}}(F)$ and $\nu_{\mathrm{op}}/\alpha^2S^\alpha_{\mathrm{op}}(F)$ are of the same order of magnitude, and we choose the time unit such that $\nu_{\mathrm{ac}}/\alpha^2\simeq\nu_{\mathrm{op}}/\alpha^2\simeq1$. We also assume that the electron–electron collision operator $\overline{\nu_e}S_e(F)$ is dominant and we let $\overline{\nu_e}=1/\beta$, $\beta\ll1$. This amounts to assuming that, for a distribution function which is constant on the energy surfaces, the energy loss due to phonon collision occurs on a longer scale than the thermalization

by electron–electron collisions. This hypothesis is certainly correct for hot-electron distribution functions F with a substantial high-energy tail. On the contrary, for ''cooler'' Fs, this hypothesis is more doubtful and we shall investigate this case in Sec. V.

Therefore, the evolution of a hot-electron energy distribution $F^\beta(x,\varepsilon,t)$ is ruled by the following equations:

$$N(\varepsilon)\,\frac{\partial F_\beta}{\partial t}+\nabla_x\cdot J^\beta+\nabla_x V\cdot\frac{\partial J^\beta}{\partial\varepsilon}=\frac{1}{\beta}\,S_e(F^\beta)+S_1(F^\beta), \tag{IV.4}$$

$$J^\beta(x,\varepsilon,t)=-D(x,\varepsilon)\left(\nabla_x F^\beta+\nabla_x V\cdot\frac{\partial F^\beta}{\partial\varepsilon}\right), \tag{IV.5}$$

with $S_e(F^\beta)$ given by (IV.3) and $S_1(F^\beta)=S_{\rm ac}(F^\beta)+S_{\rm op}(F^\beta)$ and $S_{\rm ac}$, $S_{\rm op}$ given by (IV.2). We are interested in the limit $\beta\to 0$. Again, we use a Hilbert expansion

$$F^\beta=F_0+\beta F_1+\cdots,\quad J^\beta=J_0+\beta J_1+\cdots\ .$$

Identifying equal powers of β, we obtain

$$S_e(F_0)=0, \tag{IV.6}$$

$$N(\varepsilon)\,\frac{\partial F_0}{\partial t}+\nabla_x\cdot J_0+\nabla_x V\,\frac{\partial J_0}{\partial\varepsilon}-S_1(F_0)=D_{F_0}S_e(F_1). \tag{IV.7}$$

Here $D_{F_0}S_e(F_1)$ denotes the derivative of S_e at F_0 applied to F_1. To solve (IV.6) and (IV.7), we first investigate the properties of S_e and $D_{F_0}S_e(F_1)$. We note that the scaling (IV.4) of the ''spherical'' harmonic expansion model is of hydrodynamic type and not of diffusion type. The reason is that the transport part (left-hand side of the equation) is already a diffusion model.

B. Properties of S_e and $D_{F_0}S_e$

For this section, we shall mainly rely on section 4 of Ref. 16. We have

Proposition IV.1: (i) Entropy inequality:

$$\int_{\mathbb{R}} S_e(F)\ln\left(\frac{F}{1-\eta F}\right)d\varepsilon\leqslant 0.$$

(i) $\int_{\mathbb{R}} S_e(F)\,\binom{1}{\varepsilon}d\varepsilon=0$

(ii) $S_e(F)=0\Leftrightarrow\exists\,\mu\varepsilon\mathbb{R},\ T>0$ such that

$$F=\mathscr{F}_{\mu,T}(\varepsilon)=\frac{1}{\eta+e^{(\varepsilon-\mu)/T}}. \tag{IV.8}$$

Proof: The proof is immediate from Ref. 16 by noting that, $\forall F(\varepsilon)$, $G(\varepsilon)$,

$$\begin{aligned}\int_{\mathbb{R}} S_e(F)G(\varepsilon)d\varepsilon&=\int_B Q_e(F(\varepsilon(k)))G(\varepsilon(k))dk\\&=-\frac{1}{4}\int_{B^4}\Phi_e\delta_\varepsilon\delta_k(G'+G_1'-G-G_1)\\&\quad\times(F'F_1'(1-\eta F)(1-\eta F_1)-FF_1(1-\eta F')(1-\eta F_1'))d^4k,\end{aligned}$$

where δ_ε stands for $\delta(\varepsilon' + \varepsilon_1' - \varepsilon - \varepsilon_1)$, δ_k for $\delta_p(k' + k_1' - k - k_1)$, and $d^4k = dk\ dk_1\ dk'\ dk_1'$.

We now define

$$\Sigma_{\mathscr{F}}(f) = N(\varepsilon)^{-1} D_{\mathscr{F}} S_e(f) \tag{IV.9}$$

and the Hilbert space

$$H_{\mathscr{F}} = \left\{ f(\varepsilon),\ \int_{\mathbb{R}} |f(\varepsilon)|^2 \frac{N(\varepsilon)}{\mathscr{F}(1-\eta\mathscr{F})}\, d\varepsilon < +\infty \right\},$$

provided with the obvious scalar product $\langle , \rangle_{\mathscr{F}}$ and norm $|\cdot|_{\mathscr{F}}$. We have the following.

Proposition IV.2: (i) $-\Sigma_{\mathscr{F}}$ is a bounded non-negative self-adjoint operator on $H_{\mathscr{F}}$.

(ii) $\ker \Sigma_{\mathscr{F}} = \mathrm{Span}\ (\mathscr{F}(1-\eta\mathscr{F}), \mathscr{F}(1-\eta\mathscr{F})\varepsilon)$.

(iii) $\langle -\Sigma_{\mathscr{F}}(f), f\rangle_{\mathscr{F}} \geqslant \mu |f - Pf|^2_{\mathscr{F}}$, where P is the orthogonal projection on $\mathrm{Ker}\ \Sigma_{\mathscr{F}}$ for $\langle , \rangle_{\mathscr{F}}$.

(iv) $R(\Sigma_{\mathscr{F}}) = (\mathrm{Ker}\ \Sigma_{\mathscr{F}})^{\perp} = \{ f \in H_{\mathscr{F}}, \int f\binom{1}{\varepsilon} N(\varepsilon) d\varepsilon = 0 \}$.

Proof: Again, the proof is immediate from Ref. 16. Indeed, we have

$$\langle -\Sigma_{\mathscr{F}}(f), g\rangle_{\mathscr{F}} = -\int_{\mathbb{R}} \Sigma_{\mathscr{F}}(f)(\varepsilon) g(\varepsilon) \frac{N(\varepsilon) d\varepsilon}{\mathscr{F}(1-\eta\mathscr{F})}.$$

However, differentiating (IV.3) with respect to $\mathscr{F}$ yields

$$N(\varepsilon)\Sigma_{\mathscr{F}}(f)(\varepsilon) = \int_{\varepsilon} D_{\mathscr{F}} Q_e(f)(k)\, dN_\varepsilon(k).$$

Therefore

$$\langle -\Sigma_{\mathscr{F}}(f), g\rangle_{\mathscr{F}} = -\int_B D_{\mathscr{F}} Q_e(f)(k) g(\varepsilon(k)) \frac{dk}{\mathscr{F}(\varepsilon(k))(1-\eta\mathscr{F}(\varepsilon(k)))}. \tag{IV.10}$$

Let $\mathscr{H}_{\mathscr{F}}$ be the Hilbert space

$$\mathscr{H}_{\mathscr{F}} = \left\{ \varphi(k), \int_B |\varphi(k)|^2 \frac{dk}{\mathscr{F}(\varepsilon(k))(1-\eta\mathscr{F}(\varepsilon(k)))} < +\infty \right\},$$

provided with the obvious scalar product $\ll , \gg_{\mathscr{F}}$ and norm $\|\cdot\|_{\mathscr{F}}$. In Ref. 16, the operator

$$-\mathscr{L}_{\mathscr{F}} = -D_{\mathscr{F}} Q_e - Q_0, \tag{IV.11}$$

where Q_0 is given by (II.10), is proved to be a bounded non-negative self-adjoint operator on $\mathscr{H}_{\mathscr{F}}$ for $\ll , \gg_{\mathscr{F}}$. However, since f only depends on ε, we have $Q_0(f) = 0$, so that (IV.10) can be written

$$\langle -\Sigma_{\mathscr{F}}(f), g\rangle_{\mathscr{F}} = -\ll \mathscr{L}_{\mathscr{F}} f, g(\varepsilon) \gg_{\mathscr{F}}.$$

Therefore, $-\Sigma_{\mathscr{F}}$ inherits of all the properties of $-\mathscr{L}_{\mathscr{F}}$. Proposition 4.2 follows from corollary 4.6, lemma 4.7, and proposition 4.8 of Ref. 16. ■

C. Resolution of the Hilbert expansion (4.6) and (4.7)

The solution of (IV.6) is obviously from proposition IV.1 (iii):

$$F_0(x, \varepsilon, t) = \mathscr{F}_{\mu(x,t), T(x,t)}(\varepsilon). \tag{IV.12}$$

Then, J_0 is given by (IV.5) with $\beta=0$, which yields

$$J_0(x,\varepsilon,t) = -D(x,\varepsilon)\mathscr{F}(1-\eta\mathscr{F})\left\{\left(\nabla_x\left(\frac{\mu}{T}\right)-\frac{\nabla_x V}{T}\right)-\varepsilon\nabla\left(\frac{1}{T}\right)\right\}. \tag{IV.13}$$

The search of a solution for (IV.7) leads to the following theorem.

Theorem IV.3: Let F_0 be given by (IV.12). Then, the solution of Eq. (IV.7) exists if and only if $\mu(x,t)$ and $T(x,t)$ satisfy the following set of diffusion equations:

$$\frac{\partial}{\partial t}\, n(\mu,T)-\nabla\cdot\left[\mathscr{D}_{11}\left(\nabla_x\left(\frac{\mu}{T}\right)-\frac{\nabla_x V}{T}\right)+\mathscr{D}_{12}\,\frac{\nabla_x T}{T^2}\right]=0, \tag{IV.14}$$

$$\begin{aligned}\frac{\partial}{\partial t}\, n\mathscr{E}(\mu,T)&-\nabla\cdot\left[\mathscr{D}_{21}\left(\nabla_x\left(\frac{\mu}{T}\right)-\frac{\nabla x V}{T}\right)+\mathscr{D}_{22}\,\frac{\nabla_x T}{T^2}\right]\\&+\nabla_x V\cdot\left[\mathscr{D}_{11}\left(\nabla_x\left(\frac{\mu}{T}\right)-\frac{\nabla_x V}{T}\right)+\mathscr{D}_{12}\,\frac{\nabla_x T}{T^2}\right]\\&=W(\mu,T,T_L),\end{aligned} \tag{IV.15}$$

where

$$\begin{pmatrix} n(\mu,T)\\ n\mathscr{E}(\mu,T)\end{pmatrix}=\int_{\mathbb{R}}\mathscr{F}_{\mu,T}(\varepsilon)\begin{pmatrix}1\\ \varepsilon\end{pmatrix}N(\varepsilon)\,d\varepsilon, \tag{IV.16}$$

$$\mathscr{D}_{ij}=\mathscr{D}_{ij}(x,\mu,T)=\int_{\mathbb{R}}D(x,\varepsilon)\mathscr{F}(1-\eta\mathscr{F})\chi_i\chi_j\;d\varepsilon,\quad i,j=1,2, \tag{IV.17}$$

with $\chi_1(\varepsilon)=1$, $\chi_2(\varepsilon)=\varepsilon$, and

$$W(\mu,T,T_L)=\int_{\mathbb{R}}S_1(\mathscr{F}_{\mu,T})\varepsilon\;d\varepsilon. \tag{IV.18}$$

We recall that T_L is the lattice temperature.

Proof: From Proposition IV.2 (iv), the condition for Eq. (4.7) to be solvable in F_1 is

$$\int\left[N(\varepsilon)\,\frac{\partial F_0}{\partial t}+\nabla_x J_0+\nabla x V\,\frac{\partial J_0}{\partial\varepsilon}-S_1(F_0)\right]\begin{pmatrix}1\\ \varepsilon\end{pmatrix}d\varepsilon=0.$$

With the expression (IV.13) of J_0, this immediately yields (IV.14) and (IV.15). ■

Remark IV.4: System (IV.14) and (IV.15) belongs to the class of energy-transport models. In Ref. 16, a similar model is directly derived from a diffusion approximation of the Boltzmann equation (II.13) in which the leading order collision operator is $Q_0(f)+Q_e(f)$. In that case, the diffusion matrix D_{ij} is given by a different (and more complicated) expression than (IV.16), namely,

$$\mathscr{D}_{ij}=\int_B(\chi_i\nabla_k\varepsilon)\otimes\boldsymbol{\psi}_j\;dk, \tag{IV.19}$$

where $\boldsymbol{\psi}_i$ is the unique solution in $(\ker\mathscr{L}_F)^\perp$ of

$$\mathscr{L}_{\mathscr{F}}\boldsymbol{\psi}_i=-(\chi_i\nabla_k\varepsilon)\mathscr{F}(1-\eta\mathscr{F})$$

and $\mathscr{L}_{\mathscr{T}}$ is the operator given by (IV.11). The expression (IV.17) is probably better because the electron–electron collisions in semiconductors are usually not as strong as the phonon collisions (in their elastic approximation). Therefore the relaxation towards a Fermi–Dirac distribution function is a multiscale phenomenon as described in the present paper rather than a single-scale process as implied by the analysis of Ref. 16. In Ref. 16, the connection between energy-transport models and hydrodynamic models is thoroughly investigated. We shall not develop this point here. ■

D. Properties of the diffusion matrix D and the energy relaxation term $W(\mu, T, T_L)$

From Ref. 16, Lemma 4.11, we immediately deduce the following lemma, which proves that W is a relaxation term of the electron temperature T to the lattice temperature T_L:

Lemma IV.5: $W(\mu,T,T_L)\cdot(T-T_L)\leqslant 0$.

Now, we let $\mathscr{D}$ be the block 6×6 matrix

$$\mathscr{D}=\begin{pmatrix}\mathscr{D}_{11} & \mathscr{D}_{12}\\ \mathscr{D}_{21} & \mathscr{D}_{22}\end{pmatrix}=\mathscr{D}(x,\mu,T).$$

We have the following.

Proposition IV.6:

(i) $\forall i,j\in\{1,2\}\ \mathscr{D}_{ij}^{T}=\mathscr{D}_{ij}$.

(ii) $\mathscr{D}_{12}=\mathscr{D}_{21}$.

(iii) Assume that the six functions $\partial_{k_1}\varepsilon$, $\partial_{k_2}\varepsilon$, $\partial_{k_3}\varepsilon$, $\varepsilon\partial_{k_1}\varepsilon$, $\varepsilon\partial_{k_2}\varepsilon$, $\varepsilon\partial_{k_3}\varepsilon$ are linearly independent. Then the matrix $\mathscr{D}(x,\mu,T)$ is symmetric positive definite for any $\mu\in(-\infty,+\infty)$, $T>0$.

Proof: (i) follows from the symmetry of $D(x,\varepsilon)$ and (ii) from the fact that $\chi_1\chi_2=\chi_2\chi_1$. For (iii), let ξ_1, ξ_2 be two vectors of $\mathbb{R}^3$ such that $|\xi_1|^2+|\xi_2|^2=1$, $\xi_i=(\xi_{ip})_{p=1,2,3}$. We have, using Einstein's summation convention,

$$(\mathscr{D}_{ij}\xi_i,\xi_j)=\int_{\mathbb{R}} D(x,\varepsilon).\mathscr{F}(1-\eta.\mathscr{F})\chi_i\xi_i\chi_j\xi_j\,d\varepsilon=\int_{\mathbb{R}} D_{pq}(x,\varepsilon).\mathscr{F}(1-\eta.\mathscr{F})\chi_i\xi_{ip}\chi_j\xi_{jq}\,d\varepsilon.$$

Then, by Proposition III.6, we have

$$(\mathscr{D}_{ij}\xi_i,\xi_j)\geqslant\frac{C}{N(\varepsilon)}\int_{\mathbb{R}}\left(\int_{\varepsilon}(\chi_i\partial_{k_p}\varepsilon)\xi_{ip}(\chi_j\partial_{k_q}\varepsilon)\xi_{jq}\,dN_{\varepsilon}(k)\right).\mathscr{F}(1-\eta.\mathscr{F})d\varepsilon$$

$$\geqslant\frac{C}{N(\varepsilon)}\int_{B}\left|\begin{pmatrix}\nabla_k\varepsilon\\ \varepsilon\nabla_k\varepsilon\end{pmatrix}\cdot\begin{pmatrix}\xi_1\\ \xi_2\end{pmatrix}\right|^2\mathscr{F}(1-\eta.\mathscr{F})dk. \tag{IV.20}$$

The minimal value of the right-hand side of (IV.20) for $(\xi_1,\xi_2)\in\mathbb{R}^6$, $|\xi_1|^2+|\xi_2|^2=1$ cannot be zero, otherwise it would be zero for a particular choice of (ξ_1,ξ_2), which would lead to a contradiction. ■

Remark IV.7: The assumptions on ε which appear in Proposition IV.6 are of geometric nature. They appear in the same form in the energy-transport model directly deduced from the Boltzmann equation derived in Ref. 16. ■

The diffusion matrix $\mathscr{D}$ can be explicitly computed under the simplifying assumption of the last paragraph of Sec. III D: if Φ_0 is independent of k, k' and in the case of a parabolic band structure $(\gamma(\varepsilon)=2m_*\varepsilon)$ and of a nondegenerate statistics [i.e., $\mathscr{F}(1-\eta\mathscr{F})\to\exp(-(\varepsilon-\mu)/T)$ when $\eta\to 0$], the diffusion matrix $\mathscr{D}(x,\mu,T)$ is given from (IV.17) and (III.37) by

$$\mathscr{D}(x,\mu,T)=\frac{2T^2e^{\mu/T}}{3\Phi_0(x)m_*}\begin{pmatrix}\mathrm{Id} & 2T\ \mathrm{Id}\\ 2T\ \mathrm{Id} & 6T^2\ \mathrm{Id}\end{pmatrix}.$$

Remark IV.8: (i) We have $(1/T)\mathscr{D}_{11}^{-1}\mathscr{D}_{12}-\frac{5}{2}\,\mathrm{Id}=-\frac{1}{2}\,\mathrm{Id}\neq 0$, which implies that nonvanishing cross effects such as a friction force of thermal origin (Soret effect) or a heat flux of friction origin (Peltier effect) should be expected in the hydrodynamic model of semiconductor (see Ref. 16, sections 5 and 6).

(ii) The heat conductivity κ and the electrical conductivity σ are given by[16,25]

$$\kappa=\frac{1}{T^2}\,(\mathscr{D}_{22}-\mathscr{D}_{21}\mathscr{D}_{11}^{-1}\mathscr{D}_{12}),\quad \sigma=\frac{1}{T}\,\mathscr{D}_{11}.$$

So that the Landau coefficient $\Lambda=\kappa/\sigma T=2$. In particular, Λ is constant which is the expression of the Wiedemann–Franz law. ■

E. The third macroscopic scale: The drift-diffusion model

If we look at an even longer time scale, the energy losses due to phonon collisions become important and we tend to an asymptotic regime where the electron and lattice temperatures are equal. To investigate this regime, time and space must be rescaled, and system (4.13) and (4.14) is put in the form:

$$\frac{\partial}{\partial t}\,n(\mu^\delta,T^\delta)+\boldsymbol{\nabla}\cdot I^\delta=0, \tag{IV.21}$$

$$\frac{\partial}{\partial t}\,n\mathscr{E}(\mu^\delta,T^\delta)+\boldsymbol{\nabla}\cdot I_W^\delta-\boldsymbol{\nabla}_x V\cdot I^\delta=\frac{1}{\delta}\,W(\mu^\delta,T^\delta,T_L), \tag{IV.22}$$

where $\delta\ll 1$ is a small parameter, and the current I^δ and the energy current I_w^δ are given by the constitutive relations

$$I^\delta=-\left[\mathscr{D}_{11}\left(\nabla_x\left(\frac{\mu^\delta}{T^\delta}\right)-\frac{\nabla_x V}{T^\delta}\right)+\mathscr{D}_{12}\,\frac{\nabla_x T^\delta}{(T^\delta)^2}\right], \tag{IV.23}$$

$$I_W^\delta=-\left[\mathscr{D}_{21}\left(\nabla_x\left(\frac{\mu^\delta}{T^\delta}\right)-\frac{\nabla_x V}{T^\delta}\right)+\mathscr{D}_{22}\,\frac{\nabla_x T^\delta}{(T^\delta)^2}\right]. \tag{IV.24}$$

We are now interested in the behavior of (IV.21) and (IV.22) when $\delta\to 0$. Again, a Hilbert expansion can be used:

$$\mu^\delta=\mu_0+\delta\mu_1+\cdots,\quad T^\delta=T_0+\delta T_1+\cdots,\quad I^\delta=I_0+\delta I_1+\cdots\ . \tag{IV.25}$$

The order δ^{-1} and δ^0 equations are thus written

$$W(\mu_0,T_0,T_L)=0, \tag{IV.26}$$

$$\frac{\partial}{\partial t}\,n(\mu_0,T_0)+\boldsymbol{\nabla}\cdot I_0=0, \tag{IV.27}$$

and I_0 is given by (IV.23) with μ^δ, T^δ replaced by μ_0, T_0. Then, using Lemma 4.11 of Ref. 16, we easily obtain the following.

Theorem IV.9: The solution μ_0, T_0 of system (IV.26) and (IV.27) is $T_0 = T_L$ and μ_0 given by the conventional drift-diffusion model:

$$\frac{\partial}{\partial t} n(\mu_0, T_L) + \nabla \cdot I_0 = 0, \tag{IV.28}$$

$$I_0 = -\left[\mathscr{D}_{11}(x, \mu_0, T_L) \left(\nabla_x \left(\frac{\mu_0}{T_L} \right) - \frac{\nabla_x V}{T_L} \right) + \mathscr{D}_{12}(x, \mu_0, T_L) \frac{\nabla_x T_L}{(T_L)^2} \right]. \tag{IV.29}$$

Remark IV.10: In particular, when T_L is independent of x, one recovers the more usual form

$$I_0 = -\mathscr{D}_{11}(x, \mu_0, T_L) \frac{\nabla_x (\mu_0 - V)}{T_L}, \tag{IV.30}$$

with $\mathscr{D}_{11}(x, \mu_0, T_L)$ given by formula (IV.17). ■

V. SECOND MACROSCOPIC SCALE DRIVEN BY OPTICAL PHONON COLLISIONS: THE "PERIODIZED SPHERICAL" HARMONIC EXPANSION MODEL

A. Scaling

We return to the "spherical" harmonic expansion model (3.20) and (3.21) and we investigate what happens when the optical phonon collision operator is supposed to be dominant instead of the electron–electron one as in Sec. IV. We recall that this is more likely to happen when the typical energy of the electron is of the order of the phonon energy (i.e., a few 10^{-2}–10^{-1} eV). Therefore, this assumes that the energy distribution function has no "high energy tail."

Going back to the notations of Sec. IV A, we assume $\nu_{\mathrm{ac}}/\alpha^2 \simeq \overline{\nu_e} \simeq 0(1)$ while $\nu_{\mathrm{op}}/\alpha^2 = 1/\beta$, $\beta \ll 1$. In this case, the evolution of the energy distribution function $F^\beta(x, \varepsilon, t)$ is governed by

$$N(\varepsilon) \frac{\partial F^\beta}{\partial t} + \nabla_x \cdot J^\beta + \nabla_x V \cdot \frac{\partial J^\beta}{\partial \varepsilon} = \frac{1}{\beta} S_{\mathrm{op}}(F^\beta) + S_1(F^\beta), \tag{V.1}$$

$$J^\beta(x, \varepsilon, t) = -D(x, \varepsilon) \left(\nabla_x F^\beta + \nabla_x V \frac{\partial F^\beta}{\partial \varepsilon} \right), \tag{V.2}$$

with $S_{\mathrm{op}}(F^\beta)$ given by (IV.2) and $S_1(F^\beta) = S_{\mathrm{ac}}(F^\beta) + S_e(F^\beta)$ and $S_{\mathrm{ac}}(F^\beta)$, $S_e(F^\beta)$ given by (IV.2) and (IV.3), respectively. We are again interested in the limit $\beta \to 0$ and again we use a Hilbert expansion:

$$F^\beta = F_0 + \beta F_1 + \cdots, \quad J^\beta = J_0 + \beta J_1 + \cdots .$$

Identifying equal powers of β yields

$$S_{\mathrm{op}}(F_0) = 0, \tag{V.3}$$

$$N(\varepsilon) \frac{\partial F^0}{\partial t} + \nabla_x \cdot J_0 + \nabla_x V \cdot \frac{\partial J_0}{\partial \varepsilon} - S_1(F_0) = D_{F_0} S_{\mathrm{op}}(F_1), \tag{V.4}$$

where $D_{F_0} S_{\mathrm{op}}(F_1)$ denotes the derivative of S_{op} at F_0 applied to F_1. As usual, we first investigate the properties of S_{op} and $D_{F_0} S_{\mathrm{op}}$.

B. Properties of S_{op} and $D_{F_0}S_{op}$

A straightforward computation gives (see also Ref. 10)

$$S_{\mathrm{op}}(F)=N(\varepsilon)\int_{\mathbb{R}}A(x,\varepsilon,\varepsilon')\sigma(\varepsilon,\varepsilon')(a^{-\varepsilon}F'(1-\eta F)-a^{-\varepsilon'}F(1-\eta F'))N(\varepsilon')d\varepsilon', \quad \text{(V.5)}$$

where $a=\exp(1/T_L)$,

$$\sigma(\varepsilon,\varepsilon')=a^{\varepsilon}\delta(\varepsilon'-\varepsilon+1)+a^{\varepsilon'}\delta(\varepsilon'-\varepsilon-1)=\sigma(\varepsilon',\varepsilon), \quad \text{(V.6)}$$

$$\begin{aligned}A(x,\varepsilon,\varepsilon')&=\frac{1}{N(\varepsilon)N(\varepsilon')}\int_{\varepsilon}\int_{\varepsilon'}\tilde{\Phi}_{\mathrm{op}}(x,k,k')dN_{\varepsilon}(k)dN_{\varepsilon'}(k'),\\&=A(x,\varepsilon',\varepsilon)\end{aligned} \quad \text{(V.7)}$$

and $\tilde{\Phi}_{\mathrm{op}}=\Phi_{\mathrm{op}}/(a-1)$. In (V.5), we have rescaled the energies so that the optical phonon energy is equal to 1. The form (V.5) is similar to (II.4). Following Ref. 13 or 10, we have the following.

Proposition V.1: (i) Entropy inequality: Let χ be a nondecreasing function on $\mathbb{R}_+$ and let $H(\varepsilon)$ be defined by $F(1-\eta F)^{-1}=Ha^{-\varepsilon}$. Then

$$\begin{aligned}\int_{\mathbb{R}}S_{\mathrm{op}}(F)\chi(H)d\varepsilon=-\frac{1}{2}\int_{\mathbb{R}}A(x,\varepsilon,\varepsilon')\sigma(\varepsilon,\varepsilon')(1-\eta F)(1-\eta F')a^{-\varepsilon-\varepsilon'}(H-H')\\\times(\chi(H)-\chi(H'))N(\varepsilon)N(\varepsilon')d\varepsilon d\varepsilon'\leq 0.\end{aligned}$$

(ii) We write a.e. $(N(\varepsilon)d\varepsilon)$ for ''almost everywhere with respect to the measure $N(\varepsilon)d\varepsilon$.'' For any function $q(\varepsilon)$, which is a.e. $(N(\varepsilon)d\varepsilon)$ one-periodic in ε, we have:

$$\int_{\mathbb{R}}S_{\mathrm{op}}(F)q(\varepsilon)d\varepsilon=0.$$

(iii) $S_{\mathrm{op}}(F)=0\Leftrightarrow\exists\mu(\varepsilon)$, a.e. $(N(\varepsilon)d\varepsilon)$ one-periodic function of ε such that

$$F(\varepsilon)=:\mathscr{F}_{\mu(\varepsilon),T_L}(\varepsilon)=:\mathscr{F}(\varepsilon,\mu(\varepsilon)),$$

where $\mathscr{F}_{\mu,T}(\varepsilon)$ is the Fermi–Dirac distribution (IV.8).

We now introduce the linearized operator about $\mathscr{F}(\varepsilon,\mu(\varepsilon))$:

$$L_{\mathscr{F}}(f)=\frac{1}{N(\varepsilon)}D_{\mathscr{F}}S_{\mathrm{op}}(f). \quad \text{(V.8)}$$

Following Ref. 10, we write

$$L_{\mathscr{F}}(f)=\int_{\mathbb{R}}A(x,\varepsilon,\varepsilon')\sigma(\varepsilon,\varepsilon')\sigma_{\mathscr{F}}(\varepsilon,\varepsilon')\left(\frac{f'}{\mathscr{G}'}-\frac{f}{\mathscr{G}}\right)N(\varepsilon')d\varepsilon', \quad \text{(V.9)}$$

where $\mathscr{G}=:\mathscr{F}(1-\eta\mathscr{F})$ and

$$\sigma_{\mathscr{F}}(\varepsilon,\varepsilon')=\sigma_{\mathscr{F}}(\varepsilon',\varepsilon)=a^{-\mu(\varepsilon)}\mathscr{F}\mathscr{F}', \quad \text{(V.10)}$$

where (V.10) is meaningful only for $\varepsilon'=\varepsilon\pm1$ and on Supp $(N(\varepsilon)N(\varepsilon'))$ (we denote by Supp the support of a function). Let us now assume that

$$\text{Supp } N(\varepsilon)=[0,\, b] \quad \text{and } \{N=0\}=]-\infty,0]\cup[b,+\infty[\tag{V.11}$$

and introduce the Hilbert space

$$K_{\mathscr{G}}=\left\{F(\varepsilon) \text{ s.t. } F=0 \quad \text{a.e. on } \{N=0\}, \quad \int_{\mathbb{R}}|F(\varepsilon)|^2\,\frac{N(\varepsilon)d\varepsilon}{\mathscr{G}(\varepsilon)}<+\infty\right\}, \tag{V.12}$$

provided with the obvious inner product $(,)_{\mathscr{G}}$ and norm $|\cdot|_{\mathscr{G}}$. We have the following.

Proposition V.2: (i) $-L_{\mathscr{F}}$ is a bounded non-negative self-adjoint operator on $K_{\mathscr{G}}$.

(ii) $\text{Ker } L_{\mathscr{F}}=\{p(\varepsilon)\mathscr{G}(\varepsilon)\in K_{\mathscr{G}},\ p(\varepsilon) \text{ one-periodic}\}$.

(iii) $(-L_{\mathscr{F}}f,f)_{\mathscr{G}}\geqslant \mu|f-Pf|^2_{\mathscr{G}}$, where P is the orthogonal projection on $\text{Ker } L_{\mathscr{F}}$ for $(,)_{\mathscr{G}}$.

(iv)

$$Pf(\varepsilon)=\frac{\Sigma_{i\in\mathbb{Z}}N(\varepsilon+i)f(\varepsilon+i)}{\Sigma_{i\in\mathbb{Z}}N(\varepsilon+i)\mathscr{G}(\varepsilon+i)}\,\mathscr{G}(\varepsilon).$$

(v)

$$R(L_{\mathscr{F}})=(\text{Ker } L_{\mathscr{F}})^{\perp}=\left\{f\in K_{\mathscr{G}} \text{ s.t. } \sum_{i\in\mathbb{Z}} f(\varepsilon+i)N(\varepsilon+i)=0\right\}.$$

Proof: By a straightforward computation, we have

$$\begin{aligned}-\int L_{\mathscr{F}}f(\varepsilon)g(\varepsilon)\,\frac{N(\varepsilon)d\varepsilon}{\mathscr{G}(\varepsilon)}&=(-L_{\mathscr{F}}f,g)_{\mathscr{G}}\\ &=\frac{1}{2}\int_{\mathbb{R}}\int_{\mathbb{R}}A(x,\varepsilon,\varepsilon')\sigma(\varepsilon,\varepsilon')\sigma_{\mathscr{F}}(\varepsilon,\varepsilon')\\ &\quad\times\left(\frac{f'}{\mathscr{G}'}-\frac{f}{\mathscr{G}}\right)\left(\frac{g'}{\mathscr{G}'}-\frac{g}{\mathscr{G}}\right)N(\varepsilon)N(\varepsilon')d\varepsilon d\varepsilon'\end{aligned} \tag{V.13}$$

which shows (i). (ii) follows directly from (V.13): $p(\varepsilon)$ is first an a.e. $(N(\varepsilon)d\varepsilon)$ one-periodic function but can be extended into a one-periodic function on $\mathbb{R}$ by the definition of $K_{\mathscr{G}}$ (V.12). For (iv), it is enough to prove that

$$(\text{Ker } L_{\mathscr{F}})^{\perp}=\left\{f\in K_{\mathscr{G}},\sum_{i\in\mathbb{Z}} f(\varepsilon+i)N(\varepsilon+i)=0\right\}. \tag{V.14}$$

Indeed, for $f\in(\text{Ker } L_{\mathscr{F}})^{\perp}$ and any $p(\varepsilon)\ \mathscr{G}(\varepsilon)\in\text{Ker } L_{\mathscr{F}}$, $p(\varepsilon)$ being one-periodic, we have

$$0=\int_{\mathbb{R}}f(\varepsilon)(p(\varepsilon)\mathscr{G}(\varepsilon))\,\frac{N(\varepsilon)d(\varepsilon)}{\mathscr{G}(\varepsilon)}=\int_0^1\left(\sum_{i\in\mathbb{Z}} f(\varepsilon+i)N(\varepsilon+i)\right)p(\varepsilon)d\varepsilon,$$

which gives (V.14). (v) directly follows from (iii) and (V.14). There remains to prove (iii). For that, we notice that

$$(-L_{\mathscr{F}}f,f)_{\mathscr{G}}=\int_{\mathbb{R}}A(\varepsilon,\varepsilon+1)\mathscr{F}(\varepsilon)\mathscr{F}(\varepsilon+1)a^{\varepsilon-\mu(\varepsilon)+1}\left|\frac{f(\varepsilon+1)}{\mathscr{G}(\varepsilon+1)}-\frac{f(\varepsilon)}{\mathscr{G}(\varepsilon)}\right|^2 N(\varepsilon)N(\varepsilon+1)d\varepsilon. \tag{V.15}$$

Hence

$$(-L_{\mathscr{F}}f,f)_{\mathscr{G}} \geqslant C\int_{\mathbb{R}}\left|\frac{f(\varepsilon+1)}{\mathscr{G}(\varepsilon+1)}-\frac{f(\varepsilon)}{\mathscr{G}(\varepsilon)}\right|^2 N(\varepsilon)N(\varepsilon+1)d\varepsilon.$$

Let $n=\mathrm{Int}(b)+1$, where b is defined by (V.11) and Int (b) is the integer part of the real number b. Then

$$(-L_F f,f)_{\mathscr{G}} \geqslant C\sum_{i=0}^{n-1}\int_0^1\left|\frac{f(\varepsilon+i+1)}{\mathscr{G}(\varepsilon+i+1)}-\frac{f(\varepsilon+i)}{\mathscr{G}(\varepsilon+i)}\right|^2 N(\varepsilon+i)N(\varepsilon+i+1)d\varepsilon. \tag{V.16}$$

Now let f be in $(\mathrm{Ker}\, L_{\mathscr{F}})^{\perp}$. Using the formula

$$\frac{f(\varepsilon+k)}{\mathscr{G}(\varepsilon+k)}-\frac{f(\varepsilon+l)}{\mathscr{G}(\varepsilon+l)}=\begin{cases}\displaystyle\sum_{j=l}^{k-1}\frac{f(\varepsilon+j+1)}{\mathscr{G}(\varepsilon+j+1)}-\frac{f(\varepsilon+j)}{\mathscr{G}(\varepsilon+j)}, & k>l,\\ \displaystyle-\sum_{j=k}^{l-1}\frac{f(\varepsilon+j+1)}{\mathscr{G}(\varepsilon+j+1)}-\frac{f(\varepsilon+j)}{\mathscr{G}(\varepsilon+j)}, & k<l,\end{cases}$$

which we multiply by $N\mathscr{G}(\varepsilon+l)$ and sum over all ''l''s, we find

$$h(\varepsilon)f(\varepsilon+k)=\sum_{l=-\infty}^{k-1}N(\varepsilon+l)\mathscr{G}(\varepsilon+l)\left(\sum_{j=l}^{k-1}\frac{f(\varepsilon+j+1)}{\mathscr{G}(\varepsilon+j+1)}-\frac{f(\varepsilon+j)}{\mathscr{G}(\varepsilon+j)}\right)$$
$$-\sum_{l=k+1}^{+\infty}N(\varepsilon+l)\mathscr{G}(\varepsilon+l)\left(\sum_{j=k}^{l-1}\frac{f(\varepsilon+j+1)}{\mathscr{G}(\varepsilon+j+1)}-\frac{f(\varepsilon+j)}{\mathscr{G}(\varepsilon+j)}\right)$$

where

$$h(\varepsilon)=\sum_{i\in\mathbb{Z}}N(\varepsilon+i)\mathscr{G}(\varepsilon+i).$$

Inverting the indices l and j in the above formula and taking the squares, we find

$$h^2(\varepsilon)|f(\varepsilon+k)|^2\leqslant 2\left|\sum_{j=-\infty}^{k-1}\left(\frac{f(\varepsilon+j+1)}{\mathscr{G}(\varepsilon+j+1)}-\frac{f(\varepsilon+j)}{\mathscr{G}(\varepsilon+j)}\right)\sum_{l=-\infty}^{j}N\mathscr{G}(\varepsilon+l)\right|^2$$
$$+2\left|\sum_{j=k}^{+\infty}\left(\frac{f(\varepsilon+j+1)}{\mathscr{G}(\varepsilon+j+1)}-\frac{f(\varepsilon+j)}{\mathscr{G}(\varepsilon+j)}\right)\left(\sum_{l=j+1}^{+\infty}N\mathscr{G}(\varepsilon+l)\right)\right|^2.$$

Now let $\varepsilon\in[0\ \ 1]$ and let us estimate

$$\sum_{k\in\mathbb{Z}}|f(\varepsilon+k)|^2N(\varepsilon+k)=\sum_{k=0}^{n-1}|f(\varepsilon+k)|^2N(\varepsilon+k).$$

Using the fact that $h(\varepsilon)\geqslant C>0$ and that the sums are over a finite number of indices, we deduce from the Cauchy–Schwartz inequality that

$$\sum_{k=0}^{n-1}N(\varepsilon+k)|f(\varepsilon+k)|^2\leqslant C\sum_{k=0}^{n-1}N(\varepsilon+k)\sum_{j=0}^{k-1}\left|\frac{f(\varepsilon+j+1)}{\mathscr{G}(\varepsilon+j+1)}-\frac{f(\varepsilon+j)}{\mathscr{G}(\varepsilon+j)}\right|^2\left|\sum_{l=0}^{j}N\mathscr{G}(\varepsilon+l)\right|^2$$
$$+C\sum_{k=0}^{n-1}N(\varepsilon+k)\sum_{j=k}^{n-2}\left|\frac{f(\varepsilon+j+1)}{\mathscr{G}(\varepsilon+j+1)}-\frac{f(\varepsilon+j)}{\mathscr{G}(\varepsilon+j)}\right|^2\left|\sum_{l=j+1}^{n-1}N\mathscr{G}(\varepsilon+l)\right|^2.$$

Now grouping the terms

$$\left|\frac{f(\varepsilon+j+1)}{\mathcal{G}(\varepsilon+j+1)}-\frac{f(\varepsilon+j)}{\mathcal{G}(\varepsilon+j)}\right|^2$$

corresponding to the same index j and taking a special care of terms with $j=0$ and $j=n-2$, we have

$$\begin{aligned}\sum_{k=0}^{N-1} N(\varepsilon+k)|f(\varepsilon+k)|^2 \leqslant & CN(\varepsilon)\left|\frac{f(\varepsilon+1)}{\mathcal{G}(\varepsilon+1)}-\frac{f(\varepsilon)}{\mathcal{G}(\varepsilon)}\right|^2 \\ & + CN(\varepsilon+n-1)\left|\frac{f(\varepsilon+n-1)}{\mathcal{G}(\varepsilon+n-1)}-\frac{f(\varepsilon+n-2)}{\mathcal{G}(\varepsilon+n-2)}\right|^2 \\ & + C\sum_{i=1}^{n-3}\left|\frac{f(\varepsilon+i+1)}{\mathcal{G}(\varepsilon+i+1)}-\frac{f(\varepsilon+i)}{\mathcal{G}(\varepsilon+i)}\right|^2.\end{aligned}$$

To get the above estimate, we used extensively the property $N \leqslant C$.

Using now the fact that $N(\varepsilon) \geqslant C$ on $[1, n-2]$ [see (V.11)], we finally obtain

$$\forall \varepsilon \in [0,1], \quad \sum_k N(\varepsilon+k)|f(\varepsilon+k)|^2 \leqslant C\sum_k N(\varepsilon+k)N(\varepsilon+k+1)\left|\frac{f}{\mathcal{G}}(\varepsilon+k+1)-\frac{f}{\mathcal{G}}(\varepsilon+k)\right|^2. \tag{V.17}$$

We then deduce from (V.16) that

$$\forall f \in \operatorname{Ker} L_{\mathcal{F}}^{\perp}, \quad (-L_{\mathcal{G}} f\cdot f)_{\mathcal{G}} \geqslant C\sum_k \int_0^1 N(\varepsilon+k)|f(\varepsilon+k)|^2\, d\varepsilon \geqslant C\int_{\mathbb{R}} N(\varepsilon)\left|\frac{f(\varepsilon)}{\mathcal{G}(\varepsilon)}\right|^2 d\varepsilon.$$

This ends the proof. ■

C. Resolution of the Hilbert Expansion (5.3) and (5.4)

From Proposition V.1 (iii), Eq. (V.3) implies that there exists $\mu(x,\varepsilon,t)$, a.e., $(N(\varepsilon)d\varepsilon)$ one-periodic in ε, such that

$$F_0(x,\varepsilon,t)=\mathcal{F}(\varepsilon,\mu(x,\varepsilon,t))\cdot \text{a.e.}(N(\varepsilon)d\varepsilon). \tag{V.18}$$

Then, $J_0(x,\varepsilon,t)$ is given by (V.2) with $\beta=0$, which yields

$$J_0(x,\varepsilon,t)=-D(x,\varepsilon)\mathcal{F}(1-\eta\mathcal{F})\left\{\left(\nabla_x\left(\frac{\mu}{T_L}\right)-\frac{\nabla_x V}{T_L}+\frac{\nabla_x V}{T_L}\frac{\partial\mu}{\partial\varepsilon}\right)-\varepsilon\nabla\left(\frac{1}{T_L}\right)\right\}. \tag{V.19}$$

The resolution of (V.4) leads to the following.

Theorem V.3: Let F_0 be given by (V.18). The solution of Eq. (V.4) exists if and only if $\mu(x,\varepsilon,t)$ satisfies the following system (with periodic boundary conditions on $\varepsilon\in[0,1]$):

$$\frac{\partial}{\partial t}\,\nu(\varepsilon,\mu(x,\varepsilon,t))+\nabla_x\cdot j+\nabla_x V\cdot\frac{\partial j}{\partial\varepsilon}=T_1(\mu), \tag{V.20}$$

$$j(x,\varepsilon,t)=-\left[\Delta_1(x,\varepsilon,\mu(x,\varepsilon,t))\left\{\nabla_x\left(\frac{\mu}{T_L}\right)-\frac{\nabla_x V}{T_L}+\frac{\nabla_x V}{T_L}\frac{\partial\mu}{\partial\varepsilon}\right\}+\Delta_2(x,\varepsilon,\mu(x,\varepsilon,t))\,\frac{\nabla T_L}{T_L^2}\right], \tag{V.21}$$

where for $\varepsilon\in[0,1]$, $\mu\in\mathbb{R}$, we set

$$\nu(\varepsilon,\mu)=\sum_{i\in\mathbb{Z}} N(\varepsilon+i)\mathscr{F}(\varepsilon+i,\mu), \tag{V.22}$$

$$\begin{aligned}\Delta_1(x,\varepsilon,\mu)&=\sum_{i\in\mathbb{Z}} D(x,\varepsilon+i)\mathscr{F}(\varepsilon+i,\mu)(1+\eta\mathscr{F}(\varepsilon+i,\mu)),\\ \Delta_2(x,\varepsilon,\mu)&=\sum_{i\in\mathbb{Z}} D(x,\varepsilon+i)(\varepsilon+i)\mathscr{F}(\varepsilon+i,\mu)(1+\eta\mathscr{F}(\varepsilon+i,\mu)),\end{aligned} \tag{V.23}$$

and for a one-periodic function $\mu(\varepsilon)$,

$$T_1(\mu)(\varepsilon)=\sum_{i\in\mathbb{Z}} S_1(\mathscr{F}(\varepsilon,\mu(\varepsilon)))(\varepsilon+i). \tag{V.24}$$

Proof: From Proposition V.2 (v), the condition for Eq. (V.4) to be solvable in F_1 is

$$\begin{aligned}&\sum_{i\in\mathbb{Z}}\left\{N(\varepsilon+i)\,\frac{\partial}{\partial t}\,\mathscr{F}(\varepsilon+i,\mu(x,\varepsilon,t))+\nabla_x\cdot J_0(x,\varepsilon+i,t)+\nabla_x V\cdot\frac{\partial J_0}{\partial\varepsilon}\,(x,\varepsilon+i,t)\right\}\\ &\quad=\sum_{i\in\mathbb{Z}} S_1(\mathscr{F}(\cdot,\mu(x,\cdot,t)))(\varepsilon+i),\end{aligned}$$

which obviously yields (V.20) and (V.21). ■

In (V.21), only Δ_1 acts as a diffusion coefficient. From proposition III.6, we have the following.

Proposition V.4: $\Delta_1(x,\varepsilon,\mu)$ is a symmetric non-negative 3×3 matrix. Moreover, $\exists C>0$ such that

$$\Delta_1(x,\varepsilon,\mu)\geqslant C\sum_{i\in\mathbb{Z}}\ \frac{1}{N(\varepsilon+i)}\left(\int_{\varepsilon+i}(\nabla_k\varepsilon\otimes\nabla_k\varepsilon)\,dN_{\varepsilon+i}(k)\right)\mathscr{F}(\varepsilon+i,\mu)(1-\eta\mathscr{F}(\varepsilon+i,\mu)). \tag{V.25}$$

In particular, if Q_0 is given by a relaxation time operator (III.28), the following expression of Δ_1 follows from (III.30):

$$\Delta_1(x,\varepsilon,\mu)=\sum_{i\in\mathbb{Z}}\tau(x,\varepsilon+i)\left(\int_{\varepsilon+i}(\nabla_k\varepsilon\otimes\nabla_k\varepsilon)\,dN_{\varepsilon+i}(k)\right)\mathscr{F}(\varepsilon+i,\mu)(1-\eta\mathscr{F}(\varepsilon+i,\mu)). \tag{V.26}$$

When $\Phi_0=\Phi_0(x)$ is independent of k, k', for a parabolic band structure $|k|^2=2m_*\varepsilon$ and a nondegenerate statistics $\mathscr{F}(1-\eta\mathscr{F})\to\exp-((\varepsilon-\mu)/T_L)$, we find from (III.37)

$$\begin{aligned}\Delta_1(x,\varepsilon,\mu)&=\frac{2}{3\Phi_0(x)m_*}\sum_{i\in\mathbb{N}}(\varepsilon+i)\exp\left(-\frac{(\varepsilon+i)-\mu}{T_L}\right)\\ &=\frac{2}{3\Phi_0(x)m_*}\,\frac{\varepsilon+e^{-1/T_L}(1-\varepsilon)}{(1+e^{-1/T_L})^2}\exp\left(-\frac{\varepsilon-\mu}{T_L}\right).\end{aligned} \tag{V.27}$$

D. The third macroscopic scale: The drift–diffusion model

Looking at a longer time scale, the effect of both acoustical phonon collisions and electron–electron collisions will be to relax the periodic function $\mu(x,\varepsilon,t)$ to a constant. We expect the conventional drift-diffusion model to be valid in this regime. After rescaling, system (V.20) and (V.21) is written

$$\frac{\partial}{\partial t}\,\nu(\varepsilon,\mu^{\delta}(x,\varepsilon,t))+\nabla_x\cdot j^{\delta}+\nabla_x V\cdot\frac{\partial j^{\delta}}{\partial\varepsilon}=\frac{1}{\delta}\,T_1(\mu^{\delta}), \tag{V.28}$$

$$j^{\delta}(x,\varepsilon,t)=-\left[\Delta_1(x,\varepsilon,\mu^{\delta}(x,\varepsilon,t))\left(\nabla_x\left(\frac{\mu^{\delta}}{T_L}\right)-\frac{\nabla_x V}{T_L}+\frac{\nabla_x V}{T_L}\,\frac{\partial\mu^{\delta}}{\partial\varepsilon}\right)+\Delta_2(x,\varepsilon,\mu^{\delta}(x,\varepsilon,t))\,\frac{\nabla T_L}{T_L^2}\right], \tag{V.29}$$

where $T_1(\mu^{\delta})=T_e(\mu^{\delta})+T_{\mathrm{ac}}(\mu^{\delta})$ and

$$T_e(\mu)(\varepsilon)=\sum_{i\in\mathbb{Z}} S_e(\mathscr{F}(\varepsilon,\mu(\varepsilon)))(\varepsilon+i),$$

$$T_{\mathrm{ac}}(\mu)(\varepsilon)=\sum_{i\in\mathbb{Z}} S_{\mathrm{ac}}(\mathscr{F}(\varepsilon,\mu(\varepsilon)))(\varepsilon+i),$$

and S_e and S_{ac} are given by (IV.2) and (IV.3).

For any one-periodic function $\psi(\varepsilon)$, we have, by straightforward computation,

$$\int_0^1 T_e(\mu)(\varepsilon)\psi(\varepsilon)d\varepsilon=-\frac{1}{4}\int_{B^4}\Phi_e\delta_\varepsilon\delta_k\pi(1-\eta\mathscr{F})a^{-(\varepsilon+\varepsilon_1)}(\psi'+\psi_1'-\psi-\psi_1)$$
$$\times(a^{(\mu(\varepsilon')+\mu(\varepsilon_1'))}-a^{(\mu(\varepsilon)+\mu(\varepsilon_1))})d^4k, \tag{V.30}$$

with the notations of the proof of Proposition IV.1,

$$a=e^{1/T_L},\quad \pi(1-\eta\mathscr{F})=(1-\eta\mathscr{F})(1-\eta\mathscr{F}_1)(1-\eta\mathscr{F}')(1-\eta\mathscr{F}_1'),$$

and

$$\int_0^1 T_{\mathrm{ac}}(\mu)(\varepsilon)\psi(\varepsilon)d\varepsilon=-\frac{1}{2}\int_{B^2}\frac{\Phi_{\mathrm{ac}}(x,k,k')}{a^{\varepsilon_{\mathrm{ac}}(k-k')}-1}\,\sigma_{\mathrm{ac}}(\varepsilon,\varepsilon')(1-\eta\mathscr{F})(1-\eta\mathscr{F}')$$
$$\times a^{-(\varepsilon+\varepsilon')}(\psi'-\psi)(a^{\mu(\varepsilon')}-a^{\mu(\varepsilon)})dk\,dk', \tag{V.31}$$

with Φ_{ac} and $\varepsilon_{\mathrm{ac}}$ defined in Sec. II and

$$\sigma_{\mathrm{ac}}(\varepsilon,\varepsilon')=a^{\varepsilon}\delta(\varepsilon'-\varepsilon+\varepsilon_{\mathrm{ac}}(k-k'))+a^{\varepsilon'}\delta(\varepsilon'-\varepsilon-\varepsilon_{\mathrm{ac}}(k-k'))=\sigma_{\mathrm{ac}}(\varepsilon',\varepsilon).$$

We deduce the following.

Proposition V.5:

(i) Entropy inequality:

$$\int_0^1 T_e(\mu)(\varepsilon)\mu(\varepsilon)d\varepsilon\leqslant 0,\quad \int_0^1 T_{\mathrm{ac}}(\mu)(\varepsilon)\mu(\varepsilon)d\varepsilon\leqslant 0.$$

(ii) $\int_0^1 T_e(\mu)(\varepsilon)d\varepsilon=0$, $\int_0^1 T_{\mathrm{ac}}(\mu)(\varepsilon)d\varepsilon=0$.

(iii) $T_e(\mu)+T_{\rm ac}(\mu)=0\Rightarrow\mu$ is constant.

Proof: Only the point (iii) needs to be commented on. By (i) this implies that $T_e(\mu)=0$ and thus that $\mu(\varepsilon)$ is an affine function (by the proof of proposition 4.4 of Ref. 16). However, it also needs to be one-periodic in ε, which implies that $\mu(\varepsilon)$ is constant. ■

Let now $\mu\in\mathbb{R}$ be a constant and define $\mathscr{T}_1=\mathscr{T}_{\rm ac}+\mathscr{T}_e$. With $\mathscr{T}_{\rm ac}=D_\mu T_{\rm ac}$, $\mathscr{T}_e=D_\mu T_e$ are the derivatives of $T_{\rm ac}$ and T_e about the constant function μ. By differentiating relations (V.30) and (V.31), we obtain for any ν, $\psi\in L^2(0,1)$

$$\int_0^1(\mathscr{T}_e\nu)(\varepsilon)\psi(\varepsilon)d\varepsilon=-\frac{1}{4}\int_{B^4}\Phi_e\delta_\varepsilon\delta_{\rm ac}\pi(1-\eta\mathscr{F})a^{-(\varepsilon+\varepsilon_1)}a^{2\mu}\ln a(\psi'+\psi_1'-\psi-\psi_1)\times(\nu'+\nu_1-\nu-\nu_1)d^4k \tag{V.32}$$

and

$$\int_0^1(\mathscr{T}_{\rm ac}\nu)(\varepsilon)\psi(\varepsilon)d\varepsilon=-\frac{1}{2}\int_{B^2}\tilde{\Phi}_{\rm ac}\sigma_{\rm ac}(1-\eta\mathscr{F})(1-\eta\mathscr{F}')a^{-(\varepsilon+\varepsilon')}a^{\mu}\ln a(\psi'-\psi)\times(\nu'-\nu)dk\,dk'. \tag{V.33}$$

The following proposition is a direct consequence of (V.32) and (V.33):

Proposition V.6:

(i) $\mathscr{T}_1$ is a bounded non-negative self-adjoint operator on $L^2(0,1)$.
(ii) $\mathrm{Ker}\,\mathscr{T}_1$ is spanned by the constant functions on $[0,1]$.
(iii) $-(\mathscr{T}_1\nu,\nu)_{L^2(0,1)}\geqslant C|\nu-\langle\nu\rangle|^2$, where $\langle\nu\rangle$ is the L^2 mean value.
(iv) $R(\mathscr{T}_1)=(\mathrm{Ker}\,\mathscr{T}_1)^\perp=\{\nu\in L(0,1)^2/\langle\nu\rangle=0\}$.

Proof: The only nonimmediate point is (iii) and it directly follows from Proposition IV.2 (iii). ■

The Hilbert expansion of μ^δ yields

$$\mu^\delta=\mu_0+\delta\mu_1+\cdots,\quad j^\delta=j_0+\delta j_1+\cdots,$$

and by identifying equal powers of δ, we obtain

$$T_1(\mu_0)=0, \tag{V.34}$$

$$\frac{\partial}{\partial t}\nu(\varepsilon,\mu_0(x,\varepsilon,t))+\nabla_x\cdot j_0+\nabla_x V\cdot\frac{\partial j_0}{\partial\varepsilon}=D_{\mu_0}T_1(\mu_1). \tag{V.35}$$

By Proposition V.5 (iii), (V.34) implies that $\mu_0=\mu_0(x,t)$ is independent of ε. Then by (V.29), we deduce

$$j_0(x,\varepsilon,t)=-\left[\Delta_1(x,\varepsilon,\mu_0(x,t))\left(\nabla_x\left(\frac{\mu_0}{T_L}\right)-\frac{\nabla_x V}{T_L}\right)+\Delta_2(x,\varepsilon,\mu_0(x,t))\frac{\nabla T_L}{T_L^2}\right]. \tag{V.36}$$

Proposition V.6 gives the condition for Eq. (V.35) to be solvable in μ_1 and yields the following.

Theorem V.7: Let $\mu_0(x,t)$ be independent of ε. There exists a solution μ_1 of Eq. (V.35) if and only if μ_0 satisfies the system

$$\frac{\partial}{\partial t}n(\mu_0,T_L)+\nabla_x\cdot I_0=0, \tag{V.37}$$

$$I_0 = -\left[\mathscr{D}_{11}(x,\mu_0,T_L)\left(\nabla_x\left(\frac{\mu_0}{T_L}\right) - \frac{\nabla_x V}{T_L}\right) + \mathscr{D}_{12}(x,\mu_0,T_L)\ \frac{\nabla T_L}{T_L^2}\right], \tag{V.38}$$

where $n(\mu,T)$ is defined by (IV.16) and the coefficients $\mathscr{D}_{1j}(x,\mu,T)$ are given by (IV.17).

Proof: By Proposition V.6 (iv), there exists a solution μ_1 of (V.35) if and only if

$$\int_0^1 \left(\frac{\partial}{\partial t}\ \nu(\varepsilon,\mu_0)(x,t)\right) + \nabla_x \cdot j_0 + \nabla_x V \cdot\ \frac{\partial J_0}{\partial \varepsilon} d\varepsilon = 0.$$

There remains to combine the integration on $[0,1]$ with the summation over $i \in \mathbb{Z}$ in formulas (V.22) and (V.24) to recover the formulae (IV.16) and (IV.17) and to obtain the result. ■

Remark V.8: Starting from the ''spherical'' harmonic expansion model, it is equivalent to recover the usual drift-diffusion model, either via the energy-transport model or via the ''periodized spherical'' harmonic expansion model: the expression of the diffusion coefficients is the same (compare Theorem V.7 with Theorem IV.9). ■

Energy extremes and spin configurations for the one-dimensional antiferromagnetic Ising model with arbitrary-range interaction

Jack Douthett

Richard Krantz
Department of Physics, Metropolitan State College of Denver, Denver, Colorado 80217-3362

(Received 19 October 1995; accepted for publication 18 March 1996)

The one-dimensional antiferromagnetic spin-$\frac{1}{2}$ Ising model is investigated using the formalism of Maximally/Minimally Even sets. The salient features of Maximally/Minimally Even set theory are introduced. Energy and spin content vectors are defined to facilitate the use of interval spectra used in Maximally/Minimally Even set theory. It is shown that Maximally Even sets of up- and down-spins minimize the configurational energy per spin and that Minimally Even sets maximize configurational energy per spin. An exponentially decreasing antiferromagnetic pairwise interaction of arbitrary range is used as an example interaction. The asymptotic ($N\rightarrow\infty$) configurational energy per spin and the energy per spin calculated for seven-near neighbors are compared. © *1996 American Institute of Physics.* [S0022-2488(96)00107-7]

I. INTRODUCTION

The simplest description of the pairwise interaction of spins on a lattice is given by the Ising model which yields the following for the configurational energy of a lattice of spin-$\frac{1}{2}$ ''particles:''

$$\mathscr{H}=-4\sum_{\substack{i,j=0\\ i\neq j}}^{N-1}\mathscr{J}(|i-j|)s_{iz}s_{jz},$$

where N is the total number of lattice sites, and the sum is taken over all pairs of lattice sites. The function $\mathscr{J}(|i-j|)$ is the pairwise interaction energy, the absolute value of which decreases with distance. The s_z are the z-components of the spins which may take on the values of $\pm\frac{1}{2}$. (For a discussion of lattice gas models, see the excellent reference by Simon.[1])

In a one-dimensional system, it is convenient to invoke periodic boundary conditions which requires that $s_{0z}=s_{Nz}$. Therefore, a one-dimensional spin-$\frac{1}{2}$ lattice can be thought of as a cycle of lattice sites, some of which are occupied by up-spins ($+\frac{1}{2}$) and others by down-spins ($-\frac{1}{2}$). A simplification may be made by defining $\sigma_p=2s_{pz}$. Then, the configurational energy may be written as

$$\mathscr{H}=-\sum_{\substack{i,j=0\\ i\neq j}}^{N-1}\mathscr{J}(|i-j|)\sigma_i\sigma_j,$$

where the σ take on the values of ±1. By considering antiferromagnetic pairwise interactions only (i.e., $\mathscr{J}(|i-j|)<0$), a further simplification results, and the configurational energy is given by

0022-2488/96/37(7)/3334/20/$10.00

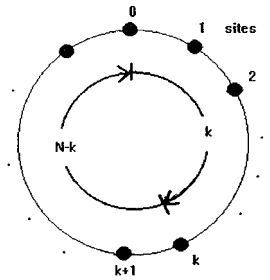

FIG. 1. Clockwise distances between pairs of lattice sites.

$$\mathscr{H}_{\text{anti}}=\sum_{\substack{i,j=0\\ i\neq j}}^{N-1} J(|i-j|)\sigma_i\sigma_j\,,$$

where $J(|i-j|)=|\mathscr{J}(|i-j|)|$.

For a given down-spin density (ratio of the number of down-spin sites to the total number of sites), the average configurational energy (energy per site) depends on the distribution of the up- and down-spin sites. Since there is a large number of sites, for a given down-spin density, there are many possible values for the average configurational energy. We will focus on the average energy extremes of this cyclic one-dimensional system by exploiting the formalism of Maximally Even and Minimally Even sets as described by Clough and Douthett[2] and Block and Douthett.[3]

Curiously, many of the tools employed in this paper have been developed in the music theory literature. Content vectors are routinely used in the analysis of twentieth-century music as well as in compositional design, and Lewin[4] was the first to explore the properties of these vectors in microtonal systems (systems that have other than 12 divisions to the octave). Block and Douthett[3] developed weighting vectors to be used in conjunction with content vectors to find pitch-class sets (collections of tones) whose members have particular pairwise intervallic relationships. In doing so, they developed a measure that compares the evenness between any two pitch-class sets of the same size. Clough and Myerson[5,6] developed interval spectra to explore combinatorial properties of diatonic scales (e.g., the white keys on the piano) and to extend these properties into microtonal systems. Clough and Douthett[2] expanded on this work and developed the theory of Maximally Even Sets. These sets, along with their iterations, model scale and chord structures in both the usual musical system (12 divisions to the octave) and microtonal systems.

II. ENERGY, CONTENT, AND SPIN CONTENT VECTORS

The method discussed in this section and the next in which the dot product of an energy vector and a content vector is used to determine the configurational energy of a particular lattice configuration is based on related work done by Block and Douthett.[3] To apply their method to the problem at hand, let N be the number of sites in the lattice, N_- be the number of these sites occupied by down-spins, and N_+ be the number occupied by up-spins. Assuming periodic boundary conditions, for each pair of sites, there are two *clockwise distances* (with respect to the number of sites that separate them) associated with this pair (Fig. 1). If the consecutive sites in the lattice are represented by the consecutive integers 0 through $N-1$, the two distances associated with site 0 and site k are k and $N-k$. Now assume J is a strictly convex function on the interval $(0,\infty)$. [Later the discussion will be restricted to pairwise interactions for which $\Sigma_{k=1}^{\infty}J(k)$ converges.] Then the absolute value of the energy contributed by a pair of sites at a distance k is

$$J_N(k)=J(k)+J(N-k).$$

Thus, if E_- is the sum of the J_N-functions over all down-spin pairs, E_+ is the sum of the J_N-functions over all the up-spin pairs, and E_0 is the sum over all the pairs with opposite orientations, the total energy of the lattice is

$$E = E_+ + E_- - E_0 .$$

It is convenient to construct vectors that allow computation of this energy via dot products. The first vector, the *energy vector*, is defined as follows:

$$W = (J_N(1), J_N(2), \ldots, J_N(\lfloor N/2 \rfloor)).$$

To construct the content vectors, consider the following example:

Suppose $N = 7$ and $N_- = 3$. (Hence, $N_+ = 4$.) Consider the distribution in Fig. 2(b) on the complete labeled graph K_7. Then the set of down-spins is $S_- = \{0,2,3\}$ and the set of up-spins is $S_+ = \{1,4,5,6\}$. Now consider the complete labeled subgraphs K_- [Fig. 2(a)] and K_+ [Fig. 2(c)]. The edges of these graphs are weighted as follows: Suppose an edge e has incident vertices whose labels are a and b. Then the weight of this edge is

$$w(e) = \min\{|a-b|, 7-|a-b|\}.$$

The *content vectors* of these graphs are three-tuples that have as their kth entries the number of edges that have weight k. Then the content vectors for K_-, K_7, and K_+ are $V_- = (1,1,1)$, $V_7 = (7,7,7)$, and $V_+ = (2,2,2)$, respectively.

It is possible to compute V_+ without its graph. Lewin[4] has shown

$$V_+ - V_- = (n,n,n),$$

where $n = N_+ - N_- = N - 2N_-$. In this case, $n = 7 - 2 \cdot 3 = 1$. Thus,

$$V_+ = (1,1,1) + V_- = (2,2,2).$$

This characterization will be useful when these results are generalized.

Now, consider the complement of $K_- \cup K_+$,

$$K_{-,+} = (K_- \cup K_+)^c$$

whose graph is illustrated in Fig. 2(d). This graph is a complete bipartite, and the edges in this graph are precisely those that are incident to one up-spin site and one down-spin site. By definition, the edge sets of K_-, K_+, and $K_{-,+}$ partition the edge set of K_7. The content vector V_0 of $K_{-,+}$ is computed as follows:

$$V_7 = V_- + V_+ + V_0, \quad V_0 = V_7 - V_- - V_+ = (4,4,4).$$

Note that this corresponds to the calculation by inspection of $K_{-,+}$ in Fig. 2(d). Finally the *spin content vector* is defined as

$$V = V_+ + V_- - V_0 = (1,1,1).$$

The above example may be extended to the general case. The lattice may be modelled with the complete labeled graph K_N whose labels range from 0 through $N-1$. Then the edge weight of an edge e whose incident vertices have labels a and b is

$$w(e) = \min\{|a-b|, N-|a-b|\}.$$

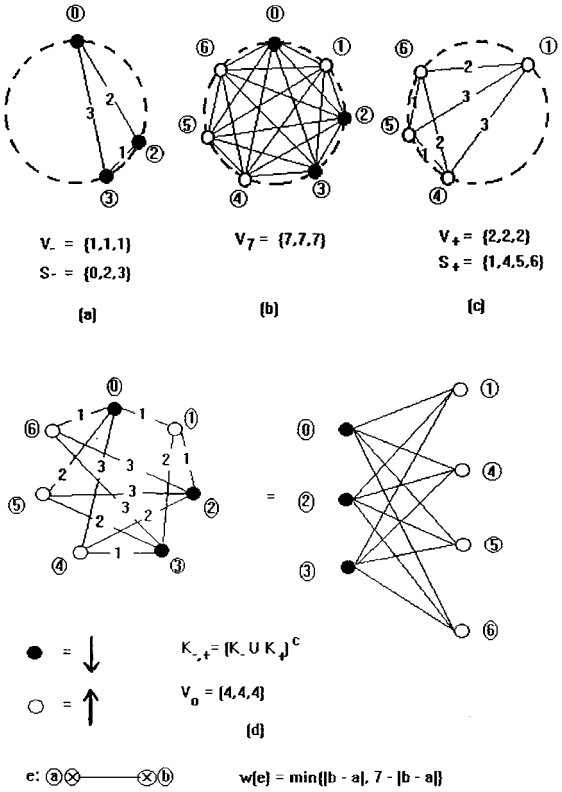

FIG. 2. Graphs and content vectors.

The notation $(\cdots n\cdots)$ indicates $a\lfloor N/2\rfloor$-tuple in which every entry is n. For convenience, assume N is odd. Then the content vector for K_N is $V_N=(\cdots N\cdots)$. [Note that if N is even, the last entry of this vector must be divided by 2. It is left to the reader to verify that the assumption that N is even will produce the same results as $N\to\infty$.]

Now let S_- and S_+ be the sets of labels of down-spins and up-spins, respectively. Then the complete labeled subgraphs K_- and K_+ on these sets and their corresponding content vectors V_- and V_+ are constructed in the same way as those in the above example. Because of symmetry, it can be assumed without loss of generality that $N_-<N/2$. Furthermore, since $N_-<N_+$, it can be shown that $V_+-V_-=(\cdots N-2N_-\cdots)$.[4] Thus,

$$V_+=(\cdots N-2N_-\cdots)+V_-. \tag{1}$$

Define the graph $K_{-,+}=(K_-\cup K_+)^c$ to be the complete bipartite graph with partitions S_- and S_+, and let its content vector be V_0. Then, since $V_N=(\cdots N\cdots)$, and the edge sets of K_-, K_+, and $K_{-,+}$ partition the edge set of K_N, (1) implies

$$V_-+V_++V_0=(\cdots N\cdots),\quad V_0=2(\cdots N_-\cdots)-2V_-. \tag{2}$$

Then, by (1) and (2),

$$V=V_++V_--V_0=4V_-+(\cdots N-4N_-\cdots).$$

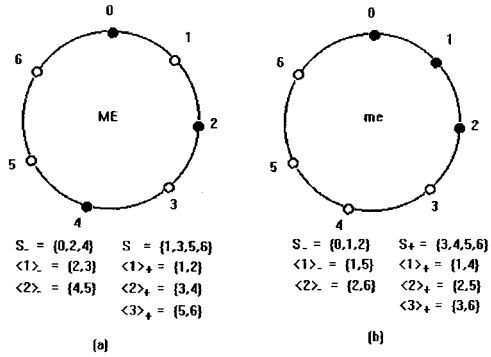

FIG. 3. ME and me distributions.

This means that the spin content vector of any configuration can be completely determined by the set of down-spin labels. The total energy can be found by taking the dot product of the spin content vector and the energy vector:

$$E=E_+ + E_- - E_0 = V_+ \cdot W + V_- \cdot W - V_0 \cdot W = (V_+ + V_- - V_0)\cdot W = V \cdot W.$$

In the previous example, $V_- = (1,1,1)$. Thus,

$$V = 4(1,1,1) + (\cdots 7 - 4(3) \cdots) = -(1,1,1).$$

So the total energy of the lattice is

$$E = V \cdot W = -(1,1,1)\cdot (J_7(1), J_7(2), J_7(3)) = -J_7(1) - J_7(2) - J_7(3).$$

III. MAXIMALLY AND MINIMALLY EVEN DISTRIBUTIONS

Consider the configurations in Fig. 3. The total energy for the configuration in Fig. 3(a) is $E=-5J_7(1)+3J_7(2)-J_7(3)$ and in Fig. 3(b), $E=3J_7(1)-J_7(2)-5J_7(3)$. For a given convex interaction J, the configuration in Fig. 3(a) will yield the least energy and in Fig. 3(b), the greatest. If J is strictly convex, the only other configurations yielding these energy extremes are rotations of the above. We now turn our attention to the unique properties of the classes of these configurations.

The *interval spectrum of near-neighbor down-spins (up-spins)* is defined to be the set of distinct clockwise distances between each pair of consecutive down-spins (up-spins). This set is denoted by $\langle 1\rangle_-(\langle 1\rangle_+)$. Thus, for the sets in Fig. 2, $\langle 1\rangle_- = \{1,2,4\}$ and $\langle 1\rangle_+ = \{1,2,3\}$; in Fig. 3(a), $\langle 1\rangle_- = \{2,3\}$ and $\langle 1\rangle_+ = \{1,2\}$; and in Fig. 3(b), $\langle 1\rangle_- = \{1,5\}$ and $\langle 1\rangle_+ = \{1,4\}$. This concept may be extended to sets of clockwise distances between pairs of next-neighbor down-spins (up-spins) [pairs that have precisely one down-spin (up-spin) site between them]. Then for the sets in Fig. 2, $\langle 2\rangle_- = \{3,5,6\}$ and $\langle 2\rangle_+ = \{2,3,4,5\}$; in Fig. 3(a), $\langle 2\rangle_- = \{4,5\}$ and $\langle 2\rangle_+ = \{3,4\}$; and in Fig. 3(b), $\langle 2\rangle_- = \{2,6\}$ and $\langle 2\rangle_+ = \{2,5\}$. In general, the *spectrum of* k, written $\langle k\rangle_\pm$, is the set of distinct clockwise distances between pairs of down-spins (up-spins) that have precisely $k-1$ down-spins (up-spins) between them. A pair of down-spins (up-spins) is *associated with* k if the pair has the above property. These spectra are defined for $1 \leqslant k \leqslant N_\pm - 1$, and they were originally defined by Clough and Myerson.[5,6] If the clockwise distances of all the pairs of sites of like spins associated with k are added together, their sum is Nk (Clough and Myerson[5,6] and Hubbard[7]). For example, in Fig. 3(a) where $\langle 2\rangle_+ = \{3,4\}$, there are two intervals of length 3 and two of length 4 associated with $k=2$. This corresponds to the equality $2\cdot 3 + 2\cdot 4 = 7\cdot 2$. Similarly, for $\langle 3\rangle_+ = \{5,6\}$, there are

three intervals of length 5 and one of length 6 associated with $k=3$, and $3\cdot5+1\cdot6=7\cdot3$. In general, if $l\in\langle k\rangle_{\pm}$ and $r_{k,l}$ is the number of down-spin (up-spin) pairs associated with k that have a clockwise distance of l, then

$$\sum_{l\in\langle k\rangle_{\pm}} r_{k,l}l=Nk.$$

Hubbard[7] observed that, for a given down-spin density, the minimum average energy occurs when each spectrum consists of one or two consecutive integers. Clough and Douthett[2] showed that, for such configurations,

$$\langle k\rangle_{\pm}=\left\{\left\lfloor\frac{Nk}{N_{\pm}}\right\rfloor,\left\lceil\frac{Nk}{N_{\pm}}\right\rceil\right\},$$

where $1\leqslant k\leqslant N_{\pm}-1$. In addition, they generated the classes of all configurations that have this property with their *maximally even (ME) algorithm*:[2]

> Let i be a fixed integer such that $0\leqslant i\leqslant N-1$, and assign down-spins (up-spins) to sites $\lfloor(Nk+i)/N_{\pm}\rfloor$ where $k=0,1,\ldots,N_{\pm}-1$. Assign up-spins (down-spins) to the remaining sites. Then each down- and up-spin spectrum consists of one or two consecutive integers. Conversely, if each down-spin (up-spin) spectrum consists of one or two consecutive integers, then there exists an i, $0\leqslant i\leqslant N-1$, such that the down-spins (up-spins) occupy the sites $\lfloor(Nk+i)/N_{\pm}\rfloor$, $k=0,1,\ldots,N_{\pm}-1$, and the up-spins (down-spins) occupy the rest.

[A slightly more restrictive form of this algorithm is discussed by Clough and Myerson[5,6] and Bak.[8]] A set of down-spins (up-spins) in which each spectrum consists of one or two consecutive integers is called a *ME set*. Clough and Douthett[2] showed that, for a given N and $N_{\pm}$, ME sets are equivalent under rotation and that the complement of a ME set is also a ME set. When S_{-} and S_{+} are ME sets, then the configuration is a *ME configuration.*

Minimally Even (me) Sets were first suggested by Block and Douthett.[3] A configuration is a *me configuration* when all the sites with like spin are clustered together, and the sets of down-spins and up-spins are called *me sets* as illustrated in Fig. 3(b). It is clear that the complement of a me set is me, and when $S_{\pm}$ is a me set then

$$\langle k\rangle_{\pm}=\{k,N-N_{\pm}+k\}$$

for all k, $1\leqslant k\leqslant N_{\pm}-1$. Moreover, for any configuration, ME, me, or otherwise, if $l\in\langle k\rangle_{\pm}$, then

$$k\leqslant l\leqslant N-N_{\pm}+k.$$

Note that the energy contributed to the lattice by the down-spins (up-spins) may be computed in the following way:

(1) For each k and each $l\in\langle k\rangle_{\pm}$, determine $r_{k,l}$.
(2) For each $l\in\langle k\rangle_{\pm}$, compute $r_{k,l}J(l)$.
(3) For each k, sum the products in (2) over $l\in\langle k\rangle_{\pm}$.
(4) Sum the results in (3) over k, $1\leqslant k\leqslant N_{\pm}-1$.

Thus,

$$E_{\pm}=\sum_{k}\sum_{l\in\langle k\rangle_{\pm}} r_{k,l}J(l).$$

This double sum is smallest when the set $S_{\pm}$ is a ME set and largest when it is a me set, and, for any strictly convex function J, the total energy E is minimum if and only if the configuration is ME and maximum precisely when the configuration is me (see Appendix A).

IV. SPIN CONTENT VECTORS AND AVERAGE ENERGY FOR ME CONFIGURATIONS

It should be noted that if J is convex but not strictly convex, for a given N and N_-, ME and me configurations still minimize and maximize total energy, respectively, but they may not have these properties uniquely. In what follows, we assume only that J is a convex function, although we will focus on ME and me configurations since much is known about their structures.

Let ρ be the down-spin density (i.e., $\rho=N_-/N$) and $\{x\}$ be the fractional part of x. It is not difficult to show that if $\rho=0$, the configurational energy per spin is $\Sigma_{k=1}^{N}J(k)$. Otherwise, for an equivalent problem. Clough and Douthett[2] have shown that, for a ME set and fixed integer k, $1\leqslant k\leqslant N_- -1$, there are $N\rho(1-\{k/\rho\})$ down-spin pairs associated with k that have length $\lfloor k/\rho\rfloor$ and $N\rho\{k/\rho\}$ down-spin pairs associated with k that have length $\lfloor k/\rho\rfloor+1$. Assuming $N_-<N/2$ and N is odd, the content vector for a ME set is

$$V_-=(\nu_1^-,\nu_2^-,\ldots,\nu_{(N-1)/2}^-)$$

where

$$\nu_j^-=\begin{cases} N\rho(1-\{k/\rho\}), & \text{if } j=\lfloor k/\rho\rfloor,\\ N\rho\{k/\rho\}, & \text{if } j=\lfloor k/\rho\rfloor+1,\\ 0, & \text{otherwise.}\end{cases}$$

Since $V=4V_-+(\cdots N-4N_-\cdots)$, the ME spin content vector is

$$V_{\mathrm{ME}}=(\nu_1,\nu_2,\ldots,\nu_{(N-1)/2}),$$

where

$$\nu_j=\begin{cases} N(1-4\rho\{k/\rho\}), & \text{if } j=\lfloor k/\rho\rfloor,\\ N(1+4\rho\{k/\rho\}-4\rho), & \text{if } j=\lfloor k/\rho\rfloor+1,\\ N(1-4\rho), & \text{otherwise.}\end{cases}$$

Then the minimum configurational energy for a given N and N_- is $E_{\min}=V_{\mathrm{ME}}\cdot W$; whence, the minimum average energy for a given down-spin density is

$$U_N^{\min}(\rho)=\frac{V_{\mathrm{ME}}\cdot W}{N}=4\rho\sum_{k=1}^{\lfloor N\rho/2\rfloor}[(1-\{k/\rho\})J_N(\lfloor k/\rho\rfloor)+\{k/\rho\}J_N(\lceil k/\rho\rceil)]+(1-4\rho)\sum_{k=1}^{N}J(k).$$

Now assume (in addition to the convexity of J) that $\Sigma_{k=1}^{\infty}J(k)$ converges, and define $U^{\min}$ as follows:

$$U^{\min}(\rho)=\begin{cases}\Sigma_{j=1}^{\infty}J(j), & \text{if } \rho=0,\\ \Sigma_{k=0}^{\infty}f_k(\rho), & \text{otherwise,}\end{cases}\tag{3}$$

where

$$f_k(\rho)=\begin{cases}(1-4\rho)\Sigma_{j=1}^{\infty}J(j), & \text{if } k=0,\\ 4\rho[(1-\{k/\rho\})J(\lfloor k/\rho\rfloor)+\{k/\rho\}J(\lceil k/\rho\rceil)], & \text{otherwise.}\end{cases}$$

Then $U_N^{\min} \to U^{\min}$ uniformly on $[0, \frac{1}{2}]$, $U^{\min}$ is uniformly continuous on $[0, \frac{1}{2}]$, and, for each $\rho \in [0, \frac{1}{2}]$, the series defining $U^{\min}(\rho)$ is absolutely convergent (Appendix B). Since this series is absolutely convergent, rearranging the terms in the series will not effect the sum. Let

$$U^{\min}(\rho) = a_1(\rho)J(1) + a_2(\rho)J(2) + a_3(\rho)J(3)\cdots$$

be a rearrangement of (3) with partial sums

$$u_n^{\min}(\rho) = a_1(\rho)J(1) + a_2(\rho)J(2) + a_3(\rho)J(3)\cdots + a_n(\rho)J(n).$$

Then, for each n, the coefficients of $u_n^{\min}$ are functions of ρ and can be determined by (3). For example, suppose the antiferromagnetic pairwise interaction is given by

$$\mathscr{J}(k) = -J_0 e^{-\alpha k}$$

where α and J_0 are positive constants. Then $J(k) = J_0 e^{-\alpha k}$, and the seventh partial sum is

$$u_7^{\min}(\rho) = a_1(\rho)J(1) + a_2(\rho)J(2) + \cdots + a_7(\rho)J(7), \tag{4}$$

where the coefficients are given below:

	a_1	a_2	a_3	a_4	a_5	a_6	a_7
$0 \leqslant \rho \leqslant \frac{1}{8}$	$1-4\rho$	$1-4\rho$	$1-4\rho$	$1-4\rho$	$1-4\rho$	$1-4\rho$	$1-4\rho$
$\frac{1}{8} < \rho \leqslant \frac{1}{7}$	$1-4\rho$	$1-4\rho$	$1-4\rho$	$1-4\rho$	$1-4\rho$	$1-4\rho$	$28\rho-3$
$\frac{1}{7} < \rho \leqslant \frac{1}{6}$	$1-4\rho$	$1-4\rho$	$1-4\rho$	$1-4\rho$	$1-4\rho$	$24\rho-3$	$5-28\rho$
$\frac{1}{6} < \rho \leqslant \frac{1}{5}$	$1-4\rho$	$1-4\rho$	$1-4\rho$	$1-4\rho$	$20\rho-3$	$5-24\rho$	$1-4\rho$
$\frac{1}{5} < \rho \leqslant \frac{1}{4}$	$1-4\rho$	$1-4\rho$	$1-4\rho$	$16\rho-3$	$5-20\rho$	$1-4\rho$	$1-4\rho$
$\frac{1}{4} < \rho \leqslant \frac{2}{7}$	$1-4\rho$	$1-4\rho$	$12\rho-3$	$5-16\rho$	$1-4\rho$	$1-4\rho$	$28\rho-7$
$\frac{2}{7} < \rho \leqslant \frac{1}{3}$	$1-4\rho$	$1-4\rho$	$12\rho-3$	$5-16\rho$	$1-4\rho$	$24\rho-7$	$9-28\rho$
$\frac{1}{3} < \rho \leqslant \frac{3}{8}$	$1-4\rho$	$8\rho-3$	$5-12\rho$	$1-4\rho$	$20\rho-7$	$9-24\rho$	$1-4\rho$
$\frac{3}{8} < \rho \leqslant \frac{2}{5}$	$1-4\rho$	$8\rho-3$	$5-12\rho$	$1-4\rho$	$20\rho-7$	$9-24\rho$	$1-4\rho$
$\frac{2}{5} < \rho \leqslant \frac{3}{7}$	$1-4\rho$	$8\rho-3$	$5-12\rho$	$16\rho-7$	$9-20\rho$	$1-4\rho$	$28\rho-11$
$\frac{3}{7} \leqslant \rho \leqslant \frac{1}{2}$	$1-4\rho$	$8\rho-3$	$5-12\rho$	$16\rho-7$	$9-20\rho$	$24\rho-11$	$13-28\rho$

Note that $u_7^{\min}$ is a continuous function made up of line segments whose end points are members of the Farey series F_8—the set of fractions between 0 and 1 inclusive whose denominators do not exceed 8. [In general, the endpoints of the line segments that make up $u_n^{\min}$ are points in the set $[0, \frac{1}{2}] \cap F_{n+1}$.] Shown in Fig. 4 is a plot of the minimum normalized energy per spin, $u_7^{\min}(\rho)/J_0$, versus the down-spin density, ρ, for a value of $\alpha = 0.01$. [A discussion of the significance of the value of α will be given in reference to Figs. 5–8 when the truncated series (4) is compared to the exact values for the minimum normalized energy per spin, which is derived below.] As inferred in

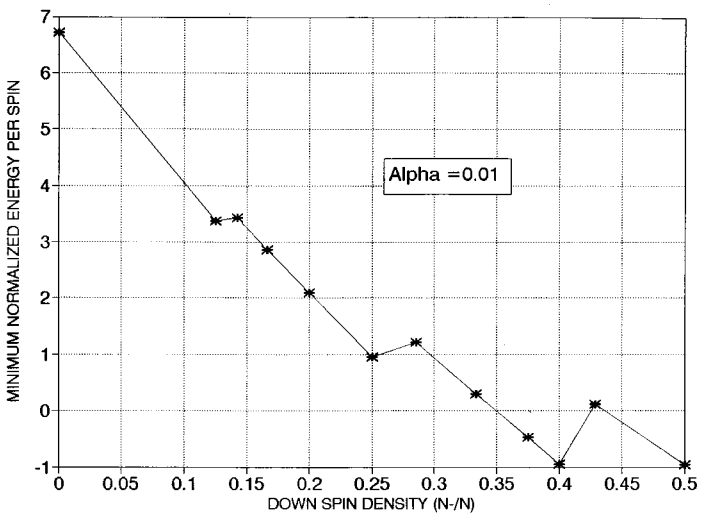

FIG. 4. Normalized configurational energy per spin verses down-spin density for a ME distribution of Ising spins with $\alpha=0.01$; seven nearest-neighbor interactions are included.

the list of coefficients above, the slope of each line segment in Fig. 4 depends on a particular subinterval of the interval $[0, \frac{1}{2}]$.

''Exact'' values can be computed for rational ρ. Let $\rho=p/q$, where p and q are integers. Then $\{k/\rho\}=\{qk/p\}$, and for $j\equiv k(\mathrm{mod}\, p)$, $\{qj/p\}=\{qk/p\}$. Whence, the coefficients, $a_k(\rho)$, cycle. Next, (3) is broken up to reflect this cycling:

$$U^{\min}\left(\frac{p}{q}\right)=\left(\frac{q-4p}{q}\right)\sum_{k=1}^{\infty} J(k)+\frac{4p}{q}\sum_{j=1}^{p}\sum_{k=1}^{\infty}\left[\left(1-\left\{\frac{qj}{p}\right\}\right)J\left(q(k-1)+\left\lfloor\frac{qj}{p}\right\rfloor\right)\right.$$
$$\left.+\left\{\frac{qj}{p}\right\}J\left(q(k-1)+\left\lceil\frac{qj}{p}\right\rceil\right)\right]. \tag{5}$$

Using (5), it is now possible to calculate the exact minimum average energy for a given rational ρ. For example, if $J(k)=J_0e^{-\alpha k}$ as above, then, for $\rho=2/7$, the exact minimum normalized energy per spin is

$$\frac{U^{\min}(\frac{2}{7})}{J_0}=-\frac{e^{-\alpha}}{7(1-e^{-\alpha})}+\frac{4e^{-3\alpha}+4e^{-4\alpha}+8e^{-7\alpha}}{7(1-e^{-7\alpha})}.$$

To compare the normalized energy per spin at the endpoints of the line segments in (4) to that calculated using (5), it is necessary to calculate the exact minimum normalized averages for $\rho\in[0, \frac{1}{2}]\cap F_8$. For $\alpha=0.01$, Fig. 5 compares the minimum normalized energy per spin versus down-spin density for the truncated series $u_7^{\min}(\rho)/J_0$ to the exact values as calculated from (5) for corresponding $p/q\in[0,\frac{1}{2}]\cap F_8$. The truncated series corresponds to approximating the minimum energy by accounting for interaction energies of the seven nearest neighbors only. As shown, for the relatively small value of $\alpha=0.01$, the seven near-neighbor approximation differs significantly from the exact result. The value of α reflects the range of the pairwise interaction. For small values of α the interaction is relatively long ranged. Therefore, more neighbors must be included to adequately approximate the average configurational energy. For $\alpha=0.01$ it is clear that more than seven neighbors are required.

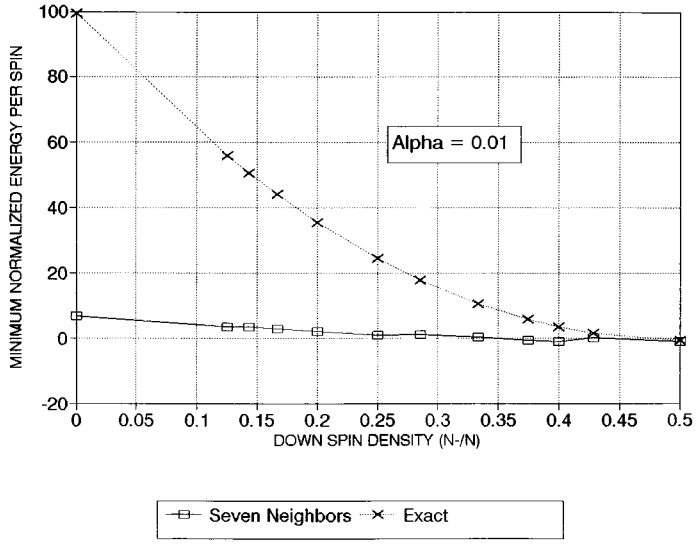

FIG. 5. Normalized configurational energy per spin verses down-spin density for a ME distribution of Ising spins with $\alpha=0.01$; exact calculations (all neighbors included in the limit as $N\rightarrow\infty$) compared to seven nearest-neighbor calculation.

