Usually quantum chains with quantum group symmetry are associated with representations of quantized universal algebras $U_q(g)$. Here we propose a method for constructing quantum chains with $C_q(G)$ global symmetry, where $C_q(G)$ is the algebra of functions on the quantum group. In particular we will construct a quantum chain with $GL_q(2)$ symmetry which interpolates between two classical Ising chains. It is shown that the Hamiltonian of this chain satisfies the generalized braid group algebra. © *1996 American Institute of Physics.* [S0022-2488(95)02912-8]

I. INTRODUCTION

Almost all integrable models in two-dimensional statistical models, quantum field theories in $1+1$ dimensions, and quantum chains[1] owe their integrability to some quantum group symmetry. For example, in lattice models, if one assigns the local Boltzman weights of a vertex or an IRF model to be the elements of the R matrix corresponding to a quantum group, then the model will be integrable due to the existence of a one-parameter family of commuting transfer matrices. In a sense one can say that local quantum group symmetry ensures integrability. Although global quantum group symmetry does not mean integrability, construction of models with such symmetries may be interesting and important as a first step toward understanding the mechanism of integrability.

Recently new types of two- and three-state quantum chains were constructed and shown to possess $U_q(\mathrm{sl}(2))$ symmetry.[2–4] The strategy followed in Ref. 4 was to define the Hamiltonian as

$$H=\sum_{j=1}^{L} id\otimes\cdots id\otimes H_j\otimes id\ldots.\otimes id, \tag{1}$$

where H_j acts on sites j and $j+1$ as

$$H_j=(\pi_j\otimes\pi_{j+1})[Q_j(\Delta(C))]. \tag{2}$$

Here j denotes the site of the lattice, C is the quadratic Casimir of $U_q(\mathrm{sl}(2))$, Δ is the coproduct, π_j is a typical type b representation[5] of $U_q(\mathrm{sl}(2))$ assigned to site j, and finally Q_j is a polynomial function of degree $d\leqslant m$ where the integer m is characterized by the value of $q(q^m=1)$. This Hamiltonian is by construction $U_q(\mathrm{sl}(2))$ invariant. The invariance is due to the centrality of the Casimir. For the particular form of the Hamiltonian of the two-state and three-state quantum chains see Ref. 4.

As is well known any quantum group is characterized by two algebras,[6,7] the first being the deformation of the universal enveloping algebra which is denoted by $U_q(g)$ and the second one which is the deformation of the algebra of functions on the group which is denoted by $C_q(G)$. So far everything which has been done concerning the construction of physical models with quantum group symmetry have been based on representation theory of $U_q(g)$. However, in the quantum case the second algebra, $C_q(G)$, has also a representation theory which is completely different from that of $U_q(g)$.[8,9]

a)Electronic mail address: alimohmd@irearn.bitnet

The novelty of the representations of $C_q(G)$ is best understood when one considers the classical $(q\to 1)$ limit of $C_q(G)$. In this limit, representations of $U_q(g)$ approach those of the classical Lie algebra g while those of $C_q(G)$ collapse to trivial one-dimensional representations, since $C_q(G)$ will become a commutative algebra. Therefore there is no parallelism between the representation theories in the deformed and the undeformed case. Naively one expects that paying attention to physical models which are $C_q(G)$ invariant may open up a new road in the study of integrable models. At the present stage this is only a hope and real justification for it will exist if one can somehow gauge a global symmetry of this kind in a particular physical model.

In this letter we construct a quantum chain which has a global $C_q(\mathrm{GL}(2))$ symmetry, hereafter called $\mathrm{GL}_q(2)$ symmetry for simplicity.

II. THE QUANTUM GROUP $GL_q(2)$ AND IT'S CYCLIC REPRESENTATIONS

The quantum group $\mathrm{GL}_q(2)$ is defined by the generators 1, a, b, c, and d, collected in the form of a quantum matrix[7]

$$T=\begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

and relations

$$\begin{gathered} ab=qba, \quad ac=qca, \quad bd=qdb, \\ cd=qdc, \quad bc=cb, \quad ad-da=(q-q^{-1})bc. \end{gathered} \tag{3}$$

The coproduct which is used in tensor multiplication of representations is defined by

$$\Delta\begin{pmatrix} a & b \\ c & d \end{pmatrix}=\begin{pmatrix} a & b \\ c & d \end{pmatrix}\otimes\begin{pmatrix} a & b \\ c & d \end{pmatrix}. \tag{4}$$

The quantum determinant $D_q=ad-qbc$ is central and grouplike; that is,

$$\Delta D_q=D_q\otimes D_q. \tag{5}$$

If q is a root of unity ($q^p=1$), in addition to the determinant, all the elements a^p, b^p, c^p, and d^p are central. In this case the algebra has a p-dimensional cyclic representation which is constructed as follows:[8] One first defines a state $|0\rangle$ which is a common eigenvector of b and c with eigenvalues μ and ν, respectively:

$$b|0\rangle=\mu|0\rangle, \quad c|0\rangle=\nu|0\rangle,$$

and then builds up the representation space V as the linear span of vectors $\{|n\rangle\equiv d^n|0\rangle,\ 0\leqslant n\leqslant p-1\}$. It is then easy to show that V is invariant under the action of $\mathrm{GL}_q(2)$:

$$\begin{gathered} d|n\rangle=|n+1\rangle, \quad d|p-1\rangle=\eta|0\rangle, \quad b|n\rangle=\mu q^n|n\rangle, \quad c|n\rangle=\nu q^n|n\rangle, \\ a|n\rangle=(\xi+q^{2n-1}\mu\nu)|n-1\rangle, \quad a|0\rangle=\frac{1}{\eta}(\xi+\mu\nu q^{-1})|p-1\rangle. \end{gathered} \tag{6}$$

Here η is the central value of d^p and ξ is the value of the q-determinant D_q.

It can be easily checked that the parameters η, ξ, μ, and ν are all independent and hence each representation is characterized by the values of these parameters and is denoted by $\pi(\eta,\xi,\mu,\nu)$.

III. QUANTUM CHAINS WITH $GL_q(2)$ SYMMETRY

We construct the quantum chains with $GL_q(2)$ symmetry as follows: To each site $1 \leqslant j \leqslant L$, we assign a representation $\pi_j = \pi(\eta_j, \xi_j, \mu_j, \nu_j)$, the Hilbert space is the tensor product $\otimes_{j=1}^{L} V_j$, where V_j is the p-dimensional representation space of π_j.

At first glance it seems that the analogue of the construction of Ref. 4 in the case of $C_q(\mathrm{GL}(2))$ is to replace the Casimir C in Eq. (2) by the quantum determinant D_q. However, this procedure leads to a trivial Hamiltonian due to the grouplike property of D_q [Eq. (5)], which makes $\pi_j \otimes \pi_{j+1}(Q_j(\Delta(D)))$ proportional to the identity. However, there is one interesting possibility and it is to define H_j as

$$H_j = \pi_j \otimes \pi_{j+1}(Q_j(\Delta(a^p), \Delta(b^p), \Delta(c^p), \Delta(d^p))). \tag{7}$$

Here the crucial point is that although in an irreducible representation a^p, b^p, c^p, and d^p are proportional to the identity, in a tensor product of representations they are not so due to the mixing of the generators in their coproducts [Eq. (4)]. The Hamiltonian constructed in this way is $GL_q(2)$ invariant by construction.

A. Two-state quantum chains

Now we restrict ourselves to the case $p=2$ $(q=-1)$. From Eq. (6) we obtain the two-dimensional cyclic representation of $GL_q(2)$, which in the explicit matrix notation takes the form

$$\begin{aligned} \pi(a) &= \begin{pmatrix} 0 & \gamma/\eta \\ \gamma & 0 \end{pmatrix}, \quad \pi(b) = \begin{pmatrix} \mu & 0 \\ 0 & -\mu \end{pmatrix}, \\ \pi(c) &= \begin{pmatrix} \nu & 0 \\ 0 & -\nu \end{pmatrix}, \quad \pi(d) = \begin{pmatrix} 0 & 1 \\ \eta & 0 \end{pmatrix}, \end{aligned} \tag{8}$$

where $\gamma = \xi - \mu\nu$. This represents a continuous four-parameter family of two-dimensional representations for $GL_q(2)$ (for $q=-1$). If t stands for a, b, c, or d, then a straightforward calculation shows that

$$(\pi_j \otimes \pi_{j+1})\Delta t^2 = l_t 1 \otimes 1 + n_t \sigma_x \otimes \sigma_x + p_t \sigma_y \otimes \sigma_y - i q_t \sigma_x \otimes \sigma_y - i r_t \sigma_y \otimes \sigma_x, \tag{9}$$

where

$$\begin{aligned} n_t &= \tfrac{1}{4}(1 - \eta_j - \eta_{j+1} + \eta_j \eta_{j+1}) m_t, \quad p_t = -\tfrac{1}{4}(1 + \eta_j + \eta_{j+1} + \eta_j \eta_{j+1}) m_t, \\ q_t &= \tfrac{1}{4}(-1 + \eta_j - \eta_{j+1} + \eta_j \eta_{j+1}) m_t, \quad r_t = \tfrac{1}{4}(-1 - \eta_j + \eta_{j+1} + \eta_j \eta_{j+1}) m_t, \end{aligned} \tag{10}$$

and

$$\begin{aligned} m_a &= \frac{2\gamma_j \gamma_{j+1} \mu_j \nu_{j+1}}{\eta_j \eta_{j+1}}, \quad m_b = -2\,\frac{\mu_j \mu_{j+1} \gamma_j}{\eta_j}, \\ m_c &= -2\,\frac{\nu_j \nu_{j+1} \gamma_{j+1}}{\eta_{j+1}}, \quad m_d = 2\mu_{j+1}\nu_j. \end{aligned} \tag{11}$$

The explicit expressions of l_ts are not necessary in this stage. As the simplest choice for the polynomial [in Eq. (7)] we set

$$Q_0 = \alpha_a a^2 + \alpha_b b^2 + \alpha_c c^2 + \alpha_d d^2, \tag{12}$$

where α_ts are arbitrary constants. Combination of Eqs. (9) and (12) leads to the following Hamiltonian:

$$H_j = A\sigma_x^j\sigma_x^{j+1} + B\sigma_y^j\sigma_y^{j+1} + -iC\sigma_x^j\sigma_y^{j+1} - iD\sigma_y^j\sigma_x^{j+1}, \tag{13}$$

where

$$\begin{aligned} A &= \beta_j(1-\eta_j-\eta_{j+1}+\eta_j\eta_{j+1}), \\ B &= -\beta_j(1+\eta_j+\eta_{j+1}+\eta_j\eta_{j+1}), \\ C &= \beta_j(-1+\eta_j-\eta_{j+1}+\eta_j\eta_{j+1}), \\ D &= \beta_j(-1-\eta_j+\eta_{j+1}+\eta_j\eta_{j+1}), \end{aligned} \tag{14}$$

and $\beta_j = \alpha_a m_a + \alpha_b m_b + \alpha_c m_c + \alpha_d m_d$. If the factor β_j is site independent, then modulo a constant overall factor the Hamiltonian becomes

$$\begin{aligned} H_0 = \sum_j \{&(1-\eta_j-\eta_{j+1}+\eta_j\eta_{j+1})\sigma_x^j\sigma_x^{j+1} - (1+\eta_j+\eta_{j+1}+\eta_j\eta_{j+1})\sigma_y^j\sigma_y^{j+1} - i(-1+\eta_j \\ &-\eta_{j+1}+\eta_j r_{j+1})\sigma_x^j\sigma_y^{j+1} - i(-1-\eta_j+\eta_{j+1}+\eta_j\eta_{j+1})\sigma_y^j\sigma_x^{j+1}\}. \end{aligned} \tag{15}$$

Now the condition of Hermiticity of the Hamiltonian restricts the parameters η_j and η_{j+1} to the following form:

$$\begin{aligned} \eta_j &= \alpha + i\sqrt{1-\alpha^2}, \\ \eta_{j+1} &= \eta_j^*, \end{aligned} \tag{16}$$

where α is a real parameter. Under this condition the Hamiltonian takes the following simple form:

$$H_0 = \sum_j \{(1-\alpha)\sigma_x^j\sigma_x^{j+1} - (1+\alpha)\sigma_y^j\sigma_y^{j+1} + \sqrt{1-\alpha^2}(\sigma_x^j\sigma_y^{j+1} - \sigma_y^j\sigma_x^{j+1})\}. \tag{17}$$

This is the desired Hamiltonian with $GL_q(2)$ symmetry.

Imposing the condition of site independence on β_j in Eq. (14), the m_ts are restricted to be site independent, as α_ts are arbitrary constants. Solving these conditions and using Eq. (16) results in the following relation between the parameters of the different representations of the sites:

$$\begin{aligned} &\gamma_j = \gamma_{j+2}, \quad \nu_j = \nu_{j+2}, \quad \mu_j = \mu_{j+2}, \\ &\frac{\gamma_j}{\eta_j} = \frac{\gamma_{j+1}}{\eta_{j+1}}, \quad \frac{\mu_j}{\nu_j} = \frac{\mu_{j+1}}{\nu_{j+1}}. \end{aligned} \tag{18}$$

So the whole representations of the sites specify only by four complex parameters ν_1, μ_1, ν_2, γ_1, and one real parameter α.

There are several observations on the above Hamiltonian [Eq. (17)]:

(1) Instead of the original continuous parameter q, the Hamiltonian depends on the continuous parameter α, which comes from the representation.
(2) In the two limits $\alpha=1$ and $\alpha=-1$, this Hamiltonian degenerates into an exactly solvable chain, that is $\Sigma_{j=1}^{L}\sigma_{\hat{n}}^j\sigma_{\hat{n}}^{j+1}$. So our $GL_q(2)$ invariant Hamiltonian interpolates between two **xx** and **yy** classical Ising chains, when α is changed continuously from -1 to 1.

(3) It is crucial to note that the Hamiltonian (17) is not equivalent to an $\hat{n}\hat{n}$ chain where $\hat{n}$ is a new unit vector in the $x-y$ plane. That is, the transformations $\sigma_x \to a\sigma_x + b\sigma_y$ and $\sigma_y \to c\sigma_x + d\sigma_y$ cannot diagonalize the Hamiltonian.

(4) If one defines $U_i = 2 + H_i$, then there exists the following interesting relations between U_i's:

$$U_i^2 = 4U_i,$$
$$(U_iU_{i\pm1}U_i - U_{i\pm1}U_iU_{i\pm1})(U_i - U_{i\pm1}) = 64(1-\alpha^2). \tag{19}$$

The above equation is the generalized braid group algebra.[2]

(5) The simplest situation in which H_0 can be solved exactly is the case of a two-site lattice. In this case there are four states with eigenvalues 2, 2, -2, and -2. It can be shown that the degenerate orthonormal states ($|2\rangle_\pm$ and $|-2\rangle_\pm$) are two-dimensional representations of $\Delta(t)$s.

B. Higher-state quantum chains

Choosing $p=3$, one may expect to obtain a three-state $GL_q(2)$ invariant quantum chain. However, for $q^3=1$ it is seen by computation that

$$\Delta a^3 = a^3\otimes a^3 + b^3\otimes c^3, \quad \Delta b^3 = a^3\otimes b^3 + b^3\otimes d^3,$$
$$\Delta c^3 = c^3\otimes b^3 + d^3\otimes d^3, \quad \Delta d^3 = c^3\otimes a^3 + d^3\otimes c^3,$$

which means that the Hamiltonian (7) is proportional to the identity. This phenomena may occur for all odd integers p.

ACKNOWLEDGMENT

Quasi-exactly solvable systems and orthogonal polynomials

Carl M. Bender

Gerald V. Dunne
Department of Physics, University of Connecticut, Storrs, Connecticut 06269

(Received 3 October 1995; accepted for publication 9 October 1995)

This paper shows that there is a correspondence between quasi-exactly solvable models in quantum mechanics and sets of orthogonal polynomials $\{P_n\}$. The quantum-mechanical wave function is the generating function for the $P_n(E)$, which are polynomials in the energy E. The condition of quasi-exact solvability is reflected in the vanishing of the norm of all polynomials whose index n exceeds a critical value J. The zeros of the critical polynomial $P_J(E)$ are the quasi-exact energy eigenvalues of the system. © *1996 American Institute of Physics.* [S0022-2488(96)03201-X]

In quantum mechanics there exist potentials for which it is possible to find a finite portion of the energy spectrum and associated eigenfunctions exactly and in closed form. These systems are said to be quasi-exactly solvable.[1–5] In such systems the potential depends on a parameter J; for positive integer values of J one can find J eigenvalues and eigenfunctions exactly. The usual approach to the analysis of quasi-exactly solvable systems is an algebraic one in which the Hamiltonian is expressed as a nonlinear combination of generators of a Lie algebra, not belonging to the center of the corresponding enveloping algebra.[4] This technique is a modification of the dynamical symmetry approach to exactly solvable quantum-mechanical systems, in which one can find by algebraic means the *entire* spectrum in closed form.[6]

In this paper we propose an alternative approach to quasi-exact solvability. We show that the solution ψ to the Schrödinger equation for a quasi-exactly solvable model,

$$H\psi = E\psi, \tag{1}$$

is the generating function for a set of polynomials $\{P_n(E)\}$ in the energy variable E. These polynomials satisfy a three-term recursion relation and therefore form an orthogonal set with respect to some weight function $w(E)$. For positive integer values of the parameter J, corresponding to quasi-exact solvability, we find that the norm of $P_n(E)$ *vanishes* for $n \geqslant J$. Moreover, all polynomials $P_n(E)$ beyond a critical polynomial $P_J(E)$, factor into a product of two polynomials, one of which is $P_J(E)$:

$$P_{n+J}(E) = P_J(E)Q_n(E) \quad (n \geqslant 0). \tag{2}$$

The zeros of the critical polynomial $P_J(E)$ are precisely the quasi-exact energy eigenvalues of the quantum-mechanical model.

We illustrate these features of quasi-exactly solvable models with the following infinite class of Hamiltonians first discussed by A. Turbiner:[1]

$$H = -\frac{d^2}{dx^2} + \frac{(4s-1)(4s-3)}{4x^2} - (4s+4J-2)x^2 + x^6. \tag{3}$$

0022-2488/96/37(1)/6/6/$6.00

Here, s is an arbitrary parameter. When s lies between $\frac{1}{4}$ and $\frac{3}{4}$, there is an attractive centrifugal term; for s outside this range the centrifugal term is repulsive. When $s=\frac{1}{4}$ or $s=\frac{3}{4}$, the centrifugal core term disappears leaving a nonsingular sextic oscillator Hamiltonian

$$H=-\frac{d^2}{dx^2}-(4s+4J-2)x^2+x^6. \tag{4}$$

When the parameter J in Eq. (3) is a nonnegative integer, the corresponding Schrödinger equation has J exact, closed-form solutions for any value of s.

We seek a solution $\psi(x)$ to the Schrödinger equation for H in Eq. (3) of the form

$$\psi(x)=\exp\left(-\frac{1}{4}x^4\right)x^{2s-1/2}\sum_{n=0}^{\infty}\left(-\frac{1}{4}\right)^n\frac{P_n(E)}{n!\Gamma(n+2s)}x^{2n}. \tag{5}$$

Observe that when $s=\frac{1}{4}$ this solution becomes an even-parity wave function of the oscillator Hamiltonian (4); when $s=\frac{3}{4}$, $\psi(x)$ becomes an odd-parity wave function of H in (4).

Demanding that $\psi(x)$ in Eq. (5) obey the Schrödinger equation (1) leads to the following recursion relation for the expansion coefficients $P_n(E)$:

$$P_n(E)=EP_{n-1}(E)+16(n-1)(n-J-1)(n+2s-2)P_{n-2}(E)\quad(n\geqslant 2), \tag{6}$$

subject to the initial conditions

$$P_0(E)=1\quad\text{and}\quad P_1(E)=E. \tag{7}$$

From these initial conditions the recursion relation (6) generates a set of monic[7] polynomials, the next four of which are

$$\begin{aligned}
P_2(E)&=E^2+(32-32J)s,\\
P_3(E)&=E^3+[(160-96J)s-32J+64]E,\\
P_4(E)&=E^4+[(448-192J)s-128J+352]E^2+(3072J^2-12288J+9216)s(s+1),\\
P_5(E)&=E^5+[(960-320J)s-320J+1120]E^3+[(15360J^2-81920J+91136)s^2\\
&\quad+(25600J^2-141312J+164864)s+6144J^2-36864J+49152]E.
\end{aligned} \tag{8}$$

These polynomials have a number of noteworthy properties. First, for all values of the parameters s and J they form an orthogonal set. This follows from the fact that they are generated by a second-order (three-term) recursion relation.[8] The appearance of a three-term recursion relation is a consequence of the form of the potential in Eq. (3). For example, the corresponding recursion relation for an x^4 anharmonic oscillator potential, whose Hamiltonian is not quasi-exactly solvable, is a higher-order recurrence relation. The harmonic oscillator system leads to a two-term recursion relation; this system is exactly solvable rather than quasi-exactly solvable.

Second, from the expansion (5) we can see that the wave function $\psi(x,E)$ is the generating function for the polynomials $P_n(E)$.

The third and most significant property of the polynomials $P_n(E)$ is that, when the parameter J takes positive integer values, the polynomials exhibit the factorization property in Eq. (2). This factorization occurs because the third term in the recursion relation (6) vanishes when $n=J+1$, so that all subsequent polynomials have the common factor $P_J(E)$. This factorization property holds for all values of the parameter s. Furthermore, this factorization leads to the result that the zeros

of the critical polynomial $P_J(E)$ are just the quasi-exact energy eigenvalues. This is true because the expansion in (5) truncates when E is a zero of $P_J(E)$; when this series truncates the wave function $\psi(x)$ is automatically normalizable.

To illustrate this factorization we list in factored form the first six polynomials $P_n(E)$ for the case $J=3$:

$$P_0(E)=1, \quad P_1(E)=E, \quad P_2(E)=E^2-64s,$$

$$P_3(E)=E^3-(128s+32)E, \quad P_4(E)=[E^3-(128s+32)E]E, \tag{9}$$

$$P_5(E)=[E^3-(128s+32)E](E^2+128s+192).$$

Observe that $P_3(E)$ is a common factor of $P_n(E)$ for $n\geqslant 3$. The zeros of $P_3(E)$ are

$$E=0, \quad E=\pm\sqrt{128s+32}, \tag{10}$$

which are the three exact energy eigenvalues for the quasi-exactly solvable Hamiltonian (3) when $J=3$. The corresponding exact eigenfunctions are obtained by evaluating $\psi(x)$ in Eq. (5) at these values of E:

$$\psi_0(x)= \exp\left(-\frac{1}{4}x^4\right)\frac{x^{2s-1/2}}{\Gamma(2s)}\left(1-\frac{x^4}{2s+1}\right),$$

$$\psi_+(x)= \exp\left(-\frac{1}{4}x^4\right)\frac{x^{2s-1/2}}{\Gamma(2s)}\left(1-\frac{\sqrt{128s+32}}{8s}x^2+\frac{x^4}{2s}\right), \tag{11}$$

$$\psi_-(x)= \exp\left(-\frac{1}{4}x^4\right)\frac{x^{2s-1/2}}{\Gamma(2s)}\left(1+\frac{\sqrt{128s+32}}{8s}x^2+\frac{x^4}{2s}\right).$$

Note that the energy levels may be ordered by the number of nodes of the corresponding wave function.

A fourth property of the polynomials $P_n(E)$ concerns their norms. The norm (squared) γ_n of $P_n(E)$ is defined as an integral:

$$\gamma_n=\int dE\, w(E)[P_n(E)]^2. \tag{12}$$

It is possible to determine the norms of an orthogonal set of polynomials directly from the recursion relation; it is not necessary to know explicitly the weight function $w(E)$ with respect to which the polynomials are orthogonal.[9] The procedure is simply to multiply the recursion relation (6) by $w(E)E^{n-2}$ and to integrate with respect to E. Using the fact that $P_n(E)$ is orthogonal to E^k, $k<n$, we obtain a simple, two-term recursion relation for γ_n:

$$\gamma_n=16n(J-n)(2s+n-1)\,\gamma_{n-1}. \tag{13}$$

The solution to this equation with $\gamma_0=1$ is

$$\gamma_n=\frac{16^n n!\,\Gamma(J)\Gamma(2s+n)}{\Gamma(J-n)\Gamma(2s)}. \tag{14}$$

This equation reveals that the space of orthogonal polynomials arising from a quasi-exactly solvable model is associated with a nonpositive definite norm. In particular, we can see from Eq.

(14) that γ_n vanishes for $n \geq J$ if J is a positive integer. The appearance of a vanishing norm coincides with the factorization mentioned above and is an alternative characterization of quasi-exact solvability.

It is interesting that while the polynomials $P_{n+J}(E)$ for $n \geq 0$ have vanishing norm when J is a positive integer, the quotient polynomials $Q_n(E)$ in Eq. (2) form a new orthogonal set of polynomials for each value of J.

Having determined the norms γ_n of the polynomials $P_n(E)$ it is natural to evaluate the integral of the square of the generating function (wave function) with respect to the weight function $w(E)$:

$$G(x) = \int dE w(E)[\psi(x,E)]^2, \tag{15}$$

where $\psi(x,E)$ is given in Eq. (5). Using the orthogonality of the polynomials $P_n(E)$, we can express $G(x)$ as a confluent hypergeometric function:

$$G(x) = \frac{\Gamma(J)}{\Gamma(2s)} \exp\left(-\frac{1}{2}x^4\right) \sum_{n=0}^{\infty} \frac{x^{4n+4s-1}}{n!\Gamma(n+2s)\Gamma(J-n)}. \tag{16}$$

When J is a positive integer, this sum truncates and we find that $G(x)$ can be expressed as a linear combination of the squares of the J quasi-exact eigenfunctions of the Hamiltonian H in Eq. (3). For example, when $J=3$, we have

$$\begin{aligned} G(x) &= \frac{1}{\Gamma(2s)} \exp\left(-\frac{1}{2}x^4\right) x^{4s-1}\left[1 + \frac{x^4}{s} + \frac{x^8}{2s(2s+1)}\right] \\ &= \Gamma(2s)\left(\frac{2s+1}{4s+1}[\psi_0(x)]^2 + \frac{s}{4s+1}[\psi_+(x)]^2 + \frac{s}{4s+1}[\psi_-(x)]^2\right), \end{aligned} \tag{17}$$

where $\psi_0(x)$ and $\psi_\pm(x)$ are taken from Eq. (11). We emphasize that this result is highly non-trivial. Expressing $G(x)$ as a linear combination of the squares of the eigenfunctions requires that one solve an overdetermined system of $2J-1$ equations for J expansion coefficients.

Let us now investigate the properties of the weight function $w(E)$. From the polynomials $P_n(E)$ we can calculate the moments of $w(E)$. Let a_n represent the $2n$th moment of $w(E)$:

$$a_n = \int dE w(E) E^{2n}. \tag{18}$$

(Because the polynomials have parity symmetry we know that the odd moments vanish.) We are free to normalize $w(E)$ so that its zeroth moment is unity:

$$a_0 = 1. \tag{19}$$

The remaining moments can then be determined algebraically:

$$\begin{aligned} a_1 &= 32(J-1)s, \\ a_2 &= 32^2(J-1)s(3Js-5s+J-2), \\ a_3 &= 32^3(J-1)s(15J^2s^2-60Js^2+61s^2+15J^2s-67Js+74s+4J^2-19J+22), \\ a_4 &= 32^4(J-1)s(105J^3s^3-735J^2s^3+1743Js^3-1385s^3+210J^3s^2-1596J^2s^2+4038Js^2 \end{aligned} \tag{20}$$

$$-3372s^2+147J^3s-1179J^2s+3114Js-2688s+34J^3-282J^2+765J-674),$$

$$\begin{aligned}a_5=32^5(J-1)s(&945J^4s^4-10080J^3s^4+40950J^2s^4-74400Js^4+50521s^4+3150J^4s^3\\&-35910J^3s^3+153990J^2s^3-292154Js^3+205228s^3+4095J^4s^2-48960J^3s^2+218337J^2s^2\\&-427524Js^2+307860s^2+2370J^4s-29306J^3s+134373J^2s-269085Js+197206s+496J^4\\&-6272J^3+29292J^2-59531J+44134).\end{aligned}$$

These moments have some interesting mathematical properties. For example, all the moments a_n, $n\geqslant 1$, have a factor of $(J-1)s$. Furthermore, in the residual factor the coefficient of $(Js)^{n-1}$ is $(2n-1)!!$ and the coefficient of s^{n-1} is the nth Euler number E_n.[10]

The outstanding property of the moments a_n concerns their rapid rate of growth. This rate of growth can be determined using the fact that there is a simple relationship between the moments a_n and the coefficients b_{n-1} of $P_{n-2}(E)$ in the recursion relation (6). Specifically, the Taylor series

$$f(z)=\sum_{n=0}^{\infty} a_n z^n, \tag{21}$$

whose coefficients are the moments in Eq. (18), is equivalent to a continued fraction

$$f(z)=1/(1-b_1z/(1-b_2z/(1-b_3z/(1-\ldots)))), \tag{22}$$

whose coefficients are b_n.[11] Since b_n is a cubic polynomial in n we deduce that the moments a_n grow like $(3n)!$.[11]

It is unusual to find orthogonal polynomials whose weight functions have moments that grow so rapidly. The classical orthogonal polynomials, such as the Hermite polynomials, typically have moments that grow like $n!$. This is also true of discrete versions of the classical orthogonal polynomials, such as the Hahn polynomials.[12] The Euler and Bernoulli polynomials are distinctive[13] in that their moments grow like $(2n)!$. However, the polynomials $P_n(E)$ associated with quasi-exact solvability are of an entirely new type due to the rapid rate of growth of their moments. Carleman's condition states that when the moments grow faster than $(2n)!$, the moment problem is not guaranteed to have a unique solution.[15] Almost certainly, the weight function $w(E)$ is not unique! This nonuniqueness corresponds to a kind of gauge invariance that underlies these quasi-exactly solvable systems. Indeed one may conjecture that the nonuniqueness of the weight function is related to the Lie algebraic symmetry of quasi-exact solvability.

We each thank the U.S. Department of Energy for Financial Support.

[13] The Euler and Bernoulli polynomials differ from the classical orthogonal polynomials in that they do not satisfy a

differential equation. This is likely to be true of the polynomials $P_n(E)$ discussed in this paper. Indeed, if the domain of the weight function for a set of orthogonal polynomials is the whole real line then the polynomials *must* be the Hermite polynomials (see Ref. 14).

A rigorous treatment of conformal blocks in a model of bosonic conformal field theory

Pierre-Alain Bovier
Institut für Mathematik, ETH Zentrum, 8092 Zürich, Switzerland

(Received 11 May 1995; accepted for publication 20 September 1995)

A free massless field coupled to a background charge Q is considered. The conformal blocks of the theory are adequately described by the N-point vertex $V_{N;0}$ which is, up to a multiplicative constant, completely determined by the Knizhnik–Zamolodchikov equations and a set of Ward identities on the sphere. The N-point g-loop vertex $V_{N;g}$ for compact Riemann surfaces Σ_g of genus $g\neq 0$ is constructed by a sewing procedure. The main new result is a rigorous proof of the fact that $V_{N;0}$ is trace class for nonoverlapping disks. This allows one to show that the set of all N-point vertices (for all N) is a modular functor. © *1996 American Institute of Physics.* [S0022-2488(96)01301-3]

I. INTRODUCTION

In two-dimensional conformal invariant quantum field theory, the minimal models of Belavin, Polyakov, and Zamolodchikov[1] belong to the simplest ones. They are built upon a finite set of irreducible highest weight modules $L(h,c)$ of the Virasoro algebra with central charge $c=1-6(p'-p)^2/pp'$ parametrized by two positive and relatively prime integers p and p'. It has been realized in Ref. 2 that these models can be constructed using a free field in a background charge. More precisely, the spaces $L(h,c)$ are isomorphic to the BRST-cohomologies of certain complexes of free field Hilbert spaces. This connection allowed the computation of conformal blocks of minimal models on Riemann surfaces.[3,4]

In this paper, we study free field theories for their own sake. We present a rigorous construction of the N-point vertex $V_{N;g}$ on compact Riemann surfaces of arbitrary genus g. Out of it, it is easy to construct the conformal blocks (i.e., the holomorphic correlation functions) which contain all the information of the theory. One simply has to saturate the vertex with the states

$$\prod t_i'(0)^{-\beta_i(\beta_i-Q)/2}|0\rangle_{\beta_i}.$$

Our guideline throughout the paper is Segal's axiomatic framework[5] (Sec. VII). Starting with the N-point vertex on the sphere, we construct the N-point g-loop vertex by a sewing procedure. Our main new result is Theorem 13 which proves the validity of the whole construction. We also show that the result we get does not depend on our particular way of sewing. If this were the case, we would have a contradiction with Segal's fourth axiom. Finally, we establish the validity of the other axioms in Sec. X. An important remark is that the axiom (iii) is not true in the presence of a background charge, which implies a lack of physical positivity. In order for our construction to be really complete, we would still have to check that we can obtain all Riemann surfaces (up to equivalence) by only sewing disks together on the sphere. Whether this is true or not is not known to the author, but is an interesting open question.

Although this paper is organized in a self-consistent way, the interested reader can find more background and computational details in Ref. 6.

II. FREE BOSONIC THEORY

For the sake of clarity and to fix the notation, we briefly review some properties of a free massless field. The coupling to a background charge Q will only play a role when we later introduce correlators.

We define the Heisenberg algebra $(a_n)_{n\in\mathbb{Z}}$ through the commutation relations

$$[a_n, a_m] = n\,\delta_{n+m,0}. \tag{1}$$

It is useful to know that for fixed $n>0$, the operators $a_n/\sqrt{n}$ and $a_{-n}/\sqrt{n}$ satisfy the canonical commutation relations

$$\left[\frac{a_n}{\sqrt{n}}, \frac{a_{-n}}{\sqrt{n}}\right] = 1.$$

a_0 is called the zero mode of the algebra. The algebra (1) has infinite dimensional representations π_μ characterized by a real number μ, a highest weight vector $|0\rangle_\mu$, and the relations

$$a_0|0\rangle_\mu = \mu|0\rangle_\mu, \quad a_n|0\rangle_\mu = 0, \quad n>0.$$

We further define e_n as the multiindex with 1 at position n and 0 otherwise. A basis of π_μ is given by

$$|\phi_\beta\rangle_\mu = \frac{a_{-1}^{\beta_1}\cdots a_{-k}^{\beta_k}}{\sqrt{\beta!}\sqrt{I^\beta}}\,|0\rangle_\mu,$$

where $\beta=(\beta_1,...,\beta_k)$ is a finite multiindex, $\beta!=\Pi\beta_i!$, $I^\beta = \Pi i^{\beta_i}$. Moreover we set $\|\beta\|=\Sigma i\beta_i$. We now have the relations

$$a_n|\phi_\beta\rangle_\mu = \sqrt{n\beta_n}\,|\phi_{\beta-e_n}\rangle_\mu, \quad n>0,$$

$$a_{-n}|\phi_\beta\rangle_\mu = \sqrt{n(\beta_n+1)}\,|\phi_{\beta+e_n}\rangle_\mu, \quad n>0,$$

where we set $|\phi_\beta\rangle_\mu=0$ if β has one or more negative components. The space π_μ of all finite linear combinations of basis vectors possesses a scalar product which is uniquely determined by the requirements $a_n^* = a_{-n}$ for all $n\in\mathbb{Z}$ and that $|0\rangle_\mu$ has norm one. We denote the completion of π_μ with respect to this scalar product by $\overline{\pi_\mu}$. The vectors $|\phi_\beta\rangle_\mu$ form an orthonormal basis of $\overline{\pi_\mu}$. We next introduce the operator

$$L_0 = \frac{1}{2}\,a_0(a_0-Q) + \sum_{n=1}^{\infty} a_{-n}a_n,$$

where the real number Q is called the background charge of the theory. L_0 is a well defined symmetric operator on π_μ and is bounded below.

Definition 1: For $R>0$ we define H_R^μ as the completion of π_μ with respect to the scalar product

$$(\varphi,\psi)_R = (R^{-L_0}\varphi, R^{-L_0}\psi).$$

It is easy to see that

$$\pi_\mu \subseteq H_R^\mu \subseteq H_{R'}^\mu, \subseteq H_1^\mu = \overline{\pi_\mu} \subseteq H_{R''}$$

for $0<R\leqslant R'\leqslant 1\leqslant R''$. An orthonormal basis of H_R^μ is given by the vectors $R^{L_0}|\phi_\alpha\rangle_\mu$. The fundamental fields of the theory are

$$J(z)=\sum_{n\in\mathbb{Z}} a_{-n}z^{n-1}=a_0 z^{-1}+\sum_{n\neq 0}\sqrt{|n|}\,\frac{a_{-n}}{\sqrt{|n|}}\,z^{n-1}$$

and

$$V_\beta(z)=T_\beta z^{\beta a_0}\exp\left(\beta\sum_{n=1}^{\infty}\frac{a_{-n}}{n}\,z^n\right)\exp\left(-\beta\sum_{n=1}^{\infty}\frac{a_n}{n}\,z^{-n}\right),\quad \beta\in\mathbb{R},$$

where $T_\beta:\pi_\mu\to\pi_{\mu+\beta}$ is the linear map sending $|\phi_\alpha\rangle_\mu$ to $|\phi_\alpha\rangle_{\mu+\beta}$ for all finite multi-indices α.

Definition 2: We define $TC_\mu^{\mu+\beta}$ as the space of all operators A with the following properties:

(a) $A(z):H_R^\mu\to H_{R'}^{\mu+\beta}$ *is an analytic (possibly many-valued) trace class operator for* $0<R<|z|<R'$.

(b) *The operator $J(z_1)A(z_2):H_R^\mu\to H_{R'}^{\mu+\beta}$ has a (possibly many-valued) trace class analytic continuation to the whole domain $R<|z_1|,|z_2|<R'$ with a possible pole at $z_1=z_2$.*

(c) *The analytic continuation is radial ordering for $|z_1|\neq|z_2|$.*

It is not too hard to show that $J\in TC_\mu^\mu$. Using generalized Laguerre polynomials,[6] it is possible to show the following result:

Proposition 3: $V_\beta\in TC_\mu^{\mu+\beta}$

To give the reader an idea of the techniques involved, we sketch the proof of property (a). The square of the Hilbert–Schmidt norm of $V_\beta(z):H_R^\mu\to H_{R'}^{\mu+\beta}$ is given by

$$\sum_{\|\alpha\|<\infty}\|R'^{-L_0}V_\beta(z)R^{L_0}|\phi_\alpha\rangle\|^2=c\sum_{\|\alpha\|<\infty}\left(\frac{R}{R'}\right)^{2\|\alpha\|}\exp\left(\sum_{k=1}^{\infty}\frac{|\beta|^2}{k}\left(\frac{|z|}{R'}\right)^{2k}\right)\times\prod_{k=1}^{\infty}L_{\alpha_k}\left(-\frac{|1-(|z|/R')^{2k}|^2}{(k/|\beta|^2)(|z|/R')^{2k}}\right),$$

where we have introduced the Laguerre polynomials

$$L_n(x)=\sum_{m=0}^{n}\binom{n}{m}\frac{(-x)^{n-m}}{(n-m)!}\tag{2}$$

The constant c comes from the purely zero mode contributions, and is therefore unimportant here. The expression we have in the sum is finite if and only if $|z|<R'$. Using the generating function

$$\sum_{n=0}^{\infty}t^n L_n(-x)=\frac{1}{1-t}\exp\left(\frac{tx}{1-t}\right),\quad |t|<1\tag{3}$$

we can compute the sum and find

$$\sum_{\|\alpha\|<\infty}\|R'^{-L_0}V_\beta(z)R^{L_0}|\phi_\alpha\rangle\|^2=c\,\exp\left(\sum_{k=1}^{\infty}\frac{|\beta|^2}{k}\left(\frac{|z|}{R'}\right)^{2k}\right)\prod_{k=1}^{\infty}\frac{1}{1-(R/R')^{2k}}\times\exp\left(\frac{(|\beta|^2/k)(R/|z|)^{2k}|1-(|z|/R')^{2k}|^2}{1-(R/R')^{2k}}\right).$$

It is not too hard to see that this sum is finite if and only if $R<|z|<R'$. Therefore, $V_\beta(z):H_R^\mu \to H_{R'}^{\mu+\beta}$ is a Hilbert–Schmidt operator for $R<|z|<R'$. A part of this result was found independently by Ref. 7 (albeit without the use of Laguerre polynomials). By a deformation argument similar to the one used in Theorem 16, we can prove that V_β is actually a trace class operator.

Considering radially ordered products of J's with V_β, we get new operators which have radial ordering as analytic continuation. We want to make this idea rigorous with the following:

Definition 4: We define the linear map $j:\pi_\beta \to TC_\mu^{\mu+\beta}$ recursively by the relations

$$j|0\rangle_\beta = V_\beta,$$

$$(j(a_n\psi))(z) = \frac{1}{2\pi i} \oint_z d\zeta (\zeta - z)^n J(\zeta)(j\psi)(z), \quad \forall \psi \in \pi_\beta, \quad \forall n \in \mathbb{Z},$$

where the arguments z and ζ are implicitly radially ordered.

As an operator $H_R \to H_{R'}$, $(j(a_n\psi))(z)$ can be practically computed as

$$(j(a_n\psi))(z) = \frac{1}{2\pi i} \oint_{|\zeta|=r'} d\zeta (\zeta - z)^n J(\zeta)(j\psi)(z) - \frac{1}{2\pi i} \oint_{|\zeta|=r} d\zeta (\zeta - z)^n (j\psi)(z) J(\zeta),$$

where $R<r<|z|<r'<R'$. All the operators $j\phi$ with $\phi \neq |0\rangle_\beta$ are called descendant fields.

Proposition 5:

(*a*) *j is well defined;*

(*b*) $(ja_{-n_1}\cdots a_{-n_k}|0\rangle_\beta)(z) = \dfrac{:\partial^{n_1-1}J\cdots\partial^{n_k-1}JV_\beta:(z)}{(n_1-1)!\cdots(n_k-1)!}$.

The dots ":" in (b) denote Wick ordering (it brings T_β and all the a_n with negative n to the left). What (a) says is that j respects the commutation relations $[a_n,a_m]=n\delta_{n+m;0}$ of the Heisenberg algebra, and that $j\psi$ is really in $TC_\mu^{\mu+\beta}$ for all $\psi \in \pi_\beta$, which can be easily proved by induction. An immediate consequence is that our operator algebra contains all fields of the form

$$:P(J,\partial J,\partial^2 J,\ldots)V_\beta:,$$

where P is an arbitrary polynomial. That it contains no other operators is the content of Theorem 6.

Theorem 6: *For all $\varphi \in \pi_{\beta_1}$, $\psi \in \pi_{\beta_2}$ the product $(j\varphi)(z_1)(j\psi)(z_2)$ is analytic (but possibly many-valued) in z_1, z_2 if $R'>|z_1|>|z_2|>R$ and has a (possibly many-valued) analytic trace class continuation to $R'>|z_1|,|z_2|>R$, $z_1 \neq z_2$. This analytic continuation can be expanded in the form*

$$(j\varphi)(z_1)(j\psi)(z_2) = (z_1-z_2)^{\beta_1\beta_2} \sum_{n \geqslant -N} (z_1-z_2)^n \psi_n(z_2),$$

where N is finite and $\psi_n \in TC_\mu^{\mu+\beta_1+\beta_2}$ are (finite sums of) descendant fields. The sum converges in the trace norm and therefore also in the operator norm if

$$|z_1-z_2| < \min(R'-|z_2|, |z_2|-R).$$

What this theorem means is that if we allow the values β of V_β to sit in a lattice L, we have a closed operator algebra in the following sense: the product of any two fields in the algebra can be expanded in a power series whose Laurent coefficients are again fields in the algebra. The operator algebra consists of all vertex operators V_β and their descendants. The properties we require of the lattice L are the following:

(a) $L \subset \mathbb{R}$;

(b) $\beta_1,\beta_2 \in L \Rightarrow \beta_1+\beta_2 \in L$;

(c) $\beta \in L \Rightarrow -\beta \in L$;

(d) $Q \in L$;
(e) L is a countable set.

III. DUAL SPACES

In order to define the N-point vertex $V_{N;0}$ in Sec. IV, and to extend the theory to Riemann surfaces, it is necessary to introduce the concept of dual module. The space π_β is graded by the eigenspaces of L_0:

$$\pi_\beta = \oplus_{n=0}^{\infty} \pi_{\beta,n},$$

where the subspace $\pi_{\beta,n}$ with L_0 eigenvalue $\frac{1}{2}\beta(\beta-Q)+n$ has dimension $p(n)$, the number of partitions of n. As a space, the dual module π_β^* is just the sum of the duals of the homogeneous components

$$\pi_\beta^* = \oplus_{n=0}^{\infty} \pi_{\beta,n}^*.$$

In addition, π_β^* is both a left and a right Heisenberg module. To see this, we have to define a left and a right action of the generators of the Heisenberg algebra on a general covector $\omega \in \pi_\beta^*$. By definition

$$(\omega a_n)(\varphi) = \omega(a_n \varphi)$$

and

$$(a_n \omega)(\varphi) = \omega((Q\delta_{n;0} - a_{-n})\varphi),$$

where $\varphi \in \pi_\beta$ and where $(\ \ )(\ \ )$ denotes duality. It is easy to check the relations

$$[a_n, a_m] = [Q\delta_{m;0} - a_{-m}, Q\delta_{n;0} - a_{-n}]$$

establishing the left module structure of π_β^*. Let us define

$$L_l = \frac{1}{2} \sum_{m \in Z} :a_m a_{l-m}: - \frac{1}{2} Q(l+1) a_l \tag{4}$$

which satisfy the Virasoro commutation relations

$$[L_n, L_m] = (n-m)L_{n+m} + \frac{c}{12} n(n^2-1)\delta_{n+m;0}$$

with $c = 1 - 3Q^2$. Now π_β^* also carries a left and right Virasoro structure. Indeed, using the definition of L_n, we find

$$(\omega L_n)(\varphi) = \omega(L_n \varphi)$$

and

$$(L_n \omega)(\varphi) = \omega(L_{-n}\varphi).$$

The vector ${}_\beta\langle 0| \in \pi_{\beta,0}^*$ with ${}_\beta\langle 0|0\rangle_\beta = 1$ is the highest weight vector of π_β^* with L_0 (left or right) eigenvalue $\frac{1}{2}\beta(\beta-Q)$. Since we will later work with the spaces $\oplus_{\beta \in L} \pi_\beta$, it is natural to define

$${}_\alpha\langle 0|0\rangle_\beta = \delta_{\alpha;\beta}. \tag{5}$$

Note that vectors in π_β^* have left a_0 eigenvalue $Q-\beta$. As a consequence, the spaces π_β^* and $\pi_{Q-\beta}$ are isomorphic as left Heisenberg modules, the isomorphism being

$$a_{n_1}\cdots a_{n_k\beta}\langle 0| \mapsto a_{n_1}\cdots a_{n_k}|0\rangle_{Q-\beta}. \tag{6}$$

IV. THE N-POINT VERTEX $V_{N;0}$

The purpose of this section is to introduce the N-point vertex $V_{N;0}$ for a free bosonic theory coupled to a background charge Q. It depends on N coordinate systems $t_1(z)=z+z_1,\ldots,t_N(z)=z+z_N$ on the Riemann sphere. In a later section, we will generalize it to arbitrary projective coordinates $t_1,\ldots,t_N$.

In any field theory, it is important to know the vacuum expectation value of a product of fields. In our case, this means the value of

$${}_Q\langle 0|(j|\psi_1\rangle)(z_1)\cdots(j|\psi_N\rangle)(z_N)|0\rangle_0 \tag{7}$$

for $|\psi_i\rangle \in \pi_{\beta_i}$ and $|z_1|>\cdots>|z_N|$. We interpret the out vacuum ${}_Q\langle 0|$ as having a charge Q. In other words, we couple the system to a charge Q sitting in the point ∞. We know from Sec. II that Eq. (7) has an analytic (possibly many-valued) continuation to noncoinciding points. Moreover, by the equality (5), the vacuum expectation value vanishes unless $\Sigma_i\beta_i=Q$. We define $V_{N;0}(t_1,\ldots,t_N)$ by

$$V_{N;0}(t_1,\ldots,t_N)|\psi_1\rangle\cdots|\psi_N\rangle={}_Q\langle 0|(j|\psi_1\rangle)(z_1)\cdots(j|\psi_N\rangle)(z_N)|0\rangle_0.$$

It is a multilinear form acting on $\pi_{\beta_1}\otimes\cdots\otimes\pi_{\beta_N}$. The next proposition states that $V_{N;0}$ is completely determined by its value on $|0\rangle_{\beta_1}\cdots|0\rangle_{\beta_N}$. Before we can state the proposition, we define $\mathscr{M}$ as the space of meromorphic functions which are regular at ∞ and have poles only at the points $t_1(0)=z_1,\ldots,t_N(0)=z_N$ with $|z_1|>\cdots>|z_N|$. In other words $\mathscr{M}$ consists of all finite linear combinations of functions of the type $(z-z_i)^m$, $m\leqslant 0$ an integer. For $f\in\mathscr{M}$ we define

$$a_{z_i}(f)=\frac{1}{2\pi i}\oint_{z_i} d\zeta\, f(\zeta)J(\zeta-z_i),$$

where the contour encircles the point z_i, but no other point z_j, $j\neq i$. Since f has at most a pole singularity at $z=z_i$, $a_{z_i}(f)$ leaves π_{β_i} invariant. By the definition of j, we can also write

$$(ja_{z_i}(f)\varphi)(z_i)=\frac{1}{2\pi i}\oint_{z_i} d\zeta\, f(\zeta)J(\zeta)(j\varphi)(z_i) \tag{8}$$

because Eq. (8) is true for all f of the form $f(z)=(z-z_i)^m$. Now comes a fundamental proposition:

Proposition 7: Let $f\in\mathscr{M}$, $|\varphi_i\rangle \in \pi_{\beta_i}$, $\Sigma\beta_i=Q$, $|z_1|>\cdots>|z_N|$. *Then*

$$\sum_{i=1}^{N} {}_Q\langle 0|(j|\varphi_1\rangle)(z_1)\cdots(j(a_{z_i}(f)|\varphi_i\rangle)(z_i))\cdots(j|\varphi_N\rangle)(z_N)|0\rangle_0$$
$$=Qf(\infty){}_Q\langle 0|(j|\varphi_1\rangle)(z_1)\cdots(j|\varphi_N\rangle)(z_N)|0\rangle_0, \tag{9}$$

where $f(\infty)=\lim_{z\to\infty} f(z)$.

These equalities are called Ward identities and reflect the $U(1)$ Kac–Moody symmetry generated by J. The proof of the proposition is a straightforward argument of contour deformation.

With Eq. (9), we can successively build down the degrees of the $|\varphi_i\rangle$ until we get a product of vacua (here, the degree of $a_{-n_1}\cdots a_{-n_k}|0\rangle_\beta$ is defined as $\Sigma_i n_i$). With the help of this proposition, it is possible to prove Proposition 8.

Proposition 8: We have

$$V_{N;0}=\delta_{\Sigma\beta_i;Q}\ {}_{\beta_1}\langle 0|\cdots{}_{\beta_N}\langle 0|\exp\left(\sum_{\substack{i,j=1\\ i<j}}^{N}\sum_{m,n=0}^{\infty} a_n^{(i)}a_m^{(j)}\,\frac{\partial_{z_i}^n}{n!}\,\frac{\partial_{z_j}^m}{m!}\log(z_i-z_j)\right).$$

Here, the upper index $^{(i)}$ means that the action is on the ith factor of the tensor product $\otimes\ \pi_{\beta_j}$.

V. THE KNIZHNIK–ZAMOLODCHIKOV EQUATIONS

In this paragraph, we want to extend the N-point vertex $V_{N;0}$ to general projective coordinates using the Knizhnik–Zamolodchikov equations. Let us start by defining the energy-momentum tensor

$$T(z)=\tfrac{1}{2}{:}(\partial\phi)^2{:}(z)-\tfrac{1}{2}Q\partial^2\phi(z)$$

with the expansion

$$T(z)=\sum_{n\in\mathbb{Z}} L_n z^{n-2}, \tag{10}$$

where the modes L_n are given by Eq. (4). Using the explicit formula we have for j (Proposition 5b) as well as the Leibniz rule for differentiating a product, we can check Proposition 9.

Proposition 9: We have the following operator equation (both sides are operators: $H_R^\alpha\to H_{R'}^{\alpha+\beta}$, $R<|z|<R'$):

$$(jL_{-1}\psi)(z)=\partial_z(j\psi)(z),\quad \psi\in\pi_\beta.$$

This proposition immediately implies that

$$\partial_{z_i}V_{N;0}(t_1,\ldots,t_N)=V_{N;0}(t_1,\ldots,t_N)L_{-1}^{(i)}. \tag{11}$$

Actually, Eq. (11) together with the Ward identities (9) uniquely characterize $V_{N;0}$ up to a multiplicative constant. The Ward identities fix its dependence on the states it acts on, while Eq. (11) fixes its dependence on t_i. From now on, we would like to admit more general projective transformations t_i. Proposition 9 tells us what happens to $V_{N;0}$ under translations. With the idea in mind that the energy-momentum tensor is the infinitesimal generator of conformal transformations, we would like to describe how $V_{N;0}$ changes under an infinitesimal projective transformation. The collection $t_1,\ldots,t_N$ of projective coordinate systems is called admissible if $t_i(0)\neq t_j(0)$ whenever $i\neq j$. Consider a connected, simply connected open neighbourhood U of one such collection $t_1^0,\ldots,t_N^0$ which contains only admissible collections of coordinates. Let ML_N be the space of multilinear forms

$$V:\pi_{\beta_1}\otimes\cdots\otimes\pi_{\beta_N}\to\mathbb{C}$$

which depend holomorphically on N coordinate systems $t_1,\ldots,t_N$ in U (for arbitrary but fixed β_i satisfying $\Sigma\beta_i=Q$). Let us now look at a coordinate change in U:

$$\tilde{t}_i(z)=t_i(z)+\epsilon v(z)\,\frac{d}{dz}\,t_i(z),$$

where $v(z)d/dz$ is some holomorphic vector field on the Riemann sphere, i.e., of the form

$$v(z)\,\frac{d}{dz}=\sum_{n=-1}^{1} v_n z^{n+1}\,\frac{d}{dz}$$

and ϵ is a real parameter. We define an action of v on π_{β_i} by

$$\pi(v)|\,\eta\rangle=-\sum_{n=-1}^{1} v_n L_n|\,\eta\rangle.$$

Only finitely many terms in the expansion

$$\frac{1}{2}\sum_{k\in\mathbb{Z}} :a_k a_{n-k}:$$

of L_n contribute for a given $|\,\eta\rangle \in \pi_{\beta_i}$, and the action is well defined. With the Lie bracket

$$\left[-z^{n+1}\,\frac{d}{dz},-z^{m+1}\,\frac{d}{dz}\right]=-(n-m)z^{n+m+1}\,\frac{d}{dz}$$

for vector fields, this becomes a Lie algebra action in correspondence with the Virasoro algebra commutation relations

$$[L_n,L_m]=(n-m)L_{n+m}$$

for $n,m\in\{-1,0,1\}$. We further define

$$\partial_v^{(i)}V(t_1,\ldots,t_N)=\frac{d}{d\epsilon}\,V(t_1,\ldots,\tilde{t}_i,\ldots,t_N)|_{\epsilon=0}$$

and

$$\nabla_v^{(i)}V=\partial_v^{(i)}V+V\pi(v)^{(i)}$$

for $V\in ML_N$. Both $\partial_v^{(i)}$ and $\nabla_v^{(i)}$ are linear maps: $ML_N\to ML_N$. Let $\mathscr{M}_N$ be the space of holomorphic functions

$$f:U\times\hat{\mathbb{C}}\to\hat{\mathbb{C}}$$

satisfying $f^{-1}(\infty)\subset\cup_{i=1}^{N}\{(t_1,\ldots,t_N,z)|z=t_i(0)\}$. We emphasize that f should have only pole singularities [in no other hyperplanes than $z=t_i(0)$]. This space carries a Lie algebra structure under the bracket

$$[f,g]=\sum_{i=1}^{N}\,\frac{1}{2\pi i}\,\oint_{z_i} g\,df=0,$$

where df denotes the differential of f with respect to z. The expression is zero because the 1-form gdf has no poles outside $z=z_i(=t_i(0))$. We now define an action of $f\in\mathscr{M}_N$ on the space ML_N by

$$(f\cdot V)(t_1,\ldots,t_N)=V(t_1,\ldots,t_N)\left(\sum_{i=1}^{N} a_{t_i}^{(i)}(f\,)-Qf(t_1,\ldots,t_N,\infty)\right),\tag{12}$$

where the upper index $^{(i)}$ *again means that the action is on the ith factor* π_{β_i} *and where* $a_t(f)$ is implicitly defined by the equation

$$j_t a_t(f)\varphi = \frac{1}{2\pi i} \oint_{t(0)} f(z)J(z)j_t\varphi \, dz. \tag{13}$$

For $t(z)=z+z_i$, we have $a_t(f) = a_{z_i}(f)$ by Eq. (8). By analyzing infinitesimal coordinate changes, we see that Eq. (13) is a good definition for $a_t(f)$ which means that $a_t(f)$ maps π_β to itself. Using the operator product

$$J(\zeta)J(z) = \frac{1}{(\zeta-z)^2} + \text{regular terms}$$

we can show that Eq. (12) defines a Lie algebra action of $\mathscr{M}_N$ on ML_N. We would now like to define the N-point vertex $V_{N;0} \in ML_N$ as a solution to the Knizhnik–Zamolodchikov equations

$$\nabla_v^{(i)} V = 0 \tag{14}$$

for all vector fields v and to the Ward identities

$$(f \cdot V) = 0 \tag{15}$$

for all $f \in \mathscr{M}_N$. That Eq. (14) is compatible is a consequence of Proposition 10.

Proposition 10: The connection ∇ *is flat, i.e.,*

$$[\nabla_u^{(i)}, \nabla_v^{(j)}] = \delta^{ij}\nabla_{[u,v]}^{(i)}.$$

Proof: For $i \neq j$ this is true because $\nabla_v^{(i)}$ and $\nabla_u^{(j)}$ act on different factors. If $i=j$, the relation is an immediate consequence of

$$[\partial_u, \partial_v] = \partial_{[u,v]}$$

and the fact that we have a Lie algebra action of vector fields. ■

We know from the previous section that the Ward identities

$$f \cdot V(t_1,\ldots,t_N) = 0, \quad \forall f \in \mathscr{M}_N$$

for the fixed collection of coordinate systems $t_i^0(z) = z + z_i$ determine the multilinear form V (for these particular t_i^0) uniquely up to a scalar multiple. The Knizhnik–Zamolodchikov equation (14) being first-order compatible differential equations allow us to extend this V uniquely to other coordinates t_i along each path starting at t_i^0 in our space of coordinate systems. The solution we get will be holomorphic in admissible $(t_1,\ldots,t_N) \in U$. Moreover, it is sufficient to impose $\nabla_v V = 0$ for $v(\zeta) = 1, \zeta, \zeta^2$. Let us call the solution we get the N-point vertex and denote it by $V_{N;0}$ (0 is the genus of the surface, which is 0 for the Riemann sphere). For all $f \in \mathscr{M}_N$ we have

$$\begin{aligned}
&(f \cdot V_{N;0})(t_1,\ldots,t_N)|\eta_1\rangle\cdots|\eta_N\rangle \\
&\quad = {}_Q\langle 0|\sum_{i=1}^N j_{t_1}|\eta_1\rangle\cdots j_{t_i}a_{t_i}^{(i)}(f)|\eta_i\rangle\cdots j_{t_N}|\eta_N\rangle|0\rangle_0 - Qf(t_1,\ldots,t_N,\infty)V_{N;0}|\eta_1\rangle\cdots|\eta_N\rangle \\
&\quad = \sum_{i=1}^N {}_Q\langle 0|\sum_{i=1}^N j_{t_1}|\eta_1\rangle\cdots \frac{1}{2\pi i}\oint_{t_i(0)} f(z)J(z)j_{t_i}|\eta_i\rangle dz\cdots j_{t_N}|\eta_N\rangle|0\rangle_0 \\
&\qquad - Qf(t_1,\ldots,t_N,\infty)V_{N;0}|\eta_1\rangle\cdots|\eta_N\rangle
\end{aligned}$$

$$
\begin{aligned}
&= {}_Q\langle 0|\ \frac{1}{2\pi i}\ \oint_{|z|\gg 1} f(z)J(z)dz\ j_{t_1}|\,\eta_1\rangle\cdots j_{t_N}|\,\eta_N\rangle|0\rangle_0 \\
&- {}_Q\langle 0|j_{t_1}|\,\eta_1\rangle\cdots j_{t_N}|\,\eta_N\rangle\ \frac{1}{2\pi i}\ \oint_0 f(z)J(z)dz|0\rangle_0 - Qf(t_1,\ldots,t_N,\infty)V_{N;0}|\,\eta_1\rangle\cdots|\,\eta_N\rangle \\
&= 0
\end{aligned}
$$

so $V_{N;0}$ automatically satisfies Eqs. (15) in all coordinate systems. Let us summarize what we have found in the following:

Proposition 11: The Ward identities (15) for a particular collection of admissible coordinate systems, together with the Knizhnik–Zamolodchikov equations (14) for all admissible $t_1,\ldots,t_N$ and $v(\zeta)=1,\zeta,\zeta^2$, determine $V \in ML_N$ uniquely up to a scalar multiple. We call this V the N-point vertex and denote it by $V_{N;0}$. It is analytic (but possibly many-valued) in $t_1,\ldots,t_N$. Moreover, it satisfies the Ward identities (15) for all admissible $t_1,\ldots,t_N$.

The next proposition gives an explicit form for $V_{N;0}$:

Proposition 12: Up to a multiplicative constant, $V_{N;0}$ is given by

$$
V_{N;0} = \delta_{\Sigma_{i=1}^N \beta_i;Q^{\beta_1}}\langle 0|\cdots_{\beta_N}\langle 0|\exp\left(-\sum_{\substack{i,j=1\\ i<j}}^{N}\ \sum_{n,m=0}^{\infty}\ \alpha_n^{(i)}D_{nm}(s_i t_j)\alpha_m^{(j)}\right), \tag{16}
$$

where t_i are projective coordinates, i.e., have the form

$$
t_i(z)=\frac{Az+B}{Cz+D},\quad AD-BC=1.
$$

$s_i t_j$ denotes composition of the maps s_i and t_j, and

$$
\alpha_n=\begin{cases} a_0, & n=0 \\ \dfrac{a_n}{\sqrt{|n|}}, & n\neq 0, \end{cases}
$$

$$
s_i(z)=\frac{1}{t_i^{-1}(z)},
$$

$$
D_{nm}(\gamma)=\frac{\sqrt{m}}{\sqrt{n}}\ \frac{\partial^m}{m!}\ \gamma(z)^n\Big|_{z=0},\quad n,\ m\neq 0,
$$

$$
D_{00}(\gamma)=\tfrac{1}{2}\log(\gamma'(z))\big|_{z=0},
$$

$$
D_{n0}(\gamma)=\frac{1}{\sqrt{n}}\ \gamma(z)^n\Big|_{z=0},\quad n\neq 0,
$$

$$
D_{0m}(\gamma)=\frac{1}{2}\ \sqrt{m}\ \frac{\partial^m}{m!}\log\ \gamma'(z)\Big|_{z=0},\quad m\neq 0.
$$

The proof splits into two parts. First, we must show that this expression agrees, up to a multiplicative constant, with the one we have found in the special case where $t_i(z)=z+z_i$. This is easy to check. The more lengthy but nevertheless straightforward part consists in checking the KZ equations.

VI. THE SCHOTTKY REPRESENTATION OF A RIEMANN SURFACE

In this section we describe how we can, starting from a punctured sphere, obtain compact Riemann surfaces. This will ultimately help us to extend the N-point vertex $V_{N;0}$ from the Riemann sphere to more general Riemann surfaces. Let S_μ $(\mu=1,...,g)$ be a set of g projective transformations, i.e.,

$$S_\mu(z)=\frac{a_\mu z+b_\mu}{c_\mu z+d_\mu}, \quad a_\mu d_\mu-b_\mu c_\mu=1 \tag{17}$$

having some characteristic circles (see below) all exterior to one another. The Schottky group $\mathscr{G}_g$ is the subgroup of PSL $(2,\mathbb{C})$ generated by the S_μ's. Therefore, an element $T\in\mathscr{G}_g$, except for the identity, can be written in the form

$$T=S_{\mu_1}^{n_1}\cdots S_{\mu_r}^{n_r}, \quad r=1,2,\ldots, \quad n_i\in\mathbb{Z}\backslash\{0\}, \quad \mu_i\neq\mu_{i+1}.$$

A more convenient way to specify the generators S_μ than Eq. (17) is by their multipliers k_μ and fixed points ξ_μ and η_μ defined by

$$\frac{S_\mu(z)-\eta_\mu}{S_\mu(z)-\xi_\mu}=k_\mu\frac{z-\eta_\mu}{z-\xi_\mu}, \quad 0<|k_\mu|<1.$$

Since for any $z\in\hat{\mathbb{C}}\{\xi_\mu,\eta_\mu\}$ we have

$$\lim_{n\to\infty} S_\mu(z)^n=\eta_\mu, \quad \lim_{n\to\infty} S_\mu(z)^{-n}=\xi_\mu$$

we call η_μ the attractive fixed point and ξ_μ the repulsive fixed point. The g generators S_μ and their inverse identify in the extended complex plane $2g$ circles $\mathscr{C}_\mu$ and $\mathscr{C}'_\mu$ for $\mu=1,...,g$, called isometric circles and defined, respectively, by

$$\left|\frac{dS_\mu}{dz}\right|^{-1}=|c_\mu z+d_\mu|^2=1, \quad \left|\frac{dS_\mu^{-1}}{dz}\right|^{-1}=|c_\mu z-a_\mu|^2=1.$$

It is easy to verify that the projective transformation S_μ maps $\mathscr{C}_\mu$ onto $\mathscr{C}'_\mu$ and that of course the inverse S_μ^{-1} maps $\mathscr{C}'_\mu$ onto $\mathscr{C}_\mu$. Moreover, the exterior of $\mathscr{C}_\mu$ will be mapped by S_μ into the interior of $\mathscr{C}'_\mu$ whereas the interior of $\mathscr{C}_\mu$ will be mapped into the exterior of $\mathscr{C}'_\mu$. In particular, this implies that the attractive fixed point η_μ is inside the circle $\mathscr{C}'_\mu$ while the repulsive fixed point ξ_μ is inside the circle $\mathscr{C}_\mu$. If we require these isometric circles to be all exterior to each other, we can deduce that the fundamental region of the Schottky group $\mathscr{G}_g$ is precisely the part of the extended complex plane which is exterior to all the circles. If we identify these circles in couple, g handles are formed and we obtain a Riemann surface Σ_g of genus g. More precisely, we have

$$\Sigma_g=\frac{\hat{\mathbb{C}}-\Lambda(\mathscr{G}_g)}{\mathscr{G}_g},$$

where $\Lambda(\mathscr{G}_g)$ is the limit set of the Schottky group, i.e., the set of accumulation points of its orbits.[8] Going around a cycle a_μ of the canonical homology basis of the Riemann surface corre-

sponds, in the Schottky representation, to going around $\mathscr{C}_\mu$ clockwise or $\mathscr{C}'_\mu$ anticlockwise while moving on a path that brings from a point z to the point $S_\mu(z) \in \mathscr{C}'_\mu$ corresponds to going around a b_μ cycle. Instead of choosing isometric circles, we could, for example, take a smaller circle $\tilde{\mathscr{C}}_\mu$ instead of $\mathscr{C}_\mu$, which is then mapped into a circle $\tilde{\mathscr{C}}'_\mu$ larger than $\mathscr{C}'_\mu$. All the properties of $\mathscr{C}_\mu$ and $\mathscr{C}'_\mu$ (apart from being isometric) remain true for $\tilde{\mathscr{C}}_\mu$ and $\tilde{\mathscr{C}}'_\mu$. In particular, we can require these new circles to be all exterior to each other, and forget about the old ones. Conversely, every compact Riemann surface Σ_g with a given homology basis can be obtained with a group of Schottky type (Ref. 9, retrosection theorem p. 222 of Ref. 10). A group of Schottky type, unlike a Schottky group, identifies pairs of analytic closed curves instead of pairs of circles, but it is still a group of projective transformations. The closed curves just mentioned correspond to the given homology basis. Unfortunately, not every group of Schottky type is a Schottky group as is shown in Ref. 11. Therefore, it is probably not true that we obtain all Riemann surfaces by sewing together pairs of circles (it may even not be true that we obtain a representative for each point in the moduli space of compact Riemann surfaces). Since we only consider Riemann spheres with N disjoint projective disks $t_1(D),\ldots,t_N(D)$ (D being the closed unit disk) and not spheres with general embedded disks, the whole discussion will be restricted to the Riemann surfaces Σ_g obtained by identifying pairs of circles $t_i(S^1)$.

VII. AXIOMATIC APPROACH

In Ref. 5, Segal formulated a set of properties or axioms which he thinks are characteristic of a conformal field theory. We now want to list these axioms in a slightly different setting, taking into account many-valuedness and the fact that we possibly do not get all compact Riemann surfaces using Schottky groups.

For Segal,[5] the basic object of a conformal field theory is a representation of the category $\mathscr{C}$ which we now want to describe. The starting point for defining $\mathscr{C}$ is a Riemann sphere with pairwise disjoint embedded disks (also called legs) $t_1(D),\ldots,t_{N+M}(D)$ where $t_1,\ldots,t_{N+M}$ are projective transformations. We can change the orientation of the disks $t_{N+1}(D),\ldots,t_{N+M}(D)$ by complex conjugation. We then get a Riemann sphere with legs $t_1(D),\ldots,t_N(D)$, $\bar{t}_{N+1}(D),\ldots,t_{N+M}(D)$ which we interpret as a morphism from N in-disks C_N to M out-disks C_M. A new morphism, i.e., a new Riemann surface, can be obtained by cutting out g pairs of in- and out-disks and sewing their boundary circles together. This is done using a Schottky group. More precisely, the sewing together of the circles $t_i(S^{-1})$ and $\bar{t}_j(S^1)$ is via the Schottky generator $t_i s_j$. We thus get g generators, and obtain a surface of genus g which carries a canonical homology basis, where the a cycles correspond to the pairs of circles that have been sewn together, and a path from a point on one circle to the corresponding point on its image circle corresponds to a b cycle. We will show later that there is a unique way to choose the homology class of the b cycle. The objects of $\mathscr{C}$ are therefore Cartesian products C_N of N unit disks D in the complex plane, and a morphism $C_N \to C_M$ is a compact (not necessarily connected) Riemann surface Σ with N in-legs and M out-legs. Each connected component of Σ is a Riemann surface X without boundary with a certain number of embedded disks $t_i(D)$ or $\bar{t}_j(D)$ and a fixed canonical homology basis (a,b). These t_i are local projective coordinates on X. Moreover, we associate to each unordered pair of distinct coordinates on X an integer $l_{ij} \in \mathbb{Z}$. Likewise, if the genus of X is not zero, we associate integers l_i^Q, l_μ^Q to each t_i (or $\bar{t}_i$) and each $a_\mu, l_{i\mu}$ to every pair t_i, a_μ, and $l_{\mu\nu} = l_{\nu\mu} \in \{0,1\}$ to every pair a_μ, a_ν (where this time μ and ν can be equal). In the case of the sphere, these integers fix a branch for each logarithm appearing in $V_{N;0}$. More precisely, the integers are defined so that

$$\pi l_{ij} \leqslant \mathrm{Im}(D_{00}(s_i t_j)) < \pi(l_{ij}+1)$$

making $V_{N;0}$ single-valued. In the same way, $V_{N;g}$ will be single-valued if the integers

$l_{i\mu}, l_{ij}, l_{\mu\nu}, l_i^Q, l_\mu^Q$ are specified along with a canonical homology basis [see the discussion after Eq. (28)]. Two morphisms Σ and Σ' which carry the same set of integers are identified whenever there exists a biholomorphic map

$$f:\Sigma \to \Sigma'$$

with $f\circ(t,\bar{t})=(t',\bar{t'})$ and $f(a_\mu)=a'_\mu, f(b_\mu)=b'_\mu$ for all $\mu\in\{1,...,g\}$. The last two equalities are to be understood in a homological sense.

Under composition of morphisms, the genus is additive, and as we will see later, the integers associated to the new surface, as well as the new homology basis are uniquely determined by the integers and homology basis we had before the sewing. The simplest example is provided by the semigroup of morphisms $C_0 \to C_0$. It is just the space of isomorphism classes of Riemann surfaces with a fixed homology basis and a fixed set of integers, the operation being disjoint union.

Let us consider the composition Σ of two morphisms corresponding to connected Riemann surfaces both coming from a Riemann sphere under the action of a Schottky group. Σ itself can be obtained from a Schottky group acting on a Riemann sphere because we can first sew both spheres together and then act with the larger Schottky group. Our space of morphisms consists of all finite unions of Riemann surfaces that we get from a sphere and a Schottky group, and what we have just shown is that a composition of morphisms is again a morphism. We are now in a position to define a conformal field theory. It consists of a complex Hilbert space $\mathscr{H}$ (the space of states) and of a continuous functor V from $\mathscr{C}$ to a category of Hilbert spaces. V is required to possess the following properties:

(i) $V(C_N)=\mathscr{H}^{\otimes N}$.

(ii) For each morphism $\Sigma:C_N\to C_M$, the operator $V:\mathscr{H}^{\otimes N}\to\mathscr{H}^{\otimes M}$ is trace class.

(iii) V is a *-functor, i.e., $V(\Sigma)^*=V(\bar{\Sigma})$ for each $(\Sigma,a,b):C_N\to C_M$ where $(\bar{\Sigma},a,-b):C_M\to C_N$ is the Riemann surface complex conjugate to Σ carrying the same set of integers as Σ but with the opposite sign.

(iv) V has the collapsing property that if a morphism $\Sigma:C_{N+R}\to C_{M+R}$ is made into a morphism $\hat{\Sigma}:C_N\to C_M$ by attaching the first R outgoing circles to the first R ingoing circles, then $V(\hat{\Sigma})=\mathrm{Tr}\, V(\Sigma)$ where the trace is taken over $\mathscr{H}^{\otimes R}$.

(v) Let $\tilde{\Sigma}:C^{N-1}\to C^{M+1}$ be the morphism obtained from $\Sigma:C^N\to C^M$ by reversing one leg (while keeping the homology basis and the integers fixed). If we interpret $V(\Sigma)$ as an operator from $\mathscr{H}^{N-1}$ to $\mathscr{H}^*\otimes\mathscr{H}^{\otimes M}$, then $V(\tilde{\Sigma})=(\varphi\otimes Id)\circ V(\Sigma)$ where $\varphi:\mathscr{H}^*\to\mathscr{H}$ is a (fixed) linear isomorphism.

A word of explanation is in order for the fourth property. By the remarks before the axioms, it is enough to know which b cycles and integers to select in the case where we sew together g pairs of circles on the sphere. What property (iv) says is that $V(\hat{\Sigma})$ is independent of the particular sewing used to obtain it.

The functor V is sometimes called modular because it only depends on the Riemann surface Σ through a homology basis, a set of integers, and the local projective coordinates t_i around the embedded disks. In the literature, modularity generally means more than this. One usually considers holomorphic and antiholomorphic sectors together and requires independence of the homology basis.

VIII. EXTENSION TO RIEMANN SURFACES

In this section, we would like to extend the N-point vertex $V_{N;0}$ from a sphere with N legs to other compact Riemann surfaces with legs by a sewing procedure. The extension will be such that the set of all N-point vertices so obtained (for all N) is a modular functor in the sense of the axioms above.

We would first like to associate $V_{N;0}$ to a Riemann sphere with N legs. The legs are $t_i(D)$, $i=1,\ldots,N$. Let us see how to get the N-point g-loop vertex $V_{N;g}$ starting with $V_{N+2g;0}$. For

notational simplicity, we label the first N legs of $V_{N+2g;0}$ with an index i running from 1 to N and divide the remaining $2g$ legs into ''odd'' legs labeled by $2\mu-1$ and ''even'' legs labeled by 2μ, $\mu=1,...,g$. This choice is particularly convenient because we will later sew together leg $2\mu-1$ with leg 2μ, $\mu=1,...,g$, thus generating g handles. The first operation we have to make is reverse the even legs. This means identifying $\mathscr{H}^*$ with $\mathscr{H}$ with the linear isomorphism (6), i.e.,

$$_{\beta_\mu+Q}\langle 0|a_{n_1}\cdots a_{n_k} \mapsto (Q\delta_{n_k;0}-a_{-n_k})\cdots(Q\delta_{n_1;0}-a_{-n_1})|0\rangle_{-\beta_\mu}$$

since

$$_{\beta_\mu+Q}\langle 0|a_{n_1}\cdots a_{n_k}=(Q\delta_{n_k;0}-a_{-n_k})\cdots(Q\delta_{n_1;0}-a_{-n_1})_{\beta_\mu+Q}\langle 0|.$$

Due to the special form of $V_{N;0}$, this corresponds to the prescription

$$_{\beta_\mu+Q}\langle 0|\mapsto|0\rangle_{-\beta_\mu}, \quad \alpha_n^{(\mu)}\mapsto\alpha_n^{+(\mu)}=-\alpha_{-n}^{(\mu)}+Q\delta_{n,0}. \tag{18}$$

This operation is motivated by the fact that by sewing together two spheres with $N+1$ and $M+1$ legs along a boundary circle, one gets a sphere with $M+N$ legs, i.e.,

$$V_{N+1;0}(1,2,\ldots,N,E)V_{M+1;0}(F^+,N+1,\ldots,N+M)=V_{N+M;0}(1,\ldots,N+M), \tag{19}$$

where F^+ means that the leg F has been reversed according to Eq. (18). Here, the Hilbert spaces of the two legs E and F have been identified. By conservation of charge, we must have

$$\beta_E=-\sum_{i=1}^{N}\beta_i+Q=-\beta_F+Q, \quad \beta_F=-\sum_{i=N+1}^{N+M}\beta_i+Q$$

so that the left-hand side of Eq. (19) can be written as

$$\begin{aligned}
&{}_{\beta_1}\langle 0|,\ldots,{}_{\beta_{N+M}}\langle 0|\,\delta_{\Sigma_{i=1}^{N+M}\beta_i;Q}\,\exp\left(-\sum_{\substack{i,j=1\\ i<j}}^{N}\sum_{n,m=0}^{\infty}\alpha_n^{(i)}D_{nm}(s_it_j)\alpha_m^{(j)}\right)\\
&\times\exp\left(-\sum_{\substack{i,j=N+1\\ i<j}}^{N+M}\sum_{n,m=0}^{\infty}\alpha_n^{(i)}D_{nm}(s_it_j)\alpha_m^{(j)}\right)\\
&\times{}_{\beta_E}\langle 0|\exp\left(-\sum_{i=1}^{N}\sum_{n,m=0}^{\infty}\alpha_n^{(i)}D_{nm}(s_it_E)\alpha_m^{(E)}\right)\\
&\times\exp\left(-\sum_{j=N+1}^{N+M}\sum_{n,m=0}^{\infty}\alpha_n^{+(E)}D_{nm}(s_Ft_j)\alpha_m^{(j)}\right)|0\rangle_{\beta_E}.
\end{aligned} \tag{20}$$

We compute the last two lines as follows: we interchange the two exponentials using the formula

$$e^Ae^B=e^{[A,B]}e^Be^A$$

and write $\alpha_0^{(E)}=\Sigma_{j=N+1}^{N+M}\beta_j$, $\alpha_0^{+(E)}=\Sigma_{i=1}^{N}\beta_i$. That way, we get

$$\exp\left(-\sum_{i=1}^{N}\sum_{j=N+1}^{N+M}\sum_{n,m=0}^{\infty}\sum_{l=1}^{\infty}\alpha_n^{(i)}D_{nl}(s_it_E)D_{lm}(s_Ft_j)\alpha_m^{(j)}\right)$$

$$\exp\left(-\sum_{i=1}^{N}\sum_{n=0}^{\infty}\alpha_n^{(i)}D_{n0}(s_it_E)\sum_{j=N+1}^{N+M}\beta_j\right)\exp\left(-\sum_{i=1}^{N}\beta_i\sum_{j=N+1}^{N+M}\sum_{m=0}^{\infty}D_{0m}(s_Ft_j)\alpha_m^{(j)}\right)$$
$$=\exp\left(-\sum_{i=1}^{N}\sum_{j=N+1}^{N+M}\sum_{n,m=0}^{\infty}\alpha_n^{(i)}D_{nm}(s_it_Es_Ft_j)\alpha_m^{(j)}\right),$$

where we have used the property

$$D_{nm}(\gamma_1\gamma_2)=\sum_{l=1}^{\infty}D_{nl}(\gamma_1)D_{lm}(\gamma_2)+D_{n0}(\gamma_1)\delta_{m,0}+D_{0m}(\gamma_2)\delta_{n,0}. \tag{21}$$

Together with the first two lines of Eq. (20) we get

$${}_{\beta_1}\langle 0|\cdots{}_{\beta_{N+M}}\langle 0|\,\delta_{\Sigma_{i=1}^{N+M}\beta_i;Q}\,\exp\left(-\sum_{\substack{i,j=1\\ i<j}}^{N+M}\sum_{n,m=0}^{\infty}\alpha_n^{(i)}D_{nm}(\tilde{s}_i\tilde{t}_j)\alpha_m^{(j)}\right)$$

with the new coordinates

$$\tilde{s}_i=\begin{cases}s_i, & i=N+1,\ldots,N+M\\ s_it_E\Gamma t_F^{-1}, & i=1,\ldots,N\end{cases},$$
$$\tilde{t}_i=\begin{cases}t_i, & i=N+1,\ldots,N+M\\ t_F\Gamma t_E^{-1}t_i, & i=1,\ldots,N\end{cases}, \tag{22}$$

where $\Gamma(z)=1/z$. We now understand the precise meaning of Eq. (19). The transformation $t_E\Gamma t_F^{-1}$ maps the "unit circle" $t_F(S^1)$ into the unit circle $t_E(S^1)$. The transformation Γ makes sure that the exterior of the circle $t_F(S^1)$ is mapped into the interior of $t_E(S^1)$. In view of the key role played by the identity (21), we check it for $n,m\neq 0$. By the explicit form of D_{nm}, we have to prove that

$$\frac{1}{m!}\frac{\sqrt{m}}{\sqrt{n}}\,\partial_z^m(\gamma_1\gamma_2(z))^n=\lim_{w\to 0}\sum_{l=1}^{\infty}\frac{1}{l!}\frac{\sqrt{l}}{\sqrt{n}}\,\partial_w^l(\gamma_1(w))^n\,\frac{1}{m!}\frac{\sqrt{m}}{\sqrt{l}}\,\partial_z^m(\gamma_2(z))^l$$

for $|z|\to 0$. It is enough to show the equality

$$(\gamma_1\gamma_2(z))^n=\sum_{l=1}^{\infty}\frac{1}{l!}\,\partial_w^l(\gamma_1(w))^n\Big|_{w=0}(\gamma_2(z))^l+(\gamma_1(0))^n.$$

The right-hand side is nothing but the Taylor expansion of the left-hand side. Let us return to the case of genus $g\geqslant 1$. According to Segal's last axiom, we have to take the partial trace

$$V_{N;g}=\prod_{\mu=1}^{g}\mathrm{Tr}_{(2\mu-1,2\mu)}V_{N+2g;0}^{+}$$

to get the g-loop vertex. The trace is to be understood as a sum over both zero and nonzero modes. More precisely, we now interpret the N-point vertex $V_{N;0}$ as acting on the N-fold tensor product $\mathscr{H}^{\otimes N}$ where the Hilbert space $\mathscr{H}$ is a direct sum of $\overline{\pi_\beta}$'s:

$$\mathscr{H}=\oplus_{\beta\in L}\overline{\pi_\beta}.$$

Here, L is the lattice of allowed zero modes. We rewrite the N-point vertex as

$$V_{N;0}=\sum_{\beta_1,\ldots,\beta_N\in L}\delta_{\Sigma_{i=1}^N\beta_i;Q}\,{}_{\beta_1}\langle 0|\cdots{}_{\beta_N}\langle 0|\exp\left(-\sum_{\substack{i,j=1\\ i<j}}^{N}\sum_{n,m=0}^{\infty}\alpha_n^{(i)}D_{nm}(s_it_j)\alpha_m^{(j)}\right). \tag{23}$$

Reversing the even legs, we get the expression

$$\begin{aligned}V^+_{N+2g;0}=&\sum_{\beta_1,\ldots,\beta_N\in L}\sum_{r_1,\ldots,r_g\in L}\delta_{\Sigma_{i=1}^N\beta_i+(g-1)Q;0}\,{}_{\beta_1}\langle 0|\cdots{}_{\beta_N}\langle 0|\\ &\times\exp\left(-\frac{1}{2}\sum_{\substack{i,j=1\\ i\neq j}}^{N}\sum_{n,m=0}^{\infty}\alpha_n^{(i)}D_{nm}(s_it_j)\alpha_m^{(j)}\right)\prod_{\substack{\mu=1\\ \text{odd}}}^{g}{}_{-r_\mu}\langle 0|\\ &\times\exp\left(-\sum_{i=1}^{N}\sum_{\mu=1}^{g}\sum_{n,m=0}^{\infty}\alpha_n^{(i)}(D_{nm}(s_it_{2\mu-1})\alpha_m^{(2\mu-1)}+D_{nm}(s_it_{2\mu})\alpha_m^{+(2\mu)})\right)\\ &\times\exp\left(-\frac{1}{2}\sum_{\substack{\mu,\nu=1\\ \mu\neq\nu}}^{g}\sum_{n,m=0}^{\infty}\alpha_n^{(2\mu-1)}D_{nm}(s_{2\mu-1}t_{2\nu-1})\alpha_m^{(2\nu-1)}\right.\\ &\left.+\alpha_n^{+(2\mu)}D_{nm}(s_{2\mu}t_{2\nu})\alpha_m^{+(2\nu)}\right)\\ &\times\exp\left(-\sum_{\mu,\nu=1}^{g}\sum_{n,m=0}^{\infty}\alpha_n^{+(2\mu)}D_{nm}(s_{2\mu}t_{2\nu-1})\alpha_m^{(2\nu-1)}\right)\prod_{\substack{\mu=1\\ \text{even}}}^{g}|0\rangle_{-r_\mu},\end{aligned} \tag{24}$$

where we have set $\beta_{2\mu}=r_\mu+Q$, $\beta_{2\mu-1}=-r_\mu$. Care is required here because the β_i still appearing in the formula correspond to the unsewn legs and are not fixed by the identities just given. Some exponents in our expression have a $\frac{1}{2}$ factor in front because we have used the property

$$D_{nm}(s_It_J)=D_{mn}(s_Jt_I).$$

The main result of this paper is Theorem 13.

Theorem 13: *$V_{N;0}:\mathscr{H}^{\otimes N}\to\mathbb{C}$ is trace class as soon as the closed disks $t_i(D)$ are all pairwise disjoint. If any two open disks $t_i(\mathring{D}),t_j(\mathring{D})$ overlap, the operator $V_{N;0}$ gets unbounded (i.e., cannot be extended to all $\mathscr{H}^{\otimes N}$ by the closed graph theorem).*

We will prove Theorem 13 in Sec. IX. Since $V^+_{N=2g;0}$ is the composition of $V_{N+2g;0}$ (which we here interpret as an operator $\mathscr{H}^{\otimes N+g}\to\mathscr{H}^{*\otimes g}$) and Eq. (18), and since Eq. (18): $\mathscr{H}^*\to\mathscr{H}$ is an isometry, the same statements with $V^+_{N+2g;0}$ instead of $V_{N+2g;0}$ are also true. This allows us to choose a basis to compute

$$V_{N:g}=\prod_{\mu=1}^{g}\mathrm{Tr}_{(2\mu-1,2\mu)}V^+_{N+2g;0}\,.$$

We first compute the trace over the nonzero modes using the coherent states method. In one dimension, the Hamiltonian of the harmonic oscillator is $H=a^*a$ with $a^*=1/\sqrt{2}(x-d/dx)$, $a=1/\sqrt{2}(x+d/dx)$ the creation and annihilation operators, respectively. A coherent state $|\alpha\rangle$ is an eigenstate of a with eigenvalue α. Explicitly

$$|\alpha\rangle=e^{\alpha a^*}|0\rangle,$$

where $|0\rangle = \pi^{-1/4} e^{-x^2/2}$ is the ground state of H. Recall that if $T: L^2(\mathbb{R}) \to L^2(\mathbb{R})$ is a trace class operator, its trace is equal to

$$\mathrm{Tr}\ T = \frac{1}{\pi} \int d^2\alpha\ e^{-|\alpha|^2} \langle \alpha | T | \alpha \rangle,$$

where the integral is over all $\alpha \in \mathbb{C}$. $V_{N;g}$ is therefore given by

$$V_{N:g} = \int \prod_{\mu=1}^{g} \prod_{n=1}^{\infty} \left(\frac{d^2\alpha_n^\mu}{\pi} \right) \exp\left[-\sum_{\mu=1}^{g} \sum_{n=1}^{\infty} |\alpha_n^\mu|^2 \right] \langle \alpha | V^+_{N+2g;0} | \alpha \rangle = \sum_{r_1,\dots,r_g \in L} \tilde{V}_{N:g}$$

which is a Gaussian functional integral. We first compute $\tilde{V}_{N:g}$. The trace calculation amounts to the substitutions

$$\alpha_n^{(2\mu-1)} \to \alpha_n^\mu, \quad \alpha_n^{+(2\mu)} \to -\bar{\alpha}_n^\mu \quad (n>0);$$

$$\alpha_0^{(2\mu-1)} \to -r_\mu, \quad \alpha_0^{+(2\mu)} \to r_\mu + Q.$$

In order to write our formulas in a more compact way, we adopt the following vectorlike notation:

$$(X_1 X_2) \begin{pmatrix} Y_1 \\ Y_2 \end{pmatrix} = \sum_{\mu=1}^{g} \sum_{n=1}^{\infty} \left((X_1)_n^\mu (Y_1)_n^\mu + (X_2)_n^\mu (Y_2)_n^\mu \right)$$

and get a result of the form

$$\tilde{V}_{N:g} = \sum_{\beta_1,\dots,\beta_N \in L} {}_{\beta_1}\langle 0| \cdots {}_{\beta_N}\langle 0|\, \delta_{\Sigma_{i=1}^N \beta_i + (g-1)Q;0}\ \exp(A) \int \prod_{\mu=1}^{g} \prod_{n=1}^{\infty} \left(\frac{d^2\alpha_n^\mu}{\pi} \right) \times \exp\left((B_1 B_2) \begin{pmatrix} \alpha \\ \bar{\alpha} \end{pmatrix} - \frac{1}{2} (\bar{\alpha}\alpha)(1-H) \begin{pmatrix} \alpha \\ \bar{\alpha} \end{pmatrix} \right), \tag{25}$$

where A denotes all the terms which do not depend on α_n^μ, $n \neq 0$. The 1 in the matrix $(1-H)$ comes from the Gaussian measure with respect to which we integrate. The integration over α_n^μ yields

$$\tilde{V}_{N;g} = \det(1-H)^{-(1/2)} {}_{\beta_1}\langle 0| \cdots {}_{\beta_N}\langle 0|\, \delta_{\Sigma_{i=1}^N \beta_i + (g-1)Q;0}\ \exp\left(A + \frac{1}{2} (B_1 B_2)(1-H)^{-1} \begin{pmatrix} B_2 \\ B_1 \end{pmatrix} \right). \tag{26}$$

If we use the explicit expressions for A, B_1, and B_2, it becomes clear that the exponent in the last expression can be separated into three pieces that are respectively quadratic, linear and independent of the zero modes r_μ. In other words, we can rewrite $\tilde{V}_{N;g}$ as

$$\tilde{V}_{N:g} = \sum_{\beta_1,\dots,\beta_N \in L} {}_{\beta_1}\langle 0| \cdots {}_{\beta_N}\langle 0|\, \delta_{\Sigma_{i=1}^N \beta_i + (g-1)Q;0}\ \det(1-H)^{-(1/2)} \times \exp\left(\frac{1}{2} \sum_{\mu,\nu=1}^{g} r_\mu C^{(1)}_{\mu\nu} r_\nu + \sum_{\mu=1}^{g} r_\mu C^{(2)}_\mu + C^{(3)} \right). \tag{27}$$

It is a lengthy, but straightforward task to compute the coefficients $C^{(1)}_{\mu\nu}, C^{(2)}_\mu, C^{(3)}$ and the determinant. The more difficult part consists in identifying the results with some geometric objects associated to the Riemann surface. A detailed account of the computation can be found in Ref. 12. In Ref. 6, the same computation was carried out more rigorously. The result is

$$\tilde{V}_{N;g} = {}_{\beta_1}\langle 0|\cdots{}_{\beta_N}\langle 0|\,\delta_{\Sigma_{i=1}^N \beta_i + (g-1)Q;0}\mathcal{N}\exp\left(\frac{\pi i}{2}\sum_{\mu,\nu=1}^{g} r_\mu (2\tau_{\mu\nu}+l_{\mu\nu})r_\nu\right)$$
$$\times\exp\left(-\sum_{\mu=1}^{g} r_\mu\left(\sum_{i=1}^{N}\sum_{m=0}^{\infty}\frac{a_m^{(i)}}{m!}\,\partial_z^m\left(\int_{z_0}^{t_i(z)}\omega_\mu\right)\Big|_{z=0} + 2\pi i Q\left(\Delta_\mu^{z_0}+\frac{1}{2}\right)\right)\right)$$
$$\times\exp\left(-\frac{1}{2}\sum_{\substack{i,j=1\\ i\neq j}}^{N}\sum_{n,m=0}^{\infty}\alpha_n^{(i)} D_{nm}(s_i t_j)\,\alpha_m^{(j)}\right)$$
$$\times\exp\left(\frac{1}{2}\sum_{i,j=1}^{N}\sum_{n,m=0}^{\infty} a_n^{(i)}\,\frac{\partial_z^n}{n!}\,\frac{\partial_y^m}{m!}\log\frac{E(t_i(z),t_j(y))}{t_i(z)-t_j(y)}\Big|_{y,z=0} a_m^{(j)}\right)$$
$$\times\exp\left(-\frac{1}{2}\,Q\sum_{i=1}^{N}\sum_{m=0}^{\infty} a_m^{(i)}\,\frac{\partial_z^m}{m!}\{\log t_i'(z) + 2\log\sigma(t_i(z))\}\Big|_{z=0}\right). \tag{28}$$

The coefficient $\mathcal{N}=\det(1-H)^{-(1/2)}$ is related to the inverse of the determinant of the scalar Laplacian on the Riemann surface Σ_g calculated in the subspace of the nonzero modes, and its dependence on the period matrix $\tau_{\mu\nu}$ is only through $\det(\mathrm{Im}\,\tau)$,[13] which is independent of the b cycles. The abelian differentials ω_μ only depend on the Riemann surface Σ_g through the a cycles. The prime form E remains invariant if its arguments are moved along a cycles, and is therefore also independent of our particular choice of b, but depends on the local coordinates t_i. The $g/2$ differential σ with no zeros or poles depends on Σ_g only through the coordinates t_i.[14] If we require $0\leqslant \mathrm{Im}(\log k_\mu) < 2\pi$ for all multipliers k_μ, we find that the vector of Riemann constants $\Delta_\mu^{z_0}$ is fixed modulo $\frac{1}{2}$. The z_0 dependence of $\tilde{V}_{N;g}$ drops out due to the Kronecker delta. The way Sciuto *et al.* obtained the period matrix $\tau_{\mu\nu}$ is ambiguous because the computation involved logarithms.[12] As a consequence, each matrix element is only clearly defined modulo $\frac{1}{2}$. If we fix a branch for each logarithm in the definition of $V_{N;0}$, i.e., if we fix each l_{ij}, this corresponds to a unique choice of b cycles. More precisely, if $V_{N;0}$ is unambiguously defined, the same is automatically true for $V_{N;g}$. The ambiguities of $V_{N;g}$ can be labeled by the set of integers $\tilde{l}_\mu^Q, \tilde{l}_{i\mu}, \tilde{l}_i^Q, \tilde{l}_{ij}$ corresponding to an unambiguous choice of the value of

$$\Delta_\mu^{z_0}, \int_{z_0}^{t_i(0)}\omega_\mu,\ \log t_i'(0) + 2\log\sigma(t_i(0))$$

and

$$D_{00}(s_i t_j) - \log\frac{E(t_i(0),t_j(0))}{t_i(0)-t_j(0)},$$

respectively, and by the choice of $l_{\mu\nu}$ and b cycles. All these integers as well as the b cycles can of course be expressed in terms of the l_{ij} on the sphere. Conversely, one can show that any choice of b cycles and of integers can be attained by a suitable choice of constants l_{ij} on the sphere. If we specify the lattice L of allowed zero modes, we can compute the sum over $r_1,\ldots,r_g \in L$, which leads to a theta function. What we have found is Proposition 14.

Proposition 14: $V_{N;g}$ is independent of the particular sewing used to obtain it. Therefore, the given construction of the g-loop vertex is consistent with axiom (iv). Indeed, the expression we get for $V_{N;g}$ depends on the Riemann surface Σ_g only through the coordinates t_i as well as a homology basis (a,b) and a set of integers.

IX. THE NONZERO MODE PROBLEM

In this section, we prove the analogous of Theorem 13 in the case of fixed zero modes. This provides a first step (the most important one) towards a proof of Segal's axioms. We start with a technical proposition

Proposition 15: Let a^* and a satisfy the commutation relation $[a,a^*]=1$. We have the following equalities:

$$\text{(a)}\quad e^{\mu a} r^{a^* a} = r^{a^* a} e^{\mu r a},$$
$$\text{(b)}\quad e^{\lambda a^*} r^{a^* a} = r^{a^* a} e^{(\lambda/r) a^*},$$
$$\text{(c)}\quad e^{\mu \sum_{n=1}^{\infty} \gamma^n a_n} r^{L_0} = r^{L_0} e^{\mu \sum_{n=1}^{\infty} \gamma^n r^n a_n},$$
$$\text{(d)}\quad e^{\lambda \sum_{n=1}^{\infty} \gamma^n a_{-n}} r^{L_0} = r^{L_0} e^{\lambda \sum_{n=1}^{\infty} \gamma^n r^{-n} a_{-n}}.$$

Proof: The core of the proposition is (a). (b), (c) and (d) are easy consequences thereof. We first observe that

$$\frac{d}{d\kappa}\, e^{-\kappa a^* a}\, a\; e^{\kappa a^* a} = e^{-\kappa a^* a}[a, a^* a] e^{\kappa a^* a} = e^{-\kappa a^* a}\, a\; e^{\kappa a^* a}.$$

Since $e^{-\kappa a^* a}\, a\; e^{\kappa a^* a}\big|_{\kappa=0} = a$, the solution of this differential equation is

$$e^{-\kappa a^* a}\, a\; e^{\kappa a^* a} = e^{\kappa} a.$$

Taking the nth power of this equation we get

$$e^{-\kappa a^* a} a^n\; e^{\kappa a^* a} = (e^{\kappa} a)^n.$$

Summing over all n with suitable coefficients leads to

$$e^{-\kappa a^* a}\; e^{\mu a}\; e^{\kappa a^* a} = e^{e^{\kappa} a \mu}.$$

If we set $e^{\kappa} = r$ we get (a). We prove (b) in exactly the same way, the only difference being the commutator $[a^*, a^* a] = -a^*$. (c) and (d) are infinite products of (a) and (b), respectively. ■

We now come to the main result. Let us consider $V_{N;0}$ as an operator from $\otimes\, \pi_{\beta_i}$ to $\mathbb{C}$ for fixed zero modes $\beta_1,\ldots,\beta_N$. We have Theorem 16.

Theorem 16: *Let D_r denote the closed disk of radius r centered around the origin. Then $V_{N;0}$ can be extended to $H^{\beta_1}_{r_1} \otimes \cdots \otimes H^{\beta_N}_{r_N}$ if the numbers r_i satisfy the following geometric condition:*

$$t_i(D_{r_i}) \cap t_j(D_{r_j}) = \varnothing, \quad i \neq j$$

Moreover, the extended map

$$V_{N;0} : H^{\beta_1}_{r_1} \otimes \cdots \otimes H^{\beta_N}_{r_N} \to \mathbb{C}$$

is trace class (meaning that $(V^*_{N;0} V_{N;0})^{1/2}$ is trace class).

Proof: We proceed in three steps. We first show that we can neglect all the contributions coming from the zero modes. Then, we show that the non zero mode core of $V_{N;0}$ is Hilbert–Schmidt and therefore bounded on $H_{r_i} \otimes \cdots \otimes H_{r_N}$. Finally, we use a deformation argument to show that $V_{N;0}$ is trace class.

We can forget the purely zero mode contributions in $V_{N;0}$ because they yield an overall constant factor. We next show that we can neglect the contributions coming from the coupling of the zero modes to the oscillators. More precisely, we claim that the map

$$\exp\left(-\sum_{n=1}^{\infty}\alpha_n^{(i)}D_{n0}(s_it_j)\alpha_0^{(j)}\right):H_r^{(i)}\to H_{\tilde r}^{(i)}$$

is Hilbert–Schmidt, and therefore bounded, as soon as $\tilde r>r$. Using multiindex notation, we can write

$$\exp\left(\sum_{n=1}^{\infty}\frac{a_n}{\sqrt{n}}\,\omega_n^+\right)|\phi_\alpha\rangle=\sum_{\gamma\leqslant\alpha}\frac{{\omega^+}^{\alpha-\gamma}}{(\alpha-\gamma)!}\frac{\sqrt{\alpha!}}{\sqrt{\gamma!}}\,|\phi_\gamma\rangle, \tag{29}$$

where $\alpha!=\Pi\alpha_i$, ${\omega^+}^{\alpha}=\Pi{\omega_i^+}^{\alpha_i}$, and where $\gamma\leqslant\alpha$ means $\gamma_j\leqslant\alpha_j$ for all j. To simplify the notation, we drop the superscript $^{(i)}$ and set $\alpha_0^{(j)}=-\beta$. We apply the exponential to a normed basis element of H_r and use Proposition 15(c) to get

$$\begin{aligned}\exp\left(\beta\sum_{n=1}^{\infty}\alpha_nD_{n0}(s_it_j)\right)r^{L_0}|\phi_\alpha\rangle&=r^{L_0}\exp\left(\beta\sum_{n=1}^{\infty}\frac{\alpha_n}{\sqrt{n}}(s_it_j(0))^nr^n\right)|\phi_\alpha\rangle\\&\overset{(29)}{=}r^{L_0}\sum_{\gamma\leqslant\alpha}\frac{{\omega^+}^{\alpha-\gamma}}{(\alpha-\gamma)!}\frac{\sqrt{\alpha!}}{\sqrt{\gamma!}}\,|\phi_\gamma\rangle,\end{aligned}$$

where $\omega_n^+=\beta(s_it_j(0))^nr^n/\sqrt{n}$. With $\|\gamma\|=\Sigma j\gamma_j$, the square of the Hilbert–Schmidt norm of the map is (we forget the zero mode factor coming from L_0)

$$\begin{aligned}\sum_{\alpha}\sum_{\gamma\leqslant\alpha}\left(\frac{r}{\tilde r}\right)^{2\|\gamma\|}\frac{|\omega^+|^{2(\alpha-\gamma)}}{(\alpha-\gamma)!^2}\frac{\alpha!}{\gamma!}&\overset{(2)}{=}\sum_{\alpha}\left(\frac{r}{\tilde r}\right)^{2\|\alpha\|}\prod_n L_{\alpha_n}\left(-|\omega_n^+|^2\left(\frac{\tilde r}{r}\right)^{2n}\right)\\&\overset{(3)}{=}\prod_n\frac{1}{1-(r/\tilde r)^{2n}}\exp\left(\frac{|\omega_n^+|^2}{1-(r/\tilde r)^{2n}}\right).\end{aligned}$$

This is convergent if $\Sigma_n|\omega_n^+|^2$ converges, which is the case if $r<|t_i^{-1}(t_j(0))|$. This last inequality is a consequence of the geometric condition. Similarly, the map

$$\exp\left(-\sum_{n=1}^{\infty}\alpha_0^{(i)}D_{0n}(s_it_j)\alpha_n^{(j)}\right):H_r^{(j)}\to H_{\tilde r}^{(j)}$$

is Hilbert–Schmidt if $\tilde r>r$. We are now left with the oscillatory part of $V_{N;0}$ which we denote by $\tilde V_{N;0}$.

An orthonormal basis of $H_{r_1}^{\beta_1}\otimes\cdots\otimes H_{r_N}^{\beta_N}$ is given by the vectors

$$r_1^{L_0^{(1)}}\cdots r_N^{L_0^{(N)}}|\phi_{\gamma^1}\rangle\cdots|\phi_{\gamma^N}\rangle,$$

where each γ^j ranges over all possible finite multi-indices. Using proposition 15(c), we get (forgetting the zero modes of $L_0^{(i)}$)

$$\tilde{V}_{N;0} r_1^{L_0^{(1)}} \cdots r_N^{L_0^{(N)}} |\phi_{\gamma^1}\rangle \cdots |\phi_{\gamma^N}\rangle$$
$$= \langle 0| \cdots \langle 0| \exp\left(- \sum_{\substack{i,j=1 \\ i<j}}^{N} \sum_{n,m=1}^{\infty} \alpha_n^{(i)} D_{nm}(s_i t_j) r_i^n r_j^m \alpha_m^{(j)} \right) |\phi_{\gamma^1}\rangle \cdots |\phi_{\gamma^N}\rangle. \qquad (30)$$

We now introduce a useful representation of the algebra a, a^* of the harmonic oscillator. This algebra can be realized on the space of polynomials in ψ as follows:

$$a f(\psi) = \frac{\partial}{\partial \psi} f(\psi), \quad a^* f(\psi) = \psi f(\psi).$$

Obviously, we have $[a, a^*] = 1$. The vacuum is represented by the function $f(\psi) = 1$ and more generally $|k\rangle = (a^*)^k / \sqrt{k!} |0\rangle$ is represented by the function $\psi^k / \sqrt{k!}$. The scalar product is represented by

$$\langle f, g \rangle = \overline{f}\left(\frac{\overline{\partial}}{\partial \psi} \right) g(\psi)|_{\psi=0}$$

because it is antilinear in the first and linear in the second factor and because

$$\langle k|l\rangle = \frac{1}{\sqrt{k!}} \left(\frac{\partial}{\partial \psi} \right)^k \frac{\psi^l}{\sqrt{l!}} \bigg|_{\psi=0} = \delta_{k,l}.$$

For expression (30), we introduce a variable ψ_n^i for each oscillator $\alpha_{-n}^{(i)}$, so we have the scalar product of

$$f(\psi^1, \ldots, \psi^N) = \frac{(\psi^1)^{\gamma^1}}{\sqrt{\gamma^1!}} \cdots \frac{(\psi^N)^{\gamma^N}}{\sqrt{\gamma^N!}}$$

with

$$g(\psi^1, \ldots, \psi^N) = \exp\left(- \sum_{\substack{i,j=1 \\ i<j}}^{N} \sum_{n,m=1}^{\infty} \psi_n^i D_{nm}(s_i t_j) r_i^n r_j^m \psi_m^j \right)$$

which is nothing else than

$$\frac{1}{\sqrt{\gamma^1!}} \left(\frac{\partial}{\partial \psi^1} \right)^{\gamma^1} \cdots \frac{1}{\sqrt{\gamma^N!}} \left(\frac{\partial}{\partial \psi^N} \right)^{\gamma^N} \exp\left(- \sum_{\substack{i,j=1 \\ i<j}}^{N} \sum_{n,m=1}^{\infty} D_{nm}(s_i t_j) r_i^n r_j^m \psi_n^i \psi_m^j \right) \bigg|_{\psi=0}.$$

The square of the Hilbert–Schmidt norm is given by

$$\sum_{\gamma^1, \ldots, \gamma^N} \frac{1}{\gamma^1! \cdots \gamma^N!} \left| \left(\frac{\partial}{\partial \psi^1} \right)^{\gamma^1} \cdots \left(\frac{\partial}{\partial \psi^N} \right)^{\gamma^N} \exp\left(- \sum_{\substack{i,j=1 \\ i<j}}^{N} \sum_{n,m=1}^{\infty} D_{nm}(s_i t_j) r_i^n r_j^m \psi_n^i \psi_m^j \right) \bigg|_{\psi=0} \right|^2.$$

It is finite if

$$\sum_{\gamma^1,\ldots,\gamma^N} \frac{1}{\gamma^1!\cdots\gamma^N!} \left| \left(\frac{\partial}{\partial\psi^1}\right)^{\gamma^1} \cdots \left(\frac{\partial}{\partial\psi^N}\right)^{\gamma^N} \exp\left(-\sum_{\substack{i,j=1\\ i<j}}^{N} \sum_{n,m=1}^{\infty} D_{nm}(s_i t_j) r_i^n r_j^m \psi_n^i \psi_m^j \right) \right|_{\psi=0}$$

is. We can rewrite the sum as

$$\begin{aligned} &\prod_{\substack{i,j=1\\ i<j}}^{N} \prod_{n,m=1}^{\infty} \sum_{\beta,\gamma=0}^{\infty} \frac{1}{\beta!\,\gamma!} \left| \left(\frac{\partial}{\partial\psi}\right)^{\beta} \left(\frac{\partial}{\partial\kappa}\right)^{\gamma} \exp(-D_{nm}(s_i t_j) r_i^n r_j^m \psi\kappa) \right|_{\psi=\kappa=0} \\ &= \prod_{\substack{i,j=1\\ i<j}}^{N} \prod_{n,m=1}^{\infty} \sum_{\beta,\gamma=0}^{\infty} \frac{1}{\beta!\,\gamma!} \left(\frac{\partial}{\partial\psi}\right)^{\beta} \left(\frac{\partial}{\partial\kappa}\right)^{\gamma} \exp(|D_{nm}(s_i t_j)| r_i^n r_j^m \psi\kappa) \Big|_{\psi=\kappa=0} \\ &= \exp\left(\sum_{\substack{i,j=1\\ i<j}}^{N} \sum_{n,m=1}^{\infty} |D_{nm}(s_i t_j)| r_i^n r_j^m \right). \end{aligned}$$

It remains to show the finiteness of the sums

$$\sum_{n,m=1}^{\infty} \left| \frac{1}{m!}\, \partial^m (s_i(t_j(z)))^n \Big|_{z=0} r_i^n r_j^m \right| \tag{31}$$

for all i,j with $i<j$ (we absorbed a factor $\sqrt{m}$ by making r_j slightly bigger). For a function $\gamma(z)$ which is analytic in a neighborhood of zero, we can write

$$\frac{1}{m!}\, \partial^m \gamma(z) \Big|_{z=0} = \frac{1}{2\pi i} \oint_0 \frac{\gamma(\zeta)}{\zeta^{m+1}}\, d\zeta,$$

where we integrate over a circle of radius R around zero with R smaller than the radius of convergence of the series

$$\sum_m \frac{1}{m!}\, \partial^m \gamma(z) \Big|_{z=0} \zeta^m.$$

Doing this for the function $\gamma(z)=(s_i t_j(z))^n$ we get the estimate

$$\left| \frac{1}{m!}\, \partial^m (s_i(t_j(z)))^n \Big|_{z=0} \right| \leqslant \frac{1}{R^m} \sup_{|\zeta|=R} |(s_i(t_j(\zeta)))^n|$$

so that our double sum (31) gets smaller than

$$\sum_{n,m=1}^{\infty} \left(\sup_{|\zeta|=R} |(s_i(t_j(\zeta)))| \right)^n r_i^n \left(\frac{r_j}{R}\right)^m.$$

We must choose R smaller than the absolute value of the pole of $s_i t_j$, which means that the circle $t_j(D_R)$ must not contain $t_i(0)$. In particular we may take R to be slightly bigger than r_j but still satisfying the geometric condition $t_i(D_{r_i}) \cap t_j(D_R) = \varnothing$. Such an R ensures the convergence of the m-sum above. As to the n-sum, it converges because $r_i < \inf_{|\zeta|=R} |t_i^{-1}(t_j(\zeta))|$. Therefore,

$$V_{N;0} : H_{r_1} \otimes \cdots \otimes H_{r_N} \to \mathbb{C}$$

is bounded. Let $\tilde{r}_i > r_i (i=1,\ldots,N)$ be such that the $t_i(D_{\tilde{r}_i})$ are still pairwise disjoint. We can decompose the map $V_{N;0}: \otimes H_{r_i} \to \mathbb{C}$ according to

$$\otimes H_{r_i} \overset{Id}{\to} \otimes_i H_{\tilde{r}_i} \overset{V_{N;0}}{\longrightarrow} \mathbb{C},$$

where Id is the embedding of $\otimes H_{r_i}$ in $\otimes H_{\tilde{r}_i}$. Since Id is trace class and since the second map is bounded, the composition is trace class. ■

The next proposition shows that the result we got is the best possible.

Proposition 17: Let $\mathring{D}_r$ denote the open disk with radius r around the origin. Then the map

$$V_{N;0}: H^{\beta_1}_{r_1} \otimes \cdots \otimes H^{\beta_N}_{r_N} \to \mathbb{C}$$

gets unbounded as soon as there exists i,j, $i \neq j$ with

$$t_i(\mathring{D}_{r_i}) \cap t_j(\mathring{D}_{r_j}) \neq \varnothing.$$

In other words $V_{N;0}$ cannot be extended to all $H^{\beta_1}_{r_1} \otimes \cdots \otimes H^{\beta_N}_{r_N}$ if the disks $t_i(\mathring{D}_{r_i})$ are not disjoint.

Proof: The effect of increasing one r_i is simply multiplication of the basis vectors

$$r_1^{L_0^{(1)}} \cdots r_N^{L_0^{(N)}} |\phi_{\gamma^1}\rangle \cdots |\phi_{\gamma^N}\rangle$$

with a constant whose norm is greater than one. Since we want to show that $V_{N;0}$ applied to these basis vectors are complex numbers whose norm is unbounded in $\gamma^1,\ldots,\gamma^N$, we can suppose without loss of generality that $t_1(\mathring{D}_{r_1})$ and $t_2(\mathring{D}_{r_2})$ are the only disks that overlap. Moreover, we can suppose that $r_i = 1$ for all $i=1,\ldots,N$ because the change from 1 to r_i is nothing else than the coordinate change $t_i(z) \mapsto \tilde{t}_i(z) = t_i(r_i z)$ [since $D_{nm}(s_j t_i) r_i^n = D_{nm}(s_j \tilde{t}_i)$ and $D_{nm}(s_i t_j) r_i^n = D_{nm}(\tilde{s}_i t_j)$]. It is enough to treat the case of small overlap, by which we mean that

$$\gamma(z) := s_1 t_2(z)$$

has the property

$$|\gamma(0)| < 1.$$

We are now ready to compute

$$\begin{aligned}
&V_{N;0} |\phi_{e_n}\rangle_{\beta_1} |\phi_{e_m}\rangle_{\beta_2} |0\rangle_{\beta_3} \cdots |0\rangle_{\beta_N} \\
&\quad = \text{const}\ {}_{\beta_2}\langle 0|_{\beta_1}\langle 0| \exp(-\alpha_n^{(1)} D_{nm}(s_1 t_2) \alpha_m^{(2)}) \exp\left(-\sum_{j\neq 1} \alpha_n^{(1)} D_{n0}(s_1 t_j) \beta_j \right) \\
&\qquad \times \exp\left(-\sum_{j\neq 2} \alpha_m^{(2)} D_{m0}(s_2 t_j) \beta_j \right) |\phi_{e_n}\rangle_{\beta_1} |\phi_{e_m}\rangle_{\beta_2} \\
&\quad = \text{const} \left(-D_{nm}(s_1 t_2) + \sum_{j\neq 1} \sum_{k\neq 2} D_{n0}(s_1 t_j) D_{m0}(s_2 t_k) \beta_j \beta_k \right) \\
&\quad = \text{const} \left(-D_{nm}(\gamma) + \left(\sum_{j\neq 1} D_{n0}(s_1 t_j) \beta_j \right) \left(\sum_{k\neq 2} D_{m0}(s_2 t_k) \beta_k \right) \right),
\end{aligned}$$

where const is a nonvanishing constant independent of n and m coming from the purely zero mode contributions. We want to show that this expression is unbounded in n and m. First of all, since $|s_i t_j(0)|<1$, $\forall i\neq j$, we see that

$$D_{n0}(s_i t_j) \to 0, \quad n \to \infty$$

so it is enough to show that $D_{nm}(\gamma)$ is unbounded in n and m. Suppose it were bounded, i.e.,

$$|D_{nm}(\gamma)|\leqslant c, \quad \forall n,m$$

for some constant c. Then for all $q,\tilde{q}<1$ and all $\varphi \in \mathbb{R}$, we would have convergence of the double sum

$$\sum_{n,m=0}^{\infty} \frac{1}{m!}\, \partial^m (\gamma(z))^n \Big|_{z=0} \tilde{q}^n (q\ e^{i\varphi})^m.$$

The m-sum yields

$$\sum_{n=0}^{\infty} \gamma(q\ e^{i\varphi})^n \tilde{q}^n.$$

For a suitable choice of q and φ, we have

$$|\gamma(q\ e^{i\varphi})|>1$$

by the overlap assumption, so the n-sum cannot converge for all $\tilde{q}<1$, a contradiction. ■

X. VERIFICATION OF THE AXIOMS

We now prove the axioms. We start with the proposition:

Proposition 18: V is a ∗ functor (i.e., the third axiom is true) if and only if $Q=0$.

Proof: We first check the proposition for the sphere (for notational simplicity, we restrict ourselves to the case $\mathscr{H}^{\otimes N} \to \mathbb{C}$). It is easy to see that

$$\bar{D}_{nm}(s_i t_j) = D_{nm}(\overline{s_i t_j})$$

so that

$$\begin{aligned}
(V_{N;0})^* &= \sum_{\beta_1,\ldots,\beta_N \in L} \left(\delta_{\sum_{i=1}^N \beta_i;Q}\, {}_{\beta_1}\langle 0|\cdots{}_{\beta_N}\langle 0| \exp\left(-\sum_{\substack{i,j=1\\ i<j}}^{N} \sum_{n,m=0}^{\infty} \alpha_n^{(i)} D_{nm}(s_i t_j) \alpha_m^{(j)} \right) \right)^* \\
&= \sum_{\beta_1,\ldots,\beta_N \in L} \delta_{\sum_{i=1}^N \beta_i;Q} \exp\left(-\sum_{\substack{i,j=1\\ i<j}}^{N} \sum_{n,m=0}^{\infty} \alpha_n^{(i)*} \bar{D}_{nm}(s_i t_j) \alpha_m^{(j)*} \right) |0\rangle_{\beta_N} \cdots |0\rangle_{\beta_1} \\
&= \sum_{\beta_1,\ldots,\beta_N \in L} \delta_{\sum_{i=1}^N \beta_i;Q} \exp\left(-\sum_{\substack{i,j=1\\ i<j}}^{N} \sum_{n,m=0}^{\infty} (-\alpha_{-n}^{(i)}) D_{nm}(\overline{s_i t_j}) (-\alpha_{-m}^{(j)}) \right) |0\rangle_{\beta_N} \cdots |0\rangle_{\beta_1} \\
&= \sum_{\beta_1,\ldots,\beta_N \in L} \delta_{\sum_{i=1}^N \beta_i;Q} \exp\left(-\sum_{\substack{i,j=1\\ i<j}}^{N} \sum_{n,m=0}^{\infty} (-(\alpha_{-n}^{(i)} - Q\delta_{n;0})) D_{nm}(\overline{s_i t_j}) (-(\alpha_{-m}^{(j)}\right.
\end{aligned}$$

$$
\left. -Q\delta_{m;0})) \right) |0\rangle_{\beta_N+Q} \cdots |0\rangle_{\beta_1+Q}
$$

$$
= \sum_{\beta_1,\ldots,\beta_N \in L} \delta_{\Sigma_{i=1}^N \beta_i;(N+1)Q} \exp\left(- \sum_{\substack{i,j=1 \\ i<j}}^{N} \sum_{n,m=0}^{\infty} \alpha_n^{(i)+} D_{nm}(\overline{s_i t_j}) \alpha_m^{(j)+} \right)
$$

$$
\times |0\rangle_{\beta_N} \cdots |0\rangle_{\beta_1}
$$

which is the N-point vertex for the complex conjugate sphere with differently oriented boundary if and only if $Q=0$ (the sum of the ''in-charges'' must be equal to the sum of the ''outcharges'' $+Q$). Under the change $D_{00} \mapsto \bar{D}_{00}$, all the integers l_{ij} change sign. Because the g-loop vertex is an appropriate trace of the zero-loop vertex, the results still hold for arbitrary genus. We finally note that taking the adjoint of Eq. (28) leads to the transformation

$$
i\pi(r_\mu(2\tau_{\mu\nu}+l_{\mu\nu})r_\nu) \mapsto i\pi(r_\mu(-2\bar{\tau}_{\mu\nu}-l_{\mu\nu})r_\nu),
$$

where $-\overline{\tau_{\mu\nu}}$ corresponds to the period matrix of the complex conjugate surface with cycles $(a, -b)$ because

$$
\int_{-b_\nu} \bar{\omega}_\mu = \overline{\int_{-b_\nu} \omega_\mu} = -2\pi i \bar{\tau}_{\mu\nu}.
$$

■

It can be shown that the axiom (iii) implies Osterwalder–Schrader positivity for symmetric surfaces (the only ones where ''time reversal'' has a meaning), so a scalar massless field coupled to a background charge $Q \neq 0$ is not a good field theory in that sense. However, it is useful in the context of minimal models.[2] We next prove Theorem 13, and then extend it to Riemann surfaces.

Proof: What we actually need is the special case $r_i=1$ for all i. The second part of the theorem follows from Proposition 17. It remains to show the first part. We note that any operator

$$
A: \mathscr{H}^{\otimes N} \to \mathbb{C}
$$

$$
A: \eta \mapsto (\psi, \eta), \quad \psi \in \mathscr{H}^{\otimes N}
$$

is trace class. Indeed,

$$
A^* A \eta = (\psi, \eta)\psi
$$

is a projection (times a constant). Its square root is also a projection, and projections on finite dimensional subspaces are trace class. Therefore, all we have to prove is that

$$
\sum_{\beta_1,\ldots,\beta_N \in L} \delta_{\Sigma_{i=1}^N \beta_i;Q\beta_1} \langle 0| \cdots {}_{\beta_N}\langle 0| \exp\left(-\frac{1}{2} \sum_{\substack{i,j=1 \\ i\neq j}}^{N} \sum_{n,m=0}^{\infty} \alpha_n^{(i)} D_{nm}(s_i t_j) \alpha_m^{(j)} \right)
$$

$$
\times \sum_{\gamma_1,\ldots,\gamma_N \in L} \exp\left(-\frac{1}{2} \sum_{\substack{i,j=1 \\ i\neq j}}^{N} \sum_{n,m=0}^{\infty} \alpha_{-n}^{(i)} \bar{D}_{nm}(s_i t_j) \alpha_{-m}^{(j)} \right) |0\rangle_{\gamma_N} \cdots |0\rangle_{\gamma_1} \tag{32}
$$

is finite. Without the β- and γ-sums, we know by theorem 16 that the expression is $\delta_{\beta_1,\gamma_1} \cdots \delta_{\beta_N,\gamma_N}$ times something finite, namely the square of the Hilbert–Schmidt norm of the map $V_{N;0}$ for the fixed zero modes $\beta_1,\ldots,\beta_N$.

Let us consider the case $Q=0$ first. By the proposition we have just proven, the second line of Eq. (32) represents the complex conjugate Riemann sphere with ''out-legs''

$$\bar{t}_i(D), \quad i=1,\ldots,N.$$

It is the mirror image of the sphere with ''in-legs''

$$t_i(D), \quad i=1,\ldots,N,$$

where the mirror symmetry is given by reflection about the x axis. The expression we have is therefore what we get by sewing together a sphere with its mirror image along the boundaries of the embedded disks. We can do the sewing in two steps: first, we only identify the legs number N. This gives us a Riemann sphere with $2N-2$ legs. Therefore, the summand of Eq. (32) is the trace over the nonzero modes of

$$\begin{aligned}
&{}_{\beta_1}\langle 0|\cdots{}_{\beta_{N-1}}\langle 0|\exp\Bigg(-\frac{1}{2}\sum_{\mu,\nu=1}^{N-1}\sum_{n,m=0}^{\infty}\alpha_n^{(2\mu-1)}D_{nm}(\tilde{s}_{2\mu-1}\tilde{t}_{2\nu-1})\alpha_m^{(2\nu-1)}\\
&\quad+\alpha_n^{+(2\mu)}D_{nm}(\tilde{s}_{2\mu}\tilde{t}_{2\nu})\alpha_m^{+(2\nu)}\Bigg)\\
&\quad\times\exp\Bigg(-\sum_{\mu,\nu=1}^{N-1}\sum_{n,m=0}^{\infty}\alpha_n^{+(2\mu)}D_{nm}(\tilde{s}_{2\mu}\tilde{t}_{2\nu-1})\alpha_m^{(2\nu-1)}\Bigg)|0\rangle_{\beta_{N-1}}\cdots|0\rangle_{\beta_1}
\end{aligned}\tag{33}$$

[see Eq. (24)], the new sum being over $\beta_1,\ldots,\beta_{N-1}\in L$. Here, $\alpha_n^{(2\mu-1)}$ acts on a vacuum to the left while $\alpha_n^{(2\mu)}$ acts on a vacuum to the right. By Eq. (22), the new coordinates are

$$\tilde{t}_{2\mu-1}=t_\mu, \quad \tilde{s}_{2\mu-1}=s_\mu,$$

$$\tilde{t}_{2\mu}=\bar{t}_N\Gamma t_N^{-1}t_\mu, \quad \tilde{s}_{2\mu}=s_\mu t_N\Gamma\bar{t}_N^{-1}.$$

The trace is to be understood as an identification of even and odd legs. Its calculation is a special case of what we have already done, namely the case where all the legs are sewn. We can read off the result (28), which means that Eq. (32) can be written as

$$\sum_{\beta_1,\ldots,\beta_{N-1}\in L}\det(1-H)^{-(1/2)}\exp\Bigg(\frac{1}{2}\sum_{\mu,\nu=1}^{N-1}\beta_\mu C_{\mu\nu}^{(1)}\beta_\nu+\sum_{\mu=1}^{N-1}\beta_\mu C_\mu^{(2)}+C^{(3)}\Bigg).$$

Since $C_{\mu\nu}^{(1)}=2\pi i\tau_{\mu\nu}$ modulo πi, and since period matrices have positive definite imaginary part,[15] the β-sum is finite. Let us now turn to the more complicated case $Q\neq 0$. The second exponential of Eq. (32) still represents the complex conjugate surface if we add an exponential which takes into account that $\alpha_0^+=Q-\alpha_0$. Instead of Eq. (33), we then find

$$\begin{aligned}
&{}_{\beta_1}\langle 0|\cdots{}_{\beta_{N-1}}\langle 0|\exp\Bigg(-\frac{1}{2}\sum_{\substack{\mu,\nu=1\\ \mu\neq\nu}}^{N-1}\sum_{n,m=0}^{\infty}(\alpha_n^{(2\mu-1)}D_{nm}(\tilde{s}_{2\mu-1}\tilde{t}_{2\nu-1})\alpha_m^{(2\nu-1)}\\
&\quad+\alpha_n^{+(2\mu)}D_{nm}(\tilde{s}_{2\mu}\tilde{t}_{2\nu})\alpha_m^{+(2\nu)})\Bigg)\exp\Bigg(-Q\sum_{m\geqslant 0}\Bigg(\sum_{\mu=1}^{N-1}D_{0m}(s_Nt_\mu)\alpha_m^{(2\mu-1)}+D_{0m}(\overline{s_Nt_\mu})(Q\\
&\quad-\alpha_m^{+(2\mu)})\Bigg)\Bigg)\exp\Bigg(-\sum_{\mu,\nu=1}^{N-1}\sum_{n,m=0}^{\infty}\alpha_n^{+(2\mu)}D_{nm}(\tilde{s}_{2\mu}\tilde{t}_{2\nu-1})\alpha_m^{(2\nu-1)}\Bigg)|0\rangle_{\beta_{N-1}}\cdots|0\rangle_{\beta_1}.
\end{aligned}$$

We can forget the exponential with the factor Q^2, because it has no influence on the convergence of the β sums. The two new exponentials with a factor Q have the effect of translating the factors B_1 and B_2 in the trace calculation by an amount independent of the zero modes, and of increasing the factor A by an amount linear in the zero modes. The contribution of Eq. (26) to $C^{(1)}_{\mu\nu}$ is therefore unchanged, and the sum over $\beta_1,...,\beta_{N-1}$ still converges. ■

Now axiom (ii) is true for the Riemann surfaces we have constructed because $V_{N;g}$ is a partial trace of the trace class operator $V_{N+2g;0}$, and partial traces are trace class. Finally, we have constructed $V_{N;g}$ so that axiom (iv) holds. More precisely, we have found that $V_{N;g}$ depends only on a canonical homology basis (a,b) and on local projective coordinates t_i associated to the Riemann surface, and is thus independent of the particular sewing used to obtain it. Identifying boundary circles on Σ_g is the same as initially identifying more pairs of circles on the sphere. Therefore, property (iv) holds and we have proved that V is a modular functor from a category of Riemann surfaces to a category of trace class operators over a Hilbert space.

ACKNOWLEDGMENT

It is a great pleasure to thank Professor Giovanni Felder for his constant encouragement, his valuable help, and his deep insight.

(Received 5 May 1994; accepted for publication 26 April 1995)

Integrable quantum systems related with two-dimensional two- and one-sheeted hyperboloid are considered. The explicit expressions of the Green's functions of the free particles on the those homogenous spaces are given. © *1996 American Institute of Physics.* [S0022-2488(95)03012-1]

I. INTRODUCTION

There exists a number of exact results about the complete systems of quantum commuting observables (quantum integrals of motion) wave functions, spectra, and so on. The review[1] presents, from a general point of view, the results obtained in these subject. The dynamics of some of these systems is closely related to free motion in the symmetric space (SS). It is known that (SS) can be realized as a set of cossets K/G of connected Lie group G on its compact subgroup K. For example, the two-sheeted hyperboloid SO(2)/SO(1,2): $[x,x]=x_0^2-x_1^2-x_2^2$, $x_0>0$, constitutes the (SS) space $K=\mathrm{SO}(2)$ keeping the point $x=(1,0,0)$ fixed. The distance r between the fixed point $x=(1,0,0)$ and an arbitrary point $x=(x_0,x_1,x_2)$ on this (SS) defined by formula $\cosh Kr=[x,\ x]=x_0>1$ is real. However, in the case of one-sheeted hyperboloid $[x,\ x]=x_0^2-x_1^2-x_2^2=-1$, stationary subgroup of fixed point $x=(0,0,1)$ is a noncompact group SO(1,1) and the distance $r=\cosh Kr=|[x,x]|=|x_2|>0$ is piecewise defined, real when $\cosh Kr>1$ and imaginary when $\cosh Kr<1$.

This is the reason why the quantum systems related to (SS) K/G have only continuous spectra of scattering states, and the quantum systems related to homogeneous spaces H/G with noncompact stationary subgroup have continuous and discrete spectra.

This report carries on the research reviewed in Ref. 2. The key point of the relation between the theory of homogeneous spaces and quantum systems is the existence of a simple transformation of Laplace–Beltrami operators on homogeneous spaces to some Hamiltonious quantum systems.

We consider different coordinate systems on hyperboloids which reduce to three different quantum systems.

The paper is organized as follows: an introduction and three sections and two appendices. Sections I and II are devoted to quantum systems related to two- and one-sheeted hyperboloids correspondingly. The review of the results concerning the two-sheeted hyperboloid is introduced for complement and also for comparison with the case of the one-sheeted hyperboloid. In Sec. III the explicit expressions of the Green's function of the free particle on two- and one-sheeted hyperboloids are calculated. The Appendices are devoted to the basic facts of the representation theory of the group SO(1,2).

II. THE QUANTUM SYSTEMS RELATED TO TWO-SHEETED HYPERBOLOID

Consider the problem, inside the cone in the three-dimensional space, on three different coordinate systems.

[a)]On leave of absence from Physical Institute of Academic Sciences of Azerbaijan Republic.

A. Spherical polar coordinates

The spherical polar coordinates are given by

$$x_0 = r \cosh \alpha,$$
$$x_1 = r \sin \alpha \sin \varphi, \tag{2.1}$$
$$x_2 = r \sin \alpha \cos \varphi,$$

where $\alpha \in [0,\infty)$ and $\varphi \in [0, 2\pi]$.

