In Sec. IV we will establish a result (Theorem A) for our discrete decay model, wherein the measures P_N^d approach a distribution with exponential waiting time to leave ϕ_d as $N\to\infty$. A similar result was previously proven for a large class of quantum processes in Kanter,[4] however, it is not evident that our discrete decay model is a member of this class.

The measures P_N^{ab} were first considered in Kanter,[5] whose results we paraphrase in the context of our discrete decay model as Theorem B in Sec. IV. This theorem establishes the least action principle associated with our discrete decay model under continuous measurement. Whereas the original version of Theorem B was proved for quantum processes whose Hamiltonian was a Hilbert–Schmidt operator, such a strong hypothesis is not necessary here. On the other hand, the model considered in this paper is special in that the measurement basis contains a distinguished state ϕ_d with the property that no change of state transitions occur unless one of the states involved is ϕ_d.

Many decay models with a distinguished state ϕ_d as above have been postulated, such as the famous Friedrichs–Lee model.[6] These models involve nonseparable Hilbert spaces, and the decay products $\{\phi_j : j \neq d\}$ contain a continuum of generalized Dirac delta functions. Thus, these models may be called ''continuous'' decay models. (Note that our simplistic approach to measurement relies on J being countable.)

Discrete decay models have been previously considered by Davis[7] and Cohen-Tannoudji *et al.*[8] In these models the set J is decomposed as

$$J = \{d\} \cup J_0, \tag{1.1}$$

where J_0 is a subset of the integers. Given a positive number Δ and a complex number c, these authors consider a Hamiltonian $H = H(\Delta, c)$ satisfying

$$H\phi_j = c\Delta^{1/2}\phi_d + j\Delta\phi_j \quad (\text{for } j \neq d). \tag{1.2}$$

With various levels of precision they show that

$$\lim_{\Delta \to 0} \langle \phi_d | e^{itH} \phi_d \rangle = \exp(-\pi\alpha|t|) \quad (\text{for } t \in R), \tag{1.3}$$

where $\alpha = |c|^2$. [Davies does not state (1.3) precisely and defines $J_0 = J_0(\Delta)$ to be the set of integers with absolute value bounded by $K\Delta^{-1}$ for some constant K. Thus, Davies' model is only an ''approximate'' discrete decay model, since ϕ_d is regular and only becomes nonregular in the limit as $\Delta \to 0$. Cohen-Tannoudji *et al.* let $J_0 = Z$ and state (1.3) precisely, indicating its connection with Fermi's ''golden rule.'' However, their treatment of the model is not mathematically rigorous.] The parameter Δ is the energy gap between the decay products ϕ_j. Thus, as $\Delta \to 0$, the decay products ϕ_j densely approach the continuum of Dirac delta functions.

In this paper we shall treat the model (1.2) with $J_0 = Z$ in a mathematically rigorous fashion to obtain the new and striking result

$$\langle \phi_d | e^{itH} \phi_d \rangle = \exp(-\pi\alpha|t|) \quad (\text{for } |t| \leqslant 2\pi\Delta^{-1}). \tag{1.4}$$

[We derive a recursive expression for $\langle \phi_d | e^{itH} \phi_d \rangle$ outside the interval $|t| \leqslant 2\pi\Delta^{-1}$.] We note that (1.3) is a direct consequence of (1.4). We shall see that $\phi_d \notin D(H)$, the domain of H, and that under continuous observation the model exhibits exact exponential decay at all times if ϕ_d is the initial state.

C. Summary of other sections

The rest of this paper is divided into five sections. In Sec. II we shall present the main features of our discrete decay model, but will delay the proofs of some of our results until Secs. V and VI. In Sec. III we will determine decay rates and bounds for all the states ϕ_j in the measurement basis for our model. In Sec. IV we will use the results of Sec. III in order to study the limiting behavior of P_N^a and P_N^{ab} for our model. In particular we will state and prove Theorems A and B. In Secs. V and VI we will put our model on a mathematically rigorous footing. In particular, Sec. VI contains a derivation of the key equation (1.4).

II. THE MODEL

In this section we will present the main features of our discrete decay model, though we will delay the nontrivial proofs of our first two theorems until Secs. V and VI. We start by gathering some definitions.

Definition 2.1: We let C stand for the set of all complex numbers c and write $\overline{c} = u - iv$ if $c = u + iv$ for $u, v \in R$. We let Z stand for the set of all integers and Z' for the set of nonzero

integers. We let $R-Z$ stand for the set of real numbers not in Z. We let $L_2(Z')$ represent the set of all square summable C-valued sequences indexed by Z'. We let $\langle\cdot|\cdot\rangle$ stand for the usual inner product on $L_2(Z')$, i.e.,

$$\langle x|y\rangle=\sum_{n\in Z'}\overline{x_n}y_n \quad [\text{for } x,y\in L_2(Z')]. \tag{2.1}$$

From now on all measurement bases will be indexed by the set

$$Z_d=\{d\}\cup Z, \tag{2.2}$$

this being a special case of (1.1). In Sec. V we shall show that each positive real number Δ and nonzero c in C specify a discrete decay model with measurement basis $\{\phi_j:j\in Z_d\}$. (We shall set $\Delta=1$ for notational simplicity throughout the paper and comment on the general case at the end of Sec. VI.) Although the models are distinct, they have essentially the same properties, hence no confusion need arise when we refer to *the* model. To briefly summarize, let $\alpha=|c|^2$. We will construct two sequences $(p_n:n\in Z')$ and $(\lambda_n:n\in Z')$ depending only on α such that $p_n\geqslant 0$, $p_n=p_{-n}$, $\lambda_n\in R-Z$, and $\lambda_n=-\lambda_{-n}$ for all n in Z'. Furthermore the following theorems hold:

Theorem 2.1: (To be proved in Sec. V.) For j in Z_d, define

$$\phi_j=\begin{cases}((p_n)^{1/2}:n\in Z') & \text{if } j=d,\\ (c(p_n)^{1/2}(\lambda_n-j)^{-1}:n\in Z') & \text{if } j\in Z.\end{cases} \tag{2.3}$$

Then $\{\phi_j:j\in Z_d\}$ is an orthonormal collection of vectors in $L_2(Z')$.

We define the unitary group $(U(t):t\in R)$ on $L_2(Z')$ via

$$(U(t)x)_n=(e^{it\lambda_n})x_n \quad (\text{for } n\in Z'), \tag{2.4}$$

where $x=(x_n:n\in Z')\in L_2(Z')$. It is clear that $U(t)$ is strongly continuous on $L_2(Z')$, and that the infinitesimal generator H of $U(t)$ is simply the multiplication operator

$$(Hx)_n=\lambda_n x_n \quad (\text{for } n\in Z'). \tag{2.5}$$

Of course Hx is defined only for $x\in D(H)$, i.e., if

$$\langle x|H^2|x\rangle=\sum_{n\in Z'}\lambda_n^2|x_n|^2<\infty. \tag{2.6}$$

We let L stand for the closed subspace of $L_2(Z')$ spanned by $\{\phi_j:j\in Z_d\}$.

Theorem 2.2: (To be proved in Sec. VI.) For all t in R, the inclusion $U(t)L\subset L$ holds.

We shall show in Sec. V that $\phi_d\notin D(H)$, hence $\langle\phi_d|H|\phi_d\rangle$ is not defined. Since $H^*=H$, all the remaining numbers $\langle\phi_j|H|\phi_k\rangle$ are formally defined by

$$\langle\phi_j|H|\phi_k\rangle=\begin{cases}\alpha\displaystyle\sum_{n\in Z'}p_n\lambda_n(\lambda_n-j)^{-1}(\lambda_n-k)^{-1} & \text{for } j,k\in Z,\\ c\displaystyle\sum_{n\in Z'}p_n\lambda_n(\lambda_n-k)^{-1} & \text{for } j=d,k\in Z.\end{cases} \tag{2.7}$$

Theorem 2.3: Given ϕ_j as defined in (2.3) and H as in (2.5), the infinite sums in (2.7) are absolutely convergent. Furthermore we can write

$$\langle \phi_j|H|\phi_k\rangle=\begin{cases} j\delta_{jk} & \text{for } j,k \text{ in } Z, \\ c & \text{for } j=d \text{ and } k \text{ in } Z, \end{cases} \tag{2.8}$$

where $\delta_{jk}=1$ if $j=k$ and 0 otherwise.

Proof: We note the identity

$$\lambda_n(\lambda_n-k)^{-1}=1+k(\lambda_n-k)^{-1} \quad (\text{for } n\in Z' \text{ and } k\in Z), \tag{2.9}$$

where we remember that $\lambda_n\notin Z$, hence both sides of (2.9) are always finite. Since Theorem 2.1 guarantees, among other things, that $\langle \phi_j|\phi_j\rangle<\infty$ for all j in Z_d, we can use the Cauchy–Schwartz inequality to conclude that the infinite sums in (2.7) are absolutely convergent. The relation (2.8) now follows from (2.9) and the orthonormality of $\{\phi_j : j\in Z_d\}$. □

Theorem 2.4: Given ϕ_j and H as in Theorem 2.3, it follows that

$$\langle \phi_j|H^2|\phi_j\rangle-(\langle \phi_j|H|\phi_j\rangle)^2=\alpha \quad (\text{for } j\in Z). \tag{2.10}$$

Proof: We can write

$$\langle \phi_j|H^2|\phi_j\rangle=\sum_{n\in Z'} \alpha p_n\lambda_n^2(\lambda_n-j)^{-2} \quad (\text{for } j\in Z) \tag{2.11}$$

as a consequence of (2.3) and (2.5). We note the identity

$$\lambda_n^2=(\lambda_n-j)^2+2\lambda_n j-j^2 \quad (\text{for } j\in Z) \tag{2.12}$$

and apply Theorem 2.1 to conclude that

$$\langle \phi_j|H^2|\phi_j\rangle=\alpha+2j\langle \phi_j|H|\phi_j\rangle-j^2 \quad (\text{for } j\in Z). \tag{2.13}$$

We recall (2.8) with $j=k$ to get (2.10). □

Remark 2.1: The expression on the left-hand side of (2.10) is called the ''energy variance'' in state ϕ_j. We conclude that all states in the measurement basis except ϕ_d have the same finite energy variance. We note also that $\phi_j\in D(H)$ if and only if ϕ_j has finite energy variance, as can easily be verified. Furthermore, we can write

$$H\phi_j=c\phi_d+j\phi_j \quad (\text{for } j\in Z), \tag{2.14}$$

as follows from (2.8). [No rigorous expression for $H\phi_d$ is possible since $\phi_d\notin D(H)$, as will be directly demonstrated in Remark 5.2.]

In the next two sections we shall see that the distinction between ϕ_d and the other states in the measurement basis has significant consequences when the quantum process is continuously measured.

III. DECAY RATES AND BOUNDS

In this section we will provide exact results and bounds for the decay out of an initial state when our model is *not* continuously observed.

Definition 3.1: For t in R, let

$$Q_{jk}(t)=|\langle \phi_j|\phi_k(t)\rangle|^2 \quad (\text{for } j,k\in Z_d), \tag{3.1}$$

where $\phi_k(t)=U(t)\phi_k$ and $U(t)=\exp(itH)$.

Remark 3.1: The normalization $\|\phi_j\|=1$ for j in Z_d ensures that the matrix $Q(t)=(Q_{jk}(t): j,k\in Z_d)$ is a doubly stochastic matrix. (All rows and columns sum to 1.)

Definition 3.2: We say ϕ_j has decay rate $\beta \in [0, \infty)$ if

$$\lim_{t \downarrow 0} t^{-1}(1 - Q_{jj}(t)) = \beta. \tag{3.2}$$

We define ϕ_j to be regular if $\beta = 0$ in (3.2).

Remark 3.2: Since $Q_{jj}(t)$ is symmetric around 0, it is clear that $\beta = 0$ in (3.2) if and only if $Q_{jj}(t)$ is differentiable at 0. It is also clear that the Zeno effect holds for a continuously observed quantum process with initial state ϕ_j if and only if ϕ_j is regular, since $\lim_{N \to \infty}(Q_{jj}(t/N))^N = 1$ for all $t > 0$ if and only if the limit in (3.2) is 0. It is obvious that the condition $\phi_j \in D(H)$ is sufficient for ϕ_j to be regular.

For j in Z_d we define the amplitude functions

$$\Phi_j(t) = \langle \phi_j | \phi_j(t) \rangle \quad (\text{for } t \in R). \tag{3.3}$$

We conclude from (2.3) and (2.4) that

$$\Phi_d(t) = \sum_{n \in Z'} p_n e^{i\lambda_n t} = 2 \sum_{n > 0} p_n \cos(\lambda_n t), \tag{3.4}$$

where the last equality follows because $p_n = p_{-n}$ and $\lambda_n = -\lambda_{-n}$ for $n \in Z'$. We shall show in Sec. VI that

$$\Phi_d(t) = \exp(-\pi\alpha|t|) \quad (\text{for } |t| \leqslant 2\pi). \tag{3.5}$$

It follows directly that

$$\lim_{t \downarrow 0} t^{-1}(1 - Q_{dd}(t)) = 2\alpha\pi, \tag{3.6}$$

i.e., ϕ_d has nonzero decay rate $2\alpha\pi$ and thus is not regular. In particular $\phi_d \notin D(H)$ as will be directly demonstrated in Remark 5.2.

Definition 3.3: For $j \in Z_d, k \in Z$, we define

$$\Psi_{jk}(t) = \langle \phi_j | \phi_k(t) \rangle e^{-ikt} \quad (\text{for } t \in R). \tag{3.7}$$

Using (2.14) or computing directly, we can differentiate (3.7) to obtain

$$\Psi'_{dk}(t) = ic\Phi_d(t)e^{-ikt} \quad (\text{for } k \in Z). \tag{3.8}$$

It follows that

$$\Psi_{dk}(s) = ic \int_0^s \Phi_d(r) e^{-ikr}\, dr \tag{3.9}$$

since $\Psi_{dk}(0) = 0$ for $k \in Z$. We conclude

$$\lim_{t \to 0} t^{-2} Q_{dk}(t) = \alpha \quad (\text{for } k \in Z). \tag{3.10}$$

We can also use (2.14) to write

$$\Psi'_{jk}(t) = ic\langle \phi_j | \phi_d(t) \rangle e^{-ikt} \quad (\text{for } j, k \in Z). \tag{3.11}$$

Since $U(t)$ is unitary we know that $\langle \phi_j | \phi_d(t) \rangle$ is the complex conjugate of $\langle \phi_d | \phi_j(-t) \rangle$. A little calculation then yields

$$\Psi'_{jk}(t) = ic\overline{\Psi}_{dj}(-t)e^{i(j-k)t} = i\overline{c\Psi}_{dj}(t)e^{i(j-k)t}, \tag{3.12}$$

where the last equality follows from (3.9).

Lemma 3.1: For $j \in Z$, ϕ_j has decay rate 0.

Proof: It follows from (3.9) and (3.12) that

$$\Psi_{jk}(t) = \delta_{jk} - \alpha \int_0^t \int_0^s \Phi_d(r) e^{-ijr} e^{-i(k-j)s}\, dr ds \tag{3.13}$$

for $j,k \in Z$. Letting $j=k$, we interchange order of integration to obtain

$$\Psi_{jj}(t) = 1 - \alpha \int_0^t (t-r)\Phi_d(r) e^{-ijr}\, dr. \tag{3.14}$$

Since $|\Phi_d| \leqslant 1$ we conclude that

$$1 - |\Psi_{jj}(t)| \leqslant (1/2)\alpha t^2 \quad (\text{for } j \in Z). \tag{3.15}$$

We also have $|\Psi_{jj}| \leqslant 1$, hence

$$1 - Q_{jj}(t) \leqslant \alpha t^2 \quad (\text{for } j \in Z). \tag{3.16}$$

The lemma now follows. □

Remark 3.3: It follows from (3.16) and Remark 3.1 that for all t in R

$$Q_{jk}(t) \leqslant \alpha t^2 \quad (\text{for } j,k \in Z_d, j \neq k). \tag{3.17}$$

Furthermore, it follows from (3.13) that

$$\lim_{t \to 0} t^{-4} Q_{jk}(t) = (\tfrac{1}{4})\alpha^2 \quad (\text{for } j,k \in Z, j \neq k). \tag{3.18}$$

IV. APPLICATIONS TO CONTINUOUS MEASUREMENT

In this section we will define the measures P_N^a and P_N^{ab} in more detail, and we will summarize their limit behavior as $N \to \infty$ via Theorems A and B.

Definition 4.1: Given $n>0$ and $t \in (0,\infty)$, let $Q^{(n)}(t)$ stand for the n-fold matrix product of $Q(t)$ with itself. For short we let Q stand for $Q(N^{-1})$ and $Q^{(n)}$ stand for $Q^{(n)}(N^{-1})$. We define the non-negative measure P_N on $(Z_d)^{N+1}$ by

$$P_N(x_0,\ldots,x_N) = \prod_{n=1}^{N} Q_{x_{n-1}x_n} \quad [\text{for } (x_0,\ldots,x_N) \in (Z_d)^{N+1}]. \tag{4.1}$$

We let Ω_a stand for the set of all sequences $(x_0,\ldots,x_N)$ in $(Z_d)^{N+1}$ such that $x_0 = a$, and we define Ω_{ab} similarly, with the additional restriction that $x_N = b$. We note that

$$P_N(\Omega_{ab}) = Q_{ab}^{(N)} = Q_{ab}^{(N)}(N^{-1}). \tag{4.2}$$

We define the conditional probability measures P_N^a and P_N^{ab} by conditioning P_N on the sets Ω_a and Ω_{ab}, respectively. [For example,

$$P_N^{ab}(G)=P_N(G\Omega_{ab})/P_N(\Omega_{ab}) \tag{4.3}$$

for $G\subset(Z_d)^{N+1}$.] Clearly P_N^a is the distribution of the Markov chain $X_0,\ldots,X_N$ with transition kernel Q, constrained so that $X_0=a$; while P_N^{ab} is similarly characterized with the additional constraint that $X_N=b$.

We can now state Theorems A and B.

Theorem A: Given a,b in Z_d and $t>0$,

$$\lim_{N\to\infty} Q_{ab}^{(N)}(t/N)=\delta_{ab}\exp(-2\alpha\delta_{ad}\pi t). \tag{4.4}$$

This result establishes exponential decay valid for all t, which is characteristic of our model in the context of continuous measurement.

Theorem B: As $N\to\infty$, the measures P_N^{ab} assign all but a vanishingly small fraction of their mass to observed state sequences with exactly $\rho(a,b)$ change of state transitions, none of which returns to a previously observed state. Here $\rho(a,b)$ is defined by

$$\rho(a,b)=\inf\left\{r:\prod_{s=1}^{r}\langle\phi_{j_{s-1}}|H|\phi_{j_s}\rangle\neq 0\right\}, \tag{4.5}$$

where the infimum is taken over all sequences $j_0,\ldots,j_r$ in Z_d satisfying

$$a=j_0\neq j_1\neq\cdots\neq j_{r-1}\neq j_r=b. \tag{4.6}$$

This result establishes the least action principle for our discrete decay model subject to continuous measurement and constraints at the initial and final states.

The rest of this section is devoted to establishing a sequence of results leading up to Theorems A and B. We note first that $\rho(a,b)$ in (4.5) is well defined for our discrete decay model, because $\langle\phi_j|H|\phi_k\rangle$ is well defined if $j\neq k$. We note also that $\rho(a,b)=0$ if and only if $a=b$. We now present a definition which will clarify the content of Theorem B.

Definition 4.2: Given any integer $r\geqslant 0$, we let $\Omega_{ab}^{(r)}$ stand for the set of all sequences $(x_0,\ldots,x_N)$ in Ω_{ab} such that for some sequence $j_0,\ldots,j_r$ in Z_d satisfying (4.6) and some sequence $n_0,\ldots,n_r$ of non-negative integers satisfying

$$r+\sum_{s=0}^{r} n_s=N \tag{4.7}$$

we have

$$x_n=j_s \qquad \left(\text{for } s+\sum_{t=0}^{s-1} n_t\leqslant n\leqslant s+\sum_{t=0}^{s} n_t\right). \tag{4.8}$$

[Thus $\Omega_{ab}^{(r)}$ consists of those sequences $(a,x_1,\ldots,x_{N-1},b)$ in Ω_{ab} which make exactly r change of state transitions.]

Remark 4.1: The set of non-negative integers $n_0,\ldots,n_s,\ldots,n_r$ satisfying (4.7) has cardinality $\binom{N}{r}$, as is obvious by interpreting the integers n_s as the number of spaces between r objects placed in N slots.

Theorem 4.1: For a in Z_d

$$\lim_{N\to\infty} P_N^{aa}(\Omega_{aa}^{(0)})=1. \tag{4.9}$$

Proof: Since $P_N(\Omega_{aa}^{(0)})=(Q_{aa})^N$, we can write

$$P_N(\Omega_{aa}) = (Q_{aa})^N + \sum (Q_{aa})^{n_0} Q_{aj} Q_{jk}^{(n_1)} Q_{ka} (Q_{aa})^{n_2}, \tag{4.10}$$

where the sum is taken over all non-negative integers n_0, n_1, n_2 satisfying (4.7) with $r=2$ and over all j,k in Z_d such that $a \neq j$ and $k \neq a$. Using (3.17) and Remark 4.1, we conclude that

$$|P_N(\Omega_{aa}) - (Q_{aa})^N| \leqslant \binom{N}{2} N^{-4} \alpha^2. \tag{4.11}$$

Furthermore, we know from (3.6) and (3.16) that

$$\lim_{N\to\infty} (Q_{aa})^N = \exp(-2\alpha \delta_{ad} \pi) \quad (\text{for } \alpha \in Z_d). \tag{4.12}$$

We obtain (4.9) from (4.11) and (4.12). □

Theorem 4.2: For b in Z

$$\lim_{N\to\infty} P_N^{db}(\Omega_{db}^{(1)}) = 1. \tag{4.13}$$

Proof: Given a,b in Z_d with $a \neq b$, write

$$P_N(\Omega_{ab}) = P_N(\Omega_{ab}^{(1)}) + \sum (Q_{aa})^{n_0} Q_{aj} Q_{jk}^{(n_1)} Q_{kb} (Q_{bb})^{n_2}, \tag{4.14}$$

where the sum is taken over all non-negative integers n_0, n_1, n_2 satisfying (4.7) with $r=2$ and all j,k in Z_d with $a \neq j$ and $k \neq b$. We can also write

$$P_N(\Omega_{ab}^{(1)}) = \sum (Q_{aa})^{n_0} Q_{ab} (Q_{bb})^{n_1}, \tag{4.15}$$

where the sum is taken over all non-negative integers n_0, n_1 satisfying (4.7) with $r=1$. It follows that

$$P_N(\Omega_{ab}^{(1)}) \geqslant N (Q_{aa})^N (Q_{bb})^N Q_{ab}. \tag{4.16}$$

We now use (3.10) and (4.12) to conclude that

$$\liminf_{N\to\infty} N P_N(\Omega_{ab}^{(1)}) \geqslant \alpha \exp(-2\alpha\pi). \tag{4.17}$$

On the other hand

$$|P_N(\Omega_{ab}) - P_N(\Omega_{ab}^{(1)})| \leqslant \binom{N}{2} N^{-4} \alpha^2, \tag{4.18}$$

using Remark 4.1, (3.17), and (4.14). We conclude (4.13) from (4.17) and (4.18) by setting $a=d$ and letting $b \in Z$. □

Theorem 4.3: Let a,b in Z with $a \neq b$. Then

$$\lim_{N\to\infty} P_N^{ab}(\Omega_{ab}^{(2)}) = 1. \tag{4.19}$$

Proof: We can write

$$P_N(\Omega_{ab}) = P_N(\Omega_{ab}^{(1)}) + P_N(\Omega_{ab}^{(2)}) + P_N\left(\bigcup_{r=3}^{N} \Omega_{ab}^{(r)}\right). \tag{4.20}$$

We use (4.15) to write

$$P_N(\Omega_{ab}^{(1)}) \leqslant N Q_{ab}, \tag{4.21}$$

and we conclude from (3.18) that

$$\limsup_{N\to\infty} N^{-3} P_N(\Omega_{ab}^{(1)}) \leqslant (\tfrac{1}{4})\alpha^2. \tag{4.22}$$

We now note that

$$P_N(\Omega_{ab}^{(2)}) \leqslant \sum (Q_{aa})^{n_0} Q_{ad} (Q_{dd})^{n_1} Q_{db} (Q_{bb})^{n_2}, \tag{4.23}$$

where the sum is taken over all non-negative integers n_0, n_1, and n_2 satisfying (4.7) with $r=2$. Using Remark 4.1, it follows that

$$P_N(\Omega_{ab}^{(2)}) \geqslant \binom{N}{2} (Q_{aa} Q_{dd} Q_{bb})^N Q_{ad} Q_{db}. \tag{4.24}$$

We conclude from (3.6) and (3.10) that

$$\liminf_{N\to\infty} N^2 P_N(\Omega_{ab}^{(2)}) \geqslant (\tfrac{1}{2})\alpha^2 \exp(-2\alpha\pi). \tag{4.25}$$

Let $p = \sup(Q_{jk})$, where the supremum is taken over all j,k in Z_d with $j \neq k$. We have

$$P_N\left(\bigcup_{r=3}^{N} \Omega_{ab}^{(r)}\right) \leqslant \binom{N}{3} p^3 \tag{4.26}$$

by virtue of Lemma 3.2 in Kanter.[9] It follows from (3.17) that

$$P_N\left(\bigcup_{r=3}^{N} \Omega_{ab}^{(r)}\right) \leqslant (\tfrac{1}{6})\alpha^3 N^{-3}. \tag{4.27}$$

Clearly (4.19) follows from (4.20), (4.22), (4.25), and (4.27). □

We conclude the section by supplying proofs for Theorems A and B.

Proof of Theorem A: We shall prove (4.4) for $t=1$. For other $t>0$ the same proof will work by redefining P_N in terms of $Q(t)$ instead of Q and making other obvious changes of scale in our argument (e.g., α is replaced by αt^2 throughout). Thus we conclude from (4.2), (4.11), (4.12), and (4.18) that (4.4) holds if $t=1$ and $a=b$. Furthermore, for a,b in Z_d with $a \neq b$ we have

$$P_N(\Omega_{ab}^{(1)}) \leqslant N Q_{ab} \leqslant \alpha N^{-1}, \tag{4.28}$$

using (3.17) and (4.15). It follows from (4.2) and (4.18) that (4.4) holds if $t=1$ and $a \neq b$. □

Remark 4.2: If $a=d$, we can interpret (4.4) as stating that under continuous observation ϕ_d decays exponentially with rate $2\alpha\pi$. Furthermore, when decay occurs, the process ''explodes'' in the sense that the distribution characterizing where it goes becomes infinitely diffuse. This result is in accordance with Theorem 2.2 in Kanter,[10] although we have not verified that our discrete

decay model satisfies the Approximation Hypothesis used there. If $a \in Z$, then (4.4) asserts that ϕ_a decays at rate zero under continuous observation, in accordance with the Zeno paradox.

Proof of Theorem B: It follows from (2.8) that

$$\rho(a,b)=\begin{cases} 0 & \text{if } a=b, \\ 1 & \text{if } a\neq b \quad \text{and } d\in\{a,b\}, \\ 2 & \text{otherwise.} \end{cases} \tag{4.29}$$

Furthermore, we can readily confirm that no returns to a previously visited state can take place in a sequence (a,b) or (a,j,b) with $a\neq b$ and $a\neq j\neq b$. Thus Theorem B follows from (4.29) and from Theorems 4.1–4.3. □

Remark 4.3: The equation (4.29) expresses the distinguished nature of the state ϕ_d, in allowing only those change of state transitions which involve ϕ_d.

V. ORTHONORMALITY OF THE MEASUREMENT BASIS

In this section we shall prove Theorem 2.1 by obtaining the Mitteg–Leffler expansion of the Laplace transform of the amplitude Φ_d in (3.4). We start with a definition.

Definition 5.1: An infinite series $\Sigma_{n\in Z'} f_n$ of meromorphic functions defined on the complex plane C is said to be *normally convergent on C* if the series is uniformly convergent on any compact set disjoint from any of the poles of the functions f_n.

Remark 5.1: If $\Sigma_{n\in Z'} f_n$ is normally convergent to f, then $\Sigma_{n\in Z'} f_n^{(p)}$ is normally convergent to $f^{(p)}$, where $g^{(p)}$ stands for the pth derivative of the meromorphic function g. (See Palka.[11])

Proof of Theorem 2.1: We start our arguments by defining the meromorphic function

$$K_\alpha(z)=(z+\alpha\pi\ \coth(\pi z))^{-1} \tag{5.1}$$

on the complex plane C. [Here $\alpha>0$ is a parameter which will be identified with $|c|^2$ in (2.3).] We shall show that

$$K_\alpha(z)=\sum_{n\in Z'} p_n(z-i\lambda_n)^{-1} \tag{5.2}$$

is normally convergent on C, where p_n and λ_n satisfy the conditions given before Theorem 2.1.

We now need the known fact that $(K_\alpha(z))^{-1}$ has only imaginary roots. (See Hille.[12]) Letting $z_n=i\lambda_n$ stand for the roots, we solve for λ_n via the equation

$$\lambda_n=\alpha\pi\ \cot(\lambda_n\pi). \tag{5.3}$$

Graphical inspection shows that the solutions of (5.3) can be indexed by n in Z' so that $\lambda_n=-\lambda_{-n}$ for n in Z' and

$$\lambda_n\in(n-1,n-2^{-1}) \quad (\text{for } n>0). \tag{5.4}$$

Since $\{i\lambda_n : n\in Z'\}$ comprises the set of all poles of K_α, we conclude that K_α has no poles of the form ij for $j\in Z$.

As a first step in demonstrating (5.2) we shall show that

$$K_\alpha(z)=\sum_{n\in Z'} p_n((z-i\lambda_n)^{-1}-i\lambda_n^{-1}) \tag{5.5}$$

is a normally convergent sum on C, where p_n is the residue of $K_\alpha(z)$ at $z=i\lambda_n$ for n in Z'. Let $G(z)=(K_\alpha(z))^{-1}$. We compute

$$p_n=\left(\frac{d}{dz}\,G(z)\bigg|_{z=i\lambda_n}\right)^{-1}=(1+\alpha\pi^2\,\sin^{-2}(\pi\lambda_n))^{-1}. \tag{5.6}$$

We note $p_n>0$ for n in Z', hence all the poles of K_α are simple.

Let M stand for a positive integer and let C_M stand for the boundary of the square with vertices at $(M+2^{-1})(\pm 1\pm i)$ in the complex plane. It is shown in Palka[13] that

$$|\coth(\pi z)|\leqslant(1+e^{-3\pi})(1-e^{-3\pi})^{-1}\quad(\text{for } z\in C_M), \tag{5.7}$$

hence it follows that

$$|K_\alpha(z)|\leqslant 2M^{-1}\quad(\text{for } z\in C_M) \tag{5.8}$$

if M is sufficiently large. (Note $|z|\geqslant|M|$ for z in C_M.) In particular, K_α is bounded on the system of contours $(C_M: M\geqslant 1)$ taken as a whole. The validity of (5.5) as a normally convergent sum now follows from the general criteria for such expansions in Titchmarsh.[14]

We can use Remark 5.1 to differentiate both sides of (5.5). We obtain

$$(K_\alpha(z))^2(1-\alpha\pi^2(\sinh(\pi z))^{-2})=\sum_{n\in Z'}p_n(z-i\lambda_n)^{-2} \tag{5.9}$$

as a normally convergent sum on C. Now for j in Z the point $z=ij$ is not a pole in the expansion (5.9), hence we conclude that

$$\lim_{x\to j}(x-\alpha\pi\,\cot(\pi x))^{-2}(1+\alpha\pi^2(\sin(\pi x))^{-2})=\sum_{n\in Z'}p_n(j-\lambda_n)^{-2}, \tag{5.10}$$

where the variable x is real. In particular the right-hand side of (5.10) is finite and

$$\alpha^{-1}=\sum_{n\in Z'}p_n(j-\lambda_n)^{-2}\quad(\text{for } j\in Z). \tag{5.11}$$

This shows that the vectors $(\phi_j: j\in Z)$ all have norm 1.

We now examine the norm of ϕ_d. We combine (5.3) and (5.6) to write

$$p_n=(1+\alpha\pi^2+\alpha^{-1}\lambda_n^2)^{-1}. \tag{5.12}$$

Remembering (5.4), we conclude that $\|\phi_d\|<\infty$. It follows that

$$\sum_{n\in Z'}p_n|c(j-\lambda_n)^{-1}|\leqslant\|\phi_d\|\|\phi_j\|<\infty\quad(\text{for } j\in Z), \tag{5.13}$$

by virtue of the Cauchy–Schwartz inequality. We conclude that

$$\sum_{n\in Z'}p_n(j-\lambda_n)^{-1}=0\quad(\text{for } j\in Z) \tag{5.14}$$

using $p_n=p_{-n}$ and $\lambda_n=-\lambda_n$ for $n\in Z'$. Letting $j=0$, this proves (5.2) as a consequence of (5.5). We define the Laplace transform of Φ_d in (3.4) via

$$\hat{\Phi}_d(z)=\int_0^\infty e^{-zt}\Phi_d(t)dt\quad[\text{for } z\in C \text{ with } \mathrm{Re}(z)>0]. \tag{5.15}$$

It follows from (5.2) that

$$\hat{\Phi}_d(z)=(z+\alpha\pi\ \coth(\pi z))^{-1} \quad [\text{for } \mathrm{Re}(z)>0]. \tag{5.16}$$

We now use the well-known relation

$$\lim_{x\to\infty} x\hat{\Phi}_d(x)=\lim_{t\downarrow 0}\Phi_d(t) \quad [\text{where } x\in(0,\infty)] \tag{5.17}$$

to conclude $\|\phi_d\|=1$, since $\lim_{x\to+\infty} x(x+\alpha\pi\coth(\pi x))^{-1}=1$.

In order to verify that $\{\phi_j: j\in Z_d\}$ are orthonormal, it remains to show that ϕ_j and ϕ_k are orthogonal if $j\neq k$, for j,k in Z. [Note that ϕ_d is orthogonal to ϕ_j for all j in Z on account of (5.14).] However, we can write

$$\sum_{n\in Z'} p_n(\lambda_n-j)^{-1}(\lambda_n-k)^{-1}=(k-j)\sum_{n\in Z'} p_n((\lambda_n-k)^{-1}-(\lambda_n-j)^{-1}) \tag{5.18}$$

for j,k in Z with $j\neq k$, where absolute convergence is assured by (5.13). Applying (5.14), we obtain

$$\sum_{n\in Z'} p_n(\lambda_n-j)^{-1}(\lambda_n-k)^{-1}=\langle\phi_j|\phi_k\rangle=0 \tag{5.19}$$

for j,k in Z with $j\neq k$. This completes the proof of Theorem 2.1. □

Remark 5.2: We note that $\phi_d\notin D(H)$. In fact, $\lambda_n^2\geqslant(|n|-1)^2$ for $n\in Z'$ by (5.4), hence $p_n\geqslant 2^{-1}\alpha\lambda_n^{-2}$ for $|n|$ sufficiently large by (5.12). It immediately follows that

$$\langle\phi_d|H^2|\phi_d\rangle=\sum_{n\in Z'}\lambda_n^2 p_n=\infty, \tag{5.20}$$

whence $\phi_d\notin D(H)$.

Remark 5.3: Not only is $\phi_d\notin D(H)$, but in fact ϕ_d is not regular by virtue of (3.6). It is therefore of interest to write down a spectral condition for regularity to facilitate comparison with (5.20). Using results in Feller,[15] such a condition is given by

$$\lim_{M\to\infty} MP[|X|\geqslant M]=0, \tag{5.21}$$

where X is a random variable with $E(\exp(itX))=\Phi_d(t)$. [Thus X has distribution p_n as in (3.4).] Arguing as for (5.20) it is easy to see that (5.21) is violated as a consequence of (5.4) and (5.12).

Remark 5.4: A set of sufficient conditions for the Zeno effect is given in Misra and Sudarshan.[16] (That paper considers projections more general than the single state projections $\phi><\phi$ in defining the quantum Zeno effect.) It can be shown that the conditions in Misra and Sudarshan are all satisfied for ϕ_d except the condition that H be semi-bounded.[17] (Similar considerations are given in Kanter[18] with respect to the trivial decay model cited at the end of Section I A.)

VI. SOLVING THE MODEL

In this section we will use classical Fourier series arguments to prove Theorem 2.2. Along the way we will give an explicit representation for the transition amplitude function Φ_d in (3.4). In particular we will show that (1.4) holds.

Lemma 6.1: Let p_n and λ_n be given as in (5.2) for n in Z'. We then have

$$[\lambda_n] \leqslant 1/2(1+(n-1)^2(\alpha\pi)^{-2})^{-1/2} \quad (\text{for } n \geqslant 1), \tag{6.1}$$

where $[\lambda_n]$ stands for λ_n minus the greatest integer less than or equal to λ_n. It is also true that $\lambda_n p_n$ is a decreasing function of n for $n \geqslant (\alpha+\alpha^2\pi^2)^{1/2}+1$ and

$$\lim_{n\to\infty} np_n|\lambda_n| = \alpha. \tag{6.2}$$

Proof: It follows from (5.3) that

$$\sin^2(\pi\lambda_n) = (1+\lambda_n^2(\alpha\pi)^{-2})^{-1}. \tag{6.3}$$

We now use the well-known inequality

$$(2/\pi)x \leqslant \sin x \quad (\text{for } 0 \leqslant x \leqslant \pi/2) \tag{6.4}$$

to conclude that

$$4[\lambda_n]^2 \leqslant (1+(n-1)^2(\alpha\pi)^{-2})^{-1} \quad (\text{for } n \geqslant 1), \tag{6.5}$$

since $\sin^2(\pi\lambda_n) = \sin^2(\pi[\lambda_n])$ and

$$0 \leqslant \lambda_n - n + 1 = [\lambda_n] \leqslant \tfrac{1}{2} \quad (\text{for } n \leqslant 1) \tag{6.6}$$

by (5.4). This proves (6.1).

We let $A = \alpha+\alpha^2\pi^2$ and use (5.12) to write

$$\lambda_n p_n = \alpha\lambda_n(A+\lambda_n^2)^{-1}. \tag{6.7}$$

Letting $f(\lambda) = \lambda(A+\lambda^2)^{-1}$, we note that $f'(\lambda) = (A-\lambda^2)(A+\lambda^2)^{-2}$. It follows that $f(\lambda)$ is decreasing for $\lambda \geqslant A^{1/2}$. Using (6.6), we conclude that $\lambda_n p_n$ is a decreasing function of n for $n \geqslant A^{1/2}+1$. Finally, (6.2) follows from (5.4) and (5.12). □

Definition 6.1: We let $2\pi Z$ stand for the set $\{2\pi j : j \in Z\}$.

Lemma 6.2: The function $\Phi_d(t)$ is differentiable at any point $t \notin 2\pi Z$. The derivative Φ_d' is bounded on any bounded set disjoint from $2\pi Z$ and continuous on any closed interval disjoint from $2\pi Z$.

Proof: Define

$$\Psi(m,t) = -2\sum_{n=1}^{m} \lambda_n p_n \sin((n-1)t). \tag{6.8}$$

It follows from Lemma 6.1 and the results of Hardy and Rogosinski[19] regarding Fourier series with decreasing coefficients that the series $\Psi(\infty,t)$ is boundedly convergent on R and is uniformly convergent on any finite closed interval disjoint from $2\pi Z$.

We now define

$$\Phi_d(m,t) = 2\sum_{n=1}^{m} p_n \cos(\lambda_n t), \tag{6.9}$$

and we let $D(m,t) = \Phi_d'(m,t) - \Psi(m,t)$. For any integers $0 < m < M$

$$|D(M,t) - D(m,t)| \leqslant 4\sum_{n=m+1}^{M} \lambda_n p_n |\sin([\lambda_n]t/2)| \tag{6.10}$$

by virtue of the trigonometric relation

$$\sin(\lambda_n t)-\sin((n-1)t)=2\sin([\lambda_n]t/2)\cos(\lambda_n^* t), \tag{6.11}$$

where $\lambda_n^* = 1/2(\lambda_n + n - 1)$. It follows from (6.1) that

$$|D(M,t)-D(M,t)|\leqslant \sum_{n=m+1}^{M} \lambda_n p_n(1+(n-1)^2(\alpha\pi)^{-2})^{-1}|t|. \tag{6.12}$$

We now use (5.4) and (5.12) to write

$$|D(M,t)-D(m,t)|\leqslant \sum_{n=m+1}^{M} \pi^2\alpha^3(n-1)^{-3}|t|. \tag{6.13}$$

Given $T>0$ it follows that

$$\lim_{m\to\infty}\left(\sup \sum_{n=m+1}^{M} |D(M,t)-D(m,t)|\right)=0, \tag{6.14}$$

where the supremum is taken over t and M such that $|t|\leqslant T$ and $M>m$. We now write

$$\Phi_d(m,t)-2\sum_{n=1}^{m} p_n=\int_0^t \Phi_d'(m,s)ds \quad (\text{for } |t|\leqslant T). \tag{6.15}$$

Since $\Phi_d'(m,t)$ converges boundedly to a limit $\Phi^*(t)$ on $[-T,T]$ by virtue of (6.14) and the bounded convergence of $\Psi(m,t)$, we can let $m\to\infty$ in (6.15) to obtain

$$\Phi_d(t)-1=\int_0^t \Phi^*(s)ds \quad (\text{for } |t|\leqslant T). \tag{6.16}$$

We also know that Φ^* is continuous on any subinterval of $[-T,T]$ disjoint from $2\pi Z$ by virtue of (6.14) and the uniform convergence of $\Psi(m,t)$ on such an interval. It follows by elementary calculus that $\Phi^* = \Phi_d'$ on $[-T,T]$ and the lemma is proved by letting $T\to\infty$. □

Lemma 6.3: We can write

$$\Phi_d'(t)=\sum_{2\pi|n|\leqslant t} -\pi\alpha\Phi_d(t-2\pi|n|) \quad (\text{for } t>0), \tag{6.17}$$

where we adopt the convention that both sides of (6.17) satisfy

$$f(t)=(\tfrac{1}{2}(\lim_{s\uparrow t} f(s)+\lim_{s\downarrow t} f(s)) \quad (\text{for } t>0). \tag{6.18}$$

Proof: Given z in C with $\mathrm{Re}(z)>0$, we define

$$B(z)=\int_0^\infty \sum_{0\leqslant 2\pi|n|\leqslant t} \Phi_d(t-2\pi|n|)e^{-zt}\,dt. \tag{6.19}$$

We can write

$$B(z)=\sum_{n\in Z}\int_{2\pi|n|}^\infty \Phi_d(t-2\pi|n|)e^{-zt}\,dt, \tag{6.20}$$

where the justification for the interchange of summation and integration is made apparent when we change variables in (6.20) to obtain

$$B(z)=\sum_{n\in Z}\int_0^\infty \Phi_d(s)e^{-zs}e^{-2\pi z|n|}\,ds \quad [\text{for } \mathrm{Re}(z)>0]. \tag{6.21}$$

[Just note that if we take the absolute value of the integrand in (6.21), then the resulting sum will be finite and then use Fubini's theorem, as given by Halmos.[20]] It follows that

$$B(z)=\hat{\Phi}_d(z)\coth(\pi z) \quad [\text{for } \mathrm{Re}(z)>0], \tag{6.22}$$

where the Laplace transform $\hat{\Phi}_d(z)$ is given as in (5.15).

If we now let $\hat{\Phi}_d'(z)$ be defined via

$$\hat{\Phi}_d'(z)=\lim_{T\to\infty}\int_0^T e^{-zt}\Phi_d'(t)dt, \tag{6.23}$$

then it is standard to verify that

$$\hat{\Phi}_d'(z)=z\hat{\Phi}_d(z)-1. \tag{6.24}$$

Combining (5.16), (6.22), and (6.24), we conclude that both sides of (6.17) have the same Laplace transform for z with $\mathrm{Re}(z)>0$. Also both sides of (6.17) are absolutely integrable on any finite interval. [We use, in particular, the boundedness of Φ_d' on bounded sets proved in Lemma 6.2. The values of Φ_d' on $2\pi Z$ are, of course, immaterial in the integral defining $\hat{\Phi}_d'$ in (6.23).] It now follows from the uniqueness result in Widder[21] that both sides of (6.17) are equal almost everywhere with respect to Lebesgue measure on the positive real numbers. Since the right-hand side of (6.17) can be modified on $2\pi Z$ so as to satisfy (6.18), it follows the same is true for the left-hand side of (6.17). □

We can now set forth a very interesting explicit determination of the amplitude function $\Phi_d(t)$.

Theorem 6.1: Let $h(t)=\exp(\pi\alpha t)\Phi_d(t)$ for $t\geqslant 0$. Then $h(t)=1$ for $0\leqslant t\leqslant 2\pi$ and

$$h(t)=h(2\pi n)-2\pi\alpha\int_{2n\pi}^{t}\sum_{m=1}^{n}\tau_m h(s-2\pi m)ds \tag{6.25}$$

for $2n\pi\leqslant t\leqslant 2(n+1)\pi$, where $\tau_m=\exp(\pi\alpha(2\pi)^m)$.

Proof: It is clear from Lemma 6.3 that $h(t)=1$ for $0\leqslant t\leqslant 2\pi$. We shall prove (6.25) by induction on n. We note that

$$h'(t)=\exp(\pi\alpha t)(\pi\alpha\Phi_d(t)+\Phi_d'(t)) \tag{6.26}$$

for $2n\pi<t<2(n+1)\pi$. Using (6.17), it follows that

$$h'(t)=-2\pi\alpha\sum_{m=1}^{n}\tau_m h(s-2\pi m). \tag{6.27}$$

for $2n\pi<t<2(n+1)\pi$. □

Remark 6.1: We note that $\Phi_d(t)$ is an even function of t, hence (6.25) gives complete information about $\Phi_d(t)$ for all t. In particular we conclude that the exact exponential decay law (3.5) holds for $|t|\leqslant 2\pi$.

Theorem 6.2: For any t in R, we have

$$\sum_{j\in Z_d} Q_{dj}(t)=1. \tag{6.28}$$

Proof: We can assume $t>0$ without loss of generality. Using (3.9) we can rewrite (6.28) as

$$1-\Phi_d(t)^2=\alpha\sum_{k\in Z}\int_0^t\int_0^t \Phi_d(r)\Phi_d(s)e^{ik(s-r)}\,dr ds. \tag{6.29}$$

Changing variables in (6.29), we obtain

$$1-\Phi_d(t)^2=\alpha\sum_{k\in Z}\int_{-t}^{t} g_t(w)e^{ikw}\,dw, \tag{6.30}$$

where

$$g_t(w)=\int_{-w^-}^{t-w^+}\Phi_d(r+w)\Phi_d(r)dr, \tag{6.31}$$

$w^+=2^{-1}(w+|w|)$ and $w^-=2^{-1}(w-|w|)$. We note that $g_t(w)=0$ if $-w^-\geqslant t-w^+$, i.e., if $|w|\geqslant t$. It follows we can write

$$g_t(w)=\int_{-\infty}^{+\infty} h_t(r+w)h_t(r)dr, \tag{6.32}$$

where $h_t(r)=\Phi_d(r)I_{[0,t]}(r)$ and $I_{[0,t]}$ is the indicator function of $[0,t]$.

We claim that the sum

$$\sum_n g_t(w+2\pi n)=\sum_{|w+2\pi n|\leqslant t} g_t(w+2\pi n) \tag{6.33}$$

is a continuous function of w. In fact, we can write

$$\sum_n g_t(w+2\pi n)=\sum_{2\pi|n|\leqslant t+2\pi} g_t(w+2\pi n) \tag{6.34}$$

for $|w|\leqslant 2\pi$, since $|w+2\pi n|\geqslant 2\pi|n|-|w|$. This proves the claim, since each summand $g_t(w+2\pi n)$ in (6.34) is a continuous function of w and the sum is periodic with period 2π.

The validity of the claim in conjunction with the fact that g_t is non-negative definite [as follows from (6.32)] shows that the conditions given by Feller[22] for the application of the Poisson summation formula to g_t are met. We conclude in particular that

$$2\pi\sum_{n\in Z} g_t(2\pi n)=\sum_{k\in Z}\int g_t(w)e^{ikw}\,dw. \tag{6.35}$$

Thus (6.30) is equivalent to the relation

$$1-\Phi_d(t)^2=2\pi\alpha\sum_{2\pi|n|\leqslant t}\int_{-(2\pi n)^-}^{t-(2\pi n)^+}\Phi_d(r+2\pi n)\Phi_d(r)dr. \tag{6.36}$$

In order to establish (6.36) it suffices to show that the derivative of both sides are equal, i.e., we need to show that

$$2\Phi_d(t)\Phi_d'(t) = -2\pi\alpha \sum_{2\pi|n|\leqslant t} \Phi_d(t)\Phi_d(t-2\pi|n|) \tag{6.37}$$

for $t \notin 2\pi Z$. However, (6.37) follows immediately from (6.17) for $t>0$. □

Proof of Theorem 2.2: We note the identity

$$\left\| \phi_d(t) - \sum_{j\in Z_d} \langle \phi_d(t)|\phi_j\rangle \phi_j \right\|^2 = 1 - \sum_{j\in Z_a} Q_{dj}(t), \tag{6.38}$$

where $\phi_j(t) = U(t)\phi_j$ for $j \in Z_d$. In combination with Theorem 6.2 this identity implies that $\phi_d(t) \in L$ for all t in R. It remains to prove that $\phi_j(t) \in L$ for $j \in Z$, where we may assume that $t>0$ without loss of generality.

We claim that for all n and j in Z with $n \geqslant 1$ we can write

$$\phi_j(t) = ijS_n(t,\phi_j) + d_n(t,j)\phi_j + (ic)\sum_{m=1}^{n} S_m(t,\phi_d), \tag{6.39}$$

where

$$S_m(t,\phi_k) = (ik)^{m-1}\int_0^t \int_0^{t_{m-1}} \cdots \int_0^{t_1} \phi_k(t_0)dt_0\cdots dt_{m-1} \tag{6.40}$$

for k in Z_d and

$$d_n(t,j) = \sum_{m=0}^{n-1} (ijt)^m/m!. \tag{6.41}$$

To show that (6.39) holds when $n=1$, we note $\phi_j \in D(H)$, hence

$$\phi_j(t) = i\int_0^t U(s)H\phi_j ds + \phi_j. \tag{6.42}$$

We now use (2.14) to obtain (6.39) with $n=1$. We will finish the proof of the claim by induction on n. Given the representation (6.39), we use (2.14) and (6.42) to conclude that (6.39) is valid when n is advanced by one.

We now note that $S_m(t,\phi_d) \in L$ for all m by virtue of the fact that $\phi_d(t) \in L$ for all t in R, which has already been demonstrated. Thus we can establish that $\phi_j(t) \in L$ by showing that

$$\lim_{n\to\infty} \|S_n(t,\phi_j)\| = 0 \quad (\text{for } t>0). \tag{6.43}$$

In fact, we have

$$\|S_n(t,\phi_j)\| \leqslant (jt)^n/n! \tag{6.44}$$

since $\|\phi_j\|=1$. The right-hand side of (6.44) tends to 0 as $n\to\infty$, hence the theorem is proved. □

Remark 6.2: For completeness we give some indications of the proof for (1.4) when $\Delta \neq 1$. We start by replacing $K_\alpha(z)$ in (5.1) by

$$K_{\Delta,\alpha}(z) = (z + \alpha\pi \coth(\pi\Delta^{-1}z))^{-1}. \tag{6.45}$$

It is then easy to show that p_n in (5.6) becomes

$$p_n=(1+\alpha\pi^2\Delta^{-1}\sin^{-2}(\pi\Delta^{-1}\lambda_n))^{-1}. \tag{6.46}$$

The arguments for (5.10) and (5.11) lead us to conclude that the basis ϕ_j is now of the form

$$\phi_j=c(\Delta p_n)^{1/2}(\lambda_n-\Delta j)^{-1}. \tag{6.47}$$

We replace $\Psi(m,t)$ in (6.8) by

$$\Psi(m,t)=-2\sum_{n=1}^{m}\lambda_n p_n\sin((n-1)\Delta t) \tag{6.48}$$

and conclude that $\Phi_d(t)$ is differentiable for any $t\notin 2\pi\Delta Z$. The argument for (1.4) is then straightforward.

ACKNOWLEDGMENT

I want to thank Professor Paul Chernoff for pointing out an omission in an earlier draft of this paper.

Feller, *An Introduction to Probability Theory and its Applications Vol. II* (Wiley, New York, 1971), pp. 565–566, where it is shown that a symmetric probability characteristic function $\Phi(t)=E(\exp(itY))$ has derivative zero at $t=0$ if and only if (5.21) holds for the random variable Y. We get rid of the symmetry restriction when we let $\Phi(t)=|\langle\phi|\phi(t)\rangle|^2=E(\exp(itY))$, where $Y=X-X'$ and X,X' are independent identically distributed random variables with characteristic function $\langle\phi|\phi(t)\rangle$. The symmetrization inequalities on p. 149 of Feller's book then yield (5.21) for the random variable X, even if X corresponds to a completely general amplitude function $\langle\phi|\phi(t)\rangle=E(\exp(itX))$.
[16] B. Misra and E. C. G. Sudarshan, J. Math. Phys. **18**, 756 (1977).
[17] Use (1.4) to show that if we set $E=\phi_d\rangle\langle\phi_d$ in Ref. 16, p. 759, then $T(t)=\exp(-\pi\alpha t)(\phi_d\rangle\langle\phi_d)$ for $t\geqslant 0$. Thus all the hypotheses in Theorem 1 of Ref. 16 are met except the semi-boundedness of H. [The antiunitary operator θ is just complex conjugation in $L^2(Z')$.]

(Received 1 August 1995; accepted for publication 28 November 1995)

We continue our study of quantum Riemann surfaces initiated in Refs. 1–3 [S. Klimek and A. Lesniewski, Commun. Math. Phys. **146**, 103–122 (1992); Lett. Math. Phys. **24**, 125–139 (1992); **32**, 45–61 (1994)]. We construct a one parameter family of deformations of compact Riemann surfaces of genus $g \geqslant 2$. Our construction does not require any discreteness condition on the value of Planck's constant. It coincides with the construction of Ref. 2 [Lett. Math. Phys. **24**, 125–139 (1992)] in the case when Planck's constant assumes the discrete set of values dictated by geometric quantization. © *1996 American Institute of Physics.*

I. INTRODUCTION

In a series of papers,[1–3] we studied nonperturbative deformation quantization of Riemann surfaces. Our approach is based on the ideas of Ref. 4 (for related developments, see also Refs. 5–7, and references therein). A satisfactory picture of uniformization of exceptional quantum Riemann surfaces emerged from these investigations. In the case of higher genus ($g \geqslant 2$) Riemann surfaces, the uniformization on the quantum level is a more complex issue. In fact, if M is a Riemann surface and N is a covering of M, then the quantization of N is a covering of the quantization of M in the sense of Ref. 3 only if the fundamental group of the covering $N \to M$ is Abelian. Part of the problem is the presence of topological sectors (similar to the θ-vacua in gauge theory) in the quantum theory, which is related to the nonsimple connectedness of the classical phase space. These sectors are classified by the characters of the fundamental group of the phase space. This does not reflect the noncommutativity of that group. On the other hand, whether the fundamental group is commutative or not seems to be important for the quantum uniformization in the sense of Ref. 3. A similar phenomenon was discussed previously in Ref. 8.

Quantization of Riemann surfaces in the framework of geometric quantization (see, e.g., Ref. 9) requires a restriction on the allowed values of the deformation parameter r (''the quantization condition''). However, it is desirable to have a definition of quantum Riemann surfaces for all values of r. A definition consistent with geometric quantization was given in Ref. 2, for $r = n(2g-2)^{-1}$, where $n \in \mathbb{N}$. In principle, quantum uniformization allows for a construction of quantum Riemann surfaces for all values of r, using the universal covering, the Poincaré disk, as the point of departure. Since the fundamental groups of higher genus Riemann surfaces are non-Abelian, it is likely, however, that the so defined algebra of quantized functions does not reduce to the algebra of Ref. 2, when $r = n(2g-2)^{-1}$.

In this paper, we construct quantization of compact Riemann surfaces for arbitrary values of $r > 0$ in a manner consistent with Ref. 2. Our starting point is a noncompact covering space $\hat{M}$ such that the group of cover transformation is the Abelian group $\mathbb{Z}$. Since $\hat{M}$ is a noncompact Riemann surface, all holomorphic line bundles are holomorphically trivial,[10] and geometric quantization does not impose any restrictions on Planck's constant. It was explained in Ref. 2 that geometric quantization of Riemann surfaces leads to certain operator algebras on Hilbert spaces of automorphic forms. We define the quantization of M in terms of Toeplitz operators with invariant

symbols on a space of automorphic forms on $\hat{M}$, and prove deformation estimates. The proof of the estimates is based on the methods developed in Ref. 2 (see Ref. 11 for a different approach).

The paper is organized as follows. In Sec. II, we study the fundamental groups of M and $\hat{M}$. We define and study suitable spaces of automorphic forms on M and $\hat{M}$ in Sec. III. Section IV contains proofs of deformation estimates.

II. THE FUNDAMENTAL GROUPS

In this section, we fix our notation and describe certain group theoretic properties of the fundamental groups of Riemann surfaces which will be useful in later sections. Let M be a compact Riemann surface of genus $g \geqslant 2$. We pick a basis $\{a_i, b_i\}$, $i=1,..,g$, of one-cycles on M. The fundamental group Γ of M is a finitely generated group with generators $\{a_i, b_i\}$, $i=1,\ldots,g$, obeying the relation (see e.g., Ref. 12)

$$\prod_{i=1}^{g} a_i b_i a_i^{-1} b_i^{-1} = 1.$$

We denote $a := a_g$ and $b := b_g$. An element $\gamma \in \Gamma$ can be represented as

$$\gamma = \prod_{j=1}^{\infty} \prod_{i=1}^{g} a_i^{n_{i,j}} b_i^{m_{i,j}},$$

where almost all integers $n_{i,j}, m_{i,j}$ are equal to zero. Consider now the homomorphism

$$\gamma \to \sum_j m_{g,j} \in \mathbb{Z}.$$

One can easily verify that the above map is well defined, i.e., it does not depend on the way we represent γ, and is indeed a homomorphism of groups. We denote the kernel of this homomorphism by Γ_0. The group Γ_0 is no longer finitely generated. In fact, it is not difficult to see that the following elements are its generators:

$$a, b^n a_i b^{-n}, b^n b_i b^{-n}, \quad \text{where} \quad n \in \mathbb{N}, \quad i = 0,1,\ldots,g-1,$$

and there are no relations among them, i.e., Γ_0 is the free product of infinite cyclic groups generated by the above generators.

Let $\hat{M}$ be a covering of M with no branching points and such that $\pi_1(\hat{M}) = \Gamma_0$. The group of cover transformations of the covering $\hat{M} \to M$ is then equal to $\mathbb{Z}$. Intuitively, $\hat{M}$ is obtained from M by cutting along the a cycle and then continuing M across the cut along the b cycle. One can visualize $\hat{M}$ as an infinite cylinder with infinite number of handle bodies attached, each handle body having $g-1$ handles. $\hat{M}$ is a noncompact Riemann surface.

The universal covering space of both M and $\hat{M}$ is the unit disk $\mathscr{U}$. The groups Γ and Γ_0 can be thought of as Fuchsian groups on $\mathscr{U}$. For

$$\gamma = \begin{bmatrix} a & b \\ \overline{a} & \overline{b} \end{bmatrix} \in \Gamma,$$

we denote

$$\gamma(z) = \frac{az+b}{\overline{bx+a}} \quad z \in \mathscr{U}. \tag{2.1}$$

Since the derivative of (2.1) is $\gamma'(z)=(\overline{bz}+\overline{a})^{-2}$, we can set:

$$\gamma'(z)^{1/2}:=(\overline{bz}+\overline{a})^{-1}.$$

Let G be either Γ or Γ_0, and let $r>0$. A multiplier of weight r for the group G is a map $v:G\to\mathbb{C}$ such that[12]

$$|v(\gamma)|=1,$$

and

$$\gamma_1'(\gamma_2(z))^{-r/2}\gamma_2'(z)^{-r/2}v(\gamma_1)v(\gamma_2)=(\gamma_1\gamma_2)'(z)^{-r/2}v(\gamma_1\gamma_2). \tag{2.2}$$

In (2.2), the standard branch of the logarithm is taken to define the rth power. The existence of multipliers is a cohomological question, see Ref. 13 for the modern treatment. Equation (2.2) can be interpreted as the triviality of a 2-cocycle in the group cohomology of G. A multiplier is essentially a 1-cochain whose coboundary is that 2-cocycle. It is well-known that multipliers exist for Γ if and only if $r=n(2g-2)^{-1}$, $n=1, 2,\ldots$. The situation is different for Γ_0.

Proposition 2.1: The second cohomology group $H^2(\Gamma_0,\mathbb{Z})$ of Γ_0 is trivial.

Proof: Since $\Gamma_0=\pi_1(\hat{M})$, and the universal covering space of $\hat{M}$ is contractible, it follows from Eilenberg–MacLane's theorem[14] that

$$H^*(\Gamma_0,\mathbb{Z})\cong H^*(\hat{M},\mathbb{Z}).$$

By Poincaré duality,[15] $H^2(\hat{M},\mathbb{Z})$ is isomorphic to the compactly supported cohomology group of $\hat{M}$ in dimension zero. The latter is trivial, as $\hat{M}$ is noncompact. □

Consequently, multipliers for Γ_0 exist for arbitrary r. Let us also remark that the ratio of two multipliers is a character of the group.

III. AUTOMORPHIC FORMS

As before, let G be either Γ or Γ_0, and let v be a multiplier for the group G. Recall that a holomorphic function $\phi:\mathcal{U}\to\mathbb{C}$ is called an automorphic form for G of weight $r>0$ with multiplier v, if:[12]

$$\phi(\gamma(z))=v(\gamma)\gamma'(z)^{-r/2}\phi(z), \tag{3.1}$$

for each $\gamma\in G$. Automorphic forms for infinitely generated Fuchsian groups like Γ_0 have been studied less extensively than those for finitely generated groups, but there is a fair amount of information available, see Refs. 16 and 17, and references therein.

Let R be a fundamental polygon for Γ. Then $R_0:=\cup_{n\in\mathbb{Z}}b^nR$ is a fundamental polygon for Γ_0. It has infinitely many sides. Here we use the same symbol b to denote the group element of Γ corresponding to the cycle $b=b_g$. For $r=n(2g-2)^{-1}$, we define $\mathcal{H}^r(\Gamma,v)$ to be the Hilbert space of automorphic forms for Γ equipped with the following scalar product:

$$(\phi,\psi):=\int_R\overline{\phi(z)}\psi(z)d\mu^r(z), \tag{3.2}$$

where the measure $d\mu^r(z)$ is

$$d\mu^r(z):=\frac{r-1}{\pi}(1-|z|^2)^{r-2}d^2z.$$

For arbitrary $r>0$, let $\mathscr{H}^r(\Gamma_0,v)$ be the space of automorphic forms for Γ_0 with the scalar product as in (3.2) but R_0 replacing R.

If v is a multiplier for Γ and $e^{i\theta}\in S^1$, we let v_θ denote a new multiplier for Γ defined by:

$$v_\theta(b)=v(b)e^{i\theta},$$

and $v_\theta=v$ on all other generators. In particular $v_0=v$. All of the multipliers v_θ are equal when restricted to the subgroup Γ_0. The restricted multiplier will be again denoted by v.

Theorem 3.1: *With the above definitions, there is a canonical isomorphism*

$$\mathscr{H}^r(\Gamma_0,v)\simeq\int_{S^1}^{\oplus}\mathscr{H}^r(\Gamma,v_\theta)d\theta,\quad r=n(2g-2)^{-1},\quad n=1,2,\ldots .$$

Proof: For an automorphic form ϕ for Γ_0, define

$$U\phi(z)=b'(z)^{r/2}\phi(bz). \tag{3.3}$$

We claim that (3.3) is again an automorphic form, and in fact U is a unitary operator on $\mathscr{H}^r(\Gamma_0,v)$. Let us first verify (3.1):

$$U\phi(\gamma z)=b'(\gamma z)^{r/2}\phi(b\gamma b^{-1}bz)=v(b\gamma b^{-1})b'(\gamma z)^{r/2}(b\gamma b^{-1})'(bz)^{-r/2}\phi(bz).$$

Using the chain rule and (2.2), we obtain (3.1). Unitary of U is a consequence of the following calculation:

$$(U\phi,U\psi)=\int_{R_0}\overline{b'(z)^{r/2}\phi(bz)}b'(z)^{r/2}\psi(bz)d\mu^r(z)=\int_{R_0}\overline{\phi(bz)}\psi(bz)d\mu^r(bz)=(\phi,\psi),$$

where we have used the transformation properties of $d\mu^r(z)$ and the fact that R_0 is invariant under b.

The isomorphism of Hilbert spaces that we want to establish is in essence the spectral decomposition of U. Explicitly, we define

$$P:\mathscr{H}^r(\Gamma_0,v)\to\int_{S^1}^{\oplus}\mathscr{H}^r(\Gamma,v_\theta)d\theta$$

by the following formula:

$$P\phi(\zeta,\theta)=\sum_{n\in\mathbb{Z}}v_\theta(b^{-n})U^n\phi(z). \tag{3.4}$$

We need to verify that the right-hand side of (3.4) is in $\mathscr{H}^r(\Gamma,v_\theta)$. If $\gamma\in\Gamma_0$, this follows from the fact that $U^n\phi(z)$ are automorphic forms for Γ_0, and the fact that $v_\theta|_{\Gamma_0}=v|_{\Gamma_0}$. If $\gamma=b$, we have

$$U\left(\sum_{n\in\mathbb{Z}}v_\theta(b^{-n})U^n\phi(z)\right)=v_\theta(b)\left(\sum_{n\in\mathbb{Z}}v_\theta(b^{-n})U^n\phi(z)\right).$$

The general case follows easily.

We verify that P is an isometry:

$$\begin{aligned}\|P\phi\|^2 &= \int_{-\pi}^{\pi}\left(\int_R |P\phi(z,\theta)|^2 d\mu^r(z)\right)\frac{d\theta}{2\pi}\\ &= \int_{-\pi}^{\pi}\left(\int_R \sum_{n,m} \overline{U^n\phi(z)}U^m\phi(z)v_\theta(b)^{n-m}d\mu^r(z)\right)\frac{d\theta}{2\pi}\\ &= \int_R \sum_n |U^n\phi(z)|^2 d\mu^r(z)\\ &= \sum_n \int_{b^n R} |\phi(z)|^2 d\mu^r(z)\\ &= \int_{R_0} |\phi(z)|^2 d\mu^r(z).\end{aligned}$$

Similar calculations show that the inverse of P is given by

$$P^{-1}\psi(z) = \int_{-\pi}^{\pi} \psi(z,\theta)d\theta.$$

□

This result implies that the quantization of Riemann surfaces proposed in this paper reduces, when $r = n(2g-2)^{-1}$, to the definition of Ref. 2.

IV. TOEPLITZ QUANTIZATION

In this section, we construct a quantization of the Riemann surface M in terms of Toeplitz operators on $\mathscr{H}^r(\Gamma, v_\theta)$. We first recall the relevant definitions. The reproducing kernel $K^r_{\Gamma_0,v}(z,w)$ for $\mathscr{H}^r(\Gamma_0,v)$ is given by the following Poincaré series:

$$K^r_{\Gamma_0,v}(z,w) = \sum_{\gamma\in\Gamma_0} v(\gamma)^{-1}\gamma'(z)^{r/2}K^r(\gamma(z),w), \tag{4.1}$$

where

$$K^r(z,w) = (1-z\overline{w})^{-1}.$$

Let $C_\Gamma(\mathscr{U})$ be the $\mathbb{C}^*$-algebra of bounded continuous functions on $\mathscr{U}$ which are invariant under Γ, so that $C_\Gamma(\mathscr{U}) \cong C(M)$. For $f \in C_\Gamma(\mathscr{U})$, we define the Toeplitz operator $T^r_{\Gamma_0,v}(f)$ on $\mathscr{H}^r(\Gamma_0,v)$ with symbol f by:

$$(T^r_{\Gamma_0,v}(f)\phi)(z) = \int_{\Gamma_0} K^r_{\Gamma_0,v}(z,w)f(w)\phi(w)d\mu^r(w). \tag{4.2}$$

The goal of this section is to prove that the correspondence $f \mapsto T^r_{G_0,v}(f)$ is a quantization of M. This means that for $f \in C_\Gamma(\mathscr{U})$ we have the norm limit

$$\lim_{r\to\infty} \|T^r_{\Gamma_0,v}(f)\| = \|f\|_\infty, \tag{4.3}$$

where $\|\cdot\|$ denotes the operator norm, and where $\|\cdot\|_\infty$ denotes the sup-norm. If, moreover, f,g are smooth, then

$$\lim_{r\to\infty}\|r[T^r_{\Gamma_0,v}(f\ ),T^r_{\Gamma_0,v}(g)]+T^r_{\Gamma_0,v}(i\{f,g\})\|=0, \tag{4.4}$$

where $\{f,g\}$ is the usual Poisson bracket,

$$\{f,g\}(z)=i(1-|z|^2)^2[\partial f(z)\overline{\partial g}(z)-\partial g(z)\overline{\partial f}(z)]. \tag{4.5}$$

Theorem 4.1: *With the above definitions, the correspondence*

$$f\mapsto T^r_{\Gamma_0,v}(f\ )$$

is a quantization of M.

Proof: The details of analogous estimates were explained in Refs. 1 and 2. Here we follow Ref. 2, where the estimates were proved for the quantization based on automorphic forms of Γ. However, the compactness of the fundamental domain of Γ was used in an essential way in several places, so that the results cannot be applied to the case of Γ_0 (as R_0 is not compact in $\mathscr{U}$). The main difference is that ''transfer of regularity'' argument has to be done more carefully in the present case.

To prove (4.3), we consider the vectors

$$\phi_w(z):=K^r_{\Gamma_0,v}(w,w)^{-1/2}K^r_{\Gamma_0,v}(z,w)$$

in $\mathscr{H}^r(\Gamma_0,v)$, and verify that:

$$\sup_{x\in R}|f(w)-(\phi_w,T^r_{\Gamma_0,v}(f\ )\phi_w)|\to 0,\quad \text{as}\ \ r\to\infty, \tag{4.6}$$

in a way analogous to Ref. 2. The proof there was based on Lemmas 4.1 and 4.2 which are also valid for $\Gamma_0\subset\Gamma$. Since f is invariant under Γ, and not just Γ_0, and since the supremum in (4.6) is taken over a compact set, (4.6) follows exactly as in Ref. 2.

The estimate (4.4) is a consequence of

$$\|r(T^r_{\Gamma_0,v}(f\ )T^r_{\Gamma_0,v}(g)-T^r_{\Gamma_0,v}(fg))+T^r_{\Gamma_0,v}((1-|z|)^2\partial f\overline{\partial g})\|\to 0,\quad \text{as}\ \ r\to\infty, \tag{4.7}$$

for $f,g\in C^\infty_\Gamma$. To prove (4.7), one expands $(\phi,T^r_{\Gamma_0,v}(f\ )T^r_{\Gamma_0,v}(g)\psi)$ in a Taylor series as in Ref. 2 formula (5.6). The first three terms in that formula combine to give the second and third terms in (4.7). The analog of the fourth term of Ref. 2, formula (5.6), is $O(r^{-2})$ as in Ref. 1. It remains to estimate the remainder.

The technique developed in Ref. 1 for estimating the remainder terms can be applied to our case with one modification. The integral $\int_{\mathscr{U}}|\psi(w)|^2d\mu^r(w)$ is infinite if $\psi\in\mathscr{H}^r(\Gamma_0,v)$, and one needs to transfer a power of $1-|w|^2$ to make it convergent. This ''transfer of regularity'' trick was explained in detail on the last two pages of Ref. 2 for Γ-automorphic forms. However, the compactness of the fundamental domain of Γ was used in an essential way. We show below that a modification of the argument used in Ref. 2 can be used in our case.

Lemma 4.2: Let $\psi\in\mathscr{H}^r(\Gamma_0,v)$ and $s>1$. Then we have:

$$\int_{\mathscr{U}}|\psi(w)|^2(1-|w|^2)^s d\mu^r(w)=O(1)\|\psi\|^2.$$

Lemma 4.3: Let $b\in SU(1,1)$ be hyperbolic, let K be a compact set in $\mathscr{U}$, and let $t>0$. Then we have:

$$\sup_{z\in K}\sum_{n\in\mathbb{Z}}|(b^n)'(z)|^t=O(1).$$

We will prove these lemmas after we have completed the main line of the argument.

We now use the above lemmas to estimate the term in formula (5.16) of Ref. 2. This will conclude the proof of Theorem 4.1. That term reads:

$$\int_{R_0\times\mathscr{U}}|\phi(z)|(1-|z|^2)^{1-r/2}|\psi(\gamma_z(w))\|\gamma_z'(w)|^{r/2}\frac{|w|^2}{(1-|w|^2)^{11}}\,d\mu^r(z)d\mu^r(w), \tag{4.8}$$

where $\gamma_z(w)=(w+z)/(\overline{z}w+1)$. Let $0<\epsilon<1/2$. We multiply and divide the integrand by $(1-|\gamma_z(w)|^2)^{1-\epsilon}$, and use the following elementary bound:

$$\frac{1}{(1-|\gamma_z(w)|^2)^{1-\epsilon}}\leqslant\frac{O(1)}{(1-|z|^2)^{1-\epsilon}(1-|w|^2)}.$$

The integral in (4.8) is consequently less then

$$O(1)\int_{R_0\times\mathscr{U}}|\phi(z)|(1-|z|^2)^{\epsilon-r/2}|\psi(\gamma_z(w))|(1-|\gamma_z(w)|^2)^{1-\epsilon}|\gamma_z'(w)|^{r/2}$$
$$\times\frac{|w|^2}{(1-|w|^2)^{12}}\,d\mu^r(z)d\mu^r(z). \tag{4.9}$$

Using the Schwarz inequality and changing variables in the ψ term, we get the following bound:

$$O(1)\|\phi\|\left(\int_{R_0}(1-|z|^2)^{2\epsilon-r}d\mu^r(z)\right)^{1/2}\left(\int_{\mathscr{U}}|\psi(w)|^2(1-|w|^2)^{2-2\epsilon}d\mu^r(w)\right)^{1/2}$$
$$\times\left(\int_{\mathscr{U}}\frac{|w|^4}{(1-|w|^2)^{24}}\,d\mu^r(w)\right)^{1/2}. \tag{4.10}$$

With our choice $0<\epsilon<1/2$, the exponent $2-2\epsilon$ in the third factor is greater than 1, and so we can apply Lemma 4.2 to it, and conclude that it is $O(1)\|\psi\|^2$. The fourth factor is $O(r^{-1})$ by Ref. 2, formula (5.18). One can analyze the second factor in (4.10) as follows:

$$\begin{aligned}\int_{R_0}(1-|z|^2)^{2\epsilon-r}d\mu^r(z)&=O(r)\int_{R_0}(1-|z|^2)^{2\epsilon}d\mu_P(z)\\&=O(r)\sum_{n\in\mathbb{Z}}\int_{b^{-n}R}(1-|z|^2)^{2\epsilon}d\mu_P(z)\\&=O(r)\sum_{n\in\mathbb{Z}}\int_R(1-|b^nz|^2)^{2\epsilon}d\mu_P(z)\\&=O(r)\int_R\sum_{n\in\mathbb{Z}}|(b^n)'(z)|^{2\epsilon}(1-|z|^2)^{2\epsilon}d\mu_P(z)\\&\leqslant O(r)\sup_{z\in R}\sum_{n\in\mathbb{Z}}|(b^n)'(z)|^{2\epsilon}.\end{aligned} \tag{4.11}$$

In (4.11), $d\mu_P(z)$ is the Poincaré measure on $\mathscr{U}$, and we have used the fact that R is compact. Since $2\epsilon>0$ it follows from Lemma 4.3 that (4.11) is $O(r)$. This concludes the transfer of regularity argument.

Proof of Lemma 4.2: We decompose $\mathscr{U}$ into the translates of R_0:

$$\begin{aligned}\int_{\mathscr{U}}|\psi(w)|^2(1-|w|^2)^s d\mu^r(w) &= \sum_{\gamma\in\Gamma_0}\int_{\gamma^{-1}R_0}|\psi(w)|^2(1-|w|^2)^s d\mu^r(w)\\ &= \sum_{\gamma\in\Gamma_0}\int_{R_0}|\psi(w)|^2(1-|\gamma(w)|^2)^s d\mu^r(w)\\ &\leqslant\left(\sup_{w\in\mathscr{U}}\sum_{\gamma\in\Gamma_0}(1-|\gamma(w)|^2)^s\right)\|\psi\|^2.\end{aligned}$$

To estimate the supremum factor, we proceed as in the proof of Ref. 2 lemma 4.2:

$$\begin{aligned}1&=(1-|w|^2)^s\int_{\mathscr{U}}|K^s(w,z)|^2 d\mu^s(z)\\ &=(1-|w|^2)^s\sum_{\gamma\in\Gamma_0}\int_{\gamma^{-1}R_0}|K^s(w,z)|^2 d\mu^s(z)\\ &=(1-|w|^2)^s\sum_{\gamma\in\Gamma_0}|\gamma'(w)|^s\int_{R_0}|K^s(\gamma(w),z)|^2 d\mu^s(z)\\ &=\sum_{\gamma\in\Gamma_0}(1-|\gamma(w)|^2)^s\int_{R_0}|K^s(\gamma(w),z)|^2 d\mu^s(z)\\ &\geqslant\sum_{\gamma\in\Gamma_0}(1-|\gamma(w)|^2)^s\frac{1}{2^{2s}}\int_{R_0}d\mu^s(z).\end{aligned}$$

Hence, $\sup_{w\in\mathscr{U}}\Sigma_{\gamma\in\Gamma_0}(1-|\gamma(w)|^2)^s = O(1)$, if $s>1$. This concludes the proof of Lemma 4.2.

Proof of Lemma 4.3: Since b is a hyperbolic element of SU(1,1), it has two real eigenvalues λ, $1/\lambda$ with $|\lambda|>1$. Letting

$$b^n=\begin{bmatrix}\alpha_n & \beta_n\\ \overline{\beta_n} & \overline{\alpha_n}\end{bmatrix},$$

we have $\alpha_n=O(|\lambda|^{|n|})$. Furthermore, we have the following bound:

$$|(b^n)'(z)|=|\overline{\beta_n}z+\overline{\alpha_n}|^{-2}=|\alpha_n|^{-2}\left|1+\frac{\overline{\beta_n}}{\overline{\alpha_N}}z\right|^{-2}\leqslant|\alpha_n|^{-2}(1-|z|)^{-2}.$$

Since z varies over a compact set and $t>0$, it follows that the series $\Sigma_{n\in\mathbb{Z}}|(b^n)'(z)|^t$ is bounded, uniformly in z, by a convergent geometric series. This concludes the proof of Lemma 4.3 and Theorem 4.1. □

Radial Coulomb and oscillator systems in arbitrary dimensions

V. Alan Kostelecký and Neil Russell
Department of Physics, Indiana University, Bloomington, Indiana 47405

(Received 30 November 1995; accepted for publication 24 January 1996)

A mapping is obtained relating analytical radial Coulomb systems in any dimension greater than one to analytical radial oscillators in any dimension. This mapping, involving supersymmetry-based quantum-defect theory, is possible for dimensions unavailable to conventional mappings. Among the special cases is an injection from bound states of the three-dimensional radial Coulomb system into a three-dimensional radial isotropic oscillator where one of the two systems has an analytical quantum defect. The issue of mapping the continuum states is briefly considered. © *1996 American Institute of Physics.* [S0022-2488(96)03105-X]

I. INTRODUCTION

Various types of correspondence between the Kepler–Coulomb and the isotropic-oscillator systems have been extensively investigated since the influential work of Levi-Civita early this century.[1] Among the correspondences of interest are mappings that can be constructed between the radial equations of the quantum systems. This subject was initiated over 50 years ago in a paper by Schrödinger[2] addressing the solution of eigenvalue problems by factorization. Schrödinger discovered a connection between the radial equation of the three-dimensional quantum Coulomb problem and the radial equation of a D-dimensional quantum harmonic oscillator. Using a quadratic transformation in the radial coordinate, he showed that the mapping images all the states in the three-dimensional discrete Coulomb spectrum only for oscillators with $D=2$ or 4.

Schrödinger's idea was subsequently rediscovered or investigated by a number of authors.[3–7] An extension relating the radial equations of the d-dimensional Coulomb system and the D-dimensional oscillator for the special case of even dimensions $d=D$ was given in Ref. 8. A more general mapping for arbitrary d and even D that involves a free parameter was presented in Ref. 9, along with the corresponding mappings to the supersymmetric partners of these systems. All these correspondences involve oscillators in even dimensions, and they incorporate constraints on the allowed range of angular momenta. It is possible in general to map all the states of the d-dimensional Coulomb system into half the states of a D-dimensional oscillator, where d is greater than one and D must be even.

Recently, it has been proposed that some restrictions on the dimensions or angular momenta can be removed with the introduction of suitable analytical deformations called quantum defects in one or both systems.[10] The motivation for this derives from the use of supersymmetric quantum mechanics[11,12] in the context of atomic physics,[13] where supersymmetry-based quantum-defect theory (SQDT)[14] provides an explicit example with direct physical relevance.

One goal of the present paper is to investigate the issue of relaxing the dimensional constraints on the radial correspondences via the introduction of analytical quantum defects. The treatment incorporates not only the Coulomb and oscillator systems but also their supersymmetric partners. We show that with a suitable choice of defect it is indeed possible to remove restrictions on the mappings. For instance, among the examples discussed below is a generalized mapping taking any state in the three-dimensional radial Coulomb problem into a state in an analytically modified three-dimensional radial oscillator. We also briefly consider the continuum states of the two radial systems.

The focus of this work is the set of radial correspondences as summarized above. We do not

0022-2488/96/37(5)/2166/16/$10.00

address here the different issue of obtaining surjective mappings between the full D-dimensional oscillator and the full d-dimensional Coulomb systems. This interesting question has been addressed by a number of authors, originating with the parabolic-coordinate transformation of Levi-Civita[1] that relates $D=2$ to $d=2$ and with the mapping of Kustaanheimo and Stiefel[15] in their work on celestial mechanics that relates $D=4$ to $d=3$. The latter transformation in particular has been much investigated in the quantum context,[16–19] and in recent years extensions connecting $D=8$ and $d=5$ have been studied.[20,21] While more complete than the purely radial mappings, all these surjective correspondences are restricted to a narrow range of dimensions.

The organization of this paper is as follows. Section II consists primarily of background on the supersymmetric radial Coulomb and oscillator systems in arbitrary dimensions and the known correspondences between them. It contains key equations needed in the subsequent sections and provides a perspective useful for our purposes. In section III, we introduce SQDT for the radial Coulomb and oscillator systems in arbitrary dimensions, and we define mappings relating these systems to the supersymmetric sectors of the associated zero-defect cases. The general correspondence between different SQDT for the Coulomb and oscillator systems in arbitrary dimensions is established in section IV. This permits, for instance, the entire set of Coulomb radial states to be injected into a subset of the oscillator radial states for any dimensions, including odd oscillator dimensions. Section V provides a short discussion of some results arising for the continuum Coulomb states. We summarize in section VI.

To distinguish comparable quantities in the two systems, we adopt the convention that lowercase letters are used for Coulomb-system variables while upper-case letters are used for oscillator-system variables. An exception is made in denoting energies, for which the symbol E with various sub- and superscripts is used in the Coulomb system while F is used in the oscillator system.

II. PRELIMINARIES

In this section, we establish our conventions and present some preliminary material and results. Section II A begins with definitions and solutions for the radial Coulomb problem in arbitrary dimensions, while in section II B we similarly treat the harmonic-oscillator radial problem. A one-parameter mapping between these systems is presented in section II C. Key equations for supersymmetric quantum mechanics are given in section II D. The supersymmetric counterpart of the results in section II A is discussed in section II E, while that of sections II B and II C is covered in section II F.

A. Coulomb bound states in *d* dimensions

The quantum Kepler–Coulomb system in d dimensions is governed by the Hamiltonian

$$h=-\frac{\hbar^2}{2\mu}\nabla^2-\frac{\kappa}{r}, \tag{1}$$

where μ is the reduced mass, κ is the force constant, and r is the usual radial variable. To avoid normalization issues, we assume $d>1$. The associated radial equation is obtained from the Schrödinger equation $h\psi=E\psi$ by separating the wave function ψ in generalized polar coordinates, $\psi(r,\theta_1,\ldots,\theta_{d-1})=s(r)\,\theta(\theta_1,\ldots,\theta_{d-1})$. Normalizable solutions to the ensuing radial equation are found for discrete eigenenergies given by

$$E_{n,\gamma}=\frac{-E_0}{4(n+\gamma)^2}, \tag{2}$$

where $E_0=2\mu\kappa^2/\hbar^2$, $\gamma=\frac{1}{2}(d-3)$, and n is the principal quantum number taking values $n=l+1, l+2, \ldots$, with l the angular-momentum quantum number arising from the separation of

variables. For $d \geqslant 3$, $l = 0, 1, 2, \ldots$ as usual. When $d = 2$, the angular-momentum quantum number takes the values $0, \pm 1, \pm 2, \ldots$. In this case, we define the symbol l to represent the modulus of the angular momentum. Note that E_0 is the magnitude of the ground-state energy in the lowest dimension considered, $d = 2$.

To simplify the equations that follow, we introduce a dimensionless radial variable $y = r/r_0$, where $r_0 = \hbar^2/2\kappa\mu$. It is also convenient for later considerations involving supersymmetry to work with a scaled radial function $w(y) = y^{\gamma+1} s(r \equiv r_0 y)$, which effectively removes the first-order derivative appearing in the radial equation for s. The radial equation becomes

$$\left\{ -\frac{d^2}{dy^2} + \frac{(l+\gamma)(l+\gamma+1)}{y^2} - \frac{1}{y} - \frac{E}{E_0} \right\} w_{d,n,l}(y) = 0. \tag{3}$$

The eigensolutions involve Sonine-Laguerre polynomials and are given by

$$w_{d,n,l}(y) = c_{dnl} y^{l+\gamma+1} \exp\left(\frac{-y}{2(n+\gamma)} \right) L_{n-l-1}^{(2l+2\gamma+1)}\left(\frac{y}{n+\gamma} \right), \tag{4}$$

with normalization

$$c_{dnl} = \left[\frac{\Gamma(n-l)}{2 r_0^d (n+\gamma)^{2l+d+1} \Gamma(n+l+d-2)} \right]^{1/2}. \tag{5}$$

B. Oscillator bound states in *D* dimensions

The quantum Hamiltonian for the isotropic harmonic oscillator in D dimensions, $D \geqslant 1$, is

$$H = -\frac{\hbar^2}{2M} \nabla^2 + \frac{1}{2} M \Omega^2 R^2, \tag{6}$$

where M is the oscillator mass, Ω is the frequency, and R is the usual radial variable. Separating variables in generalized polar coordinates as before produces a radial equation that has normalizable solutions for energy eigenvalues given by

$$F_{N,\Gamma} = F_0 (2N + 2\Gamma + 3), \tag{7}$$

where $\Gamma = \frac{1}{2}(D-3)$, $F_0 = \frac{1}{2}\hbar\Omega$ is the ground-state energy for the lowest dimension $D = 1$, and N is the principal quantum number taking values $N = L, L+2, L+4, \ldots$, with L the quantized angular momentum arising from the separation of variables. For $D \geqslant 3$, $L = 0, 1, 2, \ldots$ as usual. For $D = 2$, the angular momentum ranges over $0, \pm 1, \pm 2, \ldots$, and we define L to be its modulus. For $D = 1$, the only possibilities are $L = 0$ and 1. The corresponding angular variable has two discrete values, distinguishing the two orientations of the radial vector. These two cases represent distinct *radial* systems for the one-dimensional oscillator, as opposed to the full one-dimensional oscillator with configuration space including both positive and negative coordinate values. For convenience in what follows, we define the parity of the radial wave functions as even if $L = 0$ and odd if $L = 1$.

Defining the dimensionless variable $Y = R/R_0$ with $R_0 = (\hbar/M\Omega)^{1/2}$ and introducing for later convenience the scaled radial function $W(Y) = Y^{\Gamma+1} S(R \equiv R_0 Y)$, the radial equation becomes

$$\left\{ -\frac{d^2}{dY^2} + \frac{(L+\Gamma)(L+\Gamma+1)}{Y^2} + Y^2 - \frac{F}{F_0} \right\} W(Y) = 0. \tag{8}$$

The eigenfunctions are

$$W_{D,N,L}(Y)=C_{DNL}Y^{L+\Gamma+1}\exp(-\tfrac{1}{2}Y^2)L_{N/2-L/2}^{(L+\Gamma+1/2)}(Y^2), \tag{9}$$

with normalization

$$C_{DNL}=\left[\frac{2\Gamma(N/2-L/2+1)}{R_0^D\Gamma(N/2+L/2+D/2)}\right]^{1/2}. \tag{10}$$

With our definitions for L above, these expressions hold for all integral $D\geqslant 1$. Note that the $D=1$ normalization coefficients differ from the canonical ones by a factor of $\sqrt{2}$ because the above construction produces a normalization on the half line only.

C. Mappings between the Coulomb and oscillator problems

The wave function (4) can be mapped to the wave function (9) through the quadratic transformation

$$Y^2=\frac{y}{(n+\gamma)}. \tag{11}$$

This correspondence also interconnects the differential equations (3) and (8). The explicit relation between eigensolutions is

$$W_{D,N,L}(Y)=K_{dn\lambda}Y^{-1/2}w_{d,n,l}((n+\gamma)Y^2), \tag{12}$$

where the quantity $K_{dn\lambda}$ maintains the normalization of the wave functions and is given by

$$K_{d,n,\lambda}=\frac{(2n+d-3)r_0^{d/2}}{R_0^{d-1-\lambda}}. \tag{13}$$

The quantity λ provides an extra degree of freedom in the mapping.

The ensuing relationships among the dimensionalities and the quantum numbers of the two systems are[9]

$$D=2d-2-2\lambda, \quad N=2n-2+\lambda, \quad L=2l+\lambda. \tag{14}$$

The last of these equations constrains λ to be integral. It then follows from the first equation that this mapping has image only in the oscillators of even dimension D.

For given angular momenta l and L, the relation (14) between the principal quantum numbers ensures that the stack $n\geqslant l+1$ of Coulomb states is in one-to-one correspondence with the stack $N\geqslant L$ of oscillator states, with ground states coinciding. This relation between N and n determines a condition relating the energies E and F of the two systems:

$$\frac{F_{N,\Gamma}}{F_0}=2\sqrt{\frac{E_0}{-E_{n,\gamma}}}. \tag{15}$$

The factor of two can be viewed as originating from the scaling of N relative to n in the second equation in (14). Absorbing it in the definitions of E_0 or F_0 would change equations (3) or (8).

Condition (14) shows that successive Coulomb angular momenta l map to every second oscillator angular momentum L. The *entire* set of radial states $|n,l\rangle$ of the d-dimensional Coulomb system can be mapped into a subset of the states $|N,L\rangle$ of the D-dimensional oscillator provided D satisfies $2\leqslant D\leqslant 2d-2$. For even or odd λ, the mapping is then an isomorphism to even or odd L, respectively. For given d, the allowed values of the pair (D,λ) characterizing this mapping are distinct: $(2,d-2)$, $(4,d-3)$, ..., $(2d-4,1)$, $(2d-2,0)$. We recover in this way

Schrödinger's result that all states of the three-dimensional Coulomb system can be mapped only into oscillators of dimension two or four. Note that if instead l is taken to be fixed, so that only a subset of states is imaged, then the allowed range of D is[4] $2 \leqslant D \leqslant 2d-2+4l$.

D. Supersymmetric quantum mechanics

For the purposes of the present paper, only a few of the basic results of supersymmetric quantum mechanics are needed. We restrict our attention to systems with a quantum-mechanical Hamiltonian H_S and two supersymmetry charges Q and $Q^\dagger$, obeying the defining relations of the superalgebra sqm(2):

$$\{Q,Q^\dagger\}=H_S, \quad [Q,H_S]=[Q^\dagger,H_S]=0. \tag{16}$$

The representation of this algebra relevant here is two dimensional and may be parametrized as[11,12]

$$Q=\begin{pmatrix} 0 & 0 \\ A & 0 \end{pmatrix}, \quad Q^\dagger=\begin{pmatrix} 0 & A^\dagger \\ 0 & 0 \end{pmatrix}, \quad H_S=\begin{pmatrix} H^+ & 0 \\ 0 & H^- \end{pmatrix}. \tag{17}$$

There are two component Hamiltonians in this system and two associated Hilbert spaces. If the bosonic Hamiltonian H^+ acts on wave functions ψ^+, while the fermionic Hamiltonian H^- acts on ψ^-, then the corresponding Schrödinger equations can be written as

$$H^\pm\psi^\pm=\left[-\frac{d^2}{dy^2}+V^\pm(y)\right]\psi^\pm=E^\pm\psi^\pm, \tag{18}$$

where A is the operator $A=-i\partial_y-iU'$ and where the supersymmetric partner potentials are defined by $V^\pm(y)=U'^2\mp U''$, with $U'=\partial_y U(y)$ a specified function called the superpotential.

The ground state of a supersymmetric system lies in the bosonic sector and has zero energy. Every state in the bosonic sector other than the ground state is degenerate with a distinct state in the fermionic sector, and the operators Q, $Q^\dagger$ map between these paired states.

E. Supersymmetric Coulomb system

To construct the supersymmetric Coulomb system, the bosonic-sector combination H^+-E^+ from Eq. (18) is identified with the radial equation (3). In the latter, a suitable constant must be added to the energy eigenvalues and incorporated in the potential to ensure that the ground-state energy is zero. Thus, the eigenvalues are

$$E^+_{nl}=\frac{1}{4(l+1+\gamma)^2}-\frac{1}{4(n+\gamma)^2}, \tag{19}$$

and the bosonic potential function is

$$v^+(y)=\frac{(l+\gamma)(l+\gamma+1)}{y^2}-\frac{1}{y}+\frac{1}{4(l+1+\gamma)^2}. \tag{20}$$

The last term in Eq. (20) is the energy shift ensuring a zero ground-state energy. Since it must be constant, l must be fixed to define a supersymmetric partner.

The superpotential is specified by the function[13]

$$u(y)=\frac{y}{2(l+\gamma+1)}-(l+\gamma+1)\ln y. \tag{21}$$

The fermionic Hamiltonian and hence the associated fermionic radial equation can then be calculated as

$$\left\{-\frac{d^2}{dy^2}+\frac{(l'+\gamma)(l'+\gamma+1)}{y^2}-\frac{1}{y}+\frac{1}{4(l'+\gamma)^2}\right\}w^-(y)=E^-_{n'l'}w^-(y), \tag{22}$$

where $l'=l+1$ and n' takes on all values of n except the lowest one, $l+1$. The fermionic wave functions $w^-(y)$ have the same functional form as the bosonic wave functions $w^+(y)\equiv w(y)$ given in Eq. (4), but with n and l replaced by n' and l':

$$w^-_{d,n',l'}(y)=w_{d,n',l'}(y). \tag{23}$$

The two sets of eigenvalues are degenerate for $n'=n$: $E^-_{n'=n,l'}=E^+_{nl}$.

With fixed l, the bosonic stack of eigenstates in order of increasing energy consists of the series of kets $|n=l+1,\ l\rangle$, $|n=l+2,\ l\rangle$, ... , with lowest energy zero. The associated fermionic stack has angular momentum greater by one unit and starts with lowest energy corresponding to the second state of the bosonic sector: $|n'=l+2,\ l+1\rangle$, $|n'=l+3,\ l+1\rangle$, ... The use of n' here is consistent with spectroscopic notation. For example, when the s orbitals of lithium are interpreted as the supersymmetric partner of the hydrogen atom, $n'=2$ corresponds to the ground state, as expected.

A useful one-to-one correspondence between these two stacks identifies the lowest states with each other, and successively higher states of the bosonic sector with successively higher states of the fermionic sector. It is defined by the following replacements in the bosonic wave function:

$$n\mapsto n'=n+1, \quad l\mapsto l'=l+1. \tag{24}$$

This stack correspondence relates eigenstates with different eigenvalues. Along with similar stack correspondences defined below, it plays a useful role in the analyses to follow.

F. Supersymmetric oscillator and composition mapping

The bosonic component of the supersymmetric oscillator can be obtained from the radial equation (8) under a suitable energy shift. The eigenvalues are

$$F^+_{NL}=2(N-L). \tag{25}$$

The superpotential is specified via the function

$$U(Y)=\tfrac{1}{2}Y^2-(L+\Gamma+1)\ln Y, \tag{26}$$

which generates the fermionic equation

$$\left\{-\frac{d^2}{dY^2}+\frac{(L'+\Gamma)(L'+\Gamma+1)}{Y^2}+Y^2-(2L'+2\Gamma-1)\right\}W^-(Y)=F^-_{N'L'}W^-(Y), \tag{27}$$

where L' is defined by $L'=L+1$. The principal quantum number N' takes the values $N'=L'$, $L'+2, L'+4$, ... The fermionic wave functions $W^-(y)$ have the same functional form as the bosonic wave functions $W^+(Y)\equiv W(Y)$ of Eq. (9), with N, L replaced by N', L', respectively:

$$W^-_{D,N',L'}(Y)=W_{D,N',L'}(Y). \tag{28}$$

The fermionic energies $F^-_{N'L'}=2(N'-L'+2)$ are degenerate with the bosonic energies for $N'+1=N$, $F^-_{N'L'}=F^+_{N=N'+1,L}$.

In order of increasing energy, the bosonic stack with fixed L consists of the kets $|N=L,\ L\rangle$, $|N=L+2,\ L\rangle$, $|N=L+4,\ L\rangle$, ..., with lowest energy zero. The associated fermionic stack has angular momentum one unit greater and contains the kets $|N'=L'=L+1,\ L+1\rangle$, $|N'=L+3,\ L+1\rangle$, ...

The $D=1$ case is unusual and warrants special attention. As mentioned above, the ''angular momentum'' L for the one-dimensional oscillator takes the values zero and one, corresponding to even and odd parity. The system resembles a single stack, but is composed of two interlocking substacks. As a result, the spacing between neighboring eigenvalues is half its value in higher dimensions. Also, in constructing the supersymmetric partner, the energy shift is L dependent. Consequently, distinct shifts appear for each substack. The formalism thus establishes *two* independent supersymmetries, each of which respects the parity and only one of which may be considered at a time. These supersymmetries for the one-dimensional radial oscillator differ from the usual one for the full one-dimensional oscillator, where a single energy shift is effected and states of opposite parity are degenerate under the supersymmetry.

In later sections, for reasons that emerge from the construction of the generalized mapping, it is more natural to focus on the supersymmetric partner of the fermionic oscillator rather than the fermionic oscillator itself. This system, which we call ''second fermionic,'' has wave functions $W^{=}_{DN''L''}$ given by

$$W^{=}_{DN''L''}(Y)=W_{D,N'',L''}(Y). \tag{29}$$

Here, L'' is defined by $L''=L'+1$, and N'' takes values L'', $L''+2$, $L''+4$, ... The differential equation for this system has the same functional form as the fermionic equation (27), except for the replacement of N and L with N'' and L'', respectively.

The oscillator bosonic sector may be put into one-to-one correspondence with the second-fermionic sector by making the following replacements in the bosonic wave function:

$$N\mapsto N''=N+2, \quad L\mapsto L''=L+2. \tag{30}$$

By composition of this mapping and the ones given in sections II C and II E, a correspondence may be established between the fermionic sector of the Coulomb system and the second-fermionic sector of the oscillator. It is given by

$$W^{=}_{D,N'',L''}(Y)=K_{d,n',\lambda}Y^{-1/2}w^{-}_{dn'l'}((n'+\gamma)Y^2), \tag{31}$$

$$Y^2=\frac{y}{(n'+\gamma)}, \tag{32}$$

$$N''=2n'-2+\lambda, \tag{33}$$

$$L''=2l'+\lambda. \tag{34}$$

The dimensions are still related as in Eq. (14). See Figure 1. We emphasize that this commutative diagram involves mappings different from those presented in Ref. 9, where the second-fermionic sector is not considered.

III. GENERALIZED SUPERSYMMETRY-BASED QUANTUM-DEFECT THEORY

In this section, we introduce analytical SQDT for the Coulomb and oscillator systems in arbitrary dimensions. From the present perspective, the goal is to obtain effective radial equations

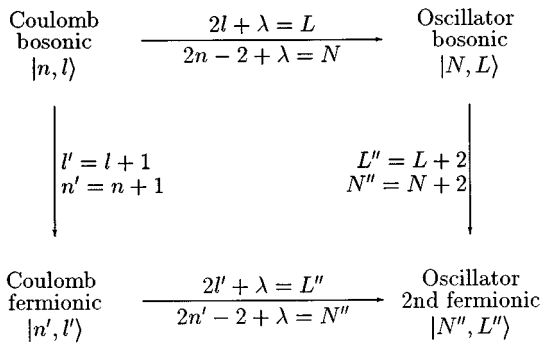

FIG. 1. Supersymmetric mappings. Relationships are shown interconnecting the bosonic and fermionic partners of the Coulomb and oscillator systems. The diagram is commutative.

that offer sufficient flexibility to obviate the dimension and angular-momentum constraints of the usual mappings, while maintaining eigensolutions with analytical structure comparable in simplicity to those of the Coulomb and oscillator systems.

The existence of suitable deformations of the Coulomb and oscillator systems satisfying these criteria is by no means apparent *a priori*. In what follows, we take as a guide the SQDT that is known to provide a useful analytical description of the valence structure of physical atoms in terms of an effective one-particle radial equation.[14] This model determines an effective radial potential modifying the three-dimensional radial Coulomb equation. It generates solutions with physical eigenvalues given by the Rydberg expression

$$E_{n^*} = -E_0/4n^{*2}. \tag{35}$$

Here, n^* is the principal quantum number modified by subtracting the quantum defect δ, which in general depends on the angular momentum and the principal quantum number. In section III A, we generalize this model to the d-dimensional situation. For simplicity, we take δ and its generalization in arbitrary dimensions to be independent of the principal quantum number. This approximation is excellent in, for example, real alkali-metal atoms.[22]

Similar ideas can be implemented for the radial equation of the D-dimensional oscillator. The resulting oscillator SQDT are presented in section III B. A possible physical application of these oscillator models is to the description of a valence particle in geonium atoms formed by a group of charged particles bound in a Penning trap.[10]

A. Generalized SQDT for the Coulomb system

Given the d-dimensional Coulomb radial equation (3) with fixed angular momentum l, we seek to implement two modifications via an effective potential $v_{\text{eff}}(y)$ added to the left-hand side. The first desired modification is a shift in dimension, from d to $d^*=d+j$, where j is an integer that in principle could depend on l. We require $d^*>1$, so j must satisfy $j>1-d$. The second desired modification is a shift in energy eigenvalues from $E_{n,\gamma}$ in Eq. (2) to the d^*-dimensional extension of the Rydberg series [see Eq. (41) below]. We want both these changes to be implemented while maintaining analytical eigenfunctions with form similar to those in Eq. (4).

Remarkably, these goals can be accomplished with a relatively simple effective potential, given by

$$v_{\text{eff}}(y) = \frac{(n+\gamma)^2-(n^*+\gamma^*)^2}{4(n+\gamma)^2(n^*+\gamma^*)^2} + \frac{(l^*+\gamma^*)(l^*+\gamma^*+1)-(l+\gamma)(l+\gamma+1)}{y^2}. \tag{36}$$

Here, the quantity γ^* is defined by $\gamma^* = (d^* - 3)/2$. The quantities n^* and l^* are defined as

$$n^* \equiv n_s - \delta = n + i - \delta, \tag{37}$$

$$l^* = l + i - \delta, \tag{38}$$

where δ is the quantum defect determining the energy shifts for the generalized Rydberg series and where $i = i(l)$ is an integral-valued function of the angular momentum. In the supersymmetric interpretation for the valence electron of physical atoms, $i(l)$ is the number of filled lower levels with angular momentum l. The introduction of n_s is motivated by the three-dimensional case, where it is equal to the principal quantum number and takes conventional values in the standard spectroscopic notation. It satisfies $n_s = n + i$, where n takes the usual values characteristic of the exact Coulomb system. As an example, the s states of the supersymmetric sodium atom in three dimensions have $i(0) = 2$, giving $n_s = 3$, $n_s = 4$, $n_s = 5$ for the first three levels.[13] The corresponding values of n are $n = 1$, $n = 2$, $n = 3$. For the supersymmetric partner of the exact Coulomb system, $i = 1$ and so $n_s = n + 1 = n'$, consistent with our previous notation for the supersymmetric case.

The first term of Eq. (36) has the effect of shifting the energy levels, while the second term performs a corresponding shift in the angular-momentum barrier. The combined effect of both terms incorporates the desired dimensional shift. With a nonzero quantum defect $\delta(l)$, the effective potential $v_{\text{eff}}(y)$ plays the role of a supersymmetry-breaking potential. The resulting radial equation has analytical solutions given in terms of the usual Coulomb solutions $w_{d,n,l}(y)$ by $w_{d^*,n^*,l^*}(y)$. These solutions exist for $n \geqslant l + 1$, or $n_s \geqslant l + i + 1$. Requiring the existence and orthonormalizability of the wave functions restricts $\delta - i$ according to

$$\delta - i < l + \gamma + 1 + \tfrac{1}{2} j. \tag{39}$$

It is convenient to define a dimensionless quantity $a(l)$ by

$$a(l) = i - \delta + \tfrac{1}{2} j. \tag{40}$$

The eigenvalues of the differential equation can then be expressed as

$$\frac{E_{n^*,\gamma^*}}{E_0} = \frac{-1}{4(n^* + \gamma^*)^2} = \frac{-1}{4(n + \gamma + a)^2}. \tag{41}$$

In this equation, we have chosen the eigenenergies so that the limiting case with $d = 3$ and $i = j = 0$ reproduces the Rydberg series (35). For i, δ, and j chosen so that $a = 0$, we obtain the bosonic equation of the Coulomb system discussed in section II E, up to an energy shift. If $a = 1$, the fermionic sector of the Coulomb problem is generated instead. Moreover, the supersymmetric partner of the fermionic sector is generated by setting $a = 2$, and each successive iteration of the supersymmetry increments a by one unit.

A useful stack correspondence can be established between the spectrum of the bosonic sector of the supersymmetric Coulomb system and the SQDT Coulomb spectrum. The map is given by making the following replacements in $w^+_{d,n,l}$:

$$\begin{aligned} d &\mapsto d^* = d + j, \\ n &\mapsto n^* = n + i - \delta = n_s - \delta, \\ l &\mapsto l^* = l + i - \delta. \end{aligned} \tag{42}$$

B. Generalized SQDT for the oscillator system

The techniques of section III A can also be applied to the radial oscillator system in D dimensions. For fixed angular momentum L, we can obtain an effective potential $V_{\rm eff}(Y)$ to be added to Eq. (8) that maintains analytical eigenfunctions while inducing an integral shift to a new dimension $D^* \equiv D+J \geq 1$ and simultaneously modifying the oscillator energy eigenvalues via a shift to a new principal quantum number N^*. We refer to the resulting theory as the oscillator SQDT.

The appropriate choice of effective potential is

$$V_{\rm eff}(Y) = 2(N-N^*+\Gamma-\Gamma^*) + \frac{(L^*+\Gamma^*)(L^*+\Gamma^*+1)-(L+\Gamma)(L+\Gamma+1)}{Y^2}, \tag{43}$$

where $\Gamma^* = (D^*-3)/2$ and the shifted quantum numbers are given by

$$N^* \equiv N_s - I - \Delta \equiv N + I - \Delta, \tag{44}$$

$$L^* = L + I - \Delta. \tag{45}$$

Here, $I = I(L)$ is an integral-valued function, analogous to $i(l)$ in the Coulomb case, that can be interpreted as the number of inaccessible lower levels. The quantity $\Delta(N,L)$ is the oscillator equivalent of the Rydberg quantum defect $\delta(n,l)$, modifying the radial-repulsion term in the differential equation. For simplicity in what follows, we take Δ to depend only on L, thereby paralleling the case of alkali-metal atoms for which δ depends only on l. We have also defined a quantity N_s playing the role of the principal quantum number in the spectroscopic notation, given by $N_s = N + 2I$. If the dimension is unmodified and $\Delta = 0$, the choice $I = 1$ yields the fermionic sector of the supersymmetry discussed in section II F. In this limit $N' = N^* = N+1 \neq N_s$, which differs from the supersymmetric limit of the Coulomb SQDT where $n' = n^* = n_s$. With our definitions, degenerate levels in the bosonic and fermionic sectors have values of N differing by $2I$ units, but have the same value of N_s.

The first term in Eq. (43) implements the eigenenergy shift to the oscillator analogue of the Rydberg series, while the second term is the corresponding anharmonic modification to the potential that maintains analytical eigensolutions. The eigenfunctions solving the resulting effective radial equation are given in terms of the oscillator wave functions $W_{D,N,L}(Y)$ of Eq. (9) by $W_{D^*,N^*,L^*}(Y)$. The existence of these solutions requires that the principal quantum number takes the values $N_s = L+2I,\ L+2I+2,\ L+2I+4,\ \ldots$, or $N = L,\ L+2,\ L+4,\ \ldots$. Requiring orthonormalizability of the wave functions restricts the range of $\Delta - I$ to

$$\Delta - I < L + \Gamma + \tfrac{3}{2} + \tfrac{1}{2}J. \tag{46}$$

We can again introduce a useful dimensionless quantity $A(L)$ by

$$A(L) = I - \Delta + \tfrac{1}{2}J. \tag{47}$$

The eigenvalues of the differential equation can be expressed as

$$\frac{F_{N^*,\Gamma^*}}{F_0} = 2N^* + 2\Gamma^* + 2A + 3 = 2N + 2\Gamma + 4A + 3. \tag{48}$$

We have chosen the ground-state eigenenergy in analogy with the Coulomb case (41). The extra factor of $2A$ appears to ensure that the bosonic and fermionic spectra of the limiting supersymmetric case with $\Delta = 0$, $J = 0$ have the characteristic degenerate pairing. If I, Δ, and J are selected so that $A = 0$, then this SQDT system reduces to the bosonic oscillator discussed in section II F, up

to an energy shift. If $A=1$, it reduces instead to the fermionic partner. If $A=2$, the second-fermionic sector of the supersymmetric oscillator is produced. Each further iteration of supersymmetry produces an additional unit increment of A. Note that for fixed L the spacing between successive eigenvalues is always four units, regardless of the value of A.

A correspondence can be established between the oscillator SQDT and the bosonic sector of the supersymmetric oscillator. The images of the wave functions are obtained by making the replacements

$$D\mapsto D^*=D+J, \quad N\mapsto N^*=N+I-\Delta, \quad L\mapsto L^*=L+I-\Delta. \tag{49}$$

IV. MAPPINGS BETWEEN BOUND STATES OF THE COULOMB AND OSCILLATOR SQDT

Composition of the mappings in sections II C, III A, and III B allows us to establish a correspondence between the d^*-dimensional Coulomb SQDT and the D^*-dimensional oscillator SQDT. This mapping is described in section IV A. One of its striking features is that the odd-dimensional oscillator can be imaged. In section IV B, we illustrate the mapping with examples involving the three-dimensional Coulomb and oscillator systems.

A. The general case

The general mapping is given by

$$W_{D^*,N^*,L^*}(Y)=K_{d^*,n^*,\lambda-J/2+j}Y^{-1/2}w_{d^*,n^*,l^*}((n^*+\gamma^*)Y^2), \tag{50}$$

$$Y^2=y/(n^*+\gamma^*), \tag{51}$$

$$D^*=2d^*-2-2\lambda+J-2j, \tag{52}$$

$$N^*=2n^*-2+\lambda-\tfrac{1}{2}J+j, \tag{53}$$

$$L^*=2l^*+\lambda-\tfrac{1}{2}J+j, \tag{54}$$

$$A=2a. \tag{55}$$

This mapping, like the Coulomb-oscillator case discussed in section II C, is based on a quadratic relationship between the radial variables of the two systems. The constant K can be chosen to preserve the normalization of the wave functions, in which case it has the functional form given in Eq. (13). Note that Eq. (53) is equivalent to a generalization of Eq. (15), given by

$$\frac{F_{N^*,\Gamma^*}}{F_0}=2\sqrt{\frac{E_0}{-E_{n^*,\gamma^*}}}+4a. \tag{56}$$

Note also that the allowed ranges of the quantum defects given in Eq. (39) and Eq. (46) are compatible with Eq. (55), which guarantees that the image of any orthonormalizable Coulomb radial system is an orthonormalizable oscillator.

To gain insight about the flexibility of this mapping, consider the choice $j=0$. Then, D^* lies in the range $1+J\leqslant D^*\leqslant 2d-2+J$ with allowed values separated by two units. Since we require $J\geqslant 1-D$, any $D^*\geqslant 1$ is possible. Moreover, d may take any value greater than one. The above general mapping therefore relates any Coulomb dimension $d>1$ to any oscillator dimension $D^*\geqslant 1$. In particular, Eq. (52) shows that D^* is odd if J is chosen to be an odd integer. This is in striking contrast to the usual restriction of D to even values only, as given by Eq. (14).

The Coulomb-oscillator mappings defined earlier are special cases of our general mapping. The correspondence of section II C is recovered by setting $i=\delta=j=0$ in the Coulomb system and

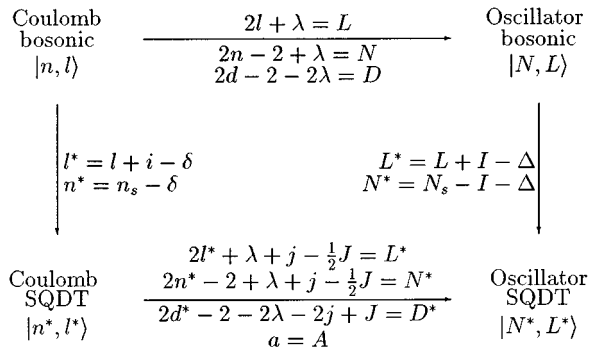

FIG. 2. SQDT mappings. Relationships are shown interconnecting the bosonic and SQDT sectors of the Coulomb and oscillator systems. The diagram is commutative.

$I=\Delta=J=0$ in the oscillator system, so that $A=2a=0$. Figure 2 is a commutative diagram showing the relationship between this simpler mapping and the general mapping. Similarly, the mapping of section II F between the fermionic sector of the supersymmetric Coulomb system and the second-fermionic sector of the supersymmetric oscillator is reproduced with the choices $i=1$, $\delta=0$, $j=0$ and $I=2$, $\Delta=0$, $J=0$, so that $A=2a=2$.

For the case of constant nonnegative integral A and a, Eq. (55) controls the relationship between the supersymmetric sectors of the two systems. While any iteration of the supersymmetry for the Coulomb system can be taken, only *even* iterations of the oscillator supersymmetry appear. This is why we introduced the second-fermionic sector of the supersymmetric oscillator in section II F. It is therefore possible to combine Figures 1 and 2 in a single commutative diagram. Moreover, the general mapping shows that Figure 1 can be extended downward to incorporate higher iterations of the supersymmetry. The result is an infinite series of mappings relating Coulomb systems with $a=2, 3, 4, \ldots$ to oscillator systems with $A=4, 6, 8, \ldots$, respectively.

B. Three-dimensional Coulomb and oscillator systems

To obtain further insight about the content of the general mapping of section IV A, we next restrict attention to the special case where both systems are three-dimensional. Since this choice can be implemented with $j=0$, we assume this in what follows.

The general mapping becomes

$$W_{3,N^*,L^*}(Y)=K_{3,n^*,1/2}Y^{-1/2}w_{3,n^*,l^*}(n^*Y^2), \tag{57}$$

$$N^*=2n^*-\tfrac{3}{2}, \tag{58}$$

$$L^*=2l^*+\tfrac{1}{2}, \tag{59}$$

$$\Delta-I=2(\delta-i)+\lambda-\tfrac{1}{2}. \tag{60}$$

The values of λ allowed by Eq. (54) are $\lambda=0,1$. The orthonormality requirements Eq. (39) and Eq. (46) become

$$\delta-i<l+1, \tag{61}$$

$$\Delta-I<L+\tfrac{3}{2}. \tag{62}$$

We can regard Eq. (61) and Eq. (62) as conditions limiting the choice of quantum defects in the two systems to a semi-infinite region of the $(\Delta - I)$ versus $(\delta - i)$ plane. The condition (60) then further restricts the choice to a straight line in this region.

One interesting special case is obtained by requiring that the oscillator be exact in the sense that $\Delta - I = 0$. Then, Eq. (60) becomes

$$\delta - i = -a = \tfrac{1}{2}(\tfrac{1}{2} - \lambda), \tag{63}$$

showing that a nonzero defect in the Coulomb system is necessary. The eigenvalues of the equations are

$$E_{n^*,\gamma^*} = \frac{-E_0}{(2n + \lambda - \frac{1}{2})^2}, \tag{64}$$

$$F_{N,\Gamma} = F_0(2N + 2\lambda + 2), \tag{65}$$

and the relationships among the principal quantum numbers and the angular momenta become

$$L = 2l^* + \tfrac{1}{2}, \tag{66}$$

$$N = 2n^* - \tfrac{3}{2}. \tag{67}$$

Selecting $\lambda = 1$ for definiteness, we see that Eq. (66) maps each successive Coulomb angular momentum $l^* = \frac{1}{4}$, $l^* = \frac{5}{4}$, $l^* = \frac{9}{4}$, ... to every second oscillator angular momentum starting at $L = \lambda$: $L = 1$, $L = 3$, $L = 5$, ... The mapping therefore preserves the degeneracy of states. For instance, the kets $|n^* = \frac{9}{4}, l^* = \frac{1}{4}\rangle$ and $|n^* = \frac{9}{4}, l^* = \frac{5}{4}\rangle$, which are degenerate in the Coulomb system, are mapped to the degenerate states $|N = 3, L = 1\rangle$ and $|N = 3, L = 3\rangle$ in the oscillator system. This feature is also a characteristic of the original mapping of section II C. The main differences here are that the Coulomb effective angular momenta l^* are nonintegral and, more importantly, that both systems are three dimensional.

A second case of interest is obtained when the Coulomb system is exact, i.e., $\delta - i = 0$. The condition $j = 0$ implies that $a = 0$ too. Then, Eq. (55) becomes $\Delta - I = \lambda - \frac{1}{2}$, showing that a nonzero defect is again needed, this time in the oscillator system. The eigenvalues are

$$E_{n,\gamma} = \frac{-E_0}{4n^2}, \tag{68}$$

$$F_{N^*,\Gamma^*} = F_0(2N - 2\lambda + 4), \tag{69}$$

and the mapping gives

$$L^* = 2l + \tfrac{1}{2}, \tag{70}$$

$$N^* = 2n - \tfrac{3}{2}. \tag{71}$$

The first of these equations shows every second oscillator angular momentum is imaged, which again preserves the degeneracy of states. If, for example, we choose $\lambda = 0$, then the degenerate Coulomb states $|n = 3, l = 1\rangle$ and $|n = 3, l = 2\rangle$ map to the degenerate oscillator states $|N^* = \frac{9}{2}, L^* = \frac{5}{2}\rangle$ and $|N^* = \frac{9}{2}, L^* = \frac{9}{2}\rangle$.

In the above examples, the quantities $\Delta - I$ and $\delta - i$ are constant. In physical systems such as alkali-metal atoms, $\delta - i$ depends on l and tends towards zero as l increases. This feature can also

TABLE I. Possible parameters for a mapping between the radial Coulomb and oscillator systems in three dimensions. For the choices $j=0$ and $\lambda=1$, values of l, i, n, n_s, and δ are tabulated for sodium along with the corresponding values of L, I, N, N_s, and Δ under the mapping (60). The quantities $I(L)$ have been selected to fill all levels below $N_s=5$.

Coulomb system (sodium)					Oscillator system				
l	i	n	n_s	δ	L	I	N	N_s	Δ
0	2	$\geqslant 1$	$\geqslant 3$	1.35	1	2	$\geqslant 1$	$\geqslant 5$	1.20
1	1	$\geqslant 2$	$\geqslant 3$	0.859	3	1	$\geqslant 3$	$\geqslant 5$	1.218
2	0	$\geqslant 3$	$\geqslant 3$	0.01	5	0	$\geqslant 5$	$\geqslant 5$	0.52
3	0	$\geqslant 4$	$\geqslant 4$	0	7	0	$\geqslant 7$	$\geqslant 7$	0.50
$\geqslant 4$	0	$\geqslant l+1$	$\geqslant l+1$	0	$\geqslant 9$	0	$\geqslant L$	$\geqslant L$	0.5

be incorporated in our general mapping. It implies a dependence of $\Delta - I$ on L, which might reflect a realistic feature of a physical oscillator such as a cloud of particles caught in a Penning trap.

As an example, we map the SQDT radial equation for the physical sodium atom into a three-dimensional SQDT oscillator. In sodium, the inaccessibility of the levels occupied by the ten inner electrons is implemented by the choices $i(0)=2$, $i(1)=1$, and $i(l\geqslant 2)=0$. The quantum defects $\delta(l)$ in this case are known.[22] Choosing for definiteness $\lambda=1$ and selecting $I(0)=2$, $I(1)=1$, $I(L\geqslant 2)=0$, the values of Δ can be found from Eq. (60). Table I lists the results. As expected, the values of Δ tend towards $\frac{1}{2}$ as L increases.

V. MAPPINGS FOR CONTINUUM STATES

In previous sections, we have explored mappings between the bound states of the Coulomb and oscillator systems. It is natural to consider whether similar mappings exist taking the unbound Coulomb states into an appropriate oscillator. This question is of lesser physical interest at present, so we restrict ourselves here to a brief outline of a possible approach to this issue.

The Coulomb problem with energies $E>0$ can be viewed as a scattering problem. Following the general procedure of section II A again yields the differential equation (3), but with $E>0$. In terms of the confluent hypergeometric function ${}_1F_1$, the solutions are

$$w_{d,E,l}(y)\propto y^{l+\gamma+1}\exp\left(\pm iy\sqrt{\frac{E}{E_0}}\right){}_1F_1\left(l+\gamma+1\pm\frac{1}{2i}\sqrt{\frac{E_0}{E}},2(l+\gamma+1),\mp 2iy\sqrt{\frac{E}{E_0}}\right). \tag{72}$$

The upper and lower signs correspond to outgoing and incoming waves, respectively. The results of section II A can be recovered by taking E to be negative and choosing the upper sign.

It turns out that the appropriate image oscillator system[23] is the *inverted* oscillator, with potential $U(R)=-\frac{1}{2}M\Omega R^2$. This system is unbound. The procedure of section II B gives a differential equation identical to Eq. (8) except that the sign of the potential Y^2 is reversed. The solutions $W_{D,F,L}(Y)$ are

$$W_{D,F,L}(Y)\propto Y^{L+\Gamma+1}\exp\left(\pm\frac{1}{2}iY^2\right){}_1F_1\left(\frac{1}{2}\left(L+\Gamma+\frac{3}{2}\right)\mp\frac{iF}{4F_0},L+\Gamma+\frac{3}{2},\mp iY^2\right). \tag{73}$$

These functions may not be physically permissible, but are relevant for the purposes of establishing a mapping. With the choice of the upper sign, the wave functions for the usual oscillator may be obtained up to a constant by the analytic continuation $Y^2\to iY^2$ and $F\to -iF$.

A correspondence analogous to the mapping of section II C exists between the continuum Coulomb states and the inverted-oscillator functions. It is

$$W_{D,F,L}(Y) \propto Y^{-1/2} w_{d,E,l}\left(\frac{Y^2}{2\sqrt{E/E_0}}\right), \tag{74}$$

$$Y^2 = 2y\sqrt{E/E_0}, \tag{75}$$

$$D = 2d - 2 - 2\lambda, \tag{76}$$

$$L = 2l + \lambda, \tag{77}$$

$$\frac{F}{F_0} = 2\sqrt{\frac{E_0}{E}}\,. \tag{78}$$

There are many similarities between this mapping and the one discussed in section II C. Again, λ must be integral, so only even-dimensional oscillators are available as images. Also, the angular momenta L are restricted to being either all odd or all even, thus eliminating half the oscillator states. However, the energy relation (78), unlike (15), involves continuous values of E and F. It also reveals that negative energies F are excluded from the mapping. As one energy tends to zero the other tends to infinity.

As an aside, we remark that the negative energies F do appear when considering the *repulsive* Coulomb problem. The differential equation of this problem is mapped into the inverted-oscillator differential equation[24] by a map with (74) through (77) unchanged but with a negative sign taken for the square root in Eq. (78).

Although this lies outside the scope of the present work, it seems feasible that supersymmetry could be introduced into these systems along with the corresponding SQDT. We conjecture that this allows for odd dimensions D. Since parabolic coordinates have some advantages for scattering problems, it would also be interesting to perform an analysis in terms of the dual parabolic-coordinate supersymmetries of Ref. 25 instead of the spherical-coordinate supersymmetry used here.

VI. SUMMARY

In this paper, we generalized the radial mappings first identified by Schrödinger that relate the Coulomb and oscillator systems. Our principal result is a mapping between the supersymmetry-based quantum-defect theories for the Coulomb and oscillator systems in arbitrary dimensions. In particular, odd oscillator dimensions can be accessed as well as the usual even ones. The mapping and some of its limits are illustrated in Figures 1 and 2.

In deriving this result, we have extended to arbitrary dimensions the analytical SQDT in three dimensions used to describe physical alkali-metal atoms. An analogous SQDT for the harmonic oscillator in arbitrary dimensions has also been presented. In suitable limits, these theories reproduce the bosonic and fermionic sectors of the corresponding supersymmetric quantum-mechanical systems. We have elucidated a basic relationship between the supersymmetric radial Coulomb and oscillator systems: the qth iteration of supersymmetry for the Coulomb system corresponds naturally to the $2q$th iteration of supersymmetry for the oscillator. For the special case of the one-dimensional radial oscillator, we uncovered a quantum-mechanical supersymmetry in which the parity is restricted to be either odd or even. We have also briefly considered mappings relating the continuum-spectrum states of the Coulomb and oscillator systems.

The issue of the physical relevance of our results has also been addressed in part. The three-dimensional Coulomb SQDT is known to provide a good analytical description of the behavior of Rydberg atoms. Our mapping provides a means of obtaining an equivalent analytical oscillator SQDT. An explicit example mapping the sodium atom to an oscillator SQDT is given in Table I. It is also possible that an oscillator SQDT could be used to describe a suitable physical

system, perhaps the Penning trap. If this can be realized in practice, the generalized mapping presented here could provide a connection between two apparently disparate physical systems.

Long-time approximation to the evolution of resonant and nonresonant anharmonic oscillators in quantum mechanics

A. W. Sáenz
Department of Physics, Catholic University of America, Washington, D.C. 20064
and Naval Research Laboratory, Washington, D.C. 20375

(Received 21 August 1995; accepted for publication 9 November 1995)

A simple normal-form approach is used to obtain uniform long-time approximations to the evolution of a resonant or nonresonant anharmonic oscillator system governed by a Hamiltonian H_ε which is a self-adjoint operator acting in the Hilbert space $\mathscr{H}=L^2(\mathbf{R}^\nu)$ $(\nu\geqslant 2)$ and is given formally by $H_0+\varepsilon V$. Here H_0 denotes the Hamiltonian of ν one-dimensional harmonic oscillators whose coupling is represented by εV, where V is an operator of multiplication by a smooth function of at most polynomial growth at infinity and $\varepsilon\geqslant 0$ is a small parameter. We consider the general situation in which $\rho\geqslant 1$ of the frequencies of these oscillators are rationally independent, imposing a standard diophantine condition on the independent frequencies if $\rho\geqslant 2$. Under these assumptions, which are stated in a mathematically precise way in the paper, an Nth-order approximant $\psi_N(t,\varepsilon)$ to the exact solution $\psi(t,\varepsilon)$ of the Schrödinger equation id $\psi(t,\varepsilon)/dt=H_\varepsilon\psi(t,\varepsilon)$ satisfying the initial condition $\psi(0,\varepsilon)=\psi_0$ is constructed inductively, ψ_0 being an arbitrary ε-independent member of a suitable family of smooth functions dense in $\mathscr{H}$. Our main result is that $\psi_N(t,\varepsilon)$ differs from $\psi(t,\varepsilon)$ in $\mathscr{H}$-norm by $\leqslant$const $\varepsilon^{N+1}(|t|+1)$ for all $t\in\mathbf{R}$ and all ε in an arbitrary compact interval $[0,\varepsilon_0]$. © *1996 American Institute of Physics.* [S0022-2488(96)00704-1]

I. INTRODUCTION

Since the earliest days of quantum mechanics, physicists have been interested in developing approximate methods for calculating the long-time evolution of quantum mechanical systems. Such methods avoid the troublesome secular terms arising when this evolution is computed via the usual time-dependent perturbation procedures. Indeed, if such a calculation is carried out by a method which leads to secular terms, it should be expected to be accurate at most over relatively small time intervals.

Shortly after the discovery of quantum mechanics, Wigner[1] gave a brief but incisive discussion of a way to obtain long-time approximate solutions of the Schrödinger equation id $\psi(t)/dt=H\psi(t)$ for time-independent Hamiltonians H. More recently, two closely related systematic approaches have been developed for deriving Nth-order approximants, free from secular terms, to the exact evolution of a variety of quantum mechanical systems: the normal-form approach and quantum averaging. Wigner's pioneering remarks are best regarded as anticipating quantum averaging in a special case. The earliest systematic treatments of quantum averaging were independently given by Lochak[2,3] and Case,[4] respectively, and the latter's ideas were elaborated by his student Lee.[5] Such averaging can be viewed as an extension of the Bogoliubov–Mitropolski averaging method for classical nonlinear systems[6] to quantum mechanics. Ellison and his student Ben Lemlih[7,8] were the first to use modern functional analysis methods to develop quantum-averaging approximations to the long-time evolution of the quartic anharmonic oscillator and other physically important systems, as well as to derive rigorous error bounds for these approximate solutions. On the other hand, Kummer[9] was the first to discuss systematically a normal-form approach to quantum evolution over long times. His work was strongly influenced by that of

0022-2488/96/37(5)/2182/24/$10.00

Moser's in classical mechanics.[10] The approach in Ref. 9 was rigorized and extended in various ways by Kummer and his students Antoniou[11] and Gompa.[12–14] In Refs. 12 and 13, two normal-form methods were applied to obtain an Nth normal-form approximation to the evolution of nonresonant quantum anharmonic oscillator systems whose Hamiltonian operators were time-independent polynomials in coordinates and momenta. In the first method, this was done in the setting of Bargmann's Hilbert space of analytic functions[15] by using graded Lie algebra procedures analogous to those applied in normal-form studies of vector fields and classical Hamiltonian systems.[16,17] In Refs. 12 and 14, this method was also applied to time-dependent quantum Hamiltonians of the latter polynomial type. The second, somewhat simpler normal-form approach is closely related to the perturbation theory discussed by Born and Jordan.[18] For further bibliographical information on normal forms in quantum mechanics, the reader is referred to Refs. 9, 13, and 19.

The principal goal of this paper is to construct in a mathematically rigorous way a long-time, uniform approximation to the solution of the initial-value problem (IVP) defined by[20]

$$i\,\frac{d\psi(t,\varepsilon)}{dt}=H_\varepsilon\psi(t,\varepsilon), \tag{1.1a}$$

$$\psi(0,\varepsilon)=\psi_0. \tag{1.1b}$$

Here H_ε denotes a self-adjoint operator acting in the Hilbert space $\mathscr{H}=L^2(\mathbf{R}^\nu)$ ($\nu\geqslant 2$) and defined formally by

$$H_\varepsilon=H_0+\varepsilon V \tag{1.2}$$

and d/dt the strong t-derivative in $\mathscr{H}$. In (1.2), H_0 is the Hamiltonian of ν uncoupled simple harmonic oscillators or, more precisely, the unique self-adjoint operator in $\mathscr{H}$ such that

$$H_0=\sum_{j=1}^{\nu}\left(-\frac{\partial^2}{\partial x_j^2}+\omega_j^2x_j^2\right) \tag{1.3}$$

when acting on functions in $C_0^\infty(\mathbf{R}^\nu)$. Moreover, $\varepsilon\geqslant 0$ is a small parameter and V denotes an operator of multiplication by a $C^\infty(\mathbf{R}^\nu)$ function which together with its derivatives has at most polynomial growth at infinity. We assume that the frequencies $\omega_1,\ldots,\omega_\nu$ are positive and that an arbitrary number ρ of them ($1\leqslant\rho\leqslant\nu$) are rationally independent. If $\rho\geqslant 2$, the rationally independent ω_is are assumed to obey a standard diophantine inequality. No other conditions are imposed on these frequencies.

Using a rigorous version of the second normal-form method in Ref. 13, we will construct for each $N\geqslant 1$ an Nth-order approximant $\psi_N(t,\varepsilon)$ to the exact solution $\psi(t,\varepsilon)$ of the IVP (1.1) satisfying the uniform error estimate

$$\|\psi(t,\varepsilon)-\psi_N(t,\varepsilon)\|\leqslant\text{const }\varepsilon^{N+1}(|t|+1) \tag{1.4}$$

for $t\in\mathbf{R}$, $0\leqslant\varepsilon\leqslant\varepsilon_0$, where ε_0 is an arbitrary positive constant and $\|.\|$ the usual $L^2(\mathbf{R}^\nu)$-norm. This error estimate is our main result. Although its rigorous proof is lengthy (Sec. IV), the basic ideas underlying it are quite simple, as will be clear from its heuristic proof given in the next section.

This paper is the first to carry out this construction for systems of resonant and nonresonant harmonic oscillators coupled by a local potential V, which is not necessarily a polynomial, under very general conditions on the frequencies ω_i. Outside of using a version of the last-mentioned normal-form method and certain other ideas in Refs. 7–9 and 13, our treatment is quite different from theirs. In particular, the fact that we allow the eigenvalues of H_0 to be degenerate and consider nonpolynomial coupling introduces nontrivial complications in the rigorous definitions of

the relevant operators, as well as self-adjointness and convergence complications not encountered in the works of these authors. Moreover, the elegant algebraic and analytic approaches used in Refs. 12–14 are inappropriate for dealing with the class of potentials considered here.

The organization of this paper is as follows. In Sec. II, we construct the above Nth-order approximant heuristically. In Sec. III, we state our assumptions on V and the frequencies ω_i precisely, and define the dense domain $C^\infty(H_0)$ in which our initial state lies. This domain is invariant under the action of the operators entering the theory, whose exact definitions are given in that section. Therein we also state Theorem 1, which asserts that the error bound (1.4) holds at the above-stated t,ε-values. This theorem is proven in Sec. IV on the basis of a series of lemmas. Results needed to establish some of these lemmas are collected in the Appendix.

Some of the conclusions of the present paper were announced without detailed proofs in an earlier publication,[21] whose main purpose was to construct uniform approximations to the long-time quantum evolution of one-dimensional anharmonic oscillators.

II. FORMAL CONSTRUCTION OF THE *N*TH-ORDER APPROXIMANT

In this section, we will review the second normal-form approach of Refs. 12 and 13 in a heuristic way which will prove convenient for the purposes of Secs. III and IV, where the procedure will be reformulated rigorously.[22] We fix $\nu \geqslant 2$ in this section.

A central role in the construction of the Nth-order approximant ($N \geqslant 1$) is played by the ''normalizing'' operator $S_N(\varepsilon)$, which reduces H_ε to normal form to order N. By this we mean that $S_N(\varepsilon)$ is such that

$$H_\varepsilon S_N(\varepsilon) = S_N(\varepsilon) K_N(\varepsilon) + \varepsilon^{N+1} R_N(\varepsilon), \tag{2.1}$$

where $K_N(\varepsilon)$, the normal form of H_ε to order N, is a self-adjoint operator commuting formally with H_ε, and $\varepsilon^{N+1} R_N(\varepsilon)$ is a ''remainder,'' with $R_N(\varepsilon) = O(1)$ in ε, again in a formal sense.[23] Here

$$S_N(\varepsilon) = I + \sum_{i=1}^{N} \varepsilon^i S^{(i)}, \tag{2.2a}$$

$$K_N(\varepsilon) = H_0 + \sum_{i=1}^{N} \varepsilon^i K^{(i)}, \tag{2.2b}$$

where the $S^{(i)}$s and $K^{(i)}$s are independent of ε and each $K^{(i)}$ commutes with H_0 formally. One obtains the following recursive formulas for the $S^{(i)}$s and $K^{(i)}$s by inserting the expressions (2.2a) and (2.2b) into (2.1) and equating coefficients of powers of ε:

$$[H_0,\, S^{(i)}] = K^{(i)} - V^{(i)} \quad (i \geqslant 1), \tag{2.3a}$$

$$R_N(\varepsilon) = V^{(1)} S^{(N)} - \sum_{j=0}^{N-1} \varepsilon^j \sum_{k=j+1}^{N} S^{(k)} K^{(N+j-k+1)}. \tag{2.3b}$$

Here the $V^{(i)}$s are determined recursively by

$$V^{(1)} = V, \tag{2.4a}$$

$$V^{(i)} = V^{(1)} S^{(i-1)} - \sum_{j=1}^{i-1} S^{(j)} K^{(i-j)} \quad (i \geqslant 2). \tag{2.4b}$$

The matrix representation of relevant operator equations such as (2.3) and (2.4) in a basis which diagonalizes H_0 is an indispensable ingredient in our analysis. Denote by $\mathbf{Z}_+^p$ ($p \in \mathbf{N}$=the positive integers) the set of all vectors $r=(r_1,\ldots,r_p)$ whose components r_i are non-negative integers. We will use the familiar basis $\Phi=\{\Phi_m\}(m \in \mathbf{Z}_+^\nu)$ consisting of the complete orthonormal set of eigenfunctions of H_0 of the form

$$\Phi_m(x_1,\ldots,x_\nu)=\prod_{i=1}^{\nu} \varphi_{m_i}^{(i)}(x_i), \tag{2.5a}$$

where $\varphi_{m_i}^{(i)}(x_i)$ is the usual (real) eigenfunction of $-d^2/dx_i^2+\omega_i^2 x_i^2$ $(i=1,\ldots,\nu)$ having unit $L^2(\mathbf{R})$-norm. Hence for all $m \in \mathbf{Z}_+^\nu$,

$$H_0\Phi_m=\lambda_m\Phi_m, \tag{2.5b}$$

with

$$\lambda_m=\sum_{i=1}^{\nu} \omega_i(m_i+\tfrac{1}{2}). \tag{2.5c}$$

Since some of the frequencies $\omega_1,\ldots,\omega_\nu$ may be rationally dependent, the eigenvalues λ_m are generally degenerate, a fact which will complicate our analysis in Sec. IV.

The scalar product in $\mathscr{H}=L^2(\mathbf{R}^\nu)$ will be denoted by $\langle .,. \rangle$, and in accordance with the usual practice in quantum mechanics it will be supposed to be *antilinear* in the first entry and *linear* in the second. Assuming for the present that they exist,[24] we will denote the quantities $\langle \Phi_m, S^{(i)}\Phi_n\rangle, \langle \Phi_m, K^{(i)}\Phi_n\rangle, \langle \Phi_m, V^{(i)}\Phi_n\rangle$ by $S_{mn}^{(i)}, K_{mn}^{(i)}, V_{mn}^{(i)}$, respectively, and will define the infinite matrices $\mathscr{S}^{(i)}=(S_{mn}^{(i)})$, $\mathscr{K}^{(i)}=(K_{mn}^{(i)})$, $\mathscr{V}^{(i)}=(V_{mn}^{(i)})$ $(m,n \in \mathbf{Z}_+^\nu)$. In general, given an operator A in $\mathscr{H}$, its matrix elements $\langle \Phi_m, A\Phi_n\rangle$ will be denoted by A_{mn}.[25]

By (2.3a) and (2.5b),

$$(\lambda_m-\lambda_n)S_{mn}^{(i)}=K_{mn}^{(i)}-V_{mn}^{(i)} \quad (i \geqslant 1). \tag{2.6}$$

Since $K^{(i)}$ has been assumed to commute with H_0, $K_{mn}^{(i)}=0$ if $\lambda_m \neq \lambda_n$. From this and (2.6) it follows that

$$S_{mn}^{(i)}=-V_{mn}^{(i)}/(\lambda_m-\lambda_n) \quad (i \geqslant 1, \lambda_m \neq \lambda_n), \tag{2.7}$$

$$K_{mn}^{(i)}=V_{mn}^{(i)}\delta_{\lambda_m,\lambda_n} \quad (i \geqslant 1). \tag{2.8}$$

Since Eq. (2.3a) leaves the matrix elements $S_{mn}^{(i)}$ with $\lambda_m=\lambda_n$ undetermined for $i \geqslant 1$, one can choose them in any manner consistent with the formal self-adjointness of the $K^{(i)}$s.[26] When all the $\omega_1,\ldots,\omega_\nu$ are rationally independent, the eigenvalues of H_0 are nondegenerate and thus the $K^{(i)}$s are formally self-adjoint, since then each $\mathscr{K}^{(i)}$ is a real diagonal matrix. Hence, in this case the above matrix elements can be chosen arbitrarily. However, if the ω_ks are not all rationally independent, such a choice is generally incompatible with the formal self-adjointness of the $K^{(i)}$s, and this would lead to a breakdown of our analysis. We will select these matrix elements in such a way that it will not be necessary to distinguish between the nondegenerate (nonresonant) and degenerate (resonant) cases. Thus, henceforth our remarks will apply to either of these two situations.

Before defining the $S_{mn}^{(i)}$s for $\lambda_m=\lambda_n$, we introduce some notation. Given an operator A in $\mathscr{H}$, we split it uniquely as follows:

$$A=\hat{A}+\tilde{A}, \tag{2.9a}$$

where

$$\hat{A}_{mn}=\delta_{\lambda_m,\lambda_n}A_{mn}, \quad \tilde{A}_{mn}=(1-\delta_{\lambda_m,\lambda_n})A_{mn}. \tag{2.9b}$$

We write $\hat{S}^{(i)}\equiv(S^{(i)})\hat{}$, $\tilde{S}^{(i)}\equiv(S^{(i)})\tilde{}$ and $\hat{S}^{(i)}_{mn}\equiv(\hat{S}^{(i)})_{mn}$, $\tilde{S}^{(i)}_{mn}\equiv(\tilde{S}^{(i)})_{mn}$. We define the operators $\hat{S}^{(i)}$ recursively by

$$\hat{S}^{(1)}=0, \tag{2.10a}$$

$$\hat{S}^{(i)}=\hat{S}^{(i)*}=-\frac{1}{2}\sum_{j=1}^{i-1}(S^{(j)}S^{(i-j)*})\hat{} \quad (i\geqslant 2). \tag{2.10b}$$

Here the notation A^* designates the adjoint of an operator A in $\mathscr{H}$, so that $(A^*)_{mn}=\overline{A_{mn}}$, the bar denoting complex conjugation. Naturally, at the moment Eq. (2.10b) is completely formal. The choice (2.10) of the $\hat{S}^{(i)}$s has two important consequences, which follow by using a simple and ingenious inductive argument presented in Ref. 13. The first is that $S_N(\varepsilon)^*$ is an approximate right-inverse of $S_N(\varepsilon)$:

$$S_N(\varepsilon)S_N(\varepsilon)^*=I+\varepsilon^{N+1}U_N(\varepsilon), \tag{2.11a}$$

where $U_N(\varepsilon)$ is a polynomial in ε defined by

$$U_N(\varepsilon)=\sum_{j=0}^{N-1}\varepsilon^j\sum_{k=j+1}^{N}S^{(k)}S^{(N+j-k+1)*}. \tag{2.11b}$$

The second consequence is that the $K^{(i)}$s are formally self-adjoint. A rigorous version of this inductive argument will be presented in Sec. IV.

In terms of matrix elements, Eqs. (2.10) can be expressed as follows by using (2.9b):

$$\hat{S}^{(1)}_{mn}=0, \tag{2.12a}$$

$$\hat{S}^{(i)}_{mn}=\overline{\hat{S}^{(i)}_{nm}}=-\frac{1}{2}\sum_{j=1}^{i-1}\sum_{r\in\mathbf{Z}_+^\nu}(\tilde{S}^{(j)}_{mr}\overline{\tilde{S}^{(i-j)}_{nr}}+\hat{S}^{(j)}_{mr}\overline{\hat{S}^{(i-j)}_{nr}})\delta_{\lambda_m,\lambda_n} \quad (i\geqslant 2). \tag{2.12b}$$

Similarly, we arrive heuristically at the following matrix form of (2.4) by invoking (2.8), in particular,

$$V^{(1)}_{mn}=V_{mn}, \tag{2.13a}$$

$$V^{(i)}_{mn}=\sum_{r\in\mathbf{Z}_+^\nu}V^{(1)}_{mr}S^{(i-1)}_{rn}-\sum_{j=1}^{i-1}\sum_{r\in\mathbf{Z}_+^\nu}S^{(j)}_{mr}K^{(i-j)}_{rn} \quad (i\geqslant 2). \tag{2.13b}$$

Equations (2.7), (2.8), (2.13), and (2.12) allow us to calculate $\mathscr{S}^{(i)}$, $\mathscr{K}^{(i)}$ for $i\geqslant 1$ and $\mathscr{V}^{(i)}$ for $i\geqslant 2$ systematically in terms of $\mathscr{V}^{(1)}=(V_{mn})$.

Assuming that the sums in (2.12b) and (2.13b) converge,[24] it follows trivially from (2.7), (2.8), (2.12), and (2.13) that all the matrix elements $S^{(i)}_{mn}, K^{(i)}_{mn}, V^{(i)}_{mn}$ $(i\geqslant 1)$ are real, making the bars in the sum over r in (2.12b) superfluous. However, the reality of these matrix elements does not play a significant role in this paper, and hence it will usually be ignored.

We define an Nth-order approximant to the exact solution of the IVP (1.1) by[20]

$$\psi_N(t,\varepsilon)=S_N(\varepsilon)\exp(-itK_N(\varepsilon))S_N(\varepsilon)^*\psi_0. \tag{2.14}$$

We conclude this section by giving the promised heuristic derivation of the basic error estimate (1.4) for $\psi_N(t,\varepsilon)$. Differentiating (2.14) formally with respect to t and using (2.1), we obtain

$$i\,\frac{d\psi_N(t,\varepsilon)}{dt}=H_\varepsilon\psi_N(t,\varepsilon)+\varepsilon^{N+1}g_N(t,\varepsilon), \tag{2.15}$$

where $\|g_N(t,\varepsilon)\|=O(1)$ in ε formally. Integrating (2.15) by the method of variation of constants and using (2.11a), we find

$$\psi_N(t,\varepsilon)=\exp(-itH_\varepsilon)[I+\varepsilon^{N+1}U_N(\varepsilon)]\psi_0-i\varepsilon^{N+1}\int_0^t \exp[-i(t-s)H_\varepsilon]g_N(s,\varepsilon)ds. \tag{2.16}$$

By (2.16), $\psi(t,\varepsilon)=\exp(-itH_\varepsilon)\psi_0$, the unitarity of $\exp(-itH_\varepsilon)$, and the boundedness of $\|g_N(t,\varepsilon)\|$ and $\|U_N(\varepsilon)\psi_0\|$ for $t\in\mathbf{R}$, $0\leqslant\varepsilon\leqslant\varepsilon_0<\infty$ [see (4.42)], because of our hypotheses on V and the ω_is in Sec. III, we infer that

$$\begin{aligned}\|\psi(t,\varepsilon)-\psi_N(t,\varepsilon)\|&=\varepsilon^{N+1}\left\|U_N(\varepsilon)\psi_0+\int_0^t \exp(isH_\varepsilon)g_N(s,\varepsilon)ds\right\|\\&\leqslant\varepsilon^{N+1}\left(\|U_N\psi_0\|+\int_0^{|t|}\|g_N(s,\varepsilon)\|ds\right)\\&\leqslant\text{const }\varepsilon^{N+1}(|t|+1)\end{aligned}$$

at these t,ε-values.

III. ASSUMPTIONS AND MAIN RESULT

The considerations of the previous section were mostly heuristic. In the present section, we will state precise definitions and assumptions under which the results of this paper hold rigorously.

Until further notice, we fix $\nu\geqslant 2$ and assume that the potential V in (1.2) has the following properties:

(I) V is a maximal operator of multiplication in $\mathscr{H}=L^2(\mathbf{R}^\nu)$ by a real-valued function in $C^\infty(\mathbf{R}^\nu)$ which will also be denoted by V.

(II) For each $r=(r_1,\ldots,r_\nu)\in\mathbf{Z}_+^\nu$, there exist non-negative constants Γ_r,μ_r such that

$$\left|\frac{\partial^{|r|}V(x)}{\partial x_1^{r_1}\cdots\partial x_\nu^{r_\nu}}\right|\leqslant\Gamma_r(|x|+1)^{\mu_r}$$

at each $x=(x_1,\ldots,x_\nu)\in\mathbf{R}^\nu$, where $|r|=r_1+\cdots+r_\nu$ and $|x|=\Sigma_{i=1}^\nu|x_i|$.

(III) The differential operator

$$\frac{1}{2}\sum_{j=1}^{\nu}\left(-\frac{\partial^2}{\partial x_j^2}+\omega_j^2x_j^2\right)+\varepsilon V(x_1,\ldots,x_\nu)$$

on $C_0^\infty(\mathbf{R}^\nu)$ is essentially self-adjoint in $\mathscr{H}$ for each $\varepsilon\geqslant 0$, its unique self-adjoint extension in $\mathscr{H}$ being denoted by H_ε at each such ε. The frequencies ω_j are fixed positive numbers.

Remark: Property (III) is implied by (I) and (II) if $\frac{1}{2}\Sigma_{i=1}^\nu\omega_i^2x_i^2+\varepsilon V(x)$ is bounded below on $\mathbf{R}^\nu$.[27]

Given the set $\{\omega_1,...,\omega_\nu\}$ of ν positive numbers, there exists a maximum number $1\leqslant\rho\leqslant\nu$ of rationally independent ω_is, which by suitable labeling can (and will) be chosen to be $\{\omega_1,...,\omega_\rho\}$. Writing $|j|_\rho=\Sigma_{i=1}^{\rho}|j_i|$ for the norm of vectors $j\in\mathbf{R}^\rho$, we suppose that the following diophantine condition is satisfied:

(IV) If $\rho\geqslant 2$, there exist positive constants $\gamma,\ \eta$ such that for all $0\neq k=(k_1,\ldots,k_\rho)\in\mathbf{Z}^\rho$,

$$\left|\sum_{i=1}^{\rho}\omega_i k_i\right|\geqslant\gamma|k|_\rho^{-\eta},\tag{3.1}$$

where $\mathbf{Z}^r$ is the set of all vectors $(j_1,\ldots,j_r)$ whose components are integers.

Remarks: (1) Note that (IV) holds trivially if $\rho=1$. For in that case, (3.1) is satisfied for $0\neq k\in\mathbf{Z}$ if $\gamma\leqslant\omega_1,\ \eta>0$.

(2) If $\rho\geqslant 2$, then for each $m\in\mathbf{Z}_+^\nu$ one has $\inf\{|\lambda_m-\lambda_n|:n\in\mathbf{Z}_+^\nu,\lambda_m\neq\lambda_n\}=0$. This can cause convergence difficulties in sums [such as the first sum in (2.13b)] which involve differences of this type as factors in denominators. Condition (IV) is introduced to help control these small denominators. These difficulties are analogous to ones occurring in perturbation problems in classical mechanics.[28]

(3) It is well known that if $\rho\geqslant 2$ and $\eta\geqslant\nu$, then the set of vectors $(\omega_1,...,\omega_\rho)$ with positive components for which there exists no $\gamma>0$ such that the condition (3.1) holds for all $0\neq k\in\mathbf{Z}^\rho$ has Lebesgue measure zero.[29]

In order for our main theorem to have a precise meaning, we need to define the Nth-order approximant $\psi_N(t,\varepsilon)$ more carefully than in Sec. II. The following definitions and remarks are made for this purpose, as well as to set the stage for the developments of Sec. IV.

Definition 1: If A is an operator in a complex, separable Hilbert space $\mathscr{X}$, then we let[30]

$$C^\infty(A)=\bigcap_{j=1}^{\infty}D(A^j).$$

Remarks: (1) If A is self-adjoint, then $C^\infty(A)$ is dense in $\mathscr{X}$.[31] In particular, $C^\infty(H_0)$ is dense in $\mathscr{H}$ and contains the Schwartz space $S(\mathbf{R}^\nu)$ of functions of fast decrease.

(2) $C^\infty(H_0)$ is invariant under H_0, V, and the other key operators in this paper.

Our last assumption, which is motivated by these properties of $C^\infty(H_0)$ and by the desire to avoid unessential complications which would ensue by admitting ε-dependent initial states, is as follows:

(V) The initial state $\psi_0=\psi(0,\varepsilon)$ has the following properties:

$$\psi_0=\psi(0,\varepsilon)\in C^\infty(H_0),\tag{3.2a}$$

$$\psi_0\ \text{ is }\ \varepsilon\text{-independent.}\tag{3.2b}$$

Remark: Fix $\varepsilon\geqslant 0$. A simple but important fact is that our assumptions on V and ψ_0 entail the relation $\psi_0\in D(H_\varepsilon)$, and thus that the IVP (1.1) has the unique solution $\psi(t,\varepsilon)=\exp(-itH_\varepsilon)\psi_0$ for all $t\in\mathbf{R}$. To prove this relation, we use the fact that the operator $(H_0+\varepsilon V)|C^\infty(H_0)$ is a symmetric extension of the essentially self-adjoint operator $(H_0+\varepsilon V)|C_0^\infty(\mathbf{R}^\nu)$, as follows by (III) and $C_0^\infty(\mathbf{R}^\nu)\subset C^\infty(H_0)$. Since H_ε is defined as the unique self-adjoint extension of $(H_0+\varepsilon V)|C_0^\infty(\mathbf{R}^\nu)$, it follows that $D(H_\varepsilon)\supset C^\infty(H_0)$. By this and (3.2a), $\psi_0\in D(H_\varepsilon)$.

Infinite sums were used heuristically in Sec. II. The next definition states the sense in which such sums will be understood henceforth.

Definition 2: Fixing $p \in \mathbf{N}$, let $\Gamma = \mathbf{Z}_+^p$; let $\{\Psi_\alpha\}$ $(\alpha \in \Gamma)$ be an orthonormal set in a Hilbert space $\mathscr{X}$; and $\{\Delta_n\}$ be a sequence of finite subsets $\Delta_n \subset \Gamma$ such that Δ_n eventually contains any given finite subset of Γ. A sum of the form $\Sigma_{\alpha\in\Gamma} g_\alpha$ with each $g_\alpha \in \mathbf{C}$ is defined as $\lim_{n\to\infty} \Sigma_{\alpha\in\Delta_n} g_\alpha$ in the $\mathbf{C}$-topology if the limit exists. Analogously, a sum of the form $\Sigma_{\alpha\in\Gamma} g_\alpha \Psi_\alpha$ is defined as s $-$ $\lim_{n\to\infty} \Sigma_{\alpha\in\Delta_n} g_\alpha \Psi_\alpha$ in the strong operator topology in $\mathscr{X}$ if the limit exists.

Definition 3: Let $\Psi = \{\Psi_\alpha\}$ $(\alpha \in \Gamma)$ be a complete orthonormal set in a complex Hilbert space $\mathscr{X}$ with inner product $\langle .,. \rangle$, which we agree is antilinear in the first argument and linear in the second. Here Γ is as above. Let $\mathscr{A} = (A_{\alpha\beta})(\alpha,\beta \in \Gamma)$ be a matrix of complex numbers which is square-summable by rows and columns, i.e., $\Sigma_{\alpha\in\Gamma} |A_{\alpha\beta}|^2 < \infty$ $(\beta \in \Gamma)$ and $\Sigma_{\beta\in\Gamma} |A_{\alpha\beta}|^2 < \infty$ $(\alpha \in \Gamma)$, respectively. Then the linear operator A with domain

$$D(A) = \left\{ f \in \mathscr{X} : \sum_{\alpha\in\Gamma} \left| \sum_{\beta\in\Gamma} A_{\alpha\beta} \langle \Psi_\beta, f \rangle \right|^2 < \infty \right\} \tag{3.3a}$$

and action

$$Af = \sum_{\alpha\in\Gamma} \left(\sum_{\beta\in\Gamma} A_{\alpha\beta} \langle \Psi_\beta, f \rangle \right) \Psi_\alpha \quad (f \in D(A)) \tag{3.3b}$$

will be said to be *associated* with $\mathscr{A}$ wrt Ψ, or $A \leftrightarrow \mathscr{A}$ wrt Ψ.

Remarks: (1) Stone[32] has considered linear operators associated with infinite matrices in the sense of Definition 3.

(2) Note that the sums over β in (3.3a) and (3.3b) converge absolutely, because of the square-summability of $\mathscr{A}$ by columns, together with Schwarz's inequality in $\ell^2(\Gamma)$ and Parseval's identity.

(3) Note also that the condition $A \leftrightarrow \mathscr{A}$ wrt Ψ implies: (i) A^* exists, (ii) $\Psi \subset D(A) \cap D(A^*)$, and (iii) $A_{\alpha\beta} = \langle \Psi_\alpha, A\Psi_\beta \rangle$ $(\alpha,\beta \in \Gamma)$. Properties (i)–(iii) follow by the square-summability properties of $\mathscr{A}$ and the orthonormality and completeness of the Ψ_αs.

(4) The product $\mathscr{A}.\mathscr{B}$ of two infinite matrices $\mathscr{A},\mathscr{B}$ with which linear operators A,B in $\mathscr{X}$ are associated wrt Ψ exists. Indeed, the square-summability of $\mathscr{A}$ by columns and of $\mathscr{B}$ by rows entails that $(\mathscr{A}.\mathscr{B})_{\alpha\beta} = \Sigma_{\sigma\in\Gamma} A_{\alpha\sigma} B_{\sigma\beta}$ converges absolutely by Schwarz's inequality in $\ell^2(\Gamma)$. However, even if the product AB of two such operators exists, it is not necessarily associated with $\mathscr{A}.\mathscr{B}$ wrt Ψ. These and other pathologies of infinite matrices generally severely limit their usefulness for investigating the properties of linear operators.[33] However, the infinite matrices associated with the linear operators considered in this paper are sufficiently well behaved to be effective tools for the task of deriving its conclusions.

Definition 4: The set of linear operators in $\mathscr{H}$ whose domains contain the dense set $C^\infty(H_0)$ and leave it invariant is denoted by $\mathscr{M}$.

In this section and Sec. IV we will proceed in a manner which is partly the reverse of that in Sec. II. This means that certain definitions in the previous section, when stated precisely, will now be consequences of Definitions 5(a)–5(c) below.

Definition 5(a): The infinite matrices $\tilde{\mathscr{S}}^{(i)} = (\tilde{S}^{(i)}_{mn})$, $\hat{\mathscr{S}}^{(i)} = (\hat{S}^{(i)}_{mn})$, $\mathscr{V}^{(i)} = (V^{(i)}_{mn})$, $\mathscr{K}^{(i)} = (K^{(i)}_{mn})$ $(i \geqslant 1)$ are defined recursively as follows:

(1) One defines

$$\tilde{S}^{(i)}_{mn} = \begin{cases} -V^{(i)}_{mn}/(\lambda_m - \lambda_n) & \lambda_m \neq \lambda_n, \\ 0, & \lambda_m = \lambda_n, \end{cases} \tag{3.4}$$

for $i \geqslant 1$ and defines $\hat{S}^{(i)}_{mn}$ by (2.12a) [resp., (2.12b)] for $i = 1$ (resp., $i \geqslant 2$).

(2) The $K^{(i)}_{mn}$s are given by (2.8) for $i \geqslant 1$. Each $V^{(1)}_{mn}$ is defined by (2.13a), with

$$V_{mn} = \langle \Phi_{mn}, V\Phi_n \rangle, \tag{3.5}$$

as before, and the $V_{mn}^{(i)}$s by (2.13b) for $i \geqslant 2$.

Remarks: (1) Note that $D(V) \supset S(\mathbf{R}^\nu) \supset \Phi$ by (I) and (II) in particular, where again $S(\mathbf{R}^\nu)$ denotes the Schwartz space of functions of fast decrease on $\mathbf{R}^\nu$ and Φ the harmonic oscillator basis defined in Sec. II. Thus definition (2.13a) makes sense.

(2) Estimates (4.13) (Sec. IV) play a central role in showing that the infinite sums over r in (2.12b) and (2.13b) converge absolutely. Thus (2.12b) and (2.13b) make sense as recursive definitions.

Definition 5(b): (1) For $i \geqslant 1$, the operators $\widetilde{S}^{(i)}, \hat{S}^{(i)}, K^{(i)}, V^{(i)}$ are those associated with the respective matrices $\widetilde{\mathscr{S}}^{(i)}, \hat{\mathscr{S}}^{(i)}, \mathscr{K}^{(i)}, \mathscr{V}^{(i)}$ wrt Φ,[34] and $S^{(i)}$ is defined as the operator sum $\widetilde{S}^{(i)} + \hat{S}^{(i)}$.

(2) For $\varepsilon \geqslant 0$, $N \geqslant 1$, the operators $S_N(\varepsilon), K_N(\varepsilon), R_N(\varepsilon)$ are defined by the rhs of (2.2a), (2.2b), (2.3b), respectively, viewed as operator sums.

Remarks: (1) Since all the matrices in part (1) of Definition 5(b) are square-summable by rows and columns, as follows by using, in particular, estimates (4.13), the definitions of $\widetilde{S}^{(i)}, \hat{S}^{(i)}, K^{(i)}, V^{(i)}$ make sense for all $i \geqslant 1$.

(2) By Lemma 4(1),[35] $\widetilde{S}^{(i)}, \hat{S}^{(i)}, K^{(i)}, V^{(i)}$ $(i \geqslant 1)$ are in $\mathscr{M}$, and therefore they and $S^{(i)}$ $(i \geqslant 1)$, $S_N(\varepsilon), K_N(\varepsilon), R_N(\varepsilon)$ are densely defined in $\mathscr{H}$. Hence the adjoints of all these operators exist, and by Lemma 4(2) they also are in $\mathscr{M}$.

Definition 5(c): The Nth-order approximant $\psi_N(t,\varepsilon)$ is defined for all $N \geqslant 1$, $t \in \mathbf{R}$, $\varepsilon \geqslant 0$ by

$$\psi_N(t,\varepsilon) = S_N(\varepsilon) \exp(-it\overline{K_N}(\varepsilon)) S_N(\varepsilon)^* \psi_0, \tag{3.6}$$

where $\overline{K_N}(\varepsilon)$ is the unique self-adjoint extension (closure) of $K_N(\varepsilon)$ in Definition 5(b), $S_N(\varepsilon)$ is as in the latter definition, and ψ_0 is an initial state satisfying conditions (3.2).

Remarks: (1) The existence of $K_N(\varepsilon)$ is guaranteed by Lemma 6.

(2) Definition 5(c) makes sense in view of (3.2a) and of the facts that $S_N(\varepsilon), S_N(\varepsilon)^* \in \mathscr{M}$ and that $\exp(-itK_N(\varepsilon))$ is a well-defined unitary operator in $\mathscr{M}$ [see step (4) of the proof of Lemma 6]. The self-adjointness of $K_N(\varepsilon)$ ensures that this exponential makes sense.

(3) The operator $K_N(\varepsilon)$ just defined is nothing more than a precise version of the operator denoted by $K_N(\varepsilon)$ is Sec. II. Indeed, all operator equations in that section involving $K_N(\varepsilon)$ hold rigorously on appropriate dense domains with $K_N(\varepsilon)$ replaced by $\overline{K_N}(\varepsilon)$, provided that the remaining operators in these equations are understood in the sense of the present section. This readily follows from the relevant definitions, together with results proved in Sec. IV.

We are now ready to state our main result.

Theorem 1: Let H_0 and V obey conditions (I)–(III), let (IV) hold if $\rho \geqslant 2$, and let the initial state satisfy condition (V). Then for each $N \geqslant 1$, $0 \leqslant \varepsilon_0 < \infty$ we have the uniform estimate

$$\|\psi(t,\varepsilon) - \psi_N(t,\varepsilon)\| \leqslant C_N \varepsilon^{N+1}(|t|+1) \tag{3.7}$$

if $t \in \mathbf{R}$, $0 \leqslant \varepsilon \leqslant \varepsilon_0$, where $\|.\|$ is the $\mathscr{H}$-norm and $C_N = C_N(\psi_0, \varepsilon_0)$ is a positive constant.

Remarks: (1) This theorem is the first rigorous result of this degree of generality applying to cases in which V is not a polynomial and/or H_0 has degenerate eigenvalues. Its conclusions hold for $\nu = 1$ under the assumption that (I)–(III) hold. The proof of this statement which is sketched in Ref. 21 is much simpler than that of Theorem 1.

(2) Lochak[3] (resp., Case[4]) arrived at an Nth-order quantum-averaging error estimate of type (3.7) [resp., stronger than (3.7)] under an assumption of operator boundedness which does not hold in the present context. Besides being partially heuristic, the corresponding proof in Ref. 4 is incomplete [there is an obvious misprint in Eq. (124) of that reference]. Rigorous estimates of type (3.7) for various quantum mechanical systems with unbounded Hamiltonian operators were first derived by Ben Lemlih and Ellison.[7,8] Estimates of this kind were proved in Refs. 12 and 13 for multi-dimensional nonresonant oscillator systems coupled by potentials which are polynomials in the coordinates and momenta.

(3) An obvious but important consequence of Theorem 1, noted in Refs. 3 and 4, is that, under the conditions in Theorem 1, $\psi_N(t,\varepsilon)$ approximates $\psi(t,\varepsilon)$ uniformly in norm over $O(\varepsilon^{-\delta})$ t-intervals for each $\delta\in(0,N+1]$. More precisely, for each such δ and each pair of positive numbers T,ε_0,

$$\|\psi(t,\varepsilon)-\psi_N(t,\varepsilon)\|\leqslant C'_{N,\delta}\varepsilon^{N+1-\delta} \tag{3.8}$$

for $0\leqslant t\leqslant T\varepsilon^{-\delta}$, where $C'_{N,\delta}=C'_{N,\delta}(\psi_0,\varepsilon_0,T)$ is a positive constant. This is a very unusual result in averaging theory, where generally the analogous approximations have only been expected (and proved) to be valid over $O(\varepsilon^{-1})$ time intervals. Key properties leading to (3.7), and hence to (3.8), are the linearity of the IVP (1.1), together with the facts that $\psi(t,\varepsilon)$ and $\psi_N(t,\varepsilon)$ exist for $t\in\mathbf{R}$, $\varepsilon\geqslant 0$, that H_ε is self-adjoint at each such ε, and that the uniform boundedness properties (4.41) hold.

IV. AUXILIARY RESULTS AND PROOF OF THEOREM 1

Lemmas 1–7 below will be used to prove our main result—Theorem 1. In this section, we fix $N\geqslant 1$, $\nu\geqslant 2$, and the number $\rho\in\{1,...,\nu\}$ of rationally independent frequencies ω_i. We will denote the positive integers by $\mathbf{N}$ and the non-negative integers by $\mathbf{Z}_+$, and, as usual, $\mathbf{Z}^\nu$ will signify the set of all vectors $(n_1,\ldots,n_\nu)$ with integer components (positive, negative, or zero). Recall that for $j=(j_1,\ldots,j_\rho)\in\mathbf{R}^\rho$ we defined $|j|_\rho=\Sigma_{i=1}^{\rho}|j_i|$. However, when $j=(j_1,\ldots j_\nu)\in\mathbf{R}^\nu$, we will write $|j|=\Sigma_{i=1}^{\nu}|j_i|$ and $(\omega,j)=\Sigma_{i=1}^{\nu}\omega_i j_i$.

The following simple lemma is relevant to the proofs of Lemmas 3 and 7.

Lemma 1: (1) For any $m,n\in\mathbf{Z}_+^\nu$ such that $\lambda_m\neq\lambda_n$, the eigenvalues of H_0 satisfy the inequality

$$|\lambda_m-\lambda_n|\geqslant\text{const}|m-n|^{-\eta}, \tag{4.1a}$$

where η is the positive constant in Condition (IV) and const is independent of m,n.[36]

(2) The following estimate holds for the multiplicity g_m of λ_m:

$$g_m\leqslant(|m|+1)^{\nu-\rho}. \tag{4.1b}$$

Proof: (1) Fix $k=(k_1,\ldots,k_\nu)\in\mathbf{Z}^\nu$ such that $(\omega,k)\neq 0$. Since $\{\omega_1,...,\omega_\rho\}$ is a maximal rationally independent subset of $\{\omega_1,...,\omega_\nu\}$,

$$(\omega,k)=\frac{1}{M}\sum_{i=1}^{\rho}\omega_i\left(\sum_{j=1}^{\nu}t_{ij}k_j\right), \tag{4.2}$$

where each $t_{ij}=t_{ij}(\rho)$ is an integer and $M=M(\rho)$ is a positive integer. Moreover, since $(\omega,k)\neq 0$, it follows trivially that $k\neq 0$ and that at least one of the integers $\Sigma_{j=1}^{\nu}t_{ij}k_j$ $(i=1,...,\rho)$ is nonvanishing. Therefore, one has for the fixed $\rho\geqslant 1$ of interest, by (4.2), (IV), and Remark (1) to (IV),

$$|(\omega,k)|\geqslant\frac{\gamma}{M}\left(\sum_{i=1}^{\rho}\left|\sum_{j=1}^{\nu}t_{ij}k_j\right|\right)^{-\eta}\geqslant\text{const}|k|^{-\eta}. \tag{4.3}$$

But (2.5c) implies that

$$\lambda_m-\lambda_n=(\omega,m-n). \tag{4.4}$$

Statement (4.1a) follows immediately for $\lambda_m\neq\lambda_n$ from (4.3) and (4.4).

(2) Estimate (4.1b) follows by the rational independence of $(\omega_1,...,\omega_\rho)$ and a simple combinatorial argument. □

The next lemma provides an estimate which is needed in the proof of Lemma 3, and in turn that lemma is a basic logical underpinning of the remainder of this section.

Lemma 2: For all $m,n\in\mathbf{Z}_+^\nu$,

$$|V_{mn}|\leqslant \text{const}\ \lambda_m^{\alpha(1,p)}\lambda_n^{-p}\quad (p\in\mathbf{N}), \tag{4.5}$$

where const and $\alpha(1,p)$ are independent of m,n, but may depend on p.

Proof: Since the spectrum of H_0 is in $(0,\infty)$, H_0^{-1} exists. Combining this fact with (3.5), the self-adjointness of V and H_0 [by (I) and (III)], and $V\Phi_n\in C^\infty(H_0)$ [by (I) and $\Phi_n\in S(\mathbf{R}^\nu)$], we may write

$$\begin{aligned}|V_{mn}|=|\langle\Phi_m,V\Phi_n\rangle|=|\langle\Phi_n,V\Phi_m\rangle|=|\langle H_0^{-p}\Phi_n,H_0^pV\Phi_m\rangle|=\lambda_n^{-p}|\langle\Phi_n,H_0^pV\Phi_m\rangle|\\ \leqslant\lambda_n^{-p}\|H_0^pV\Phi_m\|\end{aligned} \tag{4.6}$$

at each of the stated m,n,p values.

To complete the proof of the lemma, we will estimate $\|H_0^pV\Phi_m\|$ in steps (1)–(3).

(1) The first step is to prove that

$$H_0^pV\Phi_m=\sum_{k=0}^{p}E_{k,p}\lambda_m^{p-k}[\Delta,\ V]_k\Phi_m\quad (p\in\mathbf{N}), \tag{4.7}$$

where $\Delta=\Sigma_{j=1}^{\nu}\partial^2/\partial x_j^2$, the $E_{k,p}$s are constants independent of m, and the multiple commutator $[A,\ B]_k$ $(k\geqslant 0)$ of two operators A and B in a Hilbert space is defined as usual by

$$[A,\ B]_0=B,\ \ [A,\ B]_1=AB-BA,$$

$$[A,\ B]_k=[A,[A,\ B]_{k-1}]\quad (k\geqslant 2),$$

on elements in this space where these definitions make sense.

Equation (4.7) follows easily by induction, noting in particular that it holds for $p=1$, in view of

$$H_0V\Phi_m=VH_0\Phi_m+[H_0,\ V]\Phi_m=\lambda_mV\Phi_m-\tfrac{1}{2}[\Delta,\ V]\Phi_m,$$

where we have used, in particular, the fact that (1.3) holds on $S(\mathbf{R}^\nu)\supset\Phi$.

(2) Note that

$$[\Delta,\ V]_jg=\sum_{|r|+|s|=2j}F_{rs}^{(j)}D^{|r|}V.D^{|s|}g\quad [j\geqslant 1,g\in S(\mathbf{R}^\nu)], \tag{4.8}$$

where the $F_{rs}^{(j)}$s are constants and $D^{|r|}=\partial^r/\partial x_1^{r_1}\cdots\partial x_\nu^{r_\nu}$, with $r=(r_1,\ldots,r_\nu),s\in\mathbf{Z}_+^\nu$. For each such g, Eq. (4.8) holds trivially for $j=1$ and is easily proved by induction for $j\geqslant 1$.

By (4.7) and (4.8),

$$\|H_0^pV\Phi_m\|\leqslant\text{const}\sum_{k=0}^{p}\lambda^{p-k}\sum_{|r|+|s|=2k}\|D^{|r|}V.D^{|s|}\Phi_m\|\quad (p\in\mathbf{N}), \tag{4.9}$$

where the constant is independent of m.

(3) In this step, we estimate $\|D^{|r|}V.D^{|s|}\Phi_m\|$ in (4.9) for fixed $r,s\in\mathbf{Z}_+^\nu$. In doing this, we will assume wlg that μ_r in condition (II) is a *non-negative integer*.

By considering the regions $|x|<1$, $|x|>1$ in $\mathbf{R}^\nu$ and using (II), we arrive at the inequality

$$\|D^{|r|}V.D^{|s|}\Phi_m\| \leqslant \text{const}\left[\|D^{|s|}\Phi_m\| + \left\|\left(\sum_{i=1}^{\nu} x_i^2\right)^{\mu_r/2} D^{|s|}\Phi_m\right\|\right]. \tag{4.10}$$

The rhs of (4.10) may be estimated by using the inequality

$$\left\|\left(\sum_{i=1}^{\nu} x_i^2\right)^{\mu_r/2} D^{|s|}\Phi_m\right\| \leqslant \text{const } \lambda_m^{(k+|s|)/2} \quad (k \in \mathbf{Z}_+). \tag{4.11}$$

This inequality can be proved by expressing each $x_j, \partial/\partial x_j$ $(j=1,...,\nu)$ inside the norm in terms of creation and annihilation operators $a_j, a_j^{\dagger}$:

$$a_j = 2^{-1/2}\left(x_j + i\,\frac{\partial}{\partial x_j}\right), \quad a_j^{\dagger} = 2^{-1/2}\left(x_j - i\,\frac{\partial}{\partial x_j}\right),$$

and using an estimate analogous to one which holds in the case $\nu=1$.[37]

By (4.10), (4.11), and the fact that $\lambda_m^{-\mu}$ is bounded as a function of m for fixed $\mu \geqslant 0$,

$$\|D^{|r|}V.D^{|s|}\Phi_m\| \leqslant \text{const } \lambda_m^{(\mu_r+|s|)/2}. \tag{4.12}$$

The desired inequality (4.5) follows immediately from (4.6), (4.9), and (4.12). □

Lemma 3: The inductive definitions (2.12b) and (2.13b) make sense for $i \geqslant 2$ and $m,n \in \mathbf{Z}_+^{\nu}$, and the following estimates hold for all $i,p \in \mathbf{N}$ and all such m,n:

$$|V_{mn}^{(i)}| \leqslant \text{const } \lambda_m^{\alpha(i,p)}\lambda_n^{-p}, \tag{4.13a}$$

$$|V_{mn}^{(i)}| \leqslant \text{const } \lambda_n^{\alpha(i,p)}\lambda_m^{-p}, \tag{4.13b}$$

$$|\tilde{S}_{mn}^{(i)}| \leqslant \text{const } \lambda_m^{\beta(i,p)}\lambda_n^{-p} \quad (\lambda_m \neq \lambda_n), \tag{4.13c}$$

$$|\tilde{S}_{mn}^{(i)}| \leqslant \text{const } \lambda_n^{\beta(i,p)}\lambda_m^{-p} \quad (\lambda_m \neq \lambda_n), \tag{4.13d}$$

$$|\hat{S}_{mn}^{(i)}| \leqslant \text{const } \lambda_m^{\gamma(i)} \quad (\lambda_m = \lambda_n), \tag{4.13e}$$

where the real constants $\alpha(i,p), \beta(i,p), \gamma(i)$ and the other constants in these estimates are independent of m,n.

Proof: It will be inductive. Fixing $i \in \mathbf{N}$ until further notice, we remark that the assumption that (4.13a) obtains at each $p \in \mathbf{N}$, together with (2.7) and (4.1a), entails for $\lambda_m \neq \lambda_n$:

$$|\tilde{S}_{mn}^{(i)}| \leqslant \text{const } \lambda_m^{\alpha(i,q)}\lambda_n^{-q}|m-n|^{\eta} \leqslant \text{const } \lambda_m^{\alpha(i,q)+\eta}\lambda_n^{-q+\eta} \leqslant \text{const } \lambda_m^{\alpha(i,q)+\eta}\lambda_n^{-q+\eta[\eta]+1} \quad (q \in \mathbf{N}), \tag{4.14}$$

where $[y]$ denotes the greatest integer $\leqslant y \in \mathbf{R}$. In arriving at (4.14) we have also used the crude inequality $|m-n| \leqslant \text{const } \lambda_m\lambda_n$, holding for $m \neq n$, and the fact that $\lambda_n^{\eta}/\lambda_n^{[\eta]+1}$ is bounded for $|n| \to \infty$. Because of (4.14), (4.13c) holds for all $p \in \mathbf{N}$, as one sees by setting $p = q - [\eta] - 1$ and $\beta(i,p) = \alpha(i,q) + \eta$. Similar arguments entail that (4.13d) holds for all such p if (4.13b) does. We have thus reduced the task of establishing that Eqs. (4.13) obtain for each $i,p \in \mathbf{N}$ to proving that (4.13a), (4.13b), and (4.13e) do.

Note that estimates (4.13a)–(4.13e) hold for $i=1$, $p \in \mathbf{N}$, by $V_{mn}^{(1)} = V_{mn} = V_{nm}$, (4.5), (2.12a), and the results of the last paragraph. In steps (1)–(3) below, we will show that if these five estimates obtain for all $1 \leqslant i \leqslant k$ for some $k \geqslant 1$, they also obtain for $i = k+1$, and thus for all $i \geqslant 1$.[38]

(1) In order to prove that (4.13a) holds for $i=k+1$, we will use the inequality

$$|V_{mn}^{(k+1)}| \leqslant \sum_r |V_{mr}^{(1)}|(|\tilde{S}_{rn}^{(k)}|+|\hat{S}_{rn}^{(k)}|)+\sum_{j=1}^{k}\sum_r (|\tilde{S}_{mr}^{(j)}|+|\hat{S}_{mr}^{(j)}|)|K_{rn}^{(k-j+1)}|\ , \tag{4.15}$$

which is an obvious formal consequence of definition (2.13b) for $i=k+1$.[39] Our inductive approach will show that the first sum over r in (4.15) converges (the second such sum contains only a finite series of nonvanishing terms by (2.8) and $g_m<\infty$), thereby entailing that the latter definition makes sense for $i=k+1$, and hence for $i\geqslant 2$.

We claim that

$$\sum_r |V_{mr}^{(1)}|\cdot|\tilde{S}_{rn}^{(k)}| \leqslant \text{const}\ \lambda_m^{a(k,p)}\lambda_n^{-p}, \tag{4.16a}$$

$$\sum_r |V_{mr}^{(1)}|\cdot|\hat{S}_{rn}^{(k)}| \leqslant \text{const}\ \lambda_m^{b(k,p)}\lambda_n^{-p}, \tag{4.16b}$$

$$\sum_r |\tilde{S}_{mr}^{(j)}|\cdot|K_{rn}^{(k-j+1)}| \leqslant \text{const}\ \lambda_m^{c(k,p)}\lambda_n^{-p}, \tag{4.16c}$$

$$\sum_r |\hat{S}_{mr}^{(j)}|\cdot|K_{rn}^{(k-j+1)}| \leqslant \text{const}\ \lambda_m^{d(k,p)}\lambda_n^{-p}\delta_{\lambda_m,\lambda_n} \tag{4.16d}$$

for all $p\in\mathbf{N}$ and all $j=1,\ldots,k$, where const and $a(k,p),\ldots,d(k,p)$ denote constants independent of m,n. Choosing $a(k+1,p)\geqslant\max\{a(k,p),\ldots,d(k,p)\}$, (4.13a) follows for $i=k+1$ by (4.15) and (4.16). We will only prove (4.16a) and (4.16c) in detail; (4.16b) and (4.16d) can be established similarly to (4.16c).

To prove (4.16a), we need the estimate

$$\sum_{r\in\mathbf{Z}_+^\nu} \lambda_r^{-\mu}<\infty \quad (\mu>\nu), \tag{4.17}$$

which follows by (2.5c), the positivity of the ω_is, and a well-known result.[40] Using (4.5), (4.13a) for $i=1,\ldots,k$, and (4.17), we obtain

$$\sum_r |V_{mr}^{(1)}|\cdot|\tilde{S}_{rn}^{(k)}| \leqslant \text{const}\ \lambda_m^{\alpha(1,q)}\lambda_n^{-p}\sum_r \lambda_r^{\beta(k,p)}\lambda_r^{-q}<\infty$$

at each $p\in\mathbf{N}$ if $q=q(k,p)$ is a positive integer $>\beta(k,p)+\nu$. Thus (4.16a) holds with $a(k,p)=\alpha(1,q(k,p))$.

To prove (4.16c), we use (4.13a) and (4.13d) for $i=1,\ldots,k$, together with (2.8) and the inequality

$$g_n \leqslant \text{const}\ \lambda_n^{\nu-\rho} \tag{4.18}$$

[which follows from (4.1b) and (2.5c)] to infer that

$$\begin{aligned}\sum_r |\tilde{S}_{mr}^{(j)}|\cdot|K_{rn}^{(k-j+1)}| &\leqslant \text{const}\sum_r \lambda_m^{\beta(j,s)}\lambda_r^{-s}\cdot\lambda_r^{\alpha(k-j+1,1)}\lambda_n^{-1}\delta_{\lambda_r,\lambda_n}\\ &= \text{const}\ \lambda_m^{\beta(j,s)}\lambda_n^{-s+\alpha(k-j+1,1)-1}g_n \leqslant \text{const}\ \lambda_m^{\beta(j,s)}\lambda_n^{-s+\alpha(k-j+1,1)-1+\nu-\rho}\end{aligned}$$

if $s\in\mathbf{N}$. Choosing a positive integer $s=s(k,p)>p+|\alpha(k-j+1,1)|+\nu-p-1$ for every $p\in\mathbf{N}$, and since $\lambda_n^{-\mu}$ is bounded for $|n|\to\infty$ for fixed $\mu>0$, we conclude that

$$\sum_r |\tilde{S}^{(j)}_{mr}| \cdot |K^{(k-j+1)}_{rn}| \leqslant \text{const } \lambda_m^{\beta(j,s(k,p))} \lambda_n^{-p}$$

at each such p. Thus (4.16c) holds for all $p \in \mathbf{N}$ and all $j=1,\ldots,k$ if we set $c(k,p) = \max_{1\leqslant\sigma\leqslant k} \beta(\sigma,s(k,p))$.

(2) To show that (4.13b) is true for $i=k+1$, we first note that estimates (4.16a)–(4.16c) hold with m and n interchanged if $a(k,p),b(k,p),c(k,p)$ are replaced by suitable constants $\tilde{a}(k,p),\tilde{b}(k,p),\tilde{c}(k,p)$ in the respective rhs of these estimates. This remark and the fact that the rhs of (4.16d) is symmetric with respect to this interchange obviously imply that (4.13b) holds for $i=k+1$ if we choose $\alpha(k+1,p) \geqslant$ than the largest of the seven constants $a(k,p),\ldots,d(k,p)$, $\tilde{a}(k,p),\ldots,\tilde{c}(k,p)$. That estimates (4.16a)–(4.16c) hold in the modified form mentioned in the penultimate sentence follows by arguments similar to, but somewhat simpler than, those used to prove them in their original form.

(3) Recall that in step (1) we demonstrated inductively that the first sum over r in (2.13b) converges absolutely for $i \geqslant 2$, and hence that (2.13b) makes sense. We will now complete the proof of the present lemma by showing that definition (2.12b) also makes sense for $i \geqslant 2$ and that (4.13e) is true at each such i.

By (2.12b), we find formally

$$|\hat{S}^{(i)}_{mn}| \leqslant \frac{1}{2} \sum_{j=1}^{i-1} \sum_r (|\tilde{S}^{(j)}_{mr}||\tilde{S}^{(i-j)}_{nr}| + |\hat{S}^{(j)}_{mr}| \cdot |\hat{S}^{(i-j)}_{nr}|)\, \delta_{\lambda_m,\lambda_n} \quad (i \geqslant 2). \tag{4.19}$$

Because of our inductive hypothesis, the sum over r in (4.19) converges for $1 \leqslant j \leqslant i-1, 2 \leqslant i \leqslant k+1$. This assertion and the fact that (4.13e) holds for $i=k+1$ follow from the assumption that (4.13d) and (4.13e) obtain for $i=1,\ldots,k$, together with arguments similar to those adduced to derive (4.16a) and (4.16c). We have thus proved (4.13e) for arbitrary $i \geqslant 1$. Hence our proof that the sum over r in (4.19) converges for $i=k+1$ extends to all $i \geqslant 2$ and implies that the recursive definition (2.12b) makes sense for all such i. □

Lemma 4: (1) At each $i \geqslant 1$, $V^{(i)},K^{(i)},\tilde{S}^{(i)},\hat{S}^{(i)}$ are well-defined operators in $\mathscr{M}$, and hence so are $S^{(i)},S_N(\varepsilon),K_N(\varepsilon),R_N(\varepsilon)$ [Definition 5(b)].

(2) At each $i \geqslant 1$, the adjoints $V^{(i)*},K^{(i)*},\tilde{S}^{(i)*},\hat{S}^{(i)*}$ exist and are in $\mathscr{M}$, and hence so are $S^{(i)*},S_N(\varepsilon)^*,K_N(\varepsilon)^*,R_N(\varepsilon)^*$.

Proof: (1) We fix $i \geqslant 1$ in the proof. In order to show that $V^{(i)},K^{(i)},\tilde{S}^{(i)},\hat{S}^{(i)}$ are well defined, it suffices to show that the respective matrices with which they are associated are square-summable by rows and columns. This is trivially true for $\mathscr{K}^{(i)}$ and $\hat{\mathscr{S}}^{(i)}$. Indeed, by (2.8), (2.12a), and (2.12b) the $K^{(i)}_{mn}$s and $\hat{S}^{(i)}_{mn}$s are nonzero only if $\lambda_m \neq \lambda_n$, and therefore at most for a finite number of n-values for each m, and vice versa. We proceed to show that these two square-summability properties are possessed by $\mathscr{V}^{(i)}$, $\tilde{\mathscr{S}}^{(i)}$.

As to $\mathscr{V}^{(i)}$, we note that (4.13b) and (4.17) entail

$$\sum_m |V^{(i)}_{mn}|^2 \leqslant \text{const } \lambda_n^{2\alpha(i,p)} \sum_m \lambda_m^{-2p} < \infty \quad (n \in \mathbf{Z}_+^\nu) \tag{4.20a}$$

for‘ each positive integer $p > \nu/2$. The fact that

$$\sum_n |V^{(i)}_{mn}|^2 < \infty \quad (m \in \mathbf{Z}_+^\nu) \tag{4.20b}$$

follows similarly from (4.13a) and (4.17). As to $\tilde{\mathscr{S}}^{(i)}$, its square-summability by rows (resp., by columns) follows from (4.13d) [resp., (4.13c)] via considerations of the type invoked to prove (4.20a) [resp., (4.20b)].

We show next that $V^{(i)} \in \mathscr{M}$, i.e., that $H_0^p V^{(i)} f \in \mathscr{H}$ for all $p \in \mathbf{Z}_+$, $f \in C^\infty(H_0)$. This is the case iff

$$\sum_m \lambda_m^{2p} \Big| \sum_n V_{mn}^{(i)} \langle \Phi_n, f \rangle \Big|^2 < \infty \quad [p \in \mathbf{Z}_+, f \in C^\infty(H_0)], \tag{4.21}$$

as follows from $V^{(i)} \leftrightarrow \mathscr{V}^{(i)}$, the orthonormality and completeness of Φ, and the spectral theorem for H_0^p. By the positivity of the λ_ms and Schwarz's inequality in $\ell^2(\mathbf{Z}_+^\nu)$, (4.21) holds if

$$\sum_{m,n} \lambda_m^p |V_{mn}^{(i)}| \cdot |\langle \Phi_n, f \rangle| < \infty \quad [p \in \mathbf{Z}_+, f \in C^\infty(H_0)]. \tag{4.22}$$

To prove that condition (4.22) is satisfied, we invoke (4.13b), (4.17), and the inequality

$$|\langle \Phi_n, g \rangle| \leqslant \lambda_n^{-r} \| H_0^r g \| \quad [r \in \mathbf{N}, g \in C^\infty(H_0)], \tag{4.23}$$

whose derivation is similar to that of (4.6). We thus see that at each p, f in (4.22)

$$\begin{aligned} \sum_{m,n} \lambda_m^p |V_{mn}^{(i)}| \cdot |\langle \Phi_n, f \rangle| &\leqslant \text{const} \sum_{m,n} \lambda_m^p \cdot \lambda_n^{\alpha(i,q)} \lambda_m^{-q} \cdot \lambda_n^{-r} \| H_0^r f \| \\ &\leqslant \text{const} \Big(\sum_m \lambda_m^{p-q} \Big) \Big(\sum_n \lambda_n^{\alpha(i,q)-r} \Big) \| H_0^r f \| < \infty \end{aligned}$$

at every $q, r \in \mathbf{N}$, such that $q > p + \nu, r > \alpha(i,q) + \nu$.

In view of (2.8), (4.22) holds with $V_{mn}^{(i)}$ replaced by $K_{mn}^{(i)}$. This fact and $K^{(i)} \leftrightarrow \mathscr{K}^{(i)}$ entail $K^{(i)} \in \mathscr{M}$ by considerations analogous to those adduced to prove $V^{(i)} \in \mathscr{M}$. Considerations of the same type based on (4.13d) and (4.13e), in particular, show that $\tilde{S}^{(i)}, \hat{S}^{(i)} \in \mathscr{M}$. Recalling the definition $S^{(i)} = \tilde{S}^{(i)} + \hat{S}^{(i)}$, we thus conclude that $S^{(i)} \in \mathscr{M}$. Similarly, $S_N(\varepsilon), K_N(\varepsilon), R_N(\varepsilon) \in \mathscr{M}$ because the operators on the rhs of (2.2a), (2.2b), (2.3b) are in $\mathscr{M}$.

(2) We proceed to prove assertion (2) of the lemma. Since $V^{(i)}, K^{(i)}, \tilde{S}^{(i)}, \hat{S}^{(i)}$ are defined on the dense set $C^\infty(H_0)$, their adjoints exist. The following considerations show that they are all in $\mathscr{M}$. We begin by proving that $V^{(i)*}$ has this property.

Since $\mathscr{V}^{(i)}$ is quadratically-summable by rows and columns, so is $\mathscr{V}^{(i)*}$, and thus it is legitimate to define $\check{V}^{(i)}$ as the operator associated with $\mathscr{V}^{(i)*}$. To prove that $V^{(i)*}$ is in $\mathscr{M}$, we will show that $\check{V}^{(i)}$ is and that

$$\check{V}^{(i)} | C^\infty(H_0) \subset V^{(i)*}. \tag{4.24}$$

Note that $\check{V}^{(i)} \in \mathscr{M}$ if (4.22), modified by replacing $V_{mn}^{(i)}$ by $\overline{V_{nm}^{(i)}}$, holds, as one sees by arguments similar to those adduced to prove that $V^{(i)} \in \mathscr{M}$ is implied by the original equation (4.22). The modified form of (4.22) can be proved similarly to the way (4.22) itself was. Next, we note that

$$\sum_{m,n} |V_{mn}^{(i)}| \cdot |\langle \Phi_m, f \rangle| \cdot |\langle \Phi_n, g \rangle| < \infty \quad [f, g \in C^\infty(H_0)], \tag{4.25}$$

as follows by considerations of the same type as those leading to (4.22). By $V^{(i)} \leftrightarrow \mathscr{V}^{(i)}$, $\check{V}^{(i)} \leftrightarrow \mathscr{V}^{(i)*}$, $C^\infty(H_0) \subset D(V^{(i)}) \cap D(\check{V}^{(i)})$, and (4.25), we may apply Lemma A3 of the Appendix [with $\mathscr{N} = C^\infty(H_0)$] to conclude that (4.24) holds.

The property $K^{(i)*} \in \mathscr{M}$ is entailed by the fact that (4.22) [resp., (4.25)] obviously holds with $V_{mn}^{(i)}$ replaced by $\overline{K_{nm}^{(i)}}$ (resp., $K_{mn}^{(i)}$) and arguments analogous to ones invoked to prove $V^{(i)*} \in \mathscr{M}$.

The relations $\tilde{S}^{(i)*},\hat{S}^{(i)*}\in\mathscr{M}$ follow for similar reasons, and $S^{(i)*}\in\mathscr{M}$ is immediately implied by them and $S^{(i)*}\supset\tilde{S}^{(i)*}+\hat{S}^{(i)*}$, which is entailed by the definition $S^{(i)}=\tilde{S}^{(i)}+\hat{S}^{(i)}$.[41]

The relations $S_N(\varepsilon)^*,K_N(\varepsilon)^*,R_N(\varepsilon)^*\in\mathscr{M}$ follow because the adjoints of the operators on the rhs of (2.2a), (2.2b), (2.3b) are in $\mathscr{M}$, and because of familiar relations of the adjoints of operator sums and products.[41] □

The next lemma provides information on the connection between V and $V^{(1)}$ which is needed in the proof of Lemma 6.

Lemma 5: The following statements hold:

$$V^{(1)}\supset V, \tag{4.26a}$$

$$V^{(1)}=V \text{ on } C^\infty(H_0). \tag{4.26b}$$

Proof: (1) Since $\Phi\subset D(V)$, $V=V^*$ [by (I) and (II)], and $V^{(1)}\leftrightarrow\mathscr{V}^{(1)}=(V_{mn})$, Lemma A1 of the Appendix immediately implies (4.26a).

(2) The first step in proving (4.26b) is to show that

$$D(V)\supset C^\infty(H_0). \tag{4.27}$$

To this end, we fix $f\in C^\infty(H_0)$ and define

$$f_M=\sum_{|n|\leqslant M}\langle\Phi_n,f\rangle\Phi_n \quad (M\in\mathbf{Z}_+). \tag{4.28}$$

Since the sum (4.28) has only a finite number of terms and $\Phi\subset D(V)$, it follows that $f_M\in D(V)$. Since, in addition, Φ is an orthonormal basis,

$$Vf_M=\sum_{|n|\leqslant M}\langle\Phi_n,f\rangle\sum_m V_{mn}\Phi_m. \tag{4.29}$$

By (4.28) and $f\in\mathscr{H}$,

$$f=s-\lim_{M\to\infty} f_M. \tag{4.30a}$$

The second step in the proof of (4.26b) is to show that the limit

$$g=\mathrm{s}-\lim_{M\to\infty} Vf_M \tag{4.30b}$$

exists, as we will do shortly. From its existence and the fact that V is closed, Eqs. (4.30) entail that $g=Vf$, and hence that (4.27) holds. In turn, (4.26a) and (4.27) imply (4.26b).

The strong limit in (4.30b) exists because

$$\begin{aligned}\left\|\sum_{|n|\geqslant M+1}\sum_m V_{mn}\langle\Phi_n,f\rangle\Phi_m\right\| &\leqslant \sum_{|n|\geqslant M+1}\sum_m |V_{mn}|\cdot|\langle\Phi_n,f\rangle| \\ &\leqslant \text{const}\sum_{|n|\geqslant M+1}\sum_m \lambda_n^{\alpha(1,p)}\lambda_m^{-p}.\lambda_n^{-q}\|H_0^q f\| \\ &\leqslant \text{const}\left(\sum_m \lambda_m^{-p}\right)\left(\sum_{|n|\geqslant M+1}\lambda_n^{-[q-\alpha(1,p)]}\right)\to 0 \quad (M\to\infty)\end{aligned} \tag{4.31}$$

for all $p,q \in \mathbf{N}$ such that $p > \nu$ and $q > \nu + \alpha(1,p)$. To obtain the second line of (4.31), one uses (4.5), $V_{mn} = V_{nm}$, and (4.23). As to the third line of (4.31), note that the sums $\Sigma_m \lambda_m^{-p}$ and $\Sigma_n \lambda_n^{-[q-\alpha(1,p)]}$ are convergent at the stated p,q values by (4.17). □

Lemma 6: For each $\varepsilon \geqslant 0$, $K_N(\varepsilon)$ is essentially self-adjoint. Its unique self-adjoint extension $\overline{K_N(\varepsilon)}$ is the operator associated with the Hermitian matrix

$$\mathscr{K}_N(\varepsilon) = \sum_{j=0}^{N} \varepsilon^j \mathscr{K}^{(j)}(\varepsilon), \tag{4.32}$$

where $\mathscr{K}^{(0)} = (\lambda_m \delta_{\lambda_m,\lambda_n})$.

Remark: The essential self-adjointness of $K_N(\varepsilon)$ will not be used in the sequel.

Proof of Lemma 6: It is given in steps (1)–(4) below, in which $\varepsilon \geqslant 0$ should be considered fixed in the absence of an explicit statement to the contrary, and in which the dependence of the relevant operators on this parameter will usually be omitted.

(1) In this step, we show that (2.1) holds rigorously on $C^\infty(H_0)$. We *define*

$$S_{mn}^{(i)} = \langle \Phi_m, S^{(i)} \Phi_n \rangle \quad (i \geqslant 1), \tag{4.33a}$$

which together with the definitions of $S^{(i)}, \tilde{S}^{(i)}, \hat{S}^{(i)}$, and because these operators are in $\mathscr{M}$, entails

$$S_{mn}^{(i)} = \tilde{S}_{mn}^{(i)} + \hat{S}_{mn}^{(i)} \quad (i \geqslant 1). \tag{4.33b}$$

Equation (2.7) holds by (2.12), (3.4), and (4.33b). By (2.7) and definition (2.8), (2.6) follows. Fixing $i \geqslant 1$ for the moment, we now prove that (2.3a) holds on $C^\infty(H_0)$. To this end, we first calculate the action of the rhs of (2.3a) on an arbitrary element $f \in C^\infty(H_0)$ using Lemma A2 [with $r=2$; $A^{(1)}, A^{(2)} = H_0, S^{(i)}$ and $A^{(1)}, A^{(2)} = S^{(i)}, H_0$; $\mathscr{N} = C^\infty(H_0)$; etc.], whose application is justified since $H_0, S^{(i)}$ and their adjoints are in $\mathscr{M}$, and since $C^\infty(H_0) \supset \Phi$. Second, we compute the action of the lhs of (2.3a) on f by using $K^{(i)} \leftrightarrow \mathscr{K}^{(i)}$, $V^{(i)} \leftrightarrow \mathscr{V}^{(i)}$, and (2.8). Since the results of these two calculations agree, (2.3a) obtains in the stated sense. A similar approach using (2.3a), definitions (2.2b), (2.3b), and (4.27b), and the facts that (1.2) holds on $C^\infty(H_0)$ and that all the relevant operators are in $\mathscr{M}$, shows that (2.1) obtains on $C^\infty(H_0)$.

(2) Let us postmultiply (2.1) by $S_N(\varepsilon)^*$ and premultiply the equation ''adjoint'' to (2.1) by $S_N(\varepsilon)$. Subtracting the second equation from the first, we obtain formally

$$[H_0,\ S_N S_N^*] = S_N(K_N - K_N^*)S_N^* - \varepsilon[V,\ S_N S_N^*] + \varepsilon^{N+1}(R_N S_N^* - S_N R_N^*). \tag{4.34}$$

We claim that (4.34) obtains rigorously on $C^\infty(H_0)$.[42] One can prove this by using the facts that (2.1) holds on this dense subset, that the operators in (2.1) and their adjoints are in $\mathscr{M}$, and that the elementary properties of adjoints invoked above hold.[41]

(3) In this step, we show that each matrix $\mathscr{K}^{(i)}$ $(i \geqslant 1)$ is Hermitian:

$$K_{mn}^{(i)} = \overline{K_{nm}^{(i)}} \quad (i \geqslant 1), \tag{4.35}$$

and hence that the matrix $\mathscr{K}_N(\varepsilon)$ in (4.32) has this property, which is essential in proving the self-adjointness of $\mathscr{K}_N(\varepsilon)$. We will prove (4.35) by using a rigorous version of the argument in Ref. 13 alluded to in Sec. II.

Define $(S_N S_N^*)^{(i)}$ as the coefficient of ε^i in $S_N S_N^* = (\Sigma_{j=0}^N \varepsilon^j S_N^{(j)})(\Sigma_{k=1}^N \varepsilon^k S_N^{(k)*})$. We claim that

$$(S_N S_N^*)_{mn}^{(i)} \equiv \langle \Phi_m, (S_N S_N^*)^{(i)} \Phi_n \rangle = 0 \quad (1 \leqslant i \leqslant N) \tag{4.36}$$

holds for $N \geqslant 1$. We will establish this claim, and at the same time prove (4.35), in two steps. First, we note that (4.35) and (4.36) obtain for each such N if $i=1$. Indeed, $K^{(1)}_{mn} = \overline{K^{(1)}_{mn}}$ by (2.8) and $V^{(1)}_{mn} = V_{mn} = \overline{V_{nm}} = \overline{V^{(1)}_{nm}}$; and $(S_N S_N{}^*)^{(1)}_{mn}=0$ for $N \geqslant 1$ by (2.7), (2.12a), the latter property of $V^{(1)}_{mn}$, and

$$(S_N S_N{}^*)^{(1)} = S^{(1)} + S^{(1)*}.$$

Second, fixing $N \geqslant 2$ until further notice, we make the inductive hypothesis that (4.35) and (4.36) obtain for $1 \leqslant i \leqslant k$, for some positive integer $k \in \{1,\ldots,N-1\}$, and proceed to show that this implies that they obtain for $i=k+1$.

Because (4.34) holds on the dense set $C^\infty(H_0)$ for each $\varepsilon \geqslant 0$ and both sides of this equation can be expressed as polynomials in ε whose coefficients are operators defined on this set, the coefficients of equal powers of ε on the rhs and lhs are equal on $C^\infty(H_0)$. Equating the coefficients of ε^{k+1} and using our inductive hypothesis, we arrive at a relation which can be expressed in the form

$$\begin{aligned}([H_0, (S_N S_N{}^*)^{(k+1)}])_{mn} &\equiv \langle \Phi_m, [H_0, (S_N S_N{}^*)^{(k+1)}]\Phi_n\rangle \\ &= (\lambda_m - \lambda_n)(S_N S_N{}^*)^{(k+1)}_{mn} = K^{(k+1)}_{mn} - \overline{K^{(k+1)}_{nm}},\end{aligned}$$

in terms of the relevant matrix elements. Whence

$$K^{(k+1)}_{mn} = \overline{K^{(k+1)}_{nm}}, \tag{4.37a}$$

$$(S_N S_N{}^*)^{(k+1)}_{mn} = 0 \quad (\lambda_m \neq \lambda_n). \tag{4.37b}$$

We proceed to show that (4.37b) also holds for $\lambda_m = \lambda_n$, thereby completing the proof that (4.35) and (4.36) obtain for $i=k+1$.

Expressing

$$(S_N S_N{}^*)^{(k+1)} = S^{(k+1)} + S^{(k+1)*} + \sum_{k=1}^{k} S^{(j)} S^{(k+1-j)*}$$

in terms of matrix elements, one finds

$$[(S_N S_N{}^*)^{(k+1)}]_{mn} = S^{(k+1)}_{mn} + \overline{S^{(k+1)}_{nm}} + \sum_{j=1}^{k} \sum_{r} (\tilde{S}^{(j)}_{mr}\overline{\tilde{S}^{(k+1-j)}_{nr}} + \hat{S}^{(j)}_{mr}\overline{\hat{S}^{(k+1-j)}_{nr}}) \quad (\lambda_m = \lambda_n). \tag{4.38}$$

The formally obvious occurrence of the sum over r in the rhs of (4.38) can be justified by applying Lemma A2 of the Appendix [with $r=2$, $A^{(1)}=S^{(j)}$, $A^{(2)}=S^{(k+1-j)*}$, $\mathscr{N}=C^\infty(H_0)$], whose use is legitimate since each $S^{(i)}, S^{(i)*}$ is in $\mathscr{M}$. Equations (2.12b) and (4.38) immediately imply that (4.37b) obtains for $\lambda_m = \lambda_n$.

(4) Fixing $N \geqslant 1$ henceforth, we will complete the proof of the lemma by showing: (i) $K_N \subset K_N$, (ii) K_N is essentially self-adjoint, and (iii) $\overline{K_N} = K_N{}^*$. Property (i) follows directly from the relevant definitions and the Schwarz inequality in $\mathscr{C}^2(\mathbf{Z}^\nu_+)$. Property (ii) follows from (i),

$D(K_N)\supset C^\infty(H_0)$, (iii) (which we will prove shortly), and the essential self-adjointness of $K_N|C^\infty(H_0)$. This essential self-adjointness property is entailed by (iii), $D(K_N)\supset C^\infty(H_0)$, and $\exp(-itK_N)\in\mathscr{M}$.[43] The last relation follows from

$$\langle\Phi_m,\exp(-it\overline{K_N})\Phi_n\rangle=0 \quad (\lambda_m\neq\lambda_n), \tag{4.39}$$

the unitarity of $\exp(-it\overline{K_N})$, and arguments similar to those adduced to prove $V^{(i)}\in\mathscr{M}$ [step (1) of the proof of Lemma 4]. The statement (4.39) is a consequence of the fact that $\langle\Phi_m,K_N\Phi_n\rangle=\langle\Phi_m,K_N\Phi_n\rangle=0$ for $\lambda_m\neq\lambda_n$ [by $K_N\leftrightarrow\mathscr{K}_N$ and (i)], which implies that H_0 and K_N commute in the usual technical sense.[44] In turn, this commutativity entails that $\exp(-itK_N)H_0\subset H_0\exp(-itK_N)$, from which (4.39) follows immediately.

Finally, we will prove (iii). The last-mentioned property of the matrix elements $\langle\Phi_m,\overline{K_N}\Phi_n\rangle$ and the finite degeneracy of the eigenvalues λ_m play key roles in the proof. Namely, letting $\{\Lambda_\sigma\}$ ($\sigma\in\mathbf{N}$) be the set of distinct eigenvalues λ_m of H_0 (say with $\Lambda_\sigma<\Lambda_\tau$ for $\sigma<\tau$), they entail that each finite set $\mathscr{J}_\sigma=\{m\in\mathbf{Z}_+^\nu:\lambda_m\in\Lambda_\sigma\}(\sigma\in\mathbf{N})$ has the properties attributed to J_σ in the Corollary to Lemma A4. Applying this corollary (with $A=K_N$, $\mathscr{A}=\mathscr{K}_N$, $J_\sigma=\mathscr{J}_\sigma$, $\Psi=\Phi$), the self-adjointness of K_N follows. This completes the proof of the lemma. □

We recall that the Nth-approximant $\psi_N(t,\varepsilon)$ is defined by (3.6) and that this definition makes sense in view of (3.2a) and the fact that $S_N(\varepsilon),S_N(\varepsilon)^*,\exp(-itK_N(\varepsilon))\in\mathscr{M}$.

Lemma 7: The following statements hold:

(1) For all $t\in\mathbf{R}$, $\varepsilon\geqslant 0$, $\psi_N(t,\varepsilon)$ satisfies the differential equation

$$i\,\frac{d\psi_N(t,\varepsilon)}{dt}=H_\varepsilon\psi_N(t,\varepsilon)+\varepsilon^{N+1}g_N(t,\varepsilon) \tag{4.40a}$$

and the initial condition

$$\psi_N(0,\varepsilon)=[I+\varepsilon^{N+1}U_N(\varepsilon)]\psi_0, \tag{4.40b}$$

where d/dt denotes the strong derivative in $\mathscr{H}$, the operator $U_N(\varepsilon)$ is defined on $C^\infty(H_0)$ by (2.11b), and

$$g_N(t,\varepsilon)=-R_N(\varepsilon)\exp(-it\overline{K_N}(\varepsilon))S_N{}^*\psi_0. \tag{4.41}$$

(2) At each such ε, $g_N(t,\varepsilon)$ is strongly continuous in t on $\mathbf{R}$, and the following uniform boundedness properties hold:

$$\sup_{(t,\varepsilon)\in\mathbf{R}\times[0,\,\varepsilon_0]}\|g_N(t,\varepsilon)\|<0, \tag{4.42a}$$

$$\sup_{\varepsilon\in[0,\,\varepsilon_0]}\|U_N(\varepsilon)\psi_0\|<\infty, \tag{4.42b}$$

where $0\leqslant\varepsilon_0<\infty$.

Proof: (1) We proceed to prove assertion (1) of the lemma, fixing $\varepsilon\geqslant 0$ until further notice and again suppressing the ε-dependence of the pertinent vectors and operators. Our first task is to justify the equation[20]

$$i\,\frac{d\psi_N(t)}{dt}=S_N\overline{K_N}\,\exp(-it\overline{K_N})S_N{}^*\psi_0, \tag{4.43}$$

which is obtained by formally differentiating (3.6). Note that the rhs of (4.43) makes sense for reasons similar to those for which (3.6) does. If S_N were a bounded operator (which it is generally

not), then it could be interchanged with d/dt (strong derivative) without further ado, and in view of the facts that the relevant operators are in $\mathscr{M}$ and that (3.2a) holds, (4.43) would emerge immediately. We will prove (4.43) by a uniform-convergence argument which justifies this interchange.

Write

$$\psi_N(t)=\sum_m F_m(t)\Phi_m, \tag{4.44}$$

where

$$F_m(t)=\langle \Phi_m, S_N \exp(-it\overline{K_N})S_N^*\psi_0\rangle=\langle S_N^*\Phi_m, \exp(-it\overline{K_N})S_N^*\psi_0\rangle. \tag{4.45}$$

By (4.45) and because $S_N^*\Psi_0\in C^\infty(H_0)\subset D(\overline{K_N})$, it follows that $F_m\in C^1(\mathbf{R})$, with

$$\frac{dF_m(t)}{dt}=-i\langle S_N^*\Phi_m, \overline{K_N}\exp(-it\overline{K_N})S_N^*\psi_0\rangle=-i\langle \Phi_m, S_N\exp(-it\overline{K_N})\overline{K_N}S_N^*\psi_0\rangle. \tag{4.46}$$

We claim that the series

$$\sum_m \frac{dF_m(t)}{dt}\Phi_m \tag{4.47}$$

obtained from (4.44) by term-by-term strong differentiation converges uniformly wrt t on $\mathbf{R}$ in the strong $L^2(\mathbf{R}^\nu)$ sense. This entails that $d\psi_N(t)/dt$ is given by the series (4.47) at each $t\in\mathbf{R}$, and hence that (4.43) holds at all such t.

We will now show that

$$\sum_m \sup_{t\in\mathbf{R}}\left|\frac{dF_m(t)}{dt}\right|<\infty, \tag{4.48}$$

thus proving that the series (4.47) has the claimed uniform-convergence property.

Now, (4.48) holds if it does when $F_m(t)$ is replaced by each of the quantities $\tilde{F}_m^{(j)}(t)(j\geqslant 1)$ and $\hat{F}_m^{(j)}(t)$ $(j\geqslant 0)$, where $\tilde{F}_m^{(j)}(t)$ [resp., $\hat{F}_m^{(j)}(t)$] is given by the expression after the first equality in (4.45), but with the operator S_N replaced by $\tilde{S}^{(j)}$ (resp., $\hat{S}^{(j)}$), where $\hat{S}^{(0)}=I$. [Recall (2.2a) and (4.33).] Fixing $j\geqslant 1$, we will prove that

$$\sum_m \sup_{t\in\mathbf{R}}\left|\frac{d\tilde{F}_m^{(j)}(t)}{dt}\right|<\infty, \tag{4.49}$$

the proof of the analogous estimates involving $\hat{F}_m^{(k)}$ $(k\geqslant 0)$ being even simpler. Setting $w_N=\overline{K_N}S_N^*\psi_0\in C^\infty(H_0)$, we have for each $p\in\mathbf{N}$

$$\begin{aligned}\left|\frac{d\tilde{F}_m^{(j)}(t)}{dt}\right| &= |\langle \Phi_m, \tilde{S}^{(j)}\exp(-it\overline{K_N})w_N\rangle| \\ &\leqslant \sum_{r,s}|\tilde{S}_{mr}^{(j)}|\cdot|\langle \Phi_r, \exp(-it\overline{K_N})\Phi_s\rangle|\cdot|\langle \Phi_s, w_N\rangle| \\ &\leqslant \sum_r |\tilde{S}_{mr}^{(j)}|\cdot g_r\lambda_r^{-q(p,r)}\|H_0^{q(p,r)}w_N\| \\ &\leqslant \text{const}\ \lambda_m^{-p}\sum_r \lambda_r^{\alpha(r,p)}\lambda_r^{\nu-\rho}\lambda_r^{-q(p,r)}\|H_0^{q(p,r)}w_N\|\leqslant \text{const}\ \lambda_m^{-p},\end{aligned} \tag{4.50}$$

if $q(p,r)>2\nu-\rho+\alpha(r,p)$ for each such p and all $r\in\mathbf{Z}_+^\nu$. Here const is independent of m. To arrive at the second line of (4.50), we have used Lemma A2 [with $r=2$, $A^{(1)}=\tilde{S}^{(j)}$, $A^{(2)}=\exp(-itK_N)$, etc.], as we may because $\exp(-itK_N)$ and the other relevant operators are in $\mathscr{M}$. The third line of (4.50) follows from (4.39), the unitarity of $\exp(-itK_N)$, and (4.23); and the fourth line from (4.18), (4.13d), (4.23), and (4.17). The desired result (4.49) now follows from (4.50) and (4.17) by choosing $p>\nu$.

In order to complete the proof of part (1) of the lemma, we still need to show that $\psi_N(t,\varepsilon)$ satisfies (4.40a) and (4.40b) at the stated t,ε-values. The former equation follows by using (4.43) and (4.41), as well as the facts that (1.2) and (2.1), with K_N replaced by K_N, hold on $C^\infty(H_0)$, and that the pertinent operators are in $\mathscr{M}$. Equation (4.40b) is an immediate implication of (3.6) and (2.11a). Note that U_N is well defined on $C^\infty(H_0)$ by (2.11b), since all the $S^{(i)}$s and $S^{(i)}$*s are in $\mathscr{M}$. Note also that Eqs. (2.11) hold on $C^\infty(H_0)$ by (2.2a), a repeatedly used relation for the adjoint of an operator sum, the last-mentioned property of the $S^{(i)}$ s and $S^{(i)}$*s, and the fact that $(S_N S_N^*)^{(i)}=0$ on $C^\infty(H_0)$ for $1\leqslant i\leqslant N$. This fact follows from (4.36) and Lemma A1, which is applicable because the operator $S_N S_N^*$ is symmetric and in $\mathscr{M}$.

(2) The strong continuity of $g_N(t,\varepsilon)$ in t on $\mathbf{R}$ for fixed $\varepsilon\geqslant 0$ can be shown by arguments analogous to those invoked to prove (4.49). The boundedness statements (4.42a) and (4.42b) also follow from arguments of the latter type. The proof of the lemma is therefore complete. □

With the results of Lemma 7 in hand, we proceed to give a short rigorous proof of our main result.

Proof of Theorem 1: We fix $\varepsilon\geqslant 0$ in this paragraph. Since $\psi(t,\varepsilon)$ is a solution of the IVP (1.1) for $t\in\mathbf{R}$ and since $\psi_N(t,\varepsilon)$ solves the IVP (4.40) at all such t by Lemma 7(1), it follows that $f_N(t,\varepsilon)=\psi(t,\varepsilon)-\psi_N(t,\varepsilon)$ is a solution of the IVP

$$i\,\frac{df_N(t,\varepsilon)}{dt}=H_\varepsilon f_N(t,\varepsilon)-\varepsilon^{N+1}g_N(t,\varepsilon), \tag{4.51a}$$

$$f_N(0,\varepsilon)=-U_N(\varepsilon)\psi_0. \tag{4.51b}$$

By (4.51), together with the self-adjointness of H_ε and the strong continuity of $g_N(t,\varepsilon)$ stated in Lemma 7(2), it follows rigorously[45] that

$$\|f_N(t,\varepsilon)\|\leqslant\|f_N(0,\varepsilon)\|+\varepsilon^{N+1}\int_0^{|t|}\|g_N(s,\varepsilon)\|ds \tag{4.52}$$

for $t\in\mathbf{R}$.

By (4.51b), (4.52), and the boundedness properties (4.42) of $g_N(t,\varepsilon)$ and $U_N(\varepsilon)\psi_0$, we infer that

$$\|f_N(t,\varepsilon)\|\leqslant\text{const }\varepsilon^{N+1}(|t|+1)$$

for $t\in\mathbf{R}$, $\varepsilon\in[0,\varepsilon_0]$, where the constant is independent of ε. This completes the proof of Theorem 1. □

APPENDIX: SIMPLE LEMMAS ON OPERATORS IN HILBERT SPACE

In this appendix, we state Lemmas A1–A4 and a corollary to Lemma A4. Except for Lemma A4, this material is applied in Sec. IV in the proofs of Lemmas 4–7. We will use the following notation: $\mathscr{X}$ denotes a Hilbert space spanned by the orthonormal set $\Psi=\{\Psi_\alpha\}$, $A_{\alpha\beta}=0(\alpha\in\Gamma)(\alpha\in\Gamma)$, with $\Gamma=\mathbf{Z}_+^p$ for some $p\in\mathbf{N}$, and $\langle .,.\rangle$ denotes the inner product in $\mathscr{X}$ (anti-linear in the first argument and linear in the second). When the matrix element of an operator A in $\mathscr{X}$ exists, we denote it by $A_{\alpha\beta}$. The adjoint of an operator A is written as A^*, as usual, and $\mathscr{A}^*$ denotes the Hermitian adjoint of a matrix $\mathscr{A}=(A_{\alpha\beta})$. In this Appendix, all operators have domains dense in $\mathscr{X}$ and when any operator is assumed to be associated with an infinite matrix, this association is always wrt Ψ. Hence we will omit explicit references to these two properties.

We proceed to state three elementary lemmas, the proofs of the first two being based on the well-known argument in (A1) below.

Lemma A1: Let A be an operator such that $\Psi\subset D(A)\cap D(A^*)$ and let A_1 be the linear operator associated with $(A_{\alpha\beta})(\alpha,\beta\in\Gamma)$. Then $A\subset A_1$. In particular, if $A_{\alpha\beta}=0$ $(\alpha,\beta\in\Gamma)$, then A is a restriction of the zero operator.

Proof: By our assumptions on A,

$$\langle\Psi_\alpha,Ag\rangle=\langle A^*\Psi_\alpha,g\rangle=\sum_{\beta\in\Gamma}\langle\Psi_\alpha,A\Psi_\beta\rangle\langle\Psi_\beta,g\rangle=\sum_{\beta\in\Gamma}A_{\alpha\beta}\langle\Psi_\beta,g\rangle\quad(\alpha\in\Gamma),\tag{A1}$$

from which the lemma immediately follows. □

Lemma A2: Let $A^{(1)},\ldots,A^{(r)}$ $(2\leqslant r<\infty)$ be operators such that each $A^{(i)}$ has the properties:

(i) $A^{(i)}\mathscr{N}\subset\mathscr{N}$, where $\mathscr{N}$ is a subset in $\mathscr{X}$ such that $\Psi\subset\mathscr{N}\subset D(A^{(i)})$;

(ii) $D(A^{(i)}*)\supset\Psi$.

Then

$$\langle\Psi_\alpha,A^{(1)}\cdots A^{(r)}f\rangle=\sum_{\beta_1\in\Gamma}A^{(1)}_{\alpha\beta_1}\sum_{\beta_2\in\Gamma}A^{(2)}_{\beta_1\beta_2}\cdots\sum_{\beta_{r-1},\beta_r\in\Gamma}A^{(r)}_{\beta_{r-1}\beta_r}\langle\Psi_{\beta_r},f\rangle\quad(f\in\mathscr{M},\alpha\in\Gamma),$$

where the sums over $\beta_1,\ldots,\beta_r$ converge absolutely.

Lemma A3: Let A and $\check{A}$ be operators associated with the respective matrices $\mathscr{A}=(A_{\alpha\beta})(\alpha,\beta\in\Gamma)$ and $\mathscr{A}^*$, and let $\mathscr{N}$ be a dense subset in $\mathscr{X}$ contained in $D(A)\cap D(\check{A})$. In addition, let

$$\sum_{(\alpha,\beta)\in\Gamma\times\Gamma}|A_{\alpha\beta}||\langle\Phi_\alpha,g\rangle|\cdot|\langle\Phi_\beta,f\rangle|<\infty\quad(f,g\in\mathscr{N}).\tag{A2}$$

Then

$$\check{A}|\mathscr{N}\subset A^*.$$

Proof: It follows directly from the definitions and the use of (A2) to interchange the order of summation in the relevant absolutely convergent iterated sums. □

The final lemma is a version of a result of Stone, stated in Theorem 3.4, pp. 91, 92, Ref. 32.[46]

Lemma A4: Let A be an operator associated with a Hermitian matrix $\mathscr{A}=(A_{\alpha\beta})(\alpha,\beta\in\Gamma)$. Moreover, assume that for all $f,g\in D(A)$ the necessarily convergent series

$$\sum_\alpha\left(\sum_\beta A_{\alpha\beta}\langle\Psi_\beta,g\rangle\right)\overline{\langle\Psi_\alpha,f\rangle},\tag{A3a}$$

$$\sum_\beta\left(\sum_\alpha A_{\alpha\beta}\overline{\langle\Psi_\alpha,f\rangle}\right)\langle\Psi_\beta,g\rangle,\tag{A3b}$$

have the same sum.[47] Then A is self-adjoint.

Corollary to Lemma A4: Let A be an operator associated with a Hermitian matrix $\mathscr{A}=(A_{\alpha\beta})(\alpha,\beta\in\Gamma)$. In addition, assume that there exists a collection of finite subsets J_σ $(\sigma\in\mathbf{N})$ such that

$$\bigcup_{\sigma\in\mathbf{N}}J_\sigma=\Gamma,\quad J_\sigma\cap J_\tau=\varnothing\ \ (\sigma\neq\tau),\tag{A4}$$

and that $A_{\alpha\beta}\neq0$ only if $\alpha,\beta\in J_\sigma$ for some $\sigma\in\mathbf{N}$. Then A is self-adjoint.

Proof: Let $f,g\in D(A)$. Since $A\leftrightarrow\mathscr{A}=\mathscr{A}^*$, one concludes that

$$\sum_{\alpha}\left|\sum_{\beta}A_{\alpha\beta}\langle\Psi_{\beta},g\rangle\right|\cdot|\langle\Psi_{\alpha},f\rangle|<\infty,$$

$$\sum_{\beta}\left|\sum_{\alpha}A_{\alpha\beta}\overline{\langle\Psi_{\alpha},f\rangle}\right|\cdot|\langle\Psi_{\beta},g\rangle|<\infty,$$

i.e., that the sum over α (resp., over β) in (A3a) [resp., (A3b)] converges absolutely. By this conclusion, together with (A4), the finiteness of each set J_{σ}, and the assumption that $A_{\alpha\beta}\neq 0$ only if $\alpha,\beta\in J_{\sigma}$ for some $\sigma\in\mathbf{N}$, the convergent sums (A3a) and (A3b) are both equal to

$$\sum_{\sigma\in N}\sum_{\alpha,\beta\in J_0}A_{\alpha\beta}\overline{\langle\Psi_{\alpha},f\rangle}\langle\Psi_{\beta},g\rangle.$$

The self-adjointness of A now follows from Lemma A4. □

[21] A. W. Sáenz, in Ref. 19, p. 163.
[22] In this reformulation, it will turn out that all the operators defined heuristically in the present section have domains containing a common dense set in $L^2(\mathbf{R}^{\nu})$ which they leave invariant. The operator equations in this section hold on this set.
[23] If convergence questions are ignored, one can express (2.1) as $S_{\varepsilon}^{-1}H_{\varepsilon}S_{\varepsilon}=K_{\varepsilon}$, where, in a heuristic sense, S_{ε} and K_{ε} are self-adjoint and unitary operators, respectively, given by formal power series in ε. Such a heuristic equation was used by Born and Jordan[18] to create early versions of nondegenerate and degenerate perturbation theory in matrix mechanics. As mentioned in the text, our approach is very close in spirit to theirs. For a rigorous discussion of this equation for a special type of H_{ε}s with compact resolvents and simple spectra, see Ref. 11.
[24] This will be proved in Sec. IV on the basis of the assumptions on V in Sec. III.
[25] Henceforth, all equations involving free subscripts m,n labeling matrix elements of linear operators in the Φ-basis should be understood to hold for all $m,n\in\mathbf{Z}_{+}^{\nu}$. Similarly, summations over subscripts labeling such elements range over $\mathbf{Z}_{+}^{\nu}$.
[26] This merely means that the matrices $\mathscr{K}^{(i)}$ are Hermitian.

[46] Unfortunately, the crucial third sentence of this theorem is confusing. But what it was meant to state is readily reconstructed from the proof of the theorem (Ref. 32, especially p. 92), whose arguments imply a result stronger than our Lemma A4.
[47] Here and henceforth, summations over α,β range over Γ unless otherwise stated.

An equivalence proof of the background gauge field quantization and the conventional one

Fabrizio Tinebra

(Received 17 October 1995; accepted for publication 28 November 1995)

The background gauge field quantization is a convenient tool for studying weakly interacting gauge and matter fields or analyzing anomalous current conservation in fermionic structures. This method is from the mid 1970's, but it is only today that it received renewed interest for investigating nonperturbative evolution equations in Yang–Mills theory, as well as gauge field effective action formulations. We reviewed, to start with, the general formulation and assumptions about this method, and we pointed out some critical observations concerning it. In particular, we focus on some of the most common equivalence proofs presently known in the literature. We attempted to give a most convincing demonstration of this equivalence as it stands between the background gauge field scattering operator and the conventional one. The result shown here clearly indicates these methods are indeed physically equivalent. In proving that, we neglected all the infrared problems afflicting the pure Yang–Mills gauge theory; as a matter of fact, they appear to be a parallel, but nonintersecting problem with respect to the present one, i.e., to prove the equivalence. © *1996 American Institute of Physics.* [S0022-2488(96)01904-0]

I. INTRODUCTION

The theory of the background field quantization method is a convenient tool in order to study the interplay between classical and quantum interacting fields or to compute, for instance, the generation of quantum anomalies in fermion-scalar systems as well as to analyze the evolution equations of a non-Abelian quantum gauge field in four dimensions. Very recently, it has resulted in a convincing tool in the study of interacting quantum Yang–Mills fields, in effective Lagrangian theories and in beta function computations.[1] Also, in the generalization of the Nambu–Jona Lasinio model of QCD with a background gluon field,[2] it seemed to be quite appropriate. Nevertheless, the physical equivalence of such a quantization method with respect to the more conventional one, has never been proved in a full satisfactory way, at least to our knowledge. On the contrary, it ever seemed to be a bit fragile. We tried, hence, to prove this equivalence in a, possibly, more exhaustive way.

In Sec. II we recall some of the most popular concepts from the conventional functional quantization approach to gauge and non-gauge field theories, by introducing the formal scattering $\hat{S}$ operator of the LSZ reduction prescription.[3] Then, in Sec. III we deal with the proper definition of the background gauge field quantization method for a pure Yang–Mills theory, thus opening the discussion of Sec. IV, where the expression of the gauge invariant effective action is formulated and analyzed in some detail. But the original contribution to this subject stems from Sec. V, where an equivalence proof between the ordinary Yang–Mills $\hat{S}$ scattering matrix operator and the background gauge $\hat{S}_\varphi$ one is exhibited. This is obtained after a lengthy and accurate algebraic computation, which avoids any diagrammatic expansions. Quite general and conclusive remarks have thus been collected together in Sec. VI. In an appendix we explain our reasons for not making use throughout the present equivalence demonstration, of the validity of global BRS symmetry.

II. THE QUANTIZED YANG–MILLS FIELD

We will begin by reviewing some of the basic ingredients in gauge quantum field theory.[4] As is known, in the functional integral approach to gauge, Yang–Mills field theory, the classical Lagrangian density merely writes

$$L_0 = \tfrac{1}{2} F^{\mu\nu a} F^a_{\mu\nu}, \tag{2.1}$$

where the repeated indices are summed up and

$$F^a_{\mu\nu}(x) \equiv \partial_\mu A^a_\nu(x) - \partial_\nu A^a_\mu(x) + f^a_{bc} A^b_\mu(x) A^c_\nu(x). \tag{2.2}$$

In order to quantize it, one has merely to complete L_0 with two known local functionals that depend on the gauge and auxiliary fields, and to perform then a formal functional integration over the entire set of resulting *effective quantum fields*. For pure Yang–Mills gauge theory, such a quantum Lagrangian density translates into the so-called ''Faddeev–Popov Lagrangian,'' viz.

$$L_{\mathrm{FP}} = L_0 + L_{\mathrm{gf}} + L_{fpg}. \tag{2.3}$$

Here, beside the classical L_0 term of the $A^a_\mu(x)$ gauge potential, one recognizes the L_{gf} gauge fixing term used to break classical gauge invariance, written as

$$L_{\mathrm{gf}} = -\frac{1}{2\alpha} [F(A_\mu)]^2, \tag{2.4}$$

and the L_{fpg} term, which is the functional Jacobian determinant expressing the admissibility condition for the chosen gauge function. In terms of auxiliary ghost fields, $c, \overline{c}$, one has

$$L_{fpg} = \overline{c^a}(x) M^{ab}(x,y) c^b(y) = \mathrm{tr}[\partial_\mu \mathbf{c}^{\dagger a}(x) \cdot D_\mu \mathbf{c}^a(x)]. \tag{2.5}$$

But the physically most important object of this quantization method is the renormalized functional integral of connected Green's functions, $W(J,\eta) = -\ln Z[J,\eta]$, whose arguments are the ''sources'' $J^a(x)$, for the set of effective quantum fields present, and the ''external fields'', $\eta^a(x)$, coupling to the composite operators of the theory. By expressing auxiliary quantum fields in the form of a scalar field $\varphi^a(x)$, all that is written as

$$Z[J,\eta] = \int \mathscr{D}\varphi \, \mathscr{D}A_\mu \, \exp \int d^4x \{L_0 + L_{\mathrm{gf}} + L_{fpg}\}(x). \tag{2.6}$$

To each functional variation $\delta Z(J,\eta)$ induced by the external fields, it is possible, moreover, to correspond the action of a formal operator, to be contracted with $Z[J,\eta]$, namely

$$\frac{\delta Z(J,\eta)}{\delta \eta(x)} \equiv (\Delta_{\eta(x)} \cdot Z)(J,\eta). \tag{2.7}$$

This is a linear operator ''$\Delta_{\eta\cdot}$,'' consisting of insertions into the renormalized time-ordered product, which defines $Z(J,\eta)$. Sometimes one writes it as ''$[\delta/\delta\eta(x)] \int dy L(y)$,'' where the quotation marks indicate that actually we are neglecting the quantum corrections induced by the renormalization procedure.

In particular we aim to formally express the scattering $\hat{S}$ operator as the action of a local operator contracted with $Z[J,\eta]$. Such an operator would act by isolating each of the connected Green's functions obtained by $Z[J,\eta]$, would then amputate the propagators present in the external lines of the Feynman diagrams, and will set the external momenta on their physical values, the *mass shell* values. An operator expression of $\hat{S}$ satisfying that is[5]

$$\hat{S}=:\exp\int d^4x\ d^4y\ \psi^{\mathrm{in}}(x)K(x,y)\zeta\frac{\delta}{\delta J(y)}:Z(J,\eta)\Big|_{J=\eta=0}\equiv(\Sigma_J\cdot Z_{J,\eta}),\tag{2.8}$$

with $\psi\equiv(\varphi,A)$. In so doing, one introduces the *in*coming *asymptotic fields*, $\varphi^{\mathrm{in}}(x)$, the corresponding classical wave operators $K(x,y)$, the sources $J^a(x)$ for the interacting fields, and the function ζ, i.e. the residue at the pole of the propagator, which generates the Fourier transform of the two point functions on the mass shell. The subsequent choice of a gauge condition,

$$F(\varphi,A_\mu)=0,\tag{2.9}$$

makes such a procedure definitely non-gauge invariant, except for very peculiar choices of the field surface F. Note that this surface, implicitly defined by Eq. (2.9), is properly defined in the space $\Phi\times\mathbf{R}^4$, which is the quotient space

$$\Phi\times\mathbf{R}^4\approx(\Phi\times G/\text{action of } G \text{ on } \Phi)\times\mathbf{R}^4.\tag{2.10}$$

Here Φ is the representation space $\Phi\equiv V\oplus\mathscr{G}\times\mathbf{R}^4$, where V is a vector representation of the gauge group G and $\mathscr{G}$ its Lie algebra. The ''coordinates'' on $\Phi\times G$ are thus the sets $(\varphi, A_\mu, \mathbf{e}\equiv\text{identity of } G)$. To vary the φ field *on the fibers*, that is in the G space, will correspond to introduce a covariant connection 1-form, defined on G and with values in $\mathscr{G}$. This is the canonical, ''left invariant'' connection of Maureer and Cartan, $\omega(x)$, satisfying

$$\delta\omega=-[\omega,\omega],\tag{2.11}$$

with the external derivative δ acting on G. The particular value $\omega|_e\equiv\overline{c}$, is of the greatest importance for gauge theories, since it is one of the two Faddeev–Popov ghost fields. The invariance of the gauge condition on the fibers thus becomes

$$\delta F=\left(\overline{c},\frac{\delta_\omega F}{\delta\omega}\right)\equiv M\overline{c}=0.\tag{2.12}$$

We conclude by recalling a remarkable general invariance property satisfied by this theory under a particular nonlocal field transformation. This is the so-called Slavnov–Taylor identity, whose corresponding quantum analog is the *Becchi–Rouet–Stora (BRS) global symmetry transformation*,[6] which is a very general field transformation involving the fermion and boson fields together.

III. BACKGROUND GAUGE FIELD QUANTIZATION

The early formulation of such an alternative quantization method traces back on the middle of the 1970's,[7] when attempts were made to define the gauge covariance of some particular quantum field models, or, at least, of some subsectors of them. One of the most important efforts on it was done by De Witt.[8]

After some alternating issues, a clear formulation has then been consistently developed; in principle, only at one loop level,[9] soon after in the multiloop expansion.[10] At present, it is supported with a detailed proof of its renormalizability,[11] obviously only when the corresponding conventional formulation does possess it.

Initially the background field formulation provided its usefulness in computations with auto-interacting quantum gauge fields; but after a while it was also applied to many quantum and classical fields interacting together. The most typical situations occur in the interaction of a fermion field with a classical gauge potential, giving the form of the chiral anomalies and of asymmetries in the vacuum state; however, it is also used in the perturbative evaluation of the

fermion beta function,[12] as well as to generate other fermion currents. Even the propagation of quantum particles in a curved space–time,[13] or the evaluation of complex diagrams in quantum gravity models sometimes looks for it as a useful approximation.

The essence of the argument simply relies on a separation of the classical functional integration variable (viz. the quantum dynamical field) into two parts; i.e., a classical component, defined as the ''*background field*,'' and the corresponding quantum fluctuation, called the ''*fluctuation field*.'' This procedure reproduces the separation of the solution in conformal field theories, where one usually defines a classical soliton solution with the addition of a quantum correction.

The Green's functions in this method, that is, the functional derivatives of the effective action with respect to the background field, result now in gauge covariant expressions, which become independent of the gauge condition when the background fields are set on the mass-shell values. The possible existence of quantum anomalies, indeed, can only be done after defining the ''background field effective Lagrangian.''

A. Non-gauge formulation

Let $S_0[a(x)]$ be the classical action for a singlet scalar field $a(x)$,

$$S_0[a]=\int d^4x\ L_0(a(x),\partial_\mu a(x)), \tag{3.1}$$

with the usual meaning of the symbols used. The corresponding quantum generating functional is then

$$Z[J]\equiv\exp(-W[J])=N\int \mathscr{D}a\ e^{-\{S_0[a]+(J,a)\}}, \tag{3.2}$$

where (J,a) is the scalar product. This functional is trivially invariant under a shift of the integrand function of the kind

$$a(x)\rightarrow a(x)+f(x), \tag{3.3}$$

as it can be easily proved. One introduces the classical component or *background field*, $\varphi(x)$, together with its quantum fluctuation, $\phi(x)$, by means of the analogous position

$$a(x)=\phi(x)+\varphi(x), \tag{3.4}$$

and one sets

$$\exp(-\widetilde{W}[\varphi,J])\equiv N'\int \mathscr{D}\phi\ e^{-\{S_0[\phi+\varphi]+(J,\phi)\}}, \tag{3.5}$$

with the condition that $\varphi(x)$ is completely stationary in applying the variational principle to $a(x)$, i.e.

$$\int \mathscr{D}a(x)\equiv\int \mathscr{D}\phi(x). \tag{3.6}$$

As it is important to note, this definition is well posed, in the sense that the function $\widetilde{W}[J,\varphi]$ cannot be obtained by the $W[J]$ function by the shift $a(x)\rightarrow a(x)+\varphi(x)$. $\widetilde{W}[J,\varphi]$ do effectively depend on $\varphi(x)$, since the only field coupled to an external source is the quantum piece $\phi(x)$. In gauge field theory, this difference will result in the gauge fixing term too, since the corresponding field operator will now be parametrized by the φ field.

In complete analogy with the conventional formulation, one defines the *classical field* in the presence of a background field,

$$\hat{\phi}(x) \equiv \frac{\delta \widetilde{W}[\varphi, J]}{\delta J(x)}, \tag{3.7}$$

and the effective action with a background field is

$$\widetilde{\Gamma}[\hat{\phi}, \varphi] \equiv \widetilde{W}[\varphi, J] - (J, \hat{\phi}), \tag{3.8a}$$

$$\frac{\delta \widetilde{\Gamma}[\hat{\phi}, \varphi]}{\delta \hat{\phi}(x)} = -J(x). \tag{3.8b}$$

Hereafter we will indicate scalar products, such as $(J, \hat{\phi})$, with the notation

$$J \cdot \hat{\phi} \equiv \int d^4x \; J^{\mu a}(x) \hat{\phi}^a_\mu(x). \tag{3.9}$$

The relationship between $\widetilde{W}$ and W is simply

$$\widetilde{W}[\varphi, J] = W[J] - J \cdot \varphi, \tag{3.10}$$

by which

$$\widetilde{\Gamma}[\hat{\phi}, \varphi] = \Gamma[\hat{\phi} + \varphi] \equiv \Gamma[\overline{\varphi(x)}], \tag{3.11}$$

where the ''effective field'' $\overline{\varphi(x)}$ is the field resuming all the dynamical status of the theory.

An important consequence of the relationship $\Gamma[\overline{\varphi}] = \widetilde{\Gamma}[\overline{\varphi}, 0]$, is that one can get the effective action of the $\overline{\varphi}$ field by summing up the 1P*I* one-particle irreducible diagrams of the physical vacuum in the presence of the effective field only. Proper vertices and *S* matrix elements will then turn out this way, and we will perturbatively construct the effective action by merely summing up these vacuum Feynman diagrams.

B. Gauge field formulation

In the ordinary Lagrangian formulation, hereafter called the *conventional* one, the classical gauge invariant action for the potentials $A_\mu \equiv A_\mu{}^a T^a$, is customarily written as

$$S_0 = S_0[A] \equiv \int d^4x \; L_0(A_\mu, \partial_\nu A_\mu, \ldots), \tag{3.12}$$

with the dots for higher-order terms, if any. Infinitesimal gauge transformations, parametrized by the parameters $\delta\xi_a(x)$ act on it through

$$A^a_\mu \to A'^a_\mu = A^a_\mu + D^{ab}_\mu[A] \delta\xi_b, \tag{3.13}$$

and the covariant derivatives $D^{ab}_\mu[A]$ constitute the so-called gauge group $\mathcal{G}$, such that

$$\left(\frac{\delta}{\delta A^c_\nu} D^{ad}_\mu \right) D^{bc}_\nu - \left(\frac{\delta}{\delta A^c_\nu} D^{bd}_\mu \right) D^{ac}_\nu = D^{cd}_\mu f_c{}^{ab}. \tag{3.14}$$

The Green's functions generating functional of customary bare Yang–Mills theory includes, as we saw, the classical action for the integration variable $A_\mu(x)$, a Jacobian determinant for the integration measure, a source term $J^\mu(x) \equiv J^\mu_a T^a$ coupled to the gauge potential, and a gauge-fixing

functional, $(F^{\mu}A_{\mu})^2$, with the $1/\alpha$ real parameter of it actually included in the definition of F^{μ}. Frequently, in the following, we will also make use of the shortand notation A^iB_i to mean the double contraction $A^a_{\mu}B^{\mu}_a$ between Lorentz indices and internal symmetry indices, as already shown in Eq. (3.9). We then obtain

$$Z[J]=\exp(-W[J])=N\int \mathscr{D}A\ \det(F^i_aD^b_i[A])$$
$$\times\exp-\left\{S_0[A]+\frac{1}{2}\int d^4x\ \eta^{ab}\eta^{cd}F^{\mu}_{ac}F^{\nu}_{bd}A_{\mu c}A_{\nu d}+J\cdot A\right\}. \quad (3.15)$$

An easy and common assumption about F^{μ}_{ab} is

$$F^{\mu}_{ab}\equiv\frac{1}{\alpha}\,\delta_{ab}\partial^{\mu}, \quad (3.16)$$

with δ^{ab} the Kronecker symbol. In Eq. (3.15), in addition, N is a normalization constant, given by $\langle 0^{\text{in}}|0^{\text{out}}\rangle$, and η^{ab} is the metric tensor of the internal symmetry space. Just as shown in the non-gauge theory, we make now a change of variable, by setting

$$A_{\mu}=a_{\mu}+\varphi_{\mu}. \quad (3.17)$$

The integral functional that turns out is a formally well-defined quantity since we have now subtracted out the infinite factor of the orbit volume in the gauge group space; analogously to the former case, we can write

$$\overline{Z_F}[J,\varphi]=\exp(-\overline{W_F}[J,\varphi])$$
$$=N\int \mathscr{D}a\exp-\left\{S_0[a+\varphi]+\frac{1}{2}\int d^4x\ \eta^{ab}F^i_a[\varphi]F^j_b[\varphi]a_ia_j+J\cdot a\right\}$$
$$\times\det(F^i_a[\varphi]D^b_i[a+\varphi]), \quad (3.18)$$

which is in complete analogy with the treatment of Ref. 14. In this formulation the effective action $\overline{\Gamma}[\hat{\phi},\varphi]$ is deduced from $W_F[J,\varphi]$ by means of the customary Légendre transform,

$$\hat{a}(x)\equiv\frac{\delta\overline{W_F}}{\delta J(x)}[J,\varphi], \quad (3.19a)$$

$$\overline{\Gamma}[\hat{a},F[\varphi],\varphi]=\overline{W_F}[J[\hat{a}],F[\varphi],\varphi]-J^{\mu}\cdot\hat{a}_{\mu}. \quad (3.19b)$$

Remarkably, all the Green's functions out of the mass shell as well as all the counterterms needed to renormalize the physical parameters result gauge covariant, while the entangled Slavnov–Taylor identities of the original theory take now a very simple form. More explicitly, one writes

$$e^{-\overline{\Gamma}[\hat{a},\varphi]}=N''\int \mathscr{D}a\ \det[F^i_a[\varphi]D^b_i[a+\varphi]]$$
$$\times\exp-\left\{S_0[a+\varphi]+\frac{1}{2}\int d^4x\ F^{\mu a}_b[\varphi]a_{\mu a}F^b_{\nu c}[\varphi]a^{\nu c}-\frac{\delta\overline{\Gamma}[\hat{a},\varphi]}{\delta\hat{a}_i}(a_i-\hat{a}_i)\right\}, \quad (3.20)$$

corresponding to

$$e^{-\tilde{\Gamma}[\hat{A},\varphi]}=N''\int \mathscr{D}A\ \det(F^i_a[\varphi]D^b_i[A])$$
$$\times\exp-\left\{S_0[A]+\frac{1}{2}\int d^4x\ F^{\mu a}_b[\varphi](A-\varphi)_{\mu a}\right.$$
$$\left.\times F^b_{\nu c}[\varphi](A-\varphi)^{\nu c}-\frac{\delta\tilde{\Gamma}[\hat{A},\varphi]}{\delta\hat{A}_i}(A_i-\hat{A}_i)\right\}. \tag{3.21}$$

Some of the most striking aspects of the background field method are listed below.

The expectation value of the quantum a field, called $\hat{a}$, in the limit of $J_\mu\to 0$, satisfies in the quantum version the same gauge condition originally introduced to break classical gauge invariance, viz.

$$\lim_{J\to 0}\langle F^i_a\hat{a}_i\rangle=0. \tag{3.22}$$

The generating functional $\overline{W_F}[J,\varphi]\equiv\overline{W}[J,F[\varphi],\varphi]$ is invariant, inasmuch as one acts on it with a background field-induced gauge transformation $\varphi\to\varphi'$ and, simultaneously, one rotates the source field $J(x)$, i.e.

$$\frac{\delta\overline{W_F}[J,\varphi]}{\delta\varphi_i}D^a_i[\varphi]+\frac{\delta\overline{W_F}[J,\varphi]}{\delta J^i}J^jD^a_{j,i}\equiv 0. \tag{3.23}$$

In a similar fashion, one proves the relationship

$$\lim_{J\to 0}\frac{\delta\overline{\Gamma}}{\delta\hat{a}_\mu}\langle D^a_\mu[\hat{a}+\varphi]\Pi^b_a[\hat{a},\varphi]\rangle=0, \tag{3.24}$$

where, in addition, there appears the ghost field propagator in the background field gauge $\Pi^b_a[\hat{a},\varphi]$. This last is defined as the negative inverse of the $\mathscr{F}^a_b$ operator, that is

$$\mathscr{F}^a{}_b\equiv F^i{}_bD^a_i[\hat{a}+\varphi], \tag{3.25a}$$

$$\mathscr{F}^a{}_c[\hat{a},\varphi]\Pi^c{}_b[\hat{a},\varphi]=-\delta^a_b. \tag{3.25b}$$

Observe that the derivative of this operator, $V_\mu{}^a{}_b\equiv\mathscr{F}_\nu{}^aD^\nu{}_{b,\mu}$, turns out to be the usual ghost–ghost–quantum field vertex operator.

The most interesting property of this method, however, is a very peculiar gauge invariance, valid for the appropriately defined effective action, as we will show in the next section. Such a property is written as

$$\left\langle\frac{\delta\overline{\Gamma}}{\delta\varphi_i}F^a{}_i[\varphi]+\frac{\delta\overline{\Gamma}}{\delta\hat{a}_j}\frac{\delta D[\varphi]^a{}_j}{\delta\varphi_i}\hat{a}_i\right\rangle=0, \tag{3.26}$$

for some peculiar $\overline{\Gamma}[\hat{a},\varphi]$. As formerly said, in the present formulation the effective action of the effective field can be perturbatively constructed by summing only vacuum diagrams with respect to the $\hat{a}$ field.

IV. GAUGE INVARIANT EFFECTIVE ACTION

In the context of the background field method, it is possible to generate a very peculiar *gauge invariant effective action* $\tilde{\Gamma}[\varphi]$. In order to do that, let us be precise in the sense in which such an invariance holds. As we have seen, in the conventional Yang–Mills generating functional,

$$Z[J]=N\int DA'\ e^{i(S_{\rm eff}[A']+J\cdot A')}, \tag{4.1}$$

one is mainly concerned with the effective action $S_{\rm eff}$, given by

$$S_{\rm eff}\equiv S_0[A']+\frac{1}{2\alpha}\int d^4x[(\partial\cdot A')^2]+S_{fpg}[A'], \tag{4.2}$$

plus, in addition, with the so-called source term. Choosing now an arbitrary gauge function, $\theta(x)$, the classical action $S_0[A']$ results invariant under the transformation

$$\delta_\theta A'_\mu(x)=\partial_\mu\theta(x)+[A'_\mu(x),\theta(x)], \tag{4.3}$$

i.e.

$$\delta_\theta S_0[A']\equiv 0. \tag{4.4}$$

As a matter of fact, by dividing the gauge potential into a *quantum* piece, (q), and a *background* component, (b), $A'_\mu = A_\mu{}^{(q)} + A_\mu{}^{(b)}$, the classical action $S_0[A']$ is indeed invariant under a wider class of gauge transformations; these are subdivided into two classes, namely

$$\delta_\theta^{(q)}A_\mu^{(q)}=\partial_\mu\theta+[A_\mu^{(q)}+A_\mu^{(b)},\theta],\quad \delta_\theta^{(q)}A_\mu^{(b)}=0, \tag{4.5a}$$

and

$$\delta_\theta{}^{(b)}A_\mu{}^{(q)}=[A_\mu{}^{(q)},\theta],\quad \delta_\theta^{(b)}A_\mu{}^{(b)}=\partial_\mu\theta+[A_\mu{}^{(b)},\theta]. \tag{4.5b}$$

In each case it results

$$\delta_\theta{}^{(q)}S_0[A']\equiv 0,\quad \delta_\theta^{(b)}S_0[A']\equiv 0. \tag{4.6}$$

In the framework of the background field method, one can choose such a peculiar effective action $S_{\rm eff}$ (namely our $\tilde{\Gamma}[\varphi]$), such that

$$\delta_\theta{}^{(b)}S_{\rm eff}[\varphi]\equiv 0. \tag{4.7}$$

In this case the effective action $\tilde{\Gamma}[\varphi]$ is said to be the ''gauge (b) invariant effective action.'' To get this result let us begin with introducing the *background gauge* generating functional $\tilde{Z}[J,\varphi]$ in the form of

$$\begin{aligned}\tilde{Z}[J,F[\varphi],\varphi]\equiv\tilde{Z}_F[J,\varphi]&=\exp\{-\tilde{W}_F[J,\varphi]\}\\ &=N'\int\mathscr{D}\tilde{A}\ \exp-\Big\{S_0[A]+\frac{1}{2}\int d^4x\ \eta^{ab}F_a^i[\varphi]F_b^j[\varphi]\\ &\quad\times(A_i-\varphi_i)(A_j-\varphi_j)+J\cdot A\Big\}\det(F[\varphi]_a^{c\mu}D_{\mu c}^b[A]).\end{aligned} \tag{4.8}$$

In this formulation it is necessary to assume $J=J[\varphi]$. The gauge potential A_μ is evidently related to a_μ via Eq. (3.17), namely $\hat{A}_\mu=\hat{a}_\mu+\varphi_\mu$, since it results that

$$\widetilde{W}_F[J,\varphi]=\overline{W_F}[J,\varphi]+J\cdot\varphi. \tag{4.9}$$

Similarly, the effective action turns out to be

$$\begin{aligned}\overline{\Gamma}[\overline{a},F[\overline{a}],\varphi]&=\overline{W_F}[J,\varphi]-J\cdot\hat{a}=\widetilde{W}_F[J,\varphi]-J\cdot\varphi-J\cdot\hat{a}\\&=\widetilde{W}_F[J,\varphi]-J^\mu\cdot\hat{A}_\mu\equiv\widetilde{\Gamma}_F[\hat{A},\varphi].\end{aligned} \tag{4.10}$$

Observe that, in so doing, we introduced into S_{eff} two ''external sources,'' $J(x)$ and $\varphi(x)$, which are quite arbitrary and uncorrelated. We are so free to impose another, very useful constraint on the theory; we are setting $J=J[\varphi]$, or $\varphi=\varphi[J]$, such that it is

$$\varphi=\hat{A}, \quad \text{or} \quad \hat{a}=0. \tag{4.11}$$

The resulting effective action, that is $\widetilde{\Gamma}_F[\hat{A}(J[\varphi]),\varphi]\equiv\Gamma_F[\varphi]$, turns out to be our claimed gauge (b) invariant effective action, satisfying

$$\frac{\delta\widetilde{\Gamma}_F[\varphi,\varphi]}{\delta\varphi_i}F_i^a[\varphi]\equiv\left\{\frac{\delta\widetilde{\Gamma}_F[\hat{A},\varphi]}{\delta\hat{A}_i}+\frac{\delta\widetilde{\Gamma}_F[\hat{A},\varphi]}{\delta\varphi_i}\right\}\Bigg|_{\varphi=\hat{A}}\cdot F_i^a[\varphi]=0. \tag{4.12}$$

In explicit form, it becomes

$$\begin{aligned}e^{-\widetilde{\Gamma}[\hat{A},\hat{A}]}=N''\int\mathscr{D}A\ \det[F_a^i[\hat{A}]D_i^b[A]]\exp-\Bigg\{S_0[A]+\frac{1}{2}\int d^4x[F_c^{\mu a}[\hat{A}](A_{\mu a}-\hat{A}_{\mu a})\\\times F_c^{\nu b}[\hat{A}](A_{\nu b}-\hat{A}_{\nu b})]+\frac{\delta\Gamma[\hat{A}]}{\delta\hat{A}_\mu^a}(A_\mu^a-\hat{A}_\mu^a)\Bigg\},\end{aligned} \tag{4.13}$$

with

$$\frac{\delta\Gamma[\hat{A}]}{\delta\hat{A}_\mu^a}\equiv\left\{\frac{\delta\widetilde{\Gamma}[\hat{A},\varphi]}{\delta\hat{A}_\mu^a}+\frac{\delta\widetilde{\Gamma}[\hat{A},\varphi]}{\delta\varphi_\mu^a}\right\}\Bigg|_{\varphi=\hat{A}}. \tag{4.14}$$

It is important to note that to introduce the background component into the customary Yang–Mills theory can be seen as the development of the ordinary Lagrangian formulation in the presence of a *nonconventional* gauge-fixing term.[12] By generalizing the idea of Abbott *et al.*, we will assume

$$F[\varphi]_{ab}^\mu A_\mu^b\equiv\partial^\mu A_\mu^a-gf_{abc}\varphi_\mu{}^b A_\mu{}^c=B_\varphi{}^a(x), \tag{4.15a}$$

where the functions $B_\varphi^a(x)$ are independent of $a_\mu(x)$ and such that

$$\lim_{\varphi\to0}B_\varphi{}^a(x)\equiv0. \tag{4.15b}$$

The adoption of the Feynman rules into $\widetilde{\Gamma}[\hat{A},\varphi]$ will result in the usual diagrammatic expansion. All the well-known Feynman diagrams of the customary formulation will, in fact, emerge but, in addition to these, some new diagrams, will now result as vertices given by the functional derivatives of $\widetilde{\Gamma}[\hat{A},\varphi]$ with respect to φ. These new vertices require a bit more attention in the diagrammatic treatment of the theory than the conventional ones. Indeed, in order to derive the physical consequences by applying the rules of the LSZ reduction prescription to the S matrix, one should

examine all of the tree diagrams present in the background field, then to combining these together with all possible external lines, with the propagators ''amputated.'' As a matter of fact, the 1P*I* Green's functions are obtained by differentiating $\widetilde{\Gamma}[\hat{A},\varphi]$ with respect to the quantum $\hat{a}$ field, leaving φ constant. In the gauge invariant version of the background field method, however, it corresponds to functionally differentiate $\widetilde{\Gamma}[\hat{A},\varphi]$ with respect to each of the two arguments $\hat{A}$ and φ, and, after it, to set $\varphi=\hat{A}$. This is why we generate the new vertices in the background theory and, consequently, why we need to prove that the conventional S matrix operator coincides with that of the background field method, or, in other words, that all the new vertices are physically influent. Up to date such a question as well as the renormalization itself of this method have been treated in the physical condition of mass—shell with a perturbation expansion in the background field, at least to our knowledge. Frequently, moreover, one has used the global symmetries of the conventional theory, such as the BRS symmetry, to prove things, without any preliminary checks on it. A careful analysis of these basic assumptions in the background gauge (b) invariant formulation and its S matrix operator seems now to be necessary. The results of it are the following.

Let us first recall, (a), that in spite of the fact that the background gauge invariant model contains many additional (b) vertices, many remarkable shortcomings for the computation of the renormalization constants[15] are valid for it.[13] This happens because in the $\varphi\to\hat{A}$ limit the N-point vertex functions, radiatively corrected, become interrelated by the simple Ward–Lee identities, such as

$$\widetilde{\Gamma}_{,\mu\nu}=-\widetilde{\Gamma}_{,j}D^{j}{}_{a,\mu}\hat{a}^{a}{}_{\nu}. \tag{4.16}$$

Contrary to this, in the conventional Yang–Mills theory one is ever dealing with the more entangled Slavnov–Taylor identities. Hence, if the theory under consideration is more complex than bare Yang–Mills, but renormalizable, it will be sufficient to search for the little number of counterterms allowed, constructed from the most simple, admissible integral invariant terms of it, gauge (b) invariant and of the correct dimension.

Second, (b) note that the coincidence limit $\varphi\to\hat{A}$ inside $\widetilde{\Gamma}[\hat{\phi},\varphi]$ leads one to consider the background gauge φ field as a second, effective dynamical variable. As such, it also requires an additional $J'^{\mu}(x)$ source term to couple with, as well as an additional gauge fixing operator, $F'^{\mu}{}_{ab}$, needed to break gauge symmetry with respect to φ.[13] Concerning the need of such a term, let us observe that the condition

$$\varphi=\hat{A}, \quad \text{equivalent to } 0=\hat{a}=\frac{\delta\overline{W_F}}{\delta J}, \tag{4.17}$$

shows that the Légendre transform from $\overline{W_F}$ to $\overline{\Gamma_F}$ *is singular* in this value. Actually it will follow that $\Gamma[\varphi]$ is no more the Légendre transform of $\widetilde{W}[J[\varphi],\varphi]$.

As a third observation, (c) we point out that the Slavnov–Taylor identities and related BRS gauge symmetry are expressed, in their original form, acting on the generating functional $\widetilde{Z}_F[J,\varphi]$; it is only *after a Légendre transform* from $\widetilde{W}_F$ that they become a property of the $\widetilde{\Gamma}[\hat{a},\varphi]$ functional. This means, hence, that this symmetry could also be invalidated in the critical value $\hat{a}=0$, and it must be explicitly checked. Such a check, however, is a difficult task to do, because the effective action is normally expressed only in a perturbative sense. In the Appendix we give a computation showing that global BRS invariance of the effective action in this quite simple model does not seems to hold anymore.

Going on, (d) if, nevertheless, we were to analyze the bare Yang–Mills effective action and its BRS symmetry in order to ''graphically demonstrate'' that all the diagrams containing at least one functional derivative of $\widetilde{Z}_F$ with respect to φ sum up to zero, then, it would be necessary to apply these symmetries to the fully corrected functional; we mean a functional that contains the gauge fixing term $F'_{ab}{}^{\mu}$ for the background field *from the very beginning*, i.e. no more by introducing it only ''when it is required.'' Let us observe also that, following the simplest formu-

lation of the BRS invariance, one is led to hypothesize that *the same cutoff* needed to get the physical subsector of the quantum A_μ field states, which spoils these states of their null modes, *must also hold* for the auxiliary φ field. Only with this assumption one can introduce *one and the same* Faddeev–Popov's pair of ghost fields for the two subspaces considered.

To end up, (e), as previously noted,[15] to each order in the loop expansion of $\tilde{\Gamma}[\hat{a},\varphi]$, one encounters subdiagrams of the vertex functions $\tilde{\Gamma}_{,i_1,\ldots,i_n}$, or renormalization parts, which are not mere insertions of lower-order vertices and propagators. As a consequence, the renormalization program in this method will include parts that do not depend on the functional derivatives of $\tilde{\Gamma}$. The commonly used results of an iterative way to exhibit the renormalizability of a conventional theory are now insufficient. The final expression of $\tilde{\Gamma}$ will include, at least, one counterterm for each of the gauge fixing parameters. Nevertheless, the renormalization of $\tilde{\Gamma}[\hat{A},\varphi]$ can be achieved in an indirect way,[11] i.e., by proving that all the divergencies of $\tilde{W}_F[J,\varphi]$ can be subtracted with a finite number of local counterterms. This implies that the whole $\tilde{\Gamma}[\hat{A},\varphi]$ will be subtracted and regularized and, in particular, that $\tilde{\Gamma}[\varphi,\varphi]$ is also finite.

We considered this last question very briefly, by merely assuming that we can add the appropriate counterterms to the naive $\tilde{Z}_F[J,\varphi]$ generating functional, such that the renormalized expression of this model formally coincides with the naive one, namely with the expression given above [see Eqs. (3.20) and (3.21)]. Hereafter, all the involved fields shall then be considered as the renormalized versions of their naive counterpart, as assumed up to now. Since in the current literature of the background gauge field method there seems not to be any, fully satisfactory proof on the equivalence between the $\hat{S}$ matrix operators, namely a demonstration respecting all items, from (a) to (e), listed above, we proceeded as follows.

V. AN EQUIVALENCE PROOF OF THE *S* MATRIX

To start with, let us assume, in each closed and bounded domain $\mathbf{O}_L$ of an assigned space-time manifold $\mathcal{O}$, the presence of a local algebra $\mathcal{A}(\mathbf{O}_L)$ of the physical observables of a given theory or, better, a set of operations acting on the physical observables defined and with support in $\mathbf{O}_L$. We will limit ourselves to consider the presence in $\mathcal{O}$ of a self-interacting Yang–Mills field $A_\mu(x)$; we will neglect, moreover, the presence of gravity into the field dynamics. Then, let us introduce the particular functional operator $\hat{S}$, which, while acting on the local physical observables, generates the scattering matrix elements for assigned asymptotic conditions. Such a functional, as known, satisfies the algebra of the gauge transformations in $\mathbf{O}_L$, namely

$$\underline{A}_\mu \to \underline{A}^{\epsilon}_\mu = [T^a \underline{A}^a_\mu]^{\epsilon} = \underline{U}(\epsilon)\left[T^a \underline{A}^a_\mu - \frac{i}{g}\,\underline{U}(\epsilon)^{-1}\,\partial_\mu \underline{U}(\epsilon)\right]\underline{U}(\epsilon)^{-1}, \tag{5.1}$$

$$\underline{A}^a_\mu \to \underline{A}^a_\mu + \delta\underline{A}^a_\mu = \underline{A}^a_\mu - \frac{1}{g}\,\partial_\mu \epsilon^a + f^{abc}\epsilon^b \underline{A}^c_\mu, \tag{5.2}$$

where the underline means the local restriction to $\mathbf{O}_L$. These last create an *endomorphism G* into the space of the $\hat{S}$ generated physical observables, that is

$$\mathcal{G}_L : \langle \hat{S}(\mathbf{O}_L)\rangle \to \langle \hat{S}(\mathbf{O}_L)\rangle. \tag{5.3}$$

In the background gauge quantization method, the $\hat{S}$ scattering operator contracted between asymptotic states, $\langle \hat{S}\rangle$, is parametrized by the same background field, namely $\hat{S}=\hat{S}[\varphi]$. In a quite general formulation, this parametrization is reflected in the aforementioned *nonconventional* gauge fixing operator $F[\varphi]$ and in the dependence on φ of the source current $J=J[\varphi]$, in such a way as

$$\hat{S}_\varphi \equiv \hat{S}[F_\varphi] \equiv \hat{S}[F[\varphi], J[\varphi], \varphi], \tag{5.4}$$

[see Eqs. (2.11) and (3.18)]. Now it turns out that, besides the usual algebraic operations defined in the vector space of the physical states, one can introduce another *composition law* in $\mathscr{G}_L$, interesting the $\hat{S}_\varphi$ group elements. With this we mean the combined action of two or more successive scattering processes, each one parametrized by an independent, arbitrary background gauge condition, viz.

$$\hat{S}_\eta \circ \hat{S}_\zeta \equiv \hat{S}[F_\eta] \circ \hat{S}[G_\zeta] = \langle \Omega, \hat{S}_\eta \hat{S}_\zeta^{-1} \Omega \rangle. \tag{5.5}$$

Here the *in*coming fields of the second $\hat{S}_\eta$ operator are defined as the *out*going fields of the inverse $\hat{S}_\zeta$ operator, where η and ζ are two arbitrary background field configurations. Since the choice of the gauge fixing operators, F and G, for any parametrized $\hat{S}_\varphi$ scattering operator is arbitrary and physically influent, we can reduce the previous definition to

$$\hat{S}_\eta \circ \hat{S}_\zeta \equiv \hat{S}[F_\eta] \circ \hat{S}[F_\zeta], \tag{5.6}$$

and to assume $F[\varphi]$ as in Eqs. (4.15). It is then easy to derive the composition law [see Eq. (2.8)],

$$\hat{S}_\eta \circ \hat{S}_\zeta = (\Sigma_\eta \cdot ((\Sigma_\zeta \cdot Z_\zeta)^{-1} Z_\eta)), \tag{5.7}$$

in such a way as, with our choice of $F[\varphi]$, it is

$$\hat{S}_\eta \circ \hat{S}_\zeta = \hat{S}[F_\eta - F_\zeta, J_\eta - J_\zeta, \eta - \zeta] \tag{5.8a}$$

$$= \hat{S}[F_{\eta-\zeta}, J_{\eta-\zeta}, \eta - \zeta] \equiv \hat{S}_{\eta-\zeta}. \tag{5.8b}$$

In physical terms, Eqs. (5.7) and (5.8) are as follows. A gauge, self-interacting A_μ field is divided into a classical background component ζ_μ and a quantum fluctuation field a_μ, whence one derives the associated scattering operator $\hat{S}_\zeta$. After defining the inverse scattering of these fields, one similarly separates the a_μ field into another classical background component η_μ and a remaining second quantum fluctuation a'_μ. The matrix elements for the scattering of a'_μ in the presence of the classical η_μ field, will thus result the same as those for the scattering of the a_μ field in the presence of the $\zeta_\mu - \eta_\mu$ background.

With our composition law the ordinary group properties then read as

$$\begin{gathered}
\hat{S}_\varphi^{-1} \equiv \hat{S}_{-\varphi} = \hat{S}[-F_\varphi, -J_\varphi, -\varphi]; \\
\hat{S}[F_\varphi] \circ \hat{S}[F_\varphi]^{-1} = \hat{S}[0] \equiv \mathrm{Id}; \\
\hat{S}[F_\varphi] \circ \mathrm{Id} = \mathrm{Id} \circ \hat{S}[F_\varphi] = \hat{S}[F_\varphi]; \\
(\hat{S}[F_\eta] \circ \hat{S}[F_\theta]) \circ \hat{S}[F_\zeta] = \hat{S}[F_\eta] \circ (\hat{S}[F_\theta] \circ \hat{S}[F_\zeta]).
\end{gathered} \tag{5.9}$$

The key point, now, is to realize that the transition from the generic background gauge field effective action $\Gamma_F[\hat{a}, \varphi]$ to the manifestly gauge (b) invariant expression $\tilde{\Gamma}_F[\hat{A}, \varphi]|_{\varphi = A}$, can be provided by a one parameter *automorphism* acting in the quoted subalgebra of parametrized S matrix operators, $\hat{S}[F_\varphi]$.

We will begin, hence, by substituting the pair of fields $(a, \varphi) = (A - \varphi, \varphi)$ with the pair of ''interpolating fields,'' $(A^\tau, \tau\varphi)$, where

$$A^\tau{}_\mu \equiv (1 - \tau) a_\mu + \tau \varphi_\mu, \tag{5.10}$$

$0 \leqslant \tau \leqslant 1$, in such a way as to create a τ-dependent $\tilde{\Gamma}_F[\hat{A}^\tau, \tau\varphi]$ functional. Going on this way, we will arrive at a τ parametrization of the same $\hat{S}$ operator, or, in other words, to a family of S matrix operators, $\hat{S}^\tau_\varphi = \hat{S}^\tau[F_\varphi]$.

To gain our final goal, i.e., the equivalence between $\hat{S}$ matrices, two preliminary results are thus in order. If we can prove, indeed, that the transformation $\hat{S}_\varphi \to \hat{S}^\tau_\varphi$ is an automorphism in the group of the local operators $\hat{S}_\varphi$, while showing, at the same time, that the relationship

$$(\Omega, \hat{S}[F_\varphi]\Omega) = (\Omega, \hat{S}^\tau[F_\varphi]\Omega), \quad \forall \tau \in [0,1] \tag{5.11}$$

also holds, it will follow that the given transformation can be unitarily implemented, i.e.

$$\hat{S}^\tau_\varphi = U(\tau)\hat{S}_\varphi U(\tau)^{-1}. \tag{5.12}$$

This will imply that the physical predictions stemming from the model with $\tau = 1$, which is the background gauge (b) invariant one, are the same of those stemming from the $\tau = 0$ model, viz. the conventional gauge theory. From the continuity of this transformation, the result will then be true with each τ value.

We begin, thus, by showing that there is a condition of relative locality between the (a, φ) and $(A^\tau, \tau\varphi)$ pairs of fields. This corresponds to the realistic assumption that the asymptotic Hilbert spaces of this theory, $\mathscr{H}^{\text{in}}$ and $\mathscr{H}^{\text{out}}$, are unaffected by the previous transformation of field variables. In fact, to perform a translation of an integration field variable $a(x)$ by a classical component $\varphi(x)$, and to follow this with a multiplication by a real number τ, *would not affect* the asymptotic properties of the theory.

From the canonical quantization viewpoint, these conclusions can be easily supported. Let us recall, indeed, that a pair of quantum field operators $\Psi_a(x)$ and $\Psi_b(y)$ are said to be relatively local (antilocal) iff the commutation (anticommutation) relation,

$$[\Psi_a(x), \Psi_b(y)]_{-(+)} = 0, \quad \forall (x-y)^2 < 0, \tag{5.13}$$

holds, at least in a weak sense. This property verifies the transitive rule, so that if Ψ_a and Ψ_b are relatively local with respect to Ψ_c, they are also relatively local. Since a classical field, like $\varphi(x)$, defines a set of cyclic states with respect to the vacuum state, it turns out that

$$[\varphi(x), a(y)]_- = 0 = [\varphi(x), A(y)]_-, \tag{5.14}$$

and, by the transitive property,

$$[a(x), A^\tau(y)]_- = 0, \tag{5.15}$$

all that is customary in local relativistic causal quantum field theory.

The local operations obtained by acting with $\hat{S}^\tau$ on the vacuum then have support in the same space-time region $\mathbf{O}_L$ in which are supported the $\hat{S}$ generated ones. This means the transformation $\hat{S} \to \hat{S}^\tau$ lies inside the same subalgebra $\underline{\mathscr{S}}(\mathbf{O}_L)$ in which we defined $\hat{S}$.

We are now in the position to write down our interpolating transformation, as it emerges by the former functional integral expression of $\tilde{W}_F[J, \varphi]$. Taking into account the previous remarks, items from (a) to (e), the right starting point just becomes

$$\overline{Z_F}[J, J', \varphi] = N \int \mathscr{D}a \, \exp - \Big\{ S_0[a] + \frac{1}{2}\, \eta^{ab} \int d^4x [F^i_a[\varphi] F^j_b[\varphi] a_i a_j + F'^i_a + F'^j_b \varphi_i \varphi_j] + J^i \cdot a_i$$
$$+ J'^j \cdot \varphi_j \delta(\hat{a}) \Big\} \det(F^i_a[\varphi] D_{bi}[a]) \det(F'^j_a D_{jb}[\varphi]), \tag{5.16}$$

where $\delta(x)$ is Dirac's delta function. An implicit definition of $\overline{\Gamma}_F$ will then follow, namely

$$e^{-\overline{\Gamma}_F[\hat{a},\varphi]}=N''\int \mathscr{D}a\ \det(F_a^i[\varphi]D_{ib}[a+\varphi])\det(F_a'^jD_{jb}[\varphi])\exp-\Bigg\{S_0[a+\varphi]$$
$$+\frac{1}{2}\int d^4x[(F_a^i[\varphi]a_i)^2+(F_a'^i\varphi_i)^2]+\frac{\delta\overline{\Gamma}_F[\hat{a},\varphi]}{\delta\hat{a}_\mu^a}(a_\mu^a-\hat{a}_\mu^a)-\frac{\delta\overline{\Gamma}[\hat{a},\varphi]}{\delta\varphi_\mu^a}\varphi_\mu^a\delta(\hat{a})\Bigg\}. \tag{5.17}$$

This is also equivalent to

$$e^{-\widetilde{\Gamma}_F[\hat{A},\varphi]}=N''\int \mathscr{D}A\ \det(F_a^i[\varphi]D_{ib}[A])\det(F_a'^iD_{ib}[\varphi])$$
$$\times\exp-\Bigg\{S_0[A]+\frac{1}{2}\int d^4x[F_b^{\mu a}[\varphi](\hat{A}-\varphi)_\mu^aF_c^{\nu b}[\varphi](\hat{A}-\varphi)_\nu^c+F_b'^{\mu a}\varphi_{\mu a}F_b'^{\nu c}\varphi_{\nu c}]$$
$$\times\frac{\delta\widetilde{\Gamma}[\hat{A},\varphi]}{\delta\hat{A}_\mu^a}(A_\mu^a-\hat{A}_\mu^a)-\frac{\delta\widetilde{\Gamma}}{\delta\varphi_\mu^a}\varphi_\mu^a\delta(\hat{A}-\varphi)\Bigg\}. \tag{5.18}$$

With the freedom of redefining the normalization parameter N inside $\widetilde{Z}_F$, we can now neglect the last term of Eq. (5.18), since it does not depend on a_μ, so as to obtain the corresponding $\widetilde{Z}_F[J,\varphi]$ functional. With that we can introduce our *interpolating effective action* $\Gamma_\tau[\hat{A}^\tau,\tau\varphi]$, which takes the form

$$e^{-\Gamma_\tau}\equiv e^{-\widetilde{\Gamma}_F[\hat{A}^\tau,\tau\varphi]}\equiv N''\int \mathscr{D}a\ \exp-\Bigg\{S_0[A^\tau]+\frac{1}{2}\int d^4x[\{F_a^i[\tau\varphi](A_i^\tau-\tau\varphi_i)\}^2+\{F_a'^i\tau\varphi_i\}^2]$$
$$+J_\tau[\hat{A}^\tau]\cdot(A^\tau-\hat{A}^\tau)\Bigg\}\times\det(F_a^i[\tau\varphi]D_{ib}[A])\det(F_a'^iD_{ib}[\tau\varphi]), \tag{5.19}$$

$0\leqslant\tau\leqslant1$, where we defined the current

$$J_\tau^{\mu a}(x)\equiv\frac{\delta\Gamma_\tau[\hat{A}^\tau]}{\delta\hat{A}^\tau{}_{\mu a}(x)}-\frac{\delta\widetilde{\Gamma}[\hat{A}^\tau,\psi]}{\delta\psi_{\mu a}}\Bigg|_{\psi=\tau\varphi}. \tag{5.20}$$

After a customary Légendre transformation of Eq. (5.19), corresponding to get the interpolating transformation

$$\widetilde{W}_F[J,\varphi]\to W^\tau[J^\tau]\equiv\widetilde{\Gamma}_\tau[\hat{A}^\tau,\tau\varphi]+J_\tau\cdot\hat{A}^\tau, \tag{5.21}$$

we also obtain

$$Z^\tau[J_\tau,\tau\varphi]=e^{-W^\tau}\equiv N'\int \mathscr{D}a\ \exp-\Bigg\{S_0[A^\tau]+\frac{1}{2}\int d^4x\ \eta^{ab}(F_a^i[\tau\varphi]F_b^j[\tau\varphi]$$
$$\times(A_i^\tau-\tau\varphi_i)(A_j^\tau-\tau\varphi_j)+F_a'^iF_b'^j\tau^2\varphi_i\varphi_j)+J_\tau\cdot A^\tau\Bigg\}$$
$$\times\det(F_a^i[\tau\varphi]D_{ib}[A^\tau])\det(F_a'^iD_{ib}[\tau\varphi]). \tag{5.22}$$

The limits $\tau\to0$ and $\tau\to1$, of the $Z^\tau[J_\tau,\tau\varphi]$ functional, reproduce, respectively, the normally defined Yang–Mills theory generating functional and the background field (b) gauge invariant one

of Abbott *et al.* As a matter of fact, the constant term $\exp-\frac{1}{2}(F'\hat{A})^2\times\det(F'D[\hat{A}])$, which results as an additional term in Eq. (5.22), can be easily reabsorbed into the renormalization procedure of W_τ, or, in other words, into the N' normalization constant.

Hence, as an effect of the LSZ reduction prescription, we assert that the operator

$$\Sigma_\tau \equiv :\exp\int d^4x\ d^4y\left[A^\tau{}_\mu{}^{(\mathrm{in})}(x)K^{\mu\nu}(x,y)\ \frac{\delta}{\delta J^\nu{}_\tau(y)}\right]: \tag{5.23a}$$

$$=:\exp\int d^4x\ d^4y\left[(1-\tau)a_\mu{}^{(\mathrm{in})}(x)K^{\mu\nu}(x,y)\frac{\delta}{\delta J_\tau{}^\nu(y)}\right]:, \tag{5.23b}$$

while acting on $Z^\tau[J_\tau,\tau\varphi]$, for fixed τ, defines the interpolating scattering matrix elements of the $A^\tau{}_\mu$ and $\tau\varphi_\mu$ fields, namely the $\hat{S}^\tau{}_\varphi[F,F']$ operator.

The first preliminary step, that the translation $\hat{S}\to\hat{S}^\tau$ is an automorphism $\hat{\alpha}_\tau$ in the subset of local scattering operators defined in $\mathbf{O}_L$, will soon emerge by showing that $\hat{\alpha}_\tau$ is a map conserving the group and commutator operations,

$$\hat{\alpha}_\tau(aX\circ bY)=a\hat{\alpha}_\tau(X)\circ b\hat{\alpha}_\tau(Y), \tag{5.24}$$

$$\hat{\alpha}_\tau([X,Y])=[\hat{\alpha}_\tau(X),\hat{\alpha}_\tau(Y)]. \tag{5.25}$$

This corresponds to prove that the action

$$\hat{\alpha}_\tau(a\hat{S}_\eta\circ b\hat{S}_\zeta)=ab\hat{\alpha}_\tau(\hat{S}_\eta\circ\hat{S}_\zeta)=ab\hat{\alpha}_\tau(\hat{S}_{\eta-\zeta}), \tag{5.26a}$$

is exactly equivalent to the composition

$$a\hat{\alpha}_\tau(\hat{S}_\eta)\circ b\hat{\alpha}_\tau(\hat{S}_\zeta)=ab\hat{\alpha}_\tau(\hat{S}_{\eta-\zeta}). \tag{5.26b}$$

In the same time it must also be that

$$\hat{\alpha}_\tau(\hat{S}_\eta\circ\hat{S}_\zeta\circ\hat{S}_\eta^{-1}\circ\hat{S}_\zeta^{-1})=\hat{\alpha}_\tau(\hat{S}_0)=\hat{\alpha}_\tau(\hat{S}_\eta)\circ\hat{\alpha}_\tau(\hat{S}_\zeta)\circ\hat{\alpha}_\tau(\hat{S}_\eta^{-1})\circ\hat{\alpha}_\tau(\hat{S}_\zeta^{-1}). \tag{5.27}$$

Both of these relations are fulfilled if it results that

$$\hat{S}^\tau[F_\eta-F_\zeta]=\hat{S}^\tau[F_\eta]\circ\hat{S}^\tau[F_\zeta]. \tag{5.28}$$

This is nothing but our formerly defined group operation of the φ-parametrized family of $\hat{S}$ matrix operators, now extended to the arbitrary τ values. It is conceivably true that this assumption holds, since it is said that the self-interaction of the $a_\mu+\tau\eta_\mu$ field, followed by the scattering with the $a_\mu+\tau\zeta_\mu$ field, is the same as the self-interaction of the $a_\mu+\tau(\eta_\mu-\zeta_\mu)$ field. To see this, let us consider the following two transformations:

$$[\eta^{ab}(F_\eta-F_\zeta)^i_a(F_\eta-F_\zeta)^j_b a_i a_j]\to[\eta^{ab}(1-\tau)^2(F_{\tau\eta}-F_{\tau\zeta})^i_a(F_{\tau\eta}-F_{\tau\zeta})^j_b a_i a_j], \tag{5.29a}$$

$$\begin{aligned}&\{\eta^{ab}(1-\tau)^2[(F_{\tau\eta})^i_a(F_{\tau\eta})^j_b a_i a_j\circ(F_{\tau\zeta})^i_a(F_{\tau\zeta})^j_b a_i a_j]\}\\&\quad\to\{\eta^{ab}(1-\tau)^2[(F_{\tau\eta})^i_a(F_{\tau\eta})^j_b-(F_{\tau\zeta})^i_a(F_{\tau\zeta})^j_b]a_i a_j\}],\end{aligned} \tag{5.29b}$$

and the analogous ones for the $(F'_\eta)^i_a$ operators. By the symmetry in the μ, ν indices, as well as that in the η^{ab} tensor, the difference between the two transformed right-hand sides reduces to

$$\langle\Omega,[(F_\eta)^i{}_a,(F_\zeta)^j{}_b]a_i{}^a a_j{}^b\Omega\rangle. \tag{5.30}$$

This is indeed zero since the gauge fixing operators F_η and F_ζ were assumed as independent. Quite similarly, the determinantal shift,

$$\det[(F_\eta - F_\zeta)^a{}_i D^{ib}(a)] \to \det[(F_{\tau\eta} - F_{\tau\zeta})_i{}^a D^{ib}(A^\tau)], \tag{5.31a}$$

can be shown to be equivalent to

$$\det[(F_{\tau\eta})_i{}^a D^{ib}(A^\tau)] \circ \det[(F_{\tau\zeta})_i{}^a D^{ib}(A^\tau)] \to \det[(F_{\tau\eta} - F_{\tau\zeta})_i{}^a D^{ib}(A^\tau)]. \tag{5.31b}$$

By this we conclude that $\hat{\alpha}_\tau$ operates on the $\hat{S}_\varphi(F_\varphi, J_\varphi)$ family as an automorphism. What it remains to prove, then, is the validity of the relationship

$$(\Omega, \hat{S}[F_\varphi]\Omega) = (\Omega, \hat{S}^\tau[F_\varphi]\Omega), \quad \forall \tau \in [0,1]. \tag{5.32}$$

To this aim let us write it as

$$\frac{d}{d\sigma}(\Omega, \hat{S}^\sigma[F_\varphi]\Omega)\bigg|_{\sigma=\tau} = 0, \quad \forall \tau, \sigma \in [0,1], \tag{5.33a}$$

namely

$$\frac{d}{d\sigma}(\Omega, \hat{S}^\sigma \Omega)\bigg|_{\sigma=\tau} = \frac{d}{d\sigma}(\Omega, \hat{S}^{\sigma+\tau}\Omega)\bigg|_{\sigma=0} = \frac{d}{d\sigma}(\Omega, (\hat{S}^\tau)^\sigma \Omega)\bigg|_{\sigma=0} = 0. \tag{5.33b}$$

In our formulation this translates to

$$\frac{d}{d\sigma}[(\Sigma_\tau \cdot Z^\tau)^\sigma]\bigg|_{\sigma=J=0} = 0. \tag{5.34}$$

As we previously said, the $\hat{\alpha}_\tau$ interpolation is active only when the quantum field to be integrated over, $\underline{A}$, has been divided into a classical component plus a novel quantum piece, i.e. $\underline{A} \to \underline{a} + \underline{\varphi}$. In order to get the action of $\hat{\alpha}_\sigma$ after the action of $\hat{\alpha}_\tau$, it is then necessary to introduce a second decomposition, quite similar to the former one, which separates the quantum $\underline{a}$ field into a second classical component and a third quantum fluctuation, i.e.

$$\underline{a} \to \underline{a}' + \varphi'. \tag{5.35}$$

This defines a functional integral $\tilde{Z}_{F,G}[J, \varphi, \varphi']$ that depends on two background field components, as well as on two gauge fixing operators. Hence, we have to interpolate the first interpolating functional integral $Z^\tau[J^\tau, \tau\varphi]$ between the values $\varphi' = 0$ and $\varphi' = \underline{a}'$, with the condition to reproduce the known expression of the gauge invariant effective action $\tilde{\Gamma}[\varphi, \underline{\varphi}]$ in the limit $\varphi' \to \underline{a}'$, $\tau = 1$. We introduce such a ''doubly interpolating effective action,'' $\Gamma_{\tau,\sigma}[\hat{A}^{\tau,\sigma}, \tau\varphi + \sigma\varphi']$ with the positions

$$\hat{A}^{\tau,\sigma} = (1-\tau)(1-\sigma)\hat{a}' + \tau\varphi + \sigma\varphi' \tag{5.36a}$$

and

$$\Phi \equiv \varphi + \varphi'. \tag{5.36b}$$

It is to be

$$e^{-\Gamma_{0,0}} \equiv e^{-\Gamma_{\tau,\sigma}}\big|_{\tau=\sigma=0} = e^{-\overline{\Gamma}[\hat{a}]} \quad (conventional), \tag{5.37a}$$

$$e^{-\Gamma_{1,1}}=e^{-\tilde{\Gamma}[\Phi,\Phi]} \quad (gauge\ \ invariant), \tag{5.37b}$$

$$\begin{aligned} e^{-\Gamma_{\tau,0}}&=e^{-\Gamma_{\tau}[\hat{A}^{\tau}]} \\ e^{-\Gamma_{0,\sigma}}&=e^{-\Gamma_{\sigma}[A^{\sigma}]} \quad (interpolating), \end{aligned} \tag{5.37c}$$

$$\begin{aligned} e^{-\Gamma_{\tau,1}}&=C_{\tau}e^{-\tilde{\Gamma}[\Phi,\Phi]}, \\ e^{-\Gamma_{1,\sigma}}&=C_{\sigma}e^{-\tilde{\Gamma}[\Phi,\Phi]}, \end{aligned} \tag{5.37d}$$

with C a real numerical parameter. Analogously, the associated interpolating source current will be

$$J^{\mu a}_{\tau,\sigma}=\frac{\delta\Gamma_{\tau,\sigma}[\hat{A}^{\tau,\sigma}]}{\delta\hat{A}^{\tau,\sigma}{}_{\mu a}}-\left.\frac{\delta\tilde{\Gamma}[\hat{A}^{\tau,\sigma},\psi]}{\delta\psi_{\mu a}}\right|_{\psi=\tau\varphi+\sigma\varphi'}. \tag{5.38}$$

Except for very special assumptions, it is also possible to rearrange the incoming field asymptotic conditions of φ and φ', such that

$$\tau\varphi_{\mu}{}^{(\mathrm{in})}+\sigma\varphi'{}_{\mu}{}^{(\mathrm{in})}=(\tau+\sigma-\tau\sigma)a'{}_{\mu}{}^{(\mathrm{in})}, \tag{5.39}$$

for arbitrary values of τ and σ, so as to have

$$A^{\tau,\sigma}{}_{\mu}{}^{(\mathrm{in})}=a'^{(\mathrm{in})}_{\mu}, \quad \forall\,\tau,\sigma\in[0,1]. \tag{5.40}$$

After introducing the gauge fixing operators $G[\varphi']$ and G' for the a'_{μ} and φ'_{μ} fields, quite analogous to the $F[\varphi]$ and F' ones, the *doubly interpolating* $\hat{S}^{\tau,\sigma}$ *operator* will turn to be completed. By the usual group properties of the $\hat{\alpha}_{\tau,\sigma}$ endomorphism we write it as $\hat{S}^{\tau,\sigma}=(\Sigma_{\tau,\sigma}\cdot Z^{\tau,\sigma})$, with

$$\Sigma_{\tau,\sigma}\equiv:\exp\int d^4x\ d^4y\left[a'{}_{\mu}{}^{(\mathrm{in})}(x)K'^{\mu\nu}(x,y)\ \frac{\delta}{\delta J^{\nu}{}_{\tau,\sigma}(y)}\right]: \tag{5.41}$$

and

$$\begin{aligned} Z^{\tau,\sigma}=\mathcal{N}\int \mathscr{D}a'\ \exp-\Bigg\{ & S_0[A^{\tau,\sigma}]+\frac{1}{2}\int d^4x\ \eta^{ab}[\{G[\sigma\varphi']^i_a G[\sigma\varphi']^j_b+F[\tau\varphi]^i_a F[\tau\varphi]^j_b\} \\ & \times(A^{\tau,\sigma}_i-\tau\varphi_i-\sigma\varphi'_i)(A^{\tau,\sigma}_j-\tau\varphi_j-\sigma\varphi'_j)+(\sigma^2 G'^{\,i}_a G'^{\,j}_b\varphi'_i\varphi'_j+\tau^2 F'^{\,i}_a F'^{\,j}_b\varphi_i\varphi_j)]+J_{\tau,\sigma}\cdot A^{\tau,\sigma}\Bigg\} \\ & \times\det[F[\tau\varphi]^i{}_a D[A^{\tau,\sigma}]^b{}_i]\det[G[\sigma\varphi']^j{}_a D[A^{\tau,\sigma}]^b{}_j]\det[F'^{\,i}_a D[\tau\varphi]^b{}_i]\times\det[G'^{\,j}_a D[\sigma\varphi']^b_j]. \end{aligned} \tag{5.42}$$

In this way one is led to consider the equation

$$0=\left[\frac{d}{d\sigma}(\Omega,(\hat{S}^{\tau})^{\sigma}\Omega)\right]\Bigg|_{\sigma=J=0}=\lim_{\sigma\to 0}\left\{\lim_{J_{\tau,\sigma}\to 0}\left[\frac{d}{d\sigma}(\Sigma_{\tau,\sigma}\cdot Z^{\tau,\sigma}[J_{\tau,\sigma}])\right]\right\}$$

$$=\lim_{\sigma\to 0}\lim_{J_{\tau,\sigma}\to 0}\left\{\left(\Sigma_{\tau,\sigma}:\exp\int d^4x\ d^4y\left[a'^{(\mathrm{in})}_{\mu}(x)K^{\mu\nu}(x,y)\left[\frac{d}{d\sigma}\frac{\delta}{\delta J^{\nu}_{\tau,\sigma}(y)}\right]\right]:\cdot Z^{\tau,\sigma}\right)\right.$$

$$-\left(\Sigma_{\tau,\sigma}\cdot\left[\frac{\delta S_0}{\delta A^{\tau,\sigma}_i}[(\tau-1)a'_i+\varphi'_i]+\eta^{ab}(G[\sigma\varphi']^{i,k}_a G[\sigma\varphi']^{j}_b(1-\tau)^2(1-\sigma)^2 a'_i a'_j\varphi'_k\right.\right.$$

$$-\{F[\tau\varphi]^i_a F[\tau\varphi]^j_b+G[\sigma\varphi']^i_a G[\sigma\varphi']^j_b\}(1-\tau)^2(1-\sigma)a'_i a'_j+\sigma G'^{i}_a G'^{j}_b\varphi'_i\varphi'_j)$$

$$+J_{\tau,\sigma}\cdot\frac{dA^{\tau,\sigma}}{d\sigma}+A^{\tau,\sigma}_i\left[\frac{\delta^2\tilde{\Gamma}[\hat{A}^{\tau\sigma},\psi]}{\delta\hat{A}^{\tau,\sigma}_i\delta\hat{A}^{\tau,\sigma}_j}[(\tau-1)a'_j+\varphi'_j]+\frac{\delta^2\tilde{\Gamma}[\hat{A}^{\tau\sigma},\psi]}{\delta\hat{A}^{\tau,\sigma}_i\delta\psi'_j}\varphi'_j\right]\Bigg|_{\psi=\tau\varphi+\sigma\varphi'}$$

$$+\det(F[\tau\varphi]D[A])\det(F'D[\tau\varphi])(\det(G'^{i,j}_a[\sigma\varphi']D_{ib}[A]\varphi'_j)\det(G'^{i}_a D_{ib}[\sigma\varphi'])$$

$$\left.\left.+\det(G^j_a[\sigma\varphi]D_{jb}[A])\det(G'^{a}_i Di_{jb}[\sigma\varphi']\varphi_j))\right]\cdot Z^{\tau,\sigma}\right)\right\},\tag{5.43}$$

where we put (and analogously for the $D^i_a[\psi']$ operator)

$$G^{i,j}_a[\sigma\varphi']\equiv\frac{\delta G^i_a[\psi']}{\delta\psi'_j}\Bigg|_{\psi'=\sigma\varphi'}.\tag{5.44}$$

The first line of Eq. (5.43), namely $([(d/d\sigma)\Sigma_{\tau,\sigma}]\cdot Z^{\tau,\sigma})$, is zero by formally writing it as

$$\left[\frac{d}{d\sigma}\frac{\delta}{\delta J_{\tau,\sigma}}\right]\cdot Z^{\tau,\sigma}=\lim_{\sigma'\to\sigma}\frac{1}{\sigma'-\sigma}\left(\frac{\delta Z^{\tau,\sigma'}}{\delta J_{\tau,\sigma'}}-\frac{\delta Z^{\tau,\sigma}}{\delta J_{\tau,\sigma}}\right).\tag{5.45}$$

Indeed, from the linearity of the $J_{\tau,\sigma}\cdot A^{\tau,\sigma}$ coupling, and by interchanging the limits $\sigma\to 0$ and $\sigma'\to\sigma$, two identical and σ-independent expressions will result in the functional derivatives. In physical terms, that means the Σ scattering operator for the LSZ reduction prescription to the physical states is invariant under a gauge field reparametrization. We have to show, thus, that the last ten terms in Eq. (5.43), those enclosed between the external square brackets, compensate reciprocally to zero. This will conclude the present equivalence proof. Note that in Eq. (5.43) these ten terms have been written by regrouping as two by two into each line, except for the last two, which are lonely. We note first that the fifth and sixth terms of it are straightforwardly zero, 5th+6th$\equiv$0, in the prescribed limits, as well as the second and fourth term also do, after a functional integration by parts, by observing that in the limit $J_{\tau,\sigma}\to 0$ the gauge fixing functions $B^a_{\varphi}(x)$, $B^b_{\varphi'}(x)$ tend to zero, that is

$$\lim_{J_{\tau,\sigma}\to 0}\ 2\mathrm{nd}+4\mathrm{th}=0.\tag{5.46}$$

Concerning the seventh and eighth terms of it, namely those enclosed inside internal square brackets, let us write them as

$$7\mathrm{th}+8\mathrm{th}=\lim_{J_{\tau,\sigma}\to 0}\frac{\delta}{\delta\hat{A}^{\tau,\sigma}_i}\left[\frac{\delta\tilde{\Gamma}}{\delta\hat{A}^{\tau,\sigma}_j}(\tau-1)a'_j+J^k_{\tau,\sigma}\varphi'_k\right]=\frac{\delta}{\delta\hat{A}^{\tau,\sigma}_i}\left[\frac{\delta\tilde{\Gamma}}{\delta\hat{A}^{\tau,\sigma}_j}(\tau-1)a'_j\right].\tag{5.47}$$

By collecting together this resulting term with the first and third ones of Eq. (5.43), we thus obtain

$$1\text{st}+3\text{rd}+7\text{th}+8\text{th}=\frac{\delta S_0}{\delta A^{\tau,\sigma}}[(\tau-1)a'+\varphi']-\frac{1}{2}\int d^4x((F[\tau\varphi]^i(\tau-1)a_i')^2)$$
$$+A_i{}^{\tau,\sigma}\left[\frac{\delta^2\tilde{\Gamma}_{\tau,\sigma}}{\delta\hat{A}_i^{\tau,\sigma}\,\delta\hat{A}_j^{\tau,\sigma}}[(\tau-1)a_j'+\varphi_j']+\frac{\delta^2\tilde{\Gamma}_{\tau,\sigma}}{\delta\hat{A}_i^{\tau,\sigma}\delta\varphi_j'}\,\varphi_j'\right]. \tag{5.48}$$

The term

$$\lim_{\sigma\to 0}\frac{\delta S_0[A^{\tau,\sigma}]}{\delta A_k^{\tau,\sigma}}\,\varphi_k'\equiv\delta_\theta^{(q)}S_0[A^\tau], \tag{5.49}$$

annihilates in this limit because the *classical action* $S_0[A^{\tau,\sigma}]$ is a gauge (b) and (q) invariant action, whence satisfying Eqs. (4.6) with $\theta(x)\equiv\sigma\varphi'(x)$. Restricting now on a compact manifold, with the space-time boundary conditions imposing a null gauge field $A(x)$, and by performing an integration by parts on the third and seventh terms, we are then led to formally write Eq. (5.48) as

$$\lim_{J_{\tau,\sigma}\to 0}\frac{\delta}{\delta\hat{A}^{\tau,\sigma}{}_j}\left\{S_0[A^\tau]+\frac{1}{2}\int d^4x\;F^2[\tau\varphi]-\tilde{\Gamma}[\hat{A}^\tau]\right\}(\tau-1)a_j'\equiv 0. \tag{5.50}$$

Still, considering the ninth and tenth terms of Eq. (5.43), namely the variations in the determinantal factors, we proceed as follows. Let us set

$$D_i{}^a[\sigma\varphi']=D_i{}^a[0]+D_i{}^{a,j}[\sigma\varphi']\varphi_j', \tag{5.51}$$

so as to have

$$\det(G_a'{}^iD_i^b[\sigma\varphi])=\det(G_a'{}^iD_i^b[0])+\det(G_a'{}^iD_i{}^{b,j}[\sigma\varphi]\varphi_j). \tag{5.52}$$

By decomposing in such a way the ninth and tenth terms, we find

$$9\text{th}+10\text{th}=\det(G_a'{}^iD_i{}^{b,j}[\sigma\varphi']\varphi_j')\times[\det(G_a^{i,j}[\sigma\varphi']D_i{}^b[A^{\tau,\sigma}]\varphi_j')+\det(G_a^i[\sigma\varphi']D_i^b[A^{\tau,\sigma}])]$$
$$+\text{e.t.}=\det(G_a'{}^iD_i{}^{b,j}[\sigma\varphi']\varphi_j')\det\{D_i{}^b[A^{\tau,\sigma}][G_a^{i,j}[\sigma\varphi']\varphi_j'+G_a^i[A^{\tau,\sigma}]]\}+\text{e.t.}, \tag{5.53}$$

where the e.t.≡"*ending term*" of the above string will be defined in a moment. Using the linearity of the $D_\mu[\psi]$ operator, it is then easy to show that

$$\lim_{\sigma\to 0}D_i{}^{a,j}[\sigma\varphi]=\lim_{\sigma\to 0}\sigma D_i{}^{a,j}[\varphi]=0. \tag{5.54}$$

A quite similar reasoning applied to the ending term, namely to

$$\text{e.t.}=\det(G_a^{i,j}[\sigma\varphi']D_b^i[A^{\tau,\sigma}]\varphi_j')\det(G_a'{}^iD_b^i[0]), \tag{5.55}$$

then leads one to conclude that Eq. (5.53) annihilates in the $\sigma\to 0$ limit. We recall, indeed, that our gauge fixing operator $G_a^i[\varphi']$ is linear with respect to $\varphi'(x)$ [see Eq. (4.15(a)].