In Fig. 6, the minimum normalized energy per spin versus down-spin density is shown for a value of $\alpha=0.1$. Again, the seven neighbor approximation is used for comparison to the exact values. The value of $\alpha=0.1$ corresponds to a shorter range interaction than that shown in Fig. 5. As expected, the approximate results are closer to the exact results. Figures 7 and 8 show similar results for larger values of α. In Fig. 7, $\alpha=0.5$, and in Fig. 8, the minimum normalized configurational energy per site is shown for a value of $\alpha=1.0$. Clearly, as the range of the interaction

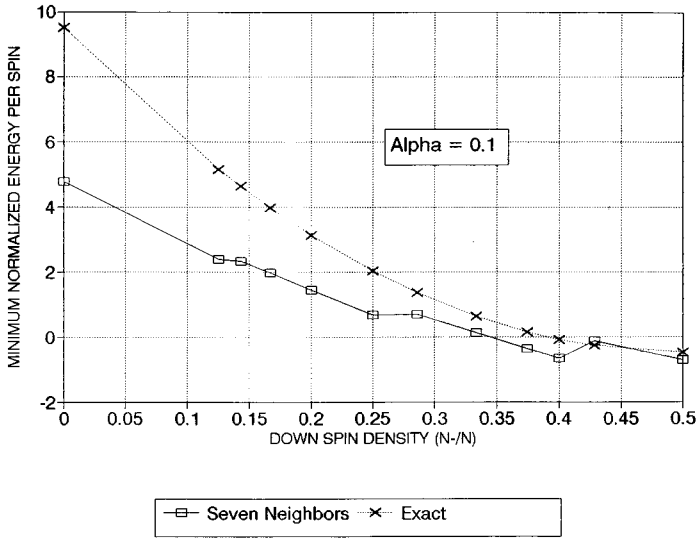

FIG. 6. Normalized configurational energy per spin verses down-spin density for a ME distribution of Ising spins with $\alpha=0.10$; exact calculations (all neighbors included in the limit as $N\rightarrow\infty$) compared to seven nearest-neighbor calculation.

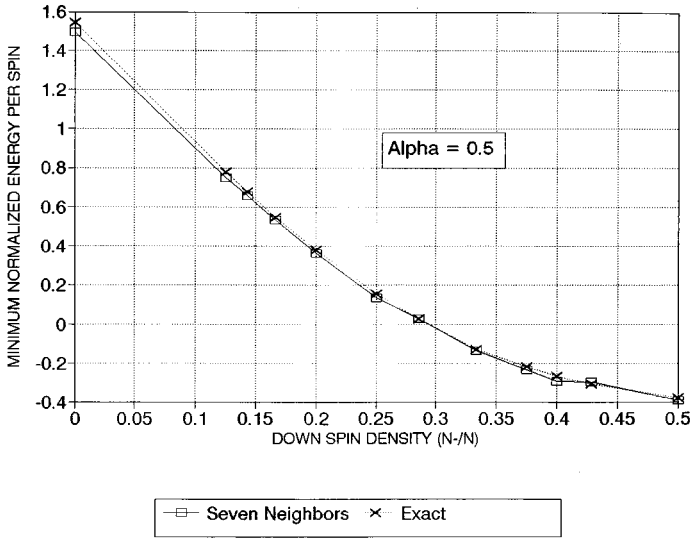

FIG. 7. Normalized configurational energy per spin verses down-spin density for a ME distribution of Ising spins with $\alpha=0.50$; exact calculations (all neighbors included in the limit as $N\rightarrow\infty$) compared to seven nearest-neighbor calculation.

becomes shorter, the truncated series approximation gets better. For large enough values of α, only near-neighbor interactions are relevant, and the minimum energy per spin is simply a linear function of the down-spin density:

$$U^{\min}(\rho)\approx u_1^{\min}(\rho)=J_0e^{-\alpha}(1-4\rho).$$

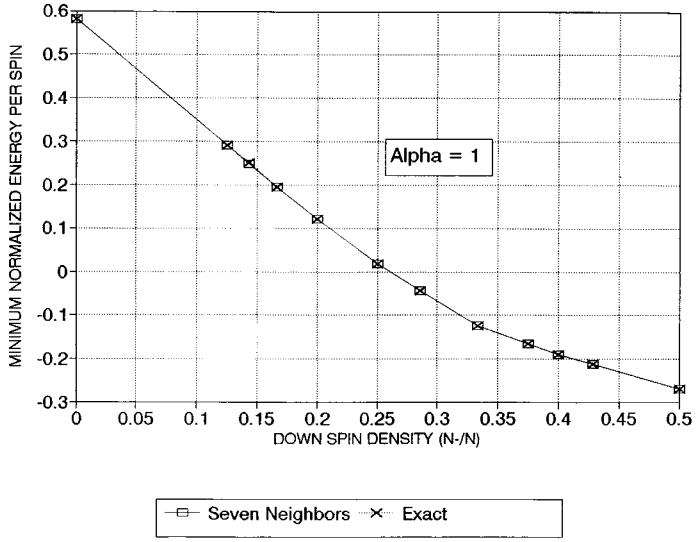

FIG. 8. Normalized configurational energy per spin verses down-spin density for a ME distribution of ising spins with $\alpha=1.00$; exact calculations (all neighbors included in the limit as $N\rightarrow\infty$) compared to seven nearest-neighbor calculation.

The specific relative error between the approximate value of the minimum energy per spin and the exact value may be used as the criterion for determining the number of pairwise neighbors needed to adequately describe the average configurational energy of the system.

V. SPIN CONTENT VECTORS AND AVERAGE ENERGY FOR me CONFIGURATIONS

Since the construction of me configurations is less complicated than that of ME configurations, a somewhat less formal approach will be taken in this section (as compared with Sec. IV and Appendix B).

For a me set with $N_- \geqslant 1$ and odd $N \geqslant 5$, it is easy to see that the content vector is

$$V_- = (\nu_1^-, \nu_2^-, \ldots, \nu_{(N-1)/2}^-),$$

where

$$\nu_k^- = \begin{cases} N_- - k, & \text{if } 1 \leqslant k \leqslant N_-, \\ 0, & \text{otherwise.} \end{cases}$$

Thus, the me spin content vector is

$$V_{\text{me}} = (\nu_1, \nu_2, \ldots, \nu_{(N-1)/2}),$$

where

$$\nu_k = \begin{cases} N - 4k, & \text{if } 1 \leqslant k \leqslant N_-, \\ N - 4N_-, & \text{otherwise.} \end{cases}$$

It follows that, for a me configuration and given N and N_-, the maximum configuration energy is

$$E_{\max} = V_{\text{me}} \cdot W = N \sum_{k=1}^{N} J(k) - 4 \sum_{k=1}^{N_-} k J_N(k) - 4N_- \sum_{k=N_-+1}^{N-N_--1} J(k).$$

Then the maximum average energy for a given down-spin density is

$$U_N^{\max}(\rho) = \frac{V_{\text{me}} \cdot W}{N} = \sum_{k=1}^{N} J(k) - \frac{4}{N} \sum_{k=1}^{N\rho} k J_N(k) - 4\rho \sum_{k=N\rho+1}^{N-N\rho-1} J(k). \tag{6}$$

A rather unexpected result turns up when the lattice has a me configuration; in the limit of large N, the configurational energy per spin is independent of the down-spin density, ρ. Let $U^{\max}(\rho) = \Sigma_{k=1}^{\infty} J(k)$. Then $U_N^{\max} \to U^{\max}$ uniformly since, as $N \to \infty$, the first sum in (6) converges to $\Sigma_{k=1}^{\infty} J(k)$ and the other two sums converge to 0. These convergences are clearly true for the first and second sums. To see that the third sum in (6) converges to 0, assume $\rho \in (0, \frac{1}{2}]$, and fix $\epsilon > 0$. Now let $\delta = \epsilon / 4\Sigma_{k=1}^{\infty} J(k)$, and choose N_0 large enough so that $\Sigma_{k=\lfloor \delta N \rfloor}^{\infty} J(k) < \epsilon/2$ whenever $N \geqslant N_0$. Then, if $\rho < \delta$,

$$4\rho \sum_{k=N\rho+1}^{N-N\rho-1} J(k) < 4\delta \sum_{k=1}^{\infty} J(k) = \epsilon.$$

On the other hand, if $\rho \geqslant \delta$, then

$$4\rho \sum_{k=N\rho+1}^{N-N\rho-1} J(k) \leqslant 2 \sum_{k=\lfloor \delta N \rfloor}^{\infty} J(k) < \epsilon$$

whenever $N \geqslant N_0$. Thus, the last sum in (6) converges to 0 independent of ρ, implying that $U_N^{\max} \to U^{\max}$ uniformly on the interval $(0, \frac{1}{2}]$. Moreover, if $\rho=0$, then me and ME configurations are identical (all spins are up), implying $U^{\max}(0)=U^{\min}(0)$. Whence, by (3), $U^{\max}(0)=\Sigma_{k=1}^{\infty} J(k)$. It follows that

$$U^{\max}(\rho)=\sum_{k=1}^{\infty} J(k),$$

for all $\rho \in [0, \frac{1}{2}]$. Thus, in the limit of large N, the maximum average energy depends only on the clustering of the down-spins and up-spins in the configuration and not on the down-spin density.

VI. SUMMARY

An analysis of the antiferromagnetic spin-$\frac{1}{2}$ Ising model with periodic boundary conditions has been carried out using the formalism of Maximally/Minimally Even sets first introduced by Clough and Douthett[2] and Block and Douthett[3] in the Music Theory literature.

Applying elementary graph theory (decomposition of complete graphs), the configurational energy of a system has been calculated by the dot product of a so-called energy vector and a spin content vector. Casting the configurational energy in this form is convenient for keeping track of the contribution to the configurational energy from each set of neighbor pairs separately. This formulation allowed us to use the theory of maximally/minimally even sets to calculate the interval spectra which is equivalent to the spin content vector.

It is shown that, for the antiferromagnetic case and fixed N and N_-, Maximally Even sets of up- and down-spins minimize the configurational energy for a given down-spin density while Minimally Even sets maximize the configurational energy (Appendix A). Furthermore, the configurational energy per site is calculated in the limit of large N (Appendix B) to yield the ''exact'' (asymptotic) expression.

In order to investigate the range on the configurational energy per site, a simple form of pairwise antiferromagnetic interaction is assumed that decreases exponentially with the distance. As expected, it is shown that the shorter the range of the interaction the fewer the number of neighbors needed to adequately describe the system. Our formulation allows the number of neighbor pairs necessary to approximate the configurational energy per site to be calculated to any desired precision.

Finally, it is shown that, for Minimally Even sets of up- and down-spins, the average configurational energy depends only on the clustering of like spins and not on the down-spin density in the limit of large N.

APPENDIX A: CONFIGURATIONS ASSOCIATED WITH ENERGY EXTREMES

Before developing the theorems and corollaries, it will be useful to summarize important properties discussed in Sec. III that are needed for our proofs. The first properties deal with interval spectra.

P1. For each k, if $l \in \langle k \rangle_{\pm}$, then $k \leqslant l \leqslant N-N_{\pm}+k$.

P2. For each k, $\Sigma_{l \in \langle k \rangle_{\pm}} r_{k,l} l = Nk$.

Properties P3–P6 involve definitions and properties of ME and me sets.

P3. The set $S_{\pm}$ is a ME set if and only if $\langle k \rangle_{\pm} = \{\lfloor Nk/N_{\pm} \rfloor, \lceil Nk/N_{\pm} \rceil\}$ for all k, $1 \leqslant k \leqslant N_{\pm}-1$.

P4. The set $S_{\pm}$ is a me set if and only if $\langle k \rangle_{\pm} = \{k, N-N_{\pm}+k\}$ for all k, $1 \leqslant k \leqslant N_{\pm}-1$.

P5. The complement of a ME set is ME.

P6. The complement of a me set is me.

The last property needed (discussed at the end of Sec. III) expresses the energy contributed by the set of down-spins (up-spins) in terms of the interval spectra and the pairwise interaction.

P7. $E_{\pm} = \Sigma_k \Sigma_{l \in \langle k \rangle_{\pm}} r_{k,l} J(l)$.

A corollary about convexity is needed to prove the assertions made in Sec. III about minimum and maximum energies. Before stating the ''Convex Corollary,'' it is necessary to state a well-known theorem[9] (without proof) to which the Convex Corollary belongs.

Theorem 1: Let J be a (strictly) convex function on the interval (a,b), and suppose that x_1, x_2, y_1, $y_2 \in (a,b)$ such that $x_1(<)\leqslant x_2<y_2$ and $x_1<y_1(<)\leqslant y_2$. Then

$$\frac{J(y_1)-J(x_1)}{y_1-x_1}\,(<)\leqslant \frac{J(y_2)-J(x_2)}{y_2-x_2}.$$

*Corollary 1 (***convex**): Let J be a (strictly) convex function on the interval $(0,\infty)$, and assume $0<h<p\leqslant q$. Then

$$J(p)+J(q)(<)\leqslant J(p-h)+J(q+h).$$

Proof: If p, q, and h are as defined above, then $p-h,p,q,q+h\in(0,\infty)$, $p-h<q<q+h$, and $p-h<p<q+h$. Thus, by the Theorem 1,

$$\frac{J(p)-J(p-h)}{p-(p-h)}\,(<)\leqslant \frac{J(q+h)-J(q)}{(q+h)-q}.$$

It follows that

$$J(p)+J(q)(<)\leqslant J(p-h)+J(q+h). \qquad \blacksquare$$

This result will be needed to prove the ''Stick Theorem,'' which, in turn, will allow us to show that the energy of the set of down-spins (up-spins) is minimum precisely when $S_{\pm}$ is a ME set and maximum when $S_{\pm}$ is a me set. Finally, the ''Energy Theorem,'' which will show that the total energy E of a lattice is minimized or maximized precisely when the lattice configuration is ME or me respectively, will be proved.

To prove the ''Stick Theorem,'' it is necessary to make the following construction.

Assume J is a strictly convex function, and let m and n be integers with $2\leqslant m\leqslant n$. Consider the sequence of sets

$$\mathbf{T}_j(n,m)=(T_1,T_2,T_3,\ldots,T_{m-1}),$$

where each set T_k, $1\leqslant k\leqslant m-1$, consists of m sticks with integer lengths. If t is a stick, the *length* of the stick will be denoted by $l_1(t)$. In addition, for each k, the set T_k has the following properties:

(1) for each $t\in T_k$, $k\leqslant l_1(t)\leqslant n-m+k$;
(2) $\Sigma_{t\in T_k} l_1(t)=nk$.

The *spectrum* $\langle k\rangle$ of the set T_k is the set of all distinct lengths of the sticks in T_k, $a_k=\min\langle k\rangle$, and $b_k=\max\langle k\rangle$. Define $\sigma_J(T_k)$ as follows:

$$\sigma_J(T_k)=\sum_{t\in T_k} J(l_1(t)).$$

Finally, define the sum $\Psi_J(n,m)$ as follows:

$$\Psi_J(n,m)=\sum_k \sigma_J(T_k).$$

Theorem 2 (stick): Let J be a strictly convex function on the interval $(0,\infty)$, and suppose $\mathbf{T}_J(n,m)$ is defined as above.

(1) The sum $\Psi_J(n,m)$ is minimum if and only if

$$\langle k\rangle=\left\{\left\lfloor \frac{nk}{m}\right\rfloor,\left\lceil \frac{nk}{m}\right\rceil\right\}$$

for all k, $1\leqslant k\leqslant m-1$.

(2) The sum $\Psi_J(n,m)$ is maximum if and only if

$$\langle k\rangle=\{k,n-m+k\}$$

for all k, $1\leqslant k\leqslant m-1$.

Proof: (1) For a given k, we say the set of sticks T_k can be *reduced* if there exists a set T_k^* such that $\sigma_J(T_k^*)<\sigma_J(T_k)$.

Now consider the family of sets of sticks

$$\mathscr{T}_k=\{T_k|b_k-a_k\geqslant 2\}.$$

Then for each $T_k\in\mathscr{T}_k$, there are sticks $t_1, t_2\in T_k$ such that $l_1(t_2)-l_1(t_1)\geqslant 2$. Replace these sticks with sticks t_1^* and t_2^* whose lengths are $l_1(t_1^*)=l_1(t_1)+1$ and $l_1(t_2^*)=l_1(t_2)-1$. Call the new set of sticks T_k^*. Thus, T_k^* is a set of m sticks and $\Sigma_{t\in T_k^*}l_1(t)=nk$. Moreover, from the Convex Corollary,

$$J(l_1(t_1^*))+J(l_1(t_2^*))<J(l_1(t_1))+J(l_1(t_2)).$$

It follows that $\sigma_J(T_k^*)<\sigma_J(T_k)$. Hence, if $T_k\in\mathscr{T}_k$, then T_k can be reduced by replacing sticks as described above.

Since $\mathscr{T}_k$ contains a finite number of sets, there exists a set $T_k^{\min}\in\mathscr{T}_k$ such that

$$\sigma_J(T_k^{\min})=\min\{\sigma_J(T_k)|T_k\in\mathscr{T}_k\}.$$

However, since $T_k^{\min}\in\mathscr{T}_k$, $T_k^{\min}$ can also be reduced by replacing sticks. Call this new set of sticks T_k^{**}. Then, for T_k^{**}, $b_k-a_k\leqslant 1$. Thus, the spectrum of T_k^{**} must contain either one or two consecutive integers. Since this is true for each k, $\Psi_J(n,m)$ is smallest precisely when

$$\langle k\rangle=\left\{\left\lfloor \frac{nk}{m}\right\rfloor,\left\lceil \frac{nk}{m}\right\rceil\right\}$$

for all k, $1\leqslant k\leqslant m-1$.

(2) For a given k we say the set of sticks T_k can be *increased* if there exists a set T_k^* such that $\sigma_J(T_k^*)>\sigma_J(T_k)$.

Note that if $m-k$ sticks have length k and k sticks have length $n-m+k$, then there is a total of m sticks, and the sum of the lengths of these sticks is nk. Let T_k^{**} be the set of these sticks.

Since, for each T_k, the sum of the lengths of the sticks in T_k is the constant nk, there are fewer than $m-k$ sticks with length k in T_k if and only if there are fewer than k sticks with length $n-m+k$. It follows that if $t_1\in T_k$ and $k<l_1(t_1)<n-m+k$, then there exists $t_2\in T_k$ such that $t_2\neq t_1$ and $k<l_1(t_2)<n-m+k$.

Now consider the family of sets of sticks

$$\mathscr{T}_k=\{T_k|\exists t\in T_k\ni:k<l_1(t)<n-m+k\}.$$

It follows that if $T_k \in \mathscr{T}_k$, then there exists t_1, $t_2 \in T_k$ such that $t_1 \neq t_2$ and $k < l_1(t_1) \leqslant l_1(t_2) < n-m+k$. Let t_1^* and t_2^* be sticks such that $l_1(t_1^*) = l_1(t_1) - 1$ and $l_1(t_2^*) = l_1(t_2) + 1$. Then by the Convex Corollary

$$J(l_1(t_1^*)) + J(l_1(t_2^*)) > J(l_1(t_1)) + J(l_1(t_2)).$$

Replace t_1 and t_2 with t_1^* and t_2^*, and call the new set of sticks T_k^*. Thus, $\sigma_J(T_k^*) > \sigma_J(T_k)$. Hence, if $T_k \in \mathscr{T}_k$, then T_k can be increased by replacing sticks as described above.

Since $\mathscr{T}_k$ contains a finite number of sets, there exists a set $T_k^{\max} \in \mathscr{T}_k$ such that

$$\sigma_J(T_k^{\max}) = \max\{\sigma_J(T_k) | T_k \in \mathscr{T}_k\}.$$

However, since $T_k^{\max} \in \mathscr{T}_k$, $T_k^{\max}$ can also be increased by replacing sticks. It follows that the new set must have sticks whose lengths are either k or $n-m+k$. Thus, this new set is T_k^{**}. Since this is true for each k, $\Psi_J(n,m)$ is maximum precisely when

$$\langle k \rangle = \{k, n-m+k\}$$

for all k, $1 \leqslant k \leqslant m-1$. ■

Corollary 2: For a fixed N and $N_\pm$,

(1) $E_\pm$ is minimum if and only if $S_\pm$ is a ME set.
(2) $E_\pm$ is maximum if and only if $S_\pm$ is a me set.
(3) *Proof:* For each length $l \in \langle k \rangle$, let $r_{k,l}$ be the number of sticks in T_k that have length l. Then

$$\sigma_J(T_k) = \sum_{l \in T_k} J(l_1(t)) = \sum_{l \in \langle k \rangle} r_{k,l} J(l).$$

It follows that

$$\Psi_J(n,m) = \sum_k \sigma_J(T_k) = \sum_k \sum_{l \in \langle k \rangle} r_{k,l} J(l).$$

Replace n with N, m with $N_\pm$, and $\langle k \rangle$ with $\langle k \rangle_\pm$. Then by properties P1, P2, and P7,

$$E_\pm = \Psi_J(N, N_\pm).$$

The corollary follows immediately from the Stick Theorem and from properties P3 and P4. ■

Theorem 3 (energy): For a fixed N (N odd) and $N_\pm$,

(1) E is minimum if and only if the lattice configuration is ME.
(2) E is maximum if and only if the lattice configuration is me.

Proof: Recall that $V_- + V_+ + V_0 = V_N = (\cdots N \cdots)$. Thus,

$$V_0 = V_N - (V_- + V_+) = (\cdots N \cdots) - (V_- + V_+).$$

However, then

$$E_0 = V_0 \cdot W = V_N \cdot W - (V_- \cdot W + V_+ \cdot W) = +N \sum_{k=1}^{N} J(k) - (E_- + E_+).$$

The first term in the last expression on the right is a constant, and by Corollary 2 and property P5 (P6), the sum $E_- + E_+$ is minimized (maximized) if and only if the lattice configuration is ME (me). It follows that E_0 is maximized (minimized). However, then the total energy

$$E = E_+ + E_- - E_0$$

is minimized (maximized). ■

We have assumed that J is strictly convex to illustrate the uniqueness of ME and me configurations. If it is only assumed that J is convex, then the configurational energy extremes still occur when the configurations are ME and me. However, these configurations no longer necessarily uniquely define these extreme states, and configurations other than ME and me may have the same average configurational energies.

APPENDIX B: THE CONVERGENCES AND CONTINUITY OF $U^{\min}$

Assume J is a convex function on the interval $(0,\infty)$ such that $\Sigma_{k=1}^{\infty} J(k)$ converges. From these restrictions, it is easy to see that $J(k)$ is a decreasing positive function, and, hence, $\Sigma_{k=1}^{\infty} J(k)$ is absolutely convergent. Now assume N is an odd positive integer, and let $\rho \in (0, 1/2]$. For notational convenience, set $p_\rho = \lfloor N\rho/2 \rfloor$ and $p_1 = (N-1)/2$. Note that p_ρ depends on N and ρ while p_1 depends only on N. Moreover, if $1 \leqslant k \leqslant p_\rho$, then $\lfloor k/\rho \rfloor$ and $\lceil k/\rho \rceil$ are both less than N; whence, $J(N - \lfloor k/\rho \rfloor)$ and $J(N - \lceil k/\rho \rceil)$ are defined.

Now let $J_N(k) = J(k) + J(N-k)$ where $1 \leqslant k \leqslant N-1$. Let $\rho \in [0, 1/2]$, and define $U_N^{\min}$ as follows:

$$U_N^{\min}(\rho) = \sum_{k=0}^{p_\rho} f_{N,k}(\rho),$$

where

$$f_{N,k}(\rho) = \begin{cases} (1-4\rho)\displaystyle\sum_{j=1}^{N} J(j), & \text{if } k = 0, \\ 4\rho[(1-\{k/\rho\})J_N(\lfloor k/\rho \rfloor) + \{k/\rho\}J_N(\lceil k/\rho \rceil)], & \text{otherwise.} \end{cases}$$

Next define $U^{\min}$ as follows:

$$U^{\min}(\rho) = \begin{cases} \displaystyle\sum_{j=1}^{\infty} J(j), & \text{if } \rho = 0, \\ \displaystyle\sum_{k=0}^{\infty} f_k(\rho), & \text{otherwise,} \end{cases}$$

where

$$f_k(\rho) = \begin{cases} (1-4\rho)\displaystyle\sum_{j=1}^{\infty} J(j), & \text{if } k = 0 \\ 4\rho[(1-\{k/\rho\})J(\lfloor k/\rho \rfloor) + \{k/\rho\}J(\lceil k/\rho \rceil)], & \text{otherwise.} \end{cases}$$

We will show that $U_N^{\min} \to U^{\min}$ uniformly on the interval $[0, 1/2]$, that $U^{\min}$ is uniformly continuous on $[0, 1/2]$, and that the series defining $U^{\min}(\rho)$ is absolutely convergent for every $\rho \in [0, 1/2]$.

Before beginning the theorems and proofs relevant to this paper, it is necessary to state a couple of well-known preliminary theorems. Although these theorems can be found in many analysis texts, we refer the reader to Rudin.[10]

Theorem 4: Suppose $f_n \to f$ uniformly on a set E in a metric space, and let x be a limit point of E. Then

$$\lim_{t\to x}\lim_{n\to\infty} f_n(t) = \lim_{n\to\infty}\lim_{t\to x} f_n(t).$$

Theorem 5: Suppose $\{f_n\}$ is a sequence of continuous functions and $f_n \to f$ uniformly on a set E in a metric space. Then f is continuous on E.

Theorem 6: For each positive integer N, the function $U_N^{\min}(\rho)$ is continuous on the interval $[0, 1/2]$.

Proof: We consider continuity at $\rho=0$ first. Let $\delta_0 = 2/N$. Then, $U_N^{\min}(\rho) = f_{N,0}(\rho)$ when $\rho < \delta_0$. Now choose $\epsilon > 0$, and let $\delta_1 = \epsilon/4\Sigma_{k=1}^{N} J(k)$. Now let $\delta = \min\{\delta_0, \delta_1\}$, and choose ρ such that $0 \leqslant \rho < \delta$. Then

$$|U_N^{\min}(\rho) - U_N^{\min}(0)| = 4\rho \sum_{k=1}^{N} J(k) < \epsilon.$$

Thus, $U_N^{\min}$ is continuous at $\rho=0$.

Now assume $\rho \in (0, 1/2]$. If it is shown that $f_{N,k}$ is continuous on $(0, 1/2]$ for all k, $0 \leqslant k \leqslant p_\rho$, then their sum is continuous.

It is clear that $f_{N,k}$, $1 \leqslant k \leqslant p_\rho$, is continuous on $(0, 1/2]$ except possibly when k/ρ is an integer. [If k/ρ is not an integer, then $f_{N,k}(\rho)$ is a linear function on some small neighborhood of ρ.] Fix k, and suppose $\rho_0 \in (0, 1/2]$ and k/ρ_0 is an integer, say $k_0 = k/\rho_0$. Let $\delta_0 = \rho_0^2/(k-\rho_0^2)$. Then $f_{N,k}(\rho_0) = 4\rho_0 J_N(k_0)$. Furthermore, for $\rho_0 < \rho < \rho_0 + \delta_0$, $\lfloor k/\rho \rfloor = k/\rho_0 - 1 = k_0 - 1$, and for $\rho_0 - \delta_0 < \rho < \rho_0$, $\lfloor k/\rho \rfloor = k/\rho_0 = k_0$. Choose $\epsilon > 0$, and let

$$\delta_1 = \frac{\epsilon}{4|k_0 J_N(k_0-1) - (k_0-1)J_N(k_0)|}$$

and

$$\delta_2 = \frac{\epsilon}{4|(k_0+1)J_N(k_0) - k_0 J_N(k_0+1)|},$$

where it is assumed that the denominators of δ_1 and δ_2 are not 0. Now let $\delta = \min\{\delta_0, \delta_1, \delta_2\}$, and choose ρ so that $|\rho - \rho_0| < \delta$. There are two cases.

Case 1: Suppose $\rho_0 < \rho < \rho_0 + \delta$. Noting that $\{k/\rho\} = k/\rho - \lfloor k/\rho \rfloor$,

$$\begin{aligned} |f_{N,k}(\rho) - f_{N,k}(\rho_0)| &= 4|[\rho(k_0-1) - k + \rho]J_N(k_0-1) - [\rho(k_0-1) - k]J_N(k_0) - \rho_0 J_N(k_0)| \\ &= 4|\rho - \rho_0||k_0 J_N(k_0-1) - (k_0-1)J_N(k_0)|. \end{aligned}$$

If the right side of the equation is 0 (i.e., if the denominator of δ_1 is 0), then $f_{N,k}(\rho) = f_{N,k}(\rho_0)$; otherwise, $|f_{N,k}(\rho) - f_{N,k}(\rho_0)| < \epsilon$. In either case, $\lim_{\rho \to \rho_0^+} f_{N,k}(\rho) = f_{N,k}(\rho_0)$.

Case 2: Suppose $\rho_0 - \delta < \rho < \rho_0$. Then

$$\begin{aligned} |f_{N,k}(\rho) - f_{N,k}(\rho_0)| &= 4|[\rho k_0 - k + \rho]J_N(k_0) - [\rho k_0 - k]J_N(k_0+1) - \rho_0 J_N(k_0)| \\ &= 4|\rho - \rho_0||(k_0+1)J_N(k_0) - k_0 J_N(k_0+1)|. \end{aligned}$$

Similar to case 1, if the right side of the equality is 0 (i.e., if the denominator of δ_2 is 0), then $f_{N,k}(\rho)=f_{N,k}(\rho_0)$; otherwise, $|f_{N,k}(\rho)-f_{N,k}(\rho_0)|<\epsilon$. Thus, $\lim_{\rho\to\rho_0^-} f_{N,k}(\rho) = f_{N,k}(\rho_0)$. It follows that, for each $k, f_{N,k}$ is continuous on the interval $[0, \frac{1}{2}]$. Whence, $U_N^{\min}$ is continuous on $[0, \frac{1}{2}]$. [In fact, $U_N^{\min}$ is uniformly continuous since the function is defined on a closed and bounded interval.] ■

Theorem 7: The sequence $U_N^{\min}\to U^{\min}$ uniformly on the interval $[0, \frac{1}{2}]$. Moreover, $U^{\min}$ is uniformly continuous on $[0, \frac{1}{2}]$.

Proof: For $\rho\in(0, \frac{1}{2}]$, we have

$$|U^{\min}(\rho)-U_N^{\min}(\rho)|\leqslant\left|\sum_{k=0}^{p_\rho}(f_k(\rho)-f_{N,k}(\rho))\right|+\left|\sum_{k=p_\rho+1}^{\infty} f_k(\rho)\right|. \tag{B1}$$

For the first sum in (B1),

$$\begin{aligned}\left|\sum_{k=0}^{p_\rho}(f_k(\rho)-f_{N,k}(\rho))\right| &= \left|(1-4\rho)\sum_{k=N+1}^{\infty} J(k)-4\rho\sum_{k=1}^{p_\rho}\left[\left(1-\left\{\frac{k}{\rho}\right\}\right)J\left(N-\left\lfloor\frac{k}{\rho}\right\rfloor\right)\right.\right.\\ &\qquad\left.\left.+\left\{\frac{k}{\rho}\right\}J\left(N-\left\lceil\frac{k}{\rho}\right\rceil\right)\right]\right|\\ &\leqslant\sum_{k=N+1}^{\infty} J(k)+4\sum_{k=1}^{p_\rho} J\left(N-1-\frac{k}{\rho}\right).\end{aligned}$$

Clearly, the first sum on the right side of the above goes to 0 as $N\to\infty$. To show the second sum does as well, note that if $k=p_\rho$, then $k\leqslant N\rho/2$, and, hence, $k/\rho\leqslant N/2$. It follows that

$$4\sum_{k=1}^{p_\rho} J(N-1-k/\rho)\leqslant 4p_\rho J(N-1-N/2)\leqslant 2N\rho J((N-2)/2)\leqslant NJ((N-2)/2)\to 0$$

as $N\to\infty$.

For the second sum in (B1),

$$\left|\sum_{k=p_\rho+1}^{\infty} f_k(\rho)\right| = 4\rho\sum_{k=p_\rho+1}^{\infty}\left[\left(1-\left\{\frac{k}{\rho}\right\}\right)J\left(\left\lfloor\frac{k}{\rho}\right\rfloor\right)+\left\{\frac{k}{\rho}\right\}J\left(\left\lceil\frac{k}{\rho}\right\rceil\right)\right]\leqslant 4\sum_{k=p_\rho+1}^{\infty} J\left(\frac{k}{\rho}-1\right).$$

To show the right side of the above inequality goes to 0 as $N\to\infty$, note that, for any non-negative integer m,

$$p_1-2+m<\frac{N+1}{2}-2+m=\frac{(N\rho/2)-(3\rho/2)+m\rho}{\rho}<\frac{\lfloor N\rho/2\rfloor+1-(3\rho/2)+m\rho}{\rho}<\frac{p_\rho+1+m}{\rho}-1.$$

Thus, since J is a decreasing function,

$$J\left(\frac{p_\rho+1+m}{\rho}-1\right)\leqslant J(p_1-2+m).$$

Finally, for any non-negative integer $M\geqslant p_1-2$,

$$4\sum_{k=p_\rho+1}^{M} J\left(\frac{k}{\rho}-1\right)\leqslant 4\sum_{k=p_1-2}^{M} J(k)\leqslant 4\sum_{k=p_1-2}^{\infty} J(k),$$

$$4\sum_{k=p_\rho+1}^{\infty} J\left(\frac{k}{\rho}-1\right)\leqslant 4\sum_{k=p_1-2}^{\infty} J(k).$$

Since the right side of the above inequality goes to zero as $N\to\infty$ (independent of ρ), the left side does as well. It follows that $U_N^{\min}\to U^{\min}$ uniformly on $(0, \frac{1}{2}]$. Moreover, since 0 is in the domain of $U_N^{\min}$, it is convenient to define $U^{\min}(0)$ as follows:

$$U^{\min}(0)=\lim_{\rho\to 0} U^{\min}(\rho)=\lim_{N\to\infty} U_N^{\min}(0)=\sum_{k=1}^{\infty} J(k)$$

(Theorem 4). Since $U_N^{\min}$ is continuous on $[0, \frac{1}{2}]$ for every N, $U^{\min}$ is continuous on $[0, \frac{1}{2}]$ (Theorem 5), and since $U^{\min}$ is defined on a closed and bounded interval, $U^{\min}$ is uniformly continuous on $[0, \frac{1}{2}]$. ■

Theorem 8: For each $\rho\in[0, \frac{1}{2}]$, the series defining $U^{\min}(\rho)$ is absolutely convergent.

Proof: Since $\rho\in[0, \frac{1}{2}]$ and $\Sigma_{k=1}^{\infty}J(k)<\infty$,

$$\sum_{k=0}^{\infty}|f_k(\rho)|\leqslant|1-4\rho|\sum_{k=1}^{\infty}J(k)+\sum_{k=1}^{\infty}|f_k(\rho)|\leqslant\sum_{k=1}^{\infty}J(k)+2\sum_{k=1}^{\infty}J(k)<\infty,$$

Whence, $U^{\min}(\rho)$ is absolutely convergent for every $\rho\in[0, \frac{1}{2}]$. ■

(Received 22 November 1995; accepted for publication 29 January 1996)

Description of the grand canonical Gibbs ensemble for classical continuous systems in terms of the nonlocally perturbed infinite-divisible generalized random fields is presented. The equivalence of the traditional description with the ones presented here on the level of DLR equations is established. The antiferromagnetism for the purely repulsive interactions has been observed. Finally, the usefulness of our description for an analysis of the high-temperature cluster expansion has been demonstrated. © *1996 American Institute of Physics.* [S0022-2488(96)02106-8]

I. INTRODUCTION

Our everyday experience shows that several matter transformations like crystallization, liquid–vapour, etc. transformation are the most natural phenomena of the phase transition type. Their physical picture can be perfectly well understood on the basis of the molecular theory of matter.[1,2] Therefore it is reasonable to expect that the corresponding mathematical description of such basic phenomena should be encompassed by the highly developed apparatus of the modern statistical mechanics. But this is not true: the rigorous microscopic description of the most natural phase transitions that take place in nature does not exist.

The conceptual background for the statistical mechanics description of the real matter in the microworld is highly developed on a more or less sophisticated level of abstraction.[3–5] However, only the (noninteresting from the point of view of physics) high-temperature/low-density regime of couplings seems to be well understood[3–6] from the point of view of basic principles of classical statistical mechanics. It seems that one of the main reasons for the lack of progress in developing the rigorous methods enabling us to penetrate the low-temperature/high-density properties of realistic models of matter is the description of the corresponding Gibbs ensembles in terms of variables that are not well suited for that purpose. The discrete spin system models are much more appropriate[3,7,8] and powerful progress has been achieved in the last decades. The only class of continuous systems whose low-temperature properties are rather well known are the so-called Widom–Rowlison type of models.[9–11] However, from the point of view of the general theory these models are rather exceptional and exotic and moreover the methods developed for the analysis of the corresponding low-temperature phase diagrams do not extend to the more typical systems. The functional integral representation (the sine-Gordon representation) of the system interacting through the two-body potential of positive-definite type has been originated by Siegert[12] and significantly extended and explored in Refs. 13 and 14. In particular, the functional integral representation of the corresponding Gibbs ensembles in terms of the perturbed gently Gaussian measures opened the opportunity to apply the powerful methods of the constructive quantum field theory[15] to the analysis of low-temperature properties of such systems. This class of models contains extremely interesting, from the point of view of physics, systems like the regularized Coulomb gases, where some phase transitions (Debye screening, for example) take place,

[a)]Electronic mail: gielerak@ift.uni.wroc.pl

0022-2488/96/37(7)/3354/21/$10.00

and indeed the methods of the constructive quantum field theory were successfully applied[16–21] to the analysis of these effects. Additionally, some further results pertaining the phase diagrams in the full range of the parameters have also been obtained.[22–25]

The above listed two classes of models for macroscopic real matter show how important a role might be played by the choice of the proper mathematical description of a given system, and this is our main motivation for writing this paper. We propose to introduce generalized random fields of the Poisson type and their nonlocal perturbations as an alternative to the existing description[3,4] of continuous systems. A large class of models for continuous systems is selected for which the description in terms of the Poisson functional integrals applies well. It is our hope that the introduced formalism will stimulate further progress on the basically open problem of low-temperature properties of continuous systems.

It is worth stressing that the Poisson functional integrals have been used in various contexts in the mathematical physics several times. For example, they were used in Refs. 26 and 27 while searching for the alternative to the conventional perturbation expansions around the Gaussian point in the quantum field theory. Recently the functional Poisson integrals have been used for the constructions of some four-dimensional 4-D quantum field-like structures[28,29] (also see Ref. 30 for a systematic approach to such constructions). Finally, they were used to describe quantum semi-relativistic statistical mechanics.[31] The systematic introduction of Poisson functional integral representations in quantum statistical mechanics of continuous systems as announced in Ref. 32 is now under preparation.[33]

Section II is devoted to the demonstration that the traditional description of the grand canonical Gibbs ensembles describing continuous systems of particles and the introduced here Poisson functional integral description are equivalent on the level of the corresponding DLR equations.

In Sec. III the lattice approximation is introduced and its convergence to the continuum is demonstrated. As a result we detect that for continuous systems of particles interacting through repulsive interaction antiferromagnetism holds.

In Sec. IV we shall demonstrate how the use of Poisson functional integrals simplifies the construction of the corresponding high-temperature cluster expansion. In particular a slight extension of the result of Ref. 34 is obtained.

II. POISSON INTEGRALS DESCRIPTION OF THE GRAND CANONICAL GIBBS ENSEMBLE

The material in this section is divided into three parts for better understanding. In the first part we collect some relevant data for the purposes of the present work properties of generalized random fields of the Poisson type. Some additional material concerning Poisson noise calculus[35–38] is included in the Appendix. In the second part of this section we recall the standard description of the grand canonical Gibbs ensemble for continuous systems of particles and then we express the finite volume quantities of the grand canonical Gibbs ensemble through the Poisson functional integrals. Finally, in the third part we shall demonstrate the equivalence of the standard description with the one introduced here in the thermodynamical limit.

A. Generalized random fields of Poisson type

Let $\mathscr{D}'(R^d)$ be the (real part of) the space of Schwartz distributions and let $\mathscr{D}(R^d)$ be the corresponding nuclear test function space. The Borel σ-algebra of sets in $\mathscr{D}'(R^d)$ will be denoted by $\mathscr{B}(\mathscr{D}'(R^d))$. A generalized random field will be identified with the corresponding probabilistic, Borel, cylindric measure on the standard measure space $(\mathscr{D}'(R^d)),\mathscr{B}(\mathscr{D}'(R^d))$. A given generalized random field μ is completely determined by its characteristic functional (Minlos theorem[39]),

$$F_\mu(f)=\int_{\mathscr{D}'(R^d)} d\mu(\varphi)e^{i\langle\varphi,f\rangle}, \tag{II.1}$$

where $f \in \mathscr{D}(R^d)$ and $\langle \varphi, f \rangle$ is the dualization between $\mathscr{D}'(R^d)$ and $\mathscr{D}(R^d)$. A given generalized random field μ is called an infinite divisible random field iff for any $f, g \in \mathscr{D}(R^d)$ with the disjoint supports we have

$$\int d\mu(\varphi) e^{i\langle \varphi, f \rangle} e^{i\langle \varphi, g \rangle} = \int d\mu(\varphi) e^{i\langle \varphi, f \rangle} \int d\mu(\varphi) e^{i\langle \varphi, g \rangle}. \tag{II.2}$$

There exists a so-called Levy–Kchintchine formula,[39] which gives the complete description of the whole class of infinitely divisible random fields in terms of their characteristic functionals, which must be of the form

$$\int_{\mathscr{D}'(R^d)} d\mu(\varphi) e^{i\langle \varphi, f \rangle} = e^{\Psi(f)},$$

where

$$\Psi(f) = \int_{R^d} dx \left(\int_{|\lambda|>0} d\sigma(\lambda)(e^{i\lambda f(x)} - \alpha(\lambda)(1 + i\lambda f(x))) + a_0 + i a_1 f(x) - a_2 \frac{(f(x))^2}{2!} \right), \tag{II.3}$$

for some positive constant a_2, any $a_1 \in R^d$, $a_0 \in R$ arbitrary, and the measure $d\sigma(\lambda)$ must fulfill certain regularity properties together with a function α (see Ref. 39 for details).

In particular, if λ is a sufficiently regular measure on R^1, then the functional

$$\Gamma(f) \equiv \exp\left\{ z \int dx \int d\lambda(\alpha)[e^{i\alpha f(x)} - 1] \right\}, \tag{II.4}$$

belongs to the class described by (II.3) for any $z > 0$. The corresponding generalized random field is called a Poisson random field with the intensity measure $z\, d\lambda$, and the corresponding measure will be denoted as $dP^{z,\lambda}$. For further use we shall collect here some basic properties of the Poisson generalized random fields.

1. Integration by parts formula

If $\int \alpha\, d\lambda(\alpha) < \infty$, then

$$\int_{\mathscr{D}'(R^d)} \langle q, f \rangle F(q) dP^{z,\lambda}(q) = z \int d\lambda(\alpha) \alpha \int_\Lambda dx\, f(x) \int F(q + \alpha \delta(-x)) dP^{z,\lambda}(dq). \tag{II.5}$$

2. Moments of $P^{z,\lambda}$

Under a suitable assumption made on $d\lambda$ the field $P^{z,\lambda}$ has moments of arbitrary order, and they are given by

$$\int_{\mathscr{D}'(R^d)} dP^{z,\lambda}(q) \prod_{i=1}^{N} \langle q, f_i \rangle = \sum_{1 \leqslant l \leqslant N_*} \sum_{\substack{m_1 v_1 + \cdots + m_l v_l = N \\ m_1 < \cdots < m_l}} z^{v_1 + \cdots + v_l} \times \sum_{\text{permut}} \hat{f}_{i_1^{(1)}, \ldots, i_{m_1}^{(1)}} \cdots \hat{f}_{i_1^{(r_l)}, \ldots, i_{m_l}^{(r_l)}} \cdots \hat{f}_{j_1^{(1)}, \ldots, j_{m_l}^{(l)}} \cdots \hat{f}_{j_l^{(r_l)}, \ldots, j_{m_l}^{(r_l)}}, \tag{II.6}$$

where $i_1^{(1)}, \ldots, j_{m_l}^{(r_l)} \in \{1, 2, \ldots, N\}$,

$$\hat{f}_{i_1,\ldots,i_{i_m}} \equiv \int dx \prod_{k=1}^{m} f_{i_k}(x) \int d\lambda(\alpha)\alpha^m \tag{II.7}$$

and

$$N_* = [\tfrac{1}{2}(8N+1)^{1/2} - 1], \tag{II.8}$$

where $[x]$ denotes the integer part of x.

3. Support property of $dP^{z,\lambda}$

Any Poisson field is supported on the set

$$\Xi_\infty = \sum_{i=1}^{\infty} \alpha_i \delta(x - x_i),$$

where $x_l \neq x_j$ for $l \neq j$ and the collection $\{x_1,\ldots,x_n,\ldots\}$ forms a locally finite configuration, $\alpha_i \in \operatorname{supp} d\lambda$ are chosen arbitrary, i.e. $P^{z,\lambda}(\Xi_\infty) = 1$.

4. Normal ordering of the Poisson fields (see Refs. 35–38)

For a given $q \in \Xi_\infty$ we shall write

$$\alpha(q) = (\alpha_1,\ldots,\alpha_n,\ldots), \quad \text{if } q = \sum_{i=1}^{\infty} \alpha_i \delta(x - x_i),$$

$$x(q) = (x_1,\ldots,x_n,\ldots), \quad \text{if } q = \sum_{i=1}^{\infty} \alpha_i \delta(x - x_i),$$

$$\alpha^2(q) = \sum_{l=1}^{\infty} \alpha_l^2, \quad \text{if } q = \sum_{i=1}^{\infty} \alpha_i \delta(x - x_i) \quad \text{and} \quad \sum_{l=1}^{\infty} \alpha_l^2 < \infty.$$

For any $q \in \Xi_\infty$ such that $q = \Sigma_i \alpha_i \delta(x - x_i)$ and all $x_i \in \Lambda$, where $\Lambda \in R^d$ is some bounded set, we define

$$:q(x)q(y): = q(x)q(y) - \delta(x-y)\alpha(q)q(y), \tag{II.9}$$

$$:qVq: = \int :q(x)V(x-y)q(y):dxdy = \int q(x)V(x-y)q(y)dxdy - \alpha(q)V(0)q(x), \tag{II.10}$$

if V is a locally integrable kernel and such that $V(0) < \infty$. If $V \in L^1_{\mathrm{loc}}(R^d)$ but $V(0) = \infty$, then we can define

$$:qVq: = \lim_{\epsilon \downarrow 0} :qV_\epsilon q:, \tag{II.11}$$

where the sequence of continuous kernels $V_\epsilon \to V$ locally in $L_1(R^d)$ as $\epsilon \downarrow 0$. See Refs. 35–38.

Also for q as above, we define

$$:q(x_1)q(x_2)q(x_3):=q(x_1)q(x_2)q(x_3)-\delta(x_1-x_2)q(x_1,\hat{\alpha}^2)q(x_3,\alpha)$$
$$-\delta(x_1-x_3)q(x_1,\alpha^2)q(x_2,\alpha)+2\,\delta(x_1-x_2)\,\delta(x_1-x_3)q(x_1,\alpha^3), \tag{II.12}$$

where for given $q(x)\equiv q(x,\alpha)=\Sigma_{i=1}\alpha_i\delta(x-x_i)$ localized in the bounded region $\Lambda\subset R^d$:

$$q(x,\hat{\alpha}^2)=\sum_{i=1}^{n}\alpha_i^2 q(x-x_i); \tag{II.13}$$

$$q(x,\alpha^p)=\sum_{i=1}^{n}\alpha_i^p q(x-x_i); \tag{II.14}$$

and similarly to (II.10) we can define define the random element: $qVqq$: for a suitably chosen kernel V on R^{3d}.

5. Conditional expectation values

For $\Lambda\subset R^d$ bounded we denote the $dP^{z,\lambda}$-completed σ-algebra $\Sigma(\Lambda)$ generated by the random elements $\{\langle q,f\rangle,\ q\in\Xi_\infty,\ f\in\mathscr{D}(\Lambda)\}$. Then we introduce the decomposition: for $q\in\Xi_\infty$: $q=\Sigma_{i=1}^{\infty}\alpha_i\delta(x-x_i)$ define

$$q_\Lambda\overset{df}{=}\sum_j \alpha_j\delta(x-x_j):x_j\in\Lambda$$

and

$$q_{\Lambda^c}=\sum_j \alpha_j\delta(x-x_j):x_j\in\Lambda^c.$$

The following formulas for the conditional expectation values are valid:

$$E_{P^{\lambda,z}}\{F|\Sigma(\Lambda^c)\}(q)=\int F(\eta_\Lambda,q_{\Lambda^c})dP^{z,\lambda}_{|\Sigma(\Lambda)}(\eta_\Lambda), \tag{II.15}$$

from which it follows rather easily that $dP^{z,\lambda}_\Lambda\equiv dP^{z,\lambda}_{|\Sigma(\Lambda)}$ is again ∞-divisible generalized random field on $\mathscr{D}'(\Lambda)$ with the characteristic functional [for $f\in\mathscr{D}(\Lambda)$],

$$\int e^{i\langle\varphi,f\rangle}dP^{z,\lambda}_\Lambda=e^{z\int_\Lambda\int(e^{i\alpha f(x)}-1)dx\,d\lambda(\alpha)} \tag{II.16}$$

and the set

$$\Xi_\Lambda=\left\{\sum_{i=1}^{n<\infty}\alpha_i\delta(x-x_i);x_i\in\Lambda,\alpha_i\in\text{supp }d\lambda\right\}$$

is the carrier set for $dP^{z,\lambda}_\Lambda$, i.e. $P^{z,\lambda}_\Lambda(\Xi_\Lambda)=1$.

B. Finite volume grand canonical Gibbs ensembles

Let Σ be a Borel subset of R^1 (in most of the applications we have in mind Σ is a discrete subset), which will be called the spaces of charges, and we shall assume that some ''*a priori*'' given regular measure λ is defined on Σ such that $\lambda(\Sigma)<\infty$ and λ has moments of all orders.

In the sets $(R^d\times\Sigma)^{\times k}$, $k=1,2,...,\infty$ the following equivalence relation is introduced: we will say that $\omega=((x_1,\alpha_1),\ldots,(x_k,\alpha_k))$ and $\omega' = ((x_1',\alpha_1'),\ldots,(x_k',\alpha_k'))$ are equivalent iff they differ only by permutations of pairs $(x_i,\alpha_i)\in R^d\times\Sigma$ composing them. Taking any $\Lambda\subset R^d$ and $\omega\in(R^d\times\Sigma)^{\times k}$, we shall denote by ω_Λ the element of $(\Lambda\times\Sigma)^{\times|\omega_\Lambda|}$ obtained from ω by removing those (x_i,α_i) for which $x_i\notin\Lambda$. The subset of $(R^d\times\Sigma)^\infty/\infty$ composing of those ω for which the following holds: *for any bounded* $\Lambda\subset R^d$, ω_Λ *belongs to some* $(\Lambda\times\Sigma)^{\times k}/\infty$ *for some finite* k will be called the set of locally finite configurations of the system and will be denoted by $C_{\mathrm{lf}}(R^d\times\Sigma)$. For a given $\Lambda\subset R^d$ we shall denote by $C(\Lambda\times\Sigma)\equiv\{\omega'=\omega_\Lambda$ for some $q\in C_{\mathrm{lf}}(R^d\times\Sigma)\}$.

Then we have

$$C_{\mathrm{lf}}(R^d\times\Sigma)\cong C_{\mathrm{lf}}(\Lambda\times\Sigma)\times C_{\mathrm{lf}}((R^d\backslash\Lambda)\times\Sigma),$$

for any $\Lambda\subset R^d$ and also $C(\Lambda\times\Sigma)=\cup_{n>0}C_n(\Lambda\times\Sigma)$ and $C_{\mathrm{lf}}(R^d\times\Sigma)=\cup_{n\geqslant 0}C_n(R^d\times\Sigma)$, where $C_n(\Lambda\times\Sigma)=\{\omega_\Lambda|\#\omega_\Lambda=n\}$, where $\#\omega_\Lambda\equiv$number of elements composing ω_Λ. The set $C_n(\Lambda\times\Sigma)$ can be identified with $(\Lambda\times\Sigma)^{\times n}/\infty$, therefore it is possible to transport the corresponding topological and measurable structures from $(\Lambda\times\Sigma)^r/\infty$ into the set $C_n(\Lambda\times\Sigma)$ and then into $C(\Lambda\times\Sigma)$ also. It is a result of Ref. 40 that the corresponding topological and measurable structures coincide on $C(\Lambda\times\Sigma)$. The corresponding σ-algebras will be denoted by $\Sigma_{(\Lambda)}$ and by $\Sigma(R^d)$ for $C_{\mathrm{lf}}(R^d\times\Sigma)$.

On the sets Δ_Λ^n defined by

$$\Delta_\Lambda^n\equiv\{\omega\in C_\Lambda(\Lambda\times\Sigma)|\#(\omega)=n,\omega=\omega_\Delta\},$$

we can define a map,

$$\Pi_{0,\Lambda}^{z,\lambda}(\Delta_\Lambda^n)\equiv\frac{z^n}{n!}\,\rho(\Delta)^n\left(\int_\Sigma\lambda(d\alpha)\right)^n \tag{II.17}$$

and then by standard construction we can extend this to a measure the σ-algebra generated by the sets Δ_Λ^n [coinciding with $\Sigma(\Lambda)$ for any Λ, including R^d also]. The corresponding measures will be called finite volume (if Λ is bounded) grand canonical free, Gibbs ensembles and will be denoted by $\tilde{\Pi}_\Lambda^{\lambda,z}$ and their corresponding normalized versions by $\Pi_\Lambda^{\lambda,z}$ and the infinite volume g.c. Gibbs free ensemble for $\Lambda=R^d$ with the notation $\tilde{\Pi}_\infty^{\lambda,z}$, respectively $\Pi_\infty^{\lambda,z}$, where $z>0$ stands for the chemical activity.

Let us define the map:

$$j_\Lambda:C(\Lambda\times\Sigma)\ni\omega=((x_1,\omega_1),\ldots,(x_n,\alpha_n))\to j_\Lambda(\omega)\equiv\Sigma_{i=1}^n\alpha_i\delta(x-x_i)\in\mathscr{D}'(\Lambda). \tag{II.18}$$

It follows easily that j_Λ is (weakly) $(\Sigma(\Lambda);\beta(\mathscr{D}'(\Lambda)))$ measurable and therefore the measure $\Pi_\Lambda^{\lambda,z}$ can be transported on the space $((\mathscr{D}'(\Lambda)),\beta(\mathscr{D}'(\Lambda)))$ by this map. Then for any bounded and measurable F on $\mathscr{D}'(\Lambda)$ we have

$$\int_{\mathscr{D}'(\Lambda)}d(j_\Lambda\circ\Pi_\Lambda^{z,\lambda})(q)F(q)=\int_{C(\Lambda\times\Sigma)}d\Pi_\Lambda^{z,\lambda}(\hat{\omega})(F\circ j_\Lambda)(\omega). \tag{II.19}$$

Taking $F(q)\equiv e^{\langle q,f\rangle}$ for $f\in\mathscr{D}(\Lambda)$ we obtain

$$\int_{\mathscr{D}'(\Lambda)}d(j_\Lambda\circ\Pi_\Lambda^{z,\lambda})(q)e^{i\langle q,f\rangle}=\exp\left\{z\int d\lambda(\alpha)\int dx(e^{i\alpha f(x)}-1)\right\} \tag{II.20}$$

by an easy $C(\Lambda\times\Sigma)$-calculation, in which we recognize a characteristic functional of Poisson g.r.f. $dP_{\Lambda}^{z,\lambda}$ on $\mathscr{D}'(\Lambda)$.

Any measurable function $\mathscr{E}^{\Lambda}:\hat{\Omega}(\Lambda)\to(-\infty,\infty]$ will be called interaction. We shall require that $\mathscr{E}^{\Lambda}$ is thermodynamically stable, i.e., there exists $B>0$ such that for any $\hat{\omega}\in\hat{\Omega}(\Lambda)$: $\mathscr{E}^{\Lambda}(\hat{\omega})\geqslant -|\hat{\omega}|B$ uniformly in Λ. Having in mind the decomposition $\hat{\Omega}(\Lambda)=\cup_{n\geqslant 0}^{\infty}\Omega_n(\Lambda)$ we can define a sequence of potentials $\mathscr{V}=(\widetilde{V}_1,\widetilde{V}_2,\ldots)$, which determines $\mathscr{E}^{(\Lambda)}$. To avoid the complicated notation, the following assumption on $\mathscr{V}$ will be made throughout this paper.

(H1) $\widetilde{\mathscr{V}}=(\widetilde{V}_2,\widetilde{V}_3,0,\ldots)$, i.e. we shall consider only two and three body forces, (H2) $\widetilde{V}_2,\widetilde{V}_3$ are of the following form:

$$\widetilde{V}_2(\hat{x},\hat{y})=\widetilde{V}_2((x,\alpha),(y,\beta))=\alpha\beta V_2(x,y),$$

$$\widetilde{V}_2((x,\alpha),(y,\beta),(z,\gamma))=\alpha\beta\gamma V_3(x,y,z).$$

The energy function is then given by

$$\mathscr{E}_{\mathscr{V}}^{\Lambda}:C(\Lambda\times\Sigma)\ni\hat{\omega}=(\hat{x}_1,\ldots,\hat{x}_n)\to\mathscr{E}_{\mathscr{V}}^{\Lambda}(\hat{\omega})$$

$$=\sum_{1\leqslant i<j\leqslant n}\alpha_i\alpha_j V_2(x_i,x_j)+\sum_{1\leqslant i<j<k\leqslant n}\alpha_i\alpha_j\alpha_k V_3(x_i,x_j,x_k) \quad \text{(II.21)}$$

The finite volume partition function $Z_{\Lambda}^{\lambda}(z,\beta)$ is given by

$$Z_{\Lambda}^{\lambda}(z,\beta)=\int_{C(\Lambda)}d\Pi_{\Lambda,0}^{z,\lambda}(\hat{\omega})\exp(-\beta\mathscr{E}_{\mathscr{V}}^{\Lambda}(\hat{\omega}), \quad \text{(II.22)}$$

and the (unconditioned) grand canonical Gibbs ensemble by the measure

$$d\Pi_{\Lambda}^{z,\lambda}(\hat{\omega})\equiv(Z_{\Lambda}^{\lambda}(z,\beta))^{-1}\exp\{-\beta\mathscr{E}_{\mathscr{V}}^{\Lambda}(\hat{\omega})\}d\Pi_{\Lambda,0}^{z,\lambda}(\hat{\omega}). \quad \text{(II.23)}$$

This measure is uniquely determined by the so-called correlation functions ρ_{Λ}. For our purposes, however, the more suitable objects are so-called reduced correlation functions $\hat{\rho}_{\Lambda}$, given by

$$\hat{\rho}_{\Lambda}(\hat{\omega}_n)=\exp\beta\mathscr{E}_{\mathscr{V}}^{\Lambda}(\hat{\omega}_n)\rho_{\Lambda}(\hat{\omega}_n)=z^n\sum_{m\geqslant 0}^{\infty}\frac{z^m}{m!}\int_{\Lambda}d\hat{y}|_1^m\frac{\exp\{-\beta\mathscr{E}_{\mathscr{V}}^{\lambda}(\hat{y}_1^n)\}\exp\{-\beta\mathscr{E}_{\mathscr{V}}^{\Lambda}(\hat{y}_1^n|\hat{x}_1^n)\}}{Z_{\Lambda}(z,\beta)}, \quad \text{(II.24)}$$

where

$$\hat{x}_1^n=(\hat{x}_1,\ldots,\hat{x}_n)=((x_1,\alpha_1),\ldots,(x_n,\alpha_n)), \quad \text{(II.25)}$$

$$\int_{\Lambda}d\hat{x}_1^n\equiv\int_{\Lambda}\prod_{i=1}^{n}dx_i\,d\lambda(\alpha_i); \quad \text{(II.26)}$$

$$\mathscr{E}_{\mathscr{V}}^{\Lambda}(\hat{y}_1^m|\hat{x}_1^n)=\mathscr{E}_{\mathscr{V}}^{\Lambda}(\hat{x}_1^n V\hat{y}_1^m)-\mathscr{E}_{\mathscr{V}}^{\Lambda}(\hat{x}_1^n)-\mathscr{E}_{\mathscr{V}}^{\Lambda}(\hat{y}_1^m). \quad \text{(II.27)}$$

For a moment we shall assume that the potentials V_2 and V_3 are bounded functions on R^{2d} and R^{3d}, respectively.

Let us consider first the case $V_3\equiv 0$.

Proposition II.1: Let us assume that $\widetilde{V}_2$ is stable, then the following formulas hold:

$$Z_\Lambda^\lambda(z,\beta)=\int_{\mathscr{D}'(\Lambda)} dP_\Lambda^{z,\lambda}(q)e^{-(\beta/2):V_2^\Lambda(q,q):} \tag{II.28}$$

(1) where

$$:V_2^\Lambda(q,q):\equiv\int_\Lambda dx\ dy:q(x)V_2(x,y)q(y):. \tag{II.29}$$

(2) The reduced, grand canonical correlation functions are given by

$$\hat\rho_\Lambda(\hat x_1^n)=z^n\int_{\mathscr{D}'(R^d)} d\mu_\Lambda^{z,\lambda}(q)\prod_{i=1}^n e^{-\beta V_2(q)(x_i)}, \tag{II.30}$$

where

$$e^{-\beta V_2(q)(x)}=e^{-\beta\int dy\ V_2(x-y)q(y)};$$

and

$$d\mu_\Lambda^{z,\lambda}(q)=\frac{\exp\left(-\frac{\beta}{2}\int_\Lambda :q(x)V(x-y)q(y):dx\ dy\right)}{Z_\Lambda^\lambda(z,\beta)}\,dP_{\Lambda,0}^{z,\lambda}. \tag{II.31}$$

(a) Proof: It follows by an easy $(C(\Lambda\times\Sigma),\Pi_{\Lambda,0}^{z,\lambda})$ calculation using the transport formula (II.20).

Similarly we obtain the following.

Proposition II.2: Let $(\widetilde V_2,\widetilde V_3)$ *be stable and such that*

$$\sup_x V_3(x,x,x)<\infty,\quad \sup_{x,y}V_3(x,x,y)<\infty,\quad V_2(0)<\infty.$$

Then the following formulas are valid:

$$Z_\Lambda^\lambda(z,\beta)=\int_{\mathscr{D}'(\Lambda)} dP_\Lambda^{z,\lambda}(q)e^{-\beta:\mathscr{E}_\Lambda^\nu(q,q,q):}, \tag{II.32}$$

(1) where

$$:\mathscr{E}_\Lambda^\nu(q):=\frac{1}{2}:V_2(q,q):+\frac{1}{3!}:V_3(q,q,q):.$$

(2) The corresponding reduced correlation functions are given by

$$\rho_\Lambda^n(\hat x_1^n)=z^n\int_{\mathscr{D}'(\Lambda)} d\mu_\Lambda(q)\prod_{i=1}^n e^{-\beta V_2(q)(x_i)}\prod_{1\le i<j\le n} e^{-\beta V_3^1(q)(x_i,x_j)}\prod_{i=1}^n e^{-\beta V_3^2(q)(x_i)}, \tag{II.33}$$

where

$$V_3^1(q)(x_i,x_j)=\int_\Lambda dy\ q(y)V_3(x_i,x_j,y);$$

$$V_3^2(q)(x)=\int_\Lambda dy\int_\Lambda dy' :q(x)q(y):V_3(x,y,y'); \tag{II.34}$$

$$d\mu_\Lambda(q)=(Z_\Lambda^\lambda(z,\beta))^{-1}e^{-\beta:\mathscr{E}_\Lambda^\nu:(q)}\ dP_\Lambda^{z,\lambda}.$$

(b) Proof: Again by passing to $(C(\Lambda\times\Sigma),\Pi_{\Lambda,0}^{z,\lambda})$ variables and the use of the normal product definition, as described in Sec. II A *4*.

Now let $(\chi_\epsilon)_{\epsilon>0}$ be a positive mollifier on R_+^d, i.e. $\chi_\epsilon(x)\in C_0^\infty(R^d)$; $\chi_\epsilon\geqslant 0$; $\sup\chi_\epsilon\subset B(0,\epsilon)$; $\|\chi_\epsilon\|_1=1$ and $\omega-\lim_{\epsilon\downarrow 0}\delta_\epsilon(x)=\delta$ (in the weak sense). Taking $V\in L^1_{\mathrm{loc}}(R^d)$ we see that $\chi_\epsilon * V\equiv V^\epsilon\epsilon C^\infty(R^d)$, and moreover, $\lim_{\epsilon\downarrow 0}V^\epsilon=V$ locally in the $L^1(R^d)$ sense.

Proposition II.3: Let $\mathscr{V}=(0,V_2,0,...)$ be such that $V_2\in L^1_{\mathrm{loc}}(R^d)$ is stable and translationally invariant.

(1) Then for any regularizing sequence χ_ϵ as above the following limit:

$$\hat\Gamma_\Lambda(f)=\lim_{\epsilon\downarrow 0}\hat\Gamma_\Lambda^\epsilon(f)=\int_{\mathscr{D}'(\Lambda)}dP_\Lambda^{z,\lambda}(q)e^{-\beta/2V_2^\epsilon(q,q)_\Lambda:}e^{i(q,f)} \tag{II.35}$$

exists and defines continuous and positively defined functional on $\mathscr{D}(\Lambda)$.

(2) For any $(\chi_\epsilon)_{\epsilon>0}$, any $p\geqslant 1$ the limit

$$\lim_{\epsilon\downarrow 0}e^{-:\beta/2V_2^\epsilon(q,q)_\Lambda:}\equiv e^{-:\beta/2V_2(q,q)_\Lambda:} \tag{II.36}$$

exist in the $L^p(\mathscr{D}'(\Lambda),dP_\Lambda^{z,\lambda})$ sense.

(3) For any $(\chi_\epsilon)\subset C_0^\infty(R^d)$ as above, the limits

$$\hat\rho_\Lambda^n(\hat x_1^n)=\lim_{\epsilon\downarrow 0}\frac{\int_{\mathscr{D}'(\Lambda)}d\mathscr{P}_\Lambda^{z,\lambda}(q)\Pi_{i=1}^n\exp(-\beta\Sigma_{i=1}^n(q*V_\epsilon)(x_i))\exp\{-\beta/2:V_\Lambda^\epsilon(q,q):\}}{\hat\Gamma_\Lambda^\epsilon(0)}, \tag{II.37}$$

exists pointwise on $(\Lambda\times\Sigma)^{\times n}/\infty$.

Remark: The same convergence results hold for many body interactions, provided they are not too singular.

As a simple corrolary, we obtain the following.

Corollary II.4: Let $V_2\in L^1_{\mathrm{loc}}(R^d)$ be stable and translationally invariant potential. Then there exists a probabilistic, Borel cylindric measure $d\mu_\Lambda^{(z,\lambda)}$ on $\mathscr{D}'(\Lambda)$, such that

$$\int_{\mathscr{D}'(\Lambda)}e^{i\langle q,f\rangle}d\mu_\Lambda^{(z,\lambda)}(q)=\frac{\hat\Gamma_\Lambda(f)}{\hat\Gamma_\Lambda(0)}\equiv\Gamma_\Lambda(f). \tag{II.38}$$

The measures $d\mu_\Lambda^{(z,\lambda)}$ are locally absolutely continuous with respect to $dP_\Lambda^{z,\lambda}$ and the corresponding Radon–Nikodym derivatives are given by

$$\frac{d\mu_\Lambda^{(z,\lambda)}(q)}{dP_\Lambda^{z,\lambda}(q)}=\exp\left\{-\frac{\beta}{2}:V_\Lambda(q,q):\right\}. \tag{II.39}$$

(c) Proof: By the $(C(\Lambda\times\Sigma);d\Pi_{\Lambda,0}^{z,\lambda})$ calculations, we have

$$\hat{\Gamma}^{\epsilon}_{\Lambda}(f)=\int_{\mathscr{D}'(\Lambda)} dP^{z,\lambda}_{\Lambda}(q)e^{i\langle q,f\rangle}\exp\left\{-\frac{\beta}{2}:V^{\epsilon}_{\Lambda}(q,q):\right\}$$
$$=e^{-z\lambda(\Sigma)|\Lambda|}\sum_{n\geqslant 0}^{\infty}\frac{z^n}{n!}\int d(\hat{x})^n_1\prod_{i=1}^{n}[e^{i\alpha_i f(x_i)}-1]e^{-\beta\mathscr{E}_{V^{\epsilon}_2}(\hat{x}^n_1)}, \tag{II.40}$$

where

$$\mathscr{E}_{V^{\epsilon}_2}(x^n_1)=\frac{1}{2}\sum_{1\leqslant i<j\leqslant n}\alpha_i\alpha_j V^{\epsilon}_2(x_i-x_j). \tag{II.41}$$

From the assumed stability of $\mathscr{E}_{V^{\epsilon}_2}$ follows the uniform (in ϵ) estimate

$$|\hat{\Gamma}^{\epsilon}_{\Lambda}(f)|\leqslant\exp\left\{z\int_{\Lambda}d(\hat{x})|e^{if(x)}|e^{\beta B}\right\}e^{-z|\lambda(\Sigma)||\Lambda|}, \tag{II.42}$$

which means that the series (II.40) is uniformly convergent in ϵ. The nth term of (II.40) can be estimated by the following inequality:

$$\left|\int_{\Lambda}d(\hat{x})^n_1\left(\prod_{i=1}^{n}e^{\alpha_i f(x_i)}e^{-\beta\mathscr{E}_{\nu^{\epsilon}_2}(\hat{x}^n_1)}-\prod_{i=1}^{n}e^{\alpha_i f(x_i)}e^{-\beta\mathscr{E}_{\nu^{\epsilon'}_2}(\hat{x}^n_1)}\right)\right|$$
$$\leqslant\int_0^1 ds\ se^{n\beta B}\sum_{1\leqslant i<j\leqslant n}\int_{\Lambda}d(\hat{x})^n_1\alpha_i\alpha_j|V^{\epsilon}_2(x_i-x_j)-V^{\epsilon'}_2(x_i-x_j)|. \tag{II.43}$$

Therefore, assuming $V_2\in L^1_{\mathrm{loc}}(R^d)$, we conclude that the nth term in (II.40) is convergent in ϵ to the corresponding expression with $\epsilon=0$.

Therefore $\lim_{\epsilon\downarrow 0}\hat{\Gamma}^{\epsilon}_{\Lambda}(f)=\Gamma_{\Lambda}(f)$ exists and is given by (II.35). From the estimate (II.42) the continuity of $\Gamma_{\Lambda}(f)$ on $\mathscr{D}'(\Lambda)$ follows easily.

Again, by $C(\Lambda\times\Sigma)$ calculations:

$$\int_{\mathscr{D}'(\Lambda)}\left|e^{-\beta/2:\nu^{\epsilon}_{2\Lambda}(q,q):}-e^{-\beta/2:\nu'_{2\Lambda}(q,q):}\right|^2 dP^{z,\lambda}_{\Lambda}(q)$$
$$=e^{-z|\lambda(\Sigma)||\Lambda|}\sum_{n\geqslant 0}^{\infty}\frac{z^n}{n!}\int_{\Lambda^n}d(\hat{x}^n_1)(e^{-2\beta\mathscr{E}_{\nu^{\epsilon}_2}(\hat{x}^n_1)}+e^{-2\beta\mathscr{E}_{\nu^{\epsilon'}_2}(\hat{x}^n_1)}-2e^{-\beta\mathscr{E}_{\nu^{\epsilon}_2}(\hat{x}^n_1)}e^{-\beta\mathscr{E}_{\nu^{\epsilon'}_2}(\hat{x}^n_1)})$$
$$\leqslant e^{-z|\lambda(\Sigma)||\Lambda|}2\sum_{n\geqslant 0}^{\infty}\frac{z^n}{n!}e^{2\beta Bn}\beta\int_{\Lambda^n}d(\hat{x})^n_1|\mathscr{E}_{\nu^{\epsilon}_2}(\hat{x}^n_1)-\mathscr{E}_{\nu^{\epsilon}_2}(\hat{x}^n_1)|. \tag{II.44}$$

The nth term of the last line is convergent to zero as $\epsilon\downarrow 0$, provided $V_2\in L^1_{\mathrm{loc}}(R^d)$. Moreover, the whole series appearing in the middle of (II.44) is uniformly convergent in ϵ as it follows from the stability of V^{ϵ}_2.

As an immediate application of our formulas we propose the following.

Corollary II.5: Let us assume that V_2 is superstable, i.e. $\mathscr{E}_{V_2}$ is superstable on $C_{\mathrm{lf}}(R^d\times\Sigma)$, that $V_2\in L^1_{\mathrm{loc}}$, and that $\mathscr{E}_{V_2}$ is lower regular on $C_{\mathrm{lf}}(R^d\times\Sigma)$ in the sense of Ruelle.[44] *Then the family of measures $(d\mu^{(z,\lambda)}_{\Lambda})_{\Lambda}$ indexed by bounded $\Lambda\subset R^d$ is precompact (in the topology of convergence of all finite-dimensional projections) in the space of measures on $(\mathscr{D}'(R^d),\mathscr{B}(\mathscr{D}'(R^d)))$.*

(d) Proof: For any $\zeta\in C$, $\zeta=t+is$ and using $C(\Lambda\times\Sigma)$ calculations, we obtain

$$\int_{\mathscr{D}'(\Lambda)} e^{\xi\langle q,f\rangle}\, d\mu_\Lambda^{(z,\lambda)}(q)=\sum_{n\geqslant 0}\frac{z^n}{n!}\int_\Lambda d(\hat{x})_1^n[e^{\xi f(x_i)}-1]\rho_\Lambda^n(\hat{x}_1^n). \tag{II.45}$$

From Ruelle's work[41] we conclude that there exists a constant C independent of z and Λ, such that

$$\operatorname*{ess\,sup}_{(\hat{x}_1^n)}|\rho_\Lambda^n(\hat{x}_1^n)|\leqslant C^n, \tag{II.46}$$

from which follows that

$$\left|\int_{\mathscr{D}'(\Lambda)} e^{\xi\langle g,f\rangle}\, d\mu_\Lambda^{(z,\lambda)}(q)\right|\leqslant\exp\left\{C|\zeta|\|f\|_1\int_0^1 e^{\xi s\|f\|_\infty}\, ds\right\}. \tag{II.47}$$

□

C. Infinite-volume grand canonical Gibbs measures

Let $\Xi_\infty\subset\mathscr{D}'(R^d)$ be the Borel subset consisting of those q that are of the form $q(x)=\Sigma_{i=1}^n\delta(x-x_i)$, where $x_i\neq x_j$ for $i\neq j$ and such that for any bounded $\Lambda\subset R^d$, the cardinality of the set of those x_i that belong to Λ is finite. The corresponding cardinality will be denoted by $\#(q_\Lambda)$. The smaller subset $\Xi_\infty^T\subset\Xi_\infty$ of so-called tempered configurations $q\in\mathscr{D}'(R^d)$ is defined by requiring that there exists a constant $a=a(q)$ such that for any $\square_r=\{x\in R^d|\mathrm{dist}(r,x)\leqslant 1\}$, we have $\#(q_{\square_r})\leqslant a\ \log_+ r$ for a sufficiently large r.

Taking a stable potential $\mathscr{V}$ we then define the following probabilistic kernels:

$${}^{\mathscr{V}}\Pi_\Lambda^{(\Lambda')}(-|-)(z,\beta,\mathscr{V})\mathscr{D}'(\Lambda)\times\Xi_{\Lambda'\setminus\Lambda}\to[0,1], \tag{II.48}$$

by

$$\begin{aligned}{}^{\mathscr{V}}\Pi_\Lambda^{(\Lambda')}(dq_\Lambda|\,\eta_{\Lambda'\setminus\Lambda})(z,\beta,\mathscr{V})&=(Z_\Lambda^{(\Lambda')}(\,\eta_{\Lambda'\setminus\Lambda}))^{-1}\ \exp\{-\beta\mathscr{E}_{\mathscr{V}}(q_\Lambda)\}\\&\quad\times\exp\{-\beta\mathscr{E}_{\mathscr{V}}^c(q_\Lambda|\,\eta_{\Lambda'\setminus\Lambda})\}dP_\Lambda^z(q_\Lambda),\end{aligned} \tag{II.49}$$

where $\Lambda\subset\Lambda'$ are bounded subsets of R^d,

$$\mathscr{E}_{\mathscr{V}}(q_\Lambda|\,\eta_{\Lambda'\setminus\Lambda})=\mathscr{E}_{\mathscr{V}}(q_\Lambda\cup\eta_{\Lambda'\setminus\Lambda})-\mathscr{E}_{\mathscr{V}}(q_\Lambda)-\mathscr{E}_V(\,\eta_{\Lambda'\setminus\Lambda}), \tag{II.50}$$

$$Z_\Lambda^{(\Lambda')}(\,\eta_{\Lambda'\setminus\Lambda})=\int_{\mathscr{D}'(R^d)}dP_\Lambda^z(q_\Lambda)\exp\{-\beta\mathscr{E}_{\mathscr{V}}(q_\Lambda)\}\exp\{-\beta\mathscr{E}_{\mathscr{V}}(q_\Lambda|\,\eta_{\Lambda'\setminus\Lambda})\}. \tag{II.51}$$

Let us define the following σ-algebras:

$$\widetilde{\Sigma}(\Lambda)\equiv\sigma\{(q,f\ )|f\in C_0^\infty(\Lambda);q\in\Xi_\Lambda\},$$

being subalgebras of the Borel σ-algebra in $\mathscr{D}'(R^d)$. For a given $\mathscr{V}$ we define $\Xi_\infty(\mathscr{V})$ as a Borel subset of Ξ_∞ consisting of those η for which

(i)

$$\lim_{\widetilde{\Lambda}\uparrow\Lambda^c} Z_\Lambda^{\widetilde{\Lambda}}(\,\eta_{\widetilde{\Lambda}})\equiv Z_\Lambda(\,\eta_{\Lambda^c}),$$

exists for any countably generated filter $\widetilde{\Lambda}$ tending to Λ^c and is filter independent and

(ii)

$$\lim_{\tilde{\Lambda}\uparrow\Lambda^c} \mathscr{E}_{\mathscr{T}}(q_\Lambda|\eta_{\tilde{\Lambda}}) \equiv \mathscr{E}_{\mathscr{T}}(q_\Lambda|\eta_{\Lambda^c}),$$

exists for any $q_\Lambda \in \Xi_\Lambda$ and any filter $(\tilde{\Lambda})$ as above, and the limit is filter independent.

Definition II.1 (after Dobrushin[42]): Any probabilistic Borel cylindric measure μ on $(\mathscr{D}'(R^d), \beta(\mathscr{D}'(R^d)))$, such that
(G0)

$$\mu(\Xi_\infty(\mathscr{T})) = 1;$$

(G1) for any bounded $\Lambda \subset R^d$, any bounded and $\Sigma(\Lambda)$-measurable function F,

$$\int_{\mathscr{D}'(P^d)} d\mu(\eta)\, {}^{\mathscr{P}}\Pi_\Lambda(F|\eta_{\Lambda^c})(z,\beta,\mathscr{T}) = \int_{\mathscr{D}'(R^d)} d\mu(q) F(q), \tag{II.52}$$

(LR)
where ${}^{P}\Pi_\Lambda(-|-)(z,\beta,\mathscr{T})$ is defined as the (weak) limit of $\Pi_\Lambda^{(\tilde{\Lambda})}(-|-)(z,\beta,\mathscr{T})$, will be called the functional, grand canonical Gibbs ensemble for a system $(\mathscr{T},\lambda,z,\beta)$. The set of all functional grand canonical Gibbs ensembles will be denoted by ${}^{\mathscr{P}}\mathscr{G}(z,\beta)$. The set of those $\mu \in {}^{\mathscr{P}}\mathscr{G}(z,\beta)$ that are supported on the tempered configurations will be denoted by ${}^{\mathscr{P}}\mathscr{G}^{T}(z,\beta)$ and will be called the set of tempered grand canonical Gibbs ensembles for $(\mathscr{T},\lambda,z,\beta)$.

There exists a corresponding notion of the grand canonical Gibbs ensembles in the language of the space $(C_{\mathrm{lf}}(R^d), \beta(C_{\mathrm{lf}}(R^d)))$ (see. e.g., Refs. 5, 6). The corresponding set of grand canonical (tempered) Gibbs ensembles for $(z,\mathscr{T},\lambda,\beta)$ will be denoted by $\mathscr{G}^{(T)}(z,\beta)$.

We extend the representation of the grand canonical Gibbs ensemble by functional integrals to the infinite volume limit situation by the following result.

Theorem II.6: *There exists a bijection $\mathscr{T}_\infty$ between the set ${}^{\mathscr{P}}\mathscr{G}(z,\beta)$ and $\mathscr{G}(z,\beta)$. The bijection $\mathscr{T}_\infty$ when restricted to the Martin–Dynkin boundary of ${}^{\mathscr{P}}\mathscr{G}(z,\beta)$ is still bijection between $\partial^{\mathscr{P}}\mathscr{G}(z,\beta)$ and $\partial\mathscr{G}(z,\beta)$.* (The existence of the Martin–Dynkin boundary and the corresponding integral decomposition follows from the general abstract arguments of Fölmer.[52])

(e) Proof: Let

$$\pi_\infty : C_{fl}(R^d) \ni \tilde{x} \to \pi_\infty(\tilde{x}) = \sum_{i=1}^{\infty} \alpha_i \delta(x - x_i) \in \mathscr{D}'(R^d). \tag{II.53}$$

It is easy to note that the map π_∞ is (weakly) measurable, and moreover, $\pi_\infty(C_{fl}(\mathscr{T})) = \Xi_\infty(\mathscr{T})$. Therefore any Borel measure $\tilde{\mu}$ concentrated on the set $C_{fl}(\mathscr{T})$ can be transported onto the Borel measure $\mu = \pi_\infty \circ \mu$ on $\beta(\mathscr{D}'(R^d))$, such that $\mu(\Xi_\infty(\mathscr{T})) = 1$.

Assuming that $\tilde{\mu} \in \mathscr{G}(z,\beta)$, it follows by an easy calculation that for any $\tilde{y} \in C_{fl}(\mathscr{T})$,

$$\begin{aligned} Z_\Lambda(\tilde{y}_{\Lambda^c}) &= \int_{C_{(\Lambda)}} d\Pi_{\Lambda,0}^{z,\lambda}(\tilde{x}) e^{-\beta \mathscr{E}_{\mathscr{T}}(\tilde{x})} e^{-\beta \mathscr{E}_{\mathscr{T}}(\tilde{x}|\tilde{y}_{\Lambda^c})} \\ &= \int_{\mathscr{D}'(R^d)} dP_\Lambda^z(q_\Lambda) \exp[-\beta \mathscr{E}_{\mathscr{T}}(q_\Lambda)] \exp[-\beta \mathscr{E}_{\mathscr{T}}(q|\pi_\infty(\tilde{y}_{\Lambda^c})], \end{aligned} \tag{II.54}$$

and for any $|\Lambda| < \infty$, $\tilde{y} \in C_{\mathrm{lf}}(\mathscr{T})$:

$$\pi_\infty \circ \Pi_\Lambda(d\tilde{x}|\tilde{y}_{\Lambda^c})(z,\beta,\mathscr{T}) = {}^{\mathscr{P}}\Pi(\pi_\infty(d\tilde{x}_\Lambda)|\pi_\infty(\tilde{y}_{\Lambda^c})). \tag{II.55}$$

Therefore, if we assume that $\tilde{\mu}$ fulfills the DLR equation on

$$(C_{\mathrm{lf}}(R^d);\beta(C_{\mathrm{lf}}(R^d))),$$

then the transported $\mu=\pi_\infty\circ\tilde{\mu}$ fulfills the corresponding DLR equation on $(\mathscr{D}'(R^d),\ \beta(\mathscr{D}'(R^d)))$, and vice versa. Thus, we have proved that $\pi_\infty\circ(\mathscr{G}(z,\beta))=^{\mathscr{P}}\mathscr{G}(z,\beta)$.

If now $\tilde{\mu}\in\partial\mathscr{G}(z,\beta)$, then the corresponding ''σ-algebra at infinity'' $\Sigma_\infty^{\tilde{\mu}}=\cap_{\Lambda\subset R^d}\Sigma_{\tilde{\mu}}(\Lambda^c)$ must be $\tilde{\mu}$-trivial (see, e.g., Refs. 3, 5, 8), and this is also sufficient for $\tilde{\mu}\in\partial\mathscr{G}(z,\beta)$.

From the formula

$$E_{\tilde{\mu}}\{F|\hat{\Sigma}(\Lambda^c)\}(\tilde{y}_{\Lambda C})=E_{\pi_\infty\circ\tilde{\mu}}\{F\circ\pi_\infty|\Sigma(\Lambda^c)\}(\pi_\infty(\tilde{y}_\Lambda c),\tag{II.56}$$

where

$$\hat{\Sigma}(\Lambda^c)\overset{df}{\equiv}\sigma\{\tilde{y}_{\Lambda^c}\}\subset\beta(C_{\mathrm{lf}}(R^d)),\tag{II.57}$$

it follows that $\pi_{\infty|\partial\mathscr{G}(z,\beta)}$ is still injective and is surjective on $^{\mathscr{P}}\mathscr{G}(z,\beta)$. □

Before closing this section let us remark that in the case of positive-definite two body potential V_2, such that $V_2(0)<\infty$ another interesting functional integral representation, that we call mixed Poisson-sine-Gordon representation exists. Let $d\mu_{V_2}$ denote the centered Gaussian measure on $\mathscr{D}'(R^d)$ with the covariance V_2. Then the following formulas are valid:

$$Z_\Lambda^\lambda(z,\beta)=\int_{\mathscr{D}'(\Lambda)\otimes\mathscr{D}'(R^d)}dP_\Lambda^{z,\lambda}(q)\otimes d\mu_V(\varphi)e^{i\sqrt{\beta}\langle\varphi,q\rangle}e^{(\beta/2)V(0)(\#(q))}\tag{II.58}$$

and

$$\rho_\Lambda^{(n)}((\hat{x})_1^n)=z^n\int_{\mathscr{D}'(\Lambda)\otimes\mathscr{D}'(R^d)}d\mu_\Lambda^{(z,\beta,\lambda)}(\varphi,q)\prod_{i=1}^n:e^{i\sqrt{\beta}\langle\varphi,q(x_i)\rangle}:,\tag{II.59}$$

where

$$d\mu_\Lambda^{(z,\beta,\lambda)}(\varphi,q)=\frac{:e^{i\sqrt{\beta}\langle\varphi,q\rangle}:d\mu_V(\varphi)\otimes dP_\Lambda^{z,\lambda}(q)}{Z_\Lambda^\lambda(z,\beta)},\tag{II.60}$$

$$:e^{i\sqrt{\beta}\langle\varphi,q(x_i)\rangle}:=\exp\left(\frac{\beta}{2}V(0)(\#q)\right)\exp(i\sqrt{\beta}\langle\phi,q(x_i)\rangle),\quad q(x_i)=q(.-x_i).\tag{II.61}$$

Whether the mixed Poisson-sine-Gordon representation might be useful remains to be investigated. (The picture arising is similar to those described in Ref. 43.)

III. CYLINDRICAL APPROXIMATIONS

For simplicity we take $\Sigma=\{1\}$ and $\lambda\{1\}=1$ in this section.