By (2.1) we have

$$(g_{ab}) = \text{diag}\,(1, -r^2, -r^2 \sinh^2 \alpha), \tag{2.2}$$

$$\sqrt{g} = (\det\,(g_{ab}))^{1/2} = r^2 \sinh \alpha. \tag{2.3}$$

The component of the Laplace–Beltrami operator

$$\Delta_{\mathrm{LB}} = \frac{-1}{\sqrt{g}}\, \partial_a g^{ab} \sqrt{g} \partial_b, \quad a,b = 1,2,3,\ldots, \tag{2.4}$$

on the hyperboloid $[x, x] = 1$ is in the following form:

$$\Delta_{\alpha,\varphi} = \frac{1}{\sinh \alpha} \frac{\partial}{\partial \alpha} \left(\sinh \alpha \frac{\partial}{\partial \alpha} \right) + \frac{1}{\sinh^2 \alpha} \frac{\partial^2}{\partial \varphi^2}. \tag{2.5}$$

The radial part of the Laplace equation,

$$\Delta_{\alpha,\varphi} \Phi(\alpha,\varphi) = \sigma(\sigma+1)\Phi(\alpha,\varphi), \tag{2.6}$$

where

$$\Phi(\alpha,\varphi) = \vartheta(\alpha) e^{in\varphi}, \tag{2.7}$$

has the form

$$\left[\frac{\partial^2}{\partial \alpha^2} + \frac{\cosh \alpha}{\sinh \alpha} \frac{\partial}{\partial \alpha} - \frac{n}{\sinh^2 \alpha} \right] \vartheta(\alpha) = \sigma(\sigma+1)\, \vartheta(\alpha) \tag{2.8}$$

using

$$dx = \sqrt{g} d\alpha\, d\varphi = \sinh \alpha d\alpha\, d\varphi, \tag{2.9}$$

and making the transformation

$$\vartheta(\alpha) = (\sinh \alpha)^{-1/2} \Psi(\alpha) \tag{2.10}$$

Eq. (2.8) becomes

$$\frac{\partial^2 \Psi(\alpha)}{\partial \alpha^2} + \left[-\frac{1}{4} - \sigma(\sigma+1) - \frac{n^2 - (1/4)}{\sinh^2 \alpha} \right] \Psi(\alpha) = 0. \tag{2.11}$$

Equivalently, defining

$$E=-\tfrac{1}{2}-\sigma(\sigma+1),\quad \sigma=-\tfrac{1}{2}+i\sqrt{E},\quad E>0, \tag{2.12}$$

$$V(\alpha)=\frac{n^2-(1/4)}{\sinh^2\alpha}, \tag{2.13}$$

Eq. (2.8) becomes the Schrödinger equation

$$\frac{\partial^2\Psi(\alpha)}{\partial\alpha^2}+[E-V(\alpha)]\Psi(\alpha)=0. \tag{2.14}$$

By considering the sign of the potential function (2.13) it is seen that only scattering takes place and that E takes positive values only. In Eq. (2.8) if the transformation

$$\vartheta(\alpha)=\left(\cosh\frac{\alpha}{2}\right)^{-n}\left(\sinh\frac{\alpha}{2}\right)^{n}W(\alpha) \tag{2.15}$$

is applied, the following equation is reached:

$$\left[\frac{d^2}{d\alpha^2}+\frac{2n+\cosh\alpha}{\sinh\alpha}\frac{d}{d\alpha}\right]W(\alpha)=\sigma(\sigma+1)W(\alpha). \tag{2.16}$$

In this equation, applying change of the variable

$$z=-\sinh^2\alpha/2, \tag{2.17}$$

the hyper-geometric equation

$$z(z-1)\frac{d^2W(z)}{dz^2}+[(n+1)-2z]\frac{dW(z)}{dz}-[-\sigma(\sigma+1)]W(z)=0 \tag{2.18}$$

is obtained. One solution of Eq. (2.18) is

$$W_1=F\left(\frac{1}{2}+i\sqrt{E},\ \frac{1}{2}-i\sqrt{E},\ n+1;-\sinh^2\frac{\alpha}{2}\right). \tag{2.19}$$

By (2.10) and (2.15) the regular solution of the Schrödinger equation at $\alpha=0$ is given by

$$\Psi(\alpha,\rho)=\frac{\Gamma(\frac{1}{2}+n+i\rho)}{\Gamma(\frac{1}{2}+i\rho)\Gamma(n+1)}\left(\sinh\frac{\alpha}{2}\right)^{1/2+n}\left(\cosh\frac{\alpha}{2}\right)^{1/2-n}$$
$$\times F\left(\frac{1}{2}+i\rho,\ \frac{1}{2}-i\rho,n+1;-\sinh^2\frac{\alpha}{2}\right), \tag{2.20}$$

where $\sqrt{E}=\rho$. On the other hand, using the relation (Ref. 3, p. 1043),

$$F(a,b,c;z)=\frac{\Gamma(c)\Gamma(b-a)}{\Gamma(b)\Gamma(c-a)}(-z)^{-a}F\left(a,a-c+1,b-a+1;\frac{1}{z}\right)$$
$$+\frac{\Gamma(c)\Gamma(a-b)}{\Gamma(a)\Gamma(c-a)}(-z)^{-b}F\left(b,b-c+1,b-a+1;\frac{1}{z}\right), \tag{2.21}$$

we find the asymptotic expression of (2.20) as

$$\Psi(\alpha,\rho)\underset{\alpha\to\infty}{\cong}A(\rho,n)e^{-i\rho\alpha}+\overline{A(\rho,n)}e^{i\rho\alpha}, \tag{2.22}$$

where

$$A(\rho,n)=\frac{\Gamma(n+1)\Gamma(-2i\rho)}{\Gamma(\frac{1}{2}-i\rho)\Gamma(\frac{1}{2}-i\rho+n)}. \tag{2.23}$$

From (2.22) it follows that the normalizing factor is chosen to satisfy the condition

$$\int_{-\infty}^{\infty}\Psi(\alpha,\rho)\overline{\Psi(\alpha,\rho')}d\alpha=\frac{1}{\rho\ \tanh\ \pi\rho}\ \delta(\rho-\rho'). \tag{2.24}$$

The S-matrix is found to be given by

$$S=\frac{A}{\bar{A}}=\frac{\Gamma(-2i\rho)\Gamma(\frac{1}{2}+i\rho)\Gamma(\frac{1}{2}+i\rho+n)}{\Gamma(2i\rho)\Gamma(\frac{1}{2}-i\rho)\Gamma(\frac{1}{2}-i\rho+n)}. \tag{2.25}$$

B. Hyperbolic coordinates

The hyperbolic coordinates are given as

$$\begin{gathered}x_0=r\ \cosh\ \gamma\ \cosh\ \beta,\\ x_1=r\ \cosh\ \gamma\ \sinh\ \beta,\\ x_2=r\ \sinh\ \gamma,\\ \gamma\in(-\infty,\infty),\quad \beta\in(-\infty,\infty).\end{gathered} \tag{2.26}$$

By (2.26), we have

$$(g_{ab})=\ \mathrm{diag}\ (1,-r^2,-r^2\ \cosh^{\,2}\ \gamma), \tag{2.27}$$

$$\sqrt{g}=(\det\ (g_{ab}))^{1/2}=r^2\ \cosh\ \gamma. \tag{2.28}$$

The component of the Laplace–Beltrami operator (2.4) on the hyperboloid $[x,\ x]=1$ is

$$\Delta_{\gamma,\beta}=\frac{1}{\cosh\ \gamma}\frac{\partial}{\partial\gamma}\left(\cosh\ \gamma\ \frac{\partial}{\partial\gamma}\right)+\frac{1}{\cosh^{\,2}\ \gamma}\frac{\partial^2}{\partial\beta^2}. \tag{2.29}$$

On the other hand, the equation

$$\Delta_{\gamma,\beta}\Phi(\gamma,\beta)=\sigma(\sigma+1)\Phi(\gamma,\beta) \tag{2.30}$$

is given by

$$\left(\frac{\partial^2}{\partial\gamma^2}+\frac{\sinh\ \gamma}{\cosh\ \gamma}\frac{\partial}{\partial\gamma}-\frac{\nu^2}{\cosh^{\,2}\ \gamma}\right)\vartheta(\gamma)=\sigma(\sigma+1)\,\vartheta(\gamma), \tag{2.31}$$

where

$$\Phi(\gamma,\beta)=\vartheta(\gamma)e^{i\nu\beta}. \tag{2.32}$$

Utilizing

$$dx=\sqrt{g}\ d\gamma d\beta=\ \cosh\ \gamma\ d\gamma d\beta \tag{2.33}$$

and making the transformation

$$\vartheta(\gamma)=(\cosh\ \gamma)^{-1/2}\psi(\gamma), \tag{2.34}$$

Eq. (2.31) reduces to

$$\frac{d^2\psi(\gamma)}{d\gamma^2}+\left[-\frac{1}{4}-\sigma(\sigma+1)-\frac{\nu^2+(1/4)}{\cosh^{\,2}\gamma}\right]\psi(\gamma)=0 \tag{2.35}$$

or, to the Schrödingers equation (2.14) with

$$E=-\tfrac{1}{4}-\sigma(\sigma+1),\quad \sigma=-\tfrac{1}{2}-i\sqrt{E}, \tag{2.36}$$

$$V(\gamma)=\frac{\nu^2+(1/4)}{\cosh^{\,2}\gamma}. \tag{2.37}$$

Applying the transformation

$$\vartheta(\gamma)=(\cosh\ \gamma)^{\sigma}w(\gamma) \tag{2.38}$$

in Eq. (2.31), we obtain

$$\frac{d^2w(\gamma)}{d\gamma^2}+(2\sigma+1)\ \tanh\ \gamma\ \frac{dw(\gamma)}{d\gamma}-\frac{\gamma^2+\sigma^2}{\cosh^{\,2}\gamma}\,w(\gamma)=0. \tag{2.39}$$

In Eq. (2.39), applying the change of variable

$$z=\ \tanh^{\,2}\gamma \tag{2.40}$$

we arrive at the hyper-geometric equation

$$z(1-z)\ \frac{d^2w(z)}{dz^2}+\left[\frac{1}{2}-(1-\sigma)z\right]\frac{dw(z)}{dz}-\frac{1}{4}\,(\nu^2+\sigma^2)w(z)=0. \tag{2.41}$$

A solution to this equation is

$$W_1=F\left(\frac{1}{4}-\frac{i\sqrt{E}}{2}-\frac{i\nu}{2},\ \frac{1}{4}-\frac{i\sqrt{E}}{2}+\frac{i\nu}{2};\ \frac{1}{2};\ \tanh^{\,2}\gamma\right). \tag{2.42}$$

The regular solution of the Schrödinger equation at $\alpha=0$ with $\sqrt{E}=\rho$ satisfying the condition

$$\int_{-\infty}^{\infty}\psi(\gamma,\rho)\overline{\psi(\gamma,\rho')}d\gamma=\frac{1}{\rho\ \tanh\ \rho\pi}\ \delta(\rho-\rho') \tag{2.43}$$

is found to be

$$\psi(\gamma,\rho)=\left(\frac{\cosh\ \pi\rho}{4\pi^3}\right)^{1/2}\Gamma\left(\frac{1}{4}+\frac{i\rho}{2}+\frac{i\nu}{2}\right)\Gamma\left(\frac{1}{4}+\frac{i\rho}{2}+\frac{i\nu}{2}\right)(\cosh\ \gamma)^{i\rho}$$
$$\times F\left(\frac{1}{4}-\frac{i\rho}{2}-\frac{i\nu}{2},\frac{1}{4}-\frac{i\rho}{2}+\frac{i\nu}{2};\frac{1}{2};\tanh^2\gamma\right). \tag{2.44}$$

On the other hand, considering

$$F(a,b,c;z)=\frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)}(z)^{-a}F\left(a,a-c+1,a+b-c+1;1-\frac{1}{z}\right)+\frac{\Gamma(c)\Gamma(a+b-c)}{\Gamma(a)\Gamma(b)}$$
$$\times(1-z)^{c-a-b}(z)^{a-c}F\left(c-a,1-a,c-a-b+1;1-\frac{1}{z}\right),$$
$$|\arg z|<\pi,\quad |\arg(1-z)|<\pi,\quad c-a-b\neq m,\quad m=0,\pm1,\pm2,\ldots, \tag{2.45}$$

the asymptotic expression for (2.44) is

$$\psi(\gamma,\rho)=A(\rho,\nu)e^{-i\rho\gamma}+\overline{A(\rho,\nu)}e^{i\rho\gamma}, \tag{2.46}$$

where

$$A(\rho,\nu)=\frac{\Gamma(\frac{1}{2})\Gamma(-i\rho)}{\Gamma\left(\frac{1}{4}-\frac{i\rho}{2}-\frac{i\nu}{2}\right)\Gamma\left(\frac{1}{4}-\frac{i\rho}{2}+\frac{i\nu}{2}\right)}2^{i\rho}. \tag{2.47}$$

The S-matrix is

$$S=\frac{A}{\bar{A}}=\frac{\Gamma(i\rho)\Gamma\left(\frac{1}{4}-\frac{i\rho}{2}-\frac{i\nu}{2}\right)\Gamma\left(\frac{1}{4}-\frac{i\rho}{2}+\frac{i\nu}{2}\right)}{\Gamma(-i\rho)\Gamma\left(\frac{1}{4}+\frac{i\rho}{2}+\frac{i\nu}{2}\right)\Gamma\left(\frac{1}{4}+\frac{i\rho}{2}-\frac{i\nu}{2}\right)}. \tag{2.48}$$

C. Parabolic coordinates

The parabolic coordinates are given by

$$x_0=r[\cosh\ \tfrac{1}{2}t+\tfrac{1}{2}e^{(1/2)t}q^2],\quad x_1=r[\sinh\ \tfrac{1}{2}t+\tfrac{1}{2}e^{(1/2)t}q^2],$$
$$x_2=re^{(1/2)t}q,\quad t\in(-\infty,\infty),\ \ q\in(-\infty,\infty). \tag{2.49}$$

From (2.49), we have

$$(g_{ab})=\ \text{diag}\ (1,-\tfrac{1}{4}r^2,-r^2e^t), \tag{2.50}$$

$$\sqrt{g}=(\det\ (g_{ab}))^{1/2}=\tfrac{1}{2}r^2e^{(1/2)t}. \tag{2.51}$$

The component of the Laplace–Beltrami operator on parabola $[x,\ x]=1$ is given as

$$\Delta_{t,q}=4\frac{\partial^2}{\partial t^2}+2\frac{\partial}{\partial t}+\frac{1}{e^t}\frac{\partial^2}{\partial q^2}. \tag{2.52}$$

On the other hand, the equation

$$\Delta_{t,q}\Phi(t,q)=\sigma(\sigma+1)\Phi(t,q), \tag{2.53}$$

where

$$\Phi(t,q)=\vartheta(t)e^{i\nu q} \tag{2.54}$$

is equivalent to

$$\left[4\,\frac{\partial^2}{\partial t^2}+2\,\frac{\partial}{\partial t}-\frac{\nu^2}{e^t}\right]\vartheta(t)=\sigma(\sigma+1)\,\vartheta(t). \tag{2.55}$$

Making use of

$$dx=\sqrt{g}dtdq=\tfrac{1}{2}e^{(1/2)t}\,dtdq \tag{2.56}$$

and applying the transformation

$$\vartheta(t)=e^{-(1/4)t}\psi(t), \tag{2.57}$$

Eq. (2.55) becomes

$$\frac{d^2\psi(t)}{dt^2}+\left[-\frac{1}{16}-\frac{1}{4}\,\sigma(\sigma+1)-\frac{(1/4)\,\nu^2}{e^t}\right]\psi(t)=0, \tag{2.58}$$

which reduces to the Schrödinger equation where

$$E=-\tfrac{1}{16}-\tfrac{1}{4}\sigma(\sigma+1), \tag{2.59}$$

$$V(t)=\frac{(1/4)\,\nu^2}{e^t}. \tag{2.60}$$

Applying the change of variables

$$z=e^{-(1/2)t} \tag{2.61}$$

in Eq. (2.58), we arrive at the equation

$$z^2\,\frac{d^2\psi(z)}{dz^2}+z\,\frac{d\psi(z)}{dz}-[\,\nu^2z^2+(i\rho)^2]\psi(z)=0. \tag{2.62}$$

Equation (2.62) is reduced to

$$z^2\,\frac{d^2\psi(z)}{dz^2}+z\,\frac{d\psi(z)}{dz}-[z^2+(i\rho)^2]\psi(z)=0, \tag{2.63}$$

the modified Bessel equation. Inserting $z'=vz$ the solution satisfying the condition

$$\int_{-\infty}^{\infty}\psi(t,\rho)\overline{\psi(t,\rho')}dt=\frac{1}{\rho\,\tanh\,\pi\rho}\,\delta(\rho-\rho') \tag{2.64}$$

is found to be

$$\psi(t,\rho)=\left(\frac{2\ \cosh\ \pi\rho}{\pi}\right)^{1/2}K_{i\rho}(\nu e^{-(1/2)t}). \tag{2.65}$$

On the other hand, considering the asymptotic expression of $K_\mu(z)$ at $z\to\infty$, we have $\psi\to 0$ for $t\to-\infty$. The expression for ψ as $t\to\infty$ can be found by regarding

$$K_\mu=\frac{\pi}{2\ \sinh\ \pi\mu}\left[I_{-\mu}(z)-I_\mu(z)\right] \tag{2.66}$$

and

$$I_\mu(z)=\frac{(z/2)^\mu e^{-z}}{\Gamma(\mu+1)}F_1(\mu+\tfrac{1}{2};2\mu+1;2z), \tag{2.67}$$

we have

$$\psi(t,\rho)\underset{t\to\infty}{\cong}A(\rho,\nu)e^{-(1/2)i\rho t}+\overline{A(\rho,\nu)}e^{(1/2)i\rho t}. \tag{2.68}$$

Here

$$A(\rho,\nu)=\left(\frac{2\ \cosh\ \pi\rho}{\pi}\right)^{1/2}\frac{-\pi(\nu/2)^{i\rho}}{2i\ \sinh\ \pi\rho\Gamma(1+i\rho)} \tag{2.69}$$

and the S-matrix is given by

$$S=\frac{A}{\bar{A}}=\left(\frac{\nu}{2}\right)^{2i\rho}\frac{\Gamma(1-i\rho)}{\Gamma(1+i\rho)}. \tag{2.70}$$

The quantum system related to the two-sheeted hyperboloid was also considered in Refs. 4 and 5.

III. THE QUANTUM SYSTEMS RELATED TO ONE-SHEETED HYPERBOLOID

Consider the problem outside the cone ($[x,\ x]<0$) in three-dimensional space on three different coordinate systems.

A. Spherical polar coordinates

The spherical polar coordinates are given by

$$x_0=r\ \sinh\ \alpha,\quad x_1=r\ \cosh\ \alpha\ \sin\ \varphi,$$

$$x_2=r\ \cosh\ \alpha\ \cos\ \varphi,\quad r>0,\quad \alpha\in(-\infty,\infty),\quad \varphi\in[0,2\pi]. \tag{3.1}$$

By (3.1) we have

$$(g_{ab})=\ \text{diag}\ (-1,r^2,-r^2\ \cosh^{\,2}\ \alpha), \tag{3.2}$$

$$\sqrt{g}=(\det(g_{ab}))^{1/2}=r^2\ \cosh\ \alpha. \tag{3.3}$$

The component of the Laplace–Beltrami operator on the hyperboloid $[x,\ x]=-1$, is

$$\Delta_{\alpha,\varphi}=\frac{\partial^2}{\partial\alpha^2}+\tanh\ \alpha\ \frac{\partial}{\partial\alpha}-\frac{1}{\cosh^{\,2}\ \alpha}\ \frac{\partial^2}{\partial\varphi^2}. \tag{3.4}$$

On the other hand, the equation

$$\Delta_{\alpha,\varphi}\Phi(\alpha,\varphi)=\sigma(\sigma+1)\Phi(\alpha,\varphi), \tag{3.5}$$

where

$$\Phi(\alpha,\varphi)=\vartheta(\alpha)e^{in\varphi}, \tag{3.6}$$

becomes

$$\left[\frac{\partial^2}{\partial\alpha^2}+\tanh\,\alpha\,\frac{\partial}{\partial\alpha}+\frac{n^2}{\cosh^2\alpha}\right]\vartheta(\alpha)=\sigma(\sigma+1)\,\vartheta(\alpha). \tag{3.7}$$

Using

$$dx=\cosh\,\alpha\;d\alpha\;d\varphi \tag{3.8}$$

and applying the transformation

$$\vartheta(\alpha)=(\cosh\,\alpha)^{-1/2}\psi(\alpha), \tag{3.9}$$

Eq. (3.7) takes the form

$$\frac{\partial^2\psi(\alpha)}{\partial\alpha^2}+\left[-\frac{1}{4}-\sigma(\sigma+1)+\frac{n^2-(1/4)}{\cosh^2\alpha}\right]\psi(\alpha)=0, \tag{3.10}$$

or inserting

$$E=-\tfrac{1}{4}-\sigma(\sigma+1),\quad \sigma=-\tfrac{1}{2}+i\sqrt{E}, \tag{3.11}$$

$$V(\alpha)=-\frac{n^2-(1/4)}{\cosh^2\alpha}, \tag{3.12}$$

reduces the equation to the Schrödinger equation. As can be seen from (3.12), E takes positive and negative values. Let us seek solutions for positive values of E first. Making the transformation

$$\vartheta(\alpha)=(\cosh\,\alpha)^{\sigma}w(\alpha) \tag{3.13}$$

in Eq. (3.7), we arrive at the equation

$$\frac{d^2w(\alpha)}{d\alpha^2}+(2\sigma+1)\,\tanh\,\alpha\,\frac{dw(\alpha)}{d\alpha}+\frac{n^2-\sigma^2}{\cosh^2\alpha}\,w(\alpha)=0. \tag{3.14}$$

Changing to variable $z=\tanh^2\alpha$ in Eq. (3.14), we obtain the equation

$$z(z-1)\,\frac{d^2w(z)}{dz^2}+\left[\frac{1}{2}-(1-\sigma)z\right]\frac{dw(z)}{dz}-\frac{1}{4}\,(\sigma^2-n^2)]w(z)=0. \tag{3.15}$$

The solutions of this equation are given by

$$w_1=F\left(\frac{1}{4}-\frac{i\sqrt{E}}{2}-\frac{n}{2},\,\frac{1}{4}-\frac{i\sqrt{E}}{2}+\frac{n}{2};\,\frac{1}{2};z\right), \tag{3.16}$$

$$w_2 = z^{(1/2)} F\left(\frac{3}{4} - \frac{i\sqrt{E}}{2} - \frac{n}{2}, \frac{3}{4} - \frac{i\sqrt{E}}{2} + \frac{n}{2}; \frac{3}{2}; z\right). \tag{3.17}$$

The function $\Phi(x)$ on the hyperboloid $[x, x] = -1$ with respect to reflection $Rx = -x$ has even and odd components. We consider only the even components.

The regular solution of the Schrödinger equation at $\alpha = 0$ with $\sqrt{E} = \rho$, satisfying the condition

$$\int_{-\infty}^{\infty} \Psi(\alpha, \rho)\overline{\Psi(\alpha, \rho')} d\alpha = \frac{1}{\rho \tanh \pi\rho}\, \delta(\rho - \rho'),$$

are found to be

$$\psi_1(\alpha, \rho) = \frac{1}{\sqrt{2}} \frac{\Gamma\left(\frac{1}{4} + \frac{i\rho}{2} + \frac{n}{2}\right)}{\Gamma\left(\frac{3}{4} - \frac{i\rho}{2} + \frac{n}{2}\right)} (\cosh \alpha)^{i\rho} F\left(\frac{1}{4} - \frac{i\rho}{2} - \frac{n}{2}, \frac{1}{4} - \frac{i\rho}{2} + \frac{n}{2}, \frac{1}{2}; \tanh^2 \alpha\right) \tag{3.18}$$

for $n = 2k$, $k = 1,2,3,...$,

$$\psi_2(\alpha, \rho) = -\frac{1}{2} \frac{\Gamma\left(\frac{3}{4} + \frac{i\rho}{2} + \frac{n}{2}\right)}{\Gamma\left(\frac{1}{4} + \frac{i\rho}{2} + \frac{n}{2}\right)} (\tanh \alpha)(\cosh \alpha)^{i\rho} F\left(\frac{3}{4} - \frac{i\rho}{2} - \frac{n}{2}, \frac{3}{4} - \frac{i\rho}{2} + \frac{n}{2}, \frac{3}{2}; \tanh^2 \alpha\right) \tag{3.19}$$

for $n = 2k + 1$, $k = 1,2,3,...$.

Using the relation (2.21), we find the asymptotic solution of (3.18),

$$\psi_1(\alpha, \rho) = A(\rho, n) e^{-i\rho\alpha} + \overline{A(\rho, n)} e^{i\rho\alpha}, \tag{3.20}$$

where

$$A(\rho, n) = \frac{\Gamma\left(\frac{1}{2}\right)\Gamma(-i\rho)}{\Gamma\left(\frac{1}{4} - \frac{i\rho}{2} - \frac{n}{2}\right)\Gamma\left(\frac{1}{4} - \frac{i\rho}{2} + \frac{n}{2}\right)} 2^{i\rho}. \tag{3.21}$$

Similarly, the asymptotic expression for (3.19) is

$$\psi_2(\alpha, \rho) = A'(\rho, n) e^{-i\rho\alpha} + \overline{A'(\rho, n)} e^{i\rho\alpha}, \tag{3.22}$$

where

$$A'(\rho, n) = \frac{\Gamma\left(\frac{3}{2}\right)\Gamma(-i\rho)}{\Gamma\left(\frac{3}{4} - \frac{i\rho}{2} - \frac{n}{2}\right)\Gamma\left(\frac{3}{4} - \frac{i\rho}{2} + \frac{n}{2}\right)} 2^{i\rho}. \tag{3.23}$$

The S-matrices for (3.20) and (3.22) are

$$S=\frac{\Gamma(-i\rho)\Gamma\left(\frac{1}{4}+\frac{i\rho}{2}-\frac{n}{2}\right)\Gamma\left(\frac{1}{4}+\frac{i\rho}{2}+\frac{n}{2}\right)}{\Gamma(i\rho)\Gamma\left(\frac{1}{4}-\frac{i\rho}{2}-\frac{n}{2}\right)\Gamma\left(\frac{1}{4}-\frac{i\rho}{2}+\frac{n}{2}\right)},\quad n=2k, \tag{3.24}$$

and

$$S=\frac{\Gamma(-i\rho)\Gamma\left(\frac{3}{4}+\frac{i\rho}{2}-\frac{n}{2}\right)\Gamma\left(\frac{3}{4}+\frac{i\rho}{2}+\frac{n}{2}\right)}{\Gamma(i\rho)\Gamma\left(\frac{3}{4}-\frac{i\rho}{2}-\frac{n}{2}\right)\Gamma\left(\frac{3}{4}-\frac{i\rho}{2}+\frac{n}{2}\right)},\quad n=2k+1. \tag{3.25}$$

The square integrable solutions for the negatives values of E are obtained from (3.18) and (3.19). By substituting

$$\sigma=-\tfrac{1}{2}-i\sqrt{E}=-1-\ell, \tag{3.26}$$

we have

$$\psi_1(\alpha,\ell)=c_1(\cosh\,\alpha)^{-|n|+1/2+2k}F(-k,|n|-k;\tfrac{1}{2};\,\tanh^2\,\alpha) \tag{3.27}$$

for $|n|-\ell=2k+1$, $k=0,1,2,...$, and

$$\psi_2(\alpha,\ell)=-c_2(\tanh\,\alpha)(\cosh\,\alpha)^{-|n|+3/2+2k}F(-k,|n|-k;\tfrac{3}{2};\,\tanh^2\,\alpha) \tag{3.28}$$

for $|n|-\ell=2k+2$, $k=0,1,2,...$

Here the normalization factors c_1 and c_2,

$$|c_1|^2=\frac{2}{2\ell+1}\,\frac{\Gamma(\frac{1}{2}+k)\Gamma(-|n|+k+\frac{1}{2})\Gamma(|n|-k)}{\pi\Gamma(1+k)\Gamma(-|n|+2k+\frac{1}{2})\Gamma(|n|-2k-\frac{1}{2})} \tag{3.29}$$

and

$$|c_2|^2=\frac{8}{2\ell+1}\,\frac{\Gamma(\frac{3}{2}+k)\Gamma(-|n|+k+\frac{3}{2})\Gamma(|n|-k)}{\pi\Gamma(1+k)\Gamma(-|n|+2k+\frac{3}{2})\Gamma(|n|-2k+\frac{3}{2})}, \tag{3.30}$$

are chosen to satisfy the condition

$$\int\,|\Psi_i|^2\,d\alpha=\frac{1}{\ell+(1/2)},\quad i=1,2. \tag{3.31}$$

The calculating of the normalization factors c_1 and c_2 are given in Appendix B.

B. Hyperbolic coordinates

The hyperbolic coordinates for $|x_2|>1$ are given as

$$\begin{aligned} x_0&=r\,\sinh\,\gamma\,\cosh\,\beta,\\ x_1&=r\,\sinh\,\gamma\,\sinh\,\beta, \end{aligned} \tag{3.32}$$

$$x_2 = r\epsilon \cosh\ \gamma,$$

$$\gamma \in (-\infty,\infty), \quad \beta \in (-\infty,\infty), \quad \epsilon = \pm 1.$$

By (3.32), we have

$$(g_{ab}) = \text{ diag } (-1, r^2, -r^2 \sinh^2\ \gamma), \tag{3.33}$$

$$\sqrt{g} = (\det\ (g_{ab}))^{1/2} = r^2 \sinh\ \gamma. \tag{3.34}$$

The component of the Laplace–Beltrami operator on the hyperboloid $[x,\ x] = -1$ is

$$\Delta_{\gamma,\beta} = \frac{\partial^2}{\partial \gamma^2} + \coth\ \gamma \frac{\partial}{\partial \gamma} + \frac{1}{\sinh^2\ \gamma} \frac{\partial^2}{\partial \beta^2}. \tag{3.35}$$

The equation

$$\Delta_{\gamma,\beta} \Phi(\gamma,\beta) = \sigma(\sigma+1)\Phi(\gamma,\beta) \tag{3.36}$$

is given by

$$\left(\frac{\partial^2}{\partial \gamma^2} + \coth\ \gamma \frac{\partial}{\partial \gamma} + \frac{\nu^2}{\sinh^2\ \gamma} \right) \vartheta(\gamma) = \sigma(\sigma+1)\,\vartheta(\gamma), \tag{3.37}$$

where

$$\Phi(\gamma,\beta) = \vartheta(\gamma) e^{i\nu\beta}. \tag{3.38}$$

Utilizing

$$dx = \sinh\ \gamma d\gamma\ d\beta \tag{3.39}$$

and making the transformation

$$\vartheta(\gamma) = (\sinh\ \gamma)^{-1/2} \psi(\gamma), \tag{3.40}$$

Eq. (3.37) reduces to

$$\frac{d^2\psi(\gamma)}{d\gamma^2} + \left[-\frac{1}{4} - \sigma(\sigma+1) + \frac{\nu^2 + (1/4)}{\sinh^2\ \gamma} \right] \psi(\gamma) = 0, \tag{3.41}$$

or to the Schrödinger's equation (2.14) with

$$E = -\tfrac{1}{4} - \sigma(\sigma+1), \quad \sigma = -\tfrac{1}{2} + i\sqrt{E}, \quad \sqrt{E} = \rho, \tag{3.42}$$

$$V(\gamma) = -\frac{\nu^2 + (1/4)}{\sinh^2\ \gamma}. \tag{3.43}$$

Applying the transformation

$$\vartheta(\gamma) = \left(\cosh \frac{\gamma}{2} \right)^{-i\nu} \left(\sinh \frac{\gamma}{2} \right)^{-i\nu} w(\gamma) \tag{3.44}$$

in Eq. (3.37), we obtain

$$\left[\frac{d^2}{d\gamma^2}+\frac{2i\nu+\cosh\ \gamma}{\sinh\ \gamma}\frac{d}{d\gamma}\right]w(\gamma)=\sigma(\sigma+1)w(\gamma). \tag{3.45}$$

In Eq. (3.45), applying the change of variable

$$z=-\sinh^2\frac{\gamma}{2}, \tag{3.46}$$

we arrive at the hyper-geometric equation

$$z(1-z)\frac{d^2w(z)}{dz^2}+[(i\nu+1)-2z]\frac{dw(z)}{dz}-[-\sigma(\sigma+1)]w(z)=0. \tag{3.47}$$

The regular solutions of the Schrödinger equation at $\gamma=0$ are found to be

$$\psi_{\pm}(\gamma,\sigma)=\left(\cosh\frac{\gamma}{2}\right)^{1/2}\left(\sinh\frac{\gamma}{2}\right)^{1/2}P_{\sigma}^{\pm i\nu}(\cosh\ \gamma), \tag{3.48}$$

where

$$P_{\sigma}^{\pm i\nu}(\cosh\ \gamma)=\frac{1}{\Gamma(1\mp i\nu)}\left(\cosh\frac{\gamma}{2}\right)^{\pm i\nu}\left(\sinh\frac{\gamma}{2}\right)^{\mp i\nu}F\left(\sigma+1,-\sigma,1\mp i\gamma,-\sinh^2\frac{\gamma}{2}\right). \tag{3.49}$$

Satisfying the condition Eq. (2.43) the solutions of the equation (3.41) have the form[2]

$$\Psi(\gamma,\sigma)=\left(\cosh\frac{\gamma}{2}\right)^{1/2}\left(\sinh\frac{\gamma}{2}\right)^{1/2}[q(\nu,\sigma)P_{\sigma}^{-i\nu}(\cosh\ \gamma)+q(-\nu,\sigma)P_{\sigma}^{i\nu}(\cosh\ \gamma)], \tag{3.50}$$

where

$$q(\nu,\sigma)=q_{\nu}=\frac{1}{\pi\sqrt{2}}\frac{\pi}{i\ \sinh\frac{-\nu}{2}\pi}\sqrt{\Gamma(\sigma+1)\Gamma(-\sigma)\Gamma(\sigma+1+i\nu)\Gamma(-\sigma+i\nu)}$$

$$\times\sqrt{\cos\frac{\sigma}{2}\pi\ \sin\frac{\sigma}{2}\pi\ \cos\left(\frac{\sigma}{2}+\frac{i\nu}{2}\right)\pi\ \sin\left(\frac{\sigma}{2}-\frac{i\nu}{2}\right)\pi}, \tag{3.51}$$

we find the asymptotic expression of (3.50) with $\sigma=-\frac{1}{2}+i\rho$, $\rho=\sqrt{E}$ as

$$\underset{\gamma\to\infty}{\Psi(\gamma,\rho)}\cong(q_{\nu}A_{\nu}+q_{-\nu}A_{-\nu})e^{-i\rho\gamma}+(q_{\nu}B_{\nu}+q_{-\nu}B_{-\nu})e^{i\rho\gamma}, \tag{3.52}$$

where

$$A_{\nu}=\frac{\Gamma(-2i\rho)}{\Gamma(\frac{1}{2}-i\rho)\Gamma(\frac{1}{2}-i\rho+i\nu)}2^{2i\rho}, \tag{3.53}$$

$$B_{\nu}=\frac{\Gamma(2i\rho)}{\Gamma(\frac{1}{2}+i\rho)\Gamma(\frac{1}{2}+i\rho+i\nu)}2^{-2i\rho}. \tag{3.54}$$

Using the conditions

$$|q_\nu|^2|A_\nu|^2+|q_{-\nu}|^2|A_{-\nu}|^2+q_\nu A_\nu\overline{q_{-\nu}A_{-\nu}}+q_{-\nu}A_{-\nu}\overline{q_\nu A_\nu}+|q_\nu|^2|B_\nu|^2+|q_{-\nu}|^2|B_{-\nu}|^2$$
$$+q_\nu B_\nu\overline{q_{-\nu}B_{-\nu}}+q_{-\nu}B_{-\nu}\overline{q_\nu B_\nu}=\frac{\pi}{2\rho\ \tanh\ \pi\rho} \tag{3.55}$$

it can be verified that the condition (2.43) for $\Psi(\gamma,\sigma)$ is satisfied.

The S-matrix is found to be given by

$$S=\frac{q_\nu A_\nu+q_{-\nu}A_{-\nu}}{q_\nu B_\nu+q_{-\nu}B_{-\nu}}. \tag{3.56}$$

The square integrable solution of Eq. (3.41) is found from (3.49) by setting $\sigma=l=0,1,2$:

$$\Psi(\gamma,l)=q(l,\nu)\left(\cosh\frac{\gamma}{2}\right)^{1/2}\left(\sinh\frac{\gamma}{2}\right)^{1/2}\left[P_l^{i\nu}(t)-\frac{\Gamma(1+l+i\nu)}{\Gamma(1+l-i\nu)}\,P_e^{-i\nu}(t)\right], \tag{3.57}$$

where

$$q(l,\gamma)=2\sqrt{\pi}\sqrt{\cot g\,\frac{i\pi\nu}{2}}\,\sqrt{\Gamma(1+\sigma-i\nu)\Gamma(-\sigma-i\nu)},$$
$$t=\cosh\ \gamma. \tag{3.58}$$

Using the relation between Legendre functions[3]

$$Q_\gamma^\mu(z)\sin\ \mu\pi=\frac{\pi}{2}\,e^{i\mu\pi}\left[P_\nu^\mu(z)-\frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu-\mu+1)}\,P_\nu^{-\mu}(z)\right] \tag{3.59}$$

we have

$$\Psi(\gamma,l)=\frac{2}{\pi}\sin\ i\nu\pi e^{-i\pi\nu}q(l,\nu)\left(\cosh\frac{\gamma}{2}\right)^{1/2}\left(\sinh\frac{\gamma}{2}\right)^{1/2}Q_l^{i\nu}(\cosh\ \gamma), \tag{3.60}$$

where

$$Q_l^{i\nu}(\cosh\ \gamma)=2^l(\cosh\ \gamma+1)^{-l-1+i\nu/2}(\cosh\ \gamma-1)^{-i\nu/2}\,\frac{\Gamma(1+l)\Gamma(1+l+i\nu)}{\Gamma(2+2l)}$$
$$\times F\left(1+l-i\nu,1+l,2+2l;\,\frac{2}{1+\cosh\ \gamma}\right). \tag{3.61}$$

The condition

$$\int_{-\infty}^{\infty}\Psi(\gamma,l)\overline{\Psi(\gamma,l')}d\gamma=\frac{1}{l+(1/2)}\,\delta ll' \tag{3.62}$$

follows from the condition

$$\int_{-\infty}^{\infty}\Psi(\gamma,\sigma)\overline{\Psi(\gamma,\sigma')}d\gamma=\frac{1}{2(\sigma+\frac{1}{2})\tanh(\sigma+\frac{1}{2})\pi}\,\delta(\sigma-\sigma') \tag{3.63}$$

by the analytic continuation.

C. Parabolic coordinates

The parabolic coordinates are given as

$$\begin{gathered} x_0 = r[\sinh \tfrac{1}{2}t - \tfrac{1}{2}e^{(1/2)t}q^2], \\ x_1 = r[\cosh \tfrac{1}{2}t + \tfrac{1}{2}e^{(1/2)t}q^2], \\ x_2 = re^{(1/2)t}q, \\ t \in (-\infty,\infty), \quad q \in (-\infty,\infty). \end{gathered} \tag{3.64}$$

By (3.64), we have

$$(g_{ab}) = \text{ diag } (-1, \tfrac{1}{4}r^2, -r^2e^t). \tag{3.65}$$

The component of the operator (2.14) on the hyperboloid $[x,\ x] = -1$ is

$$\Delta_{t,q} = 4\,\frac{\partial^2}{\partial t^2} + 2\,\frac{\partial}{\partial t} - \frac{1}{e^t}\,\frac{\partial^2}{\partial q^2}\,. \tag{3.66}$$

The equation

$$\Delta_{t,q}\Phi(t,q) = \sigma(\sigma+1)\Phi(t,q), \tag{3.67}$$

where

$$\Phi(t,q) = \vartheta(t)e^{i\nu q} \tag{3.68}$$

becomes

$$\left[4\,\frac{\partial^2}{\partial t^2} + 2\,\frac{\partial}{\partial t} + \frac{\nu^2}{e^t}\right]\vartheta(t) = \sigma(\sigma+1)\,\vartheta(t). \tag{3.69}$$

Using (2.56) and making the transformation (2.57), Eq. (3.37) becomes

$$\frac{d^2\Psi(t)}{dt^2} + \left[-\frac{1}{16} - \frac{1}{4}\,\sigma(\sigma+1) + \frac{(1/4)\,\nu^2}{e^t}\right]\Psi(t) = 0 \tag{3.70}$$

or reduces to the Schrödinger equation with

$$E = -\tfrac{1}{16} - \tfrac{1}{4}\sigma(\sigma+1), \tag{3.71}$$

$$V(t) = -\frac{(1/4)\,\nu^2}{e^t}. \tag{3.72}$$

Changing variables to (2.61) in Eq. (3.70) with $\sigma = -\frac{1}{2} + i\rho$ we obtain

$$z^2\,\frac{d^2\Psi(z)}{dz^2} + z\,\frac{d\Psi(z)}{dz} + [\nu^2z^2 + \rho^2]\Psi(z) = 0. \tag{3.73}$$

The solution which tends to zero for $t \to \infty$ and satisfies the condition (2.64),

$$\Psi(t,\rho)=\left(\frac{2\ \cosh\ \rho\pi}{\pi}\right)^{1/2}K_{i\rho}(i\nu e^{-(1/2)t}) \tag{3.74}$$

The square integrable solution of Eq. (3.73) with $\sigma(\sigma+1)=l(l+1)$ is

$$\Psi_l(t)=J_{l+1/2}(\nu e^{-(1/2)t}). \tag{3.75}$$

The orthonormality condition of Bessel functions has the form

$$\int_0^\infty J_{l+1/2}(z)J_{l'+1/2}(z)\ \frac{dz}{z}=\frac{l}{l+\frac{1}{2}}\ \delta ll'. \tag{3.76}$$

IV. THE EXPLICIT EXPRESSIONS ON THE GREEN'S FUNCTION OF THE FREE PARTICLE ON TWO- AND ONE-SHEETED HYPERBOLOIDS

A. Calculate Green's function of the free particle on hyperboloid $[x,\ x]=1$

First we consider the decomposition of the unitary representation

$$T(g)F(x)=F(xg),\quad g\in \mathrm{SO}(1,2), \tag{4.1}$$

in the space

$$\langle F_1,F_2\rangle=\int F_1(x)\overline{F_2(x)}dx \tag{4.2}$$

of function on hyperboloid. The irreducible representation $T_\sigma(g)$, $g\in$SO(1,2), can be realized in the space of the homogenous functions on cone

$$[y,\ y]=y_0^2-y_1^2-y_2^2=0,\quad y_0>0$$

(see Appendix A). Consider the functions $[x,\ y]^\sigma$, which for fixed x homogenous functions on cone

$$[x,\ dy]^\sigma=a^\sigma[x,\ y]^\sigma. \tag{4.3}$$

Since $[xg^{-1},\ y]=[x,\ yg]$, we have

$$[xg^{-1},\ s]^\sigma=(sg)_0^\sigma[x,\overline{sg}]^\sigma, \tag{4.4}$$

where $y=e^\alpha s$, $s=(1,\sin\varphi,\cos\varphi)$. The Fourier components $\tilde{F}(s;\rho)$ of the function $F(x)$ we define by formula

$$\tilde{F}(s,\rho)=\int F(x)[x,s]^{-1/2+i\rho}\ dx. \tag{4.5}$$

For the function $F_g(x)=F(xg)$ we have

$$\tilde{F}_g(s,\rho)=\int F_g(x)[x,s]^{-1/2+i\rho}\ dx=\int F(x)[xg^{-1},s]^{-1/2+i\rho}\ dx=(sg)_0^{-1/2+i\rho}F(\overline{sg},\rho). \tag{4.6}$$

Here we used Eq. (4.4) and the invariance of the volume element $dx=dxg$. Hence representation in the space of functions $F(s,\rho)$ is irreducible.

The expansion of the function $F(x)$ in an elementary harmonics reads[2]

$$F(x)=\frac{1}{\pi^2}\int \tilde{F}(s,\rho)[x,s]^{-1/2+i\rho}\rho\ \tanh\ \pi\rho\ d\rho\ ds. \tag{4.7}$$

The function $[x,\ s]^{\sigma}$ is an eigenfunction of the Laplace–Beltrami operator,

$$\Delta_{\mathrm{L,B}}[x,s]^{\sigma}=\sigma(\sigma+1)[x,s]^{\sigma}. \tag{4.8}$$

Therefore the Green's function of the quantum system with Hamiltonian

$$H=-\frac{1}{2mR^2}\Delta_{\mathrm{LB}} \tag{4.9}$$

reads

$$G(x_1,x_2;E)=\frac{1}{\pi^2}\int\int_S \frac{[x_1,s]^{-1/2+i\rho}[x_2,s]^{-1/2-i\rho}}{\frac{1}{2mR^2}\left(\rho^2+\frac{1}{4}\right)-E}\rho\ \tanh\ \pi\rho\ d\rho\ ds. \tag{4.10}$$

Using the addition theorem (see Appendix A),

$$\int\ [x_1,\ s]^{-1/2+i\rho}[x_2,\ s]^{-1/2-i\rho}\ ds=2\pi\int\ [\dot{x}g_{x_1}g_{x_2}^{-1},s]^{-1/2+i\rho}\ d\varphi, \tag{4.11}$$

and integral representation of first kind Legendre function,

$$P_{\sigma}(\cosh\ \alpha)=\frac{1}{2\pi}\int\ [x,\ s]^{\sigma}ds=\frac{1}{2\pi}\int\ (\cosh\ \alpha-\sinh\ \alpha\ \cos\ \varphi)^{\sigma}d\varphi, \tag{4.12}$$

and the relation between first kind and second kind Legendre functions (Ref. 3, p. 819),

$$\int_0^{\infty}\frac{x\ \tanh\ \pi x}{a^2+x^2}P_{-(1/2)+ix}(\cosh\ y)dx=Q_{a-(1/2)}(\cosh\ y), \tag{4.13}$$

we obtain

$$G(x_1,x_2;E)=8mR^2Q_{i\sqrt{2mR^2E-(1/4)}-(1/2)}([x_1,\ x_2]). \tag{4.14}$$

The same results were obtained by the path integral method in Refs. 6 and 7.

By a Fourier transformation we obtain the time-dependent propagator:

$$K(x_1,x_2;T)=\frac{1}{2\pi R^2}\int_0^{\infty}\exp\left[\frac{-iT(\rho^2+\frac{1}{4})}{2mR^2}\right]P_{-(1/2)+i\rho}([x_1,\ x_2])\rho\ \tanh\ \pi\rho\ d\rho. \tag{4.15}$$

The eigenfunction representation in terms of the Legendre function of the propagator is ''equivalent to the integral over classical parts.''[4,7]

Indeed, using the integral representation for the Legendre function[8]

$$\tanh(\pi\rho)P_{-(1/2)+i\rho}(\cosh\ \alpha)=\frac{\sqrt{2}}{\pi}\int_{\alpha}^{\infty}\frac{\sin\ \rho t\ dt}{(\cosh\ t-\cosh\ \alpha)^{1/2}} \tag{4.16}$$

and the formula;

$$\int_0^\infty \rho \sin(\rho t)\exp(-a\rho^2)d\rho = \sqrt{\frac{\pi}{a}}\,(t/4a)\exp(-t^2/4a) \tag{4.17}$$

we obtain

$$K(x_1,x_2;T)=\sqrt{2}\ \mathrm{Re}^{-i\pi/8mR^2}\left(\frac{m}{2\pi T}\right)^{3/2}\int_\alpha^\infty \frac{t\exp(-mRt^2/2T)dt}{(\cosh t-\cosh\alpha)^{1/2}}, \tag{4.18}$$

where $\cosh\alpha=[x_1, x_2]$.

B. The Green's function on one-sheeted hyperbolic $[x, x]=-1$

There exists the reflection operator R defined by

$$RF(x)=F(-x) \tag{4.19}$$

which commutes with the representation operator

$$T(g)F(x)=F(xg). \tag{4.20}$$

Therefore symmetric and antisymmetric parts $F^{\pm}(x)=\frac{1}{2}[F(x)\pm F(-x)]$ of the functions $F(x)$ define invariant subspaces. Notice that the one-sheeted hyperboloid $[x, x]=-1$ with identified of the opposite points x and $-x$ is called the imaginary Labochevsky space. From the results concerning the decomposition of the representation (4.20) into the irreducible components[2] follows that the Green's function in the imaginary Lobachevsky space is defined by

$$G(x_1,x_2;E)=\frac{1}{\pi}\int_0^\infty\int_S \frac{[x_1, s]^{-1/2+i\rho}[x_2, s]^{-1/2-i\rho}}{\frac{1}{2mR^2}(\rho^2+\frac{1}{4})-E}\rho\tanh\pi\rho\, d\rho\, ds$$

$$+\frac{1}{\pi}\sum_{l=0}^\infty \frac{(l+\frac{1}{2})\int|[x_1,s]|^{-1-l}|[x_2,s]|^l\, ds}{-\frac{1}{2mR^2}l(l+1)-E}. \tag{4.21}$$

By the addition theorem (see Appendix A) we get

$$G(x_1,x_2;E)=2\pi R^2\int_0^\infty \frac{P_{-(1/2)+i\rho}(|x_1,x_2|)\rho\tanh\pi\rho\, d\rho}{\rho^2-(2mR^2E+\frac{1}{4})}+2mR^2\sum_{l=0}^\infty \frac{(l+\frac{1}{2})P_l(|x_1,x_2|)}{-l(l+1)-2mR^2}. \tag{4.22}$$

In order to calculate the infinite series in (4.22) we use the Sommerfeld–Watson integral transformation

$$\sum_{l=0}^\infty \frac{(l+\frac{1}{2})}{-l(l+1)-E}P_l(t)=i\int_C d\sigma\,\frac{(\sigma+\frac{1}{2})\cos\pi\sigma}{\sin\pi\sigma[-\sigma(\sigma+1)-E]}P_\sigma(t)$$

$$=\int_{-\infty}^\infty \frac{d\rho\rho\tanh\pi\rho}{\rho^2+\frac{1}{4}+(-E)}P_{-(1/2)+i\rho}(t), \tag{4.23}$$

where contour C encounters the zeros of the function $\sin\pi l, l=0,1,2,\ldots$.

For $t>1$ then apply to last integral the formula (4.13), but for $t<1$ we define it by analytic continuation. Thus we obtain final expression for Green's function

$$G(x_1,x_2;E)=2mR^2[Q_{i\sqrt{(E/2mR^2)-(1/4)}-(1/2)}(|x_1x_2|)+Q_{i\sqrt{(-E/2mR^2)-(1/4)}-(1/2)}(|x_1x_2|)]. \tag{4.24}$$

ACKNOWLEDGMENT

The authors are indebted to Professor A. O. Barut for valuable discussions.

APPENDIX A: THE ORTHOGONALITY, COMPLETENESS CONDITIONS AND ADDITION THEOREM FOR PLANE VALUES $[x,\ s]^{\sigma}$

The irreducible representations of group SO(1,2) are constructed[9] in the space of infinitely differentiable homogenous functions $F(y)$ on the cone $[y,y]=0$; $y_0>0$,

$$F(ay)=a^{\sigma}F(y),\quad a>0. \tag{A1}$$

The representation

$$T_{\sigma}(g)F(y)=F(yg),\quad g\in \mathrm{SO}(1,2), \tag{A2}$$

can be realized in the space of infinitely differentiable functions on intersections of cone; for example, on the circle

$$T_{\sigma}(g)f(s)=(sg)_0^{\sigma}f(\overline{sg}), \tag{A3}$$

$$s=y|_{y_0=1}=(1,\ \sin\varphi,\ \cos\varphi),\quad y=y_0s=e^{\alpha}s. \tag{A4}$$

From $y'=yg$ we have

$$(sg)_0=e^{\alpha'-\alpha},\quad \overline{sg}=sg/(sg)_0=(1,\ \sin\varphi',\ \cos\varphi'). \tag{A5}$$

The unitary representation $T_{\sigma}(g)$, $g\in\mathrm{SO}(1,2)$ with respect to scalar product

$$\langle f_1,f_2\rangle=\int \overline{f_1(\varphi)}f_2(\varphi)d\varphi=\int \overline{f_1(s)}f_2(s)ds \tag{A6}$$

is defined by $\sigma=-(1/2)+i\rho$ (principle series). The unitary representation $T_{\sigma}(g)$ with respect to the scalar product

$$\langle f_1,f_2\rangle=\frac{1}{\Gamma(-r-\frac{1}{2})}\int [s,s']^{-1-\sigma}\overline{f_1(s)}f_2(s)ds\ ds' \tag{A7}$$

is defined by $-1<\sigma<0$ (complementary series) and by $\sigma=-1-l$, $l=0,1,2$ (discrete series). The matrix elements of the representation $T^{\sigma}_{0,n}(g)$ are defined by the formula

$$t^{\sigma}_{0,n}(g)=\langle 1,T_{\sigma}(g)e^{in\varphi}\rangle=\frac{1}{2\pi}\int (sg)_0^{\sigma}e^{in\varphi'}\ d\varphi'. \tag{A8}$$

Using the decomposition of the element $g\in\mathrm{SO}(1,2)$ related with the hyperboloid $[x,\ x]=1$

$$x=xg_x,\quad xK=x,\quad g=Kg_x,$$

we also have

$$t^{\sigma}_{0,n}(g_x)=\langle T_{-1-\sigma}(g_x^{-1}),e^{in\varphi}\rangle=\frac{1}{2\pi}\int (sg_x^{-1})_0^{-1-\bar{\sigma}}e^{in\varphi}\,d\varphi. \tag{A9}$$

Since

$$(sg_x^{-1})_0=[\mathring{x},\ sg_x^{-1}]=[\mathring{x}g_x,\ s]=[x,\ s],\quad \mathring{x}=(1,0,0)$$

we get

$$t^{\sigma}_{0,n}(g_x)=\frac{1}{2\pi}\int [x,s]^{-1-\bar{\sigma}}e^{in\varphi}\,d\varphi. \tag{A10}$$

Laplace–Beltrami operator Δ_{LB} on hyperboloid $[x,\ x]=1,\ x_0>0$, is a Casimir operator of the quasi-regular representation $T_g(g)F(x)=F(xg)$.

So, the matrix elements $t^{\sigma}_{0,n}(g_x)$ satisfy the equation

$$\Delta_{\mathrm{LB}}t^{\sigma}_{0,n}(g_x)=\sigma(\sigma+1)t^{\sigma}_{0,n}(g_x), \tag{A11}$$

and we have

$$\Delta_{\mathrm{LB}}[x,\ s]^{\sigma}=\sigma(\sigma+1)[x,\ s]^{\sigma}. \tag{A12}$$

The addition theorem for function $[x,s]^{-1+i\rho}$ follows from the relations

$$\sum_n t^{\sigma}_{0,n}(g_{x_1})\overline{t^{\sigma}_{0,n}(g_{x_2})}=\sum_n t^{\sigma}_{0,n}(g_{x_1})t^{\sigma}_{0,n}(g_{x_2}^{-1})=t^{\sigma}_{0,0}(g_{x_1}g_{x_2}^{-1}). \tag{A13}$$

Using the integral representation (A10) we have

$$\int [x_1,\ s]^{-(1/2)+i\rho}[x_2,\ s]^{-(1/2)-i\rho}\,ds=\frac{1}{2\pi}\int [\dot{x}g_{x_1}g_{x_2}^{-1},s]^{-(1/2)+i\rho}\,ds. \tag{A14}$$

The orthogonality condition for the matrix elements $t^{\sigma}_{0,n}(g_x)$ reads

$$\int t_{0,n}^{-(1/2)+i\rho}(g_x)\overline{t_{0,n}^{-(1/2)+i\rho'}}(g_x)dx=(2\pi)^2|c(\rho)|^2\delta(\rho-\rho')\,\delta_{nn'}, \tag{A15}$$

where $c(\rho)$, the so-called Harish–Chandra function, is defined asymptotically:[10]

$$t^{\sigma}_{0,n}(a(\alpha))\underset{\alpha\to\infty}{\cong}\int_0^{2\pi}(\cosh\,\alpha+\sinh\,\alpha\,\cos\,\varphi)^{\sigma}\,d\varphi=(\cosh\,\alpha)^{\sigma}c(\sigma), \tag{A16}$$

where

$$c(\sigma)=2^{\sigma}\frac{\Gamma(1+2\sigma)}{|\Gamma(1+\sigma)|^2}. \tag{A17}$$

Here we use Eq. (A8) and the fact that

$$\cos\,\varphi'\underset{\alpha\to\infty}{=}\frac{\sinh\,\alpha+\cosh\,\alpha\,\cos\,\varphi}{\cosh\,\alpha+\sinh\,\alpha\,\cos\,\varphi}\to 1. \tag{A18}$$

From Eq. (A15) we get to the orthogonality condition for functions $[x\ s]^{-(1/2)+i\rho}$:

$$\int [x,s]^{-(1/2)+i\rho}[x,s']^{-(1/2)-i\rho'}\,dx=\pi^2\,\frac{1}{\rho\,\tanh\,\pi\rho}\,\delta(\rho-\rho')\,\delta(s-s'). \tag{A19}$$

The completeness condition

$$\frac{1}{\pi^2}\int [x_1,\,s]^{-(1/2)+i\rho}[x_2,\,s]^{-(1/2)-i\rho}\rho\,\tanh\,\pi\rho\,d\rho\,ds=\frac{1}{\pi}\,\delta(x_1-x_2) \tag{A20}$$

follows from the fact that quantum systems related to the hyperboloid $[x,\,x]=1$, $x_0>0$, contain only scattering states (see Ref. 2).

In order to present the addition theorem for the eigenfunctions $|[x,\,s]|^{\sigma}$ of the Laplace–Beltrami operator on the one-sheeted hyperboloid $[x,\,x]=-1$ because the stationary subgroup of fixed point $x=(0,0,1)$ is noncompact $\mathrm{SO}(1,1)\equiv H$, we must consider the matrix elements of unitary representation $T_\sigma(g)$ in the basis associated with noncompact subgroup H. Realizing the representation (A2) in the space of function $f(p)=F(y)|_{x_2=\pm 1}$, where $p=(\cosh\beta,\ \sinh\beta,\epsilon)$, $\epsilon=\pm 1$, we get[2]

$$t^{\sigma,\epsilon}_{0,\nu}(g_x)=\frac{1}{2\pi}\int_S|[x,s]|^{-1-\sigma}[x,\,s]^{\sigma}\,\mathrm{sign}^{\epsilon}[x,s]\left\{\frac{[p^+,s]}{[p^-,s]}\right\}^{i\nu/2}ds, \tag{A21}$$

where $\epsilon=0,1$; $p^{\pm}=(1,\pm 1,0)$. Then from

$$\int_S t^{(\sigma,0)}_{0,0}(g_{x_1})t^{(\sigma,0)}_{0,\nu}(g^{-1}_{x_2})\,d\nu=t^{(\sigma,0)}_{0,0}(g_{x_1}g^{-1}_{x_2}) \tag{A22}$$

we obtain

$$\int_S|[x_1,s]|^{\sigma}|[x_2,s]|^{-1-\sigma}\,ds=\int_S|[xg_{x_1}g^{-1}_{x_2},s]|^{\sigma}|[x,s]|^{-1-\sigma}\,ds. \tag{A23}$$

Using the decomposition of the elements

$$g=h\tilde{g}h,\quad g\in\mathrm{SO}(1,2), \tag{A24}$$

where $\tilde{g}=a(\alpha)$ or $\tilde{g}=K(\theta)$ (see Ref. 2) associated with the hyperboloid $[x,\,x]=-1$. We have

$$t^{(\sigma,0)}_{0,0}(g)=t^{(\sigma,0)}_{0,0}(\tilde{g})=P_\sigma(t) \tag{A25}$$

for $|t|>1$, $t=\epsilon\cosh\alpha$, $\epsilon=\pm 1$, for $|t|<1$, $t=\cos\theta$.

APPENDIX B: CALCULATION OF THE NORMALIZATION FACTOR

To calculate the normalization factor in (3.27) we perform the change of variable $x=\tanh^2\alpha$ and use the formula [Ref. 11, 2.8 (17)]

$$F(-k,b;c;x)=\frac{\Gamma(c)}{\Gamma(c+k)}\,x^{1-c}(1-x)^{k+c-b}\,\frac{d^k}{dx^k}\,[x^{k+c-1}(1-x)^{b-c}]. \tag{B1}$$

Then we get

$$J=\frac{|c_1|^2\sqrt{x}}{\Gamma(\frac{1}{2}+k)}\int_0^1(1-x)^{-1}F\left(-k,n-k;\,\frac{1}{2};x\right)\frac{d^k}{dx^k}\,[x^{k-1/2}(1-x)^{n-k-1/2}]dx. \tag{B2}$$

After k-fold multiple integration by parts and using the formula [Ref. 11, 28 (25)]

$$\frac{d^k}{dx^k}\left[(1-x)^{-1}F(-k,b;c;x)\right]=\frac{\Gamma(k+1)\Gamma(c-b+k)\Gamma(c)}{\Gamma(c-b)\Gamma(c+k)}\,(1-x)^{-k-1}, \tag{B3}$$

from $J=1/[\ell+(1/2)]$ we obtain

$$|c_1|^2=\frac{2}{2\ell+1}\,\frac{\Gamma(\frac{1}{2}+k)\Gamma(-n+k+\frac{1}{2})\Gamma(n-k)}{\pi\Gamma(k+1)\Gamma(-n+2k+\frac{1}{2})\Gamma(n-2k-\frac{1}{2})}. \tag{B4}$$

We study a supersymmetric two-dimensional harmonic oscillator which carries a representation of the general graded Lie algebra GL(2|1), formulate it on the superspace, and discuss its physical spectrum. © *1996 American Institute of Physics.* [S0022-2488(96)00201-X]

I. INTRODUCTION

Supersymmetry is an interesting symmetry which transforms bosons into fermions and vice versa.[1] Quantum mechanical (or classical) theories which are supersymmetric provide realizations of graded Lie algebras (GLA).[2] The most familiar GLA is the graded Poincaré algebra which leads to relativistic, supersymmetric quantum field theories, which include supergravity.

Examples of simple and extended global supersymmetries based on the grading of space-time symmetries are abundant in simple quantum mechanical systems—the one-dimensional supersymmetric harmonic oscillator being the simplest example of such systems.[3,4] However, there exist many other GLAs which involve grading internal symmetry algebras. The most familiar of such GLAs are the OS$p(2m|n)$ and SL$(m|n)$.[5] While realizations of such algebras arise naturally in integrable models, there does not yet exist a quantum or classical mechanical realization of the most general graded Lie algebra, namely, GL$(m|n)$. In this paper, we construct a supersymmetric two-dimensional harmonic oscillator which provides a realization of GL(2|1) as its symmetry algebra. In Sec. II, we discuss the GL(2|1) algebra with raising and lowering operators. In Sec. III we present our model of a supersymmetric harmonic oscillator and discuss all the symmetries associated with this system. We show that the symmetry algebra coincides with GL(2|1). In Sec. IV, we discuss the spectrum of states associated with this Hamiltonian and present a superspace description of this theory. Finally, we discuss our conclusions in Sec. V.

II. GRADED LIE ALGEBRA GL(2|1)

Graded Lie algebras[2] include both bosonic and fermionic generators satisfying commutation and anticommutation relations, respectively, and have the following general structure:

$$[B_m,B_n]_- = f_{mn}^k B_k, \quad [B_m,F_\alpha]_- = h_{m\alpha}^\beta F_\beta, \quad [F_\alpha,F_\beta]_+ = g_{\alpha\beta}^m B_m, \tag{1}$$

with the brackets $[...,...]_{\mp}$ denoting commutators and anticommutators, respectively, $k,m,n = 1,2,\ldots,N$, and $\alpha,\beta = 1,2,\ldots,M$. The even or bosonic generators B_m form the underlying Lie algebra, while the odd or fermionic generators F_α provide a grading of this algebra consistent with the generalized Jacobi identities.

In this section we shall study the graded Lie algebra GL(2|1) whose underlying bosonic algebra is GL(2)⊕GL(1). Here we shall use the boson/fermion representation obtained with the help of canonical realizations, i.e., realizations in terms of pairs of boson/fermion creation and annihilation operators satisfying canonical (anti)commutation relations. Consider the set of bosonic and fermionic operators

[a]Electronic mail: das@urhep.pas.rochester.edu

$$\{a_k^\dagger, a_k; k=1,2\} \quad \text{and} \ \{a_3^\dagger, a_3\} \tag{2}$$

satisfying the canonical (anti)commutation relations

$$[a_k, a_m^\dagger]_- = \delta_{km}, \quad [a_3, a_3^\dagger]_+ = 1, \tag{3}$$

with all other (anti)commutators vanishing. The four bilinear operators $B \sim a_k^\dagger a_m$ define the generators of the underlying GL(2) algebra, which together with $B \sim a_3^\dagger a_3$ constitute the five bosonic generators of the GL(2|1) algebra. The four fermionic generators of this algebra are defined by the bilinear operators $F \sim a_3^\dagger a_k$ and $F \sim a_k^\dagger a_3$. All together these nine operators generate the Z_2 graded GL(2|1) algebra. It is a simple task to verify that they satisfy the algebra (1). For instance, if we denote these nine operators as

(a) bosonic generators:

$$\begin{gathered} B_1 = a_1^\dagger a_1, \quad B_2 = a_1^\dagger a_2, \quad B_3 = a_2^\dagger a_1, \\ B_4 = a_2^\dagger a_2, \quad B_5 = a_3^\dagger a_3, \end{gathered} \tag{4}$$

(b) fermionic generators:

$$\begin{gathered} F_1 = a_1^\dagger a_3, \quad F_2 = a_2^\dagger a_3, \\ F_3 = a_3^\dagger a_1, \quad F_4 = a_3^\dagger a_2, \end{gathered} \tag{5}$$

it is then a simple task to find the nonvanishing structure constants in Eq. (1).

For future convenience, we introduce a new basis of the fermionic generators as

$$\begin{gathered} Q_R = \frac{1}{\sqrt{2}}(a_1^\dagger a_3 - i a_2^\dagger a_3), \quad \bar{Q}_R = \frac{1}{\sqrt{2}}(a_3^\dagger a_1 + i a_3^\dagger a_2), \\ Q_L = \frac{i}{\sqrt{2}}(a_3^\dagger a_1 - i a_3^\dagger a_2), \quad \bar{Q}_L = \frac{-i}{\sqrt{2}}(a_1^\dagger a_3 + i a_2^\dagger a_3). \end{gathered} \tag{6}$$

The anticommutation relations among these charges are easily computed. We also redefine the five bosonic operators as

$$\begin{gathered} h_b = a_1^\dagger a_1 + a_2^\dagger a_2, \quad h_f = a_3^\dagger a_3, \\ \Delta_1 = a_1^\dagger a_1 - a_2^\dagger a_2, \quad i\Delta_2 = a_2^\dagger a_1 - a_1^\dagger a_2, \quad \Delta_3 = a_1^\dagger a_2 + a_2^\dagger a_1, \end{gathered} \tag{7}$$

and introduce the operator $H = h_b + h_f$. The algebra of the fermionic charges (6) becomes

$$\begin{gathered} [Q_R, \bar{Q}_R]_+ = \tfrac{1}{2}(H + \Delta_2 + h_f), \quad [Q_L, \bar{Q}_L]_+ = \tfrac{1}{2}(H - \Delta_2 + h_f), \\ [Q_R, Q_L]_+ = \tfrac{1}{2}(\Delta_3 + i\Delta_1), \quad [\bar{Q}_R, \bar{Q}_L]_+ = \tfrac{1}{2}(\Delta_3 - i\Delta_1). \end{gathered} \tag{8}$$

Similarly, the algebra of the new bosonic charges (7) can be computed straightforwardly, to give

$$\begin{gathered} [\Delta_k, \Delta_m]_- = 2i\epsilon_{kmn}\Delta_n, \quad [h_b, \Delta_m]_- = 0, \\ [h_f, \Delta_m]_- = 0, \quad [h_b, h_f]_- = 0, \end{gathered} \tag{9}$$

while the remaining nonvanishing boson–fermion commutation relations are

$$[h_f,Q_R]_-=-[h_b,Q_R]_-=-Q_R,\quad [h_f,\bar{Q}_R]_-=-[h_b,\bar{Q}_R]_-=+\bar{Q}_R,$$
$$[h_f,Q_L]_-=-[h_b,Q_L]_-=+Q_L,\quad [h_f,\bar{Q}_L]_-=-[h_b,\bar{Q}_L]_-=-\bar{Q}_L; \tag{10}$$

$$[\Delta_1,Q_R]_-=+i\bar{Q}_L,\quad [\Delta_1,\bar{Q}_R]_-=+iQ_L,$$
$$[\Delta_1,Q_L]_-=-i\bar{Q}_R,\quad [\Delta_1,\bar{Q}_L]_-=-iQ_R; \tag{11}$$

$$[\Delta_2,Q_R]_-=+Q_R,\quad [\Delta_2,\bar{Q}_R]_-=-\bar{Q}_R,$$
$$[\Delta_2,Q_L]_-=+Q_L,\quad [\Delta_2,\bar{Q}_L]_-=-\bar{Q}_L; \tag{12}$$

$$[\Delta_3,Q_R]_-=+\bar{Q}_L,\quad [\Delta_3,\bar{Q}_R]_-=-Q_L,$$
$$[\Delta_3,Q_L]_-=-\bar{Q}_R,\quad [\Delta_3,\bar{Q}_L]_-=+Q_R. \tag{13}$$

Using these relations we can verify that all generators satisfy the generalized Jacobi identities. Observe from Eqs. (9) and (10) that all nine generators of the GL(2|1) graded Lie algebra described above commute with H which stays in the center of the algebra.

III. TWO-DIMENSIONAL SUPERSYMMETRIC HARMONIC OSCILLATOR

In this section we introduce our model, a two-dimensional supersymmetric harmonic oscillator which, as mentioned in the Introduction, carries a representation of the graded GL(2|1) algebra described in Sec. II. This model is described by the following Lagrangian:

$$L=\frac{1}{2}\,(\dot{q}^T\dot{q}-q^Tq)+\frac{i}{2}\,\psi^T\left(\frac{d}{dt}-i\sigma_2\right)\psi, \tag{14}$$

where

$$q=\begin{pmatrix} q_1 \\ q_2 \end{pmatrix} \tag{15}$$

and

$$\psi=\begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix} \tag{16}$$

are the oscillator's bosonic and fermionic coordinates, which are assumed to be real. We have chosen the mass and the frequency to be unity, for simplicity. Here σ_k stands for the Pauli matrices and q^T and ψ^T stand for matrix transposition, as usual. Note that up to total derivatives, we can also write the Lagrangian (14) as

$$L=-\frac{1}{2}\,q^T\left(\frac{d}{dt}-i\sigma_2\right)\left(\frac{d}{dt}+i\sigma_2\right)q+\frac{i}{2}\,\psi^T\left(\frac{d}{dt}-i\sigma_2\right)\psi. \tag{17}$$

It is important to mention that compared to the *usual* two-dimensional supersymmetric harmonic oscillator, the model under investigation here is constructed with half the number of fermionic

degrees of freedom, i.e., it has two second-order bosonic variables (or four first-order) and two first-order fermionic variables. In the two-dimensional matrix space of Eqs. (15) and (16), let us denote a complete basis of real, (2×2) matrices by

$$\tau_a=(\sigma_0,\sigma_1,i\sigma_2,\sigma_3);\quad a=0,1,2,3, \tag{18}$$

where σ_0 is the (2×2) identity matrix. It is straightforward to show that the action of the theory described by Eq. (14) is invariant under the four supersymmetry transformations

$$\delta q=\epsilon_a\tau_a\psi,\quad \delta\psi=i\left(\frac{d}{dt}+i\sigma_2\right)\epsilon_a\tau_a^T q, \tag{19}$$

with ϵ_a being four infinitesimal, constant Grassmann parameters that characterize the transformations. In the Hamiltonian language,[6] which is more appropriate for our purposes, the Hamiltonian operator is given by

$$H=\tfrac{1}{2}(p^Tp+q^Tq)-\tfrac{1}{2}\psi^T\sigma_2\psi \tag{20}$$

and enjoys the following set of global invariances:

(A) Supersymmetry

$$\delta q=\frac{1}{\sqrt{2}}\,\epsilon_a\tau_a\psi,\quad \delta\psi=\frac{i}{\sqrt{2}}\,\epsilon_a(\tau_a^Tp+i\sigma_2\tau_a^Tq),\quad \delta p=\frac{i}{\sqrt{2}}\,\epsilon_a\tau_a\sigma_2\psi. \tag{21}$$

The Noether supercharges generating these transformations are given by

$$Q_a=\frac{1}{\sqrt{2}}\,(p^T\tau_a\psi-iq^T\tau_a\sigma_2\psi). \tag{22}$$

Indeed, note that given the generalized Dirac brackets [see Eq. (A5)]

$$\{q_k,p_m\}=\delta_{km},\quad \{\psi_\alpha,\psi_\beta\}=-i\delta_{\alpha\beta}, \tag{23}$$

we obtain the supersymmetry transformations (21) above as

$$\delta A=\{A,\epsilon_aQ_a\}, \tag{24}$$

where A stands for q_k, p_k, and ψ_α. The invariance of the Hamiltonian implies that $\{H,Q_a\}=0$ which in turn shows that the Q_a's are constants of motion. Besides the four supersymmetries above, this Hamiltonian is also invariant under the following global symmetries.

(B) Rotation on the four-dimensional (bosonic) phase-space
(i) The transformations

$$\delta q=-i\alpha\sigma_2q,\quad \delta p=-i\beta\sigma_2p, \tag{25}$$

with α,β bosonic, constant infinitesimal parameters are clearly symmetries of H. However, in order to preserve the canonical commutation relations (23) we must have $\alpha=\beta$. These transformations are generated by the angular momentum operator

$$J_1=\frac{i}{2}\,(q^T\sigma_2p-p^T\sigma_2q). \tag{26}$$

Note that these transformations do not mix coordinate and momentum variables.

(ii) The transformations

$$\delta q=\lambda_a\tau_a p, \quad \delta p=-\lambda_a\tau_a q, \tag{27}$$

with λ_a constant, bosonic, infinitesimal parameters are also a set of symmetries of the Hamiltonian which preserve the Dirac brackets relations, as long as the index $a\neq 2$ [see Eq. (18)]. The charges generating these transformations are

$$L_0=\tfrac{1}{2}(p^Tp+q^Tq), \quad L_1=\tfrac{1}{2}(p^T\sigma_1 p+q^T\sigma_1 q), \quad L_3=\tfrac{1}{2}(p^T\sigma_3 p+q^T\sigma_3 q). \tag{28}$$

(C) Rotation on the two-dimensional fermionic phase-space

The generalized rotation in the fermionic phase-space

$$\delta\psi=\boldsymbol{\alpha}\cdot\boldsymbol{\sigma}\psi \tag{29}$$

with $\boldsymbol{\alpha}=(\alpha_1,\alpha_2,\alpha_3)$ being a set of constant bosonic parameters, is another group of symmetries in the action. Again, preservation of the canonical commutation relations (23) imposes $\alpha_1=\alpha_3=0$ as conditions over the possible values that these parameters can take. These transformations are generated by the following charge:

$$J_2=\tfrac{1}{2}\psi^T\sigma_2\psi \tag{30}$$

representing the fermionic contribution to the total angular momentum.

Now, in order to make contact with the graded algebra GL(2|1) defined in the preceeding section, let us redefine these charges as

$$\begin{gathered} h_b=L_0=\tfrac{1}{2}(p^Tp+q^Tq), \quad h_f=-J_2=-\tfrac{1}{2}\psi^T\sigma_2\psi, \\ \Delta_1=L_1=\tfrac{1}{2}(p^T\sigma_1 p+q^T\sigma_1 q), \quad \Delta_2=J_1=(i/2)(q^T\sigma_2 p-p^T\sigma_2 q), \\ \Delta_3=L_3=\tfrac{1}{2}(p^T\sigma_3 p+q^T\sigma_3 q). \end{gathered} \tag{31}$$

The canonical Dirac bracket algebra of these charges read

$$\{\Delta_k,\Delta_m\}=2\epsilon_{kmn}\Delta_n, \quad \{h_b,\Delta_k\}=0, \quad \{h_f,\Delta_k\}=0, \tag{32}$$

and can be seen to agree with the bosonic sector of the GL(2|1) algebra, Eq. (9), when the classical Dirac bracket algebra is quantized through the usual replacement $\{\ldots,\ldots\}\to -i[\ldots,\ldots]_{\mp}$.

Next we redefine the supersymmetry generators (22) as

$$\begin{gathered} Q_R=\frac{1}{2}(Q_0+iQ_2)=\frac{1}{\sqrt{2}}(p^T+iq^T)T_+\psi, \\ \bar{Q}_R=\frac{1}{2}(Q_0-iQ_2)=\frac{1}{\sqrt{2}}(p^T-iq^T)T_-\psi, \end{gathered} \tag{33}$$

$$Q_L=\frac{1}{2}(Q_1+iQ_3)=\frac{1}{\sqrt{2}}(p^T-iq^T)\sigma_1 T_+\psi,$$

$$\bar{Q}_L=\frac{1}{2}(Q_1-iQ_3)=\frac{1}{\sqrt{2}}(p^T+iq^T)\sigma_1 T_-\psi,$$

where $T_\pm=\frac{1}{2}(1\mp\sigma_2)$ is the "helicity" projection operator. Using the generalized Dirac brackets, Eq. (23), we can verify that the nine symmetry generating operators in Eqs. (31) and (33) possess an algebra whose quantum version is isomorphic to that presented in Sec. II. Moreover, if we introduce, as usual, the representation of the phase-space variables q_k and p_k in terms of creation and annihilation operators as

$$a_k=\frac{1}{\sqrt{2}}(q_k+ip_k),\quad a_k^\dagger=\frac{1}{\sqrt{2}}(q_k-ip_k), \tag{34}$$

and define

$$a_3=\frac{i}{\sqrt{2}}(\psi_1+i\psi_2),\quad a_3^\dagger=\frac{-i}{\sqrt{2}}(\psi_1-i\psi_2), \tag{35}$$

which, by virtue of Eq. (23) do satisfy Eq. (3), then we can write the generators of symmetry in Eqs. (31) and (33) in the same form as the graded Lie algebra generators (6) and (7), defined in Sec. II. It becomes a matter of simple calculation to verify that these nine charges (five bosonic and four fermionic) exactly satisfy the graded Lie algebra GL(2|1) found in Sec. II.

IV. SPECTRUM AND SUPERSPACE FORMULATION

Let us examine in this section the action of the GL(2|1) operators, defined in the previous sections, on the states of the Hilbert space of the quantum mechanical model. The spectrum of the normal ordered theory is given by $\{\mathscr{E}_n,|n\rangle\}$, where the eigenvalues and eigenvectors are

$$\mathscr{E}_n=n_++n_-+n_f,\quad |n\rangle=|n_+,n_-,n_f\rangle, \tag{36}$$

with $n_\pm=0,1,2,\ldots$ and $n_f=0,1$. Conventionally, the states with $n_f=0(1)$ are called bosonic (fermionic). Here $n_\pm$ and n_f are the eigenvalues of the bosonic and fermionic number operators, $N_\pm=a_\pm^\dagger a_\pm$ and $N_f=a_3^\dagger a_3$, and

$$a_\pm=\frac{1}{\sqrt{2}}(a_1\pm ia_2). \tag{37}$$

By inspection we see that the ground state is a nondegenerate bosonic state with zero energy. The first excited level is threefold degenerate, possessing one fermionic and two bosonic states. The second excited energy level is fivefold degenerate, with two fermionic and three bosonic states, and so on. The states of the first few levels are displayed below:

$$
\begin{aligned}
|0\rangle &= |0,0,0\rangle, \\
|1\rangle &= \{|1,0,0\rangle, |0,0,1\rangle, |0,1,0\rangle\}, \\
|2\rangle &= \{|2,0,0\rangle, |1,0,1\rangle, |1,1,0\rangle, |0,1,1\rangle, |0,2,0\rangle\}, \\
&\vdots .
\end{aligned}
\tag{38}
$$

In terms of the raising and lowering (chiral) operators (37), the GL(2|1) generators (6) and (7) read

$$
\begin{aligned}
&Q_R = a_+^\dagger a_3, \quad \bar{Q}_R = a_+ a_3^\dagger, \quad Q_L = i a_- a_3^\dagger, \\
&\bar{Q}_L = -i a_-^\dagger a_3, \quad \Delta_1 = a_+^\dagger a_- + a_-^\dagger a_+, \quad \Delta_2 = a_+^\dagger a_+ - a_-^\dagger a_-, \\
&i\Delta_3 = a_-^\dagger a_+ - a_+^\dagger a_-, \quad h_b = a_+^\dagger a_+ + a_-^\dagger a_-, \quad h_f = a_3^\dagger a_3 .
\end{aligned}
\tag{39}
$$

On the degenerate levels the supersymmetry generators take bosonic states into fermionic ones and vice versa as

$$
\begin{aligned}
Q_R|n_+,n_-,n_f\rangle &= \sqrt{n_+ + 1}\,\delta_{n_f,1}|n_+ + 1, n_-, n_f - 1\rangle, \\
\bar{Q}_R|n_+,n_-,n_f\rangle &= \sqrt{n_+}\,\delta_{n_f,0}|n_+ - 1, n_-, n_f + 1\rangle, \\
Q_L|n_+,n_-,n_f\rangle &= i\sqrt{n_-}\,\delta_{n_f 0}|n_+, n_- - 1, n_f + 1\rangle, \\
\bar{Q}_L|n_+,n_-,n_f\rangle &= -i\sqrt{n_- + 1}\,\delta_{n_f,1}|n_+, n_- + 1, n_f - 1\rangle.
\end{aligned}
\tag{40}
$$

Quite clearly the supersymmetry charge $Q_R(\bar{Q}_R)$ creates (destroys) a right-handed boson and destroys (creates) a fermion. Similarly the $Q_L(Q_L)$ destroys (creates) a left-handed boson while creating (destroying) a fermion. Note that Q_R and Q_R (Q_L and Q_L) have no effect on the $n_-(n_+)$ eigenvalues, showing the existence of a chiral supersymmetry which, ultimately, is due to the fact that we have twice as many bosonic variables as the fermionic ones. The supersymmetry charges can be used to generate the states in a given level once the highest state is given. Then, starting from the state $|0,n,0\rangle$, one can generate all the states belonging to the $\mathscr{E}_n$ subspace by consecutive applications of Q_L and Q_R until the state $|n,0,0\rangle$ is reached:

$$
|n,0,0\rangle \overset{Q_R}{\leftarrow} |n-1,0,1\rangle \overset{Q_L}{\leftarrow} |n-1,1,0\rangle \ldots |0,n-1,1\rangle \overset{Q_L}{\leftarrow} |0,n,0\rangle. \tag{41}
$$

Similarly, starting with the state $|n,0,0\rangle$ and using consecutively the charges $\bar{Q}_R$ and $\bar{Q}_L$ one generates the whole subspace $\mathscr{E}_n$ again.

$$
|n,0,0\rangle \xrightarrow{\bar{Q}_R} |n-1,0,1\rangle \xrightarrow{\bar{Q}_L} |n-1,1,0\rangle \ldots |0,n-1,1\rangle \xrightarrow{\bar{Q}_L} |0,n,0\rangle. \tag{42}
$$

This action of the supersymmetry charges is easily seen on the set of states shown in Eq. (38).

On the other hand, the action of the bosonic operators only connect states with the same fermion number. The operators h_f, h_b, and Δ_2 are diagonal in the chiral basis (36):

$$h_b|n_+,n_-,n_f\rangle=(n_++n_-)|n_+,n_-,n_f\rangle,$$
$$\Delta_2|n_+,n_-,n_f\rangle=(n_+-n_-)|n_+,n_-,n_f\rangle, \tag{43}$$
$$h_f|n_+,n_-,n_f\rangle=n_f|n_+,n_-,n_f\rangle.$$

These operators have the usual interpretation as bosonic and fermionic Hamiltonians (h_b and h_f), and chirality operator (Δ_2). Finally, the nondiagonal bosonic operators Δ_1 and Δ_3 play the role of chirality changing operators:

$$\tfrac{1}{2}(\Delta_1+i\Delta_3)|n_+,n_-,n_f\rangle=\sqrt{(n_-+1)n_+}|n_+-1,n_-+1,n_f\rangle,$$
$$\tfrac{1}{2}(\Delta_1-i\Delta_3)|n_+,n_-,n_f\rangle=\sqrt{(n_++1)n_-}|n_++1,n_--1,n_f\rangle. \tag{44}$$

Concluding, relations (40), (43), and (44) represent the action of all the GL(2|1) generators on the Hilbert space of the 2D SUSY harmonic oscillator.

We finish this section with a discussion of the superspace formulation of this problem. To this end we rewrite the supersymmetry transformations (19) in terms of the transformations generated by the chiral supersymmetry charges (33), which seem to be more appropriate for this model. The transformations generated by Q_R, $\bar{Q}_R$, Q_L, and $\bar{Q}_L$ are, respectively,

$$\delta_R q=\epsilon_R T_+\psi, \quad \delta_R\psi=\epsilon_R T_-\mathscr{D}_+ q, \tag{45}$$

$$\bar{\delta}_R q=\bar{\epsilon}_R T_-\psi, \quad \bar{\delta}_R\psi=\bar{\epsilon}_R T_+\mathscr{D}_- q, \tag{46}$$

$$\delta_L q=\epsilon_L T_+\sigma_1\psi, \quad \delta_L\psi=\epsilon_L T_+\sigma_1\mathscr{D}_- q, \tag{47}$$

$$\bar{\delta}_L q=\bar{\epsilon}_L T_-\sigma_1\psi, \quad \bar{\delta}_R\psi=\bar{\epsilon}_L T_-\sigma_1\mathscr{D}_+ q. \tag{48}$$

Here we have introduced the notation $\mathscr{D}_\pm=i(\partial_t\pm i)$. To obtain these four supersymmetries in a superfield language, we introduce two Grassman variables for each chiral sector as θ_R, $\bar{\theta}_R$, θ_L, and $\bar{\theta}_L$, and define two chiral superfields ϕ_R and ϕ_L. The transformation in the right chiral sector can be obtained from the following superfield and (differential operator) supercharge:

$$\phi_R=q+\theta_R T_+\psi+\bar{\theta}_R T_-\psi, \quad Q_R=T_+\frac{\partial}{\partial\theta_R}-\bar{\theta}_R T_-\mathscr{D}_+, \quad \bar{Q}_R=T_-\frac{\partial}{\partial\bar{\theta}_R}-\theta_R T_+\mathscr{D}_-, \tag{49}$$

while those in the left chiral sector come from

$$\phi_L=q+\theta_L T_+\sigma_1\psi+\bar{\theta}_L T_-\sigma_1\psi, \quad Q_L=T_+\frac{\partial}{\partial\theta_L}-\bar{\theta}_L T_-\mathscr{D}_-, \quad \bar{Q}_L=T_-\frac{\partial}{\partial\bar{\theta}_L}-\theta_L T_+\mathscr{D}_+. \tag{50}$$

These transformations can be organized in a matrixlike structure with the following form:

$$\delta\Phi=\epsilon^T\mathbf{Q}\Phi, \quad \bar{\delta}\Phi=\bar{\epsilon}^T\bar{\mathbf{Q}}\Phi, \tag{51}$$

where

$$\mathbf{Q}=\begin{pmatrix} Q_R & 0 \\ 0 & Q_L \end{pmatrix}, \tag{52}$$

$$\overline{\mathbf{Q}}=\begin{pmatrix} \bar{Q}_R & 0 \\ 0 & \bar{Q}_L \end{pmatrix} \tag{53}$$

are block-diagonal (4×4) matrices and

$$\Phi=\begin{pmatrix} \phi_R \\ \phi_L \end{pmatrix}, \tag{54}$$

$$\epsilon=\begin{pmatrix} \epsilon_R \\ \epsilon_L \end{pmatrix} \tag{55}$$

are (4×1) column matrices. We notice here that a matrix structure is essential for the superspace formulation since the GLA, in this case, grades an internal symmetry algebra [e.g., Eq. (8) involves not just the Hamiltonian, but the internal symmetry generators as well which would have a matrix representation]. The matrix structure of Q would depend on the internal space upon which it acts (unlike the usual space-time supersymmetry charges) and the form given here is appropriate only for the doublet space of q and ψ. Next we introduce the four covariant derivatives as

$$D_R=T_-\frac{\partial}{\partial\theta_R}+\bar{\theta}_R T_+\mathscr{D}_+, \quad \bar{D}_R=T_+\frac{\partial}{\partial\bar{\theta}_R}-\theta_R T_-\mathscr{D}_-, \tag{56}$$

$$D_L=T_-\frac{\partial}{\partial\theta_L}+\bar{\theta}_L T_+\mathscr{D}_-, \quad \bar{D}_L=T_+\frac{\partial}{\partial\bar{\theta}_L}-\theta_L T_-\mathscr{D}_+, \tag{57}$$

and define

$$\mathbf{D}=\begin{pmatrix} D_R & 0 \\ 0 & D_L \end{pmatrix}, \tag{58}$$

$$\overline{\mathbf{D}}=\begin{pmatrix} \bar{D}_R & 0 \\ 0 & \bar{D}_L \end{pmatrix}. \tag{59}$$

These covariant derivatives can be easily seen to anticommute with all supersymmetry charges $\mathbf{Q}$ and $\overline{\mathbf{Q}}$. In terms of these covariant derivatives, the Lagrangian of this theory can be written as

$$\begin{aligned} L&=\frac{1}{2}\sum_{A=R,L}\int d\theta_A\, d\bar{\theta}_A[(\overline{\mathbf{D}}\Phi)^T\cdot(\mathbf{D}\Phi)-\Phi^T\cdot\overline{\mathbf{D}}\mathbf{D}\Phi] \\ &=\frac{1}{2}\sum_{A=R,L}\int d\theta_A\, d\bar{\theta}_A[(\bar{D}_A\phi_A)^T\cdot(D_A\phi_A)-\phi_A^T\cdot\bar{D}_A D_A\phi_A]. \end{aligned} \tag{60}$$

V. CONCLUSION

In this work we have studied a supersymmetric harmonic oscillator possessing twice as many bosonic variables than fermionic ones. The model enjoys a chiral supersymmetry when the fermionic variables are interchanged with either one of the chiral bosonic sectors. Besides the supersymmetries, we have worked out all the global symmetries of the model and verified that the generators provide a representation of the general graded Lie algebra GL(2|1). We have worked out the physical spectrum of this model and constructed the superspace formulation. It is interest-

ing to see that in the superspace language the separation of the chiral sectors are clearly displayed, and the charges and the covariant derivatives carry a matrix structure essentially because the algebra represents the grading of an internal symmetry group.

APPENDIX: GENERALIZED DIRAC BRACKETS VIA FADDEEV-JACKIW APPROACH

First-order Lagrangians are constrained systems and must be quantized with Dirac brackets instead of Poisson brackets.[7,8] The Dirac brackets of an arbitrary first-order system can be calculated with ease using the technique put forward by Faddeev and Jackiw a few years ago.[9] Consider an arbitray system with a finite number of degrees of freedom Z_A, whose Grassman parity is ϵ_A and is described by

$$L=\dot{Z}_A K_A(Z_A)-V(Z_A). \tag{A1}$$

The equations of motion read

$$\dot{Z}_B M_{BA}=-\frac{\partial V}{\partial Z_A}, \tag{A2}$$

where

$$M_{AB}=\frac{\partial K^B}{\partial Z_A}-(-1)^{\epsilon_A\epsilon_B}\frac{\partial K^A}{\partial Z_B} \tag{A3}$$

is the generalized sympletic matrix.[10] If the sympletic matrix is nonsingular, the equation of motion (A2) can be solved for the velocities as

$$\dot{Z}_A=(-1)^{\epsilon_A}M^{-1}_{AB}\frac{\partial V}{\partial Z_B} \tag{A4}$$

and be written in Hamiltonian form with the introduction of some generalized or Dirac bracket as

$$\{Z_A,Z_B\}=(-1)^{\epsilon_A}M^{-1}_{AB}. \tag{A5}$$

The equations of motion then take the following form:

$$\dot{Z}_A=\{Z_A,V(Z)\}. \tag{A6}$$

Using Eq. (A5) one can verify that the Dirac brackets for the fermionic variables of the supersymmetric two-dimensional oscillator are those given in Eq. (23).[11]

Vertex normal ordering as a consequence of nonsymmetric bilinear forms in Clifford algebras

Bertfried Fauser[a)]
Institut für Theoretische Physik, Universität Tübingen, Auf der Morgenstelle 14, Germany

(Received 2 June 1995; accepted for publication 29 August 1995)

We consider Clifford algebras with nonsymmetric bilinear forms. They parametrize the chosen ideal in the isomorphism class of the standard symmetric ones. Since the content of physical theories depends on the injection $\oplus^{n}\bigwedge^{n}\mathscr{V}\to CL(\mathscr{V},Q)$, one has to transform to the standard construction. The injection is described by the antisymmetric part of the bilinear form. This process results in the appropriate vertex normal ordering terms, which are now obtained from the theory itself and not added *ad hoc* via a regularization argument. © *1996 American Institute of Physics.* [S0022-2488(96)01601-1]

I. INTRODUCTION

Nonlinear spinor equations play an important role in high-energy, nuclear or solid state physics. Examples are the Heisenberg, Nambu, and Jona–Lasinio-like models[1,2] of elementary particle and nuclear physics. Nonlinear sigma models bear an analogous structure.[3] In solid state physics the Hubbard model[4] is applied to various phenomena from super conductivity up to spin chains and so on.

The general structure of such models is of the form

$$\left(\sum i\gamma^{\mu}\partial_{\mu}-m\right)_{II'}\Psi_{I'}=gV_{II'I''I'''}\Psi_{I'}\Psi_{I''}\Psi_{I'''}. \tag{1}$$

Here $\Sigma i\gamma^{\mu}\partial_{\mu}$ is the Dirac operator, with Euclidean or Lorentzian signature. The mass could be zero. With the multi index $I=\{K,\Lambda\}$ we represent the spinor and its adjoined by Λ and the other algebraic and spatio temporal indices by K.

If the adjoined spinor is fixed, the quadratic form of the Clifford algebra is completely determined. Usually canonical quantization is applied. The quantization procedure chooses in fact the ideal which generates the Clifford algebraic structure, i.e., the commutator

$$\{\Psi_I,\Psi_{I'}\}_{+}=\langle\Psi_I|\Psi_{I'}\rangle=\delta_{II'}. \tag{2}$$

There are several problems with these equations listed below.

(i) The equations are non-renormalizable.
(ii) In order to define a unique quantization procedure, one is troubled by the ordering problem.
(iii) The transition to normal ordered amplitudes yields additional Singularities. (In Fock space this is the Wick–Dyson normal ordering. The algebraic argument given below is also valid in the general case, defined in Ref. 5 but then only the two-point correlations are retracted.)

In solid state physics there seems to be no principal problem with (i), because there may be a physically motivated cutoff at the Brillouin zone. In the case of particle physics, several *ad hoc* regularizations become necessary. An approach to these topics will be given elsewhere[6] and we assume the theory to be regularized.

[a)]Electronic mail: ptifu01@commlink.zdv.uni-tuebingen.de

0022-2488/96/37(1)/72/12/$6.00

The second point is usually solved using causality arguments. They imply a natural ordering in the polynomials of the fields at hand. Therefore time-ordered products are used in the covariant formulation, see for example, Ref. 7. In the Hamilton formalism, the (anti)symmetric ordering could be used.

Including a somehow given Vacuum state $|0\rangle_{Ph}$, which gives the representation of the field operators $\Pi_{Ph}(\Psi_I)$, all quantities are formally (formally, because one has to show uniqueness and existence of the defined objects too, which is a nontrivial problem) defined, see part III also. One should be able to calculate this vacuum state in a nonlinear theory, by solving the dynamical problem at hand in a sort of self consistent problem.

Now the third point causes trouble, because transition from one ordering to another yields infinities. In Fock space this transformation equals a Wick–Dyson normal ordering of the vertex.[8] The Fock space is only appropriate in free theories or in perturbation theory, which proves not useful in our case. A nonperturbative treatment is given in Ref. 5. This process results in the desired amplitudes and so-called contractions, which for bilinear and higher-order terms yields singularities at least on the light cone.

Even if the propagator function is finite on the light cone, the resulting terms would destroy the accuracy of the theory by additional corrections.

These contractions are related to the finite ground state energies, which become infinite by field quantization. With the convention that the vacuum has no nonzero quantum numbers, the vertex regularization is related to finite normal ordered amplitudes.[9] The field equations read now

$$\left(\sum i\gamma^{\mu}\partial_{\mu}-m\right)_{II'}\Psi_{I'}=gV_{II'I''I'''}:\Psi_{I'}\Psi_{I''}\Psi_{I'''}: . \tag{3}$$

With the physical propagator

$$P_{II'}:={}_{Ph}\langle 0|\mathscr{T}(\Psi_I\Psi_{I'})|0\rangle_{Ph} \tag{4}$$

the vertex term changes to

$$:\Psi_{I'}\Psi_{I''}\Psi_{I'''}:=\Psi_{I'}\Psi_{I''}\Psi_{I'''}+P_{I'I''}\Psi_{I'''}-P_{I'I'''}\Psi_{I''}+P_{I''I'''}\Psi_{I'} . \tag{5}$$

However, this procedure is nothing but a shift of the problem from one equation into another, because the time-ordered equation becomes singular. The first proposed theory is then ill defined, if we require the normal-ordered equation to be finite and vice versa. Changing the ordering thus yields singularities.

In this paper we want to show how an embedding of the theory in a Clifford algebra structure can overcome this problem by generating a normal ordering, which does not produce any additional singular contributions. So above item (iii) is resolved. We consider nonsymmetric bilinear forms and the associated Clifford algebras. The transformation from such algebras to the symmetric ones is an isomorphism, but the linear space of antisymmetric p-vectors is moved. As physical information is coded therein it is therefore altered.

Progress in the relation of states and operators was made in Ref. 10. The relation of Clifford algebras and quantum mechanics was studied in Ref. 11. The algebraic differences of matrix and conventional column spinors are analyzed in Ref. 12. Nonsymmetric Clifford algebras where introduced in a more mathematical way in Ref. 13.

In Sec. II, a brief introduction to the construction of Clifford algebras with arbitrary bilinear-forms is given. In Sec. III an application is given to quantum field theory. The Appendix gives a low-dimensional example of the desired algebraic structure.

II. CLIFFORD ALGEBRAS WITH NONSYMMETRIC BILINEAR FORMS

In this section we will present Clifford algebras with nonsymmetric bilinear forms, and various multivector constructions. Choosing the appropriate one, the nonsymmetric part of the form is removed.

Clifford algebras entered particle physics with Pauli and Dirac,[14] who used it to linearize the Laplacian and the D'Alambertian.

Let $\mathscr{V}$ be a vector space over R or C and Q a quadratic form on $\mathscr{V}$. The Clifford map is an injection from $\mathscr{V}$ into $CL(\mathscr{V},Q)$ with the property that every square of a vector element of the Clifford algebra is a scalar:

$$\begin{gathered}\gamma: V \to CL(\mathscr{V},Q), \quad e_i \mapsto \gamma_i = \gamma(e_i) \\ x^2 = xx = x \cdot x = Q(x) \in (R,C).\end{gathered} \tag{6}$$

With linearization we have on a generating set of $\mathscr{V}$

$$\begin{gathered}(e_i+e_j)(e_i+e_j) = e_i^2 + e_j^2 + e_i e_j + e_j e_i, \\ e_i e_j + e_j e_i = Q(e_i+e_j) - Q(e_i) - Q(e_j) \\ =: 2G(e_i,e_j) \in (R,C).\end{gathered} \tag{7}$$

The bilinear form G is symmetric. The whole algebra is now generated from reduced products of one-vectors. Let N be the set of ordered partitions of n pieces, $|\alpha|$ the cardinality of such a subset, and include the empty set. If we define $1_A = e_0$, then an algebra element read

$$\begin{gathered}A = \sum_{\alpha \in N} a_\alpha e_\alpha = \sum_{r=0}^{n} \sum_{|\alpha|=r} a_r e_r = A_0 + A_1 + \cdots + A_n, \\ e_\alpha := e_{i_1} \wedge e_{i_2} \wedge \cdots \wedge e_{i_r}, \quad i_1 < i_2 \cdots < i_r, \quad \alpha \in N, \quad |\alpha| = r.\end{gathered} \tag{8}$$

The A_r are homogeneous of degree r and the wedge product means antisymmetric multiplication as in the Grassmann case. Indeed as a linear space these two constructions are identical. Thereby the Clifford algebra has the direct sum decompositions

$$\begin{gathered}CL(V,Q) = CL_+ \oplus CL_- \quad \text{as algebra, and} \\ CL(V,Q) = \oplus^n \wedge^n \mathscr{V} \quad \text{as linear space.}\end{gathered} \tag{9}$$

However, the Clifford product intermingles the grades. Let $\langle\ \rangle_r$ be the projector to the homogeneous part of grade r. Then one has

$$A_r B_s = \langle AB \rangle_{|r-s|} + \langle AB \rangle_{|r-s+2|} + \cdots + \langle AB \rangle_{r+s}, \tag{10}$$

where in the Grassmann case $A_r B_s = \langle AB \rangle_{r+s}$ results.

Physicists consider the anticommuting elements of grade r as, e.g., scalars, spinors (vectors), spin tensors (tensors), and so on. That is, the physical content of the theory is coded explicitly in this structure.

Now let us see in which way it is possible to introduce nonsymmetric bilinear forms. It is obvious that we have to leave the above construction in favor of a more general one. This can be done by introducing algebra derivatives as proposed by Chevalley and Riesz[15,16] or analogous to Oziewicz.[13]

First of all, we introduce two more algebraic constructions for further use. An involution (a property sometimes called conjugation) J of period two and the also involutive Reversion$\tilde{}$ by the rules

$$J\begin{cases} K^2 & := \quad id_A \\ J(XY) & := \quad j(X)J(Y), \\ J(R,C) & := \quad (R,\overline{C}), \end{cases}$$
$$\tilde{}\begin{cases} \tilde{\tilde{}} & := \quad id_A, \\ \langle\tilde{}\rangle_{0+1} & := \quad id_{A_0+A_1}, \\ (XY)\tilde{} & := \quad \tilde{Y}\,\tilde{X}. \end{cases} \tag{11}$$

Now we may introduce the desired formulas ($a \in \mathscr{V}; B \in A$)

$$a\rfloor B := \tfrac{1}{2}(aB - J(B)a), \quad a\dot{\wedge} B := \tfrac{1}{2}(aB + J(B)a); \tag{12}$$

herewith we may decompose the Clifford product to

$$aB = a\rfloor B + a\dot{\wedge} B. \tag{13}$$

The contraction $\rfloor$ is a graded derivative of degree 1, as can be seen as follows (graded Leibnitz rule):

$$\begin{aligned} a\rfloor(bc) &:= \tfrac{1}{2}(abc - J(bc)a) \\ &= \tfrac{1}{2}(abc - J(b)ac + J(b)ac - J(b)J(c)a) \\ &= (a\rfloor b)c + J(b)(a\rfloor c). \end{aligned} \tag{14}$$

With $bc = 1$ we have $a\rfloor 1 = 2a\rfloor 1$, so $a\rfloor(R,C) = 0$, from which we could prove by induction the homogeneity of $a\rfloor B_r$. Obviously the contraction is linear, that is,

$$(\alpha X + \beta Y)\rfloor A = \alpha X\rfloor A + \beta Y\rfloor A. \tag{15}$$

These properties together state that $\rfloor$ is an algebra derivation. One can easy prove the useful formulas[17]

$$(u\wedge v)\rfloor X = u\rfloor(v\rfloor(X))$$

$$a\rfloor(x_{i_1}\wedge\cdots\wedge x_{i_n}) = \sum_{i=1}^{n}(-)^{i-1}(a\rfloor x_i)(x_1\wedge\cdots\wedge_{i-1}\wedge x_{i+1}\wedge\cdots\wedge x_n)$$
$$\det(x_i\rfloor x_j) = (x_n\wedge\cdots\wedge x_1)\rfloor(x_1\wedge\cdots\wedge x_n)$$
$$= x_n\rfloor(x_{n-1}\rfloor\cdots(x_1\rfloor(x_1\wedge\cdots\wedge x_n))\cdots). \tag{16}$$

Now the asymmetry of this result is obvious, and we may define an arbitrary nondegenerate bilinear form B exactly as the contraction. In a not-necessarily orthonormalized system of generating elements e_i of $\mathscr{V}$ we have

$$B = G + F = [B_{ij}] = [e_i\rfloor e_j], \tag{17}$$

$$G^T=G, \quad F^T=-F.$$

The injection, introduced by Chevalley, $\bigwedge \mathscr{V} \to CL(\mathscr{V},Q)$, is of course known by physicists in the disguise of the Kähler–Atiyah isomorphism. (See Ref. 17 for an account on that, and for a review on the historical development.)

We have identified the Clifford algebra as a subalgebra of $End(\oplus_n \bigwedge^n \mathscr{V})$, the endomorphism algebra of the Grassmann algebra. A very explicit example will be given in the appendix, in a manner closely related to the work of Lounesto.

Clearly, if we had chosen J to be the common use involution on $\mathscr{V}$, that is, $J(\mathscr{V})=-\mathscr{V}$, we would reobtain the original formulas, with a symmetric bilinearform

$$G_{ij}=\tfrac{1}{2}(e_ie_j-J(e_j)e_i)=\tfrac{1}{2}(e_ie_j+e_je_i). \tag{18}$$

Thus, if there exists a distinct involution of period two, we have the desired extension.

Now we have from (13),

$$e_{i_1}\wedge e_{i_2}=e_{i_1}e_{i_2}-e_{i_1}\rfloor e_{i_2}=e_{i_1}e_{i_2}-B_{i_1i_2}, \tag{19}$$

which is not antisymmetric with respect to the reversion as one can see as follows:

$$\begin{aligned}(e_{i_1}\wedge e_{i_2})^{\tilde{}} &=(e_{i_1}e_{i_2}-B_{i_1i_2})^{\tilde{}}\\ &=e_{i_2}e_{i_1}-B_{i_2i_1}+(B_{i_2i_1}-B_{i_1i_2})\\ &=e_{i_2}\wedge e_{i_1}+(B^T_{i_1i_2}-B_{i_1i_2})\\ &=e_{i_2}\wedge e_{i_1}+2F_{i_1i_2}\neq e_{i_2}\wedge e_{i_1}.\end{aligned} \tag{20}$$

Here T means matrix transposition. To avoid such a situation, and for establishing the reversion as the (Hermitian) transpose of the matrix representation, we are forced to choose the bi- and multivectors in a definite way. With $i_1<i_2<\cdots$, we set

$$\begin{aligned}e_{i_1}\dot{\wedge}e_{i_2}:&=\tfrac{1}{2}(e_{i_1}\wedge e_{i_2}-e_{i_2}\wedge e_{i_1})\\ &=\tfrac{1}{2}(e_{i_1}e_{i_2}-B_{i_1i_2}-e_{i_2}e_{i_1}+B_{i_2i_1})\\ &=\tfrac{1}{2}(e_{i_1}e_{i_2}-e_{i_2e_{i_1}})-\tfrac{1}{2}(B_{i_1i_2}+B_{i_2i_1})\\ &=e_{i_1}\wedge e_{i_2}-F_{i_1i_2}\end{aligned} \tag{21}$$

where B is now split into symmetric and antisymmetric parts $B=G_S+F_A$, with respect to the usual matrix transpose. We obtain the following rules, utilizing now the *standard* involution.

$$\begin{aligned}G_{i_1i_2}&=\tfrac{1}{2}(e_{i_1}e_{i_2}+e_{i_1}e_{i_2})\\ e_{i_1}\dot{\wedge}e_{i_2}&=\tfrac{1}{2}(e_{i_1}e_{i_2}-(e_{i_1}e_{i_2})^{\tilde{}})\\ &=\tfrac{1}{2}(e_{i_1}e_{i_2}-e_{i_2}e_{i_1})\\ &=\tfrac{1}{2}(e_{i_1}\rfloor e_{i_2}+e_{i_1}\wedge e_{i_2}-e_{i_2}\rfloor e_{i_1}-e_{i_2}\wedge e_{i_1})\\ &=e_{i_1}\wedge e_{i_2}+F_{i_1i_2},\end{aligned} \tag{22}$$

and therefore now

$$(e_{i_1}\dot{\wedge}e_{i_2})\tilde{} = e_{i_2}\dot{\wedge}e_{i_1} = -e_{i_1}\dot{\wedge}e_{i_2},$$
$$J(e_{i_1}\dot{\wedge}e_{i_2}) = e_{i_1}\dot{\wedge}e_{i_2}. \tag{23}$$

A third-order term will be given as

$$e_{i_1}\dot{\wedge}e_{i_2}\dot{\wedge}e_{i_3} = \tfrac{1}{2}(e_{i_1}e_{i_2}\dot{\wedge}e_{i_3} + e_{i_2}\dot{\wedge}e_{i_3}e_{i_1})$$
$$= e_{i_1}\wedge e_{i_2}\wedge e_{i_3} + F_{i_1i_2}e_{i_3} + F_{i_2i_3}e_{i_1} - F_{i_1i_3}e_{i_2}. \tag{24}$$

If we would like to have the transposition to act trivial on the matrix representation of the vector elements, we have to introduce a dual set of generating elements, as discussed in the Appendix.

We are now able to construct a new generating system of the Clifford algebra, which is antisymmetric with respect to the reversion, by using the corresponding wedge product $\dot{\wedge}$.

$$\{e_0; e_{i_1}; e_{i_1}\dot{\wedge}e_{i_2}; e_{i_1}\dot{\wedge}e_{i_2}\dot{\wedge}e_{i_3}; \dots\}, \quad \forall i_n; \quad i_1 < i_2 < \cdots . \tag{25}$$

We finish this section by recalling the main consequences of the analysis done, with respect to the application in Sec. III.

If there is a nonsymmetric part in the contraction, then the usual multivectors are not the desired algebraic elements. The nondiagonal part of the contraction leads to a refined treatment of the algebraic properties. The antisymmetric parts are incorporated in the multivectorial structure, where as the symmetric part should be handled with dual sets of generating elements. The matrix transposition is equivalent to the reversion only in this special situation, or if $G_{i_1i_2} = \delta_{i_1i_2}$ to the Cartesian case.

By looking at these constructions, we are forced to introduce a new kind of multivector. As a Clifford algebra, the two constructions prove to be isomorphic, at least in the nondegenerate case. However, the linear spaces $\oplus^n \wedge^n \mathscr{V}$ and $\oplus^n \mathrm{span}\{e_{i_1\dots i_n}\}$ are quite differently represented. This quite general result will be applied as an example to the nonlinear spinor theory, but is not confined to that case at all.

III. APPLICATION TO THE NONLINEAR SPINOR FIELD MODEL

In this section the vertex normal ordering is given as a consequence of the algebraic formalism. The connection between $\mathscr{T}$ and $\mathscr{N}$ ordered amplitudes is one-to-one, if the construction itself exists. No *ad hoc* regularization argument is needed.

Now we want to have a look at the vertex term of the nonlinear spinor field theory. This should correctly be done in the functional space formulation, which exhibits the structure more clearly.[5] For brevity and simplicity, we will give our arguments directly on the level of the field operators.

We should note that the above construction was made with a finite Set N, where as in field theory we use the continuum indices $(\vec{r},t)$ also. Therefore we should construct infinite Clifford algebras and prove their existence. Such things are far from being easy.[18] Of course we are still considering a singular theory before introduction of a here-not-specified regularization. So we proceed with formal algebraic arguments, valid only if the symbols used are defined. Otherwise one has to use increasing nets of finite lattices and to study convergence properties.

The quantization of fermionic fields is in effect the introduction of a Clifford algebra, or CAR algebra as in this context usually named:[6,19]

$$\{\Psi_K^\dagger, \Psi_{K'}\}_+ = \delta_{KK'}\,. \tag{26}$$

With our indexing $\Psi_I = \Psi_{K\Lambda} = \{\Psi_{K1}^\dagger; \Psi_{K2}\}$ we have

$$\{\Psi_I, \Psi_{I'}\} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}_{\Lambda\Lambda'} \delta_{KK'}\,. \tag{27}$$

This is, of course, a special basis; we may call it a Witt basis.[19] If the Hermitean conjugation is the usual one, then the connection to Fock space is very close.[20] Therefore we will expect to have an (in this formulation) invisible antisymmetric part. So it is essential to have non-Fock states. This relation can be rewritten in the form

$$\Psi_I \rfloor \Psi_{I'} + \Psi_{I'} \rfloor \Psi_I = 2G_{II'} = \delta_{II'}\,, \tag{28}$$

which now can be extended to an arbitrary bilinear form B. We obtain in this way the antisymmetric part, exhibiting a new term $2F_{II'}$

$$\begin{aligned}[\Psi_I, \Psi_{I'}] &= 2F_{II'} + 2\Psi_I \barwedge \Psi_{I'} \\ &= 2\Psi_I \dot{\barwedge} \Psi_{I'}\,.\end{aligned} \tag{29}$$

From the Clifford algebraic point of view, this corresponds to the scalar and bivector part, if we use the usual wedge product.

This entity is in fact related with the propagator of the theory:

$$\begin{aligned}P_{II'} &= {}_{Ph}\langle 0|\mathscr{T}(\Psi_I \Psi_{I'})|0\rangle_{Ph} \\ &= \tfrac{1}{2}{}_{Ph}\langle 0|\,\theta(t_I - t_{I'})\Psi_I\Psi_{I'} - \theta(t_{I'} - t_I)\Psi_{I'}\Psi_I|0\rangle_{Ph}\,.\end{aligned} \tag{30}$$

For equal times we have

$$\begin{aligned}P^t_{II'} &= \tfrac{1}{2}{}_{Ph}\langle 0|\Psi_I\Psi_{I'} - \Psi_{I'}\Psi_I|0\rangle_{Ph,t=t'} \\ &= {}_{Ph}\langle 0|F_{II'} + \Psi_I \barwedge \Psi_{I'}|0\rangle_{Ph,t=t'}\,.\end{aligned} \tag{31}$$

Now the $F_{II'}$ are ''scalars'', that is, in field theory a distribution-valued function, and act *not* as operators. We have the trace as the analogous algebra property only in the appropriate basis, which of course leads to

$${}_{Ph}\langle 0|\Psi_I \barwedge \Psi_{I'}|0\rangle_{Ph} = 0 \tag{32}$$

and thus to

$$P^t_{II'} = F_{II'}\,. \tag{33}$$

Looking in this way at the vertex term, we have antisymmetric products, and are free to choose the appropriate one, which absorbs the additional terms, resulting in the normal-ordering procedure. Of course, this should be done in such a way that the transposition and reversion behave in the right way, but here we will not bother about that. (See the remarks in the Appendix.)

By comparing the ''dot'' procedure defining[5]

$$:\Psi_{I'}\Psi_{I''}\Psi_{I'''}: \quad := \Psi_{I'}\Psi_{I''}\Psi_{I'''} - P_{I'I''}\Psi_{I'''} + P_{I'I'''}\Psi_{I''} - P_{I''I'''}\Psi_{I'} \tag{34}$$

with the derived equation

$$e_{i_1}\wedge e_{i_2}\wedge e_{i_3}=e_{i_1}\dot{\wedge}e_{i_2}\dot{\wedge}e_{i_3}-F_{i_1i_2}e_{i_3}+F_{i_1i_3}e_{i_2}-F_{i_2i_3}e_{i_1}, \tag{35}$$

it is shown, that if we choose $P_{II'}$ as the antisymmetric part of the contraction, then we are forced to introduce the normal-ordering terms in the field equation from the beginning. This is, because we want the usual conjugation and the multivectorial construction to hold in the algebraic and matrix case, as the usual normal-ordered field equation.

For the time-ordered field equation this yields

$$\left(\sum\ i\gamma^\mu\partial_\mu-m\right)_{II'}\Psi_{I'}=gV_{II'I''I'''}\Psi_{I'}\wedge\Psi_{I''}\wedge\Psi_{I'''}, \tag{36}$$

or

$$\left(\sum\ i\gamma^\mu\partial_\mu-m\right)_{II'}\Psi_{I'}+gV_{II'I''I'''}\{P_{I'I2''}\Psi_{I'''}-P_{I'I'''}\Psi_{I''}+P_{I''I'''}\Psi_{I'}\}$$
$$=gV_{II'I''I'''}\Psi_{I'}\dot{\wedge}\Psi_{I''}\dot{\wedge}\Psi_{I'''}. \tag{37}$$

Omitting now the interaction term [RHS of (37)] we are left with a still singular equation, but now the singularity is only the dynamical one. As proposed in the introduction, the dynamical singularities may also be treated in an algebraic manner, which will be shown elsewhere.

The Clifford algebraic point of view should of course be taken from the very beginning.

IV. CONCLUSION

With help of some results obtained by studying Clifford algebras with nonsymmetric bilinear forms, we are able to understand the process of normal ordering in a new and deeper way. We noticed the dependence of the multivectorial structure on the antisymmetric part of the contraction. Without this sort of tool, it seems hardly possible to recognize the algebraic difference between $\mathscr{T}$- and $\mathscr{N}$-ordered transition matrix elements. In fact, they belong to quite different multivector constructions.

In ordinary treatments the vertex normal ordering is done *ad hoc*, simply motivated by obtaining an afterwards finite theory. However, this is nothing but a shift of the singularities in the $\mathscr{T}$-ordered equation. The ''dot'' procedure connects singular and regular theories, which is obviously not an equivalence relation. The theory is altered by hand.

The algebraic method distinguishes the different products in a correct way, and is sensitive to the redefinition of the multivectorial structure. So a unique and one-to-one correspondence between $\mathscr{T}$- and $\mathscr{N}$-ordered equations is established, in the case where the objects do exist.

In the computation of composites one has to expect the appearance of nonsymmetric parts of the bilinear forms. This stems from the antisymmetric constructions of the composite, in which case the effective bilinearform should have such a part.

The next step is the observation that the usually obtained divergencies are related to the dynamical ones. Therefore it is obvious that they are irrelevant to the not yet well-defined theory, because they evaporate when the theory is regularized. *A posteriori* the ''dot'' procedure is thus justified as a heuristic method. However, the important thing is that we have, even in this case, to choose another time-ordered equation by introducing wedges between the vertex Ψ's. The construction itself gives the hint that we should start from the very beginning with Clifford methods. Thereby Clifford analysis, or monogenetic function theory, should provide us a finite theory, from first principles.

APPENDIX A: PAULI ALGEBRA WITH NONSYMMETRIC BILINEAR FORM

In the Appendix an example is given, in the spirit of Lounesto.[17] Because all used quantities can only be constructed explicitly in very low-dimensional cases, we use the Pauli algebra. It is well known and the smallest Clifford algebra over the reals which exhibits a three-vector quantity.

The bilinear form is decomposed into symmetric and antisymmetric parts, using matrix transposition. We have the linear independent not normalized, not orthogonal set $\{e_1,e_2,e_3\}$ spanning $\mathscr{V}$. The algebra is generated by

$$\{Y_i\}=\{e_0;e_1,e_2,e_3;e_1\wedge e_2,e_2\wedge e_3,e_3\wedge e_1;e_1\wedge e_2\wedge e_3\}. \tag{A1}$$

In this basis the bilinear form is $(i,j \in 1,2,3)$

$$B=[B_{ij}]=[e_i\rfloor e_j]=[g_{ij}]+[f_{ij}],\quad [g_{ij}]^T=[g_{ij}],\quad [f_{ij}]^T=-[f_{ij}]. \tag{A2}$$

Next we search for a matrix representation. This can be done[17] by Clifford multiplying from the right an algebra element with all elements of the algebraic basis and expanding the result in homogeneous parts. Those are written as columns of the matrices. Matrix multiplication corresponds to the Clifford product. Of course we have

$$[1]=[\delta_{ij}], \tag{A3}$$

and we calculate as an example $[e_1]$

$$\begin{gathered}
e_1 1=e_1\\
e_1e_1=g_{11}\\
e_1e_2=e_1\rfloor e_2+e_1\wedge e_2=g_{12}+f_{12}+e_1\wedge e_2\\
e_1e_3=g_{13}+f_{13}+e_1\wedge e_3\\
e_1(e_1\wedge e_2)=e_1(e_1e_2-e_1\rfloor e_2)=g_{11}e_2-(g_{12}+f_{12})e_1\\
e_1(e_2\wedge e_3)=(g_{12}+f_{12})e_3-(g_{13}+f_{13})e_2+e_1\wedge e_2\wedge e_3\\
e_1(e_3\wedge e_1)=-g_{11}e_3+(g_{13}+f_{13})e_1\\
e_1(e_1\wedge e_2\wedge e_3)=g_{11}e_2\wedge e_3+(g_{12}+f_{12})e_3\wedge e_1+(g_{13}+f_{13})e_1\wedge e_2.
\end{gathered} \tag{A4}$$

The same can be done for the other elements, which yields

$$[e_1]=\begin{bmatrix}
0 & g_{11} & g_{12}+f_{12} & g_{13}+f_{13} & 0 & 0 & 0 & 0\\
1 & 0 & 0 & 0 & -g_{12}-f_{12} & 0 & g_{13}+f_{13} & 0\\
0 & 0 & 0 & 0 & g_{11} & -g_{13}-f_{13} & 0 & 0\\
0 & 0 & 0 & 0 & 0 & g_{12}+f_{12} & -g_{11} & 0\\
0 & 0 & 1 & 0 & 0 & 0 & 0 & g_{13}+f_{13}\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & g_{11}\\
0 & 0 & 0 & -1 & 0 & 0 & 0 & g_{12}+f_{12}\\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0
\end{bmatrix},$$

$$[e_2]=\begin{bmatrix}
0 & g_{21}+f_{21} & g_{22} & g_{23}+f_{23} & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & -f_{22} & 0 & g_{23}+f_{23} & 0\\
1 & 0 & 0 & 0 & g_{21}-f_{12} & -f_{23} & 0 & 0\\
0 & 0 & 0 & 0 & 0 & g_{22} & -g_{12}+f_{12} & 0\\
0 & -1 & 0 & 0 & 0 & 0 & 0 & g_{23}+f_{23}\\
0 & 0 & 0 & 1 & 0 & 0 & 0 & g_{12}-f_{12}\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & g_{22}\\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0
\end{bmatrix},$$

$$[e_3]=\begin{bmatrix}
0 & g_{13}-f_{13} & g_{23}-f_{23} & g_{33} & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & -g_{23}+f_{23} & 0 & g_{33} & 0\\
0 & 0 & 0 & 0 & g_{13}-f_{13} & -g_{33} & 0 & 0\\
1 & 0 & 0 & 0 & 0 & g_{23}-f_{23} & -g_{13}+f_{13} & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & g_{33}\\
0 & 0 & -1 & 0 & 0 & 0 & 0 & g_{13}-f_{13}\\
0 & 1 & 0 & 0 & 0 & 0 & 0 & g_{23}-f_{23}\\
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0
\end{bmatrix}.$$

This 8×8-dimensional representation of the Pauli algebra is not reducible to a real 4×4 or complex 2×2 one. The matrix transposition is not the reversion, because the $[e_i]$ are not symmetric matrices. Also the trace is not a map in the image of (R,C) in the algebra, because there are elements with nonvanishing trace beside $[\delta_{ij}]$, which means that the trace is not a projection onto the homogeneous part of degree zero. So the matrix trace is not a linear form *in* the algebra. The trace is clearly a linear form on the matrix representation, but into the field (R,C) itself.

The element $e_1\dot{\wedge}e_2\dot{\wedge}e_3$ reads

$$[e_1\dot{\wedge}e_2\dot{\wedge}e_3]=[e_1\wedge e_2\wedge e_3-f_{12}e_3+f_{13}e_2-f_{23}e_1], \tag{A5}$$

which yields a matrix not easy to display. The entries are linear, quadratic, and cubic functions of the f_{ij} and g_{ij} parameters.

The same procedure can be done with the reordered basis, belonging to the dotted wedge product

$$\{e_1,e_2,e_3;e_1\dot{\wedge}e_2\dot{\wedge}e_3;e_0;e_1\dot{\wedge}e_2,e_2\dot{\wedge}e_3,e_3\dot{\wedge}e_1\}, \tag{A6}$$

ordered in odd and even elements. The vector elements read

$$[e_1]=\begin{bmatrix} 0 & 0 & 0 & 0 & 1 & -g_{12} & 0 & g_{31} \\ 0 & 0 & 0 & 0 & 0 & g_{11} & -g_{13} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & g_{12} & -g_{11} \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ g_{11} & g_{12} & g_{13} & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & g_{13} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & g_{11} & 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & g_{12} & 0 & 0 & 0 & 0 \end{bmatrix},$$

$$[e_2]=\begin{bmatrix} 0 & 0 & 0 & 0 & 0 & -g_{22} & 0 & g_{23} \\ 0 & 0 & 0 & 0 & 1 & g_{12} & -g_{23} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & g_{22} & -g_{12} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ g_{12} & g_{22} & g_{23} & 0 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & g_{23} & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & g_{12} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & g_{22} & 0 & 0 & 0 & 0 \end{bmatrix},$$

$$[e_3]=\begin{bmatrix} 0 & 0 & 0 & 0 & 0 & -g_{23} & 0 & g_{33} \\ 0 & 0 & 0 & 0 & 0 & g_{13} & -g_{33} & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & g_{23} & -g_{13} \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ g_{13} & g_{23} & g_{33} & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & g_{33} & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & g_{13} & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & -g_{23} & 0 & 0 & 0 & 0 \end{bmatrix},$$

which yields a much more convenient and symmetric form. If the bilinear form is Euclidean, then this representation becomes symmetric with respect to the trace. In this case transposition and reversion are identical. The antisymmetric part has been absorbed fully in the multivectorial construction.

A fully satisfactory representation could be obtained by using a dual set of generating algebra elements, to the above ones. Therefore let the Volume element be

$$E:=e_1\dot{\wedge}e_2\dot{\wedge}e_3=-E^{\tilde{}},$$

$$E^{-1}=\frac{E^{\tilde{}}}{E^{\tilde{}}E},$$

$$E^{\tilde{}}E=\det G=|G|\neq 0. \tag{A7}$$

Then we may construct

$$e^i:=(-)^{i+1}e_1\dot{\wedge}\ldots e_{i-1}\dot{\wedge}e_{i+1}\dot{\wedge}\ldots e_nE^{-1} \tag{A8}$$

which is a generalization to nonsymmetric bilinear forms of the detailed results in Ref. 21.

Now the representation with the algebra basis $\{X^i\}$ yields via $[e_j X^i]$ symmetric matrices, even if the symmetric part of B is nontrivial.

This form is the most distinguished and symmetric one. Transposition and conjugation are the usual operations, but for arbitrary B the representation is still of dimension 8×8.

In this light, we have to change the ''quantization'' process, to use these dual elements. Therefore we should write

$$\Psi^I \Psi_{I'} + \Psi_{I'} \Psi^I = \delta^I_{I'} = 2G^I_{I'} . \tag{A9}$$

One can apply only in trivial cases (Euclidean G and vanishing F) ''canonical'' quantization without such a dual set and the above dotted wedge product.

In the general case the dual set depends on the possibly varying volume element of the algebra, and makes the definition of ''creation'' and ''annihilation'' operators position dependent. We may hope to get a better understanding of quantization on curved space in this way.

(Received 6 September 1994; accepted for publication 5 July 1995))

The diagrammatic and the Feynman rules for the higher derivative Chern–Simons theories in (2+1) dimensions coupled to fermionic matter are constructed. This is done by starting from the path-integral quantization. Once the diagrammatic and the Feynman rules are given, the regularization and renormalization problem of this higher derivative model is analysed in the framework of the perturbation theory. The unitarity problem related with the possible appearance of ghost states with negative norm is also discussed. Finally, the BRST formalism for the model is constructed and some interesting differences with respect to the formalism applied to usual Chern–Simons models are presented. © *1996 American Institute of Physics.* [S0022-2488(95)02512-9]

I. INTRODUCTION

In a recent paper,[1] we have constructed the classical and quantum formalism for the constrained Hamiltonian system with singular higher-order Lagrangian describing the Chern–Simons (CS) theories in (2+1) dimensions coupled to matter. To construct the classical generalized Hamiltonian formalism we have worked as close as possible to the Dirac algorithm. Then the canonical Dirac quantization has been performed. The path-integral quantization has also been done by extending the Faddeev–Senjanovic method,[2] to the higher-derivative case under consideration.

The classical and quantum CS theories in (2+1) dimensions have been investigated from a long time ago and with increasing interest in the last years.[3–9] Many interesting problems are present in the (2+1) dimensional physics.

Moreover, the dynamical systems described in terms of higher derivatives constitute an interesting problem of current research in quantum field theory.[10]

One of the reasons to consider these kinds of theories and in particular those containing higher derivative terms in the action, is because of their possible application to high-Tc superconductivity.

Another motivation exists from the point of view of the field theory itself. Maybe these theories have not been treated intensively not due to a lack of physical interest, but due to the underdeveloped knowledge on how to treat higher-derivative field theories. As it is well-known, they have a bad reputation because ghost states with negative norm can be causing unitarity violation.[11]

On the other hand, these theories have some kind of attraction, when terms of higher derivatives are added to the Lagrangian; the convergence of the corresponding Feynman diagrams can be improved.[12,13]

A natural higher derivative field theory is, for instance, the conformal supergravity in (2+1) dimensions which is also described by a CS term.[14] The constraints on curvatures make this feature evident and it is possible to see that the second-order canonical formalism is non-trivial

0022-2488/96/37(1)/84/16/$6.00

when it is implemented.[15] Moreover, the conformal gravity in three dimensions is finite and exactly soluble.[16]

The dynamical unitary, and possible renormalizable topologically massive three-dimensional gravity, was also investigated.[17]

The motivation of the present paper is to continue the work developed in Ref. 1, by studying the diagrammatic and the Feynman rules for that higher derivative CS model. The BRST formalism for the model is also considered.

The paper is organized as follows. In section II, we briefly recall the main results obtained in Ref. 1, for the Abelian case. In section III, we find the diagrammatic of the model. This is obtained by defining the propagator for a suitable bosonic object. The unitarity of the model is also discussed. Finally, in section VI, the BRST formalim is found.

II. DEFINITIONS AND PRELIMINARIES

In Ref. 1, our starting point was the following singular Lagrangian density:

$$\mathscr{L}=\mathscr{L}_{top}+\mathscr{L}_{h}+\mathscr{L}_{f}+\mathscr{L}_{int}, \tag{2.1}$$

describing the matter coupled to Abelian CS theories in (2+1) dimensions. In equation (2.1), $\mathscr{L}_{top}$ is the electromagnetic Lagrangian density with a topological mass term, i.e. a CS term, and it is given by

$$\mathscr{L}_{top}=-\tfrac{1}{4}F_{\mu\nu}F^{\mu\nu}+\frac{\kappa}{4\pi}\varepsilon^{\mu\nu\rho}\partial_{\mu}A_{\nu}A_{\rho}. \tag{2.2a}$$

The part containing higher derivatives is

$$\mathscr{L}_{h}=-\frac{c^{2}}{4\pi}\partial_{\rho}F_{\mu\nu}\partial^{\rho}F^{\mu\nu}, \tag{2.2b}$$

and the fermionic and interacting pieces are, respectively, given by

$$\mathscr{L}_{f}=i\left(\frac{a+1}{2}\right)\bar{\psi}\gamma^{\mu}\partial_{\mu}\psi+i\left(\frac{a-1}{2}\right)\partial_{\mu}\bar{\psi}\gamma^{\mu}\psi-m\bar{\psi}\psi, \tag{2.2c}$$

$$\mathscr{L}_{int}=e\bar{\psi}\gamma^{\mu}\psi A_{\mu}. \tag{2.2d}$$

The constant κ is the topological mass of the gauge field and its dimension is $(length)^{-1}$, the dimensional constant c has dimension $(length)^{1}$. We will use the convention $\varepsilon^{012}=\varepsilon^{12}=1$, the Minkowskian metric $g_{\mu\nu}$ is $g_{\mu\nu}=diag(1,-1,-1)$ and the Dirac γ-matrices are $\gamma^{0}=\sigma^{3}$, $\gamma^{1}=i\sigma^{1}$ and $\gamma^{2}=i\sigma^{2}$ (σ' are the Pauli matrices).

After the Ostrogradski transformation[18] is performed, the momenta P^{μ}, Q^{μ}, $\overline{\Pi}^{(\alpha)}$ and $\Pi^{(\alpha)}$ canonically conjugate to the independent field variables A_{μ}, $B_{\mu}=\dot{A}_{\mu}$, ψ_{α} and $\bar{\psi}_{\alpha}$ remain defined and they are given by

$$P^{0}=-\frac{c}{\pi}\partial_{0}\partial_{i}F^{0i}, \tag{2.3a}$$

$$P^{i}=F^{i0}+\frac{\kappa}{4\pi}\varepsilon^{ij}A_{j}+\frac{c}{\pi}(\nabla^{2}F^{0i}+\partial_{0}\partial_{j}F^{ji})-\partial_{0}Q^{i}, \tag{2.3b}$$

$$Q^{0}=0, \tag{2.3c}$$

$$Q^i = -\frac{c}{\pi}\partial_0 F^{0i}, \tag{2.3d}$$

$$\Pi_{(\alpha)}(x) = i\left(\frac{a-1}{2}\right)\gamma_0\psi_{(\alpha)}, \tag{2.3e}$$

$$\overline{\Pi}_{(\alpha)}(x) = -i\left(\frac{a+1}{2}\right)\bar{\psi}_{(\alpha)}\gamma_0, \tag{2.3f}$$

where the italic indices take the values $i,\ j\ =\ 1,2$.

The Poisson brackets for pairs of canonical conjugate variables are the usuals. The equations (2.3) show that the primary constraints are

$$\Phi_1(x) = Q^0(x) \approx 0, \tag{2.4a}$$

$$\Omega_{(\alpha)}(x) = \Pi_{(\alpha)}(x) - i\left(\frac{a-1}{2}\right)\gamma_0\psi_{(\alpha)} \approx 0, \tag{2.4b}$$

$$\overline{\Omega}_{(\alpha)}(x) = \overline{\Pi}_{(\alpha)}(x) + i\left(\frac{a+1}{2}\right)\bar{\psi}_{(\alpha)}\gamma_0 \approx 0. \tag{2.4c}$$

So, the classical canonical Hamiltonian is given by

$$\mathscr{H}_{can} = B_\mu P^\mu + \dot{B}_\mu Q^\mu + \dot{\bar{\psi}}_{(\alpha)}\Pi^{(\alpha)} + \overline{\Pi}^{(\alpha)}\dot{\psi}_{(\alpha)} - \mathscr{L}. \tag{2.5}$$

The extended Hamiltonian $H_E = \int d^2x.\mathscr{H}_E$ generator of time evolution, remains defined in terms of the following Hamiltonian density:

$$\mathscr{H}_E = \mathscr{H}_{can} + \delta\Phi_1 + \overline{\lambda}_{(\alpha)}\Omega^{(\alpha)} + \overline{\Omega}^{(\alpha)}\lambda_{(\alpha)}, \tag{2.6}$$

where δ is a bosonic Lagrange multiplier and $\overline{\lambda}$ and λ are the fermionic Lagrange multipliers.

Now, going on with the Dirac algorithm,[19] the secondary constraints can be easily found. Once the set of constraints are known, we must find all the first class ones associated with the gauge symmetries of the system, and write the Dirac brackets. Finally, the Hamiltonian system for this model is given by the total Hamiltonian,

$$H_T = \int d^2x(\mathscr{H}_{can} + \beta^a\Phi_a), \tag{2.7}$$

where β^a $(a = 1,2,3)$ are three arbitrary parameters and Φ_a are the first class constraints given by

$$\Phi_1(x) = Q^0(x) \approx 0, \tag{2.8a}$$

$$\Phi_2(x) = -P^0(x) + \partial_i Q^i(x) \approx 0, \tag{2.8b}$$

$$\Phi_3(x) = -ie(\bar{\psi}_{(\alpha)}(x)\Pi^{(\alpha)}(x) + \overline{\Pi}^{(\alpha)}(x)\psi_{(\alpha)}(x)) - \frac{\kappa}{4\pi}\partial_i A_j(x)\varepsilon^{ij} - \partial_i P^i(x) \approx 0. \tag{2.8c}$$

The equal time commutators (or anticommutators) we have found in the canonical quantum formalism are

$$[A_\mu(x),P^\nu(y)]_D=-\frac{i}{\hbar}\delta^\nu_\mu\delta(x-y), \tag{2.9a}$$

$$[B_\mu(x),Q^\nu(y)]_D=-\frac{i}{\hbar}\delta^\nu_\mu\delta(x-y), \tag{2.9b}$$

$$\{\psi_{(\alpha)}(x),\bar{\psi}_{(\beta)}(y)\}_D=\frac{i}{\hbar}(\gamma_0)_{(\alpha)(\beta)}\delta(x-y). \tag{2.9c}$$

In the next section we are going to use these results to study the diagrammatic of the model.

III. DIAGRAMMATIC AND FEYNMAN RULES

The partition function for higher derivative theories in the Hamiltonian formalism we have proposed in Ref. 1 is

$$\begin{aligned}Z=\int\ &\mathscr{D}A_\mu\mathscr{D}P^\mu\mathscr{D}B_\nu\mathscr{D}Q^\nu\mathscr{D}\bar{\psi}_{(\alpha)}\mathscr{D}\Pi^{(\alpha)}\mathscr{D}\psi_{(\beta)}\mathscr{D}\overline{\Pi}^{(\beta)}\delta(\Phi_1)\,\delta(\Phi_2)\,\delta(\Phi_3)\\ &\times\delta(f_1)\,\delta(f_2)\,\delta(f_3)\det[\Phi_1,\Phi_2,\Phi_3,f_1,f_2,f_3]_D\,\delta(\Omega_{(\alpha)})\,\delta(\Omega_{(\beta)})\det[\Omega_{(\alpha)},\Omega_{(\beta)}]\\ &\times\exp\,i\left[\int d^3x(B_\mu P^\mu+\dot{B}_\nu Q^\nu+\bar{\psi}\dot{\Pi}+\overline{\Pi}\dot{\psi})-H_E\right],\end{aligned} \tag{3.1}$$

where the functional integration is performed over all phase space volume corresponding to the independent dynamical variables A_μ, B_ν, P^μ and Q^ν.

The quantities f_1, f_2 and f_3 are gauge fixing conditions. A convenient set of such conditions compatible with the equations of motion and verifiying $\det[f_a,\Phi_b]_D\neq 0$ for all first-class constraints Φ_a, are

$$f_1=\partial_i A^i\approx 0, \tag{3.2a}$$

$$f_2=B_0\approx 0, \tag{3.2b}$$

$$f_3=\frac{\kappa}{2\pi}\nabla^2A_0+e\varepsilon_{ik}\partial^k(\bar{\psi}\gamma^i\psi)+\Box\left(1-\frac{c^2}{\pi}\Box\right)\partial_kA_i\varepsilon^{ik}\approx 0. \tag{3.2c}$$

When in equation (3.1), the determinants are explicitly computed and the path integral over the fields B_0, P^μ, Q^μ, $\overline{\Pi}^{(\alpha)}$ and $\Pi^{(\alpha)}$ have been made, the partition function results:

$$Z=\int\mathscr{D}A_\mu\mathscr{D}B_i\mathscr{D}\bar{\psi}_{(\alpha)}\mathscr{D}\psi_{(\beta)}\delta(f_1)\,\delta(f_3)\exp\,i\left[\int d^3x\mathscr{L}_{eff}\right]. \tag{3.3}$$

The Lagrangian density $\mathscr{L}_{eff}$ defined in (3.3) is given by

$$\begin{aligned}\mathscr{L}_{eff}=&-\tfrac{1}{4}F_{ij}F^{ij}-\frac{c^2}{4\pi}G_{ij}G^{ij}-\tfrac{1}{2}(B_i-\partial_iA_0)(B_i-\partial_iA_0)-\frac{c^2}{2\pi}\dot{B}_i\dot{B}^i-\frac{c^2}{4\pi}\partial_iF_{jk}\partial^iF^{jk}+\frac{c^2}{2\pi}B_j\nabla^2B^j\\ &-\frac{c^2}{\pi}\nabla^2B_j\partial^jA_0-\frac{c^2}{2\pi}(\nabla^2A_0)^2-\frac{\kappa}{4\pi}\partial_iA_0A_j\varepsilon^{ij}+\frac{\kappa}{4\pi}(\partial_iA_j)A_0\varepsilon^{ij}+\frac{\kappa}{4\pi}B_iA_j\varepsilon^{ij}\\ &+i\left(\frac{a+1}{2}\right)\bar{\psi}\gamma^\mu\partial_\mu\psi+i\left(\frac{a-1}{2}\right)(\partial_\mu\bar{\psi})\,\gamma^\mu\psi-m\bar{\psi}\psi+e\bar{\psi}\gamma_\mu\psi A^\mu,\end{aligned} \tag{3.4}$$

where $G_{ij} = \partial_i B_j - \partial_j B_i$ and $\nabla^2 = \partial_i \partial^i$.

From equation (3.3) we can see that the quantum problem remains defined in terms of a path integral in which there are four independent fields. Consequently, it is possible to apply diagrammatic techniques defining proper Feynman rules for propagators and vertices corresponding to the fields A_μ, B_i, $\psi_{(\alpha)}$ and $\bar{\psi}_{(\alpha)}$.

Alternatively, the path integral equation (3.3) can be written:

$$Z = \int \mathscr{D}A_\mu \mathscr{D}B_i \mathscr{D}\bar{\psi}_{(\alpha)} \mathscr{D}\psi_{(\beta)} \mathscr{D}\Lambda_1 \mathscr{D}\Lambda_3 \exp\, i\left[\int d^3x \mathscr{L}^*\right], \tag{3.5}$$

where

$$\mathscr{L}^* = \mathscr{L}_{eff} - \Lambda_1 f_1 - \Lambda_3 f_3, \tag{3.6}$$

for the Lagrange multipliers Λ_1 and Λ_3.

As it was carried out in a different context,[20] we can define a bosonic vector quantity X_Σ, having the same dimension as the vector field A_μ, whose components are given by

$$X_\Sigma = \left(A_\mu, cB_i, c\Lambda_1, \frac{1}{c}\Lambda_3\right), \tag{3.7}$$

where the compound index Σ takes the seven values $0,1,\ldots,6$.

Therefore, when the action is written in terms of the vector quantity (3.7) we can easily recognise the propagators defined by the quadratic part of the Lagrangian (3.6) and the remaining part of it can be represented by vertices. Consequently, the equation (3.6) can be seen as the Lagrangian density which defines the effective action for a system describing the boson vector field X_Σ coupled to a matter Dirac spinor field. The effective action $\mathscr{S}^*$ can be written:

$$\mathscr{S}^* = \mathscr{S}^*(X_\Sigma) + \mathscr{S}^*(\psi) + \mathscr{S}^*_{\text{int}}(X_\Sigma, \psi), \tag{3.8}$$

where, taking into account equation (3.4), it is

$$\mathscr{S}^*(\psi) = \int d^3x \mathscr{L}_f, \tag{3.9a}$$

$$\mathscr{S}^*(X_\Sigma, \psi) = \int d^3x [e\bar{\psi}(\Gamma_\Sigma X^\Sigma)\psi], \tag{3.9b}$$

$$\mathscr{S}^*(X_\Sigma) = \int d^3x [\tfrac{1}{2} X_\Sigma (D^{-1})^{\Sigma\Lambda} X_\Lambda]. \tag{3.9c}$$

The seven matrices $\Gamma_\Sigma = (\Gamma_{A_0}, \Gamma_{A_i}, \Gamma_{B_i}, \Gamma_{\Lambda_1}, \Gamma_{\Lambda_3})$, defined in equation (3.9b) are

$$\Gamma_{A_0} = \gamma_0, \quad \Gamma_{A_i} = \gamma_i, \quad \Gamma_{B_i} = 0, \quad \Gamma_{\Lambda_1} = 0, \quad \Gamma_{\Lambda_3} = c\gamma^i \varepsilon_{ik} \partial^k. \tag{3.10}$$

The 7×7 matrix $(D^{-1})^{\Sigma\Lambda}$ defined in equation (3.9c) is the inverse of the propagator of the bosonic object X_Σ given in (3.7). The matrix $(D^{-1})^{\Sigma\Lambda}$ is Hermitian and non-degenerate and it can be invertible and so the propagator $D_{\Sigma\Lambda}$ can be evaluated. The computation of the matrix elements $D_{\Sigma\Lambda}$ of the propagator in the general case is difficult and very complicated expressions are obtained. We can conclude that it could be useful to define a mixed propagator of the bosonic object X_Σ in order to study the simple case $\kappa = 0$, but not the general case.