This would terminate the present demonstration on the unitarity of the transformation $\hat{S}_\varphi\to\hat{S}_\sigma{}^\tau$ giving also, as a consequence, a confirmation of the equivalence between the scattering matrix $\hat{S}_\varphi$ operator of the background gauge field method and the $\hat{S}$ of the conventional one.

VI. CONCLUSION

Even though it is largely known that the scattering theory of the background field method should be physically equivalent to the conventional one, at least for renormalizable scalar and one-dimensional gauge field theories, as suggested by many conformal field theory computations, we succeeded to show it for the case of a non-Abelian, pure Yang–Mills theory. We tried to get such a proof very explicitly and our treatment was done with much care concerning all the possible troubling matters, such as those collected at the end of Sec. IV. In the present proof, indeed, there was no use of any doubtful assumptions, such as the adoption of *one and the same* pair of Faddeev–Popov's ghost fields for all the involved fields, or the hypothesized full *BRS invariance* of the background parametrized Lagrangian, or, also, the naive computation of the cancellations occurring in *customary* Feynman's diagrammatic expansion in the effective Lagrangian. In the present proof, on the contrary, we assumed to prove the equivalence of the scattering matrix from the very beginning definition of it, namely as a formal functional operator. Concerning the general, classical BRS invariance of the model theory considered here, we raised our perplexities on its supposed validity by computing it in the Appendix. The bare Yang–Mills gauge theory is also plagued, as is well known, by the most important renormalization problem of the infrared divergencies. This problem would limit the present scattering matrix definition to a mere formal, mathematical construct. On the other hand, such a problem does not seems to afflict the present equivalence proof more heavily than it does for the others, preexisting, equivalence demonstrations. This means, hence, that one will have to consider the true physical theory, that underlying the mathematical model dealt with here, simply as the infrared cutoff regularized version of this last. On a compact manifold, moreover, these problems frequently disappear. In general, however, we think that the need to cut off the intrinsic divergencies and the physical equivalence of the scattering theory could likely be considered as two separate and noninteracting problems. This will hold, at least in our effective action approximate formulation, but we are planning to investigate this problem further, as well as to check on the other, existing equivalence proofs.

APPENDIX: BRS TRANSFORMATION OF THE EFFECTIVE ACTION

We point out that in the proof presented here we have never used the global BRS symmetry of the background gauge field effective action, supposedly for it to be valid, for the gauge (b) invariant version of it. The reason for our choice lies in a trivial computation, as we show here, which, however, suggested us to avoid to apply BRS symmetry to S_{eff}, unless it shall be proved more carefully.

It is seen, in fact, that the exact Yang–Mills effective action of the background field method *does not result BRS invariant*, but, rather, such a property will hold only under very particular assumptions. By postulating, indeed, some ''ad hoc'' transformation properties for the source current $J^i[\varphi(x)]$, BRS invariance could, nevertheless, be recovered.

The functional to be varied, in accordance with the BRS transformation rules, is written as

$$\exp-\widetilde{W}[J,\varphi]=(\det\ \hat{\eta})^{-1/2}\int\ [DA\ Dc\ D\overline{c}]\exp\Bigg\{-\Bigg(S_0[A]+\frac{1}{2\alpha}\int d^4x\ \eta^{ab}[F^i_a[\varphi](A_i-\varphi_i)$$

$$\times F^j_b[\varphi](A_j-\varphi_j)+F'^{\,i}_a\varphi_i F'^{\,j}_b\varphi_j]+\int d^4x\ \eta^{ad}[\overline{c}_a F^i_d[\varphi]D_{ib}[A]c^b$$

$$+\overline{c}_a F'^{\,i}_d D_{ib}[\varphi]c^b]+\mathscr{S}..\mathscr{T}.\Bigg)\Bigg\}, \tag{A1}$$

where, in observation to the customary assumptions, the source terms of it, named the $\mathscr{S}..\mathscr{T}.$ term, will not intervene in the computation of the BRS variation of $\widetilde{W}$. Then we write such a variation,

$$\delta_{\mathrm{BRS}}\exp-\widetilde{W}[J,\varphi]=(\det\ \hat{\eta})^{-1/2}\int[\delta_{\mathrm{BRS}}(DA\ Dc\ D\overline{c})]e^{-(S_{\mathrm{eff}}+\mathscr{J}\cdot\mathscr{F}\cdot)}$$
$$-(\det\ \hat{\eta})^{-1/2}\int[DA\ Dc\ D\overline{c}](\delta_{\mathrm{BRS}}S_{\mathrm{eff}})e^{-(S_{\mathrm{eff}}+\mathscr{J}\cdot\mathscr{F}\cdot)}$$
$$=-(\det\ \hat{\eta})^{-1/2}\int[DA\ Dc\ D\overline{c}](\delta_{\mathrm{BRS}}S_{\mathrm{eff}})e^{-(S_{\mathrm{eff}}+\mathscr{J}\cdot\mathscr{F}\cdot)},\tag{A2}$$

due to the invariance of the integration measure. In order to calculate $(\delta_{\mathrm{BRS}}S_{\mathrm{eff}})$ we recall the transformations

$$\delta A^a_\mu\equiv-D^{ab}_\mu[A]c^b\ \delta\lambda=-(\partial_\mu\delta^{ab}-gf^{acb}A_{\mu c})c_b\delta\lambda,\tag{A3}$$

$$\delta c^a\equiv-\tfrac{1}{2}\,gf^{abc}c_bc_c\ \delta\lambda,\tag{A4}$$

$$\delta\overline{c^a}\equiv-\frac{1}{\alpha}\,F^{ab}_\mu[\varphi](A-\varphi)_{\mu b}\ \delta\lambda;\tag{A5}$$

and, in addition to these, we have the positions

$$\delta S_0[A]\equiv0,\tag{A6}$$

$$\delta F'_{\ \mu}{}^{dc}\equiv0,\tag{A7}$$

$$\delta F_{\mu}{}^{ac}[\varphi]\equiv\xi_{\mu}{}^{ac}\ \delta\lambda.\tag{A8}$$

Note that one must assume that $F[\varphi]$ itself, being an operator depending on the background field φ, will undergo some kind of transformation in passing through the critical value $\varphi=\hat{A}$, when the φ field is itself a dynamical variable. If the gauge fixing operator is linear in the φ and A variables, as is generally the case, the BRS variation of $F[\varphi]$ will be proportional to the BRS variation of this field, hence to $D^{ab}_\mu c^b$. In this way the result of the action of ξ^{ac}_μ on the $A_{\mu c}$ field shall be intended, then, as the writing $\sim D^{ac}_\mu c_c\ \delta\lambda$.

The BRS transformation of our effective action thus gives

$$\delta_{\mathrm{BRS}}S_{\mathrm{eff}}=\frac{1}{2\alpha}\ \eta^{ab}2(\delta F^{ac}_\mu)(A-\varphi)^c_\mu F^{bd}_\nu(A-\varphi)^d_\nu+\frac{1}{2\alpha}\ \eta^{ab}2F^{ac}_\mu(\delta A^c_\mu)F^{bd}_\nu(A-\varphi)^d_\nu+\eta^{ad}(\delta\overline{c^a})$$
$$\times(FD)_{db}c^b+\eta^{ad}\overline{c^a}(\delta F^{dc}_\mu)D^{cb}_\mu c_b+\eta^{ad}\overline{c^a}F^{dc}_\mu(\delta D^{cb}_\mu)c_b+\eta^{ad}\overline{c^a}(FD)_{db}(\delta c^b)$$
$$+\eta^{ad}(\delta\overline{c^a})(FD)_{db}c^b+\eta^{ad}\overline{c^a}(\delta F')^{dc}_\mu D^{cb}_\mu c_b+\eta^{ad}\overline{c^a}(F'D)_{db}(\delta c^b)$$
$$=\frac{1}{\alpha}\ \eta^{ab}(\xi^{ac}_\mu(A-\varphi)^c_\mu\ \delta\lambda\ F^{bd}_\nu(A-\varphi)^d_\nu+F^{ac}_\mu(-D^{cb}_\mu[A]c^b\ \delta\lambda)F^{bd}_\nu(A-\varphi)^d_\nu)$$
$$+\eta^{ad}\Big\{-\frac{1}{\alpha}\,F^{ae}_\mu(A-\varphi)^e_\mu\ \delta\lambda(FD)_{db}c^b+\overline{c^a}(\xi^{dc}_\mu\ \delta\lambda\ D_\mu[A]^{cb})c_b$$
$$+\overline{c^a}F^{dc}_\mu(-gf^{ceb}(\delta A^e_\mu))c_b+\overline{c^a}(FD)_{db}\Big[-\frac{1}{2}\,gf^{bef}c_ec_f\ \delta\lambda\Big]+\Big(-\frac{1}{\alpha}\,F^{ae}_\mu(A-\varphi)^e_\mu\ \delta\lambda\Big)$$
$$\times(F'D)_{db}c^b+\overline{c^a}(F'D)_{db}(-\tfrac{1}{2}\,gf^{bef}c_ec_f\ \delta\lambda)$$

$$= \eta^{ad}\Bigg\{ \frac{1}{\alpha}\,(\xi_\mu^{ac}(A-\varphi)_\mu^c)(F_\nu^{db}(A-\varphi)_\nu^b)\,\delta\lambda - \frac{1}{\alpha}\,(F_\mu^{ac}D_\mu^{ce}[A]c_e)(F_\nu^{db}(A-\varphi)_\nu^b)$$

$$+ \frac{1}{\alpha}\,(F_\mu^{ac}(A-\varphi)_\mu^c)(F_\nu^{db}D_\nu^{eb}[A]c_b)\,\delta\lambda + \overline{c^a}\xi_\mu^{dc}D_\mu^{cb}[A]\delta\lambda\ c_b - \overline{c^a}gf^{ceb}(F_\mu^{dc}D_\mu^{eg}[A]c_g)$$

$$\cdot\,\delta\lambda - \frac{1}{2}\,g\overline{c^a}(FD)_{db}f^{bef}c_ec_f\ \delta\lambda + \frac{1}{\alpha}\,(F_\mu^{ae}(A-\varphi)_\mu^e)(F'D[\varphi])_{db}c^b\ \delta\lambda$$

$$- \frac{1}{2}\,g\overline{c^a}(F'D[\varphi])_{db}f^{bef}c_ec_f\ \delta\lambda\Bigg\}$$

(after interchanging the μ and ν indices in the third term)

$$= \eta^{ad}\Bigg\{ \frac{1}{\alpha}\,[F_\nu^{db}(A-\varphi)_\nu^b\xi_\mu^{ac}(A-\varphi)_\mu^c + F_\nu^{de}(A-\varphi)_\nu^e(F'D[\varphi])_{ab}c^b]$$

$$- \frac{1}{\alpha}\,[F_\nu^{db}(A-\varphi)_\nu^bF_\mu^{ac}D_\mu^{ce}[A]c_e - F_\nu^{dc}(A-\varphi)_\nu^cF_\mu^{ae}D_\mu^{eb}[A]c_b] - \overline{c^a}[\xi_\mu^{dc}D_\mu^{cb}[A]c_b$$

$$+ gf^{ceb}F_\mu^{dc}D_\mu^{ef}c_fc_b + \tfrac{1}{2}\,g(FD)_{db}f^{bef}c_ec_f + \tfrac{1}{2}\,g(F'D[\varphi])_{db}f^{bef}c_ec_f]\Bigg\}\,\delta\lambda$$

$$= \eta^{ad}\Bigg\{ \frac{1}{\alpha}\,F_\nu^{db}(A-\varphi)_\nu^b[\xi_\mu^{ae}(A-\varphi)_\mu^c + F'^{ae}_\mu D_{\mu eb}[A]c^b] - \overline{c^a}[\xi_\mu^{dc}D_\mu^{cb}[A]c_b + gf^{ceb}F_\mu^{dc}D_\mu^{ef}[A]c_fc_b$$

$$+ \tfrac{1}{2}\,gf^{ceb}(FD)_{dc}c_ec_b + \tfrac{1}{2}\,gf^{ceb}(F'D[\varphi])_{dc}c_ec_b]\Bigg\}\,\delta\lambda$$

$$= \eta^{ad}\Bigg\{ \frac{1}{\alpha}\,F_\nu^{db}(A-\varphi)_\nu^b[\xi_\mu^{ac}(A-\varphi)_\mu^c + F'^{ac}_\mu(D_\mu^{ce}[A]c_e)] - \overline{c^a}(\xi_\mu^{dc}D_\mu^{cb}[A])c_b$$

$$- gF_\mu^{*df}\overline{c_a}[f^{feb}D_\mu^{ec}c_cc_b + \tfrac{1}{2}\,f^{ceb}D_\mu^{fc}c_ec_b] - \tfrac{1}{2}\,gF'^{*df}_\mu\overline{c^a}f^{ceb}D_\mu^{fc}c_ec_b\Bigg\}\,\delta\lambda$$

(by the properties of the f^{ceb} tensor, the fourth and fifth term mutually annihilate)

$$= \eta^{ad}\Bigg\{ \frac{1}{\alpha}\,F_\nu^{db}(A-\varphi)_\nu^b[\xi_\mu^{ac}(A-\varphi)_\mu^c + F'^{ac}_\mu D_\mu^{ce}c_e] - \overline{c^a}\xi_\mu^{dc}D_\mu^{cb}c_b$$

$$- \frac{1}{2}\,gF'^{*dc}_\mu\overline{c^a}f^{feb}D_\mu^{fc}c_ec_b\Bigg\}\,\delta\lambda, \tag{A9}$$

where F'^{*}_μ is the operator Hermitian conjugate to F'_μ. Finally, by writing explicitly the formal ξ_μ operator as

$$\xi_\mu^{dc} \sim gf^{dce}D_\mu^{ef}c_f\ \delta\lambda, \tag{A10}$$

which is undetermined only by a multiplicative constant, we see that the second term vanishes,

$$\xi_\mu^{dc}D_\mu^{cb}[A]c_b \sim gf^{dce}D_\mu^{ef}c_f\ \delta\lambda\ D_\mu^{cb}c_b = 0, \tag{A11}$$

as a consequence of the antisymmetry of f^{dce}. The final conclusion will thus be resumed as

$$\left\{\frac{\delta_{\mathrm{BRS}}S_{\mathrm{eff}}}{\delta\lambda}\right\}=\eta^{ad}\left\{F'^{*dc}_{\mu}\cdot\left[\overline{c^a}f^{feb}D^{fc}_{\mu}c_e c_b+\frac{1}{\alpha}F^{ab}_{\nu}(A-\varphi)^{h}_{\nu}D^{ce}_{\mu}c_e\right]\right.$$
$$\left.+\frac{1}{\alpha}\xi^{*dc}_{\mu}F^{ab}_{\nu}(A-\varphi)^{b}_{\nu}(A-\varphi)^{c}_{\mu}]\right\}. \tag{A12}$$

This result, as we previously announced, clearly indicates that the presence of the background field φ, unless other peculiar assumptions concerning $\mathscr{S}\ldots\mathscr{T}$., induces a non-complete invariance of the effective action $\widetilde{W}[J,\varphi]$ introduced above.

(Received 6 September 1995; accepted for publication 19 October 1995)

This paper treats propagation of transient waves in nonstationary media, which has many applications in, for example, electromagnetics and acoustics. The underlying hyperbolic equation is a general, homogeneous, linear, first-order 2×2 system of equations. The coefficients in this system depend on one spatial coordinate and time. Furthermore, memory effects are modeled by integral kernels, which, in addition to the spatial dependence, are functions of two different time coordinates. These integrals generalize the convolution integrals, frequently used as a model for memory effects in the medium. Specifically, the scattering problem for this system of equations is addressed. This problem is solved by a generalization of the wave splitting concept, originally developed for wave propagation in media which are invariant under time translations, and by an imbedding or a Green's functions technique. More explicitly, the imbedding equation for the reflection kernel and the Green's functions (propagator kernels) equations are derived. Special attention is paid to the problem of nonstationary characteristics. A few numerical examples illustrate this problem. © *1996 American Institute of Physics.* [S0022-2488(96)00104-8]

I. INTRODUCTION AND BASIC SYSTEM OF EQUATIONS

In a recent paper,[1] a new method of analyzing wave propagation in nonstationary or time-varying media was suggested. This method is an extension of the well-established methods of wave splitting, invariant imbedding, and Green's functions techniques (see Refs. 2–8). Wave propagation in nonstationary media has also been investigated with other methods (see, e.g., Refs. 9–11).

Nonstationary media are characterized by material parameters that are changing with time. Relevant examples are found in, e.g., telecommunication problems, such as fading and modulation problems, and in problems concerning moving media. The analysis of the wave propagation phenomena in linear, nonstationary media also serves as an indispensable tool for analyzing wave propagation in nonlinear media by means of linearization.

The investigation of wave propagation problems in nonstationary media leads to hyperbolic partial differential equations (PDE) with coefficients varying both in time and space. The purpose of this paper is to systematically investigate the wave propagation problem in a general nonstationary medium. This paper presents the theory of the techniques; subsequent papers will develop numerical solutions to pertinent problems.

Investigations of wave propagation, some of which are mentioned in Sec. II, suggest a generalized form of the dynamics of the wave fields. In the present work, the parameters of the medium are assumed to vary in one spatial direction, here taken to the z-direction, and time t. The basic equation is the following first-order 2×2 system of equations:

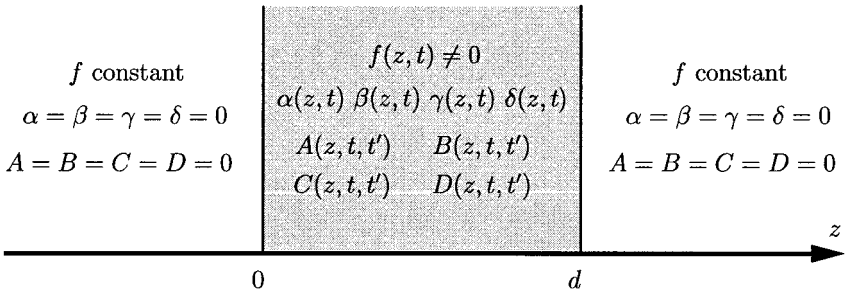

FIG. 1. Geometry of the problem.

$$\frac{\partial}{\partial z}\begin{pmatrix} u^+(z,t) \\ u^-(z,t)\end{pmatrix} = f(z,t)\begin{pmatrix} -1 & 0 \\ 0 & 1\end{pmatrix}\frac{\partial}{\partial t}\begin{pmatrix} u^+(z,t) \\ u^-(z,t)\end{pmatrix} + \begin{pmatrix} \alpha(z,t) & \beta(z,t) \\ \gamma(z,t) & \delta(z,t)\end{pmatrix}\begin{pmatrix} u^+(z,t) \\ u^-(z,t)\end{pmatrix} + \int_{-\infty}^{t}\begin{pmatrix} A(z,t,t') & B(z,t,t') \\ C(z,t,t') & D(z,t,t')\end{pmatrix}\begin{pmatrix} u^+(z,t') \\ u^-(z,t')\end{pmatrix} dt'. \tag{1}$$

The reason for the $\pm$ superscript is described in the subsequent sections. The slowness function $f(z,t)$ is a notation for

$$f(z,t) = \frac{1}{c(z,t)} > 0,$$

where $c(z,t)$ is the wave (phase) velocity. In order to model also nonstationary memory effects, integral terms have been included in the equation. These memory effects are nonlocal in time. In the integrals, the variable t describes the current time, whereas the variable t' is an integral measure, relating to the starting time of the excitation (see also Appendix B). The system (1) is a strictly hyperbolic system.

The positive function $f(z,t)$ is a continuous, bounded function of the variables z and t everywhere. Furthermore, it is assumed to be constant outside the slab $(0,d)$

$$f(z,t) = 1/c_0, \quad z<0, \quad f(z,t) = 1/c_d, \quad z>d, \tag{2}$$

and continuously differentiable, with bounded derivatives, in z and t everywhere inside the slab, i.e., $(z,t) \in (0,d)\times(-\infty,\infty)$ (see also Fig. 1). This implies that $f(0,t) = 1/c_0$ and $f(d,t) = 1/c_d$ for all times t.

The functions $\alpha(z,t)$, $\beta(z,t)$, $\gamma(z,t)$, and $\delta(z,t)$ are equal to zero outside the slab and they are continuous, bounded functions inside the slab (not necessarily continuous at the edges of the slab).

The functions $A(z,t,t')$, $B(z,t,t')$, $C(z,t,t')$, and $D(z,t,t')$ are always zero outside of the slab $(0,d)$. Due to causality, they vanish identically inside the slab provided $t<t'$. For simplicity, the functions $A(z,t,t')$, $B(z,t,t')$, $C(z,t,t')$, and $D(z,t,t')$ are assumed continuous and bounded as functions of the variables z, t, and t' in the region $t>t'$, $0<z<d$.

The assumptions described above can, of course, be relaxed, and the results presented in this paper then hold for a larger class of parameters. However, the purpose of this paper is not to formulate the results for the weakest set of assumptions possible, but to exploit the potential of the method for a set of physically reasonable assumptions.

In the scattering application addressed in this paper, the incident wave is assumed to impinge normally on a slab. Two different scattering problems can be identified. In the direct scattering

problem, the material parameters are known and the goal is to calculate the response of a known incoming field. On the other hand, the inverse problem assumes knowledge of the incident and the scattered field (data collected exterior to the medium) and the problem is to infer information about the material parameters. Both these problems can be investigated by the methods presented in this paper. However, the main pertinence of the method is in connection with applications to the direct scattering problem. Some aspects of the nonstationary inverse scattering problem were analyzed in Ref. 1.

After this introductory section, a few explicit examples of applications are given in Sec. II. The analysis of the nonstationary characteristic curves is found in Sec. III. The imbedding equation for the reflection kernel is derived in Sec. IV, and the Green's functions (propagator kernels) equations are derived in Sec. V. Some explicit simplifications and concluding remarks are given in Secs. VI and VII, respectively. Three appendices contain some technical mathematical details and some numerical illustrations of characteristic traces.

II. EXAMPLES

This section contains a few examples of general interest to the formulation presented in this paper. The underlying equations of the fields in all these examples are the Maxwell equations:

$$\nabla\times\mathbf{E}(\mathbf{r},t)=-\frac{\partial\mathbf{B}}{\partial t}(\mathbf{r},t),\quad \nabla\times\mathbf{H}(\mathbf{r},t)=\frac{\partial\mathbf{D}}{\partial t}(\mathbf{r},t).$$

Here, $\mathbf{E}(\mathbf{r},t)$ and $\mathbf{H}(\mathbf{r},t)$ are the electric and the magnetic fields, respectively, $\mathbf{B}(\mathbf{r},t)$ is the magnetic induction, and $\mathbf{D}(\mathbf{r},t)$ is the electric displacement field. All fields are assumed to be quiescent before a fixed time. This property guarantees that all fields vanish at $t\to-\infty$.

A. Electromagnetic waves in inhomogeneous and dispersive media

To model wave propagation in a nonstationary, inhomogeneous, and dispersive medium, the following constitutive relations are relevant:[1]

$$\mathbf{D}(\mathbf{r},t)=\epsilon_0\left(\epsilon(z)\mathbf{E}(\mathbf{r},t)+\int_{-\infty}^{t}\chi_e(z,t,t')\mathbf{E}(\mathbf{r},t')dt'\right),$$

$$\mathbf{B}(\mathbf{r},t)=\mu_0\mathbf{H}(\mathbf{r},t).$$

Here $\epsilon_0\epsilon(z)>0$ is the permittivity of the medium, and μ_0 is the permeability of vacuum. The nonstationary dispersive effects are modeled by the susceptibility kernel $\chi_e(z,t,t')$.

The vector wave propagation problem is reduced to a scalar problem by assuming that the electric field is transverse to the stratification of the medium, and, furthermore, depends only on the coordinates (z,t). The dynamics of the fields is cast into the form of (1) by the following nonunique wave splitting:[4]

$$\begin{pmatrix}u^+(z,t)\\ u^-(z,t)\end{pmatrix}=\frac{1}{2}\begin{pmatrix}1 & -\dfrac{c_0}{\sqrt{\epsilon(z)}}\,\partial_t^{-1}\\ 1 & \dfrac{c_0}{\sqrt{\epsilon(z)}}\,\partial_t^{-1}\end{pmatrix}\begin{pmatrix}E(z,t)\\ \partial_z E(z,t)\end{pmatrix},$$

where the antiderivative ∂_t^{-1} is defined as

$$\partial_t^{-1}g(t)=\int_{-\infty}^{t}g(t')dt'.$$

The coefficients of the dynamics, (1), in this example are

$$f(z,t)=\sqrt{\epsilon(z)}/c_0,$$

$$\alpha(z,t)=-\gamma(z,t)=-\frac{1}{4}\frac{d}{dz}\ln\epsilon(z)-\frac{1}{2c_0\sqrt{\epsilon(z)}}\chi_e(z,t,t')\Big|_{t'=t},$$

$$\beta(z,t)=-\delta(z,t)=\frac{1}{4}\frac{d}{dz}\ln\epsilon(z)-\frac{1}{2c_0\sqrt{\epsilon(z)}}\chi_e(z,t,t')\Big|_{t'=t},$$

$$A(z,t,t')=B(z,t,t')=-C(z,t,t')=-D(z,t,t')=-\frac{1}{2c_0\sqrt{\epsilon(z)}}\frac{\partial\chi_e}{\partial t}(z,t,t').$$

Note that the regularity assumptions made on the susceptibility kernel $\chi_e(z,t,t')$ in Ref. 1 [continuously differentiable in $z\in(0,L)$ and t', and twice continuously differentiable in t, $t\geqslant t'$] are stronger than needed to meet the assumptions made on the functions $A(z,t,t')$, $B(z,t,t')$, $C(z,t,t')$, and $D(z,t,t')$ in Sec. I, and are not needed if the splitting is made from Maxwell's equations directly (see Sec. II C).

B. A generalized wave equation

An obvious extension of the results presented in Ref. 1 concerning propagation of electromagnetic waves in inhomogeneous and time-varying media is to allow the permittivity $\epsilon_0\epsilon$ to vary in time as well as in space. The relevant constitutive relations in this example are

$$\mathbf{D}(\mathbf{r},t)=\epsilon_0\epsilon(z,t)\mathbf{E}(\mathbf{r},t),\quad \mathbf{B}(\mathbf{r},t)=\mu_0\mathbf{H}(\mathbf{r},t),$$

where the relative permittivity $\epsilon(z,t)>0$. This is a model of an inhomogeneous, nondispersive, nonstationary medium. For the sake of simplicity, the dispersive memory terms in Sec. II A are omitted. However, the more complex model, where these memory terms are included, is straightforward to analyze.

With the usual assumption of an electric field **E** that is transverse to the z-axis and that depends on z and t only, the wave equation is

$$\frac{\partial^2 E}{\partial z^2}(z,t)-\frac{\partial^2(f^2E)}{\partial t^2}(z,t)=0, \tag{3}$$

where

$$f(z,t)=\sqrt{\mu_0\epsilon_0\epsilon(z,t)}.$$

This equation is a special case of a more generalized wave equation

$$\frac{\partial^2 u}{\partial z^2}(z,t)-\frac{\partial^2(f^2u)}{\partial t^2}(z,t)+\mathscr{A}(z,t)\frac{\partial u}{\partial z}(z,t)+\mathscr{B}(z,t)\frac{\partial u}{\partial t}(z,t)+\mathscr{C}(z,t)u(z,t)=0, \tag{4}$$

which also has applications in, e.g., linear acoustics in media where the propagation conditions change rapidly with time.

In order to see how Eq. (4) is related to the general hyperbolic wave equation (1), the concept of wave splitting is introduced. The wave splitting can be defined in several different ways. The

definition adopted here renders a very simple $u^{\pm}$-dynamics for the wave equation in (3). Thus, proceeding formally, the wave splitting is defined by the following transformation of the dependent variables:

$$\begin{pmatrix} u^{+}(z,t) \\ u^{-}(z,t) \end{pmatrix} = \frac{1}{2} \begin{pmatrix} 1 & -\dfrac{1}{f(z,t)}\,\partial_t^{-1} \\ 1 & \dfrac{1}{f(z,t)}\,\partial_t^{-1} \end{pmatrix} \begin{pmatrix} u(z,t) \\ u_z(z,t) \end{pmatrix},$$

which generalizes the wave splitting introduced in Ref. 4. The new fields $u^{\pm}(z,t)$ satisfy a first-order 2×2 system of hyperbolic partial differential equations, which is identical to the generalized $u^{\pm}$-dynamics in (1). The explicit expressions of the coefficients are

$$\alpha(z,t) = -\frac{1}{2}\frac{\partial}{\partial z}\ln f(z,t) - \frac{3}{2}\frac{\partial f}{\partial t}(z,t) - \frac{1}{2}\mathscr{A}(z,t) + \frac{1}{2}\frac{\mathscr{B}(z,t)}{f(z,t)},$$

$$\beta(z,t) = +\frac{1}{2}\frac{\partial}{\partial z}\ln f(z,t) - \frac{1}{2}\frac{\partial f}{\partial t}(z,t) + \frac{1}{2}\mathscr{A}(z,t) + \frac{1}{2}\frac{\mathscr{B}(z,t)}{f(z,t)},$$

$$\gamma(z,t) = +\frac{1}{2}\frac{\partial}{\partial z}\ln f(z,t) + \frac{1}{2}\frac{\partial f}{\partial t}(z,t) + \frac{1}{2}\mathscr{A}(z,t) - \frac{1}{2}\frac{\mathscr{B}(z,t)}{f(z,t)},$$

$$\delta(z,t) = -\frac{1}{2}\frac{\partial}{\partial z}\ln f(z,t) + \frac{3}{2}\frac{\partial f}{\partial t}(z,t) - \frac{1}{2}\mathscr{A}(z,t) - \frac{1}{2}\frac{\mathscr{B}(z,t)}{f(z,t)},$$

and

$$A(z,t,t') = \frac{1}{2}\frac{1}{f(z,t)}\left[f(z,t')\frac{\partial \mathscr{A}}{\partial t'}(z,t') - \frac{\partial \mathscr{B}}{\partial t'}(z,t') + \mathscr{C}(z,t') \right],$$

$$B(z,t,t') = \frac{1}{2}\frac{1}{f(z,t)}\left[-f(z,t')\frac{\partial \mathscr{A}}{\partial t'}(z,t') - \frac{\partial \mathscr{B}}{\partial t'}(z,t') + \mathscr{C}(z,t') \right],$$

$$C(z,t,t') = -A(z,t,t'),$$

$$D(z,t,t') = -B(z,t,t').$$

C. Wave propagation on the transmission line

In this example, propagation of current-voltage waves on a transmission line is considered. The material of the transmission line, i.e., the conductors together with the insulation, may vary in time as well as in space. In this model, memory effects are permitted.

The equivalent circuit segment model of Fig. 2 provides the basis of the derivation of the general transmission line equations. Here, $R(z,t)$ and $G(z,t)$ are the series resistance and the shunt conductance per unit length of the transmission line, respectively. The series inductance and the shunt capacitance per unit length, which are denoted $L(z,t)$ and $C(z,t)$, respectively, are both assumed positive and finite. The voltage $v(z,t)$ and the current $i(z,t)$ are related, respectively, to the magnetic flux $\Phi(z,t)$ and the charge $q(z,t)$ through

$$\Phi(z,t) = L(z,t)i(z,t) + \int_{-\infty}^{t} \chi_m(z,t,t')i(z,t')dt',$$

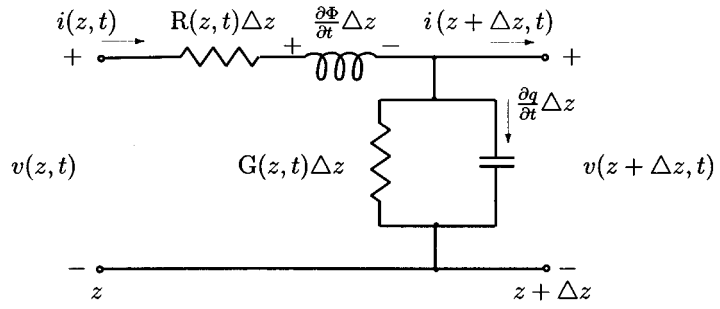

FIG. 2. Transmission line model.

$$q(z,t)=C(z,t)v(z,t)+\int_{-\infty}^{t}\chi_e(z,t,t')v(z,t')dt'.$$

The magnetic flux, $\Phi(z,t)$, and the electric charge, $q(z,t)$, depend on the current $i(z,t)$ and the voltage $v(z,t)$ at time t, respectively. In addition to these multiplicative terms, Φ and q are connected to the previous values of the currents and voltages of the transmission line. The memory functions are modeled by the two integral terms with the kernel functions $\chi_m(z,t,t')$ describing the inductive susceptibility and $\chi_e(z,t,t')$ modeling the capacitive susceptibility. Simplifications occur in a material that is invariant under time translations. In this case, the susceptibility kernels are functions of the difference argument $t-t'$ rather than of t and t'. A comparison between the pertinent parameter symbols used in this transmission line application and the material properties of Sec. II A is found in Table I.

The Kirchhoff current and voltage relations are now applied to the circuit mesh of Fig. 2. In the limit $\Delta z\to 0$, the two general transmission line equations are obtained. They are represented in the following matrix form:

$$\begin{pmatrix} 0 & C(z,t) \\ L(z,t) & 0 \end{pmatrix}\frac{\partial}{\partial t}\begin{pmatrix} i(z,t) \\ v(z,t) \end{pmatrix}+\frac{\partial}{\partial z}\begin{pmatrix} i(z,t) \\ v(z,t) \end{pmatrix}=B\begin{pmatrix} i(z,t) \\ v(z,t) \end{pmatrix}, \tag{5}$$

TABLE I. Correspondence between the parameter symbols used and the material properties relevant in the two main applicable problems.

Transmission line		Maxwell's equations	
Parameter	Symbol	Parameter	Symbol
Inductance	$L(z,t)$	Magnetic permeability	$\mu(z,t)$
Capacitance	$C(z,t)$	Electric permittivity	$\epsilon(z,t)$
Series resistance	$R(z,t)$	Magnetic conductivity	$\sigma_m(z,t)$
Shunt resistance	$G(z,t)$	Electric conductivity	$\sigma_e(z,t)$
Inductive susceptibility	$\chi_m(z,t,t')$	Magnetic susceptibility	$\chi_m(z,t,t')$
Capacitive susceptibility	$\chi_e(z,t,t')$	Electric susceptibility	$\chi_e(z,t,t')$

where the operator matrix B is given by

$$B=\begin{pmatrix} 0 & -G(z,t)-\dfrac{\partial C}{\partial t}(z,t)-\dfrac{\partial}{\partial t}\displaystyle\int_{-\infty}^{t}\chi_e(z,t,t')\bullet\, dt' \\ -R(z,t)-\dfrac{\partial L}{\partial t}(z,t)-\dfrac{\partial}{\partial t}\displaystyle\int_{-\infty}^{t}\chi_m(z,t,t')\bullet\, dt' & 0 \end{pmatrix},$$

where the symbol $\bullet$ denotes the place holder for the operand.

This system of equations is easily transformed into the general first-order 2×2 system of hyperbolic equations, (1). The following wave splitting diagonalizes the system (5):

$$\begin{pmatrix} u^+(z,t) \\ u^-(z,t) \end{pmatrix}=\frac{1}{2}\begin{pmatrix} 1 & \sqrt{\dfrac{C(z,t)}{L(z,t)}} \\ 1 & -\sqrt{\dfrac{C(z,t)}{L(z,t)}} \end{pmatrix}\begin{pmatrix} i(z,t) \\ v(z,t) \end{pmatrix}. \tag{6}$$

The explicit expressions of the coefficients are

$$\begin{aligned} f(z,t)&=\sqrt{L(z,t)C(z,t)}, \\ \alpha(z,t)&=\tfrac{1}{2}[+h_1(z,t)+h_2(z,t)-h_3(z,t)-h_4(z,t)], \\ \beta(z,t)&=\tfrac{1}{2}[-h_1(z,t)-h_2(z,t)+h_3(z,t)-h_4(z,t)], \\ \gamma(z,t)&=\tfrac{1}{2}[+h_1(z,t)-h_2(z,t)-h_3(z,t)+h_4(z,t)], \\ \delta(z,t)&=\tfrac{1}{2}[-h_1(z,t)+h_2(z,t)+h_3(z,t)+h_4(z,t)], \end{aligned} \tag{7}$$

and

$$\begin{aligned} A(z,t,t')&=-\frac{1}{2}\left[\frac{\partial\chi_e}{\partial t}(z,t,t')\sqrt{\frac{\mathrm{L}(z,t')}{\mathrm{C}(z,t')}}+\sqrt{\frac{\mathrm{C}(z,t)}{\mathrm{L}(z,t)}}\frac{\partial\chi_m}{\partial t}(z,t,t')\right], \\ B(z,t,t')&=\frac{1}{2}\left[\frac{\partial\chi_e}{\partial t}(z,t,t')\sqrt{\frac{\mathrm{L}(z,t')}{\mathrm{C}(z,t')}}-\sqrt{\frac{\mathrm{C}(z,t)}{\mathrm{L}(z,t)}}\frac{\partial\chi_m}{\partial t}(z,t,t')\right], \\ C(z,t,t')&=-B(z,t,t'),\quad D(z,t,t')=-A(z,t,t'), \end{aligned} \tag{8}$$

where the functions $h_1(z,t)$, $h_2(z,t)$, $h_3(z,t)$, and $h_4(z,t)$ are given by

$$h_1(z,t)=\frac{1}{2}\sqrt{\mathrm{L}(z,t)\mathrm{C}(z,t)}\,\frac{\partial}{\partial t}\ln\frac{\mathrm{C}(z,t)}{\mathrm{L}(z,t)},$$

$$h_2(z,t)=\frac{1}{2}\frac{\partial}{\partial z}\ln\frac{\mathrm{C}(z,t)}{\mathrm{L}(z,t)},$$

$$h_3(z,t)=\sqrt{\frac{\mathrm{L}(z,t)}{\mathrm{C}(z,t)}}\left[\mathrm{G}(z,t)+\frac{\partial\mathrm{C}}{\partial t}(z,t)+\chi_e(z,t,t')\big|_{t'=t}\right],$$

$$h_4(z,t)=\sqrt{\frac{\mathrm{C}(z,t)}{\mathrm{L}(z,t)}}\left[\mathrm{R}(z,t)+\frac{\partial L}{\partial t}(z,t)+\chi_m(z,t,t')\big|_{t'=t}\right].$$

The regularity requirements of the coefficients stated in Sec. I are met if $R(z,t)$ and $G(z,t)$ are continuous functions, and $C(z,t)$ and $L(z,t)$ continuously differentiable in both z and t. Moreover, the functions $\chi_e(z,t,t')$ and $\chi_m(z,t,t')$ are assumed continuous in z and t' and continuously differentiable in t.

The next two sections contain the main equations for the solution of the scattering problem in inhomogeneous, nonstationary, dispersive media. Specifically, the imbedding equation and the Green's functions equations are derived.

III. CHARACTERISTIC CURVES

One of the major differences between the treatment of the problems in this paper and earlier work is that the characteristics of Eq. (1) are nonstationary in time. This complicates many of the formulas when compared to those applicable to media which admit time translation symmetries. When the slowness is independent of time but the dynamics is nonstationary, there is still a lack of invariance under time translation due to lower-order terms. In this case some simplifications can be made. This is evidenced by comparing the imbedding equation (15) of Sec. IV, the Green's functions equations (21) and (22) of Sec. V, and equations (4.3), (5.2), and (5.3) of Ref. 1.

In Ref. 1, as the slowness was *not* a function of time, it was quite easy to make a transformation into travel time coordinates to straighten the characteristic curves. In the more general situation considered here, such a transformation is more difficult to perform and implies that a problem of almost the same complexity as the original problem has to be solved. No transformation to straighten the characteristic curves is therefore made in this paper. Thus, the examination of the properties of the characteristic traces of (1) is appropriate. In Appendix A some of the properties of the transformation to straighten the characteristic curves are outlined.

The characteristic traces for the u^+-equation satisfy

$$\frac{d\tau^+}{d\zeta} = f(\zeta, \tau^+(\zeta)), \tag{9}$$

with an initial condition [the curve passes through the point (z,t)]

$$\tau^+(z) = t. \tag{10}$$

The superscript plus has been used on the characteristic with positive slope; traces with negative slope appear in later sections and will have superscript minus.

The existence of a unique, locally defined, solution of the initial value problem in (9) and (10) is guaranteed by the assumption of f in Sec. I.[12,13] To emphasize the dependence of the initial conditions, the solution is written in the form

$$\tau^+ = \tau^+(\zeta; z, t), \tag{11}$$

where $(\zeta, \tau^+(\zeta;z,t))$ describes a curve in $\mathbb{R}^2$ passing through (z,t) and ζ is a parameter.

Figure 3 shows the system of coordinates (ζ,τ^+). The position of the physical slab coincides with the interval $(0,d)$ of the ζ-axis. The assumptions of the slowness f ensure that a locally defined flow has been defined.[14] Maximal extension of this flow up to any point, at which it becomes undefined, is ensured. This is a property that depends purely on the slowness f. This flow forms a group with respect to the parameter ζ and as such it has a unique inverse and unit element. For the purposes of this paper, the form of the solution formally represented by Eq. (11) suffices. The inverse elements are

$$\tau^+(\zeta; z, \tau^+(z;\zeta,t)) = t, \quad \tau^+(z;\zeta,\tau^+(\zeta;z,t)) = t,$$

and the unit element can be written as

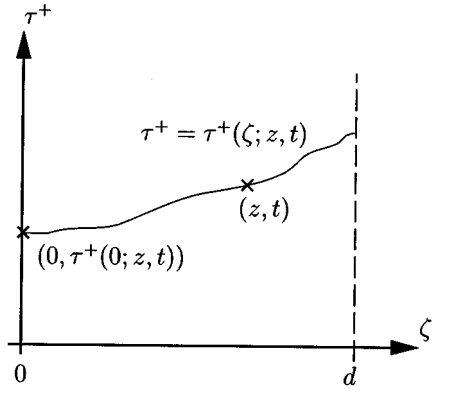

FIG. 3. The characteristic of the u^+-equation.

$$\tau^+(z;z,t)=t.$$

One other formula obtained from elementary calculus that is needed in the sequel is

$$\frac{\partial\tau^+}{\partial t}(\zeta;z,t)\bigg|_{t=\tau^+(z;\zeta,t)}=\left(\frac{\partial\tau^+}{\partial t}(z;\zeta,t)\right)^{-1}$$

or its dual

$$\frac{\partial\tau^+}{\partial t}(z;\zeta,t)\bigg|_{t=\tau^+(\zeta;z,t)}=\left(\frac{\partial\tau^+}{\partial t}(\zeta;z,t)\right)^{-1}.$$

In this paper, of particular importance is the case of $\zeta=0$.

From the presumptions of the function $f(z,t)$ given in Sec. I and from Eq. (9), it is clear that the derivative $d\tau^+/d\zeta$ is a continuous function in ζ. Furthermore, these presumptions also guarantee that the partial derivatives $\partial\tau^+/\partial z$ and $\partial\tau^+/\partial t$ exist.[13]

Also note that if (z,t) is a point on the characteristic curve, so is $(\zeta',\tau^+(\zeta';z,t))$. Thus $\tau^+=\tau^+(\zeta;z,t)$ and $\tau^+=\tau^+(\zeta;\zeta',\tau^+(\zeta',z,t))$ are two equivalent representations of the same characteristic curve.

Integration of Eq. (9) along the characteristic yields an expression for the function τ^+:

$$\tau^+(\zeta_2;z,t)-\tau^+(\zeta_1;z,t)=\int_{\zeta_1}^{\zeta_2}f(\zeta',\tau^+(\zeta';z,t))d\zeta', \tag{12}$$

which specifies the time needed for the u^+-wave to move from position ζ_1 to position ζ_2 along the characteristic passing through (z,t).

An additional relation for the u^+-characteristics, needed for the derivations in Sec. V, is now derived. In (12), let $\zeta_2=\zeta$ and $\zeta_1=z$, and differentiate the equation with respect to z and t. This shows that the function

$$\phi(\zeta;z,t)=\frac{\partial\tau^+}{\partial z}(\zeta;z,t)+f(z,t)\,\frac{\partial\tau^+}{\partial t}(\zeta;z,t)$$

is a solution to the uniquely solvable homogeneous Volterra equation of the second kind,

$$\phi(\zeta;z,t)+\int_{\zeta}^{z}\frac{\partial f}{\partial\tau^{+}}(\zeta',\tau^{+}(\zeta';z,t))\phi(\zeta';z,t)d\zeta'=0,$$

which therefore must only have the trivial solution. Thus, the following identity holds:

$$\frac{\partial\tau^{+}}{\partial z}(\zeta;z,t)+f(z,t)\frac{\partial\tau^{+}}{\partial t}(\zeta;z,t)=0. \tag{13}$$

The interpretation of this conservation equation states the obvious result that as (z,t) varies along one particular characteristic trace, for fixed ζ, τ^{+} is invariant. Another more simple proof of (13) is to use the fact that $\tau^{+}=\tau^{+}(\zeta;z,t)$ and $\tau^{+}=\tau^{+}(\zeta;\zeta',\tau^{+}(\zeta';z,t))$ are two equivalent representations of the same characteristic curve. Differentiation wrt ζ' then gives the identity (13).

Some explicit examples of characteristic curves are found in Appendix C.

IV. IMBEDDING EQUATION

The two split fields, $u^{\pm}(z,t)$, introduced in a previous section, are interrelated. This is because when the wave propagates through a medium in which the properties are changing, the $u^{\pm}$-waves are related through a scattering operator. This operator is represented by a time integral, which can be derived from Duhamel's integral (see Appendix B). The result is

$$u^{-}(z,t)=\int_{-\infty}^{t}R(z,t,t')u^{+}(z,t')dt'. \tag{14}$$

Here, the kernel $R(z,t,t')$, which is the reflection kernel of a subsection (z,d) of the total slab $(0,d)$, is identical to the one used in Ref. 1. By causality, $R(z,t,t')=0$, $t<t'$.

The reflection kernel, $R(z,t,t')$, satisfies a partial differential equation, which describes the variation in $R(z,t,t')$ as the coordinates z, t, and t' vary. This equation, the imbedding equation, is derived by differentiating (14) and using the dynamics (1). This operation yields the imbedding equation for the reflection kernel $R(z,t,t')$, valid in the domain $0<z<d$, $t>t'$:

$$\begin{aligned}
&\frac{\partial R}{\partial z}(z,t,t')-f(z,t)\frac{\partial R}{\partial t}(z,t,t')+\frac{\partial R}{\partial t'}(z,t,t')f(z,t')\\
&\quad=C(z,t,t')+\delta(z,t)R(z,t,t')+R(z,t,t')\left[-\frac{\partial f(z,t')}{\partial t'}-\alpha(z,t')\right]\\
&\qquad-\int_{t'}^{t}R(z,t,t'')\beta(z,t'')R(z,t'',t')dt''-\int_{t'}^{t}R(z,t,t'')A(z,t'',t')dt''\\
&\qquad+\int_{t'}^{t}D(z,t,t'')R(z,t'',t')dt''-\int_{t'}^{t}\left\{\int_{t'}^{t''}R(z,t,t'')B(z,t'',t''')R(z,t''',t')dt'''\right\}dt''.
\end{aligned} \tag{15}$$

The initial condition of the reflection kernel $R(z,t,t')$ is

$$R(z,t,t')|_{t'=t}=-\frac{1}{2}\frac{\gamma(z,t)}{f(z,t)} \tag{16}$$

and the boundary condition at $z=d$, $t>t'$, is

$$R(d,t,t')=0.$$

The Cauchy problem of the imbedding equation, (15), with data specified on the plane parametrized by $\mathbf{r}=(z,t,t)$ [see (16)], is well posed. This is a consequence of the nonvanishing functional determinant (Ref. 15, p. 26)

$$J=\begin{vmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 1 & -f(z,t) & f(z,t) \end{vmatrix} = 2f(z,t)\neq 0.$$

The functional differential equation for the reflection kernel $R(z,t,t')$ can be solved numerically given the material parameters. This implies that the solution to the direct scattering problem, i.e., the determination of the reflected fields, can be computed through (14). The inverse problem, i.e., the determination of the material parameters, given the reflection kernel $R(z,t,t')$, can also be approached through (15). This problem will be addressed in another paper.

A. Discontinuity of the reflection kernel

The solution of the imbedding equation, $R(z,t,t')$, is continuous everywhere except across the surface $t'=h(z,t)$, where $R(z,t,t')$ has a possible jump discontinuity. This finite jump discontinuity is introduced by the possible jump discontinuity in $\gamma(z,t)$ at $z=d$, i.e., if $\gamma(d^-,t)=\lim_{z\to d-0}\gamma(z,t)\neq 0$ [see (16)]. The normal to the surface $t'=h(z,t)$, i.e., $(h_z,h_t,-1)$, satisfies the characteristic equation

$$\frac{\partial h}{\partial z}(z,t)-f(z,t)\frac{\partial h}{\partial t}(z,t)=f(z,h(z,t))$$

and, due to (16), the surface contains the line $\mathbf{r}=(d,t,t)$, i.e., $t=h(d,t)$.

The vector field describing the characteristic traces is $(1,-f(z,t),f(z,t'))$ and it lies on a hyper-surface. The projection of this vector field onto the (z,t)-plane is described by

$$\frac{d\tau^-}{d\zeta}=-f(\zeta,\tau^-(\zeta)) \tag{17}$$

so that this curve, on planes $t'=$constant, has representation $(\zeta,\tau^-(\zeta;z,t),t')$. To emphasize the dependence of the initial conditions, the solution to (17) has been written in the form

$$\tau^-=\tau^-(\zeta;z,t).$$

Similarly, the projection of the vector field onto the (z,t')-plane is described by Eq. (9) and this curve on planes $t=$constant has representation $(\zeta,t,\tau^+(\zeta;z,t'))$. All curves of interest here will originate from the line $\mathbf{r}=(d,t,t)$, so that a characteristic trace, Γ, emanating from this line has parametric form

$$\Gamma:\mathbf{r}(z,t)=(z,\tau^-(z;d,t),\tau^+(z;d,t)).$$

As mentioned previously, the R kernel has a possible initial jump discontinuity on the (d,t,t)-line, in the direction of increasing t, of size

$$[R]_{\Gamma(z=d)}=\frac{1}{2}\frac{\gamma(d,t)}{f(d,t)}. \tag{18}$$

The bracket notation used here denotes the finite jump discontinuity of the reflection kernel R, with respect to positive t-direction. This discontinuity propagates along the characteristic as

$$\left.\frac{d[R]}{dz}\right|_{\Gamma}=\left(\delta(z,\tau^{-}(z;d,t))-\left.\frac{\partial f}{\partial t'}(z,t')\right|_{t'=\tau^{+}(z;d,t)}-\alpha(z,\tau^{+}(z;d,t))\right)[R]_{\Gamma},$$

which upon integrating from d to z, and with use of (18), yields

$$[R]_{\Gamma}=\frac{1}{2}\frac{\gamma(d,t)}{f(d,t)}\exp\left\{\int_{d}^{z}\left(\delta(z',\tau^{-}(z';d,t))-\left.\frac{\partial f}{\partial t'}(z',t')\right|_{t'=\tau^{+}(z';d,t)}-\alpha(z',\tau^{+}(z';d,t))\right)dz'\right\}.$$

V. GREEN'S FUNCTIONS

The relationship between the split fields $u^{\pm}$ in Sec. IV was evaluated at a specific z-value and the reflection kernel $R(z,t,t')$ was interpreted as the reflection kernel for a subslab (z,d) of the physical slab $(0,d)$. This interpretation was performed by the use of an imbedding argument.

In contrast to the analysis presented in the previous section, this section contains an analysis of the relationship between the exterior excitation $u^{+}(0,t)$ and the internal fields $u^{\pm}(z,t)$ of the physical slab $(0,d)$. The operator that maps the excitation $u^{+}(0,d)$ to the internal fields $u^{\pm}(z,t)$ has an integral representation. This representation leads to the definition of the Green's functions $G^{\pm}(z,t,t')$ of the propagation problem.

From Duhamel's integral (see Appendix B), an explicit mapping of the excitation $u^{+}(0,t)$ to the internal fields $u^{\pm}(z,t)$ can be obtained. For convenience this mapping is evaluated at two different times. The basic difference between the two definitions in Eqs. (19) and (20) is that, in (19), the time coordinate t is evaluated at the field position z while, in (20), it is evaluated at the left endpoint of the slab, $z=0$. Both of them are needed to derive the equations in this section. The expressions $\tau^{+}(0;z,t)$ and $\tau^{+}(z;0,t)$ denote specific points along the relevant characteristics of the wave front (see Sec. III). The expressions are

$$\begin{aligned}u^{+}(z,t)&=u^{+}(0,\tau^{+}(0;z,t))p(z,\tau^{+}(0;z,t))+\int_{-\infty}^{\tau^{+}(0;z,t)}G^{+}(z,\tau^{+}(0;z,t),t')p(z,t')u^{+}(0,t')dt',\\ u^{-}(z,t)&=\int_{-\infty}^{\tau^{+}(0;z,t)}G^{-}(z,\tau^{+}(0;z,t),t')p(z,t')u^{+}(0,t')dt',\end{aligned}\tag{19}$$

or evaluated at time $\tau^{+}(z;0,t)$ [use the fact that $\tau^{+}(0;z,\tau^{+}(z;0,t))=t$]

$$\begin{aligned}u^{+}(z,\tau^{+}(z;0,t))&=u^{+}(0,t)p(z,t)+\int_{-\infty}^{t}G^{+}(z,t,t')p(z,t')u^{+}(0,t')dt',\\ u^{-}(z,\tau^{+}(z;0,t))&=\int_{-\infty}^{t}G^{-}(z,t,t')p(z,t')u^{+}(0,t')dt',\end{aligned}\tag{20}$$

where the attenuation factor is defined as

$$p(z,t)=\exp\left\{\int_{0}^{z}\alpha(\zeta,\tau^{+}(\zeta;0,t))d\zeta\right\}.$$

In this formula, the integration of the function α is performed along the characteristics of the first equation in (1) (see Sec. III for more details on characteristic curves in nonstationary media and Appendix B for details on the propagation of finite jump discontinuities along characteristic curves). By causality, the Green's functions $G^{\pm}(z,t,t')=0$ for $t'>t$.

The Green's functions equations are derived by performing the calculation of

$$\frac{\partial}{\partial z}\begin{pmatrix} u^+ \\ u^- \end{pmatrix}$$

in two different ways. The first way is obtained through explicit differentiation of the definition of the Green's functions in (20), and the second way is obtained by using the general dynamics, (1). In both cases repeated use of the definition of the Green's functions, (20), and the general dynamics, (1), is necessary. The comparison between these two expressions leads to the following Green's functions equations, $0<z<d$, $t>t'$:

$$\begin{aligned}
&\frac{\partial G^+}{\partial z}(z,t,t') - \alpha(z,\tau^+(z;0,t))G^+(z,t,t') + G^+(z,t,t')\alpha(z,\tau^+(z;0,t')) \\
&\quad - \beta(z,\tau^+(z;0,t))G^-(z,t,t') - A(z,\tau^+(z;0,t),\tau^+(z;0,t'))\frac{\partial \tau^+}{\partial t'}(z;0,t') \\
&\quad - \int_{t'}^{t} A(z,\tau^+(z;0,t),\tau^+(z;0,t''))\frac{\partial \tau^+}{\partial t''}(z;0,t'')G^+(z,t'',t')dt'' \\
&\quad - \int_{t'}^{t} B(z,\tau^+(z;0,t),\tau^+(z;0,t''))\frac{\partial \tau^+}{\partial t''}(z;0,t'')G^-(z,t'',t')dt'' = 0,
\end{aligned} \tag{21}$$

and

$$\begin{aligned}
&\frac{\partial G^-}{\partial z}(z,t,t') - 2f(z,\tau^+(z;0,t))\left(\frac{\partial \tau^+}{\partial t}(z;0,t)\right)^{-1}\frac{\partial G^-}{\partial t}(z,t,t') - \delta(z,\tau^+(z;0,t))G^-(z,t,t') \\
&\quad + G^-(z,t,t')\alpha(z,\tau^+(z;0,t')) - \gamma(z,\tau^+(z;0,t))G^+(z,t,t') \\
&\quad - C(z,\tau^+(z;0,t),\tau^+(z;0,t'))\frac{\partial \tau^+}{\partial t'}(z;0,t') \\
&\quad - \int_{t'}^{t} C(z,\tau^+(z;0,t),\tau^+(z;0,t''))\frac{\partial \tau^+}{\partial t''}(z;0,t'')G^+(z,t'',t')dt'' \\
&\quad - \int_{t'}^{t} D(z,\tau^+(z;0,t),\tau^+(z;0,t''))\frac{\partial \tau^+}{\partial t''}(z;0,t'')G^-(z,t'',t')dt'' = 0,
\end{aligned} \tag{22}$$

with the initial condition

$$G^-(z,t,t')|_{t'=t} = -\frac{1}{2}\frac{\gamma(z,\tau^+(z;0,t))}{f(z,\tau^+(z;0,t))}\frac{\partial \tau^+}{\partial t}(z;0,t). \tag{23}$$

The initial condition on $G^+(z,t,t')|_{t'=t}$ is obtained by integrating (21), i.e.,

$$\begin{aligned}
G^+(z,t,t')|_{t'=t} = -\frac{1}{2}\int_0^z \Bigg[&\frac{\beta(z',\tau^+(z';0,t))\gamma(z',\tau^+(z';0,t))}{f(z',\tau^+(z';0,t))} \\
&- 2A(z',\tau^+(z';0,t),\tau^+(z';0,t))\Bigg]\frac{\partial \tau^+}{\partial t}(z';0,t)dz'
\end{aligned} \tag{24}$$

These differential equations for the Green's functions generalize those given in, e.g., Refs. 1, 5, and 16. Note that the Green's functions $G^{\pm}(z,t,t')=0$ for $t'>t$.

From the definition of the Green's functions $G^{\pm}(z,t,t')$, (20), and the definition of the reflection kernel $R(z,t,t')$, (14), at $z=0$, the following boundary conditions of $G^{\pm}$ at $z=0$ and $z=d$ are obtained for all times:

$$G^{+}(0,t,t')=0, \quad G^{-}(d,t,t')=0, \quad G^{-}(0,t,t')=R(0,t,t').$$

The last boundary condition is a special case of a more general interrelationship between the Green's functions $G^{\pm}(z,t,t')$ and the reflection kernel $R(z,t,t')$. Specifically, from the definition of the Green's functions $G^{\pm}(z,t,t')$, (20), and the reflection kernel $R(z,t,t')$, (14), it is straightforward to obtain for $0\leqslant z\leqslant d$, $t>t'$,

$$G^{-}(z,t,t')=R(z,\tau^{+}(z;0,t),\tau^{+}(z;0,t'))\,\frac{\partial\tau^{+}}{\partial t'}\,(z;0,t') + \int_{t'}^{t} R(z,\tau^{+}(z;0,t),\tau^{+}(z;0,t''))\,\frac{\partial\tau^{+}}{\partial t''}\,(z;0,t'')G^{+}(z,t'',t')\,dt''.$$

Notice, that

$$\frac{\partial\tau^{+}}{\partial t}\,(\zeta;z,t)\bigg|_{\zeta=z}=1.$$

This identity is easily obtained by letting $\zeta_2=\zeta$ and $\zeta_1=z$ in (12) and differentiating with respect to t and finally letting $\zeta=z$.

For completeness, an alternative definition of the Green's function equations is given:

$$u^{+}(z,t)=u^{+}(0,\tau^{+}(0;z,t))p(z,\tau^{+}(0;z,t))+\int_{-\infty}^{\tau^{+}(0;z,t)} g^{+}(z,t,t')p(z,t')u^{+}(0,t')\,dt',$$
$$u^{-}(z,t)=\int_{-\infty}^{\tau^{+}(0;z,t)} g^{-}(z,t,t')p(z,t')u^{+}(0,t')\,dt'. \tag{25}$$

These Green's functions may be more suitable for numerical computation, and the use of the transformation

$$G^{\pm}(z,t,t')=g^{\pm}(z,\tau^{+}(z;0,t),t') \tag{26}$$

enables Eqs. (21) and (22) to be transformed into

$$\frac{\partial g^{+}}{\partial z}\,(z,t,t')+f(z,t)\,\frac{\partial g^{+}}{\partial t}\,(z,t,t')-\alpha(z,t)g^{+}(z,t,t')+g^{+}(z,t,t')\alpha(z,\tau^{+}(z;0,t')) - \beta(z,t)g^{-}(z,t,t')-A(z,t,\tau^{+}(z;0,t'))\,\frac{\partial\tau^{+}}{\partial t'}\,(z;0,t') - \int_{\tau^{+}(z;0,t')}^{t} A(z,t,t'')g^{+}(z,t'',t')\,dt''-\int_{\tau^{+}(z;0,t')}^{t} B(z,t,t'')g^{-}(z,t'',t')\,dt''=0$$

and

$$\frac{\partial g^{-}}{\partial z}\,(z,t,t')-f(z,t)\,\frac{\partial g^{-}}{\partial t}\,(z,t,t')-\delta(z,t)g^{-}(z,t,t')+g^{-}(z,t,t')\alpha(z,\tau^{+}(z;0,t'))$$

$$-\gamma(z,t)g^+(z,t,t')-C(z,t,\tau^+(z;0,t'))\,\frac{\partial\tau^+}{\partial t'}\,(z;0,t')$$

$$-\int_{\tau^+(z;0,t')}^{t} C(z,t,t'')g^+(z,t'',t')dt''-\int_{\tau^+(z;0,t')}^{t} D(z,t,t'')g^-(z,t'',t')dt''=0$$

with the initial condition

$$g^-(z,t,t')|_{t'=\tau^+(0;z,t)}=-\frac{1}{2}\,\frac{\gamma(z,t)}{f(z,t)}\left(\frac{\partial\tau^+}{\partial t}\,(0;z,t)\right)^{-1}.$$

The initial condition on $g^+(z,t,t')|_{t'=\tau^+(0;z,t)}$ is obtained from the transformation (26) and the initial condition for $G^+(z,t,t')|_{t'=t}$ in (24).

The relation between the reflection kernel and this alternative definition of the Green's functions reads

$$g^-(z,t,t')=R(z,t,\tau^+(z;0,t'))\,\frac{\partial\tau^+}{\partial t'}\,(z;0,t')+\int_{\tau^+(z;0,t')}^{t} R(z,t,t'')g^+(z,t'',t')dt''.$$

A. Propagation of discontinuities

The solutions of the first-order system of PDEs (21) and (22) are continuous along the characteristic curves associated with the system, but may be discontinuous across these curves.

From (21) it is seen that the characteristic traces are $t=$constant for G^+ and as $G^+(0,t,t')$ is continuous for all t and t', it follows G^+ is continuous throughout its domain of definition. However, examination of the initial condition (23) shows that any discontinuity in the functions γ and f will be propagated along the characteristic curves described by (22). The conditions imposed on these functions in Sec. I ensure $G^-(z,t,t)$ is continuous except possibly at $z=d$. The initial value for G^- has the jump discontinuity in the direction of increasing t:

$$[G^-](d,t,t)=\frac{1}{2}\,\frac{\gamma(d,\tau^+(d;0,t))}{f(d,\tau^+(d;0,t))}\,\frac{\partial\tau^+}{\partial t}\,(d;0,t).$$

This jump in G^- will propagate along the characteristic curves of G^-.

The characteristic traces for $G^-(z,t,t')$ are independent of the third parameter t' and can be described by an equation $\eta=\eta(\zeta;z,t)$. The notation used here is similar to that used in Eq. (11). The function η satisfies the equation

$$\frac{d\eta}{d\zeta}\,(\zeta;z,t)=-2f(\zeta,\tau^+(\zeta;0,\eta(\zeta;z,t)))\,\frac{\partial\tau^+}{\partial t}\,(0;\zeta,t)|_{t=\tau^+(\zeta;0,\eta(\zeta;z,t))}.$$

The discontinuity propagates along the curve Υ emanating from the line (d,t,t) and where Υ has parametric form

$$\Upsilon:\mathbf{r}(z,t)=(z,\eta(z;d,t),t).$$

It follows that the equation describing the propagation of the discontinuity in G^- is

$$\left.\frac{d[G^-]}{dz}\right|_{\Upsilon}=(\delta(z,\tau^+(z;0,\eta(\zeta;d,t)))-\alpha(z,\tau^+(z;0,t)))[G^-]_{\Upsilon}.$$

Integrating this equation from d to z yields

$$[G^-]_Y=[G^-]_{Y(z=d)}\exp\left\{\int_d^z(\delta(z',\tau^+(z';0,\eta(z';d,t)))-\alpha(z',\tau^+(z';0,t)))dz'\right\}.$$

The discontinuous behavior of g^- can be found from the relationship between g^- and G^- [see (26)], namely

$$g^-(z,\tau^+(z;0,t),t')=G^-(z,t,t')$$

with the substitution $t\to\eta(z;d,t)$, and with use of the identity $(z=d)$

$$\tau^+(\zeta;0,\eta(\zeta;z,t))=\tau^-(\zeta;z,\tau^+(z;0,t))$$

the appropriate expression for $[g^-]$ is found.

VI. EXPLICIT EXPRESSIONS

In this section, the theory presented in the previous sections is illustrated by the examples from Sec. II.

In Sec. II A, propagation of electromagnetic waves in nonstationary, inhomogeneous, dispersive media was considered. A detailed analysis of the imbedding equation and the Green's function equations for this example was presented in Ref. 1, and the reader is referred to this paper for more details.

The generalized wave equation, (4), in Sec. II B and the transmission line equations, (5), in Sec. II C imply no significant simplifications of the results in Secs. IV and V. However, the less complex wave equation, (3), offers some simplifications. Accordingly, the wave equation (3) has an imbedding equation

$$\begin{aligned}&\frac{\partial R}{\partial z}(z,t,t')-f(z,t)\frac{\partial R}{\partial t}(z,t,t')+\frac{\partial R}{\partial t'}(z,t,t')f(z,t')\\&\quad=+\delta(z,t)R(z,t,t')+R(z,t,t')\left[-\frac{\partial f}{\partial t'}(z,t')-\alpha(z,t')\right]\\&\qquad-\int_{t'}^{t}R(z,t,t'')\beta(z,t'')R(z,t'',t')dt''\end{aligned}$$

and Green's functions equations

$$\begin{aligned}&\frac{\partial G^+}{\partial z}(z,t,t')-\alpha(z,\tau^+(z;0,t))G^+(z,t,t')+G^+(z,t,t')\alpha(z,\tau^+(z;0,t'))\\&\qquad-\beta(z,\tau^+(z;0,t))G^-(z,t,t')=0\end{aligned}$$

and

$$\begin{aligned}&\frac{\partial G^-}{\partial z}(z,t,t')-2f(z,\tau^+(z;0,t))\left(\frac{\partial\tau^+}{\partial t}(z;0,t)\right)^{-1}\frac{\partial G^-}{\partial t}(z,t,t')\\&\qquad-\delta(z,\tau^+(z;0,t))G^-(z,t,t')+G^-(z,t,t')\alpha(z,\tau^+(z;0,t'))\\&\qquad-\gamma(z,\tau^+(z;0,t))G^+(z,t,t')=0\end{aligned}$$

with

$$\alpha(z,t) = -\frac{1}{2}\frac{\partial}{\partial z}\ln f(z,t) - \frac{3}{2}\frac{\partial f}{\partial t}(z,t),$$

$$\beta(z,t) = +\frac{1}{2}\frac{\partial}{\partial z}\ln f(z,t) - \frac{1}{2}\frac{\partial f}{\partial t}(z,t),$$

$$\gamma(z,t) = +\frac{1}{2}\frac{\partial}{\partial z}\ln f(z,t) + \frac{1}{2}\frac{\partial f}{\partial t}(z,t),$$

$$\delta(z,t) = -\frac{1}{2}\frac{\partial}{\partial z}\ln f(z,t) + \frac{3}{2}\frac{\partial f}{\partial t}(z,t).$$

VII. CONCLUSIONS

This paper contains a detailed analysis of wave propagation of transient waves in media whose properties are changing in space and time—nonstationary media. The underlying dynamics of the wave propagation problem is a general, linear, homogeneous, nonstationary, first-order 2×2 system of hyperbolic equations. A new wave splitting is introduced, which is a generalization of the well-established wave splitting in media that have time translation symmetries. The scattering problem is solved by an imbedding or a Green's functions technique. Specifically, the imbedding equation for the reflection kernel is derived. This equation is a nonlinear, hyperbolic equation in one space and two time variables. Furthermore, the Green's functions equations are derived. They constitute a system of linear, hyperbolic equations in one space and two time variables. The characteristic curves of the dynamics are discussed in some detail, and a few numerical illustrations give the typical behavior of the nonstationary properties of these characteristic curves.

APPENDIX A: STRAIGHTENING THE CHARACTERISTICS

To illustrate how the characteristic of (1) may be straightened, consider

$$\frac{\partial u^{\pm}}{\partial z}(z,t) \pm f(z,t)\frac{\partial u^{\pm}}{\partial t}(z,t) = F^{\pm}(z,t,u^{+},u^{-}), \tag{A1}$$

where $f(z,t)>0$ in the domain of interest.

Introduce the diffeomorphic transformation of the independent variables

$$z = z(x,s), \quad t = t(x,s),$$

with the associated inverse functions

$$x = x(z,t), \quad s = s(z,t).$$

The PDE (A1) can then be written in terms of the new independent variables as

$$\left(\frac{\partial x}{\partial z} \pm f\frac{\partial x}{\partial t}\right)\frac{\partial u^{\pm}}{\partial x} + \left(\frac{\partial s}{\partial z} \pm f\frac{\partial s}{\partial t}\right)\frac{\partial u^{\pm}}{\partial s} = G^{\pm}(x,s,u^{+},u^{-}).$$

It is easily seen, to straighten the characteristics of the transformed equation, a necessary condition is

$$\frac{\partial x}{\partial z}+f\,\frac{\partial x}{\partial t}=a\left(\frac{\partial s}{\partial z}+f\,\frac{\partial s}{\partial t}\right),\quad \frac{\partial x}{\partial z}-f\,\frac{\partial x}{\partial t}=b\left(\frac{\partial s}{\partial z}-f\,\frac{\partial s}{\partial t}\right), \tag{A2}$$

provided

$$f^2\left(\frac{\partial s}{\partial t}\right)^2-\left(\frac{\partial s}{\partial z}\right)^2\neq 0. \tag{A3}$$

In this expression a and b are nonzero constants. The only way to violate this condition is if either $x-as=$constant or $x-bs=$constant.

The constants a and b cannot be equal if the transformation is to be diffeomorphic. For convenience, choose $a=1$, $b=-1$, so converting the system (A2) to

$$\frac{\partial}{\partial z}\begin{pmatrix}x\\ s\end{pmatrix}=\begin{pmatrix}0 & f\\ f & 0\end{pmatrix}\frac{\partial}{\partial t}\begin{pmatrix}x\\ s\end{pmatrix},$$

which can be converted by diagonalization to the uncoupled system

$$\frac{\partial}{\partial z}\begin{pmatrix}v_1\\ v_2\end{pmatrix}=\begin{pmatrix}-f & 0\\ 0 & f\end{pmatrix}\frac{\partial}{\partial t}\begin{pmatrix}v_1\\ v_2\end{pmatrix},$$

where

$$\begin{pmatrix}v_1\\ v_2\end{pmatrix}=\frac{1}{2}\begin{pmatrix}-1 & 1\\ 1 & 1\end{pmatrix}\begin{pmatrix}x\\ s\end{pmatrix},\quad \begin{pmatrix}x\\ s\end{pmatrix}=\begin{pmatrix}-1 & 1\\ 1 & 1\end{pmatrix}\begin{pmatrix}v_1\\ v_2\end{pmatrix}.$$

A convenient set of initial conditions for x and s is

$$x(z,0)=\int_0^z f(z',0)\,dz',\quad s(z,0)=0.$$

This initial value problem for the hyperbolic system has a unique solution, which means that the characteristics can always be straightened. In fact, these initial conditions imply that (A3) is always satisfied, since $f(z,t)>0$.

In the special case that $f=f(z)$, then the solution of these systems yields

$$x(z,t)=\int_0^z f(z')\,dz',\quad s(z,t)=t.$$

This is the well-known travel time transformation.

APPENDIX B: DUHAMEL'S INTEGRAL

The derivation of the imbedding equation in Sec. IV and the Green's functions equations in Sec. V relies on a result that is obtained from Duhamel's integral.[17] Since the basic first-order 2×2 system of equations, (1), has coefficients varying both in space and time, a slight modification of the standard result is needed. Therefore, it is of interest here to give a few of the intermediate steps leading to the relation (14), which defines the reflection kernel $R(z,t,t')$, and to equation (20) defining the Green's functions $G^{\pm}(z,t,t')$.

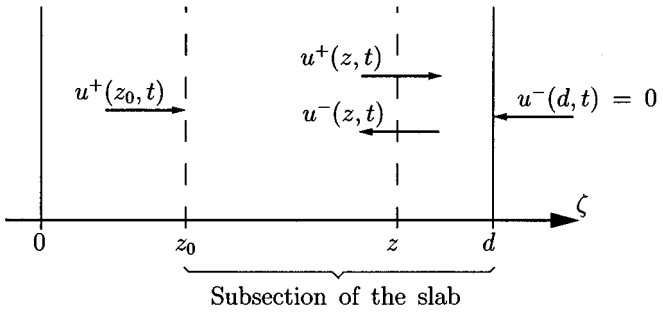

FIG. 4. The geometry used in Appendix B.

In order to cover both the definition of the reflection kernel and the definition of the Green's functions, a subsection (z_0,d) of the physical slab $(0,d)$ is considered. The full slab $(0,d)$ is therefore imbedded in a one-parameter family of sub-slabs (z_0,d), where the left end of the slab z_0 varies between 0 and d (see Fig. 4).

The basic dynamics of the problem is given by (1):

$$\frac{\partial}{\partial z}\begin{pmatrix} u^+(z,t) \\ u^-(z,t) \end{pmatrix} = f(z,t)\begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}\frac{\partial}{\partial t}\begin{pmatrix} u^+(z,t) \\ u^-(z,t) \end{pmatrix} + \begin{pmatrix} \alpha(z,t) & \beta(z,t) \\ \gamma(z,t) & \delta(z,t) \end{pmatrix}\begin{pmatrix} u^+(z,t) \\ u^-(z,t) \end{pmatrix} + \int_{-\infty}^{t}\begin{pmatrix} A(z,t,t') & B(z,t,t') \\ C(z,t,t') & D(z,t,t') \end{pmatrix}\begin{pmatrix} u^+(z,t') \\ u^-(z,t') \end{pmatrix} dt'. \tag{B1}$$

The domain of interest in this appendix is $z_0<z<d$, $t>0$.

Problem 1: A specific solution to Eq. (B1) is now considered. This solution satisfies the following mixed initial-boundary value $(t'>0)$:

$$u^{\pm}(z,0)=0, \quad z_0<z<d,$$

$$u^{+}(z_0,t)=H(t-t'), \quad t>0,$$

$$u^{-}(d,t)=0, \quad t>0.$$

The boundary condition at $z=d$ shows that there are no sources in the region to the right of the slab, $z>d$.

The solution to this problem, which is assumed to be unique, depends on the parameters $z_0\in(0,d)$ and $t'>0$, and the solution is denoted $U^{\pm}(z,t;z_0,t')$, i.e.,

$$u^{\pm}(z,t)=U^{\pm}(z,t;z_0,t').$$

Causality implies that $U^{\pm}(z,t;z_0,t')=0$ for $t'>\tau^+(z_0;z,t)$ or, stated equivalently, $t<\tau^+(z;z_0,t')$. The variable t' denotes the starting time of the excitation at the left boundary z_0 of the sub-slab (z_0,d). If the medium is invariant under time translations, the solution is only a function of z and z_0, and the difference $t-t'$.

The solutions $U^{\pm}(z,t;z_0,t')$ are continuously differentiable everywhere, except along the characteristics of the u^+-equation (see Sec. III). With the method of characteristics, it is straightforward to show that U^- is continuous at the leading edge, while U^+ has a finite jump disconti-

nuity there. The leading edge is defined as the characteristic curve in the (z,t)-plane passing through the point (z_0,t'), i.e., $t=\tau^+(z;z_0,t')$, $z_0<z<d$. The explicit values at the leading edge are

$$U^+(z,t;z_0,\tau^+(z_0;z,t))=\exp\left\{\int_{z_0}^{z}\alpha(\zeta,\tau^+(\zeta;z,t))d\zeta\right\},$$

$$U^-(z,t;z_0,\tau^+(z_0;z,t))=0.$$

Problem 2: Consider now the solution of Eq. (B1) subject to the mixed initial-boundary value $(t'>0)$

$$\begin{aligned} &u^{\pm}(z,0)=0, \quad z_0<z<d,\\ &u^+(z_0,t)=g(t), \quad t>0,\\ &u^-(d,t)=0, \quad t>0. \end{aligned} \tag{B2}$$

Again, the boundary condition at $z=d$ shows that there are no sources in the region to the right of the slab, $z>d$. Here, $g(t)$ is an arbitrary continuously differentiable function, which for $t>0$ can be approximated from below by the piecewise constant function

$$g_1(t)=g(0)H(t)+\sum_{k=1}^{\infty}[g(k\Delta t')-g((k-1)\Delta t')]H(t-k\Delta t').$$

Due to the linearity of the equation (B1), superposition is used to find the solution of the approximate boundary value $g_1(t)$. In the limit, $\Delta t'\to 0$, the result is

$$u^{\pm}(z,t)=u^+(z_0,0)U^{\pm}(z,t;z_0,0)+\int_0^{\tau^+(z_0;z,t)}\frac{\partial u^+}{\partial t'}(z_0,t')U^{\pm}(z,t;z_0,t')dt',$$

where the causality of the solutions $U^{\pm}(z,t;z_0,t')$ has been used to truncate the infinite integration range and, furthermore, the substitution $g(t)=u^+(z_0,t)$ for $t>0$ has been made. It is easy to verify that the expressions $u^{\pm}(z,t)$ satisfy the given mixed initial-boundary value problem, with the use of (13) and the fact that $U^-(z,t;z_0,\tau^+(z_0;z,t))=0$. Integration by parts now shows that the unique solution of the mixed boundary value problem (B1) and (B2) is

$$\begin{aligned} u^+(z,t)&=u^+(z_0,\tau^+(z_0;z,t))U^+(z,t;z_0,\tau^+(z_0;z,t))-\int_0^{\tau^+(z_0;z,t)}u^+(z_0,t')\frac{\partial U^+}{\partial t'}(z,t;z_0,t')dt',\\ u^-(z,t)&=-\int_0^{\tau^+(z_0;z,t)}u^+(z_0,t')\frac{\partial U^-}{\partial t'}(z,t;z_0,t')dt'. \end{aligned} \tag{B3}$$

These equations now offer two possibilities, namely to define the reflection kernel $R(z_0,t,t')$ of the sub-slab (z_0,d) and the Green's functions $G^{\pm}(z,t,t')$ of the full slab $(0,d)$.

For the definition of the reflection kernel use the second equation in (B3) and let $z=z_0$. Define the reflection kernel

$$R(z_0,t,t')=-\frac{\partial U^-}{\partial t'}(z_0,t;z_0,t').$$

The relation between the $u^{\pm}$-waves at the left endpoint of the sub-slab is (the subscript on z_0 is dropped)

$$u^-(z,t)=\int_{-\infty}^{t} R(z,t,t')u^+(z,t')dt',$$

which is identical to (14).

In the definition of the Green's functions $G^{\pm}(z,t,t')$, let $z_0=0$ in (B3). The result is

$$u^+(z,t)=u^+(0,\tau^+(0;z,t))p(z,\tau^+(0;z,t))-\int_0^{\tau^+(0;z,t)} u^+(0,t')\,\frac{\partial U^+}{\partial t'}\,(z,t;0,t')dt',$$

$$u^-(z,t)=-\int_0^{\tau^+(0;z,t)} u^+(0,t')\,\frac{\partial U^-}{\partial t'}\,(z,t;0,t')dt',$$

where

$$p(z,t)=\exp\left\{\int_0^z \alpha(\zeta,\tau^+(\zeta;0,t))d\zeta\right\}.$$

It is convenient to introduce an extra factor $p(z,t')$ in the definition of the Green's functions. Therefore, the definition of $G^{\pm}(z,t,t')$ is

$$-\frac{\partial}{\partial t'}\,U^+(z,t;0,t')=p(z,t')G^+(z,\tau^+(0;z,t),t'),$$

$$-\frac{\partial}{\partial t'}\,U^-(z,t;0,t')=p(z,t')G^-(z,\tau^+(0;z,t),t').$$

APPENDIX C: EXAMPLES ON CHARACTERISTICS OF THE u^+-EQUATION

The explicit form of the function f determines whether a closed form expression can be found for the characteristics in (9) or not. In most cases this is not possible. In this section, the theory of the characteristics is illustrated with an analytic and a numerical example.

Analytic example: The function $f(z,t)$ has to be consistent with the boundary conditions, (2), given in Sec. I, and simple enough to permit closed form solutions of (9). Thus, for $\tau^+\geqslant 0$ and $0\leqslant\zeta\leqslant d$, let

$$f(\zeta,\tau^+)=\frac{1}{v_0}\,[1+a\zeta(d-\zeta)\tau^+].$$

Here d is the thickness of the slab, v_0 is a constant, and a is a parameter. Outside the slab, i.e., for $\zeta<0$ or $\zeta>d$, and everywhere for $\tau^+<0$, let

$$f(\zeta,\tau^+)=\frac{1}{v_0}.$$

Figure 5 shows the velocity profile $c(z,t)$ inside the slab ($d=2$), surrounded by a medium with the constant wave velocity $v_0=1$, and $a=1$. A set of characteristics for this case is illustrated in Fig. 6.

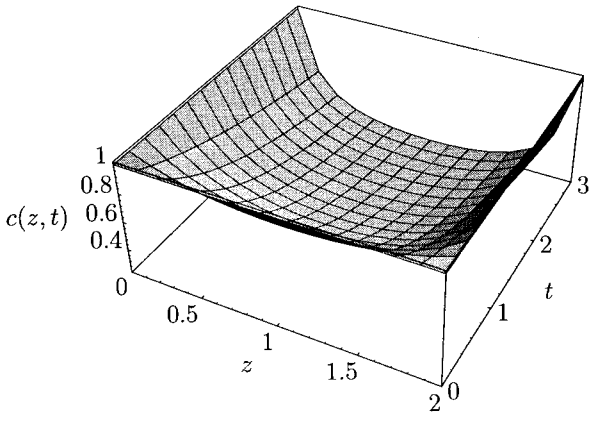

FIG. 5. The velocity profile $c(z,t)=1/(1+z(d-z)t)$, where $d=2$.

If f is inserted into Eq. (9), a linear first-order ordinary differential equation in $\tau^+(\zeta)$ is obtained. This equation is easily solvable after multiplication with the integrating factor $e^{g(\zeta)}$ where

$$g(\zeta)=\frac{1}{v_0}\,a\left(-\frac{1}{2}\,d\zeta^2+\frac{1}{3}\,\zeta^3\right).$$

The explicit form of the characteristic curve passing through the point (z,t) is

$$\tau^+(\zeta;z,t)=te^{g(z)}e^{-g(\zeta)}+\frac{1}{v_0}\,e^{-g(\zeta)}\int_z^\zeta e^{g(\zeta')}d\zeta'.$$

Specifically, the solution at $\zeta=0$ is

$$\tau^+(0;z,t)=te^{g(z)}-\frac{1}{v_0}\int_0^z e^{g(\zeta')}\,d\zeta'$$

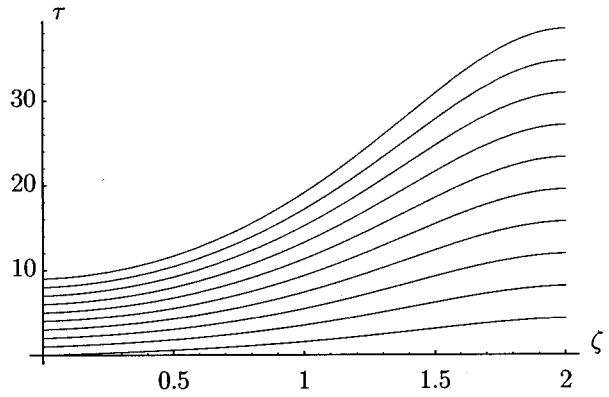

FIG. 6. A set of characteristics for the case, $f(z,t)=1+z(d-z)t$, where $d=2$.

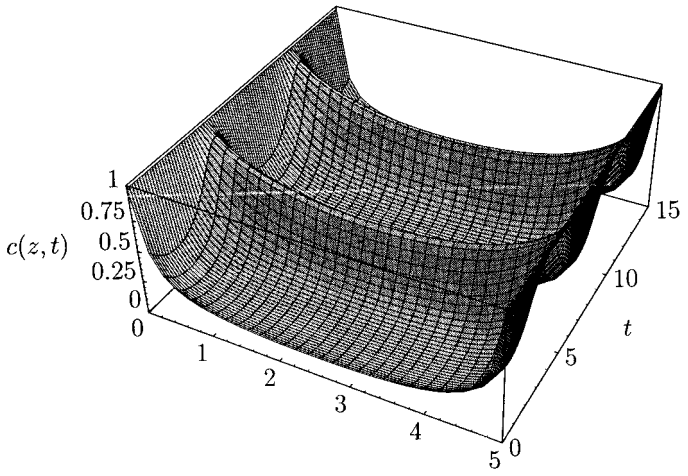

FIG. 7. The velocity profile $c(z,t)$ for the example in (C1) for $d=5$.

and the solution at z starting at $(0,t)$ is

$$\tau^+(z;0,t)=te^{-g(z)}+\frac{1}{v_0}\,e^{-g(z)}\int_0^z e^{g(\zeta')}\,d\zeta'.$$

Differentiation with respect to t and z gives

$$\frac{\partial\tau^+(\zeta;z,t)}{\partial t}=e^{g(z)}e^{-g(\zeta)}$$

and

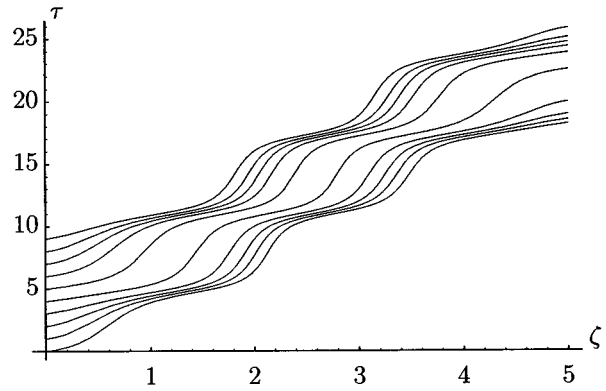

FIG. 8. A set of characteristics for the example in (C1) for $d=5$.

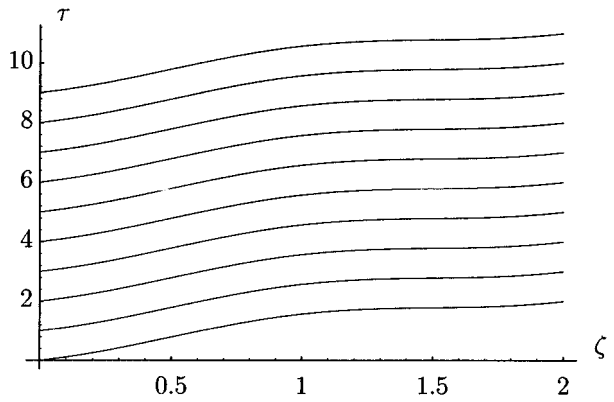

FIG. 9. A set of characteristics for the stationary case, $f(z)=1+0.9\sin 2\pi z/d$, where $d=2$.

$$\frac{\partial\tau^{+}(\zeta;z,t)}{\partial z}=tg'(z)e^{g(z)}e^{-g(\zeta)}-\frac{1}{v_0}e^{g(z)}e^{-g(\zeta)}=-f(z,t)e^{g(z)}e^{-g(\zeta)}$$

and (13) is satisfied.

Numerical example: In Figs. 7 and 8, the phase velocity and a set of characteristics, respectively, for a nonlinear case are depicted. The phase velocity of the nonstationary medium in this example is

$$f(z,t)=\begin{cases}1, & z<0;\\ 1+z(d-z)(1.1+\sin t), & 0<z<d;\\ 1, & z>d.\end{cases}\tag{C1}$$

These curves have been obtained by numerical integration.

Note that the flow depicted by Figs. 6 and 8 illustrates a flow field that is non-area preserving, i.e., the flow field has nonzero divergence (compressible). Compare this with Fig. 9 for which $f(z,t)=f(z)$ and so the flow field is area preserving.

An ongoing big bang model in the special relativistic Maxwell–Dirac equations

A. Das
Department of Mathematics and Statistics, Simon Fraser University, Burnaby, B.C. V5A 1S6, Canada

(Received 2 August 1995; accepted for publication 3 January 1996)

An exact, analytical solution of the combined Maxwell–Dirac equation is presented. The solution is regular inside a wedgelike domain of the flat space–time. On the boundary of that domain, the solution exhibits singular behavior. © *1996 American Institute of Physics.* [S0022-2488(96)01505-2]

I. INTRODUCTION

Exact, analytical solutions of interacting second-quantized fields are not available yet. However, classical interacting fields are more tractable for analysis. The coupled Maxwell–Klein–Gordon equations have yielded some exact solutions.[1] The coupled Eistein–Maxwell equations have produced scores of exact solutions.[2] Exact analytical solutions have been found within the complicated system of the coupled Einstein–Maxwell–Klein–Gordon equations.[3] The coupled Maxwell–Dirac equations are predecessors of the quantum electro-dynamics. These equations also provide some valuable insights for the standard theory.[4] The initial-value problem of the coupled Maxwell–Dirac equation has been probed by Flato, Simon, and Taflin.[5] The class of exact plane wave solutions of the type $\psi(x)=\alpha(p)\exp[ip_\mu x^\mu]$, within the framework of the Maxwell–Dirac equations, has been thoroughly explored.[6] It was discovered that, for $m\neq 0$, not a single nontrivial solution exists! However, infinitely many solutions exist for $m=0$. The coupled Maxwell–Dirac equations in the $1+1$-dimensional space–time is known as the classical Schwinger theory.[7] In the case of $m=0$, the most general solutions of the classical Schwinger theory have been discovered recently.[8] The massive Schwinger theory is much more complicated to solve. However, a particular solution of the massive theory was found in the same paper. Our present exact solution in this paper is based on that solution.

None of the exact solutions of the quasilinear, coupled field equations discussed so far uses the perturbation methods or Fourier integrals. These are the usual tools people use to explore the quantum theory of interacting fields. Unfortunately, the Fourier integral techniques discard more solutions than they generate. For example, consider the one-dimensional wave equation $[(\partial_x)^2-(\partial_t)^2]\psi(x,t)=0$. Denumerably infinite number of solutions of this equation, given by $\psi_n(x,t)=(x-t)^{2n}+(x+t)^{2n}$, $n\in\mathbb{Z}^+$, cannot be obtained by use of Fourier integrals. So, we are not surprised to find that our present solution of the Maxwell–Dirac equations cannot be captured by the Fourier integrals. However, we have managed to obtain a sequence of *approximate* solutions which can be expressed as Fourier cosine integrals. In the limit $n\to\infty$, the sequence of approximate solutions goes over into the present exact solution, which itself is not amenable to the Fourier cosine integrals.

Our exact solution can be defined only in a proper subset of flat space–time. This domain looks like a wedge (see Fig. 1) and solutions become singular on its boundary. That is why it is an ongoing big bang model in the framework of the special theory of relativity.

II. NOTATIONS AND FIELD EQUATIONS

The flat space–time manifold is denoted by M_4. A global Minkowski coordinate chart is used. A space–time event, which is an element of M_4, is coordinatized by $x:=(x^0,x^1,x^2,x^3)$. Here, x^0

0022-2488/96/37(5)/2253/7/$10.00
J. Math. Phys. **37** (5), May 1996

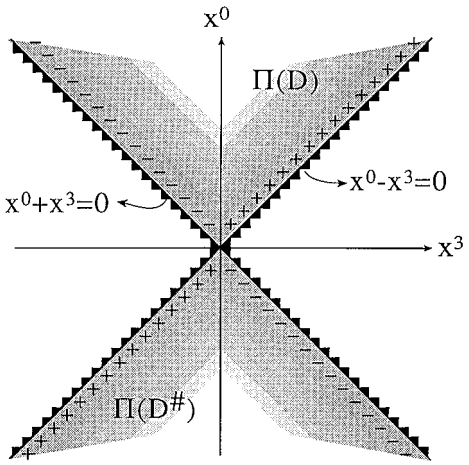

FIG. 1. Space–time diagram depicting ongoing big bang crunch followed by ongoing big bang.

denotes the time coordinate. A Greek index takes values from {0,1,2,3} and a Roman index takes from {1,2,3}. The signature of the metric tensor $\eta_{\mu\nu}$ is -2. Einstein's summation convention is followed.

The electromagnetic four-potential is denoted by $A^{\mu}(x)$. The four-component (Dirac) bispinor field and its Hermitian conjugate are indicated by $\psi(x)$ and $\psi^{\dagger}(x)$, respectively. The four Dirac matrices are denoted by γ^{μ} and we shall adopt Weyl's representation of these matrices. In an open, convex domain $D\subset\mathbb{R}^4$ corresponding to such a domain in M_4, we assume that the potential functions A^{μ} are of the differentiability class $C^3(D\subset\mathbb{R}^4;\mathbb{R})$ and the bispinor components $\psi_1,\psi_2,\psi_3,\psi_4$ are of the class $C^2(D\subset\mathbb{R}^4;\mathbb{C})$. In such a setting, the coupled Maxwell–Dirac equations (in the units $\hbar=c=1$) can be written as

$$M^{\mu}(x):=\partial^{\nu}\partial_{\nu}A^{\mu}(x)-j^{\mu}(x)=0, \tag{2.1a}$$

$$j^{\mu}(x):=e\,\psi^{\dagger}(x)\,\gamma^0\gamma^{\mu}\psi(x), \tag{2.1b}$$

$$L(x):=\partial_{\mu}A^{\mu}(x)=0, \tag{2.1c}$$

$$D(x):=\{i\gamma^{\mu}[\partial_{\mu}+ieA_{\mu}(x)]-mI_{(4)}\}\psi(x)=0, \tag{2.1d}$$

$$\gamma^0:=\begin{bmatrix}0 & I_{(2)}\\ I_{(2)} & 0\end{bmatrix},\quad \gamma^k:=\begin{bmatrix}0 & -\sigma^k\\ \sigma^k & 0\end{bmatrix}. \tag{2.1e}$$

Here, e and m are the charge and the mass parameters, respectively. Moreover, $I_{(4)},I_{(2)}$ are identity matrices and σ^ks are Pauli matrices.

Now we shall make some general observations about the system of equations (2.1a)–(2.1e). There exists one differential identity among the equations and it is given by

$$\partial_{\mu}M^{\mu}-\partial_{\mu}\partial^{\mu}L-ie[\psi^{\dagger}(x)\psi^0D(x)-D^{\dagger}(x)\gamma^0\psi(x)]\equiv 0. \tag{2.2}$$

The gauge-invariant, symmetric energy-momentum-stress tensor density is given by

$$\theta_{ab}(x):=(i/2)\{\psi^{\dagger}(x)\gamma^0\gamma_b[(\partial_a+ieA_a)\psi]-[(\partial_a-ieA_a)\psi^{\dagger}(x)]\gamma^0\gamma_b\psi(x)\}$$
$$-F^{c}{}_{a}(x)F_{bc}(x)+\tfrac{1}{4}\eta_{ab}F_{cd}(x)F^{cd}(x), \tag{2.3a}$$

$$F_{ab}(x) := \partial_b A_a - \partial_a A_b\,, \tag{2.3b}$$

$$\partial_b \theta^{ab}(x) = 0. \tag{2.3c}$$

By a straightforward computation we obtain

$$j_\mu(x) j^\mu(x) = 4e^2 |\psi_1^*(x)\psi_3(x) + \psi_2^*(x)\psi_4(x)|^2 \geqslant 0. \tag{2.4}$$

Therefore, the four-current vector $j^\mu(x)$ is always nonspacelike, irrespective of the real (or complex) values of m. Preliminary analysis of the system of equations (2.1a)–(2.1e) with $m \neq 0$ reveals that solutions of the type $|\psi_1|^2 + |\psi_2|^2 > 0$, $\psi_3 = \psi_4 \equiv 0$ or else $\psi_1 = \psi_2 \equiv 0$, $|\psi_3|^2 + |\psi_4|^2 > 0$, do *not* exist. Therefore, in every nontrivial solution of the system both particles as well as antiparticles must be present.

The Maxwell's equations (2.1a) are linear, second-order partial differential equations. In the absence of the external electromagnetic fields, these equations can be integrated to obtain

$$A_\mu(x) = e \int G_{inh}(x - x')\, \psi^\dagger(x')\, \gamma^0 \gamma_\mu \psi(x')\, d^4x', \tag{2.5}$$

where G_{inh} is a nonhomogeneous Green's function suitable for a prescribed initial-boundary-value problem. Substituting (2.5) into (2.1d) we obtain

$$[i\gamma^\mu \partial_\mu - mI_4]\psi(x) + ie^2 \left[\int G_{inh}(x - x')\, \gamma^\mu \psi^\dagger(x')\, \gamma^0 \gamma_\mu \psi(x')\, d^4x' \right] \psi(x) = 0. \tag{2.6}$$

The above is a nonlinear, integro-differential equation[9] for ψ which automatically incorporates the electro magnetic self-interactions of the Dirac particle–antiparticle system. The equation (2.6) implies that the time evolution of the system $\partial_0 \psi$ depends on the local property of the wave function $\gamma^k \partial_k \psi$ and also on the past history of the system inherent in the integral involving Green's function.

III. A PARTICULAR EXACT SOLUTION

We furnish a special, exact solution of the system (2.1a)–(2.1e) by the following:

$$A^1(x) = A^2(x) \equiv 0, \tag{3.1a}$$

$$A^0(x) = \left(\frac{m}{4e}\right) \left\{ \ln|(x^0)^2 - (x^3)^2| - 2\left[\frac{(x^0)^2 + (x^3)^2}{(x^0)^2 - (x^3)^2}\right] \right\}, \tag{3.1b}$$

$$A^3(x) = -\left(\frac{m}{4e}\right) \left\{ \ln\left|\frac{x^0 - x^3}{x^0 + x^3}\right| + \frac{4x^0 x^3}{[(x^0)^2 - (x^3)^2]} \right\}, \tag{3.1c}$$

$$\psi_2(x) = \psi_4(x) \equiv 0, \tag{3.1d}$$

$$\psi_1(x) = \left[\frac{\sqrt{m}}{e(x^0 - x^3)}\right] \exp\left\{ -i\left(\frac{m}{4}\right)[(x^0 - x^3)\ln|x^0 + x^3| + (x^0 + x^3)\ln|x^0 - x^3|] \right\}, \tag{3.1e}$$

$$\psi_3(x) = \left[\frac{\sqrt{m}}{e(x^0 + x^3)}\right] \exp\left\{ -i\left(\frac{m}{4}\right)[(x^0 - x^3)\ln|x^0 + x^3| + (x^0 + x^3)\ln|x^0 - x^3|] \right\}, \tag{3.1f}$$

$$j^1(x) = j^2(x) \equiv 0, \tag{3.1g}$$

$$j^0(x)=\left(\frac{m}{e}\right)\left[\frac{1}{(x^0-x^3)^2}+\frac{1}{(x^0+x^3)^2}\right], \tag{3.1h}$$

$$j^3(x)=\left(\frac{m}{e}\right)\left[\frac{1}{(x^0-x^3)^2}-\frac{1}{(x^0+x^3)^2}\right], \tag{3.1i}$$

$$F_{01}(x)=F_{02}(x)=F_{12}(x)=F_{23}(x)=F_{31}(x)\equiv 0, \tag{3.1j}$$

$$F_{03}(x):=\partial_3 A_0-\partial_0 A_3=\left(\frac{m}{e}\right)\left[\frac{1}{(x^0+x^3)}-\frac{1}{(x^0-x^3)}\right], \tag{3.1k}$$

$$A_\mu(x)j^\mu(x)=\left(\frac{m}{2e}\right)^2\left\{\left[\frac{1}{(x^0-x^3)^2}+\frac{1}{(x^0+x^3)^2}\right]\left[\ln|(x^0)^2-(x^3)^2|-2\left(\frac{(x^0)^2+(x^3)^2}{(x^0)^2-(x^3)^2}\right)\right]\right.$$
$$\left.+\left[\frac{1}{(x^0-x^3)^2}-\frac{1}{(x^0+x^3)^2}\right]\left[\ln\left|\frac{x^0-x^3}{x^0+x^3}\right|+\frac{4x^0x^3}{((x^0)^2-(x^3)^2)}\right]\right\}. \tag{3.1l}$$

In the above solution there are no external electromagnetic fields. The self-electric field is in the direction of the x^3 axis. There is no self-magnetic field. The current vector density is along x^3 axis. The self-energy density is given by the equation (3.1l). The particle wave function is given by $\psi_1(x)$ and the antiparticle wave function is given by $\psi_3(x)$. The corresponding phase functions satisfy $\arg\psi_1(x)=\arg\psi_3(x)+2N\pi$, where N is an integer. The solutions (2a)–(2f) are valid in the open, unbounded, convex domain D of the flat space–time characterized by

$$D:=\{(x^0,x^1,x^2,x^3):x^0>0,(x^0)^2-(x^3)^2>0,x^1\in\mathbb{R},x^2\in\mathbb{R}\}. \tag{3.2}$$

(A similar wedge-shaped domain has been considered[10] in general relativity.) The boundary of this domain is given by the three-dimensional hypersurface:

$$\partial D:=\{(x^0,x^1,x^2,x^3):x^0\geqslant 0,(x^0)^2-(x^3)^2=0,x^1\in\mathbb{R},x^2\in\mathbb{R}\}. \tag{3.3}$$

These three-dimensional edges satisfy $\phi(x):=(x^0)^2-(x^3)^2=0$, and thus imply that $\eta^{\mu\nu}(\partial_\mu\phi)(\partial_\nu\phi)=0$. Therefore, the boundary ∂D constitutes a three-dimensional null hyper-surface of two-content.[11] Precisely on this null boundary, the solutions (2a)–(2f) are undefined or singular. The particle wave function $\psi_1(x)$ is singular on $x^0-x^3=0$ and the antiparticle wave function $\psi_3(x)$ is singular on $x^0+x^3=0$. That is why these solutions constitute an ongoing big bang model.

It is understandable that the usual Fourier integral techniques of the relativistic field theory fail to capture these solutions. However, a sequence of approximate solutions, expressible by Fourier cosine integrals, exist such that the limit of the sequence yields the present solutions. The key to this construction of the approximate solutions is the Fourier cosine integral:[12]

$$\frac{1}{(u)^{(1-1/n)}}=\frac{\Gamma(1/n)}{\pi}\int_{0^+}^{\infty}\frac{\cos[pu-(\pi/2n)]dp}{p^{1/n}},\quad u>0;n\in\{2,3,4,\ldots\}. \tag{3.4}$$

Here, Γ is the usual gamma function. Note that in the limit $n\to\infty$, the left-hand side tends to u^{-1}, but the right-hand side limit does not exist. The sequence of the approximate solutions are given by

$$A^1_{(n)}(x)=A^2_{(n)}(x)\equiv 0, \tag{3.5a}$$

$$A^0_{(n)}(x)=\left[\frac{m}{4e(1-2/n)}\right]\Big\{(n/2)[(x^0+x^3)^{2/n}+(x^0-x^3)^{2/n}-2]$$
$$-\frac{(x^0+x^3)}{(x^0-x^3)^{(1-2/n)}}-\frac{(x^0-x^3)}{(x^0+x^3)^{(1-2/n)}}\Big\}, \tag{3.5b}$$

$$A^3_{(n)}(x)=-\left[\frac{m}{4e(1-2/n)}\right]\Big\{(n/2)[(x^0-x^3)^{2/n}-(x^0+x^3)^{2/n}]$$
$$+\frac{(x^0+x^3)}{(x^0-x^3)^{(1-2/n)}}-\frac{(x^0-x^3)}{(x^0+x^3)^{(1-2/n)}}\Big\}, \tag{3.5c}$$

$$\psi_{2(n)}(x)=\psi_{4(n)}(x)\equiv 0, \tag{3.5d}$$

$$\psi_{1(n)}(x)=\frac{\sqrt{m}}{e(x^0-x^3)^{(1-1/n)}}\exp\Big\{-i\left(\frac{mn}{8}\right)[(x^0+x^3)((x^0-x^3)^{2/n}-1)$$
$$+(x^0-x^3)((x^0+x^3)^{2/n}-1)]\Big\}$$
$$=\left[\frac{\sqrt{m}\Gamma(1/n)}{\pi e}\right]\cdot\exp\Big\{-i\left(\frac{mn}{8}\right)[(x^0+x^3)((x^0-x^3)^{2/n}-1)$$
$$+(x^0-x^3)((x^0+x^3)^{2/n}-1)]\Big\}\int_{0^+}^{\infty}(p)^{-1/n}\cos\left[p(x^0-x^3)-\left(\frac{\pi}{2n}\right)\right]dp, \tag{3.5e}$$

$$\psi_{3(n)}(x)=\frac{\sqrt{m}}{e(x^0+x^3)^{(1-1/n)}}\exp\Big\{-i\left(\frac{mn}{8}\right)[(x^0+x^3)((x^0+x^3)^{2/n}-1)$$
$$+(x^0-x^3)((x^0+x^3)^{2/n}-1)]\Big\}$$
$$=\left[\frac{\sqrt{m}\Gamma(1/n)}{\pi e}\right]$$
$$\cdot\exp\Big\{-i\left(\frac{mn}{8}\right)[(x^0+x^3)((x^0-x^3)^{2/n}-1)+(x^0-x^3)((x^0+x^3)^{2/n}-1)]\Big\}$$
$$\times\int_{0^+}^{\infty}(p)^{-1/n}\cos\left[p(x^0+x^3)-\left(\frac{\pi}{2n}\right)\right]dp, \tag{3.5f}$$

$$\partial^\nu\partial_\nu A^\mu_{(n)}(x)-j^\mu_{(n)}(x)=0, \tag{3.5g}$$

$$\partial_\mu A^\mu_{(n)}(x)=0, \tag{3.5h}$$

$$\{i\gamma^\mu[\partial_\mu+ieA_{\mu(n)}(x)]-mI_{(4)}\}\psi_{(n)}(x)=0(1/n). \tag{3.5i}$$

It can be proved that if the terms involving Fourier cosine integrals are not considered, then the limits $n\to\infty$ of the sequence of approximate solutions in (3.5) are precisely the solutions in (3.1).

The solutions (3b), (3c), (3e), (3f), (3h), (3i), and (3k) exhibit unphysical features in having simple poles at $e=0$ in the complex e-plane. (Such singular behaviors were predicted in Ref. 13.) However, in case the mass parameter m is not independent of the charge parameter e, and the

relation $m=e^2/r_0$ holds for some length parameter r_0, these spurious singularities at $e=0$ disappear. Making this assumption $m=e^2/r_0$, we can express the solutions in (3.1) as the following power series of e:

$$A^1(x)=A^2(x)\equiv 0, \tag{3.6a}$$

$$A^0(x)=\left(\frac{e}{4r_0}\right)\left\{\ln|(x^0)^2-(x^3)^2|-2\left[\frac{(x^0)^2+(x^3)^2}{(x^0)^2-(x^3)^2}\right]\right\}, \tag{3.6b}$$

$$A^3(x)=-\left(\frac{e}{4r_0}\right)\left\{\ln\left|\frac{x^0-x^3}{x^0+x^3}\right|+\frac{4x^0x^3}{[(x^0)^2-(x^3)^2]}\right\}, \tag{3.6c}$$

$$\psi_2(x)=\psi_4(x)\equiv 0, \tag{3.6d}$$

$$\psi_1(x)=\left[\frac{1}{\sqrt{r_0}(x^0-x^3)}\right]\sum_{k=0}^{\infty}\frac{1}{k!}\left\{\left(\frac{-ie^2}{4r_0}\right)[(x^0-x^3)\ln|x^0+x^3|+(x^0+x^3)\ln|x^0-x^3|]\right\}^k, \tag{3.6e}$$

$$\psi_2(x)=\left[\frac{1}{\sqrt{r_0}(x^0+x^3)}\right]\sum_{k=0}^{\infty}\frac{1}{k!}\left\{\left(\frac{-ie^2}{4r_0}\right)[(x^0-x^3)\ln|x^0+x^3|+(x^0+x^3)\ln|x^0-x^3|]\right\}^k, \tag{3.6f}$$

$$|\psi_1(x)|=\frac{1}{\sqrt{r_0}|x^0-x^3|}, \tag{3.6g}$$

$$|\psi_2(x)|=\frac{1}{\sqrt{r_0}|x^0+x^3|}, \tag{3.6h}$$

$$j^1(x)=j^2(x)\equiv 0, \tag{3.6i}$$

$$j^0(x)=\left(\frac{e}{r_0}\right)\left[\frac{1}{(x^0-x^3)^2}+\frac{1}{(x^0+x^3)^2}\right], \tag{3.6j}$$

$$j^3(x)=\left(\frac{e}{r_0}\right)\left[\frac{1}{(x^0-x^3)^2}-\frac{1}{(x^0+x^3)^2}\right], \tag{3.6k}$$

$$F_{12}(x)=F_{23}(x)=F_{31}(x)=F_{01}(x)=F_{02}(x)\equiv 0, \tag{3.6l}$$

$$F_{03}(x)=\left(\frac{e}{r_0}\right)\left[\frac{1}{(x^0+x^3)}-\frac{1}{(x^0-x^3)}\right], \tag{3.6m}$$

$$A_\mu(x)j^\mu(x)=\left(\frac{e^2}{4r_0^2}\right)\left\{\left[\frac{1}{(x^0-x^3)^2}+\frac{1}{(x^0+x^3)}\right]\left[\ln|(x^0)^2-(x^3)^2|-2\left(\frac{(x^0)^2+(x^3)^2}{(x^0)^2-(x^3)^2}\right)\right]+\left[\frac{1}{(x^0-x^3)^2}-\frac{1}{(x^0+x^3)^2}\right]\left[\ln\left|\frac{x^0-x^3}{x^0+x^3}\right|+\frac{4x^0x^3}{(x^0)^2-(x^3)^2}\right]\right\}. \tag{3.6n}$$

In the limit $e\to 0$, the mass $m=(e^2/r_0)$ and all solutions in (3.6), *except* (3.6e)–(3.6h) vanish. In that limit, Dirac field components go over into

$$\psi_1(x)=\frac{1}{\sqrt{r_0}(x^0-x^3)},\quad \psi_3(x)=\frac{1}{\sqrt{r_0}(x^0+x^3)},\quad \psi_2(x)=\psi_4(x)\equiv 0. \tag{3.7}$$

These are exact solutions of the *massless, free* Dirac equations. Therefore, in this model, the self-electric field and the mass vanish in case the coupling constant e goes to zero.

The solutions $(7a-n)$ of the Maxwell–Dirac equations are also valid in the alternate domain

$$D^{\#}:=\{(x^0,x^1,x^2,x^3):x^0<0,(x^0)^2-(x^3)^2>0,x^1\in\mathbb{R},x^2\in\mathbb{R}\}. \tag{3.8}$$

The solutions (3.6a)–(3.6n) in the combined domain $D^{\#}\cup D$ can be regarded as a model of an ongoing big crunch immediately followed by an ongoing big bang in the arena of the special relativistic Maxwell–Dirac equations.

To picture these domains, it will be convenient to introduce a projection function $\pi:\mathbb{R}^4\to\mathbb{R}$ such that

$$\pi(x^0,x^1,x^2,x^3):=(x^0,x^3).$$

The corresponding projections of domains are given by

$$\pi(D)=\{(x^0,x^3):x^0>0,(x^2)^2-(x^3)^2>0\},$$

$$\pi(D^{\#})=\{(x^0,x^3):x^0<0,(x^0)^2-(x^3)^2>0\}.$$

The pictures of these domains in $\mathbb{R}^2$, corresponding to two-flats[11] in M_4, are exhibited in Fig. 1.

ACKNOWLEDGMENTS

I would like to thank Dr. S. Kloster for some informal discussions. I also thank J. Fabricius for typing the manuscript and E. Carefoot for drawing the diagram. I am indebted to the late Sri Gadadhar Chattopadhyaya for inspiration.

Quantum random walk for $U_q(su(2))$ and a new example of quantum noise

Romuald Lenczewski
Hugo Steinhaus Center for Stochastic Methods, Institute of Mathematics, Technical University of Wroclaw, 50-370 Wroclaw, Poland

(Received 24 May 1995; accepted for publication 15 November 1995)

We derive the quantum version of the central limit theorem for sample sums of q-independent q-identically distributed quantum variables for $q \in \mathbf{R}^+ - \{1\}$. In particular, we consider $U_q(su(2))$, for which we obtain in the limit a state Ψ on the algebra generated by q-commuting q-oscillators indexed by pairs of real numbers (r,s), where $0 \leqslant r < s$, giving a new example of non-additive quantum noise. © *1996 American Institute of Physics.* [S0022-2488(96)00303-3]

I. INTRODUCTION

The aim of this paper is to prove the central limit theorem for sample sums of q-independent variables of the Hopf algebra $U_q(su(2))$ type, and thus is a contribution to the area of non-commutative theory of processes[1] with independent ''increments.'' More precisely, we prove convergence of finite joint correlations for sample sums of q-independent, q-identically distributed random variables indexed by pairs of positive real numbers (r,s). In particular, we take the sums of quantum variables of $U_q(su(2))$ and for that case we find a realization of the limit in terms of creation and annihilation operators satisfying certain q-commutation relations, which gives rise to a new example of non-additive quantum noise, defined on a non-separable Hilbert space. However, it should be pointed out that in this paper we do not prove the functional limit theorem (or Donsker's invariance principle[2]), but only its simplest case for sample sums and thus it can be viewed only as the central limit theorem or a quantum random walk for certain quantum q-variables, in particular those of the ''generic'' $U_q(su(2))$.

Processes with independent and stationary increments are usually called white noise. They are used to model a quantum-mechanical heat bath. It is known that functional limit theorems are the source of both classical and quantum noises. The first quantum version of the functional central limit theorem was shown by Cockroft, Gudder and Hudson,[3] who proved in 1977 a quantum mechanical analog of the functional central limit theorem and obtained a canonical Wiener process[4] in the limit. Later, the stochastic calculi for the CCR and CAR algebras were developed by Hudson and Parthasarathy[5] and Applebaum and Hudson,[6] respectively. Connected with the concept of free independence of Voiculescu[7] was the free white noise studied by Speicher[8] with the stochastic calculus developed in Ref. 9.

The framework for the general theory of quantum white noise on graded $*$-bialgebras was proposed by Accardi, Schürmann and von Waldenfels.[10] In their approach, a white noise on a $*$-bialgebra $\mathscr{B}$ is a family $(j_{rs})_{0 \leqslant r \leqslant t}$ of quantum random variables on $\mathscr{B}$, i.e., homomorphisms from $\mathscr{B}$ into a $*$-algebra $\mathscr{A}$ with a state $\hat{\phi}$ with the following properties:
(WN0) increment property: $j_{rs} * j_{st} = j_{rt}$ for $0 \leqslant r < s < t$, and $j_{rr} = \delta 1$, where δ is the co-unit and $*$ is the convolution product;
(WN1) independence, i.e., for time-ordered products the following factorization holds:

$$\hat{\phi}(j_{r_1 s_1}(b_1) \ldots j_{r_n s_n}(b_n)) = \hat{\phi}(j_{r_1 s_1}(b_1)) \ldots \hat{\phi}(j_{r_n s_n}(b_n))$$

for all $n \in \mathbf{N}$, $0 \leqslant r_1 < s_1 < \ldots < r_n < s_n$, where $b_1, \ldots, b_n \in \mathscr{B}$, and

$$j_{rs}(b) j_{r's'}(b') = j_{r's'}(b') j_{rs}(b)$$

0022-2488/96/37(5)/2260/19/$10.00

for all disjoint semi-closed time-intervals $[r,s),[r',s')$ and any $b,b' \in \mathscr{B}$;
(WN2) stationarity, i.e., $\hat{\phi} \circ j_{rs} = \hat{\phi} \circ j_{0,s-r}$ for $r<s$;
(WN3) continuity, i.e., $\lim_{r \downarrow 0} \hat{\phi} \circ j_{0,r}(b) = \delta(b)$ for all $b \in \mathscr{B}$, where δ is the co-unit.

Generalized white noises were studied by many authors.[11–18] Also, certain deformed (or, q-) white noises were considered. For instance, two examples of q-white noises were considered by Schürmann,[17,18] where q is a deformation parameter. Namely, it was shown that the normalized sample sums converge to the two-dimensional Azema noise and to an interpolation of the two-dimensional quantum Brownian motion in the case of q-right- and q-left bialgebras, respectively.

Another approach to construct q-deformed white noises was proposed by Bożejko and Speicher.[11,12] They define certain deformed creation and annihilation operators living in a generalized Fock space $\Gamma_q(\mathscr{H})$, where $\mathscr{H}=L^2(\mathbf{R})$, subject to deformed commutation relations. In the simplest case[11] they read

$$c(f)c^*(g)-qc^*(g)c(f)=\langle f,g\rangle 1$$

where $f,g \in \mathscr{H}$ and $c(f),c^*(f)$ stand for the annihilation and creation operators, respectively. Then they show that one can define a deformed scalar product on $\Gamma_q(\mathscr{H})$ which makes them mutually adjoint. This approach essentially boils down to some non-trivial positivity proofs that ensure the existence of a scalar product on a subspace of the full Fock space.

In Refs. 19 and 20 it was shown that functional limit theorems for quantum Bernoulli processes lead to the Boson and Fermion Brownian motions. Viewing quantum two-level systems as fundamental in our understanding of quantum central limit theorems (qclt), we studied first[21] the central limit in the discrete case for the q-analog of $su(2)$, namely $U_q(su(2))$, the q-deformed enveloping algebra of $su(2)$, and obtained the q-oscillator in the limit, corresponding to the q-Gaussian distribution. The result produced a commutative diagram, in which the qclt of $U_q(su(2))$ gives the q-oscillator, in addition to the qclt of Ref. 19, where the qclt of $su(2)$ gives the harmonic oscillator. Thus, in search for interesting examples of quantum noises, we study in this work the quantum random walk for $U_q(su(2))$, which we view as a fundamental structure in the q-deformed symmetries.

In our approach we obtain a quantum noise from the central limit theorem for sums of random-walk type. The object we start with is a unital $*$-algebra $\mathscr{C}_q$ over $\mathbf{C}$ generated (as a $*$-algebra) by the set $\mathscr{V}_+ \cup \{t,t^{-1}\}$, where t,t^{-1} are hermitian, subject to $t^\sigma t^{-\sigma}=1$ and $t^\sigma w = \epsilon(t^\sigma,w)wt^\sigma$, where $w \in \mathscr{V}=\mathscr{V}_+ \cup \mathscr{V}_-$, $\mathscr{V}_-=\mathscr{V}_+^*$ and $\epsilon(t^\sigma,v)=q^{-2\sigma}$, $\epsilon(t^\sigma,v^*)=q^{2\sigma}$, for $q \in \mathbf{R}^+$, $v \in \mathscr{V}_+$. We equip $\mathscr{C}_q$ with the bialgebra structure and refer to it as a q-$*$-bialgebra. Later, in Sec. VI, by adding

$$[v^*,v]=\frac{t^2-t^{-2}}{q^2-q^{-2}}$$

we consider the Hopf algebra $U_q(su(2))$, which leads to the simplest quantum noise covered by our theory.

Our approach is different from the one presented in Refs. 17 and 18 due to the fact that our collective variables are in fact not only q-independent, but also q-identically distributed. This is achieved by assuming that $\phi(t) \neq 1$, where t can be viewed as a twisted identity. This assumption is justified by the fact that $\phi(t) \neq 1$ if ϕ is the vacuum state of the representations of $U_q(su(2))$, and has its origins in Ref. 21, where we took ϕ to be the vacuum state of its fundamental representation (see also Refs. 22–24). Therefore, the qclt on coalgebras[17,18] cannot be applied here.

As we mentioned earlier, the results of Secs. II–V can be applied to q-$*$-bialgebras. However, for simplicity, in the outline of the results given below we restrict our attention to the case of

$U_q(su(2))$. Thus we consider sums of q-independent, q-identically distributed variables indexed by semi-closed time intervals, i.e., for a state ϕ on $\mathscr{C}_q$ with $\phi(t)=q$, and $w \in \mathscr{V}$ we put

$$S_{rs}^N(w)=\sqrt{\frac{q_{rs}}{N_{rs}}}\Delta_{rs}^N(w)$$

where

$$\Delta_{rs}^N(w)=\sum_{i=N_r+1}^{N_s} j_i^{N_rN_s}(w)$$

and $j_i^{N_rN_s}:\mathscr{C}_q\to\mathscr{C}_q^{\otimes\infty}$ are given by

$$j_i^{N_rN_s}(w)=1^{\otimes N_r}\otimes(t^{-1})^{\otimes(i-N_r-1)}\otimes w\otimes t^{\otimes(N_s-i)}\otimes 1^{\otimes\infty},$$

where $N_{rs}=[N_s-N_r]$, $q_{rs}=[s-r]$ and $[x]=(q^{2x}-q^{-2x})/(q^2-q^{-2})$ is the q-analog of x. In other words, $S_{rs}^N(w)$ are normalized collective variables associated with w. Note that the normalization is different from $1/\sqrt{N}$, appearing in both the classical probability and the quantum central limit theorems considered by other authors. However, in the case of Hopf algebras $U_q(g)$ deformed normalization has to be used when the vacuum state is considered. Note that q_{rs}/N_{rs} is the q-analog of $(s-r)/(N_s-N_r)$, the latter being $1/\sqrt{N}$, and in the limit, when q approaches 1, it coincides with it.

Further, we can define normalized ''increments''

$$S_{rs}^N(t^\sigma)=q^{\sigma(N_r-N_s)}\Delta_{rs}^N(t^\sigma)=q^{\sigma(N_r-N_s)}(1^{N_r}\otimes(t^\sigma)^{\otimes(N_s-N_r)}\otimes 1^{\otimes\infty})$$

where $\sigma\in\{1,-1\}$. It can be shown that in the case of $U_q(su(2))$, for all $r<s$ and $N\in\mathbf{N}$, Δ_{rs}^N are Hopf algebra homomorphisms and, viewed as functions of r and s, satisfy (WN1–WN4). However, the normalized ''increments'' fail to do so. It is due to the fact that the normalization comes from a type of group contraction which loses the Hopf algebra structure.

The central limit theorem, understood in our paper in the sense of convergence of correlations, can be written as

$$\lim_{N\to\infty}\hat{\phi}(S_{r_1s_1}^N(v_1)\ldots S_{r_ns_n}^N(v_n))=\Psi(B_{r_1s_1}(v_1)\ldots B_{r_ns_n}(v_n))$$

where $v_1,\ldots,v_n\in\{v,v^*,t,t^{-1}\}$ and $\hat{\phi}=\phi^{\otimes\infty}$. The correlations of the limiting functional Ψ can be expressed solely in terms of q_{rs}, the variance of the limiting process B_{rs}. We show that the following conditions are satisfied by the limiting correlations for $a<1$ (the case of $a>1$ is similar):

(QN0) q_{rs} is a continuous deformation of the Brownian variance, i.e.,

$$\lim_{q\to 1} q_{rs}=s-r;$$

(QN1) independence, i.e.,

$$\Psi(B_{r_1s_1}(c_1)\ldots B_{r_ns_n}(c_n))=\Psi\left(\prod_{i\in I_1}B_{r_is_i}(v_i)\right)\times\ldots\times\Psi\left(\prod_{i\in I_n}B_{r_is_i}(v_i)\right)$$

where $s_1=\ldots=s_{j_1}<\ldots<s_{j_{n-1}+1}=\ldots=s_{j_n}=s_p$ defines the partition $\{I_1,\ldots,I_n\}$ of $\{1,\ldots,p\}$ into subsets corresponding to equal upper end-points of the time intervals, with commutations for disjoint time intervals $[r,s),[r',s')$:

$$B_{rs}(w)B_{r's'}(w')=B_{r's'}(w')B_{rs}(w)$$

for $w,w' \in \mathscr{V}$, and q-commutations for non-disjoint intervals with $s'>s$:

$$B_{rs}(w)B_{r's'}(w')=q^{2d(w')}B_{r's'}(w')B_{rs}(w);$$

(QN2) stationarity, i.e., q_{rs} depends only on $s-r$,
(QN3) continuity, i.e. $\lim_{s\downarrow r}q_{rs}=0$.

In addition, our example of quantum noise satisfies the following commutation relations for (non-disjoint) time intervals with equal upper end points:
(QN4) for any $r<s$, $r'<s$ the operators $B_{rs}(v)$, $B_{r's}(v^*)$ satisfy the following relations

$$[B_{rs}(v^*),B_{r's}(v)]=\sqrt{q_{rs}q_{r's}}q^{2\hat{N}_{(r,s)}+2\hat{N}_{(r',s)}+4\hat{N}_s}$$

where $\hat{N}_{(rs)}$, $\hat{N}_s$ are the number operators that count the numbers of creation operators with the upper end-points falling into (r,s) and $\{s\}$, respectively.

This gives a new example of non-additive quantum noise, in which lengths of time intervals enter in a multiplicative fashion and the scalar product governs the behavior at the upper end-points.

In Sec. II we give basic definitions and an outline of the combinatorics involved. In Sec. III we state the qclt on q-bialgebras for fixed time-interval. In Sec. IV we derive two important lemmas, the Factorization Lemma, and the Clustering Lemma, which provide the rules for calculating arbitrary limiting correlations. Using those lemmas, in Sec. V, we state and prove the general version of the functional qclt on q-bialgebras. Finally, in Sec. VI, we give the GNS construction for the limiting functional in the case of $U_q(su(2))$. Thus, we define creation and annihilation operators acting on some generalized Fock space $\Gamma_q(\mathscr{H})$, where $\mathscr{H}=\mathscr{H}_0\otimes\mathscr{H}_1$, $\mathscr{H}_0$ comes from the GNS triple $(\mathscr{H}_0,\pi,\omega)$ for the vacuum state ϕ for the two-dimensional representation of $\mathscr{C}_q$, and the time-domain Hilbert space is $\mathscr{H}_1=l^2[0,\infty)$. Note that this example of noise is given on a non-separable Hilbert space.

II. PRELIMINARIES

Let us start with an outline of the combinatorics used in the sequel. By an *ordered partition* S of an index set I we understand an r-tuple $S=(S_1,\ldots,S_r)$, where $S_1\cup\ldots\cup S_r=I$ and $S_1,\ldots,S_r$ are mutually disjoint. The set of such partitions for fixed r will be denoted by $\mathscr{P}_r^{ord}(I)$, or $\mathscr{P}_r^{ord}\{1,\ldots,p\}$ for $I=\{1,\ldots,p\}$. In turn, $\mathscr{P}_r(I)$ will stand for the set of all (non-ordered) partitions of I consisting of r sets, i.e., $\{S_1,\ldots,S_r\}$. Thus, for each partition $S \in \mathscr{P}_r$, there exist $r!$ ordered partitions naturally associated with it. By the *signature* γ_S of an ordered partition S we understand the r-tuple

$$(\gamma_{S_1},\ldots,\gamma_{S_r})=(\#(S_1),\ldots,\#(S_r))$$

where $\#(S_j)$ denotes the number of elements in S_j. Partitions for which $\#(S_j)$ is even for all $j=1,\ldots,r$ are called *even* and the set of all ordered even partitions of $\{1,\ldots,p\}$ will be denoted by $\mathscr{P}_e^{ord}\{1,\ldots,p\}$. Further, for given $v_1,\ldots,v_p \in \mathscr{V}_+\cup\mathscr{V}_-$ and an ordered partition S of $\{1,\ldots,p\}$ associated with it, let

$$S_j^+=\{k\in S_j|v_k\in\mathscr{V}_+\},\quad S_j^-=\{k\in S_j|v_k\in\mathscr{V}_-\},$$

and, $\gamma_{S_j^+}=\#(S_j^+)$, $\gamma_{S_j^-}=\#(S_j^-)$. We also put

$$|\gamma_{S^+}|=\sum_{j=1}^{r}\gamma_{S_j^+}, \quad |\gamma_{S^-}|=\sum_{j=1}^{r}\gamma_{S_j^-}.$$

By the set of inversions of an ordered partition S we will understand the set

$$W_S=\{(i,j)|i\in S_k, j\in S_n, i<j, k>n\}.$$

Also, for a given ordered partition $S=(S_1,\ldots,S_r)$ let ${}^rS=(S_r,\ldots,S_1)$, i.e., with sets taken in the reverse order.

Let now I be a partition of $\{1,\ldots,p\}$ into r disjoint subsets $S_1,\ldots,S_r$. By an *ordered subpartition of* $\{1,\ldots,p\}$ *associated with* I we shall understand any set of ordered partitions of $\{I_1,\ldots,I_r\}$, i.e., any set of the form:

$$\mathbf{I}=\{(I_1^1,\ldots,I_1^{i_1}),\ldots,(I_r^1,\ldots,I_r^{i_r})\}$$

where $(I_k^1,\ldots,I_k^{i_k})$ is an ordered partition of I_k. In turn, such a partition will be called *even* if all its ordered partitions are even. For instance, let $\{1,\ldots,8\}$ be the index set and let $I=\{I_1,I_2\}$, where $I_1=\{1,2,4,5\}$, $I_2=\{3,6,7,8\}$. Then $\{(\{1,2\},\{4,5\}),(\{3,6\},\{7,8\})\}$ is an ordered subpartition of $\{1,\ldots,8\}$ associated with I, and is different from $\{(\{1,2\},\{4,5\}),(\{7,8\},\{3,6\})\}$. Note that the number of subpartitions associated with I is equal to the product of the numbers of ordered partitions of $I_1,\ldots,I_k$, respectively. The set of ordered subpartitions (even ordered subpartitions) of the index set $\{1,\ldots,p\}$ associated with I will be denoted by $\mathscr{P}^I\{1,\ldots,p\}$ ($\mathscr{P}_e^I\{1,\ldots,p\}$).

Since all results except the GNS construction given in Sec. V remain valid for $\mathscr{C}_q$ being a bialgebra, we start with a more general setting than the specific example of q-noise given in Sec. VI. Thus assume $\mathscr{C}$ to be a free $*$-algebra over $\mathbf{C}$ generated (as a $*$-algebra) by the set $\mathscr{V}_+$ and let $\mathscr{V}=\mathscr{V}_+\cup\mathscr{V}_-$, where $\mathscr{V}_-=\{v^*|v\in\mathscr{V}_+\}$. On $\mathscr{C}$ we define a $\mathbf{Z}$-gradation by $d(v)=1$, $d(v^*)=-1$, $d(\mathscr{C})=0$. The corresponding direct sum decomposition will be denoted by

$$\mathscr{C}=\ldots\oplus\mathscr{C}_{(-1)}\oplus\mathscr{C}_{(0)}\oplus\mathscr{C}_{(1)}\oplus\ldots.$$

We also define an $\mathbf{N}$-gradation by $d_1(v)=1$, $v\in\mathscr{V}$, $d_1(\mathbf{C})=0$, extended to all free products in the only possible way. We denote the direct sum decomposition resulting from this $\mathbf{N}$-gradation with superscripts:

$$\mathscr{C}=\mathscr{C}^{(0)}\oplus\mathscr{C}^{(1)}\oplus\ldots.$$

The algebra $\mathscr{C}$ can be twisted by adding hermitian generators t^σ, $\sigma\in\{1,-1\}$ subject to $t^\sigma t^{-\sigma}=1$ and $t^\sigma w=\epsilon(t^\sigma,w)wt^\sigma$, where $w\in\mathscr{V}$ and $\epsilon(t^\sigma,v)=q^{2\sigma}$, $\epsilon(t^\sigma,v^*)=q^{-2\sigma}$, where $q\in\mathbf{R}^+$, $v\in\mathscr{V}_+$. For details, see Ref. 24. The twisted $*$-algebra thus obtained will be denoted by $\mathscr{C}_q$. Both gradations are extended to $\mathscr{C}_q$ in the trivial way, i.e., $d(t^\sigma)=0$, $d_1(t^\sigma)=0$.

We consider the following coproduct on $\mathscr{C}_q$:

$$\Delta:\mathscr{C}_q\to\mathscr{C}_q\otimes\mathscr{C}_q$$

as the homomorphic extension of

$$\Delta(1)=1\otimes1, \quad \Delta(t^\sigma)=t^\sigma\otimes t^\sigma, \quad \Delta(v)=t^{-1}\otimes v+v\otimes t$$

where $v\in\mathscr{V}$. Further, let δ be the counit defined by $\delta(1)=\delta(t)=\delta(t^{-1})=1$, $\delta(v)=0$, $v\in\mathscr{V}$.

III. CENTRAL LIMIT THEOREM FOR FIXED INTERVAL

In this section we first introduce the increments Δ_{rs}^N. Then we calculate the variance $\hat{\phi}(\Delta_{rs}^N(v^*)\Delta_{rs}^N(v))$ for $v \in \mathscr{V}_+$ in order to find a suitable normalization. Then we define the normalized increments S_{rs}^N and state the qclt for fixed $r \leqslant s$.

Let $\mathscr{C}_q^{\otimes\infty}$ be the infinite tensor product of the $*$-algebra $\mathscr{C}_q$. Let ϕ be a state on $\mathscr{C}_q$ such that $\phi(t^\sigma)=a^\sigma$. We define injections $j_i^{N_rN_s}:\mathscr{C}_q \to \mathscr{C}_q^{\otimes\infty}$ by

$$j_i^{N_rN_s}(w)=1^{\otimes N_r}\otimes(t^{-1})^{\otimes(i-N_r-1)}\otimes w\otimes t^{\otimes(N_s-i)}\otimes 1^{\otimes\infty}.$$

Further, let

$$\Delta_{rs}^N(w)=\sum_{i=N_r+1}^{N_s} j_i^{N_rN_s}(w)$$

and $\Delta_{rr}^N(w)=0$ for $w \in \mathscr{V}$ and

$$\Delta_{rs}^N(t^\sigma)=1^{N_r}\otimes(t^\sigma)^{\otimes(N_s-N_r)}\otimes 1^{\otimes\infty}.$$

Note that if $r=0$, $s=1$, then $N_r=0$, $N_s=N$, and the projection of Δ_{rs}^N onto $\mathscr{C}_q^{\otimes N}$ becomes the $N-1$-th iteration of the coproduct. In the case of $U_q(su(2))$ it can be seen that Δ_{rs}^N is a Hopf algebra homomorphism for any pair $r<s$ and $N \in \mathbf{N}$.

We also assume that $\phi \in \mathscr{C}_q^*$ is *left and right* $\mathbf{C}[t,t^{-1}]=\mathscr{C}_q^{(0)}$*- independent*, i.e.,

$$\phi(acb)=\phi(a)\phi(c)\phi(b)$$

for any $a,b \in \mathscr{C}^{(0)}$. It should be noted that the Cauchy–Schwartz inequality implies that if ϕ is a state and a homomorphism on $\mathscr{C}_q^{(0)}$, then it is $\mathscr{C}_q^{(0)}$-independent. Also, we shall assume that ϕ is *even*, i.e., vanishes outside of $(\mathscr{C}_q)_{(0)}$. In particular, this implies that the first moments of $w \in \mathscr{V}$ vanish.

Proposition 3.1. *Let* $v \in \mathscr{V}_+$ *and let* ϕ *be an even functional and let* $\phi(t^\sigma)=a^\sigma \in \mathbf{R}^+-\{1\}$. *Then*

$$\hat{\phi}(\Delta_{rs}^N(v^*)\Delta_{rs}^N(v))=N_{rs}\phi(v^*v)$$

where $N_{rs}=[N_s-N_r]$ *and* $[x]=(a^{2x}-a^{-2x})/(a^2-a^{-2})$.

Proof. Since ϕ is even, we obtain

$$\begin{aligned}
\hat{\phi}(\Delta_{rs}^N(v^*)\Delta_{rs}^N(v)) &= \hat{\phi}\left(\sum_{i=N_r+1}^{N_s} j_i^{N_rN_s}(v^*)j_i^{N_rN_s}(v)\right)\\
&= \hat{\phi}\left(\sum_{i=N_r+1}^{N_s} 1^{\otimes N_r}\otimes(t^{-2})^{\otimes(i-N_r-1)}\otimes v^*v\otimes(t^2)^{\otimes(N_s-i)}\otimes 1^{\otimes\infty}\right)\\
&= \phi(v^*v)\sum_{i=N_r+1}^{N_s} a^{-2(i-N_r-1)+2(N_s-i)}\\
&= \phi(v^*v)a^{2N_s+2N_r+2}\sum_{i=N_r+1}^{N_s} a^{-4i}\\
&= \phi(v^*v)\frac{a^{2N_s-2N_r}-a^{-2N_s+2N_r}}{a^2-a^{-2}}=\phi(v^*v)N_{rs}. \qquad \square
\end{aligned}$$

Besides, it is clear that

$$\hat{\phi}(\Delta_{rs}^N(t^\sigma)\Delta_{rs}^N(t^\sigma))=a^{2\sigma(N_s-N_r)}.$$

This allows us to take normalized increments of the form

$$S_{rs}^N(w)=\sqrt{\frac{a_{rs}}{N_{rs}}}\Delta_{rs}^N(w)$$

for $w\in\mathscr{V}$, where $a_{rs}=[s-r]$. Then the normalization constants $\sqrt{a_{rs}/N_{rs}}=\sqrt{[s-r]/[N_s-N_r]}$ are the analogs of $\sqrt{(s-r)/(N_s-N_r)}$. Later, when considering the quantum noise obtained from $U_q(su(2))$, we will put $a=q$, which appears in the commutation factor, obtaining the simplest example of a one-parameter q-noise. Then q_{rs} will stand for the variance of that q-noise. Clearly, we also have

$$S_{rs}^N(t^\sigma)=a^{\sigma(N_r-N_s)}\Delta_{rs}^N(t^\sigma).$$

Moreover, we put $S_{rs}^N(c_1c_2)=S_{rs}^N(c_1)S_{rs}^N(c_2)$. It can be shown that with the canonical product on $\mathscr{C}^{\otimes\infty}$, the increments Δ_{rs}^N, viewed as functions of r,s, satisfy (WN1–WN4). However, it is not the case for the normalized non-additive increments.

Let us now define a two-parameter functional $\Psi_{a,q}\equiv\Psi$ on the free algebra with unity generated by $\mathscr{V}$, obtained in the qclt studied in Refs. 20–22. Let $v_1,\ldots,v_p\in\mathscr{V}$. For an ordered partition $S=(S_1,\ldots,S_r)$ of $I=\{1,\ldots,p\}$ we denote by

$$v_{S_j}=\prod_{i\in S_j} v_i$$

where the product is taken in the ascending order of indices. Then, let

$$\Psi(v_1\ldots v_p)=\sum_{r=1}^{p}\sum_{S=(S_1,\ldots,S_r)\in\mathscr{P}_e^{ord}(I)} Q(S)D(S|a)\prod_{j=1}^{r}\phi(v_{S_j})$$

where

$$D(S|a)=D_{k,r}(\gamma_{S_1},\ldots,\gamma_{S_r}|a)=\frac{(a^{-4}-1)^{p/2}}{(a^{-2\gamma_{S_1}}-1)(a^{-2\gamma_{S_1}-2\gamma_{S_2}}-1)\ldots(a^{-2\gamma_{S_1}-\cdots-2\gamma_{S_r}}-1)}$$

for $0<a<1$, and $D(S|a)=D({}^rS|a^{-1})$ for $1<a<\infty$. Here, $Q(S)$ denotes the combinatorial q-dependent commutation factor:

$$Q(S)=\prod_{(i,j)\in W_S}\epsilon(v_i,v_j)$$

where $\epsilon(v_i,v_j)=\epsilon(t,v_i)\epsilon(t,v_j)$. In particular, when $a=q$ we obtain the limit functional considered in Ref. 21, to which we will restrict our attention when constructing the q-noise.

For fixed $r\leqslant s$, the following q-analog of the qclt is merely the theorem proved in Ref. 23, restated in the new context.

Theorem 3.2. *Let $v_1,\ldots,v_p\in\mathscr{V}$. Let $\phi\in\mathscr{C}_q^*$ be an even functional that is left and right $\mathscr{C}_q^{(0)}$-independent with $\phi(t)=a\in\mathbf{R}^+-\{1\}$. Then, if $p=2k$,*

$$\lim_{N\to\infty}\hat{\phi}(S_{rs}^N(v_1)\ldots S_{rs}^N(v_p))=\Psi(B_{rs}(v_1)\ldots B_{rs}(v_p))$$

where $\Psi(B_{rs}(v_1)\ldots B_{rs}(v_p))\equiv a_{rs}^k\Psi(v_1\ldots v_p)$. *If p is odd, then the above limit vanishes.*

In the sequel we will generalize this theorem to correlations indexed by arbitrary (in general, different) time intervals.

IV. CLUSTERING AND FACTORIZATION LEMMAS

Two main features of the limiting functional we are going to obtain are factorization and ''clustering.'' Factorization of the correlations for disjoint time-intervals taken in the increasing order may be considered as standard and it can be easily proven to hold also in our case. However, we will show that for $a<1$ $(a>1)$ the limiting correlations also factorize if the upper (lower) end-points of time intervals are different. On the other hand, increments that have the same upper (lower) end points cluster together for $a<1$ $(a>1)$, thus giving rise to the property we call clustering. This allows us to express the limiting correlations as linear combinations of products of clustered correlations. It can also be noticed that the case $a>1$ is analogous to the case $a<1$ and therefore we will provide proofs only for the former and merely state the corresponding results for the latter. In the sequel the symbol $\times$ will always denote multiplication of numbers and is used for notational clarity.

Lemma 4.1 (Clustering Lemma). *Let* $v_1,\ldots,v_p\in\mathscr{V}$. *Suppose that* $\phi\in\mathscr{C}_q^*$ *is left and right* $\mathscr{C}_q^{(0)}$*- independent and even. Let* $\phi(t)=a<1$. *If* $s_1=s_2=\ldots=s_p$ *and* $r_i\leqslant s_i$, *then*

$$\lim_{N\to\infty}\hat{\phi}(S^N_{r_1s_1}(v_1)\ldots S^N_{r_ps_p}(v_p))=\Psi(B_{r_1s_1}(v_1)\ldots B_{r_ps_p}(v_p))$$

where $\Psi(B_{r_1s}(v_1)\ldots B_{r_ps}(v_p))\equiv\sqrt{\Pi_{i=1}^p a_{r_is}}\Psi(v_1\ldots v_p)$. *In particular, when p is odd, then the above limit vanishes.*

Proof. We prove only the non-trivial case, when $r_i<s_i$ for all $i=1,\ldots,p$. First we consider the special case of ordered lower end-points, which we choose to prove by induction with respect to the number of blocks for which the lower end-points of time intervals coincide. A sketch of the proof of the general case will be given below.

Thus, let n be the number of blocks with different lower end-points and let $I_1,\ldots,I_n$ be the index sets associated with those blocks. We put

$$v_{I_i}=\prod_{j\in I_i}v_j.$$

First we will calculate the limit of

$$\hat{\phi}(S^N_{r_1s_1}(v_{I_1})\ldots S^N_{r_ns_n}(v_{I_n}))$$

with $s_1=s_2=\ldots=s_p>r_1>r_2>\ldots>r_p$, i.e., in the case of ordered lower end-points. The case $n=1$ follows from Theorem 3.1. Suppose the statement holds for $n=k$. For notational convenience we put $r_{k+1}=r$, $s_{k+1}=s$, $r_k=t$. We also put $I_{k+1}=I$. Then we have

$$S^N_{rs}(v_j)=\alpha_{rts}S^N_{rt}(v_j)\Delta^N_{ts}(t)+\beta_{rts}\Delta^N_{rt}(t^{-1})S^N_{ts}(v_j)$$

for any $j\in I$, where $\alpha_{rts}=\sqrt{(a_{rs}N_{rt})/(a_{rt}N_{rs})}$ and $\beta_{rts}=\sqrt{(a_{rs}N_{ts})/(a_{ts}N_{rs})}$. Now,

$$\begin{aligned}M_N&\equiv\hat{\phi}(S^N_{r_1s_1}(v_{I_1})\ldots S^N_{r_ks_k}(v_{I_k})S^N_{rs}(v_I))\\&=\sum_{\{J,K\}\in\mathscr{P}(I)}c_{JK}\alpha_{rts}^{|J|}\beta_{rts}^{|K|}\hat{\phi}(S^N_{r_1s_1}(v_{I_1})\ldots S^N_{r_ks_k}(v_{I_k})S^N_{rt}(v_K)\Delta_{rt}(t^{|J|}))\\&\quad\times\hat{\phi}(\Delta_{ts}(t^{-|K|})S^N_{ts}(v_J))\end{aligned}$$

where $|J|$, $|K|$ denote cardinalities of the sets J and K, respectively, and c_{JK} are constants obtained from commutations. Using left and right $\mathscr{C}^{(0)}$-independence of ϕ, we obtain

$$M_N=\sum_{\{J,K\}\in\mathscr{P}(I)} c_{JK}\alpha_{rts}^{|J|}\beta_{rts}^{|K|}a^{(N_s-N_t)|J|-(N_t-N_r)|K|} \times\hat{\phi}(S^N_{r_1s_1}(v_{I_1})\ldots S^N_{r_ks_k}(v_{I_k})S^N_{rt}(v_K))\hat{\phi}(S^N_{ts}(v_J)).$$

The N-dependent parts of the coefficients are of the form:

$$\left(\frac{N_{rt}}{N_{rs}}\right)^{|J|/2}\left(\frac{N_{ts}}{N_{rs}}\right)^{|K|/2}a^{(N_s-N_t)|J|-(N_t-N_r)|K|}$$

and, if $0<a<1$, behave for large N as

$$\frac{a^{(N_r-N_t)|J|+(N_t-N_s)|K|}}{a^{(N_r-N_s)(|J|+|K|)}}a^{(N_s-N_t)|J|-(N_t-N_r)|K|}=a^{2(N_s-N_t)|J|}\to 0$$

unless $|J|=0$. Notice that for $J=\emptyset$ we have $c_{JK}=1$ and the above expression is equal to 1. Collecting the N-independent part of the coefficients α_{rts}, β_{rts} and using the induction hypothesis we obtain

$$\begin{aligned}\lim_{N\to\infty}M_N&=\left(\frac{a_{rs}}{a_{ts}}\right)^{|I|/2}\lim_{N\to\infty}\hat{\phi}(S^N_{r_1s_1}(v_{I_1})\ldots S^N_{r_ks_k}(v_{I_k})S^N_{r_ks_k}(v_{I_{k+1}}))\\&=\left(\frac{a_{rs}}{a_{ts}}\right)^{|I|/2}a_{ts}^{|I|/2}\left(\prod_{i=1}^{k}a_{r_is_i}^{|I_i|/2}\right)\Psi(v_1\ldots v_p)\\&=\left(\prod_{i=1}^{k+1}a_{r_is_i}^{|I_i|/2}\right)\Psi(v_1\ldots v_p)\end{aligned}$$

which finishes the proof in the case of ordered lower end-points. The general case is proved along the same lines. Namely, we put $R=\max\{r_1,\ldots,r_p\}$ and we decompose each $S_{r_is}(v_i)$ for all $r_i<R$ as above, i.e.:

$$S^N_{r_is}(v_i)=\alpha_{r_iRs}S^N_{r_iR}(v_i)\Delta^N_{Rs}(t)+\beta_{r_iRs}\Delta^N_{r_iR}(t^{-1})S^N_{Rs}(v_i).$$

Then the proof boils down to showing that any non-zero power of α_{r_iRs} makes the term disappear in the limit. The argument is similar to the one presented above. Namely, each α_{r_iRs} produces the N-dependent factor of the form $a^{2(N_s-N_R)}$, which goes to zero as $N\to\infty$. Thus, the only surviving terms are those involving $S^N_{Rs}(v_i)$ only. This finishes the proof. □

Lemma 4.2 (Factorization Lemma). *Let $v_1,\ldots,v_p\in\mathscr{V}$. Suppose that $\phi\in\mathscr{C}_q^*$ is left and right $\mathscr{C}_q^{(0)}$ -independent and even. Let $\phi(t)=a<1$. If $s_1\leqslant s_2\leqslant\ldots\leqslant s_p$, then*

$$\lim_{N\to\infty}\hat{\phi}(S^N_{r_1s_1}(v_1)\ldots S^N_{r_ps_p}(v_p))=\Psi\left(\prod_{i\in I_1}B_{r_is_i}(v_i)\right)\times\ldots\times\Psi\left(\prod_{i\in I_n}B_{r_is_i}(v_i)\right)$$

where $s_1=\ldots=s_{j_1}<\ldots<s_{j_{n-1}+1}=\ldots=s_{j_n}=s_p$ defines the partition $\{I_1,\ldots,I_n\}$ of $\{1,\ldots,p\}$ into subsets corresponding to equal upper end-points of the time intervals. In particular, if any of $v_{I_1},\ldots,v_{I_n}$, where $v_{I_i}=\prod_{i\in I_i}v_i$, is odd with respect to either of the gradations, then the limit vanishes.

Proof. The case $n=1$ is just the statement of the Clustering Lemma. Assume now that this lemma holds for $n=k$ blocks. Add block $I_{k+1}=I$ and let $I'=\{i \in I | r_i<s_k\}$, i.e., the subset of those indices i in I, for which time intervals $[r_i,s_i)$ are non-disjoint from all intervals associated with I_k. For any v_i, $i \in I'$, we use the decomposition familiar from the proof of the Clustering Lemma:

$$S^N_{r_i s}(v_i)=\alpha_{r_i ts}S^N_{r_i t}(v_i)\Delta^N_{ts}(t)+\beta_{r_i ts}\Delta^N_{r_i t}(t^{-1})S^N_{ts}(v_i)$$

where we denoted $s_i=s$ for any $i \in I'$. Then, supposing that the last block consists of l elements, we obtain

$$\begin{aligned}
M_N &\equiv \hat{\phi}(S^N_{r_1 s_1}(v_1)\ldots S^N_{r_p s_p}(v_p)S^N_{r_{p+1},s}(v_{p+1})\ldots S^N_{r_{p+l},s}(v_{p+l}))\\
&= \sum_{\{J,K\}\in\mathscr{P}(I')} c_{JK}\left(\prod_{j\in J}\alpha_{r_j ts}\right)\left(\prod_{k\in K}\beta_{r_k ts}\right)\\
&\quad\times\hat{\phi}\left(S^N_{r_1 s_1}(v_1)\ldots S^N_{r_p s_p}(v_p)\prod_{j\in J}S^N_{r_j t}(v_j)\prod_{k\in K}\Delta_{r_k t}(t^{-1})\right)\hat{\phi}\left(\Delta_{ts}(t^{|J|})\prod_{k\in K}S^N_{ts}(v_k)\right)\\
&= \sum_{\{J,K\}\in\mathscr{P}(I')} c_{JK}\left(\prod_{j\in J}\alpha_{r_j ts}\right)\left(\prod_{k\in K}\beta_{r_k ts}\right)\left(\prod_{k\in K}a^{-(N_t-N_{r_k})}\right)a^{(N_s-N_t)|J|}\\
&\quad\times\hat{\phi}\left(S^N_{r_1 s_1}(v_1)\ldots S^N_{r_p s_p}(v_p)\prod_{j\in J}S^N_{r_j t}(v_j)\right)\hat{\phi}\left(\prod_{k\in K}S^N_{ts}(v_k)\right)
\end{aligned}$$

where c_{JK} are constants resulting from commutations. As in the proof of the Clustering Lemma, consider the N-dependent part of each numerical coefficient appearing in the sum. It is of the following form:

$$a^{(N_s-N_t)|J|}\left(\prod_{j\in J}\left(\frac{N_{r_j t}}{N_{r_j s}}\right)^{1/2}\right)\left(\prod_{k\in K}\left(\frac{N_{ts}}{N_{r_k s}}\right)^{1/2}a^{N_{r_k}-N_t}\right)$$

which, for $0<a<1$ and large N, behaves like

$$\prod_{j\in J}\left(\frac{a^{N_{r_j}-N_t}}{a^{N_{r_j}-N_s}}a^{N_s-N_t}\right)\prod_{j\in J}\left(\frac{a^{N_t-N_s}}{a^{N_{r_k}-N_s}}a^{N_{r_k}-N_t}\right)=\prod_{j\in J}a^{2(N_s-N_t)}=a^{2|J|(N_s-N_t)}$$

and thus tends to zero when N tends to infinity unless $|J|=0$, when it goes to one. Thus the only term that survives in the limit is the one corresponding to $|J|=0$. Hence,

$$\lim_{N\to\infty}M_N=\prod_{i\in I'}\left(\frac{a_{r_i s}}{a_{ts}}\right)\lim_{N\to\infty}\hat{\phi}(S^N_{r_1 s_1}(v_1)\ldots S^N_{r_p s_p}(v_p))\lim_{N\to\infty}\hat{\phi}(S^N_{R_1,s}(v_{p+1})\ldots S^N_{R_l,s}(v_{p+l}))$$

where $R_i=\max\{r_{p+i},s_p\}$, $i=1,\ldots,l$. But the last expression is equal to

$$\left(\prod_{i=1}^{p+l}a^{1/2}_{r_i s_i}\right)\Psi(v_{I_1})\ldots\Psi(v_{I_k})\Psi(v_I)=\Psi\left(\prod_{i\in I_1}B_{r_i s_i}(v_i)\right)\times\ldots\times\Psi\left(\prod_{i\in I_{k+1}}B_{r_i s_i}(v_i)\right).$$

□

Thus, the Factorization Lemma says that correlations factorize when they have different upper end-points.

The situation for $a>1$ is similar. We obtain the following.

Lemma 4.1.* *Let $v_1,\ldots,v_p \in \mathscr{V}$. Suppose that $\phi \in \mathscr{C}_q^*$ is left and right $\mathscr{C}_q^{(0)}$- independent and even. Let $\phi(t)=a>1$. If $r_1=r_2=\ldots=r_p$ and $r_i \leqslant s_i$, then*

$$\lim_{N\to\infty} \hat{\phi}(S^N_{r_1s_1}(v_1)\ldots S^N_{r_ps_p}(v_p))=\Psi(\widetilde{B}_{r_1s_1}(v_1)\ldots\widetilde{B}_{r_ps_p}(v_p))$$

where $\Psi(\widetilde{B}_{r_1s_1}(v_1)\ldots\widetilde{B}_{r_ps_p}(v_p))=\sqrt{\prod_{i=1}^p a_{r_is_i}}\Psi(v_1\ldots v_p)$. In particular, when p is odd, then the above limit vanishes.

Lemma 4.2.* Let $v_1,\ldots,v_p \in \mathscr{V}$. Suppose that $\phi \in \mathscr{C}_q^*$ is left and right $\mathscr{C}_q^{(0)}$ -independent and even. Let $\phi(t)=a>1$. If $r_1 \geqslant r_2 \geqslant \ldots \geqslant r_p$, then

$$\lim_{N\to\infty} \hat{\phi}(S^N_{r_1s_1}(v_1)\ldots S^N_{r_ps_p}(v_p))=\Psi\left(\prod_{i\in I_1}\widetilde{B}_{r_is_i}(v_i)\right)\times\ldots\times\Psi\left(\prod_{i\in I_n}\widetilde{B}_{r_is_i}(v_i)\right)$$

where $r_1=\ldots=r_{j_1}>\ldots>r_{j_{n-1}+1}=\ldots=r_{j_n}=r_p$ defines the partition $\{I_1,\ldots,I_n\}$ of $\{1,\ldots,p\}$ into subsets associated with equal lower end-points of the time intervals. In particular, if any of $v_{I_1},\ldots,v_{I_n}$, where $v_{I_i}=\Pi_{i\in I_i}v_i$, is odd with respect to either of the gradations, then the limit vanishes.

It should be remembered that the dependence of Ψ on q and a is suppressed in the formulas given above.

V. CENTRAL LIMIT THEOREM FOR SAMPLE SUMS

We are ready to state the qclt for sample sums, of which Theorem 3.2 as well as the Clustering and Factorization Lemmas are special cases. In fact, the general case looks similar to the Factorization Lemma, except that we don't assume any ordering of the end-points, the only restriction being $r_i \leqslant s_i$ for all $i=1,\ldots,p$. Without loss of generality we assume that $r_i<s_i$, since if $r_i=s_i$ for any i, then the limit trivially vanishes.

For a given set of time intervals $T=\{[r_i,s_i)|i=1,\ldots,p\}$ let $\{I_1,\ldots,I_n\}$ be the partition of $\{1,\ldots,p\}$ into subsets for which upper (lower) end-points are equal for $a<1(a>1)$. Let us concentrate on the case $a<1$. Thus, for any $j,k \in I_i$ we have $s_j=s_k$ and for any $j \in I_i$, $k \in I_m$, $i \neq m$, we have $s_j \neq s_k$. Further, fix the order on $\{I_1\ldots,I_n\}$ according to increasing upper end-points, i.e., if $j \in I_i, k \in I_m$, then $s_j<s_k$.

We are going to express the limiting correlations

$$\lim_{N\to\infty} \hat{\phi}(S^N_{r_1s_1}(v_1)\ldots S^N_{r_ps_p}(v_p))=\begin{cases}\Psi(B_{r_1s_1}(v_1)\ldots B_{r_ps_p}(v_p)) & \text{if} \quad a<1,\\ \Psi(\widetilde{B}_{r_1s_1}(v_1)\ldots\widetilde{B}_{r_ps_p}(v_p)) & \text{if} \quad a>1\end{cases}$$

in terms of the products appearing in Lemmas 4.2., 4.2.*, except for certain commutation factors.

We concentrate on the case of $a<1$. To bring the above correlation into the product form we need to commute certain operators. That is why we associate with the set T the set of inversions of the upper end-points of time intervals, i.e.,

$$I_T=\{(s_i,s_j)|i<j, s_i>s_j, [r_i,s_i)\cap[r_j,s_j)\neq\emptyset\}.$$

Clearly, if $[r_i,s_i)\cap[r_j,s_j)=\emptyset$, then the variables commute, therefore there is no need to consider such inversions. On the other hand, each inversion $(s_i,s_j) \in I_T$ contributes a non-trivial commutation factor. Further, for given $v_1\ldots,v_p \in \mathscr{V}$, let

$$I_{T^+}=\{(s_i,s_j)\in I_T|v_j\in V_+\}, \quad I_{T^-}=\{(s_i,s_j)\in I_T|v_j\in V_-\}.$$

Our aim now is to determine the commutation factors resulting from the commutations that need to be performed in order to bring the products into their ordered forms as in the Factorization Lemma. It is also perhaps interesting to note that no simple commutation relations can be derived for $S^N_{rs}(w)$'s for non-disjoint (but not equal) time intervals. However, in the limit the (weak) commutation relations are much simpler.

Proposition 5.1. *Let* $w,w' \in \mathscr{V}$. *If* $[r,s)\cap[r',s')=\emptyset$, *then* $B_{rs}(w)$ *and* $B_{r's'}(w')$ *commute. If* $[r,s)\cap[r',s') \neq \emptyset$, $s>s'$, *then*

$$B_{rs}(w)B_{r's'}(w')=q^{2d(w')}B_{r's'}(w')B_{rs}(w).$$

Proof. Consider two cases: Case A: $r\geqslant r'$, and Case B: $r<r'$.

Case A. Let

$$S^N_{rs}(w)=\alpha_{rs's}S^N_{rs'}(w)\Delta^N_{s's}(t)+\beta_{rs's}\Delta^N_{rs'}(t^{-1})S^N_{s's}(w).$$

We showed in the proofs of the Lemmas that each $a^{N_s-N_{s'}}\alpha_{rs's}$ goes to zero when $N\to\infty$, hence only the second summand gives a non-zero contribution to the limit. Hence, when commuting $S^N_{rs}(w)$ through $S^N_{r's'}(w)$, we only need to commute $\Delta^N_{rs'}(t^{-1})S^N_{s's}(w)$ through $S^N_{r's'}(w')$. Using

$$[S^N_{s's}(w),S^N_{r's'}(w')]=0$$

and

$$[\Delta^N_{rs'}(t^{-1}),S^N_{r's'}(w')]=\epsilon(t^{-1},w')=q^{2d(w')},$$

we obtain the result.

Case B. Let $r_1>r_2$. We decompose both $S^N_{rs}(w)$ and $S^N_{r's'}(w')$, the first one in the same manner as in Case A, and the second one as

$$S^N_{r's'}(w')=\alpha_{r'rs'}S^N_{r'r}(w')\Delta^N_{rs'}(t)+\beta_{r'rs'}\Delta^N_{r'r}(t^{-1})S^N_{rs'}(w').$$

In the (weak) limit only the second terms survive in both decompositions. Hence, the commutation factor obtained in the limit comes from commuting $\Delta^N_{rs'}(t^{-1})S^N_{s's}(w)$ through $\Delta^N_{r'r}(t^{-1})S^N_{rs'}(w')$, thus it is equal to the commutator

$$[\Delta^N_{rs'}(t^{-1}),S^N_{rs'}(w')]=\epsilon(t^{-1},w').$$

This finishes the proof. □

Theorem 5.2. *Let* $v_1,\ldots,v_p \in \mathscr{V}$. *Let* $\phi \in \mathscr{C}_q^*$ *be left and right* $\mathscr{C}^{(0)}$*-independent and even and let* $q \in \mathbf{R}^+$. *Further, if* $\phi(t)=a<1$, *suppose that* $r_j\leqslant s_j$, $j=1,\ldots,p$, *and denote by* $\{I_1,\ldots,I_n\}$ *the partition of* $\{1,\ldots,p\}$ *into subsets corresponding to equal upper end-points of the time intervals. Then*

$$\lim_{N\to\infty}\hat{\phi}(S^N_{r_1,s_1}(v_1)\ldots S^N_{r_p,s_p}(v_p))=Q_T\Psi\left(\prod_{i\in I_1}B_{r_is_i}(v_i)\right)\times\ldots\times\Psi\left(\prod_{i\in I_n}B_{r_is_i}(v_i)\right)$$

where

$$Q_T=q^{2|I_{T^+}|-2|I_{T^-}|}$$

denotes the commutation factor resulting from commuting variables associated with time intervals with different upper end-points.

Proof. Immediate from the Factorization Lemma, Proposition 5.1 and the relations: $\epsilon(t^{-1},v)=q^2$, $\epsilon(t^{-1},v^*)=q^{-2}$, for $v \in \mathscr{V}_+$.

Thus, we can characterize our limiting process using the following notion of independence:
(F) the factorization principle:

$$\Psi(B_{r_1s_1}(v_1)\ldots B_{r_ps_p}(v_p))=\Psi\left(\prod_{i\in I_1} B_{r_is_i}(v_i)\right)\times\ldots\times\Psi\left(\prod_{i\in I_n} B_{r_is_i}(v_i)\right)$$

where $I_1,\ldots,I_n$ are as in Theorem 5.2;
(C) commutations for disjoint intervals:

$$B_{rs}(w)B_{r's'}(w')=B_{r's'}(w')B_{rs}(w);$$

(qC) q-commutations for non-disjoint intervals with $s'>s$:

$$B_{rs}(w)B_{r's'}(w')=q^{2d(w')}B_{r's'}(w')B_{rs}(w).$$

Thus, (F) together with (C) and (qC) give (QN1), which can be viewed as the definition of independence.

The following Corollary gives the limiting correlations in a more explicit form.

Corollary 5.3. *Under the assumptions of Theorem 5.2 we obtain*

$$\Psi(B_{r_1s_1}(v_1)\ldots B_{r_ps_p}(v_p))=\sum_{\mathbf{I}\in\mathscr{P}_e^I\{1,\ldots,p\}} Q(\mathbf{I})D(\mathbf{I})\prod_{i=1}^{n}\prod_{j=1}^{r_i}\phi(v_{S_j^i})$$

where

$$Q(\mathbf{I})=Q(I_1)\ldots Q(I_n)Q_T,\quad D(\mathbf{I})=D(I_1|a)\ldots D(I_n|a)$$

and I is the partition $\{I_1,\ldots,I_n\}$ and the summation runs over all even ordered subpartitions **I** *associated with I.*

Note that for a given ordered subpartition **I** associated with the partition I, the commutation factor $Q(\mathbf{I})$ is the product of commutation factors associated with ordered partitions of $I_1,\ldots,I_n$, respectively, resulting from the commutations with t,t^{-1} within blocks that have the same upper (lower) end-points, and Q_T resulting from the commutations bringing the product into the ordered form.

The case $a>1$ is completely analogous. As a result we obtain the analogs of Proposition 5.1, Theorem 5.2 and Corollary 5.2 with

$$\widetilde{Q}_T=q^{2|I_{T^-}|-2|I_{T^+}|}$$

and $\widetilde{D}(\mathbf{I})=D({}^rI_1|a^{-1})\ldots D({}^rI_n|a^{-1})$. They lead to
(F*) the factorization principle:

$$\Psi(\widetilde{B}_{r_1s_1}(v_1)\ldots\widetilde{B}_{r_ps_p}(v_p))=\Psi\left(\prod_{i\in I_1}\widetilde{B}_{r_is_i}(v_i)\right)\times\ldots\times\Psi\left(\prod_{i\in I_n}\widetilde{B}_{r_is_i}(v_i)\right)$$

where $I_1,\ldots,I_n$ denotes the partition of $\{1,\ldots,p\}$ into subsets corresponding to equal lower end-points of the time intervals,
(C*) commutations for disjoint intervals;

$$B\tilde{}_{rs}(w)\tilde{B}_{r's'}(w')=\tilde{B}_{r's'}(w')\tilde{B}_{rs}(w);$$

(qC^*) q-commutations for non-disjoint intervals with $r<r'$:

$$B\tilde{}_{rs}(w)\tilde{B}_{r's'}(w')=q^{-2d(w')}\tilde{B}_{r's'}(w')\tilde{B}_{rs}(w).$$

The results obtained thus far can be easily generalized to include $S^N_{rs}(t)$, $S^N_{rs}(t^{-1})$, but the limits obtained then can be expressed in terms of correlations without t,t^{-1}, as in Theorem 5.2, except that a different commutation factor replaces Q_T.

VI. AN EXAMPLE OF QUANTUM NOISE

In this section we apply our results to $\mathscr{C}_q=U_q(su(2))$, for which we give the realization of the limiting quantum stochastic processes $B_{rs}(v)$, $B_{rs}(v^*)$ ($\tilde{B}_{rs}(v)$, $\tilde{B}_{rs}(v^*)$) as creation and annihilation operators, respectively, living in a Hilbert space of Fock type. More specifically, they will be defined on a subspace of the full Fock space

$$\Gamma_f(\mathscr{H})=\bigoplus_{n\geq 0}\mathscr{H}^{\otimes n}$$

where $\mathscr{H}^{\otimes 0}=\mathbf{C}$, $\mathscr{H}=\mathscr{H}_0\otimes\mathscr{H}_1$, where $\mathscr{H}_0=\mathbf{C}^2$ and $\mathscr{H}_1=l^2[0,\infty)$. Let ω be the vacuum vector of the two-dimensional representation π of $U_q(su(2))$ and ϕ the corresponding vacuum state. Thus, we have $\phi(v^*v)=1$, $\phi(vv)=\phi(v^*v^*)=\phi(vv^*)=0$. Further, let $\phi(t)=q$, $\phi(t^{-1})=q^{-1}$.

In $\mathscr{H}_1$ we distinguish functions

$$\delta_p(x)=\begin{cases}1 & \text{if } x=p\\ 0 & \text{otherwise}\end{cases},$$

and the scalar product on $\mathscr{H}_0$ is given by $\langle\delta_p,\delta_r\rangle=\delta_{pr}$. Now, let D be the linear span of vectors

$$f_1\otimes\ldots\otimes f_p \quad \text{and} \quad \Omega=1,$$

where $f_i=\pi(v)\omega\otimes\delta_{s_i}$ and $s_1\leq s_2\leq\ldots\leq s_p$. For a given $f=\pi(v)\omega\otimes\delta_s$ we will refer to s as the support of f. The ordering of supports defines the partition $\{I_1,\ldots,I_n\}$ of $\{1,\ldots,p\}$ and we can write

$$f_1\otimes\ldots\otimes f_p=\bigotimes_{j=1}^{n}F_j$$

where $F_j=\bigotimes_{i\in I_j}f_i$. Moreover, we introduce the following notation

$$F_{s)}=\bigotimes_{s_j<s}f_j,\quad F_s=\bigotimes_{s_j=s}f_j,\quad F_{(s}=\bigotimes_{s_j>s}f_j.$$

Thus, we can also write

$$f_1\otimes\ldots\otimes f_p=F_{s)}\otimes F_s\otimes F_{(s}$$

for any $s\in\{s_1,\ldots,s_p\}$.

We also introduce the number operator

$$\hat{N}_s(f_1\otimes\ldots\otimes f_p)=N_s(f_1\otimes\ldots\otimes f_p)$$

where $N_s=\#\{s_i|s_i=s\}$. Thus, it counts functions with support s. Similarly we define other number operators, such as $\hat{N}_{(r,s)}$, $\hat{N}_{s)}$, $\hat{N}_{s]}$, with eigenvalues $N_{(r,s)}=\#\{s_i|s_i\in(r,s)\}$, $N_{s)}=\#\{s_i|s_i<s\}$, $N_{s]}=\#\{s_i|s_i\leqslant s\}$, respectively. In other words, those operators count functions whose time support falls into appropriate intervals. We will also need number operators that give us information on the supports of functions with indices smaller than or equal to k. Thus, we define $\hat{N}_s^k$ and $\hat{N}_{(r,s)}^k$ with eigenvalues $N_s^k=\#\{s_i|s_i=s,i\leqslant k\}$ and $N_{(r,s)}^k=\#\{s_i|s_i\in(r,s),i\leqslant k\}$, respectively.

We first define creation operators $B_{rs}(v)$ and annihilation operators $B_{rs}(v^*)$ (by abuse of notation we use the same notation as in the weak case) on the subspace D_s of D spanned by the vacuum vector and tensor products of functions with support equal to s. Thus, let

$$B_{rs}(v)\Omega=\sqrt{q_{rs}}\,f,$$

$$B_{rs}(v)(f_1\otimes\ldots\otimes f_p)=\sqrt{q_{rs}}\,f\otimes f_1\otimes\ldots\otimes f_p$$

be the creation operators, where $f=\pi(v)\omega\otimes\delta_s$, and let

$$B_{rs}(v^*)\Omega=0,$$

$$B_{rs}(v^*)(f_1\otimes\ldots\otimes f_p)=\sqrt{q_{rs}}\sum_{k=1}^{p}q^{4(p-k)}f_1\otimes\ldots f_{k-1}\otimes f_{k+1}\otimes\ldots\otimes f_p$$

be the annihilation operators. In fact, we could write the action of $B_{rs}(v)$, $B_{rs}(v^*)$ on vectors of the form $f^{\otimes p}$, but we choose the above definition, which is open for generalizations and bears resemblance to the one-particle case of the Fock space considered in Ref. 11 (note that here $\langle f,f\rangle=1$).

Proposition 6.1. *On the subspace D_s of D spanned by the vacuum vector and tensor products of functions with support s, the following commutation relations hold:*

$$[B_{rs}(v^*),B_{r's}(v)]=\sqrt{q_{rs}q_{r's}}q^{4\hat{N}_s}.$$

Proof.

$$\begin{aligned}
&[B_{rs}(v^*),B_{r's}(v)]\,f_1\otimes\ldots\otimes f_p\\
&\quad=\sqrt{q_{rs}q_{r's}}\left(\sum_{k=1}^{p}q^{4(p-k)}f\otimes f_1\otimes\ldots\otimes f_{k-1}\otimes f_{k+1}\otimes\ldots\otimes f_p+q^{4p}f_1\otimes\ldots\otimes f_p\right)\\
&\qquad-\sqrt{q_{rs}q_{r's}}\sum_{k=1}^{p}q^{4(p-k)}f\otimes f_1\otimes\ldots\otimes f_{k-1}\otimes f_{k+1}\otimes\ldots\otimes f_p\\
&\quad=\sqrt{q_{rs}q_{r's}}q^{4p}f_1\otimes\ldots\otimes f_p.
\end{aligned}$$

□

We are now ready to consider the general case and define $B_{rs}(v)$ and $B_{rs}(v^*)$ on all of D. Of course, the action on the vacuum is the same as above. For other vectors with ordered support we define the creation operator as follows:

$$B_{rs}(v)(f_1\otimes\ldots\otimes f_p)=q^{2N_{(r,s)}F_{s)}}\otimes(B_{rs}(v)F_s)\otimes F_{(s}=\sqrt{q_{rs}}q^{2N_{(r,s)}F_{s)}},\otimes f\otimes F_s\otimes F_{(s}.$$

Thus we can say that the operator $B_{rs}(v)$ creates function $f=\pi(v)\omega\otimes\delta_s$ at the beginning of the block with the same time support s. If such a block does not exist in the string of functions, it

creates such a block at the right place. When passing through blocks with support smaller than s, it produces q^2 whenever that support falls into the interval (r,s); otherwise, it does not produce any non-trivial commutation factor.

In turn, the annihilation operators will be defined by

$$B_{rs}(v^*)(f_1\otimes\ldots\otimes f_p)=q^{2N_{(r,s)}}F_{s)}\otimes(B_{rs}(v^*)F_s)\otimes F_{(s}$$
$$=\sqrt{q_{rs}}q^{2N_{(r,s)}}\sum_{k=N_{s)}+1}^{N_{s]}}q^{4(N_s-N_s^k)}F_{s)}\otimes\Big(\bigotimes_{s_j=s,j\neq k}f_j\Big)\otimes F_{(s}.$$

If in the tensor product $f_1\otimes\ldots\otimes f_p$ there are no functions with support equal to s, then we put

$$B_{rs}(v^*)f_1\otimes\ldots\otimes f_p=0.$$

The action of the annihilation operators can of course be written using the scalar product on $\mathscr{H}_0$ and extending the summation over all indices and not only those corresponding to functions with support equal to s, but we choose the above definition for the sake of simplicity. Thus, in other words, the annihilation operator produces the same commutation factors when passing through functions with smaller support and then acts on the block with the same support as the annihilation operator defined previously. Clearly, the previous definitions are special cases of those just given.

Proposition 6.2. *Let $s>s'$ and $w,w'\in\mathscr{V}$. If $[r,s)\cap[r',s')=\varnothing$, then $B_{rs}(w)$ and $B_{r's'}(w')$ commute. If $[r,s)\cap[r',s')\neq\emptyset$, then*

$$B_{rs}(w)B_{r's'}(w')=q^{2d(w')}B_{r's'}(w')B_{rs}(w).$$

Proof. For $s>s'$ we have

$$B_{rs}(w)B_{r's'}(w')(f_1\otimes\ldots\otimes f_p)=B_{rs}(w)(q^{2N_{(r',s')}}F_{s')}\otimes(B_{r's'}(w')F_{s'})\otimes F_{(s')}$$
$$=q^{2N_{(r',s')}+2N_{(r,s)}+2d(w')}F_{s')}\otimes(B_{r's'}(w')F_{s'})$$
$$\otimes\Big(\bigotimes_{s'<r<s}F_r\Big)\otimes(B_{rs}(w)F_s)\otimes F_{(s}.$$

On the other hand,

$$B_{r's'}(w')B_{rs}(w)(f_1\otimes\ldots\otimes f_p)=B_{r's'}(w')(q^{2N_{(r,s)}}F_{s)}\otimes(B_{rs}(w)F_s)\otimes F_{(s)}$$
$$=q^{2N_{(r',s')}+2N_{(r,s)}}F_{s')}\otimes(B_{r's'}(w')F_{s'})$$
$$\otimes\Big(\bigotimes_{s'<r<s}F_r\Big)\otimes(B_{rs}(w)F_s)\otimes F_{(s}$$

where it is understood that $N_{(r,s)}$ and $N_{(r',s')}$ refer to $f_1\otimes\ldots\otimes f_p$. □

Proposition 6.3. *Let $w\in\mathscr{V}$. The following relations hold*

$$N_{(r',s')}B_{rs}(w)=B_{rs}(w)(N_{(r',s')}+d(w)\chi_{(r',s')}(s)),$$

$$N_{s'}B_{rs}(w)=B_{rs}(w)(N_{s'}+d(w)\delta_{s's})$$

where $\chi_{(r',s')}$ is the characteristic function.

Proof. Straightforward.

Finally, we derive the commutation relation between $B_{r's}(v^*)$ and $B_{rs}(v)$. Thus we have

Proposition 6.4. *The following relations hold on D:*

$$[B_{r's}(v^*),B_{rs}(v)]=\sqrt{q_{r's}q_{rs}}q^{2\hat{N}_{(r,s)}+2\hat{N}_{(r',s)}+4\hat{N}_s}$$

Proof. Using Proposition 6.1, we obtain

$$\begin{aligned}[B_{r's}(v^*),B_{rs}(v)](\ f_1\otimes\ldots\otimes f_p)&=q^{2N_{(r,s)}+2N_{(r',s)}}(F_s)\otimes([B_{r's}(v^*),B_{rs}(v)]F_s)\otimes F_{(s}\\&=q^{2N_{(r,s)}+2N_{(r',s)}}(F_s)\otimes(q^{4\hat{N}_s}F_s)\otimes F_{(s}\\&=\sqrt{q_{r's}q_{rs}}q^{2N_{(r,s)}+2N_{(r',s)}+4N_s}(F_s)\otimes F_s\otimes F_{(s}\\&=\sqrt{q_{r's}q_{rs}}q^{2N_{(r,s)}+2N_{(r',s)}+4N_s}(\ f_1\otimes\ldots\otimes f_p),\end{aligned}$$

which ends the proof. □

Let us define a scalar product on D. Thus, writing the vectors in the block form, we put

$$\langle\Omega,\Omega\rangle_q=1,\quad \langle\Omega,F_1\otimes\ldots\otimes F_n\rangle_q=0$$

and

$$\langle F_1\otimes\ldots\otimes F_n,G_1\otimes\ldots\otimes G_m\rangle_q=\delta_{nm}\prod_{i=1}^{n}\langle F_i,G_i\rangle_q$$

where, for blocks F,G with support s,s', respectively,

$$\langle F,G\rangle_q=\langle f_1\otimes\ldots\otimes f_p,g_1\otimes\ldots\otimes g_r\rangle_q=\delta_{ss'}\delta_{rp}[[p]]!$$

where $[[p]]=(1-q^{4p})/(1-q^4)$. Let us denote the completion of D with respect to $\langle .,.\rangle_q$ by $\Gamma_q(\mathscr{H})$.

We can now state the representation theorem.

Theorem 6.5. *Let $v_1,\ldots,v_p\in\mathscr{V}$, $\phi\in\mathscr{C}_q^*$ be the vacuum state of the two-dimensional fundamental representation of $U_q(su(2))$ and let $\phi(t)=q<1$. Then, for any $r_i\leqslant s_i$, $i=1,\ldots,p$,*

$$\Psi(B_{r_1s_1}(v_1)\ldots B_{r_ps_p}(v_p))=\langle\Omega,B_{r_1s_1}(v_1)\ldots B_{r_ps_p}(v_p)\Omega\rangle_q.$$

Moreover, $B_{rs}(v)$ and $B_{rs}(v^*)$ are adjoint with respect to $\langle .,.\rangle_q$.

Proof. The commutations and q-commutations for $B_{rs}(v)$ and $B_{rs}(v^*)$ (Proposition 6.2) agree with the weak ones derived in Proposition 5.1. The factorization (F) also holds and follows directly from the definition of the action of $B_{rs}(v)$, $B_{rs}(v^*)$. In turn, relations given by Proposition 6.1 were in the weak sense derived in Ref. 21 for $\Psi(B_{01}(v_1)\ldots B_{01}(v_p))$ and that implies that they hold for $\Psi(B_{r_1s}(v_1)\ldots B_{r_ps}(v_p))$ by the Clustering Lemma. Finally, adjointness follows from the definition of the scalar product. This finishes the proof. □

The case $q>1$ is analogous and we just state the results. Thus, we introduce $\widetilde{D}$ spanned by Ω and tensor products of functions from $\mathscr{H}$ with supports ordered in the decreasing order. On $\widetilde{D}$ we define the creation operators

$$\widetilde{B}_{rs}(v)(\ f_1\otimes\ldots\otimes f_p)=q^{-2N_{(r,s)}}F_{s)}\otimes(\widetilde{B}_{rs}(v)F_s)\otimes F_{(s},$$

and the annihilation operators

$$\widetilde{B}_{rs}(v^*)(\ f_1\otimes\ldots\otimes f_p)=q^{-2N_{(r,s)}}F_{s)}\otimes(\widetilde{B}_{rs}(v^*)F_s)\otimes F_{(s}$$

where, on D_r we have

$$\widetilde{B}_{rs}(v)(\ f_1\otimes\ldots\otimes f_p)=\sqrt{q_{rs}}\ f\otimes f_1\otimes\ldots\otimes f_p$$

and

$$\widetilde{B}_{rs}(v^*)(\ f_1\otimes\ldots\otimes f_p)=\sqrt{q_{rs}}\sum_{k=1}^{p}\ q^{-4(p-k)}f_1\otimes\ldots f_{k-1}\otimes f_{k+1}\otimes\ldots\otimes f_p,$$

with the usual action on the vacuum. Similar commutation relations can be established as for $B_{rs}(v)$, $B_{rs}(v^*)$.

Proposition 6.6. *Let $w,w'\in\mathscr{V}$. Then, if $r<r'$ and $[r,s)\cap[r',s')\neq\emptyset$, then*

$$\widetilde{B}_{rs}(w)\widetilde{B}_{r's'}(w')=q^{-2d(w')}\widetilde{B}_{r's'}(w')\widetilde{B}_{rs}(w).$$

For disjoint intervals, the operators commute. In turn,

$$N_{(r',s')}\widetilde{B}_{rs}(w)=\widetilde{B}_{rs}(w)(N_{(r',s')}+d(w)\chi_{(r',s')}(s)),$$

$$N_{s'}\widetilde{B}_{rs}(w)=\widetilde{B}_{rs}(w)(N_{s'}+d(w)\delta_{s's}).$$

Finally,

$$[\widetilde{B}_{r's}(v^*),\widetilde{B}_{rs}(v)]=\sqrt{q_{r's}q_{rs}}q^{-2\hat{N}_{(r,s)}-2\hat{N}_{(r',s')}-4\hat{N}_s}.$$

Thus, it can be seen that all relations can be obtained from the previous ones by replacing q by q^{-1}.

One can also take the limit $q\to1$. However, it is interesting to note that even then we don't obtain the Brownian motion, which is illustrated by the example below. Let $B_{0s}=B_s$. Then, if $s_1=\ldots=s_4=s$, we obtain

$$\Psi(B_{s_1}(v_1)\ldots B_{s_4}(v_4))=s^2(\phi(v_1v_2)\phi(v_1v_3)+\phi(v_1v_3)\phi(v_2v_4)+\phi(v_1v_4)\phi(v_2v_3)).$$

In turn, when there are two different endpoints, for instance

$$s_{i_1}=s_{i_2}=s\neq s'=s_{i_3}=s_{i_4}$$

then we obtain

$$\Psi(B_{s_1}(v_1)\ldots B_{s_4}(v_4))=ss'\phi(v_{i_1}v_{i_2})\phi(v_{i_3}v_{i_4}).$$

This fact shows the non-interchangeability of limits in q and N. Clearly, when we take first $q\to1$ and then $N\to\infty$, we obtain the quantum Brownian motion. In turn, when we take first $N\to\infty$ and then $q\to1$, then we obtain a different noise process.

It should be possible to generalize the approach presented in this paper to other quantum groups by using the more general kind of limit theorem proved in Ref. 23.

ACKNOWLEDGMENTS

(Received 26 September 1995; accepted for publication 16 November 1995)

The asymptotic behavior of multichannel parallel relaxation processes for systems with dynamical disorder is investigated in the limit of a very large number of channels. An individual channel is characterized by a state vector **x** which, due to dynamical disorder, is a random function of time. A limit of the thermodynamic type in the **x**-space is introduced for which both the volume available and the average number of channels tend to infinity, but the average volume density of channels remains constant. Scaling arguments combined with a stochastic renormalization group approach lead to the identification of two different types of universal behavior of the relaxation function corresponding to nonintermittent and intermittent fluctuations, respectively. For nonintermittent fluctuations a dynamical generalization of the static Huber's relaxation equation is derived which depends only on the average functional density of channels, $\rho[W(t')]D[W(t')]$, the channels being classified according to their different relaxation rates $W=W(t')$, which are random functions of time. For intermittent fluctuations a more complicated relaxation equation is derived which, in addition to the average density of channels, $\rho[W(t')]D[W(t')]$, depends also on a positive fractal exponent H which characterizes the fluctuations of the density of channels. The general theory is applied for constructing dynamical analogs of the stretched exponential relaxation function. For nonintermittent fluctuations the type of relaxation is determined by the regression dynamics of the fluctuations of the relaxation rate. If the regression process is fast and described by an exponential attenuation function, then after an initial stretched exponential behavior the relaxation process slows down and it is not fully completed even in the limit of very large times. For self-similar regression obeying a negative power law, the relaxation process is less sensitive to the influence of dynamical disorder. Both for small and large times the relaxation process is described by stretched exponentials with the same fractal exponent as for systems with static disorder. For large times the efficiency of the relaxation process is also slowed down by fluctuations. Similar patterns are found for intermittent fluctuations with the difference that for very large times and a slow regression process a crossover from a stretched exponential to a self-similar algebraic relaxation function occurs. Some implications of the results for the study of relaxation processes in

I. INTRODUCTION

In the last two decades an enormous amount of experimental evidence has been accumulated showing that the decay of the average survival (relaxation) function $\langle l(t)\rangle$ in many diverse systems in condensed matter physics and in molecular biology follows the same stretched exponential law of the Kohlrausch–Williams–Watts (KWW) type

$$\langle l(t)\rangle = \exp[-(\Omega t)^{\beta}], \quad 1>\beta>0, \tag{1.1}$$

where β is a positive fractal exponent between zero and unity and Ω is a characteristic frequency. Equation (1.1) was first proposed by Kohlrausch[1] in 1864 to describe the mechanical creep and was later used by Williams and Watts[2] to describe the dielectric relaxation in polymers and by Weibull[3] for describing the failure data in reliability theory. More recently the KWW law has been used to fit the data on remanent magnetization in spin glasses,[4] the decay of luminiscence in porous glasses,[5] the relaxation processes in viscoelasticity[6] on the reaction kinetics of biopolimers,[7] and on the dynamics of recombination kinetics in radiochemistry.[8] Further applications include the description of the statistical distributions of open and closed times of ion channels in molecular biophysics[9] or even the description of the survival functions of cancer patients.[10]

The ubiquity of the stretched exponential law (1.1) has led to the idea that there should be a kind of universal mechanism generating it which is independent of the details of an individual process. An argument in favor of this opinion is the close connection between the KWW law (1.1) and the stable probability densities of the Lévy type[1,11] which emerge as a result of the occurrence of a large number of independent random events described by individual probability densities with infinite moments. Many attempts of searching for such a universal mechanism for the occurrence of the stretched exponential have been presented in the literature. A first attempt is a generalization of a mechanism of parallel relaxation initially suggested by Förster for the extinction of luminescence[12] and improved by other authors.[13] A second model assumes a complex serial relaxation on a multilevel abstract structure which emphasizes the role of hierarchically constrained dynamics.[14] A third model is a generalization of the defect-diffusion model of Shlesinger and Montroll.[15] All three of these models have been carefully examined by Klafter and Shlesinger;[16] they have shown that in spite of the different details of the three models a universal common feature exists which is the existence of a broad spectrum of relaxation rates described by a scale-invariant distribution. A complementary approach of the universal features of the stretched exponential which is mathematically oriented is based on the powerful technique of fractional calculus and its connections with the theory of Fox functions.[17]

An interesting approach has been suggested by Huber;[18] based on a careful examination of the models used for the description of the extinction of luminescence he has derived a general relaxation function

$$\langle l(t)\rangle = \exp\left\{-\int_0^{\infty}\rho(W)[1-\exp(-Wt)]dW\right\}, \tag{1.2}$$

where $\rho(W)dW$ is the number of channels involved in the relaxation process and characterized by an individual relaxation rate between W and $W+dW$. If the distribution of rates is self-similar and obeys a scaling law of the negative power law type

$$\rho(W)dW \sim \text{const}W^{-(1+\beta)}\,dW, \tag{1.3}$$

which is consistent with the general ideas of self-similarity suggested by Klafter and Shlesinger,[16] then Huber's equation (1.2) leads to the stretched exponential law (1.1). The proportionality constant in Eq. (1.3) can be easily determined in terms of the fractal exponent β and of the characteristic frequency Ω entering Eq. (1.1), resulting in

$$\rho(W)dW=[\Gamma(1-\beta)]^{-1}\beta\Omega^{\beta}W^{-(1+\beta)}\,dW, \tag{1.3$'$}$$

where $\Gamma(x)=\int_0^{\infty}t^{x-1}\exp(-t)dt,\ x>0$, is the complete gamma function. Although Huber has suggested that his equation might be generally valid for any disordered system with static disorder, the validity range of his derivation, based on the approximation of a product by an exponential, cannot be easily evaluated.

Recently two of the authors of the present paper have shown that Huber's equation (1.2) is exact for a Poissonian distribution of independent channels.[19] Moreover, it has been recently shown that Huber's equation (1.2) also holds beyond the validity range of the Poissonian distribution: it emerges as a universal scaling law for a uniform random distribution of a large number of channels characterized by nonintermittent fluctuations.[20] This result is consistent with the general idea that the Huber's equation (1.2) and the stretched exponential relaxation law (1.1) derived from it can be generated by a central limit behavior of the Lévy type which expresses the contribution of a very large number of weakly connected relaxation channels. The analysis presented in Ref. 20 also shows that Huber's equation (1.2) is not the unique universal law which emerges in the limit of a very large number of weakly coupled channels. For intermittent fluctuations of the number of channels at least one supplementary scaling law exists, which is given by

$$\langle \mathscr{C}(t)\rangle=\mathscr{J}_H\left[\int_0^{\infty}\rho(W)[1-\exp(-Wt)]dW\right], \tag{1.4}$$

where the function

$$\mathscr{J}_H(z)=H[(1+1/H)z]^{-H}\gamma(H,(1+1/H)z) \tag{1.5}$$

depends on the incomplete gamma function $\gamma(x,u)=\int_0^u t^{x-1}\exp(-t)dt$, $x>0$, $u\geqslant 0$, and H is a positive fractal exponent which characterizes the fluctuations of the number of channels. The reciprocal value of the fractal exponent, $1/H$, is a measure of the intermittency of fluctuations. In particular in the limit

$$1/H\to 0 \quad (H\to\infty), \tag{1.6}$$

the fluctuations are nonintermittent, the function $\mathscr{J}_H(z)$ becomes an exponential

$$\lim_{H\to\infty}\mathscr{J}_H(z)=\exp(-z), \tag{1.7}$$

and the scaling law (1.4) reduces to the Huber's scaling equation (1.1). The derivation of the intermittent scaling law (1.4) is based on the searching for a fixed point by means of a stochastic renormalization group approach technique.[21] Unfortunately the renormalization group technique used in Ref. 20 does not guarantee that the fixed point corresponding to Eq. (1.4) is unique, and thus other intermittent limit scaling laws corresponding to other fixed points may also exist.

By assuming that the distribution of relaxation rates is given by the scale-invariant law (1.3$'$), the intermittent generalization (1.4) of the Huber's equation leads to the relaxation law

$$\langle \mathscr{C}(t)\rangle=H(\Omega t)^{-\beta H}(1+1/H)^{-H}\gamma(H,(\Omega t)^{\beta}(1+1/H)), \tag{1.8}$$

which for small times reduces to a stretched exponential

$$\langle \mathscr{C}(t)\rangle \sim \exp[-(\Omega t)^{\beta}], \quad t \ll \Omega^{-1}, \tag{1.9}$$

and for large times it is given by a negative power law

$$\langle \mathscr{C}(t)\rangle \sim \Gamma(1+H)(\Omega t)^{-\beta H}(1+1/H)^{-H}, \quad t \gg \Omega^{-1}, \quad H = \text{finite}. \tag{1.10}$$

As the fractal exponent H increases, the intermittent nature of fluctuations becomes less and less pronounced, the stretched exponential portion of the relaxation function $\langle \mathscr{C}(t)\rangle$ given by Eq. (1.8) becomes longer and longer and the power law tail becomes shorter and shorter; eventually in the limit $H \to \infty$, corresponding to nonintermittent fluctuations, the whole relaxation function $\langle \mathscr{C}(t)\rangle$ can be represented by a stretched exponential.

All these attempts at coming up with a general derivation of the stretched exponential are based on the assumption that the disordered distribution of channels is static, i.e., that an initial fluctuation of the number of channels characterized by different relaxation rates is frozen forever; during the process of relaxation the distribution of channels remains invariant and described by the static density function $\rho(W)\, dW$. A channel initially characterized by a relaxation rate W is supposed to be characterized by the same rate W at any time in the future. Although reasonable for some problems of condensed matter physics, the validity of this assumption is questionable in molecular biology. In the case of protein–ligand interactions[7] and of ion channel kinetics[9] the distribution of relaxation channels with different rates is due to the conformational fluctuations of protein molecules which have a dynamical nature and thus the fluctuations of the numbers of channels characterized by different relaxation rates are continuously generated and destroyed by thermal agitation.

The study of rate or relaxation processes with dynamical disorder is an active field of applied statistical physics.[22–26] Although at times the possible connection between the stretched exponential relaxation and the dynamical disorder has also been considered,[27] little attention has been paid to the derivation of dynamic generalizations of the stretched exponential law which emerge in the limit of a very large number of reaction channels. The purpose of this paper is the searching for such universal scaling laws which are dynamical analogs of the general static limit laws (1.2) and (1.4). The starting point of our approach is the theory developed in Refs. 19 and 20 in which a general approach of rate processes with dynamical disorder has been suggested on the basis of the theory of random point processes.[28] In Ref. 19 in the particular case of Poissonian channels a dynamical generalization of the Huber's equation (1.2) has been suggested

$$\langle \mathscr{C}(t)\rangle = \exp\left\{ -\overline{\int\int} \rho[W(t')]D[W(t')]\left[1-\exp\left(-\int_0^t W(t')dt'\right)\right]\right\}, \tag{1.11}$$

where, due to dynamical disorder, the relaxation rate corresponding to an individual channel is a random function of time $W = W(t')$, $t \geqslant t' \geqslant 0$, $\rho[W(t')]D[W(t')]$ is an average functional density of channels characterized by different random functions $W = W(t')$, $D[W(t')]$ is a suitable integration measure over the space of functions $W(t')$, and $\overline{\int\int}$ stands for the operation of path integration. In the following we shall try to derive the dynamic analog (1.11) of Huber's law as a universal limit expression which emerges in the limit of a very large number of weakly interacting channels. We shall also try to derive a universal dynamical intermittent law which is the analog of the static scaling law (1.4):

$$\langle \mathscr{C}(t)\rangle = \mathscr{J}_H\left\{ \overline{\int\int} \rho[W(t')]D[W(t')]\left[1-\exp\left(-\int_0^t W(t')dt'\right)\right]\right\}. \tag{1.12}$$

Another objective of the article is the application of the universal laws (1.11) and (1.12) to the particular case of a self-similar dynamical distribution of channels which is the analog of the static

equation (1.3′). Carrying out this program would lead to dynamical generalizations of the stretched exponential law (1.1) and of its intermittent generalization (1.8).

The structure of the paper is as follows. In Sec. II we give a general formulation of the problem in terms of a functional generalization of the theory of random point processes. In Secs. III and IV the approach developed in Sec. II is used for the derivation of the relaxation functions (1.11) and (1.12) as universal limit laws for nonintermittent and intermittent fluctuations, respectively, valid for a very large number of weakly interacting relaxation channels. In Sec. V explicit dynamical generalizations of the stretched exponential law are derived by computing the path averages in Eqs. (1.11) and (1.12) in the particular case of a stationary self-similar dynamical distribution of relaxation channels. In Sec. VI a comparative numerical analysis of the relaxation equations for static and dynamical disorder is presented. Finally in Secs. VII and VIII some possibilities of application of our approach are analyzed and some open questions are pointed out.

II. FORMULATION OF THE PROBLEM

We consider a relaxation process in which a random (usually very large) number of relaxation modes are involved. By following the usual nomenclature in nuclear physics and molecular dynamics we shall call these modes relaxation channels. The relaxation channels are abstract entities which are characterized by different state vectors $\mathbf{x}_1(t')$, $\mathbf{x}_2(t')$,..., $t \geqslant t' \geqslant 0$, which, due to dynamical disorder, are random functions of time. The relaxation channels should not be mistaken for the actual ion channels crossing a cell membrane,[9] which are concrete objects.

The stochastic properties of the state vectors $\mathbf{x}_1(t'),..,\mathbf{x}_N(t')$ attached to the different individual relaxation channels can be described by a functional generalization of random point processes. A slightly different type of functional random point process has been suggested in Ref. 19. For describing the dynamics of the relaxation channels we introduce a set of grand canonical Janossy probability density functionals

$$Q_0, Q_N[\mathbf{x}_1(t'),\ldots,\mathbf{x}_N(t')]D[\mathbf{x}_1(t')]\cdots D[\mathbf{x}_N(t')], \tag{2.1}$$

with the normalization condition

$$Q_0+\sum_{N=1}^{\infty}\frac{1}{N!}\overline{\int\int}\cdots\overline{\int\int}Q_N[\mathbf{x}_1(t'),\ldots,\mathbf{x}_N(t')]D[\mathbf{x}_1(t')]\cdots D[\mathbf{x}_N(t')]=1. \tag{2.2}$$

Here $Q_N[\mathbf{x}_1(t'),...,\mathbf{x}_N(t')]D[\mathbf{x}_1(t')]\cdots D[\mathbf{x}_N(t')]$ is the probability that there are N relaxation channels and that these N channels are characterized by state vectors close to $\mathbf{x}_1(t'),...,\mathbf{x}_N(t')$ and $D[\mathbf{x}(t')]$ is a suitable integration measure over the space of functions $\mathbf{x}(t')$. This type of description is based on the implicit assumption that for a given realization of the process the total number N of channels is a random quantity which does not change in time. The initial number N of channels is randomly chosen and then kept constant and only the random vectors $\mathbf{x}_1(t'),...,\mathbf{x}_N(t')$ are variable in time. An alternative description of the stochastic properties of the relaxation channels is given in terms of the generating functional

$$\begin{aligned}\Lambda[f[\mathbf{x}(t')]]=Q_0+\sum_{N=1}^{\infty}\frac{1}{N!}\overline{\int\int}\cdots\overline{\int\int}Q_N[\mathbf{x}_1(t'),\ldots,\mathbf{x}_N(t')]\\ \times D[\mathbf{x}_1(t')]\cdots D[\mathbf{x}_N(t')]f[\mathbf{x}_1(t')]\cdots f[\mathbf{x}_N(t')],\end{aligned} \tag{2.3}$$

where $f[\mathbf{x}(t')]$ is a suitable test functional. The main advantage of using the generating functional $\Lambda[f[\mathbf{x}(t')]]$ is that it can be written in a form independent of the integration measure $D[\mathbf{x}(t')]$, which is generally unknown.

Considering a time interval of length t we assume that for each channel $u=1,\ldots,N$, there is a fluctuating probability of decay $p_u(t)$. This probability depends on the whole previous history of the channel, that is, $p_u(t)$ is a functional of all previous values $\mathbf{x}_u(t')$, $t\geqslant t'\geqslant 0$ of the state vector:

$$p_u(t)=p[\mathbf{x}_u(t');t]. \tag{2.4}$$

A realization of the survival (relaxation) function $\mathscr{C}(t)$, that is, the probability that the relaxation process has not occured in a time interval of length t, is simply given by the product of the complementary probabilities $1-p[\mathbf{x}_u(t');t]$ attached to all channels, which expresses the probability that none of the N channels has led to relaxation:

$$\mathscr{C}(t)=\prod_{u=1}^{N}\{1-p[\mathbf{x}_u(t');t)]\}. \tag{2.5}$$

The average relaxation function $\langle\mathscr{C}(t)\rangle$ can be computed by evaluating the average of the fluctuating function $\mathscr{C}(t)$ in terms of the grand canonical Janossy probability density functionals (2.1), which describe the random evolution of the channels:

$$\begin{aligned}\langle\mathscr{C}(t)\rangle=Q_0+\sum_{N=1}^{\infty}\frac{1}{N!}&\overline{\int\int}\cdots\overline{\int\int}\,Q_N[\mathbf{x}_1(t'),\ldots,\mathbf{x}_N(t')]D[\mathbf{x}_1(t')]\cdots D[\mathbf{x}_N(t')]\\&\times f[\mathbf{x}_1(t')]\cdots f[\mathbf{x}_N(t')]\prod_{u=1}^{N}\{1-p[\mathbf{x}_u(t');t]\}\\&=\Lambda[f[\mathbf{x}(t')]=1-p[\mathbf{x}(t');t]],\end{aligned} \tag{2.6}$$

where we have used the definition (2.3) of the generating functional $\Lambda[f[\mathbf{x}(t')]]$. It follows that the evaluation of the average relaxation function $\langle\mathscr{C}(t)\rangle$ reduces to the computation of the generating functional $\Lambda[f[\mathbf{x}(t')]]$, which describes the random couplings between the different relaxation channels, and to the computation of the probability $p[\mathbf{x}(t');t]$, which describes the individual behavior of a single channel.

For relating the generating functional, $\Lambda[f[\mathbf{x}(t')]]$, to the fluctuation dynamics of the number of channels we introduce the fluctuating functional density of channels

$$\eta[\mathbf{x}(t')]D[\mathbf{x}(t')] \quad \text{with} \quad N=\overline{\int\int}\,\eta[\mathbf{x}(t')]D[\mathbf{x}(t')], \tag{2.7}$$

characterized by a random vector near $\mathbf{x}(t')$ and the corresponding characteristic functional

$$G[K[\mathbf{x}(t')]]=\left\langle\exp\left(i\,\overline{\int\int}\,K[\mathbf{x}(t')]\,\eta[\mathbf{x}(t')]D[\mathbf{x}(t')]\right)\right\rangle, \tag{2.8}$$

where $K[\mathbf{x}(t')]$ is a suitable test functional. The fluctuations of the functional density of channels $\eta[\mathbf{x}(t')]D[\mathbf{x}(t')]$ are described in terms of the corresponding cumulants

$$\langle\langle\,\eta[\mathbf{x}_1(t')]\cdots\eta[\mathbf{x}_m(t')]\rangle\rangle, \quad m=1,2,\ldots, \tag{2.9}$$

which are assumed to exist and be finite. The characteristic functional $G[K[\mathbf{x}(t')]]$ can be expressed in terms of $\langle\langle\eta[\mathbf{x}_1(t')]\cdots\eta[\mathbf{x}_m(t')]\rangle\rangle$, $m=1,2,\ldots$, by means of the cumulant expansion

$$\ln G[K[\mathbf{x}(t')]]=\sum_{m=1}^{\infty}\frac{i^m}{m!}\overline{\int\int}\cdots\overline{\int\int}\langle\langle\eta[\mathbf{x}_1(t')]\cdots\eta[\mathbf{x}_m(t')]\rangle\rangle K[\mathbf{x}_1(t')]$$
$$\times D[\mathbf{x}_1(t')]\cdots K[\mathbf{x}_m(t')]D[\mathbf{x}_m(t')]. \tag{2.10}$$

For establishing a connection between the generating functional $\Lambda[f[\mathbf{x}(t')]]$ of the functional point process and the characteristic functional $G[K[\mathbf{x}(t')]]$ of the functional density of channels $\eta[\mathbf{x}(t')]D[\mathbf{x}(t')]$, we write a realization of the density of channels $\eta[\mathbf{x}(t')]D[\mathbf{x}(t')]$ as a sum of functional Dirac's delta symbols

$$\eta[\mathbf{x}(t')]D[\mathbf{x}(t')]=\sum_{u=1}^{N}\delta[\mathbf{x}_u(t')-\mathbf{x}(t')]D[\mathbf{x}(t')]. \tag{2.11}$$

Equation (2.11) is a functional generalization of the well-known relationship from statistical mechanics expressing the particle density fields as sums of delta functions.[29] We insert Eq. (2.11) into the definition (2.8) of the characteristic functional $G[K[\mathbf{x}(t')]]$, and compute the average in terms of the grand canonical Janossy probability density functionals (2.1). By using the definition (2.3) of the generating functional $\Lambda[f[\mathbf{x}(t')]]$ after getting rid of the functional integral in the exponent due to the filtration property of the Dirac's functional symbol and computing the resulting sum, we obtain

$$G[K[\mathbf{x}(t')]]=\Lambda[f[\mathbf{x}(t')]=\exp(iK[\mathbf{x}(t')])]. \tag{2.12}$$

It follows that the average relaxation function $\langle\mathscr{E}(t)\rangle$ can be expressed as

$$\langle\mathscr{E}(t)\rangle=G[K[\mathbf{x}(t')]=ib[\mathbf{x}(t');t]], \tag{2.13}$$

where

$$b[\mathbf{x}(t');t]=-\ln(1-p[\mathbf{x}(t');t]), \tag{2.14}$$

is the bit number[30] of the individual probability of nonrelaxation $1-p[\mathbf{x}(t');t]$ attached to an individual channel with a history characterized by the function $\mathbf{x}(t')$, $t\geqslant t'\geqslant 0$. Equation (2.13) is a dynamical generalization of a similar relationship derived in Ref. 20 for systems with static disorder by using a different method that does not make use of the theory of random point processes.

For deriving an expression for the probability of decay $p[\mathbf{x}(t');t]$ attached to an individual channel we generalize an assumption made for systems with static disorder by Huber[18] and by Vlad, Schönfisch, and Mackey.[20] We assume that a channel characterized by a state vector $\mathbf{x}$ can be either in an open state with a probability $\lambda(\mathbf{x})$ or in a closed state with a probability $1-\lambda(\mathbf{x})$. Following Ref. 20 we suppose that the state vector $\mathbf{x}$ of a channel belongs to a certain domain Σ of the state space which is simply connected and has the volume

$$V_\Sigma=\int_\Sigma d\mathbf{x}, \tag{2.15}$$

and that the probability $\lambda(\mathbf{x})$ that the channel is open is simply given by

$$\lambda(\mathbf{x})=V^*(\mathbf{x})/V_\Sigma, \tag{2.16}$$

where $V^*(\mathbf{x})$ is a characteristic volume of a neighborhood of the position $\mathbf{x}$.

We assume that an open channel characterized by a state vector $\mathbf{x}$ has a rate of relaxation $W(\mathbf{x})$ that depends only on the state vector $\mathbf{x}$. Since the state vector $\mathbf{x}$ is a random function of time, the contribution of an open state to the individual probability of survival (nonrelaxation) $1-p[\mathbf{x}(t');t]$ is given by

$$\mathcal{E}[W(\mathbf{x}(t'))]=\exp\left(-\int_0^t W(\mathbf{x}(t'))dt'\right). \tag{2.17}$$

The corresponding contribution for a closed state is simply equal to $\mathcal{E}[W(\mathbf{x}(t'))]=1$ and the individual probability of survival $1-p[\mathbf{x}(t');t]$ is given by the average of the $\mathcal{E}[W(\mathbf{x}(t'))]$-factor corresponding to the two states

$$1-p[\mathbf{x}(t');t]=\lambda(\mathbf{x}(t))\exp\left(-\int_0^t W(\mathbf{x}(t'))dt'\right)+1-\lambda(\mathbf{x}(t)), \tag{2.18}$$

from which we obtain the following expression for the individual probability of decay

$$p[\mathbf{x}(t');t]=\frac{V^*(\mathbf{x}(t))}{V_\Sigma}\left\{1-\exp\left[-\int_0^t W(\mathbf{x}(t'))dt'\right]\right\}. \tag{2.19}$$

Now the average survival function $\langle\mathcal{E}(t)\rangle$ is completely characterized by the collective stochastic properties of the fluctuations of the numbers of channels, expressed by the cumulants $\langle\langle\eta[\mathbf{x}_1(t')]\cdots\eta[\mathbf{x}_m(t')]\rangle\rangle$ given by Eqs. (2.9) or by the cumulant expansion (2.10) of the characteristic functional $G[K[\mathbf{x}(t')]]$ and by the behavior of an individual channel, characterized by the probability of decay given by Eq. (2.19). For investigating the scaling behavior emerging in the limit of a very large average number $\langle N\rangle$ of channels

$$\langle N\rangle=\overline{\int\int}\langle\langle\eta[\mathbf{x}(t')]\rangle\rangle D[\mathbf{x}(t')]\to\infty, \tag{2.20}$$

we introduce a limit of the thermodynamic type for which both the total volume V_Σ available in the $\mathbf{x}$-space and the average total number $\langle N\rangle$ of channels tend to infinity, but the average density of channels,

$$\varepsilon=\langle N\rangle/V_\Sigma, \tag{2.21}$$

remains constant

$$V_\Sigma, \quad \langle N\rangle\to\infty \quad \text{with} \quad \varepsilon=\langle N\rangle/V_\Sigma=\text{const.} \tag{2.22}$$

For evaluating the different types of asymptotic behavior emerging in the limit (2.22) we assume that the channels are weakly interacting, that is, as the total space volume increases to infinity, $V_\Sigma\to\infty$, the characteristic volumes $V^*(\mathbf{x}_1)$, $V^*(\mathbf{x}_2)$,..., of the neighborhoods of the different channels remain finite and constant; in other words, the increase of the total space volume V_Σ does not lead to an increase of the possible overlapping among the neighborhoods attached to the different channels. This assumption of locality generates the two types of asymptotic behavior investigated in Secs. III and IV.

III. LIMIT BEHAVIOR FOR NONINTERMITTENT FLUCTUATIONS

We introduce the relative fluctuations of different orders:

$$c_m[\mathbf{x}_1(t'),\ldots,\mathbf{x}_m(t')]=\frac{\langle\langle\,\eta[\mathbf{x}_1(t')]\cdots\eta[\mathbf{x}_m(t')]\rangle\rangle}{\Pi_{u=1}^{m}\{\langle\langle\,\eta[\mathbf{x}_u(t')]\rangle\rangle\}},\quad m\geqslant 2. \tag{3.1}$$

If the relative fluctuations $c_m[\mathbf{x}_1(t'),....,\mathbf{x}_m(t')]$, $m\geqslant 2$, decrease to zero in the thermodynamic limit (2.22)

$$c_m[\mathbf{x}_1(t'),\ldots,\mathbf{x}_m(t')]\to 0,\quad V_\Sigma,\langle N\rangle\to\infty,\ \text{with}\ \ \varepsilon=\text{const},m=2,3,\ldots, \tag{3.2}$$

then the fluctuations of the numbers of channels are nonintermittent. For investigating the asymptotic behavior of the survival function $\langle\not\in(t)\rangle$ for nonintermittent fluctuations in the thermodynamic limit (2.22) we introduce the average probability density functional of the state vector $\mathbf{x}(t')$ of an individual channel,

$$\xi[\mathbf{x}(t')]D[\mathbf{x}(t')]=\frac{\langle\langle\,\eta[\mathbf{x}(t')]\rangle\rangle D[\mathbf{x}(t')]}{\underline{\int\int}\langle\langle\,\eta[\mathbf{x}(t')]\rangle\rangle D[\mathbf{x}(t')]}, \tag{3.3}$$

with

$$\overline{\underline{\int\int}}\,\xi[\mathbf{x}(t')]D[\mathbf{x}(t')]=1, \tag{3.4}$$

and combine Eqs. (2.10), (2.13), (2.14), (2.19), (2.20), and (3.1). We express the cumulants of the functional density of channels in terms of the relative fluctuations $c_1[\mathbf{x}_1(t'),...,\mathbf{x}_m(t')]$ and of the average probability density functional $\xi[\mathbf{x}(t')]D[\mathbf{x}(t')]$. By inserting the resulting expression for the cumulants into the functional Taylor expansion (2.10) for the logarithm of the characteristic functional $G[K[\mathbf{x}(t')]]$ and expressing the average relaxation function $\langle\not\in(t)\rangle$ from Eqs. (2.13), (2.14), and (2.19) we obtain

$$\langle\not\in(t)\rangle=\exp\Bigg\{\sum_{m=1}^{\infty}\frac{\varepsilon^m}{m!}\overline{\underline{\int\int}}\cdots\overline{\underline{\int\int}}\,c_m[\mathbf{x}_1(t'),\ldots,\mathbf{x}_m(t')]\xi[\mathbf{x}_1(t')]D[\mathbf{x}_1(t')]\ldots\xi[\mathbf{x}_m(t')]$$
$$\times D[\mathbf{x}_m(t')]\prod_{u=1}^{m}\Bigg\{V_\Sigma\ln\Bigg\{1-\frac{V^*(\mathbf{x}_u(t))}{V_\Sigma}\Bigg[1-\exp\Bigg(-\int_0^t W(\mathbf{x}_u(t'))dt'\Bigg)\Bigg]\Bigg\}\Bigg\}\Bigg\}, \tag{3.5}$$

where

$$c_1=1. \tag{3.6}$$

From Eqs. (2.22), (3.2), (3.5), and (3.6) it follows that for nonintermittent fluctuations in the thermodynamic limit in Eq. (3.5) only the term corresponding to $m=1$ survives and the expression for the average survival function $\langle\not\in(t)\rangle$ reduces to the dynamical generalization (1.11) of Huber's equation:

$$\langle\not\in(t)\rangle\sim\exp\Bigg\{-\overline{\underline{\int\int}}\,\rho[W(t')]D[W(t')]\Bigg[1-\exp\Bigg(-\int_0^t W(t')dt'\Bigg)\Bigg]\Bigg\}\ \text{as}\ V_\Sigma,\langle N\rangle\to\infty,\varepsilon=\text{const}, \tag{3.7}$$

where

$$\rho[W(t')]D[W(t')]=\left\{\varepsilon\overline{\int\int}V^*(\mathbf{x}(t))\xi[\mathbf{x}(t')]D[\mathbf{x}(t')]\delta[W(t')-W(\mathbf{x}(t'))]\right\}D[W(t')] \tag{3.8}$$

is the average density of channels involved in the relaxation process, the channels being classified according to their relaxation rates $W(t')$, $t\geqslant t'\geqslant 0$.

IV. LIMIT BEHAVIOR FOR INTERMITTENT FLUCTUATIONS

For the study of the asymptotic scaling behavior of the average survival function for intermittent fluctuations a renormalization group technique should be used. In the following we apply a probabilistic version[21] of the Shlesinger–Hughes stochastic renormalization procedure[31] which has been recently applied to the study of space-dependent epidemic processes with high migration.[32] The method consists of starting out from an initial characteristic functional $G[K[\mathbf{x}(t')]]$ of the functional density of states for which the fluctuations are nonintermittent and constructing, by means of a succession of decimation processes, a renormalized characteristic functional $\tilde{G}[K[\mathbf{x}(t')]]$ for which the fluctuations of the density of states are intermittent. The main steps of such an approach are presented in another context in Ref. 21 and a simplified derivation is also presented in Ref. 32. Here we give only the final expression for the renormalized characteristic functional $\tilde{G}[K[\mathbf{x}(t')]]$:

$$\tilde{G}[K[\mathbf{x}(t')]]=H\int_0^1 z^{H-1}G[-i\ln[1-z[1-\exp(iK[\mathbf{x}(t')])]]]\,dz;H>0, \tag{4.1}$$

where H is a positive fractal exponent similar to the one entering the static equations (1.4)–(1.10).

For evaluating the limit scaling law for the average relaxation function $\langle\mathscr{N}(t)\rangle$ corresponding to the renormalized expression (4.1) we expand in Eq. (4.1) the nonrenormalized characteristic functional $G[K[\mathbf{x}(t')]]$ in the cumulant expansion (2.10) and express the corresponding cumulants in terms of the nonrenormalized relative fluctuations $c_m[\mathbf{x}_1(t');...;\mathbf{x}_m(t')]$ and in terms of the average renormalized density of channels

$$\varepsilon=\frac{\langle\tilde{N}\rangle}{V_\Sigma}=\frac{H}{H+1}\cdot\frac{\langle N\rangle}{V_\Sigma}. \tag{4.2}$$

Here we have used the relationship between the nonrenormalized average number of channels $\langle N\rangle$ and the corresponding renormalized average $\langle\tilde{N}\rangle$:

$$\langle\tilde{N}\rangle=\langle N\rangle H/(H+1). \tag{4.3}$$

The relationship (4.3) can be derived from the renormalization group equation (4.1) by means of functional differentiation followed by the application of the relationships

$$\langle N\rangle=\overline{\int\int}\langle\langle\eta[\mathbf{x}(t')]\rangle\rangle D[\mathbf{x}(t')]=\overline{\int\int}\frac{\delta\ln G[K=0]}{\delta K[\mathbf{x}(t')]}D[\mathbf{x}(t')], \tag{4.4}$$

$$\langle\tilde{N}\rangle=\overline{\int\int}\langle\langle\tilde{\eta}[\mathbf{x}(t')]\rangle\rangle D[\mathbf{x}(t')]=\overline{\int\int}\frac{\delta\ln\tilde{G}[K=0]}{\delta K[\mathbf{x}(t')]}D[\mathbf{x}(t')], \tag{4.5}$$

which can be derived by expanding the characteristic functionals $G[K[\mathbf{x}(t')]]$ and $\tilde{G}[K[\mathbf{x}(t')]]$ in cumulant series of the type (2.10).

By using Eqs. (2.10), (2.13), and (2.14) applied for the renormalized characteristic functional $\tilde{G}[K[\mathbf{x}(t')]]$ combined with Eqs. (4.1) and (4.2) and using the same steps as in Sec. III we obtain the following expression for the average relaxation function $\langle \mathscr{l}(t) \rangle$:

$$\langle \mathscr{l}(t) \rangle = H \int_0^1 z^{H-1}\, dz\, \exp\left\{ \sum_{m=1}^{\infty} \frac{1}{m!} \left[\varepsilon \left(1 + \frac{1}{H} \right) \right]^m \overline{\int\int} \cdots \overline{\int\int} c_m[\mathbf{x}_1(t'),\ldots,\mathbf{x}_m(t')] \xi[\mathbf{x}_1(t')] \right.$$
$$\times D[\mathbf{x}_1(t')] \cdots \xi[\mathbf{x}_m(t')] D[\mathbf{x}_m(t')] \prod_{u=1}^{m} \left\{ V_\Sigma \ln \left[1 - zV^*(\mathbf{x}_u(t))(V_\Sigma)^{-1} \right.\right.$$
$$\left.\left. \left. \times \left(1 - \exp\left(- \int_0^t W(\mathbf{x}_u(t'))dt' \right) \right) \right] \right\} \Bigg\}, \tag{4.6}$$

from which, by taking into account the nonintermittency conditions (3.2) for the nonrenormalized relative fluctuations of the density of channels we obtain the following scaling law in the thermodynamic limit (2.22):

$$\langle \mathscr{l}(t) \rangle \sim \mathscr{J}_H \left\{ \overline{\int\int} \rho[W(t')] D[W(t')] \left[1 - \exp\left(- \int_0^t W(t')dt' \right) \right] \right\},$$
$$\text{as} \quad V_\Sigma, \langle \tilde{N} \rangle \to \infty \quad \text{with} \quad \varepsilon = \langle \tilde{N} \rangle / V_\Sigma = \text{const}, \tag{4.7}$$

where the function $\mathscr{J}_H(z)$ and the functional density of channels involved in the relaxation process, $\rho[W(t')]D[W(t')]$, are given by Eqs. (1.5) and (3.8), respectively.

Equation (4.7) justifies the conjecture (1.12) made without proof in Sec. I. This equation is the dynamical analog of the intermittent scaling law (1.4) derived for systems with static disorder in Ref. 20. Just like in the static case the reciprocal value of the fractal exponent H, $1/H$, is a measure of the degree of intermittency of the fluctuations of the number of channels. In particular in the limit $H \to \infty$ the fluctuations become nonintermittent and Eq. (4.7) reduces to the dynamical analogue (1.2) of Huber's equation. The renormalization group approach for dynamical disorder used in this paper has the same drawback as the similar static approach developed in Ref. 20: it does not guarantee that the limit scaling relationship (4.7) is the unique asymptotic law which emerges in the thermodynamic limit for intermittent fluctuations. The renormalization group procedure introduced in Ref. 21 does not provide a hint that the fixed point corresponding to Eq. (4.1) is the unique fixed point of the problem. It is possible that further research may lead to other scaling laws characteristic for intermittent fluctuations.

V. DYNAMICAL GENERALIZATIONS OF STRETCHED EXPONENTIAL

The main difficulty related to the application of the dynamical scaling laws (3.7) and (4.7) is connected to the evaluation of the path integral:

$$I(t) = \overline{\int\int} \rho[W(t')] D[W(t')] \left[1 - \exp\left(- \int_0^t W(t')dt' \right) \right]. \tag{5.1}$$

The evaluation of such path integrals would be trivial provided that the functional density of states $\rho[W(t')]D[W(t')]$ would have a Gaussian behavior. Unfortunately a Gaussian form for $\rho[W(t')]D[t')]$ must be ruled out because it does not include the static power law distribution (1.3′) as a particular case.

A formal solution of the problem can be given by introducing an average probability density functional of the relaxation rates $W(t')$, $t \geqslant t' \geqslant 0$:

$$\varphi[W(t')]D[W(t')]=\rho[W(t')]D[W(t')]/\langle N^*\rangle, \tag{5.2}$$

with the normalization condition

$$\overline{\int\int}\,\varphi[W(t')]D[W(t')]=1, \tag{5.3}$$

and where

$$\langle N^*\rangle=\overline{\int\int}\,\rho[W(t')]D[W(t')]=\varepsilon\overline{\int\int}\,V^*(\mathbf{x}(t))\xi[\mathbf{x}(t')]D[\mathbf{x}(t')] \tag{5.4}$$

is the average effective number of channels involved in the relaxation process. Generally the average effective number of channels involved in relaxation, $\langle N^*\rangle$, is at most equal to the total average number of channels, $\langle N\rangle$. By using the expression (5.2) for the average probability density functional $\varphi[W(t')]D[W(t')]$, the factor $I(t)$ can be expressed in terms of a dynamical average of the random function

$$\mathcal{A}[W(t')]=\exp\left(-\int_0^t W(t')dt'\right) \tag{5.5}$$

[see also Eq. (2.17)]. We have

$$I(t)=\langle N^*\rangle\{1-\langle\mathcal{A}[W(t')]\rangle\}, \tag{5.6}$$

where the dynamical average $\langle\mathcal{A}[W(t')]\rangle$ is given by

$$\langle\mathcal{A}[W(t')]\rangle=\overline{\int\int}\,\varphi[W(t')]D[W(t')]\mathcal{A}[W(t')]. \tag{5.7}$$

In this paper we limit ourselves to the simplest case of dynamical disorder for which the random process corresponding to the average probability density functional $\varphi[W(t')]D[W(t')]$ is Markovian. Moreover we consider that the average effective number of channels involved in the relaxation process, $\langle N^*\rangle$, is time independent:

$$\langle N^*\rangle=\text{const.} \tag{5.8}$$

Under these circumstances the probability density functional $\varphi[W(t')]D[W(t')]$ can be represented as

$$\begin{aligned}\varphi[W(t')]D[W(t')]=\lim_{\substack{m\to\infty\\(\Delta t\to 0)}}\,[&\varphi(W_m;m\Delta t|W_{m-1};(m-1)\Delta t)dW_m\cdots\varphi(W_2;2\Delta t|W_1;\Delta t)dW_2\\&\times\varphi(W_1;\Delta t|W_0;0)dW_1\varphi_{st}(W_0)dW_0],\quad t\geqslant t'\geqslant 0,\end{aligned} \tag{5.9}$$

where

$$m=t/\Delta t; \tag{5.10}$$

$$\varphi_{st}(W)dW\quad\text{with}\quad\int\varphi_{st}(W)dW=1, \tag{5.11}$$

is an average one-time stationary probability density of an individual relaxation rate attached to a given channel corresponding to static disorder and

$$\varphi(W;t|W';t')dW \quad \text{with} \quad \int \varphi(W;t|W';t')dW=1 \tag{5.12}$$

is the average conditional probability density of the relaxation rate W at time t provided that at time t' the relaxation rate was W'. For a Markov process both $\varphi_{st}(W)$ and $\varphi(W;t|W';t')$ are the solutions of an evolution equation of the type

$$\partial_t\varphi=\mathbb{L}\varphi, \tag{5.13}$$

where $\mathbb{L}$ is a linear Markovian evolution operator of the Liouville, Fokker–Planck, or the master type. In this case the probability $\varphi_{st}(W)$ is the stationary solution of Eq. (5.13), whereas the conditional probability density $\varphi(W;t|W';t')$ is the Green's function of the equation (5.13) corresponding to the initial condition

$$\varphi(W;t=t'|W';t')=\delta(W-W'). \tag{5.14}$$

For the above-mentioned Markovian systems there is a general method for computing dynamical path averages of the type (5.7) without the explicit evaluation of a path integral. The method was suggested by Lax in the sixties[33] in connection with certain problems of quantum optics and rediscovered independently by Van Kampen.[34,35] For a recent application of this technique to the study of a rate process with dynamical disorder, the passage over a fluctuating activation energy barrier, see Ref. 26. The idea is based on the observation that a realization of the function $\mathscr{E}(t)=\mathscr{E}[W(t')]$ given by Eq. (5.5) obeys a stochastic differential equation with a random coefficient:

$$\frac{d\mathscr{E}(t)}{dt}=-W(t)\mathscr{E}(t) \quad \text{with} \quad \mathscr{E}(0)=1. \tag{5.15}$$

Since Eq. (5.15) is local in time and the coefficient $W(t)$ is Markovian it follows that the pair of random variables $(W(t),\mathscr{E}(t))$ is also Markovian and the one-time joint probability density,

$$P(W,\mathscr{E};t)dWd\mathscr{E} \quad \text{with} \quad \int\int P(W,\mathscr{E};t)dWd\mathscr{E}=1, \tag{5.16}$$

obeys a compound stochastic Liouville equation,[33–35]

$$\partial_t P(W,\mathscr{E};t)=\partial_{\mathscr{E}}\{W\mathscr{E}P(W,\mathscr{E};t)\}+\mathbb{L}P(W,\mathscr{E};t), \tag{5.17}$$

with the initial condition

$$P(W,\mathscr{E};t=0)=\delta(\mathscr{E}-1)\varphi_{st}(W). \tag{5.18}$$

The dynamical average $\langle\mathscr{E}[W(t')]\rangle$ can be expressed as an average value corresponding to the joint probability density $P(W,\mathscr{E};t)$:

$$\langle\mathscr{E}[W(t')]\rangle=\int\int \mathscr{E}P(W,\mathscr{E};t)dWd\mathscr{E}=\int F(W,t)dW, \tag{5.19}$$

where

$$F(W,t)=\int \mathscr{C}P(W,\mathscr{C};t)d\mathscr{C} \tag{5.20}$$

is a marginal average. By multiplying Eqs. (5.17) and (5.18) by $\mathscr{C}$ and integrating over $\mathscr{C}$ after a partial integration we obtain a closed equation for the marginal average $F(W;t)$:

$$\partial_t F(W;t)+WF(W;t)=\mathbb{L}F(W;t), \tag{5.21}$$

with the initial condition

$$F(W;t=0)=\varphi_{st}(W). \tag{5.22}$$

From the above considerations it turns out that for a stationary Markovian average random process the evaluation of the average survival function $\langle \mathscr{C}(t)\rangle$ reduces to the evaluation of the marginal average $F(W,t)$ by solving the evolution equation (5.21) with the initial condition (5.22) followed by the application of Eqs. (3.7), (4.7), (5.1), (5.6), and (5.19).

For applying the suggested Markovian approach we should come up with a suitable definition of the Markovian evolution operator $\mathbb{L}$. The simplest possible choice would be a Liouville operator of the type suggested in Ref. 26 determined by starting out from the stationary probability density $\varphi_{st}(W)$ corresponding to the static density of states (1.3′) attached to a stretched exponential of the type (1.1) and by assuming that the regression of the fluctuations of the relaxation rate is described by a generally time-dependent regression rate $\omega(t)$. Now we notice a minor difficulty related to the self-similar form (1.3′) of the static density of states $\rho(W)dW$: due to the infrared divergence of $\rho(W)$ given by Eq. (1.3′) at $W=0$, the average effective number $\langle N^*\rangle$ of channels involved in the relaxation process is infinite:

$$\langle N^*\rangle=\int_0^\infty \rho(W)dW=\int_0^\infty [\Gamma(1-\beta)]^{-1}\beta\Omega^\beta W^{-(1+\beta)}dW=\infty. \tag{5.23}$$

Due to the time independence condition (5.8) for $\langle N^*\rangle$, the divergent behavior carries over for systems with dynamical disorder. This divergence is, however, spurious because the corresponding integral expressions for the average survival function $\langle \mathscr{C}(t)\rangle$ are well behaved. The problem can be solved by introducing an infrared cutoff $W^*\neq 0$ and by passing to the limit $W^*\to 0$ after performing the computations.

For a cutoff value $W^*\neq 0$, the total effective average number of channels $\langle N^*\rangle$ is finite:

$$\langle N^*\rangle=\int_{W^*}^\infty \rho(W)dW=[\Gamma(1-\beta)]^{-1}\left(\frac{\Omega}{W^*}\right)^\beta, \tag{5.24}$$

and the stationary probability density $\varphi_{st}(W)\ dW$ is given by

$$\varphi_{st}(W)dW=\rho(W)dW/\langle N^*\rangle=\beta(W^*)^\beta W^{-(1+\beta)}dW, \tag{5.25}$$

which obviously fulfills the normalization condition

$$\int_{W^*}^\infty \varphi_{st}(W)dW=1. \tag{5.26}$$

By following the approach suggested in Ref. 26 we express $\varphi_{st}(W)$ as the normalized solution of a Bloch-like equation

$$\beta\left(\beta\varphi_{st}(W)+\frac{\partial}{\partial W}[W\varphi_{st}(W)]\right)=0, \tag{5.27}$$

and suggest a dynamical generalization of Eq. (5.27) depending on the regression frequency $\omega(t)$:

$$\frac{\partial\varphi}{\partial t}=-\beta\omega(t)\left[\beta\varphi+\frac{\partial}{\partial W}(W\varphi)\right]=\mathbb{L}\varphi, \tag{5.28}$$

where the Liouville operator $\mathbb{L}$ is given by

$$\mathbb{L}\ldots=-\beta\omega(t)\left[\beta\ldots+\frac{\partial}{\partial W}(W\ldots)\right]. \tag{5.29}$$

All solutions of the Liouville equation (5.28) should be properly defined, that is, they should be non-negative and conserve the normalization to unity at any time

$$\varphi\geqslant 0;\ \int_{W^*}^{\infty}\varphi\ dW=1. \tag{5.30}$$

By integrating Eq. (5.28) term by term it is easy to check that it conserves the normalization of φ to unity provided that the following boundary condition is fulfilled:

$$\varphi(W=W^*;t)=\beta/W^*;\quad t\geqslant 0. \tag{5.31}$$

Concerning the non-negativity of φ we express any solution of Eq. (5.28) in terms of the Green's function $\varphi(W;tW';t')$, which is the solution of Eq. (5.28) with the initial condition (5.14), and of the initial condition $\varphi(W;t=0)$:

$$\varphi(W;t)=\int_{W^*}^{\infty}\varphi(W;t|W';0)\varphi(W';t=0)dW'. \tag{5.32}$$

The Green's function $\varphi(W;t|W';0)$ can be easily evaluated by integrating Eq. (5.28) along the characteristics with the initial condition (5.14) applied for $t'=0$ and with the boundary condition (5.31), resulting in

$$\begin{aligned}\varphi(W;t|W';0)=&h\left[W^*\exp\left(\beta\int_0^t\omega(t')dt'\right)-W\right]\left(\frac{\beta}{W^*}\right)\left(\frac{W^*}{W}\right)^{1+\beta}\\&+h\left[W-W^*\exp\left(\beta\int_0^t\omega(t')dt'\right)\right]\exp\left(-\beta^2\int_0^t\omega(t')dt'\right)\\&\times\delta\left[W-W'\exp\left(\beta\int_0^t\omega(t')dt'\right)\right],\end{aligned} \tag{5.33}$$

where $h(x)$ is the Heaviside's step function. From Eqs. (5.32) and (5.33) we obtain

$$\begin{aligned}\varphi(W;t)=&h\left[W^*\exp\left(\beta\int_0^t\omega(t')dt'\right)-W\right]\left(\frac{\beta}{W^*}\right)\left(\frac{W^*}{W}\right)^{1+\beta}+h\left[W-W^*\left(\beta\int_0^t\omega(t')dt'\right)\right]\\&\times\exp\left(-\beta^2\int_0^t\omega(t')dt'\right)\varphi\left(W\exp\left(-\beta\int_0^t\omega(t')dt'\right);t=0\right).\end{aligned} \tag{5.34}$$

Both Eqs. (5.33) and (5.34) conserve the non-negativity and normalization conditions (5.30) provided that the initial probability density $\varphi(W;t=0)$ is non-negative and normalized to unity and is equal to zero for any rate smaller than the cutoff value $W=W^*$:

$$\varphi(W;t=0)\geqslant 0; \quad \int_{W^*}^{\infty}\varphi(W;t=0)dW=1; \quad \varphi(W<W^*;t=0)=0. \tag{5.35}$$

By applying the above-mentioned Markovian approach it follows that the marginal average $F(W,t)$ is the solution of the partial differential equation

$$\partial_t F(W,t)+WF(W,t)=-\beta\omega(t)[\beta F(W,t)+\partial_W[WF(W,t)]], \tag{5.36}$$

with the initial condition

$$F(W,t=0)=\beta(W^*)^{-1}(W^*/W)^{1+\beta}. \tag{5.37}$$

By integrating Eq. (5.36) by means of the method of characteristics we can express the marginal average $F(W,t)$ in terms of an arbitrary function. By determining this arbitrary function from the initial condition (5.37) we obtain

$$F(W,t)=\beta(W^*)^{-1}\left(\frac{W^*}{W}\right)^{1+\beta}\exp\left\{-Wg^{\beta}(t)\int_0^t g^{-\beta}(t')dt'\right\}, \tag{5.38}$$

where $g(t)$, the attenuation factor of the regression of fluctuations of the relaxation rate attached to a given channel, is given by

$$\frac{dg(t)}{dt}=-\omega(t)g(t), \quad g(0)=1, \tag{5.39}$$

that is,

$$g(t)=\exp\left(-\int_0^t\omega(t')dt'\right). \tag{5.40}$$

From Eqs. (5.1), (5.6), (5.19), and (5.38) if follows that the exponent $I(t)$ is equal to

$$I(t)=\frac{\beta\Omega^{\beta}}{\Gamma(1-\beta)}\int_{W^*}^{\infty}\frac{1-\exp[-Wg^{\beta}(t)\int_0^t g^{-\beta}(t')dt']}{W^{1+\beta}}\,dW. \tag{5.41}$$

As expected in the limit $W^*\to 0$, the exponent $I(t)$ is well behaved and in this limit the integral over W in Eq. (5.41) can be explicitly computed, resulting in

$$I(t)=\left[\Omega g^{\beta}(t)\int_0^t g^{-\beta}(t')dt'\right]^{\beta}. \tag{5.42}$$

From the above computations it turns out that for the model considered in this section the universal scaling laws (3.7) and (4.7) for dynamical nonintermittent and intermittent fluctuations become

$$\langle\ell(t)\rangle=\exp\left\{-\left[\Omega g^{\beta}(t)\int_0^t g^{-\beta}(t')dt'\right]^{\beta}\right\} \tag{5.43}$$

and

$$\langle\ell(t)\rangle=\mathcal{J}_H\left\{\left[\Omega g^{\beta}(t)\int_0^t g^{-\beta}(t')dt'\right]\right\}, \tag{5.44}$$

respectively. Equations (5.43) and (5.44) are dynamical analogs of the stretched exponential law (1.1) and of its static intermittent generalization (1.8). The concrete form of these two equations depends on the dynamics of the regression of the fluctuations of the relaxation rate expressed by the attenuation function $g(t)$. A comparison between the relaxation behavior corresponding to some important types of dynamical disorder and the relaxation behavior of the similar systems with static disorder is presented in the following section.

VI. STATIC VERSUS DYNAMICAL DISORDER

The dynamical relaxation equations (5.43) and (5.44) include the stretched exponential (1.1) and its static intermittent analogue (1.8) as particular cases corresponding to a regression rate $\omega(t)$ equal to zero for which there is no attenuation of the fluctuations

$$\omega(t)=0, \quad g(t)=1, \tag{6.1}$$

and an initial fluctuation of the relaxation rate is frozen forever.

In this paper we limit ourselves to the study of only two types of dynamical disorder. The first case corresponds to a fast regression of the fluctuations for which the frequency $\omega(t)$ is constant and the attenuation function $g(t)$ is exponentially decreasing in time:

$$\omega(t)=\omega_0=\text{const} \quad \text{and} \quad g(t)=\exp(-\omega_0 t). \tag{6.2}$$

The second case corresponds to a self-similar regression process described by slowly decaying functions $\omega(t)$ and $g(t)$ which obey negative power laws of time as $t \gg t_0$:

$$\omega(t)=\alpha/(t+t_0)\sim \alpha/t \quad \text{as} \quad t \gg t_0, \tag{6.3}$$

$$g(t)=[t_0/(t+t_0)]^{\alpha}\sim (t_0/t)^{\alpha} \quad \text{as} \quad t \gg t_0, \tag{6.4}$$

where $t_0>0$ is a possibly very small but, however, different from zero time constant which has been introduced in order to avoid the divergence of the frequency $\omega(t)$ in the limit $t\to 0$. The relationships between these two cases can be clarified by requiring that as $t\to 0$ the regression rates $\omega(t)$ have the same values, resulting in

$$\omega(0)=\alpha/t_0=\omega_0. \tag{6.5}$$

By using Eq. (6.5) the relationship (6.4) for the attenuation function $g(t)$ becomes

$$g(t)=[\alpha/(\omega_0 t+\alpha)]^{\alpha}. \tag{6.6}$$

For small values of α the function $g(t)$ given by Eq. (6.6) has a long tail of the negative power law type. As the fractal exponent α increases the tail of the attenuation function $g(t)$ is getting shorter and shorter and in the limit $\alpha\to\infty$ we recover the exponential decay law (6.2).

In order to outline the analogies and differences between the relaxation processes in systems with static and dynamical disorder we compare the static relaxation equations (1.1) and (1.8) for nonintermittent and intermittent fluctuations, respectively, with the dynamical relaxation equations (5.43) and (5.44) applied in the case of the attenuation functions $g(t)$ given by Eqs. (6.2) and (6.4). It is also of interest to compare the probability densities of the relaxation time

$$\psi(t)dt=-\left[\frac{\partial\langle \mathscr{C}(t)\rangle}{\partial t}\right]dt, \tag{6.7}$$

the corresponding moments

$$\langle t^m\rangle=\int_0^\infty t^m\psi(t)dt=\lim_{t\to\infty} t^m\langle\chi(t)\rangle+m\int_0^\infty t^{m-1}\langle\chi(t)\rangle dt, \tag{6.8}$$

and the effective rates of relaxation

$$W_{\text{eff}}(t)=\psi(t)/\langle\chi(t)\rangle=-\partial_t \ln\langle\chi(t)\rangle. \tag{6.9}$$

For computing these functions we express the average relaxation functions for nonintermittent and intermittent fluctuations in terms of the exponent $I(t)$ given by Eq. (5.42):

$$\langle\chi(t)\rangle=\exp[-I(t)], \tag{6.10}$$

$$\langle\chi(t)\rangle=\mathcal{J}_H[I(t)]. \tag{6.11}$$

The application of Eqs. (1.5), (5.42), and (6.7)–(6.11) leads to the following relationships for the functions $\psi(t)$ and $W_{\text{eff}}(t)$:

$$\psi(t)=q(t)I(t)\exp[-I(t)], \tag{6.12}$$

$$W_{\text{eff}}(t)=q(t)I(t), \tag{6.13}$$

for nonintermittent fluctuations and

$$\psi(t)=q(t)\mathcal{F}_H[I(t)]\mathcal{J}_H[I(t)], \tag{6.14}$$

$$W_{\text{eff}}(t)=q(t)\mathcal{F}_H[I(t)], \tag{6.15}$$

for intermittent fluctuations. Here the functions $q(t)$ and $\mathcal{F}_H(z)$ are given by

$$q(t)=\frac{d[\ln I(t)]}{dt}=\beta\left\{g^{-\beta}(t)\left[\int_0^t g^{-\beta}(t')dt'\right]^{-1}-\beta\omega(t)\right\}, \tag{6.16}$$

$$\mathcal{F}_H(z)=(H+1)\left\{1+\left[\left(1+\frac{1}{H}\right)^H z^H\right]\frac{\exp[-z(1+1/H)]}{\gamma[H+1;z(1+1/H)]}\right\}^{-1}. \tag{6.17}$$

For applying these equations for systems with nonintermittent or intermittent static disorder and for systems with nonintermittent or intermittent dynamical disorder with exponential or self-similar regression we should evaluate the functions $I(t)$ and $q(t)$ corresponding to all these particular cases. After some computations we come to

$$I(t)=(\Omega t)^\beta, \quad q(t)=\beta/t, \tag{6.18}$$

for static disorder;

$$I(t)=\left\{\frac{\Omega[1-\exp(-\omega_0\beta t)]}{[\omega_0\beta]}\right\}^\beta, \tag{6.19}$$

$$q(t)=\beta^2\omega_0\exp(-\omega_0\beta t)[1-\exp(-\omega_0\beta t)]^{-1}, \tag{6.20}$$

for nonintermittent and intermittent dynamical disorder with exponential attenuation; and

$$I(t)=\{\Omega^*[t+t_0-t_0[t_0/(t+t_0)]^{\alpha\beta}]\}^\beta, \tag{6.21}$$

$$q(t)=\beta^2\alpha(t_0)^{-1}[t_0/(t+t_0)]^{\alpha\beta+2}\{1-[t_0/(t+t_0)]^{\alpha\beta+1}\}^{-1}, \tag{6.22}$$

TABLE I. Limit behavior of the average relaxation function $\langle l(t)\rangle$ for different types of static and dynamical disorder for small and large times.

Case	$\langle l(t)\rangle$ for small times	$\langle l(t)\rangle$ for large times
(1) Nonintermittent static disorder	$\exp[-(\Omega t)^{\beta}]$	$\exp[-(\Omega t)^{\beta}]$
(2) Nonintermittent dynamical disorder with exponential regression	$\exp[-(\Omega t)^{\beta}]$; $\Omega t \ll \Omega/\omega_0$	$\exp[-(\Omega/\beta\omega_0)^{\beta}]=$const; $\Omega t \gg \Omega/\omega_0$
(3) Nonintermittent dynamical disorder with self-similar regression	$\exp[-(\Omega t)^{\beta}]$; $\Omega t \ll \Omega t_0$	$\exp[-(\Omega^* t)^{\beta}]$; $\Omega t \gg \Omega t_0$
(4) Intermittent static disorder	$\exp[-(\Omega t)^{\beta}]$; $\Omega t \ll 1$	$(\Omega t)^{-\beta H}(1+1/H)^{-H}\Gamma(1+H)$; $\Omega t \gg 1$
(5) Intermittent dynamical disorder with exponential regression	$\exp[-(\Omega t)^{\beta}]$; $\Omega t \ll \Omega/\omega_0$; $\Omega t \ll 1$	(a) $(\Omega t)^{-\beta H}(1+1/H)^{-H}\Gamma(1+H)$; $\Omega/\omega_0 \gg \Omega t \gg 1$ (b) $(\Omega/\beta\omega_0)^{-\beta H}(1+1/H)^{-H}\Gamma(1+H)$; $\Omega t \gg \Omega/\omega_0 \gg 1$
(6) Intermittent dynamical disorder with self-similar regression	$\exp[-(\Omega t)^{\beta}]$; $\Omega t \ll 1$; $\Omega t \ll \Omega t_0$	(a) $(\Omega t)^{-\beta H}(1+1/H)^{-H}\Gamma(1+H)$; $\Omega t_0 \gg \Omega t \gg 1$ (b) $(\Omega^* t)^{-\beta H}(1+1/H)^{-H}\Gamma(1+H)$; $\Omega t \gg \Omega t_0 \gg 1$

for nonintermittent and intermittent dynamical disorder with self-similar attenuation. Here

$$\Omega^* = \Omega/(1+\alpha\beta). \tag{6.23}$$

By combining Eqs. (6.7)–(6.22) we can derive six sets of functions $\langle \chi(t)\rangle$, $\psi(t)$, and $W_{\text{eff}}(t)$ corresponding to nonintermittent and intermittent static disorder, to the two types of nonintermittent dynamical disorder, and to the two types of intermittent dynamical disorder considered in this article. The resulting equations are rather complicated and to save space they are not given here. We present only two tables with the different types of limit behavior of these functions for short and large times, respectively.

Table 1 shows the asymptotic behavior of the average survival function $\langle l(t)\rangle$ in the six cases considered. For nonintermittent fluctuations the dynamical disorder decreases the efficiency of relaxation both for exponential and self-similar attenuation. The effect is much more pronounced for exponential attenuation for which the relaxation function tends towards a positive value different from zero as $t\to\infty$ and thus the relaxation process is never complete, not even after an infinitely large period of time. For self-similar attenuation this decrease in efficiency is less pronounced. An interesting effect in this case is that both for small and large times the relaxation process is described by stretched exponentials with the same exponent β and different characteristic frequencies, Ω and $\Omega^*=\Omega/(1+\alpha\beta)<\Omega$, respectively. For large times the decrease of efficiency due to dynamical disorder is displayed by the decrease of the characteristic frequency from Ω to Ω^*. Similar patterns occur in the intermittent cases for which the dynamical disorder also slows down the relaxation process. For exponential attenuation after an initial stretched exponential behavior for large times a self-similar region exists for which the relaxation function is described by a negative power law of time. The self-similar region is eventually followed by a horizontal asymptote of the relaxation function which has a positive residual value even in the limit $t\to\infty$, a situation which corresponds to incomplete relaxation. Just as in the nonintermittent

TABLE II. Limit behavior for small and large times of the effective relaxation rate $W_{\text{eff}}(t)$ and the values of the positive moments $\langle t^m \rangle$, $m \geqslant 1$, of the relaxation time for different types of static and dynamical disorder.

Case	$W_{\text{eff}}(t)$ for small times	$W_{\text{eff}}(t)$ for large times	$\langle t^m \rangle, m \geqslant 1$
(1) Nonintermittent static disorder	$\beta \Omega^{\beta} t^{\beta-1}$	$\beta \Omega^{\beta} t^{\beta-1}$	$\Omega^{-m} \Gamma(1+m/\beta) = \text{finite}$
(2) Nonintermittent dynamical disorder with exponential regression	$\beta \Omega^{\beta} t^{\beta-1}$; $\Omega t \ll \Omega/\omega_0$	~ 0; $\Omega t \gg \Omega/\omega_0$	∞
(3) Nonintermittent dynamical disorder with self-similar regression	$\beta \Omega^{\beta} t^{\beta-1}$; $\Omega t \ll \Omega t_0$	$\beta (\Omega^*)^{\beta} t^{\beta-1}$; $\Omega t \gg \Omega t_0$	finite
(4) Intermittent static disorder	$\beta \Omega^{\beta} t^{\beta-1}$; $\Omega t \ll 1$	H/t; $\Omega t \gg 1$	∞
(5) Intermittent dynmical disorder with exponential regression	$\beta \Omega^{\beta} t^{\beta-1}$; $\Omega t \ll \Omega/\omega_0$; $\Omega t \ll 1$	(a) H/t; $\Omega/\omega_0 \gg \Omega t \gg 1$ (b) ~ 0; $\Omega t \gg \Omega/\omega_0 \gg 1$	∞
(6) Intermittent dynamical disorder with self-similar regression	$\beta \Omega^{\beta} t^{\beta-1}$; $\Omega t \ll 1$; $\Omega t \ll \Omega t_0$	(a) H/t; $\Omega t_0 \gg \Omega t \gg 1$ (b) H/t; $\Omega t \gg \Omega t_0 \gg 1$	∞

case for self-similar attenuation, the decrease in efficiency of the relaxation process is less pronounced in comparison with the case of exponential attenuation. For small times a stretched exponential behavior exists with a characteristic frequency

$$\Omega^{**} = \Omega. \tag{6.24}$$

For large times both the intermittent behavior and the regression of fluctuations lead to the slowing down of the relaxation process. The intermittent behavior is dominant leading to a long time tail of the average survival function.

Table II displays the asymptotic values of the effective relaxation rate $W_{\text{eff}}(t)$ for small and large times as well as the values of the positive moments of the relaxation time. The expressions for the effective relaxation rate are consistent with the data presented in Table I for the average survival function. A survival function of the stretched exponential type corresponds to a negative power law function of time for the effective relaxation rate of the type

$$W_{\text{eff}} \sim 1/t^{1-\beta}. \tag{6.25}$$

Similarly a power law tail of the survival function corresponds to an asymptotic hyperbolic time dependence of the effective relaxation rate

$$W_{\text{eff}} \sim 1/t \quad \text{as} \quad t \to \infty, \tag{6.26}$$

whereas a positive residual value of the relaxation function for large times, $\langle l(\infty) \rangle > 0$, corresponds to an asymptotic value of the effective relaxation rate equal to zero:

$$W_{\text{eff}} \sim 0 \quad \text{as} \quad t \to \infty. \tag{6.27}$$

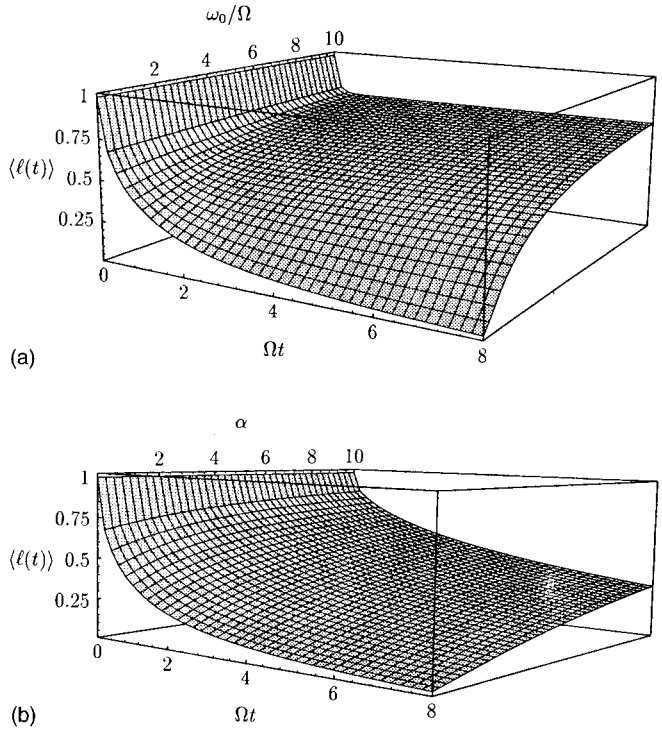

FIG. 1. (a) The dependence of the average survival function $\langle l(t) \rangle$ on the dimensionless time Ωt and on the relative frequency of regression ω_0/Ω for nonintermittent dynamical fluctuations with exponential attenuation, $\beta=0.6$. (b) The dependence of the average survival function $\langle l(t) \rangle$ on the dimensionless time Ωt and on the attenuation exponent α for nonintermittent dynamical fluctuations with self-similar regression, $\beta=0.6$ and $\Omega t_0=0.1$.

The analysis of the values of the moments of the relaxation time, $\langle t^m \rangle$, is of interest because their divergence may be related to the possible statistical fractal behavior of the probability density $\psi(t)$ of the relaxation time. To save space the asymptotic values of $\psi(t)$ are not given in Tables I and II; however, the asymptotic expressions for $\psi(t)$ can be easily evaluated from these tables by noticing that from Eq. (6.9) we have

$$\psi(t)=\langle l(t) \rangle W_{\text{eff}}(t). \tag{6.28}$$

Special attention is deserved by the investigation of the asymptotic behavior of the probability density $\psi(t)dt$ of the relaxation time in the case when a residual value different from zero exists for the average survival function, a situation which corresponds to incomplete relaxation. In this case the probability density $\psi(t)dt$ of the relaxation time is apparently not normalized to unity because we have

$$\int_0^\infty \psi(t)dt=-\int_0^\infty \partial_t \langle l(t) \rangle dt=\langle l(0) \rangle-\langle l(\infty) \rangle=1-\langle l(\infty) \rangle<1. \tag{6.29}$$

The physical explanation of this result is the following: the factor $\langle l(\infty) \rangle$ expresses the proportion of systems (particles) which never relax. Notice, however, that the violation of normalization of the probability density $\psi(t)dt$ is only apparent because the expression (6.7) for $\psi(t)dt$ does not

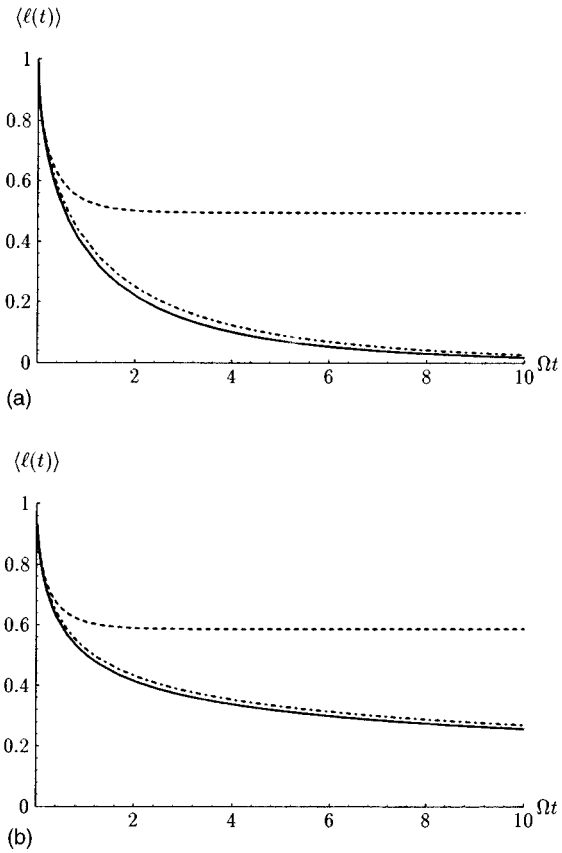

FIG. 2. (a) The dependence of the average relaxation function $\langle l(t)\rangle$ on the dimensionless time Ωt for nonintermittent fluctuations corresponding to a static process (full line), to a dynamical process with exponential attenuation (dashed line), and to a dynamical process with self-similar attenuation (dash-pointed), $\beta=0.6$, $\omega_0/\Omega=3$, $\alpha=0.3$, $\Omega t_0=0.1$. (b) The dependence of the average relaxation function $\langle l(t)\rangle$ on the dimensionless time Ωt for intermittent fluctuations corresponding to a static process (full line), to a dynamical process with exponential attenuation (dashed line), and to a dynamical process with self-similar attenuation (dash-pointed), $\beta=0.6$, $\omega_0/\Omega=3$, $\Omega t_0=0.1$, and $H=0.5$.

take into account the contribution of systems (particles) which survive up to infinity. These particles give rise to a contribution to the expression for $\psi(t)dt$ having the form of a delta function displaced to infinity. Equation (6.7) should be rewritten

$$\psi(t)=-\partial\langle l(t)\rangle/\partial t+\langle l(\infty)\rangle\delta(t-t^*) \quad \text{with} \quad t^*\to\infty. \tag{6.30}$$

This definition of the probability density $\psi(t)dt$ leads to a normalized expression even if $\langle l(\infty)\rangle\neq 0$.

The significance of the values of the moments of the relaxation time displayed in Table II is clear. A stretched exponential relaxation function is relatively fast decreasing and the resulting shape of the tail of $\psi(t)$ ensures the convergence of the moments, a situation which corresponds to static nonintermittent disorder and to dynamical nonintermittent disorder with self-similar regression. In the other four cases presented in Table II the moments are divergent. There are two different causes for this divergence. For nonintermittent and intermittent dynamical disorder with exponential regression it is due to the existence of a finite proportion of particles which never relax. For intermittent static disorder and for intermittent dynamical disorder with self-similar regression the infinite moments are generated by the self-similar features of the tails of the

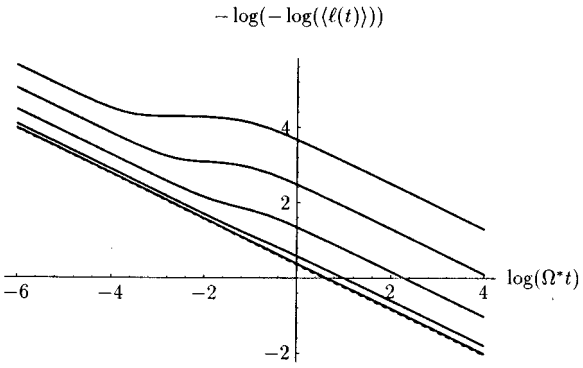

FIG. 3. The average relaxation function $\langle l(t)\rangle$ for nonintermittent, self-similar fluctuations (full line) in comparison to the static average relaxation function (dashed line). In the logarithmic coordinates used the stretched exponential portions of the relaxation functions appear as straight lines: $\beta=0.6$, $\Omega^*\equiv\Omega/(1+\alpha\beta)=1s^{-1}$, and $\Omega^* t_0=0.1$ for $\alpha=0.1$, 1, 10, 100, 1000 (from bottom to top).

probability density $\psi(t)dt$. By using Eq. (6.28) and the data displayed in Tables I and II it is easy to see that in both of these cases the large time behavior of the probability density of the relaxation time is described by

$$\psi(t)\sim t^{-(1+\beta H)} \quad \text{as} \quad t\to\infty, \tag{6.31}$$

that is, $\psi(t)$ has a power law tail with a fractal exponent $1+\beta H$. It is interesting that this fractal exponent is independent of the exponent α of attenuation; the proportionality coefficient in Eq. (6.31) is, however, generally α-dependent.

For a better understanding of the behavior of the average relaxation function $\langle l(t)\rangle$ in the different cases investigated in this paper we present some graphs of this function. As expected these graphs are consistent with the results of asymptotic analysis presented in Tables I and II. By examining Fig. 1(a) corresponding to nonintermittent dynamical fluctuations with exponential regression we notice that the fraction of particles which never relax increases with the increase of the frequency of regression ω_0, a result which is consistent with the asymptotic expression of

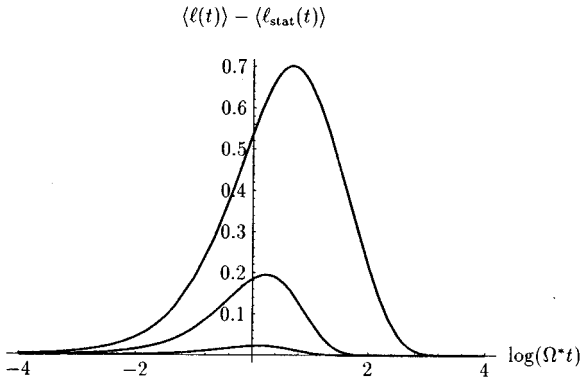

FIG. 4. The dependence of the difference $\langle l(t)\rangle - \langle l_{\text{stat}}(t)\rangle$ between the relaxation function for dynamical nonintermittent fluctuations with self-similar attenuation and the relaxation function for static systems in terms of the logarithm of dimensionless time $\ln(\Omega^* t)$, $\beta=0.6$, $\Omega^*\equiv\Omega/(1+\alpha\beta)=1s^{-1}$, and $\Omega^* t_0=0.1$ for $\alpha=0.1$, 1, 10 (from bottom to top).

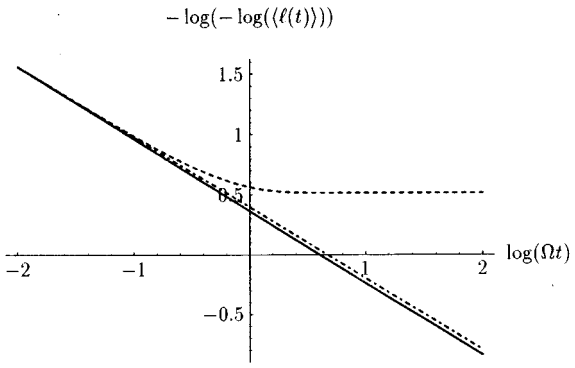

FIG. 5. Average relaxation functions for nonintermittent dynamical fluctuations with exponential attenuation (dashed) and self-similar attenuation (dash-pointed) in comparison with the static stretched exponential law (full line). In the logarithmic coordinates used, the stretched exponential portions of the relaxation functions appear as straight lines: $\beta=0.6$, $\omega_0/\Omega=3$, $\alpha=0.3$, and $\Omega t_0=0.1$.

$\langle l(t)\rangle$ for large time corresponding to this case and presented in Table I. A similar effect can be noticed in Fig. 1(b) corresponding to nonintermittent dynamical disorder with self-similar attenuation. Although in this case the decrease of efficiency of relaxation due to dynamical disorder is less pronounced and eventually as $t\to\infty$ all particles relax, the graph clearly shows that an increase of the attenuation exponent α slows down the relaxation process. Figures 2(a) and 2(b) show some graphs of the average relaxation function for static disorder, dynamical disorder with exponential and self-similar regression for nonintermittent and intermittent fluctuations, respectively. For the consistency of comparison the parameters ω_0, α, and t_0 fulfill the relationship (6.5) so that for dynamical disorder the initial frequency of regression is the same in all cases. In Fig. 2 the same pattern is observed in both cases, that is, the exponential regression leads to incomplete relaxation and, for relatively low values of the attenuation exponent, $1>\alpha\geqslant 0$, the self-similar attenuation leads to relaxation functions which are very close to the functions corresponding to the static case. Significant differences occur only if the attenuation exponent α is bigger than the unity.

The relative insensitivity with respect to the variations of the attenuation exponent α of the average relaxation function for dynamical disorder with self-similar regression is consistent with

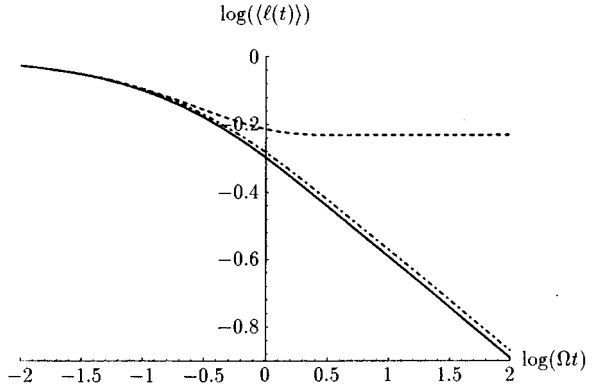

FIG. 6. Average relaxation functions for intermittent dynamical fluctuations with exponential attenuation (dashed) and self-similar attenuation (dash-pointed) in comparison with the intermittent static average relaxation function (full line). In the logarithmic coordinates used, the power law portions of the relaxation functions appear as straight lines: $\beta=0.6$, $\omega_0/\Omega=3$, $\alpha=0.3$, $\Omega t_0=0.1$, and $H=0.5$.

the ubiquity in nature of the stretched exponential. The occurrence of the stretched exponential relaxation for these types of systems is not limited to small values of the exponent α. From Table I it follows that for nonintermittent self-similar dynamical fluctuations a stretched exponential emerges for large times for any values of the exponent α, small or large. In this case the passage from small to large times corresponds to a crossover from a stretched exponential with characteristic frequency Ω to another stretched exponential with a smaller characteristic frequency $\Omega^*=\Omega/(1+\alpha\beta)<\Omega$. Figure 3 displays this crossover phenomenon for different values of the exponent α from very small to very large. For this graph multiple logarithmic coordinates have been used for which the stretched exponential portions of the average relaxation functions appear as straight lines. Stretched exponential portions of the average relaxation functions exist both for small and large times for any values of the exponent α, small or large and all these stretched exponentials have the same exponent β. We emphasize that, even though all these stretched exponentials have the same exponent β, they may actually look very different because their characteristic frequencies may vary very much. This fact is clearly illustrated in Fig. 4.

Figure 5 displays the departure of the different relaxation functions from a stretched exponential in the nonintermittent case. Even for small values of the attenuation rates the exponential regression leads to a large time saturation behavior which is very different from the one described by a stretched exponential. In contrast the self-similar regression leads to a behavior close to the one corresponding to a stretched exponential. Similarly in Fig. 6 the departure from the power law relaxation is investigated for intermittent fluctuations. In this case, too, even for small regression rates the exponential regression leads to incomplete relaxation whereas the self-similar attenuation generates an average relaxation function with a long tail which is close to the one corresponding to the static intermittent case.

The comparative analysis presented in this section shows that for the approach developed in Sec. V the dynamical disorder decreases the efficiency of relaxation. For small regression rates the self-similar attenuation of fluctuations leads to relaxation patterns similar to the ones corresponding to the static processes. For exponential attenuation, however, even the slowest regression rate leads to a different behavior corresponding to incomplete relaxation. For self-similar nonintermittent dynamical disorder the stretched exponential relaxation behavior emerges for large times even if the attenuation exponent α is very large; the corresponding stretched exponentials, although characterized by the same fractal exponent β as in the static case, may be very different from the static stretched exponential, because their characteristic frequencies may vary very much.

VII. DISCUSSION

In this section we discuss some physical implications of the approach suggested in Sec. V. The physical interpretation of the method of computing path averages based on Eqs. (5.6)–(5.17) is related to an apparently obscure mathematical problem, the choice of the initial and boundary conditions for the evolution equations (5.21) or (5.36) for the marginal average $F(W,t)$. In order to ensure the normalization to unity of the average probability density $\varphi(W)dW$ of an individual relaxation rate, for solving the evolution equation (5.28) we have used the boundary condition (5.31). This boundary condition expresses the generation of new fluctuations which are then destroyed by the regression process. In contrast, for solving the partial differential evolution equations (5.21) or (5.36) for the marginal average $F(W,t)$ no such similar boundary conditions have been used. This omission of a boundary condition is required by the main characteristics of the type of dynamical disorder investigated in Sec. V. The main assumption of our approach is that the fluctuations are generated at the beginning of the relaxation process and then they regress as the relaxation process is going on. We start out by considering an initial fluctuation with statistical properties described by the probability density $\varphi_{st}(W)dW$ given by Eq. (5.25), and then we follow its regression during the relaxation process. As time increases, due to the regression process, the channels with high relaxation rates lose their reactivity and their rates become smaller and smaller.

During the relaxation process the size of a set of channels with high relaxation rates is shrinking; of the average number $\langle N^* \rangle$ of channels involved in the process, more and more have low relaxation rates, resulting in the decrease of efficiency described by the model. No mechanism of transition of a channel from a state characterized by a small relaxation rate to a state with a high relaxation rate is supposed to exist for $t>0$. Such a mechanism acts only at the beginning of the process, for $t=0$, when the fluctuations are generated and thus we should impose a boundary condition only for this moment:

$$F(W=W^*,t=0)=\beta/W^*. \tag{7.1}$$

Such a condition, however, does not need to be taken explicitly into account in the computation because it is contained in the initial condition (5.37).

The above considerations are closely related to the physical interpretation of Eq. (5.28) for the time evolution of the probability density $\varphi(W)dW$. From the physical point of view Eq. (5.28) is a stochastic Liouville equation which describes the regression of fluctuations only and it would lead to a probability loss $\int \varphi(W)dW<1$ if the generation of new fluctuations is not taken into account. The introduction of the boundary condition (5.31) compensates the ''probability loss'' due to the regression process by an ''influx of probability fluid'' into the system. In contrast, the compound stochastic Liouville equation (5.17), which describes the relaxation process and Eq. (5.36) derived from it, cannot accomodate a boundary condition of the type (5.31). This limitation is due to the Markovian approximation introduced in Sec. V. Within its framework a given feature of the regression process can be modeled only by assuming that the regression frequency $\omega(t)$ is generally time dependent, resulting in a time-inhomogeneous evolution equation for the overall relaxation process for which a boundary condition of the type (5.31) cannot be formulated in a simple way.

We emphasize that this type of pure regression mechanism without generation of new fluctuations for $t>0$ is the only one which includes the case of the static disorder as a particular case, corresponding to the situation when the rate of regression is equal to zero. If the fluctuations are generated for $t>0$, the system is characterized by dynamical disorder, even if the regression process is missing. Although, at least in principle, this type of dynamical disorder can also be described by the dynamical Huber law (3.7) or by its intermittent analog (4.7), it is different from the type of dynamical disorder considered in Sec. V. Some preliminary research concerning the generation of fluctuations for $t>0$ is presented in Ref. 19; it has been shown that, as expected, this type of dynamical disorder leads to an increase in the efficiency of relaxation, because it generates an increase in the number of channels with high relaxation rates. In particular, if the regression process is missing, this type of dynamical disorder leads to a compressed exponential relaxation described by the average survival function

$$\langle l(t) \rangle \sim \exp(-\text{const } t^{1+\beta}); \quad 1>\beta>0. \tag{7.2}$$

Our analysis has shown that the self-similar regression has the remarkable feature that for small regression rates it does not affect the shape of the average relaxation function, generating only small corrections. Moreover, even for very large regression rates, for large times the process is described by a stretched exponential with the same fractal exponent β as in the static case. These results, which might provide an explanation for the universality of the stretched exponential relaxation law, are consistent with the ideas developed by West[36,37] concerning the insensitivity of the statistical fractal systems to random perturbations. From the mathematical point of view for the model developed in Sec. V, this insensitivity is due to the slow decrease of the relaxation rates in the case of self-similar regression, especially for large times.

At the end of this section we point out an apparent contradiction between the results reported here and the results presented in Ref. 26. In Ref. 26 an analysis of the passage over a fluctuating

activation energy barrier has been suggested based on a path average technique similar to the one used in Sec. V. Although both models assume the existence of a pure regression mechanism for $t>0$, the analysis from Ref. 26 shows that the dynamical disorder leads to an increase of the transparency factor of the barrier which apparently contradicts the results reported here. The explanation of this apparent paradox is simple. In Ref. 26 the regression of fluctuations leads to a decrease in the height of the activation energy barrier, that is, to an increase of the speed of relaxation, whereas for our model the regression of fluctuations leads to small rates.

VIII. CONCLUSIONS

In this paper an attempt has been made to construct dynamical analogs of the stretched exponential relaxation. The main idea of the suggested approach is to search for the asymptotic relaxation laws which emerge in the limit of a very large number of relaxation modes. The mathematical structure of the theory is based on a formal functional generalization of the theory of random point processes for which to each random point a random function is attached. In the limit of very large numbers of relaxation modes two universal relaxation laws have been identified corresponding to nonintermittent and intermittent dynamical fluctuations, respectively. An attempt to evaluate the path averages entering the asymptotic relaxation laws has been made for Markovian systems with pure regression. It has been shown that the regression of fluctuations leads to a decrease of the efficiency of the relaxation process. For nonintermittent fluctuations the process is relatively insensitive to the effect of self-similar attenuation of fluctuations, even for high regression rates. This effect might provide an explanation for the wide applicability of stretched exponential law for describing various relaxation processes with dynamical disorder.

Further research should focus on the evaluation of the path averages for the more general case when there is a competition between the generation and the extinction of fluctuations and on the study of suitable applications. Ideal candidates for the application of the theory are the systems in which a large number of degrees of freedom are involved in the relaxation process, for instance, the protein–ligand interactions,[7] or the ion channel kinetics,[9] where the relaxation modes correspond to a large number of molecular conformations.

ACKNOWLEDGMENTS

The subject of this article has been suggested by a collaboration of MOV and MCM with Dr. B. Schönfisch concerning the analogies between the theory of competitive risks in population biology and the relaxation dynamics in systems with static disorder.

Bi-Hamiltonian structures of the coupled AKNS hierarchy and the coupled Yajima–Oikawa hierarchy

Q. P. Liu
CCAST (World Laboratory), P.O. Box 8730, Beijing 100080, People's Republic of China and Beijing Graduate School (#65), China University of Mining and Technology, Beijing 100083, People's Republic of China[a)]

(Received 18 May 1995; accepted for publication 9 January 1996)

The Hamiltonian theory for the two-component AKNS hierarchy and Yajima–Oikawa hierarchy is considered from the viewpoint of reduction. We show that the second Hamiltonian structures of the former is a Dirac reduction of the sl(3) current algebra, while the latter is related to the classical $W_4^{(3)}$ algebra. © *1996 American Institute of Physics.* [S0022-2488(96)01905-8]

I. INTRODUCTION

The KP hierarchy is universal in the sense that various integrable systems are just special reductions of it. The best known one is the so-called n-reduction, which turns out to be the Gelfand–Dickey hierarchy. Recently, another reduction, known as constrained KP hierarchy, is proposed and studied considerably.[1–4] This hierarchy is the result of generalizing Cao's nonlinearization[5] to the 2+1-dimensional case. Interestingly, as the famous Gelfand–Dickey hierarchy,[6] the constrained KP hierarchy is not only mathematically important, but also has physical relevance. On the one hand, it contains physically applicable models, such as Yajima–Oikawa model[7] and Melnikov model.[8] On the other hand, the constrained KP hierarchy is Bi-Hamiltonian,[4] has Darboux transformation,[9] can be modified,[10] and is relevant to the W algebra theory.[11] We also point out that the constrained KP is shown to be just a special case of a more general restriction of the KP hierarchy.[12]

A generalization of the constrained KP hierarchy is considered.[13] This may be termed as multi-component constrained KP hierarchy, since it is the hierarchy associated with the following Lax operator:

$$L_n=\partial^n+u_{n-2}\partial^{n-2}+\cdots+u_0+\sum_{i=1}^{m} q_i\partial^{-1}r_i\,. \tag{1.1}$$

The corresponding flows may be constructed by means of Fractional Power Method (FPM).[6] In the case $n=1$, one has multi-component AKNS hierarchy, which includes the important coupled nonlinear Schrödinger equation[14] as a special case. For the cases $n=2$ and $n=3$, one has the multi-component generalizations of the Yajima–Oikawa hierarchy and Melnikov hierarchy, respectively. Sidorenko and Strampp[13] further constructed recursion operators for the cases $n=2$ and $n=3$ by means of variational calculus or residue calculus.[15] They claimed that the factorization of their recursion operators leads to bi-Hamiltonian structures for the related hierarchies (see Ref. 16). We remark that while the residue calculus is very effective in constructing Hamiltonian operators, this does not means that each operator calculated this way is Hamiltonian automatically.[15,17] Since these operators are rather complicated, direct proof would be too tedious to do by hand.

This paper is complemental to Sidorenko and Strampp's results.[13] The aim of the paper is twofold: correcting an error of Sidorenko and Strampp and providing a proof for the Hamiltonian

a)Please direct correspondence to this address.

nature of their operators. For simplicity, we will consider the simplest nontrivial cases: two-component cases. We will show that the second Hamiltonian operator of the coupled Yajima–Oikawa hierarchy is the Dirac reduction of the classical $W_4^{(3)}$ algebra. This algebra is calculated by Depireux and Mathieu.[18] Thus, as a by-product, the coupled Yajima–Oikawa hierarchy is shown to be related to this W algebra. This is interesting in its own right. The generalization to the multi-component case will be commented on in due course.

The paper is arranged as follows. The next section is on the two-component AKNS systems. We show that the well-known recursion operator leads to a bi-Hamiltonian structure for this hierarchy. The Hamiltonian nature of the second operator is proved by showing that it is the Dirac reduction of the sl(3) current algebra. In Sec. III we present our main results: giving Sidorenko–Strampp's operator in its correct form and proving its Hamiltonian nature. That is, we prove rigorously that the two-component Yajima–Oikawa hierarchy is bi-Hamiltonian. Section IV contains some comments on generalizations of the results of Secs. II and III.

II. THE COUPLED AKNS HIERARCHY

We consider the two-component AKNS system next. This hierarchy has been known for a long time. In fact, the very important coupled nonlinear Schrödinger equation[14] is a reduction of it. Its recursion operator is already calculated out.[19] However, to the best of my knowledge, a proof of the bi-Hamiltonian for the hierarchy is still not available. Even the hereditary property of the recursion operator is not proved.

We start with the Lax operator

$$L_1=\partial-q_1\partial^{-1}r_1-q_2\partial^{-1}r_2. \tag{2.1}$$

The corresponding flows are

$$L_{1_{t_k}}=[((L_1)^k)_+, L_1], \tag{2.2}$$

where subscript + means the projection to the differential part.

The recursion operator for the hierarchy (2.2)[19] is

$$\mathbf{R}=\begin{bmatrix} R_1 & -q_1\partial^{-1}r_2 & -2q_1\partial^{-1}q_1 & -q_1\partial^{-1}q_2-q_2\partial^{-1}q_1 \\ -q_2\partial^{-1}r_1 & R_2 & -q_1\partial^{-1}q_2-q_2\partial^{-1}q_1 & -2q_2\partial^{-1}q_2 \\ 2r_1\partial^{-1}r_1 & r_1\partial^{-1}r_2+r_2\partial^{-1}r_1 & (R_1)^* & r_1\partial^{-1}q_2 \\ r_1\partial^{-1}r_2+r_2\partial^{-1}r_1 & 2r_2\partial^{-1}r_2 & r_2\partial^{-1}q_1 & (R_2)^* \end{bmatrix}, \tag{2.3}$$

where R_1 and R_2 are defined by

$$R_1=\partial-2q_1\partial^{-1}r_1-q_2\partial^{-1}r_2, \quad R_2=\partial-q_1\partial^{-1}r_1-2q_2\partial^{-1}r_2. \tag{2.4}$$

The recursion operator (2.3) has the following factorization: $\mathbf{R}=\mathbf{B}_1(\mathbf{B}_0)^{-1}$ with

$$\mathbf{B}_0=\begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{bmatrix}, \tag{2.5}$$

and

$$\mathbf{B}_1=\begin{bmatrix} 2q_1\partial^{-1}q_1 & q_1\partial^{-1}q_2+q_2\partial^{-1}q_1 & R_1 & -q_1\partial^{-1}r_2 \\ q_1\partial^{-1}q_2+q_2\partial^{-1}q_1 & 2q_2\partial^{-1}q_2 & -q_2\partial^{-1}r_1 & R_2 \\ -(R_1)^* & -r_1\partial^{-1}q_2 & 2r_1\partial^{-1}r_1 & r_1\partial^{-1}r_2+r_2\partial^{-1}r_1 \\ -r_2\partial^{-1}q_1 & -(R_2)^* & r_1\partial^{-1}r_2+r_2\partial^{-1}r_1 & 2r_2\partial^{-1}r_2 \end{bmatrix}, \tag{2.6}$$

where $\mathbf{R}_i$ $(i=1,2)$ are given by (2.4).

Thus, the hierarchy has the following representation:

$$\mathbf{q}_{t_k}=\mathbf{B}_0\,\frac{\delta H_{k+1}}{\delta \mathbf{q}}=\mathbf{B}_1\,\frac{\delta H_k}{\delta \mathbf{q}}, \tag{2.7}$$

where $\mathbf{q}=(q_1,q_2,r_1,r_2)^T$ and H_k is defined by

$$H_k=\frac{1}{k}\,(\mathrm{Res}(L_1)^k).$$

The explicit form of the first three Hamiltonians is

$$H_1=-(q_1r_1+q_2r_2),\quad H_2=\tfrac{1}{2}(q_1r_{1_x}-r_1q_{1_x}+q_2r_{2_x}-r_2q_{2_x}),\quad H_3=\tfrac{1}{3}(-r_1q_{1_{xx}}-r_2q_{2_{xx}}+q_{1_x}r_{1_x}$$
$$+q_{2_x}r_{2_x}+3q_1^2r_1^2+3q_2^2r_2^2+6q_1q_2r_1r_2-q_1r_{1_{xx}}-q_2r_{2_{xx}}).$$

The first two flows are

$$\begin{aligned} q_{1_{t1}}&=-q_{1_x},\quad q_{2_{t1}}=-q_{2_x}, \\ r_{1_{t1}}&=-r_{1_x},\quad r_{2_{t1}}=-r_{2_x}, \end{aligned} \tag{2.8}$$

and

$$\begin{aligned} q_{1_{t2}}&=-q_{1_{xx}}+2q_1^2r_1+2q_1q_2r_2, \\ q_{2_{t2}}&=-q_{2_{xx}}+2q_2^2r_2+2q_1q_2r_1, \\ r_{1_{t2}}&=r_{1_{xx}}-2r_1^2q_1-2r_1r_2q_2, \\ r_{2_{t2}}&=r_{2^{xx}}-2r_2^2q_2-2q_1r_1r_2. \end{aligned} \tag{2.9}$$

Our next task is to prove the Hamiltonian nature of the operator (2.6). Since this operator is obviously skew-symmetric and compatible with the operator (2.5), the Hamiltonian property of the operator $\mathbf{B}_1$ will lead us to the conclusion: the coupled AKNS hierarchy (2.2) is a well-defined bi-Hamiltonian system.

Remarks:

(1) Two compatible Hamiltonian operators ensure that the resulting recursion operator is hereditary. We should stress that the hereditary property is an important property for a recursion operator since such an operator makes the related flows commute.[16]

(2) We notice that Asano and Kato[20] considered the $N\times N$ AKNS system and one may try to construct the recursion operator of the coupled AKNS hierarchy by some reduction of their

general formula. However, reduction often destroys the hereditary property, so one has to check this property for the reduced operator by hand. This will be a much more involved calculation. To prove our claim, we consider the general sl(3) spectral problem

$$\begin{bmatrix} \phi \\ \phi_1 \\ \phi_2 \end{bmatrix}_x = \begin{bmatrix} \lambda - u_1 & q_1 & q_2 \\ r_1 & u_1+u_2 & v \\ r_2 & w & -\lambda - u_2 \end{bmatrix} \begin{bmatrix} \phi \\ \phi_1 \\ \phi_2 \end{bmatrix} \equiv (\lambda A + U)\Phi, \tag{2.10}$$

now choosing the time evolution of the wave function Φ as $\Phi_t = V\Phi$. Then the zero-curvature representation leads to

$$U_t = \mathbf{P}_U(V) - \lambda \mathbf{Q}_U(V),$$

where the Poisson tensors defined by

$$\mathbf{P}_U = \partial + [\cdot, U], \quad \mathbf{Q}_U = [A, \cdot]$$

introduce a bi-Hamiltonian structure, which is referred as the Zakharov–Shabat bi-Hamiltonian structure (see Ref. 21 and the references there, for example). Our main interest is the second one and a straightforward calculation shows that the explicit form of the $\mathbf{P}_U$, which is denoted by $\mathbf{P}_{(\mathbf{q},\mathbf{u})}$ for convenience, reads as

$$\mathbf{P}_{(\mathbf{q},\mathbf{u})} = \begin{bmatrix} 0 & 0 & \partial + u_2 + 2u_1 & w & -q_1 & 0 & -q_2 & 0 \\ 0 & 0 & v & \partial - u_2 + u_1 & -q_2 & q_2 & 0 & -q_1 \\ \partial - u_2 - 2u_1 & -v & 0 & 0 & r_1 & 0 & 0 & r_2 \\ -w & \partial - u_1 + u_2 & 0 & 0 & r_2 & -r_2 & r_1 & 0 \\ q_1 & q_2 & -r_1 & -r_2 & \frac{2}{3}\partial & -\frac{1}{3}\partial & 0 & 0 \\ 0 & -q_2 & 0 & r_2 & -\frac{1}{3}\partial & \frac{2}{3}\partial & -v & w \\ q_2 & 0 & 0 & -r_1 & 0 & v & 0 & \partial - 2u_2 - u_1 \\ 0 & q_1 & -r_2 & 0 & 0 & -w & \partial + u_1 + 2u_2 & 0 \end{bmatrix}, \tag{2.11}$$

where $\mathbf{q} = (q_1, q_2, r_1, r_2)^T$ and $\mathbf{u} = (u_1, u_2, v, w)^T$.

We remark that this operator leads to so-called sl(3) current algebra.

In order to recover our candidate for the second Hamiltonian structure $\mathbf{B}_1$(2.6) from the Hamiltonian operator $\mathbf{P}_{(\mathbf{q},\mathbf{u})}$, we have to do a reduction by imposing the constraint $\mathbf{u} = 0$. Indeed, the reduction involved here is the so-called Dirac reduction which is discussed by Oevel and Ragnisco.[22] Basically, suppose we are given a space with the coordinates $\mathbf{q}$, $\mathbf{u}$ and a Poisson tensor

$$\mathbf{P}_{(\mathbf{q},\mathbf{u})} = \begin{bmatrix} P_{qq} & P_{qu} \\ P_{uq} & P_{uu} \end{bmatrix}$$

on this space; then the Dirac reduction of $\mathbf{P}_{(\mathbf{q},\mathbf{u})}$ to the subspace spanned by $\mathbf{q}$ is provided by the reduced Hamiltonian operator

$$\mathbf{P}_{\mathbf{q}}^{(\mathrm{red})} = P_{qq}(q,0) - P_{qu}(q,0)(\mathbf{P}_{uu}(q,0))^{-1} P_{uq}(q,0),$$

where the existence of the operator $(P_{uu}(q,0))^{-1}$ is assumed.