Let p_z denote the one-dimensional Poisson distribution on the real line R^1, with the intensity parameter $z>0$, i.e.

$$p_z(dx)=e^{-z}\sum_{n\geqslant 0}\frac{z^n}{n!}\delta(x-n).$$

Then the characteristic functional γ_z of p_z is given by

$$\gamma_z(\alpha)=\int e^{i\alpha x}p_z(dx)=e^{z(e^{i\alpha}-1)}. \tag{III.1}$$

Let $(\chi_\epsilon)_{\epsilon>0}$ be a positive mollifier on R^d, such that supp $\chi_\epsilon=B(0,\epsilon)$. Defining $q_\epsilon=(q*\chi_\epsilon)(x)$ and computing

$$\Gamma_\epsilon(f)\equiv\int_{\mathscr{D}'(R^d)} e^{i\langle q_\epsilon,f\rangle}\,dP^z_\Lambda(q)=\exp\left(z\int(e^{if_\epsilon(x)}-1)dx\right), \tag{III.2}$$

we see that

$$\Gamma^z_\epsilon(\alpha)\equiv\lim_{f\to\delta_x}\Gamma_\epsilon(f)=\int e^{i\langle q_\epsilon,\delta_x\rangle}\,d\mathscr{P}_\Lambda(q)=\exp z|B(0,\epsilon)|\exp z\left(\int e^{i\alpha\chi_\epsilon(y)}\,dy\right). \tag{III.3}$$

Let (B_i) be any measurable partitioning of $B(0,\epsilon)$. Then we can approximate Γ^z_ϵ by

$$\Gamma^z_\epsilon\equiv\prod_{i=1}^n\gamma_{z|B_i|}(\alpha\chi_\epsilon(y_i)), \tag{III.4}$$

where $y_i\in B_i$. Thus, if (B_{i_α}) in any family of measurable partitioning of $B(0,\epsilon)$ such that $\max\{\text{diam } B_{i_\alpha}\}\to 0$ as $m\to\infty$, then for any choice of $y_{i_\alpha}\in B_{i_\alpha}$ we have the equality

$$\Gamma^z_\epsilon=\lim_m\gamma_{i_m}|P_{z|B_{i_m}(0,\epsilon)|}(\alpha\chi_\epsilon(y_{i_m})). \tag{III.5}$$

The measure $p^z_\epsilon(dx)$ on R^1, defined by

$$\Gamma^{(z)}_\epsilon(\alpha)=\int e^{i\alpha x}p^\epsilon_z(dx), \tag{III.6}$$

will play the role of a single spin distribution in our cylindrical approximation to the measure $d\mu_\Lambda$, given by (II.34). It is easy to see that p^z_ϵ is concentrated on the real half-line $R_+=\{x\in R|x\geqslant 0\}$ and is given by a limit of an infinite divisible distribution,

$$P_{z|B_l(0,\epsilon)|}\left(\frac{dx}{\chi_\epsilon(y_i)}\right). \tag{III.7}$$

For a given small $\rho>0$, let Z^d_ρ denote the lattice of size ρ in R^d, i.e. $Z^d_\rho=\{(x_z,\ldots,x_d)|x_i=n_i\rho;n_i\in Z\}$ and we denote for a given $\Lambda\in R^d$; $\Lambda_\rho\equiv\Lambda\cap Z_\rho$. Taking $\rho>2\epsilon$ and using the independence properties of the field $P^z_\Lambda(dq)$, we can write down the following formula:

$$\begin{aligned}
&\int_{\mathscr{D}'(R^d)}dP^z_\Lambda(dq)\exp\left\{-\frac{\beta}{2}\sum_{n,n'\in\Lambda_\rho}\rho^{2d}q_\epsilon(n)V(n-n')q_\epsilon(n')\right\}\\
&\quad\times\exp\left\{\frac{\beta}{2}\sum_{n,n'\in\Lambda_\rho}\rho^{2d}\delta_\epsilon(n-n')q_\epsilon(n)V(n-n')\right\}\\
&\quad=\int_{R^{|\Lambda_\rho|}}\bigotimes_{n\in\Lambda_\rho}dp^\epsilon_z(s_n)\exp\left\{-\frac{\beta}{2}\sum_{n,n'\in\Lambda_\rho}\rho^{2d}s_nV(n-n')s_{n'}\right\}\\
&\qquad\times\exp\left\{\frac{\beta}{2}\sum_{n\in\Lambda_\rho}s_nh^\rho_\Lambda(n)\rho^d\right\},
\end{aligned} \tag{III.8}$$

where $h^{\rho}_{\Lambda}(n) \equiv \Sigma_{n' \in \Lambda_\rho} \delta_\epsilon(n-n')V(n-n')\rho^d$.

Lemma III.1: Let $V \in L_1(R^d)$ be stable and let $V(0)<\infty$. Then for any $z>0$, $\beta>0$, $|\Lambda|<\infty$ the following holds:

$$\lim_{\substack{(\epsilon,\rho)\to(0,0)\\ \epsilon>0}} \int_{\mathscr{D}'(R^d)} dP^z_\Lambda(q) \exp\left\{ -\frac{\beta}{2} \sum_{n,n' \in \Lambda_\rho} \rho^{2d} q_\epsilon(n) V(n-n') q_\epsilon(n') \right\}$$
$$\times \exp\left\{ -\frac{\beta}{2} \sum_{n,n' \in \Lambda_\rho} \rho^{2d} \delta_\epsilon(n-n') V(n-n') q_\epsilon(n) \right\}$$
$$= \int_{\mathscr{D}'(R^d)} dP^z_\Lambda(q) \exp\left\{ -\frac{\beta}{2} \int_\Lambda dx \int_\Lambda dy :q(x)q(y): V(x-y) \right\}. \tag{III.9}$$

(f) Proof: For the proof we proceed to the $C(\Lambda)$-integration picture,

$$\int_{\mathscr{D}'(R^d)} d\tilde{P}^z_\Lambda(q) \exp\left\{ -\frac{\beta}{2} \sum_{n,n' \in \Lambda_\rho} \rho^{2d} q_\epsilon(n) V(n-n') q_\epsilon(n') \right\}$$
$$\times \exp\left\{ \frac{\beta}{2} \sum_{n,n' \in \Lambda_\rho} \rho^{2d} q_\epsilon(n) \delta_\epsilon(n-n') V(n-n') \right\}$$
$$= \sum_{n \geqslant 0} \frac{z^n}{n!} \int_\Lambda d(x)^n_1 \exp\left\{ -\frac{\beta}{2} \sum_{n,n' \in \Lambda_\rho} \rho^{2d} \left(\sum_{i,j=1}^n \delta_\epsilon(n-x_i) V(n-n') \delta_\epsilon(n'-x_j) \right) \right\}$$
$$\times \exp\left\{ \frac{\beta}{2} \sum_{n,n'} \rho^{2d} \sum_{i=1}^n \delta_\epsilon(n-n') \delta_\epsilon(x_i-n) V(n-n') \right\}. \tag{III.10}$$

Noting that

$$\lim_{\substack{(\epsilon,\rho)\to(0,0)\\ e>0}} \left\{ \sum_{n,n' \in \Lambda_\rho} \rho^{2d} \sum_{i,j=1}^n \delta_\epsilon(n-x_i) V(n-n') \delta_\epsilon(n'-x_j) \right\} = \sum_{i,j=1}^n V(x_i, x_j) \tag{III.11}$$

and

$$\lim_{(\epsilon,\rho)\to(0,0)} \left\{ \sum_{n,n' \in \Lambda_\rho} \rho^{2d} \sum_{i=1}^n \delta_\epsilon(n-x_i) \delta_\epsilon(n-n') V(n-n') \right\} = nV(0). \tag{III.12}$$

Moreover, it is due to the stability of V that one can find easily a uniform [in (ρ,ϵ), $\epsilon>0$] bound on the nth term of the form

$$|(n\text{th term of rhs of (III.10)})| \leqslant \frac{z^n}{n!} e^{\beta C n} |\Lambda|^n, \tag{III.13}$$

for some constant C. This justifies the interchange of $\lim_{\substack{(\epsilon,\rho)\to(0,0)\\ \epsilon>0}}$ with the sum $\Sigma_{n\geqslant 0}$. □

If $V(0)=\infty$, then we regularize V; then we apply the above proof for V_ϵ and then we apply the proposition II.3.

Similar cylindrical approximations can be written for the (reduced) correlation functionals (II.24) also. For $\rho>2\epsilon$ the following formulas are valid:

$$\hat{\rho}_{\Lambda}^{(\rho,\epsilon)}(x_1,\ldots,x_n)=\int_{R^{|\Lambda_\rho|}}\bigotimes_{n\in\Lambda_\rho} dp^{\epsilon}_{z,\Lambda}(S_{\Lambda_\rho})\prod_{i=1}^{n}\exp\left\{-\beta\sum_{n^i\in\Lambda_\rho}\rho^d V(x_i-n^i)S(n)\right\}$$

$$=\int_{R^{|\Lambda_\rho|}} dp^{\epsilon}_{z,\Lambda_\rho}(S_{\Lambda_\rho})\prod_{n\in\Lambda_\rho}\exp\left\{-\beta\left(\sum_{i=1}^{n}\rho^d V(x_i-n)\right)S(n)\right\}, \quad \text{(III.14)}$$

where

$$dp^{\epsilon}_{z,\Lambda_\rho}(S_{\Lambda_\rho})=\exp\left\{-\frac{\beta}{2}\sum_{n,n'\in\Lambda_\rho}\rho^{2d}S(n)V(n-n')S(n')\right\},$$

$$\exp\left\{\frac{\beta}{2}\sum_{n\in\Lambda_\rho}\rho^d S(n)h^{\rho}_{\Lambda}(n)\right\}\frac{1}{Z^{\epsilon}_{\Lambda_\rho}(z,\beta)}\bigotimes_{n\in\Lambda_\rho}p^{\epsilon}_{z}(dS_n), \quad \text{(III.15)}$$

$$Z^{\epsilon}_{\Lambda_\rho}(z,\beta)=\int_{R^{|\Lambda_\rho|}}dP^{\epsilon}_{z,\Lambda_\rho}(S_{\Lambda_\rho}) \quad \text{(III.16)}$$

and

$$S_{\Lambda_\rho}=(S_n)_{n\in\Lambda_\rho}.$$

Lemma III.2: Let $V\in L_1(R^d)$ be a stable potential. Then for any $z>0$, $\beta>0$ we have

$$\lim_{\substack{(\epsilon,\rho)\to(0,0)\\ \epsilon>0}}\hat{\rho}_{\Lambda}^{(\epsilon,\rho)}(x_1,\ldots,x_n)=\hat{\rho}_{\Lambda}(x_1,\ldots,x_n),$$

pointwise on $\Lambda^{\times n}$.

In the region $\rho>2\epsilon$, the cylindric approximation to the Poisson integrals, introduced above gives the approximation of continuous systems by lattice spin systems, with unbounded spins, taking the values in the support of the measure $p^{\epsilon}_{z}(dx)$. The interaction in between spin variables is given by $\rho^{2d}V(n-n')$, and the counterterm has a meaning of an external magnetic field $h^{\delta}(n)$. Taking V to be positive, we realize that then our spin system is of an antiferromagnetic type.

IV. HIGH-TEMPERATURE CLUSTER EXPANSION

The construction of the high-temperature cluster expansion for the measure $d\mu_{\Lambda}^{(z,\lambda)}$ will be presented in this section. The cluster expansion of the Brydges–Federbush type (initiated in Ref. 44 and developed in Refs. 45, 46) is that which we would like to obtain. Demonstration of how the use of Poisson integral representations considerably simplifies the corresponding constructions is our main objective. We hope that the essential simplifications that appear in our construction can be very useful to analyze the corresponding low-temperature expansions[17–19] constructed for an analysis of the Debye screening in the (regularized) Coulomb systems.[17–21,47] Previously the corresponding high-temperature expansion has been described and analyzed by one of authors[34] for positive-definite two body potentials V_2, such that $V_2(0)<\infty$. Here we extend this construction and the convergence result for much larger class of two body interactions.

Notation in this section is very close to Refs. 45 and 34 (see also Ref. 47); therefore we refer to those papers if some confusions arise.

The reduced-correlation functions are objects for which the cluster expansion is supplied and the convergence will be demonstrated.

Let us fill up the space R^d with a set of disjoint lattice cubes of unit size. All the subsets of R^d that will appear are assumed to be unions of unit cubes. For a fixed $X_0=\{x_1,\ldots,x_m\}\subset R^{dm}$ we

define $X_1(X_0)\equiv Y_1$ to be the minimal union of lattice cubes covering X_0. Let $Y_2, Y_3,\ldots,Y_{n_\Lambda}$, where $n_\Lambda\equiv|\Lambda\backslash Y_1|+1$ will be disjoint unit cubes for which $\cup_{q\leqslant j\leqslant n_\Lambda} Y_j=\Lambda$, for a given bounded $\Lambda\subset R^d$.

Although the set V_1 is fixed, but the cubes $(Y_j)_{j=2,\ldots,n_\Lambda}$ being the variables of the corresponding series will change their positions. Let us define a new sequence (X_i) by the following recurrence:

$$X_n=Y_n\cup X_{n-1};\quad X_{n_\Lambda}=\Lambda;\quad X_n^c=\Lambda\backslash X_n. \tag{IV.1}$$

To simplify the notations we use the following abbreviations:

$$V_0(X)=V_0(X;q)=\sum_{j=1}^{n}\alpha_j\int_X V_2(x_j-y)q(y)dy, \tag{IV.2}$$

$$V(X',X'')=V(X',X'',q)=\int_X dx\int_{X''}dy\ q(x)V(x-y)q(y). \tag{IV.3}$$

Here we should stress that for X',X'' such that $X'\cap X''=\emptyset$, we have

$$:V(X',X''):=V(X',X''). \tag{IV.4}$$

Then we obtain for $\hat\rho_\Lambda(\hat x)_m^1$,

$$\rho_\Lambda(\hat x_m^1)=Z_\Lambda^\lambda(z,\beta)^{-1}\int dP_\Lambda^{z,\lambda}(q)e^{-\beta V_0(\Lambda)-1/2:V(\Lambda,\Lambda):}. \tag{IV.5}$$

To construct the cluster expansion let us introduce the following sequences:

$$V_0(X_n;(S)_{n-1})=\sum_{a\leqslant j\leqslant m}S_1\cdots S_{j-1}V_0(Y_j); \tag{IV.6}$$

$$V_1(X_n;(S)_{n-1})=\frac{1}{2}\sum_{a\leqslant j\leqslant m}V(Y_i,Y_j)+\sum_{i\leqslant i<j\leqslant n}S_i\cdots S_{j-1}V(Y_i,Y_j). \tag{IV.7}$$

The interpolation parameters $0\leqslant S_i\leqslant 1$, $i=1,\ldots,n-1$ specify the intensity of interactions between the particles lying in $X-I$ and $X_i^c=\Lambda\backslash X_i$. Equation (IV.7) corresponds to the sequence of covariances of sine-Gordon measure in Ref. 18. In our case it appears, after factorization of $e^{-\beta/2:V(\Lambda,\Lambda):}$ in (IV.5) at every step of expansion as a result of repeated application of the Newton–Leibnitz formula (see Refs. 18, 47 for details). Then taking into account (II.2) we obtain the cluster expansion in the form

$$\hat\rho_\Lambda(\hat x_1^m)=\sum_{1\leqslant n\leqslant n_\Lambda}\ \sum_{Y_2,\ldots,Y_n\subset\Lambda}b_n(X_n)f_\Lambda(X_n), \tag{IV.8}$$

where

$$b_n(X_n)=(-\beta)^{n-1}\int_0^1 d(S)_1^n\int P_\Lambda^{z,\lambda}(q)\prod_{q\leqslant j\leqslant n}\sum_{k=1}^{j-1}s_k\cdots s_{j-2}V_{kj}(q)$$
$$\times\exp(-\beta V_0(X_n;(s)_{n-1})-\beta:V(X_n;(s)_1^{n-1}):), \tag{IV.9}$$

with

$$V_{1,j}(q)=V_0(Y_j)+V(Y_1,Y_j),$$
$$V_{ij}(g)=V(Y_i,Y_j), \quad \text{if } i<1. \tag{IV.10}$$

Finally, the product of sums in (IV.9) leads to the tree-graph representation (see Refs. 45–47 for details):

$$b_n(X_n)=(-\beta)^n\sum_{\eta}\int_0^1 d(s)_1^{n-1} f_\eta((s)_1^{n-2})\int dP_\Lambda^{z,\lambda}(q)\prod_{2\leqslant j\leqslant n} V_{\eta(j),j}(q)$$
$$\times\exp\{-\beta V_0(X_n,(s)_1^{n-1})-\beta:V(X_n;(s)_1^{n-1}):\}. \tag{IV.11}$$

Now we are ready to formulate the main result of this section.

Theorem IV.1: *Let the interaction potential be stable (on* $(R^d\times\Sigma)^{\times 2}$*) and satisfy the following integrability conditions:*

$$V\equiv\max_{Y'}\sum_{Y\subset R^d}\tilde{V}_{Y',Y}<\infty;$$
$$\tilde{V}_{Y',Y}\equiv\max_{x\in Y'}\sqrt{\int_Y dy|V_2(x-y)|^2}<\infty, \tag{IV.12}$$

where Y, Y', *are unit cubes from our lattice. Then there exists a constant* $C=C(\beta,z)$ *independent of* Λ, *such that for sufficiently large* $1/\beta$ *that satisfies the condition*

$$64C\beta V<1, \tag{IV.13}$$

the infinite-volume limit $\hat{\rho}_\infty((x_1)^m)$ *of* $\hat{\rho}_\Lambda((x_1)^m)$ *exists and can be represented by the series (IV.8) with* $\Lambda=R^d$, $n_\Lambda=\infty$, *and*

$$f(X_n)=\lim_{\Lambda\uparrow R^d} f_\Lambda(X_n), \quad \text{instead of } f_\Lambda(X_n).$$

(g) Proof: We shall start with an estimation of $b_n(X)$. For this we apply the Schwartz inequality to the integrals in (IV. 11) with respect to $dP_\Lambda^{z,\lambda}$:

$$|b_n(X_n)|\leqslant\beta^{n-1}\sum_{\eta}\int_0^1 d(s)_1^{n-1} f_\eta((s)_1^{n-1})\left(\int dP_\Lambda^{z,\lambda}(q)\prod_{q\leqslant j\leqslant n} V^2_{\eta(j),j}(q)\right)^{1/2}$$
$$\times\left(\int dP_\Lambda^{z,\lambda}(q)\exp[-4\beta V_0(X_n,s_{n-1})]\right)^{1/4}$$
$$\times\left(\int dP_\Lambda^{z,\lambda}(q)\exp[-4\beta:V(X_n,(s)_1^{n-1}):]\right)^{1/4}. \tag{IV.14}$$

To estimate the last factor we define (following Brydges and Federbuch[45])

$$W_0^{X_0} = V(X_n,(s)1n-1)_{|s_1=\cdots=s_{n-1}=1};$$

$$W_i^{X_n} = (1-s_i)W_{i-1}^{X_n,X_i} + s_i W_{i-1}^{X_n};$$

$$i = 1,2,\ldots,n-2;$$

$$W_{n-1}^{X_n} = V(X_n;(s)_1^{n-1});$$

$$W_{i-1}^{X_n,X_i} = W_{i-1}^{X_i} + W_0^{X_n X_i}. \tag{IV.15}$$

Then in terms of q fields the stability condition for $V(X_n,X_n)$ is

$$:V(X_n,X_n):=:W_0^{X_n}:\geqslant -\beta\#(q)X_n \tag{IV.16}$$

[where $\#(q)X_n$ is the number of $x_1,\ldots,x_n$ composing $\Sigma\alpha_i\delta(x-x_i)$, which are located in the set X_n]. It is clear from (IV.17) and induction procedure that (IV.15) is true for $W_{i-1}^{X_n,X_i}$ for every $i=1,2,\ldots,n-1$. Noting that the induction step in (IV.15) for the construction of $W_i^{X_n}$ satisfies the inequality (IV.16) for all i, as it is a convex sum of terms that do so. So, we have

$$:V(X_n;(s)_1^{n-1}):\geqslant -\beta\#(q)X_n\,. \tag{IV.17}$$

Therefore we have

$$\begin{aligned}\int\ dP_\Lambda^{z,\lambda}(q)e^{-4\beta:V(X_n(s)_1^{n-1}):} &\leqslant \int dP_\Lambda^{z,\lambda}(q)e^{4\beta B(\#q)X_n}\\ &= e^{-z|X_n||\lambda(\sigma)|}\sum_{k\geqslant 0}\ \frac{z^k}{k!}\left(\int_\Sigma d\lambda(\alpha)\int_{X_n}dx\right)^k\\ &= e^{z(4\beta B-1)|X_1|\Lambda(\Sigma)}.\end{aligned} \tag{IV.18}$$

The integral in the middle bracket of (IV.14) can be estimated in the same way as in Ref. 46. This gives

$$\begin{aligned}&\int\ dP_\Lambda^{z,\lambda}(q)e^{-4\beta V_0(X_n,(s)_1^{n-1})} \leqslant e^{zme^{mB}c(4\beta)};\\ &c(4\beta) = \sup_{\alpha'}\int_R^d |e^{-4\beta\alpha\alpha' V(x)}-1|dx\ d\lambda(\alpha).\end{aligned} \tag{IV.19}$$

Using Lemma 1 of Ref. 34 and the Battle–Federbush estimate,[48] we finally obtain

$$|b_n(X_n)| \leqslant (64\beta z)^n \max_\eta \prod_{q\leqslant j\leqslant n} \widetilde{V}_{Y_{n(j)},Y_j}. \tag{IV.20}$$

Now the proof of the theorem follows from the estimate:

$$|f_\Lambda(X_n)| \leqslant e^{cn}, \tag{IV.21}$$

which is the consequence of the well-known method of the Kirkwood–Salsburg type of equation for the function $f_\Lambda(X_n)$ on the subsets of Λ.[44] Collecting all together, we get the convergence of the cluster expansion (IV.8) in the region $64C\beta V<1$, with

$$C = e^{z(e^{4\beta B}-1)\lambda(\Sigma)+\overline{c}}. \tag{IV.22}$$

□

Similar cluster expansions can be supplied and analyzed also for many body interactions. However, already on the the level of three body interactions it appears that for typical V_3, although individual terms of the cluster expansion converge, however, the whole expansion diverges in the limit $\Lambda \uparrow R^3$, being in some cases Borel summable.[48]

ACKNOWLEDGMENTS

We are grateful to the Polish National Committee of Science and to the Ukrainian Academy of Sciences for making our collaboration possible. Discussions with S. Albeverio, Yu Kondratiev, and Z. Haba were very helpful to us. Finally, we would like to thank the organizers of the BIBOS Research Center for fellowships that helped us to prepare the final version of the manuscript. Lagrangian dynamics for classical, Brownian, and quantum mechanical particles

Michele Pavon[a)]
Dipartimento di Elettronica e Informatica, Università di Padova, via Gradenigo 6/A, 35131 Padova, Italy and LADSEB-CNR, Italy

(Received 13 December 1995; accepted for publication 6 March 1996)

In the framework of Nelson's stochastic mechanics [E. Nelson, *Dynamical Theories of Brownian Motion* (Princeton University, Princeton, 1967); F. Guerra, Phys. Rep. **77**, 263 (1981); E. Nelson, *Quantum Fluctuations* (Princeton University, Princeton, 1985)] we seek to develop the particle counterpart of the hydrodynamic results of M. Pavon [J. Math. Phys. **36**, 6774 (1995); Phys. Lett. A **209**, 143 (1995)]. In particular, a *first form* of Hamilton's principle is established. We show that this variational principle leads to the correct equations of motion for the classical particle, the Brownian particle in thermodynamical equilibrium, and the quantum particle. In the latter case, the critical process q satisfies a stochastic Newton law. We then introduce the momentum process p, and show that the pair (q,p) satisfies canonical-like equations. © *1996 American Institute of Physics.* [S0022-2488(96)03507-4]

I. INTRODUCTION

In a recent paper,[1] we established the stochastic mechanics counterpart of the second (hydrodynamic) form of Hamilton's principle. The resulting variational picture is much richer and of a different nature with respect to the one previously considered in the literature. This paper deals with the first (particle) form of Hamilton's principle. Our principle may be viewed as a strengthening of Ref. 2 (pp. 73–75) which in turn was a modification of Yasue's original work.[3] Further related work may be found in Ref. 4 (Chap. 5). We adopt kinematical variables and stochastic derivatives different from Refs. 3 and 2. The critical stochastic process is not Markovian, but becomes Markovian if we adjoin certain mean-forward and mean-backward velocities. This picture is consistent with the classical mechanical picture.

For the purpose of later reference and comparison, we outline below one of the main results of Ref. 1. Assume that the motion of a nonrelativistic, spinless particle can be described by a stochastic process $q=\{q(t);t_0\leqslant t\leqslant t_1\}$, taking the values in $\mathbb{R}^3$ and having a stochastic differential of the form

$$dq(t)=\beta(t)dt+\left(\frac{\hbar}{m}\right)^{1/2}dw_+, \tag{1}$$

where the *forward drift* $\beta(t)$ is a measurable function of $\{q(\tau);t_0\leqslant\tau\leqslant t\}$, w_+ is a *Wiener process* with increments independent at each time of the past of q satisfying $E\{dw_+dw_+^T\}=I_3dt$. If the diffusion has finite kinetic energy

$$E\left\{\int_{t_0}^{t_1}\beta(t)\cdot\beta(t)d\tau\right\}<\infty,$$

then we also have the reverse-time representation[5]

a)Electronic mail: pavon@ladseb.pd.cnr.it

$$dq(t)=\gamma(t)dt+\left(\frac{\hbar}{m}\right)^{1/2}dw_-, \tag{2}$$

where γ, called the *backward drift*, depends at each time only on the future of the process q and w_- is another Wiener process whose increments are, at each time, independent of the future of the process q and satisfy $E\{dw_-dw_-^T\}=I_3dt$. When $\hbar$ tends to zero, both β and γ tend to the classical velocity. Hence, the *current velocity* $v(t):=\frac{1}{2}[\beta(t)+\gamma(t)]$ corresponds to the classical velocity, and the *osmotic velocity* $u(t):=\frac{1}{2}[\beta(t)-\gamma(t)]$ tends to zero in the semiclassical limit. In order to develop the Lagrangian and Hamiltonian formalism in stochastic mechanics in a way that naturally extends the classical case we are then naturally led[1,6] to introduce the *complex-valued* velocity (quantum velocity) $v_q(t):=v(t)-iu(t)$ that simultaneously captures $v(t)$ and $u(t)$. From Eqs. (1) and (2) we get

$$dq(t)=v(t)dt+\frac{1}{2}\left(\frac{\hbar}{m}\right)^{1/2}[dw_++dw_-], \tag{3}$$

$$0=u(t)dt+\frac{1}{2}\left(\frac{\hbar}{m}\right)^{1/2}[dw_+-dw_-]. \tag{4}$$

Multiplying the second equation by $-i$, and then adding it to the first, we finally get

$$dq(t)=[v(t)-iu(t)]dt+dw, \tag{5}$$

where

$$dw=\frac{1}{2}\left(\frac{\hbar}{m}\right)^{1/2}[(1-i)dw_++(1+i)dw_-].$$

For the properties of the *quantum noise* dw see Ref. 1 (Sec. VII). The differential (5) of q, differently from Eqs. (1) and (2), enjoys the *time reversal invariance* property, see Ref. 6.

Consider the situation where the particle is subject to an external conservative force deriving from the sufficiently regular potential $V(x)$. Let $L(x,y):=\frac{1}{2}my\cdot y-V(x)$ be the Lagrangian defined on $\mathbb{R}^3\times\mathbb{C}^3$, and let $\mathscr{T}$ denote the family of finite-energy, $\mathbb{C}^3$-valued stochastic processes on $[t_0,t_1]$. For ϕ_0 a complex-valued function on $\mathbb{R}^3$ such that $\psi_0(x):=\exp i/\hbar\,\varphi_0(x)$ has L^2 norm 1, consider the variational problem

$$\text{extremize}_{v_q\in\mathscr{T}}E\left\{\int_{t_0}^{t_1}L(x(t),v_q(t))dt+\varphi_0(x(t_0))\right\} \tag{6}$$

subject to the constraint that the finite-energy, possibly non-Markovian diffusion x has quantum velocity v_q and a prescribed probability density ρ_1 at time t_1. We then have the following result (Ref. 1, Sec. VIII).

Theorem 1: *Suppose that the solution* $\{\psi(x,t),t\in[t_0,t_1]\}$ *of the Schrödinger equation*

$$\frac{\partial\psi}{\partial t}=\frac{i\hbar}{2m}\Delta\psi-\frac{i}{\hbar}V(x)\psi, \tag{7}$$

with initial condition $\psi(x,t_0)=\psi_0(x)$ *never vanishes and satisfies*

$$E\left\{\int_{t_0}^{t_1}|\nabla \log \psi(x(t),t)|^2 dt\right\}<\infty$$

for each finite-energy diffusion x *on* $[t_0,t_1]$. *In Problem (6), let* $\rho_1(x)=|\psi(x,t_1)|^2$. *Then, there exists a stochastic process* $\{x^*(t);t_0\leqslant t\leqslant t_1\}$, *called the Nelson process, solving together with its quantum drift* $1/m\nabla\hbar/i \log \psi(x^*(t),t)$ *Problem (6).*

It is worthwhile to observe that the Markov property of the extremal process is a *result* of the variational principle. Also notice that the probability density $\rho(x,t)$ of $q(t)$ satisfies Born's relation $\rho(x,t)=|\psi(x,t)|^2$. The existence of the Nelson process corresponding to a given solution $\psi(x,t)$ of the Schrödinger equation is, in the general case where $\psi(x,t)$ can vanish, a challenging question that has generated considerable interest, see, e.g., Refs. 7, 4 (Chap IV), and 8, and references therein. The existence of the Nelson probability measure is established in Ref. 1 under the present assumptions by means of the Girsanov transformation theory, cf., e.g., Ref. 9 (Chap 6). The quantum Hamilton principle just recalled was also shown in Ref. 1 to be a consequence of two other variational principles of the min–max type. The first one, called the *saddle-point action principle*, contains as special cases both the Guerra–Morato variational principle[10] and Schrödinger original variational derivation of the time-independent equation, see, e.g., Ref. 11 (p. 118). The second, called the *saddle-point entropy production principle*, concerns the production of configurational entropy. The Nelson process appears then as a *saddle-point equilibrium solution* for both stochastic differential games.

In this paper, we develop the *first (particle) form* of Hamilton's principle in stochastic mechanics. We then show that this variational principle can be applied to a variety of conservative systems such as the classical particle, the Brownian particle in thermodynamical equilibrium, and the quantum particle by simply changing the family of trial motions.

The paper is outlined as follows. In Sec. II we collect some basic facts about the kinematics of stochastic processes. In Sec. III, we develop a stochastic calculus of variations. The corresponding Hamilton's principle is then applied in Sec. IV to various conservative systems. In Sec. V, we develop some basic elements of the Hamilton–Jacobi theory in stochastic mechanics.

II. BACKGROUND ON THE KINEMATICS OF STOCHASTIC PROCESSES

Let $(\Omega,\mathcal{E},\mathbf{P})$ be a complete probability space, and let $\mathcal{A}:=(\mathcal{A}_t)$, $t\in[t_0,t_1]$, be a nondecreasing family of sub σ-algebras of $\mathcal{E}$. Let $x:=\{x(t);t\in[t_0,t_1]\}$ be an $\mathbb{R}^n$-valued, second-order, $\mathcal{A}$-adapted stochastic process, namely the components of $x(t)$ are $\mathcal{A}_t$-measurable for all t in $[t_0,t_1]$. Suppose that x is a.s. and mean-square continuous. We say that x is *mean-forward differentiable* with respect to the filtration $\mathcal{A}$ if the limit

$$(D_+^{\mathcal{A}}x)(t)=\lim_{h\searrow 0} E\left\{\frac{x(t+h)-x(t)}{h}\,\middle|\,\mathcal{A}_t\right\}$$

exists for $t\in[t_0,t_1)$, and forms a continuous curve in $L_n^2(\Omega,\mathcal{E},\mathbf{P})$. In this case, it may be shown along the lines of Ref. 12 (Sec. 11) that x is a continuous semimartingale of the form

$$x(t)=x(t_0)+\int_{t_0}^{t}(D_+^{\mathcal{A}}x)(s)ds+m_+^{\mathcal{A}}(t), \tag{8}$$

where the integral is a Riemann integral in $L_n^2(\Omega,\mathcal{E},\mathbf{P})$ (Ref. 13 p. 10), and $m_+^{\mathcal{A}}$ is a square-integrable, continuous $\mathcal{A}_t$-martingale with $m_+^{\mathcal{A}}(t_0)=0$ a.s. (for the definitions, see, e.g., Ref. 14, p. 78). Similarly, if $\mathcal{B}:=(\mathcal{B}_t)$, $t\in[t_0,t_1]$, is a nonincreasing family of sub σ-algebras of $\mathcal{E}$ to which x is adapted, we say that x is *mean-backward differentiable* with respect to $\mathcal{B}$ if the limit

$$(D_-^{\mathscr{B}}x)(t)=\lim_{h\searrow 0} E\left\{ \frac{x(t)-x(t-h)}{h} \,\middle|\, \mathscr{B}_t \right\}$$

exists for $t\in(t_0,t_1]$, and forms a continuous curve in $L_n^2(\Omega,\mathscr{E},\mathbf{P})$. In that case, x admits the backward semimartingale representation

$$x(t)=x(t_1)+\int_{t_1}^{t}(D_-^{\mathscr{B}}x)(s)ds-m_-^{\mathscr{B}}(t), \tag{9}$$

where $m_-^{\mathscr{B}}$ is a reverse-time, square-integrable, continuous, $\mathscr{B}_t$-martingale with $m_-^{\mathscr{B}}(t_1)=0$ a.s. Notice that $D_+^{\mathscr{A}}x$ and $D_-^{\mathscr{B}}x$ depend crucially on the filtrations $\mathscr{A}$ and $\mathscr{B}$. Obviously, for x to be mean-square differentiable, $\mathscr{A}_t$ must contain $\mathscr{F}_t:=\sigma\{x(s);t_0\leqslant s\leqslant t\}$ and $\mathscr{B}_t$ must contain $\mathscr{G}_t:=\sigma\{x(s);t\leqslant s\leqslant t_1\}$. If x is mean-forward and mean-backward differentiable with respect to $\mathscr{F}:=(\mathscr{F}_t)$ and $\mathscr{G}:=(\mathscr{G}_t)$, respectively, we call $\beta(t):=(D_+^{\mathscr{F}}x)(t)$ the *forward drift* of x and $\gamma(t):=(D_-^{\mathscr{G}}x)(t)$ the *backward drift* of x. Of course, for mean-square differentiable processes, we have $\beta(t)=\gamma(t)=\dot{x}(t)$.

For stochastic processes that are simultaneously mean-forward and mean-backward differentiable with respect to the filtrations $\mathscr{A}$ and $\mathscr{B}$, we can introduce two more stochastic derivatives (using the notation introduced in Ref. 15) by

$$(D^{\mathscr{A},\mathscr{B}}x)(t):=\frac{(D_+^{\mathscr{A}}x)(t)+(D_-^{\mathscr{B}}x)(t)}{2},$$

$$(\delta D^{\mathscr{A},\mathscr{B}}x)(t):=\frac{(D_+^{\mathscr{A}}x)(t)-(D_-^{\mathscr{B}}x)(t)}{2}.$$

In particular, $v(t):=(D^{\mathscr{F},\mathscr{G}}x)(t)=(\beta(t)+\gamma(t))/2$ and $u(t):=(\delta D^{\mathscr{F},\mathscr{G}}x)(t)=(\beta(t)-\gamma(t))/2$ are the *current drift* and the *osmotic drift* of x, respectively. Representations (8) and (9) now give

$$x(t)-x(s)=\int_s^t(D^{\mathscr{A},\mathscr{B}}x)(\sigma)d\sigma+\frac{1}{2}[m_+^{\mathscr{A}}(t)-m_+^{\mathscr{A}}(s)+m_-^{\mathscr{B}}(t)-m_-^{\mathscr{B}}(s)], \tag{10}$$

$$0=\int_s^t(\delta D^{\mathscr{A},\mathscr{B}}x)(\sigma)d\sigma+\frac{1}{2}[m_+^{\mathscr{A}}(t)-m_+^{\mathscr{A}}(s)-m_-^{\mathscr{B}}(t)+m_-^{\mathscr{B}}(s)]. \tag{11}$$

Multiplying Eq. (11) by $-i$, and then adding it to Eq. (10), we finally get a generalization of Eq. (5),

$$x(t)-x(s)=\int_s^t((D-i\,\delta D)^{\mathscr{A},\mathscr{B}}x)(\sigma)d\sigma+m^{\mathscr{A},\mathscr{B}}(t)-m^{\mathscr{A},\mathscr{B}}(s), \tag{12}$$

where

$$m^{\mathscr{A},\mathscr{B}}(t):=\tfrac{1}{2}[(1-i)m_+^{\mathscr{A}}(t)+(1+i)m_-^{\mathscr{B}}(t)].$$

As for the diffusion processes of Sec. I, we call $v_q(t):=((D-i\,\delta D)^{\mathscr{F},\mathscr{G}}x)(t)$ the *quantum drift* of x and $dm^{\mathscr{F},\mathscr{G}}(t)$ the *quantum noise*.

Remark 1: Notice that when $((D-i\,\delta D)^{\mathscr{A},\mathscr{B}}x)=f(x(t),t)$, *$x$ is a Markov process. Indeed, it admits a forward differential given by*

$$dx=[\mathfrak{R}f(x(t),t)-\mathfrak{F}f(x(t),t)]dt+dm_+^{\mathscr{A}},$$

where $\Re$ and $\Im$ denote real and imaginary part, respectively.

We now state Nelson's product rule.

Lemma 1: Let $x,y:[t_0,t_1]\to L_n^2(\Omega,\mathcal{E},\mathbf{P})$ be two a.s. *and mean-square continuous stochastic processes. Suppose that x and y are simultaneously mean-forward and mean-backward differentiable with respect to the filtrations $\mathcal{A}$ and $\mathcal{B}$, respectively. Suppose, moreover, that the processes $D_+^{\mathcal{A}}x$, $D_-^{\mathcal{B}}x$, $D_+^{\mathcal{A}}y$, and $D_-^{\mathcal{B}}y$ have continuous paths. Then*

$$E\{x(t_1)\cdot y(t_1)-x(t_0)\cdot y(t_0)\}=E\left\{\int_{t_0}^{t_1}[(D_+^{\mathcal{A}}x)(t)\cdot y(t)+x(t)\cdot(D_-^{\mathcal{B}}y)(t)]dt\right\}. \tag{13}$$

Exchanging the roles of x and y in Eq. (13), adding and subtracting, we get two more formulas corresponding to Eqs. (10) and (11).

Corollary 1: Let x and y be as in the previous lemma. Then

$$E\{x(t_1)\cdot y(t_1)-x(t_0)\cdot y(t_0)\}=E\left\{\int_{t_0}^{t_1}[(D^{\mathcal{A},\mathcal{B}}x)(t)\cdot y(t)+x(t)\cdot(D^{\mathcal{A},\mathcal{B}}y)(t)]dt\right\}, \tag{14}$$

$$0=E\left\{\int_{t_0}^{t_1}[(\delta D^{\mathcal{A},\mathcal{B}}x)(t)\cdot y(t)+x(t)\cdot(\delta D^{\mathcal{A},\mathcal{B}}y)(t)]dt\right\}. \tag{15}$$

Multiplying Eq. (15) by $-i$, and then adding it to the first, we finally get a fundamental integration by parts formula related to representation (12).

Corollary 2: Let x and y be as in the above lemma. Then

$$\begin{aligned}&E\{x(t_1)\cdot y(t_1)-x(t_0)\cdot y(t_0)\}\\&\quad=E\left\{\int_{t_0}^{t_1}[((D-i\,\delta D)^{\mathcal{A},\mathcal{B}}x)(t)\cdot y(t)+x(t)\cdot((D+i\,\delta D)^{\mathcal{A},\mathcal{B}}y)(t)]dt\right\}.\end{aligned} \tag{16}$$

So far we have dealt with $\mathbb{R}^n$-valued stochastic processes. A moment's thought, however, reveals that everything we have done holds true if the processes are $\mathbb{C}^n$-valued.

We now consider the case where the process x is an n-dimensional, finite-energy Markovian diffusion with constant diffusion coefficient $\sigma^2 I_n$. We denote by $b_+(x(t),t)$ and $b_-(x(t),t)$ its forward and backward drifts, respectively. Moreover, let

$$v(x(t),t)=\frac{b_+(x(t),t)+b_-(x(t),t)}{2}$$

and

$$u(x(t),t)=\frac{b_+(x(t),t)-b_-(x(t),t)}{2}$$

denote the current and osmotic drifts. We then have Nelson's relation

$$u(x,t)=\frac{\sigma^2}{2}\,\nabla\,\log\,\rho(x,t), \tag{17}$$

where $\rho(x,t)$ is the sufficiently smooth probability density of $x(t)$ [set $u(x,t)$ equal to zero whenever $\rho(x,t)=0$]. Moreover, the Fokker–Planck equation governing the evolution of ρ

$$\frac{\partial\rho}{\partial t}+\nabla\cdot(b_+\rho)=\frac{\sigma^2}{2}\,\Delta\rho,$$

may be rewritten as a *continuity equation* of fluid dynamics

$$\frac{\partial \rho}{\partial t} + \nabla \cdot (v\rho) = 0. \tag{18}$$

As before, let $\mathscr{F}_t := \sigma\{x(s); t_0 \leqslant s \leqslant t\}$ and $\mathscr{G}_t := \sigma\{x(s); t \leqslant s \leqslant t_1\}$. Also let $f(x,t): \mathbb{R}^n \times [t_0, t_1] \to \mathbb{R}$ be a function with compact support of class $C^{2,1}$. From the two changes of variables formulas (Ito's rules) corresponding to the forward and backward representations for the increments of x [Eqs. (1) and (2)] we get (Ref. 12, p. 104)

$$(D_+^{\mathscr{F}} f(x(t),t)) = \left[\left(\frac{\partial}{\partial t} + b_+ \cdot \nabla + \frac{\sigma^2}{2}\Delta\right) f\right](x(t),t), \tag{19}$$

$$(D_-^{\mathscr{G}} f(x(t),t)) = \left[\left(\frac{\partial}{\partial t} + b_- \cdot \nabla - \frac{\sigma^2}{2}\Delta\right) f\right](x(t),t). \tag{20}$$

The semisum and the semidifference of Eqs. (19) and (20) give

$$(D^{\mathscr{F},\mathscr{G}} f(x(t),t)) = \left[\frac{\partial}{\partial t} + v(t) \cdot \nabla\right] f(x(t),t), \tag{21}$$

$$(\delta D^{\mathscr{F},\mathscr{G}} f(x(t),t)) = \left[u(t) \cdot \nabla + \frac{\sigma^2}{2}\Delta\right] f(x(t),t). \tag{22}$$

We can now establish a rather interesting formula.

Lemma 2: Let $x(t)$ be a finite-energy Markovian diffusion whose never vanishing probability density ρ is of class $C^{2,1}$. Then

$$[D_+^{\mathscr{F}}(D_+^{\mathscr{F}} x)](t) - [D_-^{\mathscr{G}}(D_-^{\mathscr{G}} x)](t) = 2\{[D^{\mathscr{F},\mathscr{G}}(\delta D^{\mathscr{F},\mathscr{G}} x)](t) + [\delta D^{\mathscr{F},\mathscr{G}}(D^{\mathscr{F},\mathscr{G}} x)](t)\} = 0, \text{ a.s.} \tag{23}$$

for all $t \in [t_0, t_1]$.

Proof: From Eq. (18), we get

$$\frac{\partial \log \rho}{\partial t} = -\nabla \cdot v - v \cdot \nabla \log \rho.$$

Using Eq. (17), we get

$$\frac{\partial u}{\partial t} = -\frac{\sigma^2}{2}\Delta v - u \cdot \nabla v - v \cdot \nabla u. \tag{24}$$

In view of Eqs. (21) and (22), Eq. (24) can now be written as

$$(D^{\mathscr{F},\mathscr{G}} u)(t) + (\delta D^{\mathscr{F},\mathscr{G}} v)(t) = [D^{\mathscr{F},\mathscr{G}}(\delta D^{\mathscr{F},\mathscr{G}} x)](t) + [\delta D^{\mathscr{F},\mathscr{G}}(D^{\mathscr{F},\mathscr{G}} x)](t) = 0, \tag{25}$$

which is Eq. (23). □

Equation (24) was derived by Nelson in his early work [Ref. 12, Eq. (5) on p. 106]. Curiously, nobody seems to have noticed the straightforward reformulation of Eq. (24) given by Eqs. (25) and (23). The corresponding hydrodynamical equation (Madelung equation) occurs in the context of the *saddle-point entropy production principle*, cf. Ref. 1, Sec. V.

III. STOCHASTIC CALCULUS OF VARIATIONS

Let $\mathscr{X}(x_0,x_1)$ denote the family of $\mathbb{R}^n$-valued, mean-square continuous processes $x=\{x(t);t\in[t_0,t_1]\}$ such that $x(t_0)=x_0$ a.s., $x(t_1)=x_1$ a.s., and satisfying the following two properties.

(i) x is mean-forward and mean-backward differentiable with respect to its past and future filtrations $\mathscr{F}=(\mathscr{F}_t)$ and $\mathscr{G}=(\mathscr{G}_t)$, respectively; we denote by $X(t)$ the augmented process

$$X(t)=\begin{pmatrix} x(t) \\ \beta(t) \\ \gamma(t) \end{pmatrix}.$$

(ii) The process X is a simultaneously mean-forward and mean-backward differentiable with respect to the filtrations $\mathbf{F}=(\mathbf{F}_t)$ and $\mathbf{G}=(\mathbf{G}_t)$, where $\mathbf{F}_t:=\sigma\{X(s);t_0\leqslant s\leqslant t\}$ and $\mathbf{G}_t:=\sigma\{X(s);t\leqslant s\leqslant t_1\}$.

Obviously, $\mathscr{F}_t\subseteq\mathbf{F}_t$ and $\mathscr{G}_t\subseteq\mathbf{G}_t$. In order to avoid any confusion, we stress the fact that, in general, $(D_+^{\mathbf{F}}x)(t)\neq(D_+^{\mathscr{F}}x)(t)=\beta(t)$ and $(D_-^{\mathbf{G}}x)(t)\neq(D_-^{\mathscr{G}}x)(t)=\gamma(t)$. Consequently, $(D^{\mathbf{F},\mathbf{G}}x)\times(t)\neq v(t)$ and $(\delta D^{\mathbf{F},\mathbf{G}}x)(t)\neq u(t)$. Also notice that $\mathscr{X}(x_0,x_1)$ contains as a proper subset the family of finite-energy, *Markovian* diffusions with the prescribed end-point marginals.

For each $x\in\mathscr{X}(x_0,x_1)$, we define the family of *variations* y of x to be the set $\mathscr{Y}(x)$ of $\mathbb{R}^n$-valued, mean-square continuous processes $y=\{y(t);t\in[t_0,t_1]\}$ satisfying the two properties: (i) $y(t_0)=y(t_1)=0$ a.s.; (ii) y is simultaneously mean-forward and mean-backward differentiable with respect to the filtrations $\mathbf{F}$ and $\mathbf{G}$, respectively.

Remark 2: Let $f:\mathbb{R}^n\times[t_0,t_1]\to\mathbb{R}^n$, having compact support in $\mathbb{R}^n\times(t_0,t_1)$, be of class $C^{2,1}$. Then, $y(t):=f(x(t),t)$ belongs to $\mathscr{Y}(x)$. These are precisely the variations considered by Nelson in Ref. 3.

Let $L:\mathbb{R}^n\times\mathbb{C}^n\times\mathbb{C}^n\times[t_0,t_1]\to\mathbb{C}^n$ be a sufficiently regular function. Namely, $L(x,z_1,z_2,t)$ is continuously differentiable with respect to x and t, entirely as a function of z_1 and entirely as a function of z_2. Define $I:\mathscr{X}(x_0,x_1)\to\mathbb{C}$ by

$$I(x)=E\left\{\int_{t_0}^{t_1}L(x(t),((D-i\,\delta D)^{\mathbf{F},\mathbf{G}}x)(t),((D+i\,\delta D)^{\mathbf{F},\mathbf{G}}x)(t),t)dt\right\}.$$

Notice that in this action integral appear the conditional derivatives relative to the pair of filtrations $(\mathbf{F},\mathbf{G})$ rather than with respect to $(\mathscr{F},\mathscr{G})$. Also notice that our choice of kinematical variables differs from those previously considered in the literature [Refs. 3, 2 (pp. 73–75), and 4 (Chap. 5). Let dom I denote the subset of x in $\mathscr{X}(x_0,x_1)$ such that $I(x)<\infty$.

Definition 1: The process $x\in\mathrm{dom}\,I$ is critical for I if for all processes $y\in\mathscr{Y}(x)$ we have

$$I(x+y)-I(x)=o(\|y\|),$$

where

$$\|y\|^2:=E\left\{\int_{t_0}^{t_1}[y(t)\cdot y(t)+(D^{\mathbf{F},\mathbf{G}}y)(t)\cdot(D^{\mathbf{F},\mathbf{G}}y)(t)+(\delta D^{\mathbf{F},\mathbf{G}}y)(t)\cdot(\delta D^{\mathbf{F},\mathbf{G}}y)(t)]dt\right\}.$$

We are now ready for the fundamental theorem of stochastic calculus of variations.

Theorem 2: *The stochastic process $x\in\mathrm{dom}\,I$ is critical for I if and only if it satisfies the Euler–Lagrange equations*

$$\left[(D+i\delta D)^{\mathbf{F,G}}\frac{\partial L}{\partial z_1}+(D-i\delta D)^{\mathbf{F,G}}\frac{\partial L}{\partial z_2}-\frac{\partial L}{\partial x}\right]=0 \quad \text{a.s.} \tag{26}$$

for almost all $t\in[t_0,t_1]$.

Proof: Let $x\in\operatorname{dom} I$ be critical for I, and let $y\in\mathscr{Y}(x)$ be a variation of x. By Taylor's formula

$$I(x+y)-I(x)=o(\|y\|)+E\left\{\int_{t_0}^{t_1}\left[\frac{\partial L}{\partial x}\cdot y+\frac{\partial L}{\partial z_1}\cdot((D-i\delta D)^{\mathbf{F,G}}y)+\frac{\partial L}{\partial z_2}\cdot((D+i\delta D)^{\mathbf{F,G}}y)\right]dt\right\}.$$

Applying Eq. (16), and taking into account the fact that y vanishes at the end points, we get

$$I(x+y)-I(x)=o(\|y\|)+E\left\{\int_{t_0}^{t_1}\left[\frac{\partial L}{\partial x}-(D+i\delta D)^{\mathbf{F,G}}\left(\frac{\partial L}{\partial z_1}\right)-(D-i\delta D)^{\mathbf{F,G}}\left(\frac{\partial L}{\partial z_2}\right)\right]\cdot y\,dt\right\}. \tag{27}$$

Since the expectation in Eq. (27) must vanish for all $y\in\mathscr{Y}(x)$, it follows that both the real and the imaginary parts of

$$\left[\frac{\partial L}{\partial x}-(D+i\delta D)^{\mathbf{F,G}}\left(\frac{\partial L}{\partial z_1}\right)-(D-i\delta D)^{\mathbf{F,G}}\left(\frac{\partial L}{\partial z_2}\right)\right]$$

must vanish. Conversely, if Eq. (26) holds, x is critical because of Eq. (27). □

Corollary 3: Let $L(x,z_1,z_2,t):=\frac{1}{2}mz_1\cdot z_2-V(x)$, *where* V *is of class* C^1. *Then* $x\in\operatorname{dom} I$ *is critical for* I *if and only if the stochastic Newton law*

$$m[((D^{\mathbf{F,G}}D^{\mathbf{F,G}}-\delta D^{\mathbf{F,G}}\delta D^{\mathbf{F,G}})x)(t)]=-\nabla V(x(t)) \quad \text{a.s.} \tag{28}$$

for all $t\in[t_0,t_1]$.

Proof: Notice that in this case

$$\frac{\partial L}{\partial z_1}(x(t),((D-i\delta D)^{\mathbf{F,G}}x)(t),((D+i\delta D)^{\mathbf{F,G}}x)(t),t)=\frac{m}{2}((D+i\delta D)^{\mathbf{F,G}}x)(t),$$

$$\frac{\partial L}{\partial z_2}(x(t),((D-i\delta D)^{\mathbf{F,G}}x)(t),((D+i\delta D)^{\mathbf{F,G}}x)(t),t)=\frac{m}{2}((D-i\delta D)^{\mathbf{F,G}}x)(t).$$

From Eq. (26), we get that x is critical for I if and only if

$$\frac{m}{2}[((D+i\delta D)^{\mathbf{F,G}}(D+i\delta D)^{\mathbf{F,G}}+(D-i\delta D)^{\mathbf{F,G}}(D-i\delta D)^{\mathbf{F,G}})x)](t)=-\nabla V(x(t)), \quad \text{a.s.} \tag{29}$$

and Eq. (28) follows. □

Remark 3: Notice that Eqs. (28) and (29) can also be written in the form

$$\frac{m}{2}[((D_+^{\mathbf{F}}D_-^{\mathbf{G}}+D_-^{\mathbf{G}}D_+^{\mathbf{F}})x)(t)]=-\nabla V(x(t)). \tag{30}$$

The comparison between the left-hand sides of Eqs. (29) and (30) gives the long sought probabilistic meaning for the Nelson stochastic acceleration, cf. Ref. 2, Problem 6, p. 133. Nelson's acceleration may also be viewed as the real part of $((D-i\delta D)^{\mathbf{F,G}}(D-i\delta D)^{\mathbf{F,G}})x)$ *which occurs in the global Newton's law (40) below.*

IV. HAMILTON'S PRINCIPLE

We now require that the conservative motion of a particle of mass m be critical for the action I introduced in Sec. III.

A. Classical particle

Consider a classical particle subject to an external conservative force induced by the potential function V. As trajectories we take deterministic, C^2 functions. Hence, $\mathscr{F}_t=\mathbf{F}_t=\mathscr{G}_t=\mathbf{G}_t=\{\Omega,\varnothing\}$, namely the trivial σ field. In particular, x_0 and x_1 are two points in $\mathbb{R}^3$. Moreover, $(D^{\mathbf{F},\mathbf{G}}x)(t)=\dot{x}(t)$, $(\delta D^{\mathbf{F},\mathbf{G}}x)(t)=0$, and $(D^{\mathbf{F},\mathbf{G}}\dot{x})(t)=\ddot{x}(t)$. Thus, Corollary 2 gives that x is critical for I if and only if Newton's law

$$m\ddot{x}(t)=-\nabla V(x(t)) \tag{31}$$

is satisfied for all $t\in[t_0,t_1]$.

B. Classical particle with uncertain end points

Suppose we have a classical (C^2 trajectories) particle with uncertain initial and terminal positions. This uncertainty is described through initial and final probability densities ρ_0 and ρ_1, respectively. Let x_0 and x_1 be distributed according to ρ_0 and ρ_1, respectively. Then, for all admissible motions x we have $\mathscr{F}_t=\mathbf{F}_t=\sigma(x_0)$ and $\mathscr{G}_t=\mathbf{G}_t=\sigma(x_1)$. As before, $\mathscr{D}^{\mathbf{F},\mathbf{G}}x(t)=\dot{x}(t)$, and $\delta\mathscr{D}^{\mathbf{F},\mathbf{G}}x(t)=0$. Thus, by Corollary 2, the stochastic process x satisfying $x(t_0)=x_0$ a.s., $x(t_1)=x_1$ a.s. with C^2 paths is critical for I if and only if Eq. (31) holds for all times with probability one.

C. Brownian particle

Consider a Brownian particle in thermodynamical equilibrium. We assume that its motion may be described by a stochastic process x with differentiable sample paths and that forms a diffusion with constant diffusion coefficient together with its derivative $\dot{x}$. Hence, we have $\dot{x}(t)=\beta(t)=\gamma(t)=\mathscr{D}^{\mathbf{F},\mathbf{G}}x$, and $\delta\mathscr{D}^{\mathbf{F},\mathbf{G}}x=0$. Moreover, $\mathbf{F}_t=\sigma\{x(s),\dot{x}(s);t_0\leqslant s\leqslant t\}$ and $\mathbf{G}_t=\sigma\{x(s),\dot{x}(s);t\leqslant s\leqslant t_1\}$. By Corollary 2, x is critical for I if and only if

$$m(D^{\mathbf{F},\mathbf{G}}\dot{x})(t)=-\nabla V(x(t)) \quad \text{a.s.} \tag{32}$$

for all $t\in[t_0,t_1]$. It follows, in particular, that the critical process x is such that $(x,\dot{x})$ is Markovian (see Remark 1).

Theorem 3: *The stochastic process x in the above described class is critical for I if and only if the forward drift of $\dot{x}$ is given by*

$$(D^{\mathbf{F}}\dot{x})(t)=-\lambda\dot{x}(t)-\frac{1}{m}\nabla V(x(t)), \quad \text{a.s.}, \tag{33}$$

where $\lambda=\sigma^2 m/(2kT)$ and σ^2 is the diffusion coefficient of $\dot{x}$.

Proof: By the Gibbsian postulate, the equilibrium distribution is the Maxwell–Boltzmann distribution

$$\rho(x.\dot{x})=c\ \exp\left\{\frac{-\frac{1}{2}m\dot{x}\cdot\dot{x}-V(x)}{kT}\right\}. \tag{34}$$

Moreover, since

$$\begin{pmatrix} x(t) \\ \dot{x}(t) \end{pmatrix}$$

is Markovian, Nelson's relation (17) between the forward and the backward drift of $\dot{x}$ yields

$$(D^{\mathbf{F},\mathbf{G}}\dot{x})(t) = (D_+^{\mathbf{F}}\dot{x})(t) - \frac{\sigma^2}{2}\nabla_{\dot{x}} \log \rho(x(t),\dot{x}(t)). \tag{35}$$

Equations (34) and (35) now give

$$(D^{\mathbf{F},\mathbf{G}}\dot{x})(t) = (D_+^{\mathbf{F}}\dot{x})(t) + \sigma^2 \frac{m}{2kT}\dot{x}(t). \tag{36}$$

If x is critical, then Eqs. (32) and (36) give Eq. (33). Conversely, if the process x has forward drift of $\dot{x}$ given by Eq. (33), and has the invariant density (34), then it satisfies the Newton law (32), see Refs. 1 (p. 102) and 16. □

Remark 4: It follows, in particular, that the Markovianess of $(x,\dot{x})$*, the form of the forward drift of* $\dot{x}$ *in the Ornstein–Uhlenbeck model of physical Brownian motion (Ref. 12, Chaps. 9 and 10), and its relation to the diffusion coefficient* (Einstein's fluctuation–dissipation relation) *are consequences of the Gibbsian postulate and of the Newton law (34). Conversely, given that the forward drift of* $\dot{x}$ *lies in a certain class, necessary and sufficient conditions can be given for the particle to obey the Maxwell–Boltzmann distribution in equilibrium, see Ref. 17, Sec. III.*

D. Quantum particle

Consider a nonrelativistic, spinless quantum mechanical particle moving in a force field. As class of motions we take the subclass of $\mathscr{X}(x_0,x_1)$ of the finite-energy diffusions with constant diffusion coefficient $\sigma^2=\hbar/m$. In this case, the action is given by

$$I(x) = \int_{t_0}^{t_1}\left[\frac{1}{2}m((D-i\delta D)^{\mathbf{F},\mathbf{G}}x)(t)\cdot((D+i\delta D)^{\mathbf{F},\mathbf{G}}x)(t) - V(x(t))\right]dt. \tag{37}$$

Then x satisfies Hamilton's principle if and only if it satisfies the stochastic Newton law (28) or, equivalently, Eq. (29) which may be rewritten as follows

$$m\Re[((D-i\delta D)^{\mathbf{F},\mathbf{G}}(D-i\delta D)^{\mathbf{F},\mathbf{G}}x)](t) = -\nabla V(x(t)), \quad \text{a.s.} \tag{38}$$

Next we postulate

$$[(D^{\mathbf{F},\mathbf{G}}\delta D^{\mathbf{F},\mathbf{G}} + \delta D^{\mathbf{F},\mathbf{G}}D^{\mathbf{F},\mathbf{G}})x](t) \equiv 0. \tag{39}$$

Putting together Eqs. (39) with (38), we get

$$m[((D-i\delta D)^{\mathbf{F},\mathbf{G}}(D-i\delta D)^{\mathbf{F},\mathbf{G}}x)](t) = -\nabla V(x(t)), \quad \text{a.s.} \tag{40}$$

Assumption (39) simply means that the acceleration in the left-hand side of Eq. (40) must be real. Also notice that Eq. (39) is precisely Eq. (23) for the position process x. Finally notice that the extremizing process x is such that the augmented process

$$\begin{pmatrix} x(t) \\ ((D-i\delta D)^{\mathbf{F},\mathbf{G}}x)(t) \end{pmatrix} \tag{41}$$

is Markovian. To see this, recall Remark 1 and observe that

$$\left((D-i\delta D)^{\mathbf{F},\mathbf{G}}\begin{pmatrix} x(t) \\ ((D-i\delta D)^{\mathbf{F},\mathbf{G}}x) \end{pmatrix}\right)(t)=\begin{pmatrix} ((D-i\delta D)^{\mathbf{F},\mathbf{G}}x)(t) \\ -\frac{1}{m}\nabla V(x(t)) \end{pmatrix}.$$

The process x by itself, however, is in general *non Markovian*.

We are now ready to introduce the *momentum process* corresponding to such a process by

$$p(t):=\frac{\partial L}{\partial z_2}(x(t),((D-i\delta D)^{\mathbf{F},\mathbf{G}}x)(t),((D+i\delta D)^{\mathbf{F},\mathbf{G}}x)(t),t)=m((D-i\delta D)^{\mathbf{F},\mathbf{G}}x)(t),$$

$$\overline{p(t)}:=\frac{\partial L}{\partial z_1}(x(t),((D-i\delta D)^{\mathbf{F},\mathbf{G}}x)(t),((D+i\delta D)^{\mathbf{F},\mathbf{G}}x)(t),t)=m((D+i\delta D)^{\mathbf{F},\mathbf{G}}x)(t).$$

Then Eq. (40) reads

$$((D-i\delta D)^{\mathbf{F},\mathbf{G}}p)(t)=-\nabla V(x(t)),\text{a.s.} \tag{42}$$

or equivalently

$$((D+i\delta D)^{\mathbf{F},\mathbf{G}}\overline{p)}(t)=-\nabla V(x(t)),\text{a.s.} \tag{43}$$

Let $H(x,y):=(1/2m)y\cdot y+V(x)$ be the *Hamiltonian function* defined on $\mathbb{R}^3\times\mathbb{C}^3$, and write $q(t)$ instead of $x(t)$ for the position of the quantum particle. We then get the *canonical-like equations*

$$((D-i\delta D)^{\mathbf{F},\mathbf{G}}q)(t)=\nabla_y(q(t),p(t)), \tag{44}$$

$$((D-i\delta D)^{\mathbf{F},\mathbf{G}}p)(t)=-\nabla_x(q(t),p(t)), \tag{45}$$

or equivalently

$$((D+i\delta D)^{\mathbf{F},\mathbf{G}}q)(t)=\nabla_y H(q(t),\overline{p(t)}), \tag{46}$$

$$((D+i\delta D)^{\mathbf{F},\mathbf{G}}\overline{p)}(t)=-\nabla_x H(q(t),\overline{p(t)}). \tag{47}$$

The closest in spirit previous attempt to define the momentum process within stochastic mechanics is Ref. 18. See Ref. 2, pp. 95–98 and Ref. 4, pp. 117–119] for further work and discussion on this topic.

We close the section with a comment. In Ref. 19 (p. 110), Bohm and Hiley write concerning Nelson's stochastic acceleration: ''*If it could be made clear that this definition is physically or kinematically plausible then Nelson's approach would evidently have an important advantage*.'' As observed in Remark 3, the Nelson acceleration may be viewed as the real part of the second-order stochastic derivative $((D-i\delta D)^{\mathbf{F},\mathbf{G}}(D-i\delta D)^{\mathbf{F},\mathbf{G}})x)$ which occurs in Eq. (40).

In Sec. V, we show that indeed the Nelson process associated with a particular solution of the Schrödinger equation satisfies the global Newton's law (40). Hence, we feel that the results of this paper, together with Refs. 12, 15, 2, 1, 6, clearly demonstrate the physical and kinematical plausibility of Nelson's acceleration.

V. ELEMENTS OF HAMILTON–JACOBI THEORY

Following Ref. 6, we now develop the basic elements of a Hamilton–Jacobi theory of stochastic mechanics (see Ref. 15, Sec. 1 for a beautiful account of the classical theory). Suppose $\{\psi(x,t);t_0\leqslant t\leqslant t_1\}$ is a never vanishing solution of the *Schrödinger equation*

$$\frac{\partial \psi}{\partial t} = \frac{i\hbar}{2m}\nabla\psi - \frac{i}{\hbar}V(x)\psi.$$

Then $S_q(x,t) := \hbar/i \log \psi(x,t)$ satisfies

$$\frac{\partial S_q}{\partial t} + \frac{1}{2m}\nabla S_q \cdot \nabla S_q + V(x) - \frac{i\hbar}{2m}\Delta S_q = 0. \tag{48}$$

This is the *Hamilton–Jacobi equation* of stochastic mechanics. Indeed, we can now rephrase Theorem 1 as follows. Suppose $\{S_q(x,t); t_0 \leqslant t \leqslant t_1\}$ solves Eq. (48) with the initial condition $S_q(x,t_0) = \phi_0(x)$, and satisfies

$$E\left\{\int_{t_0}^{t_1} |\nabla S_q(x(t),t)|^2 dt\right\} < \infty$$

for all finite-energy diffusions x on $[t_0,t_1]$. Let $\rho_1(x) = |\exp(i/\hbar)S_q(x,t_1)|^2$. Then, there is a stochastic process $\{q(t); t_0 \leqslant t \leqslant t_1\}$, called the Nelson process, solving together with its quantum drift $(1/m)\nabla S_q(q(t),t)$ Problem (6). Corresponding to such an S_q, we define the *momentum field* by $p(x,t) = \nabla S_q(x,t)$, and the momentum process by $p(t) := p(q(t),t) = \nabla S_q(q(t),t)$. In Ref. 6 it was shown that the process $p(t)$ has the same first and second moments as the quantum momentum operator. It was also shown that the uncertainty relations admit a simple stochastic interpretation in terms of the pair $(q(t),p(t))$.

Theorem 4: *The pair* $(q(t),p(t))$ *satisfies the stochastic Hamilton equations (44) and (45).*

Proof: Let us first notice that $(D_+^{\mathbf{F}}q)(t) = (D_+^{\mathscr{F}}q)(t) = b_+(q(t),t)$. Indeed, since $q(t)$ is Markovian, so is

$$X(t) = \begin{pmatrix} q(t) \\ b_+(q(t),t) \\ b_-(q(t),t) \end{pmatrix}.$$

We then have

$$\begin{aligned}
(D_+^{\mathbf{F}}q)(t) &= \lim_{h \searrow 0} E\left\{ \frac{q(t+h)-q(t)}{h} \,\middle|\, \mathbf{F}_t \right\} \\
&= \lim_{h \searrow 0} E\left\{ \frac{q(t+h)-q(t)}{h} \,\middle|\, \begin{pmatrix} q(t) \\ b_+(q(t),t) \\ b_-(q(t),t) \end{pmatrix} \right\} \\
&= \lim_{h \searrow 0} E\left\{ \frac{q(t+h)-q(t)}{h} \,\middle|\, q(t) \right\} \\
&= (D_+^{\mathscr{F}}q)(t) = b_+(q(t),t).
\end{aligned}$$

Similarly, we get $(D_-^{G}q)(t) = (D_-^{C}q)(t) = b_-(q(t),t)$. Hence, $(D^{\mathbf{F},\mathbf{G}}q)(t) = (D^{\mathscr{F},\mathscr{G}}q)(t) = v(q(t),t)$ and $(\delta D^{\mathbf{F},\mathbf{G}}q)(t) = (\delta D^{\mathscr{F},\mathscr{G}}q)(t) = u(q(t),t)$. We then have $((D - i\delta D)^{\mathbf{F},\mathbf{G}}q)(t) = ((D - i\delta D)^{\mathscr{F},\mathscr{G}}q)(t) = v(q(t),t) - iu(q(t),t) = v_q(q(t),t) = (1/m)\nabla S_q(q(t),t) = \nabla_y H(q(t), p(q(t),t)) = \nabla_y H(q(t),p(t))$. To prove Eq. (45), recall from Ref. 1, Sec. VII that if $\phi(x,t)$ is a complex-valued function with sufficiently regular real and imaginary parts, then

$$d[\phi(q(t),t)] = \left[\frac{\partial}{\partial t} + v_q(q(t),t)\cdot\nabla - \frac{i\hbar}{2m}\Delta\right]\phi(q(t),t)dt + \nabla\phi(q(t),t)\cdot dw, \tag{49}$$

where $dw = dq - v_q(q(t),t)dt$ is the quantum noise corresponding to q. Applying Eq. (49) to $p(q(t),t) = \nabla S_q(q(t),t)$, we get

$$d[p(q(t),t)]=\left[\frac{\partial}{\partial t}+v_q(q(t),t)\cdot\nabla-\frac{i\hbar}{2m}\nabla\right]\nabla S_q(q(t),t)dt+D(q(t),t)dw, \tag{50}$$

where the 3×3 matrix D has ijth entry $d_{ij}(q(t),t)=(\partial^2/\partial x_i\partial x_j)S_q(q(t),t)$. Replacing $v_q(q(t),t)$ in Eq. (50) with $(1/m)\nabla S_q(q(t),t)$, and then employing Eq. (48), we get

$$d[p(q(t),t)]=-\nabla V(q(t))dt+D(q(t),t)dw. \tag{51}$$

Hence, the quantum drift of $p(t)$ is $-\nabla V(q(t))$ and Eq. (45) holds. □

By the same procedure, we can handle more general (sufficiently regular) Hamiltonian functions $H(x,y,t)$ if $S_q(x,t)$ now satisfies

$$\frac{\partial S_q}{\partial t}+H(x,\nabla S_q,t)-\frac{i\hbar}{2m}\Delta S_q=0,$$

and if we can construct a Markov process q with quantum drift

$$v_q(q(t),y)=\nabla_y H(q(t),\nabla S_q(q(t),t),t),$$

and prescribed initial condition.

We now isolate a crucial step in the proof of Theorem 4. In view of Eq. (49), define the *quantum acceleration field* by the substantial derivative

$$a_q(x,t):=\left[\frac{\partial}{\partial t}+v_q(x,t)\cdot\nabla-\frac{i\hbar}{2m}\Delta\right]v_q(x,t), \tag{52}$$

where $v_q(x,t)=(1/m)\nabla S_q(x,t)$. Using Eq. (48) in Eq. (52), we finally get

$$a_q(x,t)=-\frac{1}{m}\nabla V(x). \tag{53}$$

Equation (53) is the local form counterpart of Eq. (40).

Remark 5: Let $\{\psi(x,t);t_0\leqslant t\leqslant t_1\}$ be a never vanishing solution of the Schrödinger equation satisfying Carlen's finite-energy condition (Ref. 7). Then the corresponding Nelson process satisfies Eq. (40) with end points distributed according to $\rho_0(x)=|\psi(x,t_0)|^2$ and $\rho_1(x)=|\psi(x,t_1)|^2$.

VI. DISCUSSION

In this paper, we have developed a particle form of Hamilton's principle. We have then applied the principle to various conservative systems only changing the class of admissible motions. In the case of a quantum particle, we have seen that the critical process x satisfies the stochastic Newton law (40). This process is not Markovian, but the corresponding augmented process (41) is Markovian.

In Ref. 1, see also the outline in Sec. I, we have developed the second, hydrodynamic version of Hamilton's principle in the context of stochastic mechanics. The critical process q is there Markovian. Indeed, it is the Nelson process. Introducing the momentum field, and then the momentum process p as in Sec. V, we have obtained a pair of stochastic processes satisfying the stochastic Hamilton equations (44) and (45).

If we agree that in a deterministic context Markovian means ''satisfies a first-order differential equation,'' we see that the similarity with classical mechanics is striking. Much remains to be done, however, to develop a satisfactory Lagrangian and Hamiltonian formalism in stochastic mechanics even in the simplest case considered in this paper.

(Received 29 January 1996; accepted for publication 10 April 1996)

We present a geometric framework for non-holonomic Lagrangian systems in terms of distributions on the configuration manifold. If the constrained system is regular, an almost product structure on the phase space of velocities is constructed such that the constrained dynamics is obtained by projecting the free dynamics. If the constrained system is singular, we develop a constraint algorithm which is very similar to that developed by Dirac and Bergmann, and later globalized by Gotay and Nester. Special attention to the case of constrained systems given by connections is paid. In particular, we extend the results of Koiller for Čaplygin systems. An application to the so-called non-holonomic geometry is given. © *1996 American Institute of Physics.* [S0022-2488(96)02407-3]

I. INTRODUCTION

A non-holonomic Lagrangian system consists of a regular Lagrangian $L(q^A,\dot{q}^A)$ defined on the phase space of velocities TQ of a configuration manifold Q with local coordinates $(q^A),1\leqslant A\leqslant n=\dim Q$, subjected to constraints defined by m local functions $\phi_i(q^A,\dot{q}^A)$. That means that the only allowable velocities are those verifying that $\phi_i=0$. We only consider the case of linear constraints, say those of the form $\phi_i(q^A,\dot{q}^A)=(\mu_i)_A(q)\dot{q}^A$. By applying a suitable Hamilton's principle, we arrive to the constrained Euler–Lagrange equations,

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}^A}\right)-\frac{\partial L}{\partial q^A}=-\lambda^i(\mu_i)_A,$$

where λ^i, $1\leqslant i\leqslant m$, are some Lagrange multipliers to be determined (see, for instance, Valcovici,[1] Pars,[2] Neimark and Fufaev,[3] Vershik and Faddeev,[4] Saletan and Cromer,[5] Rumiantsev,[6] Pironneau,[7] Vershik and Gershkovich,[8] Massa and Pagani[9,10]). In some of them, a more general type of constraints was discussed. We notice that Hamilton's principle in the non-holonomic framework is not a variational principle. We remit to the excellent book by Rosenberg[11] for a detailed discussion on that subject.

In the last years, there is an increasing interest in non-holonomic mechanics, and other approaches from a geometrical point of view have appeared: Weber,[12] Pitanga,[13,14] Marle,[15] Massa and Pagani,[9,10] Bates and Śniatycki,[16] Giachetta,[17] Koiller,[18] Cariñena and Rañada,[19] Rañada,[20] Dazord,[21] Cariñena and Rañada,[22] Sarlet, Cantrijn and Saunders,[23,24] Sarlet,[25,26] de León and M. de Diego.[27–31]

Our approach is a globalization of the one by Cariñena and Rañada.[19] In order to globalize their picture, we will consider a distribution D of codimension m defined on Q. The constraints

[a)]Electronic mail: mdeleon@pinar1.csic.es
[b)]Electronic mail: ceedd05@cc.csic.es

imply that the motion is only allowable for some values of velocities, those belonging to the distribution D. The constrained motion equations can be written out by modifying the motion equations for the associated free Lagrangian system as follows:

$$(i_X\omega_L - dE_L) \in (D^v)^0, \quad X \in D^c, \tag{1}$$

along the points of D, where ω_L is the symplectic Poincaré–Cartan two-form, E_L is the energy associated with L, and D^v and D^c are the lifts of D to TQ. Notice that we do not need to invoke Lagrange multipliers. This approach is the dual version (i.e., in terms of distributions) of the one by Cartan using exterior systems.

Under some regularity hypothesis we construct an almost product structure $(\mathscr{P},\mathscr{Q})$ on TQ along the linear submanifold D such that the dynamics are obtained by projecting the Euler-Lagrange vector field ξ_L which solves the motion equations of the free problem,

$$i_{\xi_L}\omega_L = dE_L .$$

That is, the solutions of the constrained dynamics are just the solutions of the second order differential equation $\xi = \mathscr{P}(\xi_L)$ (Section II).

If the constrained system is not regular, we develop in Section III a constraint algorithm which is remarkably similar to that developed by Dirac and Bergmann for singular Lagrangian systems.[32–34] We obtain the local and global aspects of the constraint algorithm. By the way, we introduce the notion of first and second class constraints in this framework.

In Section IV we consider a very important kind of constrained systems, those called generalized Čaplygin systems. A generalized Čaplygin system consists of a Lagrangian function $L:TQ\to\mathbb{R}$ and a connection Γ in a fibration $\rho:Q\to M$ such that L is invariant by the horizontal lift operation. The particular case when $\rho:Q\to M$ is a principal bundle with structure group G, L is G-invariant and Γ is a principal connection, i.e., the horizontal subspaces are G-invariant, was considered by Koiller.[18] We extend the results by Koiller, and prove that there exists a well-defined Lagrangian function $L^*:TM\to\mathbb{R}$, such that the generalized Čaplygin system (L,Γ) is equivalent to a non-conservative system on TM with Lagrangian function L^* and external force α. Here, α is an one-form on TM related with the curvature of the connection Γ. Roughly speaking, the curvature is just the force of constraint. Several examples are studied.

Finally, in Section V, we apply our procedure to give a new insight to an old problem in the so-called non-holonomic geometry. Let Q be a Riemannian manifold with Riemannian metric g and Levi-Civita connection ∇ and suppose that a distribution D on Q is given. The goal is to obtain a new linear connection ∇^* on Q such that the geodesics of ∇^* are the extremals of the variational problem subjected to these linear constraints (see Synge,[35] Vranceanu,[36] Neimark and Fufaev[3] and the references therein). We define a connection Γ^* along D by using our procedure and the relations between non-homogeneous connections and second order differential equations on TQ obtained by Grifone.[37] If the constraints are holonomic, Γ^* induces a linear connection in the vector bundle $D\to Q$.

II. NON-HOLONOMIC LAGRANGIAN SYSTEMS

Let $L:TQ\to\mathbb{R}$ be a Lagrangian function defined on the phase space of velocities TQ of a n-dimensional configuration manifold Q. Denote by (q^A,v^A) the fibered coordinates on TQ. (Sometimes we will use the notation $v^A=\dot{q}^A$.)

The motion equations for L can be derived by a variational procedure. In fact, the extremals of the action,

$$\int L(q^A,\dot{q}^A)dt,$$

where $\dot{q}^A = dq^A/dt$ are just the solutions of the Euler–Lagrange equations,

$$\frac{d}{dt}\left(\frac{\partial L}{\partial v^A}\right) - \frac{\partial L}{\partial q^A} = 0, \quad v^A = \frac{dq^A}{dt}. \tag{2}$$

Alternatively, there exists a symplectic formulation. Indeed, let $\omega_L = -d\alpha_L$ be the Poincaré-Cartan 2-form, where $\alpha_L = J^*(dL)$. Here, J is the canonical almost tangent structure on TQ. That is, J is a tensor field of type (1,1) on TQ such that $J^2 = 0$ and rank $J = n$; J is locally defined by

$$J = \frac{\partial}{\partial v^A} \otimes dq^A.$$

The energy associated with L is defined by $E_L = CL - L$, where $C = v^A(\partial/\partial v^A)$ is the Liouville vector field on TQ. That is, C is the infinitesimal generator of the dilations along the fibers.

The global motion equation for the free problem is (see Ref. 38)

$$i_X \omega_L = dE_L. \tag{3}$$

We say that the Lagrangian L is regular if the Hessian matrix $(\partial^2 L/\partial v^A \partial v^B)$ is non-singular. In such a case, the form ω_L is symplectic and, thus, (3) has a unique solution ξ_L (the Euler–Lagrange vector field) which is a second order differential equation (SODE for short). Further, the solutions of ξ_L coincide with the solutions of the Euler–Lagrange equations. More precisely, the projections onto Q of the integral curves of ξ_L are the extremals for L.

Now, we suppose that a family of linear constraints is given. In the local picture, L is subjected to constraints defined by m local functions of the form $\phi_i(q^A, v^A) = (\mu_i)_A(q)v^A$. That means that the only allowable velocities are those verifying that $\phi_i = 0$.

The purpose of this paper is to give a global picture of Lagrangian systems subjected to linear constraints.

Definition II.1: A non-holonomic Lagrangian system is given by the following data:
(i) A regular Lagrangian $L: TQ \to \mathbb{R}$*;*
(ii) An $(n-m)$*-dimensional distribution* D *on the* n*-dimensional configuration manifold* Q*.*
The constraints are said to be holonomic if D *is involutive.*

This means that the only allowable velocities are the tangent vectors belonging to D, i.e., the motion is constrained to the submanifold D. Notice that D can be viewed as a vector subbundle of $\tau_Q: TQ \to Q$, and, so, D is a submanifold of TQ.

Define two distributions D^c and D^v on TQ as follows. Suppose that $\{\mu_i; 1 \leqslant i \leqslant m\}$ is a local basis of 1-forms of the annihilator D^0 of D. Then D^c and D^v are, respectively, defined by

$$(D^c)^0 = \langle \mu_i^v, \mu_i^c \rangle, \quad (D^v)^0 = \langle \mu_i^v \rangle, \tag{4}$$

where μ_i^v (resp., μ_i^c) denotes the vertical (resp., complete) lift of the 1-form μ_i to TQ (see Refs. 38,39).

If $\{\overline{\mu_i}\}$ is another local basis of D we have

$$\overline{\mu_i} = \Lambda_i^j \mu_j,$$

where (Λ_i^j) is a regular matrix defined on the overlapping of the two local neighborhoods. Since

$$\overline{\mu_i^c} = (\Lambda_i^j)^c \mu_j^v + (\Lambda_i^j)^v \mu_j^c, \quad \overline{\mu_i^v} = (\Lambda_i^j)^v \mu_j^v, \tag{5}$$

we deduce that D^c and D^v are well-defined. Here f^v (resp., f^c) denotes the vertical (resp., complete) lift of a function f on Q to TQ (see Refs. 39, 38).

Since the allowable velocities have to belong to D, we deduce that the motion equations for the constrained mechanical systems would be

$$(i_X\omega_L - dE_L) \in (D^v)^0, \quad X \in D^c, \tag{6}$$

along the points of D.

In fact, suppose that $\mu_i = (\mu_i)_A dq^A$. Hence we have

$$\mu_i^v = (\mu_i)_A dq^A,$$
$$\mu_i^c = (\mu_i)_A^c dq^A + (\mu_i)_A dv^A,$$
$$\hat{\mu}_i = (\mu_i)_A v^A,$$

where $\hat{\mu}_i$ is the function on TQ defined by $\hat{\mu}_i(q^A, v^A) = \mu_i(v^A(\partial/\partial q^A))$.

Notice that there are many solutions of the first equation in (6), since ω_L is symplectic. Moreover, every solution of (6) is a SODE. In fact, let μ_i be a local basis of D. Then, (6) can be locally written as follows:

$$i_X\omega_L - dE_L = \lambda^i \mu_i^v, \quad \mu_i^v(X) = 0, \quad \mu_i^c(X) = 0, \tag{7}$$

for some Lagrange multipliers λ^i to be determined. If we apply i_J to the first equation in (7), we have

$$i_J i_X \omega_L - i_J(dE_L) = 0,$$

which implies $i_{JX}\omega_L = i_C\omega_L$ and, then, $JX = C$. Here, i_J denotes the derivation of type i_* in the sense of Frölicher–Nijenhuis associated with J, that is, i_J is completely defined by the formulas $i_J f = 0$ and $i_J(df) = J^*(df)$ for any function f on TQ.[38] Therefore, we deduce that the local expression of X is

$$X = v^A \frac{\partial}{\partial q^A} + X^A \frac{\partial}{\partial v^A}.$$

Thus, the solutions of X satisfy the following constrained Euler–Lagrange equations:

$$\frac{d}{dt}\left(\frac{\partial L}{\partial v^A}\right) - \frac{\partial L}{\partial q^A} = -\lambda^i (\mu_i)_A, \quad v^A = \frac{dq^A}{dt}.$$

By the way, notice that $\mu_i^v(X) = \hat{\mu}_i$ and $\mu_i^c(X) = X(\hat{\mu}_i)$. Then the second set of equations in (7) defines the submanifold D, and the third one means that X has to be tangent to D. Given the symplectic form ω_L we have the associated musical isomorphisms,

$$\flat_L : T(TQ) \to T^*(TQ)$$

and

$$\#: T^*(TQ) \to T(TQ),$$

where for any $X \in T(TQ)$, $\flat_L(X) = i_X\omega_L$, and for any $\alpha \in T^*(TQ)$, $\#\alpha = X_\alpha$ is the unique tangent vector to TQ such that $b_L(X_\alpha) = \alpha$. From $(D^v)^0$ and by using the isomorphism $\#$, we obtain a distribution S on TQ. A vector $v \in T_xTQ$ belongs to S_x if $i_v\omega_L(x) \in (D^v)_x^0$. It is clear that $\dim S = m$.

Let Z_i be the local vector field defined by

$$i_{Z_i}\omega_L=\mu_i^v, \quad 1\leqslant i\leqslant m.$$

A direct computation shows that

$$Z_i=-W^{AB}(\mu_i)_B\frac{\partial}{\partial v^A},$$

where (W^{AB}) is the inverse matrix of the Hessian matrix $(W_{AB}=\partial^2L/\partial v^A\partial v^B)$. Therefore, Z_i is vertical.

We have that S is locally generated by the vector fields $\{Z_i,\ 1\leqslant i\leqslant m\}$.

Definition II.2: The constrained system will be called regular if

$$T_xD\cap S_x=0, \quad for\ \ any\ \ x\in D.$$

The meaning of the regularity of the constrained system will become clear in a while. Notice that the regularity of the constrained system is closely related with the nature of the Lagrangian function.

Suppose that the constrained system is regular. Since for any $x\in D$, we have $\dim S_x=m$, and $\dim T_xD=2n-m$, we obtain that

$$T_xTQ=T_xD\oplus S_x, \quad \forall x\in D.$$

Thus, each tangent vector $v\in T_xTQ$ splits in a unique way as $v=v_1+v_2$, where $v_1\in T_xD$ and $v_2\in S_x$. Then, we can construct two complementary projectors $\mathscr{P}$ and $\mathscr{Q}$ as follows: $\mathscr{P}(v)=v_1$, and $\mathscr{Q}(v)=v_2$. In fact, $(\mathscr{P},\mathscr{Q})$ is a well-defined almost product structure on TQ along the points of D.

Take now the codistribution $\langle dE_L\rangle\oplus(D^v)^0$. By using the isomorphism #, we obtain a distribution S_L on TQ locally generated by $\{\xi_L,Z_1,\cdots,Z_m\}$. That is,

$$S_L=\#(\langle dE_L\rangle\oplus(D^v)^0).$$

Then, $\dim(T_xD\cap(S_L)_x)=1$, $\forall x\in D$. Moreover, there exists a unique generator ξ of the distribution $TD\cap S_L$ along the points of D such that $(J\xi=C)_{/D}$.

The vector field $\xi\in\mathscr{X}(D)$ is the solution of the Lagrangian system subjected to constraints given by a distribution D. This vector field ξ is precisely $P(\xi_{L/D})$, the projection of the Euler-Lagrange vector field of the free Lagrangian system. In fact, along the points of D, we have

$$\begin{aligned} i_{\mathscr{P}(\xi_L)}\omega_L-dE_L&=i_{\xi_L-\mathscr{Q}(\xi_L)}\omega_L-dE_L\\ &=-i_{\mathscr{Q}(\xi_L)}\omega_L\in(D^v)^0. \end{aligned}$$

Moreover, we deduce that $\mathscr{P}(\xi_L)(x)\in T_xD$ or, equivalently, $\mathscr{P}(\xi_L)\in D^c$.

In order to perform an explicit computation of the vector field ξ, we proceed as follows. Take a local basis $\{\mu_i,1\leqslant i\leqslant m\}$ of D and define $\mathscr{C}_{ij}=Z_i(\hat{\mu}_j)$. We deduce that

$$\mathscr{C}_{ij}=-W^{AB}(\mu_i)_A(\mu_j)_B. \tag{8}$$

Proposition II.3: The constrained system is regular iff *the matrices* $(\mathscr{C}_{ij})$ *are non-singular on* D.

Proof: Suppose that the constrained system is regular. Take an arbitrary linear combination of columns of $\mathscr{C}$ at some point $x\in D$ such that

$$\sum_{i=1}^{m} \lambda^i Z_i(x)(\hat{\mu}_j)=0.$$

Thus, $\Sigma\lambda^i Z_i(x)\in T_xD$ which implies that $\Sigma\lambda^i Z_i(x)=0$ and hence $\lambda^1=\lambda^2=\cdots\lambda^m=0$.

Conversely, suppose $\mathscr{C}$ ia non-singular and take $X\in S_x\cap T_xD$. Thus, $X=\Sigma\lambda^i Z_i(x)$ and $X(\hat{\mu}_j)=0$, $\forall j$, $1\leqslant j\leqslant m$ which implies that $\Sigma\lambda^i Z_i(\hat{\mu}_j)=0$. Therefore we deduce that $\lambda^1=\cdots=\lambda^m=0$ and $X=0$.

■

Thus, if D is regular, we obtain an explicit expression for the projector $\mathscr{Q}$:

$$\mathscr{Q}=\mathscr{C}^{ij}Z_j\otimes d\hat{\mu}_i,$$

where $(\mathscr{C}^{ij})$ denotes the inverse matrix of $(\mathscr{C}_{ij})$.