To obtain a suitable expression for the bosonic propagator in the general $\kappa \neq 0$ case, we are going to give an alternative approach.

Remarking the arbitrariness of the gauge fixing conditions (3.2), instead of (3.2c), we can take a different gauge fixing condition $f_3=\partial_i B^i \approx 0$. This new gauge fixing condition is also compatible with the equation of motion and independent of f_1 in the Hamiltonian formalism where the partition function (3.1) is proposed.

The condition (3.2c) is obtained from the spatial component of the Lagrangian field equation of A_μ. The presence of the gauge fixing condition (3.2c) in the partition function equation (3.1), allows to come again on the original field A_μ. Now, to come back to the original field A_μ when the new gauge fixing condition $f_3=\partial_i B^i \approx 0$ is used, we must add to the action a term of the form $\int d^3x \Lambda^\mu (B_\mu - \dot{A}_\mu)$ with arbitrary multipliers Λ^μ and perform the integration on all their possible values. Consequently, the partition function (3.1) is written:

$$
\begin{aligned}
Z=\int \mathscr{D}A_\mu \mathscr{D}P^\mu \mathscr{D}B_\nu \mathscr{D}Q^\nu \mathscr{D}\bar{\psi}_{(\alpha)} \mathscr{D}\Pi^{(\alpha)} \mathscr{D}\psi_{(\beta)} \mathscr{D}\overline{\Pi}^{(\beta)} \delta(\Phi_1)\,\delta(\Phi_2)\,\delta(\Phi_3)\,\delta(f_1) \\
\times \delta(f_2)\,\delta(f_3) \det[\Phi_1,\Phi_2,\Phi_3,f_1,f_2,f_3]_D \delta(\Omega_{(\alpha)})\,\delta(\Omega_{(\beta)})\,\delta(B_\mu - \dot{A}_\mu) \\
\times \det[\Omega_{(\alpha)},\Omega_{(\beta)}] \exp\, i\left[\int d^3x (B_\mu P^\mu + \dot{B}_\nu Q^\nu + \dot{\bar{\psi}}\Pi + \overline{\Pi}\dot{\psi}) - H_E\right].
\end{aligned}
\tag{3.11}
$$

Therefore, in equation (3.11) also the path-integral over the field B_μ can be performed, and instead of the expression (3.3), the partition function reads as

$$
Z=\int \mathscr{D}A_\mu \mathscr{D}\bar{\psi}_{(\alpha)} \mathscr{D}\psi_{(\beta)} \delta(f_1)\,\delta(f_3) \exp\, i\left[\int d^3x \mathscr{L}_{eff}\right],
\tag{3.12}
$$

where $\mathscr{L}_{eff}$ given in (3.4) must be written in terms of A_μ.

As usual, we must transfer the integration measure defined on the surface $f_1=\partial_i A^i=0$, to the surface $f_1'=\partial_\mu A^\mu=0$, which defines the Lorentz gauge. The same argument can be used on the surface f_3. Moreover, once the path integral over the field B_μ is performed in the equation (3.11), the surface f_3 becomes the time derivative of the surface f_1.

Also in higher derivative models, it is convenient to work in a generalized gauge defined by

$$
\partial_\mu A^\mu(x)=\alpha_1(x),
\tag{3.13a}
$$

$$
\partial_\mu \dot{A}^\mu(x)=\dot{\alpha}_1(x)=\alpha_2(x),
\tag{3.13b}
$$

where $\alpha_1(x)$ and $\alpha_2(x)$ are arbitrary matrices.

Finally, as the partition function (3.12) does not depend neither on α_1 nor on α_2, by integrating over both quantities with a Gaussian weight: $\exp(i\lambda_1 tr\int d^3x \alpha_1^2(x) + ic^2\lambda_2 tr\int d^3x \alpha_2^2(x))$, the following extended Lagrangian density remains defined:

$$
\mathscr{L}^*=\mathscr{L}_{eff}-\frac{\lambda_1}{2}(\partial_\mu A^\mu)^2-\frac{\lambda_2}{2}(\partial_\mu \dot{A}^\mu)^2.
\tag{3.14}
$$

Looking at the Lagrangian density (3.14), we can see that in this context the inverse of the A_μ propagator is given by the 3×3 matrix $(D^{-1})^{\mu\nu}$, defined again by the quadratic piece in A_μ. In the momentum space, this matrix has the following elements:

$$
[D^{-1}]^{00}=(1-c^2\mathbf{k}^2)\mathbf{k}^2-\lambda k_0^2,
$$

$$[D^{-1}]^{01}=[D^{-1}]^{10*}=(\lambda-1+c^2\mathbf{k}^2)k_0k_1-i\frac{\kappa}{2\pi}k_2,$$

$$[D^{-1}]^{02}=[D^{-1}]^{20*}=(\lambda-1+c^2\mathbf{k}^2)k_0k_2+i\frac{\kappa}{2\pi}k_1,$$

$$[D^{-1}]^{11}=-(1-c^2\varepsilon)(\varepsilon-k_1^2)-\lambda k_1^2, \tag{3.15}$$

$$[D^{-1}]^{12}=[D^{-1}]^{21*}=(1-c^2\varepsilon-\lambda)k_2k_1-i\frac{\kappa}{2\pi}k_0,$$

$$[D^{-1}]^{22}=-(1-c^2\varepsilon)(\varepsilon-k_2^2)-\lambda k_2^2.$$

In the above equations we have renamed the parameter c in such a way that it is not necessary to write the constant π explicitly, and we called $\mathbf{k}^2=k_1^2+k_2^2$, $\varepsilon=\mathbf{k}^2-k_0^2$ and $\lambda=\lambda_1+\lambda_2c^2k_0^2$.

Now, the propagator $D_{\mu\nu}$ can be evaluated and the following matrix elements are obtained:

$$D_{00}=\frac{(1-c^2\varepsilon)\varepsilon}{\Delta}[\lambda\mathbf{k}^2-(1-c^2\varepsilon)k_0^2]-\frac{(\kappa/2\pi)^2k_0^2}{\Delta},$$

$$D_{01}=D_{10}^*=-\frac{k_0k_1}{\Delta}\left[(1-c^2\mathbf{k}^2-\lambda)(1-c^2\varepsilon)\varepsilon+\left(\frac{\kappa}{2\pi}\right)^2\right]-i\frac{\kappa k_2}{2\pi\Delta}[-\lambda\varepsilon+c^2k_0^4],$$

$$D_{02}=D_{20}^*=-\frac{k_0k_2}{\Delta}\left[(1-c^2\mathbf{k}^2-\lambda)(1-c^2\varepsilon)\varepsilon+\left(\frac{\kappa}{2\pi}\right)^2\right]+i\frac{\kappa k_1}{2\pi\Delta}[-\lambda\varepsilon+c^2k_0^4],$$

$$\begin{aligned}D_{11}=&-\frac{k_1^2}{\Delta}\left[(1-c^2\mathbf{k}^2)(1-c^2\varepsilon-\lambda)\varepsilon+c^2k_0^4(1-c^2\mathbf{k}^2-\lambda)+\left(\frac{\kappa}{2\pi}\right)^2\right]\\&+\frac{1}{\Delta}(1-c^2\mathbf{k}^2)c^2\mathbf{k}^2k_0^4+\frac{\lambda}{\Delta}[(c^2\mathbf{k}^2-1)\varepsilon^2-c^2k_0^6],\end{aligned}$$

$$D_{12}=D_{21}^*=-\frac{k_1k_2}{\Delta}\left[(1-c^2\mathbf{k}^2)(1-c^2\varepsilon-\lambda)\varepsilon+c^2k_0^4(1-c^2\mathbf{k}^2-\lambda)+\left(\frac{\kappa}{2\pi}\right)^2\right]-i\lambda\frac{\kappa k_0\varepsilon}{2\pi\Delta},$$

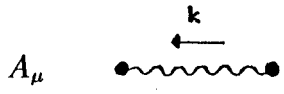
$$\begin{aligned}D_{22}=&-\frac{k_2^2}{\Delta}\left[(1-c^2\mathbf{k}^2)(1-c^2\varepsilon-\lambda)\varepsilon+c^2k_0^4(1-c^2\mathbf{k}^2-\lambda)+\left(\frac{\kappa}{2\pi}\right)^2\right]\\&+\frac{1}{\Delta}(1-c^2\mathbf{k}^2)c^2\mathbf{k}^2k_0^4+\frac{\lambda}{\Delta}[(c^2\mathbf{k}^2-1)\varepsilon^2-c^2k_0^6].\end{aligned} \tag{3.16}$$

In equations (3.16) $\Delta=\det[D^{-1}(k)]$ and it is given by

$$\Delta=\lambda\left[(1-c^2\mathbf{k}^2)(1-c^2\varepsilon)\varepsilon+\left(\frac{\kappa}{2\pi}\right)^2\right]\varepsilon^2+\lambda c^2k_0^6(1-c^2\varepsilon)\varepsilon-c^2\mathbf{k}^2k_0^4$$
$$\times\left[(1-c^2\mathbf{k}^2)(1-c^2\varepsilon)\varepsilon+\left(\frac{\kappa}{2\pi}\right)^2\right]. \tag{3.17}$$

Subsequently, the Feynman rules propagators and vertices can be written.

(i) Propagators: We associate with the propagator $D_{\mu\nu}$ of the bosonic field A_μ, a wavy line connecting two generic points:

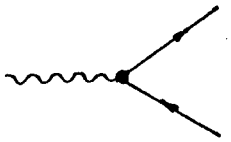


$$\equiv D_{\mu\nu}(k)\,,$$

and with a simple line the usual propagator of the fermionic field ψ

$$\equiv \frac{-i}{\gamma.p+m}=\frac{i(\gamma.p-m)}{p^2+m^2}$$

(ii) Vertices: Then, the three legs vertex of the model is:

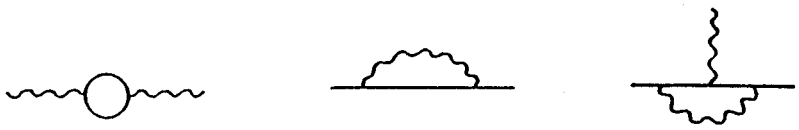


$$\equiv -ie\gamma_\mu\,.$$

Moreover, as it is usual we have to take into account a minus sign for every closed fermion loop and other minus signs for diagrams related to the exchange of two fermion lines, internal or external. A combinatorial factor correcting for double counting in case that identical particles occur, also must be taken into account.

IV. PERTURBATIVE METHOD IN HIGHER DERIVATIVE QED. ONE-LOOP STRUCTURE

Now, we proceed to examine the perturbative treatment of this gauge theory which describes the interaction of the bosonic field A_μ with the Dirac spinor field. Using the above rules, a power-counting analysis shows that the superficial degrees of divergence G are essentially those of the usual QED, so we are led to the following one loop diagrams:



which correct the fundamental parameters and fields of the theory.

If we call $\Pi_{\mu\nu}(k)$, the correction to the boson line or vacuum polarization diagram, it can be written as

$\Pi_{\mu\nu}(k) =$ 

$$= -e^2 \int \frac{d^3p}{(2\pi)^3} \frac{1}{(p^2+m^2)[(p+k)^2+m^2]} \times Tr[\gamma_\mu(\gamma.p+\gamma.k-m)\gamma_\nu(\gamma.p-m)]. \tag{4.1}$$

So, the correction to the boson line is similar to the non higher model, therefore the ultraviolet behavior of the integral (4.1) is the same as in the usual QED, i.e for large momentum p, the Feynman integral (4.1) behaves as $\sim\int dp$ and so this diagram is linearly divergent. This must be expected, because this model is a higher derivative only with respect to the boson field, and the propagator of that field does not appear in the vacuum polarization diagram. Consequently, the evaluation of the integral (4.1) is carried out by introducing a Feynman parameter and the new loop momentum $p' = p + kx$. We note that in the case in which the complete CS Lagrangian (2.2a) (with $\kappa \neq 0$) is considered, the dimensional regularization cannot be used safely due to the presence of the volume form $\varepsilon^{\mu\nu\rho}$. In that case, another gauge invariant regularization method, for instance a Pauli–Villars one,[13] must be used. The renormalization procedure is implemented as in the usual QED.

Now, we consider the second diagram given above. Let $\Sigma(p)$ be the correction to the fermion line (suppressing spinor indices). This diagram is given by the following integral expression:

$\Sigma(p) =$ 
$$= -ie^2 \int \frac{d^3k}{(2\pi)^3} \frac{\gamma_\mu(\gamma.p-\gamma.k-m)\gamma_\nu}{(p-k)^2+m^2} \times D_{\mu\nu}(k). \tag{4.2}$$

From equations (3.16), it can be seen that, for large momentum, the propagator $D_{\mu\nu}$ behaves like k^{-4}. Therefore the new propagator has an ultraviolet behavior in such a manner that the Feynman integral (4.2) gives a convergent result (for large k the integral behaves as $\sim\int dk/k^3$).

The last one-loop diagram we consider is the vertex correction, which we call $V_\xi(p,q)$, and is written as

$V_\xi(p,q) =$ 
$$= -ie^3 \int \frac{d^3k}{(2\pi)^3} \gamma_\mu \frac{(\gamma.p+\gamma.k-m)}{(p+k)^2+m^2} \gamma_\xi \times \frac{(\gamma.q+\gamma.k-m)}{(q+k)^2+m^2} \gamma_\nu \times D_{\mu\nu}(k). \tag{4.3}$$

Once more, by introducing the expressions (3.16) for the boson propagator $D_{\mu\nu}$, we can see that the diagram is also convergent, because for large momentum the integral behaves as $\sim \int dk/k^4$.

We conclude that in one-loop diagrams in which the propagator $D_{\mu\nu}$ of the field A_μ takes place, the ultraviolet behavior is improved and the divergence of these diagrams are eliminated. The remaining diagrammatic with a fermionic loop does not change and the degree of divergence is that of the usual QED. Therefore, the use of higher derivative terms in the Lagrangian allows us to improve the behavior of the correspondent propagators at large momentum, rendering the theory less divergent.

V. UNITARITY

At this stage, another important problem to take into account is the unitarity problem. It is well known,[11] that in higher derivative theories, the unitarity can be violated when ghost states with negative norm are present. To say something about the unitarity, we must analyze more carefully the bosonic propagator we have defined.

First we note that the Hermitian matrix $D_{\mu\nu}(k)$ defined in (3.16) can be diagonalized and so its eigenvalues are determined. As it is possible to see, the corresponding secular equation depends only on k^2 and k_0 and therefore we can study the problem for a given value of the three-vector k_μ. Let $k_\mu=(k_0,k_1=0,k_2)$ be the value for the three-vector momentum.

From equation (3.17) we see that Δ can be written as a six-order polynomial in the parameter ε. As the model is described by a second-order Lagrangian, there are two physical roots which are the two single poles appearing in the propagator. The remaining roots of the polynomial Δ are non-physical ones.

For appropriated values of the parameter c^2 and the topological mass κ, it is possible to obtain a factorized expression for the polynomial Δ. Considering the dimensional parameter c^2 in the physical regimes verifying the condition $c^2\mathbf{k}^2-1>0$ (i.e., $k_0^2>0$) and for values of the topological mass κ verifying $c^2\kappa^2/(c^2\mathbf{k}^2-1)\ll 1$, the polynomial Δ can be written as

$$\Delta=(\varepsilon-\alpha_1)(\varepsilon-\alpha_2)f(\lambda,\mathbf{k},\varepsilon), \tag{5.1}$$

where α_1 and α_2 are the two real roots of the polynomial $c^2\varepsilon^2-\varepsilon+[\kappa^2/4\pi^2(c^2\mathbf{k}^2-1)]=0$. These roots, which are independent of the gauge parameters, in the above approximation for the topological mass makes

$$\alpha_1\cong\frac{1}{c^2}-\frac{\kappa^2}{4\pi^2(c^2\mathbf{k}^2-1)},\qquad \alpha_2\cong\frac{\kappa^2}{4\pi^2(c^2\mathbf{k}^2-1)}. \tag{5.2}$$

Moreover, $f(\lambda,\mathbf{k},\varepsilon=\alpha_{1,2})$ is a finite and different from zero function.

As we can see, in the limit $\kappa=0$, the two poles are displaced to the values $\varepsilon_1=1/c^2$ and $\varepsilon_2=0$, respectively.

In the limit $c^2\to 0$ the only remaining pole is located at $\varepsilon=-\kappa^2/4\pi^2$, as it must be expected. The propagator (3.16) covariantly written takes the form

$$D_{\mu\nu}(k)=\frac{1}{(\varepsilon+\kappa^2/4\pi^2)}\left[g_{\mu\nu}+\left(1-\frac{1}{\lambda_1}-\frac{\kappa^2/4\pi^2}{\lambda_1\varepsilon}\right)\frac{k_\mu k_\nu}{\varepsilon}-i\frac{\kappa}{2\pi}\varepsilon_{\mu\nu\rho}\frac{k^\rho}{\varepsilon}\right]. \tag{5.3}$$

Now, the propagator (3.16) can be written as

$$D_{\mu\nu}=\frac{1}{\Delta}\times K^R_{\mu\nu}. \tag{5.4}$$

The 3×3 matrix $K^R_{\mu\nu}$ is called matrix residue. It can be diagonalized and it has three different non-zero eigenvalues $\xi_{(\alpha)}$ $((\alpha)=1,2,3)$, which can be given, for example, as power series of ε with proper coefficients depending on $\mathbf{k}^2$.

Consequently, we can define a set of real currents $J^{(\alpha)}_\mu(k)$, one for every non-zero eigenvalue, which are mutually orthogonal and eigenstates of the matrix $K^R_{\mu\nu}(k)$,[21] i.e.

$$J^{(\alpha)}_\mu(k)J^{(\beta)}_\mu(k)=0, \quad \text{if}(\alpha)\neq(\beta), \tag{5.5a}$$

$$K^R_{\mu\nu}(k)J^{(\alpha)}_\nu(k)=e^{(\alpha)}(k)J^{(\alpha)}_\mu(k). \tag{5.5b}$$

For instance, the real bosonic currents for emission of a particle corresponding to incoming particles of the S-matrix, when all the eigenvalues of the matrix K^R are positive, must be normalized in such a way that

$$J^{(\alpha)}_\mu(k)K^R_{\mu\nu}(k)J^{(\alpha)}_\nu(k)=+1. \tag{5.6}$$

The source currents thus defined are properly normalized for emission of a particle (or an antiparticle). When absorption of a particle (or an antiparticle) is considered, in the matrix K^R appearing in equation (5.5b), k must be replaced by $-k$.

On the other hand, once the matrix residue $K^R_{\mu\nu}$ is diagonalized, the above equations (5.5) imply that the currents are of the form

$$J^{(\alpha)}=(0,1/\sqrt{\xi_{(\alpha)}},0),$$

and obviously results in

$$\sum_{(\alpha)} J^{(\alpha)}J^{(\alpha)}=[K^R]^{-1}. \tag{5.7}$$

The equation (5.7) holds when the eigenvalues of the matrix K^R at the pole are positive, that is to say when the unitarity is preserved and the normalization (5.6) holds. In the case of negative eigenvalues, to recover the unitarity, the normalization in (5.6) must be done with a minus one. As it is well known, when the matrix residue K^R has a negative eigenvalue at the pole, it corresponds to states with negative norm, and they are physically unacceptable. The corresponding particles are called ghosts. This is the prescription to retrieve the unitarity of the theory and it is usually called indefinite metric prescription.

Let us consider the secular equation corresponding to the matrix K^R, which is written as

$$\xi^3-\xi^2 Tr[D_{\mu\nu}]+\xi\Delta Tr[(D^{-1})^{\mu\nu}]-\Delta^2=0. \tag{5.8}$$

From equation (5.8) it is possible to analyze the residue of the eigenvalues at every pole. The residue is given by the coefficient of ξ^2, i.e, $Tr[D_{\mu\nu}]$. At the poles $\alpha_{1,2}$ the residues, respectively, are written as

$$Tr[D_{\mu\nu}(\varepsilon=\alpha_1)]=-\frac{k_0^2}{(c^2\mathbf{k}^2-1)}\Bigg[c^4k_0^4\mathbf{k}^2(c^2\mathbf{k}^2-1)-\frac{\kappa^2}{4\pi^2}c^4k_0^4 +\lambda\left(\mathbf{k}^2(c^2\mathbf{k}^2-2)(c^2\mathbf{k}^2-1)+\frac{\kappa^2}{2\pi^2}c^2k_0^2\right)\Bigg], \tag{5.9a}$$

$$Tr[D_{\mu\nu}(\varepsilon=\alpha_2)]=-\frac{k_0^2}{(c^2\mathbf{k}^2-1)}\Bigg[c^2k_0^4(c^2\mathbf{k}^2-1)^2+\frac{\kappa^2}{4\pi^2}c^4k_0^4 +\lambda\left(c^2\mathbf{k}^4(c^2\mathbf{k}^2-1)-\frac{\kappa^2}{2\pi^2}(c^2\mathbf{k}^2+1)\right)\Bigg]. \tag{5.9b}$$

By looking at the equations (5.9), we can assert that the sign of the residues depend on λ. For instance, the signs can be determined in the physical region $c^2\mathbf{k}^2>2$ and in the Feynman gauge $\lambda_1=\lambda_2=1$. In this case, in both equations (5.9) results in $Tr[D_{\mu\nu}]<0$, and therefore the normalization in (5.6) must be given with the minus one.

Finally, as it is easy to note, when the limit $c^2=0$ is taken in the model, the set of constraints are modified. The fermionic constraints do not change, but the bosonic constraints (2.4a) disappear in this case, leaving $P^0=0$ as the unique primary bosonic constraint. The consistency condition on the constraints gives only one secondary constraint. Subsequently, it is possible to find the two first class constraints characteristic to the usual electrodynamic with the CS term. The two correspondent gauge fixing conditions are given by $f_1=\partial_i A^i\approx 0$ and $f_2=A_0\approx 0$. The partition function analogous to (3.1), after integrated in the variable A_0 by using the function $\delta(f_2)$, is reduced to

$$Z=\int \mathscr{D}A_i\mathscr{D}\bar{\psi}\mathscr{D}\psi\delta(f_2)\ \exp\, i[S_{eff}], \tag{5.10}$$

where S_{eff} is now the effective action for the electrodynamic with the topological CS term.

VI. THE BRST FORMALISM

The BRST formalism for the constrained Hamiltonian system under consideration is contructed by using most of the tools of Refs. 22–27. As it was shown, the Hamiltonian system is defined by the three first class constraints Φ_a given in (2.8), the Dirac brackets (2.9) and the Hamiltonian given in equation (2.7). The Hamiltonian density appearing in (2.7) can be written as follows:

$$\mathscr{H}=\mathscr{H}_0+\lambda^a\Phi_a, \tag{6.1}$$

where we call $\mathscr{H}_0$ the quantity given by

$$\mathscr{H}_0=\mathscr{H}_{can}+B_0\Phi_2. \tag{6.2}$$

Therefore, the following equations hold:

$$[\Phi_a,\Phi_b]_D=C^c{}_{ab}\Phi_c=0, \tag{6.3a}$$

$$[H_0,\Phi_a]_D=V_a^b\Phi_b, \tag{6.3b}$$

where $H_0=\int d^2x\mathscr{H}_0$. From now on we will write the Dirac brackets without the sub-script "D".

We note that in a usual CS theory,[24] all the coefficients V_a^b vanish for a suitable choice of the Hamiltonian density $\mathscr{H}_0$. In the present case, because of the presence of the higher derivative terms, there is no possible choice of $\mathscr{H}_0$ that could allow us the elimination of all the V_a^b

components. When we work with the Hamiltonian $\mathscr{H}_0$ given in (4.2) it results in $V_2^3 = -1$, and the other components of V_a^b are all vanishing. This is the choice that allows the elimination of the greatest number of V_a^b components.

At this stage it is convenient to treat the Lagrange multipliers λ^a defined in (6.1), on the same footing as the remainders dynamical variables, and to associate with them an equal number of canonical momenta, such that

$$[\lambda^a, \mathscr{P}_b] = \delta^a{}_b . \tag{6.4}$$

With the purpose of not changing the dynamical structure of the theory, classically the momenta are constrained to vanish. The constraints $\mathscr{P}_a$ generate the gauge transformation $\lambda^a \rightarrow \lambda^a + u^a$ of the multipliers, making evident their arbitrariness.

Consequently, from now on our dynamical variables will be

$$\boldsymbol{A}_\Sigma = (A_\mu, B_\mu, \bar{\psi}, \psi, \lambda_a). \tag{6.5}$$

The corresponding canonical conjugate momenta are written as

$$\boldsymbol{P}^\Sigma = (P^\mu, Q^\mu, \Pi, \overline{\Pi}, \mathscr{P}^a), \tag{6.6}$$

and the new set of constraints are given by

$$G_A = (\Phi_a, \mathscr{P}_b), \quad a,b = 1,2,3 \quad \text{and} \quad A = 1, \ldots, 6. \tag{6.7}$$

Therefore, the equations (6.3) take the form

$$[G_A, G_B] = 0, \tag{6.8a}$$

$$[H_0, G_A] = V_A^B G_B, \quad \text{with} \quad V_2^3 = -1. \tag{6.8b}$$

Now, by introducing the fermionic ghost fields (Majorana spinors) η_A and their canonical conjugate variables π^A, the BRST invariant gauge fixed Hamiltonian can be written as

$$H_\chi = H_0 + \pi_B V_A^B \eta^A + [\chi, Q], \tag{6.9}$$

where $\chi = \pi_B \omega^B$, being ω^B the gauge fixing conditions given by the set of quantities,

$$\omega^B = (\lambda^a, f^b). \tag{6.10}$$

Furthermore, as we deal with an Abelian model, the BRST generator Q is given by the well known expression:

$$Q = \eta_A G^A. \tag{6.11}$$

As the constraints (6.7) can be divided in two subsets, we assume that the ghosts and the antighosts are introduced in such a way that

$$\eta_A = (\eta_a, \pi_a), \tag{6.12a}$$

$$\pi^A = (\bar{\pi}^a, \bar{\eta}^a). \tag{6.12b}$$

Therefore, the following canonical brackets hold:

$$[\eta_a, \bar{\pi}^b]_+ = \delta_a^b, \tag{6.13a}$$

$$[\pi_a, \bar{\eta}^b]_+ = \delta_a^b, \tag{6.13b}$$

that is, we are working in the mixed representation in which both the ghosts and the antighosts are diagonal.

When an integration in the last term of equation (6.9) is performed, the following Hamiltonian density can be written:

$$\mathscr{H}_\chi = \mathscr{H}_0 + \lambda^a \Phi_a + f^a \mathscr{P}_a + \bar{\pi}^a \pi_a - \bar{\pi}^3 \eta_2 + \bar{\eta}^a [f_a, \Phi^b] \eta_b . \tag{6.14}$$

Thus, the BRST Lagrangian density $\mathscr{L}^{BRST}$ is given by

$$\mathscr{L}^{BRST} = B_\mu P^\mu + \dot{B}_\nu Q^\nu + \dot{\bar{\psi}}\Pi + \overline{\Pi}\dot{\psi} + \dot{\lambda}^a \mathscr{P}_a + \bar{\eta}^a \pi_a + \bar{\pi}^a \dot{\eta}_a - \mathscr{H}_\chi . \tag{6.15}$$

As in the present case, when the constrained system has first and second class constraints, the partition function in the BRST formalism is written by means of the following path integral[27]:

$$Z = \int \mathscr{D}A_\Sigma \mathscr{D}P^\Sigma \mathscr{D}\bar{\eta}_a \mathscr{D}\eta_a \mathscr{D}\bar{\pi}^a \mathscr{D}\pi^a \delta(\Omega^{(\alpha)}) \delta(\overline{\Omega}_{(\alpha)}) \times \exp\, i\left[\int d^3x \mathscr{L}^{BRST} \right]. \tag{6.16}$$

Looking at the equation (6.15), we can see that the variables P_μ do not explicitly appear in $\mathscr{L}^{BRST}$, and so the path integral over this variable must be included in the normalizing factor. Similarly, this occurs with the field components B_0 and Q_0, since the Hamiltonian $\mathscr{H}_0$ in (6.2) was chosen precisely to eliminate as dynamical variables B_0, and so its canonical momentum Q^0.

The path integral over the variables $\bar{\pi}^a$, π^a and Q^i are Gaussian and they are easily performed. The path integral over the momenta $\overline{\Pi}^{(\alpha)}$ and $\Pi^{(\alpha)}$ are also elementary by using the two Dirac's delta functions appearing in (6.16). Therefore, the partition function (6.16) takes the form

$$Z = \int \mathscr{D}A_\mu \mathscr{D}B_i \mathscr{D}\bar{\psi} \mathscr{D}\psi \mathscr{D}\lambda \mathscr{D}\mathscr{P} \mathscr{D}\bar{\eta}^a \mathscr{D}\eta^a \times \exp\, i\left[\int d^3x \mathscr{L}^* \right], \tag{6.17}$$

where the Lagrangian density we call $\mathscr{L}^*$ is written as

$$\mathscr{L}^* = \mathscr{L}_{eff} - \lambda^a \Phi_a + (\dot{\lambda}^a - f^a)\mathscr{P}_a - \bar{\eta}^a [f_a, \Phi^b] \eta_b - [\dot{\bar{\eta}}^a \eta_a + \tfrac{1}{4}\bar{\eta}^2 \eta_2 - \tfrac{1}{2}(\dot{\bar{\eta}}^3 \eta_2 + \bar{\eta}^2 \dot{\eta}_3)], \tag{6.18}$$

and we have called $\mathscr{L}_{eff}$ the Lagrangian density defined in (3.4).

With the aim to recover the expression (3.1) for the partition function in the Faddeev–Senjanovic form, the next task is to go on a relativistic gauge or non-canonical gauge (see Refs. 24 and 26). To do this we make the following replacement:

$$f_a \to \frac{1}{\tau} f'_a , \quad \mathscr{P} \to \tau \mathscr{P}_a , \quad \bar{\eta}^a \to \tau \bar{\eta}'^a ,$$

where the two last substitutions represent a change in the corresponding path integral variables. Later on, the parameter τ will go to zero by virtue of the Fradkin–Vilkovisky theorem, which has stated that the transition amplitude does not depend on this parameter. Once this is done, the partition function results:

$$Z=\int \mathscr{D}A_\mu \mathscr{D}B_i \mathscr{D}\bar{\psi}\mathscr{D}\psi \mathscr{D}\lambda^a \mathscr{D}\mathscr{P}'_a \mathscr{D}\bar{\eta}'^a \mathscr{D}\eta^a$$

$$\times \exp\, i\left[\int d^3x(\mathscr{L}_{eff}-\lambda^a\Phi_a - f'^a\mathscr{P}'_a - \bar{\eta}'^a[f'_a,\Phi^b]\eta_b)\right]. \tag{6.19}$$

After the integration over the path integral variables λ^a , $\mathscr{P}'_a$, $\bar{\eta}'^a$and η_a are performed, the final form for the partition function we can obtain is

$$Z=\int \mathscr{D}A_\mu \mathscr{D}B_i \mathscr{D}\bar{\psi}\mathscr{D}\psi\,\delta(\Phi_a)\,\delta(f'^a)\det[f'^a_{,}\,\Phi^b]\exp\, i\left[\int d^3x\mathscr{L}_{eff}\right]. \tag{6.20}$$

This last expression for the partition function can be confronted with that written in section III. Our starting expression used above in the framework of the canonical formalism to construct the diagrammatic, was proposed following the Faddeev–Senjanovic procedure. So we can conclude that both different methods give the same basic results and therefore, they can be considered as alternatives.

VII. CONCLUSIONS

To go on with the work beginning in Ref. 1, in the present paper we found the diagrammatic and the Feynman rules for a higher-derivative model coupled to matter. This was done by defining a suitable propagator of the bosonic field. The fermionic propagator for the matter field is the usual one. The model has an unique three legs vertex; and all the diagrams are obtained by connecting vertices and sources by means of the propagators thus defined. Using the perturbative theory, the one loop structure of the model was analyzed. The results obtained for the one loop diagrams in which the boson field propagator takes place allows us to guarantee that the ultraviolet behavior is improved and the divergence of these diagrams are eliminated. Therefore, we conclude that the presence of higher-derivative terms in the Lagrangian density gives rise to a new bosonic propagator, which yield that the theory is less divergent.

We have also proved, unlike what occurs in the usual quantum electrodynamics, that in this higher-derivative model there are two single poles; one of them is going to infinity in the limit $c\to 0$; and so the electrodynamic singularity is recovered.

Moreover, the prescription to eliminate the ghost states with negative norm, in such a way that the unitarity can be preserved, was also given.

Finally, by using well known tools and methods, the BRST formalism was constructed. When this formalism is applied to theories containing higher-derivative terms in the Lagrangian, there are some differences contained in the equation (6.3) upon which we have remarked. As it was shown the partition function of the model, in the BRST formalism written in the relativistic non-canonical gauge, is consistent with those obtained by means of a suitable extension of the Faddeev–Senjanovic procedure.

Asymptotic algebra for charged particles and radiation

Andrzej Herdegen[a)]

(Received 7 August 1995; accepted for publication 20 September 1995)

A C^*-algebra of asymptotic fields which properly describes the infrared structure in quantum electrodynamics is proposed. The algebra is generated by the null asymptotic of electromagnetic field and the time asymptotic of charged matter fields which incorporate the corresponding Coulomb fields. As a consequence Gauss' law is satisfied in the algebraic setting. Within this algebra the observables can be identified by the principle of gauge invariance. A class of representations of the asymptotic algebra is constructed which resembles the Kulish–Faddeev treatment of electrically charged asymptotic fields. © *1996 American Institute of Physics.* [S0022-2488(96)01701-X]

I. INTRODUCTION

It is frequently stated that the excellent experimental confirmation of quantum electrodynamics is not matched by sufficient understanding of its theoretical foundations yet. Indeed, the need for better understanding of the theory seems to be confirmed by steady fundamental research. One could even point out that experimental verification has to be considered as provisory, as long as the theory has no completely firm status. This refers not only to the existing experimental evidence. New experimental arrangements may be needed to test the results of further theoretical investigations.

This may especially be the case in relation to the problems connected with the long-range character of the electromagnetic interaction, Gauss' law, and the proper description of charged states. These problems manifest themselves in the infrared divergencies of perturbational QED,[1] the structure of uncountably many superselection sectors,[2,3] the infraparticle problem,[4,5] and the spontaneous breaking of the Lorentz group in charged representations of local observables.[5,6] All these questions have been investigated in various theoretical setups, with varying emphasis on mathematical rigor on the one hand, and concrete calculations on the other. An important step in the development of understanding of the long-range structure was the realization that it is the timelike, resp. lightlike, asymptotic structure that is relevant here.[2,7–9] The work of Kulish and Faddeev deserves special mentioning, as it generalized Dollard's idea[10] of asymptotic dynamics to the Gupta–Bleuler formulation of quantum electrodynamics. A more careful analysis of asymptotical charged states within this formalism was given by Morchio and Strocchi.[11] In rigorous mathematical terms, within the algebraic framework in quantum field theory, the asymptotic electromagnetic field has been obtained as an LSZ-type limit by Buchholz.[3] For reviews see the book by Jauch and Rohrlich,[1] the lecture notes by Morchio and Strocchi,[12] and the book by Haag.[13]

In spite of the progress brought by these works, our understanding of what an electron is is still not very concrete. So far there only exist abstract, though rigorous, characterizations of electrically charged particles.[14,15] Even more importantly, the concrete algebraic structure of the asymptotic quantum fields is still unclear. Thus investigations of properties such as the spontaneous breaking of the Lorentz group in charged sectors or the nonexistence of sharp masses (infraparticles) are frequently based on *ad hoc* assumptions. Most general results are therefore of the ''no-go'' type (see, e.g., Ref. 5).

0022-2488/96/37(1)/100/21/$6.00

It is the aim of the present work to propose a concrete formulation of the algebraic structure of asymptotic fields (and observables) of electrons interacting with radiation. This algebra resembles various elements of standard knowledge on the infrared problem. However, we would like to point out three novel aspects of our formulation.

(i) A clear and consistent algebraic framework is obtained. The asymptotic algebra is a C^*-algebra, thereby placing the problem on firm mathematical grounds.

(ii) We do not have to consider the fully interacting quantum field theory. In particular, the canonical quantization (which is taken for granted in the treatment of Kulish and Faddeev) is avoided. In fact, this heuristic procedure for obtaining the algebraic structure may fail in the field of long-range problems, as we shall discuss. Instead we base our construction on the asymptotic structure of classical electrodynamics (Maxwell and Dirac) which has been established in Ref. 16. These results lead naturally via the correspondence principle to our quantum algebra.

(iii) The algebra incorporates the Coulomb fields of the asymptotic (outgoing) particles. In this respect it resembles the theory of the quantized Coulomb field of Staruszkiewicz.[17] However, the latter is an idealized theory of certain isolated degrees of freedom, and it seems to have no natural embedding into a larger scheme.

The plan of the paper is as follows. In Sec. II we describe briefly the asymptotic structure of the classical theory. Part of the material is shifted to the Appendix. In Sec. III this structure is then quantized according to the correspondence principle. Heuristical physical considerations are presented which lead to formal algebraic relations for the fields. These relations are made mathematically precise in Sec. IV, and lead to our asymptotic C^*-algebra. A class of representations of the algebra is constructed in Sec. V. The question of physical relevance of these representations is left for future work. Section VI brings some final remarks, and comments on future perspectives of this work.

II. CLASSICAL ASYMPTOTIC STRUCTURE

In this section we give a short account of the asymptotic structure of a classical field theory with electromagnetic interaction, discussed at length in Ref. 16. For the definiteness we considered the Dirac field interacting with radiation. Complete rigorous results were obtained along the lines summarized here for the both external field problems, but the extension to the full theory is possible, as argued in Ref. 16, under plausible conjectures. (The relation of our asymptotic variables to those used by Flato *et al.*[18] in their recent solution of the Cauchy problem and proof of asymptotic completeness of the Maxwell–Dirac system is an open problem.) The aim of this summary is also, for the convenience of the reader, to rewrite in the tensor form the properties and formulas for the asymptotics of the electromagnetic field which were discussed in the two-component spinor language in Ref. 16. Equivalence to the original formulation is proved in the Appendix.

The idea of the approach deviates from the standard formulation of the scattering problem as the limit of constant time configurations with time tending to infinity. Rather, the advantage is taken of the different propagation velocities of matter and radiation, to consider their asymptotics in different space–time regions. For the electromagnetic field the known methods of the null infinity asymptotics[19,20] are applied, formulated in terms of homogeneous functions (without Penrose's space–time compactification) and further developed in some specific aspects. For the matter field a method is developed which leads to the determination of an asymptotic field inside the forward lightcone—this is sufficient, as eventually every massive particle enters the cone. Plausible arguments then indicate that asymptotics thus defined contain the full information on the system and the total Poincaré quantities (energy-momentum and four-dimensional angular momentum) of the theory may be expressed in terms of them.

The electromagnetic field of the system admits a class of gauges of the potential with the null asymptotic of the form [Eq. (2.45) in Ref. 16]

$$\lim_{R\to\infty} RA_a(x+Rl)=V_a(x\cdot l,l). \tag{2.1}$$

Here x is any space–time point in Minkowski space M and l is a future-pointing null vector. The function $V_a(s,l)$ (s is a real variable) is homogeneous of degree -1,

$$V_a(\mu s,\mu l)=\mu^{-1}V_a(s,l), \tag{2.2}$$

($\mu>0$), and satisfies

$$l\cdot V(s,l)=Q, \tag{2.3}$$

where Q is the charge of the field. Its s-derivative $\dot{V}_a(s,l):=(\partial/\partial s)V_a(s,l)$ falls off according to

$$|\dot{V}_a(s,l)|<\frac{\text{const}}{(1+|s|)^{1+\epsilon}} \tag{2.4}$$

for some $\epsilon>0$, so $V_a(s,l)$ has limits for $s\to\pm\infty$, which we denote $V_a(\pm\infty,l)$. [Null vectors l are scaled in (2.4) to $l^0=1$ in arbitrarily chosen, fixed Minkowski frame; change of frame results only in change of bounding constant.] Gauge freedom consists of the transformation $V_a(s,l)\to V_a(s,l)+\alpha(s,l)l_a$.

Further properties of the limit values $V_a(\pm\infty,l)$ involve differentiation on cone variables. A simple and explicitly Lorentz-covariant way to express the differentiations in directions tangent to the cone is to use the operator $l_a\partial_b-l_b\partial_a(\partial_a:=\partial/\partial l^a)$. One applies the operator to any differentiable extension to some neighborhood of the cone of a function defined on the cone itself, and restricts the result again to the cone. The result is independent of the extension used.

The limit values $V_a(\pm\infty,l)$ are constrained by the following gauge-invariant condition:

$$l_{[a}\partial_b V_{c]}(\pm\infty,l)=0 \tag{2.5}$$

[this is the tensor form of the conditions (3.32) with (2.54)–(2.57) in Ref. 16; see also the Appendix]. The physical content of the condition, which is satisfied in standard scattering situations, is that it allows the identification of the total angular momentum of the system, as discussed in Ref. 16. The properties (2.2), (2.3), and (2.5) allow another simple representation of $V_a(\pm\infty,l)$. It follows from (2.2) and (2.3) that $(l_b\partial_a-l_a\partial_b)V^b(\pm\infty,l)+V_a(\pm\infty,l)\propto l_a$. We denote

$$(l_b\partial_a-l_a\partial_b)V^b(+\infty,l)+V_a(+\infty,l)=2q(l)l_a, \tag{2.6}$$

$$(l_b\partial_a-l_a\partial_b)V^b(-\infty,l)+V_a(-\infty,l)=2\kappa(l)l_a. \tag{2.7}$$

Here $q(l)$ and $\kappa(l)$ are homogeneous functions of degree -2. If, for the sake of differentiation, the extensions of $V_a(\pm\infty,l)$ are chosen so as to satisfy (2.3) also in a neighborhood of the cone, then

$$q(l)=-\tfrac{1}{2}\partial_b V^b(+\infty,l),\quad \kappa(l)==-\tfrac{1}{2}\partial_b V^b(-\infty,l). \tag{2.8}$$

The charge of the field is recovered from the functions $q(l)$ and $\kappa(l)$ by the formulas

$$Q=\frac{1}{2\pi}\int q(l)d^2l=\frac{1}{2\pi}\int \kappa(l)d^2l. \tag{2.9}$$

By d^2l we denote that measure on the set of null directions which gives a Lorentz invariant result when applied to a homogeneous function of l of degree -2 (see Ref. 16 and references given there). The measure itself is homogeneous of degree 2, and for l's scaled to $l^0=1$ in any fixed

Minkowski frame it is the rotationally invariant measure on the unit sphere of vectors **l**. For future reference we note that if $\alpha(l)$ is differentiable and homogeneous of degree -2, then (see Appendix)

$$\int (l_a\partial_b - l_b\partial_a)\alpha(l)d^2l = 0. \tag{2.10}$$

Now conversely, one can show that if $q(l)$ and $\kappa(l)$ are homogeneous functions of degree -2 satisfying (2.9), then the vector functions $V_a(\pm\infty,l)$ constrained by (2.2), (2.3), and (2.5) are determined by (2.6) and (2.7) uniquely up to a gauge [Ref. 16, after Eq. (2.61)].

Physical interpretation of $\kappa(l)$ is of importance: this function determines the flux of the electromagnetic field in spacelike infinity. Explicitly, if x is any point and y a spacelike vector, then

$$\lim_{R\to\infty} R^2F_{ab}(x+Ry) = K_a(y)y_b - K_b(y)y_a, \tag{2.11}$$

where

$$K_a(y) = \frac{1}{2\pi y^2}\,\nabla_a \int \kappa(l)\,\mathrm{sgn}\, y\cdot l\, d^2l. \tag{2.12}$$

If the potential is decomposed in the standard way into the advanced and the free outgoing part $A_a = A^{\mathrm{adv}}{}_a + A^{\mathrm{out}}{}_a$, then $A^{\mathrm{adv}}{}_a$ and $A^{\mathrm{out}}{}_a$ have again asymptotics of the type (2.1) with $V_a(+\infty,l)$ and $V^{\mathrm{out}}{}_a(s,l) := V_a(s,l) - V_a(+\infty,l)$ replacing $V_a(s,l)$ on the right-hand side (rhs) of (2.1), respectively. This brings the physical interpretation of $q(l)$: this function determines the asymptotic Coulomb field of the outgoing currents.

The free outgoing field is completely determined by its asymptotic according to the formula

$$A^{\mathrm{out}}{}_a(x) = -\frac{1}{2\pi}\int \dot{V}^{\mathrm{out}}{}_a(x\cdot l,l)d^2l. \tag{2.13}$$

The flux of the field $F^{\mathrm{out}}{}_{ab}(x)$ at the spacelike infinity is again given by the formulas (2.11) and (2.12) in which $\kappa(l)$ is replaced by $\sigma(l) := \kappa(l) - q(l) = -(1/2)\partial^b V^{\mathrm{out}}{}_b(-\infty,l)$, which is therefore interpreted as the infrared characteristic of the free field. The vector function $V^{\mathrm{out}}{}_a(-\infty,l)$ is again determined up to a gauge by $\sigma(l)$, but in this case a more explicit representation is possible. One shows that Eq. (2.5) [satisfied by $V^{\mathrm{out}}{}_a(-\infty,l)$] and the condition $l\cdot V^{\mathrm{out}}(-\infty,l)=0$ together imply the existence of a real function $\Phi(l)$ homogeneous of degree 0 such that (see the Appendix)

$$l_{[a}V^{\mathrm{out}}{}_{b]}(-\infty,l) = l_{[a}\partial_{b]}\Phi(l). \tag{2.14}$$

Here $\Phi(l)$ is determined by this condition up to an additive constant. We make the choice of this constant characterize classes of gauges of $V^{\mathrm{out}}{}_a(-\infty,l)$ as follows. First, fix $\Phi(l)$ with some choice of the constant. Then, choose an antisymmetric real tensor function $G_{ab}(l) = -G_{ba}(l)$, homogeneous of degree 0, such that

$$l_{[a}G_{bc]}(l) = 0, \quad G_{ab}(l)l^b = \Phi(l)l_a. \tag{2.15}$$

This tensor is then of the form $G_{ab}(l) = l_a g_b(l) - l_b g_a(l)$, where $g_a(l)$ is homogeneous of degree -1, satisfies

$$l\cdot g(l) = \Phi(l), \tag{2.16}$$

and is determined by $G_{ab}(l)$ up to $g_a(l)\to g_a(l) + \alpha(l)l_a$. Finally, put

$$V^{\text{out}}{}_a(-\infty,l)=(l_b\partial_a-l_a\partial_b)g^b(l)+g_a(l). \tag{2.17}$$

One shows that

(i) (2.17) satisfies (2.14);
(ii) every gauge of $V^{\text{out}}{}_a(-\infty,l)$ may be represented in this way and the correspondence with the tensors $G_{ab}(l)$ is 1:1;
(iii) gauges corresponding to the choices of G_{ab}'s with a fixed constant in $\Phi(l)$ form equivalence classes with respect to the following equivalence relation: $V_1^{\text{out}}{}_a(-\infty,l)\sim V_2^{\text{out}}{}_a(-\infty,l)$ iff $\int\alpha(l)d^2l=0$, where $V_1^{\text{out}}{}_a(-\infty,l)-V_2^{\text{out}}{}_a(-\infty,l)=\alpha(l)l_a$. We shall see in Sec. III that the interpretation imposed by the above procedure on the additive constant in $\Phi(l)$ is a very natural one from the point of view of the symplectic form for electromagnetic field.

The asymptotic of the Dirac field $\psi(x)$ inside the forward lightcone is determined by considering the behavior of $\psi(\lambda v)$ for large λ, where the four-velocity v lies on the hyperboloid $H:=\{v\in M|v^2=1,\ v^0>0\}$. Physically, the most important condition for the validity of our discussion is such a choice of gauge of the electromagnetic potential, that $|v\cdot A(\lambda v)|<\text{const}\,\lambda^{-1-\epsilon}$, ($\epsilon>0$). That this is possible in our context is shown in Ref. 16 where further details are also given. One shows then that if we put

$$\psi(\lambda v)=-i\lambda^{-3/2}e^{-i(m\lambda+\pi/4)\gamma\cdot v}f_\lambda(v)$$

(γ^a are the Dirac matrices), then $\lim_{\lambda\to\infty}f_\lambda(v)=f(v)$. For the external field problem it is shown that this limit is reached strongly in the Hilbert space $\mathscr{K}$ of four-component functions on the hyperboloid H with the scalar product

$$(f,g)=\int\overline{f(v)}\gamma\cdot v g(v)d\mu(v), \tag{2.18}$$

where bar denotes the usual Dirac conjugation and $d\mu(v)=d^3v/v^0$ is the invariant measure on the hyperboloid. Moreover, free outgoing field may be determined by

$$\psi^{\text{out}}(x)=\left(\frac{m}{2\pi}\right)^{3/2}\int e^{-imx\cdot v\gamma\cdot v}\gamma\cdot v f(v)d\mu(v). \tag{2.19}$$

$\psi^{\text{out}}(x)$ has the same asymptotic as $\psi(x)$. It is argued that the structure is essentially the same in the full theory. In that case the characteristic $q(l)$ of the Coulomb field of the outgoing currents is expressed in terms of their asymptotic

$$q(l)=e\int\overline{f(v)}\gamma\cdot v f(v)\,\frac{d\mu(v)}{2(v\cdot l)^2} \tag{2.20}$$

(e is the charge of the electron).

We note for future use that explicitly Lorentz-covariant differentiation on H may be discussed with the use of operators defined in exactly the same way as it has been done in the case of the lightcone in the paragraph preceding (2.5). In the case of hyperboloid the operator contracted with v^b contains the whole information

$$\delta_a f(v):=(\partial_a-v_a v\cdot\partial)f(v). \tag{2.21}$$

Finally, total Poincaré quantities are expressed in terms of the outgoing fields. One finds that these quantities are the sums of the respective quantities for the free fields ${F^{\text{out}}}_{ab}(x)$ and $\psi^{\text{out}}(x)$ [determined by (2.13) and (2.19), respectively], with, however, one additional term in the case of angular momentum

$$\Delta M_{ab} = -\frac{1}{2\pi}\int q(l)(l_a\partial_b - l_b\partial_a)\Phi(l)d^2l. \tag{2.22}$$

This term is seen to mix the outgoing matter characteristic $q(l)$ with the infrared characteristic $\Phi(l)$. (It originates from the mixed adv–out terms of the asymptotics in null directions of the electromagnetic energy-momentum tensor.) This mixing of the long-range degrees of freedom corresponds to this remnant of interaction which is responsible for the validity of the Gauss' law. Its appearance shows that a Poisson bracket structure separating the two fields asymptotically remains in contradiction not only with the Gauss' law, but also with the Poincaré structure of the theory.

III. QUANTIZATION

We assume now that the asymptotic structure of the quantum theory may be described by quantum variables analogous to $V_a(s,l)$ and $f(v)$. By that we mean that these analogs generate an algebra, the states of which may be interpreted as scattering states in quantum electrodynamics. In the present section we give heuristic arguments which lead us to the formulation of quantization conditions for these variables. In Sec. IV, then, the appropriate algebra is constructed.

The usual quantization of the free electromagnetic field is achieved by the use of the symplectic form

$$\{F_1, F_2\} = \frac{1}{4\pi}\int_\Sigma ({F_1}^{ab}A_{2b} - {F_2}^{ab}A_{1b})d\sigma_a, \tag{3.1}$$

the integration extending over a Cauchy surface Σ. It has been observed by other authors before[18,19] that the integration surface may be shifted so as to become the future null infinity hypersurface (in the language of the compactified Minkowski space), as the fields are determined by their data on this surface. This corresponds in our language (no compactification) to the integration of "radiated" symplectic form. This is calculated in exactly the same way in which the radiated energy-momentum and angular momentum were determined in Ref. 16, Eqs. (3.6)–(3.14). The explicitly Lorentz-invariant result, denoted by $\{V_1, V_2\}$, is

$$\{V_1, V_2\} = \frac{1}{4\pi}\int (\dot{V}_1\cdot V_2 - \dot{V}_2\cdot V_1)(s,l)ds\ d^2l, \tag{3.2}$$

where V_i are asymptotics (2.1). However, we observe that also in the presence of sources the electromagnetic field is locally free in the null asymptotic region, so one can try to use the same symplectic form for the asymptotics of the interacting theory. The form (3.2) is now extended without formal change to asymptotics of all fields admitted by the framework of Sec. II. [The reason for taking (3.2) rather than directly the "radiated" analog of (3.1) for general fields as a basis for generalization is that for charged fields with nonvanishing infrared part the latter form yields no Lorentz invariant result. If the calculation is performed in a frame with the time-axis along the positive unit timelike vector t, then the result differs from (3.2) by

$$\frac{Q_2}{4\pi}\int t^a {V_1^{\text{out}}}_a(-\infty,l)\,\frac{d^2l}{t\cdot l} - \frac{Q_1}{4\pi}\int t^a {V_2^{\text{out}}}_a(-\infty,l)\,\frac{d^2l}{t\cdot l},$$

where Q_i are the charges (2.3).]

If V's are split into the free and the Coulomb part $V_a(s,l)=V^{\text{out}}{}_a(s,l)+V_a(+\infty,l)$, then

$$\{V_1,V_2\}=\{V_1^{\text{out}},V_2^{\text{out}}\}+\frac{1}{4\pi}\int (V_1(+\infty,l)\cdot V_2^{\text{out}}(-\infty,l)-V_2(+\infty,l)\cdot V_1^{\text{out}}(-\infty,l))d^2l.$$

Substituting in the second term (2.17), integrating by parts with the use of (2.10), and finally using (2.6) and (2.16) one obtains

$$\{V_1,V_2\}=\frac{1}{4\pi}\int (\dot{V}_1^{\text{out}}\cdot V_2^{\text{out}}-\dot{V}_2^{\text{out}}\cdot V_1^{\text{out}})(s,l)ds\ d^2l+\frac{1}{2\pi}\int (q_1\Phi_2-q_2\Phi_1)(l)d^2l. \quad (3.3)$$

The first term on the rhs is gauge invariant, while the second depends on gauge only through the choice of the additive constant in $\Phi(l)$, that is, on the choice of one of the equivalence classes of $V^{\text{out}}{}_a(-\infty,l)$ discussed after Eq. (2.17). The above compact form of the second term supplies justification for our interpretation of the constant in $\Phi(l)$.

Let now $V^{\text{op}}{}_a(s,l)$ be a quantum field and $V_a(s,l)$ a classical test field. The heuristic quantization rule is

$$[\{V_1,V^{\text{op}}\},\{V_2,V^{\text{op}}\}]=i\{V_1,V_2\},$$

where the real multiplicative constant on the rhs is fixed by the condition that the quantization reduces to the standard one for free infrared–regular test fields. In the Weyl exponentiated form this becomes $W(V_1)W(V_2)=e^{-(i\beta^2/2)\{V_1,V_2\}}W(V_1+V_2)$, where we put $W(V)=e^{-i\beta\{V,V^{\text{op}}\}}$, with β a real constant to be determined shortly. The Weyl operators are assumed to depend only on those variables, which enter nontrivially into the symplectic form (3.3), that is, they are insensitive to the gauge of $V^{\text{out}}{}_a(s,l)$ for finite s and to the gauge of $V_a(+\infty,l)$, and they depend on the gauge of $V^{\text{out}}{}_a(-\infty,l)$ only through the choice of constant in $\Phi(l)$. Therefore we shall write sometimes $W(V)=W(\xi,\Phi,q)$, where $\xi_{ab}(s,l):=l_aV^{\text{out}}{}_b(s,l)-l_bV^{\text{out}}{}_a(s,l)$. [Remember that $\Phi(l)$ is determined by $\xi_{ab}(-\infty,l)$ up to an additive constant.] The form (3.3) determines the physical interpretation of the Weyl operator for $q=0$, $\xi=0$, $\Phi=c=$const: $W(0,c,0)=e^{i\beta cQ^{\text{op}}}$, where Q^{op} is the operator of the charge of the field. From Weyl relations we have then

$$e^{i\beta cQ^{\text{op}}}W(V)=W(V)e^{i\beta c(Q^{\text{op}}+\beta Q)},$$

where Q is the charge of the electromagnetic test field V. For the interpretation of the classical and the quantum charge to agree we set $\beta=1$. Then the Weyl operator $W(V)$ carries a quantum charge equal to the classical charge of the test field V. More generally, it may be interpreted to carry the asymptotic field characterized by $V_a(s,l)$. The Weyl algebra

$$W(V_1)W(V_2)=e^{-(i/2)\{V_1,V_2\}}W(V_1+V_2) \quad (3.4)$$

may be considered as a theory of the asymptotic electromagnetic field. The quantization of charge demands that the space of test fields be restricted to the Abelian additive group of those Vs which carry the multiple of the elementary charge $Q=(1/2\pi)\int q(l)d^2l=ne$. The subgroup of zero-charge test fields forms a vector space. (For the discussion of an ''adiabatic limit'' of such a theory, in which only the long-range characteristics of the field survive, we refer the reader to Ref. 21.) However, the theory thus formulated is physically incomplete—it admits Coulomb fields, but there are no particles present to carry these fields. We turn now to the description of these particles.

Let us forget for the moment that there is some ''Gauss coupling'' between the asymptotic electromagnetic and Dirac fields which has to modify the Poisson bracket structure (as compared with the structure of two independent fields). Then the quantum field $f^{\text{op}}(v)$ which is to corre-

spond to the classical $f(v)$ is quantized in the standard Dirac way. We denote the quantum field smeared with the test field $f(v)$ by $B(f)$ and replace $f^{\mathrm{op}}(v)$ by $B(v)$, so that symbolically $B(f) = \int \overline{f(v)}\gamma\cdot v B(v) d\mu(v)$, where f is in $\mathscr{K}$, the Hilbert space introduced before (2.18). The standard quantization law in our notation reads

$$[B(f),\, B(g)]_+ = 0, \quad [B(f),\, B(g)^*]_+ = (f,g).$$

It will be convenient for our purposes to have fermionic operators depending on fs linearly. We introduce notation

$$B^0(f) = B(f^c) = \int B^0(v)\gamma\cdot v f(v) d\mu(v), \tag{3.5}$$

$$\bar{B}(f) = B(f)^* = \int \bar{B}(v)\gamma\cdot v f(v) d\mu(v), \tag{3.6}$$

where f^c is the charge conjugation of f defined by

$$f^c = C\bar{f}^T, \tag{3.7}$$

with C a unitary, antisymmetric matrix inducing the transformation $C^{-1}\gamma^a C = -\gamma^{aT}$. The involution law is then

$$B^0(f)^* = \bar{B}(f^c), \tag{3.8}$$

and anticommutation relations

$$[B^0(f),\, B^0(g)]_+ = 0, \quad [B^0(f),\, \bar{B}(g)]_+ = (f^c, g), \tag{3.9}$$

or, symbolically,

$$[B^0(v)_\alpha,\, B^0(v)_\beta]_+ = 0, \quad [B^0(v)_\alpha, \bar{B}(u)_\beta]_+ = \delta(v,u)(C^{-1}\gamma\cdot v)_{\alpha\beta}, \tag{3.10}$$

where $\delta(v,u)$ is the Dirac "δ-function" in the two velocities with respect to the measure $d\mu(v)$.

Physical interpretation of $B(f)$ and $B^0(f)$ justified by the Fock representation is that these operators annihilate an electron and/or create a positron. This means that they locally create charge $-e$ (if e is the charge of electron). More specifically, the operators $B(v)$ and $B^0(v)$ [resp. $\bar{B}(v)$] (forget for the moment mathematical subtleties) create the charge $-e$ (resp. e) moving with a constant four-velocity v. However, if the Gauss' law is again brought into play, creation of a charged particle must have electromagnetic consequences. Therefore, we want to extend the effect of Bs in such a way that they create (or annihilate) also the Coulomb field accompanying the charge. Basing the intuitions on pictures from perturbation calculations and on the algebraic discussion of superselection sectors of local observables, we want to admit the possibility that charged particles are in addition accompanied by "clouds" of radiation. Let the potential of the total field (Coulomb+radiation) accompanying charge e moving with velocity v be characterized by the asymptotic $V_a(v) = V_a(v;s,l)$. Then for each v this asymptotic is in the class discussed in Sec. II, and, moreover, its Coulomb part is, up to a gauge, the asymptotic of the potential $A_a(x) = ev_a/v\cdot x$, that is $V_a(v;+\infty,l) = ev_a/v\cdot l + \text{gauge}$. Now we seek operators $B^0_{-V_1}(v)$ and $\bar{B}_{V_2}(v)$ analogous to $B^0(v)$ and $\bar{B}(v)$ respectively, which, however, beside creating or annihilating material particles should also carry accompanying electromagnetic fields with asymptotics $-V_1(v)$ and $V_2(v)$, respectively, where V_1 and V_2 are in the class introduced above. Thus formulated, the problem almost uniquely determines its solution—the objects which do the electromagnetic part of the task are already there, the Weyl operators $W(-V_1(v))$, and $W(V_2(v))$ carry

exactly those charged fields. For the purpose of obtaining commutation relations we imagine the operators $B^0_{-V_1}(v)$ [resp. $\bar{B}_{V_2}(v)$] to be formed as products of $B^0(v)$ [resp. $\bar{B}(v)$] and $W(-V_1(v))$ [resp. $W(V_2(v))$] (mutually commuting). On the other hand, having attached charged fields to the matter particles in this way, we do not need any longer, as independent objects, the Weyl operators $W(V)$ for test fields with nonvanishing Coulomb part. From now on the asymptotic V in $W(V)$ is always a free-field asymptotic $[V_a(+\infty,l)=0]$.

The (naive) commutation relations resulting from the above discussion are

$$B^0_{-V_1}(v)W(V)=e^{(i/2)\{V_1(v),V\}}B^0_{-V_1+V}(v),$$

$$\bar{B}_{V_2}(v)W(V)=e^{-(i/2)\{V_2(v),V\}}\bar{B}_{V_2+V}(v),$$

$$e^{(i/2)\{V_1(v),V_2(u)\}}B^0_{-V_1}(v)_\alpha B^0_{-V_2}(u)_\beta+e^{(i/2)\{V_2(u),V_1(v)\}}B^0_{-V_2}(u)_\beta B^0_{-V_1}(v)_\alpha=0,$$

$$\begin{aligned}e^{-(i/2)\{V_1(v),V_2(u)\}}B^0_{-V_1}(v)_\alpha\bar{B}_{V_2}(u)_\beta+e^{-(i/2)\{V_2(u),V_1(v)\}}\bar{B}_{V_2}(u)_\beta B^0_{-V_1}(v)_\alpha\\ =\delta(v,u)(C^{-1}\gamma\cdot v)_{\alpha\beta}W(V_2(v)-V_1(v)),\end{aligned}$$

supplemented with the Weyl relations. Note that the asymptotic in the Weyl operator in the last line is a free-field asymptotic, as $V_2(v;+\infty,l)-V_1(v;+\infty,l)=0$.

For a precise formulation of the above quantization conditions it will not suffice, in contrast to the case of the Dirac field algebra, to have objects smeared with one-particle test functions as generating elements. Smeared products of $B^0_{-V_1}(v)$, $\bar{B}_{V_2}(v)$ and $W(V_2(v)-V_1(v))$ have to be defined, and the phase factors appearing in the above relations must become multipliers in the space of test fields. This construction is given in Sec. IV.

Before we go over to this task we want to draw attention to a known fact concerning physical interpretation of Weyl operators, which, however, in our context is of decisive importance and must not be overlooked. We illustrate our point first on the simplest possible example, the Weyl algebra of a single pair of canonical variables in quantum mechanics, $[x,p]=i\mathbf{1}$. The Weyl formulation reads in that case

$$W(x_1,p_1)W(x_2,p_2)=e^{-(i/2)\{x_1,p_1;x_2,p_2\}}W(x_1+x_2,p_1+p_2),$$

where x_i and p_i are classical ''test''-position and momentum variables, the symplectic form is $\{x_1,p_1;x_2,p_2\}=x_1p_2-x_2p_1$, and the Weyl operator is interpreted as $W(x_1,p_1)=e^{-i\{x_1,p_1;x,p\}}$. We want to point out a certain duality in the interpretation of $W(x_1,p_1)$. Let us set for simplicity $p_1=0$. Then, on the one hand, if treated as a function of observables, the Weyl operator $W(x_1,0)=e^{-ix_1p}$ ''measures'' the probability distribution of a state with respect to the momentum. On the other hand we have $W(x_1,0)^*xW(x_1,0)=x+x_1$. Hence, if treated as a unitary transformation operator, $W(x_1,0)$ ''carries'' the translation x_1; that is, when applied to a vector in Hilbert space it increases its position characteristic by the ''test''-position x_1. The characteristic which is ''carried'' by a Weyl operator in this sense is thus the one given by the test-quantity, while the ''measured'' one is dual to it, in the sense of the symplectic form. Going back to our objects we see that $B^0_{-V_1}(v)$, $\bar{B}_{V_2}(v)$ and $W(V)$ carry the respective fields in the above sense, in the case of $W(V)$ a free field. However, from the symplectic form (3.3) one reads off that the asymptotic of a free-field potential has as its dual the asymptotic of the total field, which is therefore what is ''measured'' by $W(V)$.

IV. THE ALGEBRA

Consider the set of C^∞ functions $V_a(s,l)$ [differentiations with respect to l in the sense discussed before Eq. (2.5), outside some neighborhood of the vertex of the cone] satisfying conditions (2.2)–(2.5). In this set introduce the following equivalence relation: $V_2(s,l)\sim V_1(s,l)$ iff $V_2(s,l)=V_1(s,l)+\alpha(s,l)l$ and $\int(\alpha(-\infty,l)-\alpha(+\infty,l))\,d^2l=0$ [this is the equivalence relation for the infrared characteristics of the free field component of V_a, introduced in (iii) after (2.17)]. The set of equivalence classes with respect to this relation will be denoted by L_Q. Another way of characterizing elements of L_Q is by the triples (ξ,Φ,q) introduced in the paragraph preceding Eq. (3.4). In order not to burden the notation, the elements of L_Q will be denoted by $V_a(s,l)$, but always the equivalence classes are understood. The set $\hat{L}:=\cup_{n\in\mathbf{Z}}L_{ne}$ has in a natural way the structure of an Abelian additive group. With the map $\{.,.\}:\hat{L}\times\hat{L}\to\mathbf{R}$ defined by (3.2), it becomes a symplectic group, on which $\{.,.\}$ is nondegenerate. The subgroup $L_0\subset\hat{L}$ has the structure of a vector space. Its subspace consisting of elements satisfying in addition $V_a(+\infty,l)\propto l_a$ (no Coulomb field) will be denoted by L. This symplectic space is again nondegenerate. Without loss of generality it may be assumed that for all Vs in L there is $V_a(+\infty,l)=0$. Elements of L will be the test functions of Weyl operators.

Consider, next, the class of all functions $V_a(v)$ on the hyperboloid H with values in L_e, such that

(i) $V^a(v;+\infty,l)=V_e{}^a(v,l)+\text{gauge}$, where $V_e{}^a(v,l):=ev^a/v\cdot l$, or, equivalently, $q(v,l)=q_e(v,l):=(e/2)(v\cdot l)^{-2}$;

(ii) for each $V(v)$ there is a function $F_V(v)$ such that

$$\{V(v),V(u)\}=F_V(v)-F_V(u) \tag{4.1}$$

for every v and u;

(iii) representants $V_a(v;s,l)$ may be chosen in C^∞ in v [differentiations in the sense of (2.21)] and for each $k=0,1,...$ there are constants $C_k\in\mathbf{R}$ and $m_k\in\mathbf{N}\cup\{0\}$ such that

$$|\delta_{a_1}\cdots\delta_{a_k}\dot{V}_b(v;s,l)|<C_k(v^0)^{m_k}(|s|+1)^{-1-\epsilon}$$

(in a fixed Minkowski frame, with scaling of ls fixed by $l^0=1$; the change of frame induces only a change of C_k).

Let $\mathscr{S}at_e$ be a subclass of this family of functions, such that

(iv) if $V_1(v)\in\mathscr{S}at_e$ and $V_0\in L$, then $V_2(v)=V_1(v)+V_0\in\mathscr{S}at_e$; this condition is fulfilled if $\mathscr{S}at_e$ consists of all functions satisfying (i)–(iii).

Denote, moreover, $\mathscr{S}at_{-e}:=-\mathscr{S}at_e$ and $\mathscr{R}ad:=\mathscr{S}at_e+\mathscr{S}at_{-e}$. The elements of $\mathscr{S}at_e$ and $\mathscr{S}at_{-e}$ will be the fields accompanying particles. Free fields from the class $\mathscr{R}ad$ will serve to define smeared Weyl operators.

Physical meaning of the first condition has been explained before. The next two conditions are of technical nature. The second one will guarantee the boundedness of the fermionic operators. The third implies that for $V_1,V_2\in\mathscr{S}at_e\cup\mathscr{S}at_{-e}\cup\mathscr{R}ad$ the symplectic form $\{V_1(v),V_2(u)\}$, and phase factors containing it linearly in exponent, are C^∞ functions in both variables, bounded polynomially in each of them. These properties make them multipliers in the space of Schwartz functions on $H^{\times n}$. Finally, the fourth condition says that a free field may be added to the cloud of the particle.

After these preliminaries our algebra may be constructed. We introduce formal symbols $W(V)$ for $V\in L$, W_V for $V\in\mathscr{R}ad$, B_V^0 for $V\in\mathscr{S}at_{-e}$, and B_V for $V\in\mathscr{S}at_e$. The symbol to which a given V is attached determines the class to which it belongs, so there is no need for special notation of Vs for each case separately. Let D be any finite sequence of these four symbols and χ a Schwartz function having one four-velocity argument for each of the symbols W_V, B_V^0, and B_V, and one index taking the values $\alpha=1,...,4$, for each of the symbols B_V^0 and B_V. If the sequence D

contains n symbols W_V, B^0_V and $\bar{B}_V$, and m symbols B^0_V and $\bar{B}_V$, then $\chi \in \mathscr{S}(H^n, \mathbf{C}^{4^m})$. We introduce a new symbol $[D](\chi)$, linear by assumption in χ. For a symbol consisting of only one of the operators W_V, B^0_V, or B_V, the symbolic notation is introduced

$$W_V(\chi) = \int W_V(v)\chi(v)d\mu(v), \tag{4.2}$$

$$B^0_V(f\ ) = \int B^0_V(v)\gamma\cdot v f(v)d\mu(v), \tag{4.3}$$

$$\bar{B}_V(f\ ) = \int \bar{B}_V(v)\gamma\cdot v f(v)d\mu(v), \tag{4.4}$$

[cf. (3.5) and (3.6)] and extended by linearity to general symbols $[D](\chi)$. The set of all formal finite sums of these symbols forms a vector space. We divide this space by its subspace generated by the following identifications [$G_V(v)$ is any of the symbols $W_V(v)$, $B^0_V(v)$, or $B_V(v)$]:

$$e^{(i/2)\{V_1,V_2\}}W(V_1)W(V_2) = W(V_1+V_2), \tag{4.5}$$

$$e^{(i/2)\{V_1,V_2(v)\}}W(V_1)G_{V_2}(v) = G_{V_1+V_2}(v), \tag{4.6}$$

$$e^{(i/2)\{V_2(v),V_1\}}G_{V_2}(v)W(V_1) = G_{V_1+V_2}(v), \tag{4.7}$$

$$e^{(i/2)\{V_1(v),V_2(u)\}}W_{V_1}(v)G_{V_2}(u) - e^{(i/2)\{V_2(u),V_1(v)\}}G_{V_2}(u)W_{V_1}(v) = 0, \tag{4.8}$$

$$e^{(i/2)\{V_1(v),V_2(u)\}}B^\sharp_{V_1}(v)_\alpha B^\sharp_{V_2}(u)_\beta + e^{(i/2)\{V_2(u),V_1(v)\}}B^\sharp_{V_2}(u)_\beta B^\sharp_{V_1}(v)_\alpha = 0, \tag{4.9}$$

$$\begin{aligned} &e^{(i/2)\{V_1(v),V_2(u)\}}B^0_{V_1}(v)_\alpha \bar{B}_{V_2}(u)_\beta + e^{(i/2)\{V_2(u),V_1(v)\}}\bar{B}_{V_2}(u)_\beta B^0_{V_1}(v)_\alpha \\ &\quad = \delta(v,u)(C^{-1}\gamma\cdot v)_{\alpha\beta}W_{V_1+V_2}(v); \end{aligned} \tag{4.10}$$

if $V(v) = V_0 = \text{const}(v)$ on the support of $\chi(...,v,...)$ in v, the variable connected with $W_V(v)$, then

$$[\cdots W_V \cdots](\chi) = [\cdots W(V_0)\cdots]\left(\int \chi(...,v,...)d\mu(v)\right). \tag{4.11}$$

In Eq. (4.9) $\sharp = 0$ or the bar sign, the same at both Bs. The phase factors appearing in (4.5)–(4.10) are to be understood to multiply test functions χ in the symbols $[D](\chi)$. The last relation says that constant smeared Weyl operators are identical with the standard ones.

The elements of the factor space thus obtained will be again denoted by $\Sigma_{i=1}^N [D_i](\chi_i)$ without a risk of confusion. This vector space becomes a *-algebra $\mathscr{B}$ with the multiplication and involution laws defined by

$$[D_1](\chi_1)[D_2](\chi_2) = [D_1D_2](\chi_1\otimes\chi_2), \tag{4.12}$$

$$[D](\chi)^* = [D^*](\chi^c), \tag{4.13}$$

and the unit $\mathbf{1} = W(0)$. D_1D_2 is the sequence of symbols formed of the two sequences D_1 and D_2, D_2 following D_1. χ^c results from χ by the application of the sequence of three operations: complex conjugation, reflection of the order of the variables and indices, and the matrix multipli-

cation by $C\gamma^{0T}=-\gamma^0 C$ applied to each of the indices [cf. (3.7)]. The sequence D^* results from D by reflection of its order and subsequent replacements: $W(V)\to W(-V)$, $W_V\to W_{-V}$, $B^0_V\to B_{-V}$, $B_V\to B^0_{-V}$.

In the last step we consider now the problem of introducing a C^*-norm on the *-algebra $\mathscr{B}$. Let $\mathscr{R}$ be the class of all C^*-seminorms p on $\mathscr{B}$ such that

(i) $p([D](\chi))$ is continuous in χ in the topology of $\mathscr{S}$ for each D;

(ii)

$$p(W_V(\chi))\leqslant\|\chi\|_{L^1(H,d\mu)}. \tag{4.14}$$

A comment on each of the conditions is in place. The second one is a necessary condition for the admitted representations of the smeared Weyl operators $W_V(\chi)$ to be indeed given by integrals of unitary operators with the test function χ. To see the meaning of the first condition let us compare our present context with that of the standard algebra of the Dirac field. In the latter case one has in the algebra the elements $[B^{\sharp_1}\cdots B^{\sharp_n}](f^1\otimes\cdots\otimes f^n):=B^{\sharp_1}(f^1)\cdots B^{\sharp_n}(f^n)$, ($\sharp_i=0$ or the bar sign), where $f^i\in\mathscr{S}(H,\mathbf{C}^4)\subset\mathscr{K}$. These elements are norm continuous in each of the functions f^i in the $\mathscr{S}$-topology, so by the nuclear theorem for Schwartz functions one obtains in the algebra the unique linear extension $[B^{\sharp_1}\cdots B^{\sharp_n}](\chi)$ to the whole of $\mathscr{S}(H^n,\mathbf{C}^{4^n})$, norm continuous in χ in the topology of $\mathscr{S}$. Their analogs in our algebra are symbols $[D](\chi)$. However, we had to define them from the beginning for the whole space $\mathscr{S}$ to be able to formulate the algebraic conditions. Condition (i) will guarantee that also here they will be continuous extensions of products of the basic objects.

Proposition 4.1: The class $\mathscr{R}$ contains the maximal element $p_{\max}$. A C^*-seminorm p on $\mathscr{B}$ is in $\mathscr{R}$ iff $p\leqslant p_{\max}$.

The second statement is obviously true, if the first is proved. The proof is preceded by two lemmas.

Lemma 4.2: For any C^*-seminorm $p\neq 0$ on $\mathscr{B}$ there is $p(W(V))=1$ for all $V\in L$, and $p(B^0_{V_1}(f))=p(\bar{B}_{V_2}(f))=\|f\|_{\mathscr{K}}$ for all $V_1\in\mathscr{S}at_{-e}$, $V_2\in\mathscr{S}at_e$, and $f\in\mathscr{S}$.

Proof: The first statement is the consequence of the Weyl relations. The proof of the second one is a slightly more involved version of the analogous proof for the C^*-norm on the Dirac field algebra. Let $\{V(v),V(u)\}=F(v)-F(u)$. Then (4.9) for $V_1=V_2=V$ takes the form

$$e^{iF(v)}B^0_V(v)_\alpha B^0_V(u)_\beta+e^{iF(u)}B^0_V(u)_\beta B^0_V(v)_\alpha=0.$$

For $\chi=f\otimes g$ this yields $B^0_V(e^{iF}f)B^0_V(g)+B^0_V(e^{iF}g)B^0_V(f)=0$, and for $g=f$, in particular, $B^0_V(e^{iF}f)B^0_V(f)=0$. In the same way one obtains from (4.10)

$$B^0_V(f)\bar{B}_{-V}(g)+\bar{B}_{-V}(e^{-iF}g)B^0_V(e^{iF}f)=(f^c,g). \tag{4.15}$$

The last two equations imply

$$B^0_V(f)B^0_V(g)^*B^0_V(f)=(g,f)B^0_V(f). \tag{4.16}$$

Multiplying this equation on the left by $B^0_V(f)^*$ and setting $g=f$ one obtains easily $p(B^0_V(f))=\|f\|_{\mathscr{K}}$ or 0. Assume that there is V and $g\neq 0$ such that $p(B^0_V(g))=0$. Then from (4.16) there is $|(g,f)|p(B^0_V(f))=0$ for all f, hence $p(B^0_V(f))=0$ for all such f that $(g,f)\neq 0$. Each f may be represented as $f=f_1+f_2$ with $(g,f_i)\neq 0$, so $p(B^0_V(f))=0$ for all f, which contradicts (4.15) and ends the proof of the lemma. □

Let $\chi\in\mathscr{S}(H^n,\mathbf{C}^{4^m})$, $m\leqslant n$. There always exists a representation $\chi=\Sigma_{i=1}^{\infty}f_i^1\otimes\cdots\otimes f_i^n$, where for a given k all f_i^k are either in $\mathscr{S}(H,\mathbf{C})$ or in $\mathscr{S}(H,\mathbf{C}^4)$ and the sum converges in the topology of

$\mathscr{S}$ (e.g., the N-representation[22]). There are various orders of spaces $\mathscr{S}(H,\mathbf{C})$ and $\mathscr{S}(H,\mathbf{C}^4)$ in this representation possible. Denote a fixed order by $\flat$ and the above representation with this order by $\chi=\Sigma_{i=1}^{\infty} f_i^1\otimes_\flat\cdots\otimes_\flat f_i^n$. Let

$$d_\flat(\chi):=\inf_{\chi=\Sigma_{i=1}^{\infty} f_i^1\otimes_\flat\cdots\otimes_\flat f_i^n}\sum_{i=1}^{\infty}\|f_i^1\|_\bullet\cdots\|f_i^n\|_\bullet, \tag{4.17}$$

where $\|f\|_\bullet=\|f\|_{L^1(H,d\mu)}$ if $f\in\mathscr{S}(H,\mathbf{C})$ and $\|f\|_\bullet=\|f\|_{\mathscr{K}}$ if $f\in\mathscr{S}(H,\mathbf{C}^4)$.

Lemma 4.3: $d_\flat$ are norms on $\mathscr{S}(H^n,\mathbf{C}^{4^m})$, continuous in the topology of $\mathscr{S}$.

Proof: We show first that $d_\flat$ is bounded by one of the seminorms defining the topology of $\mathscr{S}$. We assume for simplicity that $\chi\in\mathscr{S}(H^2,\mathbf{C}^4)$ and we are interested in the norm $d_\flat$ for the order of spaces $(\mathscr{S}(H,\mathbf{C}),\mathscr{S}(H,\mathbf{C}^4))$. The general case differs only by more involved notation. Choose a Minkowski frame and denote $\chi'_\alpha(v,u)=v^0(u^0)^{-1/2}\Sigma_{\beta=1}^4 S^{-1}(u)_{\alpha\beta}\chi_\beta(v,u)$, where the matrix $S^{-1}(u)=(2(u^0+1))^{-1/2}(1+\gamma^0\gamma\cdot u)$ induces the transformation $f\gamma\cdot ug=(S^{-1}(u)f)^\dagger(S^{-1}(u)g)$ (the dagger denoting the matrix Hermitian conjugation). Consider χ' as a function of variables $\vec{v}$ and $\vec{u}$ and expand it in the N-representation: $\chi'_\alpha(v,u)=\Sigma_{i=1}^{\infty} f_i(\vec{v})g_{i\alpha}(\vec{u})$, where fs and gs are multiples of products of the Hermite functions. The sum converges in $\mathscr{S}$ and $\Sigma_{i=1}^{\infty}\|f_i\|_{L^1(\mathbf{R}^3,d^3v)}(\Sigma_{\alpha=1}^4\|g_{i\alpha}\|_{L^2(\mathbf{R}^3,d^3v)})$ is bounded by one of the fundamental seminorms of χ', which in turn may be bounded by one of the seminorms of χ. Now it suffices to observe that $\Sigma_{i=1}^{\infty}(v^0)^{-1}f_i(\vec{v})(u^0)^{1/2}(S(u)g_i(\vec{u}))_\alpha$ converges to χ in $\mathscr{S}$ and $\Sigma_{i=1}^{\infty}\|(v^0)^{-1}f_i(\vec{v})\|_{L^1(H,d\mu)}\|(u^0)^{1/2}(S(u)g_i(\vec{u}))\|_{\mathscr{K}}<\text{const}\,\Sigma_{i=1}^{\infty}\|f_i\|_{L^1(\mathbf{R}^3,d^3v)}(\Sigma_{\alpha=1}^4\|g_{i\alpha}\|_{L^2(\mathbf{R}^3,d^3v)})$ to get $d_\flat(\chi)<\rho(\chi)$, where ρ is one of the fundamental seminorms. The properties of a seminorm are easily checked for $d_\flat$. That $d_\flat(\chi)=0$ implies $\chi=0$ is again illustrated in our special case. Let $\chi=\Sigma_{i=1}^{\infty} f_i\otimes g_i$, $f_i\in\mathscr{S}(H,\mathbf{C})$, $g_i\in\mathscr{S}(H,\mathbf{C}^4)$, and also choose any $h_1\in\mathscr{S}(H,\mathbf{C})$ and $h_2\in\mathscr{S}(H,\mathbf{C}^4)$. Then

$$\left|\int h_1(v)\overline{h_2(u)}\gamma\cdot u\chi(v,u)d\mu(v)d\mu(u)\right|\leqslant\sup_v|h_1(v)|\sum_{i=1}^{\infty}\|f_i\|_{L^1}\|g_i\|_{\mathscr{K}}.$$

Hence, if $d_\flat(\chi)=0$, then the lhs vanishes for all h_1 and h_2 and $\chi=0$. □

Proof of Proposition 4.1: Let $\flat(D)$ be the order of spaces $\mathscr{S}(H,\mathbf{C})$ and $\mathscr{S}(H,\mathbf{C}^4)$ corresponding to the order of symbols W_V and $B_V^\sharp$, respectively, in the sequence D. Then by the assumption (4.14) and Lemma 4.2 one has for any $p\in\mathscr{R}$

$$p([D](f^1\otimes_{\flat(D)}\cdots\otimes_{\flat(D)}f^n))\leqslant\|f^1\|_\bullet\cdots\|f^n\|_\bullet.$$

If $\chi=\Sigma_{i=1}^{\infty} f_i^1\otimes_{\flat(D)}\cdots\otimes_{\flat(D)}f_i^n$, then by the assumed continuity $p([D](\chi))\leqslant\Sigma_{i=1}^{\infty}\|f_i^1\|_\bullet\cdots\|f_i^n\|_\bullet$. Hence for any element of $\mathscr{B}$ one has

$$p\left(\sum_{k=1}^{N}[D_k](\chi_k)\right)\leqslant\sum_{k=1}^{N}d_{\flat(D_k)}(\chi).$$

We define the seminorm $p_{\max}$ on $\mathscr{B}$ by

$$p_{\max}(A)=\sup_{p\in\mathscr{R}}p(A).$$

There is $p_{\max}([D](\chi))\leqslant d_{\flat(D)}(\chi)$, so $p_{\max}\in\mathscr{R}$. □

The answer to the question whether $p_{\max}$ is a norm on $\mathscr{B}$ is not known yet. If it is not, one divides $\mathscr{B}$ through the ideal $\mathscr{T}$ of those elements for which $p_{\max}$ vanishes. The seminorm $p_{\max}$ induces then a C^*-norm $\|.\|$ on $\mathscr{B}/\mathscr{T}$ in the standard way. The completion of $\mathscr{B}/\mathscr{T}$ in this norm is

a C^*-algebra $(\mathscr{F},\|.\|)$. We propose to regard this algebra as the base of a theory of asymptotic fields. With regard to the interpretation of electromagnetic ingredients of the algebra, one should have in mind the remarks made at the end of Sec. III.

It is easy to see that representations of the algebra $(\mathscr{F},\|\cdot\|)$ are in natural 1:1 correspondence with those representations π of $\mathscr{B}$ for which $p(.)=\|\pi(.)\|\in\mathscr{R}$.

In the asymptotic algebra of fields there is no place more for the local gauge transformations. The only gauge-dependent quantity in the electromagnetic test fields is the additive constant in $\Phi(l)$. This freedom is closely connected with the global gauge transformation of the charge carrying fields, which is implemented in the algebra itself. Let $W(V)=W(0,c)$, $c=$const, (i.e., $V=$pure gauge, $\Phi=c$), and set $\gamma_c(A)=\underline{W}(0,c)AW(0,\underline{c})^*$. Then $\gamma_c(A)=A$ for $A=W(V)$ or $W_V(\chi)$, and $\gamma_c(B_V^0(f))=e^{-ice}B_V^0(f)$, $\gamma_c(B_V(f))=e^{+ice}B_V(f)$. Algebra $\mathscr{B}$ is the linear span of its subspaces $\mathscr{B}_k$, $k\in\mathbf{Z}$, where $\gamma_c=e^{icke}$ id on $\mathscr{B}_k$. The subspace $\mathscr{B}_0$ is a *-subalgebra of $\mathscr{B}$. If $\mathscr{I}\neq 0$, then it is easily seen that $\mathscr{I}$ is the linear span of $\mathscr{I}_k:=\mathscr{B}_k\cap\mathscr{I}$. The decomposition is therefore inherited by $\mathscr{F}$, and $\mathscr{F}_0$ is a C^*-algebra, which may be interpreted as the algebra of observables $\mathscr{A}\equiv\mathscr{F}_0$.

The algebraic relations of $\mathscr{B}$ have been obtained by treating $B_V^\sharp(v)$ heuristically as products of $B^\sharp(v)$ and Weyl operators for charged fields $W(V(v))$. In Sec. V we shall see that this heuristic idea may be also used to obtain a class of representations of $\mathscr{B}$ (and $\mathscr{F}$).

V. A CLASS OF REPRESENTATIONS

Let $W_0(V)$ be a representation in a Hilbert space $\mathscr{H}_1$ of the Weyl algebra over the test function space $\hat{L}$ with the symplectic form (3.2). We assume that for any $V(.)\in\mathscr{S}at_e$ it satisfies the following conditions:

(i) for every $\varphi\in\mathscr{H}_1$ the vectors $W_0(V(v))\varphi$, $v\in H$, span a separable subspace;

(ii) for every φ, $\psi\in\mathscr{H}_1$, the function $(\varphi,W_0(V(v))\psi)$ is measurable in v.

(The class of representations satisfying the conditions is nonempty—this may be shown by an explicit construction making use of the usual Fock representation and one of representations discussed in Ref. 21.) It follows that $(\varphi,W_0(V_1(v_1))...W_0(V_n(v_n))\psi)$ is also measurable. For $V_i\in\mathscr{S}at_e\cup\mathscr{S}at_{-e}\cup\mathscr{R}ad$, $i=1,\ldots,n$, $\chi\in L^1(H^n,d\mu^n)$, we denote

$$[W_{0V_1}\cdots W_{0V_n}](\chi)=\int W_0(V_1(v_1))\cdots W_0(V_n(v_n))\chi(v_1,\ldots,v_n)d\mu(v_1)\cdots d\mu(v_n),$$

the integral in the weak sense. The Weyl algebra relations imply

$$[W_{0V_1}W_{0V_2}](\chi)=[W_{0V_2}W_{0V_1}](\chi'), \tag{5.1}$$

where $\chi'(u,v)=e^{-i\{V_1(v),V_2(u)\}}\chi(v,u)$. If, in particular, $\{V_1(v),V_2(u)\}=F_{12}(v)-F_{12}(u)$, then

$$W_{0V_1}(\chi_1)W_{0V_2}(\chi_2)=W_{0V_2}(e^{iF_{12}}\chi_2)W_{0V_1}(e^{-iF_{12}}\chi_1). \tag{5.2}$$

Let further $B(f)$ [and $B^\sharp(f)$] be a concrete realization (representation) of the Dirac field algebra in a Hilbert space $\mathscr{H}_2$. We would like to define $B_V^0(v)$ as a product of $W_0(V(v))$ and $B^0(v)$, that is, to give sense to the expression

$$B_V^0(f)=\int W_0(V(v))\otimes B^0(v)\gamma\cdot v f(v)d\mu(v)$$

for $f\in\mathscr{S}(H,\mathbf{C}^4)$. [When constructing the representation we shall use the simplified notation $B_V^0(f)$ instead of the more appropriate $\pi(B_V^0(f))$, etc., which may be restored at the end of construction.] Let $\{e_i\}$ be an orthonormal basis of the Hilbert space $\mathscr{K}$. If we "expand" $B^0(v)$ in this basis, we are led to the following formulation. Consider a family of bounded operators on $\mathscr{K}_1\otimes\mathscr{K}_2$

$$B_V^0(f)_n := \sum_{i=1}^{n} W_{0V}(\overline{e_i}\Gamma f)\otimes B^0(e_i),$$

where $(\Gamma f)(v)=\gamma\cdot v f(v)$.

Proposition 5.1. The sequence of operators $B_V^0(f)_n$ converges *-strongly to a bounded operator $B_V^0(f)$, with $\|B_V^0(f)\|\leqslant\|f\|_{\mathscr{K}}$.

Proof: Let $\{V(v),V(u)\}=F(v)-F(u)$. From the Dirac field anticommutation relations and (5.2) we obtain

$$(B_V^0(f)_n-B_V^0(f)_m)^*(B_V^0(f)_n-B_V^0(f)_m)+(B_V^0(e^{-iF}f)_n-B_V^0(e^{-iF}f)_m)$$

$$(B_V^0(e^{-iF}f)_n-B_V^0(e^{-iF}f)_m)^*=\left(\sum_{i=m+1}^{n} w_i^* w_i\right)\otimes\mathbf{1},$$

where $w_i = W_{0V}(\overline{e_i}\Gamma f)$. For any vector $\psi\in\mathscr{H}_1\otimes\mathscr{H}_2$, there is then

$$\|(B_V^0(f)_n-B_V^0(f)_m)\psi\|^2+\|(B_V^0(e^{-iF}f)_n^*-B_V^0(e^{-iF}f)_m^*)\psi\|^2=p_\psi\left(\sum_{i=m+1}^{n} w_i^* w_i\right), \quad (5.3)$$

where $p_\psi(A):=(\psi,A\otimes\mathbf{1}\psi)$ agrees for positive A with one of the seminorms defining the σ-weak topology on the space of bounded operators on $\mathscr{H}_1$. We shall show below that

$$\sum_{i=1}^{\infty} w_i^* w_i=\|f\|^2\mathbf{1}, \quad (5.4)$$

and that the series converges σ-strongly. Hence $B_V^0(f)_n$ and $B_V^0(e^{-iF}f)_n^*$ converge strongly to bounded operators for all f, which implies the *-strong convergence of $B_V^0(f)_n$ for all f. Putting $m=0$ in (5.3) and taking the limit in n we obtain the bound of the norm. To prove (5.4) observe first that for any x, $y\in\mathscr{H}_1$ we have $(y,w_i x)=\int(y,W_0(V(v))x)\overline{e_i(v)}\gamma\cdot v f(v)d\mu(v)$ $=(e_i,(y,W_0(V(.))x)f)_{\mathscr{K}}$, so that

$$\sum_{i=1}^{\infty}|(y,w_i x)|^2=\|(y,W_0(V(.))x)f\|_{\mathscr{K}}^2.$$

For fixed x let $\{\varphi_j\}$ be an orthonormal basis of the subspace of $\mathscr{H}_1$ spanned by $W_0(V(v))x$, $v\in H$. Then

$$\sum_{i=1}^{\infty}(x,w_i^* w_i x)=\sum_{i,j=1}^{\infty}|(\varphi_j,w_i x)|^2=\sum_{j=1}^{\infty}\int|(\varphi_j,W_0(V(v))x)|^2\overline{f(v)}\gamma\cdot v f(v)d\mu(v)=\|f\|_{\mathscr{K}}^2\|x\|^2,$$

the last equality by the Lebesgue theorem. As $\Sigma_{i=1}^{n} w_i^* w_i$ is an increasing sequence of positive operators, the above calculation shows that (5.4) holds in the σ-strong sense (e.g., Ref. 23, Lemma 2.4.19). □

The building blocks of the representation acting on $\mathscr{K}_1\otimes\mathscr{K}_2$ are now defined by

$$W(V)=W_0(V)\otimes\mathbf{1}, \quad V\in L, \quad (5.5)$$

$$W_V(\chi)=W_{0V}(\chi)\otimes\mathbf{1}, \quad V\in\mathscr{R}ad, \quad \chi\in\mathscr{S}(H,\mathbf{C}), \quad (5.6)$$

$$B_V^\sharp(f)=\sum_{i=1}^{\infty} W_{0V}(\overline{e_i}\Gamma f)\otimes B^\sharp(e_i),\quad V\in\mathscr{S}at_e\cup\mathscr{S}at_{-e},\quad f\in\mathscr{S}(H,\mathbf{C}^4). \tag{5.7}$$

The definition of $B_V^\sharp$ is independent of the choice of the basis $\{e_i\}$, as it is easily shown that

$$(x_1\otimes y_1,B_V^\sharp(f)x_2\otimes y_2)=(y_1,B^\sharp((x_1,W_0(V(.))x_2)f)y_2). \tag{5.8}$$

If D is any sequence of the symbols $W(V)$, W_V, and $B_V^\sharp$, and $(f^1,\ldots,f^n)$ form a sequence of type $\flat(D)$, then we define $[D](f^1\otimes\cdots\otimes f^n)$ as the product of the "building blocks." In view of Prop. 5.1 and of the obvious bound $\|W_V(\chi)\|\leqslant\|\chi\|_{L^1}$, this element is norm continuous in each of f's in the topology of $\mathscr{S}$. By the nuclear theorem it extends then to the function $[D](\chi)$ norm continuous in χ in the $\mathscr{S}$-topology. The conditions (4.12) and (4.13) are satisfied, and the operator norm fulfills the defining conditions of the class $\mathscr{R}$. To complete the proof that we have thus obtained a representation of the algebra $\mathscr{F}$ it remains to show that the relations (4.5)–(4.11) are satisfied.

The conditions (4.5) and (4.11) are obviously satisfied. It is sufficient to check the other relations for elements $[D](\chi)$ with Ds being sequences of two symbols. The relations (4.6) and (4.7) are then quite obvious as well. Equation (4.8) for $G_V=W_V$ follows from (5.1). For $G_V=B_V^\sharp$ it is easy to show that

$$(x_1\otimes y_1,[W_{V_1}B_{V_2}^\sharp](\chi)x_2\otimes y_2)=\left(y_1,B^\sharp\left(\int(x_1,W_0(V_1(v))W_0(V_2(.))x_2)\chi(v,.)d\mu(v)\right)y_2\right),$$

and similarly in the opposite order of symbols, which implies (4.8).

To prove (4.9) and (4.10) we have to make a digression on the extension of products $B^{\sharp_1}(f)B^{\sharp_2}(g)$ in the algebra of the Dirac field. We have mentioned such an extension to the space of Schwartz functions, but now we need a wider family.

Let $\mathscr{K}\otimes\mathscr{K}$ be the tensor product Hilbert space. This space consists of measurable functions $\chi_{\alpha\beta}(v,u)$, for which

$$\sum_{\substack{\alpha,\alpha'\\ \beta,\beta'}}\int\chi^*_{\alpha\beta}(v,u)(\gamma^0\gamma\cdot u)_{\alpha\alpha'}(\gamma^0\gamma\cdot u)_{\beta\beta'}\chi_{\alpha'\beta'}(v,u)d\mu(v)d\mu(u)<\infty.$$

Let, further, $\mathscr{K}\otimes_1\mathscr{K}$ be the subspace of $\mathscr{K}\otimes\mathscr{K}$ consisting of those $\chi\in\mathscr{K}\otimes\mathscr{K}$ for which

$$\|\chi\|_1:=\inf_{\chi=\Sigma_{i=1}^{\infty}f_i\otimes g_i}\sum_{k=1}^{\infty}\|f_k\|\|g_k\|<\infty.$$

$\|.\|_1$ is a norm on $\mathscr{K}\otimes_1\mathscr{K}$, $\|\chi\|<\|\chi\|_1$ for $\chi\in\mathscr{K}\otimes_1\mathscr{K}$, and $(\mathscr{K}\otimes_1\mathscr{K},\|.\|_1)$ is a Banach space. These statements follow most simply from the following two observations.

(i) $(\mathscr{K}\otimes\mathscr{K},\|.\|)$ is isomorphic with the space of Hilbert–Schmidt operators on $\mathscr{K}$ by the map $\chi\to\mathscr{O}_\chi$, where for $\chi=\Sigma_{i=1}^{\infty}f_i\otimes g_i$ the operator $\mathscr{O}_\chi$ is defined by

$$\mathscr{O}_\chi h=\sum_{i=1}^{\infty}(h^c,f_i)g_i. \tag{5.9}$$

(ii) Under the same map $(\mathscr{K}\otimes_1\mathscr{K},\|.\|_1)$ is isomorphic with the Banach space of trace class operators on $\mathscr{K}$.[24] Thus, if $\chi_n\to\chi$ in $\mathscr{K}\otimes_1\mathscr{K}$, then $\chi_n\to\chi$ in $\mathscr{K}\otimes\mathscr{K}$.

Extension of the product of fundamental elements in the Dirac field algebra is now easily achieved. For $\chi=\Sigma_{i=1}^n f_i\otimes g_i$, $f_i, g_i\in\mathscr{K}$, we set $[B^{\sharp_1}B^{\sharp_2}](\chi)=\Sigma_{i=1}^n B^{\sharp_1}(f_i)B^{\sharp_2}(g_i)$. This defines a linear map of the algebraic product $\mathscr{K}\otimes_{\text{alg}}\mathscr{K}$ (densely contained in $\mathscr{K}\otimes_1\mathscr{K}$) into the

algebra, with the norm bound $\|[B^{\sharp_1}B^{\sharp_2}](\chi)\| \leqslant \|\chi\|_1$. Hence the map extends to the whole $\mathscr{K}\otimes_1\mathscr{K}$, with the conservation of the bound. For $\chi\in\mathscr{S}$ this reduces to the extension mentioned previously.

The anticommutation relations may be now extended from $\mathscr{K}\otimes_{\mathrm{alg}}\mathscr{K}$ to the whole $\mathscr{K}\otimes_1\mathscr{K}$, which gives

$$[B^{\sharp}B^{\sharp}](\chi+\chi^T)=0, \tag{5.10}$$

$$[B^0\bar{B}](\chi)+[\bar{B}B^0](\chi^T)=\mathrm{Tr}\,\mathscr{O}_\chi\mathbf{1}, \tag{5.11}$$

where ${\chi^T}_{\alpha\beta}(v,u)=\chi_{\beta\alpha}(u,v)$, and $\mathrm{Tr}\,\mathscr{O}_\chi$ is the trace of the operator (5.9), $\mathrm{Tr}\,\mathscr{O}_\chi=\Sigma_{i=1}^{\infty}(f_i^c,g_i)$ for $\chi=\Sigma_{i=1}^{\infty}f_i\otimes g_i$.

After these preparations we take up the proof of the relations (4.9) and (4.10). For $x_1,x_2\in\mathscr{H}_1$ let φ_j be an orthonormal basis of the linear span of vectors $W_0(V_1(v))^*x_1$ and $W_0(V_1(v))x_2$, $v\in H$. Let, further, ψ_λ be an orthonormal basis (not necessarily countable) of $\mathscr{H}_2$, and $f,g\in\mathscr{S}(H,\mathbf{C}^4)$. Expanding $B^{\sharp_2}_{V_2}(g)x_2\otimes y_2$ in the basis $\varphi_j\otimes\psi_\lambda$ and using (5.8) one finds

$$\begin{aligned}&(x_1\otimes y_1,B^{\sharp_1}_{V_1}(f\,)B^{\sharp_2}_{V_2}(g)x_2\otimes y_2)\\&\quad=\sum_{i=1}^{\infty}(y_1,[B^{\sharp_1}B^{\sharp_2}]((x_1,W_0(V_1(.))\varphi_i)f\otimes(\varphi_i,W_0(V_2(.))x_2)g)y_2).\end{aligned}$$

We have

$$\begin{aligned}&\sum_{i=1}^{\infty}\|(x_1,W_0(V_1(.))\varphi_i)f\|_{\mathscr{K}}\|(\varphi_i,W_0(V_2(.))x_2)g\|_{\mathscr{K}}\\&\quad\leqslant\left(\sum_{i=1}^{\infty}\|(W_0(V_1(.))^*x_1,\varphi_i)f\|^2_{\mathscr{K}}\right)^{1/2}\left(\sum_{i=1}^{\infty}\|(\varphi_i,W_0(V_2(.))x_2)g\|^2_{\mathscr{K}}\right)^{1/2}\\&\quad=\|x_1\|\|x_2\|\|f\|_{\mathscr{K}}\|g\|_{\mathscr{K}},\end{aligned}$$

the last equality by the Lebesgue theorem. Hence, the series

$$\sum_{i=1}^{\infty}(x_1,W_0(V_1(.))\varphi_i)f\otimes(\varphi_i,W_0(V_2(.))x_2)g \tag{5.12}$$

converges both in $\mathscr{K}\otimes_1\mathscr{K}$ and $\mathscr{K}\otimes\mathscr{K}$, to the same element. The limit in $\mathscr{K}\otimes\mathscr{K}$ is easily found as the point limit of functions, which yields $(x_1,W_0(V_1(v))W_0(V_2(u))x_2)f(v)g(u)$. Thus we have proved that if $\chi\in\mathscr{K}\otimes_{\mathrm{alg}}\mathscr{K}$, then

$$\begin{aligned}&(x_1,W_0(V_1(.))W_0(V_2(.))x_2)\chi\in\mathscr{K}\otimes_1\mathscr{K},\\&\|(x_1,W_0(V_1(.))W_0(V_2(.))x_2)\chi\|_1\leqslant\|x_1\|\|x_2\|\|\chi\|_1,\end{aligned} \tag{5.13}$$

and for $\chi\in\mathscr{S}(H,\mathbf{C}^4)\otimes_{\mathrm{alg}}\mathscr{S}(H,\mathbf{C}^4)\subset\mathscr{K}\otimes_{\mathrm{alg}}\mathscr{K}$

$$(x_1\otimes y_1,[B^{\sharp_1}_{V_1}B^{\sharp_2}_{V_2}](\chi)x_2\otimes y_2)=(y_1,[B^{\sharp_1}B^{\sharp_2}]((x_1,W_0(V_1(.))W_0(V_2(.))x_2)\chi)y_2). \tag{5.14}$$

By continuity (5.13) remains true for $\chi\in\mathscr{K}\otimes_1\mathscr{K}$, and (5.14) for $\chi\in\mathscr{S}(H^2,\mathbf{C}^{4^2})\subset\mathscr{K}\otimes_1\mathscr{K}$. Denote $\chi'_{\alpha\beta}(v,u)=e^{(i/2)\{V_1(v),V_2(u)\}}\chi_{\alpha\beta}(v,u)$ and $\chi''_{\alpha\beta}(v,u)=e^{(i/2)\{V_2(u),V_1(v)\}}\chi^T_{\alpha\beta}(v,u)$. Using the Weyl relations for W_0 one obtains from (5.14)

$$(x_1\otimes y_1,([B^{\sharp_1}_{V_1}B^{\sharp_2}_{V_2}](\chi')+[B^{\sharp_2}_{V_2}B^{\sharp_1}_{V_1}](\chi''))x_2\otimes y_2)=(y_1,([B^{\sharp_1}B^{\sharp_2}](\Psi)+[B^{\sharp_2}B^{\sharp_1}](\Psi^T))y_2),$$

where $\Psi_{\alpha\beta}(v,u)=(x_1,W_0(V_1(v)+V_2(u))x_2)\chi_{\alpha\beta}(v,u)$. The relation (4.9) follows now from (5.10). The proof of (4.10) will be complete by (5.11) and the definition (5.6) if we show that

$$\mathrm{Tr}\,\mathscr{O}_\Psi=\int (x_1,W_0(V_1(v)+V_2(v))x_2)\sum_{\alpha,\beta}(C^{-1}\gamma\cdot v)_{\alpha\beta}\chi_{\alpha\beta}(v,v)d\mu(v).$$

The rhs may be written as

$$\int (x_1,W_0(V_1(v))W_0(V_2(v))x_2)\sum_{\alpha,\beta}(C^{-1}\gamma\cdot v)_{\alpha\beta}\chi'_{\alpha\beta}(v,v)d\mu(v).$$

This formula defines a distribution on $\chi'\in\mathscr{S}$, so it is sufficient to take $\chi'=f\otimes g$, $f,g\in\mathscr{S}(H,\mathbf{C}^4)$. Then Ψ is given by (5.12) and

$$\begin{aligned}\mathrm{Tr}\,\mathscr{O}_\Psi&=\sum_{i=1}^{\infty}\overline{((x_1,W_0(V_1(.))\varphi_i)f^c}\,,(\varphi_i,W_0(V_2(.))x_2)g)\\&=\sum_{i=1}^{\infty}\int (x_1,W_0(V_1(.))\varphi_i)(\varphi_i,W_0(V_2(.))x_2)\overline{f^c(v)}\,\gamma\cdot v g(v)d\mu(v),\end{aligned}$$

which yields the desired relation by the Lebesgue theorem. This ends the proof of the conditions of our algebra.

VI. DISCUSSION AND OUTLOOK

We have shown how heuristic quantization of the asymptotic structure of classical field electrodynamics leads to the construction of an asymptotic algebra of fields, whose states may be expected to describe the structure of collision states in quantum electrodynamics, including the charged states. This algebra is a C^*-algebra, so there is no need for the indefinite metric formalism. The charged fields are accompanied by Coulomb fields, which solves the problem of Gauss' law in charged states. The construction depends on the choice of a class of ''satellite'' fields. This choice was left open to some extent. It corresponds to selecting various ''clouds'' of free radiation field accompanying the particle in addition to the Coulomb field. Three classes of satellite fields satisfying the defining conditions (i)–(iv) in Sec. IV are worth mentioning:

(a) the class of all fields satisfying the conditions (i)–(iv);
(b) the subclass consisting of fields of the form $V_a(v;s,l)=V_{ea}(v,l)+V_{0a}(s,l)$, where $V_{ea}(v,l)$, defined in (i), corresponds to the Coulomb field, and $V_{0a}\in L$;
(c) the subclass of fields for which $V_a(v;-\infty,l)$ does not depend on v.

The first choice is the most general one within the limits of our construction. The second possibility is the simplest one. In that case the smeared Weyl elements reduce to the (simple) Weyl elements, as the space $\mathscr{R}ad$ is then naturally isomorphic with L. We mention as an aside that an explicit faithful representation of the corresponding algebra can be constructed. The choice (c) has a clear physical interpretation: the long-range tail of the cloud accompanying the particle is chosen to compensate the velocity dependence of the tail of the Coulomb field. The total satellite field has then a velocity independent flux at spatial infinity.

The last possibility seems to be the one closest to the picture emerging from the analysis of superselection sectors structure in the algebraic framework of local observables. However, we leave the problem of specifying the physically justified choice of satellite fields open at present.

The solution of this problem may depend on the answer to the important question of whether our algebra may be obtained by some limiting procedure from the field algebra of the full theory. This seems a difficult problem, but the classical theory gives hints, how such a limiting process could look like. The quantum version of the null infinity limit of the electromagnetic field may be thought of as an LSZ-type limit in lightlike directions, which brings in mind the construction of Buchholz.[3] For the matter field one would have to choose a gauge in a class supplying a quantum analog of the class mentioned in Sec. II. An LSZ-type limit on the hyperboloid $x^2=\lambda^2$, $x^0>0$, with $\lambda\to\infty$ may then be expected to exist.

Important as the latter problem may be, the asymptotic algebra also deserves further investigations on its own. The following physically interesting problems may be posed within this framework.

(i) How can the local observables be characterized and what is their relation to the nonlocal ones? That the latter observables are present may be read off from the properties of the symplectic form.
(ii) The Poincaré group acts naturally on the algebra as a group of automorphisms. Do there exist irreducible Poincaré-covariant representations of the algebra? If so, which superselection structure of the algebra of local observables is implied? (We recall that in charged superselection sectors the Lorentz group has to be spontaneously broken.)
(iii) What is the measure class of the spectrum of energy-momentum in translation-covariant, positive energy representations (infraparticle problem)?

Finally, let us mention for completeness that the construction given in this paper may be reflected in time, yielding the asymptotic ''in''-algebra. If these two algebras fit into the interacting theory, the scattering problem may be considered. One may hope, for instance, that the perturbation calculus in a suitable gauge, starting from the quasi-free theory supplied by our algebra, should be infrared-regular.

ACKNOWLEDGMENTS

I would like to thank Professor D. Buchholz for his steady interest in my work. I have profited greatly from the many discussions which we had. A discussion with Professor R. Haag is also gratefully acknowledged. I am grateful to the II. Institut für Theoretische Physik, Universität Hamburg, for hospitality and to the Humboldt Foundation for financial support.

APPENDIX: EQUIVALENCE OF SPINOR AND TENSOR FORMULAS

We prove here the equivalence of tensor and spinor versions of those formulas which appear in Sec. II, but were given only in the spinor form in Ref. 16.

For $l_a=o_A\bar{o}_{A'}$ in the notation of Ref. 16, $\partial_A=\partial/\partial o^A$ and $\partial_a=\partial/\partial l^a$, one has $\partial_A\alpha(l)=\bar{o}^{A'}\partial_{AA'}\alpha(l)$, hence

$$(l_a\partial_b-l_b\partial_a)\alpha(l)=-(\epsilon_{A'B'}o_{(A}\partial_{B)}+\epsilon_{AB}\bar{o}_{(A'}\partial_{B')})\alpha(l), \tag{A1}$$

and the integral identity (2.10) is then equivalent to (A8) of Ref. 16.

The electromagnetic field tensor and spinor are connected by $F_{ab}=\epsilon_{A'B'}\varphi_{AB}+\epsilon_{AB}\bar{\varphi}_{A'B'}$, hence the field $\varrho_{AA'}(x)=\varphi_{AB}(x)x^B_{A'}$ [(2.28) in Ref. 16] is equivalently expressed as $\varrho_a(x)=x^b\,{}^-F_{ba}(x)$, where ${}^-F_{ba}$ is the anti-selfdual part of F_{ba}. Its null asymptotic $\lim_{R\to\infty}R\varrho_a(x+Rl)=N_a(x\cdot l,l)$ is given by $N_a(s,l)=\partial_{A'}\zeta_A(s,l)$, where $\zeta_A(s,l)=o_{A'}V^{A'}_A$, $V_a(s,l)$ defined in (2.1) [see Ref. 16, Eq. (2.44)]. We have

$$\partial_{A'}\zeta_A=-V_a+o_{B'}\partial_{A'}V^{B'}_A=-V_a-\tfrac{1}{2}\epsilon_{B'A'}o^{C'}\partial_{C'}V^{B'}_A+o_{(B'}\partial_{A')}V^{B'}_A\,.$$

In view of homogeneity (2.2) and using (A1) this may be written as

$$N_a(s,l)=\tfrac{1}{2}(s\dot{V}_a(s,l)-V_a(s,l))+{}^{+}(l_a\partial_b-l_b\partial_a)V^b(s,l),$$

where ${}^{+}(l_a\partial_b-l_b\partial_a)$ is the selfdual part of $l_a\partial_b-l_b\partial_a$. It was shown in Ref. 16 (and may be also shown without use of spinors) that from (2.2) and (2.3) now follows that the limit values $N_a(\pm\infty,l)$ are proportional to l_a, that is,

$$-\tfrac{1}{2}V_a(+\infty,l)+{}^{+}(l_a\partial_b-l_b\partial_a)V^b(+\infty,l)=-l_aq(l),$$

$$-\tfrac{1}{2}V_a(-\infty,l)+{}^{+}(l_a\partial_b-l_b\partial_a)V^b(-\infty,l)=-l_a\kappa(l),$$

which corresponds with the equations (2.54) and (2.56) of Ref. 16 (there we used $\sigma=\kappa-q$ instead of κ). The conditions of reality of q and κ [(3.32) in Ref. 16], and the above equations in that case are now equivalent to (2.5), and (2.6) and (2.7), respectively.

It was shown in Ref. 16 [Eq. (2.64)] that

$$o^{A'}V^{\text{out}}{}_{A'A}(-\infty,l)=\partial_A\Phi(l) \tag{A2}$$

for some $\Phi(l)$ homogeneous of degree 0. In view of (A1) this is equivalent to (2.14). The gauge of $V^{\text{out}}{}_a(-\infty,l)$ (2.17) is written with the use of (A1) as

$$V^{\text{out}}{}_a(-\infty,l)=\partial_A(o^Bg_{BA'}(l))+\partial_{A'}(o^{B'}g_{B'A}(l)).$$

As $o^Bg_{BA'}(l)$ are in 1:1 correspondence with G_{ab}, the gauge has the form $V^{\text{out}}{}_a(-\infty,l)=\partial_Ah_{A'}(o,\bar{o})+\partial_{A'}h_A(o,\bar{o})$, where $h_{A'}(\alpha o,\overline{\alpha o})=\bar{\alpha}^{-1}h_{A'}(o,\bar{o})$, $h_{A'}(o,\bar{o})o^{A'}=\Phi(l)$, and in the statements (i)–(iii) following (2.17) the tensor G_{ab} may be replaced by $h_{A'}(o,\bar{o})$ satisfying these conditions. This representation satisfies (A2), so (i) is proved. We get a special gauge choosing

$$h_{A'}(o,\bar{o})=\frac{t_{A'A}o^A}{t\cdot l}\,\Phi(l),$$

where t is any unit, positive timelike vector. Any other gauge differs by $\beta(l)l_a$, $\beta(l)$ homogeneous of degree -2. Let $\alpha(l)=\beta(l)-c(t\cdot l)^{-2}$, with such a constant c that $\int\alpha(l)d^2l=0$. There exists then a homogeneous of degree 0 function $A(l)$, such that $\partial_A\partial_{A'}A(l)=\frac{1}{2}o_Ao_{A'}\alpha(l)$. $A(l)$ is determined up to an additive constant. The new gauge is then determined by

$$h'_{A'}(o,\bar{o})=\frac{t_{A'A}o^A}{t\cdot l}\,(\Phi(l)+c)+\partial_{A'}A(l).$$

With this formula the statements (ii) and (iii) following (2.17) are seen to be true.

Finally, the angular momentum term ΔM_{ab} (2.22) is the tensor version of the angular momentum spinor term $\Delta\mu_{AB}=1/2\pi\int qo_{(A}\partial_{B)}\Phi d^2l$, easily obtained from $\Delta M_{ab}=\epsilon_{A'B'}\Delta\mu_{AB}+\epsilon_{AB}\overline{\Delta\mu}_{A'B'}$ by the use of (A1).

General properties between the canonical correlation and the independent-oscillator model on a partial *-algebra

Masao Hirokawa
Advanced Research Laboratory, Hitachi Ltd., Hatoyama, Saitama 350-03, Japan

(Received 22 May 1995; accepted for publication 8 August 1995)

We consider a quantum particle in thermal equilibrium with any quantum system in a finite volume under some conditions. For the Heisenberg operator of the momentum operator of the quantum particle, we show that, on a partial *-algebra, the Heisenberg operator satisfies a quantum Langevin equation, which is similar to the work of Ford *et al.* [G. W. Ford, J. T. Lewis, and R. F. O'Connell, Phys. Rev. A **37**, 4419 (1988)]. Through the Langevin equation, we show general and mathematical properties between the canonical correlation and the independent-oscillator model.
 [S0022-2488(96)02001-5]

I. INTRODUCTION

The independent-oscillator (IO) model is the model of the quantum particle surrounded by a large number of independent heat bath particles, each attached to the quantum particle by a spring. The Hamiltonian of the system is given by

$$H_{\mathrm{IO}} \overset{\mathrm{def}}{=} \frac{p^2}{2m} + V(x) + \sum_{j=1}^{\infty} \left[\frac{p_j^2}{2m_j} + \frac{1}{2} m_j \omega_j^2 (q_j - x)^2 \right]. \tag{1}$$

Here x and p are the coordinate and momentum operators of the quantum particle of mass m, while q_j and p_j are those of the jth heat bath particle of mass m_j. Of course, we have the usual commutation relations:

$$[x,\ p] = i\hbar, \quad [q_j,\ p_{j'}] = i\hbar\,\delta_{jj'}. \tag{2}$$

Here, $V(x)$ is the potential energy of the external force on the quantum particle. This model appeared in the literature.[1–5] Especially, Ford, Lewis, and O'Connell found the IO model to be convenient since other heat bath models can generally be related to the IO model in Ref. 4. They showed in Sec. IV of Ref. 4 that from the IO model H_{IO} we can derive the generalized quantum Langevin equation:

$$\frac{d}{dt} p(t) + \int_{-\infty}^{t} ds\ \mu(t-s) \frac{p(s)}{m} + V'(x) = F(t), \tag{3}$$

which is the momentum operator version of (2.1) in Ref. 4, where the prime denotes the derivative with respect to x. Here, $\mu(t)$ is the memory function given by

$$\mu(t) = \sum_{j=1}^{\infty} m_j \omega_j^2 \cos(\omega_j t)\, \theta(t), \tag{4}$$

where $\theta(t)$ is the Heaviside step function, and $F(t)$ is an operator-valued random force with mean zero, and a mean force characterized by a memory function $\mu(t)$. The symmetrized correlation function of $F(t)$ is given by

$$\frac{1}{2}\langle F(t)F(s)+F(s)F(t)\rangle_B=\frac{1}{2}\sum_{j=1}^{\infty}\hbar m_j\omega_j^3\coth(\hbar\omega_j/2kT)\cos[\omega_j(t-s)], \tag{5}$$

and the nonequal-time commutator of $F(t)$ is

$$[F(t),\,F(s)]=-i\sum_{j=1}^{\infty}\hbar m_j\omega_j^3\sin[\omega_j(t-s)]. \tag{6}$$

Here, for operator O, $\langle O\rangle_B$ means that $\langle O\rangle_B \overset{\text{def}}{=} \mathrm{tr}(Oe^{-H_B/kT})/\mathrm{tr}(e^{-H_B/kT})$, where

$$H_B \overset{\text{def}}{=} \sum_j\left[\frac{1}{2m_j}p_j^2+\frac{1}{2}m_j\omega_j^2q_j^2\right],$$

k is the Boltzmann constant, and T is absolute temperature. The Fourier–Laplace transform of the memory function is given as

$$[\mu](z)\overset{\text{def}}{=}\int_0^{\infty}dt\;e^{itz}\mu(t)=\frac{i}{2}\sum_{j=1}^{\infty}m_j\omega_j^2\left[\frac{1}{z-\omega_j}+\frac{1}{z+\omega_j}\right] \tag{7}$$

for every $\mathrm{Im}\,z>0$.

Furthermore, Li, Ford, and O'Connell investigated the symmetrized correlation of the coordinate operator and the quantum random force of the generalized quantum Langevin equation in Ref. 5.

Ford, Lewis, and O'Connell showed that properties (5) and (6) are characterization of the operator-valued random force $F(t)$ by the memory function $\mu(t)$ (see (2.2), (2.3), (4.13), and (4.14) in Ref. 4). And besides, in Sec. 3 in Ref. 1 Ford and Kac remarked that, in the generalized quantum Langevin equation, the correlation and commutator for the operator-valued random force must have the forms (5) and (6). Then, in this paper, we prove general properties including (5) and (6) between canonical correlation and the IO model on a partial *-algebra.[6–8] The partial *-algebra which we treat in this paper is given by a completion of a set of quantum operators. The completion is done by the Bogoliubov scalar product which gives the canonical correlation. In order to deal directly with bosonic operators which are unbounded, we choose the partial *-algebra, not C^*-algebra, for unbounded operators.

We consider a quantum particle in thermal equilibrium with any quantum system in a finite volume under conditions (**A.1**)–(**A.4**) below. From now on, we set the Planck constant $\hbar=1$. Let $H_{q,p,s}$ be an arbitrary total Hamiltonian which governs our system of the quantum particle with the quantum system such that $e^{-\beta H_{q,p,s}}$ is a trace class operator (where $\beta\equiv 1/kT$ denotes the inverse temperature). $H_{q,p,s}$ has the form of $H_{q,p,s}=p^2/2m+V(x)+H_{q,s}+H_{int}$, where $H_{q,s}$ denotes the Hamiltonian of a quantum system surrounding the quantum particle with (x,p), and H_{int} is the interaction Hamiltonian between the quantum particle and the quantum system. Here, of course, the form of $H_{q,s}+H_{\mathrm{int}}$ is unknown now. The canonical correlation function $R_p(t_1,t_2)$ for the momentum operator p is defined by

$$R_p(t_1,t_2)\overset{\text{def}}{=}\frac{1}{\beta\mathrm{tr}(e^{-\beta H_{q,p,s}})}\int_0^{\beta}d\lambda\;\mathrm{tr}(e^{-(\beta-\lambda)H_{q,p,s}}e^{iH_{q,p,s}t_1}pe^{-iH_{q,p,s}t_1}e^{-\lambda H_{q,p,s}}e^{iH_{q,p,s}t_2}pe^{-iH_{q,p,s}t_2}).$$

In Secs. II and III, for any p and $H_{q,p,s}$ satisfying (**A.1**)–(**A.4**), we prove that, on a partial *-algebra $\mathbf{X}_c(H_{q,p,s})$ which is called the Liouville space, the Heisenberg operator $p(t)\overset{\text{def}}{=}e^{iH_{q,p,s}t}pe^{-iH_{q,p,s}t}$ satisfies a quantum Langevin equation with a quantum fluctuation $I(t)$,

which has the similar form to (3) [see (17) in the main theorem]. Here we note that we cannot apply theories in Ref. 9 nor Ref. 10 to the momentum operator because of a condition (see Remark 3.2). We show that the memory function $\mu(t)$ for the IO model characterizes a fluctuation–dissipation relation in our Langevin equation and the canonical correlation function $R_p(t_1,t_2)$ [see (19) and (20) in the main theorem], which means that $H_{\rm int}$ is characterized by $[\mu](z)$. Furthermore the symmetrized autocorrelation and nonequal-time commutator of $I(t)$ have the similar representation to (5) and (6), which are implied by our fluctuation–dissipation relation [see (21) and (22) in the main theorem]. They are general results for p and $H_{q,p,s}$ in mathematics, so they give additional mathematical evidence that the IO model represents the system of the quantum particle with the most general quantum system, which was indicated by Ford, Lewis, and O'Connell in Ref. 4. It is a symmetry with respect to the canonical correlation that derives the close relations between the canonical correlation and the distribution of the memory function of the IO model (see Lemma 3.8 in this paper).

As mentioned above, some properties of the IO model was studied in Refs. 1–5. Especially Ford and Kac say on p.808 in Ref. 1: ''*since we have derived the quantum Langevin equation only for very special oscillator models (i.e. the IO model), one might wonder to what extent we have demonstrated the universality of the equation. The answer, of course, is that we have not. Rather, the logic is reversed: if there is a universal description, then it must be of the form we have obtained.*'' Ford, Lewis, and O'Connell showed in Ref. 4 that a number of other heat-bath models within the framework of the general macroscopic description of the quantum Langevin equation are reduced to the IO model by physically adequate reasons. In this paper, for the momentum operator of our system we shall derive a quantum Langevin equation by the general theory by Mori,[11,12] and show general properties between canonical correlation and the IO model. The author thinks that this argument is valid over not only the momentum operator of our system but also observables which are realized as self-adjoint operators in some class, which gives a physical and mathematical proof for Ford and Kac's remark above.

In Sec. IV B, we give some examples of the Hamiltonian $H_{q,p,s}$ and the momentum operator p satisfying assumptions (**A.1**)–(**A.4**).

II. THE STATEMENT OF THE MAIN THEOREM

In this section, in order to introduce canonical correlation functions defined by the Bogoliubov scalar product, the Liouville space, and explain our main theorem, we set up a general framework.

We consider a quantum particle in thermal equilibrium with any quantum system in the finite volume. So, we give a state space for our system by a separable infinite-dimensional Hilbert space, which is denoted simply by $\mathscr{F}_{q,p,s}$. And we denote the inner product of $\mathscr{F}_{q,p,s}$ by $(\ ,\ )_{q,p,s}$.

Let x and p be the coordinate and momentum operators of the quantum particle of mass m and $V(x)$ be the potential energy of the external force on the quantum particle.

For our system, there exists a Hamiltonian $H_{q,p,s}$ whose form is given by $H_{q,p,s}=p^2/2m+V(x)+H_{q,s}+H_{\rm int}$, where $H_{q,s}$ denotes the Hamiltonian of the quantum system surrounding the quantum particle with (x,p), and $H_{\rm int}$ is the interaction Hamiltonian between the quantum particle and the quantum system. Here, of course, the form of $H_{q,s}+H_{\rm int}$ is unknown now. So $H_{q,p,s}$ may be nonquadratic, but must be realized as a self-adjoint operator acting in the Hilbert space $\mathscr{F}_{q,p,s}$. Since we are now considering the thermal equilibrium quantum system, $H_{q,p,s}$ is a self-adjoint operator acting in $\mathscr{F}_{q,p,s}$ and we have the following assumption.

(**A.1**) $e^{-\tau H_{q,p,s}}$ is a trace class operator on $\mathscr{F}_{q,p,s}$ for every $\tau\in(0,\beta]$, where $\beta\equiv 1/kT$ is the inverse temperature. This condition implies that the spectra of $H_{q,p,s}$ are purely discrete and the eigenvectors $\{\varphi_n | n\in\mathbf{N}^*\}$ of $H_{q,p,s}$ form a complete orthonormal system of $\mathscr{F}_{q,p,s}$, where $\mathbf{N}^* \underset{\rm def}{=} \{0,1,\cdots\}$. We count the eigenvalues λ_n $(n\in\mathbf{N}^*)$ of $H_{q,p,s}$ in such a way that $H_{q,p,s}\varphi_n=\lambda_n\varphi_n$ and $0<\lambda_0\leqslant\lambda_1\leqslant\cdots\leqslant\lambda_n\leqslant\lambda_{n+1}\leqslant\cdots\nearrow\infty$.

For the Hamiltonian $H_{q,p,s}$, we can construct a Liouville space $\mathbf{X}_c(H_{q,p,s})$, which is a set of adequate quantum operators acting in $\mathscr{F}_{q,p,s}$.[9,13] We denote the linear hull of $\{\varphi_n | n \in \mathbf{N}^*\}$ by $\mathbf{D}_{q,p,s}$, i.e., $\mathbf{D}_{q,p,s} \stackrel{\text{def}}{=} \mathbf{L.h.}[\{\varphi_n | n \in \mathbf{N}^*\}]$. From here on, we denote the linear hull of a set S by $\mathbf{L.h.}[S]$. Obviously $\mathbf{D}_{q,p,s}$ is dense in $\mathscr{F}_{q,p,s}$. Further, we denote by $\mathbf{B}(\mathbf{D}_{q,p,s}, \mathscr{F}_{q,p,s})$ the space of bounded linear operators from $\mathbf{D}_{q,p,s}$ to $\mathscr{F}_{q,p,s}$. Every element A in $\mathbf{B}(\mathbf{D}_{q,p,s}, \mathscr{F}_{q,p,s})$ has a unique extension to an element in $\mathbf{B}(\mathscr{F}_{q,p,s})$, the space of bounded linear operators on $\mathscr{F}_{q,p,s}$. We denote the extension of A by A^-, and $A^* \restriction \mathbf{D}_{q,p,s}$ by A^+, which means that the domain of operator A^* is restricted to $\mathbf{D}_{q,p,s}$.

We first define a class $\mathbf{T}(H_{q,p,s})$ of quantum operators, which is a set of quantum operators A satisfying the following conditions: (**T.1**) the domain of each operator is equal to $\mathbf{D}_{q,p,s}$, and the domain of the adjoint operator of each operator includes $\mathbf{D}_{q,p,s}$ [i.e., $\mathrm{D}(A) = \mathbf{D}_{q,p,s}$ and $\mathrm{D}(A^*) \supset \mathbf{D}_{q,p,s}$, where $\mathrm{D}(B)$ denotes the domain of each operator B]; (**T.2**) for all τ in $(0,\beta]$ operators $e^{-\tau H_{q,p,s}} A$ and $A e^{-\tau H_{q,p,s}}$ are in $\mathbf{B}(\mathbf{D}_{q,p,s}, \mathscr{F}_{q,p,s})$, furthermore, $(e^{-\tau H_{q,p,s}} A)^-$ and $(A e^{-\tau H_{q,p,s}})^-$ are Hilbert–Schmidt operators on $\mathscr{F}_{q,p,s}$. We must now turn our attention to the unboundedness of operators because it is known that limits on the precision of the measurement of observables for bounded operators (e.g., fermion) and unbounded operators (e.g., boson) are different.[14–16] For unbounded operators, the problem of their domains is delicate, so we provide condition (**T.1**). Condition (**T.2**) addresses convergency with respect to the Bogoliubov scalar product.[9,13,17] We note here that $\mathbf{T}(H_{q,p,s})$ is a linear space. We can then introduce the Bogoliubov (Kubo–Mori) scalar product $\langle\ ;\ \rangle$ as

$$\langle A;B\rangle \stackrel{\text{def}}{=} \frac{1}{\beta Z(\beta)} \int_0^\beta d\lambda\ \mathrm{tr}((e^{-(\beta-\lambda)H_{q,p,s}} A^*)^- (e^{-\lambda H_{q,p,s}} B)^-), \quad A,B \in \mathbf{T}(H_{q,p,s}),$$

where $Z(\beta) \stackrel{\text{def}}{=} \mathrm{tr}(e^{-\beta H_{q,p,s}})$. It can be easily proven that $\langle\ ;\ \rangle$ is an inner product of $\mathbf{T}(H_{q,p,s})$ (see Ref. 13). The inner product introduces a norm: $\|A\|_{H_{q,p,s}} \stackrel{\text{def}}{=} \langle A;A\rangle^{1/2}$. We can therefore obtain the Liouville space $\mathbf{X}_c(H_{q,p,s})$ defined by a Hilbert space which is the completion of $\mathbf{T}(H_{q,p,s})$ with respect to the norm $\|\ \|_{H_{q,p,s}}$. It is interesting to note that $\mathbf{X}_c(H_{q,p,s})$ is a partial *-algebra with a unit (see Proposition 3.14 in Ref. 13). The definition of partial *-algebras is given in Refs. 6–8. We also note here that an element in $\mathbf{X}_c(H_{q,p,s})$ is not always an operator acting in $\mathscr{F}_{q,p,s}$. It is noteworthy that Naudts *et al.* attempted to argue in general about linear response theory on the Hilbert space which is constructed by a completion of a von Neumann algebra with KMS-state.[18] Roughly speaking, the von Neumann algebra with the KMS-state can be regarded as a set of quantum operators which can be taken as a statistical average with the KMS-condition, however the operators are bounded. So, for our purpose we do use the partial *-algebra instead of the von Neumann algebra because the operators we treat are unbounded. And we deal with Mori's theory on $\mathbf{X}_c(H_{q,p,s})$, which is just the partial *-algebra constructed by the completion concerning the Bogoliubov scalar product.

In order to introduce the Heisenberg operator $p(t)$ of the momentum operator, we define here the Liouville operator $\mathscr{L}_{q,p,s}$ determined by the Hamiltonian $H_{q,p,s}$.

We can define, for adequate operators A, the Liouville operator $\mathscr{L}_{q,p,s}$ by $\mathscr{L}_{q,p,s} A \stackrel{\text{def}}{=} [H_{q,p,s}, A] = H_{q,p,s} A - A H_{q,p,s}$ (see Lemma 3.8 in Ref. 13). The domain $\mathrm{D}(\mathscr{L}_{q,p,s})$ of the Liouville operator $\mathscr{L}_{q,p,s}$ then contains a dense subspace $\mathscr{D}_{q,p,s}$ of all elements $A \in \mathbf{T}(H_{q,p,s})$ satisfying that $H_{q,p,s} A$ and $A H_{q,p,s} \restriction \mathbf{D}_{q,p,s}$ are in $\mathbf{T}(H_{q,p,s})$; furthermore, Ax, $A^+ x$, $H_{q,p,s} Ax$, $H_{q,p,s} A^+ x$, $A H_{q,p,s} x$, and $A^+ H_{q,p,s} x$ are in $\mathbf{D}_{q,p,s}$ for all x in $\mathbf{D}_{q,p,s}$. Actually, the subspace $\mathscr{D}_{q,p,s}$ is a core for $\mathscr{L}_{q,p,s}$ [see (66) in Sec. IV B, Lemmas 3.7 and 3.8 in Ref. 13].

For every $A \in \mathbf{X}_c(H_{q,p,s})$, we denote the Heisenberg operator of A by $A(t)$ in the Liouville space $\mathbf{X}_c(H_{q,p,s})$, i.e.,

$$A(t) \stackrel{\text{def}}{=} e^{i\mathscr{L}_{q,p,s}t}A.$$

And we define the canonical autocorrelation function of A by

$$R_A(t) \stackrel{\text{def}}{=} R_A(0,t) \equiv \langle A(0);A(t)\rangle.$$

Remark 2.1: The time evolution $A(t)$ coincides with the Heisenberg picture $e^{iH_{q,p,s}t}Ae^{-iH_{q,p,s}t}$ for every quantum operator A in $\mathscr{D}_{q,p,s}$ and $t \in \mathbf{R}$ (see Proposition 3.13 in Ref. 13).

So, we denote the canonical autocorrelation function of the momentum operator p by $R_p(t)$. We define here a function $[R_p](z)$ ($z \in \mathbf{C}$ with $\operatorname{Im} z > 0$) by the Fourier–Laplace transform as

$$[R_p](z) \stackrel{\text{def}}{=} \int_0^\infty dt\ e^{itz}R_p(t).$$

Here, we have the properties concerning poles of $[R_p](z)$:

The spectra of $\mathscr{L}_{q,p,s}$ is given by the closure of the set of all $\lambda_m - \lambda_n$'s:

$$\sigma(\mathscr{L}_{q,p,s}) = \overline{\{\lambda_m - \lambda_n | m,n \in \mathbf{N}^*\}}^{\text{ closure}}, \tag{8}$$

which is proved in Lemma 3.1 in the following section.

There exist non-negative constants $A_{m,n}$ ($m,n \in \mathbf{N}^*$) such that

$$R_p(t) = \sum_{m,n \in \mathbf{N}^*} A_{m,n}e^{it(\lambda_m - \lambda_n)}, \tag{9}$$

whose proof is given by Lemma 3.2 in the following section.

We denote the set of all positive poles of $[R_p](z)$ by $\mathbf{P}_+^R$, and the set of all negative poles of $[R_p](z)$ by $\mathbf{P}_-^R$. Then, by (9) and the following assumption, each poles of $[R_p](z)$ agree with differences of two λ_n's.

(**A.2**) For $\mathbf{P}_+^R = \{\varepsilon_k | k = 0,1,\cdots\}$, $\inf_{k \in \mathbf{N}^*}(\varepsilon_{k+1} - \varepsilon_k) > 0$. Moreover, for $\mathbf{P}_-^R = \{\eta_k | k = 0,1,\cdots\}$, $\inf_{k \in \mathbf{N}^*}(\eta_k - \eta_{k+1}) > 0$.

We set the last two conditions: Because we consider a system governed by the Hamiltonian $H_{q,p,s} \equiv p^2/2m + V(x) + H_{q,s} + H_{\text{int}}$ with (**A.1**), the condition that $p \in \mathbf{T}(H_{q,p,s})$ is natural assumption.

(**A.3**) $p \in \mathbf{T}(H_{q,s,p})$. Furthermore,

$$\sum_{k=0}^{\infty} \left(\lim_{z \to \varepsilon_k} \frac{1}{i}(z - \varepsilon_k)[R_p](z) \right) \varepsilon_k^2 < \infty,$$

and

$$\sum_{k=0}^{\infty} \left(\lim_{z \to \eta_k} \frac{1}{i}(z - \eta_k)[R_p](z) \right) (-\eta_k)^2 < \infty.$$

(**A.4**) $\lim_{z \to 0; z \in \mathbf{C}^+} z[R_p](z) = 0$, where $\mathbf{C}^+ \stackrel{\text{def}}{=} \{z \in \mathbf{C} | \operatorname{Im} z > 0\}$.