In the present case, we have

$$P_{qq}=\begin{bmatrix} 0 & 0 & \partial+u_2+2u_1 & w \\ 0 & 0 & v & \partial-u_2+u_1 \\ \partial-u_2-2u_1 & -v & 0 & 0 \\ -w & \partial-u_1+u_2 & 0 & 0 \end{bmatrix},$$

$$P_{qu}=\begin{bmatrix} -q_1 & 0 & -q_2 & 0 \\ -q_2 & q_2 & 0 & -q_1 \\ r_1 & 0 & 0 & r_2 \\ r_2 & -r_2 & r_1 & 0 \end{bmatrix}, \quad P_{uq}=\begin{bmatrix} q_1 & q_2 & -r_1 & -r_2 \\ 0 & -q_2 & 0 & r_2 \\ q_2 & 0 & 0 & -r_1 \\ 0 & q_1 & -r_2 & 0 \end{bmatrix},$$

$$P_{uu}=\begin{bmatrix} \frac{2}{3}\partial & -\frac{1}{3}\partial & 0 & 0 \\ -\frac{1}{3}\partial & \frac{2}{3}\partial & -v & w \\ 0 & v & 0 & \partial-2u_2-u_1 \\ 0 & -w & \partial+2u_2+u_1 & 0 \end{bmatrix}.$$

Now the elementary calculation shows that the reduced Hamiltonian operator $\mathbf{P}_{\mathbf{q}}^{(\mathrm{red})}$ is nothing but our operator $\mathbf{B}_1$. Thus, we complete our proof.

Remark: The first two flows (2.8) and (2.9) have the following alternative representation:

$$\mathbf{q}_{t_k}=\hat{\mathbf{B}}_0\frac{\delta H_{k+1}}{\delta \mathbf{q}}=\hat{\mathbf{B}}_1\frac{\delta H_k}{\delta \mathbf{q}}, \quad (k=1,2),$$

where $\mathbf{q}=(q_1,q_2,r_1,r_2)^T$, and

$$\hat{\mathbf{B}}_0=\mathbf{B}_0$$

and

$$\hat{\mathbf{B}}_1=\begin{bmatrix} 2q_1\partial^{-1}q_1 & 2q_1\partial^{-1}q_2 & \partial-2q_1\partial^{-1}r_1 & -2q_1\partial^{-1}r_2 \\ 2q_2\partial^{-1}q_1 & 2q_2\partial^{-1}q_2 & -2q_2\partial^{-1}r_1 & \partial-2q_2\partial^{-1}r_2 \\ \partial-2r_1\partial^{-1}q_1 & -2r_1\partial^{-1}q_2 & 2r_1\partial^{-1}r_1 & 2r_1\partial^{-1}r_2 \\ -2r_2\partial^{-1}q_1 & \partial-2r_2\partial^{-1}q_2 & 2r_2\partial^{-1}r_1 & 2r_2\partial^{-1}r_2 \end{bmatrix}.$$

However, it can be shown that this is NOT a bi-Hamiltonian representation for the flows. In fact, it can be proved that the resulting operator $\hat{\mathbf{R}}=\hat{\mathbf{B}}_1(\hat{\mathbf{B}}_0)^{-1}$ is not even hereditary.

III. THE COUPLED YAJIMA–OIKAWA HIERARCHY

The hierarchy we are interested in is associated to the following Lax operator:

$$L_2=\partial^2-u-q_1\partial^{-1}r_1-q_2\partial^{-1}r_2. \tag{3.1}$$

The flows, which may be calculated by means of fractional power method, have the following representation:

$$\mathbf{u}_{t_k}=\mathbf{B}_0\frac{\delta H_{k+1}}{\delta \mathbf{u}}=\mathbf{B}_1\frac{\delta H_k}{\delta \mathbf{u}}, \tag{3.2}$$

where $\mathbf{u}=(u,q_1,q_2,r_1,r_2)^T$ and

$$H_k=\frac{2}{k}\,(\mathrm{Res}(L_2)^{k/2}) \tag{3.3}$$

and

$$\mathbf{B}_0=\begin{bmatrix} -2\partial & 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 0 & 1\\ 0 & -1 & 0 & 0 & 0\\ 0 & 0 & -1 & 0 & 0 \end{bmatrix} \tag{3.4}$$

and

$$\mathbf{B}_1=\begin{bmatrix} -\frac{1}{2}\partial^3+u\partial+\partial u & q_1\partial+\frac{1}{2}\partial q_1 & q_2\partial+\frac{1}{2}\partial q_2 & r_1\partial+\frac{1}{2}\partial r_1 & r_2\partial+\frac{1}{2}\partial r_2\\ \partial q_1+\frac{1}{2}q_1\partial & \frac{3}{2}q_1\partial^{-1}q_1 & I(q_1,q_2) & I_1 & -\frac{1}{2}q_1\partial^{-1}r_2\\ \partial q_2+\frac{1}{2}q_2\partial & I(q_2,q_1) & \frac{3}{2}q_2\partial^{-1}q_2 & -\frac{1}{2}q_2\partial^{-1}r_1 & I_2\\ \partial r_1+\frac{1}{2}r_1\partial & -I_1^* & -\frac{1}{2}r_1\partial^{-1}q_2 & \frac{3}{2}r_1\partial^{-1}r_1 & I(r_1,r_2)\\ \partial r_2+\frac{1}{2}r_2\partial & -\frac{1}{2}r_2\partial^{-1}q_1 & -I_2^* & I(r_2,r_1) & \frac{3}{2}r_2\partial^{-1}r_2 \end{bmatrix}, \tag{3.5}$$

where $I(v_1,v_2)\equiv\frac{1}{2}v_1\partial^{-1}v_2+v_2\partial^{-1}v_1$, $I_1\equiv\partial^2-u-\frac{3}{2}q_1\partial^{-1}r_1-q_2\partial^{-1}r_2$, and $I_2\equiv\partial^2-u-\frac{3}{2}q_2\partial^{-1}r_2-q_1\partial^{-1}r_1$

Remark: We see that the first operator $\mathbf{B}_0$ is the same as the one presented in Ref. 13. However, the second one, $\mathbf{B}_1$, is not their operator. In fact, we may easily show that their operator, which is mistakenly presented, does not qualify as a Hamiltonian operator.

Our next task is to prove that the hierarchy (3.2) is a bi-Hamiltonian system. That is to say, we shall prove $\mathbf{B}_i(i=0,1)$ are compatible Hamiltonian operators. The Hamiltonian property of $\mathbf{B}_0$ and the compatibility condition are obvious. Thus, we need only to prove the Hamiltonian nature of the operator $\mathbf{B}_1$.

Our strategy is the same as before, and we consider the following more general spectral problem:

$$\phi_x=\begin{bmatrix} 0 & 0 & 0 & 1\\ r_2 & w_1 & v_1 & 0\\ r_1 & v_2 & w_2 & 0\\ u+\lambda & q_2 & q_1 & -w_1-w_2 \end{bmatrix}\phi. \tag{3.6}$$

We see that the above form is the one presented in Ref. 18 for the classical $W_4^{(3)}$ algebra from the Hamiltonian reduction approach. To construct the related Hamiltonian structures, we may calculate the Zakharov–Shabat bi-Hamiltonian structure[21] as we did in Sec. II. Since the argument is standard, we just give the results here. Two Hamiltonian operators are defined conveniently by the following Poisson brackets:

$$\{u(x),u(y)\}_0=-2\partial\delta(x-y),\quad \{q_1(x),r_1(y)\}_0=\delta(x-y),\quad \{q_2(x),r_2(y)\}_0=\delta(x-y), \tag{3.7}$$

and

$$\{u(x),u(y)\}_1=(\tfrac{3}{4}(-\partial^3+\partial^2(w_1+w_2)-(w_1+w_2)\partial^2+(w_1+w_2)\partial(w_1+w_2))+u\partial+\partial u)\,\delta(x-y),$$

$$\{u(x),q_1(y)\}_1=(q_1\partial-q_1(w_1+2w_2)-q_2v_1)\delta(x-y),$$

$$\{u(x),q_2(y)\}_1=(q_2\partial-q_2(2w_1+w_2)-q_1v_2)\delta(x-y),$$

$$\{u(x),r_1(y)\}_1=(\partial r_1+r_1\partial+r_1(w_1+2w_2)+r_2v_2)\delta(x-y),$$

$$\{u(x),r_2(y)\}_1=(\partial r_2+r_2\partial+r_2(w_2+2w_1)+r_1v_1)\delta(x-y),$$

$$\{u(x),w_i(y)\}_1=-\tfrac{1}{4}(\partial+w_1+w_2)\partial\delta(x-y),$$

$$\{q_1(x),r_1(y)\}_1=(\partial^2+\partial w_2-u+(w_1+2w_2)(\partial-w_2)+v_1v_2)\delta(x-y),$$

$$\{q_1(x),r_2(y)\}_1=(\partial v_1+v_1\partial+2(w_1+w_2)v_1)\delta(x-y), \tag{3.8}$$

$$\{q_1(x),v_2(y)\}_1=-q_2\delta(x-y),$$

$$\{q_1(x),w_2(y)\}_1=-q_1\delta(x-y),\quad \{q_2(x),r_1(y)\}_1=(\partial v_2+v_2\partial+2(w_1+w_2)v_2)\delta(x-y),$$

$$\{q_2(x),r_2(y)\}_1=(\partial^2+\partial w_1-u+(2w_1+w_2)(\partial+w_1)+v_1v_2)\delta(x-y),$$

$$\{r_1(x),v_1(y)\}_1=r_2\delta(x-y),\quad \{r_1(x),w_2(y)\}_1=r_1\delta(x-y),$$

$$\{r_2(x),v_2(y)\}_1=r_1\delta(x-y),\quad \{r_2(x),w_1(y)\}_1=r_2\delta(x-y),$$

$$\{v_1(x),v_2(y)\}_1=(\partial-w_1+w_2)\delta(x-y),\quad \{v_1(x),w_i(y)\}_1=\mp v_1\delta(x-y),$$

$$\{v_2(x),w_i(y)\}_1=\pm v_2\delta(x-y),\quad \{w_i(x),w_j(y)\}_1=(\delta_{ij}-\tfrac{1}{4})\partial\delta(x-y),$$

where $i,j=1,2$, and all other brackets vanish.

This Poisson bracket algebra (3.8) is equivalent to the classical $W_4^{(3)}$ algebra.[18] We also notice that the spectral problem (3.6) is a special case of the more general problem considered recently by Feher and Marshall.[23] In their notation, our case corresponds to the partition: $n=4=2+1+1(r=2,s=2,p=1)$. Thus, our brackets (3.7) and (3.8) also follow from their general structures.

We see that the first Hamiltonian bracket (3.7) is degenerate in this general case. That means the general flows are not a well-defined bi-Hamiltonian system since we are not able to form the important recursion operator. Therefore, we have to do reduction. Indeed, by Dirac reduction described in the above section, we find that the Poisson bracket (3.8) is reduced to the bracket introduced by the operator $\mathbf{B}_1$. Thus, we recover the second structure $\mathbf{B}_1$ by the Dirac reduction and we complete our proof.

Here we remark that we have a by-product: we find that the coupled Yajima–Oikawa hierarchy (3.2) is the hierarchy related to the classical $W_4^{(3)}$ algebra *directly* in the sense of Ref. 18.

IV. SUMMARY

In this paper, we studied the coupled AKNS hierarchy and coupled Yajima–Oikawa hierarchy from the bi-Hamiltonian viewpoint. We prove rigorously that both hierarchies are well-defined bi-Hamiltonian systems. For the coupled Yajima–Oikawa hierarchy, we corrected an error of Ref. 13. Also, we showed that this hierarchy is just the one related to the classical $W_4^{(3)}$ algebra directly.[18] The present consideration may be generalized to the generic multi-component case although the calculation will be extremely tedious.

It is interesting and important to construct the modified hierarchies of the hierarchies of Secs. II and III. We notice that for the nonreduced hierarchies, this problem is considered in Ref. 23. In general, doing reduction often destroys the related Miura maps, and it is necessary to consider the reduced hierarchies separately.

ACKNOWLEDGMENTS

I would like to thank J. F. Gomes for bringing Ref. 19 into my attention. I would also like to thank the anonymous referee for calling my attention to Ref. 20. It is my pleasure to thank L. Feher, I. Marshall, B. Kupershmidt, and Z. Popowicz for their interests, comments, and suggestions pertaining to an early version of the results.

The $W_{1+\infty}(gl_s)$-symmetries of the s-component KP hierarchy

Johan van de Leur[a)]
University of Twente, Faculty of Applied Mathematics, 7500 AE Enschede, The Netherlands

(Received 25 May 1995; accepted for publication 21 December 1995)

Adler, Shiota, and van Moerbeke obtained for the KP and Toda lattice hierarchies a formula which translates the action of the vertex operator on tau-functions to an action of a vertex operator of pseudodifferential operators on wave functions. This relates the additional symmetries of the KP and Toda lattice hierarchy to the $W_{1+\infty-}$, respectively, $W_{1+\infty} \times W_{1+\infty-}$ algebra symmetries. In this paper we generalize the results to the s-component KP hierarchy. The vertex operators generate the algebra $W_{1+\infty}(gl_s)$, the matrix version of $W_{1+\infty}$. Since the Toda lattice hierarchy is formally equivalent to the 2-component KP hierarchy, the results of this article uncover in that particular case a much richer structure than the one obtained by Adler, Shiota, and van Moerbeke. © *1996 American Institute of Physics.* [S0022-2488(96)02004-X]

I. INTRODUCTION

The KP hierarchy is the set of deformation equations

$$\frac{\partial L}{\partial t_k} = [(L^k)_+, L],$$

for the first-order pseudodifferential operator

$$L \equiv L(x,t) = \partial + u_1(x,t)\partial^{-1} + u_2(x,t)\partial^{-2} + \cdots,$$

here $\partial = \partial/\partial x$ and $t = (t_1, t_2, \ldots)$. It is well-known that L dresses as $L = P\partial P^{-1}$ with

$$P \equiv P(\tau,x,t) = 1 + a_1(x,t)\partial^{-1} + a_2(x,t)\partial^{-2} + \cdots = \frac{\tau(x,t-[\partial^{-1}])}{\tau(x,t)},$$

where τ is the famous τ-function, introduced by the Kyoto group[1–3] and $[z] = (z, z^2/2, z^3/3, \ldots)$.

The wave or Baker–Akhiezer function

$$\Psi \equiv \Psi(\tau,x,t,z) = W(\tau,x,t,\partial)e^{zx},$$

where

$$W \equiv W(\tau,x,t,z) = P(\tau,x,t)e^{\xi(t)} \quad \text{with} \quad \xi(t) = \sum_{k=1}^{\infty} t_k \partial^k$$

is an eigenfunction of L, viz.,

a)Electronic mail: vdleur@math.utwente.nl

$$L\Psi = z\Psi \quad \text{and} \quad \frac{\partial \Psi}{\partial t_k} = (L^k)_+ \Psi .$$

From this point of view, the introduction by Orlov and Schulman[4] of another pseudodifferential operator $M \equiv M(x,t) = WxW^{-1}$ which action on Ψ amounts to

$$M\Psi = \frac{\partial \Psi}{\partial z}$$

is rather natural.

Recently, Adler, Shiota, and van Moerbeke[5,6] proved a conjecture of Orlov and Schulman, viz., that there exists a relation between $(M^l L^{k+l})_-$ acting on Ψ and the generators $W_k^{(l+1)} \sim -t^{k+l}(\partial/\partial t)^l$ of the $W_{1+\infty}$-algebra acting on the τ-function. More explicitly, let

$$Y(\tau,y,w) = \sum_{l=0}^{\infty} \frac{(y-w)^l}{l!} \sum_{k\in\mathbb{Z}} M^l L^{k+l} w^{-k-l-1}$$

be the generating series of the $M^l L^{k+l}$ and let

$$\begin{aligned} W(y,w) &= \sum_{l=0}^{\infty} \frac{(y-w)^l}{l!} \sum_{k\in\mathbb{Z}} W_k^{(l+1)} w^{-k-l-1} \\ &= \frac{1}{y-w} \exp\left(x(y-w) + \sum_{k=1}^{\infty} t_k (y^k - w^k) \right) \exp\left(-\sum_{k=1}^{\infty} \frac{\partial}{\partial t_k} \frac{y^{-k} - w^{-k}}{k} \right) \end{aligned} \tag{1.1}$$

be the vertex operator of the KP hierarchy, then one has the following formula:[5]

$$-Y(\tau,y,w)_-\Psi(\tau,x,t,z) = \Psi(\tau,x,t,z)\left(\exp -\sum_{k=1}^{\infty} \frac{\partial}{\partial t_k} \frac{z^{-k}}{k} - 1 \right)\left(\frac{W(y,w)\tau(x,t)}{\tau(x,t)} \right). \tag{1.2}$$

Dickey gave another proof of this formula.[7] The ''geometric interpretation'' of this Adler–Shiota–van Moerbeke formula is as follows. The transformation $e^{\lambda W(y,w)} = 1 + \lambda W(y,w)$ is a symmetry transformation or a kind of auto-Bäcklund transformation of the KP hierarchy. If one rewrites (1.2) as

$$-\lambda Y(\tau,y,w)_-\Psi(\tau,x,t,z) = \Psi(\tau,x,t,z)\left(\exp -\sum_{k=1}^{\infty} \frac{\partial}{\partial t_k} \frac{z^{-k}}{k} - 1 \right)\left(\frac{e^{\lambda W(y,w)}\tau(x,t)}{\tau(x,t)} \right), \tag{1.3}$$

then one easily sees that (1.2) is in fact a formula that relates this Bäcklund transformation to the so-called additional symmetries of the KP hierarchy. To be more precise, let σ be the new solution of the KP hierarchy which one obtains from τ by this Bäcklund transformation, i.e., $\sigma = e^{\lambda W(y,w)}\tau$, then

$$\begin{aligned} \Psi(\sigma,x,t,z) &= \sigma(x,t)^{-1} \exp -\sum_{k=1}^{\infty} \frac{\partial}{\partial t_k} \frac{z^{-k}}{k} \sigma(x,t) e^{\xi(t)} e^{zx} \\ &= \frac{\tau(x,t)}{\sigma(x,t)} \exp -\sum_{k=1}^{\infty} \frac{\partial}{\partial t_k} \frac{z^{-k}}{k} \left(\frac{e^{\lambda W(y,w)}\tau(x,t)}{\tau(x,t)} \right) \Psi(\tau,x,t,z) \\ &= \Psi(\tau,x,t,z) + \frac{\tau(x,t)}{\sigma(x,t)} \left(\exp -\sum_{k=1}^{\infty} \frac{\partial}{\partial t_k} \frac{z^{-k}}{k} - 1 \right)\left(\frac{e^{\lambda W(y,w)}\tau(x,t)}{\tau(x,t)} \right) \Psi(\tau,x,t,z). \end{aligned}$$

Now using (1.3) one obtains

$$\Psi(\sigma,x,t,z)=\left(1-\lambda\,\frac{\tau(x,t)}{\sigma(x,t)}\,Y(\tau,y,w)_-\right)\Psi(\tau,x,t,z).$$

Hence $Y(\tau,y,w)_-$ produces, as a consequence of formula (1.2), the Bäcklund transformation of the wave function corresponding to τ.

Adler, Shiota, and van Moerbeke also treated in Ref. 6 the Toda lattice hierarchy of Ueno and Takasaki[8] and showed that an analogous formula also holds. In their treatment they considered two vertex operators, each depending on a different time flow $t^{(j)}=(t_1^{(j)},t_2^{(j)},\ldots)$, $j=1,2$, of a form similar to that of (1.1). Hence The $W_{1+\infty}$-algebra of the KP hierarchy is replaced by two copies of this algebra.

Using 2×2-matrix pseudodifferential operators instead of infinite shift operators, one can show that the Toda lattice hierarchy is formally equivalent to the 2-component KP hierarchy as treated by Kac and the author in Ref. 9. In that case there are however more vertex operators than only the ones of the form (1.1), viz., one also has

$$W^{(ab)}(y,w)=\frac{C^{(ab)}(y,w)}{(y-w)^{\delta_{ab}}}\exp\left(x(y-w)+\sum_{k=1}^{\infty}(t_k^{(a)}y^k-t_k^{(b)}w^k)\right)$$
$$\times\exp-\sum_{k=1}^{\infty}\frac{1}{k}\left(\frac{\partial}{\partial t_k^{(a)}}\,y^{-k}-\frac{\partial}{\partial t_k^{(b)}}\,w^{-k}\right),$$

here $C^{(ab)}(y,w)$ are operators that act on the twisted group algebra of the root lattice of sl_2. A natural question now is: Are there also matrix pseudodifferential operators such that a formula as (1.2) hold for these $W^{(ab)}(y,w)$? In this article we show that a similar result holds, not only for the 2-component KP hierarchy, but in general for the s-component KP hierarchy. One finds that the natural generalization of $W_{1+\infty}$ is not $(W_{1+\infty})^s$ but $W_{1+\infty}(gl_s)$, the central extension of the algebra of differential operators on $(\mathbb{C}[t,t^{-1}])^s$. Hence one can conclude, at least formally as we will show in Sec. VII, that the results of Ref. 6 for the Toda lattice hierarchy are not complete, but that the structure is richer.

It is a pleasure to thank Gerard Helminck, Peter van den Heuvel, Pierre van Moerbeke, and Takahiro Shiota, for useful discussions.

II. a_∞ AND THE KP HIERARCHY IN THE FERMIONIC PICTURE (REF. 9)

Consider the infinite dimensional complex Lie algebra $a_\infty := \overline{gl_\infty}\oplus\mathbb{C}c$, where

$$\overline{gl_\infty}=\{a=(a_{ij})_{i,j\in\mathbb{Z}+1/2}\,|\,a_{ij}=0 \quad \text{if} \quad |i-j|\gg 0\},$$

with Lie bracket defined by

$$[a+\alpha c,b+\beta c]=ab-ba+\mu(a,b)c, \tag{2.1}$$

for $a,b\in\overline{gl_\infty}$ and $\alpha,\beta\in\mathbb{C}$. Here μ is the following 2-cocycle:

$$\mu(E_{ij},E_{kl})=\delta_{il}\delta_{jk}(\theta(i)-\theta(j)) \tag{2.2}$$

with E_{ij} the matrix that has a 1 on the (i,j)-th entry and zeros elsewhere and θ: $\mathbb{R}\to\mathbb{C}$ the function defined by

$$\theta(i):=\begin{cases}0 & \text{if } i>0,\\ 1 & \text{if } i\leqslant 0.\end{cases} \tag{2.3}$$

Let $\mathbb{C}^\infty = \oplus_{j\in\mathbb{Z}+1/2}\mathbb{C}v_j$ be the infinite dimensional complex vector space with fixed basis $\{v_j\}_{j\in\mathbb{Z}+1/2}$. The Lie algebra a_∞ acts linearly on $\mathbb{C}^\infty$ via the usual formula:

$$E_{ij}(v_k)=\delta_{jk}v_i\,.$$

We introduce, following Ref. 10, the corresponding semi-infinite wedge space $F=\Lambda^{1/2\infty}\mathbb{C}^\infty$, this is the vector space with a basis consisting of all semi-infinite monomials of the form $v_{i_1}\wedge v_{i_2}\wedge v_{i_3}\cdots$, where $i_1>i_2>i_3>\cdots$ and $i_{l+1}=i_l-1$ for $l\gg 0$. In order to describe representations of the Lie algebra on this space, we find it convenient to define wedging and contracting operators ψ_j^- and ψ_j^+ $(j\in\mathbb{Z}+\frac{1}{2})$ on F by

$$\psi_j^-(v_{i_1}\wedge v_{i_2}\wedge\cdots)=\begin{cases}0, & \text{if} \quad j=-i_s \ \text{ for some } \ s\\ (-1)^s v_{i_1}\wedge v_{i_2}\cdots\wedge v_{i_s}\wedge v_{-j}\wedge v_{i_{s+1}}\wedge\cdots\,, & \text{if} \quad i_s>-j>i_{s+1},\end{cases}$$

$$\psi_j^+(v_{i_1}\wedge v_{i_2}\wedge\cdots)=\begin{cases}0, & \text{if} \quad j\neq i_s \ \text{ for some } \ s\\ (-1)^{s+1} v_{i_1}\wedge v_{i_2}\cdots\wedge v_{i_{s-1}}\wedge v_{i_{s+1}}\wedge\cdots\,, & \text{if} \quad j=i_s\,.\end{cases}$$

These wedging and contracting operators satisfy the following relations $(i,j\in\mathbb{Z}+\frac{1}{2},\lambda,\mu=+,-)$:

$$\psi_i^\lambda\psi_j^\mu+\psi_j^\mu\psi_i^\lambda=\delta_{\lambda,-\mu}\delta_{i,-j}\,, \tag{2.4}$$

hence they generate a Clifford algebra, which we denote by $\mathcal{C}l$.

Introduce the following elements of $F(m\in\mathbb{Z})$:

$$|-m\rangle=v_{m-1/2}\wedge v_{m-3/2}\wedge v_{m-5/2}\wedge\cdots\,.$$

It is clear that F is an irreducible $\mathcal{C}l$-module such that $\psi_j^\pm|0\rangle=0$ for $j>0$. Define a representation $\hat{r}$ of a_∞ on F by

$$\hat{r}(E_{ij})=:\psi_{-i}^-\psi_j^+:, \quad \hat{r}(c)=I, \tag{2.5}$$

where : : stands for the *normal ordered product* defined in the usual way $(\lambda,\mu=+ \text{ or } -)$:

$$:\psi_k^\lambda\psi_l^\mu:=\begin{cases}\psi_k^\lambda\psi_l^\mu, & \text{if} \quad l\geqslant k\\ -\psi_l^\mu\psi_k^\lambda, & \text{if} \quad l<k.\end{cases} \tag{2.6}$$

Define the *charge decomposition*

$$F=\bigoplus_{m\in\mathbb{Z}}F^{(m)} \tag{2.7}$$

by letting

$$\text{charge}(|0\rangle)=0 \quad \text{and} \quad \text{charge}(\psi_j^\pm)=\pm 1. \tag{2.8}$$

It is easy to see that each $F^{(m)}$ is an irreducible a_∞-highest weight module with highest weight vector $|m\rangle$.

We are now able to define the *KP hierarchy in the fermionic picture*, it is the equation

$$\sum_{k\in\mathbb{Z}+\frac{1}{2}}\psi_k^+\tau\otimes\psi_{-k}^-\tau=0, \tag{2.9}$$

for $\tau \in F^{(0)}$. One can prove (see, e.g., Ref. 10 or 11) that this equation characterizes the group orbit of the vacuum vector $|0\rangle$ for the the group GL_∞. Since the group does not play an important role in this article, we will not introduce it here.

III. $W_{1+\infty}(gl_s)$ AS SUBALGEBRA OF a_∞

Let e_i, $1 \leqslant i \leqslant s$ be a basis of $\mathbb{C}^s$. By identifying $(\mathbb{C}[t,t^{-1}])^s$ with $\mathbb{C}^\infty$, we can embed $W_{1+\infty}(gl_s)$ into a_∞. This, however, can be done in many different ways, the simplest one is the following. We put $(1 \leqslant a \leqslant s,\ j \in \mathbb{Z}+\frac{1}{2})$:

$$v_j^{(a)} = v_{sj+(1/2)(s-2a+1)} = t^{-j-1/2} e_a, \quad \psi_j^{\pm(a)} = \psi^{\pm}_{sj\pm(1/2)(s-2a+1)}. \tag{3.1}$$

Notice that with this relabeling we have: $\psi_k^{\pm(a)}|0\rangle = 0$ for $k > 0$. We introduce the generating series of the fermions, the so-called fermionic fields $(z \in \mathbb{C}^\times)$:

$$\psi^{\pm(a)}(z) \overset{\text{def}}{=} \sum_{k \in \mathbb{Z}+\frac{1}{2}} \psi_k^{\pm(a)} z^{-k-1/2}. \tag{3.2}$$

We also rewrite the E_{jk}'s:

$$E_{j,k}^{(ab)} = E_{sj+(1/2)(s-sa+1),sk+(1/2)(s-2b+1)}, \tag{3.3}$$

then $\hat{r}(E_{jk}^{(ab)}) = :\psi_{-j}^{-(a)} \psi_k^{+(b)}:$.

We can associate to $(\mathbb{C}[t,t^{-1}])^s$ the Lie algebra of differential operators on this space, it has as basis the operators:

$$-t^{k+l}\left(\frac{\partial}{\partial t}\right)^l e_{ij}, \quad \text{for} \quad k \in \mathbb{Z}, \quad l \in \mathbb{Z}_+, \quad 1 \leqslant i,j \leqslant s.$$

We will denote this Lie algebra by $D(gl_s)$. We can embed this algebra via (3.1) into $\overline{gl_\infty}$ and also into a_∞, one finds

$$-t^{k+l}\left(\frac{\partial}{\partial t}\right)^l e_{ij} \mapsto \sum_{m \in \mathbb{Z}} -m(m-1)\cdots(m-l+1) E^{(ij)}_{-m-k-1/2,-m-1/2}. \tag{3.4}$$

It is straightforward, but rather tedious, to calculate the corresponding 2-cocycle, the result is as follows (see also Refs. 12–14). Let $f(t), g(t) \in \mathbb{C}[t,t^{-1}]$ and $a,b \in gl_s$ then

$$\mu\left(f(t)\left(\frac{\partial}{\partial t}\right)^l a, g(t)\left(\frac{\partial}{\partial t}\right)^m b\right) = \frac{l!m!}{(l+m+1)!} \operatorname{Res}_{t=0} dt\ f^{(m+1)}(t) g^{(l)}(t) \operatorname{trace}(ab).$$

Hence in this way we get a central extension $W_{1+\infty}(gl_s) = D(gl_s) \oplus \mathbb{C}c$ of $D(gl_s)$ with Lie bracket

$$\begin{aligned}\left[f(t)\left(\frac{\partial}{\partial t}\right)^l a + \alpha c, g(t)\left(\frac{\partial}{\partial t}\right)^m b + \beta c\right] &= f(t)\left(\frac{\partial}{\partial t}\right)^l g(t)\left(\frac{\partial}{\partial t}\right)^m ab - g(t)\left(\frac{\partial}{\partial t}\right)^m f(t)\left(\frac{\partial}{\partial t}\right)^l ba \\ &\quad + \mu\left(f(t)\left(\frac{\partial}{\partial t}\right)^l a, g(t)\left(\frac{\partial}{\partial t}\right)^m b\right) c.\end{aligned} \tag{3.5}$$

Since we have the representation $\hat{r}$ of a_∞, we find that

$$\hat{r}\left(-t^{k+l}\left(\frac{\partial}{\partial t}\right)^l e_{ba}\right) = \sum_{m \in \mathbb{Z}} m(m-1)\cdots(m-l+1) :\psi^{+(a)}_{-m-1/2} \psi^{-(b)}_{m+k+1/2}:.$$

In terms of the fermionic fields (3.2), we find

$$\sum_{k\in\mathbb{Z}} \hat{r}\left(-t^{k+l}\left(\frac{\partial}{\partial t}\right)^l e_{ba}\right) z^{-k-l-1} =: \frac{\partial^l \psi^{+(a)}(z)}{\partial z^l}\, \psi^{-(b)}(z):. \tag{3.6}$$

Now define

$$W_k^{(ab,l+1)} := \hat{r}\left(-t^{k+l}\left(\frac{\partial}{\partial t}\right)^l e_{ba}\right), \quad W^{(ab,l+1)}(z) := \sum_{k\in\mathbb{Z}} W_k^{(ab,l+1)} z^{-k-l-1}, \tag{3.7}$$

then

$$\begin{aligned} W^{(ab)}(y,z) :=: \psi^{+(a)}(y)\psi^{-(b)}(z): &= \sum_{l=0}^{\infty} \frac{(y-z)^l}{l!}\, W^{(ab,l+1)}(z) \\ &= \sum_{l=0}^{\infty} \frac{(y-z)^l}{l!} \sum_{k\in\mathbb{Z}} W_k^{(ab,l+1)} z^{-k-l-1}. \end{aligned} \tag{3.8}$$

IV. THE *s*-COMPONENT BOSON FERMION CORRESPONDENCE

Using a bosonization one can rewrite (2.9) as a system of partial differential equations and express the basis elements of $W_{1+\infty}(gl_s)$ in terms of vertex operators. We begin by introduce bosonic fields ($1\leqslant i\leqslant s$):

$$\alpha^{(i)}(z) \equiv \sum_{k\in\mathbb{Z}} \alpha_k^{(i)} z^{-k-1} \overset{\text{def}}{=} :\psi^{-(i)}(z)\psi^{+(i)}(z):. \tag{4.1}$$

Since $\alpha^{(i)}(z) = -W^{(ii,1)}(z)$, one easily checks that the operators $\alpha_k^{(i)}$ satisfy the canonical commutation relation of the associative oscillator algebra, which we denote by $\mathfrak{a}$:

$$[\alpha_k^{(i)}, \alpha_l^{(j)}] = k\,\delta_{ij}\delta_{k,-l}, \tag{4.2}$$

and one has

$$\alpha_k^{(i)}|m\rangle = 0 \quad \text{for} \quad k>0. \tag{4.3}$$

It is easy to see that restricted to $\hat{gl}_s$, which is the subalgebra generated by the elements $W_k^{(ij,1)}$, $F^{(0)}$ is its basic highest weight representation (see Ref. 15, Chap. 12).

We will now describe the s-component boson–fermion correspondence (see Ref. 9). Let L be a lattice with a basis $\delta_1,\ldots,\delta_s$ over $\mathbb{Z}$ and the symmetric bilinear form $(\delta_i|\delta_j) = \delta_{ij}$, where δ_{ij} is the Kronecker symbol. Let

$$\epsilon_{ij} = \begin{cases} -1, & \text{if} \quad i>j \\ 1, & \text{if} \quad i\leqslant j \end{cases}. \tag{4.4}$$

Define a bimultiplicative function ϵ: $L\times L\to\{\pm 1\}$ by letting

$$\epsilon(\delta_i,\delta_j) = \epsilon_{ij}. \tag{4.5}$$

Let $\delta = \delta_1+\cdots+\delta_s$, $Q = \{\gamma\in L|(\delta|\gamma)=0\}$, $\Delta = \{\alpha_{ij} := \delta_i-\delta_j | i,j=1,\ldots,s, i\neq j\}$. Of course Q is the root lattice of $sl_s(\mathbb{C})$, the set Δ being the root system.

Consider the vector space $\mathbb{C}[L]$ with basis e^{γ}, $\gamma\in L$, and the following twisted group algebra product:

$$e^{\alpha}e^{\beta}=\epsilon(\alpha,\beta)e^{\alpha+\beta}. \tag{4.6}$$

Let $\mathbb{C}[t]$ be the space of polynomials in indeterminates $t=\{t_k^{(i)}\}$, $k=1,2,...$, $i=1,2,\ldots,s$ and denote by $B=\mathbb{C}[t]\otimes_c\mathbb{C}[L]$ be the tensor product of these algebras. Then the s-component boson–fermion correspondence is the vector space isomorphism

$$\sigma: F \xrightarrow{\sim} B, \tag{4.7}$$

given by $\sigma(|0\rangle)=1$ and

$$\sigma\psi^{\pm(a)}(z)\sigma^{-1}=e^{\pm\delta_a z^{\pm\delta_a}}\exp\left(\pm\sum_{k=1}^{\infty}t_k^{(a)}z^k\right)\exp\left(\mp\sum_{k=1}^{\infty}\frac{\partial}{\partial t_k^{(a)}}\frac{z^{-k}}{k}\right), \tag{4.8}$$

where

$$\delta_a(p(t)\otimes e^{\gamma})=(\delta_a|\gamma)p(t)\otimes e^{\gamma}. \tag{4.9}$$

The transported charge then is as follows:

$$\text{charge}(p(t)\otimes e^{\gamma})=(\delta|\gamma).$$

We denote the transported charge decomposition by $B=\oplus_{m\in\mathbb{Z}}B^{(m)}$, then the transported action of the operators $\alpha_m^{(i)}$ is given by

$$\begin{cases}\sigma\alpha_{-m}^{(j)}\sigma^{-1}(p(t)\otimes e^{\gamma})=mt_m^{(j)}p(t)\otimes e^{\gamma}, & \text{if} \quad m>0,\\ \sigma\alpha_m^{(j)}\sigma^{-1}(p(t)\otimes e^{\gamma})=\dfrac{\partial p(t)}{\partial t_m}\otimes e^{\gamma}, & \text{if} \quad m>0,\\ \sigma\alpha_0^{(j)}\sigma^{-1}(p(t)\otimes e^{\gamma})=(\delta_j|\gamma)p(t)\otimes e^{\gamma}.\end{cases} \tag{4.10}$$

If one substitutes (4.8) into (3.8), one obtains the following vertex operator expression for the generating series of the fields $W^{(ab,l+1)}(z)$:

$$W^{(ab)}(y,z)=\frac{1}{(y-z)^{\delta_{ab}}}(X^{(ab)}(y,z)-\delta_{ab}),$$

where

$$X^{(ab)}(y,z)=\epsilon(\delta_a,\delta_b)e^{\delta_a-\delta_b}y^{\delta_a}z^{-\delta_b}\widetilde{X}^{(ab)}(y,z), \tag{4.11}$$

and

$$\widetilde{X}^{(ab)}(y,z)=\exp\left(\sum_{k=1}^{\infty}(t_k^{(a)}y^k-t_k^{(b)}z^k)\right)\exp\left(-\sum_{k=1}^{\infty}\left(\frac{\partial}{\partial t_k^{(a)}}\frac{y^{-k}}{k}-\frac{\partial}{\partial t_k^{(b)}}\frac{z^{-k}}{k}\right)\right).$$

The fields for which $l=0$, give the vertex operator realization of the homogeneous realization of $\hat{gl}_s$, which was first found by Frenkel and Kac[16] and independently by Segal[17] (see also Ref. 18 for more details).

Using the isomorphism σ we can reformulate the KP hierarchy (2.9) in the bosonic picture. We start by observing that (2.9) can be rewritten as follows:

$$\mathrm{Res}_{z=0}\, dz\left(\sum_{j=1}^{s}\psi^{+(j)}(z)\tau\otimes\psi^{-(j)}(z)\tau\right)=0,\quad \tau\in F^{(0)}. \tag{4.12}$$

Notice that for $\tau\in F^{(0)}$, $\sigma(\tau)=\Sigma_{\gamma\in Q}\,\tau_\gamma(t)e^\gamma$. Here and further we write $\tau_\gamma(t)e^\gamma$ for $\tau_\gamma(t)\otimes e^\gamma$. Using (4.8), Eq. (4.12) turns under $\sigma\otimes\sigma: F\otimes F\xrightarrow{\sim}\mathbb{C}[t,t']\otimes(\mathbb{C}[L]\otimes\mathbb{C}[L'])$ into the following set of equations; for all $\alpha,\beta\in L$ such that $(\alpha|\delta)=-(\beta|\delta)=1$ we have:

$$\mathrm{Res}_{z=0}\left(dz\sum_{j=1}^{s}\epsilon(\delta_j,\alpha-\beta)z^{(\delta_j|\alpha-\beta-2\delta_j)}\exp\left(\sum_{k=1}^{\infty}(t_k^{(j)}-t_k^{(j)'})z^k\right)\right.$$
$$\left.\times\exp\left(-\sum_{k=1}^{\infty}\left(\frac{\partial}{\partial t_k^{(j)}}-\frac{\partial}{\partial t_k^{(j)'}}\right)\frac{z^{-k}}{k}\right)\tau_{\alpha-\delta_j}(t)(e^\alpha)\tau_{\beta+\delta_j}(t')(e^\beta)'\right)=0. \tag{4.13}$$

Notice that if $s=2$, the set of equations (4.13) are formally equivalent (for more general τ) to the Toda lattice hierarchy of Ueno and Takasaki.[8] For this reason, *we assume from now on that* $\tau=\Sigma\tau_\alpha e^\alpha$ *is any solution of* (4.13). Hence formally the results of this article also hold for the Toda lattice hierarchy, as we will show explicitly in Sec. VII.

In order to define the equations (4.13) in terms of formal pseudodifferential operators it will be convenient to replace $t_k^{(j)}$ by $t_k^{(j)}+\delta_{k,1}x$ and to introduce the notations

$$\xi^{(j)}(t,z)=\sum_{i=1}^{\infty}t_i^{(j)}z^i,\quad \xi^{(j)}(x,t,z)=zx+\xi^{(j)}(t,z)$$

and

$$\eta^{(j)}(t,z)=\sum_{i=1}^{\infty}\frac{\partial}{\partial t_i^{(j)}}\frac{z^{-i}}{i}.$$

Next we replace α resp. β by $\alpha+\delta_i$ and $\beta-\delta_k$ then for all $\alpha,\beta\in Q$ and $1\leqslant i,k\leqslant s$ (4.13) turns into

$$\mathrm{Res}_{z=0}\, dz\left(\sum_{j=1}^{s}\epsilon(\delta_j,\alpha+\delta_i-\beta+\delta_k)z^{(\delta_j|\alpha-\beta+\delta_i+\delta_k-2\delta_j)}\right.$$
$$\times e^{\xi^{(j)}(x,t,z)-\xi^{(j)}(x',t',z)}e^{-\eta^{(j)}(t,z)+\eta^{(j)}(t',z)}\tau_{\alpha+\delta_i-\delta_j}(x,t)$$
$$\left.\times(e^{\alpha+\delta_j})\tau_{\beta+\delta_j-\delta_k}(x',t')(e^{\beta-\delta_k})'\right)=0. \tag{4.14}$$

V. THE ALGEBRA OF FORMAL PSEUDODIFFERENTIAL OPERATORS AND THE *s*-COMPONENT KP HIERARCHY AS A DYNAMICAL SYSTEM

We proceed now to rewrite the formulation (4.14) of the s-component KP hierarchy in terms of formal pseudodifferential operators, generalizing the results of Refs. 1–3. For more details see Ref. 9. For each $\alpha\in\mathrm{supp}\,\tau:=\{\alpha\in Q\,|\,\tau=\Sigma_{\alpha\in Q}\,\tau_\alpha e^\alpha,\tau_\alpha\neq 0\}$ we define the (matrix valued) functions

$$\Psi^{\pm}(\alpha,z)\equiv\Psi^{\pm}(\tau_\alpha,x,t,z)=(\Psi^{+}_{ij}(\tau_\alpha,x,t,z))_{i,j=1}^{s} \tag{5.1}$$

as follows:

$$\Psi_{ij}^{\pm}(\tau_\alpha,x,t,z)\overset{\text{def}}{=}\epsilon(\delta_j,\alpha+\delta_i)z^{(\delta_j|\pm\alpha+\delta_i-\delta_j)}e^{\pm\xi^{(j)}(x,t,z)}e^{\mp\eta^{(j)}(t,z)}\tau_{\alpha\pm(\delta_i-\delta_j)}(x,t)/\tau_\alpha(x,t)$$
$$=\epsilon(\delta_j,\alpha+\delta_i)z^{(\delta_j|\pm\alpha+\delta_i-\delta_j)}\tau_{\alpha\pm(\delta_i-\delta_j)}(x,t^{(k)}\mp\delta_{jk}[z^{-1}])/$$
$$\tau_\alpha(x,t)e^{\pm\xi^{(j)}(x,t,z)},\tag{5.2}$$

where $[w]=(w,w^2/2,w^3/3,\ldots)$. It is easy to see that Eq. (4.14) is equivalent to the following bilinear identity:

$$\mathrm{Res}_{z=0}\ \Psi^+(\tau_\alpha,x,t,z)^t\Psi^-(\tau_\beta,x',t',z)dz=0\quad\text{for all}\quad\alpha,\beta\in Q.\tag{5.3}$$

Define $s\times s$ matrices $S^{\pm(m)}(\tau_\alpha,x,t)$ by the following generating series [cf. (5.2)]:

$$\sum_{m=0}^{\infty}S_{ij}^{\pm(m)}(\tau_\alpha,x,t)(\pm z)^{-m}=\epsilon_{ji}z^{\delta_{ij}-1}e^{\mp\eta(t,z)}\tau_{\alpha\pm(\delta_i-\delta_j)}(x,t)/\tau_\alpha(x,t)$$
$$=\epsilon_{ji}z^{\delta_{ij}-1}\tau_{\alpha\pm(\delta_i-\delta_j)}(x,t^{(k)}\mp\delta_{jk}[z^{-1}])/\tau_\alpha(x,t).\tag{5.4}$$

We see from (5.2) that $\Psi^{\pm}(\tau_\alpha,x,t,z)$ can be written in the following form:

$$\Psi^{\pm}(\tau_\alpha,x,t,z)=\left(\sum_{m=0}^{\infty}S^{\pm(m)}(\tau_\alpha,x,t)R^{\pm}(\alpha,\pm z)(\pm z)^{-m}\right)e^{\pm\xi(x,t,z)},\tag{5.5}$$

where

$$R^{\pm}(\alpha,z)=\sum_{i=1}^{s}\epsilon(\delta_i,\alpha)e_{ii}(\pm z)^{\pm(\delta_i|\alpha)}.\tag{5.6}$$

As before e_{ij} stands for the $s\times s$ matrix whose (i,j) entry is 1 and all other entries are zero. Let

$$\partial=\frac{\partial}{\partial x},$$

we can now rewrite $\Psi^{\pm}(\tau_\alpha,x,t,z)$ in terms of formal pseudodifferential operators, define

$$e^{\pm\xi(t,\pm\partial)}=\sum_{j=1}^{s}e^{\pm\xi^{(j)}(t,\pm\partial)}e_{jj},$$

$$P^{\pm}(\alpha)\equiv P^{\pm}(\tau_\alpha,x,t,\partial)=I_s+\sum_{m=1}^{\infty}S^{\pm(m)}(\tau_\alpha,x,t)\partial^{-m},\tag{5.7}$$

$$R^{\pm}(\alpha)\equiv R^{\pm}(\alpha,\partial)\quad\text{and}\quad W^{\pm}(\alpha)\equiv W^{\pm}(\tau_\alpha,x,t,z)=P^{\pm}(\alpha)R^{\pm}(\alpha)e^{\pm\xi(t,\pm\partial)}$$

then

$$\Psi^{\pm}(\tau_\alpha,x,t,z)=W^{\pm}(\alpha)e^{\pm zx}=P^{\pm}(\alpha)R^{\pm}(\alpha)e^{\pm\xi(t,\pm\partial)}e^{\pm zx}.\tag{5.8}$$

As usual one denotes the differential part of $P(x,t,\partial)$ by $P_+(x,t,\partial)=\Sigma_{j\geqslant 0}\ P_j(x,t)\partial^j$, and writes $P_-=P-P_+$. The linear anti-involution $*$ is defined by the following formula:

$$\left(\sum_j P_j\partial^j\right)^* = \sum_j (-\partial)^j \circ {}^tP_j. \tag{5.9}$$

Here and further ${}^tP$ stands for the transpose of the matrix P. Then one has the following fundamental lemma:

Lemma 5.1: Let P,Q be two formal pseudodifferential operators, then

$$(PQ^*) = \sum_{i<0} R_i\partial^i$$

if and only if

$$\mathrm{Res}_{z=0}\, dz(P(x,\partial)e^{zx})^t(Q(x',\partial')e^{-zx'}) = \sum_{i<0} R_i(x)\,\frac{(x-x')^{-i-1}}{(-i-1)!}.$$

Proof: Let $y=x-x'$, $P(x,z)=\Sigma P_i(x)z^i$ and $Q(x,z)=\Sigma Q_i(x)(-z)^i$, then

$$\begin{aligned}
\mathrm{Res}_{z=0}\, dz(P(x,\partial)e^{zx})^t(Q(x',\partial')e^{-zx'}) &= \mathrm{Res}_{z=0}\, dz\; P(x,z)\sum_{k\geqslant 0}\frac{(-1)^k}{k!}\frac{\partial^k\,{}^tQ(x,-z)}{\partial x^k}y^k e^{zy}\\
&= \mathrm{Res}_{z=0}\, dz \sum_{k,l\geqslant 0,i,j}\frac{(-1)^k}{k!}P_i(x)\frac{\partial^k\,{}^tQ_j(x)}{\partial x^k}\frac{y^{k+l}}{l!}z^{i+j+l}\\
&= \sum_{k\geqslant 0,i+j\leqslant -1}\frac{(-1)^k}{k!(-i-j-1)!}P_i(x)\frac{\partial^k\,{}^tQ_j(x)}{\partial x^k}y^{k-i-j-1}\\
&= \sum_{k\geqslant 0,i+j\leqslant -1}\binom{i+j}{k}P_i(x)\frac{\partial^k\,{}^tQ_j(x)}{\partial x^k}\frac{y^{k-i-j-1}}{(k-i-j-1)!}.
\end{aligned} \tag{5.10}$$

Next we calculate

$$\begin{aligned}
(P(x,\partial)Q^*(x,\partial))_- &= \left(\sum_{i,j} P_i(x)\partial^{i+j}\,{}^tQ_j(x)\right)_-\\
&= \left(\sum_{k\geqslant 0,i,j}\binom{i+j}{k}P_i(x)\frac{\partial^k\,{}^tQ_j(x)}{\partial x^k}\partial^{i+j-k}\right)_-\\
&= \left(\sum_{k\geqslant 0,i+j-k<0}\binom{i+j}{k}P_i(x)\frac{\partial^k\,{}^tQ_j(x)}{\partial x^k}\partial^{i+j-k}\right)_-\\
&= \sum_{k\geqslant 0,i+j\leqslant -1}\binom{i+j}{k}P_i(x)\frac{\partial^k\,{}^tQ_j(x)}{\partial x^k}\partial^{i+j-k},
\end{aligned} \tag{5.11}$$

here we have used the fact that $\binom{i+j}{k}=0$ if $i+j>0$ and $i+j-k<0$. Now comparing (5.10) and (5.11) gives the desired result. □

Using this lemma one deduces the following

$$(W^+(\tau_\alpha,x,t,\partial)W^-(\tau_\beta,x,t',\partial)^*)_- = 0. \tag{5.12}$$

By putting $t=t'$, one proves in a similar way as in Ref. 9 that given $\beta\in\text{supp }\tau$, all the pseudo-differential operators $P^{\pm}(\alpha)$, $\alpha\in\text{supp }\tau$, are completely determined by $P^{+}(\beta)$ from the following equations

$$R^{-}(\alpha)^{-1}=R^{+}(\alpha)^{*}, \tag{5.13}$$

$$P^{-}(\alpha)=(P^{+}(\alpha)^{*})^{-1}, \tag{5.14}$$

$$(P^{+}(\alpha)R^{+}(\alpha-\beta)P^{+}(\beta)^{-1})_{-}=0 \quad \text{for all} \quad \alpha,\beta\in\text{supp }\tau. \tag{5.15}$$

This and the above lemma can be used to prove the following proposition which will be crucial later on. Adler, Shiota, and van Moerbeke stated this proposition in the 1-component case.[6]

Proposition 5.2: Let $\Psi^{\pm}(\alpha,x,t,z)$ satisfy the bilinear identity (5.3) for $\beta=\alpha$ and let $Q(x,t,\partial)$ be an arbitrary pseudodifferential operator. Then Q is a differential operator if and only if

$$\text{Res}_{z=0}\ dz\ Q(x,t,\partial)\Psi^{+}(\tau_{\alpha},x,t,z)^{t}\Psi^{-}(\tau_{\alpha},x',t',z)=0. \tag{5.16}$$

Proof: Suppose that Q is a differential operator, then since by Lemma 5.1 $W^{+}(\tau_{\alpha},x,t,\partial)W^{-}(\tau_{\alpha},x,t',\partial)$ is a differential operator

$$(Q(x,t,\partial)W^{+}(\tau_{\alpha},x,t,\partial)W^{-}(\tau_{\alpha},x,t',\partial)^{*})_{-}=0. \tag{5.17}$$

Conversely, suppose (5.16) holds, then again by Lemma 5.1 (5.17) holds. Now put $t=t'$, and use (5.13)–(5.14), then one deduces that $Q(x,t,\partial)_{-}=0$. □

In Ref. 9 Victor Kac and the author also showed the following.

Proposition 5.3: Consider $\Psi^{+}(\tau_{\alpha},x,t,z)$ and $\Psi^{-}(\tau_{\alpha},x,t,z)$, $\alpha\in Q$, of the form (5.8), then the bilinear identity (5.3) for all $\alpha,\beta\in\text{supp }\tau$ is equivalent to the Sato equation:

$$\frac{\partial P^{+}(\alpha)}{\partial t_{k}^{(j)}}=-(P^{+}(\alpha)e_{jj}\partial^{k}P^{+}(\alpha)^{-1})_{-}P^{+}(\alpha), \tag{5.18}$$

for each $\alpha\in\text{supp }\tau$ and the matching conditions (5.13)–(5.15) for all $\alpha,\beta\in\text{supp }\tau$.

As a consequence of (5.18) one obtains for each $W^{+}(\alpha)$:

$$\frac{\partial W^{+}(\alpha)}{\partial t_{k}^{(j)}}=(P^{+}(\alpha)e_{jj}\partial^{k}P^{+}(\alpha)^{-1})_{+}W^{+}(\alpha)=(W^{+}(\alpha)e_{jj}\partial^{k}W^{+}(\alpha)^{-1})_{+}W^{+}(\alpha). \tag{5.19}$$

Fix τ and $\alpha,\beta\in Q$, introduce the following formal pseudodifferential operators $L(\alpha)$, Γ, $M(\alpha)$, $N(\alpha,\beta)$, $\Delta^{(ij)}$, $C^{(ij)}(\alpha)$ and differential operators $B_{m}^{(ij)}(\alpha)$:

$$L(\alpha)=W^+(\alpha)\partial W^+(\alpha)^{-1}=P^+(\alpha)\partial P^+(\alpha)^{-1},$$

$$\Gamma=x+\sum_{a=0}^{s}\sum_{k=0}^{\infty} kt_k^{(a)}\partial^{k-1}e_{aa},$$

$$M(\alpha)=W^+(\alpha)xW^+(\alpha)^{-1}=P^+(\alpha)R^+(\alpha)\Gamma R^+(\alpha)^{-1}P^+(\alpha)^{-1},$$

$$N(\alpha,\beta)=W^+(\alpha)W^+(\beta)^{-1}=P^+(\alpha)R^+(\alpha-\beta)P^+(\beta)^{-1}, \tag{5.20}$$

$$\Delta^{(ij)}=\epsilon^{\xi(t,\partial)}e_{ij}e^{-\xi(t,\partial)},$$

$$C^{(ij)}(\alpha)=W^+(\alpha)e_{ij}W^+(\alpha)^{-1}=P^+(\alpha)R^+(\alpha)\Delta^{(ij)}R^+(\alpha)^{-1}P^+(\alpha)^{-1},$$

$$B_m^{(i)}(\alpha)=(W^+(\alpha)e_{ii}\partial^m W^+(\alpha)^{-1})_+.$$

Notice that $M(\alpha)$ and $C^{(ij)}(\alpha)$ are not well-defined pseudodifferential operators. One should regard them as a product of operators on $\Psi^+(\alpha,z)$.

Here we write x for xI_s. Denote by $C^{(i)}(\alpha)=C^{(ii)}(\alpha)$. Then

$$[L(\alpha),M(\alpha)]=I_s,\quad \sum_{i=1}^{s}C^{(i)}(\alpha)=I_s,\quad C^{(ij)}(\alpha)L(\alpha)=L(\alpha)C^{(ij)}(\alpha),$$

$$C^{(ij)}(\alpha)C^{(kl)}(\alpha)=\delta_{jk}C^{(il)}(\alpha),\quad L(\alpha)N(\alpha,\beta)=N(\alpha,\beta)L(\beta),$$
$$M(\alpha)N(\alpha,\beta)=N(\alpha,\beta)M(\beta),\quad C^{(ij)}(\alpha)N(\alpha,\beta)=N(\alpha,\beta)C^{(ij)}(\beta), \tag{5.21}$$

$$N(\alpha,\beta)N(\beta,\gamma)=N(\alpha,\gamma).$$

Remark 5.4: (i) It is our purpose to describe the general operators

$$Y_k^{(ab,l+1)}(\alpha,\beta)=W^+(\alpha)x^l\partial^{k+l}e_{ab}W^+(\beta)^{-1}.$$

One can express them in the operators defined in (5.20), viz.,

$$Y_k^{(ab,l+1)}(\alpha,\beta)=M(\alpha)^lL(\alpha)^{k+l}C^{(ab)}(\alpha)N(\alpha,\beta).$$

(ii) Notice that (5.14) is equivalent to $N(\alpha,\beta)_-=0$, so from now on we will assume that $N(\alpha,\beta)$ is a differential operator.

Proposition 5.5: If for every $\alpha,\beta\in Q$ the formal pseudodifferential operators $L(\alpha)$, $M(\alpha)$, $C^{(ij)}(\alpha)$ and the differential operators $N(\alpha,\beta)$ satisfy conditions (5.21) and if the equations

$$\begin{cases} L(\alpha)P^+(\alpha)R^+(\alpha)=P^+(\alpha)R^+(\alpha)\partial \quad [\text{or equivalently } L(\alpha)P^+(\alpha)=P^+(\alpha)\partial],\\ M(\alpha)P^+(\alpha)R^+(\alpha)=P^+(\alpha)R^+(\alpha)\Gamma,\\ N(\alpha,\beta)P^+(\beta)R^+(\beta)=P^+(\alpha)R^+(\alpha),\\ C^{(ij)}(\alpha)P^+(\alpha)R^+(\alpha)=P^+(\alpha)R^+(\alpha)\Delta^{(ij)},\\ \dfrac{\partial P^+(\alpha)}{\partial t_k^{(j)}}=-(C^{(j)}(\alpha)L(\alpha)^k)_-P^+(\alpha) \end{cases} \tag{5.22}$$

have a solution $P^+(\alpha)$ of the form (5.7), then the differential operators $B_k^{(j)}(\alpha)$ satisfies the following conditions:

$$\begin{cases} \dfrac{\partial L(\alpha)}{\partial t_k^{(j)}} = [B_k^{(j)}(\alpha), L(\alpha)], \\ \dfrac{\partial M(\alpha)}{\partial t_k^{(j)}} = [B_k^{(j)}(\alpha), M(\alpha)], \\ \dfrac{\partial N(\alpha,\beta)}{\partial t_k^{(j)}} = B_k^{(j)}(\alpha)N(\alpha,\beta) - N(\alpha,\beta)B_k^{(j)}(\beta), \\ \dfrac{\partial C^{(il)}(\alpha)}{\partial t_k^{(j)}} = [B_k^{(j)}(\alpha), C^{(il)}(\alpha)]. \end{cases} \tag{5.23}$$

Now (5.23) implies that

$$\frac{\partial Y_m^{(ab,l+1)}(\alpha,\beta)}{\partial t_k^{(j)}} = B_k^{(j)}(\alpha)Y_m^{(ab,l+1)}(\alpha,\beta) - Y_m^{(ab,l+1)}(\alpha,\beta)B_k^{(j)}(\beta).$$

Notice that the conditions (5.22) are equivalent to one of the following conditions:

$$\begin{cases} L(\alpha)W^+(\alpha) = W^+(\alpha)\partial, \\ M(\alpha)W^+(\alpha) = W^+(\alpha)x, \\ N(\alpha,\beta)W^+(\beta) = W^+(\alpha), \\ C^{(ij)}(\alpha)W^+(\alpha) = W^+(\alpha)e_{ij}, \\ \dfrac{\partial W^+(\alpha)}{\partial t_k^{(j)}} = B_k^{(j)}(\alpha)W^+(\alpha), \end{cases} \qquad \begin{cases} L(\alpha)\Psi^+(\alpha,z) = z\Psi^+(\alpha,z), \\ M(\alpha)\Psi^+(\alpha,z) = \dfrac{\partial \Psi^+(\alpha,z)}{\partial z}, \\ N(\alpha,\beta)\Psi^+(\beta,z) = \Psi^+(\alpha,z), \\ C^{(ij)}(\alpha)\Psi^+(\alpha,z) = \Psi^+(\alpha,z)e_{ij}, \\ \dfrac{\partial \Psi^+(\alpha,z)}{\partial t_k^{(j)}} = B_k^{(j)}(\alpha)\Psi^+(\alpha,z). \end{cases} \tag{5.24}$$

VI. THE ADLER–SHIOTA–VAN MOERBEKE FORMULA

Fix $\alpha,\beta \in Q$ and recall

$$Y_k^{(ab,l+1)}(\alpha,\beta) \equiv Y_k^{(ab,l+1)}(\tau_\alpha,\tau_\beta) = W^+(\alpha)x^l\partial^{k+l}e_{ab}W^+(\beta)^{-1}, \tag{6.1}$$

then define

$$\begin{aligned} Y^{(ab)}(\alpha,\beta,y,w) &\equiv Y^{(ab)}(\tau_\alpha,\tau_\beta,y,w) \\ &= \sum_{l=0}^{\infty} \frac{(y-w)^l}{l!} \sum_{k\in\mathbb{Z}} w^{-k-l-1} Y_k^{(ab,l+1)}(\alpha,\beta) \\ &= \sum_{l=0}^{\infty} \frac{(y-w)^l}{l!} \sum_{k\in\mathbb{Z}} w^{-k-l-1} M(\alpha)^l L(\alpha)^{k+l} C^{(ab)}(\alpha)N(\alpha,\beta). \end{aligned} \tag{6.2}$$

We write $Y_k^{(ab,l+1)}(\alpha)$ and $Y^{(ab)}(\alpha,y,w) \equiv Y^{(ab)}(\tau_\alpha,y,w)$ for, respectively, $Y_k^{(ab,l+1)}(\alpha,\alpha)$, $Y^{(ab)}(\alpha,\alpha,y,w)$, then

$$Y^{(ab)}(\alpha,y,w) = \sum_{l=0}^{\infty} \frac{(y-w)^l}{l!} \sum_{k\in\mathbb{Z}} w^{-k-l-1} M(\alpha)^l L(\alpha)^{k+l} C^{(ab)}(\alpha).$$

One deduces the following:

Proposition 6.1:

$$Y^{(ab)}(\alpha,\beta,y,w)_- = \Psi^+(\alpha,y)e_{ab}\partial^{-1t}\Psi^-(\beta,w). \tag{6.3}$$

Proof: First, notice that

$$\begin{aligned}(W^+(\alpha)x^l\partial^{k+l}e_{ab}W^+(\beta)^{-1})_- &= \sum_{j=1}^{\infty}\partial^{-j}\,\mathrm{Res}_\partial\,\partial^{j-1}W^+(\alpha)x^l\partial^{k+l}e_{ab}W^+(\beta)^{-1}\\ &= \sum_{j=1}^{\infty}\partial^{-j}\,\mathrm{Res}_{z=0}\,dz(\partial^{j-1}W^+(\alpha)x^l\partial^{k+l}e^{zx})e_{ab}{}^t(W^-(\beta)e^{-zx})\\ &= \mathrm{Res}_{z=0}\,dz\sum_{j=1}^{\infty}\partial^{-j}\left[\left(\frac{\partial}{\partial x}\right)^{j-1}\left(z^{k+l}\,\frac{\partial^l\Psi^+(\alpha,z)}{\partial z^l}\right)\right]e_{ab}{}^t\Psi^-(\beta,z)\\ &= \mathrm{Res}_{z=0}\,dz z^{k+l}\,\frac{\partial^l\Psi^+(\alpha,z)}{\partial z^l}\,e_{ab}\partial^{-1t}\Psi^-(\beta,z).\end{aligned}$$

Hence

$$\begin{aligned}Y^{(ab)}(\alpha,\beta,y,w)_- &= \sum_{l=0}^{\infty}\frac{(y-w)^l}{l!}\sum_{k\in\mathbb{Z}}w^{-k-l-1}\,\mathrm{Res}_{z=0}\,dz\,z^{k+l}\,\frac{\partial^l\Psi^+(\alpha,z)}{\partial z^l}\,e_{ab}\partial^{-1t}\Psi^-(\beta,z)\\ &= \sum_{l=0}^{\infty}\frac{(y-w)^l}{l!}\,\frac{\partial^l\Psi^+(\alpha,w)}{\partial w^l}\,e_{ab}\partial^{-1t}\Psi^-(\beta,w)=\Psi^+(\alpha,y)e_{ab}\partial^{-1t}\Psi^-(\beta,w).\end{aligned}$$

□

Proposition 6.1 was obtained in the 1-component case by Dickey.[7]

Next we calculate

$$\begin{aligned}Y^{(ab)}(\alpha,\beta,y,w)\Psi^+(\beta,z) &= \sum_{l=0}^{\infty}\frac{(y-w)^l}{l!}\sum_{k\in\mathbb{Z}}w^{-k-l-1}W^+(\alpha)x^l\partial^{k+l}e_{ab}e^{zx}\\ &= W^+(\alpha)\,\delta(w,z)e^{(y-w)(\partial/\partial z)}e^{zx}e_{ab}=W^+(\alpha)\,\delta(w,z)e^{(z+y-w)x}e_{ab}\\ &= W^+(\alpha)\,\delta(w,z)e^{yx}e_{ab}=\delta(w,z)\Psi^+(\alpha,y)e_{ab},\end{aligned}\tag{6.4}$$

where $\delta(w,z)=\Sigma_{n\in\mathbb{Z}}\,w^{-n}z^{n-1}$.

Define

$$\begin{aligned}\mathbb{X}^{(ab)}(y,w) &= X^{(ab)}(y,w)e^{(y-w)x},\\ \mathbb{W}^{(ab)}(y,w) &= \sum_{l=0}^{\infty}\frac{(y-w)^l}{l!}\sum_{k\in\mathbb{Z}}\mathbb{W}_k^{(ab,l+1)}w^{-k-l-1}=(y-w)^{-\delta_{ab}}(\mathbb{X}^{(ab)}(y,w)-\delta_{ab}),\end{aligned}\tag{6.5}$$

then

$$\mathbb{W}^{(ab)}(y,w)=:\psi^{+(a)}(y)\psi^{-(b)}(w):e^{(y-w)x}.$$

It is straightforward that the $\mathbb{W}_k^{(ab,l+1)}$ have the same commutation relations as the $W_k^{(ab,l+1)}$, since we have only replaced all $t_1^{(j)}$ by $t_1^{(j)}+x$ and kept $\partial/\partial t_1^{(j)}$ unchanged in the vertex operator (4.11) of $W^{(ab)}(y,w)$ ($\partial/\partial x$ does not appear in this expression).

One has the following:

Lemma 6.2:

$$\mathbb{X}^{(ab)}(y,w)\psi^{+(j)}(z)e^{zx}=\delta_{bj}(y-w)^{\delta_{ab}}\delta(w,z)\psi^{+(a)}(y)e^{yx}+\psi^{+(j)}(z)e^{zx}\mathbb{X}^{(ab)}(y,w).$$

Proof: Let $\gamma\in Q$, we calculate

$$\begin{aligned}\mathbb{X}^{(ab)}(y,w)\psi^{+(j)}(z)e^{zx}\tau_\gamma(x,t)e^{\gamma}=&\epsilon(\delta_a,\delta_b)\epsilon(\delta_a-\delta_b,\gamma+\delta_j)\epsilon(\delta_j,\gamma)y^{(\delta_a|\gamma+\delta_j)}w^{-(\delta_b|\gamma+\delta_j)}z^{(\delta_j|\gamma)}\\&\times(1-z/y)^{\delta_{aj}}(1-z/w)^{-\delta_{bj}}e^{\xi^{(a)}(x,t,y)-\xi^{(b)}(x,t,w)+\xi^{(j)}(x,t,z)}\\&\times e^{-\eta^{(a)}(t,y)+\eta^{(b)}(t,w)-\eta^{(j)}(t,z)}\tau_\gamma e^{\gamma+\delta_j+\delta_a-\delta_b}.\end{aligned}$$

Now use the fact that $(1-z/w)^{-1}=w\delta(w,z)-(w/z)(1-w/z)^{-1}$, $1-z/y=-(z/y)(1-y/z)$ and that $\epsilon(\delta_m,\delta_n)\epsilon(\delta_n,\delta_m)=-(-1)^{\delta_{mn}}$, then

$$\begin{aligned}&\mathbb{X}^{(ab)}(y,w)\psi^{+(j)}(z)e^{zx}\tau_\gamma(x,t)e^{\gamma}\\&\quad=\delta_{bj}\epsilon(\delta_a,\delta_b)\epsilon(\delta_a-\delta_b,\gamma+\delta_b)\epsilon(\delta_b,\gamma)(y-z)^{\delta_{ab}}\delta(w,z)y^{(\delta_a|\gamma)}w^{-(\delta_b|\gamma)}z^{(\delta_b|\gamma)}\\&\qquad\times e^{\xi^{(a)}(x,t,y)-\xi^{(b)}(x,t,w)+\xi^{(b)}(x,t,z)}e^{-\eta^{(a)}(t,y)+\eta^{(b)}(t,w)-\eta^{(b)}(t,z)}\tau_\gamma e^{\gamma+\delta_a}\\&\qquad+\epsilon(\delta_a,\delta_b)\epsilon(\delta_a-\delta_b,\gamma+\delta_j)\epsilon(\delta_j,\gamma)(-)^{\delta_{aj}}(-)^{\delta_{bj}}y^{(\delta_a|\gamma)}w^{-(\delta_b|\gamma)}z^{(\delta_j|\gamma+\delta_a-\delta_b)}\\&\qquad\times e^{\xi^{(j)}(x,t,z)}e^{\eta^{(j)}(t,z)}e^{\xi^{(a)}(x,t,y)-\xi^{(b)}(x,t,w)}e^{-\eta^{(a)}(t,y)+\eta^{(b)}(t,w)}\tau_\gamma e^{\gamma+\delta_j+\delta_a-\delta_b}\\&\quad=\{\delta_{bj}(y-w)^{\delta_{ab}}\delta(w,z)\psi^{+(a)}(y)e^{yx}+\psi^{+(j)}(z)e^{zx}\mathbb{X}^{(ab)}(y,w)\}\tau_\gamma e^{\gamma}.\end{aligned}$$

□

Recall the bilinear identity (4.14) with α replaced by $\alpha+\delta_b-\delta_a$ in a slightly different version, viz.,

$$\begin{aligned}&\mathrm{Res}_{z=0}\,dz\sum_{j=1}^{s}\psi^{+(j)}(z)e^{zx}\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(x,t)e^{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}\\&\qquad\times\psi^{-(j)'}(z)e^{-zx'}\tau_{\beta+\delta_j-\delta_k}(x',t')(e^{\beta+\delta_j-\delta_k})'=0.\end{aligned}$$

Let $\mathbb{X}^{(ab)}(y,w)$ act on this identity, then using Lemma 6.2 one obtains:

$$\begin{aligned}&\mathrm{Res}_{z=0}\,dz\Big\{\{(y-w)^{\delta_{ab}}\delta(w,z)\psi^{+(a)}(y)e^{zx}\tau_{\alpha+\delta_i-\delta_a}(x,t)e^{\alpha+\delta_i-\delta_a}\psi^{-(a)'}(z)\\&\quad+\sum_{j=1}^{s}\psi^{+(j)}(z)e^{zx}\mathbb{X}^{(ab)}(y,w)\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(x,t)e^{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}\psi^{-(j)'}(z)\Big\}\\&\quad\times e^{-zx'}\tau_{\beta+\delta_j-\delta_k}(x',t')(e^{\beta+\delta_j-\delta_k})'=0.\end{aligned}\tag{6.6}$$

Now divide by $\tau_\alpha(x,t)\tau_\beta(x',t')$ and remove the factors $e^{\alpha+\delta_i}$ and $(e^{\beta-\delta_k})'$. Notice that by doing this, the action of $\mathbb{X}^{(ab)}(y,w)$ is no longer well-defined, for that reason we introduce $\hat{X}^{(ab)}(y,w)$ by

$$\begin{aligned}\hat{X}^{(ab)}(y,w)\tau_\gamma(x,t)=&\epsilon(\delta_a,\delta_b)\epsilon(\delta_a-\delta_b,\gamma)y^{(\delta_a|\gamma)}w^{-(\delta_b|\gamma)}\\&\times e^{\xi^{(a)}(x,t,y)-\xi^{(b)}(x,t,w)}e^{\eta^{(a)}(t,y)+\eta^{(b)}(t,w)}\tau_\gamma(x,t)\end{aligned}$$

and

$$\hat{W}^{(ab)}(y,w)=\sum_{l=0}^{\infty}\frac{(y-w)^l}{l!}\sum_{k\in\mathbb{Z}}\hat{W}_k^{(ab,l+1)}w^{-k-l-1}=(y-w)^{-\delta_{ab}}(\hat{X}^{(ab)}(y,w)-\delta_{ab}). \quad (6.7)$$

Then (6.6) turns into

$$\begin{aligned}\mathrm{Res}_{z=0}\,dz\Bigg\{&(y-w)^{\delta_{ab}}\delta(w,z)\Psi_{ia}^{+}(\alpha,y)\Psi_{kb}^{-}(\beta,z)'+\sum_{j=1}^{s}e^{-\eta^{(j)}(t,z)}\\&\times\left(\frac{\hat{X}^{(ab)}(y,w)\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(x,t)}{\tau_{\alpha+\delta_i-\delta_j}(x,t)}\right)\Psi_{ij}^{+}(\alpha,z)\Psi_{kj}^{-}(\beta,z)'\Bigg\}=0. \quad (6.8)\end{aligned}$$

Using (6.4) one obtains

$$\begin{aligned}\mathrm{Res}_{z=0}\,dz\Bigg\{e_{ii}\Bigg(&(y-w)^{\delta_{ab}}Y^{(ab)}(\alpha,y,w)\Psi^{+}(\alpha,z)+\sum_{j=1}^{s}e^{-\eta^{(j)}(t,z)}\\&\times\left(\frac{\hat{X}^{(ab)}(y,w)\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(x,t)}{\tau_{\alpha+\delta_i-\delta_j}(x,t)}\right)\Bigg)\Psi^{+}(\alpha,z)e_{jj}\Bigg\}\ {}^{t}\Psi^{-}(\beta,z)'=0.\end{aligned}$$

Now notice that

$$\begin{aligned}&e^{-\eta^{(j)}(t,z)}\left(\frac{\hat{X}^{(ab)}(y,w)\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(x,t)}{\tau_{\alpha+\delta_i-\delta_j}(x,t)}\right)\Psi^{+}(\alpha,z)e_{jj}\\&=\sum_{k=0}^{\infty}c_{jk}L(\alpha)^{-k}C^{(j)}(\alpha)\Psi^{+}(\alpha,z)\\&=\left\{\left(\sum_{k=1}^{\infty}c_{jk}L(\alpha)^{-k}C^{(j)}(\alpha)\right)_{-}+\frac{\hat{X}^{(ab)}(y,w)\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(x,t)}{\tau_{\alpha+\delta_i-\delta_j}(x,t)}e_{jj}\right\}\Psi^{+}(\alpha,z),\end{aligned}$$

hence

$$\mathrm{Res}_{z=0}\,dz\;e_{ii}\left((y-w)^{\delta_{ab}}Y^{(ab)}(\alpha,y,w)+\sum_{j=1}^{s}\sum_{k=0}^{\infty}c_{jk}L(\alpha)^{-k}C^{(j)}(\alpha)\right)\Psi^{+}(\alpha,z)^{t}\Psi^{-}(\beta,z)'=0.$$

Now using Proposition 5.2 for $\beta=\alpha$, one obtains

$$e_{ii}\left((y-w)^{\delta_{ab}}Y^{(ab)}(\alpha,y,w)_{-}+\sum_{j=1}^{s}\left(\sum_{k=0}^{\infty}c_{jk}L(\alpha)^{-k}C^{(j)}(\alpha)\right)_{-}\right)=0.$$

Hence

$$
\begin{aligned}
&-e_{ii}(y-w)^{\delta_{ab}}Y^{(ab)}(\alpha,y,w)_-\Psi^+(\alpha,z)\\
&\quad=e_{ii}\sum_{j=1}^{s}e^{-\eta^{(j)}(t,z)}\left(\frac{\hat{X}^{(ab)}(y,w)\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(x,t)}{\tau_{\alpha+\delta_i-\delta_j}(x,t)}\right)\Psi^+(\alpha,z)e_{jj}\\
&\qquad-\frac{\hat{X}^{(ab)}(y,w)\tau_{\alpha+\delta_b-\delta_a}(x,t)}{\tau_\alpha(x,t)}e_{ii}\Psi^+(\alpha,z).
\end{aligned}
$$

So we obtain the following generalization of the Adler–Shiota–van Moerbeke formula

Theorem 6.3:

$$
\begin{aligned}
(y-w)^{\delta_{ab}}(-Y^{(ab)}(\alpha,y,w)_-\Psi^+(\alpha,z))_{ij}=&\left\{e^{-\eta^{(j)}(t,z)}\left(\frac{\hat{X}^{(ab)}(y,w)\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(x,t)}{\tau_{\alpha+\delta_i-\delta_j}(x,t)}\right)\right.\\
&\left.-\frac{\hat{X}^{(ab)}(y,w)\tau_{\alpha+\delta_b-\delta_a}(x,t)}{\tau_\alpha(x,t)}\right\}\Psi^+_{ij}(\alpha,z). \qquad (6.9)
\end{aligned}
$$

In a similar way as in the introduction the operator $e^{\lambda\mathbb{X}^{(ab)}(y,w)}=1+\lambda\mathbb{X}^{(ab)}(y,w)$ is an auto-Bäcklund transformation of the s-component KP hierarchy (see also Ref. 9). Now let

$$
\sigma(x,t)=\sum_{\gamma\in Q}\sigma_\gamma(x,t)e^\gamma=e^{\lambda\mathbb{X}^{(ab)}(y,w)}\sum_{\gamma\in Q}\tau_\gamma(x,t)e^\gamma=\sum_{\gamma\in Q}(\tau_\gamma(x,t)+\lambda\hat{X}^{(ab)}(y,w)\tau_{\gamma+\delta_b-\delta_a})e^\gamma,
$$

then (6.9) is equal to

$$
\begin{aligned}
&-\lambda(y-w)^{\delta_{ab}}(Y^{(ab)}(\tau_\alpha,y,w)_-\Psi^+(\tau_\alpha,x,t,z))_{ij}\\
&\quad=\left\{e^{-\eta^{(j)}(t,z)}\left(\frac{\sigma_{\alpha+\delta_i-\delta_j}(x,t)}{\tau_{\alpha+\delta_i-\delta_j}(x,t)}\right)-\frac{\sigma_\alpha(x,t)}{\tau_\alpha(x,t)}\right\}\Psi^+_{ij}(\tau_\alpha,x,t,z).
\end{aligned}
$$

So

$$
\begin{aligned}
\Psi^+_{ij}(\sigma_\alpha,x,t,z)&=\frac{e^{-\eta^{(j)}(t,z)}\sigma_{\alpha+\delta_i-\delta_j}(x,t)}{\sigma_\alpha(x,t)}e^{\xi^{(j)}(x,t,z)}\\
&=\frac{\tau_\alpha(x,t)}{\sigma_\alpha(x,t)}e^{-\eta^{(j)}(t,z)}\left(\frac{\sigma_{\alpha+\delta_i-\delta_j}(x,t)}{\tau_{\alpha+\delta_i-\delta_j}(x,t)}\right)\Psi^+_{ij}(\tau_\alpha,x,t,z)\\
&=\left(\left(1-\lambda\frac{\tau_\alpha(x,t)}{\sigma_\alpha(x,t)}(y-w)^{\delta_{ab}}Y^{(ab)}(\tau_\alpha,y,w)_-\right)\Psi^+(\tau_\alpha,x,t,z)\right)_{ij}
\end{aligned}
$$

and we obtain the following consequence of Theorem 6.3:

Corollary 6.4: Let $\tau(x,t)$ be a solution of the s-component KP hierarchy, then $\sigma(x,t)=e^{\lambda\mathbb{X}^{(ab)}(y,w)}\tau(x,t)$ is a new solution of this hierarchy and the wave functions are related by

$$
\Psi^+_{ij}(\sigma_\alpha,x,t,z)=\left(\left(1-\lambda\frac{\tau_\alpha(x,t)}{\sigma_\alpha(x,t)}(y-w)^{\delta_{ab}}Y^{(ab)}(\tau_\alpha,y,w)_-\right)\Psi^+(\tau_\alpha,x,t,z)\right)_{ij}.
$$

Hence (6.9) relates this Bäcklund transformation of the s-component KP hierarchy acting on the τ-function to a ''Bäcklund transformation'' on the wave function.

Since the left-hand-side of (6.9) is also equal to

$$\left\{ e^{-\eta^{(j)}(t,z)} \left(\frac{(\hat{X}^{(ab)}(y,w)-\delta_{ab})\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(x,t)}{\tau_{\alpha+\delta_i-\delta_j}(x,t)} \right) - \frac{(\hat{X}^{(ab)}(y,w)-\delta_{ab})\tau_{\alpha+\delta_b-\delta_a}(x,t)}{\tau_\alpha(x,t)} \right\} \Psi^+_{ij}(\alpha,z),$$

we have the following:

Corollary 6.5:

$$(-(M(\alpha)^l L(\alpha)^{k+l} C^{(ab)}(\alpha))_- \Psi^+(\alpha,z))_{ij} = \left\{ e^{-\eta^{(j)}(t,z)} \left(\frac{\hat{W}_k^{(ab,l+1)}\tau_{\alpha+\delta_i+\delta_b-\delta_j-\delta_a}(x,t)}{\tau_{\alpha+\delta_i-\delta_j}(x,t)} \right) - \frac{\hat{W}_k^{(ab,l+1)}\tau_{\alpha+\delta_b-\delta_a}(x,t)}{\tau_\alpha(x,t)} \right\} \Psi^+_{ij}(\alpha,z).$$

Proof: Compare in (6.9) the expansions for the vertex operators $Y^{(ab)}(\alpha,y,w)$ as in (6.2) and for $\hat{W}^{(ab)}(y,w)$ as in (6.7). □

As an application of Corollary 6.5 we see that if

$$\sum_{a=1}^{s}\sum_{l=0}^{\infty}\sum_{k\in\mathbb{Z}} c_{alk}(M(\alpha)^l L(\alpha)^{k+l} C^{(a)}(\alpha))_- = 0,$$

one finds that that for any $1 \leqslant j \leqslant s$

$$(e^{-\eta^{(j)}(t,z)}-1)\left(\frac{\sum_{a=1}^{s}\sum_{l=0}^{\infty}\sum_{k\in\mathbb{Z}} c_{alk}\hat{W}_k^{(a,l+1)}\tau_\alpha(x,t)}{\tau_\alpha(x,t)} \right) = 0,$$

hence

$$\sum_{a=1}^{s}\sum_{l=0}^{\infty}\sum_{k\in\mathbb{Z}} c_{alk}\mathbb{W}_k^{(a,l+1)}\tau_\alpha(x,t)e^\alpha = \text{constant } \tau_\alpha(x,t)e^\alpha.$$

Thus Corollary 6.5 provides an alternative proof of Theorem 6.5 of Ref. 19.

VII. THE ADLER–SHIOTA–VAN MOERBEKE FORMULA FOR THE 2-DIMENSIONAL TODA LATTICE HIERARCHY

To convince the reader that a generalized Adler–Shiota–van Moerbeke formula also exists for the 2-dimensional Toda lattice hierarchy of Ueno and Takasaki,[8] we reformulate the results of Sec. VI in the case that $s=2$. We will use most of the notations of the Adler–Shiota–van Moerbeke paper.[6]

From now on we assume that $s=2$ and denote by $\tau_n(t) = (-)^{n(n-1)/2}\tau_{n(\delta_1-\delta_2)}(0,t)$ (so put $x=0$). Following Ref. 6 we write $\tau \in F^{(0)}$ as an infinite column vector, viz., $\tau = (\tau_n)_{n\in\mathbb{Z}}$ and introduce the wave or Baker–Akhiezer vectors $\Psi_a^{\pm}(t,z) = (\widetilde{\Psi}_{an}^{\pm}(t,z))_{n\in\mathbb{Z}}$ for $a=1,2$, where

$$\begin{aligned}\widetilde{\Psi}^{\pm}_{1n}(t,z)&=z^{1/2\mp 1/2}\Psi^{\pm}_{11}((n+\tfrac{1}{2}\mp\tfrac{1}{2})(\delta_1-\delta_2),0,t,z)=\frac{e^{\mp\eta^{(1)}(t,z)}\tau_{n+1/2\mp 1/2}(t)}{\tau_{n+1/2\mp 1/2}(t)}\,e^{\pm\xi^{(1)}(t,z)}z^{\pm n},\\ \widetilde{\Psi}^{\pm}_{2n}(t,z)&=\mp z^{-1/2\mp 1/2}\Psi^{\pm}_{12}((n+\tfrac{1}{2}\mp\tfrac{1}{2})(\delta_1-\delta_2),0,t,z^{-1})\\ &=\frac{e^{\mp\eta^{(2)}(t,z^{-1})}\tau_{n+1/2\pm 1/2}(t)}{\tau_{n+1/2\mp 1/2}(t)}\,e^{\pm\xi^{(2)}(t,z^{-1})}z^{\pm n}.\end{aligned}\tag{7.1}$$

Then (4.13) and (5.3) is equivalent to

$$\mathrm{Res}_{z=0}\,\frac{dz}{z}\,\Psi^{+}_{1}(t,z)^{t}\Psi^{-}_{1}(t',z)-\Psi^{+}_{2}(t,z^{-1})^{t}\Psi^{-}_{2}(t',z^{-1})=0.\tag{7.2}$$

We want to write these wave vectors as the action of infinite matrices acting on the vectors $\chi(z)=\chi^{+}(z)=(z^{n})_{n\in\mathbb{Z}}$ and $\chi^{-}(z)=(z^{-n})_{n\in\mathbb{Z}}$. Let $\Lambda=\Sigma_{i\in\mathbb{Z}}\,E_{ii}$, then

$$\begin{aligned}\Psi^{\pm}_{1}(t,z)&=W^{\pm}_{1}(t,\Lambda)\chi^{\pm}(z)=S^{\pm}_{1}(t,\Lambda)e^{\pm\xi^{(1)}(t,\Lambda^{\pm 1})}\chi^{\pm}(z),\\ \Psi^{\pm}_{2}(t,z)&=W^{\pm}_{2}(t,\Lambda)\chi^{\pm}(z)=S^{\pm}_{2}(t,\Lambda)e^{\pm\xi^{(2)}(t,\Lambda^{\mp 1})}\chi^{\pm}(z),\end{aligned}\tag{7.3}$$

where

$$S^{\pm}_{1}(t,\Lambda)=\sum_{i=0}^{\infty}\,\mathrm{diag}(p^{\pm}_{ni}(t))_{n\in\mathbb{Z}}\Lambda^{\mp i},\quad S^{\pm}_{2}(t,\Lambda)=\sum_{i=0}^{\infty}\,\mathrm{diag}(q^{\pm}_{ni}(t))_{n\in\mathbb{Z}}\Lambda^{\pm i},\tag{7.4}$$

with the $p^{\pm}_{ni}$ and $q^{\pm}_{ni}$ defined by

$$\frac{e^{\mp\eta^{(1)}(t,z)}\tau_{n+1/2\mp 1/2}(t)}{\tau_{n+1/2\mp 1/2}(t)}=\sum_{i=0}^{\infty}\,p^{\pm}_{ni}(t)z^{-i},\quad \frac{e^{\mp\eta^{(2)}(t,z^{-1})}\tau_{n+1/2\pm 1/2}(t)}{\tau_{n+1/2\mp 1/2}(t)}=\sum_{i=0}^{\infty}\,q^{\pm}_{ni}(t)z^{i}.\tag{7.5}$$

As in Ref. 6 it will be convenient to take pairs of matrices, so let D be the algebra of pairs of infinite $(\mathbb{Z}\times\mathbb{Z})$ matrices (P_1,P_2) such that $(P_1)_{ij}=0$ for $j-i\gg 0$ and $(P_2)_{ij}=0$ for $i-j\gg 0$. Then

$$D_{+}=\{(P_1,P_2)\in D\,|\,P_1=P_2\},$$

$$D_{-}=\{(P_1,P_2)\in D\,|\,(P_1)_{ij}=0\quad\text{if}\quad j\geqslant i,\quad (P_2)_{ij}=0\quad\text{if}\quad i>j\},$$

so that $(P_1,P_2)=(P_1,P_2)_{+}+(P_1,P_2)_{-}$ is given by

$$\begin{aligned}(P_1,P_2)_{+}&=(P_{1u}+P_{2l},P_{1u}+P_{2l}),\\ (P_1,P_2)_{-}&=(P_{1l}-P_{2l},P_{2u}-P_{1u}),\end{aligned}\tag{7.6}$$

where P_u and P_l denote the upper (including the diagonal) and strictly lower triangular parts of the matrix P, respectively. It is straightforward to prove the following fundamental lemma (see, e.g., Ref. 6):

Lemma 7.1: Let $U=(U_1,U_2)$, $V=(V_1,V_2)\in D$ whose coefficients depend on t, then (i) the following identities hold

$$\mathrm{Res}_{z=0}\,\frac{dz}{z}\,U_i\chi^{+}(z^{-(-1)^{i}})^{t}({}^{t}V_i\chi^{-}(z^{-(-1)^{i}}))=U_iV_i,$$

(ii) we have $(UV)_-=0$ *if and only if*

$$\mathrm{Res}_{z=0}\frac{dz}{z}\{U_1\chi^+(z)^t({}^tV_1\chi^-(z))-U_2\chi^+(z^{-1})^t({}^tV_2\chi^-(z^{-1}))\}.$$

Now applying this Lemma to (7.2), using (7.3), one obtains for $W^\pm(t,\Lambda)=(W_1^\pm(t,\Lambda),W_2^\pm(t,\Lambda))$ that

$$(W^+(t,\Lambda)^tW^-(t',\Lambda))_-=(W_1^+(t,\Lambda)^tW_1^-(t',\Lambda),W_2^+(t,\Lambda)^tW_2^-(t',\Lambda))_-=0. \tag{7.7}$$

Now put $t=t'$, then one deduces that $(S^+(t,\Lambda)^tS^-(t,\Lambda))_-=(S_1^+(t,\Lambda)^tS_1^-(t,\Lambda),\ S_2^+(t,\Lambda)^tS_2^-(t,\Lambda))_-=0$, hence for $a=1,2$ one finds

$$S_a^+(t,\Lambda)=({}^tS_a^-(t,\Lambda))^{-1}. \tag{7.8}$$

Differentiate (7.2) to $\partial/\partial t_i^{(a)}$ and use (7.8) and Lemma 7.1, then it is straightforward to deduce the following Sato equations for $S^+=(S_1^+,S_2^+)$ [cf. (5.18)]

$$\frac{\partial S^+}{\partial t_i^{(1)}}=-(S_1^+\Lambda^iS_1^{+-1},0)_-S^+,\quad \frac{\partial S^+}{\partial t_i^{(2)}}=-(0,S_2^+\Lambda^{-i}S_2^{+-1})_-S^+. \tag{7.9}$$

From now on let $\Psi=(\Psi_1,\Psi_2)=(\Psi_1^+,\Psi_2^+)$, $W=(W_1,W_2)=(W_1^+,W_2^+)$, $S=(S_1,S_2)=(S_1^+,S_2^+)$ and define

$$L=(L_1,L_2)=(W_1\Lambda W_1^{-1},W_2\Lambda^{-1}W_2^{-1})=(S_1\Lambda S_1^{-1},S_2\Lambda^{-1}S_2^{-1}),$$

then (7.9) is equivalent to one of the following statements [cf. (4.24)]:

$$\begin{aligned}
&\frac{\partial S}{\partial t_i^{(1)}}=-(L_1^i,0)_-S,\quad \frac{\partial S}{\partial t_i^{(2)}}=-(0,L_2^i)_-S,\\
&\frac{\partial W}{\partial t_i^{(1)}}=(L_1^i,0)_+W,\quad \frac{\partial W}{\partial t_i^{(2)}}=(0,L_2^i)_+W,\\
&\frac{\partial \Psi}{\partial t_i^{(1)}}=(L_1^i,0)_+\Psi,\quad \frac{\partial \Psi}{\partial t_i^{(2)}}=(0,L_2^i)_+\Psi.
\end{aligned} \tag{7.10}$$

Next define

$$M=(M_1,M_2)=(W_1\epsilon_1W_1^{-1},W_2\epsilon_2W_2^{-1}),$$

where

$$\epsilon_1=\sum_{n\in\mathbb{Z}}nE_{n,n-1}\quad\text{and}\quad \epsilon_2=\sum_{n\in\mathbb{Z}}nE_{-n,1-n},$$

then $[L_a,M_a]=1$ and

$$L\Psi=(z,z^{-1})\Psi,\quad M\Psi=\left(\frac{\partial}{\partial z},\frac{\partial}{\partial z^{-1}}\right)\Psi. \tag{7.11}$$

More generally one has

$$M^k L^{k+l}\Psi = \left(z^{k+l}\left(\frac{\partial}{\partial z}\right)^k, (z^{-1})^{k+l}\left(\frac{\partial}{\partial z^{-1}}\right)^k \right)\Psi. \tag{7.12}$$

Using (7.10) or (7.11) one easily deduces the following Lax equations for the Toda lattice hierarchy [cf. (5.23)]. Let $X=M$ or L, then

$$\frac{\partial X}{\partial t_i^{(1)}} = [(L_1^i,0)_+, X], \quad \frac{\partial X}{\partial t_i^{(2)}} = [(0,L_2^i)_+, X]. \tag{7.13}$$

In a similar way as in Sec. VI we derive the generalized Adler–Shiota–van Moerbeke formula. Define [cf. (6.1)]

$$Y^{(ab)}(y,w) = \sum_{l=0}^{\infty} \frac{(y-w)^l}{l!} \sum_{k\in\mathbb{Z}} W_a(t,\Lambda)\epsilon_b^l \Lambda^{-(-1)^b(k+l)} W_b(t,\Lambda)^{-1} w^{-k-l-1}. \tag{7.14}$$

Notice that the left-hand side of (7.14) for $a\neq b$ is not well-defined. One should see this as product of operators on $\Psi_b(t,z)$.

It is easy to show that [cf. (6.4)]

$$Y^{(ab)}(y,w)\Psi_b(t,z) = \delta(w,z^{-(-1)^b})\Psi_a(t,y^{-(-1)^b}). \tag{7.15}$$

Now rewrite (6.8) for $i=k=1$, $\alpha=n(\delta_1-\delta_2)$ and $\beta=(m+1)(\delta_1-\delta_2)$ in the new notations:

$$\begin{aligned}
&\mathrm{Res}_{z=0}\frac{dz}{z}\Bigg(-(-)^b\left(\frac{w}{y^{\delta_{a2}}}\right)^{\delta_{b2}} (y-w)^{\delta_{ab}}\delta(w,z)\widetilde{\Psi}^+_{an}(t,y^{-(-1)^a})\widetilde{\Psi}^-_{bm}(t',z^{-(-1)^b}) \\
&\quad +(-)^{a+b}\Bigg\{ e^{-\eta^{(1)}(t,z)}\left(\frac{(w^{(-1)^b}/y^{(-)^a})^{n+a-b}\widetilde{X}^{(ab)}(y,w)\tau_{n+a-b}(t)}{\tau_n(t)}\right)\widetilde{\Psi}^+_{1n}(t,z)\widetilde{\Psi}^-_{1m}(t',z) \\
&\quad -e^{-\eta^{(2)}(t,z)}\left(\frac{(w^{(-1)^b}/y^{(-1)^a})^{n+a-b+1}\widetilde{X}^{(ab)}(y,w)\tau_{n+a-b+1}(t)}{\tau_{n+1}(t)}\right) \\
&\quad \times\widetilde{\Psi}^+_{2n}(t,z^{-1})\widetilde{\Psi}^-_{2m}(t,z^{-1})\Bigg\}\Bigg) = 0.
\end{aligned}$$

Next sum over all n and m and use (7.15), then this turns into

$$\begin{aligned}
&\mathrm{Res}_{z=0}\frac{dz}{z}\Bigg(-(-)^b\left(\frac{w}{y^{\delta_{a2}}}\right)^{\delta_{b2}} (y-w)^{\delta_{ab}}Y^{(ab)}(y^{(-1)^{a+b}},w)\Psi^+_b(t,z^{-(-1)^b})^t\Psi^-_b(t',z^{-(-1)^b}) \\
&\quad +(-)^{a+b}\sum_{n\in\mathbb{Z}}\Bigg\{ e^{-\eta^{(1)}(t,z)}\left(\frac{(w^{(-1)^b}/y^{(-1)^a})^{n+a-b}\widetilde{X}^{(ab)}(y,w)\tau_{n+a-b}(t)}{\tau_n(t)}\right)E_{nn} \\
&\quad \times\Psi^+_1(t,z)^t\Psi^-_1(t',z) - e^{-\eta^{(2)}(t,z)}\left(\frac{(w^{(-1)^b}/y^{(-1)^a})^{n+a-b+1}\widetilde{X}^{(ab)}(y,w)\tau_{n+a-b+1}(t)}{\tau_{n+1}(t)}\right) \\
&\quad \times E_{nn}\Psi^+_2(t,z^{-1})^t\widetilde{\Psi}^-_2(t,z^{-1})\Bigg\}\Bigg) = 0.
\end{aligned} \tag{7.16}$$

Let

$$\sum_{k=0}^{\infty} c_{kn}^{(i)} z^{-k} = e^{-\eta^{(i)}(t,z)} \left(\frac{(w^{(-1)^b}/y^{(-1)^a})^{n+a-b} \widetilde{X}^{(ab)}(y,w)\tau_{n+a-b}(t)}{\tau_n(t)} \right)$$
$$= \frac{(w^{(-1)^b}/y^{(-1)^a})^{n+a-b} \widetilde{X}^{(ab)}(y,w)\tau_{n+a-b}(t)}{\tau_n(t)} + \sum_{k=1}^{\infty} c_{kn}^{(i)} z^{-k},$$

then (7.16) is equivalent to

$$\mathrm{Res}_{z=0} \frac{dz}{z} \left(-(-)^b \left(\frac{w}{y^{\delta_{a2}}} \right)^{\delta_{b2}} (y-w)^{\delta_{ab}} Y^{(ab)}(y^{(-1)^{a+b}}, w) \Psi_b^+(t, z^{-(-1)^b}) {}^t\Psi_b^-(t', z^{-(-1)^b}) \right.$$
$$+ (-)^{a+b} \sum_{n\in\mathbb{Z}} \left\{ \sum_{k=0}^{\infty} c_{kn}^{(1)} E_{nn} L_1^{-k} \Psi_1^+(t,z) {}^t\Psi_1^-(t',z) \right.$$
$$\left. \left. - \sum_{k=0}^{\infty} c_{k+1,n}^{(2)} E_{nn} L_2^{-k} \Psi_2^+(t,z^{-1}) {}^t\Psi_2^-(t,z^{-1}) \right\} \right) = 0. \tag{7.17}$$

Using the Lemma 7.1 and (7.8) one deduces

$$\left((-)^{a+b} \sum_{n\in\mathbb{Z}} \sum_{k=0}^{\infty} c_{kn}^{(1)} E_{nn} L_1^{-k} + \delta_{b1} (y-w)^{\delta_{ab}} Y^{(a,1)}(y^{-(-1)^a}, w), (-)^{a+b} \sum_{n\in\mathbb{Z}} \sum_{k=0}^{\infty} c_{k+1,n}^{(2)} E_{nn} L_2^{-k} \right.$$
$$\left. + \delta_{b2} \frac{w}{y^{\delta_{a2}}} (y-w)^{\delta_{ab}} Y^{(a,2)}(y^{(-1)^a}, w) \right)_- = 0.$$

Hence

$$-(y-w)^{\delta_{ab}} \left(\frac{w}{y^{\delta_{a2}}} \right)^{\delta_{b2}} Y^{(ab)}(y^{(-1)^{a+b}}, w)_-$$
$$= (-)^{a+b} \left(\sum_{n\in\mathbb{Z}} \sum_{k=1}^{\infty} c_{kn}^{(1)} E_{nn} L_1^{-k}, \sum_{n\in\mathbb{Z}} \left\{ \sum_{k=0}^{\infty} c_{k+1,n}^{(2)} E_{nn} L_2^{-k} - c_{0n}^{(1)} E_{nn} \right\} \right).$$

Hence we have the following generalization of the Adler–Shiota–van Moerbeke formula for the Toda lattice hierarchy

Theorem 7.2:

$$-(y-w)^{\delta_{ab}} Y^{(ab)}(y^{a+b}, w)_- \Psi(t,z)$$
$$= (-)^{a+b} \left(\frac{y^{\delta_{a2}}}{w} \right)^{\delta_{b2}} \left(\sum_{n\in\mathbb{Z}} \{ e^{-\eta^{(1)}(t,z)} - 1 \} \left(\frac{(w^{(-1)^b}/y^{(-1)^a})^{n+a-b} \widetilde{X}^{(ab)}(y,w)\tau_{n+a-b}(t)}{\tau_n(t)} \right) E_{nn}, \right.$$
$$\sum_{n\in\mathbb{Z}} \left\{ e^{-\eta^{(2)}(t,z^{-1})} \left(\frac{(w^{(-1)^b}/y^{(-1)^a})^{n+a-b+1} \widetilde{X}^{(ab)}(y,w)\tau_{n+a-b+1}(t)}{\tau_{n+1}(t)} \right) \right.$$
$$\left. \left. - \frac{(w^{(-1)^b}/y^{(-1)^a})^{n+a-b} \widetilde{X}^{(ab)}(y,w)\tau_{n+a-b}(t)}{\tau_n(t)} \right\} E_{nn} \right) \Psi(t,z).$$

A method is developed that extends the nonlinearization technique to the hierarchy of lattice soliton equations associated with a discrete 3×3 matrix spectral problem. A new integrable symplectic map and its involutive system of conserved integrals are obtained by the nonlinearization of spatial parts and the time parts of Lax pairs and their adjoint Lax pairs of the hierarchy. Moreover, the solutions of the typical system of lattice equations in the hierarchy are reduced to the solutions of a system of ordinary differential equations and a simple iterative process of the symplectic map. © *1996 American Institute of Physics.* [S0022-2488(96)00504-3]

I. INTRODUCTION

The study of constructing finite-dimensional integrable systems from soliton hierarchies has received considerable attention in recent years. At least two systematic approaches, the nonlinearization technique[1,2] and the stationary flow technique,[3] have been developed through that quite a few new finite-dimensional integrable systems have been obtained in the Liouville sense.[1–5] Very recently, the two techniques have been generalized to lattice soliton hierarchies associated with discrete 2×2 matrix spectral problems,[6–8] and thus some integrable symplectic maps,[9] i.e., discrete version of classical integrable systems, have been presented.

In this paper, we are going to develop further the nonlinearization technique to treat the lattice soliton hierarchy associated with a discrete 3×3 matrix spectral problem. We give a Bargmann constraint between the eigenfunctions, the adjoint eigenfunctions, and potentials. The discrete 3×3 matrix spectral problem and its adjoint problem are nonlinearized to be a new integrable symplectic map. The nonlinearization of the time parts of the Lax pairs and their adjoint Lax pairs for the lattice soliton hierarchy leads to the involutive system of conserved integrals of the symplectic map. The solutions of the typical system of lattice equations in the hierarchy are reduced to the solutions of a system of ordinary differential equations and a simple iterative process of the symplectic map. We first construct the lattice soliton hierarchy associated with the discrete 3×3 matrix spectral problem and their Hamiltonian structures. Then we discuss the nonlinearization of Lax pairs and their adjoint ones of the lattice soliton hierarchy in detail.

II. THE LATTICE SOLITON HIERARCHY AND THE HAMILTONIAN STRUCTURES

Let us define the shift operator and difference operators by

$$Ef(n)=f(n+1),\quad \Delta f(n)=(E-1)f(n),\quad \Delta^{+}f(n)=(E^{-1}-1)f(n),\quad n\in\mathbf{Z}.$$

We usually write $f(n)=f$, $f(n+k)=E^{k}f$, $k\in\mathbf{Z}$, for the sake of convenience. Consider the discrete 3×3 matrix spectral problem:[10]

0022-2488/96/37(5)/2338/8/$10.00

$$E\psi(\lambda)=U\psi(\lambda),\quad U=\begin{pmatrix}0 & 1 & 0\\ b-\lambda & a & 1\\ c & 0 & 0\end{pmatrix},\quad \psi=\begin{pmatrix}\psi^1(\lambda)\\ \psi^2(\lambda)\\ \psi^3(\lambda)\end{pmatrix},\tag{1}$$

where a,b,c are three potentials and λ is a constant spectral parameter. The adjoint representation equation of (1) reads

$$(EV)U-UV=0,\quad V=(V_{ij})_{3\times 3},\tag{2}$$

where each entry $V_{ij}=V_{ij}(A(\lambda),B(\lambda),D(\lambda))$ of the 3×3 matrix V is a Laurent expansion of λ:

$$V_{11}=D(\lambda),\quad V_{12}=E^{-1}A(\lambda),\quad V_{13}=B(\lambda),$$

$$V_{21}=cEB(\lambda)+(b-\lambda)A(\lambda),\quad V_{22}=ED(\lambda)+aA(\lambda),\quad V_{23}=A(\lambda),$$

$$V_{31}=E^{-1}cE^{-1}A(\lambda)-E^{-1}acB(\lambda),\quad V_{32}=E^{-1}cB(\lambda),$$

$$V_{33}=E^2D(\lambda)+\Delta aA(\lambda)-(b-\lambda)B(\lambda),$$

$$A(\lambda)=\sum_{j\geqslant -1}A_j\lambda^{-j},\quad B(\lambda)=\sum_{j\geqslant -1}B_j\lambda^{-j},\quad D(\lambda)=\sum_{j\geqslant -1}D_j\lambda^{-j}.$$

Then adjoint representation equation (2) is equivalent to the recursion relations:

$$\begin{gathered}(E-E^{-1})A_{-1}=0,\quad (E^2-1)D_{-1}+\Delta aA_{-1}=0,\quad \Delta B_{-1}=0,\\ a\Delta(aA_{j-1}+ED_{j-1})+(Eb-bE^{-1})A_{j-1}+(EcE-E^{-1}c)B_{j-1}=(E-E^{-1})A_j,\\ (cE-E^{-1}cE^{-1}+b\Delta a)A_{j-1}+(E^{-1}ac-acE)B_{j-1}+b(E^2-1)D_{j-1}=(E^2-1)D_j+\Delta aA_j,\\ \Delta EaA_{j-1}+(E^3-1)D_{j-1}-\Delta bB_{j-1}=-\Delta B_j.\end{gathered}\tag{3}$$

The above recursion equations can be solved successively to deduce the following results:

$$\begin{gathered}A_{-1}=0,\quad B_{-1}=1,\quad D_{-1}=0,\\ A_0=c,\quad B_0=b,\quad D_0=-E^{-1}ac,\\ A_1=c(Eb+b),\quad B_1=ac+E^{-1}ac+b^2,\quad D_1=E^{-1}cE^{-1}c-E^{-1}ac(Eb+b).\end{gathered}\tag{4}$$

We define $\{F_j\}$ by the following relation:

$$cF_j=-EaA_j-E^2D_j-ED_j.\tag{5}$$

It is easy to see that

$$\begin{gathered}(\Delta-\Delta^+)D_j=\Delta^+aA_j+\Delta^+E^{-1}cF_j,\\ \Delta aA_j+(E^2-1)D_j=\Delta^+cF_j,\\ ED_j+aA_j=(\Delta-\Delta^+)^{-1}\Delta^+cF_j-(\Delta-\Delta^+)^{-1}\Delta^+aA_j,\\ \Delta EaA_j+(E^3-1)D_j=\Delta(\Delta-\Delta^+)^{-1}\Delta^+aA_j-(\Delta c-\Delta^+c)F_j-\Delta(\Delta-\Delta^+)^{-1}\Delta^+cF_j.\end{gathered}\tag{6}$$

Substituting the above expressions into (3), we obtain

$$KG_{j-1}=JG_j, \quad G_j=(A_j,B_j,F_j)^T, \quad j\geqslant 0, \tag{7}$$

where K and J, the so-called Lenard's operator pair, are two skew-symmetric operators:

$$K=\begin{pmatrix} Eb-bE^{-1}-a\Delta(\Delta-\Delta^+)^{-1}\Delta^+a & EcE-E^{-1}c & a\Delta(\Delta-\Delta^+)^{-1}\Delta^+c \\ cE-E^{-1}cE^{-1} & E^{-1}ac-acE & b\Delta^+c \\ c\Delta(\Delta-\Delta^+)^{-1}\Delta^+a & -c\Delta b & c[\Delta^+-\Delta-\Delta(\Delta-\Delta^+)^{-1}\Delta^+]c \end{pmatrix},$$

$$J=\begin{pmatrix} E-E^{-1} & 0 & 0 \\ 0 & 0 & \Delta^+c \\ 0 & -c\Delta & 0 \end{pmatrix}.$$

From (4) and (7), we have

$$G_{-1}=\begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \quad G_0=\begin{pmatrix} c \\ b \\ a \end{pmatrix}, \quad G_1=\begin{pmatrix} c(Eb+b) \\ b^2+ac+E^{-1}ac \\ a(Eb+b)-Ec-E^{-1}c \end{pmatrix}.$$

Let $\psi(\lambda)$ satisfy the spectral problem (1) and its auxiliary problem

$$\frac{\partial}{\partial t}\psi(\lambda)=V^{(m)}\psi(\lambda), \tag{8}$$

where

$$V^{(m)}=(V_{ij}^{(m)})_{3\times 3}, \quad V_{ij}^{(m)}=V_{ij}(A^{(m)}(\lambda),B^{(m)}(\lambda),D^{(m)}(\lambda)),$$

$$A^{(m)}(\lambda)=\sum_{j=-1}^{m}A_j\lambda^{m-j}, \quad B^{(m)}(\lambda)=\sum_{j=-1}^{m}B_j\lambda^{m-j}, \quad D^{(m)}(\lambda)=\sum_{j=-1}^{m}D_j\lambda^{m-j}.$$

Then the compatibility condition $(\partial/\partial t)E\psi(\lambda)=E(\partial/\partial t)\psi(\lambda)$ between (1) and (8) yields the discrete zero-curvature equation

$$\frac{\partial}{\partial t}U=(EV^{(m)})U-UV^{(m)},$$

which implies the lattice solition equations

$$\frac{\partial}{\partial t}u=X_{m+1}, \quad u=(a,b,c)^T, \quad m\geqslant -1, \tag{9}$$

where $X_j=JG_j=KG_{j-1}$, $j\geqslant 0$. When $m=-1$, (9) is reduced to

$$\frac{\partial}{\partial t}\begin{pmatrix} a(n) \\ b(n) \\ c(n) \end{pmatrix}=\begin{pmatrix} c(n+1)-c(n-1) \\ a(n-1)c(n-1)-c(n)a(n) \\ c(n)(b(n)-b(n+1)) \end{pmatrix}. \tag{10}$$

The Hamiltonian structures of lattice soliton equations (9) can be established by the trace identity.[11] We need the following quantities, which are easy to calculate:

$$\mathrm{tr}\left(\hat{V}\frac{\partial U}{\partial \lambda}\right)=-B(\lambda),\quad \mathrm{tr}\left(\hat{V}\frac{\partial U}{\partial a}\right)=A(\lambda),\quad \mathrm{tr}\left(\hat{V}\frac{\partial U}{\partial b}\right)=B(\lambda),$$

$$\mathrm{tr}\left(\hat{V}\frac{\partial V}{\partial c}\right)=c^{-1}[D(\lambda)+(\lambda-b)B(\lambda)], \tag{11}$$

where $\hat{V}=VU^{-1}$. By means of the trace identity, we have

$$\left(\frac{\delta}{\delta a},\frac{\delta}{\delta b},\frac{\delta}{\delta c}\right)(-B(\lambda))=\left[\lambda^{-\varepsilon}\left(\frac{\partial}{\partial \lambda}\right)\lambda^{\varepsilon}\right]\left(A(\lambda),B(\lambda),\frac{D(\lambda)+(\lambda-b)B(\lambda)}{c}\right), \tag{12}$$

where ε is a constant to be fixed. Equating the coefficients of λ^{-j-1} on both sides of (12), we arrive at

$$(\delta/\delta a,\delta/\delta b,\delta/\delta c)B_{j+1}=(j-\varepsilon)(A_j,B_j,c^{-1}(D_j-bB_j+B_{j+1})), \tag{13}$$

and $(\varepsilon+2)c^{-1}=0$ which implies $\varepsilon=-2$. Notice the third expression of (3), which together with (5) leads to

$$D_j-bB_j+B_{j+1}=cF_j. \tag{14}$$

By (13) and (14), we have

$$(\delta/\delta a,\delta/\delta b,\delta/\delta c)H_j=G_j^T,H_j=\frac{B_{j+1}}{j+2},\quad j\geqslant -1. \tag{15}$$

Hence we deduce that the desired Hamiltonian form of (9)

$$\frac{\partial}{\partial t}u=X_{m+1}=J(\delta/\delta a,\delta/\delta b,\delta/\delta c)^T H_{m+1},\quad m\geqslant -1. \tag{16}$$

III. A SYMPLECTIC MAP

Let us consider another discrete 3×3 matrix spectral problem

$$E\varphi(\lambda)=(U^{-1})^T\varphi(\lambda),\varphi(\lambda)=(\varphi^1(\lambda),\varphi^2(\lambda),\varphi^3(\lambda))^T, \tag{17}$$

which is usually called the adjoint spectral problem of (1). For N mutual distinct eigenvalues $\lambda_1,\ldots,\lambda_N$, the systems associated with (1) and (17) can be written in the form

$$\begin{aligned}E(q_j^1,q_j^2,q_j^3)&=(q_j^1,q_j^2,q_j^3)U(u,\lambda_j)^T,\\ E(p_j^1,p_j^2,p_j^3)&=(p_j^1,p_j^2,p_j^3)U(u,\lambda_j)^{-1},\end{aligned} \tag{18}$$

where $q_j^i=\psi^i(\lambda_j)$, $p_j^i=\varphi^i(\lambda_j)$, $1\leqslant i\leqslant 3$, $1\leqslant j\leqslant N$. It is easy to calculate that the functional gradient of the eigenvalue λ_j with regard to the potentials (a,b,c) is

$$\nabla\lambda_j=\begin{pmatrix}\delta\lambda_j/\delta a\\ \delta\lambda_j/\delta b\\ \delta\lambda_j/\delta c\end{pmatrix}=\begin{pmatrix}q_j^2p_j^3\\ q_j^1p_j^3\\ c^{-1}(q_j^1p_j^1+\lambda_j q_j^1p_j^3-bq_j^1p_j^3)\end{pmatrix}. \tag{19}$$

Such a gradient satisfies the following equation

$$K\nabla\lambda_j=\lambda_j J\nabla\lambda_j, \tag{20}$$

which can be verified by a straightforward computation.

Consider the Bargmann constraint

$$G_0=\sum_{j=1}^{N}\nabla\lambda_j, \tag{21}$$

which implies

$$\begin{gathered}a=\langle q^2,p^3\rangle^{-1}(\langle q^1,p^1\rangle+\langle \Lambda q^1,p^3\rangle-\langle q^1,p^3\rangle^2),\\ b=\langle q^1,p^3\rangle,\quad c=\langle q^2,p^3\rangle,\end{gathered} \tag{22}$$

where $\langle\cdot,\cdot\rangle$ is the standard inner-product in R^N, $\Lambda=\mathrm{diag}\ (\lambda_1,\ldots,\lambda_N)$, $q^i=(q_1^i,\ldots,q_N^i)^T$, $p^i=(p_1^i,\ldots,p_N^i)^T$, $1\leqslant i\leqslant 3$. Substituting (22) into (18) yields the discrete Bargmann system

$$\begin{gathered}Eq^1=q^2,\\ Eq^2=-\Lambda q^1+\langle q^1,p^3\rangle q^1+\langle q^2,p^3\rangle^{-1}(\langle q^1,p^1\rangle+\langle \Lambda q^1,p^3\rangle-\langle q^1,p^3\rangle^2)q^2+q^3,\\ Eq^3=\langle q^2,p^3\rangle q^1,\\ Ep^1=p^2-\langle q^2,p^3\rangle^{-1}(\langle q^1,p^1\rangle+\langle \Lambda q^1,p^3\rangle-\langle q^1,p^3\rangle^2)p^3,\\ Ep^2=p^3,\\ Ep^3=\langle q^2,p^3\rangle^{-1}[p^1+(\Lambda-\langle q^1,p^3\rangle)p^3].\end{gathered} \tag{23}$$

Equations (23) determine a symplectic map H,

$$E(q^1,q^2,q^3,p^1,p^2,p^3)=H(q^1,q^2,q^3,p^1,p^2,p^3), \tag{24}$$

because by direct calculations

$$\sum_{j=1}^{N}\sum_{i=1}^{3}d(Eq_j^i)\wedge d(Ep_j^i)=\sum_{j=1}^{N}\sum_{i=1}^{3}dq_j^i\wedge dp_j^i.$$

IV. THE INTEGRABILITY OF THE SYMPLECTIC MAP

In this section, we want to search for the conserved integrals of the symplectic map H. Let us consider the adjoint equation of (8),

$$\frac{\partial}{\partial t}\varphi(\lambda)=-V^{(m)T}\varphi(\lambda), \tag{25}$$

which together with (17) composes another kind of zero curvature representation for the lattice soliton equations (9). As a matter of fact, we can directly deduce that $(\partial/\partial t)U=(EV^{(m)})U-UV^{(m)}$ if and only if $(\partial/\partial t)(U^{-1})^T=-(EV^{(m)})^T(U^{-1})^T+(U^{-1})^TV^{(m)T}$. In what follows we discuss the nonlinearization of (8) and (25). Resorting to (7), (20), and the constraint (21), we take the following restriction:

$$G_j=\sum_{k=1}^{N}\lambda_k^j\nabla 6\lambda_k, \tag{26}$$

which is a special solution of (7). Equation (26) is equivalent to

$$A_j=\langle\Lambda^j q^2,p^3\rangle,\quad B_j=\langle\Lambda^j q^1,p^3\rangle,$$
$$F_j=c^{-1}(\langle\Lambda^j q^1,p^1\rangle+\langle\Lambda^{j+1}q^1,p^3\rangle-b\langle\Lambda^j q^1,p^3\rangle),\quad j\geqslant 0. \tag{27}$$

Substituting (27) into the first expression of (6), we obtain a solution of D_j, that is

$$D_j=\langle\Lambda^j q^1,p^1\rangle,\quad j\geqslant 0. \tag{28}$$

By using (27), (28), (23), and (22), we have

$$E^{-1}A_j=\langle\Lambda^j q^1,p^2\rangle,\quad E^{-1}cB_j=\langle\Lambda^j q^3,p^2\rangle,$$
$$cEB_j+bA_j=\langle\Lambda^j q^2,p^1\rangle+\langle\Lambda^{j+1}q^2,p^3\rangle,$$
$$E^{-1}cE^{-1}A_j-E^{-1}acB_j=\langle\Lambda^j q^3,p^1\rangle,$$
$$E^2D_j+EaA_j-aA_j-bB_j=\langle\Lambda^j q^3,p^3\rangle-\langle\Lambda^{j+1}q^1,p^3\rangle,$$
$$ED_j+aA_j=\langle\Lambda^j q^2,p^2\rangle,\quad E^{-1}c=\langle q^1,p^2\rangle,\quad Eac=\langle q^3,p^3\rangle.$$

Substituting the above expressions, (27), and (28) into N replicas of (8) and (17) associated with $\lambda_1,\ldots,\lambda_N$,

$$\frac{\partial}{\partial t}(q^1,q^2,q^3)=(q^1,q^2,q^3)V^{(m)}(u,\Lambda_j)^T,$$
$$\frac{\partial}{\partial t}(p^1,p^2,p^3)=-(p^1,p^2,p^3)V^{(m)}(u,\Lambda_j), \tag{29}$$

we arrive at the finite-dimensional Hamiltonian systems

$$\frac{\partial}{\partial t}q^i=\frac{\partial F_m}{\partial p^i},\ \frac{\partial}{\partial t}p^i=-\frac{\partial F_m}{\partial q^i},\quad m\geqslant -1,\quad 1\leqslant i\leqslant 3 \tag{30}$$

with the Hamiltonian functions

$$F_{-1}=\langle\Lambda q^3,p^3\rangle+\langle q^3,p^1\rangle+\langle q^1,p^2\rangle\langle q^2,p^3\rangle-\langle q^3,p^3\rangle\langle q^1,p^3\rangle.$$
$$F_m=\langle\Lambda^{m+2}q^3,p^3\rangle+\langle\Lambda^{m+1}q^3,p^1\rangle+\langle q^1,p^2\rangle\langle\Lambda^{m+1}q^2,p^3\rangle-\langle q^3,p^3\rangle\langle\Lambda^{m+1}q^1,p^3\rangle$$
$$+\frac{1}{2}\sum_{j=0}^{m}\sum_{i=1}^{3}\langle\Lambda^j q^i,p^i\rangle\langle\Lambda^{m-j}q^i,p^i\rangle+\sum_{j=0}^{m}\sum_{1\leqslant i<k\leqslant 3}\langle\Lambda^j q^i,p^k\rangle\langle\Lambda^{m-j}q^k,p^i\rangle. \tag{31}$$

To prove the above Hamiltonian functions are in involution in pairs, $\{F_k,F_m\}=0$, with respect to the Poisson bracket by

$$\{f,g\}=\sum_{i=1}^{3}\sum_{j=1}^{N}\left(\frac{\partial f}{\partial q_j^i}\frac{\partial g}{\partial p_j^i}-\frac{\partial f}{\partial p_j^i}\frac{\partial g}{\partial q_j^i}\right),$$

we consider a bilinear function $\overset{ik}{Q}_\lambda$ on R^N and its partial-fraction expansion and Laurent expansion:

$$\overset{ik}{Q}_\lambda=\langle(\lambda-\Lambda)^{-1}q^i,p^k\rangle=\sum_{j=1}^{N}\frac{q_j^ip_j^k}{\lambda-\lambda_j}=\sum_{m\geqslant -1}\lambda^{-m-2}\langle\Lambda^{m+1}q^i,p^k\rangle.$$

Let

$$\begin{aligned}I_\lambda&=\overset{33}{Q}_\lambda(\Lambda)+\overset{31}{Q}_\lambda+\langle q^1,p^2\rangle\overset{23}{Q}_\lambda-\langle q^3,p^3\rangle\overset{13}{Q}_\lambda,\\ T_\lambda&=\frac{1}{2}\sum_{i=1}^{3}\overset{ii}{Q}_\lambda\overset{ii}{Q}_\lambda+\sum_{1\leqslant i<k\leqslant 3}\overset{ik}{Q}_\lambda\overset{ki}{Q}_\lambda,\end{aligned}\tag{32}$$

where $\overset{ik}{Q}_\lambda(\Lambda^l)=\langle(\lambda-\Lambda)^{-1}\Lambda^lq^i,p^k\rangle$. Noticing the formulas

$$\overset{ik}{Q}_\lambda(\Lambda)=\lambda\overset{ik}{Q}_\lambda-\langle q^i,p^k\rangle,$$

$$\langle(\lambda-\Lambda)^{-1}(\mu-\Lambda)^{-1}q^i,p^k\rangle=(\mu-\lambda)^{-1}(\overset{ik}{Q}_\lambda-\overset{ik}{Q}_\mu),$$

we can verify by a direct calculation that

$$\begin{aligned}\{I_\lambda,I_\mu\}&=(\mu-\lambda)^{-1}(\overset{23}{Q}_\lambda\overset{32}{Q}_\mu-\overset{23}{Q}_\mu\overset{32}{Q}_\lambda+\overset{13}{Q}_\lambda\overset{31}{Q}_\mu-\overset{13}{Q}_\mu\overset{31}{Q}_\lambda),\\ \{I_\lambda,T_\mu\}+\{T_\lambda,I_\mu\}&=(\mu-\lambda)^{-1}(\overset{23}{Q}_\mu\overset{32}{Q}_\lambda-\overset{23}{Q}_\lambda\overset{32}{Q}_\mu+\overset{31}{Q}_\lambda\overset{13}{Q}_\mu-\overset{13}{Q}_\lambda\overset{31}{Q}_\mu),\\ \{T_\lambda,T_\mu\}&=0,\quad\forall\lambda,\mu\in\mathbf{C}.\end{aligned}\tag{33}$$

Using the bilinear property of the Poisson bracket, we have

$$\{\mathscr{F}_\lambda,\mathscr{F}_\mu\}=0,\quad\forall\lambda,\mu\in\mathbf{C},\tag{34}$$

with $\mathscr{F}_\lambda=I_\lambda+T_\lambda$. Substituting the Laurent expansion of $\overset{ik}{Q}_\lambda$ into (32), we obtain

$$\mathscr{F}_\lambda=\sum_{m\geqslant -1}\lambda^{-m-2}F_m,\tag{35}$$

which together with (34) implies $\{F_m,F_l\}=0$ for any l,m. Hence we have immediately the following fact.

Theorem 1: The symplectic map H defined by (24) is completely integrable with the involutive system of conserved integrals $\{F_m\}$.

Theorem 2: Let $(q^1(t),q^2(t),q^3(t),p^1(t),p^2(t),p^3(t))$ be a solution of the initial value problem for the system of ordinary differential equations

$$\begin{aligned}&\frac{\partial}{\partial t}q^i=\frac{\partial F_{-1}}{\partial p^i},\quad\frac{\partial}{\partial t}p^i=-\frac{\partial F_{-1}}{\partial q^i},\quad 1\leqslant i\leqslant 3,\\ &(q^i,p^i)|_{t=0}=(q^i(0),p^i(0)),\end{aligned}\tag{36}$$

and

$$(q^1(n,t),\ldots,q^3(n,t),p^1(n,t),\ldots,p^3(n,t))=H^n(q^1(t),\ldots,q^3(t),p^1(t),\ldots,p^3(t)). \tag{37}$$

Then

$$a(n,t)=\langle q^2(n,t),p^3(n,t)\rangle^{-1}(\langle q^1(n,t),p^1(n,t)\rangle+\langle \Lambda q^1(n,t),p^3(n,t)\rangle-\langle q^1(n,t),p^3(n,t)\rangle^2),$$
$$b(n,t)=\langle q^1(n,t),p^3(n,t)\rangle, c(n,t)=\langle q^2(n,t),p^3(n,t)\rangle \tag{38}$$

solve the system of lattice soliton equations (10).

Proof: Equations (37) and (36) are equivalent to (24) and the system

$$\frac{\partial}{\partial t}q^i(n)=\frac{\partial}{\partial p^i(n)}F_{-1}(q^1(n),\ldots,q^3(n),p^1(n),\ldots,p^3(n)),$$
$$\frac{\partial}{\partial t}p^i(n)=\frac{\partial}{\partial q^i(n)}F_{-1}(q^1(n),\ldots,q^3(n),p^1(n),\ldots,p^3(n)). \tag{39}$$

By using (38), (39), and (21), we obtain

$$\frac{\partial}{\partial t}u(n,t)=J\sum_{j=1}^{N}\nabla\lambda_j=JG_0(n)=X_0(n,t),$$

which is the system (10). The proof is completed.

New no-scalar-hair theorem for black holes

Alberto Saa
Departamento de Física de Partículas, Universidade de Santiago de Compostela, 15706 Santiago de Compostela, Spain

(Received 13 October 1995; accepted for publication 2 February 1996)

A new no-hair theorem is formulated which rules out a very large class of nonminimally coupled finite scalar dressing of an asymptotically flat, static, and spherically symmetric black hole. The proof is very simple and based on a covariant method for generating solutions for nonminimally coupled scalar fields starting from the minimally coupled case. Such a method generalizes the Bekenstein method for conformal coupling and other recent ones. We also discuss the role of the finiteness assumption for the scalar field. © *1996 American Institute of Physics.* [S0022-2488(96)00905-1]

I. INTRODUCTION

Black-hole solutions are very rigid in gravitational physics. We know that the Schwarzschild solution is the only asymptotically flat and spherically symmetric solution of the vacuum Einstein equations. The no-hair conjecture[1] states that the exterior region of a black hole admits only fields for which there is a geometrical Gauss-like law, as electromagnetic fields for example. Early no-hair theorems excluding for the exterior region of a black hole minimally coupled Klein–Gordon,[2] massive vectors,[3] and spinor[4] fields have stressed the conjecture.

The problem of the existence of scalar hairs for black holes has received some attention recently. Although we know that scalar fields are not elementary fields in nature, they commonly arise in effective actions. In fact, some scalar actions have been considered recently in astrophysical contexts (see, for instance Ref. 5). However, with the conformally coupled case as the only exception,[6–8] only minimally coupled scalar fields have been examined. In Ref. 9 a new theorem is presented that rules out a multicomponent scalar hair with nonquadratic Lagrangian, but with minimal coupling to gravity. As it is stressed in Ref. 9, scalar fields effective actions are obtained by integrating the functional integral of the elementary fields in nature over some of the fields, and more complicated actions involving nonminimally coupling should arise.

The purpose of the present work is to point toward the filling of this gap by presenting a theorem that excludes finite scalar hairs of any asymptotically flat, static, and spherically symmetric black hole solution of the system described by the action

$$S[g,\phi]=\int d^4x\sqrt{-g}\{f(\phi)R-h(\phi)g^{\mu\nu}\partial_\mu\phi\partial_\nu\phi\}, \tag{1}$$

with $f(\phi)$ and $h(\phi)>0$. We adopt all the conventions of Ref. 10. Many physically relevant theories belong to the class described by (1). Maybe the most popular nonminimal coupling for the scalars fields corresponds to the choice $f(\phi)=1-\xi\phi^2$ and $h(\phi)=1$. The case $\xi=\frac{1}{6}$ corresponds to the conformal coupling case, and the Bekenstein method[11] allows us to construct its exact solutions from the solutions of the minimally coupled case ($\xi=0$). A method for generating solutions for arbitrary ξ is presented in Ref. 12. The extension of Bekenstein method for n dimensions ($n>3$) was obtained recently in Ref. 6, and used to study conformal scalar hairs[6,7] and gravitational waves.[13] Dilaton-like gravity is given by $f(\phi)=\frac{1}{4}h(\phi)=e^{-2\phi}$. The general model of Bergman, Wagoner, and Nordtved discussed in Ref. 10 corresponds to the choice $f(\phi)=\phi$ and $h(\phi)=\omega(\phi)/\phi$, from which Brans–Dicke theory is obtained from the limit ω constant.

0022-2488/96/37(5)/2346/6/$10.00

The paper is organized as follows. In Section II we present a covariant method for generating solutions for the system described by (1). This method will be the central point for the formulation of the theorem, which is presented in the same section. In Section III, we analyze as particular cases the Brans–Dicke theory and one of its generalizations in order to shed light on the role of the finiteness assumption for the scalar field and its relation to naked singularities. The last section is devoted to some concluding remarks, in particular a comparison between our results and recent ones.

II. THE THEOREM

The proof of our theorem centers on a covariant method for generating solutions for the Euler–Lagrange equations of (1) starting from the well-known solutions for the minimally coupled case,

$$\overline{S[g,\phi]}=\int d^4x\sqrt{-\overline{g}}\,\{\overline{R}-\overline{g}^{\mu\nu}\partial_\mu\overline{\phi}\partial_\nu\overline{\phi}\}. \tag{2}$$

The method uses a conformal transformation, and generalizes the Bekenstein one[11] and the one proposed in Ref. 12. Such a method has a long history, and Ref. 14, for instance, presents a good set of references on the subject. A method of this type was also used in Ref. 15 to show that the action given by $\int d^4x\sqrt{-g}\{F(\phi,R)-g^{\mu\nu}\partial_\mu\phi\partial_\nu\phi\}$ is equivalent to an Einstein–Hilbert action plus minimally coupled self-interacting scalar fields, equivalent in the sense that there is a conformal transformation and ϕ-redefinition connecting them.

The Euler–Lagrange equations obtained from (1) are

$$\begin{aligned} f(\phi)R_{\mu\nu}-h(\phi)\partial_\mu\phi\partial_\nu\phi-D_\mu D_\nu f(\phi)-\tfrac{1}{2}g_{\mu\nu}\Box f(\phi)=0,\\ 2h(\phi)\Box\phi+h'(\phi)g^{\alpha\beta}\partial_\alpha\phi\partial_\beta\phi+f'(\phi)R=0, \end{aligned} \tag{3}$$

where the prime denotes derivation with respect to ϕ. Equations (3) are clearly much more complicated than the Euler–Lagrange equations derived from (2), namely

$$\begin{aligned} \overline{R}_{\mu\nu}-\partial_\mu\overline{\phi}\partial_\nu\overline{\phi}=0,\\ \overline{\Box}\ \overline{\phi}=0. \end{aligned} \tag{4}$$

In order to realize how the solutions of (3) and (4) are related, consider the conformal transformation $g_{\mu\nu}=\Omega^2\overline{g}_{\mu\nu}$. Under a conformal transformation, the scalar of curvature transforms as $R(\Omega^2\overline{g}_{\mu\nu})=\Omega^{-2}R-6\Omega^{-3}\overline{\Box}\Omega$, and with the choice

$$f(\phi)=\Omega^{-2}, \tag{5}$$

one gets from (1)

$$S[\Omega^2\overline{g},\phi]=\int d^4x\sqrt{-\overline{g}}\left\{\overline{R}-\left(\frac{3}{2}\left(\frac{d}{d\phi}\ln f(\phi)\right)^2+\frac{h(\phi)}{f(\phi)}\right)\overline{g}^{\mu\nu}\partial_\mu\phi\partial_\nu\phi\right\}. \tag{6}$$

Now, defining $\overline{\phi}(\phi)$ as

$$\overline{\phi}(\phi)=\int_a^\phi d\xi\sqrt{\frac{3}{2}\left(\frac{d}{d\xi}\ln f(\xi)\right)^2+\frac{h(\xi)}{f(\xi)}}, \tag{7}$$

with arbitrary a, we get the desired result, $S[\Omega^2\overline{g},\phi(\overline{\phi})]=\overline{S[\overline{g},\overline{\phi}]}$. Due to the assumption of f and h positive, the right-hand side of (7) is a monotonically increasing function of ϕ, which guarantees the existence of the inverse $\phi(\overline{\phi})$. The constant a is determined by the boundary conditions of ϕ and $\overline{\phi}$. Also, we have that $\lim_{\overline{\phi}\to\infty}\phi(\overline{\phi})=\infty$.

The transformation given by Eqs. (5) and (7), therefore, maps a solution $(g_{\mu\nu},\phi)$ of (3) to a solution $(\overline{g_{\mu\nu}},\phi)$ of (4). The transformation is independent of any assumption of symmetries, and in this sense is covariant. We can easily infer that the transformation is one-to-one in general, in the sense that any solution of (3) is mapped in a unique solution of (4). Also, the transformation preserves symmetries, which means that if $\overline{g_{\mu\nu}}$ admits a Killing vector ξ such that $\pounds_\xi\overline{\phi}=0$, then ξ is also a Killing vector of $g_{\mu\nu}$ and $\pounds_\xi\phi=0$. From this, one concludes if we know all solutions $(\overline{g_{\mu\nu}},\phi)$ with a given symmetry we automatically know all $(g_{\mu\nu},\phi)$ with the same symmetry. This is the base of the proof.

The general asymptotically flat, static, and spherically symmetric solution $(\overline{g_{\mu\nu}},\overline{\phi})$ of (4) is known. (See Ref. 16 for some properties of the solution and references.) It is given by a two-parameter (λ,r_0) family of solutions

$$\overline{\phi}=\sqrt{2(1-\lambda^2)}\ln\mathscr{R},$$

$$ds^2=\overline{g_{\mu\nu}}dx^\mu dx^\nu=-\mathscr{R}^{2\lambda}dt^2+\left(1-\frac{r_0^2}{r^2}\right)^2\mathscr{R}^{-2\lambda}(dr^2+r^2d\Omega^2), \tag{8}$$

where $\mathscr{R}=(r-r_0)/(r+r_0)$. The parameter λ can take values in $[-1,1]$ in principle, but we neglect the negative range because the solution will have a negative ADM mass.[16] For $\lambda=1$, the solution is the usual exterior vacuum Schwarzschild solution with the horizon at $r_0'=4r_0$, as one can check by using the coordinate transformation $r'=r(1+r_0/r)^2$. For $0\leqslant\lambda<1$, (8) does not represent a black hole due to the fact that the surface $r=r_0$ is not a horizon, i.e., a regular null surface, but it is instead a naked singularity, as we can check, for instance, by calculating the scalar of curvature

$$\overline{R}=\frac{8r_0^2r^4}{(r+r_0)^{2(2+\lambda)}}\times\frac{1-\lambda^2}{(r-r_0)^{2(2-\lambda)}}. \tag{9}$$

In total accordance with the original scalar no-hair theorem,[2] we see the only black hole solution of (8) is that one for which $\lambda=1$ and consequently $\phi=0$, i.e., the usual Schwarzschild solution.

Any asymptotically flat, static, and spherically symmetric solution of (3) can be obtained from (8) by means of the transformations (5) and (7). This provides us with a two-parameter family of $(g_{\mu\nu},\phi)$ solutions. The discussed properties of the transformation (7) and the expression for $\phi(r)$ in (8) lead to the conclusion that the only solution with ϕ finite in the surface $r=r_0$ is that one for which ϕ is constant for $r>r_0$. In this case, (5) is only a rigid scale transformation, and the solution $(g_{\mu\nu},\phi=a)$ is the usual Schwarzschild solution. This is the desired result, which we formulate for clearness as follows.

Theorem: The only asymptotically flat, static, and spherically symmetric exterior solution of the system governed by the action

$$S=\int d^4x\sqrt{-g}\{f(\phi)R-h(\phi)g^{\mu\nu}\partial_\mu\phi\partial_\nu\phi\},\quad f(\phi),h(\phi)>0,$$

with ϕ everywhere finite is the Schwarzschild solution.

It is important to note that the used conformal transformation forbids that $f(\phi)\to\infty$ for any $r\neq r_0$.

Our approach can be extended in a straightforward way to other dimensions. The transformations (5) and (7) can be defined for any dimension $n>2$. They shall be replaced by

$$f=\Omega^{2-n},$$
$$\overline{\phi}(\phi)=\int_a^{\phi} d\xi \sqrt{\frac{n-1}{n-2}\left(\frac{d}{d\xi}\ln f(\xi)\right)^2+\frac{h(\xi)}{f(\xi)}}. \tag{10}$$

The general asymptotically flat, static, and spherically symmetric solution for any space–time dimension $n>3$ of (4) is known.[16] Its expression in isotropic coordinates is given by

$$\overline{\phi}=\sqrt{\frac{n-2}{n-3}(1-\lambda^2)}\ln \mathscr{R}_n,$$
$$ds^2=\overline{g}_{\mu\nu}dx^\mu dx^\nu=-\mathscr{R}_n^{2\lambda}dt^2+\left(1-\frac{r_0^{2n-6}}{r^{2n-6}}\right)^{2/(n-3)}\mathscr{R}_n^{-2\lambda/(n-3)}(dr^2+r^2d\Omega^2), \tag{11}$$

where $\mathscr{R}_n=(r^{n-3}-r_0^{n-3})/(r^{n-3}+r_0^{n-3})$ and $d\Omega$ denotes the metric of the unitary $(n-2)$ sphere. The behavior of the solution (11) is similar to the four-dimensional case. The only true black hole solution is the usual one ($\lambda=1$), due to the fact that the hypersurface $r=r_0$ is not a regular one if $\lambda \neq 1$, as one can see from the expression for the scalar of curvature

$$\overline{R}=\frac{4(n-2)(n-3)r_0^{2(n-3)}r^{2(n-4)}}{(r^{n-3}+r_0^{n-3})^{2(n-2+\lambda)/(n-3)}}\times\frac{1-\lambda^2}{(r^{n-3}-r_0^{n-3})^{2(n-2-\lambda)/(n-3)}}. \tag{12}$$

By applying (10) and the same arguments used in the four-dimensional case we can extend our theorem for any space–time dimension $n>3$.

III. AN EXPLICIT EXAMPLE

A closer look at an explicit example will help us to understand the role of the assumption of finiteness of the scalar field. We see from (8) and (9) that for the minimal coupling, the finiteness of $\overline{\phi}$ is related to the regularity of the horizon. The scalar field diverges in the surface $r=r_0$ for $\lambda \neq 1$; in this case the scalar of curvature has a nonremovable singularity, which confirms that such surface is not a regular one, but it corresponds to a naked singularity. We will see that this is the case for some non-minimal couplings also. To this end, let us consider the Brans–Dicke theory, for which $f(\phi)=\phi$ and $h(\phi)=\omega/\phi$. Using the transformations (5) and (7) we can construct its general asymptotically flat, static, and spherical symmetric solution starting from the minimally coupled solution $(\overline{g}_{\mu\nu},\overline{\phi})$,

$$g_{\mu\nu}=\phi^{-1}\overline{g}_{\mu\nu} \qquad \overline{\phi}=\sqrt{\frac{3}{2}+\omega}\int_a^{\phi}\frac{d\xi}{|\xi|}. \tag{13}$$

The expression for $\overline{\phi}$ is divergent for $a=0$. Also, if we choose $a>0$, then ϕ must be positive too to avoid the singularity. Let us take the solution $(\overline{g}_{\mu\nu},-\overline{\phi})$ of (4), and consider $\phi \in [a,\infty)$, $a>0$. In this case we have

$$\left(\frac{\phi}{a}\right)^{\sqrt{3/2+\omega}}=\left(\frac{r+r_0}{r-r_0}\right)^{\sqrt{2(1-\lambda^2)}}. \tag{14}$$

The expression (14) hides a subtleness in the limit of large ω, maybe the most important limit in Brans–Dicke theory; recent solar system experiments have established $\omega > 600$.[10] In the limit $\omega \to \infty$, the left-hand side of (14) can be 1 or ∞, according to if $\phi = a$ or $\phi > a$. Due to the fact that the right-hand side is bounded for any λ and for $r > r_0$, the consistency of the equation implies that λ must be 1 and $\phi = a$ in the limit $\omega \to \infty$. This would guarantee that one gets the General Relativity in the limit $\omega \to \infty$. Taking this into account we have from (13)

$$\begin{aligned} \phi &= a.\mathscr{R}^{-k}, \\ ads^2 &= -\mathscr{R}^{2\lambda+k}dt^2 + \left(1 - \frac{r_0^2}{r^2}\right)^2 \mathscr{R}^{-2\lambda+k}(dr^2 + r^2 d\Omega^2), \end{aligned} \tag{15}$$

where $k = \sqrt{4(1-\lambda^2)/(3+2\omega)}$. The two-parameter (λ, r_0) family of solutions (15) corresponds to the general asymptotically flat, static, and spherically symmetrical solution of the Brans–Dicke theory.

Our theorem states that the only black hole solution of (15) with finite ϕ is the Schwarzschild one, but, at first sight, we can think that the null-surface $r = r_0$ might be a horizon for some λ or ω. We can check that such a surface is not a regular null-surface, but instead it is a naked singularity for any solution with nonconstant ϕ. To this end, consider the scalar of curvature obtained from (3),

$$R = \frac{\omega}{\phi^2} g^{\mu\nu} \partial_\mu \phi \partial_\nu \phi = \frac{4 r_0^2 r^4}{(r+r_0)^{4+2\lambda-k}} \times \frac{\omega k^2}{(r-r_0)^{4-2\lambda+k}}. \tag{16}$$

One has that $4 - 2\lambda + k > 0$ for $\lambda \in [0,1]$ and for $\omega \in [0,\infty)$, and thus (15) has a nonremovable singularity for any $\lambda \neq 1$ and $\omega \neq 0$. We see that the only true black hole solution is that one for which $\lambda = 1$, i.e., again the Schwarzschild solution with $\phi = a$, as it was predicted by the theorem. The case $\omega = 0$ can be ruled out by analyzing the singularities of quadratic invariants, as for example $R_{\mu\nu}R^{\mu\nu}$, that can be written through (3) by means of ϕ. We notice that the first no-hair theorem for Brans–Dicke theory is due to Hawking,[17] and that Bekenstein also proved recently the absence of scalar hairs in Brans–Dicke theory by using his novel no-hair theorem for minimally coupled scalar fields with non-quadratic Lagrangian.[9]

We can extend this result for theories such that $\omega(\phi)$ is a C^1 function and $\lim_{\phi\to\infty}\omega(\phi) = \omega_c$. For such a case, we can evaluate an asymptotic expression for the scalar of curvature valid for the vicinity of the horizon, and it will lead us to the conclusion that the only black hole solution also for this case is the Schwarzschild one. From (7) one can see that for $\lim_{\phi\to\infty}\omega(\phi) = \omega_c$ and $r \to r_0$ we have

$$\phi(r) \approx a.\mathscr{R}^{-\sqrt{4(1-\lambda^2)/(3-2\omega_c)}}. \tag{17}$$

From (17) we have that the expression for R valid for $r \to r_0$ is the same one of (16), from which we conclude that there is no scalar hair in the model of Bergman, Wagoner, and Nordtved with $\lim_{\phi\to\infty}\omega(\phi) = \omega_c$. The result is valid for any space–time dimension $n > 3$.

We can easily apply analogous arguments to prove the absence of scalar hair in dilaton gravity for any space-time dimension $n > 3$.

IV. FINAL REMARKS

In spite of the theorem's broad assumptions, there are situations that it does not cover. In situations where the divergence of the scalar field is not related to a naked singularity it is possible, in principle, for a scalar hair to exist. This is the case of the Bekenstein conformal scalar hair,[11] which obviously escapes from the theorem's assumptions due to the divergence of the scalar field

in the horizon. Such divergence is not related to any space–time singularity, and for an observer that does not interact directly with the scalar field the divergence is physically harmless.

A recent result due to Zannias[8] also stresses the relevant role of the divergence of the scalar field in the existence of hairs. In our approach, the finiteness of ϕ guarantees that the only null-surface of $g_{\mu\nu}$ corresponds to $r=r_0$. If ϕ diverges for some point of the space–time, say r_1, the conformal factor $\Omega(r_1)$ in (5) vanishes and consequently $g_{00}(r_1)=0$, which would induce another null-surface for $r=r_1$. This is precisely what happens with the Bekenstein conformal hair. However, in principle one can find out case by case asymptotic expressions for the geometrical quantities, as we did in Sec. III, and to control the regions very close to the horizons.

We finish noting that two recent works are devoted to problems similar to the ones discussed here. In Ref. 18 Heusler studies with great detail the case of self-gravitating nonlinear sigma models, for which the action would be given in our notation by

$$S[g,\phi^i]=\int d^4x\sqrt{-g}\{R-h_{jk}(\phi^i)g^{\mu\nu}\partial_\mu\phi^j\partial_\nu\phi^k+W(\phi^i)\}, \tag{18}$$

where $i\in(1,\ldots,N)$. He proved that the only asymptotically flat, static, and spherically symmetric black-hole solution of (18) is the Schwarzschild one. Sudarsky[19] considered the case where $h_{jk}(\phi^i)=\delta_{jk}$, getting the same result in a simpler way. These results are in agreement with our theorem since the case $N=1$ and $W(\phi)=0$ corresponds to our $f=1$ case. However, we believe that our proof is much more simple.

Projective group representations in quaternionic Hilbert space

Stephen L. Adler[a)]
Institute for Advanced Study, Olden Lane, Princeton, New Jersey 08540

(Received 16 January 1996; accepted for publication 26 January 1996)

We extend the discussion of projective group representations in quaternionic Hilbert space that was given in our recent book. The associativity condition for quaternionic projective representations is formulated in terms of unitary operators and then analyzed in terms of their generator structure. The multi-centrality and centrality assumptions are also analyzed in generator terms, and implications of this analysis are discussed. © *1996 American Institute of Physics.*

I. ASSOCIATIVITY CONDITION FOR QUATERNIONIC PROJECTIVE GROUP REPRESENTATIONS

In quaternionic quantum mechanics, all symmetries of the transition probabilities are generated by unitary transformations acting on the states of Hilbert space.[1–3] In the simplest case, the unitary transformations $U_a, U_b, \ldots$ form a representation (or vector representation) of the symmetry group with elements $a, b, \ldots$,

$$U_b U_a = U_{ba}. \tag{1}$$

A more general possibility is that the group multiplication table is represented over the *rays* corresponding to a complete set of physical states, but not over individual state vectors chosen as ray representatives. This more general composition rule defines a quaternionic *projective representation* (or ray representation), and takes the form (Ref. 4, Sec. 4.3)

$$U_b U_a |f\rangle = U_{ba} |f\rangle \omega(f;b,a), \quad |\omega(f;b,a)| = 1, \tag{2}$$

for one particular complete set of states $|f\rangle$ and a set of quaternionic phases $\omega(f;b,a)$. When we change ray representative from $|f\rangle$ to $|f_\phi\rangle \equiv |f\rangle\phi$, with $|\phi| = 1$, the phase defining the projective representation is easily seen to transform as

$$\omega(f_\phi;b,a) = \overline{\phi}\omega(f;b,a)\phi, \tag{3}$$

with the bar denoting quaternion conjugation. Equation (3) shows clearly that the projective phase ω must depend on the state label f as well as on the group elements a, b; failure to take this into account can lead[4] to erroneous conclusions (as in Ref. 5) concerning quaternionic projective representations.

The defining relation for quaternionic projective representations given in Eq. (2) can be rewritten in operator form by defining a left-acting operator $\Omega(b,a)$,

$$\Omega(b,a) = \sum_f |f\rangle \omega(f;b,a) \langle f|, \tag{4a}$$

a)Electronic mail address: adler@sns.ias.edu

0022-2488/96/37(5)/2352/9/$10.00

which, using Eq. (3), is seen to be independent of the ray representative chosen for the states $|f\rangle$. Multiplying Eq. (2) from the right by $\langle f|$ and summing over the complete set of states $|f\rangle$, we obtain the operator form of the projective representation,

$$U_b U_a = U_{ba}\Omega(b,a). \tag{4b}$$

It is also immediate from the definition of Eq. (4a), and the fact that $|\omega|=1$, that the operator $\Omega(b,a)$ is quaternion unitary,

$$\Omega(b,a)^\dagger \Omega(b,a) = \Omega(b,a)\Omega(b,a)^\dagger = 1. \tag{5}$$

Note that if we were to make the definition of a quaternionic projective representation more restrictive by requiring that Eq. (2) hold for *all* states in Hilbert space, rather than for one particular complete set of states, then we would require $\Omega(b,a)=1$, since the unit operator is the only unitary operator which is simultaneously diagonal on all complete bases in quaternionic Hilbert space. Hence this more restrictive definition excludes quaternionic embeddings of complex projective representations, whereas these are admitted as quaternionic projective representations by the definition of Eq. (2).

A nontrivial condition on the projective representation structure is obtained from the associativity of multiplication in quaternionic Hilbert space, which implies

$$(U_c U_b)U_a = U_c(U_b U_a). \tag{6}$$

Applying Eq. (4b) twice to the left-hand side of Eq. (6), we obtain

$$(U_c U_b)U_a = U_{cb}\Omega(c,b)U_a = U_{cb}U_a U_a^{-1}\Omega(c,b)U_a = U_{cba}\Omega(cb,a)U_a^{-1}\Omega(c,b)U_a, \tag{7a}$$

while applying Eq. (4b) twice to the right-hand side of Eq. (6) gives

$$U_c(U_b U_a) = U_c U_{ba}\Omega(b,a) = U_{cba}\Omega(c,ba)\Omega(b,a). \tag{7b}$$

Upon multiplying from the left by U_{cba}^{-1}, Eqs. (7a) and (7b) give the operator form of the *associativity condition*:

$$\Omega(c,ba)\Omega(b,a) = \Omega(cb,a)U_a^{-1}\Omega(c,b)U_a. \tag{8}$$

We can also express the associativity condition as a condition on the quaternionic phase $\omega(f;b,a)$ introduced in Eq. (2), by applying the spectral representation of Eq. (4a) to the operator form of the associativity condition given in Eq. (8). From Eq. (4a) we obtain

$$\Omega(c,ba) = \sum_f |f\rangle\omega(f;c,ba)\langle f|, \tag{9a}$$

which when multiplied from the right by Eq. (4a) gives

$$\Omega(c,ba)\Omega(b,a) = \sum_f |f\rangle\omega(f;c,ba)\omega(f;b,a)\langle f|. \tag{9b}$$

Equation (4a) and the unitarity of $\Omega(cb,a)$ also imply that

$$\Omega(cb,a)^{-1} = \sum_f |f\rangle\overline{\omega(f;cb,a)}\langle f|, \tag{9c}$$

and so the associativity condition of Eq. (8) can be rewritten as

$$U_a^{-1}\Omega(c,b)U_a=\Omega(cb,a)^{-1}\Omega(c,ba)\Omega(b,a)=\sum_f |f\rangle\overline{\omega(f;cb,a)}\omega(f;c,ba)\omega(f;b,a)\langle f|. \tag{10}$$

Hence $U_a^{-1}\Omega(c,b)U_a$ is diagonal in the basis spanned by the states $|f\rangle$. Taking matrix elements of Eq. (10), and using the unitarity of U_a, the associativity condition gives the two relations

$$\overline{\omega(f;cb,a)}\omega(f;c,ba)\omega(f;b,a)=\sum_{f''} \overline{\langle f''|U_a|f\rangle}\omega(f'';c,b)\langle f''|U_a|f\rangle, \tag{11}$$

and, when $\langle f'|f\rangle=0$,

$$0=\sum_{f''} \overline{\langle f''|U_a|f\rangle}\omega(f'';c,b)\langle f''|U_a|f'\rangle. \tag{12}$$

We conclude this section by comparing the quaternionic Hilbert space form of the associativity condition with the simpler form which is familiar from complex Hilbert space.[6,7] In a complex Hilbert space, the phase $\omega(f;b,a)$ introduced in Eq. (2) is a complex number, and commutes with the phase ϕ, also now complex, which we introduced in Eq. (3) to describe a change of ray representative. Hence Eq. (3) implies, in the complex case, that $\omega(f;b,a)$ is independent of the ray representative chosen for the state $|f\rangle$, and it is then consistent to assume that $\omega(f;b,a)$ is independent of the state label f, so that

$$\omega(f;b,a)=\omega(b,a) \quad \text{complex Hilbert space.} \tag{13a}$$

Substituting Eq. (13a) into Eq. (4a), we now obtain

$$\Omega(b,a)=\sum_f |f\rangle\omega(b,a)\langle f|=\omega(b,a)\sum_f |f\rangle\langle f|=\omega(b,a)1, \tag{13b}$$

where 1 denotes the unit operator in complex Hilbert space. Since the complex phase $\omega(b,a)$ is a c-number in complex Hilbert space, on substituting Eq. (13b) into Eq. (4b) we learn that

$$U_bU_a=U_{ba}\omega(b,a)=\omega(b,a)U_{ba}, \tag{14a}$$

which is the standard definition of a projective representation in complex Hilbert space. Moreover, since Eq. (13b) implies that $\Omega(b,a)$ commutes with the unitary operator U_a, the associativity condition of Eqs. (8) and (11) reduces to the familiar complex Hilbert space form

$$\omega(c,ba)\omega(b,a)=\omega(cb,a)\omega(c,b). \tag{14b}$$

II. THE ASSOCIATIVITY CONDITION IN GENERATOR FORM

Let us now assume that the symmetry group with which we are dealing is a Lie group, so that in the neighborhood of the identity e the unitary transformations $U_a, U_b, U_{ba}, \ldots$ can be written in terms of a set of anti-self-adjoint generators $\tilde{G}_A$ as

$$U_a=\exp\left(\sum_A \theta_A^a\tilde{G}_A\right), \quad U_b=\exp\left(\sum_A \theta_A^b\tilde{G}_A\right), \quad U_{ba}=\exp\left(\sum_A \theta_A^{ba}\tilde{G}_A\right),\ldots, \tag{15a}$$

with $\theta_A^e=0$ and $U_e=1$. Then Eq. (4b) implies that $\Omega(b,a)$ must be unity when either a or b is the identity, and thus the generator form for this operator is

$$\Omega(b,a)=\exp\left(\frac{1}{2}\sum_{BA}\left[\theta_B^b\theta_A^a\widetilde{I}_{BA}+\sum_C\ \theta_B^b\theta_C^b\theta_A^a\widetilde{J}^{(1)}_{(BC)A}+\sum_C\ \theta_B^b\theta_A^a\theta_C^a\widetilde{J}^{(2)}_{B(AC)}+O(\theta^4)\right]\right), \quad (15b)$$

where the parentheses ( ) around a set of indices indicate that the tensor in question is symmetric in those indices, and where we use the tilde to indicate operators which are anti-self-adjoint. The parameters θ_C^{ba} must be functions of the parameters θ_A^a and θ_B^b,

$$\theta_C^{ba}=\psi_C^{ba}(\{\theta_B^b\},\{\theta_A^a\})=\theta_C^b+\theta_C^a+\frac{1}{2}\sum_{BA}\ C_{BAC}\theta_B^b\theta_A^a+O(\theta^3), \quad (15c)$$

where in making the Taylor expansion we have used the fact that $U_{be}=U_b$ and $U_{ea}=U_a$, which fixes the linear terms in the expansion and requires the quadratic term to be bilinear.

We proceed now to derive a number of relations by combining the generator expansions of Eqs. (15a)–(15c) with the formulas of Sec. I. We begin by substituting Eqs. (15a)–(15c) into Eq. (4b) using the Baker–Campbell–Hausdorff formula,

$$\exp X\ \exp Y=\exp(X+Y+\tfrac{1}{2}[X,\ Y]+\cdots), \quad (16a)$$

to combine exponents arising from the factors on the left and right. From the left-hand side of Eq. (4b) we obtain,

$$U_bU_a=\exp\left(\sum_B\ \theta_B^b\widetilde{G}_B+\sum_A\ \theta_A^a\widetilde{G}_A+\frac{1}{2}\sum_{BA}\ \theta_B^b\theta_A^a[\widetilde{G}_B,\ \widetilde{G}_A]+O(\theta^3)\right), \quad (16b)$$

while from the right-hand side of Eq. (4b) we obtain

$$U_{ba}\Omega(b,a)=\exp\left(\sum_C\ (\theta_C^b+\theta_C^a)\widetilde{G}_C+\frac{1}{2}\sum_{CBA}\ C_{BAC}\theta_B^b\theta_A^a\widetilde{G}_C+\frac{1}{2}\sum_{BA}\ \theta_B^b\theta_A^a\widetilde{I}_{BA}+O(\theta^3)\right). \quad (16c)$$

Equating Eqs. (16b) and (16c) thus gives the relations

$$[\widetilde{G}_B,\ \widetilde{G}_A]=\sum_C\ C_{[BA]C}\widetilde{G}_C+\widetilde{I}_{[BA]} \quad (17a)$$

and

$$0=\sum_C\ C_{(BA)C}\widetilde{G}_C+\widetilde{I}_{(BA)}, \quad (17b)$$

where the square brackets [ ] around a set of indices indicates that the tensor in question is antisymmetric in these indices. We shall restrict ourselves henceforth to the case in which $C_{(BA)C}=0$, which by Eq. (17b) implies that $\widetilde{I}_{(BA)}=0$; making this assumption then implies that $C_{BAC}=C_{[BA]C}$ and $\widetilde{I}_{BA}=\widetilde{I}_{[BA]}$. In other words, we are assuming that the structure constants C_{BAC} for a projective representation have the same antisymmetric form as holds for a vector representation. Changing the summation index C to D in Eq. (17a), and then taking the commutator of Eq. (17a) with $\widetilde{G}_C$, we find

$$[\widetilde{G}_C,[\widetilde{G}_B,\ \widetilde{G}_A]]=\sum_D\ C_{[BA]D}[\widetilde{G}_C,\ \widetilde{G}_D]+[\widetilde{G}_C,\ \widetilde{I}_{[BA]}]; \quad (18a)$$

adding to this identity the two related identities obtained by cyclically permuting A,B,C, using the fact that the left-hand side of the sum vanishes by the Jacobi identity for the commutator, and substituting Eq. (17a) for the commutators appearing on the right-hand side of the sum, we obtain the identity

$$\sum_{DE}\ (C_{[BA]D}C_{[CD]E}+C_{[CB]D}C_{[AD]E}+C_{[AC]D}C_{[BD]E})\widetilde{G}_E$$
$$+\sum_{D}\ (C_{[BA]D}\widetilde{I}_{[CD]}+C_{[CB]D}\widetilde{I}_{[AD]}+C_{[AC]D}\widetilde{I}_{[BD]})$$
$$+[\widetilde{G}_C\,,\,\widetilde{I}_{[BA]}]+[\widetilde{G}_A\,,\,\widetilde{I}_{[CB]}]+[\widetilde{G}_B\,,\,\widetilde{I}_{[AC]}]=0. \tag{18b}$$

We next substitute Eqs. (15a)–(15c) into the associativity condition of Eq. (8), now keeping cubic terms in the exponent of the form $\theta_A^a\theta_B^b\theta_C^c$, but dropping cubic terms, such as $\theta_A^a\theta_B^a\theta_C^c$, that do not contain all three of the upper indices a,b,c. For the first factor on the left-hand side of Eq. (8), we find from Eqs. (15b) and (15c) that

$$\Omega(c,ba)=\exp\left(\frac{1}{2}\sum_{BA}\ \left(\ \theta_B^c\theta_A^{ba}\widetilde{I}_{[BA]}+\sum_{C}\ \theta_B^c\theta_A^{ba}\theta_C^{ba}\widetilde{J}^{(2)}_{B(AC)}\right)\right)$$
$$=\exp\left(\frac{1}{2}\sum_{BA}\ \left[\ \theta_B^c\left(\ \theta_A^b+\theta_A^a+\frac{1}{2}\sum_{DE}\ C_{[DE]A}\theta_D^b\theta_E^a\right)\widetilde{I}_{[BA]}\right.\right.$$
$$\left.\left.+2\sum_{C}\ \theta_B^c\theta_A^b\theta_C^a\widetilde{J}^{(2)}_{B(AC)}\right]\right), \tag{19a}$$

while for the second factor on the left-hand side of Eq. (8) we have

$$\Omega(b,a)=\exp\left(\frac{1}{2}\sum_{BA}\ \theta_B^b\theta_A^a\widetilde{I}_{[BA]}\right). \tag{19b}$$

Since the exponents in Eqs. (19a) and (19b) both begin at order θ^2, through order θ^3 we can simply add exponents to get the product on the left-hand side of Eq. (8). Proceeding similarly for the first factor on the right-hand side of Eq. (8), we obtain

$$\Omega(cb,a)=\exp\left(\frac{1}{2}\sum_{BA}\ \left(\ \theta_B^{cb}\theta_A^a\widetilde{I}_{[BA]}+\sum_{C}\ \theta_B^{cb}\theta_C^{cb}\theta_A^a\widetilde{J}^{(1)}_{(BC)A}\right)\right)$$
$$=\exp\left(\frac{1}{2}\sum_{BA}\ \left[\left(\ \theta_B^c+\theta_B^b+\frac{1}{2}\sum_{DE}\ C_{[DE]B}\theta_D^c\theta_E^b\right)\theta_A^a\widetilde{I}_{[BA]}\right.\right.$$
$$\left.\left.+2\sum_{C}\ \theta_B^c\theta_C^b\theta_A^a\widetilde{J}^{(1)}_{(BC)A}\right]\right), \tag{20a}$$

while for the second factor on the right-hand side of Eq. (8), use of the Baker–Campbell–Hausdorff formula gives

$$U_a^{-1}\Omega(c,b)U_a=\exp\left(-\sum_{A}\ \theta_A^a\widetilde{G}_A\right)\exp\left(\frac{1}{2}\sum_{CB}\ \theta_C^c\theta_B^b\widetilde{I}_{[CB]}\right)\exp\left(\sum_{A}\ \theta_A^a\widetilde{G}_A\right)$$

$$=\exp\left(\frac{1}{2}\sum_{CB}\ \theta_C^c\theta_B^b\widetilde{I}_{[CB]}-\frac{1}{2}\sum_{A}\ \sum_{CB}\ \theta_A^a\theta_C^c\theta_B^b[\widetilde{G}_A\,,\ \widetilde{I}_{[CB]}]\right). \tag{20b}$$

Since the exponents in Eqs. (20a) and (20b) begin at order θ^2, it again suffices to simply add the exponents to form the product appearing on the right-hand side of Eq. (8). Thus, to the requisite order, the content of Eq. (8) is obtained by equating the sum of the exponents in Eqs. (19a) and (19b) to the corresponding sum of exponents in Eqs. (20a) and (20b). The quadratic terms in θ are immediately seen to be identical on left and right, while the cubic term proportional to $\theta_A^a\theta_B^b\theta_C^c$ gives (after some relabeling of dummy summation indices) the nontrivial identity

$$\widetilde{J}^{(2)}_{C(BA)}+\frac{1}{4}\sum_{D}\ C_{[BA]D}\widetilde{I}_{[CD]}=\widetilde{J}^{(1)}_{(CB)A}+\frac{1}{4}\sum_{D}\ C_{[CB]D}\widetilde{I}_{[DA]}-\frac{1}{2}\,[\widetilde{G}_A\,,\ \widetilde{I}_{[CB]}]. \tag{21}$$

On totally antisymmetrizing with respect to the indices A,B,C, the terms in Eq. (21) involving $\widetilde{J}^{(1,2)}$ drop out, and we are left with the identity

$$\sum_{D}\ (C_{[BA]D}\widetilde{I}_{[CD]}+C_{[CB]D}\widetilde{I}_{[AD]}+C_{[AC]D}\widetilde{I}_{[BD]})+[\widetilde{G}_C\,,\ \widetilde{I}_{[BA]}]+[\widetilde{G}_A\,,\widetilde{I}_{[CB]}]+[\widetilde{G}_B\,,\widetilde{I}_{[AC]}]=0. \tag{22a}$$

In other words, associativity implies that the sum of the second and third lines of Eq. (18b) vanishes separately; hence the first line of Eq. (18b) must also vanish, and since the generators $\widetilde{G}_E$ are linearly independent this gives the Jacobi identity for the structure constants,

$$\sum_{DE}\ (C_{[BA]D}C_{[CD]E}+C_{[CB]D}C_{[AD]E}+C_{[AC]D}C_{[BD]E})=0. \tag{22b}$$

In the complex case, in which $\Omega(a,b)=\omega(a,b)1$ is a c-number, the tensor $\widetilde{I}_{[AB]}$ is a c-number ''central charge'' and the commutator terms in Eqs. (18b) and (22a) vanish identically. Therefore, in the complex case, Eq. (18b) implies both Eq. (22b) and the identity

$$\sum_{D}\ (C_{[BA]D}\widetilde{I}_{[CD]}+C_{[CB]D}\widetilde{I}_{[AD]}+C_{[AC]D}\widetilde{I}_{[BD]})=0\quad\text{complex case,} \tag{23}$$

and so one obtains the entire content of the associativity condition from the simpler analysis leading to Eq. (18b), without having to perform the third-order expansion needed to obtain Eq. (22a).

III. GENERAL, MULTI-CENTRAL, AND CENTRAL QUATERNIONIC PROJECTIVE REPRESENTATIONS

The analysis of Sec. II applies to the general case (apart from the restriction $C_{(BA)C}=0$) of a quaternionic projective representation; in order to obtain more detailed results it is necessary to introduce further structural assumptions. In Ref. 4 two special classes of quaternionic projective representations are defined. A quaternionic projective representation is defined to be *multi-central* if

$$[\Omega(b,a),\ U_a]=[\Omega(b,a),\ U_b]=0,\quad\text{all}\ \ a,b, \tag{24a}$$

while it is defined to be *central* if

$$[\Omega(b,a),\ U_c]=0,\quad\text{all}\ \ a,b,c. \tag{24b}$$

Expressed in terms of the generators introduced in Eqs. (15a)–(15b), the multi-centrality condition takes the form

$$\sum_{ABC} \theta_A^a \theta_B^b \theta_C^a [\tilde{G}_C, \tilde{I}_{[BA]}] = \sum_{ABC} \theta_A^a \theta_B^b \theta_C^b [\tilde{G}_C, \tilde{I}_{[BA]}] = 0, \quad \text{all } a,b, \tag{25a}$$

while the centrality condition becomes

$$\sum_{ABC} \theta_A^a \theta_B^b \theta_C^c [\tilde{G}_C, \tilde{I}_{[BA]}] = 0, \quad \text{all } a,b,c. \tag{25b}$$

Making the definition

$$\Delta_{[AB]C} = [\tilde{G}_C, \tilde{I}_{[BA]}], \tag{25c}$$

we see from Eq. (25a) that multi-centrality requires that $\Delta_{[AB]C}$ be antisymmetric in A,C and in B,C as well as in A,B; thus in the multi-central case Δ is totally antisymmetric, which we will indicate by writing it as $\Delta_{[ABC]}$. From Eq. (25b), we see that centrality requires that $\Delta_{[AB]C}$ must vanish.

Using the generator formulation, we proceed now to discuss successively the general, multi-central, and central cases in the light of the associativity analysis of Sec. II.

(1) *The general case.* An example given in Eqs. (13.54g) and (14.23a) of Ref. 4 shows that one can have a quaternionic projective representation which is neither central nor multi-central. The example is constructed from n independent fermion creation and annihilation operators $b_\ell^\dagger$, b_ℓ, $\ell = 1,\ldots,n$, which commute with a left algebra quaternion basis $E_0 = 1, E_1 = I, E_2 = J, E_3 = K$. Consider the set of three generators $\tilde{G}_A$ defined by

$$\tilde{G}_A = -\tfrac{1}{2} E_A N, \quad A = 1,2,3, \tag{26a}$$

with N the number operator

$$N = \sum_{\ell=1}^{n} b_\ell^\dagger b_\ell. \tag{26b}$$

The commutator algebra of these generators has the form of a projective representation of SU(2),

$$\begin{aligned} [\tilde{G}_B, \tilde{G}_A] &= -\sum_{C=1}^{3} \epsilon_{[BAC]} \tilde{G}_C + \tilde{I}_{[BA]}, \\ \tilde{I}_{[BA]} &= \sum_{C=1}^{3} \epsilon_{[BAC]} \frac{1}{2} E_C N(N-1), \end{aligned} \tag{26c}$$

with ϵ the usual three-index antisymmetric tensor. A simple calculation now shows that

$$[\tilde{G}_A, \tilde{I}_{[BC]}] = -N(N-1)(\delta_{AB}\tilde{G}_C - \delta_{AC}\tilde{G}_B), \tag{27a}$$

which is not antisymmetric in either the index pair A,C or the pair A,B, and so the multi-centrality condition is not satisfied. Another simple calculation shows that

$$\sum_D (\epsilon_{[BAD]}\tilde{I}_{[CD]} + \epsilon_{[CBD]}\tilde{I}_{[AD]} + \epsilon_{[ACD]}\tilde{I}_{[BD]}) = 0, \tag{27b}$$

by virtue of the Jacobi identity for the structure constant ϵ, and also

$$[\tilde{G}_C,\tilde{I}_{[BA]}]+[\tilde{G}_A,\tilde{I}_{[CB]}]+[\tilde{G}_B,\tilde{I}_{[AC]}]=0. \tag{27c}$$

Hence the associativity condition of Eq. (22a) is satisfied, with the first and second lines each vanishing separately.

(2) *The multi-central case*. Let us now consider the multi-central case, in which $\Delta_{[AB]C}$ defined in Eq. (25c) is totally antisymmetric in A,B,C, as indicated by the notation $\Delta_{[ABC]}$. The associativity condition of Eq. (22a) then simplifies to

$$\sum_D (C_{[BA]D}\tilde{I}_{[CD]}+C_{[CB]D}\tilde{I}_{[AD]}+C_{[AC]D}\tilde{I}_{[BD]})+3\Delta_{[ABC]}=0. \tag{28a}$$

A further equation involving Δ is obtained from the Jacobi identity

$$[\tilde{G}_D,[\tilde{G}_C,\tilde{I}_{[BA]}]]-[\tilde{G}_C,[\tilde{G}_D,\tilde{I}_{[BA]}]]=[\tilde{I}_{[BA]},[\tilde{G}_C,\tilde{G}_D]], \tag{28b}$$

which on substituting Eqs. (17a) and (25c) becomes

$$[\tilde{G}_D,\Delta_{[AB]C}]-[\tilde{G}_C,\Delta_{[AB]D}]=-\sum_E C_{[CD]E}\Delta_{[AB]E}+[\tilde{I}_{[BA]},\tilde{I}_{[CD]}], \tag{28c}$$

an equation which holds even in the general case in which Δ is not totally antisymmetric. Specializing Eq. (28c) to the multi-central case and contracting it with $\delta_{AC}\delta_{BD}$, the left-hand side vanishes because of the antisymmetry of Δ, while the commutator term on the right-hand side becomes $\Sigma_{AB}[\tilde{I}_{[BA]},\tilde{I}_{[AB]}]=0$, leaving the identity (after relabeling the dummy index E as C)

$$\sum_{ABC} C_{[AB]C}\Delta_{[ABC]}=0. \tag{29}$$

Thus in order for a multi-central projective representation to exist which has $\Delta\neq 0$ and so is not also central, there must be a three-index antisymmetric tensor $\Delta_{[ABC]}$ which vanishes when all three indices are contracted with the structure constant $C_{[AB]C}$. This condition is not easy to satisfy and so we pose the question, which we have not been able to answer: Can one construct an example of a multi-central quaternionic projective representation which is not central, or can one prove (in general, or with a restriction, e.g., to simple or semi-simple groups) that a multi-central quaternionic projective representation must always be central? The application of multi-centrality in Ref. 4 sheds no light on this issue; multi-centrality was used there (e.g., in Sec. 12.3) to show that quaternionic Poincaré group projective representations outside the zero energy sector can always be transformed to complex Poincaré group projective representations, which in the sector continuously connected to the identity are known[8] to be transformable to vector representations.

(3) *The central case*. Let us finally consider the central case in which $\Delta=0$, which by Eqs. (25c) and (28c) implies that $\tilde{I}_{[BA]}$ commutes with both $\tilde{G}_C$ and $\tilde{I}_{[CD]}$ for arbitrary values of the indices. Thus $\tilde{I}_{[BA]}$ behaves as a central charge, justifying the name ''central'' for this case. The various results obtained in Bargmann[6] can be immediately generalized to the quaternionic central case; for example, the analysis of Ref. 6 can be easily extended to show that the central charges associated with a quaternionic central projective representation of a semi-simple Lie group can always be removed by redefinition of the generators; and again, the nontrivial illustration[6] of a complex projective representation, constructed in terms of the phase space translation generators in nonrelativistic quantum mechanics, can be embedded[4] in quaternionic quantum mechanics as a central projective representation.

Derivation of conservation laws from nonlocal symmetries of differential equations

Stephen C. Anco[a] and George Bluman[b]
Department of Mathematics, University of British Columbia, Vancouver, BC V6T 1Z2 Canada

(Received 21 September 1995; accepted for publication 7 November 1995)

An identity is derived which yields a correspondence between symmetries and conservation laws for self-adjoint differential equations. This identity does not rely on use of a Lagrangian as needed to obtain conservation laws by Noether's theorem. Moreover, unlike Noether's theorem, which can only generate conservation laws from local symmetries, the derived identity generates conservation laws from *nonlocal* as well as local symmetries. It is explicitly shown how Noether's theorem is extended by the identity. Conservation laws arising from nonlocal symmetries are obtained for a class of scalar wave equations with variable wave speeds. The constants of motion resulting from these nonlocal conservation laws are shown to be linearly independent of all constants of motion resulting from local conservation laws. © *1996 American Institute of Physics.* [S0022-2488(96)02405-2]

I. INTRODUCTION

Conservation laws can be found for self-adjoint systems of differential equations by Noether's theorem.[1–3] If a local symmetry admitted by a given system leaves invariant the variational principle of the system, Noether's theorem yields a corresponding conservation law of local type. Conversely, all conservation laws of local type for a given system arise from the local symmetries admitted by the system. A limitation of Noether's theorem, however, is that it can only directly deal with local symmetries and hence conservation laws of local type. This poses a significant incompleteness in the study of differential equations since conservation laws of nonlocal type are equally as useful as those of local type. In particular, as will be shown in this article, conservation laws of nonlocal type yield additional constants of motion and thus expand the utility of methods of analysis which depend on conservation laws.

In this article we introduce an expression that yields conservation laws from nonlocal symmetries as well as local symmetries admitted by an arbitrary self-adjoint system of differential equations. Significantly, in contrast to the formulation of Noether's theorem, the expression is derived from a bilinear identity that makes no use of a Lagrangian. As preliminaries to the derivation and main results, we now give definitions of local and nonlocal symmetries and conservation laws of local and nonlocal type for self-adjoint systems of differential equations.

Consider a system of differential equations (DEs) given by

$$G_\sigma(x,u,\underset{1}{u},\ldots,\underset{K}{u})=0, \quad \sigma=1,\ldots,M \tag{1.1}$$

for $M\geqslant 1$ dependent variables $u=(u^1,\ldots,u^M)$ which are functions of $N\geqslant 1$ independent variables $x=(x^1,\ldots,x^N)$, with $\underset{J}{u}$ denoting all Jth order derivatives of u with respect to x. For the sequel, we let D_i denote total differentiation with respect to x^i, where $i=1,\ldots,N$, and we use the index notation $u^\gamma_{i_1\cdots i_J} = D_{i_1}\cdots D_{i_J}u^\gamma$ for differentiations of u, where $\gamma=1,...,M$, $i_J=1,\ldots,N$, and

[a]Electronic mail: anco@math.ubc.ca
[b]Electronic mail: bluman@math.ubc.ca

$J=1,2,\ldots$. Hereafter, unless otherwise stated, we use the index conventions that all Greek indices range from 1 to M, all Latin indices (lower case) range from 1 to N, while summation is assumed over any repeated indices in all expressions.

Definition 1.1: The Fréchet derivative associated with system (1.1) is the matrix linear operator

$$\mathscr{T}_{\sigma\rho}=\frac{\partial G_\sigma}{\partial u^\rho}+\frac{\partial G_\sigma}{\partial u^\rho_i}D_i+\cdots+\frac{\partial G_\sigma}{\partial u^\rho_{i_1\cdots i_K}}D_{i_1}\cdots D_{i_K}. \tag{1.2}$$

Definition 1.2: A symmetry admitted by system (1.1) is characterized by an infinitesimal generator

$$\mathbf{X}=\eta^\mu\partial/\partial u^\mu, \tag{1.3}$$

where η^μ *satisfies*

$$\mathscr{T}_{\sigma\rho}\eta^\rho=0 \tag{1.4}$$

for every solution $u(x)$ *of system (1.1).*

Definition 1.3: A local symmetry admitted by system (1.1) is a symmetry with an infinitesimal generator of the form

$$\mathbf{X}=\eta^\mu(x,u,\underset{1}{u},\ldots,\underset{P}{u})\partial/\partial u^\mu \tag{1.5}$$

such that, for all values of x, η^μ *depends on* $u,\underset{1}{u},\ldots,\underset{P}{u}$ *only through* $u(x),\underset{1}{u}(x),\ldots,\underset{P}{u}(x)$ *evaluated at* x.

Definition 1.4: A nonlocal symmetry admitted by system (1.1) is a symmetry with an infinitesimal generator $\mathbf{X}=\eta^\mu\partial/\partial u^\mu$ *not of the form (1.5), such that* η^μ *has other than just a local dependence on* $u(x)$ *and derivatives of* $u(x)$ *to some finite order.*

All local symmetries of system (1.1) can be determined by Lie's algorithm.[2,3] No corresponding procedure exists to find *all* nonlocal symmetries of system (1.1).

There is an algorithm[3–6] to determine special nonlocal symmetries, called *potential symmetries*, if one DE of system (1.1) is a divergence expression. These potential symmetries arise as local symmetries admitted by auxiliary systems associated to system (1.1). In the case of two independent variables ($N=2$), suppose system (1.1) has a DE of the form

$$G_\sigma(x,u,\underset{1}{u},\ldots,\underset{K}{u})=D_1f^1(x,u,\underset{1}{u},\ldots,\underset{K-1}{u})+D_2f^{\,2}(x,u,\underset{1}{u},\ldots,\underset{K-1}{u})=0,\quad \sigma=M. \tag{1.6}$$

Through Eq. (1.6) one can introduce an auxiliary potential variable v and form a potential system given by

$$G_\sigma=0,\quad \sigma=1,\ldots,M-1, \tag{1.7}$$

$$D_2v=f^1,\quad D_1v=-f^{\,2}. \tag{1.8}$$

If $(u(x),v(x))$ satisfies system (1.7)–(1.8), then $u(x)$ satisfies system (1.1); if $u(x)$ satisfies system (1.1), then there exists some $v(x)$ (unique up to the addition of an arbitrary constant) such that $(u(x),v(x))$ satisfies system (1.7)–(1.8). Since $v(x)$ is determined in terms of integrals of $u(x)$, a local symmetry of system (1.7)–(1.8) may yield a nonlocal symmetry of system (1.1). In particular, such a nonlocal symmetry arises if and only if an infinitesimal generator of a local

symmetry of system (1.7)–(1.8) does not project onto an infinitesimal generator of a local symmetry admitted by system (1.1). Similar considerations hold for the case of more than two independent variables.

Definition 1.5: A conservation law of system (1.1) is a divergence free expression $D_i\Psi^i=0$ *which holds for every solution of system (1.1) and its differential consequences. The conservation law is local (conservation law of local type) if and only if it has the form* $D_i\Psi^i(x,u,\underset{1}{u},\ldots,\underset{L}{u})=0$ *where, for all values of* x, Ψ^i *depends on* $u,\underset{1}{u},\ldots,\underset{L}{u}$ *only through* $u(x),\underset{1}{u}(x),\ldots,\underset{L}{u}(x)$ *evaluated at* x. *Otherwise the conservation law is nonlocal (conservation law of nonlocal type).*

Definition 1.6: The adjoint of the Fréchet derivative (1.2) is the matrix linear operator $\mathscr{T}^*_{\sigma\rho}$ *satisfying*

$$V^\sigma \mathscr{T}_{\sigma\rho} W^\rho - W^\sigma \mathscr{T}^*_{\sigma\rho} V^\rho = D_i P^i \tag{1.9}$$

for all K times differential functions $V^\gamma(x)$ *and* $W^\gamma(x)$, *for some* P^i *which depends on* x^i, u^γ, V^γ, W^γ *and the derivatives of* u^γ, V^γ, W^γ *to some finite order.*

Definition 1.7: The system (1.1) is self-adjoint if and only if

$$\mathscr{T}_{\sigma\rho} = \mathscr{T}^*_{\sigma\rho} \quad . \tag{1.10}$$

In Sec. II, we derive the bilinear identity giving a correspondence between symmetries and conservation laws for self-adjoint systems of DEs (1.1). From this identity we obtain an expression that yields a conservation law for each pair of symmetries, *local* or *nonlocal*, admitted by any such system (linear or nonlinear). Furthermore, as each such linear system admits a trivial scaling symmetry, we obtain a conservation law for all nontrivial symmetries of any self-adjoint linear system of DEs (1.1). In particular, each nonlocal symmetry admitted by such a linear system thereby leads to a corresponding nonlocal conservation law.

From the known connection between local conservation laws and local symmetries[2,7] for self-adjoint systems of DEs it follows that all local conservation laws obtained through the bilinear identity derived in Sec. II are also obtainable from Noether's theorem. In the case when such a system is linear, we show in Sec. III that each local symmetry leaving invariant a corresponding variational principle yields the same conservation law through our bilinear identity as through Noether's theorem.

In Sec. IV, as an example of a self-adjoint linear DE, we consider the two-dimensional scalar wave equation with a variable wave speed. For a large class of wave speeds this equation admits nonlocal symmetries realized as potential symmetries.[3–5] The nonlocal character of these symmetries means that we cannot obtain corresponding conservation laws by applying Noether's theorem to the variational principle of the scalar wave equation. Moreover, we show that the potential system for this equation does not have a variational principle, and hence Noether's theorem cannot be applied to the potential system to obtain any conservation laws. By using our conservation law expression derived in Sec. II, we obtain nonlocal conservation laws for the admitted nonlocal symmetries. In Sec. V, we obtain corresponding constants of motion for the scalar wave equation. We show that these constants of motion are linearly independent of each other as well as linearly independent of all constants of motion arising from local symmetries of the scalar wave equation.

In Sec. VI, we expand on some of the ideas and results presented in earlier sections.

II. DERIVATION OF THE CONSERVATION LAW EXPRESSION

We consider a system (1.1) that is self-adjoint. Then the DEs in system (1.1) must satisfy the following Helmholtz identities:[7]

$$\frac{\partial G_\sigma}{\partial u^\rho} = \frac{\partial G_\rho}{\partial u^\sigma} - D_i\left(\frac{\partial G_\rho}{\partial u^\sigma_i}\right) + \cdots + (-1)^K D_{i_1}\cdots D_{i_K}\left(\frac{\partial G_\rho}{\partial u^\sigma_{i_1\cdots i_K}}\right), \tag{2.1}$$

$$\frac{\partial G_\sigma}{\partial u^\rho_{i_1\cdots i_j}}=(-1)^J\frac{\partial G_\rho}{\partial u^\sigma_{i_1\cdots i_J}}+(-1)^{J+1}C_J^{J+1}D_{i_{J+1}}\left(\frac{\partial G_\rho}{\partial u^\sigma_{i_1\cdots i_{J+1}}}\right)$$
$$+\cdots+(-1)^K C_J^K D_{i_{J+1}}\cdots D_{i_K}\left(\frac{\partial G_\rho}{\partial u^\sigma_{i_1\cdots i_K}}\right),\quad J=1,\ldots,K-1, \tag{2.2}$$

$$\frac{\partial G_\sigma}{\partial u^\rho_{i_1\cdots i_K}}=(-1)^K\frac{\partial G_\rho}{\partial u^\sigma_{i_1\cdots i_K}}, \tag{2.3}$$

where $C_J^L=L!/J!(L-J)!$ for positive integers $L\geqslant J$. As a consequence of these identities, one can verify by direct calculation that the Fréchet derivative (1.2) leads to the identity

$$\mathscr{F}_{\sigma\rho}\omega^\rho=\omega^\rho\frac{\partial G_\rho}{\partial u^\sigma}-D_i\left(\omega^\rho\frac{\partial G_\rho}{\partial u^\sigma_i}\right)+\cdots+(-1)^K D_{i_1}\cdots D_{i_K}\left(\omega^\rho\frac{\partial G_\rho}{\partial u^\sigma_{i_1\cdots i_K}}\right) \tag{2.4}$$

for arbitrary functions ω^ρ.

Using Eq. (2.4) and the Leibnitz rule for differentiation, one finds that the following bilinear skew-symmetric identity holds for arbitrary functions ω^ρ and ν^ρ:

$$\nu^\sigma\mathscr{F}_{\sigma\rho}\omega^\rho-\omega^\sigma\mathscr{F}_{\sigma\rho}\nu^\rho=D_i\Phi^i[\nu,\omega], \tag{2.5}$$

where

$$\Phi^i[\nu,\omega]=-\frac{1}{2}\left\{\nu^\sigma\frac{\partial G_\rho}{\partial u^\sigma_i}\omega^\rho+(D_j\nu^\sigma-\nu^\sigma D_j)\left(\frac{\partial G_\rho}{\partial u^\sigma_{ji}}\omega^\rho\right)+\cdots+(D_{i_1}\cdots D_{i_{K-1}}\nu^\sigma\right.$$
$$\left.+\cdots+(-1)^K\nu^\sigma D_{i_1}\cdots D_{i_{K-1}})\left(\frac{\partial G_\rho}{\partial u^\sigma_{i_1\cdots i_{K-1}i}}\omega^\rho\right)\right\}$$
$$+\frac{1}{2}\left\{\omega^\sigma\frac{\partial G_\rho}{\partial u^\sigma_i}\nu^\rho+(D_j\omega^\sigma-\omega^\sigma D_j)\left(\frac{\partial G_\rho}{\partial u^\sigma_{ji}}\nu^\rho\right)+\cdots+(D_{i_1}\cdots D_{i_{K-1}}\omega^\sigma\right.$$
$$\left.+\cdots+(-1)^K\omega^\sigma D_{i_1}\cdots D_{i_{K-1}})\left(\frac{\partial G_\rho}{\partial u^\sigma_{i_1\cdots i_{K-1}i}}\nu^\rho\right)\right\}. \tag{2.6}$$

The functions ω^ρ and ν^ρ here can have arbitrary (local or nonlocal) dependence on u and derivatives of u.

This bilinear identity leads to a connection between symmetries and conservation laws:

Theorem 2.1: *Suppose* $\mathbf{X}_1=\eta_1^\mu\partial/\partial u^\mu$ *and* $\mathbf{X}_2=\eta_2^\mu\partial/\partial u^\mu$ *are infinitesimal generators of symmetries (local or nonlocal) of a self-adjoint system (1.1). The bilinear identity (2.5) then yields the conservation law*

$$D_i\Phi^i[\eta_1,\eta_2]=0 \tag{2.7}$$

with $\Phi^i[\eta_1,\eta_2]$ *defined by Eq. (2.6).*

We now specialize to the case when system (1.1) is a linear homogeneous system

$$G_\sigma(x,u,\underset{1}{u},\ldots,\underset{K}{u})=G_{\sigma\rho}(x)u^\rho+G^i_{\sigma\rho}(x)u^\rho_i+\cdots+G^{i_1\cdots i_K}_{\sigma\rho}(x)u^\rho_{i_1\cdots i_K}=0 \tag{2.8}$$

with coefficients $G_{\sigma\rho}(x), G^i_{\sigma\rho}(x), \ldots, G^{i_1\cdots i_K}_{\sigma\rho}(x)$. Every such system admits the trivial scaling symmetry

$$\mathbf{X}_s = u^\mu \partial/\partial u^\mu. \tag{2.9}$$

Using this symmetry as one of the symmetries in Theorem 2.1 now leads to the following correspondence:

Theorem 2.2: *Suppose a self-adjoint linear system (2.8) admits a nontrivial symmetry (local or nonlocal) with infinitesimal generator* $\mathbf{X} = \eta^\mu \partial/\partial u^\mu$. *Then Eq. (2.7) yields the conservation law*

$$D_i \Phi^i[u, \eta] = 0, \tag{2.10}$$

where

$$\begin{aligned}\Phi^i[u,\eta] = &-\tfrac{1}{2}\Big\{u^\sigma G^i_{\rho\sigma}(x)\,\eta^\rho + (u^\sigma_j - u^\sigma D_j)(G^{ji}_{\rho\sigma}(x)\,\eta^\rho) \\ &+ \cdots + (u^\sigma_{i_1\cdots i_{K-1}} + \cdots + (-1)^K u^\sigma D_{i_1}\cdots D_{i_{K-1}})(G^{i_1\cdots i_{K-1}i}_{\rho\sigma}(x)\,\eta^\rho)\Big\} \\ &+ \tfrac{1}{2}\Big\{\eta^\sigma G^i_{\rho\sigma}(x) u^\rho + (D_j\eta^\sigma - \eta^\sigma D_j)(G^{ji}_{\rho\sigma}(x) u^\rho) + \cdots + (D_{i_1}\cdots D_{i_{K-1}}\eta^\sigma \\ &+ \cdots + (-1)^K \eta^\sigma D_{i_1}\cdots D_{i_{K-1}})(G^{i_1\cdots i_{K-1}i}_{\rho\sigma}(x) u^\rho)\Big\}.\end{aligned} \tag{2.11}$$

III. RELATIONSHIP TO NOETHER'S THEOREM

Noether's theorem only relates local symmetries to conservation laws (of local type) for self-adjoint systems. The variational principle for a (linear or nonlinear) self-adjoint system (1.1) has Lagrangian L given by[2,7]

$$L(x, u, \underset{1}{u}, \ldots, \underset{K}{u}) = \int_0^1 u^\sigma G_\sigma(x, \lambda u, \lambda \underset{1}{u}, \ldots, \lambda \underset{K}{u})\, d\lambda. \tag{3.1}$$

Definition 3.1: An infinitesimal generator $\mathbf{X} = \eta^\mu(x, u, \underset{1}{u}, \ldots, \underset{P}{u})\partial/\partial u^\mu$ *is a variational symmetry of a self-adjoint system (1.1) if and only if*

$$\mathbf{X}^{(K)} L(x, u, \underset{1}{u}, \ldots, \underset{K}{u}) = D_i A^i \tag{3.2}$$

for some $A^i(x, u, \underset{1}{u}, \ldots, \underset{L}{u})$, *where* $\mathbf{X}^{(K)}$ *is the Kth prolongation generator given by*

$$\mathbf{X}^{(K)} = \eta^\mu \partial/\partial u^\mu + (D_i \eta^\mu)\partial/\partial u^\mu_i + \cdots + (D_{i_1}\cdots D_{i_K}\eta^\mu)\partial/\partial u^\mu_{i_1\cdots i_K}. \tag{3.3}$$

Noether's theorem yields a local conservation law for each variational symmetry admitted by system (1.1). Specifically, one can show that

$$\mathbf{X}^{(K)} L = G_\sigma \eta^\sigma + D_i S^i = D_i A^i, \tag{3.4}$$

where $S^i = \eta^\sigma \partial L/\partial u^\sigma_i + (D_j\eta^\sigma - \eta^\sigma D_j)(\partial L/\partial u^\sigma_{ji}) + \cdots + (D_{j_1}\cdots D_{j_{K-1}}\eta^\sigma + \cdots + (-1)^{K-1}\eta^\sigma D_{j_1}\cdots D_{j_{K-1}})(\partial L/\partial u^\sigma_{j_1\cdots j_{K-1}i})$.[2,3,7] Then Eq. (3.4) yields Noether's identity

$$D_i N^i[\eta] = -G_\sigma \eta^\sigma \tag{3.5}$$

with $N^i[\eta] = S^i - A^i$. Consequently, for any solution of system (1.1) we obtain the Noether conservation law

$$D_i N^i[\eta]=0. \tag{3.6}$$

Using the Helmholtz identities (2.1) to (2.3), along with Noether's identity (3.5) and the fact that the Euler–Lagrange operator annihilates divergences, one can show that any variational symmetry $\mathbf{X}=\eta^\mu\partial/\partial u^\mu$ satisfies the identity

$$\mathscr{T}_{\sigma\rho}\eta^\rho=-G_\rho\frac{\partial\eta^\rho}{\partial u^\sigma}+D_i\left(G_\rho\frac{\partial\eta^\rho}{\partial u_i^\sigma}\right)+\cdots+(-1)^{P+1}D_{i_1}\cdots D_{i_P}\left(G_\rho\frac{\partial\eta^\rho}{\partial u_{i_1\cdots i_P}^\sigma}\right). \tag{3.7}$$

From Eq. (3.7) it immediately follows that all variational symmetries are local symmetries of system (1.1). [The converse does not always hold, as seen from the fact that scaling symmetries (2.9) generally do not satisfy Eq. (3.7).]

For the rest of this section we restrict the self-adjoint system (1.1) to be a linear homogeneous system (2.8). Before relating conservation laws from Noether's theorem to conservation laws arising from the bilinear identity (2.5), we establish the following result:

Lemma 3.2: Suppose $\eta^\mu(x,u,\underset{1}{u},\ldots,\underset{P}{u})$ *is analytic in* u *and derivatives of* u. *Then any local symmetry generator of the form* $\mathbf{X}=\eta^\mu(x,u,\underset{1}{u},\ldots,\underset{P}{u})\partial/\partial u^\mu$ *admitted by a linear homogeneous system* (2.8) *can be expressed as a superposition of homogeneous local symmetry generators*:

$$\eta^\mu(x,u,\underset{1}{u},\ldots,\underset{P}{u})=\sum_{n=0}^{\infty}\overset{(n)}{\eta}{}^\mu(x,u,\underset{1}{u},\ldots,\underset{P}{u}), \tag{3.8}$$

where

$$\overset{(n)}{\eta}{}^\mu(x,u,\underset{1}{u},\ldots,\underset{P}{u})=\lambda^{-n}\overset{(n)}{\eta}{}^\mu(x,\lambda u,\lambda\underset{1}{u},\ldots,\lambda\underset{P}{u}) \tag{3.9}$$

for all positive constants λ.

Proof: Since system (2.8) admits the scaling symmetry (2.9), it must also admit the symmetry $\eta^\mu(x,\lambda u,\lambda\underset{1}{u},\ldots,\lambda\underset{P}{u})\partial/\partial u^\mu$ for all constants λ. Then the analyticity property of η^μ leads to

$$\eta^\mu(x,\lambda u,\lambda\underset{1}{u},\ldots,\lambda\underset{P}{u})=\sum_{n=0}^{\infty}\lambda^n\overset{(n)}{\eta}{}^\mu(x,u,\underset{1}{u},\ldots,\underset{P}{u}), \tag{3.10}$$

where $\overset{(n)}{\eta}{}^\mu(x,u,\underset{1}{u},\ldots,\underset{P}{u})=\partial^n\eta^\mu(x,\lambda u,\lambda\underset{1}{u},\ldots,\lambda\underset{P}{u})/\partial\lambda^n|_{\lambda=0}$ and $\overset{(n)}{\eta}{}^\mu(x,u,\underset{1}{u},\ldots,\underset{P}{u})=\eta^\mu(x,\lambda,u,\lambda\underset{1}{u},\ldots,\lambda\underset{P}{u})|_{\lambda=0}$. It then follows that each $\overset{(n)}{\eta}{}^\mu(x,u,\underset{1}{u},\ldots,\underset{P}{u})\partial/\partial u^\mu$, for $n=0,1,2,\ldots$, is a local symmetry of system (2.8). Setting $\lambda=1$ in the superposition (3.10) then yields Eq. (3.8).□

As an aside we remark that every infinitesimal generator of a point symmetry $\mathbf{X}=\eta^\mu(x,u,\underset{1}{u})\partial/\partial u^\mu$ has $\overset{(n)}{\eta}{}^\mu(x,u,\underset{1}{u})=0$ for $n\neq1$ when system (2.8) is a scalar PDE of order $K\geqslant2$ (with $N\geqslant2$).[8]

Without loss of generality we assume that each infinitesimal generator of a symmetry admitted by system (2.8) satisfies the homogeneity property (3.9). We then have the following identity

$$u^\sigma\frac{\partial\eta^\rho}{\partial u^\sigma}+u_i^\sigma\frac{\partial\eta^\rho}{\partial u_i^\sigma}+\cdots+u_{i_1\cdots i_P}^\sigma\frac{\partial\eta^\rho}{\partial u_{i_1\cdots i_P}^\sigma}=n\eta^\rho \tag{3.11}$$

for some integer $n\geqslant0$.

We now establish the relationship between Noether's conservation law expression (3.6) and our conservation law expression (2.10):

Theorem 3.3: *Suppose a variational symmetry of a self-adjoint linear system (2.8) has an infinitesimal generator* $\mathbf{X}=\eta^{\mu}\partial/\partial u^{\mu}$ *satisfying Eq. (3.11). Then up to the addition of a divergence free expression, one has*

$$\Phi^i[u,\eta]=(1+n)N^i[\eta], \tag{3.12}$$

for every solution of the system (2.8).

Proof. From the bilinear identity (2.5) we have

$$D_i\Phi^i[u,\eta]=u^{\sigma}\mathscr{F}_{\sigma\rho}\eta^{\rho}-\eta^{\sigma}\mathscr{F}_{\sigma\rho}u^{\rho}. \tag{3.13}$$

Since system (2.8) is linear, it satisfies the identity

$$\mathscr{F}_{\sigma\rho}u^{\rho}=G_{\sigma}. \tag{3.14}$$

Using the Leibnitz rule for differentiation to manipulate Eq. (3.7), we get

$$u^{\sigma}\mathscr{F}_{\sigma\rho}\eta^{\rho}=-G_{\rho}\left(u^{\sigma}\frac{\partial\eta^{\rho}}{\partial u^{\sigma}}+u_i^{\sigma}\frac{\partial\eta^{\rho}}{\partial u_i^{\sigma}}+\cdots+u^{\sigma}_{i_1\cdots i_P}\frac{\partial\eta^{\rho}}{\partial u^{\sigma}_{i_1\cdots i_P}}\right)+D_iB^i, \tag{3.15}$$

where

$$\begin{aligned}B^i=&u^{\sigma}G_{\rho}\frac{\partial\eta^{\rho}}{\partial u_i^{\sigma}}+(u_j^{\sigma}-u^{\sigma}D_j)\left(G_{\rho}\frac{\partial\eta^{\rho}}{\partial u_{ji}^{\sigma}}\right)+\cdots\\&+(u^{\sigma}_{i_1\cdots i_{P-1}}+\cdots+(-1)^{P-1}u^{\sigma}D_{i_1}\cdots D_{i_{P-1}})\left(G_{\rho}\frac{\partial\eta^{\rho}}{\partial u^{\sigma}_{i_1\cdots i_{K-1}i}}\right).\end{aligned} \tag{3.16}$$

Consequently, after substituting Eqs. (3.14) and (3.15) into Eq. (3.13) and then using Eq. (3.11), we obtain

$$D_i\Phi^i[u,\eta]=-(1+n)\,\eta^{\sigma}G_{\sigma}-D_iB^i. \tag{3.17}$$

Then Noether's identity (3.5) yields

$$D_i\Phi^i[u,\eta]=(1+n)D_iN^i[\eta]-D_iB^i. \tag{3.18}$$

Now observe that $B^i=0$ when $G_p=0$, and hence $B^i=0$ for every solution of system (2.8). Thus we arrive at Eq. (3.12). □

IV. NONLOCAL CONSERVATION LAWS FOR SCALAR WAVE EQUATIONS

Throughout the sequel, we set $x^1=x$, $x^2=t$, and we use a subscript notation for total differentiation with respect to x and t.

Consider the scalar wave equation

$$u_{xx}-c^{-2}u_{tt}=0 \tag{4.1}$$

with a variable wave speed $c(x)$. From Eq. (1.8) we introduce the corresponding potential system

$$v_t=u_x,\quad v_x=c^{-2}u_t. \tag{4.2}$$

The wave equation (4.1) has nonlocal symmetries which are realized as potential symmetries resulting from local point symmetries of potential system (4.2) if and only if the wave speed satisfies the fourth order DE[3,4]

$$(cc'(c/c')'')'=0. \tag{4.3}$$

Such wave speeds are bounded away from zero for $-\infty<x<\infty$ when $c(x)$ satisfies the first order DE

$$c'=\nu^{-1}\sin(\nu\log c),\quad \nu=\text{const}, \tag{4.4}$$

up to arbitrary scalings of c and x.[9]

Classification of the point symmetries of system (4.2) yielding nonlocal (potential) symmetries of the wave equation (4.1) leads to two cases[3–5] with, respectively, one and two admitted infinitesimal generators $\mathbf{X}=\eta\partial/\partial u$ of the form

$$\eta=f(x,t)u+g(x,t)v-\xi(x,t)u_x-\tau(x,t)u_t, \tag{4.5}$$

where $g(x,t)$ is not identically zero.

Case I (one nonlocal symmetry): The wave speed $c(x)$ satisfies

$$(c/c')'=\gamma=\text{const}. \tag{4.6}$$

Here we have

$$\begin{aligned} &f(x,t)=a'(t)(1-\tfrac{1}{2}\gamma),\quad g(x,t)=-\tfrac{1}{2}a''(t)c(x)/c'(x),\\ &\xi(x,t)=a'(t)c(x)/c'(x),\quad \tau(x,t)=a(t)(\gamma-1)+a''(t)d(x), \end{aligned} \tag{4.7}$$

where $d(x)$ is a definite integral of $1/(c(x)c'(x))$, and $a(t)$ satisfies the first order ODE $(a/t^2)'=0$, which thus leads to the existence of one generator $\mathbf{X}=\eta\partial/\partial u$.

Case II (two nonlocal symmetries): The wave speed $c(x)$ satisfies

$$cc'(c/c')''=\mu=\text{const}\neq 0. \tag{4.8}$$

Here we have

$$\begin{aligned} &f(x,t)=b'(t)(2-(c(x)/c'(x))'),\\ &g(x,t)=-\mu b(t)c(x)/c'(x),\\ &\xi(x,t)=2b'(t)c(x)/c'(x),\\ &\tau(x,t)=2b(t)((c(x)/c'(x))'-1), \end{aligned} \tag{4.9}$$

where $b(t)$ satisfies the second order ODE $b''-\mu b=0$, which thus leads to the existence of two generators $\mathbf{X}=\eta\partial/\partial u$.

Conservation laws for all symmetries admitted by the wave equation (4.1) are obtainable from Theorem 2.2 since the wave equation is linear and self-adjoint. Hence, each nonlocal symmetry $\mathbf{X}=\eta\partial/\partial u$ admitted in Cases I and II gives rise to a corresponding nonlocal conservation law. From Eqs. (2.11) and (4.5), these conservation laws are given by

$$(\Phi^1[u,\eta])_x+(\Phi^2[u,\eta])_t=0 \tag{4.10}$$

with

$$\Phi^1[u,\eta]=u\eta_x-\eta u_x+(\tau uu_x+c^{-2}\xi uu_t)_t$$
$$=g_xuv-gu_xv+f_xu^2+c^{-2}guu_t-c'c^{-1}\xi uu_x+c^{-2}\xi u_t^2+\xi u_x^2+2\tau u_xu_t, \quad (4.11)$$

$$\Phi^2[u,\eta]=c^{-2}(\eta u_t-u\eta_t)-(\tau uu_x+c^{-2}\xi uu_t)_x$$
$$=c^{-2}(-g_tuv+gu_tv-f_tu^2-guu_x+c'c^{-1}\xi uu_t-\tau u_t^2-c^2\tau u_x^2-2\xi u_xu_t), \quad (4.12)$$

where f,g,ξ,τ satisfy Eq. (4.7) in Case I and Eq. (4.9) in Case II. The identically divergence free terms in Φ^1 and Φ^2 have been added to eliminate all terms involving second order derivatives u_{xx}, u_{tt}, and u_{xt}.

These nonlocal conservation laws arising from the nonlocal symmetries $\mathbf{X}=\eta\partial/\partial u$ cannot be obtained through Noether's theorem for the scalar wave equation (4.1) since Noether's theorem is applicable only to local symmetries that leave invariant a variational principle for Eq. (4.1). Moreover, even though the symmetries $\mathbf{X}=\eta\partial/\partial u$ are realized as local symmetries of the potential system (4.2), Noether's theorem still cannot be applied since, as will now be demonstrated, the potential system is not self-adjoint and hence has no variational principle. Let

$$\begin{bmatrix}u^1\\u^2\end{bmatrix}=\begin{bmatrix}u\\v\end{bmatrix}$$

define a column vector. Then the Fréchet derivative (1.2) associated to system (4.2) is given by the matrix operator

$$\mathscr{T}=\begin{bmatrix}-\partial/\partial x & \partial/\partial t\\ -c^{-2}\partial/\partial t & \partial/\partial x\end{bmatrix}. \quad (4.13)$$

By direct calculation, using Eq. (1.9), the adjoint of the Fréchet derivative is

$$\mathscr{T}^*=-\mathscr{T}, \quad (4.14)$$

and thus the potential system is not self-adjoint.

V. NEW CONSTANTS OF MOTION FOR SCALAR WAVE EQUATIONS

Given a conservation law $(\Phi^1[u,\eta])_x+(\Phi^2[u,\eta])_t=0$ arising from Theorem 2.2 for a symmetry $\mathbf{X}=\eta\partial/\partial u$ of the scalar wave equation (4.1), we let

$$C[\eta]=\int_{-\infty}^{\infty}\Phi^2[u,\eta]dx. \quad (5.1)$$

If $u(x,t)$ has appropriate asymptotic properties as $x\to\pm\infty$, then

$$\frac{dC[\eta]}{dt}=-\Phi^1[u,\eta]|_{x=-\infty}^{x=\infty}=0, \quad (5.2)$$

from which it follows that $C[\eta]$ defines a constant of motion for Eq. (4.1).

Now consider compact support initial data

$$u(x,t_0)=\varphi(x), \quad u_t(x,t_0)=\psi(x), \quad (5.3)$$

for the scalar wave equation (4.1). This determines corresponding data for the potential system (4.2), with

$$v(x,t_0)=\theta(x)=\int_{-\infty}^{x} c(\tilde{x})^{-2}\psi(\tilde{x})d\tilde{x} \tag{5.4}$$

(up to the addition of an arbitrary constant). Evaluating the nonlocal conservation laws given by Eqs. (4.10) to (4.12) with this initial data we find

$$\lim_{x\to\pm\infty} \Phi^1[u,\eta]=0 \tag{5.5}$$

and hence Eq. (5.1) yields constants of motion for the scalar wave equation (4.1). In terms of the initial data (5.3) and (5.4) we obtain

$$C[\eta]=\int_{-\infty}^{\infty} c(x)^{-2}\{(g(x,t_0)\psi(x)-g_t(x,t_0)\varphi(x))\theta(x)-g(x,t_0)\varphi(x)\varphi'(x)-f_t(x,t_0)\varphi(x)^2$$
$$+\xi(x,t_0)(c(x)^{-1}c'(x)\varphi(x)-2\varphi'(x))\psi(x)-\tau(x,t_0)(\psi(x)^2+c(x)^2\varphi'(x)^2)\}dx. \tag{5.6}$$

For each wave speed $c(x)$ satisfying Eq. (4.6), the expression $C[\eta]$ yields one constant of motion, with f,g,ξ,τ satisfying Eq. (4.7); for each wave speed $c(x)$ satisfying Eq. (4.8), the expression $C[\eta]$ yields two constants of motion, with f,g,ξ,τ satisfying Eq. (4.9).

A. Linear independence of constants of motion

Let $C[\eta_1],C[\eta_2],\ldots,C[\eta_k]$ define $k>1$ constants of motion arising for the scalar wave equation (4.1) from symmetries $\mathbf{X}_1=\eta_1\partial/\partial u$, $\mathbf{X}_2=\eta_2\partial/\partial u,\ldots$, $\mathbf{X}_k=\eta_k\partial/\partial u$, respectively.

Definition 5.1: Suppose $c_1,\ldots,c_k$ are constants such that $c_1C[\eta_1]+\cdots+c_kC[\eta_k]$ vanishes for arbitrary initial data (5.3). Then $C[\eta_1],\ldots,C[\eta_k]$ are linearly independent constants of motion if and only if $c_1=\cdots=c_k=0$.

The following theorem now establishes that each constant of motion (5.6) arising from the admitted nonlocal symmetries (4.5) of Eq. (4.1) in Cases I and II is linearly independent of the constants of motion arising from all admitted point symmetries of Eq. (4.1). A subsequent theorem then establishes further that the two constants of motion (5.6) in Case II are linearly independent of each other modulo all point symmetry constants of motion.

Theorem 5.2: *For the scalar wave equation (4.1), the constants of motion (5.6) obtained from the admitted nonlocal symmetries (4.5) are each linearly independent of the constants of motion obtained from all admitted point symmetries.*

Proof: Every point symmetry admitted by a scalar linear PDE is characterized by an infinitesimal generator $\eta\partial/\partial u$ either with η linear in u and first order derivatives of u (in which case the symmetry is called *nontrivial*) or with η independent of u and derivatives of u (in which case the symmetry is called *trivial*).[8] Thus, for the scalar wave equation (4.1), every nontrivial point symmetry as well as every nonlocal symmetry (4.5) has an infinitesimal generator that is linear in u and first order derivatives of u. The constants of motion obtained from these symmetries through Theorem 2.2 are thereby quadratic expressions in terms of initial data $u(x,t_0)$ and $u_t(x,t_0)$, while the constants of motion obtained from trivial symmetries are only linear expressions in terms of this data.

These properties imply that the constants of motion obtained from nontrivial point symmetries and nonlocal symmetries (4.5) are linearly independent of all constants of motion obtained from trivial point symmetries, since these constants of motions have a different scaling dimension under scalings of initial data. Consequently, to complete the proof of the theorem, we need only establish that each constant of motion obtained from the nonlocal symmetries (4.5) is linearly independent of all constants of motion obtained from nontrivial point symmetries.

Let $\tilde{\eta}\partial/\partial u$ correspond to the generator of a nonlocal symmetry (4.5) admitted by Eq. (4.1), and let $\eta_1\partial/\partial u, \ldots, \eta_k\partial/\partial u$ correspond to the generators of all distinct nontrivial point symmetries admitted by Eq. (4.1). Let $C[\tilde{\eta}]$, $C[\eta_1],\ldots,C[\eta_k]$ denote the resulting constants of motion obtained through Theorem 2.2.

Consider the one-parameter family of nonnegative initial data:

$$u(x,t_0;\lambda)=\varphi(x;\lambda)\geqslant 0, \quad u_t(x,t_0;\lambda)=\psi(x;\lambda)\geqslant 0, \tag{5.7}$$

with

$$v(x,t_0;\lambda)=\theta(x;\lambda)=\int_{-\infty}^{x} c(\tilde{x})^{-2}\psi(\tilde{x};\lambda)d\tilde{x}\geqslant 0, \tag{5.8}$$

such that the supports of

$$\begin{aligned}
&\varphi_1(x)=\varphi(x;0), \quad \varphi_2(x)=\frac{\partial\varphi}{\partial\lambda}(x;0),\\
&\psi_1(x)=\psi(x;0), \quad \psi_2(x)=\frac{\partial\psi}{\partial\lambda}(x;0),
\end{aligned} \tag{5.9}$$

are compact and mutually disjoint. Now define

$$\begin{aligned}
&\theta_1(x)=\theta(x;0)=\int_{-\infty}^{x} c(\tilde{x})^{-2}\psi_1(\tilde{x})d\tilde{x},\\
&\theta_2(x)=\frac{\partial\theta}{\partial\lambda}(x;0)=\int_{-\infty}^{x} c(\tilde{x})^{-2}\psi_2(\tilde{x})d\tilde{x}.
\end{aligned} \tag{5.10}$$

If $\tilde{c},c_1,\ldots,c_k$ are constants such that

$$\tilde{c}C[\tilde{\eta}]+c_1C[\eta_1]+\cdots+c_kC[\eta_k]=0 \tag{5.11}$$

for arbitrary initial data, then

$$\tilde{c}C[\tilde{\eta};\lambda]+c_1C[\eta_1;\lambda]+\cdots c_kC[\eta_k;\lambda]=0, \tag{5.12}$$

where $C[\eta_1;\lambda],\ldots,C[\eta_k;\lambda]$ are the constants of motion evaluated for the one-parameter family of initial data (5.9) and (5.10). Hence we must have

$$\left(\tilde{c}\,\frac{\partial C[\tilde{\eta};\lambda]}{\partial\lambda}+c_1\,\frac{\partial C[\eta_1;\lambda]}{\partial\lambda}+\cdots+c_k\,\frac{\partial C[\eta_k;\lambda]}{\partial\lambda}\right)\Bigg|_{\lambda=0}=0. \tag{5.13}$$

Using the earlier remarks about the quadratic properties of $C[\eta]$ for nontrivial point symmetries, and taking account of the disjoint supports of $\varphi_1(x)$, $\varphi_2(x)$, $\psi_1(x)$, $\psi_2(x)$, we have

$$\frac{\partial C[\eta;\lambda]}{\partial\lambda}\Bigg|_{\lambda=0}=0 \tag{5.14}$$

for $\eta=\eta_1,\ldots,\eta=\eta_k$. Hence, from Eq. (5.13), we get

$$\tilde{c}\left.\frac{\partial C[\tilde{\eta};\lambda]}{\partial\lambda}\right|_{\lambda=0}=0, \tag{5.15}$$

where

$$\left.\frac{\partial C[\tilde{\eta};\lambda]}{\partial\lambda}\right|_{\lambda=0}=\int_{-\infty}^{\infty}c(x)^{-2}\{g(x,t_0)(\psi_2(x)\theta_1(x)+\psi_1(x)\theta_2(x))$$
$$-g_t(x,t_0)(\varphi_2(x)\theta_1(x)+\varphi_1(x)\theta_2(x))\}dx, \tag{5.16}$$

using Eq. (5.6).

Now we further restrict the initial data so that the supports of $\varphi_1(x),\varphi_2(x),\psi_1(x),\psi_2(x)$ are to the left of each other, respectively. Then Eq. (5.16) reduces to

$$\left.\frac{\partial C[\tilde{\eta};\lambda]}{\partial\lambda}\right|_{\lambda=0}=\int_{-\infty}^{\infty}c(x)^{-2}g(x,t_0)\psi_2(x)\theta_1(x)dx\neq 0. \tag{5.17}$$

Hence Eq. (5.15) leads to $\tilde{c}=0$ in Eq. (5.11), which implies that the constant of motion arising from the nonlocal symmetry $\tilde{\eta}\partial/\partial u$ is linearly independent of the constants of motion arising from the nontrivial point symmetries $\eta_1\partial/\partial u,\ldots,\eta_k\partial/\partial u$. □

Theorem 5.3: *The two constants of motion (5.6) obtained for the scalar wave equation (4.1) from the nonlocal symmetries (4.5) in Case II are linearly independent modulo all constants of motion obtained from point symmetries.*

Proof: We proceed by the same argument used in proving Theorem 5.2. Let $\tilde{\eta}_1\partial/\partial u$ and $\tilde{\eta}_2\partial/\partial u$ correspond to the generators of the two nonlocal symmetries (4.5) of Eq. (4.1), and let $\eta_1\partial/\partial u,\ldots,\eta_k\partial/\partial u$ correspond to the generators of all distinct nontrivial point symmetries. Let $C[\tilde{\eta}_1],C[\tilde{\eta}_2],C[\eta_1],\ldots,C[\eta_k]$ denote the resulting constants of motion. Consider the same one-parameter initial data used in the previous proof, with the supports of $\varphi_1(x),\varphi_2(x),\psi_1(x),\psi_2(x)$ lying to the left of each other.

If $\tilde{c}_1,\tilde{c}_2,c_1,\ldots,c_k$ are constants such that

$$\tilde{c}_1C[\tilde{\eta}_1]+\tilde{c}_2C[\tilde{\eta}_2]+c_1C[\eta_1]+\cdots+c_kC[\eta_k]=0 \tag{5.18}$$

for arbitrary initial data, then we have

$$\left(\tilde{c}_1\frac{\partial C[\tilde{\eta}_1;\lambda]}{\partial\lambda}+\tilde{c}_2\frac{\partial C[\tilde{\eta}_2;\lambda]}{\partial\lambda}\right)\Bigg|_{\lambda=0}=0, \tag{5.19}$$

where $C[\tilde{\eta}_1;\lambda]$ and $C[\tilde{\eta}_2;\lambda]$ are the constants of motion evaluated for the one-parameter family of initial data. From Eq. (5.16) we find that Eq. (5.19) simplifies to

$$\int_{-\infty}^{\infty}c(x)^{-2}(\tilde{c}_1g_1(x,t_0)+\tilde{c}_2g_2(x,t_0))\psi_2(x)\theta_1(x)dx=0, \tag{5.20}$$

where, by use of Eq. (4.9), we have

$$\tilde{c}_1g_1(x,t_0)+\tilde{c}_2g_2(x,t_0)=-\mu(\tilde{c}_1b_1(t_0)+\tilde{c}_2b_2(t_0))c(x)/c'(x). \tag{5.21}$$

Then Eq. (5.20) reduces to

$$-(\tilde{c}_1b_1(t_0)+\tilde{c}_2b_2(t_0))\mu\int_{-\infty}^{\infty}c(x)^{-1}c'(x)^{-1}\psi_2(x)\theta_1(x)dx=0 \tag{5.22}$$

with $\int_{-\infty}^{\infty} c(x)^{-1}c'(x)^{-1}\psi_2(x)\theta_1(x)dx \neq 0$. It then follows that $\tilde{c}_1 b_1(t_0)+\tilde{c}_2 b_2(t_0)=0$, and since we can choose the value of t_0 freely, we then must have $\tilde{c}_1 b_1(t)+\tilde{c}_2 b_2(t)=0$ for all t. However, from Eq. (4.9) we note that $b=b_1(t)$ and $b=b_2(t)$ are linearly independent functions satisfying $b''-\mu b=0$. Thus $\tilde{c}_1=0=\tilde{c}_2$. The linear independence of the constants of motion $C[\tilde{\eta}_1]$ and $C[\tilde{\eta}_2]$ modulo the constants of motion $C[\eta_1],\ldots,C[\eta_k]$ then follows from Eq. (5.18). □

B. Analytical example of new constants of motion

Theorems 5.2 and 5.3 establish new constants of motion for the scalar wave equation (4.1) for wave speeds given by Eq. (4.6) in Case I and Eq. (4.8) in Case II. The wave speeds in Case II satisfying the ODE (4.4) have the most physical interest since they are bounded (above and below) away from zero. These wave speeds $c(x)$ are implicitly given by the integral

$$\int_{c(x_0)}^{c(x)} \frac{\nu\, dc}{\sin(\nu \log c)} = x - x_0, \tag{5.23}$$

where ν and x_0 are arbitrary constant parameters. From Eq. (5.23), $c(x)$ can be shown to increase monotonically from the asymptotic value $c\to 1$ for $x\to-\infty$ to the asymptotic value $c\to e^{\pi/\nu}$ for $x\to+\infty$. In physical terms, this describes a medium of two layers, with wave speeds $c\approx 1$ and $c\approx e^{\pi/\nu}$, separated by a smoothly varying transition layer having width $\Delta x\approx \nu(e^{\pi/\nu}-1)$, controlled by the value of ν.[9]

The scalar wave equation (4.1) with wave speeds (5.23) has no constants of motion arising from nontrivial point symmetries other than time translation symmetries generated by $\mathbf{X}=u_t\partial/\partial u$. These symmetries give rise through Theorem 2.2 to an energy constant of motion

$$E=\int_{-\infty}^{\infty} c(x)^{-2}(\psi(x)^2+c(x)^2\varphi'(x)^2)dx, \tag{5.24}$$

where $\varphi(x)$ and $\psi(x)$ are initial data (5.3).

Two additional constants of motion arise from the nonlocal symmetries (4.5) admitted by the scalar wave equation (4.1) with these wave speeds. In terms of the potential v introduced through Eq. (4.2), the nonlocal symmetry generators $\mathbf{X}=\eta\partial/\partial u$ have the explicit form (4.5) with

$$\begin{aligned} f(x,t)&=\pm(1+B(x))e^{\pm t}, \quad g(x,t)=-A(x)e^{\pm t},\\ \xi(x,t)&=\pm 2A(x)e^{\pm t}, \quad \tau(x,t)=-2B(x)e^{\pm t}, \end{aligned} \tag{5.25}$$

where

$$A(x)=\nu c(x)\csc(\nu \log c(x)), \quad B(x)=\nu\cot(\nu \log c(x)). \tag{5.26}$$

The corresponding constants of motion given by Eq. (5.6) are

$$\begin{aligned} C_\pm=\int_{-\infty}^{\infty} c(x)^{-2}&(-A(x)(\psi(x)\pm\varphi(x))\theta(x)\pm(\varphi(x)-2A(x)\varphi'(x))\psi(x)\\ &-\tfrac{1}{2}(1+B(x))\varphi(x)^2+2B(x)(\psi(x)^2+c(x)^2\varphi'(x)^2))dx, \end{aligned} \tag{5.27}$$

where $\varphi(x)$ and $\psi(x)$ are initial data (5.3), and $\theta(x)$ is determined nonlocally from $\psi(x)$ by Eq. (5.4). $C_\pm$ and E comprise a linearly independent set of constants of motion as shown by Theorems 5.2 and 5.3.

The new constants of motion $C_\pm$ may have utility in the mathematical analysis of wave propagation for two layered media described by wave speeds (5.23). In particular, $C_\pm$ may supple-

ment the use of the energy constant of motion E in addressing certain problems, such as the time evolution analysis for dispersal of waves initially localized across the transition boundary between the layers, and the scattering theory analysis of traveling waves incident on the transition boundary.

VI. CONCLUDING REMARKS

(1) In Sec. II we presented an explicit conservation law arising from any pair of symmetries, local or nonlocal, admitted by an arbitrary self-adjoint system of (linear or nonlinear) DEs (1.1). This conservation law expression does not require use of a variational principle for the system. Specializing to self-adjoint systems of linear DEs, we obtained a conservation law from any admitted local or nonlocal symmetry, by using a scaling symmetry as a second symmetry. A similar conservation law also can be obtained for any nonlinear system which admits a scaling symmetry (e.g., the Einstein equations in General Relativity theory). For variational symmetries (which are always local symmetries) admitted in the case of self-adjoint linear systems, we showed in Sec. III that the resulting local conservation laws are the same as those obtained from Noether's theorem. (The proof can be generalized straightforwardly to the conservation laws arising in the case of nonlinear systems with a scaling symmetry.)

The following theorem shows how our conservation law for a pair of symmetries is connected to Noether's theorem.

Theorem 6.1: *Suppose* $\mathbf{X}_1=\eta_1^\mu(x,u,\underset{1}{u},\ldots,\underset{P_1}{u})\partial/\partial u^\mu$ *and* $\mathbf{X}_2=\eta_2^\mu(x,u,\underset{1}{u},\ldots,\underset{P_2}{u})\partial/\partial u^\mu$ *are variational symmetries of a self-adjoint (linear or nonlinear) system (1.1). Then the resulting conservation law (2.7) is the same as the conservation law obtained through Noether's theorem for the commutator symmetry*

$$[\mathbf{X}_1,\mathbf{X}_2]=\eta^\mu(x,u,\underset{1}{u},\ldots,\underset{P}{u})\partial/\partial u^\mu \tag{6.1}$$

with $P\leqslant P_1+P_2$.

Proof: The commutator $[\mathbf{X}_1,\mathbf{X}_2]=\eta^\rho\partial/\partial u^\rho$ is given by

$$\begin{aligned}\eta^\rho=&\left(\frac{\partial\eta_2^\rho}{\partial u^\sigma}\,\eta_1^\sigma+\frac{\partial\eta_2^\rho}{\partial u_i^\sigma}\,D_i\eta_1^\sigma+\cdots+\frac{\partial\eta_2^\rho}{\partial u^\sigma_{i_1\cdots i_{P_2}}}\,D_{i_1}\cdots D_{i_{P_2}}\eta_1^\sigma\right)\\&-\left(\frac{\partial\eta_1^\rho}{\partial u^\sigma}\,\eta_2^\sigma+\frac{\partial\eta_1^\rho}{\partial u_i^\sigma}\,D_i\eta_2^\sigma+\cdots+\frac{\partial\eta_1^\rho}{\partial u^\sigma_{i_1\cdots i_{P_1}}}\,D_{i_1}\cdots\,D_{i_{P_1}}\eta_2^\sigma\right).\end{aligned} \tag{6.2}$$

From Eq. (2.5) we see that

$$\eta_1^\sigma\mathscr{F}_{\sigma\rho}\eta_2^\rho-\eta_2^\sigma\mathscr{F}_{\sigma\rho}\eta_1^\sigma=D_i\Phi^i[\,\eta_1,\eta_2]. \tag{6.3}$$

Then similarly to the derivation of Eq. (3.15), the identity (3.7) now leads to

$$\eta_1^\sigma\mathscr{F}_{\sigma\rho}\eta_2^\rho=-G_\rho\left(\frac{\partial\eta_2^\rho}{\partial u^\sigma}\,\eta_1^\sigma+\frac{\partial\eta_2^\rho}{\partial u_i^\sigma}\,D_i\eta_1^\sigma+\cdots+\frac{\partial\eta_2^\rho}{\partial u^\sigma_{i_1\cdots i_{P_2}}}\,D_{i_1}\cdots D_{i_{P_2}}\eta_1^\sigma\right)+D_iH^i[\,\eta_1,\eta_2] \tag{6.4}$$

for a certain $H^i[\,\eta_1,\eta_2]$. Hence, using Eqs. (6.2) to (6.4), we have

$$G_\rho\eta^\rho=D_i\Omega^i, \tag{6.5}$$

where $\Omega^i = -\Phi^i[\eta_1, \eta_2] + H^i[\eta_1, \eta_2] - H^i[\eta_2, \eta_1]$. As the commutator of any two variational symmetries is itself a variational symmetry, we see from Eq. (3.4) that Eq. (6.5) is a conservation law obtainable from Noether's theorem. □

The set of all variational symmetries for a given self-adjoint system (1.1) forms a Lie algebra $\mathscr{A}$. If all Lie algebra generators can be realized as commutators, in which case we say $\mathscr{A}$ is ''perfect,'' then Theorem 6.1 yields all local conservation laws for the system. We remark that all semisimple Lie algebras, as well as the Poincaré algebra (which is not semisimple), are perfect.

(2) The questions of how to find and how to characterize useful potential systems in order to find nonlocal symmetries admitted by a system of DEs is considered in Ref. 6.

Potential systems of a given system (1.1) rely on the existence of at least one divergence free equation in the system. However, if an appropriate divergence free equation cannot be found, one may still be able to embed system (1.1) as a subsystem of a related potential system.[10] This may allow one to find nonlocal symmetries which are generalizations of potential symmetries.

(3) The conservation laws derived in Sec. II for a system of DEs (1.1) require that the system is self-adjoint. If a given system (1.1) is not self-adjoint, one may still be able to find a related potential system that is self-adjoint. Through the embedding into the potential system, any symmetry (local or nonlocal) admitted by the given system will induce a symmetry of the potential system. (An induced symmetry will be a nonlocal symmetry unless its generator has strictly local dependence on the dependent variables in the potential system.) As a result, conservation laws for the given system can then be obtained as conservation laws arising from the induced symmetries (local and nonlocal) of each self-adjoint potential system. If a system (1.1) is itself self-adjoint, conservation laws from *any* admitted symmetry will correspondingly arise through each self-adjoint potential system found for system (1.1) as well as through system (1.1) itself.

For the wave equation (4.1), the first order potential system (4.2) considered in Sec. IV is not self-adjoint. There are several different ways, nevertheless, to introduce potential variables for system (4.2) leading to potential systems that are self-adjoint. As we will discuss in a forthcoming article, the conservation law expressions arising through each such potential system are different from the conservation law expressions obtained through the wave equation (4.1) itself. In particular, the nonlocal symmetries admitted by Eq. (4.1) as point symmetries of system (4.2) induce nonlocal symmetries of these potential systems, leading to corresponding nonlocal conservation laws different than the ones derived in Sec. IV. These additional conservation laws for the wave equation (4.1) are not obtainable by Noether's theorem applied to any of the self-adjoint potential systems, since Noether's theorem only deals with local symmetries.

Projective representations of the 1+1-dimensional Poincaré group

S. K. Bose[a)]
Department of Physics, University of Notre Dame, Notre Dame, Indiana 46556

(Received 1 August 1995; accepted for publication 22 August 1995)

The unitary irreducible representations of the central extension of the Poincaré group in 1+1 dimensions are constructed by an application of the Kirillov theory. These are then lifted to projective unitary irreducible representations of the Poincaré group. The 1+1 Galilean group is treated separately in an appendix. © *1996 American Institute of Physics.* [S0022-2488(96)01305-X]

I. INTRODUCTION

We continue a program initiated some time ago to study the properties of symmetry groups of $d+1$-dimensional space–times with $d<3$. In earlier publications the Galilean group for the case $d=2$ was considered, its central extension carried out,[1] and the system of unitary irreducible representations, both faithful and projective, constructed.[2] The representations of the Galilean group have been constructed independently by Grigore[3] via considerations of a certain group, which is the central extension of the universal covering group of the Galilean group. The conclusions of Ref. 3 are in agreement with those of Refs. 1 and 2. In this paper we consider the Poincaré group for $d=1$ and construct its projective representations. As for the faithful representations of this group, these are well understood and are discussed, for instance, by Barut and Raczka.[4] The Galilean group for $d=1$ is discussed separately in the Appendix.

As is well understood, the projective representations of a group can be obtained from the ordinary representations of its universal central extension.[5,6] The 1+1-dimensional Poincaré group $P(1,1)$ has a one parameter family of central extensions, as shown by Bargmann.[5] This is true of central extension either by the circle group T or by the additive group R of reals. The latter choice has certain technical advantages since the corresponding centrally extended group is simply connected. Here we focus attention on $\hat{P}(1,1)$, which is the central extension of $P(1,1)$ by R.

The group $\hat{P}(1,1)$ is a (non-nilpotent) solvable group (recall that a nilpotent group is solvable but a solvable group is not necessarily nilpotent). The representations of $\hat{P}(1,1)$ may be constructed by an application of the method of Kirillov,[7] wherein the group representations are induced from one-dimensional representations of certain subgroups associated with the co-adjoint orbits of the group. An important question for a general (non-nilpotent) solvable group is if the Kirillov construction yields *all* the irreducible representations of the group. A broad criterion for this to happen is given by the Auslander–Kostant theorem.[8] The latter states that for a connected and simply connected solvable Lie group of type 1 (a Lie group whose representations generate type 1 Von Neumann algebras), the Kirillov method, or possibly a generalization of the original method involving passage from real to complex extension groups, will yield all the irreducible representations. A less general result was given earlier by Bernat,[9] which states that for a solvable Lie group which is exponential (an exponential group is one for which the canonical map from the Lie algebra to the group is surjective), the Kirillov method will give all the irreducible representations. While it is true that $\hat{P}(1,1)$ is exponential and of type 1, as will be shown below, it is actually not necessary to appeal to results of such generality.[8,9] A more restrictive result due to Kirillov,[7] which states that for a *completely solvable* group his method will yield all the representations, is sufficient for our purpose. A completely solvable group, as defined in Ref. 7, is a solvable Lie group G that contains an increasing chain of normal subgroups

$\{e\}=G_0\subset G_1\subset\cdots\subset G_n=G$ whose dimensions increase by one at each step so that dim $G_k=k$. Our $\hat{P}(1,1)$ is completely solvable by this definition (see below).

This paper is organized as follows. In the next section, we study the groups $P(1,1)$ and $\hat{P}(1,1)$ and establish some of their properties. The co-adjoint orbits of $\hat{P}(1,1)$ are obtained in Secs. III and IV. The unitary irreducible linear representations of $\hat{P}(1,1)$ are obtained in Sec. V and the corresponding projective ones of $P(1,1)$ in Sec. VI. Concluding remarks are made in Sec. VII.

The 1+1 Galilean group is treated separately (from the main body of the paper) in the Appendix. Here the only contribution that we claim as original is in the construction of the central extension of the group. Once this is done, the centrally extended group is recognized to be isomorphic with a certain group whose representations are already known in the mathematical literature.

II. THE POINCARÉ GROUP AND ITS CENTRAL EXTENSION

We denote by $P(1,1)$ the 1+1-dimensional Poincaré group. Let x and t be the coordinates of space–time. The set of transformations $(x,t)\rightarrow(x',t')$, where

$$t'=t\ \cosh z+x\ \sinh z+\eta,\quad x'=t\ \sinh z+x\ \cosh z+u \tag{2.1}$$

constitute $P(1,1)$ under composition. Here z, η, and u are real parameters and $\tanh z$ is the relative velocity connecting the two inertial frames. Thus the typical group element can be displayed in the fashion $(z,\mathbf{u})$, when $\mathbf{u}$ is a 1+1 vector and the group multiplication law is

$$(z,\mathbf{u})(z',\mathbf{u}')=(z+z',\mathbf{u}+\delta(z)\mathbf{u}'), \tag{2.2}$$

where

$$\mathbf{u}=\begin{pmatrix}\eta\\ u\end{pmatrix}\quad\text{and}\quad \delta(z)=\begin{pmatrix}\cosh z & \sinh z\\ \sinh z & \cosh z\end{pmatrix}. \tag{2.3}$$

$P(1,1)$ has two distinguished subgroups. Elements of the form $(z,0)$ generate the subgroup of homogeneous Lorentz transformations, isomorphic with the additive group R of reals. The normal subgroup of translations consists of elements $(0,\mathbf{u})$ and is a two-dimensional vector group R^2. The group $P(1,1)$ is a semi-direct product of these two subgroups. The group $P(1,1)$ as defined above is connected and simply connected and is a solvable (non-nilpotent) group of rank 2, as is easy to verify.

The central extension of $P(1,1)$ is given by Bargmann.[5] For any pair $\mathbf{u},\mathbf{u}'$ of 1+1 vectors let $\mathbf{u}\wedge\mathbf{u}'=\eta u'-u\,\eta'$. Let $r=(z,\mathbf{u})$, $r'=(z',\mathbf{u}')$; $r,r'\in P(1,1)$. Then an R-valued representative (of an equivalence class with respect to coboundaries) two-cocycle on $P(1,1)$ is[5]

$$m(r,r')=\mathbf{u}\wedge\delta(z)\mathbf{u}'. \tag{2.4}$$

The above two-cocycle gives the desired central extensions. We have the central extension of $P(1,1)$ by T (circle group) given by $\{(r,\xi)\}$, $r\in P(1,1)$, $\xi\in T$, with the composition law

$$(r,\xi)(r'\xi')=(rr',\xi\xi'\ \exp(i\lambda/2)m(r,r')). \tag{2.5}$$

On the other hand, the central extension of $P(1,1)$ by R—the group $\hat{P}(1,1)$—consists of elements (r,ω), $r\in P(1,1)$, $\omega\in R$, with the multiplication rule

$$(r,\omega)(r'\omega')=(rr',\omega+\omega'+\tfrac{1}{2}m(r,r')), \tag{2.6}$$

where rr' is given by Eq. (2.2) and $m(r,r')$ by Eq. (2.4). We proceed to analyze the structure of $\hat{P}(1,1)$.

Elements of $\hat{P}(1,1)$ of the form $(r,0)$ with $r \in P(1,1)$ restricted to be of the form $r=(z,0)$ constitute a subgroup isomorphic with the homogeneous Lorentz group. We call this subgroup L. Elements (r,ω) with r having the form $r \in P(1,1)=(0,\mathbf{u}) \equiv (0,\eta,u)$ generate a subgroup isomorphic with the Heisenberg–Weyl group (the group of 3×3 triangular matrices under matrix multiplication); the required isomorphy is given by

$$(\eta,u,\omega) \equiv (0,\eta,u,\omega) \leftrightarrow \begin{pmatrix} 1 & \eta & \omega+\frac{1}{2}\eta u \\ 0 & 1 & u \\ 0 & 0 & 1 \end{pmatrix}. \tag{2.7}$$

Call the above subgroup N. First, it is easy to check using Eq. (2.6) that the first derived group (commutator subgroup) of $\hat{P}(1,1)$ is N, the second derived group is $R=\{(0,0,\omega)\}$, and the third derived group is trivial; thus $\hat{P}(1,1)$ is a solvable group of rank 3. It is also easy to verify that $\hat{P}(1,1)$ is not nilpontent. Further, $\hat{P}(1,1)$ has the structure of a semi-direct product. This follows from the existence of a unique decomposition for every element $(r,\omega) \equiv (z,\eta,u,\omega) \in \hat{P}(1,1)$ given by

$$(z,\eta,u,\omega)=(0,\eta,u,\omega)(z,0,0,0), \tag{2.8}$$

where $(0,\eta,u,\omega) \in N$ and $(z,0,0,0) \in L$, plus the fact that the only element that N and L share in common is the identity of $\hat{P}(1,1)$. Thus $\hat{P}(1,1)=NL$ with N normal. The group $\hat{P}(1,1)$ is connected and simply connected; in fact, the group manifold is just R^4 topologically. We note next that the semi-direct product is *regular*, in the sense of Mackey. This may be seen as follows. Let N^* denote the dual space of N (the space of equivalence classes of unitary, irreducible representations of N). The unitary irreducible representations of N are of two types:[7] (i) those labeled by a nonzero real number λ, which is essentially the eigenvalue of the central charge of the Lie algebra of N, and (ii) those labeled by a pair (p_0,p) of real numbers, which is the case when the central charge has eigenvalue zero, the group effectively Abelian ($\approx R^2$), and (p_0,p) label the characters of R^2. Thus the space N^* may be visualized as a plane with a line perpendicular to it. Under the action of L the points of N^* respond as follows: the points on the line, labeled by λ, do not move, since the central charge of Lie (N) commutes with the L-action, and the points on the plane $\{(p_0,p)\}$ behave as $1+1$ vectors. We thus see that the L-orbits in N^* are as follows: (i) one-point orbits for each value of λ, (ii) the one-point orbit given by (0,0) on the plane, and (iii) the sets $\{(p_0,p)\}$ with $p_0^2-p^2=\pm m^2$, $m \geqslant 0$, the corresponding orbits being hyperbolas and ''light-cones.'' Now, the semi-direct product $\hat{P}(1,1)=NL$ will be regular if there exists in N^* a set (a Borel set) that meets each L-orbit in N^* at exactly one point.[10] The desired set is simply the union of the λ-line with S, where S is a Borel set that meets each planar orbit at one point. The set S may be constructed without difficulty. Thus the semi-direct product is regular. Consider now the stability groups (little groups) of the L-orbits in N^*. It is clear from the foregoing discussion that the stability group of each one-point orbit is L, and the stability group of each non-one-point orbit is trivial (one element group). In every case, the stability group is of type 1. From the last conclusion and using the regularity of the semi-direct product, it now follows from a theorem of Mackey[10] that $\hat{P}(1,1)$ is a group of type 1. The same conclusion may also be reached from an analysis of the co-adjoint orbits (see below).

We shall now show that the group $\hat{P}(1,1)$ is completely solvable, in the sense of Kirillov.[7] For this purpose, the coordinate system on the group that we have used thus far is not convenient. Another set of (global) coordinates on $\hat{P}(1,1)$ will be introduced in Sec. IV [see Eq. (4.2)]. Using the latter, and the corresponding group multiplication law given by Eq. (4.3), we may verify the existence of the following sequence of normal subgroups [normal in $\hat{P}(1,1)$]:

$$\{e\}=G_0 \subset G_1 \subset G_2 \subset G_3=N \subset G_4=\hat{P}(1,1), \tag{2.9}$$

where $\dim(G_k)=k$. Here $G_2=\{(0,x,0,\omega)\}=R^2$ and $G_1=\{(0,0,0,\omega)\}=R$, in the notation of Eq. (4.2). This proves that $\hat{P}(1,1)$ is completely solvable.

The sequence (2.9) gives rise to a corresponding sequence at the level of Lie algebras in which every entry G_k is replaced by its Lie algebra Lie (G_k), every Lie (G_k) is an ideal in Lie $(\hat{P}(1,1))$, and dim Lie $(G_k)=k$. Since $\hat{P}(1,1)$ is connected, simply connected, and solvable, the existence of such a sequence of ideals in its *real* Lie algebra implies, via a result due to Dixmier[11] (corollary to his theorem 3), that $\hat{P}(1,1)$ is an exponential group.

We pass on to compute the co-adjoint orbits of $\hat{P}(1,1)$.

III. COADJOINT ORBITS

The Lie algebra of $\hat{P}(1,1)$ is a four-dimensional real vector space. We may choose basis vectors N, H, P, and E that obey the commutation relations

$$[N,\ H]=P,\quad [N,\ P]=H,\quad [H,\ P]=E; \tag{3.1}$$

N,P,H are the infinitesimal generators of Lorentz transformation, space translations, and time translation, respectively, E is the central generator. The operators H, P, and E generate the Heisenberg algebra, which is an ideal.

The typical element (z,η,u,ω) of the group $\hat{P}(1,1)$ is

$$(z,\eta,u,\omega)=\exp(\omega E+\eta H+uP)\exp(zN). \tag{3.2}$$

Several comments are in order. First, in writing Eq. (3.2), we utilized the semi-direct product structure of $\hat{P}(1,1)$ plus the fact that the Heisenberg–Weyl group is nilpotent and hence exponential; here η, u and ω are the exponential coordinates. Thus (3.2) gives a globally valid coordinate system. The group multiplication law can be derived from Eqs. (3.1) and (3.2) together with the use of the Baker–Hausdorff formula; one thus obtains Eq. (2.6). An alternative route to the same conclusion will employ a faithful matrix representation of Eq. (3.1). Such a representation is

$$N=\begin{pmatrix}0&0&0&0\\0&0&1&0\\0&1&0&0\\0&0&0&0\end{pmatrix},\quad H=\begin{pmatrix}0&0&1&0\\0&0&0&1\\0&0&0&0\\0&0&0&0\end{pmatrix},$$
$$P=\begin{pmatrix}0&-1&0&0\\0&0&0&0\\0&0&0&1\\0&0&0&0\end{pmatrix},\quad E=\begin{pmatrix}0&0&0&2\\0&0&0&0\\0&0&0&0\\0&0&0&0\end{pmatrix}. \tag{3.3}$$

It is useful to note $H^2=P^2=E^2=0$ and $N^3=N$ and further that

$$N^2=\begin{pmatrix}0&0&0&0\\0&1&0&0\\0&0&1&0\\0&0&0&0\end{pmatrix}. \tag{3.4}$$

A group acts on its Lie algebra with the aid of the adjoint representation. Precisely, this action is $\mathrm{Ad}\ (g)W=gWg^{-1}$ for $g\in G$, $W\in\mathrm{Lie}(G)$. Use of the above matrix realization together with Eq. (3.2) thus allows us to explicitly compute the adjoint action. Let us write the generic element

W of the Lie algebra as $W=aE+bH+cP+dN$, where a,b,c,d are real numbers. Then the adjoint action of g^{-1} [it will turn out more useful for us to consider the action of the inverse element; here, g is given by Eq. (3.2)] is Ad $(g^{-1})W=W'=a'E+b'H+c'P+d'N$, where

$$\begin{aligned} a' &= a-c\,\eta+bu+(d/2)(u^2-\eta^2), \\ b' &= (b+du)\cosh z-(c+d\,\eta)\sinh z, \\ c' &= (c+d\,\eta)\cosh z-(b+du)\sinh z, \quad d'=d, \end{aligned} \tag{3.5}$$

as a straightforward calculation shows.

A group acts on a vector space which is dual to its Lie algebra with the aid of the co-adjoint representation. Let E^*, H^*, P^*, and N^* be a basis in the dual vector space to Lie $\hat{P}(1,1)$. This means

$$\begin{aligned} &(E^*,E)=1, \quad (E^*,X)=0 \quad \text{for } X=H,P,N, \\ &(H^*,H)=1, \quad (H^*,X)=0 \quad \text{for } X=E,P,N, \\ &(P^*,P)=1, \quad (P^*,X)=0 \quad \text{for } X=E,H,N, \\ &(N^*,N)=1, \quad (N^*,X)=0 \quad \text{for } X=E,H,P, \end{aligned} \tag{3.6}$$

where (,) denotes a scalar product. Let us consider the typical element ℓ of the dual space

$$\ell=\delta E^*+\beta H^*+\gamma P^*+\alpha N^*, \tag{3.7}$$

and let W be, as before,

$$W=aE+bH+cP+dN. \tag{3.8}$$

Then

$$(\ell,W)=a\,\delta+b\,\beta+c\,\gamma+d\,\alpha. \tag{3.9}$$

Let us write $\ell(W)=(\ell,W)$. Let K denote the co-adjoint action and $K(g)\ell$ denote that of g on ℓ. Then precisely

$$(K(g)\ell)(W)=\ell(\mathrm{Ad}(g^{-1})W) \tag{3.10}$$

defines the co-adjoint action. Let $K(g)\ell=\ell'=\delta' E^*+\beta' H^*+\gamma' P^*+\alpha' N^*$. Then we compute from Eqs. (3.5) and (3.10) that

$$\begin{aligned} \delta' &= \delta, \quad \beta'=u\,\delta+\beta\,\cosh z-\gamma\,\sinh z, \\ \gamma' &= -\,\eta\delta-\beta\,\sinh z+\gamma\,\cosh z, \\ \alpha' &= \alpha+(\delta/2)(u^2-\eta^2)+\beta(u\,\cosh z-\eta\,\sinh z)+\gamma(\eta\,\cosh z-u\,\sinh z), \end{aligned} \tag{3.11}$$

where g is given by Eq. (3.2). It follows, from the above, that $\beta^2-\gamma^2-2\delta\alpha$ remain invariant under the co-adjoint action. The co-adjoint orbits (K-orbits) are now easy to enumerate. Each K-orbit is two-dimensional, since $\{(\alpha,\beta,\gamma)\}$ generate an orbit and there is a constraint connecting these three (real) variables. Each K-orbit is characterized by two numbers: the value of δ and that of the invariant $\beta^2-\gamma^2-2\delta\alpha$. The K-orbits are of two broad types.

The K-orbits of $\hat{P}(1,1)$ for the case $\delta=0$ plainly coincide with the K-orbits of P (1,1). A complete listing of the latter may be found in a recent contribution of Ali and Mueller.[12] The representations constructed from these orbits coincide with the known[4] faithful representations of $P(1,1)$. We do not discuss these orbits any further.

Consider now the K-orbits corresponding to $\delta\neq 0$. An orbit is characterized by δ and the constant $c=\beta^2-\gamma^2-2\delta\alpha$. The point $(\alpha_0=-c/2\delta,0,0,\delta)\equiv\delta E^*+\alpha_0 N^*$ belongs to the orbit. Indeed, we can reach the typical point $(\alpha=-(c+\gamma^2-\beta^2)/2\delta,\beta,\gamma,\delta)$ on the orbit from the point $(\alpha_0,0,0,\delta)$ under the action (3.11) of the group element $(0,\eta,u,0)$ with $\eta=-\gamma/\delta$ and $u=\beta/\delta$. Thus the constant c plays no essential role and we may simply characterize an orbit by the point $(\alpha,0,0,\delta)$ belonging to it. Consider now the stability group H of the orbit, i.e., of the representative point $(\alpha,0,0,\delta)$. From Eq. (3.11) we obtain $H=\{(z,0,0,\omega)\}\equiv R\otimes R$. From the group multiplication law (2.6), it follows that every element of $\hat{P}(1,1)$ admits the decomposition

$$(z,\eta,u,\omega)=(z,0,0,\omega)(0,\eta',u',0), \tag{3.12}$$

where $\eta'=\eta\cosh z-u\sinh z$ and $u'=u\cosh z-\eta\sinh z$. Thus η and u may be chosen to (globally) parametrize the homogeneous space of right cosets of H in $\hat{P}(1,1)$. Plainly, the coset space is R^2. The K-orbit is homeomorphic to the coset space since $\hat{P}(1,1)$ is locally compact. Thus the K-orbit has trivial de Rham cohomology. In particular, the Kostant–Kirillov symplectic two-form on the K-orbit is *exact* (the conclusion remains valid for $\delta=0$ orbits).[12]

From the above it would follow, via an application of the Auslander–Kostant theorem, that $\hat{P}(1,1)$ is a group of type 1, provided the *space of orbits* can be shown to possess the T_0 separability property. As for the latter requirement, we note that each K-orbit is parametrized by the pair (α,δ) of real numbers [or equivalently by the pair (c,δ) of real numbers] and hence the space of orbits is the plane R^2 which has T_0 separability property. The conclusion, once again, is that $\hat{P}(1,1)$ belongs to type 1.

In the Kirillov method, a vital role is played by the admissible subalgebras corresponding to an orbit. We proceed to construct these. Let G be a Lie group, Lie (G) its Lie algebra, Ω a K-orbit of G, and $\tilde{\ell}$ a point belong to Ω. A sub-Lie algebra A of Lie (G) is said to be *admissible* (or *polarizing*) if the following conditions are satisfied:[13]

(1) $\tilde{\ell}([X,Y])=0$ for arbitrary X and Y belonging to A; here, as before, $\tilde{\ell}(X)\equiv(\tilde{\ell},X)$. The algebra A is said to be subordinate to the point $\tilde{\ell}$.
(2) The codimension of A in Lie(G) [that is the difference dim Lie$(G)-\dim A$] is one-half the dimension of Ω.
(3) $\tilde{\ell}+A^{\perp}\subset\Omega$; here $A^{\perp}$ is the set of all points F belonging to the dual space of Lie(G) for which $F(X)=0$ for all $X\in A$; this is Pukanszky's condition.

We select the point $\tilde{\ell}=(\alpha,0,0,\delta)$ on the orbit. Then we have two admissible subalgebras A_+ and A_-; A_+ is generated by N, P_+, and E while A_- is generated by N, P_-, and E; here $P_\pm=H\pm P$. First, these are subalgebras since $[N,P_\pm]=\pm P_\pm$. The condition (1) above is checked easily. Thus for A_+, let $X=x_1N+x_2P_++x_3E$ and $Y=y_1N+y_2P_++y_3E$. Then $[X,Y]=(x_1y_2-x_2y_1)P_+$ and $\tilde{\ell}([X,Y])=0$ follows from Eq. (3.9). Now $\dim A_\pm=3$ and dim Lie $(\hat{P}(1,1))=4$; thus codim $A_\pm=1$; moreover dim $\Omega=2$ (proved before). Thus condition (2) is satisfied. That condition (3) is fulfilled will be shown in the next section using a different set of group coordinates better suited for this purpose.

IV. LIGHT-CONE COORDINATES

As we saw above, the basis in our Lie algebra given by the basis vectors N, P_+, P_-, and E will be more convenient for the discussion to follow. Here $P_\pm=H\pm P$ and we may note

$$[N,P_\pm]=\pm P_\pm,\quad [P_-,P_+]=2E. \tag{4.1}$$

Note the existence of a sequence of ideals generated by E, (E,P_+), and (E,P_+,P_-) as stated in the penultimate paragraph of Sec. II. Corresponding to the present choice of the basis in the Lie algebra, there is a coordinate system for the group manifold. Let us write the typical group element (z,x,y,ω) in the fashion

$$(z,x,y,\omega)=e^{\omega E}e^{xP_+}e^{yP_-}e^{zN}. \tag{4.2}$$

The new coordinates are related to the old by $x+y=\eta$, $x-y=u$; the parametrization of ω above is simply related to that in Eq. (3.2), via the Baker–Hausdorff formula (see below). The group multiplication law in these coordinates is given by

$$(z,x,y,\omega)(z',x',y',\omega')=(z+z',x+e^z x',y+e^{-z}y',\omega+\omega'+2e^z yx'). \tag{4.3}$$

Note the expression for the inverse

$$(z,x,y,\omega)^{-1}=(-z,-e^{-z}x,-e^z y,2xy-\omega). \tag{4.4}$$

The co-adjoint action in the present coordinate system may be computed exactly as before. Let the typical point ℓ on the dual space be

$$\ell=\delta E^*+\tilde{\beta}P_+^*+\tilde{\gamma}P_-^*+\alpha N^*. \tag{4.5}$$

Then under the action of (z,x,y,ω), $(\delta,\tilde{\beta},\tilde{\gamma},\alpha)$ go over to $(\delta',\tilde{\beta}',\tilde{\gamma}',\alpha')$, where

$$\delta'=\delta,\quad \tilde{\beta}'=e^{-z}\tilde{\beta}-2\delta y,\quad \tilde{\gamma}'=e^z\tilde{\gamma}+2\delta x,\quad \alpha'=\alpha+xe^{-z}\tilde{\beta}-ye^z\tilde{\gamma}-2\delta xy, \tag{4.6}$$

and $\tilde{\beta}\tilde{\gamma}-2\delta\alpha$ is an invariant of the orbit. Indeed, a comparison of Eq. (4.5) with Eq. (3.7) shows $\tilde{\beta}=\beta+\gamma$, $\tilde{\gamma}=\beta-\gamma$. Further, let us call the parameter ω in Eq. (3.2) as $\overline{\omega}$ and ω be as in Eq. (4.2); then $\overline{\omega}=\omega-xy$. From these observations and the fact that $\overline{\omega}$ does not appear in Eq. (3.11), Eq. (4.6) now follows easily from Eq. (3.11). As before, the point $(\alpha,0,0,\delta)\equiv\alpha N^*+\delta E^*$ belongs to the K-orbit, and the subalgebras $A_\pm$ with codimension one are subordinate to this point. We may now verify Pukanszky's condition. The annihilators are $A_+^\perp=\{\xi P_-^*\}$, ξ real; $A_-^\perp=\{\rho P_+^*\}$, ρ real. Consider the case A_-. Then $(\alpha,0,0,\delta)+A_-^\perp$ is the set $\{(\alpha,\rho,0,\delta)\}$ as ρ ranges over reals. The question is do these points belong to the K-orbit? The answer is yes, since a point $(\alpha,\rho,0,\delta)$ may be reached from the point $(\alpha,0,0,\delta)$ on the orbit, under the action (4.6) of the group element (z,x,y,ω) with $z=x=\omega=0$ and $y=-\rho/2\delta$. One similarly verifies the condition for the subalgebra A_+. Thus, Pukansky's condition stands satisfied and the proof of the fact that $A_\pm$ are *admissible* subalgebras is now complete.

V. REPRESENTATIONS

In the Kirillov theory, the group representations are constructed as follows. One selects a point $\tilde{\ell}$ on the co-adjoint orbit and an accompanying admissible subalgebra A. Let K denote the subgroup corresponding to A. The point $\tilde{\ell}$ allows one to construct *one-dimensional* representations of K (since A is subordinate to $\tilde{\ell}$, it is *effectively* Abelian on $\tilde{\ell}$). The group representations are the induced representations; induced from the one-dimensional representations of subgroup K.

We may note the following general features of the Kirillov theory. First, the precise choice of $\tilde{\ell}$ plays no role; one can select any point on the orbit depending on one's convenience. Second, one may work with any one of the admissible subalgebras, in case there are more than one such, corresponding to a chosen $\tilde{\ell}$. Thus there is a one-to-one correspondence between representations and co-adjoint orbits. *The representation constructed as above will be irreducible*. The representations can be made unitary with respect to a suitable inner product in a Hilbert space.

Let us select the admissible subalgebra A_+ for the chosen point $\tilde{\ell}=(\alpha,0,0,\delta)$. Let K denote the subgroup corresponding to A_+. As before, A_+ is spanned by generators N, P_+, and E and is a real

subalgebra; the subgroup K is the set $\{(z,x,0,\omega)\}$ in the notation of Eq. (4.2). Notice K is *not* a normal subgroup, and A_+ *not* an ideal. Let $k=(z,x,0,\omega)$, $k\in K$, and we set

$$\chi(k)=e^{i\delta\omega}e^{i\alpha z}. \tag{5.1}$$

Then it follows that χ satisfies the character equation $\chi(k)\chi(k')=\chi(kk')$. Thus χ is a one-dimensional representation of K. We have to carry out the inducing construction from this representation χ.

At this stage, let us recall the basic idea behind the construction of induced representations. Let G be a (Lie) group, K a closed subgroup of G, and L_k a (finite dimensional) unitary representation of K in a Hilbert space L. Consider measurable L-valued functions f on G (functions of group parameters) that satisfy the condition

$$f(gk)=L_k^{-1}f(g), \quad g\in G,k\in K, \tag{5.2}$$

and let

$$(U^L(g_0)f\ )(g)=\rho_{g_0}(g)f(g_0^{-1}g), \tag{5.3}$$

where $\rho_{g_0}(g)$ is a certain positive function (see below). Then the map $g\to U^L(g)$ is a representation of G induced by the representation L_k of K. The condition (5.2) is the covariance condition on left cosets and because of it we shall be able to identify the functions f with certain functions (L-valued) defined on the left coset space $X=G/K$. The $\rho_{g_0}(g)$ appearing in (5.3) is precisely the square root of the Radon–Nikodym derivative $d\mu(g_0^{-1}x)/d\mu(x)$, where $x=\pi(g)$ and $\pi{:}G\to X$ is the natural projection. Here μ is a measure on X that is *quasi-invariant* under the action of G. Further restrictions on the functions f will be spelled out as the need arises. In our case L_k is given by χ [see (5.1)] and f are ordinary functions.

We make a remark. The above construction actually gives the group representation on the left coset space. We may similarly construct representations on the right coset space $X_R=K\backslash G$. Now Eq. (5.2) will modify to $f(kg)=L_kf(g)$ and Eq. (5.3) to $(U^L(g_0)f\ )(g)=\rho_{g_0}(g)f(gg_0)$. Here $\rho_{g_0}(g)$ is the square root of $d\mu(xg_0)/d\mu(x)$, where x belongs to the right coset and xg_0 is the right action of g_0 on x.

We proceed to construct the group representations. The covariance condition (5.2) becomes

$$f(gk)=\chi^{-1}(k)f(g). \tag{5.4}$$

Let $g=(z',x',y',\omega')$ and $k=(z,x,0,\omega)$; then using the multiplication law equation (4.3) we have

$$gk=(z'+z,x'+e^{z'}x,y',\omega'+\omega+2e^{z'}y'x), \tag{5.5}$$

and Eq. (5.4) acquires the form

$$f(z'+z,x'+e^{z'}x,y',\omega'+\omega+2e^{z'}y'x)=e^{-i\delta\omega}e^{-i\alpha z}f(z',x',y',\omega'). \tag{5.6}$$

The solution of (5.6) is shown without difficulty to be given by

$$f(z,x,y,\omega)=e^{-i\alpha z}e^{-i\delta(\omega-2xy)}F(y), \tag{5.7}$$

where $F(y)$ is a function of y alone. One may check that Eq. (5.7) solves Eq. (5.6). Because of Eq. (5.7) the group representations defined on functions f will factor into those defined on functions F; that is, on the left coset space whose point y is.

The next problem is to figure out the form of the Radon–Nikodym derivative. First, we note that every group element g admits the decomposition $g=sk$ with $k\in K$ and $s\in G$. This is given by

$$(z,x,y,\omega)=(0,0,y,0)(z,x,0,\omega-2xy) \tag{5.8}$$

and thus the left coset space may be parametrized by y [the element $(0,0,y,0)\in G$ goes over to y under natural projection]. The left action of the group on the coset space is computed as follows. With g as above we have

$$(z,x,y,\omega)(0,0,y_0,0)=(z,x,y+e^{-z}y_0,\omega)=(0,0,y+e^{-z}y_0,0)(z,x,0,\omega-2x(y+e^{-z}y_0)) \tag{5.9}$$

and thus $y_0\to e^{-z}y_0+y$ under the left action of (z,x,y,ω). Similarly, $y_0\to e^{z}(y_0-y)$ under the left action of the inverse $(z,x,y,\omega)^{-1}$. Thus the Lebesgue measure dy on the left coset space is not invariant under the group action; it is actually an example of the so-called quasi-invariant measure that behaves under group action as $dy\to e^{-z}\,dy$, and dy and its transform share the same null set. Here we choose the quasi-invariant Lebesgue measure dy and then the Radon–Nikodym derivative $d\mu(g_0^{-1}y)/d\mu(y)$ is just e^{z}. Thus $\rho_{g_0}(g)$ is $e^{z/2}$. We are now in a position to write down the explicit form of the group representation. From Eq. (5.3) we have

$$\begin{aligned}&(U(z,x,y,\omega)f\,)(z',x',y',\omega')\\&\quad=e^{z/2}f((z,x,y,\omega)^{-1}(z',x',y',\omega'))\\&\quad=e^{z/2}f(z'-z,e^{-z}(x'-x),e^{z}(y'-y),\omega'-\omega+2y(x-x')),\end{aligned} \tag{5.10}$$

where Eqs. (4.3) and (4.4) have been utilized in the second step. Equation (5.10) gives the desired representation; here the functions f satisfy the condition given by Eq. (5.7). We proceed to analyze the content of the representation obtained. First, we note

$$\begin{aligned}(U(e^{\omega E})f\,)(z',x',y'\omega')&\equiv(U(0,0,0,\omega)f\,)(z',x',y',\omega')\\&=f(z',x',y',\omega'-\omega)\\&=e^{i\delta\omega}f(z',x',y',\omega'),\end{aligned} \tag{5.11}$$

where Eq. (5.7) was used at the last step. It follows from the above that

$$E=i\delta. \tag{5.12}$$

Next we have from Eq. (5.10)

$$(U(e^{xP_+})f\,)(z',x',y',\omega')\equiv(U(0,x,0,0)f\,)(z',x',y',\omega')=f(z',x'-x,y',\omega'). \tag{5.13}$$

Differentiating the above with respect to x and then setting $x=0$, we obtain

$$(U(P_+)f\,)(z',x',y',\omega')=-\frac{\partial}{\partial x'}f(z',x',y',\omega')=-2i\delta y'f(z',x',y',\omega'), \tag{5.14}$$

where Eq. (5.7) was used at the last step. Thus acting on $f(z,x,y,\omega)$, P_+ is the operator of multiplication by $-2i\delta y$. The remaining operators of interest are similarly found. We obtain

$$(U(P_-)f\,)(z,x,y,\omega)=\left(2i\delta x-\frac{\partial}{\partial y}\right)f(z,x,y,\omega), \tag{5.15}$$

$$(U(N)f\,)(z,x,y,\omega)=\left(\frac{1}{2}-\frac{\partial}{\partial z}+y\,\frac{\partial}{\partial y}-x\,\frac{\partial}{\partial x}\right)f(z,x,y,\omega). \tag{5.16}$$

With the aid of Eq. (5.7) the above action of the operators on f may be translated into action on the functions F. The result is

$$(U(P_-)F)(y) = -\frac{d}{dy}F(y), \tag{5.17}$$

$$(U(N)F)(y) = \left(\frac{1}{2} + y\frac{d}{dy} + i\alpha\right)F(y). \tag{5.18}$$

The above expressions satisfy the correct commutation relations of operators N, P_+, P_-, and E, as may be verified.

We should finally consider the restrictions on the function F. From (5.17) we see that for *finite* translation by y to be defined, the function F must be infinitely differentiable; that is, F is an analytic function of the real variable y. Next, we shall restrict F to be square integrable with respect to the Lebesgue measure dy on the left coset space. The set of all such functions, which may be taken to be real valued, then constitute a separable Hilbert space H with respect to the inner product

$$(F_1, F_2) = \int F_1(y)F_2(y)dy. \tag{5.19}$$

Our representation is then unitary in H and is strongly continuous (continuous in the strong topology of H); it is irreducible because of reasons explained before. This concludes our discussion of the representations of $\hat{P}(1,1)$.

VI. PROJECTIVE REPRESENTATIONS OF THE 1+1 POINCARÉ GROUP

The nontrivial projective unitary irreducible representations of the Poincaré group $P(1,1)$ may now be obtained from the representations of the centrally extended group $\hat{P}(1,1)$ constructed in Sec. V.

In the light-come coordinates the typical element of the Poincaré group $P(1,1)$ is written in the fashion (z,x,y) and the multiplication law is

$$(z,x,y)(z',x',y') = (z+z', x+e^z x', y+e^{-z}y') \tag{6.1}$$

as follows from Eq. (2.2). The desired representations of $P(1,1)$ follow from Eqs. (5.10) and (5.7) upon setting $\omega=\omega'=0$. Defining $f(z,x,y)\equiv f(z,x,y,0)$ we thus have

$$(U(z,xy)f)(z',x',y') = e^{z/2}e^{2i\delta(x'-x)y}f(z'-z, e^{-z}(x'-x), e^z(y'-y)). \tag{6.2}$$

The expressions for the generators N, P_+, P_- of the Lie algebra are exactly the same as those in Sec. V. The above is a projective representation of $P(1,1)$. Indeed, from (6.2) we compute

$$(U(0,0,y)U(0,x,0)f)(z',x',y') = e^{2i\delta x'y}f(z',x'-x,y'-y). \tag{6.3}$$

On the other hand, from (6.1) and (6.2), it follows

$$(U((0,0,y)(0,x,0))f)(z',x',y') = (U(0,x,y)f)(z',x',y') = e^{2i\delta(x'-x)y}f(z',x'-x,y'-y), \tag{6.4}$$

and thus

$$U(0,0,y)U(0,x,0) = e^{2i\delta xy}U((0,0,y)(0,x,0)), \tag{6.5}$$

which shows that our representation is projective.

VII. CONCLUDING REMARKS

The faithful representations of $P(1,1)$ corresponding to timelike and lightlike representations describe the states of a massive or massless particle in one spatial dimension. The projective representations of $P(1,1)$ clearly do not admit a free-particle interpretation; the intriguing question is if they possess any physical application. Unfortunately, we have not found an answer to this question, thus far. On the other hand, the group $\hat{P}(1,1)$ does seem to possess physical utility. A *gauge* theory built upon $\hat{P}(1,1)$ was shown by Cangemi and Jackiw[14] to be efficacious in analyzing the structure of 1+1-dimensional ''black-hole'' models.

The group $\hat{P}(1,1)$ is closely related to two other groups of interest in physics and it may not be out of place to make a few remarks concerning these relationships. The group $P(1,1)$ is related to $E(2)$—the Euclidean group on the plane. Indeed, by replacing the 1+1 Lorentz transformation by a planar rotation we pass from $P(1,1)$ to $E(2)$. The central extension of these two groups are similarly related. The central extension $\hat{E}(2)$ of $E(2)$ by R is locally isomorphic with (shares an isomorphic Lie algebra with) the quantum harmonic oscillator group; the difference between the two at the global level resides entirely on the range of one of the group parameters. The parameter of rotation in $\hat{E}(2)$ is an angle that ranges from 0 to 2π; while the corresponding parameter for the oscillator group—the time parameter conjugate to the Hamiltonian—ranges over the real line. The representations of the oscillator group were constructed by Streater[15] a long time ago, using the Kirillov (actually a generalization of the original Kirillov method involving complex Lie algebras) as well as the Mackey method. The close parallelism between Streater's treatment and that of the present paper should be noted. It also follows that the projective representations of $E(2)$ can be obtained very simply from the results of Streater.[15] Actually, the projective representations of $E(2)$ are useful in the problem of electrons in a uniform magnetic field. An elegant treatment of this problem has been given by Divakaran and Rajagopal.[16]

Note added in proof. Projective representations of the 2+1 and 1+1 Galilean group are constructed independently in H. D. Doebner and H. J. Mann, J. Math. Phys. **36**, 3210 (1995). Many properties of the centrally extended 1+1 Poincaré group are discussed in D. Cangemi and R. Jackiw, Ann. Phys. (NY) **225**, 229 (1993) and Phys. Rev. D **50**, 3913 (1994). In particular, the exactness of the symplectic two-form on the co-adjoint orbit is proved by explicit construction in the latter. It is a pleasure to thank R. Jackiw for correspondence regarding these and related matters.

APPENDIX: THE 1+1 GALILEAN GROUP

The 1+1 Galilean group is the group under composition of the set of space–time transformations

$$x' = x - vt + u, \quad t' = t + \eta. \tag{A1}$$

The typical group element is (v, η, u) with the multiplication law

$$(v, \eta, u)(v', \eta', u') = (v + v', \eta + \eta', u + u' - \eta' v). \tag{A2}$$

The group is isomorphic with the Heisenberg–Weyl group, the isomorphism being explicitly

$$(v, \eta, u) \leftrightarrow \begin{pmatrix} 1 & -v & u \\ 0 & 1 & \eta \\ 0 & 0 & 1 \end{pmatrix}. \tag{A3}$$

The corresponding Lie algebra is a three-dimensional real vector space in which one can choose basis vectors N, P, H that satisfy the commutation relations

$$[N, H]=P, \quad [N, P]=0, \quad [H, P]=0. \tag{A4}$$

We consider the problem of central extension of the Galilean group. It has two equivalence classes of two-cocycles. We can choose the representative two-cocycles (one from each equivalence class) to be

$$m_1(r,r')=\tfrac{1}{2}v^2\eta'-v u', \quad m_2(r,r')=\tfrac{1}{2}v\,\eta'^2-\eta u'+v\,\eta\eta', \tag{A5}$$

where $r\equiv(v,\eta,u)$ and $r'=(v',\eta',u')$. That the above expressions satisfy the cocycle identities and are nontrivial (not coboundaries) may be checked along the same lines as in Ref. 1. We may thus construct the universal centrally extended group as follows. The typical group element is $(r,\theta_1,\theta_2)\equiv(v,\eta,u;\theta_1,\theta_2)$ with the multiplication law

$$(r,\theta_1,\theta_2)(r',\theta_1',\theta_2')=(rr',\theta_1+\theta_1'+m_1(r,r'),\theta_2+\theta_2'+m_2(r,r')). \tag{A6}$$

where θ_1 and θ_2 are a pair of real variables. It is useful to note the corresponding Lie algebra central extension, which is given by

$$[N, H]=P, \quad [N, P]=A, \quad [H, P]=B, \tag{A7}$$

where A and B are central charges (commute with every generator). Note P is no longer central.

The centrally extended group, as defined above, is connected and simply connected. Furthermore, it is a *nilpotent* Lie group (of dimension five), as is easy to check from Eq. (A6) or from Eq. (A7). At this stage we recall the fact that all nilpotent Lie groups of dimension less than 6 were classified by Dixmier[17] in 1959. Thus our centrally extended group must be one in his classification. In fact, *our group is the group* $\Gamma_{5,4}$ *in the Dixmier classification*. The complete system of unitary, irreducible representation of $\Gamma_{5,4}$ has been given in Ref. 17. Lifting the latter to projective representations of the Galilean group is trivial (be setting $\theta_1=\theta 2=0$), and there remains nothing more to discuss.

Quantum homogeneous spaces as quantum quotient spaces

Tomasz Brzeziński[a)]
Department of Applied Mathematics and Theoretical Physics, University of Cambridge, Cambridge CB3 9EW, United Kingdom

(Received 31 October 1995; accepted for publication 25 January 1996)

It is shown that certain embeddable homogeneous spaces of a quantum group that do not correspond to a quantum subgroup still have the structure of quantum quotient spaces. A construction of quantum fibre bundles on such spaces is proposed. The quantum plane and the general quantum two-spheres are discussed in detail. [S0022-2488(96)02705-1]

I. INTRODUCTION

A homogeneous space X of a Lie group G may be always identified with the quotient space G/G_0, where G_0 is a Lie subgroup of G. When the notion of a homogeneous space is generalized to the case of quantum groups or noncommutative Hopf algebras the situation becomes much more complicated. A general quantum homogeneous space of a quantum group H need not be a quotient space of H by its quantum subgroup. By a quantum subgroup of H we mean a Hopf algebra H_0 such that there is a Hopf algebra epimorphism $\pi{:}H\to H_0$. The quotient space is then understood as a subalgebra of H of all points that are fixed under the coaction of H_0 on H induced by π. A quantum homogeneous space B of H might be such a quotient space but it is not in general. There is, however, a certain class of quantum homogeneous spaces, of which the quantum two sphere of Podleś[1] is the most prominent example, that not being quotient spaces by a quantum subgroup of H, may be embedded in H. One terms such homogeneous spaces *embeddable*.[2] The general quantum two sphere $S^2_q(\mu,\nu)$ is such an embeddable homogeneous space of the quantum group $\mathrm{SU}_q(2)$, and it is a quantum quotient space in the above sense when $\nu=0$. In the latter case the corresponding subgroup of $\mathrm{SU}_q(2)$ may be identified with the algebra of functions on $U(1)$. In this article it is shown that certain embeddable quantum homogeneous spaces, and the general quantum two-sphere $S^2_q(\mu,\nu)$ among them, can still be understood as quotient spaces or fixed point subalgebras. It is shown that there is a coalgebra C and a coalgebra epimorphism $\pi{:}H\to C$ such that the fixed point subspace of H under the coaction of C on H induced from the coproduct in H by a pushout by π is a subalgebra of H isomorphic to B.

The interpretation of embeddable quantum homogeneous spaces as quantum quotient spaces allows one to develop the quantum group gauge theory of such spaces following the lines of Ref. 3. The study of such a gauge theory becomes even more important once the appearance of the quantum homogeneous spaces in the A. Connes geometric description of the standard model was announced.[4] For this purpose, however, one needs to generalize the notion of a quantum principal bundle of Ref. 3 so that a Hopf algebra playing the role of a quantum structure group there may be replaced by a coalgebra. Such a generalization is proposed (see Ref. 5 for further details). Since the theory of quantum principal bundles is strictly related to the theory of Hopf–Galois extensions (cf. Ref. 6), a generalization of such extensions is proposed.

The article is organized as follows. In Sec. II the notation used in the sequel is described. Section III shows a fixed point subalgebra structure of embeddable quantum homogeneous spaces. A suitable generalization of the notion of a quantum principal bundle in Sec. IV is proposed. Sections V and VI are devoted to careful study of two examples of quantum embeddable spaces,

namely the quantum plane $\mathbf{C}_q^2$ (Ref. 7) and the quantum sphere $S_q^2(\mu,\nu)$.[1]

II. PRELIMINARIES

In the sequel all the vector spaces are over the field k of characteristic not 2. C denotes a coalgebra with the coproduct $\Delta: C\to C\otimes C$ and the counit $\epsilon: C\to k$ which satisfy the standard axioms, cf. Ref. 8. For the coproduct the Sweedler sigma notation is used:

$$\Delta c = c_{(1)}\otimes c_{(2)} \quad (\Delta\otimes id)\circ\Delta c = c_{(1)}\otimes c_{(2)}\otimes c_{(3)}, \text{ etc.},$$

where $c\in C$, and the summation sign and the indices are suppressed. A vector space A is a left C-comodule if there exists a map $\Delta_L: A\to C\otimes A$, such that $(\Delta\otimes id)\circ\Delta_L = (id\otimes\Delta_L)\circ\Delta_L$, and $(\epsilon\otimes id)\circ\Delta_L = id$. For Δ_L we use the explicit notation

$$\Delta_L a = a_{(1)}\otimes a_{(\infty)},$$

where $a\in A$ and all $a_{(1)}\in C$ and all $a_{(\infty)}\in A$.

Similarly a vector space A is a right C-comodule if there exists a map $\Delta_R: A\to A\otimes C$, such that $(\Delta_R\otimes id)\circ\Delta_R = (id\otimes\Delta)\circ\Delta_R$, and $(id\otimes\epsilon)\circ\Delta_R = id$. For Δ_R the explicit notation is used:

$$\Delta_R a = a_{(0)}\otimes a_{(1)},$$

where $a\in A$ and all $a_{(1)}\in C$ and all $a_{(0)}\in A$.

H denotes a Hopf algebra with product $m: H\otimes H\to H$, unit 1, coproduct $\Delta: H\to H\otimes H$, counit $\epsilon: H\to k$ and antipode $S: H\to H$. Sweedler's sigma notation is used as before. Similarly as for a coalgebra right and left H-comodules are defined. For a right H-comodule A we denote by $A^{\mathrm{co}H}$ a vector subspace of A of all elements $a\in A$ such that $\Delta_R a = a\otimes 1$. A right (respectively, left) H-comodule A is a right (respectively, left) H-comodule algebra if A is an algebra and Δ_R (respectively, Δ_L) is an algebra map.

A vector subspace J of H such that $\epsilon(J)=0$ and $\Delta J\subset J\otimes H\oplus H\otimes J$ is called a *coideal* in H. If J is a coideal in H then $C=H/J$ is a coalgebra with a coproduct Δ given by $\Delta=(\pi\otimes\pi)\circ\Delta$, where $\pi: H\to C$ is a canonical surjection. The counit ϵ in C is defined by the commutative diagram

$$\begin{array}{ccc} H & \xrightarrow{\epsilon} & k \\ {\scriptstyle\pi}\downarrow & & \downarrow{\scriptstyle id} \\ C & \xrightarrow{\epsilon} & k \end{array} .$$

III. QUANTUM HOMOGENEOUS SPACES

In this section it is shown that if an embeddable quantum homogeneous space satisfies certain additional assumption it may be identified with a quantum quotient space.

Definition 3.1:[2] Let H be a Hopf algebra and B be a left H-comodule algebra with the coaction $\Delta_L: B\to H\otimes B$. B is an *embeddable quantum homogeneous space* or simply an *embeddable* H-space if there exists an algebra inclusion $i: B\hookrightarrow H$ such that $\Delta\circ i = (id\otimes i)\circ\Delta_L$, i.e., i is an intertwiner.

Proposition 3.2: (1) *A left H comodule algebra B is an embeddable H-space if and only if there exists an algebra character $\kappa: B\to k$ such that the linear map $i_\kappa: B\to H$, $i_\kappa: b\mapsto b_{(1)}\kappa(b_{(\infty)})$ is injective.* (2) *If B is an embeddable H-space then the linear map $\chi_L: B\otimes B\to H\otimes B$, $\chi_L: b\otimes b'\mapsto b_{(1)}\otimes b_{(\infty)}b'$ is injective.*

Proof: (1) If B is an embeddable quantum homogeneous space then $\kappa=\epsilon\circ i$ is a character of B. Since i is an intertwiner, for any $b\in B$, compute

$$i_\kappa(b)=b_{(1)}\epsilon(i(b_{(\infty)}))=i(b)_{(1)}\epsilon(i(b)_{(2)})=i(b),$$

thus i_κ is an inclusion.

Conversely assume that there is a character $\kappa:B\to k$ such that i_κ is injective. Then clearly i_κ is an algebra inclusion. Furthermore,

$$\Delta(i_\kappa(b))=b_{(1)}\otimes b_{(2)}\kappa(b_{(\infty)})=b_{(1)}\otimes i_\kappa(b_{(\infty)})=(id\otimes i_\kappa)\circ\Delta_L(b).$$

Therefore i_κ is an intertwiner as required.

(2) The canonical map *can:* $H\otimes H\to H\otimes H$, *can:* $u\otimes v\mapsto u_{(1)}\otimes u_{(2)}v$ is a linear isomorphism. Consider the diagram

$$\begin{array}{ccccc} & & 0 & & 0 \\ & & \downarrow & & \downarrow \\ & & B\otimes B & \xrightarrow{\chi_L} & H\otimes B \\ & & {\scriptstyle i\otimes i}\downarrow & & \downarrow{\scriptstyle id\otimes i} \\ 0 & \longrightarrow & H\otimes H & \xrightarrow{can} & H\otimes H \end{array} \quad . \tag{3.1}$$

Clearly, both the rows and the columns of diagram (3.1) are exact. Moreover for any $b,b'\in B$:

$$\begin{aligned}(id\otimes i)\circ\chi_L(b\otimes b')&=b_{(1)}\otimes i(b_{(\infty)}b')=b_{(1)}\otimes i(b_{(\infty)})i(b')=i(b)_{(1)}\otimes i(b)_{(2)}i(b')\\&=can(i(b)\otimes i(b')),\end{aligned}$$

and hence diagram (3.1) is also commutative. Therefore the sequence $0\to B\otimes B\xrightarrow{\chi_L}H\otimes B$ is exact, i.e., the map χ_L is injective. □

Remark 3.3: The second assertion of Proposition 3.2, i.e., the injectiveness of χ_L, is a dual version of the statement that the action of a group on its homogeneous space is transitive.

Proposition 3.4: *Let B be an embeddable H space corresponding to the character $\kappa:B\to k$. Define a right ideal $J_\kappa\subset H$ by $J_\kappa=\{\Sigma_j(i_\kappa(b_j)-\kappa(b_j))u_j;\forall b_j\in B,\forall u_j\in H\}$. Then J_κ is a coideal in H.*

Proof: Clearly

$$\epsilon(i_\kappa(b)-\kappa(b))=\epsilon(b_{(1)})\kappa(b_{(\infty)})-\kappa(b)=\kappa(b)-\kappa(b)=0.$$

Furthermore,

$$\begin{aligned}\Delta(i_\kappa(b)-\kappa(b))&=i_\kappa(b)_{(1)}\otimes i_\kappa(b)_{(2)}-\kappa(b)1\otimes 1=b_{(1)}\otimes(i_\kappa(b_{(\infty)})-\kappa(b_{(\infty)}))+b_{(1)}\kappa(b_{(\infty)})\otimes 1\\&\quad-\kappa(b)1\otimes 1=b_{(1)}\otimes(i_\kappa(b_{(\infty)})-\kappa(b_{(\infty)}))+(i_\kappa(b)-\kappa(b))\otimes 1.\end{aligned}$$

Therefore for any $b\in B$,

$$\Delta(i_\kappa(b)-\kappa(b))\in H\otimes J_\kappa\oplus J_\kappa\otimes H,$$

so that J_κ is a coideal as stated. □

Since J_κ is a coideal of H, the vector space $C=H/J_\kappa$ is a coalgebra and the canonical subjection $\pi:H\to C$ is a coalgebra map. This in turn implies that H is a right C-comodule with the coaction $\Delta_R=(id\otimes\pi)\circ\Delta:H\to H\otimes C$. Let $H^{coC}=\{u\in H;\Delta_R u=u\otimes\pi(1)\}$.

Proposition 3.5: *Let B be an embeddable H-space corresponding to the character $\kappa: B \to k$, J_κ be as in Proposition 3.4 and $C = H/J_\kappa$. Then: (1) H^{coC} is a subalgebra of H; (2) B is a subalgebra of H^{coC}.*

Proof: (1) Since $\ker \pi = J_\kappa$ is a right ideal in H there is a natural right action $\rho_0: C \otimes H \to C$ of H on C given by the commutative diagram

$$\begin{array}{ccc} H \otimes H & \xrightarrow{m} & H \\ {\scriptstyle \pi \otimes id}\downarrow & & \downarrow{\scriptstyle \pi} \\ C \otimes H & \xrightarrow{\rho_0} & C \end{array} .$$

In other words for any $a \in C$ and $u \in H$, $\rho_0(a,u) = \pi(vu)$, where $v \in \pi^{-1}(a)$. For any $u,v \in H^{coC}$ we compute

$$\begin{aligned} \Delta_R(uv) &= u_{(1)}v_{(1)} \otimes \pi(u_{(2)}v_{(2)}) = u_{(1)}v_{(1)} \otimes \rho_0(\pi(u_{(2)}), v_{(2)}) = uv_{(1)} \otimes \rho_0(\pi(1), v_{(2)}) \\ &= uv_{(1)} \otimes \pi(v_{(2)}) = uv \otimes \pi(1). \end{aligned}$$

Therefore $uv \in H^{coC}$ and H^{coC} is a subalgebra of H as required.

(2) For any $b \in B$ we compute

$$\Delta_R(i_\kappa(b)) = i_\kappa(b)_{(1)} \otimes \pi(i_\kappa(b)_{(2)}) = b_{(1)} \otimes \pi(i_\kappa(b_{(\infty)})) = b_{(1)} \otimes \kappa(b_{(\infty)})\pi(1) = i_\kappa(b) \otimes \pi(1).$$

Hence $i_\kappa: B \hookrightarrow H^{coC}$ is the required algebra inclusion. □

Proposition 3.5 shows therefore that if $H^{coC} \subset i_\kappa(B)$ then the embeddable H-space B may be identified with the quantum quotient space H^{coC}. For example, exploiting the argument of the proof of Proposition 1.2.4 of Ref. 9, one can conjecture that the above inclusion holds if H is a faithfully flat B-module.

IV. A POSSIBLE GENERALIZATION OF QUANTUM PRINCIPAL BUNDLES

Once an H-embeddable space B is identified with a quotient space H^{coC}, it is natural to view H as a total space of a principal bundle over B. Therefore one would like to apply the general theory of quantum principal bundles of Ref. 3 to this case too. In general, however, neither C is a Hopf algebra nor, if it happens to be a Hopf algebra, C is a quantum subgroup of H. Hence the induced coaction of C on H is not an algebra map. Therefore, to develop a gauge theory on embeddable homogeneous spaces one needs to generalize the theory of quantum principal bundles. In this section such a generalization is proposed. It is based on a simple observation that the structure of quantum principal bundles is mainly determined by the coalgebra structure of the quantum group. The notions studied in this section are developed to great extent in Ref. 5.

Let C be a coalgebra and let P be an algebra and a right C-comodule. Assume that there is an action $\rho: P \otimes C \otimes P \to P \otimes C$ of P on $P \otimes C$ and an element $1 \in C$ such that

(1) For any $u,v \in P$, $\rho(u \otimes 1, v) = uv_{(0)} \otimes v_{(1)}$;

(2) the following diagram:

$$\begin{array}{ccc} P \otimes P & \xrightarrow{m} & P \\ {\scriptstyle (\Delta_R \otimes id)}\downarrow & & \downarrow{\scriptstyle \Delta_R} \\ P \otimes C \otimes P & \xrightarrow{\rho} & P \otimes C \end{array} ,$$

where m is a product in P, is commutative.

Define $B=P^{\mathrm{co}C}=\{u\in P;\Delta_R u=u\otimes 1\}$.

Lemma 4.1: *B is a subalgebra of P.*

Proof: Take any $u,v\in B$. Then

$$\Delta_R(uv)=\rho(u_{(0)}\otimes u_{(1)},v)=\rho(u\otimes 1,v)=uv_{(0)}\otimes v_{(1)}=uv\otimes 1. \qquad \square$$

Definition 4.2: Let P, C, ρ, and B be as before. It is said that $P(B,C,\rho)$ is a *C-Galois extension or a quantum ρ-principal bundle (with universal differential structure)* if the canonical map $\chi:P\otimes_B P\to P\otimes C$, $\chi:u\otimes_B v\mapsto uv_{(0)}\otimes v_{(1)}$ is a bijection.

Example 4.3: A quantum principal bundle $P(B,H)$ as defined in Ref. 3 is a ρ-principal bundle with the action $\rho:P\otimes H\otimes P\to P\otimes H$ given by $\rho(u\otimes a,v)=uv_{(0)}\otimes av_{(1)}$.

Example 4.4: Let H be a Hopf algebra, C a coalgebra, and $\pi:H\to C$ a coalgebra surjection. Then H is a right C-comodule with a coaction $\Delta_R=(id\otimes\pi)\circ\Delta$. Denote $1=\pi(1)\in C$ and define $B=H^{\mathrm{co}C}$ as before. Assume that $\ker\pi$ is a minimal right ideal in H such that $\{u-\epsilon(u);u\in B\}\subset\ker\pi$ (compare Sec. III). Then a canonical right action $\rho_0:C\otimes H\to C$ as in the proof of Proposition 3.5 can be defined. Furthermore,

$$\rho(u\otimes a,v)=uv_{(1)}\otimes\rho_0(a,v_{(2)})$$

for any u, $v\in H$, $a\in C$. With these definitions $H(B,C,\rho)$ is a quantum ρ-principal bundle.

Proof: First we show that $\rho:H\otimes C\otimes H\to H\otimes C$ is a right action and it has the properties (1) and (2). Since ρ_0 is a right action, for any u, v, $w\in H$, $a\in C$, compute

$$\begin{aligned}\rho(u\otimes a,vw)&=uv_{(1)}w_{(1)}\otimes\rho_0(a,v_{(2)}w_{(2)})=uv_{(1)}w_{(1)}\otimes\rho_0(\rho_0(a,v_{(2)}),w_{(2)})\\&=\rho(uv_{(1)}\otimes\rho_0(a,v_{(2)}),w)=\rho(\rho(u\otimes a,v),w),\end{aligned}$$

and thus ρ is an action as required. Furthermore,

$$\rho(u\otimes 1,v)=uv_{(1)}\otimes\rho_0(1,v_{(2)})=uv_{(1)}\otimes\pi(v_{(2)})=uv_{(0)}\otimes v_{(1)}$$

and

$$\rho(u_{(0)}\otimes u_{(1)},v)=u_{(1)}v_{(1)}\otimes\rho_0(\pi(u_{(2)}),v_{(2)})=u_{(1)}v_{(1)}\otimes\pi(u_{(2)}v_{(2)})=\Delta_R(uv).$$

Therefore ρ has all the required properties.

To prove that the canonical map χ is bijective we first note that, by assumption, $\ker\pi\subset m\circ(\ker\pi|_B\otimes H)$ and then use a suitably modified argument of the proof of Lemma 5.2 of Ref. 3 to deduce that χ is a bijection. It is clear that χ is a surjection since for any $\Sigma_k u_k\otimes a_k\in H\otimes C$ we can choose $\Sigma_k u_k Sv_{k(1)}\otimes_B v_{k(2)}\in H\otimes_B H$, where $\forall k,v_k\in\pi^{-1}(a_k)$, and compute

$$\chi\left(\sum_k u_k Sv_{k(1)}\otimes_B v_{k(2)}\right)=\sum_k u_k(Sv_{k(1)})v_{k(2)}\otimes\pi(v_{k(3)})=\sum_k u_k\otimes\pi(v_k)=\sum_k u_k\otimes a_k.$$

Next we compute $\ker\chi\subset H\otimes_B H$. Take any $\Sigma_k u_k\otimes_B v_k\in\ker\chi$. Then $\Sigma_k u_k v_{k(1)}\otimes\pi(v_{k(2)})=0$. Applying $id\otimes\epsilon$ to the last equality, we find that $\Sigma_k u_k v_k=0$, i.e., $\Sigma_k u_k\otimes v_k\in\ker m$. Any $\Sigma_i w_i'\otimes w_i''\in\ker m$ can be written as $\Sigma_k u_k Sv_{k(1)}\otimes v_{k(2)}\in H\otimes H$, where $\forall k$, $v_k\in\ker\epsilon$ and u_k are linearly independent. Thus

$$\chi\left(\sum_i w_i'\otimes_B w_i''\right)=\chi\left(\sum_k u_k Sv_{k(1)}\otimes_B v_{k(2)}\right)=\sum_k u_k\otimes\pi(v_k).$$

If $\Sigma_i w_i'\otimes_B w_i''\in\ker\chi$ then $\Sigma_k u_k\otimes\pi(v_k)=0$, thus for all k, $\pi(v_k)=0$. By assumption $v_k=\Sigma_j b_k^j v_k^j$, where $b_k^j\in\ker\epsilon|_B=\ker\pi|_B$. Therefore,

$$\sum_i w_i' \otimes_B w_i'' = \sum_k u_k S v_{k(1)} \otimes_B v_{k(2)} = \sum_{j,k} u_k (S v^j_{k(1)}) S b^j_{k(1)} \otimes_B b^j_{k(2)} v^j_{k(2)}$$

$$= \sum_{j,k} \epsilon(b^j_k) u_k S v^j_{k(1)} \otimes_B v^j_{k(2)} = 0.$$

So $\ker \chi = 0$, and χ is a bijection as required. □

Therefore it is shown that an embeddable H space which is a quotient space $B = H^{\mathrm{co}C}$ as described in Sec. III may be identified with a base manifold of the generalized quantum principal bundle, or equivalently that H is a C-Galois extension of B.