Then, we get

$$\xi=\mathscr{P}(\xi_L)=\xi_L-\mathscr{C}^{ij}\xi_L(\hat{\mu}_i)Z_j.$$

Proposition II.4: If the Hessian matrix

$$\left(\frac{\partial^2 L}{\partial v^A \partial v^B}\right),$$

is positive or negative definite at each point $x\in D$, then the constrained system is regular.

Proof: The result follows from (8) (see also Cariñena and Rañada[19]).

■

Remark II.5: Proposition II.4 clarifies the usual assumption on the positive or negative character of the Hessian matrix of L. It is nothing but that a sufficient condition to ensure the regularity of the constrained system. Of course, if the Lagrangian L is natural, that is, $L=T-V$, where T is the kinetic energy of a Riemannian metric g on Q and V is a potential energy, then the constrained system would be regular.

Remark II.6: From the regularity of the matrices $\mathscr{C}$, we deduce that $(\mathscr{P},\mathscr{Q})$ may be extended (in many ways) to an open neighborhood of D. Consequently, $\mathscr{P}(\xi_L)$ may also be extended to an open neighborhood of D (see Ref. 27 for more details).

By using the almost product structure $(\mathscr{P},\mathscr{Q})$ and the musical isomorphisms, we can construct the following linear mapping $\overline{\mathscr{Q}}_x:T^*_x(TQ)\to T^*_x(TQ)$:

$$\overline{\mathscr{Q}}_x(\alpha_x)=\flat_L(\mathscr{Q}_x(\#(\alpha_x))),\quad \forall\alpha_x\in T^*_x(TQ),\quad x\in D.$$

Since $\overline{\mathscr{Q}}_x^2=\mathrm{id}$ and $Im\overline{\mathscr{Q}}_x=(D^v)^o_x$, we obtain the following splitting:

$$T^*_x(TQ)=(D^v)^o_x\oplus\overline{S_x},\quad \forall x\in D,$$

where $\overline{S_x}=Im\overline{\mathscr{P}}_x$, $\overline{\mathscr{P}}_x=\mathrm{id}-\overline{\mathscr{Q}}_x$ being the complementary projector. In fact, $\overline{\mathscr{P}}$ and $\overline{\mathscr{Q}}$ may be interpreted as tensor fields of type (1,1) on TQ defined along D.

Notice that $\overline{S}$ is the annihilator of the distribution along D locally generated by the vector fields $\{X_{\hat{\mu}_i},1\leqslant i\leqslant m\}$, where $X_{\hat{\mu}_i}$ is the Hamiltonian vector field of the function $\hat{\mu}_i$ with respect to the symplectic form ω_L.

The following result tells us that one could add the constraint forces to the energy to obtain a global force acting on the system.

Theorem II.7: *The solution of the constrained dynamics is the unique vector field ξ on D such that*

$$(i_X\omega_L=\overline{\mathscr{P}}(dE_L))_{/D}.$$

Proof: By the construction of $\overline{\mathscr{Q}}$ we have that

$$\overline{\mathscr{Q}}(dE_L)=i_{\mathscr{Q}(\xi_L)}\omega_L.$$

On the other hand, $\xi=\mathscr{P}(\xi_L)$ is the solution of the constrained dynamics. Thus, we deduce that

$$i_{\mathscr{P}(\xi_L)}\omega_L=i_{\xi_L}\omega_L-i_{\mathscr{Q}(\xi_L)}\omega_L=dE_L-\overline{\mathscr{Q}}(dE_L)=\overline{\mathscr{P}}(dE_L).$$

Since ω_L is symplectic, we conclude that the solution of the equation

$$(i_X\omega_L=\overline{\mathscr{P}}(dE_L))_{/D}$$

is unique. ■

A direct computation shows that the local expression of $\overline{\mathscr{Q}}$ is

$$\overline{\mathscr{Q}}=-\mathscr{C}^{ij}X_{\hat{\mu}_i}\otimes\mu_j^v.$$

Therefore, we obtain that

$$\overline{\mathscr{P}}(dE_L)=dE_L-\mathscr{C}^{ij}\xi_L(\hat{\mu}_i)\mu_j^v.$$

The following lemmas will be used in Section IV.

Lemma II.8: Given a regular constrained system with Lagrangian function L and linear constraints D, the vector field ξ solving the constrained dynamics satisfies

$$\mathscr{L}_\xi\alpha_L=dL-L_{\mathscr{Q}(\xi_L)}\alpha_L,$$

where $\mathscr{L}_\xi$ denotes the Lie derivative with respect to ξ.

Proof: It follows since $\xi=\mathscr{P}(\xi_L)=\xi_L-\mathscr{Q}(\xi_L)$ and $\mathscr{L}_{\xi_L}\alpha_L=dL$. ■

Lemma II.9: Under the same hypothesis as in Lemma II.8, we have

$$\mathscr{L}_{\mathscr{Q}(\xi_L)}\alpha_L\in(D^v)^0.$$

Proof: Since $\mathscr{Q}(\xi_L)=\Sigma_{j=1}^m\Lambda^jZ_j$, with $\Lambda^j=\mathscr{C}^{ij}\xi_L(\hat{\mu}_i)$, we deduce that

$$\begin{aligned}\mathscr{L}_{\mathscr{Q}(\xi_L)}\alpha_L&=\mathscr{L}\sum_{j=1}^m\Lambda^jZ_j\alpha_L\\&=i\sum_{j=1}^m\Lambda^jZ_jd\alpha_L+d(i\sum_{j=1}^m\Lambda^jZ_j\alpha_L)\\&=-i\sum_{j=1}^m\Lambda^jZ_j\omega_L=-\sum_{j=1}^m\Lambda^j\mu_j^v,\end{aligned}$$

since the vector fields Z_j are vertical and α_L is semibasic. ■

III. THE SINGULAR CASE

In this section we shall describe what happens if the given constrained system is not regular, or, in other words, $T_xD\cap S_x=0$, for some points x in D. Notice that this fact is equivalent to the non-regularity of the local matrices $(\mathscr{C}_{ij})$.

For any point $x\in D$, we have the obvious inclusion

$$T_xD\cap S_x\subset T_xD\cap(S_L)_x.$$

In the regular case, this inclusion is strict, and the jump of dimension is just 1. This jump allows us to obtain the dynamics by taking a basis ξ of $(TD\cap S_L)_{/D}$ normalized in order to get $J\xi=C$. The above remarks illuminate the way to proceed in the singular case.

Define a submanifold D_2 of TQ as follows:

$$D_2=\{x\in D/T_xD\cap S_x\subsetneqq T_xD\cap(S_L)_x\}.$$

This implies that for any point $x\in D_2$, there exists some tangent vector

$$X=\xi_L(x)+\lambda^iZ_i(x)\in T_xD\cap(S_L)_x,$$

such that $X\notin S_x$. Thus, X is a solution of the constrained equation, but, in general, it is not necessarily tangent to D_2.

Therefore, we define a new submanifold D_3 of D_2 as follows:

$$D_3=\{x\in D_2/T_xD_2\cap S_x\subsetneqq T_xD_2\cap(S_L)_x\}.$$

Proceeding further, we obtain a sequence of constraint submanifolds,

$$\cdots\to D_k\to\cdots\to D_2\to D_1=D.$$

$D=D_1$ will be called the primary constraint submanifold, D_2 the secondary constraint submanifold and so on.

As in the Gotay and Nester algorithm for singular Lagrangian systems[33,34] we also have three possibilities

(i) There exists an integer $k\geqslant 1$ such that $D_k=\varnothing$. This means that the equations (6) are not consistent.

(ii) There exists an integer $k\geqslant 1$ such that $D_k=\varnothing$ but $\dim D_k=0$. In this case, there are no dynamics. D_k consists in isolated points and the solution of the constrained dynamics is $X=0$.

(iii) There exists an integer $k\geqslant 1$ such that $D_{k+1}=D_k$ and $\dim D_k>0$. In this case the algorithm stabilizes at the final constraint submanifold $D_f=D_k$. So, there exists at least a vector field ξ on D_f satisfying the SODE condition $((J\xi=C)_{/D_f})$ and such that

$$i_\xi\omega_L-dE_L\in(D^v)^0.$$

Assume that the algorithm ends at some final constraint submanifold D_f. Thus, we have

$$T_xD_f\cap S_x\subsetneqq T_xD_f\cap(S_L)_x,\quad\forall x\in D_f.$$

We will suppose that the distribution $TD_f\cap S$ along D has constant dimension, say r, that is,

$$\dim(T_xD_f\cap S_x)=r,\quad\text{for all } x\in D_f.$$

Lemma III.1: We have that $\xi_L(x)\in T_xD_f+S_x$ for any $x\in D_f$.

Proof: Since $T_xD_f\cap S_x\subsetneqq T_xD_f\cap(S_L)_x$ for any $x\in D_f$, we deduce that there exists a tangent vector $X\in T_xD_f\cap(S_L)_x$ such that $X\notin T_xD_f\cap S_x$. Thus, $X=\xi_L(x)+\lambda^iZ_i(x)$ which implies that

$\xi_L(x)=X-\lambda^i Z_i\in T_xD_f+S_x$. ■

In order to determine the dynamics, we split S_x as a direct sum of two subspaces, say

$$S_x=\check{S}_x\oplus(T_xD_f\cap S_x). \tag{9}$$

Obviously, there are many choices for a complementary subspace of $T_xD_f\cap S_x$ into S_x. From (9) we deduce that $\check{S}_x\cap T_xD_f=0$, and we can then split $T_x(TQ)$ as follows:

$$T_x(TQ)=\check{S}_x\oplus T_xD_f\oplus M_x,\quad x\in D_f,$$

where M_x is a suitable complementary subspace. Take the corresponding three complementary projectors:

$$\mathcal{Q}_x:T_x(TQ)\to\check{S}_x,$$

$$(\mathcal{P}_1)_x:T_x(TQ)\to T_xD_f,$$

$$(\mathcal{P}_2)_x:T_x(TQ)\to M_x.$$

Consider the projector $(\mathcal{P})_x=(\mathcal{P}_1)_x+(\mathcal{P}_2)_x$. Hence, we have (along the points of D_f)

$$\begin{aligned} i_{\mathcal{P}_x(\xi_L(x))}\omega_L(x)-(dE_L)_x&=i_{\xi_L(x)-\mathcal{Q}_x(\xi_L(x))}\omega_L(x)-i_{\xi_L(x)}\omega_L(x)\\ &=-i_{\mathcal{Q}_x(\xi_L(x))}\omega_L(x)\in(D^v)^0_x. \end{aligned}$$

Moreover, for any $x\in D_f$, we deduce that

$$\mathcal{P}_x(\xi_L(x))=(\mathcal{P}_1)_x(\xi_L(x))\in T_xD_f,$$

since $\xi_L(x)\in T_xD_f+S_x$ by Lemma III.1.

A differentiable choice of both distributions $\check{S}$ and M allows us to construct an almost product structure $(\mathcal{P}_1,\mathcal{P}_2,\mathcal{Q})$ [or $(\mathcal{P},\mathcal{Q})$, where $\mathcal{P}=\mathcal{P}_1+\mathcal{P}_2$] along D_f such that $\mathcal{P}(\xi_{L/D_f})$ is a solution of the constrained dynamics. Notice that a general solution is of the form

$$\mathcal{P}(\xi_{L/D_f})+TD_f\cap S.$$

We have chosen complementary distributions $\check{S}$ and M in order to obtain the dynamics. Notice that it is possible to realize both decompositions, say $S=\check{S}\oplus(T_xD_f\cap S)$ and $T(TQ)=\check{S}\oplus TD_f\oplus M$. In fact, take a local basis $\{\mu_i\}$ of D^0 and denote by ϕ_I the constraint functions which define D_f, where $1\leqslant I\leqslant 2n-\dim D_f$. Notice that $\phi_I=\hat{\mu}_I$, for $1\leqslant I\leqslant m$. We have assumed that $TD_f\cap S$ has constant rank r. Thus, the matrix $(\mathcal{C}_{iJ})=(Z_i(\hat{\phi}_J))$ has also constant rank $m-r$. Indeed, take a local basis $Y_1,\ldots,Y_r$ of $TD_f\cap S$ such that $Y_a=\mathcal{A}^i_aZ_i$. Since Y_a is tangent to D_f, we get

$$\mathcal{A}^i_aZ_i(\phi_J)=0,\quad \text{for all } J.$$

But this implies that rank $\mathcal{C}=m-r$. The converse is proved by reversing the argument.

Assume that the submatrix $\mathcal{C}'=(\mathcal{C}_{I'J'})$, $(1\leqslant I',J'\leqslant m-r)$ is regular. In that case, we define a projector $\mathcal{Q}$ by putting

$$\mathcal{Q}=\mathcal{C}^{I'J'}Z_{J'}\otimes d\phi_{I'},$$

where $(\mathscr{C}^{I'J'})$ is the inverse matrix of $(\mathscr{C}_{I'J'})$. Notice that $\check{S}=\langle Z_{I'}\rangle$. If we put $\mathscr{P}=\mathrm{id}-\mathscr{Q}$ we obtain an almost product structure $(\mathscr{P},\mathscr{Q})$ along D_f. The decomposition $\mathscr{P}=\mathscr{P}_1+\mathscr{P}_2$ is obtained by choosing a complementary M of $\check{S}\oplus TD_f$. This choice corresponds to the ambiguity in the determination of the other Lagrange multipliers. Indeed, if we compute $\mathscr{P}(\xi_L)$ we obtain

$$\mathscr{P}(\xi_L)=\xi_L-\mathscr{C}^{I'J'}\xi_L(\phi_{I'})Z_{J'},$$

and a general solution is of the form

$$\mathscr{P}(\xi_L)+Y,$$

where $Y\in TD_f\cap S$. So, the only Lagrange multipliers determined are just the components of the $Z_{J'}$'s.

Remark III.2: A solution of (6) has the general form $X=\xi_L+\lambda^i Z_i$, where Z_i are the symplectic gradients of the 1-forms μ_i^v. The tangency condition may now be written as

$$\xi_L(\hat{\mu}_j)+\lambda^i Z_i(\hat{\mu}_j)=0,\quad 1\leqslant j\leqslant m, \tag{10}$$

or, equivalently,

$$\xi_L(\hat{\mu}_j)+\lambda^i\mathscr{C}_{ij}=0,\quad 1\leqslant j\leqslant m. \tag{11}$$

If the matrix $\mathscr{C}_{ij}$ is regular, the system of equations (11) have a solution which is obtained by the well-known Crame rule, or, in a more sophisticated way, by constructing the local almost product structure $(\mathscr{P},\mathscr{Q})$.

If the constrained system is singular, Equation (10) can be analyzed as in the Dirac-Bergmann algorithm.[32] In fact,

$$\xi_L(\hat{\mu}_j)+\lambda^i\mathscr{C}_{ij}=0,\quad 1\leqslant j\leqslant m,$$

is a system of m equations with m unknowns, the Lagrange multipliers. The system is consistent if the ranks of the matrices $(\mathscr{C}_{ij})$ and $(\mathscr{C}_{ij};-\xi_L(\hat{\mu}_j))$ coincide. (Of course, they are equal if the constrained system is regular.) Therefore, we select the points where the ranks coincide. Denote by D_2 the collection of all these points. At the points in D_2 there are solutions, but they are not necessarily tangent to D_2. By the way, new constraints may appear. In fact, notice that, if the matrix $(\mathscr{C}_{ij})$ has rank, say r, then the matrix $(\mathscr{C}_{ij};-\xi_L(\hat{\mu}_j))$ has rank greater or equal to r. Suppose that $\mathscr{M}$ is a submatrix of $(\mathscr{C}_{ij})$ of rank r. The determinants of the submatrices of $(\mathscr{C}_{ij};-\xi_L(\hat{\mu}_j))$ obtained from $\mathscr{M}$ by adding elements of the column $\xi_L(\hat{\mu}_j)$ are the new possible constraints. These secondary constraints ϕ_α have to be added to the motion equations which become

$$\begin{aligned}\xi_L(\hat{\mu}_j)+\lambda^i Z_i(\hat{\mu}_j)&=0,\\ \xi_L(\phi_\alpha)+\lambda^i Z_i(\phi_\alpha)&=0.\end{aligned} \tag{12}$$

The procedure is now repeated, and we obtain a sequence of submanifolds

$$\cdots\to\overline{D_k}\to\cdots\to\overline{D_2}\to D,$$

which are just the same that the ones previously obtained. More precisely, $\overline{D_k}$ is the intersection of D_k with the tangent bundle of the open neighborhood where the local basis μ_i is defined.

Remark III.3: We started with linear constraints, or, in the present terminology, the primary constraints are linear. However, the secondary constraints are not necessarily linear.

If we denote by $\{,\}_L$ the Poisson bracket on TQ defined from the symplectic form ω_L, we have $\{f,E_L\}_L=\xi_L(f)$, for any function f on TQ. Thus, (10) can be written as follows:

$$\{\hat{\mu}_j,E_L\}_L+\lambda^i Z_i(\hat{\mu}_j)=0, \quad 1\leqslant j\leqslant m.$$

As in the Dirac–Bergmann approach,[32] we can distinguish two different classes of constraints. A constraint f will be called first class if $\{f,\Psi\}_L\sim 0$, that is, $\{f,\Psi\}_L$ vanishes on the final constraint submanifold D_f. Otherwise, f will be called a second class constraint. We deduce that the Hamiltonian vector fields corresponding to first class constraints are tangent to D_f, and the Hamiltonian vector fields corresponding to second class constraints are transversal to D_f.

Example III.4: Consider the following Lagrangian function L defined on $T\mathbb{R}^3$ by

$$L=\frac{1}{2}((v^1)^2+(v^2)^2-(v^3)^2+(q^1)^2),$$

subjected to linear constraints given by a distribution D on $\mathbb{R}^3$ whose annihilator is

$$D^0=\langle dq^1+dq^3\rangle.$$

Here (q^1,q^2,q^3) denote the standard coordinates on $\mathbb{R}^3$, and $(q^1,q^2,q^3,v^1,v^2,v^3)$ the induced ones on $T\mathbb{R}^3$. Thus, the submanifold $D\subset T\mathbb{R}^3$ consists in those points in $T\mathbb{R}^3$ such that $v^1+v^3=0$.

The distribution S is generated by the vector field

$$Z=-\frac{\partial}{\partial v^1}+\frac{\partial}{\partial v^3}.$$

We have

$$S_x\cap T_xD=S_x,$$

for any $x\in D$. Therefore, the constrained system is singular.

Applying the constraint algorithm, we get

$$D_2=\{x\in D/T_xD\cap S_x\subsetneqq T_xD\cap(S_L)_x\},$$

so that

$$D_2=\{(q^A,v^A)\in T\mathbb{R}^3/v^1+v^3=0,\ q^1=0\}.$$

We proceed further, and obtain

$$\begin{aligned}D_3&=\{x\in D/T_xD_2\cap S_x\subsetneqq T_xD_2\cap(S_L)_x\},\\&=\{(q^A,v^A)\in T\mathbb{R}^3/v^3=0,\ q^1=0,\ v^1=0\}.\end{aligned}$$

Now, since

$$T_xD_3\cap S_x\subsetneqq T_xD_3\cap(S_L)_x,$$

for any $x\in D_3$, we deduce that D_3 is the final constraint submanifold.

The dynamics is given by the vector field $(\xi_L+\lambda Z)_{/D_3}$, for any function λ on D_3.

IV. CONSTRAINTS DEFINED BY CONNECTIONS. GENERALIZED ČAPLYGIN SYSTEMS

One of the most appealing instances of non-holonomic Lagrangian systems are those given by the existence of a connection.

Suppose that Q is a fibered manifold over a manifold M, say, $\rho:Q\to M$ is a surjective submersion. Assume that a connection Γ in $\rho:Q\to M$ is given, such that the allowable motions of a Lagrangian function $L:TQ\to\mathbb{R}$ have to be horizontal curves with respect to that connection. In other words, the allowable velocities are horizontal tangent vectors. Thus, D is just the horizontal distribution H such that

$$TQ=H\oplus V\rho.$$

Let us recall that Γ may be considered as a tensor field of type (1,1) on Q such that $\Gamma^2=\mathrm{id}$ and the eigenspaces corresponding to the eigenvalue -1 are just the vertical subspaces. Take fibered coordinates $(q^A)=(q^a,q^i)$, $1\leqslant a\leqslant n-m$, $1\leqslant i\leqslant m$, $n=\dim Q$. The horizontal distribution is locally spanned by the local vector fields

$$H_a=\left(\frac{\partial}{\partial q^a}\right)^H=\frac{\partial}{\partial q^a}-\Gamma^i_a(q^A)\frac{\partial}{\partial q^i},$$

where Y^H stands for the horizontal lift to Q of a vector field Y on M, and $\Gamma^i_a=\Gamma^i_a(q^b,q^j)$ are the Christoffel components of Γ. Thus, we obtain a local basis of vector fields on Q,

$$\left\{H_a,V_i=\frac{\partial}{\partial q^i}\right\}.$$

Its dual basis of 1-forms is

$$\{\eta_a=dq^a,\eta_i=\Gamma^i_a dq^a+dq^i\}.$$

We deduce that H^0 is locally spanned by the 1-forms $\{\eta_i\}$.

Define the curvature of Γ as the tensor field of type (1,2) on Q given by

$$R=\frac{1}{2}[\mathbf{h},\mathbf{h}],$$

where $\mathbf{h}=(1/2)(\mathrm{id}+\Gamma)$ is the horizontal projector associated with Γ, and $[\mathbf{h},\mathbf{h}]$ is its Nijenhuis tensor (see Ref. 38). Thus,

$$R(\mathbf{h}(u_1),\mathbf{h}(u_2))=v([\mathbf{h}(u_1),\mathbf{h}(u_2)]),$$

$$R(\mathbf{h}(u_1),\mathbf{v}(u_2))=0,$$

$$R(\mathbf{v}(u_1),\mathbf{v}(u_2))=0,$$

for any $u_1,u_2\in T_xQ$, where $\mathbf{v}=\mathrm{id}-\mathbf{h}$ is the complementary vertical projector. Since

$$\mathbf{h}\left(\frac{\partial}{\partial q^a}\right)=\frac{\partial}{\partial q^a}-\Gamma^i_a\frac{\partial}{\partial q^i},$$

$$\mathbf{h}\left(\frac{\partial}{\partial q^i}\right)=0,$$

we obtain

$$R\left(\frac{\partial}{\partial q^a},\frac{\partial}{\partial q^b}\right)=R^i_{ab}\frac{\partial}{\partial q^i},$$

where

$$R^i_{ab}=\frac{\partial\Gamma^i_a}{\partial q^b}-\frac{\partial\Gamma^i_b}{\partial q^a}+\Gamma^j_a\frac{\partial\Gamma^i_b}{\partial q^j}-\Gamma^j_b\frac{\partial\Gamma^i_a}{\partial q^j}.$$

We say that Γ is flat if the curvature R identically vanishes. In this case, the constrained system is holonomic.

Notice that this kind of non-holonomic constrained systems is very special, since the local constraints are of the form

$$v^i=-\Gamma^i_a(q^A)v^a,$$

that is, some velocities are explicitly written in terms of the others.

We will consider a very special kind of such constrained systems, those called generalized Čaplygin systems.

Definition IV.1: A generalized Čaplygin system consists of a Lagrangian function $L:TQ\to\mathbb{R}$ *and a connection* Γ *in a fibration* $\rho:Q\to M$ *such that*

$$L((Y^H)_q)=L((Y^H)_{\tilde{q}}),$$

for any $Y\in T_yM$, *where* $q,\tilde{q}\in Q$ *are such that* $\rho(q)=\rho(\tilde{q})=y$.

Remark IV.2: Notice that the Čaplygin systems considered by Koiller[18] are particular cases. In fact, in that case, $\rho:Q\to M$ is a principal bundle with structure group G, L is G-invariant, and Γ is a principal connection, i.e., the horizontal subspaces are G-invariant. The 1-forms η_i are just the components of the connection form. If the group G is Abelian, then the last condition implies that the Christoffel components do not depend on the fiber coordinates. So, we recover the classical setting of Čaplygin systems[18].

From the definition, one easily see that there exists a well-defined Lagrangian function $L^*:TM\to\mathbb{R}$, by setting

$$L^*(Y)=L((Y^H)_q),$$

for any $Y\in T_yM$, where q is an arbitrary point in the fiber over y. In local coordinates we have

$$L^*(q^a,v^a)=L(q^a,q^i,v^a,-\Gamma^i_a v^a).$$

Since L^* does not depend on q^i we deduce that

$$\frac{\partial L}{\partial q^i}=\frac{\partial L}{\partial v^j}\frac{\partial\Gamma^j_a}{\partial q^i}v^a. \tag{13}$$

The constrained Euler–Lagrange equations for L are the following:

$$\frac{d}{dt}\left(\frac{\partial L}{\partial v^a}\right)-\frac{\partial L}{\partial q^a}=-\sum_i\lambda^i\Gamma^i_a,$$

$$\frac{d}{dt}\left(\frac{\partial L}{\partial v^i}\right)-\frac{\partial L}{\partial q^i}=-\lambda^i,$$

$$v^a=\frac{dq^a}{dt},\quad v^i=\frac{dq^i}{dt}.$$

After some calculations, and using (13), we obtain that

$$\frac{d}{dt}\left(\frac{\partial L^*}{\partial v^a}\right)-\frac{\partial L^*}{\partial q^a}=\frac{\partial L}{\partial v^i}v^b\left(\frac{\partial \Gamma_b^i}{\partial q^a}-\frac{\partial \Gamma_a^i}{\partial q^b}+\Gamma_b^j\frac{\partial \Gamma_a^i}{\partial q^j}-\Gamma_a^j\frac{\partial \Gamma_b^i}{\partial q^j}\right),$$

where $v^a=dq^a/dt$.

As we have proved in Section II, the intrinsic motion equations are

$$\begin{gathered}(i_X\omega_L-dE_L)\in(H^v)^0,\\ X\in H^c,\end{gathered}\tag{14}$$

along H.

If we assume that the constrained system is regular (for instance, if the Lagrangian L is natural) then there exists an almost product structure $(\mathscr{P},\mathscr{Q})$ on TQ along H such that the vector field $\xi=\mathscr{P}(\xi_L)$ gives the constrained dynamics. Let us recall that ξ is a vector field defined on H, that is, $\xi\in\mathfrak{X}(H)$.

Define a 1-form $\alpha_{L,\Gamma}$ on TM as follows:

$$(\alpha_{L,\Gamma})_u(U)=-(\alpha_L)_x(\widetilde{X}),$$

for any $U\in T_u(TM)$, for any $u\in T_yM$, where $\widetilde{X}\in T_x(TQ)$ is a tangent vector which projects onto the tangent vector $R((u^H)_q,(T\tau_M(U))_q^H)\in T_qQ$, $\rho(q)=y$, and $x\in D$ with $\tau_Q(x)=q$. [Notice that there is a unique point $x\in D$ such that $\tau_Q(x)=q$ and $T\rho(x)=u$.] In local coordinates, we get

$$\alpha_{L,\Gamma}=\left[\frac{\partial L}{\partial v^i}v^bR_{ab}^i\right]dq^a.$$

It should be remarked that $\alpha_{L,\Gamma}$ is not a *bona fide* 1-form on TM, but it is a 1-form along the mapping $T\rho_{/H}:H\to TM$. For the sake of simplicity, we will assume that $\alpha_{L,\Gamma}$ is well-defined on TM, which is the case in most of the examples.

Now, consider the non-conservative Lagrangian system with Lagrangian function L and external force $\alpha_{L,\Gamma}$. The intrinsic motion equation is

$$i_Y\omega_{L^*}=dE_{L^*}+\alpha_{L,\Gamma},\tag{15}$$

on TM. We will study its solutions. Notice that the corresponding Euler–Lagrange equations are

$$\begin{gathered}\frac{d}{dt}\left(\frac{\partial L^*}{\partial v^a}\right)-\frac{\partial L^*}{\partial q^a}=-\frac{\partial L}{\partial v^i}v^bR_{ab}^i,\\ v^a=\frac{dq^a}{dt}.\end{gathered}\tag{16}$$

Theorem IV.3: *(1) The generalized Čaplygin system* (L,Γ) *is regular* iff L^* *is regular;*
(2) In this case, the vector field ξ *is projectable onto* TM, *and its projection* Y *is just the solution of (15).*

Dynamical proof: We first show how the result can be derived by using a pure dynamical argument. As we have shown, if $(q^a(t),q^i(t))$ is a solution of the constrained motion equations (14) then it is a horizontal curve, and its projection is a solution of the non-conservative equations (16). Conversely, if $(q^a(t))$ is a solution of (16), then its horizontal lift to Q is a solution of (14). Now, assume that the generalized Čaplygin system (L,Γ) is regular so that there exists one and only one solution with a fixed initial data in TM. Take an initial data in TM. Its horizontal lift

gives an initial data in TQ for which there exists one and only one solution of (14). Its projection will be a solution of (15) for the given initial data, and, furthermore, it will be the unique solution with that data. The converse is proved by a similar argument.

The same procedure proves that ξ is projectable, and its projection Y is just a solution of (15). In fact, the solutions of ξ project onto the solutions of Y, and, conversely, the horizontal lifts of the solutions of Y are just the solutions of ξ.

Next, we exhibit an alternative proof based on the geometrical ingredients of the theory. First of all, we will prove the following lemma.

Lemma IV.4: Let Γ be an arbitrary connection in a fibration $\rho:Q\to M$ with horizontal projector $\mathbf{h}$. *If μ_1 and μ_2 are two 1-forms and X is a horizontal vector field on Q such that*

$$\mathscr{L}_X\mu_1=\mu_2,$$

then we have

$$\mathscr{L}_X(\mathbf{h}^*\mu_1)=\mathbf{h}^*\mu_2-\alpha,$$

where $\mathbf{h}^*$ *is the transpose operator of* $\mathbf{h}$, *and α is the 1-form on Q defined by*

$$\alpha(Y)=-\mu_1(R(X,Y)-\mathbf{h}([X,\mathbf{v}Y])),$$

R being the curvature of Γ.

Proof: Assume that $\mathscr{L}_X\mu_1=\mu_2$ and X is a horizontal vector field. Let Y be an arbitrary vector field on Q. We have

$$\begin{aligned}(\mathscr{L}_X(\mathbf{h}^*\mu_1))(Y)&=\mathscr{L}_X(\mathbf{h}^*\mu_1)(Y)-(\mathbf{h}^*\mu_1)([X,Y])\\&=X(\mu_1(\mathbf{h}Y))-\mu_1(\mathbf{h}([X,Y])\\&=\mu_2(\mathbf{h}Y)+\mu_1([X,\mathbf{h}Y])-\mu_1(\mathbf{h}[X,Y])\\&=\mathbf{h}^*\mu_2(Y)+\mu_1(R(X,Y)-\mathbf{h}([X,\mathbf{v}Y])).\end{aligned}$$

■

Geometrical proof of the theorem: First of all, we will prove that the generalized Čaplygin system (L,Γ) is regular if L^* is regular. In fact, denote by

$$W=(W^{AB})=\begin{pmatrix}W^{ab} & W^{aj}\\ W^{ib} & W^{ij}\end{pmatrix}$$

the inverse matrix of the Hessian matrix $(\partial^2L/\partial v^A\partial v^B)$. We have

$$\mathscr{C}_{ij}=-W^{ab}\Gamma^i_a\Gamma^j_b-W^{ja}\Gamma^i_a-W^{ib}\Gamma^j_b-W^{ij},$$

or, equivalently,

$$\mathscr{C}=-(\gamma,I_{m\times m})W(\gamma,I_{m\times m})^t,$$

where γ is a matrix $m\times(n-m)$ with entries $\gamma_{ia}=\Gamma^i_a$, $1\leqslant i\leqslant m$, $1\leqslant a\leqslant n-m$, and the superindex t means that we are taking the transpose matrix.

On the other hand, the entries of the Hessian matrix $\mathscr{M}$ of L^* are

$$\frac{\partial^2L^*}{\partial v^a\partial v^b}=\frac{\partial^2L}{\partial v^a\partial v^b}-\Gamma^i_a\frac{\partial^2L}{\partial v^i\partial v^b}-\Gamma^j_b\frac{\partial^2L}{\partial v^j\partial v^a}+\Gamma^i_a\Gamma^j_b\frac{\partial^2L}{\partial v^i\partial v^j},$$

or, equivalently,

$$\mathscr{M}=(I_{(n-m)\times(n-m)},-\gamma^t)W^{-1}(I_{(n-m)\times(n-m)},-\gamma^t)^t.$$

If we put $\mathscr{A}=(\gamma,I_{m\times m})$ and $\mathscr{B}=(I_{(n-m)\times(n-m)},-\gamma^t)$, it is no hard to show that either $\mathscr{C}$ or $\mathscr{M}$ are regular, then the square matrices

$$\begin{pmatrix}\mathscr{A}\\ \mathscr{B}W^{-1}\end{pmatrix} \text{ and } \begin{pmatrix}W\mathscr{A}^t\\ \mathscr{B}^t\end{pmatrix}$$

are also regular.

The result follows taking into account that

$$\begin{pmatrix}\mathscr{A}\\ \mathscr{B}W^{-1}\end{pmatrix}\cdot\begin{pmatrix}W\mathscr{A}^t\\ \mathscr{B}^t\end{pmatrix}=\begin{pmatrix}\mathscr{A}W\mathscr{A}^t & 0\\ 0 & \mathscr{B}W^{-1}\mathscr{B}^t\end{pmatrix}.$$

Therefore, we have proved the first part of the theorem.

Next, we will prove the second part.

Given a connection Γ in the fibration $\rho:Q\to M$ we define a connection $\overline{\Gamma}$ in the fibration $T\rho:TQ\to TM$ along the submanifold H as follows. The horizontal distribution $\overline{H}$ of $\overline{\Gamma}$ is locally spanned by the vector fields

$$\left(\frac{\partial}{\partial q^a}\right)^{\overline{H}}=\frac{\partial}{\partial q^a}-\Gamma^i_a\frac{\partial}{\partial q^i}-v^b\left(\frac{\partial\Gamma^i_b}{\partial q^a}-\Gamma^j_a\frac{\partial\Gamma^i_b}{\partial q^j}\right)\frac{\partial}{\partial v^i},$$

$$\left(\frac{\partial}{\partial v^a}\right)^{\overline{H}}=\frac{\partial}{\partial v^a}-\Gamma^i_a\frac{\partial}{\partial v^i}.$$

Along H, we obtain a local basis of vector fields on TQ,

$$\left\{\left(\frac{\partial}{\partial q^a}\right)^{\overline{H}},\left(\frac{\partial}{\partial v^a}\right)^{\overline{H}},\frac{\partial}{\partial q^i},\frac{\partial}{\partial v^i}\right\}.$$

Its dual basis of 1-forms is

$$\{dq^a,dv^a,\eta^v_i,d\hat{\eta}_i\}.$$

Thus, the set $\{\eta^v_i,d\hat{\eta}_i\}$ is the annihilator of $\overline{H}$. A simple computation shows that $\overline{H}$ is globally defined along H.

If $\mathbf{h}$ is the horizontal projector associated with $\overline{\Gamma}$ we have $\overline{\mathbf{h}}^*(dq^a)=dq^a$, $\overline{\mathbf{h}}^*(dv^a)=dv^a$, $\overline{\mathbf{h}}^*(\eta^v_i)=0$ and $\overline{\mathbf{h}}^*(d\hat{\eta}_i)=0$.

Consider the pull-backs of the 1-forms α_{L*} and $dL*$ to TQ by means of $T\rho$. Along H we deduce that

$$\overline{\mathbf{h}}^*(\alpha_L)=(T\rho)^*\alpha_{L*},$$

$$\overline{\mathbf{h}}^*(dL)=(T\rho)^*dL^*.$$

From Lemma II.8 we have

$$\mathscr{L}_\xi\alpha_L=dL-\mathscr{L}_{\mathscr{Q}(\xi_L)}\alpha_L, \tag{17}$$

and from Lemma IV.4, we get

$$\mathscr{L}_{\xi}(\overline{\mathbf{h}}^{*}\alpha_L)=\overline{\mathbf{h}}^{*}(dL)-\overline{\mathbf{h}}^{*}(\mathscr{L}_{\mathcal{Q}(\xi_L)}\alpha_L)-\overline{\alpha}, \tag{18}$$

where $\overline{\alpha}$ is the 1-form on TQ along H defined by

$$\overline{\alpha}(Z)=-\alpha_L(\overline{R}(\xi,Z)-\overline{\mathbf{h}}([\xi,\overline{\mathbf{v}}(Z)])),$$

$\overline{R}$ being the curvature of $\overline{\Gamma}$. Since α_L is semibasic and $\overline{\Gamma}$ is a connection in the fibration $T\rho:TQ\to TM$ (along H), we deduce that $\alpha_L(\overline{\mathbf{h}}([\xi,\overline{\mathbf{v}}(Z)])=0$, and hence we get

$$\overline{\alpha}(Z)=-\alpha_L(\overline{R}(\xi,Z)).$$

In local coordinates we obtain

$$\overline{\alpha}=\frac{\partial L}{\partial v^i}v^b\left(\frac{\partial\Gamma^i_a}{\partial q^b}-\frac{\partial\Gamma^i_b}{\partial q^a}-\Gamma^j_b\frac{\partial\Gamma^i_a}{\partial q^j}+\Gamma^j_a\frac{\partial\Gamma^i_b}{\partial q^j}\right)dq^a.$$

Therefore, we deduce that $\overline{\alpha}$ is projectable, and its projection is just the 1-form $\alpha_{L,\Gamma}$ on TM.

From Lemma II.9 we have

$$\overline{\mathbf{h}}^{*}(\mathscr{L}_{\mathcal{Q}(\xi_L)}\alpha_L)=0,$$

and therefore (18) becomes

$$\mathscr{L}_{\xi}(T\rho)^{*}\alpha_{L^{*}}=(T\rho)^{*}(dL^{*})-\overline{\alpha}.$$

Let Y be a vector field on TM which is a solution of the equation

$$\mathscr{L}_{Y}\alpha_{L^{*}}=dL^{*}-\alpha_{L,\Gamma}.$$

Then every vector field $\widetilde{Y}$ on TQ which projects onto Y verifies

$$\mathscr{L}_{\widetilde{Y}}(T\rho)^{*}\alpha_{L^{*}}=(T\rho)^{*}(dL^{*})-\overline{\alpha}. \tag{19}$$

In particular, the horizontal lift $Y^{\overline{H}}$ with respect to $\overline{\Gamma}$ verifies (19). Since ξ also verifies (19) and $\xi\in\overline{H}$, we deduce that $Y^{\overline{H}}=\xi$.

■

Thus, we have the following.

Corollary IV.5: The generalized Čaplygin system (L,Γ) *is equivalent to a non-conservative system on* TM *with Lagrangian function* L^{*} *and external force* $\alpha_{L,\Gamma}$.

Remark IV.6: The above procedure is a sort of reduction, but not in the sense of Marsden and Weinstein.[40] In fact, we could consider the general case of a constrained Lagrangian system subjected to linear constraints given by a distribution D on Q, and such that L and D are invariant by the action of a Lie group G. This is just the case of Čaplygin systems as were considered by Koiller.

Remark IV.7: The distribution H^c satisfies the following relation:

$$T(TQ)=H^c\oplus V(T\rho),$$

along the points of H. Thus, H^c defines a connection Γ^c in the fibration $T\rho:TQ\to TM$ along the submanifold H, which could be considered as the tangent lift of the original connection Γ in the fibration $\rho:Q\to M$. We have proved that the vector field ξ is horizontal with respect to $\overline{\Gamma}$. A

similar device proves that ξ is also horizontal with respect to Γ^c, and moreover $\xi = Y^{H^c}$. The relationship between both connections $\overline{\Gamma}$ and Γ^c is the following: they coincide if and only Γ is flat, or, in other words, the constrained system is holonomic.

Remark IV.8: Assume that the constrained system is not regular. From Theorem IV.3 we deduce that L^* is a singular Lagrangian function. Thus, Equation (15) has no, in general, solution. However, we can develop a constraint algorithm as follows. Put $K_1 = TM$ and define K_2 be the submanifold of points in TM for which there exists at least a solution of (15). On K_2 there is a solution, but it is not necessarily tangent to K_2. So, we consider the submanifold K_3 consisting in those points in K_2 where a tangent solution to K_2 exists.

Proceeding further we obtain a sequence of constraint submanifolds,

$$\cdots \to K_k \to \cdots \to K_2 \to K_1 = TM.$$

On the other hand, there exists a sequence of constraint submanifolds,

$$\cdots \to H_k \to \cdots \to H_2 \to H_1 = H,$$

obtained by applying the constraint algorithm developed in Section III. It is almost obvious that both algorithms are related by the projection mapping $T\rho : TQ \to TM$, that is, we have

$$T\rho(H_r) = M_r, \quad r \geqslant 1.$$

Example IV.9 (The sleigh of Čaplygin and Carathéodory):

Consider a sleigh, that is, a body having three points of contact with a plane where two of them slide freely but the third A is subjected to a force which does not allow transversal velocity. The configuration manifold is $Q = \mathbb{R}^2 \times S^1$ with coordinates (x, y, ϕ), where (x, y) are the coordinates of the center of mass C of the sleigh, and ϕ is the angle between the x-axis and the line AC (see Ref. 18). If we denote by a the distance from A to C, by J the moment of inertia and by $m = 1$ the mass of the sleigh, the Lagrangian function is given by

$$L = \frac{1}{2}(\dot{x}^2 + \dot{y}^2) + \frac{1}{2} J \dot{\phi}^2,$$

Observe that L is a natural Lagrangian obtained from the Riemannian metric

$$g = \frac{1}{2}(dx^2 + dy^2 + J d\phi^2),$$

on $\mathbb{R}^2 \times S^1$.

Consider the fibration

$$\rho : \mathbb{R}^2 \times S^1 \to \mathbb{R}^2,$$

defined by

$$\rho(x, y, \phi) = (x, y).$$

Define a connection Γ in ρ by

$$\Gamma\left(\frac{\partial}{\partial x}\right)=\frac{\partial}{\partial x}-2\frac{\sin\phi}{a}\frac{\partial}{\partial\phi},$$

$$\Gamma\left(\frac{\partial}{\partial y}\right)=\frac{\partial}{\partial y}+2\frac{\cos\phi}{a}\frac{\partial}{\partial\phi},$$

$$\Gamma\left(\frac{\partial}{\partial\phi}\right)=-\frac{\partial}{\partial\phi}.$$

The curvature R of Γ is

$$R=\frac{1}{a^2}\frac{\partial}{\partial\phi}\otimes(dx\wedge dy).$$

The horizontal distribution of Γ is generated by

$$\left\langle\frac{\partial}{\partial x}-\frac{\sin\phi}{a}\frac{\partial}{\partial\phi},\quad\frac{\partial}{\partial y}+\frac{\cos\phi}{a}\frac{\partial}{\partial\phi}\right\rangle,$$

and the annihilator of H is generated by the 1-form

$$\eta=d\phi-\frac{\cos\phi}{a}dy+\frac{\sin\phi}{a}dx.$$

In fact, η is the connection 1-form of Γ. Therefore, the linear constraints are

$$\dot\phi-\frac{\cos\phi}{a}\dot y+\frac{\sin\phi}{a}\dot x=0.$$

Notice that ρ is a principal S^1-bundle. However, Γ is no a principal connection, since the horizontal subspaces are not S^1-invariant. Thus, (L,Γ) is not a generalized Čaplygin system. However, we can apply the general procedure developed in Section II.

Since L is natural, the constrained system is regular, and then there exists a well-defined solution of the constrained dynamics along the submanifold H of TQ.

The distribution S is generated by the vector field

$$Z=-\frac{1}{J}\frac{\partial}{\partial\dot\phi}+\frac{\cos\phi}{a}\frac{\partial}{\partial\dot y}-\frac{\sin\phi}{a}\frac{\partial}{\partial\dot x},$$

along the points of H.

The almost product structure $(\mathscr{P},\mathscr{Q})$ is given by

$$\mathscr{Q}=-\frac{Ja^2}{a^2+J}\left(-\frac{1}{J}\frac{\partial}{\partial\dot\phi}+\frac{\cos\phi}{a}\frac{\partial}{\partial\dot y}-\frac{\sin\phi}{a}\frac{\partial}{\partial\dot x}\right)$$
$$\otimes\left(\left(\frac{\sin\phi}{a}\dot y+\frac{\cos\phi}{a}\dot x\right)d\phi+\frac{\sin\phi}{a}d\dot x-\frac{\cos\phi}{a}d\dot y+d\dot\phi\right),$$

$$\mathscr{P}=\mathrm{id}-\mathscr{Q}.$$

Thus, the only vector field ξ such that $\xi_x \in (S_L)_x \cap T_x H$ and $J_x(\xi_x) = C_x$, for any $x \in H$, is given by

$$\xi = \mathscr{P}(\xi_L) = \dot{x}\frac{\partial}{\partial x} + \dot{y}\frac{\partial}{\partial y} + \dot{\phi}\frac{\partial}{\partial \phi} - \frac{J}{a^2+J}\sin\phi(\sin\phi\dot{y} + \cos\phi\dot{x})\frac{\partial}{\partial \dot{x}}$$

$$+ \frac{J}{a^2+J}\cos\phi(\sin\phi\dot{y} + \cos\phi\dot{x})\frac{\partial}{\partial \dot{y}} - \frac{a}{a^2+J}(\sin\phi\dot{y} + \cos\phi\dot{x})\frac{\partial}{\partial \dot{\phi}},$$

along the points of H.

Example IV.10 (The ''two-wheeled carriage''):

The configuration space of the ''two-wheeled carriage'' is $Q = \mathbb{R}^2 \times S^1 \times T^2$, with coordinates $(x, y, \phi, \Phi_1, \Phi_2)$ (see Refs. 18,3).

Let $2r$ be the lateral length, a the radius of the wheels, C_0 the center of mass, situated at distance l from a point (x,y). If we denote by m_0 the mass of the body without wheels, k_0 the radius of gyration about the vertical through (x,y), m_1 the mass of a wheel, C the axial moments of inertia and A its moment of inertia about a diameter, then the Lagrangian function is given by

$$L = \frac{1}{2}m(\dot{x}^2 + \dot{y}^2) + m_0 l\dot{\phi}(\dot{y}\cos\phi - \dot{x}\sin\phi) + \frac{1}{2}J\dot{\phi}^2 + \frac{1}{2}C(\dot{\Phi}_1^2 + \dot{\Phi}_2^2),$$

where $m = m_0 + 2m_1$ and $J = m_0 k_0^2 + 2m_1 r^2 + 2A$.

Consider now the fibration

$$\rho : \mathbb{R}^2 \times S^1 \times T^2 \to T^2,$$

defined by $\rho(x, y, \phi, \Phi_1, \Phi_2) = (\Phi_1, \Phi_2)$.

Define a connection Γ in ρ by

$$\Gamma\left(\frac{\partial}{\partial \Phi_1}\right) = \frac{\partial}{\partial \Phi_1} - a\cos\phi\frac{\partial}{\partial x} - a\sin\phi\frac{\partial}{\partial y} - \frac{a}{r}\frac{\partial}{\partial \phi},$$

$$\Gamma\left(\frac{\partial}{\partial \Phi_2}\right) = \frac{\partial}{\partial \Phi_2} - a\cos\phi\frac{\partial}{\partial x} - a\sin\phi\frac{\partial}{\partial y} + \frac{a}{r}\frac{\partial}{\partial \phi},$$

$$\Gamma\left(\frac{\partial}{\partial x}\right) = -\frac{\partial}{\partial x}, \quad \Gamma\left(\frac{\partial}{\partial y}\right) = -\frac{\partial}{\partial y}, \quad \Gamma\left(\frac{\partial}{\partial \phi}\right) = -\frac{\partial}{\partial \phi}.$$

The horizontal distribution H of Γ is generated by

$$\left\langle \frac{\partial}{\partial \Phi_1} - \frac{a}{2}\cos\phi\frac{\partial}{\partial x} - \frac{a}{2}\sin\phi\frac{\partial}{\partial y} - \frac{a}{2r}\frac{\partial}{\partial \phi}, \quad \frac{\partial}{\partial \Phi_2} - \frac{a}{2}\cos\phi\frac{\partial}{\partial x} - \frac{a}{2}\sin\phi\frac{\partial}{\partial y} + \frac{a}{2r}\frac{\partial}{\partial \phi} \right\rangle.$$

Thus, the annihilator of H is generated by the 1-forms

$$\eta_x = dx + \frac{a\cos\phi}{2}d\Phi_1 + \frac{a\cos\phi}{2}d\Phi_2,$$

$$\eta_y = dy + \frac{a\sin\phi}{2}d\Phi_1 + \frac{a\sin\phi}{2}d\Phi_2,$$

$$\eta_\phi = d\phi + \frac{a}{2r} d\Phi_1 - \frac{a}{2r} d\Phi_2 .$$

The linear constraints are then

$$\dot{x} = -\frac{a\cos\phi}{2}\dot{\Phi}_1 - \frac{a\cos\phi}{2}\dot{\Phi}_2 ,$$

$$\dot{y} = -\frac{a\sin\phi}{2}\dot{\Phi}_1 - \frac{a\sin\phi}{2}\dot{\Phi}_2 ,$$

$$\dot{\phi} = -\frac{a}{2r}\dot{\Phi}_1 + \frac{a}{2r}\dot{\Phi}_2 .$$

The curvature of the connection is given by the vector 2-form,

$$R = \frac{a^2}{2r}\left(-\sin\phi \frac{\partial}{\partial x} + \cos\phi \frac{\partial}{\partial y}\right) \otimes (d\Phi_1 \wedge d\Phi_2).$$

The fibration $\rho : \mathbb{R}^2 \times S^1 \times T^2 \to T^2$ is a principal $\mathbb{R}^2 \times S^1$-bundle, and Γ is a principal connection with connection 1-form

$$\eta = (\eta_x, \eta_y, \eta_\phi),$$

taking values into the Lie algebra of $\mathbb{R}^2 \times S^1$. Notice that $\mathbb{R}^2 \times S^1$ may be identified with the group of Euclidean motions of the plane (see Koiller[18]).

Thus, the system (L, Γ) is a generalized Caplygin system. By applying the general theory developed in this section, we obtain a Lagrangian function $L^* : T^2 \to \mathbb{R}$ as follows:

$$L^*(\Phi_1, \Phi_2, \dot{\Phi}_1, \dot{\Phi}_2) = \frac{1}{8} m a^2 (\dot{\Phi}_1^2 + \dot{\Phi}_2^2) + \frac{J a^2}{8 r^2} (\dot{\Phi}_2 - \dot{\Phi}_1)^2 + \frac{1}{2} C (\dot{\Phi}_1^2 + \dot{\Phi}_2^2).$$

From Corollary IV.5, we know that the constrained system (L, D) is equivalent to the nonconservative system given by L^* and the external force

$$\alpha_{L,\Gamma} = \frac{m_0 l a^3}{4 r^2} (\dot{\Phi}_2 - \dot{\Phi}_1) \dot{\Phi}_2 d\Phi_1 - \frac{m_0 l a^3}{4 r^2} (\dot{\Phi}_2 - \dot{\Phi}_1) \dot{\Phi}_1 d\Phi_2 .$$

From a tedious but straightforward computation we have that the solution Y of the equation

$$i_Y \omega_{L^*} = dE_{L^*} + \alpha_{L,\Gamma} ,$$

is the vector field,

$$Y = \dot{\Phi}_1 \frac{\partial}{\partial \Phi_1} + \dot{\Phi}_2 \frac{\partial}{\partial \Phi_2} + K_1 (\dot{\Phi}_1 - \dot{\Phi}_2)(K_2 \dot{\Phi}_2 - J a^2 \dot{\Phi}_1) \frac{\partial}{\partial \dot{\Phi}_1} + K_1 (\dot{\Phi}_2 - \dot{\Phi}_1)(K_2 \dot{\Phi}_1 - J a^2 \dot{\Phi}_2) \frac{\partial}{\partial \dot{\Phi}_2},$$

where $K_1 = m_0 l a^3 / (m^2 a^4 r^4 + 8 m a^2 r^4 C + 2 m a^4 r^2 J + 16 r^4 C^2 + 8 J C a^2 r^2)$ and $K_2 = m a^2 r^2 + 4 C r^2 + J a^2$.

We obtain the solution on TQ by taking the horizontal lift of the vector field Y by the connection $\overline{\Gamma}$.

V. AN APPLICATION: EQUATIONS OF CONSTRAINED GEODESICS

Let Q be a Riemannian manifold with Riemannian metric g and Levi-Civita connection ∇ and suppose that a distribution D on Q is given. A very old problem in the literature is to obtain a new linear connection ∇^* on Q such that the geodesics of ∇^* are the extremals of the variational problem subjected to these linear constraints (see Synge,[35] Vranceanu,[36] Neimark and Fufaev[3] and the references therein.) We shall apply our method to give a new look at Synge's paper.

The Lagrangian function is

$$L(q^A,v^A)=\frac{1}{2}g_{AB}v^Av^B,$$

that is, L is the kinetic energy of g. Take an orthonormal local basis $\{\mu_i\}$ of D. Since $E_L=L$, we obtain

$$\xi_L=v^A\frac{\partial}{\partial q^A}-\Gamma^C_{AB}v^Av^B\frac{\partial}{\partial v^C},$$

where Γ^C_{AB} are the Christoffel components of ∇. In fact, ξ_L is the geodesic spray.

A direct computation shows that

$$Z_i=-g^{AB}(\mu_i)_B\frac{\partial}{\partial v^A},$$

$$\hat{\mu}_i=(\mu_i)_Av^A,$$

$$\mathscr{C}_{ij}=Z_i(\hat{\mu}_j)=-g^{AB}(\mu_i)_A(\mu_j)_B=-\delta_{ij}.$$

Therefore, the constrained system is regular.

From Proposition II.4 there exists a unique almost product structure $(\mathscr{P},\mathscr{Q})$ such that $\mathscr{P}_x(X)\in T_xD$ and $\mathscr{Q}_x(X)\in S_x$, where $X\in T_xTQ$. We have

$$\begin{aligned}\mathscr{P}(\xi_L)&=v^A\frac{\partial}{\partial q^A}-v^Av^B\left(\Gamma^C_{AB}+\frac{\partial(\mu_i)_B}{\partial q^A}g^{CR}(\mu_i)_R-\Gamma^E_{AB}(\mu_i)_Eg^{CR}(\mu_i)_R\right)\frac{\partial}{\partial v^C}\\&=v^A\frac{\partial}{\partial q^A}-v^Av^B\left(\Gamma^C_{AB}+\left(\frac{\partial(\mu_i)_B}{\partial q^A}-\Gamma^E_{AB}(\mu_i)_E\right)g^{CR}(\mu_i)_R\right)\frac{\partial}{\partial v^C}\\&=v^A\frac{\partial}{\partial q^A}-v^Av^B(\Gamma^C_{AB}+(\mu_i)_{A;B}(\mu_i)^C)\frac{\partial}{\partial v^C},\end{aligned}$$

where

$$(\mu_i)_{A;B}=\frac{\partial(\mu_i)_A}{\partial q^B}-\Gamma^E_{AB}(\mu_i)_E$$

denote the components of the covariant derivative of μ_i, and $(\mu_i)^C=g^{CR}(\mu_i)_R$.

Since $\mathscr{P}(\xi_L)$ is a SODE and tangent to D, we know that for each tangent vector $z\in D$ there is a curve σ on Q which is a solution of $\mathscr{P}(\xi_L)$ with that initial data, i.e., $\sigma(0)=x$, $\dot{\sigma}(0)=z$ and $\dot{\sigma}$ is an integral curve of $\mathscr{P}(\xi_L)$. In fact, the solutions of $\mathscr{P}(\xi_L)$ are just the solutions of the following system of differential equations:

$$\frac{d^2q^C}{dt^2}+(\Gamma^*)^C_{AB}\frac{dq^A}{dt}\frac{dq^B}{dt}=0, \tag{20}$$

where

$$(\Gamma^*)^C_{AB}=\Gamma^C_{AB}+(\mu_i)_{A;B}(\mu_i)^C.$$

Notice that (20) are just the differential equations obtained by Synge in Ref. 35. Of course, (20) have no solutions for arbitrary initial data, since only the velocities in D are allowable.

Notice that $(\Gamma^*)^A_{BC}$ are not the Christoffel components of a linear connection ∇^* on Q. They define a more general geometric object, an spray defined on a submanifold D of TQ. Indeed, let us recall that there exists a one-to-one correspondence between sprays on TQ and linear connections on Q (see Ref. 38). In fact, if ξ is an spray, then $\Gamma=-\mathscr{L}_\xi J$ is a linear connection on Q, and, conversely, if Γ is a linear connection on Q, then its associated SODE is an spray.

The vector field $\mathscr{P}(\xi_L)$ can be extended to a vector field defined on some open neighborhood of D in TQ. Of course, there are many extensions of $\mathscr{P}(\xi_L)$. Choose an arbitrary extension and define

$$\Gamma^*=-\mathscr{L}_{P(\xi_L)}J.$$

So, Γ^* is a tensor field of type (1,1) defined on some open neighborhood of D, and its local expression is as follows:

$$\Gamma^*\left(\frac{\partial}{\partial q^A}\right)=\frac{\partial}{\partial q^A}-2(\Gamma^*)^C_{AB}v^B\frac{\partial}{\partial v^C},$$

$$\Gamma^*\left(\frac{\partial}{\partial v^A}\right)=-\frac{\partial}{\partial v^A}.$$

A direct computation shows that $(\Gamma^*)^2=\mathrm{id}$, and the vector eigenspace corresponding to the eigenvalue -1 at a point of D is just the vertical subspace at that point. Moreover, given another extension of $\mathscr{P}(\xi_L)$, we obtain that the new tensor field Γ^* coincides with the former on D.

Thus, Γ^* defines a connection on some open neighborhood of D and all these connections coincide on D.

We define the horizontal and vertical projectors of Γ^* in the usual way:

$$h^*=\frac{1}{2}(\mathrm{id}+\Gamma^*),\quad v^*=\frac{1}{2}(\mathrm{id}-\Gamma^*).$$

Their local expressions are the following ones:

$$h^*\left(\frac{\partial}{\partial q^A}\right)=\frac{\partial}{\partial q^A}-(\Gamma^*)^C_{BA}v^B\frac{\partial}{\partial v^C},$$

$$h^*\left(\frac{\partial}{\partial v^A}\right)=0,$$

$$v^*\left(\frac{\partial}{\partial q^A}\right)=(\Gamma^*)^C_{BA}v^B\frac{\partial}{\partial v^C},$$

$$v^*\left(\frac{\partial}{\partial v^A}\right)=\frac{\partial}{\partial v^A}.$$

Using the standard procedures for connections on TQ (see Refs. 37,38), we define a covariant derivative as follows. Let X be a vector field on Q and Y be a vector field which is tangent to D. In other words, X is a section of $\tau_Q:TQ\to Q$ and Y a section of $\tau_{Q/D}:D\to Q$. Define

$$(\nabla^*_X Y)(x)=\phi_{Y(x)}(v^*(dY(x)(X(x))),\quad \forall x\in Q,$$

where $\phi_{Y(x)}$ is the linear isomorphism,

$$\phi_{Y(x)}:V_{Y(x)}\tau_Q\to T_xQ$$

from the vertical subspace at $Y(x)$ onto T_xQ.

If $X=X^A(\partial/\partial q^A)$ and $Y=Y^A(\partial/\partial q^A)$, we deduce that

$$\nabla^*_X Y=X^A\left[\frac{\partial Y^C}{\partial q^A}+(\Gamma^*)^C_{AB}Y^B\right]\frac{\partial}{\partial q^C}.$$

We look for a condition which ensures that $\nabla^*_X Y\in D$. We have

$$\begin{aligned}\mu_i(\nabla^*_X Y)&=(\mu_i)_D dq^D\left[\left(X^A\frac{\partial Y^C}{\partial q^A}+X^A(\Gamma^*)^C_{AB}Y^B\right)\right]\\&=X^A\left[(\mu_i)_C\frac{\partial Y^C}{\partial q^A}+(\mu_i)_C(\Gamma^*)^C_{AB}Y^B\right].\end{aligned}$$

Since

$$(\Gamma^*)^A_{BC}=\Gamma^C_{AB}+(\mu_i)_{A;B}(\mu_i)^C,$$

we deduce that

$$\begin{aligned}(\mu_i)_C(\Gamma^*)^C_{AB}&=(\mu_i)_C\Gamma^C_{AB}+(\mu_i)_C\frac{\partial(\mu_J)_A}{\partial q^B}(\mu_j)^C-(\mu_i)^C\Gamma^E_{AB}(\mu_i)_E(\mu_j)^C\\&=\frac{\partial(\mu_i)_A}{\partial q^B}.\end{aligned}$$

Thus, we obtain that

$$\mu_i(\nabla^*_X Y)=X^A\left[(\mu_i)_B\frac{\partial Y^B}{\partial q^A}+\frac{\partial(\mu_i)_A}{\partial q^B}Y^B\right]. \tag{21}$$

But $Y\in D$, and therefore we get

$$0=\mu_i(Y)=(\mu_i)_B Y^B.$$

By deriving this last formula, we have

$$(\mu_i)_B\frac{\partial Y^B}{\partial q^A}+\frac{\partial(\mu_i)_B}{\partial q^A}Y^B=0. \tag{22}$$

From (21) and (22) we deduce the following result.

Proposition V.1: ∇^* *defines a connection in the vector bundle* $\tau_Q:D\to Q$ *if and only if* D *is involutive.*

As a consequence, if the system is holonomic, ∇^* is a derivation in the vector bundle $D \to Q$. In the general case, we only get that

$$\nabla^* : \mathfrak{X}(Q) \times \mathrm{Sec}(D) \to \mathfrak{X}(Q)$$

behaves as a derivation.

(Received 4 January 1996; accepted for publication 11 March 1996)

A higher-order nonlocal evolution equation describing internal waves in a deep fluid is shown to be asymptotically integrable only if the coefficients of the higher-order terms satisfy certain constraints. In this case, the nonlocal equation can be transformed to the integrable Benjamin–Ono equation. The asymptotic integrability of the reductions of the higher-order evolution equation to a complex Burgers equation, to an envelope-wave equation, and to a finite-dimensional dynamical system is also considered. © *1996 American Institute of Physics.*

I. INTRODUCTION

The evolution of small amplitude waves of certain nonlinear dispersive systems can be studied asymptotically using the so-called multiscale expansion method (see, e.g., Ref. 1). This method yields a basic evolution equation which is formally valid at the leading asymptotic order, as well as a sequence of evolution equations at higher asymptotic orders. It turns out that for many important physical systems the basic evolution equation is an *integrable* equation (see Ref. 2 for a discussion of this remarkable fact). Each integrable evolution equation is a member of a hierarchy of infinitely many integrable equations. It is interesting that the evolution equation valid at the next asymptotic order, differs from the next member of the associated integrable hierarchy, only in the value of the numerical coefficients of the nonlinear terms. For example, idealized unidirectional water waves of small amplitude and large wave length satisfy[3] the equation

$$\eta_t+\eta_{xxx}+6\,\eta\,\eta_x+\epsilon(\alpha_1\,\eta_{xxxxx}+\alpha_2\,\eta\,\eta_{xxx}+\alpha_3\,\eta_x\,\eta_{xx}+\alpha_4\,\eta^2\,\eta_x)+O(\epsilon^2)=0, \tag{1.1}$$

where $\alpha_1,...,\alpha_4$ are certain numbers. As $\epsilon\to 0$, this equation becomes the Korteweg–deVries (KdV) equation, which is an integrable equation. Furthermore, if $\alpha_2=10\alpha_1$, $\alpha_3=20\alpha_1$, $\alpha_4=30\alpha_1$, then the $O(\epsilon)$ term of Eq. (1.1) becomes the right-hand side of the next member of the hierarchy of integrable equations associated with the KdV equation.

If the basic evolution equation is integrable, we say that the underlying physical system is *asymptotically integrable* to $O(\epsilon)$. It turns out that in certain cases it is possible to formally extend the asymptotic integrability of the system to $O(\epsilon^2)$. For example, in the case of water waves Kodama found[4] an explicit transformation which maps Eq. (1.1) to the integrable equation obtained by Eq. (1.1) when $\alpha_2=10\alpha_1$, $\alpha_3=20\alpha_1$, and $\alpha_4=30\alpha_1$. A generalization of Kodama's transformation which actually maps Eq. (1.1) to KdV equation itself, and an extension of this result to the case of water waves without the unidirectionalization assumption, are given in Ref. 5. It is also shown in Ref. 5 that the concept of the mastersymmetries (see Ref. 6 and references therein) provides an algorithmic approach to finding the transformations which map the physical equations to the integrable ones. Similar results are valid for the case that the basic evolution equation is the nonlinear Schrödinger (NLS) equation.

In this paper we study the asymptotic integrability of the systems whose basic equation is the Benjamin–Ono (BO) equation, i.e., we study the equation

$$u_t = 2uu_x + Hu_{xx} + \epsilon[\alpha u_{xxx} + \beta_1(uHu_x)_x + \beta_2 uHu_{xx} + \beta_3 H(uu_x)_x + \gamma u^2 u_x] + O(\epsilon^2), \quad (1.2)$$

where ϵ is the small parameter of the multiscale expansion, H is the Hilbert transform,

$$(Hf)(x) = \frac{1}{\pi} \int\!\!\!\!\!\!- _{-\infty}^{\infty} \frac{f(\xi)}{\xi - x}\, d\xi, \quad (1.3)$$

and $\int\!\!\!\!\!\!-$ denotes the principal value integral.

Equation (1.2) occurs in the modeling of long internal waves in a deep continuously stratified fluid, and was recently derived in Ref. 7. In this case u denotes the horizontal velocity of the fluid and the coefficients $\alpha,\ldots,\gamma$ can be expressed through the parameters of the fluid stratification. The particular case that the stratification profile can be approximated by a two-layer model with density ρ_1 in the upper (shallow) layer and ρ_2 in the lower (deep) layer, was studied in Ref. 8 and is described by Eq. (1.2) with

$$\alpha = \frac{27}{4}\left(\frac{4\delta^2}{9} - 1\right), \quad \beta_1 = 6, \quad \beta_2 = \frac{3}{2}, \quad \beta_3 = \frac{27}{2}, \quad \gamma = -3, \quad (1.4)$$

where $\delta = \rho_1/\rho_2 < 1$.

The structure of our paper is as follows. In Sec. II we present two main results for Eq. (1.2). (a) We show that if the coefficients satisfy the numerical constraints

$$3\alpha + \beta_1 + \beta_2 + \beta_3 = 0, \quad (1.5)$$

and

$$\beta_1 + \beta_3 - \gamma = 0, \quad (1.6)$$

then Eq. (1.2) is asymptotically integrable to $O(\epsilon^2)$ (see Propositions 2.1 and 2.2).

(b) We study the pole-decomposition solution of Eq. (1.2) and establish that if Eqs. (1.5) and (1.6) are satisfied, then the system describing these solutions is asymptotically integrable to $O(\epsilon^2)$ (see Proposition 2.3). This implies that in this case the algebraic solitary waves interact without a phase shift to $O(\epsilon^2)$.

Unfortunately, in the physically important case that the coefficients of Eq. (1.2) are given by Eq. (1.4), the constraints (1.5) and (1.6) are not satisfied. This is consistent with the fact that in this case the interaction of the algebraic solitary waves exhibits phase shifts to $O(\epsilon^2)$.[9]

Although we have only shown that the validity of Eqs. (1.5) and (1.6) is a sufficient condition for asymptotic integrability, we conjecture that it is also a necessary condition. This conjecture is supported by the following arguments. There exists an exact reduction from Eq. (1.2) to a complex perturbed Burgers equation. In this case, if the coefficients of Eq. (1.2) satisfy a single constraint, denoted here by $\nu = 0$, then the perturbed Burgers equation can be mapped to the integrable Burgers equation. Furthermore, it was shown in Ref. 7 that there exists an asymptotic limit from Eq. (1.2) to a certain modulation equation for envelope waves. This equation contains a free parameter, denoted by χ and is an integrable equation if $\chi = 0$.[10] It is remarkable that the equations $\nu = 0$ and $\chi = 0$ are equivalent to Eqs. (1.5) and (1.6). The reductions related to Eq. (1.2) are discussed in Sec. III.

II. MAIN RESULTS

Proposition 2.1: Let $v(x,t)$ satisfy the BO equation,

$$v_t = 2vv_x + Hv_{xx}. \quad (2.1)$$

Let $u(x,t)$ be defined by

$$u=v+\frac{\epsilon}{2}(\lambda_1 v^2+\lambda_2 Hv_x+\lambda_3 x[2vv_x+Hv_{xx}]). \tag{2.2}$$

Then, u solves Eq. (1.2) where the coefficients of Eq. (1.2) satisfy the constraints given by Eqs. (1.5) and (1.6). Actually, these coefficients can be parametrized by λ_1, λ_2, λ_3 through the equations

$$\alpha=\lambda_3, \quad \beta_1=-\lambda_2, \quad \beta_2=\lambda_1-\lambda_3, \quad \beta_3=-\lambda_1+\lambda_2-2\lambda_3, \quad \gamma=-\lambda_1-2\lambda_3. \tag{2.3}$$

Proof: This result can be verified by a direct calculation. However, we choose to derive a more general result which contains the above as a particular case.

Let $\mathscr{H}(v)$ denote the ring consisting of smooth functions of $v(x,t)$, of its x derivatives, of the action of H on these functions, and of the multiplication by x on these functions. Let v solve the equation,

$$v_t=K(v)+\epsilon\tilde{K}(v), \tag{2.4}$$

where $K,\tilde{K}\in\mathscr{H}$. Define u by the transformation,

$$u=v+\epsilon\tilde{\tau}(v), \tag{2.5}$$

where $\tilde{\tau}\in\mathscr{H}$. Then by direct substitution it follows that u solves the equation,

$$u_t=K(u)+\epsilon(\tilde{K}(u)+[\tilde{\tau}(u),K(u)]_L)+O(\epsilon^2). \tag{2.6}$$

Here $[A,B]_L$ denotes the Lie bracket of $A,B\in\mathscr{H}$, defined by

$$[A(u),B(u)]_L=A'[B](u)-B'[A](u), \tag{2.7}$$

and where prime denotes Frechet differentiation, i.e.,

$$A'[B](u)=\frac{\partial}{\partial\epsilon}A[u+\epsilon B(u)]\Big|_{\epsilon=0}. \tag{2.8}$$

In the particular case when $\tilde{K}=0$, $\tilde{\tau}$ is given by the $O(\epsilon)$ terms of Eq. (2.2), and K is the right-hand side of the BO equation, i.e.,

$$K(v)=2vv_x+Hv_{xx}, \tag{2.9}$$

then Eq. (2.6) becomes Eq. (1.2) with its parameters given by Eq. (2.3). Eliminating the λ's from (2.3) we obtain Eqs. (1.5) and (1.6).

Proposition 2.2: Let v satisfy the integrable equation

$$v_t=K(v)+\epsilon\alpha K_1(v), \tag{2.10}$$

where $K(v)$ is given by Eq. (2.9), and $K_1(v)$ is defined by

$$K_1(v)=[v_{xx}-\tfrac{3}{2}(vHv_x+Hvv_x)-v^3]_x. \tag{2.11}$$

Define u by

$$u=v+\frac{\epsilon}{2}(\mu_1 v^2+\mu_2 Hv_x). \tag{2.12}$$

Then, u solves Eq. (1.2), where the coefficients satisfy the constraints given by Eqs. (1.5) and (1.6). Actually, these coefficients can be parametrized by

$$\beta_1=-\tfrac{3}{2}\alpha-\mu_2,\quad \beta_2=\mu_1,\quad \beta_3=-\tfrac{3}{2}\alpha-\mu_1+\mu_2,\quad \gamma=-3\alpha-\mu_1. \tag{2.13}$$

Proof: This result is a particular case of the more general result presented in the proof of Proposition 2.1.

Remark 2.1: (a) Equation (2.10) is integrable because K_1 is the first commuting flow of the BO equation, i.e.,

$$[K,K_1]_L=0. \tag{2.14}$$

(b) Let $\tau(u)\in\mathscr{H}$ be defined by

$$\tau=u^2+\tfrac{3}{2}Hu_x+x[2uu_x+Hu_{xx}]. \tag{2.15}$$

This function is the *mastersymmetry* of the BO equation.[6] It has the defining property that

$$K_1(u)=\tfrac{1}{2}[\tau,K]_L. \tag{2.16}$$

The terms of $K_1(u)$ differ from the $O(\epsilon)$ terms of Eq. (1.2) only in their numerical coefficients. Thus, in order to find the form of the transformation $\tilde{\tau}(u)$ in (2.5) it is natural to replace the numerical coefficients of $\tau(u)$ by arbitrary constants; in this way $\tau(u)$ becomes the $O(\epsilon)$ term of Eq. (2.2).

(c) If the coefficients of Eq. (1.2) are defined by Eq. (1.4), the constraints (1.5) and (1.6) are not satisfied. However, even in this case, Eq. (2.2) defines a three parameter group of infinitesimal transformations which maps Eq. (1.2) to itself. Using this group of transformations it is possible to show that the equations for the velocity amplitude, and for the fluid interface displacement, derived in Refs. 7 and 8 respectively, are equivalent.

Proposition 2.3: Let $a_j(t)$ and $X_j(t)$ be complex valued scalar functions of t, $a_j^*(t)$ and $X_j^*(t)$ denote their complex conjugation, $j=1,\ldots,N$, and assume that $\mathrm{Im}\,X_j<0$. Equation (1.2) admits the pole-decomposition solution

$$u=\sum_{j=1}^{N}\left[\frac{ia_j(t)}{x-X_j(t)}-\frac{ia_j^*(t)}{x-X_j^*(t)}\right], \tag{2.17}$$

if and only if: (a) The coefficients of Eq. (1.2) satisfy Eqs. (1.5) and (1.6);

(b) a_j is given by

$$a_j=1-\frac{\epsilon\beta_2}{2}\dot{X}_j+O(\epsilon^2); \tag{2.18}$$

(c) X_j satisfy the perturbed Calogero–Moser dynamical system,

$$\ddot{X}_j=8{\sum_k}'\frac{1}{(X_j-X_k)^3}+12\epsilon\alpha{\sum_k}'\frac{\dot{X}_j+\dot{X}_k}{(X_j-X_k)^3}+O(\epsilon^2), \tag{2.19}$$

where $\dot{X}_j=dX_j/dt$, $\ddot{X}_j=d^2X_j/dt^2$, and the sign Σ_k' denotes summation over k from 1 to N excluding j.

Proof: Substituting the pole expansion (2.17) into (1.2) one finds a fourth-order polynomial in terms of $(x-X_j)^{-n}$. Equating the coefficients of the terms with $n=4$ and $n=1$ to zero it follows that

$$6\alpha+3\beta_1+2\beta_2+3\beta_3-\gamma=0, \tag{2.20}$$

and

$$[\beta_1+\beta_2+\beta_3-\gamma]\ddot{X}_j-8\beta_2\sum_k{}' \frac{1}{(X_j-X_k)^3}=0. \tag{2.21}$$

The $O(1)$ term of Eq. (1.2) is the BO equation, thus to the leading order $\ddot{X}_j = 8\Sigma_k'(X_j - X_k)^{-3}$.[11] Substituting this expression into Eq. (2.21), we find that Eqs. (2.20) and (2.21) yield (1.5) and (1.6). Using these two equations, the coefficient of the term $(x-X_j)^{-n}$ with $n=3$ implies Eq. (2.18), while that with $n=2$ implies

$$\begin{aligned} i\dot{X}_j=&2\sum_k{}' \frac{1}{X_j-X_k}-2\sum_k \frac{1}{X_j-X_k^*}+i\epsilon\Bigg[-3\alpha\Bigg(\sum_k \sum_l{}'' \frac{1}{(X_j-X_k)(X_j-X_l)} \\ &-2\sum_k{}' \sum_l \frac{1}{(X_j-X_k)(X_j-X_l^*)}+\sum_k \sum_l \frac{1}{(X_j-X_k^*)(X_j-X_l^*)}\Bigg) \\ &+(\beta_3-\beta_1-3\beta_2)\sum_k \frac{1}{(X_j-X_k^*)^2}\Bigg]+O(\epsilon^2); \end{aligned} \tag{2.22}$$

the sign $\Sigma_k\Sigma_l''$ denotes summation over all k and l from 1 to N which are not equal to j and to each other. Equations (2.22) are different from those derived by Case[11] from the integrable equation (2.10) where the last $O(\epsilon)$ term in Eq. (2.22) is absent. However, differentiating (2.22) with respect to t and using the pole-decomposition technique discussed in Ref. 12, it can be shown that this term cancels out to $O(\epsilon^2)$, and Eq. (2.22) reduces to (2.19).

Remark 2.2: (a) Let Y_j, $j=1,\ldots,N$, satisfy the integrable Calogero–Moser dynamical system,

$$\ddot{Y}_j=8\sum_k{}' \frac{1}{(Y_j-Y_k)^3}. \tag{2.23}$$

Define X_j by

$$X_j=Y_j+\frac{\epsilon\alpha}{2}Y_j\dot{Y}_j. \tag{2.24}$$

Then, X_j satisfy Eq. (2.19) to $O(\epsilon^2)$. We note that the transformation (2.24) also follows from Proposition 2.1. Indeed, since v satisfies the BO equation (2.1), it admits the pole decomposition,

$$v=\sum_{j=1}^{N}\left[\frac{i}{x-Y_j(t)}-\frac{i}{x-Y_j^*(t)}\right]. \tag{2.25}$$

Substituting this expansion and the corresponding one for u [see (2.17)] into (2.2) with $\lambda_1=\alpha+\beta_2$, $\lambda_2=-\beta_1$, and $\lambda_3=\alpha$ we find that Eq. (2.2) reduces to (2.24).

(b) The pole decomposition of Eq. (1.2) yields an integrable dynamical systems if the coefficients satisfy the constraints given by Eq. (1.5) and (1.6). This provides further evidence that these constraints are necessary and sufficient conditions for the asymptotic integrability of Eq. (1.2). Furthermore, explicit soliton and periodic wave solutions of this equation can be found in the integrable case by means of the pole-decomposition representation (2.17) (see Ref. 11).

III. RELATED REDUCTIONS

In this section we discuss the integrability of certain equations related to Eq. (1.2).

Reduction 3.1: Let u be analytic in the upper half plane of the complex extension of x. Then $Hu=iu$, and Eq. (1.2) reduces to the complex perturbed Burgers equation

$$u_t=2uu_x+iu_{xx}+\epsilon[\alpha u_{xxx}+i(\beta_1+\beta_3)u_x^2+i(\beta_1+\beta_2+\beta_3)uu_{xx}+\gamma u^2u_x]+O(\epsilon^2). \quad (3.1)$$

It can be shown that if v satisfies the complex Burgers equation

$$v_t=2vv_x+iv_{xx}, \quad (3.2)$$

and if u is defined by

$$u=v+\frac{\epsilon}{2}(\nu_1v^2+\nu_2v_x\partial^{-1}v+\nu_3x[2vv_x+iv_{xx}]), \quad (3.3)$$

then u satisfies Eq. (3.1), where the coefficients of Eq. (3.1) satisfy the single constraint

$$\nu=3\alpha+3\beta_1+\beta_2+3\beta_3-2\gamma=0. \quad (3.4)$$

We note that the constraint (3.4) does not coincide with either Eq. (1.5) or (1.6). Moreover, Eq. (3.3) contains a nonlocal term, which is absent in Eq. (2.2). However, if the coefficients of Eq. (1.2) satisfy Eqs. (1.5) and (1.6), then both $\nu_2=0$ and $\nu=0$ are valid.

Reduction 3.2: Let u be expanded in the asymptotic form

$$u=\sqrt{\epsilon}[\Psi(X,T)\exp[i(x-t)]+\text{c.c.}]+O(\epsilon), \quad X=\epsilon(x-2t), \quad T=\epsilon^2t, \quad (3.5)$$

where c.c. denotes complex conjugation. Then, it can be shown[7] that the function $\Psi(X,T)$ satisfies the equation

$$i\Psi_T+\Psi_{XX}+\Psi[i+H](|\Psi|^2)_X+\chi|\Psi|^2\Psi=0, \quad (3.6)$$

where

$$\chi=3\alpha+2\beta_1+\beta_2+2\beta_3-\gamma. \quad (3.7)$$

It was shown in Ref. 10 that if $\chi=0$ then Eq. (3.6) is integrable. [If one applies the ansatz (3.5) to the BO equation instead of Eq. (1.2), one finds Eq. (3.6) with $\chi=0$.] We note that if Eqs. (1.5) and (1.6) are valid, then $\chi=0$. Furthermore, Eqs. (3.4) and (3.7) are equivalent to Eqs. (1.5) and (1.6).

Reduction 3.3: Let the function u be represented asymptotically as $t\to\pm\infty$ by

$$u=u_0(\theta_1^{\pm};a_1)+u_0(\theta_2^{\pm};a_2)+O(\epsilon), \quad \theta_j^{\pm}=a_j(x+v_jt+\epsilon X_j^{\pm}), \quad j=1,2, \quad (3.8)$$

where $u_0(\theta_j^{\pm};a_j)$ is the profile of the BO (algebraic) soliton solution. The parameters a_j, v_j, and $X_j^{\pm}$ describe the amplitude, the velocity, and the phase shift of the j soliton, respectively. Assume that $a_1<a_2$, which implies $v_1<v_2$. Then, the velocities of the individual BO solitons are expressed through their amplitudes by the equations

$$v_j=a_j-\frac{\epsilon a_j^2}{4}(6\alpha+7\beta_1+6\beta_2+5\beta_3-5\gamma)+O(\epsilon^2). \quad (3.9)$$

Furthermore, the total phase shifts of the BO soliton interactions, $\Delta X_j=X_j^+-X_j^-$, are given by

$$\Delta X_1 = -\frac{\pi}{(a_1+a_2)^2}\,[(3\alpha+\beta_1+\beta_2+\beta_3)(2a_1^2+4a_1a_2-2a_2^2) + (\beta_1+\beta_2-\gamma)(3a_1^2+6a_1a_2-a_2^2)], \tag{3.10}$$

$$\Delta X_2 = -\frac{\pi}{(a_1+a_2)^2}\,[(3\alpha+\beta_1+\beta_2+\beta_3)(-2a_1^2+4a_1a_2+2a_2^2) + (\beta_1+\beta_2-\gamma)(-a_1^2+6a_1a_2+3a_2^2)]. \tag{3.11}$$

When the coefficients of Eq. (1.2) are given by Eqs. (1.4), the total phase shifts (3.10) and (3.11) reduce to those found by Matsuno.[9] Here we have generalized his result to show that the total phase shifts exactly vanish only if the coefficients in (1.2) satisfy Eqs. (1.5) and (1.6). This is consistent with the fact that in this case, the interaction of the BO (algebraic) solitons is described by the integrable Calogero–Moser system (2.23) which does not produce any phase shifts of the algebraic soliton interactions.

Soliton solutions and nontrivial scattering in an integrable chiral model in (2+1) dimensions

T. Ioannidou
Department of Mathematical Sciences, University of Durham, Durham DH1 3LE, United Kingdom

(Received 5 February 1996; accepted for publication 28 March 1996)

The behavior of solitons in integrable theories is strongly constrained by the integrability of the theory; i.e., by the existence of an infinite number of conserved quantities that these theories are known to possess. One usually expects the scattering of solitons in such theories to be rather simple, i.e., trivial. By contrast, in this paper we generate new soliton solutions for the planar integrable chiral model whose scattering properties are highly nontrivial; more precisely, in head-on collisions of N indistinguishable solitons the scattering angle (of the emerging structures relative to the incoming ones) is π/N. We also generate soliton–antisoliton solutions with elastic scattering; in particular, a head-on collision of a soliton and an antisoliton resulting in 90° scattering. © *1996 American Institute of Physics.* [S0022-2488(96)02007-5]

I. INTRODUCTION

In this paper we study certain exact soliton solutions of an integrable system. Before any detailed discussion, and to avoid confusion later on, it is worthwhile clearing up a small point of terminology: the word *solitons* was introduced by mathematicians to describe lumps of energy that were stable to perturbations and did not change either velocity or shape when colliding with each other. However, in recent literature all sorts of localized energy configurations have been called solitons. We shall go along this looser definition. By a soliton we shall mean a lump of energy that moves but we shall not imply stability of the shape or the velocity or a simple behavior in collision.

An interesting problem is to look at the scattering properties of two or more solitons colliding. In some known systems with nontrivial topology, the collision of two solitons is inelastic (some radiation is emitted) and nontrivial (a head-on collision results in 90° scattering); all this has been observed analytically[1,2] and numerically.[3–6] One can construct explicit time-dependent solutions only in very special, so-called integrable models. Usually in these models extended objects interact trivially, in the sense that they pass through each other with no lasting change in velocity or shape (i.e., they behave as genuine solitons). Some examples in (2+1) dimensions are the Kadomtsev–Petviashvili equation[7] and the integrable chiral model.[8] The last system is the subject of this paper and will be described below. Until now, nontrivial scattering of solitons occurs mostly in nonintegrable systems, which is far from simple. The question that arises is whether this type of scattering can occur in integrable models too. There are some limited examples of integrable systems where soliton dynamics can be nontrivial. In (1+1) dimensions there are many models that possess nontrivial soliton-like solutions (cf. Ref. 9); like the boomeron solutions,[10] which are solitons with time-dependent velocities. In (2+1) dimensions there are the dromion solutions[11] of the Davey–Stewartson equation, which decay exponentially in both spatial coordinates and interact in a nontrivial manner;[12] and the soliton solutions[13] of the Kadomtsev–Petviashvili equations, whose scattering properties are highly nontrivial.

In the present work we are going to construct families of soliton solutions for the integrable (2+1)-dimensional chiral model and observe the occurrence of different types of behavior. This happens since the solitons in this system have internal degrees of freedom that determine their orientation in space; do not affect the initial energy density; and are important in understanding the

0022-2488/96/37(7)/3422/20/$10.00

evolution as a whole. Therefore, they can interact either trivially or nontrivially, depending on the orientation of these internal parameters and on the values of the impact parameter defined as the distance of closest of approach between their centers in the absence of interaction. Namely, if two initial soliton-like structures are sent toward each other at zero impact parameter, then, as most numerical simulations have shown, the outgoing structures emerge at 90°.

To proceed further let us specify the system. The modified SU(2) chiral model studied by Ward[8] is given by the field equation

$$\partial^{\mu}(J^{-1}J_{\mu})-\tfrac{1}{2}V_{\alpha}\epsilon^{\alpha\mu\nu}[J^{-1}J_{\mu},J^{-1}J_{\nu}]=0. \tag{1}$$

Here J takes values in the SU(2) group and is thought of as a 2×2 unitary matrix of functions of the space–time coordinates on $\mathbf{R}^{2+1}$: $x^{\mu}=(x^0,x^1,x^2)=(t,x,y)$ with $\det J=1$. Greek letters are space–time indices, taking values 0, 1, 2, ∂_{μ} denotes partial differentiation with respect to x^{μ}, while gaps $J_{\mu}\equiv\partial_{\mu}J$. The quantity $\epsilon^{\alpha\mu\nu}$ is the alternating tensor of three indices with $\epsilon^{012}=1$. Finally, V_{α} is a unit vector in space–time. The conformal properties of V_{α} determine whether the symmetry group is SO(2) or SO(1,1) (depending on whether V_{α} is time-like or space-like).

Ward[8] chooses V_{α} to have the components $V_{\alpha}=(0,1,0)$, the space-like case, so that (1) is a chiral equation with torsion term and has the same conserved energy-momentum vector as the chiral field equation. In fact, the corresponding energy density is

$$\mathscr{E}=-\tfrac{1}{2}\ \mathrm{tr}\ [(J^{-1}J_t)^2+(J^{-1}J_x)^2+(J^{-1}J_y)^2]. \tag{2}$$

Here tr denotes the matrix trace. It should be emphasized that $\mathscr{E}$ is a positive-defined functional of J, and hence a conserved energy exists that is the integral of the energy density over the space-like plane $x^0=$const. The boundary conditions are chosen so that the field configuration has finite energy. Consequently, we require that J be everywhere smooth and that

$$J=J_0+J_1(\theta)r^{-1}+O(r^{-2}), \tag{3}$$

at spatial infinity, with $x+iy=re^{i\theta}$. Here J_0 is a constant matrix, and J_1 depends only on θ (no time dependence).

The ensuing system when V_a is i times a time-like vector instead of space-like has been studied in Ref. 14. Equation (1) admits solitons, localized in two dimensions, with trivial scattering, i.e., each soliton suffers no change in velocity and no phase shift upon scattering.[8,14] It is the purpose of this paper to construct new soliton solutions for (1), and investigate their scattering behavior. Such solutions are localized along the direction of motion; they are not, however, of constant size: their height, which corresponds to the maximum of the energy density $\mathscr{E}$, is time dependent.

The rest of the paper is arranged as follows. In the next section we shall briefly discuss the integrability properties of (1), and write down a family of multisoliton solutions as configurations that are the limiting cases of the ones already obtained using the standard method of *Riemann problem with zeros*.[8] In Sec. III we construct two families of multisoliton solutions with nontrivial scattering; in particular, for the first one we prove that in all head-on collisions the N moving structures undergo π/N scattering. In Sec. IV we construct a mixture of soliton–antisoliton solutions, and in Sec. V we discuss their dynamics and scattering properties. We finish the paper with a short section containing our conclusions.