Here we introduce the symmetrized autocorrelation function $S_p(t)$ by using well-known relation in Theorem 3 in Ref. 19. For $R_A(t)$ $(A \in \mathbf{X}_c(H_{q,p,s}))$, since $R_A(t)$ is continuous and positive-definite, there exists a unique measure Δ_A^{can} such that

$$R_A(t) = \int_{-\infty}^{\infty} e^{it\omega} \Delta_A^{\mathrm{can}}(d\omega)$$

according to Bochner's theorem. Then, we define the symmetrized autocorrelation function $S_A(t)$ for $A \in \mathbf{X}_c(H_{q,p,s})$ by

$$S_A(t) \underset{=}{\mathrm{def}} \int_{-\infty}^{\infty} e^{it\omega} \beta E_\beta(\omega) \Delta_A^{\mathrm{can}}(d\omega), \tag{10}$$

where $E_\beta(\omega)$ is the average energy of the harmonic oscillator with the frequency ω at temperature $T = 1/k\beta$,

$$E_\beta(\omega) = \frac{\hbar\omega}{2} \coth \frac{\beta\hbar\omega}{2}. \tag{11}$$

(We note here that we set $\hbar = 1$ in this paper.)

For $A \in \mathbf{X}_c(H_{q,p,s})$, we define the response function $P_A(t)$ by

$$P_A(t) \underset{=}{\mathrm{def}} -\beta \frac{d}{dt} \langle A; A(t) \rangle. \tag{12}$$

We have another Liouville space $\mathbf{X}_\beta(H_{q,p,s})$ by completion of $\mathbf{T}(H_{q,p,s})$ by the following inner product:[20] For $A, B \in \mathbf{T}(H_{q,p,s})$, we set

$$\langle A|B \rangle \underset{=}{\mathrm{def}} Z(\beta)^{-1} \mathrm{tr}(\{(Ae^{-\beta H_{q,p,s}/2})^-\} * \{(Be^{-\beta H_{q,p,s}/2})^-\}). \tag{13}$$

Then, we can define the Liouville operator $\mathscr{L}^{q,p,s}$ with certain dense domain in $\mathbf{X}_\beta(H_{q,p,s})$ (see Secs. II and III in Ref. 20) in the same way as $\mathscr{L}_{q,p,s}$. So we can get the Heisenberg operator $e^{i\mathscr{L}^{q,p,s}t} A$ for $A \in \mathbf{X}_\beta(H_{q,p,s})$, which denotes

$$A[t] \underset{=}{\mathrm{def}} e^{i\mathscr{L}^{q,p,s}t} A \in \mathbf{X}_\beta(H_{q,p,s}) \tag{14}$$

in order to distinguish it from $A(t) \in \mathbf{X}_c(H_{q,p,s})$.

We denote $Z(\beta)^{-1}$ tr $(Oe^{-\beta H q,p,s})$ by $\langle O \rangle$. Then, of course, the well-known relation (see Theorem 3 in Ref. 19) means the following proposition in our Liouville's spaces: If A is a symmetric operator acting in $\mathscr{F}_{q,p,s}$ with $A \in \mathbf{X}_c(H_{q,p,s})$ and $A \in \mathbf{X}_\beta(H_{q,p,s})$, then

$$S_A(t) = \tfrac{1}{2} \langle AA[t] + A[t]A \rangle. \tag{15}$$

We will prove this relation in Proposition 3.3 in the following section.

Furthermore, concerning the response function, of course a well-known fact in our version holds: If A is a symmetric operator acting in $\mathscr{F}_{q,p,s}$ with $A \in \mathbf{X}_c(H_{q,p,s})$ and $A \in \mathbf{X}_\beta(H_{q,p,s})$, then

$$P_A(t) = -i \langle [A, A[t]] \rangle, \tag{16}$$

where, of course, $[A, A[t]] = AA[t] - A[t]A$.We will also prove this relation in Proposition 3.4 in the following section.Now, we can state our main theorem.

Theorem: *Suppose that the total Hamiltonian $H_{q,p,s}$ of the system of the quantum particle with the quantum system, and the momentum operator p of the quantum particle, satisfy assumptions* (**A.1**), (**A.2**), (**A.3**), *and* (**A.4**). *Then the function* $[R_p](z)$ can be extended to a meromorphic function on the complex plane, *and the set* $\{\omega_j\}_{j=1}^{\infty}$ *of all positive zero points of* $[R_p]$ *is counted in such a way that*

$$\omega_j \in (\varepsilon_{j-1}, \varepsilon_j), \text{ with } \varepsilon_j > 0, \ j \in \mathbf{N}.$$

Give the mass m_j *of the particle of the quantum system by*

$$m_j = \frac{2mR_p(0)}{\omega_j^2 i[R_p]'(\omega_j)}, \text{ where } [R_p]'(z) \equiv d[R_p](z)/dz.$$

Let $\mu(t)$ *be the memory function of* H_{IO} *with frequency* ω_j *and mass* m_j *above, i.e.,*

$$\mu(t) = \sum_{j=1}^{\infty} m_j \omega_j^2 \cos(\omega_j t)\,\theta(t).$$

Then, there exist a memory function $\kappa_\tau(t)$ *and quantum fluctuation* $I(t)$ *such that the Heisenberg operator* $p(t) \equiv e^{i\mathscr{L}_{q,p,s}t}p$ *of the momentum operator satisfies the following quantum Langevin equation* :

$$\frac{d}{dt}p(t) + \lim_{\tau \uparrow t} \int_{-\infty}^{t} ds\ \kappa_\tau(t-s)\frac{p(s)}{m} = I(t) \tag{17}$$

on the Liouville space $\mathbf{X}_c(H_{q,p,s})$ *with*

$$\lim_{\tau \to \infty} \kappa_\tau(t) = \mu(t), \quad t > 0, \tag{18}$$

a fluctuation-dissipation relation :

$$\frac{R_p(0)}{m}\mu(t) = \langle I(0); I(t) \rangle, \quad t > 0, \tag{19}$$

with

$$\langle p; I(t) \rangle = 0, \quad t \in \mathbf{R},$$

and

$$[R_p](z) = R_p(0)\frac{1}{-iz + [\mu](z)/m}, \quad z \in \mathbf{C} \backslash \{\omega_j\}_{j=1}^{\infty}. \tag{20}$$

Furthermore, the fluctuation-dissipation relation (19) *implies that the symmetrized autocorrelation function* $S_I(t)$ *of* $I(t)$ *is*

$$S_I(t) = \frac{1}{2kT}\sum_{j=1}^{\infty} m_j \omega_j^3 \coth\left(\frac{\omega_j}{2kT}\right)\cos(\omega_j t), \tag{21}$$

and response function $P_I(t)$ *is*

$$P_I(t)=\frac{R_p(0)}{mkT}\sum_{j=1}^{\infty} m_j\omega_j^3 \sin(\omega_j t). \tag{22}$$

(*We note here we set* $\hbar=1$ *now.*)

Remark 2.2: $I(t)$ may be decomposed into a summation of $V'(x)$ and a certain quantum force $F(t)$. However, information in the theorem is not enough to decompose $I(t)$ in such a way. As a matter of fact, the fluctuation $I(t)$ is Mori's fluctuation on the Liouville space $\mathbf{X}_c(H_{q,p,s})$, and then $\mu(t)$ agrees with Mori's memory function multiplied by the mass m for $t\geqslant 0$ [see (42) and Lemma 3.10(c) in the following section].

III. PROOFS OF THE RESULTS

A. Preliminaries

We first prove some properties concerning the poles of $[R_p]\,(z)$.

The proof of (8) is given by the following lemma:

Lemma 3.1: The spectra of $\mathscr{L}_{q,p,s}$ is the closure of the set of all $\lambda_m-\lambda_n$'s:

$$\sigma(\mathscr{L}_{q,p,s})=\overline{\{\lambda_m-\lambda_n|m,n\in\mathbf{N}^*\}}^{\text{ closure}}.$$

Proof: Simple calculation implies that linear operators $\Phi_{m,n}\colon \mathbf{D}_{q,p,s}\to\mathbf{D}_{q,p,s}$, $m,n\in\mathbf{N}^*$ defined by

$$\begin{aligned} &\mathrm{D}(\Phi_{m,n})\overset{\text{def}}{=}\mathbf{D}_{q,p,s},\\ &\Phi_{m,n}x\overset{\text{def}}{=}\beta^{1/2}Z(\beta)^{1/2}W_{m,n}^{1/2}(\varphi_n,x)_{q,p,s}\varphi_m, \qquad x\in\mathbf{D}_{q,p,s};m,n\in\mathbf{N}^*, \end{aligned} \tag{23}$$

are eigenvectors of $\mathscr{L}_{q,p,s}$ (see Proposition 3.9 in Ref. 9), where

$$W_{m,n}\overset{\text{def}}{=}\begin{cases} \dfrac{\lambda_n-\lambda_m}{e^{-\beta\lambda_m}-e^{-\beta\lambda_n}} \text{ if } \lambda_m\neq\lambda_n,\\ \beta^{-1}e^{\beta\lambda_m} \text{ if } \lambda_m=\lambda_n. \end{cases}$$

The set of all $\Phi_{m,n}$'s is also a complete orthonormal system of $\mathbf{X}_c(H_{q,p,s})$ such that

$$\mathscr{L}_{q,p,s}\Phi_{m,n}=(\lambda_m-\lambda_n)\Phi_{m,n}, \quad m,n\in\mathbf{N}^*, \quad \Phi_{m,n}^{+}=\Phi_{n,m}, m,n\in\mathbf{N}^* \tag{24}$$

(see Proposition 3.9 in Ref. 9). It must be noted that

$$W_{m,n}>0, \quad m,n\in\mathbf{N}^*, \quad W_{m,n}=W_{n,m}, \quad m,n\in\mathbf{N}^*. \tag{25}$$

The complete orthonormal system, $\{\Phi_{m,n},|m,n\in\mathbf{N}^*\}$, gives a proof that the set of all spectra of the Liouville operator $\mathscr{L}_{q,p,s}$ are equal to the closure of the set of $\lambda_m-\lambda_n$ $(m,n\in\mathbf{N}^*)$. Q.E.D.

The proof of (9) is given as follows:

Lemma 3.2: There exist non-negative constants $A_{m,n}$ $(m,n\in\mathbf{N}^*)$ such that

$$R_p(t)=\sum_{m,n\in\mathbf{N}^*} A_{m,n}e^{it(\lambda_m-\lambda_n)}.$$

Proof: By the proof of Lemma 3.1, we obtain

$$R_p(t)=\langle p;e^{i\mathscr{L}_{q,p,s}t}p\rangle=\sum_{m,n\in\mathbf{N}^*}|\langle\Phi_{m,n};p\rangle|^2e^{it(\lambda_m-\lambda_n)}. \tag{26}$$

So taking

$$A_{m,n}=|\langle\Phi_{m,n};p\rangle|^2, \tag{27}$$

we get our lemma. Q.E.D.

The proofs of (15) and (16) are given in the following Propositions 3.3 and 3.4.

Proposition 3.3: If A is a symmetric operator acting in $\mathscr{F}_{q,p,s}$ with $A\in\mathbf{X}_c(H_{q,p,s})$ and $A\in\mathbf{X}_\beta(H_{q,p,s})$, then

$$S_A(t)=\tfrac{1}{2}\langle AA[t]+A[t]A\rangle=\tfrac{1}{2}\{\langle A|A[t]\rangle+\langle A[t]|A\rangle\}.$$

Proof: According to Sec. III in Ref. 20, we define operators $\Psi_{m,n}:\mathbf{D}_{q,p,s}\to\mathbf{D}_{q,p,s}$ by

$$\begin{gathered}\mathrm{D}(\Psi_{m,n})\underset{=}{\text{def}}\mathbf{D}_{q,p,s},\\ \Psi_{m,n}x\underset{=}{\text{def}}Z(\beta)^{1/2}e^{\beta\lambda_n/2}(\varphi_n,x)_{q,p,s}\varphi_m,\qquad x\in\mathbf{D}_{q,p,s};m,n\in\mathbf{N}^*,\end{gathered} \tag{28}$$

which are eigenvectors of $\mathscr{L}^{q,p,s}$ (see Proposition 3.9 in Ref. 20). They make also a complete orthonormal system of $\mathbf{X}_\beta(H_{q,p,s})$ such that

$$\mathscr{L}^{q,p,s}\Psi_{m,n}=(\lambda_m-\lambda_n)\Psi_{m,n},m,n\in\mathbf{N}^*,\quad \Psi^+_{m,n}=e^{\beta(\lambda_n-\lambda_m)/2}\Psi_{n,m},m,n\in\mathbf{N}^* \tag{29}$$

(see Proposition 3.9 in Ref. 20). Using expansions of A and $A[t]$ by $\Psi_{m,n}$'s, we have $\langle A|A[t]\rangle=\langle AA[t]\rangle$ and $\langle A[t]|A\rangle=\langle A[t]A\rangle$, where we used the assumption that A is symmetric.

Since $\frac{1}{2}\{\langle A|A[t]\rangle+\langle A[t]|A\rangle\}$ is continuous and positive-definite, there exists a unique measure Δ_A^{sym} such that

$$\frac{1}{2}\{\langle A|A[t]\rangle+\langle A[t]|A\rangle\}=\int_{-\infty}^{\infty}e^{it\omega}\Delta_A^{\mathrm{sym}}(d\omega)$$

according to Bochner's theorem.

By using expansions

$$A(t)=\sum_{m,n}\langle\Phi_{m,n};A\rangle e^{it(\lambda_m-\lambda_n)}\Phi_{m,n}\quad\text{in}\quad\mathbf{X}_c(H_{q,p,s}),$$

$$A[t]=\sum_{m,n}\langle\Psi_{m,n}|A\rangle e^{it(\lambda_m-\lambda_n)}\Psi_{m,n}\quad\text{in}\quad\mathbf{X}_\beta(H_{q,p,s}),$$

we have

$$\Delta_A^{\mathrm{can}}(d\omega)=\sum_{m,n}|\langle\Phi_{m,n};A\rangle|^2\delta_{(\lambda_m-\lambda_n)}(d\omega), \tag{30}$$

$$\Delta_A^{\mathrm{sym}}(d\omega)=\sum_{m,n}|\langle\Psi_{m,n}|A\rangle|^2\frac{1}{2}(\delta_{(\lambda_m-\lambda_n)}(d\omega)+\delta_{(\lambda_n-\lambda_m)}(d\omega))$$

$$=\sum_{m,n}\frac{|\langle\Psi_{m,n}|A\rangle|^2+|\langle\Psi_{n,m}|A\rangle|^2}{2}\delta_{(\lambda_m-\lambda_n)}(d\omega). \tag{31}$$

We note here

$$\langle\Phi_{m,n};A\rangle=\beta^{-1/2}Z(\beta)^{-1/2}W_{m,n}^{-1/2}(\varphi_m,A\varphi_n)_{q,p,s} \tag{32}$$

by (27) in Ref. 9, and

$$\langle\Psi_{m,n}|A\rangle=Z(\beta)^{-1/2}e^{-\beta\lambda_n/2}(\varphi_m,A\varphi_n)_{q,p,s}$$

by (46) in Ref. 20. So, we have

$$\left(\frac{|\langle\Psi_{m,n}|A\rangle|^2+|\langle\Psi_{n,m}|A\rangle|^2}{2}\right)(|\langle\Phi_{m,n};A\rangle|^2)^{-1}$$

$$=\frac{\beta W_{m,n}}{2}(e^{-\beta\lambda_m}+e^{-\beta\lambda_n})$$

$$=\frac{\beta(\lambda_m-\lambda_n)}{2}\,\frac{e^{\beta(\lambda_m-\lambda_n)}+1}{e^{\beta(\lambda_m-\lambda_n)}-1}$$

$$=\frac{\beta(\lambda_m-\lambda_n)}{2}\coth\left(\frac{\beta(\lambda_m-\lambda_n)}{2}\right).$$

Therefore, we obtain

$$\Delta_A^{\mathrm{sym}}(d\omega)=\beta\frac{\omega}{2}\coth\left(\frac{\beta\omega}{2}\right)\Delta_A^{\mathrm{can}}(d\omega). \tag{33}$$

Remember we set $\hbar=1$, and (33) implies our proposition. Q.E.D.

Proposition 3.4: If A is a symmetric operator acting in $\mathscr{F}_{q,p,s}$ with $A\in\mathbf{X}_c(H_{q,p,s})$ and $A\in\mathbf{X}_\beta(H_{q,p,s})$, then

$$P_A(t)=-i\langle[A,A[t]]\rangle=-i\{\langle A|A[t]\rangle-\langle A[t]|A\rangle\}.$$

Proof: This proposition is proved in the same way as Proposition 3.3. Q.E.D.

By (26), it is clear that, for any ε_k and η_k $(k\in\mathbf{N}^*)$ there exist $m^+(k),n^+(k)\in\mathbf{N}^*$; and $m^-(k),n^-(k)\in\mathbf{N}^*$ such that

$$\varepsilon_k=-(\lambda_{m^+(k)}-\lambda_{n^+(k)}), \tag{34}$$

$$\eta_k=-(\lambda_{m^-(k)}-\lambda_{n^-(k)}), \tag{35}$$

and for the zero, 0, there exist $m^0(k),n^0(k)\in\mathbf{N}^*$ such that

$$0=-(\lambda_{m^0(k)}-\lambda_{n^0(k)}). \tag{36}$$

For every $z\in\mathbf{C}$ with $z\neq0$ and $z\notin\mathbf{P}_\pm^R$, there exists a point $c\in\{0\}\cup\mathbf{P}_+^R\cup\mathbf{P}_-^R$ such that $|z-c|\leqslant|z-c'|$ for all $c'\in\{0\}\cup\mathbf{P}_+^R\cup\mathbf{P}_-^R$ by the assumption (**A.2**). So, we have

$$\left|\int_0^\infty dt\ e^{-itc'}e^{itz}\right|\leqslant\frac{1}{|z-c|}$$

if Im $z>0$. Thus, by applying Lebesgue's dominated convergence theorem to (26), we note that for Im $z>0$

$$[R_p](z)=i\sum_{k=0}^{\infty}\left(\sum_{\substack{m^+(k),n^+(k);\\ \lambda_{m^+(k)}-\lambda_{n^+(k)}=-\varepsilon_k}} A_{m^+(k),n^+(k)}\right)\frac{1}{z-\varepsilon_k}$$
$$+i\sum_{k=0}^{\infty}\left(\sum_{\substack{m^-(k),n^-(k);\\ -\lambda_{n^-(k)}=-\eta_k\lambda_{m^-(k)}}} A_{m^-(k),n^-(k)}\frac{1}{z-\eta_k}\right.$$
$$+i\sum_{k=0}^{\infty}\left(\sum_{\substack{m^0(k),n^0(k);\\ \lambda_{m^0(k)-\lambda_{n^0(k)}=0}} A_{m^0(k),n^0(k)}\right)\frac{1}{z}. \tag{37}$$

And, for $z\notin\{0\}\cup\mathbf{P}_+^R\cup\mathbf{P}_-^R$,

$$\left|\frac{d}{dz}\left(\frac{1}{z-c'}\right)\right|\leqslant\frac{1}{|z-c|^2}.$$

Thus, by applying Weierstrass' M-test to (37), it is evident that $[R_p](z)$ can be extended into a meromorphic function on the complex plain with singularities only at points in $\{0\}\cup\mathbf{P}_+^R\cup\mathbf{P}_-^R$ by (**A.3**) and (37).

For instance, for any $z\in\mathbf{C}$ with $|z-\varepsilon_k|<\min(\varepsilon_k-\varepsilon_{k-1},\varepsilon_{k+1}-\varepsilon_k)/2$, inequalities $|z-\varepsilon_k|\leqslant|z-\varepsilon_{k'}|$ and $|z-\varepsilon_k|\leqslant|z-\eta_{k'}|$ $(k'\in\mathbf{N}^*)$ hold. So, we get $|(z-\varepsilon_k)[R_p](z)|\leqslant\|p\|_{H_{q,p,s}}^2$ for the z above. Then, the following lemma is derived from (27) and (37) by Weierstrass' M-test.

Lemma 3.5: For each $k\in\mathbf{N}^*$,

$$\lim_{z\to\varepsilon_k}\frac{1}{i}(z-\varepsilon_k)[R_p](z)=\sum_{\substack{m^+(k),n^+(k);\\ \lambda_{m^+(k)}-\lambda_{n^+(k)}=-\varepsilon_k}} A_{m^+(k),n^+(k)},$$

$$\lim_{z\to\eta_k}\frac{1}{i}(z-\eta_k)[R_p](z)=\sum_{\substack{m^-(k),n^-(k);\\ \lambda_{m^-(k)}-\lambda_{n^-(k)}=-\eta_k}} A_{m^-(k),n^-(k)},$$

$$\lim_{z\to 0}\frac{1}{i}z[R_p](z)=\sum_{\substack{m^0(k),n^0(k);\\ \lambda_{m^0(k)-\lambda_{n^0(k)}=0}} A_{m^0(k),n^0(k)}.$$

Lemma 3.6: $p\in\mathrm{D}(\mathscr{L}_{a,b})$.

Proof: Assumption (**A.3**) and Lemma 3.5 imply our lemma. Q.E.D.

By using (34), (35), (36), and (37), we can decompose $R_p(t)$ into $R_p(t)=R_0+R_1(t)+R_2(t)$, where

$$R_0\overset{\text{def}}{=}-i\lim_{z\to 0;z\in\mathbf{C}^+}z[R_p](z)=\sum_{k=0}^{\infty}\left(\sum_{\substack{m^0(k),n^0(k);\\ \lambda_{m^0(k)-\lambda_{n^0(k)}=0}} A_{m^0(k),n^0(k)}\right),$$

$$R_1(t) \overset{\text{def}}{=} \sum_{k=0}^{\infty} \left(\sum_{\substack{m^+(k),n^+(k);\\ \lambda_{m^+(k)}-\lambda_{n^+(k)}=-\varepsilon_k}} A_{m^+(k),n^+(k)} \right) e^{-it\varepsilon_k}$$

$$= \sum_{k=0}^{\infty} \left(\sum_{\substack{m^+(k),n^+(k);\\ \lambda_{m^+(k)}-\lambda_{n^+(k)}=-\varepsilon_k}} |\langle \Phi_{m^+(k),n^+(k)}; p\rangle|^2 e^{it(\lambda_{m^+(k)}-\lambda_{n^+(k)})} \right), \tag{38}$$

$$R_2(t) \overset{\text{def}}{=} \sum_{k=0}^{\infty} \left(\sum_{\substack{m^-(k),n^-(k);\\ \lambda_{m-(k)}-\lambda_{n-(k)}=-\eta_k}} A_{m^-(k),n^-(k)} \right) e^{-it\eta_k}$$

$$= \sum_{k=0}^{\infty} \left(\sum_{\substack{m^-(k),n^-(k);\\ \lambda_{m-(k)}-\lambda_{n-(k)}=-\eta_k}} |\langle \Phi_{m^-(k),n^-(k)}; p\rangle|^2 e^{it(\lambda_{m^-(k)}-\lambda_{n^-(k)})} \right). \tag{39}$$

So, by (**A.4**), we have

$$R_p(t) = R_1(t) + R_2(t). \tag{40}$$

Then we define Mori's frequency ω_0 by

$$\omega_0 \overset{\text{def}}{=} -\langle p; \mathscr{L}_{q,p,s} p\rangle \langle p; p\rangle^{-1}. \tag{41}$$

(We changed the original definition of this frequency[11,12] into the above definition, see Sec. IV A.)

Next, we define Mori's fluctuation $I(t)$ for p by

$$I(t) \overset{\text{def}}{=} ie^{i\mathscr{L}_1 t}(1-\Pi_0)\mathscr{L}_{q,p,s} p, \quad t \in \mathbf{R}, \tag{42}$$

where Π_0 is an orthogonal projection operator onto the closed subspace $\mathbf{X}_c^-(H_{q,p,s})$ generated by p, i.e., $\Pi_0 \mathbf{X}_c(H_{q,p,s}) = \mathbf{X}_c^-(H_{q,p,s}) \overset{\text{def}}{=} \overline{\{\alpha p \in \mathbf{X}_c(H_{q,p,s}) | \alpha \in \mathbf{C}\}}^{\|\ \|_{H_{q,p,s}}}$.[9,13] We denote here the closure of a linear subspace S of $\mathbf{X}_c(H_{q,p,s})$ by $\bar{S}$. And $\mathscr{L}_1$ is a self-adjoint operator acting in the Hilbert space $(1-\Pi_0)\mathbf{X}_c(H_{q,p,s})$, which is defined by $\mathscr{L}_1 A \overset{\text{def}}{=} (1-\Pi_0)\mathscr{L}_{q,p,s} A$ for $A \in \mathrm{D}(\mathscr{L}_1) \overset{\text{def}}{=} \mathrm{D}(\mathscr{L}_{q,p,s}) \cap (1-\Pi_0)\mathbf{X}_c(H_{q,p,s})$.[10]

We now define symmetric operator $\mathscr{V}$ acting in $\mathbf{X}_c(H_{q,p,s})$ by $D(\mathscr{V}) \overset{\text{def}}{=} D(\mathscr{L}_{q,p,s})$; and $\mathscr{V} \overset{\text{def}}{=} -(\Pi_0 \mathscr{L}_{q,p,s} + \mathscr{L}_{q,p,s}\Pi_0) + \Pi_0 \mathscr{L}_{q,p,s}\Pi_0$. We note here that $\Pi_0 C \in D(\mathscr{L}_{q,p,s})$ for every $C \in \mathbf{X}_c(H_{q,p,s})$ since $p \in D(\mathscr{L}_{q,p,s})$. It is evident that $(1-\Pi_0)\mathscr{L}_{q,p,s}(1-\Pi_0) = \mathscr{L}_{q,p,s} + \mathscr{V}$ on $D(\mathscr{L}_{q,p,s})$. Let $C_n \in D(\mathscr{L}_{q,p,s})$ $(n \in \mathbf{N})$ with conditions $\sup_{n\in\mathbf{N}} \|C_n\|_{H_{q,p,s}} < \infty$, and $\sup_{n\in\mathbf{N}} \|\mathscr{L}_{q,p,s} C_n\|_{H_{q,p,s}} < \infty$. Then, there exist subsequences $\{C_\kappa\}_\kappa \subset \{C_n\}_n$ and vectors $B_1, B_2 \in \mathbf{X}_c(H_{q,p,s})$ such that $\mathrm{w}-\lim_{\kappa\to\infty} C_\kappa = B_1$ and $\mathrm{w}-\lim_{\kappa\to\infty} \mathscr{L}_{q,p,s} C_\kappa = B_2$. It follows that $\mathrm{s}-\lim_{\kappa\to\infty} \Pi_0 C_\kappa = \Pi_0 B_1$ and $\mathrm{s}-\lim_{\kappa\to\infty} \Pi_0 \mathscr{L}_{q,p,s} C_\kappa = \Pi_0 B_2$ since Π_0 is a finite rank operator, so a compact operator. And besides, we have

$$\mathscr{L}_{q,p,s}\Pi_0 C_\kappa = \frac{\langle p; C_\kappa\rangle}{\langle p, p\rangle} \mathscr{L}_{q,p,s} p \to \frac{\langle p; B_1\rangle}{\langle p; p\rangle} \mathscr{L}_{q,p,s} p$$

as $\kappa\to\infty$. Therefore, we have

$$\mathscr{V}C_\kappa\to-\Pi_0B_2+\frac{\langle p;B_1\rangle}{\langle p;p\rangle}(-\mathscr{L}_{q,p,s}p+\Pi_0\mathscr{L}_{q,p,s}p)$$

as $\kappa\to\infty$. Thus, $\mathscr{V}$ is relatively compact with respect to $\mathscr{L}_{q,p,s}$, so that $\mathscr{L}_{q,p,s}+\mathscr{N}$ is self-adjoint, and $\sigma_{ess}(\mathscr{L}_{q,p,s})=\sigma_{ess}(\mathscr{L}_{q,p,s}+\mathscr{V})$, where $\sigma_{ess}(A)$ denotes the set of all essential spectra of closed operator A. Hence following lemma follows from Lemma 3.1:

Lemma 3.7: The spectrum of projected Liouville operator $\mathscr{L}_1$ has isolated points and their accumulating points only, and

$$\sigma_{ess}(\mathscr{L}_1)\subset\overline{\{\lambda_m-\lambda_n|m,n\in\mathbf{N}^*\}}^{\text{closure}}.$$

Remark 3.1: Under the condition of $\mathscr{L}_{q,p,s}\Pi_0\supset\Pi_0\mathscr{L}_{q,p,s}$, the same statement as Lemma 3.7 was proved in Theorem 4.7 in Ref. 9. However, the method in the proof of Lemma 3.7 tells us that the condition above is superfluous and so strong that the discussion of Mori's theory (see Erratum for Ref. 9). So, arguments in Secs. IV and V in Ref. 9 do not need the condition of $\mathscr{L}_{q,p,s}\Pi_0\supset\Pi_0\mathscr{L}_{q,p,s}$.

Quite generally, the Heisenberg operator $p(t)\overset{\text{def}}{=}e^{i\mathscr{L}_{q,p,s}t}p$ satisfies Mori's memory kernel equation (or Langevin equation)[9,11,12] if $p\in\mathrm{D}(\mathscr{L}_{q,p,s})$:

$$\frac{d}{dt}p(t)=-i\omega_0p(t)-\int_0^t ds\ \phi(t-s)p(s)+I(t),\quad t\in\mathbf{R}\tag{43}$$

on $\mathbf{X}_c(H_{q,p,s})$ (see Sec. IV A in this paper). Mori's memory kernel equation (43) shows the existence of Mori's memory function $\phi(t)$ satisfying the fluctuation-dissipation relation. Namely, Mori's memory function $\phi(t)$ is related to the canonical autocorrelation function of Mori's fluctuation $I(t)$ by the following fluctuation-dissipation relation:

$$\langle p;p\rangle\phi(t)=\langle I(0);I(t)\rangle,\quad t\in\mathbf{R},\tag{44}$$

with orthogonality between p and $I(t)$ $(t\in\mathbf{R})$, i.e.,

$$\langle p;I(t)\rangle=0,\quad t\in\mathbf{R}.\tag{45}$$

We note that (43) and (45) imply that

$$\frac{d}{dt}R_p(t)=-i\omega_0R_p(t)-\int_0^t ds\ \phi(t-s)R_p(s),\quad t\in\mathbf{R}.\tag{46}$$

We define here a function $[\phi](z)$ $(z\in\mathbf{C}$ with $\mathrm{Im}\,z>0)$ by

$$[\phi](z)\overset{\text{def}}{=}\int_0^\infty dt\ e^{itz}\phi(t).$$

For proving our main theorem, we prepare some lemmas.

The following Lemma 3.8 shows important symmetric properties which the Bogoliubov scalar product has:

Lemma 3.8:

(a) For each $m,n\in\mathbf{N}^*$, $|\langle\Phi_{m,n};p\rangle|^2=|\langle\Phi_{n,m};p\rangle|^2$ holds. Namely, $A_{m,n}=A_{n,m}$.

(b) For every $t\in\mathbf{R}$, $R_1(-t)=R_2(t)$, so $R_p(t)=R_1(t)+R_1(-t)$ and $R_1(0)=R_2(0)=R_p(0)/2$.

(c) For every $t\in\mathbf{R}$, $-\dot{R}_1(-t)=\dot{R}_2(t)$, where $\dot{R}_j(t)\overset{\text{def}}{=}dR_j(t)/dt$ $(j=1,2)$. So, $\dot{R}_p(t)=\dot{R}_1(t)-\dot{R}_1(-t)$ and $\dot{R}_p(0)=0$.

(d) For each $k\in\mathbf{N}^*$, $\varepsilon_k=-\eta_k$.

Proof: By (23) and (25), we have

$$\begin{aligned}\beta^{-1/2}Z(\beta)^{-1/2}W_{m,n}^{-1/2}\langle\Phi_{m,n};p\rangle&=(\varphi_m,p\varphi_n)_{q,p,s}\\&=(p\varphi_m,\varphi_n)_{q,p,s}\\&=\overline{(\varphi_n,p\varphi_m)_{q,p,s}}\\&=\beta^{-1/2}Z(\beta)^{-1/2}W_{m,n}^{-1/2}\overline{\langle\Phi_{n,m};p\rangle},\end{aligned}$$

which implies

$$\langle\Phi_{m,n};p\rangle=\overline{\langle\Phi_{n,m};p\rangle},\quad m,n\in\mathbf{N}^*. \tag{47}$$

Therefore, we obtain part (a).

Let $\mathcal{N}(\mathcal{L}_{q,p,s}-\alpha)$ be the space of the all eigenvectors of $\mathcal{L}_{q,p,s}$ with the eigenvalue α. By part (a), if $\langle\Phi_{m^+(k),n^+(k)};p\rangle\neq 0$, then $\langle\Phi_{n^+(k),m^+(k)};p\rangle\neq 0$, and $\varepsilon_k=\lambda_{n^+(k)}-\lambda_{m^+(k)}>0$. So, by the expansion (26) of $R_p(t)$, the point $-\varepsilon_k$ must be a negative pole of $[R_p](z)$, i.e., $-\varepsilon_k\in\mathbf{P}_-^R$. Thus, for any $k\in\mathbf{N}^*$ there exists $\tilde{k}\in\mathbf{N}^*$ such that $-\varepsilon_k=\eta_{\tilde{k}}$, i.e.,

$$-(\lambda_{m^+(k)}-\lambda_{n^+(k)})=\varepsilon_k=-\eta_{\tilde{k}}=\lambda_{m^-(\tilde{k})}-\lambda_{n^-(\tilde{k})}. \tag{48}$$

Conversely, for any $k'\in\mathbf{N}^*$ there exists $\overline{k'}\in\mathbf{N}^*$ such that $-\eta_{k'}=\varepsilon_{\overline{k'}}$, i.e.,

$$-(\lambda_{m^-(k')}-\lambda_{n^-(k')})=\eta_{k'}=-\varepsilon_{\bar{k}'}=\lambda_{m^+(\bar{k}')}-\lambda_{n^+(\bar{k}')}. \tag{49}$$

By assumption (**A.2**), there is a one-to-one correspondence ι between $\mathbf{N}^*$ and $\mathbf{N}^*$, which induces a one-to-one correspondence ϑ between $\mathbf{P}_+^R$ and $\mathbf{P}_-^R$, i.e.,

$$\iota:\mathbf{N}^*\ni k\mapsto\iota(k)\overset{\text{def}}{=}\tilde{k}\in\mathbf{N}^*,\quad \iota^{-1}:\mathbf{N}^*\ni k'\mapsto\iota^{-1}(k')\overset{\text{def}}{=}\bar{k}'\in\mathbf{N}^*,$$

$$\vartheta:\mathbf{P}_+^R\ni\varepsilon_k\mapsto\vartheta(\varepsilon_k)\overset{\text{def}}{=}\eta_{\tilde{k}}=-\varepsilon_k\in\mathbf{P}_-^R,$$

$$\vartheta^{-1}:\mathbf{P}_-^R\ni\eta_{k'}\mapsto\vartheta^{-1}(\eta_{k'})\overset{\text{def}}{=}\varepsilon_{\bar{k}'}=-\eta_{k'}\in\mathbf{P}_+^R.$$

Moreover, by (48), $\Phi_{n^+(k),m^+(k)}$ is an eigenvector of $\mathcal{L}_{q,p,s}$ with the eigenvalue $\lambda_{m^-(\tilde{k})}-\lambda_{n^-(\tilde{k})}=-\eta_{\tilde{k}}$, i.e.,

$$\Phi_{n^+(k),m^+(k)}\in\mathcal{N}(\mathcal{L}_{q,p,s}+\eta_{\iota(k)}). \tag{50}$$

Similarly, by (49) we get

$$\Phi_{n^-(k'),m^-(k')}\in\mathcal{N}(\mathcal{L}_{q,p,s}+\varepsilon_{\iota^{-1}(k')}). \tag{51}$$

We define a map $\Xi:\cup_{\alpha\in\sigma(\mathcal{L}_{q,p,s})}\mathcal{N}(\mathcal{L}_{q,p,s}-\alpha)\to\cup_{\alpha\in\sigma(\mathcal{L}_{q,p,s})}\mathcal{N}(\mathcal{L}_{q,p,s}-\alpha)$ by $\Xi\Phi_{m,n}\overset{\text{def}}{=}\Phi_{n,m}$. By (50) and (51), we have

$$\Xi\Phi_{m^+(k),n^+(k)}\in\mathcal{N}(\mathscr{L}_{q,p,s}+\eta_{\iota(k)}),$$

$$\Xi\Phi_{m^-(\iota(k)),n^-(\iota(k))}\in\mathcal{N}(\mathscr{L}_{q,p,s}+\varepsilon_{\iota^{-1}(\iota(k))})=\mathcal{N}(\mathscr{L}_{q,p,s}+\varepsilon_k).$$

Hence it follows that

$$\Xi\mathcal{N}(\mathscr{L}_{q,p,s}+\varepsilon_k)=\mathcal{N}(\mathscr{L}_{q,p,s}+\eta_{\tilde{k}}),\quad k\in\mathbf{N}^*. \tag{52}$$

In the same way, we get

$$\Xi\mathcal{N}(\mathscr{L}_{q,p,s}+\eta_{k'})=\mathcal{N}(\mathscr{L}_{q,p,s}+\varepsilon_{\bar{k}'}),\quad k'\in\mathbf{N}^*. \tag{53}$$

We have

$$\sum_{\substack{m^-(\tilde{k}),n^-(\tilde{k});\\ \lambda_{m^-(\tilde{k})}-\lambda_{n^-(\tilde{k})}=-\eta_{\tilde{k}}}}|\langle\Phi_{n^+(k),m^+(k)};p\rangle|^2=\sum_{\substack{m^-(\tilde{k}),n^-(\tilde{k});\\ \lambda_{m^-(\tilde{k})}-\lambda_{n^-(\tilde{k})}=-\eta_{\tilde{k}}}}|\langle\Phi_{m^-(\tilde{k}),n^-(\tilde{k})};p\rangle|^2 \tag{54}$$

since ι and ϑ are one-to-one correspondences, equalities (52) and (53) hold, and the pair $(m^-(\tilde{k}),n^-(\tilde{k}))$ in the summation of

$$\sum_{\substack{m^-(\tilde{k}),n^-(\tilde{k});\\ \lambda_{m-(\tilde{k})}-\lambda_{n-(\tilde{k})}=-\eta_{\tilde{k}}}}|\langle\Phi_{n^+(k),m^+(k)};p\rangle|^2$$

runs over all indices of eigenvectors of $\mathscr{L}_{q,p,s}$ with eigenvalue $-\eta_{\tilde{k}}$. So, by using part (a), (48), the one-to-one correspondences, and (54), we have

$$\begin{aligned}
R_1(-t)&=\sum_{k=0}^{\infty}\left(\sum_{\substack{m^+(k),n^+(k);\\ \lambda_{m^+(k)}-\lambda_{n^+(k)}=-\varepsilon_k}}|\langle\Phi_{m^+(k),n^+(k)};p\rangle|^2\exp[-it(\lambda_{m^+(k)}-\lambda_{n^+(k)})]\right)\\
&=\sum_{k=0}^{\infty}\left(\sum_{\substack{m^+(k),n^+(k);\\ \lambda_{m^+(k)}-\lambda_{n^+(k)}=-\varepsilon_k}}|\langle\Phi_{n^+(k),m^+(k)};p\rangle|^2\exp[it\varepsilon_k]\right)\\
&=\sum_{\tilde{k}=0}^{\infty}\left(\sum_{\substack{m^-(\tilde{k}),n^-(\tilde{k});\\ \lambda_{m^-(\tilde{k})}-\lambda_{n^-(\tilde{k})}=-\eta_{\tilde{k}}}}|\langle\Phi_{n^+(k),m^+(k)};p\rangle|^2\right)\exp[-it\eta_{\tilde{k}}]\\
&=\sum_{\tilde{k}=0}^{\infty}\left(\sum_{\substack{m^-(\tilde{k}),n^-(\tilde{k});\\ \lambda_{m^-(\tilde{k})}-\lambda_{n^-(\tilde{k})}=-\eta_{\tilde{k}}}}|\langle\Phi_{m^-(\tilde{k}),n^-(\tilde{k});p}\rangle|^2\right)\exp[-it\eta_{\tilde{k}}]\\
&=\sum_{k=0}^{\infty}\left(\sum_{\substack{m^-(k),n^-(k);\\ \lambda_{m^-(k)}-\lambda_{n^-(k)}=-\eta_k}}|\langle\Phi_{m^-(k),n^-(k)};p\rangle|^2\right)\exp[-it\eta_k]\\
&=\sum_{k=0}^{\infty}\left(\sum_{\substack{m^-(k),n^-(k);\\ \lambda_{m^-(k)}-\lambda_{n^-(k)}=-\eta_k}}|\langle\Phi_{m^-(k),n^-(k)};p\rangle|^2\exp[it(\lambda_{m^-(k)}-\lambda_{n^-(k)})]\right)=R_2(t),
\end{aligned}$$

thus, we have $R_1(-t)=R_2(t)$. Since we know the decomposition of $R_p(t)=R_1(t)+R_2(t)$ in (40) and $R_1(-t)=R_2(t)$, we get $R_p(0)=R_1(0)+R_2(0)=2R_1(0)=2R_2(0)$. So, we obtain part (b). Part (c) depends on part (b).

Part (d) follows from (48), (49) and $\varepsilon_k<\varepsilon_{k+1}$, $\eta_{k+1}<\eta_k$ in (**A.2**). Q.E.D.

Remark 3.2: The fact, $\lim_{z\to 0}[R_p](z)=0$ in the following Lemma 3.9(a) means that we cannot deal with the momentum operator p in our case in the same way as Ref. 9. Furthermore, we cannot apply the theory KMO-Langevin equation[10] to our case.

Lemma 3.9:

(a) $\omega_0=0$ holds, and $\lim_{z\to 0}[R_p](z)=0$.

(b) $[R_p]\,(z)$ can be extended to a meromorphic function on the complex plane.

(c) $[\phi](z)$ can be also extended to a meromorphic function on the complex plane. And the set of all positive zero points of $[R_p]\,(z)$ is equal to the set of all positive poles of $[\phi](z)$. Furthermore, if γ is a pole of $[\phi](z)$, then γ is a pole of the first order of $[\phi](z)$, and besides, there exists $k\in\mathbf{N}^*$ such that $\gamma\in(\varepsilon_k,\,\varepsilon_{k+1})$ or $\gamma\in(-\varepsilon_{k+1},-\varepsilon_k)$, and $-\gamma$ is an eigenvalue of the projected Liouville operator $\mathscr{L}_1$.

Proof: First, we prove part (a). By Lemma 3.8(c), we have $\omega_0\equiv-\langle p;\mathscr{L}_{q,p,s}p\rangle\langle p;p\rangle^{-1}=i\dot{R}_p(0)/R_p(0)=0$, where the dot denotes the derivative with respect to t.

We note here assumption (**A.2**) implies that $\inf\{\varepsilon_k|\langle\Phi_{m^+(k),n^+(k)};p\rangle\neq 0\}=\varepsilon_0>0$. Then, by (38), (39), and (40), we have by Lemma 3.8

$$[R_p](z)=i\sum_{k=0}^{\infty}\left(\sum_{\substack{m^+(k),n^+(k);\\ \lambda_{m^+(k)}-\lambda_{n^+(k)}=-\varepsilon_k}}A_{m^+(k),n^+(k)}\right)\left(\frac{1}{z-\varepsilon_k}+\frac{1}{z+\varepsilon_k}\right),\tag{55}$$

and for any $z\in\mathbf{C}$ with $|z|<\varepsilon_0/2$ and $|z|\leqslant\inf_{k\in\mathbf{N}}(\varepsilon_{k+1}-\varepsilon_k)/2$, we get $\varepsilon_0/2\leqslant|z\pm\varepsilon_0|\leqslant|z\pm\varepsilon_k|$ $(k\in\mathbf{N}^*)$, so we have

$$\sum_{k=0}^{\infty}\left(\sum_{\substack{m^+(k),n^+(k);\\ \lambda_{m^+(k)}-\lambda_{n^+(k)}=-\varepsilon_k}}A_{m^+(k),n^+(k)}\right)\left|\frac{1}{z\pm\varepsilon_k}\right|\leqslant\frac{2}{\varepsilon_0}\sum_{k=0}^{\infty}\sum_{\substack{m^+(k),n^+(k);\\ \lambda_{m^+(k)}-\lambda_{n^+(k)}=-\varepsilon_k}}A_{m^+(k),n^+(k)}.$$

By using the above inequality and Weierstrass' M-test, we obtain

$$\lim_{z\to 0}[R_p](z)=i\sum_{k=0}^{\infty}\left(\sum_{\substack{m^+(k),n^+(k);\\ \lambda_{m^+(k)}-\lambda_{n^+(k)}=-\varepsilon_k}}A_{m^+(k),n^+(k)}\right)\left(-\frac{1}{\varepsilon_k}+\frac{1}{\varepsilon_k}\right)=0,$$

which is a proof of part (a).

Part (b) follows from (55).

The Fourier–Laplace transform of (46) implies that

$$[R_p](z)=\frac{R_p(0)}{i\omega_0-iz+[\phi](z)}.\tag{56}$$

So, by part (a) and (56), we have

$$[\phi](z)=iz+\frac{R_p(0)}{[R_p](z)}.\tag{57}$$

We note that $[\phi](z)$ is meromorphic on the complex plane by (57). Let $-\gamma'$ be a pole of $[\phi](z)$. Then $-\gamma'$ is a zero point of $[R_p]\,(z)$ by (57), so there exists $p\in\mathbf{N}^*$ such that $-\gamma'\in(\varepsilon_k,\varepsilon_{k+1})$ by solving the following equation:

$$0=\frac{1}{i}[R_p](z)=\sum_{k=0}^{\infty}\left(\sum_{\substack{m^+(k),n^+(k);\\ \lambda_{m^+(k)}-\lambda_{n^+(k)}=-\varepsilon_k}} A_{m^+(k),n^+(k)}\right)\left(\frac{\mathrm{Re}\ z-\varepsilon_k}{(\mathrm{Re}\ z-\varepsilon_k)^2+(\mathrm{Im}\ z)^2}\right.$$
$$\left.+\frac{\mathrm{Re}\ z+\varepsilon_k}{(\mathrm{Re}\ z+\varepsilon_k)^2+(\mathrm{Im}\ z)^2}\right)-i(\mathrm{Im}\ z)\sum_{k=0}^{\infty}\left(\sum_{\substack{m^+(k),n^+(k);\\ \lambda_{m^+(k)}-\lambda_{n^+(k)}=-\varepsilon_k}} A_{m^+(k),n^+(k)}\right)$$
$$\times\left(\frac{1}{(\mathrm{Re}\ z-\varepsilon_k)^2+(\mathrm{Im}\ z)^2}+\frac{1}{(\mathrm{Re}\ z+\varepsilon_k)^2+(\mathrm{Im}\ z)^2}\right)$$

by (55), and

$$\lim_{z\to-\gamma'}\frac{1}{i}(z+\gamma')[\phi](z)=\lim_{z\to-\gamma'}\left((z+\gamma')z-iR_p(0)\frac{z+\gamma'}{[R_p](z)-[R_p](-\gamma')}\right)$$
$$=-i\frac{R_p(0)}{\dfrac{d}{dz}[R_p](z)\rceil_{z=-\gamma'}}$$

by (57) because $[R_p](-\gamma')=0$. And besides, by (55), we get

$$\frac{d[R_p](z)}{dz}=-i\sum_{k=0}^{\infty}\left(\sum_{\substack{m^+(k),n^+(k);\\ \lambda_{m^+(k)}-\lambda_{n^+(k)}=-\varepsilon_k}} A_{m^+(k),n^+(k)}\right)\left(\frac{1}{(z-\varepsilon_k)^2}+\frac{1}{(z+\varepsilon_k)^2}\right),$$

which implies

$$i\frac{d[R_p](z)}{dz}\rceil_{z=-\gamma'}=\sum_{k=0}^{\infty}\left(\sum_{\substack{m^+(k),n^+(k);\\ \lambda_{m^+(k)}-\lambda_{n^+(k)}=-\varepsilon_k}} A_{m^+(k),n^+(k)}\right)\left(\frac{1}{(\gamma'+\varepsilon_k)^2}+\frac{1}{(\gamma'-\varepsilon_k)^2}\right)>0.$$

Thus, $-\gamma'$ is a pole of the first order of $[\phi](z)$.

Let $\mathscr{P}^1(d\xi)$ be the spectral measure of $\mathscr{L}_1$:

$$\mathscr{L}_1=\int_{\mathbf{R}}\xi\ d\mathscr{P}^1_\xi.$$

Let $\tilde{p}\overset{\mathrm{def}}{=}(1-\Pi_0)\mathscr{L}_{q,p,s}p$. The equality

$$\left\langle\tilde{p};\frac{1}{-z-\mathscr{L}_1}\tilde{p}\right\rangle=i\langle p;p\rangle[\phi](z)$$

follows from (42), (44) and a simple calculation. And, by well-known fact, we have for every $\delta>0$

$$\mathscr{P}^1((\gamma'-\delta,\gamma'))=\mathrm{s}-\lim_{\delta_2\downarrow0}\mathrm{s}-\lim_{\delta_1\downarrow0}\frac{1}{2\pi i}\int_{\gamma'-\delta+\delta_2}^{\gamma'-\delta_2}\left(\frac{1}{x-i\delta_1-\mathscr{L}_1}-\frac{1}{x+i\delta_1-\mathscr{L}_1}\right)dx.$$

Remember that all poles of $[\phi](z)$ are isolated since $[\phi](z)$ is meromorphic, and the spectra of $\mathscr{L}_1$ consist of isolated points and their accumulating points by Lemma 3.7. Since $-\gamma'$ is a pole of the first order of $[\phi](z)$, the principal part of the Laurent expansion of $[\phi](z)$ at $z=-\gamma'$ has the form of const$\times 1/(z+\gamma')$. So, we have for sufficiently small $\delta>0$

$$\langle \tilde{p};\mathscr{P}^1((\gamma'-\delta,\gamma'))\tilde{p}\rangle = i\langle p;p\rangle \lim_{\delta_2\downarrow 0}\lim_{\delta_1\downarrow 0}\frac{1}{2\pi i}\int_{\gamma'-\delta+\delta_2}^{\gamma'-\delta_2}([\phi](i\delta_1-x)-[\phi](-i\delta_1-x))dx$$

$$=0.$$

Hence it follows that $\mathscr{P}^1((\gamma'-\delta,\gamma'))\tilde{p}=0$. In the same way, we have $\mathscr{P}^1((\gamma',\gamma'+\delta))\tilde{p}=0$. Thus, if $-\gamma'$ is a pole of $[\phi](z)$, then $\gamma'\in\sigma_p(\mathscr{L}_1)$, where $\sigma_p(\mathscr{L}_1)$ is the all point spectra of $\mathscr{L}_1$. Otherwise, suppose here that $-\gamma'$ is a pole of $[\phi_-](z)$ satisfying $\mathscr{P}^1(\{\gamma'\})=0$. By the arguments above, there exists $\delta>0$ such that $\mathscr{P}^1((\gamma'-\delta,\gamma'+\delta)\backslash\{\gamma'\})\tilde{p}=0$. Thus, we get

$$\mathscr{P}^1((\gamma'-\delta,\gamma'+\delta))\tilde{p}=(\mathscr{P}^1(\{\gamma'\})+\mathscr{P}^1((\gamma'-\delta,\gamma'+\delta)\backslash\{\gamma'\}))\tilde{p}=0,$$

which is a contradiction because $-\gamma'$ is a pole of $[\phi](z)$. Therefore, we obtain part (c). Q.E.D.

Lemma 3.10:

(a) $[R_p](-z)=-[R_p](z)$, so if γ is a zero point of $[R_p](z)$, then γ is also a zero point of $[R_p](-z)$.

(b) $[R_p]'(-z)=[R_p]'(z)$.

(c) Let $\{\omega_j\}_{j=1}^{\infty}$ be the set of all positive zero points of $[R_p](z)$. Then,

$$\phi(t)=2R_p(0)\sum_{j=1}^{\infty}\frac{1}{i[R_p]'(\omega_j)}\cos(t\omega_j).$$

So,

$$[\phi](z)=R_p(0)\sum_{j=1}^{\infty}\frac{1}{[R_p]'(\omega_j)}\left(\frac{1}{z-\omega_j}+\frac{1}{z+\omega_j}\right).$$

Proof: By (55), we have

$$[R_p](-z)=-[R_p](z),$$

which is part (a).

Part (b) follows from part (a).

By Lemma 3.9(c), there are eigenvectors $\widetilde{\Phi}_{m,n}$ $(m,n=1,2,\cdots)$ of $\mathscr{L}_1$ such that $\mathscr{L}_1\widetilde{\Phi}_{m,n}=\mu_{m,n}\widetilde{\Phi}_{m,n}$ $(\mu_{m,n}\in\sigma_p(\mathscr{L}_1))$, and $\phi(t)=\langle p;p\rangle^{-1}\Sigma_{m,n=1}^{\infty}|\langle\widetilde{\Phi}_{m,n};(1-\Pi_0)\times\mathscr{L}_{q,p,s}p\rangle|^2\exp[it\mu_{m,n}]$.

Here, let $\{\gamma_j\}_{j=1}^{\infty}$ be the set of all distinct poles of $[\phi](z)$ (i.e., $\gamma_j\neq\gamma_{j'}$ if $j\neq j'$) with $\langle\widetilde{\Phi}_{m,n};(1-\Pi_0)\mathscr{L}_{q,p,s}p\rangle\neq 0$, where, for any $j\in\mathbf{N}$, there exist $m(j),n(j)\in\mathbf{N}$ such that $-\gamma_j=\mu_{m(j),n(j)}$. So,

$$[\phi](z)=\frac{i}{\langle p;p\rangle}\sum_{m,n=1}^{\infty}|\langle\widetilde{\Phi}_{m,n};(1-\Pi_0)\mathscr{L}_{q,p,s}p\rangle|^2\frac{1}{z+\mu_{m,n}}$$

$$=\frac{i}{\langle p;p\rangle}\sum_{j;\ \langle\widetilde{\Phi}_{m(j),n(j)};(1-\Pi_0)\mathscr{L}_{q,p,s}p\rangle\neq 0}$$

$$\times\left(\sum_{\substack{m(j),n(j);\\ -\gamma_j=\mu_{m(j),n(j)}}} |\langle\widetilde{\Phi}_{m(j),n(j)};(1-\Pi_0)\mathscr{L}_{q,p,s}p\rangle|^2\right)\frac{1}{z-\gamma_j}. \tag{58}$$

Thus, we obtain by (57) and (58)

$$\begin{aligned}\sum_{\substack{m(j),n(j);\\ \mu_{m(j),n(j)}=-\gamma_j}} |\langle\widetilde{\Phi}_{m(j),n(j)};(1-\Pi_0)\mathscr{L}_{q,p,s}p\rangle|^2 &= \lim_{z\to\gamma_j}\frac{1}{i}(z-\gamma_j)[\phi](z)\langle p;p\rangle \\ &= \frac{1}{i}(R_p(0))^2\lim_{z\to\gamma_j}\frac{z-\gamma_j}{[R_p](z)-[R_p](\gamma_j)} \\ &= (R_p(0))^2\frac{1}{i[R_p]'(\gamma_j)}>0. \end{aligned}\tag{59}$$

Here, we used the fact that $[R_p](\gamma_j)=0$ by Lemma 3.9(c). By (58), we have

$$\phi(t)=\frac{1}{R_p(0)}\sum_{j=1}^{\infty}\left(\sum_{\substack{m(j),n(j);\\ \mu_{m(j),n(j)}=-\gamma_j}} |\langle\widetilde{\Phi}_{m(j),n(j)};(1-\Pi_0)\mathscr{L}_{q,p,s}p\rangle|^2\right)e^{-it\gamma_j}.$$

Therefore, by (59), we obtain

$$\phi(t)=R_p(0)\sum_{j=1}^{\infty}\frac{1}{i[R_p]'(\gamma_j)}e^{-it\gamma_j}. \tag{60}$$

By part (b), we have

$$\frac{1}{[R_p]'(\omega_j)}=\frac{1}{[R_p]'(-\omega_j)}. \tag{61}$$

And besides, by Lemma 3.9(c) and part (a), the set of all poles of $[\phi](z)$ is given by $\{\pm\omega_j\}_{j=1}^{\infty}$. Therefore, we obtain part (c) from (60) and (61). Q.E.D.

B. Proof of the main theorem

We define $\kappa_\tau(t)$ by

$$\kappa_\tau(t)\underset{=}{\text{def}} m\phi(t)\chi_{[0,\tau]}(t), \tag{62}$$

where $\chi_{[0,\tau]}(t)$ denotes the characteristic function of $[0,\tau]$.

The quantum Langevin equation (17) follows from (43), Lemma 3.9(a) and Lemma 3.10(c).

For $t>0$, it is evident that $lim_{\tau\uparrow\infty}\kappa_\tau(t)=m\phi(t)$, which implies (18).

The fluctuation-dissipation relation follows from (44) and (45).

The Fourier–Laplace transform of (46) implies (20).

Concerning the proof of (21), first we get

$$S_I(t)=\int_{-\infty}^{\infty}e^{it\omega}\beta E_\beta(\omega)\Delta_I^{\text{can}}(d\omega)$$

by the definition of symmetrized autocorrelation function (10), and

$$\Delta_I^{\mathrm{can}}(d\omega)=\sum_{j=1}^{\infty} m_j\omega_j^2\left(\frac{\delta_{\omega_j}(d\omega)+\delta_{-\omega_j}(d\omega)}{2}\right)$$

by (19). Thus, since $E_\beta(\omega)=E_\beta(-\omega)$, we have

$$S_I(t)=\frac{1}{2}\sum_{j=1}^{\infty} m_j\omega_j^2\beta(E_\beta(\omega_j)e^{it\omega_j}+E_\beta(-\omega_j)e^{-it\omega_j})=\sum_{j=1}^{\infty} m_j\omega_j^2\beta E_\beta(\omega_j)\cos(\omega_j t),$$

which implies (21).

The last equality (22) depends on (19).

ACKNOWLEDGMENTS

I wish to express my thanks to Professor R. F. O'Connell of Louisiana State University and the unknown referee for giving recent topics and references concerning coupled-oscillator Hamiltonians. Especially, I am thankful to Professor R. F. O'Connell for his advice and suggestions in his letters and E-mail.

APPENDIX

1. Mori's memory kernel equation

In this Appendix, we recall briefly Mori's memory kernel equation.[11,12] Let $\mathbf{X}$ be a Hilbert space with an inner product $(,)_{\mathbf{X}}$, $\mathscr{L}$ a self-adjoint operator in $\mathbf{X}$ with domain $\mathrm{D}(\mathscr{L})$, and A a non-zero element in $\mathrm{D}(\mathscr{L})$, where the inner product $(,)_{\mathbf{X}}$ is linear in the right vector.

We consider a stationary curve $\{A(t)|t\in\mathbf{R}\}$ defined by $A(t)\overset{\mathrm{def}}{=}e^{it\mathscr{L}}A, t\in\mathbf{R}$, and the autocorrelation function R_A of A given by $R_A(t)\overset{\mathrm{def}}{=}(A(0),A(t))_{\mathbf{X}}$.

Let $\mathbf{X}_0$ be the closed subspace generated by A, and Π_0 and $\mathbf{X}_1$ the orthogonal projection operator on $\mathbf{X}_0$ and the complementary subspace of $\mathbf{X}_0$ in $\mathbf{X}$, respectively. Then we define a linear operator $\mathscr{L}_1$ on the Hilbert space $\mathbf{X}_1$ by

$$\mathrm{D}(\mathscr{L}_1)\overset{\mathrm{def}}{=}(1-\Pi_0)\mathbf{X}\cap\mathrm{D}(\mathscr{L})$$

$$\mathscr{L}_1 x\overset{\mathrm{def}}{=}(1-\Pi_0)\mathscr{L}x,\quad x\in\mathrm{D}(\mathscr{L}_1)\ .$$

From this, we note that $\mathscr{L}_1$ is a self-adjoint operator acting in the Hilbert space $\mathbf{X}_1$.[10,11] And we define Mori's frequency ω_A, fluctuation $I_A(t), t\in\mathbf{R}$ and memory function ϕ_A by

$$\omega_A\overset{\mathrm{def}}{=}-(A(0),\mathscr{L}A(0))_{\mathbf{X}}(A(0),A(0))_{\mathbf{X}}^{-1}.\quad I_A(t)\overset{\mathrm{def}}{=}ie^{it\mathscr{L}_1}(1-\Pi_0)\mathscr{L}A,\quad t\in\mathbf{R},$$

$$\phi_A(t)\overset{\mathrm{def}}{=}(I_A(0),I_A(t))_{\mathbf{X}}(A(0),A(0))_{\mathbf{X}}^{-1},\quad t\in\mathbf{R}. \tag{A1}$$

We note here that we change the original definition of Mori's frequency into (A1) to discuss our argument. Then we have the following theorem.

Theorem A.1 (Refs. 10–12):

(a) *For all* $t\in\mathbf{R}$,

$$\frac{d}{dt}R_A(t) = -i\omega_A R_A(t) - \int_0^t ds\ \phi_A(t-s)R_A(s).$$

(b) *For all* $z \in \mathbf{C}^+ \underset{=}{\text{def}} \{z \in \mathbf{C} | \text{Im } z > 0\}$,

$$\int_0^\infty dt\ \ e^{itz}R_A(t) = R_A(0)\frac{1}{i\omega_A - iz + \int_0^\infty dt\ e^{itz}\phi_A(t)}.$$

(c) *For all* $t \in \mathbf{R}$,

$$\frac{d}{dt}A(t) = -i\omega_A A(t) - \int_0^t ds\ \phi_A(t-s)A(s) + I_A(t). \tag{A2}$$

Equation (A2) is *Mori's memory kernel equation*, or *Mori's Langevin equation*.

2. An example of the Hamiltonian and the momentum operator satisfying the assumptions

Let

$$\overline{\mathscr{D}_{q,p,s}} \underset{=}{\text{def}} \{A \in \mathbf{T}(H_{q,p,s}) | H_{q,p,s}A, AH_{q,p,s} \lceil \mathbf{D}_{q,p,s} \in \mathbf{T}(H_{q,p,s})\}.$$

Then, for every $A \in \overline{\mathscr{D}_{q,p,s}}$, by (32)

$$\begin{aligned}
\sum_{m,n=0}^{\infty} (\lambda_m - \lambda_n)^2 |\langle \Phi_{m,n}; A\rangle|^2 &\leqslant 2\sum_{m,n=0}^{\infty} (\lambda_m^2 + \lambda_n^2)|\langle \Phi_{m,n}; A\rangle|^2 \\
&= 2\sum_{m,n=0}^{\infty} (\lambda_m^2 + \lambda_n^2)\frac{|(\varphi_m, A\varphi_n)_{q,p,s}|^2}{\beta Z(\beta) W_{m,n}} \\
&= 2\sum_{m,n=0}^{\infty} \frac{1}{\beta Z(\beta) W_{m,n}}(|(\varphi_m, H_{q,p,s}A\varphi_n)_{q,p,s}|^2 \\
&\quad + |(\varphi_m, AH_{q,p,s}\varphi_n)_{q,p,s}|^2) \\
&= 2(\|H_{q,p,s}A\|^2_{H_{q,p,s}} + \|AH_{q,p,s}\|^2_{H_{q,p,s}}) < \infty.
\end{aligned} \tag{A3}$$

Therefore, we have

$$\mathscr{D}_{q,p,s} \subset \overline{\mathscr{D}_{q,p,s}} \subset \mathrm{D}(\mathscr{L}_{q,p,s}). \tag{A4}$$

Next, we prepare basic tools from Ref. 21. Let $\mathscr{F}_b^\infty$ be the symmetric Fock space, which is the Hilbert space complete of the symmetric tensor algebra over $L^2(\mathbf{R})$:

$$\mathscr{F}_b^\infty \underset{=}{\text{def}} \oplus_{n=0}^\infty \mathscr{F}_n,$$

where $\mathscr{F}_n$ is the space of n noninteracting bosons:

$$\mathscr{F}_0 \stackrel{\text{def}}{=} \mathbf{C},$$

$$\mathscr{F}_n \stackrel{\text{def}}{=} \underbrace{L^2(\mathbf{R})\otimes_s L^2(\mathbf{R})\otimes_s \cdots \otimes_s L^2(\mathbf{R})}_{n\text{factors}}, \quad n=1,2,\ldots .$$

We use the standard annihilation and creation operators $b(k)$ and $b^+(k)$, defined by

$$(b(k)\psi)_{n-1}(k_1,\ldots,k_{n-1}) \stackrel{\text{def}}{=} n^{1/2}\psi_n(k,k_1,\ldots,k_{n-1})$$

on the dense subset of vectors $\psi \equiv \{\psi_0,\psi_1,\ldots\} \in \mathscr{F}_b^\infty$ with $\psi_n=0$ for large n. And

$$(b^+(k)\psi)_{n+1}(k_1,\ldots,k_{n+1}) \stackrel{\text{def}}{=} (n+1)^{-1/2}\sum_{j=1}^{n+1} \delta(k-k_j)\psi_n(k_1,\ldots,\widehat{k_j},\ldots,k_{n+1}).$$

Here $\widehat{k_j}$ means that k_j is omitted.

For finite volume $V>0$, we define a set of lattice points $\mathbf{\Gamma}_V$ by

$$\mathbf{\Gamma}_V \stackrel{\text{def}}{=} \left\{ k \mid k=\frac{2\pi n}{V}, n=0,\pm 1,\pm 2,\ldots \right\}. \tag{A5}$$

We can define the Fock space $\mathscr{F}_b^V$ for volume V as

$$\mathscr{F}_b{}^V \stackrel{\text{def}}{=} \mathbf{C}\oplus l^2(\mathbf{\Gamma}_V)\oplus(l^2(\mathbf{\Gamma}_V)\otimes_s l^2(\mathbf{\Gamma}_\mathbf{V}))\oplus(l^2(\mathbf{\Gamma}_\mathbf{V})\otimes_s l^2(\mathbf{\Gamma}_\mathbf{V})\otimes_s l^2(\mathbf{\Gamma}_\mathbf{V}))\ldots . \tag{A6}$$

Then we can identify $\mathscr{F}_b^V$ with the subspace of $\mathscr{F}_b^\infty$ consisting of piecewise constant functions which are constant on each cube of volume $(2\pi/V)^j$ centered about a lattice point $(k_1,\ldots,k_j)\in \mathbf{\Gamma}_\mathbf{V}\times\mathbf{\Gamma}_\mathbf{V}\ldots\times\mathbf{\Gamma}_\mathbf{V}$.

The periodic annihilation and creation operators $b_V(k)$ and $b_V^+(k)$ are defined by

$$b_V(k) \stackrel{\text{def}}{=} \left(\frac{V}{2\pi}\right)^{1/2}\int_{-\pi/V}^{\pi/V} b(k+l)dl, \tag{A7}$$

$$b_V^+(k) \stackrel{\text{def}}{=} \left(\frac{V}{2\pi}\right)^{1/2}\int_{-\pi/V}^{\pi/V} b^+(k+l)dl, \tag{A8}$$

and can be extended from $\mathscr{F}_b^V$ to $\mathscr{F}_b^\infty$. We regard $\mathscr{F}_b^V$ as $\mathscr{F}_{q,p,s}$.

We define annihilation and creation operators of a quantum harmonic oscillator by

$$a \stackrel{\text{def}}{=} b_V(0), \quad a^+ \stackrel{\text{def}}{=} b_V^+(0),$$

furthermore annihilation and creation operators of bosons by

$$b_k \stackrel{\text{def}}{=} b_V(k), \quad b_k^+ \stackrel{\text{def}}{=} b_V^+(k), \quad k\in\mathbf{\Gamma}_V\backslash\{0\}.$$

And let $\mathscr{F}_{q,p,s}\equiv\mathscr{F}_b^V$.

Let w_0 be a positive number, and $\{w_k\}_{k\in\mathbf{\Gamma}_V\setminus\{0\}}$ a sequence of positive numbers with $\Sigma_{k\in\mathbf{\Gamma}_V\setminus\{0\}}w_k^{-2}<\infty$. We give a free Hamiltonian H_0 by

$$H_0 \overset{\text{def}}{=} w_0 a^+ a + \sum_{k\in\mathbf{\Gamma}_V\setminus\{0\}} w_k b_k^+ b_k .$$

Let H_I be a self-adjoint operator satisfying

$$\left.\begin{aligned} H_I &\geqslant 0, \\ H_{q,p,s} = H_0 + H_I &\text{ is essentially self}-\text{adjoint} \\ &\text{on a core } C^\infty(H_0)\cap \mathrm{D}(H_I), \\ \mathrm{D}(p) &\supset \mathrm{D}(H_I), \\ [H_I, p] &= 0. \end{aligned}\right\} \tag{A9}$$

For instance, for $n\in\mathbf{N}$, let

$$:\phi^{2n}: \equiv \lambda\int_{-\infty}^{\infty} :\phi_V(x)^{2n}: g(x)\,dx \lceil C^\infty\left(w_0 a^+ a + \sum_{k\in\mathbf{\Gamma}_V\setminus\{0\}} w_k b_k^+ b_k\right),$$

where $\lambda>0$, g is a positive function in Schwartz's class, and

$$\phi_V(x) \overset{\text{def}}{=} \frac{1}{(2V)^{1/2}} \sum_{k\in\mathbf{\Gamma}_V\setminus\{0\}} e^{-ikx}(b_k^+ + b_{-k}) w_k^{-1/2}.$$

It is well known that for $\mathscr{F}_b^V$ there exist a measure space $\mathbf{Q}$ and the Gaussian measure $d\mu_0$ such that $\mathscr{F}_b^V$ is unitary equivalent to $L^2(\mathbf{Q},d\mu_0)$. From now on, we identify $\mathscr{F}_b^V$, so $\mathscr{F}_{q,p,s}$ with $L^2(\mathbf{Q},d\mu_0)$. Let P_1 and P_2 be positive polynomials of x and $x_1,x_2,\ldots,x_n$, respectively, satisfying $P_1(p)P_2(:\phi^2:,:\phi^4:,\ldots,:\phi^2:)\in L^2(\mathbf{Q},d\mu_0)$. Then, by Theorem X.59 in Ref. 22, $H_0+P_1(p)P_2(:\phi^2:,:\phi^4:,\ldots,:\phi^2:)$ is essentially self-adjoint on $C^\infty(H_0)\cap\mathrm{D}(H_1)$ and positive. This $P_1(p)P_2(:\phi^2:,:\phi^4:,\ldots,:\phi^{2n}:)$ is an example of H_I with (71).

More concrete example is given as follows: Let

$$H_{0,I} \overset{\text{def}}{=} \lambda\int_{-\infty}^{\infty} :\phi_V(x)^4: g(x)\,dx \lceil C^\infty\left(w_0 a^+ a + \sum_{k\in\mathbf{\Gamma}_V\setminus\{0\}} w_k b_k^+ b_k\right),$$

where $\lambda>0$, g is a positive function in Schwartz's class. Since $H_{0,I}$ is extended to self-adjoint operator by claim in p.176 of Ref. 23 and Theorem VIII.33 in Ref. 24. And, we can represent p using projection valued measure E_ξ as

$$p = \int_{-\infty}^{\infty} \xi\, dE_\xi .$$

We define p_K $(K>0)$ by

$$p_K \equiv \int_{-K}^{K} \xi\, dE_\xi .$$

Let $H_{b,I}$ be a bounded symmetric operator acting in

$$\mathbf{L.h}\left[\left\{\frac{1}{\sqrt{n_{k_1}!}\cdots\sqrt{n_{k_N}!}}(b_{k_1}^{+})^{n_{k_1}}\cdots(b_{k_N}^{+})^{n_{k_N}}\Omega_0 | n_{k_1},\ldots,n_{k_N}\in\mathbf{N}^*;k_1,\ldots,k_N\in\mathbf{\Gamma}_V;N\in\mathbf{N}^*\right\}\right].$$

Here Ω_0 denotes the Fock vacuum. Then, it is clear that $H_{0,I}+p_K H_{b,I}$ is an example of H_I with (A9). Here we note that $[p_K, H_{b,I}]=0$.

For H_I with (A9), we obtain the following proposition:

Proposition B.1.

(a) $e^{-tH_{q,p,s}}$ is trace class for every $t>0$.

(b) $p\in \mathrm{D}(\mathscr{L}_{q,p,s})$.

Remark B.1: By this proposition, we know that $H_{q,p,s}$ and p argued in this subsection satisfy our assumptions (**A.1**) and (**A.3**).

Proof of Proposition B.1: First part (a) follows from Golden–Thompson inequality Corollary on p.320 in Ref. 25.

We note that

$$[H_0,q]=-iw_0p,\quad [H_0,p]=iw_0q, \tag{A10}$$

and there exist positive constants $c_n(q)$ and $c_n(p)$ $(n=1,2...)$ such that

$$\|q^n x\|\leqslant c_n(q)\|(H_0+I)^n x\|,\quad \|p^n x\|\leqslant c_n(p)\|(H_0+I)^n x\|, \tag{A11}$$

for $x\in C^\infty(H_0)$.

Here we note that by Proposition 1 in Ref. 26

$$\|H_0x\|+\|H_Ix\|\leqslant \mathrm{const}_1(\|H_{q,p,s}x\|+\|x\|) \tag{A12}$$

for all $x\in \mathrm{D}(H_0+H_I)$.

By using inequalities (A11), (A12), and the facts that $D(p)\supset C^\infty(H_0)\cap \mathrm{D}(H_I)$; $C^\infty(H_0)\cap \mathrm{D}(H_I)$ is a core for $H_{q,p,s}$; and p is closed, we have $D(p)=\mathrm{D}(p^*)\supset \mathrm{D}(H_{q,p,s})$, which implies that p satisfies (**T.1**), and $\mathrm{D}(pH_{q,p,s})\supset \mathbf{D}_{q,p,s}$. In the same way, we get $\mathrm{D}(q)\supset \mathbf{D}_{q,p,s}$. Since $H_{q,p,s}p=pH_{q,p,s}+iw_0q$, we have $\mathrm{D}(H_{q,p,s}p)=\mathrm{D}(pH_{q,p,s}+iw_0q)=\mathrm{D}(pH_{q,p,s})\cap \mathrm{D}(q)\supset \mathbf{D}_{q,p,s}$. Therefore, we can show that $pH_{q,p,s}$ and $H_{q,p,s}p$ satisfy (**T.1**).

Here we put for $t>0$,

$$A \overset{\mathrm{def}}{=} tH_0,$$

$$B \overset{\mathrm{def}}{=} tH_I,$$

$$C \overset{\mathrm{def}}{=} \|e^{-A/2}e^{-B}e^{-A/2}\|\leqslant e^{-t\inf\sigma(H_I)}\|e^{-A}\|.$$

Remember (A11) and (A12). In the same way as the proof of Theorem X.57 (Segal's lemma) in Ref. 25, since $(e^{-2^{-(n+1)}A}e^{-2^{-n}B}e^{-2^{-(n+1)}A})^{2^n}$ converges to $e^{-(A+B)}$ as $n\to\infty$, and $\|e^{-2^{-(n+1)}A}e^{-2^{-n}B}e^{-2^{-(n+1)}A}\|\leqslant C^{2^{-n}}$, we have for $x\in \mathrm{D}(p)$

$$\|e^{-(A+B)}px\|=\lim_{n\to\infty}\|(e^{-2^{-(n+1)}A}e^{-2^{-n}B}e^{-2^{-(n+1)}A})^{2^n}px\|$$

$$\leqslant c_1(p)\lim_{n\to\infty}C^{1-2^{-n}}\|e^{-A}\left(\frac{A}{t}+I\right)\|\|e^{(1-2^{-(n+1)})A}\|\|x\|$$

$$\leqslant c_1(p)e^{-t\inf\sigma(H_I)}\lim_{n\to\infty}C^{-2^{-n}}\|e^{-A}\left(\frac{A}{t}+I\right)\|\|e^{(-2^{-(n+1)})A}\|\|x\|$$

$$=c_1(p)e^{-t\inf\sigma(H_I)}\lim_{n\to\infty}C^{-2^{-n}}e^{(-2^{-(n+1)})t\inf\sigma(H_I)}\|e^{-A}\left(\frac{A}{t}+I\right)\|\|x\|$$

$$=c_1(p)e^{-t\inf\sigma(H_I)}\|e^{-A}\left(\frac{A}{t}+I\right)\|\|x\|.$$

Therefore, $e^{-tH_{q,p,s}}p$ is bounded, and similarly, $e^{-tH_{q,p,s}}q$ is also bounded. So, it follows that $e^{-tH_{q,p,s}}p$ and $e^{-tH_{q,p,s}}q$ are trace class from part (a) and boundedness of $e^{-tH_{q,p,s}}p$ and $e^{-tH_{q,p,s}}q$. Taking adjoint of them, we know $pe^{-tH_{q,p,s}}$ and $qe^{-tH_{q,p,s}}$ are also trace class. So, $pH_{q,p,s}e^{-tH_{q,p,s}}=pe^{-tH_{q,p,s}/2}H_{q,p,s}e^{-tH_{q,p,s}/2}$ is trace class. Furthermore, since $pH_{q,p,s}=H_{q,p,s}p-iw_0q$,

$$\begin{aligned}e^{-tH_{q,p,s}}pH_{q,p,s}&=e^{-tH_{q,p,s}}H_{q,p,s}p-iw_0e^{-tH_{q,p,s}}q\\&=e^{-tH_{q,p,s}/2}H_{q,p,s}e^{-tH_{q,p,s}/2}p-iw_0e^{-tH_{q,p,s}}q\end{aligned}$$

is trace class. In the same way, $e^{-tH_{q,p,s}}H_{q,p,s}p=e^{-tH_{q,p,s}/2}H_{q,p,s}e^{-tH_{q,p,s}/2}p$ is trace class, and since $H_{q,p,s}p=pH_{q,p,s}+iw_0q$,

$$H_{q,p,s}pe^{-tH_{q,p,s}}=pH_{q,p,s}e^{-tH_{q,p,s}}+iw_0qe^{-tH_{q,p,s}}=pe^{-tH_{q,p,s}/2}H_{q,p,s}e^{-tH_{q,p,s}/2}+iw_0qe^{-tH_{q,p,s}}$$

is also trace class. Thus, $p, pH_{q,p,s}$, and $H_{q,p,s}p$ satisfy (**T.2**).

Therefore, we obtain that $p\in\overline{\mathscr{D}_{q,p,s}}$. So, by (66), $p\in\mathrm{D}(\mathscr{S}_{q,p,s})$. Q.E.D.

When condition (**A.2**) and (**A.4**) do not hold, we consider the following smeared momentum operator. We can expand p as

$$p=\sum_{m,n}\langle\Phi_{m,n};p\rangle\Phi_{m,n}$$

in $\mathbf{X}_c(H_{q,p,s})$.

Definition B.1: By an observation, select ε_p and η_p with (**A.2**). Then, for p, we define the *smeared momentum operator* p^{sm} by

$$\begin{aligned}p^{sm}&\equiv p^{sm}(\varepsilon_p,\eta_p;p\in\mathbf{N}^*)\\&\overset{\mathrm{def}}{=}\sum_{k=0}^{\infty}\left(\sum_{\substack{m^+(k),n^+(k);\\ \lambda_{m^+(k)}-\lambda_{n^+(k)}=-\varepsilon_k}}\langle\Phi_{m^+(k),n^+(k)};p\rangle_{H_{q,p,s}}\right)\Phi_{m^+(k),n^+(k)}\\&\quad+\sum_{k=0}^{\infty}\left(\sum_{\substack{m^-(k),n^-(k);\\ \lambda_{m^-(k)}-\lambda_{n^-(k)}=-\eta_k}}\langle\Phi_{m^-(k),n^-(k)};p\rangle_{H_{q,p,s}}\right)\Phi_{m^-(k),n^-(k)}.\end{aligned}$$

It is evident that p^{sm} satisfies (**A.4**) automatically.

The Hamiltonian $H_{q,p,s}$ and smeared momentum operator p^{sm} which are argued in this subsection satisfy our assumptions (**A.1**)-(**A.4**), and more complicated model than the IO model is included.

Solution to three-magnon problem for $S=1/2$ periodic quantum spin chains with elliptic exchange

V. I. Inozemtsev[a)]
Institute for Solid State Physics, University of Tokyo, Roppongi, Minato-ku, Tokyo 106, Japan

(Received 14 March 1995; accepted for publication 20 September 1995)

The method of solving the three-particle quantum elliptic Calogero–Moser problem is applied to the description of three-magnon wave functions for the $S=1/2$ quantum Heisenberg chains with the exchange interaction given by the Weierstrass ϱ function. The Bethe-like algebraic equations for the three-magnon case are presented in the explicit form. © *1996 American Institute of Physics.* [S0022-2488(96)02101-X]

I. INTRODUCTION

Despite the remarkable progress in studying integrable models of field theory and statistical mechanics, the universal method of constructing their solutions in the quantum case is not found. The well-known techniques of the coordinate Bethe ansatz and its algebraic version based on the Yang–Baxter equation are still not applicable to 1-D problems proposed a long time ago within the framework of the classical Lax representation and proved also to be quantum integrable.[2,3] They can be interpreted as the systems of particles on a torus $T_{\omega_1,\omega_2}=\mathbf{C}/\mathbf{Z}\omega_1+\mathbf{Z}\omega_2, \mathcal{I}m(\omega_1\omega_2^{-1})\neq 0$, with the quantum Hamiltonian

$$H_p^{(M)}=-\frac{1}{2}\sum_{j=1}^{M}\left(\frac{\partial}{\partial x_j}\right)^2+n(n-1)\sum_{j<l}^{M}\wp(x_j-x_l), \tag{1}$$

where $\wp(x)$ is the elliptic Weierstrass function with periods ω_1 and ω_2,

$$\begin{aligned}\wp(x)&=x^{-2}+\sum_{m\in\mathbf{Z}^2,m_1^2+m_2^2\neq 0}[(x+m_1\omega_1+m_2\omega_2)^{-2}-(m_1\omega_1+m_2\omega_2)^{-2}]\\&=\left(\frac{\pi}{\omega_2}\right)^2\left(-\frac{1}{3}+\sum_{m\in\mathbf{Z}}\left[\sin\left(\pi\,\frac{x-m\omega_1}{\omega_2}\right)\right]^{-2}-2\sum_{m\in\mathbf{Z}_+}\left[\sin\frac{m\omega_1}{\omega_2}\,\pi\right]^{-2}\right).\end{aligned} \tag{2}$$

Moreover, the superintegrability of these systems at $n\in\mathbf{Z}_+$ was conjectured,[4,5] i.e., at least as $\omega_1\to\infty$ the ring of well-defined operators commuting with $H_p^{(M)}$ is larger than it is required for classical integrability in the Liouville sense. Although a number of results have been obtained in various degenerate cases of $\omega_1,\omega_2\to 0,\infty$,[2,4–8] any explicit eigenvectors of $H_p^{(M)}$ at arbitrary ω_1, ω_2 and $M>2$ have not been found.

Recently, several approaches have been proposed for explaining the phenomenon of the integrability of elliptic many-body systems and describing the spectrum of the commutative family of differential operators which includes (1). One is based on the relationship of integrable many-body problems to the theory of semisimple and affine Lie groups[9] and the use of the quantum Hamiltonian reduction described first in Ref. 10. It results in the interpretation of the eigenfunctions of the trigonometric analog of (1) as traces of the operators which intertwine some representations of gl_M.[11] The generalization of the treatment to affine Lie groups leads to the parabolic differential

[a)]On leave from the Laboratory of Theoretic Physics, JINR, Dubna, Russia.

equation which is viewed as a reduction of the KZB equations.[12] In the case of $M=2$, it has been proved in Ref. 12 that the asymptotics of the integral representations of its solutions at critical level gives the eigenfunctions of (1) at $n\in\mathbf{Z}_+$. It has been found also that there is the natural extension of the systems (1) to the relativistic Hamiltonians[13] with the symmetry related to the gauged WZW theory and quantum groups.[14]

The important results for the spectrum and eigenfunctions of (1) at $M\leqslant 3$, $n\in\mathbf{R}_+$, have been obtained within the framework of the general scheme of the separation of variables.[15]

The promising way of embedding the systems (1) into the Yang–Baxter structures is related to the construction of the representations of quadratic Sklyanin algebra with Belavin's elliptic R matrix by means of difference operators[16] and further reduction to differential ones. Being most general at the present time, this approach is still not realized completely in writing down the explicit expressions for the solutions of the eigenvalue problem for the operator (1).

In this paper, we address mainly to the lattice analogs of $H_p^{(M)}$ which are the Hamiltonians of interacting $S=1/2$ quantum spins,

$$H_s=-\frac{1}{2}\sum_{j\neq l}^{N}\wp(j-l)\left(\frac{\vec{\sigma}_j\vec{\sigma}_l-1}{2}\right). \tag{3}$$

Here $\{\sigma_j\}$ are the usual Pauli matrices labelled by the indices of lattice sites and $\wp(x)$ is defined on the torus $T_{N,\omega}$, i.e., the real period of $\wp$ coincides with the total number of spins N. The real part of ω has to vanish if H_s is self-adjoint. The corresponding lattice Schrödinger equation reads

$$\begin{aligned}L(n_1\cdots n_M)&=\sum_{\beta=1}^{M}\sum_{s\neq n_1\cdots n_M}^{N}\wp(n_\beta-s)\psi^{(M)}(n_1\cdots n_{\beta-1},s,n_{\beta+1}\cdots n_M)\\&=-\left[\sum_{\alpha\neq\beta}^{M}\wp(n_\alpha-n_\beta)+E_M-ME_0\right]\psi^{(M)}(n_1\cdots n_M),\end{aligned} \tag{4}$$

where $E_0=\Sigma_{j=1}^{N-1}\wp(j)$ and $n_1\cdots n_M$ denote the positions of spins turned over the state in which all spins are aligned identically. The M-magnon wave function $\psi^{(M)}$ must be symmetric in all its arguments.

The limits of $\mathcal{I}m\,\omega\to 0,\infty$ have been investigated by Bethe[17] and Haldane.[18] In these limits, the underlying symmetry of the model has been established by explicit construction of transfer matrices which satisfy Yang–Baxter relations.[19,20] The eigenvectors of H_s for infinite spin chains at arbitrary values of $\mathcal{I}m\,\omega$ have been completely described recently.[21]

However, in the general case of finite N and $\omega\neq 0,\infty$, which is of more interest for thermodynamics, the explicit solutions have been indicated only for the simplest two-magnon sector.[22] One of possible ways of extension of these results to $M>2$ is in finding the lattice analogs of the powerful algebraic approaches to continuous elliptic many-particle problems proposed in Refs. 9–12. However, they do not provide useful expressions for the eigenfunctions of (1) and (3) at present stage of the development. Hence the search for more simple methods is worth a trial.

In the present paper we would like to show that the eigenfunctions of the particle and spin Hamiltonians (1) and (3) can be found explicitly also for $M=3$ by using its analytic properties without any appeals to the concept of superintegrability.

It is worthwhile to outline the situation at $M=2$, $n=2$ for convenience and introduction of some basic notation. As for the two-particle interaction, the problem reduces to the well-known Lamè equation,

$$\left[-\frac{1}{2}\left(\frac{d}{dx}\right)^2+\wp(x)\right]\varphi=E\varphi. \tag{5}$$

The solutions to (4) were given by Hermite[23] more than a century ago,

$$\varphi(x)=\exp(ikx)\,\frac{\sigma(x+\gamma)}{\sigma(x)}, \tag{6}$$

where k and E are easily expressed through an arbitrary phase γ,

$$ik=-\zeta(\gamma), \quad E=-\tfrac{1}{2}\wp(\gamma).$$

Here $\zeta(x)$ and $\sigma(x)$ are the Weierstrass functions related to $\wp(x)$ as follows:

$$\frac{d\zeta(x)}{dx}=-\wp(x), \ \lim_{x\to 0}[\zeta(x)-x^{-1}]=0; \quad \frac{d\,\ln\,\sigma(x)}{dx}=\zeta(x), \ \lim_{x\to 0}\,\sigma(x)x^{-1}=1. \tag{7}$$

Unlike $\wp$, zeta and sigma are not periodic. Nevertheless both these functions can be treated on the torus T_{ω_1,ω_2} due to their quasiperiodicity,

$$\zeta(x+\omega_j)=\zeta(x)+\eta_j, \quad \sigma(x+\omega_j)=\sigma(x)\exp\left[\pi i+\eta_j\left(x+\frac{\omega_j}{2}\right)\right], \quad j=1,2, \tag{8}$$

where $\eta_1=2\zeta(\omega_1/2)$ and $\eta_2=2\zeta(\omega_2/2)$ obey the Legendre relation

$$\eta_1\omega_2-\eta_2\omega_1=2\pi i. \tag{9}$$

As it follows from (2.7), the only simple pole of $\zeta(x)$ and zero of $\sigma(x)$ on T_{ω_1,ω_2} are located at $x=0$. The Hermite result (6) is one of the consequences of the addition theorem for $\wp(x)$ and $\zeta(x)$:

$$\wp(x)+\wp(y)+\wp(x+y)=[\zeta(x)+\zeta(y)-\zeta(x+y)]^2, \quad x,y\in\mathbf{C}. \tag{10}$$

The two-magnon wave functions, as it was pointed in Ref. 22, also have the Hermite form (6), but the connection between γ and other parameters is not so simple. It will be shown in two subsequent sections that the analogy of particle and spin dynamics still takes place in the more complicated $M=3$ problem.

II. THE SOLUTION TO THREE-PARTICLE PROBLEM AT $n=2$

Let us consider a three-particle equation of Lamè type,

$$H_p^{(3)}\varphi=\left\{-\frac{1}{2}\sum_{\alpha=1}^{3}\left(\frac{\partial}{\partial x_\alpha}\right)^2+2[\wp(x_1-x_2)+\wp(x_2-x_3)+\wp(x_3-x_1)]\right\}\varphi=E\varphi. \tag{11}$$

As $H_p^{(3)}$ commutes with each of the operators $S_j^{(\alpha)}$ shifting jth argument of φ to the period ω_α of the Weierstrass function, it is natural to search for the solutions of (7) in accordance with the Floquet–Bloch theory, i.e., as quasiperiodic functions in each argument $\{x_j\}$:

$$\varphi(x_1+l_1\omega_\alpha,x_2+l_2\omega_\alpha,x_3+l_3\omega_\alpha)=\exp\left(i\sum_{j=1}^{3}q_j^{(\alpha)}l_j\right)\varphi(x_1,x_2,x_3), \quad l_1,l_2,l_3\in\mathbf{Z}. \tag{12}$$

The only singularity of $\wp(x)$ on the torus T_{ω_1,ω_2} is the second-order pole at $x=0$. Then it follows from (11) that $\varphi(x_1,x_2,x_3)$ is meromorphic on $(T_{\omega_1,\omega_2})^3$ with simple poles at $x_1=x_2$, $x_2=x_3$, $x_3=x_1$, i.e., it can be represented in the form

$$\varphi(x_1,x_2,x_3)=\frac{\Phi(x_1,x_2,x_3)}{\sigma(x_1-x_2)\sigma(x_2-x_3)\sigma(x_3-x_1)}, \tag{13}$$

where $\Phi(x_1,x_2,x_3)$ is analytic on $(T_{\omega_1,\omega_2})^3$. One can show that this condition, being combined with (12), determines the structure of Φ up to eight arbitrary parameters. In particular, the constants $q_\alpha^{(j)}$ in (12) cannot be chosen independently but are related by

$$\Omega=\sum_{j=1}^{3}\left[\omega_1 q_j^{(2)}-\omega_2 q_j^{(1)}\right]\in 2\pi(\mathbf{Z}\omega_1+\mathbf{Z}\omega_2).$$

So it is always possible to choose $\{q_j^{(\alpha)}\}$ such as Ω vanishes.

Note that the solutions to (11) of the type (12) contain only four arbitrary parameters (the common normalization factor and three particle quasimomenta). Hence finding these solutions is equivalent to some purely algebraic problem, i.e., extracting some four-dimensional manifold from $\{\Phi\}$. To formulate it in a constructive way, one needs an appropriate parametrization of $\{\Phi\}$. It can be chosen as

$$\Phi(x_1,x_2,x_3)=A\,\exp\left[i\sum_{\alpha=1}^{3}k_\alpha x_\alpha\right]\sigma(x_1-x_2+\gamma_{12})\sigma(x_2-x_3+\gamma_{23})\sigma(x_3-x_1+\gamma_{31})$$
$$\times[B+\zeta(x_1-x_2+\gamma_{12})+\zeta(x_2-x_3+\gamma_{23})+\zeta(x_3-x_1+\gamma_{31})]. \tag{14}$$

Since the poles of $\zeta(x)$ coincide with zeroes of $\sigma(x)$, the functions of the type (14) are analytic on $(T_{\omega_1,\omega_2})^3$ as required. The parameters $q_j^{(\alpha)}$ in (12) are easily expressed through $\{k\}$ and $\{\gamma\}$ with the use of (8),

$$q_j^{(\alpha)}=k_j\omega_\alpha-i\eta_\alpha(\gamma_{jl}+\gamma_{jm}), \tag{15}$$

where the auxiliary phases $\gamma_{21},\gamma_{32},\gamma_{13}$ are introduced by the relation

$$\gamma_{jm}=-\gamma_{mj} \tag{16}$$

and (jlm) is an arbitrary combination of the numbers from 1 to 3.

Upon substituting (13) and (14) into (11) one arrives at the equation

$$L(x_1,x_2,x_3)=A\,\exp\left[i\sum_{\alpha=1}^{3}k_\alpha x_\alpha\right]\frac{\sigma(y_{12})\sigma(y_{23})\sigma(y_{31})}{\sigma(z_{12})\sigma(z_{23})\sigma(z_{31})}\{[B+\zeta(y_{12})+\zeta(y_{23})+\zeta(y_{31})][-\epsilon$$
$$+i\zeta(z_{12})(k_1-k_2)+i\zeta(z_{23})(k_2-k_3)+i\zeta(z_{31})(k_3-k_1)+3(\zeta(z_{12})\zeta(z_{23})$$
$$+\zeta(z_{12})\zeta(z_{31})+\zeta(z_{23})\zeta(z_{31}))-(\zeta(y_{12})-\zeta(y_{31}))(ik_1-\zeta(z_{12})+\zeta(z_{31}))-(\zeta(y_{23})$$
$$-\zeta(y_{12}))(ik_2-\zeta(z_{23})+\zeta(z_{12}))-(\zeta(y_{31})-\zeta(y_{23}))(ik_3-\zeta(z_{31})+\zeta(z_{23}))-\zeta^2(y_{12})$$
$$-\zeta^2(y_{23})-\zeta^2(y_{31})+\zeta(y_{12})\zeta(y_{23})+\zeta(y_{12})\zeta(y_{31})+\zeta(y_{23})\zeta(y_{31})+\wp(y_{12})+\wp(y_{23})$$
$$+\wp(y_{31})]+[ik_1-\zeta(z_{12})+\zeta(z_{31})+\zeta(y_{12})-\zeta(y_{31})][\wp(y_{12})-\wp(y_{31})]+[ik_2$$
$$-\zeta(z_{23})+\zeta(z_{12})+\zeta(y_{23})-\zeta(y_{12})][\wp(y_{23})-\wp(y_{12})]+[ik_3-\zeta(z_{31})+\zeta(z_{23})$$
$$+\zeta(y_{31})-\zeta(y_{23})][\wp(y_{31})-\wp(y_{23})]+\wp'(y_{12})+\wp'(y_{23})+\wp'(y_{31})\}=0, \tag{17}$$

where

$$\epsilon = E - \tfrac{1}{2}(k_1^2 + k_2^2 + k_3^2), \quad z_{\alpha\beta} = x_\alpha - x_\beta, \quad y_{\alpha\beta} = x_\alpha - x_\beta + \gamma_{\alpha\beta}.$$

Note that $L(x_1, x_2, x_3)$, like $\varphi(x_1, x_2, x_3)$, is quasiperiodic in each argument. Let us choose one of them (say, x_1) and fix two others. When treated as a function of x_1, L obeys the relations

$$L(x_1 + \omega_j, x_2, x_3) = \exp(i q_1^{(j)}) L(x_1, x_2, x_3), \quad j = 1,2, \tag{18}$$

with $q_1^{(j)}$ given by (15). At $\gamma_{12} - \gamma_{31} \notin \mathbf{Z}\omega_1 + \mathbf{Z}\omega_2$ one has

$$q_1^{(1)}\omega_2 - q_1^{(2)}\omega_1 \notin 2\pi(\mathbf{Z}\omega_1 + \mathbf{Z}\omega_2). \tag{19}$$

The singularities of L on T_{ω_1,ω_2} at fixed x_2, x_3 are second-order poles at $x_1 = x_2$ and $x_1 = x_3$. Near these points one can write the Laurent decompositions of L as

$$\exp\left(-i\sum_{\alpha=1}^{3} k_\alpha x_\alpha\right) L(x_1, x_2, x_3) = \lambda_{-2}^{(j)}(z)(x_1 - x_j)^{-2} + \lambda_{-1}^{(j)}(z)(x_1 - x_j)^{-1} + \lambda_0^{(j)}(z, x_1 - x_j),$$

$$j = 2,3,$$

where $z = x_2 - x_3$ and $\lambda_0^{(j)}$ are regular when $x_1 \to x_j$. If one proves that all $\lambda_{-2}^{(j)}(z), \lambda_{-1}^{(j)}(z)$ vanish, then L as a function of x_1 will be analytic on T_{ω_1,ω_2}. However, according to the Liouville theorem, the only analytic function on this torus under the conditions (18) and (19) is zero. Hence (17) is equivalent to four simpler equations:

$$\lambda_{-2}^{(2)}(z) = 0, \quad \lambda_{-2}^{(3)}(z) = 0, \tag{20}$$

$$\lambda_{-1}^{(2)}(z) = 0, \quad \lambda_{-1}^{(3)}(z) = 0. \tag{21}$$

Let us first consider the equations (20). After calculation of the explicit form of leading singularities in (17) they can be written as

$$[B + \zeta(\gamma_{12}) + \zeta(z + \gamma_{23}) - \zeta(z - \gamma_{31})][i(k_1 - k_2) + 2\zeta(\gamma_{12}) + \zeta(z - \gamma_{31}) - \zeta(z + \gamma_{23})]$$
$$+ \wp(z - \gamma_{31}) + \wp(z + \gamma_{23}) - 2\wp(\gamma_{12}) = 0, \tag{22}$$

$$[B + \zeta(\gamma_{31}) + \zeta(z + \gamma_{23}) - \zeta(z - \gamma_{12})][i(k_3 - k_1) + 2\zeta(\gamma_{31}) + \zeta(z - \gamma_{12}) - \zeta(z + \gamma_{23})]$$
$$+ \wp(z - \gamma_{12}) + \wp(z + \gamma_{23}) - 2\wp(\gamma_{31}) = 0. \tag{23}$$

The left-hand sides of (22) and (23) are double periodic (i.e., elliptic) functions of z with the first-order poles at $z = -\gamma_{23}, \gamma_{31}$ for (22) and $z = -\gamma_{23}, \gamma_{12}$ for (23). If the pole residues and constant terms in the Laurent decompositions of these functions equal to zero, then, according to the Liouville theorem, they must vanish identically. These conditions can be expressed in the form of four purely algebraic equations for the parameters $B, \{k\}, \{\gamma\}$,

$$B - i(k_1 - k_2) - \zeta(\gamma_{12}) + 2\zeta(\gamma_{31} + \gamma_{23}) = 0, \tag{24}$$

$$B - i(k_3 - k_1) - \zeta(\gamma_{31}) + 2\zeta(\gamma_{12} + \gamma_{23}) = 0, \tag{25}$$

$$[B + \zeta(\gamma_{12}) + \zeta(\gamma_{31} + \gamma_{23})][i(k_1 - k_2) + 2\zeta(\gamma_{12}) - \zeta(\gamma_{31} + \gamma_{23})]$$
$$- 2\wp(\gamma_{12}) - \wp(\gamma_{31} + \gamma_{23}) = 0, \tag{26}$$

$$[B+\zeta(\gamma_{31})+\zeta(\gamma_{12}+\gamma_{23})][i(k_3-k_1)+2\zeta(\gamma_{31})-\zeta(\gamma_{12}+\gamma_{23})]$$
$$-2\wp(\gamma_{31})-\wp(\gamma_{12}+\gamma_{23})=0. \tag{27}$$

Upon eliminating k_1-k_2 and k_3-k_1 by (24) and (25), Eqs. (26) and (27) can be written as

$$[B+\zeta(\gamma_{12})+\zeta(\gamma_{31}+\gamma_{23})]^2=2\wp(\gamma_{12})+\wp(\gamma_{31}+\gamma_{23}), \tag{28}$$

$$[B+\zeta(\gamma_{31})+\zeta(\gamma_{12}+\gamma_{23})]^2=2\wp(\gamma_{31})+\wp(\gamma_{12}+\gamma_{23}). \tag{29}$$

Since the difference of (28) and (29) is linear in B, this parameter can also be expressed easily through the phases $\{\gamma\}$,

$$B=-[\zeta(\gamma_{12})+\zeta(\gamma_{23})+\zeta(\gamma_{31})]+3[\wp(\gamma_{12})-\wp(\gamma_{23})][\wp(\gamma_{23})-\wp(\gamma_{31})][\wp(\gamma_{31})-\wp(\gamma_{12})]$$
$$\times\{\wp'(\gamma_{12})[\wp(\gamma_{23})-\wp(\gamma_{31})]+\wp'(\gamma_{23})[\wp(\gamma_{31})-\wp(\gamma_{12})]+\wp'(\gamma_{31})[\wp(\gamma_{12})-\wp(\gamma_{23})]\}^{-1}. \tag{30}$$

After the substitution of (30) into one of Eqs. (28) and (29), one obtains the nonlinear constraint for $\gamma_{12},\gamma_{23},\gamma_{31}$. At first sight it seems to be enormously cumbersome but can be essentially simplified with the use of addition theorems for zeta functions,

$$\zeta(x)+\zeta(y)+\zeta(z)-\zeta(x+y+z)=2[\wp(x)-\wp(y)][\wp(y)-\wp(z)][\wp(z)-\wp(x)]\{\wp'(x)[\wp(y)$$
$$-\wp(z)]+\wp'(y)[\wp(z)-\wp(x)]+\wp'(z)[\wp(x)-\wp(y)]\}^{-1},$$
$$\wp(x)-\wp(y)=[\zeta(x)-\zeta(y)-\zeta(x+z)+\zeta(y+z)][\zeta(x)+\zeta(y)+\zeta(z)-\zeta(x+y+z)], \tag{31}$$

which are valid for all $x,y,z\in\mathbf{C}$. The result of simple but tedious calculations is

$$[\zeta(\gamma_{12})+\zeta(\gamma_{23})+\zeta(\gamma_{31})-\zeta(\gamma_{12}+\gamma_{23}+\gamma_{31})]\{9\zeta(\gamma_{12}+\gamma_{23}+\gamma_{31})$$
$$-4[\zeta(\gamma_{12}+\gamma_{23})+\zeta(\gamma_{23}+\gamma_{31})+\zeta(\gamma_{12}+\gamma_{31})]-[\zeta(\gamma_{12})+\zeta(\gamma_{23})+\zeta(\gamma_{31})]\}=0. \tag{32}$$

All zeroes of the first factor in (32) coincide with the poles of the second one as it follows from the relation

$$\zeta(x)+\zeta(y)+\zeta(z)-\zeta(x+y+z)=\frac{\sigma(x+y)\sigma(y+z)\sigma(z+x)}{\sigma(x)\sigma(y)\sigma(z)\sigma(x+y+z)}. \tag{33}$$

Hence this factor must be omitted and one finally obtains the constraint for $\{\gamma\}$ in the form

$$\zeta(\gamma_{12})+\zeta(\gamma_{23})+\zeta(\gamma_{31})+4[\zeta(\gamma_{12}+\gamma_{23})+\zeta(\gamma_{23}+\gamma_{31})+\zeta(\gamma_{31}+\gamma_{12})]-9\zeta(\gamma_{12}+\gamma_{23}+\gamma_{31})=0. \tag{34}$$

The left-hand side of (34) as a function of one of the phases (say, γ_{12}) at fixed values of two others is double periodic and has four simple poles on $\mathbf{C}/\mathbf{Z}\omega_1+\mathbf{Z}\omega_2$. So there are four roots of Eq. (34) and γ_{12} can be treated as a four-valued function of γ_{23} and γ_{31} on $(\mathbf{C}/\mathbf{Z}\omega_1+\mathbf{Z}\omega_2)^2$. The analysis of degenerate cases $\omega_1,\omega_2\to\infty$ shows that the uniformization problem for the constraint (34) is relatively complicated and its solution seems to be very nontrivial.

With the use of (24)–(27), (30), and (34) one can express the parameter B and the differences $\{k_\alpha-k_\beta\}$ through the phases $\{\gamma\}$. The result reads

$$B=\tfrac{1}{2}[\zeta(\gamma_{12})+\zeta(\gamma_{23})+\zeta(\gamma_{31})-3\zeta(\gamma_{12}+\gamma_{23}+\gamma_{31})], \tag{35}$$

$$i(k_\alpha - k_\beta) = \tfrac{1}{2}[\zeta(\gamma_{\beta\delta}) - \zeta(\gamma_{\alpha\delta}) - \zeta(\gamma_{\alpha\beta}) + 4\zeta(\gamma_{\beta\delta} - \gamma_{\alpha\delta}) - 3\zeta(\gamma_{\alpha\beta} + \gamma_{\beta\delta} - \gamma_{\alpha\delta})], \quad (36)$$

where $(\alpha\beta\delta)$ is an arbitrary permutation of (123).

The next step in constructing the solutions to (11) consists in solving Eqs. (21). The explicit form of them is as follows:

$$\begin{aligned}\lambda_{-1}^{(2)}(z) = {} & [B + \zeta(\gamma_{12}) + \zeta(z+\gamma_{23}) - \zeta(z-\gamma_{31})]\{-\epsilon + 3\wp(z) + \wp(z+\gamma_{23}) - \zeta^2(\gamma_{12}) - \wp(\gamma_{12}) \\ & + \zeta(\gamma_{12})[\zeta(z+\gamma_{23}) - \zeta(z-\gamma_{31})] - [\zeta(z+\gamma_{23}) - \zeta(z-\gamma_{31})]^2 - 3[\zeta(z) - \zeta(z-\gamma_{31})] \\ & \times [\zeta(z) - \zeta(z+\gamma_{23})] + i(k_1 - k_3)[\zeta(z) - \zeta(\gamma_{12}) - \zeta(z-\gamma_{31})] + i(k_2 - k_3)[\zeta(z) \\ & + \zeta(\gamma_{12}) - \zeta(z+\gamma_{23})]\} - \wp'(\gamma_{12}) + \wp'(z+\gamma_{23}) + [\wp(z-\gamma_{31}) - \wp(z+\gamma_{23})][i(k_3 - k_2) \\ & + \zeta(\gamma_{12}) - \zeta(z-\gamma_{31}) - 2\zeta(z+\gamma_{23}) + 3\zeta(z)] = 0, \end{aligned} \quad (37)$$

$$\begin{aligned}\lambda_{-1}^{(3)}(z) = {} & [B + \zeta(\gamma_{31}) + \zeta(z+\gamma_{23}) - \zeta(z-\gamma_{12})]\{-\epsilon + 3\wp(z) + \wp(z+\gamma_{23}) - \zeta^2(\gamma_{31}) - \wp(\gamma_{31}) \\ & + \zeta(\gamma_{31})[\zeta(z+\gamma_{23}) - \zeta(z-\gamma_{12})] - [\zeta(z+\gamma_{23}) - \zeta(z-\gamma_{12})]^2 - 3[\zeta(z) - \zeta(z-\gamma_{12})] \\ & \times [\zeta(z) - \zeta(z+\gamma_{23})] + i(k_2 - k_1)[\zeta(z) - \zeta(\gamma_{31}) - \zeta(z-\gamma_{12})] + i(k_2 - k_3)[\zeta(z) \\ & + \zeta(\gamma_{31}) - \zeta(z+\gamma_{23})]\} - \wp'(\gamma_{31}) + \wp'(z+\gamma_{23}) + [\wp(z-\gamma_{12}) - \wp(z+\gamma_{23})][i(k_3 - k_2) \\ & + \zeta(\gamma_{31}) - \zeta(z-\gamma_{12}) - 2\zeta(z+\gamma_{23}) + 3\zeta(z)] = 0. \end{aligned} \quad (38)$$

It is easy to see that both $\lambda_{-1}^{(2)}(z)$ and $\lambda_{-1}^{(3)}(z)$ are elliptic functions of z with poles at $z = 0, -\gamma_{23}, \gamma_{31}$ for (37) and at $z = 0, -\gamma_{23}, \gamma_{12}$ for (38). At arbitrary values of $B, \{k\}, \{\gamma\}$ the pole at $z = 0$ is simple and two others are of second order. With the use of (35) and (36) one can show, however, that $\lambda_{-1}^{(2)}$ and $\lambda_{-1}^{(3)}$ are analytic at $z = 0$ and the remaining poles are simple. Hence, according to the Liouville theorem, $\lambda_{-1}^{(2)}$ and $\lambda_{-1}^{(3)}$ must vanish if their residues at $z = \gamma_{23}$ and values at $z = 0$ are equal to zero. In other words, (37) and (38) are reduced to four algebraic equations,

$$\begin{aligned} & \epsilon + i(k_1 - k_3)[-\zeta(\gamma_{31}) + \zeta(\gamma_{12})] + i(k_2 - k_3)[\zeta(\gamma_{31} + \gamma_{23}) - \zeta(\gamma_{12}) - \zeta(\gamma_{31})] + 2\wp(\gamma_{31} + \gamma_{23}) \\ & \quad - 3\wp(\gamma_{31}) + \wp(\gamma_{12}) + \zeta^2(\gamma_{12}) + \zeta^2(\gamma_{31} + \gamma_{23}) + 3\zeta^2(\gamma_{31}) - \zeta(\gamma_{31} + \gamma_{23})[\zeta(\gamma_{12}) + 3\zeta(\gamma_{31})] \\ & \quad + [B + \zeta(\gamma_{12}) + \zeta(\gamma_{31} + \gamma_{23})][-i(k_1 - k_3) + 3\zeta(\gamma_{31}) - \zeta(\gamma_{12}) - \zeta(\gamma_{31} + \gamma_{23})] = 0, \end{aligned} \quad (39)$$

$$\begin{aligned} & [B + \zeta(\gamma_{12}) + \zeta(\gamma_{23}) + \zeta(\gamma_{31})][-\epsilon - 3\wp(\gamma_{31}) - 2\wp(\gamma_{23}) - \wp(\gamma_{12}) - \zeta^2(\gamma_{12}) - (\zeta(\gamma_{23}) + \zeta(\gamma_{31}))^2 \\ & \quad + \zeta(\gamma_{12})(\zeta(\gamma_{23}) + \zeta(\gamma_{31})) + 3\zeta(\gamma_{23})\zeta(\gamma_{31}) + i(k_1 - k_3)(\zeta(\gamma_{31}) - \zeta(\gamma_{12})) + i(k_2 - k_3) \\ & \quad \times (\zeta(\gamma_{12}) - \zeta(\gamma_{23}))] + [\wp(\gamma_{31}) - \wp(\gamma_{23})][i(k_1 - k_3) + \zeta(\gamma_{12}) + \zeta(\gamma_{23}) - 2\zeta(\gamma_{31})] \\ & \quad - 3\wp'(\gamma_{31}) - 2\wp'(\gamma_{23}) - \wp'(\gamma_{12}) = 0, \end{aligned} \quad (40)$$

$$\begin{aligned} & \epsilon + i(k_2 - k_1)[-\zeta(\gamma_{12}) + \zeta(\gamma_{31})] + i(k_2 - k_3)[\zeta(\gamma_{12} + \gamma_{23}) - \zeta(\gamma_{12}) - \zeta(\gamma_{31})] + 2\wp(\gamma_{12} + \gamma_{23}) \\ & \quad - 3\wp(\gamma_{12}) + \wp(\gamma_{31}) + \zeta^2(\gamma_{31}) + \zeta^2(\gamma_{12} + \gamma_{23}) + 3\zeta^2(\gamma_{12}) - \zeta(\gamma_{12} + \gamma_{23})[\zeta(\gamma_{31}) + 3\zeta(\gamma_{12})] \\ & \quad + [B + \zeta(\gamma_{31}) + \zeta(\gamma_{12} + \gamma_{23})][-i(k_2 - k_1) + 3\zeta(\gamma_{12}) - \zeta(\gamma_{31}) - \zeta(\gamma_{12} + \gamma_{23})] = 0, \end{aligned} \quad (41)$$

$$[B+\zeta(\gamma_{12})+\zeta(\gamma_{23})+\zeta(\gamma_{31})][-\epsilon-3\wp(\gamma_{12})-2\wp(\gamma_{23})-\wp(\gamma_{31})-\zeta^2(\gamma_{31})]-(\zeta(\gamma_{23})+\zeta(\gamma_{12}))^2$$
$$+\zeta(\gamma_{31})(\zeta(\gamma_{12})+\zeta(\gamma_{23}))+3\zeta(\gamma_{23})\zeta(\gamma_{12})+i(k_2-k_1)(\zeta(\gamma_{12})-\zeta(\gamma_{31}))+i(k_2-k_3)(\zeta(\gamma_{31})$$
$$-\zeta(\gamma_{23}))]+[\wp(\gamma_{12})-\wp(\gamma_{23})][i(k_2-k_1)+\zeta(\gamma_{31})+\zeta(\gamma_{23})-2\zeta(\gamma_{12})]-3\wp'(\gamma_{12})$$
$$-2\wp'(\gamma_{23})-\wp'(\gamma_{31})=0. \tag{42}$$

The essential simplification of (40) and (42) can be made if the formula

$$\wp'(x)+2\wp'(y)+3\wp'(z)=2[\wp(z)-\wp(y)][\zeta(x)+\zeta(y)-\zeta(x+y)]+[\zeta(x+y+z)-\zeta(x)$$
$$-\zeta(y)-\zeta(z)]\{6[\wp(x)+\wp(y)+\wp(z)]+2[\zeta(x)+\zeta(y)-\zeta(x+y)]$$
$$\times[\zeta(x+y)+\zeta(x+z)+\zeta(y+z)-2\zeta(x)-2\zeta(y)-2\zeta(z)]\}$$

is taken into account. Finally, with the use of (31), (35), and (36) it is possible after long calculations to show that all Eqs. (39)–(42) are mutually equivalent. Any extra constraints on the parameters $\{\gamma\}$ are absent and (39)–(42) determine the three-particle energy,

$$E=\tfrac{1}{2}(k_1^2+k_2^2+k_3^2)-\tfrac{1}{2}[\zeta^2(\gamma_{12})+\zeta^2(\gamma_{23})+\zeta^2(\gamma_{31})]+\tfrac{3}{2}\zeta(\gamma_{12}+\gamma_{23}+\gamma_{31})[\zeta(\gamma_{12})+\zeta(\gamma_{23})$$
$$+\zeta(\gamma_{31})]-2[\zeta(\gamma_{12})\zeta(\gamma_{23}+\gamma_{31})+\zeta(\gamma_{23})\zeta(\gamma_{12}+\gamma_{31})+\zeta(\gamma_{31})\zeta(\gamma_{12}+\gamma_{23})]+2[\wp(\gamma_{12})$$
$$+\wp(\gamma_{23})+\wp(\gamma_{31})]-\tfrac{9}{4}[\zeta(\gamma_{12}+\gamma_{23}+\gamma_{31})-\zeta(\gamma_{12})-\zeta(\gamma_{23})-\zeta(\gamma_{31})]^2.$$

[This result, together with the formulas (35) and (36), has been announced in Ref. 24.] Further simplification of E can be reached by extracting the energy of the center-of-mass motion with a total momentum $K=k_1+k_2+k_3$ and using expressions for relative quasimomenta $\{k_\alpha-k_\beta\}$ (36) in combination with addition theorems (10) and (31) for the Weierstrass functions,

$$E=\frac{K^2}{6}+\frac{1}{12}\{27\wp(\gamma_{12}+\gamma_{23}+\gamma_{31})-8[\wp(\gamma_{12}+\gamma_{23})+\wp(\gamma_{23}+\gamma_{31})+\wp(\gamma_{12}+\gamma_{31})]-[\wp(\gamma_{12})$$
$$+\wp(\gamma_{23})+\wp(\gamma_{31})]\}. \tag{43}$$

Formulas (13), (14), (35), (36), and (43) give a complete solution to the problem of finding the quasiperiodic functions $\varphi(x_1,x_2,x_3)$ obeying (11). Note also that with the use of (33) one can write φ's only in terms of sigma functions,

$$\varphi(x_1,x_2,x_3)=\frac{A\ \exp(i\Sigma_{\alpha=1}^3 k_\alpha x_\alpha)}{\sigma(x_1-x_2)\sigma(x_2-x_3)\sigma(x_3-x_1)}$$
$$\times\left\{\frac{\sigma(x_1-x_2+\gamma_{12})\sigma(x_2-x_3+\gamma_{23})\sigma(x_3-x_1+\gamma_{31})}{2\sigma(\gamma_{12})\sigma(\gamma_{23})\sigma(\gamma_{31})}\right.$$
$$\left.+\frac{\sigma(x_1-x_2+\gamma_{12}-\Delta)\sigma(x_2-x_3+\gamma_{23}-\Delta)\sigma(x_3-x_1+\gamma_{31}-\Delta)}{\sigma(\gamma_{12}-\Delta)\sigma(\gamma_{23}-\Delta)\sigma(\gamma_{31}-\Delta)}\right\}, \tag{44}$$

where $\Delta=\gamma_{12}+\gamma_{23}+\gamma_{31}$ and the connections (36) between ks and γs are implied. The resemblance of (44) to the classical Hermite form (6) of the solution to the Lamè equation is evident.

III. THREE-MAGNON PROBLEM

First, let us note that the lattice equation (4) always has solutions of the type

$$\psi_d^{(M)}(n_1\cdots n_M)=\sum_{\beta=1}^{M}\psi^{(M-1)}(n_1\cdots n_{\beta-1}n_{\beta+1}\cdots n_M),\quad E_M=E_{M-1}, \tag{45}$$

where $\psi^{(M-1)}(n_1\cdots n_{M-1})$ obeys the equation of the type (4) with M replaced by $M-1$. The wave functions (45) describe the M-magnon states which are generated from $(M-1)$-magnon ones by the action of the component of total spin operator reducing the absolute value of S_z. The remained M-magnon states corresponding to the lowest possible eigenvalue of the total spin are described by ψs which cannot be presented in the form (45). Now let us construct three-magnon states of this type in terms of the ansatz which is similar to the symmetrized three-particle wave function (13) and (14):

$$\psi^{(3)}(n_1,n_2,n_3)=\sum_{P\in\pi_3}\frac{\exp(i\Sigma_{\alpha=1}^{3}k_\alpha n_{P\alpha})}{\sigma(n_{P1}-n_{P2})\sigma(n_{P2}-n_{P3})\sigma(n_{P3}-n_{P1})}\left[B+\frac{\partial}{\partial\gamma_{12}}+\frac{\partial}{\partial\gamma_{23}}\right.$$
$$\left.+\frac{\partial}{\partial\gamma_{31}}\right]\sigma(n_{P1}-n_{P2}+\gamma_{12})\sigma(n_{P2}-n_{P3}+\gamma_{23})\sigma(n_{P3}-n_{P1}+\gamma_{31}). \tag{46}$$

Here π_3 is the group of all permutations of the numbers from 1 to 3. The Weierstrass functions are defined on the torus $T_{N,\omega}$. Unlike the particle case, ks and γs have to be restricted by the periodicity of ψ in each argument,

$$Nk_\alpha-i\eta_1(\gamma_{\alpha\beta}+\gamma_{\alpha\delta})=2\pi l_\alpha,\quad l_\alpha\in\mathbf{Z}, \tag{47}$$

where the auxiliary phases are defined by (16).

To calculate the left-hand side of (4) at $M=3$ with the use of (46), one should represent in a closed form the sum over lattice sites of the following type,

$$W(k,\{\gamma\},\{l\})=\sum_{s=1;s\neq l_1,l_2}^{N-1}\exp(iks)\wp(s)\,\frac{\sigma(s-l_1+\gamma_1)\sigma(s-l_2+\gamma_2)}{\sigma(s-l_1)\sigma(s-l_2)},\quad l_1,l_2\in\mathbf{Z}, \tag{48}$$

where k, γ_1, and γ_2 are chosen so as to ensure the periodicity of the summands in (48) with respect to s,

$$kN-i\eta_1(\gamma_1+\gamma_2)=0(\mathrm{mod}\,2\pi).$$

It can be done by using the technique based on the Liouville theorem and described earlier in Refs. 12 and 13. The result reads

$$W(k,\{\gamma\},\{l\})=\left[\prod_{\alpha=1}^{2}\frac{\sigma(l_\alpha-\gamma_\alpha)}{\sigma(l_\alpha)}\right]\left\{\epsilon(k,\gamma_1,\gamma_2)+f(k,\gamma_1,\gamma_2)\sum_{\alpha=1}^{2}[\zeta(l_\alpha)-\zeta(l_\alpha-\gamma_\alpha)]\right.$$
$$-[\zeta(l_1)-\zeta(l_1-\gamma_1)][\zeta(l_2)-\zeta(l_2-\gamma_2)]+\frac{1}{2}\sum_{\alpha=1}^{2}[\wp(l_\alpha-\gamma_\alpha)-\wp(l_\alpha)$$
$$\left.-(\zeta(l_\alpha)-\zeta(l_\alpha-\gamma_\alpha))^2]\right\}+2\sum_{\alpha=1}^{2}\exp(ikl_\alpha)\left[\prod_{\beta\neq\alpha}^{2}\frac{\sigma(l_\alpha-l_\beta+\gamma_\beta)}{\sigma(l_\alpha-l_\beta)}\right]\sigma(\gamma_\alpha)$$
$$\times\left\{\wp(l_\alpha)\left[f(k,\gamma_1,\gamma_2)-\zeta(\gamma_\alpha)-\sum_{\beta\neq\alpha}(\zeta(l_\alpha-l_\beta+\gamma_\beta)-\zeta(l_\alpha-l_\beta))\right]-\wp'(l_\alpha)\right\},$$

where

$$f(k,\gamma_1,\gamma_2)=\zeta_1\left(-\frac{k\omega}{2\pi}+\frac{i}{\pi}\,\zeta\left(\frac{\omega}{2}\right)(\gamma_1+\gamma_2)\right)+(\pi i)^{-1}\left[ik\zeta_1\left(\frac{\omega}{2}\right)+2\zeta_1\left(\frac{1}{2}\right)\zeta\left(\frac{\omega}{2}\right)(\gamma_1+\gamma_2)\right],$$

$$\epsilon(k,\gamma_1,\gamma_2)=\frac{1}{2}\left[\wp_1\left(-\frac{k\omega}{2\pi}+\frac{i}{\pi}\,\zeta\left(\frac{\omega}{2}\right)(\gamma_1+\gamma_2)\right)-f^2(k,\gamma_1,\gamma_2)\right],$$

and the notation $\wp_1(x),\zeta_1(x)$ is used for the Weierstrass functions defined on the torus $T_{1,\omega}$.

Now the lhs of (4) at $M=3$ can be divided into two parts,

$$L(n_1,n_2,n_3)=L_1(n_1,n_2,n_3)+L_2(n_1,n_2,n_3),$$

where

$$L_1(n_1,n_2,n_3)=\sum_{P\in\pi_3}\sum_{\alpha=1}^{3}\chi_\alpha(n_{P1},n_{P2},n_{P3}),$$

$$L_2(n_1,n_2,n_3)=\sum_{P\in\pi_3}\sum_{\alpha=1}^{3}[\mu_\alpha^{(1)}(n_{P1},n_{P2},n_{P3})+\mu_\alpha^{(2)}(n_{P1},n_{P2},n_{P3})], \tag{49}$$

and

$$\begin{aligned}\chi_1(l_1,l_2,l_3)=\exp\left(i\sum_{\alpha=1}^{3}k_\alpha l_\alpha\right)&\frac{\sigma(l_1-l_2+\gamma_{12})\sigma(l_2-l_3+\gamma_{23})\sigma(l_3-l_1+\gamma_{31})}{\sigma(l_1-l_2)\sigma(l_2-l_3)\sigma(l_3-l_1)}\{[B+\zeta(l_2-l_3\\&+\gamma_{23})+\zeta(l_1-l_2+\gamma_{12})+\zeta(l_3-l_1+\gamma_{31})][\epsilon(k_1,\gamma_{12},\gamma_{13})+(f(k_1,\gamma_{12},\gamma_{13})\\&-\zeta(\gamma_{12}))(\zeta(l_1-l_2+\gamma_{12})-\zeta(l_1-l_2))+(f(k_1,\gamma_{12},\gamma_{13})-\zeta(\gamma_{13}))(\zeta(l_1-l_3+\gamma_{13})\\&-\zeta(l_1-l_3))-(\zeta(l_1-l_2+\gamma_{12})-\zeta(l_1-l_2))(\zeta(l_1-l_3+\gamma_{13})-\zeta(l_1-l_3))-\wp(l_1\\&-l_2)-\wp(l_1-l_3)-\tfrac{1}{2}(\zeta^2(\gamma_{12})+\zeta^2(\gamma_{13})-\wp(\gamma_{12})-\wp(\gamma_{13}))]+[\zeta(l_1-l_2+\gamma_{12})\\&-\zeta(l_1-l_2)][\wp(\gamma_{12})-\wp(l_1-l_3+\gamma_{13})]+[\zeta(l_1-l_3+\gamma_{13})-\zeta(l_1-l_3)][\wp(l_1-l_2\\&+\gamma_{12})-\wp(\gamma_{13})]-\wp(l_1-l_2+\gamma_{12})[f(k_1,\gamma_{12},\gamma_{13})-\zeta(\gamma_{12})]+\wp(l_1-l_3+\gamma_{13})\\&\times[f(k_1,\gamma_{12},\gamma_{13})-\zeta(\gamma_{13})]-\wp(\gamma_{12})\zeta(\gamma_{12})+\wp(\gamma_{13})\zeta(\gamma_{13})+\tfrac{1}{2}[\wp'(\gamma_{13})\\&-\wp'(\gamma_{12})]\},\end{aligned} \tag{50}$$

$$\begin{aligned}\mu_1^{(1)}(l_1,l_2,l_3)=\exp[i(l_2(k_1+k_2)+k_3l_3)]&\frac{\sigma(l_2-l_3+\gamma_{23})\sigma(l_2-l_3+\gamma_{13})}{\sigma^2(l_2-l_3)}\sigma(\gamma_{12})\{[B+\zeta(l_2-l_3\\&+\gamma_{23})-\zeta(l_2-l_3+\gamma_{13})+\zeta(\gamma_{12})][\wp(l_1-l_2)(f(k_1,\gamma_{12},\gamma_{13})-\zeta(\gamma_{12})-\zeta(l_2-l_3\\&+\gamma_{13})+\zeta(l_2-l_3))+\wp'(l_1-l_2)]+\wp(l_1-l_2)[\wp(\gamma_{12})-\wp(l_2-l_3+\gamma_{13})]\},\end{aligned} \tag{51}$$

$$\mu_2^{(1)}(l_1,l_2,l_3)=\exp[i(l_3(k_1+k_3)+k_2l_2)]\,\frac{\sigma(l_2-l_3+\gamma_{23})\sigma(l_2-l_3-\gamma_{12})}{\sigma^2(l_2-l_3)}\,\sigma(\gamma_{13})\{[B+\zeta(l_2-l_3+\gamma_{23})-\zeta(l_2-l_3-\gamma_{12})-\zeta(\gamma_{13})][\wp(l_3-l_1)(f(k_1,\gamma_{12},\gamma_{13})-\zeta(\gamma_{13})+\zeta(l_2-l_3-\gamma_{12})-\zeta(l_2-l_3))+\wp'(l_1-l_3)]+\wp(l_3-l_1)[-\wp(\gamma_{13})+\wp(l_2-l_3-\gamma_{12})]\}. \tag{52}$$

The quantities $\chi_2,\mu_2^{(1)},\mu_2^{(2)}$ and $\chi_3,\mu_3^{(1)},\mu_3^{(2)}$ are obtained from (50)–(52) by cyclic permutations (123)→(231), (123)→(312) of the indices in $\{k_\alpha\},\{l_\alpha\},\{\gamma_{\alpha\beta}\}$. Note that $L_2(n_1,n_2,n_3)$ can be transformed as follows. If, for example, Q is the transposition $(1\leftrightarrow 2)$, then

$$\sum_{P\in\pi_3}\mu_2^{(2)}(n_{P1},n_{P2},n_{P3})=\sum_{PQ\in\pi_3}\mu_2^{(2)}(n_{PQ1},n_{PQ2},n_{PQ3})=\sum_{P\in\pi_3}\mu_2^{(2)}(n_{P2},n_{P1},n_{P3}).$$

Hence the terms in (49) can be combined as

$$\sum_{P\in\pi_3}\{[\mu_1^{(1)}(n_{P1},n_{P2},n_{P3})+\mu_2^{(2)}(n_{P2},n_{P1},n_{P3})]+[\mu_1^{(2)}(n_{P1},n_{P2},n_{P3})+\mu_3^{(1)}(n_{P3},n_{P2},n_{P1})]+[\mu_2^{(1)}(n_{P1},n_{P2},n_{P3})+\mu_3^{(2)}(n_{P1},n_{P3},n_{P2})]\}. \tag{53}$$

Now one can see with the use of the explicit expressions (51) and (52) that the terms in all the three braces of (53) vanish under the conditions which are very similar to the conditions (22) and (23) for vanishing of the second-order poles in the left-hand side of the three-particle equation (17):

$$[B+\zeta(\gamma_{12})+\zeta(z+\gamma_{23})-\zeta(z-\gamma_{31})][-f(k_1,\gamma_{12},\gamma_{13})+f(k_2,\gamma_{23},\gamma_{21})+2\zeta(\gamma_{12})+\zeta(z-\gamma_{13})-\zeta(z+\gamma_{23})]-2\wp(\gamma_{12})+\wp(z-\gamma_{31})+\wp(z+\gamma_{23})=0, \tag{54}$$

$$[B+\zeta(\gamma_{31})+\zeta(z+\gamma_{23})-\zeta(z-\gamma_{12})][-f(k_3,\gamma_{32},\gamma_{31})+f(k_1,\gamma_{12},\gamma_{13})+2\zeta(\gamma_{31})+\zeta(z-\gamma_{12})-\zeta(z+\gamma_{23})]-2\wp(\gamma_{31})+\wp(z-\gamma_{12})+\wp(z+\gamma_{23})=0, \tag{55}$$

$$z=n_{P2}-n_{P3}.$$

Really, the equations (22), (23) and (54), (55) exactly coincide after changing $k_\alpha\to if(k_\alpha,\gamma_{\alpha\beta},\gamma_{\alpha\delta})$. Hence one can use all the techniques of Sec. II for determining the relations between the parameters of the three-magnon wave function (46).

Since $L_2(n_1,n_2,n_3)$ vanishes if the conditions (54) and (55) are fulfilled, the final step of construction consists in the investigation of the structure of $L_1(n_1,n_2,n_3)$. It can be done along the lines of Sec. II with some minimal changes. One finds that $\psi(n_1,n_2,n_3)$ obeys (4) if B is expressed through the γs as in (35), ks and γs are connected by (36) after changing $ik_\alpha\to -f(k_\alpha,\gamma_{\alpha\beta},\gamma_{\alpha\delta})$, and the three-magnon energy is given by

$$E_3=\varepsilon(k_1,\gamma_{12},\gamma_{13})+\varepsilon(k_2,\gamma_{21},\gamma_{23})+\varepsilon(k_3,\gamma_{31},\gamma_{32})+\tfrac{1}{6}[f(k_1,\gamma_{12},\gamma_{13})+f(k_2,\gamma_{21},\gamma_{23})+f(k_3,\gamma_{31},\gamma_{32})]^2-\tfrac{1}{12}\{27\wp(\gamma_{12}+\gamma_{23}+\gamma_{31})-8[\wp(\gamma_{12}+\gamma_{23})+\wp(\gamma_{23}+\gamma_{31})+\wp(\gamma_{31}+\gamma_{12})]-\wp(\gamma_{12})-\wp(\gamma_{23})-\wp(\gamma_{31})\},$$

where

$$\varepsilon(k,\gamma_1,\gamma_2)=\frac{2}{\omega}\left[\zeta_1\left(\frac{\omega}{2}\right)-N\zeta\left(\frac{\omega}{2}\right)\right]-\frac{1}{2}\wp_1\left(-\frac{k\omega}{2\pi}+\frac{i}{\pi}\zeta\left(\frac{\omega}{2}\right)(\gamma_1+\gamma_2)\right).$$

The relations of the type (36) can be simplified by using the periodicity conditions (47) and Legendre relation (9). The result reads

$$\zeta_1\left(\frac{\gamma_{\alpha\beta}+\gamma_{\alpha\delta}-l_\alpha\omega}{N}\right)-\zeta_1\left(\frac{\gamma_{\beta\alpha}+\gamma_{\beta\delta}-l_\beta\omega}{N}\right)+2\zeta_1\left(\frac{\omega}{2}\right)\frac{l_\alpha-l_\beta}{N}+\frac{2}{N\omega}\left[N\zeta\left(\frac{\omega}{2}\right)-\zeta_1\left(\frac{\omega}{2}\right)\right](2\gamma_{\alpha\beta}$$

$$+\gamma_{\alpha\delta}-\gamma_{\beta\delta})+\frac{1}{2}[\zeta(\gamma_{\alpha\beta})+\zeta(\gamma_{\alpha\delta})-\zeta(\gamma_{\beta\delta})+4\zeta(\gamma_{\alpha\delta}-\gamma_{\beta\delta})+3\zeta(\gamma_{\alpha\beta}+\gamma_{\beta\delta}-\gamma_{\alpha\delta})]=0,$$

where $(\alpha\beta\gamma)$ is an arbitrary combination of (123) and $l_1,l_2,l_3\in\mathbf{Z}$. The corresponding three-magnon wave functions are determined by the solutions of these three transcendental constraints. As $\omega\to 0$, (56) transform to the Bethe-ansatz equations[17] for the periodic XXX Heisenberg chain with nearest-neighbor spin interaction. As it follows directly from the definition, the wave functions of the form (45) for three magnons are expressed through two-magnon ones found earlier in Ref. 22.

IV. SUMMARY AND DISCUSSION

The results presented above can be treated as a first step to the solution of the most general integrable 1-D translationally invariant Heisenberg chain with elliptic exchange which might provide rigorous proof of the validity of the use of asymptotic Bethe ansatz for thermodynamic description of infinite particle and spin systems with the short-range interaction $(\sinh \alpha r)^{-2}$. It is natural to expect that almost all previous results of Bethe, Sutherland, and Haldane in the integrable 1-D quantum chains will be unified by this hypothetical solution. The study of analytic properties may serve, as it was demonstrated above, as a guide to its construction.

It would be highly desirable to explain the reasons of the appearance of the Bethe-like transcendental equations (56) by clarifying the algebraic structures which give rise to the integrability of these spin chains. Some progress has been made recently in constructing the family of the operators which commute with the Hamiltonian (3).[25] The way of their extracting from some generalized transfer matrix has not yet been found. It is worth noting also that the analogy of spin and particle dynamics is extended further to give the correspondence between multimagnon wave functions and their many-particle double quasiperiodic counterparts. The details of the proof will be given elsewhere.

However, some problems are open even for the three-magnon case. In particular, it will be of interest to show that the solutions to (56) give a complete set of $\frac{1}{6}N(N-1)(N-5)$ three-magnon eigenvectors of the Hamiltonian (3) with total spin $S=S_z=N/2-3$. In the two-magnon case the answer to the similar question is positive.[26] The selection of the ground state in $M=3$ sector for antiferromagnetic type of coupling still demands nontrivial algebraic ideas and needs further detailed investigation.

On the quantum deformations of Hamiltonian systems

M. A. Lledó and M. García-Sucre
Centro de Física, Instituto Venezolano de Investigaciones Científicas, Apdo. 21827, Caracas 1020-A, Venezuela

(Received 18 July 1995; accepted for publication 18 September 1995)

In this paper we analyze the relationship between operatorial quantization and deformation quantization for Hamiltonian systems on R^{2n}. We define heuristically generalized symbols for the operators, which make this connection. We construct explicitly deformations which are not equivalent to the Moyal one and show that an infinitesimal, classical canonical transformation does not change the equivalence class of the deformation. The results are applied to the quantum integrability of some two dimensional Hamiltonian systems. © *1996 American Institute of Physics.* [S0022-2488(96)01001-6]

I. INTRODUCTION

The relationship between classical and quantum mechanics is not completely understood. Given a classical Hamiltonian system defined on the $2n$ dimensional phase space R^{2n}, with coordinates (q_i, p_i), $i=1,\ldots,n$, the quantization map is a linear map which sends a real function $f \in C^\infty(R^{2n})$ on the phase space to an Hermitian operator $\hat{f}$ on the Hilbert space of square integrable functions of variables $q_i, L^2(R^n)$. The usual rule of quantization is to associate Hermitian operators $(\hat{q}_i, \hat{p}_j)$ to the basic functions (q_i, p_j) such that,

$$\hat{q}_i \Psi(q) = q_i \Psi(q),$$
$$\hat{p}_j \Psi(q) = -i\hbar \frac{\partial}{\partial q_j} \Psi(q), \tag{1}$$

and the constant function 1 is mapped to the identity operator. The Lie bracket of these operators is related with the Poisson bracket of the corresponding functions on the phase space by

$$[\hat{q}_i, \hat{p}_j] = i\hbar \{q_i, p_j\}\hat{} = i\hbar \delta_{ij}. \tag{2}$$

As it is well known, this rule does not completely determine the quantization map. Consider for example a polynomial $q^n p^m$. We can associate several operators to it, corresponding to different ordering rules. The first attempt to select an ordering rule is due to Dirac.[1] According to the Dirac rule, one tries to associate Hermitian operators to real functions in phase space in such a way that the relation between Lie brackets and Poisson brackets (2) is maintained for all functions,

$$[\hat{f}, \hat{g}] = i\hbar \{f, g\}\hat{}; \quad f, g \in C^\infty(R^n). \tag{3}$$

It is also known that this rule is inconsistent (see Ref. 2, Chap. 5, Sec. 4 for a proof). Dirac itself noticed this could happen, and proposed to relax the rule by requiring that it were valid only to first order in $\hbar$.