V. MANIN'S PLANE AS A QUANTUM QUOTIENT SPACE

In this section we show that Manin's plane is a quotient space of the quantum general linear group $\mathrm{GL}_q(2,\mathbf{C})$. Recall that Manin's plane $\mathbf{C}^2_q$ is defined for any nonzero $q \in \mathbf{C}$ as an associative polynomial algebra over $\mathbf{C}$ generated by $1, x, y$ subject to the relations $xy = qyx$. It is a quantum homogeneous space of the quantum linear group $\mathrm{GL}_q(2,\mathbf{C})$. $\mathrm{GL}_q(2,\mathbf{C})$ is defined as follows. First consider an algebra generated by the matrix $\mathbf{t} = \left(\begin{smallmatrix} \alpha & \beta \\ \gamma & \delta \end{smallmatrix}\right)$ and the relations

$$\alpha\beta = q\beta\alpha, \quad \alpha\gamma = q\gamma\alpha, \quad \alpha\delta = \delta\alpha + (q - q^{-1})\beta\gamma, \tag{5.1a}$$

$$\beta\gamma = \gamma\beta, \quad \beta\delta = q\delta\beta, \quad \gamma\delta = q\delta\gamma. \tag{5.1b}$$

The quantum determinant $c = \alpha\delta - q\beta\gamma$ is central in the algebra (5.1); thus it can be enlarged with c^{-1}. The resulting algebra is called $\mathrm{GL}_q(2,\mathbf{C})$. The quantum linear group $\mathrm{GL}_q(2,\mathbf{C})$ is a Hopf algebra of a matrix group type, i.e.,

$$\Delta\mathbf{t} = \mathbf{t} \otimes \mathbf{t}, \quad \epsilon\mathbf{t} = 1, \quad S\mathbf{t} = c^{-1} \begin{pmatrix} \delta & -q^{-1}\beta \\ -q\gamma & \alpha \end{pmatrix}.$$

The left coaction of $\mathrm{GL}_q(2,\mathbf{C})$ on $\mathbf{C}^2_q$ is given by

$$\Delta_L \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \otimes \begin{pmatrix} x \\ y \end{pmatrix}.$$

$\mathbf{C}^2_q$ is not only a homogeneous space of $\mathrm{GL}_q(2,\mathbf{C})$ but also an embeddable $\mathrm{GL}_q(2,\mathbf{C})$ space. The linear map $\kappa: \mathbf{C}^2_q \to \mathbf{C}$, $\kappa(x^n y^m) = \delta_{m0}$, $m, n \in \mathbf{Z}_{\geqslant 0}$ is a character of $\mathbf{C}^2_q$. By Proposition 3.2 it induces an algebra map $i_\kappa: \mathbf{C}^2_q \to \mathrm{GL}_q(2,\mathbf{C})$, which is explicitly given by $i_\kappa(x) = \alpha$, $i_\kappa(y) = \gamma$. The map i_κ is clearly an inclusion. Thus the right ideal J_κ is generated by $\alpha - 1$ and γ. The coalgebra $C = \mathrm{GL}_q(2,\mathbf{C})/J_\kappa$ may be easily computed. It is spanned by $a_{m,n} = \pi(\beta^m c^n)$, $m \in \mathbf{Z}_{>0}$, $n \in \mathbf{Z}$ and $a_{0,0} = 1 = \pi(1)$, where $\pi: \mathrm{GL}_q(2,\mathbf{C}) \to C$ is a canonical surjection. To see that the $a_{m,n}$ really span C, note that since J_κ is generated by $\alpha - 1$ and γ as a right ideal in $\mathrm{GL}_q(2,\mathbf{C})$, every α which multiplies any element of $\mathrm{GL}_q(2,\mathbf{C})$ from the left is replaced by 1 and similarly any γ is replaced by 0 when the resulting element of $\mathrm{GL}_q(2,\mathbf{C})$ is acted upon by π. Then we compute

$$\pi(\alpha^k\beta^l\gamma^m\delta^n c^r) = \pi(\beta^l\gamma^m\delta^n c^r) = \delta_{m0}\pi(\beta^l\delta^n c^r) = \delta_{m0} q^{ln} \pi(\delta^n\beta^l c^r) = \delta_{m0} q^{ln} (\pi(\alpha\delta\delta^{n-1}\beta^l c^r)$$
$$- q^{-1}\pi(\gamma\beta\delta^{n-1}\beta^l c^r)) = \delta_{m0} q^{ln} \pi(\delta^{n-1}\beta^l c^{r+1}) = \cdots = \delta_{m0} q^{ln} a_{l,r+n}.$$

Therefore any element of $C = \pi(\mathrm{GL}_q(2,\mathbf{C}))$ may be expressed as a linear combination of $a_{m,n}$.

The coalgebra structure of C is found from the coalgebra structure of $\mathrm{GL}_q(2,\mathbf{C})$, since $\Delta_C = (\pi \otimes \pi) \circ \Delta_{\mathrm{GL}_q(2,\mathbf{C})}$. Explicitly

$$\Delta a_{m,n}=\sum_{k=0}^{m}\begin{pmatrix}m\\k\end{pmatrix}_q a_{k,n}\otimes a_{m-k,n+k},\quad \epsilon(a_{m,n})=\delta_{m0}, \tag{5.2}$$

where the quantum binomial coefficients are defined by

$$\begin{pmatrix}m\\k\end{pmatrix}_q=\frac{[m]_q!}{[m-k]_q![k]_q!},\quad [m]_q=\frac{q^m-q^{-m}}{q-q^{-1}},\quad [m]_q!=\prod_{k=1}^{m}[k]_q,\quad [0]_q!=1.$$

The next step in the identification of $\mathbf{C}_q^2$ as a quantum quotient space consists of computing the fixed point subalgebra $B=\mathrm{GL}_q(2,\mathbf{C})^{\mathrm{co}C}$. For a general monomial $\alpha^k\gamma^l\beta^m\delta^n c^r\in\mathrm{GL}_q(2,\mathbf{C})$, $k,l,m,n\in\mathbf{Z}_{\geqslant 0}$, $r\in\mathbf{Z}$, we find

$$\Delta_R(\alpha^k\gamma^l\beta^m\delta^n c^r)=\alpha^k\gamma^l c^r\sum_{i=0}^{m}\sum_{j=0}^{n}q^{j(m-i)}\begin{pmatrix}m\\i\end{pmatrix}_q\begin{pmatrix}n\\j\end{pmatrix}_q\alpha^{m-i}\beta^i\gamma^{n-j}\delta^j\otimes a_{m+n-(i+j),i+j+r}. \tag{5.3}$$

The right-hand side of Eq. (5.3) has the form $u\otimes 1$ for some $u\in\mathrm{GL}_q(2,\mathbf{C})$ if and only if $m=n=r=0$. Thus B is spanned by all $\alpha^k\gamma^l$. Therefore $B\subset i_\kappa(\mathbf{C}_q^2)$ and since $i_\kappa(\mathbf{C}_q^2)\subset B$ by Proposition 3.5 we conclude that $\mathbf{C}_q^2\cong\mathrm{GL}_q(2,\mathbf{C})^{\mathrm{co}C}$. By Example 4.4 $\mathrm{GL}_q(2,\mathbf{C})(\mathbf{C}_q^2,C,\rho)$ is a quantum principal ρ-bundle. The action $\rho_0: C\otimes\mathrm{GL}_q(2,\mathbf{C})\to C$ is given explicitly by

$$\rho_0(a_{i,j},\alpha^k\beta^l\gamma^m\delta^n c^r)=\delta_{m0}q^{i(n-k)+ln}a_{i+l,j+n+r}.$$

One can now proceed to define an algebra structure on C so that it becomes a Hopf algebra. Define the product in C by

$$a_{k,l}a_{m,n}=q^{lm-kn}a_{k+m,l+n}.$$

First we notice that $a_{0,0}=1$ is the unit element with respect to this product. Next we show that this product is compatible with the coalgebra structure of C. Compute

$$\begin{aligned}\Delta(a_{k,l})\Delta(a_{m,n})&=\sum_{i=0}^{k}\sum_{j=0}^{m}\begin{pmatrix}k\\i\end{pmatrix}_q\begin{pmatrix}m\\j\end{pmatrix}_q a_{i,l}a_{j,n}\otimes a_{k-i,l+i}a_{m-j,n+j}\\&=q^{lm-nk}\sum_{i=0}^{k}\sum_{j=0}^{m}q^{im-kj}\begin{pmatrix}k\\i\end{pmatrix}_q\begin{pmatrix}m\\j\end{pmatrix}_q a_{i+j,l+n}\otimes a_{k+m-(i+j),l+n+i+j}\\&=q^{lm-nk}\sum_{r=0}^{k+m}\begin{pmatrix}k+m\\r\end{pmatrix}_q a_{r,l+n}\otimes a_{k+m-r,l+n+r}=q^{lm-kn}\Delta(a_{k+m,l+n})=\Delta(a_{k,l}a_{m,n}).\end{aligned}$$

The third equality is a consequence of the following property of the q-deformed binomial coefficients

$$\forall r\in[0,k+m],\quad \sum_{i=0}^{k}\sum_{j=0}^{m}\delta_{i+j,r}q^{im-kj}\begin{pmatrix}k\\i\end{pmatrix}_q\begin{pmatrix}m\\j\end{pmatrix}_q=\begin{pmatrix}k+m\\r\end{pmatrix}_q.$$

Clearly the counit of C is an algebra homomorphism. Before defining an antipode, we show that C is a polynomial algebra. Let $a=a_{0,1}$, $a^{-1}=a_{0,-1}$, $b=a_{1,0}$. Then for any $m\in\mathbf{Z}_{>0}$, $n\in\mathbf{Z}$,

$$a_{m,n}=q^{-mn}a^n b^m,\quad ab=q^2ba,\quad aa^{-1}=a^{-1}a=1.$$

Therefore C is a polynomial algebra indeed, and it is isomorphic to $\mathbf{C}^2_{q^2}[x^{-1}]$. The coalgebra structure of C written in terms of a and b reads

$$\Delta a^{\pm 1}=a^{\pm 1}\otimes a^{\pm 1},\quad \Delta b=1\otimes b+b\otimes a,\quad \epsilon(a^{\pm 1})=1,\quad \epsilon(b)=0$$

and hence the antipode is defined as $Sa^{\pm 1}=a^{\mp 1}$, $Sb=-ba^{-1}$.

We have just shown that C may be equipped with an algebra structure of $\mathbf{C}^2_{q^2}[x^{-1}]$, and then the coalgebra structure of C becomes a standard coalgebra structure of the latter. Therefore we have proven

Theorem 5.1:

$$\mathbf{C}^2_q=\mathrm{GL}_q(2,\mathbf{C})^{\mathrm{co}\mathbf{C}^2_{q^2}[x^{-1}]}.$$

Notice that clearly neither $\pi:\mathrm{GL}_q(2,\mathbf{C})\to\mathbf{C}^2_{q^2}[x^{-1}]$ nor $\Delta_R=(id\otimes\pi)\circ\Delta:\mathrm{GL}_q(2,\mathbf{C})\to\mathrm{GL}_q(2,\mathbf{C})\otimes\mathbf{C}^2_{q^2}[x^{-1}]$ are algebra maps. Still, following the proposal of Sec. IV the generalized principal bundle $\mathrm{GL}_q(2,\mathbf{C})(\mathbf{C}^2_q,\mathbf{C}^2_{q^2}[x^{-1}],\rho,\pi)$ can be defined and analyzed. In particular one can truly develop a gauge theory, define connections and their curvature, closely following the quantum group gauge theory introduced in Ref. 3.

VI. PODLEŚ' SPHERE AS A QUANTUM QUOTIENT SPACE

In this section we prove that the quantum two-sphere is a quantum quotient space in the sense explained in Sec. III. In the presentation of the quantum sphere the conventions of Ref. 10 are followed.

The general quantum two-sphere $S^2_q(\mu,\nu)$ is a polynomial algebra generated by the unit and x,y,z, and the relations

$$xz=q^2zx,\quad xy=-q(\mu-z)(\nu+z),$$

$$yz=q^{-2}zy,\quad yx=-q(\mu-q^{-2}z)(\nu+q^{-2}z),$$

where μ, ν, and $q\neq 0$ are real parameters, $\mu\nu\geqslant 0$, $(\mu,\nu)\neq(0,0)$. The quantum sphere is a $*$ algebra with the $*$ structure $x^*=-qy$, $z^*=z$.

The quantum sphere $S^2_q(\mu,\nu)$ is an $\mathrm{SU}_q(2)$ homogeneous quantum space. $\mathrm{SU}_q(2)$ is defined as a quotient of $\mathrm{GL}_q(2,\mathbf{C})$ by the relation $c=1$, and has a $*$-structure given by $\delta=\alpha^*$, $\gamma=-q^{-1}\beta^*$. The coaction of $\mathrm{SU}_q(2)$ on $S^2_q(\mu,\nu)$ is defined as follows. Let $\phi_-=x$, $\phi_0=(1+q^{-2})^{-1/2}(\mu-\nu-(1+q^{-2})z)$, $\phi_+=y$. Then

$$\Delta_L\begin{pmatrix}\phi_-\\ \phi_0\\ \phi_+\end{pmatrix}=\begin{pmatrix}\alpha^2 & (1+q^{-2})^{1/2}\alpha\beta & \beta^2\\ (1+q^{-2})^{1/2}\alpha\gamma & 1+(q+q^{-1})\beta\gamma & (1+q^{-2})^{1/2}\beta\delta\\ \gamma^2 & (1+q^{-2})^{1/2}\gamma\delta & \delta^2\end{pmatrix}\otimes\begin{pmatrix}\phi_-\\ \phi_0\\ \phi_+\end{pmatrix}.$$

The quantum sphere $S^2_q(\mu,\nu)$ is not only a quantum homogeneous space but also an embeddable $\mathrm{SU}_q(2)$ space. There is a $*$ character $\kappa:S^2_q(\mu,\nu)\to\mathbf{C}$ given by

$$\kappa(x)=q\sqrt{\mu\nu},\quad \kappa(y)=-\sqrt{\mu\nu},\quad \kappa(z)=0.$$

Therefore there is also a $*$-algebra homomorphism $i_\kappa:S^2_q(\mu,\nu)\to\mathrm{SU}_q(2)$, which reads explicitly

$$i_\kappa(x)=\sqrt{\mu\nu}(q\alpha^2-\beta^2)+(\mu-\nu)\alpha\beta,$$

$$i_\kappa(y)=\sqrt{\mu\nu}(q\gamma^2-\delta^2)+(\mu-\nu)\gamma\delta,$$

$$i_\kappa(z) = -\sqrt{\mu\nu}(q\alpha\gamma - \beta\delta) - (\mu - \nu)\beta\gamma,$$

and is clearly an inclusion. From now on we assume that $\mu \neq \nu$ (but also see Remark 6.5). In this case $S_q^2(\mu,\nu)$ depends on two real parameters only, namely q and $p = \sqrt{\mu\nu}/(\mu - \nu)$. By Proposition 3.4 the inclusion i_κ induces a coideal $J_\kappa \subset \mathrm{SU}_q(2)$, generated as a right ideal in $\mathrm{SU}_q(2)$ by the following three elements:

$$p(q\alpha^2 - \beta^2) + \alpha\beta - pq, \quad p(q\gamma^2 - \delta^2) + \gamma\delta + p, \quad p(q\alpha\gamma - \beta\delta) + q\beta\gamma.$$

Therefore we can construct the coalgebra $C(p) = \mathrm{SU}_q(2)/J_\kappa$, and the corresponding quotient space $B(p) = \mathrm{SU}_q(2)^{\mathrm{co}C(p)}$ as described in Sec. III. At the end of this procedure we identify $B(p)$ with $S_q^2(\mu,\nu)$, $\mu \neq \nu$. We start with the coalgebra $C(p)$.

Proposition 6.1: *$C(p)$ is a vector space spanned by $1 = \pi(1)$, $x_n = \pi(\alpha^n)$ and $y_n = \pi(\delta^n)$, where $\pi: \mathrm{SU}_q(2) \to C(p)$ is a canonical surjection and $n \in \mathbf{Z}_{>0}$.*

Proof: For any $u \in \mathrm{SU}_q(2)$ we use the explicit form of the generators of J_κ and the relations in $\mathrm{SU}_q(2)$ to find that

$$\begin{aligned}\pi(\beta u) &= \pi(\beta\alpha\delta u) - q\,\pi(\beta\gamma\beta u) = q^{-1}\pi(\alpha\beta\delta u) - q\,\pi(\beta\gamma\beta u) = -p\,\pi(\alpha^2\delta u) + pq^{-1}\pi(\beta^2\delta u) \\ &\quad + p\,\pi(\delta u) + pq\,\pi(\alpha\gamma\beta u) - p\,\pi(\beta\delta\beta u) = p\,\pi(\delta u) - p\,\pi(\alpha u), \end{aligned} \tag{6.1a}$$

and similarly

$$\pi(\gamma u) = p\,\pi(\delta u) - p\,\pi(\alpha u). \tag{6.1b}$$

From Eq. (6.1) it follows that for any $u \in \mathrm{SU}_q(2)$, $\pi(u\beta^m\gamma^n) = \pi(u\beta^{m+n})$. Since $\mathrm{SU}_q(2)$ is spanned by the monomials $\alpha^m\beta^k\gamma^l, \delta^m\beta^k\gamma^l$ (cf. Lemma 7.1.2 of Ref. 11) it suffices to prove that the following elements of $C(p)$,

$$a_{k-}^{(n)} = \pi(\delta^k\beta^{n-k}), \quad a_{k+}^{(n)} = \pi(\alpha^k\beta^{n-k}), \tag{6.2}$$

where $n \in \mathbf{Z}_{>0}$, $k = 0,1,\ldots,n$ can be expressed as linear combinations of 1, x_m, y_m. Clearly $a_{0-}^{(n)} = a_{0+}^{(n)}$. Thus we simply write $a_0^{(n)}$. Also, $a_{n+}^{(n)} = x_n$ and $a_{n-}^{(n)} = y_n$. For $n = 1$, $a_0^{(1)} = \pi(\beta) = p(y_1 - x_1)$. For a general n we apply the rules (6.1) to $a_{k\pm}^{(n)}$ and express the latter in terms of $a_{l\pm}^{(m)}$, $m < n$, and x_n, y_n. We make the inductive assumption that for all $m < n$, $a_{l\pm}^{(m)}$ can be written as linear combinations of 1, x_r, y_r. Therefore, for $n \geqslant 2$ we arrive at the system of equations:

$$\begin{aligned} &a_{k\pm}^{(n)} \pm pq^{\pm k}a_{k+1\pm}^{(n)} \mp pq^{\mp(k-1)}a_{k-1\pm}^{(n)} = \pm pq^{\pm k}a_{k-1\pm}^{(n-2)}, \\ &a_0^{(n)} - pa_{1-}^{(n)} + pa_{1+}^{(n)} = 0, \end{aligned} \tag{6.3}$$

where $k = 1,2,\ldots,n-1$. This is a system of $2n-1$ equations with $2n-1$ unknowns provided that the right-hand sides and x_n, y_n are treated as known parameters. Obviously it has a solution if its determinant is nonzero. The determinant D_n of the system (6.3) may be easily computed. It does not depend on q and it can be reduced to the determinant of the following $2n-1 \times 2n-1$ matrix:

$$\begin{pmatrix} 1 & -p & p & 0 & 0 & 0 & \dots & 0 & 0 & 0 & 0 & 0 \\ p & 1 & 0 & -p & 0 & 0 & \dots & 0 & 0 & 0 & 0 & 0 \\ -p & 0 & 1 & 0 & p & 0 & \dots & 0 & 0 & 0 & 0 & 0 \\ 0 & p & 0 & 1 & 0 & -p & \dots & 0 & 0 & 0 & 0 & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & 0 & 0 & 0 & \dots & 0 & 1 & 0 & -p & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \dots & -p & 0 & 1 & 0 & p \\ 0 & 0 & 0 & 0 & 0 & 0 & \dots & 0 & p & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \dots & 0 & 0 & -p & 0 & 1 \end{pmatrix}. \tag{6.4}$$

By the Laplace theorem D_n can be further developed to give

$$D_n = A_{2n-2} + p^2(A_{2n-3} + A_{2n-4}) + p^4 A_{2n-5},$$

where A_m is zero for negative m, $A_0 = 1$ and for any $m < 2n-1$, A_m is the determinant of the matrix obtained from Eq. (6.4) by removing the first $2n-1-m$ rows and columns. The determinants A_m are the standard ones and we finally obtain the determinant of the system (6.3) as a polynomial

$$D_n = P_{n-1}(p^2) \equiv \sum_{k=0}^{n-1} \binom{2n-1-k}{k} p^{2k}.$$

For any $x \in \mathbf{R}_{\geqslant 0}$, $P_n(x) \geqslant 1$, and hence $D_n \neq 0$ for any real p. Therefore the system (6.3) always has a solution and the coalgebra $C(p)$ is spanned by x_n, y_n, $n \in \mathbf{Z}_{>0}$, and 1 as required. □

The vector space $C(p)$ has a coalgebra structure induced by π from the coalgebra structure of $\mathrm{SU}_q(2)$. The coproduct reads explicitly

$$\Delta x_n = \sum_{k=0}^{n} q^{-(n-k)k} \binom{n}{k}_q a_{k+}^{(n)} \otimes a_{k+}^{(n)}, \quad \Delta y_n = \sum_{k=0}^{n} q^{(n-k)k} \binom{n}{k}_q a_{k-}^{(n)} \otimes a_{k-}^{(n)},$$

where $a_{k\pm}^{(n)}$ are given by Eq. (6.2). Therefore the coalgebra $C(p)$ is cocommutative.

Remark 6.2: It is an interesting problem, whether it is possible to define a Hopf algebra structure on $C(p)$. For example, for $n=1$ we have

$$\Delta x_1 = (1+p^2) x_1 \otimes x_1 - p^2 (x_1 \otimes y_1 + y_1 \otimes x_1 - y_1 \otimes y_1),$$

$$\Delta y_1 = (1+p^2) y_1 \otimes y_1 - p^2 (x_1 \otimes y_1 + y_1 \otimes x_1 - x_1 \otimes x_1).$$

If one defines

$$x_1' = \frac{1}{\mu - \nu} (\mu x_1 - \nu y_1), \quad y_1' = \frac{1}{\mu - \nu} (\mu y_1 - \nu x_1)$$

then x_1' and y_1' are grouplike, i.e., $\Delta x_1' = x_1' \otimes x_1'$ and $\Delta y_1' = y_1' \otimes y_1'$. If it were possible to define a new basis of $C(p)$ consisting only of grouplike elements then clearly one would be able to solve the above problem and make $C(p)$ into a Hopf algebra of functions on $U(1)$.

Remark 6.3: According to Ref. 1 quantum spheres can also be defined for a discrete series of complex numbers p given by $p^2 = -(q^k + q^{-k})^{-2}$, $k = 1,2,\dots$. It is shown in Ref. 2 that such quantum spheres are $*$-embeddable in $\mathrm{SU}_q(2)$ for $k=1$.

One easily finds that $P_n(x - 1/4) = \sum_{k=0}^{n} c_k^n x^k$, where

$$c_k^n=\sum_{l=k}^{n}(-1/4)^{l-k}\binom{2n+1-l}{l}\binom{l}{k}.$$

For any n and any $0\leqslant k\leqslant n$, $c_k^n\geqslant c_0^n=(n+1)/4^n$ and thus all the coefficients c_k^n are positive. Therefore $P_n(x-1/4)\neq 0$ for all real $x\geqslant 0$. This implies that the determinants D_n of the proof of Proposition 6.1 are nonzero provided that $p^2\geqslant -1/4$. Since for any q, $q+q^{-1}\geqslant 2$ one sees that the assertion of Proposition 6.1 holds for the exceptional quantum spheres too.

In a different context, polynomials $P_n(x)$ appeared in Ref. 12. It was shown there that all the zeros of P_n are real and equal to $x_k=-\frac{1}{4}\sec^2(\pi k/2n+2)$, $k=1,2,\ldots,n$. The numbers $-1/x_k$ are the discrete values of the index for subfactors of type II_1 von Neumann algebras.

Proposition 6.4: *Let $C(p)$ be a coalgebra described in Proposition 6.1 and let $B(p)=\mathrm{SU}_q(2)^{\mathrm{co}C(p)}$. Then $i_\kappa(S_q^2(\mu,\nu))=B(p)$ for all $\mu\neq\nu$ such that $p=\sqrt{\mu\nu}/(\mu-\nu)$.*

Proof: By Proposition 3.5, $i_\kappa(S_q^2(\mu,\nu))\subset B(p)$, therefore one needs to show that $B(p)\subset i_\kappa(S_q^2(\mu,\nu))$. Introduce the grading $d:\mathrm{SU}_q(2)\to\mathbf{Z}$ by

$$d(\alpha)=d(\beta)=1,\quad d(1)=0,\quad d(\gamma)=d(\delta)=-1,\quad d(uv)=d(u)+d(v) \tag{6.5}$$

for any monomials $u,v\in\mathrm{SU}_q(2)$. A set of all elements of $\mathrm{SU}_q(2)$ of degree $k\in\mathbf{Z}$ forms a vector subspace of $\mathrm{SU}_q(2)$, which is denoted by $\mathrm{SU}_q(2)^{(k)}$, and $\mathrm{SU}_q(2)=\oplus_{k\in\mathbf{Z}}\mathrm{SU}_q(2)^{(k)}$. Moreover if $\Delta u=\Sigma_i u_i'\otimes u_i''$ for any $u\in\mathrm{SU}_q(2)^{(k)}$, then for all i, $d(u_i')=k$. To see that the last statement is true one can explicitly verify it for α, β, γ, δ and then use definition (6.5) of d to prove it for any $\mathrm{SU}_q(2)$. Therefore d induces a grading of $B(p)$ and $B(p)=\oplus_{k\in\mathbf{Z}}B(p)^{(k)}$.

Next, notice that $B(p)$ is contained in the subalgebra of $\mathrm{SU}_q(2)$ spanned by monomials of even degree. Therefore for any $k\in\mathbf{Z}$, $B(p)^{(2k+1)}=0$.

To prove the required inclusion observe that due to the form of π and $C(p)$, $B(p)$ is a deformation of $B(0)$, i.e., $B(0)=\lim_{p\to 0}B(p)$. Denote by $B(p)_{2n}^{(2k)}$ the vector space of homogeneous polynomials $u\in B(p)$ of degree $2n$ such that $d(u)=2k$, $|k|\leqslant n$. Notice that $B(p)_{2n}^{(2k)}$ and $B(p)_{2l}^{(2k)}$ need not be distinct for $l\neq n$. $B(0)_{2n}^{(2k)}$ is spanned by $\alpha^m\beta^{n+k-m}\gamma^{n-m}\delta^{m-k}$, where $m=k,k+1,\ldots,n$ for $k\geqslant 0$ and $m=0,1,\ldots,n+k$ for $k<0$, and hence is $n-|k|+1$-dimensional. This is exactly the dimension of $i_\kappa(S_q^2(\mu,\nu))_{2n}^{(2k)}$. Suppose that $B(p)_{2n}^{(2k)}$ is at least $n-|k|+2$-dimensional. Then one can find $u\in B(p)_{2n}^{(2k)}$ that does not contain any of the monomials spanning $B(0)_{2n}^{(2k)}$. If $\lim_{p\to 0}u\neq 0$, then one would obtain that $B(0)_{2n}^{(2k)}$ is at least $n-|k|+2$-dimensional, hence contradiction. $\lim_{p\to 0}u$ is meant as the polynomial obtained from u by replacing its coefficients with their $p=0$ limits. Assume that $\lim_{p\to 0}u=0$. The polynomial u may be written as a linear combination of monomials of degree $2n$ with coefficients that vanish as polynomials when p tends to 0. Therefore there exists a positive integer m such that $\lim_{p\to 0}p^{-m}u$ exists, is finite and nonzero, and is an element of $B(0)_{2n}^{(2k)}$. Thus we have a contradiction again. Since the above argument does not depend on n and k, and $i_\kappa(S_q^2(\mu,\nu))\subset B(p)$ we conclude that $i_\kappa(S_q^2(\mu,\nu))=B(p)$. □

Therefore we have shown that for $\mu\neq\nu$ the quantum sphere $S_q^2(\mu,\nu)$ is a quantum quotient space. By Example 4.4 one has a principal ρ-bundle, $\mathrm{SU}_q(2)(S_q^2(\mu,\nu),C(p),\rho,\pi)$.

Remark 6.5: When $\mu=\nu\neq 0$ the coideal J_κ is generated as a right ideal in $\mathrm{SU}_q(2)$ by the following elements:

$$q\alpha^2-\beta^2-q,\quad q\gamma^2-\delta^2+1,\quad q\alpha\gamma-\beta\delta.$$

Therefore for any $u\in\mathrm{SU}_q(2)$,

$$\pi(\delta u)=\pi(\alpha u),\quad \pi(\beta u)=\pi(\gamma u),\quad \pi(\gamma^2 u)=q^{-1}\pi(\alpha^2 u)-q^{-1}\pi(u),$$

and hence the coalgebra $C=\mathrm{SU}_q(2)/J_\kappa$ is spanned by $1=\pi(1)$, $x_n=\pi(\alpha^n)$, $y_n=\pi(\alpha^{n-1}\gamma)$, $n\in\mathbf{Z}_{\geqslant 1}$. We conjecture that also for this case $S_q^2(\mu,\mu)\cong\mathrm{SU}_q(2)^{\mathrm{co}C}$.

VII. CONCLUSIONS

In this article we have shown that certain embeddable quantum homogeneous spaces may be viewed as quantum quotient spaces. The examples of such quantum embeddable spaces include the general quantum two-sphere $S_q^2(\mu,\nu)$ and the quantum plane $\mathbf{C}_q^2$. The interpretation of quantum embeddable spaces presented in this article seems specially interesting from the point of view of quantum group gauge theory, the suitable generalization of which has also been proposed. We think that it would be interesting and indeed desirable to further develop this generalization of quantum group gauge theory, and in particular, to construct connections on the quantum spaces described in this article. For example this would allow for extending the construction of the Dirac q monopole of Ref. 3 to general quantum spheres. This program of studying coalgebra gauge theories, which will also incorporate braided group gauge theories, is currently being carried out and the first results may be found in Ref. 5 (cf. Ref. 13).

Note added in proof. After completing this article I have learned that the results similar to those of Sec. III were also obtained in M. S. Dijkhuizen and T. H. Koornwinder, Geom. Dedicata. **52**, 291 (1994).

(Received 1 August 1995; accepted for publication 15 February 1996)

A point group symmetrized boson representation (SBR) is introduced that is particularly convenient for describing molecular vibrations. In this paper the SBR is elucidated using the example of the molecule SF_6 with O_h symmetry. The advantages of the SBR are that its basis vectors have a clear physical picture, their number is very small (equal to one-eighth of the dimension of the reducible representation for O_h), and the irreducible bases for any concrete cases can be obtained trivially from those for the general case without any projection. All the irreducible bases for the group chains $O_h \supset D_4 \supset C_4$ or $O_h \supset D_4 \supset D_2$ are tabulated once and for all. As an application, the Hamiltonian in the algebraic model of Iachello and Oss for stretching vibrations of the molecule SF_6 is diagonalized in the symmetry adapted bases. © *1996 American Institute of Physics.* [S0022-2488(96)02905-4]

I. INTRODUCTION

The theory of point symmetry groups has long played a fundamental role in atomic and molecular physics.[1] In recent times, increasing attention has been devoted to the point groups with higher symmetry, an interest intensified by the discovery of the fullerene molecule, C_{60}.[2] Perhaps the most important contribution of this theory is to provide symmetry-adapted bases to simplify the solution of the Schrödinger equation. Despite the spectacular growth in computing power, it will continue to be important to use such bases, not only to keep the dimensionality of Hamiltonian matrices under control, but also to understand the physical significance of the results found.

As a simple example consider a molecule with v vibrational excitation quanta[3] (or vibrons[4]) distributed among n equivalent bonds, and restrict the Hamiltonian to one for which v is conserved.[3,4] Thus each value of v defines an invariant subspace, L_v, in which the Hamiltonian is to be diagonalized. For this case the dimension of L_v is equal to the dimension $d_{n,v}$ of the totally symmetric representation $[v]$ of the unitary group $U(n)$,[5]

$$d_{n,v}=\begin{pmatrix} n+v-1 \\ v \end{pmatrix},$$

where

$$\begin{pmatrix} a \\ b \end{pmatrix}$$

0022-2488/96/37(5)/2400/26/$10.00

is the binomial coefficient. For Fullerene, $d_{60,1}=60$ (one-vibron space), $d_{60,2}=1830$ (two-vibron space), $d_{60,3}=37{,}820$ (three-vibron space). Clearly, the dimension of L_v increases drastically with the number of vibrons. Without using the symmetry adapted basis, it is impossible to deal with the case with $v\geqslant 2$.

Basically, in molecular physics we encounter two kinds of symmetry adaptation problems:

(i) Point group symmetry adaptation of a system of v vibrational quanta[3] or vibrons[4] distributed over n bonds. We use

$$\varphi_0\equiv|a_1a_2\cdots a_n)\equiv|1^{a_1}2^{a_2}\cdots n^{a_n}\rangle,\qquad v=\sum_{i=1}^{n}a_i, \tag{1}$$

to denote a basis state which has a_i vibrons in the bond i, and call a_i the occupation number for the bond i.

(ii) Permutation group symmetry (or spin symmetry) adaptation of n-electron wave functions. Suppose that there are n electrons occupying n orbits $a_1,a_2,\cdots,a_n$. The vector

$$\varphi_0\equiv|a_1a_2\cdots a_n)\equiv|\psi_{a_1}(1)\psi_{a_2}(2)\cdots\psi_{a_n}(n)\rangle, \tag{2}$$

denotes an n-electron state with electron i occupying the i-th orbits a_i. The state (1) or (2) will be referred to as the normal order state.

Since any point group is isomorphic to a subgroup of the permutation group, S_n, these two problems are closely related to one another with the following dictionary for translating terminologies:

bond index$\leftrightarrow$coordinate index;

number of vibrons$\leftrightarrow$single-particle-state index.

Therefore we can borrow the techniques of the theory of the permutation groups[6] for the symmetry adaptation of Eq. (1).

Since they are simple in comparison with the permutation groups, it is somewhat surprising that up to the present the representation problem for point groups has evaded any algebraic solution. The known solutions have all been obtained by numerical procedures as by the projection operator method,[1,7] eigenfunction method (EFM),[6,8,9] or other methods.[3]

Besides the fact that it needs repetitive work, another great disadvantage of the numerical solution is that the explicit expression of an irreducible basis vector does not give a physical picture and usually involves so many terms that it looks chaotic. For example, the basis vector for the one-dimensional irrep A_{2u} of O_h in the subspace $L_{v=4}$ (to be derived in Sec. V) is

$$\begin{aligned}A_{2u}=&|1^225-2^235+3^245-4^215\rangle-|1^226-2^236+3^246-4^216\rangle\\&+|12^25-23^25+34^25-41^25\rangle-|12^26-23^26+34^26-41^26\rangle\\&+|125^2-235^2+345^2-415^2\rangle-|126^2-236^2+346^2-416^2\rangle,\end{aligned} \tag{3}$$

where $|A+B+\cdots\rangle\equiv|A\rangle+|B\rangle+\cdots$. Although this may not look too formidable in today's terms, it is considerably more complicated than the concise expression to be introduced below, and the contrast becomes really extreme for more complicated groups, such as the icosahedral group.

In this paper we will introduce a point-group symmetrized boson representation, or SBR for short, to solve the problem. As is well known, boson representation is always totally symmetric. Here the symmetrization refers to the bond indices. In the C_{4h}-SBR to be described in Sec. III, the above irreducible basis vector can be written as

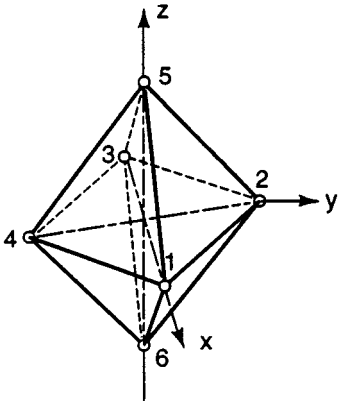

FIG. 1. Octahedron with O_h symmetry. The bonds 1,2,3,4 and 5,6 are called the horizontal and vertical bonds, respectively.

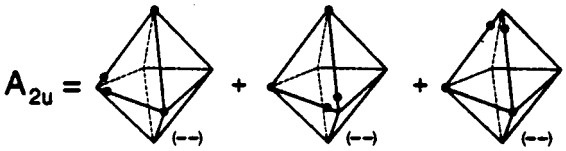
$$A_{2u}=|21;1\rangle_{--}+|12;1\rangle_{--}+|11;2\rangle_{--}, \tag{4}$$

where $|21;1\rangle_{--}$, $|12;1\rangle_{--}$ and $|11;2\rangle_{--}$ just represent the first, second and third lines in Eq. (3). For example, $|21;1\rangle_{--}$ represents a state which has three vibrons distributed over the four horizontal bonds (see Fig. 1) with one bond having two vibrons and the other having one, and one vibron distributed over the vertical bonds, with the cycle symmetry ρ (the quantum number of C_{4z})$=-1$ and the inversion symmetry $i_0=-1$. Equation (4) can be represented by the graphs,



.

In SBR we disregard the irrelevant thing—the indexing of the bonds, and focus on the essential thing—the distribution of the vibrons over the bonds, thereby greatly simplifying not only the finding but also the presentation of the irreducible bases. *The simplification can be compared to the one brought about by the second quantization over the first quantization.*

In the SBR, the reduction of the regular representation of the group O_h for the group chain $O_h\supset D_4\supset C_4$ or $O_h\supset D_4\supset D_2$ is reduced to a trivial problem, finding the eigenvectors of a 3×3 matrix

$$\begin{pmatrix} 0 & 2 & 2 \\ 2 & 0 & 2 \\ 2 & 2 & 4 \end{pmatrix}.$$

Succinct algebraic expressions for the irreducible bases of O_h in the most general cases are obtained in this way without any use of the characters or irreducible matrix elements, while the irreducible bases for any specific cases can be obtained from the general case easily by a procedure called assimilation (to be introduced below) without any projection, as in the projection operator method,[1,7] or eigenequation-solution, as in the eigenfunction method.[6] All the specific cases have been worked out and presented in tables; therefore the irreducible basis vectors for the

above two group chains have been obtained once and for all. To show the convenience of the SBR, the Hamiltonian in the algebraic model of Iachello and Oss for stretching vibrations of SF_6, which has been solved in a non-symmetrized basis, is resolved in the symmetry adapted basis. Not only is the dimension of the eigenequation reduced by one order of magnitude, but also the structure of the eigenstates are obtained. For the icosahedral group, the reduction of the dimensionality will be more drastic.

Since we are dealing with a venerable subject, and different methods may appear similar under superficial examination, we have taken great pain in the last section to compare the method developed in this paper with the prior work in order to establish unambiguously that we are not repeating a known technology.

The outline of the paper is as follows: We begin with a brief review of the EFM in Sec. II. The construction of the symmetrized boson representation for O_h and the properties of the symmetrical bases are addressed in Sec. III. The algebraic expressions of the irreducible basis of O_h is derived in Sec. IV for the most general case and in Sec. V, using the assimilation procedure, for any specified cases. The Hamiltonian of Iachello and Oss is rediagonalized in Sec. VI. The final section is a summary of various methods for symmetry adaptation.

II. BRIEF REVIEW OF THE EFM

Since the derivation of algebraic expressions for the symmetry adapted bases utilizes the EFM, it is appropriate to initiate the exposition with a summary. For details, readers are referred to Refs. 6 and 8. The essence of the EFM is best illustrated by the three-dimensional rotation group SO_3. According to the terminology in Ref. 6, the Casimir operator $\mathbf{J}^2$ is called the first kind of complete set of commuting operators (CSCO-I) of SO_3, which is a CSCO in the class parameter space. The operator set $(\mathbf{J}^2, J_z)$ is called the second kind of CSCO (CSCO-II) of SO_3, which is a CSCO in the configuration space of the unit sphere, the (θ, φ) space, while $(\mathbf{J}^2, J_z, J_z)$ is called the third kind of CSCO (CSCO-III), which is a CSCO in the group parameter space. The operator J_z is the third component of the angular momentum in the intrinsic coordinate system. The set of operators (J_x, J_y, J_z) are the generators of the intrinsic group SO_3, which commutes with and is anti-isomorphic to the rotation group SO_3, and describes the rotation of a system (such as a molecule) around its intrinsic (or body-fixed) axes.[6,1] The eigenfunctions of the CSCO-I, -II and -III in the class parameter space, ordinary configuration space, and group parameter space, respectively, give the complex conjugate of the primitive characters, the irreducible basis, and the complex conjugates of the irreducible matrices of SO_3 in the $SO_3 \supset SO_2$ classification.

It was shown that the above approach can be extended to any compact group. For a finite group G, the Casimir operator $\mathbf{J}^2$ of SO_3 is replaced by the CSCO-I of the finite group G, denoted by C, which is a linear combination of a few class operators of G, and the Casimir operator J_z of SO_2 is replaced by the CSCO-I, denoted by C', of a canonical subgroup G' of G. Similarly J_z is replaced by the operator C' of the corresponding subgroup G' of the intrinsic group G, which commutes with and is anti-isomorphic to G. The intrinsic group G is a generalization of the intrinsic rotation group SO_3.

The eigenvectors of the CSCO-I, -II and -III again give the complex conjugate of primitive characters, the irreducible basis and the complex conjugate of irreducible matrix elements of G in the $G \supset G'$ classification. The CSCO-I of G is also called the CSCO of G for simplicity. The CSCO of finite groups are easily found and those for the commonly used point groups are listed in Table I.

Finding the irreducible basis in the regular representation is equivalent to finding the simultaneous eigenvectors of the CSCO-III. For the SO_3 and a finite group G, these equations read, respectively,

TABLE I. The CSCO of point groups.

D_2	D_{2d}	D_3	D_4	D_{4d}	D_5	D_6

C_{2v}	C_{3v}	C_{4v}	C_{5v}	C_{6v}	$C_{\infty v}$	D_{6d}
(C_{2z},σ_y)	$(3\sigma_v)$	$(2C_4,2\sigma_d)$	$(2C_5,5\sigma_v)$	$(2C_6,3\sigma_v)$	$(2C_z(\varphi),\sigma_y)$	$(2S_{12},6\sigma_d)$
$D_{\infty v}$	T	T_d	O	O_h	I	I_h
$(2C_z(\varphi),\sigma_y,\hat{I})$	$(4C_3)$	$(6\sigma_d)$	$(6C_2)$	$(6\sigma,\hat{I})$	$(12C_5)$	$(12C_5,\hat{I})$

$$\begin{pmatrix} \mathbf{J}^2 \\ J_z \\ \overline{J_z} \end{pmatrix} \psi_m^{(j)\overline{m}} = \begin{pmatrix} j(j+1) \\ m \\ \overline{m} \end{pmatrix} \psi_m^{(j)\overline{m}}, \tag{5}$$

$$\begin{pmatrix} C \\ C' \\ \overline{C'} \end{pmatrix} \psi_\rho^{(\nu)\overline{\rho}} = \begin{pmatrix} \nu \\ \rho \\ \overline{\rho} \end{pmatrix} \psi_\rho^{(\nu)\overline{\rho}}. \tag{6}$$

The eigenvector $\psi_\rho^{(\nu)\overline{\rho}}$ gives the component ρ associated with the point group G with $\overline{\rho}$ as the multiplicity label of the irrep ν, but at the same time it gives the component $\overline{\rho}$ associated with the intrinsic point group G with ρ as the multiplicity label of the irrep ν. Notice that $\overline{\rho}$ and ρ have the same set of quantum numbers, just as $m,\overline{m}=j,j-1,\cdots,-j$ for the SO_3 group.

In the group space, the irreducible basis $\psi_\rho^{(\nu)\rho}$ becomes the normalized generalized projection operator $\mathbf{P}_\rho^{(\nu)\rho}$ (the usual form for the generalized projection operator is denoted as $\mathbf{P}_{\rho\rho}^{(\nu)}=\sqrt{h_\nu/g}\mathbf{P}_\rho^{(\nu)\overline{\rho}}$)

$$\mathbf{P}_\rho^{(\nu)\overline{\rho}} = \sqrt{\frac{h_\nu}{g}} \sum_{a=1}^{g} D_{\rho\overline{\rho}}^{(\nu)}(R_a)^* R_a, \tag{7}$$

where h_ν is the dimension of the irrep ν, g the order of G, R_a the a-th group element, and $D_{\rho\overline{\rho}}^{(\nu)}(R_a)$ is $(\rho,\overline{\rho})$-th entry of the irreducible matrix. For a one-dimensional irreducible basis, $\rho=\overline{\rho}$, and the quantum numbers ρ and $\overline{\rho}$ are redundant. Therefore, for this case we write $\psi_\rho^{(\nu)\rho}\equiv\psi^{(\nu)}$.

A program packet is written[9] based on the EFM which can compute *ab initio* subgroup-symmetry adapted (both single- and double-valued) irreps and Clebsch-Gordan coefficients of point groups and space groups. These are numerical solutions. Our aim in this paper is to find algebraic solutions for the irreducible bases of point groups. We still use the EFM; however, instead of solving the eigenequation of the CSCO-III in the g-dimensional group space, we solve the eigenequation of the CSCO-I in the double SBR with dimensions much lower (3 for O_h and 4 for I_h) than the group order g. Before introducing the SBR, we review some of the concepts that will be utilized in its development.

As is well known, each point group is isomorphic to a subgroup of a permutation group. However, there are two kinds of permutation groups for either of the bases represented by Eqs. (1) and (2).

(i) The coordinate permutation group S_n, whose element p permutes the bond indices or the coordinate indices. For example, the permutation $p_{123}\equiv(123)$ is defined as

$$(123)|a_2a_3a_1\rangle=(123)|\psi_{a_2}(1)\psi_{a_3}(2)\psi_{a_1}(3)\rangle$$

$$=|\psi_{a_2}(2)\psi_{a_3}(3)\psi_{a_1}(1)\rangle$$

$$\equiv|a_1a_2a_3\rangle. \tag{8}$$

(ii) The state permutation group $\mathscr{S}_n$ whose element $\wp$ permutes the state indices a_i.[10] For example, the action of $\wp_{123}\equiv(a_1a_2a_3)$ is

$$\wp_{123}|a_2a_3a_1\rangle=|a_3a_1a_2\rangle. \tag{9}$$

The operators p and $\wp$ commute and are independent, and only when acting on the normal order state φ_0 do we have $p=\wp^{-1}$,

$$p\varphi_0=\wp^{-1}\varphi_0. \tag{10}$$

Obviously, the groups S_n and $\mathscr{S}_n$ are isomorphic. S_n and $\mathscr{S}_n$ are called the permutation group on particle labels and state labels, respectively, in Ref. 11.

Returning to the consideration of the point groups, any such group has the following three kinds of realization:

(i) A point group G is isomorphic to a subgroup of the coordinate permutation group S_n, which is again denoted by G.

(ii) G is also isomorphic to a subgroup of the state-permutation group $\mathscr{S}_n$. This subgroup is called the state-point group and denoted by $\mathscr{G}$. G and $\mathscr{G}$ commute and are isomorphic. Corresponding operators, R_a and $\mathscr{R}_a$, are two different operators, but because of Eq. (10) R_a and $\mathscr{R}_a^{-1}$ are equal when acting on the normal order state,

$$R_a\varphi_0=\mathscr{R}_a^{-1}\varphi_0. \tag{11}$$

(iii) The intrinsic point group $\overline{G}$, which is defined as follows: For each element of a group G we can associate a corresponding operator R in the group space L_g through the following equation:

$$\overline{R}S=SR, \qquad \text{for all } S\in L_g. \tag{12}$$

It is important to emphasize that Eq. (12) is not an identity, but rather a definition of the operator $\overline{R}$. (For further discussion of this fundamental distinction, the reader should consult Refs. 6 and 8.) The group formed by the totality of operators $\overline{R}$ is called the intrinsic point group, denoted as $\overline{G}$, which is a generalization of the intrinsic rotation group SO_3. $\overline{G}$ commutes with and is anti-isomorphic to G.

The state-point group $\mathscr{G}$ can be regarded as a realization of the intrinsic point group $\overline{G}$ on the product space (1) or (2). The relation between the two is

$$\overline{R}=\mathscr{R}^{-1}. \tag{13}$$

From Eqs. (11) and (13) we have

$$R\varphi_0=\overline{R}\varphi_0. \tag{14}$$

An important fact is that the CSCO-I of the groups $G,\mathscr{G}$ and $\overline{G}$ are equal (cf. $\mathbf{J}^2=\overline{\mathbf{J}^2}$),

$$C=\mathscr{C}=\overline{C}. \tag{15}$$

Therefore, the irreps of G and $\overline{G}$ are labeled by the same quantum number, just as the irreps of SO_3 and SO_3 are labeled by the same quantum number j. As will be seen, our approach relies heavily on the interplay of these three groups $G, \mathscr{G}$ and G. The group $\mathscr{G}$ or G will provide the multiplicity operator for distinguishing equivalent irreps of G. In the group space, we need to use the intrinsic group G, while in the product space (1) or (2), it is more convenient to use $\mathscr{G}$.

As examples, consider the molecule XY_6. The numbering of its 6 vertices is shown in Fig. 1. For convenience, the bonds 1–4 and 5 and 6 will be referred to as the horizontal and vertical bonds, respectively. From Table I it is known that the CSCO-I of O_h is $(6\sigma,\hat{I})$. Here and in the following we will change our notation slightly by using C to denote the class operator 6σ which consists of the six reflection planes instead of denoting the CSCO-I of O_h. The CSCO-I of the cyclic group C_4 is C_{4z}. According to Fig. 1, we have

$$\begin{gathered} C=(12)(34)+(14)(23)+(15)(36)+(16)(35)+(25)(46)+(26)(45), \\ \hat{I}=(13)(24)(56), \quad C_{4z}=(1234). \end{gathered} \tag{16}$$

Now turn to the state-point group. Let us consider the most general case when the bonds 1–6 all have different non-zero number of vibrons. Suppose the bonds 1–6 have $a-f$ vibrons, respectively. If we identify $a-f$ with a_1-a_6, respectively, then the following state will be our normal order state

$$\varphi_0=|abcdef). \tag{17}$$

The counterpart of Eq. (16) for the state-point groups can be obtained from (16) by the index replacements: $1\rightarrow a, 2\rightarrow b, \cdots 6\rightarrow f$,

$$\begin{gathered} \mathscr{C}=(ab)(cd)+(ad)(bc)+(ae)(cf)+(af)(ce)+(be)(df)+(bf)(de), \\ \mathscr{I}=(ac)(bd)(ef), \quad \mathscr{C}_{4z}=\overline{C_{4z}^{-1}}=(abcd). \end{gathered} \tag{18}$$

Notice that $C=\mathscr{C}, \hat{I}=\mathscr{I}$, but $C_{4z}\neq\mathscr{C}_{4z}$.

III. THE C_4-SYMMETRIZED BOSON REPRESENTATION FOR O_h

The standard irreducible basis[12] for the group O_h is the $O_h\supset D_4\supset D_2$ basis. The components of the standard irreps E, F_1 and F_2 are labeled by $(\theta,\epsilon),(x,y,z)$ and (ξ,η,ζ), respectively, as given by Griffith.[12]

Another commonly used group chain is $O_h\supset D_4\supset C_4$. Since C_4 is a canonical subgroup of O_h (each irrep of C_4 occurs at most once in any irrep of O_h), the intermediate group D_4 is redundant for classifying the basis. Therefore we will refer the second basis as the $O_h\supset C_4$ basis. The components of the irreps F_1 and F_2 in the $O_h\supset C_4$ group chain will be labeled by (x',y',z) and (ξ',η',ζ), respectively. The relation between the two bases is

$$x'=-\sqrt{\tfrac{1}{2}}(x+iy), y'=\sqrt{\tfrac{1}{2}}(x-iy), \quad \xi'=-\sqrt{\tfrac{1}{2}}(\xi+i\eta), \eta'=\sqrt{\tfrac{1}{2}}(\xi-i\eta). \tag{19}$$

Therefore the basis vectors for the irreps A and E, as well as the third components of the irreps F are the same for the two group chains. It is known that for each irrep we only have to calculate one component, called the principal component, since owing to the existence of the Wigner-Eckart theorem, that is all we need for calculating the matrix element of any tensor operator and, consequently, any observable. We choose the second component of the irrep E and the third component of the irreps F as the principal components. Therefore, by using the $O_h\supset C_4$ group chain we can get the principal components for both the group chains. The CSCO-II for the $O_h\supset C_4$ group chain

TABLE II. The eigenvalues of the CSCO-II, $(6\sigma,\hat{I},C_{4z})$, of O_h.

	A_{1g}	A_{2g}	$E_{g,(\theta,\epsilon)}$	$F_{1g,(x',y',z)}$	$F_{2g,(\xi',\eta',\zeta)}$	A_{1u}	A_{2u}	$E_{u,(\theta,\epsilon)}$	$F_{1u,(x',y',z)}$	$F_{2u,(\xi',\eta',\zeta)}$
6σ	6	-6	0	-2	2	-6	6	0	2	-2
$\hat{I}$	1	1	1	1	1	-1	-1	-1	-1	-1
C_{4z}	1	-1	$(1,-1)$	$(-i,i,1)$	$(-i,i,-1)$	1	-1	$(1,-1)$	$(-i,i,1)$	$(-i,i,-1)$

$x'=-\sqrt{\frac{1}{2}}(x+iy)$, $y'=\sqrt{\frac{1}{2}}(x-iy)$; $\xi'=-\sqrt{\frac{1}{2}}(\xi+i\eta)$, $\eta'=\sqrt{\frac{1}{2}}(\xi-i\eta)$.

is $(6\sigma,\hat{I},C_{4z})$. The correspondence between its eigenvalues and the standard labels are listed in Table II. From the table it is seen that we only need to find the basis vectors corresponding to the real eigenvalues, $\rho=\pm 1$, of C_{4z}.

In the numerical approach to the EFM, we generate the regular representation space from $|abcdef)$ and then diagonalize the CSCO-III, $(6\sigma,\hat{I},C_{4z},C_{4z})$, in this 48-dimensional space. To obtain the algebraic solution, our strategy is first to construct the eigenspace $L^{i_0}_{\rho,\overline{\rho}}$—of the operators $(\hat{I},C_{4z}.\overline{C_{4z}})$, and then diagonalize 6σ in $L^{i_0}_{\rho,\overline{\rho}}$—with the eigenvalues $\rho,\overline{\rho}$ and i_0 as parameters. In this way we obtain a unified expression of the irreducible bases $\psi^{(\nu,i_0)\overline{\rho}}_{\rho}$ for all possible values of $\rho,\overline{\rho}$ and i_0, which is what we mean by an algebraic solution.

Since $(C_{4z},\hat{I})$ is the CSCO of C_{4h}, to finding the eigenvectors of $(C_{4z},\hat{I})$ is equivalent to find the irreducible basis of C_{4h}, which is most easily done by using the projection operators,

$$\sqrt{8}\varphi^1\equiv\sqrt{8}\varphi^1_{\rho i_0}=|abcd;ef\rangle_{\rho i_0}\equiv|abcd;ef\rangle=P^{\rho}P^{i_0}|abcdef), \tag{20}$$

where P^{ρ} and P^{i_0} are un-normalized projection operators

$$P^{\rho}=\sum_{j=0}^{3}(C_{4z})^j\rho^{*j},\qquad P^{i_0}=1+i_0\hat{I}. \tag{21}$$

Notice that φ^1 is a normalized, symmetrized vector, where the quantum numbers (ρ,i_0) are implied in the notation $|abcd;ef\rangle$, and the semicolon means symmetrization with respect to the subgroup C_{4h}. φ^1 satisfies the following equations:

$$C_{4z}\varphi^1=\rho\varphi^1,\qquad \hat{I}\varphi^1=\mathscr{I}\varphi^1=i_0\varphi^1,\quad \mathscr{C}_{4z}\varphi^1=\rho^*\varphi^1. \tag{22}$$

The eigenvalues ρ and i_0 of C_{4z} and $\hat{I}$ are referred to as the quantum numbers for cyclic and inversion symmetries, respectively. In case we need to specify (ρ,i_0) explicitly, we attach the subscripts(ρ,i_0) to the ket symbol. The four bases with $(\rho,i_0)=(1,1),(-1,1),(1,-1),(-1,-1)$ are denoted as

$$|abcd;ef\rangle_{++},\qquad |abcd;ef\rangle_{-+},\quad |abcd;ef\rangle_{+-},|abcd;ef\rangle_{--}. \tag{23}$$

The basis $|abcd;ef\rangle$ has the symmetries

$$|abcd;ef\rangle=\rho|bcda;ef\rangle=\rho^*|dabc;ef\rangle=\rho^2|cdab;ef\rangle=\cdots=i_0\rho^2|abcd;fe\rangle. \tag{24}$$

For the cases with real ρ, from (20) and (24) it is seen that the basis vector $|abcd;ef\rangle_{\rho i_0}$ can be factorized into two parts, $|abcd;\rangle_{\rho}$ and $|;ef\rangle_{i_0}$. The first one is related to the horizontal bonds carrying the quantum number ρ, while the second one is related to the vertical bonds carrying the quantum number i_0, i.e.,

TABLE III. The action of six reflections on $\varphi^1=|abcd;ef\rangle$.

$(ad)(bc)$	$(ab)(cd)$	$(ae)(cf)$	$(af)(ce)$	$(be)(df)$	$(bf)(de)$
$\|dcba;ef\rangle$	$\|badc;ef\rangle$	$\|ebfd;ac\rangle$	$\|fbed;ca\rangle$	$\|aecf;bd\rangle$	$\|afce;db\rangle$

$$|abcd;ef\rangle_{\rho i_0}=|abcd;\rangle_\rho|;ef\rangle_{i_0}, \qquad \text{for } \rho=\pm 1, \tag{25}$$

where

$$\begin{aligned}|abcd;\rangle_\rho\equiv|abcd;\rangle=P^\rho|abcd)&=|(1234+\rho^*2341+\rho^{*2}3412+\rho^{*3}4123)^{abcd}\rangle,\\ &=|abcd)+\rho|bcda)+\rho^2|cdab)+\rho^3|dabc),\end{aligned} \tag{26}$$

$$|;ef\rangle_{i_0}\equiv|;ef\rangle=P^{i_0}|5^e6^f\rangle=|(56+i_065)^{ef}\rangle\equiv|5^e6^f+i_06^e5^f\rangle, \tag{27}$$

where we used the notation

$$|(3412)^{abcd}\rangle\equiv|3^a4^b1^c2^d\rangle=|1^c2^d3^a4^b\rangle. \tag{28}$$

Notice that the bond indices are symmetrized and hidden in $|abcd;ef\rangle$. Instead of specifying how many vibrons are in each bond, we only need to specify that there are a,b,c,d vibrons distributed over the four horizontal bonds and e,f vibrons distributed over the vertical bonds with the cyclic symmetry ρ and inversion symmetry i_0. $|abcd;ef\rangle$ is a basis vector in what is called the C_{4h}-symmetrized boson representation. In analogy with the second quantization formalism which makes the particle labels meaningless, here the SBR makes the bond indices within the horizontal or vertical set meaningless, resulting in great simplification.

A usual way to construct a representation of a large group from the irreps of its subgroup is by using induction[13]; i.e., by applying the six coset representatives of O_h to φ^1, we can get six basis vectors that carry the induced representation. However, the new vectors formed in this way are no longer eigenvectors of C_{4z}, since the coset representatives do not commute with C_{4z}. But to keep within the eigenspace, L_ρ of C_{4z} is the key point to getting algebraic expressions of the irreducible bases as a function of ρ. Therefore, we have to find another way to generate the representation of O_h from the irreps of its subgroup C_{4h}.

Since the state permutation operators commutes with C_{4z} and $\hat{I}$, we may applying some state permutation operators on φ^1 to generate an eigenspace space of C_{4z}. How to find these operators? Due to the fact that $\mathscr{C}=C$, the diagonalization of C can be replaced by that of $\mathscr{C}$. Since in $|abcd;ef\rangle$ the bond indices are symmetrized and hidden, and $|abcd;ef\rangle$ is a linear combination of 10 product states, it would be rather difficult to find the action of the reflections (12), (34), etc. on $|abcd;ef\rangle$, but it is trivial to find the operation of the state permutation on it. For example $(ab)(cd)|abcd;ef\rangle=|badc;ef\rangle$. Applying the six reflections $(ab)(cd),(ad)(bc),(ae)\times(cf),(af)(ce),(be)(df)$ and $(bf)(de)$ in $\mathscr{C}$ to $|abcd;ef\rangle$, yields five additional symmetrized vectors, as shown in Table III. All these vectors are eigenvectors of C_{4z} with the same eigenvalues ρ. We might choose them as the basis vectors; however it is more convenient to choose the following six vectors as our basis,

$$\begin{aligned}&\varphi^1=\frac{1}{\sqrt{8}}|abcd;ef\rangle, \qquad \varphi^2=\frac{1}{\sqrt{8}}|adcb;fe\rangle, \quad \varphi^3=\frac{1}{\sqrt{8}}|bedf;ac\rangle,\\ &\varphi^4=\frac{1}{\sqrt{8}}|ecfa;db\rangle, \quad \varphi^5=\frac{1}{\sqrt{8}}|bfde;ca\rangle, \qquad \varphi^6=\frac{1}{\sqrt{8}}|fcea;bd\rangle.\end{aligned} \tag{29}$$

TABLE IV. The action of $\overline{C_{4z}}=(adcb)$ on $\varphi^3-\varphi^6$.

	φ^3	φ^4	φ^5	φ^6
$\overline{C_{4z}}\varphi^i$	$\rho\varphi^4$	$\rho\varphi^5$	$\rho\varphi^6$	$\rho\varphi^3$

Though different choices have no effect on the final results, a proper choice will make the intermediate steps simpler. The eigenspace $L_\rho^{i_0}=\{\varphi^i: i=1,\ldots,6\}$ is a representation space of the operator $\mathscr{C}$, called the C_{4h}-symmetrized boson representation (SBR). Notice that $L_\rho^{i_0}$ is invariant only under $\mathscr{C}$, but not under O_h, and thus is not a representation space of O_h. Only if one allows ρ to take all possible values, do they carry a representation of O_h. It should be emphasized again that SBR is not the induced representation.

IV. IRREDUCIBLE BASES OF O_h IN THE REGULAR REPRESENTATION

The original 48-dimensional group space has been reduced to six-dimensional eigenspace $L_{\underline{\rho}}^{i_0}$. To get the expression for irreducible basis of O_h which is ''analytic'' in the quantum number $\underline{\rho}$, and to further reduce the space, we construct the common eigenspace $L_{\underline{\rho\rho}}^{i_0}$ of $(\hat{I},C_{4z},\overline{C_{4z}})$, i.e., to combine $\varphi^1,\cdots,\varphi^6$ into eigenvectors $\varphi_{\underline{\rho\rho}}^i$ of $\overline{C_{4z}}=(adcb)$. φ^1 and φ^2 are already eigenvectors of $\overline{C_{4z}}$ with eigenvalue $\overline{\rho}=\rho$, ρ^*, respectively,

$$\overline{C_{4z}}\varphi^1=\frac{1}{\sqrt{8}}|dabc;ef\rangle=\rho\varphi^1=\overline{\rho\varphi}^1,\quad \overline{C_{4z}}\varphi^2=\frac{1}{\sqrt{8}}|dcba,fe\rangle=\rho^*\varphi^2=\overline{\rho\varphi}^2. \tag{30}$$

From Eq. (30) we have

$$\varphi_{\underline{\rho\rho}}^1=\varphi^1\delta_{\underline{\rho\rho}},\qquad \varphi_{\underline{\rho\rho}}^2=\varphi^2\delta_{\underline{\rho\rho}^*}. \tag{31}$$

Therefore we only need to combine $\varphi^3-\varphi^6$ into eigenvectors of $\overline{C_{4z}}$. Applying $\overline{C_{4z}}=(adcb)$ [see Eq. (18)] to $\varphi^3-\varphi^6$, we get Table IV. Using Table IV, it is easy to obtain the third eigenvector of (C_{4z},C_{4z}),

$$\varphi_{\underline{\rho\rho}}^3=\tfrac{1}{2}\overline{P^\rho}\varphi^3=\tfrac{1}{2}\sum_{j=0}^{3}(\overline{C_{4z}})^j\overline{\rho^*}^j\varphi^3=\tfrac{1}{2}[\varphi^3+\overline{\rho^*}\rho\varphi^4+(\overline{\rho\rho})^2\varphi^5+\overline{\rho\rho}^*\varphi^6]_\rho. \tag{32}$$

The basis $\varphi_{\underline{\rho\rho}}^1$ - $\varphi_{\underline{\rho\rho}}^3$ is the $C_{4h}\times\overline{C_{4h}}$- symmetrized basis, and the representation it carries may be called the double SBR. The diagonalization of the CSCO-III in the 48-dimensional space is now reduced to diagonalize the operator $\mathscr{C}$ in the three-dimensional space $L_{\underline{\rho\rho}}^{i_0}=\{\varphi_{\underline{\rho\rho}}^i: i=1,2,3\}$.

The eigenvalues of the class operator 6σ in the eigenspace of $(C_{4z},\hat{I})$ are shown in Table V. The group O_h has ten inequivalent irreps, $A_{1g},A_{2g},E_g,F_{1g},F_{2g},A_{1u},A_{2u},E_u,F_{1u}$, F_{2u}. The subscripts in the Mulliken notation are related to the eigenvalues (ρ,i_0) of the operator set $(C_{4z},\hat{I})$, as shown in Table VI. Using Table VI, Table V is reduced to Table VII.

TABLE V. The eigenvalues of 6σ in the eigenspace of $(C_{4z},\hat{I})$.

$(\rho,i_0)=(1,1)$:	A_{1g}	$E_{g,\theta}$	$F_{1g,z}$	$(1,-1)$:	A_{1u}	$E_{u,\theta}$	$F_{1u,z}$

ρi_0	$++$	$-+$	$+-$	$--$	ρi_0	$-+$	$--$
$A_{\rho i_0}$	A_{1g}	A_{2g}	A_{1u}	A_{2u}	$E_{i_0,\rho}$	$E_{g,\epsilon}$	$E_{u,\epsilon}$
$F_{\rho i_0,\rho}$	$F_{1g,z}$	$F_{2g,\zeta}$	$F_{1u,z}$	$F_{2u,\zeta}$			

To construct the representation matrix of $\mathscr{C}$ in $L^{i_0}_{\rho\overline{\rho}}$, we need first find its representation matrix in the space $L^{i_0}_{\rho}$.

By using the symmetries (24), the basis vectors in the second row of Table III can be expressed in terms of φ^1-φ^6, and from it we get the action of $\mathscr{C}$ on φ^1, as shown in the second row of Table VIII. By index replacements, from $\mathscr{C}\varphi^1$ we can get the action of $\mathscr{C}$ on φ^2-φ^6, as shown in Table VIII.

From Table VIII and (31)–(32), we can compose the representative matrix of $\mathscr{C}$ in the basis $\{\varphi^i_{\rho\overline{\rho}}: i=1,2,3\}$. Its transpose has the following form:

$$\widetilde{M}=i_0\begin{pmatrix} 0 & (\rho+\rho^*)\delta_{\overline{\rho}\rho} & 2\rho^*\delta_{\overline{\rho}\rho} \\ (\rho+\rho^*)\delta_{\overline{\rho}\rho} & 0 & 2\rho\delta_{\overline{\rho}\rho^*} \\ 2\rho\delta_{\overline{\rho}\rho} & 2\rho^*\delta_{\overline{\rho}\rho^*} & \rho^2(\overline{\rho}+\overline{\rho^*})+\overline{\rho}^2(\rho+\rho^*) \end{pmatrix}. \tag{33}$$

It is seen that when $\rho \neq \overline{\rho}, \overline{\rho^*}$, the matrix M becomes one dimensional and its solution is simply the basis vector $\varphi^3_{\rho\overline{\rho}}$,

$$\psi^{(\nu)\overline{\rho}}_{\rho}=\varphi^3_{\rho\overline{\rho}}, \qquad \rho\neq\overline{\rho,\rho^*}. \tag{34}$$

The $\rho \neq \overline{\rho,\rho^*}$ case can be subdivided into the sub-cases:

(i) Both ρ and $\overline{\rho}$ are real, $\rho,\overline{\rho}=\pm 1$. According to the possible eigenvalues of $\overline{\rho}$ and ρ in each irrep given in Table II, we know that the eigenvectors with $\overline{\rho}=\pm 1$ must belong to the irreps E,

$$\psi^{(E_{i_0})-\rho}_{\rho}=\tfrac{1}{2}(\varphi^3-\varphi^4+\varphi^5-\varphi^6)_{\rho}, \quad \rho=\pm 1. \tag{35}$$

(ii) $\overline{\rho}$ is imaginary and $\rho=\pm 1$. For the same reason we know that this case must belong to the irreps $F_{\rho i_0}$, namely

$$\psi^{(F_{\rho i_0})\overline{\rho}}_{\rho}=\tfrac{1}{2}[\varphi^3+\overline{\rho^*}\rho\varphi^4+(\overline{\rho}\rho)^2\varphi^5+\overline{\rho}\rho^*\varphi^6]_{\rho}, \quad \overline{\rho}=\pm i, \rho=\pm 1. \tag{36}$$

Since we are free to choose the multiplicity separation, the two eigenvectors $\psi^{(F_{\rho i_0})\overline{\rho}=\pm i}_{\rho}$ with imaginary quantum number $\overline{\rho}$ can be recombined into two other vectors, labeled by the multiplicity label $\tau=1,2$,

$$\psi^{(F_{\rho i_0})\tau=1}_{\rho}=\frac{1}{\sqrt{2}}[\psi^{(F_{\rho i_0})-i}_{\rho}+\psi^{(F_{\rho i_0})i}_{\rho}]=\frac{1}{\sqrt{2}}(\varphi^3_{\rho}-\varphi^5_{\rho}), \quad \rho=\pm 1, \tag{37}$$

TABLE VII. The eigenvalues of 6σ in the eigenspace $L_{\rho,\overline{\rho}=\rho}$ of $(C_{4z},\overline{C_{4z}})$.

	$A_{\rho i_0}$	$E_{i_0,\rho}$	$F_{\rho i_0}$
6σ	$6\rho i_0$	0	$-2\rho i_0$

TABLE VIII. The action of 6σ on φ^i.

	φ^1	φ^2	φ^3	φ^4	φ^5	φ^6
$(6\sigma)\varphi^1$		$(\rho+\rho^*)i_0$	$\rho^* i_0$	$\rho^* i_0$	$\rho^* i_0$	$\rho^* i_0$
$(6\sigma)\varphi^2$	$(\rho+\rho^*)i_0$		ρi_0	$\rho^* i_0$	ρi_0	$\rho^* i_0$
$(6\sigma)\varphi^3$	ρi_0	$\rho^* i_0$		$\rho^* i_0$	$(\rho+\rho^*)i_0$	ρi_0
$(6\sigma)\varphi^4$	ρi_0	ρi_0	ρi_0		$\rho^* i_0$	$(\rho+\rho^*)i_0$
$(6\sigma)\varphi^5$	ρi_0	$\rho^* i_0$	$(\rho+\rho^*)i_0$	ρi_0		$\rho^* i_0$
$(6\sigma)\varphi^6$	ρi_0	ρi_0	$\rho^* i_0$	$(\rho+\rho^*)i_0$	ρi_0	

$$\psi_\rho^{(F_{\rho i_0})\tau=2}=\frac{1}{\sqrt{2}}\rho i_0[\psi_\rho^{(F_{\rho i_0})-i}-\psi_\rho^{(F_{\rho i_0})i}]=\frac{1}{\sqrt{2}}(\varphi_\rho^4-\varphi_\rho^6),\quad \rho=\pm 1.$$

The above transformation corresponds to the basis transformation shown in Eq. (19) for the irreps F_1, F_2 of the intrinsic point group G.

For the case with $\rho=\overline{\rho}=\pm 1$ we have three linearly independent vectors,

$$\varphi^1,\quad \varphi^2,\quad \varphi^3_{\rho\rho}=\tfrac{1}{2}(\varphi^3+\varphi^4+\varphi^5+\varphi^6). \tag{38}$$

This is the only case where the operator $\mathscr{C}=6\sigma$ has to be diagonalized. Using (33) we get the eigenvalue equation for the coefficients A_i in the expansion of $\psi_\rho^{(\nu)\rho}=A_1\varphi^1+A_2\varphi^2+A_3\varphi^3_{\rho\rho}$,

$$\rho i_0\begin{pmatrix}0&2&2\\2&0&2\\2&2&4\end{pmatrix}\begin{pmatrix}A_1\\A_2\\A_3\end{pmatrix}=\nu\begin{pmatrix}A_1\\A_2\\A_3\end{pmatrix}. \tag{39}$$

The corresponding eigenvectors of $\mathscr{C}=6\sigma$ are

$$\psi^{(A_{\rho i_0})}=\psi_\rho^{(6\rho i_0)\rho}=\frac{1}{\sqrt{6}}(\varphi^1+\varphi^2+2\varphi^3_{\rho\rho}),$$

$$\psi_\rho^{(E_{i_0})\rho}=\psi_\rho^{(0)\rho}=\frac{1}{\sqrt{3}}(\varphi^1+\varphi^2-\varphi^3_{\rho\rho}), \tag{40}$$

$$\psi_\rho^{(F_{\rho i_0})\tau=3}=\psi_\rho^{(-2\rho i_0)\rho}=\frac{1}{\sqrt{2}}(\varphi^1-\varphi^2).$$

Equations (35), (37) and (40), are the algebraic expression for the standard basis of O_h, and its compactness in the double SBR is impressive. However, the basis vectors in the double SBR do not have a clear physical picture and it is preferable to express the irreducible basis in terms of the SBR, as shown in Table IX. The results are spelled out in more detail in Table X, which covers all cases.

V. IRREDUCIBLE BASIS OF O_h IN THE NON-REGULAR REPRESENTATIONS

Starting from the most general case with all the integers a-f being non-zero and different, by letting some equal to zero or equal to one another, we can cover all possible cases for stretching or bending vibrations of the molecule XY_6. This procedure is called assimilation.

TABLE IX. Analytic expressions for standard basis of O_h.

	τ	$\sqrt{8}N$	φ^1	φ^2	φ^3	φ^4	φ^5	φ^6
$A_{\rho i_0}$	1	$\sqrt{\frac{1}{6}}$	1	1	1	1	1	1
$E^{\rho}_{i_0,\rho}$	1	$\sqrt{\frac{1}{12}}$	2	2	-1	-1	-1	-1
$E^{-\rho}_{i_0,\rho}$	2	$\frac{1}{2}$			1	-1	1	-1
$F_{\rho i_0,\rho}$	1	$\sqrt{\frac{1}{2}}$			1		-1	
	2	$\sqrt{\frac{1}{2}}$				1		-1
	3	$\sqrt{\frac{1}{2}}$	1	-1				

To specify the different cases it is convenient to introduce the concept ''configuration,'' $\langle f\rangle$, for multi-vibron systems, which is defined as a given distribution pattern of v vibrons among the n bonds. The subspace $L_{\langle f\rangle}$ characterized by configuration $\langle f\rangle=\langle abcdef\rangle$ is the one generated from the basis vector $|abcdef)$ by the operators of O_h, which carries a reducible representation of O_h. The space with given number of vibrons is a direct sum of $L_{\langle f\rangle}$,

$$L_v=\sum_{\langle f\rangle}\oplus L_{\langle f\rangle}. \tag{41}$$

The following shorthand notation for configuration is also used

$$\langle abcde\rangle=\langle abcde0\rangle,$$

$$\langle abcd\rangle=\langle abcd00\rangle\cdots,$$

$$\langle ab;cd\rangle\equiv\langle ab00cd\rangle=\langle ac0db\rangle.$$

The last equation shows that the subspace $L_{\langle ab;cd\rangle}$ can be generated either from the basis vector $|ab00cd\rangle$ or $|ac0db\rangle$. Notice that $\langle f\rangle$ is similar to the ''set'' defined by Halonen *et al.* in their Table I.[3] For example, for $v=2$, we have $\langle f\rangle=\langle 2\rangle$ (two vibrons in a bond), $\langle f\rangle=\langle 11\rangle$ (two adjacent bonds each has a vibron), and $\langle f\rangle=\langle 101\rangle$ (two opposite bonds each has a vibron). It is convenient to use diagrams to denote configurations. For example, the configurations $\langle 11\rangle,\langle 101\rangle,\langle 21\rangle,\langle 201\rangle,\langle 111\rangle\langle 11;1\rangle,\langle 211\rangle$ and $\langle 21;1\rangle$ are represented by the diagrams in Fig. 2.

One of the merits of the SBR is that the assimilation is trivial as is shown by the following:

TABLE X. Standard basis of O_h in reg. rep.

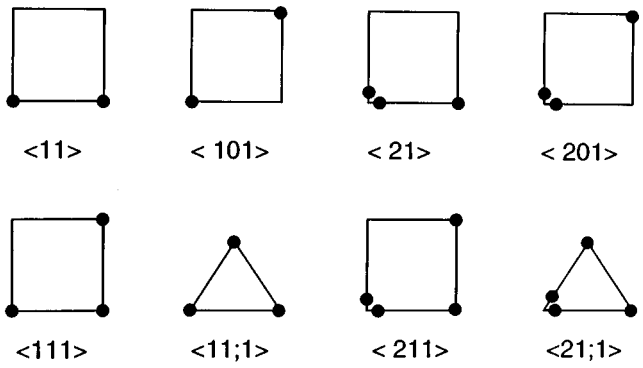

FIG. 2. Diagramatical representations of some simple configurations $\langle f\rangle$ for O_h.

$$
\begin{aligned}
|abcd;00\rangle &\equiv |abcd;0\rangle = (1+i_0)|abcd;\rangle,\\
|0000;ef\rangle &\equiv |0;ef\rangle = 4\delta_{\rho,1}|;ef\rangle,\\
|abc;\rangle &\equiv |abc0;\rangle = |(123+\rho^*234+\rho^2341+\rho412)^{abc}\rangle,\\
|ab;\rangle &\equiv |ab0;\rangle = |(12+\rho^*23+\rho^234+\rho41)^{ab}\rangle,\\
|\underline{ab};\rangle &\equiv |a0b;\rangle = |(13+\rho^*24+\rho^231+\rho42)^{ab}\rangle,\\
|a;\rangle &\equiv |a0;\rangle = |(1+\rho^*2+\rho^23+\rho4)^{a}\rangle,\\
|;a\rangle &\equiv |;a0\rangle = |5^a+i_06^a\rangle,
\end{aligned}
\tag{42}
$$

$$
\tag{43}
$$

where $|ab;\rangle(|\underline{ab};\rangle)$ indicates a state with two adjacent (opposite) bonds occupied by a and b vibrons.

Symmetries of the basis vectors are given by the equations,

$$
\begin{aligned}
&|abcd;\rangle = \rho|bcda;\rangle = \rho^2|cdab;\rangle = \rho^*|dabc;\rangle,\\
&|abc;\rangle = \rho|bc0a;\rangle = \rho^2|c0ab;\rangle = \rho^*|0abc;\rangle,\\
&|ab;\rangle = \rho^*|0ab;\rangle, \qquad |a;\rangle = \rho^*|0a;\rangle, \qquad |\underline{ab};\rangle = \rho^2|\underline{ba};\rangle,\\
&|;ef\rangle = i_0|;fe\rangle, \qquad |;e\rangle \equiv |;e0\rangle = i_0|;0e\rangle,
\end{aligned}
\tag{44}
$$

with some special cases to be noted as follows:

$$
\begin{aligned}
&|a;bb\rangle = (1+i_0)|a;\rangle|5^b6^b\rangle, \quad |;bb\rangle = (1+i_0)|5^b6^b\rangle, \qquad |aaaa;\rangle = 4\delta_{\rho,1}|1^a2^a3^a4^a\rangle,\\
&|\underline{aa};\rangle = 2|(13+\rho24)^{aa}\rangle, \qquad \rho = \pm 1.
\end{aligned}
\tag{45}
$$

It is essential to not confuse the basis $|12\rangle = |21\rangle$, a two-vibron unsymmetrized state, with $|12;\rangle = |(12+\rho23+34+\rho41)^{12}\rangle \neq |\ 21;\rangle$, a symmetrized three-vibron state.

In the process of assimilation, we find many different cases, some belonging to the regular representation and some to non-regular representations. The assimilation for the symmetrized basis is shown in Table XI.

[a]This table is valid only for real ρ. The third column gives the index of the table listing the irreducible basis for the configuration $\langle f\rangle$.

For non-regular representations, the vectors $\varphi^1 \ldots \varphi^6$ are no longer linearly independent. However, Table IX or X remains valid with φ^i replaced by the corresponding term in Table XI. The irreducible bases are no longer normalized and some may become zero or linearly dependent. We only take the linearly independent ones. Since for vibrational modes, $\lvert 1^a \cdots 6^a\rangle$ carries the

TABLE XII. $\langle abcd\rangle$; $\varphi^1_{\rho,-}=\varphi^2_{\rho,-}=0$.

identity representation, the configuration $\langle a'b'c'd'e'f'\rangle$ is equivalent to $\langle abcde\rangle$ with $a=a'$-$f',b=b'$-$f',\cdots,e=e'$-f'. The irreducible basis for $\langle abcde\rangle$ can be obtained from the configuration $\langle abcdef\rangle$ by letting $f=0$. By setting $abcde$ equal to $ac0db$, respectively, we get the configuration $\langle ab;cd\rangle$, and by letting $abcd$ equal to some special values, we get other special configurations, for example $\langle ab;bc\rangle$,$\langle ab;ab\rangle$ and $\langle ab;c\rangle$. As an example, consider the configuration $\langle abcd\rangle$, which has dimension 24. From Table IX and XI, we derive the algebraic expression of the irreducible basis of O_h for the configuration $\langle abcd\rangle$ listed in Table XII. From the latter we can obtain the explicit form shown in Table XIII. Similarly, we can obtain Tables XIV–XXIV.

The multiplicity of a given irrep in the configuration $\langle f\rangle$ can be calculated from character theory. The result is given in Table XXV (part of it were given previously by Halonen[3]). These results provide a useful check for the correctness of Tables XII–XXIV.

If a given irrep occurs only once in the representation space L_v, then it is said to be a unique state. It can be shown that a unique state is necessarily an irreducible basis of the permutation group S_6,[14] which means that these states have a symmetry higher than the geometric symmetry. The implication of the existence of a higher symmetry in molecules will be discussed in a forthcoming paper.[14]

As an application of Tables XII–XXIV, the un-normalized irreducible basis of O_h for $v=1$-3 are given below with bold-face symbols denoting the unique states. The steps for finding them are: (1) According to $\langle f\rangle$, find the corresponding table from Tables XII–XXIV. (2) according to $\langle f\rangle$ from Table XI find the expression of φ^i in the SBR, and thus yields a concise expression for the irreducible basis vectors. If one needs more explicit (but, unfortunately, more cumbersome) expressions, one can use Eq. (43) to write out the vectors in the SBR in terms of the unsymmetrized basis vectors. The results are the following:

$v=a,\langle f\rangle=\langle a\rangle$, dim= 6. From Table XXII:

TABLE XIII. $\langle abcd\rangle$, dim=24.

$$\begin{aligned}\mathbf{A}_{2u}^{\langle 21;1\rangle}&=|21;1\rangle_{--}+|12;1\rangle_{--}+|11;2\rangle_{--}\\&=|(1-3)(2-4)(1+2+3+4)(5-6)\rangle+|(12-14-23+34)\\&\quad\times(5^2-6^2)\rangle,\end{aligned}\tag{53}$$

$$\begin{aligned}\mathbf{E}_{u,\epsilon}^{\langle 21;1\rangle}&=|21;1\rangle_{--}+|12;1\rangle_{--}-2|11;2\rangle_{--}\\&=|(1-3)(2-4)(1+2+3+4)(5-6)\rangle-2|(12-14-23+34)\\&\quad\times(5^2-6^2)\rangle.\end{aligned}$$

The physical picture of the state $\mathbf{A}_{2u}^{\langle 21;1\rangle}$ is given in the Introduction.

VI. DIAGONALIZATION OF THE HAMILTONIAN IN SYMMETRY ADAPTED BASES

In the algebraic model of Iachello and Oss for stretching or bending vibration of molecules,[4,15] each bond is associated with a $U^{(i)}(2)$ algebra realized in terms of the bosons $a_i^\dagger$ and $b_i^\dagger$ and they interact with each other through diagonal and nondiagonal interactions B_{ij} (denoted as C_{ij} in Ref. 4) and M_{ij}, respectively. From the matrix elements of B_{ij} and M_{ij} given in Ref. 4 we can infer that explicit form of these operators are as follows:

$$B_{ij}=4[(J_{iz}+J_{jz})^2-(J_i+J_j)^2],\qquad M_{ij}=-2(\mathbf{J}_i\cdot\mathbf{J}_j-J_iJ_j),\tag{54}$$

with $J_i=J_j=N_i/2$, $N_i=a_i^\dagger a_i+b_i^\dagger b_i$ and $[N_i/2]$ is the total number of bound states in a Morse potential, where B_{ij} and M_{ij} are invariants of $O_{ij}(2)$ and $U_{ij}(2)$, respectively. Specified for the XY_6 molecule, the Hamiltonian they utilized has the form

$$H=aB+a'B'+\lambda M+\lambda' M',\tag{55}$$

$$B=\sum_i^6 B_i,\quad B'=\sum_{i>j}^6 B_{ij},\qquad M=\sum_{i>j}^6 M_{ij},\qquad M'=\sum_{i>j}^{6\,\prime} M_{ij},\tag{56}$$

where the prime in the summation symbol indicates exclusion of the opposite bonds $ij=13$, 24 and 56, and

$$B_i=4[(J_{iz})^2-(J_i)^2]\tag{57}$$

TABLE XXI. $\langle aaaab\rangle$, dim=6.

	ρi_0	φ^1	φ^3
A_{1g}	$++$	1	2
$E_{g,\epsilon}$	$-+$		1
$F_{1u,z}$	$+-$	1	

TABLE XXII. $\langle a\rangle$ and $\langle a0b\rangle$, dim=6.

$\langle a\rangle$	ρi_0	$\|a;\rangle$	$\|;a\rangle$

is the Hamiltonian for the Morse potential of the bond i.[16]

Notice that the parameters λ and λ' listed in Table I of Ref. 4 are not consistent with Iachello and Oss' definition as given in (12), but are the parameters λ_T and λ'_T shown below:

$$H=aB+a'B'+\lambda_T M'+\lambda'_T(M-M').$$

In Ref. 4 the Hamiltonian (55) was diagonalized in the product basis, and it is referred to as a pure numerical solution. It will be much nicer to diagonalize the Hamiltonian in the symmetry-adapted basis. The advantages of using symmetry adapted basis are:

(1) The dimension for the expectation equation of H can be reduced by one order of magnitude for O_h.

(2) Using symmetry adapted basis we can obtain the structure of the eigenstates of H, while no physical pictures of the eigenstates are emerged in a pure numerical solution.

(3) The identification of the eigenstates with irrep labels, a necessary procedure in numerical solution, is avoided.

We diagonalized the H for the molecules SF_6, WF_6 and UF_6 in the the $O_h\supset C_4$ basis $\psi_\rho^{(\nu)\langle f\rangle\tau}$. The parameters are listed in Table XXVI. The mean square deviations from the experimental values are 14.34, 4.78, and 3.76 for the molecules SF_6, WF_6, and UF_6, respectively. The fit is a little better than in Ref. 4 where the corresponding mean square deviations are 15.71, 6.60 and 3.79, respectively.

The eigen-energies and wave functions for SF_6 are listed in Tables XXVII–XXIX. The coefficients listed there are $a_{\mathscr{E},f\tau}$ in the following expansion of the eigenstate

$$\Psi_\rho^\nu(\mathscr{E})=\sum_{f\tau} a_{\mathscr{E},f\tau}\psi_\rho^{(\nu)\langle f\rangle\tau}. \tag{58}$$

From Tables XXVII–XXIX we can see clearly the distribution pattern of the vibrons in the eigenstates.

VII. DISCUSSION

In the past, several methods have been available for obtaining the subgroup-symmetry adapted bases of point groups. A separate discussion for the regular and non-regular representations is adequate.

A. Regular representation

1. The recursive or factorization method

The generalized projection operator $P^{\nu}_{\rho\rho}$ for the group chain $G \supset H$ can be factored as a product of the projection operators P^{ν} and P^{ρ} of the group G and its subgroup H, respectively by the following formula (see p. 73 in Ref. 6):

$$P^{\nu}_{\rho} \equiv P^{\nu}_{\rho\rho} = \text{const } P^{\nu} P^{\rho}, \qquad P^{\nu}_{\rho\overline{\rho}} = \text{const } P^{\nu}_{\rho} R_a P^{\overline{\rho}}, \tag{59}$$

where R_a is a properly chosen operator of G so that $P^{\rho} R_a P^{\overline{\rho}} \neq 0$.

Recently, Harter[1] gave a slightly different form for the non-diagonal part,

$$P^{\nu}_{\rho\overline{\rho}} = \text{const } P^{\nu}_{\rho} R_a P^{\nu}_{\overline{\rho}}. \tag{60}$$

It is to be noted that Eq. (59) is simpler than Eq. (60). This method depends heavily on hand calculation.

2. The eigenfunction method

With a computer code, it is much easier to obtain the generalized projection operator by the EFM. A versatile program package is available.[9]

B. Non-regular representation

1. Projection operator method in its primitive form (Refs. 1, 7, and 17)

The main shortcomings of this method are that we have to know all the irreducible matrix elements and the effects of all the g operators. For a high symmetry group it is a daunting task to

TABLE XXV. The multiplicity of an irrep in the configuration $\langle f\rangle$.

generate symmetry adapted bases in view of the mental dexterity required to envisage the effects of the g operators on a reducible basis vector.[3] A further problem is the multiple occurence of a given symmetry.

2. Coset factored projection operator

Suppose that H is an Abelian subgroup of G. The left coset decomposition of G with respect to H is denoted by $G=\Sigma_i a_i H$, a_i are the so called coset representatives, or coset leaders. The projection operator can be factored as[1]

$$P^{\nu}_{\rho\rho}=\frac{h_\nu}{g}\sum_i D^{\nu}_{\rho\rho}(a_i)^* a_i P^{\rho}, \tag{61}$$

where P^ρ is defined as in (21). The coset factorization allows one to tabulate many fewer $D(R)$ matrices and cuts the arithmetical labor down by a factor of g/h (h being the order of the subgroup H) if the dimension of the reducible representation is g/h and one induces the representation from a basis vector which belongs to the identity representation of H.

3. Double coset factored projection operator

A group G can also be decomposed in the following way:

$$G=\sum_i Ha_i+\sum_j Hb_jH, \tag{62}$$

where $Ha_i=a_iH$, i.e., the left and right coset are identical, and Hb_jH is a double coset. The generalized projection operator $P^{\nu}_{\rho\rho}$ can be factored as[18]

$$P^{\nu}_{\rho\rho}=\frac{h_\nu}{g}\left[\sum_i D^{\nu}_{\rho\rho}(a_i)^* P^{\rho} a_i+\sum_j D^{\nu}_{\rho\rho}(b_j)^* P^{\rho} b_j P^{\rho}\right]. \tag{63}$$

The methods (ii) and (iii) cannot yield algebraic expressions for the irreducible basis; therefore, tedious work cannot be avoided for each case.

4. Use of the CG coefficients of point groups

Starting from the irreducible basis for the basic configuration $\langle 1\rangle$, using the CG coefficients stepwise, we can construct the irreducible basis for other configurations.[3] The trouble is that in coupling two irreducible basis by means of CG coefficients one obtains the following linear combination:

$$\Psi_\rho^{(\nu)}=\sum_{f\tau} a_{\rho,f\tau}^{(\nu)}\psi_\rho^{(\nu)\langle f\rangle\tau}, \tag{64}$$

where $a_{\rho,f\tau}^{(\nu)}$ are coefficients, τ is the multiplicity label for the irrep ν in a given configuration $\langle f\rangle$, and the sum runs over τ and all possible $\langle f\rangle$ in the space L_v with a given vibron number v. Notice that in the above equation both $\langle f\rangle$ and τ serve as multiplicity labels for the irrep ν in L_v. The dimension of L_v can be very large for large v, and it is nontrivial to extract the irreducible basis $\psi_\rho^{(\nu)\langle f\rangle\tau}$ from the sum in Eq. (64). A code has been used in Ref. 3 to calculate the irreducible basis of O_h for $v=1-8$.

5. The eigenfunction method (Ref. 6)

The irreducible bases are obtained by solving the eigenvalue equation of the CSCO-II of G in the reducible representation space.

All the above methods are numerical. In the present work we have added a new method which gives algebraic solutions, and has a number of attractive features:

C. Regular representation

One only needs to solve an eigenequation of a 3×3 matrix to get a compact algebraic solution for irreducible basis of O_h as a function of i_0,ρ and $\overline{\rho}$,

$$\psi_\rho^{(\nu_{i_0})\overline{\rho}}=F_\rho^{(\nu_{i_0})\overline{\rho}}(\varphi^1,\cdots,\varphi^6), \tag{65}$$

which involves only 6 terms instead of 48 terms in numerical solutions.

D. Non-regular representation

(i) For non-regular representation, irreducible basis vectors are easily obtained from the above by assimilation,

where d is equal to one eighth of the dimension of the reducible representation, verses $8d$ terms in a numerical solution.

(ii) The states $|abcd;ef\rangle$ in the SBR have a clear physical picture about the distribution pattern of the vibrons over the two sets of equivalent bonds, as illustrated in the Introduction.

(iii) The results are independent of the labeling of bonds. For a molecule with many bonds, such as fullerene, C_{60}, this independence is of special value.

(iv) The multiplicity separation is automatic: the configuration $\langle f\rangle$ naturally provides one of the multiplicity labels, while the intrinsic operator $\overline{C_{4z}}$ provides the other.

(v) Facilitate the programming of diagonalization of a Hamiltonian in the symmetry adapted bases.

It is remarkable that to carry out this process, we utilize only the CSCO's of a group G and its subgroup, with no knowledge required either of the primitive characters or of the irreducible matrices, and even without using the group table!

As a first application of this new method, we have derived algebraic expressions for the irreducible bases of the group O_h for all cases of current practical interest and much more. The application to other groups is straightforward. For example, the algebraic expression of the irre-

ducible bases and irreducible matrices for the icosahedral group will be discussed in the sequent paper.[19] The combination of the algebraic model[4] and this new technique provides a powerful tool for the solution of many problems in physics and chemistry. One is now in a position to compute in a simple way, even in an algebraic way for the unique states,[14] the spectra and infrared or Raman transition rates of many molecules, including mid-size and large molecules.[3]

General eigenvalue formula for Casimir invariants of type I quantum superalgebras

M. D. Gould and J. R. Links
Department of Mathematics, University of Queensland, St. Lucia, Queensland, 4072, Australia

(Received 13 June 1995; accepted for publication 9 January 1996)

Induced invariant forms and the multiplicity labeling problem are investigated for typical summands of the tensor product of an arbitrary finite dimensional irreducible representation and a typical one, for the type I quantum superalgebras. The results are applied to obtain a general eigenvalue formula for Casimir invariants, corresponding to an arbitrary finite dimensional irreducible reference representation. © *1996 American Institute of Physics.* [S0022-2488(96)01704-8]

I. INTRODUCTION

Quantum algebras are well known for their role in solving the Yang–Baxter equation[1] which, in turn, give rise to new exactly solvable models[2,3] and link polynomials. Similarly, their $\mathbb{Z}_2$-graded counterparts, quantum superalgebras, play an equally important role in knot theory[4] and supersymmetric integrable models.[5–7] For applications in this general area, it is thus desirable to have a well developed *representation* (rep) theory for the quantum (super)algebras.

This article is concerned with an important aspect of the rep theory for the type I quantum superalgebras; namely the determination of a general eigenvalue formula for Casimir invariants. The type I quantum superalgebras, consisting of $U_q[gl(m|n)]$ and $U_q[osp(2|2n)]$, are particularly interesting for the following reasons. First, of all the quantum superalgebras (except the trivially graded case of quantum algebras), only those of type I admit finite dimensional unitary reps which will thus be of importance to physical theories where unitarity is a basic requirement. Second, they admit one parameter families of inequivalent *irreducible representations* (irreps) which have interesting applications such as providing solutions to the Yang–Baxter equation, and corresponding exactly solvable models, with extra (nonadditive) parameters. An example of the latter is the generalized Hubbard model proposed in Ref. 7 where the parameter labeling the irreps is directly related to the Hubbard interaction parameter. Another application is to the construction of two variable link polynomials[8] and their multivariable extensions.[9]

A general method for constructing Casimir invariants, corresponding to an arbitrary reference irrep, has been previously developed for both quantum algebras[10,11] and quantum superalgebras,[12,13] utilizing the universal R matrix. In the case of quantum algebras their eigenvalues have been explicitly determined,[11] based on techniques previously developed for simple Lie algebras.[14,15] However, this problem has not been solved for quantum superalgebras, or their classical counterparts, mainly due to the zero (q) supertrace problem over typical irreps. In this article we present a solution to this problem and obtain a general eigenvalue formula for Casimir invariants, valid for an arbitrary reference irrep. Our results are new, even in the classical limit $q\rightarrow 1$, and generalize, to arbitrary reference irreps, the results of Refs. 16 and 17.

Aside from their intrinsic interest to representation theory, particularly in connection with superdimensions and infinitesimal characters, our results are of importance for obtaining two variable link polynomials, in fully explicit form, corresponding to any unitary irrep for these algebras. This gives rise to infinite families of inequivalent two variable link polynomials which will be studied elsewhere.[18] As part of our approach we will also determine a useful method for obtaining the multiplicities of typical summands occurring in the tensor product of an arbitrary irrep with a typical one, and investigate the Clebsch–Gordan multiplicity problem for such cases. Moreover we obtain a symmetry relation for the corresponding Clebsch–Gordan coefficients,

0022-2488/96/37(5)/2426/31/$10.00

which are defined below with respect to the naturally induced form on the tensor product space.

The article is set up as follows. Section II summarizes previously known results on quantum superalgebras and their reps. In Sec. III we investigate invariant sesquilinear forms induced on irreps and their tensor products, and their behavior under duality. Section IV is concerned with an orthogonal labeling scheme for typical irreps occurring in the tensor product of two irreps and these results are applied in Sec. V to obtain a new supertrace formula. In Sec. VI we investigate the $1-1$ correspondence between the imbeddings $V(\nu)\subseteq V(\Lambda)\otimes V(\mu)$, $V(\mu)\subseteq V(\Lambda)^*\otimes V(\nu)$ (for μ, ν typical but Λ arbitrary) and symmetries of Clebsch–Gordan coefficients. A general eigenvalue formula for Casimir invariants is then developed in Secs. VII and VIII and we conclude in Sec. IX with a brief discussion of our main results.

II. PRELIMINARIES

Throughout, L denotes a type I basic classical Lie superalgebra of rank $l+1$, with Cartan subalgebra H. We let α_i, $0\leqslant i\leqslant l$ be a distinguished[19] system of simple roots of L with α_0 the unique odd simple root; then $\alpha_1,\ldots,\alpha_l$ constitute the simple roots of the (reductive) even Lie subalgebra L_0 of L. $\Phi^+=\Phi_0^+\cup\Phi_1^+$ denotes the set of positive roots of L with Φ_0^+ (resp. Φ_1^+) the set of even (resp. odd) positive roots. As usual we define

$$\rho_0=\frac{1}{2}\sum_{\alpha\in\Phi_0^+}\alpha,\quad \rho_1=\frac{1}{2}\sum_{\beta\in\Phi_1^+}\beta$$

and set $\rho=\rho_0-\rho_1$. We let $(\ ,\ )$ be a fixed bilinear form on H^*, the dual of the Cartan subalgebra, induced by a given nondegenerate invariant bilinear form on L; note that $(\ ,\ )$ is invariant under the Weyl group of L_0. Associated with any weight $\lambda\in H^*$, we have $h_\lambda\in H$ defined by $\mu(h_\lambda)=(\mu,\lambda)$, $\forall\mu\in H^*$. In particular we may define the Cartan elements h_{ρ_0}, h_{ρ_1}, $h_\rho=h_{\rho_0}-h_{\rho_1}$, $h_i\equiv h_{\alpha_i}$ $(0\leqslant i\leqslant l)$, which play an important role below. We let $\geqslant$ be the usual partial ordering induced on H^* by the positive roots.

Associated with L we have the quantum superalgebra $U_q(L)$ with simple generators:

$$q^{\pm(1/2)h_i},e_i,f_i,\quad 0\leqslant i\leqslant l.$$

The defining relations for $U_q(L)$ will not be given here and we refer to Refs. 20–23 for details. We merely note that $U_q(L)$ has the structure of a $\mathbb{Z}_2$-graded quasitriangular Hopf algebra with co-product defined by

$$\Delta(q^{\pm(1/2)h_i})=q^{\pm(1/2)h_i}\otimes q^{\pm(1/2)h_i},\quad \Delta(x)=x\otimes q^{-(1/2)h_i}+q^{(1/2)h_i}\otimes x;\quad x=e_i,f_i$$

which extends to an algebra homomorphism $\Delta:U_q(L)\to U_q(L)\otimes U_q(L)$ in an obvious way. We emphasize that the multiplication rule on the latter is defined for homogeneous elements $a,b,c,d\in U_q(L)$ by

$$(a\otimes b)(c\otimes d)=(-1)^{[b][c]}(ac\otimes bd) \tag{1}$$

and extended to all of $U_q(L)\otimes U_q(L)$ by linearity; here and below $[a]\in\mathbb{Z}_2$ denotes the degree[19,20] of homogeneous $a\in U_q(L)$. Throughout we adopt the sigma notation of Sweedler[24] and write

$$\Delta(a)=\sum_{(a)}a_{(1)}\otimes a_{(2)},\quad a\in U_q(L). \tag{2}$$

The antipode S is given by

$$S(a)=q^{-h_\rho}\gamma(a)q^{h_\rho},\quad a\in U_q(L), \tag{3}$$

where γ is the *principal antiautomorphism* defined on $U_q(L)$ by[25]

$$\gamma(1)=1, \quad \gamma(x)=-x; \quad x=e_i,f_i,h_i$$

and extended to a $\mathbb{Z}_2$-graded antihomorphism in the obvious way so that for homogeneous $a,b\in U_q(L)$:

$$\gamma(ab)=(-1)^{[a][b]}\gamma(b)\gamma(a).$$

We omit the formula for the co-unit ϵ: $U_q(L)\to\mathbb{C}$, since it is not required below.

It is worth noting that $U_q(L)$ also constitutes a $\mathbb{Z}_2$-graded quasitriangular Hopf algebra, with a co-unit ϵ and antipode S^{-1} under the opposite coproduct $\Delta'=T\cdot\Delta$, where $T:U_q(L)\otimes U_q(L)\to U_q(L)\otimes U_q(L)$ is the twist map defined for homogeneous $a,b,\in U_q(L)$ by

$$T(a\otimes b)=(-1)^{[a][b]}(b\otimes a).$$

This is referred to as the *opposite Hopf algebra structure* on $U_q(L)$. Δ and Δ' are related via the universal R matrix $R\in U_q(L)\otimes U_q(L)$ which satisfies the well known relations

$$R\Delta(a)=\Delta'(a)R, \quad \forall a\in U_q(L), \tag{4a}$$

$$(1\otimes\Delta)R=R_{13}R_{12}, \quad (\Delta\otimes 1)R=R_{13}R_{23}. \tag{4b}$$

A direct consequence of these relations is that R satisfies the graded Yang–Baxter equation[6,7,20]: here we again emphasize that all tensor products are to be interpreted in light of Eq. (1). Then $R^T\equiv T(R)$ also gives rise to a universal R matrix under the opposite Hopf algebra structure on $U_q(L)$.

We note that the quantum algebra $U_q(L_0)$, with generators $q^{\pm(1/2)h_i}$, e_i, f_i $(1\leqslant i\leqslant l)$, gives rise to an even Hopf subalgebra of $U_q(L)$. We let $U_q(B)$ [resp. $U_q(N)$] be the $\mathbb{Z}_2$-graded sub-Hopf algebra of $U_q(L)$ with generators $q^{\pm(1/2)h_i}$, e_i (resp. $q^{\pm(1/2)h_i}$, f_i), $0\leqslant i\leqslant l$. Following Kac,[19] we define a $\mathbb{Z}_2$-consistent $\mathbb{Z}$ gradation on $U_q(L)$ by

$$\deg(e_i)=\deg(f_i)=0, \quad 1\leqslant i\leqslant l, \quad \deg(h_i)=0, \quad 0\leqslant i\leqslant l,$$

$$\deg(e_0)=-\deg(f_0)=1.$$

This gives rise to the $\mathbb{Z}$ gradation

$$U_q(L)=\bigoplus_n U_q^{(n)}(L),$$

where $U_q^{(n)}(L)=\{a\in U_q(L)|\deg(a)=n\}$.

Below an important role is played by the operators

$$T_+=\prod_{\beta\in\Phi_1^+}E_\beta, \quad T_-=\prod_{\beta\in\Phi_1^+}F_\beta. \tag{5}$$

Here E_β,F_β are (odd) Cartan–Weyl elements of $U_q(L)$; for details we refer to Ref. 26 for the case $L=gl(m|n)$ and Ref. 27 for the case of $L=osp(2|2n)$. We set

$$\Gamma=T_+T_- \tag{6}$$

which commutes with the elements of $U_q(L_0)$. Following the Poincare–Birkhoff–Witt (PBW) theorem we may write

$$\Gamma=\Gamma_0+\Gamma_+, \tag{7}$$

where Γ_0 is a central element of $U_q(L_0)$ and $\Gamma_+\in U_q^{(-1)}(L)U_q(L)U_q^{(1)}(L)$. $T_\pm$ possess the following important properties:[26,27]

$$\begin{aligned} aT_+&=T_+a=0, \quad \forall a\in U_q^{(1)}(L),\\ aT_-&=T_-a=0, \quad \forall a\in U_q^{(-1)}(L), \end{aligned} \tag{8}$$

so that from Eq. (7),

$$T_+T_-T_+=\Gamma T_+=\Gamma_0T_+. \tag{9a}$$

Moreover, it is easily verified that

$$(1\otimes T_+)\Delta(T_-)(1\otimes T_+)=q^{h_{\rho_1}}\otimes(T_+T_-T_+)=q^{h_{\rho_1}}\otimes(\Gamma_0T_+). \tag{9b}$$

We now say something about the representation theory of $U_q(L)$. The finite dimensional irreducible $U_q(L)$ modules are uniquely labeled by their highest weights Λ and have the same dimensions and weight spectrum as the corresponding L modules of the same highest weight. We denote the set of dominant weights of L [and hence $U_q(L)$] by D^+. For $\Lambda\in D^+$, we let $V(\Lambda)$ denote the irreducible $U_q(L)$ module with highest weight Λ and we let π_Λ be the representation afforded by $V(\Lambda)$. Throughout $V_0(\Lambda)$ denotes the finite dimensional irreducible $U_q(L_0)$ module with highest weight $\Lambda\in D^+$, and we let[28,29]

$$D_q^0[\Lambda]\equiv\prod_{\alpha\in\Phi_0^+}\frac{[(\Lambda+\rho,\alpha)]_q}{[(\rho,\alpha)]_q} \tag{10}$$

be the *q dimension* of $V_0(\Lambda)$, where we have adopted the convention, maintained throughout,

$$[x]_q\equiv(q^x-q^{-x})/(q-q^{-1}).$$

We recall[26,27] that on $V_0(\Lambda)$ the $U_q(L_0)$ central element Γ_0 of Eq. (7), takes the eigenvalue

$$\chi_\Lambda(\Gamma_0)=c\prod_{\beta\in\Phi_1^+}[(\Lambda+\rho,\beta)]_q, \tag{11}$$

where $c\neq0$ is a representation-independent constant. Following Kac,[19] we say that $\Lambda\in D^+$ and the corresponding irreducible $U_q(L)$ module $V(\Lambda)$ are *typical* if this eigenvalue is nonzero, or equivalently,

$$(\Lambda+\rho,\beta)\neq0, \quad \forall\beta\in\Phi_1^+;$$

otherwise, Λ and $V(\Lambda)$ are called *atypical*. Note, from definition [cf. Eqs. (6) and (7)], Γ must vanish on all irreducible atypical modules.

Every finite dimensional irreducible $U_q(L)$ module admits a natural $\mathbb{Z}$ gradation[19,25]:

$$V(\Lambda)=\bigoplus_{k=0}^{d}V_k(\Lambda), \tag{12}$$

compatible with the $\mathbb{Z}$ gradation on $U_q(L)$, in which case we say that $V(\Lambda)$ *admits* $d+1$ *levels* ($V_d(\Lambda)\neq(0)$ assumed). Here $V_k(\Lambda)$ is the $\mathbb{Z}$-homogeneous subspace consisting of vectors of degree $-k$. In view of the PBW theorem we have

$$V(\Lambda)=U_q(L)v_+^\Lambda=U_q(N)v_+^\Lambda \tag{13}$$

with $v_+^\Lambda\in V_0(\Lambda)$ the maximal weight vector of $V(\Lambda)$. Throughout the article we assume, unless otherwise stated, that the maximal $\mathbb{Z}$-graded component $V_0(\Lambda)$ has parity $+1$ (i.e., belongs to the even subspace of $V(\Lambda)$).

If V, W are finite dimensional $U_q(L)$ modules then $\mathrm{Hom}(V,W)$, the space of linear maps from V to W, becomes a $U_q(L)$ module with the definition

$$(a\circ w)(v)=\sum_{(a)}(-1)^{[w][a_{(2)}]}a_{(1)}w(\gamma(a_{(2)})v)$$

for all homogeneous $a\in U_q(L)$, $w\in\mathrm{Hom}(V,W)$, $v\in V$, with $\Delta(a)$ as in Eq. (2). Note that this definition differs from the usual one which here would have γ replaced by the antipode S. However, in view of Eq. (3), these definitions give rise to equivalent representations.

In particular $V^*=\mathrm{Hom}(V,\mathbb{C})$ becomes a $U_q(L)$ module with the definition

$$(aw^*)(v)=(-1)^{[w^*][a]}w^*(\gamma(a))$$

for all homogeneous $a\in U_q(L)$, $w^*\in V^*$, $v\in V$. In rep theoretic terms, let $\{w_i\}$ be a homogeneous basis for V with $[i]\in\mathbb{Z}_2$ the degree of basis vector w_i. We then have the matrix representation π defined by

$$aw_i=\pi(a)_{ji}w_j,\quad \forall a\in U_q(L)$$

(summation on j assumed here and below). If $\{w_i^*\}$ denotes the corresponding dual basis for V^* so that

$$w_i^*(w_j)=\delta_{ij},$$

then the dual representation π^* is given by

$$aw_i^*=\pi^*(a)_{ji}w_j^*,\quad \forall a\in U_q(L),$$

where

$$\pi^*(a)_{ij}=(-1)^{[a][j]}\pi(\gamma(a))_{ji} \tag{14}$$

for homogeneous $a\in U_q(L)$. Equivalently

$$\pi^*(a)=\pi^T(\gamma(a)),\quad \forall a\in U_q(L),$$

where T denotes supertranspose.[30]

With these constructions, we have[11,30]

Lemma 2.1: The mapping ξ: $V^*\otimes W\to\mathrm{Hom}(V,W)$, *defined by*

$$\xi(u^*\otimes w)(v)=(-1)^{[w][v]}u^*(v)w$$

for all homogeneous $u^*\in V^*$, $v\in V$, $w\in W$, *determines a* $U_q(L)$ *module isomorphism.* □

In particular given a finite dimensional irreducible $U_q(L)$ module $V(\Lambda)$, we have the canonical isomorphism

$$V(\Lambda)^*\otimes V(\Lambda)\cong\mathrm{Hom}(V(\Lambda),V(\Lambda)). \tag{15}$$

If $\{w_i\}$ denotes a homogeneous basis for $V(\Lambda)$ with corresponding dual basis $\{w_i^*\}$ for $V(\Lambda)^*$, we obtain

Lemma 2.2: The identity module occurs exactly once in $V(\Lambda)^*\otimes V(\Lambda)$ and is spanned by the vector

$$w_\Lambda=\sum_i\ (-1)^{[i]}(q^{-h_\rho}w_i^*)\otimes w_i\,,$$

where $(-1)^{[i]}$ is the parity of basis vector w_i.

Proof: In view of Eq. (15) and Schur's lemma, the identity module must occur exactly once in the tensor product space. For homogeneous $a\in U_q(L)$ we have, in the notation of Eq. (2):

$$\Delta(a)w_\Lambda=\sum_{i,(a)}\ (-1)^{[i]+[i][a_{(2)}]}(a_{(1)}q^{-h_\rho}w_i^*)\otimes a_{(2)}w_i\,.$$

From Eq. (14) we have (summation on j)

$$\begin{aligned}a_{(1)}q^{-h_\rho}w_i^*&=q^{-h_\rho}\pi_\Lambda^*(q^{h_\rho}a_{(1)}q^{-h_\rho})_{ji}w_j^*\\&=(-1)^{[i][a_{(1)}]}q^{-h_\rho}\pi_\Lambda(\gamma[q^{h_\rho}a_{(1)}q^{-h_\rho}])_{ij}w_j^*\\&=(-1)^{[i][a_{(1)}]}q^{-h_\rho}\pi_\Lambda(S^{-1}[a_{(1)}])_{ij}w_j^*\,,\end{aligned}$$

where the last equality follows from Eq. (3). We thus arrive at

$$\begin{aligned}\Delta(a)w_\Lambda&=\sum_{i,j(a)}\ (-1)^{[i](1+[a])}(q^{-h_\rho}w_j^*)\otimes a_{(2)}\pi_\Lambda(S^{-1}[a_{(1)}])_{ij}w_i\\&=\sum_{j,(a)}\ (-1)^{([j]+[a_{(1)}])(1+[a])}(q^{-h_\rho}w_j^*)\otimes a_{(2)}S^{-1}(a_{(1)})w_j\\&=\sum_j\ (-1)^{[j](1+[a])}(q^{-h_\rho}w_j^*)\otimes\sum_{(a)}\ (-1)^{[a_{(1)}][a_{(2)}]}a_{(2)}S^{-1}(a_{(1)})w_j\\&=\sum_j\ (-1)^{[j](1+[a])}(q^{-h_\rho}w_j^*)\otimes\epsilon(a)w_j\\&=\epsilon(a)w_\Lambda\end{aligned}$$

since, for a nonzero contribution, a must be even. This is sufficient to prove the result. □

Now let Z denote the center of $U_q(L)$. A fundamental role in the construction of central elements is played by[12]

Proposition 2.1: If $c\in\mathrm{End}V(\Lambda)\otimes U_q(L)$ *satisfies* $\Delta_\Lambda(a)c=c\Delta_\Lambda(a)$, $\forall a\in U_q(L)$, *where* $\Delta_\Lambda=(\pi_\Lambda\otimes 1)\Delta$, *then*

$$C^\Lambda=(\mathrm{str}_q\otimes 1)c\in Z.$$

Here str_q *denotes the q supertrace defined by*

$$\mathrm{str}_q\pi_\Lambda(a)=\mathrm{str}\ \pi_\Lambda(q^{2h_\rho}a),\quad \forall a\in U_q(L)$$

with str *the usual supertrace.*[30] □

An important example is afforded by[12]

$$c=(I\otimes 1-R_\Lambda^TR_\Lambda)/(q-q^{-1})$$

and its powers, where $R_\Lambda=(\pi_\Lambda\otimes 1)R$. It is one of our aims in this article to derive a universal formula for the eigenvalues of the corresponding Casimir invariants

$$C_k^\Lambda=(\mathrm{str}_q\otimes 1)(c^k) \tag{16}$$

on any finite dimensional irrep, thus solving an outstanding problem in the rep theory of the type I quantum superalgebras. In particular the eigenvalue formula allows an explicit determination of link polynomials[18] associated with any finite dimensional irreducible $U_q(L)$ module $V(\Lambda)$.

Throughout the article we assume $q>0$ is a positive real parameter (although our final results will hold for complex q by analytic continuation). With this assumption we have a conjugation operation † defined on $U_q(L)$ by[25]

$$e_i^\dagger=f_i,\quad f_i^\dagger=e_i,\quad (q^{\pm(1/2)h_i})^\dagger=q^{\pm(1/2)h_i},\quad 0\leqslant i\leqslant l$$

which we extend to an (even) algebra antihomomorphism on all of $U_q(L)$ so that

$$\alpha^\dagger=\overline{\alpha},\quad \alpha\in\mathbb{C};\quad (ab)^\dagger=b^\dagger a^\dagger,\quad \forall a,b\in U_a(L),$$

where the overbar denotes normal complex conjugation in $\mathbb{C}$. We note that † so defined is indeed consistent with the $U_q(L)$ defining relations as well as the coproduct, i.e.,

$$\Delta(a)^\dagger=\Delta(a^\dagger),\quad \forall a\in U_q(L),$$

where

$$(a\otimes b)^\dagger\equiv(-1)^{[a][b]}a^\dagger\otimes b^\dagger$$

for all homogeneous $a,b\in U_q(L)$. (We stress that this rule defines a conjugation operation on $U_q(L)\otimes U_q(L)$ whereas the usual prescription $(a\otimes b)^\dagger=a^\dagger\otimes b^\dagger$ does not.) Moreover, if γ denotes the principal antiautomorphism on $U_q(L)$, we have[25]

$$\gamma(a^\dagger)=\gamma(a)^\dagger,\quad \forall a\in U_q(L)$$

so that, from Eq. (3),

$$S(a^\dagger)=[S^{-1}(a)]^\dagger,\quad \forall a\in U_q(L).$$

We conclude this section by noting that the operators $T_\pm$ of Eq. (5) satisfy the conjugation rule (up to a scalar)

$$T_+^\dagger=T_-,\quad T_-^\dagger=T_+. \tag{17}$$

Below we assume $T_\pm$ normalized so that Eq. (17) applies. With this convention $\Gamma=T_+T_-$ is a self-adjoint operator with respect to † as is the operator $\Gamma_0\in U_q(L_0)$ of Eq. (7). Taking the conjugate of Eq. (9a) we arrive at

$$T_-T_+T_-=T_-\Gamma=T_-\Gamma_0. \tag{18}$$

Finally we observe that

$$U_q(B)^\dagger=U_q(N),\quad U_q(N)^\dagger=U_q(B),\quad U_q(L)^\dagger=U_q(L).$$

III. TYPICAL COMPONENTS AND INDUCED FORMS

A sesquilinear form $\langle\ ,\ \rangle : V\otimes V\to\mathbb{C}$ on a finite dimensional $U_q(L)$ module V is called *symmetric* if

$$\langle v,w\rangle=\overline{\langle w,v\rangle},\quad \forall v,w\in V$$

and *invariant* if

$$\langle av,v\rangle=\langle v,a^{\dagger}w\rangle,\quad \forall a\in U_q(L);\quad v,w,\in V$$

with † the conjugation operation on $U_q(L)$. If moreover $\langle\ ,\ \rangle$ is nondegenerate then it has all the properties of an inner product except that it is not generally positive definite. When it is, V gives rise to a type I unitary module[25] (and thus is completely reducible) but we do not make this assumption here.

Lemma 3.1: Let V be a finite dimensional $U_q(L)$ module equipped with a symmetric invariant sesquilinear form $\langle\ ,\ \rangle$. If $V(\nu)$, $V(\nu')$ are two irreducible submodules of V with different highest weights, then they are orthogonal under the form.

Proof: Let $v_+^{\nu}, v_+^{\nu'}$ *be the maximal weight vectors of* $V(\nu)$, $V(\nu')$ resp., $\nu\neq\nu'$. Then, since the Cartan elements are self-adjoint under the form, we have

$$\begin{aligned}0&=\langle v_+^{\nu'},v_+^{\nu}\rangle=\langle v_+^{\nu'},U_q(B)v_+^{\nu}\rangle=\langle U_q(N)v_+^{\nu'},v_+^{\nu}\rangle=\langle V(\nu'),v_+^{\nu}\rangle=\langle U_q(L)V(\nu'),v_+^{\nu}\rangle\\&=\langle V(\nu'),U_q(L)v_+^{\nu}\rangle=\langle V(\nu'),V(\nu)\rangle.\end{aligned}$$

□

Note that if $V(\nu)\subseteq V$ is typical then it must split in V. We let

$$\overline{V(\nu)}=V(\nu)\oplus V(\nu)\oplus\cdots\oplus V(\nu)\subseteq V\quad (m\ \text{ copies})$$

(m the multiplicity of $V(\nu)\subseteq V$) be the corresponding isotypic component. If $\langle\ ,\ \rangle$ on V is nondegenerate, our aim here is to show that its restriction to $V(\nu)$ is also nondegenerate, so that an orthogonal labeling scheme can be found which diagonalizes the form on $V(\nu)$. This result is obvious, in view of Lemma 3.1, if V is completely reducible. The problem, however, is that in general V contains indecomposables.[19]

Following Sec. II we set

$$\Gamma=T_+T_-=\Gamma_0+\Gamma_+$$

and recall that $\Gamma_0\in U_q(L_0)$, Γ commute with the elements of $U_q(L_0)$ and are self-adjoint with respect to †. From Eq. (8) we have

$$\Gamma^2=(\Gamma_0+\Gamma_+)\Gamma=\Gamma_0\Gamma=\Gamma\Gamma_0$$

and more generally we obtain

$$\Gamma^{m+1}=\Gamma\Gamma_0^m.$$

Definition 3.1: We say a finite dimensional $U_q(L)$ module V is of *atypical type* if its irreducible composition factors are all atypical. Note that all (nonirreducible) indecomposable modules are of atypical type as are direct sums of irreducible atypical modules.

Proposition 3.1: Let V be a finite dimensional $U_q(L)$ module of atypical type. Then

$$T_-\Gamma_0V=\Gamma\Gamma_0V=(0).$$

Proof: First V decomposes into a direct sum of irreducible $U_q(L_0)$ modules:

$$V=\bigoplus_{\nu} m_\nu V_0(\nu).$$

Next Γ vanishes on all irreducible atypical modules so that Γ must be nilpotent on V; hence we may set $\Gamma^{m+1}=0$, $m\in\mathbb{Z}_+$. Then for each $V_0(\nu)$ we have

$$(0)=\Gamma^{m+1}V_0(\nu)=\Gamma\Gamma_0^m V_0(\nu)=\chi_\nu(\Gamma_0)^m T_+T_-V_0(\nu).$$

Applying T_- to the left we obtain, from Eq. (18),

$$(0)=\chi_\nu(\Gamma_0)^m T_-T_+T_-V_0(\nu)=\chi_\nu(\Gamma_0)^{m+1}T_-V_0(\nu).$$

Thus either $\chi_\nu(\Gamma_0)=0$ or else $T_-V_0(\nu)=(0)$. In either case,

$$T_-\Gamma_0V_0(\nu)=(0),\quad \forall\nu\Rightarrow T_-\Gamma_0V=(0)\Rightarrow T_+T_-\Gamma_0V=\Gamma\Gamma_0V=(0).$$

□

Clearly every finite dimensional $U_q(L)$ module V admits a $U_q(L)$ module decomposition

$$V=V_T\oplus V_A,$$

where V_T is the direct sum of the typical irreducible submodules of V (which split in V), called its *typical component*, and V_A is necessarily of atypical type. From the result above, $\Gamma\Gamma_0V_A=(0)$, so that

$$V_T=U_q(L)\Gamma\Gamma_0V.$$

Proposition 3.2: Let V be a finite dimensional $U_q(L)$ module equipped with a symmetric, invariant nondegenerate sesquilinear form $\langle\ ,\ \rangle$. Then the restriction of $\langle\ ,\ \rangle$ to V_T (or V_A) is nondegenerate.

Proof: Since $\Gamma\Gamma_0=\Gamma_0\Gamma$ is self-adjoint under the form, V_T and V_A must be orthogonal under $\langle\ ,\ \rangle$: indeed

$$\langle V_T,V_A\rangle=\langle U_q(L)\Gamma\Gamma_0V,V_A\rangle=\langle\Gamma\Gamma_0V,U_q(L)V_A\rangle=\langle\Gamma\Gamma_0V,V_A\rangle=\langle V,\Gamma\Gamma_0V_A\rangle=0,$$

where the last equality follows from Proposition 3.1. Thus the restriction of $\langle\ ,\ \rangle$ to V_T (or V_A) is nondegenerate. □

It now follows from Lemma 3.1 and Proposition 3.2 that if $V(\nu)$ is a typical irreducible submodule of V with isotypic component $V(\nu)=mV(\nu)\subseteq V$, then

Corollary (notation as above): The restriction of $\langle\ ,\ \rangle$ to $V(\nu)$ is nondegenerate. □

We recall[31] that every finite dimensional irreducible $U_q(L_0)$ module $V_0(\Lambda)$ with a real highest weight $\Lambda\in D^+$ is equivalent to a unitary module and thus may be equipped with an invariant inner product $\langle\ ,\ \rangle$ so that

$$\langle av,w\rangle=\langle v,a^\dagger w\rangle,\quad \forall a\in U_q(L_0);\quad v,w\in V_0(\Lambda).$$

We may then extend this form to the entire $U_q(L)$ module $V(\Lambda)$ with the definition[25] [notation as in Eq. (12)]

$$\langle V_0(\Lambda),V_k(\Lambda)\rangle=0,\quad 0<k\leqslant d,$$

$$\langle a^\dagger v,w\rangle=\langle v,aw\rangle,\quad \forall a\in U_q^{(1)}(L),$$

$$\langle av_1+\beta v_2,w\rangle=\overline{\alpha}\langle v_1,w\rangle+\overline{\beta}\langle v_2,w\rangle,\quad \forall\alpha,\beta\in\mathbb{C}.$$

Then it can be shown[25,32] that $\langle\ ,\ \rangle$ so defined gives rise to a symmetric, invariant nondegenerate sesquilinear form on $V(\Lambda)$. Moreover,[25,32]

Lemma 3.2: The above form $\langle\ ,\ \rangle$ induced on $V(\Lambda)$ is the unique (up to scalar multiples) symmetric, invariant nondegenerate sesquilinear form on $V(\Lambda)$. □

Throughout we let $\langle\ ,\ \rangle$ denote the above induced form on $V(\Lambda)$ so that its restriction to the maximal $\mathbb{Z}$-graded component $V_0(\Lambda)$ is positive definite (and thus gives rise to an inner product). It is worth noting (by an argument similar to that of Lemma 3.1) that $U_q(L_0)$ modules with different highest weights are orthogonal under this form. In particular the decomposition (12) is orthogonal with respect to $\langle\ ,\ \rangle$.

Given two irreducible finite dimensional $U_q(L)$ modules $V(\Lambda)$, $V(\mu)$ equipped with the natural induced forms, we have a corresponding sesquilinear form induced on $V(\Lambda)\otimes V(\mu)$ in a natural way; viz.

$$\langle w'\otimes v',w\otimes v\rangle=\langle w',w\rangle\langle v',v\rangle,\quad \forall w,w'\in V(\Lambda);\quad v,v'\in V(\mu).$$

Proposition 3.3: The sesquilinear form $\langle\ ,\ \rangle$ on $V(\Lambda)\otimes V(\mu)$ is symmetric, invariant, and nondegenerate.

Proof: It is easily seen that the form is symmetric. As to invariance we have, in the notation of Eq. (2), for all homogeneous $a\in U_q(L)$,

$$\langle\Delta(a)(w'\otimes v'),w\otimes v\rangle=\sum_{(a)}(-1)^{[a_{(2)}][w']}\langle a_{(1)}w'\otimes a_{(2)}v',w\otimes v\rangle.$$

Using

$$\begin{aligned}\langle a_{(1)}w'\otimes a_{(2)}v',w\otimes v\rangle&=\langle a_{(1)}w',w\rangle\langle a_{(2)}v',v\rangle\\&=\langle w',a_{(1)}^{\dagger}w\rangle\langle v',a_{(2)}^{\dagger}v\rangle\\&=(-1)^{[a_{(2)}][w]}\langle w'\otimes v',(a_{(1)}^{\dagger}\otimes a_{(2)}^{\dagger})(w\otimes v)\rangle\end{aligned}$$

we obtain

$$\langle\Delta(a)(w'\otimes v'),w\otimes v\rangle=\sum_{(a)}(-1)^{[a_{(2)}][a_{(1)}]}\langle w'\otimes v',(a_{(1)}^{\dagger}\otimes a_{(2)}^{\dagger})(w\otimes v)\rangle$$

since, for a nonzero contribution, we must have $[w]+[w']=[a_{(1)}]$ (Mod 2). Moreover $(-1)^{[a_{(2)}][a_{(1)}]}(a_{(1)}^{\dagger}\otimes a_{(2)}^{\dagger})=(a_{(1)}\otimes a_{(2)})^{\dagger}$,so that

$$\langle\Delta(a)(w'\otimes v'),w\otimes v\rangle=\langle w'\otimes v',\Delta(a)^{\dagger}(w\otimes v)\rangle=\langle w'\otimes v',\Delta(a^{\dagger})(w\otimes v)\rangle$$

which establishes invariance as required. It thus remains to prove $\langle\ ,\ \rangle$ is nondegenerate. □

To this end let $\{w_i\}$ be a basis for $V(\Lambda)$ and suppose $\Sigma_i w_i\otimes v_i, v_i\in V(\mu)$ belongs to the kernel of $\langle\ ,\ \rangle$ so that

$$\left\langle w\otimes v,\sum_i w_i\otimes v_i\right\rangle=0,\quad \forall w\in V(\Lambda),\quad v\in V(\mu).$$

Then, $\forall v\in V(\mu)$, we have

$$\left\langle w,\sum_i\langle v,v_i\rangle w_i\right\rangle=0,\quad \forall w\in V(\Lambda)\Rightarrow\sum_i\langle v,v_i\rangle w_i=0$$

since the form $\langle\ ,\ \rangle$ on $V(\Lambda)$ is nondegenerate. Since the w_i constitute a basis this implies

$$\langle v,v_i\rangle=0,\quad \forall v\in V(\mu),\quad \forall i\Rightarrow v_i=0,\quad \forall i$$

by the nondegeneracy of the form on $V(\mu)$. Thus $\langle\ ,\ \rangle$ on $V(\Lambda)\otimes V(\mu)$ is nondegenerate. □

We may thus apply the results of Proposition 3.2 and its corollary to the tensor product module $X\equiv V(\Lambda)\otimes V(\mu)$. In particular if $V(\nu)$ is typical and occurs with multiplicity m_ν in X then the restriction of the form $\langle\ ,\ \rangle$ on X to the isotypic component $\overline{V(\nu)}=V(\nu)\oplus\cdots\oplus V(\nu)$ (m_ν copies) is nondegenerate. This implies that an orthogonal decomposition into irreducible submodules

$$\overline{V(\nu)}=\bigoplus_{\xi=1}^{m_\nu} V^\xi(\nu)$$

can be found which diagonalizes the form $\langle\ ,\ \rangle$ restricted to $\overline{V(\nu)}$. In Sec. IV we shall consider a convenient such multiplicity labeling.

Given $v\in V^\xi(\nu)$ we have, since $\langle\ ,\ \rangle$ is symmetric, $\langle v,v\rangle=\langle\overline{v,v}\rangle$, so that $\langle v,v\rangle$ is real. The form $\langle\ ,\ \rangle$ restricted to each $V^\xi(\nu)$ will be nondegenerate and thus, from Lemma 3.2, will coincide with the naturally induced form, up to a real scalar multiple. This leads us to

Definition 3.2 (notation as above): If this scalar multiple is positive (resp. negative) we say that $V^\xi(\nu)$ has *signature* $+1$ (resp. -1); we denote this signature by ϵ_ξ. Thus the form $\langle\ ,\ \rangle$ restricted to the maximal $\mathbb{Z}$-graded component $V_0^\xi(\nu)$ of $V^\xi(\nu)$ will be positive (resp. negative) definite if $\epsilon_\xi=\pm1$, resp. □

We conclude this section with some observations on duality and induced forms. Let $\{w_i\}$ be a $\mathbb{Z}$-graded basis for $V(\Lambda)$ with $g_{ij}=\langle w_i,w_j\rangle$ the *overlap matrix* corresponding to the natural form on $V(\Lambda)$; thus $g_{ij}=0$, unless w_i,w_j belong to the same $\mathbb{Z}$-graded level. Then g is a nonsingular Hermitian matrix and we set $g^{ij}=(g^{-1})_{ij}$. It follows that $w^i=g^{ji}w_j$ (summation on j) gives rise to a basis for $V(\Lambda)$ dual to $\{w_i\}$ under the form

$$\langle w^i,w_j\rangle=\langle w_j,w^i\rangle=\delta^i_j.$$

Moreover, $g^{ij}=\langle w^j,w^i\rangle$, and we have the expansions

$$aw_i=\sum_j\ w_j\langle w^j,aw_i\rangle,\quad aw^i=\sum_j\ w^j\langle w_j,aw^i\rangle.$$

In rep theoretic terms we have the matrix representation defined by

$$aw_i=\sum_j\ \pi_\Lambda(a)_{ji}w_j$$

so that

$$\pi_\Lambda(a)_{ji}=\langle w^j,aw_i\rangle=\langle\overline{aw_i,w^j}\rangle=\langle\overline{w_i,a^\dagger w^j}\rangle\Rightarrow aw^j=\sum_i\ \langle w_i,aw^j\rangle w^i=\sum_i\ \overline{\pi_\Lambda(a^\dagger)_{ji}}w^i. \tag{19}$$

Remarks: Since the basis $\{w_i\}$ is $\mathbb{Z}$-graded it follows that the dual basis vectors w^i,w_i must belong to the same $\mathbb{Z}$-graded component. Moreover the restriction of the natural form $\langle\ ,\ \rangle$ to the minimal $\mathbb{Z}$-graded component, which constitutes an irreducible $U_q(L_0)$ module, will be nondegenerate and thus either positive or negative definite. □

Now let $\{w_i^*\},\{(w^i)^*\}$ be corresponding dual bases for $V(\Lambda)^*$ defined by

$$w_i^*(w_j)=\delta_{ij}=(w^i)^*(w^j).$$

We then have

$$(w^i)^*=g_{ik}w_k^* \quad \text{(summation on } k\text{)}. \tag{20}$$

Proposition 3.4:

$$\langle (w^i)^*, w_j^*\rangle=(-1)^{[i]}\delta_{ij}$$

with $[i]\in\mathbb{Z}_2$ *the degree of basis vector* w_i *and thus* w_i^*, *naturally gives rise to a nondegenerate, symmetric invariant sesquilinear form which is positive definite on the minimal* $\mathbb{Z}$*-graded component of* $V(\Lambda)^*$.

Proof: In view of Eq. (20), the above result may be expressed

$$\langle w_k^*, w_i^*\rangle=(-1)^{[i]}g^{ki}=(-1)^{[i]}\langle w^i, w^k\rangle \tag{*}$$

from which it follows, with this definition, that $\langle , \rangle$ on $V(\Lambda)^*$ gives rise to a nondegenerate sesquilinear form in a natural way. Moreover if w_i, w^i belong to the *maximal* $\mathbb{Z}$-graded component of $V(\Lambda)$ we have

$$\langle w_i^*, w_i^*\rangle=(-1)^{[i]}\langle w^i, w^i\rangle=\langle w^i, w^i\rangle>0,$$

where now w_i^* belongs to the *minimal* $\mathbb{Z}$-graded component of $V(\Lambda)^*$, as required. It remains to establish invariance.

To this end we have, for homogeneous $a\in U_q(L)$ (summation over repeated indices assumed below)

$$\begin{aligned}\langle aw_k^*, w_i^*\rangle&=\langle (-1)^{[a][k]}\pi_\Lambda(\gamma(a))_{kj}w_j^*, w_i^*\rangle\\&=(-1)^{[a][k]}\overline{\pi_\Lambda(\gamma(a))_{kj}}\langle w_j^*, w_i^*\rangle\\&=(-1)^{[a][k]+[i]}\overline{\langle w^k, \gamma(a)w_j\rangle}\langle w^i, w^j\rangle,\end{aligned}$$

where the last equality follows from Eq. (*). Thus

$$\langle aw_k^*, w_i^*\rangle=(-1)^{[a][k]+[i]}\langle w^i, \langle \gamma(a)w_j, w^k\rangle w^j\rangle.$$

Now from Eq. (19) we have

$$\langle \gamma(a)w_j, w^k\rangle w^j=\langle w_j, \gamma(a)^\dagger w^k\rangle w^j=\gamma(a)^\dagger w^k=\gamma(a^\dagger)w^k$$

so that

$$\begin{aligned}\langle aw_k^*, w_i^*\rangle&=(-1)^{[a][k]+[i]}\langle w^i, \gamma(a)^\dagger w^k\rangle\\&=(-1)^{[a][k]+[i]}\langle \gamma(a)w^i, w^k\rangle\\&=(-1)^{[a][k]+[i]}\pi_\Lambda(\gamma(a)^\dagger)_{ij}\langle w^j, w^k\rangle,\end{aligned}$$

where the last step again follows from Eq. (19). Utilizing Eq. (*), we thus obtain

$$\langle aw_k^*, w_i^*\rangle=(-1)^{[a][k]+[i]+[j]}\pi_\Lambda(\gamma(a^\dagger))_{ij}\langle w_k^*, w_j^*\rangle=(-1)^{[a][k]+[a]}\langle w_k^*, \pi_\Lambda(\gamma(a^\dagger))_{ij}w_j^*\rangle$$

since, in order to obtain a nonzero contribution, we must have $[a]=[i]+[j]$ (Mod 2). Now

$$\pi_\Lambda(\gamma(a^\dagger))_{ij}w_j^* = (-1)^{[a][i]}\pi_\Lambda^T(\gamma(a^\dagger))_{ji}w_j^* = (-1)^{[a][i]}\pi_\Lambda^*(a^\dagger)_{ji}w_j^* = (-1)^{[a][i]}a^\dagger w_i^* .$$

Substituting into the above we finally arrive at

$$\langle a w_k^*, w_i^* \rangle = (-1)^{[a]([k]+[i])+[a]}\langle w_k^*, a^\dagger w_i^* \rangle = \langle w_k^*, a^\dagger w_i^* \rangle$$

since, for a nonzero contribution, we must have $[a]=[k]+[i]$ (Mod 2). This completes the proof. □

Throughout the article we may thus assume that the forms induced on $V(\Lambda)$, $V(\Lambda)^*$ are dually related as above. With this convention if $\{w_i\},\{w^i\}$ are $\mathbb{Z}$-graded dual bases under the natural form on $V(\Lambda)$, with $\{w_i^*\},\{(w^i)^*\}$ the corresponding dual bases for $V(\Lambda)^*$, then the dual vector to w_i^* under the form on $V(\Lambda)^*$ is actually $(-1)^{[i]}(w^i)^*$. The significance of the phase $(-1)^{[i]}$ will be apparent later.

Note: The dual basis vectors w_i, w_i^* have the same parity $(-1)^{[i]}$. Thus if we require the maximal $\mathbb{Z}$-graded component $V_0(\Lambda)$ of $V(\Lambda)$ have positive parity, then so too must the minimal $\mathbb{Z}$-graded component of $V(\Lambda)^*$. Hence with our convention the maximal $\mathbb{Z}$-graded component of $V(\Lambda)^*$ will then have positive parity if $V(\Lambda)$ has an odd number of levels and negative parity otherwise.

IV. ORTHOGONAL LABELING FOR $V(\nu)\subseteq V(\Lambda)\otimes V(\mu)$ (μ,ν TYPICAL)

Here we consider an irreducible typical submodule $V(\nu)$ of $X=V(\Lambda)\otimes V(\mu)$ and we assume throughout that $V(\Lambda)$ is arbitrary but $V(\mu)$ is typical. We let $\langle\ ,\ \rangle$ be the natural form on X, induced by the natural forms on $V(\Lambda)$, $V(\mu)$. If $V(\nu)$ occurs in X with multiplicity m_ν we let

$$\overline{V(\nu)} = V(\nu)\oplus V(\nu)\oplus\cdots\oplus V(\nu) \quad (m_\nu \text{ copies})$$

be its isotypic component. We recall that $\overline{V(\nu)}$ splits in X and the restriction of the form $\langle\ ,\ \rangle$ on X to $\overline{V(\nu)}$ is nondegenerate. We let $P[\nu]$ be the corresponding projection onto $\overline{V(\nu)}$ which is self-adjoint under the form.

Throughout an important role is played by the subspace

$$X_0 \equiv V(\Lambda)\otimes V_0(\mu)$$

with $V_0(\mu)$ the maximal $\mathbb{Z}$-graded component of $V(\mu)$ which thus constitutes an irreducible $U_q(L_0)$ module. Clearly X_0 give rise to a $U_q(L_0)$ module and is stable under the action of $U_q(B)$. Moreover X_0 cyclically generates the tensor product space as a $U_q(L)$ module so that, in view of the PBW theorem,

$$X = U_q(L)X_0 = U_q(N)X_0 .$$

The $\mathbb{Z}$ gradation on $V(\Lambda)$ naturally induces a $\mathbb{Z}$ gradation on X_0; given an irreducible $U_q(L_0)$ module $V_0(\nu)\subseteq X_0$, we let $[\nu]$ denote its $\mathbb{Z}$-graded level. It is worth noting that $V_0(\mu)$ is orthogonal, under the natural form, to the remaining $\mathbb{Z}$-graded levels of $V(\mu)$, so that $\langle\ ,\ \rangle$ restricted to X_0 is nondegenerate. We let P_0 denote the orthogonal projection onto X_0, induced by the $\mathbb{Z}$ gradation on $V(\mu)$, so that P_0 is self-adjoint under the form $\langle\ ,\ \rangle$, and commutes with the action of $U_q(L_0)$.

Now let $\overline{V(\nu)}$ be the isotypic component of $V(\nu)\subseteq X$ with $\nu\in D^+$ typical, as above, and let

$$\overline{V_0(\nu)} = V_0(\nu)\oplus\cdots\oplus V_0(\nu) \quad (m_\nu \text{ copies})$$

be its maximal $\mathbb{Z}$-graded component so that $V_0(\nu)$ is an irreducible $U_q(L_0)$ module. We let $X_0(\nu)\subseteq X_0$ be the isotypic component of $V_0(\nu)\subseteq X_0$ so that the form $\langle\ ,\ \rangle$ restricted to $X_0(\nu)$ is nondegenerate. We then have a $U_q(L_0)$ module homomorphism $P_0: V_0(\nu)\to X_0(\nu)$. Here we show that this in fact determines an isomorphism. We first need

Lemma 4.1: Let $V_\nu = U_q(L)V_0(\nu)$ be the $U_q(L)$ module generated by $V_0(\nu)\subseteq X_0(\nu)$. Then V_ν contains a (unique) typical irreducible $U_q(L)$ module $V(\nu)$.

Proof: With the notation of Sec. II, we first observe that $\Delta(T_-)V_0(\nu)\neq(0)$, since, in view of Eq. (9b):

$$\Delta(T_-)V_0(\nu)=(0)\Rightarrow(1\otimes T_+)\Delta(T_-)V_0(\nu)=(0)$$

$$\Rightarrow(q^{h_{\rho_1}}\otimes T_+T_-)V_0(\nu)=(0)$$

$$\Rightarrow q^{(\nu-\mu,\rho_1)}\chi_\mu(\Gamma_0)V_0(\nu)=(0)$$

which would imply, since μ is typical, that $V_0(\nu)=(0)$, a contradiction.

Thus $\Delta(T_-)V_0(\nu)\neq(0)$ must be the lowest component of a typical $U_q(L)$ module (since $\nu\in D^+$ is typical) which must therefore generate an irreducible typical module $V(\nu)\subseteq V_\nu$.

Note: Above we used the fact that for $v\in V_0(\mu)$, $T_+T_-v=\Gamma v=\Gamma_0 v=\chi_\mu(\Gamma_0)v$, which follows from Eq. (7).

Proposition 4.1: (notation as above).
$P_0: V_0(\nu)\to X_0(\nu)$ determines a $U_q(L_0)$ module isomorphism.

Proof: It suffices to show P_0 is bijective. To see it suppose $V_0(\nu)\subseteq X_0(\nu)$ is orthogonal to $P_0\overline{V_0}(\nu)$ under $\langle\ ,\ \rangle$. Then

$$0=\langle P_0\overline{V_0}(\nu),V_0(\nu)\rangle=\langle\overline{V_0}(\nu),V_0(\nu)\rangle=\langle\overline{V(\nu)},V_0(\nu)\rangle\Rightarrow P[\nu]V_0(\nu)=(0)$$

which is impossible, since by Lemma 4.1, $U_q(L)V_0(\nu)$ contains a (unique) typical irreducible submodule $V(\nu)$ so that

$$(0)\neq V(\nu)=P[\nu]U_q(L)V_0(\nu)=U_q(L)P[\nu]V_0(\nu).$$

Since the form $\langle\ ,\ \rangle$ restricted to $X_0(\nu)$ is nondegenerate, this shows that $P_0\overline{V_0}(\nu)=X_0(\nu)$.

To prove P_0 is $1-1$ suppose $V_0(\nu)\subseteq V(\nu)$ is in the kernel of P_0 (which constitutes a $U_q(L_0)$ module) so that $P_0V_0(\nu)=(0)$. Then we have

$$0=\langle X_0,V_0(\nu)\rangle=\langle U_q(B)X_0,V_0(\nu)\rangle=\langle X_0,U_q(N)V_0(\nu)\rangle$$
$$=\langle X_0,V(\nu)\rangle=\langle X_0,U_q(L)V_0(\nu)\rangle=\langle U_q(L)X_0,V_0(\nu)\rangle=\langle X,V_0(\nu)\rangle\Rightarrow V_0(\nu)=(0).$$

Thus P_0 must be $1-1$ and the result is proved. □

Corollary: m_ν=multiplicity of $V_0(\nu)\subseteq V(\Lambda)\otimes V_0(\mu)$.

Remarks: The above establishes the useful result that for typical $\nu,\mu\in D^+$, the multiplicity of $V(\nu)\subseteq V(\Lambda)\otimes V(\mu)$ is equal to the multiplicity of $V_0(\nu)\subseteq V(\Lambda)\otimes V_0(\mu)$. The latter can be obtained from the $L\downarrow L_0$ branching rules for $V(\Lambda)$ together with the known[33] characters of the finite dimensional irreducible L_0 modules.

We note that $P[\nu]: X_0(\nu)\to V_0(\nu)\subseteq V(\nu)$ also determines a $U_q(L_0)$ module homomorphism in the reverse direction. In view of Lemma 4.1, $P[\nu]$ must be $1-1$ since its kernel, which constitutes a $U_q(L_0)$ module, is trivial: indeed given $V_0(\nu)\subseteq X_0(\nu)$ we have

$$U_q(L)P[\nu]V_0(\nu)=P[\nu]U_q(L)V_0(\nu)\supseteq V(\nu)\neq(0)$$

with $V(\nu)$ the (unique) typical submodule of $V_\nu=U_q(L)V_0(\nu)$. On the other hand, from Proposition 4.1, we have $\dim X_0(\nu)=\dim V_{(0)}(\nu)$, so that $P[\nu]$ must also be onto. We thus arrive at

Proposition 4.2 (notation as above):

$$P[\nu]:X_0(\nu)\to\overline{V_0}(\nu) \text{ determines a } U_q(L_0) \text{ module isomorphism.}$$

□

Below we assume an orthogonal decomposition of $\overline{V_0}(\nu)\subseteq\overline{V(\nu)}$ into eigenspaces of the $U_q(L_0)$ invariant operator $P[\nu]P_0P[\nu]$, which is self-adjoint under the form $\langle\ ,\ \rangle$ on $X=V(\Lambda)\otimes V(\mu)$:

$$\overline{V_0}(\nu)=\bigoplus_\xi V_0^\xi(\nu) \quad \text{(orthogonal direct sum)}$$

with $V_0^\xi(\nu)$ an irreducible $U_q(L_0)$ module constituting an eigenspace of $P[\nu]P_0P[\nu]$ with eigenvalue λ_ξ, say. We allow for the possibility that some eigenvalues may be equal; i.e., $\lambda_\xi=\lambda_\xi$, $\xi\neq\xi'$, but we may still assume orthogonality of the corresponding eigenspaces. The above decomposition induces a $U_q(L)$ module decomposition

$$\overline{V(\nu)}=\bigoplus_\xi V^\xi(\nu), \tag{21}$$

where $V^\xi(\nu)=U_q(L)V_0^\xi(\nu)=U_q(N)V_0^\xi(\nu)$ is an irreducible $U_q(L)$ module.

Lemma 4.2: The decomposition (21) *is orthogonal.*

Proof: For $\xi\neq\xi'$ we have

$$0=\langle V_0^\xi(\nu),V_0^{\xi'}(\nu)\rangle=\langle U_q(B)V_0^\xi(\nu),V_0^{\xi'}(\nu)\rangle=\langle V_0^\xi(\nu),U_q(N)V_0^{\xi'}(\nu)\rangle=\langle V_0^\xi(\nu),V^{\xi'}(\nu)\rangle$$
$$=\langle V_0^\xi(\nu),U_q(L)V^{\xi'}(\nu)\rangle=\langle U_q(L)V_0^\xi(\nu),V^{\xi'}(\nu)\rangle.=\langle V^\xi(\nu),V^{\xi'}(\nu)\rangle.$$

□

Throughout the remainder of this section we adopt this orthogonal multiplicity labeling (although our final results will be independent of the labeling chosen). In view of Proposition 4.1, we have a $U_q(L_0)$ module direct sum decomposition

$$X_0(\nu)=\bigoplus_\xi V_0(\nu,\xi)\subseteq X_0, \tag{22}$$

where $V_0(\nu,\xi)\equiv P_0V_0^\xi(\nu)$ is an irreducible $U_q(L_0)$ module.

Lemma 4.3:

(i) *$V_0(\nu,\xi)$ is an eigenspace of $P_0P[\nu]P_0$ with eigenvalue λ_ξ.*

(ii) *The decomposition (22) is orthogonal.*

Proof: (i) Let $v_0^\xi=P_0v^\xi\in V_0(\nu,\xi)$, where $v^\xi\in V_0^\xi(\nu)$ so that v^ξ is an eigenvector of $P[\nu]P_0P[\nu]$ with eigenvalue λ_ξ. Then

$$P[\nu]v_0^\xi=P[\nu]P_0v^\xi=P[\nu]P_0P[\nu]v^\xi=\lambda_\xi v^\xi\Rightarrow P_0P[\nu]P_0v_0^\xi=P_0P[\nu]v_0^\xi=\lambda_\xi P_0v^\xi=\lambda_\xi v_0^\xi$$

which is sufficient to prove the result.

(ii) For $\xi\neq\xi'$ we have, since $V_0^\xi(\nu)$ are eigenspaces of $P[\nu]P_0P[\nu]$,

$$\langle V_0(\nu,\xi),V_0(\nu,\xi')\rangle=\langle P_0V_0^\xi(\nu),V_0(\nu,\xi')\rangle=\langle V_0^\xi(\nu),V_0(\nu,\xi')\rangle=\langle V_0^\xi(\nu),P_0V_0^{\xi'}(\nu)\rangle$$
$$=\langle V_0^\xi(\nu),P[\nu]P_0P[\nu]V_0^{\xi'}(\nu)\rangle=\langle V_0^\xi(\nu),V_0^{\xi'}(\nu)\rangle=0$$

as required. □

It is worth noting that the eigenvalues λ_ξ are real, since $P[\nu]P_0P[\nu]$ is self-adjoint under the form $\langle\ ,\ \rangle$, moreover

Lemma 4.4.: The eigenvalues λ_ξ are all nonzero.

Proof: Suppose $\lambda_\xi=0$ for some ξ, so that $P[\nu]P_0P[\nu]V_0^\xi(\nu)=(0)$. Then for $V_0(\nu,\xi)=P_0V_0^\xi(\nu)$ we have

$$P[\nu]V_0(\nu,\xi)=P[\nu]P_0V_0^\xi(\nu)=P[\nu]P_0P[\nu]V_0^\xi(\nu)=(0)$$

in contradiction to Proposition 4.2.

Corollary: $P[\nu]V_0(\nu,\xi)=V_0^\xi(\nu)$. In particular $V^\xi(\nu)$ is the unique irreducible submodule of highest weight ν contained in $U_q(L)V_0(\nu,\xi)$.

Proof: From above,

$$P[\nu]V_0(\nu,\xi)=P[\nu]P_0P[\nu]V_0^\xi(\nu)=V_0^\xi(\nu)$$

from which the result follows. □

Since the decompositions (21) and (22) are orthogonal, the restriction of the form $\langle\ ,\ \rangle$ on X to $V^\xi(\nu)$ is nondegenerate as is its restriction to $V_0(\nu,\xi)\subseteq X_0$. We let $P[\nu,\xi]$ be the orthogonal projection onto $V^\xi(\nu)$, which is thus self-adjoint under the form and commutes with the action of $U_q(L)$; we therefore have

$$P[\nu,\xi]X=P[\nu,\xi]\overline{V(\nu)}=V^\xi(\nu).$$

We denote the orthogonal projection onto $V_0(\nu,\xi)$, which is self-adjoint and commutes with the action of $U_q(L_0)$, by $P_0[\nu,\xi]$. We conclude this section with some technical results of importance below.

Lemma 4.5: Let $V_0(\nu')\subseteq X_0$ be an irreducible $U_q(L_0)$ module with highest weight ν'. Then

(i) *$P[\nu,\xi]V_0(\nu')=(0)$ unless $\nu'\leqslant\nu$.*

(ii) *$\Delta(T_-)P[\nu,\xi]V_0(\nu')=(0)$, $\nu\neq\nu'$. Moreover, in the case $\nu'=\nu$, we have $\Delta(T_-)P[\nu,\xi]V_0(\nu)=(0)$, if $V_0(\nu)$ is orthogonal to $V_0(\nu,\xi)$.*

Proof: (i) The $U_q(L)$ module generated by $V_0(\nu')$ will consist of a direct sum of typical irreducible modules with highest weights $\nu''\geqslant\nu'$ plus an atypical component (possibly zero). Thus

$$P[\nu,\xi]V_0(\nu')=(0)\quad\text{unless}\quad\nu\geqslant\nu',$$

where we have used the result that $\overline{V(\nu)}$ is orthogonal to the atypical component of X.

As to (ii), the last statement is obvious from the corollary to Lemma 4.4. Also from part (i),

$$\Delta(T_-)P[\nu,\xi]V_0(\nu')=(0),\quad\text{unless}\quad\nu\geqslant\nu'.$$

It thus remains to consider the case $\nu>\nu'$. Then we must have

$$\Delta(T_-)P[\nu,\xi]V_0(\nu')=(0),$$

or else the left-hand side will give a $U_q(L_0)$ submodule of $V^\xi(\nu)$ with highest weight $\nu'-2\rho_1$ which is less than the highest weight $\nu-2\rho_1$ of the minimal $\mathbb{Z}$-graded component of $V^\xi(\nu)$, which is impossible. □

Utilizing this result we arrive at

Proposition 4.3: (notation as above).

$$\Delta(T_-)P[\nu,\xi]P_0=\Delta(T_-)P_0[\nu,\xi].$$

Proof: In view of the corollary to Lemma 4.4, $(1-P[\nu,\xi])V_0(\nu,\xi)$ is contained in a direct sum of typical irreducible modules with highest weights $\nu'>\nu$ plus possibly an atypical component. Thus, from Proposition 3.1 and the Lemma above, we have

$$(0)=\Delta(T_-)\Delta(\Gamma_0)(1-P[\nu,\xi])V_0(\nu,\xi)=\chi_\nu(\Gamma_0)\Delta(T_-)(1-P[\nu,\xi])V_0(\nu,\xi).$$

Since ν is typical, $\chi_\nu(\Gamma_0)\neq 0$ so that

$$\Delta(T_-)(1-P[\nu,\xi])V_0(\nu,\xi)=(0)$$

or

$$\Delta(T_-)V_0(\nu,\xi)=\Delta(T_-)P[\nu,\xi]V_0(\nu,\xi)$$

which, in view of Lemma 4.5, is sufficient to prove the result.

V. SUPERTRACE RESULT ($\nu,\mu\in D^+$ TYPICAL)

Throughout we adopt the orthogonal labeling for $\overline{V(\nu)}\subseteq X=V(\Lambda)\otimes V(\mu)$ of Sec. IV. We let $\{e(\nu)_\alpha\}$ be a ($\mathbb{Z}$-graded) basis for $V(\nu)$ with corresponding dual basis $\{\underline{e}(\nu)^\alpha\}$ under the natural form on $V(\nu)$. We let $\{e^\xi(\nu)_\alpha\}$ be the corresponding basis for $V^\xi(\nu)\subseteq V(\nu)$ and assume the labeling normalized so that

$$\langle e^\xi(\nu)_\alpha, e^{\xi'}(\nu)_\beta\rangle=\epsilon_\xi\delta_{\xi\xi'}\langle e(\nu)_\alpha, e(\nu)_\beta\rangle$$

with $\epsilon_\xi=\pm 1$ the signature of $V^\xi(\nu)$ (cf. Definition 3.2). Then ξ gives rise to a $U_q(L)$ module homomorphism

$$\xi: V(\nu)\to V(\Lambda)\otimes V(\mu),\quad \xi(e(\nu)_\alpha)=e^\xi(\nu)_\alpha \tag{23}$$

in a natural way. It is worth noting that $e^\xi(\nu)^\alpha\equiv\epsilon_\xi\xi(e(\nu)^\alpha)$ constitutes a dual basis to $\{e^\xi(\nu)_\alpha\}$ under the form $\langle\ ,\ \rangle$ on X restricted to $V^\xi(\nu)$:

$$\langle e^\xi(\nu)^\alpha, e^{\xi'}(\nu)_\beta\rangle=\delta_{\xi\xi'}\delta^\alpha_\beta.$$

We now set

$$P[\nu]_{\xi\xi'}=\sum_\alpha |e^\xi(\nu)_\alpha\rangle\langle e^{\xi'}(\nu)^\alpha|=\epsilon_\xi\epsilon_{\xi'}\sum_\alpha |e^\xi(\nu)^\alpha\rangle\langle e^{\xi'}(\nu)_\alpha| \tag{24}$$

which commute with the action of $U_q(L)$ and satisfy the algebra

$$P[\nu]_{\xi\xi'}P[\nu]_{\eta\eta'}=\delta_{\xi'\eta}P[\nu]_{\xi\eta'},\quad P[\nu]^\dagger_{\xi\xi'}=\epsilon_\xi\epsilon_{\xi'}P[\nu]_{\xi'\xi}.$$

Note that the orthogonal projection onto $V^\xi(\nu)\subseteq\overline{V(\nu)}$ is given by $P[\nu,\xi]=P[\nu]_{\xi\xi}$. Our aim here is to prove the result

Theorem 5.1:

$$\mathrm{str}_q\otimes\mathrm{str}_q[\Delta(T_+)P[\nu]_{\xi\xi'}(1\otimes T_-)]=(-1)^{|\Phi_1^+|}q^{4(\rho,\rho_1)}\mathrm{str}_q\otimes\mathrm{str}_q[\Delta(T_-)P[\nu]_{\xi\xi'}(1\otimes T_+)]=\delta_{\xi\xi'\eta},$$

where η is a constant independent of ξ given by

$$\eta=(-1)^{[\nu]}q^{-(\mu+\nu,\rho_1)}\chi_\mu(\Gamma_0)D_q^0[\nu],$$

with $[\nu]$ the $\mathbb{Z}$-graded level of $V_0(\nu)\subseteq V(\Lambda)\otimes V_0(\mu)$.

Note. It is easily checked that the first equation above holds directly by conjugation: recall, for $A\in\mathrm{End}(X)$, that $\mathrm{str}_q(A^*)=\mathrm{str}_q(A^\dagger)$, where $A^\dagger$ is the adjoint of A with respect to the form $\langle\ ,\ \rangle$ on X. It thus suffices to prove the second formula. □

We begin with the diagonal case $\xi=\xi'$. Then utilizing Proposition 4.3 we have, since $(1\otimes T_+)X=X_0$,

$$\begin{aligned}
&\mathrm{str}_q\otimes\mathrm{str}_q[\Delta(T_-)P[\nu,\xi](1\otimes T_+)]\\
&\quad=\mathrm{str}_q\otimes\mathrm{str}_q[\Delta(T_-)P_0[\nu,\xi](1\otimes T_+)]\\
&\quad=\mathrm{str}\otimes\mathrm{str}[\Delta(q^{2h_\rho})\Delta(T_-)P_0[\nu,\xi](1\otimes T_+)]\\
&\quad=q^{-4(\rho,\rho_1)}\mathrm{str}\otimes\mathrm{str}[\Delta(T_-)\Delta(q^{2h_\rho})P_0[\nu,\xi](1\otimes T_+)]\\
&\quad=q^{-4(\rho,\rho_1)}(-1)^{|\Phi_1^+|}\mathrm{str}\otimes\mathrm{str}[(1\otimes T_+)\Delta(T_-)\Delta(q^{2h_\rho})\\
&\qquad\times P_0[\nu,\xi]],
\end{aligned}$$

where the last equality follows from the cyclic rule of supertraces. Now [cf. Eq. (9b)]

$$\begin{aligned}
(1\otimes T_+)\Delta(T_-)P_0&=(q^{h_{\rho_1}}\otimes T_+T_-)P_0=\chi_\mu(\Gamma_0)(q^{h_{\rho_1}}\otimes 1)P_0\Rightarrow(1\otimes T_+)\Delta(T_-)P_0[\nu,\xi]\\
&=q^{(\rho_1,\nu-\mu)}\chi_\mu(\Gamma_0)P_0[\nu,\xi].
\end{aligned}\tag{25}$$

Substituting into the above we arrive at

$$\begin{aligned}
\mathrm{str}_q\otimes\mathrm{str}_q[\Delta(T_-)P[\nu,\xi](1\otimes T_+)]&=(-1)^{|\Phi_1|^+}q^{-4(\rho,\rho_1)}\chi_\mu(\Gamma_0)q^{(\rho_1,\nu-\mu)}\mathrm{str}\\
&\quad\otimes\mathrm{str}[\Delta(q^{2h_\rho})P_0[\nu,\xi]]\\
&=(-1)^{|\Phi_1|^+}q^{-4(\rho,\rho_1)}\eta
\end{aligned}$$

with η as in the statement of the theorem.

For the nondiagonal case a bit more work is required. Let $\{e_0^\xi(\nu)_k\}$ be a basis for the maximal $\mathbb{Z}$-graded component $V_0^\xi(\nu)$ of $V^\xi(\nu)$ with dual basis $\{e_0^\xi(\nu)^k\}$ under the form $\langle\ ,\ \rangle$ on X and let $\{e_0(\nu,\xi)_k\}$, $\{e_0(\nu,\xi)^k\}$ be corresponding dual bases for $V_0(\nu,\xi)\subseteq X_0$. Recall that $\langle\ ,\ \rangle$ restricted to the irreducible $U_q(L_0)$ modules $V_0^\xi(\nu)$, $V_0(\nu,\xi)$ is nondegenerate and thus either positive or negative definite; we let $\epsilon=\pm1$ be the *relative* signature of the two forms (the signature of the form on $V_0^\xi(\nu)$ is ϵ_ξ, defined previously).

We may thus write

$$P_0e_0^\xi(\nu)_k=\alpha_\xi e_0(\nu,\xi)_k,\quad P_0e_0^\xi(\nu)^k=\epsilon\alpha_\xi e_0(\nu,\xi)^k,\tag{26}$$

where $\alpha_\xi\in\mathbb{C}$: note, from Proposition 4.1, that $\alpha_\xi\neq0$. Clearly (no summation)

$$\begin{aligned}
|\alpha_\xi|^2&=\epsilon\langle P_0e_0^\xi(\nu)^k,P_0e_0^\xi(\nu)_k\rangle=\epsilon\langle e_0^\xi(\nu)^k,P_0e_0^\xi(\nu)_k\rangle=\epsilon\langle e_0^\xi(\nu)^k,P[\nu]P_0P[\nu]e_0^\xi(\nu)_k\rangle\\
&=\epsilon\lambda_\xi\langle e_0^\xi(\nu)^k,e_0^\xi(\nu)_k\rangle=\epsilon\lambda_\xi>0.
\end{aligned}$$

Since $|\alpha_\xi|^2=\epsilon\lambda_\xi\neq0$ (cf. also with Lemma 4.4), Eq. (26) implies

$$\begin{aligned}
P[\nu,\xi]e_0(\nu,\xi)_k&=P[\nu]e_0(\nu,\xi)_k=\alpha_\xi^{-1}P[\nu]P_0e_0^\xi(\nu)_k=\alpha_\xi^{-1}P[\nu]P_0P[\nu]e_0^\xi(\nu)_k=\alpha_\xi^{-1}\lambda_\xi e_0^\xi(\nu)_k\\
&=\epsilon\overline{\alpha_\xi}e_0^\xi(\nu)_k.
\end{aligned}\tag{27}$$

Thus we may write

$$\Delta(T_-)P[\nu]_{\xi\xi'}P_0=\Delta(T_-)P[\nu]_{\xi\xi'}P_0[\nu,\xi']=\epsilon'\overline{\alpha}_{\xi'}\Delta(T_-)\sum_k |e_0^{\xi}(\nu)_k\rangle\langle e_0(\nu,\xi')^k|,$$

where the last equality follows from Eq. (27) together with the definition of $P[\nu]_{\xi\xi'}$. Utilizing Eq. (27) then gives

$$\epsilon\overline{\alpha}_{\xi}\Delta(T_-)P[\nu]_{\xi\xi'}P_0=\epsilon'\overline{\alpha}_{\xi'}\Delta(T_-)P[\nu,\xi]\sum_k |e_0(\nu,\xi)_k\rangle\langle e_0(\nu,\xi')^k|=\epsilon'\overline{\alpha}_{\xi'}\Delta(T_-)P_0[\nu]_{\xi\xi'},$$

where the last equality follows from Proposition 4.3 and

$$P_0[\nu]_{\xi\xi'}\equiv\sum_k |e_0(\nu,\xi)_k\rangle\langle e_0(\nu,\xi')^k|$$

determines a $U_q(L_0)$ module isomorphism from $V_0(\nu,\xi')$ to $V_0(\nu,\xi)$.

For $\xi\neq\xi'$, these latter spaces are orthogonal, so we arrive at

$$\begin{aligned}\epsilon\overline{\alpha}_{\xi}\mathrm{str}_q\otimes\mathrm{str}_q(\Delta(T_-)P[\nu]_{\xi\xi'}(1\otimes T_+))&=\epsilon'\overline{\alpha}_{\xi'}\mathrm{str}_q\otimes\mathrm{str}_q[\Delta(T_-)P_0[\nu]_{\xi\xi'}(1\otimes T_+)]\\&=\epsilon'\overline{\alpha}_{\xi'q}^{4(\rho,\rho_1)}\mathrm{str}\otimes\mathrm{str}[\Delta(T_-)\Delta(q^{2h_\rho})P_0[\nu]_{\xi\xi'}(1\otimes T_+)]\\&=\epsilon'\overline{\alpha}_{\xi'q}^{4(\rho,\rho_1)}(-1)^{|\Phi_1^+|}\mathrm{str}\otimes\mathrm{str}[(1\\&\quad\otimes T_+)\Delta(T_-)\Delta(q^{2h_\rho})P_0[\nu]_{\xi\xi'}]\\&=\epsilon'\overline{\alpha}_{\xi'q}^{4(\rho,\rho_1)}(-1)^{|\Phi_1^+|}q^{(\rho_1,\nu-\mu)}\mu_\mu(\Gamma_0)\mathrm{str}\\&\quad\otimes\mathrm{str}[\Delta(q^{2h_\rho})P_0[\nu]_{\xi\xi'}]=0,\end{aligned}$$

where we have employed Eq. (25) and the first equality follows from $(1\otimes T_+)X=X_0$.

This establishes the theorem as required. We now show that this result holds for an arbitrary multiplicity labeling for $V(\nu)\subseteq V(\Lambda)\otimes V(\mu)$, and not just the orthogonal scheme adopted above.

Extension to a general labeling

As above, let m_ν be the multiplicity of $V(\nu)\subseteq X=V(\Lambda)\otimes V(\mu)$ and let $f_{\xi\xi'}$ be the entries of an arbitrary $m_\nu\times m_\nu$ nonsingular matrix. Corresponding to a basis $\{e(\nu)_\alpha\}$ for $V(\nu)$, with dual basis $\{e(\nu)^\alpha\}$, we define a new labeling scheme:

$$e_\xi(\nu,f\ )_\alpha=f_{\xi'\xi}e^{\xi'}(\nu)_\alpha$$

(summation over repeated indices assumed here and below), giving the (not necessarily orthogonal) decomposition into $U_q(L)$ modules:

$$\overline{V(\nu)}=\bigoplus_\xi V_\xi(\nu,f\ ).$$

Note that any given labeling scheme is obtainable this way and that

$$\langle e^{\xi'}(\nu)^\alpha,e_\xi(\nu,f\ )_\beta\rangle=\delta^\alpha_\beta f_{\xi'\xi}.$$

We now introduce a *left* dual basis $e^{\xi}(\nu,f\ )^\alpha$ defined by

$$\langle e^{\xi'}(\nu,f\ )^\alpha,e_\xi(\nu,f\ )_\beta\rangle=\delta^{\xi'}_\xi\delta^\alpha_\beta$$

so that

$$e^{\xi}(\nu,f\ )^{\alpha}=\overline{f^{\xi\xi''}}e^{\xi''}(\nu)^{\alpha},$$

where $f^{\xi\xi''}\equiv(f^{-1})_{\xi\xi''}$. We set

$$P_f[\nu]_{\xi\xi'}=|e_{\xi}(\nu,f\ )_{\alpha}\rangle\langle e^{\xi'}(\nu,f\ )^{\alpha}|=f_{\xi''\xi}|e^{\xi''}(\nu)_{\alpha}\rangle\langle e^{\xi'''}(\nu)^{\alpha}|f^{\xi'\xi'''}=f_{\xi''\xi}P[\nu]_{\xi''\xi'''}f^{\xi'\xi'''}$$

with $P[\nu]_{\xi\xi'}$ as in Eq. (24). Thus $P_f[\nu,\xi]\equiv P_f[\nu]_{\xi\xi}$ is the (not necessarily orthogonal) projection onto $V_{\xi}(\nu,f\ )$. As a generalization of Theorem 5.1 we have

Theorem 5.2:

$$\begin{aligned}\mathrm{str}_q\otimes\mathrm{str}_q[\Delta(T_+)P_f[\nu]_{\xi\xi'}(1\otimes T_-)]&=(-1)^{|\Phi_1^+|}q^{4(\rho,\rho_1)}\mathrm{str}_q\otimes\mathrm{str}_q[\Delta(T_-)P_f[\nu]_{\xi\xi'}(1\otimes T_+)]\\&=\delta_{\xi\xi'}\eta\end{aligned}$$

with η as in Theorem 5.1.

Proof: Using the results above, together with Theorem 5.1, we obtain

$$\begin{aligned}\mathrm{str}_q\otimes\mathrm{str}_q[\Delta(T_+)P_f[\nu]_{\xi\xi'}(1\otimes T_-)]&=f_{\xi''\xi}\mathrm{str}_q\otimes\mathrm{str}_q[\Delta(T_+)P[\nu]_{\xi''\xi'''}(1\otimes T_-)]f^{\xi'\xi'''}\\&=f_{\xi''\xi}\eta\delta_{\xi''\xi'''}f^{\xi'\xi'''}\\&=\eta f^{\xi'\xi''}f_{\xi''\xi}=\eta\delta_{\xi'\xi}\end{aligned}$$

with η as in Theorem 5.1, as required. In a similar way we can establish the second formula. □

The advantage of this result is that it shows Theorem 5.1 in fact applies to an arbitrary multiplicity labeling, and not just the orthogonal scheme adopted in Sec. IV. We shall now apply the result of Theorem 5.2 to investigate the $1-1$ correspondence between the imbeddings $V(\nu)\subseteq V(\Lambda)\otimes V(\mu)$ and $V(\mu)\subseteq V(\Lambda)^*\otimes V(\nu)$, for $\mu,\nu\in D^+$ typical.

VI. INDUCED LABELING FOR $V(\mu)\subseteq V(\Lambda)^*\otimes V(\nu)$ ($\mu,\nu\in D^+$ TYPICAL)

Here we investigate the relationship between the imbeddings $V(\nu)\subseteq V(\Lambda)\otimes V(\mu)$ and $V(\mu)\subseteq V(\Lambda)^*\otimes V(\nu)$ for typical $\mu,\nu\in D^+$ (but $\Lambda\in D^+$ arbitrary). We denote the multiplicity of $V(\mu)\subseteq V(\Lambda)^*\otimes V(\nu)$ by $m(\mu;\Lambda^*\otimes\nu)$ and similarly for $V(\nu)\subseteq V(\Lambda)\otimes V(\mu)$.

Lemma 6.1: $m(\nu;\Lambda\otimes\mu)=m(\mu;\Lambda^*\otimes\nu)$.

Proof: From Lemma 2.1 we have

$$\begin{aligned}m(\nu;\Lambda\otimes\mu)&=\dim\ \mathrm{Hom}_{U_q(L)}(V(\nu),V(\Lambda)\otimes V(\mu))\\&=\text{multiplicity of identity irrep in } V(\nu)^*\otimes V(\Lambda)\otimes V(\mu)\\&=\text{multiplicity of identity irrep in } V(\mu)^*\otimes V(\Lambda)^*\otimes V(\nu)\\&=\dim\ \mathrm{Hom}_{U_q(L)}(V(\mu),V(\Lambda)^*\otimes V(\nu))\\&=m(\mu;\Lambda^*\otimes\nu).\end{aligned}$$

□

Here we assume the orthogonal labeling scheme $V^{\xi}(\nu)$ for $V(\nu)\subseteq V(\Lambda)\otimes V(\mu)$ considered in Sec. IV. Associated with $V^{\xi}(\nu)$ is a $U_q(L)$ module monomorphism (natural imbedding) ξ: $V(\nu)\to V(\Lambda)\otimes V(\mu)$ given by Eq. (23). We let $\xi^{\dagger}$: $V(\Lambda)\otimes V(\mu)\to V(\nu)$ be its conjugate, which thus also defines a $U_q(L)$ module homomorphism; explicity

$$\langle \xi^\dagger(w\otimes v^\mu), e^\nu\rangle = \langle w\otimes v^\mu, \xi(e^\nu)\rangle, \quad \forall w\in V(\Lambda), \quad v^\mu\in V(\mu), \quad e^\nu\in V(\nu),$$

where $\langle\ ,\ \rangle$ is the natural form on $V(\Lambda)\otimes V(\mu)$. We note that $\xi^\dagger\xi'$: $V(\nu)\to V(\nu)$ is an isomorphism and by construction of the labeling

$$\xi^\dagger\xi' = \epsilon_\xi \delta_{\xi\xi'} I,$$

where I denotes the identity operator on $V(\nu)$ and ϵ_ξ is the signature of the form $\langle\ ,\ \rangle$ restricted to $V^\xi(\nu)$ (cf. Definition 3.2).

We note, however, that if $\{e(\nu)_\alpha\}$ is a basis for $V(\nu)$ with corresponding dual basis $\{e(\nu)^\alpha\}$ under the natural form on $V(\nu)$, then

$$\xi'\xi^\dagger(w\otimes v) = \sum_\alpha\ \xi'|e(\nu)_\alpha\rangle\langle e(\nu)^\alpha, \xi^\dagger(w\otimes v)\rangle$$

$$= \epsilon_\xi \sum_\alpha\ |e^{\xi'}(\nu)_\alpha\rangle\langle e^\xi(\nu)^\alpha, w\otimes v\rangle, \quad \forall w\in V(\Lambda), \quad v\in V(\mu)$$

so that

$$\xi'\xi^\dagger = \epsilon_\xi P[\nu]_{\xi'\xi}$$

with $P[\nu]_{\xi'\xi}$ as in Eq. (24).

Now let $\{w_i\}$ be a weight basis for $V(\Lambda)$, which is thus naturally $\mathbb{Z}$-graded, with corresponding dual basis $\{w_i^*\}$ for $V(\Lambda)^*$. Following Lemma 2.2, corresponding to ξ as defined, we introduce a linear map $\hat\xi$: $V(\mu)\to V(\Lambda)^*\otimes V(\nu)$ defined by

$$\hat\xi(v) = \sum_i\ (-1)^{[i]}(q^{-h_\rho}w_i^*)\otimes\xi^\dagger(w_i\otimes v), \quad \forall v\in V(\mu). \tag{28}$$

Lemma 6.2: $\hat\xi$ determines a $U_q(L)$ module monomorphism.

Proof: $\hat\xi$ is obviously well defined and nonzero. It remains to prove it gives rise to a homomorphism. Now for $a\in U_q(L)$ we have, following Sweedler,[24]

$$\Delta(a)\hat\xi(v) = \Delta^{(2)}(a)(1\otimes\xi^\dagger)\sum_i\ (-1)^{[i]}(q^{-h_\rho}w_i^*)\otimes w_i\otimes v, \quad \forall v\in V(\mu),$$

where $\Delta^{(2)}\equiv(\Delta\otimes 1)\Delta=(1\otimes\Delta)\Delta$. Since $\xi^\dagger$ determines a $U_q(L)$ module homomorphism we thus obtain, in the notation of Eq. (2):

$$\Delta(a)\hat\xi(v) = (1\otimes\xi^\dagger)\sum_{(a)}\left[\Delta(a_{(1)})\sum_i\ (-1)^{[i]}(q^{-h_\rho}w_i^*)\otimes w_i\right]\otimes a_{(2)}v$$

$$= (1\otimes\xi^\dagger)\sum_i\ (-1)^{[i]}(q^{-h_\rho}w_i^*)\otimes w_i\otimes\sum_{(a)}\ \epsilon(a_{(1)})a_{(2)}v,$$

where we have utilized Lemma 2.2. Since $\Sigma_{(a)}\epsilon(a_{(1)})a_{(2)}=a$, we thereby arrive at

$$\Delta(a)\hat\xi(v) = \sum_i\ (-1)^{[i]}(q^{-h_\rho}w_i^*)\otimes\xi^\dagger(w_i\otimes av) = \hat\xi(av), \quad \forall a\in U_q(L), \quad v\in V(\mu)$$

as required. □

We thus set

$$V_\xi(\mu)=\hat{\xi}[V(\mu)].$$

We now show that this defines a complete labeling scheme for $V(\mu)\subseteq V(\Lambda)^*\otimes V(\nu)$ in $1-1$ correspondence with the labeling scheme for $V(\underline{\nu})\subseteq V(\Lambda)\otimes V(\mu)$.

Proposition 6.1: The isotypic component $V(\mu)$ of $V(\mu)\subseteq V(\Lambda)^*\otimes V(\nu)$ admits the $U_q(L)$ module decomposition

$$\overline{V(\mu)}=\bigoplus_\xi V_\xi(\mu).$$

Proof: Let v_+^μ be the maximal weight vector of $V(\mu)$ and $v_\xi(\mu)_+\equiv\hat{\xi}(v_+^\mu)$ the corresponding maximal weight vector of $V_\xi(\mu)$. It suffices to show, from Lemma 6.2, that these vectors are linearly independent. Suppose then that

$$\sum_\xi \alpha_\xi v_\xi(\mu)_+=0, \quad \alpha_\xi\in\mathbb{C}.$$

Then, by definition, we have

$$\sum_i (-1)^{[i]}(q^{-h_\rho}w_i^*)\otimes\sum_\xi \alpha_\xi\xi^\dagger(w_i\otimes v_+^\mu)=0 \Rightarrow\sum_\xi \alpha_\xi\xi^\dagger(w_i\otimes v_+^\mu)=0, \quad \forall i$$

$$\Rightarrow\sum_\xi \alpha_\xi\xi^\dagger(V(\Lambda)\otimes v_+^\mu)=0.$$

$\Sigma_\xi\alpha_\xi\xi^\dagger$ determines a $U_q(L)$ module homomorphism, and since $V(\Lambda)\otimes V(\mu)=U_q(L)(V(\Lambda)\otimes v_+^\mu)$, we obtain

$$\sum_\xi \alpha_\xi\xi^\dagger=0\Rightarrow\alpha_\xi=0, \quad \forall\xi$$

because the $\xi^\dagger$ are linearly independent (recall that $\xi^\dagger\xi'=\epsilon_\xi\delta_{\xi\xi'}I$, I the identity operator on $V(\nu)$). This is sufficient to prove the result.

Note: With the convention of Eq. (28), $V(\mu)\subseteq V(\Lambda)^*\otimes V(\nu)$ will have parity $+1$; i.e., its maximal $\mathbb{Z}$-graded component $V_0(\mu)$ is implicitly understood to have parity $+1$ in $V(\Lambda)^*\otimes V_0(\nu)$. □

Below we show that the decomposition of Proposition 6.1 is in fact orthogonal under the form $\langle\ ,\ \rangle$ on $V(\Lambda)^*\otimes V(\nu)$. To this end let $\{v(\mu)_k\}$ be a $\mathbb{Z}$-graded basis for $V(\mu)$ with corresponding dual basis $\{v(\mu)^k\}$ under the natural form on $V(\mu)$ and set $v_\xi=\hat{\xi}(v)$, $v\in V(\mu)$. We then have the overlap matrix $g_{\xi\xi'}$ defined by

$$\langle v_\xi(\mu)^k, v_{\xi'}(\mu)_l\rangle=g_{\xi\xi'}\delta_l^k.$$

A *left* dual basis to $\{v_\xi(\mu)_k\}\subseteq V_\xi(\mu)$ is thus given by

$$v^\xi(\mu)^k=g^{\xi\xi'}v_{\xi'}(\mu)^k$$

(summation over repeated indices assumed here and below) where $g^{\xi\xi'}\equiv(g^{-1})_{\xi\xi'}$. The (not necessarily orthogonal) projection onto $V_\xi(\mu)$ is then given by

$$P[\mu,\xi]=P[\mu]_{\xi\xi},$$

where

$$P[\mu]_{\xi\xi'}=\sum_k |v_\xi(\mu)_k\rangle\langle v^{\xi'}(\mu)^k|=\sum_k |v_\xi(\mu)^k\rangle\langle v^{\xi'}(\mu)_k|.$$

Our aim then is to show that the overlap matrix $g_{\xi\xi'}$ is diagonal. An important role in our approach is played by the operators

$$Q[\mu]_{\xi\xi'}=\sum_k |v_\xi(\mu)_k\rangle\langle v_{\xi'}(\mu)^k|=\sum_k g_{\xi'\xi''}|v_\xi(\mu)_k\rangle\langle v^{\xi''}(\mu)^k|=g_{\xi'\xi''}P[\mu]_{\xi\xi''} \tag{29}$$

with $P[\mu]_{\xi\xi''}$ as above. The $Q[\mu]_{\xi\xi'}$ satisfy the algebra

$$Q[\mu]^\dagger_{\xi\xi'}=Q[\mu]_{\xi'\xi}, \quad Q[\mu]_{\xi\xi'}Q[\mu]_{\eta\eta'}=g_{\xi'\eta}Q[\mu]_{\xi\eta'}.$$

We shall need the following result:

Proposition 6.2:

$$\mathrm{str}_q\otimes\mathrm{str}_q[\Delta(T_+)Q[\mu]_{\xi\xi'}(1\otimes T_-)]=\eta_{\xi\xi'},$$

where

$$\eta_{\xi\xi'}=g_{\xi'\xi}q^{-(\mu+\nu,\rho_1)}\chi_\nu(\Gamma_0)D^0_q[\mu].$$

Proof: Using Theorem 5.2 we obtain

$$\mathrm{str}_q\otimes\mathrm{str}_q[\Delta(T_+)Q[\mu]_{\xi\xi'}(1\otimes T_-)]=g_{\xi'\xi''}\ \mathrm{str}_q\otimes\mathrm{str}_q[\Delta(T_+)P[\mu]_{\xi\xi''}(1\otimes T_-)]=g_{\xi'\xi}\eta$$

with η as in Theorem 5.1 (but with ν and μ interchanged) so that

$$\eta=q^{-(\mu+\nu,\rho_1)}\chi_\nu(\Gamma_0)D^0_q[\mu],$$

where we have used the fact that $V_0(\mu)$ has positive parity in $V(\Lambda)^*\otimes V_0(\nu)$ (cf. note following Proposition 6.1), as required. □

Now, from definition, we have the following symmetry relation (notation as above):

$$\begin{aligned}\langle v_\xi(\mu),w_i^*\otimes e(\nu)\rangle&=\sum_j (-1)^{[j]}\langle(q^{-h_\rho}(w^j)^*)\otimes\xi^\dagger(w^j\otimes v(\mu)),w_i^*\otimes e(\nu)\rangle\\&=q^{(\lambda_i,\rho)}\langle\xi^\dagger(w^i\otimes v(\mu)),e(\nu)\rangle\\&=q^{(\lambda_i,\rho)}\langle w^i\otimes v(\mu),e^\xi(\nu)\rangle\\&=\langle(q^{h_\rho}w^i)\otimes v(\mu),e^\xi(\nu)\rangle,\quad \forall v(\mu)\in V(\mu),\quad e(\nu)\in V(\nu),\end{aligned} \tag{30}$$

where $v_\xi(\mu)\equiv\hat\xi[v(\mu)]$, $e^\xi(\nu)\equiv\xi[e(\nu)]$ and $\{w^i\}$ is the basis dual to $\{w_i\}$ under the natural form on $V(\Lambda)$: here λ_i denotes the weight of w_i and thus w^i. As before, $\{(w^i)^*\}$ is the basis for $V(\Lambda)^*$ naturally dual to $\{w^i\}$ so that $(w^i)^*(w^j)=\delta_{ij}$.

Now let $\{v(\mu)_k\}$, $\{e(\nu)_\alpha\}$ be bases for $V(\mu)$, $V(\nu)$ with corresponding dual bases $\{v(\mu)^k\}$, $\{e(\nu)^\alpha\}$ under the natural forms on $V(\mu)$, $V(\nu)$, resp. The above symmetry relation together with its conjugate, then implies the useful relation

$$\begin{aligned}&\epsilon_{\xi'}\langle(q^{h_\rho}w^i)\otimes v(\mu)^l,e^\xi(\nu)_\alpha\rangle\langle e^{\xi'}(\nu)^\beta,(q^{h_\rho}w_j)\otimes v(\mu)_k\rangle\\&\quad=\langle(w^j)^*\otimes e(\nu)^\beta,v_{\xi'}(\mu)_k\rangle\langle v_\xi(\mu)^l,w_i^*\otimes e(\nu)_\alpha\rangle,\end{aligned} \tag{31}$$

where $v_\xi = \hat{\xi}(v)$, $\forall v \in V(\mu)$ while $e^\xi(\nu)_\alpha = \xi[e(\nu)_\alpha]$, $e^\xi(\nu)^\alpha = \epsilon_\xi \xi[e(\nu)^\alpha]$. We are now in a position to prove orthogonality.

Theorem 6.1 (notation as above):

$$g_{\xi\xi'} = \epsilon_\xi \delta_{\xi\xi'} g,$$

where

$$g = (-1)^{[\nu]} \frac{\chi_\mu(\Gamma_0)}{\chi_\nu(\Gamma_0)} \frac{D_q^0[\nu]}{D_q^0[\mu]}.$$

Proof: From Eq. (31) above, we have

$$\begin{aligned}
&\epsilon_{\xi'}\langle (q^{h_\rho} w^i) \otimes v(\mu)^l, \Delta(T_-) e^\xi(\nu)_\alpha \rangle \langle e^{\xi'}(\nu)^\beta, (q^{h_\rho} w_j) \otimes T_+ v(\mu)_k \rangle \\
&\quad = \langle (w^j)^* \otimes e(\nu)^\beta, \Delta(T_+) v_{\xi'}(\mu)_k \rangle \langle v_\xi(\mu)^l, w_i^* \otimes T_- e(\nu)_\alpha \rangle \\
&\quad \Rightarrow \epsilon_{\xi'} \langle (q^{h_\rho} w^i) \otimes q^{h_\rho} v(\mu)^l, \Delta(T_-) e^\xi(\nu)_\alpha \rangle \langle e^{\xi'}(\nu)^\beta, (q^{h_\rho} w_j) \otimes q^{h_\rho} T_+ v(\mu)_k \rangle \\
&\quad = \langle (w^j)^* \otimes e(\nu)^\beta, \Delta(q^{h_\rho}) \Delta(T_+) v_{\xi'}(\mu)_k \rangle \langle \Delta(q^{h_\rho}) v_\xi(\mu)^l, w_i^* \otimes T_- e(\nu)_\alpha \rangle.
\end{aligned}$$

Setting $i=j$, $\beta=\alpha$, $k=l$ (no summation) we obtain

$$\begin{aligned}
&\langle (q^{h_\rho} w^i) \otimes q^{h_\rho} v(\mu)^k, \Delta(T_-) e^\xi(\nu)_\alpha \rangle \langle e^{\xi'}(\nu)^\alpha, q^{h_\rho} w_i \otimes q^{h_\rho} T_+ v(\mu)_k \rangle \\
&\quad = \epsilon_{\xi'} \langle (w^i)^* \otimes e(\nu)^\alpha, \Delta(q^{h_\rho}) \Delta(T_+) v_{\xi'}(\mu)_k \rangle \langle \Delta(q^{h_\rho}) v_\xi(\mu)^k, w_i^* \otimes T_- e(\nu)_\alpha \rangle.
\end{aligned}$$

Now multiply both sides by $(-1)^{[i]+[k]} = (-1)^{[\alpha]+|\Phi_1^+|}$ and sum on i, k, α to give, using the definition of Eq. (29),

$$\begin{aligned}
&\epsilon_{\xi'} \ \mathrm{str} \otimes \mathrm{str}[\Delta(q^{h_\rho}) \Delta(T_-) P[\nu]_{\xi\xi'} \Delta(q^{h_\rho})(1 \otimes T_+)] \\
&\quad = (-1)^{|\Phi_1^+|} \ \mathrm{str} \otimes \mathrm{str}[\Delta(q^{h_\rho}) \Delta(T_+) Q[\mu]_{\xi'\xi} \Delta(q^{h_\rho})(1 \otimes T_-)]
\end{aligned}$$

which may be rearranged to give

$$(-1)^{|\Phi_1^+|} q^{4(\rho,\rho_1)} \ \mathrm{str}_q \otimes \mathrm{str}_q[\Delta(T_-) P[\nu]_{\xi\xi'} (1 \otimes T_+)] = \epsilon_{\xi'} \ \mathrm{str}_q \otimes \mathrm{str}_q[\Delta(T_+) Q[\mu]_{\xi'\xi} (1 \otimes T_-)].$$

Since μ, ν are typical, we may apply Theorem 5.2 to the left-hand side and Proposition 6.2 to the right-hand side to give, noting that the factors $q^{-(\mu+\nu,\rho_1)}$ cancel from both sides:

$$(-1)^{[\nu]} \chi_\mu(\Gamma_0) D_q^0[\mu] \delta_{\xi\xi'} = \epsilon_{\xi'} g_{\xi\xi'} \chi_\nu(\Gamma_0) D_q^0[\mu]$$

from which the result follows.

Corollary: The induced labeling scheme for $V(\mu) \subseteq V(\Lambda)^* \otimes V(\nu)$ is orthogonal with respect to the induced form.

VII. SUPERTRACE FORMULA FOR TYPICAL PROJECTIONS

Throughout we adopt the notation and conventions of Sec. VI. It is worth noting that Eq. (30) is reminiscent of a well known symmetry relation satisfied by the Clebsch–Gordan coefficients of a simple Lie algebra (although in such a case one usually works with an inner product). We now come to our main result on partial q supertraces of projections onto typical irreducible submodules $V(\nu) \subseteq V(\Lambda) \otimes V(\mu)$ ($\mu \in D^+$ typical as before).

Proposition 7.1:

$$(\mathrm{str}_q \otimes 1) P[\nu]_{\xi\xi'} = \delta_{\xi'\xi} g$$

with g as in Theorem 6.1.

Proof: Using the definition of $v_\xi(\mu)_k = \hat{\xi}[v(\mu)_k] \subseteq V(\Lambda)^* \otimes V(\nu)$ [cf. Eq. (28)] we have, from Theorem 6.1,

$$\begin{aligned}
&\epsilon_\xi g\, \delta_{\xi\xi'} \langle v(\mu)_k, v(\mu)_l \rangle \\
&\quad = \langle v_\xi(\mu)_k, v_{\xi'}(\mu)_l \rangle \\
&\quad = \sum_{i,j} (-1)^{[i]+[j]} \langle q^{-h_\rho}(w^i)^* \otimes \xi^\dagger(w^i \otimes v(\mu)_k), (q^{-h_\rho} w_j^*) \otimes \xi'^\dagger(w_j \otimes v(\mu)_l) \rangle \\
&\quad = \sum_{i,j} (-1)^{[i]+[j]} q^{2(\rho,\lambda_i)} \langle (w^i)^*, w_j^* \rangle \langle \xi^\dagger(w^i \otimes v(\mu)_k), \xi'^\dagger(w_j \otimes v(\mu)_l) \rangle \\
&\quad = \sum_{i,j} (-1)^{[i]} q^{2(\rho,\lambda_i)} \langle w^i \otimes v(\mu)_k, \xi\xi'^\dagger(w_i \otimes v(\mu)_l) \rangle,
\end{aligned}$$

where w^i and w_i are assumed to have weight λ_i, and the last equality follows from Proposition 3.4. In view of the fact that $\xi\xi'^\dagger = \epsilon_{\xi'} P[\nu]_{\xi\xi'}$, with $P[\nu]_{\xi\xi'}$ as in Eq. (24); we thus arrive at

$$\begin{aligned}
\epsilon_\xi g\, \delta_{\xi\xi'} \langle v(\mu)_k, v(\mu)_l \rangle &= \epsilon_{\xi'} \sum_i (-1)^{[i]} q^{2(\rho,\lambda_i)} \langle w^i \otimes v(\mu)_k, P[\nu]_{\xi\xi'}(w_i \otimes v(\mu)_l) \rangle \\
&= \epsilon_{\xi'} \langle v(\mu)_k, [(\mathrm{str}_q \otimes 1) P[\nu]_{\xi\xi'}] v(\mu)_l \rangle.
\end{aligned}$$

Thus, in view of Proposition 2.1, $(\mathrm{str}_q \otimes 1) P[\nu]_{\xi\xi'}$ determines a $U_q(L)$ invariant on $V(\mu)$ with eigenvalue determined by

$$\epsilon_\xi g\, \delta_{\xi\xi'} \langle v(\mu)_k, v(\mu)_l \rangle = \epsilon_{\xi'} \langle v(\mu)_k, v(\mu)_l \rangle (\mathrm{str}_q \otimes 1) P[\nu]_{\xi\xi'}$$

from which the result follows.

Corollary:

$$(\mathrm{str}_q \otimes 1) P[\nu, \xi] = (-1)^{[\nu]} \frac{\chi_\mu(\Gamma_0)}{\chi_\nu(\Gamma_0)} \frac{D_q^0[\nu]}{D_q^0[\mu]}$$

with $P[\nu,\xi]$ the (orthogonal) projection onto $V^\xi(\nu) \subseteq \overline{V(\nu)}$. □

Note that the above result is independent of the multiplicity labeling ξ. Now let

$$P[\nu] = \sum_\xi P[\nu, \xi]$$

be the orthogonal projection onto the isotypic component $\overline{V(\nu)}$ of $V(\nu) \subseteq V(\Lambda) \otimes V(\mu)$. Then from the results above, we arrive at

Theorem 7.1:

$$(\mathrm{str}_q \otimes 1) P[\nu] = (-1)^{[\nu]} m_\nu \frac{\chi_\mu(\Gamma_0)}{\chi_\nu(\Gamma_0)} \frac{D_q^0[\nu]}{D_q^0[\mu]}$$

with m_ν the multiplicity of $V(\nu)\subseteq V(\Lambda)\otimes V(\mu)$ and $[\nu]$ the $\mathbb{Z}$-graded level of $V_0(\nu)\subseteq V(\Lambda)\otimes V_0(\mu)$. □

The multiplicities m_ν are given explicitly by the corollary to Proposition 4.1 while the q dimensions are given by formula (10) and the $\chi_\nu(\Gamma_0)$ by formula (11); note that the ratio $\chi_\mu(\Gamma_0)/\chi_\nu(\Gamma_0)$ is independent of the constant $c\neq 0$ of Eq. (11). We emphasize that the results above only apply to typical $\mu,\nu\in D^+$. They will be utilized below to determine the eigenvalues of the Casimir invariants (16).

VIII. EIGENVALUE FORMULA FOR CASIMIR INVARIANTS

Let $V(\mu)$ be an arbitrary (possibly infinite dimensional) irreducible $U_q(L)$ module with highest weight $\mu\in H^*$. Then on $V(\mu)$ the elements of the center Z take constant values; for $z\in Z$ we denote its eigenvalue on $V(\mu)$ by $\chi_\mu(z)$. We note that χ_μ determines an algebra homomorphism:[19]

$$\chi_\mu : Z\to\mathbb{C},\quad z\mapsto\chi_\mu(z)$$

called an *infinitesimal character*. More generally we say that a $U_q(L)$ module V admits an infinitesimal character χ_μ, $\mu\in H^*$, if the central elements $z\in Z$ take constant values $\chi_\mu(z)$ on V. Note that such a module V need not possess a maximal (or minimal) weight vector.

Throughout we let $V(\Lambda)$ be a fixed, but arbitrary, finite dimensional irreducible $U_q(L)$ module with a real highest weight $\Lambda\in D^+$. We let $\{\lambda_i\}$ denote the set of distinct weights in $V(\Lambda)$ with m_i the multiplicity of the weight λ_i. Now let $c\in(Z\otimes Z)\Delta(Z)\subseteq U_q(L)\otimes U_q(L)$; an important example is afforded by

$$c=(1\otimes 1-R^TR)/(q-q^{-1}) \tag{32}$$

with R the universal R matrix. Following Proposition 2.1, we have the family of Casimir invariants

$$C_m=(\mathrm{str}_q\otimes 1)(\pi_\Lambda\otimes 1)c^m. \tag{33}$$

To determine their eigenvalues we first need[34,35]

Definition 8.1: We say that Λ is *typically subordinate* to $\mu\in D^+$ if $\mu,\mu+\lambda_i$ are all (real) dominant and typical. We denote the set of such μ by D^+_Λ. □

From Ref. 35 we have (also cf. Refs. 15 and 34)

Lemma 8.1: The eigenvalues $\chi_\mu(C_m)$ of the invariants (33), *$\mu\in H^*$, determine functions on H^* which are uniquely defined by their restriction to D^+_Λ.* □

We thus assume $\mu\in D^+_\Lambda$ so that we have the tensor product decomposition

$$V(\Lambda)\otimes V_0(\mu)=\oplus\, m_iV_0(\mu+\lambda_i)$$

which follows from the fact that $V(\Lambda)$ is subordinate to $V_0(\mu)$, the maximal $\mathbb{Z}$-graded component of $V(\mu)$, as a $U_q(L_0)$ module. Thus all $U_q(L_0)$ modules $V_0(\mu+\lambda_i)$ occur with full multiplicity m_i in $V(\Lambda)\otimes V_0(\mu)$ (cf. Kostant[34]). Since the $\mu+\lambda_i$ are all typical we obtain, from the corollary to Proposition 4.1, the tensor product decomposition

$$V(\Lambda)\otimes V(\mu)=\bigoplus_i m_iV(\mu+\lambda_i).$$

We let $P[i]$ denote the orthogonal (central) projection of the tensor product space onto the isotypic component $V(\mu+\lambda_i)\equiv m_iV(\mu+\lambda_i)$. We then have the spectral decomposition

$$c^m=\sum_i\,\langle c\rangle^m_{\mu+\lambda_i}P[i],$$

where $\langle c\rangle_{\mu+\lambda_i}$ denotes the eigenvalue of c on $V(\mu+\lambda_i)\subseteq V(\Lambda)\otimes V(\mu)$. Since $\mu,\mu+\lambda_i$ are all dominant and typical we may apply the results of Theorem 7.1 which gives, for the eigenvalues of the invariants (33):

$$\chi_\mu(C_m)=\sum_i \langle c\rangle^m_{\mu+\lambda_i}(\mathrm{str}_q\otimes 1)P[i]=\sum_i (-1)^{[i]}m_i\langle c\rangle^m_{\mu+\lambda_i}\frac{\chi_\mu(\Gamma_0)}{\chi_{\mu+\lambda_i}(\Gamma_0)}\frac{D^0_q[\mu+\lambda_i]}{D^0_q[\mu]},\quad \mu\in D^+_\Lambda,$$

where $[i]$ denotes the degree of weight λ_i. In view of Eqs. (10) and (11) and Lemma 8.1, we thereby arrive at the following eigenvalue formula:

Theorem 8.1:

$$\chi_\mu(C_m)=\sum_i (-1)^{[i]}m_i\langle c\rangle^m_{\mu+\lambda_i}\prod_{\beta\in\Phi^+_1}\frac{[(\mu+\rho,\beta)]_q}{[(\mu+\lambda_i+\rho,\beta)]_q}\prod_{\alpha\in\Phi^+_0}\frac{[(\mu+\lambda_i+\rho,\alpha)]_q}{[(\mu+\rho,\alpha)]_q},\quad \mu\in H^*.$$

Note: The above determines a well defined function on H^*. However it will be undefined as it stands if some $\mu+\lambda_i$ is atypical or $(\mu+\rho,\alpha)=0$, for some $\alpha\in\Phi^+_0$ (this latter situation can never occur for $\mu\in D^+$). In such a case the right-hand side must first be expanded in order to avoid singularities. Note however that the set of $\mu\in H^*$ for which this occurs forms a Zariski closed subset of H^*. Thus the formula is well defined on a Zariski open, and hence dense, subset of H^*; for further details see Ref. 35. □

We now investigate the important special case where c is given by Eq. (32); the corresponding invariants (33) in this case reduced to those of Eq. (16). It is a well established result for ($\mathbb{Z}_2$-graded) quasitriangular Hopf algebras that there exists a distinguished element[12]:

$$u=\sum_t (-1)^{[t]}S(b_t)a_t,$$

where a_t and b_t are the coordinates of the universal R matrix: $R=\Sigma_t a_t\otimes b_t$. Then it can be shown that u has inverse

$$u^{-1}=\sum_t (-1)^{[t]}S^{-2}(b_t)a_t$$

and satisfies

$$\begin{aligned} S^2(a)&=uau^{-1},\quad \forall a\in U_q(L),\\ \Delta(u)&=(u\otimes u)(R^TR)^{-1}. \end{aligned}\tag{34}$$

On the other hand, from Eq. (3) we have

$$S^2(a)=q^{-2h_\rho}aq^{2h_\rho},\quad \forall a\in U_q(L)$$

which follows from the fact that the principal antiautomorphism γ satisfies $\gamma^2=I$, the identity map on $U_q(L)$. Thus $v\equiv q^{2h_\rho}u$ must be a central element which, in view of Eq. (34), satisfies

$$R^TR=(v\otimes v)\Delta(v^{-1}).$$

Moreover, it can be shown that[12]

$$\chi_\Lambda(v)=q^{-(\Lambda,\Lambda+2\rho)}.$$

Thus with c as in Eq. (32), we have for its eigenvalues on $V(\mu+\lambda_i)\subseteq V(\Lambda)\otimes V(\mu)$:

$$\langle c\rangle_{\mu+\lambda_i}\equiv a_i(\mu),\quad a_i(\mu)=\frac{1-q^{-2\alpha_i(\mu)}}{q-q^{-1}},$$

where α_i denotes the linear polynomial function on H^* given by

$$\alpha_i(\mu)=\tfrac{1}{2}(\Lambda,\Lambda+2\rho)-\tfrac{1}{2}(\lambda_i,\lambda_i+2(\mu+\rho)),\quad \forall\mu\in H^*. \tag{35}$$

It is worth noting that these are the roots of the characteristic identities[36] for the Lie superalgebra L, and in the $q\to 1$ limit, $a_i(\mu)\to\alpha_i(\mu)$ while c goes over to the characteristic matrix investigated in Refs. 16 and 36.

Hence, as a special case of Theorem 8.1, we arrive at the following formula for the eigenvalues of the Casimir invariants C_m^Λ of Eq. (16):

$$\chi_\mu(C_m^\Lambda)=\sum_i\ (-1)^{[i]}m_i a_i(\mu)^m\prod_{\beta\in\Phi_1^+}\frac{[(\mu+\rho,\beta)]_q}{[(\mu+\lambda_i+\rho,\beta)]_q}\prod_{\alpha\in\Phi_0^+}\frac{[(\mu+\lambda_i+\rho,\alpha)]_q}{[(\mu+\rho,\alpha)]_q} \tag{36}$$

for $\mu\in H^*$. This generalizes, and is in agreement with, the results of Ref. 17 obtained for the case π_Λ is the vector irrep of $U_q[gl(m|n)]$ using completely different methods. Again the above formula is well defined on a Zariski dense subset of H^*, but the right-hand side will need to be expanded if some $\mu+\lambda_i$ is atypical, or $(\mu+\rho,\alpha)=0$ for some $\alpha\in\Phi_0^+$. This can always be done, in principle, since $\chi_\mu(C_m^\Lambda)$ necessarily determines a well defined function on H^* which is given by formula (36) for generic $\mu\in H^*$. This aspect of the problem will be deferred to another article (see also Ref. 35).

In the classical limit $q\to 1$, the C_m^Λ give rise to a family of Casimir invariants for the Lie superalgebra L; they generalize those constructed by Jarvis and Green[16] to arbitrary reference irreps. From Eq. (36) their eigenvalues are given by

$$\chi_\mu(C_m^\Lambda)=\sum_i\ (-1)^{[i]}m_i\alpha_i(\mu)^m\prod_{\beta\in\Phi_1^+}\frac{(\mu+\rho,\beta)}{(\mu+\lambda_i+\rho,\beta)}\prod_{\alpha\in\Phi_0^+}\frac{(\mu+\lambda_i+\rho,\alpha)}{(\mu+\rho,\alpha)}$$

with $\alpha_i(\mu)$ as in Eq. (35). This result is also new and generalizes to arbitrary reference irreps the results of Refs. 16 and 17.

Explicit examples of the above Casimir invariants and their eigenvalues will be given in Sec. IX (see also Ref. 35). Equation (36) also plays a fundamental role in the evaluation of two variable link polynomials associated with any irrep with a real highest weight $\Lambda\in D^+$; for further details we refer to Ref. 18.

IX. EXAMPLES

In order to illustrate the application of our eigenvalue formula we will consider in this section the case of $U_q(gl(m|n))$ when the reference representation is taken to be the vector irrep (simply labeled π). We let $\{\epsilon_i\}$ denote the standard basis for H^* equipped with the invariant bilinear form

$$(\epsilon_i,\epsilon_j)=(-1)^{[i]}\delta_{ij},$$

where the $\mathbb{Z}_2$ grading on the indices is given by

$$[i]=\begin{cases}0, & i\leqslant m\\ 1, & i>m.\end{cases}$$

From Ref. 37 we have expressions for the co-product intertwiners which read

$$(\pi\otimes I)R=I\otimes I+(q-q^{-1})\sum_{i\leqslant j}(-1)^{[i]}e_i^j\otimes X_j^i,$$

$$(\pi\otimes I)R^T=I\otimes I+(q-q^{-1})\sum_{i\geqslant j}(-1)^{[i]}e_i^j\otimes X_j^i,$$

where e_j^i denote the standard elementary matrices. Above, the X_j^i are elements of $U_q(gl(m|n))$ which are given by

$$X_j^i=q^{1/2((\epsilon_i,\epsilon_i)E_i^i+(\epsilon_j,\epsilon_j)E_j^j-1)}E_j^i,\quad i\neq j,$$

$$X_i^i=(\epsilon_i,\epsilon_i)\frac{q^{(\epsilon_i,\epsilon_i)E_i^i}-1}{q-q^{-1}},$$

and the E_j^i are defined recursively as

$$E_j^i=E_k^iE_j^k-q^{-(\epsilon_k,\epsilon_k)}E_j^kE_k^i,\quad i\leqslant k\leqslant j.$$

(Note that the expressions for the X_j^i differ slightly from those in Ref. 37 due to a different choice for the co-product.)

We may write Eq. (32) in the form

$$(\pi\otimes I)c=\sum_{i,j}(-1)^{[i]}2^{\delta_{ij}}e_i^j\otimes X_j^i+(q-q^{-1})\sum_{k\geqslant i,j}(-1)^{([i]+[j])([i]+[k])}e_i^j\otimes X_j^kX_k^i$$

from which the Casimir invariants C_l of Eq. (33) can be calculated. Here we will construct the first and second order Casimir invariants only. The first order Casimir invariant reads

$$C_1=2\sum_i X_i^iq^{(2\rho,\epsilon_i)}+(q-q^{-1})\sum_{i\geqslant j}(-1)^{[j]}X_j^iX_i^jq^{(2\rho,\epsilon_j)} \tag{37}$$

while the second order invariant is given by

$$C_2=\sum_{i,j}(-1)^{[j]}4^{\delta_{ij}}X_j^iX_i^jq^{(2\rho,\epsilon_j)}+(q-q^{-1})\sum_{k\geqslant i,j}(-1)^{([i]+[j])([j]+[k])}2^{\delta_{ij}}(X_i^jX_j^kX_k^iq^{(2\rho,\epsilon_i)}$$

$$+X_j^kX_k^iX_i^jq^{(2\rho,\epsilon_j)})+(q-q^{-1})^2\sum_{k,l\geqslant i,j}(-1)^{[i][j]+[j][k]+[i][k]}X_j^kX_k^iX_i^lX_l^jq^{(2\rho,\epsilon_j)}. \tag{38}$$

The sets of even and odd positive roots are, resp, given by

$$\Phi_0^+=\{\epsilon_i-\epsilon_j|1\leqslant i<j\leqslant m+n,[i]=[j]\},$$

$$\Phi_1^+=\{\epsilon_i-\epsilon_j|1\leqslant i<j\leqslant m+n,[i]\neq[j]\},$$

in terms of which ρ is expressed as

$$\rho=\frac{1}{2}\sum_{i=1}^m(m-n-2i+1)\epsilon_i-\frac{1}{2}\sum_{j=1}^n(m+n-2j+1)\epsilon_{m+j}.$$

To determine the eigenvalues of these invariants acting on the irreducible module $V(\mu)$, $\mu=\sum_{i=1}^{m+n}\mu_i\epsilon_i$, we will apply our formula (36). The weight spectrum of the vector module is just $\{\epsilon_i\}_{i=1}^{m+n}$. In this case Eq. (36) simplifies to give

$$\chi_\mu(C_l)=\sum_{i=1}^{m+n}(-1)^{[i]}[a_i(\mu)]^l\prod_{j\neq i}\frac{q^{-(\epsilon_j,\epsilon_j)}a_i(\mu)-q^{(\epsilon_j,\epsilon_j)}a_j(\mu)+(-1)^{[j]}}{a_i(\mu)-a_j(\mu)}, \tag{39}$$

where the roots $a_i(\mu)$ are given by

$$a_i(\mu)=\frac{1-q^{(\epsilon_i,\epsilon_i+2\mu+2\rho)-m+n}}{q-q^{-1}}.$$

The above eigenvalues are all polynomial functions of the variables $q^{(\mu\epsilon_i)}$ so that Eq. (39) may be simplified for each value of l. For the case of $l=1$ it is known that the eigenvalues are given by[12]

$$\chi_\mu(C_1)=\sum_{i=1}^{m+n}(q-q^{-1})^{-1}(1-(-1)^{[i]}q^{2(\mu+\rho,\epsilon_i)}).$$

However for higher order invariants one needs to employ computing techniques to simplify these expressions. For the simple case of $U_q(gl2|1))$ we have used Mathematica to obtain the following eigenvalues for the first and second order Casimir invariants:

$$\chi_\mu(C_1)=(q-q^{-1})^{-1}(1-q^{2\mu_1}-q^{2\mu_2-2}+q^{-2\mu_3-2}),$$

$$\begin{aligned}\chi_\mu(C_2)=&(q-q^{-1})^{-2}(1+q^{2\mu_1}(q^{2\mu_1}-2)+q^{2\mu_2}(q^{2\mu_2-4}-2q^{-2})-q^{-2\mu_3}(q^{-2\mu_3-6}-2q^{-2})\\&+(q^{-2}-q^{-4})(q^{2\mu_1+2\mu_2}-q^{2\mu_1-2\mu_3}-q^{2\mu_2-2\mu_3-2})).\end{aligned}$$

These results may be checked against those obtained by explicitly evaluating the action of the invariants on the highest weight state using Eqs. (37) and (38).

X. CONCLUSIONS

We have investigated several important aspects of the rep theory of the type I quantum superalgebras. In particular it was shown in Sec. III that any finite dimensional rep for these algebras admits a natural decomposition into typical and atypical components. In the case of a tensor product of two finite dimensional irreps we have shown there is a natural, invariant, nondegenerate sesquilinear form $\langle\ ,\ \rangle$ induced on the tensor product space with respect to which its typical and atypical components are orthogonal. This implies that the restriction of the form to the isotypic component of a given typical submodule is nondegenerate, thus allowing the definition of corresponding Clebsch–Gordan coefficients with respect to the form $\langle\ ,\ \rangle$.

These results were applied in Sec. IV to construct an orthogonal multiplicity labeling for $V(\nu)\subseteq V(\Lambda)\otimes V(\mu)$ with $\mu,\nu\in D^+$ typical but $\Lambda\in D^+$ arbitrary. A useful result for the multiplicities in the tensor product module was also derived (see Proposition 4.1 and its corollary). In Sec. VI we investigated the naturally induced multiplicity labeling for $V(\mu)\subseteq V(\Lambda)^*\otimes V(\nu)$ which was also shown to be orthogonal under the form on the tensor product space and gives rise to a symmetry relation for the corresponding Clebsch–Gordan coefficients. It is worth noting that this approach is capable of further generalization, particularly for the calculation of generator matrix elements and corresponding Clebsch–Gordan coefficients for unitary irreps.

In Secs. VII and VIII we obtained a general eigenvalue formula for Casimir invariants, valid for an arbitrary reference irrep. This result is new, even in the classical limit, in which case it generalizes to arbitrary reference irreps the results of Refs. 16 and 17. Aside from solving an

outstanding problem in the rep theory of the type I quantum superalgebras, our results are particularly important for the systematic construction of new two variable link polynomials which will be investigated elsewhere.[18] Finally, the eigenvalue formula of Sec. VIII, derived for real $q>0$, can be shown to hold (analytic continuation) for (generic) complex q.

Computation of Lie transformations from a power series: Bounds and optimum truncation

Ivan Gjaja
Theoretical Division and Center for Nonlinear Studies, Los Alamos National Laboratory, Los Alamos, New Mexico 87545

(Received 10 November 1994; accepted for publication 28 November 1995)

The problem considered is the computation of an infinite product (composition) of Lie transformations generated by homogeneous polynomials of increasing order from a given asymptotic power series. Bounds are computed for the infinitesimal form of the Lie transformations and for the domain of analyticity of the first n of them. Even when the power series is convergent, the estimates exhibit a factorial-type growth, and thus do not guarantee convergence of the product. The optimum truncation is determined by minimizing the remainder after the first n Lie transformations have been applied. [S0022-2488(96)01203-2]

I. INTRODUCTION

A method based on an infinite product (composition) of Lie transformations (exponentiated vector fields) generated by homogeneous polynomials of increasing order was developed a long time ago in order to efficiently perform perturbative calculations in Hamiltonian systems when the small parameters are the dynamical variables themselves.[1,2] Subsequently, the recursion formulas for the computation of the infinite product from a single Lie transformation generated by a function analytic at the origin were derived in the nonsymplectic case.[3] It was recognized from the outset[1] that the product of Lie transformations can be computed from, or be used to compute, a power series in the dynamical variables. The relation between Lie transformations and power series, however, was established only at a formal level, that is order by order.

More recent work has provided firm bounds on the results that can be obtained using the method. In Refs. 4–6 a variant of the method is applied to the problem of bringing a Hamiltonian function or a Hamiltonian vector field to normal form. In Ref. 7, and in Ref. 6 for Hamiltonian systems, sufficient conditions are given on the coefficients of the polynomials and on the domain of the dynamical variables such that the infinite product of Lie transformations is convergent. Roughly speaking, the conditions sufficient for convergence are that the coefficients of the polynomials do not grow with order more rapidly than an exponential function, and that the transformation be restricted to a suitable domain around the origin. It can be expected that the condition on the coefficients is also necessary in general, since otherwise the norm of *each* vector field over any finite domain would grow without bound as the order of the polynomial increased.

In this paper we turn to the construction of Lie transformations from an asymptotic, that is not necessarily convergent, power series. We obtain bounds for the norms of the vector fields that are computed from such a series and determine the optimum truncation of the product of Lie transformations. Even when the power series is convergent, our results do not guarantee the convergence of the infinite product, giving instead a factorial-type growth for the estimates. The asymptotic nature of the bound is not unexpected, however, as remarked in Sec. II. As in Ref. 7, we do not require that the power series or the Lie transformations be symplectic (i.e., that they arise from Hamiltonian systems).

The organization of the paper is as follows: In Sec. II we introduce notation, which for quantities that appear in both is the same as in Ref. 7, and write down an expression for the coefficients of the polynomials in terms of the coefficients of the power series. Section III contains two lemmas which allow us to pass from the expression for the coefficients to an inequality in the

form of a recursion relation for the norms of the vector fields. In Sec. IV we then use the recursion relation to obtain a bound on the norms. The analyticity of a finite product of Lie transformations and the question of optimum truncation of the product are considered in Sec. V, and a summary of the results is given in Sec. VI.

II. PRELIMINARIES

We study the transformation $\mathscr{M}$ formally defined by

$$\mathscr{M}z = e^{L_2(z)} e^{L_3(z)} \cdots e^{L_n(z)} \cdots z, \quad z \in \mathbb{C}^d. \tag{2.1}$$

Here L_n is a vector field

$$L_n(z) = \sum_{j=1}^{d} g_j^{(n)}(z) \frac{\partial}{\partial z_j}, \tag{2.2}$$

and $g_j^{(n)}$ a homogeneous polynomial in z of order $n \geqslant 2$ with complex coefficients,

$$g_j^{(n)}(z) = \sum_{|r|=n} a_{rj}^{(n)} z^r. \tag{2.3}$$

The subscript r stands for the collection of indices $r_1,\ldots,r_d$, $|r| \overset{\text{def}}{=} r_1 + \cdots + r_d$, and z^r is defined by $z^r = z_1^{r_1} \cdots z_d^{r_d}$. The exponential of L_n is given by the usual infinite series

$$e^{L_n(z)} = \sum_{s=0}^{\infty} \frac{1}{s!} [L_n(z)]^s, \tag{2.4}$$

where $s=0$ corresponds to the identity transformation. In the definition of $\mathscr{M}$ the linear transformation has been set equal to the identity, as its computation is not germane to the problem at hand. The designation of Eq. (2.1) as formal, on the other hand, reflects the fact that we have not specified a domain in $\mathbb{C}^d$, if such one exists, on which the infinite series of Eq. (2.4) acting on z are convergent for $n=2,3,\ldots$. We also define $\mathscr{M}_n$ as the product of Lie transformations of the form (2.1) truncated at order n.

The properties of Lie transformations and their use in perturbation calculations are not discussed further in this paper. The interested reader is instead directed to Ref. 8 for a sampling of the surveys of the subject.

Suppose we are given the formal power series

$$P_k(z) = z_k + \sum_{m=2}^{\infty} \sum_{|r|=m} b_{rk}^{(m)} z^r, \tag{2.5}$$

where no restrictions are placed on the behavior of the (complex) coefficients $b_{rk}^{(m)}$ as a function of m,r,k. We are going to examine the construction of vector fields L_n chosen in such a way that $\mathscr{M}z$ and $P(z)$ agree order by order in z. For the moment we do not specify the domain over which the agreement occurs. A lower bound on this domain, $\mathscr{D}_n$, as a function of n is given in Sec. V. If the series $P(z)$ is actually convergent, we will denote its domain of analyticity by $\mathscr{D}$. ($\mathscr{D}$ evidently includes the origin.) In parallel with setting the linear transformation in $\mathscr{M}$ equal to the identity, we have assumed that, to first order in z, $P(z)=z$.

For a vector v, regardless of the vector space, we define the norm $\|v\|$ by

$$\|v\| = \max_j |v_j|, \tag{2.6}$$

where $|\cdot|$ stands for the modulus [except in the definition of index summation, as given following Eq. (2.3)]. For brevity we denote the norm of z by x, $x=\|z\|$. We also define the quantity $\alpha_j^{(n)}$ by

$$\alpha_j^{(n)}=\sum_{|r|=n}|a_{rj}^{(n)}|, \tag{2.7}$$

and α_n by $\alpha_n=\|\alpha^{(n)}\|$. The following relation holds:

$$\|L_n\|=\max_j|g_j^{(n)}(z)|=\max_j\left|\sum_{|r|=n}a_{rj}^{(n)}z^r\right|\leqslant\alpha_n x^n. \tag{2.8}$$

In the subsequent sections we will obtain a bound for α_n which will thus enable us to place a bound on $\|L_n\|$ on a given domain for x.

The first step is to write down an expression for the coefficients $a_{rj}^{(n)}$ in terms of the coefficients $b_{rj}^{(n)}$. We expand the Lie transformations into power series and match terms of the same order in z to get

$$\sum_{\mathscr{C}_n=n-1}\frac{L_2^{s_2}\cdots L_n^{s_n}}{s_2!\cdots s_n!}z_k=\sum_{|r|=n}b_{rk}^{(n)}z^r. \tag{2.9}$$

The symbol $\Sigma_{\mathscr{C}_p=q}$ is defined as a sum over $s_2,\ldots,s_p$ with a condition,

$$\sum_{\mathscr{C}_p=q}=\sum_{\substack{s_2,\cdots,s_p\geqslant 0\\ s_2+2s_3+\cdots+(p-1)s_p=q}}. \tag{2.10}$$

Note that the operators $L_i^{s_i}$ and $L_j^{s_j}$, $i\neq j$, do not commute, so the ordering is important.

In Eq. (2.9) s_n can take on only the values of 0 and 1. Together with the fact that $L_n z_k=g_k^{(n)}(z)$, this allows us to transform Eq. (2.9) into a recursion relation for $a_{rk}^{(n)}$:

$$a_{rk}^{(2)}=b_{rk}^{(2)}, \tag{2.11a}$$

$$a_{rk}^{(n)}=b_{rk}^{(n)}-\frac{\partial_z^r}{r!}\sum_{\mathscr{C}_{n-1}=n-1}\frac{L_2^{s_2}\cdots L_{n-1}^{s_{n-1}}}{s_2!\cdots s_{n-1}!}z_k;\quad n\geqslant 3, \tag{2.11b}$$

where $\partial_z^r/r!\overset{\text{def}}{=}(\partial_{z_1}^{r_1}\ldots\partial_{z_d}^{r_d})/(r_1!\ldots r_d!)$. (By the definition of coefficients a and b the condition $|r|=n$ holds.)

Before proceeding further we pause to note that even if $\mathscr{D}$ is finite [that is $P(z)$ is convergent over a finite domain], we should not expect, in general, that the coefficients $a_{rk}^{(n)}$ are bounded by an exponentially growing function of n (and hence that we will be able to ascertain the convergence of $\mathscr{M}_n z$ $n\to\infty$, as discussed in the Introduction). For simplicity we set $d=1$, in which case the indices r and k can be omitted, and note that the sums $\Sigma_{\mathscr{C}_{n-1}=n-1}$ in Eq. (2.11b) always contain the term $s_2=s_{n-1}=1$, $s_i=0$, $3\leqslant i\leqslant n-2$, for which

$$\frac{1}{n!}\frac{d^n}{dz^n}a^{(2)}z^2\frac{d}{dz}a^{(n-1)}z^{n-1}\frac{d}{dz}z=(n-1)a^{(2)}a^{(n-1)}. \tag{2.12}$$

If no other terms were present on the right side of Eq. (2.11b), this, of course, would lead to the factorial growth of $a^{(n)}$ with n. Barring a detailed cancellation of terms in the sums

$\Sigma_{\mathscr{C}_{n-1}=n-1}$, which is to be considered exceptional since none of the coefficients $a^{(2)}$ through $a^{(n-1)}$ were chosen to ensure such a cancellation, we see that one should not expect that $a^{(n)}$ as $n\to\infty$ is bounded by an exponentially growing function of n.

III. A RECURSION RELATION FOR NORMS

With the definition

$$\beta_n=\max_j\left(\sum_{|r|=n}|b_{rj}^{(n)}|\right), \tag{3.1}$$

Eq. (2.11b) yields

$$\begin{aligned}\alpha_n&=\max_k\sum_{|r|=n}\left|b_{rk}^{(n)}-\frac{\partial_z^r}{r!}\sum_{\mathscr{C}_{n-1}=n-1}\frac{L_2^{s_2}\ldots L_{n-1}^{s_{n-1}}}{s_2!\ldots s_{n-1}!}z_k\right|\\&\leqslant\beta_n+\max_k\sum_{|r|=n}\left|\sum_{\mathscr{C}_{n-1}=n-1}\frac{\partial_z^r}{r!}\frac{L_2^{s_2}\ldots L_{n-1}^{s_{n-1}}}{s_2!\ldots s_{n-1}!}\right|\\&\leqslant\beta_n+\sum_{\mathscr{C}_{n-1}=n-1}\frac{1}{s_2!\ldots s_{n-1}!}\max_k\sum_{|r|=n}\left|\frac{\partial_z^r}{r!}L_2^{s_2}\cdots L_{n-1}^{s_{n-1}}z_k\right|.\end{aligned} \tag{3.2}$$

Note that the component of the vector on the right side is determined by the component of z and is labeled here by k. Our goal is to express the right side of the last inequality in (3.2) in terms of $\alpha_2,\ldots,\alpha_{n-1}$. We accomplish this through two lemmas. (The second one will also be used in Sec. V.)

Consider a vector function F whose components are homogeneous polynomials of order $l\geqslant 0$,

$$F_k^{(l)}(z)=\sum_{|i|=l}f_{ik}^{(l)}z^i;\quad 1\leqslant k\leqslant d, \tag{3.3}$$

and for which

$$\max_k\left(\sum_{|i|=l}|f_{ik}^{(l)}|\right)\leqslant\phi_l \tag{3.4}$$

for some $\phi_l\in\mathbb{R}^+$. Define the quantities c, m, and B by

$$\sum_{|t|=m(\phi_l x^l,s_2,\ldots,s_n)}c_{tk}(F,s_2,\ldots,s_n)z^t=L_2^{s_2}\cdots L_n^{s_n}F_k^{(l)}(z), \tag{3.5a}$$

$$B(\phi_l x^l,s_2,\ldots,s_n)x^{m(\phi_l x^l,s_2,\ldots,s_n)}=\left(x^2\alpha_2\frac{d}{dx}\right)^{s_2}\cdots\left(x^n\alpha_n\frac{d}{dx}\right)^{s_n}\phi_l x^l. \tag{3.5b}$$

Here use is made of the obvious fact that the power of x in (3.5b) is the same as the power of z in (3.5a). Evidently $B(\phi_l x^l,s_2,\ldots,s_n)$ is a non-negative real quantity and $m(\phi_l x^l,s_2,\ldots,s_n)$ is a non-negative integer. The arguments of c, m, and B have been chosen to be rather explicit, so that the notation is sufficiently general for the manipulations that follow. When referring to a power of only one vector field, on the other hand, we denote the summation index by s, dropping the subscript, and replace the argument $\phi_l x^l$ of m and B by l. The following holds:

Lemma 3.1: For integers $s,l\geqslant 0$,

$$\max_k\left(\sum_{|t|=m(l,s)}|c_{tk}(F,s)|\right)\leqslant B(l,s) \tag{3.6}$$

and

$$\|L_n^s F^{(l)}(z)\|\leqslant B(l,s)x^{m(l,s)}. \tag{3.7}$$

This lemma is given in Refs. 9 and 10, though its proof is only outlined there. In the Appendix we provide a more complete proof (which extends the relations derived in Appendix A of Ref. 7).

The product of operators of the form $L_i^{s_i}$ can now be bounded by the lemma below.

Lemma 3.2: For $n\geqslant 2$ and all functions F of the form (3.3), $l\geqslant 0$,

$$\max_k\sum_{|t|=m(\phi_l x^l,s_2,\ldots,s_n)}|c_{tk}(F,s_2,\ldots,s_n)|\leqslant B(\phi_l x^l,s_2,\ldots,s_n) \tag{3.8}$$

and

$$\|L_2^{s_2}\cdots L_n^{s_n}F^{(l)}(z)\|\leqslant B(\phi_l x^l,s_2,\ldots,s_n)x^{m(\phi_l x^l,s_2,\ldots,s_n)}. \tag{3.9}$$

Proof is by induction on n and is straightforward. For $n=2$ inequalities (3.8) and (3.9) hold by Lemma 3.1, inequalities (3.6) and (3.7). Assume now (3.8) and (3.9) hold for a fixed n and all functions F of the form (3.3). Then

$$\|L_2^{s_2}\cdots L_n^{s_n}L_{n+1}^{s_{n+1}}F^{(l)}(z)\|=\|L_2^{s_2}\cdots L_n^{s_n}\tilde{F}^{(l')}(z)\|, \tag{3.10}$$

where

$$\tilde{F}_k^{(l')}(z)=\sum_{|t|=l'}c_{tk}(F,s_{n+1})z^t \tag{3.11}$$

with $l'=ns_{n+1}+l$ and, by Lemma 3.1,

$$\max_k\sum_{|t|=l'}|c_{tk}(F,s_{n+1})|\leqslant B(\phi_l x^l,s_{n+1}). \tag{3.12}$$

Use of the induction assumption yields

$$\max_k\sum_{|t|=m(B(\phi_l x^l,s_{n+1})x^{l'},s_2,\ldots,s_n)}|c_{tk}(\tilde{F},s_2,\ldots,s_n)|\leqslant B(B(\phi_l x^l,s_{n+1})x^{l'},s_2,\ldots,s_n) \tag{3.13}$$

and

$$\|L_2^{s_2}\cdots L_n^{s_n}\tilde{F}^{(l')}(z)\|\leqslant B(B(\phi_l x^l,s_{n+1})x^{l'},s_2,\ldots,s_n)x^{m(B(\phi_l x^l,s_{n+1})x^{l'},s_2,\ldots,s_n)}. \tag{3.14}$$

By unfolding the definitions of m and B we obtain

$$
\begin{aligned}
&B(B(\phi_l x^l, s_{n+1})x^{l'}, s_2, \ldots, s_n) x^{m(B(\phi_l x^l, s_{n+1})x^{l'}, s_2, \ldots, s_n)} \\
&\quad = \left(x^2 \alpha_2 \frac{d}{dx} \right)^{s_2} \cdots \left(x^n \alpha_n \frac{d}{dx} \right)^{s_n} B(\phi_l x^l, s_{n+1}) x^{l'} \\
&\quad = \left(x^2 \alpha_2 \frac{d}{dx} \right)^{s_2} \cdots \left(x^n \alpha_n \frac{d}{dx} \right)^{s_n} \left(x^{n+1} \alpha_{n+1} \frac{d}{dx} \right)^{s_{n+1}} \phi_l x^l \\
&\quad = B(\phi_l x^l, s_2, \ldots, s_n, s_{n+1}) x^{m(\phi_l x^l, s_2, \ldots, s_n, s_{n+1})}, \qquad (3.15)
\end{aligned}
$$

and so replace $B(B(\phi_l x^l, s_{n+1})x^{l'}, s_2, \ldots, s_n)$ by $B(\phi_l x^l, s_2, \ldots, s_n, s_{n+1})$ and $m(B(\phi_l x^l, s_{n+1})x^{l'}, s_2, \ldots, s_n)$ by $m(\phi_l x^l, s_2, \ldots, s_n, s_{n+1})$ in inequalities (3.13) and (3.14). With the further replacement of $c_{tk}(\tilde{F}, s_2, \ldots, s_n)$ by $c_{tk}(F, s_2, \ldots, s_n, s_{n+1})$, the proof is complete. □

We can now make progress with inequality (3.2). Since

$$
\max_k \sum_{|r|=n} \left| \frac{\partial_z^r}{r!} L_2^{s_2} \cdots L_{n-1}^{s_{n-1}} z_k \right| = \max_k \sum_{|r|=n} |c_{rk}(z, s_2, \ldots, s_{n-1})|, \qquad (3.16)
$$

use of inequality (3.8) yields

$$
\alpha_n \leqslant \beta_n + \sum_{\mathscr{C}_{n-1}=n-1} \frac{1}{s_2! \cdots s_{n-1}!} B(x, s_2, \ldots, s_{n-1}). \qquad (3.17)
$$

Note that the apparent dependence of the right side of (3.2) on z (or $\|z\|$) has disappeared, as it should.

The final step is to obtain an explicit expression for $B(x, s_2, \ldots, s_{n-1})$, which requires the evaluation of the right side of Eq. (3.5b) for $l=1$, $\phi_l=1$. First we note that

$$
\left(x^n \frac{d}{dx} \right)^s x^p = \frac{(n-1)^s \Gamma\left(\frac{s(n-1)+p}{n-1} \right)}{\Gamma\left(\frac{p}{n-1} \right)} x^{p+s(n-1)}, \qquad (3.18)
$$

where we take, as it is sufficient for our purposes, n, s, and p to be integers, with $n \geqslant 2$, $s \geqslant 0$, and $p \geqslant 1$. The relation (3.18) is easily proven by induction on s. Repeated use of (3.18) on the right side of Eq. (3.5b) then leads to

$$
\begin{aligned}
B(x, s_2, \ldots, s_{n-1}) = \alpha_2^{s_2} (2\alpha_3)^{s_3} \cdots ((n-2)\alpha_{n-1})^{s_{n-1}} \frac{\Gamma\left(\frac{1+s_{n-1}(n-2)}{n-2} \right)}{\Gamma\left(\frac{1}{n-2} \right)} \\
\times \frac{\Gamma\left(\frac{1+s_{n-1}(n-2)+s_{n-2}(n-3)}{n-3} \right)}{\Gamma\left(\frac{1+s_{n-1}(n-2)}{n-3} \right)} \cdots \frac{\Gamma\left(\frac{1+s_{n-1}(n-2)+\cdots+s_2}{1} \right)}{\Gamma\left(\frac{1+s_{n-1}(n-2)+\cdots+2s_3}{1} \right)}, \qquad (3.19)
\end{aligned}
$$

which is the desired, though admittedly cumbersome, expression for B.

With the definitions $\eta_n = n\alpha_{n+1}$, $\tau_n = n\beta_{n+1}$,

$$Q_m = 1, \quad m = n-1,$$

$$Q_m = 1 + \sum_{j=1}^{n-m-1} (n-j)s_{n-j+1}, \quad 1 \leqslant m \leqslant n-2, \tag{3.20a}$$

and

$$\mathscr{G}(s_2,\ldots,s_n) = \prod_{m=1}^{n-1} \frac{\Gamma\left(s_{m+1} + \frac{Q_m}{m}\right)}{s_{m+1}!\,\Gamma\left(\frac{Q_m}{m}\right)}, \tag{3.20b}$$

inequality (3.17) and Eq. (2.11a) become

$$\eta_1 = \tau_1, \tag{3.21a}$$

$$\eta_n \leqslant \tau_n + n \sum_{\mathscr{C}_n = n} \eta_1^{s_2} \cdots \eta_{n-1}^{s_n} \mathscr{G}(s_2,\ldots,s_n), \quad n \geqslant 2. \tag{3.21b}$$

In Sec. IV we will use these relations to get an estimate for η_n. We call attention to the interesting fact that the relations (3.21), and hence the results that follow, do not depend explicitly on d. The dimensionality of the space enters only through the definition of quantities η_n and τ_n.

IV. BOUND FOR η_n

From inequality (3.21b) we get the following bound on η_n:

Theorem 4.1: Let

$$K_n = \max_{1 \leqslant j \leqslant n} \left[\frac{\tau_j}{j^j (j-1)!} \right]^{1/j}, \quad n \geqslant 1. \tag{4.1}$$

Then

$$\eta_n \leqslant (K_n n)^n n!. \tag{4.2}$$

Proof: First we manipulate the ratios of Γ functions that appear in $\mathscr{G}$. For $1 \leqslant m \leqslant n-1$ and $s_{m+1} \geqslant 1$,

$$\frac{\Gamma\left(s_{m+1} + \frac{Q_m}{m}\right)}{\Gamma\left(\frac{Q_m}{m}\right)} = \left(s_{m+1} - 1 + \frac{Q_m}{m}\right)\left(s_{m+1} - 2 + \frac{Q_m}{m}\right) \cdots \frac{Q_m}{m} \leqslant \left(s_{m+1} - 1 + \frac{Q_m}{m}\right)^{s_{m+1}}$$

$$= \frac{1}{m^{s_{m+1}}} [m(s_{m+1}-1) + Q_m]^{s_{m+1}} \leqslant \frac{1}{m^{s_{m+1}}} (n+1-m)^{s_{m+1}}. \tag{4.3}$$

The last inequality makes use of $m s_{m+1} + Q_m \leqslant n+1$, which follows from the condition on the sums over s. The last line in Eq. (4.3) is also a valid estimate when $s_{m+1} = 0$. Hence,

$$\mathscr{G}(s_2,\ldots,s_n) \leqslant \frac{n^{s_2}(n-1)^{s_3} \cdots 2^{s_n}}{s_2! \cdots s_n!\, 1^{s_2} 2^{s_3} \cdots (n-1)^{s_n}}, \tag{4.4}$$

and inequality (3.21b) becomes

$$\eta_n \leqslant \tau_n + n \sum_{\mathscr{C}_n = n} \frac{(n\eta_1)^{s_2}[(n-1)\eta_2]^{s_3}\cdots(2\eta_{n-1})^{s_n}}{s_2!\cdots s_n! 1^{s_2}\cdots(n-1)^{s_n}}. \tag{4.5}$$

Before proceeding further we establish two inequalities. The first one is given by

$$m^m(1+n-m) \leqslant n^m, \quad n \geqslant 2, \quad 1 \leqslant m \leqslant n-1. \tag{4.6}$$

Its validity can be seen directly from the binomial expansion

$$n^m = (m+(n-m))^m \geqslant m^m + m^m(n-m) = m^m(1+n-m). \tag{4.7}$$

The other one is given by the following statement:

Propositions 4.2: When $n \geqslant 2$ and the condition $\mathscr{C}_n = n$ is satisfied,

$$1!^{s_2}2!^{s_3}\cdots(n-1)!^{s_n} \leqslant (n-1)!. \tag{4.8}$$

To prove this statement note that $\mathscr{C}_n = n$ requires that there exist at least one term $(k-1)s_k \geqslant 1$, $2 \leqslant k \leqslant n$. Then define $n_{(k)} = n-(k-1)s_k$, and consider three cases: $n_{(k)} \geqslant 2$, $n_{(k)} = 1$, and $n_{(k)} = 0$.

(i) $n_{(k)} \geqslant 2$:

$$\begin{aligned}
(n-1)! &= (n_{(k)} + (k-1)s_k - 1)! \\
&= (n_{(k)} + (k-1)s_k - 1)(n_{(k)} + (k-1)s_k - 2)\cdots((k-1)s_k + 1)!((k-1)s_k)! \\
&\geqslant n_{(k)}(n_{(k)}-1)\cdots 2((k-1)s_k)! \\
&= n_{(k)}!((k-1)s_k)! \\
&\geqslant s_2!(2s_3)!\cdots((k-2)s_{k-1})!(ks_{k+1})!\cdots((n-1)s_n)!((k-1)s_k)! \\
&\geqslant 1!^{s_2}2!^{s_3}\cdots(k-2)!^{s_{k-1}}(k-1)!^{s_k}k!^{s_{k+1}}\cdots(n-1)!^{s_n},
\end{aligned} \tag{4.9}$$

which is (4.8).

(ii) When $n_{(k)} = 1$ we must have $k = n$ and $s_2 = s_n = 1$, $s_i = 0$, $3 \leqslant i \leqslant n-1$, so the result is immediate.

(iii) $n_{(k)} = 0$ implies $(k-1)s_k = n$. As the case $k = 2$ is trivial, we consider only $(k-1) \geqslant 2$, $s_k \geqslant 2$. Then,

$$\begin{aligned}
(n-1)! &= ((k-1)s_k - 1)! \\
&= \frac{((k-1)s_k)!}{(k-1)s_k} \\
&= \frac{((k-1)(s_k-1)+(k-1))!}{(k-1)s_k} \\
&\geqslant ((k-1)(s_k-1))!(k-1)! \geqslant (k-1)!^{s_k-1}(k-1)! = (k-1)!^{s_k},
\end{aligned} \tag{4.10}$$

which is (4.8). The first inequality uses the relation $\binom{p+q}{p} \geqslant p+q$ when $p,q \geqslant 2$. This completes the proof of Proposition 4.2. □

The relation (4.2) can now be proven by induction. For $n = 1$ we have

$$\eta_1 = \tau_1 = K_1, \tag{4.11}$$

as required. Assume now that (4.2) holds through $n-1$. Starting with inequality (4.5) we then obtain

$$\begin{aligned}\eta_n &\leqslant \tau_n + n \sum_{\mathscr{C}_n=n} \prod_{m=1}^{n-1} [(n+1-m)(K_m m)^m m!]^{s_{m+1}} \frac{1}{s_2!\cdots s_n! 1^{s_2}\cdots(n-1)^{s_n}} \\ &\leqslant \tau_n + nK_n^n \sum_{\mathscr{C}_n=n} \prod_{m=1}^{n-1} [(n+1-m)m^m m!]^{s_{m+1}} \frac{1}{s_2!\cdots s_n! 1^{s_2}\cdots(n-1)^{s_n}} \\ &\leqslant \tau_n + nK_n^n \sum_{\mathscr{C}_n=n} n^{s_2+2s_3+\cdots+(n-1)s_n} \prod_{m=1}^{n-1} m!^{s_{m+1}} \frac{1}{s_2!\cdots s_n! 1^{s_2}\cdots(n-1)^{s_n}} \\ &\leqslant \tau_n + (K_n n)^n n! \sum_{\mathscr{C}_n=n} \frac{1}{s_2!\cdots s_n! 1^{s_2}\cdots(n-1)^{s_n}}. \end{aligned} \tag{4.12}$$

For the second inequality we have used $K_n \geqslant K_m$, $1 \leqslant m \leqslant n-1$, for the third one we have used inequality (4.6), and for the fourth one we have used inequality (4.8). In addition, we have repeatedly used the condition on the sum to sum the power of the summand. The remaining sums over s nicely sum to $1-1/n$, as can be demonstrated using Cauchy's identity[11]

$$\sum_{\mathscr{C}_{n+1}=n} \frac{1}{s_2!\cdots s_n! s_{n+1}! 1^{s_2}\cdots(n-1)^{s_n} n^{s_{n+1}}} = 1. \tag{4.13}$$

Substitution of this result into Eq. (4.12) leads to

$$\eta_n \leqslant \tau_n + (K_n n)^n n!(1-1/n) \leqslant (K_n n)^n n!. \tag{4.14}$$

We have used the definition of K_n given by Eq. (4.1). This completes the proof of Theorem 4.1.□

By unfolding various definitions, Theorem 4.1 can be written as

$$\|L_n\| \leqslant (n-2)!(K_{n-1}(n-1))^{n-1}\|z\|^n, \quad n \geqslant 2, \tag{4.15}$$

where K_n is given by

$$K_n = \max_{1\leqslant j\leqslant n} \left[\frac{\max_l(\Sigma_{|r|=j+1}|b_{rl}^{(j+1)}|)}{j^{j-1}(j-1)!} \right]^{1/j}, \quad n \geqslant 1. \tag{4.16}$$

Thus even when $P(z)$ is a convergent series, that is $K_n \leqslant K$ for some $K \in \mathbb{R}^+$, $n \geqslant 1$, the bound on the sequence $\{\|L_n\|\}$ exhibits a factorial-type growth with n over any finite domain containing the origin. Such behavior is typical of asymptotic sequences. Specifically, with $n^n \leqslant n!\ C^n$ for some $C \in \mathbb{R}^+$, Eq. (5.5) below, it follows that $\{\|L_n\|\}$ is a Gevrey sequence of order 2.

V. PRODUCT OF LIE TRANSFORMATIONS AND OPTIMUM TRUNCATION

Having obtained an estimate for $\|L_n\|$, we turn to the product of a *finite* number of Lie transformations. Such a product is well defined on a nonvanishing domain in $\mathbb{C}^d$ as the following result shows.

Theorem 5.1: The quantity $\mathscr{M}_n z$, $n \geqslant 2$, is an analytic function of z in the open ball

$$x < \frac{1}{K_{n-1} n^2 e^{1/4}}. \tag{5.1}$$

Proof: The function $\mathscr{M}_n z$ is given by the power series in z

$$\mathscr{M}_n z_k = \sum_{q=1}^{\infty} \sum_{\mathscr{C}_n = q-1} \frac{L_2^{s_2} \cdots L_n^{s_n}}{s_2! \cdots s_n!} z_k . \tag{5.2}$$

We determine a bound on the domain on which the sum over q is absolutely convergent. Lemma 3.2 and Eq. (3.19) yield

$$\begin{aligned} \left| \sum_{\mathscr{C}_n = q-1} \frac{L_2^{s_2} \cdots L_n^{s_n}}{s_2! \cdots s_n!} z_k \right| &\leqslant \left\| \sum_{\mathscr{C}_n = q-1} \frac{L_2^{s_2} \cdots L_n^{s_n}}{s_2! \cdots s_n!} z_k \right\| \\ &\leqslant \sum_{\mathscr{C}_n = q-1} \frac{\| L_2^{s_2} \cdots L_n^{s_n} z_k \|}{s_2! \cdots s_n!} \leqslant x^q \sum_{\mathscr{C}_n = q-1} \frac{B(x, s_2, \cdots, s_n)}{s_2! \cdots s_n!} \\ &= x^q \sum_{\mathscr{C}_n = q-1} \eta_1^{s_2} \cdots \eta_{n-1}^{s_n} \mathscr{G}(s_2, \ldots, s_n). \end{aligned} \tag{5.3}$$

Before proceeding further we derive two simple inequalities. First we replace the estimate (4.2) by

$$\eta_n \leqslant (K_n n^2)^n, \quad n \geqslant 1. \tag{5.4}$$

Justification follows from the well-known formula

$$n! = \sqrt{2\pi}\, n^{n+1/2} \exp(-n + \theta/(12n)), \quad 0 < \theta < 1. \tag{5.5}$$

Since the expression $\sqrt{2\pi n}\, \exp(-n + 1/(12n))$ is monotonically decreasing with n, and at $n=2$ takes the value 0.50 0163, we get $n! \leqslant n^n$ for $n \geqslant 1$, and the estimate (5.4) from Eq. (4.2).

Second, we establish that for $n \geqslant 2$ and $1 \leqslant m \leqslant n-1$

$$m(n-m+1)^2 \geqslant 4(n-1), \tag{5.6}$$

as can be seen directly:

$$m(n-m+1)^2 - 4(n-1) = (n-m-1)(nm+3m-4-m^2) \geqslant m(n-m-1)^2 \geqslant 0. \tag{5.7}$$

Returning to Eq. (5.3), we simplify the ratio of Γ functions occurring in $\mathscr{G}$. [It is not fruitful to use Eq. (4.3) here because the condition on the sums over s is different.] For $1 \leqslant m \leqslant n-1$ and $s_{m+1} \geqslant 1$ the following holds:

$$\begin{aligned} \frac{\Gamma\left(s_{m+1} + \frac{Q_m}{m}\right)}{\Gamma\left(\frac{Q_m}{m}\right)} &= \left(s_{m+1} - 1 + \frac{Q_m}{m}\right)\left(s_{m+1} - 2 + \frac{Q_m}{m}\right) \cdots \frac{Q_m}{m} \\ &= \frac{1}{m^{s_{m+1}}} (m s_{m+1} - m + Q_m)(m s_{m+1} - 2m + Q_m) \cdots Q_m \\ &\leqslant \frac{1}{m^{s_{m+1}}} (q-m)(q-2m) \cdots (q - s_{m+1} m) \\ &\leqslant \frac{1}{m^{s_{m+1}}} (q-1)(q-2) \cdots (q - s_{m+1}) = \frac{1}{m^{s_{m+1}}} \frac{(q-1)!}{(q-1-s_{m+1})!}. \end{aligned} \tag{5.8}$$

The first inequality relies on the relation $ms_{m+1}+Q_m \leqslant q$. Again, the last line in Eq. (5.8) is also a valid estimate when $s_{m+1}=0$. Using (5.8) and (5.4), the sums over s in Eq. (5.3) become

$$\begin{aligned}
&\sum_{\mathscr{C}_n=q-1} \eta_1^{s_2}\cdots\eta_{n-1}^{s_n}\mathscr{G}(s_2,\ldots,s_n)\\
&\quad\leqslant K_{n-1}^{q-1}\sum_{\mathscr{C}_n=q-1}\frac{(1^2n^2)^{s_2}}{n^{2s_2}}\frac{(2^4(n-1)^2)^{s_3}}{(n-1)^{2s_3}}\cdots\frac{((n-1)^{2(n-1)}2^2)^{s_n}}{2^{2s_n}}\mathscr{G}(s_2,\ldots,s_n)\\
&\quad\leqslant (K_{n-1}n^2)^{q-1}\sum_{\mathscr{C}_n=q-1}\frac{\mathscr{G}(s_2,\ldots,s_n)}{n^{2s_2}(n-1)^{2s_3}\cdots 2^{2s_n}}\\
&\quad\leqslant (K_{n-1}n^2)^{q-1}\sum_{\mathscr{C}_n=q-1}\binom{q-1}{s_2}\frac{1}{n^{2s_2}}\binom{q-1}{s_3}\frac{1}{[2(n-1)^2]^{s_3}}\cdots\binom{q-1}{s_n}\frac{1}{[(n-1)2^2]^{s_n}}\\
&\quad\leqslant (K_{n-1}n^2)^{q-1}\sum_{s_2=0}^{q-1}\cdots\sum_{s_n=0}^{q-1}\binom{q-1}{s_2}\frac{1}{n^{2s_2}}\binom{q-1}{s_3}\frac{1}{[2(n-1)^2]^{s_3}}\cdots\binom{q-1}{s_n}\frac{1}{[(n-1)2^2]^{s_n}}\\
&\quad= (K_{n-1}n^2)^{q-1}\prod_{m=1}^{n-1}\left(1+\frac{1}{m(n-m+1)^2}\right)^{q-1}\\
&\quad\leqslant (K_{n-1}n^2)^{q-1}\left(1+\frac{1}{4(n-1)}\right)^{(n-1)(q-1)} < (K_{n-1}n^2e^{1/4})^{q-1}.
\end{aligned}\tag{5.9}$$

The first inequality follows from Eq. (5.4) and the fact that K_n is nondecreasing with n, the second one from Eq. (4.6), the third one from Eq. (5.8), the fourth one is evident upon an examination of the ranges of indices s_2 through s_n subject to the condition $\mathscr{C}_n=q-1$, the fifth one from Eq. (5.6), and the last one from the relation $(1+1/(4(n-1)))^{4(n-1)}<e$. For the first two inequalities we have used the condition $\mathscr{C}_n=q-1$ to sum the power of the summand.

Use of the result (5.9) in Eq. (5.3) gives

$$\left|\sum_{\mathscr{C}_n=q-1}\frac{L_2^{s_2}\cdots L_n^{s_n}}{s_2!\cdots s_n!}z_k\right| \leqslant \frac{1}{K_{n-1}n^2e^{1/4}}(K_{n-1}xn^2e^{1/4})^q \tag{5.10}$$

and so the sum over q in Eq. (5.2) is absolutely convergent for

$$x<\frac{1}{K_{n-1}n^2e^{1/4}}. \tag{5.11}$$

□

The result stated in Theorem 5.1 is a lower bound on the domain $\mathscr{D}_n$, $n\geqslant 2$, introduced following Eq. (2.5). Even though $\mathscr{M}z$ cannot be expected to be analytic over any finite domain, inequality (5.1) shows that $\mathscr{M}_nz$ is. If $P(z)$ is convergent, $\max_{n\in\mathbb{N}}K_n$ is finite and the bound on $\mathscr{D}_n$ shrinks quadratically with n. For a general asymptotic series, on the other hand, the bound may decrease more rapidly with n, depending on K_n.

Since the estimates on $\mathscr{D}_n$ do not allow the conclusion that $\mathscr{M}_nz$ is convergent as $n\to\infty$ even when $\mathscr{D}$ is finite, we turn to the asymptotic properties of this transformation. Specifically, we examine the question of optimum truncation when $\mathscr{D}$ is finite. The most natural quantity to optimize is the difference between $P(z)$ and $\mathscr{M}_nz$, denoted here by $R(n,z)$:

$$R(n,z)\overset{\text{def}}{=}\|P(z)-e^{L_2}\cdots e^{L_n}z\|. \tag{5.12}$$

The following gives the relevant estimates on $R(n,z)$.

Proposition 5.2: If $\beta_n \leqslant c^{n-1}$ for $n \geqslant 2$ and some $c \in \mathbb{R}^+$, then the remainder $R(n,z)$ is defined in the open ball

$$x < \frac{1}{cn^2 e^{1/4}} \tag{5.13}$$

and satisfies there

$$R(n,z) < x\left[\frac{(cxn^2 C_1)^n}{1-cxn^2 e^{1/4}}\right], \tag{5.14}$$

with $C_1 = e^{1/4} + \frac{1}{4}$.

Proof follows from Theorem 5.1. Using Eqs. (5.3) and (5.9) and the condition on β we have

$$\begin{aligned} R(n,z) &= \|P(z) - e^{L_2}\cdots e^{L_n} z\| \\ &= \left\| \sum_{q=n+1}^{\infty} \sum_{|r|=q} b_{rk}^{(q)} z^r - \sum_{q=n+1}^{\infty} \sum_{\mathscr{C}_n = q-1} \frac{L_2^{s_2}\cdots L_n^{s_n}}{s_2!\cdots s_n!} z_k \right\| \\ &\leqslant \sum_{q=n+1}^{\infty} x^q \beta_q + \sum_{q=n+1}^{\infty} \left\| \sum_{\mathscr{C}_n = q-1} \frac{L_2^{s_2}\cdots L_n^{s_n}}{s_2!\cdots s_n!} z_k \right\| \\ &< \frac{1}{c} \sum_{q=n+1}^{\infty} (cx)^q + \frac{1}{cn^2 e^{1/4}} \sum_{q=n+1}^{\infty} (cxn^2 e^{1/4})^q = x\left[\frac{(cx)^n}{1-cx} + \frac{(cxn^2 e^{1/4})^n}{1-cxn^2 e^{1/4}}\right]. \end{aligned} \tag{5.15}$$

For the second inequality we have replaced K_{n-1} by c, which follows from the conditions on β_n:

$$K_{n-1} = \max_{1 \leqslant j \leqslant n-1} \left[\frac{\beta_{j+1}}{j^{j-1}(j-1)!}\right]^{1/j} \leqslant \max_{1 \leqslant j \leqslant n-1} \left[\frac{c^j}{j^{j-1}(j-1)!}\right]^{1/j} \leqslant c, \quad n \geqslant 2. \tag{5.16}$$

Evidently, the infinite sums over q in Eq. (5.15) are convergent in the open ball given by Eq. (5.13). To obtain the estimate (5.14) one more step is needed:

$$\begin{aligned} R(n,z) &< x\left[\frac{(cx)^n}{1-cx} + \frac{(cxn^2 e^{1/4})^n}{1-cxn^2 e^{1/4}}\right] \\ &< x\,\frac{(cx)^n + (cxn^2 e^{1/4})^n}{1-cxn^2 e^{1/4}} \leqslant x\,\frac{(cx(n^2 e^{1/4}+1))^n}{1-cxn^2 e^{1/4}} \leqslant x\,\frac{(cxn^2(e^{1/4}+\frac{1}{4}))^n}{1-cxn^2 e^{1/4}}. \end{aligned} \tag{5.17}$$

□

We turn to optimum truncation. Since the leading order term in $\mathscr{M}z$ is z, which is of order x, it is useful to divide R by x, so that the resulting quantity R/x can be compared to one. Note also that R/x depends on c and x only through the product cx, which we denote by $\overline{x}$. The question of optimum truncation can now be formulated as follows: given $\overline{x}$, find the value of n, denoted by n_{opt}, where the estimate for R/x reaches its minimum and find the value of the minimum.

Equation (5.14) is too complicated to carry out the required calculations analytically. We thus set

$$\frac{1}{1-\overline{x}\,n^2 e^{1/4}} < C_2 \tag{5.18}$$

for some $C_2 \in \mathbb{R}^+$. We do not yet specify the value of C_2. It should, however, satisfy the following two requirements: first, that it be as small as possible, so as to keep the value of the estimate at $n = n_{\text{opt}}$ as small as possible; and second, that it be sufficiently large so that inequality (5.18) is satisfied at $n = n_{\text{opt}}$ (and hence for all $n \leqslant n_{\text{opt}}$). We then look for the minimum of the expression $C_2(\overline{x}n^2 C_1)^n$. Considering n as real and differentiating with respect to it, the minimum is easily found at $\tilde{n} = (1/e)(1/\sqrt{\overline{x}C_1})$, so that we can take

$$n_{\text{opt}} = \text{int}\left[\frac{1}{e}\,\frac{1}{\sqrt{\overline{x}C_1}}\right], \tag{5.19}$$

where int$[\cdot]$ stands for the integer part. Note that for a given value of $\overline{x}$, n_{opt} is never larger than the value of n for which the given $\overline{x}$ could be outside of the domain of analyticity of $R(u,z)$, cf. Eq. (5.13). To obtain an explicit estimate for $R(n_{\text{opt}},z)/x$ we evaluate $C_2(\overline{x}n^2 C_1)^n$ at $n = \tilde{n} - 1$. The result is an exponentially small bound for the remainder:

$$\frac{R(n_{\text{opt}},z)}{x} < C_2 e^2 \exp\left(-\frac{2}{e\sqrt{\overline{x}C_1}}\right). \tag{5.20}$$

Since $\tilde{n} \geqslant n_{\text{opt}}$, the constant C_2 can be determined by substituting the expression for $\tilde{n}$ into Eq. (5.18), which yields

$$C_2 > \frac{C_1 e^2}{C_1 e^2 - e^{1/4}} = 1.12\ 7751\ldots\ . \tag{5.21}$$

The proximity of this limit to 1 indicates that both the value of n_{opt} and the estimate for $R(n_{\text{opt}},z)/x$ are determined primarily by the leading term in Eq. (5.14), $(\overline{x}n^2 C_1)^n$.

VI. SUMMARY

An upper bound on the norm of vector fields L_n which are computed by requiring that $\mathscr{M}z$ agrees order by order with a given asymptotic power series is given in Theorem 4.1, Eqs. (4.15) and (4.16). A lower bound on the domain of analyticity of $\mathscr{M}_n z$ is given in Theorem 5.1, Eq. (5.1).

Even when $\mathscr{D}$ is finite, the estimate for η_n grows with order more rapidly than an exponential function and the estimate for $\mathscr{D}_n$ goes to zero as $n \to \infty$. We remarked that one can expect these statements to hold true even in the exact computation of $\mathscr{M}_n z$. The estimates derived can be used to optimize the bound for the difference between $\mathscr{M}_n z$ and $P(z)$ as a function of n for a given value of $\|z\|$. The result is an exponentially small bound for the remainder, given in Eq. (5.20). It seems well worthwhile to explore next whether the procedure developed in the preceding sections can be adapted to Hamiltonian normal form calculations and used to strengthen the estimates of the type given in Ref. 6 for the norm of generating polynomials and the remainders. One can also examine the bound that the present results place on the norms of the vector fields in the transformation $\mathscr{M}$, when $\mathscr{M}$ is computed from a single Lie transformation specified by a vector field analytic at the origin (a version of the Zassenhaus formula). Good estimates for the power series derived from the action of the given Lie transformation on a point z are necessary to study this question. (Provided that the analytic vector field is multiplied by a sufficiently small parameter, such a power series is convergent, as given by standard theorems on ordinary differential equations.)

APPENDIX: PROOF OF LEMMA 3.1

We first prove the relation (3.6) by induction on s. For $s=0$, $m(l,0)=l$, $c_{tk}(F,0)=f_{tk}^{(l)}$, and $B(l,0)=\phi_l$. Therefore (3.6) reduces to inequality (3.4). For $s=1$ we have

$$L_n F_k^{(l)}(z)=\sum_{j=1}^{d} g_j^{(n)} \frac{\partial}{\partial z_j} \sum_{|i|=l} f_{ik}^{(l)} z^i=\sum_{j=1}^{d} \sum_{|r|=n} \sum_{|i|=l} a_{rj}^{(n)} f_{ik}^{(l)} i_j z_1^{i_1+r_1}\cdots z_j^{i_j+r_j-1}\cdots z_d^{i_d+r_d}, \tag{A1}$$

which yields

$$\begin{aligned}\max_k\left(\sum_{|t|=m(l,1)} |c_{tk}(F,1)|\right) &\leq \max_k\left(\sum_{j=1}^{d} \sum_{|r|=n} \sum_{|i|=l} |a_{rj}^{(n)}||f_{ik}^{(l)}| i_j\right)\\ &\leq \alpha_n \max_k\left(\sum_{j=1}^{d} \sum_{|i|=l} |f_{ik}^{(l)}| i_j\right)=\alpha_n l \max_k\left(\sum_{|i|=l} |f_{ik}^{(l)}|\right)\leq \alpha_n l \phi_l = B(l,1),\end{aligned} \tag{A2}$$

as needed. Next, assume that (3.6) holds for a fixed s. Then

$$\begin{aligned}L_n^{s+1} F_k^{(l)}(z) &= \sum_{j=1}^{d} g_j^{(n)} \frac{\partial}{\partial z_j} \sum_{|t|=m(l,s)} c_{tk}(F,s) z^t\\ &= \sum_{j=1}^{d} \sum_{|r|=n} \sum_{|t|=m(l,s)} a_{rj}^{(n)} c_{tk}(F,s) t_j z_1^{t_1+r_1}\cdots z_j^{t_j+r_j-1}\cdots z_d^{t_d+r_d},\end{aligned} \tag{A3}$$

and we have

$$\begin{aligned}\max_k\left(\sum_{|t|=m(l,s+1)} |c_{tk}(F,s+1)|\right) &\leq \max_k\left(\sum_{j=1}^{d} \sum_{|r|=n} \sum_{|t|=m(l,s)} |a_{rj}^{(n)}||c_{tk}(F,s)| t_j\right)\\ &\leq \alpha_n \max_k\left(\sum_{j=1}^{d} \sum_{|t|=m(l,s)} |c_{tk}(F,s)| t_j\right)\\ &= \alpha_n m(l,s) \max_k\left(\sum_{|t|=m(l,s)} |c_{tk}(F,s)|\right)\\ &\leq \alpha_n m(l,s) B(l,s)=B(l,s+1).\end{aligned} \tag{A4}$$

The last inequality uses the induction assumption, whereas the last equality follows from the recursion relation satisfied by B. This completes the proof of relation (3.6).

It is now straightforward to establish (3.7). We proceed again by induction on s. For $s=0$ we use inequality (3.4) and the special values of m, c, and B given at the beginning of the Appendix to see that (3.7) holds. For the case $s=1$, on the other hand, we use relations (A1) and (A2) (second inequality) to obtain

$$\|L_n F^{(l)}(z)\| = \left\| \sum_{j=1}^{d} \sum_{|r|=n} \sum_{|i|=l} a_{rj}^{(n)} f_{ik}^{(l)} i_j z_1^{i_1+r_1} \cdots z_j^{i_j+r_j-1} \cdots z_d^{i_d+r_d} \right\|$$

$$\leqslant \max_k \left(\sum_{j=1}^{d} \sum_{|r|=n} \sum_{|i|=l} |a_{rj}^{(n)}||f_{ik}^{(l)}| i_j \right) x^{n+l-1} \leqslant B(l,1) x^{m(l,1)}. \tag{A5}$$

The first inequality is evident from the definition of the norm and for the last relation we have relied on the fact that $m(l,1)=n+l-1$. Assume now that (3.7) holds for a fixed s. With the help of relations (A3) and (A4) (second inequality) we obtain

$$\|L_n^{s+1} F^{(l)}(z)\| = \left\| \sum_{j=1}^{d} \sum_{|r|=n} \sum_{|t|=m(l,s)} a_{rj}^{(n)} c_{tk}(F,s) t_j z_1^{t_1+r_1} \cdots z_j^{t_j+r_j-1} \cdots z_d^{t_d+r_d} \right\|$$

$$\leqslant \max_k \left(\sum_{j=1}^{d} \sum_{|r|=n} \sum_{|t|=m(l,s)} |a_{rj}^{(n)}||c_{tk}(F,s)| t_j \right) x^{m(l,s)+n-1} \leqslant B(l,s+1) x^{m(l,s+1)}. \tag{A6}$$

We have made use of the recursion relation for m, $m(l,s+1)=m(l,s)+n-1$. This completes the proof of inequality (3.7).

Geometric interpretation of fractal symmetries of a finite linear chain

(Received 15 March 1995; accepted for publication 25 January 1996)

The recipe of Weyl has been applied to two crystallographically distinct realizations of a regular orbit of the cyclic group of order N: the linear chain and the n-dimensional toroidal crystal, with n being the number of different prime integers dividing N, and Sylow factors of N being the Born–von Kármán periods. It follows that some fractallike symmetries of the linear chain are isomorphic images of multidimensional inversions, which are purely geometric operators. © *1996 American Institute of Physics.* [S0022-2488(96)00505-6]

I. INTRODUCTION

The structure of a finite linear chain has been studied recently[1–3] using the method of a general recipe of Weyl.[4,5] The linear chain consisting of N nodes constitutes a regular orbit of the cyclic group C_N. This group is the translation group of the chain, and serves as the ''obvious'' symmetry group of the recipe. Then the ''hidden'' symmetry group is Aut C_N, which involves, according to the recipe, all intrinsic properties of the structure of the linear chain. It was argued in Refs. 1 and 2 that the only manifestly geometric operation enclosed within the hidden symmetry group Aut C_N is, for $N>2$, the one-dimensional inversion automorphism τ_{-1}, which reverses the cyclic order of the chain. All other automorphisms τ_r, with r mutually prime with N, are self-similar scalings such that $\tau_r(j)=rj \bmod N$ for each node j of the chain, and admit therefore an interpretation of fractallike symmetries which preserve the structure of the linear chain, but definitely destroy the geometry and ordering of nodes.

In the present paper we aim to extend this investigation of the structure of the finite linear chain by proposing another crystallographic realization of a regular orbit of the obvious symmetry group C_N. In our proposal, the set which constitutes an orbit of the free action of the cyclic group C_N can be viewed as an n-dimensional configuration which forms a toroidal crystal with periodic boundary conditions. The principal axes of this n-dimensional crystal are labelled by elements p of the socle π of N, i.e. of the set of all those prime integers which are divisors of N. The dimension $n=|\pi|$ is equal to the number of elements of the socle π, and the Born–van Kármán period in the pth direction coincides with the order N_p of the maximal Sylow subgroup $C_{N_p} \lhd C_N$.

We admit, therefore, another structural realization of a regular orbit of the cyclic group C_N. Clearly, both realizations, the linear ring and the n-dimensional toroidal crystal, exhibit completely different crystallographic meaning. For example, the coordination number (i.e., the number of nearest neighbors of a node of a crystal) for the linear ring is clearly 2, whereas for the toroidal crystal it is $2n$ [or $2(n-1)$ when $2 \in \pi$ and $N_2=2$]. Nevertheless, there are also some structural similarities between these two realizations which emerge from the hidden symmetry group. In this paper we aim to point out such similarities, by a systematic use of the recipe of Weyl. In practice, it involves an analysis of those one-to-one mappings between these two realizations, which are consistent with the hidden symmetry group Aut C_N. Some results of our analysis are, in fact, finite analogies of the theory of incommensurate phases based on projections from multidimensional crystals.[6,7] The associated mathematics is borrowed from number theory.[8]

0022-2488/96/37(5)/2472/12/$10.00

We point out that the multidimensional presentation of a regular orbit of the cyclic group C_N admits much more geometric interpretation for hidden symmetry operations than the case of a linear chain, since each dimension yields a one-dimensional inversion.

The paper is organized as follows. In Sec. II we formulate briefly the main definitions and results for the one-dimensional presentation of the regular orbit of the cyclic group C_N in terms of the recipe of Weyl. Section III is devoted to discussion of geometry and hidden symmetries of the toroidal crystal. In Sec. IV we present transformations between these two presentations, and in Sec. V we provide an example. The conclusions constitute Sec. VI.

II. THE LINEAR CHAIN

Let

$$\widetilde{N} =: \{j | j = 1,2,\ldots,N\} \tag{1}$$

be the set of nodes of the linear chain and

$$C_N = \{\widetilde{N}, + \bmod N\} \tag{2}$$

be the cyclic group of order N, with the additive notation. Within the terminology of the recipe of Weyl,[1–5] the set $\widetilde{N}$ exhibits the obvious symmetry, given by the group C_N. In other words, the set $\widetilde{N}$ is equipped with ordering of the group C_N, that is, with the cyclic order. This ordering is realized by a bijection $\kappa: \widetilde{N} \to C_N$, which is called a map of the group C_N on the set $\widetilde{N}$. In particular, a pramap $\kappa_0: \widetilde{N} \to C_N$ can be chosen by identifying the set $\widetilde{N}$ with the group manifold of C_N, i.e., by putting

$$\kappa_0(j) = j \in C_N, \quad j \in \widetilde{N}. \tag{3}$$

The pramap κ_0 defines canonically the action $P: C_N \times \widetilde{N} \to \widetilde{N}$ of the group C_N on the linear ring $\widetilde{N}$ by

$$P(j) = \kappa_0^{-1} \circ R^{\mathrm{reg}}(j) \circ \kappa_0, \tag{4}$$

where

$$R^{\mathrm{reg}}(j) = \begin{pmatrix} j' \\ (j + j') \bmod N \end{pmatrix}, \quad j' \in \mathbf{C}_N, \tag{5}$$

defines, for $j \in C_N$, the left regular representation $R^{\mathrm{reg}}: C_N \times C_N \to C_N$ of the group C_N acting on itself. Each permutation $P(j), j \in C_N$, realizes the obvious (translational) symmetry of the chain $\widetilde{N}$.

Clearly, the atlas of all maps $\kappa: \widetilde{N} \to C_N$ which are compatible with the action P, i.e., for which the following diagram of sets and bijections

$$\begin{array}{ccc} \widetilde{N} & \xrightarrow{P(j)} & \widetilde{N} \\ \kappa \downarrow & & \downarrow \kappa, \quad j \in \mathbf{C}_N, \\ C_N & \xrightarrow{R^{\mathrm{reg}}(j)} & C_N \end{array} \tag{6}$$

is commutative, is given by

$$\mathrm{Atl}_{\kappa_0}(\widetilde{N}, C_N) = \{\kappa = R'^{\mathrm{reg}}(j) \circ \kappa_0 | j \in C_N\}, \tag{7}$$

where

$$R'^{\mathrm{reg}}(j)=\begin{pmatrix} j' \\ (j'-j) \bmod N \end{pmatrix}, \quad j' \in C_N \tag{8}$$

defines, for $j \in C_N$, the right regular representation R'^{reg} of the group C_N on itself. The map κ differs from κ_0 in that the origin in κ is translated by the element $j \in C_N$.

The hidden symmetry of the recipe of Weyl is given by the group

$$\mathrm{Aut}\ C_N=\{\tau_r | r \in \widetilde{N}, \quad \mathrm{lcd}(r,N)=1\} \tag{9}$$

of all automorphisms

$$\tau_r=\begin{pmatrix} j \\ rj \bmod N \end{pmatrix}, \quad j \in C_N, \tag{10}$$

of the group C_N of obvious symmetry. The symbol $\mathrm{lcd}(r,N)$ in Eq. (9) denotes the largest common divisor of integers r and N. The multiplication in the group $\mathrm{Aut}\ C_N$ is specified by

$$\tau_r \tau_{r'}=\tau_{rr' \bmod N}, \quad r,r' \in \mathrm{Aut}\ C_N \tag{11}$$

(we replace τ_r by r when convenient).

The commutative diagram

$$\begin{array}{ccc} \widetilde{N} & \xrightarrow{Q(r)} & \widetilde{N} \\ \kappa_0 \downarrow & & \downarrow \kappa_0, \quad r \in \mathrm{Aut}\ C_N, \\ C_N & \xrightarrow{\tau_r} & C_N \end{array} \tag{12}$$

defines the action Q:$\mathrm{Aut}\ C_N \times \widetilde{N} \to \widetilde{N}$ of the hidden symmetry group $\mathrm{Aut}\ C_N$ on the chain $\widetilde{N}$. Each permutation $Q(r), r \in \mathrm{Aut}\ C_N$, of nodes of $\widetilde{N}$, realizes one of the ''hidden'' symmetries of the structure of the linear chain. Equations (10) and (12) imply that $Q(r), r \in \mathrm{Aut}\ C_N$, is a fractallike scaling by the factor r, centered at the node $j=N \equiv 0 \bmod N = \kappa_0(N)$.

In general, each modular scaling transformation $\tau_r, r \neq \pm 1$, yields an essential change of the initial cyclic order of the crystal $\widetilde{N}$ in a fractal manner. The only exceptions are elements of the subgroup

$$C_{1h}=\{\tau_1, \tau_{N-1}\} \lhd \mathrm{Aut}\ C_N \tag{13}$$

of all geometric symmetries of the chain. The identity τ_1 preserves the cyclic order, and the inversion $\tau_{N-1}=\tau_{-1}$ changes it into the opposite one. There are no other geometric symmetries in the case of the linear ring.

III. THE TOROIDAL CRYSTAL

We proceed to impose another crystallographic arrangement on a regular orbit of the cyclic group C_N. To this aim, we exploit the arithmetic structure of the integer N. Let

$$\pi =: \{p \in \widetilde{N} | \mathrm{lcd}(p,N)=p, p \text{ prime}\} \tag{14}$$

be the socle of N, i.e., the set of all prime divisors of $N (p>1)$. Then the arithmetic structure of N is given by the unique decomposition

$$N=\prod_{p\in\pi} N_p, \tag{15}$$

where

$$N_p=p^{\alpha_p}, \quad p\in\pi, \tag{16}$$

and α_p are arithmetic exponents. Accordingly, the Sylow decomposition of the obvious symmetry group reads

$$C_N\cong\prod_{p\in\pi}\otimes C_{N_p}=:A, \tag{17}$$

where we introduce a special symbol A for the cyclic group C_N presented in the form (17) of the direct product.

Equation (17) admits an interpretation of the direct product of cyclic groups C_{N_p} as the translation group of a new finite crystalline configuration of nodes in an n-dimensional toroid, with

$$n=|\pi| \tag{18}$$

being the number of elements in the socle π, and each $p\in\pi$ corresponding to one principal direction with the Born–van Kármán period N_p. Thus let

$$\tilde{N}_p=\{j_p=1,2,\ldots,p^{\alpha_p}\}, \quad p\in\pi, \tag{19}$$

be a regular orbit of the Sylow subgroup $C_{N_p}\lhd C_N$, and $\nu_0^p:\tilde{N}_p\to C_{N_p}$ be the pramap which identifies the set $\tilde{N}_p$ with the group C_{N_p} in the same way as in Eq. (3) for $\tilde{N}$ and C_N. Thus the pramap ν_0^p constitutes the ordering of the group C_{N_p} on the set $\tilde{N}_p$, i.e.,

$$\nu_0^p(j_p)=j_p\in C_{N_p}, \quad j_p\in\tilde{N}_p. \tag{20}$$

Moreover, let

$$\tilde{N}^{(n)}=:\prod_{p\in\pi}\times\tilde{N}_p \tag{21}$$

be the Cartesian product of sets $\tilde{N}_p, p\in\pi$, referred hereafter to as the toroidal crystal. The set $\tilde{N}^{(n)}$ is equipped with the ordering of the group A (isomorphic to the cyclic group C_N) by means of the pramap $\nu_0:\tilde{N}^{(n)}\to A$, defined by

$$\nu_0=\prod_{p\in\pi}\times\nu_0^p, \tag{22}$$

in accordance with the Cartesian product structure of $\tilde{N}^{(n)}$. This ordering defines, in fact, an n-dimensional crystallography on the set $\tilde{N}^{(n)}$. We proceed to describe it in some more detail. In the sequel, we associate the groups A and C_N with the regular orbits $\tilde{N}^{(n)}$ and $\tilde{N}$, respectively.

Elements of the Abelian group A can be uniquely presented in a form of ''vectors''

$$\mathbf{j}=(j_{p_1}\cdots j_{p_n}), \quad j_p\in\tilde{N}_p, \quad p\in\pi, \tag{23}$$

with pointwise addition

$$\mathbf{j}^{(1)}+\mathbf{j}^{(2)}=(\cdots(j_p^{(1)}+j_p^{(2)})\text{mod } N_p\cdots), \quad p\in\pi, \tag{24}$$

in the role of group multiplication in A. In particular, the vector

$$\mathbf{0}=:(\cdots N_p\cdots), \quad p\in\pi, \tag{25}$$

is the unit element of A, i.e., the null vector, and

$$-\mathbf{j}=(\cdots(N_p-j_p)\text{mod } N_p\cdots), \quad p\in\pi, \tag{26}$$

is the (additive) inverse of $\mathbf{j}\in A$. We refer herefrom to symbols $\mathbf{j}$ as vectors, and to integers $j_p\in\widetilde{N}_p, p\in\pi$, as to their components.

Let

$$\mathbf{e}_p=:(0\cdots1\cdots0), \quad p\in\pi, \tag{27}$$

be a ''unit'' vector in A, i.e., the vector with null components $(0=N_{p'} \text{ mod } N_{p'})$ for any $p'\in\pi$, $p'\neq p$, and 1 for the pth component. Then each $\mathbf{j}\in A$ can be uniquely presented as

$$\mathbf{j}=\sum_{p\in\pi} j_p\mathbf{e}_p\,. \tag{28}$$

Each set

$$\xi_p=\{\mathbf{j}=j_p\mathbf{e}_p|j_p\in\widetilde{N}_p\}\subset\widetilde{N}^{(n)}, \quad p\in\pi, \tag{29}$$

forms the pth one-dimensional coordinate ''axis,'' referred hereafter to as the pth equator on the torus. It is worthwhile to observe that the ''Cartesian coordinate system'' $\{\xi_p|p\in\pi\}$ on the toroidal crystal $\widetilde{N}^{(n)}$ can be defined globally, i.e., that it suffices to use only one map, e.g., the pramap ν_0, to cover the whole manifold $\widetilde{N}^{(n)}$ consistently with this coordinate system. As a result, the manifold resembles locally the linear structure [cf. Eq. (28)], but globally it exhibits the structure of toroid [cf. Eq. (29)].

One of characteristics of local properties of a crystalline arrangement is the coordination number q, defined as the number of nearest neighbors of a node. In the case of toroidal crystal one has

$$q=\begin{cases}2n-1, & 2\in\pi, N_2=2,\\ 2n, & \text{otherwise.}\end{cases} \tag{30}$$

The case $2\in\pi$, $N_2=2$, is distinguished since the equator ξ_2 consists of two nodes only, and thus each of them has only one neighbor.

The sequence $(\mathbf{e}_p|p\in\pi)$ of unit vectors forms an analogy of the elementary Bravais cell of the toroidal crystal $\widetilde{N}^{(n)}$. Clearly, translations of the group A of this cell reproduce the whole crystal.

The group A (as well as C_N) can be looked at as a ring, with the pointwise addition (24) and multiplication

$$\mathbf{j}^{(1)}\mathbf{j}^{(2)}=(\cdots j_p^{(1)}j_p^{(2)} \text{ mod } N_p\cdots)\in A, \quad \mathbf{j}^{(1)},\mathbf{j}^{(2)}\in A. \tag{31}$$

Accordingly, the group Aut A of hidden symmetry becomes the multiplicative group of the ring A, i.e.,

$$\text{Aut } A=A^*\subset A, \tag{32}$$

and consists of all elements of the form

$$\mathbf{r}=\sum_{p\in\pi} r_p\mathbf{e}_p,\mathrm{lcd}(r_p,N_p)=1. \tag{33}$$

The multiplicative inverse of $\mathbf{r}$ is

$$\mathbf{r}^{-1}=\sum_{p\in\pi} r_p^{(-1)}\mathbf{e}_p,\quad (r_p^{(-1)}r_p)\mathrm{mod}\ N_p=1. \tag{34}$$

In particular the neutral element of $\mathrm{Aut}\,A$ is

$$\mathbf{1}=\sum_{p\in\pi}\mathbf{e}_p. \tag{35}$$

The notation introduced for groups A and $\mathrm{Aut}\,A$ is well adapted to determination of actions $P^{(n)}:A\times\widetilde{N}^{(n)}\to\widetilde{N}^{(n)}$ and $Q^{(n)}:\mathrm{Aut}\,A\times\widetilde{N}^{(n)}\to\widetilde{N}^{(n)}$ of obvious and hidden symmetry group, respectively, on the toroidal crystal $\widetilde{N}^{(n)}$. Using the pramap $\nu_0:\widetilde{N}^{(n)}\to A$, we associate $P^{(n)}$ and $Q^{(n)}$ with the addition and multiplication in the ring A, respectively, so that

$$P^{(n)}(\mathbf{j})=\begin{pmatrix}\mathbf{j}'\\ \mathbf{j}+\mathbf{j}'\end{pmatrix},\quad \mathbf{j}'\in\widetilde{N}^{(n)},\mathbf{j}\in A, \tag{36}$$

and

$$Q^{(n)}(\mathbf{r})=\begin{pmatrix}\mathbf{j}\\ \mathbf{r}\mathbf{j}\end{pmatrix},\quad \mathbf{j}\in\widetilde{N}^{(n)},\mathbf{r}\in\mathrm{Aut}\,A. \tag{37}$$

The action $P^{(n)}$ establishes the ordering of the group A on the set $\widetilde{N}^{(n)}$. Clearly, this action is abstractly isomorphic with $P:C_N\times\widetilde{N}\to\widetilde{N}$ related to the linear chain, but the two realizations, $\widetilde{N}$ and $\widetilde{N}^{(n)}$, are crystallographically different. In particular, the ordering in each equator $\xi_p, p\in\pi$, is nowadays borrowed from the ring $\mathbb{Z}$ of integers, adapted to the value od N_p. Thus, e.g., an integer $l\in\mathbb{Z}$ can have completely different meanings, namely l mod N_p, within each equator $\xi_p, p\in\pi$. It follows that vectors $\mathbf{j}$ and $l\mathbf{j}$ in the toroidal crystal $\widetilde{N}^{(n)}$ can have, in general, different crystallographic directions. Also, the cyclic order in each equator ξ_p is only loosely related to that in the linear chain $\widetilde{N}$.

The action $Q^{(n)}$ realizes the hidden symmetry of the toroidal crystal $\widetilde{N}^{(n)}$. The actual arrangement of nodes admits much more geometric symmetry operations than in the case of the linear chain $\widetilde{N}$. Namely, each automorphism $\mathbf{i}^{(p)}\in\mathrm{Aut}\,A$, defined by its components as

$$i^{(p)}_{p'}=\begin{cases}-1 & \text{for } p'=p,\\ 1 & \text{otherwise,}\end{cases} \tag{38}$$

corresponds to the one-dimensional inversion in the pth direction. It reverses the pth component j_p of each vector $\mathbf{j}\in\widetilde{N}^{(n)}$, leaving other components unchanged, i.e.,

$$\mathbf{i}_p\mathbf{j}=\mathbf{j}-2j_p\mathbf{e}_p,\quad p\in\pi. \tag{39}$$

In the particular case when $2\in\pi$ and $N_2=2$, the automorphism $\mathbf{i}^{(2)}$ becomes identity on $\widetilde{N}^{(n)}$. In all other cases, it is a nontrivial symmetry operation.

All automorphisms $\mathbf{i}^{(p)}$ generate the group

$$E=\langle\mathbf{i}^{(p)}|p\in\pi\rangle\lhd\mathrm{Aut}\,A, \tag{40}$$

which is the group of all geometric automorphisms of the toroidal crystal $\widetilde{N}^{(n)}$. It is an Abelian elementary group

$$E=\{\mathbf{i}^{\{\sigma\}}|\sigma\subset\pi\} \tag{41}$$

with elements labeled by all subsets of the socle π, and multiplication law

$$\mathbf{i}^{\{\sigma\}}\mathbf{i}^{\{\sigma'\}}=\mathbf{i}^{\{(\sigma\cup\sigma')\setminus(\sigma\cap\sigma')\}}. \tag{42}$$

The order of this group is

$$|E|=\begin{cases}2^n & \text{for } 2\notin\pi, \text{ or } N_2>2,\\ 2^{n-1} & \text{for } N_2=2.\end{cases} \tag{43}$$

All other automorphisms $\mathbf{r}\in\mathrm{Aut}\,A$ change the ordering of the toroidal crystal in an essential, fractallike manner.

IV. PROJECTIONS FROM THE TOROIDAL CRYSTAL ONTO THE LINEAR CHAIN

In discussion of our two realizations of a regular orbit of the cyclic group C_N, we have considered, in fact, two essentially different arrangements. The main common feature is that both emerge from the same abstract group and form its regular orbits. Moreover, both realizations borrow—through the pramaps $\kappa_0:\widetilde{N}\to C_N$ and $\nu_0:\widetilde{N}^{(n)}\to A$—the natural order of the ring $\mathbb{Z}$ of integers, but they do it in definitely distinct ways! In the linear chain $\widetilde{N}$ this order is taken globally and yields a cyclic arrangement of the whole set, whereas in the toroidal crystal $\widetilde{N}^{(n)}$ the cyclic arrangement is prepared for each Sylow subgroup C_{N_p}, $p\in\pi$, separately. Thus the same group manifold is associated with two different orderings. In this section we proceed to discuss projections $\mu:\widetilde{N}^{(n)}\to\widetilde{N}$, which are consistent with the orderings imposed on the sets $\widetilde{N}^{(n)}$ and $\widetilde{N}$ by the groups A and C_N, respectively.

We start with the set $\mathrm{Iso}(A,C_N)$ of all isomorphisms $\beta:A\to C_N$ between the groups of obvious symmetry. This set can be looked at as an orbit of the right regular representation $\Xi':\mathrm{Aut}\,A\times\mathrm{Iso}(A,C_N)\to\mathrm{Iso}(A,C_N)$ of the group $\mathrm{Aut}\,A$ of hidden symmetry, in accordance with

$$\Xi(\mathbf{r})=\begin{pmatrix}\beta\\ \beta\circ\mathbf{r}^{(-1)}\end{pmatrix},\quad \beta\in\mathrm{Iso}(A,C_N),\mathbf{r}\in\mathrm{Aut}\,A. \tag{44}$$

The same set constitutes also an orbit of the left regular representation $\Theta:\mathrm{Aut}\,C_N\times\mathrm{Iso}(A,C_N)\to\mathrm{Iso}(A,C_N)$ of the other hidden symmetry group $\mathrm{Aut}\,C_N$, by virtue of

$$\Theta(r)=\begin{pmatrix}\beta\\ r\circ\beta\end{pmatrix},\quad \beta\in\mathrm{Iso}(A,C_N),r\in\mathrm{Aut}\;C_N. \tag{45}$$

Actions Ξ and Θ, together with a ''praisomorphism'' β_0 (which can be chosen arbitrarily), equip the set $\mathrm{Iso}(A,C_N)$ with group maps $\rho:\mathrm{Iso}(A,C_N)\to\mathrm{Aut}\,A$ and $\sigma:\mathrm{Iso}(A,C_N)\to\mathrm{Aut}\,C_N$, respectively, by means of formulas

$$\rho(\beta)=\mathbf{r}\quad\text{for }\beta=\beta_0\circ\mathbf{r}^{-1},\beta\in\mathrm{Iso}(A,C_N), \tag{46}$$

and

$$\sigma(\beta)=r\quad\text{for }\beta=\tau_r\circ\beta_0,\beta\in\mathrm{Iso}(A,C_N). \tag{47}$$

Mutual independence of isomorphic groups A and C_N of obvious symmetry is reflected here in arbitrariness of praisomorphism β_0. Let us choose β_0 in a way which preserves the Cartesian product structure (17) of the group A. Each Sylow subgroup

$$C_{N_p}=\{j_p\mathbf{e}_p|j_p\in\widetilde{N}_p\}\lhd A \tag{48}$$

has a natural embedding (monomorphism) $\eta_p:C_{N_p}\rightarrow C_N$ into C_N, given by

$$\eta_p(j_p\mathbf{e}_p)=j_p\overline{N_p},\quad j_p\in\widetilde{N}_p, \tag{49}$$

where

$$\widetilde{N}_p=N/N_p,\quad p\in\pi, \tag{50}$$

is the divisor of N, complementary to N_p. Clearly, each monomorphism η_p, $p\in\pi$, preserves the cyclic order of the Sylow subgroup C_{N_p}, borrowed from the ring $\mathbb{Z}$ of integers. All these monomorphisms η_p, $p\in\pi$, define uniquely the isomorphism $\beta_0:A\rightarrow C_N$, given by

$$\beta_0(\mathbf{j})=\sum_{p\in\pi} j_p\overline{N_p} \bmod N,\quad \mathbf{j}\in A. \tag{51}$$

This isomorphism preserves the Cartesian product structure of the group A, and cyclic orders for each factor C_{N_p}. It reproduces therefore the crystallography of the toroidal crystal $\widetilde{N}^{(n)}$.

Such a choice of the praisomorphism β_0 is well motivated from the point of view of the arrangement of the toroidal crystal, but, still, it is not canonical from the point of view of the more abstract ring structure of the group $A(\mathrm{End}\,A\cong A)$ and the group $C_N(\mathrm{End}\,C_N\cong C_N)$. It is a well-known fact from number theory that there is a unique ring isomorphism $\beta':A\rightarrow C_N$, which is determined by the condition of preserving the multiplicative unit of the ring, which reads

$$\beta'(\mathbf{1})=1. \tag{52}$$

Now, Eq. (44) implies that there exists such unique automorphism $\boldsymbol{\varepsilon}\in A^*$ that

$$\beta'=\beta_0\circ\boldsymbol{\varepsilon}^{(-1)}, \tag{53}$$

and

$$\sum_{p\in\pi}\varepsilon_p\overline{N_p} \bmod N=1, \tag{54}$$

where ε_p are components of the automorphism $\boldsymbol{\varepsilon}$; in particular we have

$$\mathrm{lcd}(\varepsilon_p,N_p)=1,\quad p\in\pi. \tag{55}$$

The canonical isomorphism β' is thus given explicitly by

$$\beta'(\mathbf{j})=\sum_{p\in\pi} j_p\varepsilon_p\overline{N_p} \bmod N. \tag{56}$$

The rings $\mathrm{End}\,A\cong A$ and $\mathrm{End}\,C_N\cong C_N$ are thus isomorphic, but mutually ''deformed''. The deformation is described in terms of the automorphism $\boldsymbol{\varepsilon}$. It is also worthwhile to notice that the

Bravais cell $(\mathbf{e}_p | p \in \pi)$ of the toroidal crystal $\widetilde{N}^{(n)}$ forms the unique (up to ordering) set of orthogonal idempotents of the ring A, whereas the corresponding set for the ring C_N consists of elements

$$\beta'(\mathbf{e}_p) = \varepsilon_p N_p, \quad p \in \pi. \tag{57}$$

The orthogonality of these idempotents is implied by

$$\varepsilon_p \overline{N_p} \varepsilon'_p \overline{N'_p} = \varepsilon_p \overline{N_p} \delta_{pp'}, \quad p, p' \in \pi, \tag{58}$$

since $\overline{N_p}\overline{N'_p} \bmod N = 0$ for $p \neq p'$, and the normalization is already assured by Eq. (54).