II. CONSTRUCTION OF SOLITON SOLUTIONS

The integrable nature of Eq. (1) means that there is a variety of methods for constructing exact solutions. Together with *Riemann problem with zero*,[8] both *twistor techniques*[15] and a full *inverse scattering formalism*[16] have been applied to the model. In this section we indicate a general

method for constructing soliton solutions of the integrable chiral model (1). The technique is a variation of that Ref. 8, 17, following a pioneering idea of Zakharov and his collaborators.[18]

The nonlinear equation (1) is integrable in a sense that it may be written as the compatibility condition for the following linear system:

$$\begin{aligned} L\psi &\equiv (\lambda\partial_x - \partial_u)\psi = A\psi, \\ M\psi &\equiv (\lambda\partial_v - \partial_x)\psi = B\psi. \end{aligned} \tag{4}$$

Here $\lambda \in \mathbf{C}$, (u,v,x) are coordinates on $\mathbf{R^{2+1}}$ with $u=(t+y)/2$, $v=(t-y)/2$, A and B are 2×2 anti-Hermitian trace-free matrices depending only on (u,v,x), and $\psi(\lambda,u,v,x)$ is an unimodular 2×2 matrix function satisfying the reality condition

$$\psi(\lambda,u,v,x)\psi(\overline{\lambda},u,v,x)^{\dagger} = I, \tag{5}$$

where the overbar denotes the complex conjugate, † denotes the complex conjugate transpose matrix, and I is the 2×2 identity matrix. The system (4) is overdetermined, and in order for a solution ψ to exist, A and B have to satisfy the integrability conditions, which are

$$B_x = A_v, \quad A_x - B_u - [A,\, B] = 0. \tag{6}$$

If we put $J(u,v,x) = \psi(\lambda=0,u,v,x)^{-1}$, where ψ is a solution of the system (4), we get by comparing (4) and (6) that

$$A = J^{-1}J_v, \quad B = J^{-1}J_x. \tag{7}$$

Therefore, the integrability condition for (4) implies that there exists a field J that satisfies the equation of motion (1); and moreover, the reality condition on ψ ensures that J is unitary.

Using the standard method of *Riemann problem with zeros*, in order to construct the multi-soliton solution, one may assume that the function ψ has simple poles in λ, or in other words, must possess the form

$$\psi(\lambda) = I + \sum_{k=1}^{n} \frac{M_k}{\lambda - \mu_k}, \tag{8}$$

where M_k are 2×2 matrices independent of the complex parameter λ, n is the number of solitons, and the complex parameter μ_k determines the velocity of the kth soliton. The components of the matrix M_k are given in terms of a rational function f_k of the complex variable, $\omega_k = x + \mu_k u + \mu_k^{-1} v$. [Roughly speaking, $f_k(\omega_k)$ describes the shape of the kth soliton.] In fact, the matrix M_k (cf. Ref. 8) has the form

$$M_k = -\sum_{l=1}^{n} (\Gamma^{-1})^{kl} \overline{m_a^l} m_b^k, \tag{9}$$

with Γ^{-1} the inverse of

$$\Gamma^{kl} = \sum_{a=1}^{2} (\overline{\mu_k} - \mu_l)^{-1} \overline{m_a^k} m_a^l. \tag{10}$$

Here m_a^k are holomorphic functions of ω_k, given by $m_a^k = (m_1^k, m_2^k) = (1,\, f_k)$. These solitons pass each other without any change of direction or phase shift. Infinite energy extended wave solutions[19] may be constructed by taking f_k to be an exponential function of ω_k. Such extended wave solutions suffer a phase shift upon scattering, although again there is no change in velocity.

All this assumes that the parameters μ_k are distinct, and also $\overline{\mu_k} \neq \mu_l$ for all k, l. In this paper examples are given of two generalizations of these constructions: one involving higher-order poles in μ_k and the other where $\overline{\mu_k} = \mu_l$.

Let us look at an example in which the function ψ has a a double pole in λ, and no other poles. So we take ψ to have the form

$$\psi = I + \sum_{k=1}^{2} \frac{R_k}{(\lambda - \mu)^k}, \tag{11}$$

where R_k are 2×2 matrices independent of λ. (This hypothesis can be generalized by taking the function ψ to have a pole of order n in λ.)

It has been proved[17] that ψ given by (11) satisfies the reality condition (5) if and only if it factorizes as

$$\psi(\lambda) = \left(I - \frac{(\overline{\mu} - \mu)}{(\lambda - \mu)} \frac{q_1^\dagger \otimes q_1}{\|q_1\|^2} \right) \left(I - \frac{(\overline{\mu} - \mu)}{(\lambda - \mu)} \frac{q_2^\dagger \otimes q_2}{\|q_2\|^2} \right), \tag{12}$$

where q_k are two-dimensional row vectors and $\|q_k\|^2 = q_k \cdot q_k^\dagger$.

The q_k have to satisfy a condition, which amounts to saying the matrices $A = (L\psi)\psi^{-1}$ and $B = (M\psi)\psi^{-1}$ are independent of λ. One way of obtaining q_k with this property is as a limit of the simple-pole case (8) with $n=2$. The idea is to take a limit $\mu_k \to \mu$. In order to end up with a smooth solution ψ for all (u,v,x), it is necessary that $f_2(\omega_2) - f_1(\omega_1) \to 0$ in this limit.

In our case, with $n=2$, we put $\mu_1 = \mu + \epsilon$, $\mu_2 = \mu - \epsilon$, and write $f_1(\omega_1) = f(\omega_1)$, $f_2(\omega_2) = f(\omega_2)$, with f being a rational function of one variable. In the limit $\epsilon \to 0$, ψ has the form (12), with

$$\begin{aligned} q_1 &= (1 + |f|^2)(1, f) + \varphi(\overline{\mu} - \mu)(\overline{f}, -1), \\ q_2 &= (1, f). \end{aligned} \tag{13}$$

Here f is a rational function of $\omega = x + \mu u + \mu^{-1} v$, $\varphi = (u - \mu^{-2} v) f'(\omega)$, while $f'(\omega)$ denotes the derivative of $f(\omega)$ with respect to its argument. As a result, we have a solution $J = \psi(\lambda = 0)^{-1}$ depending on the complex parameter μ and on the arbitrary function f. In fact, it has the form of the following product:

$$J = \left(I + \frac{(\overline{\mu} - \mu)}{\mu} \frac{q_2^\dagger \otimes q_2}{\|q_2\|^2} \right) \left(I + \frac{(\overline{\mu} - \mu)}{\mu} \frac{q_1^\dagger \otimes q_1}{\|q_1\|^2} \right), \tag{14}$$

with q_k given by (13). Notice that J takes values in $SU(2)$; is smooth everywhere on $\mathbf{R}^{2+1}$ (mainly because the two vectors q_1 and q_2 are nowhere zero); it satisfies the boundary condition (3); and the equation of motion (1).

To start with, and in order to illustrate the above family of soliton solutions, let us examine two simple cases, by giving specific values to the parameters μ and $f(\omega)$. (The complex parameter μ determines the velocity of the ''center-of-mass'' of the system.)

• Let us take $\mu = i$ (which corresponds to the ''center-of-mass'' of the system being stationary) and $f(\omega) = \omega$, thus $\omega = z$ and $\varphi = t$, where $z = x + iy$; $r^2 = z\overline{z}$. Therefore the row vectors (13) become

$$\begin{aligned} q_1 &= (1 + r^2)(1, z) - 2it(\overline{z}, -1), \\ q_2 &= (1, z). \end{aligned} \tag{15}$$

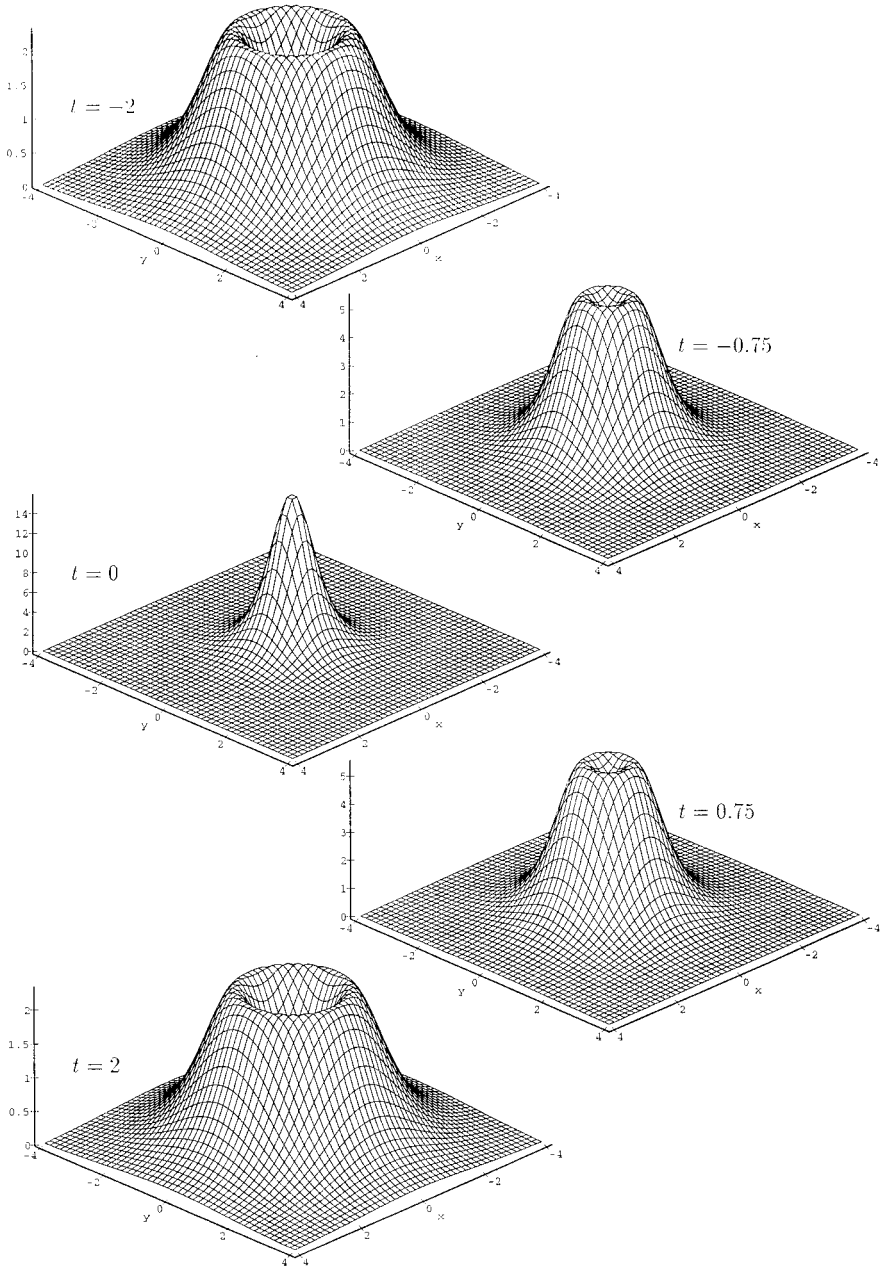

FIG. 1. The energy density $\mathscr{E}$ (16) at increasing times.

In this time-dependent solution, for t negative, a ring structure with reducing radius is obtained, which deforms to a single peak at $t=0$ and thereafter expands again to a ring. Figure 1 presents few pictures of the corresponding energy density at some representative values of time. Ring structures occur in the soliton scattering of many nonintegrable planar systems[3,5] and are an approximation of two solitons.

This picture can be confirmed by looking at the energy density of the solution, which is

$$\mathscr{E}=16\,\frac{r^4+2r^2+4t^2(2r^2+1)+1}{(r^4+2r^2+4t^2+1)^2}. \tag{16}$$

Notice that the energy density is time reversible and rotationally symmetric (see below). For large (positive) t, the height of the ring (maximum of $\mathscr{E}$) is proportional to $1/t$, while its radius is proportional to $\sqrt{t}$.

• Accordingly, let us take $\mu=i$ and $f(\omega)=\omega^2$. Thus, the row vectors (13) are

$$\begin{aligned} q_1&=(1+r^4)(1,\,z^2)-4itz(\overline{z^2},-1),\\ q_2&=(1,\,z^2). \end{aligned} \tag{17}$$

Here, for negative t, a single peak occurs with an additional ring, which changes to a ring structure at $t=0$ and reverts back to the original form, for positive t (see Fig. 2). However, these rings are not radiation since they travel with speed less than that of light. In fact, for large (positive) t, their velocity is approximately proportional to $t^{-2/3}$. (Note that we have set the velocity of the light, c, equal to the unity, so that in all our calculations we can use dimensionless quantities.)

This leads to an energy density, which is

$$\mathscr{E}=64\,\frac{r^{10}+18t^2r^8+2r^6+4t^2r^4+r^2+2t^2}{(r^8+2r^4+16t^2r^2+1)^2}. \tag{18}$$

Again, $\mathscr{E}$ has the same symmetries as in (16). For large (positive) t, the height of the soliton peak is proportional to t^2 and its radius is proportional to $1/t$; while the soliton ring spread out, becoming broader and broader, with height proportional to $t^{-2/3}$ and radius proportional to $t^{1/3}$.

Finally, a general concluding remark should be made. Although (1) is not rotationally symmetric in the xy plane; when $f(z)=z^p$ the field J (13,14) is invariant under the transformation $z\to e^{i\phi}z$, since

$$J\;\to\;J'=\begin{pmatrix} e^{i\phi p/2} & 0\\ 0 & e^{-i\phi p/2}\end{pmatrix} J \begin{pmatrix} e^{-i\phi p/2} & 0\\ 0 & e^{i\phi p/2}\end{pmatrix}. \tag{19}$$

This transformation does not affect the equation of motion (1) due to the chiral symmetry $J\to\kappa J\tau$, where κ and τ are constant $SU(2)$ matrices. The main features of this time-dependent solution may be inferred as follows. If r is large, the field J is close to its asymptotic value J_0, as long as $2tf'/|f|^2\to 0$. But as $2t|f'|/|f|^2\approx 1$, J departs from its asymptotic value J_0 and a ring structure emerges with radius proportional to $(2tp)^{1/(p+1)}$.

III. SOLITON–SOLITON SCATTERING

We now move on to the more interesting question of scattering processes. In fact, we will use the method of Sec. II to construct solutions of (1) representing scattering solitons. We will see that, in all head-on collisions of N moving solitons the scattering angle is π/N. Moreover, when the N solitons are very close together, and in particular, when they are on top of each other, the N lumps that represent them merge together to form a ring-like structure. Then, instead of moving toward the center, they emerge from the ring in a direction that bisects the angle formed by the incoming ones. As we have already mentioned this nontrivial scattering is not usual in an integrable theory, but is exceptional.

The scattering solutions arise if we take a solution of the simple-pole case (8) with $n=2$, put $\mu_1=\mu+\epsilon$, $\mu_2=\mu-\epsilon$, and take the limit $\epsilon\to 0$. The constraint $f_2(\omega_2)-f_1(\omega_1)\to 0$ as $\epsilon\to 0$ has to be imposed, in order for the resulting solution ψ to be smooth for all (u,v,x). So let us write

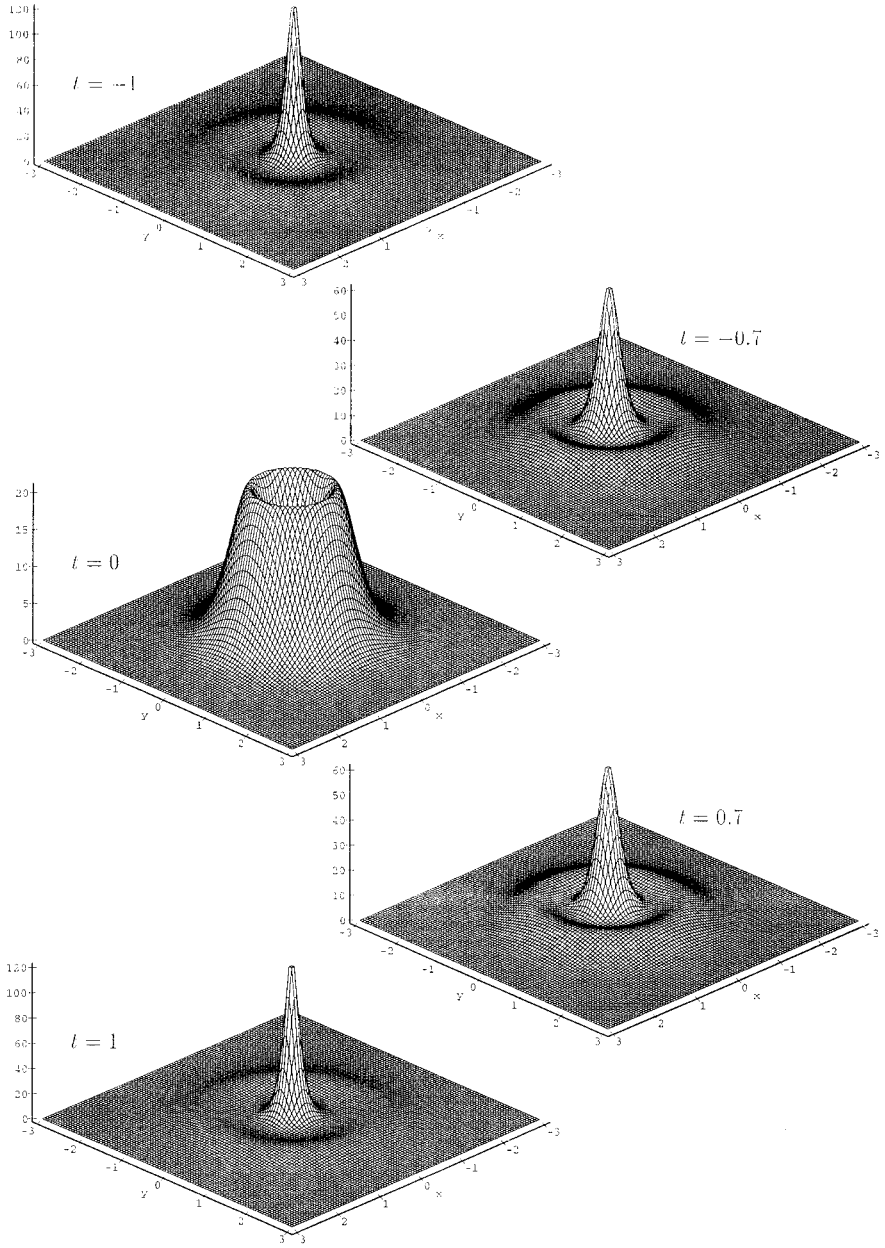

FIG. 2. The energy density $\mathscr{E}$ (18) at various times.

$f_1(\omega_1)=f(\omega_1)+\epsilon h(\omega_1)$, $f_2(\omega_2)=f(\omega_2)-\epsilon h(\omega_2)$, where f and h are both rational functions of one variable (the examples of the previous section had $h=0$). Once again J is given by (14), with the two-vectors q_k given by

$$q_1=(1+|f|^2)(1,\ f\ )+\vartheta(\overline{\mu}-\mu)(\overline{f},-1),$$
$$q_2=(1,\ f\ ), \tag{20}$$

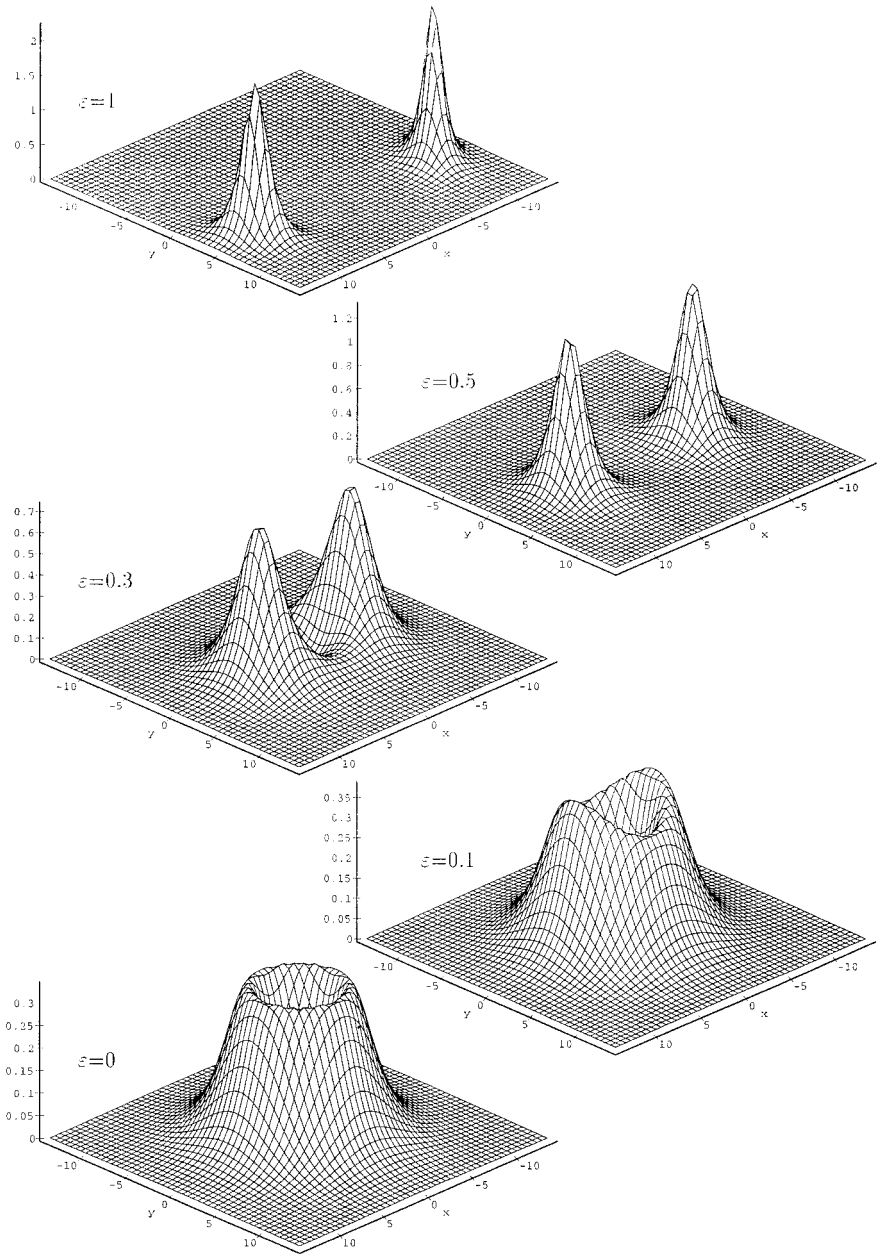

FIG. 3. Energy density at various values of ϵ for a system of two solitons ($t=-15$).

where $\vartheta=\varphi+h(\omega)$. So this solution belongs to a large family, since one may take f and h to be any rational meromorphic functions of ω. Note that J is smooth on $\mathbf{R}^{2+1}$ and satisfies its boundary condition, irrespective of the choice of f and h.

It may seem strange that one can take the limit of a family of soliton solutions with trivial scattering, and obtain a new one with nontrivial scattering. Thus, it is interesting to study how the solitons are affected by varying ϵ. To do so, let us take a solution of the simple-pole case (8) with $n=2$, put $\mu_1=i+\epsilon$, $\mu_2=i-\epsilon$, while taking $f_k=\omega_k$; and study how the configuration of the two initial well-separated solitons changes as $\epsilon\to 0$ at a fixed time ($t=-15$). Figure 3 shows that as

$\epsilon \to 0$ the solitons disperse, shift, and interact with each other. In other words, their internal degrees of freedom as well as the impact parameter change in this limit, making the process highly nontrivial.

As an example, let us present two typical cases.

• Let us take $\mu=i$, $f(\omega)=\omega$, and $h(\omega)=\omega^3$, thus $\vartheta=t+z^3$. For r large, J is equal to its asymptotic value J_0, as long as $\vartheta/z^3=1+t/z^3\approx 1$, but as z approaches any of the three cube roots of $-t$, then $\vartheta\to 0$, while J departs from J_0, and three localized solitons emerge. For t negative, the three solitons are approximately at the points $((-t)^{1/3},0)$, $(-(-t)^{1/3},\pm\sqrt{3}(-t)^{1/3})$; while for t positive, the solitons are at $(-t^{1/3},0)$, $(t^{1/3},\pm\sqrt{3}t^{1/3})$.

More information can be deduced from the energy density, which is

$$\mathcal{E}=16[2r^8+16r^6+19r^4+2r^2(1+8xy^2t)+4t^2(1+2r^2)+1+8xy^4t-8x^5t \\ -16tx(x^2-y^2)]/[4r^6+r^4+2r^2+4t^2+1+8tx(x^2-3y^2)]^2. \tag{21}$$

The density $\mathcal{E}$ is symmetric under the interchange $t\mapsto -t$, $x\mapsto -x$, and $y\mapsto -y$. For small (negative) t, the solitons form an intermediate state having the shape of a ring with three maxima on the direction of the incoming solitons that deforms to a circularly symmetric ring at $t=0$ and then energy seems to flow around, until three other maxima are formed in the transverse direction, for small (positive) t.

Figure 4 shows clearly the intermediate states with three maxima. The three new maxima then give rise to three new solitons emerging at 60° to the original direction of motion. During the intermediate phase solitons lose their identity.

Finally, something has to be said about their size. For large (positive) t, their height is proportional to $t^{-4/3}$, their radius is proportional to $t^{1/3}$, while their speed is proportional to $t^{-2/3}$: therefore, they spread out and slow down.

• Accordingly, let us take $\mu=i$ while we choose $f(\omega)=\omega^2$ and $h(\omega)=\omega^3$. Here J departs from its asymptotic value J_0 when z approaches the values $\pm\sqrt{-2t}$ or zero [since $\vartheta=z(2t+z^2)\to 0$]; and (again) three localized solitons emerge. In this case though, if t is negative, all three of them are on the x axis at $x\approx\pm\sqrt{-2t}$ and at the origin; while if t is positive, they are on the y axis at $y\approx\pm\sqrt{2t}$ and at the origin. So the picture consists of three solitons: a static one at the origin, with the other two accelerating toward the origin, scattering at right angles and then decelerating as they separate.

This can be observed from the energy density, which is

$$\mathcal{E}=32[r^{12}+2r^2(r^8+r^6+1)+36t^2r^8+4r^6+9r^4+8t^2r^4+4t^2 \\ +12t(x^{10}-y^{10})+4t(x^2-y^2)(3+2x^2y^2+6x^4y^4) \\ +4t(x^6-y^6)(9x^2y^2-2)-y^{10}]/[r^8+4r^6+2r^4+16tr^2(t+x^2-y^2)+1]^2. \tag{22}$$

Here $\mathcal{E}$ is symmetric under the interchange $t\mapsto -t$, $x\rightleftharpoons y$; therefore the collision is time symmetric, with the only effect the 90° scattering (no phase shift; no radiation). For large (positive) t, the height of the static soliton is proportional to t^2 and its radius is proportional to $1/t$; while the moving solitons expand with height proportional to $t^{-2/3}$ and radius proportional to $t^{1/3}$.

In Fig. 5 we present some pictures of the total energy densities of three solitons during a typical nontrivial evolution.

In principle one should be able to visualize the emerging soliton structures when $f(\omega)=\omega^p$ and $h(\omega)=\omega^q$, i.e., are rational of degree p, $q\in\mathbf{N}$, respectively. In fact, for $q>p$ the configuration consists of $(p-1)$ static solitons at the ''center-of-mass'' of the system (if more than one, a ring structure is formed) accompanied by $N=q-p+1$ solitons accelerating toward the ones in the middle, scattering at an angle of π/N, and then decelerating as they separate. This follows from the

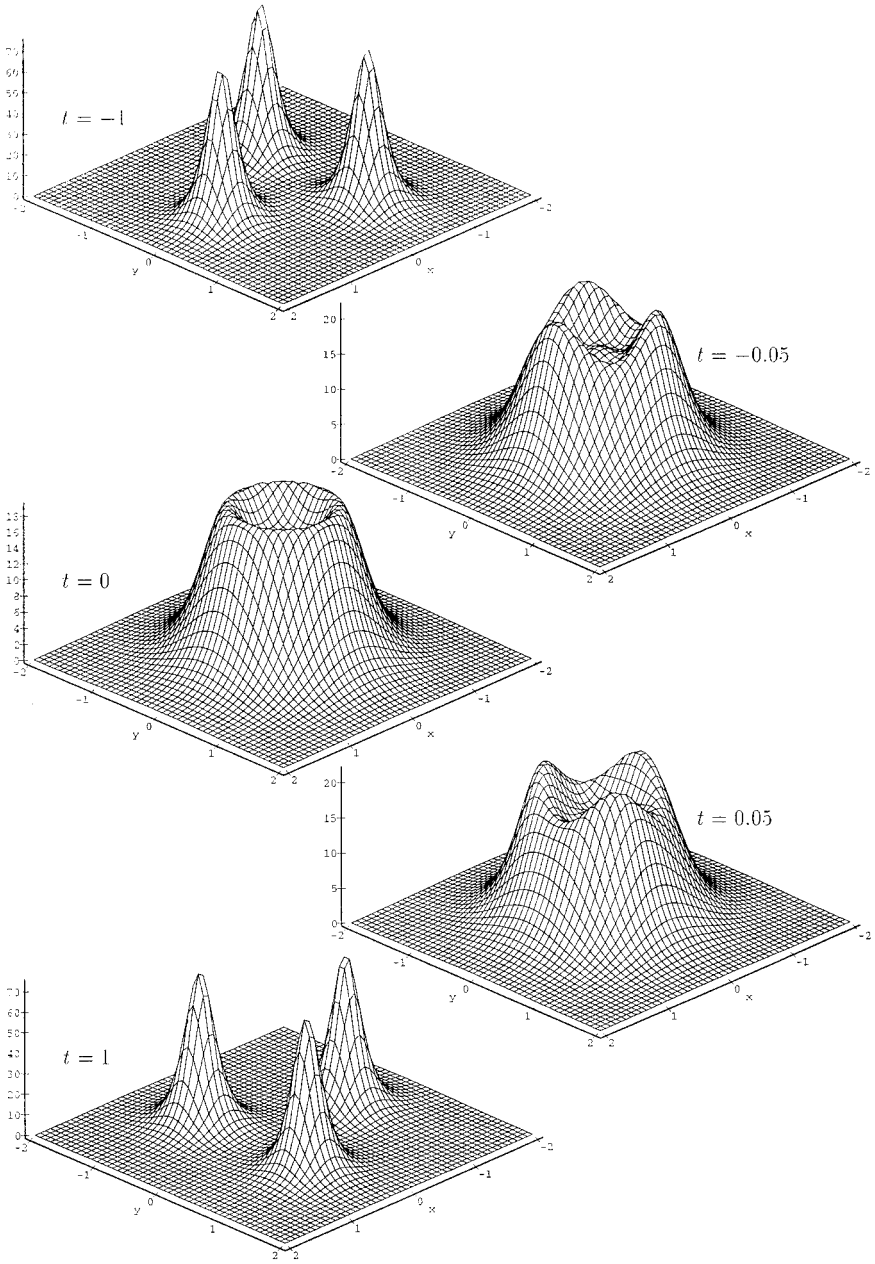

FIG. 4. Energy density at increasing times for a system of three solitons with 60° angle scattering.

fact that the field J departs from its asymptotic value J_0 when $\vartheta=\omega^{(p-1)}(p(u-\mu^{-2}v)+\omega^N)\to 0$, which is true when either $\omega^{(p-1)}=0$ or $\omega^N+p(u-\mu^{-2}v)=0$; and this is approximately where the solitons are located.

We conclude this section by investigating the corresponding case where $\psi(\lambda)$ has a triple pole (and no others). Therefore, it is taken to have the form

$$\psi(\lambda)=I+\sum_{k=1}^{3}\frac{\mathscr{R}_2}{(\lambda-\mu)^k}. \tag{23}$$

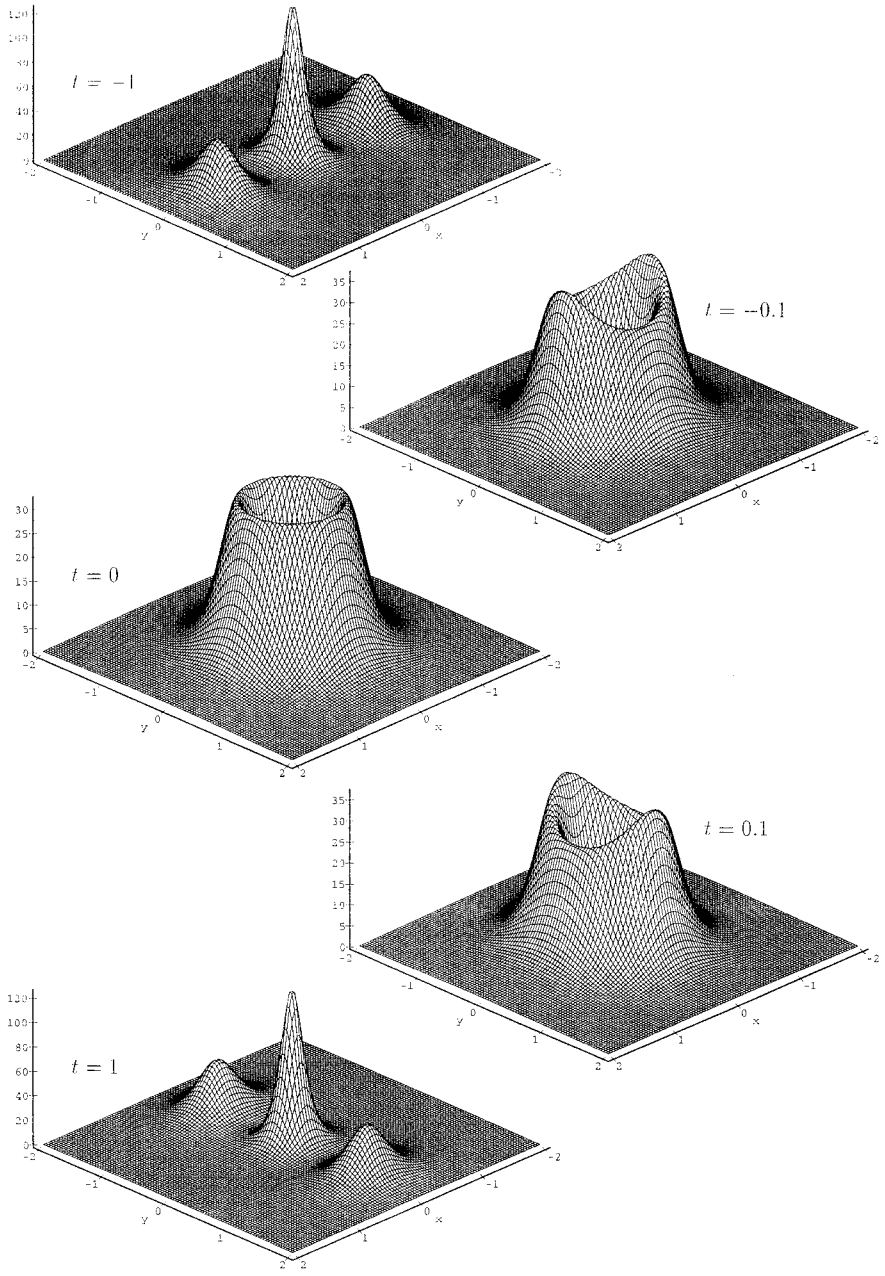

FIG. 5. Energy density at various times for the scattering of three solitons, with one being static at the origin.

As we have already mentioned, the reality condition (5) is satisfied if and only if ψ factorizes into three simple factors of the following type:

$$\psi(\lambda)=i\left(I-\frac{(\overline{\mu}-\mu)}{(\lambda-\mu)}\frac{q_1^{\dagger}\otimes q_1}{\|q_1\|^2}\right)\left(I-\frac{(\overline{\mu}-\mu)}{(\lambda-\mu)}\frac{q_2^{\dagger}\otimes q_2}{\|q_2\|^2}\right)\left(I-\frac{(\overline{\mu}-\mu)}{(\lambda-\mu)}\frac{q_3^{\dagger}\otimes q_3}{\|q_3\|^2}\right), \tag{24}$$

for some two-vectors q_k. The requirement that the matrices $A=(L\psi)\psi^{-1}$ and $B=(M\psi)\psi^{-1}$ should be independent of λ imposes differential equations on q_k; which are three nonlinear equations, and it seems difficult to find their general solution.

One way of proceeding is to take a solution for the simple-pole case (8) with $n=3$, put $\mu_1=i+\epsilon$, $\mu_2=i$, $\mu_3=i-\epsilon$, and take the limit $\epsilon\to 0$. In order to obtain a smooth solution ψ for all (u,v,x), it is necessary that $f_1(\omega_1)-f_2(\omega_2)\to 0$, $f_1(\omega_1)-f_3(\omega_3)\to 0$, $f_2(\omega_2)-f_3(\omega_3)\to 0$ as $\epsilon\to 0$. So let us write $f_1(\omega_1)=f(\omega_1)+\epsilon h(\omega_1)+\epsilon^2 g(\omega_1)$, $f_2(\omega_2)=f(\omega_2)$, $f_3(\omega_3)=f(\omega_3)-\epsilon h(\omega_3)+\epsilon^2 g(\omega_3)$, where f, h, and g are rational functions of one variable. On taking the limit, we obtain a ψ of the form (24), smooth on $\mathbf{R^{2+1}}$ and such that the matrices A and B are independent of λ.

Consequently, $J=\psi(0)^{-1}$ is a smooth solution of (1) of the form

$$J=i\left(I-\frac{2q_3^{\dagger}\otimes q_3}{\|q_3\|^2}\right)\left(I-\frac{2q_2^{\dagger}\otimes q_2}{\|q_2\|^2}\right)\left(I-\frac{2q_1^{\dagger}\otimes q_1}{\|q_1\|^2}\right), \tag{25}$$

with q_k being in terms of $f(z)$, $h(z)$, and $g(z)$ by

$$\begin{aligned} q_1&=(1+|f|^2)^2(1,f)-4i(b+id)(1+|f|^2)(\overline{f},-1)-4b^2(\overline{f}^2,-\overline{f}-2i\overline{b})-8id\overline{b}(1,f),\\ q_2&=(1+|f|^2)(1,f)-2ib(\overline{f},-1),\\ q_3&=(1,f), \end{aligned} \tag{26}$$

where $b=tf'(z)+h(z)$ and $d=t^2f''(z)/2+i(t-y)f'(z)/2+th'(z)+g(z)$. Note that the two-vectors q_2, q_3 here correspond to the ones given by (20) for $\mu=i$, respectively.

Let us examine a sample example of this solution, since we may take f, h, and g to be any rational meromorphic function of z.

• Let us take $f(z)=0$, $h(z)=z$ and $g(z)=z^2$; thus $b=z$ and $d=t+z^2$. This solution consists of two solitons coming in along the y axis merging to form a peak at the origin and then two new solitons emerging along the x axis. Figure 6 illustrates what happens near $t=0$.

The energy density of the system is

$$\mathscr{E}=32\,\frac{80r^4+32(r^2+t^2)+256t^2r^2-64t(x^2-y^2)+128tyr^2-8y+3}{[32r^4+12r^2-16yr^2+16t^2+16ty+32t(x^2-y^2)+1]^2}, \tag{27}$$

which has a reflection symmetry around the x axis. For large (positive) t, $\mathscr{E}$ is peaked at two points on the y axis, namely $y\approx\pm\sqrt{t}$. Moreover, the height of the corresponding solitons is proportional to $1/t$, and their radius is proportional to $\sqrt{t}$; which means that the y axis asymmetry vanishes at $t\to\infty$.

IV. CONSTRUCTION OF SOLITON–ANTISOLITON SOLUTIONS

In this section we construct a large family of solutions, which, as we will argue later, can be though of as representing soliton–antisoliton field configurations. Roughly speaking, solitons correspond to f being a function of the variable z, and antisolitons correspond to a function of $\overline{z}$.

One way to generate a soliton–antisoliton solution of (1), is to assume that $\psi(\lambda)$ has the form

$$\psi(\lambda)=I+\frac{n^1\otimes m^1}{(\lambda-i)}+\frac{n^2\otimes m^2}{(\lambda+i)}. \tag{28}$$

Here n^k, m^k for $k=1,2$ are complex-valued two-vector functions of $(t,z,\overline{z})$ (not depending on λ).

The idea is to find the $n_1^1,\ldots,m_1^1,\ldots$, such that the reality condition (5) holds, and such that the matrices $A=(L\psi)\psi^{-1}$ and $B=(M\psi)\psi^{-1}$ are independent of λ. One way of proceeding is to take

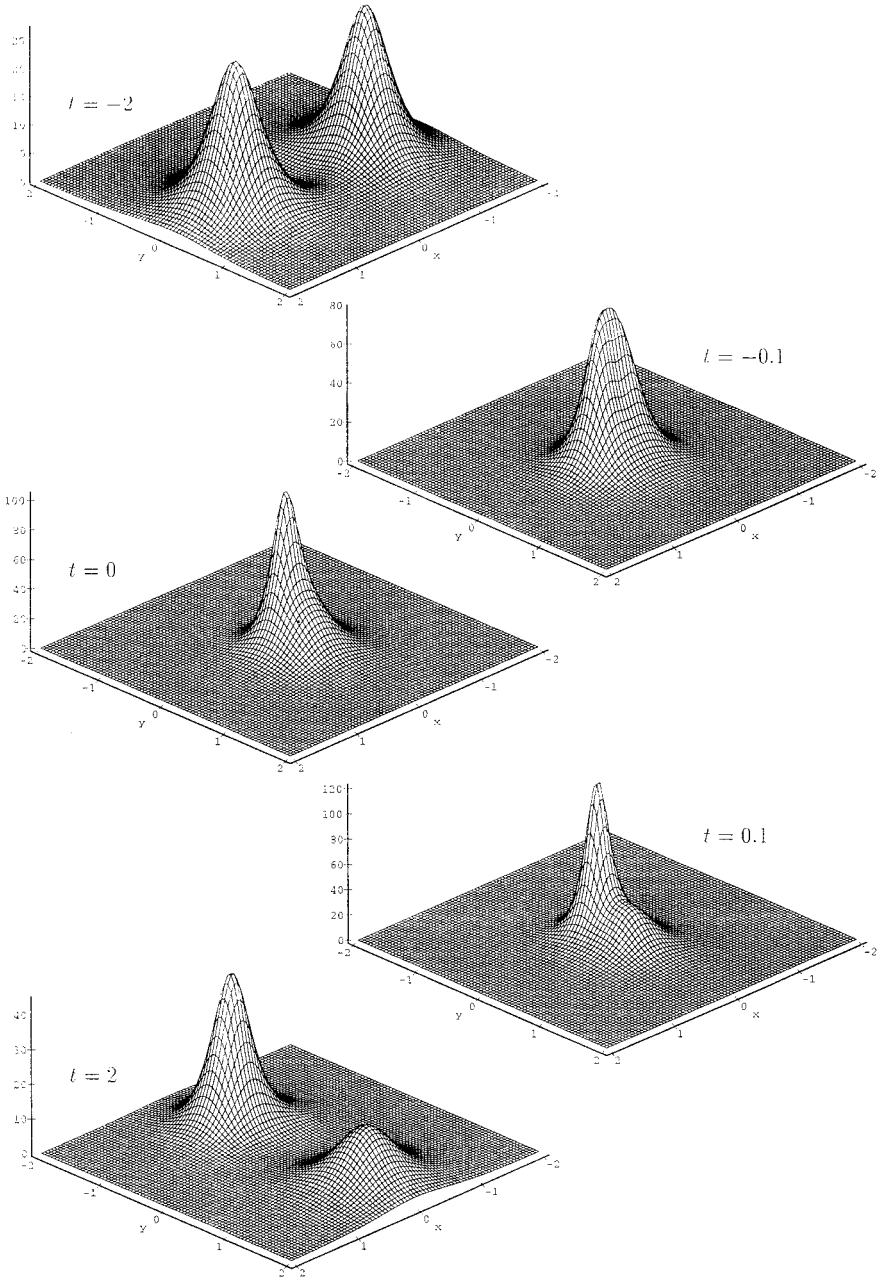

FIG. 6. Energy density at increasing times when $\psi(\lambda)$ has a triple pole (and no others).

the solution (8) with $n=2$, put $\mu_1=i+\epsilon$, $\mu_2=-i-\epsilon$, and take the limit $\epsilon\to 0$. In order for the resulting ψ to be smooth on $\mathbf{R}^{2+1}$, it is necessary to take $f_1=f(\omega_1)$, $f_2=-1/f(\omega_2)-\epsilon h(\omega_2)$, where f and h are rational functions of one variable. On taking the limit $\epsilon\to 0$, we then obtain a ψ as in (28) with $m^k=(m_1^k,m_2^k)$ being holomorphic functions of z (or $\overline{z}$), through the relations $m^1=(1,f)$, $m^2=(-f,1)$, while

$$n^1=\frac{2i(1+|f|^2)}{(1+|f|^2)^2+|w|^2}\,\overline{m^1}+\frac{2\overline{w}}{(1+|f|^2)^2+|w|^2}\,\overline{m^2},$$

$$n^2=-\frac{2w}{(1+|f|^2)^2+|w|^2}\,\overline{m^1}-\frac{2i(1+|f|^2)}{(1+|f|^2)^2+|w|^2}\,\overline{m^2}, \tag{29}$$

with

$$w\equiv\overline{hf}^2+2tf'. \tag{30}$$

So we generate a solution $J=\psi(\lambda=0)^{-1}$, which depends on the two arbitrary rational functions $f=f(z)$ and $h=h(\overline{z})$. This solution has the form

$$J=\frac{1}{(1+|f|^2)^2+|w|^2}\begin{bmatrix}|w|^2+2i(f\overline{w}+\overline{fw})-(1+|f|^2)^2 & -2i(w-f^2\overline{w})\\ -2i(\overline{w}-\overline{f}^2w) & |w|^2-2i(f\overline{w}+\overline{fw})-(1+|f|^2)^2\end{bmatrix}, \tag{31}$$

with w given by (30). In general, by taking $f(z)=z^p$ and $h(\overline{z})=\overline{z}^q$, where p is a positive integer and q is a non-negative integer; the energy, obtained by integrating (2), is $E=(2p+q)8\pi$. Roughly speaking, the solution looks like $(2p+q)$ lumps at arbitrary positions in the xy plane; which as we are going to see are a combination of solitons and antisolitons.

A topological charge may be defined for the field J (31) by exploiting the connection of it with the $O(3)$ σ-model. The unmodified chiral model [i.e., (1) with $V_\alpha=(0,0,0)$] is equivalent to the $O(4)$ σ-model[20] through the relation

$$J=I\phi_0+\mathbf{i}\boldsymbol{\sigma}\cdot\boldsymbol{\phi}, \tag{32}$$

where $\boldsymbol{\sigma}$ are the usual Pauli matrices and $(\phi_0,\boldsymbol{\phi})=(\phi_0,\phi_1,\phi_2,\phi_3)$ is a four vector of real fields that are constrained to lie on $\mathbf{S^3}$, i.e., $\phi_0^2+\boldsymbol{\phi}\cdot\boldsymbol{\phi}=1$. The only static finite energy solutions of the $O(4)$ σ- model correspond to the embedding of the $O(3)$ σ model.[21] Therefore the only static solutions of (1) are the $O(3)$ embeddings that we shall describe. This is because for the one-soliton solution (static or Lorentz boosted in the y axis) the term in (1) proportional to V_α is zero, so the system behaves like the $O(4)$ model, for which the $O(3)$ embedding is totally geodesic. [However, for time-dependent configurations, the term proportional to V_α is nonzero and will affect the evolution of the field, which will in general not lie in an $O(3)$ subspace of $O(4)$.]

To proceed further, let us mention the topological aspects of the $O(3)$ and $O(4)$ σ-models. In studying soliton-like solutions, we require that the field configuration has finite energy. This implies that the field must take the same value at all points of spatial infinity, so that space is compactified from $\mathbf{R^2}$ to $\mathbf{S^2}$. At fixed time, the field is a map from $\mathbf{S^2}$ into the target space. Now for the $O(3)$ model, the field is a map $\boldsymbol{\phi}$: $\mathbf{S^2}\to\mathbf{S^2}$, and due to the homotopy relation

$$\pi_2(\mathbf{S^2})=\mathbf{Z}, \tag{33}$$

such maps are classified by an integer winding number $\mathcal{N}$, which is a conserved topological charge. An expression for this charge is given by

$$\mathcal{N}=(8\pi)^{-1}\int \epsilon_{ij}\boldsymbol{\phi}\cdot(\partial_i\boldsymbol{\phi}\wedge\partial_j\boldsymbol{\phi})\;\; d^2x, \tag{34}$$

where $i=1,2$ with $x^i=(x,y)$.

Although, for the $O(4)$ model [the same argument is valid for (1) due to the topological aspects of the theory], the field at fixed time is a map $(\phi_0,\boldsymbol{\phi})$: $\mathbf{S^2}\to\mathbf{S^3}$ and the corresponding homotopy relation is

$$\pi_2(\mathbf{S^3})=0, \tag{35}$$

so there is no winding number. However, for soliton solutions that correspond to some initial embedding of $O(3)$ space into $O(4)$, there is a useful topological quantity, as we are going to see.

Consider the $O(4)$ configuration, which at some time corresponds to an $O(3)$ embedding, which we choose to be $\phi_0=0$ for definiteness. At this time the field is restricted to an $\mathbf{S^2}$ equator of the possible $\mathbf{S^3}$ target space. Suppose that the field never maps to the antipodal points $\{\mathscr{A}_1, \mathscr{A}_2\}=\{\phi_0=1,\ \phi_0=-1\}$ at any time, so the target space is $\mathbf{S_0^3}=\mathbf{S^3}-\{\mathscr{A}_1, \mathscr{A}_2\}$. Now $\mathbf{S_0^3}\approx\mathbf{S^2}\times\mathbf{R}$, and thus we have the homotopy relation

$$\pi_2(\mathbf{S_0^3})=\pi_2(\mathbf{S^2}\times\mathbf{R})=\pi_2(\mathbf{S^2})\oplus\pi_2(\mathbf{R})=\mathbf{Z}, \tag{36}$$

and therefore a topological winding number exists. An expression for this winding number is easy to give, since it is the winding number of the map after projection onto the chosen $\mathbf{S^2}$ equator, i.e.,

$$\mathscr{N}'=(8\pi)^{-1}\int \epsilon_{ij}\boldsymbol{\phi}'\cdot(\partial_i\boldsymbol{\phi}'\wedge\partial_j\boldsymbol{\phi}')\ d^2x, \tag{37}$$

where $\boldsymbol{\phi}'=\boldsymbol{\phi}/|\boldsymbol{\phi}|$. If the field does map to the antipodal points $\{\mathscr{A}_1, \mathscr{A}_2\}$ at some time the winding number is ill defined at this time, and if considered as a function of time $\mathscr{N}'$ will be integer valued but may suffer discontinuous jumps as the field moves through the antipodal points. In the following examples, before comparing the solution J given by (31) with the $O(3)$ embedding it is convenient to perform the transformation $J\to MJ$ with

$$M=(\sqrt{2})^{-1}\begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix}, \tag{38}$$

so that the evolution of the field remains close to the $O(3)$ embedding.

V. SOLITON–ANTISOLITON SCATTERING

Usually in the nonintegrable models, there is an attractive force between solitons of opposite topological charge. In fact, if the solitons and antisolitons are well separated, then they attract each other and eventually annihilate into a wave of pure radiation, which spreads with the velocity of light.[3,4] However, the interaction forces between solitons and antisolitons do depend on their configuration; in particular, they depend on the relative orientation between them in the internal space. Therefore, the cross section for the soliton–antisoliton elastic scattering is nonzero. (In the real world, the proton–antiproton elastic scattering is seen in a reasonable fraction of cases.) This is the first example for which there has been constructed an explicit (since the system is integrable) solution of elastic soliton–antisoliton scattering in either integrable or nonintegrable model. As a result, it provides a major link between soliton dynamics in integrable and nonintegrable systems.

The evolution is initially similar to the numerical results obtained through the connection of the integrable chiral model (1) with the $O(3)$ σ-model.[20] In particular, a soliton and an antisoliton are moving along the x axis toward each other at an accelerating rate until they merge at the origin and form a peak. Note that a peak is formed rather than a ring since the energy is mainly kinetic when a soliton and an antisoliton merge. However, rather than the peak dissipating in a wave of radiation it now reforms into two new structures that undergo 90° scattering. In general, in all head-on collisions of N moving soliton and antisoliton objects, the scattering angle is π/N degrees relative to the initial direction of motion.

Next we looked at two cases corresponding to the mixtures of solitons and antisolitons. [The configurations given by (31) when $h(\overline{z})=0$ are equivalent to the ones obtained from **(13), (14)** when $f(z)=z^p$.]

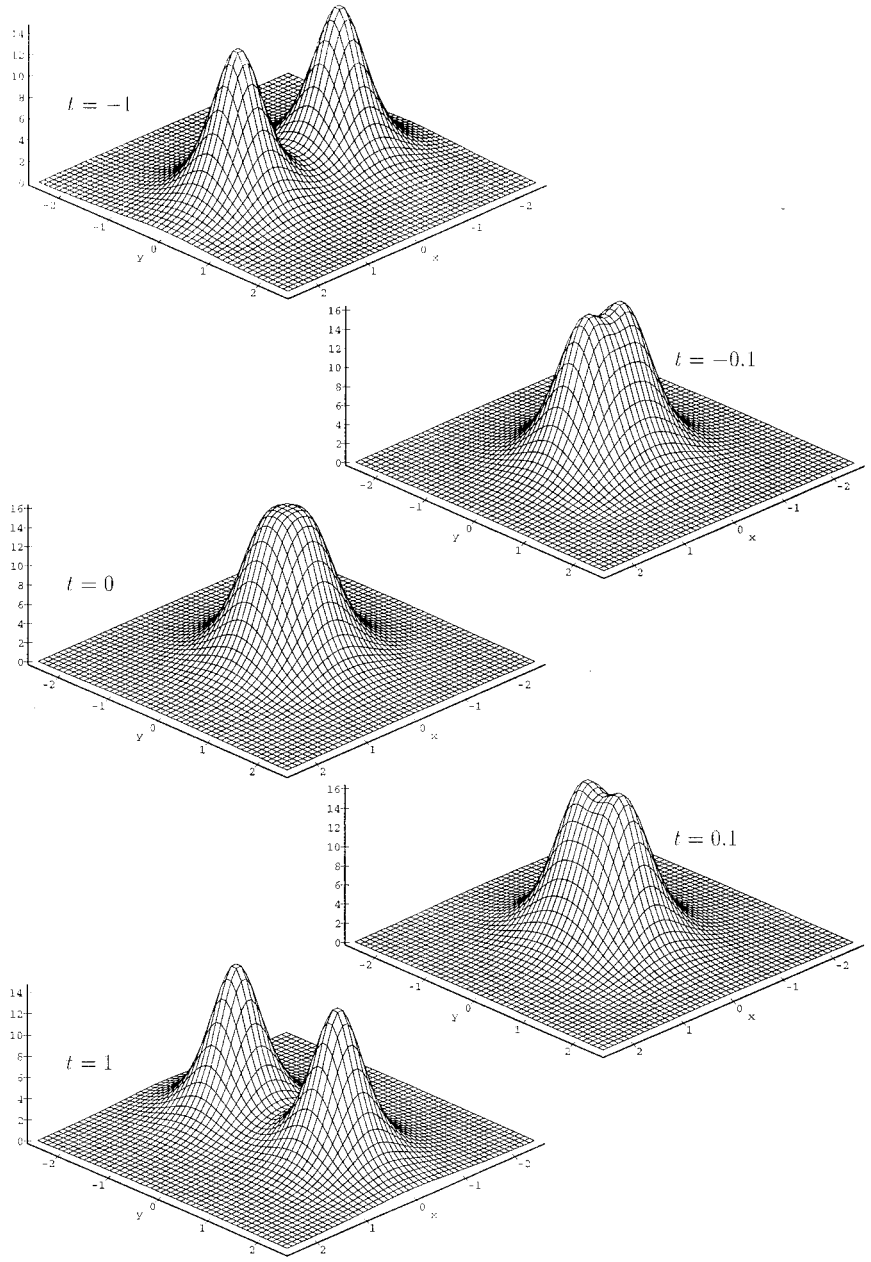

FIG. 7. Energy density at increasing times showing a 90° scattering between a soliton and an antisoliton.

• First, let us take $f(z)=z$ and $h(\overline{z})=1$. Roughly speaking, if r is large, J is close to its asymptotic value J_0, as long as $w/z^2=1+2t/z^2\approx 1$; but as z approaches $\pm\sqrt{-2t}$ then $w\to 0$, and J departs from its asymptotic value: this is where the two structures are located. More precisely, for negative t, the two objects are on the x axis, approximately at $x\approx\pm\sqrt{-2t}$; while for positive t, they are on the y axis, approximately at $y\approx\pm\sqrt{2t}$. Figure 7 illustrates what happens near $t=0$.

The picture is consistent with the properties of the energy density of the solution, which is

$$\mathscr{E}=16\,\frac{2r^4+4r^2+4t^2(1+2r^2)-4t(x^2-y^2)+1}{[2r^4+2r^2+4t(x^2-y^2)+4t^2+1]^2}. \tag{39}$$

Note the symmetry of $\mathscr{E}$ under the interchange $t\mapsto -t$, $x\rightleftharpoons y$; the time symmetry of the density confirms the lack of radiation. The corresponding localized structures are not, however, of constant size: for large (positive) t, their height is proportional to $1/t$, while their radius is proportional to $\sqrt{t}$.

The projected topological charge $\mathscr{N}'$ is zero throughout the scattering process; while the projected topological density q', i.e.,

$$\mathscr{N}'=\int q'\,dx\,dy, \tag{40}$$

has an almost identical distribution (up to a scale) to that of the energy density [see Fig. 8(a)]. Therefore, the configuration represents a soliton and an antisoliton that are clearly visible as distinct structures having, respectively, $+1$ and -1 units of topological charge concentrated in a singe lump.

Equation (1) is not Lorentz invariant and indeed is not even radially symmetric due to the presence of the vector V_a, which picks out a particular direction in space, and therefore one may expect to find different scattering behavior for more general solutions; e.g., when the soliton and the antisoliton are moving along the x axis rather that the y axis. However, this is not true since (1) is a reduction of the self-dual Yang–Mills equation in $\mathbf{R}^{2+2}$, which does have an SO(1,2) symmetry. Therefore, the SO(2) symmetry of the Yang–Mills system means that any given solution J, can, in principle, be converted to gauge fields by performing a coordinate rotation (together with a gauge transformation) and then recover the corresponding J' that will describe the same solution as J, but with a rotated coordinate system. Indeed, this is what happens by taking

$$f(z)=e^{(2i\phi)}z, \quad h(\overline{z})=1, \tag{41}$$

where ϕ is an angle in the xy-plane. This picture presents a rotated version through any angle ϕ in the xy plane of the original one (i.e., Fig. 7).

• Finally, let us take $f(z)=z$, and $h(\overline{z})=\overline{z}$. The corresponding configuration consists of one soliton and two antisolitons [see Fig. 8(b)].

It is interesting to look at the time dependence of various energies in each process. The total energy, of course, is constant and it is the spatial integral of the following energy density:

$$\mathscr{E}=8[r^8+8r^6+11r^4+4r^2-8x^5t+16ty^2(x^3+t)+8t^2+48xy^2t+2-16x^2t(x-t)+24xty^4]/$$
$$[r^6+r^4+2r^2+4t^2+4tx^3-12xy^2t+1]^2. \tag{42}$$

Obviously, the energy density $\mathscr{E}$ is symmetric under the interchange $t\mapsto -t$, $x\mapsto -x$, and $y\mapsto -y$, only. Again all three structures come together, forming a bell-like structure, and then emerge at an angle of 60° with respect to the original direction. However, by looking at the maximum of $\mathscr{E}$ we observe that, for large (positive) t, the height of the localized structures is proportional to $t^{-4/3}$, while their radius is proportional to $t^{1/3}$; thus they spread out as they move apart.

Figure 9 shows the results of a head-on collision of the one-soliton two-antisoliton system.

Let us conclude with the observation that, by taking $f(z)=z^p$ and $h(\overline{z})=\overline{z}^{\,q}$, J departs from its asymptotic value J_0 when $w=z^{p-1}(2tp+z^N)\to 0$ with $N=p+q+1$, which is true when either $z^{(p-1)}=0$ or $2tp+z^N=0$: this is approximately where the lumps are located. Therefore, J represents a family of a soliton–antisoliton solution, which consists of $(p-1)$ static soliton-like objects at the origin, with N others accelerating toward them, scattering at an angle of π/N, and then decelerating as they separate.

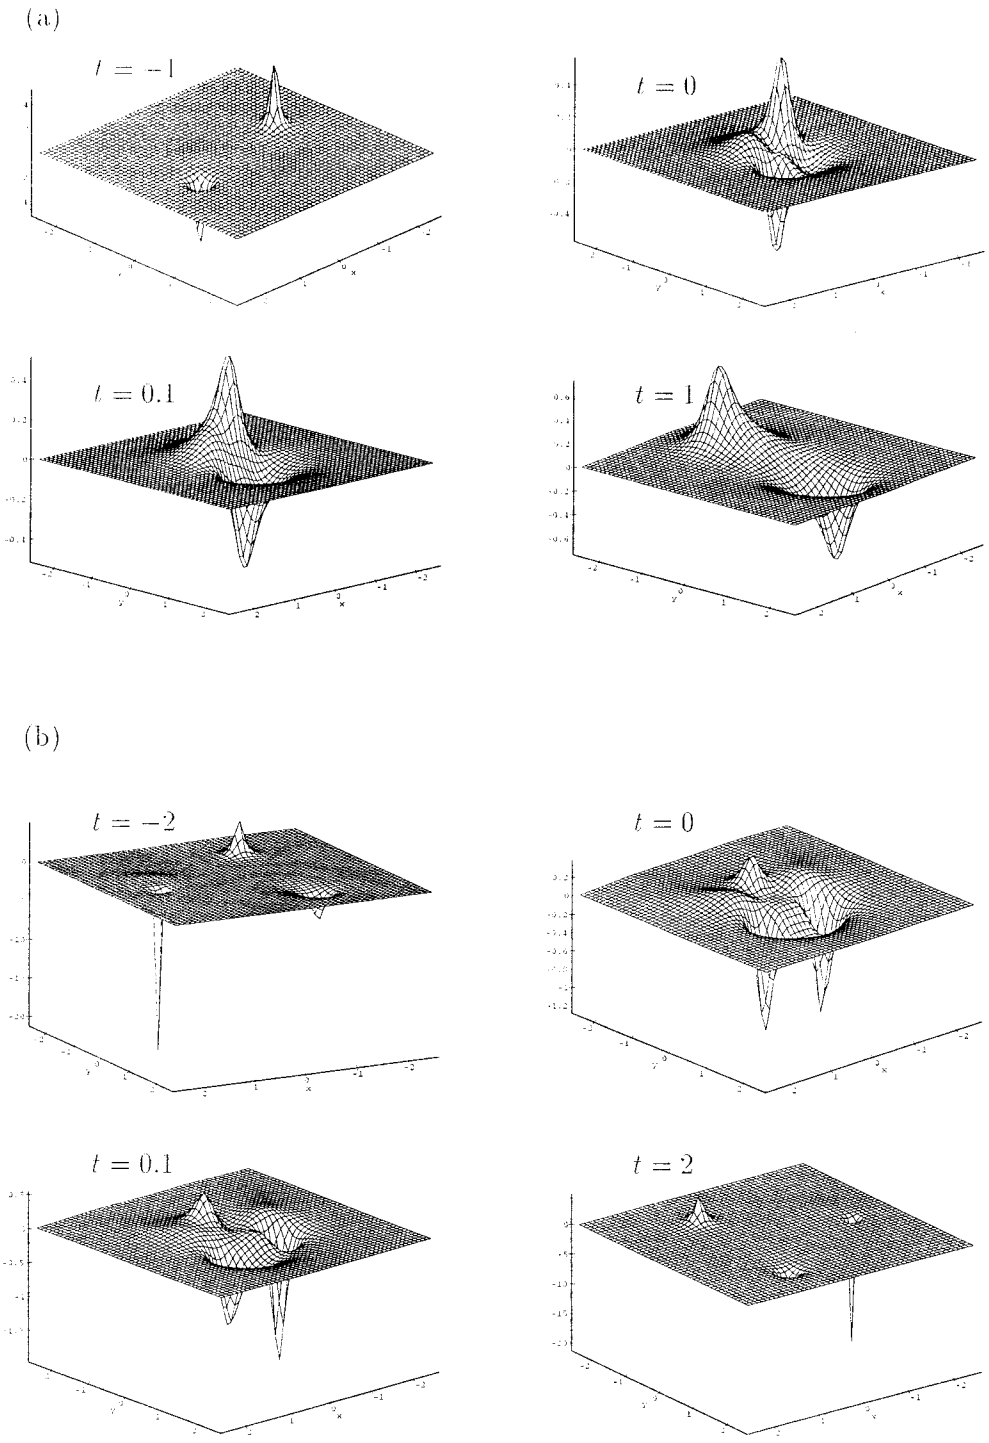

FIG. 8. Topological charge density at increasing times for (a) soliton–antisoliton scattering and (b) one-soliton two-antisoliton scattering.

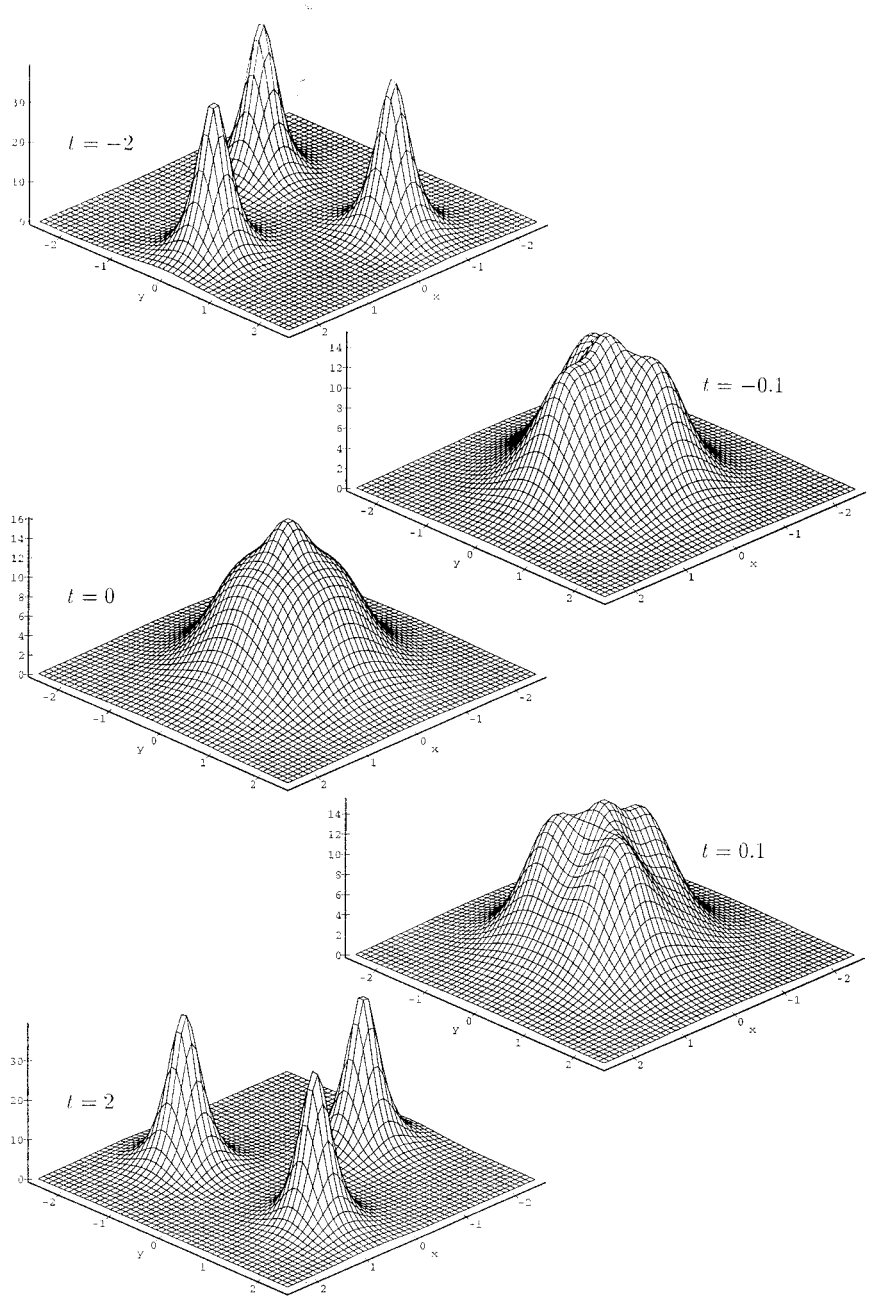

FIG. 9. Energy density of a system consisting of a soliton and two antisolitons at various times.

VI. CONCLUSION

The infinite number of conservation laws associated with a given integrable system place severe constraints upon possible soliton dynamics. The construction of exact analytic multisoliton solutions with trivial scattering properties is a result of such integrability properties. In this paper new soliton and soliton–antisoliton solutions have been obtained for the planar integrable chiral model (1). These structures travel with nonconstant velocity; their size is nonconstant; and they

interact nontrivially. Such results might be useful for connecting integrable and nonintegrable systems, which possess soliton solutions. In addition, they indicate the likely occurrence of new phenomena in higher-dimensional soliton theory that are not present in $(1+1)$ dimensions.

It seems likely that there are many more interesting solutions still to be found; an open question being what is the general form of the function ψ when it has a higher-order pole in λ. One could, for example, investigate the case $n=3$ for $\psi(\lambda)$ with a single and a double pole; and determine the scattering properties of the emerging structures, in terms of their initial velocity and of the values of the impact parameter. Finally, it would be of great interest to deduce the general form of the function $\psi(\lambda)$ for the soliton–antisoliton case (28) with the only constraint to satisfy the reality condition (5) and the requirement that the matrices $A=(L\psi)\psi^{-1}$ and $B=(M\psi)\psi^{-1}$ be independent of λ.

(Received 13 November 1995; accepted for publication 11 March 1996)

When the variational method is applied to nonlinear evolution equations for determining solitary wave dynamics, it is possible for the method to predict the pulse to be unstable when in fact it is stable. We determine the necessary conditions for this to occur as well as give sufficient conditions for avoiding such false instabilities. We also discuss the general problem of applying the method to a general evolution equation. © *1996 American Institute of Physics.* [S0022-2488(96)03406-8]

I. INTRODUCTION

In this work we determine the necessary conditions under which the Rayleigh–Ritz variational method could give rise to false instabilities when applied to the study of the dynamics of solitary waves propagating in one spatial dimension. We also give sufficient conditions in order to avoid such false instabilities.

The variational method was probably first used to study the dynamics of a solitary wave in Ref. 1. First we will briefly describe the essence of this method. Suppose one is given an evolutional partial differential equation (PDE)

$$\vec{u}_t + \vec{N}[\vec{u}] = 0, \tag{1.1}$$

where $\vec{u}(x,t) = (u_1(x,t),\ldots,u_n(x,t))^T$, $\vec{N}$ is a nonlinear operator containing derivatives with respect to the space coordinate, x, and t is the evolutional coordinate. In most cases, one is unable to obtain an exact solution of (1.1), other than the trivial solution, analytically. Then one can employ the variational method to obtain an approximate analytical solution to the equation of interest. Here we will only be concerned with the solitary wave, or pulse solutions, $\vec{u}_0(x,t)$, such that $|\vec{u}_0(x,t)|$ depends only on the single variable $\theta = (x - Vt)$, with V being constant, and $\vec{u}_0(|\theta| \to \infty) \to 0$ (the center of the pulse is at $\theta = 0$). To apply the variational method, one first takes a trial function, also called an ansatz, which is not necessarily a solution of (1.1) but still has the main characteristics of a pulse. Namely, it is usually bell-shaped (for example, a Gaussian), where its parameters can be put into correspondence with the pulse's amplitude, width, phase, etc. These parameters, called the ''variational parameters,'' are allowed to change with the time. Then one inserts the ansatz into the Lagrangian density corresponding to Eq. (1.1) and integrates it over x. The resulting function is a reduced Lagrangian, which depends explicitly on the variational parameters and possibly on the time. Finally, one uses the reduced Lagrangian to derive the Euler–Lagrange equations for the variational parameters. Thus, the study of the dynamics of the solitary pulse of the original PDE is reduced to solving a finite number of *ordinary* differential equations (ODE) and/or algebraic equations.

It is clear that the variational method is merely an optimization procedure: It allows one to determine the ''optimal'' parameters of a pulse, with the ansatz for the pulse's shape being prescribed by the researcher. The limitations of the variational method do not clearly follow from the initial assumption, as is the case with ''rigorous'' methods, such as perturbation methods.

Thus, it is the purpose of this paper to expose possible ''dangers'' which can arise in applications of the variational method as well as to show how these ''dangers'' can be avoided.

After Ref. 1, where the variational method was applied to the analysis of the dynamics of the soliton of the nonlinear Schrödinger equation (NLS), this method has been used in many other works (see, for example, Ref. 2 and references therein). It has been mostly applied to the NLS-type equations (or systems of coupled equations); its results were usually checked against a numerical solution or a solution obtained by other means, and the variational method has been found to work reasonably well. However in Ref. 3, Malomed and Tasgal reported that they had applied the variational method to the equations of the Massive Thirring Model (MTM) [see Eqs. (3.1) in Sec. III] and discovered that in a certain sector of the parameter space, the method failed to give reasonable results for any, even small, times. Namely, they took an ansatz which was a sum of the exact one-soliton solution of the MTM *plus* some small variation localized around the soliton, with this variation being of a rather general form. For some range of the soliton's parameters they found that certain components of this variation grew exponentially in time. Thus, the variational method indicated that the MTM soliton was unstable. However, since the MTM is integrable by the method of the inverse scattering transform (IST) in $1+1$ dimensions (with the ground state $u=v\equiv 0$ being stable), this is known to be untrue. In fact, our own numerical integration of Eqs. (3.1) with different near-soliton initial conditions revealed no instability. For this reason, the instability obtained in Ref. 3 can be called a ''*false* instability.''

It is of interest to understand how and why such false instabilities of a solitary wave can arise with the variational method. It is also important to determine the conditions which one needs to impose on the ansatz in order to avoid the false instability, if such occurs. Thus, let us now give a definition of stability or instability of a solitary wave, which we will use in this paper.

When one linearizes (1.1) about an exact solution, $\vec{u}_0(x,t)$, there results a linear PDE of the form:

$$\vec{\mathbf{v}}_t + L\vec{\mathbf{v}} = 0, \tag{1.2}$$

where $\vec{\mathbf{v}} = (\delta u_1, \delta u_1^*, \ldots, \delta u_n, \delta u_n^*)^T$, and the linear operator $L = (\delta \vec{N}[\vec{u}]/\delta \vec{u})|_{\vec{u}=\vec{u}_0}$. One needs to include the complex conjugates, δu_j^*, in $\vec{\mathbf{v}}$, because, in general, $\vec{N}[\vec{u}]$ may depend on $\vec{u}^*$. Letting then $\vec{\mathbf{v}}(x,t) = \vec{\mathbf{v}}(x)e^{-i\lambda t}$, one obtains from (1.2) an equation defining the eigenmode corresponding to the eigenvalue λ. These eigenmodes fall into two general classes. First, for real λ, there is a continuous spectrum, where far from the solitary wave, the modes become plane waves, $e^{ik(\lambda)x}$. Second, there is also the discrete spectrum consisting of several localized (square integrable) modes, which exist, usually, for $\lambda = 0$, and may also exist for some complex λ. The former discrete spectrum modes are the so-called ''neutral'' modes, and they correspond to the shift of the solitary wave's parameters. If in the spectrum of (1.2) there is a localized mode with $\mathrm{Im}\,\lambda > 0$, we will call both this mode and the solitary wave unstable; otherwise, they will be called stable.

Let us now state the assumptions that we make in our analysis. First, we consider a force-free motion of a solitary wave, thus all the nontrivial dynamics is due to the difference of the pulse's initial profile from the exact solution. Second, throughout the paper we assume that the form of the exact solution is known and consider only *small* (in L_2-norm) ''perturbations'' about it. Thus, expansion of such ''perturbations'' over the set of eigenmodes of (1.2) becomes relevant. In the concluding section we discuss how our analysis can be generalized if the above two assumptions are relaxed.

A general form of the ansatz representing a solution close to the exact solution $\vec{u}_0(x,t)$ is

$$\vec{u}_{\mathrm{close}}(x,t) = \vec{u}_0(x,t;\alpha_1(t),\ldots,\alpha_n(t)), \tag{1.3}$$

where one obtains $\vec{u}_0(x,t)$ upon setting all the variational parameters $\alpha_j(t)$ to zero. Without loss of generality, the α's may be taken to be real. By assumption, the α's are to be small, and then we have

$$\vec{u}_{\text{close}}(x,t)-\vec{u}_0(x,t)\approx\sum_{j=1}^{n}\alpha_j(t)\left.\frac{\partial\vec{u}}{\partial\alpha_j}\right|_{(\alpha_1,\ldots\alpha_n)=0}\equiv\sum_{j=1}^{n}\alpha_j(t)\vec{u}_{,j}(x). \tag{1.4}$$

Thus we will take the ansatz in the form:

$$\vec{u}_{\text{var}}(x,t)=\sum_{j=1}^{n}\alpha_j(t)\vec{u}_{,j}(x). \tag{1.5}$$

The quantities $\vec{u}_{,j(x)}$ will be referred to as variations. Since the α_j's are small, then the resulting Euler–Lagrange equations will be linear ODEs, with the coefficients being fixed by the choice of the variations. If this system has complex normal frequencies, it means that, according to the variational method, the solitary wave solution in question is unstable. Suppose one can prove by some means, other than the variational method, that the spectrum of the corresponding equation (1.2) does not contain eigenvalues with Im $\lambda>0$. Then we pose the following questions: (1) what is the mechanism by which the variational method can introduce a false instability for a given evolution equation? and (2) if a false instability can occur in a given problem, then how can one choose the ansatz in order to avoid the false instability?

We show that there are two mechanisms (one or the other is necessary, but neither is sufficient) by which a variational ansatz could introduce a false instability. First, any variation, $\vec{u}_{,j}(x)$, will always be some linear combination of the discrete and/or continuous modes of (1.2). Then, (1.5) requires that every mode contained in a given variation execute a common motion with the others, bound in the same variation. Consequently, we find that one mechanism by which an ansatz could introduce a *false* instability is for the variations to couple discrete modes to continuous modes. An example of this will be given later. Fortunately, this type of a false instability is easy to avoid or eliminate, as we shall see later.

The second mechanism for generating a false instability requires that a certain inner product of the continuous spectrum eigenfunctions be sign indefinite. In this case, there are two ''spaces'' of (the continuous spectrum) eigenfunctions, distinguished by the sign of that inner product. Thus, a false instability can occur via the second mechanism if a variation in the ansatz mixes the eigenfunctions from the two ''spaces.'' We remark here that the importance of having certain functionals positive definite, when studying stability of solitary wave solutions, was emphasized in a number of works.[4–6] However, in those works, no connection was established with the variational method in the form being discussed in this paper.

The rest of the paper is organized as follows. In Sec. II, we consider the case of the NLS. Here we show that if a variation couples discrete and continuous modes, then a false instability can occur via the first mechanism. However, in the case of the NLS it was shown (Ref. 7) that all the discrete spectrum modes are neutral modes, i.e., they correspond to the shifts of each of the soliton's independent parameters. Then we prove that, by allowing each and every of the soliton's parameters to vary independently of the others, one decouples the continuous and discrete spectrum modes, thereby eliminating the possibility for a false instability to occur via the first mechanism. This fact also explains why a false instability has never been found for the NLS-type equations, although the explicit decomposition of the discrete and continuous spectra was never done in the previous studies. Finally in this section we sketch a procedure by which one can construct a variational ansatz that does not contain the neutral modes. This procedure allows one to reduce the number of variational parameters in the ansatz by, naturally, exactly the number of the neutral modes.

In Sec. III, we analyze the MTM equations. Here we have an example where the continuous modes form two ''spaces.'' Therefore, a false instability for the MTM could arise via the second mechanism. This is the source of the result which Malomed and Tasgal found in Ref. 3. Conse-

quently, a simple method for avoiding false instabilities in this case would be to separate the eigenmodes belonging to the different ''spaces'' into different variations of the ansatz.

One should note that we have considered in this paper only equations integrable by the IST. This fact enabled us to completely determine the spectra of the corresponding linearized equations. In particular, we knew beforehand that there were no unstable modes. We address the general case, i.e., when the latter may be present, in the concluding section.

In Sec. IV, we show that there is a method to avoid false instabilities which could arise via the second mechanism, *without* being forced to separate the two ''spaces'' of the eigenfunctions. However, for nonlinear evolutional equations, the application of this simple method is tantamount to having the exact solution before one begins to construct a variational solution. Also in Sec. IV, we obtain a formula which elucidates the meaning of the results produced by the variational method for a particular choice of the ansatz.

In the concluding section we discuss how one can apply our approach when the exact solitary wave solution is not known, as well as what information one can glean if completeness of the corresponding set of eigenfunctions is not established. In the latter case we show that the variational method can be used to detect a *true* instability of the solitary wave. We also mention the generalization of our analysis when a solitary wave is driven by an external force.

II. THE NLS CASE

First, we consider the NLS in the following form:

$$iu_t+u_{xx}+2u|u|^2=0. \tag{2.1}$$

Its exact one-soliton solution is well known:

$$\begin{gathered} u_0(x,t|V)=A\ \text{sech}\ \theta\ \exp\left\{\frac{iV}{2A}\ \theta+i\left(A^2+\frac{V^2}{4}\right)t+i\varphi_0\right\}, \\ \theta=A(x-Vt-x_0), \end{gathered} \tag{2.2}$$

where the parameters A,V,x_0,φ_0 are constants. One can always eliminate V by the Galilean transformation, so we will take $V=0$ in what follows and denote $u_0(x,t)\equiv u_0(x,t|0)$. We still will need expression (2.2) with $V\neq 0$ later on in this section.

A variational ansatz which is usually taken to study small oscillations of the exact soliton of the NLS is the following:

$$u_{\text{var}}(x,t)=\epsilon u_0(x,t)[\,\delta\eta(t)+i\,\delta\varphi(t)+\delta A(t)\,\theta\ \tanh\ \theta+i\,\delta c(t)\,\theta^2], \tag{2.3a}$$

where $\epsilon\ll 1$; compare (2.3a) with (1.5). Here, $\delta\eta(t)$ is the variational parameter for the soliton's amplitude, $\delta\varphi(t)$—the variational parameter for its overall phase, $\delta A(t)$—the variational parameter for the width, and $\delta c(t)$ is the variational parameter for the chirp. The variations corresponding to these parameters are:

$$\begin{gathered} \delta u_{(\delta\eta)}=1\cdot u_0, \quad \delta u_{(\delta A)}=\theta\ \tanh\ \theta\cdot u_0, \\ \delta u_{(\delta\varphi)}=i\cdot u_0, \quad \delta u_{(\delta c)}=i\,\theta^2\cdot u_0. \end{gathered} \tag{2.3b}$$

Two other parameters, the coefficient of the linear phase (frequency shift) and the soliton's center coordinate are not included in (2.3) because the equations for them decouple from those for $\delta\eta,\delta\varphi,\delta A,\delta c$. At the end of this section we will show how, basing on our method, one can construct an ansatz with only *two* parameters, which, however, provides more correct description of the soliton oscillations.

The Lagrangian density for Eq. (2.1) is

$$\mathscr{L}\equiv\mathscr{L}^{\mathrm{NLS}}=\frac{i}{2}\,(u_t^*u-u^*u_t)-|u_x|^2+|u|^4. \tag{2.4}$$

With the aim in mind to study the dynamics of small variations on the background of soliton (2.2), we substitute in (2.4) $u=u_0+\delta u(x,t)$, with $|\delta u|\ll|u_0|$. Then in the main order in δu we obtain:

$$\mathscr{L}_2\equiv\mathscr{L}_2^{\mathrm{NLS}}=\tfrac{1}{2}\,\vec{\mathbf{v}}^{\dagger}\sigma_3(i\partial_t+A^2L)\vec{\mathbf{v}}, \tag{2.5}$$

where

$$\vec{\mathbf{v}}\equiv\begin{pmatrix}\mathbf{v}_1\\ \mathbf{v}_2\end{pmatrix}=\begin{pmatrix}\delta u\ e^{-iA^2t}\\ \delta u^*\ e^{iA^2t}\end{pmatrix}, \tag{2.6a}$$

$$L\equiv L^{\mathrm{NLS}}=\sigma_3(\partial_\theta^2-1)+2\,\mathrm{sech}^2\,\theta\ \ (2\sigma_3+i\sigma_2). \tag{2.6b}$$

If $u(x,t)=u_0+\delta u$ is a solution of (2.1), then the vector $\vec{\mathbf{v}}$ satisfies the equation

$$(i\partial_t+A^2L)\vec{\mathbf{v}}=0, \tag{2.7}$$

which is the linearization of (2.1) on the background of the soliton. Therefore we seek a solution of (2.7) as an expansion over the set of the eigenfunctions of the following eigenvalue problem:

$$L\vec{\mathbf{v}}=\lambda\vec{\mathbf{v}}, \tag{2.8}$$

with L given by (2.6b). The solution to this problem was given in Ref. 7 and is as follows. The basis in the class of functions which are sufficiently smooth and decay sufficiently rapidly at infinity (i.e., in the Schwartz class) is formed by the continuous spectrum of the operator L:

$$\psi_1(k)=\left[\left(1-\frac{2ike^{-\theta}}{(k+i)^2\,\cosh\,\theta}\right)\begin{pmatrix}0\\1\end{pmatrix}+\frac{1}{(k+i)^2\,\cosh^2\,\theta}\begin{pmatrix}1\\1\end{pmatrix}\right]e^{ik\theta},$$

$$\psi_2(k)=\left[\left(1+\frac{2ike^{-\theta}}{(k-i)^2\,\cosh\,\theta}\right)\begin{pmatrix}1\\0\end{pmatrix}+\frac{1}{(k-i)^2\,\cosh^2\,\theta}\begin{pmatrix}1\\1\end{pmatrix}\right]e^{-ik\theta},$$

$$\text{for real}\ \ k, \tag{2.9a}$$

such that

$$L\psi_1=(k^2+1)\psi_1,\quad L\psi_2=-(k^2+1)\psi_2; \tag{2.9b}$$

and also the discrete spectrum of L:

$$\phi_1=\begin{pmatrix}1\\-1\end{pmatrix}\mathrm{sech}\,\theta,\quad \phi_2=\begin{pmatrix}1\\1\end{pmatrix}\mathrm{sech}\,\theta\,\tanh\,\theta, \tag{2.10a}$$

where

$$L\phi_1=L\phi_2=0, \tag{2.10b}$$

and

$$\phi_1^{\mathscr{J}}=\begin{pmatrix}1\\1\end{pmatrix}(\theta\tanh\theta-1)\operatorname{sech}\theta,\quad \phi_2^{\mathscr{J}}=\begin{pmatrix}1\\-1\end{pmatrix}\theta\operatorname{sech}\theta, \tag{2.11a}$$

with

$$L\phi_j^{\mathscr{J}}=-2\phi_j,\quad j=1,2. \tag{2.11b}$$

An arbitrary two-component vector $\vec{\mathbf{w}}(\theta)=(\mathbf{w}_1,\mathbf{w}_2)^T$ from $L_2(-\infty,\infty)$ can be expanded over this basis as follows:[7]

$$\vec{\mathbf{w}}(\theta)=\int_{-\infty}^{\infty}dk(g_1(k)\psi_1(k,\theta)+g_2(k)\psi_2(k,\theta))+\sum_{j=1,2}(\beta_j\phi_j+\gamma_j\phi_j^{\mathscr{J}}), \tag{2.12}$$

where $g_j(k),\beta_j,\gamma_j$, $j=1,2$, are the scalar expansion coefficients. We note that $\phi_{1,2}^{\mathscr{J}}$, as it is seen from (2.11b), are not eigenfunctions of the operator L. They are the so-called associate, or derivative states (see Ref. 7), and are required for completeness because the operator L is not self-adjoint.

The fact that one was able to find the explicit form of the eigenfunctions of (2.8), as well as to prove the completeness of the corresponding set, has its origin in that the NLS is integrable by the IST. In general, for the operator L corresponding to an arbitrary nonlinear evolution equation, one is not able to find the eigenfunctions explicitly. However, in what follows it will be clear that for our purpose the only essential information, furnished by the IST, is that the set of eigenfunctions of L (including the associate states) forms a basis in the appropriate space of functions. The rest of the required information can be extracted from the asymptotics (for $|\theta|\to\infty$) of L. The latter does not depend on the integrability of the evolution equation under study and therefore can be found for an equation of a rather general form, with the only possible information missing being the completeness of the corresponding set of eigenfunctions. In Sec. V we will discuss how one can proceed with our approach if one does not know whether the set of eigenfunctions is complete or not.