There is a wide variety of ordering rules. All of them satisfy the last requirement, and can be expressed through the formal integral,[3]

$$\hat{f} = \int d^n s d^n t \mathcal{F}\left(\frac{i}{\hbar} s \cdot t\right) \bar{f}(s,t) \exp\left(\frac{i}{\hbar} (s \cdot \hat{p} + t \cdot \hat{q})\right), \tag{4}$$

0022-2488/96/37(1)/160/14/$6.00

where

$$\bar{f}(s,t)=\frac{1}{(2\pi\hbar)^{2n}}\int d^nq\,d^np\,\exp\left(-\frac{i}{\hbar}(s\cdot p+t\cdot q)\right)f(q,p) \tag{5}$$

is the Fourier transform of the classical observable, and $\mathscr{F}$ is an arbitrary function. Some of them associate Hermitian operators to real functions, as for example the Weyl rule, which corresponds to take $\mathscr{F}=1$.[4]

The ordering rule is not the only origin of arbitrariness in the process of quantization. One could consider quantizing a function $g(q,p,\hbar)$ whose limit when $\hbar\to 0$ is $f(q,p)$. Since the inverse process to quantization involves taking a limit $\hbar\to 0$, the operator associated to $g(q,p,\hbar)$ is a physically admissible quantization of the classical observable $f(q,p)$.

Finally, let us consider the effect of making a classical canonical transformation, $(q,p)\mapsto(Q(q,p),P(q,p))$. Let f be a classical observable, and let $\hat{f}$ and $\hat{F}$ be the corresponding quantum observables according to the Weyl rule, in the old and new canonical coordinates respectively. The map $\hat{f}\mapsto\hat{F}$ is not a unitary transformation (or more generally, an isometry[5]) for a general canonical transformation, since (3) is inconsistent. So both quantization maps are different, and as before, both are physically admissible. Each quantum theory has its own quantum canonical transformations (i.e. unitary or isometric transformations) but generally the map $\hat{f}\mapsto\hat{F}$ may not correspond to any of them. This is also true for the map given by different ordering rules.

So there is a big degree of arbitrariness when facing the problem of selecting a quantum theory once the classical theory is given. The only thing we know for sure is that the classical theory must be the limit when $\hbar\to 0$, and this limit is a sort of collapsing limit, which does not admit a unique inverse process. In order to make a selection, we must add other criteria, as for example, maintaining the symmetries present in the classical theory.

There are other methods of approaching the problem of quantization. For instance, a powerful one is the deformation theory.[6] The quantization process is understood as a deformation of the Poisson bracket of functions on phase space in terms of the parameter $\hbar$. The deformation is just an inverse process of the "contraction" $\hbar\to 0$. A deformation of the Poisson algebra was written by Moyal,[7] and it is indeed a sort of fundamental deformation on a flat Poisson manifold. The Moyal bracket is related with the Weyl quantization rule through a kind of symbols (Weyl symbols) associated to pseudodifferential operators. Other deformations are related with operators by means of other kinds of symbols. The purpose of this paper is to clarify the relationship between both methods of quantization, the deformation and operatorial approaches.

In Section II we explore the connection between symbols and ordering rules. In Section III we review some facts about deformations of Poisson algebras, construct explicitly deformations nonequivalent to the Moyal one and analyze the effect of a classical canonical transformation when going to the quantum theory. In Section IV we make some applications to the quantum integrability of two dimensional Hamiltonian systems. Finally, in Section V we state our conclusions.

II. SYMBOLS AND ORDERING RULES

A symbol of a pseudodifferential operator is a function associated to it in such a way that the operator can be obtained if the symbol is known. The product of symbols is defined as the symbol of the composite operator. The subject of pseudodifferential operators and their symbols is a well studied subject, and we only make here a rapid survey. Exact statements and proofs concerning τ-symbols can be found for example in Ref. 8.

Let us consider a differential operator A of order m which acts on $u\in C^\infty(R^n)$ through

$$Au(q)=\sum_{|\alpha|\leq m}a_\alpha(q)P^\alpha u(q), \tag{6}$$

where $\alpha=(\alpha^1,...,\alpha^n)$ is a multiindex with $\alpha^j=0,\ldots,m$ and $|\alpha|=\alpha_1+...+\alpha_n$. In what follows a greek character will denote a multiindex, and a Latin one a simple index. $a_\alpha(q)\in C^\infty(R^n)$, $P=(P_1,\ldots,P_n)$, $P_j=-i\hbar(\partial/\partial q^j)$ and $P^\alpha=P_1^{\alpha_1}\ldots P_n^{\alpha_n}$.

Let $u(q)\in S(R^n)$, the Schwartz space, and consider the Fourier transform

$$\bar{u}(p)=\frac{1}{(2\pi\hbar)^n}\int d^nq\ \exp\left(-\frac{i}{\hbar}\,q\cdot p\right)u(q),$$
$$u(q)=\int d^np\ \exp\left(\frac{i}{\hbar}\,q\cdot p\right)\bar{u}(p). \tag{7}$$

Let us apply the operator A on the second expression of (7),

$$Au(q)=\frac{1}{(2\pi\hbar)^n}\int d^npd^nq'\ \exp\left(\frac{i}{\hbar}\,p\cdot(q-q')\right)\sigma_A(q,p)u(q'), \tag{8}$$

where we have introduced the standard symbol of A as the function

$$\sigma_A(q,p)=\sum_{|\alpha|\leqslant m}a_\alpha(q)p^\alpha=\exp\left(-\frac{i}{\hbar}\,q\cdot p\right)A\ \exp\left(\frac{1}{\hbar}\,q\cdot p\right). \tag{9}$$

Equation (8) is valid even for more general functions $u(q)$ by conveniently regularizing the integral, so one can consider (8) as the definition of the operator A through his standard symbol.

One can consider more general operators,

$$Bu(q)=\frac{1}{(2\pi\hbar)^n}\int d^npd^nq'\ \exp\left(\frac{i}{\hbar}\,p\cdot(q-q')\right)b(q,q',p)u(q'), \tag{10}$$

where the function $b(q,q',p)$ is the amplitude of the operator belonging to a suitably restricted class of functions. It is a remarkable fact that an operator like (10) can be uniquely written as

$$Bu(q)=\frac{1}{(2\pi\hbar)^n}\int d^npd^nq'\ \exp\left(\frac{i}{\hbar}\,p\cdot(q-q')\right).\sigma_A^\tau((1-\tau)q+\tau q',p)u(q') \tag{11}$$

for any $\tau\in R$. The function $\sigma_A^\tau(x,p)$ is the τ-symbol of the operator A. The standard symbol (or left symbol) corresponds to take $\tau=0$. For $\tau=1$ it is called the right symbol, and for $\tau=1/2$ it is called the Weyl symbol. A differential operator is a special case of (10), so one can define its τ-symbol for any τ, and not only the standard symbol. Let τ_1 and τ_2 be two arbitrary real numbers. One can obtain the τ_2-symbol of a differential operator in terms of the τ_1-symbol through the formula,

$$\sigma^{\tau_2}(x,p)=\sum_\alpha\ (\tau_1-\tau_2)^{|\alpha|}\partial_p^\alpha P^\alpha\sigma^{\tau_1}(x,p). \tag{12}$$

An interesting point about symbols is that they have a composition rule. Let A' and A'' be differential operators with symbols σ'^τ and σ''^τ respectively, then the symbol of the composition $A'\circ A''$ has the form

$$\sigma^\tau(x,p)=\sum_{\beta,\gamma}\ \frac{(-1)^{|\beta|}\tau^{|\beta|}(1-\tau)^{|\gamma|}}{\beta!\,\gamma!}\,(\partial_p^\gamma P^\beta\sigma'^\tau(x,p))(\partial_p^\beta P^\gamma\sigma''^\tau(x,p)). \tag{13}$$

The composition formula defines an associative, noncommutative product on the space of symbols, different for each τ which we denote by $\sigma'^{\tau} *_{\tau} \sigma''^{\tau}$.

The Weyl symbol has the property

$$\sigma_A^{1/2}(x,p) = \overline{\sigma_{A^\dagger}^{1/2}(x,p)}, \tag{14}$$

where the bar means complex conjugation and $A^\dagger$ is the adjoint operator. So $A = A^\dagger$ is equivalent to the real valuedness of the Weyl symbol.

We want now to compute the standard symbol of the operator associated to a function on the phase space by one of the ordering rules (4).[3] We assume that the function $\mathscr{F}((i/\hbar)s\cdot t)$, which determines the ordering rule, is always different from zero, has $\mathscr{F}(0)=1$ and can be expanded as

$$\mathscr{F}\left(\frac{i}{\hbar}\, s\cdot t\right) = \sum_m \mathscr{F}_m \left(\frac{i}{\hbar}\, s\cdot t\right)^m. \tag{15}$$

Using that

$$\exp\left(\frac{i}{\hbar}\,(t\cdot\hat{q} + s\cdot\hat{p})\right) = \exp\frac{is\cdot t}{2\hbar}\exp\frac{it\cdot\hat{q}}{\hbar}\exp\frac{is\cdot\hat{p}}{\hbar}, \tag{16}$$

the operator $\hat{f}$ in (4) can be written as

$$\hat{f} = \int d^n s\, d^n t\, \mathscr{F}\left(\frac{i}{\hbar}\, s\cdot t\right) \bar{f}(s,t) \exp\frac{is\cdot t}{2\hbar}\exp\frac{it\cdot\hat{q}}{\hbar}\exp\frac{is\cdot\hat{p}}{\hbar}. \tag{17}$$

So, according to (9), the standard symbol of this operator is

$$\sigma_{\hat{f}}^0 = \int d^n s\, d^n t\, \mathscr{F}\left(\frac{i}{\hbar}\, s\cdot t\right) \bar{f}(s,t) \exp\frac{is\cdot t}{2\hbar}\exp\frac{it\cdot q}{\hbar}\exp\frac{is\cdot p}{\hbar} \tag{18}$$

and substituting the Taylor expansion for $\mathscr{F}$(15) and for the exponential, it is easy to see that the standard symbol $\sigma_{\hat{f}}^0(q,p)$ of $\hat{f}$ is

$$\sigma_{\hat{f}}^0(q,p) = \sum_m (-i\hbar)^m F_m \left(\sum_{i=1}^n \partial p_i \partial q_i\right)^m f(q,p), \tag{19}$$

where

$$F_m = \sum_{k=0}^m \mathscr{F}_k \frac{1}{(m-k)!}\left(\frac{1}{2}\right)^{m-k}, \tag{20}$$

that is,

$$e^{x/2}\mathscr{F}(x) = \sum_m F_m x^m. \tag{21}$$

For a monomial $f = q^l p^r$,

$$\sigma_{\hat{f}}^0(q,p) = \sum_m (-i\hbar)^m F_m \frac{1}{(l-m)!\,l!\,(r-m)!\,r!}\, q^{l-m} p^{r-m}. \tag{22}$$

Let us see some examples. If $\mathscr{F} = \exp(-is\cdot t/2\hbar)$, then

$$\sigma^0_{\hat f}(q,p)=f(q,p), \tag{23}$$

so quantizing with this ordering rule is equivalent to consider the functions on the phase space as standard symbols of the quantum operators. More generally, if $\mathscr{T}=\exp((is\cdot t)/2\hbar(\tau-1/2))$, the τ-symbol of the quantum operator is the function itself.

For a general ordering rule, the same interpretation is possible. The classical observable is considered as a new kind of symbol of the quantum operator. One can express this new symbol in the same way as (11). Let us express the action of operator $\hat f$ through the standard symbol (19),

$$\begin{aligned}\hat f u(q)&=\frac{1}{(2\pi\hbar)^n}\int d^n p\,d^n q'\,\exp\left(\frac{i}{\hbar}\,p\cdot(q-q')\right)\sigma^0_{\hat f}(q,p)u(q')\\&=\frac{1}{(2\pi\hbar)^n}\int d^n p\,d^n q'\,\exp\left(\frac{i}{\hbar}\,p\cdot(q-q')\right)\cdot\sum_m\,(-i\hbar)^m F_m\left(\sum_{i=1}^n\,\partial_{p_i}\partial_{q_i}\right)^m f(q,p)u(q').\end{aligned} \tag{24}$$

Integrating by parts ∂_{p_i},

$$\begin{aligned}\hat f u(q)&=\sum_m\,F_m\,\frac{1}{(2\pi\hbar)^n}\int d^n p\,d^n q'\,\exp\left(\frac{i}{\hbar}\,p\cdot(q-q')\right)\cdot\partial^m_\rho f(q+\rho(q'-q),p)|_{\rho=0}u(q')\\&=\sum_m\,F_m\,\frac{1}{(2\pi\hbar)^n}\,\frac{1}{2\pi\hbar}\int d^n p\,d^n q'\,d\rho\,d\zeta\,\exp\left(\frac{i}{\hbar}\,p\cdot(q-q')\right)\\&\quad\times\exp\left(-\frac{i\zeta\rho}{\hbar}\right)\cdot\left(\frac{i\zeta}{\hbar}\right)^m f(q+\rho(q'-q),p)u(q'),\end{aligned} \tag{25}$$

and finally,

$$\begin{aligned}\hat f u(q)&=\frac{1}{(2\pi\hbar)^n}\int d^n p\,d^n q'\,\exp\left(\frac{i}{\hbar}\,p\cdot(q-q')\right)\cdot\,\frac{1}{2\pi\hbar}\int d\rho\,d\zeta\\&\quad\times\exp\left(-\frac{i\zeta}{\hbar}\left(\rho-\frac{1}{2}\right)\right)\mathscr{T}\left(\frac{i\zeta}{\hbar}\right)f(q+\rho(q'-q),p)u(q').\end{aligned} \tag{26}$$

It is easy to see that for $\mathscr{T}(is\cdot t/\hbar)=\exp((is\cdot t)/2\hbar(\tau-1/2))$, one gets τ-symbol. Equation (26) can also be interpreted in the following way. For each ρ, the function $f(q+\rho(q'-q),p)$ gives, under the integral, a different operator, and we are taking a linear superposition of all of them, whose coefficients are a distribution which is the Fourier transform of the function $F(i\zeta/\hbar)=\exp(i\zeta/2\hbar)\mathscr{T}(i\zeta/\hbar)$. We will call these symbols $\mathscr{T}$-symbols, and will denote them by $\sigma^{\mathscr{T}}$.

Let $\mathscr{T}_1,\mathscr{T}_2$ be two arbitrary functions. By using the standard symbol, one can obtain the $\mathscr{T}_2$-symbol of an operator in terms of the $\mathscr{T}_1$-symbol,

$$\sigma^{\mathscr{T}^2}(q,p)=\sum_m\,(-i\hbar)^m F^{12}_m\left(\sum_{i=1}^n\,\partial_{p_i}\partial_{q_i}\right)^m\sigma^{\mathscr{T}^1}(q,p), \tag{27}$$

where

$$F^{12}_m=\sum_{r=0}^m\,F^1_{m-r}\tilde F^2_r,\quad \frac{1}{F^2(x)}=\sum_m\,\tilde F^2_m x^m,\quad \frac{F^1(x)}{F^2(x)}=\frac{\mathscr{T}^1(x)}{\mathscr{T}^2(x)}=\sum_m\,F^{12}_m x^m. \tag{28}$$

The composition formula for $\mathscr{T}$-symbols can be computed from the composition formula (13) for $\tau=0$ and substituting the standard symbols in terms of the $\mathscr{T}$-symbols, (19). The result is that the $\mathscr{T}$-symbol of the composition of operators $A'\circ A''$ in terms of the symbols $\sigma'^{\mathscr{T}}$ and $\sigma''^{\mathscr{T}}$ of A' and A'', is

$$\sigma^{\mathscr{T}}=\sigma'^{\mathscr{T}}*_{\mathscr{T}}\sigma''^{\mathscr{T}}=\sum_{\delta+\epsilon=\mu+\nu}(-i\hbar)^{|\delta+\epsilon|}C_{\delta,\epsilon,\mu,\nu}(\partial_p^{\delta}\partial_q^{\mu}\sigma'^{\mathscr{T}})(\partial_p^{\epsilon}\partial_q^{\nu}\sigma''^{\mathscr{T}}), \tag{29}$$

where

$$C_{\delta,\epsilon,\mu,\nu}=\sum_{\beta=0}^{\min(\delta,\mu)}\sum_{\gamma=0}^{\min(\epsilon,\nu)}\sum_{\alpha=0}^{\min(\delta-\beta,\nu-\gamma)}\tilde{F}_{|\delta+\epsilon-\beta-\gamma-\alpha|}F_{|\beta|}F_{|\gamma|}\cdot\frac{(\delta+\epsilon\beta-\gamma-\alpha)!}{\beta!\,\gamma!(\mu-\beta)!(\epsilon-\gamma)!\,\alpha!(\delta-\beta-\alpha)!(\nu-\gamma-\alpha)!}. \tag{30}$$

It is also easy to see that if $F_m=0$ for odd m, then Hermitian operators have real $\mathscr{T}$-symbols.

III. DEFORMATIONS OF POISSON ALGEBRAS

We consider a symplectic manifold M with local symplectic coordinates (q_i,p_i), $i=1,\ldots,n$, and symplectic two form, ω. On the associative, commutative algebra $N=C^{\infty}(M)$ there is a Poisson algebra structure given by

$$\{f,g\}=\omega(X_f,X_g), \tag{31}$$

where $f,g\in N$ and X_f,X_g are the Hamiltonian vector fields associated to f,g defined by

$$df(\cdot)=\omega(X_f,\cdot). \tag{32}$$

Let $E(N,\lambda)$ be the space of formal series in λ with coefficients in N. A formal deformation of the associative commutative algebra of pointwise multiplication $C^{\infty}(M)$ is a bilinear map $*:E(N,\lambda)\times E(N,\lambda)\to E(N,\lambda)$ given by a formal series

$$u*v=\sum_{r=0}^{\infty}\lambda^r C_r(u,v)\quad u,v\in E(N,\lambda) \tag{33}$$

with $C_r(u,v)$ bidifferential operators, $C_0(u,v)=uv$, and such that it satisfies the associativity condition

$$(u*v)*w=u*(v*w)\quad u,v,w\in E(N,\lambda). \tag{34}$$

In general, formal deformations are not commutative. Let M be R^{2n}; the product of $\mathscr{T}$-symbols (29) is a formal deformation of the associative algebra $C^{\infty}(R^{2n})$, with deformation parameter $i\hbar$. The bidifferential operators $C_r(u,v)$ have constant coefficients and the associativity is guaranteed by the associativity of the composition of operators. These deformations satisfy the additional condition

$$C_1(u,v)-C_1(v,u)=\{u,v\}. \tag{35}$$

For τ-symbols, notice that (13) can be expressed as

$$u(q,p)*_r v(q,p)=\sum_m \frac{(i\hbar)^m}{m!}\left((\tau-1)\sum_{i=1}^{n}\partial'_{p_i}\partial''_{q_i}+\tau\sum_{i=1}^{n}\partial''_{p_i}\partial'_{q_i}\right)^m (u(q,p),v(q,p)), \tag{36}$$

where the notation means

$$\partial'_p\partial''_q(u(q,p),v(q,p))=\partial_p u(q,p)\partial_q v(q,p), \tag{37}$$

so formally one can write

$$u(q,p)*_\tau v(q,p)=\exp(i\hbar)\left((\tau-1)\sum_{i=1}^{n}\partial'_{p_i}\partial''_{q_i}+\tau\sum_{i=1}^{n}\partial''_{p_i}\partial'_{q_i}\right)^m\cdot(u(q,p),v(q,p)). \tag{38}$$

For $\tau=1/2$, the argument in the exponential is (one half of) the Poisson bracket. It has been shown in Ref. 6 that the exponential is the only function of the Poisson bracket which gives an associative formal deformation.

The bracket $\{u,v\}^{(\mathcal{F})}=(i\hbar)^{-1}(u*_{\mathcal{F}}v-v*_{\mathcal{F}}u)$ satisfies the Jacobi Identity,

$$S\{\{u,v\}^{(\mathcal{F})},w\}^{(\mathcal{F})}=0, \tag{39}$$

where S means circular symmetrization with respect to the entries, u,v,w. For the formal deformation associated to any ordering rule, the zero order term in $\hbar$ of this bracket is the Poisson bracket, so we have a formal deformation of the Poisson bracket. For $\tau=1/2$, the corresponding deformation is the Moyal bracket[7]

$$\{u,v\}^{(M)}=2\sinh\left(\frac{\nu}{2}\left(\sum_{i=1}^{n}\partial''_{p_i}\partial'_{q_i}-\sum_{i=1}^{n}\partial'_{p_i}\partial''_{q_i}\right)\right)(u,v) \tag{40}$$

with $\nu=(i\hbar)^2$.

Consider an associative formal deformation, for example de Weyl deformation, $u*_W v$. Let T be a map $T:E(N,\lambda)\to E(N,\lambda)$, such that it can be expressed by the formal series

$$T=Id+\sum_{s=1}^{\infty}\lambda^s T_s, \tag{41}$$

where T_s are differential operators on N. One can construct the formal deformation given by

$$u*_T v=T(T^{-1}u*_W T^{-1}v), \tag{42}$$

where T^{-1} has an obvious meaning. It is associative by construction. One can define the T-symbol of an operator $\hat{f}$ as

$$\sigma^T_{\hat{f}}=T\sigma^W_{\hat{f}} \tag{43}$$

and the product of T-symbols is the deformation written above (42). If the series T in $\lambda=i\hbar$ is such that $T_r=0$ for odd r, then the T-symbol of an Hermitian operator is real. We must point out that in order for this definition of T-symbols to be meaningful, the formal series (43) must be convergent, so some restrictions on T or on the class of functions which are T-symbols, should be imposed. We are not going to elucidate this point in this paper.

In general, two associative formal deformations are called equivalent if there is a series T connecting them by means of Eq. (42). It is easy to see that this is an equivalence relation.

All deformations (29) are equivalent by means of the formal series (27). The quantization maps (that is, the interpretation of functions on the phase space as symbols of operators) given by

two equivalent deformations are not the same, since they associate different operators to the same classical observable. But there exists a "classical" observable $g(q,p,\hbar)$ related to the classical observable $f(q,p)$ by $g=Tf$ (in particular, $g\to f$ when $\hbar\to 0$) and such that the operator associated to g with one quantization map is the same as the operator associated to f with the other quantization map. In this sense, one can say that the quantum theories are essentially equivalent.

The commutator of T-symbols is also a formal deformation of the Poisson bracket. Following Ref. 6, two formal deformations

$$\begin{aligned}\{u,v\}^{(A)}&=\{u,v\}+\sum_{r=1}^{\infty}\lambda^r C_r^{(A)}(u,v),\\ \{u,v\}^{(B)}&=\{u,v\}+\sum_{r=1}^{\infty}\lambda^r C_r^{(B)}(u,v),\end{aligned}\tag{44}$$

are c-equivalent if there is a formal series (41) such that the relation

$$T\{u,v\}^{(A)}=\{Tu,Tv\}^{(B)}\tag{45}$$

is formally satisfied. Two equivalent associative formal deformations can give the same deformation of the Poisson bracket, and in this case the map sending the operators obtained with one quantization map to the operators obtained with the other quantization map preserves commutators, so it is a unitary transformation, irrelevant in the quantum theory. In this way, we can focus on the easier issue of equivalence of deformations of the Poisson bracket.

We are going to construct inequivalent deformations. Given a formal series like (44), it is a formal deformation if the Jacobi identity (39) is satisfied. At each order, the Jacobi identity is

$$S\sum_{r+s=t} C_s(C_r(u,v),w)=0 \quad r,s\geqslant 0,\tag{46}$$

which can be written as

$$\partial C_t(u,v,w)=SC_t(\{u,v\},w)+S\{C_t(u,v),w\}=-S\sum_{r+s=t} C_s(C_r(u,v),w) \quad r,s\geqslant 1.\tag{47}$$

The ∂ symbol in the left hand side of Eq. (47) is the differential operator of the Chevalley cohomology, acting on p-cochains which are alternate p-differential maps of N^p to N. If the Jacobi identity is satisfied up to order $t-1$, then the right hand side of Eq. (47) (notice that it only depends on C_r, $r<t$) is a 3-cocycle, and in order for the Jacobi identity to be satisfied up to order t, it must be a cobord. For $t=0$ the identity is trivially satisfied and for $t=1$

$$\partial C_1(u,v,w)=0,\tag{48}$$

which means that C_1 is a 2-cocycle in the Chevalley cohomology.

Let us write Eq. (45) at order t,

$$\sum_{r+s=t} T_s C_r^{(A)}(u,v)-\sum_{r+s+s'=t} C_r^{(B)}(T_s u,T_{s'}v)=0, \quad r,s,s'\geqslant 0,\tag{49}$$

which can be rewritten as

$$C_t^{(A)}(u,v)-C_t^{(B)}(u,v)+G_t(u,v)=\partial T_t(u,v),\tag{50}$$

where G_t collects all terms depending on $C_r^{(A)}$, $C_r^{(B)}$ and T_r for $r<t$. For our purposes, it will be enough to say that $G_t=0$ if $T_r=0$ for $r<t$. Two deformations are equivalent at order 1 if the difference of the two cocycles $C_1^{(A)}-C_1^{(B)}$ is a cobord ∂T_1. If the cocycle C_1 is itself a cobord, the deformation is equivalent to the zero deformation at order 1, and we say that the deformation is trivial to this order. For the Moyal deformation $C_1^{(M)}$ is a nontrivial 2-cocycle. Indeed, the dimension of the second order cohomology space is one for a flat Poisson manifold, so we have that at order one there is only one nontrivial possibility.

Consider a deformation $\{u,v\}^{(A)}$ as in Eq. (45). Let us construct another deformation, by modifying $C_2^{(A)}$ with a term proportional to $C_1^{(A)}$:

$$C_1^{(B)}=C_1^{(A)}, \quad C_2^{(B)}=C_2^{(A)}+\mu C_1^{(A)}. \tag{51}$$

It can be shown inductively that there is a general solution for $C_r^{(B)}$ satisfying the Jacobi identity, of the form

$$C_r^{(B)}=\sum_{s=0}^{r} \mu_s \binom{r-s}{s} C_{r-s}^{(A)}, \tag{52}$$

in terms of the binomial coefficients $\binom{r-s}{s}$. Notice that at each order the expansion in μ is finite. If we modify the term of order $t+1$ instead of the order two, then the form of the successive $C_r^{(B)}$ is

$$C_r^{(B)}=\sum_{s=0}^{[r/t]} \mu_s \binom{r-ts}{s} C_{r-ts}^{(A)}, \tag{53}$$

where $[r/t]$ is the integer part of r/t. If the cocycle $C_1^{(A)}$ is nontrivial, the deformations obtained in this way are not equivalent, neither to the original deformation, nor equivalent between them. The Moyal bracket has this feature, so this mechanism produces deformations which are not equivalent to the Moyal bracket.

Now we are going to consider the effect of making a canonical transformation. The Moyal bracket can be expressed in a covariant way by writing the differential operators $C_r^{(M)}$ as

$$C_r^{(M)}(u,v)=\frac{1}{2^{2r}(2r+1)!}\, P^{2r+1}(u,v), \tag{54}$$

$$P^r(u,v)=\Lambda^{i_1 j_1}\cdots\Lambda^{i_r j_r}\nabla_{i_1\cdots i_r}u\,\nabla_{j_1\cdots j_r}v, \tag{55}$$

where Λ^{ij} is the 2-tensor which is the inverse matrix of the symplectic form, and ∇ is the covariant derivative associated to a flat symplectic connection, that is, such that $\nabla\Lambda=0$. The bracket satisfies the Jacobi identity if both conditions are satisfied (See Ref. 6). In $M=\mathrm{R}^{2n}$, one can choose coordinates (q,p) in such way that the coefficients of the connection are zero, and we recover the Moyal bracket as in (40). If we change the flat connection, the Moyal bracket will be different, but in some symplectic coordinates (Q,P), it is expressed again in the usual form. Therefore, to quantize in different global symplectic coordinates corresponds to take the Moyal bracket with different flat connections. We can ask if the Moyal deformations obtained with different flat connections are equivalent (notice that the map T which realizes the equivalence can change even the basic commutators). We do not have a rigorous answer to that question, but we are going to show that making an infinitesimal canonical transformation we stay in the same equivalence class.

Let us make the canonical transformation $(q,p)\to(Q(q,p),P(q,p))$. A function of the phase space $\mathscr{F}$ has local representations $f(q,p)$, and $F(Q,P)$ in the old and new symplectic coordinates respectively, satisfying

$$f(q,p)=F(Q(q,p),P(q,p)). \tag{56}$$

If the transformation is infinitesimal with parameter ϵ, then

$$f(q,p)=F(Q(q,p),P(q,p))\approx F(q,p)+\epsilon\{F(q,p),\eta(q,p)\} \tag{57}$$

or

$$F(q,p)\approx f(q,p)-\epsilon\{f(q,p),\eta(q,p)\}, \tag{58}$$

where the function η is the generator of the infinitesimal canonical transformation. We denote by superindices A and B the Moyal deformations corresponding to the symplectic coordinates (q,p) and (Q,P) respectively. Let $H(Q,P)$ be the local representation of $\{\mathscr{F},\mathscr{G}\}^{(B)}$. Using (57)

$$H(Q(q,p),P(q,p))\approx H(q,p)+\epsilon\{H(q,p),\eta(q,p)\} \tag{59}$$

and

$$\begin{aligned} H(q,p)&=\{F(q,p),G(q,p)\}^{(A)}\\ &\approx\{f(q,p),g(q,p)\}^{(A)}-\epsilon\{\{f(q,p),\eta(q,p)\},g(q,p)\}^{(A)}\\ &\quad+\epsilon[\{f(q,p),\{\eta(q,p),g(q,p)\}\}^{(A)}]. \end{aligned} \tag{60}$$

So in the local representation (q,p),

$$\{\mathscr{F},\mathscr{G}\}^{(B)}-\{\mathscr{F},\mathscr{G}\}^{(A)}=\epsilon\{\{f,g\}^{(A)},\eta\}-\epsilon[\{\{f,\eta\},g\}^{(A)}-\{f,\{g,\eta\}\}^{(A)}]. \tag{61}$$

Let us look at this equation order by order in $\nu=(i\hbar)^2$,

$$\begin{aligned} C_1^{(B)}-C_1^{(A)}&\approx\epsilon[\{C_1^{(A)}(f,g),\eta\}-C_1^{(A)}(\{f,\eta\},g)-C_1^{(A)}(f,\{g,\eta\})]\\ &=\epsilon[\partial(C_1^{(A)}(.,\eta))(f,g)-\partial C_1^{(A)}(f,g,\eta)], \end{aligned} \tag{62}$$

and since $\partial C_1^{(A)}=0$, then $T_1=\epsilon C_1^{(A)}(.,\eta)$. At order r, using that the bracket A satisfies the Jacobi identity, one can see that

$$(C_r^{(B)}-C_r^{(A)}+G_t)(f,g)\approx\epsilon[\partial(C_r^{(A)}(.,\eta))(f,g)], \tag{63}$$

so $T_r=\epsilon C_r^{(A)}(.,\eta)$.

In this way we have shown that for global symplectic coordinates differing by an infinitesimal transformation, the Moyal brackets belong to the same equivalence class of deformations. It seems that all deformations used in physics to quantize a Hamiltonian system fall in the same equivalence class, and perhaps other deformations, as the ones we constructed below, inequivalent to the Moyal bracket, do not admit a representation by Hermitian operators on a Hilbert space, in the same way that the trivial deformation, the Poisson bracket, does not admit one.

IV. APPLICATIONS TO QUANTUM INTEGRABILITY OF TWO DIMENSIONAL HAMILTONIAN SYSTEMS

A Hamiltonian system with 2 degrees of freedom is classically integrable if there is a function $I(q,p)$ independent of the Hamiltonian such that the Poisson bracket $\{H,I\}=0$. A quantization map sends H and I to the operators $\hat{H}$ and $\hat{I}$, but in general, these operators do not commute. One can ask if there exists an ordering rule which makes the corresponding operators commute, or more generally, if there exists a particular quantization map for which the operators commute. We have found, when dealing with the examples that the first possibility is not satisfied in most of the

cases, so we ask for more general quantization maps. This seems possible because one can find a classical canonical transformation where H and I are the new momenta, and the Weyl quantization map brings them to operators which commute trivially. Of course, such canonical transformation could be very difficult to find, or might not be globally well defined, so this procedure seems to be impractical in order to analyze the problem of quantum integrability.

But we saw in Section III that infinitesimal classical canonical transformations are reflected in the commutator of symbols as a change to a equivalent deformation. Assuming that this is true for finite canonical transformations we can look for deformations, equivalent to the Moyal bracket, such that H and I have a vanishing bracket. The corresponding quantization map consists in interpreting the functions on the phase space as T-symbols of the quantum operators. The Weyl symbols of the quantum operators are related with the T-symbols by

$$\sigma^W_{\hat{F}} = T^{-1}\sigma^T_{\hat{F}} = T^{-1}F = VF. \tag{64}$$

In Ref. 9 the problem of quantum integrability of some two dimensional systems is analyzed in terms of the Moyal bracket. They found that one has to add, in most of the cases, quantum correction terms (of order $O(\hbar)$) to I, and sometimes to H, in order to write the Weyl symbol of the commuting quantum operators which make the system quantum integrable. So all we have to check is if these expansions in $\hbar$ for the Weyl symbols can be written in the form (64) for a series of differential operators $T^{-1}=V$.

We are going to analyze some examples of integrable systems which present quantum corrections. The quantum integrability of all the examples we use has been proved by Hietarinta.[9] We show here explicitly that the quantum corrections come from a series V satisfying (64) and consequently, that the quantum corrections can be eliminated by an appropriate choice of the quantization map, in terms of T-symbols.

Example 1: The following Hamiltonian is classically integrable

$$H_1 = \frac{1}{2}(p_x^2+p_y^2) + \frac{16}{3}y^3 + yx^2 + \frac{a}{2}(x^2+16y^2) + \mu x^{-2} + \nu x^{-6}, \tag{65}$$

with the invariant given by

$$\begin{aligned} I_1 = {} & p_x^4 + p_x^2(2ax^2 + 4x^2y + 4\mu x^{-2} + 4\nu x^{-6}) - \frac{4}{3}p_x p_y x^3 - \frac{4}{3}ax^4y - \frac{4}{3}x^4y^2 \\ & + \frac{8}{3}\mu y + 8\nu y x^{-4} - \frac{2}{9}x^6 + a^2x^4 + 4(a\nu+\mu^2)x^{-4} + 8\mu\nu x^{-8} + 4\nu^2 x^{-12}. \end{aligned} \tag{66}$$

In order to the Moyal bracket $\{H_1, I_1\}^{(M)}$ vanish, the invariant must be corrected with

$$\Delta I_1 = -\hbar^2(6\mu x^{-4} + 42\nu x^{-8}), \tag{67}$$

so the Weyl symbol of the quantum operator is $I_1 + \Delta I_1$. We want to know if there is a quantization map in which the classical observable, without quantum corrections, is the symbol of the quantum operators. It can be proven that there is no ordering rule satisfying this condition. Nevertheless, for this particular example, a trick that consists in adding a term αH_1^2 to I_1 and considering a unusual ordering rule works. This is done in Ref. 9, but we obtained a different numerical result. The value of α is -4, and the ordering rule must be such that

$$\mathscr{F}'(0) = 0; \quad \mathscr{F}''(0) = 65/128. \tag{68}$$

Both results become the same if in the computation of Ref. 9 the effect of changing the ordering rule in the new terms H_1^2 is taken into account. Nevertheless, this method does not work for other Hamiltonians, and we are lead to consider more general quantization maps.

The series

$$V_1 = Id + (i\hbar)^2\left(\frac{1}{8}\,\partial_{p_x}^2\partial_x^2 - \left(\frac{a}{16}+\frac{y}{8}\right)\partial_{p_x}^2\partial_x^2\partial_y\right), \tag{69}$$

when applied to H_1 and I_1 reproduces the quantum corrections, so the T-symbols of the quantum operators are H_1 and I_1. Since that the series V_1 is truncated at order $\hbar^2$, it is easy to get the inverse series T_1,

$$\begin{aligned} V_1 &= Id + (i\hbar)^2 A_1, \\ T_1 &= Id + \sum_{r=1} (-1)^r (i\hbar)^{2r} A_1^r. \end{aligned} \tag{70}$$

From here, we can see that if the Weyl symbol $\sigma_{\hat{F}}^W$ of an operator is a polynomial function of p_x, then the series $T_1\sigma_{\hat{F}}^W$ is truncated at some order in $(i\hbar)^2$. This is a sufficient, although not necessary, condition for the T-symbol of the operator $\hat{F}$ be well defined.

Example 2: This is another example of classically integrable system:

$$H_2 = \tfrac{1}{2}\,(p_x^2+p_y^2) + x^4 + 6x^2y^2 + 8y^4 + \kappa(x^2+4y^2) + \mu x^{-2} + \nu x^{-6} + \lambda y^{-2}, \tag{71}$$

$$\begin{aligned} I_2 = {} & p_x^4 + 4p_x^2(x^4 + 6x^2y^2 + \kappa x^2 + \mu x^{-2} + \nu x^{-6}) - 16p_xp_yx^3y + 4p_y^2x^4 + 8\lambda y^{-2}x^4 + 4\mu^2x^{-4} \\ & + 8\mu\nu x^{-8} + 8\mu x^2 + 16\mu y^2 + 4\mu^2x^{-12} + 8\nu\kappa x^{-4} + 8\nu x^{-2} + 48\nu 2x^{-4}y^2 + 4\kappa^2x^4 + 8\kappa x^6 \\ & + 16\kappa x^4y^2 + 4x^8 + 16x^6y^2 + 16x^4y^4, \end{aligned} \tag{72}$$

and the quantum corrections are

$$\Delta I_2 = -\hbar^2(6\mu x^{-4} + 42\nu x^{-8} + 12x^2). \tag{73}$$

The series V_2 is,

$$V_2 = Id + (i\hbar)^2\left(\frac{1}{8}\,\partial_x^2\partial_{p_x}^2 + \frac{a}{48}\,\partial_x^3\partial_y\partial_{p_x}\partial_{p_y} + \frac{y}{8}\,\partial_x^3\partial_{p_x}\partial_{p_y}\right). \tag{74}$$

In this example, the condition for the finiteness of the series is that the Weyl symbol of the operator must be a polynomial function of p_x and p_y.

In the following examples, the Hamiltonian also needs quantum corrections in order to be quantum integrable. In those cases, it is obvious that no ordering rule will restore the integrability.

Example 3: For the Holt Hamiltonian,[10]

$$H_3 = \tfrac{1}{2}\,(p_x^2+p_y^2) + \tfrac{3}{4}\,x^{4/3} + y^2x^{-2/3} + \delta x^{-2/3}, \tag{75}$$

which is classically integrable, the integral is

$$I_3 = p_y^3 + \tfrac{3}{2}\,p_yp_x^2 + p_y(-\tfrac{9}{2}\,x^{4/3} + 3x^{-2/3}y^2 + 3\delta x^{-2/3}) + 9x^{1/3}yp_x. \tag{76}$$

The quantum corrections are

$$\Delta H_3 = -\frac{5}{72}\hbar^2 x^{-2}, \quad \Delta I_3 = -\frac{5}{72}\hbar^2 p_y x^{-2}. \tag{77}$$

The operator reproducing the quantum corrections is

$$V_3 = Id + (i\hbar)^2 \frac{5}{144} x^{-4/3}\partial_y^2. \tag{78}$$

The series is truncated if the Weyl symbol is a polynomial function of y.

Example 4: The Hamiltonian,[11]

$$H_4 = \tfrac{1}{2}(p_x^2 + p_y^2) + (xy)^{-2/3}, \tag{79}$$

is classically integrable,[11]

$$I_4 = p_y p_x (x p_y - y p_x) + 2(xy)^{-2/3}(x p_x - y p_y). \tag{80}$$

The quantum corrections are

$$\Delta H_4 = -\frac{5}{72}\hbar^2 (x^{-2} + y^{-2}), \quad \Delta I_4 = -\frac{5}{72}\hbar^2 (x p_x y^{-2} - y p_y x^{-2}). \tag{81}$$

The operator reproducing the quantum corrections is

$$V_4 = Id + (i\hbar)^2 \frac{5}{72}\left(\frac{9(xy)^{8/3}}{10y^4}\partial_x^2 + \frac{9(xy)^{8/3}}{10x^4}\partial_y^2\right) + (i\hbar)^2 \frac{5}{72}\left(\frac{1}{xy}\partial_{p_x}\partial_{p_y} + \frac{6y}{5x^2}\partial_{p_x}^2\partial_y + \frac{6x}{5y^2}\partial_{p_y}^2\partial_x\right). \tag{82}$$

In this example, it is more difficult to analyze the convergence of the series because the non-polynomial terms in the coefficients of V_4. But let us make a canonical point transformation,

$$x = X^{-3/2}, \quad p_x = -\frac{2}{3}P_X X^{5/2}, \quad x = X^{-3/2}, \quad p_x = -\frac{2}{3}P_X X^{5/2}. \tag{83}$$

The Hamiltonian and the integral have polynomial form,

$$\begin{aligned} H_5 &= \frac{2}{9}(P_X^2 X^5 + P_Y^2 Y^5) + XY, \\ I_5 &= \frac{4}{3}(P_Y X Y^2 + P_X Y X^2) + \frac{8}{27}(P_X^2 P_Y X^5 Y + P_Y^2 P_X Y^5 X). \end{aligned} \tag{84}$$

The Hamiltonian is now ordering dependent, but the quantum corrections are also polynomial,

$$\Delta H_5 = \hbar^2 \frac{5}{18}(X^3 + Y^3), \quad \Delta I_5 = \hbar^2 \frac{10}{27}(P_Y X^3 Y + P_X Y^3 X), \tag{85}$$

and the series V_5 is now very easy to compute,

$$V_5 = Id - (i\hbar)^2 \frac{1}{32}(\partial_X^2 \partial_{P_X}^2 + \partial_Y^2 \partial_{P_Y}^2). \tag{86}$$

The series giving the T-symbol in terms of the Weyl symbol is truncated if the Weyl symbol is polynomial in P_X and P_Y.

V. CONCLUSIONS

In this paper we have analyzed the relationship between the quantum deformations of the Poisson algebra of classical observables and the operatorial quantization. We have described this relationship in terms of generalized symbols of operators, not only for different ordering rules but for more general quantization maps. We have found that the effect of an infinitesimal classical canonical transformation in the quantum theory is just a change to an equivalent deformation. This result suggests that all quantization maps currently used fall into the same equivalence class of deformations. We have explicitly written deformations inequivalent to the Moyal bracket. It is an open question if these deformations have a representation in terms of operators on a Hilbert space.

We have applied these results to the study of two dimensional integrable systems. For the examples considered, we have eliminated the quantum corrections which arise when one requires the preservation of the symmetry in the quantum theory. This procedure could be generalized to other systems presenting more complicated symmetries.

In this paper we deal with an alternative approach to the description of massless particles of arbitrary spin. Within this scheme chiral components of a spinor field are regarded as fundamental quantities and treated as independent field variables. The free field Lagrangian is built up from the requirement of chiral invariance. This formulation is parallel to the neutrino theory and allows for a formulation that generalizes, to particles of arbitrary spin, the two-component neutrino theory. We achieve a spinor formulation of electrodynamics. In the case of the photon, the nonzero helicity components satisfy Weyl's equations and are associated to observables (electromagnetic fields) whereas the zero helicity components are related to nonobservables (electromagnetic potentials). Within the spinor formulation of electrodynamics the minimal coupling substitution follows as a consequence of the linearity of the interaction and the preference of nature for chiral components, that is, of the left–right asymmetry of nature. © *1996 American Institute of Physics.* [S0022-2488(96)01310-4]

I. INTRODUCTION

Nowadays there is plenty of evidence that nature is asymmetric with respect to chirality (left and right handedness).[1] Within the realm of the fundamental interactions this asymmetry has been realized since the *V-A* theory[2] of weak interactions and has been verified empirically in 1957 in a parity violating process occurring as a result of weak processes.[3] In this paper we will show that, within an alternative scheme for treating massless particles, electrodynamics is also a left–right asymmetric theory. In this way we extend even further the notion that fundamental interactions violate left–right symmetry.

Within the usual formulation of electrodynamics (the tensorial method) the seemingly asymmetrical magnetism[1] cannot be entirely understood in view of the fact that the electromagnetic fields are fundamentally symmetrical (the Lagrangians, in terms of these fields, do not exhibit any left–right asymmetry). Within the spinor method, the one that will be employed in this paper, one has an equivalent formulation of electrodynamics allowing us to understand that magnetism and electrodynamics is, in fact, a basic departure from the left–right asymmetry of nature.

The spinorial formulation proposed here allows us to formulate theories involving massless spin 1 particles in close analogy with massless spin $\frac{1}{2}$ particles. The requirement of chiral invariance, at the free field level, leads to Maxwell's equation in vacuum. The requirement of chiral asymmetry for the linear interaction of the spinor field with matter leads to Maxwell's equation in the presence of matter. Previous spinorial formulations of electrodynamics can be found in Refs. 4 and 5.

In order to generalize the left–right asymmetry to other interactions, as will be done in this paper, let us recall that for massless spin $\frac{1}{2}$ particles one can define chiral components ψ_L and ψ_R of a basic field ψ as follows:

$$\psi_R = \tfrac{1}{2}(I+\gamma^5)\psi, \quad \psi_L = \tfrac{1}{2}(I-\gamma^5)\psi.$$

0022-2488/96/37(1)/174/22/$6.00

Furthermore, under space reflection (P) these components transform as

$$\psi_R \overset{P}{\rightarrow} \psi_R'(x') = \xi \gamma_0 \psi_L(-\mathbf{x},t), \quad \psi_L \overset{P}{\rightarrow} \psi_L'(x') = \xi \gamma_0 \psi_L(-\mathbf{x},t).$$

The intriguing aspect of the weak interactions is that, at low energies, the right and left components interact in a different way with ordinary matter. As a matter of fact, there is no evidence at all that the right-hand component interacts with ordinary matter. Weak interactions are definitely asymmetric with regard to left and right. This follows from the fact that right and left components interact with different strength to matter.

At the Lagrangian level this preference of nature for chiral components can be formulated in a simple way by stating that the Lagrangian is not invariant under the transformation

$$\psi_R \rightarrow \psi_L .$$

Due to the transformation properties of $\psi_R(\psi_L)$ under space reflections, the noninvariance of the Lagrangian under the left–right transformation implies breakdown of space reflection.

The first question that we deal with in this paper is the possibility of extending, to massless particles of arbitrary spin, the usual neutrino theory. We shall see that the spinor method provides an approach that permits us such a generalization. Within the spinor method it is possible to generalize the notion of chiral invariance for particles of arbitrary spin as well as to define chiral components analogous to the ones associated to massless particles of spin $\frac{1}{2}$. Within the spinor method one assigns to a particle of spin s a symmetric spinor ψ of rank $2s$. The definition of chiral components, for a particle of arbitrary spin, is the tensor product of the usual ones.

We propose that these chiral components should be treated as independent variables and that they satisfy extended Dirac equations analogous to the ones satisfied by the left and right neutrino field components. These equations, as will be shown later, follow from the requirement that the free field Lagrangian be chiral invariant.

The generalized chiral components provide a very simple criterion on whether a theory involving masslessness is left–right symmetric or not. The theory is left–right symmetric if the Lagrangian is invariant under the subscript interchange $L \rightarrow R$ (or $R \rightarrow L$). Otherwise the theory is $L-R$ asymmetric. The theory is left–right asymmetric if the coupling of the chiral components to the matter fields occurs with different strengths.

As a byproduct of the formulation of zero-mass particles in terms of chiral components, we will show that it is possible to generalize the two-component neutrino theory to particles of arbitrary spin. The generalized two-component fields satisfy generalized Weyl's equations.

It seems to be worthwhile to analyze whether, besides the neutrinos, there is other evidence in nature of an asymmetric coupling of chiral components of zero-mass particles to ordinary matter. The next, nontrivial, zero-mass particles that couple to ordinary particles are the photons. We find that the coupling of photons reflects some kind of asymmetry between the coupling of chiral components to ordinary matter. We will show that, as in other theories, in electrodynamics chiral asymmetry and parity nonconservation are intimately connected. We shall see that, in electrodynamics, the only consequence of violation of these symmetries is a dynamical one, namely, the minimal substitution way of coupling the electromagnetic fields to matter.

In Sec. II we present a novel approach to the study of massless particles of arbitrary spin. In close analogy with the spin $\frac{1}{2}$ particles we generalize, to arbitrary spin s particles, the usual spin $\frac{1}{2}$ chiral components. One can also generalize the two-component neutrino theory to massless particles of arbitrary spin. This extension is possible in the context of the Bargmann–Wigner (BW) theory. The totally right (left) components have generalized helicity components s $(-s)$ and obey the generalized Weyl's equation.

In order to illustrate how the spinor method works we present in Sec. III the BW theory for spin 1 massive particles. The interesting point here is that clearly BW theory leads to a complete

description of massive particles by associating to these particles a symmetric rank 2 tensor field instead of associating particles to a rank 1 tensor (the usual procedure). The subsidiary condition $\partial^\mu B_\mu = 0$, for instance, follows naturally from the decomposition of the basic BW field into the spinor space and the BW equation.

In Sec. IV we present an alternative approach to spin 1 massless particles. We show how Maxwell's equation in vacuum emerges from the requirement of chiral invariance and the treatment of the chiral components as independent variables.

In Sec. V we formulate electrodynamics in terms of the chiral components ψ_{RR}, ψ_{RL}, ψ_{LR}, and ψ_{LL}. Here we show explicitly that one can formulate QED as long as matter couples only to some components of the chiral fields. That is, QED is manifestly left–right asymmetric.

In Sec. VI we touch on the question of the quantization of the BW fields. This is achieved by imposing an appropriate commutation relation among the BW components.

We end this paper with a section dedicated to conclusions.

II. ALTERNATIVE METHOD FOR THE DESCRIPTION OF MASSLESS PARTICLES

A. Bargmann–Wigner method—Massive particles

It has long been recognized that spinor quantities can be regarded as fundamental in any particle description within the field theoretical approach. In this chapter we will describe the spinor method, proposed by Bargmann and Wigner,[6] for studying massive particles and an alternative method, based on treating the chiral components of a spinor field as independent variables, for the description of massless particles.

Before setting the framework it is important to recall that the description of processes involving particles, within the field theoretic approach, requires the assignment to every particle a set of basic fields. In order to have Lorentz covariance explicitly the fields should have a well defined Lorentz transformation property. It just happens that, as in the case of spin 1 particles, the fields contain more degrees of freedom than the particles they are describing. These extra degrees of freedom of the field are eliminated by imposing complementary conditions on the fields. The case of massive (mass m) spin 1 particles is a very good example of this situation. In this case one associates to these particles (three polarization states) a four-component vector field B_μ. In order to eliminate the extra degree of freedom one imposes the covariant restriction

$$\partial_\mu B^\mu = 0. \tag{2.1}$$

The free field equation is

$$\partial_\mu G^{\mu\nu} = 0, \tag{2.2}$$

where

$$G_{\mu\nu} = \partial_\nu B_\mu - \partial_\mu B_\nu . \tag{2.3}$$

It was pointed out by Bargmann and Wigner[6] that the assignment particle→field is not unique. In fact, within the Bargmann–Wigner method one assigns to a massive particle of mass m and spin s a spinor field of rank $2s$:

$$\psi_{a_1 a_2 \cdots a_{2s}}(x), \quad a_k = 1,2,3,4. \tag{2.4}$$

Since the rank $2s$ spinor field contains, for particles of spin larger than $\frac{1}{2}$, much more degrees of freedom than the particle description requires, one has to impose further restrictions on the field ψ. One requires, as proposed by Bargmann–Wigner, that ψ be symmetric in its spin indices and imposes further that ψ satisfies a set of $2s$ Dirac-like equations; that is,

$$i\partial\!\!\!/_{a_k a_k'}\psi_{a_1\cdots a_k'\cdots a_{2s}}(x)=m\psi_{a_1\cdots a_k\cdots a_{2s}}(x),$$
$$k=1\ldots 2s. \tag{2.5}$$

The set of equations (2.5) can be written under the equivalent form, or permutation of it,

$$i\partial\!\!\!/\otimes I\otimes\cdots\otimes I\psi=m\psi. \tag{2.6}$$

It is then evident, from (2.6), that the Bargmann–Wigner approach is just an extension of Dirac's theory to particles of arbitrary spin.

As a final remark on the whole framework, not only valid for the Bargmann–Wigner method but also for the generalized four-component and two-component theory that will be presented next, we would like to emphasize the need for an explicit representation for $2s$ rank spinors. The method that will be used is to express the $2s$ rank spinor fields as linear combinations of symmetric 4×4 matrices (within the four-spinor framework), or symmetric 2×2 matrices (for the two-spinor framework). The coefficients in these expansions are new fields. The properties of the new fields allow us to establish the connection of our approach to the usual electrodynamics.

In the four-spinor case the symmetric matrices are, by using the notation of Bjorken and Drell,[7]

$$(\sigma_{\mu\nu}C)\quad\text{and}\quad(\gamma_\mu C), \tag{2.7}$$

whereas in the two-spinor case the symmetric matrices are

$$(\sigma^k C_1),\quad k=1,2,3, \tag{2.8}$$

where C is charge conjugation matrix and C_1 is the 2×2 charge conjugation matrix (see Appendix B).

As an example, let us write the decomposition of the rank 2 spinor field $\psi_{a_1a_2}$ associated to a mass m and spin 1 particle in terms of the symmetric matrices $(\gamma^\mu C)$ and $(\sigma^{\mu\nu}C)$. $\psi_{a_1a_2}$ admits the following decomposition:

$$\psi_{a_1a_2}(x)=\sqrt{m}\left\{B_\mu(x)(\gamma^\mu C)_{a_1a_2}-\frac{1}{2m}G_{\mu\nu}(x)(\sigma^{\mu\nu}C)_{a_1a_2}\right\}, \tag{2.9}$$

where the field $B_\mu(x)$ is a vector field (which, as will be shown later, is the usual spin 1 field), and $G_{\mu\nu}(x)$ is a field not yet determined and that, in principle, should involve derivatives of the $B_\mu(x)$ field. This is actually what happens. As will be shown in the next section, from (2.6) and (2.9) it follows that $G_{\mu\nu}$ in (2.9) can be written as

$$G_{\mu\nu}(x)=\partial_\nu B_\mu(x)-\partial_\mu B_\nu(x). \tag{2.10}$$

B. Massless particles—Chiral components

For the description of spin $\frac{1}{2}$ massless particles (neutrinos) one defines, as usual, the right and left components of a four-component spinor $\tilde{\psi}$ as

$$\tilde{\psi}_R=\tfrac{1}{2}(I+\gamma^5)\tilde{\psi}, \tag{2.11a}$$

$$\tilde{\psi}_L=\tfrac{1}{2}(I-\gamma^5)\tilde{\psi}. \tag{2.11b}$$

The free field Lagrangian, in terms of the right and left components, is

$$L=\bar{\tilde{\psi}}_R i\ \partial\!\!\!/\psi_L+\bar{\tilde{\psi}}_L i\ \partial\!\!\!/\psi_R\equiv\bar{\psi} i\ \partial\!\!\!/\psi. \tag{2.12}$$

By treating the left and right components independently one gets as equations of motion the following equations:

$$i\partial\!\!\!/\psi_R=0, \tag{2.13a}$$

$$i\partial\!\!\!/\psi_L=0. \tag{2.13b}$$

For the description of massless particles of arbitrary spin we assume, in analogy with the BW theory for massive particles, that a particle of spin s is associated to a symmetric spinor field of rank $2s$:

$$\tilde{\psi}_{a_1\cdots a_k\cdots a_{2s}}(x),\quad a_k=1,2,3,4. \tag{2.14}$$

For the rank $2s$ spinor field (2.14) one can define a set of chiral components as follows:

$$\tilde{\psi}_{R\cdots R}(x)\equiv\tilde{\psi}_{R_{a_1}\cdots R_{a_{2s}}}(x)=\tfrac{1}{2}(I+\gamma^5)_{a_1a_1'}\tfrac{1}{2}(I+\gamma^5)_{a_2a_2'}\cdots\tfrac{1}{2}(I+\gamma^5)_{a_{2s}a_{2s}'}\tilde{\psi}_{a_1'\cdots a_{2s}'}(x),$$

$$\tilde{\psi}_{R\cdots RL}(x)\equiv\tilde{\psi}_{R_{a_1}\cdots R_{a_{2s-1}}L_{a_{2s}}}(x)=\tfrac{1}{2}(I+\gamma^5)_{a_1a_1'}\cdots\tfrac{1}{2}(I+\gamma^5)_{a_{2s-1}a_{2s-1}'}\cdot\tfrac{1}{2}(I-\gamma^5)_{a_{2s}a_{2s}'}\tilde{\psi}_{a_1'\cdots a_{2s}'}(x),$$

$$\vdots$$

$$\tilde{\psi}_{L\cdots L}(x)\equiv\tilde{\psi}_{L_{a_1}\cdots L_{a_{2s}}}(x)=\tfrac{1}{2}(I-\gamma^5)_{a_1a_1'}\cdots\tfrac{1}{2}(I-\gamma^5)_{a_{2s}a_{2s}'}\tilde{\psi}_{a_1'\cdots a_{2s}'}(x). \tag{2.15}$$

We propose that these components satisfy an equation analogous to (2.13); that is,

$$i\partial\!\!\!/_{a_1a_1'}\tilde{\psi}_{R_{a_1'}R_{a_2}\cdots R_{a_{2s}}}(x)=0,$$

$$i\partial\!\!\!/_{a_1a_1'}\tilde{\psi}_{R_{a_1'}R_{a_2}\cdots L_{a_{2s}}}(x)=0,$$

$$\vdots$$

$$i\partial\!\!\!/_{a_1a_1'}\tilde{\psi}_{L_{a_1'}L_{a_2}\cdots L_{a_{2s}}}(x)=0. \tag{2.16}$$

We shall see in Sec. IV A that these equations follows from chiral invariance of the free Lagrangian.

C. Massless particles—Generalized two-component theory[8]

It is well known that massless particles of spin $\frac{1}{2}$ can be described by a two-component theory. We will show that this is also true for massless particles of arbitrary spin. That is, we will show that one can describe massless particles of arbitrary spin by means of a generalized two-component theory. Furthermore, we will show that these components satisfy equations analogous to Weyl's equations for particles of spin $\frac{1}{2}$.

In order to extend the two-component neutrino theory we just recall that one can write a four-component spinor as

$$\tilde{\psi}(x)=\begin{bmatrix}\xi(x)\\ \dot{\chi}(x)\end{bmatrix}=\psi_R+\psi_L\,, \tag{2.17}$$

where $\xi(x)$ and $\dot{\eta}(x)$ are two-component spinors, and ψ_R, ψ_L are defined in (2.11).

The set of equations (2.13) for ψ_R and ψ_L is equivalent to the following Weyl's equations for the two-component spinors ξ and $\dot{\eta}$:

$$(-i\sigma_0\partial_0 - i\boldsymbol{\sigma}\cdot\boldsymbol{\nabla})\,\xi(x)=0, \quad (-i\sigma_0\partial_0 + i\boldsymbol{\sigma}\cdot\boldsymbol{\nabla})\,\dot{\eta}(x)=0. \tag{2.18}$$

The two-component spinors ξ and $\dot{\chi}$ are eigenstates of the helicity operator $\frac{1}{2}\boldsymbol{\sigma}\cdot\mathbf{n}(\mathbf{n}=\mathbf{p}/|\mathbf{p}|)$ with eigenvalues $\pm\frac{1}{2}$.

The formulation of massless particles, in terms of generalized two-component spinors, can now be implemented by recalling that if $\tilde{\psi}$ transforms, under a Poincaré transformation, as a tensor product of $2s$ bispinors,

$$\tilde{\psi}\sim\begin{bmatrix}\xi_I\\ \dot{\chi}_I\end{bmatrix}\otimes\cdots\otimes\begin{bmatrix}\xi_{IIS}\\ \dot{\chi}_{IIS}\end{bmatrix}, \tag{2.19}$$

then, in chiral representation, the one that we will use from now on in the massless case, $\tilde{\psi}_{R\cdots R}, \tilde{\psi}_{R\cdots RL}, \tilde{\psi}_{L\cdots L}$, will transform like

$$\begin{aligned}
\tilde{\psi}_{R\cdots R}&\sim\begin{bmatrix}\xi_I\\ 0\end{bmatrix}\otimes\cdots\otimes\begin{bmatrix}\xi_{IIS}\\ 0\end{bmatrix}=\begin{bmatrix}\xi_I\cdots\xi_{IIS}\\ 0\\ \vdots\\ 0\end{bmatrix},\\
\tilde{\psi}_{R\cdots RL}&\sim\begin{bmatrix}\xi_I\\ 0\end{bmatrix}\otimes\cdots\otimes\begin{bmatrix}\xi_{IIS_{-1}}\\ 0\end{bmatrix}\otimes\begin{bmatrix}0\\ \dot{\chi}_{IIS}\end{bmatrix}=\begin{bmatrix}0\\ \xi_I\cdots\xi_{IIS_{-1}}\dot{\chi}_{IIS}\\ 0\\ \vdots\\ 0\end{bmatrix},\\
&\vdots\\
\tilde{\psi}_{L\cdots L}&\sim\begin{bmatrix}0\\ \dot{\chi}_I\end{bmatrix}\otimes\cdots\otimes\begin{bmatrix}0\\ \dot{\chi}_{IIS}\end{bmatrix}=\begin{bmatrix}0\\ \vdots\\ 0\\ \dot{\chi}_I\cdots\dot{\chi}_{IIS}\end{bmatrix}.
\end{aligned} \tag{2.20}$$

From (2.20), one can write, by using (2.15),

$$\begin{aligned}
\tilde{\psi}_{R\cdots R}&\sim\begin{bmatrix}\varphi^{(1)}\\ 0\\ \vdots\\ 0\end{bmatrix},\\
\tilde{\psi}_{R\cdots RL}&\sim\begin{bmatrix}0\\ \varphi^{(2)}\\ 0\\ \vdots\\ 0\end{bmatrix},\\
&\vdots
\end{aligned} \tag{2.21}$$

$$\tilde{\psi}_{L\cdots L}\sim\begin{bmatrix}0\\ \vdots\\ 0\\ \varphi^{(2s)}\end{bmatrix},$$

where $\varphi^{(1)},\varphi^{(2)},...,\varphi^{(2s)}$, are, respectively, the only nonzero components of $\tilde{\psi}_{R\cdots R},\tilde{\psi}_{R\cdots RL},\ldots,\tilde{\psi}_{L\cdots L}$ and are two-component spinors of rank $2s$:

$$\begin{aligned}\varphi^{(1)}&=\varphi_{b_1b_2\cdots b_{2s}},\\ \varphi^{(2)}&=\varphi'_{b_1b_2\cdots b_{2s}},\\ &\vdots\\ \varphi^{(2s)}&=\varphi^{(2s-1)}_{b_1b_2\cdots b_{2s}},\\ b_1,b_2,\ldots,b_{2s}&=1,2.\end{aligned}\tag{2.22}$$

Using Eqs. (2.16) we can see that $\varphi^{(1)}$ and $\varphi^{(2s)}$ satisfy generalized Weyl's equations:

$$(-i\sigma^0\partial_0-i\boldsymbol{\sigma}\cdot\boldsymbol{\nabla})\otimes\mathbf{1}\otimes\cdots\otimes\mathbf{1}\varphi^{(1)}(x)=0,\tag{2.23a}$$

$$(-i\sigma^0\partial_0+i\boldsymbol{\sigma}\cdot\boldsymbol{\nabla})\otimes\mathbf{1}\otimes\cdots\otimes\mathbf{1}\varphi^{(2s)}(x)=0,\tag{2.23b}$$

where $\varphi^{(1)}$ and $\varphi^{(2s)}$ are symmetric two-component spinors of rank $2s$. Equation (2.23b) can be derived from (2.23a) by space reflection, so one can consider just one of the equations (2.23).

The other components $\varphi^{(2)},...,\varphi(2s-1)$ satisfy equations analogous to Weyl's.

Since the spin operator, in chiral representation, is given by

$$\boldsymbol{\Sigma}=\tfrac{1}{2}(\boldsymbol{\Sigma}\otimes\mathbf{1}\otimes\mathbf{1}\cdots\otimes\mathbf{1}+\cdots+\mathbf{1}\otimes\mathbf{1}\otimes\mathbf{1}\cdots\otimes\boldsymbol{\Sigma}),\tag{2.24}$$

then the generalized helicity operator W is

$$W=\mathbf{n}\cdot\boldsymbol{\Sigma}.\tag{2.25}$$

The eigenvalues of $W(\omega)$ lie in the range $-s\leqslant\omega\leqslant s$. In particular, we have

$$W\psi_{R\cdots R}=s\psi_{R\cdots R},\quad W\psi_{L\cdots L}=-s\psi_{L\cdots L}.\tag{2.26}$$

Our proposal for treating massless particles is then parallel to the neutrino theory. For the free field theory one requires chiral invariance. For massless particles it is sensible to define chiral components and treat them as independent variables. For free fields, by using four-spinors, these equations are (2.16), whereas, by using two-spinors, the basic equations are (2.23). We shall see that this leads to Maxwell's equation in vacuum in the case of spin 1 particles.

III. BW THEORY FOR MASSIVE SPIN 1 PARTICLES

A. Free fields

This chapter shows how one describes massive spin 1 particles with the spinor method proposed by Bargmann and Wigner.

Within the BW method a spin 1 massive particle of mass m is described, in the noninteracting case, by a rank 2 symmetric spinor $\psi_{a_1a_2}(x)$ obeying a system of two Dirac-type equations:

$$(i\partial\!\!\!/\otimes I)\psi = m\psi, \quad (I\otimes i\partial\!\!\!/)\psi = m\psi. \tag{3.1}$$

Equations (3.1) may be derived from the following Lagrangian:[6]

$$\mathscr{L}_0 = \bar{\psi}\left\{\frac{i}{2}[\gamma^\mu\otimes I + I\otimes\gamma^\mu]\partial_\mu - mI\otimes I\right\}\psi. \tag{3.2}$$

If we treat the field $\psi_{a_1a_2}$ as the independent variable, one gets, in particular,

$$\{i\partial\!\!\!/ - m\}_{a_1a_s'}\psi_{a_1'a_2}(x) = 0. \tag{3.3}$$

We replace $\psi_{a_1'a_2}$ in (3.3) by its decomposition (2.9) and obtain

$$\begin{aligned} i\gamma^\alpha_{a_1a_1'}\partial_\alpha\left\{B_\mu(x)(\gamma^\mu C)_{a_1'a_2} - \frac{1}{2m}G_{\mu\nu}(x)(\sigma^{\mu\nu}C)_{a_1'a_2}\right\} \\ = m\left\{B_\mu(x)(\gamma^\mu C)_{a_1a_2} - \frac{1}{2m}G_{\mu\nu}(x)(\sigma^{\mu\nu}C)_{a_1a_2}\right\}. \end{aligned} \tag{3.4}$$

In order to see that (3.4) leads to the usual equations one has to make some simple operations involving γ matrices. For instance, if one multiplies (3.4) by $(C^{-1})_{a_2a_1}$ and sums over a_1a_2, one gets

$$i\partial_\alpha B_\mu \operatorname{Tr}(\gamma^\alpha\gamma^\mu) = 0,$$

from which it follows that

$$\partial_\mu B^\mu = 0. \tag{3.5}$$

It is interesting to see that the subsidiary condition $\partial_\mu B^\mu = 0$ follows directly from the BW equation. If, on the other hand, one multiplies (3.4) by $(C^{-1}\gamma^\beta)_{a_2a_1}$, one gets

$$-\frac{1}{2m}\partial_\alpha G_{\mu\nu}\operatorname{Tr}(\gamma^\alpha\sigma^{\mu\nu}\gamma^\beta) = mB_\mu\operatorname{Tr}(\gamma^\mu\gamma^\beta),$$

from which one gets

$$-\partial^\mu G_{\mu\beta} + m^2 B_\beta = 0. \tag{3.6}$$

Finally, if we multiply (3.4) by $(C^{-1}\gamma^\beta\gamma^\lambda)_{a_2a_1}$, one gets

$$i\partial_\alpha B_\mu \operatorname{Tr}(\gamma^\alpha\gamma^\mu\gamma^\beta\gamma^\lambda) = -\frac{1}{2m}G_{\mu\nu}\operatorname{Tr}(\sigma^{\mu\nu}\gamma^\beta\gamma^\lambda),$$

from which it follows that

$$\partial_\mu B^\mu g^{\beta\lambda} + \partial^\lambda B^\beta - \partial^\beta B^\lambda = G^{\beta\lambda}. \tag{3.7}$$

By using (3.5) in (3.7) one gets

$$G^{\beta\lambda} = \partial^\lambda B^\beta - \partial^\beta B^\lambda; \tag{3.8}$$

that is, in the decomposition (2.9) of the field ψ, the only acceptable tensor is $\partial^\nu B^\mu - \partial^\mu B^\nu$.

We have then seen that BW equations lead to the following restrictions upon the fields B^{μ} and $G^{\mu\nu}$:

$$\partial^{\mu}B_{\mu}=0, \quad G_{\mu\nu}=\partial_{\nu}B_{\mu}-\partial_{\mu}B_{\nu}, \quad -\partial^{\mu}G_{\mu\nu}+m^{2}B_{\nu}=0. \tag{3.9}$$

In order to see the equivalence between the BW method and the usual approach, in which we assign to a vector field B_{μ} a spin 1 particle, let us now write $\mathscr{L}_0$ in terms of B_{μ}.

By using decomposition (2.9) one gets

$$\mathscr{L}_0=4m^{2}B^{\mu}B_{\mu}-2G^{\mu\nu}G_{\mu\nu} \tag{3.10}$$

or, using (3.8),

$$\mathscr{L}_0=4m^{2}B^{\mu}B_{\mu}+4\partial^{\mu}B^{\nu}(\partial_{\nu}B_{\mu}-\partial_{\mu}B_{\nu}). \tag{3.11}$$

If we consider B_{μ} as the independent field, then one gets from (3.11) the usual Euler–Lagrange for the B_{μ} field; that is,

$$m^{2}B_{\nu}-\partial^{\mu}G_{\mu\nu}=0, \tag{3.12}$$

where

$$G_{\mu\nu}=\partial_{\nu}B_{\mu}-\partial_{\mu}B_{\nu}.$$

Equation (3.12) is the same as Eq. (3.6).

B. Interacting fields

Let us consider the interaction of massive spin 1 particles with massive spin $\frac{1}{2}$ particles, described, as usual, by a rank 1 spinor field η.

If we restrict ourselves to Lagrangians that are linear in the ψ fields (which leads, ultimately, to renormalizable models), then the forms that are compatible with Lorentz invariance are

$$\mathscr{L}_{\text{int}}=g_1\bar{\psi}_{a_1a_2}\eta^{c}_{a_1}\eta^{c}_{a_2}+g_2\bar{\psi}_{a_1a_2}\eta^{c}_{a_1}\eta^{c}_{a_2}+\text{h.c.}=g_1\eta^{c}\bar{\psi}\eta+g_2\eta\bar{\psi}\eta+\text{h.c.}, \tag{3.13}$$

where g_1 and g_2 are constants with dimension $[L]^{1/2}=1/[M]^{1/2}$.

In the following we shall take $g_2=0$. As we shall see later in the zero-mass limit nature seems to prefer this type of coupling.

We shall study the following total Lagrangian for a spin 1 massive field interacting with a spin $\frac{1}{2}$ massive field:

$$\mathscr{L}=\bar{\psi}\{\tfrac{1}{2}(\gamma^{\mu}\otimes I+I\otimes\gamma^{\mu})\partial_{\mu}-mI\otimes I\}\psi+g_1\eta^{c}\bar{\psi}\eta+\bar{\eta}(i\partial\!\!\!/-m_f)\eta. \tag{3.14}$$

Treating now $\bar{\psi}_{a_1a_2}$, $\psi_{a_1a_2}$, η as independent fields, we obtain using (3.9) and Lagrange equations

$$\partial_{\mu}G^{\rho\mu}=-m^{2}B^{\rho}+g_1\frac{\sqrt{m}}{4}\bar{\eta}\gamma^{\rho}\eta. \tag{3.15}$$

Model (3.15) leads to equations analogous to Maxwell's. In fact, in analogy with the massless case, we name

$$G^{0k}=E^{k}, \quad G^{jk}=\epsilon^{ljk}H^{l}. \tag{3.16}$$

We obtain from (3.15) the following set of equations:

$$\nabla\cdot\mathbf{E}+m^2B^0=g_1\frac{\sqrt{m}}{4}\,\bar{\eta}\gamma^0\eta,$$

$$\partial^0\mathbf{E}-\nabla\wedge\mathbf{H}-m^2\mathbf{B}=-g_1\frac{\sqrt{m}}{4}\,\bar{\eta}\gamma^0\eta,$$

$$\nabla\cdot\mathbf{H}=0,\quad \partial^0\mathbf{H}+\nabla\wedge\mathbf{E}=0. \tag{3.17}$$

Equations (3.17) are analogous to Maxwell's. That is, we get a set of coupled equations of first order in terms of the observables **E** and **H**.

C. Hamiltonian

We take the form (3.14) of $\mathscr{L}$ as a starting point. The two fields η and ψ are independent. We construct conjugate momenta from $\mathscr{L}$ by the standard prescription, so we obtain

$$\pi_{a_1a_2}=\frac{\partial\mathscr{L}}{\partial(\partial^0\psi)_{a_1a_2}}=\bar{\psi}_{a_1'a_2'}\frac{i}{2}\{\gamma^0_{a_1'a_1}\delta_{a_2'a_2}+\delta_{a_1'a_1}\gamma^0_{a_2'a_2}\},$$
$$\pi_{a_1}=\frac{\partial\mathscr{L}}{\partial(\partial^0\eta)_{a_1}}=\bar{\eta}_{a_2}i\gamma^0_{a_2a_1}. \tag{3.18}$$

The Hamiltonian is defined by

$$\mathbf{H}=\pi_{a_1a_2}\partial^0\psi_{a_1a_2}+\pi_{a_1}\partial^0\eta_{a_1}-\mathscr{L}. \tag{3.19}$$

Replacing $\psi_{a_1a_2}(\bar{\psi}_{a_1a_2})$ by its decomposition (2.9), one gets

$$\mathbf{H}=4\{G^{0\mu}\partial_0B_\mu+\partial_0B_\mu G^{0\mu}\}-4\{m^2B^\mu B_\mu-\tfrac{1}{2}G^{\mu\nu}G_{\mu\nu}\}$$
$$+g_1\sqrt{m}\left\{B_\mu\bar{\eta}\gamma^\mu\eta-\frac{1}{2m}\,G_{\mu\nu}\bar{\eta}\sigma^{\mu\nu}\eta\right\}-\bar{\eta}(i\gamma^k\partial_k-m_f)\eta, \tag{3.20}$$

where

$$k,j=1,2,3,$$

$$\mu,\nu=0,1,2,3.$$

Now, following Bjorken–Drell[7] we adopt the notation

$$E^j=E^j_l+E^j_t=-\partial_jB^0-\partial_0B^j$$

and we assume that the fields **E** and **H** are real, so we obtain

$$\mathbf{H}=4(\mathbf{H}^2+\mathbf{E}_t^2)-4\mathbf{E}_l^2-4m^2B^\mu B_\mu+g_1\sqrt{m}\left\{B^0\bar{\eta}\gamma^0\eta+B_j\bar{\eta}\gamma^j\eta-\frac{1}{2m}\,G_{\mu\nu}\bar{\eta}\sigma^{\mu\nu}\eta\right\}$$
$$-\bar{\eta}(i\gamma^k\partial_k-m_f)\eta. \tag{3.21}$$

IV. ALTERNATIVE APPROACH TO SPIN 1 MASSLESS PARTICLES

A. Spin 1 massless particles

In this section we will see how one can apply the two-component and the four-component spinorial formalism in the description of spin 1 massless particles. In this case one works with a rank 2 spinor field ψ_{ab}. Our starting point could be the zero-mass limit of (3.2). The Lagrangian that one gets in this limit is

$$\mathscr{L}_0=\bar{\psi}\left\{\frac{i\partial\!\!\!/}{2}\otimes\mathbf{1}+\mathbf{1}\otimes\frac{i\partial\!\!\!/}{2}\right\}\psi. \tag{4.1}$$

Lagrangian (4.1) is not, however, the appropriate Lagrangian for spin 1 massless particles. The reason why the extension of the Bargmann–Wigner theory, in this case, is not straightforward is chiral symmetry. $\mathscr{L}_0$ defined in (4.1) is not invariant under the generalized chiral transformation

$$\psi\rightarrow\psi'=e^{i\alpha\gamma_5}\otimes e^{i\alpha\gamma_5}\psi. \tag{4.2}$$

Only the equivalent Lagrangians

$$\mathscr{L}=\bar{\psi}(i\partial\!\!\!/\otimes 1)\psi \quad [\mathscr{L}'=\bar{\psi}(1\otimes i\partial\!\!\!/)\psi] \tag{4.3}$$

are invariant under the chiral transformations

$$\psi\rightarrow\psi'=(e^{i\alpha\gamma_5}\otimes 1)\psi \quad [\psi'=(1\otimes e^{i\alpha\gamma_5})\psi]. \tag{4.4}$$

Expressions (4.3) suggest that the Lagrangian for massless spin 1 particles is not uniquely defined. This would be the case if the field ψ is asymmetric. However, for a symmetric ψ field both expressions in (4.3) are equivalent. The problem is that we are not able to impose, at the Lagrangian level, the symmetry properties of the ψ field.

The need to work with asymmetric ψ fields lead us eventually to difficulties in dealing with discrete symmetries. This is due to the fact that depending on the Lagrangian we take we might get a different transformation law for the fields ψ. These transformation laws are equivalent only in the case of symmetric ψ fields. This is just to call attention to the fact that some care is needed when dealing with discrete symmetries.

For the Lagrangian $\mathscr{L}$ ($\mathscr{L}'$) one can introduce, in close analogy with the spin $\frac{1}{2}$ case, the chiral components

$$\begin{aligned}
\psi_{RR}&=\frac{(1+\gamma_5)}{2}\otimes\frac{(1+\gamma_5)}{2}\,\psi, \quad \psi_{RL}=\frac{(1+\gamma_5)}{2}\otimes\frac{(1-\gamma_5)}{2}\,\psi,\\
\psi_{LR}&=\frac{(1-\gamma_5)}{2}\otimes\frac{(1+\gamma_5)}{2}\,\psi, \quad \psi_{LL}=\frac{(1-\gamma_5)}{2}\otimes\frac{(1-\gamma_5)}{2}\,\psi,
\end{aligned} \tag{4.5}$$

where, by definition,

$$\psi=\psi_{RL}+\psi_{RR}+\psi_{LR}+\psi_{LL}. \tag{4.6}$$

These chiral components are eigenstates of the chirality operator $\gamma_5\otimes 1(1\otimes\gamma_5)$ with eigenvalues $+1$ or (-1). That is, they are polarized either to the right or to the left.

For massless particles the most general decomposition of the ψ field is now

$$\psi_{a_1a_2}=C_1A_\mu(\gamma^\mu C)_{a_1a_2}-C_2F_{\mu\nu}(\sigma^{\mu\nu}C)_{a_1a_2}, \tag{4.7}$$

where C_1 and C_2 in (4.7) are arbitrary constants that, in the massless case, cannot be related to each other as in the massive case [expression (2.9)], since C_1 and C_2 are dimensional constants having different dimensions.

The chiral components defined in (4.5) assume, after inserting (4.7) in (4.5), the following form:

$$\begin{aligned}
(\psi_{RR}(x))_{a_1a_2} &= -C_2[\tfrac{1}{2}(1+\gamma_5)\sigma^{\mu\nu}C]_{a_1a_2}F_{\mu\nu},\\
(\psi_{RL}(x))_{a_1a_2} &= C_1[\tfrac{1}{2}(1+\gamma_5)\gamma^{\mu}C]_{a_1a_2}A_{\mu},\\
(\psi_{LR}(x))_{a_1a_2} &= C_1[\tfrac{1}{2}(1-\gamma_5)\gamma^{\mu}C]_{a_1a_2}A_{\mu},\\
(\psi_{LL}(x))_{a_1a_2} &= -C_2[\tfrac{1}{2}(1-\gamma_5)\sigma^{\mu\nu}C]_{a_1a_2}F_{\mu\nu}.
\end{aligned} \tag{4.8}$$

That is, ψ_{RL},ψ_{RR} are related to potentials whereas ψ_{RR},ψ_{LL} are related to observables (electromagnetic fields).

Our proposal for treating massless spin 1 particles is, in close analogy with spin $\frac{1}{2}$ particles, to treat all chiral components $(\psi_{RL},\psi_{LR},\psi_{LL},\psi_{RR})$ as independent field variables. These chiral components describe, in principle, different species of spin 1 massless particles. In this way we consider all chiral components as dynamical variables. This approach leads to a formulation of QED in which potentials and observable fields are treated on equal footing. It is simple to check that the substitution of (4.6) into (4.3) leads to the following Lagrangian density:

$$\tilde{\mathscr{L}}_0=\bar{\tilde{\psi}}_{RL}(i\partial\!\!\!/\otimes I)\tilde{\psi}_{RR}+\bar{\tilde{\psi}}_{LR}(i\partial\!\!\!/\otimes I)\tilde{\psi}_{LL}+\bar{\tilde{\psi}}_{RR}(i\partial\!\!\!/\otimes I)\tilde{\psi}_{RL}+\bar{\tilde{\psi}}_{LL}(i\partial\!\!\!/\otimes I)\tilde{\psi}_{LR}. \tag{4.9}$$

By treating all chiral components as independent field variables one gets the following equations of motion:

$$\begin{aligned}
&(i\partial\!\!\!/\otimes I)\tilde{\psi}_{RR}=0, \quad (i\partial\!\!\!/\otimes I)\tilde{\psi}_{RL}=0,\\
&(i\partial\!\!\!/\otimes I)\tilde{\psi}_{LR}=0, \quad (i\partial\!\!\!/\otimes I)\tilde{\psi}_{LL}=0.
\end{aligned} \tag{4.10}$$

We will be interested in analyzing whether the interaction of photons with matter exhibits any preference of nature with regard to chiral components and, if this occurs, if there is violation of parity. The free field Lagrangian is invariant under space reflection ($\mathbf{x}\to-\mathbf{x}$) if the chiral fields transform as

$$\begin{aligned}
\psi_{LP} &\overset{P}{\to} \psi'_{LR}(x')=\xi(\gamma_0\otimes 1)\psi_{RR}(+\mathbf{x},t),\\
\psi_{LL} &\overset{P}{\to} \psi'_{LL}(x')=\xi(\gamma_0\otimes 1)\psi_{RL}(+\mathbf{x},t),\\
\psi_{RR} &\overset{P}{\to} \psi'_{RR}(x')=\xi(\gamma_0\otimes 1)\psi_{LR}(+\mathbf{x},t),\\
\psi_{RL} &\overset{P}{\to} \psi'_{RL}(x')=\xi(\gamma_0\otimes 1)\psi_{LL}(+\mathbf{x},t).
\end{aligned} \tag{4.11}$$

From (4.11) and (4.8) one would conclude that the mirror fields of the potentials are the observable fields (**E** and **H**) and vice-versa. This example illustrates, as pointed out before, the difficulty which we might run into when dealing with discrete symmetries within the spinors method.

There are two alternatives in dealing with discrete symmetries that can easily be checked taking the explicit example of space reflection. In the first case one can use the explicitly symmetric representation (4.7) in any of the alternative forms in (4.3) and analyze the symmetry properties of the Lagrangian in terms of the fields A_μ and $F_{\mu\nu}$. The Lagrangian is the standard one of electromagnetism as we shall see later.

The other alternative is to impose, from the very beginning, that ψ is symmetric. Under these circumstances Lagrangians (4.3) and (4.1) are equivalent. These equivalent Lagrangians would now be invariant under space reflections if the chiral fields transform as

$$\psi'_{RR}(x')=\xi(\gamma^0\otimes\gamma^0)\psi_{LL}(x), \quad \psi'_{RL}(x')=\xi(\gamma^0\otimes\gamma^0)\psi_{LR}(x),$$

$$\psi'_{LR}(x')=\xi(\gamma^0\otimes\gamma^0)\psi_{RL}(x), \quad \psi'_{LL}(x')=\xi(\gamma^0\otimes\gamma^0)\psi_{RR}(x).$$

It can be checked explicitly that these transformations lead to the proper transformation properties of the A_μ and $F_{\mu\nu}$ fields.

The generalized helicity operator W is now

$$\tfrac{1}{2}(\boldsymbol{\Sigma}\cdot\mathbf{n}\otimes I+I\otimes\boldsymbol{\Sigma}\cdot\mathbf{n})\equiv W, \quad \mathbf{n}=\frac{\mathbf{p}}{|\mathbf{p}|}. \tag{4.12}$$

It is straightforward to show that $\psi_{RR},\psi_{RL},\psi_{LR},\psi_{LL}$ are eigenstates of W with eigenvalues $+1,0,-1$; that is,

$$\begin{aligned}&\tfrac{1}{2}(\boldsymbol{\Sigma}\cdot\mathbf{n}\otimes I+I\otimes\boldsymbol{\Sigma}\cdot\mathbf{n})\tilde{\psi}_{RR}=\psi_{RR}, \quad \tfrac{1}{2}(\boldsymbol{\Sigma}\cdot\mathbf{n}\otimes I+I\otimes\boldsymbol{\Sigma}\cdot\mathbf{n})\tilde{\psi}_{RL}=0,\\ &\tfrac{1}{2}(\boldsymbol{\Sigma}\cdot\mathbf{n}\otimes I+I\otimes\boldsymbol{\Sigma}\cdot\mathbf{n})\tilde{\psi}_{LR}=0, \quad \tfrac{1}{2}(\boldsymbol{\Sigma}\cdot\mathbf{n}\otimes I+I\otimes\boldsymbol{\Sigma}\cdot\mathbf{n})\tilde{\psi}_{LL}=-\psi_{LL}.\end{aligned} \tag{4.13}$$

B. Free electrodynamics

Let us check, finally, that the Lagrangian density (4.9) provides an alternative formulation of free electrodynamics. By substituting (4.8) into Eqs. (4.10) and furthermore multiplying (4.10) by (C) and taking the trace, we get

$$\partial^\mu A_\mu=0; \tag{4.14}$$

that is, we get a Lorentz condition. Furthermore, multiplying (4.10) by $(C^{-1}\gamma^\beta)$ we get the equation of motion for the $F^{\mu\nu}$ field,

$$\partial^\mu F_{\mu\nu}=0. \tag{4.15}$$

We shall see, by employing the two-spinor approach, that $F_{\mu\nu}$ can be written, in terms of an antisymmetric field tension $\mathscr{F}_{\mu\nu}$, as

$$F_{\mu\nu}=\mathscr{F}_{\mu\nu}+i\tilde{\mathscr{F}}_{\mu\nu}, \tag{4.16}$$

where

$$\tilde{\mathscr{F}}^{\mu\nu}=\tfrac{1}{2}\epsilon^{\mu\nu\alpha\beta}\mathscr{F}_{\alpha\beta}. \tag{4.17}$$

The equation of motion for $\mathscr{F}_{\mu\nu}$ and $\tilde{\mathscr{F}}_{\mu\nu}$ is, from (4.15),

$$\partial_\mu \mathscr{F}^{\mu\nu}=0, \quad \partial_\mu \tilde{\mathscr{F}}^{\mu\nu}=0. \tag{4.18}$$

It should be pointed out at this point that since in the massless case ψ_{RL} and ψ_{RR} components are treated as independent variables there is no connection between $\mathscr{F}^{\mu\nu}$ and the derivatives of the field A_μ. That is, in this case A_μ and $F_{\mu\nu}$ are independent field variables. We shall see, however, that within the generalized two-component theory of massless spin 1 particles this connection emerges from Maxwell's equations for the observable fields. We shall see that, also in this case, one can write

$$\mathscr{F}^{\mu\nu}=\partial^\mu A^\nu-\partial^\nu A^\mu \tag{4.19}$$

and, as a result, from (4.19) and (4.14), it follows that the A^μ field satisfies, by using (4.18),

$$\Box A^\mu=0. \tag{4.20}$$

C. Two-component formulation of free electrodynamics

We shall now consider the formulation of free electrodynamics within the generalized two-component theory presented in Sec. I. In the case of spin 1 particles the field ψ transforms as

$$\psi\sim\begin{bmatrix}\xi^I\\ \dot{\chi}^I\end{bmatrix}\otimes\begin{bmatrix}\xi^{II}\\ \dot{\chi}^{II}\end{bmatrix} \tag{4.21}$$

so that the fields $\psi_{RL},\psi_{LR},\psi_{RR},\psi_{LL}$ defined in (4.5) transform like

$$\begin{aligned}
&\tilde{\psi}_{RR}\sim\begin{bmatrix}\xi^I\\ 0\end{bmatrix}\otimes\begin{bmatrix}\xi^{II}\\ 0\end{bmatrix}, \quad \tilde{\psi}_{RL}\sim\begin{bmatrix}\xi^I\\ 0\end{bmatrix}\otimes\begin{bmatrix}0\\ \dot{\chi}^{II}\end{bmatrix},\\
&\tilde{\psi}_{LR}\sim\begin{bmatrix}0\\ \dot{\chi}^I\end{bmatrix}\otimes\begin{bmatrix}\xi^{II}\\ 0\end{bmatrix}, \quad \tilde{\psi}_{LL}\sim\begin{bmatrix}0\\ \dot{\chi}^I\end{bmatrix}\otimes\begin{bmatrix}0\\ \dot{\chi}^{II}\end{bmatrix}.
\end{aligned} \tag{4.22}$$

The generalized Weyl's equations satisfied by the nonzero components of ψ_{RR} and ψ_{LL} are

$$\begin{aligned}
&(-i\sigma^0\partial_0-i\boldsymbol{\sigma}\cdot\boldsymbol{\nabla})_{aa'}\xi^I_{a'}\xi^{II}_b=0,\\
&(-i\sigma^0\partial_0+i\boldsymbol{\sigma}\cdot\boldsymbol{\nabla})_{aa'}\dot{\chi}^I_{a'}\dot{\chi}^{II}_b=0,
\end{aligned} \tag{4.23}$$

where symmetrization in the spin indices is assumed in Eq. (4.23).

Equations (4.23) can be written, in terms of $\varphi^{(1)}$ and $\varphi^{(4)}$ defined in (2.21), as

$$(-i\sigma^0\partial_0-i\boldsymbol{\sigma}\cdot\boldsymbol{\nabla})\varphi^{(1)}(\mathbf{x},t)=0, \tag{4.24a}$$

$$(-i\sigma_0\partial_0+i\boldsymbol{\sigma}\cdot\boldsymbol{\nabla})\varphi^{(4)}(\mathbf{x},t)=0. \tag{4.24b}$$

We are now ready to get the field equations of electrodynamics. As in the generalized four-component approach, one tries to write $\varphi^{(1)}$ and $\varphi^{(4)}$ as a linear combination of 2×2 symmetric matrices. In this case, the candidate matrices are the matrices (2.8), $\boldsymbol{\sigma}C_1$, where C_1 is the 2×2 charge conjugation matrix. One can then write

$$\varphi^{(1)}(x)=\mathbf{f}(x)(\boldsymbol{\sigma}\cdot C_1), \tag{4.25}$$

where $\mathbf{f}$ is a vector that satisfies, after substituting (4.25) into (4.24), the following equations:

$$\nabla \cdot \mathbf{f} = 0, \tag{4.26}$$

$$i\partial^0 \mathbf{f} = \nabla \times \mathbf{f}. \tag{4.27}$$

We have shown in Sec. IV A that $\varphi^{(1)}$ and $\varphi^{(4)}$ (or, equivalently, ψ_{RR} and ψ_{LL}) should be built from an antisymmetric tensor $F_{\mu\nu}$. More specifically, it follows from (4.8) and (4.25) that the ith component f_i can be written as

$$f_i = \tfrac{1}{2}\,\epsilon_{0i\alpha\beta}F^{\alpha\beta} = \tfrac{1}{2}\,\epsilon_{i\alpha\beta}F^{\alpha\beta}, \tag{4.28}$$

with $i,\alpha,\beta = 1,2,3$.

As pointed out in Ref. 5 $F_{\mu\nu}$ in (4.28) should be self-dual. In this way if one assumes that $\mathscr{F}_{\mu\nu}$ is an antisymmetrical tensor, then one can construct from this tensor a self-dual one by writing

$$F^{\mu\nu} = \mathscr{F}^{\mu\nu} + i\tilde{\mathscr{F}}^{\mu\nu}, \tag{4.29}$$

where

$$\tilde{\mathscr{F}}^{\mu\nu} = \tfrac{1}{2}\epsilon^{\mu\nu\alpha\beta}\mathscr{F}_{\alpha\beta}. \tag{4.30}$$

If one defines further,

$$E^i \equiv \mathscr{F}_0 i, \quad H^i = \tilde{\mathscr{F}}_0 i. \tag{4.31}$$

It follows that Eqs. (4.26) and (4.27) for $\mathbf{f}$ imply Maxwell's equations for the $\mathbf{E}$ and $\mathbf{H}$ fields defined in (4.31). That is,

$$\begin{gathered} \nabla \cdot \mathbf{E} = 0, \quad \nabla \cdot \mathbf{H} = 0, \\ \nabla \times \mathbf{E} - \partial_0 \mathbf{E} = 0, \quad \nabla \times \mathbf{H} - \partial_0 \mathbf{H} = 0. \end{gathered} \tag{4.32}$$

Finally, it follows from Maxwell's equation (4.32) and from (4.31) that $\mathscr{F}_{\mu\nu}$ can be written as

$$\mathscr{F}_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu. \tag{4.33}$$

It is worth commenting, at this point, on the connection between $\mathscr{F}_{\mu\nu}$ and the derivatives of the field A_μ in the case of massless particles. In the massive case the connection analogous to (4.33) follows from the restriction imposed by BW equations. In the massless case the possibility of writing $\mathscr{F}_{\mu\nu}$ under the form (4.33) follows from Maxwell's equations that allows us to write the observable fields in terms of derivatives of the four-potentials. We will show, in the interaction case, how expression (4.33) can be derived by adding chiral violating terms to the Lagrangian.

The conclusion is that, within the spinor method proposed here, Maxwell's equation in vacuum emerges from the requirement of chiral invariance of the free field Lagrangian. Maxwell's equations for the fields $\mathbf{E}$ and $\mathbf{H}$ emerge from the equations analogous to Weyl's equation in the two-component neutrino theory.

V. INTERACTING FIELDS—QED

A. Linear interactions

Let us now consider the interaction of massless spin 1 fields. We will mainly be concerned with the interaction of these particles with ordinary matter. That is, we will be concerned with the most general interaction Lagrangian describing massless spin 1 particles interacting with spin $\frac{1}{2}$ massive (m_f) particles.

The most general Lagrangian involving the interaction of the chiral fields (4.5) with ordinary matter (here represented by the Fermi on field η) is

$$\mathscr{L}=\bar{\psi}_{RL}(i\partial\!\!\!/\otimes 1)\psi_{RR}+\bar{\psi}_{LR}(i\partial\!\!\!/\otimes 1)\psi_{LL}+\bar{\psi}_{RR}(i\partial\!\!\!/\otimes 1)\psi_{RL}+\bar{\psi}_{LL}(i\partial\!\!\!/\otimes 1)$$
$$\times\psi_{LR}+\bar{\eta}(i\partial\!\!\!/-m)\eta+\mathscr{L}_{\text{int}}(\psi_{RR},\ \psi_{RL},\ \psi_{LR},\ \psi_{LL},\ \eta). \tag{5.1}$$

By imposing that the Lagrangian is linear in the ψ fields, then the most general form that is bilinear in the matter field η that we can construct with the four independent fields ψ_{RR}, ψ_{RL}, ψ_{LR}, and ψ_{LL} is

$$\mathscr{L}_{\text{int}}=A\bar{\psi}_{R_{a_1}R_{a_2}}\eta_{a_1}\eta_{a_2}+B\bar{\psi}_{L_{a_1}L_{a_2}}\eta_{a_1}\eta_{a_2}+D\bar{\psi}_{R_{a_1}L_{a_2}}\eta_{a_1}\eta_{a_2}+E\bar{\psi}_{L_{a_1}R_{a_2}}\eta_{a_1}\eta_{a_2}+F\bar{\psi}_{R_{a_1}R_{a_2}}\eta^c_{a_1}\eta_{a_2}$$
$$+J\bar{\psi}_{L_{a_1}L_{a_2}}\eta^c_{a_1}\eta_{a_2}+K\bar{\psi}_{R_{a_1}L_{a_2}}\eta^c_{a_1}\eta_{a_2}+L\bar{\psi}_{L_{a_1}R_{a_2}}\eta^c_{a_1}\eta_{a_2}+\text{h.c.}, \tag{5.2}$$

where A, B, D, E, F, J, K, and L are arbitrary constants.

The reason for so many terms is that we shall assume, to start with, that ordinary matter couples with different strengths to the chiral components of the field ψ. As a matter of fact, we shall see that, in this case, only the zero helicity components couple to ordinary matter.

It is trivial to check that if nature is asymmetric with regard to left and right (that is, if it prefers chiral components), then the theory violates parity [in the sense that the Lagrangian is not invariant under transformations (4.11)]. The physical consequences, however, depend on how this symmetry is broken. We will show that within the field theoretical context the breakdown of parity, and consequently of left–right symmetry, does not lead always to processes occurring with different probabilities in the actual system or in its mirror image. That is, for theories in which not all the fields are observables, the parity symmetry breakdown might not be accompanied by observable effects. Electrodynamics follow into this category of field theories. In order to illustrate this relevant aspect let us consider two parity nonconserving Lagrangians:

$$\mathscr{L}_1^{\text{int}}=D(\psi_{LR})\eta_c\eta, \tag{5.3}$$

$$\mathscr{L}_2^{\text{int}}=K(\psi_{RL}+\psi_{LR})\eta_c\eta, \tag{5.4}$$

where K and D are coupling constants.

The first Lagrangian leads to left–right asymmetry leading to observable effects as far as parity breaking is concerned. In fact, Lagrangian (5.3) describes essentially the interaction of a vector field A_μ coupled to a vector and axial vector current $[\bar{\eta}(1-\gamma_5)\gamma_\mu\eta]$. As will be shown in the next section, the Lagrangian (5.4) is an equivalent formulation of QED.

If one wants to ensure that there are no observable effects in the breakdown of parity of Lagrangian (5.2), one has to require that

$$\begin{aligned} A&=B, \quad D=E,\\ F&=J, \quad K=L. \end{aligned} \tag{5.5}$$

Under restrictions (5.5), the most general interaction Lagrangian is then

$$\mathscr{L}_{\text{int}}=A(\bar{\psi}_{RR}\eta\eta+\bar{\psi}_{LL}\eta\eta)+D(\bar{\psi}_{RL}\eta\eta+\bar{\psi}_{LR}\eta\eta)+F(\bar{\psi}_{RR}\eta^c\eta+\bar{\psi}_{LL}\eta^c\eta)$$
$$+K(\bar{\psi}_{RL}\eta^c\eta+\bar{\psi}_{LR}\eta^c\eta). \tag{5.6}$$

We now consider the particular interaction Lagrangian obtained by taking $A=D=K=0$:

$$\mathscr{L}_{\text{int}} = F(\bar{\tilde{\psi}}_{RR}\eta^c\eta + \bar{\tilde{\psi}}_{LL}\eta^c\eta). \tag{5.7}$$

The complete Lagrangian is then

$$\begin{aligned}\mathscr{L} = {} & \bar{\tilde{\psi}}_{RL}(i\partial\!\!\!/\otimes I)\tilde{\psi}_{RR} + \bar{\tilde{\psi}}_{LR}(i\partial\!\!\!/\otimes I)\tilde{\psi}_{LL} + \bar{\tilde{\psi}}_{RR}(i\partial\!\!\!/\otimes I)\tilde{\psi}_{RL} \\ & + \bar{\tilde{\psi}}_{LL}(i\partial\!\!\!/\otimes I)\tilde{\psi}_{LR} + F(\bar{\tilde{\psi}}_{RR}\eta^c\eta + \bar{\tilde{\psi}}_{LL}\eta^c\eta) + \bar{\eta}(i\partial\!\!\!/ - m_f)\eta.\end{aligned} \tag{5.8}$$

Writing Lagrange equations explicitly, one has

$$i\partial\!\!\!/\otimes I\bar{\tilde{\psi}}_{LR} + F\eta^c\eta = 0, \tag{5.9a}$$

$$i\partial\!\!\!/\otimes I\bar{\tilde{\psi}}_{RL} + F\eta^c\eta = 0, \tag{5.9b}$$

$$i\partial\!\!\!/\otimes I\bar{\tilde{\psi}}_{RR} = 0, \tag{5.9c}$$

$$i\partial\!\!\!/\otimes I\bar{\tilde{\psi}}_{LL} = 0. \tag{5.9d}$$

Equations (5.9) and (4.8) imply, in particular, the following relations:

$$2iC_1\partial_\mu A^\mu = F\bar{\eta}\eta, \tag{5.10}$$

$$\partial^\mu F_{\mu\nu} = 0. \tag{5.11}$$

The conclusion is that Lagrangian (5.8) describes the interaction of massless spin 1 particles with matter but this theory is not electrodynamics.

B. Electrodynamics and chiral asymmetry

Let us consider now the interaction of massless particles with ordinary matter described by the interaction Lagrangian:

$$\mathscr{L}_{\text{int}} = K\{\bar{\tilde{\psi}}_{RL}\eta^c\eta + \bar{\tilde{\psi}}_{LR}\eta^c\eta\}. \tag{5.12}$$

By adding the free field Lagrangians we end up with the following total Lagrangian:

$$\begin{aligned}\mathscr{L} = {} & \bar{\tilde{\psi}}_{RL}(i\partial\!\!\!/\otimes I)\tilde{\psi}_{RR} + \bar{\tilde{\psi}}_{LR}(i\partial\!\!\!/\otimes I)\tilde{\psi}_{LL} + \bar{\tilde{\psi}}_{RR}(i\partial\!\!\!/\otimes I)\tilde{\psi}_{RL} + \bar{\tilde{\psi}}_{LL}(i\partial\!\!\!/\otimes I)\tilde{\psi}_{LR} \\ & + K\{\bar{\tilde{\psi}}_{RL}\eta^c\eta + \bar{\tilde{\psi}}_{LR}\eta^c\eta\} + \bar{\eta}(i\partial\!\!\!/ - m_f)\eta + \alpha\bar{\tilde{\psi}}_{RR}\psi_{LL} + \alpha\bar{\tilde{\psi}}_{LL}\psi_{RR}.\end{aligned} \tag{5.13}$$

One of the basic features of this approach is that although only some chiral components couple with the usual matter, all chiral components should be considered as dynamical variables. That is, one should write five Lagrange equations, one for each of the independent fields (ψ_{RR}, ψ_{RL}, ψ_{LR}, ψ_{LL}, and η).

With $\mathscr{L}$ given by (5.13), they lead to

$$i\partial\!\!\!/\otimes I\tilde{\psi}_{RL} + \alpha\tilde{\psi}_{LL} = 0, \tag{5.14a}$$

$$i\partial\!\!\!/\otimes I\tilde{\psi}_{RR} + K\eta^c\eta = 0, \tag{5.14b}$$

$$i\partial\!\!\!/\otimes I\tilde{\psi}_{LL} + K\eta^c\eta = 0, \tag{5.14c}$$

$$i\partial\!\!\!/\otimes I\tilde{\psi}_{LR} + \alpha\tilde{\psi}_{RR} = 0, \tag{5.14d}$$

$$K\eta^c\{\bar{\tilde{\psi}}_{RL}+\bar{\tilde{\psi}}_{LR}\}-m_f\bar{\eta}-i\partial_\mu(\bar{\eta})\gamma^\mu=0. \tag{5.14e}$$

From equation (5.14e) it follows that

$$K\eta^c_{a_1}\{\bar{\tilde{\psi}}_{RL}+\bar{\tilde{\psi}}_{LR}\}_{a_1a_2}-m_f\bar{\eta}_{a_2}-i\partial_\mu\bar{\eta}_{a_1}\gamma^\mu_{a_1a_2}=0. \tag{5.15}$$

Or, replacing $\bar{\tilde{\psi}}_{RL}$ and $\bar{\tilde{\psi}}_{LR}$ by expression (4.8),

$$-KC_1\bar{\eta}_{a_1}A_\mu(\gamma^\mu)_{a_1a_2}-m_f\bar{\eta}_{a_2}-i\partial_\mu\bar{\eta}_{a_1}\gamma^\mu_{a_1a_2}=0. \tag{5.16}$$

Taking the Hermitian conjugate of (5.16) one gets

$$(i\partial\!\!\!/-m_f)_{a_1a_2}\eta_{a_2}=KC_1(\gamma^\mu)_{a_1a_2}A_\mu\eta_{a_2}. \tag{5.17}$$

Now adding (5.14b) and (5.14c) and replacing $\tilde{\psi}_{RR}$ and $\tilde{\psi}_{LL}$ by expressions (4.8) we get

$$\partial_\mu F^{\beta\mu}=-\frac{K}{4C_2}\,\bar{\eta}\gamma^\beta\eta. \tag{5.18}$$

Similarly, adding (5.14a) and (5.14d) and replacing $\tilde{\psi}_{LR}$ and $\tilde{\psi}_{RL}$ by expressions (4.8) we get the following constraint:

$$\partial^\mu A_\mu=0; \tag{5.19}$$

that is, one gets the Lorentz condition and

$$\mathscr{F}^{sr}=\frac{C_1}{2\alpha C_2}(\partial^sA^r-\partial^rA^s). \tag{5.20}$$

This implies the usual relationship if one takes

$$\frac{C_1}{2\alpha C_2}=1. \tag{5.21}$$

The conclusion is that, by adding chiral asymmetric terms in the Lagrangian, one can get the usual relation (4.33).

We have seen in Sec. IV that the most general form for $F_{\mu\nu}$ is

$$F_{\mu\nu}=\mathscr{F}_{\mu\nu}+i\tilde{\mathscr{F}}_{\mu\nu}. \tag{5.22}$$

Replacing $F_{\mu\nu}$ given by (5.22) in Eq. (5.18) we get an alternative form for Eq. (5.18). This alternative form is

$$\begin{cases}\partial_\mu\mathscr{F}^{\beta\mu}=-\dfrac{K}{4C_2}\,\bar{\eta}\gamma^\beta\eta,\\ \partial_\mu\tilde{\mathscr{F}}^{\beta\mu}=0.\end{cases} \tag{5.23}$$

These are Maxwell's equations in Lorentz gauge if one writes $\mathscr{F}_{\mu\nu}$ under the form (4.33) and imposes the restriction

$$-\frac{K}{4C_2}=e. \tag{5.24}$$

In order to see this equivalence in terms of the observables **E** and **H** one writes

$$f^{ok}=E^k,$$
$$f^{jk}=e^{ljk}H^l, \quad k,j,l=1,2,3. \tag{5.25}$$

Equations (5.23) give rise to the following equations;

$$\nabla\cdot\mathbf{E}=e\bar{\eta}\gamma^0\eta, \quad \partial^0\mathbf{E}-\nabla\wedge\mathbf{H}=-e\bar{\eta}\boldsymbol{\gamma}\eta,$$
$$\nabla\cdot\mathbf{H}=0, \quad \partial^0\mathbf{H}+\nabla\wedge\mathbf{E}=0. \tag{5.26}$$

Equations (5.26) are Maxwell's equation in the presence of matter.

As a final remark we would like to show the equivalence between the spinor method and the usual tensor method. In order to show this all one has to do is to substitute in Lagrangian (5.13) the expression for the chiral components (4.8). In terms of the fields $F_{\mu\nu}$ and A_μ the Lagrangian density can be written as

$$\mathscr{L}[F^{\mu\nu},\ A^\mu]=-8\alpha C_2^2\{F^{*\mu\nu}(\partial_\nu A_\mu-\partial_\mu A_\nu)-A_\mu^*(\partial_\nu F^{\mu\nu}-\partial_\nu F^{\mu\nu})\}+2K\alpha C_2\bar{\eta}\gamma^\mu\eta A_\mu^*$$
$$+\bar{\eta}(i\partial\!\!\!/-m_f)\eta-8\alpha C_2^2F_{\mu\nu}^*F^{\mu\nu}, \tag{5.27}$$

where we have used condition (5.21).

By treating $F_{\mu\nu}^*$, A_μ^*, and η as independent field variables one gets the following equations:

$$\partial_\nu F^{\mu\nu}=-\frac{K}{4C_2}\,\bar{\eta}\gamma^\mu\eta, \tag{5.28}$$

$$(i\partial\!\!\!/-m_f)\eta=-2K\alpha C_2\gamma^\mu\eta A_\mu, \tag{5.29}$$

$$\mathscr{F}_{\mu\nu}=\partial^\mu A_\nu-\partial^\nu A^\mu. \tag{5.30}$$

Finally, one gets the usual Lagrangian of electrodynamics in terms of A_μ if one uses (5.30) and makes a proper choice of the constant α.

VI. QUANTIZATION

In this section we will consider the quantization of massive fields within the BW theory. We also propose an extension to the zero-mass case. We show that there is no basic distinction between this method and the usual approach. The relevant point is that it is possible to quantize the spinor fields by imposing appropriate commutation relations for these fields.

We quantize the BW fields by imposing the following commutation relations for BW's massive fields:

$$[\psi_{a_1a_2\cdots a_{2s}}(x),\ \psi^+_{a_1'a_2'\cdots a_{2s}'}(y)]_s=(-i)^{2s-1}\kappa\sum_{\mathscr{P}}\ i(i\partial\!\!\!/_x+m)_{a_1a_1'}\cdots i(i\partial\!\!\!/_x+m)_{a_{2s}a_{2s}'}\Delta(x-y),$$
$$a_1,\ldots,a_1',\ldots=1,2,3,4. \tag{6.1}$$

$\Delta(x-y)$ is the Jordan Pauli function, κ is a constant to be determined, $\mathscr{P}$ denotes all possible permutations among the spinor indices, and we use, in (6.1), the following notation:

$$[\phi,\psi]_s=\phi\psi+(-1)^{2s-1}\phi\psi, \tag{6.2}$$

where s is the spin of the fields in (6.2).

In the case of massless particles, and as pointed out in Sec. II, the fundamental objects are two-component spinors of rank $2s$ $\varphi^{(1)}\cdots\varphi^{(2s)}$. For the massless case the quantization is carried out by imposing the following commutation relations for the two-component Weyl spinors φ:

$$[\varphi_{b_1\cdots b_{2s}}(x),\ \varphi^{+}_{b'_1\cdots b'_{2s}}(y)]_x=(-i)^{2s-1}\kappa\sum_{\mathscr{P}} i(i\sigma^0\partial_0-i\boldsymbol{\sigma}\cdot\boldsymbol{\nabla})_{b_1b'_1}\cdots i(i\sigma^0\partial_0-i\boldsymbol{\sigma}\cdot\boldsymbol{\nabla})_{b_{2s}b'_{2s}} \times D(x-y), \tag{6.3}$$

where $D(x-y)$ is the Jordan Pauli function for massless particles, κ is a constant to be determined, $\mathscr{P}$ denotes all possible permutations among the spinor indices, and where we use convention (6.2).

One can now use, for spin 1 massive particles, the decomposition (2.9) and write the usual plane wave expansion for the field B_μ. In the case of the photon this decomposition for the A_μ field is

$$A^\mu(x)=\frac{1}{(2\pi)^3}\int\frac{d^3\mathbf{p}}{\sqrt{2p^0}}\sum_{\lambda=1}^{2}\epsilon^\mu(p,\lambda)[A(p,\lambda)e^{-ipx}+A^+(p,\lambda)e^{ipx}], \tag{6.4}$$

where $p=(p^0,\mathbf{p})$.

If one uses the decomposition (4.25) with $\mathbf{f}$ given by (4.28), then the commutation relations (6.3) imply the following commutation relations for the creation (A^+) and annihilation (A) operators:

$$[A(p,\lambda),A^+(p',\lambda')]=\delta^3(p-\mathbf{p}')\delta_{\lambda\lambda'}. \tag{6.5}$$

By analyzing the behavior of observables such as the energy, as we did in Sec. III C, and momentum we would realize that these fields describe particles.

We shall not further analyze the question of the quantization of the spinor fields. We just wanted to point out that one can provide a quantization method for spinor fields as well Feynman rules for the interaction of these fields. Most of the questions on computing cross sections for specific processes and the analysis of renormalization can be carried out in a simpler manner within the usual approach (tensor method).

VII. CONCLUSIONS

In this paper we have presented the description of electrodynamics in terms of spinors. The spinor method provides a description of massless particles in terms of chiral components when they are treated as independent field variables.

We have shown that, within the spinorial approach proposed here, photons can be described in close analogy with neutrinos. The requirement of chiral invariance, at the free field level, leads to Maxwell's equation in vacuum. The requirement of chiral asymmetry for the linear interaction of the spinor field with matter fields leads, for a proper choice of chiral components, to Maxwell's equations in the presence of matter.

One of the advantages of this approach is that it allows one to formulate electrodynamics in terms of potentials or, by using two-component spinors, in terms of the observable fields (Maxwell equation) E and H.

The question is whether electrodynamics is a left–right asymmetric theory. If matter does not distinguish between chiral components, then it should couple with the field ψ. That is not, however, the case. On the other hand, if ordinary matter couples only with $\psi_{RR}\psi_{LL}$ we would have electrodynamics formulated entirely in terms of observables. That is not the alternative that nature chooses either.

The usual QED is compatible with a theory in which only $\psi_{LR}+\psi_{RL}$ couples with ordinary matter. From this point of view QED is another example of an asymmetric interaction between chiral components. The conclusion is that the Lagrangian describing electrodynamics, in this four-component (chiral components) framework, is

$$\mathscr{L}_{\mathrm{QED}}=\bar{\psi}_{RL}(i\partial\!\!\!/\otimes 1)\psi_{RR}+\bar{\psi}_{LR}(i\partial\!\!\!/\otimes 1)\psi_{LL}+\bar{\psi}_{RR}(i\partial\!\!\!/\otimes 1)\psi_{RL}+\bar{\psi}_{LL}(i\partial\!\!\!/\otimes I)\psi_{LR}+\bar{\eta}(i\partial\!\!\!/-m)\eta+F(\bar{\psi}_{RL}+\bar{\psi}_{LR})\eta_c\eta.$$

Within this spinor framework it is easy to see that electrodynamics is a parity nonconserving theory. Although electrodynamics is asymmetric with regard to left and right and usually chiral asymmetry is connected to parity nonconservation, it is obvious that in this case the consequence of symmetry does not lead to processes occurring differently in the actual systems or in its mirror image. There are no observable consequences for the breakdown of parity.

There is a dynamical consequence for the particular way in which nature chooses to break chiral symmetry. Violation of chiral symmetry in this case reflects the preference of matter in interacting through the electromagnetic potentials rather than interacting through the electromagnetic fields. The linear nature of the interaction and the breakdown of the symmetry implies the minimal coupling substitution.

Our conclusion is that the linearity of the theory and left–right asymmetry implies the minimal substitution way of coupling the electromagnetic fields to matter.

The extension of this method to spin 2 field is under preparation.[9,10]

APPENDIX A: RANK 2*s* FOUR SPINORS

Remembering that a rank one spinor transforms, under Poincaré transformation, as

$$\eta(x)\to\eta'(x')=D(l)\eta(x),$$

a $2s$ rank spinor $\psi(x)$ transforms as

$$\psi(x)\to\psi'(x')=\underbrace{D(l)\otimes\cdots\otimes D(l)}_{2s\ \text{factors}}\psi(x).$$

Analogously, the $2s$ rank spinor $\bar{\psi}(x)$ defined by

$$\bar{\psi}(x)=\psi^{+}(x)\underbrace{\gamma^0\otimes\cdots\otimes\gamma^0}_{2s\ \text{factors}}$$

transforms like

$$\bar{\psi}(x)\to\bar{\psi}'(x')=\bar{\psi}(x)\underbrace{D^{-1}(l)\otimes\cdots\otimes D^{-1}(l)}_{2s\ \text{factors}},$$

where we have used the property that

$$\gamma^0 D^+(l)\gamma^0 = D^{-1}(l).$$

APPENDIX B: NOTATION AND γ MATRICES

(1) The metric used is $g_{\mu\nu}=(1,-1,-1,-1)$.
(2) Dirac's matrices commutation rules are those of Bjorken and Drell.[7]
(3) In chiral representation

$$\gamma^5=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix},\quad \mathbf{\Sigma}=\begin{bmatrix}\boldsymbol{\sigma} & 0\\ 0 & \boldsymbol{\sigma}\end{bmatrix},\quad \gamma^{\mu}_{\alpha\dot{\beta}}=\begin{bmatrix}0 & -(\sigma_\mu)_{\alpha\dot{\beta}}\\ -(\sigma^\mu)^{\alpha\dot{\beta}} & 0\end{bmatrix}.$$

(4) Charge conjugation matrix

$$(C)_{\alpha\dot{\beta}}=\begin{bmatrix}-i\sigma^2_{\alpha\dot{\beta}}=C_1 & 0\\ 0 & i\sigma^2_{\alpha\dot{\beta}}=C_1\end{bmatrix}.$$

(5) Pauli matrices are defined by

$$\sigma^0=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix},\quad \sigma^1=\begin{bmatrix}0 & 1\\ 1 & 0\end{bmatrix},\quad \sigma^2=\begin{bmatrix}0 & -i\\ i & 0\end{bmatrix},\quad \sigma^0=\begin{bmatrix}1 & 0\\ 0 & -1\end{bmatrix}.$$

By convention $\sigma^\mu=(\sigma^0=1,\ \boldsymbol{\sigma})$ designates $(\sigma^\mu)_{\alpha\dot{\beta}}$.

We have used also the property that

$$(\sigma^0)_{\alpha\dot{\beta}}=(\sigma_0)_{\alpha\dot{\beta}},\quad (\sigma^k)_{\alpha\dot{\beta}}=-(\sigma_k)_{\alpha\dot{\beta}}.$$

C_1 denotes the charge conjugation matrix in (2,2) space and obeys ${}^tC_1=-C_1$, $C_1^+=C_1^{-1}$.

Involutions on the algebra of physical observables from reality conditions

Guillermo A. Mena Marugán

(Received 19 June 1995; accepted for publication 29 September 1995)

Some aspects of the algebraic quantization program proposed by Ashtekar are revisited in this article. It is proven that, for systems with first-class constraints, the involution introduced on the algebra of quantum operators via reality conditions can never be projected unambiguously to the algebra of physical observables, i.e., of quantum observables modulo constraints. It is nevertheless shown that, under sufficiently general assumptions, one can still induce an involution on the algebra of physical observables from reality conditions, though the involution obtained depends on the choice of particular representatives for the equivalence classes of quantum observables. © *1996 American Institute of Physics.* [S0022-2488(96)03801-8]

I. INTRODUCTION

Recently, Ashtekar *et al.*[1–3] have elaborated a program for the nonperturbative quantization of dynamical systems with first-class constraints. This program is specially designed to deal with the problem of quantizing general relativity, and has already been carried out successfully in a number of lower dimensional gravitational models, including minisuperspaces[4–6] and $2+1$ gravity.[1,3,7] The program proposed by Ashtekar is an extension, based on the algebraic approach to quantum mechanics,[8] of Dirac's canonical quantization method.[9] One of the main novelties with respect to Dirac's procedure is the introduction of a prescription to find the inner product in the space of quantum states. This allows one to adhere to the standard probabilistic interpretation of quantum mechanics when the quantization can be achieved.

Ashtekar's program consists of a series of steps that, after completion, should provide us with a consistent quantum theory. It can be applied, in principle, to any classical system whose phase space Γ is a real symplectic manifold.[1]

One must first choose a subspace S of the vector space of smooth complex functions on Γ. This subspace must contain the unit function and be closed both under complex conjugation and Poisson brackets.[2] In addition, S has to be complete, in the sense that any sufficiently regular complex function on phase space should be expressable as a sum of products of elements in S (or as a limit of this type of sums).[2]

Each element X in S is to be regarded as an elementary classical variable which is unambiguously associated with an abstract operator $\hat{X}$. One then constructs the free associative algebra $\mathcal{F}$ generated by these elementary quantum operators. On this algebra, one imposes the commutation relations that follow from the classical Poisson brackets, namely, if $X, Y \in S$, one must demand that (at least up to terms proportional to $\hbar^2$)

$$[\hat{X},\hat{Y}]-i\hbar\widehat{\{X,Y\}}=\hat{0}. \tag{1.1}$$

If there exist algebraic relations of the form

$$f_i(X_1,\ldots,X_n)=0 \quad (i=1,\ldots,m) \tag{1.2}$$

0022-2488/96/37(1)/196/10/$6.00

between the elements in S (e.g., when the dimension of S is greater than that of Γ), such relations have also to be imposed on the corresponding quantum operators, with a suitable choice of factor ordering, if needed.[2] The imposition of these commutation and algebraic relations simply amounts to taking the quotient of the free algebra $\mathscr{F}$ by the ideal $\mathscr{T}_{\mathscr{F}}$ generated by the left-hand sides of Eq. (1.1) and the quantum counterpart of Eq. (1.2). The algebra of operators obtained in this way will be called $\mathscr{A}$.

At this point one should promote the complex conjugation relations in S to an involution on $\mathscr{A}$. We recall that an involution $\star$ on the algebra $\mathscr{A}$ is a map $\star: \mathscr{A}\rightarrow\mathscr{A}$ that satisfies

$$(\hat{X}^{\star})^{\star}=\hat{X}, \tag{1.3}$$

$$(\hat{X}+\lambda\hat{Y})^{\star}=\hat{X}^{\star}+\overline{\lambda}\hat{Y}^{\star}, \quad (\hat{X}\hat{Y})^{\star}=\hat{Y}^{\star}\hat{X}^{\star}, \tag{1.4}$$

for all $\hat{X},\hat{Y}\in\mathscr{A}$ and complex numbers λ. Here, $\overline{\lambda}$ is the complex conjugate to λ. To introduce the desired involution on $\mathscr{A}$, one can proceed in the following manner. For every $X,Y\in S$ such that Y is the complex conjugate to X, define $\hat{X}^{\star}=\hat{Y}$, and use properties (1.4) to extend this definition to all the operators in the free algebra $\mathscr{F}$. It is straightforward to check that one then gets an involution on $\mathscr{A}$ provided that the ideal $\mathscr{T}_{\mathscr{F}}$ of operators which vanish modulo commutation and algebraic relations is invariant under the $\star$-operation, i.e., that $\mathscr{T}_{\mathscr{F}}$ is a $\star$-ideal of $\mathscr{F}$. We will assume hereafter that this is in fact the case, and denote the resulting $\star$-algebra by $\mathscr{A}^{(\star)}$. The $\star$-relations in $\mathscr{A}^{(\star)}$ are usually called reality conditions,[1] for they capture the complex conjugation relations between elementary classical variables.

The next step in the quantization consists in finding a faithful representation for the abstract algebra $\mathscr{A}$ by linear operators acting on a complex vector space V. If the classical system possesses first-class constraints $\{C_i\}$, these constraints must now be explicitly represented by operators $\{\hat{C}_i\}$. In general, a choice of factor ordering, and of regularization in infinite dimensional systems,[2,3] are needed at this point in order to get a consistent algebra of quantum constraints,[9] that is, to guarantee that

$$[\hat{C}_i,\ \hat{C}_j]=\hat{f}_{ij}{}^{k}\hat{C}_k, \tag{1.5}$$

where $\hat{f}_{ij}{}^{k}\in\mathscr{A}$ and we use the convention that pairs of contracted indices are summed over.

The kernel $V_p\subset V$ of the constraints $\{\hat{C}_i\}$ supplies the vector subspace of quantum states. One must then determine the subalgebra $\mathscr{A}_p\subset\mathscr{A}$ of operators which leave V_p invariant. These operators commute weakly with the quantum constraints,

$$\hat{A}\in\mathscr{A}_p\Leftrightarrow[\hat{A},\ \hat{C}_i]=\hat{h}_i{}^{j}\hat{C}_j \quad (\hat{h}_i{}^{j}\in\mathscr{A}). \tag{1.6}$$

Let us define now

$$\mathscr{T}_C\equiv\{\hat{X}^i\hat{C}_i;\hat{X}^i\in\mathscr{A}\}. \tag{1.7}$$

Using Eqs. (1.5) and (1.6) one can show that $\mathscr{T}_C\subset\mathscr{A}_p$ and that, $\forall\hat{I}\in\mathscr{T}_C$ and $\forall\hat{A}\in\mathscr{A}_p$, both $\hat{A}\hat{I}$ and $\hat{I}\hat{A}$ belong to $\mathscr{T}_C$, so that $\mathscr{T}_C$ is an ideal of $\mathscr{A}_p$. On the other hand, if $\hat{A}\in\mathscr{A}_p$, all the operators of the form $\hat{B}=\hat{A}+\hat{I}$, with $\hat{I}\in\mathscr{T}_C$, have exactly the same action on quantum states, for V_p is annihilated by the quantum constraints. In order to obtain the algebra $\mathscr{A}'_p$ of operators with a well-defined action on V_p, one should therefore take the quotient of $\mathscr{A}_p$ by the ideal $\mathscr{T}_C$:[2]

$$\mathscr{A}'_p\equiv\mathscr{A}_p/\mathscr{T}_C. \tag{1.8}$$

The operators in $\mathscr{A}'_p$ are the quantum physical observables of the system.[10]

The quantization program presented so far leaves a certain freedom in the following steps: (a) the selection of the subspace S of elementary classical variables, (b) the construction of the linear

representation for the algebra $\mathscr{A}$ of quantum operators, and (c) the choice of factor ordering in the quantum constraints $\{\hat{C}_i\}$. The final result of the quantization process will depend on these inputs.[2] In particular, Ashtekar and Tate[2] assumed at this stage that, with a judicious choice of such inputs and at least for a large variety of physical systems, the involution defined on $\mathscr{A}^{(\star)}$ would induce an involution on $\mathscr{A}'_p$.

It is worth remarking in this sense that the $\star$-relations will project unambiguously to the algebra of physical observables only if two conditions are fulfilled. On the one hand, $\mathscr{A}_p \subset \mathscr{A}$ must be invariant under the $\star$-operation: $\forall \hat{A} \in \mathscr{A}_p$, $\hat{A}^\star \in \mathscr{A}_p$. On the other hand, it is necessary that $\mathscr{I}_C \subset \mathscr{A}_p$ be a $\star$-ideal of $\mathscr{A}_p$: $\forall \hat{I} \in \mathscr{I}_C$, $\hat{I}^\star \in \mathscr{I}_C$. When this is the case, the $\star$-operation provides a uniquely defined map between equivalence classes in $\mathscr{A}'_p$ which satisfies the properties (1.3) and (1.4) of an involution. The involution induced on $\mathscr{A}'_p$ will be denoted again by $\star$, and the resulting $\star$-algebra of physical observables by $\mathscr{A}'^{(\star)}_p$.

The idea suggested by Ashtekar[1–3] is to employ the involution on $\mathscr{A}'^{(\star)}_p$ to select the inner product $\langle , \rangle$ on V_p and, therefore, the Hilbert space $\mathscr{H}$ of physical states (normalizable quantum states). More specifically, he proposed to determine the inner product on V_p by demanding that the $\star$-relations between physical observables are realized as adjoint relations on the Hilbert space $\mathscr{H}$, i.e.,

$$\langle \Psi, \hat{A}' \Phi \rangle = \langle \hat{B}' \Psi, \Phi \rangle \quad \forall \Phi, \Psi \in \mathscr{H}, \quad \forall \hat{A}', \hat{B}' = (\hat{A}')^\star \in \mathscr{A}'^{(\star)}_p. \tag{1.9}$$

Rendall showed[11] that this condition is such a severe restriction on the inner product that, if an admissible inner product exists, it is unique (up to a positive global factor) under very general assumptions.

This completes the quantization program put forward by Ashtekar. If this program can be carried out for a given classical system, one would arrive at a mathematically consistent quantum theory in which real physical observables would be represented by self-adjoint operators acting on a Hilbert space of physical states.

The purpose of this work is to demonstrate however that there exists an impediment to achieving one of the steps of the above quantization method. We will prove in Sec. II that the $\star$-relations in $\mathscr{A}^{(\star)}$ never project unambiguously to the algebra of physical observables. This problem can be nonetheless overcome by slightly modifying Ashtekar's program, as we will show in Sec. III. The price to be paid is to allow a new freedom in the quantization process. A particular procedure to introduce an involution on $\mathscr{A}'_p$ from reality conditions should then be adopted. The subtleties that arise in defining such an involution are illustrated in Sec. IV by considering some simple physical systems. We finally discuss the physical implications of our results and conclude in Sec. V.

II. AMBIGUITIES IN THE REALITY CONDITIONS ON PHYSICAL OBSERVABLES

We want to prove that reality conditions (i.e., the $\star$-relations between quantum operators) never project unambiguously to the algebra of physical observables when there exist first-class constraints on the system. We will assume that the faithful, linear representation constructed for the algebra $\mathscr{A}$ of quantum operators is irreducible. Otherwise, one should decompose it in irreducible components, and apply the proof to follow to each component separately.

We have seen that, in order to obtain a uniquely defined involution on physical observables from reality conditions, it is necessary that both $\mathscr{A}_p$ and $\mathscr{I}_C$ be invariant under the $\star$-operation. In particular, we should have

$$\forall \hat{I} \in \mathscr{I}_C, \quad \hat{I}^0 \equiv \hat{I}^\star \in \mathscr{I}_C. \tag{2.1}$$

Select now in $\mathscr{T}_C$ one of the quantum constraints, e.g., $\hat{C}_1$, and consider also all the operators of the form $\hat{I}_1=\hat{Z}\hat{C}_1\in\mathscr{T}_C$, with $\hat{Z}\in\mathscr{A}$. Employing condition (2.1), and recalling definition (1.7), we obtain

$$\hat{C}_1^\star=\hat{Y}_1^j\hat{C}_j\,, \tag{2.2}$$

$$(\hat{I}_1)^\star=\hat{C}_1^\star\hat{Z}^\star=\hat{Y}_1^j\hat{C}_j\hat{Z}^\star\equiv\hat{I}_1^0=\hat{X}_1^k\hat{C}_k\,, \tag{2.3}$$

for some $\hat{Y}_1^j,\hat{X}_1^k\in\mathscr{A}$.

On the other hand, the image $\hat{Z}^\star$ of all the operators $\hat{Z}\in\mathscr{A}$ is again the whole algebra $\mathscr{A}$, because the $\star$-operation is an involution. Relation (2.3) therefore implies that, $\forall\,\hat{Z}\in\mathscr{A}$, there exist $\hat{X}_1^k\in\mathscr{A}$ such that

$$\hat{Y}_1^j\hat{C}_j\hat{Z}=\hat{X}_1^k\hat{C}_k\,. \tag{2.4}$$

This identity between operators must hold on any element of V, the vector space on which $\mathscr{A}$ has been represented. Choosing then $\Phi\in V_p\subset V$ with Φ different from zero, it follows from Eq. (2.4) that, $\forall\,\hat{Z}\in\mathscr{A}$,

$$\hat{Y}_1^j\hat{C}_j(\hat{Z}\Phi)=\hat{X}_1^k\hat{C}_k\Phi=0, \tag{2.5}$$

for the physical state Φ is annihilated by all quantum constraints. Besides, since the representation constructed is irreducible and $\Phi\neq0$, the range of $\hat{Z}\Phi(\forall\,\hat{Z}\in\mathscr{A})$ must be the whole vector space V. So, the above equation states that V is the kernel of the operator $\hat{Y}_1^j\hat{C}_j$. Being the representation for $\mathscr{A}$ faithful, we then must have

$$\hat{Y}_1^j\hat{C}_j=\hat{0}. \tag{2.6}$$

But this is clearly inconsistent with the fact that the $\star$-operation is an involution, because, using Eqs. (2.2) and (2.6), we get that $\hat{C}_1=(\hat{C}_1^\star)^\star=\hat{0}$. In this way, we conclude that, when there exist first-class constraints, $\mathscr{T}_C$ can never be invariant under the $\star$-operation and, therefore, reality conditions do not project unambiguously to the algebra of physical observables.

Moreover, it is generally the case that the $\star$-image of $\mathscr{T}_C$ is not even contained in $\mathscr{A}_p$, so that $\mathscr{A}_p$ is not a $\star$-subalgebra of $\mathscr{A}$. This can be proved, for instance, under the assumptions that (a) Eq. (2.2) holds for a certain quantum constraint $\hat{C}_1$ and (b) there exists at least one operator $\hat{W}\in\mathscr{A}$ whose commutator with $\hat{C}_1$ does not belong to $\mathscr{A}_p$. One can then check that, while $\hat{W}^\star\hat{Y}_1{}^j\hat{C}_j$ belongs to $\mathscr{T}_C$, its $\star$-conjugate, given by $\hat{C}_1\hat{W}$, is not included in $\mathscr{A}_p$. Hence, even though one could find a representative $\hat{A}$ for a given physical observable $\hat{A}'$ such that $\hat{A}^\star\in\mathscr{A}_p$, the $\star$-conjugates of all other operators in the equivalence class $\hat{A}'$ (i.e., the operators $\hat{A}+\hat{I}$, with $\hat{I}\in\mathscr{T}_C$) will in general not belong to the algebra $\mathscr{A}_p$.

For the sake of an example, let us consider a classical system whose phase space admits a set of global coordinates of the form $s\equiv\{t,H,x,p\}$, with $t,H,x,p\in\mathbb{R}$, and H and p the momenta canonically conjugate to t and x, respectively. Suppose, in addition, that there exists only one first-class constraint on the system, given by $H=0$. This extremely simple example describes, for instance, a Kantowski–Sachs model with positive cosmological constant.[5]

As elementary classical variables, we can choose the complex vector space spanned by s and the unity. The $\star$-operation on the corresponding algebra $\mathscr{A}$ of quantum operators is defined by

$$\hat{t}^\star=\hat{t},\quad \hat{H}^\star=\hat{H}, \tag{2.7}$$

$$\hat{x}^\star=\hat{x},\quad \hat{p}^\star=\hat{p},\quad \hat{1}^\star=\hat{1}, \tag{2.8}$$

and the properties (1.4) of an involution. The only quantum constraint is $\hat{H}=0$. On the other hand, it is not difficult to prove that the equivalence classes of the operators $\hat{1}$, $\hat{x}$, and $\hat{p}$ form a complete set of physical observables. We point out, nevertheless, that the algebra $\mathscr{A}_p$ is not generated by $\{\hat{1},\hat{x},\hat{p},\hat{H}\}$, but contains also operators like $\hat{t}\hat{H}$ and $(\hat{t})^2\hat{H}$ which are elements in $\mathscr{T}_C$. From Eq. (2.8) it follows that each equivalence class of observables possesses at least a representative whose $\star$-conjugate belongs to $\mathscr{A}_p$. In general, however, the $\star$-image of different representatives do not coincide modulo the constraint $H=0$, because the $\star$-operation does not leave the ideal $\mathscr{T}_C$ invariant. Namely, from Eqs. (2.7), (2.8) and the commutator $[\hat{t},\hat{H}]=i\hbar\hat{1}$, we get

$$(\hat{t}\hat{H})^\star=\hat{t}\hat{H}-i\hbar\hat{1}, \quad ((\hat{t})^2\hat{H})^\star=(\hat{t})^2\hat{H}-2i\hbar\hat{t}, \tag{2.9}$$

so that the $\star$-conjugate to $\hat{t}\hat{H}$ belongs to $\mathscr{A}_p$, but not to $\mathscr{T}_C$, whereas the $\star$-conjugate to $(\hat{t})^2\hat{H}$ is not even in $\mathscr{A}_p$.

III. INVOLUTIONS ON PHYSICAL OBSERVABLES

We have seen that the $\star$-relations in $\mathscr{A}^{(\star)}$ do not project unambiguously to $\mathscr{A}'_p$, because the $\star$-operation never maps all the representatives of a class of physical observables into another equivalence class. In order to define the $\star$-conjugate to a physical observable, one is therefore forced to choose first a particular representative for it. We now want to discuss under which circumstances it is possible to introduce an involution on $\mathscr{A}'_p$ by this procedure.

To construct an involution $\star$ on $\mathscr{A}'_p$, it actually suffices to define the $\star$-operation on an (over-) complete set of physical observables, and demand that this operation verifies conditions (1.4). Suppose then that $\{\hat{U}'_a\}$ is a complete set in $\mathscr{A}'_p$, that is, that $\mathscr{A}'_p$ can be obtained from the free associative algebra $\mathscr{B}'$ generated by $\{\hat{U}'_a\}$ by imposing the commutation relations between the observables $\hat{U}'_a$, as well as any algebraic relation that could exist between them. Assume also that one can find representatives $\{\hat{U}_a\}$ of the observables $\{\hat{U}'_a\}$ such that their $\star$-conjugates $\{\hat{U}^\star_a\}$ belong to $\mathscr{A}_p$. One might then hope that the $\star$-operation on $\mathscr{A}'_p$ could be defined by

$$(\hat{U}'_a)^\star=(\hat{U}^\star_a)', \tag{3.1}$$

where $(\hat{U}^\star_a)'$ denotes the equivalence class of $\hat{U}^\star_a$. However, we will prove that the assumptions introduced above do not guarantee that Eq. (3.1) leads to a well-defined involution on the algebra of physical observables.