The projection $\mu: \widetilde{N}^{(n)} \to \widetilde{N}$ from the multidimensional toroid $\widetilde{N}^{(n)}$ onto the linear chain $\widetilde{N}$ which is consistent with orderings of groups A and C_N on $\widetilde{N}^{(n)}$ and $\widetilde{N}$, respectively, can now be determined as follows. Let $\nu: \widetilde{N}^{(n)} \to A$ and $\kappa: \widetilde{N} \to C_N$ be maps which impose appropriate orderings, e.g., $\nu \in Atl_{\nu_0}(\widetilde{N}^{(n)}, A)$, $\kappa \in Atl_{\kappa_0}(\widetilde{N}, C_N)$, and let $\beta \in \mathrm{Iso}(A, C_N)$. Then the projection μ, consistent with the triad (ν, κ, β), is uniquely determined by the requirement that the following diagram

$$\begin{array}{ccc} \widetilde{N}^{(n)} & \xrightarrow{\mu} & \widetilde{N} \\ \nu \downarrow & & \downarrow \kappa, \\ A & \xrightarrow{\beta} & C_N \end{array} \tag{59}$$

should be commutative, or, formally, that

$$\mu = \kappa^{-1} \circ \beta \circ \nu. \tag{60}$$

Mappings μ, given by Eq. (60), constitute a finite analogy of incommensurate phases as projections from multidimensional crystals. Let us choose, for simplicity, the natural orderings ν_0 and κ_0, and let $\beta = \beta_0$ be specified by Eq. (51). Then the regularly periodic, finite n-dimensional crystal $\widetilde{N}^{(n)}$ is projected by means of μ onto the one-dimensional crystal $\widetilde{N}$. Clearly, each dimension $p \in \pi$ yields a one-dimensional ''sublattice'' $N_p, 2N_p, \ldots, N_p N_p$ of N_p nodes, with the lattice constant N_p. It is well known ''from the beginning'' that various lattice constants are mutually commensurate, but the common unit is just 1, which can be readily seen small when comparing to $\overline{N_p}$ for N being large enough and having a rich arithmetic structure (14)–(16). Lattice constants N_p, $p \in \pi$, can be seen as ''macroscopically'' incommensurate, just as incommensurate phases really observed in laboratories, which cannot be experimentally distinguished from ''weakly commensurate'' structures, with large sizes of Bravais cells.

The projection determined by the isomorphism β_0 schuffles the sites belonging to different dimensions p, but faithfully reproduces the cyclic order corresponding to each p. The situation changes drastically after replacing β_0 by the canonical isomorphism β', given by Eqs. (56) and (57). Now, due to the modular magnification of the lattice constant N_p by the factor $\varepsilon_p > 1$ [cf. Eq. (57)], the projection μ changes the cyclic order of $\widetilde{N}_p$ in a fractallike manner. For example, nearest neighbors in the toroidal crystal $\widetilde{N}^{(n)}$ become in $\widetilde{N}$ more separated spatially than the neighbors from the ε_p-coordination sphere. Thus, the canonical isomorphism β' involves much more essential structural reconstruction of the toroidal crystal than the noncanonical but geometrically more natural isomorphism β_0.

V. AN EXAMPLE

We demonstrate behavior of hidden symmetries of a toroidal crystal in an example of $N = 36 = 2^2 \circ 3^2$. Our socle is thus $\pi = \{2,3\}$, and the toroidal crystal is two-dimensional, with $N_2 = 4$ and $N_3 = 9$ being the Born–von Kármán periods in the direction $\mathbf{e}_2$ and $\mathbf{e}_3$, respectively. FIG. 1. Actions $P^{(n)}:A\times\widetilde{N}^{(n)}\to\widetilde{N}^{(n)}$ and $Q^{(n)}:A\times\widetilde{N}^{(n)}\to\widetilde{N}^{(n)}$ of the group A on the toroidal crystal $\widetilde{N}^{(n)}$ for $N=36$: (a) the identity permutation $P^{(n)}(4\mathbf{e}_2+9\mathbf{e}_3)$, (b) the translation $P^{(n)}(\mathbf{e}_2+2\mathbf{e}_3)$, (c) the one-dimensional inversion along the $\mathbf{e}_2$ axis $Q^{(n)}(3\mathbf{e}_2)$, and (d) the fractallike symmetry $Q^{(n)}(2\mathbf{e}_3)$.

hidden symmetry group thus consists of $|\mathrm{Aut}\, C_{36}|=|\mathrm{Aut}\, C_4||\mathrm{Aut}\, C_9|=2\circ 6=12$ elements. Actions $P^{(n)}:A\times\widetilde{N}^{(n)}\to\widetilde{N}^{(n)}$ and $Q^{(n)}:A\times\widetilde{N}^{(n)}\to\widetilde{N}^{(n)}$ are examplified in Fig. 1 by permutations $P^{(n)}(4\mathbf{e}_2+9\mathbf{e}_3)$, $P^{(n)}(\mathbf{e}_2+2\mathbf{e}_3)$, $Q^{(n)}(3\mathbf{e}_2)$, and $Q^{(n)}(2\mathbf{e}_3)$, representing, respectively, the pramap ν_0, the translation $4\mathbf{e}_2+9\mathbf{e}_3$, the one-dimensional inversion along the axis $\mathbf{e}_2$, and the fractallike operation $\mathbf{r}=2\mathbf{e}_3$.

The subgroup E of geometric symmetry is

$$E=\{\mathbf{1},\mathbf{i}_2=3\mathbf{e}_2+\mathbf{e}_3,\mathbf{i}_3=\mathbf{e}_2+8\mathbf{e}_3,\mathbf{i}=\mathbf{i}_2\mathbf{i}_3=3\mathbf{e}_2+8\mathbf{e}_3\}. \tag{61}$$

The projection β_0, which preserves a bit of crystallography of the toroidal crystal, is given in this case by the formula

$$\beta_0(\mathbf{j})=(9j_2+4j_3)\mathrm{mod}\ 36, \tag{62}$$

and presented in Fig. 2(a). We observe that β_0 preserves the cyclic order of each equator of the toroidal crystal (i.e., the sequence 9,18,27,36 and 4,8,12,...,36 along unit vectors $\mathbf{e}_2$ and $\mathbf{e}_3$, respectively), so that the embedding of each factor C_{N_p} in C_{36} consists in rescaling its members by the factor N_p (=9 and 4 for $p=2$ and 3, respectively). However, β_0 ceases to be an isomorphism of hidden symmetry groups! We have $\beta_0(\mathbf{1})=13\neq 1$, so that already a multiplicative unit is deformed. The subgroup $E\lhd\mathrm{Aut}\, A$ of geometric symmetry is mapped under β_0 onto the set $\{\beta_0(\mathbf{1})=13, \beta_0(\mathbf{i}_2)=31, \beta_0(\mathbf{i}_3)=5, \beta_0(\mathbf{i})=23\}$, which is a subset of Aut C_{36}, but it does not form any group. The group C_{36} in its natural order is reproduced from the toroidal crystal when starting from $\mathbf{j}=\mathbf{e}_2+7\mathbf{e}_3=\beta_0^{-1}(1)$ with the step $\Delta\mathbf{j}=\mathbf{e}_2+7\mathbf{e}_3$.

The deformation vector for this case is

$$\boldsymbol{\varepsilon}=\mathbf{e}_2+7\mathbf{e}_3, \tag{63}$$

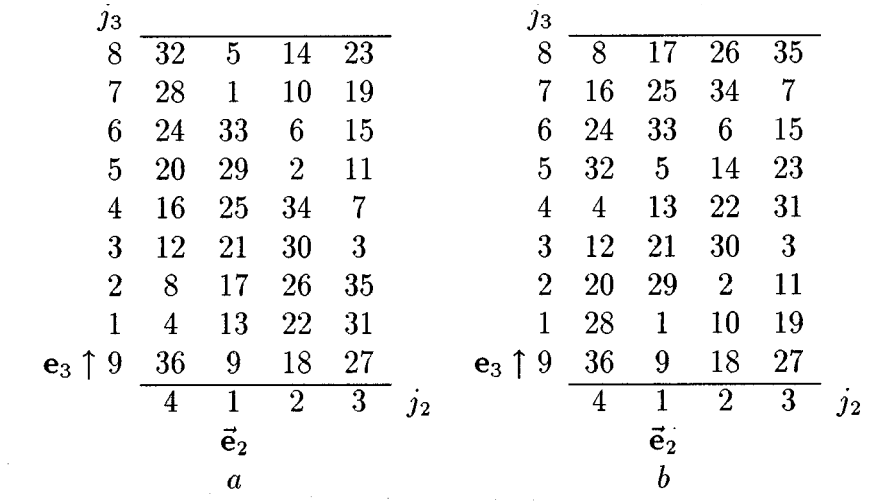

FIG. 2. Projections (a) β_0 and (b) β' of the two-dimensional toroidal crystal onto the linear chain for $N=36$. The number j in the rectangle is the value of $\beta_0(\mathbf{j})$ and $\beta'(\mathbf{j})$ for (a) and (b), respectively. The natural order of the ring Z_{36} is achieved when starting from $j=1$ along the direction $\mathbf{e}_2+7\mathbf{e}_3$ and $\mathbf{e}_2+\mathbf{e}_3$ for β_0 and β', respectively.

and the canonical isomorphism β' is given by the formula

$$\beta'(\mathbf{j})=(9j_2+28j_3)\bmod 36 \tag{64}$$

and shown in Fig. 2(b). Its restriction $\beta'|_{A^*}$ to the hidden symmetry group A^* is also an isomorphism of this group onto $\mathrm{Aut}\, C_{36}$. In particular, $\beta'(\mathbf{1})=1$, and the subgroup E of geometric symmetries of the toroidal crystal is mapped onto the subgroup

$$\{\beta'(\mathbf{1})=1,\beta'(\mathbf{i}_2)=19,\beta'(\mathbf{i}_3)=17,\beta'(\mathbf{i})=35\}\lhd \mathrm{Aut}\; C_{36}. \tag{65}$$

From the other side, however, this projection changes the crystallographic arrangement of nodes of the toroidal crystal: e.g., it preserves the cyclic order for the factor C_4, and reverses it for the factor C_9 [cf. Fig. 2(b)].

VI. FINAL REMARKS AND CONCLUSIONS

We have examined an application of the general recipe of Weyl to a special case of a regular orbit of the cyclic group C_N, by discussion of two realizations of such an orbit: the linear chain and the n-dimensional toroidal crystal, with n being the number of elements of the socle of N. These two realizations differ appreciably by their crystallographic structure, but share the obvious and hidden symmetry groups of the recipe of Weyl. It follows from our discussion that the meaning of hidden symmetry operations changes substantially from one realization to another. In particular, we have demonstrated that fractallike symmetry operations of the linear chain are isomorphic images of purely geometric symmetries of the n-dimensional toroidal crystal. Geometric origin of these n-dimensional inversions is obscured due to the fact that the two realizations are related to different orderings of the obvious symmetry group, within the same group structure. The relation between these two orderings is expressed therefore in terms of a special automorphism $\boldsymbol{\varepsilon}$ belonging to the hidden symmetry group, and describing the deformation of orthogonal idempotents of rings associated with the two crystallographic arrangements.

(Received 31 July 1995; accepted for publication 1 February 1996)

We define and study noncommutative generalizations of submanifolds and quotient manifolds using the derivation-based differential calculus introduced by M. Dubois-Violette and P. Michor. We give examples to illustrate these definitions.
 [S0022-2488(96)00705-9]

I. INTRODUCTION

Various noncommutative generalizations of differential forms have been proposed as well as generalizations of vector bundles and connections. What is still missing is the concept of a submanifold and of a quotient manifold, that is, how the differential structure of a given algebra must be related to the differential structure of a subalgebra (''quotient manifold'') or a quotient algebra (''submanifold''). In this paper, we propose a definition of a noncommutative submanifold and of a noncommutative quotient manifold within the context of the derivation-based differential calculus first introduced by M. Dubois-Violette,[1] and completed[2,3] with P. Michor.

In the first section, we recall various definitions related to this differential calculus. In the second section, we recall the definition of Hochschild cohomology and other cohomologies which will be used later. Submanifolds and quotient manifolds are defined respectively in Secs. IV and V.

II. NONCOMMUTATIVE DIFFERENTIAL STRUCTURES

In noncommutative geometry, the algebra of smooth functions on a manifold is replaced by a noncommutative algebra (see, for example, Refs. 4 and 5). Geometric objects are first expressed in terms of the algebra of functions and then they can be generalized to the noncommutative case. In this section, we recall the definition of differential forms, central bimodules, and connections as they are given in Refs. 1–3.

A. Noncommutative differential forms

Let $\mathscr{A}$ denote an associative algebra with unit. It is then the generalization of the algebra of smooth functions on a compact manifold. The center of the algebra will be denoted by $\mathscr{Z}(\mathscr{A})$. The differential forms we wish to introduce are based on derivations, the algebraic generalizations of vector fields on a manifold:

$$\mathrm{Der}(\mathscr{A}) = \{X : \mathscr{A} \to \mathscr{A} / X(ab) + X(a)b + aX(b)\};$$

$\mathrm{Der}(\mathscr{A})$ is naturally a $\mathscr{Z}(\mathscr{A})$-module and a Lie algebra.

The two noncommutative generalizations of the graded differential algebra of differential forms which we shall need[1,2] are constructed as follows. Let $C_{\mathscr{Z}(\mathscr{A})}(\mathrm{Der}(\mathscr{A}),\mathscr{A})$ be the graded algebra of antisymmetric $\mathscr{Z}(\mathscr{A})$-multilinear mappings from $\mathrm{Der}(\mathscr{A})$ to $\mathscr{A}$. Notice that this algebra is not graded commutative. In degree 0 we take $C^0_{\mathscr{Z}(\mathscr{A})}(\mathrm{Der}(\mathscr{A}),\mathscr{A}) = \mathscr{A}$. We introduce a differential d by the Koszul formula:

[b)]Laboratoire associé au CNRS, URA-D0063.

0022-2488/96/37(5)/2484/14/$10.00

$$d\omega(X_1,\ldots,X_{n+1})=\sum_{i=1}^{n+1}(-1)^{i+1}X_i\omega(X_1,\ldots,\overset{i}{\overset{V}{\cdot}},\ldots,X_{n+1})$$

$$+\sum_{1\leqslant i<j\leqslant n+1}(-1)^{i+j}\omega([X_i,X_j],\ldots,\overset{i}{\overset{V}{\cdot}},\ldots,\overset{j}{\overset{V}{\cdot}},\ldots,X_{n+1}),$$

for any $\omega\in C^n_{\mathcal{Z}(\mathcal{A})}(\mathrm{Der}(\mathcal{A}),\mathcal{A})$ and any set of derivations X_i.

Now, we can introduce the first generalization of differential forms over $\mathcal{A}$. We define $\Omega_{\mathrm{Der}}(\mathcal{A})$ to be the smallest differential graded subalgebra of the algebra $C_{\mathcal{Z}(\mathcal{A})}(\mathrm{Der}(\mathcal{A}),\mathcal{A})$ which contains $\mathcal{A}$. Every element $\omega\in\Omega^n_{\mathrm{Der}}(\mathcal{A})$ can be written as a finite sum of elements of the type $a_0da_1\cdots da_n$, where $da\in\Omega^1_{\mathrm{Der}}(\mathcal{A})$ is the one-form $X\mapsto Xa\in\mathcal{A}$, and where the product is that of $C_{\mathcal{Z}(\mathcal{A})}(\mathrm{Der}(\mathcal{A}),\mathcal{A})$.

The second differential graded algebra of forms we shall use is the algebra $C_{\mathcal{Z}(\mathcal{A})}(\mathrm{Der}(\mathcal{A}),\mathcal{A})$ itself, denoted by $\underline{\Omega}_{\mathrm{Der}}(\mathcal{A})$. We refer the reader to Ref. 3 for the relation between $\Omega_{\mathrm{Der}}(\mathcal{A})$, $\mathrm{Der}(\mathcal{A})$ and $\underline{\Omega}_{\mathrm{Der}}(\mathcal{A})$ from the point of view of duality.

There is a canonical Cartan operation i_X of the Lie algebra $\mathrm{Der}(\mathcal{A})$ on $\Omega_{\mathrm{Der}}(\mathcal{A})$ and $\underline{\Omega}_{\mathrm{Der}}(\mathcal{A})$.[1] For any $X\in\mathrm{Der}(\mathcal{A})$, one defines the antiderivation of degree -1

$$i_X:\Omega^n_{\mathrm{Der}}(\mathcal{A})\to\Omega^{n-1}_{\mathrm{Der}}(\mathcal{A})$$

by

$$(i_X\omega)(X_1,\ldots,X_{n-1})=\omega(X,X_1,\ldots,X_{n-1}),$$

with $i_Xa=0$ for any $a\in\mathcal{A}=\Omega^0_{\mathrm{Der}}(\mathcal{A})$. It follows that $L_X=i_Xd+di_X$ is a derivation of degree 0 on $\Omega_{\mathrm{Der}}(\mathcal{A})$.

B. Central bimodules and connections

In ordinary differential geometry, vector bundles of finite rank can be considered from an algebraic point of view through their space of sections. In fact this space is a finite projective module over the algebra of smooth functions. In noncommutative geometry, the generalization of a vector bundle will then be such a module over the algebra. However, since $\mathcal{A}$ is noncommutative this can be a right module, or a bimodule.

In Ref. 2 it was proposed that this generalization should at least have the structure of a central bimodule. We recall that a central bimodule $\mathcal{M}$ is a bimodule over $\mathcal{A}$ and which is also a module over the center $\mathcal{Z}(\mathcal{A})$ of $\mathcal{A}$ in the commutative sense. That is, for any $z\in\mathcal{Z}(\mathcal{A})$ and $m\in\mathcal{M}$, one has $zm=mz$.

It is then easy to introduce the notion of a connection on a central bimodule. A connection on $\mathcal{M}$ is a linear mapping $\boldsymbol{\nabla}$ from $\mathrm{Der}(\mathcal{A})$ into the linear endomorphisms of $\mathcal{M}$ such that

$$\boldsymbol{\nabla}_{zX}m=z\boldsymbol{\nabla}_Xm,\quad \boldsymbol{\nabla}_X(amb)=(Xa)mb+a(\boldsymbol{\nabla}_Xm)b+am(Xb)$$

for any $X\in\mathrm{Der}(\mathcal{A})$, $z\in\mathcal{Z}(\mathcal{A})$, $a,b\in\mathcal{A}$, and $m\in\mathcal{M}$.

The curvature of this connection is defined by the usual formula

$$R(X,Y)=\boldsymbol{\nabla}_X\boldsymbol{\nabla}_Y-\boldsymbol{\nabla}_Y\boldsymbol{\nabla}_X-\boldsymbol{\nabla}_{[X,\,Y]}$$

for any $X,Y\in\mathrm{Der}(\mathcal{A})$. Here $R(X,Y)$ is an $\mathcal{A}$-bimodule endomorphism of $\mathcal{M}$, antisymmetric and $\mathcal{Z}(\mathcal{A})$-linear in X,Y. We refer the reader to Ref. 3 for more properties on these connections.

III. HOCHSCHILD COHOMOLOGY AND RELATED COHOMOLOGIES

In this section we introduce a class of subcomplexes of the Hochschild complex of an associative algebra, and their cohomology. These cohomologies, in degree 1, will be useful in the next section.

A. Hochschild cohomology

We recall the definition of the ordinary Hochschild cohomology. Let $\mathscr{A}$ be an associative algebra with unit over $\mathbb{C}$, and $\mathscr{M}$ a bimodule over $\mathscr{A}$.

We define the complex $C(\mathscr{A};\mathscr{M})$ as follows: $C^n(\mathscr{A};\mathscr{M})$ is the linear space of $\mathbb{C}$-linear mappings from $\mathscr{A}^{\otimes^n}$ to $\mathscr{M}$. In degree 0, we set $C^0(\mathscr{A};\mathscr{M})=\mathscr{M}$. We set $C(\mathscr{A};\mathscr{M})=\oplus_{n\geqslant 0}C^n(\mathscr{A};\mathscr{M})$. Then we introduce the Hochschild differential δ on the space $C(\mathscr{A};\mathscr{M})$ by the formula

$$(\delta f)(a_1\otimes\cdots\otimes a_{n+1})=a_1 f(a_2\otimes\cdots\otimes a_{n+1})+\sum_{i=1}^{n}(-1)^i f(a_1\otimes\cdots\otimes a_i a_{i+1}\otimes\cdots\otimes a_{n+1})$$

$$+(-1)^{n+1}f(a_1\otimes\cdots\otimes a_n)a_{n+1}$$

for any $f\in C^n(\mathscr{A};\mathscr{M})$. Because $\mathscr{A}$ is an associative algebra, one has $\delta^2=0$. The cohomology of this differential complex is denoted by $H(\mathscr{A};\mathscr{M})$. It is the Hochschild cohomology of $\mathscr{A}$ with values in $\mathscr{M}$.

The bimodule of interest for our purpose is $\mathscr{A}$ itself. In this case, the complex $C(\mathscr{A};\mathscr{A})$ is an associative algebra (see Refs. 6 and 7 and references therein) and $H(\mathscr{A};\mathscr{A})$ inherits a structure of graded commutative algebra.

Let us consider now the previous case with $n=1$. Then $Z^1(\mathscr{A};\mathscr{A})=\mathrm{Im}\,\delta\cap C^1(\mathscr{A};\mathscr{A})$ is the Lie algebra $\mathrm{Der}(\mathscr{A})$ of derivations of $\mathscr{A}$, and $B^1(\mathscr{A};\mathscr{A})=\mathrm{Ker}\,\delta\cap C^1(\mathscr{A};\mathscr{A})$ is the Lie subalgebra $\mathrm{Int}(\mathscr{A})$ of $\mathrm{Der}(\mathscr{A})$ of inner derivations of $\mathscr{A}$. This is an ideal of $\mathrm{Der}(\mathscr{A})$, so $H^1(\mathscr{A};\mathscr{A})$ is a Lie algebra, denoted $\mathrm{Out}(\mathscr{A})$.

B. Relative Hochschild cohomology

We follow here the exposition in Ref. 6 (see also Ref. 7). Let $\mathscr{S}$ denote a subalgebra of $\mathscr{A}$, and $\mathscr{M}$ a bimodule over $\mathscr{A}$. The complex $C(\mathscr{A},\mathscr{S};\mathscr{M})$ is defined by

$$C^0(\mathscr{A},\mathscr{S};\mathscr{M})=\mathscr{M}^{\mathscr{S}}=\{m\in\mathscr{M}/sm=ms\,\forall\, s\in\mathscr{S}\}$$

and $C^n(\mathscr{A},\mathscr{S};\mathscr{M})$ is the linear space of n-linear mappings $f:\mathscr{A}\otimes\cdots\otimes\mathscr{A}\to\mathscr{M}$ such that

$$f(sa_1\otimes\cdots\otimes a_n)=sf(a_1\otimes\cdots\otimes a_n),\quad f(a_1\otimes\cdots\otimes a_n s)=f(a_1\otimes\cdots\otimes a_n)s,$$

$$f(a_1\otimes\cdots\otimes a_i s\otimes a_{i+1}\otimes\cdots\otimes a_n)=f(a_1\otimes\cdots\otimes a_i\otimes sa_{i+1}\otimes\cdots\otimes a_n)$$

for any $a_i\in\mathscr{A}$ and $s\in\mathscr{S}$. Then f is a $\mathscr{S}$-bimodule homomorphism $\mathscr{A}\otimes_{\mathscr{S}}\cdots\otimes_{\mathscr{S}}\mathscr{A}\to\mathscr{M}$.

The Hochschild differential δ maps $C^n(\mathscr{A},\mathscr{S};\mathscr{M})$ into $C^{n+1}(\mathscr{A},\mathscr{S};\mathscr{M})$, and then defines a cohomology $H(\mathscr{A},\mathscr{S};\mathscr{M})$. This is the relative Hochschild cohomology of $\mathscr{A}$ in $\mathscr{M}$ for $\mathscr{S}$. This cohomology can be calculated on a subcomplex of $C(\mathscr{A},\mathscr{S};\mathscr{M})$.[6] Let us denote by $\overline{C}(\mathscr{A},\mathscr{S};\mathscr{M})$ the linear subspace of $C(\mathscr{A},\mathscr{S};\mathscr{M})$ of elements f such that f vanishes when at least one of its arguments is in $\mathscr{S}$. This is the normalized complex of the relative Hochschild cohomology. These two complexes have the same cohomology.

Let us now consider the case where $\mathscr{S}=\mathscr{Z}(\mathscr{A})$. Then the relative Hochschild cohomology is well adapted to study central bimodules. In degree 0, one has $C^0(\mathscr{A},\mathscr{Z}(\mathscr{A});\mathscr{M})=\mathscr{M}$ for $\mathscr{M}$ a

central bimodule. In higher degrees, one can remark that $\mathcal{A} \otimes_{\mathcal{Z}(\mathcal{A})} \cdots \otimes_{\mathcal{Z}(\mathcal{A})} \mathcal{A}$ is a central bimodule, and then the normalized relative complex is a set of homomorphisms of central bimodules.

For future use, consider the case $\mathcal{S}=\mathcal{Z}(\mathcal{A})$, $\mathcal{M}=\mathcal{A}$, and $n=1$. Then $Z^1(\mathcal{A},\mathcal{Z}(\mathcal{A});\mathcal{A})$ is exactly the Lie algebra of derivations of $\mathcal{A}$ which vanish on the center $\mathcal{Z}(\mathcal{A})$. Remark that $B^1(\mathcal{A},\mathcal{Z}(\mathcal{A});\mathcal{A})$ is equal to $B^1(\mathcal{A};\mathcal{A})$. So, one has the two left exact sequences:

$$0 \to Z^1(\mathcal{A},\mathcal{Z}(\mathcal{A});\mathcal{A}) \to \mathrm{Der}(\mathcal{A}) \to \mathrm{Der}(\mathcal{Z}(\mathcal{A})),$$

$$0 \to H^1(\mathcal{A},\mathcal{Z}(\mathcal{A});\mathcal{A}) \to \mathrm{Out}(\mathcal{A}) \to \mathrm{Der}(\mathcal{Z}(\mathcal{A})),$$

which are not short exact sequences in general. The condition $H^1(\mathcal{A},\mathcal{Z}(\mathcal{A});\mathcal{A})=0$; which means that any derivation of $\mathcal{A}$ which vanishes on $\mathcal{Z}(\mathcal{A})$ is an inner derivation, gives the injectivity of the canonical homomorphism $\mathrm{Out}(\mathcal{A}) \to \mathrm{Der}(\mathcal{Z}(\mathcal{A}))$.

C. Constrained Hochschild cohomology

Let us now introduce a new subcomplex of the Hochschild complex. As before, $\mathcal{A}$ is an associative algebra with unit and $\mathcal{M}$ is a bimodule over $\mathcal{A}$. Let $\mathcal{C}$ be an ideal in $\mathcal{A}$ and $\mathcal{N}$ a sub-bimodule of $\mathcal{M}$ such that $cm, mc \in \mathcal{N}$ for any $c \in \mathcal{C}$ and $m \in \mathcal{M}$. This is equivalent to saying that $\mathcal{C}$ is included in the two side ideal

$$\mathcal{I}_{\mathcal{N}} = \{a \in \mathcal{A} / a\mathcal{M} \subset \mathcal{N} \text{ and } \mathcal{M}a \subset \mathcal{N}\}.$$

We define the subcomplex $C(\mathcal{A},\mathcal{C};\mathcal{M},\mathcal{N})$ of $C(\mathcal{A};\mathcal{M})$ of the mappings $f:\mathcal{A}\otimes\cdots\otimes\mathcal{A} \to \mathcal{M}$ such that $f(a_1\otimes\cdots\otimes a_n) \in \mathcal{N}$ if at least one of the a_i is in $\mathcal{C}$. In degree 0, $C^0(\mathcal{A},\mathcal{C};\mathcal{M},\mathcal{N})=\mathcal{M}$. It is easy to see that this subcomplex is stable by the Hochschild differential δ. So one has a cohomology $H(\mathcal{A},\mathcal{C};\mathcal{M},\mathcal{N})$. This is the constrained cohomology of $\mathcal{A}$ in $\mathcal{M}$ by $(\mathcal{C},\mathcal{N})$. One has then the following lemma:

Lemma III.1: In the above situation, one has a canonical mapping of graded vector spaces

$$H(\mathcal{A},\mathcal{C};\mathcal{M},\mathcal{N}) \to H(\mathcal{A}/\mathcal{C};\mathcal{M}/\mathcal{N}),$$

where the second cohomology is the ordinary Hochschild cohomology of the bimodule $\mathcal{M}/\mathcal{N}$ over the algebra $\mathcal{A}/\mathcal{C}$.

Proof: Let $pr:\mathcal{M} \to \mathcal{M}/\mathcal{N}$ denote the projection from the bimodule $\mathcal{M}$ over $\mathcal{A}$ on the bimodule $\mathcal{M}/\mathcal{N}$ over $\mathcal{A}/\mathcal{C}$, and $a \to [a]$ the projection $\mathcal{A} \to \mathcal{A}/\mathcal{C}$. Then one has $pr(am) = [a]pr(m)$ for any $a \in \mathcal{A}$ and $m \in \mathcal{M}$, and a similar formula for ma.

Any $f \in C(\mathcal{A},\mathcal{C};\mathcal{M},\mathcal{N})$ can be mapped into $\chi(f) \in C(\mathcal{A}/\mathcal{C};\mathcal{M}/\mathcal{N})$ by the definition

$$\chi(f)([a_1]\otimes\cdots\otimes[a_n]) = (pr\circ f)(a_1\otimes\cdots\otimes a_n).$$

Then it is easy to see that

$$pr\circ\delta = \overline{\delta}\circ pr,$$

where δ is the Hochschild differential on $C(\mathcal{A},\mathcal{C};\mathcal{M},\mathcal{N})$ and $\overline{\delta}$ the Hochschild differential on $C(\mathcal{A}/\mathcal{C};\mathcal{M}/\mathcal{N})$. □

A simpler situation occurs when one takes $\mathcal{M}=\mathcal{A}$ and $\mathcal{N}=\mathcal{C}$. Then the subcomplex is a subalgebra of $C(\mathcal{A};\mathcal{A})$, but not an ideal. We denote it by $C_{\mathcal{C}}(\mathcal{A};\mathcal{A})$, and its cohomology by $H_{\mathcal{C}}(\mathcal{A};\mathcal{A})$. In degree 1, one has obviously $B^1_{\mathcal{C}}(\mathcal{A};\mathcal{A}) = B^1(\mathcal{A};\mathcal{A})$. Here $Z^1_{\mathcal{C}}(\mathcal{A};\mathcal{A})$ is the Lie algebra of derivations of $\mathcal{A}$ which preserve $\mathcal{C}$ and $B^1_{\mathcal{C}}(\mathcal{A};\mathcal{A})$ is an ideal in this Lie algebra. Then $H^1_{\mathcal{C}}(\mathcal{A};\mathcal{A})$ is a Lie algebra.

IV. NONCOMMUTATIVE SUBMANIFOLDS

In this section, we introduce a noncommutative generalization of the notion of submanifold of a manifold.

A. The commutative case

We first recall the situation in the commutative case. Let M be a smooth compact manifold, and let $N \subset M$ be a closed submanifold. Any smooth function $f: M \to \mathbb{R}$ can be restricted to N. Thus one has a mapping

$$\mathscr{F}(M) \overset{p}{\to} \mathscr{F}(N),$$

where $\mathscr{F}(M)$ is the algebra of smooth functions on M. This mapping is in fact surjective, and there exists a short exact sequence

$$0 \to \mathscr{C} \to \mathscr{F}(M) \overset{p}{\to} \mathscr{F}(N) \to 0,$$

where $\mathscr{C}$ is the ideal of $\mathscr{F}(M)$ of functions vanishing on N.

A vector field $X \in \Gamma(M)$ on M, which satisfies $Xf \in \mathscr{C}$ for any $f \in \mathscr{C}$, can be restricted to a vector field X on N. Thus one has a homomorphism of Lie algebras

$$\Gamma_{\mathscr{C}}(M) \overset{\pi}{\to} \Gamma(N),$$

where $\Gamma_{\mathscr{C}}(M) = \{X \in \Gamma(M) / X\mathscr{C} \subset \mathscr{C}\}$. This mapping is surjective, and there exists a short exact sequence of Lie algebras:

$$0 \to \Gamma_{\mathscr{F}} \to \Gamma_{\mathscr{C}}(M) \overset{\pi}{\to} \Gamma(N) \to 0,$$

where $\Gamma_{\mathscr{F}} = \{X \in \Gamma(M) / X.\mathscr{F}(M) \subset \mathscr{C}\}$ is an ideal of the Lie algebra $\Gamma_{\mathscr{C}}(M)$.

B. The noncommutative case

Now we can generalize these notions to the framework of noncommutative geometry. Let $\mathscr{A}$ be an associative algebra over $\mathbb{C}$ with unit and let $\mathscr{C}$ be an ideal in $\mathscr{A}$. We denote by $\mathscr{Q} = \mathscr{A}/\mathscr{C}$ the quotient algebra and by $p: \mathscr{A} \to \mathscr{Q}$ the quotient mapping.

We can consider the two following Lie subalgebras of $\mathrm{Der}(\mathscr{A})$:

$$\mathscr{G}_{\mathscr{C}} = \{X \in \mathrm{Der}(\mathscr{A}) / X\mathscr{C} \subset \mathscr{C}\}$$

and

$$\mathscr{G}_{\mathscr{A}} = \{X \in \mathrm{Der}(\mathscr{A}) / X.\mathscr{A} \subset \mathscr{C}\}.$$

One sees that $\mathscr{G}_{\mathscr{A}}$ is an ideal in $\mathscr{G}_{\mathscr{C}}$. One has a mapping $\mathscr{G}_{\mathscr{C}} \overset{\pi}{\to} \mathrm{Der}(\mathscr{Q})$ defined by $\pi(X)p(a) = p(Xa)$ for any $a \in \mathscr{A}$ and $X \in \mathscr{G}_{\mathscr{C}}$. The kernel of this mapping is exactly $\mathscr{G}_{\mathscr{A}}$.

Definition IV.1: The quotient algebra $\mathscr{Q} = \mathscr{A}/\mathscr{C}$ will be called a submanifold algebra of $\mathscr{A}$ if π is surjective. The ideal $\mathscr{C}$ of $\mathscr{A}$ is called the constraint ideal for $\mathscr{Q}$.

In this situation, one has the short exact sequence of Lie algebras

$$0 \to \mathscr{G}_{\mathscr{A}} \to \mathscr{G}_{\mathscr{C}} \overset{\pi}{\to} \mathrm{Der}(\mathscr{Q}) \to 0. \tag{1}$$

The condition of the definition imposes a strong relation between the differential structure on $\mathscr{A}$ and the differential structure on $\mathscr{Q}$. This strong relation is revealed in the following proposition:

Proposition IV.1: There exists a short exact sequence of graded differential algebras

$$0 \to \Omega_{\mathrm{Der},\mathscr{C}} \to \Omega_{\mathrm{Der}}(\mathscr{A}) \xrightarrow{p} \Omega_{\mathrm{Der}}(\mathscr{Q}) \to 0. \tag{2}$$

Proof: Let $\overline{X} = \pi(X) \in \mathrm{Der}(\mathscr{Q})$ for any $X \in \mathscr{G}_{\mathscr{C}}$ and let $\overline{a} = p(a) \in \mathscr{Q}$ for any $a \in \mathscr{A}$. Then one has over $\mathscr{Q}$

$$d\overline{a}(\overline{X}) = \overline{X}\overline{a} = p(Xa) = p(da(X)).$$

One then extends p in a mapping $\Omega^n_{\mathrm{Der}}(\mathscr{A}) \to \Omega^n_{\mathrm{Der}}(\mathscr{Q})$ by the relation

$$p(a_0 da_1 \cdots da_n) = p(a_0) dp(a_1) \cdots dp(a_n),$$

and then one has

$$d \circ p = p \circ d$$

and

$$i_{\overline{X}} \circ p = p \circ i_X .$$

It is easy to see that p is surjective; so we obtain the short exact sequence (2). □

Remark 1: In the short exact sequence (2), one has

$$\Omega^n_{\mathrm{Der},\mathscr{C}} = \{\omega \in \Omega^n_{\mathrm{Der}}(\mathscr{A}) / \forall X \in \mathscr{G}_{\mathscr{C}}, i_X \omega \in \Omega^{n-1}_{\mathrm{Der},\mathscr{C}}\}$$

with $\Omega^0_{\mathrm{Der},\mathscr{C}} = \mathscr{C}$. For example, for any $a \in \mathscr{C}$, $da \in \Omega^1_{\mathrm{Der},\mathscr{C}}$.

Remark 2: In general there are no relations between $\Omega_{\mathrm{Der}}(\mathscr{A})$ and $\Omega_{\mathrm{Der}}(\mathscr{Q})$.

Let us now study the derivations of $\mathscr{Q}$. Any inner derivation of $\mathscr{A}$ is obviously in $\mathscr{G}_{\mathscr{C}}$. In the quotient homomorphism $\mathscr{G}_{\mathscr{C}} \xrightarrow{\pi} \mathrm{Der}(\mathscr{Q})$, these inner derivations are mapped on inner derivations, from the very definition of π. It is easy to see that π restricted to inner derivations is surjective on inner derivations of $\mathscr{Q}$ (even if π does not satisfy the condition of Definition IV.1, i.e., π is not surjective) and one has $\pi(ad(a)) = ad(p(a))$ for any $a \in \mathscr{A}$. So, the kernel of π contains $ad(\mathscr{C}) = \{ad(c) / c \in \mathscr{C}\} \subset \mathrm{Der}(\mathscr{A})$.

Lemma IV.1: If $\mathscr{Q} = \mathscr{A}/\mathscr{C}$ has only inner derivations, then the mapping $\mathscr{G}_{\mathscr{C}} \to \mathrm{Der}(\mathscr{Q})$ is surjective. Then $\mathscr{Q}$ is a submanifold algebra.

Proof: This is a direct consequence of the previous discussion about inner derivations. □

It is now interesting to say something about the other derivations of $\mathscr{Q}$, that is, about the first Hochschild cohomology of $\mathscr{Q}$ with values in itself. One has the following lemma:

Lemma IV.2: One has a surjective homomorphism of Lie algebras

$$H^1_{\mathscr{C}}(\mathscr{A}; \mathscr{A}) \to H^1(\mathscr{Q}; \mathscr{Q}).$$

Proof: This is a direct consequence of Lemma III.1 (with $\mathscr{M} = \mathscr{A}$ and $\mathscr{N} = \mathscr{C}$), the previous remark about inner derivations, and the surjectivity of π from Definition IV.1. □

One can say something about the kernel of this mapping, if one imposes a supplementary condition on the ideal $\mathscr{C}$.

Proposition IV.2: If the constraint ideal $\mathscr{C}$ for the submanifold algebra $\mathscr{Q}$ satisfies

$$ad(\mathscr{C}) = \{ad(a) / a \in \mathscr{A} \text{ and } [a, \mathscr{A}] \subset \mathscr{C}\}.$$

or, equivalently, if $\mathrm{Ker}\pi\cap\mathrm{Int}(\mathscr{A})=ad(\mathscr{C})$, then one has the short exact sequence of Lie algebras

$$0\to H^1(\mathscr{A};\mathscr{C})\to H^1_{\mathscr{C}}(\mathscr{A};\mathscr{A})\to H^1(\mathscr{Q};\mathscr{Q})\to 0. \tag{3}$$

In $H^1(\mathscr{A};\mathscr{C})$, $\mathscr{C}$ is considered as a bimodule over $\mathscr{A}$.

Proof: The condition on $\mathscr{C}$ means, in fact, that one has the short exact sequence of Lie algebras

$$0\to B^1(\mathscr{A};\mathscr{C})\to B^1_{\mathscr{C}}(\mathscr{A};\mathscr{A})=B^1(\mathscr{A};\mathscr{A})\to B^1(\mathscr{Q};\mathscr{Q})\to 0.$$

The new information is the exactness at $B^1_{\mathscr{C}}(\mathscr{A};\mathscr{A})$. If one associates this short exact sequence with the short exact sequence (1) written as

$$0\to Z^1(\mathscr{A};\mathscr{C})\to Z^1_{\mathscr{C}}(\mathscr{A};\mathscr{A})\to Z^1(\mathscr{Q};\mathscr{Q})\to 0,$$

then one obtains the exactness of (3). □

In algebraic geometry (Ref. 8 and references therein), one works with the commutative algebra with unit $\mathscr{A}=\mathbb{C}[X_1,\ldots,X_n]$ of complex polynomials of n variables. The geometric objects are considered as zero sets of polynomials. An ideal $\mathscr{C}$ represents the set of points $V(\mathscr{C})=\{x\in\mathbb{C}^n/P(x)=0\,\forall P\in\mathscr{C}\}$. From the point of view of the ''duality'' *set of points↔algebra of functions*, the set $V(\mathscr{C})$ is represented by the algebra $\mathscr{Q}=\mathbb{C}[X_1,\ldots,X_n]/\mathrm{Rad}(\mathscr{C})$, where $\mathrm{Rad}(\mathscr{C})=\{P\in\mathbb{C}[X_1,\ldots,X_n]/\exists k\in\mathbb{N}\ P^k\in\mathscr{C}\}$ is the radical of $\mathscr{C}$. If $\mathscr{Q}$ admits ideals, then the set $V(\mathscr{C})$ admits subsets. But if $\mathscr{Q}$ does not have any ideal, then the set $V(\mathscr{C})$ can be considered as a *point*. This is equivalent to the fact that $\mathscr{C}$ is a maximal ideal in $\mathscr{A}$. Notice that from the point of view of ordinary geometry, points are the minimal sets. The only maximal ideals of $\mathscr{A}$ are generated by n polynomials X_i-a_i where $a_i\in\mathbb{C}$. The point represented by this ideal is obviously $(a_i)\in\mathbb{C}^n$. Notice that maximal ideals are in one-to-one correspondence with the characters of $\mathscr{A}$. The quotient mapping $\mathscr{A}\to\mathscr{A}/\mathscr{C}$ is the restriction at the set of points represented by $\mathscr{C}$. If $\mathscr{C}$ is maximal, the restriction of an element $P\in\mathscr{A}$ at $\mathscr{C}$ is exactly the value of this polynomial at the point of $\mathbb{C}^n$ represented by $\mathscr{C}$.

This correspondence *points↔maximal ideals* is also used in the theory of commutative Banach algebras and commutative C^*-algebras.[9] In this context, maximal ideals are also in one-to-one correspondence with characters. If $\mathscr{C}$ is a maximal ideal in the commutative Banach algebra with unit $\mathscr{A}$, then the quotient $\mathscr{A}/\mathscr{C}$ is isomorphic to $\mathbb{C}$. (The quotient mapping $\mathscr{A}\to\mathscr{A}/\mathscr{C}$ is a character). In the theory of commutative C^*-algebras, by the Gel'fand transformation, the set of characters is exactly the set of points on which it is possible to put a canonical topology. One says that a point takes its values in the quotient $\mathscr{A}/\mathscr{C}\simeq\mathbb{C}$. So, in those two situations, points are maximal ideals, and take their values in the field $\mathbb{C}$.

In noncommutative geometry, an ideal $\mathscr{C}$ of a given complex algebra with unit $\mathscr{A}$ can also be interpreted as a ''subspace'' of the noncommutative ''space'' dually represented by $\mathscr{A}$. This subspace can be considered as a ''submanifold'' if the differential structure of $\mathscr{A}/\mathscr{C}$ is compatible with the differential structure of $\mathscr{A}$. One of the compatibility conditions one can take is Definition IV.1.

Now, if the ideal is maximal, then the quotient algebra is simple. It is then a ''point,'' in the sense that it cannot have ''proper subspaces.'' However, considering the quotient $\mathscr{Q}=\mathscr{A}/\mathscr{C}$, one sees that points take their values in (*a priori* noncommutative) simple algebras and not in fields as in the commutative case. There is then a residual structure of purely noncommutative origin. See Example 5 below for applications in physics.

To any ideal $\mathscr{C}$ in $\mathscr{A}$, one can construct $\mathscr{G}_{\mathscr{A}}\subset\mathrm{Der}(\mathscr{A})$. If $\mathscr{C}$ is a maximal ideal, the quotient of linear space $T_{\mathscr{C}}=\mathrm{Der}(\mathscr{A})/\mathscr{G}_{\mathscr{A}}$ can be considered as the ''tangent space'' at the point $\mathscr{C}$ in the ''manifold'' represented by $\mathscr{A}$. The value of a derivation X at the ''point'' $\mathscr{C}$ is the image of X by

the quotient mapping $\mathrm{Der}(\mathscr{A})\to T_{\mathscr{C}}$. One can also take the value of a one-form $\alpha\in\Omega^1(\mathscr{A})$ at $\mathscr{C}$ by the definition $\alpha_{\mathscr{C}}:T_{\mathscr{C}}\to\mathscr{Q},\alpha_{\mathscr{C}}(X_{\mathscr{C}})=p\circ\alpha(X)$ for any $X\in\mathrm{Der}(\mathscr{A})$ whose value at $\mathscr{C}$ is $X_{\mathscr{C}}$. This can be generalized for any n-form in $\Omega^n(\mathscr{A})$.

C. Examples

Example 1: The commutative case.

In the commutative case, any smooth closed submanifold of a smooth compact manifold gives a submanifold algebra: the algebra of smooth functions on this submanifold.

Example 2: The tensor algebra.

Let $\mathscr{A}$ be the free algebra with unit over $\mathbb{C}$ generated by n elements $x^1,\ldots,x^n$, with $n\geqslant 2$.

Any derivation of $\mathscr{A}$ is given by n elements $P^i(x^1,\ldots,x^n)\in\mathscr{A}$. We denote it by $D=(P^i)_{1\leqslant i\leqslant n}$. The value of this derivation on any element of $\mathscr{A}$ is obtained by the Leibniz rule and the definition $D(x^i)=P^i(x^1,\ldots,x^n)$.

If one takes $\mathscr{C}$ the ideal in $\mathscr{A}$ generated by x^1, then the algebra $\mathscr{Q}$ is the free algebra with unit over $\mathbb{C}$ generated by $x^2,\ldots,x^n$, and one has $\mathscr{A}=\mathscr{C}\oplus\mathscr{Q}$ as vector spaces.

Any derivation in $\mathscr{G}_{\mathscr{C}}$ is the sum of two kinds of derivation: $(P^i)_{1\leqslant i\leqslant n}$, with $P^i\in\mathscr{Q}$ and $P^1=0$ ($\mathscr{Q}$ is considered here as a subalgebra of $\mathscr{A}$), and $(P^i)_{1\leqslant i\leqslant n}$, with $P^i\in\mathscr{C}$. Any derivation in $\mathscr{G}_{\mathscr{A}}$ is of the second kind, and the Lie algebra of derivation of $\mathscr{Q}$ is the set of the first kind derivations in $\mathscr{G}_{\mathscr{C}}$. So the condition of the Definition IV.1 is fulfilled. Thus $\mathscr{Q}$ is a submanifold algebra of $\mathscr{A}$. In this case, one has $\mathscr{G}_{\mathscr{C}}=\mathscr{G}_{\mathscr{A}}\oplus\mathrm{Der}(\mathscr{Q})$.

As maximal ideals of $\mathscr{A}$, one has the ideals generated by the n elements x^i-a_i, where $a_i\in\mathbb{C}$. Then the point associated to such an ideal is a point in $\mathbb{C}^n$, with values in $\mathbb{C}$. This situation is analogous to the situation of the polynomial algebra generated by the n variables x^i, for which there are only those maximal ideals. It is not difficult to see that such an ideal contains the ideals generated by the expressions $x^ix^j-x^jx^i$. In the case of the tensor algebra $\mathscr{A}$, there are other interesting maximal ideals, as the following examples show.

Example 3: The Heisenberg algebra.

Let $\mathscr{A}$ be the free algebra with unit generated by two elements x,y. Consider in $\mathscr{A}$ the ideal generated by $xy-yx-i\mathbb{1}$. Then the quotient algebra is the Heisenberg algebra $\mathscr{H}$, generated by two elements p,q and the relation $pq-qp=i\mathbb{1}$. It is well known that this algebra is simple. The ideal is maximal. In the quotient, we take $x\mapsto p$ and $y\mapsto q$.

Now let us consider derivations. If we denote by $D=(X,Y)$ the derivation $D(x)=X$ and $D(y)=Y$, then one has

$$\mathscr{G}_{\mathscr{C}}=\{(X,Y)/[X,\,y]+[x,\,Y]\in\mathscr{C}\},$$

where $X,Y\in\mathscr{A}$, and

$$\mathscr{G}_{\mathscr{A}}=\{(X,Y)/X,Y\in\mathscr{C}\}.$$

On the other hand, one knows that $\mathscr{H}$ has only inner derivations (see Ref. 5, for instance), so

$$\mathrm{Der}(\mathscr{H})=\{([A,\,p],[A,\,q])/A\in\mathscr{H}\}$$

with the same notations as above. It is easy to prove that the mapping $\mathscr{G}_{\mathscr{C}}\to\mathrm{Der}(\mathscr{H})$ (the quotient by $\mathscr{G}_{\mathscr{A}}$) is surjective (one can use Lemma IV.1, but the direct calculation shows in this particular case how that works). Indeed, take $A\in\mathscr{H}$ and let $A\in\mathscr{A}$ be such that $A\mapsto A$ in the quotient mapping $\mathscr{A}\to\mathscr{H}$. Then the derivation $([A,\,x],[A,\,y])$ maps to $([A,\,p],[A,\,q])\in\mathrm{Der}(\mathscr{H})$. One must then show that this derivation is indeed in $\mathscr{G}_{\mathscr{C}}$. This is equivalent to showing $[[A,\,x],y]+[x,[A,\,y]]\in\mathscr{C}$. However, this expression equals $-[[x,\,y],\,A]$, which is obviously in the kernel of the mapping $\mathscr{A}\to\mathscr{H}$. So, it is in $\mathscr{C}$.

The Heisenberg algebra is then a submanifold algebra, which can be regarded, from the point of view of algebraic geometry, as a point in the free algebra with unit $\mathscr{A}$. Its tangent space is the linear space $\mathscr{H}\oplus\mathscr{H}$.

Example 4: The matrix algebra.

Let $\mathscr{A}$ denote as above the free algebra with unit generated by two elements x,y. Let $q\in\mathbb{C}$ be an nth unit root, $q^n=1$. Let $\mathscr{C}$ denote the ideal in $\mathscr{A}$ generated by the relations

$$xy-qyx, \quad x^n-\mathbb{1}, \quad y^n-\mathbb{1},$$

and denote by U and V the images of x and y in the quotient mapping $\mathscr{A}\to\mathscr{Q}$. Let us show that this algebra is the matrix algebra $M(n,\mathbb{C})$. Any element of $\mathscr{Q}$ can be written as

$$\sum_{0\leqslant k,l\leqslant n-1} a_{k,l}U^kV^l,$$

so $\dim\mathscr{Q}\leqslant n^2$. Now, the following two matrices in $M(n,\mathbb{C})$,

$$U=\begin{pmatrix} 1 & 0 & 0 & \cdots & 0 \\ 0 & q & 0 & \cdots & 0 \\ 0 & 0 & q^2 & \cdots & 0 \\ \vdots & \vdots & & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & q^{n-1} \end{pmatrix}, \quad V=\begin{pmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 & 1 \\ 1 & 0 & \cdots & 0 & 0 \end{pmatrix}$$

satisfy the relations of the algebra $\mathscr{Q}$, and then generate a subalgebra of $M(n,\mathbb{C})$. Because the only matrices which commute with this subalgebra are the multiple of identity, this is the full matrix algebra.

It is well known that the matrix algebra has only inner derivations. By Lemma IV.1, $M(n,\mathbb{C})$ can be considered as a submanifold algebra of the tensor algebra. Notice that this algebra is simple, and so can be considered as a ''point'' in the tensor algebra.

Example 5: The matrix-valued functions.

Consider, as in Ref. 10, the algebra $\mathscr{A}=C^\infty(V)\otimes M(n,\mathbb{C})$ of matrix-valued functions on a manifold V. Let $p\in V$ any point of the manifold. Take $\mathscr{C}$ to be the ideal of functions vanishing at p. This is obviously a maximal ideal. It has been shown in Ref. 10 that $\mathrm{Der}(\mathscr{A})=[\mathrm{Der}(C^\infty(V))\otimes\mathbb{1}]\oplus[C^\infty(V)\otimes\mathrm{Der}(M(n,\mathbb{C}))]$. Then a simple calculation shows that $\mathscr{Q}=\mathscr{A}/\mathscr{C}$ is the matrix algebra $M(n,\mathbb{C})$ and is a submanifold algebra of $\mathscr{A}$. The ''tangent space'' at p is $T_pV\oplus\mathrm{Der}(M(n,\mathbb{C}))$, where T_pV is the ordinary tangent space of V at p.

The physical interpretation of this situation is the following: from the point of view of noncommutative differential geometry, each point of space–time is a matrix, instead of $\mathbb{C}$ (or $\mathbb{R}$) in ordinary differential geometry. The structure looks like a fiber bundle, the fiber being a matrix algebra, but the differential structure is different, because the purely noncommutative differential structure of the matrix algebra (which is far from being trivial) is taken into account at each point of V. This supplementary differential structure of points has important consequences for gauge fields theory, as has been shown in Ref. 10.

This situation can be modified without many changes, by taking the algebra of sections of bundle over M, with fiber $M(n,\mathbb{C})$.

V. NONCOMMUTATIVE QUOTIENT MANIFOLDS

In this section, we introduce a generalization to the noncommutative framework of the notion of quotient manifold. We then introduce the generalization of the action of a group on a manifold which gives a way to construct such quotient manifolds. We give examples and we examine the possible relations with connections on central bimodules.

A. Quotient manifold algebra

Let $\mathscr{A}$ be an associative algebra with unit. Let $\mathscr{B}$ be a subalgebra of $\mathscr{A}$. Then we define the Lie subalgebras of $\mathrm{Der}(\mathscr{A})$:

$$\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})=\{X\in\mathrm{Der}(\mathscr{A})/X.\mathscr{B}=0\}$$

and

$$\mathscr{N}_{\mathrm{Der}}(\mathscr{B})=\{X\in\mathrm{Der}(\mathscr{A})/X.\mathscr{B}\subset\mathscr{B}\}.$$

Notice that $\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$ is an ideal in $\mathscr{N}_{\mathrm{Der}}(\mathscr{B})$, i.e., $[\mathscr{N}_{\mathrm{Der}}(\mathscr{B}),\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})]\subset\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$. One can call $\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$ the centralizer of $\mathscr{B}$ in $\mathrm{Der}(\mathscr{A})$ and $\mathscr{N}_{\mathrm{Der}}(\mathscr{B})$ the normalizer of $\mathscr{B}$ in $\mathrm{Der}(\mathscr{A})$.

One has a natural homomorphism of Lie algebras $\rho:\mathscr{N}_{\mathrm{Der}}(\mathscr{B})\to\mathrm{Der}(\mathscr{B})$, $X\mapsto\widetilde{X}$, the restriction of X to $\mathscr{B}$. The kernel of this homomorphism is exactly $\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$.

Definition V.1: The subalgebra $\mathscr{B}$ of $\mathscr{A}$ is a quotient manifold algebra of $\mathscr{A}$ if the following three conditions are fulfilled

(i) $\mathscr{Z}(\mathscr{B})=\mathscr{B}\cap\mathscr{Z}(\mathscr{A})$,
(ii) $\mathrm{Der}(\mathscr{B})\simeq\mathscr{N}_{\mathrm{Der}}(\mathscr{B})/\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$,
(iii) $\mathscr{B}=\{a\in\mathscr{A}/Xa=0\,\forall X\in\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})\}$.

Condition (i) gives to $\mathscr{N}_{\mathrm{Der}}(\mathscr{B})$ and $\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$ a structure of $\mathscr{Z}(\mathscr{B})$-module. Then $\mathscr{N}_{\mathrm{Der}}(\mathscr{B})/\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$ is naturally a $\mathscr{Z}(\mathscr{B})$-module, and condition (ii) is an isomorphism of $\mathscr{Z}(\mathscr{B})$-modules. One then has the short exact sequence of Lie algebras and $\mathscr{Z}(\mathscr{B})$-modules

$$0\to\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})\to\mathscr{N}_{\mathrm{Der}}(\mathscr{B})\xrightarrow{\rho}\mathrm{Der}(\mathscr{B})\to 0. \tag{4}$$

Now, the Lie subalgebra $\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$ of $\mathrm{Der}(\mathscr{A})$ gives a Cartan operation on $\underline{\Omega}_{\mathrm{Der}}(\mathscr{A})$. Condition (iii) says that $\mathscr{B}$ is exactly the basic algebra in $\mathscr{A}$ for this operation.

Let $\omega\in\underline{\Omega}^n_{\mathrm{Der}}(\mathscr{A})$ be a basic element for the operation of $\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$, $i_X\omega=0$, and $L_X\omega=0$ for any $X\in\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$. Then $d\omega$ is also basic. One can then define $\widetilde{\omega}\in\underline{\Omega}^n_{\mathrm{Der}}(\mathscr{B})$ by the relation

$$\widetilde{\omega}(\widetilde{X}_1,\ldots,\widetilde{X}_n)=\omega(X_1,\ldots,X_n)$$

for any $\widetilde{X}_1,\ldots,\widetilde{X}_n\in\mathrm{Der}(\mathscr{B})$ and any representatives $X_1,\ldots,X_n\in\mathscr{N}_{\mathrm{Der}}(\mathscr{B})$. By the Koszul formula and condition (iii), it is easy to show that $\omega(X_1,\ldots,X_n)\in\mathscr{B}$ for $X_i\in\mathscr{N}_{\mathrm{Der}}(\mathscr{B})$. Note that condition (ii) is essential to ensure the consistency of this definition. Condition (i) shows that $\widetilde{\omega}$ is $\mathscr{Z}(\mathscr{B})$-linear. The Koszul formula shows then that $d\widetilde{\omega}=\widetilde{d\omega}$.

So one has the following lemma:

Lemma V.1: One has a mapping of graded differential algebras

$$\underline{\Omega}_{\mathrm{Der},B}(\mathscr{A})\to\underline{\Omega}_{\mathrm{Der}}(\mathscr{B}),$$

where $\underline{\Omega}_{\mathrm{Der},B}(\mathscr{A})$ *is the subalgebra of* $\underline{\Omega}_{\mathrm{Der}}(\mathscr{A})$ *of basic elements for* $\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$.

Remark 1: In degree 0, by the very definition, one has $\underline{\Omega}^0_{\mathrm{Der},B}(\mathscr{A})=\mathscr{B}=\underline{\Omega}^0_{\mathrm{Der}}(\mathscr{B})$.

Remark 2: No canonical mapping can be constructed between the basic elements of $\Omega_{\mathrm{Der}}(\mathscr{A})$ and $\Omega_{\mathrm{Der}}(\mathscr{B})$ without more information on the algebras $\mathscr{A}$ and $\mathscr{B}$.

Remark 3: Condition (ii) can be relaxed if we define $\mathrm{Der}(\mathscr{B})$ to be the Lie algebra $\mathscr{N}_{\mathrm{Der}}(\mathscr{B})/\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$, even if $\mathscr{B}$ admitted other derivations. In this situation, one has a kind of induced differential structure on $\mathscr{B}$ (see Example 1 below).

Proposition V.1: If the $\mathscr{Z}(\mathscr{A})$-module induced by $\mathscr{N}_{\mathrm{Der}}(\mathscr{B})$ in $\mathrm{Der}(\mathscr{A})$ is $\mathrm{Der}(\mathscr{A})$ itself, then we have an isomorphism of graded differential algebras

$$\underline{\Omega}_{\mathrm{Der},B}(\mathscr{A}) \simeq \underline{\Omega}_{\mathrm{Der}}(\mathscr{B}).$$

Proof: First, let us prove that the mapping $\underline{\Omega}_{\mathrm{Der},B}(\mathscr{A}) \to \underline{\Omega}_{\mathrm{Der}}(\mathscr{B})$ constructed above is injective. If $\tilde{\omega}$ is zero in $\underline{\Omega}^n_{\mathrm{Der}}(\mathscr{B})$, then for any $X_1,\ldots,X_n \in \mathscr{N}_{\mathrm{Der}}(\mathscr{B})$ we have $\omega(X_1,\ldots,X_n)=0$. Now, ω is $\mathscr{Z}(\mathscr{A})$-linear, so ω is zero on the $\mathscr{Z}(\mathscr{A})$-module induced by $\mathscr{N}_{\mathrm{Der}}(\mathscr{B})$ in $\mathrm{Der}(\mathscr{A})$. This proves injectivity.

Let $\tilde{\omega} \in \underline{\Omega}^n_{\mathrm{Der}}(\mathscr{B})$ be any n-form. Define ω as an antisymmetric n-$\mathscr{Z}(\mathscr{B})$-linear mapping from $\mathscr{N}_{\mathrm{Der}}(\mathscr{B}) \otimes_{\mathscr{Z}(\mathscr{B})} \cdots \otimes_{\mathscr{Z}(\mathscr{B})} \mathscr{N}_{\mathrm{Der}}(\mathscr{B})$ to $\mathscr{B}$ by the relation

$$\omega(X_1,\ldots,X_n) = \tilde{\omega}(\tilde{X}_1,\ldots,\tilde{X}_n) \in \mathscr{B} \subset \mathscr{A}$$

for any $X_1,\ldots,X_n \in \mathscr{N}_{\mathrm{Der}}(\mathscr{B})$. Then we extend ω on the $\mathscr{Z}(\mathscr{A})$-module induced by $\mathscr{N}_{\mathrm{Der}}(\mathscr{B})$, by $\mathscr{Z}(\mathscr{A})$ linearity. Notice that ω is already $\mathscr{Z}(\mathscr{B})$ linear. By hypothesis, ω is then an element of $\underline{\Omega}^n_{\mathrm{Der}}(\mathscr{A})$. We have $i_X\omega=0$ for any $X \in \mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$, so ω is horizontal for the action of $\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$ in $\underline{\Omega}_{\mathrm{Der}}(\mathscr{A})$. Now, notice that the $(n+1)$-form in $\underline{\Omega}_{\mathrm{Der}}(\mathscr{A})$ which comes from $d\tilde{\omega}$ is exactly $d\omega$, because by the Koszul formula they coincide on $\mathscr{N}_{\mathrm{Der}}(\mathscr{B})$. So $d\omega$ is also horizontal, and then ω is basic in $\underline{\Omega}_{\mathrm{Der}}(\mathscr{A})$. This proves surjectivity. □

B. Action

Let M be a manifold and G be a Lie group. An action of G on M gives a Lie algebra homomorphism $\mathfrak{g} \to \Gamma(M)$ from the Lie algebra $\mathfrak{g}$ of G to the Lie algebra of vector fields on M. Then one has a Cartan operation of the Lie algebra $\mathfrak{g}$ on the graded commutative differential algebra $\Omega(M)$ of de Rham differential forms on M.

In the noncommutative case, we will say we have an action of the Lie algebra $\mathfrak{g}$ on an associative algebra with unit $\mathscr{A}$ if there is a homomorphism of Lie algebras $\mathfrak{g} \to \mathrm{Der}(\mathscr{A})$. In this situation one has an operation of $\mathfrak{g}$ on the graded differential algebra $\underline{\Omega}_{\mathrm{Der}}(\mathscr{A})$.

Then one can take as subalgebra of $\mathscr{A}$ the basic algebra for this operation. In this situation, if $\mathscr{B}$ is a quotient manifold algebra, then one has the noncommutative version of the quotient manifold by the ''leaves'' defined by $\mathfrak{g}$.

If the homomorphism $\mathfrak{g} \to \mathrm{Der}(\mathscr{A})$ is injective (take the image of $\mathfrak{g}$ if not), one can identify $\mathfrak{g}$ with its image. Then, one has the inclusion $\mathfrak{g} \subset \mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$, but the equality is not the generic case. Between these two Lie algebras, one has a third one, the $\mathscr{Z}(\mathscr{A})$-module induced by $\mathfrak{g}$ in $\mathrm{Der}(\mathscr{A})$, denoted by $\mathfrak{g}_{\mathscr{Z}(\mathscr{A})}$. If $\mathscr{B}$ is the basic algebra in $\mathscr{A}$ for the operation of $\mathfrak{g}$, the condition (iii) of Definition V.1 is fulfilled.

C. Examples

Example 1: The inner derivations.

Let $\mathscr{A}$ be an associative algebra with unit for which there are inner derivations. Suppose one has $H^1(\mathscr{A},\mathscr{Z}(\mathscr{A});\mathscr{A})=0$. Take the operation of $\mathfrak{g}=\mathrm{Int}(\mathscr{A})$ on $\mathscr{A}$. Then one has $\mathscr{B}=\mathscr{Z}(\mathscr{A})$, $\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})=\mathfrak{g}$ because the first relative cohomology group vanishes, and $\mathscr{N}_{\mathrm{Der}}(\mathscr{B})=\mathrm{Der}(\mathscr{A})$. Take then the induced differential structure on $\mathscr{B}$ by setting $\mathrm{Der}(\mathscr{B})=\mathrm{Out}(\mathscr{A})=\mathscr{N}_{\mathrm{Der}}(\mathscr{B})/\mathfrak{g}$. The algebra of differential forms associated to $\mathscr{B}$ is then, by Proposition V.1, the algebra $\underline{\Omega}_{\mathrm{Out}}(\mathscr{A})$ introduced in Ref. 3.

Example 2: The noncommutative torus.

Let T_q denote the complex associative algebra with unit of elements of the form

$$a=\sum_{k,l\in\mathbb{Z}} c_{kl}U^kV^l$$

with

$$\|a\|_m=\sup_{k,l\in\mathbb{Z}}|c_{kl}|(1+|k|+|l|)^m<\infty$$

and the relation

$$UV=qVU$$

for $q\in\mathbb{C}$ such that $q^N=1$ for $N\in\mathbb{N}$. We take N to be the minimal one for which this is true. The center of this algebra is the set of elements depending only on U^N and V^N.

The derivations of this algebra are the inner derivations and the derivations of the form

$$a(U^N,V^N)D_U+b(U^N,V^N)D_V,$$

where $D_U(U)=U$, $D_U(V)=0$, $D_V(U)=0$ and $D_V(V)=V$, and $a(U^N,V^N)$ and $b(U^N,V^N)$ belong to $\mathcal{Z}(T_q)$.

Take $\mathfrak{g}=\mathrm{Int}(T_q)$. Then $\mathcal{B}=\mathcal{Z}(T_q)$, $\mathcal{Z}_{\mathrm{Der}}(\mathcal{B})=\mathfrak{g}$, and $\mathcal{N}_{\mathrm{Der}}(\mathcal{B})=\mathrm{Der}(T_q)$. We are then in the situation of the previous example. Then the differential algebra of forms on $\mathcal{Z}(T_q)$ is the basic algebra of the differential algebra of forms on T_q. But now, remark that the center $\mathcal{Z}(T_q)$ is isomorphic to the algebra $C^\infty(S^1\times S^1)$ of smooth functions on the (ordinary) torus. This isomorphism is $U^N\mapsto e^{2\pi it}$ and $V^N\mapsto e^{2\pi is}$. Then an element $a\in\mathcal{Z}(T_q)$ is mapped on the Fourier expansion of an element of $C^\infty(S^1\times S^1)$. Thus, the algebra of forms on $\mathcal{Z}(T_q)$ is the de Rham algebra of forms on the torus.

D. Connections

Let $\mathcal{B}$ be a quotient manifold algebra of $\mathcal{A}$. Then $\mathcal{A}$ is a central bimodule over the algebra $\mathcal{B}$. Let $\psi:\mathrm{Der}(\mathcal{B})\to\mathcal{N}_{\mathrm{Der}}(\mathcal{B})$ be a splitting of the short exact sequence (4), considered as a short exact sequence of $\mathcal{Z}(\mathcal{B})$-modules (forgetting the Lie algebra structures).

Proposition V.2: For any $X\in\mathrm{Der}(\mathcal{B})$, the mapping

$$\nabla_X:\mathcal{A}\to\mathcal{A},\quad a\mapsto\psi(X)a,$$

is a connection on the central bimodule $\mathcal{A}$ over $\mathcal{B}$.

The curvature of this connection is the obstruction on ψ to be a splitting of the short exact sequence (4) of Lie algebras.

Proof: This is an immediate consequence of the fact that ψ is a $\mathcal{Z}(\mathcal{B})$-modules homomorphism, such that $\psi(X)b=Xb$ for any $b\in\mathcal{B}\subset\mathcal{A}$. The curvature of this connection is

$$R(X,Y)=[\psi(X),\ \psi(Y)]-\psi([X,\ Y]),$$

which proves the Proposition. □

Such a connection gives a projection $P:\mathcal{N}_{\mathrm{Der}}(\mathcal{B})\to\mathcal{Z}_{\mathrm{Der}}(\mathcal{B})\subset\mathcal{N}_{\mathrm{Der}}(\mathcal{B})$ of $\mathcal{Z}(\mathcal{B})$-modules defined by $P(X)=X-\psi\circ\rho(X)$. Then one has $\mathcal{N}_{\mathrm{Der}}(\mathcal{B})=\mathrm{Ker}\,P\oplus\mathcal{Z}_{\mathrm{Der}}(\mathcal{B})$.

Conversely, a projection $P:\mathcal{N}_{\mathrm{Der}}(\mathcal{B})\to\mathcal{Z}_{\mathrm{Der}}(\mathcal{B})\subset\mathcal{N}_{\mathrm{Der}}(\mathcal{B})$ of $\mathcal{Z}(\mathcal{B})$-modules defines a split, and so a connection on $\mathcal{A}$.

In Ref. 11, one can find another approach to group actions, bundles, and connections in noncommutative differential geometry.

Let $P(M,G)$ be a principal bundle, where M is the base manifold and G is the structure group, and let $\mathfrak{g}$ be its Lie algebra. Denote by $\mathcal{A}$ the (commutative) algebra of smooth functions

on P, and $\mathscr{B}$ the algebra of smooth functions on M. Then one can consider that $\mathscr{B}\subset\mathscr{A}$ because of the projection $P\to M$. The Lie algebra $\mathfrak{g}$ can be injectively mapped into $\Gamma(P)$, the vector fields on P, and, more precisely, into the vertical vector fields. Thus $\mathfrak{g}$ operates on $\mathscr{A}$. The algebra $\mathscr{B}$ is obviously the basic algebra for this operation and $\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$ is exactly the Lie algebra of vertical vector fields on P.

It is well known that a connection on P can be given as a $\mathscr{B}$-linear mapping $\Gamma(M)\to\Gamma(P), X\mapsto X^h$, the horizontal lift, with its usual properties, one of them being $[\mathfrak{g},X^h]=0$ for all $X\in\Gamma(M)$. In fact this mapping is a splitting of (4) [remember here that $\mathscr{B}=\mathscr{Z}(\mathscr{B})$].

Then one could think that the connections introduced by the construction of Proposition V.2 are generalizations of connections on principal bundles. However, this is not completely true, because a principal bundle has many more properties than a couple $(\mathscr{A},\mathscr{B})$ of an algebra and a quotient manifold algebra. For example, one can introduce associated bundles, on which connections can be transported.

In order to obtain a similar situation, one must introduce a more restrictive definition. Given a couple $(\mathscr{A},\mathscr{B})$ of an algebra and a quotient manifold algebra, suppose there exists a Lie algebra $\mathfrak{g}$ and an injective homomorphism of Lie algebras $\mathfrak{g}\to\mathrm{Der}(\mathscr{A})$ such that $\mathscr{B}$ is the basic algebra for the operation of $\mathfrak{g}$ on $\mathscr{A}$ [then $\mathfrak{g}\subset\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$]. A connection on this triple $(\mathscr{A},\mathscr{B},\mathfrak{g})$ is a splitting $\psi:\mathrm{Der}(\mathscr{B})\to\mathscr{N}_{\mathrm{Der}}(\mathscr{B})$ of $\mathscr{Z}(\mathscr{B})$-modules compatible with the operation of $\mathfrak{g}$ in the sense $[\mathfrak{g},\psi(X)]=0$ for all $X\in\mathrm{Der}(\mathscr{B})$. Such a connection is also given by a covariant projection $P:\mathscr{N}_{\mathrm{Der}}(\mathscr{B})\to\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$ where the covariance means $[Y,P(X)]=P([Y,X])$ for all $Y\in\mathfrak{g}$ and $X\in\mathscr{N}_{\mathrm{Der}}(\mathscr{B})$.

In this situation, if V is a linear space on which $\mathfrak{g}$ is represented by $\eta:\mathfrak{g}\to\mathrm{End}(V)$, then one has an associated central bimodule over $\mathscr{B}$ defined by

$$\mathscr{M}_V=\{a_i\otimes v^i\in\mathscr{A}\otimes V/(Ya_i)\otimes v^i+a_i\otimes\eta(Y)v^i=0\,\forall Y\in\mathfrak{g}\},$$

where the structure of bimodule over $\mathscr{B}$ is localized on $\mathscr{A}$.

Proposition V.3: Let $\psi:\mathrm{Der}(\mathscr{B})\to\mathscr{N}_{\mathrm{Der}}(\mathscr{B})$ be a connection on $(\mathscr{A},\mathscr{B},\mathfrak{g})$. Then, the mapping

$$\boldsymbol{\nabla}^V_X:\mathscr{M}_V\to\mathscr{M}_V,\quad a_i\otimes v^i\mapsto(\psi(X)a_i)\otimes v^i,$$

is well defined and is a connection on $\mathscr{M}_V$. This is the associated connection to ψ on $\mathscr{M}_V$.

Proof: $\nabla^V_X\mathscr{M}_V\subset\mathscr{M}_V$ because $[\mathfrak{g},\psi(X)]=0$. Other properties of ∇^V_X are immediate consequences of the definition of ψ as in Proposition V.2. □

In the case of a principal bundle, $\mathscr{M}_V$ is the module over $\mathscr{B}$ of sections of the associated vector bundle for (V,η). This module of sections is considered here as the module of equivariant mapping $P\to V$.

Let us now turn to a different problem. From the point of view of characteristic classes (even if there is not yet such a theory for the definition of connection used here), what is important in a connection is its curvature. Given a couple $(\mathscr{A},\mathscr{B})$ of an algebra and a quotient manifold algebra, suppose one has a central bimodule $\mathscr{M}$ over $\mathscr{A}$ and a connection $\boldsymbol{\nabla}$ on $\mathscr{M}$, such that its curvature is zero if one of its argument is in $\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$. Then one can transport the connection on a central bimodule over $\mathscr{B}$. Define the reduced central bimodule over $\mathscr{B}$

$$\mathscr{M}^{\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})}=\{m\in\mathscr{M}/\boldsymbol{\nabla}_X m=0\,\forall X\in\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})\}.$$

For any $\widetilde{X}\in\mathrm{Der}(\mathscr{B})$, take any $X\in\mathscr{N}_{\mathrm{Der}}(\mathscr{B})$ such that $\rho(X)=\widetilde{X}$. Then define, for any $m\in\mathscr{M}^{\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})}$,

$$\widetilde{\boldsymbol{\nabla}}_{\widetilde{X}}m=\boldsymbol{\nabla}_X m.$$

Then, because the curvature of $\boldsymbol{\nabla}$ is zero on $\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})$, this is a well-defined mapping from $\mathscr{M}^{\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})}$ into itself. It is easy to verify that $\widetilde{\boldsymbol{\nabla}}$ is a connection, the curvature of which is

$$\widetilde{R}(\widetilde{X},\widetilde{Y})m = R(X,Y)m$$

for any $m \in \mathscr{M}^{\mathscr{Z}_{\mathrm{Der}}(\mathscr{B})}$.

In the case where $\mathrm{Der}(\mathscr{A}) = \mathrm{Int}(\mathscr{A})$, it has been shown in Ref. 3 that any central bimodule $\mathscr{M}$ over $\mathscr{A}$ admits the canonical connection $\nabla_{ad(a)}m = am - ma$. The curvature of this connection is zero.

Now, in the general case $[\mathrm{Der}(\mathscr{A}) \neq \mathrm{Int}(\mathscr{A})]$, if one can take this connection on $\mathrm{Int}(\mathscr{A})$ and a prolongement on $\mathrm{Der}(\mathscr{A})$, then the curvature is zero on $\mathrm{Int}(\mathscr{A})$. So one can hope to transport the connection on a reduced module over $\mathscr{B} = \mathscr{Z}(\mathscr{A})$ while keeping the same information on the curvature.

VI. CONCLUSION

In this paper we have proposed definitions of the noncommutative generalization of a submanifold and of a noncommutative quotient manifold. Various examples and related constructions seem to give them an importance for the study of derivations-based differential structures of algebras. What must be notice is the different use of the two generalizations of differential forms: $\underline{\Omega}_{\mathrm{Der}}(\mathscr{A})$ and $\Omega_{\mathrm{Der}}(\mathscr{A})$. This shows the importance of introducing various generalizations of a commutative concept adapted to different situations.

(Received 27 March 1995; accepted for publication 7 February 1996)

We present a set of tensors which are shift tensors (Wigner tensors) in accordance with the definitions of Biedenharn and Louck and satisfy the coherence conditions of Flath and Towber. Our tensors are defined for all connected compact Lie groups and for finite-dimensional representations of connected reductive Lie groups. Thus, we have a realization of the coherent tensors in a rather general setting. Moreover, this realization enables us to confirm most of the conjectures of Flath and Towber concerning the properties of coherent tensors. © *1996 American Institute of Physics.* [S0022-2488(96)03405-9]

I. INTRODUCTION

In the application of group theory in quantum mechanics, one needs to know the representations of Lie groups and their Lie algebras and the ways in which tensor products of representations decompose and recouple. The analysis of tensor coupling and recoupling has been developed to a fine art for SU(2) and is often referred to as the Racah–Wigner calculus.

Some years ago Biedenharn and his colleagues[1] initiated a program to extend the Racah–Wigner calculus to other unitary groups. They focused on the Racah–Wigner algebras of tensors on model spaces and introduced the concept of Wigner operators as the components of shift tensors (also called unit tensors). These tensors have some remarkable properties. As observed by Biedenharn *et al.*, they can be labeled by *operator patterns* in parallel with the Gel'fand patterns used to label basis vectors of an irreducible U(n) representation. Moreover, they form a basis for the Racah–Wigner algebra over the ring of scalar (invariant) operators. Shift tensors have also been used by Hughes[2] and others.

Subsequently, Flath and Towber[3] refined the definition of a shift tensor by introducing the idea of coherence. This enabled them to relate the actions of a tensor on different irreps. It also enabled them to prove a number of theorems for SU(3) and conjecture the general validity of their theorems for other connected compact Lie groups.

In this note, we give a set of tensors which are shift tensors and satisfy the coherence condition of Flath and Towber. They also have the property of being asymptotically orthonormal. Our tensors are given for connected compact Lie groups or the finite-dimensional representations of connected reductive Lie groups. The space spanned by these tensors is uniquely determined by the coherence condition. Thus, we claim to have identified the Biedenharn–Louck–Flath–Towber tensors in a rather general setting. Moreover, with explicit expressions for the coherent tensors, we find that most of Flath and Towber's conjectures concerning their properties follow automatically.

We use the following notations: G is a connected compact semisimple Lie group and $\mathfrak{g}$ is the complex extension of its Lie algebra; Λ is the set of dominant integral weights for G; V^λ is a module for an irrep R^λ of highest weight $\lambda \in \Lambda$. The direct sum $V = \Sigma_{\lambda \in \Lambda} V^\lambda$ is a model space[4] for a universal representation $R = \Sigma_{\lambda \in \Lambda} R^\lambda$, where the latter is a representation which contains every irrep of G once and once only.

If U and W are modules for representations of G, then a $U \to W$ tensor is a G-invariant set of linear $U \to W$ maps. Thus, a tensor T is a module for a representation of G. Basis elements for a tensor are referred to as components of the tensor. An irreducible tensor T^λ is characterized by a

0022-2488/96/37(5)/2498/12/$10.00

'highest weight $\lambda \in \Lambda$ and it has components $\{T^{\lambda}_{\alpha\nu}\}$ indexed by a weight ν, relative to a Cartan subalgebra, and a multiplicity index α. An irreducible tensor $T^{\lambda\mu}$ of highest weight λ on a model space V is called a *shift tensor* of shift μ if every component $T^{\lambda\mu}_{\alpha\nu}$ of $T^{\lambda\mu}$ maps any irreducible subspace $V^{\lambda_1} \subset V$ into the irreducible subspace $V^{\lambda_1+\mu} \subset V$.

Biedenharn *et al.*[1] sought a particular set of shift tensors $\{T^{\lambda\beta\mu}\}$ having the property that if $T^{\lambda\beta\mu}(\lambda_1)$ denotes the restriction of $T^{\lambda\beta\mu}$ to the subspace $V^{\lambda_1} \subset V$ then the set of tensors $\{T^{\lambda\beta\mu}(\lambda_1)\}$ (with μ fixed) spans the linear space of $V^1 \to V^{\lambda_1+\mu}$ tensors. We refer to such tensors as Biedenharn–Louck tensors. As Biedenharn[5] has observed, any $V \to V$ tensor can be expressed as a linear combination of Biedenharn–Louck tensors with G-invariant linear operators (tensors of highest weight $\lambda = 0$) as scalar multipliers; we say that such a set of shift tensors is complete.

We first show that a module for the universal representation is spanned, in a coherent state representation, by a subset of generalized Wigner functions. We then give a set of Biedenharn–Louck shift tensors on this space and show that they are coherent according to the definition of Flath and Towber.[3]

II. A COHERENT STATE REPRESENTATION

Let $\{|\psi^{\lambda}_{\alpha\nu}\rangle\}$ be an orthonormal basis for an irreducible subspace V^{λ} of a model space V and let $\{\langle\psi^{\lambda}_{\alpha\nu}|\}$ be the dual basis in Dirac's bra–ket notation. The inner product in this notation is then expressed

$$\langle \psi^{\lambda}_{\alpha\mu} | \psi^{\lambda'}_{\beta\nu} \rangle = \delta_{\lambda\lambda'} \delta_{\alpha\beta} \delta_{\mu\nu}. \tag{1}$$

A generalized Wigner function $\mathscr{D}^{\lambda}_{\beta\mu,\alpha\nu}$ is a $G \to \mathbb{C}$ function with

$$\mathscr{D}^{\lambda}_{\beta\mu,\alpha\nu}(g) = \langle \psi^{\lambda}_{\beta\mu} | R^{\lambda}(g) | \psi^{\lambda}_{\alpha\nu} \rangle. \tag{2}$$

From the Peter–Weyl theorem, one knows that the functions $\{\mathscr{D}^{\lambda}_{\beta\mu,\alpha\nu}\}$ span the Hilbert space $\mathscr{L}^2(G)$ and satisfy the orthogonality relation

$$d(\lambda_1) \int \mathscr{D}^{\lambda_1 *}_{\beta_1\mu_1,\alpha_1\nu_1}(g) \mathscr{D}^{\lambda_2}_{\beta_2\mu_2,\alpha_2\nu_2}(g) dv(g) = \delta_{\lambda_1\lambda_2} \delta_{\beta_1\beta_2} \delta_{\alpha_1\alpha_2} \delta_{\mu_1\mu_2} \delta_{\nu_1\nu_2}, \tag{3}$$

where dv is a suitably normalized invariant measure.

The orthornormal basis states $\{|\psi^{\lambda}_{\alpha\nu}\rangle\}$ have coherent-state wave functions $\{\psi^{\lambda}_{\alpha\nu}\}$ given by

$$\psi^{\lambda}_{\alpha\nu}(g) = \langle \psi^{\lambda}_{\lambda} | R^{\lambda}(g) | \psi^{\lambda}_{\alpha\nu} \rangle = \mathscr{D}^{\lambda}_{\lambda,\alpha\nu}(g), \tag{4}$$

where $|\psi^{\lambda}_{\lambda}\rangle$ is the (multiplicity free) highest weight state in the set $\{|\psi^{\lambda}_{\alpha\nu}\rangle\}$ (cf. Ref. 6 and references therein). Thus, the above coherent state representation is a nonisometric embedding of V in $\mathscr{L}^2(G)$

$$Q: V \to \mathscr{L}^2(G); \quad |\psi^{\lambda}_{\alpha\nu}\rangle \mapsto \psi^{\lambda}_{\alpha\nu} = \mathscr{D}^{\lambda}_{\lambda,\alpha\nu}. \tag{5}$$

It follows that the corresponding representation of the dual vector is given by

$$\langle \Psi^{\lambda}_{\alpha\nu}| \to d(\lambda) \mathscr{D}^{\lambda *}_{\lambda,\alpha\nu} \tag{6}$$

The model space V is thereby identified with a subspace of $\mathscr{L}^2(G)$. Conversely, there is a map

$$P: \mathscr{L}^2(G) \to V; \quad \mathscr{D}^{\lambda}_{\beta\mu,\alpha\nu} \mapsto \delta_{\mu\lambda} |\psi^{\lambda}_{\alpha\nu}\rangle, \tag{7}$$

which is uniquely defined by specification of the phases of the (normalized) highest weight states $|\psi^{\lambda}_{\lambda}\rangle \in V^{\lambda}$. The composition QP is seen to be a projection from $\mathscr{L}^2(G)$ to a subspace isomorphic to the model space. This subspace is invariant under the right regular representation but not under the left regular representation. This observation reflects the fact that the maps P and Q are equivariant relative to the action of the right regular representation of G on $\mathscr{L}^2(G)$ but not relative to the action of the left regular representation.

The set of coherent state wave functions $\{\psi^{\lambda}_{\alpha\nu}\}$ (i.e., the set of Wigner functions $\{\mathscr{D}^{\lambda}_{\lambda,\alpha\nu}\}$ which are of highest weight relative to the left regular representation) are a basis for the so-called *shape algebra* Λ^+G used by Flath and Towber.[3] Thus, the map $Q: V\to\Lambda^+G\subset\mathscr{L}^2(G)$ has been considered by Flath and Towber. As pointed out to us by Flath, the projection map P was also used previously by Bernstein, Gelfand, and Gelfand.[7] The coherent-state representation gives these maps a new interpretation.

The combination rule for the shape algebra (the so-called Cartan product) is simple multiplication of wave functions; i.e.,

$$[\psi^{\lambda_2}_{\alpha_2\nu_2}\cdot\psi^{\lambda_1}_{\alpha_1\nu_1}](g)=\psi^{\lambda_2}_{\alpha_2\nu_2}(g)\psi^{\lambda_1}_{\alpha_1\nu_1}(g). \tag{8}$$

Recall that Wigner functions can be combined according to the equation

$$\mathscr{D}^{\lambda}_{\beta\mu,\alpha\nu}(g)\mathscr{D}^{\lambda_1}_{\beta_1\mu_1,\alpha_1\nu_1}(g)=\sum_{\sigma\lambda_3\beta_3\alpha_3}(\lambda_1\beta_1\mu_1,\lambda\beta\mu|\sigma\lambda_3\beta_3\mu_3)\times(\lambda_1\alpha_1\nu_1,\lambda\alpha\nu|\sigma\lambda_3\alpha_3\nu_3)^*\mathscr{D}^{\lambda_3}_{\beta_3\mu_3,\alpha_3\nu_3}(g), \tag{9}$$

where $(\lambda_1\beta_1\mu_1,\lambda\beta\mu|\sigma\lambda_3\beta_3\mu_3)$ is a Clebsch–Gordan coefficient, $\mu_3=\mu_1+\mu$, $\nu_3=\nu_1+\nu$ and σ indexes the multiplicity of irreps equivalent to R^{λ_3} in the Kronecker product $R^{\lambda}\otimes R^{\lambda_1}$ (cf. Ref. 8, for example, for a derivation of this equation). It follows that the Cartan product can be expressed

$$\psi^{\lambda_2}_{\alpha_2\nu_2}\cdot\psi^{\lambda_1}_{\alpha_1\nu_1}=\sum_{\beta}\psi^{\lambda_1+\lambda_2}_{\beta\nu_1+\nu_2}(\lambda_1\lambda_1,\lambda_2\lambda_2|\lambda_1+\lambda_2,\lambda_1+\lambda_2)\times(\lambda_1\alpha_1\nu_1,\lambda_2\alpha_2\nu_2|\lambda_1+\lambda_2,\beta,\nu_1+\nu_2)^*. \tag{10}$$

Thus, if the Clebsch–Gordan coefficients are normalized such that $(\lambda_1\lambda_1,\lambda_2\lambda_2|\lambda_1+\lambda_2,\lambda_1+\lambda_2)$ is equal to 1, according to convention, the Cartan product simplifies to

$$\psi^{\lambda_2}_{\alpha_2\nu_2}\cdot\psi^{\lambda_1}_{\alpha_1\nu_1}=\sum_{\beta}\psi^{\lambda_1+\lambda_2}_{\beta\nu_1+\nu_2}(\lambda_1\alpha_1\nu_1,\lambda_2\alpha_2\nu_2|\lambda_1+\lambda_2,\beta,\nu_1+\nu_2)^*. \tag{11}$$

We shall assume in the following that Clebsch–Gordan coefficients are normalized in this way. The map $P:\mathscr{L}^2(G)\to V$ then induces a corresponding Cartan product on the model space in which

$$|\psi^{\lambda_2}_{\alpha_2\nu_2}\rangle\cdot|\psi^{\lambda_1}_{\alpha_1\nu_1}\rangle=\sum_{\beta}|\psi^{\lambda_1+\lambda_2}_{\beta\nu_1+\nu_2}\rangle(\lambda_1\alpha_1\nu_1,\lambda_2\alpha_2\nu_2|\lambda_1+\lambda_2,\beta,\nu_1+\nu_2)^*. \tag{12}$$

To simplify the notation, it will be convenient to write

$$|\psi^{\lambda_2}_{\alpha_2\nu_2}\cdot\psi^{\lambda_1}_{\alpha_1\nu_1}\rangle=|\psi^{\lambda_2}_{\alpha_2\nu_2}\rangle\cdot|\psi^{\lambda_1}_{\alpha_1\nu_1}\rangle. \tag{13}$$

We can now express Flath and Towber's definition of a coherent shift tensor in language familiar to physicists.

Definition (coherent tensor): A $V\to V$ shift tensor T^{μ} is said to be coherent if each component of T^{μ} satisfies the equation

$$\frac{1}{d(\lambda_3)}\langle\psi^{\lambda_3}_{\alpha_3\nu_3}|T^{\mu}_{\alpha\nu}|\psi^{\lambda_1}_{\alpha_1\nu_1}\rangle=\frac{1}{d(\lambda_3+\lambda_2)}\sum_{\alpha_2\nu_2}\langle\psi^{\lambda_2}_{\alpha_2\nu_2}\cdot\psi^{\lambda_3}_{\alpha_3\nu_3}|T^{\mu}_{\alpha\nu}|\psi^{\lambda_2}_{\alpha_2\nu_2}\cdot\psi^{\lambda_1}_{\alpha_1\nu_1}\rangle. \tag{14}$$

for all λ_1 and $\lambda_2\in\Lambda$, where $\lambda_3=\lambda_1+\mu$ and $d(\lambda)=\dim(V^{\lambda})$. An arbitrary coherent tensor is a finite linear combination of coherent shift tensors and a coherent linear operator is a component of a coherent tensor.

III. WIGNER TENSORS

It follows, from Eqs. (3)–(9), that the Wigner functions, with $\lambda\beta\mu$ held fixed, in the set $\{\mathscr{D}^{\lambda}_{\beta\mu,\alpha\nu}\}$ are the components of an $\mathscr{L}^2(G)\to\mathscr{L}^2(G)$ tensor with multiplicative action given by Eq. (8). Since the maps P and Q are G-equivariant [relative to the right action on $\mathscr{L}^2(G)$], it also follows that the set of operators

$$W^{\lambda\beta\mu}_{\alpha\nu}=P\mathscr{D}^{\lambda}_{\beta\mu,\alpha\nu}Q, \tag{15}$$

with $\lambda\beta\mu$ held fixed, are the components of a $V\to V$ tensor with action

$$W^{\lambda\beta\mu}_{\alpha\nu}|\psi^{\lambda_1}_{\alpha_1\nu_1}\rangle=\sum_{\sigma\alpha_3}(\lambda_1\lambda_1,\lambda\beta\mu|\sigma\lambda_3\lambda_3)(\lambda_1\alpha_1\nu_1,\lambda\alpha\nu|\sigma\lambda_3\alpha_3\nu_3)^*|\psi^{\lambda_3}_{\alpha_3\nu_3}\rangle, \tag{16}$$

where $\lambda_3=\lambda_1+\mu$ and $\nu_3=\nu_1+\nu$. We see that $W^{\lambda\beta\mu}$ is an irreducible $V\to V$ shift tensor of highest weight λ and shift μ. If we define the coupled state

$$[W^{\lambda\beta\mu}\otimes|\psi^{\lambda_1}\rangle]^{\sigma\lambda_3}_{\alpha_3\nu_3}=\sum_{\alpha_1\nu_1\alpha\nu}(\lambda_1\alpha_1\nu_1,\lambda\alpha\nu|\sigma\lambda_3\alpha_3\nu_3)^*W^{\lambda\beta\mu}_{\alpha\nu}|\psi^{\lambda_1}_{\alpha_1\nu_1}\rangle, \tag{17}$$

the action of $W^{\lambda\beta\mu}$ can be expressed in the succinct form

$$[W^{\lambda\beta\mu}\otimes|\psi^{\lambda_1}\rangle]^{\sigma\lambda_3}_{\alpha_3\nu_3}=(\lambda_1\lambda_1,\lambda\beta\mu|\sigma\lambda_3\lambda_3)|\psi^{\lambda_3}_{\alpha_3\nu_3}\rangle. \tag{18}$$

We now show that the tensors $\{W^{\lambda\beta\mu}\}$ are complete in the sense that the tensors $\{W^{\lambda\beta\mu}(\lambda_1)\}$ span the space of $V^{\lambda_1}\to V^{\lambda_1+\mu}$ tensors for all $\lambda_1\in\Lambda$, where $W^{\lambda\beta\mu}(\lambda_1)$ denotes the restriction of $W^{\lambda\beta\mu}$ to V^{λ_1}. Recall that the linear space of $V^{\lambda_1}\to V^{\lambda_3}$ tensors has a Hermitian inner product given[8] by

$$(A^{\lambda},B^{\lambda'})=\delta_{\lambda\lambda'}\sum_{\sigma}\langle\psi^{\lambda_3}||A^{\lambda}||\psi^{\lambda_1}\rangle^*_{\sigma}\langle\psi^{\lambda_3}||B^{\lambda}||\psi^{\lambda_1}\rangle_{\sigma}, \tag{19}$$

where $\langle\psi^{\lambda_3}||A^{\lambda}||\psi^{\lambda_1}\rangle_{\sigma}$ is a reduced matrix element defined by the Wigner–Eckart theorem

$$\langle\psi^{\lambda_3}_{\alpha_3\nu_3}|A^{\lambda}_{\alpha\nu}|\psi^{\lambda_1}_{\alpha_1\nu_1}\rangle=\sum_{\sigma}(\lambda_1\alpha_1\nu_1,\lambda\alpha\nu|\sigma\lambda_3\alpha_3\nu_3)^*\langle\psi^{\lambda_3}||A^{\lambda}||\psi^{\lambda_1}\rangle_{\sigma}. \tag{20}$$

It follows that the tensors $\{W^{\lambda\beta\mu}\}$ have reduced matrix elements

$$\langle\psi^{\lambda_3}||W^{\lambda\beta\mu}||\psi^{\lambda_1}\rangle_{\sigma}=(\lambda_1\lambda_1,\lambda\beta\mu|\sigma\lambda_3\lambda_3) \tag{21}$$

and that

$$(W^{\lambda\beta\mu}(\lambda_1),W^{\lambda\beta'\mu}(\lambda_1))=N^{\lambda\mu}_{\beta\beta'}(\lambda_1), \tag{22}$$

where

$$N^{\lambda\mu}_{\beta\beta'}(\lambda_1)=\sum_{\sigma}(\lambda_1\lambda_1,\lambda\beta\mu|\sigma\lambda_3\lambda_3)^*(\lambda_1\lambda_1,\lambda\beta'\mu|\sigma\lambda_3\lambda_3) \tag{23}$$

and $\lambda_3=\lambda_1+\mu$. We have shown, in Theorem 1 of Ref. 8, that the rank of the matrix $N^{\lambda\mu}(\lambda_1)$ is equal to $m(\lambda_1,\lambda;\lambda_3)$, where $m(\lambda_1,\lambda;\lambda_3)$ is the multiplicity of irreps equivalent to R^{λ_3} in the tensor product $R^{\lambda}\otimes R^{\lambda_1}$. Since this theorem is vital for the claims made in this paper, the proof is given, in more detail, in the Appendix. It follows from the theorem that the tensors $\{W^{\lambda\beta\mu}(\lambda_1)\}$ are a complete set of $V^{\lambda_1}\to V^{\lambda_1+\mu}$ tensors. We shall also show by means of the following claim that $N^{\lambda\mu}_{\beta\beta'}(\lambda_1)\to\delta_{\beta\beta'}$, for finite λ, as $\lambda_1\to\infty$. Thus, in the asymptotic limit, the tensors $\{W^{\lambda\beta\mu}(\lambda_1)\}$ become an orthonormal set. This shows that the shift tensors $\{W^{\lambda\beta\mu}\}$ are a complete, but not overcomplete, set.

Fix a highest weight λ, and consider $V^{\lambda}\otimes V^{\lambda_1}$ as $\lambda_1\to\infty$. When we write $\lambda_1\to\infty$, we will mean that λ_1 goes to ∞ ''away from the walls,'' i.e., inside a cone in the positive chamber whose only intersection with the walls is the origin. In particular, this implies that the Killing form inner product (λ_1,η) goes to infinity for any positive root η. Roughly speaking, this means that in V^{λ_1} it is possible to ''ladder down'' a large number of times from the highest weight, in the direction opposite to any positive root.

Claim: As $\lambda_1\to\infty$, any highest weight vector $|\Psi^{\sigma\lambda_3}_{\lambda_3}\rangle$ in $V^{\lambda}\otimes V^{\lambda_1}$ tends to a simple product;

$$|\Psi^{\sigma\lambda_3}_{\lambda_3}\rangle\to\left(\sum_{\alpha}(\lambda_1\lambda_1,\lambda\alpha\mu|\sigma\lambda_3\lambda_3)^*|\psi^{\lambda}_{\alpha\mu}\rangle\right)|\psi^{\lambda_1}_{\lambda_1}\rangle. \tag{24}$$

Specifically, if we fix a weight μ which occurs in V_{λ}, then any highest weight vector of weight $\lambda_3=\lambda_1+\mu$ tends to a simple product.

Proof: Note that if $V^{\lambda}\otimes V^{\lambda_1}$ contains a highest weight vector of weight λ_3, then λ_3 differs from λ_1 by a weight μ of V^{λ}. Moreover, $\lambda_3=\lambda_1+\mu\to\infty$ and (λ_3,η) goes to infinity, as $\lambda_1\to\infty$, for any positive root η.

Expand a highest weight vector as

$$|\Psi^{\sigma\lambda_3}_{\lambda_3}\rangle=\sum\epsilon_{\alpha\mu,\beta\nu}|\psi^{\lambda}_{\alpha\mu}\rangle|\psi^{\lambda_1}_{\beta\nu}\rangle. \tag{25}$$

Since $|\Psi^{\sigma\lambda_3}_{\lambda_3}\rangle$ is killed by any raising operator e_i, we find

$$\sum\epsilon_{\alpha\mu,\beta\nu}(e_i|\psi^{\lambda}_{\alpha\mu}\rangle)|\psi^{\lambda_1}_{\beta\nu}\rangle+\sum\epsilon_{\alpha'\mu',\beta'\nu'}|\psi^{\lambda}_{\alpha'\mu'}\rangle(e_i|\psi^{\lambda_1}_{\beta'\nu'}\rangle)=0, \tag{26}$$

or, taking the inner product with a fixed $\langle\psi^{\lambda}_{\alpha'\mu'}|$,

$$\sum\epsilon_{\alpha\mu,\beta\nu}\langle\psi^{\lambda}_{\alpha'\mu'}|e_i|\psi^{\lambda}_{\alpha\mu}\rangle|\psi^{\lambda_1}_{\beta\nu}\rangle+\sum\epsilon_{\alpha'\mu',\beta'\nu'}e_i|\psi^{\lambda_1}_{\beta'\nu'}\rangle=0. \tag{27}$$

If a vector $|\psi^{\lambda_1}_{\beta'\nu'}\rangle$, appearing on the r.h.s. of this equation, is not a highest weight vector, it is possible to find e_i so that $e_i|\psi^{\lambda_1}_{\beta'\nu'}\rangle\neq 0$. Moreover, as we now show, $\|e_i|\psi^{\lambda_1}_{\beta'\nu'}\rangle\|^2=\langle\psi^{\lambda_1}_{\beta'\nu'}|f_ie_i|\psi^{\lambda_1}_{\beta'\nu'}\rangle$ then tends to ∞ as $\lambda_1\to\infty$, when f_i is the Hermitian adjoint of e_i in any unitary representation. Consider the su(2) algebra spanned by e_i,f_i,h_i, with

$$[e_i,f_i]=h_i,\quad [h_i,e_i]=2e_i,\quad [h_i,f_i]=-2f_i. \tag{28}$$

Applied to $|\psi^{\lambda_1}_{\beta'\nu'}\rangle$, it generates a space which is a direct sum of su(2) irreps. The highest weights of these irreps tend to infinity with λ_1. So $\langle\psi^{\lambda_1}_{\beta'\nu'}|f_ie_i|\psi^{\lambda_1}_{\beta'\nu'}\rangle$ is a normalized sum of su(2) matrix elements

$$\langle JM|J_-J_+|JM\rangle=(J-M)(J+M+1), \tag{29}$$

with J tending to ∞ and $M\neq J$. We conclude that $\|e_i|\psi^{\lambda_1}_{\beta'\nu'}\rangle\|^2=\langle\psi^{\lambda_1}_{\beta'\nu'}|f_ie_i|\psi^{\lambda_1}_{\beta'\nu'}\rangle\to\infty$.

If $\langle\varphi(i,\lambda_1\beta'\nu')|$ is the vector dual to $e_i|\psi^{\lambda_1}_{\beta'\nu'}\rangle$, we can write

$$\epsilon_{\alpha'\mu',\beta'\nu'}=-\sum\ \epsilon_{\alpha\mu,\beta\nu}\langle\psi^{\lambda}_{\alpha'\mu'}|e_i|\psi^{\lambda}_{\alpha\mu}\rangle\langle\varphi(i,\lambda_1\beta'\nu')|\psi^{\lambda_1}_{\beta\nu}\rangle, \tag{30}$$

where the sum is over a basis $\alpha\mu$ of V^λ and the corresponding basis vectors $\beta\nu$ of V^{λ_1} with $\mu+\nu=\lambda_3$. If $\|e_i|\psi^{\lambda_1}_{\beta'\nu'}\rangle\|^2\to\infty$, then $|\varphi(i,\lambda_1\beta'\nu')\rangle\to0$. Therefore $\epsilon_{\alpha'\mu',\beta'\nu'}\to0$ as $\lambda_1\to\infty$, for all coefficients for which $e_i|\psi^{\lambda_1}_{\beta'\nu'}\rangle\neq0$. This means that the only terms in the expansion (25) that survive are the leading terms, i.e.,

$$|\Psi^{\sigma\lambda_3}_{\lambda_3}\rangle\to\sum_\alpha\ \epsilon_{\alpha\mu,\lambda_1}|\psi^{\lambda}_{\alpha\mu}\rangle|\psi^{\lambda_1}_{\lambda_1}\rangle. \tag{31}$$

This completes the proof of the claim.

Since $\{|\Psi^{\sigma\lambda_3}_{\lambda_3}\rangle\}$ and $\{|\psi^{\lambda}_{\alpha\mu}\rangle|\psi^{\lambda_1}_{\lambda_1}\rangle\}$ are orthonormal sets, it follows that the matrix O, with coefficients

$$O_{\sigma\alpha}=(\lambda_1\lambda_1,\lambda\alpha\mu|\sigma\lambda_3\lambda_3)^*, \tag{32}$$

tends to a unitary matrix as $\lambda_1\to\infty$. Therefore, it follows from the claim that

$$N^{\lambda\mu}_{\beta\beta'}(\lambda_1)=\sum_\sigma\ O_{\sigma\beta}O^*_{\sigma\beta'}\to\delta_{\beta\beta'}. \tag{33}$$

Theorem I: The tensors $\{W^{\lambda\beta\mu}\}$ are coherent.

Proof: First observe, from the definition, that the state $|\psi^{\lambda_2}_{\alpha_2\nu_2}\cdot\psi^{\lambda_1}_{\alpha_1\nu_1}\rangle$ has coherent state wave function

$$\psi^{\lambda_2}_{\alpha_2\nu_2}\cdot\psi^{\lambda_1}_{\alpha_1\nu_1}=\mathscr{D}^{\lambda_2}_{\lambda_2,\alpha_2\nu_2}\mathscr{D}^{\lambda_1}_{\lambda_1,\alpha_1\nu_1}=\sum_\beta\ (\lambda_1\alpha_1\nu_1,\lambda_2\alpha_2\nu_2|\lambda_1+\lambda_2,\beta,\nu_1+\nu_2)^*\mathscr{D}^{\lambda_1+\lambda_2}_{\lambda_1+\lambda_2,\beta\nu_1+\nu_2} \tag{34}$$

whereas, from Eq. (6), we infer that the dual state $\langle\psi^{\lambda_2}_{\alpha_2\nu_2}\cdot\psi^{\lambda_3}_{\alpha_3\nu_3}|$ has wave function

$$\begin{aligned}&d(\lambda_2+\lambda_3)\sum_\beta\ (\lambda_3\alpha_3\nu_3,\lambda_2\alpha_2\nu_2|\lambda_3+\lambda_2,\beta,\nu_3+\nu_2)\mathscr{D}^{\lambda_3+\lambda_2*}_{\lambda_1+\lambda_2,\beta\nu_1+\nu_2}\\&\quad=d(\lambda_2+\lambda_3)\mathscr{D}^{\lambda_3*}_{\lambda_3,\alpha_3\mu_3}\mathscr{D}^{\lambda_2*}_{\lambda_2,\alpha_2\nu_2}.\end{aligned} \tag{35}$$

It follows that

$$\sum_{\alpha_2\nu_2} \langle \psi^{\lambda_2}_{\alpha_2\nu_2} \cdot \psi^{\lambda_3}_{\alpha_3\nu_3} | W^{\lambda\beta\mu}_{\alpha\nu} | \psi^{\lambda_2}_{\alpha_2\nu_2} \cdot \psi^{\lambda_1}_{\alpha_1\nu_1} \rangle$$

$$= d(\lambda_2+\lambda_3) \sum_{\alpha_2\nu_2} \int \mathscr{D}^{\lambda_3 *}_{\lambda_3,\alpha_3\nu_3}(g) \mathscr{D}^{\lambda_2 *}_{\lambda_2,\alpha_2\nu_2}(g) \mathscr{D}^{\lambda}_{\beta\mu,\alpha\nu}(g) \mathscr{D}^{\lambda_2}_{\lambda_2,\alpha_2\nu_2}(g) \mathscr{D}^{\lambda_1}_{\lambda_1,\alpha_1\nu_1}(g) dv(g)$$

$$= d(\lambda_2+\lambda_3) \int \mathscr{D}^{\lambda_3 *}_{\lambda_3,\alpha_3\nu_3}(g) \mathscr{D}^{\lambda}_{\beta\mu,\alpha\nu}(g) \mathscr{D}^{\lambda_1}_{\lambda_1,\alpha_1\nu_1}(g) dv(g)$$

$$= \frac{d(\lambda_2+\lambda_3)}{d(\lambda_3)} \langle \psi^{\lambda_3}_{\alpha_3\nu_3} | W^{\lambda\beta\mu}_{\alpha\nu} | \psi^{\lambda_1}_{\alpha_1\nu_1} \rangle, \tag{36}$$

where we have used the unitarity relationship

$$\sum_{\alpha_2\nu_2} \mathscr{D}^{\lambda_2 *}_{\lambda_2,\alpha_2\nu_2}(g) \mathscr{D}^{\lambda_2}_{\lambda_2,\alpha_2\nu_2}(g) = 1. \tag{37}$$

Thus, the tensors $\{W^{\lambda\beta\mu}\}$ are coherent according to the definition.

From the way in which the tensors $\{W^{\lambda\beta\mu}\}$ are defined in terms of Wigner functions, it would appear to be manifestly appropriate to call them *Wigner tensors* in parallel with the usage of this terminology by Biedenharn *et al.* and Flath and Towber. They are shift tensors, they are irreducible, and they are coherent. The components of the Wigner tensors are also naturally called *Wigner operators*. Operators of this type were used in the paper of Bernstein *et al.*[7]

The relationship between these tensors and Wigner functions through

$$\mathscr{D}^{\lambda}_{\beta\mu,\alpha\nu} \to W^{\lambda\beta\mu}_{\alpha\nu} = P \mathscr{D}^{\lambda}_{\beta\mu,\alpha\nu} Q \tag{38}$$

gives a precise group theoretical meaning to the $\beta\mu$ labels (operator patterns). Since the $\beta\mu$ labels of the Wigner functions $\{\mathscr{D}^{\lambda}_{\beta\mu,\alpha\nu}\}$ index a basis for the left regular representation of G, it is tempting to suppose that the operators $\{W^{\lambda\beta\mu}_{\alpha\nu}\}$, with λ and $\alpha\nu$ held fixed, might span a module for a corresponding representation. However, as Biedenharn[9] has pointed out in parallel circumstances, such is not the case. The reason is that the maps P and Q are not equivariant relative to a left group action.

Theorem II: The product of two coherent tensors is a tensor which is asymptotically coherent.

Proof: First observe that the space of coherent tensors is uniquely defined by the tensors $\{W^{\lambda\beta\mu}(\lambda_1)\}$ which are an orthonormal set in the $\lambda_1 \to \infty$ asymptotic limit. Consider the product

$$(W^{\lambda_3\beta_3\mu_3}_{\alpha_3\nu_3} W^{\lambda_2\beta_2\mu_2}_{\alpha_2\nu_2} | \psi^{\lambda_1}_{\alpha_1\nu_1} \rangle)(g) = P \mathscr{D}^{\lambda_3}_{\beta_3\mu_3,\alpha_3\nu_3}(g) Q P \mathscr{D}^{\lambda_2}_{\beta_2\mu_2,\alpha_2\nu_2}(g) \mathscr{D}^{\lambda_1}_{\lambda_1,\alpha_1\nu_1}(g). \tag{39}$$

The second pair of Wigner functions on the right of this expression can be combined to give

$$\mathscr{D}^{\lambda_2}_{\beta_2\mu_2,\alpha_2\nu_2}(g) \mathscr{D}^{\lambda_1}_{\lambda_1,\alpha_1\nu_1}(g) = \sum_{\sigma\lambda\beta\alpha} (\lambda_1\lambda_1, \lambda_2\beta_2\mu_2 | \sigma\lambda\beta\mu) \times (\lambda_1\alpha_1\nu_1, \lambda_2\alpha_2\nu_2 | \sigma\lambda\alpha\nu)^* \mathscr{D}^{\lambda}_{\beta\mu,\alpha\nu}(g). \tag{40}$$

The only terms in this expression which survive, in the asymptotic limit, are those with $\lambda = \lambda_1 + \mu_2$. To show this, we first consider the highest weight state

$$|\Psi^{\sigma\lambda}_{\lambda}\rangle = \sum_{\beta_1\mu_1\beta_2\mu_2} (\lambda_1\beta_1\mu_1, \lambda_2\beta_2\mu_2 | \sigma\lambda\lambda)^* | \psi^{\lambda_2}_{\beta_2\mu_2} \rangle | \psi^{\lambda_1}_{\beta_1\mu_1} \rangle \tag{41}$$

in the tensor product space $V^{\lambda_1} \otimes V^{\lambda_2}$. We have already shown that, as $\lambda_1 \to \infty$, this state becomes

$$|\Psi_\lambda^{\sigma\lambda}\rangle \to \sum_{\beta_2} (\lambda_1\lambda_1, \lambda_2\beta_2\mu_2|\sigma\lambda\lambda)^* |\psi_{\beta_2\mu_2}^{\lambda_2}\rangle |\psi_{\lambda_1}^{\lambda_1}\rangle = \sum_{\beta_2} O_{\sigma\beta_2} |\psi_{\beta_2\mu_2}^{\lambda_2}\rangle |\psi_{\lambda_1}^{\lambda_1}\rangle \tag{42}$$

with μ_2 taking the value $\lambda - \lambda_1$. It then follows that

$$\sum_\sigma (\lambda_1\lambda_1, \lambda_2\beta_2\mu_2|\sigma\lambda\lambda)(\lambda_1\lambda_1, \lambda_2\beta_2'\mu_2|\sigma\lambda\lambda)^* = \sum_\sigma O_{\sigma\beta_2}^* O_{\sigma\beta_2'} \to \delta_{\beta_2\beta_2'}. \tag{43}$$

But, we know that

$$\sum_{\sigma\lambda'\beta} |(\lambda_1\lambda_1, \lambda_2\beta_2\mu_2|\sigma\lambda'\beta\lambda)|^2 = 1. \tag{44}$$

We conclude that

$$(\lambda_1\lambda_1, \lambda_2\beta_2\mu_2|\sigma\lambda'\beta\lambda) \to \delta_{\lambda\lambda'}(\lambda_1\lambda_1, \lambda_2\beta_2\mu_2|\sigma\lambda\lambda). \tag{45}$$

Equation (40) becomes

$$\mathscr{D}_{\beta_2\mu_2,\alpha_2\nu_2}^{\lambda_2}(g)\mathscr{D}_{\lambda_1,\alpha_1\nu_1}^{\lambda_1}(g) \to \sum_{\sigma\beta} (\lambda_1\lambda_1, \lambda_2\beta_2\mu_2|\sigma\lambda\lambda) \times (\lambda_1\alpha_1\nu_1, \lambda_2\alpha_2\nu_2|\sigma\lambda\alpha\nu)^* \mathscr{D}_{\lambda,\alpha\nu}^{\lambda}(g) \tag{46}$$

and we have shown that the intermediate projection operator QP in Eq. (39) becomes redundant, i.e.,

$$QP\mathscr{D}_{\beta_2\mu_2,\alpha_2\nu_2}^{\lambda_2}(g)\mathscr{D}_{\lambda_1,\alpha_1\nu_1}^{\lambda_1}(g) \to \mathscr{D}_{\beta_2\mu_2,\alpha_2\nu_2}^{\lambda_2}(g)\mathscr{D}_{\lambda_1,\alpha_1\nu_1}^{\lambda_1}(g). \tag{47}$$

Therefore, Eq. (39) gives

$$(W_{\alpha_3\nu_3}^{\lambda_3\beta_3\mu_3} W_{\alpha_2\nu_2}^{\lambda_2\beta_2\mu_2} |\psi_{\alpha_1\nu_1}^{\lambda_1}\rangle)(g) \to \sum_{\sigma\lambda\beta\mu\alpha\nu} (\lambda_2\beta_2\mu_2, \lambda_3\beta_3\mu_3|\sigma\lambda\beta\mu) \times (\lambda_2\alpha_2\nu_2, \lambda_3\alpha_3\nu_3|\sigma\lambda\alpha\nu)^* (W_{\alpha\nu}^{\lambda\beta\mu}|\psi_{\alpha_1\nu_1}^{\lambda_1}\rangle)(g) \tag{48}$$

as $\lambda_1 \to \infty$. If we denote the coupled product of Wigner tensors by

$$[W^{\lambda_3\beta_3\mu_3} \otimes W^{\lambda_2\beta_2\mu_2}]_{\alpha\nu}^{\sigma\lambda\beta\mu} = \sum_{\alpha_2\nu_2\alpha_3\nu_3} (\lambda_2\alpha_2\nu_2, \lambda_3\alpha_3\nu_3|\sigma\lambda\alpha\nu)^* W_{\alpha_3\nu_3}^{\lambda_3\beta_3\mu_3} W_{\alpha_2\nu_2}^{\lambda_2\beta_2\mu_2}, \tag{49}$$

this equation can be expressed in the succinct form

$$[W^{\lambda_3\beta_3\mu_3} \otimes W^{\lambda_2\beta_2\mu_2}]_{\alpha\nu}^{\sigma\lambda\beta\mu}(\lambda_1) \to (\lambda_2\beta_2\mu_2, \lambda_3\beta_3\mu_3|\sigma\lambda\beta\mu) W_{\alpha\nu}^{\lambda\beta\mu}(\lambda_1). \tag{50}$$

This completes the proof.

A corollary of Theorem II is that coherent tensors commute in the $\lambda_1 \to \infty$ asymptotic limit as Flath and Towber have conjectured. In particular, the Wigner tensors satisfy the equation

$$[W_{\alpha_3\nu_3}^{\lambda_3\beta_3\mu_3}, W_{\alpha_2\nu_2}^{\lambda_2\beta_2\mu_2}]|\psi_{\alpha_1\nu_1}^{\lambda_1}\rangle \to 0. \tag{51}$$

This follows, once the projection operator in Eq. (39) has been shown to be redundant, because Wigner functions commute.

It is interesting to note that, in specializing to SU(2), Biedenharn[9] defined a shift tensor $T^{j\mu}$ with components

$$T^{j\mu}_m = \sum |\psi^{\,j_3}_{m_3}\rangle (j_1 m_1, jm | j_3 m_3) \langle \psi^{\,j_1}_{m_1}|, \tag{52}$$

where the sum is over all j_1, m_1, j_3, and m_3 with $j_3 = j_1 + \mu$ and $m_3 = m_1 + m$. Biedenharn's tensors act on model states according to the equation

$$[T^{j\mu} \otimes |\psi^{\,j_1}\rangle]^{j_3}_{m_3} = |\psi^{\,j_3}_{m_3}\rangle \tag{53}$$

where $j_3 = j_1 + \mu$ and $m_3 = m_1 + m$. As Biedenharn observed, these tensors can be coupled according to the equation

$$[T^{j_3\mu_3} \otimes T^{j_2\mu_2}]^J_M(j_1) = \sqrt{(2J+1)(2J'+1)}\, W(j_1 j_2 j_4 j_3 : J' J) T^{J\mu}_M(j_1), \tag{54}$$

where $J' = j_1 + \mu_2$, $\mu = \mu_2 + \mu_3$, $j_4 = j_1 + \mu_2 + \mu_3$, and $W(j_1 j_2 j_4 j_3 : J' J)$ is a Racah coefficient. The $\{T^{j\mu}\}$ tensors are not coherent. However, by comparison of Eqs. (18) and (53) and noting that $(j_1 j_1, j\mu | j_3 j_3) \to 1$ as $j_1 \to \infty$, we see that Biedenharn's tensors become equal to coherent Wigner tensors in the limit; i.e.,

$$T^{j\mu}(j_1) \to W^{j\mu}(j_1), \quad \text{as} \quad j_1 \to \infty. \tag{55}$$

Thus Eq. (54) can be compared with Eq. (50) which, for SU(2), gives

$$[W^{j_3\mu_3} \otimes W^{j_2\mu_2}]^J_M(j_1) = (j_2\mu_2, j_3\mu_3 | J\mu) W^{J\mu}_M(j_1) \tag{56}$$

with $\mu = \mu_2 + \mu_3$. From the equivalence of these two expressions, it follows that

$$\sqrt{(2J+1)(2J'+1)}\, W(j_1 j_2 j_4 j_3 : J' J) \to (j_2\mu_2, j_3\mu_3 | J\mu) \tag{57}$$

as $j_1 \to \infty$, with $\mu_2 = J' - j_1$, $\mu_3 = j_4 - J'$, and $\mu = \mu_2 + \mu_3$.

IV. SUMMARY OF RESULTS

We summarize by listing some of the properties of the above-defined Wigner tensors, which generalize results of Biedenharn and Louck[1] for the unitary groups and confirm conjectures expressed by Flath and Towber[3] and proved by them in special cases.

(i) A tensor of highest weight λ is a complex vector space isomorphic to V^λ. The linear space $\mathscr{T}^{\lambda\mu}(\lambda_1)$ of all $V^{\lambda_1} \to V^{\lambda_1+\mu}$ tensors of highest weight λ (and shift μ) has dimension equal to the multiplicity, $m(\lambda_1, \lambda, \lambda_1 + \mu)$, of irreps equivalent to $R^{\lambda_1+\mu}$ in the Kronecker product $R^\lambda \otimes R^{\lambda_1}$.

(ii) The set $\mathscr{W}^{\lambda\mu}$ of all coherent tensors of highest weight λ and shift μ is a complex vector space of dimension equal to the multiplicity, $m(\mu;\lambda)$, of the weight μ in the irrep R^λ. Moreover,

$$m(\mu;\lambda) \geqslant m(\lambda_1, \lambda, \lambda_1 + \mu), \tag{58}$$

and the equality holds for sufficiently large λ_1.

(iii) For every $\lambda_1 \in \Lambda$, the map

$$\mathscr{W}^{\lambda\mu} \to \mathscr{T}^{\lambda\mu}(\lambda_1) \tag{59}$$

obtained by restricting the tensors in $\mathscr{W}^{\lambda\mu}$ from V to V^{λ_1} is subjective. Moreover, the coherent tensors $\{W^{\lambda\beta\mu}(\lambda_1)\}$ become an orthonormal set in the $\lambda_1\to\infty$ limit.

(iv) Let $\mathscr{W}$ be the linear space of all finite linear combinations of coherent linear operators on V. Equation (14) shows that the elements of $\mathscr{W}$ are associated to components of tensors on $\mathscr{L}^2(G)$ given by multiplication by Wigner functions. The Wigner functions have a dual role: (i) as components of tensors on $\mathscr{L}^2(G)$, and (ii) as elements of $\mathscr{L}^2(G)$. Thus, we obtain a map $\pi:\mathscr{W}\to\mathscr{L}^2(G)$, defined by

$$\pi(W^{\lambda\beta\mu}_{\alpha\nu})=\mathscr{D}^{\lambda}_{\beta\mu,\alpha\nu}\ . \tag{60}$$

With $\mathscr{L}^2(G)$ regarded as a module for the right regular representation, this map π is a group isomorphism from $\mathscr{W}$ onto a dense subspace of $\mathscr{L}^2(G)$. The correspondence between Wigner operators and Wigner functions, expressed by this relationship, gives a precise group theoretical meaning to the $\beta\mu$ labels (operator patterns).

(v) Let λ denote the lowest weight in the irrep R^{λ}. Then, every product of coherent tensors of the form

$$\left(\prod_i W^{\lambda_i\overline{\lambda_i}}\right)\circ\left(\prod_j W^{\lambda_j\lambda_j}\right) \tag{61}$$

is a coherent tensor. The tensors $W^{\lambda\lambda}$ (maximal-positive shift tensors) send vectors in V^{λ_1} to vectors in $V^{\lambda_1+\lambda}$. The tensors $W^{\lambda\overline{\lambda}}$ (maximal-negative shift tensors) send vectors in V^{λ_1} to vectors in $V^{\lambda_1+\overline{\lambda}}$ if $\lambda_1+\overline{\lambda}\in\Lambda$ and are zero otherwise.

(vi) The commutator of two Wigner tensors is not, in general, coherent. Because of the completeness of the Wigner tensors, a commutator can be expanded

$$[W^{\lambda_3\beta_3\mu_3}_{\alpha_3\nu_3},\ W^{\lambda_2\beta_2\mu_2}_{\alpha_2\nu_2}]=\sum\ S\left(\lambda_2{}^{\beta_2\mu_2}_{\alpha_2\nu_2},\lambda_3{}^{\beta_3\mu_3}_{\alpha_3\nu_3}\middle|\lambda_4{}^{\beta_4\mu_4}_{\alpha_4\nu_4}\right)W^{\lambda_4\beta_4\mu_4}_{\alpha_4\nu_4}, \tag{62}$$

where each $S(\lambda_2{}^{\beta_2\mu_2}_{\alpha_2\nu_2},\lambda_3{}^{\beta_3\mu_3}_{\alpha_3\nu_3}|\lambda_4{}^{\beta_4\mu_4}_{\alpha_4\nu_4})$ is a scalar, i.e., a tensor of rank $\lambda=0$. If we write $S(\lambda_2{}^{\beta_2\mu_2}_{\alpha_2\nu_2},\lambda_3{}^{\beta_3\mu_3}_{\alpha_3\nu_3}|\lambda_4{}^{\beta_4\mu_4}_{\alpha_4\nu_4})(\lambda_1)$ for the value of this scalar on the space V^{λ_1}, then as $\lambda_1\to\infty$,

$$S\left(\lambda_2{}^{\beta_2\mu_2}_{\alpha_2\nu_2},\lambda_3{}^{\beta_3\mu_3}_{\alpha_3\nu_3}\middle|\lambda_4{}^{\beta_4\mu_4}_{\alpha_4\nu_4}\right)(\lambda_1)\to 0. \tag{63}$$

Properties (i)–(iv) have been proved either above or in Ref. 8. Property (v) follows from the observation that

$$\left(\prod_i P\mathscr{D}^{\lambda_i}_{\lambda_i,\alpha_i\nu_i}Q\right)\circ\left(\prod_j P\mathscr{D}^{\lambda_j}_{\lambda_j,\alpha_j\nu_j}Q\right)=P\left(\prod_i \mathscr{D}^{\lambda_i}_{\overline{\lambda_i},\alpha_i\nu_i}\right)\circ\left(\prod_j \mathscr{D}^{\lambda_j}_{\lambda_j,\alpha_j\nu_j}\right)Q. \tag{64}$$

Property (vi) follows from the corollary to Theorem II and the asymptotic orthonormality of Wigner tensors, expressed by Eqs. (19) and (33).

ACKNOWLEDGMENTS

The authors are pleased to acknowledge helpful discussions with H. de Guise. They also thank D. E. Flath for bringing the paper of Bernstein, Gel'fand, and Gel'fand[7] to their attention and J. Towber for constructive suggestions.

APPENDIX: THEOREM (ROWE AND REPKA, REF. 8)

The rank of the Hermitian matrix $N^{\lambda\mu}(\lambda_1)$ with entries

$$N^{\lambda\mu}_{\beta\beta'}(\lambda_1)=\sum_{\sigma}(\lambda_1\lambda_1,\lambda\beta\mu|\sigma\lambda_3\lambda_3)^*(\lambda_1\lambda_1,\lambda\beta'\mu|\sigma\lambda_3\lambda_3) \tag{A1}$$

is equal to the multiplicity of R^{λ_3} in $R^{\lambda}\otimes R^{\lambda_1}$.

Proof: The proof is given in a sequence of steps.

(i) If $\psi^{\lambda_1}_{\lambda_1}$ is a highest weight vector in the module V^{λ_1} for the irrep R^{λ_1}, then the action of the group on the subset of vectors

$$S=\{\varphi\otimes\psi^{\lambda_1}_{\lambda_1};\varphi\in V^{\lambda}\} \tag{A2}$$

generates the whole of $V^{\lambda}\otimes V^{\lambda_1}$.

(ii) Some vector in every invariant subspace $\mathscr{V}^{\alpha\lambda_3}\subset V^{\lambda}\otimes V^{\lambda_1}$ has a nonzero overlap with some vector in S. For, if this were not so, the action of the group on S must generate a space which excludes $\mathscr{V}^{\alpha\lambda_3}$ and this contradicts (i).

(iii) A highest weight vector $\Psi^{\alpha\lambda_3}_{\lambda_3}$ for the invariant subspace $\mathscr{V}^{\alpha\lambda_3}\subset V^{\lambda}\otimes V^{\lambda_1}$ has nonzero overlap with some vector in S. This is proved by showing that, if it were not so, then no vector in $\mathscr{V}^{\alpha\lambda_3}$ could have a nonzero overlap with any vector in S, which contradicts (ii). Let $\varphi\otimes\psi^{\lambda_1}_{\lambda_1}$, be a vector in S which has a nonzero overlap with some vector in $\mathscr{V}^{\alpha\lambda_3}$ and expand

$$\varphi\otimes\psi^{\lambda_1}_{\lambda_1}=C^{\alpha\lambda_3}\Psi^{\alpha\lambda_3}+\sum_{\beta\lambda_3'\neq\alpha\lambda_3}C^{\beta\lambda_3'}\Psi^{\beta\lambda_3'}, \tag{A3}$$

where $\Psi^{\beta\lambda_3'}\in\mathscr{V}^{\beta\lambda_3'}$. Let Z be a product of raising operators in $\mathfrak{g}$, the Lie algebra of G, which raises the particular vector $\Psi^{\alpha\lambda_3}$ to a highest weight vector; i.e., Z is defined such that

$$Z\Psi^{\alpha\lambda_3}=\Psi^{\alpha\lambda_3}_{\lambda_3}. \tag{A4}$$

Applying Z to both sides of Eq. (A3) gives

$$(Z\varphi)\otimes\psi^{\lambda_1}_{\lambda_1}=C^{\alpha\lambda_3}\Psi^{\alpha\lambda_3}_{\lambda_3}+\sum_{\beta\lambda_3'\neq\alpha\lambda_3}C^{\beta\lambda_3'}Z\Psi^{\beta\lambda_3'}, \tag{A5}$$

and shows that $\Psi^{\alpha\lambda_3}_{\lambda_3}$ has nonzero overlap with the nonzero vector $(Z\varphi)\otimes\psi^{\lambda_1}_{\lambda_1}\in S$.

(iv) Let $\varphi_{\alpha_1\nu_1}(\alpha\lambda_3)\in V^{\lambda}$ denote the cofactor of $\psi^{\lambda_1}_{\alpha_1\nu_1}$ in the expansion of a highest weight vector $\Psi^{\alpha\lambda_3}_{\lambda_3}$, i.e.,

$$\Psi^{\alpha\lambda_3}_{\lambda_3}=\varphi_{\lambda_1}(\alpha\lambda_3)\psi^{\lambda_1}_{\lambda_1}+\sum_{\alpha_1,\nu_1\neq\lambda_1}\varphi_{\alpha_1\nu_1}(\alpha\lambda_3)\psi^{\lambda_1}_{\alpha_1\nu_1}. \tag{A6}$$

We now claim that, if $\{\Psi^{\alpha\lambda_3}_{\lambda_3};\alpha=1,\ldots,N\}$ is a maximal set of linearly independent highest weight vectors of highest weight λ_3 in $V^{\lambda}\otimes V^{\lambda_1}$, then the corresponding vectors $\{\varphi_{\lambda_1}(\alpha\lambda_3)\}$ in V^{λ} are also linearly independent. For, if they were not, it would be possible to construct a nonzero highest weight vector $\Sigma_{\alpha}a_{\alpha}\Psi^{\alpha\lambda_3}_{\lambda_3}$ for which $\Sigma_{\alpha}a_{\alpha}\varphi_{\lambda_1}(\alpha\lambda_3)=0$ and this would contradict (iii).

(v) Let $\varphi_{\lambda_1}(\alpha\lambda_3)$ be expanded on the orthonormal basis $\{\psi^{\lambda}_{\beta\mu}\}$ for V^{λ};

$$\varphi_{\lambda_1}(\alpha\lambda_3)=\sum_{\beta\mu} C_{\beta\mu}(\alpha\lambda_3)\psi^{\lambda}_{\beta\mu}\ . \tag{A7}$$

Since the vectors $\{\varphi_{\lambda_1}(\alpha\lambda_3);\alpha = 1,\ldots,N\}$ are a linearly independent set, it follows that the N columns $\{C(\alpha\lambda_3)\}$ of the rectangular matrix $C(\lambda_3)$ are linearly independent and, hence, that the rank of the matrix M^{λ} with entries

$$M^{\lambda}_{\beta\mu,\beta'\mu'}=\sum_{\alpha} C_{\beta\mu}(\alpha\lambda_3)^* C_{\beta'\mu'}(\alpha\lambda_3) \tag{A8}$$

is equal to the number N of values the multiplicity index α can take; i.e., the multiplicity of the $\lambda\otimes\lambda_1\rightarrow\lambda_3$ coupling.

(vi) Finally, if the vectors $\{\Psi^{\alpha\lambda_3}_{\lambda_3}\}$ are an orthonormal set, the coefficients $C_{\beta\mu}(\alpha\lambda_3)$ are the Clebsch–Gordan coefficients

$$C_{\beta\mu}(\alpha\lambda_3)=(\lambda_1\lambda_1,\lambda\beta\mu|\alpha\lambda_3\lambda_3). \tag{A9}$$

Moreover, the weight μ takes the unique value $\mu=\lambda_3-\lambda_1$. It follows that the matrix $N^{\lambda\mu}(\lambda_1)$ of the theorem is given by

$$N^{\lambda\mu}_{\beta\beta'}(\lambda_1)=M^{\lambda}_{\beta\mu,\beta'\mu}\,\delta_{\mu,\lambda_3-\lambda_1} \tag{A10}$$

and that it has the same rank as M^{λ}. This complete the proof of the theorem.

Eichler integrals and string theory

Leonidas Sandoval, Jr.[a)]
Department of Mathematics, King's College London, Strand, WC2R 2LS, London, United Kingdom

(Received 30 August 1995; accepted for publication 13 October 1995)

In this article, it is shown how to obtain objects called *Eichler integrals* in the mathematical literature that can be used for calculating scattering amplitudes in string theory. These Eichler integrals are also new examples of Eichler integrals with poles. © *1996 American Institute of Physics.* [S0022-2488(96)00804-2]

I. INTRODUCTION

The concept of an Eichler integral is closely related to the concept of automorphic forms. Although automorphic forms have a large range of applications in physics and, in particular, in string theory, Eichler integrals remain relatively unknown objects to both mathematicians and physicists. One can picture Eichler integrals as a generalization of the concept of automorphic forms, and they are related to the better known *Beltrami differentials* that are used in string theory, in particular, in the calculation of multiloop scattering amplitudes of strings.

This article begins with a description of the main properties of automorphic forms with some examples that will be useful when we describe the new Eichler integrals. The definition of Eichler integrals is given next, with some examples that can be used in string theory.

II. AUTOMORPHIC FORMS

An automorphic form of weight q is a function[1] $\phi(z)$ that transforms in the following way under a projective transformation P_a:

$$\phi(P_a(z))=\left[\frac{\partial P_a(z)}{\partial z}\right]^q \phi(z).$$

Automorphic forms with just one pole will be more of our interest, since the order of the pole is limited in a simple way by the Riemann–Roch theorem.[2] We now give some examples of these functions.

A. Example 1

A simple example of an automorphic form of weight q can be given for the case where there is just one projective transformation $P(z)$, given by

$$P(z)=w(z-\alpha)+\alpha,$$

where α is the finite fixed point of the transformation (the other fixed point is at infinity) and w is the multiplier. An automorphic form $\phi(z)$ of weight q can then be given by

$$\phi(z)=(z-\alpha)^q.$$

In the case where $P(z)$ has two finite fixed points, when it can be expressed by

[a)]Electronic mail: udah257@bay.cc.kcl.ac.uk

0022-2488/96/37(5)/2510/17/$10.00

$$P(z)=\frac{\alpha(z-\beta)-w\beta(z-\alpha)}{(z-\beta)-w(z-\alpha)},$$

an automorphic form of weight q is given by

$$\phi(z)=[(z-\alpha)(z-\beta)]^q.$$

B. Example 2

In the case of a single projective transformation $P(z)$ with just one finite fixed point, we may have automorphic forms with poles, given by

$$\phi_n(z)=(z-\alpha)^q\left(\frac{\partial}{\partial t}\right)^{n-1}\wp(t),\quad t=\ln(z-\alpha)-\ln(-\alpha),$$

where n is the order of the pole and $\wp(t)$ is the Weierstrass $\wp$ function[3] with periods $\ln w$ and $2\pi i$. These functions have poles of orders $\leqslant n$ at $z=0$.

In the case of $P(z)$ having two finite fixed points, we have

$$\phi_n(z)=[(z-\alpha)(z-\beta)]^q\left(\frac{\partial}{\partial t}\right)^{n-1}\wp(t),\quad t=\ln\left(\frac{z-\alpha}{z-\beta}\right)-\ln\left(\frac{\alpha}{\beta}\right)$$

instead.

C. Example 3

Still another way of obtaining an automorphic form on a genus g Riemann surface is considering the following function[1] (called a Poincaré series):

$$\phi(z,\zeta)=\sum_a\left[\frac{dT_a(z)}{dz}\right]^{-q}\frac{\zeta-k}{T_a(z)-\zeta},$$

where k is an arbitrary constant and the sum Σ_a is over all the elements $T_a(z)$ of the Schottky group, which is the group of all possible combinations of the projective transformations $P_b(z)$, $b=1,\ldots,g$.

Under a transformation $z\to T_b(z)$, one gets

$$\phi(T_b(z),\zeta)=\sum_a\left[\frac{dT_a\ T_b(z)}{dz}\right]^{-q}\frac{\zeta-k}{T_aT_b(z)-\zeta}.$$

We now perform a change of variables $T_aT_b(z)=T_c(z)$. Using the chain rule we have

$$\frac{d}{dz}\,T_c(z)=\left[\frac{d}{dz}\,T_aT_b(z)\right]\times\frac{d}{dz}\,T_b(z),$$

so that we have

$$\phi(T_b(z),\zeta)=[T_b'(z)]^q\sum_a\left[\frac{dT_c(z)}{dz}\right]^{-q}\frac{\zeta-k}{T_c(z)-\zeta}.$$

Since we are summing over all the elements of the Schottky group, the series above is equivalent to the original one, so that we have

$$\phi(T_b(z),\zeta)=[T_b'(z)]^q\phi(z,\zeta),$$

i.e. it is an automorphic form of weight q.

D. Example 4

In the multiloop case, let us consider only projective transformations P_a with finite fixed points α_a and β_a. We then consider the following series:

$$P_w(z)=\sum_b \frac{(z-\alpha_b)(z-\beta_b)}{w_b(\alpha_b-\beta_b)}\frac{\delta w_b}{\epsilon}, \tag{1}$$

where the sum is over all the elements of the Schottky group formed by these transformations and δw_b and ϵ are infinitesimals. We then have that

$$\begin{aligned}P_w(T_a(z))&=\sum_b [T_a(z)-\alpha_b][T_a(z)-\beta_b]\\&=\frac{T_a'(z)}{w_a(\alpha_a-\beta_a)^2}\times\sum_b \frac{1}{w_b(\alpha_b-\beta_b)}(\alpha_a-w_a\beta_a-\alpha_b+w_a\alpha_b)\\&\quad\times(\alpha_a-w_a\beta_a-\beta_b+w_a\beta_b)\left[z-\frac{(\alpha_a\beta_a-w_a\alpha_a\beta_a-\alpha_b\beta_a+w_a\alpha_b\alpha_a)}{(\alpha_a-w_a\beta_a-\alpha_b+w_a\alpha_b)}\right]\\&\quad\times\left[z-\frac{(\alpha_a\beta_a-w_a\alpha_a\beta_a-\beta_b\beta_a+w_a\beta_b\alpha_a)}{(\alpha_a-w_a\beta_a-\beta_b+w_a\beta_b)}\right]\frac{\delta w_b}{\epsilon}.\end{aligned}$$

Making then the following change of variables:

$$\alpha_c=\frac{(1-w_a)\alpha_a\beta_a-(\beta_a-w_a\alpha_a)\alpha_b}{\alpha_a-w_a\beta_a-(1-w_a)\alpha_b}, \tag{2}$$

$$\beta_c=\frac{(1-w_a)\alpha_a\beta_a-(\beta_a-w_a\alpha_a)\beta_b}{\alpha_a-w_a\beta_a-(1-w_a)\beta_b}, \tag{3}$$

$$w_c=w_b, \tag{4}$$

we may write

$$P_w(T_a(z))=T_a'(z)\sum_c \frac{(z-\alpha_c)(z-\beta_c)}{w_c(\alpha_c-\beta_c)}\frac{\delta w_c}{\epsilon},$$

where we have used

$$\delta w_c=\frac{\partial w_c}{\partial w_b}\delta w_b.$$

Since we are summing over all elements of the Schottky group (with the condition that the fixed points are finite), we then see that the expression on the right-hand side is equivalent to the series we started with, so that

$$P_w(T_a(z))=T_a'(z)P_w(z).$$

We may also consider the following two series:

$$P_\alpha(z)=\sum_b \frac{(1-w_b)}{w_b(\alpha_b-\beta_b)^2}(z-\beta_b)^2\frac{\delta\alpha_b}{\epsilon}, \tag{5}$$

$$P_\beta(z)=-\sum_b \frac{(1-w_b)}{(\alpha_b-\beta_b)^2}(z-\alpha_b)^2\frac{\delta\beta_b}{\epsilon}. \tag{6}$$

Using the same change of variables (2)–(4) and the fact that

$$\delta\alpha_c=\frac{\partial\alpha_c}{\partial\alpha_b}\,\delta\alpha_b=\frac{w_a(\alpha_a-\beta_a)^2}{[\alpha_a-w_a\beta_a-(1-w_a)\alpha_b]^2}\,\delta\alpha_b,$$

$$\delta\beta_c=\frac{\partial\beta_c}{\partial\beta_b}\,\delta\beta_b=\frac{w_a(\alpha_a-\beta_a)^2}{[\alpha_a-w_a\beta_a-(1-w_a)\beta_b]^2}\,\delta\beta_b,$$

we then obtain

$$P_\alpha(T_a(z))=T_a'(z)P_\alpha(z),$$

$$P_\beta(T_a(z))=T_a'(z)P_\beta(z).$$

We have then obtained three examples of automorphic forms with weight 1.

III. EICHLER INTEGRALS

An Eichler integral of order q is defined in the following way:[4,5] it is a function $f(z)$ that transforms like

$$f(T_a(z))=\left[\frac{\partial T_a(z)}{\partial z}\right]^q[f(z)+P^{q+1}(z)],$$

where $P^{q+1}(z)$ is a polynomial at most of order $q+1$. It can be pictured as a generalization of the concept of automorphic form. Eichler integrals are related with automorphic forms in the following way:[4] given an Eichler integral of order q, we then have

$$\phi(z)=\left(\frac{\partial}{\partial z}\right)^{2q+1}f(z), \tag{7}$$

where $\phi(z)$ is an automorphic form of weight $q+1$, i.e.

$$\phi(T_a(z))=\left[\frac{\partial T_a(z)}{\partial z}\right]^{q+1}\phi(z).$$

Here are some examples of Eichler integrals.

A. Example 1

A trivial example of an Eichler integral is given by any polynomial of order 2, i.e. any function of the form

$$f(z)=a+bz+cz^2,$$

where a, b, and c are constants. Such a function transforms like

$$f(T_a(z))=T_a'(z)\left[f(z)+\frac{1}{w(\alpha-\beta)^2}\,(d+ez+fz^2)\right],$$

where

$$d=(1-w)^2a+(1-w)(\alpha-w\beta)b-[w\beta^2(1-w)-2w(\alpha\beta-1)+w\alpha^2]c,$$

$$e=2(w\alpha-\beta)(1-w)a-2\alpha\beta(1-w)^2b+[2w\beta(\alpha+\beta)-2\alpha\beta(w\beta+\alpha)]c,$$

$$f=(\beta^2-w\alpha^2)(1-w)a+\alpha\beta(1-w)(\beta-w\alpha)b-w\alpha\beta^2(2-w\alpha)c.$$

Differentiating it three times, we obtain

$$\frac{d^3}{dz^3}\,f(z)=0,$$

which is a sort of automorphic form (a trivial one) so Eq. (7) holds.

B. Example 2

There are not many examples of Eichler integrals with poles in the literature. The first one was given by Ahlfors.[4] In our notation, his Eichler integral is given by

$$f(z,\zeta)=\sum_b\,[z-T_b(\zeta)]^{-1}[T_b'(\zeta)]^q,$$

where the sum is over all elements of the Schottky group.

This function transforms in the following way:

$$f(T_a(z),\zeta)=[T_a'(z)]^{q-1}\left\{f(z,\zeta)+\sum_b\,\left[\frac{T_a'T_b(\zeta)}{(T_a'(z))^{q-1/2}}-1\right]\times[z-T_b(\zeta)]^{-1}[T_b'(\zeta)]^q\right\}.$$

The second term on the right-hand side can be shown to be a polynomial of degree q. This Eichler integral has just one simple pole at $\zeta=z$.

In order to obtain Eichler integrals with poles of higher orders, one just has to form derivatives with respect to ζ:

$$f_{k+1}(z,\zeta)=\frac{\partial^k}{\partial\zeta^k}\,f(z,\zeta),$$

where $f_{k+1}(z,\zeta)$ is an Eichler integral with a pole of order $k+1$ at $\zeta=z$.

C. Example 3

As it will be shown now, not all Eichler integrals must transform in such a complicated way. It is not hard to find examples of Eichler integrals with simple and useful transformations.

As explained before, an Eichler integral can be obtained by simply integrating an automorphic form a certain number of times. It is possible to show that every automorphic form of weight q can be expressed in terms of the following Poincaré series:

$$g(z,\zeta)=\sum_b\,[T_b'(z)]^{-q}\,\frac{\zeta-k}{T_b(z)-\zeta},\tag{8}$$

where k is an arbitrary constant.

If we now take the case $q=-1$, we have simply

$$g(z,\zeta)=\sum_b\ [T_b'(z)]^{-1}\ \frac{\zeta-k}{T_b(z)-\zeta}=\sum_b\ (\zeta-k)\left[\frac{1}{z+(b_b-d_b\zeta)/(a_b-c_b\zeta)}-\frac{1}{z+d_b/c_b}\right],$$

and, by (7), we may obtain an Eichler integral of weight zero simply by integrating this expression once. Doing this we obtain the following:

$$f(z,\zeta)=\sum_b\ (\zeta-k)\ln\left(\frac{c_b}{(a_b-c_b\zeta)}\ \frac{[(a_b-c_b\zeta)z+(b_b-d_b\zeta)]}{(c_bz+d_b)}\right)+c',$$

where c' is a constant of integration that can be set to zero.

We may then make the following change of coefficients:

$$\begin{aligned} a_m&=a_b-c_b\zeta, \quad c_m=c_b,\\ b_m&=b_b-d_b\zeta, \quad d_m=d_b, \end{aligned} \tag{9}$$

and the function $f(z,\zeta)$ becomes simply

$$f(z,\zeta)=\sum_m\ (\zeta-k)\ln\left(\frac{c_m}{a_m}\ \frac{(a_mz+b_m)}{(c_mz+d_m)}\right).$$

Performing the conformal transformation,

$$T_a(z)=\frac{a_az+b_a}{c_az+d_a},$$

with $c_a\neq 0$ in the expression above, we obtain

$$f(T_a(z),\zeta)=\sum_m\ (\zeta-k)\ln\left(\frac{c_m}{a_m}\ \frac{[a_m(a_az+b_a)+b_m(c_az+d_a)]}{[c_m(a_az+b_a)+d_m(c_az+d_a)]}\right). \tag{10}$$

If we now make another change of variables,

$$\begin{aligned} a_b&=a_ma_a+b_mc_a, \quad c_b=c_ma_a+d_mc_a,\\ b_b&=a_mb_a+b_md_a, \quad d_b=c_mb_a+d_md_a, \end{aligned} \tag{11}$$

we then have

$$\begin{aligned} f(T_a(z),\zeta)&=\sum_b\ (\zeta-k)\ln\left(\frac{(c_bd_a-c_ad_b)}{(a_bd_a-c_ab_b)}\ \frac{(a_bz+b_b)}{(c_bz+d_b)}\right)\\ &=\sum_b\ (\zeta-k)\left[\ln\left(\frac{c_b}{a_b}\ \frac{(a_bz+b_b)}{(c_bz+d_b)}\right)+\ln\left(\frac{a_b(c_bd_a-c_ad_b)}{c_b(a_bd_a-c_ab_b)}\right)\right]. \end{aligned} \tag{12}$$

Since we are summing over all transformations $T_b(z)$ with $c_b\neq 0$, the first term of expression (12) is just $f(z,\zeta)$, and we then have

$$f(T_a(z),\zeta)=f(z,\zeta)+\sum_b\ (\zeta-k)\ln\left(\frac{a_b(c_bd_a-c_ad_b)}{c_b(a_bd_a-c_ab_b)}\right). \tag{13}$$

The second term of expression (13) can be readily identified as a constant, i.e. a polynomial in z of degree 0, so that it is proved that the function $f(z,\zeta)$ is an Eichler integral with weight 0.

We now consider automorphic form (8) with weight -2:

$$g(z,\zeta)=\sum_b\ [T_b'(z)]^2\ \frac{\zeta-k}{T_b(z)-\zeta},$$

where k is a constant and the sum is over all elements of the Schottky group. According to the theory of Eichler integrals, if we integrate an automorphic form of weight -2 three times, we shall obtain an Eichler integral of weight 1. If we take $T_b(z)$ to be of the form

$$T_b(z)=\frac{a_bz+b_b}{c_bz+d_b},$$

we may then write this function in the following form:

$$g(z,\zeta)=\sum_b\ \frac{\zeta-k}{(a_b-c_b\zeta)}\frac{1}{(c_bz+d_b)^3[z+(b_b-d_b\zeta)/(a_b-c_b\zeta)]}.$$

This can be easily integrated. Considering the case where $c_b\neq 0$ and performing integration three times on this automorphic form, we obtain the following function:

$$\begin{aligned}f(z,\zeta)=\sum_b\ &\frac{1}{2}(\zeta-k)[(a_b-c_b\zeta)z+(b_b-d_b\zeta)]^2\\&\times\ln\left(\frac{c_b}{(a_b-c_b\zeta)}\frac{[(a_b-c_b\zeta)z+(b_b-d_b\zeta)]}{(c_b+d_b)}\right)\\&+\frac{1}{2c_b(a_b-c_b\zeta)}z-\frac{2(a_b-c_b\zeta)d_b+1}{4c_b^2(a_b-c_b\zeta)^2}+c_1z^2+c_2z+c_3,\end{aligned}\tag{14}$$

where c_1, c_2, and c_3 are constants resulting from the integrations. Choosing these integration constants in such a way as to cancel with the polynomial part of expression (14), we then obtain

$$\begin{aligned}f(z,\zeta)=\sum_b\ &\frac{1}{2}(\zeta-k)[(a_b-c_b\zeta)z+(b_b-d_b\zeta)]^2\\&\times\ln\left(\frac{c_b}{(a_b-c_b\zeta)}\frac{[(a_b-c_b\zeta)z+(b_b-d_b\zeta)]}{(c_b+d_b)}\right).\end{aligned}\tag{15}$$

We can now make the change of coefficients (9) and the function $f(z,\zeta)$ becomes

$$f(z,\zeta)=\sum_m\ \frac{1}{2}(\zeta-k)(a_mz+b_m)^2\ \ln\left(\frac{c_m}{a_m}\frac{(a_mz+b_m)}{(c_mz+d_m)}\right).\tag{16}$$

This expression should be an Eichler integral and we are going to show it indeed is. If we perform the conformal transformation

$$T_a(z)=\frac{a_az+b_a}{c_az+d_a},\tag{17}$$

with $c_a\neq 0$ in the expression above, we obtain

$$f(T_a(z),\zeta)=\sum_m \frac{1}{2}(\zeta-k)\left[\frac{a_m(a_az+b_a)+b_m(c_az+d_a)}{c_az+d_a}\right]^2 \times\ln\left(\frac{c_m}{a_m}\frac{[a_m(a_az+b_a)+b_b(c_az+d_a)]}{[c_m(a_az+b_a)+d_m(c_az+d_a)]}\right). \tag{18}$$

If we now make another change of variables, given by (11), we then have

$$f(T_a(z),\zeta)=T_a'(z)\sum_b \frac{1}{2}(\zeta-k)(a_bz+b_b)^2\ln\left(\frac{(d_ba_a-c_bb_a)}{(b_ba_a-a_bb_a)}\frac{(a_bz+b_b)}{(c_bz+d_b)}\right)$$
$$=T_a'(z)\sum_b \frac{1}{2}(\zeta-k)(a_bz+b_b)^2\left[\ln\left(\frac{c_b}{a_b}\frac{(a_bz+b_b)}{(c_bz+d_b)}\right)+\ln\left(\frac{a_b(d_ba_a-c_bb_a)}{c_b(b_ba_a-a_bb_a)}\right)\right]. \tag{19}$$

Since we are summing over all transformations $T_b(z)$ with $c_b\neq 0$, the first term of expression (19) is just $f(z,\zeta)$, and we then have

$$f(T_a(z),\zeta)=T_a'(z)\left[f(z,\zeta)+\sum_b \frac{1}{2}(\zeta-k)(a_bz+b_b)^2\ln\left(\frac{a_b(d_ba_a-c_bb_a)}{c_b(b_ba_a-a_bb_a)}\right)\right]. \tag{20}$$

The second term of expression (20) can be readily identified with a polynomial in z of degree 2 so that it is proved that the function $f(z,\zeta)$ is an Eichler integral.

D. Example 4

We consider now the case where there is just one projective transformation,

$$T(z)=\frac{az+d}{cz+d}, \tag{21}$$

that can be written in terms of the finite fixed point α and the multiplier w as

$$T(z)=w(z-\alpha)+\alpha. \tag{22}$$

In string theory, and, in particular, in the group theoretic approach,[6] we will be interested in functions that are associated with conformal transformations that cause infinitesimal changes in the moduli of a Riemann surface with genus g. In one loop, i.e., a Riemann surface with genus 1, we have one finite fixed point α, one fixed point at infinity, and the multiplier w. In order to fix the modular invariance of the theory, we must fix three variables. Besides the one fixed point that has been already fixed at infinity, we can choose to fix the finite fixed point and one of the variables associated with the incoming strings so that the multiplier w will be the only variable associated with the loop left.

We then want a function that has the effect of changing the multiplier w infinitesimally, i.e. we want a function that transforms like

$$f(T(z))=T'(z)f(z)-\frac{\partial T(z)}{\partial w}\frac{\delta w}{\epsilon}, \tag{23}$$

i.e.

$$f(T(z))=T'(z)\left[f(z)-\frac{\delta w}{\epsilon w}(z-\alpha)\right] \tag{24}$$

and

$$f(S(z))=f(z), \tag{25}$$

where $S(z)=e^{2\pi i}z$ and where ϵ and δw are infinitesimals.

A function that transforms in this way was found in Refs. 6 and 7 in the context of string theory. It is given by

$$f(z)=\frac{\delta w}{\epsilon w}(z-\alpha)\overline{\zeta}(\ln(z-\alpha)), \tag{26}$$

where the function $\overline{\zeta}(t)$ is given by

$$\overline{\zeta}(t)=\zeta(t)-\frac{\zeta(\pi i)}{\pi i}t.$$

The function $\zeta(t)$ is Weierstrass' ζ function,

$$\zeta(t)=\frac{1}{t}+\sum_{p\neq 0}\left(\frac{1}{t-p}+\frac{1}{p}+\frac{1}{p^2}\right),$$

where p is the semi-period of the function and is given by $p=nw_1+mw_2$, $(n,m\in\mathbf{Z})$, where

$$w_1=\ln w, \quad w_2=2\pi i.$$

The Weierstrass ζ function transforms in the following way:

$$\zeta(t+w_1)=\zeta(t)+2\zeta(w_1/2),$$

$$\zeta(t+w_2)=\zeta(t)+2\zeta(w_2/2),$$

and the term $\ln(z-\alpha)$ transforms like

$$\ln(T(z)-\alpha)=\ln w+\ln(z-\alpha),$$

$$\ln(e^{2\pi i}z-e^{2\pi i}\alpha)=\ln(2\pi i)+\ln(z-\alpha),$$

so that we have

$$f(T(z))=T'(z)\left[f(z)-\frac{\delta w}{\epsilon w}(z-\alpha)\right]. \tag{27}$$

The function $\overline{\zeta}(t)$ can be related to the theta function[3] in the following way:

$$\overline{\zeta}(t)=\frac{d}{dt}\ln\theta(t,\tau),$$

where $\theta(t,\tau)$ has periods $w_1=\ln w$ and $w_2=2\pi i$.

If we take the third derivative of the function $f(z)$, we obtain

$$g(z)=f'''(z)=\frac{\delta w}{\epsilon w}\frac{1}{(z-\alpha)^2}\left[\wp(t)+\frac{\zeta(\pi i)}{\pi i}-\wp''(t)\right],$$

where $t=\ln(z-\alpha)$ and $\wp(t)$ is Weierstrass' $\wp$ function with periods $w_1=\ln w$ and $w_2=2\pi i$, given by

$$\wp(t)=-\frac{d}{dt}\zeta(t)$$

which transforms like

$$\wp(t+w_1)=\wp(t+w_2)=\wp(t),$$

i.e. it is an elliptic function.

Since $\wp(t)$ and its derivatives do not change under a transformation of $t+\ln w$ or $t+2\pi i$, we then have

$$g(T(z))=\frac{1}{w^2}g(z)=[T'(z)]^{-2}g(z),$$

i.e. $g(z)$ is an automorphic form with weight -2, as expected from the relation (7). So we have verified that $f(z)$ is an Eichler integral.

E. Example 5

We shall now search for a function with transformation properties similar to those of (23), but now for the case of many projective transformations. We want a function that transforms like

$$f_w(T_a(z))=T_a'(z)f_w(z)-\frac{\partial T_a(z)}{\partial w_a}\frac{\delta w_a}{\epsilon}, \tag{28}$$

where

$$T_a(z)=\frac{\alpha_a(z-\beta_a)-w_a\beta_a(z-\alpha_a)}{(z-\beta_a)-w_a(z-\alpha_a)},$$

for every $a=1,\ldots,g$, i.e. the action of $T_a(z)$ on this function causes infinitesimal changes in the multipliers w_a. So this function must transform like

$$f_w(T_a(z))=T_a'(z)\left[f_w(z)+\frac{(z-\alpha_a)(z-\beta_a)}{w_a(\alpha_a-\beta_a)}\frac{\delta w_a}{\epsilon}\right]. \tag{29}$$

In addition to this, we also demand that

$$f_a(S_a(z))=f_a(z), \tag{30}$$

where $z\to S_a(z)$ is the transformation that takes z once around the a_a loop for $a=1,\ldots,g$.

In order to find the Eichler integral that transforms like this, we shall make analogies between the function in one loop and the function that we must have for the multiloop case. First we notice that the series $P_w(z)$ defined in (1),

$$P_w(z)=\sum_b \frac{(z-\alpha_b)(z-\beta_b)}{w_b(\alpha_b-\beta_b)}\frac{\delta w_b}{\epsilon}$$

transforms like

$$P_w(T_a(z))=T_a'(z)P_w(z),$$

so that it is the generalization for the multiloop case of the polynomial $(z-\alpha)$ for the one loop case.

Now we must try to find an analog of the Weierstrass ζ function suitable to the multiloop case. This can be obtained by first generalizing the concept of a θ function and of the Weierstrass ζ function. This function is given by the hyperelliptic ζ function[8,9] or best, the ζ function defined in the Appendix. In our first attempt we attach a $\zeta_b(v)$ function to every element of the series $P_w(z)$, so that we have

$$f_{1w}(z)=\sum_b \frac{\delta w_b}{\epsilon}\frac{(z-\alpha_b)(z-\beta_b)}{w_b(\alpha_b-\beta_b)}\overline{\zeta_b}(v).$$

This function will not transform the way we want, since the term $(z-\alpha_b)(z-\beta_b)/(\alpha_b-\beta_b)$ and the first Abelian integrals $v_b(z)$ do not transform in the same way. We then go to the next step, which is making ζ a function not of the first Abelian integrals $v_b(z)$, but of variables $u_b(z)$ (such a change of variables can be justified, as in Baker,[8] Sec. 192), such that

$$u_b(z)=\ln\left(\frac{z-\alpha_b}{z-\beta_b}\right)-\ln\left(\frac{\alpha_a}{\beta_a}\right).$$

Under a change $z\to T_a(z)$, these variables will change like

$$u_b(T_a(z))=\frac{T_a(z)-\alpha_b}{T_a(z)-\beta_b}=\frac{(\alpha_a-w_a\beta_a-\alpha_b+w_a\alpha_b)}{(\alpha_a-w_a\beta_a-\beta_b+w_a\beta_b)}$$
$$\times\frac{[z-(\alpha_a\beta_a-w_a\alpha_a\beta_a-\alpha_b\beta_a+\alpha_bw_a\alpha_a)/(\alpha_a-w_a\beta_a-\alpha_b+w_a\alpha_b)]}{[z-(\alpha_a\beta_a-w_a\alpha_a\beta_a-\beta_b\beta_a+\beta_bw_a\alpha_a)/(\alpha_a-w_a\beta_a-\beta_b+w_a\beta_b)]}.$$

Performing the same change of variables as in (2)–(4), we then obtain

$$\frac{T_a(z)-\alpha_b}{T_a(z)-\beta_b}=w_{ca}\frac{z-\alpha_c}{z-\beta_c},$$

where the coefficient w_{ca} is given by

$$w_{ca}=\frac{(1-w_a)\beta_c-(\beta_a-w_a\alpha_a)}{(1-w_a)\alpha_c-(\beta_a-w_a\alpha_a)},$$

so that

$$u_b(T_a(z))=\ln w_{ca}+u_c(z).$$

We then redefine the generalized θ function $\theta(v)$ in the following way:

$$\theta(u)=\sum_{n=-\infty}^{\infty}\exp\left[\sum_{c,d=1}^{g}(n_c+\delta_c)\frac{1}{2}\ln w_{cd}(n_d+\delta_d)+\sum_{c=1}^{g}2\pi i\gamma_c(n_c+\delta_c)+\sum_{c=1}^{g}u_c(n_c+\delta_c)\right].$$

This function transforms like

$$\theta(u+\Omega)=\exp\left\{-\sum_{c=1}^{g}p_c\left(u_c+\frac{1}{2}\Omega_c\right)-\sum_{c=1}^{g}[\pi ip_cq_c-2\pi i(q_c\delta_c-p_c\gamma_c)]\right\}\theta(u),$$

where Ω_b is now given by

$$\Omega_b=\sum_{c=1}^{g}(2\pi i\ \delta_{bc}p_c+\ln w_{bc}q_c)=2\pi ip_b+\sum_{c=1}^{g}\ln w_{bc}q_c.$$

Defining now

$$\overline{\zeta}_b(u)=\frac{\partial}{\partial u_b}\ln\theta(u), \tag{31}$$

we have

$$\overline{\zeta}_b(u(T_a(z)))=\overline{\zeta}_b(u)-\delta_{ab}$$

and

$$\overline{\zeta}_b(u(S_a(z)))=\overline{\zeta}_b(u).$$

We then define the following function:

$$f(z)=\sum_b\frac{\delta w_b}{\epsilon}\frac{(z-\alpha_b)(z-\beta_b)}{w_b(\alpha_b-\beta_b)}\overline{\zeta}_b(u(z)). \tag{32}$$

This function transforms like

$$\begin{aligned}f_w(T_a(z))&=T_a'(z)\sum_c\frac{\delta w_c}{\epsilon}\frac{(z-\alpha_c)(z-\beta_c)}{w_c(\alpha_c-\beta_c)}[\overline{\zeta}_c(u(z))-\delta_{ac}]\\&=T_a'(z)\left[\sum_c\frac{\delta w_c}{\epsilon}\frac{(z-\alpha_c)(z-\beta_c)}{w_c(\alpha_c-\beta_c)}\overline{\zeta}_c(u(z))-\frac{\delta w_a}{\epsilon}\frac{(z-\alpha_a)(z-\beta_a)}{w_a(\alpha_a-\beta_a)}\right]\end{aligned}$$

and

$$f_w(S_a(z))=f_w(z).$$

Since we are summing over all the elements of the Schottky group, we then have

$$f_w(T_a(z))=T_a'(z)\left[f_w(z)-\frac{\delta w_a}{\epsilon}\frac{(z-\alpha_a)(z-\beta_a)}{w_a(\alpha_a-\beta_a)}\right],$$

$$f_w(S_a(z))=f_w(z),$$

which are the transformation properties we wanted. So we have obtained the Eichler integral that has the effect of changing infinitesimally the variables w_a of a Riemann surface of genus g.

One way to verify this is a true Eichler integral is to take its third derivative. The result must be an automorphic form of weight -2. Taking the third derivative of (32), we have

$$g_w(z)\equiv\frac{d^3}{dz^3}f_a(z)=\sum_b\ \frac{\delta w_b}{\epsilon w_b}\left[\frac{(\alpha_b-\beta_b)}{(z-\alpha_b)(z-\beta_b)}\right]^2[\overline{\wp}_{bc}(u(z))-\overline{\wp}''_{bc}(u(z))],\tag{33}$$

where

$$\overline{\wp}_{bc}(u)=-\frac{\partial}{\partial u_c}\overline{\zeta}_b(u)$$

is the hyperelliptic $\wp$ function and

$$\overline{\wp}''_{bc}(u)=\left(\frac{\partial}{\partial u_c}\right)\overline{\wp}_{bc}(u_b).$$

It can be easily verified that $\overline{\wp}_{bc}(u)$ and its derivatives are invariant under changes $z\to T_a(z)$ and $z\to S_a(z)$, so that the function $g(z)$ transforms like

$$g_w(T_a(z))=(T'_a(z))^{-2}g_w(z),\tag{34}$$

i.e. it is an automorphic form of weight -2. This confirms $f_w(z)$ as an Eichler integral.

F. Example 6

In the same way we found a function (Eichler integral) that changes the variables w_a of a Riemann surface infinitesimally we now want to find a function that will change the variables α_a infinitesimally. This means this function must transform like

$$f_\alpha(T_a(z))=T'_a(z)f_\alpha(z)-\frac{\partial T_a(z)}{\partial\alpha_a}\frac{\delta\alpha_a}{\epsilon},$$

for every $a=1,\ldots,g$, what implies that we want this function to transform like

$$f_\alpha(T_a(z))=T'_a(z)\left[f_\alpha(z)+\frac{(1-w_a)}{w_a(\alpha_a-\beta_a)^2}(z-\beta_a)^2\frac{\delta\alpha_a}{\epsilon}\right].\tag{35}$$

We also demand that

$$f_a(S(z))=f_a(z).\tag{36}$$

The method to obtain this function is analogous to the one used in example 5, but now we use, instead of the series $P_w(z)$, the series (5)

$$P_\alpha(z)=\sum_b\ \frac{\delta\alpha_b}{\epsilon}\frac{(1-w_b)}{w_b(\alpha_b-\beta_b)^2}(z-\beta_b)^2.$$

The function (Eichler integral) with the properties we need is then given by

$$f_\alpha(z)=\sum_b\ \frac{\delta\alpha_b}{\epsilon}\frac{(1-w_b)}{w_b(\alpha_b-\beta_b)^2}(z-\beta_b)^2\overline{\zeta}_b(u).\tag{37}$$

G. Example 7

Similarly, if we want a function that changes the variables β_a infinitesimally, we then need it to transform like

$$f_\beta(T_a(z))=T_a'(z)f_\beta(z)-\frac{\partial T_a(z)}{\partial\beta_a}\frac{\delta\beta_a}{\epsilon},$$

i.e.

$$f_\beta(T_a(z))=T_a'(z)\left[f_\beta(z)+\frac{(1-w_a)}{(\alpha_a-\beta_a)^2}(z-\alpha_a)^2\frac{\delta\beta_a}{\epsilon}\right]. \tag{38}$$

We also demand that

$$f_\beta(S(z))=f_\beta(z). \tag{39}$$

We then use the series (6)

$$P_\beta(z)=\sum_b \frac{\delta\beta_b}{\epsilon}\frac{(1-w_b)}{(\alpha_b-\beta_b)^2}(z-\beta_b)^2,$$

and build the Eichler integral,

$$f_\beta(z)=\sum_b \frac{\delta\beta_b}{\epsilon}\frac{(1-w_b)}{(\alpha_b-\beta_b)^2}(z-\alpha_b)^2\overline{\zeta_b}(u), \tag{40}$$

which has the correct transformation properties.

This concludes our series of examples. The last three examples can be used in order to calculate the measure of the scattering of N bosonic strings in any order of perturbation theory (order g) through the Group Theoretic approach to string theory. These are also new examples of Eichler integrals with poles with some nicer transformation properties.

ACKNOWLEDGMENTS

The author would like to thank Professor P. C. West, under whose supervision this work was completed, and Dr. J. Harvey for directing me to Eichler integrals as possible solutions to my measure problem with strings.

I also would like to thank CAPES (Brazilian government) for financing this work.

APPENDIX: SOME GEOMETRICAL OBJECTS DEFINED ON A GENUS g RIEMANN SURFACE

1. Generalized θ functions

The generalized ϑ function is defined in the following way:[8]

$$\vartheta(v;\gamma,\delta)=\sum_{n=-\infty}^{\infty}\exp\left\{\sum_{a,b=1}^{g}\left[\frac{1}{2\pi i}v_a\eta_{(2)ab}v_b+\pi i(n_a+\delta_a)\tau_{ab}(n_b+\delta_b)\right]\right.$$
$$\left.+\sum_{a=1}^{g}\left[v_a(n_a+\delta_a)+2\pi i\gamma_a(n_a+\delta_a)\right]\right\},$$

where the sum $\Sigma_{n=-\infty}^{\infty}$ means the sum over all n_a, $a=1,\ldots,g$. Here, v_a, v_b are the g first Abelian integrals, $\eta_{(2)ab}$ is a symmetric $g\times g$ matrix, τ_{ab} is the period matrix, n_a, n_b are integers and γ_a, δ_a are vectors with g components that are the characteristics of the function.

If all the elements in the rows p and q are integers, this function transforms like[8]

$$\vartheta(v+\Omega;\gamma,\delta)=\exp\left\{\sum_{a=1}^{g}\left[H_a\left(v_a+\frac{1}{2}\,\Omega_a\right)-\pi i p_a q_a+2\pi i(q_a\delta_a-p_a\gamma_a)\right]\right\}\vartheta(v;\gamma,\delta),$$

where

$$H_a=\sum_{b=1}^{g}\left[2\,\eta_{(1)ab}p_b+2\,\eta_{(2)ab}q_b\right],$$

$$\Omega_a=2\pi i\sum_{b=1}^{g}\tau_{ab}p_b+2\pi i q_a,$$

where $\eta_{(1)ab}$ is a symmetric $g\times g$ matrix.

We can fix $\eta_{(2)ab}=0$. This implies

$$\eta_{(1)ab}=-\tfrac{1}{2}\,\delta_{ab}.$$

We then have the following function:

$$\theta(v;\gamma,\delta)=\sum_{n=-\infty}^{\infty}\exp\left\{\sum_{a,b=1}^{g}\pi i(n_a+\delta_a)\tau_{ab}(n_b+\delta_b)+\sum_{a=1}^{g}\left[v_a(n_a+\delta_a)+2\pi i\,\gamma_a(n_a+\delta_a)\right]\right\},$$

which transforms like

$$\theta(v+\Omega;\gamma,\delta)=\exp\left\{\sum_{a=1}^{g}\left[H_a\left(v_a+\frac{1}{2}\,\Omega_a\right)-\pi i p_a q_a+2\pi i(q_a\delta_a-p_a\gamma_a)\right]\right\}\theta(v;\gamma,\delta).$$

This is the function that is generally refered to as the generalized θ function in the literature.

We may define the well-known object called the prime form in terms of the generalized θ function, which is its most general definition. It is given by

$$E(z,\zeta)=\theta(v(z)-v(\zeta))\left[\sum_{a=1}^{g}\partial_a\theta(0)w_a(z)\right]^{-1/2}\left[\sum_{b=1}^{g}\partial_b\theta(0)w_b(\zeta)\right]^{-1/2},$$

where

$$\partial_a\theta(0)\equiv\frac{\partial}{\partial v_a}\,\theta(v)\bigg|_{v=0},\quad \partial_b\theta(0)\equiv\frac{\partial}{\partial v_b}\,\theta(v)\bigg|_{v=0},$$

and $w_a(v)$, $w_b(v)$ are first Abelian differentials.

2. Hyperelliptic ζ function

We now define the *hyperelliptic ζ function*:[8,9]

$$\zeta_a(v)=\frac{\partial}{\partial v_a}\ln\,\vartheta(v;\gamma,\delta).$$

This function transforms in the following way:

$$\zeta_a(v+\Omega)=H_a+\zeta_a(v)=\sum_{b=1}^{g}(2\eta_{(1)ab}p_b+2\eta_{(2)ab}q_b)+\zeta_a(v).$$

The analogy with the one loop ζ functions is complete when we associate the matrices $\eta_{(1)}$ and $\eta_{(2)}$ with the numbers $\zeta(w_1/2)$ and $\zeta(w_2/2)$, respectively. We then have the identity

$$\sum_{c=1}^{g}2\pi i\tau_{ac}\eta_{(2)cb}-2\pi i\eta_{(1)ab}=\pi i\delta_{ab}.$$

A function that will be more useful to us is one that is invariant under a change $\Omega_a=2\pi iq_a$ so that we must fix $\eta_{(2)ab}=0$. Such a function, say $\overline{\zeta}_a$, is defined by

$$\overline{\zeta}_a(v)=\frac{\partial}{\partial v_a}\ln\,\theta(v;\gamma,\delta)$$

and transforms like

$$\overline{\zeta}_a(v+\Omega)=-p_a+\overline{\zeta}_a(v).$$

More particularly, this function shows that the function $\overline{\zeta}$ is invariant under a change $\Omega_a=2\pi i\tau_{ab}p_b$ for $b\neq a$. It only changes, and then only by a constant term, under the transformation $\Omega_a=2\pi i\tau_{aa}p_a$ for any p_a.

3. Hyperelliptic $\wp$ function

We may now define a hyperelliptic $\wp$ function in the following way:[8,9]

$$\wp_{ab}=-\frac{\partial}{\partial v_b}\zeta_a(v)=-\frac{\partial}{\partial v_b}\frac{\partial}{\partial v_a}\ln\,\theta(v).$$

This function is invariant under changes $\Omega_a=2\pi i\Sigma_{b=1}^{g}\tau_{ab}+2\pi iq_a$, i.e.

$$\wp_{ab}(v+\Omega)=\wp_{ab}.$$

(α,β)-derivations on quantum function algebras

L. J. Swank
Department of Physics, University of Maryland, College Park, Maryland 20742-4111

(Received 27 October 1994; accepted for publication 9 February 1996)

(α,β)-derivations, introduced by Cohn, are defined on several noncommutative function algebras including the Hopf function algebras of the quantum groups $SL_q(n)$, $n=2,3$, where their interpretation is most apparent. In analogy with algebraic groups, left-invariant (α,β)-derivations on the Hopf function algebra of $SL_q(n)$, $n=2,3$, generate its quantum universal enveloping algebra $U_q(\mathrm{sl}(n))$. Derivations and their algebras are also found on the non-Hopf, function algebras of two noncommutative varieties, which are constructed similarly to $SL_q(2)$ and $SL_q(3)$. General (α,β) derivations (analogs of arbitrary vector fields) are found for $SL_q(2)$ and the quantum plane. The analog of the tangent bundle $TSL_q(2)$ is defined, and its relation to derivations is discussed. Some examples of (α,β) derivations on commutative algebras are also given. Generalities about (α,β) derivations and their algebras are discussed. © *1996 American Institute of Physics.*

I. INTRODUCTION

In algebraic group theory, derivations on the commutative Hopf function algebra (FA) of a Lie group can define the Lie algebra.[1] In this article a similar role is considered for (α,β) derivations (to be called (α,β)-D) on Hopf FAs dual to quantum groups. More generally (α,β)-Ds and algebras they generate are found on various other noncommutative, deformed (quantum) FAs. (α,β)-Ds have been defined and used in the theory of noncommutative rings.[2]

This work is in the spirit of algebraic groups and fits most naturally into the approach to quantum groups given by Manin[3] in noncommutative algebraic geometry (NAG). Because of its greater complexity (compared to algebraic geometry (AG)) NAG is barely in its formative stage.[2,4] However, algebraic quantum groups occupy such a special, small corner of NAG that at least some (α,β)-Ds can be fairly easily defined there, and they seem to fit into the theory in much the same way that ordinary derivations do in algebraic groups. We explain this a little more after giving, in the following paragraph, a brief summary of those aspects of algebraic groups which have been a useful guide.[1]

The Lie algebra of a Lie group G (over k) may be defined as the Lie algebra g of left-invariant vector fields on G or as the Lie algebra T_eG of tangent vectors to G at the identity $e\in G$. On the dual Hopf FA, H, these correspond, respectively, to the Lie algebra of left-invariant derivations $D:H\to H$ denoted by $\mathrm{der}_L(H)$ and the Lie algebra of derivations $d:H\to k$ denoted by $\mathrm{der}(H,k)$. These are all isomorphic, $g\cong T_eG\cong \mathrm{der}_L(H)\cong \mathrm{der}(H,k)$. The universal enveloping algebra (UEA) of g, $U(g)$, can then be defined as $U(\mathrm{der}_L(H))$ (and similarly for $\mathrm{der}(H,k)$). In later discussions this algebra will be denoted by Der. Thus, in summary, $U(g)\cong U(\mathrm{der}_L(H))\equiv \mathrm{Der}_L(H)$.

In this article (α,β)-Ds are defined on the Hopf FAs of $SL_q(2)$, $SL_q(3)$,[5] on two FAs which will often be referred to by their noncommutative varieties we call $V_{q,p}(2)$, $V_q(3)$, on two quantum planes, and on several commutative FAs. For the quantum groups $SL_q(2)$ and $SL_q(3)$, (α,β)-Ds provide a link between FAs and quantum UEA which parallels that in algebraic groups described above, e.g., $\mathrm{Der}_L(H_q)\cong U_q(\mathrm{sl}(2))$ where H_q is the Hopf FA of $SL_q(2)$. The (α,β)-Ds on the FAs of the other noncommutative varieties, $V_{q,p}(2)$, $V_q(3)$, and the quantum planes, are found in order to show that (α,β)-Ds exist on more general FAs than those of quantum groups. Generally ''FA'' will mean a noncommutative algebra which is a deformation of a commutative FA, e.g., the ones

just mentioned. In principle, general noncommutative algebras could be considered, but the valuable guidance of nearby commutative FAs would not be available.

There is some indication that, roughly, the pattern of (α,β)-Ds found in the above cases may also be present for (α,β)-Ds on many such varieties. This motivates the definition of a q variety (q-V) such that $V_{q,p}(2)$, $V_q(3)$, $\mathrm{SL}_q(2)$, and $\mathrm{SL}_q(3)$ appear as examples of q-Vs. Here the terminology of q-V is in analogy with an algebraic group, which is a variety. However, this is mostly formal. Except in Sec. IX, where varieties are explicitly defined, we work entirely with their FAs, even when ''variety'' is mentioned. Thus ''derivations on V'' will mean ''derivations on the FA of V.''

Unfortunately our notion of a q-V is too close to quantum groups to expose much about a possible role for (α,β)-Ds more generally in NAG. A discussion of that question is beyond the scope of this work.

Here is a summary of the contents. In Sec. II (α,β)-Ds are defined in more generality than is strictly necessary for the present work. However, an example of this generality is given in Sec. V in the construction of q-Vs. In Sec. III we discuss how Hopf algebras can arise from (α,β)-Ds of an unspecified FA. Section IV is not essential, but it shows the curious possibility of antiderivations on noncommutative FAs. In Sec. V q-Vs are defined from bialgebras, and the general structure of their derivations is outlined. Two examples of q-Vs, $V_{q,p}(2)$ and $V_q(3)$, are defined in Secs. VI and VII. In Sec. VI, (α,β)-Ds are defined on $V_{q,p}(2)$ and their derivation Hopf algebra $\mathrm{Der}_0(A)$ is found. Left-invariant (α,β)-Ds on $\mathrm{SL}_q(2)$ and the Hopf algebra $\mathrm{Der}_L(H_q)\cong U_q(\mathrm{sl}(2))$ appear as a special case. The adjoint action ''$\triangleright$'' is briefly considered in the context of (α,β)-Ds. In Sec. VII an algebra $\mathrm{Der}_0(A)$ of (α,β)-Ds on $V_q(3)$ is found and compared with $U_q(\mathrm{sl}(3))$, which is realized by left-invariant (α,β)-Ds on $\mathrm{SL}_q(3)$. In Sec. VIII general (α,β)-Ds and their Hopf algebra Der are found for the quantum plane. Two subalgebras of Der are found, including a Euclidean quantum group. Another Euclidean quantum group and the Heisenberg quantum group are found from a different quantum plane. Some general non-left-invariant derivations are found on $\mathrm{SL}_q(2)$. In Sec. IX we define a noncommutative variety which is formally the q analog of the tangent bundle of SL(2). This article is primarily concerned with (α,β)-Ds on noncommutative FAs. However, in Sec. X, (α,β)-Ds on several commutative FAs are considered. For other approaches to derivations and quantum groups see Refs. 6–8.

II. (α,β)-DERIVATIONS

In this section (α,β)-derivations[2] are defined on a generally noncommutative k-algebra A, and various preliminary results and general examples of (α,β)-Ds are given for use in later sections.

An (α,β)-D has two algebra homomorphisms (Homs), α and β which go into the definition of the Leibniz rule. (The name ''(α,β)-D'' will be a generic name for any such derivation as well as for a specific one involving α and β.) The following notation will be useful. The action of α (or any Hom) on $f\in A$ will be written variously as $\alpha(f)=\alpha f=f^\alpha$, according to economy and clarity. The action of a derivation D is similarly denoted by $D(f)=Df=f^D$. Reference to k, the ground field, is usually suppressed. Thus Hom means k-Hom (k-linear map), etc.

Let A, A', and A'' be noncommutative k-algebras, and let M be a left A' module and a right A'' module. M is not necessarily a left–right A'–A'' bimodule because module multiplication may not be associative; that is, for $f'\in A'$, $g''\in A''$, and $m\in M$, it may be that $f'(mg'')\neq(f'm)g''$; an example of this occurs in Sec. V. However, algebra Homs $\alpha{:}A\to A'$ and $\beta{:}A\to A''$ may exist such that

$$f^\alpha(mg^\beta)=(f^\alpha m)g^\beta \tag{2.1}$$

for all $f,g\in A$. Then M is an Im α-Im β bimodule which we call an (α,β) bimodule. Assume M to be an (α,β) bimodule. Let $D{:}A\to M$, $\alpha{:}A\to A'$, and $\beta{:}A\to A''$ be Homs which satisfy

$$(fg)^D = f^\alpha g^D + f^D g^\beta,$$
$$(f_1 f_2)^\alpha = f_1^\alpha f_2^\alpha, \quad (g_1 g_2)^\beta = g_1^\beta g_2^\beta \tag{2.2}$$

for all $f, g, f_1, f_2, g_1, g_2 \in A$. D, α, β are linear: $D(f+g) = Df + Dg$, etc.

The first equation expresses the derivation character of D in terms of α and β. The last two equations just state that α and β are *algebra* Homs, which, together with the (α,β) bimodule structure of M in Eq. (2.1), is necessary to make D well defined on arbitrary products. For example, the two ways to apply Eq. (2.2) to $(fgh)^D$ agree if $(fg)^\alpha h^D = f^\alpha g^\alpha h^D$, $f^D(gh)^\beta = f^D f^\beta g^\beta$, and $f^\alpha(g^D h^\beta) = (f^\alpha g^D)h^\beta \equiv f^\alpha g^D g^\beta$. Equations (2.2) constitute the (α,β) Leibniz rule, and D is called an (α,β)-D, often denoted by $\{\alpha,\beta,D\}$.

Comments on the Leibniz rule.

(1) It reduces to the ordinary Leibniz rule if $M = A' = A'' = A$ and $\alpha = \beta = id_A$, the identity map on A. This is the usual situation.

(2) Algebra Homs preserve the unit ($\alpha 1_A = 1_{A'}$ and $\beta 1_A = 1_{A''}$), so $D(1_A) = 0$, which makes D a k-derivation, i.e., $D: k \to 0$. α could be interpreted as an $(\alpha,0)$-D or a $(0,\alpha)$-D, but obviously it would not be a k-derivation, i.e., $\alpha 1_A = 1_{A'} \neq 0$ (similarly for β). In this work the terms ''derivation'' and ''(α,β)-D'' will always mean that $\alpha,\beta \neq 0$.

(3) It allows the possibility of having two derivations which act identically on the generators of A but differently on products, i.e., $D = D'$ on the generators but $(\alpha,\beta) \neq (\alpha',\beta')$. It can also happen that $D \neq D'$, while D and D' are both (α,β)-Ds. Both of these situations arise. A zero (α,β)-D and a zero (α',β')-D are equivalent.

(4) The Leibniz rule (2.2) can be represented by commutative diagrams as shown in Fig. 1, which will be used to define comultiplication in Sec. III.

(5) Our approach will start with (α,β)-Ds and see what structure they generate. On hindsight, interest in (α,β)-Ds for noncommutative A may be seen by reversing the logic. A and Der(A) are contravariantly related, so noncommutativity of A corresponds to noncocommutativity of Der(A). This in turn leads via (4) above to (α,β)-Ds and the Leibniz rule. The particular form of the coproduct of the (α,β)-Ds, as in Eq. (3.6), is discussed in the *comment on [,]* near the end of Sec. III.

(6) More general objects θ^i_j, $i, j = 1,\ldots,n$ can be defined[6]:

$$(fg)^{\theta^i_j} = \sum_k f^{\theta^i_k} g^{\theta^k_j}. \tag{2.3}$$

For $n=2$, θ^1_2 is a (θ^1_1,θ^2_2)-D.

Examples: The Leibniz rule is easily checked in each case.

(1) Let $M = A \otimes A$ have the usual left–right A–A bimodule structure and α, $\beta: A \to A$ be algebra Homs. Then $D: A \to A \otimes A$ defined by

$$D(f) = 1 \otimes f^\beta - f^\alpha \otimes 1$$

is an (α,β)-D. If $\alpha = \beta = id_A$, then D is the usual universal derivation defined for noncommutative algebras.[9]

(2) Given (α,β), $m \in M$ defines an (α,β)-D $D_m: A \to M$:

$$D_m f = f^\alpha m - m f^\beta.$$

(3) A recurring special case of (2) takes $M = A' = A'' = A$ and $m = 1_A$ [usually $m = c1_A$, $c \in k$; see (5) below]. Then we write $D = \alpha - \beta$:

$$(fg)^{\alpha-\beta} = f^\alpha g^\alpha - f^\beta g^\beta = f^\alpha g^{\alpha-\beta} + f^{\alpha-\beta} g^\beta. \tag{2.4}$$

(4) Let $D:A\to A$ be an (α,β)-D and ϕ, $\psi:A\to A$ be algebra Homs, then $\varphi D\psi$ is a $(\varphi\alpha\psi,\varphi\beta\psi)$-D. (Here $\varphi D\psi\equiv\phi\circ D\circ\psi$, $\phi\alpha\psi\equiv\phi\circ\alpha\circ\psi$, etc., mean composition of maps.) In particular, if α^{-1} exists, then $\alpha^{-1}D$ and $D\alpha^{-1}$ are, respectively, $(id,\alpha^{-1}\beta)$- and $(id,\beta\alpha^{-1})$-Ds. An analogous statement holds for β if β^{-1} exists. (In the general case (2.2), ΦD is an (α,β)-D, where $\Phi:M\to M$ is an (A',A'') bimodule homomorphism.)

(5) If D is an (α,β)-D and $f\in A$, then ''$f\cdot D$'' (left ''multiplication'' of D by f) is not in general an (α,β)-D or even necessarily a derivation at all. (This is not actually module multiplication; see Sec. VIII.) However, since $D:k\to 0$, multiplication by $c\in k$ makes sense, and $cD=Dc$ is an (α,β)-D. In particular, $c(\alpha-\beta)$ is an (α,β)-D. Note that $\alpha-\beta=-(\beta-\alpha)$ is also a (β,α)-D.

III. ALGEBRA OF DERIVATIONS

In this section $M=A'=A''=A$ is an unspecified FA. The (α,β) derivations $\{\alpha,\beta,D\}$ on A generate an associative algebra $\mathscr{D}er(A)$. Multiplication $m:\mathscr{D}er(A)\otimes\mathscr{D}er(A)\to\mathscr{D}er(A)$ is given by composition and the unit $\eta:k\to\mathscr{D}er(A)$ by $\eta(1)=id_A$. In general $\mathscr{D}er(A)$ is infinitely generated. In this section we consider a Hopf subalgebra $\mathrm{Der}(A)\subset\mathscr{D}er(A)$. $\mathrm{Der}(A)$ may also be infinitely generated. For most of the FAs considered later, we are interested in some finitely generated (denoted by subscript 0) Hopf subalgebra $\mathrm{Der}_0(A)\subset\mathrm{Der}(A)$. However, this distinction is unimportant in this section. Here the purpose is to formulate relations (abbreviated Rels.) which are natural for derivations to satisfy and which make $\mathrm{Der}(A)$ a Hopf algebra. Since A is unspecified, $\mathrm{Der}(A)$ only attains a general form; the structure constants remain undetermined. This general form of $\mathrm{Der}(A)$ gives a perspective on later examples.

Consider a set of derivations on A, $\{\alpha_i,\beta_i,D_i\}_{i=1,2,\ldots}$, which generate the algebra $\mathrm{Der}(A)=k\langle\alpha_1,\beta_1,D_1,\ldots\rangle$ with as yet unspecified Rels. The Leibniz rule (2.2) does not guarantee (in contrast to the usual Leibniz rule) that the commutator $[D_i,D_j]$ of two derivations is again a derivation. For this, $\{\alpha_i,\beta_i,D_i\}$ and $\{\alpha_j,\beta_j,D_j\}$ have to satisfy certain Rels., which we now find. Consider the action of $[D_i,D_j]$ on a product $fg\in A$:

$$(fg)^{[D_i,D_j]}=f^{D_iD_j}g^{\beta_i\beta_j}-f^{D_jD_i}g^{\beta_j\beta_i}+f^{\alpha_i\alpha_j}g^{D_iD_j}-f^{\alpha_j\alpha_i}g^{D_jD_i}+f^{\alpha_iD_j}g^{D_i\beta_j}-f^{D_j\alpha_i}g^{\beta_jD_i}+f^{D_i\alpha_j}g^{\beta_iD_j}-f^{\alpha_jD_i}g^{D_j\beta_i}. \tag{3.1}$$

Here $i\neq j$ is assumed; the case $i=j$ will be discussed below. In general the first four terms on the right-hand side will make the commutator a derivation if the following Rels. are satisfied:

$$\alpha_i\alpha_j=\alpha_j\alpha_i,\quad \beta_i\beta_j=\beta_j\beta_i, \tag{3.2a}$$

$$D_i\alpha_j=t_{ij}\alpha_jD_i,\quad D_j\beta_i=t_{ij}\beta_iD_j, \tag{3.2b}$$

$$D_j\alpha_i=t_{ji}\alpha_iD_j,\quad D_i\beta_j=t_{ji}\beta_jD_i, \tag{3.2c}$$

where $t_{ij},t_{ji}\in k$. If Eqs. (3.2) hold, then $[D_i,D_j]$ is an $(\alpha_i\alpha_j,\beta_i\beta_j)$-D:

$$(fg)^{[D_iD_j]}=f^{\alpha_i\alpha_j}g^{[D_i,D_j]}+f^{[D_i,D_j]}g^{\beta_i\beta_j}.$$

Rels. (3.2) are generally satisfied. If they are not satisfied and thus do not cause a pairwise cancellation among the last four terms in Eq. (3.1), then at least one of three things happens: (1) the commutator $[D_i,D_j]$ is not a derivation, (2) $[D_i,D_j]$ may still be an $(\alpha_i\alpha_j,\beta_i\beta_j)$-D due to more complicated cancellations among these terms, (3) $[D_i,D_j]$ may ''accidentally'' be a derivation but of a different type, say an (α,β)-D where $(\alpha,\beta)\neq(\alpha_i\alpha_j,\beta_i\beta_j)$. Situation (2) occurs in the Euclidean quantum group, example (4) in Sec. VIII, and (3) occurs in Sec. X: see Eq. (10.6).

Consider one of the Rels. (3.2b) or (3.2c), say the first one. By example (4) of Sec. II, $D_i\alpha_j$ is an $(\alpha_i\alpha_j,\beta_i\alpha_j)$-D, and α_jD_i is an $(\alpha_j\alpha_i,\alpha_j\beta_i)$-D. These must represent the same derivation. This is true iff $\alpha_j\alpha_i=\alpha_i\alpha_j$ and $\alpha_j\beta_i=\beta_i\alpha_j$. Extending this to all the Rels. in Eqs. (3.2b) and (3.2c) requires two more Rels.:

$$\alpha_j\beta_i=\beta_i\alpha_j, \quad \alpha_i\beta_j=\beta_j\alpha_i. \tag{3.2d}$$

If α_i^{-1} and β_i^{-1} exist, then there may be further Rels.:

$$\alpha_i\beta_i=\beta_i\alpha_i=id_A. \tag{3.3}$$

If so, then the two Rels. in Eqs. (3.2b) and (3.2c) involving D_j become the same, which can be written as $\alpha_iD_j\beta_i=t_{ij}D_j$, where $t_{ij}=(t_{ji})^{-1}$. In addition, the Rels. in Eq. (3.2d) become a consequence of Eqs. (3.3) and (3.2a). The same comment about D_i holds if $\alpha_j\beta_j=\beta_j\alpha_j=id_A$. Then one of the Rels. (3.2a) becomes dependent. Rels. (3.3) do not always exist as $V_{q,p}(2)$ shows, but we impose them when possible.

In the diagonal case $i=j$, where $[D_i,D_j]=0$ is a trivial derivation, Eq. (3.1) reduces to $0=0$ and does not yield any Rels. of the type (3.2). Thus, the Rels. (3.2) are assumed only for $i\neq j$. Any such Rels. which exist for $i=j$, do so ''voluntarily'' as happens for $V_{q,p}(2)$.

Suppose Rels. (3.2) are satisfied, so $[D_i,D_j]$ is an $(\alpha_i\alpha_j,\beta_i\beta_j)$-D. Then there are two possibilities for further Rels. among $\{\alpha_i,\beta_i,D_i\}$ and $\{\alpha_j,\beta_j,D_j\}$. One is that $[D_i,D_j]$ is proportional to $(\alpha_i\alpha_j-\beta_i\beta_j)$, which, is also an $(\alpha_i\alpha_j,\beta_i\beta_j)$-D (see example (3) in Sec. II):

$$[D_i,D_j]=c_{ij}(\alpha_i\alpha_j-\beta_i\beta_j), \tag{3.4}$$

where $c_{ij}\in k$. The second possibility is that among the derivations $\{\alpha_i,\beta_i,D_i\}_{i=1,\ldots}$ there is one, $\{\alpha_l,\beta_l,D_l\}$, which is proportional to $\{\alpha_i\alpha_j,\beta_i\beta_j,[D_i,D_j]\}$. Then there are Rels.

$$\alpha_i\alpha_j=\alpha_l, \quad \beta_i\beta_j=\beta_l, \quad [D_i,D_j]=c_{ij}^lD_l. \tag{3.5}$$

Generally Der(A) will satisfy Rels. (3.2), and some combination of Eqs. (3.4) and (3.5). These are either verified or imposed as constraints as follows. Each side of $\alpha_j\beta_i=\beta_i\alpha_j$ is an algebra Hom, so it is sufficient to check it on the generators of A. Each side of $D_i\alpha_j=t_{ij}\alpha_jD_i$ is a derivation of the same type, so if it holds on generators then it extends to A by the Leibniz rule. Equations (3.4) and (3.5) are proved similarly. The t_{ij} in Eqs. (3.2b) and (3.2c), c_{ij} in Eq. (3.4) and c_{ij}^l in Eq. (3.5) are the structure constants of Der(A).

Der(A) as a Bialgebra. Rels. (3.2)–(3.5) give Der(A) a bialgebra structure which we now discuss. The Leibniz rule as represented in Fig. 1 suggests a comultiplication for Der(A), namely, the map which takes the bottom arrows to the top arrows. Thus we define Δ:Der(A) $\rightarrow$Der(A)$\otimes$Der(A) by

$$\Delta D_i=\alpha_i\otimes D_i+D_i\otimes\beta_i,$$

$$\Delta\alpha_i=\alpha_i\otimes\alpha_i, \quad \Delta\beta_i=\beta_i\otimes\beta_i. \tag{3.6}$$

A coproduct of this form is naturally constructed for any (α,β)-D.

Rel. (3.3) is assumed whenever possible in order to give ΔD_i the same form as the coproducts for the quantized Kac–Moody algebras given in Ref. 5. Other choices, such as $\alpha_i=id$ or $\beta_i=id$ could have been made instead of Eq. (3.3). An example of this is mentioned in connection with the algebra (6.14).

Comment. Comultiplication for the θ^i_j in Eq. (2.3) would be[6]

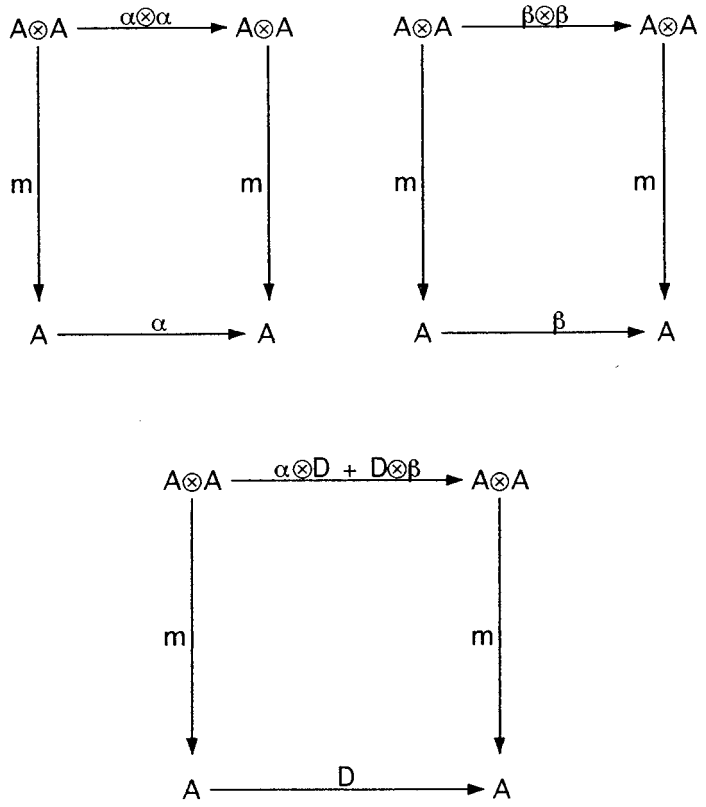

FIG. 1. Commutative diagrams expressing the Leibniz rule for an (α, β)-derivation.

$$\Delta(\theta_j^i) = \sum_k \theta_k^i \otimes \theta_j^k .$$

The counit ϵ:Der$(A) \to k$ consistent with Δ (i.e., satisfies $(\epsilon \otimes id)\Delta = id = (id \otimes \epsilon)\Delta$) is defined by

$$\epsilon(\alpha_i) = \epsilon(\beta_i) = 1, \quad \epsilon(D_i) = 0. \tag{3.7}$$

As is necessary, Δ and ϵ respect Rels. (3.2)–(3.5).

From example (4) of Sec. II, $\alpha_i D_j$ would appear in Fig. 1 as an $(\alpha_i\alpha_j, \alpha_i\beta_j)$-D and so has comultiplication

$$\Delta(\alpha_i D_j) = \alpha_i\alpha_j \otimes \alpha_i D_j + \alpha_i D_j \otimes \alpha_i\beta_j = (\alpha_i \otimes \alpha_i)(\alpha_j \otimes D_j + D_j \otimes \beta_j) = \Delta(\alpha_i)\Delta(D_j). \tag{3.8}$$

The second equality uses the definition of multiplication in Der$(A) \otimes$Der(A). Thus, Δ is an algebra Hom, which is necessary for Der(A) to form a bialgebra. Δ is coassociative, which is also necessary. Therefore the derivations $\{\alpha_i, \beta_i, D_i\}_{i=1,2,\ldots}$ generate a bialgebra $(\text{Der}(A), m, \eta, \Delta, \epsilon)$.

Der(A) as a Hopf algebra. If α_i^{-1} and β_i^{-1} exist for all i, then an antipode ι:Der$(A) \to$Der(A) can be defined by

$$\iota(\alpha_i) = \alpha_i^{-1}, \quad \iota(\beta_i) = \beta_i^{-1}, \quad \iota(D_i) = -\alpha_i^{-1} D_i \beta_i^{-1}. \tag{3.9}$$

ι preserves Rels. (3.2)–(3.5) and satisfies the compatibility conditions: $m(\iota\otimes id)\Delta = \eta\epsilon = m(id\otimes\iota)\Delta$. Then $(\mathrm{Der}(A), m, \eta, \Delta, \epsilon, \iota)$ forms a generally noncommutative and noncocommutative Hopf algebra.

Comment: $\mathrm{Der}(A)$ is defined to be a minimal algebra in the sense that it contains only those algebra Homs α_i, β_i which appear in derivations, i.e., in $\{\alpha_i, \beta_i, D_i\}_{i=1,2,\ldots}$. $\mathrm{Der}(A)$ could be enlarged by adding an unnecessary $\phi \in \mathrm{Hom}_{k\text{-}A}(A)$ to get $k\langle D_1, \alpha_1, \beta_1, \ldots, \phi\rangle$, which would contain, e.g., ϕD_i, a $(\phi\alpha_i, \phi\beta_i)$-D. Note that if D_i and D_j satisfy Eq. (3.2), then $\{\psi\alpha_i, \psi\beta_i, \psi D_i\}$ and the $\{\phi\alpha_j, \phi\beta_j, \phi D_j\}$ generally do not, even for new values of t_{ij} and t_{ji}. Thus, $[\psi D_i, \phi D_j]$ would not, in general, be an $(\psi\alpha_i\phi\alpha_j, \psi\beta_i\phi\beta_j)$-D. (See, however, the construction of the algebra (6.13)). This is true also for necessary αs and βs. Note that Eq. (3.8) also applies to a more general $(\phi\alpha\psi, \phi\beta\psi)$-D, $\phi D\psi$, where $\phi, \psi: A\to A$ are any algebra Homs and $\Delta\phi = \phi\otimes\phi$ and $\Delta\psi = \psi\otimes\psi$.

Special case: Let $i \neq j$, and suppose $\alpha_i = \alpha_j = \alpha$ and $\beta_i = \beta_j = \beta$, i.e., D_i, D_j are both (α,β)-Ds. Then the derivation Rels. reduce to

$$\alpha\beta = \beta\alpha, \quad D_i\alpha = u\alpha D_i, \quad D_j\beta = u\beta D_j,$$
$$D_j\alpha = v\alpha D_j, \quad D_i\beta = v\beta D_i, \tag{3.10a}$$

where $t_{ij} = u$, $t_{ji} = v$, and Eq. (3.4) becomes

$$[D_i, D_j] = c_{ij}(\alpha^2 - \beta^2). \tag{3.10b}$$

This is the form of $\mathrm{SL}_q(2)$ in Eq. (6.12), where α, β also satisfy Eq. (3.3).

Comment on [,]. The development of $\mathrm{Der}(A)$ starting with Eq. (3.1) has relied on the ''classical'' commutator. The coproduct (3.6) in $\mathrm{Der}(A)$ follows directly from the definition (2.2) (via the third of the diagrams in Fig. 1). The commutator and the coproduct (3.6) (or equivalently the (α,β)-Ds) are linked by Rels. (3.2b) and (3.2c). On the one hand these Rels. arise as derivation conditions on the commutator and on the other they impose conditions on the α_i, β_i, which show up in the coproducts (3.6). Instead of $[D_i, D_j]$, the adjoint action[8,10] $D_i \triangleright D_j$ could be considered in Eq. (3.1). This would alter Rels. (3.2b) and (3.2c), thereby also possibly alter the coproduct (3.6). The resulting derivation algebra $\mathrm{Der}_{\triangleright}(A)$ may, in general, be different from $\mathrm{Der}(A)$. $\mathrm{Der}_{\triangleright}(A)$ and $\mathrm{Der}(A)$ are compared for the case of $\mathrm{SL}_q(2)$ at the end of Sec. VI.

Comment on Der(H,k). For algebraic Lie groups, the Lie algebra of left-invariant derivations $D: H\to H$ is isomorphic to the Lie algebra of derivations $D': H\to k$; $\mathrm{Der}_L(H) \cong \mathrm{Der}(H,k)$.[1] They are related by $D' = \epsilon D$ and $D = (id\otimes D')\Delta$. The same result holds for (α,β)-Ds on noncommutative Hopf algebras. Thus, for the FA H_q, the algebra of left-invariant (α,β)-Ds α, β, $D: H_q\to H_q$ is isomorphic to the algebra of (α',β')-Ds $\{\alpha', \beta', D'\}: H_q\to k$, i.e., $\mathrm{Der}_L(H_q) \cong \mathrm{Der}(H_q, k)$. D and D' are related by $\epsilon: H_q\to k$: $D' = \epsilon D$, $\alpha' = \epsilon\alpha$, $\beta' = \epsilon\beta$, and $D = (id\otimes D')\Delta$, $\alpha = (id\otimes\alpha')\Delta$, $\beta = (id\otimes\beta')\Delta$. $\mathrm{Der}(H_q, k)$ will not be discussed further in this work.

IV. ANTIDERIVATIONS

In this section it is shown how a noncommutative FA, A, allows antiderivations, which are just a novelty here and are not used elsewhere in the article. An algebra antiHom is a Hom $\kappa: A\to A$ satisfying $(fg)^\kappa = g^\kappa f^\kappa$. Antiderivations stand in the same relation to algebra antiHoms as derivations do to algebra Homs.

E will be called a (π,ω) antiderivation (antiD) if $E, \pi, \omega: A\to A$ are Homs satisfying the (reversing) Leibniz rule

$$(fg)^E = g^\pi f^E + g^E f^\omega,$$
$$(g_1 g_2)^\pi = g_2^\pi g_1^\pi, \quad (f_1 f_2)^\omega = f_2^\omega f_1^\omega \tag{41}$$

for fs and gs in A.

The derivations given in the examples at the end of Sec. II have their counterparts for antiderivations which are briefly stated here. (i) Two algebra antiHoms π and ω define a (π,ω) antiD $E:A\to A\otimes A$, $Ef=1\otimes f^{\omega}-f^{\pi}\otimes 1$. (ii) $m\in M$ and the antiHoms $\chi:A\to A'$ and $\kappa:A\to A''$ define the (χ,κ) antiD $E_m:A\to M$ given by $E_m f=f^{\chi}m-mf^{\kappa}$. (iii) $D=\omega-\pi:A\to A$ is a (π,ω) antiD. (iv) If E is a (π,ω) antiD and ϕ is an algebra Hom then ϕE (recall $\phi E=\phi\circ E$) is a $(\phi\pi,\phi\omega)$ antiD. (Note that $\phi\pi$ and $\phi\omega$ are algebra antiHoms.) There is a similar statement for $E\phi$. Algebra antiHoms can be used to map derivations to antiderivations and vice versa. Thus, for example, if D is an (α,β)-D and κ is an algebra antiHom, then κD is a $(\kappa\beta,\kappa\alpha)$ antiD, and $D\kappa$ is an $(\alpha\kappa,\beta\kappa)$ antiD.

Many antiderivations can be formed from a derivation and vice versa. For example, if $\xi=\alpha^m\beta^n\kappa^{2k+1}$ and $\zeta=\alpha^{m'}\beta^{n'}\kappa^{2k'}$, then $\xi D\zeta$ is a $(\xi\beta\zeta,\xi\alpha\zeta)$ antiD. This suggests that if an antiautomorphism exists, then there are as many antiderivations as derivations.

V. DERIVATIONS AND q-VARIETIES

This section consists of three parts. The first part presents two types of derivations, L,R, to add to the examples in Sec. II. In the second part, it is shown how L,R can be used to construct FAs of the quantum groups $\mathrm{SL}_q(2)$, $\mathrm{SL}_q(3)$ and also $V_{q,p}(2)$, $V_q(3)$ (given in Secs. VI and VII). The latter are not quantum groups, but their construction is inspired by $\mathrm{SL}_q(2)$ and $\mathrm{SL}_q(3)$. We refer to an object constructed from L,R as a q-V. The third part describes, in a general way, how derivations on q-Vs are defined.

(i) *Derivations L and R.* The derivations L,R depend only on operations available in any bialgebra B. Thus, B could be taken to be an arbitrary bialgebra even though applications only use free matrix bialgebras (to yield q-Vs).

Let $(B,m,\eta,\Delta,\epsilon)$ be a bialgebra considered as a FA. $L,R:B\to B$ are defined in terms of an algebra antiHom $s:B\to B$, $(fg)^s=g^sf^s$:

$$\eta\epsilon,\quad l=m(id\otimes s)\Delta,\quad r=m(s\otimes id)\Delta, \tag{5.1}$$

$$L=l-\eta\epsilon,\quad R=r-\eta\epsilon. \tag{5.2}$$

R and L are not derivations like Eq. (2.4) because l and r are not algebra Homs like α and β (and $\eta\epsilon$) (i.e., $(fg)^l\neq f^lg^l$). Nevertheless, L and R can be interpreted as derivations in the more general context of Eq. (2.2). l and r in Eq. (5.1) are reinterpreted in terms of

$$\lambda=(id\otimes\sigma)\Delta:B\to B\otimes B^{\mathrm{op}},\quad \rho=(\sigma\otimes id)\Delta:B\to B^{\mathrm{op}}\otimes B, \tag{5.3}$$

$$\sigma:B\overset{s}{\to}B\overset{\mathrm{op}}{\to}B^{\mathrm{op}},$$

where B^{op} is the opposite algebra to B. σ is an algebra Hom (because s and op are algebra antiHoms) and thus λ and ρ are also algebra Homs. The target B of $L,R:B\to B$ will be interpreted, respectively, as $(\lambda,\eta\epsilon)$ and $(\eta\epsilon,\rho)$ bimodules. In the notation of Eq. (2.2), $A'=B\otimes B^{\mathrm{op}}$ and $A''=B$ for L ($A'=B$ and $A''=B^{\mathrm{op}}\otimes B$ for R) which uses left $B\otimes B^{\mathrm{op}}$ (right $B^{\mathrm{op}}\otimes B$) module multiplication $(f\otimes g^{\mathrm{op}})h=fhg$ ($h(f^{\mathrm{op}}\otimes g)=fhg$). Note that $(\lambda,\eta\epsilon)$ and $(\eta\epsilon,\rho)$ satisfy Eq. (2.1). With these definitions L,R satisfy the Leibniz rule:

$$(fg)^L=f^{\lambda}g^L+f^Lg^{\eta\epsilon},\quad (fg)^R=f^{\eta\epsilon}g^R+f^Rg^{\rho}, \tag{5.4}$$

which shows that L is a $(\lambda,\eta\epsilon)$-D and R is an $(\eta\epsilon,\rho)$-D.

(ii) *q-Vs from L,R.* Here, L and R in Eqs. (5.2) and (5.4) can be used to define (the FAs of) q-Vs such as $\mathrm{SL}_q(2)$, $\mathrm{SL}_q(3)$, $V_{q,p}(2)$, and $V_q(3)$. Let X_i, $i=1,2,\ldots,n$ be the generators of B. Consider the ideal $I\subset B$,

$$I=(L(X_i),R(X_i))_{i=1,2,\ldots,n}. \tag{5.5}$$

The Rels. $L(X_i),R(X_i)$ are not necessarily independent. Note that L and R are actually derivations to I, i.e., $L,R:B\to I$.

Each choice of s in $L=L_s$ and $R=R_s$ defines an ideal $I=I_s$ in Eq. (5.5). This defines the FA, $A=A_s$, dual to a q-V, $A_s\leftrightarrow V_s$:

$$A_s=B/I_s. \tag{5.6}$$

$\mathrm{SL}_q(2)$, $V_{q,p}(2)$, and $V_q(3)$ are of this form. The construction of I for $\mathrm{SL}_q(3)$ needs several derivations L,R to be defined as a q-V. Although this will not be given, the general situation is briefly discussed here.

Suppose there are many derivations, L_{lm} and R_{kn}, constructed from algebra Homs and anti-Homs $\Phi_m,S_l:B\to B$ as in Eqs. (5.1) and (5.2):

$$L_{kl}=m(\Phi_{Lk}\otimes S_{Ll})\Delta-\eta\epsilon,\quad R_{mn}=m(S_{Rm}\otimes\Phi_{Rn})\Delta-\eta\epsilon.$$

As in Eqs. (5.5) and (5.6) a collection of Rels. $\mathscr{R}$ generates an ideal, which in turn defines a FA:

$$\begin{gathered}\mathscr{R}=\{L_{kl}(X_i),R_{mn}(X_i),L_{k'l'}(X_i)-R_{m'n'}(X_i)\},\\ I_{\mathscr{R}}=(\mathscr{R}),\quad A_{\mathscr{R}}=B/I_{\mathscr{R}}.\end{gathered} \tag{5.7}$$

(iii) *Construction of Der(A).* $\mathrm{Der}(A)$ (or $\mathrm{Der}_0(A)$) is constructed from the subalgebra $\mathrm{Der}_I(B)\subset\mathscr{D}\mathscr{E}\mathscr{R}(B)$ of derivations which preserve I:

$$I^D\subset I,\quad I^\alpha\subset I,\quad I^\beta\subset I. \tag{5.8}$$

If the projection $B\to A$ is denoted by $f\to[f]$ then $D\in\mathrm{Der}_I(B)$ defines $D_A\in\mathrm{Der}(A)$ by $D_A[f]=[Df]$, $\alpha_A[f]=[\alpha f]$, etc. This gives a map $\mathrm{Der}_I(B)\to\mathrm{Der}(A)$. We will construct derivations $D\in\mathrm{Der}_I(B)$ and then not generally distinguish between $D\in\mathrm{Der}_I(B)$ and the corresponding $D_A\in\mathrm{Der}(A)$. D_A will be denoted by D. The conditions (5.8) impose Rels. on the α, β, $D\in\mathrm{Der}(A)$ which become the Rels. of $\mathrm{Der}(A)$.

The general structure of the $D\in\mathrm{Der}_0(A)$, as it exists for the examples $V_{q,p}(2)$, $\mathrm{SL}_q(2)$, and $V_q(3)$, is briefly discussed. $\mathrm{Der}_0(A)$ may be defined as generated by either or both of two types of derivations $D^l,D^r:B\to B$. Consider the decomposition

$$I=I_R+I_L,\quad I_L=(L(X_i))_{i=1,2,\ldots,n},\quad I_R=(R(X_i))_{i=1,2,\ldots,n}$$

of the ideal (5.5). Then Eq. (5.8) is satisfied by $\{\alpha^l,\beta^l,D^l\}$ and $\{\alpha^r,\beta^r,D^r\}$ each preserving I_L and I_R separately: $D^lI_L\subset I_L$, $D^lI_R\subset I_R$. $\alpha^lI_L\subset I_L$, $\alpha^lI_R\subset I_R$ etc. Actually, slightly more is true:

$$D^lL(X_i)=0,\quad D^lR(X_i)\in I_R, \tag{5.9a}$$

$$D^rR(X_i)=0,\quad D^rL(X_i)\in I_L. \tag{5.9b}$$

For purposes of example, as a matter of choice, we define $\mathrm{Der}_0(A)$ to include both D^l,D^r for $V_{q,p}(2)$ but only D^l for $V_q(3)$. When A is a Hopf algebra the $D^l(D^r)$ are actually left- (right-) invariant.

VI. (α,β) DERIVATIONS ON $V_{q,p}(2)$ AND $SL_q(2)$

In this section we define the FA, $A_{q,p}(2)=A$, of $V_{q,p}(2)$ and find a derivation algebra $\mathrm{Der}_0(A)$ with the structure (3.2) and (3.4). We get $\mathrm{Der}_L(H_q)$ of the Hopf FA, H_q, of $SL_q(2)$ as a special case.

A is constructed, as in Eq. (5.6), from the following free matrix bialgebra B and the antiHom $s:B\to B$:

$$B=k\langle T_{11},\ldots,T_{22}\rangle,$$

$$T^s_{11}=T_{22},\quad T^s_{22}=T_{11},\quad T^s_{12}=-pT_{12},\quad T^s_{21}=-q^{-1}T_{21},$$

with $q,p\in k$. Generally $p\neq q$; the case $p=q$ defining $SL_q(2)$ is discussed separately. The Rels. defined from s (as in Eq. (5.5)) are

$$l_{ij}=LT_{ij}=(TT^s-1)_{ij},\quad r_{ij}=RT_{ij}=(T^sT-1)_{ij},$$

where T is the matrix (T_{ij}). One Rel. is dependent. The ideals and algebras of interest corresponding to Eqs. (5.5) and (5.6) are

$$I_{q,p}\equiv I=(l_{ij},r_{ij})_{i,j=1,2},\quad I_q=I\big|_{p=q},$$

$$A=B/I,\quad H_q=B/I_q.$$

A is not a Hopf algebra, but H_q is the Hopf FA of $SL_q(2)$.

$\mathrm{Der}_0(A)$ is generated by derivations $\{\alpha^a_i,\beta^a_i,D^a_i\}:B\to B$ for $a=l,r$ and $i=1,2$ which satisfy

$$D^a_iI\subset I,\quad \alpha^a_iI\subset I,\quad \beta^a_iI\subset I. \tag{6.1}$$

They are defined on the generators of B by

$$\begin{gathered}D^l_{1,2}T_{ij}=T_{ij\pm1},\quad D^r_{1,2}T_{ij}=T_{i\pm1j},\\ \alpha^a_iT_{kl}=(\boldsymbol{\alpha}^a_i)_{kl}T_{kl},\quad \beta^a_iT_{kl}=(\boldsymbol{\beta}^a_i)_{kl}T_{kl},\end{gathered} \tag{6.2}$$

($T_{3j}=T_{i3}\equiv0$ by definition) and then extended to B by the Leibniz rule (2.2) (the scale factors $(\boldsymbol{\alpha}^a_i)_{kl},(\boldsymbol{\beta}^a_i)_{kl}\in k$). The Rels. defining $\mathrm{Der}_0(A)$ follow from Eqs. (6.1) and (3.2).

In the present case Rels. (3.2a)–(3.2d) have the form

$$\alpha^a_i\alpha^b_j=\alpha^b_j\alpha^a_i,\quad D^a_i\alpha^b_j=u^{ab}_{ij}\alpha^b_jD^a_i,\quad D^b_j\beta^a_i=u^{ab}_{ij}\beta^a_iD^b_j,\quad \text{etc.,} \tag{6.3}$$

which are obtained from the substitutions $\alpha_i\to\alpha^a_i$, $\alpha_j\to\alpha^b_j$, $\beta_i\to\beta^a_i$, $\beta_j\to\beta^b_j$, $D_i\to D^a_i$, $D_j\to D^b_j$, $t_{ij}\to u^{ab}_{ij}$, $t_{ji}\to u^{ba}_{ji}$. It is convenient to divide the discussion of Rels. (6.3) into three cases.

Case 1. Two subcases: $a=b=l$, $i=1$, $j=2$ *and* $a=b=r$, $i=1$, $j=2$. It turns out that all the constraints on the α^a_i, β^a_i, and u^{ab}_{ij} that come from Eq. (6.3) are supplied by these two subcases. The αs and βs in Eq. (6.2) are presented by the diagonal matrices ([...]=diag[...])

$$\begin{gathered}Q=[q^{1/2},q^{-(1/2)}],\quad P=[p^{1/2},p^{-(1/2)}],\\ X=[x,x^{-1}],\quad Y=[y,y^{-1}],\end{gathered} \tag{6.4}$$

where $x,y\in k$ are arbitrary parameters. Then α^a_i and β^a_i are expressed by their actions on the matrix T:

$$\begin{aligned} \alpha_1^l T &= TXQ^{-1}, \quad \beta_1^l T = QP^{-1}TPX, \\ \alpha_2^l T &= TX^{-1}P^{-1}, \quad \beta_2^l T = PQ^{-1}TQX^{-1}, \\ \alpha_1^r T &= YQ^{-1}TQP^{-1}, \quad \beta_1^r T = YPT, \\ \alpha_2^r T &= Y^{-1}P^{-1}TPQ^{-1}, \quad \beta_2^r T = Y^{-1}QT. \end{aligned} \tag{6.5}$$

$\alpha_1^a \neq \alpha_2^a$ and $\beta_1^a \neq \beta_2^a$ but they are related; for example, $\beta_1^r \beta_2^r T = PQT$. In the case of $\mathrm{SL}_q(2)$, $\alpha_1^a = \alpha_2^a$ and $\beta_1^a = \beta_2^a$.

The label $l(r)$ does not quite mean left (right) invariance in B because the associated $\beta_i^l(\alpha_i^r)$ is not left- (right)-invariant: $\Delta\beta_i^l \neq (id \otimes \beta_i^l)\Delta(\Delta\alpha_l^r \neq \alpha_i^r \otimes id)\Delta)$. Note, however, that the product $\beta_1^l \beta_2^l(\alpha_1^r \alpha_2^r)$ is left- (right)-invariant. Of course, since $\alpha_i^l(\beta_l^r)$ is left- (right)-invariant so is $\alpha_1^l \alpha_2^l(\beta_1^r \beta_2^r)$. This will make Eq. (6.11) left- or right-invariant. (Since A has no comultiplication, left and right invariance are not defined in A.)

Note the two Rels. evident from Eqs. (6.5):

$$\alpha_1^l \alpha_2^l \beta_1^l \beta_2^l = id_A, \quad \alpha_1^r \alpha_2^r \beta_1^r \beta_2^r = id_A. \tag{6.6}$$

The four structure constants in Eqs. (6.3) are

$$\begin{aligned} u_{12}^{ll} &= x^{-2}p^{-1}, \quad u_{21}^{ll} = x^{-2}q, \\ u_{12}^{rr} &= y^{-2}p^{-1}, \quad u_{21}^{rr} = y^{-2}q. \end{aligned} \tag{6.7}$$

Case 2. $a=b$, $i=j$. This is the diagonal case, $0=0$, mentioned in the discussion of Eq. (3.2) as not required and not assumed. Nevertheless, the following ''voluntary'' commutation Rels. exist:

$$D_i^a \alpha_i^a = u_i^a \alpha_i^a D_i^a, \quad D_i^a \beta_i^a = v_i^a \beta_i^a D_i^a; \quad a = l,r; \quad i = 1,2. \tag{6.8}$$

Note that Eq. (6.3) would have required $u_i^a = v_i^a$. However, $u_i^a \neq v_i^a$:

$$\begin{aligned} u_1^l &= v_2^l = x^2 q^{-1}, \quad u_2^l = v_1^l = x^2 p, \\ u_1^r &= v_2^r = y^2 q^{-1}, \quad u_2^r = v_1^r = y^2 p. \end{aligned} \tag{6.9}$$

Case 3. $a \neq b$. Here the conditions that make $[D_i^l, D_j^r]$ a derivation are already implied by Eq. (6.5). The structure constants are

$$\begin{aligned} u_{11}^{lr} = u_{22}^{lr} = qp^{-1}, \quad u_{12}^{lr} = u_{21}^{lr} = pq^{-1}, \\ u_{11}^{rl} = u_{12}^{rl} = u_{21}^{rl} = u_{22}^{rl} = 1. \end{aligned} \tag{6.10}$$

$[D_i^l, D_j^r]$ is a zero derivation (recorded in Eq. (6.11)). This completes the discussion of Eq. (6.3).

From the discussion of Eq. (3.2) and the above results, $[D_1^a, D_2^a]$ is an $(\alpha_1^a \alpha_2^a, \beta_1^a \beta_2^a)$-D, in fact one of the form (3.4):

$$[D_1^a, D_2^b] = \delta^{ab}(\alpha_1^a \alpha_2^b - \beta_1^a \beta_2^b)/((pq)^{1/2} - (pq)^{-(1/2)}). \tag{6.11}$$

The above results are summarized in the definition of the following derivation algebra of A and the two subalgebras;

$$\mathrm{Der}_0(A) = k\langle \alpha_i^a, \beta_i^a, D_i^a \rangle_{a=1,r,i=1,2}, \quad \mathrm{Der}_0^a(A) = k\langle \alpha_i^a, \beta_i^a, D_i^a \rangle_{i=1,2}, \quad a = l,r,$$

whose Rels. include all those of the form (3.2). Explicitly, the Rels. for $\mathrm{Der}_0(A)$ are Eq. (6.3) with structure constants (6.7) and (6.10), Rels. (6.8) with structure constants (6.9), Rels. (6.6) and (6.11) and Rels of the form (3.2a) and (3.2d). The Rels. for the subalgebras are the appropriate subsets. (Here, $x,y\in k$ are considered to have single fixed values, so $\mathrm{Der}_0(A)$ is finitely generated.) $\mathrm{Der}_0^l(A)$ and $\mathrm{Der}_0^r(A)$ do not commute (see Eq. (6.10)) because α_i^r and β_i^l act both on the right and left.

Here we note a phenomenon mentioned in Sec. II; two different derivations can act identically on generators. The first is the $(\alpha_1^l\alpha_2^l,\beta_1^l\beta_2^l)$-D in Eq. (6.11). The second is an (id,id)-D, D_3^l. Both give $T_{ij}\rightarrow(-1)^jT_{ij}$. The analogous situation holds for $a=b=r$.

The case of $SL_q(2)$. Consider the case $p=q$ when $A=H_q$, the Hopf FA of $\mathrm{SL}_q(2)$. Unlike A, comultiplication exists for H_q and left, right invariance in H_q can be considered. Then $\mathrm{Der}_0(H_q)=\mathrm{Der}_0(A)|_{p=q}$ decomposes into two commuting subalgebras:

$$\mathrm{Der}_0(H_q)=\mathrm{Der}_0^l(H_q)\cdot\mathrm{Der}_0^r(H_q).$$

Consider one of the subalgebras, say $\mathrm{Der}_0^l(H_q)$, and choose a subset of derivations with $\alpha_1^l\beta_1^l=\alpha_2^l\beta_2^l=id$. This implies that $x=1$ in Eq. (6.4) and that $\alpha_1^l=\alpha_2^l$ and $\beta_1^l=\beta_2^l$. For simplicity, the generators are renamed: $D_1^l=D_+$, $D_2^l=D_-$, $\alpha_1^l=\alpha$, and $\beta_1^l=\beta$. Then, the following algebra and relations are obtained:

$$\mathrm{Der}_L(H_q)=\mathrm{Der}_0^l(H_q)|_{x=1}=k\langle D_+,D_-,\alpha,\beta\rangle,$$

$$\alpha\beta=id,\quad \alpha\beta=\beta\alpha,\quad \alpha D_\pm\beta=q^{\pm1}D_\pm, \tag{6.12}$$

$$[D_+,D_-]=\frac{\alpha^2-\beta^2}{q-q^{-1}},$$

with the Hopf algebra operations (3.6), (3.7), and (3.9).

Connection with $U_q(\mathrm{sl}(2))$. The two rational forms of $U_q(\mathrm{sl}(2))$ (Ref. 11, p. 281) can be constructed from $\mathrm{Der}_L(H_q)$. The *simply connected form P* is the algebra generated by the two derivations, $E_+=q^{1/2}\beta D_+$ and $E_-=q^{-(1/2)}D_-\alpha$, and the (renamed) Homs $\alpha=a$ and $\beta=b$:

$$\mathrm{Der}_L^P(H_q)=k\langle E_+,E_-,a,b\rangle\cong U_q^P(\mathrm{sl}(2)). \tag{6.13}$$

The Rels. have the same form as those of $\mathrm{Der}_L(H_q)$ in Eq. (6.12). However, E_+ is an (id,b^2)-D and E_- is a (a^2,id)-D, so the Hopf algebra operations found from Eqs. (3.6), (3.7), and (3.9) are altered accordingly. The factors $q^{\pm(1/2)}$ are just to make $E_\pm$ agree with $D_\pm$ on the generators T_{ij}. The *adjoint form Q* is defined by taking $E_\pm$, $A=\alpha^2$, and $B=\beta^2$ as generators. The algebra and relations are

$$\mathrm{Der}_L^Q(H_q)=k\langle E_+,E_-,A,B\rangle\cong U_q^Q(\mathrm{sl}(2)),$$

$$AB=id,\quad AB=BA,\quad AE_\pm B=q^{\pm2}E_\pm, \tag{6.14}$$

$$[E_+,E_-]=\frac{A-B}{q-q^{-1}}.$$

E_+ is an (id,B)-D and E_- is an (A,id)-D, and the Hopf algebra operations are again determined accordingly.

Note that the adjoint form can also be obtained from $\mathrm{Der}_0^l(H_q)|_{x=p=q}\cong\mathrm{Der}_L^Q(H_q)$, i.e., $\alpha_1^l=id$, $\beta_2^l=id$ in Eq. (6.5). Note also that the simply connected form P can be considered to be the extension of the adjoint form Q by ''square-root'' generators $\sqrt{A}=a$, $\sqrt{B}=b$,[11]

$$\mathrm{Der}_L^P(H_q)=\mathrm{Der}_L^Q(H_q)\langle a,b\rangle,$$

with the appropriate change to Rels. involving a,b. This is used to obtain the simply connected form of $U_q(\mathrm{sl}(3))$ in Sec. VII.

An example of $Der_{\triangleright}(H_q)$. As a follow-up to the *comment on* [,] near the end of Sec. III, $\mathrm{Der}_{\triangleright}(H_q)$ for $\mathrm{SL}_q(2)$ is presented here and shown to have the adjoint form. Let F_i be a left-invariant (a_i,b_i)-D, $i=1,2$, where F_1,F_2 act on the generators of H_q as $D_{\pm}$ in Eq. (6.12) do. In this example it is assumed that the adjoint action

$$F_1\triangleright F_2=a_1[a_1^{-1}F_1,F_2]b_1^{-1} \tag{6.15}$$

is a derivation. Equivalently (by example (4) of Sec. II), the *deformed* commutator $[a_1^{-1}F_1,F_2]$ is a derivation. Because $a_1^{-1}F_1$ is an $(id,a_1^{-1}b_1)$-D, the derivation conditions (3.2c) are $t_{21}=1$ and $F_1b_2=b_2F_1$, which implies $b_2=id$. This determines a_2: $a_2T_{i1}=q^{-1}T_{i1}$ and $a_2T_{i2}=qT_{i2}$. a_1 is still undetermined; if $a_1=id$ is chosen (only to simplify the following isomorphism), then $b_1=a_2^{-1}$ and $\mathrm{Der}_{\triangleright}(H_q)$ has the familiar form (6.14). In fact, the map $F_1\to E_+$, $F_2\to E_-$, $a_2\to A$, $b_1\to B$ gives the isomorphism

$$\mathrm{Der}_{\triangleright}(H_q)=k\langle F_1,F_2,a_2,b_1\rangle\simeq\mathrm{Der}_L^Q(H_q).$$

Thus, the *adjoint action* gives the *adjoint form*.

Let ''$\triangleleft$'' be defined analogously to ''$\triangleright$'': $F'\triangleleft F=\iota(F_{(1)})F'F_{(2)}$, where $\Delta(F)=F_{(1)}\otimes F_{(2)}$ and ι is the antipode. Then, in contrast to Eq. (6.15), $F_1\triangleleft F_2=a_2^{-1}[F_1,F_2b_2^{-1}]b_2$. The derivation Hopf algebras resulting from the other adjoint actions, $-F_2\triangleleft F_1$, $F_1\triangleleft F_2$, and $-F_2\triangleright F_1$, all turn out to be isomorphic to $\mathrm{Der}_{\triangleright}(H_q)$, which was defined from $F_1\triangleright F_2$ in Eq. (6.15).

VII. DERIVATIONS OF $\mathrm{SL}_q(3)$ AND $V_q(3)$

The purpose of this section is to see how the picture of derivations in Sec. VI extends to higher dimensions. We find derivation algebras $\mathrm{Der}_L(H_q)$ on the Hopf FA $H_q(3)=H_q$ of $\mathrm{SL}_q(3)$ and $\mathrm{Der}_0(A)$ on a nonHopf FA $A_q(3)=A$ of $V_q(3)$. It is shown how $\mathrm{Der}_L(H_q)$ is related to $U_q(\mathrm{sl}(3))$. $V_q(3)$ is a deformation of SL(3) and, like $V_{q,p}(2)$, does not correspond to a quantum group. $\mathrm{Der}_0(A)$ is generated by a set $\{\alpha^l,\beta^l,D^l\}$ with the structure of Eq. (5.9a).

Defining H_q according to Eq. (5.7) requires a lengthy discussion which will not be given. A has the form (5.6). H_q and A are presented first; then $\mathrm{Der}_L(H_q)$ and $\mathrm{Der}_0(A)$.

The Hopf algebra H_q *of* $\mathrm{SL}_q(3)$. Although H_q is well known[5] it is stated here for convenience. H_q is a quotient of the bialgebra

$$B=k\langle T_{11},\ldots,T_{33}\rangle,\quad H_q=B/I_q, \tag{7.1}$$

where $I_q\subset B$ is the ideal generated by the Rels.:

$$\begin{aligned}
&T_{ij}T_{il}-q^{-1}T_{il}T_{ij},\quad l>j,\\
&T_{ij}T_{kj}-q^{-1}T_{kj}T_{ij},\quad i<k,\\
&T_{il}T_{kj}-T_{kj}T_{il},\quad i<k,\quad l>j,\\
&[T_{il},T_{kj}]-(q-q^{-1})T_{ij}T_{kl},\quad i>k,\quad l>j,\\
&\sum T_{1i_1}T_{2i_2}T_{3i_3}(-q^{-1})^{l(i_1i_2i_3)}-1.
\end{aligned} \tag{7.2}$$

The antipode derives from the antiautomorphism $s:B\to B$ defined by

$$T_{ij}^s=(-q^{-1})^{i-j}\det_q T(ji), \tag{7.3}$$

where $T(ij)$ is the 2×2 matrix obtained by deleting the ith row and jth column of the 3×3 matrix $T=(T_{ij})$.

The algebra A. A is defined from B in Eq. (7.1) and s in Eq. (7.3) as an example of Eqs. (5.5) and (5.6):

$$\begin{aligned} &L(T)=TT^s-1, \quad R(T)=T^sT-1, \\ &I=(L(T),R(T)), \quad A=B/I. \end{aligned} \tag{7.4}$$

Relations in (7.4) are implied by those of Eq. (7.2) giving $I\subset I_q$.

Derivations on H_q. Left-invariant derivations $\{\alpha_\mu^\pm,\beta_\mu^\pm,D_\mu^\pm\}$, $\mu=1,2$ on B are defined on the generators by

$$D_1^+T_{i1}=T_{i2}, \quad D_1^-T_{i2}=T_{i1}, \quad D_2^+T_{i2}=T_{i3}; \quad D_2^-T_{i3}=T_{i2}, \tag{7.5}$$

$$\alpha_\mu^\pm T_{ij}=(\boldsymbol{\alpha}_\mu^\pm)_jT_{ij}, \quad \beta_\mu^\pm T_{ij}=(\boldsymbol{\beta}_\mu^\pm)_jT_{ij} \tag{7.6}$$

for $i,j=1,2,3$ and extended to B by the Leibniz rule. The scale factors $(\boldsymbol{\alpha}_\mu^\pm)_j$, $(\boldsymbol{\beta}_\mu^\pm)_j\in k$ define diagonal matrices, and Eq. (7.6) can be written as $\alpha_\mu^\pm T=T\boldsymbol{\alpha}_\mu^\pm$, $\beta_\mu^\pm T=T\boldsymbol{\beta}_\mu^\pm$. These $\{\alpha_\mu^\pm,\beta_\mu^\pm,D_\mu^\pm\}$ define derivations on H_q if they satisfy the ideal conditions

$$D_\mu^\pm I_q\subset I_q, \quad \alpha_\mu^\pm I_q\subset I_q, \quad \beta_\mu^\pm I_q\subset I_q. \tag{7.7}$$

The last two conditions of Eq. (7.7) give

$$\det\,\boldsymbol{\alpha}_\mu^\pm=1, \quad \det\,\boldsymbol{\beta}_\mu^\pm=1, \tag{7.8}$$

which follow from the last Rel. of Eq. (7.2). The other Rels. of Eq. (7.2) are already preserved by the Ansatz (7.6).

The first condition of Eq. (7.7), after some calculation, implies

$$\boldsymbol{\alpha}_1^\pm=[q^{-1},q,1]\boldsymbol{\beta}_1^\pm, \quad \boldsymbol{\alpha}_2^\pm=[1,q^{-1},q]\boldsymbol{\beta}_2^\pm, \tag{7.9}$$

where [...] indicates a diagonal matrix.

From the derivations $\{\alpha_\mu^\pm,\beta_\mu^\pm,D_\mu^\pm\}$ satisfying, Eqs. (7.8) and (7.9), we choose a subset normalized by

$$\alpha_\mu^\pm\beta_\mu^\pm=id\Leftrightarrow\boldsymbol{\alpha}_\mu^\pm\boldsymbol{\beta}_\mu^\pm=\mathbb{1}, \quad \mu=1,2, \tag{7.10}$$

where $\mathbb{1}$ is the 3×3 identity matrix. These imply that $\alpha_\mu^+=\alpha_\mu^-\equiv\alpha_\mu$ and $\beta_\mu^+=\beta_\mu^-\equiv\beta_\mu$, which are then represented by the diagonal matrices

$$\begin{aligned} &\boldsymbol{\alpha}_1=[q^{-(1/2)},q^{1/2},1], \quad \boldsymbol{\beta}_1=\boldsymbol{\alpha}_1^{-1}, \\ &\boldsymbol{\alpha}_2=[1,q^{-(1/2)},q^{1/2}], \quad \boldsymbol{\beta}_2=\boldsymbol{\alpha}_2^{-1}. \end{aligned} \tag{7.11}$$

Derivations $\{\alpha_\mu,\beta_\mu,D_\mu^\pm\}$ defined by Eq. (7.11) form a ''basis'' in the following sense. A derivation $\{\alpha_\mu^\pm,\beta_\mu^\pm,D_\mu^\pm\}$ defined only by Eqs. (7.8) and (7.9) can be written in terms of a derivation $\{\alpha_\mu,\beta_\mu,D_\mu^\pm\}$ defined by Eq. (7.11) as $\{\phi_\mu^\pm\circ\alpha_\mu,\phi_\mu^\pm\circ\beta_\mu,c_\mu^\pm\phi_\mu^\pm\circ D_\mu^\pm\}$ where $\phi_\mu^\pm:H_q\to H_q$ is some left-invariant algebra automorphism of the type (7.6), and $c_\mu^\pm\in k$ is a multiplication factor. It is also possible to write $c_\mu'^\pm D_\mu^\pm\circ\phi_\mu^\pm$.

The basis derivations define the following algebra and Rels:

$$\begin{gathered}\mathrm{Der}_L(H_q)=k\langle D_\mu^{\pm},\alpha_\mu,\beta_\mu\rangle,\\ \alpha_\mu\beta_\mu=\beta_\mu\alpha_\mu=id,\quad \alpha_\mu\alpha_\nu=\alpha_\nu\alpha_\mu,\\ \alpha_\nu D_\mu^{\pm}\beta_\nu=q^{\pm A_{\mu\nu}}D_\mu^{\pm},\quad [D_\mu^{+},D_\nu^{-}]=\delta_{\mu\nu}\frac{\alpha_\mu^2-\beta_\mu^2}{q-q^{-1}},\\ D_\mu^{\pm 2}D_\nu^{\pm}-(q+q^{-1})D_\mu^{\pm}D_\nu^{\pm}D_\mu^{\pm}+D_\nu^{\pm}D_\mu^{\pm 2}=0,\quad \mu\neq\nu,\end{gathered}\tag{7.12}$$

where $A_{\mu\nu}=\frac{1}{2}a_{\mu\nu}$ and $a_{\mu\nu}$ is the Cartan matrix for the Lie algebra A_2. The last Rels. are proved by showing that the left-hand side is an $(\alpha_\mu^2\alpha_\nu,\beta_\mu^2\beta_\nu)$-D which is zero on the generators T_{ij}. $\mathrm{Der}_L(H_q)$ has the Hopf algebra operations corresponding to Eqs. (3.6), (3.7), and (3.9).

Connection with $U_q(\mathrm{sl}(3))$. Here, two *rational forms* of $U_q(\mathrm{sl}(3))$ are constructed from $\mathrm{Der}_L(H_q)$.[11] Let us define the derivations and Homs, $E_\mu^{+}=q^{1/2}\beta_\mu D_\mu^{+}$, $E_\mu^{-}=q^{-(1/2)}D_\mu^{-}\alpha_\mu$, $A_\mu=\alpha_\mu^2$, and $B_\mu=\beta_\mu^2$. Then the *adjoint rational form* Q is given by (compare Eq. (6.14))

$$\mathrm{Der}_L^{Q}(H_q)=k\langle E_\mu^{\pm},A_\mu,B_\mu\rangle_{\mu=1,2}\cong U_q^{Q}(\mathrm{sl}(3)).$$

E_μ^{+} is an (id,B_μ)-D and E_μ^{-} is an (A_μ,id)-D with the corresponding Hopf algebra operations, deduced from Eqs. (3.6), (3.7), and (3.9). The factors $q^{\pm(1/2)}$ make $E_\mu^{\pm}$ agree with $D_\mu^{\pm}$ on the generators T_{ij}. $\mathrm{Der}_L(H_q)$ is not a *rational form* [$q^{1/2}$ in Eq. (7.12)] of $U_q(\mathrm{sl}(3))$. ($\mathrm{SL}_q(2)$ is a special case; $\mathrm{Der}_L(H_q(2))$ is rational because $\frac{1}{2}a_{11}=1$.)

To obtain the *simply connected rational form* P, define the left-invariant automorphisms a_μ,b_μ, represented, as in Eq. (7.11), by

$$\boldsymbol{a}_1=[q^{-(2/3)},q^{1/3},q^{1/3}],\quad \boldsymbol{b}_1=\boldsymbol{a}_1^{-1},\quad \boldsymbol{a}_2=[q^{-(1/3)},q^{-(1/3)},q^{2/3}],\quad \boldsymbol{b}_2=\boldsymbol{a}_2^{-1}.$$

Then the form P is the extension of the form Q by a_μ,b_μ:

$$\mathrm{Der}_L^{P}(H_q)=k\langle E_\mu^{\pm},a_\mu,b_\mu\rangle_{\mu=1,2}\cong U_q^{P}(\mathrm{sl}(3)).$$

E_μ^{+} is an $(id,b_\mu^2a_\nu)$-D and E_μ^{-} is an $(a_\mu^2b_\nu,id)$-D, $\mu\neq\nu$, with the corresponding operations of Eqs. (3.6), (3.7), and (3.9). The Rels. can be obtained from those of $\mathrm{Der}_L(H_q)$ by the following replacements in Eq. (7.12): $\alpha_\mu\to a_\mu$ and $\beta_\mu\to b_\mu$ in the first three Rels.; $A_{\mu\nu}\to\delta_{\mu\nu}$; $\alpha_\mu^2\to a_\mu^2b_\kappa$ and $\beta_\mu^2\to b_\mu^2a_\kappa$, $\mu\neq\kappa$, in the next to last Rels.

We end the discussion of H_q with a comment that is relevant in comparing $\mathrm{Der}_L(H_q)$ with $\mathrm{Der}_0(A)$. Derivations on H_q of the form

$$D_3^{+}T_{i1}=T_{i3},\quad D_3^{-}T_{i3}=T_{i1}\tag{7.13}$$

do not exist. There are no algebra automorphisms $\alpha_3^{\pm}$, $\beta_3^{\pm}$ on H_q (at least of the form (7.6)) such that $D_3^{\pm}$ is an $(\alpha_3^{\pm},\beta_3^{\pm})$-D. The k-Homs $[D_2^{\pm},D_1^{\pm}]$ act like $\pm D_3^{\pm}$ on generators, but they are not derivations. (Of course, in the SL(3) limit $q\to1$, $[D_2^{\pm},D_1^{\pm}]$ and $\pm D_3^{\pm}$ both become derivations which are equal to each other.) Derivations of the type $D_3^{\pm}$ do exist on A, to which we now turn.

Derivations on A. Here $\mathrm{Der}_0(A)$ is similar to but larger than $\mathrm{Der}_L(H_q)$. Actually $\mathrm{Der}_0(A)$ has a subalgebra isomorphic to $\mathrm{Der}_L(H_q)$. Thus, we build on the results for H_q and use the same notation for this subalgebra.

Derivations (7.5) and (7.6) also exist on A because the conditions

$$D_\mu^{\pm}I\subset I,\quad \alpha_\mu^{\pm}I\subset I,\quad \beta_\mu^{\pm}I\subset I,\tag{7.14}$$

are less restrictive than those in Eq. (7.7). In fact, the same formulas (7.8) and (7.9) are implied by the conditions (7.14). Conditions (7.10) again give $\alpha_\mu^{\pm}=\alpha_\mu$ and $\beta_\mu^{\pm}=\beta_\mu$ on A which satisfy

$\alpha_\mu\beta_\mu = id$. Then we arrive at derivations on A, $\{\alpha_\mu,\beta_\mu,D_\mu^\pm\}$, which satisfy the Rels. (7.12). The new results are first stated, and then a few comments are made about how they are derived.

Derivations $D_3^\pm$ in Eq. (7.13), the new feature of A, deviate from the pattern of $D_1^\pm$ and $D_2^\pm$. After choosing a basis with

$$\alpha_3^\pm \beta_3^\pm = \beta_3^\pm \alpha_3^\pm = id_A, \tag{7.15}$$

$D_3^\pm$ is an $(\alpha_3^\pm,\beta_3^\pm)$-D, where $\alpha_3^\pm,\beta_3^\pm$ are represented by the diagonal matrices

$$\begin{aligned} \boldsymbol{\alpha}_3^+ &= [q^{-(3/2)},q,q^{1/2}], \quad \boldsymbol{\beta}_3^+ = (\boldsymbol{\alpha}_3^+)^{-1}, \\ \boldsymbol{\alpha}_3^- &= [q^{-(1/2)},q^{-1},q^{3/2}], \quad \boldsymbol{\beta}_3^- = (\boldsymbol{\alpha}_3^-)^{-1}, \end{aligned} \tag{7.16}$$

which act on T by matrix multiplication on the right as in Eq. (7.6). The Rels. satisfied by $\{\alpha_3^\pm,\beta_3^\pm,D_3^\pm\}$ are

$$\begin{gathered} \alpha_\mu\alpha_3^\pm = \alpha_3^\pm\alpha_\mu, \qquad \alpha_3^+\alpha_3^- = \alpha_3^-\alpha_3^+, \\ \alpha_3^a D_3^\pm \beta_3^a = q^{\pm 2} D_3^\pm, \qquad a = +,-, \\ \alpha_\mu D_3^\pm \beta_\mu = q^{\pm(1/2)} D_3^\pm, \qquad \mu = 1,2, \\ \alpha_3^a D_\mu^\pm \beta_3^a = q^{\pm A_{\mu a}} D_\mu^\pm, \quad A_{1+} = A_{2-} = \tfrac{5}{2}, \quad A_{1-} = A_{2+} = -\tfrac{1}{2}, \\ [D_3^+,D_3^-] = \frac{\alpha_3^+\alpha_3^- - \beta_3^+\beta_3^-}{q^2 - q^{-2}}, \\ [D_2^+,D_3^+] = 0, \quad [D_1^-,D_3^-] = 0. \end{gathered} \tag{7.17}$$

These results are summarized in the derivation algebra

$$\mathrm{Der}_0(A) = k\langle \alpha_\mu,\beta_\mu,D_\mu^\pm,\alpha_3^\pm,\beta_3^\pm,D_3^\pm\rangle_{\mu=1,2},$$

which satisfies the Rels. (7.15) and (7.17) as well as the Rels. of $\mathrm{Der}_L(H_q)$ in Eq. (7.12). $\mathrm{Der}_0(A)$ is a Hopf algebra, with operations of the form (3.6), (3.7), and (3.9).

Comment: The extra $(\alpha_3^\pm,\beta_3^\pm)$-Ds $D_3^\pm$, existing on A but not on H_q, reflect the fact that $I \subset I_q$ and $D_3^\pm$ have to satisfy fewer Rels. in I than in I_q. This is not general, but specific to this case. There could be a situation where $I_2 \subset I_1$ and $DI_1 \subset I_1$ but $DI_2 \not\subset I_2$. Then D would define a derivation on $A_1 = B/I_1$ but not on $A_2 = B/I_2$.

We now indicate how the above results leading to $\mathrm{Der}_0(A)$ were derived. As in Eq. (7.8) the last two conditions of Eq. (7.14) imply

$$\det \boldsymbol{\alpha}_\mu^\pm = 1, \quad \det \boldsymbol{\beta}_\mu^\pm = 1, \quad \mu = 1,2,3,$$

which in turn help to determine the action of α,β on T^s:

$$\alpha_\mu^\pm(T_{ij}^s) = (\boldsymbol{\alpha}_\mu^\pm)_i^{-1}(T_{ij}^s), \quad \beta_\mu^\pm(T_{ij}^s) = (\boldsymbol{\beta}_\mu^\pm)_i^{-1}(T_{ij}^s). \tag{7.18}$$

The conditions $D_\mu^\pm I \subset I$, $\mu = 1,2,3$, correspond to Eq. (5.9a). They are

$$T^\alpha T^{Ds} + T^D T^{\beta s} = 0, \quad T^{\alpha s} T^D + T^{Ds} T^\beta \in (T^s T - 1),$$

whose entries are homogeneous third degree polynomials in T_{ij}. These equations are equivalent to the following simpler ones:

$$D_1^+(T_{2j}^s)=-q^{-1}(\boldsymbol{\beta}_1^+)_3T_{1j}^s,\quad D_1^-(T_{1j}^s)=-q(\boldsymbol{\beta}_1^-)_3T_{2j}^s,$$

$$D_2^+(T_{3j}^s)=-q^{-1}(\boldsymbol{\beta}_2^+)_1T_{2j}^s,\quad D_2^-(T_{2j}^s)=-q(\boldsymbol{\beta}_2^-)_1T_{3j}^s,$$

$$D_3^+(T_{3j}^s)=-q^{-1}(\boldsymbol{\beta}_3^+)_2T_{1j}^s,\quad D_3^-(T_{1j}^s)=-q(\boldsymbol{\beta}_3^-)_2T_{3j}^s.$$

$D_\mu^\pm(T_{ij}^s)=0$ otherwise. Equations (7.18) were used in deriving these. Finally, to complete the discussion of $\mathrm{Der}_0(A)$, basis derivations satisfying $\alpha_\mu\beta_\mu=id$ and Eq. (7.15) have the solutions (7.11) and (7.16).

The results for $\mathrm{SL}_q(3)$ and $V_q(3)$ (i.e., $\mathrm{Der}_L(H_q)$ and $\mathrm{Der}_0(A)$) suggest the following conjectures.

(1) For the Hopf FA, $H_q(n)$, of $\mathrm{SL}_q(n)$, left-invariant derivations, $\{\alpha_\mu^\pm,\beta_\mu^\pm,D_\mu^\pm\}$, exist for the $\pm$ simple roots $i=1,\ldots,n-1$ of $sl(n)$. There are basis derivations, $\{\alpha_\mu,\beta_\mu,D_\mu^\pm|i=1,\ldots,n-1\}$, satisfying $\alpha_i\beta_i=id$. They generate $\mathrm{Der}_L(H_q(n))$ from which the adjoint form can be defined: $\mathrm{Der}_L^Q(H_q(n))\cong U_q^Q(sl(n))$. ''$n$th root'' Homs a_μ on $H_q(n)$ exist and give the simply connected form, $\mathrm{Der}_L^P(H_q(n))\equiv k\langle D_\mu^\pm,a_\mu,b_\mu\rangle\cong U_q^P(sl(n))$, as an extension.

(2) Let $V_q(n)$, $n>3$, be defined in analogy to $V_q(3)$ as the FA $A(n)=B(n)/I(n)$ where $I(n)=(T^sT-1,TT^s-1)$ with T the $n\times n$ matrix of generators T_{ij} of the matrix bialgebra $B(n)$ and s the antiHom of $B(n)$ generalizing Eq. (7.3). Then there are (α,β)-Ds on $A(n)$,

$$\{\alpha_i,\beta_i,D_i^\pm,\alpha_j^\pm,\beta_j^\pm,D_j^\pm|i=1,\ldots,n-1;\ \ j=n,\ldots,n(n-1)/2\},$$

where the (α_i,β_i) correspond to the simple roots of $sl(n)$, and the $(\alpha_j^\pm,\beta_j^\pm)$ to the nonsimple roots.

(3) Some form of (1) and (2) generalize to all simple Lie groups.

VIII. GENERAL DERIVATIONS: THE QUANTUM PLANE AND $\mathrm{SL}_q(2)$

In this section some general (α,β)-Ds are defined on the FA of $\mathrm{SL}_q(2)$ and the quantum plane. The usual quantum plane is

$$A=k\langle X,Y\rangle/I,\quad I=(XY-q^{-1}YX) \tag{8.1}$$

for which we give an infinitely generated Hopf algebra and two finitely generated subalgebras Der_0. Also Der_0 algebras on a different quantum plane are given in examples (4) and (5). They are isomorphic to Euclidean and Heisenberg quantum groups, respectively.

The results are presented in the following six examples.

(1) *An infinitely generated algebra of* (α,β) *derivations*. Derivations on the generators of $k\langle X,Y\rangle$ are defined by

$$E_{mn}X=q^{(1/2)n(m+1)}X^{m+1}Y^n,\quad E_{mn}Y=0,\quad m\geqslant -1,n\geqslant 0,$$

$$F_{mn}Y=q^{(1/2)m(n+1)}X^mY^{n+1},\quad F_{mn}X=0,\quad n\geqslant -1,\quad m\geqslant 0,$$

$$\alpha_{mn}X=q^{(1/2)n}X,\quad \alpha_{mn}Y=q^{-(1/2)m}Y,$$

$$\beta_{mn}X=q^{-(1/2)n}X,\quad \beta_{mn}Y=q^{(1/2)m}Y.$$

E_{mn} and F_{mn} are (α_{mn},β_{mn})-Ds on A (for which we use the same notation) because they preserve the ideal I in the sense of Eq. (5.8).

Der(A) is the associative algebra generated by the infinite set $\{\alpha_{mn},\beta_{mn},E_{mn},F_{mn}\}$. Der($A$) has the following Rels.:

$$\alpha_{00}=id_A,\quad \alpha_{mn}\beta_{mn}=\beta_{mn}\alpha_{mn}=id_A,$$

$$\alpha_{mn}\alpha_{m'n'}=\alpha_{m+m',n+n'},\quad \beta_{mn}\beta_{m'n'}=\beta_{m+m',n+n'},$$

$$\alpha_{mn}E_{m'n'}\beta_{mn}=q^{1/2(m'n-mn')}E_{m'n'},$$

$$\alpha_{mn}F_{m'n'}\beta_{mn}=q^{1/2(m'n-mn')}F_{m'n'},$$

$$[E_{mn},\ E_{m'n'}]=(m'-m)E_{m+m',n+n'},$$

$$[F_{mn},\ F_{m'n'}]=(n'-n)F_{m+m',n+n'},$$

$$[E_{mn},\ F_{m'n'}]=m'F_{m+m',n+n'}-nE_{m+m',n+n'}.$$

These Rels. are verified, according to the discussion in Sec. III, by acting on the generators X,Y. The Rels. $\alpha E\beta=qE$ equate derivations of the same type, and they guarantee that the commutators, $[E,E]$, are derivations, which can then be checked on X,Y.

(2) *A Hopf algebra* $Der_0(A)\cong U_q(sl(2))$. Let $\mathrm{Der}_0(A)$ denote the algebra generated by the following two (α,β)-Ds on A:

$$D_1X=Y,\quad D_1Y=0,\quad D_2Y=X,\quad D_2X=0,$$

$$\alpha X=q^{-(1/2)}X,\quad \alpha Y=q^{1/2}Y,\quad \beta X=q^{1/2}X,\quad \beta Y=q^{-(1/2)}Y.$$

$\mathrm{Der}_0(A)$ is isomorphic to $U_q(sl(2))$ (see $\mathrm{Der}_L(H_q)$ in Eq. (6.12)). It is not a subalgebra of Der(A) defined above.

(3) *A Euclidean quantum group.* Let $\mathrm{Der}_0^E(A)=k\langle D_1,D_2,\alpha,\beta\rangle$ be defined by its action on the quantum plane (8.1):

$$D_1X=1,\quad D_1Y=0,\quad D_2X=0,\quad D_2Y=1,$$

$$\alpha X=q^{-(1/2)}X,\quad \alpha Y=q^{1/2}Y,\quad \beta X=q^{1/2}X,\quad \beta Y=q^{-(1/2)}Y.$$

$\mathrm{Der}_0^E(A)$ is a Hopf algebra with the Rels.

$$\alpha\beta=id_A,\quad \alpha\beta=\beta\alpha,$$

$$\alpha D_1\beta=q^{1/2}D_1,\quad \alpha D_2\beta=q^{-(1/2)}D_2,$$

$$[D_1,D_2]=0.$$

The derivation conditions are satisfied, and the commutator $[D_1,D_2]$ is the zero (α,β)-D. $\mathrm{Der}_0^E(A)$ is a quantum deformation of the Euclidean group of the plane. Namely, set $\alpha=\beta^{-1}=q^K$ and take the limit $q\to1$. Then $\{K,D_1,D_2\}$ generates the Lie algebra of the Euclidean group of the two-dimensional plane.

(4) *A second Euclidean quantum group.* This example is the Euclidean quantum group, which was found as a contraction of $\mathrm{SU}_q(2)$ and was called $E(2)_q$.[12] Here $E(2)_q$ is presented as an algebra of (α,β)-Ds. For ease of comparison the notation of Ref. 12 is used here.

Define another quantum plane different from Eq. (8.1),

$$A_\xi = k\langle X,Y\rangle / I, \quad I = (XY - YX + \xi Y), \tag{8.2}$$

and two (α,β)-Ds, P_y and J, by their action on A_ξ:

$$P_y X = 0, \quad P_y Y = 1, \quad JX = iY, \quad JY = -iX,$$

$$\alpha X = X - \frac{\xi}{2}, \quad \alpha Y = Y, \quad \beta X = X + \frac{\xi}{2}, \quad \beta Y = Y.$$

These generate the algebra $\mathrm{Der}_0^E(A_\xi) = k\langle P_y, J, \alpha, \beta\rangle$ with Rels.

$$\alpha\beta = \beta\alpha = id, \quad \alpha P_y \beta = P_y, \quad \alpha J \beta = J + \frac{i\xi}{2} P_y,$$

$$[J, P_y] = \frac{i}{2\xi}(\alpha^2 - \beta^2).$$

The derivation Rels. (3.2b) and (3.2c) (compare Eq. (3.10a)) which generally have been valid in this work do not hold here for J and P_y. Nevertheless, $[J, P_y]$ is an (α^2,β^2)-D of the form (3.10b). This demonstrates the case where the last four terms in Eq. (3.1) do not cancel pairwise as a consequence of Eqs. (3.2b) and (3.2c); nevertheless, they do cancel.

The isomorphism $\mathrm{Der}_0^E(A_\xi) \cong E(2)_q$ is established by introducing an (id,id)-D P_x and expressing $\mathrm{Der}_0^E(A_\xi)$ in terms of P_x:

$$P_x X = 1, \quad P_x Y = 0, \quad \alpha = e^{-(1/2)\xi P_x}, \quad \beta = e^{(1/2)\xi P_x}.$$

(5) *Heisenberg quantum group.* The Heisenberg quantum group $H(1)_q$ has also been found as a contraction of $\mathrm{SU}_q(2)$.[12] Here $H(1)_q$ is presented as an algebra of (α,β)-Ds acting on the quantum plane (8.2). Define two (α,β)-Ds a, a^+ by

$$aX = 0, \quad aY = 1, \quad a^+ X = Y, \quad a^+ Y = 0,$$

$$\alpha X = X - \frac{\xi}{2}, \quad \alpha Y = Y, \quad \beta X = X + \frac{\xi}{2}, \quad \beta Y = Y.$$

The algebra $\mathrm{Der}_0^H(A_\xi) = k\langle a, a^+, \alpha, \beta\rangle$ has the Rels.

$$\alpha\beta = \beta\alpha, \quad \alpha\beta = id, \quad \alpha a \beta = a, \quad \alpha a^+ \beta = a^+,$$
$$[a, a^+] = \frac{-1}{2\xi}(\alpha^2 - \beta^2), \tag{8.3}$$

which are of the form (3.10). The isomorphism $\mathrm{Der}_0^H(A_\xi) \cong H(1)_q$ is found in terms of an (id,id)-D h:

$$hX = 1, \quad hY = 0, \quad \alpha = e^{-(1/2)\xi h}, \quad \beta = e^{(1/2)\xi h}.$$

This example should be contrasted with the different deformation given in example (4) of Sec. X; compare Rels. (8.3) with (10.3).

(6) *Derivations on* $\mathrm{SL}_q(2)$. General derivations on $\mathrm{SL}_q(2)$ are more complicated; only a simple class of derivations on H_q is given. We have no results on the algebra $\mathrm{Der}(H_q)$. Consider derivations whose action on generators of H_q is defined by

$$D_{c_i f} T_{i1} = c_i f T_{i2}, \quad D_{c_i f} T_{i2} = 0, \tag{8.4}$$

where $f \in H_q$ is a monomial. In particular consider

$$D_{nmk} T_{i1} = c_i T_{12}^n T_{21}^m T_{22}^k T_{i2},$$

where $c_2 = c_1^{-1} = q^{1/4(k+m+n)}$. D_{nmk} can be shown to be an (a,b)-D where $a = a_{nmk}$ and $b = b_{nmk}$ are representable as follows:

$$aT = WTV, \quad bT = W^{-1} T V^{-1}, \quad W = KMN, \quad V = K^{-1} M N Q^{-1},$$

$$K = [q^{k/4}, q^{-(k/4)}], \quad M = [q^{m/4}, q^{-(m/4)}], \quad N = [q^{n/4}, q^{-(n/4)}], \quad Q = [q^{1/2}, q^{-(1/2)}].$$

a and b have been normalized by $ab = id$. As would be expected a, b are not left- or right-invariant.

Comment on derivations. The derivation in Eq. (8.4), abbreviated $D_{c_i f} = D$ here, provides a convenient form for a general comment about derivations on noncommutative FAs. If we were to imitate the commutative theory, we would write $D = f D_+$ (D_+ is the (α,β)-D in Eq. (6.12)) and try to interpret this as module multiplication of the derivation D_+ by $f \in H_q$. That is, Eq. (8.4) would extend to $D(g) = f D_+(g)$ for any $g \in H_q$. However, in noncommutative theory, such an interpretation of D would conflict with the Leibniz rule (2.2). Thus, D is interpreted, not as a derivation D_+ multiplied by an element $f \in H_q$, but as a k-Hom $H_q \to H_q$ defined on products by the Leibniz rule for a suitable pair (α,β). At best "$f D_+$" can serve as a mnemonic for the action (8.4) of D on generators T_{ij}. Note that factors of the form $f_1 T_{ij+1} f_2$ could also have been used in Eq. (8.4).

IX. ON THE TANGENT BUNDLE OF $SL_q(2)$

The tangent bundle of an algebraic group can be defined from its Hopf FA. In this section we apply this definition to $SL_q(2)$ to obtain the deformed analog $TSL_q(2)$ of the tangent bundle TSL(2). The analogy is to the fact that a tangent bundle of a Lie group is itself a Lie group. In particular, TSL(2) is a Lie group. Here, the "tangent bundle" $TSL_q(2)$ of $SL_q(2)$ is a deformation of TSL(2). That is, the FA of $TSL_q(2)$ is a Hopf algebra, which is a q deformation of the Hopf FA of TSL(2). First, the commutative case is briefly reviewed for SL(2).

For a commutative k algebra K (e.g., $K = k$) and the commutative Hopf k algebra $H = H_{q|q=1}$ (see, Sec. VI), SL(2,K) is the set of k algebra Homs,

$$\mathrm{SL}(2,K) = \mathrm{Hom}_{k-A}(H,K), \tag{9.1}$$

called the K points (K variety) of H.

Define the K algebra (and therefore k algebra) $K[\epsilon] = K \oplus K\epsilon$ with $\epsilon^2 = 0$ called the ring of dual numbers.[1] The tangent bundle is defined as the $K[\epsilon]$ points of H:

$$\mathrm{SL}(2,K[\epsilon]) = \mathrm{Hom}_{k-A}(H,K[\epsilon]) \tag{9.2}$$

[written as TSL(2,K) below].

The tangent bundle is a Lie group over K, so it can be represented as the K points of a Hopf k algebra, called here TH, which includes generators V_{ij} for the tangent spaces:

$$TH = k[T_{11}, \ldots, T_{22}, \ V_{11}, \ldots, V_{22}]/J,$$

$$J = (T^s T - 1, \ T^s V + V^s T).$$

That is, the $K[\epsilon]$ points of H are the K points of TH, rewritten as

$$\mathrm{TSL}(2,K)=\mathrm{Hom}_{k-A}(TH,K). \tag{9.3}$$

The connection with derivations is that $\Phi=\phi+\epsilon\delta\in\mathrm{SL}(2,K[\epsilon])$ iff $\phi,\ \delta: H\to K$ and

$$(fg)^{\phi}=f^{\phi}g^{\phi},\quad (fg)^{\delta}=f^{\phi}g^{\delta}+f^{\delta}g^{\phi}. \tag{9.4}$$

Thus, $\mathrm{SL}(2,K[\epsilon])$ is the set of (ϕ,ϕ)-Ds $H\to K$, where $\phi\in\mathrm{SL}(2,K)$.

We apply the above ideas to H_q and $\mathrm{SL}_q(2)$. To get a ''rich'' set of points of H_q, K should be replaced by a noncommutative k algebra R which reflects the noncommutativity of H_q. Then the objects for $\mathrm{SL}_q(2)$ corresponding to Eqs. (9.1) and (9.2) are

$$\mathrm{SL}_q(2,R)=\mathrm{Hom}_{k-A}(H_q,R), \tag{9.5}$$

$$\mathrm{SL}_q(2,R[\epsilon])=\mathrm{Hom}_{k-A}(H_q,R[\epsilon]). \tag{9.6}$$

Denote the $R[\epsilon]$ points of H_q by $\Phi\in\mathrm{SL}_q(2,R[\epsilon])$, and let their images, $\Phi(T)=x+\epsilon y$, $x,y\in R^4$ serve as coordinates of the variety (9.6):

$$\{(x,y)\in R^8 | x^s x=1,\ xx^s=1,\ x^s y+y^s x=0,\ xy^s+yx^s=0\}. \tag{9.7}$$

$s: R\to R$ is defined from the antipode of H_q: $\Phi(T^s)=x^s+\epsilon y^s$.

The function Hopf k algebra of the variety (9.6) and (9.7) is

$$TH_q=k\langle T_{11},\ldots,T_{22},V_{11},\ldots,V_{22}\rangle/J,$$

$$J=(T^sT-1,\ TT^s-1,\ T^sV+V^sT,\ TV^s+VT^s).$$

V^s is defined from the algebra Homs Ψ: $TH_q\to R$ by $\Psi(V^s)=y^s$. [Note that J has the structure of Eq. (5.5). The coalgebra operations on V_{ij} in TH_q are $\Delta(V_{ij})=T_{ik}\otimes V_{kj}+V_{ik}\otimes T_{kj}$ and $\epsilon(V_{ij})=0$. The antipode is s.] In analogy with Eq. (9.3) the $R[\epsilon]$ points of H_q can be represented as the R points of TH_q. Writing $\mathrm{TSL}_q(2,R)$ for $\mathrm{SL}_q(2,R[\epsilon])$,

$$\mathrm{TSL}_q(2,R)=\mathrm{Hom}_{k-A}(TH_q,R).$$

How do (α,β)-Ds fit in with the above ideas? In analogy with Eq. (9.4), $\mathrm{SL}_q(2,R[\epsilon])$ would be (ϕ,ϕ)-Ds $\{\phi,\phi,\delta\}$: $H_q\to R$, where $\phi\in\mathrm{SL}_q(2,R)$. To get (ϕ,ψ)-Ds with $\phi\neq\psi$, we replace $R[\epsilon]$ by another R algebra, which is conveniently defined as an ideal I. Let $R\langle e_1,e_2,\epsilon\rangle$ be the R algebra generated by three indeterminates which satisfy

$$e_1^2=e_1,\quad e_2^2=e_2,\quad e_1e_2=e_2e_1=0,$$

$$\epsilon^2=0,\quad e_1\epsilon=\epsilon,\quad \epsilon e_1=0,\quad e_2\epsilon=0,\quad \epsilon e_2=\epsilon.$$

Define the ideal $I=(e_1,e_2,\epsilon)\subset R\langle e_1,e_2,\epsilon\rangle$. An element $r\in I$ has the form $r=x_1e_1+x_2e_2+y\epsilon$ with $x_1,x_2;y\in R$. 1_R, the zeroth power of any generator, e.g., $1_R=(e_1)^0$, $\notin I$, but $1_R(e_1+e_2)$ ''acts like'' an identity for I, and $1_R\to 1_R(e_1+e_2)$ gives the R algebra structure $R\to I$.

Now consider the I points of H_q:

$$\mathrm{SL}_q(2,I)=\mathrm{Hom}_{k-A}(H_q,I).$$

$\Phi=\phi e_1+\psi e_2+\delta\epsilon: H_q\to I$ is an I point, i.e., $(fg)^{\Phi}=f^{\Phi}g^{\Phi}$ iff the Homs $\phi,\psi,\delta: H_q\to R$ satisfy the Leibniz rule

$$(fg)^{\delta}=f^{\phi}g^{\delta}+f^{\delta}g^{\psi},\quad (fg)^{\phi}=f^{\phi}g^{\phi},\quad (fg)^{\psi}=f^{\psi}g^{\psi}.$$

$\mathrm{SL}_q(2,I)$ is the set of (α,β)-Ds $H_q \to R$. Note that $1^{\Phi}_{H_q} = 1_R(e_1 + e_2)$.

Define the ideal $I' = (e_1, e_2, \epsilon) \subset H_q\langle e_1, e_2, \epsilon\rangle$, and consider the I' points of H_q. $\mathrm{SL}_q(2,I') = \mathrm{Hom}_{k-Alg}(H_q, I')$ is the set of (α,β)-Ds $H_q \to H_q$. For example, $\Psi = \alpha e_1 + \beta e_2 + D\epsilon \in \mathrm{SL}_q(2,I')$ could correspond to one of the left-invariant derivations $\{\alpha,\beta,D^{\pm}\}$ of $\mathrm{Der}_L(H_q)$ in Eq. (6.12) or any more general $\{a,b,D\}$ in Eq. (8.4). Derivations $H_q \to R$ may be considered as the image of the map

$$\mathrm{SL}_q(2,R) \times \mathrm{SL}_q(2,I') \to \mathrm{SL}_q(2,I),$$

$$(\varphi;\alpha,\beta,D) \to \Psi = \varphi(e_1\alpha + e_2\beta + \epsilon D).$$

X. COMMUTATIVE FUNCTION ALGEBRAS

In this section several examples of (α,β)-Ds acting on commutative FAs are given. The FAs do not contain a deformation parameter q related to noncommutativity, so q in the (α,β)-Ds and their algebras is not controlled by the FA but is free to be varied independently. Some of the derivation algebras are not Hopf.

(1) *Representation of* $U_q(\mathrm{sl}(2))$ *on* $k[T]$. Consider $k[T]$, the FA of polynomials in one indeterminate T, the k line. Here (α,β)-Ds $D_{\pm}$ on $k[T]$ are defined on the generator T by

$$D_+T = T^2, \quad D_-T = -1, \quad T^{\alpha} = qT, \quad T^{\beta} = q^{-1}T, \tag{10.1}$$

which extend to T^n by the Leibniz rule (2.2):

$$(T^n)^{\alpha} = q^n T^n, \quad (T^n)^{\beta} = q^{-n}T^n, \quad D_{\pm}T^n = \pm c_n T^{n\pm 1}. \tag{10.2}$$

Here and in the following, we abbreviate $c_n = c_n(q) = (q^n - q^{-n})/(q - q^{-1})$. $\mathrm{Der}_0(k[T]) = k\langle \alpha,\beta,D_{\pm}\rangle$ is isomorphic to $U_q(\mathrm{sl}(2))$ (see Eq. (6.12)).

(2) *The ''projectivized'' representation of* sl(2).[13] Consider the following k linear maps and their action on $k[T]$:

$$J_- = D_-, \quad J_-T^n = -c_n T^{n-1}, \quad J_+ = D_+ - c_N T, \quad J_+T^n = (c_n - c_N)T^{n+1}.$$

$D_{\pm}$ are defined in Eq. (10.1), and T means multiplication by T. J_- is a derivation, but J_+ is not.

Let $P_N(T) \subset k[T]$ be the k linear subspace of polynomials spanned by 1, T, $T^2,\ldots,T^N$. J_+ is constructed so that $J_+T^N = 0$ and therefore restricts to a k-Hom on $P_N(T)$. Thus, $P_N(T)$ is closed under the actions of $\{J_{\pm},\alpha,\beta\}$. Let $k\langle J_{\pm},\alpha,\beta\rangle$ denote the algebra generated by these Homs acting on $P_N(T)$. It has the Rels.

$$\alpha\beta = \beta\alpha = id, \quad \alpha J_{\pm}\beta = q^{\pm 1}J_{\pm},$$

$$[J_+, J_-] = \frac{\alpha^2 - \beta^2}{q - q^{-1}} - c_N \frac{q^{1/2}\alpha + q^{-(1/2)}\beta}{q^{1/2} + q^{-(1/2)}}.$$

J_+ is not a derivation, so $k\langle J_{\pm},\alpha,\beta\rangle$ does not have the Hopf structure of Sec. III. Some relations in this and later examples involve Homs which are not derivations and cannot be verified by the argument ''both sides are (α,β)-Ds which agree on generators.'' The relations have to be proved by acting on a general monomial.

(3) (α,β) *Derivations on the Laurent polynomials*. In this example, we define (α,β)-Ds on the Hopf algebra $H = k[T,T^{-1}] \cong k[X,Y]/(XY-1)$ of Laurent polynomials in the indeterminate T (k=complex numbers). The set of k points of H is $\mathrm{Hom}_{k-A}(H,k) = k^*$, where $k^* = k\backslash\{0\}$ is the punctured complex plane. Two different deformations are stated. For another discussion of derivations on H see Ref. 14.

Deformation 1. The basis derivations D_n, $n=0,\pm1,\pm2,...$ are (α_n,α_n)-Ds defined on generators by

$$D_nT=T^{n+1},\quad \alpha_nT=q^nT,\quad \Rightarrow D_nT^k=kq^{n(k-1)}T^{k+n}.$$

The algebra $\mathrm{Der}_1(H)=k\langle\alpha_n,D_n\rangle_{n\in Z}$ has the Rels.

$$\alpha_0=id,\quad \alpha_n\alpha_m=\alpha_{n+m},\quad \alpha_nD_m=q^{mn}D_m\alpha_n,$$

$$[D_m,D_n]=(n-m)q^{mn}D_{m+n}.$$

Rels. (3.2) are satisfied, so $[D_m,D_n]$ is an $(\alpha_m\alpha_n,\beta_m\beta_n)$-D, as is given. $\mathrm{Der}_1(H)$ is an infinitely generated Hopf algebra of a form discussed in Sec. III. It has no subalgebra isomorphic to $U_q(sl(2))$.

Deformation 2. This is an example of a derivation algebra which is not Hopf. Here, the basis derivations are defined by

$$D_nT=-T^{n+1},\quad T^\alpha=qT,\quad T^\beta=q^{-1}T,\quad \Rightarrow D_nT^k=-c_kT^{k+n}.$$

$\mathrm{Der}(H)=k\langle\alpha,\beta,D_n\rangle_{n\in Z}$ has the Rels.

$$\alpha\beta=\beta\alpha=id,\quad \alpha D_n\beta=q^nD_n,$$

$$[D_m,D_n]=c_{1/2(m-n)}\{q^{-(1/2)(m+n)}\alpha+q^{1/2(m+n)}\beta\}D_{m+n},$$

$$D_0=-\frac{\alpha-\beta}{q-q^{-1}}.$$

The last Rel. holds because both sides are (α,β)-Ds which agree on generators. Note that in the case $m=-n$:

$$[D_n,D_{-n}]=c_n(\alpha+\beta)D_0=-c_n\frac{\alpha^2-\beta^2}{q-q^{-1}}.$$

$[D_m,D_n]$ is not, in general, a basis derivation but is the sum of an $(\alpha^2,\alpha\beta)$-D, αD_{n+m} and a $(\beta\alpha,\beta^2)$-D, βD_{n+m}. $[D_m,D_n]$ is a derivation only for $m=-n$, which is when derivation Rels. (3.2b) and (3.2c) hold. A related fact is that $\mathrm{Der}(H)$ does not have the Hopf structure of Sec. III. But it does have a Hopf subalgebra $\mathrm{Der}_2(H)=k\langle\alpha,\beta,D_{\pm1}\rangle$, which is isomorphic to $\mathrm{Der}_L(H_q)$ in Eq. (6.12) under $\{\alpha,\beta,D_{\pm1}\}\to\{\alpha,\beta,\pm D_\pm\}$.

(4) *Creation and annihilation operators*. Let $a,a^+:k[T]\to k[T]$ be k linear operators where a^+ is multiplication by T and a is an (α,β)-D given by

$$a^+f=Tf,\quad aT=1,\quad T^\alpha=xT,\quad T^\beta=x^{-1}T. \tag{10.3}$$

Then, the algebra $A=k\langle a,a^+,\alpha,\beta\rangle$ has Rels.

$$\begin{aligned}&\alpha\beta=\beta\alpha=id,\quad \alpha a^+\beta=xa^+,\quad \alpha a\beta=x^{-1}a,\\ &a^+a=\frac{\alpha-\beta}{x-x^{-1}},\quad aa^+=\frac{x\alpha-x^{-1}\beta}{x-x^{-1}}.\end{aligned} \tag{10.4}$$

$(a^+)^na$ is an (α,β)-D, and, in particular, a^+a is the indicated (α,β)-D, $(\alpha-\beta)/(x-x^{-1})$, which is the deformed ''number operator.'' This derivation (and more generally A) can be expressed in terms of the (id,id)-D, $NT^n=nT^n$, which is the undeformed number operator. Namely,

$a^+a=(x^N-x^{-N})/(x-x^{-1})$, where $\alpha=x^N$ and $\beta=x^{-N}$. (N is not actually the number operator since $k[T]$ is not Fock space.) Because α and β were introduced, the canonical commutator is a dependent Rel. Here two forms are written in terms of N:

$$[a,a^+]=\frac{x^{N+1/2}+x^{N-(1/2)}}{x^{1/2}+x^{-(1/2)}}, \quad aa^+-xa^+a=x^{-N}.$$

The second form was proposed as a q deformed oscillator algebra.[15] This is not a Hopf algebra (a^+ is not a derivation).

Two comments: (i) This picture extends to n independent sets of operators and parameters $\{a_i,a_i^+,\alpha_i,\beta_i,x_i\}$, $i=1,\ldots,n$ acting on $k[T_1,\ldots,T_n]$ with

$$\begin{gathered} a_i^+(f\,)=T_if, \quad a_i(T_j)=\delta_{ij}, \\ \alpha_i(T_j)=(x_i)^{\delta_{ij}}T_j, \quad \beta_i(T_j)=(x_i)^{-\delta_{ij}}T_j, \end{gathered} \tag{10.5}$$

and each set satisfies Eq. (10.4). (ii) The case when a is an (α,id)-D leads to an algebra corresponding to Eq. (10.4) with dependent Rels.,

$$[a,a^+]=x^N, \quad aa^+-xa^+a=1.$$

The second form is the q-mutator algebra.[16]

(5) *Deformation of an a,a^+ representation of* sl(2). In this example, a and a^+, in Eq. (10.4), are used to construct $J_+=\xi a^+a^+$ and $J_-=-\xi aa$, where $x=q^{1/2}$ and $\xi=(q^{1/2}+q^{-(1/2)})^{-1}$. Acting on $k[T]$, the Homs $J_\pm$, α, and β generate $k\langle J_\pm,\alpha,\beta\rangle$ with the Rels.

$$\alpha\beta=\beta\alpha=id, \quad \alpha J_\pm\beta=q^{\pm1}J_\pm, \quad [J_+,J_-]=\frac{q^{1/2}\alpha^2-q^{-(1/2)}\beta^2}{q-q^{-1}}.$$

$J_\pm$ are not derivations, and $k\langle J_\pm,\alpha,\beta\rangle$ does not have the usual Hopf algebra structure of Sec. III. The commutator is not an (α^2,β^2)-D of the form $c(\alpha^2-\beta^2)$ (or any derivation). Here and in the following, there are Rels. among $\{J_+J_-,\alpha,\beta\}$, and also among $\{J_-J_+,\alpha,\beta\}$, resulting from Eq. (10.4), but they are not given. Thus, $[J_+,J_-]=\ldots$ is a dependent Rel. in $k\langle J_\pm,\alpha,\beta\rangle$.

(6) *Other deformations of $U(sl(2))$ using a,a^+*. Let $\{a_i,a_i^+,\alpha_i,\beta_i,x_i\}$, $i=1,2$, be as in Eq. (10.5) and define two k-Homs $J_\pm$ on $A=k[T_1,T_2]$: $J_+=a_1^+a_2$, $J_-=a_2^+a_1$. In contrast to example (5), here J_+ is an (α_2,β_2)-D (since a_2 is), and J_- is an (α_1,β_1)-D (since a_1 is). Thus, for example, $J_+T_2=T_1$ extends to A according to

$$J_+(T_1^mT_2^n)=c_n(x_2)T_1^{m+1}T_2^{n-1}.$$

The Rels. for $\mathrm{Der}_0(A)=k\langle\alpha_i,\beta_i,J_\pm\rangle$ can be worked out keeping x_1,x_2 as two independent parameters, but we prefer to present two special cases each with a single parameter. As usual, Rels. of the type (3.2a), (3.2d), and (3.3) exist, but are not stated here.

Deformation 1. $x_1=q$, $x_2=q^{-1}$. $\mathrm{Der}_0(A)_1$ has Rels.

$$\alpha_iJ_\pm\beta_i=q^{\pm1}J_\pm, \quad [J_+,J_-]=\frac{\alpha_1\alpha_2-\beta_1\beta_2}{q-q^{-1}}.$$

$J_\pm$ satisfy Eqs. (3.2b) and (3.2c), which is related to $[J_+,J_-]$ being the $(\alpha_1\alpha_2,\beta_1\beta_2)$-D in the last Rel. $\mathrm{Der}_0(A)_1$ has the Hopf algebra structure (3.6), (3.7), and (3.9).

Deformation 2. $x_1=x_2=q$. In this case $\mathrm{Der}_0(A)_2$ has Rels.

$$\alpha_1 J_\pm \beta_1 = q^{\pm 1} J_\pm , \quad \alpha_2 J_\pm \beta_2 = q^{\mp 1} J_\pm ,$$
$$[J_+ , J_-] = \frac{\alpha_1\beta_2 - \alpha_2\beta_1}{q - q^{-1}}. \tag{10.6}$$

The derivation conditions (3.2b) and (3.2c) are not satisfied, so the commutator $[J_+ , J_-]$ does not have to be an $(\alpha_1\alpha_2, \beta_1\beta_2)$-D or any derivation. Nevertheless, it turned out to be an $(\alpha_1\beta_2, \alpha_2\beta_1)$-D as shown. $\mathrm{Der}_0(A)_2$ can be given a Hopf algebra structure if J_+ is given a coproduct Δ' which is different from the one induced by its (α_2, β_2)-D structure in Eq. (3.6): $\Delta' J_+ = \beta_2 \otimes J_+ + J_+ \otimes \alpha_2$. The antipode is $\iota J_+ = -\beta_2^{-1} J_+ \alpha_2^{-1}$. While this example makes a point, it is due to the flexibility of a commutative FA.

Comment. We end this section by noting that inconsistencies can arise in trying to define (α,β)-Ds on commutative FAs with more than one generator. For example, define an (α,β)-D, D, on $k[X,Y]$ by $DX=0$, $DY\neq 0$, $\alpha Y = \beta Y = Y$, and $\alpha X \neq \beta X$. Then $(XY)^D = X^\alpha Y^D$ but $(YX)^D = Y^D X^\beta$. This amounts to trying to define a derivation on $k[X,Y] = k\langle X,Y\rangle / I$ which fails to preserve the ideal $I = (XY - YX)$.

XI. CONCLUSION

We conclude with three comments about the results, and possible further work.

(1) Application of (α,β)-Ds on Hopf FAs corresponding to the algebraic quantum groups $\mathrm{SL}_q(2)$ and $\mathrm{SL}_q(3)$ establish an interpretation similar to that of derivations in algebraic groups. The conjectures at the end of Sec. VII suggest this role of (α,β)-Ds should extend to other algebraic quantum groups. (α,β)-Ds on slightly more general noncommutative q-Vs suggest that wider applications may be tractable.

(2) When the ideal I defining a FA, $A = k\langle X_1, \ldots, \rangle / I$, has no special structure of homogeneity and symmetry (as in quantum algebras) it becomes difficult if not impossible to determine α,β. In this case explicit (α,β)-Ds in specific examples lose importance. To be interesting here, they would probably have to be absorbed into a general theory, which would deal with arbitrary ideals.

(3) Whenever differentiation is defined on noncommutative algebras (α,β)-Ds can be considered. For example, differentiation is obviously of interest on noncommutative smooth FAs.[17] Also derivations have been used on C^* algebras.[18] Examples would be needed to help interpret (α,β)-Ds in any new context.

ACKNOWLEDGMENT

(Received 23 October 1995; accepted for publication 6 December 1995)

We define n-algebras as linear spaces on which the internal composition law involves n elements: $m:V^{\otimes n}\Rightarrow V$. It is known that such algebraic structures are interesting for their applications to problems of modern mathematical physics. Using the notion of a commutant of two subalgebras of an n-algebra, we distinguish certain classes of n-algebras with reasonable properties: semisimple, Abelian, nilpotent, solvable. We also consider a few examples of n-algebras of different types, and show their properties. © *1996 American Institute of Physics.*

I. INTRODUCTION

In 1973, Nambu[1] proposed an interesting generalization of classical Hamiltonian mechanics. It is based on a new notion of brackets, now called *the Nambu bracket*, generalizing the usual Poisson bracket, which is a binary operation on an algebra of classical observables on a phase space, to the multiple operation of higher order $n\geqslant 3$. This new operation is skew-symmetric and satisfies the Leibniz rule with respect to the usual multiplication of functions as well as the so-called *fundamental identity*, which is a natural generalization of the Jacobi identity. Takhtajan called this generalization of the Lie algebra to the multiple operation of higher order by *Nambu–Lie algebra*.[2] The homology theory and the deformation theory for Nambu–Lie gebras were considered in Ref. 3.

The canonical Nambu bracket for n classical observables on the phase space R^n with coordinates x_1, $x_2,\ldots,x_n$ is defined by $\{f_1,f_2,\ldots,f_n\}:=J(f_1,f_2,\ldots,f_n)$, where the right-hand side stands for the Jacobian of the mapping $f=\{f_1,f_2,\ldots,f_n\}:R^n\to R^n$. This formula naturally generalizes the usual canonical Poisson bracket from binary to n-ary operation on classical observables. The generalized Nambu–Hamilton equation of motion involves $n-1$ Hamiltonians H_1, $H_2,\ldots,H_{n-1}$:

$$\frac{df}{dt}=\{H_1,H_2,\ldots,H_{n-1},f\}.$$

The phase flow in the corresponding phase space is divergence-free and preserves the standard volume form $dx_1\wedge dx_2\wedge\cdots\wedge dx_n$—this is the analog of the Liouville theorem. One can find a description of the foundations of the generalized Nambu mechanics in Ref. 2 as well as a discussion of related higher-order algebraic structures. The author of Ref. 2 suspects that such structures might clarify many important problems of modern mathematical physics (Yang–Baxter equation, Poisson–Lie groups, quantum groups) for higher-dimensional cases. For the Yang–Baxter equation of higher order, it was done by Lawrence.[4,5] It should be noted that one of us emphasized in Refs. 6–9 that ternary Z_3-graded algebras are important for their applications in physics of elementary interactions.

[a]Permanent address: International Solomon University, Zabolotny Str. 38, Apt. 61, Kiev 252187, Ukraine.

Ternary Nambu–Lie gebras ($n=3$) look similar to *Lie triple systems*, introduced in Ref. 10 and studied in Refs. 11 and 12. The Lie triple system is defined as a vector space V equipped with the ternary bracket which satisfies the same fundamental identity as a Nambu–Lie bracket, but instead of being skew symmetric, satisfies some other condition. The fundamental fact of the theory of Lie triple systems is the existence of standard imbedding of any such system in certain Lie algebra, sending the ternary bracket to $[[\cdot,\cdot]\cdot]$, where $[\cdot,\cdot]$ stands for the operation in the Lie algebra. Another, different generalization of Lie algebras for higher-order algebraic operations is given in Ref. 13.

There were also some attempts to find a generalization of the concept of associative algebras for higher-order algebraic operations, but only some partial results are presented in Refs. 14, 4, 5, and 3. In particular, one can introduce in a partially associative n-algebra,[14] a natural analog of Lie brackets satisfying a generalized Jacobi identity in the sense of Ref. 13.

It is well known that semisimple, Abelian, nilpotent, and solvable algebras form the most important classes of binary associative and Lie algebras. This is why our aim is to find reasonable generalizations of these notions for higher-order algebraic operations.

We define *n-algebras* as linear spaces (mainly finite dimensional) on which the internal composition law involves n elements: $m: V^{\otimes n} \Rightarrow V$. The term n-algebra has been introduced by Lawrence[4,5] to denote the objects with a richer structure, but we hope that the use of this term in our context will not lead to any confusion. The similar notion was used also in Ref. 14. Let us give an example of such a structure for the case $n=3$. An arbitrary element $a \in V \otimes V \otimes V$ can be written in the basis $\{e_k\}$ as

$$a=\sum_{k,l,m} a_{klm} e_k \otimes e_l \otimes e_m ,$$

which defines a one-to-one correspondence between the elements of $V \otimes V \otimes V$ and the three-tensors a_{klm}, which we call also *cubic matrices*.

The natural internal composition law that generalizes the multiplication of ordinary matrices is given by the following rule:

$$m(a \otimes b \otimes c)_{ijk} = (a*b*c)_{ijk} := \sum_{p,q,r} a_{ipq} b_{pjr} c_{qrk} . \tag{1}$$

In contrast with ordinary matrix multiplication it is nonassociative, neither in the strong sense, i.e.

$$(a*(b*c*d)*e) \neq (a*b*c)*d*e \neq a*b*(c*d*e),$$

nor in the sense of other generalizations of associativity presented in Refs. 14, 4, 5, and 3.

Such a ternary product has been in fact introduced by one of the authors[7,9] and independently by Lawrence.[4] It is a particular case of a more general *n-fold* multiplication defined on the n-tensors as follows:

$$m(a^{(1)} \otimes a^{(2)} \otimes \cdots \otimes a^{(n)})_{i_1 i_2 \cdots i_n} = \sum_{j_{kr}=1(k<r)}^{l} a^{(1)}_{i_1 j_{12} \cdots j_{1n}} a^{(2)}_{j_{12} i_2 j_{23} \cdots j_{2n}} \times \cdots \times a^{(k)}_{j_{1k} \cdots j_{k-1k} i_k j_{kk+1} \cdots j_{kn}} \times \cdots \times a^{(n)}_{j_{1n} \cdots j_{n-1n} i_n} , \tag{2}$$

also studied by Lawrence.[4,5]

From the mathematical point of view this structure seems to be rather complicated, so the first question is whether it is possible to distinguish the subalgebras of 3-tensors (n-tensors) with reasonable properties. We succeeded here to introduce subalgebras similar to binary Abelian, nilpotent, solvable, and semisimple algebras.

The groups S_3 and Z_3 act on cubic matrices by permuting their indices. Therefore, it is natural to distinguish subspaces of such matrices that provide the irreducible representations of these groups; e.g., there is the subspace of totally symmetric cubic matrices satisfying $a_{klm}=a_{lmk}=a_{mlk}=\ldots$, etc.

Our paper is organized as follows. In Sec. II we give basic definitions and examples related to general n-algebras (for simplicity, over the field C). Many of these definitions, such as a subalgebra, an ideal, a homomorphism are scattered in the literature, but we prefer a self-contained discussion. In Sec. III, using the important notion of a commutant of two subalgebras of an n-algebra, we distinguish several classes of n-algebras: semisimple, Abelian, nilpotent, solvable. We show that the three latter classes are invariant with respect to the operations of taking a subalgebra, a factor algebra and a homomorphic image. In Sec. IV, we consider the special case of cubic matrices and discuss a few examples of ternary algebras, which could be interesting for their applications in physics of elementary interactions.

II. BASIC DEFINITIONS AND EXAMPLES.

Definition 1: We call an n-algebra ($n\in N$) over the field C a linear space A endowed with a linear mapping (multiplication) $m:A^{\otimes n}\to A$.

One defines in an obvious way a subalgebra of an n-algebra A and the n-algebra structure in the nth tensor power $A^{\otimes n}$. The group S_n acts in $A^{\otimes n}$ in a natural way:

$$\pi(g)(a_1\otimes\cdots\otimes a_n):=a_{g(1)}\otimes\cdots\otimes a_{g(n)},$$

for arbitrary $g\in S_n$, $a_1,\ldots,a_n\in A$. In particular, the cyclic group Z_n is represented automatically (by means of the reduction of π), in the tensor product $A^{\otimes n}$.

Definition 2: An n-algebra A is called S_n commutative (Z_n commutative), if $m\circ\pi(g)=m$ for any $g\in S_n$ (resp., for any $g\in Z_n$).

Definition 3: An n-algebra A is said to be strongly associative if

$$m\circ(m\otimes id\otimes\cdots id)=m\circ(id\otimes m\otimes id\cdots\otimes id)=m\circ(id\otimes id\cdots\otimes m),$$

where all linear mappings act from $A^{\otimes(2n-1)}$ to A.