Thus, we will come back to Eq. (2.8) and proceed as though if we did not know the explicit form of the eigenfunctions. The purpose of doing this is to demonstrate how our procedure can be applied to evolution equations, for which an exact form of the eigenfunctions is not available. To this end, let us first notice that the operator L has the following symmetry:

$$\sigma_1 L\sigma_1=-L=-L^*. \tag{2.13}$$

Let us emphasize that this symmetry exists since, from the definition of $\vec{\mathbf{v}}$, it follows that

$$\vec{\mathbf{v}}=\sigma_1\vec{\mathbf{v}}^*. \tag{2.14}$$

Consequently, if ψ is a solution of (2.8) with the eigenvalue λ, then

$$\psi_2(k)=\sigma_1\psi_1(k)^* \tag{2.15}$$

is another solution with the eigenvalue $-\lambda$. (Since L is real valued, we could have as well used $\psi_2=\sigma_1\psi_1$; we used (2.15) instead because it will be a convenient form later.) From the asymptotics of L, one finds the asymptotic form of the eigenfunctions, say, at $\theta\to-\infty$:

$$\underline{\theta\to-\infty}\quad \psi_1\to\begin{pmatrix}0\\1\end{pmatrix}e^{ik\theta},\quad \psi_2\to\begin{pmatrix}1\\0\end{pmatrix}e^{-ik\theta}. \tag{2.16}$$

Also from the asymptotics, one finds the eigenvalues corresponding to real k:

$$\lambda \equiv \lambda_{\psi_1} = k^2 + 1, \quad \lambda_{\psi_2} = -(k^2+1), \tag{2.17}$$

which is consistent with (2.9). The asymptotics of $\psi_{1,2}$ at the other end, $\theta \to +\infty$, can be obtained from the asymptotics of L only in the following general form:

$$\underline{\theta \to +\infty} \quad \psi_1 \to a(k) \begin{pmatrix} 0 \\ 1 \end{pmatrix} e^{ik\theta} + b(k) \begin{pmatrix} 0 \\ 1 \end{pmatrix} e^{-ik\theta}, \tag{2.18}$$

with some coefficients $a(k)$, $b(k)$. [Note that the first component of ψ_1 must be zero in order that the first equation of (2.9b) be satisfied.] We address the general case (2.18) in Appendix A. Below in this section we will make use of the well-known fact that the soliton (2.2) is a reflectionless potential in the corresponding scattering problem in the IST. Then it follows that in (2.18) $|a(k)| = 1$, $|b(k)| = 0$. This is of course consistent with the explicit form (2.9) of $\psi(k)$, with $a(k) = [(k-i)/(k+i)]^2$. Using this will significantly simplify the calculations. The result found in Appendix A is qualitatively the same as that of this section.

As for the discrete spectrum, this can be easily found explicitly. Let us denote $\overline{u_{(0)}} = u_0(x,t)e^{-iA^2t}$. Then, by differentiating the equation for $\overline{u_0}$, one observes that

$$\phi_1 \equiv \left(-i \frac{\partial}{\partial \varphi_0} \overline{u_0}, \ \text{c.c.} \right)^T, \quad \phi_2 \equiv \left(\frac{\partial}{\partial x_0} \overline{u_0}, \ \text{c.c.} \right)^T \tag{2.19a}$$

satisfy (2.10b), and

$$\phi_1^{\mathscr{D}} \equiv \left(\frac{\partial}{\partial A} \overline{u_0}, \ \text{c.c.} \right)^T, \quad \phi_2^{\mathscr{D}} \equiv \left(-i \frac{\partial}{\partial V} \overline{u(x,t|V)} \Big|_{V=0}, \ \text{c.c.} \right)^T \tag{2.19b}$$

satisfy (2.11b). We remark that in the last expression in (2.19b) one should set $\partial_V \theta \equiv 0$. Thus, the discrete spectrum modes correspond to the shift of the soliton's parameters.

Inserting (2.12) into (1.5), one has

$$\vec{\mathbf{v}}_{\text{var}} = \sum_{j=1}^{n} \alpha_j(t) \left\{ \int_{-\infty}^{\infty} dk [g_{1j}(k)\psi_1(k,\theta) + g_{2j}(k)\psi_2(k,\theta)] + \sum_{m=1,2} (\beta_{mj}\phi_j + \gamma_{mj}\phi_j^{\mathscr{D}}) \right\}. \tag{2.20}$$

From (2.14), (2.15), and (2.20), one finds

$$g_{2j}(k) = g_{1j}^*(k), \quad j = 1,\ldots n;$$

$$\text{Re}(\beta_{1j}) = \text{Re}(\gamma_{2j}) = 0 = \text{Im}(\beta_{2j}) = \text{Im}(\gamma_{1j}). \tag{2.21}$$

To calculate the reduced Lagrangian

$$\langle \mathscr{L}_2 \rangle \equiv \int_{-\infty}^{\infty} dx \ \mathscr{L}_2,$$

we need certain inner products between the eigenfunctions of L. These can be obtained in a standard manner from the Wronskian relation. Namely, from the equation

$$\phi^A(\lambda', \theta)L = \lambda' \phi^A(\lambda', \theta),$$

which is adjoint to (2.8), Eq. (2.8) itself, and (2.6b) one finds

$$\partial_\theta W(\phi^A(\lambda',\theta),\phi(\lambda,\theta)) \equiv \partial_\theta(\partial_\theta\phi^A(\lambda',\theta)\sigma_3\phi(\lambda,\theta) - \phi^A(\lambda',\theta)\sigma_3\partial_\theta\phi(\lambda,\theta))$$
$$= (\lambda'-\lambda)\phi^A(\lambda',\theta)\phi(\lambda,\theta), \tag{2.22}$$

where $\phi(\lambda,\theta)$ is a solution of (2.8). From the explicit form of L it follows that one can choose

$$\phi^A(\lambda,\theta) = \phi^\dagger(\lambda,\theta)\sigma_3. \tag{2.23}$$

Then from (2.22)–(2.23), (2.16)–(2.17), and (2.10)–(2.11), one obtains that the only nonzero inner products between the eigenfunctions of L are the following ones:

$$\langle\psi_1^\dagger(k')|\sigma_3|\psi_1(k)\rangle = -\langle\psi_2^\dagger(k')|\sigma_3|\psi_2(k)\rangle = -2\pi\delta(k-k'), \tag{2.24a}$$

$$\langle\phi_1^\dagger|\sigma_3|\phi_1^{\mathscr{S}}\rangle = -\langle\phi_2^\dagger|\sigma_3|\phi_2^{\mathscr{S}}\rangle = -2, \tag{2.24b}$$

where

$$\langle\psi_1^\dagger(k')|\sigma_3|\psi_1(k)\rangle = \int_{-\infty}^{\infty} d\theta\ \psi_1^\dagger(k',\theta)\sigma_3\psi_1(k,\theta),$$

etc. Using (2.5), (2.20), (2.24), and (2.21), one finds

$$\langle\mathscr{S}_2\rangle = \sum_{j,l=1}^{n}\{i\alpha_l\dot{\alpha}_j(\langle g_{1j}|g_{1l}\rangle - \langle g_{1l}|g_{1j}\rangle) - \alpha_l\alpha_j A^2(\langle g_{1j}|\lambda|g_{1l}\rangle + \langle g_{1l}|\lambda|g_{1j}\rangle)$$
$$+ i\alpha_l\dot{\alpha}_j(\beta_{1l}\gamma_{1j} - \beta_{1j}\gamma_{1l} + \beta_{2l}\gamma_{2j} - \beta_{2j}\gamma_{2l}) + 2\alpha_l\alpha_j A^2(\gamma_{1l}\gamma_{1j} + \gamma_{2l}\gamma_{2j})\}, \tag{2.25}$$

where now

$$\langle f|h\rangle = \pi\int_{-\infty}^{\infty} dk\ f^*(k)h(k), \quad \langle f|m|h\rangle = \pi\int_{-\infty}^{\infty} dk\ f^*(k)m(k)h(k).$$

From (2.25) one sees that the variations in the ansatz can be chosen so that to decouple the discrete and continuous modes of the operator L in the reduced Lagrangian. This is analogous to the well-known fact that the evolutions of the discrete and continuous scattering data in the framework of the IST are decoupled in the first-order perturbation theory. If the decomposition of the two parts of the spectrum is achieved in (2.25), then the reduced Lagrangian splits into two parts, with one corresponding to the continuous spectrum and the other, to the discrete spectrum. The latter part [which has all $g_{1j}(k)=0$, $j=1,\ldots n$] yields trivial evolution of its parameters: All the time derivatives are either zero or constant in time. Indeed, this second part of the reduced Lagrangian is due to the variations composed entirely from the neutral modes, which correspond to the shift of the soliton's parameters, see (2.19). But it is obvious that in the absence of a driving force, which is the case we consider, one can ''zero out'' the trivial dynamics of the soliton's parameters by re-adjusting the parameters of the background solution $u_0(x,t)$. In other words, by properly choosing the background solution $u_0(x,t)$, one can set $\beta_{mj}=\gamma_{mj}=0$, $j=1,\ldots n$, $m=1,2$.

Considering then only the continuous spectrum part in (2.25) and letting $\alpha_j(t)=\overline{\alpha_j}e^{i\omega t}$, $j=1,\ldots N$, with $\overline{\alpha_j}$'s being independent of t, we arrive at the following set of Euler–Lagrange equations:

$$\sum_{j=1}^{n}\overline{\alpha_j}\{2\omega(\langle g_{1j}|g_{1l}\rangle - \langle g_{1l}|g_{1j}\rangle) + A^2(\langle g_{1j}|\lambda|g_{1l}\rangle + \langle g_{1l}|\lambda|g_{1j}\rangle)\} = 0, \tag{2.26}$$

for $l=1,\ldots n$. In a matrix form, this reads as follows:

$$(M+\omega N)\vec{\alpha}=0, \tag{2.27}$$

where $\vec{\alpha}=(\overline{\alpha_1},\ldots\overline{\alpha_n})^T$ and M and N are Hermitian matrices (see below). It is known (see, e.g., Ref. 8 and Secs. 10.5 and 10.8 of Ref. 9) that if either M or N is sign definite, then all the ω's are real valued. If neither M or N is sign definite, then one cannot determine whether ω's are real or complex valued. In our case, N is clearly not sign definite since it is Hermitian and antisymmetric. However, the matrix M with the entries

$$M_{jl}=(\langle g_{1j}|\lambda|g_{1l}\rangle+\langle g_{1l}|\lambda|g_{1j}\rangle) \tag{2.28}$$

is the Gram matrix (see, e.g., Sec. 9.5 of Ref. 9) and thus is positive definite, provided that all the functions $g_{1j}(k)$, $j=1,\ldots n$ are linearly independent (cf. Ref. 10). The standard proof of this fact goes as follows. For n arbitrary complex numbers c_i, define $\vec{\mathbf{x}}=(c_1 g_{11}(k),\ldots c_n g_{1n}(k))^T$, $\vec{\mathbf{y}}=(c_1^* g_{11}(k),\ldots c_n^* g_{1n}(k))^T$, $\vec{\mathbf{c}}=(c_1,\ldots c_n)^T$, and then consider

$$\vec{\mathbf{c}}^\dagger M\vec{\mathbf{c}}=\sum_{lj} c_l c_j^*(\langle g_{1j}|\lambda|g_{1l}\rangle+\langle g_{1l}|\lambda|g_{1j}\rangle)=\left\|\sum_{j=1}^{n}\mathbf{x}_j\sqrt{\lambda}\right\|^2+\left\|\sum_{j=1}^{n}\mathbf{y}_j\sqrt{\lambda}\right\|^2, \tag{2.29}$$

which is positive if $g_{1j}(k)$, $j=1,\ldots n$ are linearly independent. Hence M is positive definite. Thus, we have proved that if the ansatz for the NLS does not contain components of the discrete spectrum (or decouples them from the continuous spectrum), then a false instability can never occur.

We will shortly present an example showing how one can construct an ansatz not containing the discrete spectrum. But at this moment, let us note that one can effectively achieve the decomposition by simply allowing *each* of the soliton parameters to vary, even if the variations in the ansatz mix the components of the discrete and continuous spectra. Let us consider a variational ansatz of the form

$$\vec{\mathbf{v}}_{\text{var}}=[\text{r.h.s. of (2.20)}]+\nu_1(t)i\phi_1(\theta)+\nu_2(t)\phi_2(\theta)+\mu_1(t)\phi_1^{\mathscr{D}}(\theta)+\mu_2(t)i\phi_2^{\mathscr{D}}(\theta), \tag{2.30}$$

where $\nu_{1,2}$ and $\mu_{1,2}$ are real [see (2.21)]. Thus, we have allowed each of the soliton parameters to vary independently of each other and of the continuous modes. Note that variations corresponding to variational parameters α_j's still may contain the components of the discrete spectrum. Then the reduced Lagrangian can be shown, after some straightforward algebra, to be of the form:

$$\begin{aligned}\langle\mathscr{L}_2\rangle-&[\text{r.h.s. of (2.25) with all } \beta_{mj}=\gamma_{mj}=0]\\ &=2A^2(\mu_1+\langle\alpha|\gamma_1\rangle)^2+2A^2(i\mu_2+\langle\alpha|\gamma_2\rangle)^2+2\dot{\nu}_1(\mu_1+\langle\alpha|\gamma_1\rangle)\\ &\quad-2i\dot{\nu}_2(i\mu_2+\langle\alpha|\gamma_2\rangle)-2i\langle\dot{\alpha}|\beta_1\rangle(\mu_1+\langle\alpha|\gamma_1\rangle)-2i\langle\dot{\alpha}|\beta_2\rangle(i\mu_2+\langle\alpha|\gamma_2\rangle).\end{aligned} \tag{2.31}$$

In Eq. (2.31) and Eq. (2.32) below we use the bracket notations as follows:

$$\langle\alpha|\gamma_1\rangle\equiv\sum_{j=1}^{n}\alpha_j(t)\gamma_{1j},$$

etc. From (2.31) one sees that $\nu_{1,2}$ are cyclic coordinates, so the corresponding momenta are constants of the motion, and then

$$\dot{\mu}_1+\langle\dot{\alpha}|\gamma_1\rangle=0,\quad i\dot{\mu}_2+\langle\dot{\alpha}|\gamma_2\rangle=0. \tag{2.32}$$

Then the first two terms on the r.h.s. of (2.31) are constants while the others are total time derivatives. Thus the reduced Lagrangian (2.31), calculated for the ansatz (2.30), is equivalent to one calculated without the contribution from the discrete spectrum.

It is clear that mixing components of the discrete and continuous spectra, without allowing the soliton parameters to vary independently, is only a *necessary* condition for the ansatz to produce a false instability. A false instability can be expected to occur if the coupling between the discrete and continuous spectra in the ansatz is, in a certain sense, strong enough. Below we present an example of such an ansatz:

$$u(x,t)=u_0\cdot[\,\delta\eta(t)+\delta\varphi(t)\,\theta+i\,\delta\varphi(t)\,]. \tag{2.33}$$

The corresponding Euler–Lagrange equations for $\delta\eta(t),\delta\varphi(t)$ reveal oscillations with $\omega^2=-(28/9-8\pi^2/27)A^4<0$, which are therefore unstable.

To conclude this section, we will demonstrate how one can construct an ansatz which does not contain the neutral modes. Let us take ansatz (2.3a) as a starting point. By calculating the inner products, defined by formulae (2.24), of its variations (2.3b) with the discrete spectrum (2.10), (2.11) and inspecting them, one finds that the following combinations:

$$\begin{aligned}
&\vec{\mathbf{v}}_{(\delta\eta)}-\vec{\mathbf{v}}_{(\delta A)}\equiv W_1=(1-2\,\theta\,\tanh\,\theta)\operatorname{sech}\,\theta\,\begin{pmatrix}1\\1\end{pmatrix},\\
&\vec{\mathbf{v}}_{(\delta\varphi)}+\frac{12}{\pi^2}\,\vec{\mathbf{v}}_{(\delta c)}\equiv W_2=i\left(1+\frac{12}{\pi^2}\,\theta^2\right)\operatorname{sech}\,\theta\,\begin{pmatrix}1\\-1\end{pmatrix},
\end{aligned} \tag{2.34}$$

are orthogonal (with weight function σ_3) to the discrete spectrum. Thus, the ansatz

$$u(x,t)=u_0\cdot\left[\,\alpha_1(t)(1-2\,\theta\,\tanh\,\theta)+i\,\alpha_2(t)\left(1+\frac{12}{\pi^2}\,\theta^2\right)\right] \tag{2.35}$$

does not contain the neutral modes. This ansatz has only two variational parameters instead of four in ansatz (2.3a). Still, using (2.35) one can match any initial condition allowed by ansatz (2.3a), if one adjusts the background soliton's parameters properly. To see this, it is enough to notice that

$$\begin{aligned}
&\vec{\mathbf{v}}_{(\delta\eta)}=-W_1-2\,\phi_1^{\mathscr{D}},\quad \vec{\mathbf{v}}_{(\delta\varphi)}=i\,\phi_1,\\
&\vec{\mathbf{v}}_{(\delta A)}=-W_1-\phi_1^{\mathscr{D}},\quad \vec{\mathbf{v}}_{(\delta c)}=\frac{\pi^2}{12}\,(W_2-i\,\phi_1).
\end{aligned} \tag{2.36}$$

Finally, we note that the results produced by (2.3a) and (2.36) are equivalent, which is in agreement with the result proven above for the ansatz of the form (2.30); here $\mu_1=(\delta A-\delta\eta)$, $\nu_1=\delta\varphi$, $\mu_2=\nu_2=0$.

In summary, in this section we have shown that in order to guarantee that the ansatz will not give a false instability for the NLS, it is sufficient to require that the discrete and continuous spectrum modes be decoupled in the ansatz.

III. THE MTM CASE

The considerations in this section are very similar to those in the previous one, so we present here only the most necessary details. We consider the equations of the MTM in the laboratory coordinates:

$$i(u_x+u_t)+v+|v|^2u=0,\quad i(-v_x+v_t)+u+|u|^2v=0. \tag{3.1}$$

Its one-soliton solution is given by[11]:

$$u_0(x,t|V)=\left(\frac{1+V}{1-V}\right)^{1/4}\sin Q\ \mathrm{sech}\left(\theta\sin Q-\frac{iQ}{2}\right)\cdot\exp\{-it\sqrt{1-V^2}\cos Q+iV\theta\cos Q+i\varphi_0\},$$

$$v_0(x,t|V)=-\left(\frac{1-V}{1+V}\right)^{1/4}\sin Q\ \mathrm{sech}\left(\theta\sin Q+\frac{iQ}{2}\right)\cdot\exp\{-it\sqrt{1-V^2}\cos Q+iV\theta\cos Q+i\varphi_0\}, \tag{3.2}$$

where $\theta=(x-x_0-Vt)/\sqrt{1-V^2}$, x_0, φ_0 are arbitrary constants, and the constants Q and V satisfy: $0<Q<\pi$, $-1<V<1$. Equations (3.1) are Lorentz-invariant, so one can consider only the solution with $V=0$, which we will denote as $u_0(x,t)$, $v_0(x,t)$.

The Lagrangian density for Eqs. (3.1) is

$$\mathscr{L}\equiv\mathscr{L}^{\mathrm{MTM}}=\frac{i}{2}\left[(u^*u_t+u^*u_x+v^*v_t-v^*v_x)-\mathrm{c.c.}\right]+(u^*v+v^*u)+|u|^2|v|^2. \tag{3.3}$$

We substitute into (3.3) $u=u_0+\delta u$, $v=v_0+\delta v$ with $|\delta u|\ll|u_0|$, $|\delta v|\ll|v_0|$, and find

$$\mathscr{L}_2\equiv\mathscr{L}_2^{\mathrm{MTM}}=\frac{1}{2}\,\vec{\mathbf{w}}^{\dagger}\begin{pmatrix}\sigma_3 & 0\\ 0 & \sigma_3\end{pmatrix}(i\partial_t+L)\vec{\mathbf{w}}, \tag{3.4a}$$

where

$$\vec{\mathbf{w}}=\begin{pmatrix}\delta u\ e^{it\cos Q}\\ \delta u^*\ e^{-it\cos Q}\\ \delta v\ e^{it\cos Q}\\ \delta v^*\ e^{-it\cos Q}\end{pmatrix}. \tag{3.4b}$$

In (3.4a),

$$L\equiv L^{\mathrm{MTM}}=i\begin{pmatrix}I_2 & 0\\ 0 & -I_2\end{pmatrix}\frac{\partial}{\partial\theta}+\begin{pmatrix}\cos Q+|u_0|^2 & 0 & 1+\overline{u_0v_0^*} & \overline{u_0v_0}\\ 0 & -(\cos Q+|u_0|^2) & -\overline{u_0^*v_0^*} & -(1+\overline{u_0^*v_0})\\ 1+\overline{u_0^*v_0} & \overline{u_0v_0} & \cos Q+|u_0|^2 & 0\\ -\overline{u_0^*v_0^*} & -(1+\overline{u_0v_0^*}) & 0 & -(\cos Q+|u_0|^2)\end{pmatrix}, \tag{3.5}$$

where $\overline{u_0}=u\exp(it\cos Q)$, $\overline{v_0}=v\exp(it\cos Q)$. If the pair (u_0,v_0) is a solution of (3.1), then the vector $\vec{\mathbf{w}}$ satisfies the equation:

$$(i\partial_t+L)\vec{\mathbf{w}}=0, \tag{3.6}$$

which is the linearization of (3.1) on the background of the soliton (3.2). Then we have to consider the eigenvalue problem

$$L\vec{\mathbf{w}}=\lambda\vec{\mathbf{w}}, \tag{3.7}$$

with L given by (3.5). Its solution was found by the present authors in Ref. 12. Here, however, we will proceed by using the asymptotic form of L and the corresponding eigenfunctions, with the reason being the same as in Sec. II. The only result from Ref. 12 which we will use here will be the completeness of a certain set of the eigenfunctions of (3.7). In Appendix B we present the explicit form of these eigenfunctions, found in Ref. 12.

Equation (3.7) has four linearly independent solutions with the following asymptotics, say, at $\theta\to-\infty$:

$$\underline{\theta\to-\infty}\quad \psi_1\to\begin{pmatrix}1\\0\\r(k)\\0\end{pmatrix}e^{ik\theta},\quad \psi_2\to\begin{pmatrix}0\\1\\0\\r(k)\end{pmatrix}e^{-ik\theta},$$
$$\psi_3\to\begin{pmatrix}1\\0\\-r(-k)\\0\end{pmatrix}e^{ik\theta},\quad \psi_4\to\begin{pmatrix}0\\1\\0\\-r(-k)\end{pmatrix}e^{-ik\theta}, \tag{3.8}$$

for real k, where

$$r(k)=k+\sqrt{k^2+1}. \tag{3.9}$$

Also from the asymptotic form of L, one finds that

$$L\psi_1=\lambda(k)\psi_1,\quad L\psi_2=-\lambda(k)\psi_2,\quad L\psi_3=\mu(k)\psi_3,\quad L\psi_4=-\mu(k)\psi_4, \tag{3.10a}$$

with

$$\lambda(k)=\cos Q+\sqrt{k^2+1},\quad \mu(k)=\cos Q-\sqrt{k^2+1}. \tag{3.10b}$$

In complete analogy with (2.13)–(2.15), one obtains

$$\begin{pmatrix}\sigma_1&0\\0&\sigma_1\end{pmatrix}L\begin{pmatrix}\sigma_1&0\\0&\sigma_1\end{pmatrix}=-L^*, \tag{3.11}$$

$$\psi_2(k,\theta)=\begin{pmatrix}\sigma_1&0\\0&\sigma_1\end{pmatrix}\psi_1^*(k,\theta),\quad \psi_4(k,\theta)=\begin{pmatrix}\sigma_1&0\\0&\sigma_1\end{pmatrix}\psi_3^*(k,\theta). \tag{3.12}$$

Notice that no involution can be established between ψ_1 and ψ_3.

Considering the asymptotics allows one only to obtain the general form of the eigenfunctions at $\theta\to+\infty$ [cf. (2.18)]. Here, as in the case of the NLS, we will make use of the fact that soliton (3.2) is the reflectionless potential in the corresponding scattering problem. This allows one to state that

$$\underline{\text{for }\ \theta\to+\infty}\quad \psi_1\to a(k)\begin{pmatrix}1\\0\\r(k)\\0\end{pmatrix}e^{ik\theta},\quad \psi_3\to\tilde{a}(k)\begin{pmatrix}1\\0\\-r(-k)\\0\end{pmatrix}e^{ik\theta}, \tag{3.13}$$

with $|a(k)|=|\tilde{a}(k)|=1$ for real k, and the asymptotics of ψ_2, ψ_4 at $\theta\to+\infty$ are then found from (3.12).

In Sec. II it was explained how the neutral modes of L can be found. So here we will only state that these modes, together with the set $\{\psi_i(k)\}_{i=1,\ldots,4}$ for all real k, form a basis in the space of four-component vector functions with entries from the Schwartz class; see Appendix B for details. Now, as was also discussed in Sec. II, the contributions from the continuous and discrete spectra of L can be decoupled in the averaged Lagrangian, with it being possible to effectively ''zero out'' the contribution of the discrete spectrum. Thus, below we will only consider the variations which do not contain the discrete spectrum components. Then, similarly to (2.20), any ansatz with smooth entries can be represented as follows:

$$\vec{\mathbf{w}}(\theta)=\sum_{j=1}^{n}\alpha_j\int_{-\infty}^{\infty}dk\sum_{m=1}^{4}g_{mj}(k)\psi_m(k,\theta). \tag{3.14}$$

From (3.14) and (3.12) one obtains an analog of (2.21):

$$g_{2j}(k)=g_{1j}^{*}(k),\quad g_{4j}(k)=g_{3j}^{*}(k),\quad j=1,\ldots n. \tag{3.15}$$

However, there is no relation between $g_{1j}(k)$ and $g_{3j}(k)$ because, as mentioned earlier, no involution exists between ψ_1 and ψ_3.

Using the same technique as for the NLS, we obtain the following inner products (defined in the x space):

$$\begin{aligned}
&\langle\psi_1^{\dagger}(k')|\begin{pmatrix}\sigma_3 & 0\\ 0 & \sigma_3\end{pmatrix}|\psi_1(k)\rangle=4\pi\sqrt{k^2+1}(\sqrt{k^2+1}+k)\,\delta(k-k'),\\
&\langle\psi_2^{\dagger}(k')|\begin{pmatrix}\sigma_3 & 0\\ 0 & \sigma_3\end{pmatrix}|\psi_2(k)\rangle=-4\pi\sqrt{k^2+1}(\sqrt{k^2+1}+k)\,\delta(k-k'),\\
&\langle\psi_3^{\dagger}(k')|\begin{pmatrix}\sigma_3 & 0\\ 0 & \sigma_3\end{pmatrix}|\psi_3(k)\rangle=4\pi\sqrt{k^2+1}(\sqrt{k^2+1}-k)\,\delta(k-k'),\\
&\langle\psi_4^{\dagger}(k')|\begin{pmatrix}\sigma_3 & 0\\ 0 & \sigma_3\end{pmatrix}|\psi_4(k)\rangle=-4\pi\sqrt{k^2+1}(\sqrt{k^2+1}-k)\,\delta(k-k').
\end{aligned} \tag{3.16}$$

Let us note that the eigenfunctions $\{\psi_i(k)\}_{i=1,\ldots,4}$ can be divided into two ''spaces,'' $S^{+}=\{\psi_1(k),\psi_2(k)\}$ and $S^{-}=\{\psi_3(k),\psi_4(k)\}$, depending on the sign of the following inner product:

$$\langle\psi^{\dagger}(k')|\begin{pmatrix}\sigma_3 & 0\\ 0 & \sigma_3\end{pmatrix}L|\psi(k)\rangle; \tag{3.17}$$

(we consider the δ function to be positive). Also notice that in the case of Eq. (2.1), there is only one ''space.''

Inserting (3.14) into (3.4a) and using (3.10), (3.15), and (3.16), one obtains the reduced Lagrangian for Eqs. (3.1):

$$\begin{aligned}
\langle\mathscr{L}_2\rangle=\sum_{jl}\{&i\alpha_l\dot{\alpha}_j(\langle h_l|h_j\rangle-\langle h_j|h_l\rangle+\langle\tilde{h}_l|\tilde{h}_j\rangle-\langle\tilde{h}_j|\tilde{h}_l\rangle)\\
&+\alpha_l\alpha_j(\langle h_j|\lambda|h_l\rangle+\langle h_l|\lambda|h_j\rangle+\langle\tilde{h}_l|\mu|\tilde{h}_j\rangle+\langle\tilde{h}_j|\mu|\tilde{h}_l\rangle)\},
\end{aligned} \tag{3.18}$$

where

$$h_j = g_{1j}(k)\sqrt{2(k^2+1+k\sqrt{k^2+1})},$$

$$\tilde{h}_j = g_{3j}(k)\sqrt{2(k^2+1-k\sqrt{k^2+1})}.$$

The corresponding Euler–Lagrange equations for $\overline{\alpha_j} = \alpha_j e^{-i\omega t}$, $j=1,\ldots n$, have the following matrix form [compare with (2.27)]:

$$((M_1 - M_2) + \omega(N_1 + N_2))\vec{\alpha} = 0, \tag{3.19}$$

where

$$(M_1)_{lj} = \langle h_j|\lambda|h_l\rangle + \langle h_l|\lambda|h_j\rangle, \quad (M_2)_{lj} = \langle h_j||\mu||\tilde{h}_l\rangle + \langle \tilde{h}_l||\mu||\tilde{h}_j\rangle,$$

$$(N_1)_{lj} = 2(\langle h_l|h_j\rangle - \langle h_j|h_l\rangle), \quad (N_2)_{lj} = 2(\langle \tilde{h}_l|\tilde{h}_j\rangle - \langle \tilde{h}_j|\tilde{h}_l\rangle).$$

In the expression for $(M_2)_{lj}$ we wrote $|\mu|$ in order to stress that $\mu(k)$ is always negative, while $\lambda(k)$ is always positive. The matrix $N = N_1 + N_2$ is, as for the NLS, not sign definite. M_1 and M_2 separately are positive definite, but $M = M_1 - M_2$ is not sign definite since the entries of M_1 are not related to those of M_2 [see the note (3.15)]. Therefore, the normal frequencies ω in (3.19) could be real or complex. One can show that, because N is Hermitian and anti-symmetric, the corresponding characteristic polynomial contains only even powers of ω. So, if there is a normal frequency ω with Im $\omega > 0$, then there necessarily is another normal frequency $(-\omega)$ with Im $(-\omega) < 0$. Thus the variational method could (incorrectly) predict that the soliton solution of the MTM equations is unstable. Thus, we conclude that if the ansatz for Eqs. (3.1) ''mixes'' the components corresponding to the two sets S^+ and S^-, then it may produce a false instability.

Let us remark that the ansatz used in Ref. 3 *did* contain components of the discrete spectrum, so the instability found there could be due to that reason. However, we performed the calculations with a similar ansatz from which the discrete spectrum was excluded, and we still found an instability setting in for $Q \approx 1$ [see (3.2)], which is close to the result of Ref. 3. Therefore we conclude that the instability found in Ref. 3 can be attributed to ''mixing of the spaces'' S^+ and S^-.

One would like to have some methods for choosing the variational ansatz so as to avoid such false instabilities. One simple way which would guarantee that the frequencies ω produced by the variational method would always be real would be to choose the ansatz in such a form so as to have: $h_j(k) \cdot \tilde{h}_j(k) = 0$, $j = 1,\ldots n$. Then all variations would be expandable over either the set S^+ or S^-, but not the whole set $S = \{\psi_1(k), \psi_2(k), \psi_3(k), \psi_4(k)\}$. In this case, Eq. (3.19) would decompose into two equations:

$$(M^{\pm} + \omega N^{\pm})\vec{\alpha}^{\pm} = 0, \tag{3.20}$$

where $M^{\pm} = \pm M_{1,2}$, $N^{\pm} = N_{1,2}$. Then one would be able to guarantee that the corresponding ω's would be real valued, and thus false instabilities will not occur.

Let us then observe that when the soliton parameter $Q \ll 1$, and the variations are expanded mainly over the eigenmodes with $|k| \ll 1$, it is possible to construct variations which *almost* entirely consist of the eigenfunctions from only one of the spaces. First, notice that these two limits, $Q \ll 1$ and $|k| \ll 1$, are compatible in the following sense: a soliton with $Q \ll 1$ has a large width, and the corresponding variations, whose scale is usually taken to be of the same order of magnitude as that of the soliton, are expandable mostly over the eigenmodes with $|k| \ll 1$. Next, from (3.4b) one has:

$$\delta u = \int_{-\infty}^{\infty} dk (g_1(k)\psi_1^{(1)}(k,\theta) + g_3(k)\psi_3^{(1)}(k,\theta)),$$

$$\delta v = \int_{-\infty}^{\infty} dk (g_1(k)\psi_1^{(3)}(k,\theta) + g_3(k)\psi_3^{(3)}(k,\theta)),$$

where $\psi_{1,3}^{(j)}$ is the jth entry of $\psi_{1,3}(k,\theta)$. But from (3.5) and (3.8) one can see that for $Q \ll 1$, $|k| \ll 1$, the ratios $\psi_1^{(3)}(k,\theta)/\psi_1^{(1)}(k,\theta)$ and $\psi_3^{(3)}(k,\theta)/\psi_3^{(1)}(k,\theta)$ are approximately $+1$ and -1, respectively. Then, taking the variations in the ansatz to be either symmetric ($\delta u = \delta v$, $g_3(k) \approx 0$) or anti-symmetric ($\delta u = -\delta v$, $g_1(k) \approx 0$), one can, in the considered limit, attain approximate decoupling of S^+ and S^- and thus avoid false instabilities more easily than by simply using an arbitrary guess. This conclusion is in excellent agreement with the results of Ref. 3.

In summary, in this section we have considered the MTM equation and have concluded that the false instability, found in Ref. 3, is due to the coupling of eigenfunctions from two different ''spaces'' in the ansatz.

IV. A CASE WHEN ANSATZ HAS ONLY TWO VARIATIONAL PARAMETERS

The purpose of this section is twofold. First, taking the ansatz in a simple form, we provide a justification to the intuitive idea that the variational method gives, in a sense, an averaged description of the pulse's dynamics. Second, for the same simple form of the ansatz, we introduce a method which allows one to avoid false instabilities, arising due to the second mechanism, *without* separation of the two ''spaces'' of the eigenfunctions.

For definiteness, let us restrict our consideration to Eqs. (3.1). Similar results can be obtained for any other evolution equation. Let the ansatz contain only two variations:

$$\begin{aligned}\vec{\mathbf{w}}_{\text{var}} &= \alpha(t)\vec{\mathbf{w}}_\alpha(\theta) + \beta(t)\vec{\mathbf{w}}_\beta(\theta) \\ &\equiv \alpha(t)\int_{-\infty}^{\infty}\sum_{j=1}^{4} g_{j\alpha}(k)\psi_j(k,\theta)dk + \beta(t)\int_{-\infty}^{\infty}\sum_{j=1}^{4} g_{j\beta}(k)\psi_j(k,\theta)dk, \end{aligned} \tag{4.1}$$

where $\alpha(t)$, $\beta(t)$ are the (real) variational parameters. As before, we exclude the discrete spectrum. We will denote the eigenvalues $\lambda(k) \equiv \lambda_1(k)$ and $\mu(k) \equiv \lambda_3(k)$. Then from (3.15) and (3.18) one obtains the Euler–Lagrange equations for ansatz (4.1). Using them, we arrive, after some involved algebra, at the following expression for the frequency ω:

$$\begin{aligned} -\omega^2 &\left[\int_{-\infty}^{\infty} dk \sum_{j=1,3} \nu_j(k)(g_{j\alpha}^*(k)g_{j\beta}(k) - g_{j\alpha}(k)g_{j\beta}^*(k))\right]^2 \\ &= \int\int_{-\infty}^{\infty} dk\, dk' \sum_{\{j,m\}=\{1,3\}} \lambda_j(k)\lambda_m(k')\nu_j(k)\nu_m(k') \\ &\quad \times (|g_{j\alpha}^*(k)g_{m\beta}(k') - g_{m\alpha}(k')g_{j\beta}^*(k)|^2 + |g_{j\alpha}(k)g_{m\beta}(k') - g_{m\alpha}(k')g_{j\beta}(k)|^2), \end{aligned} \tag{4.2}$$

where $\nu_j(k) = (k^2 + 1 + (-1)^{(j-1)/2}k\sqrt{k^2+1})$, $j = 1,3$. The l.h.s. of (4.2) is always non-negative since the integrand is purely imaginary. Since $\lambda_1(k) > 0$ and $\lambda_3(k) < 0$, the expansion coefficients $g_{j\alpha}(k)$, $g_{j\beta}(k)$ can be chosen so that to make the r.h.s. of (4.2) negative. That would yield $\omega^2 < 0$, which implies a false instability. Thus we see that it is *always* possible to construct an ansatz which would introduce a false instability when the linearized evolution equation has two ''spaces'' of the eigenfunctions.

Let us now choose $g_{j\beta}(k) = ig_{j\alpha}(k)$ ($j = 1,3$) for all k in the expansion. Then the second term in the r.h.s. of (4.2) vanishes, and (4.2) becomes

$$\omega^2\left[\int_{-\infty}^{\infty}\sum_{j=1,3} dk\ \nu_j(k)|g_{j\alpha}(k)|^2\right]^2=\left[\int_{-\infty}^{\infty}\sum_{j=1,3} dk\ \lambda_j(k)\nu_j(k)|g_{j\alpha}(k)|^2\right]^2. \tag{4.3}$$

This implies that (i) $\omega^2\geqslant 0$, i.e. the ansatz with $g_{j\beta}(k)=ig_{j\alpha}(k)$ will never produce a false instability, even though the two ''spaces'' S^+ and S^- are not separated; and (ii) the frequency given by the variational method is simply a weighed average of $\lambda(k)$.

Now let us note that *away* from the center of the soliton,

$$\psi_j(k,\theta)=\hat{\sigma}_3\psi_j(k,\theta), \tag{4.4}$$

where $\hat{\sigma}_3=\mathrm{diag}(\sigma_3,\sigma_3)$ [see (3.8)]. Equation (4.4), together with the assumption $g_{j\beta}(k)=ig_{j\alpha}(k)$, implies that

$$\vec{\mathbf{w}}_\beta=i\hat{\sigma}_3\vec{\mathbf{w}}_\alpha. \tag{4.5}$$

However, near the center of the soliton, Eq. (4.4) and, consequently, Eq. (4.5) do not hold. This is the key reason why it is not straightforward to use the above method to construct an ansatz which would guarantee absence of false instabilities. Namely, when one is designing an ansatz, one knows the θ dependence of the variations but not the expansion coefficients $g(k)$. Obviously, if one knows $\psi(k,\theta)$, then having an expansion coefficient is equivalent to having the explicit form of the corresponding variation. The question of whether this simple method could be applied without using the eigenfunctions remains open.

V. CONCLUSION AND GENERAL DISCUSSION

The main result of this paper has been to present the necessary conditions for the variational method to give rise to false instabilities, and also to give sufficient conditions in order to avoid such false instabilities.

For a false instability to occur, it is necessary (but not sufficient) that the variational ansatz satisfy at least one of the following two conditions:

(1) At least one of the variations contains both neutral and continuous spectrum modes. This is the first mechanism via which false instabilities can occur; it was discussed in Sec. II.
(2) There are two different ''spaces'' of the continuous spectrum eigenfunctions, and at least one of the variations contains eigenfunctions from both spaces. This is the second mechanism, which was discussed in Sec. III.

Note that if a background solution of the evolution equation is a reflectionless potential for the continuous spectrum eigenfunctions, as it was in all the examples considered here, then the existence of the two ''spaces'' is manifested by sign indefiniteness of the ''natural'' inner product (3.17). We emphasize that this condition is not equivalent to the condition of sign definiteness of the continuous spectrum of the Hermitian operator $\hat{\sigma}_3 L$, where $\hat{\sigma}_3=\mathrm{diag}(\sigma_3,\sigma_3,...)$, because $\psi(k)$ in (3.17) are eigenfunctions of the non-Hermitian operator L. In a more general case of a nonintegrable equation, the existence of the two ''spaces'' is equivalent to nonsign definiteness of the matrix M introduced in Sec. II; see Appendix A for technical details of how one can determine whether M is or is not sign definite.

Consequently, in order to guarantee that false instabilities will never occur, it is sufficient (but not necessary) to impose on the ansatz the following restrictions:

(1) Either no variation in the ansatz contains the neutral modes, or each and every one of the solitary wave's *independent* parameters is allowed to vary.
(2) If there are two different spaces of the eigenfunctions in the continuous spectrum, then each variation contains components from only one of the two spaces.

In a particular case when the ansatz contains only two real variational parameters, $\alpha(t)$ and $\beta(t)$, we proved in Sec. IV that the second necessary condition above can be replaced by the following requirement on the corresponding expansion coefficients: $g_\beta(k)=ig_\alpha(k)$. Even though the variations in this case may contain eigenfunctions from the two different ''spaces,'' the ansatz so constructed will never produce a false instability.

Let us now address the application of these results to a general (and usually nonintegrable) nonlinear evolution equation. It is obvious that these results are only strictly true for small variations about a solitary wave. However, if variations are not so small that nonlinear effects can be ignored, then one certainly should insure that the corresponding linear limit is free of false instabilities. With this said, for the rest of the discussion, we shall only consider the case where the variations are small.

First we consider the case when the exact solitary wave solution of this evolution equation is known. One starts by constructing, by either of the methods presented in Sec. II, an ansatz which either does not contain the neutral modes or, which is effectively the same, includes variations corresponding to each and every solitary wave's parameter. The neutral modes are found by varying the independent solitary wave's parameters. Note that there can also exist additional discrete spectrum modes, different from the neutral ones; as it is known, not only their form, but also their very presence in the spectrum, can be determined analytically only in exceptional cases (see, for example, Ref. 13). Such modes may or may not make the solitary wave unstable, depending on their time evolution in the linearized evolution equation.

Next, one follows the outline of Sec. II and determines whether the corresponding matrix M is sign definite (see Appendix A for technical details). If it is not, then the ansatz can produce a false instability, unless one can separate S^+ and S^- (see, for example, the discussion at the end of Sec. III). If a false instability can arise via the second mechanism, then the results of the variational method might be questionable, and in this case one cannot say anything about the existence of any unstable modes in the discrete spectrum.

Now, suppose that the matrix M can be shown to be sign definite or to separate into two sign-definite matrices, as in (3.20). Let us then discuss the possibility of detecting, by means of the variational method, an unstable mode in the discrete spectrum. In the case considered, the variational method can either produce or not, an instability. If the former is the case, then one can claim that the linearized operator has an unstable eigenmode in the discrete spectrum, because it would be the only manner in which an instability can arise in this case. Then it follows that the solitary wave is truly linearly unstable. Thus, the variational method provides an analytical means of detecting the existence of an unstable mode in the spectrum of a linearized evolution equation. However, the opposite statement, namely: ''if under the above specified conditions an instability does not arise, then the solitary wave is linearly stable,'' is not true. The trivial counterexample here is that of the ansatz which simply does not contain the unstable mode. But even if we exclude this trivial possibility, then calculations analogous to those presented in Appendix A did not give us any affirmative answer. So it would be interesting to compare the results of the variational method, applied to the problem of linear stability of a solitary wave, with those obtained by other methods.

Now, suppose that the exact solution of the evolution equation in question is not available. Then one may take an ansatz (usually a Gaussian) and determine the stationary points of the corresponding Euler–Lagrange equations, written for the ansatz' parameters. This yields a profile approximating the exact solitary wave. This profile will have the analogues of the soliton parameters, and then one can obtain the ''approximate neutral modes'' by an analog of formula (2.19). The rest is then similar to the consideration in the above paragraphs.

If the equation has a perturbation such that a Lagrangian density of the perturbed equation still exists, then the variational ansatz must contain both the continuous and discrete spectra, but the two should not be coupled in the same variation.

ACKNOWLEDGMENTS

APPENDIX A: THE CASE OF NLS-TYPE EQUATION WITH ARBITRARY NONLINEARITY

Here we present the details of the proof that for a general one-component NLS-type equation, i.e., the equation with the same linear but different nonlinear part, a false instability does not occur. We assume that the ansatz does not contain components of the discrete spectrum.

From (2.22) it follows that $\partial_\theta W(\psi_1(k),\psi_1(k))=0$. Then using asymptotics (2.16), (2.18) and comparing the values of $W(\psi_1(k),\psi_1(k))$ at $\theta\to-\infty$ and $\theta\to+\infty$, one finds

$$|a(k)|^2=1+|b(k)|^2. \tag{A1}$$

Denoting by $\phi_1(k)$ a solution of (2.8) with the asymptotics

$$\underline{\theta\to+\infty} \quad \phi_1(k)\to\begin{pmatrix}0\\1\end{pmatrix}e^{ik\theta},$$

one finds from (2.18):

$$\psi_1(k)=a(k)\phi_1(k)+b(k)\phi_1(-k). \tag{A2}$$

We assume the corresponding operator L to be real, which is so if the nonlinearity in the evolution equation is of the form $uV(|u|^2)$. Then

$$\psi_1^*(-k)=\psi_1(k), \quad \phi_1^*(-k)=\phi_1(k). \tag{A3}$$

and from (A2) and (A3) one obtains:

$$a^*(-k)=a(k), \quad b^*(-k)=b(k). \tag{A4}$$

Using (A1) and (A4) one obtains a generalization of (2.24a):

$$\langle\psi_1^\dagger(k')|\sigma_3|\psi_1(k)\rangle=-2\pi(|a(k)|^2\delta(k-k')+a(k)b(k)\delta(k+k')), \tag{A5a}$$

$$\langle\psi_2^\dagger(k')|\sigma_3|\psi_2(k)\rangle=2\pi(|a(k)|^2\delta(k-k')+a^*(k)b^*(k)\delta(k+k')). \tag{A5b}$$

Then from (A4) and (A5) it is straightforward to obtain a generalization of (2.27). Namely, the matrices M, N now have the entries:

$$N_{jl}=\langle g_j||a|^2|g_l\rangle+\langle g_j(-k)|ab|g_l\rangle-\text{c.c.}; \tag{A6a}$$

$$M_{jl}=\langle g_j|\lambda|a|^2|g_l\rangle+\langle g_j(-k)|\lambda ab|g_l\rangle+\text{c.c.} \tag{A6b}$$

In (A6) we have omitted the subindex ''1'' of g_{1j}, and we also omit the argument of functions if it is k. As before, N is Hermitian with $\mathrm{Tr}\,N=0$, so in order to guarantee that $\omega^2\geqslant 0$, one needs to prove that M is positive definite. Similar to (2.29), denote $\vec{\mathbf{x}}=\sqrt{\lambda}(c_1g_1,\ldots c_ng_n)^T$, $\vec{\mathbf{y}}=\sqrt{\lambda}(c_1^*g_1,\ldots c_n^*g_n)^T$, $\vec{\mathbf{c}}=(c_1,\ldots c_n)^T$, and then consider $\vec{\mathbf{c}}^\dagger M\vec{\mathbf{c}}$. Taking into account the identity

$$\langle g_j(-k)|\lambda ab|g_l\rangle=\langle g_j(k)|\lambda a^*b^*|g_l(-k)\rangle$$

and (A1) and (A4) one obtains that

$$\vec{\mathbf{c}}^{\dagger}M\vec{\mathbf{c}}=(\vec{\mathbf{x}}\ \text{part})+(\vec{\mathbf{y}}\ \text{part}), \tag{A7}$$

where

$$\begin{aligned}(\vec{\mathbf{x}}\ \text{part})=\frac{1}{2}\Bigg[&\left\|\sum_{j=1}^{n}x_j(k)|a(k)|\right\|^2+\left\|\sum_{j=1}^{n}x_j(k)|b(k)|\right\|^2+\left\|\sum_{j=1}^{n}x_j(k)\right\|^2\\&+\sum_{j,l}\langle\mathbf{x}_j^*(-k)|a(k)b(k)|\mathbf{x}_l(k)\rangle+\sum_{j,l}\langle\mathbf{x}_j^*(k)|a^*(k)b^*(k)|\mathbf{x}_l(-k)\rangle\Bigg]\\=\frac{1}{2}\Bigg[&\left\|\sum_{j=1}^{n}(\mathbf{x}_j(-k)a(-k)+\mathbf{x}_j(k)b(k))\right\|^2+\left\|\sum_{j=1}^{n}\mathbf{x}_j(k)\right\|^2\Bigg]>0.\end{aligned}$$

Similarly, the $\vec{\mathbf{y}}$ part in (A7) is positive, thus M is positive definite.

APPENDIX B: COMPLETENESS OF THE SET OF SOLUTIONS OF EQ. (3.7)

Below we present the explicit expressions of the eigenfunctions of Eq. (3.7), which form a complete set in the Schwartz class. Let us first introduce the notations. Let $f(\xi,\theta)=(f_1(\xi,\theta),f_2(\xi,\theta))^T$ be an arbitrary vector function with the entries f_1, f_2 bounded for any real θ and for Im $\xi^2=0$, and the pair $u\equiv u(x,t)$, $v\equiv v(x,t)$ be a solution of (3.1). Denote

$$Y(f(\xi,\theta))\equiv(Y_1,Y_2,Y_3,Y_4)^T, \tag{B1a}$$

where

$$\begin{aligned}Y_1=\frac{1}{\xi}f_2^2+uf_1f_2,\quad Y_2=\frac{1}{\xi}f_1^2-u^*f_1f_2,\\Y_3=-\xi f_2^2-vf_1f_2,\quad Y_4=-\xi f_1^2+v^*f_1f_2.\end{aligned} \tag{B1b}$$

Let now $f(\xi,\theta)$ be a Jost solution of the x-operator in the Lax pair corresponding to Eq. (3.1) (Refs. 11 and 12). Then in Ref. 12 a result was proven which, in terms relevant to this paper, is the following. The function Y defined in (B1) is a solution of Eq. (3.7) with $\lambda(\xi)=\cos Q-\frac{1}{2}(\xi^2+\xi^{-2})$. Moreover, a certain set of these functions is complete. In particular, when the pair (u,v) is the exact one-soliton solution (3.2), then the two linearly independent Jost solutions with oscillatory asymptotics at $|\theta|\to\infty$ are

$$\begin{aligned}\chi(\xi,\theta)=\begin{pmatrix}0\\1\end{pmatrix}e^{-iA(\theta)-i/2\,k(\xi)\theta}-\frac{\sin Q e^{-(i/2)k(\xi)\theta}}{\xi^2-\xi_1^{*2}}\\\cdot\begin{pmatrix}\xi\ \operatorname{sech}\left(\theta\sin Q+\dfrac{iQ}{2}\right)\cdot\ \exp(-iB-iQ+iA(\theta))\\i\ \operatorname{sech}\left(\theta\sin Q-\dfrac{iQ}{2}\right)\cdot\ \exp(\theta\sin Q-iA(\theta)-iQ/2)\end{pmatrix},\end{aligned} \tag{B2a}$$

and

$$\overline{\chi(}\xi,\theta)=\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}\chi^*(\xi^*,\theta), \tag{B2b}$$

where Q was defined in Sec. III,

$$A(\theta)=\arctan\left(\tan\left(\frac{Q}{2}\right)\tanh(\theta\ \sin\ Q)\right)+\frac{Q}{2},$$

$$\xi_1=\exp\left(\frac{i}{2}\,Q\right),\quad B=-t\ \cos\ Q,\quad k(\xi)=\frac{1}{2}\,(\xi^2-\xi^{-2}).$$

The two Jost solutions vanishing at $|\theta|\to\infty$ are

$$\chi_1(\theta)\equiv\chi(\xi_1,\theta)=\frac{1}{2}\begin{pmatrix} i\ \mathrm{sech}\left(\theta\ \sin\ Q+\dfrac{iQ}{2}\right)\cdot\ \exp(-iB+iA(\theta)+(\theta\ \sin\ Q-iQ)/2)\\ \mathrm{sech}\left(\theta\ \sin\ Q-\dfrac{iQ}{2}\right)\cdot\ \exp(-iA(\theta)-(\theta\ \sin\ Q-iQ)/2)\end{pmatrix}, \tag{B3a}$$

and

$$\overline{\chi_1}(\theta)\equiv\overline{\chi(}\xi_1^*,\theta). \tag{B3b}$$

Then any four-component vector $\vec{\mathbf{w}}$ with the entries from the Schwartz class can be expanded as follows:

$$\vec{\mathbf{w}}(\theta)=\int_0^\infty d\xi[c_1(\xi)Y(\chi(i\xi,\theta))+c_2(\xi)Y(\overline{\chi(}i\xi,\theta))+c_3(\xi)Y(\chi(\xi,\theta))+c_4(\xi)Y(\overline{\chi(}\xi,\theta))]$$
$$+d_1Y(\chi_1(\theta))+d_2Y(\overline{\chi_1}(\theta))+d_3\,\frac{\partial}{\partial\xi}\,Y(\chi(\xi,\theta))\Big|_{\xi_1}+d_4\,\frac{\partial}{\partial\xi}\,Y(\overline{\chi(}\xi,\theta))\Big|_{\xi_1}. \tag{B4}$$

Finally, from (B1) and (B2) and (3.8) one observes that

$$Y(\chi(i\xi,\theta))=-\frac{i}{\xi}\,\psi_1(k(\xi),\theta),\quad Y(\overline{\chi(}i\xi,\theta))=-\frac{i}{\xi}\,\psi_2(k(\xi),\theta),$$

$$Y(\chi(\xi,\theta))=\frac{1}{\xi}\,\psi_3(-k(\xi),\theta),\quad Y(\overline{\chi(}\xi,\theta))=\frac{1}{\xi}\,\psi_4(-k(\xi),\theta), \tag{B5}$$

with in (B5) $\xi>0$. Notice that (B5) is in accordance with (3.13). Thus formula (3.14) is justified.

(Received 3 April 1995; accepted for publication 26 September 1995)

We study a new quite general family of dynamical r-matrices for an auxiliary loop algebra $\mathscr{L}(su(2))$ related to restricted flows for equations of the KdV type. This underlying r-matrix structure allows us to reconstruct Lax representations and to find variables of separation for a wide set of the integrable natural Hamiltonian systems. © *1996 American Institute of Physics.* [S0022-2488(96)01906-8]

I. INTRODUCTION

The main aim of this paper is to study the r-matrix formulation for mechanical systems embedded as restricted flows into KdV type equations and to investigate its connection with Lax representations and with the method of separation of variables. Lax representations are essential for solving these mechanical systems either by linearization on the Jacobian of determinant curve of the Lax matrix or by determining variables of separation through the functional Bethe ansatz.[1,2]

Restricted flows are easiest understood as stationary flows of soliton hierarchies with sources.[3] Many well known integrable mechanical systems, such as Henon-Heiles, Garnier, Neumann (and many others) can be embedded into the KdV and other soliton hierarchies as restricted flows.[4]

The main advantage of such embedding is that important structure elements for restricted flows, such as Lax representation, bi-Hamiltonian formulation, Newton parametrization[5] can be systematically derived from the underlying soliton hierarchies. But it is not the case, as yet, for the r-matrix formulation of these mechanical systems. There is no direct way of transporting the well known r-matrix formulation for soliton hierarchies[6] to their stationary and restricted flows. The underlying r-matrix structure for finite-dimensional systems appears to be more complicated than for integrable PDE's. A new type of, so called, dynamical r-matrices depending both on the spectral parameter and on dynamical variables has to be considered. The first example of such an r-matrix has been found for the Calogero–Moser system[7] and then for the parabolic and elliptic separable potentials.[8,9,10]

It appears that the parabolic and elliptic r-matrices belong to a quite general family of dynamical r-matrices which we introduce in this paper through a convenient ansatz which generalizes our r-matrix from Refs. 9 and 10. We study the general algebraic properties of these r-matrices and derive Lax representations through proper specializations. These specializations are guided by the known integrable cases of natural Hamiltonian systems related to restricted flows for equations of the KdV type.[3,9] Further we use these Lax representations for finding variables of separation and explain how starting with variables of separation these Lax representations can be reconstructed by using the Sklyanin approach.[1,2]

J. Math. Phys. **37** (7), July 1996

The paper is organized as follows.

In section II we consider additive algebraic deformations of linear r-matrix algebras on an auxiliary loop algebra $\mathbf{g}=\mathscr{L}(\mathrm{su}(2))$. Kernels of these r-matrices have either rational, trigonometric and elliptic dependence on the spectral parameter.[6,11,12] We consider deformations $L(\lambda)=L_0(\lambda)+F(\lambda)\in\mathscr{L}(\mathrm{su}(2))$ of a certain Lax matrix $L_0(\lambda)\in\mathscr{L}(su(2))$, which satisfies the standard r-matrix brackets. These deformed Lax matrices obey a dynamical rs-matrix algebra. From dynamical point of view the deformed Lax matrices correspond to systems with additively shifted integrals of motion,

$$I_k^{new}=I_k^{old}+f_k.$$

Further, for r-matrices of the XXX and XXZ type we consider projection of deformations $F(\lambda)$ on finite-dimensional Poisson (ad_R^*-invariant) subspaces $\mathscr{L}_{M,N}(\mathrm{su}(2))$. Their Lax matrices $L_{MN}(\lambda)$ obey the rs-matrix brackets as well. At the end of section II we construct Lax pairs from the rs-matrix algebra and prove that these Lax pairs are related to stationary flows for equations of the KdV type.

In section III we express matrix elements of the matrices $L_0(\lambda)$ and $L_{MN}(\lambda)$, defined on a direct sum of loop algebras $\oplus\mathscr{L}(\mathrm{su}(2))$, through canonically conjugated variables of separation and prove that these matrices obey the rs-matrix brackets. Such matrices describe a geodesic motion and a potential motion on a Riemannian manifold with complex diagonal meromorphic Riemannian metrices of a special type. Corresponding potentials are the finite gap potentials on these manifolds. The problem of quantization is discussed briefly.

In section IV we consider finite-dimensional integrable systems of natural type and investigate three types of canonical transformations of variables prescribed by the linear r-matrix structure. Two of these are pure coordinate transformations to generalized elliptic coordinates and to Jacobi coordinates, while the third one provides an example of a momentum dependent change of variables. We exemplify our approach with a quartic potential of two degrees of freedom.

In the concluding remarks we discuss shortly an application of our constructions to other nonlinear integrable PDE's such as the AKNS and the sine-Gordon hierarchies.

II. DEFORMATIONS OF LINEAR *r*-MATRIX ALGEBRA

We shall use basic algebraic constructions in the r-matrix scheme for loop algebras in accordance with Refs. 12 and 13.

In this paper we consider the loop algebra $\mathscr{L}(\mathbf{a})$ under Lie algebra $\mathbf{a}=\mathrm{su}(2)$ only and shall use tensor form of r-brackets which is more common in the inverse scattering method.[6,11,14] We also fix the representation of the algebra su(2) and shall work in the matrix notation, although the underlying constructions are independent of particular matrix representation. In the following we shall consider spin one half representations of su(2) or shall use the direct sum of these representations. This means that we restrict ourselves to two-dimensional auxiliary space in which su(2) matrices act.

There are two important Lie–Poisson brackets (R-brackets)[12,13] which can be considered as linear classical limit of the fundamental commutator relations in the quantum inverse scattering method.[15,11] They are the r-bracket,

$$\{\overset{1}{L}(\lambda),\overset{2}{L}(\mu)\}=[r(\lambda,\mu),\overset{1}{L}(\lambda)+\overset{2}{L}(\mu)], \tag{II.1}$$

and the rs-bracket,

$$\{\overset{1}{L}(\lambda),\overset{2}{L}(\mu)\}=[r(\lambda,\mu),\overset{1}{L}(\lambda)+\overset{2}{L}(\mu)]+[s(\lambda,\mu),\overset{1}{L}(\lambda)-\overset{2}{L}(\mu)], \tag{II.2}$$

which is related to the reflection equations.[15,10] Here we use the standard notations $\overset{1}{L}(\lambda) = L(\lambda) \otimes I$, $\overset{2}{L}(\mu) = I \otimes L(\mu)$. The brackets (II.1)–(II.2) are Lie–Poisson brackets, if the matrices $r(\lambda,\mu)$ and $s(\lambda,\mu)$ satisfy the modified classical Yang–Baxter equations.[12,13]

For a traceless 2×2 matrix $L_0(\lambda)$ (which we shall call Lax matrix),

$$L_0(\lambda)=\sum_{k=1}^{3} s_k(\lambda)\cdot\sigma_k, \tag{II.3}$$

which obeys the linear r-matrix algebra (II.1) the r-matrix is an antisymmetric function of one argument $r(\lambda,\mu)\equiv r(\lambda-\mu)$ and $r(\lambda)=-r(-\lambda)$. Namely, put

$$r(\lambda)=\sum_{k=1}^{3} w_k(\lambda)\cdot\sigma_k\otimes\sigma_k. \tag{II.4}$$

The σ_k are Pauli matrices and coefficients $w_k(\lambda)$ are functions of spectral parameter only. They are determined by construction of the R-matrix on loop algebra $\mathcal{L}(\mathbf{a})$[12,13] or by the requirement that the r-matrix obeys classical Yang–Baxter equations.[6,11,14] In the quantum inverse scattering method r-matrices with rational, trigonometric and elliptic dependence on the spectral parameter are called r-matrices of XXX, XXZ and XYZ types, respectively.[6,11,14]

It follows from the algebra (II.1) that the determinant $d_0(\lambda)\equiv\det L_0(\lambda)$ can be taken as a generating function of commuting integrals of motion I_k since

$$\{d_0(\lambda),d_0(\mu)\}=0,\quad d_0(\lambda)=\sum_k I_k\lambda^k,\quad \lambda,\mu\in\mathbf{C}\ \text{ implies }\ \{I_k,I_j\}=0. \tag{II.5}$$

A similar property is valid for the rs-algebra (II.2) too.

Here we consider deformations $L(\lambda)\in\mathcal{L}(\mathbf{a})^*$ of the Lax matrix $L_0(\lambda)\in\mathcal{L}(\mathbf{a})^*$ with $\mathbf{a}=su(2)$. The main stimulus for considering such deformations has been inspired by the study of Lax representation and r-matrix formulation for restricted flows of the KdV and coupled KdV hierarchies,[3,9] which describe many physically interesting integrable natural Hamiltonian systems such as Neumann, Garnier, Henon-Heiles systems and an infinite family of integrable polynomial potentials.[16]

Now we find a new natural generalization of this result where the deformed matrix $L(\lambda)$ belongs the same phase space. The additive deformation of $L_0(\lambda)$ has the form

$$L(\lambda)=\sum_{k=1}^{3}\left(s_k(\lambda)+\alpha_k(\lambda)\cdot\frac{f(\lambda)}{2\tilde{b}(\lambda)}\right)\cdot\sigma_k=L_0(\lambda)+F(\lambda), \tag{II.6}$$

where

$$\tilde{b}(\lambda)=\sum_{i=1}^{3}\alpha_i(\lambda)s_i(\lambda), \tag{II.7}$$

and

$$\alpha_1^2(\lambda)+\alpha_2^2(\lambda)+\alpha_3^2(\lambda)=0. \tag{II.8}$$

Here functions $\alpha_j(\lambda)$ and the arbitrary function $f(\lambda)$ are complex-valued functions of the spectral parameter λ only. The condition (II.8) guarantees that determinant of $L(\lambda)$ has the additive property

$$d(\lambda)=d_0(\lambda)+f(\lambda),$$

which means that integrals of the motion $d(\lambda)=\Sigma\ I_k\lambda^k$ of the deformed integrable systems differ by some constants,

$$I_k^{new}=I_k^{old}+f_k, \quad f_k\in\mathbf{C}.$$

The requirement that the deformed Lax matrix $L(\lambda)$ satisfy the rs-bracket (II.2) with the same r-matrix $r(\lambda-\mu)$ yields four algebraic equations for the unknown functions $\alpha_k(\lambda)$, $k=1,2,3$ and a certain function $g(\lambda,\mu)$.

Theorem 1: *The deformed Lax matrix (II.6)–(II.8) satisfies the linear rs-algebra (II.2), if*

$$w_j(\lambda,\mu)\alpha_j(\mu)\alpha_i(\lambda)-w_i(\lambda,\mu)\alpha_i(\mu)\alpha_j(\lambda)=g(\lambda,\mu)\cdot\alpha_k(\lambda), \tag{II.9}$$

where (j,i,k) *are cyclic permutations of indices* $(1,2,3)$ *and the scale function* $g(\lambda,\mu)$ *depends only on the spectral parameters* λ *and* μ. *The corresponding matrix* $s(\lambda,\mu)$ *is given by*

$$s(\lambda,\mu)=\sum_{i,j=1}^{3}\alpha_{ij}(\lambda,\mu)\sigma_i\otimes\sigma_j, \tag{II.10}$$

with

$$\alpha_{ij}(\lambda,\mu)=w_i(\lambda,\mu)\cdot g(\lambda,\mu)\cdot\frac{\alpha_i(\mu)\alpha_j(\mu)f(\mu)}{\tilde{b}^2(\mu)}-w_j(\lambda,\mu)\cdot g(\mu,\lambda)\cdot\frac{\alpha_i(\lambda)\alpha_j(\lambda)f(\lambda)}{\tilde{b}^2(\lambda)}. \tag{II.11}$$

Proof: The proof is a direct but lengthy computation.

Notice that the function $f(\lambda)$ is quite arbitrary here. A compact form of the equation (II.9) follows from the ideas of Sklyanin in Ref. 1:

Lemma 1: The condition (II.9) of Theorem 1 for the coefficients $\alpha_k(\lambda)$ *is equivalent to the equation*

$$\{\tilde{b}(\lambda),\tilde{b}(\mu)\}=g(\lambda,\mu)\cdot\tilde{b}(\lambda)-g(\mu,\lambda)\cdot\tilde{b}(\mu). \tag{II.12}$$

Proof: This lemma is proved by direct substitution of the equality (II.9) into the equation (II.12) and vice versa.

Let us present some of the best known[6,11,14] r-matrices and the related solutions for $\alpha_k(\lambda)$ and $g(\lambda,\mu)$. The r-matrix of the XXX and XXZ types are

$$w_1=w_2\equiv w(\lambda)=\frac{\eta}{\varphi(\lambda)} \quad \text{and} \quad w_3(\lambda)=\frac{\eta\varphi'(\lambda)}{\varphi(\lambda)},$$

with

$$\varphi(\lambda)=\lambda \quad \text{in the } XXX \text{ case}, \tag{II.13}$$

and

$$\varphi(\lambda)=\sinh\lambda \quad \text{in the } XXZ \text{ case}; \tag{II.14}$$

here η is constant and $\varphi'(\lambda)$ denotes the derivative with respect to λ.

An interesting particular class of solutions to equations (II.8)–(II.9) is distinguished by the conditions

$$\alpha_3=0, \quad \alpha_1^2+\alpha_2^2=0. \tag{II.15}$$

They represent two points on the circle in complex plane with the phase difference equal to $\pi/2$, for instance $\alpha_1=1$, $\alpha_2=i$. For these solutions the function $g(\lambda,\mu)$ is equal to zero ($g(\lambda,\mu)=0$). A different example of solutions for r-matrix of XXZ type is

$$\alpha_1=\cosh\lambda, \quad \alpha_2=i\sinh\lambda, \quad \alpha_3=i.$$

Usually one uses the following rational parametrization for an r-matrix of the XXZ type:

$$w_1(u-v)=w_2(u-v)=\eta\frac{2uv}{u^2-v^2}, \quad w_3(u-v)=\eta\frac{u^2+v^2}{u^2-v^2}, \tag{II.16}$$

$$\varphi(u)=u-\frac{1}{u}, \quad \text{with } u=e^{\lambda}, \quad v=e^{\mu},$$

as, for example, in the description of the sine-Gordon equation.[6]

An elliptic r-matrix of the XYZ type has

$$w_1(\lambda)=\eta\frac{\Theta_{11}'}{\Theta_{10}}\frac{\Theta_{10}(\lambda,k)}{\Theta_{11}(\lambda,k)}, \quad w_2(\lambda)=\eta\frac{\Theta_{11}'}{\Theta_{00}}\frac{\Theta_{00}(\lambda,k)}{\Theta_{11}(\lambda,k)}, \tag{II.17}$$

$$w_3(\lambda)=\eta\frac{\Theta_{11}'}{\Theta_{01}}\frac{\Theta_{01}(\lambda,k)}{\Theta_{11}(\lambda,k)},$$

with

$$\alpha_1=-1; \quad \alpha_2=\frac{i}{k}\frac{\mathrm{dn}(\lambda,k)}{\mathrm{cn}(\lambda,k)}, \quad \alpha_3=\frac{k'}{k}\frac{1}{\mathrm{cn}(\lambda,k)}.$$

Here k and k' denote modulus of the Jacobi elliptic functions and $\Theta_{ij}(\lambda,k)$ are the elliptic theta function in the notation of Ref. 15. We have to emphasize that the functions $\tilde{b}(\lambda)$ (II.7) with the coefficients $\alpha_k(\lambda)$ (II.17) and the function $g(\lambda,\mu)$ were introduced in Ref. 1 for the quadratic r-matrix algebra as a solution of the equation (II.12). The function $g(\lambda,\mu)$ is independent from the second parameter μ function and it is equal to

$$g(\lambda,\mu)=\eta\frac{\Theta_{11}'}{\Theta_{10}}\frac{\Theta_{10}(\lambda-K,k)}{\Theta_{11}(\lambda-K,k)}.$$

This solution has a natural relation with a similar transformation of the Lax matrix $L_0(\lambda)$ introduced in Ref. 15.

It is well known that r-brackets (II.1) are the Lie–Poisson brackets if the r-matrix obeys the classical Yang–Baxter equations.[6,12,13] The Yang–Baxter equation is an equation on matrices in the space $\mathbf{C}^2\otimes\mathbf{C}^2\otimes\mathbf{C}^2$. We use the familiar tensor notations L_j for the matrix acting as matrix L in the j's factor of the product and trivially acting in the remaining factors, for example $L_1=L\otimes I\otimes I$. In similar way a matrix r_{ij} is acting trivially in the third k's factor and it works as a matrix r in the product of the other ij's factors. The classical Yang–Baxter equation for pure numerical r-matrices has the form

$$[d_{12}^{\pm}(\lambda,\mu),d_{13}^{\pm}(\lambda,\nu)]+[d_{12}^{\pm}(\lambda,\mu),d_{23}^{\pm}(\mu,\nu)]+[d_{32}^{\pm}(\nu,\mu),d_{13}^{\pm}(\lambda,\nu)]=0. \tag{II.18}$$

Following[7,8] we introduce dynamical Yang–Baxter equations for this new family of a dynamical rs-matrix. Let us consider matrices $d^{\pm}\equiv r\pm s$ corresponding to a particular class of solutions α_k (II.15).

Theorem 2: *For the rs-algebra (II.2) with matrices (II.4)–(II.11), the following equations are valid:*

$$[d^{\pm}_{12}(\lambda,\mu),d^{\pm}_{13}(\lambda,\nu)]+[d^{\pm}_{12}(\lambda,\mu),d^{\pm}_{23}(\mu,\nu)]+[d^{\pm}_{32}(\nu,\mu),d^{\pm}_{13}(\lambda,\nu)]+[L_2(\mu),d^{\pm}_{13}(\lambda,\nu)]$$
$$-[L_3(\nu),d^{\pm}_{12}(\lambda,\mu)]+[X(\lambda,\mu,\nu),L_2(\mu)-L_3(\nu)]=0. \tag{II.19}$$

The matrix $X(\lambda,\mu,\nu)$ *is*

$$X(\lambda,\mu,\nu)=\beta(\lambda,\mu,\nu)\cdot\sigma_-\otimes\sigma_-\otimes\sigma_-,$$
$$\beta(\lambda,\mu,\nu)=\frac{f(\lambda)b^{-3}(\lambda)\cdot(\mu-\nu)+f(\mu)b^{-3}(\mu)\cdot(\nu-\lambda)+f(\nu)b^{-3}(\nu)\cdot(\lambda-\mu)}{(\lambda-\mu)(\mu-\nu)(\nu-\lambda)}. \tag{II.20}$$

The other two equations are obtained from (II.19) by cyclic permutation.

Proof: This Theorem also can be proved by a straightforward computation.

Tensor $X(\lambda,\mu,\nu)$ is a completely symmetric tensor with respect to any permutations of auxiliary spaces. For the quite arbitrary solutions α_k to the equations (II.8)–(II.9) we can introduce an asymmetric tensor $X^{(i,j,k)}(\lambda,\mu,\nu)$. Then dynamical Yang–Baxter equations take the general form introduced in Ref. 7.

Now we consider the special deformations of the XXX and XXZ cases using the list of formulas collected in Refs. 8, 9, 10 and on meaning its in general rs-matrix approach to loop algebras.

Our purpose is to apply the rs-matrix formulation for description of natural Hamiltonian systems in order to solve them through separation of variables. For separating variables we shall apply the functional Bethe ansatz.[1,2] Using similar transformations of the Lax matrix $L_0(\lambda)$ and corresponding renormalization of the Baker–Akhiezer vector-function we can restrict ourselves to a particular class of deformations obtained by certain projections of the matrix,

$$L(\lambda)=\begin{pmatrix} a & b \\ f(\lambda)b^{-1}+c & -a\end{pmatrix}(\lambda)=L_0(\lambda)+\begin{pmatrix} 0 & 0 \\ f(\lambda)b^{-1} & 0\end{pmatrix}. \tag{II.21}$$

Also, we shall require that entries of $L_0(\lambda)$ be the absolutely convergent Laurent series in the XXX case or the absolutely convergent Fourier series in the XXZ case,

$$a(\lambda)=\sum_k a_k\lambda^k \quad \text{or} \quad a(\lambda)=\sum_k a_k\exp(k\cdot\lambda) \tag{II.22}$$

for XXX and XXZ cases, respectively, and similarly for $b(\lambda)$ and $c(\lambda)$.

It is well known[12] that the standard R-bracket on $\mathcal{S}(\mathbf{a})^*$ associated with a general R-brackets has a large collection of finite-dimensional Poisson (ad^*_R-invariant) subspaces,

$$\mathcal{S}_{M,N}=\oplus_{j=-M}^{N}\mathbf{a}^*\lambda^j, \quad \text{provided } M\geqslant 0;\ N\geqslant -1. \tag{II.23}$$

In other words the subspaces $\mathcal{S}_{M,0}$ and $\mathcal{S}_{1,N}$ are invariant under the coadjoint action of the subalgebras $\mathbf{g}_+$ and $\mathbf{g}_-$.[12].

Let us introduce the following projection operators $[\cdot]_{MN}$ on these Poisson subspaces:

$$[z]_{MN}=\left[\sum_{k=-\infty}^{+\infty} z_k\lambda^k\right]_{MN}\equiv\sum_{k=-M}^{N} z_k\lambda^k,$$
$$[z]_{MN}=\left[\sum_{k=-\infty}^{+\infty} z_k\exp(k\cdot\lambda)\right]_{MN}\equiv\sum_{k=-M}^{N} z_k\exp(k\cdot\lambda), \tag{II.24}$$

for the Laurent and for the Fourier series.

We shall define a new additive deformation of $L_0(\lambda)$ as

$$L_{MN}(\lambda)=L_0(\lambda)+F_{MN}(b,\lambda)\equiv\begin{pmatrix} a & b \\ G_{MN}(b,\lambda)+c & -a\end{pmatrix}(\lambda), \tag{II.25}$$

where $G_{MN}(b,\lambda)$ is a function of the spectral parameter λ and of the entry $b(\lambda)$. It reads as

$$G_{MN}(b,\lambda)=[f(\lambda)\cdot b^{-1}(\lambda)]_{MN}, \tag{II.26}$$

$$f(\lambda)=\sum_{k=-\infty}^{\infty} f_k\lambda^k,\quad \text{or}\quad f(\lambda)=\sum_{k=-\infty}^{\infty} f_k\exp(k\lambda). \tag{II.27}$$

The essential feature of this deformation is, in comparison with (II.6), that the determinant of the modified matrix $L_{MN}(\lambda)$ is different from $d_0(\lambda)+f(\lambda)$,

$$d(\lambda)=d_0(\lambda)+b\cdot G_{MN}\neq d_0(\lambda)+f(\lambda),$$

and therefore integrals of motion I_k^{new} of the deformed system are functionally different from the undeformed integrals I_k^{old}, and yet the $L_{MN}(\lambda)$ matrix belongs to a certain rs-algebra.

Theorem 3: *The matrix $L_{MN}(\lambda)$ (II.25) satisfies the linear rs-matrix algebra (II.2), with the matrix $s_{MN}(\lambda,\mu)$ given by*

$$s(\lambda,\mu)=\alpha_{MN}(\lambda,\mu)\sigma_-\otimes\sigma_-,\quad \sigma_-=\begin{pmatrix}0&0\\1&0\end{pmatrix}.$$

The function $\alpha_{MN}(\lambda,\mu)$ is defined by

$$\alpha_{MN}(\lambda,\mu)=-w(\lambda-\mu)([f(\lambda)b^{-2}(\lambda)]_{MN}-[f(\mu)b^{-2}(\mu)]_{MN}), \tag{II.28}$$

where $w(\lambda)\equiv w_1(\lambda)=w_2(\lambda)$.

Proof: The proof is a straightforward calculation.

The Theorem 3 has a transparent meaning in the framework of the general r-matrix approach to loop algebras. The Theorem 3 asserts that the matrix $s(\lambda,\mu)$ can be restricted to subspaces $\mathscr{S}_{M,N}$ (II.23) and subspaces $\mathscr{S}_{M,N}$ is a common Poisson subspace for the rs-brackets (II.2) with matrix $s_{MN}=[s(\lambda,\mu)]_{MN}$. Since the deformations (II.3) are directly connected with the KdV equation,[9] matrices $d^{\pm}=r\pm s_{MN}$ obey dynamical Yang–Baxter equations, which are obtained by restriction of the equation (II.19)–(II.20) to the corresponding subspace $\mathscr{S}_{MN}$. For certain matrices $L_{MN}(\lambda)$ and s_{MN} this proposition has been proved in Ref. 8.

In order to describe Lax representations for integrable Hamiltonian systems related to matrices $L_0(\lambda)$ and $L_{MN}(\lambda)$ we introduce matrices[12,13]

$$d_{12}(\lambda,\mu)=r(\lambda,\mu)+s(\lambda,\mu),\quad \text{and}\quad d_{21}(\lambda,\mu)=r(\lambda,\mu)-s(\lambda,\mu).$$

In terms of these matrices the Lie–Poisson rs-brackets read as

$$\{\overset{1}{L}(\lambda),\overset{2}{L}(\mu)\}=[d_{12}(\lambda,\mu),\overset{1}{L}(\lambda)]+[d_{21}(\lambda,\mu),\overset{2}{L}(\mu)]. \tag{II.29}$$

For constructing Lax representations we shall make use of the following lemma.[6]

Lemma 2: If matrix $L(\lambda)$ *obeys the Lie–Poisson algebra (II.29) then the spectral invariants,*

$$H_n(\lambda)=\mathrm{tr}(L^n), \quad n=1,2,\ldots;, \tag{II.30}$$

are integrals of motion in involution $\{H_n,H_m\}=0$ *and the Lax equation are given by*

$$\dot{L}(\mu)=\{H_n(\lambda),L(\mu)\}=[M_n(\lambda,\mu),L(\mu)], \tag{II.31}$$

with

$$M_n(\lambda,\mu)=n\ \mathrm{tr}_1(\overset{1}{L}{}^{n-1}(\lambda)d_{21}(\lambda,\mu)), \quad n=1,2\ldots, \tag{II.32}$$

where tr_1 *means a trace in the first auxiliary space and a dot over L means a derivative with respect to time corresponding to the Hamiltonian* $H_n(\lambda)$. In two dimensional auxiliary space $d(\lambda)\equiv\det L(\lambda)=-\frac{1}{2}(\mathrm{tr}(L^2)=-\frac{1}{2}H_2(\lambda))$.

In order to get a Hamiltonian H, which does not depend on the spectral parameter, one needs a linear functional (a projection) Φ_λ which selects, for example (in the *XXX* case), a coefficient at certain power of λ,

$$H=\tfrac{1}{2}\,\Phi_\lambda[H_2(\lambda)]=\Phi_\lambda[d(\lambda)]. \tag{II.33}$$

For instance, it can be defined as a residue of order m at λ_0,

$$\Phi_\lambda[z]=\mathrm{Res}^m_{\lambda_0} z(\lambda)=\frac{1}{(m-1)!}\,\frac{d^{m-1}}{d\lambda^{m-1}}\,((\lambda-\lambda_0)^m z(\lambda))\bigg|_{\lambda=\lambda_0}. \tag{II.34}$$

Then the Lax representation for the Lax matrices [(II.3) or (II.21)] with the Hamiltonian (II.33) has the form

$$\begin{gathered}\dot{L}(\mu)=\{H,L(\mu)\}=\{\tfrac{1}{2}\,\Phi_\lambda[\mathrm{tr}_1\overset{1}{L}{}^2(\lambda)],L(\mu)\}=[M(\mu),L(\mu)],\\ M(\mu)=\Phi_\lambda[\mathrm{tr}_1(\overset{1}{L}(\lambda)\cdot d_{21}(\lambda,\mu))]=\Phi_\lambda[M(\lambda,\mu)].\end{gathered} \tag{II.35}$$

In particular, for the initial Lax matrix L_0 (II.3) one gets $s=0$; $d_{21}(\lambda,\mu)=r(\lambda-\mu)$ and then

$$\dot{L}_0(\mu)=[M_0(\mu),L_0(\mu)] \quad \text{and} \quad M_0(\mu)=\Phi_\lambda\left[2\sum_{k=1}^{3} s_k(\lambda)\cdot w_k(\lambda-\mu)\cdot\sigma_k\right]. \tag{II.36}$$

In this paper we start with the requirement that

$$M_0=\sigma_+\equiv\begin{pmatrix}0 & 1\\ 0 & 0\end{pmatrix} \tag{II.37}$$

and choose $L_0(\lambda)$ and Φ_λ appropriately. It is a rather strong restriction for the matrices L_0 (II.3) and for the corresponding Hamiltonians. This requirement comes from the study of rs-representations for natural Hamiltonian systems related to stationary flows for equations of KdV type.[9,10]

As an immediate consequence of the Lax representation (II.35) with the matrix M_0 (II.37) we can rewrite the Lax matrix L_0 in the form

$$L_0(\mu)=\begin{pmatrix} -\frac{b_x}{2} & b \\ -\frac{b_{xx}}{2} & \frac{b_x}{2} \end{pmatrix}, \quad b_x=\{H_0,b\}, \tag{II.38}$$

where H_0 is a Hamiltonian corresponding to L_0. Since the determinant of $L_0(\lambda)$ is a generating function of integrals of motion, we see that it obeys the equation

$$-\{H_0,d_0(\lambda)\}=-d_{0,x}(\lambda)=\partial_x^3\cdot b=b_{xxx}=0. \tag{II.39}$$

Now for a fixed triad (L_0,M_0,Φ_λ) we introduce a modified matrix $L(\lambda)$ (II.21). In this case the matrix $M(\mu)$ is constructed according to (II.35) with $d_{21}(\lambda,\mu)=r-s$ and with the use of the same projector Φ_λ. It reads as

$$M(\mu)=\begin{pmatrix} 0 & 1 \\ -u(\mu) & 0 \end{pmatrix}, \quad u(\mu)=f(\mu)b^{-2}(\mu), \tag{II.40}$$

due to the linearity of Φ_λ,

$$\begin{aligned}&\Phi_\lambda[w_1\cdot(-f(\lambda)b^{-1}(\lambda)+c(\lambda)+(f(\lambda)b^{-2}(\lambda)-f(\mu)b^{-2}(\mu))\cdot b(\lambda))]\\ &\quad=-f(\mu)b^{-2}(\mu)=-u(\mu).\end{aligned} \tag{II.41}$$

Then from the Lax representation (II.35) it follows that the deformed matrix $L(\lambda)$ has to be equal to

$$L(\lambda)=\begin{pmatrix} -\frac{b_x}{2} & b \\ -b(\lambda)u(\lambda)-\frac{b_{xx}}{2} & \frac{b_x}{2} \end{pmatrix}, \quad b_x=\{H,b\}, \tag{II.42}$$

where the Hamiltonian $H=\Phi_\lambda[d(\lambda)]$ is obtained by applying the old projector Φ_λ to the modified determinant. The determinant $d(\lambda)$ of the modified matrix $L(\lambda)$ obeys the equation

$$-d_x(\lambda)=\left(\frac{1}{4}\,\partial_x^3+u\partial_x+\frac{1}{2}\,u_x\right)\cdot b=B_1[u]\cdot b=0. \tag{II.43}$$

Here $B_1[u]$ is the Hamiltonian pencil operator for the coupled KdV equation.[4,3]

For the deformed [according to (II.25)] matrix $L_{MN}(\lambda)$ the Lax equation is constructed analogously (II.40)–(II.42) and (II.43). One has to replace $u(\mu)=f(\mu)b^{-2}(\mu)$ with the potential $u_{MN}(\mu)=[f(\mu)b^{-2}(\mu)]_{MN}$.

Equation (II.43) shows that our deformation is connected to the stationary problems for equations of the KdV type. The Hamiltonian and some properties of motion for the finite-dimensional integrable systems connected with stationary flows of the KdV equations were considered in Refs. 17, 18. Lax representations, bi-Hamiltonian structures, Newton representations

and some other properties for these systems were introducing in Refs. 4, 5 through the method of the restricted flows for nonlinear equations. Some particular systems were studied in the r-matrix approach.[8,9,10] In the next section we tie these different methods to the Lie algebraic method of constructing matrices $L(\lambda)$ on the loop algebras.

In the next section we shall assume that the Lax matrix M_0 has the form

$$M_0=\begin{pmatrix} v_0 & u_0 \\ 0 & -v_0 \end{pmatrix}. \tag{II.44}$$

It introduces certain technical complications without influence on the conceptual structure.

III. CONSTRUCTION OF LAX MATRICES $L(\lambda)$ FOR SEPARABLE SYSTEMS

The main problem for a given integrable Hamiltonian system with a complete set of functionally independent and commuting integrals of motion $H_1,\ldots,H_n$ is to determine its solutions. The construction in the Liouville theorem has a local character and there is no general way to describe solutions globally unless some additional information about the system is known, such as a complete, spectral parameter dependent Lax representation or variables of separation.

For the Lax matrices $L_0(\lambda)$ satisfying r-matrix algebra with the r-matrix of the XXX, XXZ and XYZ types the problem of determining variables of separation has been essentially solved by Sklyanin.[2]

Proposition 1 (Sklyanin[1,2]): Take the poles of the properly normalized Baker–Akhiezer function and the corresponding eigenvalues of the Lax matrix and you obtain the separation of variables. It turns out that in the case of the $GL(N)$-invariant r-matrix the normalization of the Baker–Akhiezer function corresponding to any constant numeric vector produces separation of variables.

In our case $N=2$ and coordinates u_k, v_k, $k=1,\ldots,n$ defined as

$$b(\lambda=u_k)=0, \quad v_k=a(\lambda=u_k), \tag{III.1}$$

are canonically conjugate variables of separation and corresponding separation equations are

$$v_k^2=-d(u_k), \tag{III.2}$$

where $d(\lambda)\equiv\det L(\lambda)$.

A general construction of matrices $L_0(\lambda)$ with multiple poles on a direct sum of loop algebras $\oplus\mathscr{L}(su(2))$ has been presented in detail in Ref. 12. The Lax matrix is assumed in the form

$$L_0(\lambda)=\sum_{\alpha=1}^{3}\sum_{j}^{N} s_j^{\alpha} w_{\alpha}(\lambda-\nu_j)\sigma_{\alpha}, \tag{III.3}$$

where σ_α are Pauli matrices, $w_\alpha(\lambda)$ are coefficients of the corresponding r-matrix and ν_j are simple poles of the fixed divisor $D=\{\nu_1,\ldots,\nu_N\}$. Residues s_j^α are the standard linear coordinates on $su(2)^*$ with Lie-Poisson brackets,

$$\{s_j^{\alpha},s_k^{\beta}\}=\delta_{jk}\epsilon_{\alpha\beta\gamma}\cdot s_j^{\gamma}.$$

The corresponding phase space is the direct sum of N copies $su(2)^*$. These matrices describe systems of N interacting Euler tops. The case of higher order of poles can be treated as a degeneration of (III.3). It describes different tops[12] as well. For all these system we can apply a procedure of separation of variables.

In contrast to Ref. 12, we provide a solution of the converse problem of how to construct Lax matrices $L(\lambda)$ satisfying the rs-matrix algebra for an integrable system given in terms of variables

of separation. We express first $L(\lambda)$ in terms of variables of separation (u_k, v_k), $k=1,\ldots,n$ and then we shall use the canonical transformations naturally determining from the r-matrix structure to the ''physical'' variables (x_k, p_k), $k=1,\ldots,n$.