The proof makes use of the fact that, being $\{\hat{U}'_a\}$ complete in $\mathscr{A}'_p$, any operator in the algebra $\mathscr{A}_p$ should be expressable, modulo an element in the ideal $\mathscr{T}_C$ (1.7), as (possibly a limit of) a sum of products of the representatives $\{\hat{U}_a\}$. In particular, since every $\hat{U}^\star_a\in\mathscr{A}_p$, one gets

$$\hat{U}^\star_a=\sum_n \lambda_a^{b_1\cdots b_n}\hat{U}_{b_1}\cdots\hat{U}_{b_n}+\hat{X}^i_a\hat{C}_i, \tag{3.2}$$

with $\hat{X}^i_a\in\mathscr{A}$ and the $\lambda_a^{b_1\cdots b_n}$'s some complex numbers. Hence, from Eq. (3.1),

$$(\hat{U}'_a)^\star=\sum_n \lambda_a^{b_1\cdots b_n}\hat{U}'_{b_1}\cdots\hat{U}'_{b_n}. \tag{3.3}$$

This $\star$-operation will be an involution on $\mathscr{A}'_p$ only if $((\hat{U}'_a)^\star)^\star=\hat{U}'_a$ for all $\hat{U}'_a$. This, together with Eqs. (1.4), (3.1), and (3.3), implies

$$\hat{U}'_a=\sum_n \overline{\lambda_a^{b_1\cdots b_n}}(\hat{U}^\star_{b_n})'\cdots(\hat{U}^\star_{b_1})'. \tag{3.4}$$

On the other hand, we have from Eq. (3.2)

$$\hat{U}_a = \sum_n \overline{\lambda_a^{b_1 \cdots b_n}} \hat{U}^\star_{b_n} \cdots \hat{U}^\star_{b_1} + \hat{C}_i^\star \hat{X}_a^{i\star}, \tag{3.5}$$

since the $\star$-operation is an involution on $\mathscr{A}^{(\star)}$. Consistency of Eq. (3.4) with (3.5) requires then

$$\hat{C}_i^\star \hat{X}_a^{i\star} = \hat{Y}^i_a \hat{C}_i\,, \tag{3.6}$$

for some operators $\hat{Y}^i_a \in \mathscr{A}$. This condition will not be satisfied by generic operators $\hat{X}^i_a \hat{C}_i \in \mathscr{I}_C$, because the ideal $\mathscr{I}_C$ is not invariant under the $\star$-operation when there exist first-class constraints on the system. Therefore, the $\star$-relations (3.3) will not supply in general an involution on $\mathscr{A}'_p$. To obtain that involution, it is necessary that both conditions (3.2) and (3.6) are satisfied by the representatives of our complete set of physical observables.

We will study now the case in which these requirements hold for our particular choice of representatives. Our previous discussion shows that the $\star$-operation defined by Eqs. (3.3) and (1.4) is then an involution on $\mathscr{B}'$, the free associative algebra generated by $\{\hat{U}'_a\}$. Recalling that the algebra $\mathscr{A}'_p$ of physical observables can be obtained from $\mathscr{B}'$ by imposing on its generators the commutation relations and any existing algebraic relations, we conclude that the $\star$-operation introduced on $\mathscr{B}'$ straightforwardly supplies an involution on $\mathscr{A}'_p$ provided that such an operation is compatible with the relations imposed on the generators $\{\hat{U}'_a\}$. In other words, the ideal of $\mathscr{B}'$ generated by those relations should be invariant under the $\star$-operation. When this requisite is fulfilled, one gets an involution on $\mathscr{A}'_p$ which captures the reality conditions on quantum operators.

Notice that the involution at which one arrives depends, nevertheless, on two choices: the complete set of physical observables and the representatives for them. In general, distinct choices may lead to different involutions on the algebra of physical observables. We will comment on this point further in Sec. V.

A situation which is often encountered in physical applications[4,5] is that one can find a complete set in $\mathscr{A}'_p$ admitting representatives $\{\hat{U}_a\}$ such that the complex vector space spanned by them is closed under reality conditions, i.e.,

$$\hat{U}^\star_a = \lambda^b_a \hat{U}_b\,. \tag{3.7}$$

In this case, assumption (3.2) holds with $\hat{X}^i_a \hat{C}_i = \hat{0}$, so that Eq. (3.6) is trivially satisfied. It is then at least possible to obtain an involution on the free algebra $\mathscr{B}'$ by replacing the operators $\hat{U}_a$ in Eq. (3.7) with their corresponding equivalence classes of physical observables.

IV. EXAMPLES

Let us illustrate our discussion by dealing with some examples. Consider, for instance, the physical system that was analyzed at the end of Sec. II. A complete set of physical observables for this system is $\mathscr{O}' \equiv \{\hat{1}', \hat{x}', \hat{p}'\}$, where $\hat{1}'$, $\hat{x}'$, and $\hat{p}'$ are the equivalence classes of the operators $\hat{1}$, $\hat{x}$, and $\hat{p}$, respectively. We can select these operators as the representatives of $\mathscr{O}'$. The associated reality conditions, which are given by Eq. (2.8), have the form (3.7). So, hypotheses (3.2) and (3.6) apply. We can therefore try to induce an involution on $\mathscr{A}'_p$ by the procedure explained in Sec. III. Since there exist no algebraic relations in $\mathscr{O}'$, the only consistency requirement that must be satisfied in order to get the desired involution is that reality conditions (2.8) are compatible with the commutators of the physical observables in $\mathscr{O}'$. There is just one commutator different from zero: $[\hat{x}', \hat{p}'] = i\hbar \hat{1}'$. On the other hand, we obtain from Eqs. (2.8) and (3.1)

$$(\hat{x}')^\star = \hat{x}', \tag{4.1}$$

$$(\hat{p}')^\star=\hat{p}', \quad (\hat{1}')^\star=\hat{1}'. \tag{4.2}$$

Taking then the $\star$-conjugate to $[\hat{x}', \hat{p}']$, we get

$$([\hat{x}', \hat{p}'])^\star=[(\hat{p}')^\star, (\hat{x}')^\star]=[\hat{p}', \hat{x}']=-i\hbar\hat{1}', \tag{4.3}$$

which is precisely $(i\hbar\hat{1}')^\star$. All other commutators between $(\hat{1}')^\star$, $(\hat{x}')^\star$, and $(\hat{p}')^\star$ vanish identically. Hence, the $\star$-operation constructed is compatible with the structure of $\mathscr{A}'_p$, and provides an involution on this algebra.

Let us consider now other choices of representatives of $\mathscr{O}'$. Adopt, e.g., the choice $\{\hat{1}, \hat{x}+\hat{t}(\hat{H})^2, \hat{p}\}$. It follows from Eqs. (2.7) and (2.8) that

$$(\hat{x}+\hat{t}(\hat{H})^2)^\star=\hat{x}+\hat{t}(\hat{H})^2-2i\hbar\hat{H}, \quad \hat{p}^\star=\hat{p}, \quad \hat{1}^\star=\hat{1}. \tag{4.4}$$

These reality conditions are of the type (3.2), with $\hat{X}^i_a\hat{C}_i=-2i\hbar\hat{H}$ for $\hat{U}_a=\hat{x}+\hat{t}(\hat{H})^2$, vanishing otherwise. In particular, assumption (3.6) is verified. Therefore, one can introduce a $\star$-operation on $\mathscr{A}'_p$ by applying Eq. (3.1) to the present case. In this way, one recovers the $\star$-relations (4.1) and (4.2), and thus the same involution on the algebra of physical observables that was obtained above.

Choose now the operators $\hat{1}$, $\hat{x}+\hat{t}\hat{H}$, and $\hat{p}$ as representatives of $\mathscr{O}'$. The reality conditions are then given by

$$(\hat{x}+\hat{t}\hat{H})^\star=\hat{x}+\hat{t}\hat{H}-i\hbar\hat{1}, \quad \hat{p}^\star=\hat{p}, \quad \hat{1}^\star=\hat{1}. \tag{4.5}$$

These reality conditions are of the form (3.7), and induce on $\mathscr{A}'_p$ the $\star$-operation defined through Eq. (4.2) and

$$(\hat{x}')^\star=\hat{x}'-i\hbar\hat{1}'. \tag{4.6}$$

Since Eqs. (4.2) and (4.6) imply again relation (4.3), and $(\hat{1}')^\star$ commutes with $(\hat{x}')^\star$ and $(\hat{p}')^\star$, the introduced $\star$-operation is compatible with the commutators of the physical observables, and is therefore an involution on $\mathscr{A}'_p$. However, this involution differs from that obtained in Eqs. (4.1) and (4.2). This proves that the involution induced on $\mathscr{A}'_p$ from reality conditions depends on the particular selection of representatives made for the complete set of physical observables under consideration.

Note, nonetheless, that the two involutions induced on $\mathscr{A}'_p$ in the example discussed above are equivalent in the sense that the two resulting $\star$-algebras $\mathscr{A}'^{(\star)}_p$ are isomorphic, as one can easily check by identifying the physical observable $\hat{x}'$ in Eq. (4.1) with $\hat{x}'-i(\hbar/2)\hat{1}'$ in (4.6). For infinite dimensional systems, however, one should expect that the involutions constructed by choosing different complete sets in $\mathscr{A}'_p$ and appropriate representatives for them would lead in general to inequivalent $\star$-algebras of physical observables.

Suppose, on the other hand, that we can represent the $\star$-relations on $\mathscr{A}'_p$ as adjoint relations on a Hilbert space of physical states, as suggested by Ashtekar. From the involution provided by Eqs. (4.1) and (4.2), we would then arrive at a quantum theory in which the observable $\hat{x}'$ would be self-adjoint. The involution defined through Eqs. (4.2) and (4.6) would lead instead to a quantum theory in which $\hat{x}'$ would not be represented by a self-adjoint operator, so that it should not correspond to a real physical observable of the system. In order to resolve this ambiguity one can insist, for instance, on that the real classical variable x should be represented by the quantum observable $\hat{x}'$. One would thus expect that the spectrum of $\hat{x}'$ should be real to guarantee that this observable has always real expectation values. Hence, $\hat{x}'$ should be self-adjoint. By itself, this condition supports the use of involution (4.1), (4.2) in the quantization, rather than other possible $\star$-relations on $\mathscr{A}'_p$ which, like relation (4.6), are inconsistent with the identification of $\hat{x}'$ as the quantum physical observable corresponding to x.

To close this section, we will present an example in which the involution induced on $\mathscr{B}'$ via reality conditions is not compatible with the structure of the algebra of physical observables. Let us consider a physical system with a first-class constraint of the form $H=0$, where $H\in\mathbb{R}$ is the momentum canonically conjugate to a certain variable $t\in\mathbb{R}$. We will assume that the reduced phase space of the system is the cotangent bundle over the unit circle S^1. As elementary variables, we can choose the complex vector space spanned by $\{1, t, H, c_\theta\equiv\cos\theta, s_\theta\equiv\sin\theta, p_\theta\}$. Here, $\theta\in S^1$, and $p_\theta\in\mathbb{R}$ is the momentum conjugate to θ. The reality conditions on the corresponding algebra $\mathscr{A}^{(\star)}$ of quantum operators are given by Eq. (2.7) and

$$\hat{c}_\theta^\star=\hat{c}_\theta,\quad \hat{s}_\theta^\star=\hat{s}_\theta,\quad \hat{p}_\theta^\star=\hat{p}_\theta,\quad \hat{1}^\star=\hat{1}. \tag{4.7}$$

Besides, since $\cos^2\theta+\sin^2\theta=1$, we will impose the algebraic relation

$$(\hat{c}_\theta)^2+(\hat{s}_\theta)^2=\hat{1}. \tag{4.8}$$

A complete set of physical observables is $\mathscr{O}'\equiv\{\hat{1}',\hat{c}'_\theta,\hat{s}'_\theta,\hat{p}'_\theta\}$, the prime denoting equivalence classes. The only nonvanishing commutators in $\mathscr{O}'$ are

$$[\hat{c}'_\theta,\hat{p}'_\theta]=-i\hbar\hat{s}'_\theta,\quad [\hat{s}'_\theta,\hat{p}'_\theta]=i\hbar\hat{c}'_\theta. \tag{4.9}$$

In addition, relation (4.8) implies that the physical observables in $\mathscr{O}'$ must satisfy

$$(\hat{c}'_\theta)^2+(\hat{s}'_\theta)^2=\hat{1}'. \tag{4.10}$$

If one chooses $\hat{1}$, $\hat{c}_\theta$, $\hat{s}_\theta$, and $\hat{p}_\theta$ as the representatives of $\mathscr{O}'$, the procedure explained in Sec. III allows one to obtain a $\star$-operation on $\mathscr{B}'$ (the free associative algebra generated by $\mathscr{O}'$) which is compatible with the commutators (4.9) and the algebraic relation (4.10), and hence provides an involution on $\mathscr{A}'_p$. Let us select instead the representatives $\mathscr{O}\equiv\{\hat{1},(\hat{c}_\theta+\hat{t}\hat{H}),\hat{s}_\theta,\hat{p}_\theta\}$. From Eqs. (2.7) and (4.7) (and the commutator of $\hat{t}$ and $\hat{H}$), we get

$$\hat{1}^\star=\hat{1},\quad (\hat{c}_\theta+\hat{t}\hat{H})^\star=(\hat{c}_\theta+\hat{t}\hat{H})-i\hbar\hat{1},\quad \hat{s}_\theta^\star=\hat{s}_\theta,\quad \hat{p}_\theta^\star=\hat{p}_\theta. \tag{4.11}$$

These reality conditions are of the type (3.7). Thus, we can apply the results of Sec. III to arrive at an involution on $\mathscr{B}'$ which is defined through the $\star$-relations (4.11), but imposed on equivalence classes in $\mathscr{O}'$. However, such a $\star$-operation is incompatible with the algebraic relation (4.10), because

$$((\hat{c}'_\theta)^2+(\hat{s}'_\theta)^2-\hat{1})^\star=(\hat{c}'_\theta-i\hbar\hat{1}')^2+(\hat{s}'_\theta)^2-\hat{1}'\neq 0. \tag{4.12}$$

So, the involution introduced on $\mathscr{B}'$ does not supply a well-defined involution on the algebra $\mathscr{A}'_p$ of physical observables. This example shows that the freedom in choosing representatives of the complete set of physical observables is in general restricted by the consistency of the algebraic structures with the $\star$-operation constructed on $\mathscr{A}'_p$.

V. CONCLUSIONS AND FURTHER COMMENTS

We have shown that, in systems with first-class constraints, the involution defined on the algebra $\mathscr{A}^{(\star)}$ of quantum operators does not ever project unambiguously to the algebra $\mathscr{A}'_p$ of physical observables. The reason for this is that the $\star$-conjugates of all the representatives of any class of observables never belong to the same equivalence class in $\mathscr{A}_p$, and, in general, not even to $\mathscr{A}_p$.

We have also proved that, under sufficiently general circumstances, it is nevertheless possible to obtain a well-defined involution on $\mathscr{A}'_p$ via reality conditions by making a particular choice of

representatives for the equivalence classes of physical observables. The procedure to arrive at this involution is the following. One must first find a complete set of physical observables $\{\hat{U}'_a\}$ in $\mathscr{A}'_p$, and select representatives $\{\hat{U}_a\}$ of them such that their $\star$-conjugates $\{\hat{U}^\star_a\}$ satisfy requirements (3.2) and (3.6), namely, such that every $\hat{U}^\star_a$ belongs to the free associative algebra generated by $\{\hat{U}_a\}$ up to an operator which, as well as its $\star$-conjugate, vanish modulo quantum constraints. One can then introduce an involution $\star$ in the free associative algebra $\mathscr{B}'$ by defining $(\hat{U}'_a)^\star$ as the equivalence class of the observable $\hat{U}^\star_a$ [see Eqs. (3.2),(3.3)]. This involution on $\mathscr{B}'$ straightforwardly supplies an involution on $\mathscr{A}'_p$, provided that the constructed $\star$-operation is compatible with the commutation and algebraic relations which exist between the physical observables in the complete set $\{\hat{U}'_a\}$.

The involution obtained in this way on $\mathscr{A}'_p$ depends on the selection of a complete set of physical observables and of specific representatives for them. While these choices are severely restricted by the consistency conditions explained above, there is in general some freedom left, so that, by adopting different choices, one might in principle arrive at nonequivalent involutions on the algebra of physical observables.

This extra freedom in the quantization method suggested by Ashtekar, rather than being a supplementary complication, might actually become an additional help when attempting to complete the quantization. This is due to the fact that, given an involution $\star$ on the algebra $\mathscr{A}'_p$ and a certain representation for $\mathscr{A}'_p$ on a vector space V_p of quantum states, there is *a priori* no guarantee that there exists an inner product on V_p with respect to which the $\star$-relations on physical observables are realized as Hermitian adjoint relations in the resulting Hilbert space. Thus if such an inner product does not exist for a particular involution on $\mathscr{A}'_p$, one can always try to induce a different involution on this algebra via reality conditions, and see whether it is possible to then find an inner product with the desired properties.

We notice, on the other hand, that the introduction of an involution on $\mathscr{A}'_p$ amounts essentially to determine the $\star$-conjugate to a complete set of physical observables. When one expects that a set of this kind, or at least some of its elements, correspond classically to real observables of the system, it is reasonable to assume that they should be represented by self-adjoint operators. The involution defined on $\mathscr{A}'_p$ should therefore ensure that these operators coincide with their $\star$-conjugates. These requirements clearly restrict the physically admissible involutions on $\mathscr{A}'_p$. Moreover, in the case that this type of physical arguments would apply to a complete set in $\mathscr{A}'_p$, one would fully specify the involution on this algebra. In this way, one can use physical intuition as a guideline to resolve (either partially or totally) the ambiguity encountered when inducing an involution on the algebra of physical observables from reality conditions.

Finally, an alternative strategy to remove such an ambiguity could consist in adopting a specific procedure to induce the involution $\star$ on $\mathscr{A}'_p$. A procedure of this type might be, e.g., the following:[12] Let us denote by $\mathscr{A}_s \subset \mathscr{A}_p$ the subalgebra formed by all the strong quantum observables of the theory (that is, the operators which commute exactly with all the quantum constraints $\{\hat{C}_i\}$), and define $\mathscr{I}_s \equiv \mathscr{I}_C \cap \mathscr{A}_s$. It is immediate to check that $\mathscr{I}_s$ is an ideal of $\mathscr{A}_s$. Suppose then that, in the system under consideration, the involution $\star$ defined on $\mathscr{A}^{(\star)}$ and the representation constructed for the algebra $\mathscr{A}$ and for the constraints $\{C_i\}$ are such that: (a) The complex vector space spanned by the quantum constraints $\{\hat{C}_i\}$ is closed under reality conditions, i.e., $\hat{C}^\star_i = \lambda^j_i \hat{C}_j$, where the λ^j_i's are complex numbers. (b) The algebra $\mathscr{A}'_s \equiv \mathscr{A}_s / \mathscr{I}_s$ is isomorphic to $\mathscr{A}'_p$. (c) The ideal $\mathscr{I}_s$ is invariant under the $\star$-operation. Notice that hypothesis (c) is in principle compatible with the fact that $\mathscr{I}_C$ is not a $\star$-ideal of $\mathscr{A}_p$. Requirement (b), on the other hand, guarantees that each physical observable in $\mathscr{A}'_p$ possesses (at least) one representative which is a strong observable.

Using condition (a), it is possible to prove that the $\star$-operation leaves $\mathscr{A}_s$ invariant. Assumption (c) ensures then that the $\star$-relations project unambiguously to $\mathscr{A}'_s$. One hence obtains a well-defined involution on $\mathscr{A}'_s$ which, given condition (b), supplies a unique involution on $\mathscr{A}'_p$ through the existing isomorphism between these two algebras. So, provided that hypotheses (a)–

(c) are satisfied, the above strategy allows one to induce an unambiguous involution on $\mathscr{A}'_p$ from reality conditions.

In fact, this strategy is partially motivated by the refined version of Ashtekar's program which has been recently proposed.[13] In this new version of the program, it is supposed that all first-class constraints can be represented by self-adjoint operators on an auxiliary Hilbert space on which one has constructed a $\star$-representation of $\mathscr{A}^{(\star)}$. Hypothesis (a) must hence hold. Besides, rather than considering the whole algebra $\mathscr{A}_p$, one restricts one's attention to a certain $\star$-subalgebra of strong observables $\mathscr{B}^{(\star)}_{\rm phys} \subset \mathscr{A}_s$.[13] After completion of the quantization, one obtains a physical Hilbert space $\mathscr{H}_{\rm phys}$ which carries a $\star$-representation of $\mathscr{B}^{(\star)}_{\rm phys}$. Let us point out that this representation will not be faithful in general, for there may exist a subalgebra $\mathscr{I}_{\mathscr{B}} \subset \mathscr{B}^{(\star)}_{\rm phys}$ that annihilates the whole space of physical states. It seems reasonable to assume that $\mathscr{I}_{\mathscr{B}} = \mathscr{I}_C \cap \mathscr{B}^{(\star)}_{\rm phys}$, i.e., that the operators in $\mathscr{B}^{(\star)}_{\rm phys}$ with zero action on physical states are those which vanish modulo constraints.[14] On the other hand, it is possible to show[14] that Ashtekar's refined program can be consistently implemented only if $\mathscr{I}_{\mathscr{B}}$ is a $\star$-ideal of $\mathscr{B}^{(\star)}_{\rm phys}$, requirement which is the analog of hypothesis (c) above.

According to our discussion, $\mathscr{H}_{\rm phys}$ should finally provide a faithful representation of $\mathscr{B}'_{\rm phys} \equiv \mathscr{B}^{(\star)}_{\rm phys}/\mathscr{I}_{\mathscr{B}}$. In order that all relevant physical information can be extracted from the quantum theory obtained, it is then necessary that $\mathscr{B}'_{\rm phys}$ be isomorphic to $\mathscr{A}'_p$ (or at least to a sufficiently large subalgebra of it). This last condition parallels hypothesis (b). In this sense, the strategy presented here to induce an involution on $\mathscr{A}'_p$ actually is implicitly incorporated in Ashtekar's refined program, with the only generalization that one can consider a $\star$-subalgebra of strong observables $\mathscr{B}^{(\star)}_{\rm phys}$ as the substitute for $\mathscr{A}_s$.

New features of a previously introduced group approach to quantization are presented. We show that the construction of the symmetry group associated with the system to be quantized (the ''quantizing group'') does not require, in general, the explicit construction of the phase space of the system, i.e., does not require the actual knowledge of the general solution of the classical equations of motion; in many relevant cases an implicit construction of the group can be given, directly, on configuration space. To show an application, we construct the symmetry group for the conformally invariant massless scalar and electromagnetic fields and the scalar and Dirac fields evolving in a symmetric curved space-time or interacting with symmetric classical electromagnetic fields. Further generalizations of the present procedure are also discussed and in particular the conditions under which non-Abelian groups (mainly affine groups and more general gauge groups) can be included. © *1996 American Institute of Physics.* [S0022-2488(96)02401-7]

I. INTRODUCTION

The conventional perturbative methods of quantization do not work properly with several relevant field theories. In addition, even in the case of theories for which a perturbative approach is possible, some information cannot be obtained by perturbative techniques because of its global nature. Therefore, it is necessary to look for other nonperturbative methods to extract this information from these quantum theories. A quantization method which might be especially suitable to perform this task is the group approach to quantization (GAQ) formalism.

The GAQ formalism was introduced several years ago (see, e.g., Refs. 1 and 2, and references therein) as an improved version of the geometric quantization and the Kirillov coadjoint orbit methods of quantization.[3,4] One of the major aims in the construction of the algorithm was to achieve the quantum solutions of a given physical system without explicitly solving the corresponding classical equation of motion, thus allowing for a quantum system for which a classical limit is not properly defined or the classical equations do not have a well-defined general solution. However, the required understanding of the basic symmetry group[5] is so accurate that, in many cases, the effort to finding it could be nearly equivalent to solving the problem. In this sense, GAQ is perhaps more useful as a tool for associating exactly solved (quantum systems) with already

classified Lie groups than as a method to quantize physical systems originally defined by a Lagrangian.

This paper is intended to be a first step in the opposite direction, i.e., towards the construction of quantizing groups, closely related to actual Lagrangians (or, equivalently, equations of motions), and dependent on fields given in configuration space, that is to say, formal groups of sections of a given fiber bundle on space–time directly attached to the physical system. We shall call this *configuration-space image* of the formalism. As the basic result, prior to this goal, it will be shown that the construction of the quantizing group does not, in principle, require the previous step of going to the phase space of the system; i.e., the explicit solution of the classical equations of motion is not required.

The configuration-space image of the formalism will also provide us a clearer view of the exact nature of the quantizing group and will clarify the relationship of this formalism with the Lagrangian and canonical formalisms.

We shall also show some of the advantages of expressing the formalism in the configuration-space image by constructing the quantizing group for several nontrivial fields in a natural and straightforward way: the conformally invariant massless scalar and electromagnetic fields, and the scalar field in symmetric curved space–time or interacting with arbitrary symmetric classical electromagnetic fields (Sec. III).

This image of the formalism, as well as the examples presented here, can also serve as a guide for further generalizations. We shall discuss some of these, arguing that a direct generalization for non-Abelian affine groups, or more general Kac–Moody groups and gauge groups[6,7] (see also Refs. 8 and 9), requires the equations of motion to be of first order. We shall show by means of two examples that this is not the case for other types of non-Abelian groups (Sec. IV).

In this article we shall not discuss the subtleties of the proper quantization procedure. The interested reader may explore these in some of the quoted references.

II. THE HARMONIC OSCILLATOR AND THE KLEIN–GORDON FIELD

In this section we shall use two simples examples, the harmonic oscillator and the Klein–Gordon field, to present the basic features of the GAQ formalism when the quantizing group can be written in terms of fields in configuration space.

The group law proposed in Ref. 1 for the one-dimensional harmonic oscillator [the extended one-dimensional Galilei group, the quantizing group for the nonrelativistic free particle can be obtained as the limiting case $\omega\to 0$] was

$$A''=A+A'\cos\omega B+\left(\frac{V'}{\omega}\right)\sin\omega B,$$

$$V''=V+V'\cos\omega B-\omega A'\sin\omega B,\quad B''=B+B', \tag{2.1}$$

$$\zeta''=\zeta\zeta'\exp\frac{i}{2}\left[V\left(A'\cos\omega B+\frac{V'}{\omega}\sin\omega B\right)-A(V'\cos\omega B-\omega A'\sin\omega B)\right].$$

Nevertheless, apart from the fact that the algebra of this group is isomorphic to the algebra of the basic observables of the harmonic oscillator little has been explained concerning the manner in which this group is actually associated with the harmonic oscillator (HO). Let us consider, however, the harmonic oscillator (HO) from the Lagrangian viewpoint. The action is

$$S_{\mathrm{HO}}=\frac{1}{2}m\int dt[\dot{q}^2-\omega^2q^2]. \tag{2.2}$$

The equations of motion are

$$\left[\frac{d^2}{dt^2}+\omega^2\right]q=0 \tag{2.3}$$

with the general solution

$$q(t)=q_0\ \cos\ \omega t+\frac{\dot{q}_0}{\omega}\ \sin\ \omega t,\quad \Rightarrow\dot{q}(t)=\dot{q}_0\ \cos\ \omega t-\omega q_0\ \sin\ \omega t. \tag{2.4}$$

Hence, by means of the identification $A\equiv q_0$, $V\equiv\dot{q}_0$, $t\equiv B$; and associating a time evolution to the coordinates of the phase space in the natural manner, the group law in Eq. (2.1) can be written in the form

$$\begin{gathered}A''=A+A'(B),\quad V''=V+V'(B),\quad B''=B+B',\\ \zeta''=\zeta\zeta'\ \exp\frac{i}{2}\,m[VA'(B)-AV'(B)].\end{gathered} \tag{2.5}$$

Now, taking into account that $\dot{q}\equiv\dot{A}=V$, this group law can straightforwardly be written on configuration space:

$$\begin{gathered}B''=B+B',\quad q''(t)=q(t)+q'(t+B),\\ \zeta''=\zeta'\zeta\ \exp\frac{i}{2}\,m[\dot{q}(t)q'(t+B)-q(t)\dot{q}'(t+B)]_{t=t_0}.\end{gathered} \tag{2.6}$$

Instead of discussing here what we can learn from the simple manipulations above and the results obtained, it is preferable to consider first the case of a field such as the Klein–Gordon field. The action and equations of motion are

$$S_{\mathrm{KG}}=\frac{1}{2}\int d^4x[\partial^\mu\phi\partial_\mu\phi-m^2\phi^2], \tag{2.7}$$

$$\Rightarrow[\Box+m^2]\phi=0. \tag{2.8}$$

The analogy with the harmonic oscillator can serve as a guide to propose a quantizing group for the fields directly on configuration space (to simplify the discussion we shall not consider here Lorentz transformations, but only the symmetries associated with space–time translations). Let us consider the following composition law:

$$a''=a+a',\quad a\ \in\ R^4,\quad \phi''(x)=\phi(x)+\phi'(x+a), \tag{2.9}$$

$$\zeta''=\zeta'\zeta\ \exp\frac{i}{2}\,\xi_{\mathrm{KG}}(g',g)\equiv\zeta'\zeta\ \exp\frac{i}{2}\int_\Sigma d\sigma_\mu(x).\mathscr{T}^\mu_{\mathrm{KG}}(g,g')(x),$$

where

$$\mathscr{T}^\mu_{\mathrm{KG}}(g,g')(x)=\partial^\mu\phi(x)\phi'(x+a)-\phi(x)\partial^\mu\phi'(x+a) \tag{2.10}$$

and Σ is any spacelike hypersurface.

Now, let us expand the fields ϕ that solve the equation of motion (2.8) in Fourier modes by means of

$$\phi(x)=\int \frac{d^3k}{2k^0}\,(\Phi(k)e^{-ikx}+\Phi^+(k)e^{ikx}). \tag{2.11}$$

It is not difficult to see that for the Fourier modes $\Phi(k)$ we get the composition law postulated in Ref. 10. This implies that the composition law above is actually a group law. Nonetheless, it is easy to see that we need not use the general solution (2.11) to show that Eqs. (2.9) and (2.10) define a group law. In fact, the requirement that the fields in Eq. (2.10) be solutions of the equation of motion is enough to show that

(a) the quantity $\xi(g',g)$ fulfills the cocycle property:

$$\xi(g'',g')+\xi(g''*g',g)=\xi(g'',g'*g)+\xi(g',g) \tag{2.12}$$

and that

(b) the current $\mathscr{T}^\mu$ is conserved:

$$\partial_\mu \mathscr{T}^\mu=0. \tag{2.13}$$

In fact, in all the cases studied in this paper there is a double implication (a) $\Leftrightarrow$ (b): Finding a divergenceless current composed of the fields solution of the equations of motion has consistently proved sufficient for the quantity ξ, constructed on it, to fulfill the cocycle property. We do not know whether this is the general case.

We can, therefore, state the following features of the formalism expressed in configuration space:

(1) The basic group (the group to be centrally extended) is a group irrespective of whether or not the fields involved fulfill the equations of motion.

(2) The central extension involves the integral of a divergenceless current $\mathscr{T}^\mu$ over an hypersurface Σ. This current has null divergence only over the fields that obey the equations of motion.

Therefore, the centrally extended group, the quantizing group, *involves only the fields that are solutions of the equations of motion*. It is constructed upon the *phase space* of the system. [For the (covariant) description of the phase space of a system as the set of all solutions of the classical equations of motion see, e.g., Ref. 11, and references therein.]

In this phase space, different coordinates can be chosen. The choice of the Fourier modes $\Phi(k)$ leads us to the composition law in Ref. 10. Another choice is the familiar one of fields and timelike derivatives of the fields in the hypersurface Σ. We can write the group law in these coordinates by using the following propagation property:

$$\phi(y)=\int_\Sigma d\sigma_\mu(x)[\,\partial^\mu\Delta(y-x)\,\phi(x)-\Delta(y-x)\,\partial^\mu\phi(x)\,], \tag{2.14}$$

where the propagator Δ obeys the equation of motion:[12]

$$[\Box+m^2]\Delta=0. \tag{2.15}$$

(3) The classical equations of motion, *but not their general solution*, are required to show that the quantizing group is, in fact, a group.

(4) The equations of motion are not uniquely determined by the group; Eq. (2.13) implies Eq. (2.8) for *some* m but not for a particular m. Therefore Eq. (2.13) *almost* implies Eq. (2.8) but there is not a complete implication. The groups in configuration space for the harmonic oscillator and the free particle are the same, whereas the equations of motion are not. It is in terms of phase-space coordinates that the difference between these systems explicitly appears in the group.

III. APPLICATIONS

In this section we shall construct the quantizing group for several physically interesting systems to present an application of the formalism presented above: the conformally invariant massless scalar and electromagnetic fields, the scalar and Dirac field in a symmetric curved space–time, and these same fields interacting with symmetric electromagnetic fields.

[Unlike in the previous section, where the semidirect action of the space-time symmetries was given in a rather unnatural way—a way adapted to the Schrödinger representation—in the sequel we shall write the quantizing groups in the natural way; the other expression can be obtained by a simple change of coordinates.]

A. Conformally invariant fields

The conformal group, for which the composition law has not, up to now, been given in a closed form, is made up of compositions of the following actions on the space–time:

(a) space time translations: $(ux)^{\alpha}=x^{\alpha}+a^{\alpha}$;

(b) Lorentz transformations: $(ux)^{\alpha}=\Lambda^{\alpha}_{\mu}x^{\mu}$;

(c) dilatations: $(ux)^{\alpha}=e^{\lambda}x^{\alpha}$;

(d) special conformal tranformations: $(ux)^{\alpha}=\dfrac{x^{\alpha}+c^{\alpha}x^{2}}{1+2cx+c^{2}x^{2}}$.

1. The massless scalar field

The group law (in four dimensions, in which case the conformal dimension of a scalar field is $l=-1$) is

$$\begin{aligned} u''&=u'*\dot{u}, \quad \text{conformal (sub)group,}\\ \phi''(x)&=\phi'(x)+\Omega^{-1}(u'^{-1},x)\,\phi(u'^{-1}(x)), \end{aligned} \tag{3.1}$$

$$\zeta''=\zeta'\zeta\,\exp\frac{i}{2}\,\xi_{MS}(g',g)=\zeta\zeta'\,\exp\frac{i}{2}\int_{\Sigma}d\sigma_{\mu}(x).\mathscr{T}^{\mu}_{MS}, \tag{3.2}$$

where

$$\mathscr{T}^{\mu}_{MS}=\phi'(x)\partial^{\mu}[\Omega^{-1}(u'^{-1},x)\,\phi(u'^{-1}(x))]-\partial^{\mu}\phi'(x)[\Omega^{-1}(u'^{-1},x)\,\phi(u'^{-1}(x))] \tag{3.3}$$

and the function Ω is given by

$$\Omega(u,x)=\begin{cases} 1+2cx+c^{2}x^{2} & \text{for special conformal transformation}\\ e^{-\lambda} & \text{for dilatations}\\ 1 & \text{for the Poincaré subgroup}\end{cases}.$$

The function Ω for a general conformal transformation can be obtained by using its property

$$\Omega(u,x)\Omega(u',ux)=\Omega(u'u,x) \tag{3.4}$$

which is required for Eq. (3.1) to define a group.

It is not difficult to show that if $\phi(x)$ and $\phi'(x)$ are solution of the equations of motion

$$\partial^{\mu}\partial_{\mu}\phi(x)=0 \tag{3.5}$$

so is $\phi''(x)$. It is also straightforward to show, by using Eqs. (3.4) and (3.5), that the current $\mathcal{T}^{\mu}$ is divergenceless and fulfills the cocycle property (2.12).

2. The electromagnetic field

The group law is given by

$$\begin{aligned} &u''=u'*u, \quad \text{conformal (sub)group,} \\ &A''_{\mu}(x)=A'_{\mu}(x)+\frac{\partial u'^{-1\alpha}}{\partial x^{\mu}}A_{\alpha}(u'^{-1}x)\equiv A'_{\mu}(x)+(S(u'^{-1})A)_{\mu}(x), \end{aligned} \tag{3.6}$$

where S is the representation of the conformal group that acts on the electromagnetic vector field. This action is the natural one and means that the potential vector has null conformal weight. This action induces the following one on the tensor field $F_{\mu\nu}$:

$$F''_{\mu\nu}(x)=F'_{\mu\nu}(x)+\frac{\partial u'^{-1\alpha}}{\partial x^{\mu}}\frac{\partial u'^{-1\beta}}{\partial x^{\nu}}F_{\alpha\beta}(u'^{-1}x), \tag{3.7}$$

$$\equiv F'_{\mu\nu}(x)+(S(u'^{-1})F)_{\mu\nu}(x). \tag{3.8}$$

It is easy to show that this action leaves invariant Maxwell's action:

$$S_M=\int d^4x\ F_{\mu\nu}F^{\mu\nu} \tag{3.9}$$

and, therefore, leaves Maxwell's equations invariant.

The central extension is given by

$$\zeta''=\zeta'\zeta\ \exp\frac{i}{2}\,\xi_M(g',g)=\zeta'\zeta\ \exp\frac{i}{2}\int_{\Sigma}d\sigma_{\mu}(x).\mathcal{T}^{\mu}_M(g',g)(x) \tag{3.10}$$

with divergenceless current

$$\mathcal{T}^{\mu}_M(g',g)(x)=F'^{\mu\nu}(x)(S(u'^{-1})A)_{\nu}(x)-A'_{\nu}(x)(S(u'^{-1})F)^{\mu\nu}(x). \tag{3.11}$$

If we restrict ourselves to the symmetry group of space–time translations, the group is written

$$\begin{aligned} &a''=a+a', \quad A''_{\mu}(x)=A'_{\mu}(x)+A_{\mu}(x-a'), \\ &\zeta''=\zeta\zeta'\ \exp\frac{i}{2}\int_{\Sigma}d\sigma_{\mu}(x).\mathcal{T}^{\mu}_M(g',g)(x), \end{aligned} \tag{3.12}$$

with a current

$$\mathcal{T}^{\mu}_M(g',g)(x)=F'^{\mu\nu}(x)A_{\nu}(x-a')-A'_{\nu}(x)F^{\mu\nu}(x-a'). \tag{3.13}$$

In this last example, we again see the issue discussed above: The current $\mathcal{T}^{\mu}_M$ is divergenceless and fulfills the cocycle property if Maxwell equations are obeyed, but a Proca-like equation $\partial_{\mu}F^{\mu\nu}+m^2A^{\nu}=0$, with a non-null mass m, is also allowed. This is, however, no longer the case when the full conformal group is considered.

B. Matter fields in a symmetric curved space–time

In this section we shall present the quantizing group for matter fields, the Klein–Gordon and Dirac fields, evolving in a symmetric, but on the other hand arbitrary, curved space–time with metric $g_{\mu\nu}$.

Let us assume that a set of transformations v is a group of isometries of the metric (see, e.g., Refs. 13 and 14). Then we have

$$g_{\mu\nu}(vx)\,\frac{\partial(vx)^{\mu}}{\partial x^{\alpha}}\,\frac{\partial(vx)^{\nu}}{\partial x^{\beta}}=g_{\alpha\beta}(x) \tag{3.14}$$

and, in the same way,

$$g^{\mu\nu}(vx)=g^{\alpha\beta}(x)\,\frac{\partial(vx)^{\mu}}{\partial x^{\alpha}}\,\frac{\partial(vx)^{\nu}}{\partial x^{\beta}}. \tag{3.15}$$

1. The scalar field

The equations of motion for a scalar field evolving in this background metric are (see, e.g., Refs. 15 and 16):

$$[\Box(x)+\alpha R(x)+m^2]\phi(x)=0 \tag{3.16}$$

with

$$\Box(x)\phi(x)\equiv\frac{1}{\sqrt{g(x)}}\,\partial_{\mu}(\sqrt{g(x)}g^{\mu\nu}(x)\partial_{\nu})\phi(x). \tag{3.17}$$

The group law that would describe the quantum dynamics of this system is given by

$$v''=v'*v,\quad \phi''(x)=\phi'(x)+\phi(v'^{-1}(x)), \tag{3.18}$$

$$\zeta''=\zeta\zeta'\,\exp\frac{i}{2}\int_{\Sigma}d\sigma_{\mu}(x)\mathscr{T}^{\mu}_{SCS} \tag{3.19}$$

with

$$\mathscr{T}^{\mu}_{SCS}=\sqrt{g(x)}g^{\mu\nu}(x)[\phi'(x)\partial_{\nu}[\phi(v'^{-1}(x))]-\partial_{\nu}\phi'(x)\phi(v'^{-1}(x))]. \tag{3.20}$$

[Notice that Eq. (3.14) implies $\Box(x)=\Box(vx)$ and $R(vx)=R(x)$ (see also Ref. 14).]

2. The Dirac field

Let Ψ be a Dirac field with equations of motion (see, e.g., Refs. 13 and 15):

$$[i\hat{\gamma}^{\mu}(\partial_{\mu}+\tfrac{1}{2}i\Gamma^{a}{}_{\mu}{}^{b}\Sigma_{ab})-m]\Psi=0, \tag{3.21}$$

where

$$g_{\mu\nu}=\eta_{ab}e^{a}_{\mu}e^{b}_{\nu}, \tag{3.22}$$

$$\hat{\gamma}^{\mu}=\gamma^{a}e_{a}{}^{\mu},\quad \Sigma_{ab}=\tfrac{1}{4}i[\gamma_a,\gamma_b], \tag{3.23}$$

$$\Gamma^{c}_{ab}=e^{c}{}_{\nu}e^{\mu}_{a}(\partial_{\mu}e_{b}{}^{\nu}+e_{b}{}^{\lambda}\Gamma^{\nu}_{\mu\lambda}). \tag{3.24}$$

The transformations v, being isometries, imply that there exists a set of local Lorentz transformations $\Lambda(v,x)$ such that

$$e^a{}_\mu(vx)\,\frac{\partial(vx)^\mu}{\partial x^\lambda}=\Lambda(v,x)^a{}_c e^c{}_\lambda(x). \tag{3.25}$$

On these grounds it can be shown that the following set of transformations is a (super)group:

$$\begin{gathered} v''=v'*v, \\ \Psi''(x)=\Psi'(x)+\rho(\Lambda(v'^{-1},x))\Psi(v'^{-1}(x)), \end{gathered} \tag{3.26}$$

$$\begin{gathered} \overline{\Psi}''(x)=\overline{\Psi}'(x)+\overline{\Psi}(v'^{-1}(x))\rho(\Lambda(v'^{-1},x))^{-1}, \\ \zeta''=\zeta'\zeta\,\exp\frac{i}{2}\,\xi_{DCS}(g',g)=\zeta'\zeta\,\exp\frac{i}{2}\int_\Sigma d\sigma_\mu(x)\mathscr{T}^\mu_{DCS}(g',g)(x), \end{gathered} \tag{3.27}$$

where

$$\begin{aligned} \mathscr{T}^\mu_{DCS}(g',g)(x)=i[&\overline{\Psi}'(x)\hat{\gamma}^\mu(x)\rho(\Lambda(v'^{-1},x))\Psi(v'^{-1}x) \\ &-\overline{\Psi}(v'^{-1}x)\rho(\Lambda(v'^{-1},x))^{-1}\hat{\gamma}^\mu(x)\Psi'(x)] \end{aligned} \tag{3.28}$$

and ρ is the usual spin representation of the Poincaré group which verifies

$$\rho(\Lambda)^{-1}\gamma^a\rho(\Lambda)=\Lambda^a{}_b\gamma^b. \tag{3.29}$$

C. Matter fields coupled to symmetric electromagnetic fields

In this section, we shall present the quantizing group for matter fields, the Klein–Gordon and Dirac fields, coupled to a symmetric, but on the other hand arbitrary, electromagnetic field.

The space–time in this section will be flat, with a Minkowskian metric $\eta_{\mu\nu}$. The set of transformation v will be any subgroup of the Poincaré group leaving the electromagnetic field invariant: $A_\mu(vx)=A_\mu(x)$.

1. The Klein–Gordon field

Let the scalar field ϕ obeys the equations of motion

$$(D_\mu D^\mu+m^2)\phi=0 \tag{3.30}$$

with $D_\mu\equiv\partial_\mu-iA_\mu$.

Then the following composition law defines a group:

$$v''=v'*v, \tag{3.31}$$

$$\phi''(x)=\phi'(x)+\phi(v'^{-1}(x)), \tag{3.32}$$

$$\zeta''=\zeta'\zeta\,\exp\frac{i}{2}\,\xi_{SAF}(g',g)=\zeta'\zeta\,\exp\frac{i}{2}\int_\Sigma d\sigma_\mu(x)\mathscr{T}^\mu_{SAF}(g',g)(x) \tag{3.33}$$

with

$$\mathscr{T}^\mu_{SAF}(g',g)(x)=D^\mu\phi(v'^{-1})\phi^{*\prime}(x)-\phi(v'^{-1})(D^\mu\phi)^{*\prime}(x)$$

$$+(D^{\mu}\phi(v'^{-1}))^{*}\phi'(x)-\phi(v'^{-1})^{*}(D^{\mu}\phi)'(x). \tag{3.34}$$

2. The Dirac field

Let Ψ be a Dirac field with equations of motion:

$$(i\gamma^{\mu}D_{\mu}-m)\Psi=0. \tag{3.35}$$

Then the following set of transformations is a group:

$$v''=v'*v,$$

$$\Psi''(x)=\Psi'(x)+\rho(\Lambda(v'^{-1}))\Psi(v'^{-1}(x)), \tag{3.36}$$

$$\overline{\Psi}''(x)=\overline{\Psi}'(x)+\overline{\Psi}(v'^{-1}(x))\rho(\Lambda(v'^{-1}))^{-1},$$

$$\zeta''=\zeta'\zeta\ \exp\frac{i}{2}\,\xi_{DAF}(g',g)=\zeta'\zeta\ \exp\frac{i}{2}\int_{\Sigma}d\sigma_{\mu}(x).\mathscr{T}^{\mu}_{DAF}(g',g)(x) \tag{3.37}$$

with

$$\mathscr{T}^{\mu}_{DAF}(g',g)(x)=i[\overline{\Psi}'(x)\gamma^{\mu}\rho(\Lambda(v'^{-1}))\Psi(v'^{-1}x)-\overline{\Psi}(v'^{-1}x)\rho(\Lambda(v'^{-1}))^{-1}\gamma^{\mu}\Psi'(x)]. \tag{3.38}$$

Comments: We should point out here that the requirement of being symmetric for the classical ''source'' fields considered above, such as the space-time metric or the electromagnetic field in Secs. III B and III C, respectively, is not a strict requirement: many relevant systems, such as the one of fields evolving in a Schwarzchild black hole background,[15,17] are not excluded by this constraint.

IV. GENERALIZATIONS. THE VIRASORO GROUP AND THE SCHWARZIAN DERIVATIVE

Let us consider from another perspective the manner in which we arrived at the group law for the harmonic oscillator in Sec. II, Eq. (2.1). (Similar considerations can be made on the group laws for the other fields mentioned above.) We started with an Abelian gauge group (the group of functions on R with values in a group G and pointwise group composition) (composed in a semidirect way with the temporal translations which are the zero modes of the group of diffeomorphisms of the real line). From this group, we extracted the subgroup of the functions that obey certain differential equations (the equations of motion). The subgroup obtained this way can be extended, the principal ingredient for the extension being a divergenceless current.

This point of view leads us immediately to a possible generalization: instead of an Abelian gauge group let us consider more general, non-Abelian gauge groups. However, we should ask what differential equations (equations of motion) are to be applied to the basic group. In other words, the question is: what differential equation is there such that if $g(t)$ and $h(t)$ are solutions of this equation, $g(t)*h(t)$ is also for a general non-Abelian affine group? (This is a kind of symmetry that goes beyond those usually considered in the literature.) For the Abelian group, the solution was obvious: any linear differential equation is such that if $h(t),g(t)$ are solutions so is $h(t)+g(t)$. From this simple property, we have constructed the quantizing group for the harmonic oscillator, the nonrelativistic free particle, the Klein–Gordon and Maxwell fields, etc. We might ask though what differential equation fulfills this property for, say, a current SU(2) group.

There are strong indications that no equation of order greater than one with this property exists for any non-Abelian gauge group. In fact, let us consider the Lie algebra of these gauge groups. For any Abelian gauge group, the basic Lie algebra is

$$\{\varphi_a(x),\varphi_b(y)\}=0. \tag{4.1}$$

From this algebra, we have to extract the subalgebra made up of the tangent fields that obey the (linearized) equations of motion and further extend it. In the Abelian case, this can be done with the result

$$\{\varphi_a(x),\varphi_b(y)\}=\Delta_{ab}(x-y), \tag{4.2}$$

where Δ_{ab} is the propagator similar to that of Eqs. (2.14) and (2.15). [If $\Delta(x-y)$ is the propagator for the Klein–Gordon field, the propagator for the Dirac field is $\Delta_D(x-y)=(i\gamma^\mu\partial_\mu+m)\Delta(x-y)$ and for the electromagnetic (or Proca) field is $\Delta_{M_{\mu\nu}}(x-y)=-\eta_{\mu\nu}\Delta(x-y)$. For the harmonic oscillator it is $\Delta_{\mathrm{HO}}(B)=(1/\omega)\sin\omega B$ and for the nonrelativistic free particle $\Delta_{FP}(B)=B$.] This central extension is consistent with the (linearized) equations of motion for the tangent fields.

For non-Abelian fields, we should start from the basic Lie algebra:

$$\{T^a(x),T^b(y)\}=f_c^{ab}T^c(x)\,\delta(x-y). \tag{4.3}$$

The Lie bracket of two elements of the Lie algebra

$$X=\int dx\ f_a(x)T^a(x),\quad Y=\int dx\ g_a(x)T^a(x) \tag{4.4}$$

is given by

$$[X,Y]=\int dx\ f_a(x)g_b(x)f_c^{ab}T^c(x). \tag{4.5}$$

Therefore the Lie algebra (4.3) can equivalently be written in terms of the coefficient functions f as follows:

$$[f,g]_c(x)=f_a(x)g_b(x)f_c^{ab}. \tag{4.6}$$

For any equation of motion that we impose now on the group elements, the induced linearized equations of motion for the elements of the Lie algebra will, of course, be linear. But, for non-null structure constants f_c^{ab}, Eq. (4.6) implies that no subalgebra can be defined by linear equations of an order greater than one.

This result is a sort of *no-go* theorem which implies that the construction above for Abelian groups (fields), with equations of motion of a second order, cannot be *directly* extended to non-Abelian groups (fields). This extension would require the equations of motion to be of a typically Hamiltonian form. Only in the case of Abelian centrally extended gauge groups (fields), the splitting of coordinate momentum can be made without breaking the group structure.

Now, we shall show that this obstruction is not present in other kinds of non-Abelian groups. Let us consider, as an example, the Schwarzian derivative $S(f)$:

$$S(f)=\partial_t\left\{\frac{\partial_t^2 f}{\partial_t f}\right\}-\frac{1}{2}\left(\frac{\partial_t^2 f}{\partial_t f}\right)^2=\frac{\partial_t^3 f}{\partial_t f}-\frac{3}{2}\left(\frac{\partial_t^2 f}{\partial_t f}\right)^2. \tag{4.7}$$

This operator fulfills the so-called Cayley property:

$$S(fog)=S(f)og(\dot g)^2+S(g), \tag{4.8}$$

where o stands for composition of functions. Therefore we shall find that

$$S(f)=0,\quad S(g)=0\Rightarrow S(fog)=0. \tag{4.9}$$

Therefore, for the Virasoro group, the group of diffeomorphisms of the real line, the vanishing of the Schwarzian derivative is a differential equation with the property we were seeking. (We will say that the Schwarzian derivative is *closed* under the Virasoro group.) Since the group of diffeomorphisms *does not have* a pointwise composition law, it does not fulfill the hypothesis of the no-go theorem above, and we shall show that it does not fulfill its thesis either.

The algebra of the group of diffeomorphisms on R is the Lie algebra of all vector fields $v(t)\partial_t$ with the Lie bracket:

$$\{u,v\}(t)=-(\dot{u}(t)v(t)-u(t)\dot{v}(t)). \tag{4.10}$$

If the functions of the group satisfy $S(f)=0$, by taking variation and taking into account that the identity function is $f(t)=t$, we arrive at the following (of course, linear) equation for the functions in the Lie algebra of the group

$$\partial_t^3 v(t)=0. \tag{4.11}$$

It is straightforward to show by applying the linear operator ∂_t^3 to both sides of Eq. (4.10) that the set of functions which satisfy Eq. (4.11) close into a subalgebra.

The general solution of Eq. (4.11) is a general linear combination of $1,t,t^2$ which generates the general solution of the equation $S(f)=0$:

$$f(t)=\frac{at+b}{ct+d} \quad \text{with} \quad ad-bc=1. \tag{4.12}$$

Therefore the subgroup of the Virasoro group generated by functions obeying $S(f)=0$ is the SL(2,R) group.

A. The Virasoro gauge group and the induced 2D gravity in the light-cone gauge

A construction similar to the one presented above for the Virasoro group can also be made for the *Virasoro gauge group*. [This group should not be confused with the affine Virasoro group, which is a realization of the Virasoro group (generators), the Sugawara construction, in terms of currents from an affine (Kac–Moody) algebra (see Ref. 8).] This is the set of functions

$$\begin{gathered} f: R \rightarrow \text{Virasoro}, \\ \sigma \rightarrow f(\sigma) \end{gathered} \tag{4.13}$$

with the composition law $(f*g)(\sigma)(\tau)=(f(\sigma)og(\sigma))(\tau)$. The elements of this group are, therefore, parametrized by two coordinates, σ and τ, and can be considered to be functions of two variables, $f(\sigma,\tau)$.

The vanishing of the Schwarzian derivative

$$\{f(\sigma,\tau),\tau\}=0 \tag{4.14}$$

is, of course, a *closed* equation for this group, thus defining a subgroup, the SL(2,R) affine group in this case.

The identifications $\sigma\equiv x^+=t+x$, $\tau\equiv x^-=t-x$ transform Eq. (4.14) into the equation of motion, $\{f,x^-\}=0$, of the induced 2D gravity in the light-cone gauge.[11] Moreover, in this gauge, the symplectic form is the canonical one of the SL(2,R) affine (sub)group. All this would indicate that the quantum theory of this system should be described in terms of irreducible, unitary representations of the SL(2,R) affine group. However, it is well known that there are no unitary, standard highest-weight representations with a nonzero central charge. In fact, a more rigorous analysis of this theory based on a local form of the action shows that its true reduced phase space

is quite different from that proposed above and cannot be obtained as a constrained version of the former.[11] Therefore, the role played by the SL(2,*R*) affine symmetry is in any case different from the one expected from the analysis of the nonlocal theory in the light-cone gauge.

V. DISCUSSION

We have presented the basic features of the GAQ formalism when the quantizing group can be written in terms of fields given on configuration space. It was not our intention to be exhaustive. On the contrary: many question have been raised which will have to be addressed in future publications.

The quantizing groups for several physically relevant systems have been given, albeit most of them in an implicit form. However, one might question the utility of writing down the quantizing group in this implicit form. The key point in considering the quantizing group is that it collects all the information about both the classical and the quantum theories. Of course, we can achieve the most with it when we know the general solution of the equations of motion, i.e., the phase space of the theory (and, in fact, there are many important examples in which this is the case), but we believe that, even when the general solution is not known, there can still be a large amount of information of the quantum theory that we can possibly extract from the quantizing group.

An interesting case occurs when we know only *some* of the classical solutions of the theory. With the GAQ formalism, we would be able to quantize these solutions, provided that we were able to find pairs of solutions that are coordinate-momentum conjugates of each other. (In the GAQ formalism, the cocycle may be viewed as a sort of ''symplectic product'' which measures the extent to which two classical solutions are coordinate-momentum conjugates of each other.) This sort of *minisuperspace* approach would provide us with a preliminary draft of the quantum theory and deserves independent study.

In addition, the phase space of any classical theory is, in some sense, always roughly known: it is characterized by the fields and time derivative of the fields in a Cauchy hypersurface and evolve in time in accordance with the classical equations of motion. Putting aside topological or, in general, global issues of the phase space, the GAQ formalism equipped with this rough description of the phase space must necessarily work better than the familiar canonical quantization does.

Furthermore, the configuration-space image of the GAQ formalism appears as a well-suited formalism to deal with gauge theories. Indeed, gauge symmetries, far from being a mere useful tool to solve a previously given theory, determine the theory, and this philosophy is the same that inspires the GAQ formalism. However, we have proven in Sec. IV a sort of no-go theorem which delimits the type of equations of motion in a (nonlinear) system defined by a non-Abelian basic current group; these equations must be kept in a Hamiltonian-like, first-order form, since the restriction to the pure coordinate space satisfying second-order equations would destroy the group structure. This situation resembles that of WZW models[18] where the Kac–Moody symmetry comes out in a natural way when written in a set of coordinates (light-cone coordinates) where the Lagrangian is not regular, making this way the difference between the modified and ordinary Hamilton principle.

[5] The customary name for these groups has, until now, been ''quantum groups.'' However, this term is by now the standard one for Hopf algebras (which, it is worth to point out here, are not groups). In addition to this, a more appropriate name for these groups, which best mirrows their *raison d'etre* and utility, is ''quantizing groups.'' This, quantizing groups, will therefore be the terminology used in this paper and we shall try to maintain it in future publications on the subject.

The Hamiltonian describing fermion pair production from an arbitrarily time-varying electric field in two dimensions is studied using a group-theoretic approach. We show that this Hamiltonian can be encompassed by two, commuting SU(2) algebras, and that the two-dimensional problem can therefore be reduced to two one-dimensional problems. We compare the group structure for the two-dimensional problem with that previously derived for the one-dimensional problem, and verify that the Schwinger result is obtained under the appropriate conditions. © *1996 American Institute of Physics.* [S0022-2488(96)01201-4]

I. INTRODUCTION

Fermion pair production takes place in a large number of physical situations; a comprehensive review of its applications in atomic, nuclear, elementary particle physics, astrophysics, and cosmology is given in Ref. 1. Consequently, the problem of pair production from classical external electric fields has been the subject of considerable theoretical interest.[2–17] The rate of fermion pair production from a uniform, static electric field was originally calculated by Schwinger[2] to be

$$\omega = \frac{\alpha E^2}{\pi^2} \sum_{n=1}^{\infty} \frac{1}{n^2} \exp\left(- \frac{n \pi m^2}{|eE|} \right), \tag{1}$$

where m is the mass of the produced fermions. To date, an analytic formalism that successfully addresses the general problem of fields which vary arbitrarily in both time and space has not been developed. However, numerous approaches have been suggested which address particular special cases. We previously discussed an approach for predicting the rate of pair production from a spatially homogeneous but arbitrarily time-varying field, provided the field is constrained to point in a fixed direction.[17] We now investigate an extension to this formalism that allows for a field varying in two dimensions.

We begin by writing the interaction Hamiltonian for fermions in an electric field. We adopt the gauge

$$A_0 = 0, \quad A_i = - \int_{-\infty}^{t} E_i(t) dt. \tag{2}$$

The interaction Hamiltonian is then given by

$$H_I = - e A_i \int d^3x \; \bar{\psi}_{\rm in}(x) \gamma_i \psi_{\rm in}(x), \tag{3}$$

[a)]E-mail: jseger@creighton.edu
[b)]E-mail: baha@nucth.physics.wisc.edu

where γ_i is the ith 4×4 Dirac γ-matrix, and summation over like indices is assumed. The incoming Dirac field ψ_{in} is that of free fermions,

$$\psi_{\text{in}}=\int \frac{d^3\mathbf{k}}{(2\pi)^{3/2}}\sqrt{\frac{m}{k_0}}\sum_{\beta}\left[b_\beta(k)u_\beta(k)e^{-ik\cdot x}+d^\dagger_\beta(\tilde{k})v_\beta(\tilde{k})e^{ik\cdot x}\right], \tag{4}$$

where b and $d^\dagger$ are the usual fermion creation and antifermion annihilation operators, and u and v are the two-component fermion and antifermion spinors. We use the symbol k to denote the four-vector $(k_0,\mathbf{k})$ and $\tilde{k}$ to denote $(k_0,-\mathbf{k})$; k represents the initial momentum of the fermions, and is a time-independent quantity. The mass of the created fermions is given by m, and their charge by e.

We chose the one-dimensional configuration as a starting point because, if the field varies in only one direction, the Hamiltonian contains only one Dirac γ-matrix, and an SU(2) algebra is sufficient to encompass the Hamiltonian. In the two-dimensional case, the Hamiltonian contains two Dirac γ-matrices. The appropriate algebra is then an SO(4) algebra, which is isomorphic to two commuting SU(2) algebras, as we illustrate below.

II. PAIR EMISSION FROM A TWO-DIMENSIONAL ELECTRIC FIELD

For an electric field that varies in the plane defined by the directions $i=1,2$, the interaction picture Hamiltonian is

$$H=\int d^3\mathbf{k}\left\{\left(2k_0-2e\frac{A_ik_i}{k_0}\right)J_0(k)-\frac{e\mu_iA_i}{k_0}\left[J^{(i)}_+(k)+J^{(i)}_-(k)\right]\right\}, \tag{5}$$

where summation of i over indices 1 and 2 is implied. μ_i in this expression is defined as $\mu_i=\sqrt{k_0^2-k_i^2}$. We have defined the operators in analogy to the one-dimensional case:[17]

$$\begin{aligned} J^{(i)}_+&=\frac{m}{\mu_i}\sum_{\alpha\beta}b^\dagger_\alpha(k)d^\dagger_\beta(\tilde{k})\bar{u}_\alpha(k)\gamma_iv_\beta(\tilde{k}),\quad i=1,2,\\ J^{(i)}_-&=[J^{(i)}_+]^\dagger,\quad i=1,2,\\ J_0&=\frac{1}{2}\sum_\alpha\left[b^\dagger_\alpha(k)b_\alpha(k)-d_\alpha(\tilde{k})d^\dagger_\alpha(\tilde{k})\right]. \end{aligned} \tag{6}$$

With an additional operator,

$$Q=\sum_{\alpha\beta}\left[b^\dagger_\alpha b_\beta\bar{u}_\alpha\gamma_3\gamma_5u_\beta+d_\alpha d^\dagger_\beta\bar{v}_\alpha\gamma_3\gamma_5v_\beta\right], \tag{7}$$

these operators form an SO(4) algebra.

From linear combinations of these operators, we can form two commuting SU(2) algebras, which we denote by $I_{+,-,0}$ and $T_{+,-,0}$, as follows:

$$\begin{aligned} I_+&=aJ^{(1)}_++a^*J^{(2)}_+,\\ I_-&=[I_+]^\dagger,\\ I_0&=\frac{1}{2}J_0+\frac{m}{4\mu}Q, \end{aligned} \tag{8}$$

$$T_+ = a^* J_+^{(1)} + a J_+^{(2)},$$
$$T_- = [T_+]^\dagger, \tag{9}$$

and

$$T_0 = \frac{1}{2} J_0 - \frac{m}{4\mu} Q,$$

where

$$a = \sqrt{\frac{\mu_1 \mu_2}{8(\mu_1 \mu_2 - k_1 k_2)}} + i \sqrt{\frac{\mu_1 \mu_2}{8(\mu_1 \mu_2 + k_1 k_2)}}, \tag{10}$$

and we have defined $\mu = \sqrt{k_0^2 - k_1^2 - k_2^2}$. Each of these SU(2) algebras is in the $j = \frac{1}{2}$ representation.

The group-theoretic approach has been previously discussed by Perelemov,[18] but the algebras we have derived are distinct from the algebras he considered. The SU(2) algebras utilized in Ref. 18 are constructed from the Dirac γ-matrices, whereas the SU(2) commutation relations of the operators in Eqs. (8) and (9) follow from the completeness and orthogonality of the Dirac spinors $u(p)$ and $v(p)$.

The Hamiltonian in Eq. (5) can be rewritten as a linear combination of elements of these two SU(2) algebras, and diagonalized via a Bogoliubov[19] transformation. The Bogoliubov transformation takes the usual form

$$\tilde{b}_\alpha(k) = \mathscr{U}_{\alpha\beta}(k) b_\beta(k) + \mathscr{V}_{\alpha\beta}(k) d_\beta^\dagger(\tilde{k}), \tag{11}$$

$$\tilde{d}_\alpha(\tilde{k}) = \mathscr{X}_{\alpha\beta}(k) d_\beta(\tilde{k}) + \mathscr{Y}_{\alpha\beta}(k) b_\beta^\dagger(k), \tag{12}$$

where the coefficients are time-dependent, 2×2 matrices. Requiring that the transformation preserve the canonical commutation relations constrains the coefficients to satisfy the relations

$$\mathscr{U}\mathscr{U}^\dagger + \mathscr{V}\mathscr{V}^\dagger = 1, \quad \mathscr{X}\mathscr{X}^\dagger + \mathscr{Y}\mathscr{Y}^\dagger = 1,$$
$$\mathscr{U}\mathscr{V}^T + \mathscr{V}\mathscr{X}^T = 0.$$

We further require that the Bogoliubov transformation yield the diagonal Hamiltonian,

$$H = \int d^3\mathbf{k}\ \epsilon(k) \sum_{\alpha\beta} [\tilde{b}_\alpha^\dagger(k) \tilde{b}_\alpha(k) - \tilde{d}_\alpha(\tilde{k}) \tilde{d}_\alpha^\dagger(\tilde{k})], \tag{13}$$

where ϵ is the total energy

$$\epsilon = \sqrt{m^2 + (\mathbf{k} - e\mathbf{A})^2}.$$

This requirement constrains the coefficients to be

$$\mathscr{U} = \cos\ \theta I \tag{14}$$

and

$$\mathscr{Z} = \mathscr{U}^{-1}\mathscr{V} = \frac{-mA_i \tan\ \theta}{\sqrt{k_0^2 \mathbf{A}^2 - (\mathbf{A}\cdot\mathbf{k})^2}} [\bar{u}_\alpha \gamma_i v_\beta], \tag{15}$$

and summation over i is implied. θ is defined by the relations

$$\cos\ \theta = \sqrt{\frac{\epsilon+\rho}{2\epsilon}}, \quad \sin\ \theta = -\sqrt{\frac{\epsilon-\rho}{2\epsilon}}, \tag{16}$$

and ρ is defined by

$$\rho = k_0 - \frac{e\mathbf{A}\cdot\mathbf{k}}{k_0}. \tag{17}$$

Alternatively, one can write the Bogoliubov transformation as a linear operator,

$$R = R_1 R_2, \tag{18}$$

such that

$$\tilde{b} = R(t) b R^{\dagger}(t). \tag{19}$$

R_1 and R_2 can each be written in terms of only one of the two commuting SU(2) algebras:

$$\begin{aligned} R_1 &= \exp[\,\eta I_+]\exp[\log(1+|\,\eta|^2) I_0]\exp[-\eta^* I_-], \\ R_2 &= \exp[\,\eta^* T_+]\exp[\log(1+|\,\eta|^2) T_0]\exp[-\eta T_-], \end{aligned} \tag{20}$$

where

$$\eta = \frac{-1}{(a^2 - a^{*2})}\left[\frac{\tan\ \theta(a\mu_1 A_1 - a^*\mu_2 A_2)}{\sqrt{k_0^2\mathbf{A}^2 - (\mathbf{A}\cdot\mathbf{k})^2}}\right] \tag{21}$$

gives the desired diagonal Hamiltonian.

Writing the Bogoliubov transformation as a linear operator is useful when calculating the rate of pair production from an electric field. The physical vacuum after the field has been turned off ($t>T$), $|Z(T)\rangle$, is related to the vacuum before the field was turned on ($t<-T$), $|0_i\rangle$, by

$$|Z(T)\rangle = R(T)|0_i\rangle. \tag{22}$$

Similarly, the physical creation operators for fermions and antifermions at times $t>T$ are $\tilde{b}^{\dagger}(k)$ and $\tilde{d}^{\dagger}(k)$, respectively.[17] The probability amplitude of producing no pairs, S_0, is therefore given by

$$S_0 = \lim_{t\to\infty}\langle Z|U_I|0_i\rangle = \langle 0_i|\tilde{U}|0_i\rangle, \tag{23}$$

where $\tilde{U} = R^{\dagger}U_I$. One can solve for $\tilde{U}$ directly, through

$$i\,\frac{d\tilde{U}}{dt} = \tilde{H}\tilde{U},$$

where

$$\tilde{H} = R^{\dagger}HR - iR^{\dagger}R. \tag{24}$$

The probability amplitude for producing no pairs is related to the rate of pair production ω by

$$|S_0|^2 = e^{-\int \omega \, d^4x}. \tag{25}$$

The operator R_1 has the matrix representation

$$R_1 = \begin{pmatrix} \cos\dfrac{\alpha_1}{2} & \sin\dfrac{\alpha_1}{2}\, e^{-i\gamma_1} \\ -\sin\dfrac{\alpha_1}{2}\, e^{-i\gamma_1} & \cos\dfrac{\alpha_1}{2} \end{pmatrix}, \tag{26}$$

where $\eta = \tan(\alpha/2)e^{-i\gamma}$. R_2 is defined analogously. One observes that, to satisfy Eq. (20), $\alpha_1 = \alpha_2$ and $\gamma_1 = -\gamma_2$; the subscripts on α and γ are therefore dropped. The matrix representation allows one to easily calculate the Hamiltonian $\tilde{H}$. By substituting Eqs. (8) and (9) into the Hamiltonian of Eq. (5), one can show that this Hamiltonian can be written $H = H_1 + H_2$, where

$$H_1 = \int d^3k \left\{ \left(2k_0 - \frac{2eA_i k_i}{k_0} \right) I_0 + 2ie\mu \left[\left(\frac{aA_1}{\mu_2} - \frac{a^*A_2}{\mu_1} \right) I_+ - \left(\frac{a^*A_1}{\mu_2} - \frac{aA_2}{\mu_1} \right) I_- \right] \right\} \tag{27}$$

and

$$H_2 = \int d^3k \left\{ \left(2k_0 - \frac{2eA_i k_i}{k_0} \right) T_0 + 2ie\mu \left[\left(\frac{-a^*A_1}{\mu_2} + \frac{aA_2}{\mu_1} \right) T_+ + \left(\frac{aA_1}{\mu_2} - \frac{a^*A_2}{\mu_1} \right) T_- \right] \right\}. \tag{28}$$

It follows that $\tilde{H}$ can be written $\tilde{H} = \tilde{H}_1 + \tilde{H}_2$, where

$$\tilde{H}_1 = R_1^\dagger H_1 R_1 - i R_1^\dagger \dot{R}_1 \tag{29}$$

and

$$\tilde{H}_2 = R_2^\dagger H_2 R_2 - i R_2^\dagger \dot{R}_2. \tag{30}$$

The explicit expressions for $\tilde{H}_1$ and $\tilde{H}_2$ are then

$$\tilde{H}_1 = \int d^3k \left\{ \left[2\epsilon(k) + 2\left(\dot{\gamma} \sin^2\frac{\alpha}{2} \right) \right] I_0 - \frac{1}{2} \left[(i\dot{\alpha} + \dot{\gamma} \sin\alpha) e^{-i\gamma} I_+ + (-i\dot{\alpha} + \dot{\gamma} \sin\alpha) e^{i\gamma} I_- \right] \right\}, \tag{31}$$

$$\tilde{H}_2 = \int d^3k \left\{ \left[2\epsilon(k) - 2\left(\dot{\gamma} \sin^2\frac{\alpha}{2} \right) \right] T_0 - \frac{1}{2} \left[(i\dot{\alpha} - \dot{\gamma} \sin\alpha) e^{i\gamma} T_+ + (-i\dot{\alpha} - \dot{\gamma} \sin\alpha) e^{-i\gamma} T_- \right] \right\}. \tag{32}$$

If we now write $\tilde{U}$ as a product, $\tilde{U} = \tilde{U}_1 \tilde{U}_2$, where $\tilde{U}_1$ and $\tilde{U}_2$ are each written in the most general form of an element of the respective SU(2) groups:

$$\tilde{U}_1 = \exp\left[-i \int d^3\mathbf{k} \; \phi_1 I_0 \right] \exp\left[\int d^3\mathbf{k} \; \tau_1 I_+ \right] \exp\left[\int d^3\mathbf{k} \; \log(1 + |\tau_1|^2) I_0 \right] \exp\left[-\int d^3\mathbf{k} \; \tau_1^* I_- \right] \tag{33}$$

and

$$\tilde{U}_2 = \exp\left[-i \int d^3\mathbf{k} \; \phi_2 T_0 \right] \exp\left[\int d^3\mathbf{k} \; \tau_2 T_+ \right] \exp\left[\int d^3\mathbf{k} \; \log(1 + |\tau_2|^2) T_0 \right] \exp\left[-\int d^3\mathbf{k} \; \tau_2^* T_- \right], \tag{34}$$

then the differential equation for $\tilde{U}$,

$$i\,\frac{d\tilde{U}}{dt}=\tilde{H}\tilde{U},$$

separates into two independent equations for $\tilde{U}_1$ and $\tilde{U}_2$. We show this as follows:

$$i\,\frac{d\tilde{U}}{dt}=i\,\frac{d\tilde{U}_1}{dt}\,\tilde{U}_2+i\tilde{U}_1\,\frac{d\tilde{U}_2}{dt}=(\tilde{H}_1+\tilde{H}_2)\tilde{U}_1\tilde{U}_2. \tag{35}$$

This is the sum of the two equations:

$$\left[i\,\frac{d\tilde{U}_1}{dt}=\tilde{H}_1\tilde{U}_1\right]\tilde{U}_2 \tag{36}$$

and

$$\tilde{U}_1\left[i\,\frac{d\tilde{U}_2}{dt}=\tilde{H}_2\tilde{U}_2\right]. \tag{37}$$

These are independent differential equations for $\tilde{U}_1$ and $\tilde{U}_2$, each equation containing elements of only one SU(2) algebra. When we insert our ansatz for $\tilde{U}_1$ and $\tilde{U}_2$ into the above differential equations, we obtain differential equations for the coefficients τ_1, τ_2, ϕ_1, and ϕ_2. One can proceed to solve these differential equations in precisely the same manner as in the one-dimensional case.[17]

Let

$$z=\tau\,\exp(-i\phi+i\gamma). \tag{38}$$

The resulting differential equation for z_1 is

$$i\dot{z}_1=-\tfrac{1}{2}(\dot{\gamma}\,\sin\,\alpha+i\dot{\alpha})+2[\epsilon(k)-\dot{\gamma}\,\cos\,\alpha]z_1+\tfrac{1}{2}(\dot{\gamma}\,\sin\,\alpha-i\dot{\alpha})z_1^2. \tag{39}$$

The corresponding differential equation for z_2 is

$$i\dot{z}_2=-\tfrac{1}{2}(-\dot{\gamma}\,\sin\,\alpha+i\dot{\alpha})+2[\epsilon(k)+\dot{\gamma}\,\cos\,\alpha]z_2+\tfrac{1}{2}(-\dot{\gamma}\,\sin\,\alpha-i\dot{\alpha})z_2^2. \tag{40}$$

One can write $\dot{\alpha}$ and $\dot{\gamma}$ explicitly, in terms of the electric field and vector potential. The expression for $\dot{\alpha}$ is

$$\dot{\alpha}=\left(\frac{e}{\epsilon^2}\right)\frac{[(\mathbf{k}-e\mathbf{A})\times\mathbf{E}]\cdot(\mathbf{k}\times\mathbf{A})+m^2(\mathbf{E}\cdot\mathbf{A})}{\sqrt{k_0^2\mathbf{A}^2-(\mathbf{A}\cdot\mathbf{k})^2}}, \tag{41}$$

with $\dot{\alpha}=0$ at $t=-\infty$. The expression for $\dot{\gamma}$ is

$$\dot{\gamma}=-\frac{\mu k_0|\mathbf{A}\times\mathbf{E}|}{k_0^2\mathbf{A}^2-(\mathbf{A}\cdot\mathbf{k})^2}. \tag{42}$$

Note that only $\dot{\gamma}$ appears explicitly in the equations; when calculating $|\tau|$ (see Eq. (43) below), the initial condition on γ is irrelevant. When $\mathbf{A}$ and $\mathbf{E}$ are parallel ($\dot{\gamma}=0$), Eqs. (39) and (40) reduce to the corresponding equation calculated for the one-dimensional case.[17] When $\dot{\gamma}\neq 0$, the two-dimensional nature of the equations is manifested.

Finally, one can calculate the rate of pair production ω via S_0. The above definitions give

$$S_0=\langle 0_i|\tilde{U}|0_i\rangle=\exp\left[i\int d^3\mathbf{k}\left(\frac{\phi_1+\phi_2}{2}\right)\right]\exp\left[-\int d^3\mathbf{k}\,\log\sqrt{(1+|\tau_1|^2)(1+|\tau_2|^2)}\right]. \quad (43)$$

Then

$$|S_0|^2=|\langle 0_i|\tilde{U}|0_i\rangle|^2=\exp\left\{-\int d^3\mathbf{k}\,\log[(1+|z_1|^2)(1+|z_2|^2)]\right\}. \quad (44)$$

Once the differential equations have been solved for z_1 and z_2 (in general, this must be done numerically), the rate of pair production is easily obtained.

To verify this approach, consider the very simple example of a uniform, static electric field which is oriented at an angle θ to the x-axis. Then $|\mathbf{E}\times\mathbf{A}|=0$, and $\dot{\gamma}=0$. In this case, $\dot{\alpha}$ reduces to

$$\dot{\alpha}=\frac{ek_\perp E_0}{\epsilon^2}, \quad (45)$$

where

$$k_\perp=\sqrt{k_0^2-k_\parallel^2}=\sqrt{k_0^2-\frac{(\mathbf{k}\cdot\mathbf{E})^2}{\mathbf{k}^2}}. \quad (46)$$

With these values, the expressions for $i\dot{z}_1$ and $i\dot{z}_2$ are identical, and each is equal to the expression which applied in the one-dimensional case.[17] With $z_1=z_2$, Eq. (44) reduces to

$$|S_0|^2=|\langle 0_i|\tilde{U}|0_i\rangle|^2=\exp\left[-2\int d^3\mathbf{k}\,\log(1+|z_1|^2)\right], \quad (47)$$

which again is identical to the one-dimensional result.[17] In this case, the rate of pair production has been shown to be equal to that calculated by Schwinger, given in Eq. (1).

III. CONCLUSIONS

We have shown that the Hamiltonian describing fermion pair production from an arbitrarily time-varying electric field in two dimensions is encompassed by an SO(4) algebra. We have also explicitly constructed the two commuting SU(2) algebras in the direct product SU(2)×SU(2), which is isomorphic to this SO(4) algebra. The one-dimensional problem is described by an SU(2) algebra in the $j=1$ representation, while the two-dimensional problem is described by two SU(2) algebras in the $j=\frac{1}{2}$ representation. However, when the one-dimensional problem and the two-dimensional problem are each considered in the lowest-dimensional representation, one sees that the off-diagonal elements are real in the one-dimensional case and complex in the two-dimensional case. The extra degree of freedom present in the two-dimensional case is manifested in this way. Indeed, it can easily be shown that the factor γ in Eq. (38) is the Berry's phase.

This group-theoretic approach may simplify the calculation of the rate of fermion pair production from the field, since the two-dimensional problem can in this way be reduced to two one-dimensional problems. We verify our approach by showing that the Schwinger formula for pair production can be obtained for the special case of a uniform, static electric field.

Hidden local gauge invariance in the one-dimensional Heisenberg *XXZ* model with the general boundary terms is studied in the framework of the quantum inverse scattering method. The Bethe ansatz equations are established for the model with the special boundary terms. Our results show that the Hamiltonian and its eigenvectors are explicitly gauge dependent whereas the energy eigenvalues and the Bethe ansatz equations are gauge invariant. © *1996 American Institute of Physics.* [S0022-2488(95)01512-6]

I. INTRODUCTION

One of the recent developments of the theory of completely integrable quantum systems is Sklyanin's work[1] on the reflection equations (RE),[2] who showed that there is a variant of the usual formalism of the quantum inverse scattering method (QISM)[3–5] which may be used to describe systems on a finite interval with independent boundary conditions on each end. Central to his approach is the introduction of a new algebraic structure-RE called the quantum Sklyanin algebras. The latter plays the same role in the theory of a completely integrable quantum systems with boundary terms as the quantum Yang–Baxter algebras (QYBA) do in the usual formalism of QISM. Now much attention has been paid to the solutions of RE which present the boundary K matrices compatible with the integrability.[6–9] Recently, the general boundary K matrices have been constructed by de Vega and González Ruiz[6] for the six-vertex model.

On the other hand, de Vega and Lopes[10] studied an interesting feature of completely integrable quantum systems with periodic boundary conditions, i.e., what they referred to as hidden local gauge invariance (see also, Refs. 5, 11–13). They showed that the combination of the quantum integrability, i.e., the existence of the R matrix, with a global gauge transformation group leads to an Abelian local gauge invariance in the Heisenberg *XXZ* model. As a consequence, one may construct a more general family of completely integrable quantum systems. Further, they also showed that in this model the exact energy spectrum turns out to be gauge invariant whereas the eigenvectors are explicit gauge dependent. Thus, it seems interesting to explore hidden local gauge invariance in completely integrable lattice spin systems with boundary terms.

The aim of this article is to give a detailed study of hidden local gauge invariance in the one-dimensional (1-D) Heisenberg *XXZ* model with the general boundary terms. We show that the Hamiltonian and its eigenvectors are explicitly gauge dependent whereas the energy eigenvalues and the Bethe ansatz equations are gauge invariant.

The outline of this article is the following. In Sec. II, we define the basic notations for later use. In Sec. III, we discuss hidden local gauge invariance in the 1-D Heisenberg *XXZ* model with the general boundary terms. In Sec. IV, we present a derivation of the Bethe ansatz equations for

[a)]Mailing address: Department of Physics, Chongqing University, Chongqing, Sichuan 630044, People's Republic of China.

the gauge-transformed system with the special boundary terms. Lastly, Sec. V is devoted to the conclusions.

II. BASIC NOTATIONS

To describe completely integrable quantum systems on a finite interval with independent boundary conditions on each end, Sklyanin[1] has introduced two algebras $\mathscr{T}_+$ and $\mathscr{T}_-$ associated with a given R matrix, defined by the generators $(\mathscr{T}_+)_{\alpha\beta}$ and $(\mathscr{T}_-)_{\alpha\beta}$ ($\alpha,\beta=1,2,...,\dim W_0, W_0$ is the auxiliary space), and by the relations (called Sklyanin relations)

$$R_{12}(u_1-u_2)\overset{1}{\mathscr{T}}_-(u_1)R_{12}(u_1+u_2)\overset{2}{\mathscr{T}}_-(u_2)=\overset{2}{\mathscr{T}}_-(u_2)R_{12}(u_1+u_2)\overset{1}{\mathscr{T}}_-(u_1)R_{12}(u_1-u_2) \tag{1}$$

and

$$R_{12}(-u_1+u_2)\overset{1}{\mathscr{T}}{}^{t_1}_+(u_1)R_{12}(-u_1-u_2-2\eta)\overset{2}{\mathscr{T}}{}^{t_2}_+(u_2)$$

$$=\overset{2}{\mathscr{T}}{}^{t_2}_+(u_2)R_{12}(-u_1-u_2-2\eta)\overset{1}{\mathscr{T}}{}^{t_1}_+(u_1)R_{12}(u_1-u_2), \tag{2}$$

respectively. Here $\overset{1}{X}\equiv X\otimes id_{V_2}$, $\overset{2}{X}\equiv id_{V_1}\otimes X$ for any matrix $X\in\mathrm{End}(V)(V=W_0)$. It follows that the transfer matrices $\tau(u)$ defined by

$$\tau(u)=\mathrm{tr}\,\mathscr{T}_+(u)\mathscr{T}_-(u) \tag{3}$$

commute with each other for different values of the spectral parameter u. Therefore, one may consider $\tau(u)$ (3) as a generating function of the integrals of motion for quantum systems defined by specifying some concrete representations of the algebras $\mathscr{T}_\pm$ on the quantum spaces $W_\pm$. A class of important realizations of the algebras $\mathscr{T}_\pm$ are provided by the 1-D lattice spin models with boundary terms. In these cases, the explicit realizations of the algebras $\mathscr{T}_\pm$ may be chosen in the form

$$\mathscr{T}_-(u)=T(u)K_-(u)T^{-1}(-u) \tag{4}$$

and

$$\mathscr{T}_+(u)=K_+(u), \tag{5}$$

respectively. Here $K_\pm(u)$ are representations of $\mathscr{T}_\pm$ in C^1, i.e., C-number matrices, while $T(u)\equiv L_N(u)\cdots L_1(u)$ is the representation of the associative algebra T on the quantum space $\mathscr{H}\equiv W_N\otimes W_{N-1}\cdots\otimes W_1$. The algebra T is defined by the generators $T_{\alpha\beta}(u)$ ($\alpha,\beta=1,2,...,\dim W_0$), considered as the elements of the square matrix $T(u)$, and by the relations (QYBA)

$$R(u_1-u_2)\overset{1}{T}(u_1)\overset{2}{T}(u_2)=\overset{2}{T}(u_2)\overset{1}{T}(u_1)R(u_1-u_2). \tag{6}$$

Here and hereafter, we assume that the L matrix $L_n(u)$ coincides with the R matrix $R(u)$ in the space $W_n\otimes W_0$

$$L_n(u)=R_{n0}(u). \tag{7}$$

Further, $R(u)$ and $K_-(u)$ satisfy $R_{mn}(0)=P_{mn}$ and $K_-(0)=1$, respectively, and P_{mn} is the permutation operator in $W_m\otimes W_n$, satisfying $P(x\otimes y)=y\otimes x$, for $x,y\in W$. It follows that there exists a relation between the transfer matrix $\tau(u)$ and the Hamiltonian for the lattice spin open chain:

$$\tau'(0)=2H\ \mathrm{tr}\ K_+(0)+\mathrm{tr}\ K'_+(0), \tag{8}$$

where

$$H=\sum_{j=1}^{N-1} H_{j,j+1}+\frac{1}{2}\ \mathrm{tr}\ P_{10}K'_-(0)P_{10}^{-1}+\frac{\mathrm{tr}\ K_+(0)L'_{N0}(0)P_{N0}}{\mathrm{tr}\ K_+(0)}, \tag{9}$$

with

$$H_{j,j+1}=L'_{j,j+1}(0)P_{j,j+1}^{-1}. \tag{10}$$

Here the prime denotes the derivative with respect to the spectral parameter u.

III. HIDDEN LOCAL GAUGE INVARIANCE

Let us now study hidden local gauge invariance in the 1-D Heisenberg *XXZ* open chain with the general boundary terms. Notice that for a given R matrix $R(u)$, if there exist $N\times N$ ($N=\dim W_0$) matrices g and h satisfying

$$[g\otimes g,\ R]=0, \tag{11}$$

$$[h\otimes h,\ R]=0, \tag{12}$$

then the Sklyanin relations (1) and (2) are invariant under the gauge transformation

$$L_j^{(g)}(u)=g(k_j)L_j(u)h^{-1}(l_j). \tag{13}$$

Further, the transformed transfer matrix $\tau^{(g)}(u)$ defined by

$$\tau^{(g)}(u)=\mathrm{tr}\ K_+(u)T^{(g)}(u)K_-(u)(T^{(g)}(-u))^{-1}, \tag{14}$$

with

$$T^{(g)}(u)=L_N^{(g)}(u)\cdots L_1^{(g)}(u) \tag{15}$$

and the transformed Hamiltonian $H^{(g)}$ still satisfy Eq. (8). That is,

$$\tau^{(g)\prime}(0)=\sum_{j=1}^{N-1} H_{j,j+1}^{(g)}+\frac{1}{2}\ \mathrm{tr}\ P_{10}^{(g)}K'_-(0)(P_{10}^{(g)})^{-1}+\frac{\mathrm{tr}\ K_+(0)(L_{N0}^{(g)}(0))'(P_{N0}^{(g)})^{-1}}{\mathrm{tr}\ K_+(0)}, \tag{16}$$

where

$$H_{j,j+1}^{(g)}=P_{j+1,0}^{(g)}L_{j,0}^{\prime(g)}(0)(P_{j,0}^{(g)})^{-1}(P_{j+1,0}^{(g)})^{-1}, \tag{17}$$

with

$$P_{j,0}^{(g)}=g(k_j)P_{j,0}h^{-1}(l_j). \tag{18}$$

For the 1-D Heisenberg *XXZ* open chain, the L matrix is

$$L_j(u)=\begin{pmatrix} \frac{\sinh(u+\eta)+\sinh u}{2}+\frac{\sinh(u+\eta)-\sinh u}{2}\sigma_j^z & \sinh\ \eta\sigma_j^- \\ \sinh\ \eta\sigma_j^+ & \frac{\sinh(u+\eta)+\sinh u}{2}-\frac{\sinh(u+\eta)-\sinh u}{2}\sigma_j^z \end{pmatrix}, \tag{19}$$

with the corresponding R matrix

$$R(u)=\begin{pmatrix} \sinh(u+\eta) & 0 & 0 & 0 \\ 0 & \sinh u & \sinh\ \eta & 0 \\ 0 & \sinh\ \eta & \sinh u & 0 \\ 0 & 0 & 0 & \sinh(u+\eta) \end{pmatrix}. \tag{20}$$

According to de Vega and González,[6] the boundary K matrices $K_\pm$ may be taken as

$$K_-(u)=K_-(u,k_-,\lambda_-,u_-,\xi_-)=\begin{pmatrix} k_-\ \sinh(u+\xi_-) & u_-\ \sinh 2u \\ \lambda_-\ \sinh 2u & -k_-\ \sinh(u-\xi_-) \end{pmatrix}, \quad k_-=\frac{1}{\sinh\ \xi_-} \tag{21}$$

and

$$K_+(u)=K_+(u,k_+,\lambda_+,u_+,\xi_+)=\begin{pmatrix} k_+\ \sinh(u+\eta+\xi_+) & u_+\ \sinh 2(u+\eta) \\ \lambda_+\ \sinh 2(u+\eta) & -k_+\ \sinh(u-\xi_++\eta) \end{pmatrix}, \tag{22}$$

respectively. From Eqs. (11), (12), and (20), we get

$$g(k_j)=h(k_j)=\begin{pmatrix} e^{ik_j} & 0 \\ 0 & e^{-ik_j} \end{pmatrix}, \quad k_j\in R. \tag{23}$$

From Eqs. (14)–(18), we immediately obtain the transformed Hamiltonian for the 1-D Heisenberg *XXZ* model with the general boundary terms

$$\begin{aligned} H^{(9)}=&\sum_{j=1}^{N-1}\left[\cosh\ \eta\sigma_j^z\sigma_{j+1}^z+2e^{2i(k_j-l_{j+1})}\sigma_j^-\sigma_{j+1}^++2e^{-2i(k_j-l_{j+1})}\sigma_j^+\sigma_{j+1}^-\right] \\ &+\sinh\ \eta\Bigg[\coth\ \xi-\sigma_1^z+\coth\ \xi_+\sigma_N^z+2\lambda_-e^{2il_1}\sigma_1^-+\frac{2\lambda_+}{k_+\ \sinh\ \xi_+}e^{2ik_N}\sigma_N^- \\ &+2u_-e^{-2il_1}\sigma_1^++2\frac{u_+}{k_+\ \sinh\ \xi_+}e^{-2ik_N}\sigma_N^+\Bigg]. \end{aligned} \tag{24}$$

In particular, setting $\lambda_\pm=0$, $u_\pm=0$, and $k_+=1$, one gets

$$\begin{aligned} H^{(g)}=&\sum_{j=1}^{N-1}\left[\cosh\ \eta\sigma_j^z\sigma_{j+1}^z+2e^{2i(k_j-l_{j+1})}\sigma_j^-\sigma_{j+1}^++2e^{-2i(k_j-l_{j+1})}\sigma_j^+\sigma_{j+1}^-\right] \\ &+\sinh\ \eta(\sigma_1^z\coth\ \xi_-+\sigma_N^z\coth\ \xi_+). \end{aligned} \tag{25}$$

This is the transformed Hamiltonian of the model first solved in Ref. 14 by the coordinate Bethe ansatz approach.

IV. BETHE ANSATZ EQUATIONS

The diagonalization of the transfer matrix for the model Hamiltonian (24) is not an easy problem,[6] so we restrict ourselves to study the model Hamiltonian (25). This can be done by using the algebraic Bethe ansatz approach modified by Sklyanin.[1]

Repeating the same reasoning as in Ref. 1, we can diagonalize the transfer matrix for the Hamiltonian (25)

$$\tau^{(g)}(u)|v_1\cdots v_m\rangle = V^{(g)}(u)|v_1\cdots v_m\rangle, \tag{26}$$

where the eigenvalue $V^{(g)}(u)$ is given by

$$\begin{aligned} V^{(g)}(u) = \frac{(-1)^N}{\sinh(2u+\eta)\sinh\ \eta_-\,\delta\{T^{(g)}(-u-(1/2)\,\eta)\}}\Bigg[& \sinh(2u+2\,\eta)\sinh(u+\xi_+) \\ & \times\sinh(u+\xi_-)\sinh^{2N}(u+\eta)\prod_{m=1}^{M}\ \frac{\sinh(u-v_m-(1/2)\,\eta)\sinh(u+v_m-(1/2)\,\eta)}{\sinh(u-v_m+(1/2)\,\eta)\sinh(u+v_m+(1/2)\,\eta)} \\ & +\sinh 2u\ \sinh(u-\xi_++\eta)\sinh(u-\xi_-+\eta)\sinh^{2N} \\ & \times u\prod_{m=1}^{M}\ \frac{\sinh(u-v_m+(3/2)\,\eta)\sinh(u+v_m+(3/2)\,\eta)}{\sinh(u-v_m+(1/2)\,\eta)\sinh(u+v_m+(1/2)\,\eta)}\Bigg], \end{aligned} \tag{27}$$

with $\delta\{T^{(g)}(-u-\frac{1}{2}\eta)\}$ the quantum determinant of the matrix $T^{(g)}(-u-\frac{1}{2}\eta)$

$$\delta\{T^{(g)}(-u-\tfrac{1}{2}\eta)\} = \sinh^N(u+\eta)\sinh^N(u-\eta). \tag{28}$$

This result holds, provided that the parameters $\{v_1, v_2, \ldots, v_m\}$ satisfy the Bethe ansatz equations

$$\begin{aligned} \prod_{\substack{k=1\\k\neq m}}^{M}\ \frac{\sinh(v_m-v_k+\eta)\sinh(v_m+v_k+\eta)}{\sinh(v_m-v_k-\eta)\sinh(v_m+v_k-\eta)} & \\ = \frac{\sinh(v_m+\xi_+-(1/2)\,\eta)\sinh(v_m+\xi_--(1/2)\,\eta)\sinh^{2N}(v_m+(1/2)\,\eta)}{\sinh(v_m-\xi_++(1/2)\,\eta)\sinh(v_m-\xi_-+(1/2)\,\eta)\sinh^{2N}(v_m-(1/2)\,\eta)}, & \\ (m=1,2,\ldots,M). & \end{aligned} \tag{29}$$

Since the transformed transfer matrices $\tau^{(g)}(u)$ for different values of the spectral parameter u commute, the eigenvectors are u-independent and then the eigenvalues of the Hamiltonian (25) can be determined from Eq. (8). Explicitly, we have

$$\begin{aligned} E^{(g)} = & -\frac{\coth\ \eta}{\sinh\ \xi_-}+\coth 2\eta+\frac{1}{2}\,(1+\coth\ \xi_-)-\frac{1}{2}\tanh\ \eta+N\ \coth\ \eta \\ & +\sinh\ \eta\sum_{m=1}^{M}\ \frac{1}{\sinh(v_m+(1/2)\,\eta)\sinh(v_m-(1/2)\,\eta)}. \end{aligned} \tag{30}$$

From this we see that the eigenvalues of the gauge-transformed transfer matrix $\tau^{(g)}(u)$ and hence those of the Hamiltonian as well as the Bethe ansatz equations are gauge invariant whereas the Hamiltonian and its eigenvectors are explicitly gauge dependent. These results are different from those for the 1-D Heisenberg *XXZ* model with the periodic boundary conditions.[7] Evidently, this difference results from the fact that the transfer matrix for the open chain involves both $T(u)$ and

$T^{-1}(-u)$, while the corresponding transfer matrix in the case of the periodic boundary conditions involves only $T(u)$. This implies that the eigenvalues of the transfer matrix for the open chain on the pseudovacuum are gauge invariant, while the eigenvalues of the transfer matrix for the periodic chain are not. Thus, our conclusion must be a consequence of the fact that the gauge factors appearing in the eigenvalues of the transfer matrix as well as in the Bethe ansatz equations only originate from the eigenvalues of the transfer matrix on the pseudovacuum.

V. CONCLUSION

In this article we have studied hidden local gauge invariance in the 1-D Heisenberg *XXZ* model with the general boundary terms in the framework of QISM. The Bethe ansatz equations are established for the model with the special boundary terms. From this we have concluded that the Hamiltonian and its eigenvectors are explicitly gauge dependent whereas the energy eigenvalues and the Bethe ansatz equations are gauge invariant.

In conclusion we would like to point out that the model Hamiltonian (25) may be mapped into a 1-D lattice model of fermions by the Jordan–Wigner transformation.[15–17] Since the model (25) has the quantum symmetry $U_q(su_2)$ for a special choice of boundary terms,[18–20] we may expect that the 1-D lattice model of fermions (the 1-D small-polaron model) for a special choice of the boundary terms also has the quantum symmetry $U_q(su_2)$. This requires us to construct a new realization of the generators of the quantum algebra $U_q(su_2)$ in terms of the lattice fermion operators. Thus, further work is required for an understanding of the unclear algebraic structure of lattice models of fermions with boundary terms.

ACKNOWLEDGMENT

We would like to express our sincere thanks to Jing-Song He for his generous help in the preparation of the manuscript.

I. INTRODUCTION

The problem of determination of a field created by the unaccelerated point charge is the eldest problem of classical electrodynamics (see Ref. 1, and references therein). We discuss this problem from the point of view of the Goursat problem (GP) in which the boundary conditions are given over the characteristics $\xi=ct-z$ and $\eta=ct+z$.[2,3] In such a formulation of the problem the fundamental solutions (FS) of the wave equation (WE) (the so-called Riemann functions) are classified as belonging to the two-dimensional Minkowski space M^2.[4] In particular, in the timelike space $M^2_{(+)}$, where $\xi\eta=c^2t^2-z^2\geqslant 0$ the Riemann function has a form:[5]

$$G_R^{(+)}=J_0(\sqrt{\xi\eta(-\Delta_\perp)})|i\rangle, \tag{1}$$

where J_0 is the Bessel function of the first kind and zero order, $\Delta_\perp=(\partial^2/\partial x_1^2)+(\partial^2/\partial x_2^2)$ is the two-dimensional Laplace operator, and $|i\rangle$ is the boundary condition on the characteristics $\xi=0$ and $\eta=0$. Using this boundary value in the form of the two-dimensional delta function we obtain the Riemann function $G_R^{(+)}$:[4,5]

$$G_R^{(+)}=\frac{\delta(\sqrt{\xi\eta}-x_\perp)}{2\pi x_\perp}=\frac{\delta(|t|-r/c)}{2\pi cr}=\frac{1}{\pi c^2}\,\delta(t^2-r^2/c^2), \tag{2}$$

where $x_\perp=\sqrt{x_1^2+x_2^2}$.

In spacelike $M^2_{(-)}$ where $-\xi\eta=z^2-c^2t^2\geqslant 0$ the Riemann function $G_R^{(-)}$ is[5]

$$G_R^{(-)}=J_0(\sqrt{(-\xi\eta)\Delta_\perp})|i\rangle, \tag{3}$$

where $|i\rangle$ is a nonlocalized and smooth delta function (here we have used the Feinberg terminology). It is constructed from the Macdonald function K_0:

$$|i\rangle=\frac{1}{2\pi}\int_0^\infty K_0(kx_\perp)k\,dk=\frac{1}{2\pi x_\perp^2}. \tag{4}$$

After the substitution of Eq. (4) into Eq. (3) we can find the FS of WE:[5]

$$G_R^{(-)}=\frac{1}{2\pi}\,\frac{1}{(-\xi\eta+x_\perp^2)}=\frac{1}{2\pi}\,\frac{1}{(r^2-c^2t^2)}>0. \tag{5}$$

The GP solutions with the Riemann function $G_R^{(+)}$ for WE with the source ρ:

$$\Box^2\phi(x_1,x_2,z,t)=-4\pi\rho(x_1,x_2,z,t)$$

and zero boundary conditions on the characteristics have the following form:

$$\phi(x_1,x_2,z,t)=\int_0^{ct-z}d\xi'\int_0^{ct+z}d\eta'\int(d\mathbf{x}'_\perp)\,\frac{\delta(\sqrt{(ct-z-\xi')(ct+z-\eta')}-|\mathbf{x}_\perp-\mathbf{x}'_\perp|)}{2|\mathbf{x}_\perp-\mathbf{x}'_\perp|}$$
$$\times Q(x'_1,x'_2,\xi',\eta') \tag{6}$$

in $M^2_{(+)}$ space and, respectively,

$$\phi(x_1,x_2,z,t)=-\frac{1}{2\pi}\int_0^{z-ct}d\xi'\int_0^{ct+z}d\eta'\int d(\mathbf{x}'_\perp)$$
$$\times\frac{Q(x'_1,x'_2,\xi',\eta')}{(z-ct-\xi')(z+ct-\eta')+|\mathbf{x}_\perp-\mathbf{x}'_\perp|^2} \tag{7}$$

in $M^2_{(-)}$ space, where $Q(x_1,x_2,\xi,\eta)=\rho[x_1,x_2(\eta-\xi)/2,(\eta+\xi)/2c]$.

The existence and uniqueness of the GP solutions in the general case should be a subject of the special consideration and will not be discussed here.

The aim of this paper is to obtain the solutions of the WE on the background of expressions (6) and (7) for the unaccelerated source and their comparison with the Kirchhoff formula results, in which only the retarded potential has been used. Special attention will be paid to the performance of the Lorentz condition.

II. THE FIELD OF A CHARGE MOVING WITH THE SUBLUMINAL VELOCITY

Let the charge density ρ and the current density J_z of the point charge (source) which moves with a constant velocity $v<c$ have the form

$$\rho(x_1,x_2,z,t)=e\,\delta(x_1,x_2)\,\delta(z-vt),\quad J_z=\rho v \tag{8}$$

or, in the characteristic variables,

$$\rho(x_1,x_2,z,t)=Q(x_1,x_1,\xi,\eta)=\frac{2ec}{c+v}\,\delta(\xi-\alpha\eta)\,\delta(x_1,x_2), \tag{9}$$

where the parameter α is

$$\alpha=\frac{c-v}{c+v}. \tag{10}$$

In the following we shall apply either formula (6) or (7) depending on the sign α.

For the charge at rest one has that $\alpha=1$, and the line $\xi=\eta$ belongs to the $M^2_{(+)}$ space. In this case formula (6) gives the potential of the immovable charge[5]

$$\phi=e\Theta(\sqrt{\xi\eta}-x_\perp)/r,\quad x_\perp=\sqrt{x_1^2+x_2^2}, \tag{11}$$

where $\Theta(\tau)$ is the Heaviside step function. The condition $\sqrt{\xi\eta}>x_\perp$ is equivalent to the condition $c|t|>r$. The potential (11) is not the solution of the Maxwell equations for the charge at rest because it does not comply with the Lorentz condition $(1/c)(\partial\phi/\partial t)=0$, but it satisfies the more weak condition $\Box^2[(1/c)(\partial\phi/\partial t)]=0$.

The possibility of the existence of electrodynamics with the weak Lorentz condition was considered by many authors.[6–8] To satisfy the Lorentz condition we determine the vector potential **A**, obeying the homogeneous WE:

$$\mathbf{A}=\nabla\chi, \quad \text{div } \mathbf{A}=\Delta\chi=-\frac{1}{c}\frac{\partial\phi}{\partial t}=-e\epsilon(t)\delta(\sqrt{\xi\eta}-x_\perp)/x_\perp, \tag{12}$$

where $\epsilon(t)$ is the sign function. The scalar function χ of the gauge transformation satisfies not only the homogeneous wave equation but also the inhomogeneous nonrelativistic Poisson equation (12).

Using the FS of the Poisson equation $-1/4\pi|\mathbf{r}-\mathbf{r}'|$ we obtain the partial solution of Eq. (12) in the form

$$\chi=e\epsilon(t)\left[\frac{c|t|}{r}\,\Theta(x_\perp-\sqrt{\xi\eta})+\Theta(\sqrt{\xi\eta}-x_\perp)\right] \tag{13}$$

with the time derivative $(1/c)(\partial\chi/\partial t)=e\Theta(x_\perp-\sqrt{\xi\eta})/r$. Next we calculate the field strength created by the potentials **A** and ϕ:

$$\mathbf{E}=-\frac{1}{c}\frac{\partial\mathbf{A}}{\partial t}-\nabla\phi=-\nabla\left(\frac{1}{c}\frac{\partial\chi}{\partial t}+\phi\right)=-e\nabla\left(\frac{\Theta(x_\perp-\sqrt{\xi\eta})}{r}+\frac{\Theta(\sqrt{\xi\eta}-x_\perp)}{r}\right)=\frac{e\mathbf{r}}{r^3}. \tag{14}$$

Thus, the new Coulomb solution (11) differs from the usual Coulomb potential by the gauge.

Next we consider the subluminal source that has the velocity $v\to c-0$ (it is the ultrarelativistic case). In this case the parameter $\alpha\to+0$ and formula (6) gives the potential

$$\phi=e\Theta(\sqrt{\xi\eta}-x_\perp)/|\xi|, \quad A_z=\frac{v}{c}\,\phi=\phi. \tag{15}$$

The potential (15) has the singularity on the characteristics $\xi=0$. For the point source with the density $\rho=e\delta(x_1,x_2)\delta(z-ct)$ it should be multiplied by $\Theta(\xi)$ [this means that the variables $\xi=ct-z$, $\eta=ct+z$ in Eq. (15) belong to $M^2_{(+)}$—the future space], or by $-\Theta(-\xi)$ (the variables ξ,η belong to $M^2_{(+)}$—the past space). The solution (15) does not satisfy the Lorentz condition either because

$$\frac{1}{c}\frac{\partial\phi}{\partial t}+\frac{\partial A_z}{\partial z}=\frac{e\delta(\sqrt{\xi\eta}-x_\perp)\Theta(\xi)}{x_\perp}\neq 0. \tag{16}$$

To satisfy the Lorentz condition in the Lorentz gauge we introduce the transverse vector **A** by the relations

$$A_i=\frac{\partial\chi}{\partial x_i}, \quad \partial_i A_i=\Delta_\perp\chi=-\frac{2\partial\phi}{\partial\eta}=-\frac{e\delta(\sqrt{\xi\eta}-x_\perp)}{x_\perp}\,\Theta(\xi), \tag{17}$$

where $i=1,2$ and the scalar function χ obeys not only the homogeneous WE but also the two-dimensional Poisson equation with the fundamental solution

$$\frac{1}{2\pi}\log\sqrt{(x_1-x_1')^2+(x_2-x_2')^2}. \tag{18}$$

The partial solution of Eq. (17):

$$\chi=-e[\log x_\perp\Theta(x_\perp-\sqrt{\xi\eta})+\log\sqrt{\xi\eta}\Theta(\sqrt{\xi\eta}-x_\perp)]\Theta(\xi) \tag{19}$$

creates the potentials

$$A_i=\frac{\partial\chi}{\partial x_i}=-e(x_i/x_\perp^2)\Theta(x_\perp-\sqrt{\xi\eta})\Theta(\xi) \tag{20}$$

that enables us to find the strengths **E** and **H**. It will be convenient to introduce the cylindrical coordinates with the basic unit vectors $\mathbf{x}^0$, $\boldsymbol{\psi}^0$, $\mathbf{z}^0$, by the relations

$$\mathbf{x}^0=\left(\frac{x_1}{x_\perp},\frac{x_2}{x_\perp},0\right),\quad \boldsymbol{\psi}^0=\left(-\frac{x_2}{x_\perp},\frac{x_1}{x_\perp},0\right),\quad \mathbf{z}^0=(0,0,1). \tag{21}$$

Thus the electric field strength **E** is

$$\mathbf{E}=\mathbf{x}^0E_x+\mathbf{z}^0E_z, \tag{22}$$

where

$$E_x=e\left(\frac{\delta(\sqrt{\xi\eta}-x_\perp)}{x_\perp}\frac{z}{x_\perp}\Theta(\xi)+\frac{\delta(\xi)}{x_\perp}\right)=e\left(\frac{\delta(t-r/c)}{cr}\frac{z}{x_\perp}\Theta(\xi)+\frac{\delta(\xi)}{x_\perp}\right), \tag{23}$$

$$E_z=-e\left(\frac{\delta(\sqrt{\xi\eta}-x_\perp)}{x_\perp}\right)\Theta(\xi)=-e\,\frac{\delta(t-r/c)}{cr}\Theta(\xi), \tag{24}$$

and the magnetic field strength is

$$\mathbf{H}=\mathrm{rot}\,\mathbf{A}=e\boldsymbol{\psi}^0\left(\frac{\delta(t-r/c)}{cr}\frac{ct}{x_\perp}\Theta(\xi)+\frac{\delta(ct-z)}{x_\perp}\right). \tag{25}$$

As follows from formulas (23) and (25), the field strengths can be rewritten in the form

$$\mathbf{E}=\mathbf{E}^{(0)}+\mathbf{E}^{(1)},\quad \mathbf{H}=\mathbf{H}^{(0)}+\mathbf{H}^{(1)}, \tag{26}$$

where

$$\mathbf{E}^{(1)}=e\,\frac{\delta(\sqrt{\xi\eta}-x_\perp)}{x_\perp}\Theta(\xi)\left(\mathbf{x}^0\frac{z}{x_\perp}-\mathbf{z}^0\right)=e\,\frac{\delta(t-r/c)}{cr}\Theta(\xi)(\mathbf{x}^0\cot\theta-\mathbf{z}^0), \tag{27}$$

$$\mathbf{H}^{(1)}=e\,\frac{\delta(\sqrt{\xi\eta}-x_\perp)}{x_\perp}\Theta(\xi)\boldsymbol{\psi}^0\frac{ct}{x_\perp}=e\,\frac{\delta(t-r/c)}{cr}\frac{\boldsymbol{\psi}^0}{\sin\theta}\Theta(\xi), \tag{28}$$

and

$$\mathbf{E}^{(0)}=e\,\frac{\delta(ct-z)}{x_\perp}\mathbf{x}^0=e\,\frac{\delta(ct-r\cos\theta)}{r\sin\theta}\mathbf{x}^0, \tag{29}$$

$$\mathbf{H}^{(0)}=e\,\frac{\delta(ct-r\cos\theta)}{r\sin\theta}\boldsymbol{\psi}^0, \tag{30}$$

where θ is the polar angle between the directions of the vectors $\mathbf{z}^0$ and $\mathbf{r}^0=\mathbf{r}/r=\mathbf{x}^0\sin\theta+\mathbf{z}^0\cos\theta$.

It is easy to verify that

$$|\mathbf{E}^{(1)}|=|\mathbf{H}^{(1)}|, \quad \mathbf{E}^{(1)}=\mathbf{H}^{(1)}\times\mathbf{r}^0, \quad \mathbf{H}^{(1)}=\mathbf{r}^0\times\mathbf{E}^{(1)}, \tag{31}$$

where $\mathbf{E}^{(1)}$ and $\mathbf{H}^{(1)}$ are called the radiation fields. The strengths $\mathbf{E}^{(0)}$ and $\mathbf{H}^{(0)}$ which fall off with the fixed r as $1/r^2$ must be called quasistationary. The electric field strength $\mathbf{E}^{(0)}$ plays an important role in the validity of Gauss' theorem

$$\int \text{div } \mathbf{E}(d\mathbf{r})= \oint \mathbf{E}^{(0)}\mathbf{r}^0 r^2 \, d\Omega = 2\pi e \int_0^\pi \delta(ct/r-\cos\,\theta)\sin\,\theta \, d\theta = 4\pi e. \tag{32}$$

The Poynting vector $\mathbf{S}$ which determines the energy flux at large distances from the point charge is connected with the radiation fields $\mathbf{E}^{(1)}$ and $\mathbf{H}^{(1)}$ only:

$$\mathbf{S}=\frac{c}{4\pi}\,\mathbf{E}^{(1)}\times\mathbf{H}^{(1)}=\frac{c}{4\pi}\,\mathbf{E}^{(1)^2}\mathbf{r}^0. \tag{33}$$

To end with the radiation one needs to consider the energy balance and the force balance following the Maxwell equations. The energy balance in the integral form for the solution of Eqs. (23)–(25) is represented by the formula

$$\int (d\mathbf{r})\,\frac{\partial}{\partial t}\left(\frac{E^2+H^2}{8\pi}\right)=-\int (d\mathbf{r})(\mathbf{JE})-\frac{c}{4\pi}\oint d\boldsymbol{\sigma}, \quad \mathbf{E}\times\mathbf{H}. \tag{34}$$

The term on the left-hand side of Eq. (34) represents, by itself, the change of the total electromagnetic field energy, besides in the wave zone ($r\to\infty$ or $t\to\infty$) it tends to zero. The latter means that the energy losses per time unit are equal to the energy emitted by the ultrarelativistic source

$$\int (d\mathbf{r})J_zE_z=-\frac{c}{4\pi}\oint d\boldsymbol{\sigma}, \quad \mathbf{E}\times\mathbf{H}. \tag{35}$$

The substitution of expressions (23)–(25) into Eq. (35) shows that the energy losses

$$\int (d\mathbf{r})J_zE_z=-e^2c\int_0^\infty k\,dk\to -ce^2k^2 \tag{36}$$

and the energy flux per the time unit which is integrated over the sphere of radius r:

$$\frac{c}{4\pi}\oint d\boldsymbol{\sigma}, \quad \mathbf{E}\times\mathbf{H}=\frac{e^2}{c}\,[\delta(t-r/c)]^2\to e^2\omega^2/c \tag{37}$$

are infinite. Being interpreted in terms of the cutting parameters ω and k they become finite. From Eqs. (35)–(37) we obtain the relation connecting the cutting parameters. It is valid only for the electromagnetic waves in vacuum:

$$k=\frac{\omega}{c}=\frac{2\pi}{\lambda}. \tag{38}$$

Let us calculate the volume density of the Lorentz force in the fields (23)–(25):

$$\mathbf{f}=\rho\mathbf{E}+\frac{1}{c}\,(\mathbf{J}\times\mathbf{H})=\rho\mathbf{E}^{(1)}+\frac{1}{c}\,(\mathbf{J}\times\mathbf{H}^{(1)})=\mathbf{z}^0\rho E_z=\mathbf{r}^0\rho E_z\,. \tag{39}$$

We recall that

$$\rho = e\,\delta(x_1,x_2)\,\delta(z-ct), \quad E_z = -e\,\frac{\delta(t-r/c)}{cr}\,\Theta(ct-z), \quad \mathbf{J}=(0,0,c\rho).$$

In Eq. (39) we take into account the relation

$$\rho\mathbf{E}^{(0)} + \frac{1}{c}\,(\mathbf{J}\times\mathbf{H}^{(0)}) = 0. \tag{40}$$

Except this, the multiplication by the above delta functions leads to the relations $z=r=ct$ and $\mathbf{z}^{(0)}=\mathbf{r}^{(0)}$.

Thus the Lorentz force $\mathbf{f}$ is indeed the spatial component of the four-dimensional vector f_μ:

$$f_\mu = (\mathbf{f}, i\rho E_z), \quad f_\mu^2 = f^2 - f_0^2 = 0. \tag{41}$$

This vector has a zero four-dimensional length, that is, the energy momentum tensor $T_{\mu v}$ of the field created by the ultrarelativistic source possesses the correct properties under the Lorentz transformation.

One can calculate the number of the photons N of the frequency ω emitted on the path $d=ct$:

$$N = (e^2\omega^2/c)(d/c)(1/h\omega) = 2\pi(e^2/hc)(d/\lambda). \tag{42}$$

In conclusion to this section we want to note that the solution (15) is absent in the classical electrodynamics. It appears only in the Goursat problem.[8]

III. THE FIELD OF SUPERLUMINAL SOURCE

For the point source that moves with the velocity $v>c$ the parameter $\alpha<0$ [see Eq. (10)] and the characteristic variables of the source belong to the space $M^2_{(-)}$. Using formula (7) we obtain[5]

$$\phi = -(e/R)\log(vt-z-R)/(vt-z+R), \quad A_z = (v/c)\,\phi, \tag{43}$$

where

$$R = \sqrt{(vt-z)^2 - (v^2/c^2-1)x_\perp^2}. \tag{44}$$

Solution (43) depends on z and t in the combination $\zeta = vt-z$ so that the Lorentz condition performs automatically. In solution (43) the wave operator is

$$\Box^2 = -(v^2/c^2-1)\,\frac{\partial^2}{\partial\zeta^2} + \Delta_\perp\,. \tag{45}$$

As $v\to c+0$ $(R=|vt-z|)$ solution (43) does not exist because the wave operator is independent of z and t. This dependence remains in the source density. By the Kirchhoff formula the potential of the superluminal source is equal to

$$\phi = \frac{2e}{R}. \tag{46}$$

This is the Heaviside–Sommerfeld solution.[9] The potential (43) as well as the potential (46) cannot be created by the source with the density $e\,\delta(x_1,x_2)\,\delta(z-vt)$. This fact will take place even if they are multiplied by steps $\theta(\zeta - \sqrt{v^2/c^2-1}\,x_\perp)\,\theta(\zeta)$. Let us emphasize that

$$\lim_{vt-z\to 0,\ x_\perp\to 0} R(x_\perp, vt-z) \neq \lim_{x_\perp\to 0,\ vt-z\to 0} R(x_\perp, vt-z). \tag{47}$$

The latter fact induced Sommerfeld to refuse the point source model. The analysis of solutions (43) and (46) shows that the inhomogeneous WE at the source velocity $v \geqslant c+0$ has no solution.

IV. CONCLUSION

Formula (42) allows us to make the following conclusion: the charged particle that moves uniformly along the straight line in vacuum emits electromagnetic waves only in the ultrarelativistic case $(v \to c-0)$. This contradicts the assertion that the free uniformly moving particle in vacuum can radiate electromagnetic waves at $v > c$.[9]

(Received 2 February 1994; accepted for publication 29 August 1995)

A complete list of all transitive symplectic manifolds of the Poincaré and Galilei group in 1+2 dimensions is given. © *1996 American Institute of Physics.* [S0022-2488(96)00601-6]

I. INTRODUCTION

Recently the author gave a complete analysis of the projective unitary irreducible representations of the Poincaré and Galilei groups in 1+2 dimensions.[1,2] In the context of constant interest in physics in 1+2 dimensions, the author believes it useful to provide the same analysis in the framework of Hamiltonian mechanics. Namely, to provide a complete list of all the transitive symplectic actions for the Poincaré and Galilei groups in 1+2 dimensions. The method used is, essentially, the orbit method of Kostant, Souriau, and Kirillov.[3–6] However, if we want the complete list of these symplectic actions (not only up to a covering like in the usual formulation of the orbit method) one needs a generalization of this method appearing in Ref. 7.

Section II presents the method following Ref. 7 In Secs. III and IV the method for the Poincaré and the Galilei groups, respectively are applied. The first case is rather standard and offers no surprises. The second case is on the contrary a very good ''laboratory'' for practically all the symplectic techniques described in full generality in Sec. II.

After some preliminaries, in Sec. IV C the transitive symplectic manifolds of the (proper orthochronous) Galilei group in a rather abstract way directly following the method outlined in Sec. II is described. In Secs. V A–V D to give more explicit realizations of some of these manifolds using the coadjoint orbits of the Galilei group and of his central extensions.

Note that some of these coadjoint orbits have appeared in Ref. 8.

II. TRANSITIVE SYMPLECTIC ACTIONS OF LIE GROUPS

A. Basic definitions

Let (M_i,Ω_i) $i=1,2$ be symplectic manifolds. A diffeomorphism $\phi: M_1 \to M_2$ is called *symplectic* if

$$\phi^* \Omega_2 = \Omega_1 . \tag{2.1}$$

Let (M,Ω) be a symplectic manifold and G a Lie group (not necessarily connected) acting on $M: G \ni g \mapsto \phi_g \in Diff(M)$.

This action is called *symplectic* and (M,Ω) is called a *G-symplectic manifold* if:

$$(\phi_g)^* \Omega = \Omega, \quad \forall g \in G. \tag{2.2}$$

If (M_i,Ω_i) $i=1,2$ are two G-symplectic manifolds, they are called *G-symplectomorphic* if there exists a symplectic map $\phi: M_1 \to M_2$ which is also G-equivariant.

Physically, a G-symplectic manifold can be considered as the phase space of a given Hamiltonian system for which G is the covariance group. Two such Hamiltonian system are identical from the physical point of view if the corresponding G-symplectic manifolds are

0022-2488/96/37(1)/240/14/$6.00

G-symplectomorphic. One can also argue that elementary systems are described by transitive G-symplectic manifolds. The orbit method describes transitive G-symplectic manifolds up to G-symplectomorphisms.

B. The basic theorem

Denote by $\mathrm{Lie}(G)\equiv T_e(G)$ the Lie algebra of G, by $G \ni g\mapsto Ad_g \in \mathrm{End}(\mathrm{Lie}(G))$ the adjoint action and by $G \ni g\mapsto Ad_g^{\#} \in \wedge(\mathrm{Lie}(G)^*)$ the (dual) action of G (see Ref. 6, p. 172). In particular, the restriction of $Ad_g^{\#}$ to $(\mathrm{Lie}(G))^*$ is the usual coadjoint action of G. Call $Ad_g^{\#}$ *the induced action*. A 2-*cocycle* for $\mathrm{Lie}(G)$ is a bilinear antisymmetric map: $\sigma:\mathrm{Lie}(G)\times\mathrm{Lie}(G)\to\mathbb{R}$ verifying the cocycle identity:[6]

$$\sigma([X_1,X_2],X_3)+\textit{cyclic permutations}=0 \quad \forall\, X_i \in \mathrm{Lie}(G)\ (i=1,2,3). \tag{2.3}$$

Denote by $Z^2(\mathrm{Lie}(G),\mathbb{R})$ the linear space of all 2-cocycles. If $\sigma \in Z^2(\mathrm{Lie}(G),\mathbb{R})$ we define:

$$h_\sigma\equiv\{X\in\mathrm{Lie}(G)\,|\,\sigma(X,Y)=0,\forall Y\in\mathrm{Lie}(G)\} \tag{2.4}$$

and one finds out that $h_\sigma\subset\mathrm{Lie}(G)$ is a Lie subalgebra. Denote by $H_\sigma\subset G$ the connected Lie subgroup immersed in G and associated to the Lie subalgebra h_σ.

The natural action of G on $Z^2(\mathrm{Lie}(G),\mathbb{R})$, namely the induced action is given by:

$$(Ad_g^{\#}\sigma\,)(X_1,X_2)\equiv\ \sigma(Ad_{g^{-1}}(X_1),Ad_{g^{-1}}(X_2)). \tag{2.5}$$

Denote by $G_\sigma\subset G$ the stability subgroup of σ with respect to this action. H_σ is a normal subgroup of G_σ. An $Ad^{\#}$-orbit $\mathcal{O}$ in $Z^2(\mathrm{Lie}(G),\mathbb{R})$, is called *regular* if for some $\sigma \in \mathcal{O}$ (then for all $\sigma \in \mathcal{O}$), the subgroup H_σ is closed.

If K is a Lie group and $N\subset K$ is a normal subgroup denote by K/N the factor Lie group. Two subgroups $Q,Q'\subset K/N$ are called *conjugated* if there exists $k_0 \in K$ such that

$$Q'=\{k_0kk_0^{-1}N\,|\,kN\in Q\}. \tag{2.6}$$

Now formulate the main theorem[7]:

Theorem 1: Take one representative σ from every regular orbit in $Z^2(\mathrm{Lie}(G),\mathbb{R})$. Let $\mathcal{H}_\sigma$ be the set of discrete subgroups of G_σ/H_σ and $\mathcal{C}_\sigma$ the set of conjugacy classes in $\mathcal{H}_\sigma$. Let $\bar{H} \in \mathcal{H}_\sigma$ be a representative of a given conjugacy class $[\bar{H}] \in \mathcal{C}_\sigma$ and

$$H\equiv\{h\in G_\sigma\,|\,hH_\sigma\in\bar{H}\}. \tag{2.7}$$

Then $H\subset G$ is a closed subgroup and G/H is a G-symplectic manifold with the symplectic form Ω^σ uniquely determined by

$$\sigma=(\pi^*\Omega^\sigma)_e. \tag{2.8}$$

(Here $\pi:G\to G/H$ is the canonical submersion.)

Every G-symplectic manifold of G is G-symplectomorphic to a manifold of the form $(G/H,\Omega^\sigma)$ described above. Moreover, to different couples $(\sigma,[\bar{H}])=(\sigma',[\bar{H}'])$ correspond G-symplectic manifolds which are not G-symplectomorphic.

This theorem is quite general and affords a complete classification in a very constructive way. Loosely speaking, the regular orbits classify the G-symplectic manifolds, up to a covering; the various coverings are classified by the classes of discrete subgroups in G_σ/H_σ. It is an improvement of a similar result from Ref. 6 (see p. 178) where it is shown that every G-symplectic manifold is covered by a *maximal* G-symplectic manifold, i.e., a manifold constructed as in the statement of the theorem for $H=H_\sigma$.

In applications, one determines for every regular orbit the maximal symplectic manifold. Then the various symplectic manifolds covered by this maximal manifold will be determined by factorizing $(G/H_\sigma,\Omega^\sigma)$ to the (symplectic) action of some suitable chosen discrete subgroup of G.

C. A particular case

A 2-*coboundary* is an element of $Z^2(\mathrm{Lie}(G),\mathbb{R})$ of the form

$$\sigma(X_1,X_2)=-\langle \eta,[X_1,X_2]\rangle, \quad \forall X_1,X_2\in \mathrm{Lie}(G). \tag{2.9}$$

Here $\langle,\rangle$ is the duality form between $\mathrm{Lie}(G)$ and $(\mathrm{Lie}(G)^*$ and $\eta\in(\mathrm{Lie}(G)^*$ is arbitrary. The linear space of all 2-coboundaries is denoted by $B^2(\mathrm{Lie}(G),\mathbb{R})$. We will also need the *second cohomology group* with real coefficients:

$$H^2(\mathrm{Lie}(G),\mathbb{R})\equiv Z^2(\mathrm{Lie}(G),\mathbb{R})/B^2(\mathrm{Lie}(G),\mathbb{R}).$$

Finally, a 1-*cocycle* for $\mathrm{Lie}(G)$ is any element $\eta\in(\mathrm{Lie}(G))^*$ verifying

$$\langle \eta,[X_1,X_2]\rangle>=0, \quad \forall X_1,X_2\in \mathrm{Lie}(G). \tag{2.10}$$

Denote by $Z^1(\mathrm{Lie}(G),\mathbb{R})$ the linear space of all 1-cocycles and by $H^1(\mathrm{Lie}(G),\mathbb{R})=Z^1(\mathrm{Lie}(G),\mathbb{R})$ the *first cohomology group* with real coefficients.

Now consider the coadjoint action of G in $(\mathrm{Lie}(G))^*$ defined similarly to Eq. (2.5):

$$(Ad_g^*\eta)(X)\equiv \eta(Ad_{g^{-1}}(X)), \tag{2.11}$$

and let $\mathcal{O}\subset(\mathrm{Lie}(G))^*$ be an orbit with respect to this action (i.e., a coadjoint orbit). For every $X\in\mathrm{Lie}(G)$, let $X_\mathcal{O}$ be the associated vector field on $\mathcal{O}$:

$$X_\mathcal{O}\equiv \frac{d}{ds}Ad^*_{\exp(-sX)}\big|_{s=0}. \tag{2.12}$$

Then we have Corollary 1.

Corollary 1: Let $\mathcal{O}\subset(\mathrm{Lie}(G))^*$ *be a coadjoint orbit. Then* $\mathcal{O}$ *becomes a symplectic manifold with respect to the Kostant–Souriau–Kirillov* (KSK) *symplectic form* Ω^{KSK} *which is uniquely determined by*

$$\Omega^{\mathrm{KSK}}_\eta(X_\mathcal{O},Y_\mathcal{O})=-\langle \eta,[X,Y]\rangle \tag{2.13}$$

$(\forall \eta\in\mathcal{O},\forall X,Y\in\mathrm{Lie}(G))$.

Two different coadjoint orbits are not G-symplectomorphic.

Suppose that $H^i(\mathrm{Lie}(G),\mathbb{R})=0$ $(i=1,2)$. If the stability subgroup G_η ($\eta\in\mathcal{O}$ arbitrary) is connected, then every transitive G-symplectic manifold is G-symplectomorphic with a coadjoint orbit. If G_η is not connected, then the coadjoint orbits are the minimal symplectic manifolds and the various symplectic manifolds covering $\mathcal{O}$ are classified by the conjugacy classes in $G_\eta/(G_\eta)^0$.

(See Theorem 25.2 of Refs. 6 and 7).

In applications one can use the factorization method outlined at the end of Sec. II B. If $H^i(\mathrm{Lie}(G),\mathbb{R})\neq 0$ for $i=1$ or $i=2$ then the list of all transitive G-symplectic manifolds is not exhausted by the construction outlined above and based on coadjoint orbits.

D. Extended coadjoint orbits

This section closes with another interesting construction. As seen in Sec. II C, if $H^i(\mathrm{Lie}(G),\mathbb{R}) = 0$ $(i = 1,2)$ then one can conveniently describe transitive G-symplectic manifolds as coadjoint orbits of G (or their factorization). One may wonder if something analogous works in the general case. The answer is positive and the construction works as follows.[4,5]

Let c be a 2-cocycle for the Lie group G, i.e., a map $c: G\times G\to\mathbb{R}$ verifying

$$c(g_1,g_2) + c(g_1g_2,g_3) = c(g_2,g_3) + c(g_1,g_2g_3) \quad (\forall\ g_1,g_2,g_3 \in G), \tag{2.14}$$

$$c(e,g)=c(g,e) = 0 \quad (\forall\ g \in G). \tag{2.15}$$

We construct the *central extension* G^c of G which is set-theoretically $G^c=G\times\mathbb{R}$ with the composition law

$$(g;\zeta)\cdot(g';\zeta')=(gg';\zeta +\zeta' +c(g,g')). \tag{2.16}$$

Then if c is smooth, G^c is also a Lie group. One identifies $\mathrm{Lie}(G^c) \simeq \mathrm{Lie}(G) + \mathbb{R}$ and $(\mathrm{Lie}(G^c))^* \simeq (\mathrm{Lie}(G))^* + \mathbb{R}$ in a natural way.

Then one can show that the coadjoint action of G^c has the form

$$Ad^*_{g;\zeta}(\eta;\rho)=(Ad^*_g(\eta)+\rho\alpha_{g^{-1}};\rho). \tag{2.17}$$

Here $\alpha_g \in (\mathrm{Lie}(G))^*$ is given by

$$\langle\alpha_g,X\rangle=\frac{d}{ds}[c(g,e^{sX})-c(e^{sAd_g(X)},g)]|_{s=0}. \tag{2.18}$$

One notices that the orbits of the action (2.17) are of the form $(\mathcal{O};\rho)$ where $\mathcal{O}$ are orbits in $(\mathrm{Lie}(G))^*$ relative to a modified coadjoint action. In particular, we consider the case $\rho=1$ and obtain the modified coadjoint action:

$$Ad^c_g(\eta)\equiv Ad^*_g(\eta)+\alpha_{g^{-1}}. \tag{2.19}$$

Because Ad^*_g is modified only by an η-independent translation, it is clear that Ad^c_g will remain a symplectic transformation with respect to Ω^{KSK}. It follows that in this way we obtain modified coadjoint orbits as transitive G-symplectic manifolds.

One can prove that two constructions of this type, based on the 2-cocycles c_1 and c_2, respectively, give the same result (up to a G-symplectomorphism) *if* c_1 and c_2 are cohomologous, i.e.,

$$c_1(g,g')-c_2(g,g')=d(g)-d(gg')+d(g') \tag{2.20}$$

for some smooth $d: G\to\mathbb{R}$.

In conclusion one can obtain new G-symplectic manifolds (beside the usual coadjoint orbits), by classifying all 2-cocycles of G, up to the equivalence relation (2.20), selecting a representative from every cohomology class and working with the central extension G^c.

There is no guarantee that one will obtain all the transitive G-symplectic manifolds in this way although this happens, for instance, for the Galilei group in 1+3 dimensions. In fact the Galilei group in 1+2 dimensions provide an example for which one does not obtain all the transitive G-symplectic manifolds in this way. However, the list can be completed by some simple tricks performed on the coadjoint orbits.

Finally, note that if a transitive symplectic manifold can be realized as an (extended) coadjoint orbit then one can obtain a momentum map in an obvious way.

III. TRANSITIVE SYMPLECTIC ACTIONS FOR THE POINCARÉ GROUP IN 1+2 DIMENSIONS

Denote by M the 1+2-dimensional Minkowski space i.e., $\mathbb{R}^3$ with coordinates (x^0,x^1,x^2) and with the Minkowski bilinear form

$$\{x,y\}\equiv x^0y^0-x^1y^1-x^2y^2. \tag{3.1}$$

One also needs the Minkowski norm: $\|x\|^2 \equiv \{x,x\}$.

The Lorentz group is

$$\mathscr{L}\equiv\{\Lambda\in \mathrm{End}(M)\,|\,\{Lx,Ly\}=\{x,y\},\forall x,y\in M\}$$

considered as a group with respect to operator multiplication.

The proper orthochronous Lorentz group is $\mathscr{L}_+^\uparrow\subset\mathscr{L}$:

$$\mathscr{L}_+^\uparrow\equiv\{\Lambda\in\mathscr{L}\,|\det(L)=1,L_{00}>0\}.$$

The proper orthochronous Poincaré group is a semidirect product: set theoretically $\mathscr{P}_+^\uparrow$ is formed from couples (L,a) with $L\in\mathscr{L}_+^\uparrow$ and $a\in M$ and the composition law is

$$(L,a)\cdot(L',a')=(LL',a+La'). \tag{3.2}$$

It is well known that: $H^i(\mathrm{Lie}(\mathscr{P}_+^\uparrow),\mathbb{R})=0$ $(i=1,2)$ (see, e.g. Ref. 6) so we can apply the corollary from Sec. II 2C.

One can identify $(\mathrm{Lie}(\mathscr{P}_+^\uparrow))^*\simeq\wedge^2M+M$ (see Ref. 6). One can naturally extend to this space the Minkowski bilinear form $\{,\}$ and the Minkowski norm $\|\cdot\|$. Next, one easily computes the coadjoint action of $\mathscr{P}_+^\uparrow$ in this representation:

$$Ad^*_{L,a}(\Gamma,P)=(L\Gamma+a\wedge LP,LP). \tag{3.3}$$

Here $\Gamma\to L\Gamma$ is the action of the Lorentz group on $\wedge^2M$ (it is defined in an elementary way on decomposable elements and afterwards is extended by linearity).

One can easily compute the coadjoint orbits of $\mathscr{P}_+^\uparrow$. If e_0,e_1,e_2 is the canonical base in M, then they are:

(a) $M^\epsilon_{m,s}\equiv\{(\Gamma,P)\,|\,\|P\|^2=m^2,\mathrm{sign}(P_0)=\epsilon,\Gamma\wedge P=\epsilon ms e_0\wedge e_1\wedge e_2\}$ $(m\in\mathbb{R}_+,s\in\mathbb{R},\epsilon=\pm)$;

(b) $M^\epsilon_s\equiv\{(\Gamma,P)\,|\,\|P\|^2=0,\mathrm{sign}(P_0)=\epsilon,\Gamma\wedge P=\epsilon s\, e_0\wedge e_1\wedge e_2\}$ $(s\in\mathbb{R},\epsilon=\pm)$;

(c) $M_{m,s}\equiv\{(\Gamma,P)\,|\,\|P\|^2=-m^2,\Gamma\wedge P=ms\, e_0\wedge e_1\wedge e_2\}$ $(m\in\mathbb{R}_+,s\in\mathbb{R})$;

(d1) $M^\epsilon_m\equiv\{(\Gamma,0)\,|\,\|*\Gamma\|^2=m^2,\mathrm{sign}((*\Gamma)_{00})=\epsilon\}$ $(m\in\mathbb{R}_+,\epsilon=\pm)$;

(d2) $M^\epsilon\equiv\{(\Gamma,0)\,|\,\|*\Gamma\|^2=0,\ \mathrm{sign}((*\Gamma)_{00})=\epsilon\}$ $(\epsilon=\pm)$;

(d3) $M_m\equiv\{(\Gamma,0)\,|\,\|*\Gamma\|^2=-m^2\}$ $(m\in\mathbb{R}_+)$.

(Here $*$ is the Hodge operator.)

Computing the stability subgroups for a given reference point from every orbit we obtain only connected Lie subgroups. Applying the corollary from Sec. II C it follows that (a)–(d) is the complete list of the transitive $\mathscr{P}_+^\uparrow$-symplectic manifolds.

A different realization of $M^\epsilon_{m,s}$ also appeared in Ref. 9. It is interesting to establish the connection between these two realizations. The idea is to identify

$$\wedge^2M\ni\Gamma\leftrightarrow J=*\Gamma\in M. \tag{3.4}$$

Then the action (3.3) becomes

$$Ad^*_{L,a}(J,P)=(LJ+a\times LP,LP), \tag{3.5}$$

where, for any $a,b \in M$ we define $a\times b \in M$ according to

$$(a\times b)^{\rho}\equiv\varepsilon^{\rho\mu\nu}a_{\mu}b_{\nu}. \tag{3.6}$$

The manifolds (a)–(d) above are mapped into $(J,P) \in M\times M$:
(a) $M^{\epsilon}_{m,s}\equiv\{(J,P)|\|P\|^2=m^2,\text{sign}(P_0)=\epsilon,\{J,P\}=\epsilon ms\}$ $(m\in\mathbb{R}_+,s\in\mathbb{R},\epsilon=\pm)$;
(b) $M^{\epsilon}_{s}\equiv\{(J,P)\mid\|P\|^2=0,\text{sign}(P_0)=\epsilon,\{J,P\}=\epsilon s\}$ $(s\in\mathbb{R},\epsilon=\pm)$;
(c) $M_{m,s}\equiv\{(J,P)|\|P\|^2=m^2,\{J,P\}=ms\}$ $(m\in\mathbb{R}_+,s\in\mathbb{R})$;
(d1) $M^{\epsilon}_{m}\equiv\{(J,0)|\|J\|^2=m^2,\text{sign}(J_0)=\epsilon\}$ $(m\in\mathbb{R}_+,\epsilon=\pm)$;
(d2) $M^{\epsilon}\equiv\{(J,0)|\|J\|^2=0,\text{sign}(J_0)=\epsilon\}$ $(\epsilon=\pm)$;
(d3) $M_m\equiv\{(J,0)|\|J\|^2=-m^2\}$ $(m\in\mathbb{R}_+)$.