There exist other definitions of the associativity in n-algebras (see Refs. 14, 4, 5, and 3).

Example 1 (Algebra of multidimensional matrices): Consider the set A=Mat(l,n;C) of complex multidimensional matrices $a=(a_{i_1i_2\cdots i_n})$, with $i_1,i_2,\ldots,i_n=1,2,\ldots,l$ of dimension $l\times l\times\cdots\times l=l^n$. One can introduce the n-fold multiplication on this space (i.e., the product of n elements) by means of (2). Let us introduce matrix units:

$$(e_{i_1i_2\cdots i_n})_{j_1j_2\cdots j_n}:=\delta_{i_1j_1}\delta_{i_2j_2}\cdots\delta_{i_nj_n}.$$

For their product in the above-mentioned sense, we have

$$m(e_{i^{(1)}{}_1i^{(1)}{}_2\cdots i^{(1)}{}_n}\otimes\cdots\otimes e_{i^{(n)}{}_1i^{(n)}{}_2\cdots i^{(n)}{}_n})_{j_1\cdots j_n}$$
$$=\delta_{i^{(1)}{}_1j_1}\cdots\delta_{i^{(n)}{}_nj_n}\delta_{i^{(2)}{}_1i^{(1)}{}_2}\cdots\delta_{i^{(k)}{}_ri^{(r)}{}_k}\cdots\delta_{i^{(n-1)}{}_ni^{(n)}{}_{n-1}}.$$

One can easily see now that all diagonal matrix units are idempotents:

$$m(e_{i\cdots i}\otimes\cdots\otimes e_{i\cdots i})_{j_1\cdots j_n}=\delta_{ij_1}\cdots\delta_{ij_n},$$

and that all nondiagonal matrix units are nilpotents:

$$m(e_{i_1i_2\cdots i_n}\otimes\cdots\otimes e_{i_1i_2\cdots i_n})_{j_1j_2\cdots j_n}=0,$$

if at least two indices are different. If in a product of the diagonal matrix units there are at least two different indices, the product is equal to 0. The n-algebra of all the diagonal matrices gives an example of S_n-commutative n-algebra.

Obviously, for $n=2$ we get the usual matrix multiplication. For $n>2$, this operation is not associative, neither in the sense of Definition 3 nor in the sense of other generalizations of associativity presented in Refs. 3, 4, 5, and 14.

The notion of a determinant of multidimensional matrix (the so-called hyperdeterminant) has been considered in Ref. 15 (the hyperdeterminants have been considered for the first time by Cayley in the early 1840s).

Example 2: Any binary algebra A over the field C, with the multiplication p: $A\otimes A\to A$, is an n-algebra with a naturally extended multiplication by means a binary one as

$$m:=p\circ(id\otimes p)\circ(id\otimes id\otimes p)\circ(id\otimes id\otimes\cdots id\otimes p):A^{\otimes n}\to A. \tag{3}$$

If the binary multiplication p is associative, then the multiplication m defined above is obviously strongly associative, too.

Nevertheless, there exist two-dimensional ternary algebras whose multiplication cannot be expressed by means of any binary one as (3). Indeed, suppose that $m(a\otimes b\otimes c)=p(a\otimes p(b\otimes c))$ for any $a,b,c\in A$. Let us fix a basis $\{e_1,e_2\}$ in A. Then m and p can be expressed with the help of structure constants as follows:

$$m(e_i\otimes e_j\otimes e_k)=\sum_{l=1}^{2} c_{ijk}^{l}e_l,\quad p(e_i\otimes e_j)=\sum_{r=1}^{2} x_{ij}^{r}e_r,$$

for all $i,j,k\in\{1,2\}$. If the above equality is satisfied, it leads to the following system of linear equations:

$$c_{ijk}^{l}=\sum_{r=1}^{2} x_{jk}^{r}x_{ir}^{l},$$

for all values of $i,j,k,l\in\{1,2\}$. This system contains 16 equations for 8 variables. It is easy to choose c_{ijk}^{l} in such a way that this system will have no solution. Note that the ternary algebra constructed in Refs. 4 and 5 using the $6j$ symbols of the representations of quantum groups also has the multiplication that cannot be expressed via (3) with the help of a binary one.

Definition 4: An n-algebra A is called Z_k graded ($k\in N$), if $A=A_0\oplus A_1\oplus\cdots\oplus A_{k-1}$ (direct sum of linear spaces) and if there exists a mapping $g:A_i\to i\in\{0,1,\ldots,k-1\}$ having the property: $g(m(a_1\otimes a_2\otimes\cdots\otimes a_n))=g(a_1)+g(a_2)+\cdots+g(a_{n-1})(mod\ k)$ for all $a_1\in A_i$, $a_2\in A_j,\ldots,a_{n-1}\in A_l(i,j,l\in\{0,1,\ldots,k-1\})$. The elements belonging to the spaces A_i are called homogeneous of grade i, and we suppose that the product of homogeneous elements is also a homogeneous element. Evidently, A_0 is a subalgebra of A.

Definition 5: We call ideal *of an n-algebra A a linear space B, such that $m(a_1\otimes\cdots\otimes a_{n-1}\otimes b)\in B$, $m(a_1\otimes\cdots\otimes a_{n-2}\otimes b\otimes a_{n-1})\in B$, $m(b\otimes a_1\otimes\cdots\otimes a_{n-1})\in B$ for any $b\in B$, $a_1,\ldots,a_{n-1}\in A$.*

If an n-algebra A contains no other ideals except $\{0\}$ and A, it is called simple.

Remark 1: Definition 5 applied to usual binary algebras gives the definition of a two-sided ideal. Obviously, one can give an analog of the definition of a one-sided ideal extended to the n-algebras. For example, the n-algebra described in Example 1 is simple, but it has many one-sided ideals.

Example 3: Consider the following sets (the ''slices'') in Mat$(l,n;C)$*:*

$$T^s_{ip} := \{a \in \mathrm{Mat}(l,n;C) : (a_{i_1 i_2 \cdots i_n})^l_{i_1, i_2, \cdots i_n = 1} = \delta^s_{i_p} (a_{i_1 i_2 \cdots i_n})^l_{i_1, \cdots i_{p-1}, i_{p+1} \cdots, i_n = 1}\},$$

where $p,s = 1,\ldots,l$.

Every such ''slice'' $T^s_{i_p}$ defines a one-sided ideal in the n-algebra Mat$(l,n;C)$*, because applying (2), we have for all* $a^{(1)},\ldots,a^{(n)} \in Mat(l,n;C)$, $a^{(p)} \in T^s_{i_p}$*:*

$$m(a^{(1)} \otimes a^{(2)} \otimes \cdots \otimes a^{(n)})_{i_1 i_2 \cdots i_n} = \delta^s_{i_p} \sum_{j_{kr}=1 (k<r)}^{l} a^{(1)}_{i_1 j_{12} \cdots j_{1n}} a^{(2)}_{j_{12} i_2 j_{23} \cdots j_{2n}} \times \cdots \times a^{(p)}_{j_{1k} \cdots j_{p-1 p} s j_{p p+1} \cdots j_{kn}} \times \cdots \times a^{(n)}_{j_{1n} \cdots j_{n-1 n} i_n}.$$

If $a^{(q)} \in T^{s_q}_{i_p}$, then

$$m(a^{(1)},\ldots,a^{(p)},\ldots,a^{(n)})_{i_1 \cdots i_{p-1} s_p i_{p+1} \cdots i_n} = a^{(p)}_{s_1 \cdots s_n} m(a^{(1)},\ldots,a^{(p-1)},a^{(p+1)},\ldots,a^{(n)})_{i_1 \cdots i_{p-1} i_{p+1} \cdots i_n},$$

where the last of these multiplications coincides with the multiplication in $Mat(l,n-1;C)$.

Obviously, an ideal is automatically a subalgebra. The intersection of a set of ideals is also an ideal. If B and C are two ideals of n-algebra A, then the linear subspace $B+C := \{b + c | b \in B, c \in C\}$ is also the ideal of A. So we can introduce a notion of a *sum of an arbitrary set of ideals.*

Definition 6: A homomorphism of n-algebras (A_1,m_1) *and* (A_2,m_2) *is a linear mapping* $\rho: A_1 \to A_2$*, such that* $m_2 \circ (\rho \otimes \rho \otimes \cdots \otimes \rho) = \rho \circ m_1$.

The definitions of a homomorphism, a subalgebra, and an ideal have their natural extensions to the Z_k-graded n-algebras. We call the *kernel* of a homomorphism ρ the set $\mathrm{Ker}(\rho) := \{a \in A_1 : \rho(a) = 0\}$.

A representation of the n-algebra A in a linear space of dimension l is a homomorphism of A to the n-algebra $\mathrm{Mat}(l,n;C)$ (also see Ref. 4).

Theorem 1: *There exists a one-to-one correspondence between the kernels of the homomorphisms of* Z_n*-graded n-algebras* (A_1,m_1) *and* (A_2,m_2) *and the ideals of* A_1*. The images of the homomorphisms of n-algebras having the same kernels are mutually isomorphic.*

Proof: It is obvious that $\mathrm{Ker}(\rho)$ is an ideal of A_1. Let us suppose indeed that $b \in \mathrm{Ker}(\rho)$, a_1, $a_2,\ldots,a_{n-1} \in A_1$; in that case,

$$\rho \circ m_1(a_1 \otimes a_2 \otimes \cdots \otimes a_{n-1} \otimes b) = m_2(\rho(a_1) \otimes \rho(a_2) \otimes \cdots \otimes \rho(a_{n-1}) \otimes \rho(b)) = 0,$$

and one has $m(a_1 \otimes \cdots \otimes a_{n-1} \otimes b) \in \mathrm{Ker}(\rho)$. Other properties mentioned in Definition 5 can be checked in a similar way.

On the contrary, if B is an ideal in the n-algebra A, we can consider the factor space A/B of the classes of equivalency of the form $B+a$, where $(a \in A)$. It is possible to define on this space a new multiplication $\tilde{m}: (A/B)^{\otimes n} \to A/B$: $\tilde{m}((B+a_1) \otimes \cdots \otimes (B+a_n)) := B + m(a_1 \otimes \cdots \otimes a_n)$. In

this way we defined the structure of n-algebra on A/B and we showed that the linear canonical application $\pi: A \to A/B$ is the homomorphism of n-algebras. The algebra A/B is named the factor-n-algebra of A by the ideal B. Obviously, $B = \mathrm{Ker}(\pi)$.

Finally, if $\rho: A_1 \to A_2$ is a homomorphism of n-algebras, then the n-algebras $\mathrm{Im}(\rho)$ and $A/\mathrm{Ker}(\rho)$ are isomorphic. This proof is evidently valid also for Z_n-graded n-algebras. □

Now one can easily prove that if B is an ideal in the n-algebra A, then the following occurs.

(1) There exists a natural one-to-one correspondence (conserving the inclusion relation) between all subalgebras of A/B and all subalgebras of A containing B.

(2) The above correspondence also gives a one-to-one correspondence between all ideals of A/B and all ideals of A containing B, the corresponding factor algebras being isomorphic.

Remark 2: Let us define similarly the dual category of n-coalgebras. We call n-coalgebra ($n \in N$) *over the field C a linear space M endowed with a linear application (comultiplication)* $\Delta: M \to M^{\otimes n}$.

We produce a standard example of an n-coalgebra by considering the algebra M of complex-valued functions on a group with multioperators[16,17] with a unique n-ary operation ω. In this example $(\Delta f)(x_1,\ldots,x_n) := f(\omega(x_1,\ldots,x_n))$ is the homomorphism of binary algebras M and $M^{\otimes n}$.

If we introduce the structure of an n-algebra in M with the help of Definition 3 and the similar structure in $M^{\otimes n}$, it is obvious that Δ is a homomorphism of n-algebras M and $M^{\otimes n}$. This means that we have here an example of n-bialgebra in the sense of the following definition.

Definition 7: We call an n-bialgebra ($n \in N$) *over the field C a linear space A endowed with a multiplication* $m: A^{\otimes n} \to A$ *and a comultiplication* $\Delta: A \to A^{\otimes n}$, *which is the homomorphism relatively m (recall that* $A^{\otimes n}$ *has a natural structure of n-algebra generated by m).*

III. SPECIAL CLASSES OF *n*-ALGEBRAS

Definition 8: If B,C are two subalgebras of an n-algebra (A,m), *their commutant* $[B,C]_m$ *is the ideal in* (A,m), *generated by all the elements of the form*

$$[b_1,b_2,\ldots,b_n;c_1,c_2,\ldots,c_n]_m = m((b_1+c_1)\otimes(b_2+c_2)\otimes\cdots\otimes(b_n+c_n)) - m(b_1\otimes b_2\otimes\cdots\otimes b_n) - m(c_1\otimes c_2\otimes\cdots\otimes c_n), \tag{4}$$

where $b_1, b_2,\ldots,b_n \in B$, $c_1, c_2,\ldots,c_n \in C$; *in other words, the intersection of all the ideals containing all the above elements*. Obviously, $[B,C]_m = [C,B]_m$. In particular, we consider $A' := [A,A]_m$.

Lemma 1: A subalgebra B of an n-algebra (A,m) *is an ideal if and only if* $[A,B]_m \subseteq B$.

Proof: If B is an ideal, all the elements mentioned in (4), where $b_1, b_2,\ldots,b_n \in B$, $c_1, c_2,\ldots,c_n \in A$, are elements of B, and the necessary inclusion is evident. On the contrary, if this inclusion is true, then all the elements of the form (4), where $b_1, b_2,\ldots,b_n \in B$, $c_1, c_2,\ldots,c_n \in A$, are elements of B. If, in particular, all $b_i = 0$, except one, then B satisfies the definition of ideal. □

As $[A,B]_m \subseteq A' := [A,A]_m$, this lemma says that every subalgebra of the n-algebra A containing A', is an ideal in A.

Definition 9: We call an n-algebra (A,m) *Abelian, if* $[A,A]_m = \{0\}$.

Obviously, this condition is equivalent to the condition

$$m((b_1+c_1)\otimes(b_2\otimes c_2)\cdots\otimes(b_n\otimes c_n)) = m(b_1\otimes b_2\otimes\cdots\otimes b_n) + m(c_1\otimes c_2\otimes\cdots\otimes c_n),$$

where $b_1, b_2,\ldots,b_n, c_1, c_2,\ldots,c_n \in A$. If, in particular, all $b_i = 0$, except one, then $m(a\otimes b\otimes\cdots\otimes c) = 0$ for every $a, b,\ldots,c \in A$.

This means that Abelian n-algebras are exactly n-algebras with a zero multiplication. So every subalgebra, factor algebra, and homomorphic image of an Abelian n-algebra is Abelian itself.

Lemma 2: A factor algebra A/B of an n-algebra A by the ideal B is Abelian if and only if $[A,A]_m \subseteq B$.

Proof: If A/B is Abelian, then we have $[b_1+B, b_2+B,\ldots,b_n+B; c_1+B, c_2+B,\ldots,c_n+B]_m = B$ for every b_1, $b_2,\ldots,b_n$, c_1, $c_2,\ldots,c_n \in A$, from where $[b_1,b_2,\ldots,b_n;c_1,c_2,\ldots,c_n] \in B$, which means $[A,A]_m \subseteq B$. □

In particular, the factor algebra $A/[A,A]_m$ is always Abelian.

Definition 10: We call a normal series of an n-algebra (A,m) *such a finite system of subalgebras* $\{0\}=A_k \subset A_{k-1} \subset \cdots \subset A_1 \subset A_0 = A$ *that every* A_i *is a proper ideal in* A_{i-1} $(i=1,\ldots,k)$. *The natural number k is called the length of this series, and the factor algebras* A_{i-1}/A_i *are called the factors of this series.*

A normal series $\{0\}=A_k \subset A_{k-1} \subset \cdots \subset A_1 \subset A_0 = A$ *of an n-algebra* (A,m) *is called central series, if* $[A_i,A]_m \subseteq A_{i+1}$ $(i=0,1,\ldots,k-1)$.

This definition gives $[A_i,A]_m \subseteq A_i$ $(i=0,1,\ldots,k-1)$ for any central series, and Lemma 1 shows that all A_i are the ideals in A. So a central series is also an *invariant* series, i.e., a finite series of ideals of A, ordered by inclusion.

Definition 11: We call an n-algebra (A,m) nilpotent, if it has at least one central series.

In particular, every Abelian n-algebra is nilpotent because it has a central series of the form $\{0\} \subset A$.

We call a *lower central chain* of an n-algebra A the following chain of ideals: $\cdots \subseteq \hat{A}_k \subseteq \hat{A}_{k-1} \subseteq \cdots \subseteq \hat{A}_1 \subseteq \hat{A}_0 = A$, where $\hat{A}_{k+1} := [\hat{A}_k, A]_m$, $k=0,1,2,\ldots$.

Lemma 3: An n-algebra A is nilpotent if and only if in its lower central chain $\hat{A}_k=\{0\}$ *fo for some natural k.*

Proof: In fact, if $\hat{A}_k=\{0\}$, the above lower central chain becomes the central series of the n-algebra A. On the contrary, consider a central series $\{0\}=A_i \subset A_{i-1} \subset \cdots \subset A_1 \subset A_0 = A$ of the n-algebra A. Let $\hat{A}_0 = A = A_0$. Evidently, $\hat{A}_1 := [A,\hat{A}_0]_m = [A,A]_m \subseteq A_1$ and, if it has already been proved that $\hat{A}_i \subseteq A_i$, then according to the definition of the lower central chain, we have $\hat{A}_{i+1} := [\hat{A}_i, A]_m \subseteq [A_i, A]_m \subseteq A_{i+1}$, from where $\hat{A}_k \subseteq A_k = \{0\}$, i.e., $\hat{A}_k = \{0\}$.

Corollary 1: Every subalgebra B of a nilpotent n-algebra A is also nilpotent.

Proof: Let $\cdots \subseteq \hat{B}_i \subseteq \hat{B}_{i-1} \subseteq \cdots \subseteq \hat{B}_1 \subseteq \hat{B}_0 = B$ be a lower central chain for B. Then $\hat{B}_0 = B \subseteq A = \hat{A}_0$, $\hat{B}_1 = [B,\hat{B}_0]_m \subseteq [A,\hat{A}_0]_m = \hat{A}_1$, and, if it is already proved that $\hat{B}_i \subseteq \hat{A}_i$ then $\hat{B}_{i+1} := [B,\hat{B}_i]_m \subseteq [A,\hat{A}_i]_m \subseteq \hat{A}_{i+1}$. From the equality $\hat{A}_k = \{0\}$ we have now that $\hat{B}_k = \{0\}$.

Corollary 2: Every homomorphic image $H=\rho(A)$ *of a nilpotent n-algebra A is also nilpotent.*

Proof: In fact, let $\cdots \subseteq \hat{A}_i \subseteq \hat{A}_{i-1} \subseteq \cdots \subseteq \hat{A}_1 \subseteq \hat{A}_0 = A$ and $\cdots \subseteq \hat{H}_i \subseteq \hat{H}_{i-1} \subseteq \cdots \subseteq \hat{H}_1 \subseteq \hat{H}_0 = H$ be the lower central chains for A and H, respectively. Then $H = \hat{H}_0 = \rho(A) = \rho(\hat{A}_0)$. Let it be already proved that $\hat{H}_i \subseteq \rho(\hat{A}_i)$. Then $\forall a'_1,\ldots,a'_n \in \hat{H}_i$, $b'_1,\ldots,b'_n \in H \exists a_1,\ldots,a_n \in \hat{A}_i$, $b_1,\ldots,b_n \in A$, such that $a'_l = \rho(a_l)$, $b'_l = \rho(b_l) \forall l = 1,\ldots,n$; this is why $\rho([a_1,\ldots,a_n; b_1,\ldots,b_n]_m) = [a'_1,\ldots,a'_n;b'_1,\ldots,b'_n]_m$.

As the image $\rho(\hat{A}_{i+1})$ of the ideal $\hat{A}_{i+1}$ is the ideal in H (one can verify this directly), then from the above relation we have $\hat{H}_{i+1} = [\hat{H}_i, H]_m \subseteq \rho(\hat{A}_{i+1})$. From the equality $\hat{A}_k = \{0\}$ we have now that $\hat{H}_k = \{0\}$. □

Definition 12: A normal series $\{0\}=A_k \subset A_{k-1} \subset \cdots \subset A_1 \subset A_0 = A$ *of an n-algebra* (A,m) *is*

called solvable, if all factor algebras A_i/A_{i+1} $(i=0,1,\ldots,k-1)$ *of this series are Abelian, i.e., using Lemma 2, if* $[A_i,A_i]_m\subseteq A_{i+1}$ $(i=0,1,\ldots,k-1)$. *An n-algebra is called solvable if it has at least one solvable series.*

Every nilpotent *n*-algebra is solvable. In fact, let $\{0\}=A_k\subset A_{k-1}\subset\cdots\subset A_1\subset A_0=A$ be its central series; then using the relation $[A_i,A]_m\subseteq A_{i+1}$, we have $[A_i,A_i]_m\subseteq[A_i,A]_m\subseteq A_{i+1}$ $(i=0,1,\ldots,k-1)$. □

Definition 13: We call chain of commutants *of an n-algebra A a chain of its subalgebras* $\cdots\subseteq A^{(i)}\subseteq\cdots\subseteq A''\subseteq A'\subseteq A^{(0)}=A$, *such that* $A^{(i+1)}=[A^{(i)},A^{(i)}]_m$, $i=0,1,2,\ldots$.

Lemma 4: An n-algebra A is solvable if and only if in its chain of commutants $A^{(k)}=\{0\}$ *for some natural k.*

Proof: In fact, if $A^{(k)}=\{0\}$, then the above chain of commutants becomes a solvable series of the *n*-algebra *A*. On the contrary, let *A* have a solvable series $\{0\}=A_k\subset A_{k-1}\subset\cdots\subset A_1\subset A_0=A$. Put $A^{(0)}=A_0=A$. Let it be already proved that $A^{(i)}\subseteq A_i$. Then, using the Definitions 12 and 13, we have $A^{(i+1)}=[A^{(i)},A^{(i)}]_m\subseteq[A_i,A_i]_m\subseteq A_{i+1}$, from where, in particular, $A^{(k)}\subseteq A_k=\{0\}$, i.e., $A^{(k)}=\{0\}$. □

Corollary 3: Every subalgebra B of a solvable n-algebra A is also solvable.

Proof: Let $\cdots\subseteq B^{(i)}\subseteq\cdots\subseteq B''\subseteq B'\subseteq B^{(0)}=B$ be a chain of commutants for *B*. Then $B^{(0)}=B\subseteq A=A^{(0)}$. If it has already been proved that $B^{(i)}\subseteq A^{(i)}$, then $B^{(i+1)}:=[B^{(i)},B^{(i)}]_m\subseteq[A^{(i)},A^{(i)}]_m\subseteq A^{(i+1)}$. From the equality $A^{(k)}=\{0\}$ we have now that $B^{(k)}=\{0\}$. □

Lemma 5: If B and C are solvable ideals in an n-algebra A, so is $B+C$.

Proof: From Definition 8 one can easily get that

$$(B+C)'\subseteq B'+C'+B\cap C.$$

If it has already been proved that $(B+C)^{(i)}\subseteq B^{(i)}+C^{(i)}+B\cap C$, then $(B+C)^{(i+1)}:=[(B+C)^{(i)},(B+C)^{(i)}]_m\subseteq[B^{(i)}+C^{(i)}+B\cap C,\ B^{(i)}+C^{(i)}+B\cap C]_m\subseteq[B^{(i)}+C^{(i)},B^{(i)}+C^{(i)}]_m+B\cap C\subseteq B^{(i+1)}+C^{(i+1)}+B^{(i)}\cap C^{(i)}+B\cap C\subseteq B^{(i+1)}+C^{(i+1)}+B\cap C$.

Therefore, there must be an integer *k* such that $(B+C)^{(k)}\subseteq B\cap C$, which is solvable by Corollary 3. From this we deduce that $B+C$ is solvable. □

Now form $R(A):=\Sigma_\alpha B_\alpha$, where α runs over the set of all solvable ideals of *A*. Due to Lemma 5, $R(A)$ is the unique maximal solvable ideal in *A*. After this remark the following definition makes sense.

Definition 14: The radical $R(A)$ *of an n-algebra is the unique maximal solvable ideal of A. In case* $R(A)=0$, *A is called semisimple.*

Obviously, any simple *n*-algebra is automatically semisimple. Since the *n*-algebra of multidimensional matrices (Example 1) is simple, it gives automatically the example of semisimple *n*-algebra.

In order to show that every homomorphic image of the solvable *n*-algebra is also solvable, we need some general facts.

Lemma 6: Let B be an ideal and C a subalgebra of an n-algebra A. Then every element of the subalgebra $\{B,C\}$ *of A, generated by B and C, may be written as* $b+c$, *where* $b\in B$, $c\in C$, *so one can write* $\{B,C\}=B+C$.

Proof: Obviously, all elements of the form $b+c$ are contained in $\{B,C\}$. On the other hand, the set of all elements of this form is a subalgebra of *A*, containing *B* and *C*. In fact, by the definition of ideal we have for every $b_1, b_2,\ldots,b_n\in B$, $c_1, c_2,\ldots,c_n\in C$: $m((b_1+c_1)\otimes\cdots\otimes(b_n+c_n))=m(c_1\otimes\cdots\otimes c_n)+B\subseteq B+C$. □

The following theorem is often referred to as the *isomomorphism theorem.*

Theorem 2: *Let B,C be two subalgebras of an n-algebra A, and let B be ideal in the subalgebra $\{B,C\}$. Then $B\cap C$ is the ideal in C and $\{B,C\}/B$ is isomorphic to $C/(B\cap C)$.*

Proof: In fact, Lemma 6 shows that every conjugacy class of the n-algebra $\{B,C\}$ by the ideal B contains at least one element from C. Then the canonical homomorphism of $\{B,C\}$ on $\{B,C\}/B$ sends the subalgebra C onto this factor algebra. Evidently, $B\cap C$ is the kernel of this homomorphism. Theorem 1 shows that $B\cap C$ is the ideal in C. The n-algebras $\{B,C\}/B$ and $C/(B\cap C)$ consist from the conjugacy classes of the form $B+c$ and $B\cap C+c$, respectively, so one can establish an obvious one-to-one correspondence between them and verify directly that it is an isomorphism. □

A more general case is considered in the following lemma.

Lemma 7: Let B,B', C,C' be two subalgebras of an n-algebra A, let B' be an ideal in B, and let C' be an ideal in C. Then $B'+(B\cap C')$ is the ideal in $B'+(B\cap C)$, $C'+(C\cap B')$ is the ideal in $C'+(C\cap B)$, and the n-algebras $B'+(B\cap C)/B'+(B\cap C')$ and $C'+(C\cap B)/C'+(C\cap B')$ are isomorphic.

Proof: Let $D=B\cap C$. As C' is the ideal in C and $D\subseteq B$, then Theorem 2 shows that $D\cap C'=B\cap C\cap C'=B\cap C'$ is the ideal in D. The same is true for $C\cap B'$ and for the sum D' of these ideals: $D'=(B\cap C')+(C\cap B')$.

On the other hand, as B' is the ideal in B, then according to Lemma 6 $\{B',B\cap C\}=B'+(B\cap C)=B'+D$. One can represent every element from this n-algebra in the form $b'+d$, where $b'\in B'$, $d\in D$. There exists a correspondence between all elements of this form and elements of the form $D'+d$ of the algebra $E=D/D'$.

In fact, one can write the element $b'+d$ as b'_1+d_1, where $b'_1\in B'$, $d_1\in D$, so that $-b'_1+b'=d_1-d\in B'\cap D\subseteq B'\cap C\subseteq D'$; this is why $d_1=(-b'_1+b')+d\in D'+d$.

The above correspondence is a homomorphism of the n-algebra $B'+D$ into the n-algebra E: as B' is the ideal in $B'+D$, D is the subalgebra of A; then $m((b'_1+d_1)\otimes\cdots\otimes(b'_n+d_n))=b'_0+m(d_1\otimes\cdots\otimes d_n)$, where $b'_0\in B'$, $m(d_1\otimes\cdots\otimes d_n)\in D$. The kernel of this homomorphism is $B'+(B\cap C')$. In fact, this sum is contained in the kernel, because $B\cap C'\subseteq D'$.

On the other hand, if the image of the element $b'+d\in B'+D$ is contained in D', then $d\in D'=(B\cap C')+(C\cap B')$; this is why one can write $d=u+v$, where $u\in C\cap B'$, $v\in B\cap C'$. Finally, $b'+d=b'+u+v\in B'+(B\cap C')$.

One can see now that $B'+(B\cap C')$ is an ideal in $B'+D=B'+(B\cap C)$, and the n-algebras $B'+(B\cap C)/B'+(B\cap C')$ and E are isomorphic. One can similarly prove that $C'+(C\cap B')$ is an ideal in $C'+(C\cap B)$, and that the n-algebras $C'+(C\cap B)/C'+(C\cap B')$ and E are isomorphic. □

Remark 3: If $C\subseteq B,C'=\{0\}$ *Lemma 7 becomes the isomorphism theorem.*

Definition 15: We say that a normal series $\{0\}=B_l\subset B_{l-1}\subset\cdots\subset B_1\subset B_0=A$ is a condensation of a normal series $\{0\}=A_k\subset A_{k-1}\subset\cdots\subset A_1\subset A_0=A$, if every A_i $(i=1,2,\ldots,k-1)$ coincides with one from B_j (it is obvious that $k\leqslant l$). We say that two normal series are isomorphic if $k=l$, and there exists such a one-to-one correspondence between their factors, that the corresponding factors are isomorphic as n-algebras (we do not suppose that precisely the factors with the same indices are isomorphic).

Theorem 3: *Every two normal series for an n-algebra A have isomorphic condensations.*

Proof: Let $\{0\}=A_k\subset A_{k-1}\subset\cdots\subset A_1\subset A_0=A$ and $\{0\}=B_l\subset B_{l-1}\subset\cdots\subset B_1\subset B_0=A$ be two normal series for A. Put $A_{ij}=A_i+(A_{i-1}\cap B_j)$ $(i=1,\ldots,k,\ j=0,\ldots,l)$, $B_{ji}=B_j+(B_{j-1}\cap A_i)$ $(i=0,\ldots,k,\ j=1,\ldots,l)$. This makes sense according to Lemma 6: in fact, for example, A_i is an ideal and $A_{i-1}\cap B_j$ is a subalgebra in A_{i-1}. One can also remark that for $i=1,\ldots,k$, $j=1,\ldots,l$ we have $A_i=A_{il}\subseteq A_{ij}\subseteq A_{ij-1}\subseteq A_{i0}=A_{i-1}$, $B_j=B_{jk}\subseteq B_{ji}\subseteq B_{ji-1}\subseteq B_{j0}=B_{j-1}$.

According to Lemma 7, A_{ij} and B_{ji} are the ideals in A_{ij-1} and B_{ji-1}, respectively, and the

n-algebras A_{ij-1}/A_{ij} and B_{ji-1}/B_{ji} are isomorphic. If now we put all A_{ij} $(j=1,\ldots,l-1)$ between A_{i-1} and A_i $(i=1,\ldots,k)$, we get a condensation of this series, in which some members can coincide. Similarly, one can get a condensation of a second series. But using the above isomorphism, one can exclude the coinciding members. □

Now we can show that every hormomorphic image of the solvable n-algebra is also solvable. In fact, according to Theorem 1, it is sufficient to prove this statement for a factor algebra A/B. Since any condensation of a solvable series is solvable itself, then, according to Theorem 3, there exists a solvable condensation of a series $\{0\}\subset B\subset A$. According to the statements formulated just after Theorem 1, we get a solvable series in A/B. After this remark we are able to prove the following theorem about semisimple n-algebras.

Theorem 4: *If R is the radical of an n-algebra A, then A/R is semisimple, and if B is an ideal in A, such that A/B is semisimple, then* $R\subseteq B$.

Proof: (1) The ideals of A/R have the form C/R, where C is an ideal of A containing R (see the remarks following Theorem 1). Since $(C/R)^{(i)}=(C^{(i)}+R)/R$, if C/R is solvable, then, for some k, $C^{(k)}\subseteq R$. This implies that C is solvable in A, hence $C=R$, and A/R is semisimple.

(2) Suppose A/B is semisimple and consider its ideal R/B, which is solvable due to the remark preceding this theorem. Since it should be 0, then $R\subseteq B$. □

Generally, the class of solvable n-algebras is wider then the class of nilpotent ones, but they coincide if the multiplication is strongly associative. In this special case one can define a product of any $1+k(n-1)$ elements (here $k\in N\cup\{0\}$).

Lemma 8: An ideal of a strongly associative n-algebra generated by all possible products of any $1+k(n-1)$ *elements (*$k\in N\cup\{0\}$ *is fixed), coincides with the set of all linear combinations of these elements.*

Proof: In fact, multiplying any linear combination of the above products by $n-1$ arbitrary elements of A in any order, we get a linear combination of some products of $1+(k+1)(n-1)$ elements. Replacing in any such product any group of n neighboring elements by their product, we get again a linear combination of the initial form. On the other hand, the above set can be reduced to the set of all linear combinations of the elements from A. □

Corollary 4: The subalgebra $A^{(i)}$ *in a chain of commutants of a strongly associative n-algebra* $A(i\in N\cup\{0\})$ *is the ideal generated by the set of all possible products from* n^i *elements from A.*

Proof: For $n=0$ the statement is obvious; for $n=1$ it follows from the definition of a commutant. If this statement holds for some natural i, then $A^{(i+1)}=[A^{(i)},A^{(i)}]_m$ is generated by the set of all possible products from $n\circ n^i=n^{i+1}$ elements from A. □

Note that n^i can always be represented as $1+k(n-1)$ for some k.

Corollary 5: The ideal A_i in a lower central chain of a strongly associative n-algebra $A(i\in N\cup\{0\})$ is the ideal generated by the set of all possible products from $1+i(n-1)$ elements from A.

Proof: For $n=0$ the statement is obvious; for $n=1$ it follows from the definition of commutant. If this statement holds for some natural i, then $A_{i+1}=[A_i,A_i]_m$ is generated by the set of all possible products of $1+(i+1)(n-1)$ elements from A. □

Corollary 6: A strongly associative n-algebra is solvable if and only if it is nilpotent.

Proof: From the previous corollaries we have $A^{(i)}=A_{n_i}$, where $n_i=(n^i-1)/(n-1)$, so that $A^{(k)}=\{0\}$ for some natural k if and only if $A_{n_k}=\{0\}$ for this k. □

In the next section we will look more closely at the ternary algebra of complex-valued cubic matrices with $l=2$ and 3. Such a study seems to be particularly important in view of the pertinence of these matrices to a possible generalization of quantum mechanics and field theory. On the other hand, in this special case we are able to gather more information about the structure of entire algebra and its subalgebras.

IV. CUBIC MATRICES WITH *l*=2 AND 3

Consider the example 1 of multidimensional matrices for the simplest case $l=2$, $n=3$. Let us show that it is possible to obtain a decomposition of this eight-dimension alternary algebra (as a linear space) into the direct sum of its three special subalgebras. In fact, there are eight matrix units in the algebra. Three of them, e_{111}, e_{222}, e_{333}, generate a subalgebra Diag of diagonal matrices, which is obviously S_n commutative in the sense of Sec. II.

Using the formula (2) in the special case considered here, one can see that the subalgebra generated by the matrix units e_{112}, e_{121}, e_{122} has a zero multiplication, and consequently it is Abelian in the sense of Sec. IV. The same is true for the subalgebra generated by the matrix units e_{221}, e_{212}, e_{211}. Thus, we have a decomposition,

$$\mathrm{Mat}(2,3;C)=\mathrm{Diag}\oplus\{e_{112},e_{121},e_{122}\}\oplus\{e_{221},e_{212},e_{211}\},$$

in which the first summand is S_n commutative and the other two are Abelian subalgebras. This decomposition looks like a decomposition of 2×2 matrices into the diagonal and two triangular subalgebras. But it is not unique; one can get at least two similar decompositions:

$$\mathrm{Mat}(2,3;C)=\mathrm{Diag}\oplus\{e_{112},e_{212},e_{211}\}\oplus\{e_{121},e_{122},e_{221}\}$$

and

$$\mathrm{Mat}(2,3;C)=\mathrm{Diag}\oplus\{e_{121},e_{221},e_{211}\}\oplus\{e_{112},e_{122},e_{212}\}.$$

Thus, we have a few examples of Abelian ternary algebras that are automatically nilpotent and solvable. Recall that the algebra of all multidimensional matrices (Example 1) gives the example of simple *n*-algebra, which is automatically semisimple.

Since the groups S_n and Z_n act (by permutation of indices) on $\mathrm{Mat}(l,n;C)$, it is also natural to present this *n*-algebra as a direct sum of the corresponding irreducible linear subspaces. If, in particular, $n=3$ and $j=e^{2\pi i/3}$, then introduce the following subspaces:

$$M_m:=\{a\in\mathrm{Mat}(l,3;C):a_{ijk}=j^m a_{jki},\quad \text{for all } i,j,k=1,2,3\},$$

where $m=0,1,2$. For $m=1,2$ we have $\dim(M_m)=(l^3-l)/3$, and $M_0=\mathrm{Diag}\oplus M_0'$, where $\dim(M_0')=(l^3-l)/3$. Finally,

$$\mathrm{Mat}(l,3;C)=\mathrm{Diag}\oplus M_0'\oplus M_1\oplus M_2.$$

Here Diag is the S_n-commutative ternary algebra, but other summands are not ternary algebras with respect to the multiplication (4). The situation changes if we introduce a new multiplication that follows the particular symmetry of the given type of matrices. For example, in Refs. 9 and 7, the following multiplication was introduced for the two matrices $\rho^{(\alpha)}$ belonging to M_1:

$$\{\rho^{(\alpha)},\rho^{(\beta)},\rho^{(\gamma)}\}=\rho^{(\alpha)}*\rho^{(\beta)}*\rho^{(\gamma)}+j\rho^{(\beta)}*\rho^{(\gamma)}*\rho^{(\alpha)}+j^2\rho^{(\gamma)}*\rho^{(\alpha)}*\rho^{(\beta)},$$

where $\alpha,\beta,\gamma=1,2,\ldots,(l^3-l)/3$, $\rho^{(\alpha)}$, $\rho^{(\beta)}$, $\rho^{(\gamma)}\in M_1$, *and*

$$(\rho^{(\alpha)}*\rho^{(\beta)}*\rho^{(\gamma)})_{isk}:=\sum_{pqr}\rho^{(\alpha)}_{piq}\rho^{(\beta)}_{qsr}\rho^{(\gamma)}_{rkp},$$

where $i,s,k,p,q,r=1,2,\ldots,1$.

Then it is obvious that because of the symmetry of the ternary *j bracket*, one has

$$\{\rho^{(\alpha)},\rho^{(\beta)},\rho^{(\gamma)}\}_{isk}=j\{\rho^{(\alpha)},\rho^{(\beta)},\rho^{(\gamma)}\}_{ski},$$

so that it is easy to see that M_1 is a ternary algebra with respect to the *j-bracket* multiplication. Moreover, for $l=2$ we have

$$\{\rho^{(1)},\rho^{(2)},\rho^{(1)}\}=-\rho^{(2)};\quad \{\rho^{(2)},\rho^{(1)},\rho^{(2)}\}=-\rho^{(1)};$$

all other combinations being proportional to the above ones with a factor j or j^2, whereas the j brackets of three identical matrices do obviously vanish.

A natural question to ask now concerns the nature of the automorphisms of this simple ternary algebra. The most general homogeneous transformation of the cubic matrices $\rho^{(\alpha)}$ involves all their indices:

$$\tilde{\rho}^{\ (\alpha)}_{ikm}=\Lambda^{\alpha}_{\beta}U^{p}_{i}U^{r}_{k}U^{s}_{m}\rho^{(\beta)}_{prs},\quad \alpha,\beta,i,k,\ldots=1,2,$$

with (invertible) matrices Λ^{α}_{β}, U^{p}_{i} chosen in such a way that the ternary relations between the transformed cubic matrices $\tilde{\rho}^{\ (\alpha)}$ remain the same as defined above.

Let us show that even in a simplified case when we choose $U^{p}_{q}=\delta^{p}_{q}$, the condition of invariance of the ternary algebra leads to nontrivial solutions for the group of matrices Λ^{α}_{β}. As a matter of fact, we get the following system of equations for Λ^{α}_{β}:

$$\Lambda^1_1(\Lambda^2_2\Lambda^1_1-\Lambda^1_2\Lambda^2_1)=\Lambda^2_2;\quad \Lambda^1_2(\Lambda^2_1\Lambda^1_2-\Lambda^1_1\Lambda^2_2)=\Lambda^2_1,\quad \text{and}$$

$$\Lambda^2_2(\Lambda^1_1\Lambda^2_2-\Lambda^2_1\Lambda^1_2)=\Lambda^1_1;\quad \Lambda^2_1(\Lambda^1_2\Lambda^2_1-\Lambda^2_2\Lambda^1_1)=\Lambda^1_2,$$

from which it follows that $[\det(\Lambda)]^2=1$, so that either

$$\det(\Lambda)=1\quad \text{and}\ \ \Lambda^1_1=\Lambda^2_2,\quad \Lambda^1_2=-\Lambda^2_1,\quad \text{or}$$

$$\det(\Lambda)=-1\quad \text{and}\ \ \Lambda^1_1=-\Lambda^2_2,\quad \Lambda^1_2=\Lambda^2_1.$$

This group has two disjoint components; the simply connected component of unit element is a subgroup, whereas the second component can be obtained from the first one by multiplication by the matrix $\left(\begin{smallmatrix}1 & 0\\ 0 & -1\end{smallmatrix}\right)$.

The simply connected subgroup is an Abelian real two-dimensional Lie group of matrices whose general form is

$$\begin{pmatrix} a & b\\ -b & a\end{pmatrix},\quad \text{with}\ \ a,\quad b\ \ \text{complex numbers satisfying}\ \ a^2+b^2=1,$$

which can be decomposed into a product of two matrices:

$$\begin{pmatrix} \cosh\psi & i\sinh\psi\\ -i\sinh\psi & \cosh\psi\end{pmatrix}\quad (\psi\in R)\quad \text{and}\quad \begin{pmatrix} \cos\phi & \sin\phi\\ -\sin\phi & \cos\phi\end{pmatrix}\quad (\phi\in[0,2\pi)).$$

This group can be represented as the isometry group of a Minkowskian hyperboloid parametrized with two variables, ψ and ϕ, as $[0\leqslant\phi\leqslant 2\pi]\times[-\infty\leqslant\psi\leqslant\infty]$, embedded in a three-dimensional Minkowskian space as the pseudosphere $x^2+y^2-\tau^2=R^2$, so that $x=R\cosh\psi\cos\phi$, $y=R\cosh\psi\sin\phi$, $\tau=\sinh\psi$.

This invariance group reduces to $U(1)$ if we impose the reality condition on the matrices $\rho(\alpha)$, requiring that $\rho^{(\alpha)}_{ikl}=\overline{\rho}^{\ (\alpha)}_{lki}$.

A similar subspace of cubic $2\times2\times2$ matrices can be introduced, with the adjoint representation of the group Z_3 acting on them, i.e. belonging to M_2:

$$\kappa_{ikm}=j^2\kappa_{kmi}=j\kappa_{mik},$$

which is close under a j^2-skew ternary commutator composition law. Its group of automorphisms has the similar structure.

Our next aim is to find a representation of the above ternary algebra in terms of a *j-commutator* defined in an associative algebra of matrices $M_2(C)$ as follows:

$$[A,B,C]:=ABC+jBCA+j^2CAB.$$

It is easy to note that the trace of any j bracket of three matrices must vanish; therefore, the matrices that would represent the cubic matrices $\rho^{(\alpha)}$ must be traceless. Then, it is a matter of simple exercise to show that any two of the three Pauli sigma matrices divided by $\sqrt{2}$ provide us with a representation of the ternary j-skew algebra of the ρ matrices; e.g.

$$\sigma^1\sigma^2\sigma^1+j\sigma^2\sigma^1\sigma^1+j^2\sigma^1\sigma^1\sigma^2=-2\sigma^2, \quad \sigma^2\sigma^1\sigma^2+j\sigma^1\sigma^2\sigma^2+j^2\sigma^2\sigma^2\sigma^1=-2\sigma^1$$

(the same result can be obtained with the couples $\{\sigma^3,\sigma^1\}$ or $\{\sigma^2,\sigma^3\}$). Thus, it is possible to find nontrivial representations of the nonassociative j-bracket ternary algebra in the associative matrix algebra.

A similar representation can be found for cubic matrices $\kappa^{(\alpha)}$ with the j^2-skew bracket.

It is also worthwhile to note that ordinary Lie algebras with the skew-symmetric composition law can be found in the representation of the ternary j-bracket algebra in associative algebra, provided the latter is endowed with a central (unit) element. Indeed, we have

$$[A,1,C]=A1C+j1CA+j^2CA1=AC+(j+j^2)CA=AC-CA. \tag{5}$$

The ternary algebra of complex cubic matrices with $l=3$ is much more complicated. Here again, subspaces displaying a partial Z_3-symmetry can be defined, so that the whole algebra of the dimension 27 decomposes as $M=\mathrm{Diag}\oplus M_0\oplus M_1\oplus M_2$. The part Diag is three dimensional, while each of the subspaces M_a, $a=0,1,2$ contains eight independent generators. As in the previous example, M_1 becomes a ternary algebra with respect to the *j-skew* bracket $[K^{(a)},K^{(b)},K^{(c)}]=K^{(a)}*K^{(b)}*K^{(c)}+jK^{(b)}*K^{(c)}*K^{(a)}+j^2K^{(c)}*K^{(a)}*K^{(b)}$.

The group of automorphisms of this algebra is essentially richer than the two-parameter group discussed above, and we describe it in a separate paper.

The most general Skyrme–Sigma models in two and three Euclidean dimensions described by $O(3)$ and $O(4)$ fields, respectively, are studied first by numerical methods, and analytic proofs of existence are subsequently given. Particular emphasis is given to the special cases of these models, where the topological inequalities can be saturated by self-duality equations. The $O(d+1)$ models in d dimensions exhibit qualitatively similar features. © *1996 American Institute of Physics.* [S0022-2488(96)00105-0]

I. INTRODUCTION

The $O(d+1)$ Sigma models in d Euclidean dimensions described in terms of scalar fields ϕ^a, $a=1,2,..,(d+1)$, subject to the condition $\phi^a\phi^a=1$ can have kinetic terms which are the squares of the n-fold antisymmetrized products of the fields $\phi_i^a=\partial_i\phi^a$, starting from $n=d$ down to $n=0$, the last one being a potential term which breaks the global $O(d+1)$ symmetry. That these kinetic terms should be the squares of antisymmetric n-forms, and not simply the squares of some arbitrary n-rank tensor field, is because we require that in any kinetic term there should be no higher power than the quadratic power of a velocity field. In the usual Skyrme model,[1] the $n=1$ and $n=2$ kinetic terms occur and the $n=3$ kinetic term as well as the $n=0$ potential term are absent. We shall refer to the class of such models as Skyrme–Sigma models after the usual Skyrme model[1] in three dimensions which features a quartic kinetic Skyrme term. In the present paper, we shall study the most general such model in any given dimension d, and will concentrate on an interesting limiting case of such models that support self-dual solutions.

While the main aim of the present work is to study the properties of the most general $O(d+1)$ Skyrme–Sigma model in d Euclidean dimensions, the particular cases of $d=2,3$ are of definite physical relevance. In $2+1$ dimensions the inclusion of a $(n=2)$ Skyrme term and a $(n=0)$ potential term in the usual $O(3)$ Sigma model renders the otherwise unstable soliton lump, stable.[2] In three dimensions, the addition of a $(n=3)$ sextic kinetic term and a $(n=0)$ potential term introduces new parameters which are exploited[3] in the phenomenological analysis of nuclear forces. Thus the mathematical problem under consideration in the present work is justified on the grounds of its physical relevance.

To make a representative study of these models, it is necessary to consider at least up to $d=3$ since $d=2$ is a very special case. One special feature of the $d=2$ case is that there exist radially symmetric solutions of arbitrary topological charge, or vorticity, all satisfying the same boundary conditions while in all higher dimensions starting with $d=3$ the spherically symmetric solution of a given topological charge satisfies a particular boundary condition specific to that topological charge. Another special feature of Sigma models in two dimensions is that they can be reparametrized in terms of the CP^1 valued fields z^α, $\alpha=1,2$, constrained by $\overline{z^\alpha}z_\alpha=1$, in which case the

additional free component in z parametrizes a local $U(1)$ invariance in the reparametrized system. This is a low-dimensional accident.

Even the $d=3$ models are in some sense special in that, due to a low-dimensional accident, it is possible to express the field ϕ^a instead as an SU(2) group element $U=\phi^a\sigma^a$, and its inverse $U^{-1}=U^\dagger=\phi^a\tilde{\sigma}^a$ in the usual way.[1] However, in this case the fields ϕ^a and U have exactly the same number of independent components and hence the question of a new local invariance resulting from the reparametrization does not arise. We shall therefore ignore this special feature of the three-dimensional models and treat them as typical examples of Sigma models in dimensions greater than 2.

We define the generic $O(d+1)$ Skyrme–Sigma model in d Euclidean dimensions by the system

$$\mathscr{L}=\kappa_d^{2d}\phi(d)^2+\kappa_{d-1}^{2(d-1)}\phi(d-1)^2+\cdots+\kappa_1^2\phi(1)^2+\lambda_0\phi(0)^2 \tag{1}$$

in terms of the d form fields defined by

$$\phi(n)=\phi^{a_1a_2\ldots a_n}_{i_1i_2\ldots i_n}=\phi^{[a_1}_{[i_1}\phi^{a_2}_{i_2}\cdots\phi^{a_n]}_{i_n]}. \tag{2}$$

where the brackets [...] imply total antisymmetrization. The notation $\phi^a_i=\partial_i\phi^a$ is used for the velocity fields, and the square of the zero-form $\phi(0)^2=V$, which is the only term in (1) that does not involve velocity fields, is an $O(d+1)$ breaking potential. We exclude all kinetic terms featuring a velocity field to a power higher than *two* in the definitions of the models (1).

The coupling constants κ_n all have the dimensions of a length, while the constant λ_0 is dimensionless. Since our study of the solutions of models (1) will be restricted to radially/spherically symmetric field configurations only, we shall find it convenient to rescale the radial variable as $r=\kappa\rho$ in terms of the constant κ with the dimensions of a length, so that the rescaled radial variable ρ is dimensionless. At that stage, the dimensional constants κ_n in (1) will be replaced by the dimensionless coupling constants λ_n defined by $\lambda_n=(\kappa_n/\kappa)^{2n}$.

The topological charge densities of these models are

$$\varrho_d=\varepsilon_{i_1i_2\cdots i_d}\varepsilon^{a_1a_2\cdots a_da_{d+1}}\phi^{a_1}_{i_1}\phi^{a_2}_{i_2}\cdots\phi^{a_d}_{i_d}\phi^{a_{d+1}}, \tag{3}$$

which provides a (topological) lower bound on the density (1). The topological charge is given by the volume integral of ϱ,

$$q_d=\int\varrho_d\,d^dx=\Omega_d\int\overline{\varrho_d}(\rho)\rho^{d-1}\,d\rho, \tag{4}$$

where Ω_d is the angular volume in d Euclidean dimensions and $\overline{\varrho_d}(\rho)$ is the density remaining in the integrand of (8) after imposing spherical symmetry on the fields $\phi^a=(\phi^\alpha,\phi^{d+1})$, $\alpha=1,2,..,d$, and integrating over the angular coordinates.

The radially/spherically symmetric Ansatz, in which n^α is the *unit* radius vector in d dimensions, is

$$\phi^\alpha=\sin f(\rho)n^\alpha,\quad \phi^{d+1}=\cos f(\rho). \tag{5}$$

Substituting (5) in (4), the topological charge reduces to a one-dimensional integral over ρ with integrand

$$\varsigma_d=\rho^{d-1}\overline{\varrho_d}=f_\rho\sin^{d-1}f, \tag{6}$$

where we have used the notation $f_\rho=\partial_\rho f$.

From (6), we can now infer a well-known property of the topological charge of the three-dimensional spherically symmetric Skyrmions,[4] namely that by choosing the asymptotic values suitably as follows,

$$\lim_{\rho\to 0} f(\rho)=m\pi, \quad \lim_{\rho\to\infty} f(\rho)=0, \tag{7}$$

one has a Skyrmion of topological charge m, where the energy of the $m=2$ Skyrmion is much larger than the energy of the unit charge Hedgehog.[4] It is easy to see by inspection of the integrals $\int \sin^{d-1} df$ between the limits (7), that for **even** d the topological charge will vanish except when m is chosen to be odd and for all odd m it equals one. For **odd** d, however, the corresponding value of the topological charge equals m, for all even and odd m. Our subsequent analyses of the $d=2$ and $d=3$ cases therefore will typify these two categories.

The main thrust of the present work is to study a particular aspect of the models (1) for $d=2,3$. It is the special subclasses of these models that support self-dual solutions.

The first such subclass of solutions is already known, namely the scale invariant hierarchy of $O(2p+1)$ Sigma models in $2p$ dimensions given in Ref. 5, the first member of which is the familiar $O(3)$ sigma model[6] in two dimensions. These are the subclass of (1) with all κ_n vanishing *except* $\kappa_{d/2}=\kappa_p$. The self-duality equations for the pth member of that hierarchy are

$$\phi(p)=*\phi(p) \tag{8}$$

with $*\phi(p)$ defined by

$$*\phi(p)=\varepsilon_{i_1\cdots i_p i_{p+1}\cdots i_{2p}}\varepsilon^{a_1\cdots a_p a_{p+1}\cdots a_{2p+1}}\phi^{a_{p+1}\cdots a_{2p}}_{i_{p+1}\cdots i_{2p}}\phi^{2p+1}. \tag{9}$$

The topologically stable and finite *energy* self-dual solutions of these scale invariant models are *power* localized to an arbitrary scale, namely to κ introduced above. With the exception of the case $p=1$, the self-duality equations (8) are overdetermined[7] and support *only* spherically symmetric solutions. The new hierarchy of models that we shall introduce here differ from the scale invariant hierarchy[5] on both those counts. As we shall see below, with a suitable choice of V in (1), they are *exponentially* localized. Furthermore, the new hierarchy of self-duality equations are not overdetermined.

The new hierarchy of $O(d+1)$ models are those obtained from (1) by setting all κ_n equal to zero with the exception of κ_d and λ_0:

$$\mathscr{L}_0=\kappa_d^{2d}\phi(d)^2+\lambda_0 V. \tag{10}$$

It is clear that the *energy* densities (10) can be absolutely minimized by a self-duality equation. In terms of the dimensionless variable $y_i=x_i/\kappa$, where κ is a constant with the dimensions of length so that $\lambda_2=(\kappa_d/\kappa)^{2d}$, this self-duality equation can be expressed as

$$\varrho_d=d!\sqrt{\frac{\lambda_0 V}{\lambda_2}}, \tag{11}$$

where ϱ_d is defined by (3).

The energy densities for fields satisfying (11) are equal to the topological charge densities, which are proportional to $\sqrt{V}\varrho_d$. The volume integral of the latter takes the same values as that of (3).

The new hierarchy of models (10) is analogous to a class of d-dimensional symmetry-breaking global $O(d)$ models introduced in Ref. 8, and further studied in Ref. 9. We shall discuss the relative properties of the $O(d+1)$ models (10) and of the $O(d)$ models of Ref. 8 in some detail. In addition to this, we shall discuss some general properties of the full models (1), but

always restricting to the radially/spherically symmetric field configurations. The cases of $d=2$ and $d=3$ are discussed respectively in Secs. II and III below, each section being subdivided into subsections dealing with the hierarchy of the full models (1) and the new hierarchy (10) supporting self-dual solutions. The self-dual solutions of the restricted models are found explicitly in Secs. II B and III B, respectively, while the solutions of the full models not admitting self-dual solutions are studied numerically in Sec. II A.

II. THE TWO-DIMENSIONAL CASE

The full model (1) in this case was studied in detail, in the context of a particular application, in Ref. 10. We shall nevertheless give a fairly complete account of it here so that the discussion of the special case (10) can be presented in a natural way. In terms of the dimensionless coordinates $y_i=x_i/\kappa$, (1) takes the form

$$\mathscr{L}=\lambda_2\phi(2)^2+\lambda_1\phi(1)^2+\lambda_0 V \tag{12}$$

in which the potential V will be specified later.

The radially symmetric field configuration of $\phi^a=(\phi^\alpha,\phi^3)$, with $\alpha=1,2$, is defined by

$$\phi^\alpha=\sin f(\rho)n^\alpha, \quad \phi^3=\cos f(\rho), \tag{13}$$

characterized by its vorticity n, defining the unit vector $n^\alpha=(\cos n\theta,\sin n\theta)$ in (13), in terms of the azimuthal angle θ. For this field configuration, the system (12) reduces to the following one-dimensional subsystem given by

$$L_2=\left(\lambda_1\rho+\lambda_2 n^2\,\frac{\sin^2 f}{\rho}\right)f_\rho^2+\lambda_2 n^2\,\frac{\sin^2 f}{\rho}+\lambda_0\rho V \tag{14}$$

defined via the *energy* integral

$$\int \mathscr{L}_2\, d^2x=2\pi\int L_2\, d\rho. \tag{15}$$

A. The full model

Here we take the full system (14) with all coupling constants λ_0, λ_1, and λ_2 nonzero, and with the choice for the potential

$$V=(1-\phi^3)^2=(1-\cos f)^2 \tag{16}$$

differing from the choice made in Ref. 10. This is done in anticipation of the considerations of the next subsection. The resulting Euler–Lagrange equations are

$$\left(\lambda_1\rho+\lambda_2 n^2\,\frac{\sin^2 f}{\rho}\right)f_{\rho\rho}+\lambda_2 n^2\,\frac{\sin f\cos f}{\rho}\,f_\rho^2+\left(\lambda_1-\lambda_2 n^2\,\frac{\sin^2 f}{\rho^2}\right)f_\rho$$
$$-\lambda_2 n^2\,\frac{\sin f\cos f}{\rho}-2\lambda_0\rho(1-\cos f)\sin f=0. \tag{17}$$

Assuming sufficiently strong decay in the $\rho\gg 1$ region, we linearize equation (17) around the asymptotic value of f given by (7)

$$\rho^2 f_{\rho\rho}+\rho f f_\rho-\frac{\lambda_2}{\lambda_1}\,n^2 f=0, \tag{18}$$

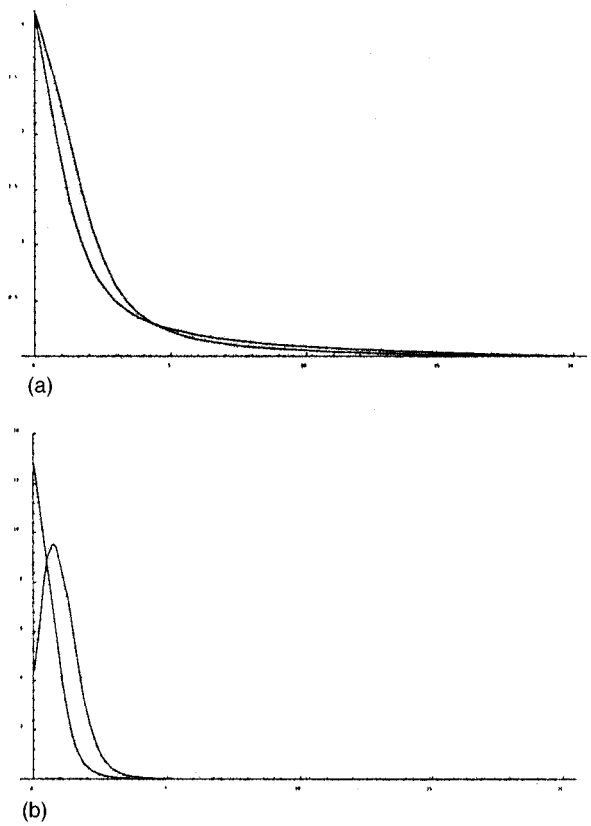

FIG. 1. (a) Profiles of f for the $d=2$ model (14) with the potential (16) and $\lambda_0=\lambda_1=\lambda_2=1$, for vorticities $n=1,2$, from left to right. (b) Profiles of the energy densities for the vortices in (a). The $n=2$ profile is ring shaped.

which yields the decaying solution

$$f \approx \frac{1}{\rho^{n\sqrt{\lambda_2/\lambda_1}}}, \tag{19}$$

justifying our linearization (18).

In the $\rho \ll 1$ region, we try a power series solution and find

$$f = \pi + A\rho^n + B\rho^{n+2} \tag{20}$$

for the two vorticities $n=1$ and $n=2$ and find

$$B = -A\,\frac{6\lambda_0 + 2\lambda_1 A^2 - \lambda_2 A^4}{24(\lambda_1 + \lambda_2 A^2)}, \quad B = -A\,\frac{\lambda_0 + 8\lambda_2 A^2}{6\lambda_1}, \tag{21}$$

respectively, with the constant A to be determined by the numerical integration. In (20), we have restricted to the value of $m=1$ given in the general case in (7). Recall that for all *even d* only *odd* values of m lead to nontrivial topological solutions and all have the same topological charge, and hence $m=1$ is essentially the unique choice.

The numerical integrations were performed for the systems with $\lambda_0=\lambda_1=\lambda_2=1$, for $n=1$ and $n=2$ with the values of $A=-1.5\,199\,879$ and $A=-12.227\,601$, respectively. The profiles of the

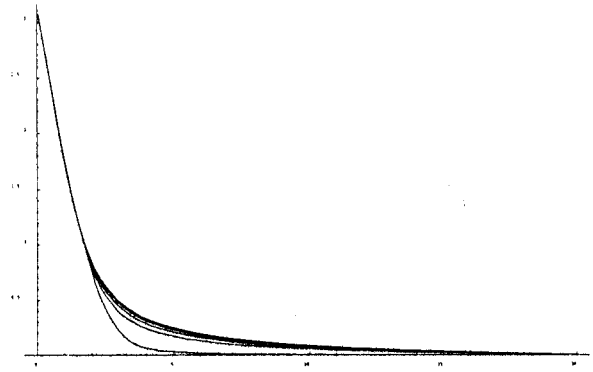

FIG. 2. Profiles of f with unit vorticity ($n=1$) for the $d=2$ model (14) with the potential (16), with $\lambda_0=\lambda_2=1$ and with λ_1 decreasing as in Table II. Lower curves correspond to lower values of λ_1.

functions f are given in Fig. 1(a), and the energy density profiles in Fig. 1(b). The total energies for these two cases were calculated to be: $E(n=1)=8.2\,259\,968$ and $E(n=2)=16.6\,605\,004$ where we find, as in Ref. 10, that $E(n=2)>2E(n=1)$, so there are no radially symmetric bound states.

Perhaps the most important lesson learnt from the work of this subsection is that the constant B in the asymptotic solution (20) for $n=1$ is nonsingular in the limit of $\lambda_1\to 0$, as seen from the first member of (21), which implies that a self-dual solution to the $p=1$ member of the hierarchy (10) exists as a limit of the $n=1$ solution found above. This is interesting in the background of the corresponding situation for the two-dimensional $O(2)$ models studied in Ref. 11. In that case the self-dual solutions to the systems introduced in Ref. 8 are not smooth limits of the solutions to the generic systems, analogous to (12) here, introduced in Ref. 11, since the expressions corresponding to (21) become infinite in this limit.

B. Restricted model: Self-dual solution

Here we ignore the well-known subsystem of (12) with $\lambda_0=\lambda_2=0$, where the self-dual solutions are known analytically[6] and which is the $p=1$ member of the hierarchy of self-duality equations (8). Rather, we consider the $p=1$, or $d=2$, member of the new hierarchy of models (10) with $\lambda_1=0$.

The $d=2$ member of the hierarchy of self-duality equations (11) with V given by (16), in the $n=1$ radially symmetric field configuration (13), reduces to an ordinary first-order equation which is immediately integrated to give the solution for f in terms of ρ^2:

$$\cos f=1-2e^{-\rho^2}, \tag{22}$$

where we have set $\lambda_0=\lambda_2=1$. It is easy to verify that (22) satisfies the asymptotic conditions (7) with $m=1$.

We have numerically integrated the equations (17) for the systems with $\lambda_0=\lambda_2=1$, and with progressively smaller values of λ_1, starting from $\lambda_1=1$ down to $\lambda_1=0.001$. The profiles of the function f for all these cases are plotted in Fig. 2. The numerical integrations were performed for each λ_1 with the values of the parameter A listed in Table I. The total energies pertaining to each of these solutions are listed in Table II, in which the lowest value is closest to the energy pertaining to the self-dual solution which in the normalization used equals 4.

It should be noted here that our ability to obtain a solution satisfying the asymptotic conditions (7) is dependent on our choice of potential. Our choice of (16), which is not unique, has led to the solution (22), which is differentiable at the origin for vorticity $n=1$ only. It is possible to

TABLE I. The parameter A for $n=1$ vortices for the two-dimensional model with potential $V(f)=(1-\cos(f))^2$.

λ_1	A
1.0	−1.5199879
0.8	−1.5042582
0.6	−1.4865913
0.4	−1.4664522
0.2	−1.4429800
0.001	−1.4143832

find well-behaved solutions for other values of the vorticity with suitable choices of V, and for each such choice the corresponding solutions for the system with nonvanishing λ_1 will be well behaved for all values of the vorticity n.

III. THE THREE-DIMENSIONAL CASE

In terms of the dimensionless coordinates $y_i=x_i/\kappa$, the full model (1) in this case reduces to

$$\mathscr{L}_3=\lambda_3\phi(3)^2+\lambda_2\phi(2)^2+\lambda_1\phi(1)^2+\lambda_0 V. \tag{23}$$

The one-dimensional subsystem L_3 defined by $\int\mathscr{L}_3\,d^3x=\int L_3\,d\rho$ is now

$$L_3=\lambda_3\,\frac{\sin^4 f}{\rho^2}\,f_\rho^2+\lambda_2\,\sin^2 f\left(2\,f_\rho^2+\frac{\sin^2 f}{\rho^2}\right)+\lambda_1(\rho^2 f_\rho^2+2\sin^2 f)+\lambda_0\rho^2 V, \tag{24}$$

leading to the Euler–Lagrange equation

$$\left(\lambda_3\,\frac{\sin^4 f}{\rho^2}+2\lambda_2\,\sin^2 f+\lambda_1\rho^2\right)f_{\rho\rho}+\left(2\lambda_3\,\frac{\sin^3 f\cos f}{\rho^2}+2\lambda_2\,\sin f\cos f\right)f_\rho^2$$
$$+2\left(-\lambda_3\,\frac{\sin^4 f}{\rho^3}+\lambda_1\rho\right)f_\rho-2\lambda_2\,\frac{\sin^3 f\cos f}{\rho^2}-2\lambda_1\,\sin f\cos f-\lambda_0\rho^2\,\frac{\partial V}{\partial f}=0, \tag{25}$$

where we have not yet specified the potential V. Unlike in the previous section dealing with the $d=2$ case, here we shall choose different potentials in the generic case where all λ_A, $A=0,1,2,3$, are nonzero, and in the case belonging to the hierarchy (10) where only λ_0 and λ_3 are nonzero. The reason for this is that in the second case our choice for V will by necessity be a highly nonlinear infinite series in the field ϕ^a like, for example, in the Sine–Gordon model, and it is probably reasonable to give the numerical demonstration of the existence of the solutions in the generic case with a simple choice of V.

A. The full model

First we choose the simplest potential, used in Ref. 10,

$$V=1-\phi^4. \tag{26}$$

Assuming exponential decay in the region $\rho\gg 1$, we linearize (25) around the asymptotic value $f=0$,

$$\rho^2 f_{\rho\rho}+2\rho f_\rho-2\left(1+\frac{\lambda_0}{2\lambda_1}\rho^2\right)f=0, \tag{27}$$

which yields the exponentially decaying behavior

$$f\approx\frac{1}{\rho}\,e^{\sqrt{\lambda_0/\lambda_1}\rho}, \tag{28}$$

justifying our linearization (27).

It is appropriate to make a remark about the exponential behavior (27) here. This is a result of the presence of the $O(4)$ breaking potential (26) in (24). Setting $\lambda_0=0$ would yield the usual Skyrme model[1] supplemented by the *sextic* term $\phi(3)^2$ as in Ref. 12. In this case, as also in the usual Skyrme model,[1] the behavior of f in the $\rho\gg 1$ region is a power decay. The linear equation (27) with λ_0 in it set equal to zero in fact admits the solution $f\approx\rho^{-2}$.

In the $\rho\ll 1$ region, we try a power series solution and find

$$f=m\pi+A\rho+A\,\frac{\lambda_0+\lambda_1A^2-\frac{4}{3}\lambda_2A^4+\lambda_3A^6}{14\lambda_1+92\lambda_2A^2+30\lambda_3A^4}. \tag{29}$$

With $\lambda_0=\lambda_1=\lambda_2=\lambda_3=1$, we have integrated Eq. (25) numerically both for unit topological charge $m=1$ in (29) and for topological charge 2 corresponding to $m=2$. The profiles of the function f are plotted in Fig. 3(a), and the profiles of their energy densities are plotted in Fig. 3(b). The values of the parameter A in (29) for which the asymptotic behaviors (28) and (29) were achieved numerically are $A=-1.4\,990\,144$ for the $m=1$ solution and $A=-2.0\,554\,812$ for the $m=2$ case. The total energies corresponding to these solutions are $E(m=1)=16.0\,015\,959$ and $E(m=2)=54.3\,091\,345$. We see that $E(m=2)>E(m=1)$ for the most general $O(4)$ model as was the case[4] for the usual Skyrme model.[1]

B. Restricted model: Self-dual solution

To enable us to find a solution which is differentiable at the origin and satisfies the asymptotic conditions (7), with $m=1$, we have made a particular choice for the potential V. Unlike in the previous section, we have not found an adequate potential which is a simple function of the fields ϕ^a and, to avoid writing a cumbersome expression for it, we express this potential in terms of the function f pertaining to the spherically symmetric field configuration (5) as

$$V=\tfrac{1}{4}(\tfrac{1}{2}\sin 2f-f)^2. \tag{30}$$

With this potential, the $d=3$ member of the hierarchy of self-duality equations (11) for the spherically symmetric field configuration reduces to a first-order equation which is immediately integrated to give f as a function of ρ^3:

$$\frac{1}{2}\left(f-\frac{1}{2}\sin 2f\right)=\frac{\pi}{2}\,e^{-\rho^3}. \tag{31}$$

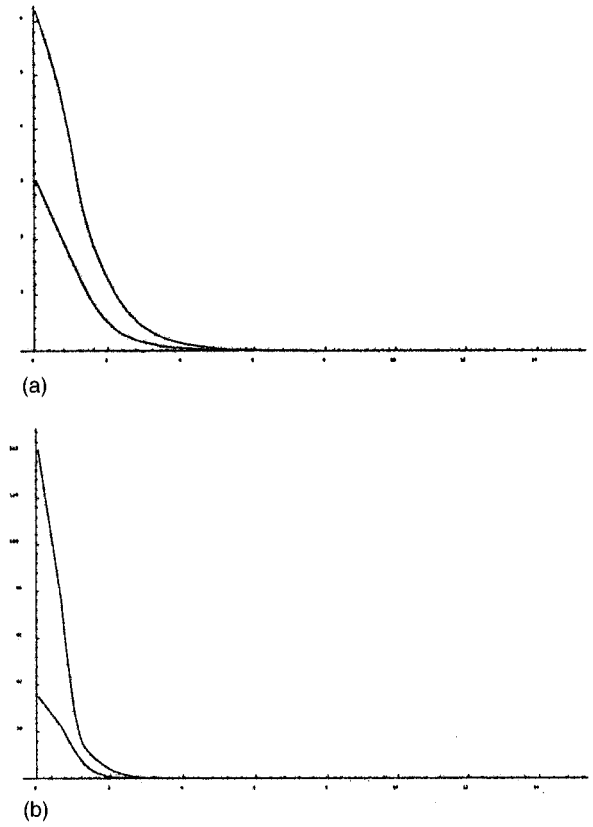

FIG. 3. (a) Profiles of f for the model (24) and $\lambda_0=\lambda_1=\lambda_2=\lambda_3=1$ with the potential (26) with topological charges $m=1,2$, from left to right. (b) Profiles of the energy densities for the hedgehogs in (a), left to right.

The function f given by (31) is easily verified to satisfy the requisite asymptotic conditions (7) with $m=1$ and to be differentiable at the origin.

In the particular normalization we are working in, the energy pertaining to this *unit* topological charge solution equals $\pi^2/4$. This absolutely minimal energy is a lower bound on the energies of the solutions of all the models defined by this potential but with nonvanishing values of the coupling constants λ_1 and λ_2.

To demonstrate this, we set out to integrate (25) with the potential (30) this time. The asymptotic behavior (28) in the region $\rho \gg 1$ is still valid in this case, but in the $\rho \ll 1$ region we compute it again and find

$$f=\pi+A\rho+A\,\frac{\lambda_0\pi^4-4\lambda_1A^2-2\lambda_2A^4+2\lambda_3A^6}{30(\lambda_1+2\lambda_2A^2+\lambda_3A^4)}\,\rho^3. \tag{32}$$

Inspecting (32), we can see that in the limit of λ_1 and λ_2 vanishing, f is well behaved near the origin. This is because the second term in (32) does not become infinite in this limit. The implication is that it should be possible to integrate (25) numerically for progressively decreasing values of λ_1 and λ_2, say with $\lambda_1=\lambda_2$, approaching the self-dual limit. To this end, Eq. (25) with the potential (30) was integrated numerically for each pair of $\lambda_1=\lambda_2$ for the values of the parameter A in (32) listed in Table III. The profiles of the function f for these solutions with $m=1,2$, are plotted in Fig. 4. The total energies pertaining to these solutions were calculated and are listed in

TABLE III. The parameter A for the $m=1$ hedgehogs for the three-dimensional model with potential $V(f)=\frac{1}{4}(\frac{1}{2}\sin(f/2)-f)^2$.

Table IV. Again as in the two-dimensional case, the last entry in this table is the value closest to the energy of the self-dual solution, which in this case is $\pi^2/3=2.4\,674\,011$.

IV. ANALYTIC PROOFS OF EXISTENCE

In this section, we give proofs of existence for the most general two- and three-dimensional Skyrme models studied in the previous sections. We employ the simplest choices for the potentials $V=(1-\phi^{d+1})$ with $d=2,3$, respectively, which is the choice made in Ref. 9 in the $d=2$ case, and also the choice (26) made in the $d=3$ case. One may check that our method actually covers the general situation where $V=(1-\phi^{d+1})^k$ $(k\geqslant 1)$. Note that the technically easier situation of the usual[1] hedgehog SU(2) Skyrmions in three dimensions was already considered in Ref. 13. The two- and three-dimensional cases are given respectively in the following two subsections. Again the $d=3$ case is less technical and will only be discussed briefly.

A. Two-dimensional case

The energy or mass density for radially symmetric fields is given by (14), with the choice of $V=(1-\cos f)$ for the potential. Without loss of generality, in the following we shall also use the specific values of the parameters: $\lambda_1=\lambda_2=\lambda_0=1$. The boundary conditions are stated by (7) with $m=1$.

The associated Euler–Lagrange equation of (14) governing the detailed behavior of the two-dimensional Skyrmion solitons is

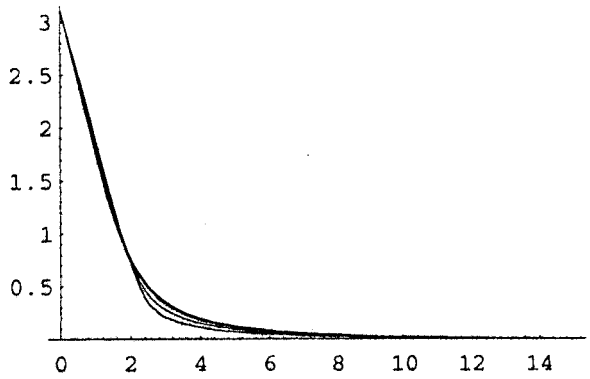

FIG. 4. Profiles of f with unit topological charge ($m=1$) hedgehogs of the $d-3$ model (24) with the potential (30), with $\lambda_0=\lambda_3=1$, and with $\lambda_1=\lambda_2$ decreasing as in Table IV.

$$\left(\rho+n^2\,\frac{\sin^2 f}{\rho}\right)\frac{\mathrm{d}^2 f}{\mathrm{d}\rho^2}+\left(n^2\,\frac{\sin f\,\cos f}{\rho}\,\frac{\mathrm{d}f}{\mathrm{d}\rho}+\left[1-n^2\,\frac{\sin^2 f}{\rho^2}\right]\right)\frac{\mathrm{d}f}{\mathrm{d}\rho}$$
$$=n^2\,\frac{\sin f\,\cos f}{\rho}+\rho\,\sin f,\quad \rho>0. \tag{33}$$

Here is the main result of this subsection, namely the existence of a radially symmetric Skyrmion in two dimensions.

Theorem 1: For any winding number n the energy (15) has a minimizer which is a smooth solution of the two-dimensional Skyrme equation (33) subject to the boundary condition

$$f(0)=\pi,\quad f(\infty)=0.$$

Moreover, this solution is strictly decreasing in $\rho>0$ and is ultimately concave up.

Note: The properties of the solution f stated above confirm precisely the numerical results obtained in Ref. 9. The rate of convergence of f at both $\rho=0$ and $\rho=\infty$ is also established.

We shall apply a variational method to prove the theorem. For this purpose, it turns out that the most natural admissible space should be defined by the prescription

$$X=\{f|f(\rho)\ \text{is continuous on}\ [0,\ \infty)\ \text{and absolutely continuous on every compact subinterval of}\ (0,\ \infty)\ \text{so that}\ f(0)=\pi, f(\infty)=0,\quad \text{and}\ E(f)<\infty\}, \tag{34}$$

where the energy $E(f)$ is defined by (14) and (15).

Our proof follows from the existence of a solution to the following optimization problem:

$$\eta\equiv\min\{E(f)|f\in X\}. \tag{35}$$

The proof splits into a few steps.

Lemma 2: Let $\{f_k\}$ be a minimizing sequence of (35). We can always modify the sequence to make it satisfy the uniform bounds

$$0\leqslant f_k\leqslant\pi,\quad k=1,2,\ldots. \tag{36}$$

Proof: We first claim that we can modify $\{f_k\}$ so that it fulfills

$$0\leqslant f_k\leqslant 2\pi,\quad k=1,2,\ldots. \tag{37}$$

In fact, if (37) is violated at some k, we can define a new function $g_k\in X$ by

$$g_k(\rho)=\begin{cases}0, & \text{if } f_k(\rho)\leqslant 0,\\ x, & \text{if } f_k(\rho)\leqslant\pi.\end{cases}$$

Then $0\leqslant g_k\leqslant\pi$, $g_k\in X$, and $E(g_k)=E(f_k)$ in view of (14). The lemma is proven.

Hence for any pair of numbers $0<\rho_1<\rho_2$ we can use Lemma 2 to assert that (35) has a $W^{1,2}(\rho_1,\rho_2)$-bounded minimizing sequence $\{f_k\}$ satisfying (36). A standard diagonal subsequence argument shows that there exists a subsequence of $\{f_k\}$ for which we still denote by the same numeration, $\{f_k\}$, so that

$$\lim_{k\to\infty} f_k=f \quad \text{weakly in } W^{1,2}(\rho_1,\rho_2) \text{ for any } 0<\rho_1<\rho_2. \tag{38}$$

The compact embedding $W^{1,2}(\rho_1,\rho_2)\to C[\rho_1,\rho_2]$ says that

$$\lim_{k\to\infty} f_k=f \quad \text{strongly in } C[\rho_1,\ \rho_2]. \tag{39}$$

It then follows from (38), (39), and (14) that

$$E(f\ )\leqslant \lim_{\rho_1\to 0,\rho_2\to\infty}\sup \lim_{k\to\infty}\inf\int_{\rho_1}^{\rho_2}\mathscr{E}(f_k)\mathrm{d}\rho\leqslant \lim_{k\to\infty}E(f_k)=\eta. \tag{40}$$

In order to show that f is a solution of (35), we still need to achieve $f\in X$. This fact is established in the following.

Lemma 3: The function f obtained above satisfies the boundary condition stated in (34).

Proof: First for the minimizing sequence $\{f_k\}$ satisfying (38) and (39) we have in view of the Schwarz inequality

$$\sin^2 f_k(\rho)=2\int_0^{\rho}\frac{\mathrm{d}f_k}{\mathrm{d}\rho'}\sin f_k\cos f_k\mathrm{d}\rho'\leqslant 2\rho\left(\int_0^{\rho}\left(\frac{\mathrm{d}f_k}{\mathrm{d}\rho'}\right)^2\frac{\sin^2 f_k'}{\rho}\,\mathrm{d}\rho'\right)^{1/2}\leqslant\frac{2\rho}{n}\sup_k E^{1/2}(f_k).$$

In particular $\sin^2 f_k(\rho)\to 0$ as $\rho\to 0$ uniformly with respect to $k=1,2,\ldots$. Therefore, $f_k(\rho)\to\pi$ as $\rho\to 0$ uniformly as well. Thus $f(0)=\pi$ as expected.

We next consider the asymptotic behavior of f as $\rho\to\infty$. We note that (36) is valid for $\{f_k\}$. Consequently,

$$\begin{aligned}1-\cos f_k&=\frac{f_k^2}{2!}\left(1-\frac{f_k^2}{3\cdot 4}\right)+\frac{f_k^6}{6!}\left(1-\frac{f_k^2}{7\cdot 8}\right)+\frac{f_k^{10}}{10!}\left(1-\frac{f_k^2}{11\cdot 12}\right)+\cdots\\&\geqslant\frac{f_k^2}{2!}\left(1-\frac{\pi^2}{3\cdot 4}\right)+\frac{f_k^6}{6!}\left(1-\frac{\pi^2}{7\cdot 8}\right)+\frac{f_k^{10}}{10!}\left(1-\frac{\pi^2}{11\cdot 12}\right)+\cdots\\&>\frac{12-\pi^2}{4!}f_k^2.\end{aligned} \tag{41}$$

Using (41) in (15) we see that f_k satisfies

$$\int_0^{\infty}\rho\left(f_k^2+\left[\frac{\mathrm{d}f_k}{\mathrm{d}\rho}\right]^2\right)\mathrm{d}\rho<C \tag{42}$$

with $C>0$ a constant independent of k. Applying the condition $f_k(\infty)=0$, we have by virtue of the Schwarz inequality again

$$f_k^2(\rho)=-2\int_{\rho}^{\infty}f_k\frac{\mathrm{d}f_k}{\mathrm{d}\rho'}\,\mathrm{d}\rho'\leqslant\frac{2}{\rho}\left(\int_0^{\infty}\rho' f_k^2(\rho')\mathrm{d}\rho'\right)^{1/2}\left(\int_0^{\infty}\rho'\left[\frac{\mathrm{d}f_k}{\mathrm{d}\rho'}\right]^2\mathrm{d}\rho'\right)^{1/2}.$$

Inserting (42) into the above we see that $f_k(\rho)\to 0$ as $\rho\to\infty$ uniformly with respect to k. Thus $f(\infty)=0$ and the lemma follows.

Since $f\in X$, we see that it indeed solves (35). The standard elliptic theory then implies that f is a smooth solution of (33). To complete the proof of Theorem 1, we have to study also the monotonicity and concavity of f.

Lemma 4: The solution f of (35) or (33) obtained above is actually positive valued.

Proof: Otherwise suppose there is a point $\rho_0>0$ so that $f(\rho_0)=0$. Since $f(\rho)\geqslant 0$, we see that ρ_0 is a minimum point of f and $(\mathrm{d}f/\mathrm{d}\rho)(\rho_0)=0$. Using these initial data in (33) and applying the uniqueness theorem of ordinary differential equations we obtain $f(\rho)\equiv 0$, which is false. Thus $f(\rho)>0$ for all $\rho>0$.

Lemma 5: Let f be the function stated in Lemma 4. Then f is strictly decreasing.

Proof: We first show that $(\mathrm{d}f/\mathrm{d}\rho)(\rho)\leqslant 0$ everywhere. Otherwise let us assume that $(\mathrm{d}f/\mathrm{d}\rho)(\rho_0)>0$ at some $\rho_0>0$. Then $f(\rho)>f(\rho_0)$ when ρ is near ρ_0 from the right: $\rho>\rho_0$. Set

$$\rho_{\min}=\max\{\rho'\in[0,\,\rho_0]\,|\,f(\rho')=\min\{f(\rho)\,|\,\rho\in[0,\,\rho_0]\}\}.$$

The property $f(\rho)\to 0$ as $\rho\to\infty$ implies that

$$S_{\min}=\{\rho\in(\rho_0,\infty)\,|\,f(\rho)=f(\rho_{\min})\}$$

is a nonempty compact subset of $(0,\infty)$. Define

$$\rho'_{\min}=\min\{\rho\,|\,\rho\in S_{\min}\}.$$

Then $\rho_{\min}<\rho'_{\min}$ of course. Let $\rho_{\max}\in(\rho_{\min},\rho'_{\min})$ be such that

$$f(\rho_{\max})=\max\{f(\rho)\,|\,\rho\in[\rho_{\min},\rho'_{\min}]\}.$$

We also have $f(\rho_{\min})=f(\rho'_{\min})<f(\rho_{\max})$.

There are two cases we need to consider separately.

(i) $f(\rho_{\max})\leqslant\frac{1}{2}\pi$.

Since both $\sin^2\theta$ and $1-\cos\theta$ are increasing functions in $0\leqslant\theta\leqslant\frac{1}{2}\pi$, we have

$$\sin^2 f(\rho_{\min})<\sin^2 f(\rho),\quad 1-\cos f(\rho_{\min})<1-\cos f(\rho),\quad \rho\in(\rho_{\min},\rho'_{\min}).$$

We can define a new function $g\in X$ by setting

$$g(\rho)=\begin{cases} f(\rho_{\min}), & \rho\in(\rho_{\min},\rho'_{\min}),\\ f(\rho), & \text{otherwise.}\end{cases}$$

Then $E(g)<E(f)$, which contradicts the property of f.

(ii) $f(\rho_{\max})>\frac{1}{2}\pi$.

In this case we introduce two numbers $0<\rho_0<\rho'_0$ by setting

$$\rho_0=\max\{\rho<\rho_{\max}\,|\,f(\rho)=\tfrac{1}{2}\pi\},$$

$$\rho'_0=\min\{\rho>\rho_{\max}\,|\,f(\rho)=\tfrac{1}{2}\pi\}.$$

Then $f(\rho)>\frac{1}{2}\pi$ for $\rho\in(\rho_0,\rho'_0)$. Define

$$g(\rho)=\begin{cases} \pi-f(\rho), & \rho\in(\rho_0,\rho'_0),\\ f(\rho), & \text{otherwise.}\end{cases}$$

Then we can check that $E(g)<E(f)$ because $\sin^2\theta$ is even about $\theta=\frac{1}{2}\pi$ and $1-\cos\theta$ is increasing for $0\leqslant\theta\leqslant\pi$. Hence we arrive at another contradiction and the proof that f is nonincreasing is complete.

We now show that f is strictly decreasing. In fact, if there are $0<\rho_1<\rho_2$ so that $f(\rho_1)=f(\rho_2)$, then $f(\rho)=f(\rho_1)$ for all $\rho\in[\rho_1,\rho_2]$. Inserting this information into Eq. (33) we obtain $\sin f(\rho_1)=0$. By Lemma 4 we must have $f(\rho_1)=\pi$. The uniqueness theorem of ordinary differential equations then implies that $f(\rho)\equiv\pi$, which is false. This proves the lemma.

Lemma 6: The solution f obtained above is ultimately concave up. More precisely, let $\rho_1>0$ be the unique point so that $f(\rho_1)=\frac{1}{2}\pi$. Then $(\mathrm{d}^2f/\mathrm{d}\rho^2)(\rho)>0$ for $\rho>\rho_0$, where $\rho_0=\max\{\rho_1,n\}$.

Proof: Lemma 5 allows us to rewrite (33) in the region $\rho\geqslant\rho_0$ as

$$\left(\rho+n^2\,\frac{\sin^2 f}{\rho}\right)\frac{\mathrm{d}^2f}{\mathrm{d}\rho^2}=\left(n^2\,\frac{\sin f|\cos f|}{\rho}\left|\frac{\mathrm{d}f}{\mathrm{d}\rho}\right|+\left[1-n^2\,\frac{\sin^2 f}{\rho^2}\right]\right)\left|\frac{\mathrm{d}f}{\mathrm{d}\rho}\right|+\left(\rho-n^2\,\frac{|\cos f|}{\rho}\right)\sin f.$$

The right-hand side of this equation is obviously positive. The lemma follows.

In summary, the proof of Theorem 1 is finished.

B. Three-dimensional case

We now consider the situation in the case $d=3$. The energy density is defined by (24) with the potential density given by (26) or

$$V(f)=1-\cos f. \tag{43}$$

Since (24) has the same monotonicity properties as the energy density (14) in the case $d=2$, the method of the previous subsection shows that an energy minimizer satisfying the boundary condition $f(0)=\pi$, $f(\infty)=0$, must be a globally decreasing function which becomes concave up outside a local region. So it remains to examine the existence of such a solution.

In fact, it suffices to see whether the boundary behavior of a field configuration can be controlled. To this end, we observe in view of (24) and the Schwarz inequality that for any ρ and function f defined on $[0,\infty)$ satisfying $f(0)=\pi$ and $f(\infty)=0$, there hold

$$\begin{aligned}\sin^2 f(\rho)&=\int_0^\rho 2\sin f(\rho')\cos f(\rho')\,\frac{\mathrm{d}f}{\mathrm{d}\rho'}\,(\rho')\mathrm{d}\rho'\\&\leqslant 2\rho^{1/2}\int_0^\rho \sin^2 f(\rho')\left(\frac{\mathrm{d}f}{\mathrm{d}\rho'}\right)^2\mathrm{d}\rho'\\&\leqslant C\rho^{1/2}E^{1/2}(f)\quad\text{for }\rho\text{ small},\end{aligned}$$

$$|f(\rho)|\leqslant\rho^{-1/2}\left(\int_0^\infty(\rho')^2\left(\frac{\mathrm{d}f}{\mathrm{d}\rho'}\right)^2(\rho')\mathrm{d}\rho'\right)^{1/2}\leqslant C\rho^{-1/2}E^{1/2}(f)\quad\text{for }\rho\text{ large}.$$

The above estimates indicate that the boundary condition is easily preserved. Consequently, the existence of an energy minimizer in the $d=3$ case is ensured as before. Thus we can state the following.

Theorem 7: In the case $d=3$, the energy $E(f)=\int L_3\,d\rho$ with L_3 being defined in (24) and the hedgehog field configuration f subject to the boundary condition $f(0)=\pi$, $f(\infty)=0$, has a minimizer. The function f is a smooth solution of the associated Euler–Lagrange equation (25). Furthermore, f is strictly decreasing in the entire region $\rho>0$ and is concave up for ρ sufficiently large.

The method employed here can be applied to obtain existence and global behavior results for many other related problems in classical field theory. For example, the SU(3) Skyrme model[14] governed by the reduced hedgehog energy functional $M(F)=\lambda_1 M_{\rm cl}(F)+\lambda_2 m_{\rm cl}(F)$, where $\lambda_1,\lambda_2>0$ and

$$M_{\rm cl}(F)=\int\left\{\frac{\rho^2}{8}\left(\frac{{\rm d}F}{{\rm d}\rho}\right)^2+\frac{\sin^2 F}{4}+\frac{\sin^4 F}{2\rho^2}+\left(\frac{{\rm d}F}{{\rm d}\rho}\right)^2\right\}{\rm d}\rho,$$

$$m_{\rm cl}(F)=\int(1-\cos F)\rho^2\,{\rm d}\rho,$$

is useful in modelling the top quark. The field F has the same boundary condition $F(0)=\pi$, $F(\infty)=0$, as before. We can show without difficulty that Theorem 7 is valid for this model.

V. SUMMARY

We have studied the radially/spherically symmetric solutions to the most general class of Skyrme models in two and three dimensions, which capture all the features that we are concerned with in all higher *even* and *odd* dimensions. Special attention is given to a subclass of these models which support self-dual solutions, which are found explicitly. In the general case, the Euler–Lagrange equations could not be explicitly integrated so their integration was performed numerically and analytic proofs for the existence of these solutions were given.

In the odd-dimensional case $d=3$ where it is possible to find finite energy topologically stable solutions of arbitrary topological charge, we have considered the charge-2 solution and found that it is heavier than two charge-1 solutions, as in the case of the usual Skyrmions.[4] In the even-dimensional case $d=2$, it is possible to find *unit* charge solutions only, but due to the low dimensionality it was possible to study solutions of arbitrary vorticity n.

One of the main purposes of this work was the study of the most general d-dimensional $O(d+1)$ Skyrme models, whose properties are typified by the $d=2$ even-, and the $d=3$ odd-, dimensional cases, respectively. These were studied both numerically and analytically. Our numerical studies lead to the conclusion that *radially and spherically symmetric static* bound states are absent in all Skyrme models with *exponentially localized* hedgehogs with $m=1$.

The other main purpose of this work was the study of a special subclass of the most general Skyrme models, defined by (10), which support self-dual solutions. This new subclass of systems differs from the previously known scale-invariant hierarchy[5,6] of scale invariant Skyrme–Sigma models in a very important respect. The latter[5] support self-dual solutions **power** localized to an arbitrary scale related to the scale invariance, while the solutions of the new system (10) by contrast can be localized **exponentially**.

Another very important difference between the self-duality equations of the two hierarchies is that, with the exception of the first[6] member of the former[5] case, they are overdetermined[7] as a result of which the only solutions these[5] support are spherically symmetric. By contrast, the hierarchy of self-duality equations (11) are underdetermined. While in this paper we have restricted ourselves to the study of radially/spherically symmetric solutions only, this last property indicates that there must exist solutions with symmetries less restrictive than radial/spherical. Indeed, the underdetermined nature of our self-duality equations results in the generation of a large class of new solutions from any given one. These aspects of the present work are deferred to a future investigation. It is expected that this would follow the lines of two intensive studies[9] of the analogous properties in a related class of d-dimensional $O(d)$ models, where multi-center solutions were found.

Perhaps the most interesting property of the systems (10) is that the self-dual solutions it supports are smoothly related to the non-self-dual solutions of the general systems (1), by letting the constants κ_p in (1) for $p=1,2,..,(d-1)$ vanish. This aspect of the $O(d)$ models was studied recently in detail in Ref. 11.

Finally, we mention a certain inflexible property of our subclass of models (10) which are essentially characterized by the potential V. The solutions of the d-dimensional self-duality equation are functions of the variable ρ^d and are differentiable at the origin **only** for suitable but nonunique choices of V. In dimensions $d>2$ the only solutions which are differentiable at the origin are the spherically symmetric solutions with unit topological charge. Only in dimension $d=2$ is it possible to find solutions of higher charge with vorticity n, where a given choice of V can lead to a well-behaved solution for a given n only.

The kind of information provided by a measurement is determined in terms of the correlation established between observables of the apparatus and the measured system. Using the framework of quantum measurement theory, necessary and sufficient conditions for a measurement interaction to produce strong correlations are given and are found to be related to properties of the final object and apparatus states. These general results are illustrated with reference to the *standard model* of the quantum theory measurement. © *1996 American Institute of Physics.* [S0022-2488(96)03506-2]

I. INTRODUCTION

Any physical measurement is carried out in order to provide information about a specified system, its state prior to or after the measurement. The procedure generally is to ascertain the values of a pointer observable, which have become correlated with some observable of the measured system. Thus the kind of information available by a given measurement depends on the statistical dependencies established by the interaction between the apparatus, or some probe system, and the object.

The minimal content of the notion of measurement in quantum mechanics is given by the *probability reproducibility* requirement; according to this condition, a particular measurement scheme qualifies as a measurement of a given observable E if for all initial states of the object system the associated probability distributions of E are reproduced in the resulting statistics of pointer readings.[1] Regarding a large ensemble of object plus apparatus systems as one individual system, this situation can be described in terms of strong correlations between the values of the frequency operators (see, e.g., Ref. 1) associated with the observable E and the pointer observable, respectively. In the present context we shall not be concerned with the ensembles regarded as individual objects but rather we shall analyze statistical dependencies between individual members of the ensembles as they show up in certain correlation quantities. The following three kinds of correlations appear naturally in the measurement context: correlations between an object observable E and the pointer observable; correlations between the values of these observables; and correlations between the conditional final states of the object system and apparatus, respectively. Our goal is to give exhaustive characterizations of the conditions under which these correlations are established. It will be found that the final component states of the object and apparatus must possess certain properties in order that such correlations may be strong.

Our investigation builds on previous work published in Ref. 2. Correcting an erroneous characterization of strong correlations used in that paper, we give here a complete account of necessary and sufficient conditions for the occurrence of strong correlations. In addition, the scope of the results is extended beyond unitary measurements and sharp observables to cover arbitrary measurements and pointer observables and general object observables. Finally, possible fields of

[b)]Electronic mail: pekka.lahti@utu.fi

applications are indicated on the basis of the standard model of measurement theory, which was recently used in various proposals for quantum and atomic optics QND measurements.[3]

II. FRAMEWORK

2.1. We follow here the Hilbert space formulation of quantum mechanics in which the description of a physical system $\mathscr{S}$ is based on a complex separable Hilbert space $\mathscr{H}$, with the inner product $\langle\cdot|\cdot\rangle$, and which builds on the dual concepts of states and observables reflecting the general structure of an experiment: preparation of the system followed by a measurement.

2.2. Let $\mathscr{L}(\mathscr{H})$ denote the set of bounded linear operators on $\mathscr{H}$ and $\mathscr{T}(\mathscr{H})$ its subset of trace class operators. A *state* of $\mathscr{S}$ is given as a positive linear operator $T:\mathscr{H}\to\mathscr{H}$ of trace one. We let $\mathscr{S}(\mathscr{H}):=\{T\in\mathscr{T}(\mathscr{H})|T\geqslant O,\ \mathrm{tr}[T]=1\}$ denote the set of states of $\mathscr{S}$, and we recall that $\mathscr{S}(\mathscr{H})$ is a (σ-)convex subset of $\mathscr{T}(\mathscr{H})$, the one-dimensional projection operators $P[\varphi]$ (generated by the unit vectors $\varphi\in\mathscr{H}$) being its extremal elements. The $P[\varphi]$ shall be called *vector states*.

2.3. Let Ω be a set and $\mathscr{F}$ a σ-algebra of subsets of Ω. An *observable* of $\mathscr{S}$ is represented as (and identified with) a normalized positive operator valued measure, a POV measure, $E:\mathscr{F}\to\mathscr{L}(\mathscr{H})$, that is, an operator valued mapping $X\mapsto E(X)$ on $\mathscr{F}$ with the properties: (i) $E(\Omega)=I$, (ii) $E(X)\geqslant O$, and $E(\cup X_i)=\Sigma E(X_i)$ for any disjoint sequence $(X_i)\subset\mathscr{F}$, with the series $\Sigma E(X_i)$ converging in the weak operator topology of $\mathscr{L}(\mathscr{H})$. We recall that the projection valued measures, the PV measures, are a particular case of the POV measures; furthermore a POV measure E is a PV measure, that is, $E(X)^2=E(X)$ for all $X\in\mathscr{F}$, if and only if E is multiplicative, that is, $E(X\cap Y)=E(X)E(Y)$ for all $X,Y\in\mathscr{F}$. Observables which are represented by PV measures are called *sharp* observables. It is by now well established that the extension of the notion of observables from PV measures to POV measures is a necessity in quantum mechanics.

2.4. The probability measure

$$p_T^E:\mathscr{F}\to[0,1],\quad X\mapsto p_T^E(X):=\mathrm{tr}[TE(X)] \tag{1}$$

defined by an observable E and a state T is related to a measurement by virtue of the minimal interpretation of quantum mechanics: *the number $p_T^E(X)$ is the probability that a measurement of the observable E performed on the system $\mathscr{S}$ in the state T leads to a result in the set X*. The intended empirical content of this statement is the following: If the same E-measurement were repeated sufficiently many times under the same conditions (characterized by T), then in the long run the relative frequency of the occurrence of the measurement results in X would approach the number $p_T^E(X)$.

III. MEASUREMENT

A. General

3.1. A *measurement scheme* for the (object) system $\mathscr{S}$ consists of a *measuring apparatus* $\mathscr{A}$ [with its Hilbert space $\mathscr{H}_\mathscr{A}$], a *pointer observable* $Z:\mathscr{F}_\mathscr{A}\to\mathscr{L}(\mathscr{H}_\mathscr{A})$ [with its ''space of values'' $(\Omega_\mathscr{A},\mathscr{F}_\mathscr{A})$], an *initial state* $T_\mathscr{A}$ of the apparatus, a *measurement coupling* V [a linear state transformation on $\mathscr{T}(\mathscr{H}\otimes\mathscr{H}_\mathscr{A})$], and a [measurable] *pointer function* $f:\Omega_\mathscr{A}\to\Omega$, with the assumption that if $T\in\mathscr{S}(\mathscr{H})$ is an initial state of $\mathscr{S}$, then $V(T\otimes T_\mathscr{A})$ is the final state of the compound object–apparatus system $\mathscr{S}+\mathscr{A}$. Taking the partial traces of $V(T\otimes T_\mathscr{A})$ over $\mathscr{H}_\mathscr{A}$ and $\mathscr{H}$, respectively, one gets the corresponding reduced states $\mathscr{R}_\mathscr{S}(V(T\otimes T_\mathscr{A}))$ and $\mathscr{R}_\mathscr{A}(V(T\otimes T_\mathscr{A}))$ of $\mathscr{S}$ and $\mathscr{A}$, respectively; then the probability measure of the pointer observable Z in the final apparatus state is completely determined as $Y\mapsto p^Z_{\mathscr{R}_\mathscr{A}(V(T\otimes T_\mathscr{A}))}(Y)=\mathrm{tr}[\mathscr{R}_\mathscr{A}(V(T\otimes T_\mathscr{A}))Z(Y)]$, $Y\in\mathscr{F}_\mathscr{A}$.

3.2. A measurement scheme $\mathscr{M}:=\langle\mathscr{H}_\mathscr{A},Z,T_\mathscr{A},V,f\rangle$ defines an observable $E^\mathscr{M}$ of $\mathscr{S}$ with the space of values $(\Omega,\mathscr{F})$ via the relation: for any $X\in\mathscr{F}$ and $T\in\mathscr{S}(\mathscr{H})$,

$$p_T^{E^\mathscr{M}}(X):=p^Z_{\mathscr{R}_\mathscr{A}(V(T\otimes T_\mathscr{A}))}(f^{-1}(X)). \tag{2}$$

This is the observable *measured* by means of the scheme $\mathscr{M}$ in the sense that the totality of the distributions $p^Z_{\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))}$ (for all $T\in\mathscr{S}(\mathscr{H})$) of the pointer outcomes in the final apparatus states determine the POV measure $E^{\mathscr{M}}$ via Eq. (2). A measurement scheme $\mathscr{M}$ is a measurement of a given observable E if the measured observable $E^{\mathscr{M}}$ equals E.

3.3. There is an important subclass of measurement schemes for $\mathscr{S}$. They consist of a sharp pointer observable Z, a vector state preparation of $\mathscr{A}$, $T_{\mathscr{A}}=P[\phi]$, $\phi\in\mathscr{H}_{\mathscr{A}}$, $\langle\phi|\phi\rangle=1$, and a unitary measurement coupling $V(T\otimes T_{\mathscr{A}})=UT\otimes T_{\mathscr{A}}U^*$, with a unitary map U on $\mathscr{H}\otimes\mathscr{H}_{\mathscr{A}}$. Subsuming the possible pointer function in the definition of Z by identification of Ω and $\Omega_{\mathscr{A}}$, we denote such a scheme $\mathscr{M}_U:=\langle\mathscr{H}_{\mathscr{A}}, Z, P[\phi], U\rangle$ and call it a *unitary measurement scheme* (with the understanding that Z is a sharp observable). It is a basic result of the quantum theory of measurement that every observable E of $\mathscr{S}$ admits a unitary measurement, that is, there is a unitary measurement scheme $\mathscr{M}_U$ such that $E^{\mathscr{M}_U}=E$.[4] Thus the relation between measurement schemes and POV measures induced by Eq. (2) defines a map from the former onto the latter. In spite of this fundamental result, it is important to consider general measurement schemes $\mathscr{M}$, since in many applications the choices of a sharp pointer and a vector state preparation of the apparatus are not physically realizable.

3.4. Another basic condition for a measurement scheme $\langle\mathscr{H}_{\mathscr{A}}, Z, T_{\mathscr{A}}, V, f\rangle$ to qualify as a measurement is the requirement that the measurement should lead to a definite result. We take this requirement to entail, first of all, that the pointer observable Z should have assumed a definite value after the measurement. One should then be able to ''read the actual value'' of the pointer observable Z and deduce from this the value of the measured observable. As is well known, the task of explaining the occurrence of a definite pointer value at the end of a measuring process presents one of the major open problems in quantum mechanics. We do not enter this difficult question here. (For an overview of the issues involved, the reader may wish to consult Ref. 1.) There are, however, some necessary conditions for the pointer observable Z to assume a definite value in the final apparatus state $\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))$, conditions which are tractable and which call for the study of the correlation properties of a measurement. These conditions are the subject of the present paper.

B. Reading of pointer values

3.5. The reading of measurement outcomes involves the discrimination between the elements of a finite (or, as an idealization, countable) set of alternative pointer values. In order to formulate this idea in the general context of an E-measurement $\mathscr{M}$, we introduce the notion of a *reading scale* as a countable partition of the value space of the pointer observable, $\Omega_{\mathscr{A}}=\cup f^{-1}(X_i)$, induced by a countable partition of the value space of the measured observable, $\Omega=\cup X_i$, $X_i\in\mathscr{F}$, $X_i\cap X_j=0$ for $i\neq j$. Such a reading scale will be denoted $\mathscr{R}$, and we let $\mathbf{I}$ denote its index set.

3.6. A reading scale $\mathscr{R}$ determines discrete, coarse-grained versions of the pointer observable Z and the measured observable E

$$Z^{\mathscr{R}}: i\mapsto Z_i:=Z(f^{-1}(X_i)),\quad i\in\mathbf{I}, \tag{3a}$$

$$E^{\mathscr{R}}: i\mapsto E_i:=E(X_i),\quad i\in\mathbf{I}. \tag{3b}$$

The $Z^{\mathscr{R}}$-value i refers to the pointer reading $f^{-1}(X_i)$ which, in turn, is correlated to the value set X_i of the measured observable E. If E itself is discrete there is a natural (finest) reading scale $\mathscr{R}$ such that $E=E^{\mathscr{R}}$ and $Z^f=Z^{\mathscr{R}}$. It should be noted that we have included the pointer function f in the definition of $Z^{\mathscr{R}}$ so that the two discrete observables (3) do have the same set of values.

3.7. We say that the (discrete) pointer observable $Z^{\mathscr{R}}$ *has the value* i in the state $\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))$ if and only the measurement outcome probability for this value equals one: $\mathrm{tr}[\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))Z_i]=1$. Since $\mathrm{tr}[TE_i]=\mathrm{tr}[\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))Z_i]$, and, in general, $0\neq p^E_T(X_i)\neq 1$, the pointer observable does not have a value at the end of the measurement. It may, however,

occur that the state $\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))$ is a *mixture of eigenstates of* $Z^{\mathscr{R}}$ *with the weights* $p_T^E(X_i)$. This is indeed a necessary condition for the assertion that the pointer observable Z has assumed a definite value with respect to a reading scale $\mathscr{R}$ at the end of the measurement $\mathscr{M}$. We go on to specify this case further.

3.8. We consider a measurement $\langle \mathscr{K}_{\mathscr{A}}, Z, T_{\mathscr{A}}, V, f\rangle$ of E with a fixed reading scale $\mathscr{R}$. Any X_i, $i\in\mathbf{I}$, defines a (unnormalized) *conditioned state*

$$V_i(T) := I\otimes Z_i^{1/2} V(T\otimes T_{\mathscr{A}}) I\otimes Z_i^{1/2}, \tag{4}$$

the state of $\mathscr{S}+\mathscr{A}$ on the condition that the pointer observable $Z^{\mathscr{R}}$ has value i. The (trace) norm of this state is $\mathrm{tr}[V_i(T)]=\mathrm{tr}[V(T\otimes T_{\mathscr{A}})I\otimes Z_i]=p_T^E(X_i)$, and the corresponding (normalized) reduced states, the *final component states* of $\mathscr{S}$ and $\mathscr{A}$ are

$$T_{\mathscr{S}}(i,T) := p_T^E(X_i)^{-1}.\mathscr{R}_{\mathscr{S}}(V_i(T)), \tag{5a}$$

$$T_{\mathscr{A}}(i,T) := p_T^E(X_i)^{-1}.\mathscr{R}_{\mathscr{A}}(V_i(T)). \tag{5b}$$

(If $p_T^E(X_i)=0$, we put $T_{\mathscr{S}}(i,T)=T_{\mathscr{A}}(i,T)=O$). The conditional interpretation of the states (4) and (5) presupposes, however, that the pointer observable $Z^{\mathscr{R}}$ has value i in state $T_{\mathscr{A}}(i,T)$, that is, $\mathrm{tr}[T_{\mathscr{A}}(i,T)Z_i]=1$ for all i and T whenever $p_T^E(X_i)\neq 0$.[5] This requirement is always satisfied if the pointer observable is sharp. In general this is a condition to be imposed on the measurement scheme. We call it the *pointer value-definiteness* condition and note that it may be written in either of the following equivalent forms:

$$\mathrm{tr}[T_{\mathscr{A}}(i,T)Z_i]=1 \quad (\text{whenever } p_T^E(X_i)\neq 0), \tag{6a}$$

$$Z_i T_{\mathscr{A}}(i,T) = T_{\mathscr{A}}(i,T), \tag{6b}$$

for all $i\in\mathbf{I}$ and all initial states T of $\mathscr{S}$.

3.9. For any reading scale $\mathscr{R}$ and any state $T\in\mathscr{S}(\mathscr{H})$ one has

$$\mathscr{R}_{\mathscr{S}}(V(T\otimes T_{\mathscr{A}})) = \sum\, p_T^E(X_i) T_{\mathscr{S}}(i,T); \tag{7}$$

this is to say that the final object state behaves additively with respect to the pointer conditioning: That is, the state of $\mathscr{S}$ on the plain condition that the measurement has been performed, is the same as the state of $\mathscr{S}$ after the measurement conditional on the fact that the pointer value is registered with respect to the reading scale $\mathscr{R}$.[6] Although it also holds true that for any $i\in\mathbf{I}$ and $T\in\mathscr{S}(\mathscr{H})$

$$T_{\mathscr{A}}(i,T) = p_T^E(X_i)^{-1} Z_i^{1/2}.\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))Z_i^{1/2}, \tag{8}$$

it is not the case, in general, that the final apparatus state $\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))$ is conditioned with respect to $\mathscr{R}$; thus, in general,

$$\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}})) \neq \sum\, p_T^E(X_i) T_{\mathscr{A}}(i,T). \tag{9}$$

The requirement that $\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))$ is a mixture of the final component states $T_{\mathscr{A}}(i,T)$ is therefore another condition on the measurement;[2] we call it the *pointer mixture condition*

$$\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}})) = \sum\, p_T^E(X_i) T_{\mathscr{A}}(i,T) \tag{10}$$

for all initial states T of $\mathscr{S}$.

3.10. The pointer value-definiteness condition (6) and the pointer mixture condition (10) imply that the final apparatus state is a mixture of the pointer eigenstates $T_{\mathscr{A}}(i,T)$ with the weights $p_T^E(X_i)$; this means that the final apparatus state $\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))$ is conditioned with respect to the reading scale $\mathscr{R}$.[2,6] One may consider the assumption that in addition to this, the state $\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))$ admits the *ignorance interpretation* with respect to the decomposition (10): that is, the apparatus [in state $\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))$] is actually in one of the component states $T_{\mathscr{A}}(i,T)$, and this is the case with the subjective probability $p_T^E(X_i)$. As is well known, such an interpretation of the mixed state $\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))$ is extremely problematic and in most cases impossible; but if it were the case then the pointer could be claimed to have a definite value i (with respect to a reading scale $\mathscr{R}$) after the measurement with the subjective probability $p_T^E(X_i)$. Setting aside the difficulties with the ignorance interpretation (and thus with explaining the occurrence of definite measurement outcomes in quantum mechanics), it still is important to investigate more closely the conditions (6) and (10) and to see how these possible properties of a measurement are related to the structure of the final state of the object system.

Theorem 3.11: *Let $\mathscr{M}$ be a measurement of an observable E and $\mathscr{R}$ any reading scale. For any initial state T of the object system, the condition (a) implies the conditions (b) and (c):*

$$\text{(a)}\quad T_{\mathscr{S}}(i,T)\cdot T_{\mathscr{S}}(j,T)=O \quad \text{for } i\neq j;$$

$$\text{(b)}\quad \mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))=\Sigma p_T^E(X_i)T_{\mathscr{A}}(i,T) \quad \text{for all } i;$$

$$\text{(c)}\quad Z_i T_{\mathscr{A}}(i,T)=T_{\mathscr{A}}(i,T) \quad \text{for all } i.$$

If $\mathscr{M}$ is a unitary measurement $\mathscr{M}_U$, then (a) and (b) are equivalent conditions for any initial vector state $T=P[\varphi]$ of $\mathscr{S}$.

Proof:

(a)⇒(b)&(c): For each i, let F_i be the support projection of $T_{\mathscr{S}}(i,T)$, that is, the smallest projection of Q such that $QT_{\mathscr{S}}(i,T)=T_{\mathscr{S}}(i,T)$. Then one gets (for $i\neq j$)

$$\begin{aligned}
T_{\mathscr{S}}(i,T)\cdot T_{\mathscr{S}}(j,T)=0 &\Leftrightarrow F_i T_{\mathscr{S}}(j,T)=O\\
&\Leftrightarrow \mathrm{tr}[F_i\otimes I V_j(T)]=0\\
&\Leftrightarrow F_i\otimes Z_j^{1/2}V(T\otimes T_{\mathscr{A}})I\otimes Z_j^{1/2}=O\\
&\Leftrightarrow F_i\otimes Z_j^{1/2}V(T\otimes T_{\mathscr{A}})^{1/2}=O\\
&\Rightarrow F_i\otimes Z_j V(T\otimes T_{\mathscr{A}})^{1/2}=O. \qquad (\alpha)
\end{aligned}$$

By the definition of F_i one also has

$$\begin{aligned}
F_i T_{\mathscr{S}}(i,T)=T_{\mathscr{S}}(i,T) &\Leftrightarrow F_i\otimes Z_i^{1/2}V(T\otimes T_{\mathscr{A}})I\otimes Z_i^{1/2}=I\otimes Z_i^{1/2}V(T\otimes T_{\mathscr{A}})I\otimes Z_i^{1/2}\\
&\Rightarrow F_i\otimes Z_i V(T\otimes T_{\mathscr{A}})^{1/2}=I\otimes Z_i V(T\otimes T_{\mathscr{A}})^{1/2}. \qquad (\beta)
\end{aligned}$$

Combining (α) and (β) and using the fact that $\Sigma Z_i=I$ yields

$$F_i\otimes IV(T\otimes T_{\mathscr{A}})^{1/2}=F_i\otimes Z_i V(T\otimes T_{\mathscr{A}})^{1/2}=I\otimes Z_i V(T\otimes T_{\mathscr{A}})^{1/2}. \qquad (\gamma)$$

From this one obtains $I\otimes Z_i V(T\otimes T_{\mathscr{A}})=I\otimes Z_i^2 V(T\otimes T_{\mathscr{A}})$, which gives (c). Using (c), one shows similarly that

$$I\otimes Z_i V(T\otimes T_{\mathscr{A}})^{1/2}=I\otimes Z_i^{1/2}V(T\otimes T_{\mathscr{A}})^{1/2}.$$

Inserting this in (γ), multiplying each term with its adjoint and summing over i, one obtains

$$\sum F_i\otimes IV(T\otimes T_{\mathscr{A}})F_i\otimes I=\sum I\otimes Z_i^{1/2}V(T\otimes T_{\mathscr{A}})I\otimes Z_i^{1/2}.$$

Taking the partial trace with respect to $\mathscr{H}$ finally yields (b).

(b)⇒(a): This implication will be shown for a unitary measurement $\mathscr{M}_U$ and for vector state preparations $T=P[\varphi]$. In that case $T_{\mathscr{A}}=P[\phi]$ and $V(T\otimes T_{\mathscr{A}})=P[U(\varphi\otimes\phi)]$. Denoting the biorthogonal decomposition of this state as $U(\varphi\otimes\phi)=\Sigma_{nk}c_n\varphi_{nk}\otimes\phi_{nk}$, with $c_n>0$, we obtain $T_{\mathscr{A}}(\Omega,T)=\Sigma_{nk}|c_n|^2P[\phi_{nk}]$. Now (b) implies that all the projections Z_i commute with $T_{\mathscr{A}}(\Omega,T)$. Therefore, one can choose the orthonormal system $\{\phi_{nk}\}$ such that $Z_i\phi_{nk}=\phi_{nk}$ or $Z_i\phi_{nk}=0$. Thus there is a renumbering of this system, $\{\phi_{nk}\}=\{\phi_{il}\}$, such that $Z_i\phi_{il}=\phi_{il}$. It follows that there are corresponding renumberings $\{\varphi_{il}\}=\{\varphi_{nk}\}$ and $\{d_{il}\}=\{c_n\}$ such that $U(\varphi\otimes\phi)=\Sigma d_{il}\varphi_{il}\otimes\phi_{il}$. Then $T_{\mathscr{S}}(i,T)=\Sigma_l|d_{il}|^2P[\varphi_{il}]$. Since the subsets of vectors φ_{il} with different values of i are mutually disjoint and therefore orthogonal, one concludes that (a) holds. This completes the proof.

It can be demonstrated by means of examples that the implication (b)⇒(a) need not hold if the measurement is not unitary or if the initial pointer state is not pure.[1]

C. First kind and repeatable measurements

3.12. A measurement $\mathscr{M}$ of an observable E is of the *first kind* if the probability for a given result is the same both before and after the measurement, that is, for any $T\in\mathscr{S}(\mathscr{H})$ and for all $X\in\mathscr{F}$,

$$p_T^E(X)=p^E_{\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))}(X). \tag{11}$$

Unitary measurement schemes with a coupling $U=e^{i\lambda A\otimes B}$, $\lambda\in\mathbf{R}$, A (on $\mathscr{H}$) and B (on $\mathscr{H}_{\mathscr{A}}$) self-adjoint, do give rise to such measurements; we refer to Sec. VIII for an analysis of this model.

3.13. A measurement $\mathscr{M}$ of an observable E is *repeatable* if its repetition does not lead to a new result. One way to express the requirement is the following: For any $T\in\mathscr{S}(\mathscr{H})$ and $X\in\mathscr{F}$, if $p_T^E(X)\neq 0$, then

$$p^E_{T_{\mathscr{S}}(X,T)}(X)=1, \tag{12}$$

(where $T_{\mathscr{S}}(X,T)$ is defined by Eqs. (3a), (4) and (5a) with $X=X_i$). Equivalently, $\mathscr{M}$ is a repeatable E-measurement if for any $T\in\mathscr{S}(\mathscr{H})$ and $X\in\mathscr{F}$, for which $p_T^E(X)\neq 0$, it holds true that

$$E(X)T_{\mathscr{S}}(X,T)=T_{\mathscr{S}}(X,T). \tag{13}$$

Another basic result of measurement theory is that an observable E which admits a repeatable measurement is discrete.[4,7]

3.14. According to Eq. (13), a repeatable measurement drives the object system into an eigenstate of the measured observable $E:i\mapsto E_i$. The orthogonality conditions of Theorem 3.11 are then satisfied and the final apparatus state $\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))$ is the mixture of the eigenstates $T_{\mathscr{A}}(i,T)$ of $Z:i\mapsto Z_i$ with the weights $\mathrm{tr}[TE_i]$.

3.15. It is evident that repeatable measurements are also of the first kind. However, as will be demonstrated in Sec. VIII, a first kind measurement need not be repeatable, though for sharp observables the two notions coincide.[8]

IV. STATISTICAL DEPENDENCE AND CORRELATIONS

A measurement $\mathscr{M}$ of an observable E brings the compound object–apparatus system into an entangled state $V(T\otimes T_{\mathscr{M}})$. The possibility of transferring information from $\mathscr{A}$ to $\mathscr{S}$ rests on the fact that this state entails *statistical dependencies* between quantities pertaining to these systems. Accordingly, three types of *correlations* inherent in the state $V(T\otimes T_{\mathscr{M}})$ are of special interest for characterizing the measurement: (i) correlations between the measured observable and the pointer observable; (ii) correlations between the corresponding values of these observables; and (iii) correlations between the final component states of the two subsystems. For their study it is helpful to recall some basic notions and facts concerning the relation between statistical dependence and correlation.

4.1. Let μ be a probability measure on the real Borel space $(\mathbf{R}^2,\mathscr{B}(\mathbf{R}^2))$, and let μ_1 and μ_2 be the marginal measures of μ with respect to a Cartesian coordinate system: For $X,Y\in\mathscr{B}(\mathbf{R})$,

$$\mu_1(X)=\mu(X\times\mathbf{R}),\quad \mu_2(Y)=\mu(\mathbf{R}\times Y). \tag{14}$$

These marginal measures correspond to the coordinate projections (random variables) π_1: $(x,y)\mapsto x$ and π_2: $(x,y)\mapsto y$ in the sense that $\mu_i=\mu^{\pi_i}$, that is, $\mu_i(X)=\mu^{\pi_i}(X):=\mu(\pi_i^{-1}(X))$ for all $X\in\mathscr{B}(\mathbf{R})$, $i=1,2$. Assume that the expectations and the variances of μ_i are well defined and finite: $\epsilon_i=\int x\, d\mu_i(x)$, $\sigma_i^2=\int(x-\epsilon_i)^2\, d\mu_i(x)$, and let $\epsilon_{12}=\int xy\, d\mu(x,y)$. The (normalized) *correlation* of the marginal measures μ_1 and μ_2 in μ is then defined as

$$\rho(\mu_1,\mu_2;\mu):=\int \frac{(x-\epsilon_1)(y-\epsilon_2)}{\sigma_1\sigma_2}\, d\mu(x,y)=\frac{\epsilon_{12}-\epsilon_1\epsilon_2}{\sigma_1\sigma_2} \tag{15}$$

(whenever $\sigma_1\neq 0\neq\sigma_2$). The Schwarz inequality entails $|\rho(\mu_1,\mu_2;\mu)|\leqslant 1$. The marginals μ_1,μ_2 are *uncorrelated* if $\rho(\mu_1,\mu_2;\mu)=0$ (that is, $\epsilon_{12}=\epsilon_1\epsilon_2$), *strongly correlated* if $\rho(\mu_1,\mu_2;\mu)=1$ (that is, $\epsilon_{12}-\epsilon_1\epsilon_2=\sigma_1\sigma_2$), and *strongly anticorrelated* if $\rho(\mu_1,\mu_2;\mu)=-1$ (that is, $\epsilon_{12}-\epsilon_1\epsilon_2=-\sigma_1\sigma_2$). The strong correlation conditions can also be written in terms of the coordinate projections π_1 and π_2

$$\rho(\pi_1,\pi_2;\mu)=+1 \ \text{ iff } \ \pi_1=\frac{\sigma_1}{\sigma_2}(\pi_2-\epsilon_2)+\epsilon_1=:l_+\circ\pi_2 \quad (\mu\text{-a.e.}), \tag{16a}$$

$$\rho(\pi_1,\pi_2;\mu)=-1 \ \text{ iff } \ \pi_1=-\frac{\sigma_1}{\sigma_2}(\pi_2-\epsilon_2)+\epsilon_1=:l_-\circ\pi_2 \quad (\mu\text{-a.e.}). \tag{16b}$$

(Here, we have introduced the function $l_\pm: y\mapsto l_\pm(y):=\pm(\sigma_1/\sigma_2)(y-\epsilon_2)+\epsilon_1)$. A case of special interest arises when the marginals μ_1 and μ_2 have the same (finite) first and second moments so that $\epsilon_1=\epsilon_2$, $\sigma_1=\sigma_2$. Then one has

$$\rho(\mu_1,\mu_2;\mu)=+1 \ \text{ iff } \ \epsilon_{12}=\epsilon_1^2+\sigma_1^2, \quad \text{iff } \ \pi_1=\pi_2 \quad (\mu\text{-a.e.}), \tag{17a}$$

$$\rho(\mu_1,\mu_2;\mu)=-1 \ \text{ iff } \ \epsilon_{12}=\epsilon_1^2-\sigma_1^2, \quad \text{iff } \ \pi_1=-\pi_2+2\epsilon_1 \quad (\mu\text{-a.e.}). \tag{17b}$$

4.2. The notion of correlation can be applied to quantify the degree of mutual dependence of the marginal measures. In order to avoid dealing with unnecessary complications, we assume that μ_1 and μ_2 are no $\{0,1\}$-valued measures; equivalently, we let $\sigma_1\neq 0\neq\sigma_2$. μ_1 and μ_2 are *independent* if $\mu=\mu_1\times\mu_2$. Otherwise, μ_1,μ_2 are *dependent*. They are *completely dependent* if there is a (measurable) function $h:\mathbf{R}\to\mathbf{R}$ such that $\mu(X\times Y)=\mu_2(h^{-1}(X)\cap Y)$ for $X,Y\in\mathscr{B}(\mathbf{R})$. That is, the marginal measure μ_2 suffices to determine the whole measure μ. The relation of complete dependence is symmetric with respect to the two marginals only if h is bijective. This is the case of concern here.

4.3. It is evident that the statistical independence of μ_1,μ_2 implies $\rho(\mu_1,\mu_2;\mu)=0$. However, the latter condition is not sufficient to ensure their independence. (For a counter example, see, for instance, Ref. 9). On the other hand, Eqs. (16a) and (16b) show that strong (anti)correlation entails complete dependence, the dependence being given by the linear function $l_\pm$. Indeed, the condition $\pi_1=l_\pm\circ\pi_2$ (μ-a.e.) implies that $\mu(X\times Y)=0$ for all X and Y for which $l_\pm^{-1}(X)\cap Y=0$. Thus in particular, for any X and Y, and with X' denoting the complement of X one has $\mu(X'\times l_\pm^{-1}(X)\cap Y)=0=\mu(X\times l_\pm^{-1}(X')\cap Y)$. The additivity properties of μ allow one then to verify that for all $X,Y,\mu_2(l_\pm^{-1}(X)\cap Y)=\mu(X\times Y)$, that is, μ_1 and μ_2 are completely dependent with $l_\pm$. By a direct computation one can confirm that the converse implication holds true whenever the function h is linear. Therefore, we have

$$\rho(\mu_1,\mu_2;\mu)=+1 \text{ iff } \mu_1,\mu_2 \text{ are completely dependent with } h(y)=ay+b, \quad a>0, \tag{18a}$$

$$\rho(\mu_1,\mu_2;\mu)=-1 \text{ iff } \mu_1,\mu_2 \text{ are completely dependent with } h(y)=ay+b, \quad a<0. \tag{18b}$$

In both cases the constants are $a=\pm\sigma_1/\sigma_2$, $b=\epsilon_1-a\epsilon_2$, so that $h=l_\pm$.

V. STRONG CORRELATIONS BETWEEN OBSERVABLES

5.1. According to the condition (2), in an E-measurement the initial E-outcome distribution is recovered from the final Z-outcome distribution. In addition to this basic requirement, a measurement may also establish complete statistical dependence between the measured observable and the pointer observable after the measurement; that is, the observables E and Z^f may become strongly correlated in the final object–apparatus state $V(T\otimes T_{\mathscr{A}})$. In order to avoid technical complications in the formulation of this correlation, we assume that the value space of E is the real Borel space, $(\Omega,\mathscr{F})=(\mathbf{R},\mathscr{B}(\mathbf{R}))$. Then for any state $T\in\mathscr{S}(\mathscr{H})$ the map

$$\mu: X\times Y\mapsto \mathrm{tr}[V(T\otimes T_{\mathscr{A}})E(X)\otimes Z^f(Y)] \tag{19}$$

extends to a probability measure on $(\mathbf{R}^2,\mathscr{B}(\mathbf{R}^2))$.[10] The marginal distributions are

$$\mu_1: X\mapsto \mathrm{tr}[\mathscr{R}_{\mathscr{S}}(V(T\otimes T_{\mathscr{A}}))E(X)], \tag{20a}$$

$$\mu_2: Y\mapsto \mathrm{tr}[\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))Z^f(Y)]=\mathrm{tr}[TE(Y)]. \tag{20b}$$

Denoting the correlation of μ_1 and μ_2 in μ as $\rho(E,Z^f;V(T\otimes T_{\mathscr{A}}))$, we say that the measurement $\mathscr{M}$ of E produces *strong observable-(anti)correlation* in state T if this number equals $1(-1)$. According to Eq. (18), this occurs exactly when the probability measures [(20a) and (20b)] are completely dependent, with the function $l_\pm$. In order to analyze the statistical dependence of μ_1 and μ_2 we shall make use of the concept of a state transformer (also known as an instrument) associated with a measurement.

5.2. Consider a measurement $\langle\mathscr{H}_{\mathscr{A}},Z,T_{\mathscr{A}},V,f\rangle$ of E. Any $X\in\mathscr{F}$ defines a non-normalized state

$$V_X(T):=I\otimes Z^{1/2}(f^{-1}(X))V(T\otimes T_{\mathscr{A}})I\otimes Z^{1/2}(f^{-1}(X)), \tag{21}$$

the (trace) norm of which is $\mathrm{tr}[V_X(T)]=p_T^E(X)$. Taking the partial trace of $V_X(T)$ over $\mathscr{H}_{\mathscr{A}}$ one gets the (non-normalized) reduced state of $\mathscr{S}$,

$$\mathscr{T}_X(T):=\mathscr{R}_{\mathscr{S}}(V_X(T)). \tag{22}$$

For any $X \in \mathcal{F}$ and $T \in \mathcal{S}(\mathcal{H})$, $\mathrm{tr}[\mathcal{I}_X(T)] = \mathrm{tr}[TE(X)]$, and $T \mapsto \mathcal{I}_X(T)$ is a (contractive) state transformation. The mapping $\mathcal{I}: X \mapsto \mathcal{I}_X$ has the measure property $\mathrm{tr}[\mathcal{I}_{\cup X_i}(T)] = \Sigma \mathrm{tr}[\mathcal{I}_{X_i}(T)]$ for any disjoint sequence $(X_i) \subset \mathcal{F}$ and for all $T \in \mathcal{S}(\mathcal{H})$. Moreover, $\mathrm{tr}[\mathcal{I}_\Omega(T)] = 1$ for any T. We call $\mathcal{I}$ the *state transformer* induced by the measurement $\mathcal{M}$. It describes the object system's state changes under the measurement, and it uniquely defines the measured observable via the relation $\mathrm{tr}[\mathcal{I}_X(T)] = \mathrm{tr}[TE(X)]$. We note also that $p_T^E(X) T_{\mathcal{I}}(X,T) = \mathcal{I}_X(T)$, and, in particular, $\mathcal{R}_{\mathcal{I}}(V(T \otimes T_{\mathcal{M}})) = \mathcal{I}_\Omega(T)$.

5.3. The probability measure (19) can be written as

$$\mu(X \times Y) = \mathrm{tr}[\mathcal{I}_Y(T)E(X)] = \mathrm{tr}[\mathcal{I}_X(\mathcal{I}_Y(T))], \tag{23}$$

and the second marginal is $\mu_2(Y) = \mathrm{tr}[\mathcal{I}_Y(T)]$. The strong (anti-)correlation then amounts to

$$\mathrm{tr}[\mathcal{I}_X(\mathcal{I}_Y(T))] = \mathrm{tr}[\mathcal{I}_{l_\pm^{-1}(X) \cap Y}(T)]. \tag{24}$$

A special case of complete dependence arises with l_+ being the identity function

$$\mathrm{tr}[\mathcal{I}_X(\mathcal{I}_Y(T))] = \mathrm{tr}[\mathcal{I}_{X \cap Y}(T)]. \tag{25}$$

This relation is easily seen to coincide with Eq. (12).[8] Thus if valid for all states T, Eq. (25) expresses the repeatability of the measurement, and we may conclude that any repeatable measurement leads to strong observable-correlations. The repeatability condition (25) is not necessary for the strong observable-correlation (24).

5.4. Condition (25) implies, in particular, the equality of the marginal measures μ_1, μ_2 of Eqs. (20): for all X,

$$p_T^E(X) = p^E_{\mathcal{R}_{\mathcal{I}}(V(T \otimes T_{\mathcal{M}}))}(X). \tag{26}$$

This is just the first-kind property of the measurement. It may occur that these marginal measures coincide irrespectively of whether Eq. (25) holds or not; in that case conditions (17) give the relevant characterisations of strong (anti)correlations.

Theorem 5.5: *Let $\mathcal{M}$ be a measurement of an observable E, and let $\mathcal{R}$ be any reading scale. Then (a) implies (b), where*

$$\text{(a)} \quad E(X_i) T_{\mathcal{I}}(i,T) = T_{\mathcal{I}}(i,T) \quad \text{for all} \quad T \in \mathcal{S}(\mathcal{H}), \quad X_i \in \mathcal{R};$$

$$\text{(b)} \quad \sigma(p^{E^{\mathcal{R}}}_{\mathcal{R}_{\mathcal{I}}(V(T \otimes T_{\mathcal{M}}))}) \neq 0 \ \text{ and } \ \rho(E^{\mathcal{R}}, Z^{\mathcal{R}}; V(T \otimes T_{\mathcal{M}})) = 1$$

$$\text{for all } T \in \mathcal{S}(\mathcal{H}) \text{ with } \sigma(p_T^{E^{\mathcal{R}}}) \neq 0.$$

If the reading scale $\mathcal{R}$ is finite, then (a) and (b) are equivalent.

Proof: The eigenstate condition (a) is equivalent with the repeatability condition (with respect to $\mathcal{R}$). Therefore, if (a) holds, then also (b) is true. It remains to show that (b) implies (a) whenever $\mathcal{R}$ is finite. According to Eq. (18a), the statement $\rho(E^{\mathcal{R}}, Z^{\mathcal{R}}; V(T \otimes T_{\mathcal{M}})) = 1$ is equivalent to the complete dependence, $\mu(i,j) = \mu_2(j)\delta_{i,l_+(j)}$, with a bijective linear mapping $i = l_+(j) = aj + b$, $a > 0$, between those values i,j for which $\mu_2(j) \neq 0$ (and hence $\mu_1(i) = \mu_2(\frac{1}{a}(i-b)) \neq 0$).

Case 1. Let T be such that $0 \neq \mathrm{tr}[TE_i] \neq 1$ for all $i \in \mathbf{I}$. Then $\mu(i,j)$ correlates, via $i = l_+(j) = aj + b$, *all* values $j \in \mathbf{I}$ with values $i \in \mathbf{I}$. Since l_+ is onto and monotonically increasing, $l_+(j) = j$. But the complete dependence condition, with $l_+(j) = j$, is nothing but Eq. (25) (with respect to $\mathcal{R}$), which is equivalent to (a).

Case 2. Let T be any state such that $0 \neq \mathrm{tr}[TE_k] \neq 1$ holds exactly for all $k \in \mathbf{I}_1$, a proper nonempty subset of $\mathbf{I}$. Take any T' for which $0 \neq \mathrm{tr}[T'E_l] \neq 1$ exactly for all $l \in \mathbf{I}_1'$, the complement of $\mathbf{I}_1$. Then the reasoning of Case 1 applies to $\hat{T} := \frac{1}{2}T + \frac{1}{2}T'$. Hence, $E_i \mathscr{I}_i(\hat{T}) = \mathscr{I}_i(\hat{T})$ for all $i \in \mathbf{I}$. Inserting in this equation the relation $\mathscr{I}_k(T') = O$, which holds for $k \in \mathbf{I}_1$, it follows that $E_i \mathscr{I}_i(T) = \mathscr{I}_i(T)$ for $i \in \mathbf{I}_1$. But this relation holds trivially also for $i \in \mathbf{I}_1'$ since in that case $\mathscr{I}_i(T) = O$. This completes the proof.

VI. STRONG CORRELATIONS BETWEEN VALUES

6.1. The observable $E^{\mathscr{R}}$ measured by the scheme $\mathscr{M}$ with the reading scale $\mathscr{R}$ is discrete. One may therefore ask to what degree the *values* of this observable and the pointer observable $Z^{\mathscr{R}}$ become correlated in the measurement. To answer this question requires studying the correlation $\rho(E_i, Z_i; V(T \otimes T_{\mathscr{M}}))$ of the ith values of these observables in the final object–apparatus state, that is, the correlation of quantities $E_i \otimes I$ and $I \otimes Z_i$ in the state $V(T \otimes T_{\mathscr{M}})$

$$\rho(E_i, Z_i; V(T \otimes T_{\mathscr{M}})) = \frac{\epsilon_{12} - \epsilon_1 \epsilon_2}{\sigma_1 \sigma_2}. \tag{27}$$

The respective quantities are easily determined

$$\epsilon_{12} = \mathrm{tr}[\mathscr{I}_i^2(T)], \tag{28a}$$

$$\epsilon_1 = \mathrm{tr}[\mathscr{I}(\mathbf{I})(T)E_i], \tag{28b}$$

$$\epsilon_2 = \mathrm{tr}[TE_i], \tag{28c}$$

$$\sigma_1^2 = \mathrm{tr}[\mathscr{I}(\mathbf{I})(T)E_i^2] - \mathrm{tr}[\mathscr{I}(\mathbf{I})(T)E_i]^2, \tag{28d}$$

$$\sigma_2^2 = tr[\mathscr{R}_{\mathscr{M}}(V(T \otimes T_{\mathscr{M}}))Z_i^2] - \mathrm{tr}[TE_i]^2. \tag{28e}$$

Strong correlation is then equivalent to

$$\epsilon_{12} - \epsilon_1 \epsilon_2 = \sigma_1 \sigma_2 \tag{29}$$

whenever the right-hand side is nonzero.

6.2. Assume that the final component state $T_{\mathscr{I}}(i,T)$ is a 1-eigenstate of E_i (whenever $p_T^E(X_i) \neq 0$); then one obtains $\epsilon_{12} = \epsilon_1 = \epsilon_2$ for all T. It follows that $\epsilon_{12} - \epsilon_1 \epsilon_2 = \sigma_1^2 \leqslant \sigma_1 \sigma_2$ and thus $\sigma_1 \leqslant \sigma_2$. On the other hand, the relation $\epsilon_1 = \epsilon_2 = \epsilon_{12}$ together with $\sigma_2^2 \leqslant \epsilon_2 - \epsilon_2^2 = \epsilon_{12} - \epsilon_1 \epsilon_2 = \sigma_1^2$ implies $\sigma_2 \leqslant \sigma_1$. Therefore, the correlation $\rho(E_i, Z_i; V(T \otimes T_{\mathscr{M}}))$ equals 1 whenever $0 \neq p_T^E(X_i) \neq 1$.

Another interesting implication of the eigenstate condition $\epsilon_{12} = \epsilon_2$ and the ensuing equality $\sigma_2 = \epsilon_2 - \epsilon_2^2$ is the fact that the state $T_{\mathscr{M}}(i,T)$ is a 1-eigenstate of Z_i. With these observations we have established the following result.

Theorem 6.3: *Let $\mathscr{M}$ be a measurement of an observable E and let $\mathscr{R}$ be any reading scale. Then for any state T of $\mathscr{S}$, (a) implies (b) and (c)*:

(a) $E_i T_{\mathscr{I}}(i,T) = T_{\mathscr{I}}(i,T)$ for each i;

(b) $\sigma(E_i \otimes I; V(T \otimes T_{\mathscr{M}})) \neq 0$ and $\rho(E_i, Z_i; V(T \otimes T_{\mathscr{M}})) = 1$ for each i with $0 \neq p_T^E(X_i) \neq 1$;

(c) $T_{\mathscr{M}}(i,T)$ is a 1-eigenstate of Z_i for each i with $p_T^E(X_i) \neq 0$.

This result entails that a repeatable measurement is a strong value-correlation measurement. Moreover, a necessary condition for $\mathscr{M}$ to be a repeatable measurement is that the final component state $T_{\mathscr{A}}(i,T)$ of $\mathscr{A}$ is a 1-eigenstate of the pointer observable, that is, $\mathscr{M}$ must fulfill the pointer value-definiteness condition. We recall that this last property and in addition the pointer mixture property arise already as consequences of the mutual orthogonality of the component states $T_{\mathscr{S}}(i,T)$ of $\mathscr{S}$ (Theorem 3.11). The notion of a correlation between values suggests that the observables in question do have definite values; yet it turns out that strong value-correlation does not require pointer value-definiteness, nor repeatability. Even the combination of (b) and (c) does not require the property (a) to hold, as can be demonstrated by simple examples.[1]

Theorem 6.4: *Let $\mathscr{M}$ be a measurement of a sharp observable E and $\mathscr{R}$ any reading scale. For any initial state T of $\mathscr{S}$, (a) is equivalent to (b) & (c)*:

$$\text{(a)} \quad E_i T_{\mathscr{S}}(i,T) = T_{\mathscr{S}}(i,T) \quad \text{for each } i;$$

$$\text{(b)} \quad \sigma(E_i \otimes I; V(T \otimes T_{\mathscr{A}})) \neq 0 \text{ and } \rho(E_i, Z_i; V(T \otimes T_{\mathscr{A}})) = 1 \quad \text{for each } i \text{ with } 0 \neq p_T^E(X_i) \neq 1;$$

$$\text{(c)} \quad T_{\mathscr{A}}(i,T) \text{ is a 1-eigenstate of } Z_i \text{ for each } i \text{ with } p_T^E(X_i) \neq 0.$$

Proof: In view of Theorem 6.3, we only need to show that (b) & (c) implies (a). Hence let $\epsilon_{12} - \epsilon_1 \epsilon_2 = \sigma_1 \sigma_2$ hold for each i. Condition (c) implies $\sigma_2^2 = \epsilon_2 - \epsilon_2^2$. Similarly the relation $E_i^2 = E_i$ implies $\sigma_1^2 = \epsilon_1 - \epsilon_1^2$. From Eqs. (28) we obtain $\epsilon_{12} \leqslant \epsilon_1$, $\epsilon_{12} \leqslant \epsilon_2$, and therefore

$$\sigma_1 \sigma_2 = \epsilon_{12} - \epsilon_1 \epsilon_2 \leqslant \sigma_1^2, \quad \sigma_1 \sigma_2 = \epsilon_{12} - \epsilon_1 \epsilon_2 \leqslant \sigma_2^2.$$

This implies $\sigma_1 = \sigma_2$. On the other hand,

$$\epsilon_1 \epsilon_2 + \sigma_1 \sigma_2 = \epsilon_{12} \leqslant \epsilon_1 = \sigma_1^2 + \epsilon_1^2, \quad \epsilon_1 \epsilon_2 + \sigma_1 \sigma_2 = \epsilon_{12} \leqslant \epsilon_2 = \sigma_2^2 + \epsilon_2^2.$$

Using $\sigma_1 = \sigma_2$, one concludes that $\epsilon_1 = \epsilon_2 = \epsilon_{12}$. But the last equation is equivalent to (a). This completes the proof.

VII. STRONG CORRELATIONS BETWEEN FINAL COMPONENT STATES

7.1. In the two preceding sections it was demonstrated in which way strong observable and value correlations serve as characterizations of repeatable measurements. The corresponding eigenstate condition $E_i T_{\mathscr{S}}(i,T) = T_{\mathscr{S}}(i,T)$ entails, in particular, that the final component states of the object associated with different outcomes i,j are mutually orthogonal, $T_{\mathscr{S}}(i,T) \cdot T_{\mathscr{S}}(j,T) = 0$. In some cases this orthogonality can be characterized in terms of strong correlations between the final component states of $\mathscr{S}$ and $\mathscr{A}$.

Consider a measurement scheme $\mathscr{M}$ of an observable E with respect to a reading scale $\mathscr{R}$. We say that $\mathscr{M}$, with $\mathscr{R}$, is a *strong state-(anti)correlation* measurement of E if for each initial state T of $\mathscr{S}$ it correlates strongly the final component states $T_{\mathscr{S}}(i,T)$ and $T_{\mathscr{A}}(i,T)$ of the object and the apparatus. This calls for the study of the correlation $\rho(T_{\mathscr{S}}(i,T), T_{\mathscr{A}}(i,T); V(T \otimes T_{\mathscr{A}}))$ of the probability measure defined by the self-adjoint operators $T_{\mathscr{S}}(i,T) \otimes I$ and $I \otimes T_{\mathscr{A}}(i,T)$ and the final object–apparatus state $V(T \otimes T_{\mathscr{A}})$.

Theorem 7.2: *Let $\mathscr{M}$ be a measurement of an observable E and $\mathscr{R}$ any reading scale. For any initial state T of the object system for which the component states $T_{\mathscr{S}}(i,T)$ and $T_{\mathscr{A}}(i,T)$ are vector states, (a) is equivalent to (b) & (c)*:

$$\text{(a)} \quad T_{\mathscr{S}}(i,T) \cdot T_{\mathscr{S}}(j,T) = O \quad \text{for } i \neq j;$$

$$\text{(b)}\quad \rho(T_{\mathscr{S}}(i,T),T_{\mathscr{A}}(i,T);V(T\otimes T_{\mathscr{A}}))=1 \quad \text{for each } i \text{ with } 0\neq p_T^E(X_i)\neq 1;$$

$$\text{(c)}\quad T_{\mathscr{A}}(i,T) \text{ is a 1-eigenstate of } Z_i \quad \text{for each } i \text{ with } 0\neq p_T^E(X_i)\neq 1.$$

Proof: The equivalence is shown to hold under the assumptions $T_{\mathscr{S}}(i,T)=P[\varphi_i]$ and $T_{\mathscr{A}}(i,T)=P[\phi_i]$. These two relations imply that $I\otimes Z_i^{1/2}V(T\otimes T_{\mathscr{A}})I\otimes Z_i^{1/2}$ is a vector state of the product form, that is,

$$I\otimes Z_i^{1/2}V(T\otimes T_{\mathscr{A}})I\otimes Z_i^{1/2}=p_T^E(X_i)P[\varphi_i\otimes\phi_i]. \qquad (\alpha)$$

If (a) holds, then by Theorem 3.11, $\mathscr{M}$ fulfils the pointer value-definiteness condition (c). Thus for both implications one can make use of the fact that $Z_i\phi_i=\phi_i$. Then (α) implies

$$I\otimes P[\phi_i]V(T\otimes T_{\mathscr{A}})I\otimes P[\phi_i]=p_T^E(X_i)P[\varphi_i\otimes\phi_i].$$

With this one computes

$$\epsilon_{12}=\mathrm{tr}[P[\varphi_i]\otimes P[\phi_i]V(T\otimes T_{\mathscr{A}})]=p_T^E(X_i),$$

$$\epsilon_1=\mathrm{tr}[P[\varphi_i].\mathscr{R}_{\mathscr{S}}(V(T\otimes T_{\mathscr{A}}))]=\sum_j p_T^E(X_j)\mathrm{tr}[P[\varphi_i]P[\varphi_j]],$$

$$\epsilon_2=\mathrm{tr}[I\otimes P[\phi_i]V(T\otimes T_{\mathscr{A}})]=p_T^E(X_i),$$

$$\sigma_1^2=\epsilon_1-\epsilon_1^2,\quad \sigma_2^2=\epsilon_2-\epsilon_2^2.$$

(a)⇒(b): (a) is equivalent to $\mathrm{tr}[P[\varphi_i]P[\varphi_j]]=\delta_{ij}$, one has $\epsilon_1=\epsilon_2=\epsilon_{12}$, and $\sigma_1=\sigma_2$. Thus $\epsilon_{12}-\epsilon_1\epsilon_2=\sigma_1\sigma_2$, that is, (b).

(b)&(c)⇒(a): Let $\epsilon_{12}-\epsilon_1\epsilon_2=\sigma_1\sigma_2$. Using the inequalities $\epsilon_{12}-\epsilon_1\epsilon_2\leqslant\sigma_k^2$, $k=1,2$, one concludes that $\sigma_1=\sigma_2$. Since $\epsilon_{12}=\epsilon_2$, one also has $\epsilon_{12}-\epsilon_1\epsilon_2=\sigma_2^2=\epsilon_2-\epsilon_2^2$, and therefore $\epsilon_1=\epsilon_2$. But from the definition of ϵ_1 one has $\epsilon_1\geqslant\epsilon_2$, so that the equality of these numbers implies $\mathrm{tr}[P[\varphi_i]P[\varphi_j]]=0$ whenever $i\neq j$, that is (a). This completes the proof.

7.3. One may also ask whether the requirement of strong correlation between the $\mathscr{S}$ and $\mathscr{A}$ states $\mathscr{R}_{\mathscr{S}}(V(T\otimes T_{\mathscr{A}}))$ and $\mathscr{R}_{\mathscr{A}}(V(T\otimes T_{\mathscr{A}}))$ imposes any constraint on the measurement scheme under consideration. That this cannot be expected in general can be seen in the case of a unitary measurement $\mathscr{M}_U$. Note first that the reduced states of $P[U(\varphi\otimes\phi)]$ have the same spectra, including multiplicities. The spectral decompositions can be given in terms of orthonormal systems $\{\varphi_i\}$, $\{\phi_i\}$ defined by the biorthogonal decomposition $U(\varphi\otimes\phi)=\Sigma_i c_i\varphi_i\otimes\phi_i (c_i>0)$, and a straightforward calculation shows that

$$\rho(\mathscr{R}_{\mathscr{S}}(P[U(\varphi\otimes\phi)]),\mathscr{R}_{\mathscr{A}}(P[U(\varphi\otimes\phi)]);P[U(\varphi\otimes\phi)])=1. \qquad (30)$$

Hence these states are always strongly correlated.

VIII. EXAMPLES

8.1. A particularly interesting class of measurements arises if the coupling is generated by a unitary map of the form

$$U=e^{i\lambda A\otimes B}, \qquad (31)$$

where A and B are self-adjoint operators in $\mathscr{H}$ and $\mathscr{H}_{\mathscr{A}}$, respectively, and $\lambda\in\mathbf{R}$ is a coupling constant. The operator A is usually taken to represent the (sharp) observable one aims to measure.

In order to specify the full measurement scheme and thus the actually measured observable, one needs to choose the pointer observable Z and fix the initial preparation $T_{\mathscr{A}}$ of the apparatus; the measured observable is then given by Eq. (2). Using the spectral decomposition of A, $A=\int aE^A(da)$, and denoting

$$T_{\mathscr{A}}^{\lambda a} := e^{i\lambda aB} T_{\mathscr{A}} e^{-i\lambda aB}, \tag{32}$$

the final apparatus state, for $T\in\mathscr{S}(\mathscr{H})$, assumes the form

$$\mathscr{R}_{\mathscr{A}}(UT\otimes T_{\mathscr{A}}U^*)=\int \mathrm{tr}[TE^A(da)]T_{\mathscr{A}}^{\lambda a}. \tag{33}$$

Since it is of interest to compare the measured observable E with E^A we assume from the outset that the value space of Z is $(\mathbf{R},\mathscr{B}(\mathbf{R}))$. In view of the coupling constant $\lambda(\neq 0)$ it is also convenient to introduce a pointer function $f(x)=\lambda^{-1}x$. The observable E measured by the scheme $\langle \mathscr{H}_{\mathscr{A}}, Z, T_{\mathscr{A}}, f, U\rangle$ takes then the following form: For any $X\in\mathscr{B}(\mathbf{R})$,

$$E(X)=\int_{\mathbf{R}} \mathrm{tr}[T_{\mathscr{A}}^{\lambda a} Z(\lambda X)]E^A(da). \tag{34}$$

The structure of the operators $E(X)$ show that in general the measured observable E is not the sharp observable E^A, but a smeared version of it.[11] One may ask which choices of Z and $T_{\mathscr{A}}$ would possibly yield $E=E^A$. Obviously, this is the case if and only if for (E^A-almost) all $a\in\mathbf{R}$, $\mathrm{tr}[T_{\mathscr{A}}^{\lambda a}Z(\lambda X)]=\chi_X(a)$, where χ_X is the characteristic function of the set X.

The measurement scheme thus defined is always of the first kind: The measurement outcome probabilities for E are the same both before and after the measurement; for any $T\in\mathscr{S}(\mathscr{H})$ and for all $X\in\mathscr{B}(\mathbf{R})$,

$$\mathrm{tr}[TE(X)]=\mathrm{tr}[UT\otimes T_{\mathscr{A}}U^*E(X)\otimes I]. \tag{35}$$

It may also be noticed that the measurement does neither alter the measurement outcome probabilities of E^A, though, as a rule, it is not a measurement of E^A. In fact, if the measurement were an E^A-measurement, it would also be repeatable (3.15) and A would thus have to be discrete, $A=\Sigma a_i E^A(\{a_i\})$ (3.13). In that case the measurement would also produce all the strong correlations discussed in the previous sections. In general, this is, however, not the case.

Consider next this measurement scheme with a fixed reading scale $\mathscr{R}$. The pointer observable Z as well as the measured observable E become discretized,

$$Z^{\mathscr{R}}: i\mapsto Z_i := Z(\lambda X_i), \tag{36a}$$

$$E^{\mathscr{R}}: i\mapsto E_i := E(X_i), \tag{36b}$$

and the final component states are

$$\begin{aligned} T_{\mathscr{S}}(i,T)&=p_T^E(X_i)^{-1}\mathscr{R}_{\mathscr{S}}(V_i(T))=p_T^E(X_i)^{-1}\int\int \mathscr{R}_{\mathscr{S}}(E^A(da)TE^A(da') \\ &\quad\otimes Z_i^{1/2}e^{iaB}T_{\mathscr{A}}e^{-ia'B}Z_i^{1/2}) \\ &=p_T^E(X_i)^{-1}\sum t_n\sum L_{kn}^i TL_{kn}^{i*} \qquad (37a) \\ &\quad\text{with } L_{kn}^i := \int \langle\psi_k|Z_i^{1/2}\phi_n^{\lambda a}\rangle E^A(da)\in\mathscr{L}(\mathscr{H}), \end{aligned}$$

$$T_{\mathscr{A}} = \sum\ t_n P[\phi_n] \quad \text{(spectral decomposition)}$$

$$\phi_n^{\lambda a} = e^{i\lambda a B}\phi_n\,,$$

$$\{\psi_k\} \subset \mathscr{K}_{\mathscr{A}} \text{ an orthonormal basis,}$$

$$T_{\mathscr{A}}(i,T) = p_T^E(X_i)^{-1}\mathscr{R}_{\mathscr{A}}(V_i(T)) = p_T^E(X_i)^{-1}\int \mathrm{tr}[TE^A(da)]Z_i^{1/2}T_{\mathscr{A}}^{\lambda a}Z_i^{1/2}, \tag{37b}$$

(provided that $p_T^E(X_i) \neq 0$). If $E_i^2 = E_i$ for all $i \in \mathbf{I}$, the measurement is repeatable with respect to $\mathscr{R}$, and

$$E(X_i)T_{\mathscr{A}}(i,T) = T_{\mathscr{A}}(i,T), \tag{38a}$$

$$T_{\mathscr{A}}(i,T)\cdot T_{\mathscr{A}}(j,T) = O, \quad i \neq j, \tag{38b}$$

in which case the implications of Theorems 3.11, 5.5, 6.3, 6.4, and 7.2 all hold true. We specify next two instances of the above model, one in which $E_i^2 = E_i$ and another one with $E_i^2 < E_i$.

8.2. Consider a discrete observable $A = \Sigma a_k E^A(\{a_k\})$, and assume that the set of eigenvalues of A is closed. As the apparatus (or a part of it, called probe) take a particle moving in one-dimensional space, so that $\mathscr{K}_{\mathscr{A}} = L^2(\mathbf{R})$, and couple A with its momentum $P_{\mathscr{A}}$ according to Eq. (31). Since the momentum generates translations on the position, it is natural to choose the position $Q_{\mathscr{A}}$ conjugate to $P_{\mathscr{A}}$ as the pointer observable. Assuming that the initial state of $\mathscr{A}$ is a vector state $P[\phi]$, then, in the position representation (for $\mathscr{A}$) one has $\phi^{\lambda a_k}(x) = \phi(x + \lambda a_k)$, with $\phi^{\lambda a_k} = e^{i\lambda a_k P_{\mathscr{A}}}\phi$. Assuming that the spacing between the eigenvalues a_k is greater than (δ/λ) and that ϕ is supported in $(-\frac{\delta}{2}, \frac{\delta}{2})$, then the pointer states $\phi^{\lambda a_k}$ are supported in the mutually disjoint sets λI_k, where $I_k = (a_k - (\delta/2\lambda), a_k + (\delta/2\lambda))$. Introducing yet another pointer function g such that $g(I_k) = \{a_k\}$ for each k, and $g((\cup_k I_k)') \subset \{a_k : k = 1,2,\ldots\}'$, one obtains from Eq. (34)

$$E(\{a_k\}) = \sum\ \langle \phi^{\lambda a_i} | E^{Q_{\mathscr{A}}}(\lambda I_k)\phi^{\lambda a_i}\rangle E^A(\{a_i\}) = E^A(\{a_k\}), \tag{39}$$

for each k, which shows that the observable measured by this scheme is indeed E^A. The measurement is repeatable, even a Lüders measurement with the state transformer $T \mapsto \mathscr{T}_k(T) = \mathscr{R}_{\mathscr{A}}(V_k(T)) = E^A(\{a_k\})TE^A(\{a_k\})$, and all the correlations introduced above are strong.

As an elementary quantum optical application, one may consider the measurement of the number observable $N = a^*a$ of a (single-mode) signal field by means of coupling it, via $e^{i\lambda N \otimes b^p}$, with one of the quadrature components $b^p = i/\sqrt{2}(b^* - b)$, say, of another single-mode (probe) field, and using the other quadrature component $b^q = 1/\sqrt{2}(b^* + b)$ as the readout observable. With the above choices of the initial probe state ϕ and the pointer functions one obtains a number measurement. It may be noted that neither the beam splitter coupling nor the number–number coupling leads to a sharp number measurement.[11]

8.3. The second illustration of the above model concerns the case of A being a continuous observable, such as the position of a particle or a quadrature component of a single-mode electromagnetic field. Using the quantum optical nomenclature, we take $A = a^q = 1/\sqrt{2}(a^* + a)$, the amplitude quadrature of the (single-mode) signal field with the bosonic annihilation and creation operators a, a^*. For B we take the corresponding quadrature component b^q of a (single-mode) probe field, with the annihilation and creation operators b, b^*. Using the phase quadrature

$b^p := i/\sqrt{2}(b^* - b) = \int_{\mathbf{R}} x Z(dx)$ of the probe field as the readout observable, and assuming that the probe field is prepared in a vector state $P[\phi]$ determines the measured observable (34) to be of the form

$$E(X) = \int \int |\hat{\phi}|^2(y - \lambda x)\chi_{\lambda X}(y)dy \; E^A(dx) = \int |\hat{\phi}|^2(y - \lambda a^q)\chi_{\lambda X}(y)dy$$
$$\equiv (e_\lambda * \chi_X)(a^q),$$
$$e_\lambda(y) := \lambda |\hat{\phi}|^2(-\lambda y), \tag{40}$$

where $e_\lambda * \chi_X$ denotes the convolution of the density function e_λ with the characteristic function of the set X, and $\hat{\phi}$ is the Fourier transform of ϕ.

In the present case the measured observable is the POV measure $E: X \mapsto (e_\lambda * \chi_X)(a^q)$ and not the spectral measure $X \mapsto \chi_X(a^q)$ of a^q; this is to say that the measured field observable is not the amplitude quadrature a^q but a smearing of it. In fact, if e were replaced by a delta function (concentrated at 0), then Eq. (40) would simply give the amplitude quadrature a^q. But this can never occur since the readout observable b^p has no eigenstates, that is, the initial state of the probe field cannot be so chosen that e were a delta function. We observe also that the measurement is not repeatable (since E is not discrete) though still of the first kind. Therefore, the strong correlations are not guaranteed from the outset but need to be studied separately.

Before calculating the observable-correlation produced by the measurement we compare the variance of E with that of a^q in a vector state $P[\varphi]$. Direct application of Eq. (2) yields (assuming that the involved quantities are finite)

$$\mathrm{Var}(E, \varphi) = \mathrm{Var}(a^q, \varphi) + \frac{1}{\lambda^2} \mathrm{Var}(b^p, \phi). \tag{41}$$

The initial state $P[\phi]$ of the probe field can be chosen such that $\langle \phi | b^p \phi \rangle = 0$. In this case the measured observable appears, in view of the first moments, as the amplitude quadrature a^q. However, the second moment $\langle \phi | (b^p)^2 \phi \rangle$ never equals 0, meaning that Var $(E, P[\varphi])$ is strictly greater than Var $(a^q, P[\varphi])$. However, in the limit of strong coupling, $\lambda \to \infty$, the measurement noise term $(1/\lambda^2)$Var $(b^p, P[\phi])$ tends to zero. In any case, this shows once more that the actually measured observable is not the amplitude quadrature.

The observable-correlation produced by the measurement is now found to be

$$\rho(E, Z^f; P[U(\varphi \otimes \phi)]) = \frac{\mathrm{Var}(a^q, P[\varphi])}{\mathrm{Var}(E, P[\varphi])}, \tag{42}$$

a quantity always strictly less than 1. The measurement, though of the first kind, does never lead to strong observable-correlation. Yet,

$$\lim_{\lambda \to \infty} \rho(E, Z^f; P[U(\varphi \otimes \phi)]) = 1. \tag{43}$$

In order to discuss the value- and state-correlations produced by the measurement scheme one needs to introduce a reading scale $\mathscr{R}$. The discrete observable $E^{\mathscr{R}}: i \mapsto E_i$ thus measured is

$$E_i = (e_\lambda * \chi_{X_i})(a^q), \tag{44}$$

whereas the final component states (37a) are of the form

$$T_{\mathscr{A}}(i,P[\varphi])=\langle\varphi|E_i\varphi\rangle^{-1}\int_{\lambda X_i} L_y P[\varphi]L_y^*\,dy \quad \text{with} \quad L_y:=\hat{\phi}(y-\lambda a^q). \tag{45}$$

Neither the eigenvalue condition (38a) nor the orthogonality condition (38b) can be satisfied for all initial vector states of the signal field. Therefore, the strong value and state-correlations cannot be inferred by using Theorems 6.3 and 7.2. Still the value-correlation is always strong: $\rho(E_i,Z_i;P[U(\varphi\otimes\phi)])=1$ for all i and for any $P[\varphi]$ for which $\langle\varphi|E_i\varphi\rangle\neq 0$. Indeed, due to the commutativity of the operators L_y of Eq. (45) with E_i, ϵ_{12} of Eq. (28a) equals $\langle\varphi|E_i^2\varphi\rangle$; furthermore the first kind property of the measurement and the sharp pointer yield for Eqs. (28b)–(28d): $\epsilon_1=\epsilon_2=\langle\varphi|E_i\varphi\rangle$, and $\sigma_1^2=\sigma_2^2=\mathrm{Var}(E_i,P[\varphi])$. Therefore, $\epsilon_{12}-\epsilon_1\epsilon_2=\sigma_1\sigma_2$, so that $\rho(E_i,Z_i;P[U(\varphi\otimes\phi)])=\mathrm{Var}(E_i,P[\varphi])/\mathrm{Var}(E_i,P[\varphi])=1$. Finally, a direct computation of the state-correlation $\rho(T_{\mathscr{A}}(i,P[\varphi]),T_{\mathscr{M}}(i,P[\varphi]);P[U(\varphi\otimes\phi)])$ shows that this number is not, in general, equal to one.

IX. CONCLUSION

In this paper we have investigated possible properties of the final component states of the object system and the apparatus (or probe) arrived at in a quantum measurement, properties which must be required if the occurrence of definite measurement outcomes is to be understood as the conjunction of pointer value definiteness (PVD), pointer mixture property (PM), plus the ignorance interpretation for the final reduced apparatus state. According to Theorem 3.11, the properties (PVD) and (PM) are ensured if the final component states of the object system are mutually orthogonal. Considering initial states of $\mathscr{S}$ which are vector states, this latter condition is also necessary for (PM) in the case of a unitary measurement $\mathscr{M}_U$, where (PVD) is automatically fulfilled since the pointer is a sharp observable. The orthogonality of the states $T_{\mathscr{A}}(i,T)$ is not always guaranteed.[12]

Next we have considered conditions for strong correlations between observables, their values, or between the final component states of $\mathscr{S}$ and $\mathscr{A}$. It turns out that repeatable measurements give strong observable- as well as strong value-correlations (Theorems 5.5, 6.3, 6.4). Furthermore, strong observable-correlation for finite reading scales entails repeatability and thus the orthogonality of the states $T_{\mathscr{A}}(i,T)$ and hence (PVD), via Eq. (3.11). On the other hand, strong value-correlation may occur independently of (PVD). Finally, strong state-correlation may occur under more general circumstances than the other correlations since it is independent of the repeatability property, but its implying the orthogonality of the final component states of $\mathscr{S}$ may be limited to the case where these states are vector states. However, in that case, and for a unitary measurement $\mathscr{M}_U$, strong state-correlation is equivalent to the said orthogonality and thus to the pointer mixture condition.

In conclusion, we wish to emphasize that our investigation provides an illustration of how interpretational demands entail formal constraints on measurements that may or may not be fulfilled in a concrete case. These formal features have thus to be made explicit if the consistency of an interpretation is to be demonstrated. With these findings we believe to have settled the questions left open in previous work.[2]

Canonical quantization of spontaneously broken topologically massive gauge theory

Lusheng Chen, Gerald Dunne, Kurt Haller, and Edwin Lim-Lombridas

(Received 1 June 1995; accepted for publication 26 January 1996)

In this paper we investigate the canonical quantization of a non-Abelian topologically massive Chern–Simons theory in which the gauge fields are minimally coupled to a multiplet of scalar fields in such a way that the gauge symmetry is spontaneously broken. Such a model produces the Chern–Simons–Higgs mechanism in which the gauge excitations acquire mass both from the Chern–Simons term and from the Higgs–Kibble effect. The symmetry breaking is chosen to be only partially broken, in such a way that in the broken vacuum there remains a residual non-Abelian symmetry. We develop the canonical operator structure of this theory in the broken vacuum, with particular emphasis on the particle-content of the fields involved in the Chern–Simons–Higgs mechanism. We construct the Fock space and express the dynamical generators in terms of creation and annihilation operator modes. The canonical apparatus is used to obtain the propagators for this theory, and we use the Poincaré generators to demonstrate the effect of Lorentz boosts on the particle states. © *1996 American Institute of Physics.* [S0022-2488(96)03106-4]

I. INTRODUCTION

Field theories in $(2+1)$-dimensional space–time exhibit many interesting and important properties related to the masses of the particle excitations of the quantum fields. For example, gauge theories involving a Chern–Simons term support massive gauge field excitations,[1,2] which differ from the Higgs–Kibble excitations produced in conventional spontaneous symmetry breaking.[3] The combination of *both* spontaneous symmetry breaking *and* a Chern–Simons (CS) term for the gauge field leads to the Chern–Simons–Higgs (CSH) mechanism, in which the physical fields are transmuted in a process that combines the Chern–Simons and Higgs–Kibble mass-generating effects in a particularly interesting and instructive manner.

An analysis of the covariant gauge field propagator[4,5] indicates the presence of two distinct mass poles, with masses given as complicated functions of the Higgs mass scale (set by the tree-approximation minimum of the symmetry breaking potential) and the CS mass scale [coming from the CS coupling parameter which has dimensions of mass in $(2+1)$-dimensional space–time]. The two distinct mass poles may also be seen in a factorization of the Chern–Simons–Proca equations of motion.[6] A Schrödinger representation approach[7] provides a simple physical picture based on a quantum mechanical analogue which identifies the two masses precisely with the two characteristic frequencies of the planar quantum mechanical model of charged particles moving in both a uniform magnetic field and a harmonic potential well. In this present paper we investigate field theoretic aspects of the CSH mechanism more deeply, presenting a detailed analysis of the canonical quantization of spontaneously broken CS theories. In this work, we pay particular attention to the relation between the quantized fields and their particle excitation modes and to the structure of the Poincaré generators as functionals of these particle excitation operators.

We have chosen to consider a non-Abelian theory in which the non-Abelian gauge symmetry is spontaneously broken in a manner that preserves a residual non-Abelian symmetry in the broken vacuum. This choice is motivated by the question of how a spontaneously broken CS theory 'knows' to quantum-mechanically protect the residual non-Abelian gauge symmetry from topo-

0022-2488/96/37(6)/2602/26/$10.00

logically nontrivial gauge transformations. For non-Abelian Chern–Simons theories, quantum consistency[1] requires that the CS coupling parameter takes quantized integer values, in appropriate units. Qualitatively, this consistency condition is reminiscent of Dirac's quantum mechanical quantization condition for the magnetic monopole,[8] but since the Chern–Simons theory is a *field theory* further subtleties (such as renormalization) arise. Pisarski and Rao[9] showed that, for a Chern–Simons–Yang–Mills theory (with no matter fields or symmetry breaking), a consistent one-loop renormalization involves a finite additive renormalization of the CS mass, with the finite shift depending on the gauge group and being such that the integer quantization condition is preserved. Subsequent calculations have confirmed the conjecture[9] that there are no further radiative corrections to this result.[10] Perturbative analyses of Abelian Chern–Simons theories subject to spontaneous symmetry breaking confirm the topological basis of the integer quantization of the renormalization of the CS term.[11–13] This work has shown that, in the Abelian case, in which topological arguments do not apply, the Chern–Simons mass receives a shift, in the broken vacuum, which is not an integer, but a complicated function of the various bare mass scales. (In Ref. 14 it is suggested that this shift should not be interpreted as a finite renormalization of the Chern–Simons mass, but rather as an indication of the appearance of parity-violating terms in the effective action. This reformulation of the result extends the Coleman–Hill theorem,[15] concerning the absence of loop corrections to the Chern–Simons mass, to the case of Abelian spontaneously broken Chern–Simons theories.) In a spontaneously broken non-Abelian Chern–Simons theory, with a *completely* broken symmetry in which the invariance of the effective theory to gauge transformations is no longer supported,[13] similar behavior was found.[16] More interesting is the situation in which the non-Abelian gauge symmetry is only *partially* broken, leaving a residual *non-Abelian* symmetry in the broken phase. The presence of the non-Abelian residual symmetry suggests that the CS coupling parameter should again be quantized, and indeed a direct perturbative computation shows that the CS coupling parameter receives a quantized finite shift which preserves the quantum consistency condition in the broken vacuum.[17] An earlier calculation, by the authors who first considered this model, incorrectly reported the opposite conclusion.[18] This work confirms the validity of the effective theory that describes the quantum fluctuations of the field about the spontaneously broken vacuum; it motivates an investigation into the origins of the massive propagating particle excitations of this model, and the mechanisms by which they obtain their mass.

In this paper, we consider the canonical quantization of such a non-Abelian model, with a partially broken symmetry leaving a residual non-Abelian symmetry in the broken phase, and develop the underlying dynamical theory. We make explicit the representation of the operator-valued fields in terms of excitations that correspond to observable, propagating particles in the spontaneously broken vacuum. We formulate the model in $(2+1)$-dimensional Minkowski space–time and for definiteness we consider an octet of SU(3) gauge fields interacting with a triplet of scalar fields in the fundamental representation of SU(3). The scalar fields Φ are coupled gauge-invariantly to the gauge fields, and self-coupled through a quartic potential $V(\Phi^\dagger\Phi) = -\mu^2\Phi^\dagger\Phi + \frac{1}{2}h(\Phi^\dagger\Phi)^2$, where $\mu^2 > 0$ and $h > 0$, so that, in the tree approximation, the scalar fields have nonvanishing vacuum expectation values. The vacuum expectation values of the three constituent fields in Φ are chosen so that the residual ''effective'' fields, which represent fluctuations of these scalar fields about their tree-approximation vacuum expectation values, still maintain an unbroken SU(2) symmetry in their coupling to the gauge fields. In the canonical quantization of this model we construct time-dependent fields in an interaction picture that includes, in the ''free'' Hamiltonian that drives it, the interaction terms that become bilinear in fields when the charged scalar field Φ is expanded about its constant vacuum expectation value. We use these time-dependent interaction-picture fields to evaluate the propagators. And finally, we construct the particle states that correspond to the two different mass singularities in the propagator for this model. We express the trilinear and quartic interaction Lagrangian as a functional of these interaction-picture fields, and obtain a set of vertices that can be used to describe the theory. In

addressing these problems, we make use of technical developments that originated from separate earlier work by the authors.[7,19–23]

In Section II, we formulate the model and describe the spontaneous symmetry breaking process. In Section III, we construct the required Fock spaces, express the scalar and gauge fields as superpositions of particle and ghost excitations, and implement Gauss's law and the gauge condition. In Section IV, we construct the interaction-picture scalar and gauge fields, and evaluate their time-ordered vacuum expectation values in the spontaneously broken vacuum state to obtain the propagators for this theory. In Section V, we construct the Poincaré generators for this theory, demonstrate the validity of the Poincaré algebra, and evaluate the effect of Lorentz boosts on each of the massive gluon states. Detailed forms of the interaction Lagrangian are given in an Appendix.

II. FORMULATION OF THE MODEL

The Lagrangian for this model is given by

$$\mathcal{L}=-\frac{1}{4}\mathcal{F}^a_{\mu\nu}\mathcal{F}^{a\mu\nu}+\frac{1}{4}m\epsilon^{\mu\nu\rho}\left(\mathcal{F}^a_{\mu\nu}A^a_\rho+\frac{2}{3}ef^{abc}A^a_\mu A^b_\nu A^c_\rho\right)$$
$$+(D^\mu\Phi)^\dagger(D_\mu\Phi)+\mu^2\Phi^\dagger\Phi-\frac{1}{2}h(\Phi^\dagger\Phi)^2+\mathcal{L}_{\rm fp}+\mathcal{L}_{\rm G}, \tag{1}$$

where $\mathcal{F}^a_{\mu\nu}$ designates the SU(3) gauge field strength

$$\mathcal{F}^a_{\mu\nu}=\partial_\mu A^a_\nu-\partial_\nu A^a_\mu-2ef^{abc}A^b_\mu A^c_\nu; \tag{2}$$

we denote by $F^a_{\mu\nu}$ the ''Abelian'' part of the field strength,

$$F^a_{\mu\nu}=\partial_\mu A^a_\nu-\partial_\nu A^a_\mu, \tag{3}$$

and f^{abc} represents the SU(3) structure constants. The implied summations over repeated Latin superscripts, such as a, b, and c, are from 1 to 8 unless otherwise specified. The covariant derivative of the scalar triplet $D_\mu\Phi$ is given by

$$D_\mu\Phi=\partial_\mu\Phi+ie\lambda^a A^a_\mu\Phi, \tag{4}$$

where λ^a represents the Gell-Mann matrices which satisfy the commutation relations $[\lambda^a,\lambda^b]=2if^{abc}\lambda^c$. $\mathcal{L}_{\rm fp}$ is the part of the Lagrangian that couples the gauge fields to the Faddeev–Popov ghosts, and is given by

$$\mathcal{L}_{\rm fp}=i\partial_\mu\sigma^a_{\rm f}\partial^\mu\sigma^a_{\rm p}-2ief^{abc}A^a_\mu\sigma^b_{\rm f}\partial^\mu\sigma^c_{\rm p}+ie\sigma^a_{\rm f}\frac{\delta\mathcal{U}^a}{\delta\chi^c}\sigma^c_{\rm p}, \tag{5}$$

where $\sigma^a_{\rm f}$ and $\sigma^a_{\rm p}$ are the two self-adjoint operator-valued anticommuting scalar Faddeev–Popov fields; $\mathcal{U}^a$ is given by

$$\mathcal{U}^a=i(1-\gamma)(\langle\Phi\rangle^\dagger_0\lambda^a\Phi'-\Phi'^\dagger\lambda^a\langle\Phi\rangle_0) \tag{6}$$

and $\delta\chi^c$ is the infinitesimal gauge shift that parameterizes the first-order gauge transformation of $\mathcal{U}^a$. $\mathcal{L}_{\rm G}$ is the gauge fixing term in the Lagrangian, and is given by

$$\mathcal{L}_{\rm G}=\frac{1}{2}(1-\gamma)G^aG^a-[\partial_\mu A^{a\mu}-ie(1-\gamma)(\langle\Phi\rangle^\dagger_0\lambda^a\Phi'-\Phi'^\dagger\lambda^a\langle\Phi\rangle_0)]G^a; \tag{7}$$

G^a is the gauge-fixing field used to impose the gauge condition for the t'Hooft gauge,

$$[\partial_\mu A^{a\mu} - ie(1-\gamma)(\langle\Phi\rangle_0^\dagger \lambda^a \Phi' - \Phi'^\dagger \lambda^a \langle\Phi\rangle_0)] = 0, \tag{8}$$

which is a covariant gauge that involves both the tree-approximation vacuum expectation value (v.e.v.) of the scalar field $\langle\Phi\rangle_0$ and the fluctuation of the scalar field about that vacuum expectation value $\Phi' = \Phi - \langle\Phi\rangle_0$. The first-order variation of $\mathcal{L}$ with respect to G^a leads to an equation of motion that enables us to contain the time-evolution of the interaction-picture fields entirely within a Hilbert space in which matrix elements of G^a always vanish; that fact secures Eq. (8) as the gauge condition for this model. The technical arrangements that permit — in fact require — time evolution of the interaction-picture fields to be contained within a subspace in which matrix elements of G^a vanish will be discussed in Section III.

We choose a scheme for breaking the SU(3) symmetry that preserves an SU(2) symmetry in the effective Lagrangian. In the tree-approximation vacuum state for this effective Lagrangian, the self-interaction $V(\Phi^\dagger\Phi)$ takes on its classical minimum value for the tree-approximation v.e.v. $\langle\Phi\rangle_0$. A choice for $\langle\Phi\rangle_0$ that satisfies this requirement is

$$\langle\Phi\rangle_0 = \frac{v}{\sqrt{2}} \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \equiv \frac{v}{\sqrt{2}} \langle\phi\rangle_0, \tag{9}$$

where $v = (2\mu^2/h)^{1/2}$. To analyze this model in the broken vacuum, we expand the scalar field Φ in terms of its fluctuations about the v.e.v. $\langle\Phi\rangle_0$,

$$\Phi' = \Phi - \langle\Phi\rangle_0, \tag{10}$$

and expand the Lagrangian as

$$\mathcal{L} = \mathcal{L}_0 + \mathcal{L}_1 + \mathcal{L}_2. \tag{11}$$

Here $\mathcal{L}_0$ represents the ''free'' Lagrangian in which the interaction have been shut off, and $\mathcal{L}_1$ and $\mathcal{L}_2$ represent terms that are first and second order in e, respectively. Note that there are several coupling constants and mass scales to consider when making this expansion, and we need to be specific about how coupling constants are ''shut off'' in taking $\mathcal{L}$ to its noninteracting limit $\mathcal{L}_0$. The CS coupling constant m has dimensions of mass, as do e^2 (the square of the scalar-gauge coupling), v^2 (the square of the magnitude of the scalar field v.e.v.), and ev. The noninteracting limit $\mathcal{L}_0$ of the full Lagrangian $\mathcal{L}$ is defined to be the limit $e \to 0$ and $h \to 0$ with the ''Higgs'' mass scale ev kept constant, and the CS mass scale unaffected. Then the noninteracting Lagrangian is

$$\begin{aligned}
\mathcal{L}_0 = & -\frac{1}{4} F^a_{\mu\nu} F^{a\mu\nu} + \frac{m}{4} \epsilon^{\mu\nu\rho} F^a_{\mu\nu} A^a_\rho + \frac{e^2 v^2}{4} A^a_\mu A^{b\mu} \langle\phi\rangle_0^\dagger \{\lambda^a, \lambda^b\} \langle\phi\rangle_0 + |\partial_\mu \Phi'|^2 - \frac{\mu^2}{2} (\langle\phi\rangle_0^\dagger \Phi' \\
& + \Phi'^\dagger \langle\phi\rangle_0)^2 + i \frac{ev}{\sqrt{2}} A^a_\mu [(\partial^\mu \Phi')^\dagger \lambda^a \langle\phi\rangle_0 - \langle\phi\rangle_0^\dagger \lambda^a \partial^\mu \Phi'] \\
& - \left[\partial_\mu A^{a\mu} + i \frac{ev}{\sqrt{2}} (1-\gamma)(\langle\phi\rangle_0^\dagger \lambda^a \Phi' - \Phi'^\dagger \lambda^a \langle\phi\rangle_0) \right] \\
& \times G^a + \frac{1}{2}(1-\gamma) G^a G^a + i \partial_\mu \sigma^a_{\mathrm{f}} \partial^\mu \sigma^a_{\mathrm{p}}.
\end{aligned} \tag{12}$$

The $\mathcal{O}(e)$ interaction Lagrangian is[24]

$$\mathcal{L}_1 = e\Bigg\{ f^{abc}F^a_{\mu\nu}A^{b\mu}A^{c\nu} - \frac{m}{3}\epsilon^{\mu\nu\rho}f^{abc}A^a_\mu A^b_\nu A^c_\rho - 2if^{abc}A^a_\mu \sigma^b_{\rm f}\partial^\mu \sigma^c_{\rm p} + i\sigma^a_{\rm f}\frac{\delta \mathcal{U}^a}{\delta \chi^c}\sigma^c_{\rm p}$$
$$+ \frac{ev}{2\sqrt{2}}A^a_\mu A^{b\mu}(\Phi'^\dagger\{\lambda^a,\lambda^b\}\langle\phi\rangle_0 + \langle\phi\rangle_0^\dagger\{\lambda^a,\lambda^b\}\Phi')$$
$$- iA^a_\mu[\Phi'^\dagger\lambda^a\partial^\mu\Phi' - (\partial^\mu\Phi')^\dagger\lambda^a\Phi'] - \sqrt{2}\frac{\mu^2}{ev}|\Phi'|^2(\langle\phi\rangle_0^\dagger\Phi' + \Phi'^\dagger\langle\phi\rangle_0)\Bigg\}, \tag{13}$$

and the $\mathcal{O}(e^2)$ interaction Lagrangian is

$$\mathcal{L}_2 = e^2\Bigg(-f^{abc}f^{ade}A^b_\mu A^{d\mu}A^c_\nu A^{e\nu} - \frac{\mu^2}{e^2v^2}|\Phi'|^4 + \frac{1}{2}A^a_\mu A^{b\mu}\Phi'^\dagger\{\lambda^a,\lambda^b\}\Phi'\Bigg). \tag{14}$$

We note that the presence of the CS term in the original Lagrangian Eq. (11) introduces a new quadratic piece $\sim\epsilon FA$ in $\mathcal{L}_0$ and a new 3-gluon vertex piece $\sim\epsilon AAA$ in $\mathcal{L}_1$.

To identify the physical and unphysical fields in the broken vacuum, we first express Φ' in terms of *real* scalar fields

$$\Phi' = \frac{1}{\sqrt{2}}\begin{pmatrix} i\xi^4 + \xi^5 \\ i\xi^6 + \xi^7 \\ -i\xi^8 + \psi \end{pmatrix}. \tag{15}$$

Then, using the explicit form given in Eq. (9) of the v.e.v. $\langle\phi\rangle_0$, together with the Gell-Mann matrix anticommutation relations

$$\{\lambda^a,\lambda^b\} = \tfrac{4}{3}\delta^{ab}\mathbf{1} + 2d^{abc}\lambda^c, \tag{16}$$

we write the free Lagrangian $\mathcal{L}_0$ as

$$\mathcal{L}_0 = -\frac{1}{4}F^a_{\mu\nu}F^{a\mu\nu} + \frac{m}{4}\epsilon^{\mu\nu\rho}F^a_{\mu\nu}A^a_\rho + \frac{1}{2}\sum_{a=4}^{8}M^2_{(a)}A^a_\mu A^{a\mu} + \sum_{a=4}^{8}M_{(a)}A^{a\mu}\partial_\mu\xi^a$$
$$+ \frac{1}{2}\sum_{a=4}^{8}\partial_\mu\xi^a\partial^\mu\xi^a + \frac{1}{2}\partial_\mu\psi\partial^\mu\psi - \mu^2\psi^2 + \frac{1}{2}(1-\gamma)G^aG^a - \partial_\mu A^{a\mu}G^a$$
$$+ (1-\gamma)\sum_{a=4}^{8}M_{(a)}\xi^aG^a + i\partial_\mu\sigma^a_{\rm f}\partial^\mu\sigma^a_{\rm p} - i(1-\gamma)\sum_{a=4}^{8}M^2_{(a)}\sigma^a_{\rm f}\sigma^a_{\rm p}. \tag{17}$$

Here the symmetry breaking mass scales $M_{(a)}$ are given by

$$M_{(a)} = \begin{cases} 0, & a = 1,2,3, \\ M_{\rm D} = ev, & a = 4,5,6,7, \\ M_{\rm S} = \dfrac{2}{\sqrt{3}}ev, & a = 8. \end{cases} \tag{18}$$

From Eq. (17), we recognize ψ as the Higgs scalar field, with mass $\sqrt{2}|\mu|$, and ξ^a $(a = 4,\ldots,8)$ as the massless unphysical scalar fields. Furthermore, the gauge fields A^a_μ

($a=1,2,3$) have a quadratic Lagrangian of the Maxwell–Chern–Simons form, while the gauge fields A_μ^a ($a=4,\ldots,8$) have an additional Proca-like quadratic term with mass scale parameters $M_{(a)}$ as given in Eq. (18).

The interaction Lagrangians $\mathcal{L}_1$ and $\mathcal{L}_2$ can also be expanded in terms of the real fields in Eq. (15) and the symmetry breaking mass scales in Eq. (18); the resulting expansions are recorded in the Appendix. It is important to observe that (as expected) the gauge field A_μ^a ($a=1,2,3$) form an SU(2) triplet corresponding to the residual SU(2) symmetry of the broken vacuum. It proves convenient to group the real scalar fields into SU(2) ''isospinors:''

$$\Psi_1=\frac{1}{\sqrt{2}}\begin{pmatrix} i\xi^4+\xi^5 \\ i\xi^6+\xi^7 \end{pmatrix}, \tag{19}$$

$$\Psi_2=\frac{1}{\sqrt{2}}\begin{pmatrix} i\xi^4+\xi^5 \\ \psi-i\xi^8 \end{pmatrix}, \tag{20}$$

and

$$\Psi_3=\frac{1}{\sqrt{2}}\begin{pmatrix} i\xi^6+\xi^7 \\ \psi-i\xi^8 \end{pmatrix}. \tag{21}$$

With this notation, the fields A_μ^a ($a=1,2,3$) couple to Ψ_1 in an SU(2)-invariant manner, while the two gauge field doublets (A_μ^4,A_μ^5) and (A_μ^6,A_μ^7) couple to Ψ_2 and Ψ_3 so that the part of the isospin invariance that corresponds to rotation in the $i=1,2$ plane is preserved; but this latter interaction is not invariant to rotation in the entire isospin space. The remaining gauge field A_μ^8 is an SU(2) singlet.

In earlier work on Abelian theories with Chern–Simons interactions,[19–21] we implemented Gauss's law and developed a canonical formulation for the entire Lagrangian, with all interactions included. In a non-Abelian gauge theory, such a program becomes much more problematical. We will therefore implement Gauss's law only for the partial theory described by $\mathcal{L}_0$. In this case, however, because of the spontaneously broken symmetry, even the Abelian $\mathcal{L}_0$ contains part of the interaction — not only the part of the Φ^4 self-interaction implicit in the spontaneously broken vacuum state, but also the part of the gauge-invariant coupling of the gauge field to the ''charged'' scalar Φ that remains bilinear in operator-valued fields after Φ has been expressed as $\Phi=\Phi'+\langle\Phi\rangle_0$. Although this part of the interaction term is proportional to e, it does not vanish in the ''interaction-free'' limit because e combines with $h^{-1/2}$ to become one of the masses that are kept constant in the $\mathcal{L}\to\mathcal{L}_0$ limit. Implementing Gauss's law and the gauge condition, and developing the canonical formulation of the part of the theory described by $\mathcal{L}_0$, will enable us to construct the Fock space for the particle states observed in the broken vacuum. In the course of this work, we will demonstrate the process by which the masses that stem from the Higgs–Kibble effect[3] combine with the topological mass to form the masses of the propagating modes of the gauge field in this model. $\mathcal{L}_0$, defined as we have specified here, is the Lagrangian that drives the interaction-picture fields when a Higgs–Kibble effect occurs. The corresponding ''free'' Hamiltonian H_0, which is the $e\to 0$ limit of H obtained by this same limiting process, accounts for the particle spectrum of this model. Once $\mathcal{L}_0$ and H_0 have been identified, and Gauss's law and the covariant gauge condition have been imposed, the resulting apparatus can be used to develop a Fock space as well as propagators and vertices for evaluating the S-matrix elements and renormalization constants for the full theory, with $\mathcal{L}_1$ and $\mathcal{L}_2$ included.

The Euler–Lagrange equations determined by $\mathcal{L}_0$ are

$$\partial_\mu F^{a\nu\mu} - \frac{1}{2} m \epsilon^{\mu\rho\nu} F^a_{\mu\rho} - \partial^\nu G^a = M^2_{(a)} A^{a\nu} + \partial^\nu \alpha^a, \tag{22}$$

$$\partial_\mu A^{a\mu} - (1-\gamma)\alpha^a = (1-\gamma) G^a, \tag{23}$$

$$\partial_\mu \partial^\mu \psi + 2\,\mu^2 \psi = 0, \tag{24}$$

and

$$\partial_\mu \partial^\mu \xi^a + M_{(a)} \partial_\mu A^{a\mu} = (1-\gamma) M_{(a)} G^a, \tag{25}$$

where $\alpha^a = M_{(a)} \xi^a$,

$$\partial_\mu \partial^\mu \sigma^a_{\mathrm{f}} + (1-\gamma) M^2_{(a)} \sigma^a_{\mathrm{f}} = 0, \tag{26}$$

and

$$\partial_\mu \partial^\mu \sigma^a_{\mathrm{p}} + (1-\gamma) M^2_{(a)} \sigma^a_{\mathrm{p}} = 0. \tag{27}$$

From these equations, we get

$$\partial_\mu \partial^\mu G^a + (1-\gamma) M^2_{(a)} G^a = 0. \tag{28}$$

Equation (22) represents the Maxwell–Ampere law (for $\nu = 1,2$) as well as Gauss's law (for $\nu = 0$); however, as is to be expected in covariant gauges, this equation differs from the classical form of Maxwell–Ampere and Gauss's laws by the gauge-fixing term — in this case, $\partial^\nu G^a$. Implementation of the correct form of these laws will have the effect of defining a subspace for the dynamical time evolution of state vectors in which the gauge-fixing term will have vanishing matrix elements. Equation (23) will be used to impose the covariant gauge condition: $\gamma = 0$ corresponds to the Feynman, and $\gamma = 1$ to the Landau version of the covariant (t'Hooft) gauge.

To quantize this theory, we need to express the Hamiltonian in terms of the canonical momenta given by $\Pi^{a\mu} = \partial \mathcal{L}_0 / \partial(\partial_0 A^a_\mu)$. These canonical momenta are:

$$\Pi^{a\mu} = F^{a\mu 0} + \frac{1}{2} m \epsilon^{0\mu\nu} A^a_\nu - g^{0\mu} G^a, \tag{29}$$

$$\Pi_\psi = \partial_0 \psi, \tag{30}$$

$$\Pi^a_\xi = \partial_0 \xi^a + M_{(a)} A^a_0, \tag{31}$$

$$\Pi^a_{\mathrm{f}} = i \partial_0 \sigma^a_{\mathrm{p}}, \tag{32}$$

and

$$\Pi^a_{\mathrm{p}} = -i \partial_0 \sigma^a_{\mathrm{f}}; \tag{33}$$

Π^a_{f} and Π^a_{p} are the conjugate momenta to the fields σ^a_{f} and σ^a_{p}, respectively.

The only equation that does not contain any time-derivatives of fields (and therefore is a constraint) is $\Pi^{a0} = -G^a$. This constraint is manifestly consistent with canonical (Poisson) equal-time commutation rules, which we impose. The equal-time commutation rules (ETCR) are:

$$[A^q_l(\mathbf{x}), \Pi^b_n(\mathbf{y})] = i \delta_{ln} \delta^{ab} \delta(\mathbf{x} - \mathbf{y}), \tag{34}$$

$$[A_0^a(\mathbf{x}),G^b(\mathbf{y})]=-i\delta^{ab}\delta(\mathbf{x}-\mathbf{y}), \tag{35}$$

$$[\xi^a(\mathbf{x}),\Pi_\xi^b(\mathbf{y})]=i\delta^{ab}\delta(\mathbf{x}-\mathbf{y}), \tag{36}$$

$$[\psi(\mathbf{x}),\Pi_\psi(\mathbf{y})]=i\delta(\mathbf{x}-\mathbf{y}), \tag{37}$$

and all other commutators among these fields are zero. The anticommutation rules for the Faddeev–Popov ghost fields are

$$\{\sigma_{\rm f}^a(\mathbf{x}),\Pi_{\rm f}^b(\mathbf{y})\}=i\delta^{ab}\delta(\mathbf{x}-\mathbf{y}), \tag{38}$$

$$\{\sigma_{\rm p}^a(\mathbf{x}),\Pi_{\rm p}^b(\mathbf{y})\}=i\delta^{ab}\delta(\mathbf{x}-\mathbf{y}), \tag{39}$$

and all other combinations anticommute.

The Hamiltonian density $\mathcal{H}_0$, determined by $\mathcal{L}_0$ and by the canonical momenta, will be expressed as

$$\mathcal{H}_0=\sum_{a=1}^{8}\mathcal{H}^a+\mathcal{H}_\psi+\sum_{a=1}^{8}\mathcal{H}_{\rm fp}^a; \tag{40}$$

for $a=1,2,3$:

$$\mathcal{H}^a=\frac{1}{2}\Pi_l^a\Pi_l^a+\frac{1}{4}F_{ln}^aF_{ln}^a+\frac{1}{8}m^2A_n^aA_n^a+\frac{1}{2}m\epsilon_{ln}A_l^a\Pi_n^a$$
$$+A_0^a\left(\partial_l\Pi_l^a-\frac{1}{4}m\epsilon_{ln}F_{ln}^a\right)+G^a\partial_lA_l^a-\frac{1}{2}(1-\gamma)G^aG^a; \tag{41}$$

for $a=4,5,6,7,8$:

$$\mathcal{H}^a=\frac{1}{2}\Pi_l^a\Pi_l^a+\frac{1}{4}F_{ln}^aF_{ln}^a+\frac{1}{2}\left[\frac{1}{4}m^2+M_{(a)}^2\right]A_n^aA_n^a+\frac{1}{2}m\epsilon_{ln}A_l^a\Pi_n^a$$
$$+A_0^a\left[\partial_l\Pi_l^a-\frac{1}{4}m\epsilon_{ln}F_{ln}^a-M_{(a)}\Pi_\xi^a\right]+G^a[\partial_lA_l^a-(1-\gamma)M_{(a)}\xi^a]-M_{(a)}A_l^a\partial_l\xi^a$$
$$-\frac{1}{2}(1-\gamma)G^aG^a+\frac{1}{2}\Pi_\xi^a\Pi_\xi^a+\frac{1}{2}\partial_l\xi^a\partial_l\xi^a; \tag{42}$$

the other parts of $\mathcal{H}_0$ are

$$\mathcal{H}_\psi=\frac{1}{2}\Pi_\psi\Pi_\psi+\frac{1}{2}\partial_l\psi\partial_l\psi+\mu^2\psi^2; \tag{43}$$

and

$$\mathcal{H}_{\rm fp}^a=i\Pi_{\rm p}^a\Pi_{\rm f}^a+i\partial_l\sigma_{\rm f}^a\partial_l\sigma_{\rm p}^a+i(1-\gamma)M_{(a)}^2\sigma_{\rm f}^a\sigma_{\rm p}^a. \tag{44}$$

The Hamiltonian, $H_0=\int d\mathbf{x}\mathcal{H}_0(\mathbf{x})$, is the ''free'' kinetic energy limit of the entire Hamiltonian, with the proviso that in this model the free kinetic energy limit includes the part of the interaction term in which the constant tree-approximation v.e.v. of Φ combines with the charge e to form a

new constant (dimensionally a mass) whose operator-valued coefficient is bilinear in fields. This part of the interaction is not shut off in the $H \to H_0$ limit, and is absorbed into a generalized, more encompassing kinetic energy operator H_0.

III. PARTICLE STATES AND GAUSS'S LAW

Equation (22), when $\nu = 0$ and the canonical momenta replace the time derivatives of fields, has the form[25]

$$\partial_l \Pi_l^a + \frac{1}{2} m \epsilon_{ln} \partial_l A_n^a - M_{(a)} \Pi_\xi^a = \partial^0 G^a. \tag{45}$$

The right-hand side of Eq. (45) would have to vanish to express Gauss's law. But since $\partial^0 G^a = 0$ is not one of the Euler–Lagrange equations, we therefore have to take some further measures to implement Gauss's law. For later reference, we will define the ''Gauss's law operator'' $\mathcal{G}^a$ as

$$\mathcal{G}^a = \partial_l \Pi_l^a + \frac{1}{2} m \epsilon_{ln} \partial_l A_n^a - M_{(a)} \Pi_\xi^a. \tag{46}$$

In order to describe the particle states of this theory, we must construct a ''suitable'' representation for the operator-valued fields in terms of creation and annihilation operators for the observable propagating particles described by this model — and, in the case of gauge theories, generally also in terms of additional 'ghost' excitations. The first requirement for such a suitable representation is that it must be consistent with the equal-time commutation rules given in Eqs. (34)–(37). This requirement, however, though necessary, is not sufficient to provide for a consistent theory. Another requirement that a representation must satisfy in order to be suitable, is that the excitation modes for propagating, observable particles must appear in the Hamiltonian H_0 — the Hamiltonian that time-translates the interaction picture fields — in such a manner that one-particle states or noninteracting multiparticle states are eigenstates of H_0, with eigenvalues $E_k = \sqrt{m^2 + k^2}$ for one-particle states of mass m and momentum k, and with eigenvalues $\Sigma_{i=1}^n E_k(i)$ for noninteracting n-particle states. Clearly, these states must also remain invariant to the temporal evolution mediated by $\exp(-iH_0 t)$, except for time-dependent phase factors, $\exp(-iE_k t)$ for one-particle, and $\exp\{\Sigma_{i=1}^n [-iE_k(i)t]\}$ for noninteracting n-particle states. In particular, it is crucial that time-translation by $\exp(-iH_0 t)$ does not cause particle states to penetrate into the part of the Hilbert space in which probability measure is absorbed by ghost states at the expense of the observable propagating states. Once a representation in terms of particle modes — and ghosts, if required — has been constructed and demonstrated to lead to a consistent form of H_0, that fact confirms the identification of the particle modes: their existence, their masses, their stability to time-translation as noninteracting states, and ultimately through the use of the other Poincaré operators, their other kinematic properties as well. In this way, the canonical quantization procedure formally demonstrates the existence of propagating particle modes that, in the absence of explicit representations of the gauge fields as superpositions of creation and annihilation operators, can only be inferred indirectly on the basis of equations of motion and on the supposition that propagator poles are not ''spurious,'' but reflect the existence of propagating particle modes.

Although representations in terms of particle excitation operators for many familiar operator-valued fields — scalar Klein–Gordon fields or spinor Dirac fields, for example — are commonplace and easily obtained, representations for the fields that appear in this model are much less trivial to construct. The masses of the gauge field excitations in this model combine the topological mass induced by the Chern–Simons term with the effect of the v.e.v. of the scalar field, that causes parts of the cubic and quartic terms in the Lagrangian to mimic mass terms. As a result, we expect the observable particle modes of the combined scalar and gauge fields to consist of Higgs

scalars as well as gauge field excitations — massive gluons with both topological mass and mass from the spontaneously broken symmetry. The eight gauge fields in this model fall into three classes, and should give rise to particle excitations with different mass: one SU(2) triplet of gauge fields with $M_{(a)}=0$ and excitation modes that have only topological mass; two doublets of gauge fields with $M_{(a)}=M_{\mathrm{D}}$ excitations whose mass depends on both the topological mass and M_{D}; and a singlet similar to the doublet, but with M_{D} replaced by M_{S}. The pole structure of the propagator[4,5] and earlier work on related systems[6,7] suggest that the gauge fields in the doublet and singlet sectors each have two different massive gluon states. The gauge fields in the unbroken SU(2) triplet have just a single gluon excitation mode. We will make an initial *ansatz* that incorporates this set of particle states into the representation of the gauge fields. If more particle states are needed than the ones included in our *ansatz*, or if an entirely different set is required, it will be impossible to construct a suitable representation using these excitation modes. If fewer particle modes are sufficient, then it will become evident that a mode is redundant. Mistakes in the tentative choices of particle modes will therefore be self-correcting. Conversely, a consistent and suitable representation of the gauge fields will confirm that the identification of the particle excitations is correct.

It is apparent that the observable, propagating gluon modes listed above will not suffice to represent *all* the commutation rules included in Eqs. (34) and (35). Further modes, in the form of ghost excitations, are required. These ghost modes are identical to the ones that appear in Abelian Maxwell–Chern–Simons theory,[19–21] and that are also required in $(3+1)$-dimensional QED (QED_4) in covariant and axial (except for the spatial axial) gauges.[26] The excitation operators for the massive gluons are the annihilation operator $a^c(\mathbf{k})$ and its adjoint creation operator $a^{c\dagger}(\mathbf{k})$, which obey the commutation rule $[a^c(\mathbf{k}),a^{d\dagger}(\mathbf{q})]=\delta^{cd}\delta_{\mathbf{kq}}$. For the gauge fields in the doublet and singlet sectors, the second observable, propagating mode will be designated by the annihilation operator $b^c(\mathbf{k})$ and its adjoint creation operator $b^{c\dagger}(\mathbf{k})$, which obey the commutation rule $[b^c(\mathbf{k}),b^{d\dagger}(\mathbf{q})]=\delta^{cd}\delta_{\mathbf{kq}}$.

Ghost excitation operators exist in pairs. In this work, we will use the ghost annihilation operators $a_Q^c(\mathbf{k})$ and $a_R^c(\mathbf{k})$ and their respective adjoint creation operators $a_Q^{c\star}(\mathbf{k})$ and $a_R^{c\star}(\mathbf{k})$ in the representations of the gauge field. Ghost states have zero norm, but the single-particle ghost states $a_Q^{c\star}(\mathbf{k})|0\rangle$ and $a_R^{c\star}(\mathbf{k})|0\rangle$ have a nonvanishing inner product; similar nonvanishing inner products also arise for n-particle states with equal numbers of Q and R ghosts. These properties of the ghost states are implemented by the commutator algebra

$$[a_Q^c(\mathbf{k}),a_R^{d\star}(\mathbf{q})]=[a_R^c(\mathbf{k}),a_Q^{d\star}(\mathbf{q})]=\delta^{cd}\delta_{\mathbf{kq}} \tag{47}$$

and

$$[a_Q^c(\mathbf{k}),a_Q^{d\star}(\mathbf{q})]=[a_R^c(\mathbf{k}),a_R^{d\star}(\mathbf{q})]=0, \tag{48}$$

which, in turn, imply that the unit operator in the one-particle ghost (OPG) sector is

$$1_{\mathrm{OPG}}=\sum_{\mathbf{k}}\,[a_Q^{c\star}(\mathbf{k})|0\rangle\langle 0|a_R^c(\mathbf{k})+a_R^{c\star}(\mathbf{k})|0\rangle\langle 0|a_Q^c(\mathbf{k})]; \tag{49}$$

the obvious generalization of Eq. (49) applies in the n-particle sectors. The ghost excitations enable us to satisfy the equal-time commutation relations, Eqs. (34) and (35).

The requirements that Gauss's law ($\mathcal{G}^c=0$) be implemented, and that the time evolution mediated by $\exp(-iH_0t)$ keep probability measure contained within the subspace spanned by propagating, observable particle modes, have the following further consequences: The Gauss's law operator $\mathcal{G}^c(\mathbf{x})$ must be restricted to a linear combination of ghost operators for a single kind

of ghost. We will therefore express $\mathcal{G}^c(\mathbf{x})$ as a superposition of $a_Q^c(\mathbf{k})$ and $a_Q^{c\star}(\mathbf{k})$ operators only. Furthermore, the gauge-fixing field, G^c, must be expressed as a superposition of the same $a_Q^c(\mathbf{k})$ and $a_Q^{c\star}(\mathbf{k})$ ghost operators as is $\mathcal{G}^c(\mathbf{x})$.

We have found the required suitable representation of the fields by a combination of unitary transformations similar to the ones used in previous work[19–21] and of ''trial fields'' with arbitrary parameters which we then adjusted to arrive at ''suitable'' field representations. For example, we used the trial field

$$\begin{aligned}
A_l^c(\mathbf{x}) = &\sum_{\mathbf{k}} [\alpha_1(k)\epsilon_{ln}k_n + \alpha_2(k)k_l][a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] + \sum_{\mathbf{k}} i[\alpha_3(k)\epsilon_{ln}k_n + \alpha_4(k)k_l] \\
&\times [a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] + \sum_{\mathbf{k}} [\alpha_5(k)\epsilon_{ln}k_n + \alpha_6(k)k_l][b^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + b^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] \\
&+ \sum_{\mathbf{k}} i[\alpha_7(k)\epsilon_{ln}k_n + \alpha_8(k)k_l][b^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - b^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] + \sum_{\mathbf{k}} [\alpha_9(k)\epsilon_{ln}k_n + \alpha_{10}(k)k_l] \\
&\times [a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] + \sum_{\mathbf{k}} i[\alpha_{11}(k)\epsilon_{ln}k_n + \alpha_{12}(k)k_l] \\
&\times [a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] + \sum_{\mathbf{k}} [\alpha_{13}(k)\epsilon_{ln}k_n + \alpha_{14}(k)k_l][a_R^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} \\
&+ a_R^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] + \sum_{\mathbf{k}} i[\alpha_{15}(k)\epsilon_{ln}k_n + \alpha_{16}(k)k_l][a_R^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a_R^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}], \qquad (50)
\end{aligned}$$

where $\alpha_1(k), \ldots, \alpha_{16}(k)$ are arbitrary real parameters. Similar substitutions were made for the other fields in the model. The previously specified requirements of ''suitability'' were then translated into a set of equations which was solved using a customized operator algebra manipulation package in MATHEMATICA.[27] The resulting gauge field representations for the SU(2)-symmetric triplet ($c=1,2,3$) that has topological mass only are

$$\begin{aligned}
A_l^c(\mathbf{x}) = &\sum_{\mathbf{k}} \frac{8ik\epsilon_{ln}k_n}{m^{5/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] + (1-\gamma)\sum_{\mathbf{k}} \frac{2k_l}{m^{3/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] \\
&- \sum_{\mathbf{k}} \frac{4k^2k_l}{m^{7/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] + \sum_{\mathbf{k}} \frac{m^{3/2}k_l}{16k^3}[a_R^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_R^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] \\
&- \sum_{\mathbf{k}} \frac{\sqrt{\omega(k)}k_l}{\sqrt{2}mk}[a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] + \sum_{\mathbf{k}} \frac{i\epsilon_{ln}k_n}{k\sqrt{2\omega(k)}}[a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}],
\end{aligned} \qquad (51)$$

$$\begin{aligned}
\Pi_l^c(\mathbf{x}) = &-\sum_{\mathbf{k}} \frac{4ikk_l}{m^{3/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] + (1-\gamma)\sum_{\mathbf{k}} \frac{\epsilon_{ln}k_n}{\sqrt{m}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] \\
&+ \sum_{\mathbf{k}} \frac{6k^2\epsilon_{ln}k_n}{m^{5/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] + \sum_{\mathbf{k}} \frac{m^{5/2}\epsilon_{ln}k_n}{32k^3}[a_R^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_R^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] \\
&+ \sum_{\mathbf{k}} \frac{imk_l}{2^{3/2}k\sqrt{\omega(k)}}[a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] + \sum_{\mathbf{k}} \frac{\sqrt{\omega(k)}\epsilon_{ln}k_n}{2^{3/2}k} \\
&\times [a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}],
\end{aligned} \qquad (52)$$

$$A_0^c(\mathbf{x}) = -\sum_{\mathbf{k}} \frac{4k^3}{m^{7/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] - (1-\gamma)\sum_{\mathbf{k}} \frac{2k}{m^{3/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]$$
$$+\sum_{\mathbf{k}} \frac{m^{3/2}}{16k^2}[a_R^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_R^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] - \sum_{\mathbf{k}} \frac{k}{m\sqrt{2\omega(k)}}[a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}], \tag{53}$$

and

$$G^c(\mathbf{x}) = \sum_{\mathbf{k}} \frac{8ik^2}{m^{3/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}], \tag{54}$$

where $\omega(k) = \sqrt{m^2+k^2}$; and for the doublet and singlet sectors with combined topological and ''Higgs–Kibble'' mass ($c = 4, \ldots, 8$), the fields are represented by

$$A_l^c(\mathbf{x}) = -\sum_{\mathbf{k}} \sqrt{\frac{\omega_c(k)}{2\mathrm{m}_c(\mathrm{m}_c+\bar{\mathrm{m}}_c)}}\,\frac{k_l}{k}[a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]$$
$$+\sum_{\mathbf{k}} \sqrt{\frac{\mathrm{m}_c}{2\omega_c(k)(\mathrm{m}_c+\bar{\mathrm{m}}_c)}}\,\frac{i\epsilon_{ln}k_n}{k}[a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]$$
$$+\sum_{\mathbf{k}} \sqrt{\frac{\overline{\omega_c}(k)}{2\bar{\mathrm{m}}_c(\mathrm{m}_c+\bar{\mathrm{m}}_c)}}\,\frac{ik_l}{k}[b^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - b^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]$$
$$-\sum_{\mathbf{k}} \sqrt{\frac{\bar{\mathrm{m}}_c}{2\overline{\omega_c}(k)(\mathrm{m}_c+\bar{\mathrm{m}}_c)}}\,\frac{\epsilon_{ln}k_n}{k}[b^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + b^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]$$
$$-\sum_{\mathbf{k}} \frac{4k^3k_l}{\kappa_c(k)\mathrm{m}_c\bar{\mathrm{m}}_c(\mathrm{m}_c-\bar{\mathrm{m}}_c)^{3/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]$$
$$+\sum_{\mathbf{k}} \frac{(\mathrm{m}_c-\bar{\mathrm{m}}_c)^{3/2}k_l}{16k^3}[a_R^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_R^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}], \tag{55}$$

$$\Pi_l^c(\mathbf{x}) = \sum_{\mathbf{k}} \sqrt{\frac{\mathrm{m}_c(\mathrm{m}_c+\bar{\mathrm{m}}_c)}{8\omega_c(k)}}\,\frac{ik_l}{k}[a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]$$

$$+\sum_{\mathbf{k}} \sqrt{\frac{\bar{\mathrm{m}}_c(\mathrm{m}_c+\bar{\mathrm{m}}_c)}{8\overline{\omega_c}(k)}}\,\frac{k_l}{k}[b^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + b^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]$$
$$+\sum_{\mathbf{k}} \sqrt{\frac{\overline{\omega_c}(k)(\mathrm{m}_c+\bar{\mathrm{m}}_c)}{8\bar{\mathrm{m}}_c}}\,\frac{i\epsilon_{ln}k_n}{k}[b^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - b^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]$$
$$-\sum_{\mathbf{k}} \frac{2k^3\epsilon_{ln}k_n}{\kappa_c(k)\mathrm{m}_c\bar{\mathrm{m}}_c\sqrt{\mathrm{m}_c-\bar{\mathrm{m}}_c}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]$$
$$+\sum_{\mathbf{k}} \frac{(\mathrm{m}_c-\bar{\mathrm{m}}_c)^{5/2}\epsilon_{ln}k_n}{32k^3}[a_R^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_R^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}], \tag{56}$$

$$A_0^c(\mathbf{x}) = -\sum_{\mathbf{k}} \frac{k}{\sqrt{2\omega_c(k)\mathsf{m}_c(\mathsf{m}_c+\bar{\mathsf{m}}_c)}}[a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]$$
$$+\sum_{\mathbf{k}} \frac{ik}{\sqrt{2\bar{\omega}_c(k)\bar{\mathsf{m}}_c(\mathsf{m}_c+\bar{\mathsf{m}}_c)}}[b^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - b^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]$$
$$-\sum_{\mathbf{k}} \frac{4k^3}{\mathsf{m}_c\bar{\mathsf{m}}_c(\mathsf{m}_c-\bar{\mathsf{m}}_c)^{3/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]$$
$$+\sum_{\mathbf{k}} \frac{\kappa_c(k)(\mathsf{m}_c-\bar{\mathsf{m}}_c)^{3/2}}{16k^3}[a_R^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_R^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}], \tag{57}$$

and

$$G^c(\mathbf{x}) = \sum_{\mathbf{k}} \frac{8ik^3}{\kappa_c(k)(\mathsf{m}_c-\bar{\mathsf{m}}_c)^{3/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]. \tag{58}$$

The unphysical scalar fields for $c=4,\ldots,8$ are

$$\xi^c(\mathbf{x}) = -\sum_{\mathbf{k}} \frac{4ik^3}{\kappa_c(k)(\mathsf{m}_c\bar{\mathsf{m}}_c)^{1/2}(\mathsf{m}_c-\bar{\mathsf{m}}_c)^{3/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]$$
$$-\sum_{\mathbf{k}} \frac{i(\mathsf{m}_c\bar{\mathsf{m}}_c)^{1/2}(\mathsf{m}_c-\bar{\mathsf{m}}_c)^{3/2}}{16k^3}[a_R^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - a_R^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}] \tag{59}$$

and their canonically conjugate momenta

$$\Pi_\xi^c(\mathbf{x}) = -\sum_{\mathbf{k}} k\sqrt{\frac{\bar{\mathsf{m}}_c}{2\omega_c(k)(\mathsf{m}_c+\bar{\mathsf{m}}_c)}}\,[a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]$$
$$+\sum_{\mathbf{k}} ik\sqrt{\frac{\mathsf{m}_c}{2\bar{\omega}_c(k)(\mathsf{m}_c+\bar{\mathsf{m}}_c)}}[b^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} - b^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]$$
$$-\sum_{\mathbf{k}} \frac{8k^3}{(\mathsf{m}_c\bar{\mathsf{m}}_c)^{1/2}(\mathsf{m}_c-\bar{\mathsf{m}}_c)^{3/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}], \tag{60}$$

where $\omega_c(k)=\sqrt{\mathsf{m}_c^2+k^2}$, $\bar{\omega}_c(k)=\sqrt{\bar{\mathsf{m}}_c^2+k^2}$, and

$$\kappa_c(k)=\sqrt{k^2+(1-\gamma)\mathsf{m}_c\bar{\mathsf{m}}_c}. \tag{61}$$

m_c and $\bar{\mathsf{m}}_c$ are the masses of $a^c(\mathbf{k})$ and $b^c(\mathbf{k})$ modes, respectively. They are combinations of the Chern–Simons topological mass m and of the Higgs–Kibble mass m_c; their values are

$$\mathsf{m}_c = \frac{\sqrt{4M_c^2+m^2}+m}{2} \tag{62}$$

and

$$\bar{m}_c = \frac{\sqrt{4M_c^2 + m^2} - m}{2}. \tag{63}$$

The masses M_c are given by Eq. (18). The Higgs field ψ is treated as a ''standard'' Hermitian scalar field; ψ and its canonical momentum Π_ψ and represented as

$$\psi(\mathbf{x}) = \sum_{\mathbf{k}} \frac{1}{\sqrt{2\Omega(k)}} [\alpha(\mathbf{k}) e^{i\mathbf{k}\cdot\mathbf{x}} + \alpha^\dagger(\mathbf{k}) e^{-i\mathbf{k}\cdot\mathbf{x}}] \tag{64}$$

and

$$\Pi_\psi(\mathbf{x}) = -\sum_{\mathbf{k}} i \sqrt{\frac{\Omega(k)}{2}} [\alpha(\mathbf{k}) e^{i\mathbf{k}\cdot\mathbf{x}} - \alpha^\dagger(\mathbf{k}) e^{-i\mathbf{k}\cdot\mathbf{x}}], \tag{65}$$

where $\Omega(k)$ is given by

$$\Omega(k) = \sqrt{2\mu^2 + k^2}. \tag{66}$$

The Faddeev–Popov ghost fields are represented as[28]

$$\sigma_{\mathrm{f}}^c(\mathbf{x}) = \sum_{\mathbf{k}} \frac{1}{\sqrt{2\kappa_c(k)}} [g_{\mathrm{f}}^c(\mathbf{k}) e^{i\mathbf{k}\cdot\mathbf{x}} + g_{\mathrm{f}}^{c\,\star}(\mathbf{k}) e^{-i\mathbf{k}\cdot\mathbf{x}}], \tag{67}$$

$$\sigma_{\mathrm{p}}^c(\mathbf{x}) = -\sum_{\mathbf{k}} \frac{i}{\sqrt{2\kappa_c(k)}} [g_{\mathrm{p}}^c(\mathbf{k}) e^{i\mathbf{k}\cdot\mathbf{x}} - g_{\mathrm{p}}^{c\,\star}(\mathbf{k}) e^{-i\mathbf{k}\cdot\mathbf{x}}], \tag{68}$$

$$\Pi_{\mathrm{f}}^c(\mathbf{x}) = \sum_{\mathbf{k}} i \sqrt{\frac{\kappa_c(k)}{2}} [g_{\mathrm{p}}^c(\mathbf{k}) e^{i\mathbf{k}\cdot\mathbf{x}} + g_{\mathrm{p}}^{c\,\star}(\mathbf{k}) e^{-i\mathbf{k}\cdot\mathbf{x}}], \tag{69}$$

and

$$\Pi_{\mathrm{p}}^c(\mathbf{x}) = \sum_{\mathbf{k}} \sqrt{\frac{\kappa_c(k)}{2}} [g_{\mathrm{f}}^c(\mathbf{k}) e^{i\mathbf{k}\cdot\mathbf{x}} - g_{\mathrm{f}}^{c\,\star}(\mathbf{k}) e^{-i\mathbf{k}\cdot\mathbf{x}}], \tag{70}$$

where $g_{\mathrm{f}}^c(\mathbf{k})$, $g_{\mathrm{p}}^c(\mathbf{k})$, $g_{\mathrm{f}}^{c\,\star}(\mathbf{k})$, and $g_{\mathrm{p}}^{c\,\star}(\mathbf{k})$ obey the anticommutation rules

$$\{g_{\mathrm{f}}^a(\mathbf{k}), g_{\mathrm{p}}^{b\,\star}(\mathbf{q})\} = \{g_{\mathrm{p}}^a(\mathbf{k}), g_{\mathrm{f}}^{b\,\star}(\mathbf{q})\} = \delta^{ab}\delta_{\mathbf{kq}} \tag{71}$$

and

$$\{g_{\mathrm{f}}^a(\mathbf{k}), g_{\mathrm{f}}^{b\,\star}(\mathbf{q})\} = \{g_{\mathrm{p}}^a(\mathbf{k}), g_{\mathrm{p}}^{b\,\star}(\mathbf{q})\} = 0. \tag{72}$$

When Eqs. (55)–(70) are substituted into the Hamiltonian H_0 given in Eq. (40), we obtain the expression

$$H_0 = \sum_{c=1}^{8} H^c + H_\psi + \sum_{c=1}^{8} H_{\mathrm{fp}}^c, \tag{73}$$

where H^c is given by

$$H^c=\sum_{\mathbf{k}}\ \omega(k)a^{c\dagger}(\mathbf{k})a^c(\mathbf{k})+\sum_{\mathbf{k}}\ k[a_R^{c\star}(\mathbf{k})a_Q^c(\mathbf{k})+a_Q^{c\star}(\mathbf{k})a_R^c(\mathbf{k})]$$

$$-(1-\gamma)\sum_{\mathbf{k}}\ \frac{64k^4}{m^3}a_Q^{c\star}(\mathbf{k})a_Q^c(\mathbf{k}) \tag{74}$$

for the $c=1,2,3$ sector of unbroken SU(2) gluon triplet, and

$$H^c=\sum_{\mathbf{k}}\ [\omega_c(k)a^{c\dagger}(\mathbf{k})a^c(\mathbf{k})+\overline{\omega_c}(k)b^{c\dagger}(\mathbf{k})b^c(\mathbf{k})]$$

$$+\sum_{\mathbf{k}}\ \kappa_c(k)[a_R^{c\star}(\mathbf{k})a_Q^c(\mathbf{k})+a_Q^{c\star}(\mathbf{k})a_R^c(\mathbf{k})], \tag{75}$$

for $c=4,\ldots,8$. For the doublet ($c=4,5,6,7$) and singlet ($c=8$) sectors, m_c and $\bar{\mathsf{m}}_c$ are given by Eqs. (62) and (63), respectively; for $c=1,2,3$ there is only a single gluon mode and the mass m is the topological mass. The Higgs Hamiltonian H_ψ is given by

$$H_\psi=\sum_{\mathbf{k}}\ \Omega(k)\alpha^\dagger(\mathbf{k})\alpha(\mathbf{k}); \tag{76}$$

and the Faddeev–Popov ghost part of the Hamiltonian H_{fp}^c, by

$$H_{\mathrm{fp}}^c=\sum_{\mathbf{k}}\ \kappa_c(k)[g_{\mathrm{f}}^{c\star}(\mathbf{k})g_{\mathrm{p}}^c(\mathbf{k})+g_{\mathrm{p}}^{c\star}(\mathbf{k})g_{\mathrm{f}}^c(\mathbf{k})]. \tag{77}$$

Inspection confirms that H_0 is diagonal in the particle number for the observable, propagating particle modes (the massive gluons and the Higgs excitations) of this model and that to this extent the representations of the gauge fields have turned out to be ''suitable.'' Explicit construction of a Fock space for this model will demonstrate that the ghost components of the Hamiltonian also satisfy the suitability requirement. We can construct a Fock space $\{|h\rangle\}$ for this model, on the foundation of the perturbative vacuum $|0\rangle$ which is annihilated by all the annihilation operators: $a^c(\mathbf{k})$, $b^c(\mathbf{k})$, $a_Q^c(\mathbf{k})$ and $a_R^c(\mathbf{k})$, as well as $\alpha(\mathbf{k})$ and the Faddeev–Popov ghosts, $g_{\mathrm{f}}^c(\mathbf{k})$ and $g_{\mathrm{p}}^c(\mathbf{k})$. In this construction, we make use of techniques developed in earlier work.[19,21,26,29] This perturbative Fock space includes all multiparticle states $|N\rangle$ consisting of observable, propagating particles (Higgs particles and massive gluons) that are created when $\alpha^\dagger(\mathbf{k})$, $a^{c\dagger}(\mathbf{k})$, and $b^{c\dagger}(\mathbf{k})$, respectively, act on $|0\rangle$. All such states $|N\rangle$ are eigenstates of H_0. States, such as $a_Q^{c\star}(\mathbf{k})|N\rangle$ or $a_Q^{c\star}(\mathbf{k})a_Q^{d\star}(\mathbf{q})|N\rangle$, in which a single variety of ghost creation operator acts on one of these multiparticle states $|N\rangle$ have zero norm; they have no probability of being observed, and have vanishing expectation values of energy, momentum, as well as all other observables. We will designate as $\{|n\rangle\}$ that subspace of $\{|h\rangle\}$ which consists of all states $|N\rangle$ and of all states in which a chain of $a_Q^{c\star}(\mathbf{k})$ operators — but *no* $a_R^{c\star}(\mathbf{k})$ operators — act on $|N\rangle$. States in which both varieties of ghosts appear simultaneously, such as $a_Q^{c\star}(\mathbf{k})a_R^{d\star}(\mathbf{q})|N\rangle$, are in the Fock space $\{|h\rangle\}$, but not in $\{|n\rangle\}$; because these states have a nonvanishing norm and contain ghosts, they are not probabilistically interpretable. Their appearance in the course of time evolution signals a defect in the theory. Since the states $|N\rangle$ constitute the set of states in $\{|n\rangle\}$ from which all zero norm states (the ones with ghost constituents) have been excised, we will sometimes speak of the set of $|N\rangle$ as a quotient space of observable propagating states. The time-evolution operator $\exp(-iH_0t)$ has the important property that, if it acts on a state vector $|n_i\rangle$ in $\{|n\rangle\}$, it can only propagate it within $\{|n\rangle\}$. We observe that the only parts of H_0 that could possibly cause a state vector to leave the subspace $\{|n\rangle\}$, are those that contain either $a_R^{c\star}(\mathbf{k})$ or $a_R^c(\mathbf{k})$ operators. The only part of H_0 that has that feature contains the combination of operators

$\Gamma^c = a_R^{c\star}(\mathbf{k})a_Q^c(\mathbf{k}) + a_Q^{c\star}(\mathbf{k})a_R^c(\mathbf{k})$. When $a_R^c(\mathbf{k})$ acts on a state vector $|n_i\rangle$, it either annihilates the vacuum or annihilates one of the $a_Q^{c\star}(\mathbf{k})$ operators in $\{|n\rangle\}$. In the latter case, Γ^c replaces the annihilated $a_Q^{c\star}(\mathbf{k})$ operator with an identical one. When $a_Q^c(\mathbf{k})$ acts on a state vector $|n_i\rangle$, it always annihilates it. It is therefore impossible for Γ^c to transform a state vector in $\{|n\rangle\}$ to one external to $\{|n\rangle\}$ in which an $a_R^{c\star}(\mathbf{k})$ operator acts on $|n_i\rangle$. The only effect of Γ^c is to translate $|n_i\rangle$ states within $\{|n\rangle\}$. These features of the Hamiltonian H_0 confirm that Eqs. (51)–(60) are suitable representations of the gauge fields. H_0 counts the number of massive gluons of momentum $\mathbf{k}$ belonging to the unbroken SU(2) sector of the original SU(3) system, and assigns an energy $\omega(k)$ to each of them. It similarly counts the two varieties of massive gluons in the doublet and singlet sectors, and assigns the energy ω_c and $\overline{\omega_c}(k)$ to the $a^c(\mathbf{k})$ and $b^c(\mathbf{k})$ varieties respectively. And lastly, H_0 counts the number of Higgs particles of mass $\sqrt{2}\mu$ and assigns the energy $\sqrt{2\mu^2+k^2}$ to each. Beyond that, the form of H_0 guarantees that any state vector initially in $\{|n\rangle\}$ is propagated by $\exp(-iH_0t)$ entirely within $\{|n\rangle\}$.

We next turn to the implementation of Gauss's law and the gauge condition. We have previously noted in Eqs. (45)–(46) that Gauss's law, $\mathcal{G}^a(\mathbf{x})=0$, is not a consequence of the Euler–Lagrange equations, and that further analysis is required to demonstrate that it is properly implemented. We further observe that, when Eqs. (51)–(70) are substituted into Eq. (46), $\mathcal{G}^a$ turns out to be a linear combination of only those ghost excitations that can live in the subspace $\{|n\rangle\}$ — $a_Q^a(\mathbf{k})$ and $a_Q^{a\star}(\mathbf{k})$. All other excitation operators — $a_R^a(\mathbf{k})$ and $a_R^{a\star}(\mathbf{k})$, and the annihilation and creation operators for both varieties of propagating particles, $a^c(\mathbf{k})$ and $b^c(\mathbf{k})$ as well as $a^{c\dagger}(\mathbf{k})$ and $b^{c\dagger}(\mathbf{k})$, respectively — cancel in $\mathcal{G}^a$. The explicit expression for $\mathcal{G}^a$ obtained from this substitution is

$$\mathcal{G}^a(\mathbf{x}) = \sum_{\mathbf{k}} \frac{8k^3}{m^{3/2}}[a_Q^a(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}} + a_Q^{a\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}}]. \tag{78}$$

The implementation of Gauss's law is an immediate consequence of this expression for $\mathcal{G}^a$. A state vector that describes an observable state is one of the $|N\rangle$ states in the quotient space discussed earlier. The time evolution generated by $\exp(-iH_0t)$ has previously been shown to keep any state vector that initially was an $|N\rangle$ state contained in the subspace $\{|n\rangle\}$. And the Gauss's law operator $\mathcal{G}^a$, as well as any other operator that is a linear combination of $a_Q^a(\mathbf{k})$ and $a_Q^{a\star}(\mathbf{k})$ operators, must vanish in $\{|n\rangle\}$. These facts provide for the permanent validity of Gauss's law as long as the state vector representing the system is initially one of the $|N\rangle$ states — even a state in $\{|n\rangle\}$ will suffice — and provided that $\exp(-iH_0t)$ is the time-evolution operator for the system. Similarly, G^c is also represented as a superposition of $a_Q^c(\mathbf{k})$ and $a_Q^{c\star}(\mathbf{k})$ ghost excitation operators only, so that $\langle n_b|G^c|n_a\rangle = 0$ for the same reason that $\langle n_b|\mathcal{G}^c|n_a\rangle = 0$. Equation (23) therefore shows that in the subspace $\{|n\rangle\}$, the t'Hooft gauge condition, $\partial_\mu A^{a\mu} - (1-\gamma)\alpha^a = 0$, holds. We thus have shown not only that the time-displacement operator $\exp(-iH_0t)$ keeps state vectors permanently within the subspace $\{|n\rangle\}$, but that it is also precisely in this subspace that Gauss's law and the gauge condition are permanently implemented.

It is apparent that the explicit representations of the fields we have given in Eqs. (55)–(60) are instrumental in obtaining the results we have demonstrated above. But the confirmation of the particle mode content of these fields that the self-consistency of this formulation provides is not weakened by its dependence on an explicit representation of the fields. A representation in terms of creation and annihilation operators, and the choice of a Hilbert space in which to embed the formalism — in this case the Fock spaces $\{|n\rangle\}$ and $\{|h\rangle\}$ — are inevitably important parts of the axiomatic structure of the theory. And it is a significant fact that a representation of the operator-valued fields and a Fock space have been found that permit a consistent interpretation of H_0 as a kinetic energy operator for a system of noninteracting particles in a new vacuum state, even though part of the interaction described by $\mathcal{L}$ is included in H_0. Moreover, a Fock space has been constructed within which H_0 time displaces state vectors so that unitarity, Gauss's law, and the

gauge condition are all permanently guaranteed. It should be noted that when *all* interactions are included in a *complete* Hamiltonian H, these conditions no longer apply. Under the influence of the time-evolution operator $\exp(-iHt)$, state vectors ''leak out'' of $\{|n\rangle\}$, and probabilistically uninterpretable state vectors that contain combination of ghosts, for example $a_Q^{c\star}(\mathbf{k})a_R^{d\star}(\mathbf{q})|N\rangle$, develop. Combinations of Faddeev–Popov ghosts are then necessary to compensate for such combinations of Q and R ghosts,[28] and loops of Faddeev–Popov ghost play an important role in maintaining the unitarity of the theory. One reason for the interpretability of this model is that the ''interaction-free'' limit we have described — the limit as $e\to 0$ and $h\to 0$ while e^2/h remains constant — leads to an essentially Abelian theory. The fact that $[\mathcal{G}^a(\mathbf{x}),\mathcal{G}^b(\mathbf{y})]=0$ confirms that observation. In a non-Abelian theory this commutator would not vanish, but would regenerate the Gauss's law operator $\mathcal{G}^c(\mathbf{x})$ in a pattern determined by the structure constants of the corresponding Lie group. Because of the Abelian nature of this limiting form of the theory, the Faddeev–Popov ghosts are not required in this stage of the work, and have not been included in the Fock space $\{|h\rangle\}$ or $\{|n\rangle\}$.

The more general question that pertains to the containment of the particle modes of the Heisenberg fields — i.e., the fields in the fully interacting theory — in a suitably defined subspace within which unitarity is preserved, is beyond our scope in this paper. In the simpler case of an Abelian gauge theory with a spontaneously broken gauge symmetry, the unitarity of the fully interacting theory has been resolved in earlier work.[22] In the case of non-Abelian gauge theories in axial gauges, in which Faddeev–Popov ghosts are not required, this demonstration has also been given.[30,31] The demonstration of unitarity of the S-matrix for Yang–Mills theory in covariant gauges has also been discussed elsewhere.[28] For non-Abelian theories in covariant gauges the demonstration of unitarity demands extensive algebraic manipulations, and is not pertinent to the main point of this work — the identification of the particle modes generated by the spontaneous breaking of the gauge theory of this model.

IV. THE PERTURBATIVE THEORY

The propagator for the gauge field is given by

$$D_{\mu\nu}(x_1,x_2)=\langle 0|\mathsf{T}[A_\mu(x_1),A_\nu(x_2)]|0\rangle, \tag{79}$$

where T designates time ordering, $A_\mu(x)$ is the interaction-picture field

$$A_\mu(x)=e^{iH_0t}A_\mu(\mathbf{x})e^{-iH_0t}, \tag{80}$$

$A_\mu(\mathbf{x})$ is the Schrödinger picture field, and $|0\rangle$ is the vacuum state of the $\{|n\rangle\}$ space. Similarly, the propagator for an unphysical scalar $\xi(x)$ is

$$\Delta_\xi(x_1,x_2)=\langle 0|\mathsf{T}[\xi(x_1),\xi(x_2)]|0\rangle, \tag{81}$$

and, for the Higgs field,

$$\Delta_\psi(x_1,x_2)=\langle 0|\mathsf{T}[\psi(x_1),\psi(x_2)]|0\rangle. \tag{82}$$

There are other propagators in this theory, but they vanish for $\gamma=1$ (Landau gauge) which we use in our work, and therefore are not of primary interest to us. We find that the relevant interaction-picture fields for $c=1,2,3$ are

$$A_l^c(x)=\sum_{\mathbf{k}}\frac{8ik\epsilon_{ln}k_n}{m^{5/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-ikt}-a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+ikt}]$$
$$+(1-\gamma)\sum_{\mathbf{k}}\frac{2k_l}{m^{3/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-ikt}+a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+ikt}]$$
$$-\sum_{\mathbf{k}}\frac{4k^2k_l}{m^{7/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-ikt}+a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+ikt}]$$
$$+\sum_{\mathbf{k}}\frac{m^{3/2}k_l}{16k^3}[a_R^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-ikt}+a_R^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+ikt}]$$
$$-\sum_{\mathbf{k}}\frac{\sqrt{\omega(k)}k_l}{\sqrt{2}mk}[a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\omega(k)t}+a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\omega(k)t}]$$
$$+\sum_{\mathbf{k}}\frac{i\epsilon_{ln}k_n}{k\sqrt{2\omega(k)}}[a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\omega(k)t}-a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\omega(k)t}] \tag{83}$$

and

$$A_0^c(\mathbf{x})=-\sum_{\mathbf{k}}\frac{4k^3}{m^{7/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-ikt}+a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+ikt}]$$
$$-(1-\gamma)\sum_{\mathbf{k}}\frac{2k}{m^{3/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-ikt}+a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+ikt}]$$
$$+\sum_{\mathbf{k}}\frac{m^{3/2}}{16k^2}[a_R^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-ikt}+a_R^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+ikt}]$$
$$-\sum_{\mathbf{k}}\frac{k}{m\sqrt{2\omega(k)}}[a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\omega(k)t}+a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\omega(k)t}]; \tag{84}$$

for $c=4,\ldots,8$, they are

$$A_l^c(x)=-\sum_{\mathbf{k}}\sqrt{\frac{\omega_c(k)}{2\mathrm{m}_c(\mathrm{m}_c+\bar{\mathrm{m}}_c)}}\frac{k_l}{k}[a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\omega_c(k)t}+a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\omega_c(k)t}]$$
$$+\sum_{\mathbf{k}}\sqrt{\frac{\mathrm{m}_c}{2\omega_c(k)(\mathrm{m}_c+\bar{\mathrm{m}}_c)}}\frac{i\epsilon_{ln}k_n}{k}[a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\omega_c(k)t}-a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\omega_c(k)t}]$$
$$+\sum_{\mathbf{k}}\sqrt{\frac{\overline{\omega_c}(k)}{2\bar{\mathrm{m}}_c(\mathrm{m}_c+\bar{\mathrm{m}}_c)}}\frac{ik_l}{k}[b^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\overline{\omega_c}(k)t}-b^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\overline{\omega_c}(k)t}]$$
$$-\sum_{\mathbf{k}}\sqrt{\frac{\bar{\mathrm{m}}_c}{2\overline{\omega_c}(k)(\mathrm{m}_c+\bar{\mathrm{m}}_c)}}\frac{\epsilon_{ln}k_n}{k}[b^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\overline{\omega_c}(k)t}+b^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\overline{\omega_c}(k)t}]$$
$$-\sum_{\mathbf{k}}\frac{4k^3k_l}{\kappa_c(k)\mathrm{m}_c\bar{\mathrm{m}}_c(\mathrm{m}_c-\bar{\mathrm{m}}_c)^{3/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\kappa_c(k)t}+a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\kappa_c(k)t}]$$
$$+\sum_{\mathbf{k}}\frac{(\mathrm{m}_c-\bar{\mathrm{m}}_c)^{3/2}k_l}{16k^3}[a_R^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\kappa_c(k)t}+a_R^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\kappa_c(k)t}], \tag{85}$$

$$A_0^c(x) = -\sum_{\mathbf{k}} \frac{k}{\sqrt{2\omega_c(k)\mathrm{m}_c(\mathrm{m}_c+\bar{\mathrm{m}}_c)}}[a^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\omega_c(k)t} + a^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\omega_c(k)t}]$$
$$+\sum_{\mathbf{k}} \frac{ik}{\sqrt{2\bar{\omega}_c(k)\bar{\mathrm{m}}_c(\mathrm{m}_c+\bar{\mathrm{m}}_c)}}[b^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\bar{\omega}_c(k)t} - b^{c\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\bar{\omega}_c(k)t}]$$
$$-\sum_{\mathbf{k}} \frac{4k^3}{\mathrm{m}_c\bar{\mathrm{m}}_c(\mathrm{m}_c-\bar{\mathrm{m}}_c)^{3/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\kappa_c(k)t} + a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\kappa_c(k)t}]$$
$$+\sum_{\mathbf{k}} \frac{\kappa_c(k)(\mathrm{m}_c-\bar{\mathrm{m}}_c)^{3/2}}{16k^3}[a_R^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\kappa_c(k)t} + a_R^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}-i\kappa_c(k)t}], \tag{86}$$

$$\xi^c(x) = -\sum_{\mathbf{k}} \frac{4ik^3}{\kappa_c(k)(\mathrm{m}_c\bar{\mathrm{m}}_c)^{1/2}(\mathrm{m}_c-\bar{\mathrm{m}}_c)^{3/2}}[a_Q^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\kappa_c(k)t} - a_Q^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\kappa_c(k)t}]$$
$$-\sum_{\mathbf{k}} \frac{i(\mathrm{m}_c\bar{\mathrm{m}}_c)^{1/2}(\mathrm{m}_c-\bar{\mathrm{m}}_c)^{3/2}}{16k^3}[a_R^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\kappa_c(k)t} - a_R^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\kappa_c(k)t}], \tag{87}$$

and

$$\psi(x) = \sum_{\mathbf{k}} \frac{1}{\sqrt{2\Omega(k)}}[\alpha(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\Omega(k)t} + \alpha^{\dagger}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\Omega(k)t}]. \tag{88}$$

The Faddeev–Popov ghost fields are

$$\sigma_{\mathrm{f}}^c(x) = \sum_{\mathbf{k}} \frac{1}{\sqrt{2\kappa_c(k)}}[g_{\mathrm{f}}^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\kappa_c(k)t} - g_{\mathrm{f}}^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\kappa_c(k)t}] \tag{89}$$

and

$$\sigma_{\mathrm{p}}^c(x) = \sum_{\mathbf{k}} \frac{i}{\sqrt{2\kappa_c(k)}}[g_{\mathrm{p}}^c(\mathbf{k})e^{i\mathbf{k}\cdot\mathbf{x}-i\kappa_c(k)t} - g_{\mathrm{p}}^{c\star}(\mathbf{k})e^{-i\mathbf{k}\cdot\mathbf{x}+i\kappa_c(k)t}]. \tag{90}$$

The propagators for the gauge fields can be expressed as

$$D_{\mu\nu}^{ab}(x_1,x_2) = -i\delta^{ab}\int \frac{d^3k}{(2\pi)^3} D_{\mu\nu}^{(a)}(k)e^{-ik^{\alpha}(x_1-x_2)_{\alpha}}; \tag{91}$$

for $a=1,2,3$:

$$D_{\mu\nu}^{(a)}(k) = (1-\gamma)\frac{k_\mu k_\nu}{(k^\alpha k_\alpha + i\epsilon)^2} - \frac{k_\mu k_\nu}{(k^\alpha k_\alpha + i\epsilon)(k^\alpha k_\alpha - m^2 + i\epsilon)}$$
$$+\frac{g_{\mu\nu}}{k^\alpha k_\alpha - m^2 + i\epsilon} + \frac{im\epsilon_{\mu\nu\lambda}k^\lambda}{(k^\alpha k_\alpha + i\epsilon)(k^\alpha k_\alpha - m^2 + i\epsilon)}; \tag{92}$$

and for $a=4,\ldots,8$:

$$D^{(a)}_{\mu\nu}(k)=\frac{(k^\alpha k_\alpha-\mathsf{m}_a\bar{\mathsf{m}}_a)g_{\mu\nu}}{(k^\alpha k_\alpha-\mathsf{m}_a^2+i\epsilon)(k^\alpha k_\alpha-\bar{\mathsf{m}}_a^2+i\epsilon)}+\frac{i(\mathsf{m}_a-\bar{\mathsf{m}}_a)\epsilon_{\mu\nu\rho}k^\rho}{(k^\alpha k_\alpha-\mathsf{m}_a^2+i\epsilon)(k^\alpha k_\alpha-\bar{\mathsf{m}}_a^2+i\epsilon)}$$
$$-\frac{\gamma(k^\alpha k_\alpha-\mathsf{m}_a\bar{\mathsf{m}}_a k_\mu k_\nu}{[k^\alpha k_\alpha-(1-\gamma)\mathsf{m}_a\bar{\mathsf{m}}_a+i\epsilon](k^\alpha k_\alpha-\mathsf{m}_a^2+i\epsilon)(k^\alpha k_\alpha-\bar{\mathsf{m}}_a^2+i\epsilon)}$$
$$-\frac{(1-\gamma)(\mathsf{m}_a-\bar{\mathsf{m}}_a{}^2k_\mu k_\nu}{[k^\alpha k_\alpha-(1-\gamma)\mathsf{m}_a\bar{\mathsf{m}}_a+i\epsilon](k^\alpha k_\alpha-\mathsf{m}_a^2+i\epsilon)(k^\alpha k_\alpha-\bar{\mathsf{m}}_a^2+i\epsilon)}. \tag{93}$$

These expressions agree with the gauge field propagators reported in Ref. 9 for $a=1,2,3$ and with Refs. 4, 5, and 18 for $a=4,\ldots,8$. These propagators were obtained by inverting the quadratic part of the gauge-fixed Lagrangian. The other propagators are given in terms of the Fourier integral

$$\Delta(x_1,x_2)=-i\int\frac{d^3k}{(2\pi)^3}\Delta(k^2)e^{-ik^\alpha(x_1-x_2)_\alpha}, \tag{94}$$

where

$$\Delta_\psi(k^2)=\frac{-1}{k^\alpha k_\alpha-2\mu^2+i\epsilon}, \tag{95}$$

$$\Delta^{(a)}_\xi(k^2)=\frac{-\delta^{ab}}{k^\alpha k_\alpha-(1-\gamma)\mathsf{m}_a\bar{\mathsf{m}}_a+i\epsilon}, \tag{96}$$

and

$$\Delta^{(a)}_{\rm fp}(k^2)=\frac{-\delta^{ab}}{k^\alpha k_\alpha-(1-\gamma)\mathsf{m}_a\bar{\mathsf{m}}_a+i\epsilon}. \tag{97}$$

In a canonical theory, the vertices are dictated by the interaction Hamiltonian $H_{\rm int}$. Since, in this model, time derivatives of operator-valued fields appear in the interaction Lagrangian as well as in $\mathcal{L}_0$, $H_{\rm int}$ will differ from $-\int d\mathbf{x}(\mathcal{L}_1+\mathcal{L}_2)$. The resulting vertices will be determined by $H_{\rm int}$, and the propagators will consist of vacuum expectation values of the time-ordered fields that appear in $H_{\rm int}$. In expanding the S-matrix for scattering from an initial state $|i\rangle$ to a final state $|f\rangle$,

$$S_{fi}=\langle f|\mathsf{T}\exp\left(-i\int dt\ e^{iH_0t}H_{\rm int}e^{-iH_0t}\right)|i\rangle, \tag{98}$$

by using the Wick theorem,[32] we will sometimes encounter time-ordered products of fields and, at other times, time-ordered products of space–time derivatives of fields. When time derivatives of fields appear as arguments of a time-ordering operation, we will replace the time-ordering operator T with the ''T-star ordering'' operator T^* which is defined so that any derivatives acting on time-ordered fields are to be taken only *after* time ordering has been carried out. In transforming T-ordered to T^*-ordered fields, additional terms are generated, which contain the $\delta(x_0-y_0)$ that is produced when time derivatives are extracted from T-ordered products of time-differentiated fields. As was pointed out by Matthews, these extra terms in which $\delta(x_0-y_0)$-functions appear just cancel the difference between $H_{\rm int}$ and $-\int d\mathbf{x}(\mathcal{L}_1+\mathcal{L}_2)$, so that the perturbative theory requires only the propagators given in Eqs. (91)–(96) and the vertices dictated by the interaction

Lagrangian.[33] Application of the Matthews rule to a model with a spontaneously broken gauge symmetry that produces massive gauge excitations also applies to this case.[22]

V. POINCARÉ STRUCTURE AND LORENTZ TRANSFORMATIONS OF MASSIVE GAUGE BOSONS

In this section we will construct the six canonical Poincaré generators in $2+1$ dimensions: the time-evolution operator, $P_0=H_0$; the two-component space-displacement operator P_l; the (scalar) rotation operator J; and the two-component Lorentz boost K_l. We will also use the Lorentz boost generators to transform the single-particle massive gauge boson states, to display their properties under Lorentz transformations as well as to obtain further confirmation of the consistency of our canonical formulation of this model.

The canonical Poincaré generators for this model are: $P_0=\int d\mathbf{x}\mathcal{P}_0(\mathbf{x})$, where $\mathcal{P}_0=\mathcal{H}_0$ with $\mathcal{H}_0$ given by Eq. (40);

$$P_l=\int d\mathbf{x}\mathcal{P}_l(\mathbf{x}), \tag{99}$$

where

$$\mathcal{P}_l=-\Pi_\xi\partial_l\xi-\Pi_n\partial_lA_n+G\partial_lA_0-\Pi_\psi\partial_l\psi-\Pi_{\mathrm{f}}\partial_l\sigma_{\mathrm{f}}-\Pi_{\mathrm{p}}\partial_l\sigma_{\mathrm{p}}; \tag{100}$$

$$J=\int d\mathbf{x}\epsilon_{ln}x_l\mathcal{P}_n(\mathbf{x})+\int d\mathbf{x}\kappa_{\mathrm{rotation}}(\mathbf{x}) \tag{101}$$

and

$$K_l=x_0P_l-\int d\mathbf{x}\; x_l\mathcal{P}_0(\mathbf{x})+\int d\mathbf{x}\;\kappa_l^{\mathrm{boost}}(\mathbf{x}) \tag{102}$$

where

$$\kappa_{\mathrm{rotation}}=\epsilon_{ln}A_l\Pi_n \tag{103}$$

and

$$\kappa_l^{\mathrm{boost}}=-A_lG+A_0\Pi_l. \tag{104}$$

The term $\kappa_{\mathrm{rotation}}$ implements the mixing of the space components of the fields during a rotation. It arises from the fact that, under an infinitesimal rotation $\delta\theta$ about an axis perpendicular to the 2-D plane, the components of A^μ transform as follows:

$$\delta A_l(\mathbf{x})=-[\epsilon_{ij}x_i\partial_jA_l(\mathbf{x})+\epsilon_{ln}A_n(\mathbf{x})]\delta\theta \tag{105}$$

and

$$\delta A_0(\mathbf{x})=-\epsilon_{ij}x_i\partial_jA_0(\mathbf{x})\,\delta\theta. \tag{106}$$

Under an infinitesimal boost $\delta\beta_l$ along the l-direction, the components of A^μ transform as follows

$$\delta A_0(\mathbf{x})=-[x_0\partial_lA_0(\mathbf{x})+x_l\partial_0A_0(\mathbf{x})-A_l(\mathbf{x})]\delta\beta_l \tag{107}$$

and

$$\delta A_i(\mathbf{x})=-[x_0\partial_lA_i(\mathbf{x})+x_l\partial_0A_i(\mathbf{x})-\delta_{il}A_0(\mathbf{x})]\delta\beta_l. \tag{108}$$

Use of the canonical commutation rules leads to the following commutation rules for the Poincaré generators:

$$[P_l,P_n]=0, \tag{109}$$

$$[H,P_l]=[H,J]=0, \tag{110}$$

$$[H,K_l]=iP_l, \tag{111}$$

$$[P_l,K_n]=i\delta_{ln}H, \tag{112}$$

$$[P_l,J]=-i\epsilon_{ln}P_n, \tag{113}$$

$$[J,K_l]=i\epsilon_{ln}K_n, \tag{114}$$

and

$$[K_l,K_n]=-i\epsilon_{ln}J. \tag{115}$$

We observe that these commutation rules form a closed Lie algebra, and that they are consistent with the transformations given in Eqs. (105)–(108).

To facilitate this investigation of the Lorentz transformation of states that are eigenstates to H_0, we shift to a description of excitation operators that have an invariant norm under Lorentz transformations. We observe, for example, that the norm of the one-particle state $a^{c\dagger}(\mathbf{k})|0\rangle$,

$$|a^{c\dagger}(\mathbf{k})|0\rangle^2=\sum_{\mathbf{q}}\langle 0|[a^c(\mathbf{q}),a^{c\dagger}(\mathbf{k})]|0\rangle=\int d\mathbf{q}\ \delta(\mathbf{k}-\mathbf{q}), \tag{116}$$

is not a Lorentz scalar because $d\mathbf{k}$ is not the Lorentz invariant measure for the phase space. The invariant measure can be established by noting that the invariant delta function

$$\delta(\mathbf{k}-\mathbf{q})\,\delta(k_0-q_0)\,\delta(q_\mu q^\mu-\mathsf{m}_c^2)\Theta(q_0)=\frac{\delta(\mathbf{k}-\mathbf{q})\,\delta[k_0-\omega_c(k)]}{2\omega_c(k)}, \tag{117}$$

so that the states $A^{c\dagger}(\mathbf{k})|0\rangle$, created by operators that obey

$$[A^c(\mathbf{k}),A^{d\dagger}(\mathbf{q})]=2\omega_c(k)(2\pi)^2\delta^{cd}\delta(\mathbf{k}-\mathbf{q}), \tag{118}$$

have unit norms in every Lorentz frame. Similarly, the normalized operators for the other modes of the gauge field obey

$$[B^c(\mathbf{k}),B^{d\dagger}(\mathbf{q})]=2\overline{\omega_c}(k)(2\pi)^2\delta^{cd}\delta(\mathbf{k}-\mathbf{q}); \tag{119}$$

and the equivalently normalized ghost operators satisfy

$$[A_Q^c(\mathbf{k}),A_R^{d\star}(\mathbf{q})]=[A_R^c(\mathbf{k}),A_Q^{d\star}(\mathbf{q})]=2\kappa_c(k)(2\pi)^2\delta^{cd}\delta(\mathbf{k}-\mathbf{q}). \tag{120}$$

The normalized operators corresponding to the mode $\alpha(\mathbf{k})$ of the Higgs field and the two Faddeev–Papov ghosts $g_{\mathrm{f}}^a(\mathbf{k})$ and $g_{\mathrm{p}}^a(\mathbf{k})$ are given by $\hat{\alpha}(\mathbf{k})$, $\hat{g}_{\mathrm{f}}^a(\mathbf{k})$, and $\hat{g}_{\mathrm{p}}^a(\mathbf{k})$, respectively. These normalized operators satisfy the following commutation and anticommutation relations:

$$[\hat{\alpha}(\mathbf{k}),\hat{\alpha}^\dagger(\mathbf{q})]=2\Omega(k)(2\pi)^2\delta(\mathbf{k}-\mathbf{q}) \tag{121}$$

and

$$\{\hat{g}^a_{\rm f}(\mathbf{k}),\hat{g}^{b\,\star}_{\rm p}(\mathbf{q})\}=\{\hat{g}^a_{\rm p}(\mathbf{k}),\hat{g}^{b\,\star}_{\rm f}(\mathbf{q})\}=2\kappa_a(k)(2\pi)^2\delta^{ab}\delta(\mathbf{k}-\mathbf{q}). \tag{122}$$

Hence, the boost operator K_l is written as

$$\begin{aligned}
K_l=&\sum_{c=1}^{8}\sum_{\mathbf{k}}\frac{\mathsf{m}_c\epsilon_{ln}k_n}{2k^2\omega_c(k)}A^{c\dagger}(\mathbf{k})A^c(\mathbf{k})-\sum_{c=4}^{8}\sum_{\mathbf{k}}\frac{\bar{\mathsf{m}}_c\epsilon_{ln}k_n}{2k^2\overline{\omega_c}(k)}B^{c\dagger}(\mathbf{k})B^c(\mathbf{k})\\
&+\sum_{c=1}^{8}\sum_{\mathbf{k}}\frac{i}{4}\left[\frac{\partial}{\partial k_l}A^{c\dagger}(\mathbf{k})A^c(\mathbf{k})-A^{c\dagger}(\mathbf{k})\frac{\partial}{\partial k_l}A^c(\mathbf{k})\right]\\
&+\sum_{c=4}^{8}\sum_{\mathbf{k}}\frac{i}{4}\left[\frac{\partial}{\partial k_l}B^{c\dagger}(\mathbf{k})B^c(\mathbf{k})-B^{c\dagger}(\mathbf{k})\frac{\partial}{\partial k_l}B^c(\mathbf{k})\right]\\
&+\sum_{c=4}^{8}\sum_{\mathbf{k}}\frac{i}{4}\left[\frac{\partial}{\partial k_l}\hat{\alpha}^{c\dagger}(\mathbf{k})\hat{\alpha}^c(\mathbf{k})-\hat{\alpha}^{c\dagger}(\mathbf{k})\frac{\partial}{\partial k_l}\hat{\alpha}^c(\mathbf{k})\right]\\
&+\sum_{c=1}^{8}\sum_{\mathbf{k}}\frac{i}{2}\left[\frac{\partial}{\partial k_l}A^{c\,\star}_Q(\mathbf{k})A^c_R(\mathbf{k})-A^{c\,\star}_R(\mathbf{k})\frac{\partial}{\partial k_l}A^c_Q(\mathbf{k})\right]\\
&+\sum_{c=1}^{8}\sum_{\mathbf{k}}\frac{i}{2}\left[\frac{\partial}{\partial k_l}\hat{g}^{c\,\star}_{\rm f}(\mathbf{k})\hat{g}^c_{\rm p}(\mathbf{k})-\hat{g}^{c\,\star}_{\rm p}(\mathbf{k})\frac{\partial}{\partial k_l}\hat{g}^c_{\rm f}(\mathbf{k})\right]\\
&+\sum_{c=1}^{8}\sum_{\mathbf{k}}\frac{5ik_l}{4k^2}[A^{c\,\star}_Q(\mathbf{k})A^c_R(\mathbf{k})-A^{c\,\star}_R(\mathbf{k})A^c_Q(\mathbf{k})]\\
&-(1-\gamma)\sum_{c=1}^{3}\sum_{\mathbf{k}}\frac{16ik^3}{m^3}\left[\frac{\partial}{\partial k_l}A^{c\,\star}_Q(\mathbf{k})A^c_Q(\mathbf{k})-A^{c\,\star}_Q(\mathbf{k})\frac{\partial}{\partial k_l}A^c_Q(\mathbf{k})\right].
\end{aligned} \tag{123}$$

Using the commutations rules given by Eqs. (118) and (119), we find that

$$\delta A^{c\dagger}(\mathbf{k})=\left[\frac{i\mathsf{m}_c\epsilon_{ln}k_n}{k^2}A^{c\dagger}(\mathbf{k})-\omega_c(k)\frac{\partial}{\partial k_l}A^{c\dagger}(\mathbf{k})\right]\delta\beta_l \tag{124}$$

and

$$\delta B^{c\dagger}(\mathbf{k})=\left[-\frac{i\bar{\mathsf{m}}_c\epsilon_{ln}k_n}{k^2}B^{c\dagger}(\mathbf{k})-\overline{\omega_c}(k)\frac{\partial}{\partial k_l}B^{c\dagger}(\mathbf{k})\right]\delta\beta_l. \tag{125}$$

Equations (124) and (125) show that all the massive gauge boson states — the single excitation mode $A^{c\dagger}(\mathbf{k})|0\rangle$ in the $(c=1,2,3)$ sectors with the residual SU(2) invariance, and the two excitation modes $A^{c\dagger}(\mathbf{k})|0\rangle$ and $B^{c\dagger}(\mathbf{k})|0\rangle$ in the $(c=4,\ldots,8)$ 'broken' doublet and singlet sectors — transform *without any mixing* with other modes. The phase factors $(\mathsf{m}_c\epsilon_{ln}k_n/k^2)\delta\beta_l$ and $-(\bar{\mathsf{m}}_c\epsilon_{ln}k_n/k^2)\delta\beta_l$ generated by the boost operator K_l, which appear in Eqs. (124) and (125), are the cocycles mentioned in Ref. 21. These phase factors have no physical implications. The physically observable consequence of Eqs. (124) and (125) is that, under a Lorentz transformation, the topologically massive gauge excitations behave like the massive excitations of a scalar field — each topologically massive gauge excitation transforms only into itself at a new space–time point.

VI. CONCLUSION

In this paper we have presented a detailed analysis of the canonical quantization of spontaneously broken topologically massive gauge theory. In $2+1$ dimensions the possibility of including a CS term in the gauge field Lagrangian leads to new forms of mass-generating effects for gauge fields. The resulting CSH mechanism differs in interesting ways from the conventional Higgs–Kibble mechanism, and in this paper we have explored the CSH mechanism by concentrating on the relation between the quantized fields and their particle excitation modes. We have found, by a series of unitary transformations, a consistent particle-mode representation of the operator-valued fields and we have constructed the corresponding Fock space which permits a consistent interpretation of the diagonalized noninteracting Hamiltonian H_0 as an energy operator for a system of noninteracting particles in a new vacuum state. Within this Fock space, H_0 acts unitarily as a time-translation generator, in such a way that Gauss's law and the gauge condition are manifestly preserved. We have computed the gauge field propagators as vacuum expectation values of time-ordered products of the gauge field operators, and formulated the corresponding perturbative expansion of the interacting theory. We have chosen to present our analysis for a non-Abelian Chern–Simons theory in which the original non-Abelian symmetry is spontaneously broken, but with a residual non-Abelian symmetry in the broken vacuum. Such a non-Abelian model clearly illustrates the interplay of the space–time and algebraic features of the CSH mechanism. This particular model is also motivated by the question of its quantum consistency. Indeed, the result reported in Ref. 17, that the bare quantum consistency condition of Deser–Jackiw–Templeton[2] is maintained at one-loop in such a broken vacuum, was in fact first obtained by us using the techniques and formalism described in this paper. An interesting further application would be to the analysis of the non-Abelian versions of the self-dual CSH systems considered in Ref. 34.

APPENDIX: INTERACTION LAGRANGIAN

In this Appendix, we record the explicit expansions of the interaction Lagrangians $\mathcal{L}_1$ and $\mathcal{L}_2$ in terms of real fields. These interaction Lagrangians define the vertices required for perturbative computations. When the Lagrangians given in Eqs. (13) and (14) are expanded in terms of the real fields in Eq. (15) and the symmetry breaking mass scales in Eq. (18), we obtain the following: the $\mathcal{O}(e)$ interaction Lagrangian becomes

$$
\begin{aligned}
\mathcal{L}_1 = {} & e f^{abc} F^a_{\mu\nu} A^{b\mu} A^{c\nu} - \frac{1}{3} e m \epsilon^{\mu\nu\rho} f^{abc} A^a_\mu A^b_\nu A^c_\rho + \sum_{a=4}^{7} e M_{\mathrm{D}} A^{a\mu} A^a_\mu \psi + \frac{2e}{\sqrt{3}} M_{\mathrm{S}} A^{8\mu} A^8_\mu \psi \\
& + e M_{\mathrm{D}} d^{ab4} A^{a\mu} A^b_\mu \xi^5 - e M_{\mathrm{D}} d^{ab5} A^{a\mu} A^b_\mu \xi^4 + e M_{\mathrm{D}} d^{ab6} A^{a\mu} A^b_\mu \xi^7 - e M_{\mathrm{D}} d^{ab7} A^{a\mu} A^b_\mu \xi^6 \\
& - ie[\Psi_1^\dagger \mathbf{A}^\mu \cdot \boldsymbol{\tau} \partial_\mu \Psi_1 - (\partial_\mu \Psi_1)^\dagger \mathbf{A}^\mu \cdot \boldsymbol{\tau} \Psi_1] \\
& - ie[\Psi_2^\dagger (A^{4\mu}\tau^1 + A^{5\mu}\tau^2) \partial_\mu \Psi_2 - (\partial_\mu \Psi_2)^\dagger (A^{4\mu}\tau^1 + A^{5\mu}\tau^2) \Psi_2] \\
& - ie[\Psi_3^\dagger (A^{6\mu}\tau^1 + A^{7\mu}\tau^2) \partial_\mu \Psi_3 - (\partial_\mu \Psi_3)^\dagger (A^{6\mu}\tau^1 + A^{7\mu}\tau^2) \Psi_3] \\
& - ie(\Phi'^\dagger A^{8\mu} \lambda^8 \partial_\mu \Phi' - \partial_\mu \Phi'^\dagger A^{8\mu} \lambda^8 \Phi') \\
& - \frac{e\mu^2}{M_{\mathrm{D}}} \psi[(\xi^4)^2 + (\xi^5)^2 + (\xi^6)^2 + (\xi^7)^2 + (\xi^8)^2 + \psi^2]
\end{aligned}
$$

$$
\begin{aligned}
&-2ief^{abc}A^a_\mu\sigma^b_{\rm f}\partial^\mu\sigma^c_{\rm p}-ie(1-\gamma)\\
&\times M_{\rm D}\sum_{a=4}^{7}\psi\sigma^a_{\rm f}\sigma^a_{\rm p}-ie(1-\gamma)\frac{2}{\sqrt{3}}M_{\rm S}\psi\sigma^8_{\rm f}\sigma^8_{\rm p}\\
&-ie(1-\gamma)\sum_{a,b,c=4}^{8}M_{(a)}f^{abc}\xi^a\sigma^b_{\rm f}\sigma^c_{\rm p}-ie(1-\gamma)\\
&\times M_{\rm D}\sum_{a,c=4}^{7}(d^{ac5}\xi^4-d^{ac4}\xi^5+d^{ac7}\xi^6-d^{ac6}\xi^7)\sigma^a_{\rm f}\sigma^c_{\rm p} \qquad \text{(A1)}
\end{aligned}
$$

and the $\mathcal{O}(e^2)$ interaction Lagrangian becomes

$$
\begin{aligned}
\mathcal{L}_2=&-e^2f^{abc}f^{ade}A^b_\mu A^{d\mu}A^c_\nu A^{e\nu}+\frac{1}{3}e^2A^a_\mu A^{a\mu}[(\xi^4)^2+(\xi^5)^2+(\xi^6)^2+(\xi^7)^2+(\xi^8)^2+\psi^2]\\
&+e^2d^{ab1}A^{a\mu}A^b_\mu(\xi^5\xi^7+\xi^4\xi^6)+e^2d^{ab2}A^{a\mu}A^b_\mu(\xi^5\xi^6-\xi^4\xi^7)+\frac{1}{2}e^2d^{ab3}A^{a\mu}A^b_\mu[(\xi^4)^2+(\xi^5)^2\\
&-(\xi^6)^2-(\xi^7)^2]+e^2d^{ab4}A^{a\mu}A^b_\mu(\xi^5\psi-\xi^4\xi^8)-e^2d^{ab5}A^{a\mu}A^b_\mu(\xi^5\xi^8+\xi^4\psi)\\
&+e^2d^{ab6}A^{a\mu}A^b_\mu(\xi^7\psi-\xi^6\xi^8)-e^2d^{ab7}A^{a\mu}A^b_\mu(\xi^7\xi^8+\xi^6\psi)+\frac{1}{2\sqrt{3}}e^2d^{ab8}A^{a\mu}A^b_\mu[(\xi^4)^2\\
&+(\xi^5)^2+(\xi^6)^2+(\xi^7)^2-2(\xi^8)^2-2\psi^2]-\frac{e^2\mu^2}{4M_{\rm D}^2}[(\xi^4)^2+(\xi^5)^2+(\xi^6)^2+(\xi^7)^2+(\xi^8)^2+\psi^2]^2. \qquad \text{(A2)}
\end{aligned}
$$

In these expressions, $\boldsymbol{\tau}$ designates the Pauli spin matrices, and $\mathbf{A}^\mu$ denotes the gauge field triplet $A^{a\mu}$ $(a=1,2,3)$ in the unbroken SU(2) ''isospin'' subgroup. The isospinors Ψ_a $(a=1,2,3)$ are the combinations of the Higgs field ψ and the ξ^a fields given by Eqs. (19)–(21).

The *q*-Coulomb problem

Robert J. Finkelstein
Department of Physics and Astronomy, University of California, Los Angeles, California 90095-1547

(Received 3 January 1996; accepted for publication 23 February 1996)

There exist operator solutions of the *q*-Coulomb problem in both configuration and momentum space. Since the arguments of the corresponding amplitudes are noncommuting, however, there are problems of physical interpretation. Here we answer the question of physical interpretation by associating with the operator amplitude in momentum space a numerically valued amplitude lying in a Hilbert space defined by the $SU_q(2)$ algebra. This new amplitude, now depending on commuting arguments, may be interpreted by the usual rules of quantum mechanics and may also be Fourier transformed to yield the amplitude in configuration space. © *1996 American Institute of Physics.* [S0022-2488(96)01706-9]

I. INTRODUCTION

Solutions of the *q*-deformed Coulomb problem have been found in both momentum[1] and configuration[2] space. In both cases the solution amplitudes are operator wave functions lying in either the $SU_q(2)$ or $SO_q(3)$ algebra. If a direct physical interpretation of these amplitudes is attempted, it is necessary to assume that the coordinates are noncommuting in both configuration and momentum space.

One makes a less radical departure from quantum mechanics by associating numerical wave functions with the operator wave functions and basing the physical interpretation on these associated numerical amplitudes. If one follows the latter path, one is deforming not the underlying space but the wave functions lying in the usual space. In order to do this, it is necessary to introduce a Hilbert space on which the operator wave functions can operate. In the following we shall carry out this procedure for the known operator solutions in momentum space.

II. THE *q*-DEFORMED MOMENTUM STATES

Let us recall the procedure for obtaining the undeformed states of momentum in a form which makes explicit the underlying symmetry of the Coulomb problem.[3] First one transforms the Schrödinger differential equation to an integral equation on momentum space. Next momentum space is mapped onto the group space of SU(2) or SO(3) according to

$$e^{(i/2\boldsymbol{\sigma}\mathbf{w})}=\frac{p_0-i\mathbf{p}\boldsymbol{\sigma}}{p_0+i\mathbf{p}\boldsymbol{\sigma}}, \tag{2.1}$$

where $\mathbf{w}$ fixes the magnitude and axis of rotation while p_0 and $\mathbf{p}$ refer to the corresponding energy and momentum. The integral equation on momentum space then becomes an integral equation on group space,

$$\int \widetilde{K}(\mathbf{p},\mathbf{p}')\Phi(\mathbf{p}')d\tau(\mathbf{p}')=\lambda\Phi(\mathbf{p}), \tag{2.2}$$

where the momentum $\mathbf{p}$ parametrizes the group element and $d\tau(\mathbf{p})$ is the invariant volume element on group space:

$$d\tau=\sqrt{g}d\mathbf{p}, \tag{2.3}$$

0022-2488/96/37(6)/2628/9/$10.00

where g is the determinant of the group metric.

Here $\Phi(\mathbf{p})$ and $\widetilde{K}(\mathbf{p},\mathbf{p})$ are rescaled Fourier transforms of the wave function and the potential, respectively.

In the Coulomb case (2.2) becomes

$$\int K(\mathbf{p},\mathbf{p}')D^{j}_{mm'}(\mathbf{p}')d\tau(\mathbf{p}')=(2j+1)D^{j}_{mm'}(\mathbf{p}), \tag{2.4}$$

where the $D^{j}_{mm'}(p)$ are Wigner functions (matrix elements of irreducible representations of the rotation group). The actual wave function in momentum space is connected to $D^{j}_{mm'}(\mathbf{p})$ by a scaling function,

$$\Phi^{j}_{mm'}(\mathbf{p})=G^{2}(p)D^{j}_{mm'}(\mathbf{p}), \tag{2.5}$$

$$G=\frac{p_0^2}{p_0^2+p^2}, \tag{2.6}$$

and the energy levels are determined in terms of the eigenvalue $(2j+1)$ of the integral equation by

$$E=-\frac{m}{2}\frac{e^4}{\hbar^2}\frac{1}{(2j+1)^2} \tag{2.7}$$

so that the principal quantum number N is related to j by

$$N=2j+1. \tag{2.8}$$

The other indices, m and m', labelling $\Phi^{j}_{mm'}$, refer to the z-components of the Lenz and angular momentum vectors; but $\Phi^{j}_{mm'}$ is not an eigenfunction of the total angular momentum.

The ground state corresponds to $N=1$ or $j=0$ and the corresponding wave function is then simply

$$G^{2}D^{0}_{00}=\left(\frac{p_0^2}{p_0^2+p^2}\right)^{2} \quad 1, \tag{2.9}$$

which Fourier transforms into the usual exponential for the ground state.

In our earlier work[1] the deformation was accomplished by replacing the integral equation (2.4) by the corresponding Woronowicz integral equation on $\mathrm{SU}_q(2)$:

$$\int_W K_q(\alpha,\alpha')D^{j}_{mm'}(\alpha'|q)d_W\tau(\alpha')=\lambda^{j}_{m'}D^{j}_{mm'}(\alpha|q), \tag{2.10}$$

where W means the Woronowicz integral and where α and α' denote two distinct points in the space of the pseudogroup. The solutions of this equation are the matrix elements of the irreducible representations of $\mathrm{SU}_q(2)$, namely $D^{j}_{mm'}(\alpha|q)$, and the eigenvalues are

$$\lambda^{j}_{m'}=\frac{q^{2m'}}{[2j+1]_q^2}. \tag{2.11}$$

Assuming the same connection between energy and eigenvalues as in the $q=1$ case, one has

$$E(n,m')=-\frac{m}{2}\frac{e^4}{\hbar^2}\frac{q^{4m'}}{[n]_q^2}, \tag{2.12}$$

which approaches the Balmer formula in limit $q=1$. Here the square bracket has its usual meaning

$$[n]=\frac{q^n-q^{-n}}{q-q^{-1}}. \tag{2.13}$$

The deformed wave functions are now $G^2D^j_{mm'}(\alpha|q)$, where α stands for the set of elements defining the algebra and on which $D^j_{mm'}(\alpha|q)$ depends.

There is now the problem of interpreting these deformed wave functions since they are operator rather than c-number functions. For example, the first four excited states correspond to $N=2$ or $j=1/2$ and may be displayed as elements of the following matrix:[1]

$$D^{1/2}_{mm'}=\begin{pmatrix} a & b \\ -q_1\overline{b} & \overline{a} \end{pmatrix}, \tag{2.14}$$

where $q_1=q^{-1}$.

If $q=1$, we may parametrize $D^j_{mm'}$ by three variables such as the three components of $\mathbf{p}$ (or by other coordinate systems such as the Eulerian angles).

If the components of $\mathbf{p}$ are chosen as parameters, then in the undeformed limit we have

$$a=\frac{p_0^2-p^2}{p_0^2+p^2}+\frac{2ip_0p_3}{p_0^2+p^2}, \quad b=\frac{2ip_0(p_1-ip_2)}{p_0^2+p^2},$$

$$d=\frac{p_0^2-p^2}{p_0^2+p^2}-\frac{2ip_2p_3}{p_0^2+p^2}, \quad c=\frac{2ip_0(p_1+ip_2)}{p_0^2+p^2}, \tag{2.15}$$

$$d=\overline{a}, \quad c=-q_1\overline{b}.$$

Then the wave functions in momentum space are given by (2.5) where (a,b,c,d) are expressed as functions of the momentum. After deformation the Wigner functions become the q-Wigner functions depending on $(a,\overline{a},\overline{b},b)$, which all lie in the $SU_q(2)$ algebra and therefore obey the commutation rules of that algebra. If the connection with the components of the momentum described in (2.15) were maintained, then of course the components of momentum would also become noncommuting and momentum space would become a noncommuting space.

Instead of taking the next step of passing to a noncommuting space, however, we shall deform only the solutions of the Coulomb problem without altering the space in which they lie. This can be done by passing from the operator wave functions depending on $(abcd)$ to associated numerical wave functions obtained by evaluating the operator functions on an appropriate Hilbert space, which we shall next describe.

III. HILBERT SPACE

The natural Hilbert space is already indicated by the algebra: since b and c are commuting, we take their common eigenfunctions as reference states lying in the Hilbert space. We also pass to the notation $(a,b,b,\overline{a})$, where

$$\overline{b}=-qc, \quad \overline{a}=d. \tag{3.1}$$

Then

$$ab = qba, \quad \overline{b}\overline{a} = q\overline{a}\overline{b}, \quad a\overline{b} = q\overline{b}a, \quad b\overline{a} = q\overline{a}b. \tag{3.2}$$

Assume that $|0\rangle$ and $\langle 0|$ are common eigenfunctions of b and $\overline{b}$ such that

$$\begin{aligned} b|0\rangle &= \beta|0\rangle, \quad \langle 0|\overline{b} = \langle 0|\beta^* \\ \overline{b}|0\rangle &= \beta^*|0\rangle, \quad \langle 0|b = \langle 0|\beta, \end{aligned} \tag{3.3}$$

when β and β^* are conjugate complex numbers. Assume

$$\langle 0|0\rangle = 1. \tag{3.4a}$$

Then

$$\langle 0|b|0\rangle = \beta, \quad \langle 0|\overline{b}|0\rangle = \beta^*. \tag{3.4b}$$

One now shows that a and $\overline{a}$ behave as annihilation and creation operators since

$$ab|0\rangle = qba|0\rangle \tag{3.5}$$

or

$$b \cdot a|0\rangle = (q^{-1}\beta) \cdot a|0\rangle. \tag{3.6}$$

By iteration

$$b \cdot a^N|0\rangle = (q^{-N}\beta) \cdot a^N|0\rangle \tag{3.7}$$

and also

$$\overline{b} \cdot a^N|0\rangle = (q^{-N}\beta^*) \cdot a^N|0\rangle \tag{3.8}$$

since b and $\overline{b}$ have the same commutation relations with a. Likewise,

$$b \cdot \overline{a^N}|0\rangle = (q^N\beta) \cdot \overline{a^N}|0\rangle, \tag{3.9}$$

$$\overline{b} \cdot \overline{a^N}|0\rangle = (q^N\beta^*) \cdot \overline{a^N}|0\rangle. \tag{3.10}$$

Let

$$a^N|0\rangle = |-N\rangle, \tag{3.11}$$

$$\overline{a^N}|0\rangle = |N\rangle \tag{3.12}$$

up to a normalization. Then

$$b|-N\rangle = (q^{-N}\beta)|-N\rangle, \tag{3.13}$$

$$\overline{b}|-N\rangle = (q^{-N}\beta^*)|-N\rangle, \tag{3.14}$$

$$b|N\rangle = (q^N\beta)|N\rangle, \tag{3.15}$$

$$\overline{b}|N\rangle = (q^N\beta^*)|N\rangle. \tag{3.16}$$

By the usual argument the basis states are orthogonal since

$$\langle N|b|M\rangle=\langle N|q^M\beta|M\rangle \tag{3.17a}$$

$$=\langle N|q^N\beta|M\rangle \tag{3.17b}$$

or, by (3.13),

$$(q^M-q^N)\langle N|M\rangle=0. \tag{3.18}$$

Therefore

$$\langle N|M\rangle=0, \quad N\neq M. \tag{3.19}$$

Set

$$\overline{a}|N\rangle=\lambda_N|N+1\rangle, \quad \langle N|a=\langle N+1|\lambda_N^* \tag{3.20}$$

or

$$a|N\rangle=\mu_n|N-1\rangle, \quad \langle N|\overline{a}=\langle N-1|\mu_N^*. \tag{3.21}$$

Then

$$\langle N|a\overline{a}|N\rangle=\langle N+1|\lambda_N^*\lambda_N|N+1\rangle. \tag{3.22}$$

However,

$$a\overline{a}+b\overline{b}=1. \tag{3.23}$$

Therefore

$$\langle N|1-b\overline{b}|N\rangle=(\lambda_N)^2\langle N+1|N+1\rangle$$

and

$$(\lambda_N)^2=1-|\beta|^2q^{2N}, \tag{3.24}$$

as we assume the same normalization for all states. Likewise

$$\langle N|\overline{a}a|N\rangle=\langle N-1|\mu_N^*\mu_N|N-1\rangle. \tag{3.25}$$

However,

$$\overline{a}a+q_1^2\overline{b}b=1; \tag{3.26}$$

therefore

$$\langle N|1-q_1^2\overline{b}\overline{b}|N\rangle=(\mu_N)^2\langle N-1|N-1\rangle$$

and

$$(\mu_N)^2=1-q_1^2|\beta|^2q^{2N}. \tag{3.27}$$

Therefore to obtain the Nth state from the standard state $|0\rangle$ we form

$$\overline{a^N}|0\rangle=\overline{a}\ldots\overline{a}|0\rangle \tag{3.28}$$

$$= \prod_0^{N-1} \lambda_s |N\rangle \tag{3.29}$$

$$= \prod_0^{N-1} (1-|\beta|^2 q^{2s})^{1/2} |N\rangle \tag{3.30}$$

$$= (|\beta|^2 \| q^2)_N^{1/2} |N\rangle, \tag{3.31}$$

where $(x|q)_N$ is the shifted factorial:

$$(x|q)_N = \prod_0^{N-1} (1-xq^s). \tag{3.32}$$

The normalized eigenstates of b and $\overline{b}$ are then

$$|N\rangle = \frac{\overline{a}^N}{(|\beta|^2 \| q^2)_N^{1/2}} |0\rangle. \tag{3.33}$$

IV. EVALUATION OF $\langle N|D^j_{mm'}|N'\rangle$

After deformation, the Wigner functions $D^j_{mm'}$ become the operator functions[1]

$$D^j_{mm'} = \Delta^j_{mm'} \sum \begin{pmatrix} n_+ \\ s \end{pmatrix}_1 \begin{pmatrix} n_- \\ t \end{pmatrix}_1 q_1^{(n_+ - s+1)t} (-)^t \delta(s+t, n'_+) a^s b^{n_+ - s} \overline{b}^t \overline{a}^{n_- - t}, \tag{4.1}$$

where

$$\Delta^j_{mm'} = \left(\frac{\langle n'_+ \rangle_1 ! \langle n'_- \rangle_1 !}{\langle n_t \rangle_1 ! \langle n_- \rangle_1 !} \right)^{1/2} \quad \begin{matrix} n_\pm = j \pm m, \\ n'_\pm = j \pm m', \end{matrix} \tag{4.2}$$

and $\langle\rangle_1 = \langle\rangle_{q_1^2}$ with $q_1 = q^{-1}$. Here $(a, \overline{a}, b, \overline{b})$ lie in the $\mathrm{SU}_q(2)$ algebra. Let

$$\Pi = a^s b^{n_+ - s} \overline{b}^t \overline{a}^{n_- - t}. \tag{4.3}$$

Then we must evaluate $\langle N|\Pi|N'\rangle$.

Let us rearrange Π:

$$\Pi = (b^{n_+ - s} \overline{b}^t a^s \overline{a}^{n_- - t}) q^{n_+ + t - s}. \tag{4.4}$$

Note that

$$a^s \overline{a}^{n_- - t} = (a^s \overline{a}^s) \overline{a}^{n_- - t - s} = (b\overline{b}|q^2)_s \overline{a}^{n_- - t - s}. \tag{4.5}$$

Then

$$\Pi = q^{n_+ + t - s} b^{n_+ - s} \overline{b}^t (b\overline{b}|q^2)_s \overline{a}^{n_- - t - s} \tag{4.6}$$

$$= q^{n_+ + t - s} b^{n_+ - s - t} (b\overline{b})^t (b\overline{b}|q^2)_s \overline{a}^{n_- - t - s} \tag{4.7}$$

and

$$\langle N|\Pi|N'\rangle = q^{n_+ + t - s} (q^N \beta)^{n_+ - s - t} |\beta|^{2t} q^{2Nt} (|\beta|^2 q^{2N}|q^2)_s \langle N|\overline{a}^{n_- - t - s}|N'\rangle. \tag{4.8}$$

To evaluate this matrix element note that by (3.20)

$$\overline{a^k}|N\rangle = \prod_{N}^{N+k-1} \lambda_s |N+k\rangle \tag{4.9}$$

$$= \left[\frac{\Pi_0^{N+k-1}\lambda_s}{\Pi_0^{N-1}\lambda_s}\right]|N+k\rangle. \tag{4.10}$$

By (3.31)

$$= \left[\frac{(|\beta|^2|q^2)_{N+k}^{1/2}}{(|\beta|^2|q^2)_N^{1/2}}\right]|N+k\rangle. \tag{4.11}$$

Therefore, by (3.19),

$$\langle N|\overline{a^k}|N'\rangle = \left[\frac{(|\beta|^2|q^2)_N}{(|\beta|^2|q^2)_{N'}}\right]^{1/2}\delta(N,N'+k) \tag{4.12}$$

and

$$\langle N|\Pi|N'\rangle = q^{n_+ + t - s}q^{N(n_+ - s + t)}\beta^{n_+ - s - t}|\beta|^{2t}(|\beta|^2 q^{2N}|q^2)_s\left[\frac{(|\beta|^2|q^2)_N}{(|\beta|^2|q^2)_{N'}}\right]^{1/2}\delta(N,N'+n_- - t - s). \tag{4.13}$$

The double sum on (s,t) in (4.1) is now restricted by the following conditions;

$$n'_+ = s+t, \quad N' - N + n_- = s + t.$$

Therefore

$$N' - N = n'_+ - n_- = m' + m \tag{4.14}$$

and

$$\langle N|D^j_{mm'}|N'\rangle = \Delta^j_{mm'}\sum \left\langle \begin{matrix} n_+ \\ s \end{matrix} \right\rangle_1 \left\langle \begin{matrix} n_- \\ t \end{matrix} \right\rangle_1 (-)^t q_1^{(n_+ - s + 1)t} q^{(N+1)(n_+ + t - s)}\beta^{n_+ - s - t}|\beta|^{2t}$$
$$\times (|\beta|^2 q^{2N}|q^2)_s\left[\frac{(|\beta|^2|q^2)_N}{(|\beta|^2|q^2)_{N'}}\right]^{1/2}\delta(s+t,n'_+)\,\delta(N'-N,m+m'). \tag{4.15}$$

In particular,

$$\langle 0|D^j_{mm'}|0\rangle = \Delta^j_{mm'}\sum \left\langle \begin{matrix} n_+ \\ s \end{matrix} \right\rangle_1 \left\langle \begin{matrix} n_- \\ t \end{matrix} \right\rangle_1 q_1^{(n_+ - s)(1-t)}(-)^t\beta^{n_+ - s - t}|\beta|^{2t}$$
$$\times (|\beta|^2|q^2)_s\delta(s+t,n'_+)\,\delta(m+m',0). \tag{4.16}$$

In general, if we set $N=0$, then

$$\langle 0|D^j_{mm'}|m+m'\rangle = \Delta^j_{mm'}\sum \left\langle \begin{matrix} n_+ \\ s \end{matrix} \right\rangle_1 \left\langle \begin{matrix} n_- \\ t \end{matrix} \right\rangle_1 q^{(n_+ - s)(1-t)}(-)^t\beta^{n_+ - s - t}|\beta|^{2t}(|\beta|^2 q^2)_s$$
$$\times (|\beta|^2|q^2)^{-1/2}_{m+m'}\delta(s+t,n'_+). \tag{4.17}$$

In this way one may associate a numerically valued function $\langle 0|D^j_{mm'}|m+m'\rangle$ with the operator $D^j_{mm'}$. There is, of course, an associated degeneracy since any solution of $N'-N=m+m'$ is also acceptable.

The limit of (4.17) as $q\to 1$ is

$$\Delta^j_{mm'}\sum \binom{n_+}{s}\binom{n_-}{t}(-)^t\beta^{n_+-s-t}|\beta|^{2t}(|\beta|^2|1)_s(|\beta|^2|1)^{-1/2}_{m+m'}\delta(s+t,n'_+), \tag{4.18}$$

where

$$\beta^{n_+-s-t}|\beta|^{2t}(|\beta|^2|1)_s(|\beta|^2|1)^{-1/2}_{m+m'}=\beta^{n_+-n'_+}|\beta|^{2t}(1-|\beta|^2)^{s-(m+m')/2}. \tag{4.19}$$

Set

$$\beta=\sin\frac{\theta}{2}\,e^{i\chi}. \tag{4.20}$$

Then (4.19) becomes

$$\left(\sin\frac{\theta}{2}\right)^{m-m'+2t}\left(\cos\frac{\theta}{2}\right)^{2s-m-m'}e^{i(m-m')\chi}. \tag{4.21}$$

Then

$$\lim_{q\to 1}\langle 0|D^j_{mm'}|m+m'\rangle=\Delta^j_{mm'}\sum \binom{n_+}{s}\binom{n_-}{t}(-)^t\left(\sin\frac{\theta}{2}\right)^{2t+m-m'}\left(\cos\frac{\theta}{2}\right)^{2s-m-m'}e^{i(m-m')\chi}\delta(s+t,j+m') \tag{4.22}$$

as required.

Notice that if we let q approach unity before taking the matrix element, then $\langle 0|D^j_{m+m'}|m+m'\rangle=0$ unless $m+m'=0$. On the other hand, if we take the matrix element first, then according to (4.22) we obtain the correct $q=1$ amplitude.

V. q-DEFORMED AMPLITUDES IN MOMENTUM SPACE

The result obtained for $\langle 0|D^j_{mm'}|m+m'\rangle$ depends on q, β, and β^*. Since β and β^* are eigenvalues rather than operators, they may be parametrized by three commuting parameters (p_1,p_2,p) which we identify with two components and the magnitude of momentum

$$\beta=\frac{2ip_0(p_1-ip_2)}{p_0^2+p^2}, \tag{5.1}$$

$$\beta^*=-\frac{2i(p_1+ip_2)}{p_0^2+p^2}, \tag{5.2}$$

and we also define p_3 by

$$p_3^2=p^2-p_1^2-p_2^2. \tag{5.3}$$

Here p_0 is a constant.

Let

$$\mathscr{D}(\beta,\beta^*)\equiv\langle 0|D^j_{mm'}|m+m'\rangle. \tag{5.4}$$

Then the amplitude in momentum space is

$$\Phi(\mathbf{p})=\left(\frac{p_0}{p_0^2+p^2}\right)^2\mathscr{D}\left(\frac{2i(p_0(p_1-ip_2))}{p_0^2+p^2},\ \frac{-2ip_0(p_1+ip_2)}{p_0^2+p^2}\right). \tag{5.5}$$

This amplitude may be Fourier transformed back to configuration space by the usual rules of quantum mechanics. In this way we may obtain a q-deformed solution of the Coulomb problem in configuration space.

VI. REMARKS

The operator form of the amplitude in configuration space obtained by Feigenbaum and Freund[2] is not simply related to the operator form of the amplitude in momentum space discussed in this paper because the symmetry algebras for the two amplitudes, namely $SO_q(3)$ and $SU_q(2)$, are not the same (although the undeformed algebras are of course the same). In addition the momentum amplitude presented here is an eigenfunction of the z-components of the Lenz and angular momentum vectors while the configuration space amplitude to which it is compared is an eigenfunction of the total angular momentum and its z-component. With both of these operator amplitudes, one has the problem of physical interpretation, i.e., of relating numerical probabilities to the amplitudes.

In an earlier discussion of the harmonic oscillator a different course was followed.[4] There the amplitude in configuration space is presented as a function which both lies in the $SU_q(2)$ algebra and independently depends on the coordinates of configuration space; further, the coordinates of configuration space are required to freely commute with the $SU_q(2)$ algebra. The amplitude in momentum space has a similar structure, dependent on both the $SU_q(2)$ algebra and the coordinates of the momentum which freely commute with the algebra. The amplitudes in configuration and momentum space are related by a q-Fourier transform which is integrated over the eigenvalues of one of the conjugate operators and maps onto eigenfunctions of the other.

The numerical probability associated with either amplitude is then obtained by a Woronowicz integration over the $SU_q(2)$ algebra. This procedure differs from both conventional quantum mechanics and quaternion quantum mechanics, since in those cases the amplitude lies in either the complex plane or the SU(2) algebra, while here it lies in the $SU_q(2)$ algebra. The only natural choice for probability in the $SU_q(2)$ case is the Woronowicz measure, since it is invariant under $SU_q(2)$ transformations and still depends on x or p. The same approach can, in principle, be followed for a system with more degrees of freedom such as the q-Coulomb problem, but this has not yet been done.

Lattice properties of quantum effects

Stanley Gudder
Department of Mathematics and Computer Science, University of Denver, Denver, Colorado 80208

(Received 13 November 1995; accepted for publication 12 March 1996)

Sufficient conditions for the existence of the infimum $A\wedge B$ of two quantum effects A and B are given. The existence of $A\wedge B$ is characterized for commuting A and B with pure point spectrum. Properties of a generalized infimum and supremum are studied. Some previous finite dimensional, commutative results are extended to the infinite dimensional and noncommutative case. © *1996 American Institute of Physics.* [S0022-2488(96)03306-3]

I. INTRODUCTION

The basic axiomatic elements of the operational approach to quantum mechanics are the effects.[1–5] In this approach, effects represent sharp and unsharp properties of a physical system. The set of effects $\mathscr{E}$ for a physical system S carry a natural partial order, where we define $A\leqslant B$ if the expectation of the values of a measurement of A does not exceed that of B for every state of S. If H is the Hilbert space that describes the states of S, then $\mathscr{E}$ is represented by the set of self-adjoint operators on H that satisfy $0\leqslant A\leqslant I$ and $A\leqslant B$ if and only if $\langle Ax,x\rangle\leqslant\langle Bx,x\rangle$ for all $x\in H$.

Since $(\mathscr{E},\leqslant)$ is a partially ordered set, it is of interest to study the lattice properties of $\mathscr{E}$. Except in the trivial case $\dim(H)=1$, $\mathscr{E}$ is not a lattice.[6,7] This leads to the natural problem of characterizing those pairs of effects $A,B\in\mathscr{E}$ for which the greatest lower bound (infimum) $A\wedge B$ or the least upper bound (supremum) $A\vee B$ exists. Although this characterization problem has been solved for the cases $\dim(H)=2,3$,[6,8] it remains open in general. It is obvious that if A and B are comparable ($A\leqslant B$ or $B\leqslant A$) then $A\wedge B$ and $A\vee B$ exist. However, there are many examples of incomparable effects for which $A\wedge B$ (or $A\vee B$) exist.

In this paper, we give some sufficient conditions for the existence of $A\wedge B$ and solve the characterization problem for the case of commuting effects with pure point spectrum. [Note that it is not necessary to study both $A\wedge B$ and $A\vee B$ since they are related by DeMorgan's laws $(A\wedge B)'=A'\vee B'$, $(A\vee B)'=A'\wedge B'$ when one side of the equations exist, where $A'=I-A$.] We also consider the concepts of a generalized infimum $A\sqcap B$ and generalized supremum $A\sqcup B$. We show that $A\sqcap B$ and $A\sqcup B$ have many of the properties of the usual $A\wedge B$, $A\vee B$ and reduce to these when they exist. Finally, we extend some finite dimensional, commutative results in Ref. 7 to the infinite dimensional and noncommutative case.