Let us take the meromorphic matrix-function $L_0(\lambda)$ and consider the coefficients $w_1(\lambda)=w_2(\lambda)$ of the r-matrices (II.13)–(II.14) with one distinguished point at infinity (it is zero by both arguments and their residues at infinity are equal to -1). Let us choose the linear functional Φ_λ as the higher residue fixed order K at infinity,

$$\Phi_\lambda[z] = -\mathrm{Res}_\infty^K z(\lambda). \tag{III.4}$$

Then (II.35) and (II.44) gives

$$-\mathrm{Res}_\infty^K\left[\frac{b(\lambda)}{\varphi(\lambda-\mu)}\right]=u_0, \quad -\mathrm{Res}_\infty^K\left[\frac{c(\lambda)}{\varphi(\lambda-\mu)}\right]=0, \tag{III.5}$$

$$-\mathrm{Res}_\infty^K\left[\frac{a(\lambda)\varphi'(\lambda-\mu)}{\varphi(\lambda-\mu)}\right]=v_0. \tag{III.6}$$

In particular $u_0=1$, $v_0=0$ for the matrix M_0 (II.37). In the XXX case it means that entries $b(\lambda)$ and $a(\lambda)$ have the highest in λ terms in power $K+1$ equal to u_0 and v_0, respectively. The entry $c(\lambda)$ has the highest term of order K only. Note that the conditions for the entry $a(\lambda)$ and $c(\lambda)$ (III.5)–(III.6) in the Lax pair (L_0, M_0) (II.37) follow from the first condition (III.5) for entry $b(\lambda)$ and from the definitions $a(\lambda)=-b_x/2=-\partial_x b/2$ and $c(\lambda)=-b_{xx}/2$, since the derivative ∂_x commutes with the functional Φ_λ.

Just as in Ref. 12 we can fix one divisor D consisting of poles in the matrix-function $L_0(\lambda)$ and a second divisor U consisting of zeroes of the entry $b(\lambda)$. Let them have the form

$$\begin{gathered} D=\{(e_j,m_j)j=1,\ldots,\tilde{m};\}, \quad U=\{(u_k,n_k)k=1,\ldots,\tilde{n};\}, \\ u_k\neq\infty, \quad \text{and} \quad e_j\neq u_k, \forall j,k, \end{gathered} \tag{III.7}$$

where D, $U\subset \mathbf{CP_1}=\mathbf{C}\cup\{\infty\}$ for the XXX model and D, $U\subset \mathbf{CP_1}/2\pi\mathbf{Z}$ for the XXZ model. We consider the simple zeroes u_k, $n_k\equiv 1$; $k=1,\ldots,n$, only. This restriction is related to the r-matrix structure. The poles at e_j can be multiple poles and their orders m_j are fixed. In the formulae below each pole is counted according to its multiplicity and we do not use special indices when it is clear from a context.

Now we introduce the following ansatz for the entry $b(\lambda)$:

$$\begin{gathered} b(\lambda)=u_0\cdot\frac{\Pi_{k=1}^n\varphi(\lambda-u_k)}{\Pi_{j=1}^m\varphi(\lambda-e_j)}, \\ \varphi(\lambda)\equiv w^{-1}(\lambda)=\lambda \quad \text{in the } XXX \text{ case}, \\ \varphi(\lambda)=\sinh\lambda \quad \text{in the } XXZ \text{ case}, \end{gathered} \tag{III.8}$$

where u_0 is either a constant or a dynamical variable. The function $\varphi(\lambda)$ depends from the type of the r-matrix and the functional Φ_λ (III.4) is residue with $K=1$ for $n<m$ and $K=n-m+1$ for $n\geqslant m$.

The entry $a(\lambda)$ has m poles at points e_j of the divisor D and its values at n points u_k are given $(a(\lambda=u_k)=v_k)$ (III.1). The asymptotic behavior at infinity is fixed by Lax representation (III.5). By a Lagrange interpolation formula the entry $a(\lambda)$ can be represented as

$$a(\lambda)=b(\lambda)\cdot\left(v_0+\sum_{i=1}^{n} v_i\cdot w_3(\lambda-u_i)\cdot g_{ii}\right),$$

where

$$g_{ii}=\left[\left.\frac{\partial b}{\partial\lambda}\right|_{\lambda=u_i}\right]^{-1}=\mathrm{Res}_{u_i}b^{-1}(\lambda)=\frac{\Pi_{j=1}^{m}\varphi(u_i-e_j)}{\Pi_{k\neq i}^{n}\varphi(u_i-u_k)}. \tag{III.9}$$

The $w_3(\lambda)=\varphi'(\lambda)/\varphi(\lambda)$ is the coefficient in the definition of the corresponding r-matrix. Variables u_0, v_0 are connected to the Lax matrix M_0 (II.44).

Further, from the Lax representation (II.38) for the initial matrix $L_0(\lambda)$, we can construct the entry $a(\lambda)$. It reads as

$$a(\lambda)=-\frac{b_x}{2}=\frac{b(\lambda)}{2}\cdot\left(-\frac{\dot u_0}{u_0}+\sum_{i=1}^{n}\dot u_i\cdot w_3(\lambda-u_i)\right), \tag{III.10}$$

where

$$\dot u_k\equiv u_{k,x}=\partial_x u_k,\quad \text{and}\quad w_3(\lambda)=\frac{\varphi'(\lambda)}{\varphi(\lambda)}. \tag{III.11}$$

We set now, for simplicity, $u_0=1$ and $v_0=0$ as in the Lax matrix (II.37). Definition of entry $c(\lambda)$ follows from (II.38) as well,

$$c(\lambda)=-\frac{b_{xx}}{2}=-\frac{a^2(\lambda)}{b(\lambda)}+\frac{b(\lambda)}{2}\cdot\sum_{i=1}^{n}\left(\ddot u_i w_3(\lambda-u_i)-\dot u_i^2\,\frac{\partial w_3(\lambda-u_i)}{\partial u_i}\right), \tag{III.12}$$

where $\ddot u_i$ and $\dot u_i$ are defined below.

From comparison of two forms of the entry $a(\lambda)$ (III.9) and (III.10) we can introduce the following Hamiltonian:

$$H_0=\sum_{i=1}^{n} v_i^2\cdot g_{ii}=\sum_{i=1}^{n} v_i^2\cdot\left[\left.\frac{\partial b(\lambda)}{\partial\lambda}\right|_{\lambda=u_i}\right]^{-1}, \tag{III.13}$$

using the Hamilton–Jacobi equations.

The remaining symbols in the entry $c(\lambda)$ are defined as

$$\dot u_i\equiv\frac{\partial H_0}{\partial v_i}=2\cdot v_i\cdot g_{ii},$$

$$\ddot u_i=2\sum_{j=1}^{m} v_i^2\cdot g_{ii}^2\cdot\frac{\varphi'(u_i-e_j)}{\varphi(u_i-e_j)}+2\sum_{k=1}^{n}\left[(v_k+v_i)^2 g_{ii}g_{kk}-v_i^2(g_{kk}-g_{ii})g_{ii}\right]\varphi(u_i-u_k)\varphi'(u_i-u_k),$$

where $\varphi(\lambda)=w_1^{-1}(\lambda)=\lambda$ or $\varphi(\lambda)=\sinh(\lambda)$. Then a direct calculation shows that the Hamiltonian (III.13) is equal to the Hamiltonian (II.33) $H_0=\Phi_\lambda[d_0(\lambda)]$.

The matrix $L_0(\lambda)$ with entries (III.8)–(III.9) and (III.12) obeys the r-matrix structure (II.1) as we can check it directly using the additive theorems for $\varphi(\lambda)$.

So, we have constructed the initial matrix $L_0(\lambda)$ in terms of variables of separation. From the initial matrices $L_0(\lambda)$ we can construct modified matrices $L_{MN}(\lambda)$ (II.25). These matrices describe integrable Hamiltonian system with the Hamiltonian $H=\Phi_\lambda[d(\lambda)]$ and a complete set of

the integrals of motion can be obtained from determinants of these matrices as well. The determinant $d(\lambda)$ is a meromorphic function with the divisors of poles determined by divisors of the entries of $L_0(\lambda)$ or of $L_{MN}(\lambda)$. Therefore the rational algebraic functions $d(\lambda)$ can be written as a quotient of two products or it can be decomposed into a simple fraction according to the Mittag-Leffler theorem,

$$d(\lambda)=\frac{P_d^N(\lambda)}{Q_d^m(\lambda)}=\frac{\Pi_{k=1}^N\varphi(\lambda-h_k)}{\Pi_{j=1}^m\varphi(\lambda-e_j)}=P_d^{N-m}(\lambda)+\sum_{j,i} H_{ji}\cdot\varphi^{-i}(\lambda-e_j)$$
$$=\prod_{k=1}^{N-m}\varphi(\lambda-H_k)+\sum_{j,i} H_{ji}\cdot\varphi^{-i}(\lambda-e_j), \qquad \text{(III.14)}$$

where $N=n$ for the initial matrix $L_0(\lambda)$. Both decompositions provide us with sets of integrals of motion.

So, zeroes h_k of the function $P_d^N(\lambda)$ can be chosen as a first set of integrals of motion in involution for the Hamiltonian systems related to the Lax matrices $L_0(\lambda)$ and $L_{MN}(\lambda)$. Zeroes H_k of the function $P_d^{N-m}(\lambda)$ and the residues H_{ji} at points e_j constitute a second set of the integrals of motion in involution. Integrals of motion I_k^{new} of the deformed system are functionally different from the undeformed integrals I_k^{old} and it reads as

$$I_k^{new}=I_k^{old}+V_k^{MN}(u_1,\ldots,u_n),$$

where $V_k^{MN}(u_1,\ldots,u_n)$ are functions on coordinates only. The proof of involutivity of I_k^{new} is based on the equality (II.5) and completeness and functional independence of these integrals follow from completeness and functional independence of I_k^{old}, which have been proved by Mishchenko and Fomenko (see the review[12]).

We summarize these considerations as the following.

Proposition 2: The Lax matrix $L_0(\lambda)$ (III.8), (III.9), (III.12) describes geodesic motions on the Riemannian manifold with the complex diagonal meromorphic Riemannian metrics,

$$g^{kj}=\delta_k^j\cdot\left[\frac{\partial b(\lambda)}{\partial\lambda}\bigg|_{\lambda=u_i}\right]^{-1}\cdot=\delta_k^j\cdot\frac{\Pi_{j=1}^m\varphi(u_i-e_j)}{\Pi_{k\neq i}^n\varphi(u_i-u_k)}, \qquad \text{(III.15)}$$

defined on moduli of n-dimensional Jacobi varieties in terms of complex elliptic (root) coordinates u_k. The Hamiltonian system (III.13),

$$H_0=\sum_i^n v_i^2 g_{ii},$$

has a complete system of first integrals v_k and it defines a Lagrangian submanifold of the phase space $\mathbf{C}^{2n}$ which has the form of symmetric product $((\Gamma\times\ldots\times\Gamma)/\sigma_n)$ of n copies of Riemannian surfaces,[18]

$$\Gamma: v_k^2=-d(\lambda)|_{\lambda=u_k}=-\left[\frac{P_d(\lambda)}{Q_d(\lambda)}\right]_{\lambda=u_k}. \qquad \text{(III.16)}$$

A modified Lax matrix $L_{MN}(\lambda)$ (II.25) describes potential motion on the same Riemannian manifold with a Hamiltonian of a natural type,

$$H=H_0+V_{MN}(u_1,u_2\ldots,u_n;f_{-M},f_{-M+1},\ldots,f_N), \qquad \text{(III.17)}$$

f_j are coefficients of the function $f(\lambda)=\Sigma\ f_k\lambda^k$ or of $f(\lambda)=\Sigma\ f_k e^{k\lambda}$. These matrices obey the rs-matrix structure (II.2) with the s_{MN}-matrix given by the Theorem 3.

For these systems we can define a Riemann matrix of periods of holomorphic differentials and by using the Abel–Jacobi map we can find the action-angle variables. The potentials V_{MN} are the finite gap potentials on these manifolds.[17,18] For details about geodesic and potential motion with metric (III.15) in the *XXX* case see Refs. 17,18.

Thus we have constructed initial matrices L_0 and modified matrices L_{MN} (II.21)–(II.25) which correspond to a geodesic motion and a potential motion on Riemannian manifolds with metric (III.15), respectively. For the *XXX* case the initial matrix $L_0(\lambda)$ (III.8), (III.9), (III.12) was considered in Ref. 19 and the Hamiltonian H_0 (III.13) describes free motion on Riemannian spaces of constant curvature.

The above results describe motions on a Jacobi variety $((\Gamma\times\ldots\times\Gamma)/\sigma_n)$ which is a symmetric product of uniform Riemannian surfaces,

$$\Gamma: v_k^2=-d(\lambda)|_{\lambda=u_k}. \tag{III.18}$$

This scheme can be generalized to the case of the more general Jacobi variety $((\Gamma_1\times\Gamma_2\ldots\times\Gamma_n))$ with different Riemannian surfaces,

$$\Gamma_k^{(j)}: v_k^{(j)2}=-d^{(j)}(\lambda)|_{\lambda=u_k},\quad k=1,\ldots,n_j, j=1,\ldots,n, \tag{III.19}$$

where k and j are two numbers indexing curves. Motion on such manifolds can be described with the use of the block matrices,

$$L(\lambda)=\oplus_j^n L^{(j)}(\lambda,v_1^{(j)},u_1^{(j)};\ldots;v_{n_j}^{(j)},u_{n_j}^{(j)}), \tag{III.20}$$

acting in the auxiliary space,

$$V_{aux}=\oplus_j V_{aux}^{(j)}. \tag{III.21}$$

Here j denotes numbers of blocks and k denotes the number of degrees of freedom related to each block. Each block,

$$L^{(j)}(\lambda,v_1^{(j)},u_1^{(j)};\ldots;v_{n_j}^{(j)},u_{n_j}^{(j)}),$$

is a matrix of type $L_0(\lambda)$ or $L_{MN}(\lambda)$ (II.21), respectively. These manifolds have been investigated in Ref. 20 and such block matrices were considered in Ref. 10.

In the *XYZ* case parametrization of the entry $b(\lambda)$ is more complicated. For instance, it has to comply with the equality (II.12),

$$\{\tilde{b}(\lambda),\tilde{b}(\mu)\}=g(\lambda,\mu)\cdot\tilde{b}(\lambda)-g(\mu,\lambda)\cdot\tilde{b}(\mu).$$

In order to bypass this difficulty we can use two-dimensional lattice averaging[6] for the constructing matrices $L_0(\lambda)$ from the corresponding matrices of the rational model.

IV. CANONICAL TRANSFORMATIONS OF VARIABLES

We can represent meromorphic matrix-functions $L(\lambda)$ by means of generators of various Lie groups, which one can consider as the various phase spaces for the integrable systems. This leads to links among different integrable systems: the Neumann problem, Gaudin magnets and Euler tops.[12,19] In this paper we shall consider finite-dimensional integrable systems of the natural type and shall investigate three types of canonical transformations of variables prescribed by a linear r-matrix structure (II.1), (II.2).

A. Generalized elliptic coordinates

If the limit orders of poles m_j at the points e_j are fixed, then the Poisson brackets at different poles are independent and the corresponding orbits are a direct product of orbits of algebra $su(2)$. This factorization is independent of the points e_j.[12] By the Mittag–Leffler theorem we can decompose rational functions $b(\lambda)$ (III.8) and $a(\lambda)$ (III.9) into partial fractions,

$$b(\lambda)=P_b^{n-m}(\lambda)+\sum_{j,i} b_{ji}\cdot\varphi^{-i}(\lambda-e_j)=\prod_{k=1}^{n-m}\varphi(b_k-\lambda)+\sum_{j,i} b_{ji}\cdot\varphi^{-i}(\lambda-e_j),$$
$$a(\lambda)=P_a^{n-m-1}(\lambda)+\sum_{j,i} a_{ji}\cdot\varphi^{-i}(\lambda-e_j)=\prod_{k=1}^{n-m-1}\varphi(a_k-\lambda)+\sum_{ji} a_{ji}\cdot\varphi^{-i}(\lambda-e_j), \tag{IV.1}$$

where b_k and a_k are zeroes of the polynomials $P_b^{n-m}(\lambda)$ and $P_a^{n-m-1}(\lambda)$, respectively. The residues b_{ji} and a_{ji} at the points e_j are linear coordinates on the algebra $su(2)^*$ (III.3). We use the later two representations for generators of this algebra in terms of canonical variables,

$$b_j=x_j^2,\quad a_j=x_jp_j,\quad c_j=p_j^2, \tag{IV.2}$$

$$b_j=2x_jX_j,\quad a_j=x_jp_j+X_jP_j,\quad c_j=2p_jP_j. \tag{IV.3}$$

We omit here the double indexes ji which are necessary for higher order poles and we used notation c_j for residues of entry $c(\lambda)$. Variables x_j, p_j and X_j, P_j are canonically conjugate coordinates and momenta. Generalized elliptic coordinates correspond to the first representation (IV.2) and in our scheme they are a simple consequence of the Mittag–Leffler theorem for meromorphic functions.

The other $(n-m)$ variables can be chosen as zeroes of the polynomial $P_b^{n-m}(\lambda=x_k)$ and as the values of function $P_a^{n-m-1}(\lambda)$ at these zeroes x_k,

$$P_b^{n-m}(\lambda=x_k)=0,\quad p_k=P_a^{n-m-1}(\lambda=x_k). \tag{IV.4}$$

Variables x_k, $k=m+1,\ldots,n$ are calculated from the coefficients of the polynomial $P_b^{n-m}(\lambda)=\Sigma\ B_k\lambda^k$. For instance, in the XXX case with simple poles these coefficients are equal to

$$B_k=\frac{1}{(k-1)!}\frac{d^{k-1}}{d\lambda^{k-1}}\,b(\lambda)\bigg|_{\lambda=0}+(-1)^k\sum_{j=1}^{m}\frac{x_j^2}{e_j^{k+1}}, \tag{IV.5}$$

then the conjugate (to the x_k) momenta p_k, $k=m+1,\ldots,n$ are

$$p_k=a(\lambda)|_{\lambda=x_k}-\sum_{j=1}^{m}\frac{x_jp_j}{x_k-e_j}. \tag{IV.6}$$

Lemma 3: Variables x_j,p_j $j=1,\ldots,m$ and x_k,p_k $k=m+1,\ldots,n$ are a system of canonically conjugate variables.

Proof: The Mittag–Leffler theorem defines a unique, invertible map between old n pairs of variables (u_k,v_k), $k=1,\ldots,n$ and the new n pairs of variables (x_k,p_k), $k=1,\ldots,n$. The proof of canonical conjugation of these variables is based on the r-matrix structure. The technique developed by Sklyanin (see Ref. 1) has to be employed.

In the case of higher order poles we have an additional freedom in representing residues through canonical variables. There are two approaches to this problem. The first one is connected with standard degenerations of simple divisors, for example $e_j \to e_{j+1}$ or $e_j \to \infty$. This approach is developed in Refs. 9,21. Our approach is different.

We shall show how the variables (q_j, p_j) are connected to Newton type variables for stationary flows of KdV type equations introduced in Ref. 5. We shall consider the XXX case but generalization for the XXZ case is transparent. The r-matrix algebra is associative; a linear combination of any two matrices L_1 and L_2 satisfying (II.1) satisfies (II.1) too. Let us consider the polynomial part of $L_0(\lambda)$ corresponding to poles at infinity. The determinants of $L_0(\lambda)$ and $L(\lambda)$ from (II.39)–(II.43) are

$$d_0(\lambda) = \frac{b \cdot b_{xx}}{2} - \frac{b_x^2}{4}, \quad d(\lambda) = \frac{b \cdot b_{xx}}{2} - \frac{b_x^2}{4} + b^2 \cdot u_{MN}(\lambda). \tag{IV.7}$$

They are integrated forms of the KdV recursion relations.[5]

A simple substitution for the entries of matrix $L_0(\lambda)$,

$$b(\lambda) = \mathscr{B}^2, \quad a(\lambda) = -b_x/2 = -\mathscr{B}\mathscr{B}_x, \qquad c(\lambda) = -b_{xx}/2 = -\mathscr{B}_x^2 - \mathscr{B}\mathscr{B}_{xx}, \tag{IV.8}$$

turns determinants (IV.7) into the form

$$d_0(\lambda) = \mathscr{B}^3 \mathscr{B}_{xx}, \quad d(\lambda) = \mathscr{B}^3 \mathscr{B}_{xx} + \mathscr{B}^4 \left[\frac{f(\lambda)}{\mathscr{B}^4} \right]_{MN}, \tag{IV.9}$$

if we use an explicit formula for the potential $u_{MN}(\lambda)$. These equations have the form of Newton equations for $\mathscr{B}$,

$$\mathscr{B}_{xx} = d_0(\lambda) \mathscr{B}^{-3}, \quad \mathscr{B}_{xx} = d(\lambda) \mathscr{B}^{-3} - \mathscr{B} \left[\frac{f(\lambda)}{\mathscr{B}^4} \right]_{MN}. \tag{IV.10}$$

If we assume that $\mathscr{B} = \Sigma_{j=0}^{N} q_{N-j} \lambda^j$ is a polynomial then its coefficients q_j obey the Newton equation of motion (IV.10) with $d(\lambda) = \Sigma\, I_k \lambda^k$, where I_k are integrals of motion. It becomes clear in terms of variables q_j that deformation of integrals of motion I_k affects only the potential (q-dependent) part. The kinetic (momentum dependent) part of I_k remains unchanged.

Coefficients of all entries $a(\lambda)$, $b(\lambda)$ and $c(\lambda)$ are easily expressed in terms of coefficients of $\mathscr{B}$. Let us fix the highest order of λ in entry as K, then

$$b(\lambda) = \sum_{j=0}^{K} b_j \lambda^j, \quad a(\lambda) = \sum_{j=0}^{K} a_j \lambda^j, \quad c(\lambda) = \sum_{j=0}^{K} c_j \lambda^j, \tag{IV.11}$$

with

$$b_K = 1, \quad a_K = 0, \quad c_K = 0, \tag{IV.12}$$

due to the definition of M_0 and Φ_λ. Let

$$\mathscr{B}(\lambda) = \sum_{j=0}^{K} q_{K-j} \lambda^j, \quad \text{with } q_0 = 1,$$

where the set $\mathscr{B}$ we consider as a formal set. After substitution of these definitions into (IV.8) we obtain

$$b_j=\sum_{i=0}^{K-j} q_i q_{K-j-i}, \quad a_j=-\sum_{i=0}^{K-j} q_{i,x} q_{K-j-i},$$
$$c_j=-\sum_{i=0}^{K-j} q_{i,x} q_{K-j-i,x}-\sum_{i=0}^{K-j} q_{i,xx} q_{K-j-i}, \tag{IV.13}$$

where q_x is derivate with respect to x, and we used the Newton formulae for a product of sets. From $q_0=1$ and the definitions (IV.13) the restrictions (IV.12) for the higher coefficients of entries of matrix L_0 follow automatically. Canonically conjugate (to the coordinates q_j) momenta p_j can be derived from the r-matrix algebra (II.1) and from the definitions (IV.11)–(IV.13),

$$p_j=q_{K+1-j,x}, \quad \{p_j,q_k\}=\delta_{jk}.$$

As an example, we present first polynomials,

$$K=1, \quad b(\lambda)=\lambda+2q_1, \quad -a(\lambda)=p_1,$$
$$K=2, \quad b(\lambda)=\lambda^2+2\lambda x_1+(2x_2+x_1^2), \quad -a(\lambda)=\lambda p_2+(p_1+p_2 x_1), \tag{IV.14}$$
$$K=3, \quad b(\lambda)=\lambda^3+2\lambda^2 x_1+\lambda(2x_2+x_1^2)+2(x_3+x_1 x_2),$$
$$-a(\lambda)=\lambda^2 p_3+\lambda(p_2+p_3 x_1)+(p_1+p_2 x_1+p_3 x_2).$$

All integrals of motion can be expressed in terms of new variables directly from the equations (IV.9) by taking residues. Notice that the kinetic part of the Hamiltonian $H=\Phi_\lambda[d(\lambda)]$ has the nondiagonal form

$$T=\sum_{j=1}^{K+1} p_j p_{K-j}. \tag{IV.15}$$

Definition of the variables of separation is not changed by deforming the Lax matrix $L_0(\lambda)$ (II.21). For instance, the free motion Hamiltonian $H=T$ (IV.15) and the corresponding Hamiltonian with potential terms $H=T+V_{MN}$ separate in the same coordinate systems.

A. Jacobi coordinates

Let us take a simplest matrix $L_0^{(k)}(\lambda)$ with the entry $b(\lambda)$ of (III.8) which has only one zero,

$$L_0^{(k)}(\lambda,v_k,u_k)=\begin{pmatrix} -v_k & \varphi(\lambda-u_k) \\ 0 & v_k \end{pmatrix}. \tag{IV.16}$$

It obeys the linear r-matrix algebra (II.1) with the r-matrix (II.13) or (II.14). Let

$$L_0(\lambda)=\oplus_k^n L_0^{(k)}(\lambda,v_k,u_k), \tag{IV.17}$$

which means that we associate to our system a matrix L, which has blocks structure, and each block $L_0^{(k)}$ obeys the r-algebra with the same r-matrix.

A modified matrix $L(\lambda)$ (II.21) is equal to

$$L(\lambda)=\oplus_k^n L_{MN}^{(k)}(\lambda,v_k,u_k), \tag{IV.18}$$

where blocks $L_{MN}^{(k)}(\lambda,v_k,u_k)$ are

$$L_{MN}^{(k)}(\lambda,v_k,u_k)=\begin{pmatrix} -v_k & \varphi(\lambda-u_k) \\ \left[\dfrac{f(\lambda)}{\varphi(\lambda-u_k)}\right]_{MN} & v_k \end{pmatrix}. \tag{IV.19}$$

These matrices are deformations of the initial matrices $L_0(\lambda,v_k,u_k)$ (IV.16) and each block $L_{MN}^{(k)}$ obeys the rs-algebra with a common r-matrix but different (since they depend on u_k) matrices $s_{MN}^{(k)}$ constructed according to (II.28).

The matrix L_0 (IV.16) and the modified matrix L_{MN} (IV.19) have an internal structure,[21]

$$\begin{aligned} L_0(\lambda,v_k,u_k)&=\begin{pmatrix} -v_k & \varphi(\lambda-u_k) \\ 0 & v_k \end{pmatrix}=\begin{pmatrix} -\Sigma\alpha_j p_j^{(k)} & \varphi(\lambda-\Sigma\alpha_j^{-1}q_j^{(k)}) \\ 0 & \Sigma\alpha_j p_j^{(k)} \end{pmatrix}, \\ L_{MN}(\lambda,v_k,u_k)&=\begin{pmatrix} -\Sigma\alpha_j p_j^{(k)} & \varphi(\lambda-\Sigma\alpha_j^{-1}q_j^{(k)}) \\ \left[\dfrac{f(\lambda)}{\varphi(\lambda-\Sigma\alpha_j^{-1}q_j^{(k)})}\right]_{MN} & \Sigma\alpha_j p_j^{(k)} \end{pmatrix}, \end{aligned} \tag{IV.20}$$

if variables v_k and u_k are considered as linear combinations of certain canonical variables $p_j^{(k)}$, $q_j^{(k)}$ $j=1,\ldots,K$. If we consider a system with an n degree of freedom and require that the Hamiltonian has a natural canonical form with the kinetic energy form,

$$T^{(n)}=\sum_{k=1}^{n} v_k^2=\sum\ q_j^2;$$

then the internal structure of (IV.20) leads to the Jacobi transformations for a n-degrees of freedom systems. It is then a pure coordinate change of variables. As before free motion equations corresponding to the undeformed matrix and motion with potential corresponding to the modified matrix separate in the same system of coordinates.

B. Momentum dependent change of variables

Let us consider functions $B_j(\lambda)$ and $A_j(\lambda)$, which are algebraic functions of entries of the matrix $L(\lambda)$ and which satisfy suitable Poisson brackets, for example

$$\{A_j(\lambda),A_k(\mu)\}=\{B_j(\lambda),B_k(\mu)\}=0,$$

$$\{A_j(\lambda),B_k(\mu)\}=\delta_{jk}\cdot g(\lambda,\mu)\cdot(B_j(\lambda)-B_k(\mu)).$$

We shall require that zeroes of the functions $B_j(\lambda)$ and values of functions $A_j(\lambda)$ at these zeroes define a new system of coordinates. Because functions $B_j(\lambda)$ and $A_j(\lambda)$ are meromorphic functions it will also be interesting to consider the corresponding residues. The first example of the such transformations associated to Henon-Heiles system has been considered in Ref. 10.

Now we present new transformation related to the two particles quartic potential.[22] In the same way as for the Jacobi transformations we consider the block matrices $L(\lambda)$ (IV.18) with the two simplest blocks (IV.19).[10]

Lemma 4: The map $(u_1,u_2,v_1,v_2)\to(x,p,p_x,p_y)$ *given by*

$$x^2=\alpha\frac{d_1(\lambda)-d_2(\lambda)}{b_1^2(\lambda)-b_2^2(\lambda)}\bigg|_{\lambda=0};\quad \alpha\in\mathbf{R},\quad p_x=\frac{a_1(\lambda)b_1(\lambda)-a_2(\lambda)b_2(\lambda)}{b_1^2(\lambda)-b_2^2(\lambda)}\bigg|_{\lambda=0}\cdot x;$$
$$y^2=\beta(b_1^2(\lambda)+b_2^2(\lambda))_{\lambda=0}-\frac{\alpha\beta p_x^2}{2x^2}+\frac{x^2}{2},\quad \beta\in\mathbf{R};\tag{IV.21}$$
$$p_y y=\frac{1}{4\beta}(a_1(\lambda)b_1(\lambda)+a_2(\lambda)b_2(\lambda))_{\lambda=0}+\alpha\beta\frac{p_x}{x}\left(1+\frac{p_x^2}{x^2}\right)+p_x x;$$

where $a_k(\lambda)$ *and* $b_k(\lambda)$ *are the entries of matrices* $L_{MN}(\lambda,v_k,u_k)$; $k=1,2$ (IV.19) *and* $d_k(\lambda)$ *are the corresponding determinants, is a canonical transformation.* Proof is based on the undeformed r-matrix algebra and on the following relation:

$$\{d_k(\lambda),d_j(\mu)\}=0,$$

which is given by the rs-algebra (II.2) with $s_{MN}^{(k)}$-matrices (II.28).

We emphasize that it is a non-pure coordinate change of variables and that a free motion on the manifold and a potential motion on it separate in different systems of coordinates.

V. CONCLUSIONS

We have developed here the rs-matrix scheme for natural finite-dimensional integrable systems connected to the KdV and the coupled KdV hierarchies. But it applies to other hierarchies of integrable nonlinear evolution equations as well. For the hierarchy of the KdV type equations the Lax matrix M_0 (II.37) is independent of the spectral parameter. The corresponding matrices for the AKNS hierarchy and for the SG hierarchy have one pole at infinity or two poles at infinity and at zero correspondingly.[6] For applying our scheme in these cases one has to redefine the projector Φ_λ:

$$\Phi_{\lambda\mu}=\varphi(\mu)\cdot\mathrm{Res}_{\lambda=\infty}^{K}+\mathrm{Res}_{\lambda=\infty}^{K-1},\quad \varphi(\mu)=\mu\ \text{ or }\ \varphi(\mu)=\mu+\frac{1}{\mu}.\tag{V.1}$$

These two choices of the function $\varphi(\mu)$ correspond to the AKNS and to the SG hierarchy if we use the second rational parametrization for the r-matrix of XXZ type (II.16) for the SG equation. The Hamiltonians in terms of the root variables u_k of finite-dimensional systems connected with stationary flows for this hierarchies were introduced in Refs. 17, 18.

In order to apply our approach to restricted flows of the AKNS hierarchy of equations[23] we have to fix the form of the matrix M_0 as

$$M_0(\mu)=\begin{pmatrix}\mu & w\\ u & -\mu\end{pmatrix},$$

and to choose the projector $\Phi_{\lambda\mu}$ in the form (V.1).

In the next step one has to consider the undeformed matrix $L_0(\lambda)$ corresponding to this choice of M_0 and $\Phi_{\lambda\mu}$ and prove that it obeys the r-matrix algebra. Let the matrix $L_0(\lambda)$ have the form

$$L_0(\lambda)=L_0^{\infty}(\lambda)+L_0^{D}(\lambda),$$

where we split $L_0(\lambda)$ into the polynomial (pole at infinity) part and the D-divisor part corresponding to finite poles. One finds the following sequence of L_0^{∞} matrices yielding the prescribed M_0 and $\Phi_{\lambda\mu}$ and satisfying the r-matrix algebra (II.1):

$$L_0^{\infty}(\lambda)=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix},$$

$$L_0^{\infty}(\lambda)=\begin{pmatrix}\lambda & q_1\\ p_1 & -\lambda\end{pmatrix}, \quad \{p_1,q_1\}=1,$$

$$L_0^{\infty}(\lambda)=\begin{pmatrix}\lambda^2-\dfrac{q_1q_2}{2} & \lambda q_1-2p_2\\ \lambda q_2-2p_1 & -\lambda^2+\dfrac{q_1q_2}{2}\end{pmatrix}, \quad \{p_2,q_2\}=1.$$

The analog of the parametrization related to the Newton representation (IV.14)[5] for the recurrent construction of these matrices is not known as yet. In this case the Hamiltonians are equal to $H=\Phi_{\lambda\mu}[d(\lambda)]$, but they do not depend on the spectral parameter μ since the corresponding residues are equal to zero.

The matrix M_0 is more symmetric by its entries in this case and respective integrable systems are of the non-natural type[23] one can use various solutions of the equations (II.15) for the deformation coefficients α_j. Systems with such deformations will be investigated in detail in the forthcoming publications.

Finally, we remark that the rs-matrix scheme presented in this paper applies to the discrete time analogs of soliton hierarchies. It yields an rs-matrix description of integrable symplectic maps.

(Received 18 October 1995; accepted for publication 26 February 1996)

Lie superalgebraic methods are used to establish a connection between the huge Lie superalgebra Ξ of super- (pseudo-) differential operators and various super KP-hierarchies. We show in particular that Ξ splits into $5=2\times2+1$ graded algebras expected to correspond to five classes of super-KP-hierarchies generalizing the well-known Manin–Radul and Figueroa–Mas–Ramos supersymmetric KP-hierarchies. © *1996 American Institute of Physics.* [S0022-2488(96)02506-6]

I. INTRODUCTION

Recently, there has been much interest in studying two-dimensional integrable models.[1,2] Known as the generalized KdV-hierarchies, these models are incorporated into a much larger integrable system, namely the KP-hierarchy.[3] This is defined as a set of multitime evolution equations, which read in the Lax form as

$$\frac{\partial L}{\partial t_r}=[L_+^r,L],\quad r=1,2,3,\dots, \tag{1}$$

where L is a pseudo-differential operator given by

$$L=\partial+\sum_{i\geqslant1} U_i(z)\partial^{1-i},\quad \partial=\frac{\partial}{\partial z}. \tag{2}$$

There are various remarkable properties of the KP-hierarchy. The most essential ones are its bi-Hamiltonian structures[1,4] and the fact that it admits a Lax formulation.[1,5] Several extensions of the standard KP-hierarchy, Eqs. (1), (2), are possible. The more known ones, given by the supersymmetric extensions of the hierarchy, Eqs. (1), (2), are based on the Manin–Radul odd pseudo-superdifferential operator,[6]

$$L=D+\sum_{i\geqslant0} U_{(i+1)/2}(\hat{z})D^{-i}, \tag{3}$$

and the Figueroa O'Farrill–Mas–Ramos even pseudo-superdifferential operator,[7]

$$L=D^2+\sum_{i\geqslant0} U_{(i+2)/2}(\hat{z})D^{-i}, \tag{4}$$

with $D=\partial_\theta+\theta\partial$.

In this Letter we propose a consistently algebraic formulation of the extended KP-integrable systems. We will present a systematic description of the Lie superalgebra Ξ of supersymmetric

[a)]Mailing address: Section de Physique des Hautes Energies, LMPHE, Faculté des Sciences, Ibn Batouta, B.P. 1014-Rabat Morocco.

pseudo-differential operators and we will show, in particular, that it splits into $6=3\times2$ Lie superalgebras. To establish a connection with the supersymmetric extensions of the KP-hierarchy, Eqs. (1), (2), we will define $5=2\times2+1$ graded spaces of pseudo-superdifferential operators containing as a particular element the Figueroa–Mas–Ramos, Eq. (4), and the Manin–Radul, Eq. (3), superdifferential Lax operators, and we will conclude by expecting that these five graded spaces correspond to five classes of supersymmetric KP-hierarchies.

II. THE ALGEBRA Ξ OF SUPER-PSEUDO-DIFFERENTIAL OPERATORS

A. The ring $\mathscr{R}$ of analytic superfields

Let us first consider the ring of analytic superfields $U_{k/2}(\hat{z})$, $k\in\mathbf{Z}$, which depend on $(1|1)$ superspace coordinates $\hat{z}=(z,\theta)$. In this supercommutative $\mathbf{Z}_2$-graded ring $\mathscr{R}$, one can define an odd superderivative $D=\partial_\theta+\theta\partial$, the $N=1$ supercovariant derivative that obeys the $N=1$ supersymmetric algebra $D^2=\partial$ with $\theta^2=0$ and $\partial_\theta=\int d\theta$. Following the analysis developed in Ref. 8, the ring $\mathscr{R}$ can be decomposed as

$$\mathscr{R}=\bigoplus_{k\in\mathbf{Z}}\mathscr{R}_{k/2}^{(0,0)}, \tag{5}$$

where $\mathscr{R}_{k/2}^{(0,0)}$ is the set of superfields $U_{k/2}(\hat{z})$ labeled by half-integer conformal spin $k/2$, $K\in\mathbf{Z}$. The upper indices (0,0), carried by $\mathscr{R}$ and that we shall drop whenever no confusion can arise, are special values of general indices (p,q) to be introduced later on. One can also define the following product:

$$\langle U_{k/2},U_{l/2}\rangle=\delta_{k+l,1}\int d\hat{z}\,\frac{U_k}{2}(\hat{z})U_{(1-k)/2}(\hat{z}), \tag{6}$$

showing that the one-dimensional subspaces $\mathscr{R}_{k/2}$ and $\mathscr{R}_{(1-k)/2}$ are dual to each other. Using dimensional arguments, it is not difficult to see that the product $\langle\cdot,\cdot\rangle$, Eq. (6), carries a conformal spin $\Delta=-\frac{1}{2}$. Later on, we shall introduce a combined scalar product $\langle\langle\cdot,\cdot\rangle\rangle$ built out of Eq. (6) and the pairing product (,) of conformal spin $\Delta=1/2$, so that we get $\Delta[\langle\langle,\rangle\rangle]=0$.

Since the conformal spin product, Eq. (6), gets induced here, we have that $\mathscr{R}=\mathscr{H}_+\oplus\mathscr{H}_-$, where $\mathscr{H}_+$ and $\mathscr{H}_-$ are two dual semi-infinite tensor subspaces characterized, respectively, by positive and negative conformal spin as shown here below,

$$\mathscr{H}_+=\bigoplus_{k>0}\mathscr{R}_{k/2},\quad \mathscr{H}_-=\bigoplus_{k>0}\mathscr{R}_{(1-k)/2}. \tag{7}$$

We learn, in particular, that the space $\mathscr{R}_0$ of vanishing conformal spin superfields $U_0(\hat{z})$, is the dual of the space $\mathscr{R}_{1/2}$ generated by the superfield $U_{1/2}(\hat{z})$ of conformal spin 1/2. We remark, also, that the conformal spin product, Eq. (6), agrees with the $\mathbf{Z}_2$-grading,

$$\mathscr{R}=\mathscr{R}_{\bar{0}}\oplus\mathscr{R}_{\bar{1}}, \tag{8a}$$

with

$$\mathscr{R}_{\bar{0}}=\mathscr{H}_{+\bar{0}}\oplus\mathscr{H}_{-\bar{0}},\quad \mathscr{R}_{\bar{1}}=\mathscr{H}_{+\bar{1}}\oplus\mathscr{H}_{-\bar{1}}, \tag{8b}$$

where $\mathscr{H}_{\pm,0}$ and $\mathscr{H}_{\pm,1}$ are subspaces related to each other by the duality conjugation,

$$[\mathscr{H}_\pm]_0^*=[\mathscr{H}_\mp]_{\bar{1}}. \tag{8c}$$

B. The superspace $\Xi_{m/2}^{(p,q)}$ and super Lax operators

Consider the superspace $\Xi_{m/2}^{(p,q)}$ labeled by three quantum numbers $m/2$, p, and q defining, respectively, the conformal spin, the lowest, and the highest degrees. Typical elements of this superspace are given by

$$L_{m/2}^{(p,q)}[u]=\sum_{i=p}^{q} U_{(m-i)/2}(\hat{z})D^i, \quad p,q,m\in\mathbf{Z}, \tag{9}$$

where $U_{(m-i)/2}/(\hat{z})$ are an analytic superfield of conformal spin $(m-i)/2\cdot\Xi_{m/2}^{(p,q)}$ behaves then as a $(1+q-p)$-dimensional superspace generated by $L_{m/2}^{(p,q)}$ and whose superspace decomposition is given by the linear sum

$$\Xi_{m/2}^{(p,q)}=\bigoplus_{i=p}^{q}\Xi_{m/2}^{(i,i)}, \tag{10a}$$

with

$$\Xi_{m/2}^{(i,i)}=\mathscr{R}_{(m-i)/2}\oplus D^i, \tag{10b}$$

where $\mathscr{R}_{k/2}=\Xi_{k/2}^{(0,0)}$ is the ring of analytic superfields $U_{k/2}(\hat{z})$ introduced previously. For any element $L_{m/2}^{(p,q)}$ of the superspace $\Xi_{m/2}^{(p,q)}$, one can introduce the conformal spin Δ, the degrees (deg), and the grading $|\cdot|$, properties, which are summarized in the following table:

$$\begin{array}{ccccc} & \Delta & \deg & |\cdot| \\ U_{i/2}\ D^j & \dfrac{i+j}{2} & (j,j) & (i+j)\bmod 2 \\ \Xi_{m/2}^{(p,q)} & \dfrac{m}{2} & (p,q) & m(\mathrm{mod}\ 2) \end{array} \tag{11}$$

An element $L_{m/2}^{(p,q)}$ is called a super Lax operator, if it is homogeneous under the $\mathbf{Z}_2$-grading,

$$|x|=\begin{cases} 0, & \text{for } x \text{ even}, \\ 1, & \text{for } x \text{ odd}, \end{cases} \tag{12}$$

and have the following form at order $m,m\in\mathbb{N}$,

$$L_{m/2}^{(0,m)}=D^m+\sum_{i=1}^{m} U_{i/2}(\hat{z})D^{m-i}. \tag{13}$$

The homogeneity condition simply states that the $\mathbf{Z}_2$-grading of the analytic superfield $U_{i/2}(\hat{z})$ is defined as

$$|U_{i/2}(\hat{z})|=i(\mathrm{mod}\ 2). \tag{14}$$

Setting $m=2n$, $p=1$, and $q=2n$ into Eq. (9), one recovers the Inami Kanno super Lax operator of $2n$th order,[9] associated to the affine Lie superalgebra $A(n-1|n-1)^{(1)}$, namely

$$L_n^{(1,2n)}[u]=D^{2n}+\sum_{i=1}^{n-1}[U_i(\hat{z})D^{2(n-i)}+U_{(2i+1)/2}(\hat{z})D^{2(n-i)-1}]. \tag{15}$$

The space of supersymmetric Lax operators, Eq. (13), is given by the coset space

$$\mathscr{M}^{(m-1)}=\Xi^{(0,m)}_{m/2}/\Xi^{(m-1/m-1)}_{m/2}, \tag{16}$$

which exhibits a dimension $m-1$.

To define a Lie algebraic structure on the superspace $\Xi^{(p,q)}_{m/2}$, one needs to introduce a Lie bracket defined for two arbitrary operators X and Y as

$$[X,Y]=XY-(-)^{|X|\cdot|Y|}YX. \tag{17}$$

It follows then that $\Xi^{(p,q)}_{m/2}$ defines a Lie superalgebra, provided that

$$m=0 \qquad \text{and} \quad p\leqslant q\leqslant 1. \tag{18}$$

The multiplication of operators in $\Xi^{(p,q)}_{m/2}$ is given by the generalized Leibnitz rule,[6]

$$D^i\phi(\hat{z})=\sum_{k=0}^{\infty}\begin{bmatrix} i \\ i-k \end{bmatrix}(-)^{|\phi|(i-k)}\phi^{(k)}(\hat{z})D^{i-k}, \tag{19}$$

where $\phi^{(k)}=D^k\phi$ and $[{}^{i}_{i-k}]$, $i\in\mathbf{Z}$, is the superbinomial coefficient given by

$$\begin{bmatrix} i \\ k \end{bmatrix}=\begin{cases} 0, & \text{for } k>i \quad \text{or} \quad (i,k)\equiv(0,1) \mod 2, \\ \begin{pmatrix} [i/2] \\ [k/2] \end{pmatrix} & \text{otherwise.} \end{cases} \tag{20}$$

The symbol $[x]$ stands for the integer part of $x\in(1/2)\mathbf{Z}$ and $\binom{i}{j}$ is the usual binomial coefficient.

C. The huge Lie superalgebra Ξ

A larger set of supersymmetric pseudo-differential operators than $\Xi^{(p,q)}_{m/2}$ is give by the infinite-dimensional vector space $\Xi^{(p,q)}$ of superdifferential operators with given degrees $(p,q),p,q\in\mathbf{Z}$, but indefinite conformal spins,

$$\Xi^{(p,q)}=\bigoplus_{m\in\mathbf{Z}}\Xi^{(p,q)}_{m/2}. \tag{21}$$

The set $\Xi^{(p,q)}$ exhibits a Lie superalgebra structure wth respect to the bracket, Eq. (17), provided that

$$p\leqslant q\leqslant 1. \tag{22}$$

Using the conformal spin product, Eq. (6), it follows that $\Xi^{(p,q)}$ decomposes as

$$\Xi^{(p,q)}=\Lambda^{(p,q)}_{+}\oplus\Lambda^{(p,q)}_{-}, \tag{23a}$$

with

$$\Lambda^{(p,q)}_{+}=\bigoplus_{k>0}\Xi^{(p,q)}_{k/2}, \quad \Lambda^{(p,q)}_{-}=\bigoplus_{k>0}\Xi^{(p,q)}_{(1-k)/2}. \tag{23b}$$

Setting $(p,q)=(0,0)$, Eqs. (21) and (23) reduce, respectively, to Eqs. (5) and (7) with $\Xi^{(0,0)}=\mathscr{R}$ and $\Lambda^{(0,0)}_{\pm}=\mathscr{H}_{\pm}$.

A huge Lie superalgebra is obtained by summing from Eq. (21) over all the allowed values of the degrees (p,q). It is defined by

$$\Xi=\bigoplus_{p\leqslant q}\Xi^{(p,q)}, \tag{24a}$$

or equivalently

$$\Xi = \bigoplus_{p\in\mathbf{Z}}\Big[\bigoplus_{n\in\mathbb{N}}\Xi^{(p,p+n)}\Big]. \tag{24b}$$

Remark that the infinite-dimensional superspace Ξ is closed under the Lie bracket, Eq. (17), without any constraint. Remark also that combining the conformal spin and the degrees quantum numbers, one can write

$$\Xi = \bigoplus_{p\in\mathbf{Z}}\bigoplus_{n\in\mathbb{N}}\bigoplus_{m\in\mathbf{Z}}\Xi^{(p,q)}_{m/2}. \tag{25}$$

Let us now consider $L^{(p,q)}$ and $P^{(r,s)}$, two super-(pseudo-) differential operators with fixed degrees but indefinite conformal spin. The degree pairing product $(\cdot,\cdot)$ associated to $L^{(p,q)}$ and $P^{(r,s)}$ is defined as

$$(L^{(p,q)},P^{(r,s)}) = \delta_{p+s+1,0}\delta_{q+r+1,0}\delta\ \mathrm{res}(L^{(p,q)}\cdot P^{(r,s)}), \tag{26}$$

where $(\delta\,\mathrm{res})$ is the super-residue operation given by

$$\delta\ \mathrm{res}\ D^i = \delta_{i+1,0}. \tag{27}$$

Using Eqs. (25) and (26), one can easily check that $\Delta[(\cdot,\cdot)]=\frac{1}{2}$. Combining the conformal spin and the degree pairing products Eqs. (6) and (26), one defines the following combined scalar product:

$$\langle\langle L^{(p,q)}_{m/2},P^{(r,s)}_{m/2}\rangle\rangle = \delta_{p+s+1,0}\delta_{q+r+1,0}\delta_{n+m,0}\int d\hat{z}\ \delta\ \mathrm{res}[L^{(p,q)}_{m/2}\circ P^{(r,s)}_{n/2}], \tag{28}$$

so that $\Delta[\langle\langle\cdot,\rangle\rangle]=0$.

The combined scalar product we have defined in Eq. (28) plays an important role in the construction of the supersymmetric Gelfand–Dickey (SGD) Poisson bracket; see Ref. 10.

As shown in the bosonic case,[8] we note that the superspaces $\Xi^{(p,q)}$ and $\Xi^{(-q-1,-p-1)}$ are dual to each other, with respect to the degree pairing product, Eq. (26). It is then straightforward to see that the Lie superalgebra Ξ decomposes as

$$\Xi = \Xi^{+}\oplus\Xi^{-}, \tag{29a}$$

with

$$\Xi^{+} = \bigoplus_{p\geqslant 0}\bigoplus_{n\in\mathbb{N}}\Xi^{(p,p+n)},\quad \Xi^{-} = \bigoplus_{p\geqslant 0}\bigoplus_{n\in\mathbb{N}}\Xi^{(-p-n-1,-p-1)}, \tag{29b}$$

or equivalently, by using the combined scalar product, Eq. (28),

$$\Xi^{+} = \bigoplus_{p\geqslant 0}\bigoplus_{n\in\mathbb{N}}\bigoplus_{m\in\mathbf{Z}}\Xi^{(p,p+n)}_{m/2},\quad \Xi^{-} = \bigoplus_{p\geqslant 0}\bigoplus_{n\in\mathbb{N}}\bigoplus_{m\in\mathbf{Z}}\Xi^{(-p-n-1,-p-1)}_{m/2}. \tag{29c}$$

Next, we introduce the graded algebras Σ^{k}_{ij} and their dual $(\Sigma^{k}_{ij})^{*}=\Sigma^{-k}_{-i,j}$, with respect to Eq. (28), where the indices $k=\pm$, $i=0,\pm$, and $j=0,1(\mathrm{mod}\ 2)$ refer, respectively, to the degrees, the conformal spin, and the grading quantum numbers. As an example, Σ^{+}_{+0} is the bosonic Lie algebra of superdifferential operators of positive definite spins and degrees and Σ^{-}_{-0}, its dual, the Lie algebra of super pseudo-differential operators of negative definite spins and degrees. Σ^{+}_{+0} is just

the Lie algebra of Lorentz scalar differential operators containing the Lie algebra of vector fields on the circle, namely, diff(S^1) and its dual is $\Sigma^{-}_{-\,0}$. The graded Lie algebras Σ^{k}_{ij} are related to the superalgebras $\Xi^{\pm}$, Eqs. (29), as

$$\Xi^{+} \oplus \bigoplus_{i=0,\pm} \bigoplus_{j=\overline{0,1}} \Sigma^{+}_{i,j}, \quad \Xi^{-} \oplus \bigoplus_{i=0,\pm} \bigoplus_{j=\overline{0,1}} \Sigma^{-}_{-i,j}. \tag{30}$$

A remarkable property of the infinite-dimensional Lie superalgebra Ξ is that it splits into a linear sum of $6=3\times 2$ graded subalgebras given by

$$\Xi = \bigoplus_{i=0,\pm} (S_i \oplus S_i^{*}), \tag{31}$$

where the graded Lie subalgebra S_i and its dual S_i^{*} split for a fixed conformal spin index i into

$$S_i = \Sigma^{+}_{i,0} \oplus \Sigma^{+}_{i,1}, \quad S_i^{*} = \Sigma^{-}_{-i,0} \oplus \Sigma^{-}_{-i,1}, \tag{32a}$$

or equivalently,

$$S_{-} = \Sigma^{+}_{-,0} \oplus \Sigma^{+}_{-,1} \quad S_0 = \Sigma^{+}_{0,0}, \quad S_{+} = \Sigma^{+}_{+,0} \oplus \Sigma^{+}_{+,1}, \tag{32b}$$

and

$$S_{+}^{*} = \Sigma^{-}_{-,0} \oplus \Sigma^{-}_{-,1}, \quad S_0^{*} = \Sigma^{-}_{0,0}, \quad S_{-}^{*} = \Sigma^{-}_{+,0} \oplus \Sigma^{-}_{+,1}. \tag{32c}$$

III. THE HUGE LIE SUPERALGEBRA Ξ AND SUPER-KP-HIERARCHIES

Motivated by the well-known idea that the Lie (super) algebra methods allow for a unifying treatment of nonlinear integrable systems, we try in this section to find a relation between the Lie superalgebra Ξ of supersymmetric (pseudo-) differential operators discussed previously and the various (super-) KP integrable hierarchies. We first briefly review what is known about KP-hierarchy. The latter can be thought of as a dynamical system defined on a space whose functions $U_j(z)$ are elements of the ring $\mathscr{R}_j$ of analytic fields of conformal spin $j \in \mathbf{Z}$. It is also defined as the universal family of isospectral deformations of the pseudo-differential operator,[3]

$$L = \partial + \sum_{i \geqslant 1} U_i(z)\, \partial^{1-i}. \tag{33}$$

The evolution of L is given by a commuting family of flows $\partial_i = \partial/\partial t$, in terms of which we have

$$\partial_i L_1 = [(L^i)_{+}, L] = -[(L^i)_{-}, L]. \tag{34}$$

The subscript $+$(resp., $-$) means taking the purely differential (resp., pseudo-differential) part of L^i and $t=\{t_i\}$ an infinite system of time variables. The flows, Eq. (34), are bi-Hamiltonians in the sense that there exist two Poisson bracket structures $\{.,\}_{1,2}$ such that we can rewrite Eq. (34) as

$$\partial_i L = \{H_i, L\}_2 = \{H_{i+1}, L\}_1. \tag{35}$$

Here the Hamiltonians for the KP-hierarchy are $H_r = 1/r \int \mathrm{res}\, L^r$, with $\mathrm{res}\, \partial^{-1} = 1$.

There are two usual supersymmetric extensions of the standard KP-hierarchy, Eqs. (33),(34). The first one is given by the Manin–Radul supersymmetric KP-hierarchy associated to the odd super Lax operator,[6]

$$L=D+\sum_{i\geqslant 0} U_{(i+1)/2}(\hat{z})D^{-i}. \tag{36}$$

The second one is given by the supersymmetric KP-hierarchy associated to the even super Lax operator,[7]

$$L=D^2+\sum_{i\geqslant 0} U_{(i+2)/2}(\hat{z})D^{-i}. \tag{37}$$

The interesting consequence of the choice of L, Eq. (37), is that under a suitable choice of reduction, it reduces to the Inami–Kanno super Lax operator describing the generalized $N=2$ super KdV-hierarchy.[9]

Using the $6=3\times 2$ decomposition of the Lie superalgebra Ξ, Eqs. (31),(32), one suspects that there exist $5=2\times 2+1$ classes of supersymmetric KP-hierarchies. The origin of these hierarchies can be traced to the fundamental fact that there exist precisely five graded algebras,

$$\begin{aligned}
&\text{(a)}\quad g_1=(S_+\oplus S_-^*)_{\overline{0}}=\Sigma^{+}_{+0}\oplus\Sigma^{-}_{+0},\\
&\text{(b)}\quad g_2=(S_+\oplus S_-^*)_{\overline{1}}=\Sigma^{+}_{+1}\oplus\Sigma^{-}_{+1},\\
&\text{(c)}\quad g=(S_0\oplus S_0^*)_{\overline{0}}=\Sigma^{+}_{00}\oplus\Sigma^{-}_{00},\\
&\text{(d)}\quad g_2^*=(S_-\oplus S_+^*)_1=\Sigma^{-}_{-1}\oplus\Sigma^{+}_{-1},\\
&\text{(e)}\quad g_1^*=(S_-\oplus S_+^*)_{\overline{0}}=\Sigma^{-}_{0}\oplus\Sigma^{+}_{-0},
\end{aligned} \tag{38}$$

where $g_1=\Sigma^{+}_{+0}\oplus\Sigma^{-}_{+0}$, Eq. (38a), is the Lie algebra containing as a particular element, the even super Lax operator, Eq. (37), of the Figueroa–Mas–Ramos super KP-hierarchy. $g_2=\Sigma^{+}_{+1}\oplus\Sigma^{-}_{+1}$ is the graded space generated by elements like the odd super Lax operator, Eq. (36), corresponding to the Manin–Radul super KP-hierarchy. The graded spaces g_2^* and g_1^* are just the dual of g_2 and g_1 with respect to the combined scalar product, Eq. (28). Note also that the self-dual Lie algebra $g=\Sigma^{+}_{00}\oplus\Sigma^{-}_{00}$, Eq. (38c), containing the superdifferential operators of vanishing conformal spin type,

$$L=U_{-1/2}(\hat{z})D+\sum_{i\geqslant 0} U_{i/2}(\hat{z})D^{-i}, \tag{39}$$

necessitate in itself a particular interest, as it can lead to a new class of super KP-hierarchy. A more explicit description of these five super KP-hierarchies will be considered in a future paper.

IV. CONCLUSION

Using the huge Lie superalgebra Ξ of pseudo-superdifferential operators that splits into $6=3\times 2$ Lie superalgebras, Eqs. (31),(32), we have defined $5=2\times 2+1$ graded algebras, Eqs. (38). These graded algebras are expected to correspond to five classes of super KP-hierarchies generalizing the usual Manin–Radul and Figueroa–Mas–Ramos supersymmetric KP-hierarchies. We expect moreover that these $5=2\times 2+1$ super KP-hierarchies will provide a unified framework that exhibits the underlying structure of $2d$ quantum supergravity.

(Received 14 September 1995; accepted for publication 28 March 1996)

The prolongation structure of Zhiber–Mikhailov–Shabat (ZMS) equation is studied by using Wahlquist–Estabrook's method. The Lax pair for ZMS and Riccati equations for pseudopotentials are formulated respectively from linear and nonlinear realizations of the prolongation structure. Based on nonlinear realization of the prolongation structure, an auto-Bäcklund transformation of ZMS equation is obtained. © *1996 American Institute of Physics.* [S0022-2488(96)03007-1]

I. INTRODUCTION

The off-conformally integrable models in two-dimensional space-time have some common features. They have spectrum-dependent Lax pairs, an infinite number of conserved currents and the underlying nonlinear symmetries, and can be solved by means of inverse scattering method. The $a_2^{(2)}$ Toda model, i.e. Zhiber–Mikhailov–Shabat (ZMS) model, is of such a fascinating class of integrable two-dimensional field theories. It is the third and last relativistic single scalar Toda model (the others are Liouville and sine-Gordon models),[1,2] and has significant applications in physical context. To our knowledge, the equation of motion of ZMS model (ZMS equation) governs the propagation of resonant ultra-short plane wave optical pulses in certain *degenerate* media.[3] The integrability of ZMS model has been confirmed for a long time. The soliton solutions of the ZMS equation by means of inverse scattering method were given in Ref. 4. The S-matrix approach to the quantum version of the model was seriously investigated by Izergin and Korepin[5] in terms of the quantum inverse scattering method, and by Smirnov[6] and Efthimiou[7] in the framework of perturbative conformal field theory. Recently, we have studied the infinitesimal dressing transformations and Lie–Poisson structure hidden in ZMS model.[8] Nevertheless, there would not seem to be a good knowledge of the finite nonlinear symmetries (such as the dressing group symmetry and Bäcklund transformation) of the model. In order to fill in the gap, we study the prolongation structure of ZMS equation in the spirit of Wahlquist–Estabrook's (WE's) prolongation approach[9,10] in the present paper. Owing to the so-called prolongation structure, we discover an auto-Bäcklund transformation of ZMS equation, which turns out to be a set of Riccati-type differential equations of the so-called pseudopotentials.

II. PROLONGATION STRUCTURE OF ZMS EQUATION

WE's prolongation structure is a very useful medium for searching Bäcklund transformation of nonlinear differential equations. To obtain the prolongation structure of ZMS equation:

[a)]Mailing address.

$$\partial_+\partial_-\phi-2(e^{\phi}-e^{-2\phi})=0, \tag{2.1}$$

we define the following two-forms on a four-dimensional manifold with coordinates associated with Eq. (2.1),

$$\begin{cases}\alpha_1=d\phi\wedge dx^+-\pi_\phi dx^-\wedge dx^+,\\ \alpha_2=d\pi_\phi\wedge dx^-+2(e^{\phi}-e^{-2\phi})dx^-\wedge dx^+.\end{cases} \tag{2.2}$$

These two-forms constitute a closed ideal and would become null on the solution manifold $(\phi(x^+,x^-),\pi_\phi(x^+,x^-),x^+,x^-)$. They are the Pfaff forms of ZMS equation. For the above Pfaff forms we will assume that prolongation forms can be given by some one-forms $\Omega^a(a=1,2,3,\ldots,\ N)$,

$$\Omega^a=-dq^a+F^a(\phi,\pi_\phi,q)dx^-+G^a(\phi,\pi_\phi,q)dx^+, \tag{2.3}$$

where N is an outstanding integer, q^a are the so-called pseudopotentials, and F^a and G^a are functionals of fields π_ϕ, ϕ and q^a.

The concept of pseudopotential plays a crucial role in the discussions of Bäcklund transformations and Lax pairs in WE's prolongation method. As a matter of fact, the expected Bäcklund transformation and the first-order differential equations satisfied by Lax pair of ZMS Eq. (2.1) will be formulated as the differential equations for suitably defined pseudopotentials q^a. The integrability of pseudopotentials q^a requires that the ideal generated by the form sets $\{\alpha^a\}$ and $\{\Omega^a\}$ is closed, i.e.,

$$d\Omega^a=\eta_b^a\wedge\Omega^b+f^{a,i}\alpha_i, \tag{2.4}$$

where η_b^a and $f^{a,i}$ are some one-forms and zero-forms respectively. When (2.4) is explicitly written out by using (2.2) and (2.3), it splits up into a set of partial differential equations:

$$\begin{gathered}\partial_\phi F^a=0,\quad \partial_{\pi_\phi}G^a=0,\\ F^b\partial_b G^a-G^b\partial_b F^a+\pi_\phi\partial_\phi G^a-2(e^{\phi}-e^{-2\phi})\partial_{\pi_\phi}F^a=0,\end{gathered} \tag{2.5}$$

where the derivative $\partial/\partial q^a$ is abbreviated to ∂_a. Analyzing these equations we find,

$$F^a=X_0^a+X_1^a\pi_\phi,\quad G^a=2Y_0^a e^{\phi}+2Y_1^a e^{-2\phi}. \tag{2.6}$$

In the ansatz (2.6) X_i^a and Y_i^a $(i=0,1)$ are assumed to be functions of q^a only.

For the convenience of the later discussions we now introduce some vector fields (Lie derivatives) X_i and Y_i in N-dimensional space of pseudopotentials (q-space),

$$X_i=X_i^a\partial_a,\quad Y_i=Y_i^a\partial_a. \tag{2.7}$$

It is then a direct consequence of (2.5)–(2.7) that,

$$[X_0,Y_0]=X_1,\ [X_0,Y_1]=-X_1,\ [X_1,Y_0]=-Y_0,\ [X_1,Y_1]=2Y_1. \tag{2.8}$$

Because of the absence of $[X_0,X_1]$ and $[Y_0,Y_1]$, the set of Lie brackets given by (2.8) does not form a closed linear algebra. It is obviously impossible that one may close the algebra by setting the unknown commutators to be linear combinations of the given generators such that the results are consistent with the Jacobi identities. This is a big difference between the prolongation structure of ZMS equation and those of sine-Gordon equation, Ernst equation and chiral model.[10,11] However, the algebra can be closed by assigning new generators to the unknown commutators and

repeating the process of working through the Jacobi identities. After a tedious but straightforward computation, we see that the enlarged algebra becomes an infinite-dimensional algebra $a_2^{(2)}$ (without center), which coincides with a well-known fact that ZMS model is the Toda field theory over the twisted Kac–Moody algebra $a_2^{(2)}$.[1,2] Let $\{H_i^{(m)}, E_{\pm\alpha}^{(m)}\}$ be the Cartan–Weyl basis of $a_2^{(2)}$, which obeys the following commutation relations:

$$
\begin{aligned}
[H_i^{(m)}, E_{\pm\beta}^{(n)}] = & \pm \delta_{i1}\delta_{\beta 1} E_{\pm 1}^{(m+n)} \mp 2\,\delta_{i1}\delta_{\beta 2} E_{\pm 2}^{(m+n)} \mp \delta_{i1}\delta_{\beta 3} E_{\pm 3}^{(m+n)} \\
& \pm 3\,\delta_{i2}\delta_{\beta 1} E_{\mp 3}^{(m+n)} \mp 3\,\delta_{i2}\delta_{\beta 3} E_{\mp 1}^{(m+n)},
\end{aligned}
$$

$$
[E_{\pm\alpha}^{(m)}, E_{\pm\beta}^{(n)}] = \mp \delta_{\alpha 1}\delta_{\beta 2} E_{\pm 3}^{(m+n)} \pm \delta_{\alpha 1}\delta_{\beta 3} H_2^{(m+n)}, \tag{2.9}
$$

$$
\begin{aligned}
[E_{\alpha}^{(m)}, E_{-\beta}^{(n)}] = & (\delta_{\alpha 1}\delta_{\beta 1} - \delta_{\alpha 2}\delta_{\beta 2} - \delta_{\alpha 3}\delta_{\beta 3}) H_1^{(m+n)} - \delta_{\alpha 3}\delta_{\beta 2} E_1^{(m+n)} - \delta_{\alpha 2}\delta_{\beta 3} E_{-1}^{(m+n)} \\
& + 2\,\delta_{\alpha 3}\delta_{\beta 1} E_2^{(m+n)} + 2\,\delta_{\alpha 1}\delta_{\beta 3} E_{-2}^{(m+n)},
\end{aligned}
$$

where $(m, n = 0, \pm 1, \pm 2, \pm 3, \ldots; i = 1, 2; \alpha, \beta = 1, 2, 3)$. Then we have the following identifications,

$$
X_0 = E_1^{(-1)} + E_2^{(0)}, \quad X_1 = H_1^{(0)}, \quad Y_0 = E_{-1}^{(1)}, \quad Y_1 = E_{-2}^{(0)}. \tag{2.10}
$$

Now we study the linear realizations of the vector fields X_i and Y_i in an infinite-dimensional q-space which has coordinate variables $\{q_j^{(m)}; j = 1, 2, 3; m = 0, \pm 1, \pm 2, \pm 3, \ldots\}$. Following Omote,[10] we introduce some auxiliary vector fields $\{A_{ij}^{(m)}\}$:

$$
A_{ij}^{(m)} = \sum_{n=-\infty}^{+\infty} q_i^{(m+n)} \frac{\partial}{\partial q_j^{(n)}}. \tag{2.11}
$$

They can be shown to satisfy commutator relations

$$
[A_{ij}^{(m)}, A_{kl}^{(n)}] = \delta_{jk} A_{il}^{(m+n)} - \delta_{il} A_{kj}^{(m+n)}. \tag{2.12}
$$

This fact implies that the set of vector fields $\{A_{ij}^{(m)}\}$ provide an operator version of graded matrices $\{e_{ij}^{(m)} = e_{ij} \otimes \lambda^m\}$ (λ is a gradation parameter). Therefore, the Cartan–Weyl basis of $a_2^{(2)}$ under consideration has the following linear realization[8] in a triplicated infinite-dimensional q-space:

$$
\begin{cases}
H_1^{(m)} = A_{11}^{(m)} - A_{33}^{(m)}, \\
H_2^{(m)} = A_{11}^{(m)} - 2A_{22}^{(m)} + A_{33}^{(m)}, \\
E_2^{(m)} = A_{31}^{(m)}, \\
E_{-2}^{(m)} = A_{13}^{(m)},
\end{cases}
\qquad
\begin{cases}
E_1^{(m)} = A_{12}^{(m)} - A_{23}^{(m)}, \\
E_{-1}^{(m)} = A_{21}^{(m)} - A_{32}^{(m)}, \\
E_3^{(m)} = A_{32}^{(m)} + A_{21}^{(m)}, \\
E_{-3}^{(m)} = A_{12}^{(m)} + A_{23}^{(m)}.
\end{cases}
$$

Explicitly,

$$
\begin{aligned}
X_0 &= \sum_{n=-\infty}^{+\infty}\left[q_1^{(n-1)}\frac{\partial}{\partial q_2^{(n)}} - q_2^{(n-1)}\frac{\partial}{\partial q_3^{(n)}} + q_3^{(n)}\frac{\partial}{\partial q_1^{(n)}}\right],\\
X_1 &= \sum_{n=-\infty}^{+\infty}\left[q_1^{(n)}\frac{\partial}{\partial q_1^{(n)}} - q_3^{(n)}\frac{\partial}{\partial q_3^{(n)}}\right],\\
Y_0 &= \sum_{n=-\infty}^{+\infty}\left[q_2^{(n+1)}\frac{\partial}{\partial q_1^{(n)}} - q_3^{(n+1)}\frac{\partial}{\partial q_2^{(n)}}\right],\\
Y_1 &= \sum_{n=-\infty}^{+\infty}\left[q_1^{(n)}\frac{\partial}{\partial q_3^{(n)}}\right],
\end{aligned}
\tag{2.13}
$$

i.e., the components of F^a and G^a are assigned to the following linear representations in a triplicated infinite-dimensional q-space :

$$
\begin{aligned}
&F_1^{(n)} = q_3^{(n)} + q_1^{(n)}\pi_\phi, \qquad F_2^{(n)} = q_1^{(n-1)}, \qquad F_3^{(n)} = -q_2^{(n-1)} - q_3^{(n)}\pi_\phi,\\
&G_1^{(n)} = 2q_2^{(n+1)}e^{\phi}, \qquad G_2^{(n)} = -2q_3^{(n+1)}e^{\phi}, \qquad G_3^{(n)} = 2q_1^{(n)}e^{-2\phi}.
\end{aligned}
\tag{2.14}
$$

Relying on the one-form (2.3), we see that the pseudopotentials introduced in (2.14) satisfy equations

$$
\partial_-\begin{bmatrix} q_1^{(n)} \\ q_2^{(n)} \\ q_3^{(n)} \end{bmatrix} = \begin{bmatrix} \partial_-\phi & 0 & 1 \\ 0 & 0 & 0 \\ 0 & -1 & -\partial_-\phi \end{bmatrix}\begin{bmatrix} q_1^{(n)} \\ q_2^{(n-1)} \\ q_3^{(n)} \end{bmatrix} + \begin{bmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}\begin{bmatrix} q_1^{(n-1)} \\ q_2^{(n)} \\ q_3^{(n)} \end{bmatrix},
$$

$$
\partial_+\begin{bmatrix} q_1^{(n)} \\ q_2^{(n)} \\ q_3^{(n)} \end{bmatrix} = \begin{bmatrix} 0 & 2e^{\phi} & 0 \\ 0 & 0 & -2e^{\phi} \\ 2e^{-2\phi} & 0 & 0 \end{bmatrix}\begin{bmatrix} q_1^{(n)} \\ q_2^{(n+1)} \\ q_3^{(n+1)} \end{bmatrix},
\tag{2.15}
$$

on the solution surface $(\phi(x^+,x^-),\pi_\phi(x^+,x^-),x^+,x^-)$ of ZMS Eq. (2.1). Let us define a parameter-dependent potential $\Psi(\lambda)$ by

$$
\Psi(\lambda) \equiv \begin{bmatrix} \psi_1(\lambda) \\ \psi_2(\lambda) \\ \psi_3(\lambda) \end{bmatrix} = \sum_{n=-\infty}^{+\infty}\lambda^n\begin{bmatrix} q_1^{(n)} \\ q_2^{(n)} \\ q_3^{(n)} \end{bmatrix}.
\tag{2.16}
$$

Then we get from (2.15) the partial differential equations for $\Psi(\lambda)$: $\partial_\pm\Psi = A_\pm\Psi$, where

$$
\begin{cases} A_+ = \dfrac{2}{\lambda}e^{\phi}E_1 + 2e^{-2\phi}E_2, \\ A_- = \partial_-\phi H_1 + \lambda E_{-1} + E_{-2}. \end{cases}
\tag{2.17}
$$

Such $A_\pm$ do just constitute a Lax pair representation of ZMS Eq. (2.1), which gives Eq. (2.1) as the zero-curvature equation $[\partial_+ - A_+, \partial_- - A_-] = 0$, the consistency condition of the equations for Ψ. In (2.17), H_1, $E_{\pm1}$ and $E_{\pm2}$ are some 3×3 matrices defined as $H_1 = e_{11} - e_{33}$, $E_1 = e_{12} - e_{23}$, $E_2 = e_{31}$, $E_{-1} = e_{21} - e_{32}$ and $E_{-2} = e_{13}$ respectively. These matrices are among the independent generators of $SL(3,\mathscr{R})$ group.[8]

Another aspect of the prolongation structure is the nonlinear realizations of the vector fields X_i and Y_i $(i = 0, 1)$ in a finite-dimensional q-space. In Refs. 10 and 11, the authors cited some

instances in illustration of the fact that the linear realizations of the vector fields are relevant to Lax representation while the nonlinear realizations of these fields associate themselves with the Bäcklund transformation of the considered nonlinear differential equation. We will show that this conclusion is also true for ZMS Eq. (2.1).

It is worthwhile to indicate that there does not exist an unpenetrable barrier between the linear realizations and the nonlinear realizations of the vector fields. In fact, there is a standard method to get the nonlinear realizations of the vector fields from their linear realizations, in which the Lax pair plays the crucial role.[12] Let us apply the method to ZMS model. Defining $q_1=\psi_1/\psi_2, q_2=-\psi_3/\psi_2$ as new pseudopotentials, we see from Lax pair (2.17) and auxiliary linear equations that these pseudopotentials[13] satisfy a set of Riccati-type equations:

$$\begin{aligned} &\partial_+ q_1=\frac{2}{\lambda}(1-q_1q_2)e^{\phi}, \qquad \partial_+ q_2=-2q_1e^{-2\phi}-\frac{2}{\lambda}q_2^2e^{\phi}, \\ &\partial_- q_1=-(q_2+\lambda q_1^2)+q_1\pi_\phi, \quad \partial_- q_2=\lambda(1-q_1q_2)-q_2\pi_\phi, \end{aligned} \tag{2.18}$$

where $\pi_\phi=\partial_-\phi$. On the other hand, it follows from (2.3) and (2.6) that

$$\begin{aligned} &\partial_+ q_1=2Y_0^1e^{\phi}+2Y_1^1e^{-2\phi}, \quad \partial_+ q_2=2Y_0^2e^{\phi}+2Y_1^2e^{-2\phi}, \\ &\partial_- q_1=X_0^1+X_1^1\pi_\phi, \qquad \partial_- q_2=X_0^2+X_1^2\pi_\phi, \end{aligned} \tag{2.19}$$

in two-dimensional q-space. Therefore, the vector fields acquire the following nonlinear realizations:

$$\begin{cases} X_0=-(q_2+\lambda q_1^2)\partial_1+\lambda(1-q_1q_2)\partial_2, \\ X_1=q_1\partial_1-q_2\partial_2, \\ Y_0=\dfrac{1}{\lambda}(1-q_1q_2)\partial_1-\dfrac{1}{\lambda}q_2^2\partial_2, \\ Y_1=-q_1\partial_2. \end{cases} \tag{2.20}$$

Simultaneously, the prolongated algebra $a_2^{(2)}$ is nonlinearly realized as,

$$\begin{cases} H_1^{(m)}=\lambda^{-m}(q_1\partial_1-q_2\partial_2), \\ H_2^{(m)}=3\lambda^{-m}(q_1\partial_1+q_2\partial_2), \\ E_2^{(m)}=-\lambda^{-m}q_2\partial_1, \\ E_{-2}^{(m)}=-\lambda^{-m}q_1\partial_2, \end{cases} \quad \begin{cases} E_1^{(m)}=-\lambda^{-m}[q_1^2\partial_1-(1-q_1q_2)\partial_2], \\ E_{-1}^{(m)}=\lambda^{-m}[(1-q_1q_2)\partial_1-q_2^2\partial_2], \\ E_3^{(m)}=\lambda^{-m}[(1+q_1q_2)\partial_1+q_2^2\partial_2], \\ E_{-3}^{(m)}=-\lambda^{-m}[q_1^2\partial_1+(1+q_1q_2)\partial_2]. \end{cases} \tag{2.21}$$

In (2.20) and (2.21), λ is an arbitrary spectral parameter and m takes integer value. Notably, the vector fields (2.20) are not among a finite-dimensional subalgebra of $a_2^{(2)}$ unless λ equals to *one*. This is another important difference in the prolongation structure of ZMS equation from those of sine-Gordon equation, Ernst equation and chiral model.[10]

III. THE BÄCKLUND TRANSFORMATION OF ZMS EQUATION

The aim of this section is to search the auto-Bäcklund transformation of ZMS Eq. (2.1) on the basis of the prolongation structure. We assume that the new ZMS field variables $\tilde{\phi}$ and $\tilde{\pi}$ are functions of the old ϕ, π_ϕ and the pseudopotentials q^a. The new forms $\alpha_i(i=1,2)$ which are gotten from the old ones by replacing ϕ and π_ϕ with $\tilde{\phi}(\phi,\pi_\phi,q^a)$ and $\tilde{\pi}(\phi,\pi_\phi,q^a)$ should vanish modulo the old α_i and the prolongation one-forms Ω^a; i.e., there should exist some zero-forms g_{ij} and one-forms ν_i^a such that

$$\tilde{\alpha}_i(\tilde{\phi},\tilde{\pi}_\phi)=g_{ij}\alpha_j(\phi,\pi_\phi)+\nu_i^a\wedge\Omega^a. \tag{3.1}$$

This is the condition for the existence of Bäcklund transformations. In terms of (2.2) and (2.3), the condition can be recast as

$$\partial_{\pi_\phi}\tilde{\phi}=0,\ \ \partial_\phi\tilde{\pi}_\phi=0,\ \ \tilde{\pi}_\phi=\pi_\phi(\partial_\phi+X_1)\tilde{\phi}+X_0\tilde{\phi} \tag{3.2}$$

and

$$e^{\tilde{\phi}}-e^{-2\tilde{\phi}}=(e^{\phi}-e^{-2\phi})\partial_{\pi_\phi}\tilde{\pi}+(e^{\phi}Y_0+e^{-2\phi}Y_1)\tilde{\pi}_\phi. \tag{3.3}$$

The special expressions of Eqs. (3.2) lead to the following ansatz solutions for the new ZMS field variables $\tilde{\phi}$ and $\tilde{\pi}_\phi$

$$\begin{cases}\tilde{\phi}=c\phi+f(q^a),\\ \tilde{\pi}_\phi=\pi_\phi[c+X_1f(q^a)]+X_0f(q^a),\end{cases} \tag{3.4}$$

where c is an outstanding constant. Substituting (3.4) into (3.3) we get,

$$X_1f(q^a)=c_1, \tag{3.5}$$

and

$$e^{c\phi}e^{f(q^a)}-e^{-2c\phi}e^{-2f(q^a)}=e^{\phi}[c+c_1+Y_0X_0f(q^a)]-e^{-2\phi}[c+c_1-Y_1X_0f(q^a)]. \tag{3.6}$$

where c_1 is another constant.

We now apply the nonlinear expressions (2.20) of the vector fields X_i and Y_i $(i=0, 1)$ in the two-dimensional q-space to Eqs. (3.4)–(3.6). In this case, (3.5) becomes a first-order quasi-linear differential equation whose general solution reads:

$$f(q_1,q_2)=c_1\ln q_1+\omega(q_1q_2), \tag{3.7}$$

where $\omega(q_1q_2)$ is an arbitrary differentiable function of its variable q_1q_2. Generally speaking, Eq. (3.5) would have another particular solution beyond (3.7). But we quit finding such a particular solution here. One of the reason is that there is no systematic method for searching it. What is more, even if we happened to find out a particular solution for Eq. (3.5), it would be excessive to expect this solution satisfying Eq. (3.6) further. If the Bäcklund transformation of ZMS equation exists, it is bound to connect with the general solution (3.7).

To determine the function $\omega(q_1q_2)$ in (3.7) and then resolve completely the Bäcklund transformation for ZMS Eq. (2.1), Eq. (3.6) must be taken into account. After a simple and straightforward calculation we find,

$$c=1,\quad c_1=0,\quad \omega(q_1q_2)=\ln(2q_1q_2-1). \tag{3.8}$$

Namely, the auto-Bäcklund transformation of ZMS Eq. (2.1) is as follows:

$$\tilde{\phi}=\phi+\ln(2q_1q_2-1), \tag{3.9}$$

where the auxiliary pseudopotentials are determined by Riccati equations

$$\begin{aligned}\partial_+q_1&=\frac{2}{\lambda}(1-q_1q_2)e^{\phi}, &\partial_+q_2&=-2q_1e^{-2\phi}-\frac{2}{\lambda}q_2^2e^{\phi},\\ \partial_-q_1&=-(q_2+\lambda q_1^2)+q_1\partial_-\phi, &\partial_-q_2&=\lambda(1-q_1q_2)-q_2\partial_-\phi,\end{aligned} \tag{3.10}$$

for a given ϕ. One can easily justify that $\tilde{\phi}$ is a solution of ZMS Eq. (2.1) once ϕ fulfills Eq. (2.1) and vice versa. The problem of Bäcklund transformation of ZMS equation was ever discussed in Refs. 14 and 15. The Bäcklund transformation obtained by Sharipov and Yamilov[14] is a set of second order differential equations, which is very cumbersome for solving single soliton solutions[15] and is difficult to turn to our Bäcklund transformation (3.9)–(3.10).

IV. DISCUSSIONS

In the previous sections we have studied the prolongation structure of Zhiber–Mikhailov–Shabat equation. The prolongation structure yields an incomplete set of commutators of vector fields in the pseudopotential space. Following Omote[10] and Ablowitz *et al.*,[12] we have found out the linear and nonlinear differential realizations of the vector fields respectively. It is shown that the linear realizations of the vector fields give the linear auxiliary equations (Lax pair) of ZMS equation, while their nonlinear realizations are connected with the Bäcklund transformation of the equation. Nevertheless, the application of this Bäcklund transformation to constructing new analytical solutions of ZMS equation from some old ones, e.g., constructing the single-soliton solution from vacuum solution, remains an open problem. It is easy to see that ZMS Eq. (2.1) has an analytical solution governed by the first-order equations $\partial_{\pm}\phi=\mu^{\pm}\sqrt{2(2e^{\phi}+e^{-2\phi}-3)}$ (μ is an arbitrary constant). But we have not driven out these equations from the Bäcklund transformation laws yet. Another even more interesting problem is perhaps to study the dressing group symmetry in ZMS model by virtue of prolongation structure. By some naive perception we conjecture that the finite dressing transformations of ZMS equation may be exposed through a slightly different nonlinear realization of the prolongation structure. The dressing procedure is a useful method for solving single soliton solution. The detail for such problems are now in preparation.

(Received 27 December 1994; accepted for publication 9 February 1996)

Curvature collineations of some static spherically symmetric space–times are derived and compared with isometries and Ricci collineations for corresponding space–times. © *1996 American Institute of Physics.* [S0022-2488(96)04106-0]

I. INTRODUCTION

Over the past few years there has been much interest in the classification of solutions of the Einstein field equations in terms of their isometries. These isometries are given by Killing vectors (KVs), along which the Lie derivative of the metric tensor is zero, admitted by the space–time. Each independent KV gives rise to a conservation law for the spacetime. The classification by Petrov[1,2] was incomplete in that it did not provide a list of metrics for a given set of isometries, though a complete list of isometries was available. In an extensive study of spherically symmetric spacetimes, Takeno[3] used the curvature invariants of such space–times to classify them according to their isometries and these invariants. Following a different approach Qadir *et al.*[4] obtained a classification of such space–times by their isometries and provided a complete list of distinct space–time metrics. It appears that Takeno missed some metrics (for example, nonstatic spacetime like the Einstein universe but with the role of t and r inter changed, so that the isometry group is SO(1,3)XR instead of SO(4)XR).

Though the classification of space–times in terms of their isometries is important, Katzin, Davies, and Lavine[5,6] argue that the symmetries of the matter field would be given by Ricci collineations (RCs), along which the Lie derivative of the Ricci tensor is zero. A complete classification of spherically symmetric, static metrics in terms of RCs has been obtained[7,8] and is being extended to the nonstatic cases.[9]

Katzin *et al.* also argue that the symmetries of the Riemann tensor, called curvature collineations (CCs), would also provide insights into general relativity. Though they give a theorem on connection between RCs and CCs, no explicit attempt to classifying spacetimes according to their CCs has been given. Keeping this point in mind and the complexity of the system of CC equations, we consider some specific spacetimes to obtain their CCs using some special methods. It is hoped that this would enable one to extend these methods to obtain a classifications of general space–times according to their CCs.

In the next section we give the set of coupled quadratic CC equations and their form for spherically symmetric static space–times. In the third section we solve this set of equations for various specific cases. A summary and conclusion is given in the last section.

II. CC EQUATIONS

A CC, $\boldsymbol{\xi}$, satisfies the equation

$$\mathop{\mathscr{L}}_{\boldsymbol{\xi}} R = 0, \tag{1}$$

where R is the Riemann Christoffel curvature tensor. In a torsion free space, in a coordinate basis, this equation reduces to the set of partial differential equations (PDEs)

$$R^{\alpha}{}_{bcd,f}\xi^{f} + R^{\alpha}{}_{fcd}\xi^{f}{}_{,b} + R^{\alpha}{}_{bfd}\xi^{f}{}_{,c} + R^{\alpha}{}_{bcf}\xi^{f}{}_{,d} - f^{f}{}_{bcd}\xi^{\alpha}{}_{,f} = 0. \tag{2}$$

0022-2488/96/37(7)/3498/7/$10.00

In a given 4-dimensional space–time there are actually 256 coupled PDEs to be solved for four unknown functions of four variables. However, for spherically symmetric static space–times in which at the most only six independent components (3 $R^0{}_{i0i}$, where $i=1,...,3$, 2 $R^1{}_{\alpha1\alpha}$, where $\alpha=1$, 2, and 1 $R^2{}_{323}$) of the Riemann tensor can survive, the system of CC equations reduces to 22 sets of coupled CC equations consisting of *54* PDEs to be solved only. These coupled CC equations (without requiring summation over repeated indices) are given by

$$R^i{}_{1i1}\xi^1{}_{,0}+R^\alpha{}_{0\alpha0}\xi^0{}_{,1}=0, \quad (i,\alpha)=(0,1),(2,2),(3,3), \tag{3}$$

$$R^i{}_{2i2}\xi^2{}_{,0}+R^\alpha{}_{0\alpha0}\xi^0{}_{,2}=0, \quad (i,\alpha)=(0,2),(1,1),(3,3), \tag{4}$$

$$R^i{}_{3i3}\xi^3{}_{,0}+R^\alpha{}_{0\alpha0}\xi^0{}_{,3}=0, \quad (i,\alpha)=(0,3),(1,1),(2,2), \tag{5}$$

$$R^i{}_{1i1,f}\xi^f+2R^i{}_{1i1}\xi^1{}_{,1}=0, \quad i=0,2,3 \text{ and } f=1 \text{ or } 2, \tag{6}$$

$$R^i{}_{1i1}\xi^1{}_{,2}+R^\alpha{}_{2\alpha2}\xi^2{}_{,1}=0, \quad (i,\alpha)=(0,0),(2,1),(3,3), \tag{7}$$

$$R^i{}_{1i1}\xi^1{}_{,3}+R^\alpha{}_{3\alpha3}\xi^3{}_{,1}=0, \quad (i,\alpha)=(0,0),(3,1),(2,2), \tag{8}$$

$$R^i{}_{2i2}\xi^2{}_{,3}+R^\alpha{}_{3\alpha3}\xi^3{}_{,2}=0, \quad (i,\alpha)=(0,0),(1,1),(3,2), \tag{9}$$

$$R^i{}_{2i2,f}\xi^f+2R^i{}_{2i2}\xi^2{}_{,2}=0, \quad i=0,1,3 \text{ and } f=1 \text{ or } 2, \tag{10}$$

$$R^i{}_{3i3,f}\xi^f+2R^i{}_{3i3}\xi^3{}_{,3}=0, \quad i=0,1,2 \text{ and } f=1 \text{ or } 2, \tag{11}$$

$$R^i{}_{0i0,f}\xi^f+2R^i{}_{0i0}\xi^0{}_{,0}=0, \quad i=1,2,3 \text{ and } f=1 \text{ or } 2, \tag{12}$$

$$(R^0{}_{i0i}-R^\alpha{}_{i\alpha i})\xi^0{}_{,\alpha}=0, \quad (i,\alpha)=(1,3),(2,3),(1,2),(3,2),(2,1),(3,1), \tag{13}$$

$$(R^0{}_{i0i}-R^\alpha{}_{i\alpha i})\xi^\alpha{}_{,0}=0, \quad (i,\alpha)=(1,3),(2,3),(1,2),(3,2),(2,1),(3,1), \tag{14}$$

$$(R^\alpha{}_{i\alpha i}-R^\beta{}_{i\beta i})\xi^\alpha{}_{,\beta}=0, \quad (i,\alpha,\beta)=(0,1,2),(3,1,2),(0,1,3),(2,1,3), \tag{15}$$

$$(R^\alpha{}_{i\alpha i}-R^\beta{}_{i\beta i})\xi^\beta{}_{,\alpha}=0, \quad (i,\alpha,\beta)=(0,1,2),(3,1,2),(0,3,2),(1,3,2), \tag{16}$$

$$(R^\alpha{}_{i\alpha i}-R^\beta{}_{i\beta i})\xi^\beta{}_{,\alpha}=0, \quad (i,\alpha,\beta)=(0,1,3),(2,1,3),(0,2,3),(1,2,3). \tag{17}$$

III. SOLUTION OF THE CC EQUATIONS

We solve the CC equations for Minkowski, De Sitter (anti-De Sitter), Einstein (anti-Einstein), Schwarzschild, and Reissner–Nordstrom metrics along with three Bertotti–Robinson-like metrics.[10] However, since the problem of solving CC equations is trivial in Minkowski space–time, we do not solve this case explicitly and only give results. The CC equations in the De Sitter and anti-De Sitter metrics reduce to the Killing equations. We therefore only quote results without giving details for these two cases. We present the complete procedure for solving the CC equations for the Einstein metric. As the same methods apply for the anti-Einstein, Schwarzschild, Reissner–Nordstrom, and Bertotti–Robinson-like metrics, we again only quote the results for them.