Remark 1: One can investigate now the notion of localizability for the systems described above following the lines of Ref. 10. *It is not hard to establish that only the system corresponding to* $M^{\epsilon}_{m,s}$ *can be localizable, namely on the Euclidean space* $\mathbb{R}^2$.

Remark 2: If we compare the actions above with the list of projective unitary irreducible representations of the same group[1] *it is apparent that there are representations which do not have a classical analog.*

IV. THE TRANSITIVE SYMPLECTIC ACTIONS FOR THE GALILEI GROUP IN 1+2 DIMENSIONS

A. Notations

We define directly the proper orthochronous Galilei group in $1+2$ dimensions $\mathcal{G}^{\uparrow}_{+}$ as the group of 4×4 real matrices of the form

$$(R,\mathbf{v},\tau,\mathbf{a})\equiv\begin{pmatrix} R & \mathbf{v} & \mathbf{a}\\ 0 & 1 & \tau\\ 0 & 0 & 1\end{pmatrix}, \tag{4.1}$$

where $\tau\in\mathbb{R}$, $R\in SO(2)$ is a 2×2 real orthogonal matrix and the vectors $\mathbf{v},\mathbf{a}\in\mathbb{R}^2$ are considered as column matrices.

As for any matrix group, we identify the Lie algebra $\text{Lie}(\mathcal{G}^{\uparrow}_{+})$ with the linear space of 4×4 real matrices of the form

$$(\alpha,\mathbf{u},t,\mathbf{x})\equiv\begin{pmatrix} \alpha A & \mathbf{u} & \mathbf{x}\\ 0 & 0 & t\\ 0 & 0 & 0\end{pmatrix}. \tag{4.2}$$

Here $\mathbf{u},\mathbf{x}\in\mathbb{R}^2,t,\ \alpha\in\mathbb{R}$, and

$$A\equiv\begin{pmatrix} 0 & 1\\ -1 & 0\end{pmatrix}.$$

One obtains the Lie bracket as

$$[(\alpha_1,\mathbf{u}_1,t_1,\mathbf{x}_1),(\alpha_2,\mathbf{u}_2,t_2,\mathbf{x}_2)]=(0,A(\alpha_1\mathbf{u}_2-\alpha_2\mathbf{u}_1),0,A(\alpha_1\mathbf{x}_2-\alpha_2\mathbf{x}_1)+t_2\mathbf{u}_1-t_1\mathbf{u}_2). \tag{4.3}$$

We have established[2] that $H^2(\text{Lie}(\mathcal{G}^{\uparrow}_{+}),\mathbb{R})\neq0$ (in fact it is a three-dimensional real space) so we will have to apply directly the theorem from Sec. II B.

First we choose a convenient representation for an arbitrary element from the 2-cocycle space $Z^2(\mathrm{Lie}(\mathscr{G}_+^\uparrow),\mathbb{R})$. From Ref. 2 it follows that a generic element is of the form $[m,F,S,\mathbf{G},\mathbf{P}]$ $(m,F,S\in\mathbb{R},\mathbf{G},\mathbf{P}\in\mathbb{R}^2)$ given by the following formula:

$$[m,F,S,\mathbf{G},\mathbf{P}]=m\xi_0+F\xi_1+S\xi_2+[\mathbf{G},\mathbf{P}], \tag{4.4}$$

where ξ_0,ξ_1,ξ_2 are nontrivial cocycles (i.e., they are not coboundaries) and they have the following expressions:

$$\xi_0((\alpha_1,\mathbf{u}_1,t_1,\mathbf{x}_1),(\alpha_2,\mathbf{u}_2,t_2,\mathbf{x}_2))=\mathbf{x}_1\cdot\mathbf{u}_2-\mathbf{x}_1\cdot\mathbf{u}_2, \tag{4.5}$$

$$\xi_1((\alpha_1,\mathbf{u}_1,t_1,\mathbf{x}_1),(\alpha_2,\mathbf{u}_2,t_2,\mathbf{x}_2))=\langle\mathbf{u}_1,\mathbf{u}_2\rangle, \tag{4.6}$$

$$\xi_2((\alpha_1,\mathbf{u}_1,t_1,\mathbf{x}_1),(\alpha_2,\mathbf{u}_2,t_2,\mathbf{x}_2))=\alpha_1t_2-\alpha_2t_1 \tag{4.7}$$

and $[\mathbf{G},\mathbf{P}]$ is a coboundary of the form

$$[\mathbf{G},\mathbf{P}]((\alpha_1,\mathbf{u}_1,t_1,\mathbf{x}_1),(\alpha_2,\mathbf{u}_2,t_2,\mathbf{x}_2))=\langle\mathbf{P},\alpha_1\mathbf{x}_2-\alpha_2\mathbf{x}_1\rangle+\mathbf{P}\cdot(t_2\mathbf{u}_1-t_1\mathbf{u}_2)-\langle\mathbf{G},\alpha_1\mathbf{u}_2-\alpha_2\mathbf{u}_1\rangle. \tag{4.8}$$

We have denoted the usual scalar product in $\mathbb{R}^2$ by $\mathbf{x}\cdot\mathbf{y}$ and $\langle,\rangle$ is the symplectic form on $\mathbb{R}^2$:

$$\langle\mathbf{x},\mathbf{y}\rangle\equiv\mathbf{x}\cdot A\mathbf{y}. \tag{4.9}$$

B. Orbits of $\mathscr{G}_+^\uparrow$ in $Z^2(\mathrm{Lie}(\mathscr{G}_+^\uparrow),\mathbb{R})$

First, we compute from Eqs. (4.1) and (4.2) the adjoint action:

$$\begin{aligned}Ad_{R,\mathbf{v},\tau,\mathbf{a}}(\alpha,\mathbf{u},t,\mathbf{x})&=(R,\mathbf{v},\tau,\mathbf{a})(\alpha,\mathbf{u},t,\mathbf{x})(R,\mathbf{v},\tau,\mathbf{a})^{-1}\\&=(\alpha,R\mathbf{u}-\alpha A\mathbf{v},t,R\mathbf{x}+t\mathbf{v}+\alpha A(\tau\mathbf{v}-\mathbf{a})-\tau R\mathbf{u}).\end{aligned} \tag{4.10}$$

Then, applying Eq. (2.5) we get the desired induced action:

$$Ad^{\#}_{R,\mathbf{v},\tau,\mathbf{a}}[m,F,S,\mathbf{G},\mathbf{P}]=[m,F,S,R(\mathbf{G}+m\mathbf{a})-\tau R(\mathbf{P}+m\mathbf{v})-FA\mathbf{v},R\mathbf{P}+m\mathbf{v}]. \tag{4.11}$$

It is clear that the structure of the orbits with respect to this induced action will depend on F. In particular we have two cases $F=0$ and $F\neq0$.

(I) $\underline{F=0}$

In this case the orbits are

(a) $\mathscr{O}^1_{m,S}\equiv\{[m,0,S,\mathbf{G},\mathbf{P}]\,|\,\mathbf{G},\mathbf{P}\in\mathbb{R}^2\}\quad m\in\mathbb{R}^*,\quad S\in\mathbb{R}$,

(b) $\mathscr{O}^2_{S,k,\lambda}\equiv\{[0,0,S,\mathbf{G},\mathbf{P}]\,|\,\mathbf{P}^2=k^2,\mathbf{G}\wedge\mathbf{P}=\lambda k\mathbf{e}_1\wedge\mathbf{e}_2\}\quad k\in\mathbb{R}_+,\quad S,\lambda\in\mathbb{R}$,

(c) $\mathscr{O}^3_{S,k}\equiv\{[0,0,S,\mathbf{G},\mathbf{0}]\,|\,\mathbf{G}^2=k^2\}\quad k\in\mathbb{R}_+\cup\{0\},\quad S\in\mathbb{R}$

(II) $\underline{F\in\mathbb{R}^*}$

The orbits are

(a) $\mathscr{O}^4_{m,F,S}\equiv\{[m,F,S,\mathbf{G},\mathbf{P}]\,|\,\mathbf{G},\mathbf{P}\in\mathbb{R}^2\}\quad m\in\mathbb{R}^*,\quad S\in\mathbb{R}$,

(b) $\mathscr{O}^5_{F,S,k}\equiv\{[0,F,S,\mathbf{G},\mathbf{P}]\,|\,\mathbf{G}\in\mathbb{R}^2,\mathbf{P}^2=k^2\}\quad k\in\mathbb{R}_+\cup\{0\},\quad S\in\mathbb{R}$.

Above we have denoted with $\mathbf{e}_1$ and $\mathbf{e}_2$ the natural basis in $\mathbb{R}^2$.

C. Computation of the transitive symplectic actions

As indicated in the statement of Theorem 1, one needs to provide a list of subgroups $H \subset \mathcal{G}_+^\uparrow$ such that $\mathcal{G}_+^\uparrow/H$ is a symplectic manifold with the symplectic form given by Eq. (2.8). Of course, this is a very implicit way to exhibit the symplectic transitive actions of $\mathcal{G}_+^\uparrow$.

As suggested in Sec. IV B, one divides the study in two cases corresponding to $F=0$ and $F\neq 0$, respectively. One has to take some reference point σ on every orbit $\mathcal{O}^i$ $(i=1,...,5)$ and thereafter to compute G_σ and H_σ and the discrete subgroups of G_σ/H_σ. The computations are elementary and we provide only the final results. We point out that in all the cases the action of G_σ on G_σ/H_σ is trivial, so $\mathcal{C}_\sigma = \mathcal{H}_\sigma$ (in the notations of the theorem from Sec. II B).

(I) $\underline{F=0}$

(a) $\underline{\sigma=[m,0,S,\mathbf{0},\mathbf{0}]}$, $m\in\mathbb{R}^*$, $\quad S\in\mathbb{R}$.

One finds two subcases:

(a1) $\underline{S=0}$

$$H_\sigma=\{(R,\mathbf{0},\tau,\mathbf{0})|R\in SO(2),\tau\in)\mathbb{R}\};$$

(a2) $\underline{S\neq 0}$

$$H_\sigma=\{(\ \mathbf{1},\mathbf{0},0,\mathbf{0})\}.$$

In both cases we have

$$G_\sigma=\{(R,\mathbf{0},\tau,\mathbf{0})|R\in SO(2),\tau\in\mathbb{R}\}.$$

So, in the case (a1), G_σ/H_σ is trivial and in the case (a2) $G_\sigma/H_\sigma\simeq G_\sigma\simeq SO(2)\times\mathbb{R}$.

(b) $\underline{\sigma=[0,0,S,\lambda\ \mathbf{e}_1,k\mathbf{e}_2]}$, $k\in\mathbb{R}_+$, $S,\lambda\in\mathbb{R}$.

One finds

$$H_\sigma=\{(\mathbf{1},\mathbf{v},0,\mathbf{a})|v_2=0,\quad a_1=0\},$$

$$G_\sigma=\{(\mathbf{1},\mathbf{v},0,\mathbf{a})|\mathbf{v},\quad \mathbf{a}\in\mathbb{R}^2\},$$

$$G_\sigma/H_\sigma\simeq\{(\mathbf{1},\mathbf{v},0,\mathbf{a})|v_1=0,\quad a_2=0\}\simeq\mathbb{R}\times\mathbb{R}.$$

(c) $\underline{\sigma=[0,0,S,k\ \mathbf{e}_2,\mathbf{0}]}$, $k\in\mathbb{R}_+\cup\{0\}$, $S\in\mathbb{R}$.

Again we have two subcases:

(c1) $\underline{k\in\mathbb{R}_+}$:

$$H_\sigma=\left\{(\mathbf{1},\mathbf{v},\tau,\mathbf{a})\middle| v_1=-\frac{S}{k}\tau,\tau,v_2\in\mathbb{R},\ \mathbf{a}\in\mathbb{R}^2\right\},$$

$$G_\sigma=\{(\mathbf{1},\mathbf{v},\tau,\mathbf{a})|\tau\in\mathbb{R},\ \mathbf{v},\mathbf{a}\in\mathbb{R}^2\},$$

$$G_\sigma/H_\sigma\simeq\{(\mathbf{1},\mathbf{v},0,\mathbf{0})|v_2=0\}\simeq\mathbb{R}.$$

(c2) $\underline{k=0}$

If $S\neq 0$, we have

$$H_\sigma=\{(\mathbf{1},\mathbf{v},0,\mathbf{a})|\mathbf{v},\mathbf{a}\in\mathbb{R}^2\},$$

$$G_\sigma=\mathcal{G}_+^\uparrow,$$

$$G_\sigma/H_\sigma\simeq\{(R,\mathbf{0},\tau,\mathbf{0})|R\in SO(2),\tau\in\mathbb{R}\}\simeq SO(2)\times\mathbb{R}.$$

If $S=0$, we have $G_\sigma=H_\sigma=\mathscr{P}_+^\uparrow$ so this case is trivial.

(II) $F\in\mathbb{R}^*$

(a) $\sigma=[m,F,S,\mathbf{0},\mathbf{0}]$, $m\in\mathbb{R}^*$, $S\in\mathbb{R}$.

We obtain the same subgroups G_σ and H_σ as in the case $F=0$.

(b) $\sigma=[0,F,S,\mathbf{0},k\mathbf{e}_2]$, $k\in\mathbb{R}_+\cup\{0\}$, $S\in\mathbb{R}$.

We have two subcases:

(b1) $k\in\mathbb{R}_+$.

$$H_\sigma=\left\{\left(\mathbf{1},v\mathbf{e}_1,\frac{Fv}{k},\left(\frac{SFv}{k^2}+\frac{Fv^2}{2k}\right)\mathbf{e}_1+a\mathbf{e}_2\right)\middle| v,a\in\mathbb{R}\right\},$$

$$G_\sigma=\left\{\left(\mathbf{1},v\mathbf{e}_1,\frac{Fv}{k},\mathbf{a}\right)\middle| v\in\mathbb{R},\mathbf{a}\in\mathbb{R}^2\right\},$$

$$G_\sigma/H_\sigma=\{(\mathbf{1},\mathbf{0},0,b\mathbf{e}_1)|b\in\mathbb{R}\}\simeq\mathbb{R}.$$

(b2) $k=0$.

There are two possibilities:

(b2.1) $S\neq0$.

$$H_\sigma=\{(\mathbf{1},\mathbf{0},0,\mathbf{a})|\mathbf{a}\in\mathbb{R}^2\}.$$

(b2.2) $S=0$.

$$H_\sigma=\{(R,\mathbf{0},\tau,\mathbf{a})|R\in SO(2),\tau\in\mathbb{R},\mathbf{a}\in\mathbb{R}^2\}.$$

Regardless of the value of S we have

$$G_\sigma=\{(R,\mathbf{0},\tau,\mathbf{a})|R\in SO(2),\tau\in\mathbb{R},\mathbf{a}\in\mathbb{R}^2\}.$$

So we have for the first possibility

$$G_\sigma/H_\sigma=\{(R,\mathbf{0},\tau,\mathbf{0})|R\in SO(2),\quad\tau\in\mathbb{R}\}\simeq SO(2)\times\mathbb{R}$$

and for the second possibility the factor group is trivial.

Regarding the discrete subgroups of G_σ/H_σ we have only three nontrivial possibilities: $\mathbb{R}$, $\mathbb{R}\times\mathbb{R}$, and $SO(2)\times\mathbb{R}$ as is apparent from the list above. It is well known that the discrete subgroups are in these cases $H_\gamma\equiv\gamma\mathbf{Z}$, $H_{\gamma_1,\gamma_2}\equiv\gamma_1\mathbf{Z}\times\gamma_2\mathbf{Z}$ and $H_{r,\gamma}\equiv Z_r\times\gamma\mathbf{Z}$, respectively. Here $\gamma,\gamma_1,\gamma_2\in\mathbb{R}_+\cup\{0\}$ and $Z_r\in SO(2)$ is the cyclic group of order $r\in\mathbb{N}^*$: $Z_r\equiv\{R(2\pi k/r)|k=0,\ldots,r-1\}$ (as usual $R(\phi)=e^{\phi A}$ is the rotation of angle ϕ).

Combining the results obtained above, we can formulate the main result:

Proposition 1: Every transitive $\mathscr{P}_+^\uparrow$-symplectic manifold is $\mathscr{P}_+^\uparrow$-symplectomorphic to one of the form $(\mathscr{P}_+^\uparrow/H,\Omega^\sigma)$ where H and σ can be

$$(1)\qquad H^1=\{(R,\mathbf{0},\tau,\mathbf{0})|R\in SO(2),\quad\tau\in\mathbb{R}\},$$

$$\sigma^1=[m,F,0,\mathbf{0},\mathbf{0}]\quad m\in\mathbb{R}^*,\quad F\in\mathbb{R};$$

$$(2)\qquad H^2=\{(R(2\pi k/r),\mathbf{0},n\gamma,\mathbf{0})|k=0,\ldots,r-1,n\in\mathbf{Z}\},$$

$$\sigma^2=[m,F,S,\mathbf{0},\mathbf{0}]\quad m,S\in\mathbb{R}^*,\quad F\in\mathbb{R},\quad r\in\mathbb{N}^*,\quad\gamma\in\mathbb{R}_+\cup\{0\};$$

$$(3)\qquad H^3=\{(\ \mathbf{1},v\mathbf{e}_1+\gamma_1 n\mathbf{e}_2,0,\gamma_2 m\mathbf{e}_1+a\mathbf{e}_2)\,|\,v,a\in\mathbb{R},m,n\in\mathbf{Z}\},$$

$$\sigma^3=[0,0,S,\lambda\mathbf{e}_1,k\mathbf{e}_2]\quad k\in\mathbb{R}_+,\ \lambda,S\in\mathbb{R},\ \gamma_1,\gamma_2\in\mathbb{R}_+\cup\{0\};$$

$$(4)\qquad H^4=\left\{\left(\mathbf{1},v\mathbf{e}_1,\frac{Fv}{k},\left(\frac{SFv}{k^2}+\frac{Fv^2}{2k^2}+\gamma n\right)\mathbf{e}_1+a\mathbf{e}_2\right)\middle|\,v,a\in\mathbb{R},n\in\mathbf{Z}\right\}$$

$$\sigma^4=[0,F,S,\mathbf{0},k\mathbf{e}_2]\quad k\in\mathbb{R}_+,\quad S\in\mathbb{R},\quad F\in\mathbb{R}^*,\quad \gamma\in\mathbb{R}_+\cup\{0\};$$

$$(5)\qquad H^5=\left\{\left(\ \mathbf{1},\left(n\gamma-\frac{S\tau}{k}\right)\mathbf{e}_1+v\mathbf{e}_2,\tau,\mathbf{a}\right)\middle|\,\tau,v\in\mathbb{R},\ \mathbf{a}\in\mathbb{R}^2,n\in\mathbf{Z}\right\},$$

$$\sigma^5=[0,0,S,k\mathbf{e}_2,\mathbf{0}],\quad k\in\mathbb{R}_+,\quad S\in\mathbb{R},\quad \gamma\in\mathbb{R}_+\cup\{0\};$$

$$(6)\qquad H^6=\{(R(2\pi\ k/r),\ \mathbf{v},n\gamma,\mathbf{a})\,|\,k=0,\ldots,r-1,\mathbf{v},\mathbf{a}\in\mathbb{R}^2,n\in\mathbf{Z}\},$$

$$\sigma^6=[0,0,S,\mathbf{0},\mathbf{0}]\quad S\in\mathbb{R}^*,r\in\mathbb{N}^*,\gamma\in\mathbb{R}_+\cup\{0\};$$

$$(7)\qquad H^7=\{(R(2\pi\ k/r),\mathbf{0},n\gamma,\mathbf{a})\,|\,k=0,\ldots,r-1,\mathbf{a}\in\mathbb{R}^2,n\in\ \mathbf{Z},$$

$$\sigma^7=[0,F,S,\mathbf{0},\mathbf{0}]\quad F,S\in\mathbb{R}^*,\quad r\in\mathbb{N}^*,\quad \gamma\in\mathbb{R}_+\cup\{0\};$$

$$(8)\qquad H^8=\{(R,\ \mathbf{0},\tau,\mathbf{a})\,|\,R\in SO(2),\tau\in\mathbb{R},\mathbf{a}\in\mathbb{R}^2\},$$

$$\sigma^8=[0,F,0,\mathbf{0},\mathbf{0}]\quad F\in\mathbb{R}^*.$$

For distinct couples $(H,\Omega)\neq(H',\Omega')$ the corresponding manifolds are not $\mathscr{P}_+^\uparrow$-symplectomorphic.

V. SOME EXPLICIT REALIZATIONS

In principle, the analysis of the transitive symplectic manifolds for $\mathscr{P}_+^\uparrow$ was completed above. However, it is interesting to give various realizations of these manifolds. In this way one could conjecture perhaps a reasonable physical interpretation. One will obtain some of these representations systematically using the extended action from 2D; this will be done in Secs. V A and V B. Sections V C and V D contain some unsystematic guesses for some other cases not covered by the previous analysis.

A. Central extensions of $\mathscr{G}_+^\uparrow$

As outlined in Sec. II D we first need $H^2(\mathscr{G}_+^\uparrow,\mathbb{R})$. One computes this group taking advantage of the knowledge of $H^2(\tilde{\mathscr{G}}_+^\uparrow,\mathbb{R})$ which was determined in Ref. 2. For the definitions of $\tilde{\mathscr{G}}_+^\uparrow$ and of the covering map $\delta:\tilde{\mathscr{G}}_+^\uparrow\to\mathscr{G}_+^\uparrow$ see also Ref. 2.

Let $c\in Z^2(\mathscr{G}_+^\uparrow,\mathbb{R})$ be arbitrary. One defines $\tilde{c}:\tilde{\mathscr{G}}_+^\uparrow\times\tilde{\mathscr{G}}_+^\uparrow\to\mathbb{R}$ by

$$\tilde{c}(\tilde{g},\tilde{g}')\equiv c(\delta(\tilde{g}),\delta(\tilde{g}')).$$

Then it is elementary to show that $\tilde{c}\in Z^2(\tilde{\mathscr{G}}_+^\uparrow,\mathbb{R})$. Applying the result obtained in Ref. 2 it follows that $\tilde{c}$ is cohomologous to $m\tilde{c}_0+F\tilde{c}_1+S\tilde{c}_2$ where:

$$\tilde{c}_0(\tilde{g},\tilde{g}')\equiv\tfrac{1}{2}[\mathbf{a}\cdot R(x)\mathbf{v}'-\mathbf{v}\cdot R(x)\mathbf{a}'+\tau'\mathbf{v}\cdot R(x)\mathbf{v}'], \tag{5.1}$$

$$\tilde{c}_1(\tilde{g},\tilde{g}')\equiv\tfrac{1}{2}\langle\mathbf{v},R(x)\mathbf{v}'\rangle, \tag{5.2}$$

$$\tilde{c}_2(\tilde{g},\tilde{g}')\equiv\tau x'. \tag{5.3}$$

Here $\tilde{g}=(x,\mathbf{v},\tau,\mathbf{a}),\tilde{g}'=(x',\mathbf{v}',\tau',\mathbf{a}')$. Explicitly one has

$$c(\delta(\tilde{g}),\delta(\tilde{g}'))=m\tilde{c}_0(\tilde{g},\tilde{g}')+F\tilde{c}_1(\tilde{g},\tilde{g}')+S\tilde{c}_2(\tilde{g},\tilde{g}')+\tilde{d}(\tilde{g})-\tilde{d}(\tilde{g}\tilde{g}')+\tilde{d}(\tilde{g}') \tag{5.4}$$

with $\tilde{d}:\tilde{\mathscr{G}}_+^\uparrow\to\mathbb{R}$ a smooth function. By redefining $\tilde{d}\to\tilde{d}'$ where

$$\tilde{d}'(x,\mathbf{v},\tau,\mathbf{a})=\tilde{d}(x,\mathbf{v},\tau,\mathbf{a})-\frac{x}{2\pi}\tilde{d}(2\pi,\mathbf{0},0,\mathbf{0})$$

one still has Eq. (5.4) but the new $\tilde{d}$ also verifies

$$\tilde{d}(0,\mathbf{0},0,\mathbf{0})=\tilde{d}(2\pi,\mathbf{0},0,\mathbf{0})=0.$$

If we make $x\to x+2\pi$ in Eq. (5.4) one gets more, namely that the function $\tilde{d}$ is periodic in x with period 2π. Finally, if one makes $x'\to x'+2\pi$ in Eq. (5.4) one gets $S=0$. Then it follows from Eq. (4.15) that

$$c(g,g')=mc_0(g,g')+Fc_1(g,g')+d(g)-d(gg')+d(g'),$$

where

$$c_0(g,g')\equiv\tfrac{1}{2}(\mathbf{a}\cdot R\mathbf{v}'-\mathbf{v}\cdot R\mathbf{a}'+\tau'\mathbf{v}\cdot R\mathbf{v}'), \tag{5.5}$$

$$c_1(g,g')\equiv\tfrac{1}{2}\langle\mathbf{v},R\mathbf{v}'\rangle \tag{5.6}$$

with $g=(R,\mathbf{v},\tau,\mathbf{a})$, $g'=(R',\mathbf{v}',\tau',\mathbf{a}')$ and d is uniquely determined by $d\circ\delta=\tilde{d}$.

Proposition 2: $H^2(\mathscr{G}_+^\uparrow,\mathbb{R})$ is a two-dimensional real space. Explicitly, every 2-cocycle of $\mathscr{G}_+^\uparrow$ is cohomologous to one of the form mc_0+Fc_1.

Remark 3: In Ref. 8 only the central extensions of $\mathscr{G}_+^\uparrow$ are considered. So in computing the corresponding coadjoint orbits one finds out only the case $S=0$ from our analysis.

According to Sec. II D one must consider the central extension $(\mathscr{G}_+^\uparrow)^c$ where $c=mc_0+Fc_1$.

It is to be expected that one will obtain only the symplectic manifolds corresponding to $S=0$ from the list included in the statement of Proposition 1.

B. Coadjoint orbits of $(\mathscr{G}_+^\uparrow)^c$

First compute the function α_g according to Eq. (2.18). An elementary computation gives

$$\alpha_{R,\mathbf{v},\tau,\mathbf{a}}(\alpha,\mathbf{u},t,\mathbf{x})=m(R^{-1}\mathbf{a}\cdot\mathbf{u}-R^{-1}\mathbf{v}\cdot\mathbf{x}-\alpha\langle\mathbf{a},\mathbf{v}\rangle-\tfrac{1}{2}t\mathbf{v}^2)+F(\tfrac{1}{2}\alpha\mathbf{v}^2+\langle R^{-1}\mathbf{v},\mathbf{u}\rangle). \quad (5.7)$$

To compute the extended action (2.17) one identifies $(\mathrm{Lie}(\mathscr{G}_+^\uparrow))^*\simeq\mathbb{R}+\mathbb{R}^2+\mathbb{R}+\mathbb{R}^2$ using the duality form

$$\langle(\beta,\mathbf{G},E,\mathbf{P}),(\alpha,\mathbf{u},t,\mathbf{x})\rangle=-\beta\alpha-\mathbf{G}\cdot\mathbf{u}-Et+\mathbf{P}\cdot\mathbf{x}. \quad (5.8)$$

Then Eq. (2.19) gives for the modified coadjoint action:

$$\begin{aligned}Ad^c_{R,\mathbf{v},\tau,\mathbf{a}}(\beta,\mathbf{G},E,\mathbf{P})=(&\beta+\langle R\mathbf{G}+m\mathbf{a},\mathbf{v}\rangle-\langle R\mathbf{P},\mathbf{a}\rangle-\tfrac{1}{2}F\mathbf{v}^2,\\ &R\mathbf{G}+m\mathbf{a}-\tau(R\mathbf{P}+m\mathbf{v})-FA\mathbf{v},\\ &E+R\mathbf{P}\cdot\mathbf{v}+\tfrac{1}{2}m\mathbf{v}^2,R\mathbf{P}+m\mathbf{v}).\end{aligned} \quad (5.9)$$

It is elementary to compute the orbits of this action. They are

(a) $\mathscr{O}^{*1}_{m,s,F,\mathscr{E}}\equiv\{(\beta,\mathbf{G},E,\mathbf{P})|\|\mathbf{P}\wedge\mathbf{G}-(FE-m\beta)\mathbf{e}_1\wedge\mathbf{e}_2\|=ms,E-\mathbf{P}^2/2m=\mathscr{E}\}$, $m\in\mathbb{R}^*$, $s\in\mathbb{R}_+\cup\{0\},F,\mathscr{E}\in\mathbb{R}$.

(b) $\mathscr{O}^{*2}_{k,\lambda,F}\equiv\{(\beta,\mathbf{G},E,\mathbf{P})|\mathbf{P}\wedge\mathbf{G}=(FE-\lambda k)\mathbf{e}_1\wedge\mathbf{e}_2,\mathbf{P}^2=k^2\}$, $k\in\mathbb{R}_+$, $\lambda,F\in\mathbb{R}$.

(c) $\mathscr{O}^{*3}_{E,s,F}\equiv\{(\beta,\mathbf{G},E,\mathbf{0})|2F\beta+\mathbf{G}^2=s\}$, $s,E,F\in\mathbb{R}$.

Now it is easy to match these coadjoint orbits with symplectic manifolds appearing in the statement of Proposition 1 and corresponding to $S=0$. One will get maximal manifolds as it is easy to anticipate. Namely one has

(1) $\mathscr{O}^{*1}_{m,s,F,\mathscr{E}}$ is for any $s,\mathscr{E}$ the maximal manifold of case (1);

(2) $\mathscr{O}^{*2}_{k,\lambda,F}$ is the maximal manifold of cases (3) and (4), respectively (both for $S=0$);

(3) $\mathscr{O}^{*3}_{E,s,F}$ is for any E, s the maximal manifold of cases (5) (for $S=0$) and (8), respectively.

The fact that one can obtain some of the maximal symplectic manifolds of $\mathscr{G}_+^\uparrow$ using the action Ad^c has an accidental nature as already mentioned at the end of paragraph of Sec. II D. However it is quite possible that results of a general nature can be established.

C. Maximal symplectic manifolds for $S\neq 0$

To obtain case (1) one gives another realization of case (2), namely $M=\mathbb{R}^2\times\mathbb{R}^2$ with coordinates $(\mathbf{q},\mathbf{p})$, the symplectic form

$$\Omega=\sum_{i=1}^{2}dq_i\wedge dp_i+\frac{2F}{m^2}dp_1\wedge dp_2 \quad (5.10)$$

and the action of $\mathscr{G}_+^\uparrow$:

$$\phi_{R,\mathbf{v},\tau,\mathbf{a}}(\mathbf{q},\mathbf{p})=\left(R\mathbf{q}+\mathbf{a}-\frac{\tau}{m}(R\mathbf{p}+m\mathbf{v}),R\mathbf{p}+m\mathbf{v}\right). \quad (5.11)$$

One can see in Ref. 7 the corresponding 1+3-dimensional case. Taking a suggestion from this case one builds case (1) as follows. $M=\mathbb{R}^2\times\mathbb{R}^2\times S^1\times\mathbb{R}$ with coordinates $(\mathbf{q},\mathbf{p},\nu,l)$, the symplectic form

$$\Omega=\sum_{i=1}^{2} dq_i\wedge dp_i+\frac{2F}{m^2}dp_1\wedge dp_2+\frac{S}{m}d\varphi\wedge dl \tag{5.12}$$

where $\nu=(\cos(\varphi),\sin(\varphi))$, and the action

$$\phi_{R,\mathbf{v},\tau,\mathbf{a}}(\mathbf{q},\mathbf{p},\nu,l)=\left(R\mathbf{q}+\mathbf{a}-\frac{\tau}{m}(R\mathbf{p}+m\mathbf{v}),R\mathbf{p}+m\mathbf{v},R\nu,l+m\tau\right). \tag{5.13}$$

In the cases (3)–(5) for $S\neq 0$, the trick is to modify a little the extended action (5.9), namely

$$Ad^{c,S}_{R,\mathbf{v},\tau,\mathbf{a}}(\beta,\mathbf{G},E,\mathbf{P})=(\beta+\langle R\mathbf{G},\mathbf{v}\rangle-\langle R\mathbf{P},\mathbf{a}\rangle-\tfrac{1}{2}F\mathbf{v}^2-S\tau,R\mathbf{G}-\tau R\mathbf{P}-FA\mathbf{v},E+R\mathbf{P}\cdot\mathbf{v},R\mathbf{P}) \tag{5.14}$$

and to keep the KSK-symplectic form unchanged.

Case (6) can be realized by $M=\mathbb{R}\times S^1$ with coordinates (T,ν), the symplectic form

$$\Omega=S\ d\varphi\wedge dT \tag{5.15}$$

and the action

$$\phi_{R,\mathbf{v},\tau,\mathbf{a}}(T,\nu)=(T+\tau,R\nu). \tag{5.16}$$

Here $\nu=(\cos(\varphi),\sin(\varphi))$ as above.

Finally case (7) is given by $M=\mathbb{R}\times\mathbb{R}^2\times S^1$ with coordinates $(T,\mathbf{V},\nu)$, the symplectic form

$$\Omega=F\ dV_1\wedge dV_2+S\ d\varphi\wedge dT+k(-\sin(\varphi)dV_1+\cos(\varphi)dV_2)\wedge dT \tag{5.17}$$

and the action

$$\phi_{R,\mathbf{v},\tau,\mathbf{a}}(T,\mathbf{V},\nu)=(T+\tau,R\mathbf{V}+\mathbf{v},R\nu). \tag{5.18}$$

Of course in Eqs. (5.15) and (5.17) $\nu=(\cos(\varphi),\sin(\varphi))$ as in case (1).

D. Factorized symplectic manifolds

In all cases except (1) and (8) one has, beside the maximal manifolds exhibited above, some families of factorized manifolds. The results in these remaining cases are indicated briefly.

(2) If $\gamma=0$ and $r=2,3,\ldots$ then modify Eq. (5.13) as follows:

$$\phi_{R,\mathbf{v},\tau,\mathbf{a}}(\mathbf{q},\mathbf{p},\nu,l)=\left(R\mathbf{q}+\mathbf{a}-\frac{\tau}{m}(R\mathbf{p}+m\mathbf{v}),R\mathbf{p}+m\mathbf{v},R^r\nu,l+m\tau\right). \tag{5.19}$$

To obtain the cases with $\gamma\in\mathbb{R}_+$ one factorizes the previous cases by the following action of $\mathbf{Z}$:

$$n\cdot(\mathbf{q},\mathbf{p},\nu,l)=(\mathbf{q},\mathbf{p},\nu,l+n\gamma m). \tag{5.20}$$

(3) One factorizes the maximal manifolds to an action of $\mathbf{Z}\times\mathbf{Z}$, namely,

$$(n,m)\cdot(\beta,\mathbf{G},E,\mathbf{P})=(\beta+mk\gamma_2,\mathbf{G},E+nk\gamma_1,\mathbf{P}). \tag{5.21}$$

(4)–(5) The maximal manifold is factorized to the following action of $\mathbf{Z}$:

$$n\cdot(\beta,\mathbf{G},E,\mathbf{P})=(\beta+nk\gamma,\mathbf{G},E,\mathbf{P}). \tag{5.22}$$

(6) If $\gamma=0$ and $r=2, 3,...$ proceed as case (2) above, namely modify Eq. (5.16) to

$$\phi_{R,\mathbf{v},\tau,\mathbf{a}}(T,\nu)=(T+\tau,R^r\nu). \tag{5.23}$$

The case $\gamma \in \mathbb{R}_+$ is obtained factorizing the previous cases to the following action of $\mathbf{Z}$:

$$n\cdot(T,\nu)=(T+n\gamma,\nu). \tag{5.24}$$

(7) Similarly with (6): the action on the variable $\mathbf{V}$ is not changed.

Remark 4: The notion of localizability can be investigated as in Ref. 10. It is manifest from the first part of Sec. V F that cases (1) and (2) (i.e., nonzero mass systems) are localizable on $\mathbb{R}^2$. One also finds that the cases (5)–(7) are localizable on S^1.

Dielectric screening in a plasma: Some rigorous results

Bhimsen K. Shivamoggi[a)]
Technische Hochschule Darmstadt, Germany

(Received 31 July 1995; accepted for publication 19 September 1995)

In this article, we give some rigorous results about the properties of the solution of Poisson's equation describing dielectric screening by electrons trapped and/or untrapped in the Coulomb field of the test charge. © *1996 American Institute of Physics.* [S0022-2488(96)02501-6]

I. INTRODUCTION

Introduction of a test charge q (say, at $\mathbf{r}=\mathbf{0}$) polarizes the plasma and produces a shielding cloud around the charge. If the plasma were cold and there were no thermal agitation, the shielding would be perfect and the potential of the test charge would drop to zero outside the cloud. The test charge would be electrically invisible there! If the plasma were not cold, however, there would be a few particles at the edge of the cloud which would have enough thermal energy to escape from the cloud so that the shielding will not be complete.

The effective potential field $\phi(\mathbf{r})$ around the test charge q is calculated by taking into account the dielectric screening produced by other charged particles. Poisson's equation gives

$$\nabla^2\phi=-4\pi(n_i-n_e)-4\pi q\,\delta(\mathbf{r}), \tag{1}$$

where n is the number density of the particles and the subscripts i and e denote the ions and the electrons, respectively. The ions are assumed not to participate in the shielding process and to form only a uniform neutralizing background, so

$$n_i=n_0. \tag{2}$$

The full (trapped plus untrapped) electrons subjected to the Coulomb field of the test charge are assumed to be distributed in space according to the Boltzmann distribution

$$n_e(\mathbf{r})=n_0 e^{(e\phi)/kT_e}, \tag{3}$$

T being the temperature.

If the plasma is weakly coupled, the coupling parameter Γ satisfies

$$\Gamma=\frac{\text{mean Coulomb interaction energy}}{\text{thermal energy}}\sim\left|\frac{e\phi}{KT_e}\right|\ll 1. \tag{4}$$

Equation (4), in conjunction with Eqs. (2) and (3), leads to a linearization of Eq. (1):

$$\nabla^2\phi_{\text{lin}}=\lambda_D^{-2}\phi_{\text{lin}}-4\pi q\,\delta(\mathbf{r}) \tag{5}$$

with the well-known solution[1]

$$\phi_{\text{lin}}=\frac{q}{r}\,e^{-(r)/\lambda_D}, \tag{6}$$

[a)]Permanent address: University of Central Florida, Orlando, Florida.

0022-2488/96/37(1)/254/9/$6.00

where λ_D is the Debye length

$$\lambda_D = \sqrt{\frac{KT_e}{4\pi n_0 e^2}}.$$

On the other hand, the electrons untrapped by the Coulomb field of the test charge are distributed according to the Maxwell–Boltzmann distribution

$$f_e^{(u)}(\mathbf{r},\mathbf{v}) = \begin{cases} n_0\left(\frac{m_e}{2\pi KT_e}\right)^{3/2} \exp\left[-\left(\frac{m_e\nu^2}{2} - e\phi\right)\frac{1}{KT_e}\right], & \frac{m_e\nu^2}{2} > |e\phi| \\ 0, & \frac{m_e\nu^2}{2} < |e\phi| \end{cases}. \tag{7}$$

The number density of the untrapped electrons is then given by

$$n_e^{(u)}(\mathbf{r}) = \int_0^\infty f_e^{(u)}(\mathbf{r},\mathbf{v}) 4\pi\nu^2 \, d\nu = n_0\left\{ e^{(e\phi)/KT_e}\left[1 - erf\left(\sqrt{\frac{e\phi}{KT_e}}\right)\right] + \frac{2}{\sqrt{\pi}}\sqrt{\frac{e\phi}{KT_e}}\right\}. \tag{8}$$

The number of the trapped electrons, from Eqs. (3) and (8), is thus given by

$$n_e^{(t)}(\mathbf{r}) = n_e(\mathbf{r}) - n_e^{(u)}(\mathbf{r}) = n_0\left[e^{(e\phi)/KT_e} erf\left(\sqrt{\frac{e\phi}{KT_e}}\right) - \frac{2}{\sqrt{\pi}}\sqrt{\frac{e\phi}{KT_e}}\right]. \tag{9}$$

In this paper, we propose to give some rigorous results about the properties of the solution of Eq. (1) in conjunction with Eq. (3), (8), or (9).

II. SCREENING BY THE FULL ELECTRONS

Let us nondimensionalize according to

$$\hat{\phi} = \frac{e\phi}{KT_e}, \quad \hat{r} = \frac{r}{\lambda_D}, \tag{10}$$

and drop the hats. Equation (1), on using Eqs. (2) and (3), then becomes

$$(r\phi)'' = r(e^\phi - 1) - rq\,\delta(\mathbf{r}), \tag{11}$$

where primes denote differentiation with respect to r.

Lampert and Crandall[2] rigorously proved that the solution of Eq. (11) is monotonically decreasing. The occurrence of dielectric screening would indicate that this result can be sharpened further, as given below.

Theorem 1: Let ϕ be a solution of

$$(r\phi)'' = r(e^\phi - 1) - rq\,\delta(\mathbf{r}). \tag{11}$$

Then ϕ decreases more rapidly than the shieldless decay law $1/r$, $\forall r$.

Proof: The proof is adapted from that given by Lampert and Crandall.[2]

Let $\phi > 0$, $\forall r$. Upon integrating Eq. (11) once over $0 < r_1 \leqslant r \leqslant r_2 < \infty$, we obtain

$$(r\phi)_2' - (r\phi)_1' = \int_{r_1}^{r_2} r(e^\phi - 1)\,dr. \tag{12}$$

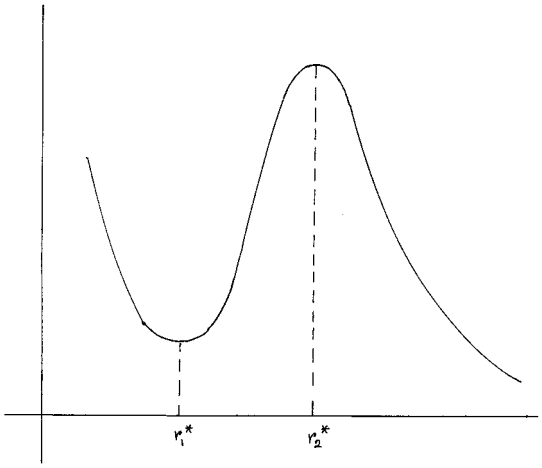

FIG. 1. $r\phi$ vs r.

If we now suppose that $(r\phi)$ does not decrease monotonically with r, then $(r\phi)$ must have a minimum for $r = r_1^* < \infty$. However, since

$$e^{\phi} - 1 \approx \phi, \quad \phi \ll 1 \tag{13}$$

ϕ must eventually decrease more rapidly than $1/r$; so it is clear that $(r\phi)$ must have a maximum for $r = r_2^*$ with $r_1^* < r_2^* < \infty$ (see Fig. 1).

Taking $r_1 = r_1^*$ and $r_2 = r_2^*$, Eq. (12) gives

$$0 = \int_{r_1^*}^{r_2^*} r(e^{\phi} - 1)\, dr$$

which is, of course, impossible since $\phi > 0$, $\forall r$.

Now, according to Eq. (13), the dielectric screening by the full electrons resembles, in the far field ($r \gg 1$), a linearized screening. (Physically this is appreciable because, according to Eqs. (8) and (9), the untrapped electrons outnumber the trapped electrons, for $r \gg 1$.) However, the numerical work of Lampert and Crandall[2] as well as that of Mak[3] indicated that the linearization condition (4) is unnecessarily stringent and that the exact solution of Eq. (11) remains close to the linearized solution (6) well after the linearization condition (4) is violated. Actually, the exact solution is bounded from below by the linearized solution (6), as shown below.

Lemma 1: The function

$$f(\phi) = e^{\phi} - 1 - \phi, \quad \phi > 0 \tag{14}$$

is positive and monotonically increasing (see Fig. 2).

Theorem 2: Let ϕ be a solution of

$$(r\phi)'' = r(e^{\phi} - 1) - rq\,\delta(\mathbf{r}). \tag{11}$$

Then, ϕ is bounded from below, $\forall r$, by the linearized solution

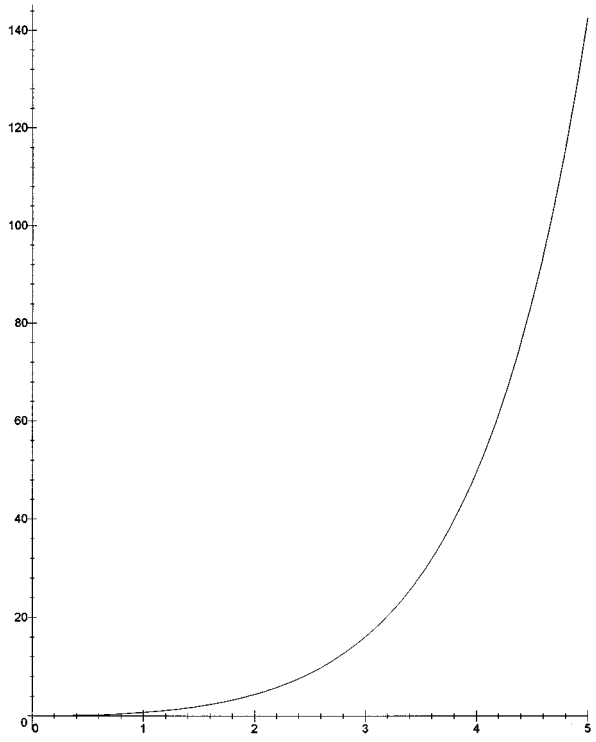

FIG. 2. $f(\phi)$ vs ϕ.

$$\phi_{\text{lin}}=\frac{q}{r}\,e^{-\mathbf{r}}. \tag{6}$$

Proof: The exact solution of Eq. (11) can be written formally as

$$(r\phi)=\int_r^\infty (r'-r)r'[\phi(r')+\{e^{\phi(r')}-1-\phi(r')\}-q\,\delta(\mathbf{r}')]dr \tag{15}$$

from which

$$(r\phi)=q\;e^{-r}+\int_r^\infty (r'-r)r'[e^{\phi(r')}-1-\phi(r')]dr'. \tag{16}$$

Using Lemma 1, Eq. (16) then implies that

$$(r\phi)\geqslant q\;e^{-r},\quad \forall r.$$

Q.E.D.

According to Theorem 2, the exact screening of the test change is weaker than linearized screening for the full electrons.

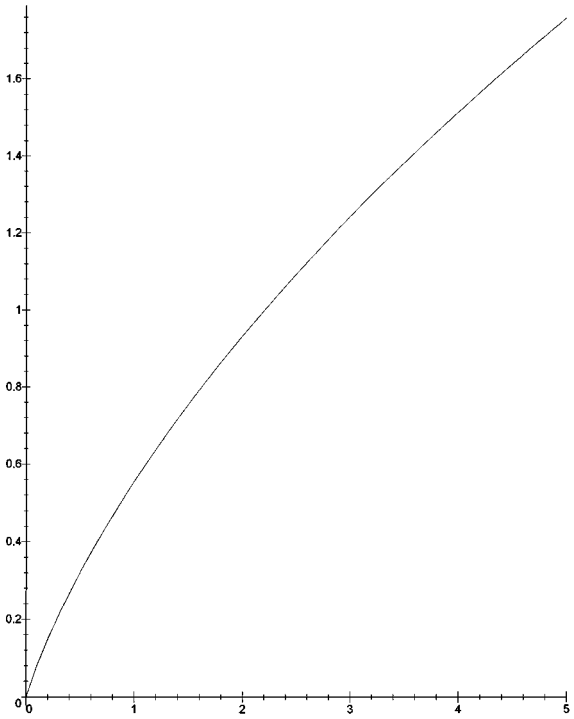

FIG. 3. $F(\phi)$ vs ϕ.

III. SCREENING BY UNTRAPPED ELECTRONS

On nondimensionalizing according to Eq. (10), and using Eqs. (2) and (8), Eq. (1) gives for the untrapped-electron screening

$$(r\phi)''=r\left[e^{\phi}\{1-erf(\sqrt{\phi})\}+\frac{2}{\sqrt{\pi}}\sqrt{\phi}-1\right]-rq\delta(\mathbf{r}). \tag{17}$$

The occurrence of dielectric screening again implies that the solution of Eq. (17) decreases more rapidly than the shieldless decay law $1/r$, $\forall r$, as deduced below.

Lemma 2: The function

$$F(\phi)=e^{\phi}[1-erf(\sqrt{\phi})]+\frac{2}{\sqrt{\pi}}\sqrt{\phi}-1 \tag{18}$$

is positive and monotonically increasing (see Fig. 3).

Theorem 3: Let ϕ be a solution of

$$(r\phi)''=r\left[e^{\phi}\{1-erf(\sqrt{\phi})\}+\frac{2}{\sqrt{\pi}}\sqrt{\phi}-1\right]-rq\delta(\mathbf{r}). \tag{19}$$

Then, ϕ decreases more rapidly than $1/r$, $\forall r$.

Proof: The proof is similar to that for Theorem 1.

Let $\phi>0$, $\forall r$. Upon integrating Eq. (17) once over $0<r_1\leqslant r\leqslant r_2<\infty$, we obtain

$$(r\phi)_2'-(r\phi)_1'=\int_{r_1}^{r_2}\left[e^{\phi}\{1-erf(\sqrt{\phi})\}+\frac{2}{\sqrt{\pi}}\sqrt{\phi}-1\right]dr. \tag{20}$$

If we now suppose that $(r\phi)$ does not decrease monotonically with r, then $(r\phi)$ must have a minimum for $r=r_1^*<\infty$. However, since

$$e^{\phi}[1-erf(\sqrt{\phi})]+\frac{2}{\sqrt{\pi}}\sqrt{\phi}-1\approx\phi,\quad \phi\ll 1$$

we have from Eq. (17) that

$$\phi_{\text{lin}}\sim\frac{q}{r}e^{-r},\quad r\gg 1 \tag{21}$$

showing that ϕ eventually decreases more rapidly than $1/r$. Therefore, $(r\phi)$ must have a maximum for $r=r_2^*$ with $r_1^*<r_2^*<\infty$.

Taking $r_1=r_1^*$ and $r_2=r_2^*$ Eq. (19) then gives

$$0=\int_{r_1^*}^{r_2^*}r\left[e^{\phi}\{1-erf(\sqrt{\phi})\}+\frac{2}{\sqrt{\pi}}\sqrt{\phi}-1\right]dr$$

which, from Lemma 2, is impossible.

Therefore, $(r\phi)$ must decrease monotonically, $\forall r$.

Now, in view of Eq. (20), the dielectric screening by untrapped electrons resembles, in the far field ($r\gg 1$), a linearized screening. However, the exact screening of the test charge by the untrapped electrons turns out to be stronger than linearized screening, as deduced below.

Lemma 3: The function

$$G(\phi)=e^{\phi}[1-erf(\sqrt{\phi})]+\frac{2}{\sqrt{\pi}}\sqrt{\phi}-1-\phi \tag{22}$$

is negative and monotonically decreasing (see Fig. 4).

Theorem 4: Let ϕ be a solution of

$$(r\phi)''=r\left[e^{\phi}\{1-erf(\sqrt{\phi})\}+\frac{2}{\sqrt{\pi}}\sqrt{\phi}-1\right]-rq\delta(\mathbf{r}). \tag{19}$$

Then, ϕ is bounded from above, $\forall r$, by the linearized solution

$$\phi_{\text{lin}}=\frac{q}{r}e^{-r}. \tag{6}$$

Proof: The exact solution of Eq. (17) can be written formally as

$$(r\phi)=\int_r^{\infty}(r'-r)r'\left[\phi(r')+\left\{e^{\phi(r')}[1-erf(\sqrt{\phi(r')})]+\frac{2}{\sqrt{\pi}}\sqrt{\phi(r')}-1-\phi(r')\right\}-q\delta(\mathbf{r}')\right]dr' \tag{23}$$

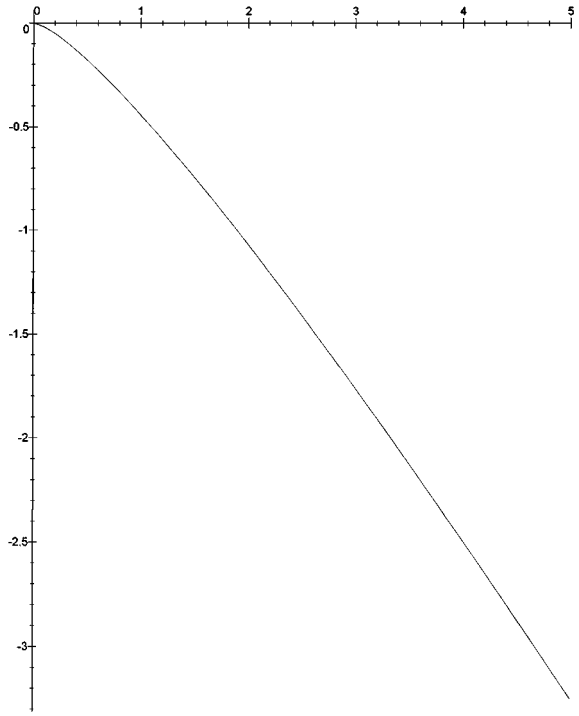

FIG. 4. $G(\phi)$ vs ϕ.

from which

$$(r\phi)=q\ e^{-r}+\int_r^{\infty}(r'-r)r'\left\{e^{\phi(r')}[1-erf(\sqrt{\phi(r')})]+\frac{2}{\sqrt{\pi}}\sqrt{\phi(r')}-1-\phi(r')\right\}dr'. \tag{24}$$

Using Lemma 3, Eq. (24) then implies that

$$(r\phi)\leqslant q\ e^{-r},\ \ \forall r.$$

$Q.E.D.$

According to Theorem 4, the exact screening of the test change is stronger than linearized screening for the untrapped electrons.

IV. SCREENING BY TRAPPED ELECTRONS

Nondimensionalizing according to Eq. (10), and using Eqs. (2) and (9), Eq. (1) gives for the trapped-electron screening,

$$(r\phi)''=r\left[e^{\phi}erf(\sqrt{\phi})-\frac{2}{\sqrt{\pi}}\sqrt{\phi}\right]-rq\,\delta(\mathbf{r}). \tag{25}$$

The solution of Eq. (2) decreases again more rapidly than the shieldless decay law $1/r$, $\forall r$, as deduced below.

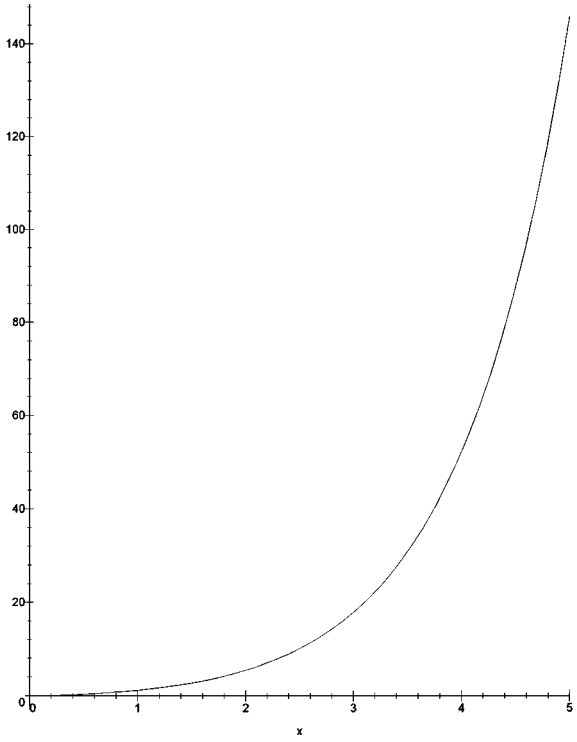

FIG. 5. $H(\phi)$ vs ϕ.

Lemma 4: The function

$$H(\phi)=e^{\phi}erf(\sqrt{\phi})-\frac{2}{\sqrt{\pi}}\sqrt{\phi} \tag{26}$$

is positive and monotonically increasing (see Fig. 5).

Theorem 5: Let ϕ be a solution of

$$(r\phi)''=r\left[e^{\phi}erf(\sqrt{\phi})-\frac{2}{\sqrt{\pi}}\sqrt{\phi}\right]-rq\delta(\mathbf{r}). \tag{25}$$

Then, ϕ decreases more rapidly than $1/r$, $\forall r$.

Proof: The proof is entirely similar to that of Theorem 3 and uses Lemma 4. Q.E.D.

Now, since

$$e^{\phi}erf(\sqrt{\phi})-\frac{2}{\sqrt{\pi}}\sqrt{\phi}\approx\frac{2}{\sqrt{\pi}}\phi^{3/2},\quad \phi\ll 1 \tag{27}$$

observe that the dielectric screening by trapped electrons does not resemble, in the far field, a linearized screening. However, on using Eq. (27), Eq. (25) becomes

$$(r\phi)''\approx\frac{2}{\sqrt{\pi}}r\phi^{3/2}-rq\delta(\mathbf{r}) \tag{28}$$

so that the classical trapped-electron dielectric screening process approaches, in the far field ($r \gg 1$), the semiclassical Thomas–Fermi screening (Ashcroft and Mermin[4]) regime!

V. DISCUSSION

In this paper, we have given some rigorous results about the properties of the solution of Poisson's equation describing dielectric screening by electrons trapped and/or untrapped in the Coulomb field of the test charge. For the full (untrapped) electrons, the exact screening of the test charge is shown to be weaker (stronger) than linearized screening; this is due to the fact that the linearized screening overestimates (underestimates) the screening of the test charge for the full (untrapped) electrons.

ACKNOWLEDGMENTS

This work was carried out when the author was a Visiting Research Professor at the Technische Hochschule Darmstadt. The author is very thankful to Professor Peter Mulser for his immense hospitality and valuable discussions. The author also acknowledges with gratitude the helpful criticism of the referee that led to a major sharpening of the discussions. The author is thankful to Dr. David Rollins for his assistance in carrying out the numerical calculations.

Global cocycle dynamics for infinite mean field quantum systems interacting with the boson gas

Reinhard Honegger
Institut für Theoretische Physik, Universität Tübingen, 72076 Tübingen, Germany

(Received 22 September 1994; accepted for publication 14 September 1995)

In the framework of operator algebraic quantum statistical mechanics, the global nonequilibrium dynamics for a general class of interactions of infinite mean field quantum lattice systems with the boson field is investigated. The associated interaction operators consist of arbitrary powers of the collective density operators of the mean field system and are linear with respect to the bosonic field operators. Instead of the usual perturbation expansions, here the interacting dynamics are studied by means of cocycle techniques. The cocycle methods are more appropriate to the considered class of interactions, and lead to explicit closed expressions for the dynamical automorphism groups. The cocycle equations connect the classical, collective dynamical behavior of the mean field system with the one-boson dynamics. In physical applications such systems are due to collectively ordered finite-level atoms or the Josephson junction in the thermodynamic limit weakly interacting with the electromagnetic field. © *1996 American Institute of Physics.* [S0022-2488-(96)00801-4]

I. INTRODUCTION

There is a great variety of papers where (starting from a microscopic quantum description) many aspects of the usual phenomenological descriptions of the Josephson effect and Josephson oscillator are obtained in the thermodynamic limit. The limit is performed as the particle number N becomes infinite with fixed particle density. The commonly accepted interpretation of the Josephson effect is in terms of a nondissipative process between two weakly linked superconductors, where the weakness of the interaction is expressed by the factor N^{-1} for each superconductor.

The same weak link also is taken for the Josephson oscillator; here, in addition, the two superconductors are coupled to the quantized electromagnetic field.[1]

In quantum optics such a weak coupling has been used for the Dicke model in the thermodynamic limit $N\to\infty$ (here N means the number of two-level atoms; the coupling strength also is rescaled by N^{-1}).[2–4]

In many theoretical treatments of the BCS model and the Josephson effect the thermodynamic limit has been performed within the formalism of infinite mean field quantum lattice systems. However, the Josephson oscillator model in Ref. 1, as well as the infinite atom Dicke model in Refs. 2 and 5, are not calculated within the mean field setup.

For the coupling of the photon field to some kind of (postulated) finite-dimensional classical material system in Refs. 2 and 5, Davies used cocycle techniques to obtain an explicit closed form for the unitary time evolution group in some specific Hilbert space representation. The results of Refs. 2 and 5 are used in Ref. 1.

Here we generalize the above ''limiting'' weak couplings and investigate the nonequilibrium dynamics for a general class of interactions of infinite mean field quantum lattice systems with the boson field. Inspired by the methods of Davies, we develop cocycle techniques for the description of the interacting systems. The cocycle equations connect the classical, collective dynamical behavior of the mean field system with the one-boson dynamics. Each solution of the cocycle equations leads to a different interaction. And thus, the whole of all solutions gives our treated class of interactions, which correspond to coupling operators of the form

$$P=\sum_{k=1}^{l}\left[D_k\otimes a_b^*(\phi_k)+D_k^*\otimes a_b(\phi_k)\right]. \tag{1.1}$$

Here the mean field part of P consists of arbitrary powers D_k of the collective density operators, i.e., the D_k are arbitrary classical observables of the mean field system. And the $a_b^{\#}(\phi_k)$ denote the bosonic annihilation, resp., creation operators smeared with the one-boson ''test functions'' ϕ_k. The ϕ_k express the coupling constants between the mean field system (e.g., an atomic system, or some superconductors) and the modes of the boson system (e.g., the electromagnetic field). In suitable subrepresentations the interacting cocycle dynamics are approximated by local (finite volume) expressions in the thermodynamic limit (see Theorem 4.10 below). Indeed, the above-mentioned weak couplings for the Josephson oscillator and the Dicke model lead in the thermodynamic limit to a special form of (1.1) for the interaction operators.

In contrast to the Hilbert space ansatz in Refs. 1, 2, and 5, here we use the general operator algebraic approach. We use the concept of global dynamical descriptions, where the dynamics in the Schrödinger picture is given by a group of affine bijections on some suitable convex subset (folium)—the physical states—of the state space of the associated C^*-algebra so that the expectation values are time continuous (cf. Definition 1.2 below). This dynamical concept is more general than those of C^*- and W^*-dynamical systems. Below it is presented in detail. Even for the free time evolutions of the infinite mean field, as well as of the boson system, it is necessary to work with the global dynamical concept, if one wants to cover a great variety of states, which show some continuity concerning their time evolutions.

Recently, great progress has been made concerning the rigorous formulation of the general, i.e. nonequilibrium dynamics of infinite quantum lattice systems with mean field interactions.[6–9] Due to the extremely long range of the interaction, the mean field limiting dynamics is not given as an automorphism group on the original quasilocal C^*-algebra,[10] but with the general global dynamical concept on the folium generated by the perturbation invariant states. The collective (classical) observables are the continuous functions on a classical phase space, the dynamics of which is given by a classical phase flow, which is generated by a Hamiltonian function Q and which is the restriction of the above limiting mean field dynamics.

The (quasi-)free boson dynamics is defined in terms of Bogoliubov transformations on (an enlargement of) the associated bosonic Weyl algebra (CCR algebra). It is well known that here one does not have a C^*-dynamical system. A global dynamical description with time continuity of the expectation values is not obtained for all states, but on the folium of states, which are chosen to be continuous with respect to some topology τ on the one-boson test function space.

Because here we cover such a great variety of states (i.e., very large folia, resp. representations) for both systems, the infinite mean field systems and the boson gas, the free dynamics are not given as W^*-dynamical systems. But the perturbation expansions (Ref. 11, Sec. 5.4.1) (with the interaction operator as perturbation) need the W^*-time continuity for the free evolution group. Hence, it is not possible to introduce interactions by using the perturbation theory. The unboundedness of the considered interaction operators (1.1) would be a second problem for the convergence of the perturbational expansion series. The difficulties of introducing the above class of mean field–boson interactions we overcome by the cocycle techniques. The advantage of the cocycle methods is that one directly obtains an explicit closed form (and not only an expansion series, as in the perturbational case) for the coupled time evolution automorphisms. More exactly, with the cocycle techniques we first construct the class of dynamical groups of interacting automorphisms, and then, in a second step, we determine the associated interactions.

Using the cocycle dynamics of the present investigation in Ref. 12 for very general initial states of the total system, we consider the infinite time limit ($t\to\infty$) of the boson field. In the resulting bosonic time-asymptotic states one partially rediscovers the collective ordering of the infinite mean field quantum lattice system, which also reflects the influence of the interaction (1.1) to the bose gas (cf. also Refs. 13 and 14).

In Ref. 4 for the special case of the infinite Dicke model in a specific (covariant) GNS representation, the opposite way has also been carried through. There, by means of Trotter's product formula and perturbation techniques the explicit expressions for the unitary time evolutions are derived. The emitted radiation, i.e. the time-asymptotic photon states, turns out to be quantum optically coherent,[15] which follows from the influence of the collective atomic behavior.[3,16]

An application of the present investigation and the one of the time-asymptotic boson states[12] to the general weakly coupled Dicke model is found in Ref. 17, and an application to the Josephson microwave radiation in Ref. 18.

The preparatory section (II) is devoted to the considered class of infinite mean field models. In Sec. III we develop the global dynamical description of the free boson field. In the main part of the paper (Sec. IV) the global interacting cocycle dynamics is investigated.

We start our exposition with the global dynamical concept we are confrontated in the subsequent sections, at the free systems, the mean field lattice, resp. the boson gas, and at the interacting system.

A. The algebraic dynamical concept

Let $\mathscr{A}$ be an arbitrary C^*-algebra with state space $\mathscr{S}(\mathscr{A})$ describing a physical system. Denote by $\mathscr{M}^u \equiv \mathscr{M}^u(\mathscr{A})$ the universal enveloping W^*-algebra of $\mathscr{A}$ associated with the universal representation Π^u, and its center by $\mathscr{Z}^u$.[19,20] We do not distinguish between a state on $\mathscr{A}$ and its unique normal extension to $\mathscr{M}^u$.

The notion of a folium was introduced by Haag *et al.*[21] (cf. also Ref. 22). A folium $\mathscr{F}$ of $\mathscr{A}$ is a norm-closed, convex subset of $\mathscr{S}(\mathscr{A})$, which is invariant under "perturbations," in the sense that $\omega \in \mathscr{F}$ implies $\omega_B \in \mathscr{F}$ for all $B \in \mathscr{A}$ with $\langle \omega;\ B^*B\rangle \neq 0$, where ω_B is the state on $\mathscr{A}$ given by $\langle \omega_B; \cdot \rangle = \langle \omega; B^* \cdot B\rangle / \langle \omega; B^*B\rangle$.

Folia arise naturally as the set of Π-normal states of any representation Π of $\mathscr{A}$. More exactly, we have the following well-known results (see, e.g., Refs. 21 and 20).

Proposition 1.1: There is a one-to-one correspondence between the folia of $\mathscr{A}$, the quasiequivalence classes of representations, and the orthogonal projectors in the center $\mathscr{Z}^u$, which preserves the partial orderings, respectively. That is, if for $j \in \{1,2\}$ $\mathscr{F}_j$, Π_j, and $c_j \in \mathscr{Z}^u$ are in correspondence, then

$$\mathscr{F}_1 \subseteq \mathscr{F}_2 \subseteq \mathscr{S}(\mathscr{A}) \Leftrightarrow \Pi_1 \leqslant \Pi_2 \leqslant \Pi^u \Leftrightarrow c_1 \leqslant c_2 \leqslant \mathbb{1}^u.$$

Moreover, if $\mathscr{F}$, $\Pi_{\mathscr{F}}$, and $c_{\mathscr{F}}$ are in correspondence one has $\mathscr{M}_{\mathscr{F}} := \Pi_{\mathscr{F}}(\mathscr{A})'' = c_{\mathscr{F}}\mathscr{M}^u$, $\mathscr{Z}_{\mathscr{F}} := \mathscr{M}_{\mathscr{F}} \cap \mathscr{M}'_{\mathscr{F}} = c_{\mathscr{F}}\mathscr{Z}^u$, $\mathscr{F}$ are just the $\Pi_{\mathscr{F}}$-normal states, that is, $\mathscr{M}_{\mathscr{F}} = LH(\mathscr{F})^*$. $\Pi_{\mathscr{F}}$ extends to a normal representation $\tilde{\Pi}_{\mathscr{F}}$ of $\mathscr{M}^u$ with $\tilde{\Pi}_{\mathscr{F}}(\mathscr{M}^u) = \mathscr{M}_{\mathscr{F}}$, $\tilde{\Pi}_{\mathscr{F}}(\mathscr{Z}^u) = \mathscr{Z}_{\mathscr{F}}$.

A folium $\mathscr{F}$ expresses classical, macroscopic aspects of the physical system, which one also may refind in the center $\mathscr{Z}_{\mathscr{F}}$ of the associated W^*-algebra $\mathscr{M}_{\mathscr{F}}$. Thus, dealing with a subfolium of $\mathscr{F}$ instead of $\mathscr{F}$ itself, means a restriction of the considered collective, macroscopic aspects of the physical system. Disjoint folia give macroscopically totally different aspects and define two superselection sectors, which is also demonstrated by the orthogonality of the associated central projectors.

In the Schrödinger picture Roos[24] introduced the following dynamical description on the folium $\mathscr{F}$ of $\mathscr{A}$.

Definition 1.2: Let $\nu \equiv \{\nu_t | t \in \mathbb{R}\}$ be a one-parameter group of affine maps $\nu_t : \mathscr{F} \to \mathscr{F}$, that is, ν_0 is the identity and $\nu_s \circ \nu_t = \nu_{s+t}$, $\forall s,t \in \mathbb{R}$, which obeys the continuity conditions

$$\lim_{t \to 0} \langle \nu_t(\omega); A\rangle = \langle \omega; A\rangle, \quad \forall \omega \in \mathscr{F}, \quad \forall A \in \mathscr{A}. \tag{1.2}$$

Then the triple $(\mathscr{A}, \mathscr{F}, \nu)$ is denoted a dynamical description of our physical system.

Obviously, the group property yields each ν_t to be an affine bijection on $\mathscr{F}$. By duality, for each $t\in\mathbb{R}$ there exists a unique Jordan automorphism τ_t on $\mathscr{M}_{\mathscr{F}}$ (Ref. 25, Theorem 3.2.8), such that

$$\langle \nu_t(\omega);A\rangle=\langle \omega;\tau_t(A)\rangle,\quad \forall\,\omega\in\mathscr{F},\quad \forall A\in\mathscr{M}_{\mathscr{F}}. \tag{1.3}$$

Since in applications the dynamics is motivated by Hamiltonians, in the sequel we always assume τ_t to be an automorphism (cf., e.g., Ref. 26 and Subsection 2.3, where ν_t is approximated by finite Hamiltonian dynamics). The group $\tau\equiv\{\tau_t|t\in\mathbb{R}\}$ describes the dynamics in the Heisenberg picture on the W^*-algebra $\mathscr{M}_{\mathscr{F}}$, which is denoted by $(\mathscr{M}_{\mathscr{F}},\tau)$.

Roos's dynamical concept is a generalization of Kadison's classical definition of a dynamical system;[23] the difference is that here the weak* continuity of $\omega\in\mathscr{F}\mapsto\nu_t(\omega)$ on $\mathscr{A}$, t fixed, is dropped. This weak* continuity property is equivalent to $\tau_t(\mathscr{A})\subseteq\mathscr{A}$, and its failure plays a crucial role for the mechanisms of symmetry breaking.[10]

Because of the restricted continuity in time (1.2), in general $(\mathscr{M}_{\mathscr{F}},\tau)$ does not define a W^*-dynamical system (e.g. Ref. 11, Definition 2.7.1). However, $(\mathscr{M}_{\mathscr{F}},\tau)$ is a W^*-dynamical system, if (1.2) is also valid for each $A\in\mathscr{M}_{\mathscr{F}}$, that is, $t\mapsto\nu_t(\omega)$ is $\sigma(\mathscr{M}_{\mathscr{F}*},\mathscr{M}_{\mathscr{F}})$ continuous for every $\omega\in\mathscr{F}$, which by Ref. 25, Corollary 3.1.8 is equivalent to the norm continuity of $t\mapsto\nu_t(\omega)$. Then, by duality, $t\mapsto\tau_t(A)$ is $\sigma(\mathscr{M}_{\mathscr{F}},\mathscr{M}_{\mathscr{F}*})$ continuous for all $A\in\mathscr{M}_{\mathscr{F}}$.

The C^*-dynamical system $(\mathscr{A},\tau)$ is obtained (e.g., Ref. 11, Definition 2.7.1), if the folium $\mathscr{F}$ is the whole state space $\mathscr{S}(\mathscr{A})$: By duality arguments, each τ_t leaves $\mathscr{A}$ invariant and the $\sigma(\mathscr{A}^*,\mathscr{A})$ continuity of $t\mapsto\nu_t(\omega)$, $\forall\omega\in\mathscr{S}(\mathscr{A})$ from (1.2) is equivalent to the $\sigma(\mathscr{A},\mathscr{A}^*)$ continuity of $t\mapsto\tau_t(A)$, $\forall A\in\mathscr{A}$, which by Ref. 25, Corollary 3.1.8 leads to $\lim_{t\to0}\|\tau_t(A)-A\|=0$ for each $A\in\mathscr{A}$.

Definition 1.3: If $\mathscr{F}'\subseteq\mathscr{F}$ is a ν-invariant subfolium, that is $\nu_t(\mathscr{F}')\subseteq\mathscr{F}'$, $\forall t\in\mathbb{R}$, then $(\mathscr{A},\mathscr{F}',\nu)$ is called a dynamical subdescription of $(\mathscr{A},\mathscr{F},\nu)$.

If one has the continuity condition, $\lim_{t\to0}\|\nu_t(\omega)-\omega\|=0$, $\forall\omega\in\mathscr{F}'$, which is stronger than (1.2), then the dynamical (sub-)description $(\mathscr{A},\mathscr{F}',\nu)$ is called covariant.

$(\mathscr{A},\mathscr{F}',\nu)$ to be a dynamical subdescription is equivalent to $\tau_t(c_{\mathscr{F}'})=c_{\mathscr{F}'}$, $\forall t\in\mathbb{R}$ for the central projector $c_{\mathscr{F}'}\in\mathscr{Z}_{\mathscr{F}}$ associated with the subfolium $\mathscr{F}'$, $\mathscr{M}_{\mathscr{F}'}=c_{\mathscr{F}'}\mathscr{M}_{\mathscr{F}}$, of the above proposition. The associated dynamics in the Heisenberg picture $(\mathscr{M}_{\mathscr{F}'},\tau)$ is obtained by restricting τ from $\mathscr{M}_{\mathscr{F}}$ to $\mathscr{M}_{\mathscr{F}'}=c_{\mathscr{F}'}\mathscr{M}_{\mathscr{F}}$ with the central projection $c_{\mathscr{F}'}$.

Consequently, if one wants to consider a very great variety of collective, macroscopic observables of the physical system (in the center $\mathscr{Z}_{\mathscr{F}}$), which may evolve in time, it is necessary to work with a dynamical description $(\mathscr{A},\mathscr{F},\nu)$ with some folium $\mathscr{F}$, which is chosen as large as possible.

The covariance of $(\mathscr{A},\mathscr{F}',\nu)$ is equivalent for $(\mathscr{M}_{\mathscr{F}'},\tau)$ to constitute a W^*-dynamical system. In a standard representation of $\mathscr{M}_{\mathscr{F}'}$ on the standard Hilbert space $\mathscr{H}^{\rm std}_{\mathscr{F}'}$[27] then one gets a strongly continuous unitary group $e^{it\mathrm{H}}$, $t\in\mathbb{R}$, on $\mathscr{H}^{\rm std}_{\mathscr{F}'}$, which implements the Heisenberg dynamics τ: $\tau_t(M)=e^{it\mathrm{H}}Me^{-it\mathrm{H}}$, $\forall M\in\mathscr{M}_{\mathscr{F}'}$, $\forall t\in\mathbb{R}$. However, in general, $e^{it\mathrm{H}}\notin\mathscr{M}_{\mathscr{F}'}$, that is, the renormalized Hamiltonian H is not affiliated with $\mathscr{M}_{\mathscr{F}'}$. These results are proven with the general modular formalism.[28,20,29,30]

Selecting in our dynamical description $(\mathscr{A},\mathscr{F},\nu)$ those $\omega\in\mathscr{F}$, which fulfill the norm continuity $\lim_{t\to0}\|\nu_t(\omega)-\omega\|=0$, leads to a subfolium $\mathscr{F}_{\rm cov}\subseteq\mathscr{F}$ invariant with respect to the Schrödinger dynamics ν. Hence $(\mathscr{A},\mathscr{F}_{\rm cov},\nu)$ gives the largest covariant dynamical subdescription of $(\mathscr{A},\mathscr{F},\nu)$, an idea that goes back to Ref. 31 (cf. also Refs. 8 and 32).

If $\omega\in\mathscr{F}$ is a ν-invariant state, then, $\nu_t(\mathscr{F}_\omega)=\mathscr{F}_\omega$, $\forall t\in\mathbb{R}$, where $\mathscr{F}_\omega$ is the subfolium of $\mathscr{F}$ generated by ω (the smallest folium containing ω), and $(\mathscr{A},\mathscr{F}_\omega,\nu)$ is a dynamical subdescription. Because of the uniqueness of the GNS representation $(\Pi_\omega,\mathscr{H}_\omega,\Omega_\omega)$ of ω up to unitary equivalence, there exist unitary operators U_t^ω on $\mathscr{H}_\omega$ with $\tau_t(M)=U_t^\omega MU_t^\omega$, $\forall M\in\mathscr{M}_{\mathscr{F}_\omega}\equiv\mathscr{M}_\omega$, and $U_t^\omega\Omega_\omega=\Omega_\omega$ for each $t\in\mathbb{R}$. By (1.2) one easily checks the strong continuity of $t\mapsto U_t^\omega$. Consequently, $\mathscr{F}_\omega\subseteq\mathscr{F}_{\rm cov}$, and thus $\mathscr{F}_\omega$ defines a covariant subdescription.

II. INFINITE MEAN FIELD QUANTUM LATTICE SYSTEMS

In this section, we give a short self-contained description of the theory of infinite mean field systems and their dynamics for the extent necessary for the present purposes. For more information and additional references, we refer the reader to the original works.[35,6,7,32,8] Our notation resembles the one in Ref. 8.

For the numbering of the spatial lattice we use the natural numbers $\mathbb{N}$. The set of finite subsets Λ of $\mathbb{N}$, $\mathcal{L}:=\{\Lambda\subset\mathbb{N}||\Lambda|<\infty\}$, where $|\Lambda|$ denotes the cardinality of Λ, is directed by inclusion. Quantities indexed by $\Lambda\in\mathcal{L}$ are usually called local. The limit of a net of local elements $(a_\Lambda)_{\Lambda\in\mathcal{L}}$ we denote by $\lim_{\Lambda\in\mathcal{L}} a_\Lambda$.

At each lattice point $n\in\mathbb{N}$ we have the same finite subsystem described by the $m\times m$ matrices $\mathbb{M}_m$ as algebra of observables. The observables for the finite lattice region $\Lambda\in\mathcal{L}$ are given by $\mathcal{A}(\Lambda):=\otimes_{n\in\Lambda}\mathbb{M}_m$, and for the total infinite system by the C^*-inductive limit $\mathcal{A}:=\otimes_{n\in\mathbb{N}}\mathbb{M}_m$.[33,34] The C^*-algebra $\mathcal{A}$ is simple, and thus any nontrivial representation of $\mathcal{A}$ is faithful. The local algebras $\mathcal{A}(\Lambda)$, $\Lambda\in\mathcal{L}$ are embedded into $\mathcal{A}$ by adjoining the unit $\mathbb{1}_m$ of $\mathbb{M}_m$ at the lattice points $n\notin\Lambda$.

A. Kinematical structure

Denote by $\mathcal{F}_a^p$ the folium of $\mathcal{A}$ generated by the permutation invariant states $\mathcal{S}^p(\mathcal{A})$ [smallest folium containing $\mathcal{S}^p(\mathcal{A})$], and let Π_a^p be the associated representation with corresponding von Neumann algebra $\mathcal{M}_a^p:=\Pi_a^p(\mathcal{A})''$ by Proposition 1.1. Then, for every $a\in\mathbb{M}_m$ the limit

$$m(a)=s-\lim_{\Lambda\in\mathcal{L}}\Pi_a^p(m_\Lambda(a))\in\mathcal{Z}_a^p,$$

of the local density operators,

$$m_\Lambda(a):=\frac{1}{|\Lambda|}\sum_{n\in\Lambda}\mathbb{1}_m\otimes\cdots\otimes\mathbb{1}_m\otimes\underbrace{a}_{n\text{th place}}\otimes\mathbb{1}_m\otimes\mathbb{1}_m\otimes\cdots\in\mathcal{A}(\Lambda),\quad\Lambda\in\mathcal{L},\tag{2.1}$$

exists in the strong operator topology and is an element of the center $\mathcal{Z}_a^p$ of $\mathcal{M}_a^p$. Let us denote by $\mathcal{N}_{\mathrm{cl}}$ the C^*-subalgebra of the center $\mathcal{Z}_a^p$, which is generated by the set $\{m(a)|a\in\mathbb{M}_m\}$, respectively, by $\{m(a)|a\in\mathcal{G}\}$, where

$$\mathcal{G}:=\{a\in\mathbb{M}_m|a=a^*,\ \mathrm{tr}[a]=0\},$$

the Lie algebra corresponding to the Lie group $SU(m)$.

$\mathcal{N}_{\mathrm{cl}}$ is a commutative C^*-algebra, which we want to identify with the C^*-algebra $C(P)$ of continuous functions on the state space $P\equiv\mathcal{S}(\mathbb{M}_m)$ of $\mathbb{M}_m$. We also regard P as a compact, convex subset of the vector space dual $\mathcal{G}^*$ of the Lie algebra $\mathcal{G}$, which is a real vector space of dimension m^2-1. The duality relation $\langle x;a\rangle$ for $x\in\mathcal{G}^*$ and $a\in\mathcal{G}\subset\mathbb{M}_m$ is a restriction of the duality relation on $\mathbb{M}_m$.

$a\in\mathcal{G}\mapsto\exp\{im(a)\}\in\mathcal{Z}_a^p$ is a unitary representation of the additive group $\mathcal{G}$. Thus, by the SNAG theorem there exists a unique projection-valued measure $\mathcal{P}$ from the Borel subsets of $\mathcal{G}^*$ into the set of orthogonal projections of the center $\mathcal{Z}_a^p$ such that $m(a)=\int_{\mathcal{G}^*}\langle x;a\rangle d\mathcal{P}(x)$ for each $a\in\mathcal{G}$, respectively, for each $a\in\mathbb{M}_m$. It follows that P is just the support of $\mathcal{P}$. Now the spectral calculus defines the desired isomorphism,

$$\hat{\mathcal{P}}:C(P)\to\mathcal{N}_{\mathrm{cl}},\quad\xi\mapsto\int_P\xi(x)d\mathcal{P}(x).$$

$\mathcal{N}_{\mathrm{cl}} \cong C(P)$ is interpreted as the C^*-algebra of classical observables for the infinite mean field system. Let us define the enlargement $\mathcal{A}_e := \mathcal{A} \otimes C(P)$ of the original C^*-algebra $\mathcal{A}$ with the associated classical $C(P)$. $\mathcal{A}_e$ is isomorphic to the C^*-algebra $C(P, \mathcal{A})$ of continuous $\mathcal{A}$-valued functions on P.

The representation Π_a^p of $\mathcal{A}$ extends to a representation of $\mathcal{A}_e$ by defining $\Pi_a^p(X \otimes \xi) = \Pi_a^p(X)\hat{\mathcal{P}}(\xi) \in \mathcal{M}_a^p$ for $X \in \mathcal{A}$ and $\xi \in C(P)$. That is, $\Pi_a^p(\mathcal{A}_e)$ is just the C^*-subalgebra of $\mathcal{M}_a^p$, which is generated by $\Pi_a^p(\mathcal{A})$ and $\mathcal{N}_{\mathrm{cl}}$. Since the folium $\mathcal{F}_a^p$ of $\mathcal{A}$ agrees with the normal states on $\mathcal{M}_a^p$, it follows that $\mathcal{F}_a^p$ is just the folium of $\mathcal{A}_e$ associated with the representation Π_a^p of $\mathcal{A}_e$ (cf. Proposition 1.1).

B. The classical phase space

The state space of $C(P)$ is the convex set $M_+^1(P)$ of (positive) probability measures on P. Thus, the restriction $\omega|_{\mathcal{N}_{\mathrm{cl}}}$ of $\omega \in \mathcal{S}^p(\mathcal{A})$ from $\mathcal{M}_a^p$ to $\mathcal{N}_{\mathrm{cl}}$ gives the probability measure $\omega|_{\mathcal{N}_{\mathrm{cl}}} \circ \hat{\mathcal{P}}^{-1} =: \mu_\omega$ on P, which implies the affine bijection $\omega \mapsto \mu_\omega$ from $\mathcal{S}^p(\mathcal{A})$ onto $M_+^1(P)$. The point measure at $x \in P$ gives the product state $\omega_x = \otimes_{n \in \mathbb{N}} x$ on $\mathcal{A}$. Consequently, the permutation invariant states $\mathcal{S}^p(\mathcal{A})$ of $\mathcal{A}$ form a Bauer simplex with the extreme boundary $\partial_e \mathcal{S}^p(\mathcal{A}) = \{\omega_x | x \in P\}$. The probability measure $\mu_\omega \in M_+^1(P)$ gives the central decomposition of $\omega \in \mathcal{S}^p(\mathcal{A})$, $\omega = \int_P \omega_x \, d\mu_\omega(x)$.[36,8]

P is the classical phase space of the considered mean field system. The tangent space at each point $x \in P$ of the manifold P is just the dual $\mathcal{G}^*$, and the cotangent space is $\mathcal{G}^{**}$, which is canonically identified with $\mathcal{G}$. With the Lie product on $\mathcal{G}$ (i times the commutator $[\cdot, \cdot]$) the Poisson bracket $\{\xi, \eta\}$ of two differentiable, real-valued functions ξ, η on the manifold P is introduced by

$$\{\xi, \eta\}(x) := i\langle x; [d\xi_x, d\eta_x] \rangle, \quad \forall x \in P, \tag{2.2}$$

which uses the differentials $d\xi_x \in \mathcal{G}$ and $d\eta_x \in \mathcal{G}$ at $x \in P$. However, (2.2) is not quite a Poisson bracket in the sense of the theory of classical Hamiltonian mechanics (e.g., Ref. 37), since the underlying symplectic form is degenerate (for more details see Refs. 7, 32, and 38).

C. The limiting dynamics

With a fixed orthonormal base $\{a^1, \ldots, a^{m^2-1}\}$ of $\mathcal{G}$ (with respect to the Hilbert–Schmidt scalar product), $\mathcal{G}^*$ is parametrized, and thus $\mathcal{G}^* \cong \mathbb{R}^{m^2-1}$.

The dynamics is given with an arbitrary real-valued polynomial Q on $\mathbb{R}^{m^2-1} \cong \mathcal{G}^*$ in terms of the local Hamiltonians,

$$A_\Lambda := |\Lambda| Q(m_\Lambda(a^1), \ldots, m_\Lambda(a^{m^2-1})), \quad \forall \Lambda \in \mathcal{L}, \tag{2.3}$$

which define the local time evolutions,

$$\alpha_t^{Q,\Lambda}(\cdot) = \exp\{itA_\Lambda\} \cdot \exp\{-itA_\Lambda\}, \quad t \in \mathbb{R}, \quad \Lambda \in \mathcal{L}. \tag{2.4}$$

New developments[9] generalize to arbitrary $\mathcal{C}^\infty$-functions Q.

1. The Schrödinger picture

For each $t \in \mathbb{R}$ there exists an affine bijection ν_t^Q on the folium $\mathcal{F}_a^p$ such that

$$\langle \nu_t^Q(\omega); X \rangle = \lim_{\Lambda \in \mathcal{L}} \langle \omega; \Pi_a^p(\alpha_t^{Q,\Lambda}(X)) \rangle, \quad \forall X \in \mathcal{A}, \quad \forall \omega \in \mathcal{F}_a^p.$$

The group $\nu^Q \equiv \{\nu_t^Q | t \in \mathbb{R}\}$ induces the dynamical descriptions $(\mathcal{A}, \mathcal{F}_a^p, \nu^Q)$ and $(\mathcal{A}_e, \mathcal{F}_a^p, \nu^Q)$ in the sense of Definition 1.2.

2. The Heisenberg picture

By the duality (1.3) we get the dynamics $(\mathscr{M}_a^p, \alpha^Q)$ in the Heisenberg picture. The group $\alpha^Q \equiv \{\alpha_t^Q | t \in \mathbb{R}\}$ of automorphisms on $\mathscr{M}_a^p$ leaves the represented algebra $\Pi_a^p(\mathscr{A})$ invariant, if and only if Q is linear. But α^Q leaves the C^*-algebra $\Pi_a^p(\mathscr{A}_e) \subset \mathscr{M}_a^p$ invariant, and lifts to the C^*-dynamical system $(\mathscr{A}_e, \alpha^Q)$ (since the representation Π_a^p of $\mathscr{A}_e$ is faithful). We also regard $(\mathscr{A}_e, \alpha^Q)$ as the dynamics in the Heisenberg picture.

D. The classical (sub-)dynamics

1. The classical Hamiltonian phase flow

With the Poisson bracket (2.2) and the polynomial Q as a Hamiltonian function it is introduced the Hamiltonian vector field $\lambda_Q : P \mapsto \mathscr{G}^*$ in the standard way, $\langle \lambda_Q(x); a \rangle := \{Q,a\}(x), \forall a \in \mathscr{G}$ for $x \in P$ (here $a \in \mathscr{G} = \mathscr{G}^{**}$ is considered as a mapping on P). The associated classical Hamiltonian phase flow $\varphi^Q \equiv \{\varphi_t^Q | t \in \mathbb{R}\}$ on the classical phase space P then is obtained from the differential equation $(d/dt)\varphi_t^Q(x) = \lambda_Q(\varphi_t^Q(x)), \forall x \in P$.

2. The Schrödinger picture

The group ν^Q leaves $\partial_e \mathscr{S}^p(\mathscr{A})$ and $\mathscr{S}^p(\mathscr{A})$ invariant. More exactly, it is $\nu_t^Q(\omega_x) = \omega_{\varphi_t^Q(x)}, \forall x \in P$ with the above phase flow φ^Q. The time evolution $\nu_t^Q(\omega)$ for $\omega \in \mathscr{S}^p(\mathscr{A})$ then is given by $\mu_\omega \circ \varphi_{-t}^Q =: (\varphi_t^Q)^{**}(\mu_\omega)$ with the associated measure $\mu_\omega \in M_+^1(P)$. This implies $(\mathscr{N}_{\mathrm{cl}}, \mathscr{S}^p(\mathscr{A}), \nu^Q) \cong (C(P), M_+^1(P), (\varphi^Q)^{**})$ to be the dynamical description of the classical part of the mean field system in the Schrödinger picture.

Thus we have $\|\nu_t^Q(\omega_x) - \omega_x\| = \|\omega_{\varphi_t^Q(x)} - \omega_x\| = 2$ for small t for some $x \in P$, whenever Q is not constant (since $\|\omega_x - \omega_y\| = 2$ for $x \neq y$), which demonstrates that the dynamical description $(\mathscr{A}, \mathscr{F}_a^p, \nu^Q)$ is not covariant (cf. Definition 1.3).

3. The Heisenberg picture

Let us turn to the classical dynamics in the Heisenberg picture. It is $\alpha_t^Q(\mathscr{N}_{\mathrm{cl}}) = \mathscr{N}_{\mathrm{cl}} \forall t \in \mathbb{R}$, and via the isomorphism $\hat{\mathscr{P}}$ the restriction is given by $\alpha_t^Q|_{\mathscr{N}_{\mathrm{cl}}} = \hat{\mathscr{P}} \circ (\varphi_t^Q)^* \circ \hat{\mathscr{P}}^{-1}$, where $(\varphi_t^Q)^*(\xi) := \xi \circ \varphi_t^Q$ for $\xi \in C(P)$. Thus the C^*-dynamical system $(\mathscr{N}_{\mathrm{cl}}, \alpha^Q)$ is isomorphic to $(C(P), (\varphi^Q)^*)$, the well-known classical dynamics of the observables.

III. THE BOSON FIELD

The one-boson test function space (E, σ) is a real vector space E equipped with the symplectic form σ [i.e., $\sigma : E \times E \to \mathbb{R}$ is bilinear with $\sigma(f,g) = -\sigma(g,f), \forall f,g \in E$], which may be degenerate.

A. The C^*-Weyl algebra of the boson field

The C^*-algebra for the boson system is set up as the Weyl algebra $\mathscr{W}(E,\sigma)$ over (E,σ), which is constructed from unitary elements $W(f), f \in E$—the Weyl operators—satisfying for all $f,g \in E$,

$$W(f)W(g) = \exp\left\{-\frac{i}{2}\sigma(f,g)\right\} W(f+g), \quad W(f)^* = W(-f), \tag{3.1}$$

and by means of the minimal regular norm.[39,11,40,13] $\mathscr{W}(E,\sigma)$ is simple, if and only if σ is nondegenerate [i.e., $\sigma(f,g) = 0, \forall g \in E$ implies $f = 0$]. For the subspace $D \subseteq E$ the C^*-subalgebra of $\mathscr{W}(E,\sigma)$ generated by $\{W(f) | f \in D\}$ just agrees with the Weyl algebra $\mathscr{W}(D,\sigma)$. It holds $\mathscr{W}(D,\sigma) = \mathscr{W}(E,\sigma)$, if and only if $D = E$.

A linear mapping $b:E\to E$ is denoted a symplectic transformation on (E,σ), if b is bijective and satisfies $\sigma(bf,bg)=\sigma(f,g),\forall f,g\in E$. For each symplectic b on (E,σ) there exists a unique automorphism β_b on $\mathscr{W}(E,\sigma)$ with $\beta_b(W(f))=W(bf),\forall f\in E$, which is called the associated Bogoliubov transformation.

A representation Π of $\mathscr{W}(E,\sigma)$ is called regular, if for each $f\in E$ the unitary group $t\in\mathbb{R}\mapsto\Pi(W(tf))$ is strongly continuous. Their generators $\Phi_\Pi(f),f\in E$, are the so-called field operators, $\Pi(W(tf))=\exp\{it\Phi_\Pi(f)\},\forall t\in\mathbb{R}$. Obviously, $f\in E\mapsto\Phi_\Pi(f)$ is linear, and on suitable dense domains they fulfill the canonical commutation relations $\Phi_\Pi(f)\Phi_\Pi(g)-\Phi_\Pi(g)\Phi_\Pi(f)=i\sigma(f,g)\mathbb{1}_\Pi,\forall f,g\in E$.

The characteristic function of the state ω on $\mathscr{W}(E,\sigma)$ is defined to be the mapping $C_\omega:E\to\mathbb{C}$, $f\mapsto\langle\omega;W(f)\rangle=C_\omega(f)$. Let us characterize the state space of $\mathscr{W}(E,\sigma)$ by the characteristic functions. $\mathsf{C}(E,\sigma)$ is the convex set of functions $C:E\to\mathbb{C}$ with $C(0)=1$ and for which the map $(f,g)\mapsto\exp\{(i/2)\sigma(f,g)\}C(g-f)$ constitutes a positive-definite kernel $E\times E\to\mathbb{C}$.[41] From Eqs. (2.17) and (3.2) in Ref. 39 (cf. also Ref. 15) it follows the affinity and bijectivity of the map

$$\mathscr{S}(\mathscr{W}(E,\sigma))\to\mathsf{C}(E,\sigma),\quad \omega\mapsto C_\omega. \tag{3.2}$$

B. The folium of τ-continuous states

Definition 3.1: Denote by $\mathscr{T}(E,\sigma)$ the set of all topologies τ on E such that for each $f\in E$ the maps $g\in E\mapsto f+g\in E$ and $g\in E\mapsto\sigma(f,g)\in\mathbb{R}$ are continuous with respect to the τ topology.

Proposition 3.2: For each $\tau\in\mathscr{T}(E,\sigma)$ the set of τ-continuous states,

$$\mathscr{F}_b^\tau(E,\sigma):=\{\omega\in\mathscr{S}(\mathscr{W}(E,\sigma))|C_\omega\ \text{ is }\ \tau\ \text{ continuous}\},$$

is a folium on $\mathscr{W}(E,\sigma)$.

Proof: Let $\omega\in\mathscr{F}_b^\tau(E,\sigma)$. Obviously $\mathscr{F}_b^\tau(E,\sigma)$ is convex. Using an $\epsilon/3$ argument one easily checks that $\mathscr{F}_b^\tau(E,\sigma)$ is norm closed. For $\omega\in\mathscr{F}_b^\tau(E,\sigma)$ the map (use the Weyl relations)

$$f\in E\mapsto\langle\omega;W(g)W(f)W(h)\rangle=\exp\left\{-\frac{i}{2}(\sigma(g,f)+\sigma(g+f,h))\right\}\langle\omega;W(g+f+h)\rangle$$

is τ continuous, from which by an $\epsilon/3$ argument the continuity of $f\in E\mapsto\langle\omega;B^*W(f)B\rangle$ for each $B\in\mathscr{W}(E,\sigma)$ follows. ■

The natural ordering on $\mathscr{T}(E,\sigma)$ obviously carries over to the associated folia:

$$\tau_1\leqslant\tau_2\leqslant d\ \Rightarrow\ \mathscr{F}_b^{\tau_1}(E,\sigma)\subseteq\mathscr{F}_b^{\tau_2}(E,\sigma)\subseteq\mathscr{F}_b^{d}(E,\sigma)=\mathscr{S}(\mathscr{W}(E,\sigma)),$$

where $d\in\mathscr{T}(E,\sigma)$ means the discrete topology.

Proposition 3.3: Let $\tau\in\mathscr{T}(E,\sigma)$, then $f\in E\mapsto\Pi_b^\tau(W(f))=:W_b^\tau(f)$ is continuous with respect to the topology τ on E and the strong operator topology on $\mathscr{M}_b^\tau:=\Pi_b^\tau(\mathscr{W}(E,\sigma))''$, where Π_b^τ is the representation associated with $\mathscr{F}_b^\tau(E,\sigma)$.

Proof: Let $\omega\in\mathscr{F}_b^\tau(E,\sigma)$. For $f,g,h\in E$ by the Weyl relations one gets

$$\begin{aligned}&\|(\Pi_\omega(W(f))-\Pi_\omega(W(g)))\Pi_\omega(W(h))\Omega_\omega\|^2\\&\quad=\langle\omega;W(-h)(W(-f)-W(-g))(W(f)-W(g))W(h)\rangle\\&\quad=2-2\ \mathrm{Re}(\exp\{(i/2)\sigma(f,g)+i\sigma(h,g-f)\}\langle\omega;W(g-f)\rangle),\end{aligned}$$

from which by an $\epsilon/3$ argument it follows the continuity of $f\in E\mapsto\Pi_\omega(W(f))$. Now observe that $\Pi_b^\tau=\oplus_{\omega\in\mathscr{F}_b^\tau}\Pi_\omega$, and the assertion is proved. ■

We mention, because of Proposition 3.3 the representation Π_b^τ is regular, if $t\in\mathbb{R}\mapsto tf\in E$ is τ continuous for each $f\in E$. Thus, in the case of a vector space topology $\tau\in\mathcal{T}(E,\sigma)$ the field operators $\Phi_b^\tau(f),f\in E$, associated with Π_b^τ exist.

C. The (quasi-)free boson dynamics

The subsequent definition of a quasi-free dynamics generalizes an idea in Ref. 24.

The single particle dynamics is given by a group $v\equiv\{v_t|t\in\mathbb{R}\}$ of symplectic transformations v_t on a larger symplectic space $(\mathcal{E},\sigma)\supseteq(E,\sigma)$ (i.e., v_0 is the identity, and $v_s\circ v_t=v_{s+t},\forall s,t\in\mathbb{R}$). Unfortunately, in many physical cases E is a proper subspace of $\mathcal{E}$, which is not v invariant [i.e., $v_t(E)$ is not a subset of E for some $t\neq0$].

The group of v on $\mathcal{E}$ is assumed to be connected with E by a topology τ fulfilling

- $\tau\in\mathcal{T}(\mathcal{E},\sigma)$ is a locally convex topology on $\mathcal{E}$;
- $f\in\mathcal{E}\mapsto v_tf\in\mathcal{E}$ is τ-τ continuous for each $t\in\mathbb{R}$;
- $t\in\mathbb{R}\mapsto v_tf\in\mathcal{E}$ is τ continuous for each $f\in\mathcal{E}$;
- $\mathcal{E}$ is τ-complete, and E is τ dense in $\mathcal{E}$.

1. The Schrödinger picture

By construction for every $\omega\in\mathcal{F}_b^\tau(E,\sigma)$, the characteristic function $C_\omega\in\mathsf{C}(E,\sigma)$ τ continuously extends to $C_\omega\in\mathsf{C}(\mathcal{E},\sigma)$. Moreover, for each $\omega\in\mathcal{F}_b^\tau(E,\sigma)$ the mapping $f\in E\mapsto C_\omega(v_tf)$ is τ continuous and an element of $\mathsf{C}(E,\sigma)$, and thus by the relation (3.2) and Proposition 3.2 defines a unique state $\nu_t^v(\omega)\in\mathcal{F}_b^\tau(E,\sigma)$. One easily checks that the mapping ν_t^v is affine and bijective on the folium $\mathcal{F}_b^\tau(E,\sigma)$. The continuity of $t\mapsto v_t$ and the group property of v imply $\nu^v\equiv\{\nu_t^v|t\in\mathbb{R}\}$ to be a group that satisfies the continuity conditions (1.2). Summarizing, we have shown the following.

Proposition 3.4: $(\mathcal{W}(E,\sigma),\mathcal{F}_b^\tau(E,\sigma),\nu^v)$ *is a dynamical description in the sense of Definition 1.2, where* $C_{\nu_t^v(\omega)}=C_\omega\circ v_t,\forall t\in\mathbb{R}$ *for each* $\omega\in\mathcal{F}_b^\tau(E,\sigma)$.

Let us give some physically relevant examples.

Example 3.5: For thermodynamical reasons the Weyl algebra $\mathcal{W}(E,\sigma)$ *should have a quasilocal structure.*[11] *Thus one usually takes* $E=\mathcal{D}(\mathbb{R}^p)$ *the space of all infinitely differentiable functions with compact support in* $\mathbb{R}^p$ *and* σ *to be the imaginary part of the scalar product* $\langle f|g\rangle=\int_{\mathbb{R}^p}\bar{f}g\,d^px$. *On* $\mathcal{W}(E,\sigma)$ *the thermodynamic limits for local Gibbs states are performed. The local Gibbs states are defined on the local algebras* $\mathcal{W}(\mathcal{D}(\Gamma),\sigma)$, *where the* Γ *are open, bounded regions of* $\mathbb{R}^p$ *(e.g., for the Bose–Einstein condensation, cf. Refs. 42, 43, 11, and 24).*

The one-particle dynamics of the bosons is $v_t=\exp\{-it\Delta\}$ *on* $\mathsf{L}^2(\mathbb{R}^p)$. *It is obtained by the thermodynamic limit of the local time translations* $\exp\{-it\Delta_\Gamma\}$, *where the local Laplacians* $-\Delta_\Gamma$ *obey some boundary conditions for the local regions* Γ. *It is well known that for* $0\neq f\in\mathcal{D}(\mathbb{R}^p)$ *the evolved* $v_t(f)$ *no longer has compact support, i.e.,* $v_t(f)\notin\mathcal{D}(\mathbb{R}^p)$ *for* $t\neq0$.

There are several possibilities for choosing a larger symplectic space $(\mathcal{E},\sigma)$ *and a suitable topology* τ *fulfilling the above assumptions. For example, let* $\mathcal{E}$ *be the set of functions with rapid decrease on* $\mathbb{R}^p$, *equipped with the natural Fréchet topology* τ_{Fr}, *which leads to the folium* $\mathcal{F}_b^{Fr}$ *of* τ_{Fr}*-continuous states on* $\mathcal{W}(E,\sigma)$. *Or,* $\mathcal{E}=\mathsf{L}^2(\mathbb{R}^p)$ *with the scalar product topology* τ_s, *which gives the folium* $\mathcal{F}_b^s$ *of* τ_s*-continuous states on* $\mathcal{W}(E,\sigma)$. *Since* $\tau_s<\tau_{Fr}$, $\mathcal{F}_b^s$ *is a proper subfolium of* $\mathcal{F}_b^{Fr}$. *And the dynamical description* $(\mathcal{W}(E,\sigma),\mathcal{F}_b^s,\nu^v)$ *is a dynamical subdescription of* $(\mathcal{W}(E,\sigma),\mathcal{F}_b^{Fr},\nu^v)$. *The limiting Gibbs states, however, are elements of* $\mathcal{F}_b^{Fr}$ *but not of* $\mathcal{F}_b^s$. *In Sec. IV C further examples are given.*

For photons one has a similar situation,[44] *where the one-photon Hamiltonians are the square roots of the Laplacians.*

2. The Heisenberg picture

As an immediate consequence of (3.2) and the Propositions 3.2, 3.3, and 3.4 we have that the restrictions of the states in $\mathcal{F}_b^\tau(\mathcal{E},\sigma)$ from the enlarged Weyl algebra $\mathcal{W}(\mathcal{E},\sigma)$ to the subalgebra

$\mathscr{W}(E,\sigma)$ just give the folium $\mathscr{F}_b^\tau(E,\sigma)$, which in the sequel is denoted by $\mathscr{F}_b^\tau$. Moreover, the representation Π_b^τ of $\mathscr{W}(E,\sigma)$ is the restriction of the representation Π_b^τ of $\mathscr{W}(\mathscr{E},\sigma)$, and $\mathscr{M}_b^\tau=\Pi_b^\tau(\mathscr{W}(\mathscr{E},\sigma))''=\Pi_b^\tau(\mathscr{W}(E,\sigma))''$.

By the duality (1.3) we get from $(\mathscr{W}(E,\sigma),\mathscr{F}_b^\tau,\nu^v)$ the dynamics $(\mathscr{M}_b^\tau,\beta^v)$ in the Heisenberg picture. The group β^v is just the Π_b^τ-normal extension to $\mathscr{M}_b^\tau$ of the group of Bogoliubov transformations $\beta^v\equiv\{\beta_t^v|t\in\mathbb{R}\}$ (denoted by the same symbol) on the enlarged Weyl algebra $\mathscr{W}(\mathscr{E},\sigma)$, $\beta_t^v(W(f))=W(v_t f),\forall f\in\mathscr{E}$ for every $t\in\mathbb{R}$. From $\|W(f)-W(g)\|=2$ for $f\neq g$ it immediately follows that $(\mathscr{W}(\mathscr{E},\sigma),\beta^v)$ is not a C^*-dynamical system (whenever v is nontrivial). We also regard $(\mathscr{W}(\mathscr{E},\sigma),\beta^v)$ as the dynamics in the Heisenberg picture for our boson field.

IV. COCYCLE DYNAMICS FOR THE INTERACTING SYSTEM

Here let us fix an arbitrary polynomial Q for the dynamics of the mean field system and an arbitrary one-boson dynamics $v\equiv\{v_t|t\in\mathbb{R}\}$ on the larger symplectic space $(\mathscr{E},\sigma)\supseteq(E,\sigma)$ with the associated topology τ from Sec. III C.

The free dynamics in the Schrödinger picture is the dynamical description $(\mathscr{C},\mathscr{F},\nu)$ on the C^*-algebra $\mathscr{C}:=\mathscr{A}\otimes\mathscr{W}(E,\sigma)$ of the composite mean field–boson system. Here $\mathscr{F}:=\mathscr{F}_a^p\otimes\mathscr{F}_b^\tau$ is the folium of $\Pi_a^p\otimes\Pi_b^\tau$-normal states on $\mathscr{C}$, and $\nu_t:=\nu_t^Q\otimes\nu_t^v,\forall t\in\mathbb{R}$.

Let $\gamma_t:=\alpha_t^Q\otimes\beta_t^v,\forall t\in\mathbb{R}$. The free dynamics in the Heisenberg picture is $(\mathscr{M},\gamma)$, where $\mathscr{M}:=\mathscr{M}_a^p\overline{\otimes}\mathscr{M}_b^\tau=\Pi_a^p\otimes\Pi_b^\tau(\mathscr{C})''=\Pi_a^p\otimes\Pi_b^\tau(\mathscr{C}_e)''$, which is obtained from $(\mathscr{C},\mathscr{F},\nu)$ by the duality relation (1.3).

Another formulation of the dynamics in the Heisenberg picture is given in terms of the extended C^*-algebras. For the mean field we have the C^*-dynamical system $(\mathscr{A}_e,\alpha^Q)$, and for the bosons we have the time-noncontinuous group of Bogoliubov transformations $(\mathscr{W}(\mathscr{E},\sigma),\beta^v)$. The tensor product gives the Heisenberg dynamics $(\mathscr{C}_e,\gamma)$ with the extended composite C^*-algebra,

$$\mathscr{C}_e:=\mathscr{A}_e\otimes\mathscr{W}(\mathscr{E},\sigma)=\mathscr{A}\otimes C(P)\otimes\mathscr{W}(\mathscr{E},\sigma)\cong C(P,\mathscr{A}\otimes\mathscr{W}(\mathscr{E},\sigma))\cong\mathscr{A}\otimes C(P,\mathscr{W}(\mathscr{E},\sigma))$$

[which is unique since $\mathscr{A}$ and $C(P)$ are nuclear], where $C(P,\mathscr{V})$ ($\mathscr{V}$ is Banach space) denotes the Banach space of all continuous $\mathscr{V}$-valued functions with the uniform norm $\|X\|_\infty=\sup_{x\in P}\|X(x)\|$ [as usual $C(P)\equiv C(P,\mathbb{C})$].

With the help of cocycle techniques we first construct a class of interacting dynamics in the Heisenberg picture as time-noncontinuous groups of automorphisms on $\mathscr{C}_e$. Each solution of the cocycle equations gives a different interaction. And thus, the whole of all solutions gives our treated class of interactions.

Then we extend by W^*-continuity to $\mathscr{M}$, i.e., in the representation $\Pi_a^p\otimes\Pi_b^\tau$ of $\mathscr{C}_e$. Here we need the generalized spectral integral, which is presented in the Appendix. And in a third step we formulate the above class of interactions in the Schrödinger picture as dynamical descriptions (see Definition 1.2) on the folium $\mathscr{F}$ of $\mathscr{C}$, resp., of $\mathscr{C}_e$.

We investigate the cocycle dynamics in suitable covariant subrepresentations, which leads to an enlarged system of cocycle equations for the unitary implementation of the cocycle automorphism group. We finally turn to some concretizations and realize the cocycle dynamics as a thermodynamic limit in suitable subrepresentations.

Let us mention that similar to the previous sections it would also be possible to start with the Schrödinger dynamical description of the interacting systems, and then to turn over to the Heisenberg picture.

A. The algebraic cocycle dynamics

1. The Heisenberg dynamics on the extended C^*-algebra

Using the above isomorphies for $\mathscr{C}_e$ we have the following.

Theorem 4.1: *Let $\psi:\mathbb{R}\times P\to\mathscr{E}$, $(t,x)\mapsto\psi(t,x)$ be a function so that $x\in P\mapsto\sigma(\psi(t,x),f)$ is continuous for all $t\in\mathbb{R}$ and each $f\in\mathscr{E}$. Then, for each $t\in\mathbb{R}$,*

$$\gamma_t^{\psi}(Z)(x) := [1_{\mathscr{A}} \otimes W(\psi(t,x))][\gamma_t(Z)(x)][1_{\mathscr{A}} \otimes W(-\psi(t,x))], \quad \forall x \in P, \quad Z \in \mathscr{C}_e,$$

defines the automorphism γ_t^{ψ} *on* $\mathscr{C}_e$. $\psi \equiv 0$ *gives the free time evolutions* $\gamma_t^0 = \gamma_t$, $\forall t \in \mathbb{R}$.

Moreover, if $\psi(t,x)$ *satisfies the cocycle equations*

$$\psi(s+t,x) = \psi(s,x) + v_s \psi(t, \varphi_s^Q x), \quad \forall x \in P, \quad \forall s,t \in \mathbb{R}, \tag{4.1}$$

then $\gamma^{\psi} \equiv \{\gamma_t^{\psi} | t \in \mathbb{R}\}$ *is a group, i.e.,* $\gamma_s^{\psi} \circ \gamma_t^{\psi} = \gamma_{s+t}^{\psi}$, $\forall s,t \in \mathbb{R}$, *and* γ_0^{ψ} *is the identity.*

Proof: We define the implementing map for $Z \in \mathscr{C}_e \cong C(P, \mathscr{A} \otimes \mathscr{W}(\mathscr{E},\sigma))$ and $t \in \mathbb{R}$,

$$\chi_t(Z): P \to \mathscr{A} \otimes \mathscr{W}(\mathscr{E},\sigma), \quad x \mapsto [1_{\mathscr{A}} \otimes W(\psi(t,x))] Z(x) [1_{\mathscr{A}} \otimes W(-\psi(t,x))].$$

By the unitarity of the Weyl operators one gets $\|\chi_t(Z)\|_{\infty} = \|Z\|_{\infty}$. We prove the continuity of the function $\chi_t(Z)$. First, let $Z = X \otimes W(f)$ with $X \in \mathscr{A}_e \cong C(P, \mathscr{A})$ and $f \in \mathscr{E}$. The Weyl relations yield $\chi_t(Z)(x) = \exp\{-i\sigma(\psi(t,x), f)\} X(x) \otimes W(f)$, $\forall x \in P$, which is continuous in $x \in P$. Now we approximate an arbitrary $Z \in \mathscr{C}_e$ by linear combinations of elements $X \otimes W(f)$, and the continuity follows with an $\epsilon/3$ argument.

$\chi_t : \mathscr{C}_e \to \mathscr{C}_e$, $Z \mapsto \chi_t(Z)$ obviously is an automorphism on $\mathscr{C}_e$, whose inverse is given by $\chi_t^{-1}(Z)(x) = [1_{\mathscr{A}} \otimes W(-\psi(t,x))] Z(x) [1_{\mathscr{A}} \otimes W(\psi(t,x))], \forall Z \in \mathscr{C}_e$, $\forall t \in \mathbb{R}, \forall x \in P$. Consequently, $\gamma_t^{\psi} = \chi_t \circ \gamma_t$ is an automorphism too.

Let (4.1) be valid. From Sec. II it immediately follows that $\alpha_t^Q \otimes id_{\mathscr{W}(\mathscr{E},\sigma)}$ maps $1_{\mathscr{A}} \otimes Y \in 1_{\mathscr{A}} \otimes C(P, \mathscr{W}(\mathscr{E},\sigma)) \subset \mathscr{C}_e$ onto the continuous function $1_{\mathscr{A}} \otimes Y(\varphi_t^Q(\cdot)) \in \mathscr{C}_e$. Now, for $Z = A \otimes Y$, where $A \in \mathscr{A}$ and $Y \in C(P, \mathscr{W}(\mathscr{E},\sigma))$, one checks that for all $s,t \in \mathbb{R}$ and each $x \in P$,

$$\gamma_s \circ \chi_t(Z)(x) = [1_{\mathscr{A}} \otimes W(v_s \psi(t, \varphi_s^Q(x)))][\gamma_s(Z)(x)][1_{\mathscr{A}} \otimes W(-v_s \psi(t, \varphi_s^Q(x)))],$$

which then extends to all $Z \in \mathscr{C}_e$. Using this and the Weyl relations, the group property of γ^{ψ} is immediate. Since (4.1) yields $\psi(0,x) = 0$, $\forall x \in P$, we have that γ_0^{ψ} is the identity on $\mathscr{C}_e$. ■

Obviously, for each solution ψ of the cocycle equations (4.1) we have a different group γ^{ψ} of automorphisms on $\mathscr{C}_e$. The cocycle equations define an initial value problem.

Theorem 4.2: *For any* $\phi \in C(P,\mathscr{E})$ *it holds: The cocycle equations (4.1) with the initial value* $(\partial\psi/\partial t)(0,x) = \phi(x), \forall x \in P$ *are uniquely solvable, with the solution* $\psi : \mathbb{R} \times P \to \mathscr{E}$,

$$\psi(t,x) = \int_{r=0}^{t} v_r \phi(\varphi_r^Q x) dr, \quad x \in P, \quad t \in \mathbb{R}. \tag{4.2}$$

The integrals and the derivatives are understood with respect to the τ *topology, where their existences are ensured by the completeness of* $\mathscr{E}$.

Proof: That (4.2) fulfills the cocycle equations (4.1) is easily checked. The cocycle equations imply $\psi(0,x) = 0, \forall x \in P$. $t \to 0$ in $[\psi(s+t,x) - \psi(s,x)]/t = v_s \psi(t, \varphi_s^Q x)/t$ gives the partial differential equation $(\partial\psi/\partial s)(s,x) = v_s \phi(\varphi_s^Q x)$, which is uniquely solvable with the initial value $\psi(0,x) = 0$. ■

The above theorem characterizes the solutions $\psi \equiv \psi^{\phi}$ of the cocycle equations by their initial values $\phi \in C(P,\mathscr{E})$. In the sequel we will call the initial value ϕ a *coupling function* for our mean field–boson system. Every coupling function $\phi \in C(P,\mathscr{E})$ gives rise to an interaction between the mean field system and the boson field, and the interacting dynamics is given by the group γ^{ψ} on $\mathscr{C}_e$. And thus, the interactions treated in the present work may be indexed by $C(P,\mathscr{E})$. In Proposition 4.5 it becomes transparent how the coupling operator corresponding to the coupling function ϕ looks.

2. The Heisenberg dynamics on the composite W*-algebra

Here the time-noncontinuous Heisenberg dynamics $(\mathscr{C}_e,\gamma^\psi)$ from Theorem 4.1 for an arbitrary solution ψ of the cocycle equations is considered in the representation $\Pi_a^p \otimes \Pi_b^\tau$ of $\mathscr{C}_e=\mathscr{A}_e\otimes\mathscr{W}(\mathscr{E},\sigma)$, i.e., on the W^*-tensor product, $\mathscr{M}=\mathscr{M}_a^p\overline{\otimes}\mathscr{M}_b^\tau$.

However, we need some preparatories. With the projection-valued measure $\mathscr{P}$ of Sec. II A and the general spectral integral of the Appendix we define

$$V(\zeta;\eta):=\int_P \exp\{i\zeta(x)\}[\mathbb{1}_a^p\otimes W_b^\tau(\eta(x))]d(\mathscr{P}(x)\otimes\mathbb{1}_b^\tau)\in\mathscr{Z}_a^p\overline{\otimes}\mathscr{M}_b^\tau, \tag{4.3}$$

for every $\zeta\in C(P,\mathbb{R})$ and $\eta\in C(P,\mathscr{E})$. For the existence of the integrals observe the continuity of $x\in P\mapsto W_b^\tau(\eta(x))$ in the strong operator topology by Proposition 3.3.

Lemma 4.3: Let $\zeta_1,\zeta_2,\zeta\in C(P,\mathbb{R})$ and $\eta_1,\eta_2,\eta\in C(P,\mathscr{E})$. Then

(a) $V(\zeta;\eta)$ is unitary with $V(\zeta;\eta)^*=V(-\zeta;-\eta)$.

(b) $V(\zeta_1;\eta_1)V(\zeta_2;\eta_2)=V(\zeta_{1,2};\eta_1+\eta_2)$, where

$$\zeta_{1,2}(x):=\zeta_1(x)+\zeta_2(x)-\tfrac{1}{2}(\eta_1(x),\eta_2(x)),\quad \forall x\in P.$$

(c)$\alpha_s^Q\otimes\beta_t^v(V(\zeta;\eta))=V(\zeta\circ\varphi_s^Q;v_t(\eta\circ\varphi_s^Q)),\forall s,t\in\mathbb{R}$, where

$$v_t(\eta\circ\varphi_s^Q):P\to\mathscr{E},\quad x\mapsto v_t\eta(\varphi_s^Q x).$$

Proof: The proof is easily checked by the weak definition of $V(\zeta;\eta)$ in Theorem A.1 of the Appendix and by observing $\alpha_t^Q(\int_P\xi\,d\mathscr{P})=\int_P\xi\circ\varphi_t^Q\,d\mathscr{P}$ for $\xi\in C(P)$ (see Sec. II D). ■

Theorem 4.4: *Let $\psi:\mathbb{R}\times P\to\mathscr{E},(t,x)\mapsto\psi(t,x)=:\psi_t(x)$ be a continuous function. Then, for each $t\in\mathbb{R}$ the automorphism γ_t^ψ on $\mathscr{C}_e$ in the representation $\Pi_a^p\otimes\Pi_b^\tau$ W^*-continuously extends to an automorphism on $\mathscr{M}$ denoted by the same symbol, which with arbitrary $\zeta\in C(P,\mathbb{R})$ (one may choose $\zeta=0$) is given by*

$$\gamma_t^\psi(Z)=V(\zeta;\psi_t)\,\gamma_t(Z)V(\zeta;\psi_t)^*,\quad \forall Z\in\mathscr{M}.$$

Proof: For each $t\in\mathbb{R}$ $\tilde{\gamma}_t^\psi(\cdot):=V(0;\psi_t)\,\gamma_t(\cdot)V(0;\psi_t)^*$ is an automorphism on $\mathscr{M}$. With Lemma 4.3 and $V(0;g)=\mathbb{1}_a^p\otimes W_b^\tau(g)$ (where $g\in\mathscr{E}$ is considered as a constant function on P) one establishes for each $X\in\mathscr{M}_a^p$ and $f\in\mathscr{E}$,

$$\begin{aligned}V(\zeta;\psi_t)\,\gamma_t(X\otimes W_b^\tau(f\ ))V(\zeta;\psi_t)^*&=V(\zeta;\psi_t)[\alpha_t^Q(X)\otimes\mathbb{1}_b^\tau][\mathbb{1}_a^p\otimes W_b^\tau(v_tf\ )]V(\zeta;\psi_t)^*\\&=[\alpha_t^Q(X)\otimes\mathbb{1}_b^\tau][V(\zeta;\psi_t)V(0;v_tf\ )V(-\zeta;-\psi_t)]\\&=[\alpha_t^Q(X)\otimes\mathbb{1}_b^\tau]V(-\sigma(\psi_t(\cdot),v_tf\ );v_tf\ )\\&=[\alpha_t^Q(X)\otimes\mathbb{1}_b^\tau][V(0;\psi_t)V(0;v_tf\ )V(0;-\psi_t)]\\&=\tilde{\gamma}_t^\psi(X\otimes W_b^\tau(f\ )).\end{aligned}$$

We now prove the agreement of $\tilde{\gamma}_t^\psi\circ(\Pi_a^p\otimes\Pi_b^\tau)$ with $(\Pi_a^p\otimes\Pi_b^\tau)\circ\gamma_t^\psi$,

$$\begin{aligned}\tilde{\gamma}_t^\psi(X\otimes W_b^\tau(f\ ))&=[\alpha_t^Q(X)\otimes\mathbb{1}_b^\tau]V(-\sigma(\psi_t(\cdot),v_tf\ );v_tf\ )\\&=[\alpha_t^Q(X)\otimes\mathbb{1}_b^\tau]\left(\int_P\exp\{-i\sigma(\psi_t(x),v_tf\ )\}d\mathscr{P}(x)\right)\otimes W_b^\tau(v_tf\ )\\&=\left[\int_P\exp\{-i\sigma(\psi_t(x),v_tf\ )\}d\mathscr{P}(x)\otimes\mathbb{1}_b^\tau\right][\gamma_t(X\otimes W_b^\tau(f\ ))].\end{aligned}$$

On the other side $\gamma_t^{\psi}(X\otimes W(f))(x)=\exp\{-i\sigma(\psi_t(x),v_tf)\}\,\gamma_t(X\otimes W(f))(x)$. ■

As a corollary of the above proof we have the explicit evaluation on elements of the form $X\otimes W_b^{\tau}(f)$, where $X\in\mathscr{M}_a^p$ and $f\in\mathscr{E}$:

$$\gamma_t^{\psi}(X\otimes W_b^{\tau}(f))=\Bigg[\underbrace{\left(\int_P \exp\{-i\sigma(\psi(t,x),v_tf)\}d\mathscr{P}(x)\right)}_{\in\mathscr{Z}_a^p=\mathscr{M}_a^p\cap\mathscr{M}_a^{p\prime}}\alpha_t^Q(X)\Bigg]\otimes W_b^{\tau}(v_tf).$$

3. Coupling functions and interaction operators

Let us first consider an arbitrary C^*- or W^*-dynamical system $(\mathscr{B},\tau)$, which we perturb with $P=P^*\in\mathscr{B}$. If δ is the generator of τ, $\delta=(d/dt)\tau_t|_{t=0}$, then $\delta+i[P,\cdot]$ is the generator of the perturbed dynamical one-parameter group τ^P on $\mathscr{B}$. τ^P may be calculated by the Dyson expansion (Ref. 11, Proposition 5.4.1),

$$\tau_t^P(B)=\sum_{n=0}^{\infty} i^n\int_{t_1=0}^{t}dt_1\cdots\int_{t_n=0}^{t_{n-1}}dt_n[\tau_{t_n}(P),[\cdots[\tau_{t_1}(P),\tau_t(B)]\cdots]],\quad B\in\mathscr{B}. \tag{4.4}$$

From the unperturbed (free) dynamics τ and the perturbed (interacting) dynamics τ^P, the perturbation P is obtained back by $i[P,B]=(d/dt)\tau_t^P(\tau_{-t}(B))|_{t=0},\forall B=\mathscr{B}$.

As in the above case of a bounded perturbation of a C^*- or W^*-dynamical system we now determine the perturbation (interaction) operator P^{ϕ} associated with our interacting dynamics γ^{ψ} by comparing with the free dynamics γ, where $\psi=\psi^{\phi}$ is the solution (4.2) of the cocycle equations (4.1) associated with the coupling function $\phi\in C(P,\mathscr{E})$. Formally we have $i[P^{\phi},Z]=(d/dt)\gamma_t^{\psi}(\gamma_{-t}(Z))|_{t=0}$ for $Z\in\mathscr{M}$. Since $\gamma_t^{\psi}(\gamma_{-t}(Z))=V(0;\psi_t)ZV(0;\psi_t)^*,\forall Z\in\mathscr{M}$, we conclude that P^{ϕ} is affiliated to $\mathscr{M}$ and given (up to an additive term in the center of $\mathscr{M}$) by

$$P^{\phi}=\frac{d}{dt}\,V(0;\psi_t)|_{t=0}. \tag{4.5}$$

Proposition 4.5: The formal calculation of the derivation in (4.5) gives

$$P^{\phi}=\int_P[\mathbb{1}_a^p\otimes\Phi_b^{\tau}(\phi(x))]d(\mathscr{P}(x)\otimes\mathbb{1}_b^{\tau}),$$

which justifies our above notion of a coupling function for $\phi\in C(P,\mathscr{E})$, and where $\Phi_b^{\tau}(f)$, $f\in\mathscr{E}$, are the field operators associated with the representation Π_b^{τ} of $\mathscr{W}(\mathscr{E},\sigma)$.

Sketch of Proof: Suppose $h:\mathbb{R}\to\mathscr{E}$ to be continuously differentiable. With the Weyl relations we obtain, in a regular representation of $\mathscr{W}(\mathscr{E},\sigma)$,

$$\begin{aligned}\frac{d}{dt}\,W(h(t))&=\lim_{\epsilon\to0}\frac{1}{\epsilon}\,(W(h(t+\epsilon))-W(h(t)))\\&=\lim_{\epsilon\to0}\frac{\exp\{(i/2)\sigma(h(t+\epsilon),h(t))\}-1}{\epsilon}\,W(h(t+\epsilon)-h(t))W(h(t))\\&\quad+\lim_{\epsilon\to0}\frac{\exp\{i\Phi(h(t+\epsilon)-h(t))\}-\mathbb{1}}{\epsilon}\,W(h(t))\\&=i(\tfrac{1}{2}\,\sigma(h'(t),h(t))+\Phi(h'(t)))W(h(t)),\end{aligned}$$

where we have used the formal calculation

$$\frac{\exp\{i\Phi(h(t+\epsilon)-h(t))\}-\mathbb{1}}{\epsilon}=i\Phi\left(\frac{h(t+\epsilon)-h(t)}{\epsilon}\right)\sum_{n=1}^{\infty}\frac{i^{n-1}}{n!}\,\Phi(h(t+\epsilon)-h(t))^{n-1}$$

$$\xrightarrow{\epsilon\to 0} i\Phi(h'(t)).$$

Now, with $\psi(0,x)=0$ and $(\partial\psi/\partial t)(0,x)=\phi(x)$, the differentiation in (4.5) is easily performed. ■

4. The cocycle dynamics in the Schrödinger picture

The unitary $V(\zeta;\eta)\in\mathscr{M}$ from Eq. (4.3) uniquely defines an affine bijection $\kappa(\zeta;\eta)$ on the folium $\mathscr{F}$, satisfying

$$\langle\kappa(\zeta;\eta)(\omega);Z\rangle:=\langle\omega;V(\zeta;\eta)ZV(\zeta;\eta)^*\rangle,\quad\forall\,\omega\in\mathscr{F},\quad\forall\,Z\in\mathscr{M}.$$

Thus, for each $t\in\mathbb{R}$ the affine bijection ν_t^{ψ} on the folium $\mathscr{F}$ of normal states on $\mathscr{M}$, which is obtained from γ_t^{ψ} by the duality relation (1.3), is given by

$$\nu_t^{\psi}=\kappa(\zeta,\psi_t)\circ\nu_t,\quad\forall\,\zeta\in C(P,\mathbb{R}).$$

As an immediate consequence of the weak definition of the spectral integral in Theorem A.1 we get the following.

Theorem 4.6: *Let $\psi:\mathbb{R}\times P\to\mathscr{E},(t,x)\mapsto\psi(t,x)=:\psi_t(x)$ be a continuous function. Then $t\in\mathbb{R}\mapsto V(0,\psi_t)$ is continuous in the strong operator topology.*

Thus, if ψ satisfies the cocycle equations (4.1), then $(\mathscr{C},\mathscr{F},\nu^{\psi})$ and $(\mathscr{C}_e,\mathscr{F},\nu^{\psi})$ are dynamical descriptions in the sense of Definition 1.2.

B. Unitary cocycle dynamics

1. The cocycle dynamics in subrepresentations

Let $\mathscr{F}_a\subseteq\mathscr{F}_a^p$ and $\mathscr{F}_b\subseteq\mathscr{F}_b^{\tau}$ be subfolia, invariant with respect to the free dynamics ν^Q and ν^v, respectively. Then $(\mathscr{A},\mathscr{F}_a,\nu^Q)$ and $(\mathscr{W}(E,\sigma),\mathscr{F}_b,\nu^v)$ are dynamical subdescriptions. Denote by $c_a\in\mathscr{Z}_a^p$ and $c_b\in\mathscr{Z}_b^{\tau}$ the associated central projections, and by $\Pi_a\leqslant\Pi_a^p$, resp $\Pi_b\leqslant\Pi_b^{\tau}$, the corresponding subrepresentations. Moreover, let $\mathscr{M}_a:=\Pi_a(\mathscr{A})''=c_a\mathscr{M}_a^p$ and $\mathscr{M}_b:=\Pi_b(\mathscr{W}(E,\sigma))''=c_b\mathscr{M}_b^{\tau}$ (cf. Proposition 1.1). The normal states on $\mathscr{M}_{a,b}:=\mathscr{M}_a\overline{\otimes}\mathscr{M}_b=(c_a\otimes c_b)\mathscr{M}$ are given by $\mathscr{F}_{a,b}=\mathscr{F}_a\otimes\mathscr{F}_b\subseteq\mathscr{F}$.

The central projection $c_a\otimes c_b\in\mathscr{Z}_a^p\overline{\otimes}\mathscr{Z}_b^{\tau}\subset\mathscr{M}$ is invariant with respect to the Heisenberg dynamics γ^{ψ} on $\mathscr{M}$. Consequently, $\mathscr{F}_{a,b}$ is ν^{ψ} invariant, and the associated cocycle dynamics in both, the Schrödinger and the Heisenberg picture, are obtained by restricting ν^{ψ}, resp. γ^{ψ}, to $\mathscr{F}_{a,b}$, resp. $\mathscr{M}_{a,b}$, in the manner described in the Introduction.

Let $\mathscr{P}_a:=c_a\mathscr{P}$ be the restriction of the projection-valued measure $\mathscr{P}$, which now has values in the set of orthogonal projections of the center $\mathscr{Z}_a$ of $\mathscr{M}_a$. From the theory of the infinite mean field systems, it is well known that the support $P_a\subseteq P$ of $\mathscr{P}_a$ is invariant with respect to the flow φ^Q. Denote by $\mathbb{1}_a\cong c_a$ the unit in $\mathscr{M}_a$ and $\mathbb{1}_b\cong c_b$ the one in $\mathscr{M}_b$. $W_b(f):=c_bW_b^{\tau}(f)\in\mathscr{M}_b$, $f\in\mathscr{E}$, are the represented Weyl operators with respect to $\Pi_b\leqslant\Pi_b^{\tau}$. Then the restriction of the unitaries (4.3) from $\mathscr{M}$ to $\mathscr{M}_{a,b}$ is

$$V_{a,b}(\zeta;\eta):=(c_a\otimes c_b)V(\zeta;\eta)=\int_{P_a}\exp\{i\zeta(x)\}[\mathbb{1}_a\otimes W_b(\eta(x))]\,d(\mathscr{P}_a(x)\otimes\mathbb{1}_b)\in\mathscr{Z}_a\overline{\otimes}\mathscr{M}_b.$$

And thus it suffices that the functions ζ and η are defined on P_a.

2. Unitary implementations of the cocycle dynamics

From now on let us suppose that the dynamical (sub-)descriptions $(\mathscr{A},\mathscr{F}_a,\nu^Q)$ and $(\mathscr{W}(E,\sigma),\mathscr{F}_b,\nu^v)$ are covariant, which is equivalent that $(\mathscr{M}_a,\alpha^Q)$ and $(\mathscr{M}_b,\beta^v)$ both are W^*-dynamical systems. By Theorem 4.6, $t\mapsto V(0;\psi_t)$ is strongly continuous. Thus, it follows that the dynamical (sub-)description $(\mathscr{C},\mathscr{F}_{a,b},\nu^\psi)$ is covariant, or equivalently, that the Heisenberg (sub-)dynamics $(\mathscr{M}_{a,b},\gamma^\psi)$ defines a W^*-dynamical system.

Let us assume standard representations of $\mathscr{M}_a$ and $\mathscr{M}_b$ on the Hilbert spaces $\mathscr{H}_a^{\mathrm{std}}$ and $\mathscr{H}_b^{\mathrm{std}}$, respectively, such that the W^*-groups α^Q and β^v are unitarily implementable with the Hamiltonians A_a, resp. B_b,

$$\alpha_t^Q(X)=e^{itA_a}Xe^{-itA_a},\quad \forall X\in\mathscr{M}_a,\quad \beta_t^v(Y)=e^{itB_b}Ye^{-itB_b},\quad \forall Y\in\mathscr{M}_b. \tag{4.6}$$

We now search for a strongly continuous unitary group, which implements $(\mathscr{M}_{a,b},\gamma^\psi)$.

Theorem 4.7: *Let $\zeta:\mathbb{R}\times P\to\mathbb{R}$, $(t,x)\mapsto\zeta(t,x)=:\zeta_t(x)$ and $\psi:\mathbb{R}\times P\to\mathscr{E}$, $(t,x)\mapsto\psi(t,x)=:\psi_t(x)$ be continuous functions. For each $t\in\mathbb{R}$ it follows that γ_t^ψ is implemented by the unitary*

$$U_t^{\psi,\zeta}:=V_{a,b}(\zeta_t;\psi_t)[e^{itA_a}\otimes e^{itB_b}], \tag{4.7}$$

that is, $\gamma_t^\psi(Z)=U_t^{\psi,\zeta}Z(U_t^{\psi,\zeta})^*$, $\forall Z\in\mathscr{M}_{a,b}$.

Moreover, the family $U^{\psi,\zeta}\equiv\{U_t^{\psi,\zeta}\mid t\in\mathbb{R}\}$ defines a strongly continuous group on $\mathscr{H}_a^{\mathrm{std}}\otimes\mathscr{H}_b^{\mathrm{std}}$, if ψ and ζ satisfy the cocycle equations,

$$\psi(s+t,x)=\psi(s,x)+v_s\psi(t,\varphi_s^Q x), \tag{4.8}$$

$$\zeta(s+t,x)=\zeta(s,x)+\zeta(t,\varphi_x^Q x)-\tfrac{1}{2}\,\sigma(\psi(s,x),v_s\psi(t,\varphi_s^Q x)), \tag{4.9}$$

for all $s,t\in\mathbb{R}$ and each $x\in P_a$.

Proof: $\gamma_t^\psi(\cdot)=U_t^{\psi,\zeta}\cdot(U_t^{\psi,\zeta})^*$ is obvious. With Lemma 4.3 and (4.6) we get

$$\begin{aligned}U_s^{\psi,\zeta}U_t^{\psi,\zeta}&=V_{a,b}(\zeta_s;\psi_s)[e^{isA_a}\otimes e^{isB_b}]V_{a,b}(\zeta_t;\psi_t)[e^{itA_a}\otimes e^{itB_b}]\\&=V_{a,b}(\zeta_s;\psi_s)V_{a,b}(\zeta_t\circ\varphi_s^Q;v_s(\psi_t\circ\varphi_s^Q))[e^{i(s+t)A_a}\otimes e^{i(s+t)B_b}]\\&=V_{a,b}(\zeta_{s,t};\psi_s+v_s(\psi_t\circ\varphi_s^Q))[e^{i(s+t)A_a}\otimes e^{i(s+t)B_b}],\end{aligned}$$

with $\zeta_{s,t}:=\zeta(s,x)+\zeta(t,\varphi_s^Q x)-(1/2)\sigma(\psi(s,x),\,v_s\psi(t,\varphi_s^Q x))$. This agrees with $U_{s+t}^{\psi,\zeta}$, if the cocycle equations (4.8) and (4.9) are fulfilled. ∎

The cocycle equations (4.8) are the restriction of (4.1) to the φ^Q-invariant subset P_a of the classical phase space P. Analogously to Theorem 4.2, the unique solution $\psi:\mathbb{R}\times P_a\to\mathscr{E}$ of (4.8) with initial value $(\partial\psi/\partial t)(0,x)=\phi(x)$, $\forall x\in P_a$, where $\phi\in C(P_a,\mathscr{E})$ is an arbitrary coupling function, is given by Eq. (4.2), but for $x\in P_a\subseteq P$. Using a solution ψ for (4.8) we may solve the equations (4.9), that determine the correct phase of the group $U^{\psi,\zeta}$. Similar to Theorem 4.2, one proves the following.