II. A GENERALIZED INFIMUM

Let H be a complex Hilbert space and denote the set of bounded self-adjoint operators on H by $\mathscr{S}(H)$ and the set of (orthogonal) projections on H by $\mathscr{P}(H)$. We say that an element $A\in\mathscr{S}(H)$ is *positive* and write $A\geqslant 0$ if $\langle Ax,x\rangle\geqslant 0$ for all $x\in H$. For $A,B\in\mathscr{S}(H)$, we write $A\leqslant B$ if $B-A\geqslant 0$. In this way $(\mathscr{S}(H),\leqslant)$ becomes a partially ordered set. An element $A\in\mathscr{S}(H)$ that satisfies $0\leqslant A\leqslant I$ is called an *effect* and the set of effects on H is denoted $\mathscr{E}(H)$. It is well known that $(\mathscr{S}(H),\leqslant)$ and $(\mathscr{E}(H),\leqslant)$ are not lattices (unless $\dim(H)\leqslant 1$).[6,7,9] However, we shall introduce generalized infima and suprema that possess many of the properties of the usual infima and suprema and reduce to these constructs when they exist. For $A,B\in\mathscr{E}(H)$, when we write $A\wedge B$ we are always referring to the infimum (greatest lower bound) of A and B within $\mathscr{E}(H)$. The next two lemmas give useful properties of the order.

J. Math. Phys. **37** (6), June 1996

Lemma 2.1: Let $A,B,C\in\mathscr{E}(H)$. (a) Then $BAB\in\mathscr{E}(H)$ and $0\leqslant BAB\leqslant B^2\leqslant I$. (b) If $C\leqslant A$, then $BCB\leqslant BAB$. (c) If $AB=BA$, then $0\leqslant AB\leqslant B$.

Proof: (a) That $B^2\leqslant I$ follows from the spectral theorem. The result follows because $\langle BABx,x\rangle=\langle ABx,Bx\rangle$ and

$$0\leqslant\langle ABx,Bx\rangle\leqslant\langle Bx,Bx\rangle=\langle B^2x,x\rangle.$$

(b) This follows from

$$\langle BCBx,x\rangle=\langle CBx,Bx\rangle\leqslant\langle ABx,Bx\rangle=\langle BABx,x\rangle.$$

(c) The result holds because $\langle ABx,x\rangle=\langle AB^{1/2}x,B^{1/2}x\rangle$ and

$$0\leqslant\langle AB^{1/2}x,B^{1/2}x\rangle\leqslant\langle B^{1/2}x,B^{1/2}x\rangle=\langle Bx,x\rangle.$$ □

For $A\in\mathscr{S}(H)$, let $R(A)$ be the closure of the range AH of A and $N(A)$ be the null space of A. For $A,B\in\mathscr{S}(H)$ we denote the projection onto $R(A)$ by P_A and the projection onto $R(A)\cap R(B)$ by $P_{A,B}$.

Lemma 2.2: Let $A,B,C\in\mathscr{E}(H)$. (a) If $C\leqslant A$, then $CP_A=P_AC=C$ and $C\leqslant P_A$. (b) If $C\leqslant A,B$, then $CP_{A,B}=P_{A,B}C=C$ and $C\leqslant P_{A,B}$.

Proof: (a) If $x\in N(A)$, then

$$0\leqslant\langle C^{1/2}x,C^{1/2}x\rangle=\langle Cx,x\rangle\leqslant\langle Ax,x\rangle=0.$$

Hence, $C^{1/2}x=0$ so $Cx=0$. Therefore, $N(A)\subseteq N(C)$ so

$$R(C)=N(C)^{\perp}\subseteq N(A)^{\perp}=R(A).$$

Hence, for every $y\in H$ we have $Cy=P_ACy$ so $C=P_AC$ and

$$C=C^*=(P_AC)^*=CP_A.$$

Applying Lemma 2.1(a) gives

$$C=P_ACP_A\leqslant P_A^2=P_A.$$

(b) If $C\leqslant A,B$ then from part (a) we have $R(C)\subseteq R(A),R(B)$ so $R(C)\subseteq R(A)\cap R(B)$. The result follows using the same argument as in part (a). □

For $A\in\mathscr{S}(H)$, we define $|A|=(A^2)^{1/2}$ where $(A^2)^{1/2}$ is the unique positive square root of A^2. For $A,B\in\mathscr{S}(H)$, we define the *generalized infimum* $A\sqcap B$ by

$$A\sqcap B=\tfrac{1}{2}(A+B-|A-B|).$$

The generalized infimum has been studied by various investigators.[7,9,10] Of course, $A\sqcap B$ always exists. However, for $A,B\in\mathscr{E}(H)$, it is not necessarily true that $A\sqcap B\in\mathscr{E}(H)$ because $A\sqcap B$ may not be positive.[7,10] Nevertheless, for important special cases, we do have $A\sqcap B\in\mathscr{E}(H)$. For example, if A and B are comparable or if A and B commute, then $A\sqcap B\in\mathscr{E}(H)$. It is shown in Ref. 7 that if $\dim(H)<\infty$ and A,B are commuting effects, then $A\sqcap B$ is a maximal lower bound for A,B. We shall prove a generalization of this result by showing that $\dim(H)<\infty$ can be dropped and that $AB=BA$ can be replaced by a more general condition.

Theorem 2.3: (a) If $A,B\in\mathscr{S}(H)$, then $A\sqcap B\leqslant A,B$ and

$$(A-A\sqcap B)(B-A\sqcap B)=0.$$

(b) If $A,B\in\mathscr{E}(H)$ and $A\sqcap B\geqslant 0$, then

$$(A-A\sqcap B)\wedge(B-A\sqcap B)=0.$$

Proof: (a) It follows from the spectral theorem that $A-B\leqslant|A-B|$. Hence, $A-|A-B|\leqslant B$ so $A+B-|A-B|\leqslant 2B$ and

$$A\sqcap B=\tfrac{1}{2}(A+B-|A-B|)\leqslant B.$$

Similarly, $A\sqcap B\leqslant A$. Since $A-B$ and $|A-B|$ commute, we have

$$(A-A\sqcap B)(B-A\sqcap B)=\tfrac{1}{4}(A-B+|A-B|)(B-A+|A-B|)=\tfrac{1}{4}(|A-B|^2-(A-B)^2)=0.$$

(b) Since $A\sqcap B\leqslant A,B$ and $A\sqcap B\geqslant 0$, we have $A-A\sqcap B,B-A\sqcap B\in\mathscr{E}(H)$. Suppose that $C\in\mathscr{E}(H)$ with $C\leqslant A-A\sqcap B,B-A\sqcap B$. If

$$x\in(A-A\sqcap B)H\cap(B-A\sqcap B)H,$$

then

$$x=(A-A\sqcap B)y=(B-A\sqcap B)z,$$

for some $y,z\in H$. Hence, by part (a) we have

$$\|x\|^2=\langle x,x\rangle=\langle(B-A\sqcap B)(A-A\sqcap B)y,z\rangle=0.$$

Thus, $P=P_{A-A\sqcap B,B-A\sqcap B}=0$ so by Lemma 2(b) we have $C=CP=0$. The result now follows.□

Corollary 2.4: For $A,B\in\mathscr{E}(H)$, suppose that $A\sqcap B\geqslant 0$. (a) Then $A\sqcap B$ is a maximal lower bound for A and B in $\mathscr{E}(H)$. (b) If $A\wedge B$ exists, then $A\wedge B=A\sqcap B$.

Proof: (a) From Theorem 2.3(a) we have $0\leqslant A\sqcap B\leqslant A,B$. Suppose that $A\sqcap B\leqslant C\leqslant A,B$. Then

$$0\leqslant C-A\sqcap B\leqslant A-A\sqcap B,B-A\sqcap B$$

Applying Theorem 2.3(b) gives $C-A\sqcap B=0$ so $C=A\sqcap B$. (b) Since $A\sqcap B\leqslant A\wedge B\leqslant A,B$, applying part (a) gives $A\wedge B=A\sqcap B$. □

If A and B are commuting effects, it follows from the spectral theorem that $A\sqcap B\geqslant 0$. Hence, the conclusions of Corollary 2.4 hold. This generalizes the main result in Ref. 7 to Hilbert spaces of arbitrary dimension. The next result has been proved in Ref. 10.

Lemma 2.5: For $A,B\in\mathscr{E}(H)$, $A\sqcap B=0$ if and only if $AB=0$.

In Ref. 7 it is shown that if $A,B\in\mathscr{E}(H)$ with $AB=0$ and $\dim(H)<\infty$, then $A\wedge B=0$. We now show that $\dim(H)<\infty$ is unnecessary.

Corollary 2.6: For $A,B\in\mathscr{E}(H)$, if $AB=0$, then $A\wedge B=0$.

Proof: If $AB=0$, then by Lemma 2.5 we have $A\sqcap B=0$. Since, by Corollary 2.4(a), $A\sqcap B$ is a maximal lower bound for A and B, we have $A\wedge B=0$. □

For $A\in\mathscr{E}(H)$, we define $A'\in\mathscr{E}(H)$ by $A'=I-A$.

Corollary 2.7: If $A\wedge A'$ exists, then $A\wedge A'=\tfrac{1}{2}(I-|2A-I|)$.

Proof: Since A and A' commute, if $A\wedge A'$ exists it follows from Corollary 2.4 that

$$A\wedge A'=A\sqcap A'=\tfrac{1}{2}(A+A'-|A-A'|)=\tfrac{1}{2}(I-|2A-I|).$$ □

The next corollary gives a well-known characterization of projections.[11,12]

Corollary 2.8: An effect A is a projection if and only if $A\wedge A'=0$

Proof: If $A\wedge A'=0$, then by Corollary 2.4, $A\sqcap A'=A\wedge A'=0$. Applying Lemma 2.5, we have $AA'=0$. Hence, $A-A^2=A(I-A)=0$ so A is a projection. Conversely, if A is a projection, then $AA'=0$. Applying Corollary 2.6 gives $A\wedge A'=0$. □

For $A,B\in\mathscr{S}(H)$, we defined the *generalized supremum* $A\sqcup B$ by

$$A \sqcup B = \tfrac{1}{2}(A + B + |A - B|).$$

The following theorem is analogous to Theorem 2.3 and Corollary 2.4.

Theorem 2.9: (a) If $A, B \in \mathscr{S}(H)$, then $A, B \leqslant A \sqcup B$ and

$$(A \sqcup B - A)(A \sqcup B - B) = 0.$$

Let $A, B \in \mathscr{E}(H)$ with $A \sqcup B \leqslant I$. (b) Then

$$(A \sqcup B - A) \wedge (A \sqcup B - B) = 0.$$

(c) $A \sqcup B$ is a minimal upper bound for A and B in $\mathscr{E}(H)$. (d) If $A \vee B$ exists, then $A \vee B = A \sqcup B$.

The next result gives relationships between $A \sqcap B$ and $A \sqcup B$.

Lemma 2.10: For $A, B \in \mathscr{S}(H)$ we have (a) $A \sqcap B + A \sqcup B = A + B$ and $A \sqcup B - A \sqcap B = |A - B|$; (b) $(A \sqcup B)' = A' \sqcap B'$ and $(A \sqcap B)' = A' \sqcup B'$.

Proof: (a) is clear. For (b) we have

$$A' \sqcap B' = \tfrac{1}{2}(2I - A - B - |A - B|) = I - \tfrac{1}{2}(A + B + |A - B|) = (A \sqcup B)'$$

and the last equation is similar. □

We conclude that for effects A and B that $A \sqcap B$ and $A \sqcup B$ always exist in $\mathscr{S}(H)$ and have many of the properties of an infimum and supremum, respectively. Moreover, when $A \wedge B (A \vee B)$ exists and $A \sqcap B (A \sqcup B)$ is in $\mathscr{E}(H)$, then $A \wedge B = A \sqcap B (A \vee B = A \sqcup B)$.

III. EXISTENCE OF INFIMA

An important open problem is to characterize the pairs of effects A, B for which $A \wedge B$ exists. This problem was solved for the case $\dim(H) = 2$ in Ref. 6 where it was shown that $A \wedge B$ exists if and only if A and B are comparable or $\dim P_{A,B} \leqslant 1$. This section presents some sufficient conditions for the existence of infima and the characterization problem is solved for the case of commuting effects with pure point spectrum.

Theorem 3.1: Let $A, B \in \mathscr{E}(H)$. (a) If $P \in \mathscr{P}(H)$ satisfies $AP = PA$, $BP = PB$ and if $A \wedge B$ exists, then $(PA) \wedge (PB)$ exists and equals $P(A \wedge B)P$. (b) If A and B both commute with $P_{A,B}$, then $(AP_{A,B}) \wedge (BP_{A,B})$ exists if and only if $A \wedge B$ exists and moreover, when they exist, they coincide.

Proof: (a) By Lemma 2.1(a), $PA, PB, P(A \wedge B)P \in \mathscr{E}(H)$. Since $A \wedge B \leqslant A, B$, by Lemma 2.1(b), $P(A \wedge B)P \leqslant PA, PB$. Suppose that $C \leqslant PA, PB$, where $C \in \mathscr{E}(H)$. By Lemma 2.1(c) we have $C \leqslant PA \leqslant P$ and applying Lemma 2.2(a) gives $CP = PC = C$. By Lemma 2.1(c) we have $PA \leqslant A$, $PB \leqslant B$ so $C \leqslant A, B$. Hence, $C \leqslant A \wedge B$ so applying Lemma 2.1(b) gives $C = PCP \leqslant P(A \wedge B)P$. Hence, $P(A \wedge B)P = (PA) \wedge (PB)$. (b) If $A \wedge B$ exists, it follows from part (a) that $(AP_{A,B}) \wedge (BP_{A,B})$ exists. Conversely, suppose that $(AP_{A,B}) \wedge (BP_{A,B})$ exists. As in part (a) $AP_{A,B} \leqslant A$ and $BP_{A,B} \leqslant B$ so $(AP_{A,B}) \wedge (BP_{A,B}) \leqslant A, B$. Now suppose that $C \in \mathscr{E}(H)$ with $C \leqslant A, B$. Applying Lemma 2.2(b) gives $CP_{A,B} = P_{A,B}C = C$. By Lemma 2.1(b) we have

$$C = P_{A,B}CP_{A,B} \leqslant P_{A,B}AP_{A,B} = AP_{A,B}.$$

Similarly, $C \leqslant BP_{A,B}$ so $C \leqslant (AP_{A,B}) \wedge (BP_{A,B})$ and the result follows. □

As a corollary, we obtain the following well known result.[9]

Corollary 3.2: If $A, B \in \mathscr{P}(H)$, then $A \wedge B = P_{A,B}$.

Proof: We have

$$AP_{A,B} = P_{A,B}A = BP_{A,B} = P_{A,B}B = P_{A,B}.$$

Applying Theorem 3.1(b) gives

$$P_{A,B}=P_{A,B}\wedge P_{A,B}=(AP_{A,B})\wedge(BP_{A,B})=A\wedge B. \qquad \square$$

If A and B both commute with $P_{A,B}$, then by Theorem 3.1, a sufficient condition for the existence of $A\wedge B$ is that $AP_{A,B}$ and $BP_{A,B}$ are comparable. The next theorem gives another sufficient condition.

Theorem 3.3: For $A,B\in\mathscr{E}(H)$, if $\dim(P_{A,B})\leqslant 1$, then $A\wedge B$ exists.

Proof: Suppose that $\dim(P_{A,B})\leqslant 1$ and let $C\in\mathscr{E}(H)$ satisfy $C\leqslant A,B$. By Lemma 2.2(b) $CP_{A,B}=P_{A,B}C=C$. If $P_{A,B}=0$, then $C=0$ so $A\wedge B=0$. Suppose that $P=P_{A,B}\neq 0$ so $\dim(P)=1$. Let $Px=x$ with $\|x\|=1$. Then for every $y\in H$ we have

$$Cy=CPy=C\langle y,x\rangle x=\langle y,x\rangle PCy=\langle y,x\rangle\langle Cx,x\rangle x=\langle Cx,x\rangle Px.$$

Hence, $C=\langle Cx,x\rangle P$. Let

$$t=\sup\{0\leqslant s\leqslant 1: sP\leqslant A,B\}.$$

We claim that $A\wedge B=tP$. Indeed, $tP\leqslant A$ because there exists a sequence s_i such that $0\leqslant s_i\leqslant 1$, $s_iP\leqslant A$ and $t=\lim s_i$. For $y\in H$, we have $s_i\langle Py,y\rangle\leqslant\langle Ay,y\rangle$ so

$$\langle tPy,y\rangle=t\langle Py,y\rangle=\lim(s_i\langle Py,y\rangle)\leqslant\langle Ay,y\rangle.$$

Similarly, $tP\leqslant B$. Since

$$C=\langle Cx,x\rangle P\leqslant A,B$$

we have $\langle Cx,x\rangle\leqslant t$. Hence, $C\leqslant tP$ so $A\wedge B=tP$. $\square$

The next result characterizes the existence of $A\wedge B$ for commuting effects with pure point spectrum. In this theorem we assume that H is separable.

Theorem 3.4: If A and B are commuting effects with pure point spectrum, then $A\wedge B$ exists if and only if $AP_{A,B}$ and $BP_{A,B}$ are comparable. Moreover, in this case $A\wedge B$ is the smaller of $AP_{A,B}$ and $BP_{A,B}$.

Proof: If $AP_{A,B}$ and $BP_{A,B}$ are comparable, then applying Theorem 3.1(b), we conclude that $A\wedge B$ exists and is the smaller of $AP_{A,B}$ and $BP_{A,B}$. Conversely, suppose that $A\wedge B$ exists. We can assume without loss of generality that $P_{A,B}=I$ (that is, A and B both have full rank). This is because $A\wedge B$ exists if and only if $(AP_{A,B})\wedge(BP_{A,B})$ exists [Theorem 3.1(b)] and $AP_{A,B}$ and $BP_{A,B}$ have full rank on $P_{A,B}H$. We must now show that A and B are comparable. By the spectral theorem, we can write $A=\Sigma a_iP_i$, $B=\Sigma b_iP_i$, where a_i and b_i are the eigenvalues of A and B respectively (repeated according to multiplicity) and the P_i are one-dimensional projections forming a resolution of the identity. Since A and B have full rank, we have $a_i>0$, $b_i>0$ for all i. Suppose that A and B are incomparable. Then without loss of generality, we may assume that $a_1<b_1$ and $a_2>b_2$. Letting P be the projection onto the two-dimensional subspace generated by P_1H and P_2H, we have $PA=a_1P_1+a_2P_2$ and $PB=b_1P_1+b_2P_2$. Applying Theorem 3.1 (a), we conclude that $(PA)\wedge(PB)$ exists. Since PA and PB are incomparable effects on the two-dimensional Hilbert space PH, it follows from the two-dimensional case cited previously[6] that PA or PB is a multiple of a one-dimensional projection. Hence, $a_1=0$ or $b_2=0$. But this is a contradiction so A and B are comparable. $\square$

Examples are given in Ref. 7 for which $A\wedge A'$ exists and for which $A\wedge A'$ does not exist. Such examples follow from the next result.

Corollary 3.5: If H is separable and $A\in\mathscr{E}(H)$ has pure point spectrum, then $A\wedge A'$ exists if and only if $AP_{A,A'}$ and $\frac{1}{2}P_{A,A'}$ are comparable.

Proof: Let $P=P_{A,A'}$. Applying Theorem 3.4, $A\wedge A'$ exists if and only if AP and $A'P$ are comparable. But

$$AP \leqslant A'P = P - AP$$

if and only if $AP \leqslant \frac{1}{2}P$ and $A'P \leqslant AP$ if and only if $AP \geqslant \frac{1}{2}P$. ■

Example 1: For $A = \text{diag}(1/2,1,1/3)$ we have $A' = \text{diag}(1/2,0,2/3)$. Then A and A' are incomparable, but letting $P = P_{A,A'}$ we have $P = \text{diag}(1,0,1)$ and

$$AP = \text{diag}(1/2,0,1/3) \leqslant \tfrac{1}{2}\,\text{diag}(1,0,1) = \tfrac{1}{2}P,$$

so $A \wedge A'$ exists and $A \wedge A' = \text{diag}(1/2,0,1/3)$.

Example 2: For $A = \text{diag}(1/3,2/3)$ we have $A' = \text{diag}(2/3,1/3)$. Since, $P_{A,A'} = I$ and $A, \frac{1}{2}I$ are incomparable, $A \wedge A'$ does not exist.

Example 3: If $A = \text{diag}\ (0,a)$ for $0 \leqslant a \leqslant 1$, then $A \wedge B$ exists for all $B \in \mathscr{E}(\mathbb{C}^2)$.

Example 4: Let $A = \text{diag}(1,3/8,0)$, $B = \text{diag}(1,1/3,0)$ and

$$C = \begin{bmatrix} 1/2 & 0 & 0 \\ 0 & 1/2 & 1/4 \\ 0 & 1/4 & 1/2 \end{bmatrix}.$$

Then $A \wedge C = \text{diag}(1/2,3/8,0)$ but $B \wedge C$ does not exist.

On the diagonalization of quantum Birkhoff–Gustavson normal form

A. S. Nikolaev[a)]
Institute for High Energy Physics, 142284 Protvino, Moscow Region, Russia

(Received 6 February 1995; accepted for publication 31 August 1995)

An application to quantum mechanics of one of classical perturbation theory methods, the Birkhoff–Gustavson normal form (BGNF), is described. In the quantum case it results in the Van Vleck perturbation theory performed upon Wick normal ordered operators. Algebraic aspects of this procedure and formal construction of invariants (integrals of motion) for a perturbed system are considered. It turned out that a larger set of such operators existed in the quantum mechanics, rather than in the classical one. It is demonstrated that, according to general results of the quantum mechanical perturbation theory, the quantum BGNF may always be diagonalized, and two formal processes for such diagonalization are constructed. In the opposite case, the classical BGNF is, in general, nondiagonalizable. This reflects the fact that the classical perturbation theory cannot handle a system with two or more resonances. Possible reasons for such different behavior of two very close, in spirit, perturbation procedures are discussed. Results of the described procedure, entirely performed upon the Wick normal ordered operators, are equivalent to those of Rayleigh–Schrödinger perturbation expansion. © *1996 American Institute of Physics.* [S0022-2488(96)01803-7]

I. INTRODUCTION

Birkhoff method[1] in classical mechanics provides a procedure to transform the original nonseparable **d** dimensional oscillator Hamiltonian canonically into the normal form consisting of a power series in one-dimensional uncoupled harmonic oscillator Hamiltonians

$$H(p_1,q_1,\ldots,p_{\mathbf{d}},q_{\mathbf{d}})\rightarrow\mathscr{H}(\zeta_1^2+\eta_1^2,\ldots,\zeta_{\mathbf{d}}^2+\eta_{\mathbf{d}}^2),$$

where ζ_k and η_k are canonical coordinates and momenta, and $\mathscr{H}$ is a formal power series in $\zeta_k^2+\eta_k^2$. If the series $\mathscr{H}$ were to converge, the new equation could be easily integrated, **d** independent isolating invariants would exist, and the motion would be multiple periodic. Unfortunately it was shown that the Birkhoff normal form diverged in general because of small divisors in the coefficients.

The Birkhoff method was applied by Gustavson[2] in order to obtain power series expressions for invariants and analytically predict the Poincaré surfaces of section for the Henon-Heiles system. Doing that, Gustavson had to modify the original Birkhoff method in order to include resonances. Such calculations showed that, despite the known divergence of the power series representing the normal form, a truncated series could give accurate approximations to regular trajectories.[3]

The Birkhoff–Gustavson normal form was successfully applied to the semiclassical Einstein–Brillouin–Kemmer quantization of various systems, such as the Henon–Heiles system[4,5] and the hydrogen atom (Stark and Stark–Zeeman effects[6]) up to very high order of coupling constant.

Ali[7] and then Eckhard[8] showed that formalism of the so-called Lie-algebraic perturbation theory in classical mechanics[9,10] might be applied to the Birkhoff–Gustavson normalization and

a)Electronic mail: nikolaev@mx.ihep.su

extended to quantum mechanical systems, either directly, resulting in the expansion which, in the classical limit, is reduced to the Birkhoff–Gustavson normal form, or within a framework of an algebraic quantization.[11] This approach culminates in Ref. 12, where the exactness of the algebraic quantization prescription was proved up to any order of $\hbar$ for the polynomially perturbed nondegenerate harmonic oscillator.

An opposite trend of investigations originates from the canonical Van Vleck perturbation theory.[13,14] This procedure is a quantum mechanical analogue of the classical Lie-algebraic perturbation method. Surprisingly it dates back about 40 years before the corresponding procedures in classical mechanics[15,16] became available. Now the Van Vleck perturbation theory is widely used in quantum chemistry both for the analytical and numerical treatment of electronic degrees of freedom and analyses of molecular vibrations (see Refs. 17 and 18 and referencies therein). Several equivalent forms of such perturbation expansions were reviewed in Ref. 19. We choose here the most conceptually simple iterative order by order reduction of the Hamiltonian.

In this paper we will review algebraic aspects of the Birkhoff–Gustavson normalization for polynomially perturbed quantum mechanical harmonic oscillator. We describe it as a procedure to construct unitary transformation of an initial Hamiltonian into an operator belonging to the algebra of invariants for an unperturbed problem. Both the transformation and the transformed Hamiltonian are obtained as a (formal) power series in the perturbation constant. Doing this, we discuss the Gustavson invariants, their validity in the quantum case and a set of new, specific to quantum mechanics, invariants. Then, we demonstrate that, unlike the classical case, we can construct a formal process of diagonalization of the quantum mechanical Birkhoff–Gustavson normal form. In fact this process is a standard block diagonalization used in the Rayleigh–Schrödinger perturbation theory, recasted in the form of Wick normal ordered operators. We also describe another diagonalization process, which is a nonlinear generalization of Bogolyubov transformations used for the diagonalization of finite dimensional bilinear operator forms.[20] After this we discuss possible origins of the different behavior of classical and quantum mechanical perturbation procedures. Thus the Birkhoff–Gustavson normalization procedure for perturbed quantum mechanical harmonic oscillator is extended to a full equivalent of the Rayleigh–Schrödinger perturbation expansion applied for such a system (under the Rayleigh–Schrödinger perturbation expansion we assume the standard quantum mechanical perturbation treatment, including the expansion of operator resolvent and the subsequent diagonalization of energy shift operator by degenerate blocks[21,22]). All steps of the described procedure are entirely made with the Wick normal ordered operators.

Note that all calculations here are only formal, in a sense that neither discussion of power series convergence nor conditions for the existence of constructed operators are present.

Let us consider a **d** dimensional system with a Hamiltonian

$$\hat{H}(\hat{p},\hat{q}) = \sum_{k=0}^{\mathbf{d}} (\hat{p}_k^2 + \omega_k^2 \hat{q}_k^2) + \alpha \hat{H}_i(\hat{p},\hat{q}), \tag{1}$$

where $\hat{H}_i(\hat{p},\hat{q})$ is some polynomial in $\hat{p}_i$, $\hat{q}_i$. These operators of momentum and coordinate satisfy the canonical commutation relations

$$[\hat{p}_i,\hat{q}_j] = -i\,\delta_{ij}.$$

We are going to simplify the Hamiltonian performing subsequent unitary transformations according to Van Vleck[13] method.

A first step in the reduction of our Hamiltonian to the Birkhoff–Gustavson normal form will be the diagonalization of the unperturbed harmonic oscillator Hamiltonian. To do this, we had to perform the canonical transformation to the representation of ladder operators

$$\hat{a}_k=\frac{1}{\sqrt{2\omega_k}}(\hat{p}_k-i\omega_k\hat{q}_k),\quad k=1,\ldots,\mathbf{d}, \tag{2}$$

$$\hat{a}_k^+=\frac{1}{\sqrt{2\omega_k}}(\hat{p}_k+i\omega_k\hat{q}_k),$$

with commutation relations

$$[\hat{a}_k,\hat{a}_l^+]=\delta_{kl},$$

and all other commutators identical to zero.

In terms of the ''number'' operators $\hat{N}_k=\hat{a}_k^+\hat{a}_k$, the initial Hamiltonian will take the form

$$\hat{H}=\sum_{k=0}^{n}\omega_k\left(\hat{N}_k+\frac{1}{2}\right)+\alpha\hat{H}_i(\hat{a}_k^+,\hat{a}_k)=\hat{H}_0+\alpha\hat{H}_i,$$

where $\hat{H}_i(\hat{a}_k^+,\hat{a}_k)$ is a polynomial in $\hat{a}_k^+$, $\hat{a}_k$.

Before describing the Birkhoff–Gustavson perturbative treatment of the above system, let us remember some facts about its zero order approximation.

II. UNPERTURBED SYSTEM—MULTIDIMENSIONAL HARMONIC OSCILLATOR

In what follows it will be very convenient for us to use a compact ''vector'' notation for multi-indices. We will write $\overline{\mathbf{n}}$ as an abbreviation for a set of $\mathbf{d}$ non-negative integer indices $(n_1,\ldots,n_{\mathbf{d}})$. We will use other related notations:

- ''scalar'' product: $(\overline{\omega}\overline{\mathbf{n}})\overset{\text{def}}{=}\sum_{i=1}^{\mathbf{d}}\omega_i n_i$,
- ''norm'': $|\overline{\mathbf{n}}|\overset{\text{def}}{=}\sum_{i=1}^{\mathbf{d}}n_i$,
- multiindex factorials and binomial coefficients:

$$\overline{\mathbf{n}}!\overset{\text{def}}{=}n_1!\ldots n_{\mathbf{d}}!,$$

$$C_{\overline{\mathbf{n}}}^{\overline{\mathbf{m}}}\overset{\text{def}}{=}\prod_{k=1}^{\mathbf{d}}C_{n_k}^{m_k},$$

- product of operators: $\hat{a}^{\overline{\mathbf{m}}}\overset{\text{def}}{=}\hat{a}_1^{m_1}\ldots\hat{a}_{\mathbf{d}}^{m_d}$,
- and as a compact form for the system of inequalities we will write:

$$\overline{\mathbf{n}}\leqslant\overline{\mathbf{m}}\overset{\text{def}}{=}\begin{cases}n_1\leqslant m_1,\\ \ldots\\ n_{\mathbf{d}}\leqslant m_{\mathbf{d}}.\end{cases}$$

Before performing any actions on operators polynomial in $\hat{a}_k^+$, $\hat{a}_k$, we must, at first, reduce these operators to some standard ordering in constituent ladder operators. We will use the Wick

normal ordering prescription, in which any raising operator must be moved, using commutation relations, to the left and any lowering operator remains on the right. The Wick normal ordered form of the operator $\hat{A}$ will look like

$$\hat{A}=\sum A^{(W)}_{\mathbf{m},\mathbf{n}}\frac{\hat{a}^{+\overline{\mathbf{m}}}}{\sqrt{\overline{\mathbf{m}!}}}\frac{\hat{a}^{\overline{\mathbf{n}}}}{\sqrt{\overline{\mathbf{n}!}}}. \tag{3}$$

Note that we explicitly write out here normalizing denominators. This will be convenient for us when discussing the Rayleigh–Schrödinger transformations. Besides, several identities in this section will take the remarkably symmetrical form with such normalization.

The reduction to the Wick normal ordering may be extremely efficiently realized with the computer algebra system, since one may take full advantage of the following identity:

$$\hat{a}^{\overline{\mathbf{n}}}\hat{a}^{+\overline{\mathbf{m}}}=\sum_{\substack{\overline{\mathbf{k}}\leqslant\overline{\mathbf{n}}\\ \overline{\mathbf{k}}\leqslant\overline{\mathbf{m}}}}\overline{\mathbf{k}!}C^{\overline{\mathbf{k}}}_{\overline{\mathbf{m}}}C^{\overline{\mathbf{k}}}_{\overline{\mathbf{n}}}\hat{a}^{+\overline{\mathbf{m}}-\overline{\mathbf{k}}}\hat{a}^{\overline{\mathbf{n}}-\overline{\mathbf{k}}}. \tag{4}$$

This identity is a direct consequence of the Wick theorem on the product of two normal ordered operators. The theorem states that the Wick normal form of this product is equal to the sum of normal operator products with *all possible couplings* between operators. For any k couplings between multipliers, one has $C^k_n C^k_m$ different choices of two sets consisting of k indices of $\hat{a}$ and $\hat{a}^+$ in multipliers and $k!$ different couplings between these sets. The generalization to many dimensional cases using the ''vector'' notation is straightforward.

Explicitly writing out the normalizing denominators, we will use this reordering identity in the form

$$\frac{\hat{a}^{\overline{\mathbf{n}}}}{\sqrt{\overline{\mathbf{n}!}}}\frac{\hat{a}^{+\overline{\mathbf{m}}}}{\sqrt{\overline{\mathbf{m}!}}}=\sum_{\substack{\overline{\mathbf{k}}\leqslant\overline{\mathbf{n}}\\ \overline{\mathbf{k}}\leqslant\overline{\mathbf{m}}}}\sqrt{C^{\overline{\mathbf{k}}}_{\overline{\mathbf{m}}}C^{\overline{\mathbf{k}}}_{\overline{\mathbf{n}}}}\frac{\hat{a}^{+\overline{\mathbf{m}}-\overline{\mathbf{k}}}}{\sqrt{(\overline{\mathbf{m}}-\overline{\mathbf{k}})!}}\frac{\hat{a}^{\overline{\mathbf{n}}-\overline{\mathbf{k}}}}{\sqrt{(\overline{\mathbf{n}}-\overline{\mathbf{k}})!}}. \tag{5}$$

Now let us more closely consider the structure of the harmonic oscillator Hilbert space (Fock space) and operators on it.[23] This space has a ground state $|\overline{\mathbf{0}}\rangle$ and a complete orthonormal basis set created by powers of the raising operator

$$|\overline{\mathbf{m}}\rangle=\frac{\hat{a}^{+\overline{\mathbf{m}}}}{\sqrt{\overline{\mathbf{m}!}}}|\overline{0}\rangle.$$

This basis naturally induces the corresponding basis for operators. Indeed, any operator on Fock space may be decomposed as

$$\hat{A}=\sum_{\mathbf{m},\mathbf{n}}A^{(M)}_{\mathbf{m},\mathbf{n}}|\overline{\mathbf{m}}\rangle\langle\overline{\mathbf{n}}|=\sum_{\mathbf{m},\mathbf{n}}A^{(M)}_{\mathbf{m},\mathbf{n}}\frac{\hat{a}^{+\overline{\mathbf{m}}}}{\sqrt{\overline{\mathbf{m}!}}}\hat{P}_{\overline{\mathbf{0}}}\frac{\hat{a}^{\overline{\mathbf{n}}}}{\sqrt{\overline{\mathbf{n}!}}}, \tag{6}$$

where $\hat{P}_{\overline{\mathbf{0}}}=|\overline{\mathbf{0}}\rangle\langle\overline{\mathbf{0}}|$ is a projector on the ground state. This decomposition is the ''matrix'' form of the operator $\hat{A}$.

For any Wick normal ordered operator one may obtain its matrix form inserting an identity expansion

$$\hat{A}=\sum_{\bar{\mathbf{m}},n}A^{(W)}_{\bar{\mathbf{m}},\bar{\mathbf{n}}}\frac{\hat{a}^{+\bar{\mathbf{m}}}}{\sqrt{\bar{\mathbf{m}}!}}\frac{\hat{a}^{\bar{\mathbf{n}}}}{\sqrt{\bar{\mathbf{n}}!}}=\sum_{\bar{\mathbf{m}},\bar{\mathbf{n}}}A^{(W)}_{\bar{\mathbf{m}},\bar{\mathbf{n}}}\frac{\hat{a}^{+\bar{\mathbf{m}}}}{\sqrt{\bar{\mathbf{m}}!}}\left\{\sum_{\bar{\mathbf{k}}}|\bar{\mathbf{k}}\rangle\langle\bar{\mathbf{k}}|\right\}\frac{\hat{a}^{\bar{\mathbf{n}}}}{\sqrt{\bar{\mathbf{n}}!}}$$

$$=\sum_{\bar{\mathbf{m}},\bar{\mathbf{n}},\bar{\mathbf{k}}}A^{(W)}_{\bar{\mathbf{m}},\bar{\mathbf{n}}}\frac{\hat{a}^{+\bar{\mathbf{m}}+\bar{\mathbf{k}}}}{\sqrt{\bar{\mathbf{m}}!\bar{\mathbf{k}}!}}\hat{P}_{\bar{\mathbf{0}}}\frac{\hat{a}^{\bar{\mathbf{n}}+\bar{\mathbf{k}}}}{\sqrt{\bar{\mathbf{n}}!\bar{\mathbf{k}}!}}.$$

Changing summation indices, we conclude matrix elements of the operator $\hat{A}$ to be

$$A^{(M)}_{\bar{\mathbf{m}},\bar{\mathbf{n}}}=\sum_{\substack{\bar{\mathbf{k}}\le\bar{\mathbf{n}}\\ \bar{\mathbf{k}}\le\bar{\mathbf{m}}}}\sqrt{C^{\bar{\mathbf{k}}}_{\bar{\mathbf{m}}}C^{\bar{\mathbf{k}}}_{\bar{\mathbf{n}}}}A^{(W)}_{\bar{\mathbf{m}}-\bar{\mathbf{k}},\bar{\mathbf{n}}-\bar{\mathbf{k}}}. \tag{7}$$

One may obtain the inverse transformation from the matrix to the Wick normal ordered form of an operator using the following formula for the normal ordered form of the ground state projector[23]

$$\hat{P}_{\bar{\mathbf{0}}}=:\exp(-\hat{a}^{+}a):=\sum_{\bar{\mathbf{n}}}(-1)^{|\bar{\mathbf{n}}|}\frac{\hat{a}^{+\bar{\mathbf{n}}}\hat{a}^{\bar{\mathbf{n}}}}{\bar{\mathbf{n}}!}. \tag{8}$$

It is easy to check that the only nonzero matrix element of the above operator will be between a ground state wavefunctions. The substitution of this ground state projector into the definition of matrix form (6) results in the following connection between coefficients of normal and matrix forms of the operator:

$$A^{(W)}_{\bar{\mathbf{m}},\bar{\mathbf{n}}}=\sum_{\substack{\bar{\mathbf{k}}\le\bar{\mathbf{m}}\\ \bar{\mathbf{k}}\le\bar{\mathbf{n}}}}(-1)^{|\bar{\mathbf{k}}|}\sqrt{C^{\bar{\mathbf{k}}}_{\bar{\mathbf{m}}}C^{\bar{\mathbf{k}}}_{\bar{\mathbf{n}}}}A^{(M)}_{\bar{\mathbf{m}}-\bar{\mathbf{k}},\bar{\mathbf{n}}-\bar{\mathbf{k}}}. \tag{9}$$

Note the similarity of coefficients in (5), (7), and (9).

Now we proceed to the discussion of dynamical features of the harmonic oscillator. It is amazing that all in the rest of this section is a consequence of the following two commutators:

$$\begin{aligned}[\hat{N}_k,\hat{a}_k^m]&=-m\hat{a}_k^m,\\ [\hat{N}_k,\hat{a}_k^{+m}]&=m\hat{a}_k^{+m}.\end{aligned} \tag{10}$$

Commutation properties and unitary transformations of operators may be treated in a convenient way with the help of the superoperator formalism.[14] Here we will only outline some basics of it. For any operator $\hat{H}$ one may introduce the quantum Liouville superoperator which acts on the operator space

$$\hat{\mathscr{L}}_{\hat{H}}=[\hat{H},.],\quad \hat{\mathscr{L}}_{\hat{H}}\hat{A}=[\hat{H},\hat{A}]$$

(we will use the *calligraphic* style letters here to denote the superoperators)

Corresponding Liouville operator in the classical mechanics acts upon any function on the phase space resulting in the Poisson bracket with H:

$$\hat{\mathscr{L}}^{cl}_{H}A=\{H,A\}=\sum_k\left(\frac{\partial H}{\partial p_k}\frac{\partial A}{\partial q_k}-\frac{\partial A}{\partial p_k}\frac{\partial H}{\partial q_k}\right).$$

An interest to study $\hat{\mathscr{L}}_{\hat{H}}$ originates from the well-known fact that the exponent of this superoperator is a unitary map in the operator space

$$\tilde{A} = e^{i\alpha\hat{\mathscr{L}}_{\hat{H}}}\hat{A} = e^{i\alpha\hat{H}}\hat{A}e^{-i\alpha\hat{H}}.$$

Some properties of the general Liouville superoperator are summarized in Appendix A.

Here, in the harmonic oscillator context, we are particularly interested in $\hat{\mathscr{L}}_{\hat{H}_0} = [\Sigma_0^n \omega_k \hat{N}_k, .]$. Using the commutation properties (10) one can verify that any Wick normal ordered monomial is an eigenoperator of $\hat{\mathscr{L}}_{\hat{H}_0}$

$$\hat{\mathscr{L}}_{\hat{H}_0}\hat{a}^{+\mathbf{m}}\hat{a}^{\mathbf{n}} = (\overline{\omega,\mathbf{m}} - \overline{\mathbf{n}})\hat{a}^{+\mathbf{m}}\hat{a}^{\mathbf{n}}. \tag{11}$$

Since it is linear, the superoperator $\hat{\mathscr{L}}_{\hat{H}_0}$ admits the decomposition of its domain $\mathscr{D}$ into the direct sum $\mathscr{D} = \mathscr{N} \oplus \mathscr{R}$, where $\mathscr{N}$ or $\mathscr{R}$ are the kernel and the range space, respectively. The decomposition of the domain $\mathscr{D}$ into the desired form means that any element of it can be written uniquely as the sum of an element in the kernel space and an element in the range space. Now it may be easily seen that the linear superoperator $\hat{\mathscr{L}}_{\hat{H}_0}$ has the above decomposition, since each term in $\mathscr{D}$ is a linear combination of monomial terms, and since each monomial belongs to the kernel (range) space of $\hat{\mathscr{L}}_{\hat{H}_0}$ if and only if $(\overline{\omega,\mathbf{m}} - \overline{\mathbf{n}})$ equals (does not equal) zero.

In other words, every polynomial operator $\hat{P}$ on the harmonic oscillator Hilbert space may be uniquely decomposed into parts commutative and noncommutative with $\hat{H}_0$

$$\begin{aligned} &\hat{P} = \langle\hat{P}\rangle + \{\hat{P}\}, \\ &\hat{\mathscr{L}}_{\hat{H}_0}\langle\hat{P}\rangle = 0, \quad \langle\hat{P}\rangle \in \mathscr{N}; \\ &\hat{\mathscr{L}}_{\hat{H}_0}\{P\} \neq 0, \quad \{\hat{P}\} \in \mathscr{R}. \end{aligned} \tag{12}$$

In the classical mechanics the above appears as the decomposition of function on the phase space into the *secular* and the *periodical* parts.

For the perturbation theory which we will discuss further, it is crucial that on the range space of $\hat{\mathscr{L}}_{\hat{H}_0}$ this superoperator may be inverted. This means that for any polynomial operator $\hat{P}$ there exists another polynomial operator $\hat{G} \in \mathscr{R}$, such that

$$\hat{\mathscr{L}}_{\hat{H}_0}\hat{G} = -\hat{\mathscr{L}}_{\hat{G}}\hat{H}_0 = \{\hat{P}\}.$$

We will denote this operator as $\hat{G} = \hat{\mathscr{L}}_{\hat{H}_0}^{-1}\hat{P}$. If we demand that $\hat{\mathscr{L}}_{\hat{H}_0}^{-1}\langle\hat{P}\rangle = 0$, then the explicit construction of $\hat{G}$ for $\hat{P}$ will be

$$\hat{\mathscr{L}}_{\hat{H}_0}^{-1}\hat{P} = \sum{}' \frac{1}{(\overline{\omega,\mathbf{m}} - \overline{\mathbf{n}})} P^{(W)}_{\mathbf{m},\mathbf{n}}\hat{a}^{+\mathbf{m}}\hat{a}^{\mathbf{n}}, \tag{13}$$

where the prime indicates that all the terms with the vanishing denominators must be omitted from the sum.

One may easily check that for any Hermitian polynomial operator $\hat{P}$, operators $\hat{\mathscr{L}}_{\hat{H}_0}\hat{P}$ and $\hat{\mathscr{L}}_{\hat{H}_0}^{-1}\hat{P}$ are anti-Hermitian. We also mention here the superoperators $\hat{\mathscr{P}}_{\mathscr{R}} = \hat{\mathscr{L}}_{\hat{H}_0}^{-1}\hat{\mathscr{L}}_{\hat{H}_0}$ and $\hat{\mathscr{P}}_{\mathscr{N}} = 1 - \hat{\mathscr{P}}_{\mathscr{R}}$, projectors on $\mathscr{R}$ and $\mathscr{N}$ spaces, respectively. Primas[14] established formal expressions for these superoperators without any explicit reference to the matrix or the Wick normal ordered forms

$$\hat{\mathscr{P}}_{\mathscr{N}} = \lim_{\alpha \to 0} \alpha \int_0^\infty dt e^{-\alpha t} e^{-it\hat{\mathscr{L}}_{\hat{H}_0}}, \tag{14}$$

$$\hat{\mathscr{L}}_{\hat{H}_0}^{-1} = i \lim_{\alpha \to 0} \int_0^\infty dt e^{-\alpha t} e^{-it\hat{\mathscr{L}}_{\hat{H}_0}} (1 - \hat{\mathscr{P}}_{\mathscr{N}}).$$

Let us describe now a null subspace $\mathscr{N}$. This is the space of operators commutative with $\hat{H}_0$—a space of invariants of the harmonic oscillator. Due to the linearity of $\hat{\mathscr{L}}_{\hat{H}_0}$ and the Liebniz property

$$\hat{\mathscr{L}}_{\hat{H}}(\hat{A}\hat{B}) = \hat{A}(\hat{\mathscr{L}}_{\hat{H}}\hat{B}) + (\hat{\mathscr{L}}_{\hat{H}}\hat{A})\hat{B},$$

this space receives an algebraic structure. In fact $\mathscr{N}$ is the representation of the algebra of invariants for the harmonic oscillator, and we are going to describe now its basis.

First of all, there are **d** invariants, commutative with each other, which corresponded to the individual dimensions

$$\hat{N}_i = \hat{a}_i^+ \hat{a}_i, \quad i,j = 1, \ldots, \mathbf{d}, \tag{15}$$

$$[\hat{N}_i, \hat{N}_j] = 0.$$

The oscillator Hamiltonian $\hat{H}_0$ is the function of these invariants. In the classical mechanics the corresponding invariants are called *actions*.

At this point we will distinguish between the degenerate (resonance in classical mechanics) and nondegenerate case. One has $\mathbf{r}^{th}$-fold degeneracy whenever the ω_i, $i = 1, \ldots, \mathbf{d}$, are connected by **r** (and only **r**) linearly independent relations of commensurability

$$\sum_{i=1}^{\mathbf{d}} D_{ki}\omega_i = 0, \quad k = 1, \ldots, \mathbf{r}, \tag{16}$$

where all D_{ki} are integers. We will use this in more convenient vector form

$$(\overline{\omega}, \vec{D}_k) = 0, \tag{17}$$

where $\vec{D}_k$ is the set of **r** independent vectors with integer coefficients. If ω_i are rationally independent, the problem is nondegenerate (nonresonance).

As is known from the classical mechanics, otherwise ergodic on the surface of constant actions (N_i), the phase space trajectory of the classical oscillator with commensurability relations between frequencies will be bounded to the lower dimensional tori. Projection of such tori on the coordinate space of a two-dimensional oscillator, for example, is the famous Lissajous figures. The quantum mechanical oscillator with commensurable frequencies will have degenerate energy levels. This particular type of the degeneracy is historically named *accidental*, in contrast with the another *intrinsical* degeneracy of quantum mechanical systems originated from the spatial symmetries. Our attention will be focused here on the accidentally degenerate systems, since this type of degeneracy is responsible for most of the resonances in the classical limit.

In the nondegenerate case operators $\hat{N}_i$ form a full system of **d** invariants for the anisotropic harmonic oscillator with incommensurable frequencies. But in the degenerate case the harmonic oscillator has some hidden symmetry (responsible for the accidental degeneracy), which reveals itself in the existence of $2\mathbf{r}$ additional noncommutative non-Hermitian invariants $\hat{K}_i$ and $\hat{K}_i^+$

$$\hat{K}_i=\prod_{k=1}^{\mathbf{d}} \hat{b}_k^{|D_{ik}|}(\mathrm{sign}D_{ik}), \quad \hat{b}_k(l)=\begin{cases}\hat{a}_k^+, & l=+1,\\ \hat{a}_k, & l=-1,\end{cases} \quad i=1,\ldots,\mathbf{r}. \tag{18}$$

In general not all of these invariants ($\hat{N}$'s, $\hat{K}$'s and $\hat{K}^+$'s) are independent. We will neither construct here a maximal set of independent Hermitian invariants, nor explicitly establish their algebraic properties. We only note that in the classical mechanics the corresponding polynomials form a Lie algebra, but the quantum mechanical case is more complicated, and nonlinear extensions or quantum deformations of this Lie algebra arise.[24]

Instead we will focus our attention on the set of operators that form the center of the above algebra—the set of invariants commutative with all other invariants of the harmonic oscillator. As was explicitly shown in Ref. 25 any operator commutative with all the above written invariants ($\hat{N}$'s, $\hat{K}$'s and $\hat{K}^+$'s) for the **d** dimensional harmonic oscillator with **r** commensurability relations between frequencies is a function of **d** independent operators. These operators are divided into two distinct subgroups

•$\mathbf{d}-\mathbf{r}$ operators (Gustavson invariants) of form:

$$\hat{I}_i=\sum_{j=1}^{\mathbf{d}} \alpha_{ij}\hat{N}_j, \quad i=1,\ldots,\mathbf{d}-\mathbf{r}. \tag{19}$$

Here $\vec{\alpha}_i$ is any set of $\mathbf{d}-\mathbf{r}$ independent vectors orthogonal to all **r** commensurability vectors $\vec{D}_k$

$$\sum_{j=1}^{\mathbf{d}} \alpha_{ij}D_{kj}=0, \quad \begin{matrix} i=1,\ldots,\mathbf{d}-\mathbf{r},\\ k=1,\ldots,\mathbf{r}.\end{matrix}$$

A classical version of these invariants appeared in Ref. 2 as ''integrals of motions for normal form.'' Since $(\overline{\omega,\vec{D}_k})=0$, it is clear that the oscillator Hamiltonian $\hat{H}_0$ is a linear function of these invariants $\hat{I}_i$. Sometimes such operators are named the ''first order Casimirs.''

•New complementary **r** periodic invariants (''generalized parities''[25]), without the classical counterpart, of the form

$$\hat{V}_i=\exp\left(2\pi i\sum_{j=0}^{\mathbf{d}} \beta_{ij}\hat{N}_j\right), \quad i=1,\ldots,\mathbf{r}. \tag{20}$$

Here $\vec{\beta}_i$ is a set of **d** vectors dual to $\vec{D}_k$. Such β_{ij} satisfy the system

$$\sum_j \beta_{ij}D_{kj}=\delta_{ik}, \quad i=1,\ldots,\mathbf{r}.$$

The existence of these invariants for the quantum mechanical oscillator is a direct consequence of the general commutation relation $\hat{F}(\hat{N})\hat{a}^{+m}\hat{a}^n=\hat{a}^{+m}\hat{a}^n\hat{F}(\hat{N}+m-n)$, which may be proven for any operator function $\hat{F}$ if one compares matrix elements in both sides of the identity.

As we will see further, these invariants ($\hat{I}_i$ and $\hat{V}_i$) will survive under the general perturbation of the harmonic oscillator. Unlike them, the invariants $\hat{N}_i$ and $\hat{K}_i$ will be destroyed under the perturbation. This means that there is no analytical extension of these invariants to the perturbed case.

Now, having described the unperturbed system we will return to the perturbed one.

III. THE BIRKHOFF–GUSTAVSON NORMALIZATION

In this section we will briefly describe the formal reduction of the general Hamiltonian

$$\hat{H}=\sum_{i=0}^{\infty}\alpha^i\hat{H}_i, \tag{21}$$

into a simpler form by unitary transformations with generators chosen from the range of $\hat{\mathscr{L}}_{\hat{H}_0}$. As we will see further, the word ''simpler'' means that the transformed Hamiltonian will have the diagonal or the block-diagonal matrix form. Since we deal now with the Wick normal ordered operators, we will use the following definition by Gustavson[2] for the Hamiltonian in the Birkhoff–Gustavson normal form (BGNF):

The Hamiltonian $\hat{H}=\Sigma_{i=0}^{\infty}\alpha^i\hat{H}_i$ *is in BGNF up to the order* α^n *if all terms in it of the order* α^i, $i<n$ *belong to the kernel subspace of* $\hat{\mathscr{L}}_{\hat{H}_0}$.

In other words, part of our Hamiltonian transformed into the BGNF will be commutative with the unperturbed Hamiltonian, and thus belongs to the algebra of invariants for the unperturbed problem. Note that by assumption our Hamiltonian is normalized (is in BGNF) at least up to the first order ($\hat{H}_0\in\ker\hat{\mathscr{L}}_{\hat{H}_0}$).

This definition of the normalized Hamiltonian was used by Gustavson in the case of the classical mechanics to describe the formal process of the reduction of the classical Hamiltonian to a simpler (integrable) form. The original version of normalization process used the formalism of *generating functions*, which in quantum mechanics leads to additional complications due to the noncommutability of operators. An example of a similar approach may be found in Ref. 26. Fortunately, the original Gustavson algorithm was modified[8] using formalism of *generators* of symplectic transformations,[9] which has the direct quantum mechanical counterpart. Let us now describe it.

Assume that quantum mechanical Hamiltonian of type (21) is in BGNF up to the order n. Our aim is to find such unitary transformation, after application of which, the original Hamiltonian will be normalized up to the order $n+1$

$$\begin{aligned}\hat{H}_{BG}=e^{i\alpha^n\hat{G}_n}\hat{H}e^{-i\alpha^n\hat{G}_n}&=e^{i\alpha^n\hat{\mathscr{L}}_{\hat{G}_n}}\left(\sum_{m=0}^{\infty}\alpha^m\hat{H}_m\right)\\&=\sum_{m=0}^{\infty}\alpha^m\left(\sum_{k=0}^{[m/n]}\frac{1}{k!}\hat{\mathscr{L}}^k_{i\hat{G}_n}\hat{H}_{m-nk}\right)\\&=\hat{H}_0+\alpha\hat{H}_1+\cdots+\alpha^{n-1}\hat{H}_{n-1}+\alpha^n(\hat{H}_n+\hat{\mathscr{L}}_{i\hat{G}_n}\hat{H}_0)+O(\alpha^{n+1})\\&=\text{(already normalized terms)}+\alpha^n(\hat{H}_n-i\hat{\mathscr{L}}_{\hat{H}_0}\hat{G}_n)+O(\alpha^{n+1});\end{aligned}$$

here $[m/n]$ denote an integer part of this quotient.

As was demonstrated in the previous section, we may always find the Hermitian operator $\hat{G}_n=-i\hat{\mathscr{L}}^{-1}_{\hat{H}_0}\{\hat{H}_n\}$ from $\mathscr{R}$ such that

$$\hat{\mathscr{L}}_{\hat{H}_0}\hat{G}_n=-i\{\hat{H}_n\}.$$

After the unitary transformation with generator $\hat{G}_n$ our Hamiltonian becomes normalized up to the order $n+1$ too,

$$\hat{H}_{BG}=\hat{H}_0+\alpha\langle\hat{H}_1\rangle+\cdots+\alpha^{n-1}\langle\hat{H}_{n-1}\rangle+\alpha^n\langle H_n\rangle+O(\alpha^{n+1}).$$

It is clear from the above that repeating the procedure for $n+1$, etc., we obtain a formal process of normalization of the original Hamiltonian to subsequently higher orders.

In summary, we describe the construction for initial Hamiltonian (21) and any number n of such unitary transformation

$$e^{i\alpha\hat{\Gamma}_{(n)}(\alpha)}=e^{i\alpha^n\hat{G}_n}\cdots e^{i\alpha^2\hat{G}_2}e^{i\alpha\hat{G}_1}, \tag{22}$$

that our Hamiltonian will be in the Birkhoff–Gustavson normal form up to the order $n+1$. Now we will demonstrate an application of the above defined procedure to two general classes of quantum mechanical systems.

A. Nondegenerate systems

In the case when no commensurability relations (16) exist, the unperturbed system has commutative symmetry algebra, and the kernel subspace of $\hat{\mathscr{L}}_{\hat{H}_0}$ consists only of polynomials of $\hat{N}_k$. In this case the Hamiltonian reduced to Birkhoff–Gustavson normal form became diagonal in representation of $\hat{N}_k$ operators.

A normalized part of the nondegenerate Hamiltonian will be a function of **d** Hermitian operators $\hat{N}_k$, each being commutative with all others (and the normalized part of Hamiltonian). These **d** operators form a Complete Set of Commutative Operators for such system. The explicit form of these operators in the initial representation is

$$\tilde{N}_k=e^{-i\alpha\hat{\mathscr{L}}_{\hat{\Gamma}_{(n)}}}\hat{N}_k=e^{-i\alpha\hat{G}_1}\cdots e^{-i\alpha^n\hat{G}_n}\hat{N}_k e^{i\alpha^n\hat{G}_n}\cdots e^{i\alpha\hat{G}_1}, \tag{23}$$

and may be easily calculated as a power series expansions up to the desired order in α.

Approximations of perturbed eigenvalues and eigenfunctions up to $o(\alpha^n)$ are classified by the complete set of **d** quantum numbers n_k and are given by

$$E_{\tilde{\mathbf{n}}}=H_{BG}(n_1,\ldots,n_{\mathbf{d}}),\quad |\tilde{\mathbf{n}}\rangle=e^{-i\alpha\hat{\Gamma}_{(n)}}|\overline{\mathbf{n}}\rangle. \tag{24}$$

Due to the uniqueness of asymptotic power series in α, the results of the above procedure coincide with the Rayleigh–Schrödinger perturbation expansion for eigenvalues and eigenfunctions of the perturbed quantum mechanical system.

Note that, if we restore powers of $\hbar$ in the above formulas, operators $\tilde{N}_k$ will naturally realize the program of the Einstein–Brillouin–Kemmer quantization for all orders of α in the quasi-classical approximation.[26] This fact leads also to the success of the so-called quasi-classical quantization of the Birkhoff normal form.[4]

1. Example 1. One-dimensional anharmonic oscillator

The system described by Hamiltonian

$$\hat{H}=\hat{p}^2+\hat{q}^2+\alpha\hat{q}^4.$$

After normalization of the Hamiltonian up to α^6

$$\begin{aligned}\hat{H}_{BG}=&2\left(\hat{N}+\frac{1}{2}\right)\\&+\alpha\left(\frac{3}{8}+\frac{3}{2}\left(\hat{N}+\frac{1}{2}\right)^2\right)\\&-\alpha^2\left(\frac{67}{32}\left(\hat{N}+\frac{1}{2}\right)+\frac{17}{8}\left(\hat{N}+\frac{1}{2}\right)^3\right)\end{aligned}$$

$$+\alpha^3\left(\frac{1539}{1024}+\frac{1707}{128}\left(\hat{N}+\frac{1}{2}\right)^2+\frac{375}{64}\left(\hat{N}+\frac{1}{2}\right)^4\right)$$
$$-\alpha^4\left(\frac{305141}{8192}\left(\hat{N}+\frac{1}{2}\right)+\frac{89165}{1024}\left(\hat{N}+\frac{1}{2}\right)^3+\frac{10689}{512}\left(\hat{N}+\frac{1}{2}\right)^5\right)$$
$$+\alpha^5\left(\frac{1456569}{32768}+\frac{9317949}{16384}\left(\hat{N}+\frac{1}{2}\right)^2+\frac{587265}{1024}\left(\hat{N}+\frac{1}{2}\right)^4+\frac{87549}{1024}\left(\hat{N}+\frac{1}{2}\right)^6\right)$$
$$+\cdots.$$

Here we see the first terms of the Rayleigh–Schrödinger perturbation expansion for the anharmonic oscillator. The growth of numerical coefficients in higher order terms reflects an asymptotic behavior of perturbative approximations. Using (24) we obtain perturbed eigenfunctions (not presented here).

The discussion of perturbation expansion for the quartic anharmonic oscillator and the reasons why coefficients in eigenvalues series are polynomials with the definite parity of $(\hat{N}+1/2)$ alone, may be found in Ref. 27.

B. Accidentally degenerate systems

Now we will consider a case of nonzero number of commensurability vectors (16). The unperturbed quantum mechanical system in such a case will have accidentally degenerate energy levels, and, as we have previously discussed, additional noncommutative invariants. Now the kernel subspace of $\hat{\mathscr{L}}_{\hat{H}_0}$ consists of not only polynomials of $\hat{N}_k$, but also includes all the Wick normal ordered monomials for which $(\omega,\overline{\mathbf{m}}-\overline{\mathbf{n}})=0$. The corresponding classical system is referred to as resonance.

Here and in what follows we will suppose that Hamiltonian is in BGNF up to sufficiently high order in α, and will usually omit the unnormalized part of it, dealing only with the normalized one.

It is clear from the previous section that the normalized Hamiltonian may be written in the form of power series in invariants of the unperturbed system. Due to noncommutativity of these invariants, some ordering for any term in this series must be imposed. Since not all of the above invariants are independent, this power series may be even nonunique. Series of such type appear as the ''standard form'' of the classical BGNF in Ref. 11 (in fact no connection was established in this paper between such series and the invariants of the unperturbed system).

Because **d** invariants $\hat{I}$ and $\hat{V}$ are commutative with all other invariants of the unperturbed problem, these operators will be commutative with the normalized Hamiltonian as well. This means that for the degenerate system we again have **d** commutative with each other and the Hamiltonian operators (compare to $\mathbf{d}-\mathbf{r}$ Gustavson invariants for the corresponding classical system). But now the reduced Hamiltonian $\hat{H}_{BG}$ is *not* a function of $\hat{I}$ and $\hat{V}$ operators only, and these **d** commutative operators *do not* form the Complete Set of Commutative Operators for the degenerate system.

Note, that any degenerate eigensubspace of the oscillator Hamiltonian is the degenerate eigensubspace for each of the **d** invariant operators $\hat{I}$ and $\hat{V}$ as well. This follows from the fact that quantum numbers $\vec{N}$ for two eigenvectors of $\hat{H}_0$ with the same eigenvalue may differ only in integer coefficient combination of $\vec{D}_i$. As a result eigenvalues of **d** operators $\hat{I}$ and $\hat{V}$ will *not* classify the degenerate eigenstates of the perturbed system. This is not surprising, since the splitting of $\hat{H}$ eigenvalues depends on the *perturbation* $\hat{H}_i$, and cannot be described by operators originating from the center of the algebra of invariants for the *unperturbed* system. One may obtain these perturbative invariants in the initial representation similar to those in (23).

1. Example 2. The Henon–Heiles system

The Henon–Heiles two-dimensional system was originally used by Gustavson[2] as the first example of BGNF. This system is described by (1:1) resonance Hamiltonian

$$\hat{H}=\tfrac{1}{2}(\hat{p}_1^2+\hat{q}_1^2+\hat{p}_2^2+\hat{q}_2^2)+\alpha(\hat{q}_2^3-\tfrac{1}{3}\hat{q}_1^2 q_2).$$

After normalization of Hamiltonian up to α^4

$$\begin{aligned}\hat{H}_{BG}=&\left(1-\frac{1}{9}\alpha^2-\frac{11}{108}\alpha^4\right)+\left(1-\frac{2}{3}\alpha^2-\frac{61}{54}\alpha^4\right)(\hat{a}_1^+\hat{a}_1+\hat{a}_2^+\hat{a}_2)\\&-\frac{1}{12}\alpha^2\left(5+\frac{47}{4}\alpha^2\right)(\hat{a}_1^{+2}\hat{a}_1^2+\hat{a}_2^{+2}\hat{a}_2^2)-\frac{7}{12}\alpha^2\left(1-\frac{1}{4}\alpha^2\right)(\hat{a}_1^{+2}\hat{a}_2^2+\hat{a}_2^{+2}\hat{a}_1^2)\\&+\frac{1}{3}\alpha^2\left(1-\frac{27}{4}\alpha^2\right)\hat{a}_1^+\hat{a}_2^+\hat{a}_1\hat{a}_2\\&+\alpha^4\left(+\frac{101}{432}\hat{a}_1^{+3}\hat{a}_1^3-\frac{161}{144}\hat{a}_1^{+3}\hat{a}_1\hat{a}_2^2-\frac{65}{16}\hat{a}_1^{+2}\hat{a}_2^+\hat{a}_1^2\hat{a}_2+\frac{175}{144}\hat{a}_1^{+2}\hat{a}_2^+\hat{a}_2^3\right.\\&\left.-\frac{235}{432}\hat{a}_2^{+3}\hat{a}_2^3-\frac{161}{144}\hat{a}_1^+\hat{a}_2^{+2}\hat{a}_1^3+\frac{47}{16}\hat{a}_1^+\hat{a}_2^{+2}\hat{a}_1\hat{a}_2^2+\frac{175}{144}\hat{a}_2^{+3}\hat{a}_1^2\hat{a}_2\right)\\&+\ldots\ .\end{aligned}\tag{25}$$

The above discussion systematizes the structure of the normalized Hamiltonian, but unfortunately has not answered the question about eigenvalues and eigenfunctions of the perturbed system. The definite solution of this may be obtained following the guidelines of the Rayleigh–Schrödinger perturbation theory for degenerate systems.

As we have already noticed, in the degenerate case the Hamiltonian reduced to the BGNF is, in general, not diagonal in the $\hat{N}_k$ representation. But, since the normalized part of the Hamiltonian $\hat{H}_{BG}$ is *commutative* with the unperturbed Hamiltonian $\hat{H}_0$, the matrix of $\hat{H}_{BG}$ must be *block-diagonal* in this representation, with blocks corresponding to degenerate eigenstates of $\hat{H}_0$. This apparently becomes evident if one converts $\hat{H}_{BG}$ into the matrix form. Doing this, it is easy to recognize that the condition $(\overline{\omega,\mathbf{n}})=(\overline{\omega,\mathbf{m}})$ means that all nonzero matrix elements of $\hat{H}_{BG}$ must connect only states corresponding to the same energy of the unperturbed system.

At this point one usually performs the standard procedure for the Rayleigh–Schrödinger perturbation theory:

With account for the matrix form of $\hat{H}_{BG}$ being block-diagonal, one needs solve secular equations for these blocks and perform a unitary diagonalizing transformation inside each block independently, obtaining eigenvalues and eigenvectors for the perturbed system.

This procedure supposes the conversion of $\hat{H}_{BG}$ into the matrix form. But it is interesting that we can perform essentially the same diagonalization in the Wick normal form of operators as well. This leads to an unusual class of unitary transformations, not infinitesimal in nature, which we will also refer to as the Rayleigh–Schrödinger transformations.

IV. RAYLEIGH–SCHRÖDINGER TRANSFORMATIONS

We will utilize now the obvious fact that due to algebraic structure, the kernel subspace of $\hat{\mathscr{L}}_{\hat{H}_0}$ is stable against unitary transformations from it. For any monomial, belonging to the kernel subspace $\mathscr{N}$ of $\hat{\mathscr{L}}_{\hat{H}_0}$ (or, equivalently, the algebra of invariants for the harmonic oscillator), we introduce the characteristic functional Λ

$$\Lambda(\hat{a}^{+\overline{\mathbf{n}}}\hat{a}^{\overline{\mathbf{m}}}) \overset{\text{def}}{=} (\overline{\omega,\mathbf{m}}) = (\overline{\omega,\mathbf{n}}). \tag{26}$$

This characteristic functional will take values of energy levels of the unperturbed system. The value of this characteristic functional for a polynomial operator will be the minimum of Λ values for individual monomials in that operator.

Now we can group the terms of the reduced Hamiltonian by Λ values

$$\hat{H}_{BG} = \sum_{\Lambda} \sum_{\substack{\overline{\mathbf{m},\mathbf{n}} \\ (\omega,\overline{\mathbf{n}})=\Lambda \\ (\omega,\overline{\mathbf{m}})=\Lambda}} H^{(W)}_{\overline{\mathbf{m},\mathbf{n}}} \frac{\hat{a}^{+\overline{\mathbf{m}}}}{\sqrt{\overline{\mathbf{m}!}}} \frac{\hat{a}^{\overline{\mathbf{n}}}}{\sqrt{\overline{\mathbf{n}!}}}. \tag{27}$$

We note here that the expansion of any operator belonging to $\mathcal{N}$ into the power series in $\hat{a}^+$ and $\hat{a}$ leads to the expansion in monomials with increasing values of characteristic functional Λ.

Whereas all presented in this section is quite clear from the matrix form point of view, it is not the case with the Wick normal ordered form of operators. Appendix B will shed some light on the underlying mathematics for products of Wick normal ordered operators belonging to $\mathcal{N}$.

In this appendix we demonstrate that:

- The value of characteristic functional Λ for the product of two operators is greater or equal to that of multipliers

$$\Lambda(\hat{A}\hat{B}) \geqslant \max(\Lambda(\hat{A}), \Lambda(\hat{B})).$$

- Terms having the minimal allowed value of $\Lambda = \Lambda_0$ in the product of two homogeneous operators: $\hat{A}, \hat{B} \in \mathcal{N}$, $\Lambda(\hat{A}) = \Lambda(\hat{B}) = \Lambda_0$, will obey the matrix multiplication law

$$\sum_{\mathbf{k}\mathbf{l}} A_{\overline{\mathbf{k}\mathbf{l}}} \frac{\hat{a}^{+\overline{\mathbf{k}}}}{\sqrt{\overline{\mathbf{k}!}}} \frac{\hat{a}^{\overline{\mathbf{l}}}}{\sqrt{\overline{\mathbf{l}!}}} \sum_{\mathbf{m}\mathbf{n}} B_{\overline{\mathbf{m}\mathbf{n}}} \frac{\hat{a}^{+\overline{\mathbf{m}}}}{\sqrt{\overline{\mathbf{m}!}}} \frac{\hat{a}^{\overline{\mathbf{n}}}}{\sqrt{\overline{\mathbf{n}!}}} = \sum_{\mathbf{k}\mathbf{n}} \left(\sum_{\mathbf{m}} A_{\overline{\mathbf{k}\mathbf{m}}} B_{\overline{\mathbf{m}\mathbf{n}}} \right) \frac{\hat{a}^{+\overline{\mathbf{k}}}}{\sqrt{\overline{\mathbf{k}!}}} \frac{\hat{a}^{\overline{\mathbf{n}}}}{\sqrt{\overline{\mathbf{n}!}}} + (\cdots).$$

We proceed now to the explicit construction of the diagonalizing transformation. Let us consider, for any possible value of $\Lambda = \Lambda_0$, a subspace of our Hilbert space spanned by eigenvectors of $\hat{H}_0$ with an eigenvalue equal to Λ_0. The orthogonal projector on this finite-dimensional subspace is

$$\hat{P} = \sum_{\substack{\overline{\mathbf{n}} \\ (\omega,\overline{\mathbf{n}})=\Lambda_0}} |\overline{\mathbf{n}}\rangle\langle\overline{\mathbf{n}}|.$$

Using (9) we convert this projector into the Wick normal ordered form

$$\hat{P} = \sum_{\Lambda \geqslant \Lambda_0} \sum_{\substack{\overline{\mathbf{n}} \\ (\omega,\overline{\mathbf{n}})=\Lambda}} \left\{ \sum_{\substack{\overline{\mathbf{k}\leqslant\mathbf{n}} \\ (\omega,\overline{\mathbf{k}})=\Lambda-\Lambda_0}} (-1)^{|\overline{\mathbf{k}}|} C^{\overline{\mathbf{k}}}_{\overline{\mathbf{n}}} \right\} \frac{\hat{a}^{+\overline{\mathbf{n}}}\hat{a}^{\overline{\mathbf{n}}}}{\overline{\mathbf{n}!}}. \tag{28}$$

For any unitary matrix $u_{\overline{\mathbf{m}\mathbf{n}}}$ with dimensions equal to those of this Λ_0 subspace we construct corresponding operator $\hat{u} = \Sigma u_{\overline{\mathbf{m}\mathbf{n}}} |\overline{\mathbf{m}}\rangle\langle\overline{\mathbf{n}}|$ with the properties

$$\hat{u}^+\hat{u} = \hat{P},$$
$$\hat{u}\hat{P} = \hat{P}\hat{u} = \hat{u},$$
$$[\hat{H}_0, \hat{u}] = 0.$$

Again we convert this ''unitary inside block'' operator into the Wick normal ordered form as

$$\hat{u}=\sum_{\Lambda\geqslant\Lambda_0}\left\{\sum_{\substack{\overline{\mathbf{m}},\overline{\mathbf{n}},\overline{\mathbf{k}}\\(\omega,\overline{\mathbf{n}})=\Lambda_0\\(\omega,\overline{\mathbf{m}})=\Lambda_0\\(\omega,\overline{\mathbf{k}})=\Lambda-\Lambda_0}}(-1)^{|\overline{\mathbf{n}}|}u_{\overline{\mathbf{m}},\overline{\mathbf{n}}}\sqrt{C^{\overline{\mathbf{k}}}_{\overline{\mathbf{m}}+\overline{\mathbf{k}}}C^{\overline{\mathbf{k}}}_{\overline{\mathbf{n}}+\overline{\mathbf{k}}}}\frac{\hat{a}^{+\overline{\mathbf{m}}+\overline{\mathbf{k}}}}{\sqrt{(\overline{\mathbf{m}}+\overline{\mathbf{k}})!}}\frac{\hat{a}^{\overline{\mathbf{n}}+\overline{\mathbf{k}}}}{\sqrt{(\overline{\mathbf{n}}+\overline{\mathbf{k}})!}}\right\}. \tag{29}$$

To finish the construction of the commutative with $\hat{H}_0$ unitary operator we must extend $\hat{u}$ to our full Hilbert space as

$$\hat{U}=1-\hat{P}+\hat{u}. \tag{30}$$

This operator is the normal form of the unitary transformation performed in the Λ_0 block of the matrix form independently. The transformation of this type is used in the Rayleigh–Schrödinger perturbation theory for the final diagonalization of the degenerate block in the Hamiltonian. We explicitly present here expressions [(28)–(30)] to outline the cumbersome structure of $\hat{U}$ in the Wick normal ordered form. The construction of the above operator makes it clear that performing the subsequent unitary transformations of type (30) we will diagonalize the Hamiltonian reduced to BGNF by blocks with increasing values of characteristic functional Λ.

Indeed, suppose that all terms in our Hamiltonian with the value of characteristic functional $\Lambda<\Lambda_0$ are already diagonalized

$$\hat{H}_{BG}=\sum_{(\omega,\mathbf{k})<\Lambda_0}H^{(\Lambda)}_{\mathbf{kk}}\frac{\hat{a}^{+\overline{\mathbf{k}}}\hat{a}^{\overline{\mathbf{k}}}}{\mathbf{k}!}+\sum_{\substack{(\omega,\overline{\mathbf{n}})=\Lambda_0\\(\omega,\overline{\mathbf{m}})=\Lambda_0}}H^{(\Lambda_0)}_{\overline{\mathbf{mn}}}\frac{\hat{a}^{+\overline{\mathbf{m}}}}{\sqrt{\overline{\mathbf{m}}!}}\frac{\hat{a}^{\overline{\mathbf{n}}}}{\sqrt{\overline{\mathbf{n}}!}}+(\cdots). \tag{31}$$

In order to construct the diagonalizing transformation $\hat{U}$ we must solve the following secular equation:

$$\det\left(H^{(\Lambda_0)}_{\overline{\mathbf{mn}}}+\sum_{(\omega,\mathbf{k})<\Lambda_0}H^{(\Lambda)}_{\mathbf{kk}}C^{\overline{\mathbf{k}}}_{\overline{\mathbf{n}}}\delta_{\overline{\mathbf{mn}}}-E_{\overline{\mathbf{nn}}}\delta_{\overline{\mathbf{mn}}}\right)=0. \tag{32}$$

Suppose that we can obtain its solution at least as a power series in some rational power of α (Puizeaux series). After this we will have the diagonalizing unitary finite-dimensional matrix $u_{\overline{\mathbf{mn}}}$ and construct its normal form (30). In the transformed operator

$$\hat{H}_D=\hat{U}\hat{H}_{BG}\hat{U}^{+},$$

all terms with the characteristic value $\Lambda=\Lambda_0$ will also be diagonal.

This process results in the expansion of the Hamiltonian in diagonal operators with increasing characteristic values of Λ, or equivalently, the increasing powers of raising and lowering operators. If we cut this expansion on some value of $\Lambda=\Lambda_0$, then analytical expressions for all exited states originating from states of the unperturbed Hamiltonian with the energy $E\leqslant\Lambda_0$ will be obtained up to the desired order of perturbation parameter α.

After such transformation the diagonalized part of $\hat{H}_D$ will be an (operator) function of **d** commutative operators $\widetilde{N}_i$. Eigenvalues of these operators will classify eigenvalues of the perturbed system with the complete set of **d** quantum numbers.

1. Example 2 (continued). Complete diagonalization of the Henon–Heiles system

As one may see from the previous example, for the reduced to the BGNF Henon–Heiles Hamiltonian (25), the first excited state, corresponding to $\Lambda=1$, is doubly degenerate. But the reduced Hamiltonian is already diagonal on the subspace spanned by kets $\hat{a}_1^+|\mathbf{0}\rangle$ and $\hat{a}_2^+|\mathbf{0}\rangle$.

On subspaces of the next exited states, corresponding to $\Lambda=2$ and 3 this Hamiltonian will be diagonalized by the unitary transformation $\hat{H}_D=\hat{U}\hat{H}_{BG}\hat{U}^+$, where

$$\begin{aligned}\hat{U}=1&+\frac{\sqrt{2}}{4}\hat{a}_2^{+2}\hat{a}_1^2-\frac{1}{2}\left(1-\frac{\sqrt{2}}{2}\right)\hat{a}_2^{+2}\hat{a}_2^2-\frac{\sqrt{2}}{4}\hat{a}_1^{+2}\hat{a}_2^2-\frac{1}{2}\left(1-\frac{\sqrt{2}}{2}\right)\hat{a}_1^{+2}\hat{a}_1^2\\&+\left(\frac{1}{3}-\frac{\sqrt{2}}{4}\right)\hat{a}_1^{+3}\hat{a}_1^3+\frac{1}{4}\hat{a}_1^{+3}\hat{a}_1^2\hat{a}_2+\frac{\sqrt{2}}{4}\hat{a}_1^{+3}\hat{a}_1\hat{a}_2^2-\frac{1}{12}\hat{a}_1^{+3}\hat{a}_2^3\\&+\frac{1}{4}\hat{a}_1^{+2}\hat{a}_2^+\hat{a}_1^3-\frac{\sqrt{2}}{4}\hat{a}_1^{+2}\hat{a}_2^+\hat{a}_1^2\hat{a}_2+\frac{1}{4}\hat{a}_1^{+2}\hat{a}_2^+\hat{a}_1\hat{a}_2^2+\frac{\sqrt{2}}{4}\hat{a}_1^{+2}\hat{a}_2^+\hat{a}_2^3\\&-\frac{\sqrt{2}}{4}\hat{a}_1^+\hat{a}_2^{+2}\hat{a}_1^3+\frac{1}{4}\hat{a}_1^+\hat{a}_2^{+2}\hat{a}_1^2\hat{a}_2-\frac{\sqrt{2}}{4}\hat{a}_1^+\hat{a}_2^{+2}\hat{a}_1\hat{a}_2^2+\frac{1}{4}\hat{a}_1^+\hat{a}_2^{+2}\hat{a}_2^3\\&+\frac{1}{12}\hat{a}_2^{+3}\hat{a}_1^3-\frac{\sqrt{2}}{4}\hat{a}_2^{+3}\hat{a}_1^2\hat{a}_2-\frac{1}{4}\hat{a}_2^{+3}\hat{a}_1\hat{a}_2^2+\left(\frac{1}{3}-\frac{\sqrt{2}}{4}\right)\hat{a}_2^{+3}\hat{a}_2^3+(\cdots).\end{aligned}\tag{33}$$

Here the first row diagonalizes $\Lambda=2$ part of $\hat{H}_{BG}$. It is easy to check the unitarity (up to $\Lambda=3$) of the above transformation. The transformed Hamiltonian will now take the following diagonal form:

$$\begin{aligned}\hat{H}_D=&\left(1-\frac{1}{9}\alpha^2-\frac{11}{108}\alpha^4\right)+\left(1-\frac{2}{3}\alpha^2-\frac{61}{54}\alpha^4\right)\hat{N}_1+\left(1-\frac{2}{3}\alpha^2-\frac{61}{54}\right)\alpha^4\hat{N}_2\\&+\alpha^2\left(\frac{1}{3}-\frac{9}{4}\alpha^2\right)\hat{N}_1\hat{N}_2\\&+\frac{1}{2}\alpha^2\left(\frac{1}{3}-\frac{9}{4}\alpha^2\right)(\hat{N}_1-1)_2-\alpha^2\left(1+\frac{5}{6}\alpha^2\right)(\hat{N}_2-1)_2\\&+\alpha^2\left(\frac{7}{6}+\frac{229}{216}\alpha^2\right)(\hat{N}_2-2)_3-\frac{95}{54}\alpha^4(\hat{N}_1-2)_3\\&-\alpha^2\left(\frac{7}{6}+\frac{1}{8}\alpha^2\right)\hat{N}_1(\hat{N}_2-1)_2-\alpha^2\left(\frac{7}{3}-\frac{1}{6}\alpha^2\right)\hat{N}_2(\hat{N}_1-1)_2+(\cdots).\end{aligned}\tag{34}$$

Notation $(x)_n$ is used here for the Pochammer polynomial

$$(x)_n=x(x+1)\cdots(x+n-1).$$

Note that (34) holds only for the values of quantum numbers n_1 and n_2 such that $n_1+n_2\leqslant 3$. This formula provides us with analytical expressions up to $o(\alpha^4)$ for the 10 lowest eigenvalues of the Henon–Heiles system.

An alternative to the above diagonalization process may be established. Since we deal with the Wick normal ordered operators, it is even more natural to diagonalize $\Lambda=\Lambda_0$ terms in (31) using the explicitly unitary operator

$$\hat{H}_D=e^{i\hat{\mathscr{Z}}_{\hat{w}}}\hat{H}_{BG}=\hat{U}\hat{H}_{BG}\hat{U}^+,$$

where

$$\hat{U}=e^{i\hat{w}}=\exp\left(i\sum_{\substack{(\omega,\mathbf{n})=\Lambda_0\\(\omega,\overline{\mathbf{m}})=\Lambda_0}} w_{\overline{\mathbf{mn}}}\frac{\hat{a}^{+\overline{\mathbf{m}}}}{\sqrt{\overline{\mathbf{m}!}}}\frac{\hat{a}^{\overline{\mathbf{n}}}}{\sqrt{\overline{\mathbf{n}!}}}\right), \tag{35}$$

and $w_{\overline{\mathbf{mn}}}$ is a finite dimensional Hermitian matrix such that the exponent of it coincides with the used above finite dimensional diagonalizing unitary matrix $u_{\overline{\mathbf{mn}}}$

$$u_{\overline{\mathbf{mn}}}=(e^{iw})_{\overline{\mathbf{mn}}}. \tag{36}$$

It immediately follows from the results of Appendix B that $\Lambda=\Lambda_0$ terms in operator (35) coincide with those of the Rayleigh–Schrödinger transformation (28)–(30), and therefore the transformed Hamiltonian will also become diagonal in Λ_0 terms. To continue the diagonalization process, we need to calculate terms with characteristic value $\Lambda>\Lambda_0$ in operator exponent (35). We can perform this exponentiation using the block-diagonality of the operator

$$\hat{w}=\sum_{\substack{(\omega,\mathbf{n})=\Lambda_0\\(\omega,\overline{\mathbf{m}})=\Lambda_0}} w_{\overline{\mathbf{mn}}}\frac{\hat{a}^{+\overline{\mathbf{m}}}}{\sqrt{\overline{\mathbf{m}!}}}\frac{\hat{a}^{\overline{\mathbf{n}}}}{\sqrt{\overline{\mathbf{n}!}}}.$$

At first we convert the operator $\hat{w}$ into the matrix form. Since it is block-diagonal, the exponent of $\hat{w}$ is reduced to exponentiation of independent finite-dimensional blocks, and may be performed by algebraic methods. The last step will be to convert the resulting operator again into the Wick normal ordered form. Unfortunately secular equations appearing during the application of this process are, in general, more complicated.

2. Example 3. Exponent of block diagonal operator

Diagonalization of $\Lambda=2$ terms in the Hamiltonian of Henon–Heiles system (25) was done in Example 2 by the first row of (33). Alternatively we may use the operator:

$$\hat{U}=\exp\frac{\pi}{8}(\hat{a}_2^{+2}\hat{a}_1^2-\hat{a}_1^{+2}\hat{a}_2^2).$$

For illustration purposes we calculate the Wick normal ordered form of this operator up to $\Lambda=3$ terms using the above procedure

$$\begin{aligned}\hat{U}=1&+\frac{\sqrt{2}}{4}\hat{a}_2^{+2}\hat{a}_1^2-\frac{1}{2}\left(1-\frac{\sqrt{2}}{2}\right)\hat{a}_2^{+2}\hat{a}_2^2-\frac{\sqrt{2}}{4}\hat{a}_1^{+2}\hat{a}_2^2-\frac{1}{2}\left(1-\frac{\sqrt{2}}{2}\right)\hat{a}_1^{+2}\hat{a}_1^2\\&+\left(\frac{1}{3}-\frac{\sqrt{2}}{4}+\frac{1}{6}\cos\left(\frac{\sqrt{3}}{4}\pi\right)\right)(\hat{a}_2^{+3}\hat{a}_2^3+\hat{a}_1^{+3}\hat{a}_1^3)\\&+\left(\frac{\sqrt{2}}{4}-\frac{\sqrt{3}}{6}\sin\left(\frac{\sqrt{3}}{4}\pi\right)\right)(\hat{a}_1^{+3}\hat{a}_1\hat{a}_2^2+\hat{a}_1^{+2}\hat{a}_2^+\hat{a}_2^3-\hat{a}_1^+\hat{a}_2^{+2}\hat{a}_1^3-\hat{a}_3^{+3}\hat{a}_1^2\hat{a}_2)\\&+\left(\frac{1}{2}\cos\left(\frac{\sqrt{3}}{4}\pi\right)-\frac{\sqrt{2}}{4}\right)(\hat{a}_1^+\hat{a}_2^{+2}\hat{a}_1\hat{a}_2^2+\hat{a}_1^{+2}\hat{a}_2^+\hat{a}_1^2\hat{a}_2)+(\cdots).\end{aligned}$$

We note that (35) is a straightforward generalization of the transformation used by Bogolyubov and Bogolyubov[20] for the diagonalization of $\Lambda=1$ bilinear operator forms.

If we restore the $\hbar$ in the above constructions, it becomes clear that these diagonalization processes are of pure quantum origin, without the classical analogue. Indeed, increasing powers of $\hbar$ will appear in the denominators of expressions corresponding to the higher energy levels. In the classical region ($N_i \to \infty$, $\hbar \to 0$, $\hbar N_i = \text{const}$), whenever the multiplicity of the degenerate energy levels tends to infinity, such diagonalizing transformations, as well as the additional perturbative invariants $\hat{V}_i$ will not have the definite limit. However more detailed studies of the intermediate quasiclassical region should be performed.

V. SUMMARY AND DISCUSSIONS

In this paper we have described the Birkhoff–Gustavson normalization as a procedure to transform the Hamiltonian of **d** dimensional harmonic oscillator with polynomial perturbation into the operator belonging to the algebra of invariants for the unperturbed problem. The transformed Hamiltonian was obtained (at least formally) as an expansion in powers of perturbation constant and generators of this algebra.

It is known[10] that in the classical perturbation theory the **d** dimensional system with the **r** resonance conditions between frequencies may be (formally) reduced to the **r** dimensional system. This reduction is made using $\mathbf{d}-\mathbf{r}$ Gustavson invariants, since each of them may be analytically continued to the invariant of perturbed system. But the classical Hamiltonian with more than one degree of freedom is, in general, nonintegrable. This means that, in general, the classical perturbation theory failed to give analytical predictions for the system with two or more resonance conditions. The perturbative description of such systems is possible only for very special classes of resonance conditions and/or perturbations.

Unlike this, the quantum mechanical perturbation theory does not have this conceptual difficulty and always results in definite (formal, but frequently asymptotic) approximations to eigenvalues and eigenvectors of the perturbed system. As has been shown in the previous section, this leads to the fact that we can always construct the process of diagonalization of the quantum mechanical Birkhoff–Gustavson normal form. Possibly, this rather different behavior of two very close in spirit procedures may be attributed to the existence of **r** additional quantum mechanical invariants.

From the other point of view, we note that the described diagonalization of the quantum mechanical BGNF is achieved using two different power series expansions. One of them was made in powers of the perturbation constant α, and the other in powers of ladder operators $\hat{a}$ and $\hat{a}^+$. Classical mechanics is more restrictive. Since all classical variables are commutative, the BGNF expansion in powers of α coincides with the expansion in powers of a and a^+. Moreover, the original definitions by Birkhoff[1] and Gustavson[2] of normalization procedure were made in terms of power series in variables, rather than the perturbation constant. Because of this, one cannot, in general, diagonalize the reduced-to-BGNF classical Hamiltonian.

It is worth mentioning that the described diagonalization process, when applied to the Wick normal ordered operators, includes the construction of very interesting, not infinitesimally close to unity, unitary transformations. These transformations may be treated as nonlinear generalizations of the finite dimensional Bogolyubov transformations.

In summary, we demonstrate that the Birkhoff–Gustavson normalization procedure for the perturbed multidimensional harmonic oscillator may be extended, in the quantum mechanics, to the full equivalent of the Rayleigh–Schrödinger perturbation expansion for such a system. All steps of this procedure are performed on Wick normal ordered operators.

APPENDIX A: THE LIOUVILLE SUPEROPERATOR

We summarize here some of the properties of general Liouville superoperator $\hat{\mathscr{L}}_{\hat{H}}$ (α, β and ϵ constants):

1. $\hat{\mathscr{L}}_{\hat{H}}$ is linear: $\hat{\mathscr{L}}_{\hat{H}}(\alpha\hat{A}+\beta B)=\alpha\hat{\mathscr{L}}_{\hat{H}}A+\beta\hat{\mathscr{L}}_{\hat{H}}B$,
2. and antisymmetric: $\hat{\mathscr{L}}_{\hat{A}}\hat{B}=-\hat{\mathscr{L}}_{\hat{B}}\hat{A}$,
3. it obeys the Liebniz rule: $\hat{\mathscr{L}}_{\hat{H}}(\hat{A}\hat{B})=\hat{A}(\hat{\mathscr{L}}_{\hat{H}}B)+(\hat{\mathscr{L}}_{\hat{H}}A)\hat{B}$,
4. and the Jakoby identity: $\hat{\mathscr{L}}_{\hat{H}}([\hat{A},\hat{B}])=[\hat{A},\hat{\mathscr{L}}_{\hat{H}}\hat{B}]+[\hat{\mathscr{L}}_{\hat{H}}\hat{A},\hat{B}]$,
5. or equivalently: $\hat{\mathscr{L}}_{[\hat{A},\hat{B}]}=[\hat{\mathscr{L}}_{\hat{A}},\hat{\mathscr{L}}_{\hat{B}}]$,
6. $\hat{\mathscr{L}}^{n}_{\hat{H}}[\hat{A},\hat{B}]=\Sigma^{n}_{m=0}C^{m}_{n}[\hat{\mathscr{L}}^{m}_{\hat{H}}\hat{A},\hat{\mathscr{L}}^{n-m}_{\hat{H}}\hat{B}]$,

an exponent of it is the linear map which preserves the algebraic properties of operators:

7. $e^{\epsilon\hat{\mathscr{L}}_{\hat{H}}}(\alpha\hat{A}+\beta B)=\alpha e^{\epsilon\hat{\mathscr{L}}_{\hat{H}}}\hat{A}+\beta e^{\epsilon\hat{\mathscr{L}}_{\hat{H}}}\hat{B}$,
8. $e^{\epsilon\hat{\mathscr{L}}_{\hat{H}}}(\hat{A}\hat{B})=(e^{\epsilon\hat{\mathscr{L}}_{\hat{H}}}\hat{A})(e^{\epsilon\hat{\mathscr{L}}_{\hat{H}}}\hat{B})$,
9. $e^{\epsilon\hat{\mathscr{L}}_{\hat{H}}}[\hat{A},\hat{B}]=[e^{\epsilon\hat{\mathscr{L}}_{\hat{H}}}\hat{A},e^{\epsilon\hat{\mathscr{L}}_{\hat{H}}}\hat{B}]$,
10. and may be decomposed as: $e^{\epsilon\hat{\mathscr{L}}_{\hat{H}}}\hat{A}=e^{\epsilon\hat{H}}\hat{A}e^{-\epsilon\hat{H}}$.

Properties 1–9 take place both in the quantum and classical case with the corresponding change, whenever needed, of the commutator to the Poisson bracket ($[.,.]\to\{.,.\}$).

APPENDIX B: PRODUCTS OF INVARIANT POLYNOMIALS

Consider the product of two operators $\hat{A}$ and $\hat{B}$ belonging to the kernel subspace of $\hat{\mathscr{L}}_{\hat{H}_0}$. We assume that minimal values of the characteristic functional $\Lambda(\hat{a}^{+\overline{\mathbf{m}}}\hat{a}^{\overline{\mathbf{n}}})=(\overline{\omega,\mathbf{m}})=(\overline{\omega,\mathbf{n}})$ for monomials in each of the above operators are Λ_A and Λ_B, respectively. We are interested in terms with the minimal value of Λ in this product. Using (4) we may write down these terms as

$$\sum_{\overline{\mathbf{kl}}}\frac{A_{\overline{\mathbf{kl}}}}{\sqrt{\mathbf{k!l!}}}\hat{a}^{+\overline{\mathbf{k}}}\hat{a}^{\overline{\mathbf{l}}}\sum_{\overline{\mathbf{mn}}}\frac{B_{\overline{\mathbf{mn}}}}{\sqrt{\mathbf{m!n!}}}\hat{a}^{+\overline{\mathbf{m}}}\hat{a}^{\overline{\mathbf{n}}}=\sum_{\overline{\mathbf{klmn}}}D_{\overline{\mathbf{klmn}}}\hat{a}^{+\overline{\mathbf{k}}+\overline{\mathbf{m}}-\min(\overline{\mathbf{l}},\overline{\mathbf{m}})}\hat{a}^{\overline{\mathbf{n}}+\overline{\mathbf{l}}-\min(\overline{\mathbf{l}},\overline{\mathbf{m}})}+(\cdots)$$

$$=\sum_{\overline{\mathbf{klmn}}}D_{\overline{\mathbf{klmn}}}\hat{a}^{+\overline{\mathbf{k}}-\overline{\mathbf{l}}+\max(\overline{\mathbf{l}},\overline{\mathbf{m}})}\hat{a}^{\overline{\mathbf{n}}-\overline{\mathbf{m}}+\max(\overline{\mathbf{l}},\overline{\mathbf{m}})}+(\cdots), \tag{B1}$$

where terms with the greater value of characteristic functional Λ are denoted by $(\cdots)$. The notation ''$\max(\overline{\mathbf{l},\mathbf{m}})$'' is used for the vector, each component of which is the maximum of the correspondent component of $\overline{\mathbf{l}}$ and $\overline{\mathbf{m}}$. Coefficients D are

$$D_{\overline{\mathbf{klmn}}}=\frac{A_{\overline{\mathbf{kl}}}}{\sqrt{\mathbf{k!l!}}}\frac{B_{\overline{\mathbf{mn}}}}{\sqrt{\mathbf{m!n!}}}(\min(\overline{\mathbf{l},\mathbf{m}}))!C^{\overline{\mathbf{m}}-\min(\overline{\mathbf{l}},\overline{\mathbf{m}})}_{\overline{\mathbf{m}}}C^{\overline{\mathbf{l}}-\min(\overline{\mathbf{l}},\overline{\mathbf{m}})}_{\overline{\mathbf{l}}}.$$

Let us calculate characteristic values Λ for explicitly written terms in (B1)

$$\Lambda=(\overline{\omega,\mathbf{n}}-\overline{\mathbf{m}}+\max(\overline{\mathbf{l},\mathbf{m}}))=(\overline{\omega,}\max(\overline{\mathbf{l},\mathbf{m}}))\geqslant\begin{cases}(\omega,\overline{\mathbf{l}})=\Lambda_A,\\(\omega,\overline{\mathbf{m}})=\Lambda_B,\end{cases}$$

since all $\omega_i>0$.

Consider now the homogeneous case, whenever each monomial in both operators has equal characteristic value Λ_0. The minimal allowed value of Λ in product $\hat{A}\hat{B}$ will have terms with $\Lambda=\Lambda_0$, or

$$(\overline{\omega},\max(\overline{\mathbf{l}},\overline{\mathbf{m}}))=(\overline{\omega},\overline{\mathbf{l}}),$$

$$(\overline{\omega},\max(\overline{\mathbf{l}},\overline{\mathbf{m}}))=(\overline{\omega},\overline{\mathbf{m}}).$$

The above equalities may take place only for $\overline{\mathbf{l}}=\overline{\mathbf{m}}$. So, the product of homogeneous in Λ polynomials will take the form

$$\sum_{\mathbf{k}\,\mathbf{l}} A_{\overline{\mathbf{k}\,\mathbf{l}}}\frac{\hat{a}^{+\overline{\mathbf{k}}}}{\sqrt{\mathbf{k}!}}\frac{\hat{a}^{\overline{\mathbf{l}}}}{\sqrt{\mathbf{l}!}}\sum_{\mathbf{m}\,\mathbf{n}} B_{\overline{\mathbf{m}\,\mathbf{n}}}\frac{\hat{a}^{+\overline{\mathbf{m}}}}{\sqrt{\overline{\mathbf{m}!}}}\frac{\hat{a}^{\overline{\mathbf{n}}}}{\sqrt{\overline{\mathbf{n}!}}}=\sum_{\mathbf{k}\,\overline{\mathbf{n}}}\left(\sum_{\mathbf{m}} A_{\overline{\mathbf{k}\mathbf{m}}}B_{\overline{\mathbf{m}\,\mathbf{n}}}\right)\frac{\hat{a}^{+\overline{\mathbf{k}}}}{\sqrt{\mathbf{k}!}}\frac{\hat{a}^{\overline{\mathbf{n}}}}{\sqrt{\overline{\mathbf{n}!}}}+(\cdots). \tag{B2}$$

This is the standard matrix multiplication law.

Geometries of quantum states

Dénes Petz[a] and Csaba Sudár
Department of Mathematics, Faculty of Chemical Engineering,
Technical University Budapest, H-1521 Budapest XI. Sztoczek u. 2, Hungary

(Received 15 February 1995; accepted for publication 14 February 1996)

The quantum analog of the Fisher information metric of a probability simplex is searched and several Riemannian metrics on the set of positive definite density matrices are studied. Some of them appeared in the literature in connection with Cramér–Rao-type inequalities or the generalization of the Berry phase to mixed states. They are shown to be stochastically monotone here. All stochastically monotone Riemannian metrics are characterized by means of operator monotone functions and it is proven that there exist a maximal and a minimal among them. A class of metrics can be extended to pure states and a constant multiple of the Fubini–Study metric appears in the extension. © *1996 American Institute of Physics.* [S0022-2488(96)00706-2]

I. INTRODUCTION

The state space of a classical system with n alternatives is the simplex of probability distributions on the n-point-space. The probability simplex is an $n-1$- dimensional manifold with boundary and its affine structure is fairly trivial. The extreme boundary consists of n discrete points. In quantum mechanics, the state space of an n level system is identified with the set of all $n\times n$ positive semidefinite complex matrices of trace 1. (They are called density matrices.) The case $n=2$ is easily visualized as the unit ball in the three-space.

$$\frac{1}{2}\begin{pmatrix} 1+x & y+iz \\ y-iz & 1-x \end{pmatrix} \leftrightarrow (x,y,z)\in\mathbb{R}^3 \quad (x^2+y^2+z^2\leqslant 1).$$

The boundary consists of noninvertible matrices and it is an infinite set. The case $n=2$ is simple but for higher n the structure of the topological boundary is rather complicated. The extreme boundary consists of the density matrices of rank one and for $n>2$ it is much smaller than the topological boundary. As far as dimensionality is concerned, the topological boundary has dimension n^2-2 and the extreme one has dimension $2n-2$. The extreme states are usually called pure and they are described in the textbooks by nonzero vectors of a complex Hilbert space of linear dimension n. The same state is described by a vector ψ as well as $\lambda\psi$, where λ is any complex number different from 0. This means that pure states are in one-to-one correspondence to rays $\{\lambda\psi: 0\neq\lambda\in\mathbb{C}\}$. The rays form a smooth manifold called complex projective space, $\mathbb{C}P^{(n-1)}$.

On the level of convex structure the difference between the classical and quantum state space is well understood. The classical one is a Choquet simplex and different axiomatizations of the quantum one are available in the literature; the reader may be referred to Ref. 1, for example. Our main concern here is the possible Riemannian structure in the quantum case. Before turning to that subject, we review briefly the classical case, that is, the Riemannian structure on the space of measures.

From the viewpoint of information geometry, the spherical representation of the probability simplex is adequate, because the squared length of the tangent vector of a curve equals the Fisher

[a]Additional address: Mathematical Institute of the Hungarian Academy of Sciences, H-1364 Budapest, PF. 127, Hungary.

0022-2488/96/37(6)/2662/12/$10.00

information. Indeed, introduce the parameters $z_i=2\sqrt{p_i}$, where $1\leqslant i\leqslant n$ and $\Sigma_i p_i=1$. Then $\Sigma_i z_i^2=4$ and the probability simplex is parametrized with a portion of the n-sphere. Let $x(t)$ be a curve on the sphere. The square of the length of the tangent is

$$\langle \partial_t x, \partial_t x\rangle=\sum_i\ (\partial_t x_i)^2=\sum_i\ p_i(t)(\partial_t\ \log\ p_i(t))^2,$$

which is the Fisher information. The geodesic distance between two probability distributions Q and R can be computed along a great circle and it is a simple transform of the Hellinger distance. Reference 2 contains further details as well as statistical applications of this geometric approach. To the best of our knowledge, Riemannian metric on quantum states was first considered by Helstrom in connection with state estimation theory.[3] Since Helstrom's work, several other metrics appeared in the literature (see, for example, Refs. 4–7) and Uhlmann approached Helstrom's metric in a different way.[8,9]

The present paper is organized as follows. In Sec. II we survey the work of Chentsov both in the probabilistic and in the quantum case. We explain how he arrived at the study of invariant metrics on the space of probability measures, motivated by decision theory, and how far he could go towards the quantum generalization after his unicity result about the Fisher information in the probabilistic context. The survey on Chentsov's work is believed to be essential. On the one hand, his papers are not easy to access and on the other hand our main result is the completion of the program he initiated. Our results are contained in Secs. III and IV. We construct monotone metrics by means of operator monotone functions and prove that all monotone metrics are obtained in this way. It turns out that the symmetric logarithmic derivative metric of Helstron (which is the same as the metric studied by Uhlmann) is monotone. Furthermore, this metric is minimal among all monotone metrics. The subject of Sec. IV is the extension of monotone metrics to pure states. We prove that if the extension exists, then it coincides with the standard metric on pure states up to a constant factor. Only the metric of the symmetric logarithmic derivative yields the Fubini–Study extension.

II. THE VIEWPOINT OF CHENTSOV

Chentsov was led by decision theory when he considered a category whose objects are probability spaces and whose morphisms are Markov kernels. Although he worked in Ref. 10 with arbitrary probability spaces, his idea can be demonstrated very well on finite ones. In this case a morphism from the probability n-simplex $\mathscr{S}_n$ to an m-simplex $\mathscr{S}_m$ is an $m\times n$ stochastic matrix. If Π is such a matrix and $P\in\mathscr{S}_n$, then $\Pi P\in\mathscr{S}_m$ is considered more random than P. Generally speaking, the parametrized family (Q_i) is more random than the parametrized family (P_i) (with the same parameter set) if there exists a stochastic matrix Π such that $\Pi P_i=Q_i$ for every value of the parameter i. Two parametric families (P_i) and (Q_i) are equivalent in the theory of statistical inferences if there are two stochastic matrices $\Pi^{(12)}$ and $\Pi^{(21)}$ such that

$$\Pi^{(12)}P_i=Q_i\quad\text{and}\quad\Pi^{(21)}Q_i=P_i \tag{2.1}$$

for every i. Chentsov said a numerical function f defined on pairs of measures to be invariant if

$$(P_1,P_2)\sim(Q_1,Q_2)\quad\text{implies}\quad f(P_1,P_2)=f(Q_1,Q_2) \tag{2.2}$$

and monotone if

$$f(P_1,P_2)\geqslant f(\Pi P_1,\Pi P_2) \tag{2.3}$$

for every stochastic matrix Π. A monotone function f is obviously invariant. Statistics and information theory know a lot of monotone functions, relative entropy, and its generalizations are so.

If a Riemannian metric is given on all probability simplexes, then this family of metrics is called invariant (respectively, monotone) if the corresponding geodesic distance is an invariant (respectively, monotone) function. Chentsov's great achievement was that up to a constant factor the Fisher information yields the only monotone family of Riemannian metrics on the class of finite probability simplexes (Ref. 10; see also Ref. 11). A decade later Chentsov turned to the quantum case, where the probability simplex is replaced by the set of density matrices. A linear mapping between two matrix spaces sends a density matrix into a density matrix if the mapping preserves trace and positivity (i.e., positive semidefiniteness). By now it is well understood that complete positivity is a natural and important requirement in the noncommutative case.[12,13] Therefore, we call a trace preserving completely positive mapping stochastic. One of the equivalent forms of the complete positivity of a map T is the following:

$$\sum_{i=1}^{n}\sum_{j=1}^{n} a_i^* T(b_i^* b_j) a_j \geqslant 0$$

for all possible choice of a_i, b_i, and n. A completely positive mapping T satisfies the Schwarz inequality: $T(a^*a) \geqslant T(a)^* T(a)$.

Chentsov recognized that stochastic mappings are the appropriate morphisms in the category of quantum state spaces. (Reference 12 contains more information about stochastic mappings; see also Ref. 13.) The above definitions of invariance and monotonicity make sense when stochastic matrices are replaced by stochastic mappings. Chentsov (with Morozova) aimed to find the invariant (or monotone) Riemannian metrics in quantum setting as well. They obtained the following result.[14] Assume that a family of Riemannian metrics is given on all spaces of density matrices, which is invariant. Then there exist a function $c(x,y)$ and a constant C such that the squared length of a tangent vector $A=(A_{ij})$ at a diagonal point $D=\mathbf{Diag}(p_1,p_2,\ldots,p_n)$ is of the form

$$C\sum_{k=1}^{n} p_k^{-1} A_{kk}^2 + 2\sum_{j<k} c(p_j,p_k)|A_{jk}|^2. \tag{2.4}$$

Furthermore, the function $c(x,y)$ is symmetric and $c(\lambda x,\lambda y)=\lambda^{-1}c(x,y)$. This result of Morozova and Chentsov was not complete. Although they had proposals for the function $c(x,y)$, they did not prove monotonicity or invariance of any of the corresponding metrics. A complete result will be given here but now a few comments on (2.4) are in order.

Both the function $c(x,y)$ and the constant are independent from the matrix size n. Restricting ourselves to diagonal matrices, which is in some sense a step back to the probability simplex, we can see that there is no ambiguity of the metric. Loosely speaking, the unicity result in the simplex case survives along the diagonal and the off-diagonal provides new possibilities for the definition of a stochastically invariant metric.

III. RIEMANNIAN METRICS ON QUANTUM STATES

The demand for Riemannian structure on the whole quantum state space or on a parametrized family of density operators appeared in mathematical physics a long time ago and in rather different contexts.

In the parametric problem of quantum statistics a family (D_θ) of states of a systems is given and one has to decide between several alternative values of the parameter by using measurements. The set of outcomes of the applied measurements is the parameter set Θ and we assume that it is a region in $\mathbb{R}^m$. So an estimator measurement M is a positive-operator-valued measure on the Borel sets of Θ and its values are observables of the given quantum system. The probability measure $B\mapsto\mu_\theta(B)=\mathrm{Tr}(D_\theta M(B))(B\subset\Theta)$ represents the result of the measurement M when the ''true'' state is D_θ. The choice of the estimators has to be made by taking into account the expected errors. The aim of an optimal decision process is to search for estimators with small

error. To an error one can attribute several sizes. For example, one can seek a measurement such that its value is ''approximately'' equal to the true parameter value. If this holds ''in the mean,'' then the estimator is free of distorsion and such an estimator is commonly called unbiased. The accuracy of an unbiased measurement is described by the total mean-square deviation which should be small on the parameter space if we want to choose an effective estimator measurement.

The quantum state estimation was initiated by Helstrom in the 1960s (Ref. 3, see also Ref. 15). He followed the Cramér–Rao pattern of mathematical statistics and introduced the concept of symmetric logarithmic derivative. Let M be a positive-operator-valued measure on $\mathbb{R}^n$. The corresponding measurement is an unbiased estimator of the parameter $\theta=(\theta_1,...,\theta_m)$ if

$$\int_{\mathbb{R}^m} \theta_i \, d\mathrm{Tr}(D_t M)(\theta) = t_i \tag{3.1}$$

for every $1 \leqslant i \leqslant m$. [The integration is taken with respect to the measure $B \mapsto \mathrm{Tr}(D_t M(B))$.] The symmetric logarithmic derivatives L_θ^i are observables defined as

$$\frac{\partial \mathrm{Tr}(D_\theta A)}{\partial \theta_i} = \frac{1}{2}\,\mathrm{Tr}((L^i(\theta)D_\theta + D_\theta L^i(\theta))A) \tag{3.2}$$

for every observable A. The measurement has two characteristic matrices, the covariance matrix $C(\theta)=(C_{ij}(\theta))$ and the information matrix $J(\theta)=(J_{ij}(\theta))$. They are determined as follows:

$$C_{ij}(\theta) = \int_{\mathbb{R}^m} (t_i-\theta_i)(t_j-\theta_j) d\mathrm{Tr}(D_\theta M)(t), \quad J_{ij}(\theta) = \mathrm{Tr}(D_\theta L^i(\theta) L^j(\theta)). \tag{3.3}$$

A quantum version of the Cramér–Rao inequality, due to Helstrom, says that

$$C(\theta) \geqslant J(\theta)^{-1} \tag{3.4}$$

for an unbiased measurement. (The inequality means that the difference is positive semidefinite.) The information matrix $J(\theta)$ may be regarded as the metric tensor on the parameter space.

From the point of view of the statistical state estimation problem, the number n of the real parameters is much smaller than the dimension of the whole state space. However, we can parametrize the whole state space as well. Assume that the parametrization is affine,

$$D_\theta = I/n + \sum_i \theta_i a_i, \tag{3.5}$$

where a_i are traceless selfadjoint matrices. Here D_θ is positive definite if θ is in a certain open subset of $\mathbb{R}^{n^2-1}$ and the mapping $D_\theta \mapsto \theta \in \mathbb{R}^{n^2-1}$ yields an atlas of a single chart. We refer to (3.5) as the affine parametrization of invertible density matrices $\mathscr{D}_n$.

The Riemannian metric of the symmetric logarithmic derivative may be written in the form (2.4) as

$$\|(A_{ij})\|_D^2 = \sum_{k=1}^n p_k^{-1} A_{kk}^2 + 2\sum_{j<k} \frac{2}{p_j+p_k} |A_{jk}|^2, \tag{3.6}$$

where $D=\mathbf{Diag}(p_1,p_2,\ldots,p_n)$ is a diagonal footpoint and A is a tangent vector at D (that is, $A=A^*$ and $\mathrm{Tr}\,A=0$). So the Morozova–Chentsov function of the metric of the symmetric logarithmic derivative is

$$c(x,y)=\frac{2}{x+y}. \tag{3.7}$$

Uhlmann obtained essentially the same Riemannian metric in a completely different approach. He wrote the density matrices D in the form

$$W^*W=D. \tag{3.8}$$

Since $\mathrm{Tr}\, W^*W=\mathrm{Tr}\, D=1$, W can be regarded as a unit vector in a larger Hilbert space, and W is often called a purification of the density matrix D. There are many choices for W when D is given. Let $D(t)$ be a smooth curve of density matrices with purification $W(t)$. If the arclength of $W(t)$ with respect to the standard Fubini–Study metric is minimal, then the so-called paralellity condition

$$W(t)^*\dot{W}(t)=\dot{W}(t)^*W(t), \quad \dot{W}(t)=\frac{dW(t)}{dt}, \tag{3.9}$$

is satisfied. The shortest purification curve leads to the Bures distance on the set of density matrices and the corresponding Riemannian metric is the metric of symmetric logarithmic derivative (see Refs. 8 and 9 for details). It is worthwhile to mention that Dittmann computed several geometric characteristics of the space of density matrices endowed with the above metric.[16] For example, this space is not locally symmetric and all sectional curvatures are greater than 1. Braunstein and Caves obtained recently the same metric by optimizing over all generalized quantum measurements that can be used to distinguish neighboring quantum states D and $D+dD$.[5]

If a distance between density matrices expresses statistical distinguishability, then this distance must decrease under coarse-graining. A good example of coarse-graining arises when a density matrix is partitioned in the form of a 2×2 block matrix, and the coarse-graining forgets about the offdiagonal:

$$\begin{pmatrix} A & B \\ B^* & C \end{pmatrix} \mapsto \begin{pmatrix} A & 0 \\ 0 & C \end{pmatrix}.$$

In the mathematical formulation, a coarse-graining is a completely positive mapping which preserves the trace and hence sends density matrix into density matrix. Such a mapping will be called stochastic below. A Riemannian metric is defined to be monotone if the differential of any stochastic mapping is a contraction. If the affine parametrization is considered, then $D_t=D+tA$ is a curve for an invertible density D and for a self-adjoint traceless A. Under a stochastic mapping $\mathbf{T}$ this curve is transformed into $\mathbf{T}(D_t)=\mathbf{T}(D)+t\mathbf{T}(A)$ provided that $\mathbf{T}(D)$ is an invertible density and the real number t is small enough. The monotonicity condition for the Riemannian metric g on $\mathscr{M}_n$ reads as

$$g_{\mathbf{T}(D)}(\mathbf{T}(A),\mathbf{T}(A))\leqslant g_D(A,A), \tag{3.10}$$

where D is an invertible density, A is traceless self-adjoint, and $\mathbf{T}$ is stochastic. Our goal is to show many examples of monotone metrics and to give their characterization in terms of operator monotone functions.

Let us recall that a function $f:\mathbb{R}^+\to\mathbb{R}$ is called operator monotone if the relation $0\leqslant K\leqslant H$ implies $0\leqslant f(K)\leqslant f(H)$ for any matrices K and H (of any order). The theory of operator monotone functions was established in the 1930s by Löwner and there are several reviews on the subject, for example, Refs. 17 and 18 are suggested.

Let us introduce some superoperators as

$$\mathbf{L}_D(A)=DA, \quad \mathbf{R}_D(A)=AD, \quad A\in M_n(\mathbb{C}). \tag{3.11}$$

Theorem 3.1: Let $f:\mathbb{R}^+\to\mathbb{R}^+$ be an operator monotone function such that $f(t)=tf(t^{-1})$ for every $t>0$ and set a superoperator

$$\mathbf{K}_D=\mathbf{R}_D^{1/2}f(\mathbf{L}_D\mathbf{R}_D^{-1})\mathbf{R}_D^{1/2} \tag{3.12}$$

acting on matrices. Then the relation

$$g_D(A,B)=\mathrm{Tr}(\mathbf{K}_D^{-1}(A)B) \tag{3.13}$$

determines a monotone Riemannian metric on $\mathscr{M}_n$.

Proof: Since an operator monotone function is analytic, the bilinear form (3.13) is smooth in D. The condition $f(t)=tf(t^{-1})$ on f makes sure that $\mathbf{K}_D^{-1}(A)$ is self-adjoint whenever A is so. Hence the bilinear form (3.13) is real. For an invertible D the superoperator $\mathbf{K}_D$ is invertible and positive definite. So (3.13) is really a nondegenerate metric and its monotonicity is to be checked.

In Ref. 19 the following inequality was obtained:

$$\mathbf{T}\mathbf{R}_F^{1/2}f(\mathbf{L}_E\mathbf{R}_F^{-1})\mathbf{R}_F^{1/2}\mathbf{T}^\star\leqslant\mathbf{R}_{\mathbf{T}(F)}^{1/2}f(\mathbf{L}_{\mathbf{T}(E)}\mathbf{R}_{\mathbf{T}(F)}^{-1})\mathbf{R}_{\mathbf{T}(F)}^{1/2}, \tag{3.14}$$

if E,F are positive definite matrices, $\mathbf{T}$ is a stochastic mapping, and $\mathbf{T}^\star$ denotes its adjoint with respect to the Hilbert–Schmidt inner product. Putting $E=F=D$, (3.14) becomes

$$\mathbf{T}\mathbf{K}_D\mathbf{T}^\star\leqslant\mathbf{K}_{\mathbf{T}(D)},$$

which is equivalent to

$$\mathbf{T}^\star\mathbf{K}_{\mathbf{T}(D)}^{-1}\mathbf{T}\leqslant\mathbf{K}_D^{-1}. \tag{3.15}$$

The latter condition is exactly the monotonicity of the metric (3.13). □

It is in order to make a comment on the relation of the function f in Theorem 3.1 and the Morozova–Chentsov function $c(x,y)$ in (2.4). Given f, we have $c(x,y)=1/yf(x/y)$ and conversely $f(t)=1/c(t,1)$. Some examples of functions f satisfying the hypothesis of Theorem 3.1 are the following:

$$\frac{2x^{\alpha+1/2}}{1+x^{2\alpha}}, \quad \frac{x-1}{\log x}, \quad \frac{x-1}{\log x}\,\frac{2\sqrt{x}}{1+x}, \quad \left(\frac{x-1}{\log x}\right)^2\frac{2}{1+x}, \quad \frac{1+x}{2}, \tag{3.16}$$

where $0\leqslant\alpha\leqslant1/2$. The lattest function f gives the Morozova–Chentsov function (3.7) and we obtain that the metric of the symmetric logarithmic derivative is monotone.

The metrics on $\mathscr{M}_2$ provided by Theorem 3.1 are rotation invariant, they depend only on $r=\sqrt{x^2+y^2+z^2}$, and split into radial and tangential components:

$$ds^2=\frac{1}{1-r^2}\,dr^2+\frac{1}{1+r}\,g\left(\frac{1-r}{1+r}\right)dn^2 \quad \text{where } g(t)=\frac{1}{f(t)}. \tag{3.17}$$

The radial component is independent of the function f. In the case of the metric of the symmetric logarithmic derivative, the tangential component is independent of r.

Theorem 3.2: Every monotone metric is provided by Theorem 3.1.

Proof: A monotone metric is invariant in the sense of Sec. II, and due to the result of Chentsov and Morozova the metric is of the form (2.4). Set a function f as $f(t)=1/c(t,1)$, where c is the function of two variables from (2.4). By means of this function the monotone metric can

be written in terms of f exactly in the form described in Theorem 3.1 [see (3.12) and (3.11)]. What we have to prove is that f is operator monotone. This will be shown following Ref. 20.

We choose a particular stochastic mapping **T**:

$$\mathbf{T}:X\equiv\begin{pmatrix} X_1 & A \\ B & X_2 \end{pmatrix}\mapsto\frac{1}{2}\begin{pmatrix} X_1+X_2 & A+B \\ A+B & X_1+X_2 \end{pmatrix}.$$

With this choice the monotonicity condition yields that

$$Y\mapsto f(\mathbf{L}_Y\mathbf{R}_Y^{-1})\mathbf{R}_Y$$

is a concave mapping, or equivalently

$$Y\mapsto f(Y\otimes(Y^{-1})^t)(I\otimes Y^t) \tag{3.18}$$

is concave for a positive definite density matrix Y. The concavity extends to all positive definite matrices obviously. We write (3.18) for a block matrix

$$Y=\begin{pmatrix} Y_1 & 0 \\ 0 & Y_2 \end{pmatrix},$$

then we observe that concavity of (3.18) implies the concavity of the mapping

$$(Y_1,Y_2)\mapsto f(Y_1\otimes(Y_2^{-1})^t)(I\otimes Y_2^t). \tag{3.19}$$

Now the choice $Y_2=I$ gives that the mapping $Y_1\mapsto f(Y_1)$ must be concave. What we have arrived at is the operator concavity of f which is known to be equivalent to the operator monotonicity of f (cf. Ref. 18). □

Let f_1 and f_2 be functions satisfying the hypothesis of Theorem 3.1 and let $\mathbf{K}^1$ and $\mathbf{K}^2$ be the corresponding superoperators defined by (3.12). If $f_1\leqslant f_2$, then $\mathbf{K}^1_D\leqslant\mathbf{K}^2_D$. The inverse changes this ordering, hence $g^1_D(A,A)\geqslant g^2_D(A,A)$ for the corresponding metrics. The relation between operator monotone functions and monotone metrics established by Theorems 3.1 and 3.2 respects ordering in the sense that bigger function gives a smaller metric. Comparison of different metrics is meaningful only under some normalization. The most natural is

$$g_D(A,A)=\mathrm{Tr}\ D^{-1}A^2 \quad \text{whenever}\ \ DA=AD, \tag{3.20}$$

which corresponds to $f(1)=1$. It is known (see Ref. 21) that among all operator monotone functions with $f(1)=1$ and $f(t)=tf(t^{-1})$ there is a minimal and a maximal. They are

$$f_{\min}(t)=\frac{2t}{1+t},\quad f_{\max}(t)=\frac{1+t}{2}. \tag{3.21}$$

So we obtain the following theorem.

Theorem 3.3: Under the normalization (3.20), the metric of the symmetric logarithmic derivative is minimal among all monotone metrics.

Proof: One has to verify that the function $f_{\max}$ yields the stated metric. From (3.12) and (3.13) we have

$$g_D(A,A)=2\langle(\mathbf{L}_D+\mathbf{R}_D)^{-1}A,A\rangle \tag{3.22}$$

and $L=2(\mathbf{L}_D+\mathbf{R}_D)^{-1}$ is exactly the solution of Eq. (3.2). Hence (3.22) matches (3.7).

We have to emphasize that the theorem states the minimality of the logarithmic derivative metric only under the essential condition that the whole state space of a spin is parametrized. If this is not the case, then no information is provided by the theorem. The largest monotone metric is the metric of the so-called left logarithmic derivative. That appeared in the literature in connection with Cramér–Rao-type inequalities. Its monotonicity was established in Ref. 7. The fact that the left logarithmic metric is larger than the symmetric one is elementary and it has been known (for example, Ref. 15, p. 282).

The metric corresponding to the Morozova–Chentsov function

$$\frac{\log x - \log y}{x-y}$$

is the Kubo (or Mori, or Bogoliubov) inner product which showed up in Ref. 7 and was studied in Ref. 22. In particular, it was proved that the Kubo product is monotone, under more general assumption than a finite spin, and a conjecture was made. Namely, the scalar curvature of the Kubo metric is monotone as well. Monotonicity of the Kubo metric is not surprising because this result is a kind of reformulation of the Lieb convexity theorem.[23] However, the monotonicity of the scalar curvature seems to be an inequality of new type (provided that the conjecture is really true). Concerning details we refer to Refs. 7 and 22.

In Ref. 6 Hasegawa introduced a family of metrics. It was proved that they can be obtained by the above construction of monotone metric.[24] The Kubo–Mori metric is an element of the family, otherwise their physical (or statistical) importance is not clear yet.

IV. EXTENSION TO PURE STATES

The objective of this section is to discuss the extension of monotone metrics of $\mathscr{M}_n$ to pure states $\mathbb{C}P^{(n-1)}$. Since pure states form a low-dimensional part of the topological boundary of $\mathscr{M}_n$, it should be well specified how the extension is understood.

Let $\mathscr{M}_n^0$ denote the set of all elements of $\mathscr{M}_n$ whose eigenvalues are distinct and define a projection $\pi:\mathscr{M}_n^0 \to \mathbb{C}P^{(n-1)}$ as follows. Let $\pi(D)$ be the one-dimensional eigenspace corresponding to the largest eigenvalue of $D \in \mathscr{M}_n^0$. This map is smooth (see Ref. 25, II.5.8) and $\mathscr{M}_n^0$ is a smooth fiber bundle over $\mathbb{C}P^{(n-1)}$ with projection π (see Ref. 26, I.5.). [The structure group of this bundle is $U(1)\times U(n-1)$, where $U(k)$ is the group of $k\times k$ unitary matrices.] The fiber space is $\pi^{-1}(e)$, where e is the ray generated by the vector $(1,0,...,0) \in \mathbb{C}^n$.

Let $T_D\pi$ be the differential of π at D and let H_D be the orthogonal complement of Ker $T_D\pi$ in $T_D\mathscr{M}_n^0$ with respect to a fixed monotone Riemannian metric $g_D(\cdot,\cdot)$. Since $T_D\pi$ is surjective, the restriction of $T_D\pi$ gives a linear isomorphism between H_D and $T_{\pi(D)}\mathbb{C}P^{(n-1)}$. If $v \in T_{\pi(D)}\mathbb{C}P^{(n-1)}$, then we can define a unique lift $\tilde{v} \in H_D$ of v such that $T_D\pi(\tilde{v}) = v$. Using this lift we can define the following inner product $k^D_{\pi(D)}(\cdot,\cdot)$ on $T_{\pi(D)}\mathbb{C}P^{n-1}$:

$$k^D_{\pi(D)}(u,v) = g_D(\tilde{u},\tilde{v}), \quad u,v \in T_{\pi(D)}\mathbb{C}P^{(n-1)}. \tag{4.1}$$

We say that a sequence $D_n \in \mathscr{M}_n^0$ is radial at $p \in \mathbb{C}P^{(n-1)}$ if $\pi(D_n) = p$ for every n and D_n is convergent to p when p is considered as a density matrix (that is, a one-dimensional projection operator). Now we can define the radial extension of $g(\cdot,\cdot)$. A smooth metric $k(\cdot,\cdot)$ on $\mathbb{C}P^{(n-1)}$ is called the radial extension of $g(\cdot,\cdot)$ if for every $p \in \mathbb{C}P^{(n-1)}, u,v \in T_p\mathbb{C}P^{(n-1)}$, and for every radial sequence D_n at p

$$\lim_{n\to\infty} g_p^{D_n}(u,v) = k_p(u,v)$$

holds. In the next theorem we give a necessary and sufficient condition for the existence of the radial extension.

Theorem 4.1: Let $g(\cdot,\cdot)$ be a monotone Riemannian metric on $\mathscr{M}_n$ and let $f:\mathbb{R}^+\to\mathbb{R}^+$ be the corresponding operator monotone function (described in Theorem 3.1). The radial extension $k(\cdot,\cdot)$ of the given metric $g(\cdot,\cdot)$ of $\mathscr{M}_n$ exists if and only if $f(0)\neq 0$. In the case of existence

$$k(\cdot,\cdot)=\frac{1}{2f(0)}\langle\cdot,\cdot\rangle,$$

where $\langle\cdot,\cdot\rangle$ is the standard Riemannian metric on $\mathbb{C}P^{(n-1)}$.

Proof: The proof is based on the direct computation of $k^D_{\pi(D)}(\cdot,\cdot)$. For any unitary matrix U and $D\in\mathscr{M}_n^0$ we have

$$\pi(UDU^{-1})=U\pi(D),$$

which implies

$$T_{UDU^{-1}}\pi(UXU^{-1})=UT_D\pi(X),\quad X\in T_D\mathscr{M}_n^0,$$

by differentiation. Since $k(\cdot,\cdot)$ is unitary invariant,

$$U(\mathrm{Ker}\ T_D\pi)U^{-1}=\mathrm{Ker}\ T_{UDU^{-1}}\pi\quad\text{and}\quad UH_DU^{-1}=H_{UDU^{-1}}.$$

Moreover, $U\widetilde{v}U^{-1}=\widetilde{U}v$ for any $v\in T_{\pi(D)}\mathbb{C}P^{(n-1)}$, hence we obtain

$$g^D_{\pi(D)}(u,v)=g^{UDU^{-1}}_{U\pi(D)}(Uu,Uv). \tag{4.2}$$

From this equality it follows that it is sufficient to compute $k^D(\cdot,\cdot)$ if D is diagonal and $\pi(D)$ is the projection onto e. Assume these and let $X\in T_D\mathscr{M}_n^0$ and let $\lambda(t)$ and $v(t)$ be the largest eigenvalue and the unit eigenvector corresponding to $\lambda(t)$ of $D+tX$ where $t\in\mathbb{R}$. For sufficiently small t, $D+tX\in\mathscr{M}_n^0$ and $\lambda(t)$ and $v(t)$ are smooth functions of t. For $D(t)=D+tX$ we have

$$(D(t)-\lambda(t))v(t)=0.$$

Differentiating this expression we obtain that $\lambda'(0)=x_{11}$ and

$$T_D\pi(X)=v'(0)=\left(0,\frac{x_{21}}{\lambda_1-\lambda_2},\ldots,\frac{x_{n1}}{\lambda_1-\lambda_n}\right), \tag{4.3}$$

where $\lambda_1,\ldots,\lambda_n$ are the eigenvalues of D, $\lambda_1=\lambda(0)$, and $X=(x_{ij})$. If $X\in\mathrm{Ker}\ T_D\pi$, then the expression of $T_D\pi(X)$

$$X=\begin{pmatrix} x_{11} & 0 & \cdots & 0\\ 0 & x_{22} & \cdots & x_{2n}\\ \vdots & \vdots & \ddots & \vdots\\ 0 & x_{n2} & \cdots & x_{nn}\end{pmatrix}.$$

Let $\mathbf{K}_D^{-1}=f(\mathbf{L}_D\mathbf{R}_D^{-1})\mathbf{R}_D$ as in (3.12). Since D is diagonal,

$$K_D(X)_{ij}=\frac{x_{ij}}{f(\lambda_i/\lambda_j)\lambda_j}, \tag{4.4}$$

hence we get $K_D(\mathrm{Ker}\ T_D\pi)=\mathrm{Ker}\ T_D\pi$. If $V\in H_D$, then the last equation gives

$$V=\begin{pmatrix} 0 & \overline{v_2} & \cdots & \overline{v_n} \\ v_2 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ v_n & 0 & \cdots & 0 \end{pmatrix}, \tag{4.5}$$

where $v_i \in \mathbb{C}$ for $i=2,\ldots,n$. If $v=(0,v_2,\ldots,v_n) \in T_{[e]}\mathbb{C}P^{(n-1)}$, then (4.3) and (4.5) give

$$\tilde{v}=\begin{pmatrix} 0 & (\lambda_1-\lambda_2)\overline{v_2} & \cdots & (\lambda_1-\lambda_n)\overline{v_n} \\ (\lambda_1-\lambda_2)v_2 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ (\lambda_1-\lambda_n)v_n & 0 & \cdots & 0 \end{pmatrix}.$$

Now we can express $g^D(\cdot,\cdot)$:

$$g^D(u,v)=\mathrm{Re}\sum_{i=2}^{n}\frac{(\lambda_1-\lambda_i)^2}{f(\lambda_i/\lambda_1)\lambda_1}\,u^i\overline{v^i}, \tag{4.6}$$

where $u,v \in T_{[e]}\mathbb{C}P^{(n-1)}$.

Let us consider now the general case. Let (D_m) be a radial sequence at p and let $u,v \in T_p\mathbb{C}P^{(n-1)}$. Let B_p^m be linear operators on $T_p\mathbb{C}P^{(n-1)}$ such that

$$g_p^{D_m}(u,v)=\langle B_p^m u,v\rangle_p,$$

where $\langle\cdot,\cdot\rangle_p$ is the inner product on $T_p\mathbb{C}P^{(n-1)}$ induced by the standard metric. Let U_m be unitary operators such that $D_m^0=U_mD_mU_m^{-1}$ is diagonal and $\pi(D_m^0)=p_0$ with $p_0=[e]$. Using (4.2) we have

$$B_p^m=U_m^{-1}\cdot B_{p_0}^m\cdot U_m. \tag{4.7}$$

Since $\lim_{m\to\infty}\lambda_1^m=1$ and $\lim_{m\to\infty}\lambda_i^m=0$ for $i=2,\ldots,n$, by (4.6)

$$\lim_{m\to\infty}\|B_{p_0}^m-cI_{p_0}\|_{p_0}=0,\quad c=1/2\ f(0), \tag{4.8}$$

where I_{p_0} is the identity map on $T_{p_0}\mathbb{C}P^{(n-1)}$ and $\|\cdot\|$ is the operator norm induced by $\langle\cdot,\cdot\rangle$. It follows from (4.7) that

$$\begin{aligned}\|B_p^m-cI_p\|&=\|U_m^{-1}\cdot B_{p_0}^m\cdot U_m-cU_m^{-1}\cdot I_{p_0}\cdot U_m\|\\&=\|U_m^{-1}\cdot(B_{p_0}^m-cI_{p_0})\cdot U_m\|\\&\leqslant\|U_m^{-1}\|\cdot\|B_{p_0}^m-cI_{p_0}\|\cdot\|U_m\|.\end{aligned}$$

Since U_m are isometries from $T_p\mathbb{C}P^{(n-1)}$ to $T_{p_0}\mathbb{C}P^{(n-1)}$, $\|U_m\|=1$ and by (4.8) we obtain

$$\lim_{m\to\infty}\|B_p^m-cI_p\|=0,\quad c=1/2\ f(0).$$

So we have proved that the radial extension exists if $f(0)\neq 0$.

The special case $n=2$ is very transparent from (3.17) and it explains the terminology ''radial extension.'' The 2×2 case shows also that the condition $f(0)\neq 0$ is necessary to speak about extension. □

V. DISCUSSION

In the classical case, decision theory provides a unique monotone metric, namely, the Fisher information. In the quantum case, there are infinitely many monotone metrics on the state space. Among them the metric of symmetric logarithmic derivative possesses several mathematically attractive properties, it is minimal among all monotone metrics, and its extension to pure state is exactly the Fubini–Study metric. In accordance with the work of Braunstein and Caves, this seems to be the canonical metric of parameter estimation theory. However, expectation values of certain relevant observables are known to lead to statistical inference theory provided by the maximum entropy principle or the minimum relative entropy principle when *a priori* information on the state is available.[27] The best prediction is a kind of generalized Gibbs state. On the manifold of those states, the differentiation of the entropy functional yields the Kubo–Mori metric, which is different from the metric of the symmetric logarithmic derivative.[4,7] Therefore, more than one privileged metric shows up in quantum mechanics. The exact clarification of this point requires and is worth further studies.

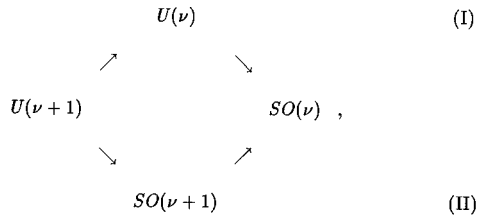
We derive a general expression for the transformation brackets between the chains U(ν+1)⊃U(ν)⊃SO(ν) and U(ν+1)⊃SO(ν+1)⊃SO(ν) for $\nu \geqslant 2$. © *1996 American Institute of Physics.* [S0022-2488(96)00703-9]

I. INTRODUCTION

The properties of bound states in a large variety of physical systems can be described by writing the Hamiltonian and other operators in terms of a spectrum generating algebra, G. In many applications the spectrum generating algebra is taken to be the unitary algebra $G=\mathrm{U}(\nu+1)$,[1] where ν denotes the dimension. Examples of this approach are the description of the five quadrupole degrees of freedom of the interacting boson model in nuclear physics in terms of the algebra U(6),[2] the description of the three dipole degrees of freedom of the vibron model in molecular physics in terms of the algebra U(4),[3] and the description of the six degrees of freedom (two dipoles) of the valence quark model of baryons in hadronic physics in terms of the algebra U(7).[4] The algebra U(ν+1) always admits (for $\nu \geqslant 2$) two subalgebra chains,



(1)

in addition, eventually, to other chains. [The special case, $\nu=1$, with U(2)⊃U(1) and U(2)⊃SO(2), in which the two subalgebras U(1) and SO(2) are isomorphic, is treated in detail in Refs. 3 and 5, and it will not be discussed further.] In the applications mentioned above, the first chain has the physical meaning of a spherical oscillator in ν dimensions, with U(ν) being the degeneracy algebra, while the second chain has the meaning of a displaced (or deformed) oscillator in ν dimensions. The best known example of the latter is the SO(6) chain of the interacting boson model,[6] which has played an important role in nuclear structure physics. In view of the fact that the algebraic method is presently being applied to a variety of problems in physics with different number of dimensions, it is of interest to derive a general expression for the transformation brackets between the two chains given in the group lattice of Eq. (1), which includes the known cases $\nu=5$ and $\nu=3$,[5] but extends the results to arbitrary $\nu(\geqslant 2)$. These transformation brackets are particularly useful if one wants to evaluate analytically certain quantities of physical interest, in

0022-2488/96/37(6)/2674/8/$10.00

particular matrix elements of operators, such as the electromagnetic transition operators, as discussed at length in Ref. 6. In this paper, the general result for arbitrary $\nu \geqslant 2$ will be presented.

II. SPECTRUM GENERATING ALGEBRA

As mentioned above, many applications of the method of spectrum generating algebras (SGA) for bound-state problems in ν dimensions, have made use of the unitary algebra $U(\nu+1)$. By generalizing the well-known cases of $\nu=5$[2] and $\nu=3$,[3] we introduce a realization of $U(\nu+1)$ in terms of $\nu+1$ boson operators, divided into a set of ν operators, $b_j^\dagger (j = 1,\ldots,\nu)$, which transform as the fundamental representation of $U(\nu)$ and an additional boson operator, $b_0^\dagger = s^\dagger$, which transforms as a scalar under $U(\nu)$. The $\nu+1$ boson operators, $b_j^\dagger (j = 0,\ldots,\nu)$, span the $(\nu+1)$-dimensional space of $U(\nu+1)$. The elements of $U(\nu+1)$ can be written as the bilinear products,

$$\mathcal{G} \equiv U(\nu+1); \quad G_{jk} = b_j^\dagger b_k \quad (j,k=0,1,\ldots,\nu). \tag{2}$$

The states constructed by applying the boson creation operators to a vacuum state,

$$\mathcal{B}: \quad \frac{1}{\mathcal{N}} (b_j^\dagger)^{n_j} (b_k^\dagger)^{n_k} \cdots |0\rangle \tag{3}$$

(where $\mathcal{N}$ is a normalization constant) transform as the symmetric representation $[N]$ of $U(\nu+1)$, where N is the total number of bosons,

$$\hat{N} = \sum_{j=0}^{\nu} \hat{n}_j = \sum_{j=0}^{\nu} b_j^\dagger b_j . \tag{4}$$

In the algebraic approach to bound state problems, the Hamiltonian (and other) operators are expressed as functions of the elements of $U(\nu+1)$, i.e. they are in the enveloping algebra of $U(\nu+1)$, and the basis states are the $[N]$ irreps of $U(\nu+1)$.

In this paper we discuss (i) the explicit construction of the basis states in terms of bosons operators for $U(\nu+1) \supset U(\nu) \supset SO(\nu)$ and $U(\nu+1) \supset SO(\nu+1) \supset SO(\nu)$, and (ii) the transformation brackets relating the basis states in the two chains.

A. The chain $U(\nu+1) \supset U(\nu) \supset SO(\nu)$

First we consider the chain

$$U(\nu+1) \supset U(\nu) \supset SO(\nu). \tag{5}$$

The basis states of this chain are denoted by $|[N], n, \tau\rangle$, where N is the total number of bosons with $j=0,1,\ldots,\nu$, describing the irreps $[N] \equiv [N,0,\ldots,0]$ of $U(\nu+1)$, n is the number of bosons with $j=1,\ldots,\nu$, describing the irreps $[n] \equiv [n,0,\ldots,0]$ of $U(\nu)$, and τ is the quantum number (boson seniority), describing the irreps $(\tau) \equiv (\tau,0,...,0)$ of $SO(\nu)$. The branching rules are

$$\begin{gathered} n = 0,1,\ldots,N, \\ \tau = n, n-2, \ldots, 1 \text{ or } 0 \quad (n \text{ odd or even and } \nu > 2), \\ \tau = -n, -n+2, \ldots, n \quad (\nu = 2). \end{gathered} \tag{6}$$

The branching of irreps of $SO(\nu)$ into irreps of (eventual) subalgebras of $SO(\nu)$, is of no interest for the present problem and will not be discussed.

The elements (generators) of $U(\nu)$ and $SO(\nu)$ can be written as

$$\begin{aligned} &\mathrm{U}(\nu):\ \ G_{jk}=b_j^\dagger b_k \quad (j,k=1,\ldots,\nu),\\ &\mathrm{SO}(\nu):\ \ L_{jk}=i(b_j^\dagger b_k-b_k^\dagger b_j) \quad (j<k \quad \text{and} \ \ j,k=1,\ldots,\nu). \end{aligned} \tag{7}$$

The basis states of the chain (5) can be written in a compact form as

$$\begin{aligned} |[N],n,\tau\rangle &= \frac{1}{\sqrt{(N-n)!}}\,(s^\dagger)^{N-n}|[n],n,\tau\rangle,\\ |[n],n,\tau\rangle &= B_{n\tau}(I_\nu^\dagger)^{(n-\tau)/2}|[\tau],\tau,\tau\rangle. \end{aligned} \tag{8}$$

The normalization coefficient $B_{n\tau}$ can be derived by making use of the SU(1,1) algebra, given in Eqs. (A2) and (A3) of Appendix A,

$$B_{n\tau}=(-1)^{(n-\tau)/2}\sqrt{\frac{(2\tau+\nu-2)!!}{(n+\tau+\nu-2)!!(n-\tau)!!}}. \tag{9}$$

The operator $I_\nu^\dagger$ denotes the pair creation operator in ν dimensions,

$$I_\nu^\dagger=\sum_{j=1}^{\nu} b_j^\dagger b_j^\dagger, \tag{10}$$

and commutes with the generators of SO(ν), $[I_\nu^\dagger,L_{jk}]=0$. The operator $s^\dagger(=b_0^\dagger)$ has been used in (8) to make it conform with the standard notation used in the literature.

B. The chain U(ν+1)⊃SO(ν+1)⊃SO(ν)

Next, we consider the chain

$$\mathrm{U}(\nu+1)\supset\mathrm{SO}(\nu+1)\supset\mathrm{SO}(\nu). \tag{11}$$

The basis states of this chain are denoted by $|[N],\sigma,\tau\rangle$, where $[N]$ and τ label as before the symmetric irreps of U(ν+1) and SO(ν), while $(\sigma)\equiv(\sigma,0,\ldots,0)$ labels the symmetric representation of SO(ν+1). The branching rules are

$$\begin{aligned} &\sigma=N,N-2,\ldots,1 \quad \text{or} \quad 0 \quad (N \ \text{odd or even}),\\ &\tau=0,1,\ldots,\sigma \quad (\nu>2),\\ &\tau=-\sigma,-\sigma+1,\ldots,\sigma \quad (\nu=2). \end{aligned} \tag{12}$$

The generators of SO(ν+1) and SO(ν) can be written as

$$\begin{aligned} &\mathrm{SO}(\nu+1):\ \ L_{jk}=i(b_j^\dagger b_k-b_k^\dagger b_j) \quad (j<k \quad \text{and} \ \ j,k=0,\ldots,\nu),\\ &\mathrm{SO}(\nu):\ \ L_{jk}=i(b_j^\dagger b_k-b_k^\dagger b_j) \quad (j<k \quad \text{and} \ \ j,k=1,\ldots,\nu). \end{aligned} \tag{13}$$

It is customary to separate the generators of SO(ν+1) into two pieces,

$$\begin{aligned} &L_{jk}=i(b_j^\dagger b_k-b_k^\dagger b_j) \quad (j<k \quad \text{and} \ \ j,k=1,\ldots,\nu),\\ &D_j=i(b_0^\dagger b_j-b_j^\dagger b_0)=i(s^\dagger b_j-b_j^\dagger s) \quad (j=1,\ldots,\nu). \end{aligned} \tag{14}$$

Using the same SU(1,1) algebra, as discussed in Appendix A, but with the sum in (A2) extending from $j=0$ to $j=\nu$, the basis states of the chain (11) can be written as

$$|[N],\sigma,\tau\rangle = A_{N\sigma}(I^{\dagger}_{\nu+1})^{(N-\sigma)/2}|[\sigma],\sigma,\tau\rangle. \tag{15}$$

Here $A_{N\sigma}$ is a normalization coefficient,

$$A_{N\sigma}=(-1)^{(N-\sigma)/2}\sqrt{\frac{(2\sigma+\nu-1)!!}{(N+\sigma+\nu-1)!!(N-\sigma)!!}}, \tag{16}$$

and $I^{\dagger}_{\nu+1}$ represents the pair creation operator in $\nu+1$ dimensions,

$$I^{\dagger}_{\nu+1}=\sum_{j=0}^{\nu} b^{\dagger}_j b^{\dagger}_j = s^{\dagger}s^{\dagger}+I^{\dagger}_{\nu}. \tag{17}$$

This pair creation operator commutes with the generators of SO($\nu+1$), $[I^{\dagger}_{\nu+1},L_{jk}]=[I^{\dagger}_{\nu+1},D_j]=0$. In Appendix B we show that the states $|[\sigma],\sigma,\tau\rangle$ can be written as

$$|[\sigma],\sigma,\tau\rangle = \sum_{k=0}^{[(\sigma-\tau)/2]} F_k(\sigma,\tau)(s^{\dagger})^{\sigma-\tau-2k}(I^{\dagger}_{\nu+1})^k|[\tau],\tau,\tau\rangle, \tag{18}$$

where the expansion coefficients are given by[7]

$$F_k(\sigma,\tau)=\left[\frac{(\sigma-\tau)!(2\tau+\nu-2)!!}{(2\sigma+\nu-3)!!(\sigma+\tau+\nu-2)!}\right]^{1/2}\left(-\frac{1}{2}\right)^k\frac{(2\sigma+\nu-3-2k)!!}{(\sigma-\tau-2k)!k!}. \tag{19}$$

Another realization of SO($\nu+1$) that is used frequently in physical applications, is by the generators $\overline{D}_j = s^{\dagger}b_j + b^{\dagger}_j s$ with $j=1,\ldots,\nu$ and $L_{jk}=i(b^{\dagger}_j b_k - b^{\dagger}_k b_j)$ with $j<k$ and $j,k=1,\ldots,\nu$. The corresponding pair creation operator differs from $I^{\dagger}_{\nu+1}$ in Eq. (17) by a relative sign,

$$\overline{I}^{\dagger}_{\nu+1}=s^{\dagger}s^{\dagger}-I^{\dagger}_{\nu}. \tag{20}$$

III. TRANSFORMATION BRACKETS

The transformation brackets between the two chains are obtained by taking the overlap between the two sets of basis states. Since both are written explicity in terms of the states $|[\tau],\tau,\tau\rangle$, the overlap is straightforward and yields the result

$$c^{\tau}_{n\sigma}=\langle[N],n,\tau|[N],\sigma,\tau\rangle=\sqrt{(N-n)!}\,\frac{A_{N\sigma}}{B_{n\tau}}\sum_{k=k_0}^{[(\sigma-\tau)/2]}F_k(\sigma,\tau)\begin{pmatrix} k+\dfrac{N-\sigma}{2} \\ \dfrac{n-\tau}{2}\end{pmatrix}, \tag{21}$$

with $k_0=\max(0,\frac{1}{2}(n-\tau-N+\sigma))$. For the second realization of the SO($\nu+1$) with the pair creation operator of Eq. (20), the transformation brackets have an additional sign $(-1)^{(n-\tau)/2}$. The transformation brackets of Eq. (21) can be obtained by inserting the expressions for the coefficients of Eqs. (9), (16), and (19),

$$c^{\tau}_{n\sigma}=(-1)^{(N-\sigma-n+\tau)/2}\left[\frac{(N-n)!(n+\tau+\nu-2)!!(\sigma-\tau)!(2\sigma+\nu-1)}{(N+\sigma+\nu-1)!!(N-\sigma)!!(\sigma+\tau+\nu-2)!(n-\tau)!!}\right]^{1/2}$$
$$\times\sum_{k=k_0}^{[(\sigma-\tau)/2]}(-1)^k\frac{(2\sigma+\nu-3-2k)!!(N-\sigma+2k)!!}{(\sigma-\tau-2k)!(2k)!!(N-\sigma-n+\tau+2k)!!}, \tag{22}$$

or by introducing Pochhammer's symbol, $(a)_k=\Gamma(a+k)/\Gamma(a)$, as

$$c^{\tau}_{n\sigma}=\left(-\frac{1}{2}\right)^{(N-\sigma-n+\tau)/2}(2\sigma+\nu-1)!!$$
$$\times\left[\frac{(N-n)!(N-\sigma)!!(n+\tau+\nu-2)!!}{(\sigma-\tau)!(n-\tau)!!(\sigma+\tau+\nu-2)!(N+\sigma+\nu-1)!!(2\sigma+\nu-1)}\right]^{1/2}$$
$$\times\sum_{k=k_0}^{[(\sigma-\tau)/2]}\frac{1}{k!}\frac{((N-\sigma)/2+1)_k((\tau-\sigma)/2)_k((\tau-\sigma+1)/2)_k}{((N-\sigma-n+\tau)/2+k)!(-\sigma-(\nu-3)/2)_k}. \tag{23}$$

Equations (22) and (23) reduce for $\nu=5$ and $\nu=3$ to the expressions derived in Refs. 5, 8, and 9.

For the lowest SO($\nu+1$) representation $\sigma=N$, the sum appearing in the general expression for the transformation bracket can be carried out explicitly to give

$$c^{\tau}_{nN}=\left[\frac{(N-\tau)!(N+\tau+\nu-2)!}{(N-n)!(n+\tau+\nu-2)!!(n-\tau)!!(2N+\nu-3)!!}\right]^{1/2}, \tag{24}$$

in agreement with the results obtained previously[6] for $\nu=5$ and $\nu=3$.

Equations (22) and (23) conclude the derivations of the transformation brackets for arbitrary $\nu(\geq 2)$,

$$|[N],\sigma,\tau\rangle=\sum_n c^{\tau}_{n\sigma}|[N],n,\tau\rangle. \tag{25}$$

IV. CONCLUSIONS

In this paper, we have reported a closed expression for the transformation brackets between the chains of Eq. (1) for an arbitrary number of dimensions $\nu(\geq 2)$. These transformation brackets are useful in a variety of problems that are being investigated at the present time within the framework of the algebraic method. For example, the case $\nu=2$ is of interest in the treatment of bending vibrations of linear molecules, while the case $\nu=9$ is of interest in the treatment of rotations and vibrations of nonplanar tetratomic molecules.

The transformation brackets derived here can be used to evaluate matrix elements of an operator $\hat{T}$ in the ''deformed'' chain (of great physical interest) by a two-step process, i.e. by first evaluating them in the ''spherical'' chain (which is a relatively easy calculation) and subsequently transforming the results to the ''deformed'' chain,

$$\langle[N],\sigma',\tau'|\hat{T}|[N],\sigma,\tau\rangle=\sum_{n',n}c^{\tau'}_{n'\sigma'}c^{\tau}_{n\sigma}\langle[N],n',\tau'|\hat{T}|[N],n,\tau\rangle, \tag{26}$$

where the coefficients c are the transformation brackets derived in this paper.

APPENDIX A: THE REDUCTION U(ν)⊃SO(ν)

The normalization coefficients $B_{n\tau}$ and $A_{N\sigma}$ of Eqs. (9) and (16), can be found by making use of the properties of the SU(1,1) ''quasi-spin'' algebra for a system of bosons.[10,11] Consider a system of bosons in ν dimensions with the algebraic structure

$$\mathrm{U}(\nu)\supset\mathrm{SO}(\nu). \tag{A1}$$

The corresponding basis states are characterized by $|[n],\tau\rangle$. The operators

$$\hat{Q}_+=\frac{1}{2}\sum_{j=1}^{\nu} b_j^\dagger b_j^\dagger, \quad \hat{Q}_-=\frac{1}{2}\sum_{j=1}^{\nu} b_j b_j, \tag{A2}$$

$$\hat{Q}_0=\frac{1}{4}\sum_{j=1}^{\nu}(b_j^\dagger b_j+b_j b_j^\dagger)=\frac{1}{2}\left(\hat{n}+\frac{1}{2}\,\nu\right),$$

satisfy the commutation relations

$$[\hat{Q}_+,\hat{Q}_-]=-2\hat{Q}_0, \quad [\hat{Q}_0,\hat{Q}_\pm]=\pm\hat{Q}_\pm, \tag{A3}$$

of the SU(1,1) algebra. The basis states are labeled by $|q,q_0\rangle$. The generators of the SU(1,1) algebra defined in (A2) commute with the generators of SO(ν), L_{jk} of Eq. (7). The relation between the two sets of basis states $|q,q_0\rangle$ and $|[n],\tau\rangle$ can be found by using the generators of (A2). First, $\hat{Q}_0$ is diagonal in the basis states,

$$\begin{aligned}\hat{Q}_0|q,q_0\rangle&=q_0|q,q_0\rangle,\\ \hat{Q}_0|[n],\tau\rangle&=\tfrac{1}{2}(n+\tfrac{1}{2}\nu)|[n],\tau\rangle,\end{aligned} \tag{A4}$$

and hence $q_0=\frac{1}{2}(n+\frac{1}{2}\nu)$. Furthermore, $\hat{Q}_-$ annihilates the highest-weight state,

$$\hat{Q}_-|q=q_0,q_0\rangle=\hat{Q}_-|[n=\tau],\tau\rangle=0, \tag{A5}$$

which gives $q=\frac{1}{2}(\tau+\frac{1}{2}\nu)$. The basis states can be expanded as

$$\begin{aligned}|q,q_0\rangle&=A_{qq_0}(\hat{Q}_+)^{q_0-q}|q,q_0=q\rangle,\\ A_{qq_0}&=(-1)^{q_0-q}\sqrt{\frac{(2q-1)!}{(q_0-q)!(q_0+q-1)!}},\end{aligned} \tag{A6}$$

or alternatively as

$$\begin{aligned}|[n],\tau\rangle&=B_{n\tau}(I_\nu^\dagger)^{(n-\tau)/2}|[\tau],\tau\rangle,\\ B_{n\tau}&=(-1)^{(n-\tau)/2}\sqrt{\frac{(2\tau+\nu-2)!!}{(n+\tau+\nu-2)!!(n-\tau)!!}}.\end{aligned} \tag{A7}$$

The choice of phase in (A6) is conventional.

APPENDIX B: THE REDUCTION SO(ν+1)⊃SO(ν)

The SU(1,1) algebra of (A2) can be used for the reductions U(ν)⊃SO(ν) and U(ν+1)⊃SO(ν+1). For the chain (11) we need the further reduction SO(ν+1)⊃SO(ν). This is by far more complex. Here we use Ref. 12 and a generalization of the method discussed on pp. 152–157 of Ref. 5. The defining equations are

$$\begin{aligned}
&\hat{N}|[N],\sigma,\tau\rangle = N|[N],\sigma,\tau\rangle,\\
&\hat{C}_{\mathrm{SO}(\nu+1)}|[N],\sigma,\tau\rangle = \sigma(\sigma+\nu-1)|[N],\sigma,\tau\rangle,\\
&\hat{C}_{\mathrm{SO}(\nu)}|[N],\sigma,\tau\rangle = \tau(\tau+\nu-2)|[N],\sigma,\tau\rangle.
\end{aligned} \tag{B1}$$

The notation for the states is the same as in Sec. II A. $\hat{C}_G$ represents the quadratic Casimir invariant of G. These equations can be expressed in terms of a set of separable differential equations by introducing hyperspherical coordinates,

$$(x_1,\ldots,x_{\nu+1}) \rightarrow (r,\phi,\theta_{\nu-1},\ldots,\theta_1), \tag{B2}$$

by

$$\begin{aligned}
x_1 &= r\ \sin\ \phi\ \sin\ \theta_{\nu-1}\cdots\sin\ \theta_2\ \cos\ \theta_1,\\
x_2 &= r\ \sin\ \phi\ \sin\ \theta_{\nu-1}\cdots\sin\ \theta_2\ \sin\ \theta_1,\\
x_3 &= r\ \sin\ \phi\ \sin\ \theta_{\nu-1}\cdots\cos\ \theta_2,\\
&\vdots\\
x_\nu &= r\ \sin\ \phi\ \cos\ \theta_{\nu-1},\\
x_{\nu+1} &= r\ \cos\ \phi,
\end{aligned} \tag{B3}$$

with $0\leqslant r<\infty$ and $0\leqslant\phi,\ \theta_{\nu-1},\ldots,\theta_2<\pi$ and $0\leqslant\theta_1<2\pi$. The volume element is given by

$$dx_1\cdots dx_{\nu+1} = r^\nu(\sin\ \phi)^{\nu-1}(\sin\ \theta_{\nu-1})^{\nu-2}\cdots\sin\ \theta_2\ dr\ d\phi\ d\theta_{\nu-1}\cdots d\theta_2\ d\theta_1. \tag{B4}$$

The Casimir invariants can be obtained from the Laplacian in ν+1 dimensions and a recursion relation between the Casimir operators of the orthogonal groups (see p. 493 of Ref. 12),

$$\begin{aligned}
\nabla^2_{\nu+1} &= \frac{1}{r^\nu}\frac{\partial}{\partial r}\left(r^\nu\frac{\partial}{\partial r}\right) - \frac{1}{r^2}\hat{C}_{\nu+1}(\phi,\theta),\\
\hat{C}_{\nu+1}(\phi,\theta) &= -\frac{1}{(\sin\ \phi)^{\nu-1}}\frac{\partial}{\partial\phi}\left((\sin\ \phi)^{\nu-1}\frac{\partial}{\partial\phi}\right) + \frac{1}{(\sin\ \phi)^2}\hat{C}_\nu(\theta).
\end{aligned} \tag{B5}$$

Here $(\theta)=(\theta_{\nu-1},\ldots,\theta_1)$. The number operator expressed in hyperspherical coordinates is given by

$$\hat{N} = \frac{1}{2}\left[-\frac{1}{r^\nu}\frac{\partial}{\partial r}\left(r^\nu\frac{\partial}{\partial r}\right) + r^2 + \frac{1}{r^2}\hat{C}_{\nu+1}(\phi,\theta) - (\nu+1)\right]. \tag{B6}$$

The eigenvector equations can be solved by separation of variables and have solutions in terms of products of Laguerre and Gegenbauer polynomials,

$$\begin{aligned}\psi_{N\sigma\tau\alpha}(r,\phi,\theta) &= f_{N\sigma}(r)g_{\sigma\tau}(\phi)\Phi_{\tau\alpha}(\theta),\\ &= A_{N\sigma\tau}r^{\sigma}e^{-r^2/2}L^{(2\sigma+\nu-1)/2}_{(N-\sigma)/2}(r^2)(\sin\phi)^{\tau}C^{(2\tau+\nu-1)/2}_{\sigma-\tau}(\cos\phi)\Phi_{\tau\alpha}(\theta),\end{aligned} \tag{B7}$$

with

$$A_{N\sigma\tau}=(-1)^{(N-\sigma)/2}(2\tau+\nu-3)!!\left[\frac{2^{(2\sigma+\nu+1)/2}(2\sigma+\nu-1)(N-\sigma)!!(\sigma-\tau)!}{\pi(N+\sigma+\nu-1)!!(\sigma+\tau+\nu-2)!}\right]^{1/2}. \tag{B8}$$

Next we apply Dragt's theorem to the highest weight state with $N=\sigma$,

$$\psi_{\sigma\sigma\tau\alpha}(r,\phi,\theta)=\frac{A_{\sigma\sigma\tau}}{A_{\tau\tau\tau}}\,r^{\sigma-\tau}C^{(2\tau+\nu-1)/2}_{\sigma-\tau}(\cos\phi)\psi_{\tau\tau\tau\alpha}(r,\phi,\theta), \tag{B9}$$

by replacing

$$r\rightarrow(I^{\dagger}_{\nu+1}/2)^{1/2},\quad \cos\phi\rightarrow t^{\dagger}=s^{\dagger}/(I^{\dagger}_{\nu+1})^{1/2}, \tag{B10}$$

to obtain

$$\begin{aligned}|[\sigma],\sigma,\tau\rangle &= \frac{A_{\sigma\sigma\tau}}{A_{\tau\tau\tau}}\left(\frac{I^{\dagger}_{\nu+1}}{2}\right)^{(\sigma-\tau)/2}C^{(2\tau+\nu-1)/2}_{\sigma-\tau}(t^{\dagger})|[\tau],\tau,\tau\rangle,\\ &= \left[\frac{(\sigma-\tau)!(2\tau+\nu-2)!!}{(2\sigma+\nu-3)!!(\sigma+\tau+\nu-2)!}\right]^{1/2}\sum_{k=0}^{[(\sigma-\tau)/2]}\left(-\frac{1}{2}\right)^{k}\\ &\quad\times\frac{(2\sigma+\nu-3-2k)!!}{k!(\sigma-\tau-2k)!}\,(s^{\dagger})^{\sigma-\tau-2k}(I^{\dagger}_{\nu+1})^{k}|[\tau],\tau,\tau\rangle.\end{aligned} \tag{B11}$$

By comparing (B11) with (18), one finds the expression of Eq. (19) for the expansion coefficients $F_k(\sigma,\tau)$.

Applications of quantum and classical Fisher information to two-level complex and quaternionic and three-level complex systems

Paul B. Slater[a)]
Community and Organization Research Institute, University of California, Santa Barbara, California 93106-2150

(Received 31 October 1995; accepted for publication 5 February 1996)

In the Bayesian theory of statistical inference, as first suggested by Harold Jeffreys in highly influential work, one can employ the square root of the determinant of an $n\times n$ Fisher information matrix as a reparametrization-invariant prior (generally unnormalized) measure over an n-dimensional family (Riemannian manifold) of probability distributions. Jeffreys' ansatz is adopted here to the quantum context, that is, with regard to density matrices rather than probability distributions, by computing the *quantum* Fisher information matrices (associated with Helstrom and Holevo) for the three-, five-, and eight-dimensional convex sets of two-level complex, two-level quaternionic, and three-level complex systems, respectively. In both the two-level cases, the priors have been normalized to probability distributions over the 2×2 density matrices, while, in the much more computationally demanding three-level situation, no such normalization has been accomplished. An argument is made for the general form, in terms of eigenvalues, that the (unnormalized) prior should assume over the (n^2-1)-dimensional convex set of $n\times n$ density matrices. © *1996 American Institute of Physics.* [S0022-2488(96)00506-3]

In the study of random matrices,[1] the objective is often to obtain the distribution of the eigenvalues in an ensemble of $n\times n$ Hermitian matrices as $n\to\infty$. The stochastic element is introduced by assuming that the real (complex) parts of the off-diagonal elements are identically distributed random variables. The matrices can be regarded as Hamiltonians and their eigenvalues as energy levels.

Here, a quite different—somewhat complementary—approach to ''random'' matrices is taken. Rather than viewing the matrices as Hamiltonians, they are regarded as density matrices, thus requiring in addition to Hermiticity, the nontrivial properties of non-negative definiteness and unit trace. Also, the analysis is nonasymptotic in character, focusing on the cases $n=2$ and 3, and is not—to begin with—principally concerned with the distribution of eigenvalues (two distinct density matrices can, of course, possess the same eigenvalues). The matrix ensembles under study here are the three-dimensional convex set of 2×2 (complex) density matrices, the five-dimensional convex set of 2×2 (quaternionic) density matrices, and the eight-dimensional convex set of 3×3 (complex) density matrices.

The random element is introduced by adopting an *ansatz* of Harold Jeffreys,[2,3] which has been widely applied in classical (commutative) probability,[4] to the quantum (noncommutative) domain.[5,6] In this generic approach, one computes an appropriate (classical or quantum) Fisher information matrix[4,7] and employs the square root of its determinant as a (prior) measure over a family of probability distributions (in the classical case) or density matrices (in the quantum case). The measure is invariant under reparametrizations, that is, it transforms according to the Jacobian of the transformation taking one parametrization of the probability distributions or density matrices to another.

The Fisher information matrix defines a metric (the Jeffreys' prior serving as its volume element),[8] which, in the quantum case, is equivalent[9]—up to a proportionality factor of 4—to the Bures metric. This constitutes the extension to mixed states of the Fubini Study metric on pure states and has been widely studied.[10,11]

We now consider the three cases under examination.

(i) $n=2$ *(complex)*

The 2×2 density matrices, in quaternionic form,[12] can be parametrized as

$$\rho=\frac{1}{2}\begin{pmatrix} 1+z & x-iy-ju-kv \\ x+iy+ju+kv & 1-z \end{pmatrix}, \tag{1}$$

where $i^2=j^2=k^2=-1$, $ij=-ji=k$, $jk=-kj=i$, and $ki=-ik=j$. To begin with, let us set $u=v=0$, so that we have the usual Bloch sphere (unit ball in three-space) representation of the 2×2 density matrices.

To obtain the 3×3 quantum Fisher information matrix (J), one must first find the three symmetric logarithmic derivatives (L_x,L_y,L_z) satisfying[5,6,13]

$$\frac{\partial\rho}{\partial\alpha}=\frac{\rho L_\alpha+L_\alpha\rho}{2}, \quad \alpha=x,y,z, \tag{2}$$

and then compute entries of the form

$$J_{\beta\gamma}=\mathrm{Tr}[\rho(L_\beta L_\gamma+L_\gamma L_\beta)/2], \quad \beta,\gamma=x,y,z. \tag{3}$$

Now,

$$L_x=\frac{1}{(1-x^2-y^2-z^2)}\begin{pmatrix} x(z-1) & 1-ixy-y^2-z^2 \\ 1+ixy-y^2-z^2 & -x(z+1) \end{pmatrix},$$

$$L_y=\frac{1}{(1-x^2-y^2-z^2)}\begin{pmatrix} y(z-1) & -i(1-x^2+ixy-z^2) \\ i(1-x^2-ixy-z^2) & -y(z+1) \end{pmatrix}, \quad \text{and} \tag{4}$$

$$L_z=\frac{1}{(1-x^2-y^2-z^2)}\begin{pmatrix} 1-x^2-y^2-z & xz-iyz \\ xz+iyz & -1+x^2+y^2-z \end{pmatrix},$$

so the quantum information matrix given by (3) is

$$\frac{1}{(1-x^2-y^2-z^2)}\begin{pmatrix} 1-y^2-z^2 & xy & xz \\ xy & 1-x^2-z^2 & yz \\ xz & yz & 1-x^2-y^2 \end{pmatrix}. \tag{5}$$

Its determinant is

$$1/(1-x^2-y^2-z^2). \tag{6}$$

[The determinant of (1), with $u=v=0$, is $(1-x^2-y^2-z^2)/4$.] The square root of (6), the volume element (up to a proportionality factor) for the Bures metric,[9–11] can be normalized to form the probability distribution

$$P(x,y,z)=1/\pi^2(1-x^2-y^2-z^2)^{1/2}, \quad x^2+y^2+z^2\leqslant 1. \tag{7}$$

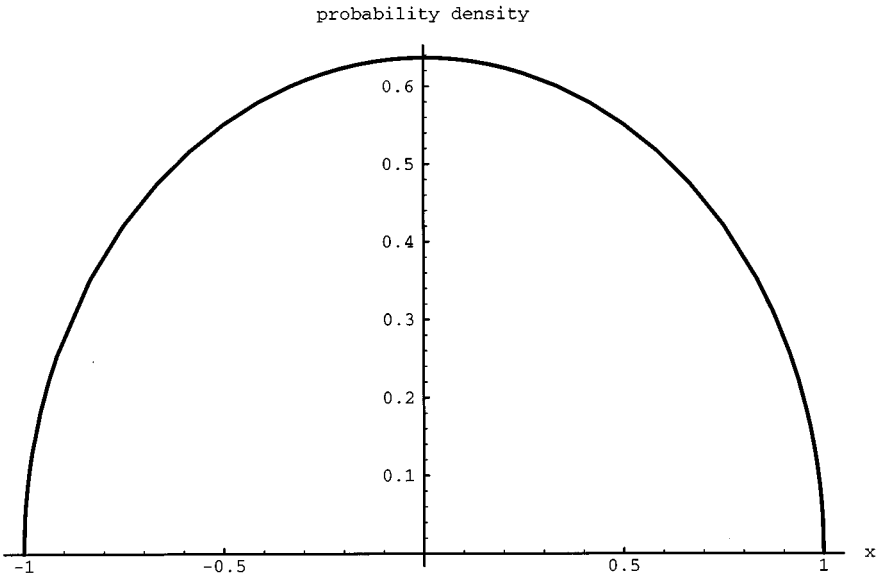

FIG. 1. Univariate marginal probability distribution, $2(1-x^2)^{1/2}/\pi$, for two-level complex quantum systems.

Our assertion is, thus, that if one chooses 2×2 complex density matrices according to this distribution, so doing will constitute a ''random'' sampling of these two-level quantum systems. If one averages the von Neumann entropy, $-\operatorname{Tr}\rho\ln\rho$, with respect to the prior (7), one obtains $2\ln 2-7/6\approx0.2196277$ for the average entropy of a 2×2 density matrix (cf. Ref. 14).

It is of interest to note that with the substitutions $x=A^{1/2}$, $y=B^{1/2}$, $z=C^{1/2}$, (7) becomes the Jeffreys' prior probability (a trivariate beta or Dirichlet distribution)

$$1/\pi^2 A^{1/2}B^{1/2}C^{1/2}(1-A-B-C)^{1/2} \tag{8}$$

for the (classical) quadrinomial distribution with probabilities A, B, C, and $1-A-B-C$.[15] Since

$$\int_{-(1-x^2-y^2)^{1/2}}^{(1-x^2-y^2)^{1/2}} P(x,y,z)\,dz=\frac{1}{\pi}, \tag{9}$$

the (three) bivariate marginal probabilities of (7) are uniform distributions over unit disks $(x^2+y^2\leqslant1,...)$. (So, Laplace's principle of insufficient reason[16] is manifested in such a form.) Then, the three univariate distributions are of the form (Fig. 1)

$$\int_{-(1-x^2)^{1/2}}^{(1-x^2)^{1/2}} \frac{1}{\pi}\,dy=\frac{2(1-x^2)^{1/2}}{\pi}. \tag{10}$$

Under the transformation, $x=2\lambda-1$, this becomes a beta distribution

$$8\lambda^{1/2}(1-\lambda)^{1/2}/\pi, \quad 0\leqslant\lambda\leqslant1 \tag{11}$$

with its two parameters equaling 1.5.

As a numerical illustration of the application of Bayes' Theorem[3,4] to the estimation of quantum systems,[17–19] let us hypothesize an experimental situation in which spin measurements are performed on each of 14 replicas of a two-level quantum system: three are taken in the X

direction: with two ''ups'' recorded, five in the Y direction with three ''ups,'' and six in the Z direction with two ''ups.'' Then the posterior (modified) probability distribution over the unit ball is proportional to the product of the prior (7) and the likelihood.

$$\left(\frac{1-x}{2}\right)\left(\frac{1+x}{2}\right)^2\left(\frac{1-y}{2}\right)^2\left(\frac{1+y}{2}\right)^3\left(\frac{1-z}{2}\right)^4\left(\frac{1+z}{2}\right)^2, \tag{12}$$

since in a two-level system with parameters x,y,z, the probability of an ''up'' in the X direction is $(1+x)/2$ and a ''down,'' $(1-x)/2$,... . This product can be normalized, through an integration over the unit ball, to comprise the posterior probability distribution

$$\frac{7168(1-x)(1+x)^2(1-y)^2(1+y)^3(1-z)^4(1+z)^2}{1903\pi^2(1-x^2-y^2-z^2)^{1/2}}. \tag{13}$$

The inverse of the information matrix (5) takes the particularly simple form

$$\begin{pmatrix} 1-x^2 & -xy & -xz \\ -xy & 1-y^2 & -yz \\ -xz & -yz & 1-z^2 \end{pmatrix}. \tag{14}$$

This serves as a (Cramér–Rao) lower bound (in the sense of positive definiteness) on the covariance matrix of unbiased estimates of the parameters of the density matrix.[5,6,13] [Each diagonal element of (14) furnishes a bound itself.]

Let us note that by transforming from Cartesian coordinates (x,y,z) to spherical ones (r,θ_1,θ_2), the Fisher information matrix (5) assumes a diagonal form

$$\begin{pmatrix} 1/(1-r^2) & 0 & 0 \\ 0 & r^2 & 0 \\ 0 & 0 & r^2 \sin\theta_1 \end{pmatrix}. \tag{15}$$

The prior probability (normalized form of the square root of its determinant) is then

$$\frac{r^2 \sin\theta_1}{\pi^2(1-r^2)^{1/2}}, \quad 0 \leqslant r \leqslant 1; 0 \leqslant \theta_1 \leqslant \pi; 0 \leqslant \theta_2 \leqslant 2\pi, \tag{16}$$

where $r^2 \sin\theta_1$ is the Jacobian of the transformation, in accordance with the principle of reparametrization invariance.[2–4]

(ii) *n=2 (quaternionic)*

The domain of the five parameters, u,v,x,y,z is the unit ball in five-space, $u^2+v^2+x^2+y^2+z^2 \leqslant 1$. Using the relations between the quaternionic elements $(1,i,j,k)$ and the Pauli matrices (Ref. 12, p. 495; Ref. 20, p. 197), the density matrix (1) can be reexpressed as the 4×4 Hermitian non-negative definite matrix of unit trace,

$$\rho = \frac{1}{4}\begin{pmatrix} 1+z & 0 & x-iy & u+iv \\ 0 & 1+z & -u+iv & x+iy \\ x+iy & -u-iv & 1-z & 0 \\ u-iv & x-iy & 0 & 1-z \end{pmatrix}. \tag{17}$$

Then, applying the formulas (2) and (3) to this matrix, we obtain the quantum Fisher information matrix

$$\frac{1}{(1-u^2-v^2-x^2-y^2-z^2)}$$

$$\times\begin{pmatrix} 1-v^2-x^2-y^2-z^2 & uv & ux & uy & uz \\ uv & 1-u^2-x^2-y^2-z^2 & vx & vy & vz \\ ux & vx & 1-u^2-v^2-y^2-z^2 & xy & xz \\ uy & vy & xy & 1-u^2-v^2-x^2-z^2 & yz \\ uz & vz & xz & yz & 1-u^2-v^2-x^2-y^2 \end{pmatrix}. \tag{18}$$

Its inverse,

$$\begin{pmatrix} 1-u^2 & -uv & -ux & -uy & -uz \\ -uv & 1-v^2 & -vx & -vy & -vz \\ -ux & -vx & 1-x^2 & -xy & -xz \\ -uy & -vy & -xy & 1-y^2 & -yz \\ -uz & -vz & -xz & -yz & 1-z^2 \end{pmatrix}, \tag{19}$$

serves as a Cramér–Rao lower bound, in the sense of non-negative definiteness, on unbiased estimates of u,v,x,y,z.[5,6,13]

The square root of the determinant of (18) can be normalized to the probability distribution

$$2/\pi^3(1-u^2-v^2-x^2-y^2-z^2)^{1/2}, \quad u^2+v^2+x^2+y^2+z^2\leqslant 1. \tag{20}$$

With the transformations, $x=A^{1/2}$, $y=B^{1/2}$, $z=C^{1/2}$, $u=D^{1/2}$, and $v=E^{1/2}$, this becomes the Jeffreys' prior

$$2/\pi^3[ABCDE(1-A-B-C-D-E)]^{1/2} \tag{21}$$

for a sextanomial distribution.[15] The marginal distribution of (20) over any of the five coordinates is a uniform distribution $(2/\pi^2)$ over a unit ball in four-space. The lower-dimensional marginals are then of the forms

$$4(1-x^2-y^2-z^2)^{1/2}/\pi^2, \quad x^2+y^2+z^2\leqslant 1, \tag{22}$$

$$2(1-x^2-y^2)/\pi, \quad x^2+y^2\leqslant 1 \tag{23}$$

(Fig. 2) and

$$8(1-x^2)^{3/2}/3\pi, \quad -1\leqslant x\leqslant 1 \tag{24}$$

[Fig. 3, cf. (10) and Fig. 1]. The conditional probability distribution of (20) with $u=v=0$ is simply (7).

In spherical coordinates $(r,\theta_1,\theta_2,\theta_3,\theta_4)$, (18) assumes the diagonal form

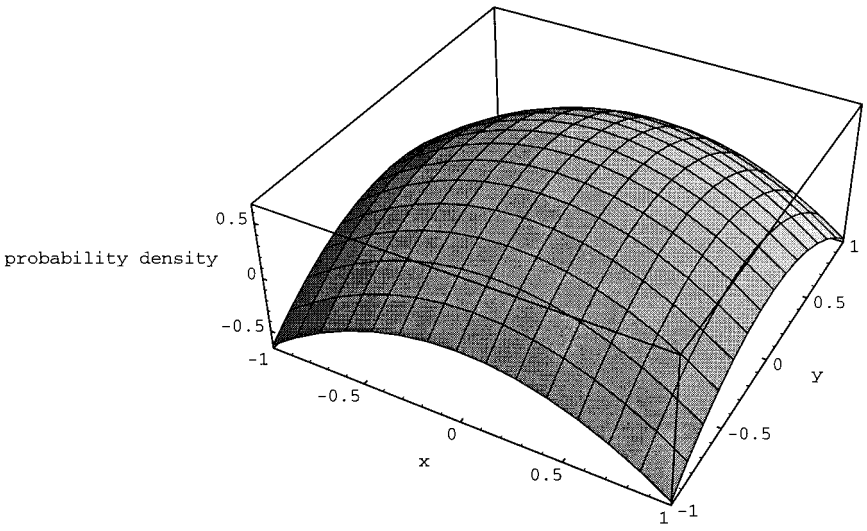

FIG. 2. Bivariate marginal probability distribution, $2(1-x^2-y^2)/\pi$, for two-level quaternionic quantum systems.

$$\begin{pmatrix} 1/(1-r^2) & 0 & 0 & 0 & 0 \\ 0 & r^2 & 0 & 0 & 0 \\ 0 & 0 & r^2 \sin^2 \theta_1 & 0 & 0 \\ 0 & 0 & 0 & r^2 \sin^2 \theta_1 \sin^2 \theta_2 & 0 \\ 0 & 0 & 0 & 0 & r^2 \sin^2 \theta_1 \sin^2 \theta_2 \sin^2 \theta_3 \end{pmatrix}. \quad (25)$$

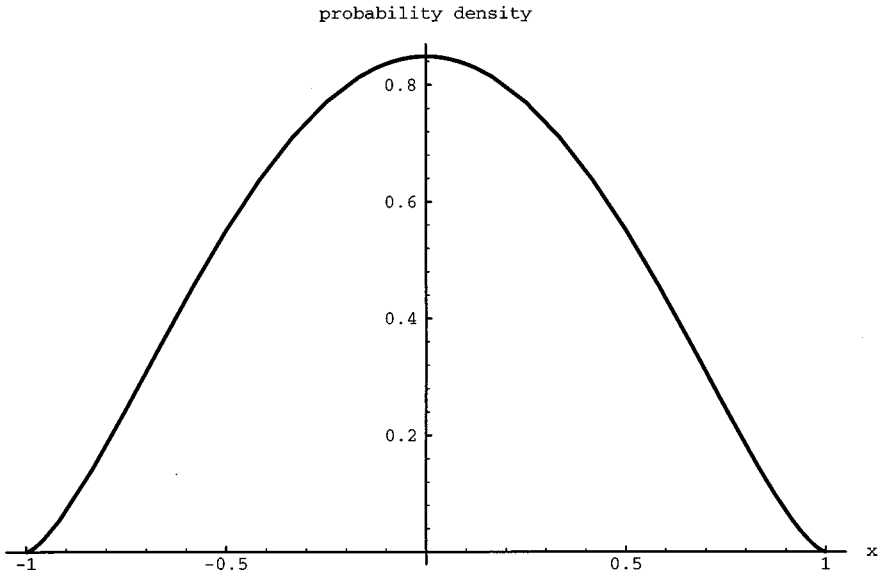

FIG. 3. Univariate marginal probability distribution, $8(1-x^2)^{3/2}/3\pi$, for two-level quaternionic quantum systems.

The normalized square root of its determinant is

$$\frac{2r^4 \sin^3 \theta_1 \sin^2 \theta_2 \sin \theta_3}{\pi^3(1-r^2)^{1/2}}, \quad 0 \leqslant r \leqslant 1; 0 \leqslant \theta_1, \theta_2, \theta_3 \leqslant \pi, 0 \leqslant \theta_4 < 2\pi, \tag{26}$$

the numerator of which is (twice) the Jacobian of the transformation from Cartesian to spherical coordinates. This reflects the property of reparametrization invariance possessed by Jeffreys' prior[2–4] [cf. (20)].

A single measurement of a two-level complex quantum system provides 0.140186 ''nats'' of information (1 nat equals 1/ln 2 bits), while a single measurement of a two-level quaternionic system furnishes less—0.090 186 2 nats. These results were obtained by computing the relative entropy (Kullback–Liebler distance or mutual information) of a posterior distribution based on one measurement [cf. (13), where 14 measurements were hypothesized] with respect to the priors (10) and (24). The relative entropy of the trivariate prior (16) with respect to the uniform distribution ($3r^2 \sin \theta_1/4\pi$) over the unit ball in three-space is 0.336099, while the relative entropy of the quintivariate prior (26) with respect to the uniform distribution ($15r^4 \sin^3 \theta_1 \sin^2 \theta_2 \sin \theta_3/8\pi^2$) over the unit ball in five-space is 0.3629558. The distribution (16), or, equivalently, (7), is thus, in this sense, smoother or less informative, closer to a uniform distribution than (26), or, equivalently, (20).

(iii) $n=3$ *(complex)*

A 3×3 density matrix is of the general form

$$\rho = \begin{pmatrix} p & r+si & t+ui \\ r-si & q & v+wi \\ t-ui & v-\omega i & 1-p-q \end{pmatrix}, \tag{27}$$

being Hermitian, non-negative definite and of trace 1.[21] Since 3 is a prime number, one can find a set of four mutually unbiased (orthonormal) bases of three-dimensional complex Hilbert space.[22–24] Following Wootters [Ref. 23, formula (3)], one such set of bases is

$$\begin{aligned} B^0 &= \left\{ \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \right\}, \\ B^1 &= \left\{ \begin{pmatrix} \mathscr{S}/\sqrt{3} \\ 1/\sqrt{3} \\ \mathscr{S}/\sqrt{3} \end{pmatrix}, \begin{pmatrix} 1/\sqrt{3} \\ \mathscr{S}/\sqrt{3} \\ \mathscr{S}/\sqrt{3} \end{pmatrix}, \begin{pmatrix} \mathscr{S}/\sqrt{3} \\ \mathscr{S}/\sqrt{3} \\ 1/\sqrt{3} \end{pmatrix} \right\}, \\ B^2 &= \left\{ \begin{pmatrix} \eta/\sqrt{3} \\ 1/\sqrt{3} \\ \eta/\sqrt{3} \end{pmatrix}, \begin{pmatrix} 1/\sqrt{3} \\ \eta/\sqrt{3} \\ \eta/\sqrt{3} \end{pmatrix}, \begin{pmatrix} \eta/\sqrt{3} \\ \eta/\sqrt{3} \\ 1/\sqrt{3} \end{pmatrix} \right\}, \\ B^3 &= \left\{ \begin{pmatrix} \mathscr{S}/\sqrt{3} \\ \eta/\sqrt{3} \\ 1/\sqrt{3} \end{pmatrix}, \begin{pmatrix} \eta/\sqrt{3} \\ \mathscr{S}/\sqrt{3} \\ 1/\sqrt{3} \end{pmatrix}, \begin{pmatrix} 1/\sqrt{3} \\ 1/\sqrt{3} \\ 1/\sqrt{3} \end{pmatrix} \right\}, \end{aligned} \tag{28}$$

where $\mathscr{S}=\exp(2\pi i/3)$ and $\eta=\exp(-2\pi i/3)$. (The square of the inner product of any two vectors from different bases is $\frac{1}{3}$.) Now, by solving a set of linear equations, one can reparametrize ρ [Eq. (27)] using the relations

$$p=b_{01},\quad q=b_{02},\quad r=(2-b_{11}-b_{12}-b_{21}-b_{22}-b_{31}-b_{32})/2,$$
$$s=(b_{11}-b_{12}-b_{21}+b_{22}-b_{31}+b_{32})/2\sqrt{3},\quad t=(b_{11}+b_{21}-b_{31}-b_{32})/2,$$
$$u=(-b_{11}-2b_{12}+b_{21}+2b_{22}+b_{31}-b_{32})/2\sqrt{3},\quad v=(b_{12}+b_{22}-b_{31}-b_{32})/2,$$
$$w=(-2b_{11}-b_{12}+2b_{21}+b_{22}-b_{31}+b_{32})/2\sqrt{3}, \tag{29}$$

where b_{ij} is the expected value of ρ in the jth state of the ith base ($i=0,1,2,3$) of (28). (Alternative parametrizations of three-level quantum systems are, of course, available.[21,25–27]) It is important to note that $b_{ij}\geqslant 0$ for all i and j, and $\Sigma_{j=1}^{3} b_{ij}=1$ for all i, so four trinomial probability distributions are at hand—having a total of eight degrees of freedom. (In the two-level complex case, there are correspondingly three binomial distributions, while in the two-level quaternionic case, there are five relevant binomial distributions.)

Formula (3.8) of Ref. 11,

$$\frac{1}{4}\,\mathrm{Tr}\left\{ d\rho d\rho+\frac{3}{1-\mathrm{Tr}\,\rho^3}\,(d\rho-\rho d\rho)(d\rho-\rho d\rho)+\frac{3|\rho|}{1-\mathrm{Tr}\,\rho^3}\,(d\rho-\rho^{-1}d\rho)(d\rho-\rho^{-1}d\rho)\right\}, \tag{30}$$

gives the Bures metric over the 3×3 density matrices (ρ). This has been computed using the parametrization (29) and placed in matrix form. The result, by the analysis of Ref. 9, is proportional to the 8×8 quantum Fisher information matrix for the same parametrization.

It has not been possible to symbolically compute the determinant of this matrix since its entries are all highly involved expressions. However, several conditional results were more easily obtainable, having fixed some of the eight parameters beforehand. For example, if all the eight parameters (b_{ij}) are equated to a single one—call it b—then the square root of the Bures determinant is

$$3\cdot 3^{1/2}/256b^2(-1+2b)^2(-1+4b)^{1/2} \tag{31}$$

(Fig. 4). The range of permissible values of b is $[\frac{1}{4},\frac{1}{2}]$. If all the parameters except b_{i1} and b_{i2} (for $i=0$, 1, 2, or 3) are set equal to $\frac{1}{3}$, the conditional prior is then of the form

$$3\cdot 3^{1/2}/32(-1+b_{i1})(-1+b_{i2})(b_{i1}+b_{i2})(b_{i2}b_{i2}(1-b_{i1}-b_{i2}))^{1/2} \tag{32}$$

(Fig. 5).

Remarks: In a recent paper (Ref. 19, cf. Ref. 28), the author has presented results analogous to those given above for $n=2$ (both complex and quaternionic), but based on Fisher information matrices defined classically. These matrices were obtained by considering an $n\times n$ density matrix to represent a complex n-variate normal (Gaussian) distribution over the vectors of n-dimensional Hilbert space. For the case $n=2$ (complex), the counterpart of the information matrix (5) was [Ref. 19; Ref. 28, formula (11)]

$$\frac{1}{(1-x^2-y^2-z^2)^2}\begin{pmatrix} 2(1+x^2-y^2-z^2) & 4xy & 4xz \\ 4xy & 2(1-x^2+y^2-z^2) & 4yz \\ 4xz & 4yz & 2(1-x^2-y^2+z^2) \end{pmatrix}. \tag{33}$$

The square root of its determinant is

$$\frac{2\cdot 2^{1/2}(1+x^2+y^2+z^2)^{1/2}}{(1-x^2-y^2-z^2)^2}, \tag{34}$$

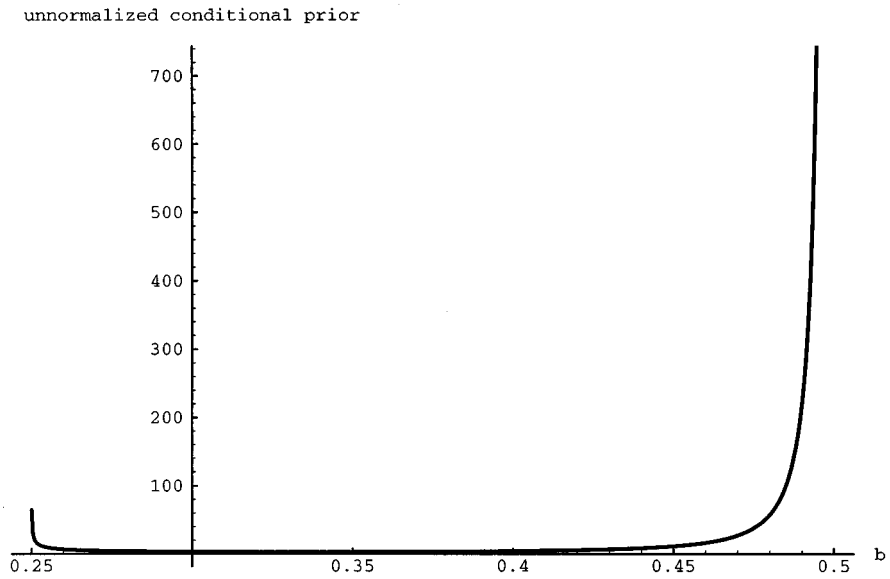

FIG. 4. Univariate unnormalized conditional prior (31) for three-level complex systems.

which *cannot* [cf. (6) and (7)] be normalized over the unit ball in three-space, though, through a limiting procedure,[19,28] one can obtain bivariate marginal probability distributions of the form

$$1/2\pi(1-x^2-y^2)^{1/2}, \quad x^2+y^2\leqslant 1. \tag{35}$$

[The quantum counterpart of this result—reported above—is the uniform distribution $(1/\pi)$.] Relatedly, one could not then obtain trivariate posterior probabilities [cf. (13)], but only bivariate ones.[19]

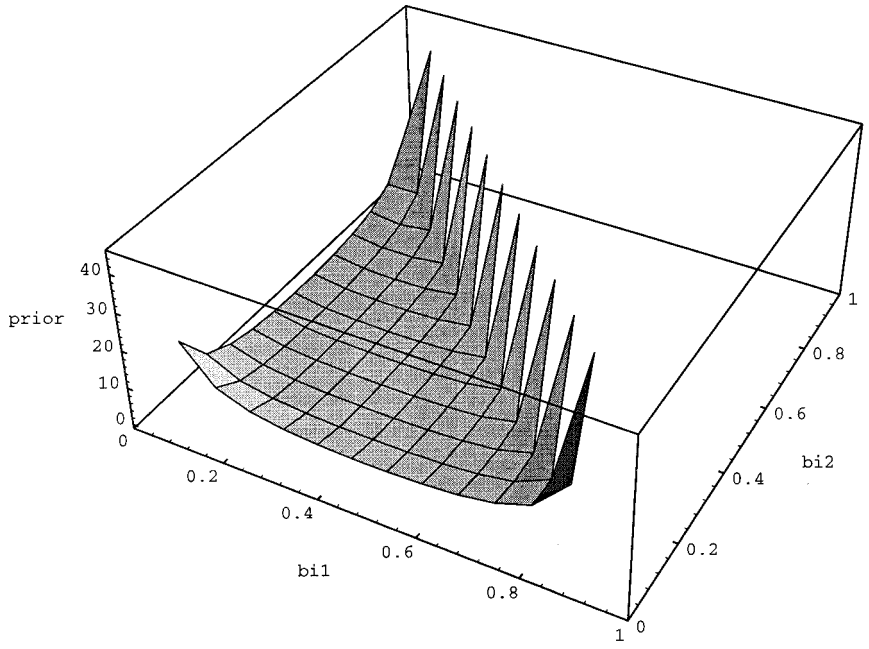

FIG. 5. Bivariate unnormalized conditional prior (32) for three-level complex systems.

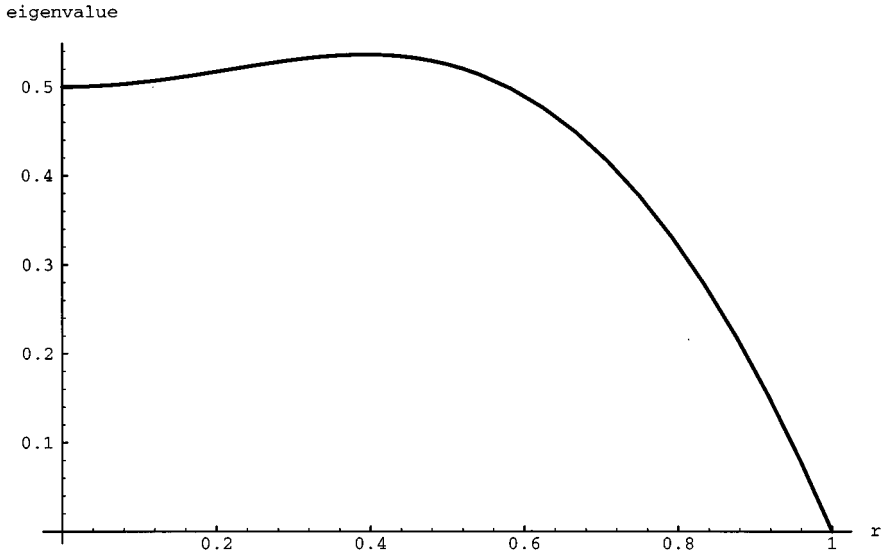

FIG. 6. Unrepeated eigenvalue of difference of inverses of 3×3 quantum and classical Fisher information matrices for two-level complex systems (spherical coordinates).

If the inverse of (33) is subtracted from the inverse of (5), that is, (14), the resulting difference has two eigenvalues both equal to $(1+x^2+y^2+z^2)/2$, which are clearly positive, and a third, which can be expressed in spherical coordinates as

$$\frac{1+2r^2-3r^4}{2(1+r^2)}. \tag{36}$$

This is positive for r, $0\leqslant r<1$ (Fig. 6). The non-negative nature of these three eigenvalues demonstrates that this difference of inverses is non-negative definite. Hence, in the sense of the Cramér–Rao lower bound,[5,6] the quantum Fisher information analysis provides a greater lower bound on the covariance matrices of unbiased estimates of x,y,z than the classical Fisher information analysis previously reported.[19,28] This result is plausible in that one can obtain only partial information concerning a quantum state through a quantum measurement.

A parallel analysis was also conducted involving the inverses of the quantum and classical quaternionic 5×5 Fisher information matrices (19). Four of the five eigenvalues of the matrix difference equalled, in spherical coordinates, $(3+r^2)/4$, where $r^2=u^2+v^2+x^2+y^2+z^2$. This value is clearly positive for r, $0\leqslant r\leqslant1$. The fifth eigenvalue (Fig. 7),

$$\frac{3+2r^2-5r^4}{4(1+r^2)} \tag{37}$$

is (cf. Fig. 6) also non-negative in the range of interest. Consequently, in the quaternionic as well as complex realms of two-level systems, the inverses of the quantum Fisher information matrices provide more stringent bounds than do the classical information matrices.[19,28] For $r=1$, that is, the pure states, since the unrepeated eigenvalues (36) and (37) are zero, there is a partial degeneracy in this regard.

For the classical Fisher information analysis of three-level systems, the counterparts of (31) and (32) have been found to be

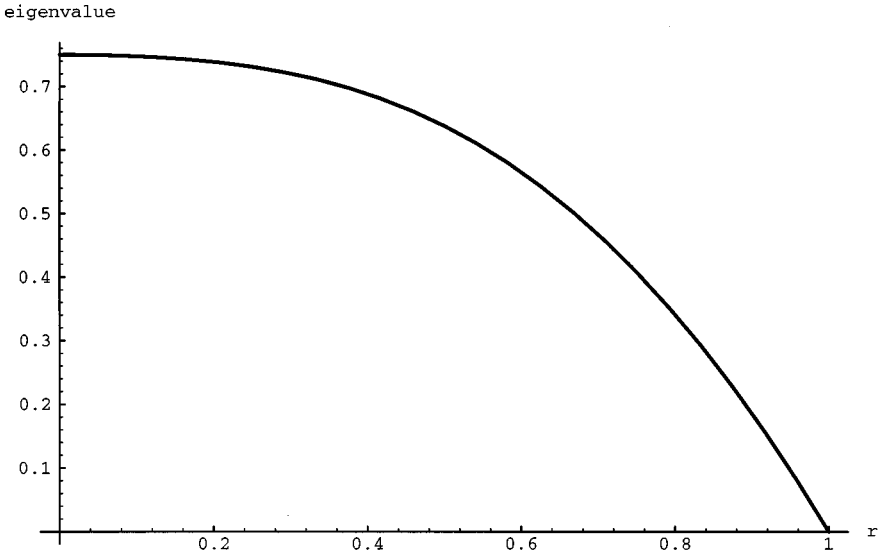

FIG. 7. Unrepeated eigenvalue of difference of inverses of 5×5 quantum and classical Fisher information matrices for two-level quaternionic systems (spherical coordinates).

$$\frac{3\cdot 3^{1/2}(3-16b+24b^2)^{1/2}}{(-1+2b)^6(-1+4b)^3} \tag{38}$$

and

$$\frac{3\cdot 3^{1/2}(1-2b_{i1}+2b_{i1}^2-2b_{i2}+2b_{i2}b_{i2}+2b_{i2}^2)^{1/2}}{(b_{i1}b_{i2}(1-b_{i1}-b_{i2}))^3}. \tag{39}$$

Dittmann [Ref. 11, formula (2.4)] has expressed the Bures metric, in general form, as

$$\tfrac{1}{2}\,\mathrm{Tr}(L_\rho+R_\rho)^{-1}(d\rho)d\rho, \tag{40}$$

where L_ρ and R_ρ are the operators of left and right multiplication of matrices by ρ. It was also observed that $L_\rho+R_\rho$ has the spectrum $\{\lambda+\mu|\ \lambda,\mu$ are eigenvalues of $\rho\}$. We have computed for the cases studied above ($n=2,3$) square roots of products of the form [that is, the square roots of the determinants of $(L_\rho+R_\rho)^{-1}$]

$$\prod_{i,j=1}^{n} 1 \Big/ (\lambda_i+\lambda_j) \tag{41}$$

and have found that this formula (conjectured to be proportional to the determinant of the quantum Fisher information matrix for all n) yields, up to proportionality, the results (6), (20), (31), and (32) reported here. [Note that, in this regard, the eigenvalues of the matrices from which (31) and (32) were generated are $(1-2b)$ (repeated) and $(-1+4b)$ and b_{i1}, b_{i2}, and $1-b_{i1}-b_{i2}$, respectively.] By the properties of the characteristic polynomial of a matrix,[29] these results would indicate that the three-level quantum prior, in general, is inversely proportional to the product of the square root of the determinant of ρ and the expression obtained by subtracting the determinant of ρ from the sum of the three principal minors of order two of the three-dimensional matrix ρ.

ACKNOWLEDGMENT

I would like to express appreciation to the Institute for Theoretical Physics for computational support in this research.

Free quantum fields on the Poincaré group

M. Toller
Dipartimento di Fisica dell'Università, Trento, Istituto Nazionale di Fisica Nucleare, Gruppo collegato di Trento, Italia

(Received 19 September 1995; accepted for publication 29 January 1996)

A class of free quantum fields defined on the Poincaré group is described by means of their two-point vacuum expectation values. They are not equivalent to fields defined on the Minkowski space–time and they are ''elementary'' in the sense that they describe particles that transform according to irreducible unitary representations of the symmetry group, given by the product of the Poincaré group and of the group SL(2,**C**) considered as an internal symmetry group. Some of these fields describe particles with positive mass and arbitrary spin and particles with zero mass and arbitrary helicity or with an infinite helicity spectrum. In each case the allowed SL(2,**C**) internal quantum numbers are specified. The properties of local commutativity and the limit in which one recovers the usual field theories in Minkowski space–time are discussed. By means of a superposition of elementary fields, one obtains an example of a field that presents a broken symmetry with respect to the group Sp(4,**R**) that survives in the short-distance limit. Finally, the interaction with an accelerated external source is studied and it is shown that, in some theories, the average number of particles emitted per unit of proper time diverges when the acceleration exceeds a finite critical value. © *1996 American Institute of Physics.* [S0022-2488(96)02005-7]

I. INTRODUCTION

Quantum field theories defined on the Poincaré group manifold $\mathscr{P}$ instead of the Minkowski space–time have been introduced by Lurçat[1] in 1964. A motivation of these investigations was a symmetric treatment of translations, rotations, and Lorentz boosts, namely of all the restricted Poincaré transformations. Later[2,3] it has been recognized that this point of view, in order to be really consistent, requires a symmetric treatment of velocity, angular velocity, and acceleration; since in relativistic theories there is an upper bound to the velocity of material objects, one has to introduce similar limitations to angular velocity and acceleration. The existence of an upper bound to the proper acceleration has also been suggested in Ref. 4. Brandt[5,6] has shown that a maximal acceleration of the order of $c^2 l_{\mathrm{P}}^{-1}$, where l_{P} is the Planck length, is expected as a quantum gravitational effect.

The theories studied in Ref. 1 are symmetric with respect to both the left and the right translations of the group $\mathscr{P}$. We suggest that the physical symmetry group is smaller, namely it contains all the left translations, but only the right translations generated by the homogeneous Lorentz group [or its universal covering SL(2,**C**)]. The aim of the present paper is to analyze the free fields on $\mathscr{P}$ (or on its universal covering $\tilde{\mathscr{P}}$) that satisfy this weaker symmetry requirement besides the natural positivity and spectral conditions. We begin by considering ''elementary'' fields, namely fields that describe particles that transform according to irreducible unitary representations (IURs) of the symmetry group. Other fields can be obtained by superposition of elementary fields, which could provide the building blocks for the construction of theories implementing the physical ideas indicated above.

We do not claim to have found all the fields with the assumed properties. A formal proof of this statement would require a more precise formulation of the problem, for instance, a specification of the distribution space to which the fields have to belong. We think that in a first approach

0022-2488/96/37(6)/2694/37/$10.00

it is more useful to find as many examples as possible and to introduce technical assumptions only when they are found to be necessary.

In order to clarify the physical meaning of our assumptions, it is convenient to consider the theories on an arbitrary group manifold as special cases of theories of a much larger class,[7–10] based on an n-dimensional differentiable manifold $\mathscr{S}$ endowed with a geometric structure defined by n vector fields A_α ($\alpha=0,...,n-1$) linearly independent at every point of $\mathscr{S}$. If $\mathscr{S}=\mathscr{G}$ is a group manifold, the vector fields A_α are the generators of the right translations (invariant under left translations)[11] and form a basis of the Lie algebra $\mathbf{l}$ of $\mathscr{G}$.

In another interesting case, $\mathscr{S}$ is the ten-dimensional principal bundle[12] of the pseudo-orthonormal frames (tetrads) of a (3+1)-dimensional pseudo-Riemannian space–time $\mathscr{M}$. The fields

$$A_4=A_{23}, \quad A_5=A_{31}, \quad A_6=A_{12}, \quad A_7=A_{10}, \quad A_8=A_{20}, \quad A_9=A_{30} \tag{1.1}$$

are the generators of the structural group of the bundle, namely of the Lorentz group acting on the tetrads. They define a basis of the ''vertical'' subspaces of the tangent spaces of $\mathscr{S}$. The fields $A_0,\ldots,A_3$ describe the infinitesimal parallel displacements along the tetrad vectors, namely they generate the ''horizontal'' subspaces which define a connection. If $\mathscr{M}$ is the flat Minkowski space–time, one can identify the bundle of frames $\mathscr{S}$ with the Poincaré group. In a similar way the de Sitter (or anti-de-Sitter) group can be identified with the bundle of frames $\mathscr{S}$ of a pseudo-Riemannian space–time $\mathscr{M}$ with constant positive (or negative) curvature.

Classical field theories including gravitation based on these ideas have been developed in Refs. 8–10, 13, and 14. If one identifies $\mathscr{S}$ with a principal bundle with a larger structural group, one can also treat Maxwell and Yang–Mills fields.[8,15] Any classical or quantum field defined on the pseudo-Riemannian space–time $\mathscr{M}$ can easily be translated into a field defined on the bundle of frames $\mathscr{S}$. We think, however, that the new formalism should be used to formulate new physical ideas.

The fields A_α define a ''teleparallelism'' in $\mathscr{S}$, namely a set of isomorphisms between all the tangent spaces of $\mathscr{S}$ and a fixed vector space $\mathscr{T}=\mathbf{R}^n$. A closed wedge $\mathscr{T}^+\subset\mathscr{T}$ defines a field of wedges in the tangent spaces of $\mathscr{S}$ which describes the causal properties of the theory and in particular the upper bounds to velocity, angular velocity, and acceleration.[2,3]

It is useful to introduce the structure coefficients $F^\gamma_{\alpha\beta}$ defined by

$$[A_\alpha, A_\beta]=F^\gamma_{\alpha\beta}A_\gamma, \tag{1.2}$$

where $[A, B]$ is the Lie bracket of two vector fields. If $\mathscr{S}$ is a group manifold, they are the structure constants of the corresponding Lie algebra. If $\mathscr{S}$ is a bundle of frames, some of the structure coefficients are the components of the curvature and torsion tensors and in a theory of gravitation they have a dynamical character, namely they depend on the distribution of matter.

In accord with the ideas indicated above, it is natural to consider theories in which all the structure coefficients $F^\gamma_{\alpha\beta}$ and all the vector fields A_α have a dynamical character. In a theory of this kind, the field equations determine both the fields A_α that describe the geometry and the fields ψ_ρ that describe matter. We assume that this theory is invariant under all the diffeomorphisms of $\mathscr{S}$ and under a symmetry group $\mathscr{F}$ acting linearly in the following way:

$$\psi_\rho\to S_\rho{}^\sigma(k)\psi_\sigma, \tag{1.3}$$

$$A_\alpha\to C_\alpha{}^\beta(k)A_\beta, \quad k\in\mathscr{F}, \tag{1.4}$$

where S and C are linear representations of $\mathscr{F}$. The representation C is real and one can consider it as acting on the vector space $\mathscr{T}$. It is natural to require that the transformations $C(k)$ leave the

wedge $\mathscr{T}^+$ invariant. It follows from the physical interpretation of the fields A_α that the element k cannot depend on the point of $\mathscr{S}$, namely $\mathscr{F}$ is a global symmetry group.

In the physically most interesting example, $\mathscr{S}$ is a ten-dimensional manifold, the group $\mathscr{F}$ contains a subgroup isomorphic to the restricted Lorentz group $SO\uparrow(3,1)$, and the representation C restricted to this subgroup is the direct sum of the vector and the antisymmetric tensor representations. Actually, in order to treat matter fields with half-integral spin, it is convenient to assume that $\mathscr{F}$ contains the universal covering of $SO^\uparrow(3,1)$, namely $SL(2,\mathbf{C})$. Under these conditions, if we assume that $\mathscr{T}^+$ is a cone (namely that $\mathscr{T}^+ \cap -\mathscr{T}^+ = \{0\}$) with interior points, this cone is determined up to a change of the units of time and length.[2,3] It has a large symmetry group given by $L(4,\mathbf{R})$ acting on $\mathscr{T}$ by means of its symmetric tensor representation.[2] In this framework, it is natural to assume that the symmetry group $\mathscr{F}$ of the theory is $L(4,\mathbf{R})$ or one of its subgroups that contain $SL(2,\mathbf{C})$. Possible choices are $SL(4,\mathbf{R})$, $Sp(4,\mathbf{R})$ or $SL(2,\mathbf{C})$.

In the present paper we consider the fields A_α as fixed classical fields and we concentrate our attention on the quantum fields that describe matter. The symmetry group of this partial theory contains only the elements of the symmetry group of the complete theory that do not affect the geometric fields A_α. For instance, the elements of $\mathscr{F}$ that do not preserve the values of the structure coefficients $F^\gamma_{\alpha\beta}$ represent broken symmetries. If we consider the values of the structure coefficients as expectation values of some fields in a vacuum state of the complete theory, this is a spontaneous symmetry breaking.

In Sec. II we discuss some general properties of quantized matter fields on an arbitrary connected Lie group. In Sec. III we begin the treatment of free quantum fields on the universal covering $\tilde{\mathscr{P}}$ of the restricted Poincaré group [namely the inhomogeneous $SL(2,\mathbf{C})$ group]. The subgroup of $\mathscr{F}$ that survives the symmetry breaking must preserve both the cone $\mathscr{T}^+$ and the structure constants of the Poincaré Lie algebra. It follows that it must coincide with $SL(2,\mathbf{C})$, as we have anticipated above. The unbroken symmetry group of the theory is the product of $\tilde{\mathscr{P}}$ and $SL(2,\mathbf{C})$, considered as an internal symmetry group. The free quantum fields are completely described by the two-point Wightman distributions [or vacuum expectation values, (VEVs)] and we give a general representation of the distributions that satisfy the appropriate symmetry, spectral, and positivity conditions. In Sec. IV we treat the commutation or anticommutation properties of the free fields and we discuss the connection between spin and statistics, which is not the usual one. For instance, a ''scalar'' field, namely a field with only one component, has to be quantized with commutators, but it can describe particles with any spin. In Sec. V we treat the positive-mass case with arbitrary spin and we write explicitly a wide class of VEVs in terms of the matrix elements of the IURs of $SL(2,\mathbf{C})$. In Sec. VI we consider the more delicate zero-mass case and find theories that describe particles with an infinite helicity spectrum (not observed in nature) and particles with an arbitrary given helicity. Scalar fields that describe particles with zero mass and given nonvanishing helicity have pathological features.

Since the nontrivial IURs of $SL(2,\mathbf{C})$ are infinite dimensional, the mass spectrum of these theories is infinitely degenerate. In order to avoid evident contradictions with the known physical phenomena, we have to require that, when the mass is within the range of presently available energies, only a finite number of internal states of the particles can be excited by the field with appreciable probability. This happens when the parameters which label the IURs of $SL(2,\mathbf{C})$ approach the limit $M=j=0$, $c\to 1$. Actually, in this limit the VEVs tend to the ones that define the usual scalar free field in Minkowski space–time. This problem is less relevant when the mass is of the order of the Planck mass. The theories with a broken higher symmetry satisfy these requirements automatically.

In Sec. VII we find the differential equations satisfied by the quantum fields defined in the preceding sections and compare them with some field equations in a flat ten-dimensional space. In Sec. VII we introduce the concept of ''spin-mass-shell'' and discuss the relation between the VEVs on $\tilde{\mathscr{P}}$ and the corresponding distributions defined on $\mathbf{R}^{10}$. We show that not all the free fields on the flat space have a corresponding field on $\tilde{\mathscr{P}}$.

In the remaining sections we give some examples, in order to illustrate the general formalism. A more complete treatment will be given elsewhere. In Sec. IX we consider a theory on the flat space symmetric with respect to the group Sp(4,**R**) and build the corresponding theory on $\tilde{\mathscr{P}}$. In this theory the higher symmetry is broken, but the VEVs maintain the higher symmetry in the short-distance limit. This is an explicit example of a new kind of broken symmetry in quantum field theory.

In Sec. X we consider an external source, represented by an accelerated disk, interacting with one of the fields defined in the present paper. We consider with more detail the field introduced in Sec. IX and we show that the number of particles emitted per unit of proper time diverges when the acceleration exceeds a finite critical value. This result shows that the formalism really contains, in some sense, the ideas that provided its motivation. Brandt[6] has suggested that, when the acceleration of a particle approaches a critical value, the energy radiated in the form of quantum black holes diverges, preventing a larger acceleration. The formalism presented here could provide a simplified model for this process, if the particles described by our fields are interpreted as quantum black holes.[16] This interpretation, however, raises several difficult problems.

II. QUANTUM FIELDS ON A GROUP MANIFOLD

As we have anticipated in the Introduction, we consider an n-dimensional manifold $\mathscr{S}$ with n vector fields A_α ($\alpha=0,...,n-1$) that, being linearly independent, define a basis in each tangent space of $\mathscr{S}$. As a consequence, we can identify all the tangent spaces with a single vector space $\mathscr{T}$. These vector fields describe the gravitational field and possibly other gauge fields, while matter is described by a set of fields ψ_ρ, on the manifold $\mathscr{S}$.[7–10] We assume that the complete field equations, including gravitation, are invariant under all the diffeomorphisms of $\mathscr{S}$ and under a group $\mathscr{F}$ which acts on the matter fields and on the geometric fields according to the linear formulas (1.3) and (1.4).

We consider the fields A_α as classical external fields and we restrict our considerations to symmetry transformations that leave them invariant. The transformations which have this property are implemented by unitary or antiunitary operators acting on the Hilbert space $\mathscr{H}$ which describes the states of matter. Since we consider only connected symmetry groups, we deal only with unitary symmetry operators.[17] Moreover, we assume that they form a continuous representation of the symmetry group.[18] The fields ψ_ρ are operator-valued distributions on $\mathscr{S}$ that act in a dense linear subspace $\mathscr{D}$ of $\mathscr{H}$. We assume that both the smeared field operators and the symmetry operators transform $\mathscr{D}$ into itself.

Field theories on an n-dimensional manifold $\mathscr{S}$ which has a symmetry group have been treated in Ref. 7. Here we consider the case in which the vector fields A_α generate a connected n-dimensional Lie group $\mathscr{G}$ of diffeomorphisms of $\mathscr{S}$. It is convenient to assume that $\mathscr{G}$ acts on the right in the space $\mathscr{S}$, namely the action of the element $g\in\mathscr{G}$ on the element $s\in\mathscr{S}$ is written as $(g,s)\to sg$. We assume also that $\mathscr{G}$ acts freely and transitively; it follows that if we choose an origin $s_0\in\mathscr{S}$, the mapping $g\to s=s_0g$ is a diffeomorphism of $\mathscr{G}$ onto $\mathscr{S}$. The action of $\mathscr{G}$ on $\mathscr{S}$ takes the form

$$s=s_0g\to s'=s_0gh=sh,\quad g,h\in\mathscr{G}, \tag{2.1}$$

namely, it corresponds to a right translation of $\mathscr{G}$. The vector fields A_α can also be considered as fields on $\mathscr{G}$, which generate the right translations. They form a basis of the Lie algebra $\mathbf{l}$ of $\mathscr{G}$, that, as a vector space, can be identified with $\mathscr{T}$.

The vector fields A_α are invariant under the left translations of $\mathscr{G}$; it follows that a transformation of the kind

$$s=s_0g\to s'=s_0hg,\quad g,h\in\mathscr{G}, \tag{2.2}$$

is a symmetry transformation that leaves the geometry of $\mathscr{S}$ invariant. It can be interpreted as a change of the origin s_0.

The diffeomorphisms of the kind (2.2) provide a first class of symmetry transformations. They act on the matter fields in the following way:

$$\psi_\rho(s_0 h^{-1} g) = U(h)^{-1} \psi_\rho(s_0 g) U(h), \quad g,h \in \mathscr{G}. \tag{2.3}$$

Note that the indices of the fields are not involved: every component behaves as a scalar field. We indicate by $U(A_\alpha)$ the generators of the continuous unitary representation U corresponding to the elements A_α of $\mathbf{l}$. The operators $iU(A_\alpha)$ are self-adjoint and are interpreted as the energy, the momentum, the relativistic angular momentum, and possibly (if $n>10$) the charges that generate some gauge transformations. Note that, as it is expected, these operators, as well as the unitary operators $U(h)$, depend on the choice of the frame s_0.

The diffeomorphisms of the kind (2.1) affect the geometric fields according to the formula

$$A_\alpha \to A_\beta B^\beta{}_\alpha(h), \tag{2.4}$$

where $B^\beta{}_\alpha(h)$ is the adjoint representation of $\mathscr{G}$. They give rise to symmetry transformations only if Eq. (2.4) can be compensated by a transformation of the kind (1.4), namely, if

$$B^\beta{}_\alpha(h) = C_\alpha{}^\beta(\hat{h}^{-1}), \quad h \in \mathscr{G}, \quad \hat{h} \in \mathscr{F}. \tag{2.5}$$

This condition defines a subgroup $\mathscr{G}_2 \subset \mathscr{G}$ and we assume that $h \to \hat{h}$ is a continuous homomorphism of $\mathscr{G}_2$ onto a subgroup $\mathscr{F}_2 \subset \mathscr{F}$. In the following we write $S(h)$ instead of $S(\hat{h})$. Then we have

$$S_\rho{}^\sigma(h) \psi_\sigma(sh) = V(h)^{-1} \psi_\rho(s) V(h), \quad h \in \mathscr{G}_2. \tag{2.6}$$

The operators $V(h)$ commute with the operators $U(g)$ and do not depend on the choice of s_0. They describe a kind of internal symmetry.

The internal automorphisms of $\mathscr{G}$, given by $g \to hgh^{-1}$, are the product of a right and a left translation and do not require a separate treatment. The external automorphisms of $\mathscr{G}$ (for instance, the space–time dilatations in the Poincaré group) give rise to a new kind of symmetry if their action on the fields A_α can be compensated by a transformation of the kind (1.4). This compensation is not possible in the cases we shall treat in the following sections.

Several general features of the quantum field theories on Minkowski space–time[19,20] can be extended to the theories on a group manifold. We assume that there is a vacuum state $\Omega \in \mathscr{D}$ invariant with respect to both the representations U and V, and we define the VEV

$$(\Omega, \psi_\rho(s_1) \psi_\sigma(s_2) \Omega) = \mathscr{W}_{\rho\sigma}(s_1, s_2). \tag{2.7}$$

It follows from Eq. (2.3) that this quantity can be considered as a distribution on $\mathscr{G}$. In fact, we have

$$\mathscr{W}_{\rho\sigma}(s_1, s_2) = \mathscr{W}_{\rho\sigma}(s_0 g_1, s_0 g_2) = W_{\rho\sigma}(g_1^{-1} g_2). \tag{2.8}$$

In the following we understand a fixed choice of s_0 and we write $\psi_\rho(g)$ instead of $\psi_\rho(s_0 g)$. The VEV of $m+1$ fields is defined in the following way as a distribution on $\mathscr{G}^m$:

$$(\Omega, \psi_{\rho_1}(g_1) \cdots \psi_{\rho_{m+1}}(g_{m+1}) \Omega) = W^{(m)}_{\rho_1 \cdots \rho_{m+1}}(g_1^{-1} g_2, \ldots, g_m^{-1} g_{m+1}). \tag{2.9}$$

If the fields $\psi_\rho(g)$ are not Hermitean, we have to consider the Hermitean conjugate as a different field and we use the notation

$$\psi^{\dagger}_{\rho}(g)=\psi_{\overline{\rho}}(g), \quad S_{\overline{\rho}}^{\ \overline{\sigma}}(h)=\overline{S_{\rho}^{\ \sigma}}(h). \tag{2.10}$$

In all the formulas any index can be replaced by a barred index and vice versa, unless it is stated otherwise. If the field is Hermitean, we have to put $\overline{\rho}=\rho$ and the representation S must be real. Then from the definition we obtain

$$\overline{W^{(m)}_{\rho_1\cdots\rho_{m+1}}}(g_1,\ldots,g_m)=W^{(m)}_{\overline{\rho}_{m+1}\cdots\overline{\rho}_1}(g_m^{-1},\ldots,g_1^{-1}) \tag{2.11}$$

and from Eq. (2.6) we obtain the symmetry property

$$S_{\rho_1}^{\ \ \sigma_1}(h)\cdots S_{\rho_{m+1}}^{\ \ \sigma_{m+1}}(h)W^{(m)}_{\sigma_1\cdots\sigma_{m+1}}(h^{-1}g_1h,\ldots,h^{-1}g_mh)=W^{(m)}_{\rho_1\cdots\rho_{m+1}}(g_1,\ldots,g_m), \quad h\in\mathscr{G}_2. \tag{2.12}$$

If we deal with free fields, all the VEVs can be obtained from the two-point distributions by means of the Wick theorem. In this case, the vectors of the kind

$$\Phi(f)=\int f^{\rho}(g)\psi^{\dagger}_{\rho}(g)dg\Omega, \tag{2.13}$$

where f is a test function and dg is an invariant measure on $\mathscr{G}$, are dense in the Hilbert space $\mathscr{H}^{(1)}$ of the ''one-particle'' states. The square of the norm of the vector (2.13) is given by

$$(\Phi(f),\Phi(f))=\int \overline{f^{\rho}}(g_1)f^{\sigma}(g_2)W_{\rho\overline{\sigma}}(g_1^{-1}g_2)dg_1dg_2\geqslant 0. \tag{2.14}$$

This is the positivity condition. For interacting field theories, we have more complicated positivity conditions that involve all the other VEVs.

The symmetry operators defined in Eqs. (2.3) and (2.6) act on the one-particle states in the following way:

$$U^{(1)}(h)\Phi(f)=\Phi(f'), \quad f'^{\rho}(g)=f^{\rho}(h^{-1}g), \tag{2.15}$$

$$V^{(1)}(h)\Phi(f)=\Phi(f'), \quad f'^{\rho}(g)=f^{\sigma}(gh)\overline{S_{\sigma}^{\ \rho}}(h^{-1}). \tag{2.16}$$

Equations (2.14)–(2.16) permit, in the usual way, the reconstruction of the one-particle Hilbert space (as the completion of a quotient) and of the operators $U^{(1)}(h)$ and $V^{(1)}(h)$. If the unitary representation $U^{(1)}\times V^{(1)}$ of $\mathscr{G}\times\mathscr{G}_2$ is irreducible, we say that the free field is ''elementary.''

III. FREE FIELDS ON THE POINCARÉ GROUP

Now we apply the general results of the preceding section to the Poincaré group. We consider the ten-dimensional manifold $\mathscr{S}$ of all the Lorentz reference frames in the Minkowski space $\mathscr{M}$ which are left-handed and future-directed. If we fix a reference frame s_0, for each reference frame s there is one and only one element of the proper orthochronous Poincaré group $\mathscr{P}$ that transforms s_0 into s. Then we can identify the space $\mathscr{S}$ with $\mathscr{P}$ and consider quantum fields defined on it. Actually, in order to treat fields with half-integral spin, it is convenient to use the universal covering $\tilde{\mathscr{P}}$ of $\mathscr{P}$, namely the semidirect product of the four-dimensional translation group $\mathbf{R}^4$ and SL(2,**C**). For the elements of this group and for their multiplication rule, we use the standard notation

$$(x,a)(y,b)=(x+\Lambda(a)y,ab), \quad x,y\in\mathbf{R}^4, \quad a,b,\in \mathrm{SL}(2,\mathbf{C}), \tag{3.1}$$

where $\Lambda(a)$ is the 4×4 Lorentz matrix corresponding to the element $a\in \mathrm{SL}(2,\mathbf{C})$. For the scalar product of two four-vectors we use the notation

$$g_{ik}x^i y^k = x\cdot y = -x^0y^0+\mathbf{x}\cdot\mathbf{y}, \quad \mathbf{x}\cdot\mathbf{y}=x^1y^1+x^2y^2+x^3y^3. \tag{3.2}$$

The one-parameter subgroups of $\mathrm{SL}(2,\mathbf{C})$ that correspond to rotations around the axes and to pure Lorentz transformations along the axes are written as

$$u_k(\theta)=\exp(-\tfrac{1}{2}i\theta\sigma_k), \quad a_k(\zeta)=\exp(\tfrac{1}{2}\zeta\sigma_k), \tag{3.3}$$

where σ_k are the Pauli matrices.

We assume that the group $\mathscr{T}$ contains $\mathrm{SL}(2,\mathbf{C})$ and that it preserves the cone $\mathscr{T}^+$ defined in Refs. 2 and 3. It is easy to see that the translations (acting on $\mathscr{T}$ by means of the adjoint representation of $\mathscr{P}$) and the space–time dilatations (which are external automorphisms of $\widetilde{\mathscr{P}}$ and of the corresponding Lie algebra) do not preserve the cone $\mathscr{T}^+$. It follows that we have to put $\mathscr{G}_2=\mathrm{SL}(2,\mathbf{C})$. Then the general equations (2.3) and (2.6) take the form

$$\psi_\rho((y,b)^{-1}(x,a))=\psi_\rho(\Lambda(b)^{-1}(x-y),b^{-1}a)=U(y,b)^{-1}\psi_\rho(x,a)U(y,b), \tag{3.4}$$

$$S_\rho{}^\sigma(b)\psi_\sigma(x,ab)=V(b)^{-1}\psi_\rho(x,a)V(b). \tag{3.5}$$

If $V(b)=1$, from Eq. (3.5) we have

$$\psi_\rho(x,a)=S_\rho{}^\sigma(a^{-1})\psi_\sigma(x,1), \tag{3.6}$$

and we are dealing with a field $\psi_\sigma(x)=\psi_\sigma(x,1)$ defined on the Minkowski space–time. From Eq. (3.4), we obtain the usual covariance property

$$S_\rho{}^\sigma(b)\psi_\sigma(\Lambda(b)^{-1}(x-y))=U(y,b)^{-1}\psi_\rho(x)U(y,b). \tag{3.7}$$

In the following we consider the case in which $V(b)$ is not trivial.

A free-field theory is completely described by the two-point VEVs

$$(\Omega,\psi_\rho(x,a)\psi_\sigma(y,b)\Omega)=W_{\rho\sigma}((x,a)^{-1}(y,b))=W_{\rho\sigma}(\Lambda(a^{-1})(y-x),a^{-1}b). \tag{3.8}$$

From the covariance property (3.5) we obtain the formula

$$W_{\rho\sigma}(\Lambda(b)x,bab^{-1})=S_\rho{}^\mu(b)S_\sigma{}^\nu(b)W_{\mu\nu}(x,a) \tag{3.9}$$

(remember our conventions about the introduction of barred indices). If the field is not Hermitean, we assume

$$W_{\rho\sigma}(x,a)=W_{\overline{\rho\sigma}}(x,a)=0 \tag{3.10}$$

(here the bars over the indices cannot be modified) and the distributions $W_{\rho\overline{\sigma}}(x,a)$ and $W_{\overline{\rho}\sigma}(x,a)$ can be treated independently unless we introduce some requirement of local commutativity (see Sec. IV).

The states of the form

$$\Phi(f)=\int f^\rho(x,a)\psi_\rho^\dagger(x,a)d^4x d^6a\,\Omega, \tag{3.11}$$

where f is an arbitrary test function with compact support and d^6a is an invariant measure on $\mathrm{SL}(2,\mathbf{C})$, form a dense set in the Hilbert subspace $\mathscr{H}^{(1)}$ of the one-particle states. Their norm is given by the formula

$$(\Phi(f),\Phi(f))=\int \overline{f^{\rho}}(x,a)f^{\sigma}(y,b)W_{\rho\sigma}(\Lambda(a^{-1})(y-x),a^{-1}b)d^4x d^6a d^4y d^6b \geqslant 0, \quad (3.12)$$

which also gives the positivity property of the two-point distribution.

We want to find the solutions of the conditions (3.9) and (3.12) that describe elementary free fields. More general solutions can be obtained by means of sums or integrals of these solutions. If we introduce the Fourier transformations

$$W_{\rho\sigma}(x,a)=\int \exp(-ik\cdot x)\widetilde{W}_{\rho\sigma}(k,a)d^4k, \quad (3.13)$$

$$\widetilde{f}^{\rho}(k,a)=\int \exp(-ik\cdot x)f^{\rho}(x,a)d^4x, \quad (3.14)$$

Eq. (3.12) takes the form

$$(\Phi(f),\Phi(f))=\int \overline{\widetilde{f}^{\rho}}(k,a)\widetilde{f}^{\sigma}(k,b)\widetilde{W}_{\rho\sigma}(\Lambda(a^{-1})k,a^{-1}b)d^6a d^6b d^4k \geqslant 0, \quad (3.15)$$

and Eq. (3.9) gives

$$\widetilde{W}_{\rho\sigma}(\Lambda(b)k,bab^{-1})=S_{\rho}{}^{\mu}(b)\overline{S_{\sigma}{}^{\nu}}(b)\widetilde{W}_{\mu\nu}(k,a). \quad (3.16)$$

We assume that the distribution $\widetilde{W}_{\rho\sigma}(k,a)$ vanishes if k does not belong to the future cone (spectral condition). Since the elementary fields have a definite mass μ, this distribution has support on the orbit defined by

$$k\cdot k=-\mu^2, \quad k^0>0, \quad (3.17)$$

and has the form

$$\widetilde{W}_{\rho\sigma}(k,a)=(2\pi)^{-3}w_{\rho\sigma}(k,a)\,\theta(k^0)\,\delta(k\cdot k+\mu^2), \quad (3.18)$$

where θ is the step function.

Following a procedure introduced by Wigner,[21] we choose a representative element on each orbit,

$$\hat{k}=(\mu,0,0,0), \quad \mu>0, \quad (3.19)$$

$$\hat{k}=(1,0,0,1), \quad \mu=0 \quad (3.20)$$

and for each value of the four-momentum k on the orbit, we choose an element $a_k\in \mathrm{SL}(2,\mathbf{C})$ with the property

$$k=\Lambda(a_k)\hat{k}. \quad (3.21)$$

Then we see from Eq. (3.16) that we can put

$$w_{\rho\sigma}(k,a)=S_{\rho}{}^{\mu}(a_k)\overline{S_{\sigma}{}^{\nu}}(a^{-1}a_k)w_{\mu\nu}(a_k{}^{-1}aa_k), \quad (3.22)$$

where

$$w_{\rho\sigma}(a)=\overline{S_{\sigma}{}^{\nu}}(a)w_{\rho\nu}(\hat{k},a). \quad (3.23)$$

In this way we obtain the integral representation

$$W_{\rho\dot{\sigma}}(x,a)=(2\pi)^{-3}\int \exp(-ik\cdot x)S_\rho{}^\mu(a_k)\overline{S_\sigma}{}^\nu(a^{-1}a_k)w_{\mu\dot{\nu}}(a_k{}^{-1}aa_k)\,\theta(k^0)\,\delta(k\cdot k+\mu^2)d^4k. \tag{3.24}$$

The positivity condition (3.15) takes the form

$$(\Phi(f),\Phi(f))=(2\pi)^{-3}\int \overline{\tilde{f}^\rho}(k,a_k a)\tilde{f}^\sigma(k,a_k b)S_\rho{}^\mu(a^{-1})\overline{S_\sigma}{}^\nu(b^{-1}) \times w_{\mu\dot{\nu}}(ba^{-1})\,\theta(k^0)\,\delta(k\cdot k+\mu^2)d^6a\,d^6b\,d^4k\geqslant 0, \tag{3.25}$$

which is equivalent to the simpler condition

$$\int \overline{f^\rho}(a)f^\sigma(b)w_{\rho\dot{\sigma}}(ba^{-1})d^6a\,d^6b\geqslant 0. \tag{3.26}$$

The little group $\mathscr{K}$ corresponding to the representative element $\hat{k}$ is defined by the condition[21]

$$\Lambda(u)\hat{k}=\hat{k},\quad u\in\mathscr{K}\subset \mathrm{SL}(2,\mathbf{C}). \tag{3.27}$$

For $\mu>0$ we have $\mathscr{K}=\mathrm{SU}(2)$, the universal covering of the rotation group SO(3). For $\mu=0$, we have $\mathscr{K}=\tilde{E}(2)$, a double covering of the Euclidean group $E(2)$. From Eq. (3.16) we get the condition

$$w_{\rho\dot{\sigma}}(uau^{-1})=S_\rho{}^\mu(u)\overline{S_\sigma}{}^\nu(u)w_{\mu\dot{\nu}}(a),\quad u\in\mathscr{K}. \tag{3.28}$$

From Eq. (2.11) we also get the property

$$\overline{W}_{\rho\dot{\sigma}}(x,a)=W_{\sigma\dot{\rho}}((x,a)^{-1}). \tag{3.29}$$

An equivalent condition is

$$\overline{w}_{\rho\dot{\sigma}}(a)=w_{\sigma\dot{\rho}}(a^{-1}), \tag{3.30}$$

which is a consequence of Eq. (3.26).

Our problem is to find solutions of the conditions (3.26) and (3.28). Then we have to verify that the product of distributions that appears in Eq. (3.24) is meaningful.

If the theory can be interpreted as a theory in Minkowski space–time, namely if $V(b)=1$, the VEVs satisfy the additional symmetry property

$$W_{\rho\dot{\sigma}}(x,ab^{-1})=\overline{S_\sigma}{}^\nu(b)W_{\rho\dot{\nu}}(x,a). \tag{3.31}$$

An equivalent condition is to require that the function $w_{\rho\dot{\sigma}}(a)$ defined by Eq. (3.23) does not depend on a.

IV. LOCAL COMMUTATIVITY

The study of the distribution $W_{\rho\dot{\sigma}}(x,a)$ can be simplified if we find an element b in such a way that

$$a=bu_3(\alpha)a_3(\beta)b^{-1},\quad -2\pi<\alpha\leqslant 2\pi,\quad \beta\geqslant 0. \tag{4.1}$$

This is possible outside the four-dimensional submanifold of SL(2,**C**) where the eigenvalues of a are equal. Since these eigenvalues are given by $\exp(\pm\frac{1}{2}(\beta - i\alpha))$, we have to avoid the ''singular'' points $\alpha = 0, 2\pi, \beta = 0$; namely, we have to impose the condition

$$\cosh\beta - \cos\alpha = 2|\sinh(\tfrac{1}{2}(\beta - i\alpha)|^2 > 0. \tag{4.2}$$

We also introduce the quantities

$$\rho^2 = (\cosh\beta - \cos\alpha)^{-1}(\cosh\beta\, x\cdot x - x\cdot\Lambda(a)x), \tag{4.3}$$

$$\sigma^2 = (\cosh\beta - \cos\alpha)^{-1}(\cos\alpha\, x\cdot x - x\cdot\Lambda(a)x), \tag{4.4}$$

which, when $a = u_3(\alpha)a_3(\beta)$, take the form

$$\rho^2 = (x^1)^2 + (x^2)^2, \quad \sigma^2 = (x^0)^2 - (x^3)^2. \tag{4.5}$$

In order to simplify the formalism, we assume that $W_{\rho\dot{\sigma}}(x,a)$ is a tempered distribution in x that depends continuously on a. This is true for the massive free fields described in Sec. V. From Eqs. (3.9) and (4.1), we see that in the open set defined by Eq. (4.2) we have

$$W_{\rho\dot{\sigma}}(x,a) = S_\rho{}^\mu(b)\overline{S_\sigma{}^\nu}(b)W_{\mu\dot{\nu}}(\Lambda(b^{-1})x, u_3(\alpha)a_3(\beta)). \tag{4.6}$$

The spectral condition implies, as in the Minkowskian field theory, that the distribution $W_{\rho\dot{\sigma}}(x,u_3(\alpha)a_3(\beta))$ for fixed values of α and β is the boundary value of an analytic function of x defined in the tube $\mathrm{Im}\, x \in V_+$, where V_+ is the open future cone. From Eq. (3.9) we also obtain

$$W_{\rho\dot{\sigma}}(\Lambda(u_3(\psi)a_3(\xi))x, u_3(\alpha)a_3(\beta))$$

$$= S_\rho{}^\mu(u_3(\psi)a_3(\xi))\overline{S_\sigma{}^\nu}(u_3(\psi)a_3(\xi))W_{\mu\dot{\nu}}(x, u_3(\alpha)a_3(\beta)). \tag{4.7}$$

If we fix the variables α,β, it is a simple application of the Bargmann Hall Wightman theorem[19,20] to find by means of Eq. (4.7) an analytic continuation of the VEV (Wightman function) which is covariant with respect to the complex two-dimensional Lorentz group acting on the coordinates x^0,x^3 and to the real rotations acting on the coordinates x^1,x^2. The real points which satisfy the condition $\sigma^2 < 0$ belong to the analyticity domain.

The universal covering of the proper complex Lorentz group is SL(2,**C**)×SL(2,**C**). We indicate its elements by the notation (a,b); the real Lorentz transformations correspond to the elements of the kind $(a,\overline{a})$. If $S(a)$ is the irreducible spinor representation $S^{(s,s')}(a) = S^{(s,0)}(a)\otimes S^{(s',0)}(\overline{a})$, its analytic continuation is given by $S^{(s,s')}(a,b) = S^{(s,0)}(a)\otimes S^{(s',0)}(b)$. $\overline{S(a)}$ is equivalent to $S^{(s',s)}(a)$ and its analytic continuations is equivalent to $S^{(s',s)}(a,b)$. We consider the following product of a complex Lorentz transformation acting on x^0,x^3 and a real rotation acting on x^1,x^2:

$$(\exp(-\tfrac{1}{2}i\pi\sigma_3), \exp(-\tfrac{1}{2}i\pi\sigma_3))(\exp(-\tfrac{1}{2}i\pi\sigma_3), \exp(\tfrac{1}{2}i\pi\sigma_3)) = (-1,1), \tag{4.8}$$

$$\Lambda(-1,1) = -1, \quad S^{(s,s')}(-1,1) = (-1)^{2s}. \tag{4.9}$$

Then, from the covariance property of the Wightman function, we obtain

$$W_{\rho\dot{\sigma}}(-x, u_3(\alpha)a_3(\beta)) = (-1)^{2(s+s')}W_{\rho\dot{\sigma}}(x, u_3(\alpha)a_3(\beta)), \tag{4.10}$$

and the same equality holds for real x if $\sigma^2<0$. The same result is valid if S is a direct sum of irreducible spinor representations all with the same value of $(-1)^{2(s+s')}$. If we use Eq. (4.6) and the general expression (4.4) for σ^2, we see that

$$W_{p\overline{\sigma}}(-x,a)=(-1)^{2(s+s')}W_{\rho\overline{\sigma}}(x,a) \tag{4.11}$$

in the open set $\mathscr{C}\subset\widetilde{\mathscr{P}}$ defined by the condition

$$\cos\ \alpha\ x\cdot x-x\cdot\Lambda(a)x<0. \tag{4.12}$$

One can show that this condition implies Eq. (4.2).

If we consider a scalar field and we introduce the variables

$$\begin{aligned} x&=(\epsilon\sigma\ \cosh\ \xi',\rho\ \cos\ \psi',\rho\ \sin\ \psi',\epsilon\sigma\ \sinh\ \xi'),\quad \sigma>0,\\ x&=(\epsilon|\sigma|\sinh\ \xi',\rho\ \cos\ \psi',\rho\ \sin\ \psi',\epsilon|\sigma|\cosh\ \xi'),\quad \sigma^2<0,\quad \epsilon=\pm 1, \end{aligned} \tag{4.13}$$

Eq. (4.7) shows that $W(x,u_3(\alpha)a_3(\beta))$ does not depend on the variables ψ' and ξ'. From Eq. (4.10) we see that if $\sigma^2<0$ it does not even depend on ϵ. In conclusion, for $\sigma^2<0$, W can be considered as a distribution in the variables $\alpha,\beta,x^1,x^2,|\sigma|$ invariant with respect to rotations acting on x^1,x^2. In particular, since a and a^{-1} have the same eigenvalues, from Eqs. (4.3) and (4.4) we obtain

$$W(x,a)=W(-x,a)=W(-x,a^{-1}),\quad (x,a)\in\mathscr{C}. \tag{4.14}$$

The commutator or the anticommutator of a free field is a numerical distribution given by

$$\begin{aligned} [\psi_\rho(x,a),\ \psi^\dagger_\sigma(y,b)]_\pm&=W_{\rho\overline{\sigma}}((x,a)^{-1}(y,b))\pm W_{\overline{\sigma}\rho}((y,b)^{-1}(x,a))\\ &=W_{\rho\overline{\sigma}}((x,a)^{-1}(y,b))\pm\overline{W}_{\overline{\rho}\sigma}((x,a)^{-1}(y,b)). \end{aligned} \tag{4.15}$$

If we consider a Hermitean scalar field, and we use Eq. (3.9), we have the simpler relation

$$[\psi(x,a),\ \psi(y,b)]_-=W(x-y,ba^{-1})-W(y-x,ab^{-1})=2i\ \mathrm{Im}\ W(x-y,ba^{-1}), \tag{4.16}$$

and from Eq. (4.14) we obtain

$$[\psi(x,a),\ \psi(y,b)]_-=0\quad \text{for}\ (x,a)^{-1}(y,b)\in\mathscr{C}. \tag{4.17}$$

We see that in the formulation of local commutativity, Eq. (4.12) is the analog of the inequality $x\cdot x>0$ in Minkowski field theory.

In the general case, if we impose a local (anti)commutativity condition of the kind

$$[\psi_\rho(x,a),\ \psi^\dagger_\sigma(y,b)]_\pm=0\quad \text{for}\ (x,a)^{-1}(y,b)\in\mathscr{C}, \tag{4.18}$$

from Eqs. (4.11) and (4.15) we obtain

$$W_{\overline{\rho\sigma}}(x,a)=\mp(-1)^{2(s+s')}\overline{W}_{\rho\overline{\sigma}}(-\overline{x,a}),\quad (x,a)\in\mathscr{C}. \tag{4.19}$$

This relation can be continued analytically in the tube $\mathrm{Im}\ x\in V_+$ and, as an equality of distributions, it holds for any real x. It is compatible with the spectral and covariance conditions, but it satisfies the positivity condition only if $\mp(-1)^{2(s+s')}=1$. In conclusion, the local (anti)commutativity relation (4.18) is satisfied if we put

$$W_{\overline{\rho\sigma}}(x,a)=\overline{W}_{\rho\overline{\sigma}}(-x,a), \tag{4.20}$$

and the statistics is determined by $(-1)^{2(s+s')}$. We shall see that $s+s'$ is not directly related to the spin of the particles described by the field and the usual relation between spin and statistics is not necessarily valid. From Eq. (3.24) we see that Eq. (4.20) is equivalent to the condition

$$w_{\overline{\rho\sigma}}(a)=\overline{w_{\rho\sigma}}(a). \tag{4.21}$$

For a Hermitean field this condition requires that $w_{\rho\sigma}(a)$ is real.

It is interesting to study the integral (3.24) in the scalar case with more detail. If $w(a)=1$, Eq. (3.24) gives the usual VEV for the Minkowskian free scalar field, namely,

$$\begin{aligned} W(x)=&i(4\pi)^{-1}\epsilon(x^0)\,\delta(s^2)+(2\pi)^{-2}\theta(-s^2)\mu|s|^{-1}K_1(\mu|s|)+(8\pi)^{-1}\\ &\times\theta(s^2)\mu s^{-1}(Y_1(\mu s)-i\epsilon(x^0)J_1(\mu s)),\quad s^2=-x\cdot x=\sigma^2-\rho^2, \end{aligned} \tag{4.22}$$

where $\epsilon(x^0)$ is the sign of x^0. The corresponding commutator vanishes for $\sigma^2<\rho^2$.

If the function $w(a_k^{-1}aa_k)$ decreases for large k, the distribution $W(x,a)$ is less singular. In order to simplify the integral (3.24), it is convenient to write the four-vector k in the following way,

$$\begin{gathered} k=(q\ \cosh\xi, p\ \cos\psi, p\ \sin\psi, q\ \sinh\xi),\quad q=(p^2+\mu^2)^{1/2},\\ 0\leqslant p<\infty,\quad -\infty<\xi<\infty,\quad 0\leqslant\psi<2\pi,\\ (2k^0)^{-1}d^3\mathbf{k}=\tfrac{1}{2}p\,dp\,d\xi\,d\psi, \end{gathered} \tag{4.23}$$

and to choose

$$a_k=u_3(\psi)a_3(\xi)a_\eta. \tag{4.24}$$

For $\mu>0$ we take

$$a_\eta=a_1(\eta),\quad p=\mu\ \sinh\ \eta,\quad q=\mu\ \cosh\ \eta,\quad 0\leqslant\eta<\infty, \tag{4.25}$$

and for $\mu=0$

$$a_\eta=a_1(\eta)u_2(\tfrac{1}{2}\pi),\quad p=q=\exp\ \eta,\quad -\infty<\eta<\infty. \tag{4.26}$$

From Eq. (4.13) we obtain

$$\begin{aligned} k\cdot x&=-\epsilon q\sigma\ \cosh(\xi-\xi')+p\rho\ \cos(\psi-\psi'),\quad \sigma^2>0,\\ k\cdot x&=\epsilon q|\sigma|\sinh(\xi-\xi')+p\rho\ \cos(\psi-\psi'),\quad \sigma^2<0. \end{aligned} \tag{4.27}$$

The integrations over the variables ξ and ψ in Eq. (3.24) can be performed in terms of Bessel functions[22] and we obtain the following formula

$$W(x,a)=(2\pi)^{-1}\int_0^\infty \Delta(q\sigma,\epsilon(x^0))\ J_0(p\rho)w(\alpha,\beta,p)p\ dp, \tag{4.28}$$

where

$$\Delta(q\sigma,\epsilon(x^0))=(2\pi)^{-1}\theta(-\sigma^2)K_0(q|\sigma|)-\tfrac{1}{4}\theta(\sigma^2)(Y_0(q\sigma)-i\epsilon(x^0)J_0(q\sigma)) \tag{4.29}$$

and

$$w(\alpha,\beta,p)=w(a_\eta^{-1}u_3(\alpha)a_3(\beta)a_\eta). \tag{4.30}$$

The commutator of a scalar Hermitean field follows from Eqs. (4.16) and (4.28) and has the form

$$2i\ \mathrm{Im}\ W(x,a)=i(4\pi)^{-1}\theta(\sigma^2)\epsilon(x^0)\int_0^\infty J_0(q\sigma)J_0(p\rho)w(\alpha,\beta,p)p\ dp. \tag{4.31}$$

We see that it vanishes for $\sigma^2<0$. Equation (4.31) can be considered as a Hankel transformation.[22] By considering the corresponding inverse transformation, one can easily see that a necessary condition to have a commutator vanishing for large ρ is that $w(\alpha,\beta,p)$ is an entire analytic function of p^2. This does not happen for the elementary fields considered in the following sections.

When $w(\alpha,\beta,p)$ is an even function of p, it is useful to rewrite Eq. (4.31) as an integral in the complex p plane,

$$2i\ \mathrm{Im}\ W(x,a)=i2^{-3}\pi^{-1}\theta(\sigma^2)\epsilon(x^0)\int_C J_0(q\sigma)H_0^{(1)}(p\rho)w(\alpha,\beta,p)p\ dp, \tag{4.32}$$

where the integration path C lies just above the real axis. For $|p|\to\infty$, $\mathrm{Im}\ p>0$, we have

$$pJ_0(q\sigma)H_0^{(1)}(p\rho)\simeq\pi^{-1}(\rho\sigma)^{-1/2}\exp(ip(\rho-\sigma)). \tag{4.33}$$

If $w=1$ and $\rho>\sigma$, we can close the integration path at infinity in the upper half-plane and the integral vanishes in accord with Eq. (4.22). Actually, the integral (4.32) is meaningful only in the sense of distribution theory; in order to deal with a convergent integral, one can multiply the integrand by $(p+i)^{-\nu}$ and take the limit $\nu\to0$ at the end. If w has singularities in the upper half-plane, one has to take into account their contributions.

V. POSITIVE-MASS FREE FIELDS

In the positive-mass case, we can find the function $w_{\rho\bar\sigma}(a)$ by exploiting the positivity properties of the matrix elements $D^{Mc}_{jmj'm'}(a)$ of the IURs of SL(2,**C**) described in Refs. 23–27. The parameter c is the same as in Ref. 23 and is called λ in Ref. 25. The parameter M is the same as in Ref. 25 and corresponds to the parameter $-\frac{1}{2}m=\pm k_0$ of Ref. 23. For the IURs of the principal series, c lies on the imaginary axis and M is an integral or half-integral number. For the IURs of the supplementary series, $M=0$ and $-1<c<1$. The representations D^{Mc} and $D^{-M,-c}$ are unitarily equivalent. The indices j,j' take the values $|M|$, $|M|+1$,..., and, if we indicate by $R^j_{mm'}(u)$ the $(2j+1)$-dimensional representation of SU(2), we have

$$D^{Mc}_{jmj'm'}(u)=\delta_{jj'}R^j_{mm'}(u),\quad u\in\mathrm{SU}(2). \tag{5.1}$$

Then we put

$$w_{\rho\bar\sigma}(a)=(2s+1)(2J+1)^{-1}\sum_{mnn'}C_{js}(J,m;n',\rho)C_{js}(J,m;n,\sigma)D^{Mc}_{jnjn'}(a), \tag{5.2}$$

where C indicates the Clebsch–Gordan coefficients. The parameters M,c,j,J,s characterize the theory; they are fixed and no sum over them is understood. After some calculation we have

$$w_{\rho\bar\sigma}(uau^{-1})=R^s_{\rho\mu}(u)\overline{R^s_{\sigma\nu}}(u)w_{\mu\bar\nu}(a), \tag{5.3}$$

and we see that Eq. (3.28) is satisfied if

$$S_\rho{}^\sigma(\mu)=R^s_{\rho\sigma}(u),\quad u\in \mathrm{SU}(2). \tag{5.4}$$

If we indicate by $S^{(s,s')}$ an irreducible spinor representation, we can put, with an appropriate choice of the basis,

$$S(a)=S^{(s,0)}(a)\quad \text{or}\quad S(a)=S^{(0,s)}(a). \tag{5.5}$$

In order to prove the positivity property, we substitute Eq. (5.2) into Eq. (3.25) and we obtain the positive expression

$$(\Phi(f),\Phi(f))=\int \sum_{mj'm'} |f_{mj'm'}(k)|^2\theta(k^0)\,\delta(k\cdot k+\mu^2)d^4k, \tag{5.6}$$

where

$$f_{mj'm'}(k)=(2\pi)^{-3/2}(2s+1)^{1/2}(2J+1)^{-1/2}C_{js}(J,m;n,\mu)\int \tilde f^\rho(k,a_k a)\overline{S_\rho}^{\mu}(a^{-1})D^{Mc}_{jnj'm'}(a)d^6a. \tag{5.7}$$

It is clear that the quantity (5.7) is the wave function in momentum space of the one-particle state $\Phi(f)$ and that its indices represent the spin and the internal quantum numbers.

Equation (2.15) takes the form

$$U^{(1)}(y,b)\Phi(f)=\Phi(f'),\quad f'^\rho(x,a)=f^\rho(\Lambda(b^{-1})(x-y),b^{-1}a). \tag{5.8}$$

The Fourier transformation (3.14) gives

$$\tilde f'^\rho(k,a)=\exp(-ik\cdot y)\tilde f^\rho(k',b^{-1}a),\quad k'=\Lambda(b^{-1})k, \tag{5.9}$$

and from Eq. (5.7) we obtain

$$f'_{mj'm'}(k)=\exp(-ik\cdot y)R^J_{mm''}(a_k^{-1}ba_{k'})f_{m''j'm'}(k'),\quad a_k^{-1}ba_{k'}\in \mathrm{SU}(2). \tag{5.10}$$

We see that the wave function transforms according to the IUR with mass $\mu>0$ and spin J defined by Wigner.[21] Equation (5.7) shows that spin has a double origin, namely the dependence of $f^\rho(x,a)$ on the index ρ and on the group element a. From Eqs. (3.24) and (5.2) we have

$$W_{\rho\sigma}(x,-a)=(-1)^{2J}W_{\rho\sigma}(x,a), \tag{5.11}$$

and a similar formula holds for the field $\psi_\rho(x,a)$, which is a one- or two-valued function on $\mathscr{P}$ if $2J$ is, respectively, even or odd.

Equation (2.16) takes the form

$$V^{(1)}(b)\Phi(f)=\Phi(f'),\quad f'^\rho(x,a)=f^\sigma(x,ab)\overline{S_\sigma}^{\rho}(b^{-1}), \tag{5.12}$$

and from Eqs. (3.14) and (5.7) we obtain

$$f'_{mj'm'}(k)=f_{mj''m''}(k)D^{Mc}_{j''m''j'm'}(b^{-1})=\overline{D}^{Mc}_{j'm'j''m''}(b)f_{mj''m''}(k). \tag{5.13}$$

We see that the wave function transforms according to the IUR $\overline{D}^{Mc}$ of the internal symmetry group SL(2,**C**). This IUR is equivalent to D^{Mc}.

The general formalism described above becomes simpler in some special cases. If $s=0$, $S(a)=1$, we have a scalar field. It is $J=j$ and Eq. (5.2) takes the form

$$w(a)=w^{Mcj}(a)=(2j+1)^{-1}\sum_m D^{Mc}_{jmjm}(a). \tag{5.14}$$

If $j=M=0$, we have $J=s$ and

$$w_{\rho\sigma}(a)=\delta_{\rho\sigma}D^{0c}_{0000}(a)=\delta_{p\sigma}w^{0c0}(a). \tag{5.15}$$

In order to give more explicit expressions for the functions $w^{Mcj}(a)$, we write the IURs of SU(2) and of SL(2,**C**) in the form

$$R^j_{mm'}(u_3(\phi)u_2(\theta)u_3(\psi))=\exp(-im\phi)r^j_{mm'}(\theta)\exp(-im'\psi), \tag{5.16}$$

$$D^{Mc}_{jmj'm'}(ua_3(\zeta)u')=\sum_{m''} R^j_{mm''}(u)d^{Mc}_{m''jj'}(\zeta)R^{j'}_{m''m'}(u'). \tag{5.17}$$

Then the function defined by Eq. (5.14) can be written as

$$w^{Mcj}(ua_3(\zeta)u')=w^{Mcj}(a_3(\zeta)u_3(\phi+\psi)u_2(\theta))=(2j+1)^{-1}\sum_m d^{Mc}_{mjj}(\zeta)r^j_{mm}(\theta)$$
$$\times\exp(-im(\phi+\psi)),\quad u'u=u_3(\phi)u_2(\theta)u_3(\psi). \tag{5.18}$$

The quantities $d^{Mc}_{mjj}(\zeta)$ are given in Refs. 24 and 25 in terms of elementary functions. It follows that the expression (5.18), too, is a combination of elementary functions. For instance, we have

$$w^{0c0}(ua_3(\zeta)u')=d^{0c}_{000}(\zeta)=(c\ \sinh(\zeta))^{-1}\ \sinh(c\zeta), \tag{5.19}$$

but the expressions become more and more complicated when the parameters M and j increase. A useful integral representation of $w^{Mcj}(a)$ is given in Appendix A, where one derives also a simple approximate expression valid for $a\to 1$.

Note that we have

$$\lim_{c\to 1} w^{0c0}(a)=\lim_{c\to 1} D^{0c}_{0000}(a)=1. \tag{5.20}$$

In this limit the distribution $w_{\rho\sigma}(a)$ given by Eq. (5.15) becomes independent of a and we have a theory which can be defined in Minkowski space–time. From the unitarity condition we also have

$$\lim_{c\to 1} D^{0c}_{00jm}(a)=\lim_{c\to 1} D^{0c}_{jm00}(a)=0,\quad j>0, \tag{5.21}$$

and if $j=M=0$ the components of the wave function (5.7) tend to zero for $j'>0$. We conclude that the theories with $M=j=0$ can possibly describe small deviations from the known physical theories. For other values of the parameters, we get theories which can only apply to the unknown physics of masses and energies beyond the Planck mass. From the mathematical point of view, Eqs. (5.20) and (5.21) show that in the limit $c\to 1$, the representation D^{0c} becomes reducible and we have[23]

$$\lim_{c\to 1} D^{0c}=1\oplus D^{1,0}. \tag{5.22}$$

We see from Eq. (3.18) that $\widetilde{W}_{\rho\bar{\sigma}}(k,a)$ can be considered as a tempered distribution in the variables k that depends continuously on the group element a and a similar statement holds for its Fourier transform $W(x,a)$. If $a=1$, Eq. (5.2) gives

$$w_{\rho\bar{\sigma}}(1)=\delta_{\rho\sigma}, \tag{5.23}$$

and from Eq. (3.24) we see that $W_{\rho\bar{\sigma}}(x,1)$ is the VEV of a field in Minkowski space, given, in the scalar case, by Eq. (4.22). If $a\neq 1$, the function $w_{\rho\bar{\sigma}}(a_k^{-1}aa_k)$ decreases for large k and the distribution $W_{\rho\bar{\sigma}}(x,a)$ is less singular.

For a scalar field we can use Eq. (4.28) and from Eq. (4.30) we obtain

$$w(\alpha,\beta,p)=w(a_3(\zeta)u_3(\phi)u_2(\theta)), \tag{5.24}$$

where

$$\cosh\,\zeta=(\cosh\,\eta)^2\,\cosh\,\beta-(\sinh\,\eta)^2\,\cos\,\alpha=\cosh\,\beta+p^2\mu^{-2}(\cosh\,\beta-\cos\,\alpha), \tag{5.25}$$

$$\cos\frac{\theta}{2}\exp\left(i\,\frac{\phi}{2}\right)=\left(\cosh\frac{\zeta}{2}\right)^{-1}\cos\frac{\alpha}{2}\cosh\frac{\beta}{2}+i\left(\sinh\frac{\zeta}{2}\right)^{-1}\sin\frac{\alpha}{2}\sinh\frac{\beta}{2}. \tag{5.26}$$

For $j=M=0$, we see that the expression (5.19) is an analytic function of $\cosh\,\zeta$ with a branch point at $\cosh\,\zeta=-1$. From Eq. (5.25) we see that it is not an entire analytic function of p^2 and the commutator function (4.31) cannot vanish for large ρ.

VI. ZERO-MASS FREE FIELDS

In order to use the method described in Sec. V in the zero-mass case, we have to write the IURs of SL(2,**C**) in a basis that evidentiates the decomposition of the representation space into spaces where IURs of $\widetilde{E}(2)$ operate. In this case, we have a direct integral decomposition and we have to introduce a ''continuous'' basis.[28]

We start from the realization of the operator $D^{Mc}(a)$ in a space of functions of a complex variable z:

$$[D^{Mc}(a)f](z)=(a_{21}z+a_{11})^{-c+M-1}(\overline{a_{21}z+a_{11}})^{-c-M-1}f((a_{22}z+a_{12})(a_{21}z+a_{11})^{-1}), \tag{6.1}$$

where

$$a=\begin{pmatrix}a_{11} & a_{12}\\ a_{21} & a_{22}\end{pmatrix}\in \mathrm{SL}(2,\mathbf{C}). \tag{6.2}$$

This representation is equivalent to the one defined in Refs. 23 and 24, which in our notation is given by $D^{-M,-c}(u_1(\pi)au_1(-\pi))$.

The elements of the little group $\widetilde{E}(2)$ have the form

$$h=\begin{pmatrix}\exp(-\frac{1}{2}i\phi) & \xi\,\exp(-\frac{1}{2}i\phi)\\ 0 & \exp(\frac{1}{2}i\phi)\end{pmatrix}\in\widetilde{E}(2), \tag{6.3}$$

with ϕ real and ξ complex. We have

$$[D^{Mc}(h)f](z)=\exp(-iM\phi)f(\exp(i\phi)z+\xi). \tag{6.4}$$

We see that $\widetilde{E}(2)$ acts on the complex z plane by means of Euclidean transformations. If we introduce the (non-normalizable) basis vectors

$$f_{\kappa m}(z)=(z|z|^{-1})^{-m}J_{-m}(\kappa|z|), \quad \kappa>0, \quad m=0,\pm 1,\pm 2,\ldots, \tag{6.5}$$

the matrix that represents an Euclidean transformation is diagonal in the index κ; namely, we have

$$f_{\kappa m}(\exp(i\phi)z+\xi)=f_{\kappa m'}(z)R^{\kappa}_{m'm}(h), \tag{6.6}$$

where the matrix

$$R^{\kappa}_{m'm}(h)=\exp(-im'\phi)(\xi|\xi|^{-1})^{m'-m}J_{m'-m}(\kappa|\xi|) \tag{6.7}$$

is unitary.[27] From Eq. (6.4), we obtain

$$[D^{Mc}(h)f_{\kappa m}](z)=\exp(-iM\phi)R^{\kappa}_{m'm}(h)f_{\kappa m'}(z). \tag{6.8}$$

We see from Eq. (6.7) that the factor $\exp(-iM\phi)$ can be eliminated by means of a ''translation'' of the indices m',m, which is irrelevant if M is an integer. If M is half-odd, we get a representation of $\widetilde{E}(2)$ that is double-valued on $E(2)$.

In analogy with Eq. (5.14) we put

$$w(a)=\sum_m (f_{\kappa m},D^{Mc}(a)f_{\kappa m}). \tag{6.9}$$

Also in this case, the conditions (3.26) and (3.28) are satisfied. In the same way as in Sec. V, we can show that the fields constructed by means of the distributions found above represent zero-mass particles with an infinite helicity spectrum[21] and with internal quantum numbers described by the IUR D^{Mc} of SL(2,**C**). Since particles of this kind are not observed in nature, we shall not discuss these fields with more detail.

The zero-mass particles present in nature have only one value m of the helicity (two if parity is taken into account) and they are described by one-dimensional IURs of the little group[21] of the kind

$$R^{m}(h)=\exp(-im\phi), \quad h\in\widetilde{E}(2), \quad m=0,\pm\tfrac{1}{2},\pm 1,\ldots, \tag{6.10}$$

where h is given by Eq. (6.3). These IURs are not contained in the IURs of SL(2,**C**) and we have to use a different method in order to find the corresponding w functions. We propose the following solutions, without explaining how they have been obtained:

$$w_0^{0c}(a)=|a_{21}|^{2c-2}, \quad 0<c<1, \tag{6.11}$$

$$w_0^{Mc}(a)=\delta^2(a_{21})a_{22}{}^{c-M}\overline{a_{22}}{}^{c+M}, \quad \text{Re } c=0. \tag{6.12}$$

It is easy to show that the symmetry condition (3.28) is satisfied. The positivity condition (3.26) follows from the formulas

$$w_0^{0c}(ba^{-1})=\int |a_{22}|^{2c}\delta^2(a_{21}-z'a_{22})|z'-z|^{2c-2}|b_{22}|^{2c}\delta^2(b_{21}-zb_{22})d^2zd^2z', \tag{6.13}$$

$$w_0^{Mc}(ba^{-1})=\int \overline{a_{22}}{}^{-c-M}a_{22}{}^{-c+M}\delta^2(a_{21}-za_{22})b_{22}{}^{c-M}\overline{b_{22}}{}^{c+M}\delta^2(b_{21}-zb_{22})d^2z. \tag{6.14}$$

Note that $|z'-z|^{2c-2}$ is a positive integral kernel, the one that defines the scalar product in the space of an IUR of the supplementary series.[23,24]

The norm (3.25) in the case (6.11) can be written as

$$(\Phi(f),\Phi(f))=\int \overline{f(k,z')}|z'-z|^{2c-2}f(k,z)\,\theta(k^0)\,\delta(k\cdot k)\,d^2z\,d^2z'\,d^4k, \tag{6.15}$$

and in the case (6.12) we obtain

$$(\Phi(f),\Phi(f))=\int |f(k,z)|^2\,\theta(k^0)\,\delta(k\cdot k)\,d^2z\,d^4k, \tag{6.16}$$

where in both cases

$$f(k,z)=(2\pi)^{-3/2}\int \tilde{f}(k,a_k a)\,a_{22}{}^{c-M}\overline{a_{22}}^{c+M}\,\delta^2(a_{21}-z a_{22})\,d^6a. \tag{6.17}$$

Of course, in the first case we have to put $M=0$.

If we consider a Poincaré transformation of the kind (5.8) and (5.9), the wave function (6.17) transforms in the following way,

$$f'(k,z)=\exp(-ik\cdot y)R^M(a_k^{-1}ba_{k'})f(k',z), \tag{6.18}$$

where k' is given by Eq. (5.9). This is the transformation property[21] of the wave function of a particle of zero mass and helicity M.

Under the ''internal'' transformation (5.12) the wave function transforms as

$$\begin{gathered} f'(k,z)=(b_{22}+zb_{12})^{-c+M-1}(\overline{b_{22}+zb_{12}})^{-c-M-1}f(k,z'),\\ z'=(b_{21}+zb_{11})(b_{22}+zb_{12})^{-1}, \end{gathered} \tag{6.19}$$

namely according to the IUR $D^{-M,-c}$ defined in Refs. 23 and 24, which is equivalent to the IUR D^{Mc}. Note that, if we fix up to equivalence the IUR D^{Mc}, we have two possible theories with helicity $\pm M$.

In order to compute the integral (3.24), we use the variables introduced in Sec. IV. If we put

$$\tilde{a}=a_\eta^{-1}u_3(\alpha)a_3(\beta)a_\eta, \tag{6.20}$$

from Eq. (4.26) we obtain

$$\tilde{a}_{21}=-p\,\sinh(\tfrac{1}{2}(\beta-i\alpha)),\quad \tilde{a}_{22}=\cosh(\tfrac{1}{2}(\beta-i\alpha)). \tag{6.21}$$

We see that the quantity $\delta^2(\tilde{a}_{21})$ that appears in Eq. (6.12) is rather badly defined when considered as a distribution in the variables k^1,k^2 for fixed values of α,β satisfying Eq. (4.2). Other difficulties arise when one tries to perform the integrals (3.24) or (4.28). We conclude that, even if the expression (6.12) satisfies the required positivity and symmetry conditions, it does not give rise to a well-behaved field theory. All the calculations based on this expression have a purely formal character.

When we substitute Eqs. (6.11) and (6.21) into Eqs. (4.28) and (4.31), the integrals can be performed in terms of Legendre functions[22,29] and we obtain

$$\begin{aligned} W_0^{0c}(x,a)=&\,2^{c-3}\pi^{-2}(\Gamma(c))^2(\cosh\beta-\cos\alpha)^{c-1}(\rho^2-\sigma^2)^{-c}\\ &\times P_{c-1}((\sigma^2+\rho^2)(\sigma^2-\rho^2)^{-1}),\quad \sigma^2<0. \end{aligned} \tag{6.22}$$

$$2i\ \mathrm{Im}\ W_0^{0c}(x,a)=i2^{c-2}\pi^{-1}\epsilon(x^0)\,\theta(\sigma^2)\Gamma(c)(\Gamma(1-c))^{-1}$$
$$\times(\cosh\,\beta-\cos\,\alpha)^{c-1}|\sigma^2-\rho^2|^{-c}P_{c-1}((\sigma^2+\rho^2)|\sigma^2-\rho^2|^{-1}). \quad (6.23)$$

The real part for $\sigma^2>0$ can be obtained by analytic continuation of Eq. (6.22). In the special case $\rho=0$, we have

$$W_0^{0c}(x,a)=2^{c-3}\pi^{-2}(\Gamma(c))^2(\cosh\,\beta-\cos\,\alpha)^{c-1}|\sigma^2|^{-c}(\,\theta(-\sigma^2)+\theta(\sigma^2)\exp(i\pi c\,\epsilon(x^0))). \quad (6.24)$$

Since we are not able to build fields starting from Eq. (6.12), in order to describe particles with a nonvanishing helicity we have to use nonscalar fields. From Eq. (6.3) we have

$$h\begin{pmatrix}1\\0\end{pmatrix}=\exp\left(-\frac{1}{2}\,i\phi\right)\begin{pmatrix}1\\0\end{pmatrix}. \quad (6.25)$$

We remark that the spinor representations $S^{(s,0)}(h)$ and $S^{(0,s)}(h)$ are equivalent to symmetrized tensor products of $2s$ matrices equal, respectively, to h or $\bar{h}$ and we adopt conventions in agreement with Eqs. (5.4) and (5.5). Then, if we put

$$S(a)=S^{(m,0)}(a),\quad m\geqslant 0,\quad S(a)=S^{(0,|m|)}(a),\quad m\leqslant 0, \quad (6.26)$$

we have

$$S_\rho{}^m(h)=\exp(-im\phi)\,\delta_\rho^m,\quad h\in\tilde{E}(2). \quad (6.27)$$

As a consequence, the expression

$$w_{\rho\bar{\sigma}}(a)=\delta_{\rho m}\delta_{\sigma m}|a_{21}|^{2c-2} \quad (6.28)$$

satisfies the symmetry condition (3.28).

Equation (6.15) is still valid if we modify Eq. (6.17) in the following way:

$$f(k,z)=(2\pi)^{-3/2}\int \tilde{f}^\rho(k,a_k a)\overline{S_\rho}{}^m(a^{-1})|a_{22}|^{2c}\delta^2(a_{21}-za_{22})d^6a. \quad (6.29)$$

Equation (6.18) holds with M replaced by m and Eq. (6.19) holds with $M=0$; this means that the theory describes zero mass particles with helicity m that transform according to the representation D^{0c} of the internal symmetry group. In the limit $c\to 1$, the expression (6.28) becomes independent of a and we get a Minkowskian theory of the kind usually adopted to describe neutrinos, photons, or gravitons.

VII. FIELD EQUATIONS

Now we find the wave equations satisfied by the scalar fields defined in the preceding sections; nonscalar fields will be treated elsewhere. We indicate by $L_{ik}=-L_{ki}$ the generators of the right translations on SL(2,**C**), considered as differential operators acting on smooth functions defined on the group. They satisfy the commutation relations

$$[L_{ik},\,L_{rs}]=g_{ir}L_{ks}-g_{kr}L_{is}-g_{is}L_{kr}+g_{ks}L_{ir} \quad (7.1)$$

of sl(2,**C**), commute with the left translations, and have the following commutation property with the finite right translation represented by the operator $T(b)$:

$$T(b^{-1})L_{ik}T(b)=\Lambda_i{}^r(b)\Lambda_k{}^s(b)L_{rs}. \quad (7.2)$$

We also need the generators L'_{ik} of the left translations, which satisfy commutation relations with the opposite sign. We have

$$L'_{ik}=\Lambda_i{}^r(a)\Lambda_k{}^s(a)L_{rs}\,, \tag{7.3}$$

and their commutation relation with a finite left translation $T'(b)$ is

$$T'(b)L'_{ik}T'(b^{-1})=\Lambda_i{}^r(b)\Lambda_k{}^s(b)L'_{rs}\,. \tag{7.4}$$

We also consider the generators A_k and A_{ik} of the right translations on the group $\tilde{\mathscr{P}}$ that satisfy the Poincaré Lie algebra. They act on functions of the kind $f(x,a)$ in the following way:

$$A_i=\Lambda^k{}_i(a)\,\frac{\partial}{\partial x^k}\,,\quad A_{ik}=L_{ik}\,. \tag{7.5}$$

For the generators of the left translations of $\tilde{\mathscr{P}}$ we have

$$A'_i=\frac{\partial}{\partial x^k}\,,\quad A'_{ik}=L'_{ik}+x_i\,\frac{\partial}{\partial x^k}-x_k\,\frac{\partial}{\partial x^i}\,. \tag{7.6}$$

From Eqs. (3.24), (7.5), and (7.6) we obtain immediately the differential equation

$$g^{ik}A_iA_kW(x,a)=g^{ik}A'_iA'_kW(x,a)=\mu^2W(x,a), \tag{7.7}$$

which is essentially the Klein–Gordon equation.

If the function $w(a)$ is a linear combination of matrix elements of the representation $D^{Mc}(a)$, as in Eqs. (5.2) and (6.9), it satisfies the differential equations[23,24]

$$\tfrac{1}{2}g^{ir}g^{ks}L_{ik}L_{rs}w(a)=\tfrac{1}{2}g^{ir}g^{ks}L'_{ik}L'_{rs}w(a)=(1-c^2-M^2)w(a), \tag{7.8}$$

$$\tfrac{1}{8}e^{ikrs}L_{ik}L_{rs}w(a)=\tfrac{1}{8}e^{ikrs}L'_{ik}L'_{rs}w(a)=-iMcw(a). \tag{7.9}$$

The functions (6.11) and (6.12) are not defined in terms of matrix elements, but it is easy to show directly that they satisfy the differential equations

$$(L'_{10}-L'_{31})w(a)=0,\quad (L'_{20}+L'_{23})w(a)=0, \tag{7.10}$$

$$L'_{12}w(a)=-iMw(a),\quad L'_{30}w(a)=(1-c)w(a). \tag{7.11}$$

By means of the formulas

$$\tfrac{1}{2}g^{ir}g^{ks}L'_{ik}L'_{rs}=-(L'_{10}+L'_{31})(L'_{10}-L'_{31})-(L'_{20}-L'_{23})(L'_{20}+L'_{23})+(L'_{12})^2-(L'_{30})^2+2L'_{30}, \tag{7.12}$$

$$\tfrac{1}{8}e^{ikrs}L'_{ik}L'_{rs}=\tfrac{1}{2}(L'_{20}-L'_{23})(L'_{10}-L'_{31})-\tfrac{1}{2}(L'_{10}+L'_{31})(L'_{20}+L'_{23})-L'_{30}L'_{12}+L'_{12}, \tag{7.13}$$

we can derive also in this case Eqs. (7.8) and (7.9).

The Casimir operators that appear in Eqs. (7.8) and (7.9) commute with the left and the right translations on SL(2,**C**) and from Eqs. (3.24) and (7.5) we obtain, for a scalar field,

$$\tfrac{1}{2}g^{ir}g^{ks}A_{ik}A_{rs}W(x,a)=(1-c^2-M^2)W(x,a), \tag{7.14}$$

$$\tfrac{1}{8}e^{ikrs}A_{ik}A_{rs}W(x,a)=-iMcW(x,a). \tag{7.15}$$

Equations (7.7), (7.14), and (7.15) identify the mass and the internal quantum numbers and hold for all the scalar fields. There are other equations that identify spin or helicity. In the positive-mass case the generators of the little group $\mathscr{K}=\mathrm{SU}(2)$ are L_{12}, L_{23}, L_{31}, and from Eqs. (5.1) and (5.2), taking into account the properties of the representations of SU(2), we obtain

$$((L'_{12})^2+(L'_{23})^2+(L'_{31})^2)w(a)=-j(j+1)w(a). \tag{7.16}$$

If $j=0$, we have the stronger result

$$L'_{12}w(a)=L'_{23}w(a)=L'_{31}w(a)=0. \tag{7.17}$$

From Eqs. (3.19) and (7.16) we obtain

$$\tfrac{1}{4}e^{jirs}\hat{k}_i L'_{rs}e_j{}^{kpq}\hat{k}_k L'_{pq}w(a)=-\mu^2 j(j+1)w(a), \tag{7.18}$$

and from Eqs. (3.21), (3.22), and (7.4)

$$\tfrac{1}{4}e^{jirs}k_i L'_{rs}e_j{}^{kpq}k_k L'_{pq}w(k,a)=-\mu^2 j(j+1)w(k,a). \tag{7.19}$$

By substitution into Eq. (3.24) we obtain the differential equation

$$g_{ik}\Sigma'^i\Sigma'^k W(x,a)=\mu^2 j(j+1)W(x,a), \tag{7.20}$$

where

$$\Sigma'^i=\tfrac{1}{2}e^{ijrs}A'_jA'_{rs}=\tfrac{1}{2}\,e^{ijrs}\frac{\partial}{\partial x^j}L'_{rs}. \tag{7.21}$$

If we also introduce the differential operators

$$\Sigma^i=\tfrac{1}{2}e^{ijrs}A_jA_{rs}=\Lambda_k{}^i(a)\Sigma'^k, \tag{7.22}$$

we have

$$g_{ik}\Sigma^i\Sigma^k W(x,a)=\mu^2 j(j+1)W(x,a). \tag{7.23}$$

If $j=0$, we have the stronger result

$$\Sigma^i W(x,a)=\Sigma'^i W(x,a)=0. \tag{7.24}$$

In the zero-mass case, the generators of the little group $\mathscr{K}=\widetilde{E}(2)$ are L_{12}, $(L_{10}-L_{31})$, $(L_{20}+L_{23})$. From Eqs. (6.8) and (6.9) we obtain the differential equation

$$((L'_{10}-L'_{31})^2+(L'_{20}+L'_{23})^2)w(a)=-\kappa^2 w(a), \tag{7.25}$$

which can be written in the form

$$\tfrac{1}{4}e^{jirs}\hat{k}_i L'_{rs}e_j{}^{kpq}\hat{k}_k L'_{pq}w(a)=-\kappa^2 w(a). \tag{7.26}$$

By means of the procedure used above, for a field with zero mass and infinite helicity spectrum we find the equation

$$g_{ik}\Sigma^i\Sigma^k W(x,a)=g_{ik}\Sigma'^i\Sigma'^k W(x,a)=\kappa^2 W(x,a). \tag{7.27}$$

If we consider a field with zero mass and given helicity M based on the functions (6.11) and (6.12), we see that Eqs. (7.10) and (7.11) can be written in the form

$$\tfrac{1}{2}e^{jirs}\hat{k}_i L'_{rs} w(a) = -iM\hat{k}^j w(a), \tag{7.28}$$

$$\hat{k}^i L'_{ik} w(a) = (c-1)\hat{k}_k w(a). \tag{7.29}$$

Proceeding as in the other cases, we obtain

$$\Sigma'_i W(x,a) = -iMA'_i W(x,a), \quad \Sigma_i W(x,a) = -iMA_i W(x,a), \tag{7.30}$$

$$A^i A_{ik} W(x,a) = (c-1)A_k W(x,a). \tag{7.31}$$

From Eqs. (3.8), (3.29), and (4.20) we obtain

$$(\Omega, \psi(x,a)\psi^\dagger(y,b)\Omega) = \overline{W}((y,b)^{-1}(x,a)), \tag{7.32}$$

$$(\Omega, \psi^\dagger(y,b)\psi(x,a)\Omega) = \overline{W}((-y,b)^{-1}(-x,a)). \tag{7.33}$$

If the function $\overline{W}(x,a)$ satisfies a differential equation invariant under left translations and under the reflection $x \to -x$, from the Wightman reconstruction theorem[19,20] we have that $\psi(x,a)$ satisfies the same equation. In this way we obtain the field equations

$$g^{ik}A_i A_k \psi(x,a) = \mu^2 \psi(x,a), \tag{7.34}$$

$$\tfrac{1}{2}g^{ir}g^{ks}A_{ik}A_{rs}\psi(x,a) = (1-c^2-M^2)\psi(x,a), \tag{7.35}$$

$$\tfrac{1}{8}e^{ikrs}A_{ik}A_{rs}\psi(x,a) = -iMc\psi(x,a). \tag{7.36}$$

For $\mu > 0$, $j > 0$, we have

$$g_{ik}\Sigma^i\Sigma^k \psi(x,a) = \mu^2 j(j+1)\psi(x,a), \tag{7.37}$$

for $\mu > 0$, $j = 0$, we have

$$\Sigma^i \psi(x,a) = 0; \tag{7.38}$$

for $\mu = 0$ and infinite helicity spectrum, we have

$$g_{ik}\Sigma^i\Sigma^k \psi(x,a) = \kappa^2 \psi(x,a); \tag{7.39}$$

and for $\mu = 0$ and helicity M, we have

$$\Sigma_i \psi(x,a) = iMA_i \psi(x,a), \tag{7.40}$$

$$A^i A_{ik}\psi(x,a) = (\overline{c} - 1)A_k \psi(x,a). \tag{7.41}$$

We have seen in Sec. VI that there is some difficulty in the definition of fields starting from the function (6.12). For these fields, the calculations given above have a purely formal character.

VIII. FLAT-SPACE THEORIES AND SPIN-MASS-SHELLS

We approximate a small region of the group manifold $\tilde{\mathscr{P}}$ by means of a tangent space with coordinates x^i and $x^{ik} = -x^{ki}$, which can be identified with the vector space $\mathscr{T}$. The operators A_i and A_{ik}, which appear in the differential equations satisfied by the fields and by their VEVs, can

be replaced by the partial derivatives with respect to these coordinates. We get in this way a field theory in the flat ten-dimensional space and the Fourier transforms of the fields and of the VEVs have their support in a Lorentz invariant manifold defined by some polynomial equations in the ten-dimensional ''spin-momentum space'' $\mathscr{T}^*$ with coordinates k_i and $k_{ik}=-k_{ki}$. These equations are obtained from the field equations by means of the substitutions $A_i \to -ik_i$, $A_{ik} \to -ik_{ik}$. To indicate the positive-energy part ($k^0=-k_0>0$) of this manifold, we use the term ''spin-mass-shell.'' The two-point VEV of the flat-space theory is the Fourier transform of a positive Lorentz invariant measure on the spin-mass-shell. As we shall see, in some cases the replacement of noncommuting operators by commuting quantities may lead to inconsistencies or ambiguities. Nevertheless, the correspondence between theories in $\tilde{\mathscr{P}}$ and in the flat space is an unavoidable heuristic instrument. Note that there is no ambiguity in the higher-degree terms of the equations defining the spin-mass-shell. If we drop all the other terms, we get a set of homogeneous equations that define an unambiguous dilatation invariant ''asymptotic'' manifold.

From Eqs. (7.7), (7.14), and (7.15) we get the following equations valid on the spin-mass-shell of all the elementary field theories.

$$g^{ik}k_ik_k=-\mu^2, \quad \tfrac{1}{2}g^{ir}g^{ks}k_{ik}k_{rs}=c^2+M^2-1, \quad \tfrac{1}{8}e^{ikrs}k_{ik}k_{rs}=iMc. \tag{8.1}$$

In a similar way from Eqs. (7.23), (7.24), (7.27), (7.30), and (7.31) we obtain other equations valid for the various specific cases.

Since the spin-mass-shell is Lorentz invariant, it is determined by its intersection with the hyperplane $k_i=\hat{k}_i$. This intersection can be considered as a manifold in the six-dimensional ''spin space'' with coordinates k_{ik} and we call it the ''spin-shell.'' Its dimension is given by the dimension of the spin-mass-shell minus three. It is convenient to introduce the three-dimensional vectors

$$\mathbf{k}=(k^1,k^2,k^3), \quad \mathbf{k}'=(k^{23},k^{31},k^{12}), \quad \mathbf{k}''=(k^{10},k^{20},k^{30}), \tag{8.2}$$

and similar notations for the coordinates x^i,x^{rs}. Then the last two conditions of Eq. (8.1) take the form

$$(\mathbf{k}')^2-(\mathbf{k}'')^2=c^2+M^2-1, \quad \mathbf{k}'\cdot\mathbf{k}''=iMc. \tag{8.3}$$

The spin-shell in the case $\mu>0$ is described by the equations

$$(\mathbf{k}')^2=j(j+1), \quad (\mathbf{k}'')^2=j(j+1)+1-c^2-M^2, \quad \mathbf{k}'\cdot\mathbf{k}''=iMc. \tag{8.4}$$

Note that the right-hand sides are real and satisfy the inequality

$$j(j+1)(j(j+1)+1-c^2-M^2)+M^2c^2=(\mathbf{k}')^2(\mathbf{k}'')^2-(\mathbf{k}'\cdot\mathbf{k}'')^2\geqslant 0. \tag{8.5}$$

If $j>0$, this manifold has dimension three, but if $j=M=0$, Eq. (8.4) takes the simpler form

$$\mathbf{k}'=0, \quad (\mathbf{k}'')^2=1-c^2, \tag{8.6}$$

and describes a two-dimensional manifold. In both cases the spin-shell is compact and the rotation group acts transitively on it; namely, the spin-shell is an orbit of the rotation group in the spin space. It follows that the spin-mass-shell is an orbit of the Lorentz group in the spin-momentum space.

The orbits of the rotation or of the Lorentz group which correspond to a field on the group $\tilde{\mathscr{P}}$ are called ''allowed orbits.'' It is useful to consider all the orbits, not necessarily allowed, which can be classified by means of the invariants $(\mathbf{k}')^2$, $(\mathbf{k}'')^2$ and $\mathbf{k}'\cdot\mathbf{k}''$ satisfying the condition (8.5). One can also use Eq. (8.4) to introduce the parameters j, c, and M, even when they do not label

any IUR. Given an orbit with $\mathbf{k}'\cdot\mathbf{k}''\neq 0$, Eq. (8.4) determines the real quantities j, M and the imaginary quantity c, up to a common change of sign of M and c. They satisfy the conditions

$$j>0, \quad c^2<0, \quad 0<M^2\leqslant j(j+1)(1+(j(j+1)+|c^2|)^{-1}). \tag{8.7}$$

Note that only some discrete values of the parameters j and M are allowed and that they are rather uniformly distributed in the set defined by Eq. (8.7). These orbits are three-dimensional in the general case, but have dimension two when the equality sign holds in Eq. (8.5) or in the last Equation (8.7), namely when the vectors $\mathbf{k}'$ and $\mathbf{k}''$ are parallel. The two-dimensional orbits correspond to values of M which are not allowed, but for large j are relatively near to the allowed values $M=\pm j$.

If $\mathbf{k}'\cdot\mathbf{k}''=0$, we have two possible choices of M and c, namely,

$$M=0, \quad 1-c^2=(\mathbf{k}'')^2-(\mathbf{k}')^2, \quad j\geqslant 0, \tag{8.8}$$

or

$$c=0, \quad M^2-1=(\mathbf{k}')^2-(\mathbf{k}'')^2, \quad j(j+1)=(\mathbf{k}')^2\geqslant M^2-1. \tag{8.9}$$

There is some ambiguity in the parametrization of the orbits, which disappears if we consider only allowed orbits and allowed values of the parameters. These orbits are three-dimensional in the general case and two-dimensional if $\mathbf{k}'=0$ or $\mathbf{k}''=0$. If both these vectors vanish, we have a zero-dimensional orbit, corresponding to $j=M=0$, $c^2=1$, namely to a Minkowskian theory.

In the case $\mu=0$, infinite helicity spectrum, the spin-shell is described by the equations (8.3) and

$$(k_{10}-k_{31})^2+(k_{20}+k_{23})^2=\kappa^2>0. \tag{8.10}$$

It has dimension three and it is an unbounded orbit of the little group $\widetilde{E}(2)$.

In the case $\mu=0$, helicity M, from Eq. (7.30) we obtain the equations

$$k_{10}=k_{31}, \quad k_{20}=-k_{23}, \quad k_{12}=M. \tag{8.11}$$

Equation (7.31) contains products of noncommuting operators and gives ambiguous results. A direct substitution gives

$$k_{30}=i(1-c), \tag{8.12}$$

but this result is not compatible with Eq. (8.3). We consider the equation

$$k_{30}=N(c), \tag{8.13}$$

without specifying the function $N(c)$, apart from the conditions $N(1)=0$ and $N(c)\simeq -ic$ for large imaginary c. If $N(c)$ is real, Eqs. (8.11) and (8.13) define a two-dimensional unbounded orbit of $\widetilde{E}(2)$, unless $M=N=0$.

In order to complete the list of the orbits of $\widetilde{E}(2)$ in the spin space, we have to consider the zero-dimensional trivial orbit, corresponding to a Minkowskian scalar field, and a set of one-dimensional bounded orbits defined by the conditions

$$k_{10}=k_{31}, \quad k_{20}=-k_{23}, \quad k_{12}=k_{30}=0, \quad (k_{31})^2+(k_{23})^2=\nu^2>0. \tag{8.14}$$

The corresponding orbits of the Lorentz group are four-dimensional and have a large symmetry group[2,7] locally isomorphic to L(4,**R**). It has been shown in Ref. 7 that they are not allowed according to our definition.

Now we study the VEVs of the flat-space theories with $\mu>0$. Given a positive-mass orbit of the Lorentz group in the spin-momentum space and positive Lorentz-invariant measure m on it, the VEV can be written in the form

$$V(x,\mathbf{x}',\mathbf{x}'')=(2\pi)^{-3}\int \exp(-ik\cdot x+i\mathbf{k}'\cdot\mathbf{x}'-i\mathbf{k}''\cdot\mathbf{x}'')\,dm$$

$$=(2\pi)^{-3}\int \exp(-ik\cdot x+i\mathbf{k}'\cdot\mathbf{x}'-i\mathbf{k}''\cdot\mathbf{x}'')\tilde{v}(\hat{\mathbf{k}}',\hat{\mathbf{k}}'')\,\theta(k^0)$$

$$\times\delta(k\cdot k+\mu^2)d^4k\,d^3\mathbf{k}'\,d^3\mathbf{k}'', \tag{8.15}$$

where

$$\hat{k}_{ik}=\Lambda^r{}_i(a_k)\Lambda^s{}_k(a_k)k_{rs}, \tag{8.16}$$

$\tilde{v}(\mathbf{k}',\mathbf{k}'')d^3\mathbf{k}'d^3\mathbf{k}''$ represents a positive rotation-invariant measure concentrated on the spin-shell, and a_k is defined by Eq. (3.21).

The integral (8.15) can be written in the form

$$V(x,\mathbf{x}',\mathbf{x}'')=(2\pi)^{-3}\int \exp(-ik\cdot x)v(\hat{\mathbf{x}}',\hat{\mathbf{x}}'')\,\theta(k^0)\,\delta(k\cdot k+\mu^2)d^4k, \tag{8.17}$$

where

$$\hat{x}^{ik}=\Lambda_r{}^i(a_k)\Lambda_s{}^k(a_k)x^{rs} \tag{8.18}$$

and

$$v(\mathbf{x}',\mathbf{x}'')=\int \exp(i\mathbf{k}'\cdot\mathbf{x}'-i\mathbf{k}''\cdot\mathbf{x}'')\tilde{v}(\mathbf{k}',\mathbf{k}'')d^3\mathbf{k}'\,d^3\mathbf{k}''. \tag{8.19}$$

If the vectors $\mathbf{k}'$, $\mathbf{k}''$ represent an arbitrary point of the spin-shell, we can put

$$v(\mathbf{x}',\mathbf{x}'')=I(\mathbf{k}',\mathbf{k}'',\mathbf{x}',\mathbf{x}'')=\int_{\mathrm{SO}(3)}\exp(iR\mathbf{k}'\cdot\mathbf{x}'-iR\mathbf{k}''\cdot\mathbf{x}'')d^3R, \tag{8.20}$$

where R is a three-dimensional rotation matrix and d^3R is the normalized invariant measure on the rotation group. In the general case, this integral cannot be expressed in terms of elementary functions, but if the vectors $\mathbf{k}'$,$\mathbf{k}''$ are parallel or antiparallel, we have

$$v(\mathbf{x}',\mathbf{x}'')=t^{-1}\sin t, \tag{8.21}$$

where

$$t^2=(\|\mathbf{k}'\|\mathbf{x}'\mp\|\mathbf{k}''\|\mathbf{x}'')^2. \tag{8.22}$$

If we consider a theory with $j=M=0$, from Eq. (8.6) we obtain

$$t^2=(1-c^2)(\mathbf{x}'')^2. \tag{8.23}$$

Equation (8.17) is similar to Eq. (3.24) and it is interesting to compare the functions $v(\mathbf{x}',\mathbf{x}'')$ and $w(a)$, where a is given by the exponential

$$a=\exp(\tfrac{1}{2}(\mathbf{x}''-i\mathbf{x}')\cdot\sigma). \tag{8.24}$$

Equation (A27) gives the power expansion of the integral (8.20) up to quadratic terms in the variables $\mathbf{x}',\mathbf{x}''$. A comparison with Eq. (A26) shows that, disregarding higher-order terms, we have

$$w(a)\simeq v(\mathbf{x}',\mathbf{x}''). \tag{8.25}$$

It follows that if $f(x)$ is a test function and a is given by Eq. (8.24), we have

$$\int f(x)W(x,a)d^4x\simeq\int f(x)V(x,\mathbf{x}',\mathbf{x}'')d^4x \tag{8.26}$$

up to terms of the second order.

In order to simplify the integral (8.17), we proceed as in Sec. IV, namely, we put

$$\mathbf{x}'=(0,0,\alpha),\quad \mathbf{x}''=(0,0,\beta), \tag{8.27}$$

and we use the definitions (4.23)–(4.25). From Eq. (8.18) we obtain

$$\begin{aligned}\hat{\mathbf{x}}'&=(0,-\beta\ \sinh\ \eta,\alpha\ \cosh\ \eta)=\mu^{-1}(0,-\beta p,\alpha q),\\ \hat{\mathbf{x}}''&=(0,\alpha\ \sinh\ \eta,\beta\ \cosh\ \eta)=\mu^{-1}(0,\alpha p,\beta q).\end{aligned} \tag{8.28}$$

The analogue of Eq. (4.28) is

$$V(x,\alpha,\beta)=(2\pi)^{-1}\int_0^\infty \Delta(q\sigma,\epsilon(x^0))J_0(p\rho)v(\mathbf{x}',\mathbf{x}'')p\ dp, \tag{8.29}$$

and in a similar way one writes the analogues of Eqs. (4.31) and (4.32), which determine the commutator.