For the Einstein metric

$$ds^2=dt^2-\frac{dr^2}{1-r^2/R^2}-r^2(d\vartheta^2+\sin^2\vartheta\, d\phi^2), \tag{18}$$

the nonzero Riemann tensor components are given by

$$R^1{}_{212}=r^2/R^2, \quad R^1{}_{313}=\frac{r^2}{R^2}\sin^2\vartheta=R^2{}_{323}. \tag{19}$$

With these values in the CC equations, some of the equations [Eqs: (3)–(5), (8), and (15)–(17)] are identically satisfied, while Eqs. (13) and (14), respectively, yield

$$\left.\begin{aligned}\xi^0{}_{,\alpha}&=0 \quad (\alpha=1,2,3),\\ \xi^\alpha{}_{,0}&=0 \quad (\alpha=1,2,3).\end{aligned}\right\} \tag{20}$$

Now using Eqs. (20), Eqs. (6)–(11), respectively, yield

$$r\xi^1+R^2(1-r^2/R^2)\xi^1{}_{,1}=0, \tag{21}$$

$$\xi^1{}_{,2}+r^2(1-r^2/R^2)\xi^2{}_{,1}=0, \tag{22}$$

$$\xi^1{}_{,3}+r^2(1-r^2/R^2)\sin^2\vartheta\,\xi^3{}_{,1}=0, \tag{23}$$

$$\xi^2{}_{,3}+\sin^2\vartheta\,\xi^3{}_{,2}=0, \tag{24}$$

$$\xi^1+r\xi^2{}_{,2}=0, \tag{25}$$

$$\xi^1+r\cot\vartheta\,\xi^2+r\xi^3{}_{,3}=0. \tag{26}$$

To solve this system of PDEs we first consider Eq. (21), writing it in the form

$$\xi^1{}_{,1/\xi^1}=\frac{r/R^2}{(1-r^2/R^2)}. \tag{27}$$

In view of Eq. (20), Eq. (27) yields

$$\xi^1=\sqrt{1-r^2/R^2}A(\vartheta,\phi), \tag{28}$$

where $A(\vartheta,\phi)$ is a function of integration. Now differentiating Eq. (28) with respect to ϑ comparing with Eq. (22) and solving while using Eq. (20), gives

$$\xi^2=\frac{\sqrt{1-r^2/R^2}}{r}A_\vartheta(\vartheta,\phi)+B(\vartheta,\phi), \tag{29}$$

where $B(\vartheta,\phi)$ is some function of integration. Now using Eqs. (28) and (29), Eq. (25) yields

$$\frac{\sqrt{1-r^2/R^2}}{r}(A_{\vartheta\vartheta}(\vartheta,\phi)+A(\vartheta,\phi))+B_\vartheta(\vartheta,\phi)=0, \tag{30}$$

which is satisfied only when

$$B_\vartheta(\vartheta,\phi)=0=A_{\vartheta\vartheta}(\vartheta,\phi)+A(\vartheta,\phi). \tag{31}$$

These equations can be easily solved to give

$$\left.\begin{aligned}A&=A_1(\phi)\cos\vartheta+A_2(\phi)\sin\vartheta,\\ B&=B_1(\phi),\end{aligned}\right\}, \tag{32}$$

where $A_1(\phi)$, $A_2(\phi)$ and $B_1(\phi)$ are again functions of integration. Now using Eqs. (28), (29), and (32), Eq. (23) give

$$\xi^3=\frac{\sqrt{1-r^2/R^2}}{r\ \sin^2\ \vartheta}\ (A_{1\phi}(\phi)\cos\ \vartheta+A_{2\phi}(\phi)\sin\ \vartheta)+D(\vartheta,\phi), \tag{33}$$

where $D(\vartheta,\phi)$ is some function of integration. At this stage we substitute these values of ξ^1, ξ^2, and ξ^3 into Eq. (24). It turns out that this is satisfied only when

$$A_{1\phi}=0=D_{\vartheta}(\vartheta,\phi)+\frac{1}{\sin^2\ \vartheta}\ B_{1\phi}(\phi). \tag{34}$$

This equation can be easily solved to obtain,

$$\left.\begin{aligned} &A_1=\alpha_1\\ &D(\vartheta,\phi)=\cot\ \vartheta B_{1\phi}(\phi)+E(\phi),\end{aligned}\right\} \tag{35}$$

where α_1 is a constant and $E(\phi)$ some integration function. Inserting Eqs. (35) into Eq. (26) and requiring consistency give

$$\left.\begin{aligned} &A_{2\phi\phi}(\phi)+A_2(\phi)=0,\\ &B_{1\phi\phi}(\phi)+B_1(\phi)=0=E_{\phi}(\phi).\end{aligned}\right\} \tag{36}$$

These equations can again be easily solved to give

$$\left.\begin{aligned} &A_2=\alpha_2\ \cos\ \phi+\alpha_3\ \sin\ \phi,\\ &B_1=\alpha_4\ \cos\ \phi+\alpha_5\ \sin\ \phi,\\ &E=\alpha_6,\end{aligned}\right\} \tag{37}$$

where α_2 to α_6 are integration constants. Inserting Eqs. (32) and (34)–(37), the CCs become

$$\left.\begin{aligned} &\xi^1=\sqrt{1-r^2/R^2}(\alpha_1\ \cos\ \vartheta+(\alpha_2\ \cos\ \phi+\alpha_3\ \sin\ \phi)\sin\ \vartheta],\\ &\xi^2=\frac{\sqrt{1-r^2/R^2}}{r}\ (-\alpha_1\ \sin\ \vartheta+(\alpha_2\ \cos\ \phi+\alpha_3\ \sin\ \phi)\cos\ \vartheta]+(\alpha_4\ \cos\ \phi+\alpha_5\ \sin\ \phi),\\ &\xi^3=\frac{\sqrt{1-r^2/R^2}}{r\ \sin\ \vartheta}\ [-\alpha_2\ \sin\ \phi+\alpha_3\ \cos\ \phi]+\cot\ \vartheta[(-\alpha_4\ \sin\ \phi+\alpha_5\ \cos\ \phi)]+\alpha_6,\\ &\xi^0=\xi^0(t).\end{aligned}\right\} \tag{38}$$

Notice that these are six CCs for the spatial components of $\boldsymbol{\xi}$ and the temporal component of, $\boldsymbol{\xi}$, is an arbitrary function of t only. Similarly for the anti-Einstein metric ''R^2'' is replaced by ''$-R^2$'' in the metric. It is easily verified that the number of CCs in the anti-Einstein metric turn out to be the same as the number of CCs in the Einstein metric with the only difference that R^2 in Eqs. (38) is replaced by $-R^2$.

For the Schwarzschild metric

$$ds^2=\left(1-\frac{2m}{r}\right)dt^2-\left(1-\frac{2m}{r}\right)^{-1}\ dr^2-r^2\ d\Omega^2$$

the surviving Riemann Christoffel curvature tensor components are

$$R^0{}_{101}=\frac{2m}{r^3\left(1-\frac{2m}{r}\right)}, \quad R^0{}_{202}=-\frac{m}{r}=R^1{}_{212},$$

$$R^0{}_{303}=-\frac{m}{r}\sin^2\vartheta=R^1{}_{313}, \quad R^2{}_{323}=-\frac{2m}{r}\sin^2\vartheta.$$

The CCs in this case turn out to be the same as four KVs for this metric,

$$\xi^\alpha=\{\alpha_0,0,(\alpha_1\cos\phi+\alpha_2\sin\phi),-\cot\vartheta(\alpha_1\sin\phi-\alpha_2\cos\phi)+\alpha_3\}. \tag{39}$$

In the Reissner–Nordstrom spacetime

$$ds^2=\left(1-\frac{2m}{r}+\frac{4\pi Q^2}{r^2}\right)-\left(1-\frac{2m}{r}+\frac{4\pi Q^2}{r^2}\right)^{-1}dr^2-r^2\,d\Omega^2,$$

the nonzero Riemann tensor components are given by

$$R^0{}_{101}=\frac{(2Mr-12\pi Q^2)}{r^2(r^2-2Mr+4\pi Q^2)}, \quad R^0{}_{202}=-\frac{(2Mr-4\pi Q^2)}{r^2},=R^1{}_{212},$$

$$R^0{}_{303}=-\frac{(2Mr-4\pi Q^2)}{r^2}\sin^2\vartheta=R^1{}_{313}, \quad R^2{}_{323}=\left(\frac{2Mr-4\pi Q^2}{r^2}\right)\sin^2\vartheta.$$

The CCs in this case are again same as four KVs of Schwarzschild metric given by Eq. (39).

The De Sitter and anti-De Sitter space–times, respectively, have their metrics given by

$$ds^2=\left(1\mp\frac{r^2}{R^2}\right)dt^2-\left(1\mp\frac{r^2}{R^2}\right)^{-1}dr^2-r^2\,d\Omega^2.$$

In this case the surviving Riemann Christoffel curvature tensor component are given by

$$R^0{}_{101}=\frac{1/R^2}{1\mp r^2/R^2}, \quad R^0{}_{202}=\frac{r^2}{R^2}=R^1{}_{212},$$

$$R^0{}_{303}=\frac{r^2}{R^2}\sin^2\vartheta=-R^1{}_{313}=R^2{}_{323}.$$

If we write the CC equations for the above metrics, it is seen that the CC equations become same as Killing equations, hence in both cases the CCs are same as ten KVs there.[3]

There exists three Bertotti–Robinson-like metrics in the literature. In the first case the metric is given by

$$ds_1^2=(B+r)^2\,dt^2-dr^2-a^2\,d\Omega^2.$$

Here, only one Riemann tensor component given by

$$R^2{}_{323}=\sin^2\vartheta$$

survives and CCs in this case become

TABLE I. Comparison of KVs, RCs, and CCs for some specific spherically symmetric static metrics.

	KVs	RCs	CCs
Minkowski	10	Arbitrary	Arbitrary
De Sitter/anti	10	10	10
Einstein/anti	7	$6+\xi^0$ (arbt) (x^α)	$6+\xi^0$ (arbt) (t)
Bertotti–Robinson$_{\rm I}$	6	$3+\xi^0$ (x^α) & ξ^1 (x^α),	$3+\xi^0$ (t,r), ξ^1 (t,r)
Bertotti–Robinson$_{\rm II}$	6	6	6
Bertotti–Robinson$_{\rm III}$	6	6	6
Schwarzschild	4	Arbitrary	4
Reissner–Nordstrom	4	4	4

$$\xi^0=f(t,r), \quad \xi^1=g(t,r),$$

$$\xi^2=(C_1\cos\phi+C_2\sin\phi), \quad \xi^3=\cot\vartheta(-C_1\sin\phi+C_2\cos\phi)+C_3.$$

In the other two Bertotti–Robinson-like metrics given by

$$ds^2_{\rm II}=\cos^2(c+\sqrt{\alpha}r)dt^2-dr^2-a^2\,d\Omega^2,$$

$$ds^2_{\rm III}=\cosh^2(C+\sqrt{\alpha}r)dt^2-dr^2-a^2\,d\Omega^2$$

only $R^0{}_{101}$ and $R^2{}_{323}$ survive. Here, $R^0{}_{101_{\rm II}}=-R^0{}_{101_{\rm III}}=\alpha$ (constant), whereas, $R^2{}_{323_{\rm II}}=R^2{}_{323_{\rm III}}$. The CCs in both cases again turn out to be same as six KVs of these metrics.[3]

IV. CONCLUSION

In the hope of understanding how the information about the symmetries implicit in the geometry, and relevant for the matter–energy field (through the Einstein equations), is distributed between the metric tensor, the Ricci tensor, and the Riemann tensor, we have explicitly computed the CCs for some specific spherically symmetric static metrics. We discuss our results in the light of Table I for KVs, RCs, and CCs of the corresponding space–times.

While the isometries must always be definite, collineations can be unlimited. This is due to the fact that the metric tensor is nondegenerate while the Ricci tensor and Riemann tensor need not be nondegenerate. Where degeneracy arises there are arbitrary many collineations possible. In particular, if the relevant tensor is zero all vectors are collineations. Since there is a unique space–time that is Riemann flat (the Minkowski space–time) every vector is a CC. Any vacuum space–time is Ricci flat and hence has all vectors as RCs. In the same way there is a greater freedom of RCs than of CCs in the Einstein and anti-Einstein spaces. For the former there is one arbitrary function of four variables (i.e., α^4) while for the latter it depends on only one variable (i.e., α^1). Similarly, for the flat Bertotti–Robinson-like metric there are two arbitrary functions. For RCs we have $(\alpha^4)^2$ while for CCs we have $(\alpha^2)^1$. The most striking case is for the Schwarzschild metric where the CCs are identical with the KVs but *every vector* is an RC. Clearly, the CCs are closer to the more restricted KVs than are the RCs.

It would be important to develop general methods of classifying space–times with some minimal symmetry group in terms of their CCs and seeing how this general classification compares with KVs and RCs. The easiest for this purpose is the class of all spherically symmetric static space–times (of which only the generic case remains to be dealt with). Then one could hope to extend the discussion by dropping the requirement of staticity, going over to cylindrical or plane symmetry, and then reducing the minimal symmetry group further. Finally, it would be necessary to compare the results with other classification schemes, such as Petrov classification.

(Received 31 October 1995; accepted for publication 15 January 1996)

We study the real, massive Klein–Gordon field on a C^∞ globally-hyperbolic background space–time with compact Cauchy hypersurfaces. In particular, the parametrization of this system as initiated by Dirac and Kuchař is put on a rigorous basis. The discussion is focussed on the structure of the set of spacelike embeddings of the Cauchy manifold into the space–time, and on the associated e-tensor density bundles and their tangent and cotangent bundles. The dynamics of the field is expressed as a set of automorphisms of the space of initial data in which each pair of embeddings defines one such automorphism. Using these results, the extended phase space of the system is shown to be a weak-symplectic manifold, and the Kuchař constraint is shown to define a smooth constraint submanifold which is foliated smoothly by the constraint orbits. The pull-back of the symplectic form to the constraint surface is a presymplectic form which is singular on the tangent spaces to the constraint orbits. Thus, the geometric structure of this infinite-dimensional system is analogous to that of a finite-dimensional, first-class parametrized system, and hence many of the results for the latter can be transferred to the infinite-dimensional case without difficulty. © *1996 American Institute of Physics.* [S0022-2488(96)02807-1]

I. INTRODUCTION

The long history of studies of quantum field theory in a background space–time peaked sharply in the seventies (for reviews from that era, see Refs. 1 and 2) following Hawking's discovery of the quantum radiation produced by a black hole.[3] In those days, the main aim was to find a direct quantization of the true physical degrees of freedom of the system. However, much earlier, Dirac had reformulated this system in a parametrized form so that it could be used as a model for general relativity proper.[4] The idea is to treat embeddings of Cauchy hypersurfaces in the space–time as additional degrees of freedom of the system. Together with their conjugate momenta and the Cauchy data of the scalar field on the embeddings, they define an extended phase space. To retrieve the original dynamics one has to impose constraints. This procedure was studied in some detail in Refs. 5, 6 and 7; a shorter exposition can be found in Ref. 8. The resulting system can be classified as a ''first-class parametrized system.''

A method of quantizing first-class parametrized systems was initiated by Dirac; in particular, he studied a system of massive particles in Minkowski space–time.[9] A generalization of this method to any *finite*-dimensional first-class parametrized system was given by Hájíček[10] using a combination of Dirac's ideas with the group quantization method of Isham[11] and the algebraic quantization method of Ashtekar.[12] In what follows, this generalization will be referred to as the ''perennial formalism.''

[a)]Electronic mail: hajicek@butp.unibe.ch
[b)]Electronic mail: c.isham@ic.ac.uk

If one is interested in extending the perennial formalism to infinite-dimensional systems, the scalar field on a fixed space–time offers itself naturally as a well-understood and much-discussed model. However, the perennial formalism is based on a geometrical form of Hamiltonian dynamics, whereas the existing formulations of the parametrized scalar field are non-geometrical. The main purpose of the present article is to recast the classical theory of a parametrized scalar field in a fixed background into the geometrical, Hamiltonian form for infinite-dimensional systems developed by Marsden and collaborators (see Ref. 13). The ensuing results are of interest in themselves and are also used in the accompanying article[14] dealing with the application of the perennial formalism to the quantum theory of a field propagating on a curved background.

Marsden's techniques have been applied to a variety of systems, including general relativity itself.[15] In all these examples, the extended phase space is an (open) subset of a linear space, and hence the tangent space at any point in the phase space can be naturally identified with this linear space. The resulting significant simplifications have been thoroughly exploited in the literature (for example, see Ref. 15). However, in our case, the space of embeddings is a genuine manifold, not just a subspace of a linear space. Of course, the rough idea of how the theory is to be applied in general to such cases is well-known,[13] but—as we shall see—the specific system of interest to us possesses some crucial additional structure that is very helpful in the detailed analysis.

The plan of the article is as follows. In section II, the theory of the Cauchy problem of a hyperbolic, partial differential equation (as reviewed, for example, in Ref. 15) is applied to the dynamics of a massive scalar field in a globally hyperbolic space–time. The Cauchy hypersurfaces are assumed to be compact, but it seems likely that—if desired—the proofs (which are relegated to the Appendix) could be adapted to deal with asymptotically flat Cauchy hypersurfaces. The set of all Cauchy data is given the structure of a topological vector space Γ_ϕ, and an automorphism of this space is associated with each oriented pair of embeddings of the Cauchy manifold in the space–time, thereby producing a rather generalized concept of ''time evolution.''

In section III, we extend the phase space from Γ_ϕ to $\Gamma_\phi \times T^*\mathscr{E}$, where $\mathscr{E}$ is the space of embeddings introduced by Kuchař in Ref. 5. This way of parametrizing the system was discussed in detail by Isham and Kuchař.[7] The structure of the e-tensor density bundles over $\mathscr{E}$ is described, and their tangent and cotangent bundles are studied; this is where we lay the foundation for the subsequent mathematical developments. Our approach to the resulting infinite-dimensional Hamiltonian system is based on the geometrical ideas of Chernov, Fischer, and Marsden.[13,15] The constructions of the phase space manifold, the symplectic structure, and the Poisson brackets are all described explicitly.

In section IV, we show that (i) the constraint set is a submanifold of the phase space; (ii) the constraint orbits are submanifolds of the constraint surface; and (iii) the vector space defined by the right hand side of the evolution equation coincides with the tangent space of a constraint orbit. For the model we study, the proofs (which are adapted from Ref. 15) are straightforward. The resulting structure is analogous to a high degree to that of a finite-dimensional first-class parametrized system, and hence the application of the perennial formalism is relatively unproblematic.

II. FIELD DYNAMICS

We are interested in the theory of a relativistic field propagating on a fixed background space–time $\mathscr{M}$. The associated dynamical equation defines an evolution map between Cauchy data along two arbitrary Cauchy hypersurfaces. We shall need various properties of these maps that can be derived from results concerning the Cauchy problem for linear hyperbolic systems as described—for example—in Refs. 15 and 16.

The following properties of the space–time $(\mathscr{M},g)$ will be assumed:

(1) The space–time $\mathscr{M}$ is equipped with a C^∞ differential structure. In particular, this means that diffeomorphisms do not mix the different Sobolev structures that will be placed on various function spaces associated with Σ and $\mathscr{M}$.

(2) The Lorentzian metric g is such that the pair $(\mathscr{M},g)$ is globally hyperbolic. Thus the four-manifold $\mathscr{M}$ is necessarily diffeomorphic to $\Sigma\times\mathbb{R}$ where the three-manifold Σ is a model for any Cauchy hypersurface in $\mathscr{M}$.

(3) The three-manifold Σ is compact. This assumption is made for the sake of simplicity, but we expect that similar results can be obtained for asymptotically flat space–times using analogous—but more laborious—methods; see Ref. 15).

The relativistic wave equation of interest is the Klein–Gordon equation for a real scalar field:

$$|\det g|^{-1/2}\partial_\mu(|\det g|^{1/2}g^{\mu\nu}\partial_\nu\phi)+m^2\phi=0 \tag{1}$$

where the real, non-negative constant m is the mass parameter.

A central role in the theory is played by C^{r+1} $(r>2)$ embeddings $X:\Sigma\to\mathscr{M}$ that are spacelike with respect to g. We shall refer to any such X simply as an ''embedding,'' and denote by $\mathrm{Emb}_g(\Sigma,\mathscr{M})$ the space of all such (see Refs. 5 and 7). Each embedding X determines a positive-definite C^r-metric γ on Σ as the pull-back X^*g of g by X; i.e., in local coordinates on both Σ and $\mathscr{M}$,

$$\gamma_{ab}(x):=g_{\mu\nu}(X(x))X^\mu{}_{,a}(x)X^\nu{}_{,b}(x). \tag{2}$$

The map X also determines a future-oriented, unit normal vector $n(X(x))$ at each point of the hypersurface $X(\Sigma)$ in $\mathscr{M}$.

Any embedding $X\in\mathrm{Emb}_g(\Sigma,\mathscr{M})$ defines a ''Cauchy datum'' for ϕ along the hypersurface $X(\Sigma)$. This is a pair (φ,π) of fields on Σ, where the scalar φ and the density (of weight $w=1$) π are defined by

$$\varphi(x):=\phi(X(x)), \tag{3}$$

$$\pi(x):=(\det\gamma)^{1/2}(x)n^\mu(X(x))\partial_\mu\phi(X(x)), \tag{4}$$

for all $x\in\Sigma$, and where γ is defined in Eq. (2).

We shall need certain Sobolev spaces of tensor-density fields on Σ (for more details see Ref. 16). The first step is to introduce a fixed, auxiliary C^r Riemannian metric f_{kl} on Σ. Let $I,J,K,\ldots$ denote multiple indices, and let $|I|$ be the number of simple indices within I. Let f_{IJ} be the abbreviation for the tensor product of $|I|=|J|$ copies of the covariant tensors f_{ij}, and—similarly—f^{IJ} denotes the appropriate tensor product of contravariant fields f^{ij}. If T^J_I is a C^r tensor-density field on Σ of type $(|I|,|J|,w)$ (w is the weight), $T^J_{I|K}$ will denote the tensor-density field obtained from T^J_I by a $|K|$-fold covariant derivative (covariant with respect to the auxiliary metric f). Then the Sobolev space scalar product $(T,S)^s_f$ between two tensor-density fields T^J_I and S^J_I is defined by

$$(T,S)^s_f:=\sum_{|M|=|N|=0}^{s}\int_\Sigma d^3x(\det f)^{1/2-w}f^{IK}f^{MN}f_{JL}T^J_{I|M}S^L_{K|N} \tag{5}$$

where $s\leqslant r$. We denote the corresponding Sobolev space by $H^s_{|I||J|w}(\Sigma)$, or simply $H^s_w(\Sigma)$ if no confusion can result. Note that the topology of these spaces is independent of the auxiliary metric f provided that Σ is compact (which we are assuming).

Using this notation, we can introduce the space Γ^s_ϕ of Cauchy data:

$$\Gamma^s_\phi:=H^s_0(\Sigma)\times H^{s-1}_1(\Sigma) \tag{6}$$

with $\varphi \in H_0^s(\Sigma)$ and $\pi \in H_1^{s-1}(\Sigma)$. The dynamics of the field ϕ as determined by Eq. (1) defines maps between the spaces of Cauchy data corresponding to different embeddings. The relevant facts about these maps (which are more or less well-known; see Ref. 15) are listed in Appendix 1, and culminate in the following theorem:

Theorem: Let X_1 and X_2 be two arbitrary C^{r+1} embeddings with $r \geqslant 4$. Then each pair $(\varphi_1, \pi_1) \in \Gamma_\phi^s$ (with $2 \leqslant s \leqslant r-2$) defines a unique solution ϕ of the field equation (1) such that

(1) the Cauchy datum associated with the embedding X_1 is the given pair (φ_1, π_1);

(2) the embedding X_2 gives a well-defined Cauchy datum (φ_2, π_2) that belongs to Γ_ϕ^s

(3) the map $\rho_{X_1 X_2}: \Gamma_\phi^s \to \Gamma_\phi^s$ thus defined is an automorphism of the Sobolev space Γ_ϕ^s.

Note that we obtain a maximal classical solution in the sense that the embedding X_2 can be chosen to map Σ so that it passes through any given point of $\mathscr{M}$.

The theorem above implies that a differentiable solution is obtained if s is sufficiently large. Indeed, the famous Sobolev lemma asserts that $H_w^s(\Sigma) \subset C_w^{s'}(\Sigma)$ if $s > s' + \frac{1}{2} \dim \Sigma$. For example, ϕ will be C^2 if $s = 4$. The index s can be taken as large as one wishes if r is sufficiently large. In particular, for $r = \infty$, one can take the intersection Γ_ϕ^∞ of the Hilbert spaces Γ_ϕ^s, $s = 4,5, \ldots$, to give the space of all pairs of C^∞-functions and densities that is equipped with the structure of a countably Hilbert nuclear space (see Ref. 17).

III. THE EXTENDED PHASE SPACE

The theory of a scalar field on a curved background was rewritten in the form of a parametrized system in Refs. 7 and 18. In this section, we shall reformulate a part of this work so that it becomes compatible with the mathematical formalism of Fischer and Marsden.[15] First however, the studies in Refs. 5 and 7 of the differential geometry of the space of embeddings $\mathscr{E}$ must be extended to include certain bundles over $\mathscr{E}$.

The construction of a smooth differential structure on a space of continuous maps between two finite-dimensional manifolds was described as early as 1958 by Eells,[19] but we shall use the method developed more recently in Ref. 20. Recall that, in a pair of local charts

$$(U,h) \text{ of } \Sigma \text{ and } (\overline{V,h}) \text{ of } \mathscr{M} \tag{7}$$

[where $X(U) \cap \overline{V} \neq \varnothing$], a given embedding $X: \Sigma \to \mathscr{M}$ can be represented by the function $\overline{h} \circ X \circ h^{-1}: h(U) \to \mathbb{R}^4$. We say that X belongs to the space $H^s(\Sigma, \mathscr{M})$ if these local representatives are in the Sobolev space $H^s(h(U), \mathbb{R}^4)$ for all such pairs of local charts. This notion can be shown to be atlas-independent for $s > 3/2$ [which means that X is continuous since, according to the Sobolev lemma, $X \in C^r(\mathscr{N}, \mathscr{M})$ if $s > r + \dim(\mathscr{N})/2$].

In what follows, a major role is played by the tangent and cotangent bundles to the infinite-dimensional manifold of embeddings. In the differential geometry of a finite-dimensional manifold $\mathscr{N}$, a tangent vector τ at a point $p \in \mathscr{N}$ can be defined in several different ways. One algebraic approach is to view τ as a derivation at p of the ring $C^\infty(\mathscr{N})$ of smooth functions on $\mathscr{N}$: i.e., $\tau: C^\infty(\mathscr{N}) \to \mathbb{R}$ is a linear map with the property that if $f, g \in C^\infty(\mathscr{N})$, then $\tau(fg) = f(p)\tau(g) + g(p)\tau(f)$. A more geometrical approach is to define τ as an equivalence class of local curves $\sigma: (-\epsilon, \epsilon) \to \mathscr{N}$ where (i) $\epsilon > 0$ (and can be σ-dependent); (ii) $\sigma(0) = p$; and (iii) two local curves σ_1 and σ_2 are regarded as being equivalent if their tangent vectors at $p \in \mathscr{N}$ are equal as computed in a local coordinate system around p (the equivalence classes are independent of choice of coordinate system).

In the finite-dimensional case, these two definitions can be shown to be equivalent. However, the situation in infinite dimensions is quite different since complicated functional-analytical problems need to be resolved before the algebraic definition can even be posed. Fortunately, the geometrical definition of a tangent vector as an equivalence class of curves still works well and, when applied to the case of interest, leads naturally to the definition of the tangent space

$T_X H^s(\Sigma,\mathscr{M})$ to $H^s(\Sigma,\mathscr{M})$ at the embedding X as the set of maps $V:\Sigma\to T\mathscr{M}$ with the property that the image $V(x)$ of a point $x \in \Sigma$ is a tangent vector on $\mathscr{M}$ at the point $X(x)$; i.e., $V(x) \in T_{X(x)}\mathscr{M}$; more formally, V satisfies the relation $X=\chi\circ V$, where $\chi:T\mathscr{M}\to\mathscr{M}$ is the bundle projection of the tangent bundle $T\mathscr{M}$ of $\mathscr{M}$.

This defining property of $V \in T_X H^s(\Sigma,\mathscr{M})$ can be expressed in another way that will be useful later. Namely, we recall that if $\rho:E\to\mathscr{M}$ is the projection map of any fibre bundle E over a manifold $\mathscr{M}$, and if $f:\mathscr{N}\to\mathscr{M}$ is a map from another manifold $\mathscr{N}$ into $\mathscr{M}$, then the pull-back bundle f^*E over $\mathscr{N}$ is defined as

$$f^*E:=\{(x,e)\in\mathscr{N}\times E\,|\,f(x)=\rho(e)\}, \tag{8}$$

and a cross-section of this bundle is given by any map $\psi:\mathscr{N}\to E$ such that $\rho(\psi(x))=f(x)$. It follows therefore that a vector $V \in T_X H^s(\Sigma,\mathscr{M})$ can be regarded as a cross-section of the bundle $X^*(T\mathscr{M})$.

Note that the vector space $T_X H^s(\Sigma,\mathscr{M})$ can be given an H^s-structure so that the function space $H^s(\Sigma,\mathscr{M})$ becomes a Banach manifold modelled on the Banach space $T_X H^s(\Sigma,\mathscr{M})$ (for example, via an exponential map in $\mathscr{M}$). We shall assume from now on that this has been done, and we shall consider only embeddings that lie in $H^s(\Sigma,\mathscr{M})$, and (with the value s of the Sobolev class understood) denote the set of all such by $\mathscr{E}$; i.e., $\mathscr{E}:=\mathrm{Emb}_g(\Sigma,\mathscr{M})\cap H^s(\Sigma,\mathscr{M})$. It can be shown that $\mathscr{E}$ is an open subset of $H^s(\Sigma,\mathscr{M})$, and hence $\mathscr{E}$ is a Banach manifold with the same tangent spaces and analogous manifold structure as that of $H^s(\Sigma,\mathscr{M})$ itself.

The above definition of a tangent vector leads immediately to the definition of the tangent bundle $T\mathscr{E}$ of $\mathscr{E}$. More generally, if ${}^R_S T\mathscr{M}$ is the tensor bundle of type (R,S) over $\mathscr{M}$ (R times contravariant and S times covariant), we obtain an ''e-tensor bundle'' ${}^R_S T\mathscr{E}$ over $\mathscr{E}$ by defining an e-tensor at the point $X \in \mathscr{E}$ to be a map $\psi:\Sigma\to{}^R_S T\mathscr{M}$ such that $\psi(x) \in {}^R_S T_{X(x)}\mathscr{M}$; i.e., $X=\chi\circ\psi$, where χ now denotes the bundle projection of ${}^R_S T\mathscr{M}$. Equivalently, ψ can be regarded as a cross-section of the bundle $X^*({}^R_S T\mathscr{M})$ over Σ.

We shall need an even more general e-tensor of the type defined in Ref. 5 which transforms as a tensor density of type (r,s,w) with respect to a coordinate change in Σ around x, and as a tensor of type (R,S) with respect to a coordinate change in $\mathscr{M}$ around the point $X(x) \in \mathscr{M}$. The precise definition of such an e-tensor is that it is a cross-section ψ of the bundle ${}^{r,w}_{s} T\Sigma\otimes X^*({}^R_S T\mathscr{M})$ over Σ, where ${}^{r,w}_{s} T\Sigma$ is the bundle of tensors over Σ that are r times contravariant, s times covariant, and of tensor-density weight w. It follows that, for all $x \in \Sigma$, we have $\psi(x) \in {}^{r,w}_{s} T_x\Sigma\otimes{}^R_S T_{X(x)}\mathscr{M}$, and hence $\psi(x)$ can be represented by its components $\psi^{k_1\ldots k_r\mu_1\ldots\mu_R}_{l_1\ldots l_s\nu_1\ldots\nu_S}(x)$ on Σ defined with respect to an appropriate pair of coordinate charts on Σ and $\mathscr{M}$.

There is another way of representing e-tensors which is particularly useful for discussing tangent vectors to the collection of all e-tensors of a certain type. Namely, recall that if V and W are any pair of finite-dimensional vector spaces, then there is a canonical isomorphism of $V^*\otimes W$ with the space $L(V,W)$ of linear maps from V to W in which the linear map $L_{\ell\otimes w}$ associated with $\ell\otimes w \in V^*\otimes W$ is defined by $L_{\ell\otimes w}(v):=\langle\ell,v\rangle w$ for all $v \in V$. In particular, we note that ${}^{r,w}_{s} T_x\Sigma$ is the algebraic dual of ${}^{s,-w}_{r} T_x\Sigma$, and hence it follows that if ψ is an e-tensor with $\psi(x) \in {}^{r,w}_{s} T_x\Sigma\otimes{}^R_S T_{X(x)}\mathscr{M}$, then we can identify $\psi(x)$ as a linear map $\psi(x):{}^{s,-w}_{r} T_x\Sigma\to{}^R_S T_{X(x)}\mathscr{M}$. This can be summarized rather neatly by defining an e-tensor to be a vector bundle map ψ from ${}^{s,-w}_{r} T\Sigma$ to ${}^R_S T\mathscr{M}$, i.e., the following diagram is commutative

$$\begin{array}{ccc} {}^{s,-w}_{r} T\Sigma & \overset{\psi}{\to} & {}^R_S T\mathscr{M} \\ \downarrow\rho & & \downarrow\chi \\ \Sigma & \overset{X}{\to} & \mathscr{M} \end{array} \tag{9}$$

where ρ and χ are the projection maps in the indicated tensor bundles over Σ and $\mathscr{M}$, respectively. Thus if $\tau \in {}^{s,-w}_{r}T_{x}\Sigma$, we have $\psi(\tau) \in {}^{R}_{S}T_{X(x)}\mathscr{M}$.

We shall denote the bundle of such e-tensors by ${}^{R,r,w}_{S,s}T\mathscr{E}$. The linear space ${}^{R,r,w}_{S,s}T_{X}\mathscr{E}$ can be given a Sobolev structure with an arbitrary Sobolev class (not necessarily the same as that of $\mathscr{E}$). An easy, ''covariant'' method for doing so can be obtained by using an auxiliary Riemannian metric on $\mathscr{M}$ in addition to that on Σ. This enables covariant derivatives of e-tensors to be defined (see Ref. 5). However, a ''coordinate dependent'' method is even easier to define, and is more general in the sense that it can also be used for objects of higher rank, like the elements of $T_{(X,P)}(T^{*}\mathscr{E})$ (see below). This is based on pairs of charts Eq. (7), which will associate a map of $h(X^{-1}(X(U)\cap V))\subset\mathbb{R}^{3}$ into $\mathbb{R}^{m}$ with any e-tensor. One can then define a Sobolev scalar product by patching together the integrands within each set $h(X^{-1}(X(U)\cap V))$ with the aid of a partition of unity corresponding to a covering of Σ by these sets. This scalar product depends on the system of charts chosen, but the topology does not and is equivalent to that obtained using the covariant method.

It is clear that the usual tensor operations, such as linear combination, tensor product, and contraction at a point $x \in \Sigma$ or $X(x) \in \mathscr{M}$, define corresponding operations on the e-tensors (for details see Ref. 5). The result is an e-tensor whose Sobolev class coincides with the lowest class involved in the operation.

There is one more operation of importance that we shall call ''pairing.'' Let $\xi \in {}^{R,r,w}_{S,s}T_{X}\mathscr{E}$ and $\eta \in {}^{S,s,1-w}_{R,r}T_{X}\mathscr{E}$. The pairing $\langle \xi,\eta\rangle$ is defined by

$$\langle \xi,\eta\rangle := \int_{\Sigma} d^{3}x\,\xi(x)\cdot\eta(x) \tag{10}$$

where $\xi(x)\cdot\eta(x)$ denotes the contractions at x and $X(x)$ such that all indices of ξ are contracted with those of η in the order in which they appear. Then $\xi(x)\cdot\eta(x)$ is a scalar density on Σ, and hence $\langle \xi,\eta\rangle$ is a coordinate independent real number.

A particularly important example of a bundle of e-tensors is the tangent bundle $T\mathscr{E} := {}^{1,0,0}_{0,0}T\mathscr{E}$ whose points ξ are pairs (X,V) where $X \in \mathscr{E}$, and V is a $T\mathscr{M}$-valued function on Σ with $V(x) \in T_{X(x)}\mathscr{M}$; equivalently, V is a cross-section of $X^{*}(T\mathscr{M})$. Even more important for our purposes is the cotangent bundle $T^{*}\mathscr{E}$. To define cotangent vectors we have to identify $T^{*}_{X}\mathscr{E}$ with a particular topological vector space of real-valued, linear functions on $T_{X}\mathscr{E}$. The appropriate choice for our purposes is the space ${}^{0,0,1}_{1,0}T_{X}\mathscr{E}$ of Sobolev class s', the linear operation being the pairing (the class parameter s' must satisfy the condition $s'\leqslant s$, where s is the class parameter of $\mathscr{E}$, but can otherwise be arbitrary). Thus, $P \in T^{*}_{X}\mathscr{E} := {}^{0,0,1}_{1,0}T_{X}\mathscr{E}$ is a cross-section of the bundle $\mathscr{D}^{1}\Sigma\otimes X^{*}(T^{*}\mathscr{M})$ where, in general, $\mathscr{D}^{w}\Sigma$ is shorthand for the real-line bundle ${}^{0,w}_{0}T\Sigma$ of scalar densities on Σ of weight w. Thus $P(x) \in \mathscr{D}^{1}_{x}\Sigma\otimes T^{*}_{X(x)}\mathscr{M}$; equivalently, P is a bundle map from $\mathscr{D}^{-1}\Sigma$ to $T^{*}\mathscr{M}$ that ''covers'' X in the sense that $P(\tau) \in T^{*}_{X(x)}\mathscr{M}$ for all $\tau \in \mathscr{D}^{-1}_{x}\Sigma$.

With respect to a local coordinate chart y^{μ}, $\mu=0,1,2,3$, on $\mathscr{M}$, the pair $(X,P) \in T^{*}\mathscr{E}$ is represented by local functions (X^{μ},P_{ν}) on Σ, where X^{μ} is defined by

$$X^{\mu}(x) := y^{\mu}(X(x)), \tag{11}$$

and where the four scalar-density functions P_{ν}, $\nu=0,1,2,3$, on Σ are defined by the expansion

$$P(x) = P_{\nu}(x)\,dy^{\nu}|_{X(x)} \tag{12}$$

using the differentials dy^{ν} associated with the local coordinate system y^{ν} on $\mathscr{M}$ (as usual, summation over repeated indices is understood) and using a local coordinate system on Σ to locally trivialize the line bundle $\mathscr{D}^{-1}\Sigma$. In terms of these local functions, the pairing operation is

$$\langle (X,P),(X,V)\rangle = \int_\Sigma d^3x P_\mu(x) V^\mu(x) \tag{13}$$

where the functions V^μ on Σ are defined by the equation

$$V(x) = V^\mu(x)\left(\frac{\partial}{\partial y^\mu}\right)_{X(x)}. \tag{14}$$

The e-tensor bundles can be given a manifold structure based on that of $\mathscr{E}$. A point in such a bundle ${}^{R,r,w}_{S,s}T\mathscr{E}$ is represented by a pair (X,ψ) where $X \in \mathscr{E}$, and $\psi \in {}^{R,r,w}_{S,s}T_X\mathscr{E}$ is a cross-section of the bundle ${}^{r,w}_{s}T\Sigma \otimes X^*({}^R_S T\mathscr{M})$ or—better for our purposes—the pair (X,ψ) fits into the commutative diagram Eq. (9). A tangent vector is defined as an equivalence classes of curves $t \mapsto (X_t,\psi_t)$, and it is clear from this geometrically that a tangent vector at (X,ψ) consists of a pair of objects (V,W) where (i) $V \in T_X\mathscr{E}$ (i.e., $V(x) \in T_{X(x)}\mathscr{M}$); (ii) W is a bundle map from ${}^{s,-w}_{r}T\Sigma$ to $T({}^R_S T\mathscr{M})$ such that, for all $\tau \in {}^{s,-w}_{r}T_x\Sigma$, we have $W(\tau) \in T_{\psi(\tau)}({}^R_S T\mathscr{M})$; and (iii) $\chi_*(W(\tau)) = V(x)$ where $\chi_*: T({}^R_S T\mathscr{M}) \to T\mathscr{M}$ is induced from the bundle projector $\chi: {}^R_S T\mathscr{M} \to \mathscr{M}$ in Eq. (9). Note that V and W both take their values in vector spaces, and hence the collection of all such pairs (V,W) can be given an appropriate Sobolev structure to become Banach spaces. By this means, the bundle of e-tensors over $\mathscr{E}$ becomes a Banach manifold.

Now, in general, if E is any vector bundle over $\mathscr{M}$, the tangent space T_pE splits into a direct sum $E_{\pi(p)} \oplus T_{\pi(p)}\mathscr{M}$ where $E_{\pi(p)}$ denotes the fiber of E over the point $\pi(p) \in \mathscr{M}$. However, in the absence of any connection on E there is no natural way of performing such a split. Note that in our case, where $E = {}^R_S T\mathscr{M}$, this (non-canonical) split means that the vector $W(\tau) \in T_{\psi(\tau)}({}^R_S T\mathscr{M})$ (with $\tau \in {}^{s,-w}_{r}T_x\Sigma$) can be written as a sum of an element of ${}^R_S T_{X(x)}\mathscr{M}$ (the analogue of $E_{\pi(p)}$) and an element [in fact, $V(x)$] of $T_{X(x)}\mathscr{M}$. This means that, using a local coordinate system on $\mathscr{M}$, the vector $W(\tau)$ can be written as a collection of numbers associated with the point $X(x) \in \mathscr{M}$, namely the components $V^\mu(x)$ of the vector $V(x)$, and the components of the space–time object in ${}^R_S T_{X(x)}\mathscr{M}$, which we shall write as $W^{\mu_1 \cdots \mu_R}_{\nu_1 \cdots \nu_S}(\tau)$.

A particularly simple example is the tangent bundle $T(T^*\mathscr{E})$. The bundle $T^*\mathscr{E}$ consists of pairs (X,P) where $X \in \mathscr{E}$, and where P is a bundle map $P: \mathscr{D}^{-1}\Sigma \to T^*\mathscr{M}$ that covers $X: \Sigma \to \mathscr{M}$, i.e., $P(\tau) \in T^*_{X(x)}\mathscr{M}$ for all $\tau \in \mathscr{D}_x^{-1}\Sigma$. Then, according to the discussion above, a tangent vector to $T^*\mathscr{E}$ at the point (X,P) consists of a pair (V,W) where $V \in T_X\mathscr{E}$ and where $W: \mathscr{D}^{-1}\Sigma \to T(T^*\mathscr{M})$ satisfies $W(\tau) \in T_{P(\tau)}(T^*\mathscr{M})$ with $\pi_*(W(\tau)) = V(x)$ for all $\tau \in \mathscr{D}_x^{-1}\Sigma$, where $\pi: T^*\mathscr{M} \to \mathscr{M}$ is the bundle projection.

The problem occasioned by the non-canonical split can be seen by looking at the situation using a local coordinate system. The element $(X,P) \in T^*\mathscr{E}$ is represented by the local functions (X^μ, P_ν) on Σ, and a transformation of coordinates in $\mathscr{M}$ from y^μ to y'^α leads to new functions (X'^α, P'_β) satisfying

$$X'^\alpha(x) = y'^\alpha(X(x)), \tag{15}$$

$$P'_\beta(x) = J^\nu_{\beta'}(X(x)) P_\nu(x), \tag{16}$$

where $J^\nu_{\beta'}$ denotes the matrix $\partial y^\mu / \partial y'^\beta$. As emphasized earlier, a tangent vector in infinite-dimensional differential geometry is defined as an equivalence class of curves and, with respect to the pair of charts Eq. (7), a curve in $T^*\mathscr{E}$ is represented by functions $(t,x) \mapsto (X^\mu(x,t), P_\nu(x,t))$. Hence the tangent vector to this curve is represented by the functions $\dot{X}^\mu$ and $\dot{P}_\nu$ on Σ where

$$\dot{X}^{\mu}(x) := \left.\frac{\partial X^{\mu}(x,t)}{\partial t}\right|_{t=0}, \quad \dot{P}_{\nu}(x) := \left.\frac{\partial P_{\nu}(x,t)}{\partial t}\right|_{t=0}. \tag{17}$$

Note that $P_{\mu}(x,t)$ are components with respect to coordinates at the point $X(x,t)$ of $\mathscr{M}$ while $P_{\mu}(x,t+dt)$ are those at another point $X(x,t+dt)$ of $\mathscr{M}$.

Differentiating formula Eq. (15) along the curve with respect to t, we obtain

$$\dot{X}'^{\alpha}(x) := \left.\frac{\partial X'^{\alpha}(x,t)}{\partial t}\right|_{t=0} = \left.\frac{\partial y'^{\alpha}(X(x,t))}{\partial t}\right|_{t=0} = \frac{\partial y'^{\alpha}}{\partial y^{\mu}}(X(x)) \left.\frac{\partial y^{\mu}(X(x,t))}{\partial t}\right|_{t=0}$$

$$= J^{\alpha'}_{\mu}(X(x))\dot{X}^{\mu}(x), \tag{18}$$

which shows that, as expected, the derivatives $\dot{X}^{\mu}(x)$ transform on $\mathscr{M}$ in a tensorial way. On the other hand, the analogous calculations for Eq. (16) yield

$$\dot{P}'_{\beta}(x) = J^{\nu}_{\beta'\mu}(X(x))\dot{X}^{\mu}(x)P_{\nu}(x) + J^{\nu}_{\beta'}(X(x))\dot{P}_{\nu}(x) \tag{19}$$

where $J^{\nu}_{\beta'\mu}$ denotes the derivative of the matrix $J^{\nu}_{\beta'}$ with respect to the original coordinates y^{μ}. This shows that the four quantities $\dot{P}'_{\beta}(x)$ cannot be regarded as the components of any tensorial object on $\mathscr{M}$. In general, a tangent vector to $(X,P) \in T^*\mathscr{E}$ can be represented by the functions (V^{μ},W_{ν}) on Σ which transform under a change of coordinates on $\mathscr{M}$ as

$$\begin{pmatrix} V'^{\alpha}(x) \\ W'_{\beta}(x) \end{pmatrix} = \begin{pmatrix} J^{\alpha'}_{\mu}(X(x)) & 0 \\ J^{\rho}_{\beta'\mu}(X(x))P_{\rho}(x) & J^{\nu}_{\beta'}(X(x)) \end{pmatrix} \begin{pmatrix} V^{\mu}(x) \\ W_{\nu}(x) \end{pmatrix}. \tag{20}$$

We shall often need to work with the cotangent vectors from $T^*(T^*\mathscr{E})$. Let us describe their most important properties. As discussed above, a vector in $T_{(X,P)}(T^*\mathscr{E})$ is a pair (V,W) where $V \in T_X\mathscr{E}$, and $W:\mathscr{D}^{-1}\Sigma \to T(T^*\mathscr{M})$ is such that $\pi_*(W(\tau)) = V(x) \in T_{X(x)}\mathscr{M}$ for all $\tau \in \mathscr{D}_x^{-1}\Sigma$, where $\pi:T^*\mathscr{M} \to \mathscr{M}$ is the bundle projection. By definition, the kernel of the map $\pi_*:T(T^*\mathscr{M}) \to T\mathscr{M}$ is the set of vertical vectors in $T(T^*\mathscr{M})$, and at each $k \in T^*\mathscr{M}$ there is a natural isomorphism ι of $V_k(T^*\mathscr{M})$ (the vertical tangent vectors at k) with $T^*_{\pi(k)}\mathscr{M}$. In fact, at each $k \in T^*\mathscr{M}$, the map π_* fits into the short exact sequence

$$0 \to T^*_{\pi(k)}\mathscr{M} \xrightarrow{\iota} T_k(T^*\mathscr{M}) \xrightarrow{\pi_*} T_{\pi(k)}\mathscr{M} \to 0. \tag{21}$$

The dual of this sequence is the short exact sequence

$$0 \to T^*_{\pi(k)}\mathscr{M} \xrightarrow{\pi^{\dagger}_*} T^*_k(T^*\mathscr{M} \xrightarrow{\iota^{\dagger}} T^{**}_{\pi(k)}\mathscr{M} \to 0 \tag{22}$$

where a † superscript denotes the adjoint of the linear map to which it is attached. Note that, since $\mathscr{M}$ is finite-dimensional, the third term in Eq. (22) (i.e., $T^{**}_{\pi(k)}\mathscr{M}$) is (non-canonically) isomorphic to $T_{\pi(k)}\mathscr{M}$.

Using the ideas above, it is natural to define an element of $T^*_{(X,P)}(T^*\mathscr{E})$ as a pair (A,B) where $B:\Sigma \to T^{**}\mathscr{M} \simeq T\mathscr{M}$, and where the bundle map $A:\mathscr{D}^{-1}\Sigma \to T^*(T^*\mathscr{M})$ satisfies $A(\tau) \in T^*_{P(\tau)}(T^*\mathscr{M})$ with $\iota^{\dagger}(A(\tau)) = B(x)$ for all $\tau \in \mathscr{D}_x^{-1}\Sigma$. In local coordinates on $\mathscr{M}$, an element $(A,B) \in T^*_{(X,P)}(T^*\mathscr{E})$ can be represented by a set of local functions (A_{μ},B^{ν}) on Σ (each A_{μ} is actually a scalar density on Σ; B^{ν} are genuine scalar functions). The pairing of such an object with a vector (V,W) in $T_{(X,P)}(T^*\mathscr{E})$ is defined by

$$\langle (A,B),(V,W)\rangle := \int_\Sigma d^3x (A_\mu(x)V^\mu(x) + B^\mu(x)W_\mu(x)). \tag{23}$$

The condition that the result be independent of coordinates on $\mathscr{M}$ determines the transformation of $(A_\mu(x), B^\nu(x))$ to be

$$\begin{pmatrix} A'_\alpha(x) \\ B'^\beta(x) \end{pmatrix} = \begin{pmatrix} J^\mu_{\alpha'} & -J^\rho_{\alpha'\nu}(X(x))P_\rho(x) \\ 0 & J^{\beta'}_\nu(X(x)) \end{pmatrix} \begin{pmatrix} A_\mu(x) \\ B^\nu(x) \end{pmatrix}. \tag{24}$$

Thus $V^\mu(x)$ and $B^\mu(x)$ represent tensorial objects on $\mathscr{M}$, but $W_\mu(x)$ and $A_\mu(x)$ do not.

A key observation is the following. If the transformation law Eq. (20) is compared with Eq. (24), it is clear that the quantity $(G^\mu, -F_\mu)$ formed from the ''components'' of a covector on $T^*\mathscr{E}$ transforms as a tangent vector on $T^*\mathscr{E}$. Thus we have a map $J_{\mathscr{E}}: T^*(T^*\mathscr{E}) \to T(T^*\mathscr{E})$ defined in local coordinates on the component functions by

$$J_{\mathscr{E}}(A_\alpha, B^\nu) = (B^\mu, -A_\alpha). \tag{25}$$

We can choose the Sobolev classes so that the classes of the functions V^α, X^α and B^α coincide, and so do those of P_β, W_β and A_β. Then $J_{\mathscr{E}}$ is a Sobolev space isomorphism.

More abstractly, we recall that if Q is any finite-dimensional manifold there is a canonical isomorphism $j: T^*_p(T^*Q) \to T_p(T^*Q)$ defined on any cotangent vector ℓ at the point p in T^*Q by

$$\omega(j(\ell), v) = \langle \ell, v\rangle_p \quad \text{for all} \quad v \in T_p(T^*Q) \tag{26}$$

where ω is the canonical two-form on the cotangent bundle T^*Q. In the context of the embedding space, if $(A,B) \in T^*_{(X,P)}(T^*\mathscr{E})$, then $A(\tau) \in T^*_{P(\tau)}(T^*\mathscr{M})$, and hence we can use the isomorphism $j: T^*_{P(\tau)}(T^*\mathscr{M}) \to T_{P(\tau)}(T^*\mathscr{M})$ to define a map $J: T^*_{(X,P)}(T^*\mathscr{E}) \to T_{(X,P)}(T\mathscr{E})$ by requiring that $J(A,B)(\tau) := j(A(\tau))$. This is the coordinate-free definition of the object given in Eq. (25).

The phase space Γ_ϕ of the scalar field ϕ was introduced in section II. We note now that Γ_ϕ can be considered as the cotangent bundle $T^*\mathscr{Q}$, where $\mathscr{Q}$ is the space H^∞_0 of all C^∞-scalar fields on Σ. As $\mathscr{Q}$ is a linear space, there is a natural identification between the spaces $T^*\mathscr{Q}$ and $\mathscr{Q} \times T^*_\varphi\mathscr{Q}$ for any $\varphi \in \mathscr{Q}$. Also, $T^*_\varphi\mathscr{Q} = H^\infty_1$ is itself a linear space, and so there is an identification between the spaces $T_{(\varphi,\pi)}(T^*\mathscr{Q})$ and $T^*\mathscr{Q} \simeq H^\infty_0 \times H^\infty_1$. Similarly, $T^*_{(\varphi,\pi)}(T^*\mathscr{Q}) \simeq H^\infty_1 \times H^\infty_0$. More precisely, if $(\xi,\eta) \in T_{(\varphi,\pi)}(T^*\mathscr{Q})$ and $(f,h) \in H^\infty_1 \times H^\infty_0$, then the pairing $(f,h): T_{(\varphi,\pi)}(T^*\mathscr{Q}) \to \mathbb{R}$ is defined by

$$\langle (f,h),(\xi,\eta)\rangle := \int_\Sigma d^3x (f\xi + h\eta). \tag{27}$$

The extended phase space Γ of the parametrized scalar field of Ref. 7 is defined as $\Gamma := \Gamma_\phi \times T^*\mathscr{E}$. Hence $\Gamma \simeq T^*(\mathscr{Q} \times \mathscr{E})$, so that the extended phase space is again a cotangent bundle. In the context of the full space Γ, a tangent vector from $T_{(\varphi,\pi,X,P)}\Gamma$ can be specified by its ''components'' (Φ,Π,V,W), where $(V,W) \in T_{(X,P)}(T^*\mathscr{E})$ and $(\Phi,\Pi) \in T_{(\varphi,\pi)}(T^*\mathscr{Q})$. Similarly, a cotangent vector from $T^*_{(\varphi,\pi,X,P)}\Gamma$ can be specified by (A_φ, A_π, A, B), where $(A,B) \in T^*_{(X,P)}(T^*\mathscr{E})$ and $(A_\varphi, A_\pi) \in T^*(T^*\mathscr{Q})$. The natural pairing is

$$\langle (A_\varphi, A_\pi, A, B),(\Phi,\Pi,V,W)\rangle := \int_\Sigma d^3x (A_\varphi\Phi + A_\pi\Pi + A_\mu V^\mu + B^\mu W_\mu). \tag{28}$$

There is an isomorphism $J: T^*_{(\varphi,\pi,X,P)}\Gamma \to T_{(\varphi,\pi,X,P)}\Gamma$ (if the Sobolev classes are chosen to match each other) given by

$$J(A_\varphi, A_\pi, A_X, A_P) := (A_\pi, -A_\varphi, A_P, -A_X). \tag{29}$$

Using this isomorphism, a symplectic structure Ω on Γ can be defined as follows. Let v_1 and v_2 be two vectors in $T_{(\varphi,\pi,X,P)}\Gamma$. Then

$$\Omega(v_1, v_2) := -\langle J^{-1} v_1, v_2 \rangle \tag{30}$$

or, in ''component'' form,

$$\Omega((\Phi_1,\Pi_1,V_1,W_1),(\Phi_2,\Pi_2,V_2,W_2)) = \int_\Sigma d^3x (\Pi_1\Phi_2 - \Phi_1\Pi_2 + W_{1\mu}V_2^\mu - V_1^\mu W_{2\mu}). \tag{31}$$

It follows at once that (i) $\Omega(v_1,v_2) = -\Omega(v_2,v_1)$; (ii) Ω is weakly non-degenerate (see Ref. 13); and (iii) Ω is not only closed but also exact.

As Ω is only a weak symplectic form, not every differentiable function on Γ will have a Hamiltonian vector field. The class of functions that do can be characterized as follows. If $F:\Gamma\to\mathbb{R}$, we say that F has a gradient if the following two conditions are satisfied:

(1) the Fréchet derivative, $\mathrm{D}F|_{(\varphi,\pi,X,P)}: T_{(\varphi,\pi,X,P)}\Gamma \to \mathbb{R}$ is a bounded linear map;

(2) there exists $\mathrm{grad}F \in T^*_{(\varphi,\pi,X,P)}\Gamma$ such that $\langle \mathrm{grad}F, v\rangle = \mathrm{D}F|_{(\varphi,\pi,X,P)}(v)$ for all $v \in T_{(\varphi,\pi,X,P)}\Gamma$. The ''components'' of this gradient will be denoted by the collection of functions $(\mathrm{grad}_\varphi F, \mathrm{grad}_\pi F, (\mathrm{grad}_X F)_\mu, (\mathrm{grad}_P F)^\nu)$.

Condition (2) means that DF must be regular (no distributions are accepted!), and hence we have to work with smeared objects. This will not lead to any real loss of generality. The quantity grad F is calculated from DF as usual by integration by parts (if F contains derivatives).

For a differentiable function with a gradient, we can define an associated ''Hamiltonian vector field.'' Specifically, if F is such a function, then $\xi_F \in T_{(\varphi,\pi,X,P)}\Gamma$ is defined by the relation

$$\langle \mathrm{grad}\ F, v\rangle = \Omega(v, \xi_F) \quad \text{for all} \quad v \in T_{(\varphi,\pi,X,P)}\Gamma. \tag{32}$$

Hence, because of Eq. (30), we see that $\langle \mathrm{grad}F, v\rangle = \langle J^{-1}\xi_F, v\rangle$ for all v, and so $\xi_F = J(\mathrm{grad}\ F)$.

Finally, the Poisson bracket of a pair of differentiable functions F and G is defined as $\{F,G\} := -\Omega(\xi_F, \xi_G)$, and we see immediately that

$$\{F,G\} = \langle \mathrm{grad}\ F, \xi_G\rangle. \tag{33}$$

This Poisson bracket is antisymmetric and, since Ω is closed, it satisfies the Jacobi identity.

IV. THE CONSTRAINT MANIFOLD

The parametrized scalar field theory possesses a set of constraints $\mathscr{H}_\mu = 0$ on the Cauchy data (φ,π,X,P). These constraints are contained in the map

$$C:\Gamma \to T^*\mathscr{E}, \tag{34}$$

$$(\varphi,\pi,X,P) \mapsto (X, \mathscr{H}(\varphi,\pi,X,P)) \tag{35}$$

where $\mathscr{H}(\varphi,\pi,X,P) \in T^*_X\mathscr{E}$, i.e., $\mathscr{H}(\varphi,\pi,X,P)(x) \in T^*_{X(x)}(\mathscr{M})$ for all $x \in \Sigma$, so that $\mathscr{H}(\varphi,\pi,X,P)(x) = \mathscr{H}(\varphi,\pi,X,P)_\mu(x) dy^\mu|_{X(x)}$ in a coordinate system y^μ on $\mathscr{M}$. The specific form of the constraints $\mathscr{H}_\mu(x)$ is given in Ref. 7 as

$$\mathscr{H}_\mu = P_\mu + \mathscr{H}^\phi_\mu, \tag{36}$$

$$\mathscr{H}^\phi_\mu = -\mathscr{H}^\phi_\perp n_\mu + \mathscr{H}^\phi_k X^k_\mu, \tag{37}$$

where $n_\mu(x)$ is the unit normal space–time vector at $X(x)\in\mathscr{M}$, and where $X^k_\mu(x):=g_{\mu\nu}(x)\gamma^{kl}(X(x))X,^\nu_l(x)$. The components $\mathscr{H}^\phi_\mu(\varphi,\pi,X)$ can be projected normal, and tangential, to the hypersurface $X(\Sigma)$ to give

$$\mathscr{H}^\phi_\perp=\tfrac{1}{2}(\det\ \gamma)^{1/2}\left(\frac{\pi^2}{\det\gamma}+\gamma^{kl}\varphi_k\varphi_l+m^2\varphi^2\right), \tag{38}$$

$$\mathscr{H}^\phi_k=\pi\varphi,_k\,. \tag{39}$$

The goal of this section is to explore the pre-symplectic structure of the manifold $\widetilde{\Gamma}$ of solutions to these constraints, i.e., $\widetilde{\Gamma}:=\{(\varphi,\pi,X,P)\in\Gamma|C(\varphi,\pi,X,P)=(X,0)\}$. In particular, we have the following theorem.

Theorem 2: Let the Sobolev class of all spaces involved be ∞. Then, $\widetilde{\Gamma}$ is a C^∞-submanifold of Γ in a neighborhood of any of its points. This constraint manifold $\widetilde{\Gamma}$ is given by $\widetilde{\Gamma}=\widetilde{C}(\Gamma_\phi\times\mathscr{E})$, where $\widetilde{C}:\Gamma_\phi\times\mathscr{E}\to\Gamma$ is defined by $\widetilde{C}(\varphi,\pi,X):=(\varphi,\pi,X,-\mathscr{H}^\phi(\varphi,\pi,X))$.

Proof: The proof is similar to that in Ref. 15, but requires less sophisticated functional analysis because our constraints are available in an explicit form; in particular—unlike the case in Ref. 15—we do not need to use the Fredholm alternative theorem.

We start by assuming that $T^*\Gamma$ is C^∞, and postulate that the Sobolev class of Π and W is $s-1$, where s is the class of X, Φ and V. Consider the map $\mathrm{D}C|_{(\varphi,\pi,X,P)}:T_{(\varphi,\pi,X,P)}\Gamma\to T_{\mathscr{H}(\varphi,\pi,X,P)}(T^*\mathscr{E})$. To use the implicit function theorem, this map must be a surjection with a splitting kernel (see, e.g., Ref. 21). However, $\mathrm{D}C|_{(\varphi,\pi,X,P)}$ is trivially surjective. Moreover, its kernel in $T_{\widetilde{C}(X,\varphi,\pi)}\Gamma$ is given by $\mathrm{D}\widetilde{C}|_{(\varphi,\pi,X)}(T_{(\varphi,\pi,X)}(\Gamma_\phi\times\mathscr{E}))$. We shall now show that $\mathrm{D}C|_{(\varphi,\pi,X)}$ is injective with a splitting image.

The map $\mathrm{D}\widetilde{C}|_{(\varphi,\pi,X)}:T_{(\varphi,\pi,X)}(\Gamma_\phi\times\mathscr{E})\to T_{\widetilde{C}(\varphi,\pi,X)}\Gamma$ between the Sobolev spaces $T_{(\varphi,\pi,X)}(\Gamma_\phi\times\mathscr{E})\simeq\Gamma^s_\phi\times H^s_0$ and $T_{\widetilde{C}(\varphi,\pi,X)}\Gamma\simeq\Gamma^s_\phi\times H^s_0\times H^{s-1}_1$ has a derivative given by

$$\mathrm{D}\widetilde{C}|_{(\varphi,\pi,X)}(\Phi,\Pi,V)=(\Phi,\Pi,V,-\mathrm{D}\mathscr{H}^\phi|_{(\varphi,\pi,X)}(\Phi,\Pi,V)), \tag{40}$$

where

$$\mathrm{D}\mathscr{H}^\phi|_{(\varphi,\pi,X)}(\Phi,\Pi,V)=\mathrm{D}_\varphi\mathscr{H}^\phi|_{(\varphi,\pi,X)}(\Phi)+\mathrm{D}_\pi\mathscr{H}^\phi|_{(\varphi,\pi,X)}(\Pi)+\mathrm{D}_X\mathscr{H}^\phi|_{(\varphi,\pi,X)}(V). \tag{41}$$

Using the results of Ref. 7 and Eqs. (37)–(39), we find after some calculation that

$$\mathrm{D}_\varphi\mathscr{H}^\phi_\mu|_{(\varphi,\pi,X)}(\Phi)=(\det\ \gamma)^{1/2}(L^k_\mu\Phi_{\|k}-n_\mu m^2\varphi\Phi), \tag{42}$$

$$\mathrm{D}_\pi\mathscr{H}^\phi_\mu|_{(\varphi,\pi,X)}(\Pi)=L^\perp_\mu\Pi, \tag{43}$$

$$\mathrm{D}_X\mathscr{H}^\phi_\mu|_{(\varphi,\pi,X)}(V)=\frac{1}{2}(\det\ \gamma)^{1/2}K^k_{\mu\nu}V^\nu_{\|k}+\mathscr{H}^\phi_\kappa\Gamma^\kappa_{\mu\nu}V^\nu, \tag{44}$$

where

$$L^k_\mu=-\gamma^{kl}\varphi_{\|l}n_\mu+\frac{\pi}{(\det\ \gamma)^{1/2}}X^k_\mu, \tag{45}$$

$$L^\perp_\mu=-\frac{\pi}{(\det\ \gamma)^{1/2}}n_\mu+\varphi_{\|k}X^k_\mu, \tag{46}$$

$$K^m_{\mu\nu}=\left(\frac{\pi^2}{\det\ \gamma}-\gamma^{kl}\varphi_{\|k}\varphi_{\|l}-m^2\varphi^2\right)n_\mu X^m_\nu+\left(\frac{\pi^2}{\det\ \gamma}+\gamma^{kl}\varphi_{\|k}\varphi_{\|l}+m^2\varphi^2\right)$$

$$\times X^m_\mu n_\nu+2\ \varphi_{\|k}\varphi_{\|l}\gamma^{km}n_\mu X^k_\nu-2\frac{\pi}{(\det\ \gamma)^{1/2}}\varphi_{\|k}(\gamma^{km}n_\mu n_\nu+X^k_\nu X^m_\mu), \tag{47}$$

and ''$\|$'' denotes the bi-covariant derivative, for example $Y^\mu_{k\|l}=Y^\mu_{k,l}+\Gamma^\mu_{\rho\sigma}Y^\rho_k X^\sigma_l-\gamma^m_{kl}Y^\mu_m$, where $\Gamma^\mu_{\rho\sigma}$ is the Christoffel symbol of the metric $g_{\mu\nu}$ on M, and γ^m_{kl} is the Christoffel symbol of the pull-back of g to Σ by X. By inspection, these formulas imply the crucial result that the map $\mathrm{D}\mathscr{H}^\phi|_{(\varphi,\pi,X)}:H^s_0\times\Gamma^s_\phi\to H^{s-1}_1$ is continuous and bounded (recall that φ, π and X are C^∞). Hence, for all $(\Phi,\Pi,V)\in\Gamma^s_\phi\times H^s_0$, the map $\mathrm{D}\widetilde{C}|_{(\varphi,\pi,X)}$ is continuous and bounded, and—by inspection—injective. It follows from the closed graph theorem that the image $\mathrm{D}\widetilde{C}|_{(\varphi,\pi,X)}(\Gamma^s_\phi\times H^s_0)$ is therefore closed in $\Gamma^s_\phi\times H^s_0\times H^{s-1}_1$. However, a closed subspace of a Hilbert space splits, which proves the theorem. **QED**

By abuse of language, we will often call $\Gamma_\phi\times\mathscr{E}$ the ''constraint manifold.''

For each fixed value of x and μ, the quantity $\mathscr{H}_\mu(x)$ can be viewed as a function on the phase space, but it has no gradient; in particular, the Poisson bracket of a pair of such functions is not well-defined. Constraint functions with gradients can be constructed by ''smearing.'' Specifically, if $N\in T_X\mathscr{E}$ [i.e., $N(x)\in T_{X(x)}\mathscr{M}$], then $\mathscr{H}_N$ is defined as

$$\mathscr{H}_N:=\int_\Sigma d^3x N^\mu(x)\mathscr{H}_\mu(x). \tag{48}$$

It is clear that the equations $\mathscr{H}_N=0$ for all $N\in T_X\mathscr{E}$ are equivalent to $\mathscr{H}_\mu(x)=0$ for all μ,x. In particular, let U be a C^∞ vectorfield on $\mathscr{M}$. Then each embedding X determines an element, $x\mapsto U^\mu(X(x))(\partial/\partial y^\mu)_{X(x)}$, of $T_X\mathscr{E}$. This is the type of smearing used in Ref. 7.

Let us calculate the gradient of $\mathscr{H}_N$. Starting from Eq. (37), using Eqs. (42), (43) and (44), and integrating by parts, we obtain

$$\mathrm{grad}_\varphi\mathscr{H}_N=(\det\gamma)^{1/2}[-(N^\mu L^k_\mu)_{\|k}-m^2\varphi n_\mu N^\mu], \tag{49}$$

$$\mathrm{grad}_\pi\mathscr{H}_N=L^\perp_\mu N^\mu, \tag{50}$$

$$(\mathrm{grad}_X\mathscr{H}_N)_\nu=N^\mu_{\|\nu}\mathscr{H}_\mu-\tfrac{1}{2}(\det\ \gamma)^{1/2}(N^\mu K^k_{\mu\nu})_{\|k}-P_\kappa\Gamma^\kappa_{\mu\nu}N^\mu, \tag{51}$$

$$(\mathrm{grad}_P\mathscr{H}_N)^\nu=N^\nu, \tag{52}$$

where $L^\perp_\mu, L^k_\mu$ and $K^k_{\mu\nu}$ are given by Eqs. (45), (46) and (47). In Ref. 7, the following theorem was shown:

Theorem 3: Let M and N be two C^∞ vector fields on $\mathscr{M}$. Then

$$\{\mathscr{H}_M,\mathscr{H}_N\}=-\mathscr{H}_{[M,N]}, \tag{53}$$

where $[M,N]$ is the Lie bracket of the fields M^μ and N^μ.

Substituting the expressions Eqs. (49)–(52) for the gradients into the Poisson brackets (53) we obtain an identity that plays an important role in some proofs:

$$\frac{1}{2}\int_\Sigma d^3x(\det\gamma)^{1/2}[(M^\mu K^k_{\mu\nu})_{\|k}N^\nu-(N^\mu K^k_{\mu\nu})_{\|k}M^\nu]$$

$$=\int_\Sigma d^3x(\mathrm{grad}_\varphi\mathscr{H}_M\mathrm{grad}_\pi\mathscr{H}_N-\mathrm{grad}_\pi\mathscr{H}_M\mathrm{grad}_\varphi\mathscr{H}_N). \tag{54}$$

The following theorem was essentially shown in Ref. 7:

Theorem 4: Let ϕ satisfy the Klein–Gordon equation (1) on $\mathscr{M}$. Then for each curve $\lambda \mapsto X_\lambda$ with the tangent vector field N on $\mathscr{E}$, the initial data $(\varphi_\lambda, \pi_\lambda)$ for ϕ on $X_\lambda(\Sigma)$ satisfy the evolution equation

$$(\dot{\varphi}, \dot{\pi}, \dot{X}, \dot{P}) = J(\text{grad}\, \mathscr{H}_N). \tag{55}$$

The equation for $\dot{P}$ is a consequence of the first three equations and the constraints $\mathscr{H}_N = 0$ for all $N \in T_X\mathscr{E}$.

Conversely, if a curve $\lambda \mapsto (\varphi_\lambda, \pi_\lambda, X_\lambda)$ on $\Gamma_\phi \times \mathscr{E}$ satisfies the evolution equations (55), then it defines a unique solution ϕ of the Klein–Gordon equation.

Thus the Hamiltonian vector fields $J(\text{grad}\, \mathscr{H}_N)$ of the functions $\mathscr{H}_N$ are tangential to $\widetilde{\Gamma}$, and hence the system is first class, according to the definition given in Ref. 10.

A simple consequence of theorem 4 is that the pull-back of the vector field (55) to $\Gamma_\phi \times \mathscr{E}$ is given by

$$\dot{\varphi} = \text{grad}_\pi \mathscr{H}_N, \tag{56}$$

$$\dot{\pi} = -\text{grad}_\varphi \mathscr{H}_N, \tag{57}$$

$$\dot{X} = N. \tag{58}$$

Let us denote the space of longitudinal vectors at $(\varphi, \pi, X) \in \Gamma_\phi \times \mathscr{E}$ by $\Xi_{(\varphi,\pi,X)}$, i.e.,

$$\Xi_{(\varphi,\pi,X)} := \{(\Phi, \Pi, V) \in T_{(\varphi,\pi,X)}\widetilde{\Gamma} \,|\, \Phi = \text{grad}_\pi \mathscr{H}_N, \Pi = -\text{grad}_\varphi \mathscr{H}_N, V = N \in T_X\mathscr{E}\}. \tag{59}$$

The map $(\text{grad}_\pi \mathscr{H}_N, -\text{grad}_\varphi \mathscr{H}_N): T_X\mathscr{E} \to T_{(\varphi,\pi)}\Gamma_\phi$ is continuous and hence, by the closed graph theorem, $\Xi_{(\varphi,\pi,X)}$ is a *closed* subspace of $T_{(\varphi,\pi,X)}\widetilde{\Gamma}$.

Another consequence of theorem 4 is that the Fréchet derivative of the map $\rho_{XX'}$ with respect to X' is given by

$$\mathrm{D}_{X'}\rho_{XX'}|_{(\varphi,\pi)}(V) = (\text{grad}_\pi \mathscr{H}_V(\varphi', \pi', X'), -\text{grad}_\varphi \mathscr{H}_V(\varphi', \pi', X')), \tag{60}$$

where $(\varphi', \pi') := \rho_{XX'}(\varphi, \pi)$.

We shall need the pull-back of the symplectic form to the constraint manifold. This is given by the following theorem.

Theorem 5: The pull-back $\widetilde{\Omega}$ of the form Ω is given by the formula

$$\begin{aligned}\widetilde{\Omega}((\Phi_1, \Pi_1, V_1), (\Phi_2, \Pi_2, V_2)) \\ = \int_\Sigma d^3x [(\Pi_1 + \text{grad}_\varphi \mathscr{H}_{V_1})(\Phi_2 - \text{grad}_\pi \mathscr{H}_{V_2}) \\ - (\Pi_2 + \text{grad}_\varphi \mathscr{H}_{V_2})(\Phi_1 - \text{grad}_\pi \mathscr{H}_{V_1})].\end{aligned} \tag{61}$$

Proof: The pull-back by the map $\widetilde{C}$ of the form Ω is given by

$$\widetilde{\Omega}((\Phi_1, \Pi_1, V_1), (\Phi_2, \Pi_2, V_2)) := \Omega(\mathrm{D}\widetilde{C}(\Phi_1, \Pi_1, V_1), \mathrm{D}\widetilde{C}(\Phi_2, \Pi_2, V_2)). \tag{62}$$

Substituting into this equation the expressions for $\mathrm{D}\widetilde{C}$ from Eqs. (40) and (41), and using Eq. (54), one easily arrives at Eq. (61). **QED**

Thus, $\widetilde{\Omega}$ is degenerate, and the degeneracy subspace at the point $(\varphi, \pi, X) \in \widetilde{\Gamma}$ coincides with $\Xi_{(\varphi,\pi,X)}$.

The last important notion involving the constraint submanifold is that of a ''c-orbit,'' defined to be the set of points in $\tilde{\Gamma}$ that correspond to just one maximal classical solution (see Ref. 10). Let $\tilde{\gamma}_{(\varphi,\pi,X)}$ be the map $\tilde{\gamma}_{(\varphi,\pi,X)}:\mathscr{E}\to\Gamma_\phi\times\mathscr{E}$ defined by

$$\tilde{\gamma}_{(\varphi,\pi,X)}(X'):=(\rho_{XX'}(\varphi,\pi),X'). \tag{63}$$

Then the c-orbit $\gamma_{(\varphi,\pi,X)}$ through the point $(\varphi,\pi,X)\in\Gamma_\phi\times\mathscr{E}$ is defined as

$$\gamma_{(\varphi,\pi,X)}:=\tilde{\gamma}_{(\varphi,\pi,X)}(\mathscr{E}) \tag{64}$$

i.e., $\gamma_{(\varphi,\pi,X)}$ is the collection of all embeddings, and Cauchy data on such, induced by the unique solution to the field equations whose Cauchy data on $X(\Sigma)$ is (φ,π).

We shall show that the c-orbits are smooth submanifolds of $\tilde{\Gamma}$ and that their tangent spaces coincide with $\Xi_{(\varphi,\pi,X)}$; the proof is analogous to that of theorem 2.

The tangent space to γ at $\tilde{\gamma}_{(\varphi,\pi,X)}(X')$ is the image of the map $\mathrm{D}\tilde{\gamma}_{(\varphi,\pi,X)}|_{X'}:T_{X'}\mathscr{E}\to T_{(\varphi',\pi',X')}(\Gamma_\phi\times\mathscr{E})$, where $(\varphi',\pi'):=\rho_{XX'}(\varphi,\pi)$. Using Eq. (60) we obtain, for all $V\in T_{X'}\mathscr{E}$,

$$\begin{aligned}\mathrm{D}\tilde{\gamma}_{(\varphi,\pi,X)}|_{X'}(V)&=(\mathrm{D}\rho_{XX'}(\varphi,\pi)|_{X'}(V),V)\\&=(\mathrm{grad}_{\pi'}\mathscr{H}_V(\varphi',\pi',X'),-\mathrm{grad}_{\varphi'}\mathscr{H}_V(\varphi',\pi',X'),V).\end{aligned} \tag{65}$$

Hence, $\mathrm{D}\tilde{\gamma}_{(\varphi,\pi,X)|_{X'}}$ is injective, and a comparison of Eq. (65) with Eqs. (56)–(58) shows that $\mathrm{D}\tilde{\gamma}_{(\varphi,\pi,X)}|_{X'}(T_{X'}\mathscr{E})=\Xi_{(\varphi,\pi,X)}$. As Ξ is a closed subspace of a Hilbert space, it splits, and the claims above are proved.

V. CONCLUSIONS

We have shown that, with proper functional-analytical care, the geometrical structure of an infinite-dimensional parametrized system can be developed in a way that is analogous to that of a finite-dimensional system. In particular, for the model considered, the extended phase space is a (weak-)symplectic infinite-dimensional manifold, the constraint set is a submanifold of the phase space, and the c-orbits are submanifolds of the constraint set. The criteria for a constrained system to be first class are of the same form as those of a finite-dimensional system. Many constructions available for a finite-dimensional system can now be performed in the infinite-dimensional case. The only difference is that the symplectic form is only weakly non-degenerate. However, physicists usually work with a restricted class of functions so that the Poisson brackets are still well-defined.

We anticipate that our main results are broadly generalizable. For example, an extension to the case where the Cauchy hypersurfaces are asymptotically flat is likely to be relatively straightforward. We hope that our results will be useful for a number of purposes. In particular, our main goal was to apply the perennial formalism to the scalar field system; this is be done in the accompanying article.

APPENDIX: CAUCHY PROBLEM

We collect together some well-known results about the Cauchy problem of linear hyperbolic systems and then use them to sketch a proof of the theorem 1 in section II.

First, we state some lemmas about the space–time $(\mathscr{M},g)$.

Lemma 1: Let X and X' be two embeddings in $\mathscr{E}$ such that $X'(\Sigma)\subset I^+(X(\Sigma))$. Then, given $T>0$ and $\epsilon>0$, there is a one-dimensional family $\{X_t\}$, $t\in(-\epsilon,T+\epsilon)$, of embeddings such that:

(a) $X_0=X$, $X_T(\sigma)=X'(\Sigma)$;

(b) if (U,h) is a chart of Σ $[h(U)\subset\mathbb{R}^3]$, then $(\cup_{t\in(-\epsilon,T+\epsilon)}X_t(U),[X_t(h^{-1}(x))]^{-1})$ is a C^{r+1} chart in $\mathscr{M}$, where $X_t(h^{-1}(x))$ is considered as a map

$$X_t((h^{-1}(x))):(-\epsilon,T+\epsilon)\times h(U)\to\mathscr{M}; \tag{A1}$$

(c) the components $g_{\alpha\beta}(t,x)$ of the metric in any such chart satisfy the equations

$$g_{00}(t,x)<0 \tag{A2}$$

in $(-\epsilon,T+\epsilon)\times h(U)$ (the t-curves are everywhere timelike), and

$$\begin{aligned} g_{00}(0,x) &= g_{00}(T,x) = -1, \\ g_{0i}(0,x) &= g_{0i}(T,x) = 0, \end{aligned} \tag{A3}$$

for all $x\in h(U)$.

The proof is simple. Observe that g^{00} is negative and g_{kl} is positive-definite everywhere in $(-\epsilon,T+\epsilon)\times h(U)$; this is because any $X_t(U)$ hypersurface is a part of a Cauchy hypersurface, and hence spacelike. Then the condition that g^{kl} is also positive-definite everywhere is equivalent to Eq. (A2). Hence, for any $t\in[0,T]$ and $x\in h(U)$, we have

$$|g^{00}|>c_1, \tag{A4}$$

$$g^{kl}\xi_k\xi_l>c_2e^{kl}\xi_k\xi_l, \tag{A5}$$

where c_1 and c_2 are positive constants, e_{kl} is a positive-definite C^∞ metric on Σ, and ξ_k is an arbitrary covector field on Σ.

The proof of the following lemma can be found in Ref. 16:

Lemma 2: If Σ_1 and Σ_2 are two Cauchy hypersurfaces in $(\mathscr{M},g)$, then there is a Cauchy hypersurface Σ_3 such that

$$\Sigma_3\subset[I^+(\Sigma_1)\cap I^-(\Sigma_2)]. \tag{A6}$$

Thus, $\Sigma_1\cap\Sigma_3=\Sigma_2\cap\Sigma_3=\varnothing$.

Next, consider the Klein–Gordon equation (1) for the field ϕ, and the associated Cauchy problem. In the chart described in lemma I, Eq. (1) has the form

$$\begin{aligned} -g^{00}\frac{\partial^2\phi}{\partial t^2} &= g^{kl}\frac{\partial^2\phi}{\partial x^k\partial x^l}+2g^{0k}\frac{\partial^2\phi}{\partial t\partial x^k}+|\det g|^{-1/2}\partial_\mu(|\det g|^{1/2}g^{0\mu})\frac{\partial\phi}{\partial t} \\ &\quad +|\det g|^{-1/2}\partial_\mu(|\det g|^{1/2}g^{k\mu})\frac{\partial\phi}{\partial x^k}+m^2\phi. \end{aligned} \tag{A7}$$

An initial datum for ϕ at the time t is the pair of scalar fields $(\varphi_t,\dot\varphi_t)$ on Σ given by

$$\varphi_t(x)=\phi(t,x), \tag{A8}$$

$$\dot\varphi_t(x)=\frac{\partial\phi}{\partial t}, \tag{A9}$$

where $\varphi_t(x)$ coincides with the Cauchy datum for $X_t(\Sigma)$ as defined by Eq. (4). For $t=0$ and $t=T$, we have also

$$(\det\ \gamma)^{1/2}\dot{\varphi}_0(x)=\pi_0(x), \tag{A10}$$

$$(\det\ \gamma)^{1/2}\dot{\varphi}_T(x)=\pi_T(x), \tag{A11}$$

where $\pi_0(x)$ and $\pi_T(x)$ are the pieces of Cauchy data defined by Eq. (3) for $X_0(\Sigma)$ and $X_T(\Sigma)$.

Consider the coefficient functions of Eq. (A7). They define tensor fields on Σ. Indeed,

$$a^{00}(t,x)=-g^{00}(t,x), \tag{A12}$$

$$a^{0}(t,x)=|\det\ g|^{-1/2}\partial_\mu(|\det\ g|^{1/2}g^{0\mu})|_{t,x}, \tag{A13}$$

$$a(t,x)=m^2, \tag{A14}$$

are scalar fields on Σ for each t, whereas

$$a^{0k}(t,x)=g^{0k}(t,x), \tag{A15}$$

$$a^{k}(t,x)=|\det\ g|^{-1/2}\partial_\mu(|\det\ g|^{1/2}g^{k\mu})|_{t,x}, \tag{A16}$$

are contravariant vector fields for each t, and

$$a^{kl}(t,x)=g^{kl}(t,x) \tag{A17}$$

is a contravariant tensor of second rank on Σ for each t.

The C^{r+1}-differentiability of X implies the following properties of these tensor fields:

$$\begin{aligned} &a^{\alpha\beta}\in \mathrm{Lip}([0,T];H_0^{r-1}(\Sigma))\subset L^\infty([0,T];H_0^r(\Sigma)),\\ &a^{\alpha}\in \mathrm{Lip}([0,T];H_0^{r-2}(\Sigma))\subset L^\infty([0,T];H_0^{r-1}(\Sigma)),\\ &a\in \mathrm{Lip}([0,T];H_0^{\infty}(\Sigma))=L^\infty([0,T];H_0^r(\Sigma)). \end{aligned} \tag{A18}$$

Moreover, according to Eqs. (A4) and (A5), we have $a^{00}(t,x)\geqslant c_1$ for all $t\in[0,T]$ and $x\in\Sigma$, and

$$a^{kl}(t,x)\xi_k(x)\xi_l(x)\geqslant c_2' e^{kl}(x)\xi_k(x)\xi_l(x), \tag{A19}$$

for all $t\in[0,T]$ and $x\in\Sigma$. The relations above enable us to use ''localized'' forms of the theorems 4.15 and 4.13 in Ref. 15, and to apply them to construct unique local evolution systems $F_{t,s}$ which can be ''patched together.'' By this means we are able to prove the following lemma (for further details see Ref. 15):

Lemma 3: Let the assumptions of Lemma 1 be satisfied, and let $r\geqslant 4$. Then, each initial datum $(\varphi_0(x),\dot{\varphi}_0(x))\in H_0^{s+1}(\Sigma)\times H_0^s(\Sigma)$ on $X_0(\Sigma)$, where $1\leqslant s\leqslant r-1$, defines a unique solution ϕ to the equation (1) in U whose initial datum $(\varphi_T(X),\dot{\varphi}_T(x))$ on $X_T(\Sigma)$ belongs to the Sobolev space $(\varphi_T(X),\dot{\varphi}_T(x))\in H_0^{s+1}(\Sigma)\times H_0^s(\Sigma)$. Furthermore, the maps $U(0,T):H_0^{s+1}(\Sigma)\times H_0^s(\Sigma)\to H_0^{s+1}(\Sigma)\times H_0^s(\Sigma)$ are automorphisms of Banach spaces.

Note that it is a trivial matter to pass from the initial data $(\varphi,\dot{\varphi})$ to the Cauchy data (φ,π): since $(\det\gamma)^{1/2}$ is C^∞ and bounded below by zero in U, the definition $\pi(x):=(\det\gamma)^{1/2}\dot{\varphi}(x)$ describes an isomorphism between the Banach spaces $H_0^s(\Sigma)$ and $H_1^s(\Sigma)$ for any $s\leqslant r$.

Finally, given any pair of arbitrary embeddings X_1 and X_2, we can use lemma 2 to find an ''intermediate'' embedding X_3. To be able to apply lemma 1 to the pairs $\{X_1,X_3\}$ and $\{X_3,X_2\}$, we must find two embeddings X_3' and X_3'' such that the corresponding t-curves are

timelike, and with $X_3'(\Sigma)=X_3''(\Sigma)=X_3(\Sigma)$. Then, we can use lemma 3 and the diffeomorphism invariance of B to prove the theorem 1. **QED**