If in Eq. (8.20) we replace the integrand by the maximum of its modulus, we obtain the inequality

$$\begin{aligned}|I(\mathbf{k}',\mathbf{k}'',\mathbf{x}'+i\mathbf{y}',\mathbf{x}''+i\mathbf{y}'')|\leqslant\exp((\mathbf{k}')^2(\mathbf{y}')^2+(\mathbf{k}'')^2(\mathbf{y}'')^2\\ +2(\mathbf{k}'\cdot\mathbf{k}'')(\mathbf{y}'\cdot\mathbf{y}'')+2\|\mathbf{k}'\times\mathbf{k}''\|\|\mathbf{y}'\times\mathbf{y}''\|)^{1/2}.\end{aligned} \tag{8.30}$$

For large $|p|$ we have $\mathrm{Im}\,q\simeq\mathrm{Im}\,p$ and, with this approximation, from Eq. (8.28) we obtain

$$|v(\hat{\mathbf{x}}',\hat{\mathbf{x}}'')|\leqslant\exp(\mu^{-1}|\mathrm{Im}\ p|(\alpha^2+\beta^2)^{1/2}((\mathbf{k}')^2+(\mathbf{k}'')^2+2\|\mathbf{k}'\times\mathbf{k}''\|)^{1/2}). \tag{8.31}$$

If we take into account Eq. (4.33), we see that in the analogue of Eq. (4.32) we can close the integration path at infinity in the upper half-plane if

$$\rho>\sigma+\mu^{-1}(\alpha^2+\beta^2)^{1/2}((\mathbf{k}')^2+(\mathbf{k}'')^2+2\|\mathbf{k}'\times\mathbf{k}''\|)^{1/2}, \tag{8.32}$$

and under this condition the commutator of the flat-space theory vanishes. We remark that the flat-space theory has stronger local commutation properties than the corresponding theory on $\tilde{\mathscr{P}}$.

For $j=M=0$, we can use Eqs. (8.21) and (8.23) and from Eq. (8.28) we have

$$t^2=(1-c^2)(\alpha^2(\sinh\ \eta)^2+\beta^2(\cosh\ \eta)^2)=(1-c^2)(\beta^2+(\alpha^2+\beta^2)\mu^{-2}p^2). \tag{8.33}$$

If we remark that, for small values of α and β, Eq. (5.25) gives

$$\zeta^2\simeq\alpha^2(\sinh\ \eta)^2+\beta^2(\cosh\ \eta)^2, \tag{8.34}$$

we can easily verify Eq. (8.26) in this special case.

IX. A THEORY WITH BROKEN Sp(4,R) SYMMETRY

Now we consider a scalar flat-space theory invariant with respect to a group $\mathscr{T}$ larger than SL(2,**C**). It is defined by a spin-mass-shell which is an orbit of $\mathscr{T}$ and can be decomposed into orbits of the Lorentz group. As a consequence, its two-point VEV is a superposition (an integral) of the Lorentz invariant VEVs $V(x,\mathbf{x}',\mathbf{x}'')$ described in Sec. VIII. If all the Lorentz orbits which appear in the decomposition are allowed (apart from a set of vanishing measure), we can consider the analogous superposition of the VEVs $W(x,a)$ and we find the VEV of a nonelementary theory on $\tilde{\mathscr{P}}$ which corresponds, in some sense, to the $\mathscr{T}$-invariant theory on the flat space. In general, the theory on $\tilde{\mathscr{P}}$ has lost the symmetry under the large group $\mathscr{T}$, but some consequence of this higher symmetry remains in the short-distance limit.

In Refs. 7 and 30 we have described several flat-space theories symmetric with respect to SL(4,**R**) or to one of its subgroups isomorphic to Sp(4,**R**), which form a one-parameter family.[2] The positivity of the energy requires that the spin-mass-shell is contained in a closed invariant cone $\mathscr{T}^{*+}$, the dual of the cone $\mathscr{T}^{+}$ that describes the causal properties of the theory. Therefore, only the allowed Lorentz orbits contained in $\mathscr{T}^{*+}$ are interesting for the purpose we are discussing. The corresponding spin-shells must be bounded, and this requirement excludes all the zero-mass allowed theories considered in Sec. VIII, but the Minkowskian zero-mass theory corresponding to the spin-shell reduced to the origin. In addition to this theory, only positive-mass elementary theories can be used in the construction of a theory on $\tilde{\mathscr{P}}$ with broken higher symmetry. If we look at the definition of the cone $\mathscr{T}^{*+}$,[7] we see that for $\mu>0$ the spin-shell must be contained in the set defined by

$$(\mathbf{k}')^2+(\mathbf{k}'')^2+2\|\mathbf{k}'\times\mathbf{k}''\|\leqslant\mu^2 \tag{9.1}$$

(see Appendix B). This inequality gives rise to a complicated constraint on the parameters j, M, and c; in particular, we obtain

$$j(j+1)+1-c^2\leqslant\mu^2. \tag{9.2}$$

The mass μ is measured in natural units of the order of the Planck mass and for the observable particles it is very small. It follows that we must have $j=M=0$ and $1-c^2\ll 1$, namely the theory must be very near to the Minkowskian limit. We also see that the particles with small μ and nonvanishing spin cannot be described by scalar fields. We have already remarked in Sec. V that spin has two different origins: in this case the spin is generated by the field indices, as in Eqs. (5.15) and (6.28). Combined with Eq. (8.32), Eq. (9.1) ensures that the commutator of the flat-space theory vanishes for

$$\rho>\sigma+(\alpha^2+\beta^2)^{1/2}. \tag{9.3}$$

We consider the spin-mass-shells described in Refs. 7 and 30 and we exclude the four-dimensional one, composed of a single zero-mass not-allowed Lorentz orbit. The decomposition of these spin-mass-shells (disregarding a set of vanishing measure) contains only positive-mass Lorentz orbits. In general, not all these orbits are allowed, but one can try to replace the integral over the continuous parameters j and M by a sum over the discrete allowed values. In this way, we may also obtain a discrete mass spectrum. This procedure will be examined elsewhere; in the following we consider a particular choice of the group $\mathscr{T}$ isomorphic to Sp(4,**R**) and a particular class of orbits in such a way that all the Lorentz orbits that appear in the decomposition are allowed.

For the description of the spin-mass-shells invariant with respect to Sp(4,**R**), locally isomorphic to the anti-de-Sitter group $SO^{\uparrow}(2,3)$, it is convenient to introduce the notation

$$k^{5i}=-k^{i5}=k^i, \quad i=0,1,2,3, \tag{9.4}$$

and to consider the quantities k^{uv} as the components of an antisymmetric tensor in a five-dimensional space with metric $g_{55}=g_{00}=-1$, $g_{11}=g_{22}=g_{33}=1$. In the following the indices u,v,w,x,y,z take the values 5,0,1,2,3.

We consider the orbit which contains the point defined by $k^0=s>0$, $\mathbf{k}=\mathbf{k}'=\mathbf{k}''=0$. Then it also contains the Lorentz orbit that corresponds to a Minkowskian theory with mass $\mu=s$. It is six-dimensional and in Ref. 30 it has been called $\mathscr{O}_{4,(1/2)s,(1/2)s}$. The following O(2,3)-invariant set of conditions is satisfied on the orbit for all the values of s:

$$e^{uvwxy}k_{vw}k_{xy}=0. \tag{9.5}$$

In the four-dimensional formalism these conditions take the form

$$e^{ikrs}k_{ik}k_{rs}=0, \quad e^{ikrs}k_k k_{rs}=0, \tag{9.6}$$

and in the three-dimensional formalism we can write

$$\mathbf{k}\cdot\mathbf{k}'=0, \quad \mathbf{k}'\cdot\mathbf{k}''=0, \tag{9.7}$$

$$\mathbf{k}'=(k^0)^{-1}\mathbf{k}''\times\mathbf{k}. \tag{9.8}$$

It is clear that Eq. (9.8) implies Eq. (9.7) and therefore the whole set of conditions (9.5). We see that these conditions are not independent and define a seven-dimensional manifold.

The O(2,3)-invariant manifold defined by Eq. (9.5) can be parametrized by means of the coordinates $\mathbf{k}$, $\mathbf{k}''$, k^0 and it is easy to control that the measure defined by

$$(k^0)^{-2}d^3\mathbf{k}d^3\mathbf{k}''dk^0 \tag{9.9}$$

is invariant under O(2,3). In order to get an orbit of $SO^{\uparrow}(2,3)$, we have to introduce the further invariant condition

$$\tfrac{1}{2}\,g^{ux}g^{vy}k_{uv}k_{xy}=(k^0)^2-(\mathbf{k})^2+(\mathbf{k}')^2-(\mathbf{k}'')^2=s^2, \tag{9.10}$$

that, together with Eq. (9.8), gives

$$k^0=\pm\left(\tfrac{1}{2}((\mathbf{k})^2+(\mathbf{k}'')^2+s^2)\pm\tfrac{1}{2}(((\mathbf{k})^2+(\mathbf{k}'')^2+s^2)^2-4\|\mathbf{k}''\times\mathbf{k}\|^2)^{1/2}\right)^{1/2}. \tag{9.11}$$

This formula describes the orbit we are considering if we choose the sign + twice.

From Eqs. (9.8) and (9.10) we see that in the decomposition of this orbit into orbits of the Lorentz group we find, besides the above-mentioned orbit with mass $\mu=s$, the allowed orbits labelled, in accord with Eq. (8.4), by the parameters

$$M=j=0, \quad \mu^2=1-c^2+s^2>s^2. \tag{9.12}$$

In order to find an invariant measure on this orbit, we have to multiply Eq. (9.9) by the appropriate invariant δ-function and integrate over dk^0. The result is

$$\begin{aligned} dm_s&=\delta((k^0)^2-(\mathbf{k})^2+(\mathbf{k}')^2-(\mathbf{k}'')^2-s^2)(k^0)^{-2}d^3\mathbf{k}d^3\mathbf{k}''dk^0\\ &=\tfrac{1}{2}(k^0)^{-1}((k^0)^2-(\mathbf{k}')^2)^{-1}d^3\mathbf{k}d^3\mathbf{k}'', \end{aligned} \tag{9.13}$$

where $\mathbf{k}'$ and k^0 are given by Eqs. (9.8) and (9.11).

The Fourier transform of this measure can be performed in two steps:

$$V_s(x,\mathbf{x}',\mathbf{x}'')=(2\pi)^{-3}\int \exp(-ik\cdot x)A(k^0,\mathbf{k},\mathbf{x}',\mathbf{x}'')d^4k, \tag{9.14}$$

$$A(k^0,\mathbf{k},\mathbf{x}',\mathbf{x}'')=(k^0)^{-2}\int \exp(i\mathbf{k}'\cdot\mathbf{x}''-i\mathbf{k}''\cdot\mathbf{x}'')\,\theta(k^0-2^{-1/2}((\mathbf{k})^2+(\mathbf{k}'')^2+s^2)^{1/2})$$
$$\times\delta((k^0)^2-(\mathbf{k})^2+(\mathbf{k}')^2-(\mathbf{k}'')^2-s^2)d^3\mathbf{k}''. \tag{9.15}$$

If $\mathbf{k}=0$, we also have $\mathbf{k}'=0$ and, therefore,

$$A(k^0,0,\mathbf{x}',\mathbf{x}'')=\theta(k^0-s)(k^0)^{-2}\int \exp(-i\mathbf{k}''\cdot\mathbf{x}'')\,\delta((\mathbf{k}'')^2-(k^0)^2+s^2)d^3\mathbf{k}''$$
$$=2\pi(k^0)^{-2}((k^0)^2-s^2)^{1/2}\theta(k^0-s)v^{0c0}(\mathbf{x}''), \tag{9.16}$$

where $v^{0c0}(\mathbf{x}'')$ is given by Eqs. (8.21) and (8.23) with $1-c^2=\mu^2-s^2$. In general, by means of the Lorentz transformation a_k we obtain

$$A(k^0,\mathbf{k},\mathbf{x}',\mathbf{x}'')=2\pi\mu^{-2}(\mu^2-s^2)^{1/2}\theta(\mu^2-s^2)\,\theta(k^0)v^{0c0}(\hat{\mathbf{x}}''), \tag{9.17}$$

where $\hat{\mathbf{x}}''$ is given by Eq. (8.18) and $\mu^2=(k^0)^2-(\mathbf{k})^2$. In conclusion, we have

$$V_s(x,\mathbf{x}',\mathbf{x}'')=(2\pi)^{-2}\int \exp(-ik\cdot x)\mu^{-2}(\mu^2-s^2)^{1/2}\theta(\mu^2-s^2)\,\theta(k^0)v^{0c0}(\hat{\mathbf{x}}'')d^4k. \tag{9.18}$$

In order to obtain the VEVs of the theory defined on $\tilde{\mathscr{P}}$, we just have to replace v^{0c0} by w^{0c0} and we obtain

$$W_s(x,a)=(2\pi)^{-2}\int \exp(-ik\cdot x)\mu^{-2}(\mu^2-s^2)^{1/2}\theta(\mu^2-s^2)\,\theta(k^0)w^{0c0}(a_k^{-1}aa_k)d^4k. \tag{9.19}$$

Also in this case we can introduce the parameters α and β, parametrize k as in Eq. (4.23), and perform the integration over the variables ξ and ψ. We obtain

$$V_s(x,\alpha,\beta)=2\int_0^\infty\int_0^\infty (q^2-p^2)^{-1}(q^2-p^2-s^2)^{1/2}$$
$$\times\theta(q^2-p^2-s^2)\Delta(q\sigma,\epsilon(x^0))J_0(p\rho)t^{-1}\sin t\; pdp\; qdq, \tag{9.20}$$

where

$$t^2=(q^2-p^2)^{-1}(q^2-p^2-s^2)(p^2\alpha^2+q^2\beta^2) \tag{9.21}$$

and

$$W_s(x,u_3(\alpha)a_3(\beta))=2\int_0^\infty\int_0^\infty (q^2-p^2)^{-1}(q^2-p^2-s^2)^{1/2}\theta(q^2-p^2-s^2)$$
$$\times\Delta(q\sigma,\epsilon(x^0))J_0(p\rho)(c\sinh\zeta)^{-1}\sinh(c\zeta)pdp\; qdq, \tag{9.22}$$

where

$$c^2=s^2-q^2+p^2+1,\quad \cosh\zeta=(q^2-p^2)^{-1}(q^2\cosh\beta-p^2\cos\alpha). \tag{9.23}$$

The field defined by W_s satisfies the equations

$$e^{uvwxy}A_{vw}A_{xy}\psi=0, \tag{9.24}$$

$$\tfrac{1}{2}g^{ux}g^{vy}A_{uv}A_{xy}\psi=-s^2\psi, \tag{9.25}$$

written in the five-dimensional formalism. In fact, it is a direct integral of fields that satisfy Eqs. (7.34)–(7.36) and (7.38) with the parameters constrained by Eq. (9.12). This field describes ''particles'' with vanishing spin and a continuous mass spectrum lying on the half-line $\mu\geqslant s$.

The function V_s has been computed in Ref. 30 and, with the conventions adopted here, is given by

$$V_s(x,\mathbf{x}',\mathbf{x}'')=\lambda_1^{-1}\lambda_2^{-1}(\lambda_1+\lambda_2)^{-1}\ \exp(-\tfrac{1}{2}s(\lambda_1+\lambda_2)), \tag{9.26}$$

where λ_1,λ_2 are given by

$$\lambda_{1,2}^2=A\pm(A^2-B)^{1/2}, \tag{9.27}$$

$$\begin{aligned} A&=-\sigma^2+\rho^2-\alpha^2+\beta^2,\\ B&=(\sigma^2-\rho^2-\alpha^2-\beta^2)^2-4\rho^2(\alpha^2+\beta^2) \end{aligned} \tag{9.28}$$

(see Appendix B for more details). The signs of λ_1,λ_2 are determined in such a way that their real parts are positive or, if one of them vanishes, it becomes positive after the addition of a small positive imaginary part to x^0.

Starting from Eqs. (9.20)–(9.23), and introducing the new integration variables $p'=\epsilon p$, $q'=\epsilon q$, it is easy to prove that

$$\lim_{\epsilon\to 0}(\epsilon^3 W_s(\epsilon x,u_3(\epsilon\alpha)a_3(\epsilon\beta)))=V_0(x,\alpha,\beta), \tag{9.29}$$

$$\lim_{\epsilon\to 0}(\epsilon^3 V_s(\epsilon x,\epsilon\alpha,\epsilon\beta))=V_0(x,\alpha,\beta). \tag{9.30}$$

This means that in the short-distance limit, namely near to the unit of the group, the VEV W_s coincides with the distribution V_0, symmetric with respect to Sp(4,**R**). In other words, the symmetry broken by the structure of the Poincaré group survives in the short-distance limit. We also see that in the short-distance limit the dependence on the parameter s disappears.

X. RADIATION FROM AN ACCELERATED SOURCE

The simplest exercise with a free quantum field is its interaction with an external source. We consider a scalar Hermitian field and we write the time integral of the interaction Hamiltonian in the form

$$F=\int H'(t)dt=\int f(x,a)\psi(x,a)d^4x\ d^6a. \tag{10.1}$$

The scattering operator is given by

$$S=\exp(-iF)=\exp(-\tfrac{1}{2}\|F\Omega\|^2):\exp(-iF): \tag{10.2}$$

(time ordering is not necessary, since it introduces only an overall phase factor). The number of emitted particles follows a Poisson distribution with average value

$$\langle n\rangle = \|F\Omega\|^2. \tag{10.3}$$

This is just the quantity given by Eq. (3.12).

In general, the function f that describes the source is not arbitrary; it may be subject to some conservation law or to some other constraint arising from the field equations. For instance, it is not clear if a point particle has to be be described by a one-dimensional trajectory in $\tilde{\mathscr{P}}$ or by a manifold with higher dimension as it is discussed in Ref. 31. The formulation of possible constraints requires a deeper understanding of the theory and we disregard this problem in the following exercise. We consider a source that is bound to an accelerated frame, obtained from an initial frame by means of the following one-parameter group of Poincaré transformations:

$$t \to ((a^{-1}\sinh(at),0,0,a^{-1}(\cosh(at)-1)),a_3(at)). \tag{10.4}$$

An infinitesimal transformation of this group is the product of a time translation by an infinitesimal amount dt and a boost along the z axis with infinitesimal velocity $a\,dt$, where a represents a constant acceleration. The parameter t is the proper time of the accelerated frame.

Since a point source is too singular, we consider a source concentrated on a disk lying in the x^1,x^2 plane of the accelerated frame; then we have

$$F = \int P(r)Q(t)\psi((a^{-1}\sinh(at),r\cos\phi,r\sin\phi,a^{-1} \times(\cosh(at)-1)),a_3(at))r\,dr\,d\phi\,dt, \tag{10.5}$$

where $P(r)$ is the ''density'' of the disk and $Q(t)$ is a function equal to one in an interval of length T and going smoothly to zero outside this interval. We expect that when T is large, $\langle n\rangle$ is proportional to T.

Then from Eq. (10.3) we obtain

$$\langle n\rangle = \int P(r_1)P(r_2)Q(t_1)Q(t_2)W(x,a_3(at_2-at_1))r_1dr_1\,d\phi_1\,r_2dr_2\,d\phi_2\,dt_1\,dt_2, \tag{10.6}$$

where

$$x^0 = a^{-1}\sinh(at),\quad x^3 = a^{-1}(\cosh(at)-1),\quad t=t_2-t_1,\quad x^1 = r_2\cos\phi_2 - r_1\cos\phi_1,$$
$$x^2 = r_2\sin\phi_2 - r_1\sin\phi_1. \tag{10.7}$$

Note that W depends on the quantities (4.5), which take the form

$$\rho^2 = r_1^2 + r_2^2 - 2r_1r_2\cos(\phi_2-\phi_1), \tag{10.8}$$

$$\sigma = 2a^{-1}\sinh(\tfrac{1}{2}at). \tag{10.9}$$

We can also write

$$\langle n\rangle = 2\pi\int \hat{P}(\rho)\hat{Q}(t)W(x,a_3(\beta))\rho d\rho\,dt, \tag{10.10}$$

where

$$x=(\sigma,\rho,0,0),\quad \beta = at, \tag{10.11}$$

$$\hat{P}(\rho)=\int P(r)P(\rho^2+r^2+2\rho r\cos\phi)r\,dr\,d\phi, \tag{10.12}$$

$$\hat{Q}(t)=\int Q(t_1)Q(t+t_1)dt_1. \tag{10.13}$$

When the proper time interval T is large, we have

$$T^{-1}\hat{Q}(t)\simeq 1-|t|T^{-1}. \tag{10.14}$$

It follows that in the same limit the average number of produced particles per unit of proper time is given by

$$T^{-1}\langle n\rangle=2\pi\int_{-\infty}^{\infty}dt\int_0^{\infty}\hat{P}(\rho)W(x,a_3(\beta))\rho d\rho, \tag{10.15}$$

if the integral converges. If we take Eq. (3.29) into account, we can write

$$T^{-1}\langle n\rangle=4\pi\int_0^{\infty}dt\int_0^{\infty}\hat{P}(\rho)\mathrm{Re}\ W(x,a_3(\beta))\rho d\rho. \tag{10.16}$$

Now we consider the theory defined in Sec. IX and we look for singularities of the integral (10.16). Since the singularities arise for small values of t and ρ, we approximate the function W by means of Eqs. (9.26)–(9.29); namely, we use the formula

$$W(x,a_3(\beta))\simeq\lambda_1^{-1}\lambda_2^{-1}(\lambda_1+\lambda_2)^{-1}=(\lambda_1^2-\lambda_2^2)^{-1}(\lambda_2^{-1}-\lambda_1^{-1})=(4\rho\beta)^{-1}$$
$$\times(((\rho-\beta)^2-\sigma^2)^{-1/2}-((\rho+\beta)^2-\sigma^2)^{-1/2}), \tag{10.17}$$

where β and σ are given as functions of t by Eqs. (10.9) and (10.11).

After some calculation, we obtain

$$\int\hat{P}(\rho)\mathrm{Re}\ W(x,a_3(\beta))\rho d\rho=(4\beta)^{-1}\int_{\sigma}^{\infty}(\hat{P}(r+\beta)-\hat{P}(|r-\beta|))(r^2-\sigma^2)^{-1/2}\,dr+\theta(\beta-\sigma)$$
$$\times(2\beta)^{-1}\int_{\sigma}^{\beta}\hat{P}(\beta-r)(r^2-\sigma^2)^{-1/2}\,dr. \tag{10.18}$$

If $\hat{P}(\rho)$ has a bounded derivative, the first integral on the right-hand side has at most a logarithmic singularity for small t. The second integral is present only if $a>1$ and for small t it behaves as

$$\hat{P}(0)(2at)^{-1}\log(a+(a^2-1)^{1/2}). \tag{10.19}$$

As a consequence, if $a>1$, the integral over t in Eq. (10.16) diverges. In other words, if the acceleration a is larger than a critical value, conventionally taken equal to 1, the number of particles and the energy radiated per unit proper time become infinite.

APPENDIX A: PROPERTIES OF THE FUNCTIONS $w^{Mcj}(a)$

The quantities defined by Eqs. (5.14) or (5.18) are elementary functions, but for large values of j they are too complicated and it is preferable to introduce some integral representations. We start from the realization[23–26] of the representation D^{Mc} by means of operators acting on the square integrable functions defined on SU(2) which have the covariance property

$$f(u_3(\phi)u)=\exp(-iM\phi)f(u). \tag{A1}$$

An orthonormal basis in this Hilbert space is given by the functions

$$f_{jm}(u)=(2j+1)^{1/2}R^j_{Mm}(u). \tag{A2}$$

The invariant measure d^3u on SU(2) is normalized in such a way that the measure of the whole group is one.

We consider the decomposition

$$a=k(a)a_0, \tag{A3}$$

where

$$a=\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} \in \mathrm{SL}(2,\mathbf{C}), \tag{A4}$$

$$k(a)=\begin{pmatrix} (p(a))^{-1} & q(a) \\ 0 & p(a) \end{pmatrix}, \quad p(a)>0, \tag{A5}$$

$$a_0=\begin{pmatrix} \alpha & \beta \\ -\overline{\beta} & \overline{\alpha} \end{pmatrix} \in \mathrm{SU}(2), \quad |\alpha|^2+|\beta|^2=1. \tag{A6}$$

We see that

$$p(a)=(|a_{21}|^2+|a_{22}|^2)^{1/2}, \tag{A7}$$

$$\alpha=(p(a))^{-1}\overline{a_{22}}, \quad \beta=-(p(a))^{-1}\overline{a_{21}}. \tag{A8}$$

We shall use the properties

$$p(au)=p(a), \quad (au)_0=a_0u, \quad u\in \mathrm{SU}(2), \tag{A9}$$

$$p(u_3(\phi)a)=p(a), \quad (u_3(\phi)a)_0=u_3(\phi)a_0. \tag{A10}$$

The representation operator is defined by

$$[D^{Mc}(a)f](u)=(p(ua))^{2c-2}f((ua)_0) \tag{A11}$$

and the matrix elements we need are given by

$$D^{Mc}_{jmjm}(a)=(f_{jm},D^{Mc}(a)f_{jm})=(2j+1)\int_{\mathrm{SU}(2)}\overline{R^j_{Mm}}(u)(p(ua))^{2c-2}R^j_{Mm}((ua)_0)d^3u. \tag{A12}$$

If we sum over m and use Eq. (A9), we obtain the required formula

$$w^{Mcj}(a)=\int_{\mathrm{SU}(2)}(p(ua))^{2c-2}R^j_{MM}((uau^{-1})_0)d^3u. \tag{A13}$$

We can also use the integral representation[27]

$$R^j_{MM}(u)=(2\pi)^{-1}\int_0^{2\pi}F^{Mj}(u_3(-\phi)uu_3(\phi))d\phi, \tag{A14}$$

where

$$F^{Mj}(u)=(\alpha-\overline{\beta})^{j+M}(\overline{\alpha}+\beta)^{j-M} \tag{A15}$$

and we have used the expression (A6) for the matrix u. If we substitute Eq. (A14) into Eq. (A13) and we use the properties (A9) and (A10), we obtain

$$w^{Mcj}(a)=\int_{\mathrm{SU}(2)}(p(ua))^{2c-2}F^{Mj}((uau^{-1})_0)d^3u \tag{A16}$$

or, more explicitly,

$$w^{Mcj}(a)=\int_{\mathrm{SU}(2)}(|b_{21}|^2+|b_{22}|^2)^{c-1-j}(\overline{b_{22}}+b_{21})^{j+M}(b_{22}-\overline{b_{21}})^{j-M}\,d^3u, \tag{A17}$$

where

$$b=uau^{-1}. \tag{A18}$$

The exponential mapping can be written in the form

$$a=\exp(\tfrac{1}{2}(\mathbf{x}''-i\mathbf{x}')\cdot\sigma)=\cosh\,\chi+\tfrac{1}{2}\chi^{-1}\,\sinh\,\chi\,(\mathbf{x}''-i\mathbf{x}')\cdot\sigma, \tag{A19}$$

where

$$\chi^2=\tfrac{1}{4}(\mathbf{x}''-i\mathbf{x}')\cdot(\mathbf{x}''-i\mathbf{x}'). \tag{A20}$$

If we indicate by $R(u)$ the SO(3) rotation matrix corresponding to the element $u\in\mathrm{Su}(2)$ and we put

$$\mathbf{y}'=R(u)\mathbf{x}',\quad \mathbf{y}''=R(u)\mathbf{x}'', \tag{A21}$$

we have

$$b=uau^{-1}=\cosh\,\chi+\tfrac{1}{2}\chi^{-1}\,\sinh\,\chi\,(\mathbf{y}''-i\mathbf{y}')\cdot\sigma. \tag{A22}$$

In particular, it is

$$b_{21}=\tfrac{1}{2}(y_1''-iy_1'+iy_2''+y_2')\chi^{-1}\,\sinh\,\chi,$$

$$b_{22}=\cosh\,\chi+\tfrac{1}{2}(-y_3''+iy_3')\chi^{-1}\,\sinh\,\chi. \tag{A23}$$

If we substitute these expressions into Eq. (A17) and disregard terms of order higher than the second in the variables $\mathbf{x}'$ and $\mathbf{x}''$, we can perform the integral by means of the formulas

$$\int_{\mathrm{SU}(2)}\mathbf{y}'\,d^3u=0, \tag{A24}$$

$$\int_{\mathrm{SU}(2)}y_r'y_s''\,d^3u=\frac{1}{3}\,\delta_{rs}\mathbf{x}'\cdot\mathbf{x}'' \tag{A25}$$

and other similar consequences of Eq. (A21). The result is

$$w^{Mcj}(a)\simeq 1-\tfrac{1}{6}j(j+1)(\mathbf{x}')^2-\tfrac{1}{6}(j(j+1)+1-c^2-M^2)(\mathbf{x}'')^2+\tfrac{1}{3}iMc\mathbf{x}'\cdot\mathbf{x}''. \tag{A26}$$

Now we want to compare the integral (A17) with the integral (8.20). We can expand the exponential in Eq. (8.20), keeping terms up to the second order in the variables $\mathbf{x}'$ and $\mathbf{x}''$, and perform the integral by means of Eqs. (A24) and (A25). We obtain

$$I(\mathbf{k}',\mathbf{k}'',\mathbf{x}',\mathbf{x}'')\simeq 1-\tfrac{1}{6}(\mathbf{k}')^2(\mathbf{x}')^2-\tfrac{1}{6}(\mathbf{k}'')^2(\mathbf{x}'')^2+\tfrac{1}{3}\mathbf{k}'\cdot\mathbf{k}''\mathbf{x}'\cdot\mathbf{x}'' \tag{A27}$$

and Eq. (8.25) follows immediately.

Another interesting limit can be derived from Eqs. (A17) and (A23):

$$\begin{aligned}\lim_{n\to\infty}\ & w^{nM,nc,nj}(\exp((2n)^{-1}(\mathbf{x}''-i\mathbf{x}')\cdot\sigma))\\ &=\int_{\mathrm{SU}(2)}\exp((j-c)y_3'')\exp(\tfrac{1}{2}(j+M)(-y_3''-iy_3'+y_1''-iy_1'+iy_2''+y_2'))\\ &\quad\times\exp(\tfrac{1}{2}(j-M)(-y_3''+iy_3'-y_1''-iy_1'+iy_2''-y_2'))d^3u=I(\mathbf{k}',\mathbf{k}'',\mathbf{x}',\mathbf{x}''),\end{aligned} \tag{A28}$$

where

$$\mathbf{k}'=(-j,-iM,-M),\quad \mathbf{k}''=(iM,-j,-ic). \tag{A29}$$

The quantity $I(\mathbf{k}',\mathbf{k}'',\mathbf{x}',\mathbf{x}'')$ defined in Eq. (8.20) is an entire analytic function of its arguments and it depends on $\mathbf{k}',\mathbf{k}''$ through the invariants

$$(\mathbf{k}')^2=j^2,\quad (\mathbf{k}'')^2=j^2-c^2-M^2,\quad \mathbf{k}'\cdot\mathbf{k}''=iMc. \tag{A30}$$

If we indicate by $\mathbf{k}_n',\mathbf{k}_n''$ the coordinates of a representative point of the orbit defined by the parameters nM,nc,nj, we have

$$\begin{aligned}\lim_{n\to\infty} v^{nM,nc,nj}(n^{-1}\mathbf{x}',n^{-1}\mathbf{x}'')&=\lim_{n\to\infty} I(\mathbf{k}_n',\mathbf{k}_n'',n^{-1}\mathbf{x}',n^{-1}\mathbf{x}')\\ &=\lim_{n\to\infty} I(n^{-1}\mathbf{k}_n',n^{-1}\mathbf{k}_n'',\mathbf{x}',\mathbf{x}')=I(\mathbf{k}',\mathbf{k}'',\mathbf{x}',\mathbf{x}'),\end{aligned} \tag{A31}$$

where

$$\mathbf{k}'=\lim_{n\to\infty}(n^{-1}\mathbf{k}_n'),\quad \mathbf{k}''=\lim_{n\to\infty}(n^{-1}\mathbf{k}_n''). \tag{A32}$$

Since these limits satisfy Eq. (A30), we see that the limits (A28) and (A31) are equal. This result can be used to generalize the treatment of Sec. IX to a larger class of theories with a broken higher symmetry.

APPENDIX B: GEOMETRY OF THE VECTOR SPACES $\mathscr{T}$ AND $\mathscr{T}^*$

In this Appendix we summarize some results of Refs. 2, 3, and 7. We use the Dirac matrices with the properties

$$\gamma_i\gamma_k+\gamma_k\gamma_i=2g_{ik},\quad {\gamma_k}^T=-C^{-1}\gamma_kC,\quad C^T=-C. \tag{B1}$$

We adopt the Majorana representation in which the Dirac matrices are real and we put $C=\gamma_0$. The vectors of $\mathscr{T}$ and $\mathscr{T}^*$ can be labelled, respectively, by means of the real symmetric 4×4 matrices

$$\hat{x}=\tfrac{1}{2}x^k C^{-1}\gamma_k-\tfrac{1}{4}x^{rs}C^{-1}\gamma_r\gamma_s, \tag{B2}$$

$$\hat{k}=-\tfrac{1}{2}k_k\gamma^{\,k}C+\tfrac{1}{4}k_{rs}\gamma^{\,r}\gamma^{\,s}C. \tag{B3}$$

The closed cones $\mathscr{T}^+$ and $\mathscr{T}^{*+}$ contain the elements labelled by positive semidefinite matrices.

The following formulas are useful:

$$\mathrm{Tr}(\hat{k}\hat{x})=-k_k x^k+\tfrac{1}{2}k_{rs}x^{rs}=k^0x^0-\mathbf{k}\cdot\mathbf{x}+\mathbf{k}'\cdot\mathbf{x}'-\mathbf{k}''\cdot\mathbf{x}'', \tag{B4}$$

$$A=\mathrm{Tr}(C\hat{x})^2=x_k x^k-\tfrac{1}{2}x_{rs}x^{rs}=-(x^0)^2+(\mathbf{x})^2-(\mathbf{x}')^2+(\mathbf{x}'')^2, \tag{B5}$$

$$-s^2=\mathrm{Tr}(\hat{k}C^{-1})^2=k_k k^k-\tfrac{1}{2}k_{rs}k^{rs}=-(k^0)^2+(\mathbf{k})^2-(\mathbf{k}')^2+(\mathbf{k}'')^2, \tag{B6}$$

$$\begin{aligned}B=16\det\hat{x}=&((x^0)^2-(\mathbf{x})^2-(\mathbf{x}')^2-(\mathbf{x}'')^2)^2-4\|\mathbf{x}\times\mathbf{x}'\|^2-4\|\mathbf{x}'\times\mathbf{x}''\|^2\\&-4\|\mathbf{x}''\times\mathbf{x}\|^2-8x^0\mathbf{x}''\cdot\mathbf{x}'\times\mathbf{x},\end{aligned} \tag{B7}$$

and a similar formula for $\det\hat{k}$. Note that the parameter s which appears in Eqs. (B6) and (9.10) was indicated by $2s$ in Ref. 30.

A vector of $\mathscr{T}$ belongs to $\mathscr{T}^+$ when x^0 is larger or equal to the largest root of the equation $\det\hat{x}=0$ and a similar statement holds for $\mathscr{T}^{*+}$. For $\mathbf{k}=0$ and $k^0=\mu>0$, we have

$$16\det\hat{k}=(\mu^2-(\mathbf{k}')^2-(\mathbf{k}'')^2)^2-4\|\mathbf{k}'\times\mathbf{k}''\|^2, \tag{B8}$$

and the condition for belonging to $\mathscr{T}^{*+}$ is just Eq. (9.1).

The quantities $\pm\lambda_{1,2}$ introduced in Sec. IX are the eigenvalues of the matrix $2C\hat{x}$ (the factor 2 was not present in Ref. 30). They are given by Eq. (9.27), where A and B are given by Eqs. (B5) and (B7). If we assume Eqs. (4.5) and (8.27), we get Eq. (9.28). It has been shown in Ref. 30 that in a flat-space theory invariant under $\mathrm{Sp}(4,\mathbf{R})$ the commutator vanishes unless one of the quantities $\lambda_{1,2}^2$ is real negative. This means that the commutator vanishes if $A^2-B<0$ or if $A>0$, $B>0$. These conditions are satisfied if $\sigma^2<0$ or if Eq. (9.3) holds.

The Stückelberg–Kibble model as an example of quantized symplectic reduction

(Received 1 September 1995; accepted for publication 2 January 1996)

Recently, it has been observed that a certain class of classical theories with constraints can be quantized by a mathematical procedure known as Rieffel induction. After a short exposition of this idea, we apply the new quantization theory to the Stückelberg–Kibble model. We explicitly construct the physical state space $\mathscr{H}_{\text{phys}}$, which carries a massive representation of the Poincaré group. The longitudinal one-particle component arises from a particular Bogoliubov transformation of the five (unphysical) degrees of freedom one has started with. Our discussion exhibits the particular features of the proposed constrained quantization theory in great clarity. © *1996 American Institute of Physics.* [S0022-2488(96)02105-3]

I. INTRODUCTION

Classical gauge field theories may be defined by a set of fields $\mathscr{A}$, subject to a set of constraints $\mathscr{B}$, which, in turn, generate gauge transformations. The quantization of such theories is not a unique procedure. Indeed, already in the two best-established quantization methods very different technical setups are chosen. On the one hand, one has the canonical operator formalism, originating with Heisenberg and Pauli,[1] and now well adapted to handle non-Abelian gauge theories,[2] whereas on the other hand Feynman's path integral formalism[3] allows the quantization of such theories through the Faddeev–Popov procedure.[4] Both methods lead to identical perturbative expansions, but even at a mathematically heuristic level their possible equivalence is only known in perturbation theory.

It is certainly of general interest to have as many conceptually and mathematically different quantization schemes as possible, and to examine the particular features of each of them. The hope of obtaining some hints on how to quantize gravity may provide further motivation for investigating new quantization schemes. Especially, the modern formulation of classical mechanics in terms of symplectic manifolds and Poisson algebras (see, e.g., Ref. 5) has suggested more refined quantization procedures, such as geometric quantization[6] and strict deformation quantization.[7,8]

A particular feature of classical gauge theories that should somehow be reflected in the quantization method is that the physical (reduced) phase space may be written as a so-called Marsden–Weinstein quotient.[9,10] Given that this powerful technique can be used to construct the physical state space of the classical theory, it appears most natural to look for a quantum analogue which mimicks it. This was found by one of the authors in Ref. 11 where Rieffel induction,[12] a technique from operator algebra theory used for the construction of representations of algebras, was shown to provide a satisfactory quantum analogue of the classical Marsden–Weinstein reduction. In practice, this allows one to perform a quantization of a classical unreduced model, and to find (via Rieffel induction) the quantum-reduced phase space which coincides with a direct quantization of the reduced classical phase space.

The method advocated in Ref. 11 provides a conceptually and technically new approach to the quantization of certain gauge field theories. It has already been successfully applied to certain

finite-dimensional constrained systems,[11] as well as to free quantum electrodynamics.[13,14] These applications are mainly operator-theoretic, but a certain aspect of the path integral formalism, viz. the integration over the gauge group, will play a role as well.

The present work draws on these results. Its aim is twofold. First, we would like to present the strategy of this new quantization method in a form accessible to a wider scientific community. Therefore, in Sec. II, we briefly review the main line of argument, leading to the quantization proposal. To keep our presentation reasonably short, we refer for some of the technicalities to the aforementioned papers. Subsequently, in Sec. III we apply the new quantization scheme to the Stückelberg–Kibble model. This toy model has often been used in the investigation of the Higgs mechanism and of spontaneous symmetry breaking, see, e.g., Ref. 15. Here, we have chosen it since it already shows many of the typical complications of spontaneously broken gauge theories without the need to restrict oneself to a perturbative discussion.

As we shall demonstrate explicitly for this model, the Rieffel induction procedure provides a scheme for the construction of the physical state space of a constrained quantum theory, starting from a larger (unphysical) state space on which the unconstrained theory is defined. Our discussion will focus on the particular properties of this Rieffel-induced physical Hilbert space $\mathscr{H}_{\rm phys}$. Especially, we find that $\mathscr{H}_{\rm phys}$ carries a trivial representation of the gauge group and a massive representation of the Poincaré group. Also, the positive spectrum condition turns out to be satisfied. As an important by-product, we are able to trace back how ''would-be Goldstone bosons rearrange to a massive, longitudinal component'' in a theory exhibiting the Higgs mechanism.

The context of our work is modern symplectic geometry and reduction theory on the classical side, and algebraic quantum field theory on the quantum side. We only use the ''soft'' side of these theories. Good recent introductions are Refs. 5, 16, and 17, respectively.

II. THE QUANTIZATION OF GAUGE THEORIES WITH RIEFFEL INDUCTION

After presenting schematically the strategy which leads to Rieffel induction in the quantization of theories with constraints, in the remainder of this section we briefly specify some notational and technical prerequisites.

A. Quantization of Marsden–Weinstein reduction

The general symplectic reduction procedure, which is quantized by Rieffel induction in its full generality, is described in Ref. 11. Here we are merely concerned with a special case, viz. Marsden–Weinstein reduction at the zero level of the moment map, (cf. Refs. 5 and 18). To introduce our notation, let us consider free classical electrodynamics. For the functional-analytic and other details which are suppressed in what follows, we refer the interested reader to Ref. 13.

We start with the space M of four-component real-valued weak solutions A_μ of the wave equation whose Fourier-transformed Cauchy-data lie in $L^2(\mathbb{R}^3)\otimes\mathbb{C}^4$. That is, $M=\{A_\mu|\Box A_\mu=0\}$. The imaginary part

$$B(A,A')=2\,\mathrm{Im}(A,A')_M=-i\int \frac{d^3\mathbf{p}}{(2\pi)^3}\,[A^\mu(\mathbf{p})\overline{A'_\mu}(\mathbf{p})-\overline{A^\mu}(\mathbf{p})A'_\mu(\mathbf{p})] \tag{II.1}$$

of the indefinite covariant scalar product $(*,*)_M$ turns M into a symplectic space (M,B), which is the phase space of the unconstrained classical system. The set of constraints is given by the gauge group G, which acts on M via $A_\mu\to A_\mu+\partial_\mu g$, where

$$G=\{g\in\mathscr{S}'(\mathbb{R}^4)|\Box g=0;dg\in M\}. \tag{II.2}$$

Here, the space of distributions $\mathscr{S}'(\mathbb{R}^4)$ is the dual of the usual Schwartz space of rapidly decreasing test functions. In the present example, the reduced phase space (M_c,B_c) of the corresponding constrained system may be obtained by a so-called Marsden–Weinstein reduction.[18] This involves the moment map J from M into the dual of the Lie algebra of G. As G is a vector space, we may

identify it with its Lie algebra, so we simply write $J_g(A)$ for the value of $J(A)$ on $g \in G$. Explicitly, the moment map turns out to be $J_g(A) = \mathrm{Im}(\partial g, A)_M$ (cf. Ref. 13). The preimage of its zero level is

$$J^{-1}(0) = \{A_\mu \in M \,|\, \partial_\mu A^\mu = 0\}. \tag{II.3}$$

Then, M_c is given by the Marsden–Weinstein quotient

$$M_c = J^{-1}(0)/G, \tag{II.4}$$

and B_c inherits its structure from B. It is easy to see that (M_c, B_c) defined this way indeed describes the physical degrees of freedom of free electrodynamics: picking $J^{-1}(0)$ fixes the gauge (thus imposing the Gauss law constraint, which on elements of M becomes the Lorentz gauge condition), and quotienting by G removes the gauge degeneracy of the symplectic form B with respect to the action of G on $J^{-1}(0)$.

In principle, there are two possibilities to quantize a reduced phase space (M_c, B_c). Either, we directly quantize the Marsden–Weinstein reduced (i.e., constrained) classical system (M_c, B_c), or we quantize the unconstrained classical system (M, B) together with the set of constraints. In the latter case, a scheme has to be found which imposes constraints on the unconstrained quantized theory, thereby providing a quantum analogue of the classical Marsden–Weinstein reduction. Examples of such schemes are the Dirac or the BRST method. According to the proposal of Ref. 11, the so-called Rieffel induction procedure of operator algebra theory[12] (which we explain below) provides a rival scheme, which in all examples studied so far works as well as, or better than, the methods mentioned above.

More precisely, let us consider schematically a quantization prescription $Q_\hbar$ which relates the symplectic space (M, B) (or rather the Poisson algebra of functions on it) to some algebra of field operators on a Hilbert space $\mathscr{A}$, G to some algebra $\mathscr{B}$ generated by G, and (M_c, B_c) to some (*a priori* unknown) algebra of observables (in the sense of gauge-invariant operators) $\mathscr{A}_{\mathrm{obs}}$. Then, according to our quantization proposal, the following diagram commutes:

$$\begin{array}{ccc} & \overset{Q_\hbar}{} & \\ (M,B);G & \rightarrow & \mathscr{A};\mathscr{B} \\ \text{Marsden–Weinstein Reduction} \downarrow & & \downarrow \text{ Rieffel Induction}. \\ & \overset{Q_\hbar}{} & \\ (M_c, B_c) & \rightarrow & \mathscr{A}_{\mathrm{obs}} \end{array} \tag{II.5}$$

Our program in this paper is to specify the entries of this diagram for the Stückelberg–Kibble model. To this end, we briefly recall how, for a linear field theory, a symplectic space (M, B) can be related to a field algebra $\mathscr{A}$ of canonical commutation relations, and we explain how Rieffel induction allows one to construct new Hilbert spaces for quantum field theories, thereby eventually specifying $\mathscr{A}_{\mathrm{obs}}$.

B. Weyl algebras of canonical commutation relations

The general theory behind this subsection is explained in great detail and rigor in, e.g., Ref. 17, and the application to electromagnetism is from Ref. 19. We merely mention some of the main points.

For ϕ, $\phi' \in M$, the operators $W(\phi)$, $W(\phi')$, satisfying the Weyl form of the canonical commutation relation (CCR)

$$W(\phi)W(\phi') = W(\phi + \phi')e^{(-i/2)B(\phi,\phi')}, \tag{II.6}$$

specify a field algebra with C^*-structure which we denote by $\mathscr{A}(M,B)$. In most cases, one is primarily interested in the properties of the operator vector potential A_μ, for which we use the same notation as for its classical counterpart, as no confusion will arise. The A_μ satisfy the canonical commutation relations

$$[A_\mu(x),\, A_\nu(y)] = -ig_{\mu\nu}\, D(x-y), \tag{II.7}$$

where D denotes the commutator function satisfying $\Box D=0$, with initial conditions $D(\mathbf{x},0)=0$, $(\partial/\partial t)D(\mathbf{x},t)|_{t=0} = -\delta^{(3)}(\mathbf{x})$. To see the connection between (II.6) and (II.7), we consider the vector potential $A(f)=\int d^4x A_\mu(x) f^\mu(x)$, smeared with real test functions f. Now, (II.7) reads $[A(f),A(g)] = i\sigma(f,g)$, where $\sigma(f,g) = -\int d^4x d^4y D(x-y) f^\mu(x) g_\mu(y)$. Formally, this allows for the introduction of the operators $U(f)=e^{[iA(f)]}$, which, according to the Baker–Campbell–Haussdorff formula, satisfy the Weyl form of the canonical commutation relations $U(f)U(g) = U(f+g)e^{[-(i/2)\sigma(f,g)]}$. Here, however, $U(f)$ and $U(f')$ have the same commutation relations as long as $\int d^4x D(x-y)(f^\mu(x)-f'^\mu(x))=0$ for almost all y. To remove this degeneracy and to obtain a one-to-one correspondence between Weyl operators and test functions, one uses the map $f\to\phi$, defined by the convolution $\phi_\mu = D*f_\mu$. Then, the space M of solutions of the wave equation

$$\Box\phi_\mu = 0, \quad \phi_\mu(\mathbf{x},t) = \frac{1}{(2\pi)^3}\int \frac{d^3\mathbf{k}}{2k_0}\,[\phi_\mu(\mathbf{k})e^{-ikx} + \overline{\phi_\mu}(\mathbf{k})e^{ikx}]$$

is (our notation does not distinguish between functions ϕ and their Fourier transforms, since no confusion should arise)

$$M = \overline{\{\phi = D*f\}} = L^2(\mathbb{R}^3)\otimes\mathbb{C}^4. \tag{II.8}$$

Now, the operators $W(\phi)=U(f)$, $\phi\in M$, satisfy (II.6) with symplectic form B induced by σ and given in (II.1).

Having established the connection between Weyl operators and vector potentials, we can introduce formal annihilation and creation operators a_μ, a_μ^*, e.g., for the free electromagnetic field,

$$A_\mu(x) = \int \frac{d^3\mathbf{k}}{(2\pi)^3 2k_0}\,[e^{-ikx}a_\mu(\mathbf{k}) + e^{ikx}a_\mu^*(\mathbf{k})]|_{k_0=\mathbf{k}},$$

$$iA(f) = \int \frac{d^3\mathbf{k}}{(2\pi)^3 2k_0}\,[a_\mu(\mathbf{k})\overline{\phi_\mu}(\mathbf{k}) - a_\mu^*(\mathbf{k})\phi_\mu(\mathbf{k})] =: a_\mu(\phi^\mu) - a_\mu(\phi^\mu)^*. \tag{II.9}$$

Clearly, in terms of the annihilation and creation operators, the Weyl operators read $W(\phi^\mu)=\exp[a_\mu(\phi^\mu) - a_\mu(\phi^\mu)^*]$, where $[a_\mu(\phi^\mu), a_\nu(\phi'^\nu)^*] = (\phi',\phi)_M$, $(.,.)_M$ denoting the indefinite Minkowski inner product. Heuristically, one has

$$\frac{d}{d\lambda}\, W(\lambda\phi)\bigg|_{\lambda=0} = iA(f). \tag{II.10}$$

It is well known that this derivative does not exist in the operator norm but with respect to regular representations only, and thereby the a_μ, a_μ^* only exist in such representations, too. Nevertheless, in what follows we shall adopt the formal expressions (II.9) and (II.10), even when no explicit reference to a particular representation is made.

As a final preparatory step, we point out that subalgebras of $\mathscr{A}(M,B)$ can be specified by selecting subspaces of M. In particular, for free QED,

$$N=\{\phi_\mu\in M\,|\,k^\mu\phi_\mu(\mathbf{k})=0\}=\{\phi_\mu\in M\,|\,\partial^\mu\phi_\mu(x)=0\},$$
$$T=\{\phi_\mu\in M\,|\,\phi_\mu(\mathbf{k})=ik_\mu g(\mathbf{k})\}=\{\phi_\mu\in M\,|\,\phi_\mu(x)=\partial_\mu g(x),\Box g(x)=0\} \tag{II.11}$$

define subalgebras $\mathscr{A}(N,B)$, $\mathscr{A}(T,B)$ of $\mathscr{A}(M,B)$. Note that $T\subset N$, so that $\mathscr{A}(T,B)\subset\mathscr{A}(N,B)$. These subalgebras are Poincaré-invariant, as may be seen by recalling that the action of elements (Λ,a) of the Poincaré group $\mathscr{P}$ on $\mathscr{A}(M,B)$ is defined via the algebraic automorphism $\alpha_{(\Lambda,a)}$,

$$\alpha_{(\Lambda,a)}(W(\phi^\mu))=W(\gamma_{(\Lambda,a)}(\phi^\mu)) \quad \text{with} \quad (\gamma_{(\Lambda,a)}(\phi^\mu))(x)=\Lambda^\mu\phi'(\Lambda^{-1}(x-a)). \tag{II.12}$$

C. Rieffel induction

This subsection gives a quick ''review by example'' of some parts of the theory developed in Refs. 11 and 13.

In physics, induction methods are mainly known from Wigner's classification and construction of all irreducible unitary representations of the Poincaré group $\mathscr{P}$. In general, the method of induced representations of (locally compact) groups allows one to construct a representation of the complete group from a representation of a subgroup (cf., e.g., Ref. 20).

Also, in the theory of operator algebras (particularly C^*-algebras) a method exists for constructing a representation of an algebra, given a representation of some other algebra.[12] The latter is not necessarily a subalgebra of the former; instead, the two algebras need to be connected by a bimodule with certain additional properties. Whatever the technical details, the main idea is that the representation one induces from should be straightforward, and yet capable of producing an appropriate representation of the algebra one is really interested in. This idea will be fully realized in our context, for the second algebra will be the algebra generated by the gauge group, and the representation induced from is the trivial one. With a suitable choice of bimodule, the induced representation of the algebra of observables turns out to be the vacuum representation on a Fock space of physical photon states.

To facilitate our presentation, we proceed by example, abstracting general features afterwards. For free QED, in the diagram (II.5) we choose the field algebra $\mathscr{A}=\mathscr{A}(M,B)$ and the ''algebra of constraints'' $\mathscr{B}=\mathscr{A}(T,B)$ (cf. the previous subsection), where the choice of $\mathscr{B}$ is motivated by observing that the gauge group G equals T [cf. (II.11)]. Also, we introduce the ''algebra of weak observables'' $\mathscr{A}_c:=\mathscr{A}(N,B)$, which is the largest subalgebra of $\mathscr{A}=\mathscr{A}(M,B)$ commuting with $\mathscr{B}=\mathscr{A}(T,B)$. For simplicity, we here ignore some mathematical difficulties in defining algebras $\mathscr{B}$ for groups G which are not locally compact. This greatly simplifies our presentation. For more details, we refer to Refs. 13 and 14.

The Rieffel induction procedure will produce a representation of $\mathscr{A}_c$ induced from a representation of $\mathscr{B}$. To this end, we need a bimodule for $\mathscr{A}_c$ and $\mathscr{B}$, that is, a linear space on which $\mathscr{A}_c$ acts from the left, and $\mathscr{B}$ acts from the right (that is, in an antirepresentation), so that these two actions commute. In the case at hand, $\mathscr{A}_c$ and $\mathscr{B}$, which is Abelian, are each other's commutant in the field algebra $\mathscr{A}$, so that a representation of $\mathscr{A}$ on a Hilbert space $\mathscr{H}$ automatically defines such a bimodule. Finally, we need a representation of $\mathscr{B}$ to induce from. This is the trivial one, defined on the Hilbert space $\mathscr{H}_{\rm tr}=\mathbb{C}$. Schematically,

$$\mathscr{A}_c\rightarrow\mathscr{H}\leftarrow\mathscr{B}\rightarrow\mathscr{H}_{\rm tr}. \tag{II.13}$$

The choice of the trivial representation to Rieffel induce from is dictated by the fact that Marsden–Weinstein reduction of the classical theory is performed from the zero level of the momentum map [cf. (II.4)] (that is, the point 0 in the dual of the Lie algebra of the gauge group G corresponds to the trivial representation).[21]

The restriction of the action π on $\mathscr{H}$ of $\mathscr{A}$ to its subalgebra $\mathscr{B}$ defines a representation U of the gauge group, that is, one has $U(\phi)=\pi(W(\phi))$.

As will be discussed in more detail below, this setup allows the construction of a positive semidefinite sesquilinear form $(.,.)_0$ on $L\otimes\mathscr{H}_{\rm tr}$, where L is a suitable dense subspace of L. In the present case, this form is given by

$$(\psi\otimes v,\varphi\otimes w)_0=v\overline{w}\int_G[\mathscr{D}\phi](U(\phi)\psi,\varphi). \tag{II.14}$$

Here $[\mathscr{D}\phi]$ denotes the nonexistent ''Lebesgue'' measure on the gauge group G. The point is, however, that this flat ''measure'' combines with a factor in the integrand to define a mathematically well-defined path integral (cylindrical) measure on G.[13] Furthermore, ψ,φ are in $\mathscr{H}$, $v,w\in\mathscr{H}_{\rm tr}=\mathbb{C}$, and $(.,.)$ is the inner product on $\mathscr{H}$.

Irrespective of the explicit form of $(.,.)_0$, the induced physical Hilbert space is then defined as the completion of the quotient of $L\otimes\mathscr{H}_{\rm tr}$ by the null space of $(.,.)_0$, i.e.,

$$\mathscr{H}_{\rm phys}=\overline{(L\otimes\mathscr{H}_{\rm tr})/\mathscr{N}}, \tag{II.15}$$

where $\mathscr{N}\subset L\otimes\mathscr{H}_{\rm tr}$ is the subset of vectors with vanishing $(.,.)_0$ norm. The collection of vectors in $\mathscr{H}_{\rm phys}$ of the form $\psi\widetilde{\otimes}$v, defined as the image of $\psi\otimes v\in L\otimes\mathscr{H}_{\rm tr}$ under the quotient projection from $L\otimes\mathscr{H}_{\rm tr}$ to $\mathscr{H}_{\rm phys}$, are clearly dense in $\mathscr{H}_{\rm phys}$. The action of elements A of $\mathscr{A}_c$ on $\mathscr{H}_{\rm phys}$ is then given on this dense set by $\pi_{\rm phys}(A)\psi\widetilde{\otimes}\mathrm{v}=(\pi(A)\psi)\widetilde{\otimes}v$. Under appropriate continuity conditions[12,13] this action may be extended to all of $\mathscr{H}_{\rm tr}$.

The reader should note that $\mathscr{H}_{\rm phys}$ satisfies an essential requirement of a nondegenerate physical Hilbert space: the gauge degeneracy of elements $\mathscr{A}_c$ is removed in $\pi_{\rm phys}(\mathscr{A}_c)$. To see this, choose an arbitrary element $W(\phi)\in\mathscr{A}_c$. From equation (II.14), it is obvious that for $\phi_t\in T$ (which, we recall, coincides with the gauge group G), $\pi_{\rm phys}(W(\phi))\psi\widetilde{\otimes}v=\pi_{\rm phys}(W(\phi+\phi_t))\psi\widetilde{\otimes}v$ for all vectors $\psi\widetilde{\otimes}\mathrm{v}\in\mathscr{H}_{\rm phys}$. Hence, $\pi_{\rm phys}(W(\phi))=\pi_{\rm phys}(W(\phi+\phi_t))$. This removal of the gauge degeneracy of $\mathscr{A}_c$ is independent of the choice of $\mathscr{H}$, and hence we identify $\pi_{\rm phys}(\mathscr{A}_c)$ with the representation-independent algebra of observables $\mathscr{A}_{\rm obs}$ [cf. (II.5)].

Let us now turn to the abstract setting which has led to the $(.,.)_0$ inner product (II.14). As stated, the aim of the Rieffel induction procedure is to obtain a representation $\pi_{\rm phys}$ of $\mathscr{A}_c$ induced from a representation of $\mathscr{B}$ on some Hilbert space $\mathscr{H}_\chi$. Our example, and all similar examples involving gauge theories, have the special feature that $\mathscr{H}_\chi=\mathscr{H}_{\rm tr}=\mathbb{C}$, that is, one induces from the trivial representation of the gauge group. This will imply that the algebra of constraints $\mathscr{B}$ is represented trivially on the induced space $\mathscr{H}_{\rm phys}$. Technically, the construction of $\pi_{\rm phys}$ proceeds according to the following three-step method.

(1) Given a bimodule L for $\mathscr{A}_c$ and $\mathscr{B}$, a $\mathscr{B}$-valued scalar product $\langle.,.\rangle_{\mathscr{B}}$ has to be found on L, that is, for $\psi,\ \varphi\in L\subset\mathscr{H}$, $\langle\psi,\varphi\rangle_{\mathscr{B}}\in\mathscr{B}$.[22]

(2) Given such an operator-valued scalar product, the tensor product $L\otimes\mathscr{H}_\chi$ is equipped with a sesquilinear form $(.,.)_0$,

$$(\psi\otimes v,\varphi\otimes w)_0:=(\pi_\chi(\langle\varphi,\psi\rangle_{\mathscr{B}})v,w)_\chi. \tag{II.16}$$

Crucially, this form is positive semidefinite if the postivity condition $\pi_\chi(\langle\psi,\psi\rangle_{\mathscr{B}})\geqslant 0$ for all $\psi\in L$ is satisfied, which is the case in all our examples.

(3) The subspace $\mathscr{N}\subset L\otimes\mathscr{H}_{\rm tr}$ of vectors with vanishing $(.,.)_0$-norm is determined and the physical Hilbert space is defined as in (II.15).

The most difficult part of this procedure is to find $\langle.,.\rangle_{\mathscr{B}}$. Here, one is guided by mathematical examples.[11] One may consider, e.g., $\mathscr{B}=C^*(G)$, the C^*-group algebra of a locally compact group G (cf. Ref. 17; this is essentially the convolution algebra on the group w.r.t. the Haar measure). Then, it can be shown that a rigging map $\langle.,.\rangle_{\mathscr{B}}$ is defined as follows: $\langle\psi,\varphi\rangle_{\mathscr{B}}$ has to be some element of $C^*(G)$, i.e., a function on the group, and we prescribe that the value of this function

at $g \in G$ is given by $\langle \psi,\varphi\rangle_{\mathscr{B}}(g)=(U(g)\varphi,\psi)$, where U is a continuous unitary representation of G on $\mathscr{H}$, commuting with $\pi(\mathscr{A}_c)$, $x \in G$. Inducing from the trivial representation $\mathscr{H}_{\rm tr}=\mathbb{C}$, the general formalism leads to the prescription

$$(\psi,\varphi)_0=\int_G dx(U(x)\psi,\varphi). \tag{II.17}$$

(Here and in what follows, we use the shorthand $(\psi,\varphi)_0$ for $(\psi\otimes v,\varphi\otimes\omega)_0$, since $v,w \in \mathbb{C}$ are complex numbers which can be absorbed in the definition of ψ and φ.) At least in a heuristic sense, (II.14) is a special case of this.

So far, our presentation of the Rieffel induction procedure for quantum field theories has been slightly oversimplified with respect to one point: While the existence of a so-called ''rigged'' inner product $(.,.)_0$, defined in (II.16), is always sufficient for the quantization proposal to apply, it is not always possible to derive it from a mathematically well-defined rigging map $\langle .,.\rangle_{\mathscr{B}}$. We refer to Ref. 13 for a discussion of the technical points involved. In such cases, one cannot derive (II.17), but it still provides a well-defined starting point motivated by the general theory explained above.

In fact, in what follows, we shall base our arguments on a suitable generalization of (II.17).

To sum up: In this chapter, we have seen that Rieffel induction provides a well-defined scheme for the construction of a physical Hilbert space $\mathscr{H}_{\rm phys}$, on which gauge transformations act trivially. In the corresponding algebra of observables $\pi_{\rm phys}(\mathscr{A}_c)$, all gauge degeneracies are removed, i.e., Rieffel induction is a method to impose constraints on quantum field theories. The physical Hilbert space $\mathscr{H}_{\rm phys}$ is obtained by forming the quotient of a larger Hilbert space $L\otimes.\mathscr{H}_{\rm tr}$ with respect to a null space.

This is somewhat reminiscent of the BRST (or, in case of QED, the Gupta–Bleuler) procedure, with the major difference that with Rieffel induction no negative-norm subspace exists, obviating the need to select a physical subspace of $\mathscr{H}$. Also, certain functional-analytic problems that appear in the BRST as well as in the Dirac method are absent with our present techniques.[11,13] By definition of the inner product on the physical Hilbert space $\mathscr{H}_{\rm phys}$ calculations of correlation functions of operators in $\mathscr{A}_c$ (as represented on $\mathscr{H}_{\rm phys}$) may be performed in $L\otimes.\mathscr{H}_{\rm tr}$.[14]

Clearly, an alternative method is to construct the reduced (physical) Hilbert space using spectral analysis of the algebra of constraints. In this case, however, one has to guess the inner product on the ''improper'' subspace of the Hilbert space of the unconstrained system on which the constraints are zero. Also, the connection with the classical treatment of constraints is obscured somehow. This may be regarded as a drawback compared to the method advocated here.

III. APPLICATION TO THE STÜCKELBERG–KIBBLE MODEL

In this chapter, we specify (II.13) and (II.14) for the Stückelberg–Kibble model, thereby constructing a physical Hilbert space $\mathscr{H}_{\rm phys}$ for this model. The Stückelberg–Kibble model is an Abelian Higgs model with the modulus η of the scalar field $\phi(x)=\eta(x)e^{i\varphi(x)}$ frozen to unity, $\eta(x)=1$. It is given by the Lagrangian

$$\mathscr{L}=-\tfrac{1}{4}F_{\mu\nu}F^{\mu\nu}-\tfrac{1}{2}(\partial_\mu\varphi+eA_\mu)(\partial^\mu\varphi+eA^\mu). \tag{III.1}$$

Despite its linearity, this model has nontrivial features, and has been used as testing ground for investigations of the Higgs mechanism before.[15] Its equations of motion can be written in terms of a gauge-invariant current $j^\mu=\partial^\mu\varphi+eA^\mu$, satisfying

$$(\Box+e^2)j^\mu=0; \quad \partial_\mu j^\mu=0. \tag{III.2}$$

In fact, this is nothing but the Proca equation[23] of a massive gauge-invariant vector field. To make this model amenable to treatment by symplectic reduction and quantum induction methods, we

now make a move that is analogous to rewriting the Maxwell equation for A_μ as a massless Klein–Gordon equation plus a subsidiary Lorentz condition. Thus we pass back to the gauge-dependent fields A_μ and φ, and choose what is essentially the 't Hooft gauge as the subsidiary condition:

$$\partial_\mu A^\mu = e\varphi. \tag{III.3}$$

With this constraint, the equations of motion read

$$(\Box + e^2)A^\mu = 0, \quad (\Box + e^2)\varphi = 0, \tag{III.4}$$

and the gauge group $G = \{g | (\Box + e^2)g = 0\}$ acts on A_μ, φ via

$$A_\mu \to A_\mu + \partial_\mu g, \quad \varphi \to \varphi - eg. \tag{III.5}$$

A. Marsden–Weinstein reduction for the Stückelberg–Kibble model

A mathematically rigorous treatment of the following material, in the style of Ref. 13, is possible, but we leave the details to the interested reader; instead, readability commands us to give somewhat loose formulations.

Our investigation of the Stückelberg–Kibble model starts from the symplectic space (M_{sk}, B_{sk}), defined by

$$\begin{gathered} M_{sk} = \{(A_\mu, \varphi) | A_\mu \in L^2(\mathbb{R}^3) \otimes \mathbb{C}^4, \varphi \in L^2(\mathbb{R}^3); (\Box + e^2)A_\mu = (\Box + e^2)\varphi = 0\}, \\ B_{sk}(A_\mu, \varphi; A'_\mu, \varphi') = 2\,\mathrm{Im}(A_\mu, A'_\mu)_M - 2\,\mathrm{Im}(\varphi, \varphi'). \end{gathered} \tag{III.6}$$

The gauge group G acts on this space by the gauge transformation (III.5). This action is strongly Hamiltonian, and hence, in particular, it is symplectic. We evidently may identify the gauge group with the following subspace of M_{sk}:

$$T_{sk} = \{(A_\mu, \varphi) \in M_{sk} | A_\mu = \partial_\mu g, \varphi = -eg; g \in L^2(\mathbb{R}^3); (\Box + e^2)g = 0\}. \tag{III.7}$$

From this, the Marsden–Weinstein reduced space $(M_{c,sk}, B_{c,sk})$ is easily calculated. With similar notation as in Sec. (II. A), the moment map reads

$$J_g(A_\mu, \varphi) = 2\,\mathrm{Im}(\partial_\mu g, A_\mu)_M - 2\,\mathrm{Im}(-eg, \varphi), \tag{III.8}$$

which leads to

$$J^{-1}(0) = \{(A_\mu, \varphi) \in M_{sk} | \partial_\mu A^\mu = e\varphi\}. \tag{III.9}$$

Hence in view of (III.3) the Marsden–Weinstein quotient reads

$$M_{c,sk} = J^{-1}(0)/G = \{j_\mu \in L^2(\mathbb{R}^3) \otimes \mathbb{C}^4 | (\Box + e^2)j_\mu = 0; \partial_\mu j^\mu = 0\}. \tag{III.10}$$

The symplectic form $B_{c,sk}$ on $M_{c,sk}$ inherits its structure from B_{sk}, and is given by

$$B_{c,sk}(j, j') = \frac{2}{e^2}\,\mathrm{Im}(j_\mu, j'_\mu)_M. \tag{III.11}$$

Clearly, $(M_{c,sk}, B_{c,sk})$ is the phase space of a massive vector boson, which indeed represents the physical degrees of freedom of the Stückelberg–Kibble model. This completely specifies the left-hand side of the diagram (II.5).

B. Rieffel induction for the Stückelberg–Kibble model

1. Construction of the field algebra

Consider the canonical commutation relations of the operator fields A_μ and φ (denoted by the same symbol as their classical counterparts):

$$[\varphi(x),\ \varphi(y)]=i\Delta(x-y),$$
$$[A_\mu(x),\ A_\nu(y)]=-ig_{\mu\nu}\Delta(x-y), \tag{III.12}$$

where the commutator function Δ satisfies $(\Box+e^2)\Delta(x)=0$ with initial conditions $\Delta(\mathbf{x},0)=0$, $(\partial/\partial t)\Delta(\mathbf{x},t)|_{t=0}=-\delta^{(3)}(\mathbf{x})$. In analogy with our discussion of free QED, we specify the formal connection between the fields A_μ, φ and the corresponding Weyl operators, $W(\phi_\mu,\phi)=e^{iA_\mu(f^\mu)+i\varphi(f)}$, where $\phi_\mu=\Delta*f_\mu$, $\phi=\Delta*f$. Here, either as a consequence of (III.12) or imposed axiomatically, the operators $W(\phi_\mu,\phi)$, $W(\phi'_\mu,\phi')$ satisfy the Weyl form of the canonical commutation relations

$$W(\phi_\mu,\phi)W(\phi'_\mu,\phi')=W(\phi_\mu+\phi'_\mu,\phi+\phi')e^{-(i/2)B_{sk}(\phi_\mu,\phi;\phi'_\mu,\phi')}. \tag{III.13}$$

The field algebra of the model is then defined as the Weyl algebra $\mathcal{A}(M_{sk},B_{sk})$ generated by the Ws subject to these commutation relations (cf. Ref. 17).

Now, we want to construct the quantum counterpart of Marsden–Weinstein reduction, i.e., we want to complete the right-hand side of the diagram (II.5). Therefore, we invoke the quantization prescription for symplectic spaces as discussed in Sec. II. This leads to the field algebra $\mathcal{A}\equiv\mathcal{A}(M_{sk},B_{sk})$ defined by (III.6). Also, in analogy with our discussion in Sec. II, we choose the algebra of constraints $\mathcal{B}=\mathcal{A}(T_{sk},B_{sk})$; once again, the motivation for this is that it is the (C^*) algebra generated by the gauge group. Consequently, the algebra of weak observables, which by definition is the largest subalgebra of $\mathcal{A}(M_{sk},B_{sk})$ commuting with $\mathcal{B}(T_{sk},B_{sk})$, is given by $\mathcal{A}_c=\mathcal{A}(N_{sk},B_{sk})$, where

$$N_{sk}=\{(\phi_\mu,\phi)\,|\,\partial^\mu\phi_\mu=e\phi\}\subset M_{sk}; \tag{III.14}$$

compare this with (III.9). The subspaces N_{sk} and $T_{sk}\subset N_{sk}$ of M_{sk} are invariant under the action of symplectic transformations $\gamma_{\Lambda,a}$ associated with elements (Λ,a) of the Poincaré group $\mathcal{P}$,$(\gamma_{\Lambda,a}(\phi_\mu,\phi))(x):=(\Lambda^\nu_\mu\phi_\nu,\phi)(\Lambda^{-1}(x-a))$ [cf. (II.12)]. Consequently, the subalgebras, $\mathcal{A}_c$ and $\mathcal{B}$ are Poincaré invariant.

2. Representing the algebra of observables

Rieffel induction starts from the input data of diagram (II.13). So far, we have determined the algebra of weak observables $\mathcal{A}_c=\mathcal{A}(N_{sk},B_{sk})$ and the algebra of constraints $\mathcal{B}=\mathcal{A}(T_{sk},B_{sk})$ of the Stückelberg–Kibble model; note that $\mathcal{B}\subset\mathcal{A}_c$. What is needed is a representation of these algebras on some subspace L of a Hilbert space $\mathcal{H}$. In this subsection, we give such a representation on a bosonic Fock space (cf. the corresponding procedure for QED in Ref. 13).

For simplicity, in a first step we introduce a representation for elements $W(\phi_\mu,\phi=0)\in\mathcal{A}(M_{sk},B_{sk})$ only. This will subsequently be generalized to the whole algebra. We start from the canonical commutation relations for the smeared annihilation and creation operators $\hat{a}_\mu,\hat{a}^*_\mu$

$$\hat{a}(f)=\hat{a}_\mu(f^\mu)=\int\frac{d^3\mathbf{k}}{(2\pi)^3 2k_0}\,[\hat{a}_0(\mathbf{k})\overline{f_0}(\mathbf{k})+\hat{a}_i(\mathbf{k})\overline{f_i}(\mathbf{k})], \tag{III.15}$$

namely

$$[\hat{a}(f),\hat{a}^*(g)]=(g,f)_E:=\int \frac{d^3\mathbf{k}}{(2\pi)^3 2k_0}\, g_\mu(\mathbf{k})\,\delta^{\mu\nu}\overline{f_\nu}(\mathbf{k}). \tag{III.16}$$

For reasons to become clear soon, we have employed the so-called Fermi trick[19] which consists of defining the creation and annihilation operators of a vector field such that their commutator is a Euclidean scalar product. Introducing a vacuum state $|0\rangle$ with the property $\hat{a}(f)|0\rangle=0$ for all f, the creation and annihilation operators generate a bosonic Fock space $\mathscr{H}_1$ in the usual way. Mathematically $\mathscr{H}_1$ is, of course, the symmetric Hilbert space[24] over $L^2(\mathbb{R}^3)\otimes\mathbb{C}^4$.

We can now represent the field algebra $\mathscr{A}$, and thence its subalgebras $\mathscr{A}_c$ and $\mathscr{B}$, on $\mathscr{H}_1$ as follows:

$$\pi(W(\phi^\mu,\phi=0))=e^{[\hat{a}_\mu(\tilde{\phi}_\mu)-\hat{a}_\mu(\tilde{\phi}_\mu)^*]}, \tag{III.17}$$

where $\tilde{\phi}_\mu=(-\overline{\phi_0},\ \phi_i)$, and the symbol π for a representation has been introduced. The essential point is that the Euclidean commutation relations (III.16) are able to represent the Minkowski commutators (III.12) because of the special definition of $\tilde{\phi}_\mu$.

Now, we present a very economical notation for symmetric n-particle states by introducing ''exponential vectors.'' [24] To this aim, we represent the algebra $\mathscr{A}_c$ on the dense subset L_1 of $\mathscr{H}_1$, which is the span of all exponential vectors

$$L_1=\left\{\sum_{i=1}^{N}\lambda_i e^{\psi^{(i)}}\,\middle|\,\lambda_i\in\mathbb{C},\psi^{(i)}\in L^2(\mathbb{R}^3)\otimes\mathbb{C}^4,N<\infty\right\};$$
$$e^{\psi}:=1\oplus\psi\oplus\frac{1}{\sqrt{2}}\,\psi\otimes\psi\oplus\frac{1}{\sqrt{3!}}\,\psi\otimes\psi\otimes\psi\oplus\cdots, \tag{III.18}$$

where the tensor products are understood to be symmetrized. Note that the prefactors $1/\sqrt{n!}$ of the n-particle contributions to e^{ψ} have been chosen differently from those of a Taylor expansion of e^x. This allows for a simple form of the scalar product on L_1,

$$(e^{\psi},e^{\varphi})=e^{(\psi,\varphi)_E}. \tag{III.19}$$

A useful remark is now that symmetric n-particle states can be obtained from suitably normalized derivatives of exponential vectors,

$$\psi_1\otimes_s\cdots\otimes_s\psi_n=\frac{1}{\sqrt{n!}}\,\frac{d}{dr_1}\cdots\frac{d}{dr_n}\,e^{\Sigma_i r_i\psi_i}\bigg|_{r_i=0}. \tag{III.20}$$

The representation of $W(\phi_\mu,0)$ takes a very simple form on L_1. From (III.18) we have $e^{\hat{a}_\mu(\phi^\mu)}e^{\psi}=e^{(\psi,\phi)E}e^{\psi}$, $e^{\hat{a}_\mu(\phi^\mu)^*}e^{\psi}=e^{(\psi+\phi)}$ and hence[25]

$$\pi(W(\phi_\mu,0))e^{\psi}=e^{(-1/2)(\phi,\phi)_E+(\psi,\tilde{\phi})_E}e^{(\psi-\tilde{\phi})}. \tag{III.21}$$

The construction given above is easily generalized to the whole algebra $\mathscr{A}(M_{sk},B_{sk})$ acting on the dense subspace $L=L_1\otimes L_2$ of $\mathscr{H}=\mathscr{H}_1\otimes\mathscr{H}_2$, where $\mathscr{H}_2$ is the bosonic Fock space over $L^2(\mathbb{R}^3)$. With

$$L_2=\left\{\sum_{i}^{N}\lambda_i e^{\psi^{(i)}}\,\middle|\,\psi^{(i)}\in L^2(\mathbb{R}^3);\lambda_i\in\mathbb{C},N<\infty\right\}, \tag{III.22}$$

the scalar product of vectors in L reads

$$(e^{\psi_\mu}\otimes e^{\psi}, e^{\chi_\mu}\otimes e^{\chi}) = e^{(\psi_\mu,\chi_\mu)_E+(\psi,\chi)}, \tag{III.23}$$

and the action of $\mathscr{A}(M_{sk},B_{sk})$ (denoted by π as well, with slight abuse of notation) is

$$\pi(W(\phi_\mu,\phi))e^{\psi_\mu}\otimes e^{\psi} = e^{(-1/2)(\phi_\mu,\phi_\mu)_E+(\psi_\mu,\tilde{\phi}_\mu)_E}e^{(-1/2)(\phi,\phi)+(\psi,\phi)}e^{\psi_\mu-\tilde{\phi}_\mu}\otimes e^{\psi-\phi}. \tag{III.24}$$

It should be pointed out that L (which is the natural domain of the rigged inner product[13]) is only stable under finite linear combinations of the Ws (which span a dense subalgebra of $\mathscr{A}$), and not under all elements of $\mathscr{A}$, i.e., strictly speaking, the induction process is performed relative to the corresponding dense subalgebras of $\mathscr{A}_c$ and $\mathscr{B}$. Despite the use of bounded operators, the choice of L as a dense subspace of the Hilbert space of the unconstrained system is essential whenever the constraints have continuous spectrum. This is because in that case the rigged inner product is not defined on the whole Hilbert space. In its abstract formulation, Rieffel induction is even formulated in terms of L alone, without a Hilbert space it is embedded in.[12]

3. Constructing the physical one-particle Hilbert space

With (III.24), we have specified the bimodule L for $\mathscr{A}_c$ and $\mathscr{B}$, which in this case is a subspace of an ''unphysical'' Hilbert space $\mathscr{H}$. Our next step is to construct the corresponding physical Hilbert space, i.e., to carry out the discussion following (II.13). In this and the next subsection, we determine the null space $\mathscr{N}_{sk}$ for the Stückelberg–Kibble model, thereby eventually obtaining $\mathscr{H}_{\text{phys}}$.

We start from the inner product on elementary vectors in L

$$(e^{\psi_\mu}\otimes e^{\psi}, e^{\chi_\mu}\otimes e^{\chi})_0 = \int_{T_{sk}} [\mathscr{D}g](\pi(W(\partial_\mu g,-eg))e^{\psi_\mu}\otimes e^{\psi}, e^{\chi_\mu}\otimes e^{\chi}), \tag{III.25}$$

which is a natural generalization of (II.14) (and can, at least heuristically, be derived from an appropriate rigging map defined by a unitary representation of the gauge group on $\mathscr{H}$). As in Ref. 13, the heuristic path integral (III.25) can be turned into a well-defined integral wrt a certain cylindrical measure on $T_{sk}=G$, but here we shall proceed with the formal flat measure $\mathscr{D}g$, and certify that all manipulations below can be rigorously justified.

Using the representation (III.24) of $\mathscr{A}(N_{sk},B_{sk})$, we obtain, with $k_0=\sqrt{e^2+\mathbf{k}^2}$, and $d\tilde{k}=d\mathbf{k}^3/(2\pi)^3 2k_0$,

$$\begin{aligned}(e^{\psi_\mu}\otimes e^{\psi}, e^{\chi_\mu}\otimes e^{\chi})_0 = {} & e^{\int \tilde{d}k(-1/k_0^2)[(k_i\psi_i-ie\psi)k_0\psi_0+(k_i\overline{\chi_i}+ie\overline{\chi})k_0\overline{\chi_0}]} \\ & \times e^{\int \tilde{d}k\psi_i(\delta_{ij}-(k_ik_j/\mathbf{k}^2))\overline{\chi_j}+((e/k_0)\psi_i+i(k_i/k_0)\psi)(k_ik_j/\mathbf{k}^2)\overline{((e/k_0)\chi_j+i(k_j/k_0)\chi)}},\end{aligned} \tag{III.26}$$

where we have used $(\delta_{ij}-k_ik_j/k_0^2)=(\delta_{ij}-k_ik_j/\mathbf{k}^2)+e^2k_ik_j/k_0^2\mathbf{k}^2$ to write (III.26) in terms of projection operators.

To investigate the structure of the null space $\mathscr{N}_{sk}$, we derive the $(.,.)_0$ inner product for n-particle vectors in $\mathscr{H}$ from (III.26). For one-particle vectors in the (unphysical) space $\mathscr{H}$, we have

$$\left.\frac{d}{dr}\, e^{r\psi_\mu}\otimes e^{r\psi}\right|_{r=0} = \psi_\mu\otimes\Omega' + \Omega''\otimes\psi, \tag{III.27}$$

where $\Omega=\Omega''\otimes\Omega'$ denotes the vacuum state in $\mathscr{H}$. Since such expressions become cumbersome for higher derivatives, for notational convenience we define

$$\psi_*^{(1)}\times\cdots\times\psi_*^{(n)}:=\frac{1}{\sqrt{n!}}\frac{d}{dr_1}\cdots\frac{d}{dr_n}\,e^{\Sigma_i r_i\psi_\mu^{(i)}}\otimes e^{\Sigma_j r_j\psi^{(j)}}\Big|_{r_i=0}. \tag{III.28}$$

Then, the $(.,.)_0$ inner product on one-particle vectors in $\mathscr{H}$ reads

$$(\psi_*,\chi_*)_0=\int\tilde{d}k\,\psi_i\left(\delta_{ij}-\frac{k_ik_j}{\mathbf{k}^2}\right)\overline{\chi_j}+\left(\frac{e}{k_0}\,\psi_i+i\,\frac{k_i}{k_0}\,\psi\right)\frac{k_ik_j}{\mathbf{k}^2}\overline{\left(\frac{e}{k_0}\,\chi_j-i\,\frac{k_j}{k_0}\,\chi\right)}. \tag{III.29}$$

Clearly, the two transversal components $P_T\psi_*:=(\delta_{ij}-k_ik_j/\mathbf{k}^2)\psi_j$ and a linear combination $P_L\psi_*$ of the longitudinal component $(k_ik_j/\mathbf{k}^2)\psi_j(\mathbf{k})$ with the scalar component $\psi(\mathbf{k})$ survive, while the remaining two components lie in $\mathscr{N}_{sk}$. To be more precise, we introduce for ψ_* the *Bogoliubov-transformed components* ψ_L,ψ_N,

$$\begin{aligned}\psi_{L,i}(\mathbf{k}):&=\cos\,\theta\,\frac{k_ik_j\psi_j(\mathbf{k})}{\mathbf{k}^2}+i\,\sin\,\theta\,\frac{k_i\psi(\mathbf{k})}{|\mathbf{k}|},\\ \psi_{N,i}(\mathbf{k}):&=-\sin\,\theta\,\frac{k_ik_j\psi_j(\mathbf{k})}{\mathbf{k}^2}+i\,\cos\,\theta\,\frac{k_i\psi(\mathbf{k})}{|\mathbf{k}|},\end{aligned} \tag{III.30}$$

where $\cos\theta=e/k_0$, $\sin\theta=|\mathbf{k}|/\mathrm{k}_0$. With ψ_L, ψ_T, and ψ_N, the five-component vector $\psi_*^{(i)}$ can be specified as

$$\psi_*(\mathbf{k}):=(P_T\psi_\mu(\mathbf{k}),\psi_L(\mathbf{k}),\psi_N(\mathbf{k}),\psi_0(\mathbf{k})), \tag{III.31}$$

and the projection operator P_p onto the ''physical'' one-particle components is given by

$$(P_p\psi_*)(\mathbf{k})=(P_T\psi_\mu(\mathbf{k}),\psi_L(\mathbf{k}),0,0). \tag{III.32}$$

This is exactly what one expects: the five 'unphysical' degrees of freedom have combined into three physical ones in such a way that the longitudinal component in $\mathscr{H}$ has mixed with the scalar component.

4. The physical Hilbert space $\mathscr{H}_{phys}$

To extend (III.32) to n-particle states, we rewrite (III.26), using

$$\begin{aligned}\exp\left(\sum_i\,r_i\psi_*^{(i)}\right):&=\exp\left(\sum_i\,r_i\psi_\mu^{(i)}\right)\otimes\exp\left(\sum_i\,r_i\psi^{(i)}\right),\\ (e^{\psi_*},e^{\chi_*})_0&=(e^{\psi_*},\Omega)_0(\Omega,e^{\chi_*})_0(e^{P_p\psi_*},e^{P_p\chi_*}).\end{aligned} \tag{III.33}$$

Here we have used the remark following (III.29), which implies that

$$(\exp(P_p\psi_*),\exp(P_p\chi_*))_0=(\exp(P_p\psi_*),\exp(P_p\chi_*)).$$

From (III.33) we obtain

$$\psi_*^{(1)}\times\cdots\times\psi_*^{(n)}=\frac{d}{dr_1}\cdots\frac{d}{dr_n}\,(e^{\Sigma_i r_i\psi_*^{(i)}},\Omega)_0 e^{\Sigma_i r_i\psi_*^{(i)}}\Big|_{r_i=0}$$

$$=\sum_{q=0}^{n}\sum_{(p_i)_1^q\in\mathscr{P}_{q,n}}\lambda_{(p_i)_1^q}(P_p\psi_*^{(p_1)})\times\cdots\times(P_p\psi_*^{(p_p)})+\mathbf{n},\tag{III.34}$$

where $\mathscr{P}_{q,n}$ contains all sets of q indices $\{(p_i)_1^q\}$ out of $\{1,...,n\}$, such that $\{(p_i)_1^q\}\cup\{(\hat{p}_i)_1^{n-q}\}=\{1,\ldots,n\}$. Here,

$$\lambda_{(p_i)_1^q}=\sqrt{\frac{(q)!(n-q)!}{n!}}\,(\psi_*^{(\hat{p}_1)}\times\cdots\times\psi_*^{(\hat{p}_{n-q})}|_{p_q(I_{n,q})},\Omega)_0\tag{III.35}$$

are c-number coefficients and $\mathbf{n}$ denotes an element in $\mathscr{N}_{sk}$.

Vectors of the type (III.32) generate a Hilbert space of physical one-particle states. The bosonic Fock space over this one-particle space is evidently $\mathscr{F}_{\rm phys}:=S(L^2(\mathbb{R}^3)\otimes\mathbb{C}^3)$, the symmetric Hilbert space over $L^2(\mathbb{R}^3)\otimes\mathbb{C}^3$. It should be clear from Eq. (III.34) that the induced space $\mathscr{H}_{\rm phys}$ from the Rieffel induction procedure is naturally isomorphic to this physical Fock space.[26] To prove this, we define a map $V:L\to\mathscr{F}_{\rm phys}$ by linear extension of $V\exp(\psi_*)=(\exp(\psi_*),\Omega)_0\exp(P_p\psi_*)$. It follows from an argument similar to the one in section 3.3 of Ref. 13 that this map is well defined [which is a nontrivial property, as the basis $\{\exp(\psi_*)\}$ is overcomplete]. Equation (III.33), and the fact that the inner product in $\mathscr{F}_{\rm phys}$ is just the one in $\mathscr{H}$, restricted to the physical states, then implies the crucial property

$$(V\Psi,V\Phi)=(\Psi,\Phi)_0,\tag{III.36}$$

for all $\Psi,\Phi\in L$, where the inner product on the lhs is evidently the one in $\mathscr{F}_{\rm phys}$. Hence the null space $\mathscr{N}_{sk}$ of $(.,.)_0$ is precisely the kernel of V, and the quotient map $\tilde{V}:L/\mathscr{N}_{sk}\to\mathscr{F}_{\rm phys}$ can be extended to a unitary map (denoted by the same symbol) $\tilde{V}:\mathscr{H}_{\rm phys}\to\mathscr{F}_{\rm phys}$.

5. n-point correlation functions and gauge invariance

Having specified the physical Hilbert space $\mathscr{H}_{\rm phys}$, the next step is to determine the action of $\pi_{\rm phys}(\mathscr{A}_c)$. To this end, we consider the generating functional $\omega_{\rm vac}$ for vacuum expectation values,

$$\omega_{\rm vac}(\phi^\mu,\phi):=(\pi(W(\phi_\mu,\phi))\Omega,\Omega)_0=e^{(1/2)(\phi_\mu\phi_\mu)_M}e^{-(1/2)(\phi,\phi)}e^{-(1/k_0^2)(k_0\overline{\phi_0}(k_\mu\phi_\mu+ie\phi))},\tag{III.37}$$

where $\Omega\in\mathscr{H}$ is the (unphysical) ''vacuum'' state. By construction, only $\mathscr{A}_c=\mathscr{A}(N_{sk},B_{sk})$ acts on $\mathscr{H}$ [cf. (III.14)], and for $(\phi_\mu,\phi)\in N_{sk}$, $k_0\phi_0=k_i\phi_i-ie\phi$, we obtain

$$\omega_{\rm vac}(\phi^\mu,\phi)=e^{-(1/2)(\phi_\mu,P_T\phi_\mu)_E}e^{-(1/2)((e/k_0)\phi_i+i(k_i/k_0)\phi)(k_ik_j/\mathbf{k}^2)((e/k_0)\overline{\phi_j}-i(k_j/k_0)\overline{\phi})}$$

$$=:(\pi_{\rm phys}(\tilde{W}(P_p\phi_*))\Omega_{\rm phys},\Omega_{\rm phys})_{\rm phys}$$

$$=e^{-(1/2)\int d\tilde{k}[\overline{P_T\phi(\mathbf{k})}P_T\phi(\mathbf{k})+\overline{\phi}_{L,i}(\mathbf{k})\phi_{L,i}(\mathbf{k})]}.\tag{III.38}$$

Here, $\Omega_{\rm phys}\in\mathscr{H}_{\rm phys}$ is the physical vacuum state; it is just the projection of $\Omega\in L$ onto $L/\mathscr{N}_{sk}\subset\mathscr{H}_{\rm phys}$.

We observe that for $(\phi_\mu,\phi)\in T_{sk}$, $\pi(\mathrm{W}(\phi_\mu,\phi))$ equals the unit operator [cf. (III.7)]. This implies that the gauge group is represented trivially on $\mathscr{H}_{\rm phys}$. Moreover, one infers that $\mathscr{A}_{\rm obs}:=\pi(\mathscr{A}_c)\simeq\mathscr{A}(N_{sk}/T_{sk},B_{c,sk})$, since the image of a representation of a C^*-algebra is isomorphic to the algebra quotiented by the kernel of the representation. Now $N_{sk}/T_{sk}\simeq P_pN_{sk}$ as vector spaces (but not as carrier spaces of actions of the Poincaré group!), so that, equally well,

$\mathscr{A}_{\rm obs}\simeq\mathscr{A}(P_pN_{sk},B_{sk})$.[27] Then, it is clear from Sec. III A that $\mathscr{A}_{\rm obs}$ is precisely the Weyl algebra over the Marsden–Weinstein reduced space (i.e., the physical phase space) of the Stückelberg–Kibble model. Hence it describes three gauge-invariant, massive field components.

Thus $\widetilde{W}(P_p\phi_*)$ can be viewed as a Weyl operator in $\mathscr{A}(P_pN_{sk},B_{sk})$. In particular, the representation of $\mathscr{A}(P_pN_{sk},B_{sk})$ on exponential vectors $e^{\psi}\in\mathscr{H}_{\rm phys}=S(L^2(\mathbb{R}^3)\otimes\mathbb{C}^3)$ is given by

$$\pi_{\rm phys}(\widetilde{W}(P_p\phi_*))e^{\psi}=e^{-(1/2)(P_p\phi_*,P_p\phi_*)_p+(\psi_iP_p\phi_*)_p}e^{(\psi-P_p\phi_*)},$$
$$(\psi,P_p\phi_*)_p=\int d\tilde{k}[\overline{P_T\phi(\mathbf{k})}P_T\phi(\mathbf{k})+\overline{\phi}_{L,i}(\mathbf{k})\phi_{L,i}(\mathbf{k})]. \tag{III.39}$$

From $\omega_{\rm vac}(\phi_\mu,\phi)$, n-point correlation functions can be obtained as multiple derivatives of $\widetilde{W}(P_p\phi_*):=e^{i\widetilde{A}(f)}$, where $P_p\phi_*=\Delta*f\in\mathbb{L}^2(\mathbb{R}^3)\otimes\mathbb{C}^3$,

$$\begin{aligned}
&i^n(\pi_{\rm phys}(\widetilde{A}(f_1)\cdots\widetilde{A}(f_n))\Omega_{\rm phys},\Omega_{\rm phys})_{\rm phys}\\
&\quad=\frac{d}{dr_1}\cdots\frac{d}{dr_n}\,\omega_{\rm vac}\Big(\sum_i r_i\phi_\mu^{(i)},\sum_i r_i\phi^{(i)}\Big)\Big|_{r_i=0}\\
&\quad=\sum_{(p_i,q_i)_i^{n/2}\in\mathscr{S}_n}\prod_{i=1}^{n/2}(\pi_{\rm phys}(\widetilde{A}(f_{p_i})\widetilde{A}(f_{q_i}))\Omega_{\rm phys},\Omega_{\rm phys})_{\rm phys}\\
&\qquad\times(-1)^{n/2}
\end{aligned} \tag{III.40}$$

for n even, and zero otherwise. Here, $\mathscr{S}_n$ denotes the set of all symmetric partitions of $\{1,...,n\}$ into a set of unordered pairs (p_i,q_i). We conclude from (III.40) that the n-point correlation functions can be decomposed into products of two-point correlation functions, i.e., Wick's theorem is satisfied. The reader should note, however, that this form of Wick's theorem is satisfied for elements in $\mathscr{A}(N_{sk},B_{sk})$ only. The crucial point is that, in general, the $(.,.)_0$ inner product preserves the adjoint for test functions in N_{sk} only. This can be seen by comparing, e.g., $(d/dr_1)(d/dr_2)(\pi(W(\Sigma_i r_i\phi_\mu^{(i)},\Sigma_i r_i\phi^{(i)}))\Omega,\Omega)_0|_{r_i=0}$ with $(d/dr_1)(d/dr_2)(\pi(W(\phi_\mu^{(1)},\phi^{(1)}))\Omega,\pi(W(\phi_\mu^{(2)},\phi^{(2)}))\Omega)_0|_{r_i=0}$ [cf. III.37)].

There is an interesting parallel between this restriction of the Rieffel induced expectation values to $\mathscr{A}(N_{sk},B_{sk})$ and the general setup of the Gupta–Bleuler indefinite metric formalism as presented in Ref. 28. In the latter, one starts from an unphysical Hilbert space $\mathscr{H}_{\rm GB}$ from which the physical one is obtained as a quotient $\mathscr{H}'/\mathscr{H}''$. Without reviewing this construction, we note that $\mathscr{H}$ has to be restricted to a suitable subspace $\mathscr{H}'\subset\mathscr{H}_{\rm GB}$ before quotienting by a null space $\mathscr{H}'$. Obviously, in our setting, a similar restriction is needed on the level of the algebra, $\mathscr{A}(N_{sk},B_{sk})\subset\mathscr{A}(M_{sk},B_{sk})$. This restriction emerges in a systematic way, for as we pointed out before, the subalgebra in question is the commutant of the algebra generated by the constraints (i.e., by the gauge group).

This observation is closely related to the result of Narnhofer and Thirring[29] that covariant formulations without indefinite inner metric are possible as long as the representation on the physical Hilbert space is restricted to a certain subalgebra of weak observables. In the example of Narnhofer and Thirring, nonregular states have to be introduced. This can be avoided in the Rieffel induction setting [cf. Refs. 13 and 14 for further details].

6. Positivity of the Hamiltonian and action of the Poincaré group

On the algebra of weak observables of the Stückelberg–Kibble model $\mathscr{A}(N_{sk},B_{sk})$, the time evolution is given as an automorphism group τ,

$$\tau_t[W(\phi_\mu,\phi)]=W(e^{it\sqrt{D+e^2}}\phi_\mu,e^{it\sqrt{D+e^2}}\phi), \tag{III.41}$$

where $(D\phi)_\mu=(-\Delta\phi_0,-\Delta\phi_1,-\Delta\phi_2,-\Delta\phi_3)$. We want to construct the Hamiltonian H, corresponding to τ_t on $\mathscr{H}$. H is a representation-dependent operator, implementing the time evolution τ_t in the representation π by

$$e^{itH}\pi(W(\phi_\mu,\phi))e^{-itH}=\pi(\tau_t[W(\phi_\mu,\phi)]). \tag{III.42}$$

Comparing this with the explicit form of the representation in terms of annihilation and creation operators $\hat{a}^*_\mu,\hat{a}_\mu$ for the vector field and $\hat{b}^*,\hat{b}$ for the scalar field, we obtain

$$H=-\int d\tilde{k}\sqrt{\mathbf{k}^2+e^2}\hat{a}^*_\mu(\mathbf{k})g^{\mu\nu}\hat{a}_\nu(\mathbf{k})+\int d\tilde{k}\sqrt{\mathbf{k}^2+e^2}\hat{b}^*(\mathbf{k})\hat{b}(\mathbf{k}). \tag{III.43}$$

Regarded as an operator on $\mathscr{H}$ (with its Hilbert space inner product), this Hamiltonian clearly has the entire real axis as its spectrum. However, it is easy to see that

$$(\Psi,H\Psi)_0\geqslant 0 \tag{III.44}$$

for all $\Psi\in\mathscr{H}$. The point is that arbitrary (normalized) components of the physical one-particle state space, $(\delta_{ij}-k_ik_j/\mathbf{k}^2)\psi_j$ and $(k_i/\mathbf{k})\psi_i\cos\theta+i\psi\sin\theta$ pick up (the same) positive energy contributions. For multi-particle states, this holds true due to their decomposition into such components. The elements of $\mathscr{H}$ carrying the negative energy spectrum have ended up in the null space. Hence the induced Hamiltonian H_{phys} on $\mathscr{H}_{\text{phys}}$ is positive.

Finally, we note that $\mathscr{H}_{\text{phys}}$ carries a massive representation of the Poincaré group $\mathscr{P}$. Indeed, ω_{vac} is Poincaré invariant on N_{sk} and hence[16,17] there exists a Poincaré invariant vacuum state $\Omega_{\text{phys}}\in\mathscr{H}_{\text{phys}}$ and a representation U_p of the Poincaré group such that

$$U_p(\Lambda,a)\pi_{\text{phys}}(W(\phi_\mu,\phi))\Omega_{\text{phys}}=\pi_{\text{phys}}(W(\gamma_{\Lambda,a}(\phi_\mu,\phi)))\Omega_{\text{phys}} \tag{III.45}$$

for all $(\phi_\mu,\phi)\in N_{sk}$. It is easily shown that H_{phys} is the generator of the time-translation part of the representation thus defined. Since the spectrum of the Hamiltonian H_{phys} shows a mass gap, we are dealing with a massive representation ($m^2=e^2$) of the Poincaré group, i.e., the three components of the vector $P_p\psi^{(i)}_*$ transform as a massive one-particle state under the action of the little group SO(3).[20]

We conclude that $\mathscr{H}_{\text{phys}}$ has the main properties required by a physical Hilbert space; it transforms trivially under the gauge group, satisfies the positive spectrum condition, and carries a unitary representation of the Poincaré group.

IV. CONCLUSION

The quantization proposal employed in this paper provides a detailed scheme for imposing constraints on gauge quantum field theories. As explained in Sec. II, the main tool of this proposal is the Rieffel induction procedure, which provides a systematic scheme for the construction of representations of C^*-algebras. It may be viewed as the quantum counterpart of the symplectic reduction technique; as we have shown, this is particularly obvious for Weyl C^*-algebras. This leads to a new quantization method for gauge field theories.

In the present work, we have applied this method to the Stückelberg–Kibble model. To this end, we have defined a field algebra $\mathscr{A}$ corresponding to the field content of the Lagrangian, and an algebra of constraints $\mathscr{B}$ corresponding to the gauge group acting on $\mathscr{A}$. Also, we have specified a representation π of subalgebras of $\mathscr{A}$ on a (unphysical) Hilbert space $\mathscr{H}$. From these input data, we have constructed a representation of the physical, gauge-invariant fields on a new Hilbert space $\mathscr{H}_{\text{phys}}$.

The construction of $\mathscr{H}_{\text{phys}}$ shows some parallels to the Gupta–Bleuler indefinite metric formalism. In both settings, a degenerate inner product is defined on a (unphysical) Hilbert space $\mathscr{H}$, and $\mathscr{H}_{\text{phys}}$ is constructed by quotienting $\mathscr{H}$ by a null space with respect to this degenerate inner product. Yet, there are important differences. In contrast to the indefinite metric inner product $\langle .,. \rangle$, defined on $\mathscr{H}_{\text{GB}}$ in the Gupta–Bleuler formalism, the $(.,.)_0$ inner product is positive semidefinite. More importantly, it is a conceptual advantage of our quantization method that $(.,.)_0$ is derived from first principles (namely from the requirement to impose quantum constraints by a quantized version of the classical phase space reduction method), whereas the Gupta–Bleuler formalism takes $\langle .,. \rangle$ as starting point without further justification. A similar comment applies to the BRST technique: although a classical analogue of this procedure exists, the quantum BRST procedure is *not* in any satisfactory sense the quantization of the classical scheme.

Another remarkable difference between both formalisms is that the Gupta–Bleuler formalism restricts the unphysical Hilbert space before forming the quotient whereas the proposal of Ref. 11 restricts itself to a representation of the subalgebra $\mathscr{A}_c$ of weak observables on $\mathscr{H}$, before quotienting by the appropriate null space. As a consequence, the $(.,.)_0$ inner product preserves the adjoint for elements in $\mathscr{A}_c$ only. It remains to be seen how far this feature alters applications of usual perturbative techniques in more complicated models.

The fact that in our approach the spectral condition does not hold in the Hilbert space of the unconstrained system is of little importance, since the original inner product in this space is related to the one in the physical state space only through the rigged inner product. Also, the absence of a unitary implementation of the full Poincaré group does not lead to conceptual or technical complications. In fact, we do not exclude the existence of a Krein space with a suitable dense subspace L, on which our method is manifestly covariant in all its steps.

Most of our effort in Sec. III has gone into characterizing the particular features of the physical state space $\mathscr{H}_{\text{phys}}$. By construction, $\mathscr{H}_{\text{phys}}$ carries a trivial representation of the gauge group. Also, the states are physical in the sense that they obey a positive spectrum condition and that they carry a massive representation of the Poincaré group. Since the Stückelberg–Kibble model has been widely used in investigations of the Higgs mechanism, we emphasize again the result obtained for the one-particle subspace in $\mathscr{H}_{\text{phys}}$. The point is that in our proposal, the particular construction method of $\mathscr{H}_{\text{phys}}$ allows one to trace back how the (unphysical) components of $\mathscr{H}$ end up in the physical Hilbert space. In the present case, we have shown that the longitudinal physical one-particle component arises from a particular Bogoliubov transformation of the unphysical longitudinal and the scalar component. As expected from general considerations, two of the five components in $\mathscr{H}$ have ended up in the one-particle null space.

We conclude our discussion of the Rieffel induction procedure by pointing out that our presentation has focused on a particular way of applying Rieffel induction to gauge quantum field theories. Conceptually, the scheme is much wider. It remains to be seen how far other choices for the inner product $(.,.)_0$ and the unphysical Hilbert space $\mathscr{H}$ allow for other realizations of the physical observables of gauge field theories.

[21] In gauge theories without anomalies, one always reduces from the zero level (Refs. 9 and 10), irrespective of whether charged states are present. Especially, the reader should note that, applied to full electrodynamics, our formalism does not exclude the existence of charged states, since it imposes consistently the constraint generating gauge transformation, $\nabla\cdot\mathbf{E}-\rho=0$. In gauge theories with θ-vacua, these are found in our method by inducing from a nontrivial one-dimensional representation of G. In anomalous gauge theories, Rieffel induction is performed with respect to a central extension of G, and from a nontrivial representation, cf. section 3.3 of Ref. 11
[22] Mathematically, $\langle .,. \rangle_{\mathscr{B}}$ is a so-called rigging map which has to satisfy the following conditions for all $\psi,\varphi\in L$ (Ref. 12):

(1) $\langle \lambda\psi,\mu\varphi\rangle_{\mathscr{B}}=\overline{\lambda}\mu\langle\psi,\varphi\rangle_{\mathscr{B}}$ for all $\lambda,\mu\in\mathbb{C}$;
(2) $\langle\psi,\varphi\rangle_{\mathscr{B}}^{*}=\langle\varphi,\psi\rangle_{\mathscr{B}}$ (where the * denotes the Hermitian conjugate in $\mathscr{B}$);
(3) $\langle\psi,\varphi B\rangle_{\mathscr{B}}=\langle\psi,\varphi\rangle_{\mathscr{B}}B$ for all $B\in\mathscr{B}$ (on the left-hand side, B acts in the given right-representation on the bimodule L,
whereas on the right-hand side B acts by multiplication in the algebra $\mathscr{B}$);
(4) $\langle A\psi,\varphi\rangle_{\mathscr{B}}=\langle\psi,A^{*}\varphi\rangle_{\mathscr{B}}$ for all $A\in\mathscr{A}$;
(5) $\langle A\psi,A\psi\rangle\leqslant\|A\|^{2}\langle\psi,\psi\rangle$ for all $\psi\in L,A\in\mathscr{A}$.

[25] To see that this defines a representation, we check that

$$\pi(W(\sigma_\mu,0))\pi(W(\varphi_\mu,0))=e^{[i\ \mathrm{Im}[(\overline{\phi_0},\overline{\varphi_0})_E+(\sigma_i,\varphi_i)_E]]}\pi(W(\sigma_\mu+\varphi_\mu,0)),$$

where $\mathrm{Im}[(\overline{\phi_0},\overline{\varphi_0})_E+(\phi_i,\varphi_i)_E]=B_{sk}(\varphi_\mu,0;\phi_\mu,0)$.
[26] Of course, all Hilbert spaces of the same dimension are unitarily equivalent, but to impose such equivalence one generally has to pick a basis. We use the term ''naturally isomorphic'' to indicate that a unitary equivalence exists which does not require the choice of a basis. From the point of view of representation theory, this equivalence intertwines the actions of appropriate operator algebras, cf. the next subsection.
[27] However, the isomorphism between $\mathscr{A}(P_pN_{sk},B_{sk})$ and $\mathscr{A}(N_{sk}/T_{sk})$ does not preserve the (automorphic) action of the Poincaré group, which, indeed, acts on the latter but not on the former, cf. Ref. 19.

The Manev problem (a two-body problem given by a potential of the form $A/r+B/r^2$, where r is the distance between particles and A,B are positive constants) comprises several important physical models, having its roots in research done by Isaac Newton. We provide its analytic solution, then completely describe its global flow using McGehee coordinates and topological methods, and offer the physical interpretation of all solutions. We prove that if the energy constant is negative, the orbits are, generically, precessional ellipses, except for a zero-measure set of initial data, for which they are ellipses. For zero energy, the orbits are precessional parabolas, and for positive energy they are precessional hyperbolas. In all these cases, the set of initial data leading to collisions has positive measure. [S0022-2488(96)00205-7]

I. INTRODUCTION

The question we fully answer in this paper has a long history. We deal with a two-body problem given by a potential of the form $A/r+B/r^2$, where r is the distance between particles and A,B are positive constants. Newton was the first to consider it in his *Principia*. In Book I, Article IX, Proposition XLIV, Theorem XIV, Corollary 2, he claimed that such a force leads to a *precessionally elliptic* relative orbit; this means that, with respect to a fixed frame having one particle at the origin, the other particle moves on an ellipse that rotates in its plane of motion. This was the only result Newton published in connection with this gravitational model, but he tackled it for many years to follow his first edition of *Principia*. The 1888 catalogue of the Portsmouth Collection of unpublished manuscripts that are stored today in the library of Cambridge University shows Newton's interest in this model, interest which was aroused by the difficulties he encoun-

0022-2488/96/37(6)/2748/14/$10.00

tered in trying to explain the apsidal motion of the moon within the framework of the inverse-square-force model. After Newton, the $A/r+B/r^2$ potential was tackled by Clairaut, who finally abandoned it in favor of the classical one.

Physicists claim today that this is a well-known problem: in an equivalent formulation it appears as Problem 14 in Chapter 3 of Goldstein's *Classical Mechanics*.[1] Unfortunately Goldstein's statement is incorrect, as we will further see in the qualitative sections of this paper. Goldstein, like Newton, thought that all orbits are precessional ellipses, which is wrong. It is an error that has remained in place for a long time due to the fact that the problem has never been considered from the point of view of the qualitative theory of dynamical systems. We will see that the problem is more complex, and we will fully solve it here. For this we will use a powerful mathematical method: the McGehee transformations—well known in celestial mechanics but little known among mathematical physicists; we would like to emphasize here the importance of the McGehee transformations, because they can be applied to the study of solutions of differential equations near singularities.

Using physical principles, the Bulgarian physicist Manev[2] (or Maneff—in French and German spelling) obtained a similar potential during the third decade of our century. Assigning the mass M to the particle at the origin, the unit mass to the rotating particle and denoting $\mu=GM$, $\beta=A/\mu-1$, $\gamma=2B/\mu$, where G is the constant of gravitation, Manev's potential corresponds to the values $\beta=0$, $\gamma=3\mu/c^2$ of the constants, where c is the speed of light. This model allowed a good theoretical justification of the perihelion advance of Mercury and of the other inner planets as well as an accurate description of the moon's motion.

It is interesting to look at the physical interpretation of Manev's model. The classical point of view is that the orbit of celestial objects around the sun must be an ellipse, a parabola, or a hyperbola (depending on the initial data). However, because of the perturbation of the other objects in the system, the orbit is in fact a precessional ellipse, parabola, hyperbola, or can take a more complicated shape. Unfortunately, this classical point of view encounters difficulties: the theoretical calculations do not fit the observations, and this happens especially for celestial objects coming close to the sun. The perihelion advance of Mercury and of the other inner planets cannot be explained within the the framework of the Newtonian theory.

The study of the solar system can be maintained within the framework of classical mechanics by substituting Newton's model with the one of Manev. This is especially convenient for celestial mechanics. Of help in this sense are the results of the KAM theory. As it has been shown in a paper by Lacomba, Llibre, and Nunes,[3] if the equations of motion describing Manev's problem are slightly perturbed by some external force, which *does not have to be* Hamiltonian, ''most'' invariant cylinders and tori are (topologically) preserved under this perturbation. From the physical point of view this means that the natural (unperturbed) orbit of a celestial object around the sun is not an ellipse, parabola, or hyperbola, but a precessional ellipse, precessional parabola, or precessional hyperbola (as defined in the first paragraph), the precessional effect becoming more evident the closer the orbit is to the sun. Under the perturbation of the other celestial objects, the orbit continues to remain, in general, a precessional ellipse, precessional parabola, or precessional hyperbola, but there are exceptions. Nevertheless they are unlikely in the sense that the set of initial data for which they occur has measure zero.

Several other Manev-type models have recently been the subject of research. Mioc[4] has considered Fock's relativistic field, truncating the negligible terms and obtaining the values $\beta=2(E^2-1)$, $\gamma=6\mu E^2/c^2$ of the parameters, where $E=1+h/c^2$ and h is the total energy per unit mass of the rotating particle. Saslaw,[5] and later Mioc and Radu,[6] have considered the motion in the photogravitational field generated by a source of radiation, taking the values $\beta=-\sigma L/(4\pi\mu mc)$, $\gamma=0$ of the parameters, where σ and m are the cross-sectional area and the mass of the rotating body and L is the luminosity of the central body. The two-body problem with equivalent gravitational parameter ($\beta\neq 0$, $\gamma=0$) has been considered by Şelaru, Cucu-Dumitrescu, and Mioc.[7]

There are other directions of research where this potential occurs: Ureche[8] analyzed the

astrophysical problem of the free-fall collapse of a homogeneous sphere; Diacu[9] considered generalizations to the three-body problem in the more general mathematical context of *quasihomogeneous potentials*, showing that Manev's case represents the only bifurcation of the flow in the quasihomogeneous case. Diacu[10] also studied the gravitational isosceles three-body case, pointing out possible applications in atomic physics.

The general case of the Manev potential for any positive values of the constants A and B has been considered, in Hamiltonian formulation and for negative total energy, by Lacomba, Llibre, and Nunes (see Ref. 3), who have also applied KAM (Kolmogorov–Arnold–Moser) theory to a perturbed Manev potential, to prove the invariance of nonresonant cylinders and tori. The Melnikov integral associated with the nonhyperbolic equilibria was computed by Casasayas, Fontich, and Nunez.[11] The analytic solution and the local flow of the Manev model near collision has been obtained by Diacu, Mingarelli, Mioc, and Stoica.[12] The more complicated anisotropic Manev problem (important for understanding the connections between classical and quantum mechanics) has been recently investigated by Craig, Diacu, Lacomba, and Perez,[13] who have fully understood the flow near collision and have described some elements of the global flow, obtaining in particular the complete picture of the zero-energy case.

The goal of this paper is to provide the complete analytic, geometric, and physical description of the Manev problem. In Secs. II–IV, we compute the analytic solution, which, from the practical point of view, can be used in numerical endeavors. This has been previously done in different forms and contexts, the one we use here presenting interest mainly for astronomers. Unfortunately, the complicated closed form of the solution hides the nice properties of the model, and this is the reason why Goldstein's problem is the subject of physical misinterpretations. Therefore we continue with a qualitative analysis, which reveals the geometrical nature of the orbits. In Sec. V we use the McGehee technique[14] to blow up the collision singularity and offer new, regularized equations of motion. The main idea of this method is to paste, instead of the collision singularity, a manifold to the phase space. This manifold, though now part of the phase space, has nothing to do with the real physical orbits. Its advantage, however, is that, due to the continuity of solutions with respect to the initial data, it provides information about orbits passing close to collision. The study of the (fictitious) flow on the collision manifold is therefore important for the understanding of the local flow near collision. In this case, however, the regularized equations of motion allow us to provide a full description of the global flow. The flow on the torus is formed by periodic orbits, except the upper and lower circle, which are formed by degenerate equilibria. We observe that the global flow has a rotational symmetry, which we use to reduce the dimension of the phase space. In this reduced phase space, the collision manifold is a circle of equilibria: two of these equilibria correspond to the circles of equilibria on the torus, while all the others correspond to the periodic orbits on the torus (see Fig. 2).

In Sec. VI we treat the negative-energy case. Every energy level is a spherical cap (which is obviously topologically equivalent with a disk—see Fig. 3). There are infinitely many heteroclinic orbits connecting the equilibria of the collision circle, two homoclinic orbits, and infinitely many periodic orbits. The heteroclinic and homoclinic solutions correspond physically to orbits ejecting from a collision and also ending in a collision. The periodic orbits correspond to tori of solutions in phase space. In Sec. VII we prove that most of the tori of solutions correspond to quasiperiodic orbits (precessional ellipses), while a set of measure zero of initial data leads to elliptic orbits. In Sec. VIII we study the zero-energy and positive-energy cases. Each energy level is topologically equivalent with an annulus: in the zero-energy case it is a paraboloid with the cap removed (see Fig. 4), while in the positive-energy case, depending on the initial data, it is part of a hyperboloid of one sheet [see Fig. 5(a)], one sheet of a cone of two sheets with the cap removed [see Fig. 5(b)], or one sheet of a hyperboloid of two sheets with the cap removed [see Fig. 5(c)]. All these surfaces are bordered by the collision circle. From the physical point of view, the zero-energy case solutions correspond to precessional parabolas, whereas the positive-energy ones correspond to precessional branches of hyperbolas. In all cases, and in general, the set of initial data leading to

collisions has positive measure. Also, as we have proved in Ref. 12, the collision is not regularizable, in the sense that continuity with respect to the initial data is lost after collision.

II. THE RADIUS VECTOR—DIRECT APPROACH

The Manev problem is described by a Hamiltonian system, i.e., a system of the type

$$\dot{\mathbf{q}}=\frac{\partial H(\mathbf{p},\mathbf{q})}{\partial \mathbf{p}},\quad \dot{\mathbf{p}}=\frac{-\partial H(\mathbf{p},\mathbf{q})}{\partial \mathbf{q}},$$

where the Hamiltonian function H has the property $H(\mathbf{p},\mathbf{q})=h$ (constant), i.e., it is a first integral (called the integral of energy) of the system.

In our case, the Hamiltonian H is given by

$$H(\mathbf{p},\mathbf{q})=\frac{1}{2}\,(|\mathbf{p}_1|^2+|\mathbf{p}_2|^2)-\frac{A}{|\mathbf{q}_1-\mathbf{q}_2|}-\frac{B}{|\mathbf{q}_1-\mathbf{q}_2|^2},$$

where we have denoted by $\mathbf{q}=(\mathbf{q}_1,\mathbf{q}_2)$ the *configuration* of the system of two particles and by $\mathbf{p}=(\mathbf{p}_1,\mathbf{p}_2)$ the *momentum*, A and B being positive constants.

Since H depends only on the relative positions $\mathbf{q}_1-\mathbf{q}_2$ and not on the position vectors $\mathbf{q}_1$ and $\mathbf{q}_2$, we can reduce the Manev problem to a central force problem by introducing the relative coordinates $\mathbf{r}=\mathbf{q}_1-\mathbf{q}_2$, which transform the Hamiltonian into

$$H(\mathbf{p},\mathbf{r})=(1/2)|\mathbf{p}|^2-A/|\mathbf{r}|-B/|\mathbf{r}|^2.$$

We will use this formulation of the problem in our qualitative endeavors (Secs. V–VIII). To obtain the analytic expression of the solution (Secs. II–IV), we eliminate the momentum from the above equations and express them as a second-order system of the form

$$\ddot{\mathbf{r}}=\frac{-(1+\beta)\mu\mathbf{r}}{r^3}-\frac{\gamma\mu\mathbf{r}}{r^4},\tag{2.1}$$

where $\beta=A/\mu-1$, $\gamma=2B/\mu$, $\mu=GM$, G is the gravitational constant, $\beta=A/\mu-1$, $\gamma=2B/\mu$, $\mu=GM$, G is the gravitational constant, M is the mass of one particle, the other having mass 1, and $r=|\mathbf{r}|$.

Using polar coordinates (r,u), the equations (2.1) become

$$\ddot{r}-r\dot{u}^2=-(\mu/r^2)(1+\beta+\gamma/r),\quad r\ddot{u}+2\dot{r}\dot{u}=0.\tag{2.2}$$

Let us attach to the equations (2.2) the initial conditions

$$(r,u,\dot{r},\dot{u})(t_0)=(r_0,u_0,V_0\cos\psi,V_0\sin\psi/r_0),$$

where $V_0=V(t_0)$, $V=|\dot{\mathbf{r}}|$, and ψ is the angle between the initial radius vector and the initial velocity. Since the force field is central, the angular momentum is conserved, so the second equation in (2.2) yields the integral

$$r^2\dot{u}=C,\tag{2.3}$$

where $C=r_0V_0\sin\psi$ is the constant of the angular momentum. The integral of energy is

$$V^2=\dot{r}^2+r^2\dot{u}^2=(\mu/r)[2(1+\beta)+\gamma/r]+h,\tag{2.4}$$

where h is the energy constant.

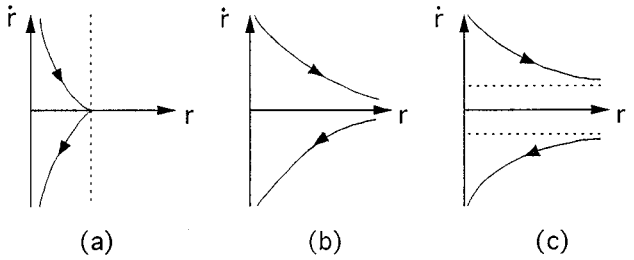

FIG. 1. (a) The case $h<0$, where $r_0 = (-A-\sqrt{A^2-2Bh})/h$. (b) The case $h=0$. (c) The case $h>0$.

The rectilinear case (which corresponds to the zero angular momentum, $C=0$) is easy to solve. The phase-space picture is given in Fig. 1. (In fact, we will recover these orbits in the qualitative analysis performed in Secs. V–VIII.) Throughout Secs. II–IV, we will assume $C\neq 0$.

Using the relation $dt=(r^2/C)du$ obtained from (2.3), the first equation in (2.1) takes the Binet-type form

$$\frac{d^2(1/r)}{du^2}+\left(1-\frac{\gamma\mu}{C^2}\right)\frac{1}{r}=\frac{(1+\beta)\mu}{C^2}, \tag{2.5}$$

with the initial conditions

$$\left(r,\frac{d(1/r)}{du}\right)(u_0)=\left(r_0,-\frac{1}{r_0\tan\psi}\right).$$

The solution of the initial value problem attached to the equations (2.5) depends on the value of the constant $\alpha=\gamma\mu/C^2$. We distinguish three cases: (a) $\alpha<1$, (b) $\alpha=1$, and (c) $\alpha>1$:

$$r=\left[\left(\frac{1}{r_0}-\frac{(1+\beta)\mu}{(1-\alpha)C^2}\right)C_\alpha(\mu)-\frac{S_\alpha(u)}{r_0\tan\psi}+\frac{(1+\beta)\mu}{(1-\alpha)C^2}\right]^{-1}, \tag{2.6a}$$

$$r=\left[\frac{(1+\beta)\mu(u-u_0)^2}{2C^2}-\frac{u-u_0}{r_0\tan\psi}+\frac{1}{r_0}\right]^{-1}, \tag{2.6b}$$

$$r=\left[\left(\frac{1}{r_0}+\frac{(1+\beta)\mu}{(\alpha-1)C^2}\right)\widetilde{C}_\alpha(u)-\frac{\widetilde{S}_\alpha(u)}{r_0\tan\psi}-\frac{(1+\beta)\mu}{(\alpha-1)C^2}\right]^{-1}, \tag{2.6c}$$

where

$$S_\alpha(u)=(1-\alpha)^{-1/2}\sin(\sqrt{1-\alpha}(u-u_0)),\quad C_\alpha(u)=\cos(\sqrt{1-\alpha}(u-u_0)),$$

$$\widetilde{S}_\alpha(u)=(1-\alpha)^{-1/2}\sinh(\sqrt{\alpha-1}(u-u_0)),\quad \widetilde{C}_\alpha(u)=\cosh(\sqrt{\alpha-1}(u-u_0)).$$

III. THE ORBITAL ELEMENTS—PERTURBATIVE APPROACH

Let us now isolate the Newtonian attraction term per unit mass, $-\mu\mathbf{r}/\mathbf{r}^3$, on the right-hand side of the equations (2.1), and treat the remaining term $-\beta\mu\mathbf{r}/r^3-\gamma\mu\mathbf{r}/r^4$ as a perturbing acceleration. In this way we can tackle the problem in the frame of the classical perturbation theory.

According to this theory, developed primarily by Lagrange and based on the variation of parameters,[15] the real (perturbed) trajectory can be regarded as the envelope of a family of oscu-

lating Keplerian orbits (conic sections) whose initial conditions change continuously. The motion will then be described by a set of relations between the Keplerian orbital elements, their time derivatives, and time; these form the so-called Newton–Euler or Gauss equations.[16] If the components of the perturbing accelerations (which appear in these equations) do not contain the time explicitly, one can choose another independent variable: one of the anomalies (as in Ref. 16, p. 157) or the argument of latitude.

We will further express the trajectory of the particle with respect to the time-dependent osculating Keplerian orbital elements: a=*the semimajor axis*, Ω=*the longitude of the ascending node*, i=*the inclination*, e=*the eccentricity*, ω=*the argument of the pericenter*, and u=*the argument of the latitude*. We will also use $p=a(1-e^2)$=*the semilatus rectum*, $v=u-\omega$=*the true anomaly*, and the parameters $q=e\cos\omega$, $k=e\sin\omega$, which are suitable for the study of small-eccentricity orbits (those close to circles), for which the pericenter is not well—or not at all—defined.[17]

Let S,T,W denote the radial, transverse, and binormal components of the perturbing acceleration, respectively. Since they do not depend explicitly on the time t, we can describe the perturbed motion by means of the Newton–Euler equations written with respect to u in the form (see, e.g., Ref. 5)

$$
\begin{aligned}
&p'=2\left(\frac{Z}{\mu}\right)r^3T, \quad \Omega'=\left(\frac{Z}{\mu}\right)r^3W\,\frac{\sin u}{p\,\sin i}, \quad i'=\left(\frac{Z}{\mu}\right)r^3W\,\frac{\cos u}{p},\\
&q'=\left(\frac{Z}{\mu}\right)\left\{r^3kW\sin u\,\frac{\cot i}{p}+r^2T\left[r\,\frac{q+\cos u}{p}+\cos u\right]+r^2S\sin u\right\},\\
&k'=\left(\frac{Z}{\mu}\right)\left\{-r^3qW\sin u\,\frac{\cot i}{p}+r^2T\left[r\,\frac{k+\sin u}{p}+\sin u\right]-r^2S\cos u\right\},\\
&t'=\frac{Zr^2}{\sqrt{\mu p}},
\end{aligned}
\tag{3.1}
$$

where $'=d/du$ and $Z=[1-r^2\dot{\Omega}(\cos i)/\sqrt{\mu p})^{-1}]$, with the initial conditions

$$(p,\Omega,i,q,k,t)(u_0)=(p_0,\Omega_0,i_0,q_0,k_0,t_0).$$

Since the perturbing force in the equations (2.1) is radial, the components of the perturbing acceleration are $S=-(\mu/r^2)(\beta+\gamma/r)$, $T=W=0$. Also notice that $Z=1$. Replacing these values into the equations (3.1), we obtain

$$p'=\Omega'=i'=0, \quad q'=-(\beta+\gamma/r)\sin u, \quad k'=(\beta+\gamma/r)\cos u, \quad t'=r^2/\sqrt{\mu p}. \tag{3.2}$$

Integrating the first three equations and using the initial data, we obtain that all along the motion $p=p_0$, $\Omega=\Omega_0$, and $i=i_0$, which means that the *semilatus rectum* is constant and the motion is planar.

According to the perturbation theory we use, we may describe the real trajectory by the equation of a conic section $r=p/(1+e\cos v)$, whose parameters are functions of u. From the definition of q and k, the relation $v=u-\omega$, and the constancy of p, this equation becomes

$$r(u)=\frac{p_0}{(1+q\cos u+k\sin u)}. \tag{3.3}$$

On the other hand, since for osculating conic sections $p=p_0=\text{const}$ (the same constant as in the Kepler problem) and C has the same value as in the Kepler problem[18] (given by $C^2/\mu=p$), we put $C^2=\mu p_0$, which, according to the previous section, leads to $\alpha=\gamma/p_0$. With this expression for α, and with (3.3), the coupled equations for q and k in (3.1) have the exact solution, for (a) $\alpha<1$, (b) $\alpha=1$, and (c) $\alpha>1$, respectively:

$$\begin{aligned} q(u)=&\{S_\alpha(u)[\sin(u-u_0)-\alpha\cos u_0\sin u]+C_\alpha(u)\cos(u-u_0)\}q_0\\ &+\{S_\alpha(u)[\cos(u-u_0)-\alpha\sin u_0\sin u]-C_\alpha(u)\sin(u-u_0)\}k_0\\ &-(\alpha+\beta)S_\alpha(u)\sin u+[(\alpha+\beta)/(1-\alpha)][1-C_\alpha(u)]\cos u,\\ k(u)=&\{-S_\alpha(u)[\cos(u-u_0)-\alpha\cos u_0\cos u]+C_\alpha(u)\sin(u-u_0)\}q_0\\ &+\{S_\alpha(u)[\sin(u-u_0)+\alpha\sin u_0\cos u]+C_\alpha(u)\cos(u-u_0)\}k_0\\ &+(\alpha+\beta)S_\alpha(u)\cos u+[(\alpha+\beta)/(1-\alpha)][1-C_\alpha(u)]\sin u, \end{aligned} \tag{3.4a}$$

$$\begin{aligned} q(u)=&[\cos(u-u_0)-(u-u_0)\sin u_0\cos u]q_0-[\sin(u-u_0)-(u-u_0)\cos u_0\cos u]\\ &\times k_0-[(1+\beta)/2](u-u_0)[2\sin u-(u-u_0)\cos u],\\ k(u)=&[\sin(u-u_0)-(u-u_0)\sin u_0\sin u]q_0+[\cos(u-u_0)+(u-u_0)\cos u_0\sin u]\\ &\times k_0+[(1+\beta)/2](u-u_0)[2\cos u+(u-u_0)\sin u], \end{aligned} \tag{3.4b}$$

$$\begin{aligned} q(u)=&\{\tilde{S}_\alpha(u)[\sin(u-u_0)-\alpha\cos u_0\sin u]+\tilde{C}_\alpha(u)\cos(u-u_0)\}q_0\\ &+\{S_\alpha(u)[\cos(u-u_0)-\alpha\sin u_0\sin u]-\tilde{C}_\alpha(u)\sin(u-u_0)\}k_0\\ &-(\alpha+\beta)\tilde{S}_\alpha(u)\sin u+[(\alpha+\beta)/(1-\alpha)][1-\tilde{C}_\alpha(u)]\cos u,\\ k(u)=&\{-\tilde{S}_\alpha(u)[\cos(u-u_0)-\alpha\cos u_0\cos u]+\tilde{C}_\alpha(u)\sin(u-u_0)\}q_0\\ &+\{S_\alpha(u)[\sin(u-u_0)+\alpha\sin u_0\cos u]+\tilde{C}_\alpha(u)\cos(u-u_0)\}k_0\\ &+(\alpha+\beta)\tilde{S}_\alpha(u)\cos u+[(\alpha+\beta)/(1-\alpha)][1-\tilde{C}_\alpha(u)]\sin u. \end{aligned} \tag{3.4c}$$

Plugging (3.4) into (3.3) we obtain the formulas of the radius vector for (a) $\alpha<1$, (b) $\alpha=1$, and (c) $\alpha>1$:

$$r=p_0\left[\frac{1+\beta}{1-\alpha}-\left(\frac{\alpha+\beta}{1-\alpha}-e_0\cos v_0\right)C_\alpha(u)-e_0\sin v_0 S_\alpha(u)\right]^{-1}, \tag{3.5a}$$

$$r=p_0\left[\frac{1+\beta}{2}(u-u_0)^2-e_0\sin v_0(u-u_0)+1+e_0\cos v_0\right]^{-1}, \tag{3.5b}$$

$$r=p_0\left[-\frac{1+\beta}{\alpha-1}+\left(\frac{\alpha+\beta}{\alpha-1}+e_0\cos v_0\right)\tilde{C}_\alpha(u)-e_0\sin v_0\tilde{S}_\alpha(u)\right]^{-1}, \tag{3.5c}$$

where $e_0=(q_0^2+k_0^2)^{1/2}$ and $v_0=u_0-\arctan(k_0/q_0)$ stay for initial conditions. These formulas are equivalent to (2.6).

IV. RELATIONSHIP BETWEEN TIME AND POLAR ANGLE

In Sec. III we have described the evolution of the radius vector as a function of the argument of latitude. To complete the integration of the equations (3.1), we will determine the function $t=t(u)$, which allows us to express the solution as a function of the time variable. For this, consider first the following notations:

$$\overline{A}=\frac{(1-\alpha)e_0\cos v_0-(\alpha+\beta)}{1+\beta},\quad \overline{B}=\frac{(1-\alpha)^{1/2}e_0\sin v_0}{1+\beta},\quad \widetilde{B}=\frac{(\alpha-1)^{1/2}e_0\sin v_0}{1+\beta},$$

$$K=2(1-\alpha)^{3/2}(1+\beta)^{-2},\quad \widetilde{K}=2(\alpha-1)^{3/2}(1+\beta)^{-2},$$

$$e^*=(\overline{A}^2+\overline{B}^2)^{1/2},\quad w=(1-e^{*2})^{1/2},\quad \widetilde{w}=(e^{*2}-1)^{1/2},$$

$$f(u)=\cot[(1/2)\sqrt{1-\alpha}(u-u_0)],\quad \widetilde{f}(u)=\coth[(1/2)\sqrt{\alpha-1}(u-u_0)],$$

$$X(u)=(\overline{A}+1)f(u)-\overline{B},\quad Y(u)=(\overline{A}+e^{*2})f(u)-\overline{B},\quad Z(u)=w^2+X^2(u),$$

$$\widetilde{X}(u)=(\overline{A}+1)\widetilde{f}(u)+\widetilde{B},\quad \widetilde{Y}(u)=(\overline{A}+e^{*2})\widetilde{f}(u)+\widetilde{B},\quad \widetilde{Z}(u)=w^2-\widetilde{X}^2(u),$$

$$x=1+e_0\cos v_0,\quad y=-e_0\sin v_0,\quad D=2(1+\beta)x-y^2,$$

$$\hat{X}(u)=\frac{2[(1+\beta)x-y^2](u-u_0)-(1+\beta)y(u-u_0)^2}{x[2x+2y(u-u_0)+(1+\beta)(u-u_0)^2]},$$

$$\hat{Y}(u)=\frac{u-u_0}{2x+y(u-u_0)},\quad \hat{Z}(u)=\frac{(1+\beta)(u-u_0)}{2y[y+(1+\beta)(u-u_0)]}.$$

Direct computations give us the following relations in each of the cases (a) $\alpha<1$, (b) $\alpha=1$, and (c) $\alpha>1$, respectively:

$$t=t_0+(Kp_0^{3/2}/w^3\sqrt{\mu})[\arctan(wX(u))-wY(u)/Z(u)],\quad \text{for } e^*<1,$$

$$t=t_0+(Kp_0^{3/2}/3\sqrt{\mu})[(2+3X(u)f(u))/X^3(u)],\quad \text{for } e^*=1, \tag{4.1a}$$

$$t=t_0+(Kp_0^{3/2}/\widetilde{w}^3\sqrt{\mu})[\widetilde{w}Y(u)/Z(u)-\operatorname{arg\,tanh}(\widetilde{w}/X(u))],\quad \text{for } e^*>1,$$

$$t=t_0-\frac{p_0^{3/2}}{D\sqrt{\mu}}[\hat{X}(u)+(2(1+\beta)/\sqrt{-D})\operatorname{arg\,tanh}(\sqrt{-D}\hat{Y}(u))],\quad \text{for } D<0,$$

$$t=t_0+4p_0^{2/3}\hat{Z}(u)/\sqrt{\mu},\quad \text{for } D=0, \tag{4.1b}$$

$$t=t_0+\frac{p_0^{3/2}}{D\sqrt{\mu}}[\hat{X}(u)+(2(1+\beta)/\sqrt{D})\arctan(\sqrt{D}\hat{Y}(u))],\quad \text{for } D>0,$$

$$t=t_0+(\widetilde{K}p_0^{3/2}/w^3\sqrt{\mu})[\operatorname{arg\,tanh}(w/\widetilde{X}(u))+w\widetilde{Y}(u)/\widetilde{Z}(u)],\quad \text{for } e^*<1,$$

$$t=t_0+(\widetilde{K}p_0^{3/2}/3\sqrt{\mu})[(3\widetilde{X}(u)\widetilde{f}(u)-2)/\widetilde{X}^3(u)],\quad \text{for } e^*=1, \tag{4.1c}$$

$$t=t_0+(\widetilde{K}p_0^{3/2}/\widetilde{w}^3\sqrt{\mu})[\widetilde{w}\widetilde{Y}(u)/\widetilde{Z}(u)+\arctan(\widetilde{w}/\widetilde{X}(u))],\quad \text{for } e^*>1.$$

Relations $p=p_0$, $\Omega=\Omega_0$, $i=i_0$, (3.4), and (4.1) give now, in closed form, the solution of the equations of motion (3.2) of the Manev problem.

V. BLOW UP AND REDUCTION

To begin our qualitative endeavors, let us write the Manev problem in Hamiltonian form, as we did at the beginning of Sec. II, with a Hamiltonian of the type

$$H(\mathbf{p},\mathbf{q})=\frac{1}{2}\,(|\mathbf{p}_1|^2+|\mathbf{p}_2|^2)-\frac{1}{|\mathbf{q}_1-\mathbf{q}_2|}-\frac{k}{|\mathbf{q}_1-\mathbf{q}_2|^2}, \tag{5.1}$$

where the units (including those of the masses) have been chosen such that the constants A and B take the values 1 and k, respectively.

Considering polar coordinates $r>0$, $\theta\in S^1$, where S^1 is the segment $[0,\ 2\pi]$ with the end points identified, the Hamiltonian takes the form

$$H(p_r,p_\theta,r)=\tfrac{1}{2}(p_r^2+p_\theta^2/r^2)-1/r-k/r^2, \tag{5.2}$$

where p_r,p_θ are the new polar variables.

To blow up the collision singularity that occurs at $r=0$, we formally multiply the energy integral by r^2 [a detailed justification of this step was given in the local study near the collision performed in a previous paper that uses McGehee transformations (see Ref. 12)]. The energy relation takes now the form

$$\tfrac{1}{2}r^2p_r^2+p_\theta^2-r-k=hr^2. \tag{5.3}$$

Introducing further the transformations $v=rp_r$ and $u=p_\theta$ and scaling the time variable by using $dt=r^2\,d\tau$, the equations given by the Hamiltonian (5.2) take the form

$$r'=rv,\quad v'=r(1+2hr),\quad \theta'=u,\quad u'=0, \tag{5.4}$$

having the energy relation (5.3) transformed into

$$v^2+u^2-2r-2hr^2=2k. \tag{5.5}$$

The prime denotes here differentiation with respect to the new, fictitious, time variable τ.

Define the *collision manifold* as the set of solutions given by relation (5.5) when $r=0$. Notice that, geometrically, the collision manifold is a cylinder in the three-dimensional space of the coordinates (u,θ,v), and, since $\theta\in[0,\ 2\pi]$, it follows that this cylinder can be identified with a torus. In fact, the two-dimensional torus representing the collision manifold is imbedded in the full four-dimensional phase space of the coordinates (r,u,θ,v). The equations (5.4) show that the flow on the collision manifold is formed almost exclusively by periodic orbits, except the upper and lower circles of the torus given by $r=0$, $u=0$, $v=\pm\sqrt{2k}$, which consist of equilibrium points [see Fig. 2(a)].

Since θ does not appear explicitly in the equations (5.4) or in the energy relation (5.5), we can further reduce the four-dimensional phase space to dimension three by factorizing the flow to S^1. Exploiting this symmetry (characteristic to this problem), we will obtain clear pictures of the global flow in phase space. In what follows we will describe the global reduced flow as well as the flow in phase space, by regarding the energy as a parameter.

Factorizing the collision manifold to S^1, the torus becomes a circle [see Fig. 2(b)]. The points M and N on this circle correspond to the circles of equilibria on the torus, while all the other points correspond to the periodic orbits on the torus.

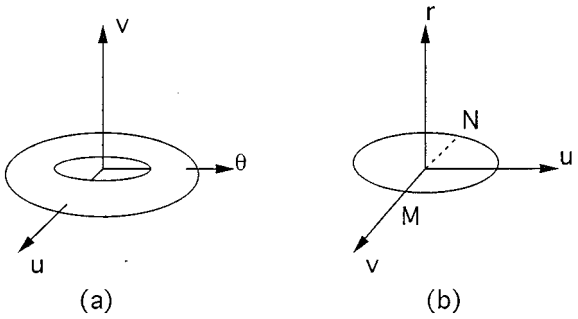

FIG. 2. (a) The collision manifold imbedded in the four-dimensional phase space. (b) The collision manifold in the reduced phase space.

VI. ORBITS OF ELLIPTIC TYPE

In this section we consider the negative-energy case, $h<0$. Let us first write the energy relation (5.5) in a convenient way as

$$v^2+u^2-2h(r+1/2h)^2=2k-1/2h, \tag{6.1}$$

which shows that, in the reduced phase space, every energy level is a two-dimensional sphere [in the three-dimensional Euclidean space (r,v,u) with $r\geqslant 0$ (see Fig. 3)]. In other words, every negative-energy level is homeomorphic with a two-dimensional disk. The boundary of this disk is $r=0$, $v^2+u^2=2k$, i.e., the circle that defines the collision manifold.

The analysis of the equations (5.4) allows us to describe the flow on the negative-energy levels. There are two equilibria outside the collision manifold, located at $r=-1/2h$, $v=0$, $u=\pm\sqrt{2k-1/2h}$. Since u is a first integral, all solutions are represented by curves lying in parallel planes, $u=$const. Therefore, depending on the constant value of u, the orbits are heteroclinic if $|u|<\sqrt{2k}$, homoclinic for $u=\pm\sqrt{2k}$, and periodic for $\sqrt{2k}<|u|<\sqrt{2k-1/2h}$. Note that in the unreduced phase space all these ''orbits'' are in fact manifolds. Each manifold consists of the product between an ''orbit'' and S.[1]

The physical interpretation in each of these cases is as follows. The heteroclinic orbit connecting M and N corresponds to rectilinear solutions starting from a collision and ending in a collision. They are homothetic orbits. All the other heteroclinic orbits connecting equilibria of the collision circle are, in full phase space, heteroclinic orbits between the periodic orbits on the collision torus. Physically they also correspond to solutions ejecting from collision and then

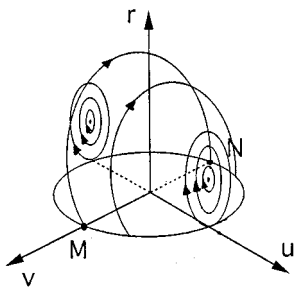

FIG. 3. The flow on each negative-energy level.

tending to collision, but the collision is not rectilinear anymore: the particle colliding with the center spirals around the center. There are, in fact, infinitely many rotations before collision, as we will prove in Sec. VII. The homoclinic orbits in Fig. 3 correspond, in full phase space, to orbits ejecting from the *big* circle of the torus and returning to it and to orbits ejecting from the *small* circle of the torus and returning to it. (The *big* and *small* circles are the ones in the ''equatorial'' plane $v=0$). Their physical interpretation is similar to that of the heteroclinic ones that spiral at ejection-collision. As we have already proved in Ref. 11, this also shows that there exists a set of positive measure of initial data that leads to collisions.

The case of periodic orbits, for $\sqrt{2k}<|u|<\sqrt{2k-1/2h}$, is the most interesting one from the mathematical point of view. In full phase space each of these orbits corresponds to a linear flow on a torus: $S^1\times S^1$. Each torus is therefore filled with either periodic or with quasiperiodic orbits (this is a well-known fact in the qualitative theory of dynamical systems[19]). It is the goal of Sec. VII to find the frequency ratio and prove that most of the tori are filled with quasiperiodic orbits and that only a negligible set of them consists of tori foliated by periodic orbits. Physically, the quasiperiodic solutions correspond to precessional ellipses that fill an annulus densely, whereas the periodic ones are either elliptic orbits or precessional orbits that close after a finite number of rotations.

The last case to discuss is that of the two equilibria outside the collision manifold at $r=-1/2h$, $v=0$, $u=\pm\sqrt{2k-1/2h}$. In full phase space they correspond to periodic orbits, and are circular orbits in physical space. This completes the description of the negative-energy case.

VII. PERIODIC AND QUASIPERIODIC ORBITS

In this section we want to determine the nature of the tori of orbits in Sec. VI. For this we will compute the frequency ratio, which will tell us whether the corresponding orbits are periodic or quasiperiodic. Periodic orbits correspond to rational ratios, whereas quasiperiodic ones correspond to irrational ratios.

Let $\rho=\sqrt{-2h}(r+1/2h)$, and observe that $\rho=1/\sqrt{-2h}=\alpha$ represents collision. From the equations of motion (5.4) we obtain

$$\rho'=(\rho+1/\sqrt{-2h})v,\quad v'=-\rho(\rho+1/\sqrt{-2h}).$$

Now observing that

$$v^2+\rho^2=2k-\frac{1}{2h}-u^2=I^2,$$

we introduce polar coordinates (I,ϕ) in the (ρ,v) plane. Notice that

$$\phi'=\frac{v\rho'-\rho v'}{\rho^2+v^2}=\rho+\alpha=I\sin\phi+\alpha.$$

Taking now $z=\tan(\phi/2)$, the equivalent equation

$$d\tau=\frac{d\phi}{I\sin\phi+\alpha}$$

takes the form

$$d\tau=\frac{2dz}{\alpha z^2+2Iz+\alpha}=\frac{2dz}{\alpha[(z+I/\alpha)^2+1-I^2/\alpha^2]}.$$

Note that $I<\alpha$ corresponds to noncollision orbits. Integrating the last equation, we obtain

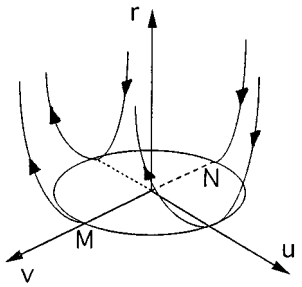

FIG. 4. The flow in the zero-energy case.

$$\tau = \frac{2}{a\alpha} \arctan \frac{z + I/\alpha}{a} + \text{const},$$

where $a = \sqrt{1 - I^2/\alpha^2}$.

The period T is given by

$$T = \tau|_0^T = \int_0^{2\pi} F(\phi) d\phi,$$

where the right-hand side is a (convergent) improper integral at $\phi = \pi$. Then

$$T = \frac{4}{a\alpha} \lim_{\phi \to \pi} \left[\arctan \frac{I/\alpha + \tan \phi/2}{a} - \arctan \frac{I}{a\alpha} \right] = \frac{2}{a\alpha} \left[\pi - 2 \arctan \frac{I}{a\alpha} \right],$$

and after replacing the values of α, a, and I we obtain

$$T = \frac{2\sqrt{-2h}}{\sqrt{2h(2k - u^2)}} \left[\pi - 2 \arctan \frac{\sqrt{1 + 2h(u^2 - 2k)}}{\sqrt{2h(2k - u^2)}} \right].$$

Notice now that if $\rho \to \alpha$, then $a \to \infty$ and $T \to \infty$. Also, if $I \to 0$, then $a \to 1$ and $T \to 2\pi/\alpha$.

Finally, the frequency ratio of the torus is

$$\frac{T}{u} = \frac{2}{u\sqrt{u^2 - 2k}} \left[\pi - 2 \arctan \frac{\sqrt{1 + 2h(u^2 - 2k)}}{\sqrt{2h(2k - u^2)}} \right].$$

It becomes clear now that, for fixed k, most of the values taken by the frequency ratio, as a continuous function of u, are irrational. This proves that, except for a set of measure zero of tori foliated by periodic orbits, most of the tori are generated by quasiperiodic orbits.

VIII. ORBITS OF PARABOLIC AND HYPERBOLIC TYPE

Let us finally consider the zero-energy, $h = 0$, and the positive-energy, $h > 0$, cases.

In the zero-energy case, the energy relation takes the form

$$v^2 + u^2 = 2r + 2k,$$

which implies that the zero-energy level is a paraboloid with the cap removed (see Fig. 4). (The cap is removed because $r \geqslant 0$.) From the topological point of view this is the complement of a disk bordered by the collision circle, i.e., an annulus. Again, the first integral, $u = \text{const}$, foliates the

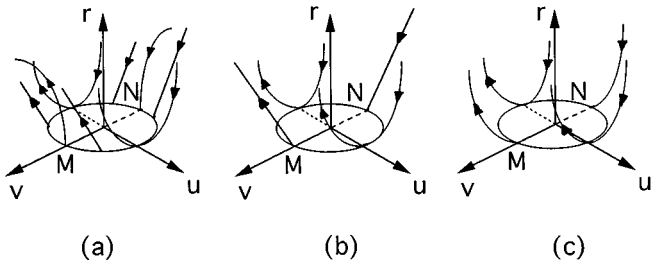

FIG. 5. The flows in the three cases of the positive-energy levels.

zero-energy level into curves lying in parallel planes. The curves are either parabolas, for $|u| \geqslant \sqrt{2k}$, or arcs of parabolas, for $|u| < \sqrt{2k}$. There are no equilibria outside the collision circle.

The physical interpretation of the orbits corresponding to the arc of parabola tending to N or ejecting from M is that of rectilinear orbits that come from (or tend to) infinity with asymptotic velocity zero. The other orbits corresponding to arcs of parabolas that tend to (or eject from) the collision circle are those of precessional parabolas that spiral at collision (ejection) and have asymptotic velocity zero at infinity. The orbits corresponding to parabolas do not encounter collisions and are precessional parabolas with asymptotic velocity zero at infinity.

In the positive-energy case, the energy relation takes the form

$$v^2+u^2-2h(r+1/2h)^2=2k-1/2h.$$

Depending on the relation between h and k, three possibilities arise: (1) $h>1/4k$, (2) $h=1/4k$, and (3) $h<1/4k$.

In case (1), the energy relation describes a hyperboloid of one sheet intersected with $r\geqslant 0$ [see Fig. 5(a)]. The first integral, $u=$const, foliates the surface in branches of hyperbolas or arcs of branches of hyperbolas and two pairs of lines. The physical interpretation is similar to that of the zero-energy case, just that parabolas are now substituted by branches of hyperbolas and the asymptotic velocity at infinity is not zero but positive.

In case (2), the energy relation is a cone intersected with $r\geqslant 0$ [see Fig. 5(b)], and the first integral, $u=$const, foliates the surface in branches of hyperbolas or arcs of branches of hyperbolas and two half-lines (those corresponding to M and N). The physical interpretation of the corresponding orbits is similar to the one of the previous case, (1).

In case (3), the energy relation is a hyperboloid of two sheets intersected with $r\geqslant 0$, i.e., one sheet with the cap removed [see Fig. 5(c)]. The first integral, $u=$const, foliates the surface in branches of hyperbolas and arcs of branches of hyperbolas. The physical interpretation of the corresponding orbits is the same as in case (1) above.

This gives the complete picture of the Manev problem.

(Received 4 December 1995; accepted for publication 19 December 1995)

The scattering of time harmonic electromagnetic waves by a perfectly conducting surface that is the boundary of a ''disturbed half-space'' is considered. This problem is translated in a boundary value problem for an elliptic system of partial differential equations. Under appropriate hypotheses an existence theorem and an integral representation formula for the solution of this boundary value problem is given. Based on this integral representation formula a new method to compute the solution of the boundary value problem is proposed. This method involves only quadratures and is fully parallelizable. Finally some numerical examples of the results obtained on test problems with this computational method are shown. [S0022-2488(96)00805-5]

I. INTRODUCTION

Integral equation methods are often used to study the electromagnetic scattering by bounded obstacles (see Refs. 1 and 2). In this paper we consider the case when the scattering surface is a plane with a local disturbance. This surface as assumed to be perfectly conducting so that the electromagnetic field propagates in a ''disturbed half-space.'' This scattering problem is translated in a boundary value problem for a system of elliptic partial differential equations. Under appropriate hypotheses an existence theorem for the solution of this boundary value problem is proved. Moreover, we describe a new method to compute the electromagnetic field that is fully parallelizable. The analogous problems in the acoustic case have been studied in many papers including Refs. 3–8.

Let $\mathbf{R}^n$ be the n-dimensional real Euclidean space, $\underline{x}=(x_1,x_2,\ldots,x_n)^T\in\mathbf{R}^n$ be a generic vector, where the superscript T means transposed, and let $\mathbf{C}^n$ be the n-dimensional complex vector space, and $\underline{z}=(z_1,z_2,\ldots,z_n)^T\in\mathbf{C}^n$ be a generic vector. Let $(\cdot,\cdot)$ be the Euclidean scalar product, $\|\cdot\|$ be the Euclidean norm and $[\cdot,\cdot]$ be the Euclidean vector product. In the following, with abuse of notation, we use the notation $(\cdot,\cdot)$ and the notation $[\cdot,\cdot]$ to denote also the Euclidean scalar product and the Euclidean vector product of complex vectors. Let $\Omega\subseteq\mathbf{R}^n$ be an open set, $\mathscr{C}^k(\Omega)$, $k=0,1,2,\ldots$, be the space of real or complex-valued k-times continuously differentiable functions in Ω with the appropriate sup-norm and let $\mathscr{C}_0^k(\Omega)$, $k=0,1,2,\ldots$, be the normed space of functions belonging to $\mathscr{C}^k(\Omega)$ with compact support in Ω. Let $\mathscr{C}^\infty(\Omega)$ be the space of real- or complex-valued infinitely continuously differentiable functions defined in Ω, and $\mathscr{C}_0^\infty(\Omega)$ be the space of $\mathscr{C}^\infty(\Omega)$ functions with compact support in Ω. Let $\mathscr{S}(\mathbf{R}^n)$ be the space of fast-decreasing functions

in $\mathbf{R}^n$ equipped with the usual Frechet structure and $\mathcal{S}'(\mathbf{R}^n)$ be the space of tempered distributions, that is the dual space of $\mathcal{S}(\mathbf{R}^n)$ (see Ref. 9, p. 219).

Let $\rho(x_1,x_2)\in\mathbf{C}_0^2(\mathbf{R}^2)$; we denote with supp $\rho\subset\mathbf{R}^2$ the support of ρ. Let

$$D=\{\underline{x}=(x_1,x_2,x_3)^T\in\mathbf{R}^3 | x_3<\rho(x_1,x_2),(x_1,x_2)^T\in\mathbf{R}^2\}. \tag{1.1}$$

It is easy to see that D is an open simply connected unbounded set. Let $\overline{D}$ be the closure of D; we have

$$D^c=\mathbf{R}^3\backslash\overline{D}=\{\underline{x}=(x_1,x_2,x_3)^T\in\mathbf{R}^3 | x_3>\rho(x_1,x_2),(x_1,x_2)^T\in\mathbf{R}^2\}. \tag{1.2}$$

We call disturbed half-space the sets of the form (1.1) and (1.2). Let ∂D be the boundary of D, that is,

$$\partial D=\{\underline{x}=(x_1,x_2,x_3)^T\in\mathbf{R}^3 | x_3=\rho(x_1,x_2),(x_1,x_2)^T\in\mathbf{R}^2\}. \tag{1.3}$$

We define

$$S_0=\{\underline{x}=(x_1,x_2,x_3)^T\in\mathbf{R}^3 | x_3=\rho(x_1,x_2),(x_1,x_2)^T\in \text{supp } \rho\}, \tag{1.4}$$

so that, since $\rho\in\mathbf{C}_0^2(\mathbf{R}^2)$, S_0 is a compact set, $S_0\subset\partial D$, and $\partial D\backslash S_0$ is an open subset of the plane $\{x_3=0\}$. Let $\underline{n}(\underline{x})$ be the outward unit normal vector to ∂D; that is,

$$\underline{n}(\underline{x})=\frac{1}{\sqrt{1+\left(\frac{\partial\rho}{\partial x_1}\right)^2+\left(\frac{\partial\rho}{\partial x_2}\right)^2}}\left(-\frac{\partial\rho}{\partial x_1},-\frac{\partial\rho}{\partial x_2},1\right)^T,\quad \underline{x}\in\partial D, \tag{1.5}$$

and let $\underline{g}(\underline{x})=(g_1(\underline{x}),g_2(\underline{x}),g_3(\underline{x}))^T$ be a continuous complex-valued vector field with compact support ''tangential'' to ∂D, that is, $(\underline{g}(\underline{x}),\underline{n}(\underline{x}))=0$, $\forall\underline{x}\in\partial D$. Let $\underline{0}=(0,0,0)^T$, let $k_0>0$ be a constant, and ι be the imaginary unit, and let $\hat{\underline{x}}=\underline{x}/\|\underline{x}\|$, for $\underline{x}\neq\underline{0}$. We consider the following boundary value problem:

$$(\Delta+k_0^2)\underline{E}(\underline{x})=0,\quad \underline{x}\in D^c, \tag{1.6}$$

$$\text{div } \underline{E}(\underline{x})=0,\quad \underline{x}\in D^c, \tag{1.7}$$

$$[\underline{n},\underline{E}](\underline{x})=\underline{g}(\underline{x}),\quad \underline{x}\in\partial D, \tag{1.8}$$

and

$$[\text{curl } \underline{E}(\underline{x}),\hat{\underline{x}}]-\iota k_0\underline{E}(\underline{x})=0\left(\frac{1}{\|\underline{x}\|}\right),\quad \|\underline{x}\|\to+\infty,\quad \underline{x}\in D^c, \tag{1.9}$$

where $\Delta(\cdot)=\Sigma_{j=1}^3\partial^2(\cdot)/\partial x_j^2$, $\text{div}(\cdot)=\Sigma_{j=1}^3\partial(\cdot)/\partial x_j$,

$$\underline{E}(\underline{x})=(E_1(\underline{x}),E_2(\underline{x}),E_3(\underline{x}))^T,\quad \Delta\underline{E}(\underline{x})=(\Delta E_1(\underline{x}),\Delta E_2(\underline{x}),\Delta E_3(\underline{x}))^T,$$

and

$$\text{curl } \underline{E}(\underline{x})=\left(\frac{\partial E_3(\underline{x})}{\partial x_2}-\frac{\partial E_2(\underline{x})}{\partial x_3},\frac{\partial E_1(\underline{x})}{\partial x_3}-\frac{\partial E_3(\underline{x})}{\partial x_1},\frac{\partial E_2(\underline{x})}{\partial x_1}-\frac{\partial E_1(\underline{x})}{\partial x_2}\right)^T.$$

It is easy to see (Ref. 1, Ch. 4) that the scattering of time harmonic electromagnetic waves by a perfectly conducting surface in a homogeneous isotropic medium that does not contain free electric charges and fills the disturbed half-space D^c reduces to the boundary value problem (1.6)–(1.9). In fact, let $\underline{E}^i$ be the incident electric field solution of (1.6) and (1.7) and let $\underline{E}^s$ be the electric field scattered by the perfectly conducting surface ∂D. We express the scattered field $\underline{E}^s$ as follows:

$$\underline{E}^s = \underline{E}^1 + \underline{E}^2, \tag{1.10}$$

where $\underline{E}^1(\underline{x}) = (-E_1^i, -E_2^i, E_3^i)^T(x_1, x_2, -x_3)$ is the electric field that would be scattered by the perfectly conducting plane $\{x_3 = 0\}$, and $\underline{E}^2$ is the contribution to the scattered field due to the presence of the perturbation S_0. It is easy to see that $\underline{E}^2$ solves the boundary value problem (1.6)–(1.9) with $\underline{g}(\underline{x}) = -[\underline{n}, \underline{E}^1 + \underline{E}^i](\underline{x})$, $\underline{x} \in \partial D$. Moreover, we have support of $\underline{g}$, supp $\underline{g} \subseteq S_0$. Finally, it is easy to see that for time harmonic waves the magnetic field is given by $\underline{H}(\underline{x}) = (1/\iota k_0)\text{curl}\, \underline{E}(\underline{x})$. In this paper we study the problem of the existence and uniqueness of the solution of the boundary value problem (1.6)–(1.9). In particular, we use the method of boundary integral equations to establish the existence of the solution. We reduce the boundary value problem (1.6)–(1.9) to an integral equation of the second kind for a vector density function $\underline{a}$ such that the vector field $\underline{E}$ solution of (1.6)–(1.9) is given by

$$\underline{E}(\underline{x}) = \int_{\partial D} \text{curl}_{\underline{x}}\{\Phi(\underline{x}, \underline{y})\underline{a}(\underline{y})\} ds(\underline{y}), \tag{1.11}$$

where $\text{curl}_{\underline{x}}$ denotes the curl operator with respect to the variable $\underline{x}$, $ds(\underline{y})$ is the surface measure on ∂D, and $\Phi(\underline{x}, \underline{y})$ is given by

$$\Phi(\underline{x}, \underline{y}) = \frac{\exp(\iota k_0 \|\underline{x} - \underline{y}\|)}{4\pi \|\underline{x} - \underline{y}\|}, \quad \underline{x} \neq \underline{y}, \quad \underline{x}, \underline{y} \in \mathbf{R}^3. \tag{1.12}$$

The uniqueness theorem is given for solutions of the boundary value problem (1.6)–(1.9), while the existence theorem is given for solutions that can be represented by (1.11) with a suitable choice of the density $\underline{a}$ in an appropriate function space. We prove an integral representation formula for $\underline{E}$ in terms of the value for $\underline{x} \in \partial D$ of $[\underline{n}, \underline{E}](\underline{x})$, $[\underline{n}, \text{curl}\, \underline{E}](\underline{x})$, and a series expansion of $\underline{E}$ when $\|\underline{x}\| \to \infty$ whose leading term contains the so-called far field. Moreover, we introduce a new numerical method to compute the function $\underline{E}(\underline{x})$ solution of (1.6)–(1.9) when ∂D is smooth, i.e., $\rho \in \mathbf{C}_0^\infty(\mathbf{R}^2)$. This method is based on the integral representation formula for $\underline{E}$ quoted above and on a new formalism that generalizes the formalism introduced in acoustics by Milder.[5] Milder[10] has also considered the electromagnetic case obtaining results similar to the ones contained in Sec. V. Let $\underline{f}(\underline{x}) = (f_1(\underline{x}), f_2(\underline{x}), f_3(\underline{x}))^T$ be a vector field defined in $\mathbf{R}^3$. We denote with $\underline{f}_{|\partial D}$ the restriction of $\underline{f}$ on ∂D, we think of $\underline{f}_{|\partial D}$ as a function of $(x_1, x_2)^T \in \mathbf{R}^2$, i.e., $\underline{f}_{|\partial D}(x_1, x_2) = (f_{1,|\partial D}, f_{2,|\partial D}, f_{3,|\partial D})^T(x_1, x_2) = \underline{f}(x_1, x_2, \rho(x_1, x_2)), (x_1, x_2)^T \in \mathbf{R}^2$.

Let $\mathcal{T} \subset S'(\mathbf{R}^2)$ and $\widetilde{\mathcal{H}}$ be the vector space given by

$$\widetilde{\mathcal{H}} = \{\underline{g}(x_1, x_2) = (g_1, g_2, g_3)^T(x_1, x_2) \in \mathbf{C}^3, \quad (x_1, x_2)^T \in \mathbf{R}^2 | \exists \underline{f}: \mathbf{R}^3 \to \mathbf{C}^3, \underline{g}(x_1, x_2) = \underline{f}_{|\partial D}(x_1, x_2), \quad (\underline{f}(\underline{x}), \underline{n}(\underline{x})) = 0, \quad \forall \underline{x} \in \partial D, \quad f_{j,|\partial D} \in \mathcal{T}, \quad j = 1,2,3\}. \tag{1.13}$$

We define (formally) a nonlocal operator $\widetilde{M}: \widetilde{\mathcal{H}} \to \widetilde{\mathcal{H}}$ such that

$$(\widetilde{M}\underline{g})(\underline{x}) = \underline{v}(\underline{x}), \quad \underline{x} \in \partial D, \tag{1.14}$$

where the vector field $\underline{v} \in \widetilde{\mathscr{H}}$ is defined as follows:

Let $\underline{E}$ be the unique solution of the boundary value problem (1.6), (1.7), (1.9) with the boundary condition

$$[\underline{n}, \underline{E}](\underline{x}) = \underline{g}(\underline{x}), \quad \underline{x} \in \partial D. \tag{1.15}$$

Then we define

$$\underline{v}(\underline{x}) = [\underline{n}, \text{ curl } \underline{E}](\underline{x}) \quad \underline{x} \in \partial D. \tag{1.16}$$

The operator $\widetilde{M}$ allows us to determine the vector field $\underline{E}$ using the integral representation formula previously announced.

In Sec. II we give some preliminary results needed to prove the main theorems. In Sec. III we give a representation theorem for $\underline{E}$, an expansion of $\underline{E}$ when $\|\underline{x}\| \to \infty$, and a uniqueness theorem for the solution of the boundary value problem (1.6)–(1.9). In Sec. IV we introduce a system of integral equations associated to the boundary value problem (1.6)–(1.9) and we prove an existence and uniqueness theorem for the solution of this system. In Sec. V we introduce a computational method that is based on a ''power'' series expansion of the operator $\widetilde{M}$. This method involves only quadratures and is fully parallelizable. In Sec. VI some numerical results obtained on test problems with the computational method of Sec. V are shown.

II. SOME PRELIMINARY RESULTS

Let R, R' be positive constants with $R' > R$, and D, D^c be given by (1.1) and (1.2). Let

$$B(\underline{0},R) = \{\underline{y} \in \mathbf{R}^3 | \|\underline{y}\| < R\}, \tag{2.1}$$

$$\Omega_R^+ = \{\underline{y} \in D^c | \|\underline{y}\| = R\}, \tag{2.2}$$

$$D_{R,R'} = \{\underline{y} \in D^c | R < \|\underline{y}\| < R'\}, \tag{2.3}$$

$$C(\underline{0},R,R') = \{\underline{y} \in \partial D | R < \|\underline{y}\| < R'\}. \tag{2.4}$$

We denote with $S_{R_0} = \overline{B(\underline{0},R_0)} \cap \partial D$ a compact subset of ∂D such that $S_0 \subseteq S_{R_0}$. We have the following lemma.

Lemma 2.1: Let $\Phi(\underline{x},\underline{y})$ be given by (1.12) and $\underline{n}$ be given by (1.5). We have

$$\frac{\partial \Phi(\underline{x},\underline{y})}{\partial \underline{n}(\underline{y})} = O\left(\frac{x_3}{\|\underline{y}\|^2}\right), \quad \text{when } \|\underline{y}\| \to +\infty, \quad \underline{y} \in \partial D \backslash S_{R_0}, \quad \underline{x} \in D^c. \tag{2.5}$$

Proof: It follows from some elementary computations and the fact that

$$(\underline{n}(\underline{y}), \underline{x} - \underline{y}) = x_3, \quad \underline{x} \in D^c, \quad \underline{y} \in \partial D \backslash S_{R_0}. \tag{2.6}$$ ■

Let $\underline{y} = (y_1, y_2, y_3)^T \in \mathbf{R}^3$, $\nabla_{\underline{y}} = (\partial/\partial y_1, \partial/y_2, \partial/\partial y_3)^T$, $R > 0$, and $B(\underline{0},R)$ be such that $S_{R_0} \subset B(\underline{0},R)$. We define the following integral kernels:

$$K_R(\underline{x},\underline{z}) = 2 \int_{\partial D \backslash B(\underline{0},R)} \Phi(\underline{x},\underline{y}) \frac{\partial \Phi(\underline{y},\underline{z})}{\partial \underline{n}(\underline{y})} \, ds(\underline{y}), \quad \underline{x},\underline{z} \in (D^c \backslash \overline{B(\underline{0},R)}) \cup S_{R_0}, \tag{2.7}$$

and

$$V_R(\underline{x},\underline{z}) = -2\int_{\partial D\setminus B(\underline{0},R)} (\underline{n}(\underline{y}),[\underline{\nabla}_{\underline{y}}\Phi(\underline{x},\underline{y}),\ \underline{\nabla}_{\underline{y}}\Phi(\underline{y},\underline{z})])ds(\underline{y}),\quad \underline{x},\underline{z}\in(D^c\setminus\overline{B(\underline{0},R)})\cup S_{R_0}. \tag{2.8}$$

We have the following Lemma.

Lemma 2.2: Let Φ be given by (1.12), $\underline{x}=(x_1,x_2,x_3)^T$, and $\underline{x}^*=(x_1,x_2,-x_3)^T$; let $\underline{\tilde{n}}$ be the outward unit normal vector to $\partial B(\underline{0},R)$, and let $G^{\pm}$ be given by

$$G^{\pm}(\underline{x},\underline{y}) = \Phi(\underline{x},\underline{y}) \pm \Phi(\underline{x}^*,\underline{y}),\quad \underline{x},\underline{y}\in\mathbf{R}^3,\quad \underline{x}\neq\underline{y}. \tag{2.9}$$

The following identities hold:

$$K_R(\underline{x},\underline{z}) - \int_{\Omega_R^+}\left\{ G^+(\underline{x},\underline{y})\,\frac{\partial\Phi}{\partial\underline{\tilde{n}}(\underline{y})}(\underline{y},\underline{z}) - \frac{\partial G^+}{\partial\underline{\tilde{n}}(\underline{y})}(\underline{x},\underline{y})\Phi(\underline{y},\underline{z})\right\}ds(\underline{y})$$
$$= \begin{cases} 0, & \underline{x},\underline{z}\in S_{R_0},\\ -\Phi(\underline{x},\underline{z}), & \underline{x}\in D^c\setminus\overline{B(\underline{0},R)},\quad \underline{z}\in S_{R_0}, \end{cases} \tag{2.10}$$

and

$$K_R(\underline{z},\underline{x}) + \int_{\Omega_R^+}\left\{ G^-(\underline{x},\underline{y})\,\frac{\partial\Phi}{\partial\underline{\tilde{n}}(\underline{y})}(\underline{y},\underline{z}) - \frac{\partial G^-}{\partial\underline{\tilde{n}}(\underline{y})}(\underline{x},\underline{y})\Phi(\underline{y},\underline{z})\right\}ds(\underline{y})$$
$$= \begin{cases} 0, & \underline{x},\underline{z}\in S_{R_0},\\ +\Phi(\underline{x},\underline{z}), & \underline{x}\in D^c\setminus\overline{B(\underline{0},R)},\quad \underline{z}\in S_{R_0}. \end{cases} \tag{2.11}$$

Proof: Given $\underline{x}\in S_{R_0}$ and $\underline{z}\in S_{R_0}$, we consider the functions $\Phi(\underline{x},\underline{y})$ and $\Phi(\underline{y},\underline{z})$, $\underline{y}\in D_{R,R'}$. Since $\partial D_{R,R'} = \Omega_R^+\cup\Omega_{R'}^+\cup\overline{C(\underline{0},R,R')}$, applying Green's formulas to $\Phi(\underline{x},\underline{y})$ and $\Phi(\underline{y},\underline{z})$, on $D_{R,R'}$ and using the Helmholtz equation we obtain

$$0 = \int_{\Omega_R^+}\left\{\Phi(\underline{x},\underline{y})\,\frac{\partial\Phi}{\partial\underline{\tilde{n}}(\underline{y})}(\underline{y},\underline{z}) - \frac{\partial\Phi}{\partial\underline{\tilde{n}}(\underline{y})}(\underline{x},\underline{y})\Phi(\underline{y},\underline{z})\right\}ds(\underline{y})$$
$$+\int_{\Omega_{R'}^+}\left\{\Phi(\underline{x},\underline{y})\,\frac{\partial\Phi}{\partial\underline{\tilde{n}}(\underline{y})}(\underline{y},\underline{z}) - \frac{\partial\Phi}{\partial\underline{\tilde{n}}(\underline{y})}(\underline{x},\underline{y})\Phi(\underline{y},\underline{z})\right\}ds(\underline{y})$$
$$+\int_{\overline{C(\underline{0},R,R')}}\left\{\Phi(\underline{x},\underline{y})\,\frac{\partial\Phi}{\partial\underline{\tilde{n}}(\underline{y})}(\underline{y},\underline{z}) - \frac{\partial\Phi}{\partial\underline{\tilde{n}}(\underline{y})}(\underline{x},\underline{y})\Phi(\underline{y},\underline{z})\right\}ds(\underline{y}),$$
$$\underline{x},\underline{z}\in S_{R_0}. \tag{2.12}$$

Since Φ satisfies the Sommerfeld radiation condition at infinity, we have

$$\lim_{R'\to\infty}\int_{\Omega_{R'}^+}\left\{\Phi(\underline{x},\underline{y})\,\frac{\partial\Phi}{\partial\underline{\tilde{n}}(\underline{y})}(\underline{y},\underline{z}) - \frac{\partial\Phi}{\partial\underline{\tilde{n}}(\underline{y})}(\underline{x},\underline{y})\Phi(\underline{y},\underline{z})\right\}ds(\underline{y}) = 0,\quad \underline{x},\underline{z}\in S_{R_0}, \tag{2.13}$$

and since $\overline{C(\underline{0},R,R')}$ coincides with $\partial D\setminus B(\underline{0},R)$ when $R'\to+\infty$, from (2.12) and (2.13) we obtain

$$0=\int_{\Omega_R^+}\left\{\Phi(\underline{x},\underline{y})\,\frac{\partial\Phi}{\partial\underline{\tilde{n}}(\underline{y})}\,(\underline{y},\underline{z})-\frac{\partial\Phi}{\partial\underline{\tilde{n}}(\underline{y})}\,(\underline{x},\underline{y})\Phi(\underline{y},\underline{z})\right\}ds(\underline{y})$$
$$-\int_{\partial D\setminus B(\underline{0},R)}\left\{\Phi(\underline{x},\underline{y})\,\frac{\partial\Phi}{\partial\underline{n}(\underline{y})}\,(\underline{y},\underline{z})-\frac{\partial\Phi}{\partial\underline{n}(\underline{y})}\,(\underline{x},\underline{y})\Phi(\underline{y},\underline{z})\right\}ds(\underline{y}),\quad \underline{x},\underline{z}\in S_{R_0}. \tag{2.14}$$

Arguing as above with $\Phi(\underline{x}^*,\underline{y})$, $\Phi(\underline{y},\underline{z})$, $\underline{y}\in D_{R,R'}$, we have

$$0=\int_{\Omega_R^+}\left\{\Phi(\underline{x}^*,\underline{y})\,\frac{\partial\Phi}{\partial\underline{\tilde{n}}(\underline{y})}\,(\underline{y},\underline{z})-\frac{\partial\Phi}{\partial\underline{\tilde{n}}(\underline{y})}\,(\underline{x}^*,\underline{y})\Phi(\underline{y},\underline{z})\right\}ds(\underline{y})$$
$$-\int_{\partial D\setminus B(\underline{0},R)}\left\{\Phi(\underline{x}^*,\underline{y})\,\frac{\partial\Phi}{\partial\underline{n}(\underline{y})}\,(\underline{y},\underline{z})-\frac{\partial\Phi}{\partial\underline{n}(\underline{y})}\,(\underline{x}^*,\underline{y})\Phi(\underline{y},\underline{z})\right\}ds(\underline{y}),\quad \underline{x},\underline{z}\in S_{R_0}. \tag{2.15}$$

It is easy to see that

$$G^+(\underline{x},\underline{y})=2\Phi(\underline{x},\underline{y}),\quad \frac{\partial G^+}{\partial\underline{n}(\underline{y})}\,(\underline{x},\underline{y})=0,\quad \underline{x}\in S_{R_0},\quad \underline{y}\in\partial D\setminus\overline{B(\underline{0},R)}, \tag{2.16}$$

$$G^-(\underline{x},\underline{y})=0,\quad \frac{\partial G^-}{\partial\underline{n}(\underline{y})}\,(\underline{x},\underline{y})=2\,\frac{\partial\Phi}{\partial\underline{n}(\underline{y})}\,(\underline{x},\underline{y}),\quad \underline{x}\in S_{R_0},\quad \underline{y}\in\partial D\setminus\overline{B(\underline{0},R)}. \tag{2.17}$$

For $\underline{x}\in S_{R_0}$ and $\underline{z}\in S_{R_0}$ from (2.14)–(2.16) we have (2.10), and from (2.14), (2.15), and (2.17) we have (2.11).

The proofs of the identities (2.10) and (2.11) for $\underline{x}\in D^c\setminus\overline{B(\underline{0},R)}$ and $\underline{z}\in S_{R_0}$ are analogous to the previous ones. This concludes the proof. ■

Lemma 2.3: Let $R>0$, $B(\underline{0},R)\supset S_{R_0}$, Ω_R^+ and $\underline{\tilde{n}}$ be as above, and let Φ and V_R be given by (1.12) and (2.8), respectively. We have

$$V_R(\underline{x},\underline{z})=2\int_{\Omega_R^+}(\underline{\tilde{n}}(\underline{y}),\mathrm{curl}_{\underline{x}}\{\Phi(\underline{x},\underline{y})\boldsymbol{\nabla}_{\underline{y}}\Phi(\underline{y},\underline{z})\})ds(\underline{y}),\quad \underline{x},\underline{z}\in(D^c\setminus\overline{B(\underline{0},R)})\cup S_{R_0}. \tag{2.18}$$

Proof: Let $R'>R>0$, let $D_{R,R'}$ be given by (2.3), and let $\underline{\hat{n}}$ be the outer normal vector to $\partial D_{R,R'}$. Applying the divergence theorem and some elementary vector identities we obtain

$$\int_{D_{R,R'}}\mathrm{div}_{\underline{y}}\,\mathrm{curl}_{\underline{x}}\{\Phi(\underline{x},\underline{y})\boldsymbol{\nabla}_{\underline{y}}\Phi(\underline{y},\underline{z})\}d\underline{y}$$
$$=-\int_{D_{R,R'}}\mathrm{div}_{\underline{y}}\{[\boldsymbol{\nabla}_{\underline{y}}\Phi(\underline{x},\underline{y}),\ \boldsymbol{\nabla}_{\underline{y}}\Phi(\underline{y},\underline{z})]\}d\underline{y}$$
$$=-\int_{\partial D_{R,R'}}(\underline{\hat{n}}(\underline{y}),[\boldsymbol{\nabla}_{\underline{y}}\Phi(\underline{x},\underline{y}),\ \boldsymbol{\nabla}_{\underline{y}}\Phi(\underline{y},\underline{z})])ds(\underline{y}),$$
$$\underline{x},\underline{z}\in(D^c\setminus\overline{B(\underline{0},R)})\cup S_{R_0}. \tag{2.19}$$

We have

$$\int_{D_{R,R'}} \operatorname{div}_{\underline{y}}\{[\nabla_{\underline{y}}\Phi(\underline{x},\underline{y}),\ \nabla_{\underline{y}}\Phi(\underline{y},\underline{z})]\}d\underline{y}=0, \quad \underline{x},\underline{z}\in(D^c\backslash\overline{B(\underline{0},R)})\cup S_{R_0}; \tag{2.20}$$

moreover, we obtain by straightforward calculation

$$\lim_{R'\to+\infty}\int_{\Omega^+_{R'}}(\hat{\underline{n}}(\underline{y}),[\nabla_{\underline{y}}\Phi(\underline{x},\underline{y}),\ \nabla_{\underline{y}}\Phi(\underline{y},\underline{z})])ds(\underline{y})=0. \tag{2.21}$$

Let $C(\underline{0},R,R')$ be given by (2.4). Since $\partial D_{R,R'}=\Omega^+_R\cup\Omega^+_{R'}\cup\overline{C(\underline{0},R,R')}$ and $\overline{C(\underline{0},R,R')}$ coincides with $\partial D\backslash B(\underline{0},R)$ when $R'\to+\infty$, from (2.19) using (2.20) and (2.21) we have the thesis.■

Lemma 2.4: Let Φ and K_R be given by (1.12) and (2.7). Let $R>0$ be such that $S_{R_0}\subset B(\underline{0},R)$, we have:

$$\int_{\partial D\backslash B(\underline{0},R)}\left\{\frac{\partial\Phi}{\partial x_j}(\underline{x},\underline{y})\,\frac{\partial\Phi}{\partial\underline{n}(\underline{y})}(\underline{y},\underline{z})\right\}ds(\underline{y})=\frac{1}{2}\,\frac{\partial K_R}{\partial x_j}(\underline{x},\underline{z}),$$

$$j=1,2, \quad \underline{x}\in(D^c\backslash\overline{B(\underline{0},R)})\cup S_{R_0}, \quad \underline{z}\in S_{R_0}. \tag{2.22}$$

Proof: For $\underline{x}\in(D^c\backslash\overline{B(\underline{0},R)})\cup S_{R_0}$ and $\underline{z}\in S_{R_0}$ we consider the following functions:

$$\frac{\partial\Phi}{\partial x_j}(\underline{x},\underline{y}), \quad \Phi(\underline{y},\underline{z}), \quad \underline{y}\in D_{R,R'}, \tag{2.23}$$

and

$$\frac{\partial\Phi}{\partial x_j}(\underline{x}^*,\underline{y}), \quad \Phi(\underline{y},\underline{z}), \quad \underline{y}\in D_{R,R'}, \tag{2.24}$$

the proof now follows as in Lemma 2.2. ■

Let $\mathscr{F}$ be the Fourier transform defined on $\mathscr{S}(\mathbf{R}^2)$, that is,

$$\hat{f}(\underline{k})=(\mathscr{F}f)(\underline{k})=\int_{\mathbf{R}^a}f(\underline{\xi})e^{-\iota(\underline{k},\underline{\xi})}d\underline{\xi}, \quad f\in\mathscr{S}(\mathbf{R}^2), \quad \underline{k}\in\mathbf{R}^2, \tag{2.25}$$

and $\mathscr{F}^{-1}$ be the inverse Fourier transform, where $\underline{k}=(k_1,k_2)^T\in\mathbf{R}^2$ is the conjugate variable of $\underline{\xi}=(\xi_1,\xi_2)^T\in\mathbf{R}^2$. We continue to denote with $\mathscr{F}$ and $\mathscr{F}^{-1}$ the extension of $\mathscr{F}$ and $\mathscr{F}^{-1}$ to $\mathscr{S}'(\mathbf{R}^2)$. Let $p:\mathbf{R}^2\to\mathbf{C}$ be the function defined by

$$p(\underline{k})=p(k_1,k_2)=\begin{cases}\sqrt{k_0^2-k_1^2-k_2^2}, & k_1^2+k_2^2\leqslant k_0^2,\\ \iota\sqrt{k_1^2+k_2^2-k_0^2}, & k_1^2+k_2^2>k_0^2,\end{cases} \tag{2.26}$$

and let $l_j:\mathbf{R}^2\to\mathbf{C}$, $j=1,2$, be the functions defined by $l_j(\underline{k})=l_j(k_1,k_2)=k_j$, $j=1,2$. From now on, with abuse of notation, we denote with f the maximal multiplication operator associated to the function $f(\underline{x})$. We define the operators $\tilde{q}$, $\tilde{q}_j$, $j=1,2$,: $\mathscr{S}'(\mathbf{R}^2)\to\mathscr{S}'(\mathbf{R}^2)$, as follows

$$\tilde{q}=\mathscr{F}^{-1}p\mathscr{F}, \tag{2.27}$$

$$\tilde{q}_j=\mathscr{F}^{-1}l_j\mathscr{F}, \quad j=1,2. \tag{2.28}$$

Let $\underline{\xi}=(\xi_1,\xi_2)^T\in\mathbf{R}^2$, $\underline{x}=(\underline{\xi}^T,x_3)^T$ be a generic vector in $\mathbf{R}^3$, let $\rho\in\mathscr{C}_0^2(\mathbf{R}^2)$ [see (1.1)–(1.3)], and D_ρ be the open set defined by

$$D_\rho=\{(\underline{\xi}^T,x_3)^T\in\mathbf{R}^3|\min\{\rho(\underline{\xi}),0\}<x_3,\underline{\xi}\in\mathbf{R}^2\}. \tag{2.29}$$

Let $z_0\in\mathbf{R}$ be a constant such that $z_0<\min_{\underline{\xi}\in\mathbf{R}^2}\{\rho(\underline{\xi})\}$. For $\tilde{u}\in\mathscr{S}'(\mathbf{R}^2)$ we define

$$F_1(\underline{k})=\frac{\iota e^{-\iota p(\underline{k})z_0}}{2p(\underline{k})}(\mathscr{F}\tilde{u})(\underline{k}),\quad \underline{k}\in\mathbf{R}^2, \tag{2.30}$$

and

$$\tilde{\mathscr{O}}=\left\{f:D_\rho\to\mathbf{C}\,\middle|\,\exists\tilde{u}\in\mathscr{S}'(\mathbf{R}^2)\right.$$
$$\text{such that } f(\underline{\xi}^T,x_3)=\int_{\mathbf{R}^2}F_1(\underline{k})e^{\iota p(\underline{k})x_3}e^{\iota(\underline{k},\underline{\xi})}\frac{d\underline{k}}{4\pi^2},$$
$$\left.\text{where } F_1(\underline{k}) \text{ is given by (2.30)},\quad (\underline{\xi}^T,x_3)^T\in D_\rho\right\}. \tag{2.31}$$

Moreover, let

$$\tilde{F}(\underline{k})=-\frac{e^{\iota p(k)z_0}}{2p(\underline{k})}[(k_1,k_2,p(\underline{k}))^T,\ ((\mathscr{F}u_1)(\underline{k}),(\mathscr{F}u_2)(\underline{k}),(\mathscr{F}u_3)(\underline{k}))^T], \tag{2.32}$$

and

$$\tilde{\mathscr{H}}=\left\{\underline{F}:D_\rho\to\mathbf{C}^3,\quad \underline{F}(\underline{x})=(F_1(\underline{x}),F_2(\underline{x}),F_3(\underline{x}))^T,\right.$$
$$|\exists\underline{u},\underline{u}(\underline{\xi})=(u_1(\underline{\xi}),u_2(\underline{\xi}),u_3(\underline{\xi}))^T,\underline{\xi}\in\mathbf{R}^2,u_j\in\mathscr{S}'(R^2),\quad j=1,2,3,$$
$$\text{such that } \underline{F}(\underline{\xi}^T,x_3)=\int_{\mathbf{R}^2}\tilde{\underline{F}}(\underline{k})e^{\iota p(\underline{k})x_3}e^{\iota(\underline{k},\underline{\xi})}d\underline{k}/4\pi^2,$$
$$\left.\text{where } \tilde{\underline{F}}(\underline{k}) \text{ is given by (2.32)},\quad (\underline{\xi}^{\mathrm{T}},\mathrm{x}_3)^{\mathrm{T}}\in\mathrm{D}_\rho\right\}. \tag{2.33}$$

We have the following.

Lemma 2.5: Let $\tilde{q},\tilde{q}_j$, $j=1,2$, be given by (2.27), (2.28), and $f\in\tilde{\mathscr{O}}$. Then f is a solution of the Helmholtz equation in D_ρ and we have

$$\frac{\partial f}{\partial x_3}(\underline{x})=\iota(\tilde{q}f\ )(\underline{x}),\quad \underline{x}\in\{x_3=0\}, \tag{2.34}$$

$$\frac{\partial f}{\partial x_j}(\underline{x})=\iota(\tilde{q}_jf\ )(\underline{x}),\quad \underline{x}\in\{x_3=0\},\quad j=1,2. \tag{2.35}$$

Moreover, let $\tilde{Z}$ be the operator defined by

$$\tilde{Z}:f(\underline{\xi}^T,0)\to f(\underline{\xi}^T,\rho(\underline{\xi})),\quad \underline{\xi}\in\mathbf{R}^2,\quad f\in\tilde{\mathscr{O}}. \tag{2.36}$$

Then the formal expansion of $\tilde{Z}$ in ''powers of ρ'' is given by

$$\tilde{Z}=\sum_{m=0}^{\infty}\frac{1}{m!}\rho^m(\iota\tilde{q})^m, \tag{2.37}$$

where we have denoted with ρ the maximal multiplication operator associated to $\rho(\underline{\xi})$, $\underline{\xi}\in\mathbf{R}^2$.

Proof (formal): An easy computation shows that any function $f\in\tilde{\mathscr{O}}$ is a solution of the Helmholtz equation in D_ρ. Formulas (2.34) and (2.35) are obtained differentiating the representation formula of $f\in\tilde{\mathscr{O}}$ [see (2.31)] and using the definition of $\tilde{q}$, $\tilde{q}_j$, $j=1,2$. The formal expansion

in ''powers of ρ'' of the operator $\tilde{Z}$ is obtained from the representation formula of $f \in \tilde{\mathcal{Q}}$ and the Taylor's expansion of $e^{\iota p(\underline{\xi})\rho(\underline{\xi})}$, with base point zero. ■

Lemma 2.6: Let $\underline{F} \in \tilde{\mathcal{A}}$. Then $F_j \in \tilde{\mathcal{Q}}$, $j=1,2,3$, and $\underline{F}(\underline{x})$, $\underline{x} \in D_\rho$ is a divergence free vector field solution of the vector Helmholtz equation on D_ρ.

Proof: In fact, we have

$$\int_{\mathbf{R}^2} \underline{\tilde{F}}(\underline{k}) e^{\iota p(\underline{k}) x_3} e^{\iota(\underline{k},\underline{\xi})} \frac{d\underline{k}}{4\pi^2} = \int_{\mathbf{R}^2} \mathrm{curl}_{\underline{x}} \{\underline{F}^*(\underline{k}) e^{\iota p(\underline{k}) x_3} e^{\iota(\underline{k},\underline{\xi})}\} \frac{d\underline{k}}{4\pi^2}, \quad (\underline{\xi}^T, x_3)^T \in D_\rho, \tag{2.38}$$

where $\underline{F}^*$ is the vector field given by

$$\underline{F}^*(\underline{k}) = \frac{\iota e^{-\iota p(\underline{k}) z_0}}{2p(\underline{k})} ((\mathcal{F}u_1)(\underline{k}), (\mathcal{F}u_2)(\underline{k}), (\mathcal{F}u_3)(\underline{k}))^T. \tag{2.39}$$

The thesis follows from the representation formula of $\underline{F} \in \tilde{\mathcal{A}}$ [see (2.33)]. ■

III. A REPRESENTATION FORMULA AND THE FAR-FIELD EXPANSION

Let $\mathcal{R}(D^c)$ be given by

$$\mathcal{R}(D^c) = \{\underline{E}: \mathbf{R}^3 \backslash D \to \mathbf{C}^3 | \underline{E} \in \mathcal{C}^2(\mathbf{R}^3 \backslash \overline{D}) \cap \mathcal{C}^0(\mathbf{R}^3 \backslash D), \quad \mathrm{div}\ \underline{E},\ \mathrm{curl}\ \underline{E} \in \mathcal{C}^0(\mathbf{R}^3 \backslash D)\},$$

and let $|\underline{E}|^2 = (\underline{E}, \overline{\underline{E}})$, where the overbar denotes the complex conjugate.

Lemma 3.1: Let $\underline{E} \in \mathcal{R}(D^c)$ be a solution of the boundary value problem (1.6)–(1.9). Then there exist two constants $c>0$, $R>0$ such that

$$\int_{\Omega_R^+} |\underline{E}(\underline{x})|^2 ds(\underline{x}) \leqslant c < \infty, \quad R > \overline{R}, \tag{3.1}$$

where Ω_R^+ is given by (2.2).

Proof: Let $D_R = D^c \cap B(\underline{0}, R)$, and let $\underline{n}_R$ be the outward unit normal vector to ∂D_R. We have

$$\partial D_R = \Omega_R^+ \cup (\partial D \cap \overline{B(\underline{0}, R)}), \tag{3.2}$$

$$\underline{n}_R(\underline{x}) = -\underline{n}(\underline{x}), \quad \underline{x} \in \partial D \cap \overline{B(\underline{0}, R)}, \tag{3.3}$$

where ∂D is given by (1.3) and $\underline{n}$ by (1.5). From the first Green's theorem and the radiation condition (1.9) we have

$$\begin{aligned} 0 &= \lim_{R \to +\infty} \int_{\Omega_R^+} |[\mathrm{curl}\ \underline{E}(\underline{y}),\ \underline{n}_R(\underline{y})]|^2 + k_0^2 |\underline{E}(\underline{y})|^2\ ds(\underline{y}) \\ &= -2\,\mathrm{Im}\left\{ k_0 \int_{\partial D} ([\underline{n}(\underline{y}),\ \underline{E}(\underline{y})], \mathrm{curl}\ \overline{\underline{E}(\underline{y})}) ds(\underline{y}) \right\}, \end{aligned} \tag{3.4}$$

where $\mathrm{Im}\{\cdot\}$ denotes the imaginary part of $\{\cdot\}$. The thesis follows from (3.4) and (1.8) noting that the last integral in (3.4) is convergent. ■

Theorem 3.2: Let $\underline{E} \in \mathcal{R}(D^c)$ be the vector field of Lemma 3.1 and let Φ be given by (1.12). Then the following representation formula holds:

$$\int_{\partial D} \mathrm{curl}_{\underline{x}}\{[\underline{n}(\underline{y}),\ \underline{E}(\underline{y})]\Phi(\underline{x},\underline{y})\}ds(\underline{y}) + \frac{1}{k_0^2}\int_{\partial D} \mathrm{curl}_{\underline{x}}\ \mathrm{curl}_{\underline{x}}\{[\underline{n}(\underline{y}),\ \mathrm{curl}\ \underline{E}(\underline{y})]\Phi(\underline{x},\underline{y})\}ds(\underline{y})$$

$$= \begin{cases} \underline{E}(\underline{x}), & \underline{x} \in D^c, \\ 0, & \underline{x} \in D. \end{cases} \tag{3.5}$$

Proof: The proof of formula (3.5) is analogous to the proof of a similar formula for the solution of the Helmholtz equation in the exterior of a bounded domain (see Ref. 1, Th. 4.5, p. 113). ■

Theorem 3.3: Let $\underline{E} \in \mathscr{R}(D^c)$ be the vector field of Lemma 3.1. There exists $R>0$ such that $\underline{E}$ can be extended to a vector field $\widetilde{\underline{E}}$ defined in $\mathbf{R}^3\backslash\overline{B(\underline{0},R)}$ and

$$\widetilde{\underline{E}}(\underline{x}) = \frac{e^{ik_0\|\underline{x}\|}}{4\pi\|\underline{x}\|}\sum_{n=0}^{\infty}\frac{\underline{F}_n(\hat{\underline{x}})}{\|\underline{x}\|^n}, \quad \hat{x} = \frac{\underline{x}}{\|\underline{x}\|}, \quad \underline{x} \neq \underline{0}, \quad \underline{x} \in \mathbf{R}^3\backslash\overline{B(\underline{0},R)}, \tag{3.6}$$

where the expansion (3.6) converges absolutely and uniformly for $\|\underline{x}\|>R$.

Moreover, we have

$$(\hat{\underline{x}}, \underline{F}_0(\hat{\underline{x}})) = 0. \tag{3.7}$$

Proof: Let $R>0$, such that $B(\underline{0},R)\supset \mathrm{supp}\ \underline{g}\cup S_0$ [see (1.4), (1.8), and (2.1)], $S_R = B(\underline{0},R)\cap\partial D$, $\underline{x} = (x_1,x_2,x_3)^T \in D^c\backslash\overline{B(\underline{0},R)}$, and $\underline{x}^* = (x_1,x_2,-x_3)^T \in D$. We define the following vector functions:

$$\underline{\eta}^{\pm} = (\eta_1^{\pm},\eta_2^{\pm},\eta_3^{\pm})^T = \mathrm{curl}_{\underline{s}}\{\Phi(\underline{s},\underline{y})[\underline{n}(\underline{y}),\ \underline{E}(\underline{y})]\}_{|_{\underline{s}=\underline{x}}} \pm \mathrm{curl}_{\underline{s}}\{\Phi(\underline{s},\underline{y})[\underline{n}(\underline{y}),\ \underline{E}(\underline{y})]\}_{|_{\underline{s}=\underline{x}^*}},$$

$$\underline{y} \in \partial D, \tag{3.8}$$

and

$$\underline{\chi}^{\pm} = (\chi_1^{\pm},\chi_2^{\pm},\chi_3^{\pm})^T = \mathrm{curl}_{\underline{s}}\ \mathrm{curl}_{\underline{s}}\{\Phi(\underline{s},\underline{y})[\underline{n}(\underline{y}),\mathrm{curl}\ \underline{E}(\underline{y})]\}_{|_{\underline{s}=\underline{x}}} \pm \mathrm{curl}_{\underline{s}}\ \mathrm{curl}_{\underline{s}}\{\Phi(\underline{s},\underline{y})$$

$$[\underline{n}(\underline{y}),\mathrm{curl}\ \underline{E}(\underline{y})]\}_{|_{\underline{s}=\underline{x}^*}}, \quad \underline{y} \in \partial D. \tag{3.9}$$

For $\underline{y} \in \partial D\backslash S_R$ we have

$$\chi_j^-(\underline{x},\underline{y}) = 0, \quad j=1,2, \quad \underline{y} \in D\backslash S_R, \quad \underline{x} \in D^c\backslash\overline{B(\underline{0},R)}, \tag{3.10}$$

and

$$\chi_3^+(\underline{x},\underline{y}) = 0, \quad \underline{y} \in \partial D\backslash S_R, \quad \underline{x} \in D^c\backslash\overline{B(\underline{0},R)}. \tag{3.11}$$

From Theorem 3.2, (3.10), (3.11), and (1.8) we obtain

$$E_j(\underline{x}) = \int_{S_R}\eta_j^-(\underline{x},\underline{y})ds(\underline{y}) + \frac{1}{k_0^2}\int_{S_R}\chi_j^-(\underline{x},\underline{y})ds(\underline{y}), \quad j=1,2, \quad \underline{x} \in D^c\backslash\overline{B(\underline{0},R)} \tag{3.12}$$

and

$$E_3(\underline{x}) = \int_{S_R}\eta_3^+(\underline{x},\underline{y})ds(\underline{y}) + \frac{1}{k_0^2}\int_{S_R}\chi_3^+(\underline{x},\underline{y})ds(\underline{y}), \quad \underline{x} \in D^c\backslash\overline{B(\underline{0},R)}. \tag{3.13}$$

Using (3.12) and (3.13), $\underline{E}$ can be extended to a vector field $\underline{\tilde{E}}$ defined in $\mathbf{R}^3\backslash\overline{B(\underline{0},R)}$, which is a divergence-free vector field satisfying the vector Helmholtz equation and the radiation condition (1.9). This field has an expansion of the form (3.6) [see Ref. 1, Th. 4.8, p. 116]. The proof of (3.7) follows from (3.6) and (1.9). ■

Corollary 3.4: Let $\hat{\underline{x}} = (\sin\theta\cos\varphi, \sin\theta\sin\varphi, \cos\theta)^T$. Then, the coefficients $\underline{F}_n(\hat{\underline{x}}) = \underline{F}_n(\theta,\varphi)$ in (3.6) are given by

$$2\imath k_0 n\underline{F}_n = n(n-1)\underline{F}_{n-1} + \mathscr{B}\underline{F}_{n-1}, \quad n=1,2,\ldots, \tag{3.14}$$

where

$$\mathscr{B} = \frac{1}{\sin(\theta)}\frac{\partial}{\partial\theta}\left(\sin(\theta)\frac{\partial}{\partial\theta}\right) + \frac{1}{\sin^2(\theta)}\frac{\partial^2}{\partial\varphi^2} \tag{3.15}$$

is the Beltrami operator on the sphere.

Proof: The proof follows from Theorem 3.3, since the expansion in (3.6) satisfies term-by-term the vector Helmholtz equation. ■

Corollary 3.5: Let $\underline{E} \in \mathscr{R}(D^c)$ be the vector field of Lemma 3.1. If $\underline{F}_0(\hat{\underline{x}}) \equiv 0$, $\hat{\underline{x}} = \underline{x}/\|\underline{x}\|$, $\underline{x} \neq \underline{0}$, $\underline{x} \in D^c$, then $\underline{E}(\underline{x}) \equiv \underline{0}$.

Proof: From Corollary 3.4 it is easy to see that $\underline{F}_0(\hat{\underline{x}}) \equiv 0$ implies $\underline{F}_n(\hat{\underline{x}}) \equiv 0$, $n=1,2,\ldots$. The proof follows from Theorem 3.3 using the expansion in (3.6). ■

Lemma 3.6: Let $\underline{E} \in \mathscr{R}(D^c)$ be the vector field of Lemma 3.1 and let $\underline{n}$ be given by (1.5). If

$$\mathrm{Im}\left\{k_0\int_{\partial D} ds(\underline{y})(\underline{n}(\underline{y}), [\underline{E}(\underline{y}), \mathrm{curl}\,\overline{\underline{E}(\underline{y})}])\right\} \geq 0, \tag{3.16}$$

then we have

$$\underline{E}(\underline{x}) = \underline{0}, \quad \underline{x} \in D^c. \tag{3.17}$$

Proof: The proof follows from a standard argument (see Ref. 1, Th. 4.17, p. 125), using (1.8) and (1.9). ■

Theorem 3.7: Let $\mathrm{Im}\{k_0\} \geq 0$. Then the boundary value problem (1.6)–(1.9) has at most one solution in $\mathscr{R}(D^c)$.

Proof: We assume by contradiction that $\underline{E}$ and $\underline{E}^*$ are two solutions of the boundary value problem (1.6)–(1.9). The vector field $\underline{\tilde{E}} = \underline{E} - \underline{E}^*$ is a solution of the boundary value problem (1.6)–(1.9) with homogeneous boundary condition; that is,

$$[\underline{n}(\underline{x}), \underline{\tilde{E}}(\underline{x})] = \underline{0}, \quad \underline{x} \in \partial D. \tag{3.18}$$

From condition (3.18) and the properties of the triple product $(\cdot,[\cdot,\cdot])$ we obtain

$$\mathrm{Im}\left\{k_0\int_{\partial D} (\underline{n}(\underline{y}), [\underline{\tilde{E}}(\underline{y}), \mathrm{curl}\,\overline{\underline{\tilde{E}}(\underline{y})}])\right\} = 0. \tag{3.19}$$

The thesis follows from (3.19) and Lemma 3.6. ■

IV. AN EXISTENCE AND UNIQUENESS THEOREM FOR THE SOLUTION OF THE SYSTEM OF INTEGRAL EQUATIONS

Let $S_{R_0} = \overline{B(\underline{0},R_0)} \cap \partial D$ be a compact subset of ∂D such that $S_{R_0} \supseteq S_0$. Let $\tilde{\mathscr{C}}(S_{R_0})$ be the Cartesian product of three copies of $\mathbf{C}^0(S_{R_0})$, and let $\underline{\varphi} \in \tilde{\mathscr{C}}(S_{R_0})$ be a vector continuous tangential density, that is,

$$(\underline{\varphi}(\underline{x}),\underline{n}(\underline{x}))=0, \quad \underline{x} \in S_{R_0}, \tag{4.1}$$

where $\underline{n}$ is given by (1.5).

Let $\tilde{\underline{\varphi}}$ be the vector function defined on the set $\partial D \backslash S_{R_0}$ given by

$$\tilde{\underline{\varphi}}(\underline{x}) = -2\int_{S_{R_0}} [\underline{n}(\underline{x}), \operatorname{curl}_{\underline{x}}\{\phi(\underline{x},\underline{y})\underline{\varphi}(\underline{y})\}]ds(\underline{y}), \quad \underline{x} \in \partial D \backslash S_{R_0}, \tag{4.2}$$

where the integral in (4.2) exists as a Cauchy principal value when $\underline{x} \in \partial S_{R_0}$.

Lemma 4.1: Let $\underline{\varphi}$, $\tilde{\underline{\varphi}}$ be given by (4.1) and (4.2), respectively. Then $\tilde{\underline{\varphi}}$ is a continuous tangential vector function on $\partial D \backslash S_{R_0}$, i.e., $\tilde{\underline{\varphi}} \in \tilde{\mathscr{C}}(\partial D \backslash S_{R_0})$ and we have

$$\begin{aligned}\tilde{\varphi}_1(\underline{y}) &= -2\int_{S_{R_0}} \frac{\partial \phi}{\partial y_1}(\underline{y},\underline{z})\varphi_3(\underline{z})ds(\underline{z}) + 2\int_{S_{R_0}} \frac{\partial \phi}{\partial \underline{n}(\underline{y})}(\underline{y},\underline{z})\varphi_1(\underline{z})ds(\underline{z}) \\ &= O\left(\frac{1}{\|\underline{y}\|}\right), \quad \|\underline{y}\| \to +\infty, \quad \underline{y} \in \partial D \backslash S_{R_0},\end{aligned} \tag{4.3}$$

$$\begin{aligned}\tilde{\varphi}_2(\underline{y}) &= -2\int_{S_{R_0}} \frac{\partial \phi}{\partial y_2}(\underline{y},\underline{z})\varphi_3(\underline{z})ds(\underline{z}) + 2\int_{S_{R_0}} \frac{\partial \phi}{\partial \underline{n}(\underline{y})}(\underline{y},\underline{z})\varphi_2(\underline{z})ds(\underline{z}) \\ &= O\left(\frac{1}{\|\underline{y}\|}\right), \quad \|\underline{y}\| \to +\infty, \quad \underline{y} \in \partial D \backslash S_{R_0},\end{aligned} \tag{4.4}$$

$$\tilde{\varphi}_3(\underline{y}) = 0, \quad \underline{y} \in \partial D \backslash S_{R_0}, \tag{4.5}$$

$$\tilde{\varphi}_2(\underline{y})(x_1-y_1) - \tilde{\varphi}_1(\underline{y})(x_2-y_2) = O\left(\frac{f(\underline{x})}{\|\underline{y}\|}\right), \quad \|\underline{y}\| \to +\infty, \quad \underline{y} \in \partial D \backslash S_{R_0}, \quad \underline{x} \in S_{R_0}, \tag{4.6}$$

where $f \in \mathscr{C}^0(S_{R_0})$ is a suitable function.

Proof: The proof follows by an easy computation from the definitions (1.12), (4.2), and Lemma 2.1. ■

Let K be the operator on $\tilde{\mathscr{C}}(S_{R_0})$ defined by

$$\begin{aligned}(K\underline{\varphi})(\underline{x}) &= 2\int_{S_{R_0}} [\underline{n}(\underline{x}),\ \operatorname{curl}_{\underline{x}}\{\phi(\underline{x},\underline{y})\underline{\varphi}(\underline{y})\}]ds(\underline{y}) \\ &\quad + 2\int_{\partial D \backslash S_{R_0}} [\underline{n}(\underline{x}),\ \operatorname{curl}_{\underline{x}}\{\phi(\underline{x},\underline{y})\tilde{\underline{\varphi}}(\underline{y})\}]ds(\underline{y}), \quad \underline{x} \in S_{R_0},\end{aligned} \tag{4.7}$$

where $\underline{\varphi}, \tilde{\underline{\varphi}}$ are given by (4.1) and (4.2).

Lemma 4.2: The operator K in (4.7) is a compact operator on $\tilde{\mathscr{C}}(S_{R_0})$.

Proof: Let $B(\underline{0},R)$ given by (2.1) such that $B(\underline{0},R)\supset S_{R_0}$. From the definition (4.7) we obtain

$$(K\underline{\varphi})(\underline{x})=2\int_{S_{R_0}}[\underline{n}(\underline{x}),\ \mathrm{curl}_{\underline{x}}\{\phi(\underline{x},\underline{y})\underline{\varphi}(\underline{y})\}]ds(\underline{y})$$
$$+2\int_{(\partial D\cap B(\underline{0},R))\setminus S_{R_0}}[\underline{n}(\underline{x}),\ \mathrm{curl}_{\underline{x}}\{\phi(\underline{x},\underline{y})\widetilde{\underline{\varphi}}(\underline{y})\}]ds(\underline{y})$$
$$+2\int_{\partial D\setminus B(\underline{0},R))}[\underline{n}(\underline{x}),\ \mathrm{curl}_{\underline{x}}\{\phi(\underline{x},\underline{y})\widetilde{\underline{\varphi}}(\underline{y})\}]ds(\underline{y}),\quad \underline{x}\in S_{R_0}. \tag{4.8}$$

It is easy to see that the first two integrals on the right-hand side of (4.8) have weakly singular kernels on bounded surfaces, so that they are compact operators on $\widetilde{\mathscr{C}}(S_{R_0})$ (see Ref. 1, Th.1.11, p. 6). Now we study the last integral in (4.8). From the definition (4.2) and Lemmas 2.2, 2.3, and 2.4 we have

$$\int_{\partial D\setminus B(\underline{0},R)}\mathrm{curl}_{\underline{x}}\{\phi(\underline{x},\underline{y})\widetilde{\underline{\varphi}}(\underline{y})\}ds(\underline{y})$$
$$=2\int_{S_{R_0}}ds(\underline{z})\varphi_3(\underline{z})\int_{\partial D\setminus B(\underline{0},R)}[\boldsymbol{\nabla}_{\underline{y}}\phi(\underline{x},\underline{y}),\boldsymbol{\nabla}_{\underline{y}}\phi(\underline{y},\underline{z})]ds(\underline{y})$$
$$+2\int_{S_{R_0}}ds(\underline{z})\mathrm{curl}_{\underline{x}}\left\{\underline{\varphi}(\underline{z})\int_{\partial D\setminus B(\underline{0},R)}\phi(\underline{x},\underline{y})\frac{\partial\phi}{\partial\underline{n}(\underline{y})}(\underline{y},\underline{z})ds(\underline{y})\right\},\quad \underline{x}\in S_{R_0}. \tag{4.9}$$

By an easy computation we obtain

$$\int_{\partial D\setminus B(\underline{0},R)}[\boldsymbol{\nabla}_{\underline{y}}\phi(\underline{x},\underline{y}),\ \boldsymbol{\nabla}_{\underline{y}}\phi(\underline{y},\underline{z})]ds(\underline{y})$$
$$=\frac{1}{2}\left(-\frac{\partial K_R}{\partial x_2}(\underline{x},\underline{z})+\frac{\partial K_R}{\partial z_2}(\underline{z},\underline{x}),\ \frac{\partial K_R}{\partial x_1}(\underline{x},\underline{z})-\frac{\partial K_R}{\partial z_1}(\underline{z},\underline{x}),V_R(\underline{x},\underline{z})\right)^T,$$
$$\underline{x}\in S_{R_0},\quad \underline{z}\in S_{R_0}, \tag{4.10}$$

where K_R, V_R are the kernels given by (2.7) and (2.8). The thesis follows from (4.9) and (4.10) using the representation formulas (2.10), (2.11), (2.18), and (2.22). ■

Let $\varphi,\widetilde{\varphi}$ be the functions given by (4.1) and (4.2), and let $\underline{a}$ be the following vector function:

$$\underline{a}(\underline{x})=\begin{cases}\underline{\varphi}(\underline{x}), & \underline{x}\in S_{R_0},\\ \widetilde{\underline{\varphi}}(\underline{x}), & \underline{x}\in\partial D\setminus S_{R_0}.\end{cases} \tag{4.11}$$

Theorem 4.3: Let K and $\underline{a}$ be given by (4.7) and (4.11) and let $\underline{g}$ be the vector function in (1.8) with supp $\underline{g}\subseteq S_{R_0}$. If $\varphi\in\widetilde{\mathscr{C}}(S_{R_0})$ satisfies condition (4.1) and is a solution of the integral equation

$$\underline{\varphi}(\underline{x})+(K\underline{\varphi})(\underline{x})=2\underline{g}(\underline{x}),\quad \underline{x}\in S_{R_0}, \tag{4.12}$$

then we have

$$\left| \int_{\partial D} \operatorname{curl}_{\underline{x}}\{\phi(\underline{x},\underline{y})\underline{a}(\underline{y})\}ds(\underline{y}) \right| < \infty, \quad \underline{x} \in D^c, \tag{4.13}$$

$$\underline{a} \in \widetilde{\mathscr{C}}(\partial D), \quad (\underline{a}(\underline{x}),\underline{n}(\underline{x})) = 0, \quad \underline{x} \in \partial D, \tag{4.14}$$

and the vector $\underline{E}$ given by (1.11) is a solution of the boundary value problem (1.6)–(1.9).

Proof: Formula (4.13) follows from the definition of $\underline{a}$ using Lemmas 2.1 and 4.1. Moreover, it is easy to see that $\underline{E}$ is a free divergence field, solution of the vector Helmholtz equation (1.6). Now we prove the radiation condition (1.9). Let $R>0$, $B(\underline{0},R) \supset S_{R_0}$, and $\underline{e}_3 = (0,0,1)^T \in \mathbf{R}^3$. We have

$$\begin{aligned} \underline{E}(\underline{x}) = & \int_{S_{R_0}} \operatorname{curl}_{\underline{x}}\{\phi(\underline{x},\underline{y})\varphi(\underline{y})\}ds(\underline{y}) + \int_{(\partial D \cap B(\underline{0},R))\setminus S_{R_0}} \operatorname{curl}_{\underline{x}}\{\phi(\underline{x},\underline{y})\widetilde{\varphi}(\underline{y})\}ds(\underline{y}) \\ & + \int_{\partial D \setminus B(\underline{0},R)} \operatorname{curl}_{\underline{x}}\{\phi(\underline{x},\underline{y})\widetilde{\varphi}(\underline{y})\}ds(\underline{y}), \quad \underline{x} \in D^c. \end{aligned} \tag{4.15}$$

Let K_R and V_R be the kernels defined by (2.7) and (2.8). Applying Lemma 2.5 and the Lebesgue Theorem to interchange the order of integration we obtain

$$\begin{aligned} & \int_{\partial D \setminus B(\underline{0},R)} \operatorname{curl}_{\underline{x}}\{\phi(\underline{x},\underline{y})\widetilde{\varphi}(\underline{y})\}ds(\underline{y}) \\ & \quad = \int_{S_{R_0}} \varphi_3(\underline{y}) \operatorname{curl}_{\underline{y}}\{K_R(\underline{y},\underline{x})\underline{e}_3\}ds(\underline{y}) + \int_{S_{R_0}} \operatorname{curl}_{\underline{x}}\{K_R(\underline{x},\underline{y})\varphi(\underline{y})\}ds(\underline{y}) \\ & \qquad - \int_{S_{R_0}} \operatorname{curl}_{\underline{x}}\{K_R(\underline{x},\underline{y})\varphi_3(\underline{y})\underline{e}_3\}ds(\underline{y}) + \underline{e}_3 \int_{S_{R_0}} V_R(\underline{x},\underline{y})\varphi_3(\underline{y})ds(\underline{y}), \\ & \qquad \underline{x} \in D^c \setminus \overline{B(\underline{0},R)}. \end{aligned} \tag{4.16}$$

The radiation condition (1.9) follows from (4.15) and (4.16) using Lemmas 2.2 and 2.3 and the theory of electromagnetic field generated by a magnetic dipole. We note that when $\underline{a}$ satisfies (4.14) the boundary condition (1.8) follows immediately from the jump relations. So, we must prove (4.14). From the definition of $\underline{a}$ given by (4.11), using the integral equation (4.12) and Lemma 4.2, we have

$$\varphi(\underline{x}) = -(K\varphi)(\underline{x}), \quad \underline{x} \in \partial S_{R_0}. \tag{4.17}$$

By an easy computation, from the assumption (4.1) and noting that $(\partial\phi(\underline{x},\underline{y})/\partial\underline{n}(\underline{x})) = 0$, $\underline{x},\underline{y} \in \partial D \setminus S_{R_0}$ [see (1.4)], we obtain

$$[\underline{n}(\underline{x}),\ \operatorname{curl}_{\underline{x}}\{\phi(\underline{x},\underline{y})\underline{a}(\underline{y})\}] = 0, \quad \underline{x} \in \partial S_{R_0}, \quad \underline{y} \in \partial D \setminus S_{R_0}. \tag{4.18}$$

Taking the definitions (4.2), (4.7), and (4.11) into account, from (4.17) and (4.18) we obtain $\underline{a} \in \widetilde{\mathscr{C}}(\partial D)$. Finally from the definition of $\underline{a}$ and Lemma 4.1 it follows $(\underline{a}(\underline{x}),\underline{n}(\underline{x})) = 0$, $\underline{x} \in \partial D$. This concludes the proof. ■

Theorem 4.4: The boundary integral equation (4.12) has a unique solution $\varphi \in \widetilde{\mathscr{C}}(S_{R_0})$.

Proof: The thesis follows from the Fredholm theory using Lemma 4.2, Theorems 4.3 and 3.7, and the jump relation for vector potential with continuous tangential density. ■

V. A METHOD TO COMPUTE THE ELECTRIC FIELD IN A DISTURBED HALF-SPACE

We remind the reader that the content of this section is mainly formal. Let $\mathscr{T} \subseteq \mathscr{S}'(\mathbf{R}^2)$ be a vector subspace of the space of tempered distributions such that the operator compositions used later are defined in $\mathscr{T}$.

Let $\rho_l(x_1,x_2) \in \mathbf{C}^2(\mathbf{R}^2)$, $l=1,2$, be a bounded function on R^2, Γ_l, $l=1,2$, be the following surfaces:

$$\Gamma_l = \{\underline{x} = (x_1,x_2,x_3)^T \in \mathbf{R}^3 | x_3 = \rho_l(x_1,x_2), (x_1,x_2)^T \in \mathbf{R}^2\}, \quad l=1,2, \tag{5.1}$$

and D_{Γ_l}, $l=1,2$, be the following domains:

$$D_{\Gamma_l} = \{\underline{x} = (x_1,x_2,x_3)^T \in \mathbf{R}^3 | x_3 < \rho_l(x_1,x_2), (x_1,x_2)^T \in \mathbf{R}^2\}, \quad l=1,2. \tag{5.2}$$

For $l=1,2$, let $\underline{n}_{\Gamma_l}(\underline{x})$ be the unit vector normal to Γ_l in $\underline{x} \in \Gamma_l$ pointing inside $\mathbf{R}^3 \backslash \overline{D_{\Gamma_l}}$. We denote with $\mathscr{H}_{\Gamma_l}$ the vector spaces

$$\begin{aligned}\mathscr{H}_{\Gamma_l} = \{&\underline{g}(x_1,x_2) = (g_1,g_2,g_3)^T(x_1,x_2) \in \mathbf{C}^3, (x_1,x_2)^T \in \mathbf{R}^2 | \exists \underline{f}: \mathbf{R}^3 \to \mathbf{C}^3, \underline{g}(x_1,x_2) \\ &= \underline{f}_{|\Gamma_l}(x_1,x_2), (\underline{f}(\underline{x}), \underline{n}_{\Gamma_l}(\underline{x})) = 0, \forall \underline{x} \in \Gamma_l, f_{j,|\Gamma_l} \in \mathscr{T}, j=1,2,3\}.\end{aligned} \tag{5.3}$$

We define two transformations $\widetilde{L}_{\Gamma_l}: \mathscr{H}_{\Gamma_l} \to \mathscr{H}_{\Gamma_l}$, $l=1,2$, such that

$$(\widetilde{L}_{\Gamma_l} \underline{g}_{\Gamma_l})(\underline{x}) = \underline{v}_{\Gamma_l}(\underline{x}), \quad \underline{x} \in \Gamma_l, \quad l=1,2, \tag{5.4}$$

where the vector field $\underline{v}_{\Gamma_l}$, $l=1,2$, is defined as the vector field $\underline{v}$ in (1.14), when we replace ∂D with Γ_l, $l=1,2$, in (1.15) and (1.16) and D^c with $\mathbf{R}^3 \backslash \overline{D_{\Gamma_l}}$, $l=1,2$, in (1.6), (1.7), and (1.9). We introduce the transformation $\widetilde{G}: \mathscr{H}_{\Gamma_1} \to \mathscr{H}_{\Gamma_2}$ such that

$$(\widetilde{G} \underline{g}_{\Gamma_1})(\underline{x}) = \underline{g}_{\Gamma_2}(\underline{x}), \quad \underline{x} \in \Gamma_2, \tag{5.5}$$

where $\underline{g}_{\Gamma_2}$ is defined as follows:

Let $\underline{E}_{\Gamma_1}$ be the unique solution of the boundary value problem

$$(\Delta + k_0^2) \underline{E}_{\Gamma_1}(\underline{x}) = \underline{0}, \quad \underline{x} \in \mathbf{R}^3 \backslash \overline{D_{\Gamma_1}}, \tag{5.6}$$

$$\operatorname{div} \underline{E}_{\Gamma_1}(\underline{x}) = 0, \quad \underline{x} \in \mathbf{R}^3 \backslash \overline{D_{\Gamma_1}}, \tag{5.7}$$

$$\left[\operatorname{curl} \underline{E}_{\Gamma_1}(\underline{x}), \frac{\underline{x}}{\|\underline{x}\|}\right] - \iota k_0 \underline{E}_{\Gamma_1}(\underline{x}) = o\left(\frac{1}{\|\underline{x}\|}\right), \quad \|\underline{x}\| \to +\infty, \underline{x} \in \mathbf{R}^3 \backslash \overline{D_{\Gamma_1}}, \tag{5.8}$$

$$[\underline{n}_{\Gamma_1}, \underline{E}_{\Gamma_1}](\underline{x}) = \underline{g}_{\Gamma_1}(\underline{x}), \quad \underline{x} \in \Gamma_1. \tag{5.9}$$

We assume that there exists a unique function $\underline{F}$ defined in $\mathbf{R}^3 \backslash (D_{\Gamma_1} \cap D_{\Gamma_2})$ solution of (5.6)–(5.8) in $\mathbf{R}^3 \backslash (\overline{D_{\Gamma_1} \cap D_{\Gamma_2}})$ that coincides with $\underline{E}_{\Gamma_1}$ in $\mathbf{R}^3 \backslash \overline{D_{\Gamma_1}}$, and that belongs to $\widetilde{\mathscr{H}}$ [see (2.33)] and whose components belong to $\widetilde{\mathscr{O}}$ [see (2.31)] when D_ρ is replaced by $\mathbf{R}^3 \backslash (\overline{D_{\Gamma_1} \cap D_{\Gamma_2}})$. Then we define

$$\underline{g}_{\Gamma_2}(\underline{x}) = [\underline{n}_{\Gamma_2}, \underline{F}](\underline{x}), \quad \underline{x} \in \Gamma_2. \tag{5.10}$$

In this section we choose

$$\rho_1(x_1,x_2)=0, \quad (x_1,x_2)^T\in\mathbf{R}^2, \tag{5.11}$$

$$\rho_2(x_1,x_2)=\rho(x_1,x_2), \quad (x_1,x_2)^T\in\mathbf{R}^2. \tag{5.12}$$

We have $\Gamma_1=\{x_3=0\}$, $\Gamma_2=\partial D$, $D_{\Gamma_1}=\{\underline{x}\in\mathbf{R}^3|x_3<0\}$ and $D_{\Gamma_2}=D$, $\mathscr{H}_{\Gamma_2}=\widetilde{\mathscr{H}}$, with $\widetilde{\mathscr{H}}$ given by (1.13). With this particular choice we have

$$\widetilde{M}=\widetilde{L}_{\Gamma_2}; \tag{5.13}$$

moreover,

$$\widetilde{M}=\widetilde{G}\widetilde{L}_{\Gamma_1}\widetilde{G}^{-1}. \tag{5.14}$$

It is easy to see that $\widetilde{L}_{\Gamma_l}$, $l=1,2$, are linear transformation of $\mathscr{H}_{\Gamma_l}$ into $\mathscr{H}_{\Gamma_l}$, $l=1,2$, and $\widetilde{G}$ is a linear transformation of $\mathscr{H}_{\Gamma_1}$ into $\mathscr{H}_{\Gamma_2}$ so that $\widetilde{L}_{\Gamma_l}=((\widetilde{L}_{\Gamma_l,ij}))$, $\widetilde{G}=((\widetilde{G}_{ij}))$, $i,j=1,2,3$, $l=1,2$, can be represented by three-by-three operator-valued matrices. From (5.13) we have

$$\widetilde{M}=((\widetilde{M}_{ij})), \quad \widetilde{M}_{ij}=\widetilde{L}_{\Gamma_2,ij}, \quad i,j=1,2,3. \tag{5.15}$$

The computational method proposed here is a consequence of a nonlocal expansion ''in powers of ρ'' of $\widetilde{M}$ (see Proposition 5.9). The expansion is obtained using (5.14) and expanding the elements $\widetilde{M}_{ij}$, $i,j=1,2,3$, of the operator-valued matrix $\widetilde{M}$. Different choices of the reference surface $\Gamma_1=\{x_3=0\}$ generate different expansions of the operator $\widetilde{M}$ analogous to the one derived here. We note that the procedure to construct the operators $\widetilde{G}$, $\widetilde{L}_{\Gamma_1}$ is only formal. In fact, the existence of the operator $\widetilde{G}$ is based on the assumption that there exists a unique function $\underline{F}$ solution of (5.6)–(5.8) in $\mathbf{R}^3\backslash(\overline{D_{\Gamma_1}\cap D_{\Gamma_2}})$ that coincides in $\mathbf{R}^3\backslash\overline{D_{\Gamma_1}}$ with the unique solution $\underline{E}_{\Gamma_1}$ of the boundary value problem (5.6)–(5.9). Moreover, we assume that $\underline{F}\in\widetilde{\mathscr{H}}$ with $\widetilde{\mathscr{H}}$ given by (2.33). This is not proved here and is far from obvious. Moreover, the expansion of $\widetilde{M}$ is formal, that is, its convergence is not proved.

We construct now the expansion ''in powers of ρ'' of $\widetilde{M}$. Let $\widetilde{q}$, $\widetilde{q}_j$, $j=1,2$, and $\widetilde{Z}$ be the operators given by (2.27), (2.28), and (2.37), respectively. From (2.37) we have (formally)

$$\widetilde{Z}^{-1}=\sum_{m=0}^{\infty}(-1)^m\frac{1}{m!}\rho^m(\iota\widetilde{q})^m. \tag{5.16}$$

Lemma 5.1: Let $\widetilde{\mathscr{H}}$ be given by (2.33), $\underline{E}$ be the solution of the boundary value problem (1.6)–(1.9), let $\underline{E}\in\widetilde{\mathscr{H}}$. We have

$$\widetilde{Z}:E_j(x_1,x_2,0)\rightarrow E_j(x_1,x_2,\rho(x_1,x_2)), \quad j=1,2,3,(x_1,x_2)^T\in\mathbf{R}^2, \tag{5.17}$$

$$E_3(\underline{x})=-(\widetilde{q}^{-1}\widetilde{q}_1E_1)(\underline{x})-(\widetilde{q}^{-1}\widetilde{q}_2E_2)(\underline{x}), \quad \underline{x}\in\Gamma_1, \tag{5.18}$$

$$E_3(\underline{x})=-(\widetilde{Z}\widetilde{q}^{-1}\widetilde{q}_1\widetilde{Z}^{-1}E_1)(\underline{x})-(\widetilde{Z}\widetilde{q}^{-1}\widetilde{q}_2\widetilde{Z}^{-1}E_2)(\underline{x}), \quad \underline{x}\in\Gamma_2. \tag{5.19}$$

Proof: The thesis follows immediately from Lemmas 2.5 and 2.6. ■

Lemma 5.2: Let $\widetilde{\mathscr{Q}}$ be given by (2.31) and let $\widetilde{D}:\widetilde{\mathscr{Q}}\rightarrow\widetilde{\mathscr{Q}}$, $\widetilde{D}_j:\widetilde{\mathscr{Q}}\rightarrow\widetilde{\mathscr{Q}}$, $j=1,2$, be the operators defined as follows:

$$\widetilde{D}=\widetilde{Z}(\iota\widetilde{q})\widetilde{Z}^{-1}, \tag{5.20}$$

$$\widetilde{D}_j=\widetilde{Z}(\widetilde{q}^{-1},\widetilde{q}_j)\widetilde{Z}^{-1},\quad j=1,2. \tag{5.21}$$

Then we have

$$\widetilde{D}_j\widetilde{D}=\widetilde{D}\widetilde{D}_j,\quad j=1,2,\quad \widetilde{D}_1\widetilde{D}_2=\widetilde{D}_2\widetilde{D}_1. \tag{5.22}$$

Proof: The proof follows from a simple computation based on the definitions of the operators $\widetilde{Z},\widetilde{q},\widetilde{q}_j,j=1,2$. ■

In the following, we denote with I the identity operator.

Lemma 5.3: Let $\widetilde{L}_{\Gamma_1}$ be the operator defined by (5.4) when $\Gamma_1=\{x_3=0\}$. Then we have

$$\widetilde{L}_{\Gamma_1}=\begin{pmatrix} \iota\widetilde{q}_1\widetilde{q}^{-1}\widetilde{q}_2 & -\iota(\widetilde{q}+\widetilde{q}_1\widetilde{q}^{-1}\widetilde{q}_1) & 0\\ \iota(\widetilde{q}+\widetilde{q}_2\widetilde{q}^{-1}\widetilde{q}_2) & -\iota\widetilde{q}_2\widetilde{q}^{-1}\widetilde{q}_1 & 0\\ 0 & 0 & I\end{pmatrix}. \tag{5.23}$$

Proof: Let $\underline{E}_{\Gamma_1}$ be the solution of the boundary value problem (5.6)–(5.9). The proof follows evaluating curl $\underline{E}_{\Gamma_1}(\underline{x})$ on Γ_1 through the representation formula in (2.33) and using formula (5.18), Lemmas 2.5 and 2.6, and the fact that since $\Gamma_1=\{x_3=0\}$ we have

$$\underline{g}_{\Gamma_1}(\underline{x})=[\underline{n}_{\Gamma_1},\ \underline{E}_{\Gamma_1}](\underline{x})=\begin{pmatrix} 0 & -1 & 0\\ 1 & 0 & 0\\ 0 & 0 & 1\end{pmatrix}\begin{pmatrix} E_{\Gamma_1,1}(\underline{x})\\ E_{\Gamma_1,2}(\underline{x})\\ 0\end{pmatrix},\quad \underline{x}\in\Gamma_1. \tag{5.24}$$

This concludes the proof. ■

Lemma 5.4: Let $\widetilde{Z}$, $\widetilde{G}$, and $\widetilde{D}_j$, $j=1,2$, be the operators given by (2.37), (5.5), and (5.21). Then we have

$$\widetilde{G}=\begin{pmatrix} \left(I-\dfrac{\partial\rho}{\partial x_2}\widetilde{D}_2\right)\widetilde{Z} & \dfrac{\partial\rho}{\partial x_2}\widetilde{D}_1\widetilde{Z} & 0\\ \dfrac{\partial\rho}{\partial x_1}\widetilde{D}_2\widetilde{Z} & \left(I-\dfrac{\partial\rho}{\partial x_1}\widetilde{D}_1\right)\widetilde{Z} & 0\\ \dfrac{\partial\rho}{\partial x_1}\widetilde{Z} & \dfrac{\partial\rho}{\partial x_2}\widetilde{Z} & \widetilde{Z}\end{pmatrix}. \tag{5.25}$$

Proof: We have assumed that there exists a function $\underline{F}(\underline{x})\in\widetilde{\mathscr{H}}$ [see (2.33)] solution of (5.6)–(5.8) in $\mathbf{R}^3\backslash\overline{D_{\Gamma_1}\cap D_{\Gamma_2}}$ that coincides in $\mathbf{R}^3\backslash\overline{D_{\Gamma_1}}$ with the unique solution of the boundary value problem (5.6)–(5.9). The proof follows using (5.19) and (5.24) from the fact that $\underline{n}_{\Gamma_1}(\underline{x})=(0,0,1)^T,\forall\underline{x}\in\Gamma_1$, computing the function $\underline{g}_{\Gamma_2}(\underline{x}),\underline{x}\in\Gamma_2$, given by (5.10). ■

Proposition 5.5: Let $\widetilde{Z}^{-1},\widetilde{G}^{-1}$ be the (formal) inverse of the operators $\widetilde{Z},\widetilde{G}$ respectively. We have

$$\widetilde{G}^{-1}=\begin{pmatrix} \widetilde{Z}^{-1}\left(I+\dfrac{\partial\rho}{\partial x_2}\widetilde{h}^{-1}\widetilde{D}_2\right) & -\widetilde{Z}^{-1}\dfrac{\partial\rho}{\partial x_2}\widetilde{h}^{-1}\widetilde{D}_1 & 0\\ -\widetilde{Z}^{-1}\dfrac{\partial\rho}{\partial x_1}\widetilde{h}^{-1}\widetilde{D}_2 & \widetilde{Z}^{-1}\left(I+\dfrac{\partial\rho}{\partial x_1}\widetilde{h}^{-1}\widetilde{D}_1\right) & 0\\ -\widetilde{Z}^{-1}\dfrac{\partial\rho}{\partial x_1} & -\widetilde{Z}^{-1}\dfrac{\partial\rho}{\partial x_2} & \widetilde{Z}^{-1}\end{pmatrix}, \tag{5.26}$$

where $\tilde{h}$ is the operator defined by

$$\tilde{h}=I-\tilde{D}_2\frac{\partial\rho}{\partial x_2}-\tilde{D}_1\frac{\partial\rho}{\partial x_1}, \tag{5.27}$$

and $\tilde{h}^{-1}$ is the (formal) inverse operator of $\tilde{h}$.

Proof (formal): From (5.25) we have

$$\tilde{G}\begin{pmatrix}\tilde{Z}^{-1}&0&0\\0&\tilde{Z}^{-1}&0\\0&0&\tilde{Z}^{-1}\end{pmatrix}=\begin{pmatrix}I&0&0\\0&I&0\\0&0&I\end{pmatrix}+\begin{pmatrix}\frac{\partial\rho}{\partial x_2}&0\\-\frac{\partial\rho}{\partial x_1}&0\\0&I\end{pmatrix}\begin{pmatrix}-\tilde{D}_2&\tilde{D}_1&0\\\frac{\partial\rho}{\partial x_1}&\frac{\partial\rho}{\partial x_2}&0\end{pmatrix}. \tag{5.28}$$

Now formula (5.26) follows from a simple computation. ■

Proposition 5.6: Let $\mathscr{F}$, $\tilde{L}_{\Gamma_1}$ be the operators in (2.25) and (5.23) and p, l_j, $j=1,2$, be the maximal multiplication operators defined in Sec. II. Then the inverse operator $\tilde{L}_{\Gamma_1}^{-1}$ is (formally) given by

$$\tilde{L}_{\Gamma_1}^{-1}=\begin{pmatrix}\tilde{l}_{11}&\tilde{l}_{12}&0\\\tilde{l}_{21}&\tilde{l}_{22}&0\\0&0&I\end{pmatrix}, \tag{5.29}$$

where

$$\tilde{l}_{11}=\frac{\iota}{k_0^2}\,\mathscr{F}^{-1}(l_1p^{-1}l_2)\mathscr{F}, \tag{5.30}$$

$$\tilde{l}_{12}=-\frac{\iota}{k_0^2}(\mathscr{F}^{-1}(p)\mathscr{F}+\mathscr{F}^{-1}(l_1p^{-1}l_1)\mathscr{F}), \tag{5.31}$$

$$\tilde{l}_{21}=\frac{\iota}{k_0^2}(\mathscr{F}^{-1}(p)\mathscr{F}+\mathscr{F}^{-1}(l_2p^{-1}l_2)\mathscr{F}), \tag{5.32}$$

$$\tilde{l}_{22}=-\tilde{l}_{11}. \tag{5.33}$$

Proof (formal): The proof follows from formula (5.23) and the definitions (2.27) and (2.28). ■

Let us define the following operators $\tilde{V}_j:\tilde{\mathscr{Q}}\to\tilde{\mathscr{Q}}$, $j=1,2$:

$$\tilde{V}_j=\tilde{Z}(\iota\tilde{q}_j)\tilde{Z}^{-1},\quad j=1,2. \tag{5.34}$$

We have the following lemma.

Lemma 5.7: Let $\tilde{M}$ be given by (5.14), $\tilde{M}=((\tilde{M}_{ij}))$, $i,j=1,2,3$, and let $\tilde{D},\tilde{D}_j,\tilde{h},\tilde{V}_j$, $j=1,2$, be the operators given by (5.20), (5.21), (5.27), (5.34) respectively. Then we have

$$\tilde{M}_{11}=\frac{\partial\rho}{\partial x_2}\tilde{V}_1+\tilde{V}_1\tilde{h}^{-1}\tilde{D}_2+\tilde{D}\frac{\partial\rho}{\partial x_1}\tilde{h}^{-1}\tilde{D}_2+\frac{\partial\rho}{\partial x_2}\left(\tilde{V}_1\frac{\partial\rho}{\partial x_2}-\tilde{V}_2\frac{\partial\rho}{\partial x_1}\right)\tilde{h}^{-1}\tilde{D}_2, \tag{5.35}$$

$$\widetilde{M}_{12}=-\widetilde{D}+\frac{\partial\rho}{\partial x_2}\,\widetilde{V}_2-\widetilde{V}_1\widetilde{h}^{-1}\widetilde{D}_1-\widetilde{D}\,\frac{\partial\rho}{\partial x_1}\,\widetilde{h}^{-1}\widetilde{D}_1-\frac{\partial\rho}{\partial x_2}\left(\widetilde{V}_1\,\frac{\partial\rho}{\partial x_2}-\widetilde{V}_2\,\frac{\partial\rho}{\partial x_1}\right)\widetilde{h}^{-1}\widetilde{D}_1, \quad (5.36)$$

$$\widetilde{M}_{21}=\widetilde{D}-\frac{\partial\rho}{\partial x_1}\,\widetilde{V}_1+\widetilde{V}_2\widetilde{h}^{-1}\widetilde{D}_2+\widetilde{D}\,\frac{\partial\rho}{\partial x_2}\,\widetilde{h}^{-1}\widetilde{D}_2+\frac{\partial\rho}{\partial x_1}\left(\widetilde{V}_1\,\frac{\partial\rho}{\partial x_2}-\widetilde{V}_2\,\frac{\partial\rho}{\partial x_1}\right)\widetilde{h}^{-1}\widetilde{D}_2, \quad (5.37)$$

$$\widetilde{M}_{22}=-\frac{\partial\rho}{\partial x_1}\,\widetilde{V}_2-\widetilde{V}_2\widetilde{h}^{-1}\widetilde{D}_1-\widetilde{D}\,\frac{\partial\rho}{\partial x_2}\,\widetilde{h}^{-1}\widetilde{D}_1-\frac{\partial\rho}{\partial x_1}\left(\widetilde{V}_1\,\frac{\partial\rho}{\partial x_2}-\widetilde{V}_2\,\frac{\partial\rho}{\partial x_1}\right)\widetilde{h}^{-1}\widetilde{D}_1, \quad (5.38)$$

$$\widetilde{M}_{31}=-\frac{\partial\rho}{\partial x_1}+\frac{\partial\rho}{\partial x_2}\,\widetilde{D}+\left(\frac{\partial\rho}{\partial x_1}\,\widetilde{V}_1+\frac{\partial\rho}{\partial x_2}\,\widetilde{V}_2\right)\widetilde{h}^{-1}\widetilde{D}_2+\left(\frac{\partial\rho}{\partial x_1}\,\widetilde{D}\,\frac{\partial\rho}{\partial x_1}+\frac{\partial\rho}{\partial x_2}\,\widetilde{D}\,\frac{\partial\rho}{\partial x_2}\right)\widetilde{h}^{-1}\widetilde{D}_2, \quad (5.39)$$

$$\widetilde{M}_{32}=-\frac{\partial\rho}{\partial x_2}-\frac{\partial\rho}{\partial x_1}\,\widetilde{D}-\left(\frac{\partial\rho}{\partial x_1}\,\widetilde{V}_1+\frac{\partial\rho}{\partial x_2}\,\widetilde{V}_2\right)\widetilde{h}^{-1}\widetilde{D}_1-\left(\frac{\partial\rho}{\partial x_1}\,\widetilde{D}\,\frac{\partial\rho}{\partial x_1}+\frac{\partial\rho}{\partial x_2}\,\widetilde{D}\,\frac{\partial\rho}{\partial x_2}\right)\widetilde{h}^{-1}\widetilde{D}_1, \quad (5.40)$$

$$\widetilde{M}_{13}=0, \quad \widetilde{M}_{23}=0, \quad \widetilde{M}_{33}=I. \quad (5.41)$$

Proof: The proof follows from (5.14), (5.23), (5.25), and (5.26) by a simple computation. ■

To obtain the formal expansion ''in powers of ρ'' of $\widetilde{M}$ we need of the expansions of $\widetilde{D},\widetilde{D}_j,\widetilde{h},\widetilde{V}_j$, $j=1,2$, that appear in the elements $((\widetilde{M}_{ij}))$, $i,j=1,2,3$, of $\widetilde{M}$. We have the following proposition.

Proposition 5.8: Let $\widetilde{D},\widetilde{D}_j,\widetilde{h},\widetilde{V}_j$, $j=1,2$, be given by (5.20), (5.21), (5.27), and (5.34). We denote with δ the functional differentiation with respect to $\rho(\underline{x})$. We have

$$\widetilde{D}=\sum_{m=0}^{\infty}\widetilde{D}_m, \quad \widetilde{D}_j=\sum_{m=0}^{\infty}\widetilde{D}_{j,m}, \quad \widetilde{V}_j=\sum_{m=0}^{\infty}\widetilde{V}_{j,m}, \quad \widetilde{h}=\sum_{m=0}^{\infty}\widetilde{h}_m, \quad j=1,2, \quad (5.42)$$

where

$$\widetilde{D}_m=\frac{1}{m!}\,(\delta^m\widetilde{D})[\rho], \quad \widetilde{D}_{j,m}=\frac{1}{m!}\,(\delta^m\widetilde{D}_j)[\rho], \quad \widetilde{V}_{j,m}=\frac{1}{m!}\,(\delta^m\widetilde{V}_j)[\rho], \quad (5.43)$$

$$\widetilde{h}_0=I, \quad \widetilde{h}_m=-\frac{1}{m!}\left(\widetilde{D}_{2,m-1}\,\frac{\partial\rho}{\partial x_2}+\widetilde{D}_{1,m-1}\,\frac{\partial\rho}{\partial x_1}\right), \quad m=1,2,\ldots\,. \quad (5.44)$$

In particular the first two terms of these expansions ''in powers of ρ'' are given by

$$\widetilde{D}_0=\iota\widetilde{q}, \quad \widetilde{D}_1=(\rho(\iota\widetilde{q})-(\iota\widetilde{q})\rho)(\iota\widetilde{q}), \quad (5.45)$$

$$\widetilde{D}_{j,0}=\widetilde{q}^{-1}\widetilde{q}_j, \quad \widetilde{D}_{j,1}=(\rho(\widetilde{q}^{-1}\widetilde{q}_j)-(\widetilde{q}^{-1}\widetilde{q}_j)\rho)(\iota\widetilde{q}), \quad j=1,2, \quad (5.46)$$

$$\widetilde{V}_{j,0}=\iota\widetilde{q}_j, \quad \widetilde{V}_{j,1}=(\rho(\iota\widetilde{q}_j)-(\iota\widetilde{q}_j)\rho)(\iota\widetilde{q}_j), \quad j=1,2, \quad (5.47)$$

$$\widetilde{h}_0^{-1}=I, \quad \widetilde{h}_1^{-1}=\widetilde{q}^{-1}\widetilde{q}_2\,\frac{\partial\rho}{\partial x_2}+\widetilde{q}^{-1}\widetilde{q}_1\,\frac{\partial\rho}{\partial x_1}. \quad (5.48)$$

Proof (formal): The formulas in (5.43) are obtained from Taylor's formula with base point $\rho=\rho_1(\underline{x})=0$, $\underline{x}=(x_1,x_2)^T\in\mathbf{R}^2$. We prove formulas (5.46) for $\widetilde{D}_j$, $j=1,2$. The (formal) proof of the expansion of $\widetilde{D}$ and $\widetilde{V}_j$, $j=1,2$, are analogous. The operators $\widetilde{D}_j$, $j=1,2$, satisfy the following relation:

$$\widetilde{D}_j\widetilde{Z}=\widetilde{Z}(\iota\widetilde{q})^{-1}(\iota\widetilde{q}_j),\quad j=1,2. \tag{5.49}$$

A variation in $\widetilde{Z}$ induces a variation in $\widetilde{D}_j$, $j=1,2$, as follows:

$$\delta\widetilde{D}_j=\delta\widetilde{Z}(\iota\widetilde{q})^{-1}(\iota\widetilde{q}_j)\widetilde{Z}^{-1}-\widetilde{D}_j\delta\widetilde{Z}\widetilde{Z}^{-1}=\delta\rho\widetilde{D}\widetilde{D}_j-\widetilde{D}_j\delta\rho\widetilde{D}+(\delta\rho\widetilde{D}_j\widetilde{D}-\delta\rho\widetilde{D}_j\widetilde{D}),\quad j=1,2. \tag{5.50}$$

From (5.50), applying Lemma 5.2 we obtain

$$\delta\widetilde{D}_j=(\delta\rho\widetilde{D}_j-\widetilde{D}_j\delta\rho)\widetilde{D},\quad j=1,2. \tag{5.51}$$

Using the Taylor's formula of $\widetilde{D}_j$, $j=1,2$, with base point $\rho=\rho_1(\underline{x})=0$, $\underline{x}=(x_1,x_2)^T\in\mathbf{R}^2$, that is,

$$\widetilde{D}_j[\rho_1+\delta\rho]=\widetilde{D}_j[\rho_1]+\delta\widetilde{D}_j+\cdots,\quad j=1,2, \tag{5.52}$$

and choosing $\delta\rho(x_1,x_2)=\rho(x_1,x_2)$, we have

$$\widetilde{D}_j[\rho]=\widetilde{D}_j[0]+(\delta\widetilde{D}_j)[0]+\tfrac{1}{2}(\delta^2\widetilde{D}_j)[0]+\cdots,\quad j=1,2. \tag{5.53}$$

Since $\widetilde{Z}[0]=I$, $\widetilde{D}[0]=\iota\widetilde{q}$, $\widetilde{D}_j[0]=\widetilde{q}^{-1}\widetilde{q}_j$, $j=1,2$, from (5.50) and (5.53) we obtain (5.46). Formula (5.44) follows from the definition of $\widetilde{h}$ and (5.43). Formula (5.48) is obtained by applying the Cauchy rule to the product of the series expansion ''in powers of ρ'' of the operators $\widetilde{h}$ and $\widetilde{h}^{-1}$.■

Proposition 5.9: Let $\widetilde{M}$ given by (5.14). Then $\widetilde{M}=\Sigma_{m=0}^{\infty}\widetilde{M}_m$, $\widetilde{M}_m=((\widetilde{M}_{ij,m}))$, $i,j=1,2,3$, $m=0,1,2,...$, where $((\widetilde{M}_{ij,m}))$, $i,j=1,2,3$, are obtained plugging the expansions in (5.42) into the formulas (5.35)–(5.41).

Proof (formal): The proof is a straightforward consequence of Lemma 5.7 and Proposition 5.8. ■

We note that due to the definitions of the operators $\widetilde{q},\widetilde{q}_j$, $j=1,2$, the computation of the expansion of the operator $\widetilde{M}$ involves only quadratures and is fully parallelizable.

Proposition 5.10: Let $\widetilde{M}=\Sigma_{m=0}^{\infty}\widetilde{M}_m$ be the formal expansion ''in powers of ρ'' of the operator $\widetilde{M}$ obtained in Proposition 5.9. The function $\underline{E}(\underline{x})$ solution of (1.6)–(1.9) can be (formally) expanded as follows:

$$\underline{E}(\underline{x})=\int_{\partial D}\mathrm{curl}_{\underline{x}}\{\Phi(\underline{x},\underline{y})\underline{g}(\underline{y})\}ds(\underline{y})+\frac{1}{k_0^2}\sum_{m=0}^{\infty}\int_{\partial D}\mathrm{curl}_{\underline{x}}\,\mathrm{curl}_{\underline{x}}\{\Phi(\underline{x},\underline{y})(\widetilde{M}_m\underline{g})(\underline{y})\}ds(\underline{y}),$$
$$\underline{x}\in D^c, \tag{5.54}$$

where Φ is given by (1.12).

Proof (formal): The proof follows immediately from (5.13), Proposition 5.9, and the integral representation formula (3.5) of Theorem 3.2. ■

Formula (5.54) can be used to approximate $\underline{E}(\underline{x})$ truncating the series on the right-hand side of (5.54) and using numerical quadrature formulas to compute the relevant integrals, so that the computation of $\underline{E}(\underline{x})$ is also fully parallelizable.

Finally we give the first two terms of the expansion ''in powers of ρ'' of the operator $\widetilde{M}$ that are used to obtain the numerical results of Sec. VI. A simple computation gives

$$\widetilde{M}_{11,0}=\iota\mathscr{F}^{-1}l_1p^{-1}l_2\mathscr{F}, \tag{5.55}$$

$$\widetilde{M}_{11,1}=+\mathscr{F}^{-1}l_1p^{-1}l_2\mathscr{F}\rho\mathscr{F}^{-1}p\mathscr{F}-\rho\mathscr{F}^{-1}l_1l_2\mathscr{F}+\iota\Bigg(\frac{\partial\rho}{\partial x_2}\mathscr{F}^{-1}l_1\mathscr{F}$$
$$+\mathscr{F}^{-1}l_1p^{-1}l_2\mathscr{F}\frac{\partial\rho}{\partial x_2}\mathscr{F}^{-1}p^{-1}l_2\mathscr{F}+\mathscr{F}^{-1}l_1p^{-1}l_1\mathscr{F}\frac{\partial\rho}{\partial x_1}\mathscr{F}^{-1}p^{-1}l_2\mathscr{F}$$
$$+\mathscr{F}^{-1}p\mathscr{F}\frac{\partial\rho}{\partial x_1}\mathscr{F}^{-1}p^{-1}l_2\mathscr{F}\Bigg), \tag{5.56}$$

$$\widetilde{M}_{12,0}=-\iota(\mathscr{F}^{-1}p\mathscr{F}+\mathscr{F}^{-1}l_1p^{-1}l_1\mathscr{F}), \tag{5.57}$$

$$\widetilde{M}_{12,1}=-\mathscr{F}^{-1}p\mathscr{F}\rho\mathscr{F}^{-1}p\mathscr{F}-\mathscr{F}^{-1}l_1p^{-1}l_1\mathscr{F}\rho\mathscr{F}^{-1}p\mathscr{F}+\rho k_0^2-\rho\mathscr{F}^{-1}l_2^2\mathscr{F}$$
$$+\iota\Bigg(-\mathscr{F}^{-1}l_1p^{-1}l_1\mathscr{F}\frac{\partial\rho}{\partial x_1}\mathscr{F}^{-1}p^{-1}l_1\mathscr{F}+\frac{\partial\rho}{\partial x_2}\mathscr{F}^{-1}l_2\mathscr{F}-\mathscr{F}^{-1}l_1p^{-1}l_2$$
$$\mathscr{F}\frac{\partial\rho}{\partial x_2}\mathscr{F}^{-1}p^{-1}l_1\mathscr{F}-\mathscr{F}^{-1}p\mathscr{F}\frac{\partial\rho}{\partial x_1}\mathscr{F}^{-1}p^{-1}l_1\mathscr{F}\Bigg), \tag{5.58}$$

$$\widetilde{M}_{21,0}=\iota(\mathscr{F}^{-1}p\mathscr{F}+\mathscr{F}^{-1}l_2p^{-1}l_2\mathscr{F}), \tag{5.59}$$

$$\widetilde{M}_{21,1}=+\mathscr{F}^{-1}p\mathscr{F}\rho\mathscr{F}^{-1}p\mathscr{F}+\mathscr{F}^{-1}l_2p^{-1}l_2\mathscr{F}\rho\mathscr{F}^{-1}p\mathscr{F}-\rho k_0^2+\rho\mathscr{F}^{-1}l_1^2\mathscr{F}$$
$$+\iota\Bigg(+\mathscr{F}^{-1}l_2p^{-1}l_2\mathscr{F}\frac{\partial\rho}{\partial x_2}\mathscr{F}^{-1}p^{-1}l_2\mathscr{F}-\frac{\partial\rho}{\partial x_1}\mathscr{F}^{-1}l_1\mathscr{F}+\mathscr{F}^{-1}l_1p^{-1}l_2\mathscr{F}\frac{\partial\rho}{\partial x_1}$$
$$\mathscr{F}^{-1}p^{-1}l_2\mathscr{F}+\mathscr{F}^{-1}p\mathscr{F}\frac{\partial\rho}{\partial x_2}\mathscr{F}^{-1}p^{-1}l_2\mathscr{F}\Bigg), \tag{5.60}$$

$$\widetilde{M}_{22,0}=-\iota\mathscr{F}^{-1}l_1p^{-1}l_2\mathscr{F}, \tag{5.61}$$

$$\widetilde{M}_{22,1}=-\mathscr{F}^{-1}l_1p^{-1}l_2\mathscr{F}\rho\mathscr{F}^{-1}p\mathscr{F}+\rho\mathscr{F}^{-1}l_1l_2\mathscr{F}+\iota\Bigg(-\frac{\partial\rho}{\partial x_1}\mathscr{F}^{-1}l_2\mathscr{F}$$
$$-\mathscr{F}^{-1}l_1p^{-1}l_2\mathscr{F}\frac{\partial\rho}{\partial x_1}\mathscr{F}^{-1}p^{-1}l_1\mathscr{F}-\mathscr{F}^{-1}l_2p^{-1}l_2\mathscr{F}\frac{\partial\rho}{\partial x_2}\mathscr{F}^{-1}p^{-1}l_1\mathscr{F}$$
$$-\mathscr{F}^{-1}p\mathscr{F}\frac{\partial\rho}{\partial x_2}\mathscr{F}^{-1}p^{-1}l_1\mathscr{F}\Bigg), \tag{5.62}$$

$$\widetilde{M}_{31,0}=0, \tag{5.63}$$

$$\widetilde{M}_{31,1}=\iota\frac{\partial\rho}{\partial x_1}\mathscr{F}^{-1}l_1p^{-1}l_2\mathscr{F}-\frac{\partial\rho}{\partial x_1}+\iota\frac{\partial\rho}{\partial x_2}\mathscr{F}^{-1}p\mathscr{F}+\iota\frac{\partial\rho}{\partial x_2}\mathscr{F}^{-1}l_2p^{-1}l_2\mathscr{F}, \tag{5.64}$$

$$\widetilde{M}_{33,0}=I, \tag{5.71}$$

$$\widetilde{M}_{33,1}=0. \tag{5.72}$$

VI. SOME NUMERICAL RESULTS

In this section we show some numerical results obtained computing the electric field $\underline{E}^2(\underline{x})$ of (1.10).

We compute an approximation of $\underline{E}^2(\underline{x})$ using formula (5.54) when $\Gamma_2=\partial D=\{x_3=\rho(x_1,x_2)\}$ [see (1.3)] and the reference surface is $\Gamma_1=\{x_3=0\}$. In particular, the first two terms of the expansion ''in powers of ρ'' of $\widetilde{M}$ are used [see (5.55)–(5.72)]. We remind the reader that the choice of the reference surface influences the numerical approximation of the electric field $\underline{E}^2(\underline{x})$. In fact, to obtain a good approximation using only a few terms of the expansion (5.54), we can choose $\Gamma_1=\{x_3=c\}$, where c is the constant solution of the following problem:

$$\min_{c\in\mathbf{R}} \max_{\underline{x}\in\mathbf{R}^2} |\rho(\underline{x})-c|. \tag{6.1}$$

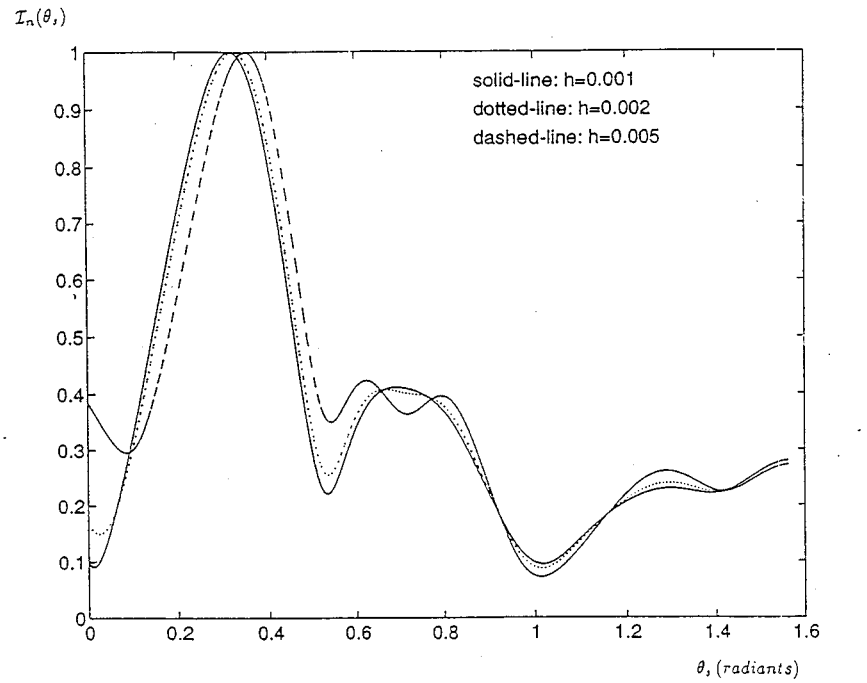

FIG. 1. Normalized scattering pattern as a function of the scattered angle θ_s.

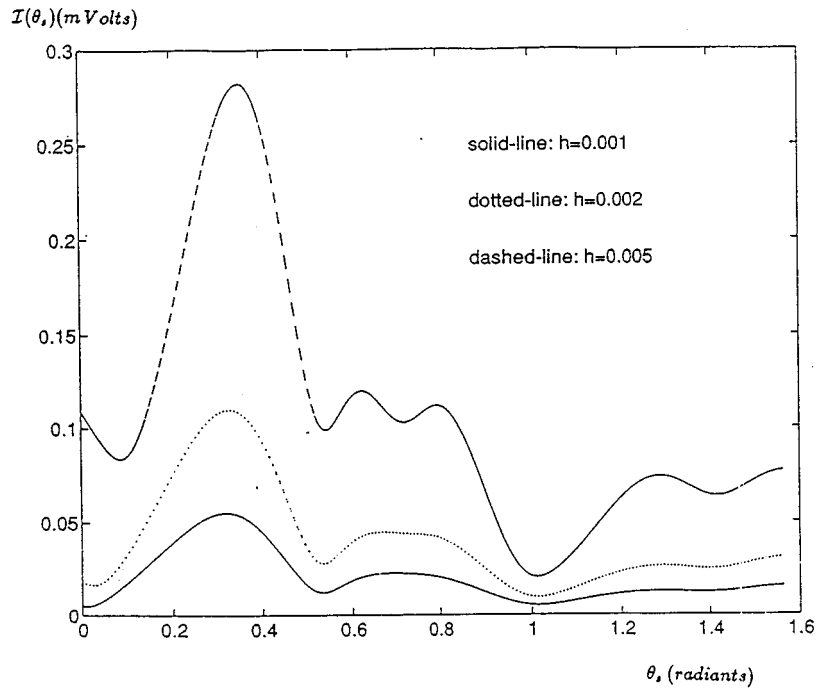

FIG. 2. This figure is analogous to Fig. 1 with the scattering intensity patterns instead of the normalized ones.

Formula (5.54) with the series truncated at $m=1$ has been implemented in a FORTRAN program. The computations are performed on a VAX-ALPHA 7000-610, using VMS ALPHA V1.5 double-precision arithmetic. We use quadrature formulas presented in Ref. 11.

In the numerical experiments we have chosen a plane linearly polarized incident wave; that is,

$$\underline{E}^i(\underline{x})=\underline{\Omega}e^{\iota k_0(\underline{x},\underline{\alpha})}, \quad \underline{x}\in\mathbf{R}^3, \tag{6.2}$$

where $\underline{\Omega}\in\mathbf{R}^3$ is the polarization vector, $\underline{\alpha}\in\mathbf{R}^3$, $\|\underline{\alpha}\|=1$, is the propagation direction of the incoming electric field, and $k_0>0$ is the wave number. Moreover, we assume $\operatorname{div}\underline{E}^i(\underline{x})=0$, $\underline{x}\in\mathbf{R}^3\backslash D$; that is,

$$(\underline{\Omega},\underline{\alpha})=0. \tag{6.3}$$

The function ρ [see (1.1)–(1.3)] is given by

$$\rho(x_1,x_2)=\begin{cases} h\ \sin(fx_1)e^{-1/(1-x_1^2-x_2^2)}, & x_1^2+x_2^2<1, \\ 0, & x_1^2+x_2^2\geqslant 1, \end{cases} \tag{6.4}$$

with f and h positive constants. The propagation direction $\underline{\alpha}$ is given by

$$\underline{\alpha}=(\cos\ \varphi_i\ \sin\ \theta_i,\sin\ \varphi_i\ \sin\ \theta_i,-\cos\ \theta_i)^T, \quad 0\leqslant\varphi_i<2\pi,0\leqslant\theta_i<\pi/2. \tag{6.5}$$

All of the calculations presented here are for normal incident $\theta_i=0$, and φ_i arbitrary, for the polarization vector $\underline{\Omega}=(1,1,0)^T$, for different values of the scattered angle θ_s and for $\varphi_s=\pi$.

The scattering intensity $\mathcal{I}(\theta_s)$ and the associated normalized intensity $\mathcal{I}_n(\theta_s)$ are defined by

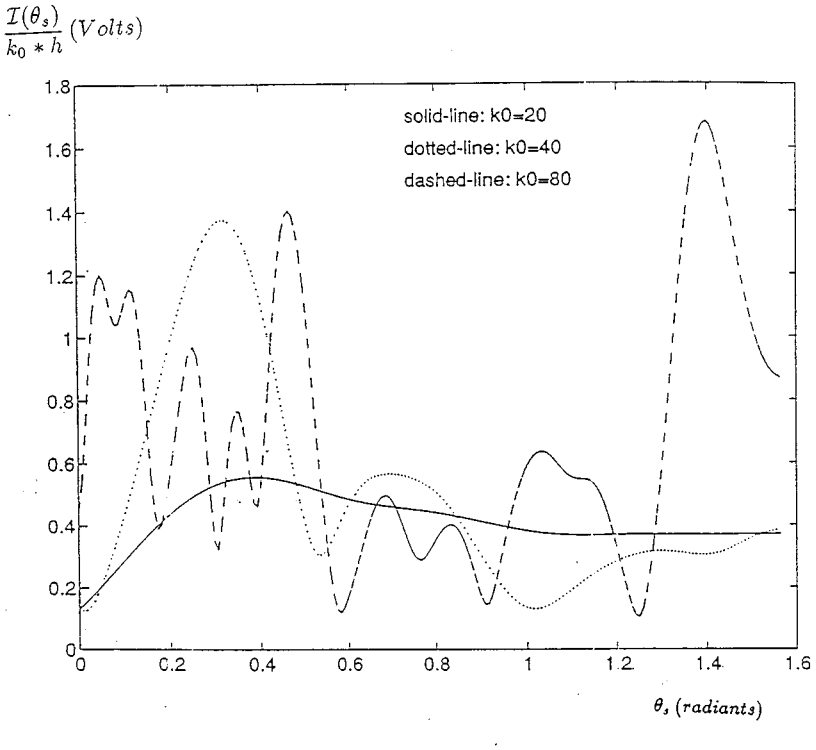

FIG. 3. Intensity patterns divided by k_0h as a function of the scattered angle θ_s.

$$\mathcal{I}(\theta_s) := \frac{|\underline{F}_0(\theta_s,\varphi_s)|}{k_0}, \quad \varphi_s=\pi, \quad 0\leqslant\theta_s<\frac{\pi}{2}, \tag{6.6}$$

$$\mathcal{I}_n(\theta_s) := \frac{|\underline{F}_0(\theta_s,\varphi_s)|}{\max_{\theta_s}|\underline{F}_0(\theta_s,\varphi_s)|}, \quad \varphi_s=\pi, \quad 0\leqslant\theta_s<\frac{\pi}{2}, \tag{6.7}$$

where $\underline{F}_0$ is the electric far field associated with $\underline{E}^2$ [see (3.6)], and $|\underline{F}_0|^2 = (\underline{F}_0, \overline{\underline{F}_0})$. We note that three parameters determine the behavior of the scattered field $\underline{E}_2$: the roughness h, the period $L=2\pi/f$ of the corrugation of the surface ∂D, and the incident wave number k_0.

The following figures show that for sufficiently large values of k_0 when $h\ll 2\pi/k_0$, a Bragg-like structure is presented with periodicity L and split depth h.

Figure 1 shows normalized scattering patterns as a function of the scattered angle θ_s, calculated for $\varphi_s=\pi$, $k_0=40$, $f=48$, and various values of the roughness $h=0.001$, 0.002, and 0.005. These scattering intensity patterns show that the peaks of the intensity are more or less independent of the value of the roughness h.

Figure 2 is analogous to Fig. 1 with the scattering intensity patterns instead of the normalized ones. We can see that the intensity increases when the roughness increases.

Figure 3 shows the intensity patterns divided by k_0h as a function of the scattered angle θ_s for $h=0.001$, $k_0=20$, 40, and 80, and $f=8$. We note that the peaks are located at $\theta_s\approx\theta_{s,m}$, where $\theta_{s,m}$ according to Bragg law is given by $\theta_{s,m}=\arcsin(mf/k_0)$, $m=1,2,\ldots$.

Figure 4 shows the normalized intensity for $\theta_s=0$, i.e., the backscattering direction, as a function of the incident wave number, k_0, and for different values of f [see (6.4)], $f=128$, 192,

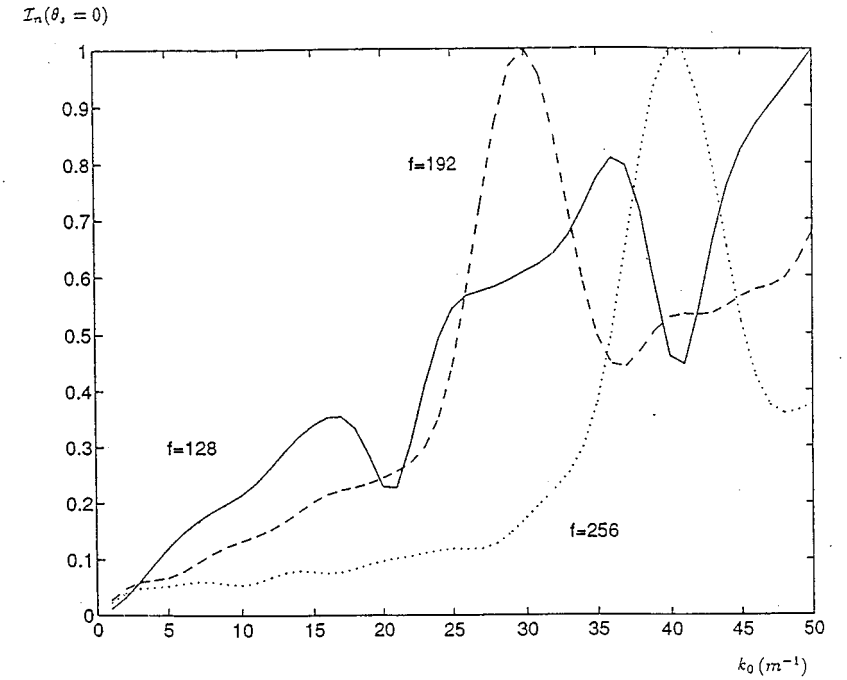

FIG. 4. Normalized intensity for $\theta_s=0$.

and 256. We note that a resonance phenomenon occurs, i.e., the first peak of each scattering pattern appears when $k_0/f \approx 0.15$.

(Received 27 July 1995; accepted for publication 12 February 1996)

After reviewing the complete Lie group for the full Boltzmann equation, it is shown that projective transformations play a special role in the general case, and the class of invariant solutions giving rise to homoenergetic affine flows is presented. Homoenergetic affine flows in the two-dimensional case [potential $U(r)\propto r^{-2}$] are considered in detail: It is shown that the general solution of this problem can be essentially simplified by projective transformations. © *1996 American Institute of Physics.* [S0022-2488(96)02505-9]

I. INTRODUCTION

The group analysis, which is one of the most powerful general methods in mathematical physics,[1,2] was recently applied to the full spatially inhomogeneous Boltzmann equation in Ref. 3, where the complete (with certain natural restrictions) Lie group was constructed.

As it occurs to many classical equations of mathematical physics (for example, Euler gas dynamics equations), almost all point symmetries of the Boltzmann equation can be easily found from physical considerations. The only exception, as in the case of Euler equations,[1] is perhaps the so-called *projective invariance*.[4,5] Many attempts to construct special classes of relatively simple solutions to the Boltzmann equation have been previously made by different authors[6–10] (see also Refs. 11 and 12 for a review) without any connection with group properties of the equation. However the well known results of Refs. 6–10 could be understood more deeply just on that basis. We should also mention Refs. 13–18, in which the related problems are treated by means of Lie group methods. However, all these articles are not concerned with the full Boltzmann equation, but with very special cases. In the present article we use the results of group analysis of the Boltzmann equation, with special attention to the projective symmetry and its consequences: the Lemma from Sec. II clarifies a very special role of projective transformations for the Boltzmann equation in its general form. Sections III–IV are mostly devoted to the application of projective transformations to the so-called *homoenergetic affine flows*.[11,19] The classification of such flows for the *most symmetric* two-dimensional Boltzmann equation in the case of a potential $U(r)\propto r^{-2}$ is given in Sec. IV. It is shown that arbitrary (with some restrictions) four-parameter solutions can be expressed through a simpler two-parameter solution by projective transformations.

II. COMPLETE LIE GROUP, PROJECTIVE TRANSFORMATIONS, AND CONSERVATION LAWS

We consider the Boltzmann equation (BE) for the distribution function $f(\mathbf{x},\mathbf{v},t)$ ($\mathbf{x}\in\mathbb{R}^n$ denotes position, $\mathbf{v}\in\mathbb{R}^n$ velocity, $n=2,3,...$, while $t>0$ is the time variable)

$$\frac{\partial f}{\partial t}+\mathbf{v}\cdot\frac{\partial f}{\partial \mathbf{x}}=I(f,f),$$

$$\mathbf{x}\equiv\{x_1,\ldots,x_n\},\quad \mathbf{v}\equiv\{\nu_1,\ldots,\nu_n\},$$

$$I(f,f)=\int_{\mathbb{R}^n\times S^{n-1}} d\mathbf{w}\,d\mathbf{n}\,u\sigma\left(u,\frac{\mathbf{u}\cdot\mathbf{n}}{u}\right)\{f(\mathbf{v}')f(\mathbf{w}')-f(\mathbf{v})f(\mathbf{w})\},\tag{1}$$

$$\mathbf{u}=\mathbf{v}-\mathbf{w},\quad u=|\mathbf{u}|,\quad |\mathbf{n}|=1,$$

$$\mathbf{v}'=\tfrac{1}{2}(\mathbf{v}+\mathbf{w}+u\mathbf{n}),\quad \mathbf{w}'=\tfrac{1}{2}(\mathbf{v}+\mathbf{w}-u\mathbf{n}),$$

where $\sigma(u,\mu=\cos\theta)$ denotes the differential cross section (we use the same terminology for all number of dimensions $n=2,3,\ldots$) at the scattering angle $0<\theta\leqslant\pi$. We note that for the powerlike intermolecular potential $U(r)\propto r^{-m}$, $m>1$, the cross section reads as

$$\sigma(u,\mu)=u^{\gamma-1}g_\gamma(\mu),\quad \gamma=\frac{m-2(n-1)}{m};$$

the limiting case $m=\infty$ ($\gamma=1$) corresponds to hard spheres. A detailed investigation of group properties of the BE (with respect to Lie transformations) is presented in Ref. 3. The results are summarized as follows.

The most important (from the physical point of view) class of Lie (i.e., point) transformations for the BE can be represented as a linear transformation of the distribution function

$$f_\theta(\mathbf{x},\mathbf{v},t)=\exp(\theta\hat{L})f(\mathbf{x},\mathbf{v},t),\tag{2}$$

where $\hat{L}$ is a first order differential operator, i.e.,

$$\hat{L}=\Omega(\mathbf{x},\mathbf{v},t)+\mathbf{X}(\mathbf{x},\mathbf{v},t)\cdot\frac{\partial}{\partial\mathbf{x}}+\mathbf{V}(\mathbf{x},\mathbf{v},t)\cdot\frac{\partial}{\partial\mathbf{v}}+T(\mathbf{x},\mathbf{v}.t)\frac{\partial}{\partial t},\tag{3}$$

θ (positive or negative) being the *group parameter*. The following theorem describes the complete symmetry group for the BE in this class of transformations.

Theorem:[3] The complete list of admissible operators $\hat{L}$ for the BE consists of the following operators (A)–(C),

$$\text{(A)}\quad \hat{L}_{ij}^{(0)}=\left(x_1\frac{\partial}{\partial x_j}-x_j\frac{\partial}{\partial x_i}\right)+\left(\nu_i\frac{\partial}{\partial\nu_j}-\nu_j\frac{\partial}{\partial\nu_1}\right),\quad i,j=1,\ldots,n,$$

$$\text{(B)}\quad \hat{L}_i^{(1)}=\frac{\partial}{\partial x_i},\quad \hat{L}_i^{(2)}=t\frac{\partial}{\partial x_i}+\frac{\partial}{\partial\nu_i},\quad i=1,\ldots,n,$$

$$\text{(C)}\quad \hat{L}^{(3)}=\frac{\partial}{\partial t},\quad \hat{L}^{(4)}=t\frac{\partial}{\partial t}+\mathbf{x}\cdot\frac{\partial}{\partial\mathbf{x}}+1,$$

of the additional symmetry operator (D):

$$\text{(D)}\quad \hat{L}^{(5)}=t\frac{\partial}{\partial t}+(1-\rho)\mathbf{x}\cdot\frac{\partial}{\partial\mathbf{x}}-\rho\mathbf{v}\cdot\frac{\partial}{\partial\mathbf{v}},\quad \rho=\frac{m}{m(n+1)-2(n-1)}$$

in the case of powerlike potential $U \propto r^{-m}$, $m>1$ (with or without angular cutoff), and, finally, of a special symmetry operator (E):

$$\text{(E)}\quad \hat{L}^{(6)} = t^2 \frac{\partial}{\partial t} + t\mathbf{x}\cdot \frac{\partial}{\partial \mathbf{x}} + (\mathbf{x}-\mathbf{v}t)\cdot \frac{\partial}{\partial \mathbf{v}},$$

valid for the case $m=2$ (i.e., for $U \propto r^{-2}$).

If we now introduce the group transformations $T_\theta = \exp(\theta \hat{L})$, it is easy to obtain the explicit representation of the above written (in infinitesimal form) transformations. In particular one has, corresponding to the operator (D), the special class of scaling transformations

$$f_\theta^{(5)} = f[e^{(1-\rho)\theta}\mathbf{x}, e^{-\rho\theta}\mathbf{v}, e^{\theta}t],$$

and, for the special symmetry operator (E):

$$f_\theta^{(6)} = f\left[\frac{\mathbf{x}}{1-\theta t}, \mathbf{v}+\theta(\mathbf{x}-\mathbf{v}t), \frac{t}{1-\theta t}\right],$$

i.e., the class of the so-called projective transformations.[1–3] This symmetry is valid only for potential $U(r) \propto r^{-2}$. We consider here a little bit more in detail these nontrivial symmetry transformations.

The specific role of projective transformations for different classical and quantum systems has been pointed out in Ref. 3. Its role for the Boltzmann equation is connected with the following lemma.

Lemma. Let $f(\mathbf{x},\mathbf{v},t)$ be a solution of the generalized Boltzmann equation (1) with time-dependent differential cross section $\sigma(u,\mu,t)$. Then the function

$$F(\mathbf{x},\mathbf{v},t) = f\left[\frac{\mathbf{x}}{1+at}, \mathbf{v}(1+at)-a\mathbf{x}, \frac{t}{1+at}\right]$$

also satisfies, for $0<t<(1/a)$, the generalized Boltzmann equation with another time-dependent cross section:

$$\sigma_a(u,\mu,t) = (1+at)^{n-1}\sigma\left[u(1+at), \mu, \frac{t}{1+at}\right].$$

This lemma generalizes the related results of Ref. 4. To prove it, it is sufficient to make direct calculations, which we omit for brevity.

Corollary. The function $F(\mathbf{x},\mathbf{v},t)$ satisfies the usual Boltzmann equation with powerlike cross section $\sigma^{(\gamma)}(u,\mu) = u^{\gamma-1} g_\gamma(\mu)$ if and only if the function $f(\mathbf{x},\mathbf{v},t)$ satisfies the generalized Boltzmann equation with the cross section $\sigma_a^{(\gamma)}(u,\mu,t) = (1-at)^{n+\gamma-2} u^{\gamma-1} g_\gamma(\mu)$.

Hence, the projective transformations (E) are the equivalence transformations for the whole class of generalized Boltzmann equations with a time-dependent cross section, i.e., they change only the cross section, not the general form of the Boltzmann equation. In the special case

$$\sigma(u,\mu,t) = g(\mu)u^{1-n},$$

which corresponds to the potential $U(r) \propto r^{-2}$, the cross section is invariant under these transformations. We notice that the invariant transformation

$$F(\mathbf{x},\mathbf{v},t) = f\left[\frac{\mathbf{x}}{|t|}, |t|\left(\mathbf{v}-\frac{\mathbf{x}}{t}\right), \text{const}-\frac{1}{t}\right]$$

for the potential $U(r)\propto r^{-2}$ was found for the first time by Nikol'skii;[8] its connection with the projective transformations is clear.

Two additional conservation laws can be derived immediately from the above lemma. We note that the fundamental conservation laws (mass, momentum, and energy) for the Boltzmann equation do not depend on the cross section. Therefore, for any solution $f(\mathbf{x},\mathbf{v},t)$, with finite total second moments, the integral

$$E_a=\frac{1}{2}\int_{\mathbb{R}^n\times\mathbb{R}^n} d\mathbf{x}\, d\mathbf{y}\, f\left[\frac{\mathbf{x}}{1+at},\mathbf{v}(1+at)-a\mathbf{x},\frac{t}{1+at}\right]\nu^2$$
$$=\frac{1}{2}\int_{\mathbb{R}^n\times\mathbb{R}^n} d\tilde{\mathbf{x}}\, d\tilde{\mathbf{y}}\, f(\tilde{\mathbf{x}},\tilde{\mathbf{v}},\tilde{t})[\tilde{\mathbf{v}}+a(\tilde{\mathbf{x}}-\tilde{\mathbf{v}}\tilde{t})]^2$$

does not depend on time for any value of the group parameter a. Noting that

$$2E_a=2E_0+2aI_1+a^2I_2,$$

where

$$I_1=\int d\mathbf{x}\, d\mathbf{v}\, \mathbf{v}\cdot(\mathbf{x}-\mathbf{v}t)f(\mathbf{x},\mathbf{v},t),$$

$$I_2=\int d\mathbf{x}\, d\mathbf{v}(\mathbf{x}-\mathbf{v}t)^2 f(\mathbf{x},\mathbf{v},t),$$

one can immediately conclude that $I_{1,2}=$const. These conservation laws are not new (see, for instance, Ref. 20), however their connection with projective transformations seems very important.

III. HOMOENERGETIC AFFINE FLOWS AND SOME APPLICATIONS OF PROJECTIVE TRANSFORMATIONS

The infinitesimal operators (A)–(E) determine a Lie algebra, as it can be verified after a straightforward calculation of Lie brackets. For all cases (A)–(E) we can construct group invariants and the simplest invariant solutions of the BE, which are functions of these invariants. In this way we can again find all well known classes of invariant solutions, so that their group nature can be clarified. However, all really interesting invariant solutions are invariant under multiparameter groups. Therefore we formally need to classify, for each p, all corresponding multidimensional (with dimension not greater than p) subalgebras of the above-mentioned Lie algebra. This problem is rather complicated even in one dimension.[2] At the same time, most of the solutions obtained in such a way have no physical meaning.

Just for this reason we restrict ourselves to an interesting example having clear physical sense. Let us consider a linear combination of vector operators $\hat{\mathbf{L}}^{(1)}$ and $\hat{\mathbf{L}}^{(2)}$, i.e.,

$$L=\mathbf{a}\cdot\hat{\mathbf{L}}^{(1)}+\mathbf{b}\cdot\hat{\mathbf{L}}^{(2)},$$

with arbitrary vector parameters $\mathbf{a}$ and $\mathbf{b}$. To pass to n-parameter groups, we put

$$\mathbf{b}=\mathscr{K}\mathbf{a}\Leftrightarrow b_i=\sum_j K_{ij}a_j$$

with any matrix $(n\times n)$ $\mathscr{K}\equiv(K_{ij})$. Then

$$L=\sum_j \left\{ a_j \left[\hat{L}_j^{(1)} + \sum_i K_{ij} \hat{L}_i^{(2)} \right] \right\}$$

is the n-parameter infinitesimal operator of the corresponding group.

We can obtain, in this case, the independent invariants

$$\psi_0(t)=t, \quad \boldsymbol{\psi}=(\psi_1,\ldots,\psi_n)=\mathbf{v}-\hat{K}(t)\mathbf{x}, \qquad \hat{K}(t)=(\mathfrak{I}+t\mathscr{K})^{-1}\mathscr{K}, \tag{4}$$

$\mathfrak{I}$ denoting the identity matrix operator. We note that $\hat{K}(t)$ is the solution of the Cauchy problem

$$\frac{d}{dt}\hat{K}(t)+\hat{K}^2(t)=0, \quad \hat{K}(0)=\mathscr{K}.$$

The corresponding invariant solution reads

$$f(\mathbf{x},\mathbf{v},t)=F[\mathbf{v}-\hat{K}(t)\mathbf{x},t], \tag{5}$$

where $F(\mathbf{v},t)$ satisfies the equation

$$\frac{\partial F}{\partial t}-[\hat{K}(t)\mathbf{v}]\cdot\frac{\partial F}{\partial \mathbf{v}}=I(F,F\ ). \tag{6}$$

This class of solutions to the Boltzmann equation is also well known.[19] It describes the so-called *homoenergetic affine flows* (in the absence of external forces), first observed in Refs. 6 and 7 for the moments of distribution function in the case of Maxwellian molecules.

The existence and uniqueness of the corresponding distribution function for the general molecular model were recently proven in Ref. 19. In that article the solutions (5) were introduced on the basis of homoenergetic affine flow properties. The above derivation of Eq. (5) on the basis of symmetry considerations are perhaps simpler and more natural. We shall return to these solutions later.

The simplest application of group invariant transformations is transforming known exact solutions into new ones. One can start with the simplest exact solution $f(\mathbf{x},\mathbf{v},t)=\exp(-\ \nu^2)$, and then apply to this distribution function any above described transformation. It is easy to show that we obtain in such a way the complete class of the local Maxwellian solutions.

Less trivial example is given by the Nikol'skii transformation[9] of arbitrary space homogeneous solutions for powerlike potentials. Let us show that this transformation is closely connected with the above considered projective invariance. We consider the Boltzmann equation (1) with the cross section $\sigma(u,\mu)=u^{\gamma-1}g_\gamma(\mu)$. In accordance with the Lemma from Sec. II (see also Corollary), one can construct the solution of Eq. (1) in the form

$$f(\mathbf{x},\mathbf{v},t)=F\left[\mathbf{v}(1+at)-a\mathbf{x},\ \frac{t}{1+at}\right],$$

where $F(\mathbf{v},\tau)$ satisfies the generalized space homogeneous Boltzmann equation

$$\frac{\partial F}{\partial \tau}=(1-a\tau)^{n+\gamma-2}I(F,F\ ).$$

Putting

$$S(\tau)=\int_0^\tau d\tau'(1-a\tau')^{n+\gamma-2}$$

we can replace $F(\mathbf{v},\tau)$ by any solution $\Phi[\mathbf{v},S(\tau)]$ of the space homogeneous Boltzmann equation. In conclusion, we obtain the following well known formula for the Nikol'skii solution (see, for example, Ref. 12):

$$f(\mathbf{x},\mathbf{v},t)=\Phi[\mathbf{v}(1+at)-a\mathbf{x},T_a(t)],$$

$$T_a(t)=\int_0^{t/(1+at)} d\tau(1-a\tau)^{n+\gamma-2}=\frac{(1+at)^{n+\gamma-1}-1}{a(n+\gamma-1)(1+at)^{n+\gamma-1}},\quad n+\gamma>1.$$

Hence, the Nikol'skii transformation can be introduced on the basis of projective invariance. Therefore, if we apply this transformation to the Nikol'skii solution in the special case $n+\gamma=2$, then we obtain the same solution with another value of the group parameter a.

Let us now try to apply this transformation to homoenergetic affine flows described above, i.e., to the distribution function (5). Then we obtain, after some calculations,

$$f_a(\mathbf{x},\mathbf{v},t)=F\left\{(1+at)[\mathbf{v}-\hat{K}_a(t)\mathbf{x}],\ \frac{t}{1+at}\right\}, \tag{7}$$

where the matrix $\hat{K}_a(t)$ is the solution of the Cauchy problem

$$\frac{d}{dt}\hat{K}_a(t)+\hat{K}_a^2(t)=0,\quad \hat{K}_a(0)=\hat{K}(0)+a\mathfrak{I}.$$

Hence, the total class of homoenergetic affine flows is invariant under projective transformations. For the special case $n+\gamma=2$, the above formula (7) defines a solution of the Boltzmann equation, provided that $F(\mathbf{v},t)$ satisfies Eq. (6). We note that the matrix $\hat{K}(0)$ is the main parameter of this class of solutions. Equation (7) establishes (for $n+\gamma=2$) the exact connection between solutions $f(\mathbf{x},\mathbf{v},t)$, with given matrix $\hat{K}(0)$, and solutions $f_a(\mathbf{x},\mathbf{v},t)$, with a one-parameter set of matrices $\hat{K}_a(0)=\hat{K}(0)+a\mathfrak{I}$.

In particular we obtain the following correspondence between velocity moments:

$$M_a^{(p)}(t)=\int_{\mathbb{R}^n} d\mathbf{v}\ f_a(\mathbf{x},\mathbf{v},t)[\mathbf{v}-\hat{K}_a(t)\mathbf{x}]^p=(1+at)^{-(n+p)}M_0^{(p)}\left(\frac{t}{1+at}\right),\quad p=0,1,\ldots\ .$$

We consider below these flows for the two-dimensional ($n=2$) case in more detail.

IV. CLASSIFICATION OF HOMOENERGETIC AFFINE FLOWS FOR THE TWO-DIMENSIONAL BOLTZMANN EQUATION

We note that in two dimensions the potential $U(r)\propto r^{-2}$ corresponds to the value $\gamma=0$ [see comment after formula (1)]. Therefore, the case $n=2$, $m=2$ corresponds to the largest number of symmetries. The Boltzmann equation for the function $F(\mathbf{v},t)$ in Eq. (5) in this case reads

$$\frac{\partial F}{\partial t}-(\hat{K}(t)\mathbf{v})\cdot\frac{\partial F}{\partial \mathbf{v}}=I(F,F)=\int_{\mathbb{R}^2\times S^1} d\mathbf{w}\ d\mathbf{n}\ g\left(\frac{\mathbf{u}\cdot\mathbf{n}}{u}\right)[f(\mathbf{v}')f(\mathbf{w}')-f(\mathbf{v})f(\mathbf{w})],$$
$$\mathbf{u}=\mathbf{v}-\mathbf{w},\quad \hat{K}(t)=[1+t\hat{K}(0)]^{-1}\hat{K}(0) \tag{8}$$

with any given (2×2) matrix $\hat{K}(0)$.

In general, the solution of Eq. (8) depends on four parameters (matrix elements) provided that the initial distribution function $F(\mathbf{v},0)$ is fixed. We show now how to simplify this four-parameter solution in the special case when eigenvalues $\lambda_{1,2}$ of the matrix $\hat{K}(0)$ are real. Moreover we assume that $\lambda_1 \geqslant \lambda_2 \geqslant 0$, so that the solution exists and is positive for all $t>0$.[19] We note also that any such matrix $\hat{K}(0)$ reduces by rotations to the form

$$\hat{K}'(0)=\begin{pmatrix} \lambda_1 & b \\ 0 & \lambda_2 \end{pmatrix}, \tag{9}$$

therefore we consider only such three-parameter matrices. One more reduction can be obtained by applying a projective transformation. In order to do it, we first write down the solution of Eq. (8) with the initial matrix (9) in the form

$$F(\mathbf{v},t)\equiv F(\mathbf{v},t|\lambda_1,\lambda_2,b).$$

Then the application of the equality (7) with $a=\lambda_2$ results in the following formula:

$$F(\mathbf{v},t|\lambda_1,\lambda_2,b)=F\left[(1+\lambda_2 t)\mathbf{v},\frac{t}{1+\lambda_2 t}\middle|\lambda_1-\lambda_2,0,b\right].$$

Hence, it is sufficient to consider the two-parameter row matrix

$$\hat{K}''(0)=\begin{pmatrix} \lambda & b \\ 0 & 0 \end{pmatrix}\Rightarrow \hat{K}''(t)=[\mathfrak{I}+t\hat{K}''(0)]^{-1}\hat{K}''(0)=\frac{1}{1+\lambda t}\,\hat{K}''(0).$$

Finally we obtain from Eq. (8) the following equation for the function $F(\mathbf{v},t|\lambda,0,b)$:

$$\frac{\partial F}{\partial t}-\frac{1}{1+\lambda t}\,(\lambda \nu_x+b\nu_y)\,\frac{\partial F}{\partial \nu_x}=I(F,F\,).$$

Putting

$$F(\mathbf{v},t)=\Psi[\mathbf{v},(1/\lambda)\ln(1+\lambda t)](1+\lambda t)^{-1},$$

we obtain the resulting equation for $\Psi(\mathbf{v},\tau)$:

$$\frac{\partial \Psi}{\partial \tau}-\frac{\partial}{\partial \nu_x}\,[(\lambda \nu_x+b\nu_y)\Psi]=I(\Psi,\Psi).$$

In the case of zero initial drift velocity (relaxing this condition would be only matter of technical complication), and omitting all details, the first moment equations read

$$\rho_0=\int_{\mathbb{R}^2} d\mathbf{v}\;\Psi=\text{const},\qquad \int_{\mathbb{R}^2} d\mathbf{v}\;\mathbf{v}\Psi=0,$$

$$\frac{\partial}{\partial \tau}\,p_{xy}+[\lambda p_{xy}+bp_{yy}]=-\rho_0 S p_{xy},$$

$$\frac{\partial}{\partial t}\,(p_{xx}-p_{yy})+2(\lambda p_{xx}+bp_{xy})=-\rho_0 S(p_{xx}-p_{yy}), \tag{10}$$

$$\frac{\partial}{\partial \tau}(p_{xx}+p_{yy})+2(\lambda p_{xx}+b p_{xy})=0,$$

where

$$p_{ij}=\int_{\mathbb{R}^2} d\mathbf{v}\ \Psi \nu_i \nu_j, \quad i,j=x,y;$$

$$S=\int d\mathbf{n}\ g\left(\frac{\mathbf{u}\cdot\mathbf{n}}{u}\right)\left[1-\left(\frac{\mathbf{u}\cdot\mathbf{n}}{u}\right)^2\right]=\int_0^{2\pi} d\theta\ g(\cos\ \theta)\sin^2\ \theta.$$

Substituting here $p_{ij}(t)=p_{ij}(0)e^{z\tau}$, we obtain the following algebraic equation for the eigenvalue z:

$$(z+\lambda+\rho_0 S)[(z+\lambda)(z+\lambda+\rho_0 S)-\lambda^2]=b^2\rho_0 S.$$

It is convenient to pass to dimensionless values

$$\tilde{b}=\frac{b}{\rho_0 S}, \quad \tilde{\lambda}=\frac{\lambda}{\rho_0 S}, \quad \tilde{z}=\frac{z}{\rho_0 S}, \quad \theta=\tilde{z}+\tilde{\lambda},$$

so that we obtain the simple equation

$$(\theta+1)[\theta(\theta+1)-\tilde{\lambda}^2]=\tilde{b}^2. \tag{11}$$

The general analysis of this equation is similar to the case $\tilde{\lambda}=0$ observed in Ref. 11. There is always one positive root $\theta=R(\tilde{\lambda}^2,\tilde{b}^2)$, which defines the large time asymptotics of the pressure tensor $p_{ij}(\tau)$ by the formulas

$$p_{ij}(\tau)=p_{ij}^*(0)\exp[(-\lambda+\theta\rho_0 S)\tau], \quad i,j=x,y, \tag{12}$$

where $p_{ij}^*(0)$ are the corresponding projections of initial data.

Finally we return to initial variables and obtain general formulas for density $\rho(t|\lambda_1,\lambda_2,b)$ and pressure $p_{ij}(t|\lambda_1,\lambda_2,b)$, which correspond to an arbitrary initial matrix (9):

$$\rho(t|\lambda_1,\lambda_2,b)=\frac{\rho_0}{(1+\lambda_1 t)(1+\lambda_2 t)},$$

$$p_{ij}(t|\lambda_1,\lambda_2,b)=\tilde{p}_{ij}\left(\frac{1}{\lambda}\ln\frac{1+\lambda_1 t}{1+\lambda_2 t}\right)\Big/[(1+\lambda_2 t)^3(1+\lambda_1 t)],$$

where $\tilde{p}_{ij}(t|\lambda_1,\lambda_2,b)$ are defined by Eqs. (10) with $\lambda=\lambda_1-\lambda_2$. In particular the asymptotic formula (12) results in the following general asymptotic formula:

$$p_{ij}(t|\lambda_1,\lambda_2,b)=\frac{p_{ij}^*(0)}{[(1+\lambda_1 t)(1+\lambda_2 t)]^2}\left(\frac{1+\lambda_1 t}{1+\lambda_2 t}\right)^{R/\tilde{\lambda}},$$

where $\tilde{\lambda}=(\lambda_1-\lambda_2)/(\rho_0 S)$, $\tilde{b}=b/(\rho_0 S)$, $R(\tilde{\lambda}^2,b^2)$ denotes the maximal positive root of Eq. (11).

The higher moments of the distribution function can be obtained by the same method. Thus, using projective transformations one can easily generalize the well known exact results[11,21] for the uniform shear flow to the case of arbitrary initial matrix $\hat{K}(0)$ with real eigenvalues. A similar approach in the three-dimensional case will be considered elsewhere.

ACKNOWLEDGMENTS

This work was supported by CNR through Grant No. 93.00553.CT01, at least in its initial stage. Additional support from the Italian MURST and from International Science Foundation and Russian Government (Grant No. J2Y100) is also gratefully acknowledged.