Theorem 4.8: *Let $\psi(t,x)=\int_{r=0}^t v_r\phi(\varphi_r^Q x)dr,\forall x\in P_a$ be the unique solution of (4.8) with the initial value $\phi\in C(P_a,\mathscr{E})$ by Theorem 4.2. Then, for arbitrary $\lambda\in C(P_a,\mathbb{R})$ it holds: The cocycle equations (4.9) with the initial value $(\partial\zeta/\partial t)(0,x)=\lambda(x),\forall x\in P_a$ are uniquely solvable, and the solution $\zeta:\mathbb{R}\times P_a\to\mathbb{R}$ is given by*

$$\zeta(t,x)=\int_{r=0}^t\lambda(\varphi_r^Q x)dr-\frac{1}{2}\int_{p=0}^t\int_{r=0}^p\sigma(v_r\phi(\varphi_r^Q x),v_p\phi(\varphi_p^Q x))dr\,dp.$$

3. The generator of the unitary cocycle dynamics

Here, let us assume the solutions ψ and ζ of the cocycle equations given with the initial values $\phi \in C(P_a, \mathscr{E})$ and $\lambda \in C(P_a, \mathbb{R})$ by Theorem 4.8.

Similar to Proposition 4.5, one formally calculates the Hamiltonian H^ϕ associated with the unitary group $U^{\psi,\zeta}$ of Theorem 4.7,

$$H^\phi := -i \frac{d}{dt} U_t^{\psi,\zeta}\Big|_{t=0} = A_a \otimes \mathbb{1}_b + \mathbb{1}_a \otimes B_b + \int_{P_a} [\mathbb{1}_a \otimes \Phi_b(\phi(x))] d(\mathscr{P}_a(x) \otimes \mathbb{1}_b) + \left(\int_{P_a} \lambda \, d\mathscr{P}_a \right) \otimes \mathbb{1}_b , \tag{4.10}$$

where the $\Phi_b(f)$, $f \in \mathscr{E}$, denote the field operators associated with the representation Π_b of $\mathscr{W}(\mathscr{E},\sigma)$. The central part $\int_{P_a} \lambda \, d\mathscr{P}_a \in \mathscr{Z}_a$ in H^ϕ is irrelevant for the Heisenberg dynamics $(\mathscr{M}_{a,b}, \gamma^\psi)$. Thus, in the sequel let us assume $\lambda \equiv 0$. The interacting part of H^ϕ agrees with $(c_a \otimes c_b) P^\phi$, where P^ϕ is from Proposition 4.5.

C. The cocycle dynamics as a thermodynamic limit

If E and thus $\mathscr{E}$ are complex vector spaces (the multiplication with the complex i is τ continuous), and σ is the imaginary part of a τ-continuous positive sesquilinear form $\langle \cdot | \cdot \rangle$ on $\mathscr{E}$, then one may introduce the annihilation and creation operators, $a_b(f) := (1/\sqrt{2})(\Phi_b(f) + i\Phi_b(if))$ and $a_b^*(f)$ as the adjoint, for the regular representation Π_b of $\mathscr{W}(\mathscr{E},\sigma)$. Throughout the present section we consider the coupling function

$$\phi(x) = \sqrt{2} \sum_{k=1}^{l} \xi_k(x) \phi_k , \quad x \in P, \tag{4.11}$$

for some $l \in \mathbb{N}_0$, where $\xi_k \in C(P)$ and $\phi_k \in \mathscr{E}$. With this ϕ we obtain the familiar form [cf. Eq. (1.1)] of the interaction operator from Proposition 4.5,

$$P^\phi = \sum_{k=1}^{l} \left[\left(\int_P \xi_k \, d\mathscr{P} \right) \otimes a_b^*(\phi_k) + \left(\int_P \overline{\xi_k} \, d\mathscr{P} \right) \otimes a_b(\phi_k) \right]. \tag{4.12}$$

The local time evolutions $\alpha^{Q,\Lambda}$, $\Lambda \in \mathscr{L}$, of the mean field system from Eq. (2.4) converge in the representation Π_a^p of $\mathscr{A}$ in some sense to the limiting Heisenberg dynamics α^Q. Also, the mean field parts $\int_P \xi_k \, d\mathscr{P} \in \mathscr{Z}_a^p$ of the above interaction P^ϕ may be approximated by uniformly bounded (with respect to $\Lambda \in \mathscr{L}$) local polynomials Ξ_k^Λ of the local density operators $m_\Lambda(b)$ from Eq. (2.1).

Thus, it should be possible that the interacting dynamics γ^ψ is approximated by the local time evolution groups $\gamma^{\psi,\Lambda}$, $\Lambda \in \mathscr{L}$, which are given by the perturbation of $\alpha^{Q,\Lambda} \otimes \beta^v$ with the local interaction

$$P^{\phi,\Lambda} = \sum_{k=1}^{l} [\Xi_k^\Lambda \otimes a_b^*(\phi_k) + (\Xi_k^\Lambda)^* \otimes a_b(\phi_k)].$$

For such an approximation procedure we want to use perturbation techniques. Because the field operators (respectively, the annihilation and creation operators) are unbounded, for general bosonic representations $\Pi_b \leqslant \Pi_b^\tau$ it is not possible to control the growth of the expansion series (4.4) uniformly for $\Lambda \in \mathscr{L}$.

However, for the field, annihilation, and creation operators there exist estimates on the finite particle vectors in Fock space. This suggests that the necessary growth control of the expansion series can be done for Fock-like representations Π_b of $\mathscr{W}(E,\sigma)$. A Fock-like representation Π_b, for example, is obtained as the GNS representation of a suitable (ν^v-invariant) gauge-invariant

quasi-free factor state on $\mathscr{W}(E,\sigma)$, where the GNS–Hilbert space is the tensor product of two Fock spaces.[40,11,45] Let us outline in more detail a typical situation, where here the temperature states (without condensation) of the boson system are considered. The associated estimates for the perturbation expansions are derived in Ref. 47.

E usually is chosen to be a complex pre-Hilbert space with (right-linear) scalar product $\langle\cdot|\cdot\rangle$ (σ is the imaginary part of $\langle\cdot|\cdot\rangle$). The single particle Hamiltonian S (self-adjoint operator on the completion E of E with respect to $\langle\cdot|\cdot\rangle$) is positive, not having zero as its eigenvalue. We assume $E\subseteq D(S^{-1/2})=:\mathscr{E}$ to be a core for $S^{-1/2}$. The τ topology is chosen to arise from the inner product $\langle f|g\rangle_\tau:=\langle f|g\rangle+\langle S^{-1/2}f|S^{-1/2}g\rangle$, which defines the graph norm of $S^{-1/2}$. The one-boson dynamics is $v_t:=e^{itS}|_{\mathscr{E}}$, $t\in\mathbb{R}$. That $v=\{v_t|t\in\mathbb{R}\}$ is a strongly continuous unitary group on the Hilbert space $\mathscr{E}=(D(S^{-1/2}),\langle\cdot|\cdot\rangle_\tau)$ is immediate.

Remark 4.9: If E is any subset of the domain $D(S^{-1/2})$, which is invariant with respect to the one-boson dynamics v, then by Ref. 46, Theorem 4 E is a core for $S^{-1/2}$.

In the special case, where $E=\mathscr{D}(\mathbb{R}^p)$ is from Example 3.5, and $S=-\Delta$, resp. $S=\sqrt{-\Delta}$, then E is a core for $S^{-1/2}$ (cf. Refs. 44, 24, and 42).

Let $T_\beta:=e^{-\beta S}(\mathbb{1}-e^{-\beta S})^{-1}$ for $\beta>0$, and $T_\infty:=0$ for $\beta=\infty$. Then by

$$\langle\omega_b^\beta;W(f\ )\rangle=\exp\{-\tfrac{1}{4}\|f\|^2-\tfrac{1}{2}\|T_\beta^{1/2}f\|^2\},\quad f\in E,$$

the characteristic function of the temperature state ω_b^β for the inverse temperature $\beta\in]0,\infty]$ is given (for $\beta=\infty$ the Fock vacuum state is obtained). Since for each $\beta\in]0,\infty[$ the graph norm for $T_\beta^{1/2}$ is equivalent to the above $\|\cdot\|_\tau$, and $D(T_\beta^{1/2})=D(S^{-1/2})$, it follows that ω_b^β is an element of the folium $\mathscr{F}_b^\tau$ of τ-continuous states on $\mathscr{W}(E,\sigma)$.

Since ω_b^β is invariant with respect to the dynamical description $(\mathscr{W}(E,\sigma),\mathscr{F}_b^\tau,\nu^v)$, its GNS representation $(\Pi_b^\beta,\mathscr{H}_b^\beta,\Omega_b^\beta)$ defines a covariant dynamical subdescription (cf. the Introduction). The above Hamiltonian $B_b\equiv B_b^\beta$ is chosen so that $B_b^\beta\Omega_b^\beta=0$.

With (2.3) we define in the representation $\Pi_a^p\otimes\Pi_b^\beta$ the local interacting Hamiltonians,

$$H^{\phi,\Lambda}:=A_\Lambda\otimes\mathbb{1}_b^\beta+\mathbb{1}_a^p\otimes B_b^\beta+P^{\phi,\Lambda},$$

which are essentially self-adjoint.[47] Then the local perturbed time evolutions are

$$\gamma_t^{\psi;\Lambda}(\cdot):=\exp\{itH^{\phi,\Lambda}\}\cdot\exp\{-itH^{\phi,\Lambda}\},\quad \Lambda\in\mathscr{L}.$$

Since ω_b^β is a gauge-invariant quasi-free factor state on $\mathscr{W}(E,\sigma)$, we are in the above mentioned situation, and the expansion (4.4) can be controlled uniformly in $\Lambda\in\mathscr{L}$,[47] which gives the following result proven in Ref. 13 ($\odot$ means the algebraic tensor product).

Theorem 4.10: *$\gamma_t^\psi(Z)=s-\lim_{\Lambda\in\mathscr{L}}\gamma_t^{\psi,\Lambda}(Z)$, for $Z\in\Pi_a^p(\mathscr{A})\odot\Pi_b^\beta(\mathscr{W}(\mathscr{E},\sigma))$.*

The result is also interesting insofar that the perturbation techniques are valid here for the free dynamics γ on $\mathscr{M}_a^p\overline{\otimes}\mathscr{M}_b^\beta$, which is not a W^*-dynamical system.

With the above perturbation techniques using the Fock-like temperature representation Π_b^β in addition to the above result it is also possible to make rigorous the differentiation in the formal sketch of proof of Proposition 4.5; we refer to Refs. 47 and 13.

Theorem 4.11: *Let $\Pi_a\leqslant\Pi_a^p$ be a covariant subrepresentation for α^Q as in Sec. IV D. Then*

$$H^\phi=A_a\otimes\mathbb{1}_b^\beta+\mathbb{1}_a\otimes B_b^\beta+(c_a\otimes c_b^\beta)P^\phi,$$

where P^ϕ is from (4.12), is essentially self-adjoint, and is indeed the generator of the unitary group $U^{\psi,\zeta}$ on $\mathscr{H}_a^{std}\otimes\mathscr{H}_b^\beta$ [cf. Eq. (4.10)].

APPENDIX: SPECTRAL INTEGRALS

For integrating general operator-valued functions with respect to a projection-valued measure, there are very strong conditions[48] (cf. also Ref. 49, Chap. 6). Here, however, we have some special cases of such integrals, for which the conditions for existence are weaker.

Let $\mathscr{H}$ and $\mathscr{K}$ be (complex) Hilbert spaces, $\mathscr{B}(\mathscr{K})$ the bounded operators of $\mathscr{K}$, and $\mathscr{P}$ a projection-valued measure from the Borel subsets $B(\mathbb{R}^p)$ of $\mathbb{R}^p$ ($p\in\mathbb{N}$) into the orthogonal projections of $\mathscr{H}$. Then, the map $\Delta\in B(\mathbb{R}^p)\mapsto\mathscr{P}(\Delta)\otimes 1_{\mathscr{K}}$ is a projection-valued measure on $\mathscr{H}\otimes\mathscr{K}$. For operator-valued functions $X:\mathbb{R}^p\to\mathscr{B}(\mathscr{K})$ we now develop the theory of the spectral integrals,

$$\int_{\mathbb{R}^p}(1_{\mathscr{H}}\otimes X(x))d(\mathscr{P}(x)\otimes 1_{\mathscr{K}}). \tag{A1}$$

We do not give the long proofs here and refer the reader to Ref. 13, Sec. A.4, where the connection with the direct integral is also pointed out.

Theorem A.1: *Let $X:\mathbb{R}^p\to\mathscr{B}(\mathscr{K})$ be weakly measurable with $\sup\{\|X(x)\|\,|x\in\mathbb{R}^p\}<\infty$. Then by*

$$\left\langle \phi_1\otimes\psi_1\middle|\int_{\mathbb{R}^p}(1_{\mathscr{H}}\otimes X(x))d(\mathscr{P}(x)\otimes 1_{\mathscr{K}})\phi_2\otimes\psi_2\right\rangle := \int_{\mathbb{R}^p}\langle\psi_1|X(x)\psi_2\rangle d\langle\phi_1|\mathscr{P}(x)\phi_2\rangle,$$

$$\forall\,\phi_1,\phi_2\in\mathscr{H},\quad \forall\,\psi_1,\psi_2\in\mathscr{K},$$

and by linear and continuous extension on $\mathscr{H}\otimes\mathscr{K}$ the bounded operator (A1) is well defined. Moreover,

(a) $\|\int_{\mathbb{R}^p}(1_{\mathscr{H}}\otimes X(x))d(\mathscr{P}(x)\otimes 1_{\mathscr{K}})\|\leq\sup\{\|X(x)\|\;\;|x\in\mathbb{R}^p\}$.

(b) $(\int_{\mathbb{R}^p}(1_{\mathscr{H}}\otimes X(x))d(\mathscr{P}(x)\otimes 1_{\mathscr{K}}))^*=\int_{\mathbb{R}^p}(1_{\mathscr{H}}\otimes(X(x))^*)d(\mathscr{P}(x)\otimes 1_{\mathscr{K}})$.

(c) *If $\mathscr{H}$ and $\mathscr{K}$ are separable, then we have the product property*

$$\int_{\mathbb{R}^p}(1_{\mathscr{H}}\otimes X(x)Y(x))d(\mathscr{P}(x)\otimes 1_{\mathscr{K}})=\int_{\mathbb{R}^p}(1_{\mathscr{H}}\otimes X(x))d(\mathscr{P}(x)\otimes 1_{\mathscr{K}})\int_{\mathbb{R}^p}(1_{\mathscr{H}}\otimes Y(x))d(\mathscr{P}(x)\otimes 1_{\mathscr{K}}).$$

(d) *If $\mathscr{K}$ is separable, then the measurability of $x\in\mathbb{R}^p\mapsto\|X(x)\|$ follows, and for all $\xi\in\mathscr{H}\otimes\mathscr{K}$ it is*

$$\left\|\int_{\mathbb{R}^p}(1_{\mathscr{H}}\otimes X(x))d(\mathscr{P}(x)\otimes 1_{\mathscr{K}})\xi\right\|^2\leq\int_{\mathbb{R}^p}\|X(x)\|^2 d\langle\xi|(\mathscr{P}(x)\otimes 1_{\mathscr{K}})\xi\rangle.$$

With some stronger conditions for $X:\mathbb{R}^p\to\mathscr{B}(\mathscr{K})$ and $Y:\mathbb{R}^p\to\mathscr{B}(\mathscr{K})$, we may drop in (c) the separability condition for $\mathscr{H}$ and $\mathscr{K}$. Let $P\in B(\mathbb{R}^p)$. We call $X:P\to\mathscr{B}(\mathscr{K})$ with $\sup\{\|X(x)\|\;\;|x\in P\}<\infty$ a $\mathscr{T}$ function, if X is approximable for $\mathscr{P}$—almost all $x\in P$ in the strong operator topology by a sequence of elementary functions $X_n:P\to\mathscr{B}(\mathscr{K})$ for which $\|X_n(x)\|\leq c$, $\forall x\in P$, $\forall n\in\mathbb{N}$ for some $c>0$ (cf. Ref. 50, Appendix to IV.5, p. 115). [An elementary function is of the form $\Sigma_{k=1}^m\chi_{\Delta_k}Q_k$, where χ_Δ is the characteristic function of $\Delta\in B(P)$ and $Q_k\in\mathscr{B}(\mathscr{K})$.] If $X:P\to\mathscr{B}(\mathscr{K})$ and $Y:P\to\mathscr{B}(\mathscr{K})$ are $\mathscr{T}$ functions, so are $XY:P\to\mathscr{B}(\mathscr{K})$, $x\mapsto X(x)Y(x)$, and $X^*:P\to\mathscr{B}(\mathscr{K})$, $x\mapsto X(x)^*$. Especially, each with respect to the strong operator topology piecewise continuous function $X:P\to\mathscr{B}(\mathscr{K})$ with $\sup\{\|X(x)\|\;\;|x\in P\}<\infty$ is of class $\mathscr{T}$. Each $\mathscr{T}$ function is weakly measurable, and hence the operator $\int_P(1_{\mathscr{H}}\otimes X(x))d(\mathscr{P}(x)\otimes 1_{\mathscr{K}})$ exists.

Proposition A.2: Let $X:P\to\mathscr{B}(\mathscr{K})$ be a $\mathscr{T}$ function with some associated sequence $(X_n)_{n\in\mathbb{N}}$ of elementary functions. Then it follows in the strong operator topology,

$$\int_P(1_{\mathscr{H}}\otimes X(x))d(\mathscr{P}(x)\otimes 1_{\mathscr{K}})=s-\lim_{n\to\infty}\int_P(1_{\mathscr{H}}\otimes X_n(x))d(\mathscr{P}(x)\otimes 1_{\mathscr{K}}).$$

Corollary A.3: If $X:P\to\mathcal{B}(\mathcal{K})$ and $Y:P\to\mathcal{B}(\mathcal{K})$ are $\mathcal{T}$ functions, then the product property is valid in any case concerning the separability or nonseparability of $\mathcal{H}$ and $\mathcal{K}$.

Moreover, in each case, where the product property of Theorem A.1(c) is valid, one has for all $\phi\in\mathcal{H}$ and $\psi\in\mathcal{K}$,

$$\left\| \int_P (1_{\mathcal{H}}\otimes X(x))d(\mathcal{P}(x)\otimes 1_{\mathcal{K}})\phi\otimes\psi \right\|^2 = \int_P \|X(x)\psi\|^2 d\langle\phi|\mathcal{P}(x)\phi\rangle.$$

On stochastic diffusion equations and stochastic Burgers' equations

A. Truman and H. Z. Zhao
Department of Mathematics, University of Wales Swansea, Singleton Park, Swansea SA2 8PP, United Kingdom

(Received 26 December 1994; accepted for publication 7 September 1995)

In this paper we construct a strong solution for the stochastic Hamilton Jacobi equation by using stochastic classical mechanics before the caustics. We thereby obtain the viscosity solution for a certain class of inviscid stochastic Burgers' equations. This viscosity solution is not continuous beyond the caustics of the corresponding Hamilton Jacobi equation. The Hopf–Cole transformation is used to identify the stochastic heat equation and the viscous stochastic Burgers' equation. The exact solutions for the above two equations are given in terms of the stochastic Hamilton Jacobi function under a no-caustic condition. We construct the heat kernel for the stochastic heat equation for zero potentials in hyperbolic space and for harmonic oscillator potentials in Euclidean space thereby obtaining the stochastic Mehler formula. © *1996 American Institute of Physics.* [S0022-2488(96)00401-8]

I. INTRODUCTION

Inspired by Maslov's quasiclassical asymptotics of quantum mechanics,[1] Truman,[2] Elworthy and Truman[3–5] developed the path-space Hamilton Jacobi theory (elementary formula method or semiclassical analysis) in order to treat the deterministic heat equation (and Schrödinger equation) to get quasiclassical expansions for their solutions. It was proved that before the caustic time the Hamilton Jacobi equation has a $C^{1,2}$ solution which gives the exact solution of the diffusion equation (and Schrödinger equation) geared to small time asymptotics. From Varadhan's or Wentzell–Freidlin's large deviation theories (Varadhan,[6] Freidlin and Wentzell[7]), we only know that the Hamilton Jacobi function gives the leading term. The new method resulted in the discovery of a new ''Brownian Riemannian'' bridge process on manifolds and an elegant new version of the Feynman–Kac formula in curved space geared to simplifying small-time and small-$\hbar$ asymptotics. The same methods have been applied to traveling waves for nonlinear reaction diffusion equations in Elworthy, Truman, and Zhao.[8] A generalization of this Brownian Riemannian bridge process has been obtained in Watling.[9] Quite recently we developed the corresponding stochastic Hamilton Jacobi theory in Truman and Zhao.[10] Using these results, certain stochastic partial differential equations have been solved explicitly and heat kernels and small time asymptotics have been obtained. The stochastic Hamilton Jacobi theory is the main tool used to obtain the results in the present paper.

In this paper we first construct a strong solution for the stochastic Hamilton Jacobi equation and examine the stochastic heat equation with Stratonovich white noise in time. As long as the map defined by the stochastic Hamiltonian system is a diffeomorphism on the configuration space the stochastic Hamilton Jacobi equation has a strong solution. Here we simplify the Feynman–Kac integral for the solution of the stochastic heat equation and get a rigorous semiclassical representation by changing measures using the stochastic Hamilton Jacobi theory. As applications, we take the limits $\mu\to 0$ to get WKB expansions for the solutions. We continue by considering the heat kernel on a complete Riemannian manifold with a pole and using the harmonic oscillator potential we obtain the stochastic Mehler formula.

By the well known Hopf–Cole transformation, the stochastic heat equation is equivalent to the viscous stochastic Burgers' equation which is the KPZ model for the dynamics of the interface introduced by Kardar, Parisi, and Zhang.[11] (See Sec. V for more details.) In the limit $\mu\to 0$ the

equation is the inviscid stochastic Burgers' equation which is the gradient of the stochastic Hamilton Jacobi equation. Using the logarithmic transformation and the stochastic Hamilton Jacobi theory, we get a rigorous formula relating the solutions for the viscous stochastic Burgers' equation and inviscid stochastic Burgers' equation before the caustic time of the corresponding stochastic classical mechanics. We identify the inviscid limit and semiclassical limit under the no-caustics condition. Beyond the caustics we show the solution of the inviscid Burgers' equation is discontinuous. For certain types of equations we prove the existence and uniqueness of the viscosity solution and generalize Wentzell–Freidlin's large deviation theory from deterministic heat equations to stochastic ones as an easy consequence of our theory. Some examples of random shock waves beyond the caustics are given. Needless to say, the occurrence of caustics for the heat equation leads to the appearance of shock waves for the corresponding inviscid Burgers' equation. Indeed a classification of the caustics could lead to a classification of shock waves (Arnold[12]).

In this paper we restrict the Stratonovich white noise term to be white noise in time. We are currently investigating whether our treatment can be generalized to include white noise in space and the (much more difficult) white noise in space–time. The method can clearly be extended to include random initial data but we do not do so here because of restrictions on the length of the paper.

II. THE STOCHASTIC HAMILTON JACOBI EQUATIONS AND STOCHASTIC DIFFUSION EQUATIONS

(1) Let M be an n-dimensional Riemannian manifold. For $c\in C^{1,2}([0,+\infty)\times M,R)$, $S_0\in C^2(M,R)$ and $k\in C^{1,2}([0,+\infty)\times M,R^m)$ and an m-dimensional Brownian motion w_s on probability space $(\Omega,\mathcal{F}_t,P)$, define $\Phi_s:M\times\Omega\to M$ by the following stochastic mechanical system for each $x\in M$:

$$\begin{cases} d\dot{\Phi}_s(x)=-\nabla c(s,\Phi_s(x))ds-\nabla\langle k(s,\Phi_s(x)),dw_s\rangle \\ \dot{\Phi}_0(x)=\nabla S_0(x), \quad \Phi_0(x)=x \end{cases}. \tag{2.1}$$

Here $\langle\cdot,\cdot\rangle$ denotes the inner product in R^m. For a mechanical system without noise set $k\equiv 0$. This shows that c is a potential energy function.

First we prove a diffeomorphism result:

Proposition 2.1: If M is compact or if M is complete, ∇c, $\nabla^2 c$, ∇k, $\nabla^2 k$, ∇S_0, $\nabla^2 S_0$ and the curvature tensor R of the manifold M are all bounded, then there exists $T(\omega)>0$ a.s. such that $\Phi_s(\omega):M\to M$ is a diffeomorphism for $0\leqslant s\leqslant T(\omega)$ for a.e. $\omega\in\Omega$.

Proof: Integrating Eq. (2.1) we obtain

$$\dot{\Phi}_s(x)=\nabla S_0(x)-\int_0^s \nabla c(\sigma,\Phi_\sigma(x))d\sigma-\int_0^s \nabla\langle k(\sigma,\Phi_\sigma(x)),dw_\sigma\rangle.$$

It follows that $\dot{\Phi}_s(x)$ is bounded P-a.s. for $s\in[0,T^*]$ for any fixed $T^*>0$. To investigate the gradients of Φ_s, for $v\in T_xM$ and $q:(-1,1)\to M$ with $q(0)=x$ and $\dot{q}(0)=v$, we have

$$d\,\frac{\partial}{\partial s}\,\frac{\partial}{\partial s'}\,\Phi_s(q(s'))=\frac{D}{\partial s'}\,d\,\frac{\partial}{\partial s}\,\Phi_s(q(s'))+R\left\{\frac{\partial}{\partial s}\,\Phi_s(q(s')),\,\frac{\partial}{\partial s'}\,\Phi_s(q(s'))\right\}\dot{\Phi}_s(q(s'))ds.$$

Taking $s'=0$ and from Eq. (2.1) again we have

$$d\,\frac{\partial}{\partial s}\,T_x\Phi_s(v)=R(\dot{\Phi}_s(x),T_x\Phi_s(v))\dot{\Phi}_s(x)ds-\nabla^2 c_s(\Phi_s(x))T_x\Phi_s(v)ds$$

$$-\nabla^2\langle k_s(\Phi_s(x)),dw_s\rangle T_x\Phi_s(v)$$

with $T_x\Phi_0(v)=I$ and $T_x\dot{\Phi}_0(v)=\nabla^2 S_0(x)$. Note that the above equation for $T_x\Phi_s(v)$ is a perturbed linear one with some perturbation, $R(\dot{\Phi}_s(x),T_x\Phi_s(v))\dot{\Phi}_s(x)$ which is bounded P-a.s. because $\dot{\Phi}_s$ is bounded P-a.s. Therefore, the solution $T_x\Phi_s(v)$ is bounded P-a.s. for $s\in[0,T^*]$ for any fixed $T^*>0$. Integration of the above equation gives a semimartingale

$$T_x\Phi_t(v)=I+\nabla^2 S_0(x)t+\int_0^t\int_0^\sigma R(\dot{\Phi}_s(x),T_x\Phi_s(v))\dot{\Phi}_s(x)ds\ d\sigma$$
$$-\int_0^t\int_0^\sigma \nabla^2 c_s(\Phi_s(x))T_x\Phi_s(v)ds\ d\sigma-\int_0^t\int_0^\sigma \nabla^2\langle k_s(\Phi_s(x)),dw_s\rangle T_x\Phi_s(v)d\sigma.$$

It is clear now that there exists $T(\omega)>0$ (let $T<T^*$ if necessary) such that for $0\leqslant t\leqslant T(\omega)$, the matrix norm $\|\nabla^2 S_0(x)t+\int_0^t\int_0^\sigma R(\dot{\Phi}_s(x),T_x\Phi_s(v))\dot{\Phi}_s(x)ds\ d\sigma-\int_0^t\int_0^\sigma\nabla^2 c_s(\Phi_s(x))T_x\Phi_s(v)ds\ d\sigma-\int_0^t\int_0^\sigma\nabla^2\langle k_s(\Phi_s(x)),dw_s\rangle T_x\Phi_s(v)d\sigma\|<1$ for a.e. $\omega\in\Omega$. By a similar argument to the one in Elworthy and Truman[4] we know for $0\leqslant t\leqslant T(\omega)$, $T_x\Phi_t(v)(\omega)$ is nonsingular. The diffeomorphism follows from the global inverse function theorem. (See, Ref. 4 for example.) ■

For $t\geqslant 0$, $y\in M$ define $\tilde{S}:[0,+\infty)\times M\to R$ by the following nonanticipating Itô stochastic integral:

$$\tilde{S}_t(y,\omega)=\frac{1}{2}\int_0^t|\dot{\Phi}_s(y)|^2ds+S_0(y)-\int_0^t c(s,\Phi_s(y))ds-\int_0^t\langle k(s,\Phi_s(y)),dw_s\rangle. \tag{2.2}$$

We assume a no-caustic condition: there exists $T(\omega)>0$ a.s. such that for $0\leqslant s\leqslant T(\omega)$, $\Phi_s(\omega):M\to M$ is a diffeomorphism for a.e. $\omega\in\Omega$. This is always true provided the conditions in Proposition 2.1 are satisfied. With this assumption we define $S_t(\omega):M\to R^1$ for a.e. $\omega\in\Omega$ and $0\leqslant t\leqslant T(\omega)$ by

$$S_t(x)=\tilde{S}_t(\Phi_t^{-1}(x)). \tag{2.3}$$

We proved the following theorem in Truman and Zhao:[10]

Theorem 2.1 (Truman and Zhao[10]): (i) *Let* Φ *be defined by* Eq. (2.1) *and satisfy the no-caustic condition for* $0\leqslant t\leqslant T(\omega)$ *and* $S_t(x)$ *be defined by* Eq. (2.3) *for* a.e. $\omega\in\Omega$. *Then for any* $0\leqslant t\leqslant T(\omega)$, $x\in M$ *for* a.e. $\omega\in\Omega$:

$$\dot{\Phi}_t(x)=\nabla S_t(\Phi_t(x)). \tag{2.4}$$

(ii) *For any* $0\leqslant t\leqslant T(\omega)$, $x\in M$ *for* a.e. $\omega\in\Omega$, *S satisfies the following stochastic Hamilton Jacobi equation*:

$$dS_t(x)+[\tfrac{1}{2}\|\nabla S_t(x)\|^2+c(t,x)]dt+\langle k(t,x),dw_t\rangle=0. \tag{2.5}$$

Note that $S(t,x)$ is continuous with respect to t and C^2 with respect to x for $0\leqslant t\leqslant T(\omega)$. We call $S(t,x)$ a strong solution of the stochastic Hamilton Jacobi equation (2.5). Another useful identity is the following continuity equation:

Theorem 2.2: *Define* $\phi_t(\omega):M\to R$ *by* $\phi(t,x)=|\det T_x\Phi_t^{-1}|$ (*using the Riemannian metric of* M) *for any* $0\leqslant t\leqslant T(\omega)$ *for* a.e. $\omega\in\Omega$. *Then* ϕ *satisfies the continuity equation*

$$\frac{\partial\phi}{\partial t}(t,x)+\operatorname{div}(\phi(t,x)\nabla S(t,x))=0. \tag{2.6}$$

Proof: Take any C^∞ function $f:M\to R$ with compact support. Integrating by parts,

$$\int_M \operatorname{div}(\phi(t,-)\nabla S(t,-))(x)f(x)dx = -\int_M \phi(t,x)\langle \nabla S(t,x), \nabla f(x)\rangle dx$$

$$= -\int_M \langle \nabla S(t,\Phi_t(x)), \nabla f(\Phi_t(x))\rangle dx$$

$$= -\int_M df(\dot{\Phi}_t(x))dx = -\frac{d}{dt}\int_M f(\Phi_t(x))dx$$

$$= -\frac{d}{dt}\int_M f(x)\phi(t,x)dx$$

$$= -\int_M f(x)\frac{\partial}{\partial t}\phi(t,x)dx$$

using Eq. (2.4). As f is an arbitrary $C^\infty(M,R)$ function then the continuity equation follows. ■

(2) Consider the following stochastic diffusion equation:

$$\begin{cases} du_t^\mu(x) = \left[\frac{1}{2}\mu^2\Delta u_t^\mu(x) + \frac{1}{\mu^2}c(t,x)u_t^\mu(x)\right]dt + \frac{1}{\mu^2}u_t^\mu(x)\langle k(t,x), \partial w_t\rangle \\ u_0^\mu(x) = T_0(x)\exp\left\{-\frac{S_0(x)}{\mu^2}\right\} \end{cases}, \tag{2.7}$$

where $x \in M$, an n-dimensional Riemannian manifold and Δ its Laplace–Beltrami operator, $c \in C^{1,2}(R^1 \times M, R^1)$, $k \in C^{1,2}(R^1 \times M, R^m)$ and w_t an m-dimensional Brownian motion, ∂ being the Stratonovich derivative. Given $T_0 : M \to R^1$ a bounded measurable function and $S_0 : M \to R^1$ a C^2 function, let $u_t^\mu(x)$ denote the solution of Eq. (2.7). We do not treat the existence theory of the solution for the stochastic diffusion equation here. For this we refer the readers to Flandoli.[13] In the following we always suppose the solution to Eq. (2.7) exists and is regular. Clearly the solution is positive if $T_0 > 0$ and in this case for given mild conditions on c and k there is a unique positive solution to Eq. (2.7).

For such $c \in C^{1,2}([0,+\infty)\times M, R)$ and $k \in C^{1,2}([0,+\infty)\times M, R)$ and $S_0 \in C^2(M,R)$, let $S_t(x)$ be defined by Eq. (2.3) for $0 \leqslant t \leqslant T(\omega)$ for a.e. $\omega \in \Omega$ if the map $\Phi_t : M \to M$ satisfies the no-caustic condition for $0 \leqslant t \leqslant T(\omega)$ in configuration space M for a.e. $\omega \in \Omega$.

Here we use some of the results of Eells and Elworthy (Elworthy[14]). Let $\Pi : O(M) \to M$ be the orthonormal frame bundle of M. The Levi-Civita connection of M determines a map $\chi : O(M) \times R^n \to TO(M)$ into the tangent space to $O(M)$, which trivializes the horizontal tangent bundle of M. Let $\tilde{A}_t : O(M) \to TO(M)$ be its horizontal lift: so $T\Pi(\tilde{A}_t(\mathscr{U})) = A_t(\Pi(\mathscr{U}))$, $0 \leqslant t \leqslant \tau$, $\mathscr{U} \in O(M)$, where $T\Pi : TO(M) \to TM$ is the derivative map of Π.

For $x_0 \in M$ take $\mathscr{U}_0 \in \Pi^{-1}(x_0)$ and consider the Stratonovich stochastic equation for $\mathscr{U} : [0,\xi_A) \times \hat{\Omega} \to O(M)$ with $\mathscr{U}(0,\hat{\omega}) = \mathscr{U}_0$, $0 \leqslant s \leqslant t$:

$$d\mathscr{U}_s^{t,\mu} = \mu\chi(\mathscr{U}_s^{t,\mu}) \cdot dB_s + \tilde{A}_s^t(\mathscr{U}_s^{t,\mu})ds, \tag{2.8}$$

where B_s is an n-dimensional Brownian motion defined on the probability space $(\hat{\Omega}, \hat{\mathscr{F}}, \hat{P})$. Define $\hat{\mathscr{F}}_s = \sigma\{B_{s_1} : 0 \leqslant s_1 \leqslant s\}$. The solution $\mathscr{U}_s^{t,\mu}$ with explosion time $0 < \xi_A \leqslant +\infty$ for all $\hat{\omega} \in \hat{\Omega}$ is $\hat{\mathscr{F}}_s$ measurable. Finally we define $X_s^{t,\mu}$ on M by $X_s^{t,\mu} = \Pi(\mathscr{U}_s^{t,\mu})$. Let $\{B_s^{t,\mu} : 0 \leqslant s \leqslant t\}$ be the solution of Eq. (2.8) with $A \equiv 0$. Note that $B_s^{t,\mu}$, $X_s^{t,\mu} \in \hat{\mathscr{F}}_s$.

Given the initial condition $u_0^\mu(x)$ for Eq. (2.7), then by the Feynman–Kac formula we have

$$u_t^\mu(x)=\hat{E}T_0(B_t^{t,\mu})\exp\left\{-\frac{1}{\mu^2}S_0(B_t^{t,\mu})+\frac{1}{\mu^2}\int_0^t c(t-s,B_s^{t,\mu})ds+\frac{1}{\mu^2}\int_0^t\langle k(t-s,B_s^{t,\mu}),dw_{t-s}\rangle\right\}. \tag{2.9}$$

Given a drift A_s^t, we have a solution X_s^t to Eq. (2.8). If X_s^t is nonexplosive and the stochastic integral $\int_0^t\langle k(t-s,X_s^{t,\mu}(x)),dw_{t-s}\rangle$ is well defined in the Itô sense, then we can use the Maruyama–Girsanov–Cameron–Martin formula to give

$$u_t^\mu(x)=\hat{E}T_0(X_t^{t,\mu}(x))\exp\left\{-\frac{1}{\mu^2}S_0(X_t^{t,\mu}(x))+\frac{1}{\mu^2}\int_0^t c(t-s,X_s^{t,\mu}(x))ds+\frac{1}{\mu^2}\int_0^t\langle k(t-s,X_s^{t,\mu}(x)),dw_{t-s}\rangle\right\}\mathscr{M}_t^\mu, \tag{2.10}$$

where

$$\mathscr{M}_t^\mu=\exp\left\{-\frac{1}{\mu}\int_0^t\langle A_s^t(X_s^{t,\mu}(x)),\mathscr{C}_s^{t,\mu}dB_s\rangle-\frac{1}{2\mu^2}\int_0^t\|A_s^t(X_s^{t,\mu}(x))\|^2ds\right\}. \tag{2.11}$$

On the other hand if we choose $A_s^t=\nabla Y_s^t$ for some suitable $Y_s^t:0\leqslant s\leqslant t$, then Itô's formula yields

$$Y_t(X_t^{t,\mu}(x))-Y_0(x)=\int_0^t\{\langle\nabla Y_s(X_s^{t,\mu}(x)),\mu\mathscr{C}_s^{t,\mu}\,dB_s\rangle+[\tfrac{1}{2}\mu^2\Delta Y_s(X_s^{t,\mu}(x))+\langle\nabla Y_s(X_s^{t,\mu}(x)),A_s(X_s^{t,\mu}(x))\rangle]ds+dY_s(X_s^{t,\mu}(x))\}. \tag{2.12}$$

Substituting $\int_0^t\langle\nabla Y_s(X_s^{t,\mu}(x)),\mathscr{C}_s^{t,\mu}\,dB_s\rangle$ in Eq. (2.11) by solving for $\int_0^t\langle\nabla Y_s(X_s^{t,\mu}(x)),\mathscr{C}_s^{t,\mu}\,dB_s\rangle$ in Eq. (2.12) we get

$$\mathscr{M}_t^\mu=\exp\left\{\frac{1}{\mu^2}(Y_0(x)-Y_t(X_t^{t,\mu}(x)))+\frac{1}{2}\int_0^t\Delta Y_s(X_s^{t,\mu}(x))ds+\frac{1}{\mu^2}\int_0^t\left(dY_s(X_s^{t,\mu}(x))+\frac{1}{2}\|A_s^t(X_s^{t,\mu}(x))\|^2ds\right)\right\}. \tag{2.13}$$

(3) Denote $w_s^*=w_{t-s}$ and $\mathscr{F}_s^*$ to be the enlargement of the filtration $\{\mathscr{F}_s^0\}$, where

$$\mathscr{F}_s^0=\sigma\{w_r^*:r\leqslant s\}. \tag{2.14}$$

Then $w_{t-s}=w_s^*$ is $\mathscr{F}_s^*$ measurable and $\mathscr{F}_{s_1}^*\subset\mathscr{F}_{s_2}^*$ if $s_1\leqslant s_2$. See Rogers and Williams[15] for the filtration $\mathscr{F}_s^*$.

If we take $Y_s=-S_{t-s}$ and if ∇S_{t-s} is $\mathscr{F}_s^*$ measurable for $0\leqslant s\leqslant t$ for fixed t, then we have a $\mathscr{F}_s^*$ measurable solution $X_s^{t,\mu}(x)$ to Eq. (2.8). Then we have the following theorem:

Theorem 2.3: *Assume* $c\in C^{1,2}([0,+\infty)\times M,R^1)$, $k\in C^{1,2}([0,+\infty)\times M,R^m)$ *and* $S_0\in C^2(M,R)$ *and* $T_0:M\to R^1$ *bounded and measurable,* w_t *is an* m*-dimensional Brownian motion on probability space* $(\Omega,\mathscr{F},P)$*. Let the map defined by Eq. (2.1) satisfy the no-caustic condition for* $0\leqslant t\leqslant T(\omega)$ *for a.e.* $\omega\in\Omega$ *and let* $S_t(x)$ *be the Hamilton Jacobi function defined by Eqs. (2.2) and (2.3) and* $X_s^{t,\mu}(x)$ *be the Markov process defined by Eq. (2.8) with* $Y_s=-S_{t-s}$*. If* $X_s^{t,\mu}(x)$ *is* $\mathscr{F}_s^*$ *measurable for fixed* t *and nonexplosive, then for* $0\leqslant t\leqslant T(\omega)$ *for a.e.* $\omega\in\Omega$,

$$u_t^\mu(x)=\exp\left\{-\frac{S_t(x)}{\mu^2}\right\}\hat{E}T_0(X_t^{t,\mu}(x))\exp\left\{-\frac{1}{2}\int_0^t \Delta S_{t-s}(X_s^{t,\mu}(x))ds\right\}. \tag{2.15}$$

Proof: Taking $Y_s=-S_{t-s}$, as long as $X_s^{t,\mu}(x)$ is $\mathscr{F}_s^*$ measurable and nonexplosive for $0\leqslant s\leqslant t$ for any fixed t, from Eqs. (2.10) and (2.13) we have

$$\begin{aligned}u_t^\mu(x)=\hat{E}T_0(X_t^{t,\mu}(x))\exp\Bigg\{&-\frac{1}{\mu^2}S_0(X_t^{t,\mu}(x))+\frac{1}{\mu^2}\int_0^t c(t-s,X_s^{t,\mu}(x))ds\\&+\frac{1}{\mu^2}\int_0^t\langle k(t-s,X_s^{t,\mu}(x)),dw_{t-s}\rangle\Bigg\}\\&\times\exp\Bigg\{\frac{1}{\mu^2}\{-S_t(x)+S_0(X_t^{t,\mu}(x))\}-\frac{1}{2}\int_0^t\Delta S_{t-s}(X_s^{t,\mu}(x))ds\\&+\frac{1}{\mu^2}\int_0^t\Bigg(-dS_{t-s}(X_s^{t,\mu}(x))+\frac{1}{2}\|\nabla S_{t-s}(X_s^{t,\mu}(x))\|^2ds\Bigg)\Bigg\}.\end{aligned}$$

From the stochastic Hamilton–Jacobi equation, i.e.,

$$-dS_{t-s}(X_s^{t,\mu}(x))+\{\tfrac{1}{2}\|\nabla S_{t-s}(X_s^{t,\mu}(x))\|^2+c(t-s,X_s^{t,\mu}(x))\}ds+\langle k(t-s,X_s^{t,\mu}(x)),dw_{t-s}\rangle=0,$$

formula (2.15) follows. ■

Remark 2.1: For $\mu=1$, we get Theorem 2.1 in Truman and Zhao.[10]

From Theorem 2.2 we have

$$-\Delta S(t,x)=\frac{\partial}{\partial t}\log\,\phi(t,x)+\langle\nabla\,\log\,\phi(t,x),\nabla S(t,x)\rangle. \tag{2.16}$$

In particular we obtain

$$-\Delta S(t-s,z_s^t(x))=-\frac{\partial}{\partial s}\log\,\phi(t-s,z_s^t(x)), \tag{2.17}$$

where $z_s^t(x)=\Phi_{t-s}(\Phi_t^{-1}(x))$. By Eq. (2.4) we have

$$\frac{\partial}{\partial s}z_s^t(x)=-\nabla S_{t-s}(z_s^t(x)). \tag{2.18}$$

For each $\omega\in\Omega$, if ∇S_{t-s} is bounded then as $\mu\to 0$, $X_s^{t,\mu}(x)\to z_s^t(x)$ in $\hat{P}$ probability. Therefore, applying Lebesgue's dominated convergence theorem to Eq. (2.15) we have

$$\lim_{\mu\to 0}\exp\left\{\frac{S_t(x)}{\mu^2}\right\}u_t^\mu(x)=T_0(z_t^t(x))\exp\left\{-\frac{1}{2}\int_0^t\Delta S_{t-s}(z_s^t(x))ds\right\}$$

for each $\omega\in\Omega$. The following theorem follows from Eq. (2.17).

Theorem 2.4: *Assume all the conditions in Theorem* 2.3 *and, for a.e.* $\omega\in\Omega$, ∇S *is bounded and* ΔS *is bounded from below for* $0\leqslant t\leqslant T(\omega), x\in M$, *and* T_0 *is continuous. Then for a.e.* $\omega\in\Omega$, $0\leqslant t\leqslant T(\omega)$:

$$\lim_{\mu\to 0}\exp\left\{\frac{S_t(x)}{\mu^2}\right\}u_t^\mu(x)=T_0(\Phi_t^{-1}(x))\sqrt{\phi_t(x)}. \tag{2.19}$$

Here $\phi_t(x)=|\det T_x\Phi_t^{-1}|$

For $0\leqslant t\leqslant T(\omega)$, let

$$\psi(t,x)=T_0(\Phi_t^{-1}(x))\sqrt{\phi_t(x)}. \tag{2.20}$$

Then if T_0 is positive and C^1 we have the continuity equation for $\psi_t(x)$. It turns out that

$$\frac{\partial}{\partial t}\log\,\psi_t(x)=-\frac{1}{2}\,\Delta S_t(x)-\langle\nabla\,\log\,\psi_t(x),\nabla S_t(x)\rangle. \tag{2.21}$$

Now take $Y(s,a)=-S(t-s,a)+\mu^2\log\,\psi_{t-s}(a)$ and let $X_s^{t,\mu}(x)$ be the solution of Eq. (2.8) for Y. Note X_s is nonexplosive if ∇S and $\nabla\log\psi$ are bounded P-a.s. By Eq. (2.13) we calculate the martingale $\mathscr{M}_t^\mu$:

$$\begin{aligned}\mathscr{M}_t^\mu=&\exp\Bigg\{\frac{1}{\mu^2}\,[-S_t(x)+\mu^2\,\log\,\psi_t(x)+S_0(X_t^{t,\mu}(x))-\mu^2\,\log\,\psi_0(X_t^{t,\mu}(x))]\\&-\frac{1}{2}\int_0^t\Delta S_{t-s}(X_s^{t,\mu}(x))ds+\frac{1}{2}\int_0^t\mu^2\Delta\,\log\,\psi_{t-s}(X_s^{t,\mu}(x))ds+\frac{1}{\mu^2}\int_0^t\Bigg[-dS_{t-s}(X_s^{t,\mu}(x))\\&+\Bigg(\mu^2\frac{\partial}{\partial s}\log\,\psi_{t-s}(X_s^{t,\mu}(x))+\frac{1}{2}\,\|-\nabla S_{t-s}(X_s^{t,\mu}(x))+\mu^2\nabla\,\log\,\psi_{t-s}(X_s^{t,\mu}(x))\|^2\Bigg)ds\Bigg]\Bigg\}\\=&\exp\Bigg\{-\frac{S_t(x)}{\mu^2}\Bigg\}\psi_t(x)\exp\Bigg\{\frac{1}{\mu^2}\,S_0(X_t^{t,\mu}(x))-\log\,\psi_0(X_t^{t,\mu}(x))-\frac{1}{2}\int_0^t\Delta S_{t-s}(X_s^{t,\mu}(x))ds\\&+\frac{1}{2}\,\mu^2\int_0^t\psi_{t-s}^{-1}(X_s^{t,\mu}(x))\Delta\psi_{t-s}(X_s^{t,\mu}(x))ds-\frac{1}{2}\int_0^t\mu^2\|\nabla\,\log\,\psi_{t-s}(X_s^{t,\mu}(x))\|^2ds\\&+\frac{1}{\mu^2}\int_0^t\Bigg\{-dS_{t-s}(X_s^{t,\mu}(x))+\frac{1}{2}\,\|\nabla S_{t-s}(X_s^{t,\mu}(x))\|^2ds\Bigg\}+\int_0^t\Bigg[\frac{\partial}{\partial s}\log\,\psi_{t-s}(X_s^{t,\mu}(x))\\&-\langle\nabla S_{t-s}(X_s^{t,\mu}(x)),\nabla\,\log\{\psi_{t-s}(X_s^{t,\mu}(x))\rangle\Bigg]ds+\frac{1}{2}\int_0^t\mu^2\|\nabla\,\log\,\psi_{t-s}(X_s^{t,\mu}(x))\|^2ds\Bigg\}.\end{aligned}$$

Therefore by Eqs. (2.21) and (2.10) and the stochastic Hamilton–Jacobi equation we have the following formula as long as $\int_0^t\langle k(t-s,X_s^{t,\mu}(x)),dw_{t-s}\rangle$ is well defined.

Theorem 2.5: *Assume that c and k and* S_0 *are* C^3 *with all the conditions of Theorem* 2.3 *and also that* ∇S *and* $\nabla\log\psi_t$ *are bounded and* ψ_{t-s} *is* $\mathscr{T}_s^*$ *measurable for any* $0\leqslant s\leqslant t$ *and fixed* t. *Then for any* $\mu\neq 0$, $0\leqslant t\leqslant T(\omega)$ *for a.e.* $\omega\in\Omega$,

$$u_t^\mu(x)=\exp\Bigg\{-\frac{1}{\mu^2}\,S_t(x)\Bigg\}\psi_t(x)\hat{E}\,\exp\Bigg\{\frac{1}{2}\,\mu^2\int_0^t\psi_{t-s}^{-1}(X_s^{t,\mu}(x))\Delta\psi_{t-s}(X_s^{t,\mu}(x))ds\Bigg\}, \tag{2.22}$$

where $X_s^{t,\mu}(x)$ *is defined by Eq.* (2.8) *with* $Y_s=-S_{t-s}+\mu^2\log\psi_{t-s}$.

Remark 2.2: For $k\equiv 0$, we get Formula B of Elworthy and Truman.[5]

As $\mu\to 0$, $X_s^{t,\mu}(x)$ converges to $z_s^t(x)$ in $\hat{P}$ probability for each $\omega\in\Omega$. As long as $\psi^{-1}\Delta\psi$ is bounded we can apply Lebesgue's dominated convergence theorem and the Taylor expansion theorem to give the following post-WKB expansion:

Theorem 2.6: *Assume all the conditions of Theorem* 2.5 *and* $\psi^{-1}\Delta\psi$ *is bounded for all* $0\leqslant t\leqslant T(\omega)$ *for a.e.* $\omega\in\Omega$ *and* $x\in M$. *Then for sufficiently small* $\mu\neq 0$, $0\leqslant t\leqslant T(\omega)$ *for a.e.* $\omega\in\Omega$:

$$u_t^{\mu}(x)=\exp\left\{-\frac{1}{\mu^2}S_t(x)\right\}\psi_t(x)\left\{1+\frac{1}{2}\mu^2\int_0^t\psi_{t-s}^{-1}(z_s^t(x))\Delta\psi_{t-s}(z_s^t(x))ds+\circ(\mu^2)\right\}. \tag{2.23}$$

Remark 2.3: As long as the stochastic integral $\int_0^t\langle k(t-s,X_s^{t,\mu}),dw_{t-s}\rangle$ is well defined in Itô's sense, Theorems 2.3–2.6 are still true. In most of the situations, this condition is satisfied.

III. THE HEAT KERNEL

(1) Let M be an n-dimensional Riemannian manifold, with global normal coordinates and a Riemannian metric $r(\cdot,\cdot)$. Consider the following stochastic heat equation:

$$du_t(x)=[\tfrac{1}{2}\Delta u_t(x)+c(t,x)u_t(x)]dt+u_t(x)(\langle\gamma(t),\partial w_t\rangle+\langle x,\eta\partial w_t\rangle), \tag{3.1}$$

where $x\in M$, Δ is a Laplace Beltrami operator, w_t is an m-dimensional Brownian motion, $\eta:R^m\to R^n$ is a linear map, $\gamma\in C^1([0,\infty),R^m)$ is bounded. Let $p_t^{\lambda}(x,y)$ be the solution of Eq. (3.1) with the initial condition

$$p_0^{\lambda}(x,y)=\frac{1}{(2\pi\lambda)^{n/2}}\exp\left\{-\frac{r^2(x,y)}{2\lambda}\right\}. \tag{3.2}$$

Then the heat kernel $p_t(x,y)$ of Eq. (3.1) is given by

$$p_t(x,y)=\lim_{\lambda\to 0}p_t^{\lambda}(x,y). \tag{3.3}$$

Suppose $y\in M$ is a pole for M so that $\exp_y:T_yM\to M$ is a C^{∞} diffeomorphism. Denote $x=\exp_y(v)$. Therefore we have a global system of normal coordinates from y in which the geodesics from y are represented as straight lines from the origin. Let $\theta_y(v)$ be the Jacobian determinant of $\exp_y$ at v (Ruses' invariant): $\theta_y(v)=|\det_M T_v\exp_y|$, where $\det_M$ indicates that the inner product of T_yM and $T\exp_y(v)M$ are used to define the determinant. We shall often write θ for θ_y.

From now on let the stochastic process $X_s^{t,\lambda}$ be defined in our normal coordinates by Eq. (2.8) where we take $\mu=1$ with

$$A_s^{t,\lambda}(x)=\eta w_{t-s}-\frac{v+\int_0^{t-s}\eta w_\sigma\,d\sigma}{\lambda+t-s}-\frac{1}{2}\nabla\log\theta\left(v+\int_0^{t-s}\eta w_\sigma\,d\sigma\right). \tag{3.4}$$

Let $\xi_s^{t,\lambda}=v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\,d\sigma$. Then from Eq. (2.8) $\xi_s^{t,\lambda}$ satisfies an equation which does not include the stochastic process w except for the initial condition $\xi_0^{t,\lambda}=v_0+\int_0^t\eta w_\sigma\,d\sigma$. Thus we can write $\xi_s^{t,\lambda}=F_s^{t,\lambda}(v_0+\int_0^t\eta w_\sigma\,d\sigma)$ for some functional $F_s^{t,\lambda}$ which is independent of w. Recall $v_s^{t,\lambda}=\xi_s^{t,\lambda}-\int_0^{t-s}\eta w_\sigma\,d\sigma=F_s^{t,\lambda}(v_0+\int_0^t\eta w_\sigma\,d\sigma)-\int_0^t\eta w_\sigma\,d\sigma+\int_{t-s}^t\eta w_\sigma\,d\sigma$. Thus the stochastic integral $\int_0^t\langle X_s^{t,\lambda},\eta\,dw_{t-s}\rangle$ is well defined in Itô's sense.

Lemma 3.1: As $\lambda\to 0$, $\{X_s^{t,\lambda}:0\leqslant s\leqslant t\}$ converges in law $(\hat{P})$ to the process $\{X_s^t(x):0\leqslant s\leqslant t\}$ which is sample continuous, agrees with $X_s^{t,0}$ for $0\leqslant s<t$ and $X_t^t(x)=y$.

Proof: As for $0\leqslant s<t$, as $\lambda\to 0$, $A_s^{t,\lambda}\to Z_s^t$ where

$$Z_s^t=\eta w_{t-s}-\frac{v_s+\int_0^{t-s}\eta w_\sigma\,d\sigma}{t-s}-\frac{1}{2}\nabla\log\theta\left(v_s+\int_0^{t-s}\eta w_\sigma\,d\sigma\right),\quad 0\leqslant s<t. \tag{3.5}$$

It follows from Sec. 4 Chap. VIII and Theorem 8C of Chap. VII of Elworthy[14] [that as $\lambda\to 0$ so $X_s^{t,\lambda}$ converges in $\hat{P}$ probability for $0\leqslant s<t$, to a standard Brownian motion $X_s^{t,0}$ with a drift Z_s^t. Note that Z_s^t as well as $A_s^{t,\lambda}$ depends on the Brownian motion w_s on the probability space

$(\Omega,\mathcal{F},P)$. However this does not affect our argument. To see what happens at time t define $r_s: M \to R$ by $r_s(v) = r(v + \int_0^{t-s} \eta w_\sigma \, d\sigma, y)$. Then $r_s(-)$ is C^2 on $M - \{y\}$ while, if $n \geqslant 2$, and $x \neq y$, with $\hat{P}$ probability one $X_s^{t,\lambda}$ avoids y for $0 \leqslant s < t$ as does $X_s^{t,0}(x)$ for $0 \leqslant s < t$. Therefore by Itô's formula, for $0 \leqslant s < t$,

$$r_s(v_s^t) = r_0(x) + \int_0^s dr_\sigma(\mathscr{U}_\sigma \, dB_\sigma) + \int_0^s dr_\sigma \, Z_\sigma^t(v_\sigma^t) d\sigma + \frac{1}{2} \int_0^s \Delta r_\sigma(v_\sigma^t) d\sigma + \int_0^s \frac{\partial r_\sigma}{\partial \sigma}(v_\sigma^t) d\sigma. \tag{3.6}$$

We see from Elworthy[14] that

$$\Delta r = \frac{n-1}{r} + \frac{\partial}{\partial r} \log \theta. \tag{3.7}$$

Then it follows that

$$\frac{1}{2} \Delta r_\sigma(v_\sigma) = \frac{1}{2} \frac{n-1}{r(v_\sigma^t + \int_0^{t-\sigma} \eta w_\sigma \, d\sigma)} + \frac{1}{2} \frac{\partial}{\partial r} \log \theta \left(v_\sigma^t + \int_0^{t-\sigma} \eta w_\sigma \, d\sigma \right). \tag{3.8}$$

In our coordinates

$$\nabla r_\sigma(v) = \frac{v + \int_0^{t-\sigma} \eta w_\sigma \, d\sigma}{|v + \int_0^{t-\sigma} \eta w_\sigma \, d\sigma|}.$$

Therefore,

$$dr_\sigma \, Z_\sigma^t(v_\sigma) = dr_\sigma \, \eta w_{t-\sigma} - \frac{r(v_\sigma^t + \int_0^{t-\sigma} \eta w_\sigma \, d\sigma)}{t-\sigma} - \frac{1}{2} \frac{\partial}{\partial r} \log \theta \left(v_\sigma^t + \int_0^{t-\sigma} \eta w_\sigma \, d\sigma \right). \tag{3.9}$$

Therefore if we let $r_s = r(v_s^t(x) + \int_0^{t-s} \eta w_\sigma \, d\sigma)$ and $\tilde{B}_s = \int_0^s dr_\sigma(\mathscr{U}_\sigma \, dB_\sigma)$, and note the cancellation of the terms $dr_\sigma \, \eta w_{t-\sigma}$ and $\partial r_\sigma / \partial \sigma(v_\sigma^t)$, then

$$r_s = r_0(x) + \tilde{B}_s + \frac{1}{2}(n-1) \int_0^s \frac{d\sigma}{r_\sigma} - \int_0^s \frac{r_\sigma}{t-\sigma} \, d\sigma. \tag{3.10}$$

It turns out from Ikeda and Watanabe[16] that with $\hat{P}$ probability one, r_s converges to 0 as $s \to t$. That is to say $X_s^t(x) \to y$ as $s \to t$. ■

We call $\{X_s^t(x): 0 \leqslant s \leqslant t\}$ a stochastic Brownian Riemannian bridge from x to y in time t on M.

(2) Now if $f: M \to R$ is smooth with $f(x) = F[r(x)]$ for some smooth $F: (0, +\infty) \to R$, then by Elworthy,[17]

$$\Delta f(x) = \frac{\partial^2 F}{\partial r^2} + \left(\frac{n-1}{r(x)} + \frac{\partial}{\partial r} (\log \theta(x)) \right) \frac{\partial F}{\partial r}. \tag{3.11}$$

In particular

$$-\Delta r^2 = -2 - 2(n-1) - 2r \frac{\partial}{\partial r} \log \theta = -2n - 2r \frac{\partial}{\partial r} \log \theta. \tag{3.12}$$

Moreover

$$-\tfrac{1}{2}\,\Delta\,\log\,\theta=\theta^{1/2}\Delta\,\theta^{-(1/2)}-|\nabla\,\log\,\theta^{1/2}|^2. \tag{3.13}$$

We give the heat kernel representation theorem in terms of the stochastic Brownian Riemannian bridge as follows:

Theorem 3.1: *Suppose y is a pole on the n-dimensional Riemannian manifold M. If $\theta^{1/2}\Delta\theta^{-1/2}$ and $c\in C^{1,2}(R\times M,R)$ are bounded above and $\gamma\in C^1(R,R^m)$ is bounded, then the heat kernel of Eq. (3.1) on the Riemannian manifold M is given by*

$$\begin{aligned}p_t(x,y)=&\frac{1}{(2\pi t)^{n/2}}\,\theta^{-(1/2)}\left(\exp(\exp^{-1}(x)+\int_0^t\eta w_s\,ds)\right)\exp\left\{\int_0^t\langle\gamma(s),dw_s\rangle+\frac{1}{2}\int_0^t|\eta w_s|^2ds\right.\\&\left.+\langle x,\eta w_t\rangle-\frac{r^2\{\exp(\exp^{-1}(x)+\int_0^t\eta w_s\,ds),y\}}{2t}\right\}\\&\cdot\hat{E}\,\exp\left\{\frac{1}{2}\int_0^t(\theta^{1/2}\Delta\theta^{-(1/2)})\left(\exp\left(v_s^t+\int_0^{t-s}\eta w_\sigma\,d\sigma\right)\right)ds+\int_0^t c(t-s,X_s^t)ds\right\},\end{aligned} \tag{3.14}$$

where $X_s^t=\exp(v_s^t)$ is the stochastic Brownian Riemannian bridge from x to y at time t on M.

Proof: Define $S_t^\lambda(x)$ by

$$S_t^\lambda(x)=-\int_0^t\langle\gamma(\sigma),dw_\sigma\rangle-\frac{1}{2}\int_0^t|\eta w_\sigma|^2d\sigma-\langle x,\eta w_t\rangle+\frac{r^2(\exp(v+\int_0^t\eta w_\sigma\,d\sigma),y)}{2(\lambda+t)}. \tag{3.15}$$

Take $Y_s^{t,\lambda}(x)=-S_{t-s}^\lambda(x)-\frac{1}{2}\log\theta(v+\int_0^{t-s}\eta w_\sigma\,d\sigma)$. Then $A_s^{t,\lambda}$ is defined by Eq. (3.4) and the stochastic process $X_s^{t,\lambda}\in\mathcal{F}_s^*$. Thus we can use Eq. (2.13) to calculate $\mathcal{M}_t^\lambda$ as follows:

$$\begin{aligned}\mathcal{M}_t^\lambda=\exp&\left\{-S_t^\lambda(x)-\frac{1}{2}\log\,\theta\left(v+\int_0^t\eta w_s\,ds\right)+\frac{r^2(X_t^{t,\lambda},y)}{2\lambda}+\frac{1}{2}\log\,\theta(X_t^{t,\lambda})\right.\\&+\frac{1}{2}\int_0^t\left[-\frac{\Delta r^2(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\,d\sigma)}{2(\lambda+t-s)}-\frac{1}{2}\Delta\,\log\,\theta\left(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\,d\sigma\right)\right]ds\\&+\int_0^t\left[-dS_{t-s}(X_s^{t,\lambda})+\left(\nabla\,\log\,\theta^{-(1/2)}\left(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\,d\sigma\right)(-\eta w_{t-s})\right.\right.\\&+\frac{1}{2}\left\|\eta w_{t-s}-\frac{r(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\,d\sigma)\nabla r(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\,d\sigma)}{\lambda+t-s}\right\|^2\\&+\frac{1}{2}\left\|\nabla\,\log\,\theta^{-(1/2)}\left(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\,d\sigma\right)\right\|^2+\nabla\,\log\,\theta^{-(1/2)}\left(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\,d\sigma\right)\eta w_{t-s}\\&+\frac{1}{2}\frac{r(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\,d\sigma)\nabla r(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\,d\sigma)}{\lambda+t-s}\\&\left.\left.\cdot\nabla\,\log\,\theta\left(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\,d\sigma\right)\right)ds\right]\right\}.\end{aligned}$$

The first cancellation comes out from $\nabla\log\theta^{-(1/2)}(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\,d\sigma)(-\eta w_{t-s})+\nabla\log\theta^{-(1/2)}(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\,d\sigma)\,\eta w_{t-s}\equiv 0$. Then by Eqs. (3.12) and (3.13) we have

$$\mathscr{M}_t = \exp\{-S_t^\lambda(x)\}\theta^{-(1/2)}\left(v+\int_0^t \eta w_s\, ds\right)\cdot\exp\left\{\frac{r^2(X_t^{t,\lambda},y)}{2\lambda}+\frac{1}{2}\log\,\theta(X_t^{t,\lambda})\right.$$
$$+\frac{1}{2}\int_0^t\left[-\frac{n}{\lambda+t-s}-\frac{r(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\, d\sigma)}{\lambda+t-s}\cdot\frac{\partial}{\partial r}\log\,\theta\left(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\, d\sigma\right)\right.$$
$$+\theta^{1/2}\left(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\, d\sigma\right)\Delta\,\theta^{-(1/2)}\left(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\, d\sigma\right)$$
$$-\left|\nabla\,\log\,\theta^{1/2}\left(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\, d\sigma\right)\right|^2\Bigg]ds+\int_0^t\Bigg[-dS_{t-s}(X_s^{t,\lambda})$$
$$+\left(\frac{1}{2}\|\nabla S_{t-s}(X_s^{t,\lambda})\|^2+\frac{1}{2}\left\|\nabla\,\log\,\theta^{-(1/2)}\left(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\, d\sigma\right)\right\|^2\right.$$
$$\left.\left.+\frac{1}{2}\frac{r(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\, d\sigma)}{\lambda+t-s}\cdot\frac{\partial}{\partial r}\log\,\theta\left(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\, d\sigma\right)\right)ds\Bigg]\right\}.$$

Thus after the cancellations we have

$$\mathscr{M}_t = \exp\{-S_t^\lambda(x)\}\theta^{-(1/2)}\left(v+\int_0^t \eta w_s\, ds\right)\left(\frac{\lambda}{\lambda+t}\right)^{n/2}\exp\left\{\frac{r^2(X_t^{t,\lambda},y)}{2\lambda}+\frac{1}{2}\log\,\theta(X_t^{t,\lambda})\right.$$
$$+\frac{1}{2}\int_0^t\theta^{1/2}\left(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\, d\sigma\right)\Delta\,\theta^{-(1/2)}\left(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\, d\sigma\right)ds$$
$$\left.+\int_0^t\left[-dS_{t-s}(X_s^{t,\lambda})+\frac{1}{2}\|\nabla S_{t-s}(X_s^{t,\lambda})\|^2 ds\right]\right\}. \tag{3.16}$$

Now by the definition of $p_t^\lambda(x,y)$ and Eq. (2.10),

$$p_t^\lambda(x,y)=\frac{1}{(2\pi\lambda)^{n/2}}\hat{E}\,\exp\left\{-\frac{r^2(X_t^{t,\lambda},y)}{2\lambda}+\int_0^t c(t-s,X_s^{t,\lambda})ds\right.$$
$$\left.+\int_0^t\langle\gamma(t-s),dw_{t-s}\rangle+\int_0^t\langle X_s^{t,\lambda},\eta\, dw_{t-s}\rangle\right\}\cdot\mathscr{M}_t. \tag{3.17}$$

From Eq. (3.16) and the fact that S^λ satisfies the stochastic Hamilton Jacobi equation (Truman and Zhao[10]):

$$-dS_{t-s}(X_s^{t,\lambda})+\tfrac{1}{2}\|\nabla S_{t-s}(X_s^{t,\lambda})\|^2 ds+\langle\gamma(t-s),dw_{t-s}\rangle+\langle X_s^{t,\lambda},\eta\, dw_{t-s}\rangle\equiv 0, \tag{3.18}$$

it turns out that

$$p_t^{\lambda}(x,y)=\frac{1}{(2\pi(t+\lambda))^{n/2}}\,\theta^{-(1/2)}\left(v+\int_0^t \eta w_s\,ds\right)\exp\left\{\int_0^t\langle\gamma(t-s),dw_{t-s}\rangle+\frac{1}{2}\int_0^t|\eta w_s|^2ds\right.$$
$$\left.+\langle x,\eta w_t\rangle-\frac{r^2(\exp(v+\int_0^t\eta w_s\,ds),y)}{2(\lambda+t)}\right\}$$
$$\cdot\hat{E}\,\exp\left\{\frac{1}{2}\int_0^t\theta^{1/2}\left(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\,d\sigma\right)\Delta\theta^{-(1/2)}\left(v_s^{t,\lambda}+\int_0^{t-s}\eta w_\sigma\,d\sigma\right)ds\right.$$
$$\left.+\int_0^t c(t-s,X_s^{t,\lambda})ds+\frac{1}{2}\log\,\theta(X_t^{t,\lambda})\right\}. \tag{3.19}$$

The theorem follows by taking the limit $\lambda\to 0$ in Eq. (3.19) and applying Lebesgue's dominated convergence theorem and Lemma 3.1. ■

With the representation theorem in our hands, using the iterated logarithm law of Brownian motion, the small time asymptotics is a straightforward corollary of Theorem 3.1.

Corollary 3.1: Assume all the conditions of Theorem 3.1. Then for x,y in any compact subset of M as $t\to 0$, the heat kernel $p_t(x,y)$ of Eq. (3.1) satisfies

$$p_t(x,y)=\frac{1}{(2\pi t)^{n/2}}\exp\left\{-\frac{r^2(x,y)}{2t}\right\}\left\{1+\circ\left(\left(t\,\log\frac{1}{t}\right)^{1/2}\right)\right\}\quad P-\text{a.s.} \tag{3.20}$$

If $M=R^n$, then $\theta\equiv 1$, the following theorem in Truman and Zhao[10] follows from Theorem 3.1.

Theorem 3.2 (Truman and Zhao[10]): *Consider Eq. (3.1) for the case $M=R^n$. Assume $c\in C^{1,2}([0,\infty)\times R^n,R^1)$ and $\gamma\in C^1([0,\infty),R^m)$ with c bounded above and γ bounded. Then the heat kernel is given by*

$$p_t(x,y)=\frac{1}{(2\pi t)^{n/2}}\exp\left\{\int_0^t\langle\gamma(\sigma),dw_\sigma\rangle+\frac{1}{2}\int_0^t|\eta w_\sigma|^2d\sigma+\langle x,\eta w_t\rangle-\frac{r^2(x+\int_0^t\eta w_\sigma\,d\sigma,y)}{2t}\right\}$$
$$\cdot\hat{E}\,\exp\left\{\int_0^t c(t-s,X_s^t)ds\right\}. \tag{3.21}$$

Here $\{X_s^t:0\leqslant s\leqslant t\}$ is the stochastic semiclassical bridge in R^n from x to y in time t.

If $\eta\equiv 0$, $\gamma\equiv 0$, Eq. (3.1) is a deterministic equation on M. The Elworthy and Truman[5] Theorem follows from Theorem 3.1.

Theorem 3.3 (Elworthy and Truman[5]): *Suppose y is a pole on the Riemannian manifold M. If $\theta^{1/2}\Delta\theta^{-(1/2)}$ and c are bounded, then the heat kernel of Eq. (3.1) for $\eta\equiv 0$, $\gamma\equiv 0$ on the Riemannian manifold M is given by*

$$p_t(x,y)=\frac{1}{(2\pi t)^{n/2}}\,\theta^{-(1/2)}(x)\exp\left\{-\frac{r^2(x,y)}{2t}\right\}$$
$$\times\hat{E}\,\exp\left\{\frac{1}{2}\int_0^t\theta^{1/2}(X_s^t)\Delta\theta^{-(1/2)}(X_s^t)ds+\int_0^t c(t-s,X_s^t)ds\right\}, \tag{3.22}$$

where X_s^t is the Brownian Riemannian bridge from x to y at time t on M.

(3) For hyperbolic n-space H^n with constant sectional curvatures $-(1/R^2)$ we have

$$\theta_y(x)=\left(\frac{R}{r}\sinh\frac{r}{R}\right)^{n-1}$$

for $r(x)=r(x,y)$. From Elworthy[14] we see that

$$\frac{1}{2}\,\theta^{1/2}\Delta\,\theta^{-(1/2)}=-\frac{(n-1)^2}{8R^2}+\frac{(n-1)(n-3)}{8}\left\{r^{-2}-\left(R^2\,\sinh^2\left(\frac{r}{R}\right)\right)^{-1}\right\}.$$

Therefore the heat kernel of Eq. (3.1) on H^n is given by

$$\begin{aligned}p_t(x,y)=&\frac{1}{(2\pi t)^{n/2}}\\&\times\left[\frac{r\{\exp(\exp^{-1}(x)+\int_0^t\eta w_s\,ds),y\}}{R}\,\frac{1}{\sinh[r\{\exp(\exp^{-1}(x)+\int_0^t\eta w_s\,ds),y\}/R]}\right]^{(n-1)/2}\\&\cdot\exp\left\{\int_0^t\langle\gamma(s),dw_s\rangle+\frac{1}{2}\int_0^t|\eta w_s|^2ds+\langle x,\eta w_t\rangle-\frac{r^2\{\exp(\exp^{-1}(x)+\int_0^t\eta w_s\,ds),y\}}{2t}\right.\\&\left.-\frac{(n-1)^2}{8R^2}\,t\right\}\cdot\hat{E}\,\exp\left\{\frac{(n-1)(n-3)}{8}\int_0^t\left[r^{-2}\left(\exp\left\{\exp^{-1}(X_s^t(x))\right.\right.\right.\\&\left.\left.\left.+\int_0^{t-s}\eta w_\sigma\,d\sigma\right\},y\right)-\left(R^2\,\sinh^2\left(\frac{r(\exp\{\exp^{-1}(X_s^t(x))+\int_0^{t-s}\eta w_\sigma\,d\sigma\},y)}{R}\right)\right)^{-1}\right]ds\right\}.\end{aligned}\tag{3.23}$$

Here $X_s^t(x)$ is the stochastic Brownian Riemannian bridge on H^n. In particular for hyperbolic 3-space H^3, we have

$$\begin{aligned}p_t(x,y)=&\frac{1}{(2\pi t)^{3/2}}\\&\times\frac{r\{\exp(\exp^{-1}(x)+\int_0^t\eta w_s\,ds),y\}}{R}\,\frac{1}{\sinh[r\{\exp(\exp^{-1}(x)+\int_0^t\eta w_s\,ds),y\}/R]}\\&\times\exp\left\{\int_0^t\langle\gamma(s),dw_s\rangle+\frac{1}{2}\int_0^t|\eta w_s|^2ds+\langle x,\eta w_t\rangle-\frac{r^2\{\exp(\exp^{-1}(x)+\int_0^t\eta w_s\,ds),y\}}{2t}\right.\\&\left.-\frac{1}{2R^2}\,t\right\}.\end{aligned}\tag{3.24}$$

IV. THE STOCHASTIC MEHLER FORMULA

(1) Consider the following stochastic harmonic oscillator in R^1

$$\begin{cases}d\dot{\Phi}_s=-\alpha^2\Phi_s\,ds-\eta\,dw_s\\ \Phi_0(x)=x,\quad \Phi_0(x)=\dfrac{x}{\lambda}\end{cases},\tag{4.1}$$

where $\alpha,\lambda>0,\eta\geqslant 0$ are constants, which is Eq. (2.1) in the case $c(s,x)=\frac{1}{2}\alpha^2x^2$, $k(s,x)=\eta x$, and $S_0(x)=x^2/2\lambda$ and $M=R^1$. See McKean,[18] Markus and Weerasinghe,[19] and Albeverio *et al.*[20] for some important properties of the stochastic harmonic oscillator. Solving Eq. (4.1) we have

$$\Phi_s(x)=x\,\cos\,\alpha s+\frac{x}{\lambda\alpha}\,\sin\,\alpha s-\frac{\eta}{\alpha}\int_0^s\sin\,\alpha(s-\sigma)dw_\sigma.\tag{4.2}$$

The map $\Phi_s: R^1 \to R^1$ satisfies the no caustic condition for $s < (1/\alpha)\mathrm{ctg}^{-1}(-(1/\alpha\lambda))$ and the inverse function is given by

$$\Phi_t^{-1}(x) = \frac{\lambda(\alpha x + \eta \int_0^t \sin\ \alpha(t-\sigma) dw_\sigma)}{\alpha\lambda\ \cos\ \alpha t + \sin\ \alpha t} \quad \text{for } 0 < t < \frac{1}{\alpha}\ \mathrm{ctg}^{-1}\left(-\frac{1}{\alpha\lambda}\right). \tag{4.3}$$

By the definition of $\tilde{S}_t(x)$, Eq. (2.2), and careful calculations we have

$$\begin{aligned}\tilde{S}_{t,\lambda}(y) = &\left[\frac{\sin 2\alpha t}{4\alpha\lambda^2} + \frac{\cos 2\alpha t}{2\lambda} - \frac{1}{4}\ \alpha\ \sin 2\alpha t\right] y^2 \\ &- \frac{\eta}{\alpha\lambda}\ (\alpha\lambda\ \cos\ \alpha t + \sin\ \alpha t) \int_0^t \cos\ \alpha(t-\sigma) dw_\sigma\ y \\ &+ \frac{1}{2}\ \eta^2 \int_0^t \left\{ \left(\int_0^s \cos\ \alpha(s-\sigma) dw_\sigma \right)^2 - \left(\int_0^s \sin\ \alpha(s-\sigma) dw_\sigma \right)^2 \right\} ds \\ &+ \frac{\eta^2}{\alpha} \int_0^t \int_0^s \sin\ \alpha(s-\sigma) dw_\sigma\ dw_s .\end{aligned}$$

It turns out from the definition of S_t, Eq. (2.3),

$$\begin{aligned}S_{t,\lambda}(x) = \tilde{S}_{t,\lambda}[\Phi_t^{-1}(x)] = &\left[\frac{\sin 2\alpha t}{4\alpha\lambda^2} + \frac{\cos 2\alpha t}{2\lambda} - \frac{1}{4}\ \alpha\ \sin 2\alpha t\right] \frac{\lambda^2(\alpha x + \eta \int_0^t \sin\ \alpha(t-\sigma) dw_\sigma)^2}{(\alpha\lambda\ \cos\ \alpha t + \sin\ \alpha t)^2} \\ &- \frac{\eta}{\alpha} \int_0^t \cos\ \alpha(t-\sigma) dw_\sigma \left(\alpha x + \eta \int_0^t \sin\ \alpha(t-\sigma) dw_\sigma \right) + \frac{1}{2}\ \eta^2 \int_0^t \left\{ \left(\int_0^s \cos\ \alpha(s \right.\right. \\ &\left.\left. - \sigma) dw_\sigma \right)^2 - \left(\int_0^s \sin\ \alpha(s-\sigma) dw_\sigma \right)^2 \right\} ds + \frac{\eta^2}{\alpha} \int_0^t \int_0^s \sin\ \alpha(s-\sigma) dw_\sigma\ dw_s \end{aligned} \tag{4.4}$$

for $0 < t < (1/\alpha)\mathrm{ctg}^{-1}[-(1/\alpha\lambda)]$. It is a very complicated formula. However we can simplify it by taking the limit $\lambda \to 0$ to get an illuminating formula for S:

$$\begin{aligned}S_t(x) = \lim_{\lambda \to 0} S_{t,\lambda}(x) = &\frac{\cos\ \alpha t}{2\alpha\ \sin\ \alpha t} \left(\alpha x + \eta \int_0^t \sin\ \alpha(t-\sigma) dw_\sigma \right)^2 - \frac{\eta}{\alpha} \int_0^t \cos\ \alpha(t-\sigma) dw_\sigma \\ &\times \left(\alpha x + \eta \int_0^t \sin\ \alpha(t-\sigma) dw_\sigma \right) + \frac{1}{2}\ \eta^2 \int_0^t \left\{ \left(\int_0^s \cos\ \alpha(s-\sigma) dw_\sigma \right)^2 \right. \\ &\left. - \left(\int_0^s \sin\ \alpha(s-\sigma) dw_\sigma \right)^2 \right\} ds + \frac{\eta^2}{\alpha} \int_0^t \int_0^s \sin\ \alpha(s-\sigma) dw_\sigma\ dw_s \end{aligned} \tag{4.5}$$

for $t < \pi/\alpha$. Note $T_{\alpha,\lambda} = (1/\alpha)\mathrm{ctg}^{-1}[-(1/\alpha\lambda)]$ is the caustic time of our stochastic oscillator (4.1). $T_\alpha = \pi/\alpha$ is the $\lambda \to 0$ limit of the caustic time $T_{\alpha,\lambda}$.

At the moment let us consider the Stratonovich stochastic heat equation with the harmonic oscillator potential

$$du_t = [\tfrac{1}{2}\Delta u_t + \tfrac{1}{2}\alpha^2 x^2 u_t] dt + \eta x u_t \partial w_t . \tag{4.6}$$

Here $x \in R^1$. Let $p_t^\lambda(x)$ be the solution of Eq. (4.6) with the initial condition $p_0^\lambda(x) = (1/\sqrt{2\pi\lambda})\exp\{-(x^2/2\lambda)\}$ and $p_t(x) = \lim_{\lambda\to 0} p_t^\lambda(x)$. We shall apply Theorem 2.5. Note first $\psi_{t,\lambda}(x) = \sqrt{\alpha/2\pi}(\alpha\lambda\cos\alpha t + \sin\alpha t)$ by Eqs. (2.20) and (4.3) so that $\nabla\psi_{t-s,\lambda} \equiv 0$ for $0 \leqslant s \leqslant t < T_{\alpha,\lambda}$. Moreover for $0 \leqslant s \leqslant t < T_{\alpha,\lambda}$,

$$\nabla S_{t-s,\lambda}(x) = \left[\frac{\sin 2\alpha(t-s)}{4\alpha\lambda^2} + \frac{\cos 2\alpha(t-s)}{2\lambda} - \frac{1}{4}\,\alpha\,\sin 2\alpha(t-s)\right] \cdot \frac{2\alpha\lambda^2(\alpha x + \eta\int_0^{t-s}\sin\alpha(t-s-\sigma)dw_\sigma)}{(\alpha\lambda\cos\alpha(t-s) + \sin\alpha(t-s))^2} - \eta\int_0^{t-s}\cos\alpha(t-s-\sigma)dw_\sigma .$$

Let $\xi_s^{t,\lambda} = X_s^{t,\lambda} + \eta/\alpha\int_0^{t-s}\sin\alpha(t-s-\sigma)dw_\sigma$. Then from Eq. (2.8) $\xi_s^{t,\lambda}$ satisfies an equation which does not include the stochastic process w except for the initial condition $\xi_0^{t,\lambda} = x + \eta/\alpha\int_0^t \sin\alpha(t-\sigma)dw_\sigma$. Thus we can write $\xi_s^{t,\lambda} = F_s^{t,\lambda}(x + \eta/\alpha\int_0^t \sin\alpha(t-\sigma)dw_\sigma)$. Recall $X_s^{t,\lambda} = \xi_s^{t,\lambda} - \eta/\alpha\int_0^{t-s}\sin\alpha(t-s-\sigma)dw_\sigma = F_s^{t,\lambda}(x + \eta/\alpha\int_0^t \sin\alpha(t-\sigma)dw_\sigma) - \eta/\alpha\int_0^t \times\sin\alpha(t-s-\sigma)dw_\sigma + \eta/\alpha\int_{t-s}^t \sin\alpha(t-s-\sigma)dw_\sigma$. Thus $\eta\int_0^t X_s^{t,\lambda}\,dw_{t-s}$ is well defined in Itô's sense for fixed $t < T_{\alpha,\lambda}$. Then applying Eq. (2.22) of Theorem 2.5 and Remark 2.3 we have

$$p_t^\lambda(x) = \sqrt{\frac{\alpha}{2\pi(\alpha\lambda\cos\alpha t + \sin\alpha t)}}\,\exp\{-S_{t,\lambda}(x)\}. \tag{4.7}$$

It turns out by taking the limits $\lambda \to 0$ in Eq. (4.7) that

Theorem 4.1: For $0 < t < \pi/\alpha$,

$$\begin{aligned} p_t(x) = \sqrt{\frac{\alpha}{2\pi\sin\alpha t}}\,\exp\Bigg\{ & -\frac{\cos\alpha t}{2\alpha\sin\alpha t}\left(\alpha x + \eta\int_0^t \sin\alpha(t-\sigma)dw_\sigma\right)^2 \\ & + \frac{\eta}{\alpha}\int_0^t \cos\alpha(t-\sigma)dw_\sigma\left(\alpha x + \eta\int_0^t \sin\alpha(t-\sigma)dw_\sigma\right) \\ & - \frac{1}{2}\,\eta^2\int_0^t\left\{\left(\int_0^s \cos\alpha(s-\sigma)dw_\sigma\right)^2 - \left(\int_0^s \sin\alpha(s-\sigma)dw_\sigma\right)^2\right\}ds \\ & - \frac{\eta^2}{\alpha}\int_0^t\int_0^s \sin\alpha(s-\sigma)dw_\sigma\,dw_s\Bigg\}. \end{aligned} \tag{4.8}$$

And as $t \to \pi/\alpha$, $p_t(x) \to +\infty$ P-a.s. for any $x \neq -\eta/\alpha\int_0^t \sin\alpha(t-\sigma)dw_\sigma$.

Proof: Formula (4.8) follows taking the limits $\lambda \to 0$ in Eq. (4.7). The rest of the theorem is easy to see if we notice that the last three terms in the $\exp\{-\}$ in Eq. (4.8) remain bounded when we take the limit $t \to \pi/\alpha$.

Remark 4.1: For $\eta = 0$, then for $0 < t < \pi/\alpha$:

$$p_t(x) = \sqrt{\frac{\alpha}{2\pi\sin\alpha t}}\,\exp\left\{-\frac{\alpha\cos\alpha t}{2\sin\alpha t}\,x^2\right\} \tag{4.9}$$

which was given in Elworthy, Truman, and Zhao.[8]

(2) Similarly we consider

$$\begin{cases} d\dot{\Phi}_s^1 = \alpha^2\Phi_s^1\,ds - \eta\,dw_s \\ \Phi_0^1(x) = x, \quad \dot{\Phi}_0^1(x) = \dfrac{x}{\lambda}, \end{cases} \tag{4.10}$$

where $\alpha>0$, which is Eq. (2.1) in the case $c(s,x)=-\frac{1}{2}\alpha^2x^2$, $k(s,x)=\eta x$ *and* $S_0(x)=x^2/2\lambda$. *Similarly with* (1) *we have*

$$\Phi_s^1(x)=x\cosh\alpha s+\frac{x}{\lambda\alpha}\sinh\alpha s-\frac{\eta}{\alpha}\int_0^s\sinh\alpha(s-\sigma)dw_\sigma. \tag{4.11}$$

The map $\Phi_s^1:R^1\to R^1$ satisfies the no-caustic condition for $0\leqslant s<+\infty$ and the inverse function is given by

$$\Phi_t^{1^{-1}}(x)=\frac{\lambda(\alpha x+\eta\int_0^t\sinh\alpha(t-\sigma)dw_\sigma)}{\alpha\lambda\cosh\alpha t+\sinh\alpha t}. \tag{4.12}$$

Similar calculations give

$$\begin{aligned}S_t^1(x)=&\frac{\cosh\alpha t}{2\alpha\sinh\alpha t}\left(\alpha x+\eta\int_0^t\sinh\alpha(t-\sigma)dw_\sigma\right)^2\\&-\frac{\eta}{\alpha}\int_0^t\cosh\alpha(t-\sigma)dw_\sigma\left(\alpha x+\eta\int_0^t\sinh\alpha(t-\sigma)dw_\sigma\right)\\&+\frac{1}{2}\eta^2\int_0^t\left\{\left(\int_0^s\cosh\alpha(s-\sigma)dw_\sigma\right)^2+\left(\int_0^s\sinh\alpha(s-\sigma)dw_\sigma\right)^2\right\}ds\\&+\frac{\eta^2}{\alpha}\int_0^t\int_0^s\sinh\alpha(s-\sigma)dw_\sigma\,dw_s.\end{aligned} \tag{4.13}$$

A quick way to get these formulas is to write Eq. (4.10) as $d\Phi_s^1=-(\alpha i)^2\Phi_s^1\,ds-\eta\,dw_s$. Then $\Phi_s^1(x,\alpha)=\Phi_s(x,\alpha i)$ and $S_t^1(x,\alpha)=S_t(x,\alpha i)$. Note $\cos(\alpha is)=\cosh\alpha s$ and $(1/i)\sin(\alpha is)=\sinh\alpha s$.

Consider the Stratonovich stochastic heat equation with harmonic oscillator potential

$$du_t=[\tfrac{1}{2}\Delta u_t-\tfrac{1}{2}\alpha^2x^2u_t]dt+\eta xu_t\partial w_t. \tag{4.14}$$

Here $x\in R^1$. As before we can prove $\eta\int_0^tX_s^{t,\lambda}dw_{t-s}$ is well defined in Itô's sense for any fixed $t\geqslant0$. Let $q_t^\lambda(x)$ be the solution of Eq. (4.14) with the initial condition $q_0^\lambda(x)=(1/\sqrt{2\pi\lambda})\times\exp\{-(x^2/2\lambda)\}$ and $q_t(x)=\lim_{\lambda\to0}q_t^\lambda(x)$. It turns out from Eqs. (4.12) and (2.22) in Theorem 2.5 and Remark 2.3 that

$$q_t^\lambda(x)=\sqrt{\frac{\alpha}{2\pi(\alpha\lambda\cosh\alpha t+\sinh\alpha t)}}\exp\{-S_{t,\lambda}^1(x)\}. \tag{4.15}$$

Here it is enough to know $S_{t,\lambda}^1(x)\to S_t^1(x)$ as $\lambda\to0$ since we have written $S_t^1(x)$ in Eq. (4.13). One can write $S_{t,\lambda}^1(x)$ explicitly without any difficulty. Taking the limit $\lambda\to0$ we have

Theorem 4.2: For any $t>0$,

$$\begin{aligned}q_t(x)=&\sqrt{\frac{\alpha}{2\pi\sinh\alpha t}}\exp\left\{-\frac{\cosh\alpha t}{2\alpha\sinh\alpha t}\left(\alpha x+\eta\int_0^t\sinh\alpha(t-\sigma)dw_\sigma\right)^2\right.\\&\left.+\frac{\eta}{\alpha}\int_0^t\cosh\alpha(t-\sigma)dw_\sigma\left(\alpha x+\eta\int_0^t\sinh\alpha(t-\sigma)dw_\sigma\right)\right.\end{aligned}$$

$$-\frac{1}{2}\,\eta^2\int_0^t\left\{\left(\int_0^s \cosh\,\alpha(s-\sigma)dw_\sigma\right)^2+\left(\int_0^s \sinh\,\alpha(s-\sigma)dw_\sigma\right)^2\right\}ds$$
$$-\frac{\eta^2}{\alpha}\int_0^t\int_0^s \sinh\,\alpha(s-\sigma)dw_\sigma\,dw_s\Bigg\}. \tag{4.16}$$

Corollary 4.1: For $\eta\equiv 0$ we get

$$q_t(x)=\sqrt{\frac{\alpha}{2\pi\,\sinh\,\alpha t}}\exp\left\{-\frac{\alpha\,\cosh\,\alpha t}{2\,\sinh\,\alpha t}\,x^2\right\}. \tag{4.17}$$

Remark 4.2: Formula (4.17) is the classical Mehler formula (cf. Berline, Getzler, and Vergne[21]). Therefore we call Eq. (4.16) the stochastic Mehler formula. Note for any $t>0$, $q_t(x)$ is well defined.

Remark 4.3: For $\alpha=0$, Eqs. (4.8) and (4.16) are no longer true. However we have the formulas given in Sec. III and Truman and Zhao[10] instead.

(3) Now we consider the more interesting case: the Itô stochastic heat equation with the harmonic oscillator potential

$$du_t(x)=[\tfrac{1}{2}\Delta u_t(x)+\tfrac{1}{2}\alpha^2x^2u_t]dt+\eta x u_t\,dw_t. \tag{4.18}$$

For a given initial condition $u_0(x)$ from the Feynman–Kac formula we have

$$u_t(x)=\hat{E}u_0(B_t^x)\exp\left\{\frac{1}{2}\,(\alpha^2-\eta^2)\int_0^t(B_s^x)^2ds+\eta\int_0^t B_s^x\,dw_s\right\}.$$

Here $B_s^x=x+B_s$, B_s is a one-dimensional Brownian motion in the probability space $(\hat{\Omega},\hat{\mathcal{F}},\hat{P})$ with $B_0=0$ P-a.s. Therefore $u_t(x)$ satisfies the following Stratonovich stochastic heat equation:

$$du_t(x)=[\tfrac{1}{2}\Delta u_t(x)+\tfrac{1}{2}(\alpha^2-\eta^2)x^2u_t]dt+\eta x u_t\partial w_t. \tag{4.19}$$

Let $p_t^\lambda(x)(I)$ denote the solution of Eq. (4.18) with the initial condition $p_0^\lambda(x)(I)=(1/\sqrt{2\pi\lambda})\exp\{-(x^2/2\lambda)\}$ and $p_t(x)(I)=\lim_{\lambda\to 0}p_t^\lambda(x)(I)$. From the results on the Stratonovich equation we easily formulate the following theorem:

Theorem 4.3: (i) For $|\eta|<|\alpha|$, let $\alpha_1=\sqrt{\alpha^2-\eta^2}$, then for $0<t<\pi/\alpha_1$,

$$p_t(x)(I)=\sqrt{\frac{\alpha_1}{2\pi\,\sin\,\alpha_1 t}}\exp\left\{-\frac{\cos\,\alpha_1 t}{2\alpha_1\,\sin\,\alpha_1 t}\left(\alpha_1 x+\eta\int_0^t \sin\,\alpha_1(t-\sigma)dw_\sigma\right)^2\right.$$
$$+\frac{\eta}{\alpha_1}\int_0^t \cos\,\alpha_1(t-\sigma)dw_\sigma\left(\alpha_1 x+\eta\int_0^t \sin\,\alpha_1(t-\sigma)dw_\sigma\right)$$
$$-\frac{1}{2}\,\eta^2\int_0^t\left\{\left(\int_0^s \cos\,\alpha_1(s-\sigma)dw_\sigma\right)^2-\left(\int_0^s \sin\,\alpha_1(s-\sigma)dw_\sigma\right)^2\right\}ds$$
$$\left.-\frac{\eta^2}{\alpha_1}\int_0^t\int_0^s \sin\,\alpha_1(s-\sigma)dw_\sigma\,dw_s\right\}. \tag{4.20}$$

And as $t\to\pi/\alpha_1$, $p_t(x)(I)\to+\infty$ P-a.s. for any $x\neq-(\eta/\alpha_1)\int_0^t\sin\,\alpha_1(t-\sigma)dw_\sigma$.

(ii) For $|\eta|=|\alpha|$ we have

$$p_t(x)(I)=\frac{1}{\sqrt{2\pi t}}\exp\left\{-\frac{(x+\int_0^t \eta w_\sigma\, d\sigma)^2}{2t}+\eta x w_t+\frac{1}{2}\int_0^t \eta^2 w_\sigma^2\, d\sigma\right\}. \tag{4.21}$$

(iii) For $|\eta|>|\alpha|$, let $\alpha_2=\sqrt{\eta^2-\alpha^2}$, we have for any $t>0$,

$$\begin{aligned}p_t(x)(I)=&\sqrt{\frac{\alpha_2}{2\pi\sinh\alpha_2 t}}\exp\left\{-\frac{\cosh\alpha_2 t}{2\alpha_2\sinh\alpha_2 t}\left(\alpha_2 x+\eta\int_0^t \sinh\alpha_2(t-\sigma)dw_\sigma\right)^2\right.\\&+\frac{\eta}{\alpha_2}\int_0^t\cosh\alpha_2(t-\sigma)dw_\sigma\left(\alpha_2 x+\eta\int_0^t\sinh\alpha_2(t-\sigma)dw_\sigma\right)\\&-\frac{1}{2}\eta^2\int_0^t\left\{\left(\int_0^s\cosh\alpha_2(s-\sigma)dw_\sigma\right)^2+\left(\int_0^s\sinh\alpha_2(s-\sigma)dw_\sigma\right)^2\right\}ds\\&\left.-\frac{\eta^2}{\alpha_2}\int_0^t\int_0^s\sinh\alpha_2(s-\sigma)dw_\sigma\,dw_s\right\}.\end{aligned} \tag{4.22}$$

V. STOCHASTIC BURGERS' EQUATIONS

(1) As the simplest model for the differential equation of fluid flow, Burgers[22,23] introduced the equation (called viscous Burgers' equation nowadays)

$$\frac{\partial}{\partial t}v^\mu(t,x)+v^\mu(t,x)\frac{\partial}{\partial x}v^\mu(t,x)=\frac{1}{2}\mu^2\frac{\partial^2}{\partial x^2}v^\mu(t,x). \tag{5.1}$$

The well known logarithm transformation

$$v^\mu(t,x)=-\mu^2\nabla\log u^\mu(t,x) \tag{5.2}$$

given by Hopf in his pioneering work (Hopf[24]) on Burgers' equation transforms the nonlinear Burgers' equation into a linear heat equation

$$\frac{\partial u^\mu(t,x)}{\partial t}=\frac{1}{2}\mu^2\frac{\partial^2 u^\mu(t,x)}{\partial x^2} \tag{5.3}$$

with the initial condition $u^\mu(0,x)=\exp\{[\int_0^x v^\mu(0,x)dx/\mu^2]\}$. Very recently stochastic Burgers' equations have been studied by Kardar, Parisi, and Zhang,[11] Bertini, Cancrini, and Jona-Lasinio,[25] Bertini and Cancrini,[26] Albeverio, Molchanov, and Surgailis,[27] Da Prato, Debusche, and Temam,[28] Holden *et al.*,[29,30] Oksendal,[31] and Newman,[32] to name but a few. The KPZ model has been given and a representation theorem for the solution of the viscous stochastic Burgers' equation has been obtained by initial condition and a diffusion process via a stochastic heat equation for which the solution can be represented by a Feynman–Kac formula. In this section of this paper we consider the following viscous stochastic Burgers' equation

$$dv^{\mu}(t,x)+v^{\mu}(t,x)\,\frac{\partial}{\partial x}\,v^{\mu}(t,x)dt=\frac{1}{2}\,\mu^{2}\,\frac{\partial^{2}v^{\mu}(t,x)}{\partial x^{2}}\,dt+e_{1}(t,x)dt+e_{2}(t,x)dw_{t}, \tag{5.4}$$

with the initial condition $v^{\mu}(0,x)=\nabla S_{0}(x)$ for a certain C^{2} function S_{0}. Here w_{t} is a one-dimensional Brownian motion. For simplicity we suppose initially the configuration space is R^{1}. Assume $e_{1},e_{2}\in C^{1,1}([0,+\infty)\times R^{1},R^{1})$. Let us also make the transformation (5.2). Suppose there exist functions $c(t,x)$ and $k(t,x)$ such that $e_{1}(t,x)=-(\partial/\partial x)c(t,x)$ and $e_{2}(t,x)=-(\partial/\partial x)k(t,x)$. Direct computation using Itô's formula gives the stochastic heat equation of the Stratonovich type

$$du^{\mu}(t,x)=\left[\frac{1}{2}\,\mu^{2}\Delta u^{\mu}(t,x)+\frac{c(t,x)}{\mu^{2}}\,u^{\mu}(t,x)\right]dt+\frac{k(t,x)}{\mu^{2}}\,u^{\mu}(t,x)\partial w_{t} \tag{5.5}$$

with the initial condition $u^{\mu}(t,x)=\exp\{-S_{0}(x)/\mu^{2}\}$.

(2) Consider the related inviscid stochastic Burgers' equation

$$dv(t,x)+v(t,x)\,\frac{\partial}{\partial x}\,v(t,x)dt=e_{1}(t,x)dt+e_{2}(t,x)dw_{t} \tag{5.6}$$

with the initial condition $v(0,x)=\nabla S_{0}(x)$. Note it can be obtained by letting $\mu=0$ in Eq. (5.4). More importantly we note the solution $v(t,x)$ of Eq. (5.6) is the gradient of the solution $S(t,x)$ of the stochastic Hamilton Jacobi equation

$$dS(t,x)+[\tfrac{1}{2}\,|\nabla S(t,x)|^{2}+c(t,x)]dt+k(t,x)dw_{t}=0 \tag{5.7}$$

with the initial condition $S(0,x)=S_{0}(x)$, which was studied in Sec. II.

As before let Φ be defined by Eq. (2.1). In our case

$$\begin{cases} d\dot{\Phi}_{s}(x)=e_{1}(s,\Phi_{s}(x))ds+e_{2}(s,\Phi_{s}(x))dw_{s} \\ \dot{\Phi}_{0}(x)=v(0,x), \quad \Phi_{0}(x)=x \end{cases}. \tag{5.8}$$

Suppose for $0\leqslant s\leqslant T(\omega)$, $\Phi_{s}:R^{1}\to R^{1}$ satisfies the no-caustic condition for a.e. $\omega\in\Omega$. From Sec. II we know that for a.e. $\omega\in\Omega$ and $0\leqslant t\leqslant T(\omega)$, $v(t,x)=\nabla S(t,x)$ is well defined and continuous with respect to t and C^{1} with respect to x. Later we will prove that $v(t,x)$ is not continuous at the caustic points of the stochastic classical mechanics.

Let us come back to study the viscous stochastic Burgers' equation under the no-caustic condition. We always suppose the existence and uniqueness of the regular solution for the viscous equation as from the existence and uniqueness of the regular solutions of the stochastic heat equations studied by Flandoli.[13] In the following we give the explicit formulas between the solution of the viscous stochastic Burgers' equation and the solution of the inviscid one under the no-caustic condition. Let $X_{s}^{t,\mu}(x)$ be the solution of Eq. (2.8) with $Y(s,-)=-S(t-s,-)$. That is,

$$dX_{s}^{t,\mu}(x)=\mu\ dB_{s}-v_{t-s}(X_{s}^{t,\mu}(x))ds, \quad X_{0}^{t,\mu}(x)=x. \tag{5.9}$$

Here B_{s} is a one-dimensional Brownian motion on the probability space $(\hat{\Omega},\hat{\mathscr{F}},\hat{P})$ from the origin.

Theorem 5.1: *Assume all the conditions of Theorem* 2.3 *and the map defined by* Eq. (5.8) *satisfies the no-caustic condition for* $0\leqslant t\leqslant T(\omega)$ *for* a.e. $\omega\in\Omega$ *and* $S(t,x)$ *is defined by* Eq. (2.3). *Then for* a.e. $\omega\in\Omega$ *and any* $0\leqslant t\leqslant T(\omega)$, *the solution* $v(t,x)$ *of the inviscid stochastic Burgers' equation* (5.6) *exists and is given by* $v(t,x)=\nabla S(t,x)$.

Let $X_{s}^{t,\mu}(x)$ *be defined by* Eq. (5.9). *If* $X_{s}^{t,\mu}(x)$ *is nonexplosive and* $\mathscr{F}_{s}^{*}$ *measurable then for any* $\mu\neq 0$, *the solution* $v^{\mu}(t,x)$ *(if it exists and is unique) of the viscous stochastic Burger's equation* (5.4) *is given by*

$$v^{\mu}(t,x)=v(t,x)-\mu^2\nabla\ \log\ \hat{E}\exp\left\{-\frac{1}{2}\int_0^t\frac{\partial}{\partial x}v(t-s,X_s^{t,\mu}(x))ds\right\},\tag{5.10}$$

for a.e. $\omega\in\Omega$ *and any* $0\leqslant t\leqslant T(\omega)$.

Proof: Claim $v(t,x)=\nabla S(t,x)$ was already shown. The solution $u^{\mu}(t,x)$ of Eq. (5.5) is given by Eq. (2.15) where $T_0=1$. Therefore, $u_t^{\mu}(t,x)>0$ for a.e. $\omega\in\Omega$ and $0\leqslant t\leqslant T(\omega)$. Take the logarithm to Eq. (2.15) and differentiate it with respect to x. We get Eq. (5.11) from $v^{\mu}(t,x)=-\mu^2\nabla\log u^{\mu}(t,x)$. ■

Recall $\psi(t,x)=(|\det T_x\Phi_t^{-1}|)^{1/2}>0$ for a.e. $\omega\in\Omega$ and $0\leqslant t\leqslant T(\omega)$. Instead of Eq. (5.10) now we let $X_s^{t,\mu}(x)$ be defined by

$$\begin{cases}dX_s^{t,\mu}(x)=\mu\ dB_s-v_{t-s}(X_s^{t,\mu}(x))ds+\mu^2\nabla\ \log\ \psi(t-s,X_s^{t,\mu}(x))ds\\ X_0^{t,\mu}(x)=x\end{cases}.\tag{5.11}$$

If $X_s^{t,\mu}(x)$ is $\mathcal{F}_s^*$ measurable and nonexplosive we have the solution $u^{\mu}(t,x)$ given by Eq. (2.22) and $u^{\mu}(t,x)>0$ for a.e. $\omega\in\Omega$ and $0\leqslant t\leqslant T(\omega)$. Take logarithms of Eq. (2.22) and differentiate it with respect to x. By Eq. (5.2) we have the following theorem:

Theorem 5.2: *Assume all the conditions of Theorem* 2.5. *Then for any* $\mu\neq 0$, a.e. $\omega\in\Omega$ *and* $0\leqslant t\leqslant T(\omega)$ *the solution* $v^{\mu}(t,x)$ *(if it exists and is unique) of the viscous stochastic Burgers' equation* (5.4) *is given by*

$$v^{\mu}(t,x)=v(t,x)-\mu^2\nabla\log\psi(t,x)-\mu^2\nabla\log$$
$$\hat{E}\exp\left\{\frac{1}{2}\mu^2\int_0^t\psi^{-1}(t-s,X_s^{t,\mu}(x))\Delta\psi(t-s,X_s^{t,\mu}(x))ds\right\},\tag{5.12}$$

if $X_s^{t,\mu}(x)$ is $\mathcal{F}_s^*$ measurable and nonexplosive, where $X_s^{t,\mu}(x)$ is defined by Eq. (5.11).

Remark 5.1: Theorems 5.1 and 5.2 are true for any $\mu\neq 0$. Therefore Eqs. (5.10) and (5.12) are exact solutions rather than asymptotic solutions of the viscous stochastic Burgers' equation. It seems that this solution cannot be easily obtained by the Maslov canonical operator method (Mishchenko, Shatalov, and Sternin[33]).

Remark 5.2: It is trivial to get from Theorem 5.2 that for a.e. $\omega\in\Omega$ and $0\leqslant t\leqslant T(\omega)$, $v^{\mu}(t,x)\to v(t,x)$ as $\mu\to 0$ as long as $\nabla\log\psi$ and $\psi^{-1}\Delta\psi$ are bounded. That means the inviscid limit is the semiclassical limit under the no-caustic condition.

(3) In the following we will prove that $v(t,x)$, the solution of the inviscid equation (5.6), is not continuous at the caustic points of the stochastic classical mechanics. Examples given later demonstrate shock waves in the presence of the caustics.

By Eq. (2.4) we have for a.e. $\omega\in\Omega$ and $0\leqslant t\leqslant T(\omega)$:

$$\dot{\Phi}_t(x)=v(t,\Phi_t(x)).\tag{5.13}$$

Note this is the same as the characteristic equation in a lot of the literature for the deterministic inviscid Burgers' equations [of course when $e_2(t,x)=0$, Eq. (5.6) is deterministic] (see Smoller [34]).

Let $\tau(a)$ be first time such that there exist $x_1\neq x_2, x_1, x_2\in R^1$ such that $\Phi_\tau(x_1)=\Phi_\tau(x_2)=a$ and $\dot{\Phi}_\tau(x_1)\neq\dot{\Phi}_\tau(x_2)$, i.e., τ is a caustic time at point a.

Theorem 5.3: The function $v(t,x)$ is discontinuous at (τ,a).

Proof: For any $t<\tau$ from Eq. (5.13), we have $\dot{\Phi}_t(x_1)=v(t,\Phi_t(x_1))$ and $\dot{\Phi}_t(x_2)=v(t,\Phi_t(x_2))$. If $v(t,x)$ is continuous at (τ,a) we can take the limit $t\to\tau$ to $v(t,\Phi_t(x_1))$ and $v(t,\Phi_t(x_2))$. Thus $\lim_{t\to\tau}v(t,\Phi_t(x_1))=v(\tau,a)=\lim_{t\to\tau}v(t,\Phi_t(x_2))$. It turns out that $\dot{\Phi}_\tau(x_1)=\dot{\Phi}_\tau(x_2)$. This is in contradiction to our hypothesis on (τ,a). The theorem follows. ■

Remark 5.3: If $e_2 \equiv 0$, one can prove that the assumption that there exist $x_1 \neq x_2, x_1, x_2 \in R^1$ such that $\Phi_\tau(x_1) = \Phi_\tau(x_2)$ implies $\dot{\Phi}_\tau(x_1) \neq \dot{\Phi}_\tau(x_2)$ from the uniqueness of the backward deterministic ordinary differential equation. Therefore $\tau(a)$ is the first time such that there exist $x_1 \neq x_2, x_1, x_2 \in R^1$ such that $\Phi_\tau(x_1) = \Phi_\tau(x_2) = a$.

Remark 5.4: Apparently this theorem is true for any manifold M as our configuration space.

If c and k are smooth and bounded, then the stochastic heat equation (5.5) has a classical solution therefore the viscous stochastic Burgers' equation (5.4) has a classical solution $v^\mu(t,x)$. Therefore we have the following important remark:

Remark 5.5: Beyond the caustics, Eqs. (5.10) and (5.12) can hardly be true as in general v^μ is smooth and v is discontinuous at the caustics by Theorem 5.3. This leads us to pose an open problem:

Problem: What change of measure should be used to deduce the detailed asymptotics of the solution beyond the caustics?

The answer to this problem is not clear even in Elworthy and Truman's deterministic Hamilton Jacobi theory (deterministic here means that the Hamilton Jacobi equation is deterministic).

(4) In order to understand some of the simplest inviscid stochastic Burgers' equations beyond caustics we first give a very simple lemma which transforms a certain class of the stochastic equations to random equations which are easily handled. For this let g be the solution of the nonlinear random equation

$$g_t(t,x) + g(t,x)g_x(t,x) = f\left(t, x - \int_0^t \eta w_\sigma \, d\sigma, g_x, g_{xx}, \ldots\right), \tag{5.14}$$

where $g_x(t,x) = (\partial/\partial x)g(t,x)$, etc. The equation can be treated as a deterministic equation as $\int_0^t \eta w_\sigma \, d\sigma$ is a continuous stationary process. All the conclusions on deterministic equations are still true for Eq. (5.14). The following lemma can be proved directly by calculations:

Lemma 5.1: The function

$$v(t,x) = g\left(t, x + \int_0^t \eta w_\sigma \, d\sigma\right) - \eta w_t \tag{5.15}$$

satisfies the following stochastic equation:

$$dv(t,x) + v(t,x)\frac{\partial}{\partial x} v(t,x)dt = f(t,x,v_x,v_{xx},\ldots)dt - \eta \, dw_t, \quad v(0,x) = g(0,x). \tag{5.16}$$

Conversely if $v(t,x)$ is a solution of Eq. (5.16), then $g(t,x) = v(t, x - \int_0^t \eta w_\sigma \, d\sigma) + \eta w_t$ is a solution of Eq. (5.14).

Lemma 5.1 is true for some special cases such as the viscous stochastic Burgers' equation, the inviscid stochastic Burgers' equation which are studied in this paper and the stochastic KdV equation (Dankel[35]).

(5) Consider the inviscid stochastic Burgers' equation

$$dv(t,x) + v(t,x)\frac{\partial}{\partial x} v(t,x)dt = -\eta \, dw_t \tag{5.17}$$

with $v(0,x) = 1$ for $x < 0$ and $v(0,x) = 0$ for $x > 0$. Let g be the solution of the Burgers' equation $(\partial/\partial t)g(t,x) + g(t,x)(\partial/\partial x)g(t,x) = 0$ with the same initial condition. It is well known that g is a discontinuous solution and $g(t,x) = 1$ for $x < \frac{1}{2}t$ and $g(t,x) = 0$ for $x > \frac{1}{2}t$ (see, e.g., Smoller[34]). It is a deterministic shock wave. From Lemma 5.1 we have $v(t,x) = 1 - \eta w_t$ for $x < \frac{1}{2}t - \int_0^t \eta w_\sigma \, d\sigma$ and $v(t,x) = -\eta w_t$ for $x > \frac{1}{2}t - \int_0^t \eta w_\sigma \, d\sigma$. This is the simplest example of stochastic shock

waves. The wave front is a random curve $x=\frac{1}{2}t-\int_0^t \eta w_\sigma\, d\sigma$, the structure of the wave is that: the trough $-\eta w_t$ and the crest $1-\eta w_t$, both behave randomly as a Brownian motion. Note $\tau=0$ is the caustic of the classical mechanics.

(6) We shall demonstrate another shock wave from the harmonic oscillator. Consider the deterministic equation first:

$$\frac{\partial}{\partial t}\, g(t,x)+g(t,x)\,\frac{\partial}{\partial x}\, g(t,x)=-x, \quad g(0,x)=x. \tag{5.18}$$

From formula (4.4) where we take $\lambda=1$, $\alpha=1$, $\eta=0$ we have

$$g(t,x)=\nabla S_\lambda(t,x)=\frac{\cos t-\sin t}{\cos t+\sin t}\, x. \tag{5.19}$$

For $t<\frac{3}{4}\pi, g(t,x)$ is smooth and as $t\uparrow\frac{3}{4}\pi, g(t,x)\to+\infty$ for $x<0$ and $g(t,x)\to-\infty$ for $x>0$. Note $\frac{3}{4}\,\pi$ is the caustic time of the classical mechanics and Theorem 5.3. If we consider the stochastic Burgers' equation

$$dv(t,x)+v(t,x)\,\frac{\partial}{\partial x}\, v(t,x)dt=-x\, dt-\eta\, dw_t, \quad v(0,x)=x, \tag{5.20}$$

then from Eq. (4.4) where we take $\lambda=1,\alpha=1$,

$$v(t,x)=\frac{\cos t-\sin t}{\cos t+\sin t}\left(x+\eta\int_0^t \sin(t-\sigma)dw_\sigma\right)-\eta\int_0^t \cos(t-\sigma)dw_\sigma. \tag{5.21}$$

Therefore for $t<\frac{3}{4}\pi, v(t,x)$ is well defined and continuous and as $t\uparrow\frac{3}{4}\pi, v(t,x)\to+\infty$ P-a.s. for $x<-\eta\int_0^{(3/4)\pi}\sin(\frac{3}{4}\pi-\sigma)dw_\sigma$ and $v(t,x)\to-\infty$ $P-$a.s. for $x>-\eta\int_0^{(3/4)\pi}\sin(\frac{3}{4}\pi-\sigma)dw_\sigma$.

(7) We have not proved the existence of the piecewise continuous solution for the inviscid stochastic Burgers' equation. Nevertheless, we believe

Conjecture: Given some bounds on e_1 and e_2 the stochastic Burgers' equation (5.6) has a unique viscosity solution.

It may not be true if e_1 and e_2 are not bounded. See Sec. V (6) for a counterexample. For some more special equations we can prove:

Theorem 5.4: If $V(t,x)=\int_0^{x-\int_0^t \eta w_\sigma\, d\sigma} e_1(t,y)dy$ is bounded below and strictly convex in space variable x, then the stochastic Burgers' equation

$$dv(t,x)+v(t,x)\,\frac{\partial}{\partial x}\, v(t,x)=e_1(t,x)dt-\eta dw_t \tag{5.22}$$

with a bounded initial condition has a unique viscosity solution.

Proof: From Davies and Truman[36] we know $G(t,x)=\min\{\frac{1}{2}\int_0^t|\dot z(s)|^2ds+\int_0^t V(s,z(s))ds+\int_0^{z_t}v(0,y)dy: z_0=x, z_s$ is absolutely continuous for $0\leqslant s\leqslant t\}$ has a unique global solution and from Fleming[37,38] we know $G(t,x)$ satisfies the following Hamilton Jacobi equation:

$$\frac{\partial}{\partial t}\, G(t,x)+\frac{1}{2}\,|\nabla G(t,x)|^2+c^*(t,x)=0 \tag{5.23}$$

with $G(0,x)=\int_0^x v(0,x)dx$ and $c^*=-V$. Although $V(t,x)$ is random here it does not affect the argument. By Rademacher's theorem a Lipschitz continuous function is differentiable almost everywhere, therefore almost everywhere $g(t,x)=\nabla G(t,x)$ satisfies

$$\frac{\partial}{\partial t} g(t,x)+g(t,x)\ \frac{\partial}{\partial x} g(t,x)=e_1\left(t,x-\int_0^t \eta w_\sigma\ d\sigma\right). \tag{5.24}$$

Let $v(t,x)=g(t,x+\int_0^t \eta w_\sigma\ d\sigma)-\eta w_t$. By Lemma 5.1, for almost everywhere $v(t,x)$ is the solution of Eq. (5.22). By the uniqueness of Eqs. (5.23) and (5.24) we have the uniqueness of Eq. (5.22). The theorem follows. ■

Here we have not striven for the maximum generality. For alternative formulations see Fleming.[37,38]

Theorem 5.5: Consider the solution $u^\mu(t,x)$ of the following stochastic heat equation on R^1:

$$\begin{cases} du_t^\mu(x)=\left[\frac{1}{2}\ \mu^2\Delta u_t^\mu(x)+\frac{1}{\mu^2}\ c(t,x)u_t^\mu(x)\right]dt+\frac{1}{\mu^2}\ \eta x u_t^\mu(x)\partial w_t \\ u_0^\mu(x)=T_0(x)\exp\left\{-\frac{S_0(x)}{\mu^2}\right\} \end{cases}. \tag{5.25}$$

Assume $-c(t,x-\int_0^t \eta w_\sigma\ d\sigma)$ is bounded below and strictly convex in space variable x. Then the following stochastic Hamilton Jacobi equation:

$$dS(t,x)+[\tfrac{1}{2}|\nabla S(t,x)|^2+c(t,x)]dt+\eta x\ dw_t=0, \tag{5.26}$$

with the initial condition $S(0,x)=S_0(x)$ has a unique Lipschitz continuous solution. If T_0 is bounded and positive, then

$$\lim_{\mu\to 0}\ \mu^2\ \log\ u^\mu(t,x)=-S(t,x), \tag{5.27}$$

uniformly in any compact subset of $[0,+\infty)\times R^1, P$-a.s.

Proof: The existence and uniqueness of the Lipschitz continuous solution to Eq. (5.26) follows from Theorem 5.4. Let

$$dJ^\mu(t,x)+[\tfrac{1}{2}|\nabla J^\mu(t,x)|^2+c(t,x)]dt+\eta x\ dw_t=\tfrac{1}{2}\mu^2\Delta J^\mu(t,x)dt \tag{5.28}$$

with $J^\mu(0,x)=S_0(x)$. Let G^μ and G satisfy

$$\frac{\partial}{\partial t} G^\mu(t,x)+\frac{1}{2}\ |\nabla G^\mu(t,x)|^2+c\left(t,x-\eta\int_0^t w_\sigma\ d\sigma\right)=\frac{1}{2}\ \mu^2\Delta G^\mu(t,x) \tag{5.29}$$

and

$$\frac{\partial}{\partial t} G(t,x)+\frac{1}{2}\ |\nabla G(t,x)|^2+c\left(t,x-\eta\int_0^t w_\sigma\ d\sigma\right)=0 \tag{5.30}$$

with $G^\mu(0,x)=G(0,x)=S_0(x)$. Then direct calculations give that J is unique and $J^\mu(t,x)=G^\mu(t,x+\eta\int_0^t w_\sigma\ d\sigma)-\eta x w_t-\frac{1}{2}\eta^2\int_0^t w_\sigma^2\ d\sigma$, $S(t,x)=G(t,x+\eta\int_0^t w_\sigma\ d\sigma)-\eta x w_t\ -\frac{1}{2}\eta^2\int_0^t w_\sigma^2\ d\sigma$. From the results of Hopf[24] and Fleming[37] we know as $\mu\to 0$, $G^\mu(t,x)\to G(t,x)$ uniformly in any compact subset of $[0,+\infty)\times R^1$ P-a.s. The randomness does not affect the result. Therefore $\mu\to 0$, $J^\mu(t,x)\to S(t,x)$ uniformly in any compact subset of $[0,+\infty)\times R^1$ P-a.s. Let the stochastic process $X_s^{t,\mu}(x)$ be defined by

$$dX_s^{t,\mu}(x)=\mu\ dB_s-\nabla J^\mu(t-s,X_s^{t,\mu}(x))ds,\quad X_0^{t,\mu}(x)=x. \tag{5.31}$$

As in Sec. III we know $\int_0^t X_s^{t,\mu}(x)dw_{t-s}$ is well defined in Itô's sense. Then using formulas (2.10), (2.13), and (5.28) we have

$$u^\mu(t,x)=\exp\left\{-\frac{J^\mu(t,x)}{\mu^2}\right\}\hat{E}T_0(X_t^{t,\mu}(x)), \quad P\text{-a.s.} \tag{5.32}$$

Therefore $\mu^2 \log u^\mu(t,x)=-J^\mu(t,x)+\mu^2 \log \hat{E}T_0(X_t^{t,\mu}(x))$ P-a.s. Thus Eq. (5.27) follows. ■

Remark 5.6: We believe that Eq. (5.32) is of independent interest.

Remark 5.7: We also believe Eq. (5.27) is true in general

Conjecture: As long as the stochastic Hamilton Jacobi equation (2.5) has a Lipschitz solution $S(t,x)$, the solution of stochastic heat equation (2.7) satisfies

$$\lim_{\mu\to 0} \mu^2 \log u^\mu(t,x)=-S(t,x),$$

uniformly in any compact subset of $[0,+\infty)\times M, P$-a.s.

(Received 7 April 1995; accepted for publication 24 July 1995)

We demonstrate a simple procedure for finding the squared eigenfunctions of an integrable system and illustrate the method by deriving the squared eigenfunctions of the massive Thirring model. We give the formula for the inner products between the direct squared eigenfunction problem and its adjoint. We also demonstrate closure and express the variations of the potentials in terms of variations of the scattering data. © *1996 American Institute of Physics.* [S0022-2488(96)02201-9]

I. INTRODUCTION

Besides being a simple integrable model in field theory, the massive Thirring model[1] also plays a certain role in nonlinear optics in a problem of wave propagation in a periodically modulated nonlinear fiber.[2]

Naturally, in such situations, one at times needs to understand how perturbations can affect such a system. For this, one needs to know the squared eigenfunctions for the appropriate eigenvalue problem and their closure. In this paper, we solve that problem.

There are two standard methods for finding squared eigenfunctions. One method, the first one discovered,[3] involves obtaining the equations for perturbations solving the adjoint problem and then determining the inner products between the original eigenfunctions and the adjoint eigenfunctions. The main part of this technique consists of finding the equation for the squared eigenfunctions, which can require much trial and error, and thus the success of the method significantly depends on the researcher's ingenuity. On the other hand, there is a procedure based on the Riemann–Hilbert method that will always work.[4] However, in the interesting case when one is interested in the perturbation on the background of a soliton (or a N-soliton solution), this method becomes technically very complex.

We have found a simple regular procedure that allows one to eliminate the trial and error from the former method. We do not start by seeking an equation for the squared eigenfunctions, but instead assume a particular general structure for the Wronskian relation between certain eigenstates related to the original eigenvalue problem. Then one proceeds to determine the coefficients in the general Wronskian relation. The method is simple to use and is straightforward to apply. There seem to be no serious restrictions on the structure of the original eigenvalue problem. In particular, it would work even in the case where eigenvalues can occur in an arbitrary polynomial form inside the eigenvalue problem. We note, however, that at the moment our method does not allow one to find the equation for the squared eigenfunctions; we discuss this point later in Secs. III and VI.

In Sec. II, we review the direct and inverse scattering problems for the massive Thirring model. In Sec. III, we solve the above for variations of the scattering data in terms of variations of the potentials. We then discuss the problem of inverting this relation in order to obtain the variations of the potentials in terms of variations of the scattering data. Then, in Sec. IV, we solve

[a)]Electronic mail address: kaup@sun.mcs.clarkson.edu

0022-2488/96/37(1)/308/16/$6.00

this problem by the method outlined in the preceding paragraph. We start from a general Wronkian relation and use the original and adjoint eigenvalue problems to fully determine all coefficients in it. This results in obtaining the specific Wronskian relation required for the massive Thirring model. Now it becomes trivial to obtain the inner products and a bit less trivial to verify closure, which we do in Sec. V. Also in that section, we give the variations of the potentials in terms of variations of the scattering data. In Sec. VI we make some concluding remarks. In the Appendix the method based on the Riemann–Hilbert formulation is briefly considered.

II. THE DIRECT AND INVERSE SCATTERING PROBLEMS

We consider the equations of the massive Thirring model (MTM) in the laboratory coordinates:

$$i(u_x+u_t)+v+u|v|^2=0, \quad i(-v_x+v_t)+u+v|u|^2=0. \tag{1}$$

Here x and t are the space and time coordinates, respectively. The initial conditions for the fields u and v are

$$u(x,t=0)=u_0(x), \quad v(x,t=0)=v_0(x) \tag{2}$$

on the whole x-axis $\mathbf{R}$, and $|u_0(x)|$ and $|v_0(x)|$ are assumed to be integrable on $\mathbf{R}$ and sufficiently smooth (e.g., from the Schwartz class). Equations (1) are the compatibility condition for the following linear system:[1]

$$\left(\frac{\partial}{\partial x}-L\right)\psi=0, \tag{3a}$$

$$\left(\frac{\partial}{\partial t}-A\right)\psi=0, \tag{3b}$$

where ψ is a two-vector and L and A are 2×2 matrices. Here we will only need the expression for L:

$$L=\frac{i}{4}(|u|^2-|v|^2)\sigma_3-\frac{i\lambda}{2}\begin{pmatrix}0 & v^*\\ v & 0\end{pmatrix}+\frac{i}{2\lambda}\begin{pmatrix}0 & u^*\\ u & 0\end{pmatrix}+\frac{i}{4}\left(\lambda^2-\frac{1}{\lambda^2}\right)\sigma_3, \tag{4}$$

where we have used the notations for the Pauli matrices:

$$\sigma_1=\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}, \quad \sigma_2=\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix}, \quad \sigma_3=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}.$$

An asterisk in (4) and everywhere below stands for complex conjugation. Notice that the notations in (4) are slightly different from those in Ref. 1, where the representation (3) was first found.

The problem that we solve in this paper is the following: what quadratic combinations of the eigenfunctions (we will term them ''squared eigenfunctions'' for brevity) of (3a) does one need in order to be able to expand over them the variations $\delta u, \delta u^*, \delta v, \delta v^*$ of the potentials u and v of the operator L. Before passing to the solution of the problem stated we will give a brief summary of the results on the direct and inverse scattering problems for the operator L, obtained in Ref. 1.

Let us introduce two pairs of the Jost solutions of (3a):

$$\chi(\lambda)\to\begin{pmatrix}0\\1\end{pmatrix}\exp(-ikx),\quad x\to-\infty$$

$$\bar{\chi}(\lambda)\to\begin{pmatrix}1\\0\end{pmatrix}\exp(ikx),\quad x\to-\infty \tag{5a}$$

$$\phi(\lambda)\to\begin{pmatrix}1\\0\end{pmatrix}\exp(ikx),\quad x\to+\infty$$

$$\bar{\phi}(\lambda)\to\begin{pmatrix}0\\-1\end{pmatrix}\exp(-ikx),\quad x\to+\infty \tag{5b}$$

where $k\equiv k(\lambda)=\frac{1}{4}(\lambda^2-\lambda^{-2})$. The operator L satisfies the relation

$$\sigma_2 L^*(\lambda^*)\sigma_2=L(\lambda). \tag{6}$$

So if $\psi(x,\lambda)$ is a solution of (3a), then

$$\bar{\psi}(x,\lambda)=i\sigma_2\psi^*(x,\lambda^*) \tag{7}$$

is another solution. In particular, the solutions $\bar{\chi}$ and $\bar{\phi}$ are related by involution (7) to χ and ϕ, respectively. Also,

$$\tilde{\psi}(x,\lambda)=\pm\sigma_3\psi(x,-\lambda) \tag{8}$$

is yet another solution of (3a). If ψ is any of the Jost solutions, then it is invariant under transformation (8), with the sign in the rhs of (8) being chosen in accordance with asymptotics (5). The Wronskian

$$W(f,g)=\det\begin{pmatrix}f_1 & g_1\\ f_2 & g_2\end{pmatrix}$$

of any two solutions f and g of (3a) with the same λ is independent of x. This yields that $\bar{\psi}(\lambda)$ and $\psi(\lambda)$ are linearly independent (i.e., their Wronskian is nonzero), where the ψ denotes any of the Jost solutions.

Now let us introduce the scattering matrix for $\mathrm{Im}\,\lambda^2=0$:

$$\phi=a(\lambda)\bar{\chi}+b(\lambda)\chi,\quad \bar{\phi}=-\bar{a}(\lambda)\chi+\bar{b}(\lambda)\bar{\chi}. \tag{9a}$$

From (7) it follows that

$$\bar{a}(\lambda)=a^*(\lambda^*),\quad \bar{b}(\lambda)=b^*(\lambda^*). \tag{10}$$

In a standard way one shows that $\chi(\lambda)e^{ikx}$ and $\phi(\lambda)e^{-ikx}$ are analytic where $\mathrm{Im}\,\lambda^2\geqslant 0$, and $\bar{\chi}(\lambda)e^{-ikx}$ and $\bar{\phi}(\lambda)e^{ikx}$ are analytic where $\mathrm{Im}\,\lambda^2\leqslant 0$. From (9a) one finds

$$a=W(\phi,\chi),\quad b=W(\bar{\chi},\phi), \tag{11}$$

whence $a(\lambda)$ is analytic for $\mathrm{Im}\,\lambda^2>0$, and accordingly $\bar{a}(\lambda)$ is analytic for $\mathrm{Im}\,\lambda^2<0$; $b(\lambda)$ and $\bar{b}(\lambda)$ are, in general, defined only for $\mathrm{Im}\,\lambda^2=0$. From (11), (8), and (5) it follows that

$$a(-\lambda)=a(\lambda),\quad b(-\lambda)=-b(\lambda), \tag{12}$$

and also that, for $\mathrm{Im}\,\lambda^2=0$,

$$a\bar{a}+b\bar{b}=1. \tag{13}$$

From (9a) and (13) one determines the inverse of (9a):

$$\chi=-a\bar{\phi}+\bar{b}\phi, \quad \bar{\chi}=\bar{a}\phi+b\bar{\phi}. \tag{9b}$$

At the points of the discrete spectrum $\lambda_n(\mathrm{Im}\,\lambda_n^2>0)$ and $\lambda_n^*\equiv\lambda_{\bar{n}}$ such that $a(\lambda_n)=\bar{a}(\lambda_{\bar{n}})=0$, one has

$$\begin{aligned} &\chi_n=\bar{b}_n\phi_n, \quad \bar{\chi}_{\bar{n}}=b_{\bar{n}}\bar{\phi}_{\bar{n}}, \\ &\phi_n=b_n\chi_n, \quad \bar{\phi}_{\bar{n}}=\bar{b}_{\bar{n}}\bar{\chi}_{\bar{n}}, \end{aligned} \tag{9c}$$

where $\phi_n=\phi(x,\lambda_n)$, etc. Note that these points appear in pairs: if λ_n is an eigenvalue, then so is $-\lambda_n$, since $a(\lambda)$ is an even function. The asymptotic values of $a(\lambda)$ can be obtained from (3a) and (11):

$$\left.\begin{array}{ll} \underline{\lambda\to\infty} & a(\lambda)\to\exp(-i\hat{Q}) \\ \underline{\lambda\to 0} & a(\lambda)\to\exp(i\hat{Q}) \end{array}\right\} \mathrm{Im}(\lambda^2)\geqslant 0, \tag{14}$$

where $\hat{Q}=\frac{1}{4}\int_{-\infty}^{\infty}(|u|^2+|v|^2)dx$. The asymptotics of the Jost solutions for large and small λ are the following (for $\mathrm{Im}\,\lambda_n^2\geqslant 0$):

$$\begin{aligned} \underline{\lambda\to\infty} \quad \chi&\to\begin{pmatrix} v^*\lambda^{-1} \\ 1 \end{pmatrix}(1+\mathcal{O}(\lambda^{-1}))\exp(-ikx-iQ^-(x)), \\ \phi&\to\begin{pmatrix} 1 \\ -v\lambda^{-1} \end{pmatrix}(1+\mathcal{O}(\lambda^{-1}))\exp(ikx-iQ^+(x)), \end{aligned} \tag{15a}$$

$$\begin{aligned} \underline{\lambda\to 0} \quad \chi&\to\begin{pmatrix} \lambda u^* \\ 1 \end{pmatrix}(1+\mathcal{O}(\lambda))\exp(-ikx+iQ^-(x)), \\ \phi&\to\begin{pmatrix} 1 \\ -\lambda u \end{pmatrix}(1+\mathcal{O}(\lambda))\exp(ikx+iQ^+(x)), \end{aligned} \tag{15b}$$

where

$$Q^{\pm}(x)=\pm\frac{1}{4}\int_x^{\pm\infty}(|u|^2+|v|^2)dx'.$$

To complete the review of the discrete and inverse scattering problems for the operator L, we present the singular integral equation which allows one to reconstruct the Jost solutions from known scattering data $S=\{\rho(\lambda)=b/a|\lambda^2$ is real; λ_n, $c_n=b_n/\dot{a}_n|n=-N,\ldots,N,\ n\neq 0\}$:

$$Y(x,\lambda)=\sum_{n=-N,n\neq 0}^{N}\frac{c_n\chi_n e^{-ik_nx}}{\lambda-\lambda_n}+\begin{pmatrix}1\\0\end{pmatrix}e^{iQ^-(x)}+\frac{1}{2\pi i}\int_\Gamma\frac{\rho(\lambda')\chi(x,\lambda')e^{-ik'x}}{\lambda'-\lambda}\,d\lambda', \tag{16a}$$

where

$$Y(x,\lambda)=\begin{cases}(\phi/a)e^{-ikx}, & \mathrm{Im}\,\lambda^2>0, \\ \bar{\chi}e^{-ikx}, & \mathrm{Im}\,\lambda^2<0. \end{cases} \tag{16b}$$

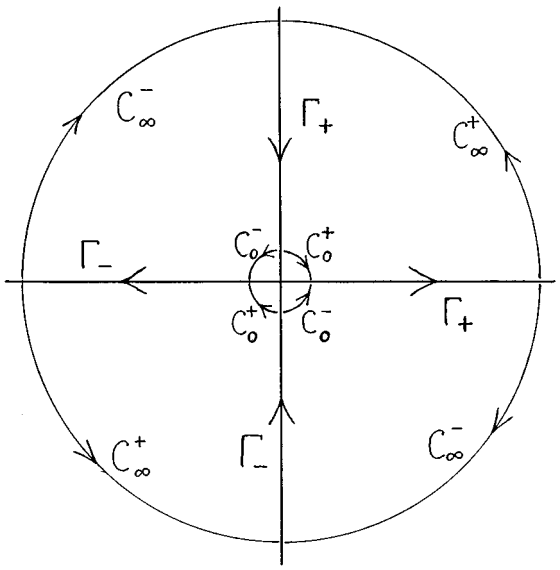

FIG. 1. Contours $C_0^{\pm}$, $C_\infty^{\pm}$, and $\Gamma^{\pm}$ in the complex λ-plane. Contour Γ is the union of Γ^+ and Γ^-.

Above we have used the following notations: $\dot{a}_n = (da/d\lambda)|_{\lambda=\lambda_n}$, $k_n=k(\lambda_n)$, $k'=k(\lambda')$, $\lambda_{-n}=-\lambda_n$, and the contour Γ is shown in Fig. 1.

Now let us pass to the solution of the problem stated in the beginning. We have four variations of the potentials: δu, δu^*, δv, and δv^*. In order to map them one-to-one into variations of the scattering data, we need four independent components of the latter. If we ignore for now the discrete spectrum, then we seem to have only two functions: $\rho(\lambda)$ and $\overline{\rho}(\lambda)=\rho^*(\lambda^*)$ on Γ. However, in reality we have exactly four of these. Indeed, the natural spectral parameter for (3a) is not the λ but rather $k(\lambda)$. On Γ, $k(\lambda)$ is fourfold degenerate since, for each value of k, there are four different possible values of λ, namely, λ itself, $-\lambda$, and $\pm i\lambda^{-1}$. As λ moves along each of the four rays of which the contour Γ is composed, k ranges from $-\infty$ to ∞. From (12) one deduces the relation $\rho(-\lambda)=-\rho(\lambda)$ [and consequently, $\overline{\rho}(-\lambda)=-\overline{\rho}(\lambda)$]. Thus, although the scattering data at $-\lambda$ is always related to the scattering data at λ, there is no such a relation connecting the scattering data at $\pm i\lambda^{-1}$ with that at λ. Therefore, the four independent functions in the set of scattering data are $\rho(\lambda)$ and $\overline{\rho}(\lambda)$ on contour Γ_+ (see Fig. 1).

III. VARIATIONS OF POTENTIALS AND SCATTERING DATA

Before going on to the solution of the problem, we note the following. As it was pointed out in the Introduction, there exist two equivalent ways of finding variations of the potentials via the components of the Jost solutions. The first way (see, for example, Ref. 4) employs the Riemann–Hilbert formulation of the corresponding scattering problem. This method would readily give us the answer if no discrete spectrum was present, but it becomes technically very cumbersome when one seeks to obtain the contribution to the variations of the potentials from the variation of the discrete spectrum. Therefore, here we have chosen to use the other method, which is based on calculating the variations of the scattering data via the variations of the potentials, and then inverting this relation. This latter method was used, for example, in Refs. 3, 5–8. In the Appendix we give, for the sake of completeness of presentation, a brief exposition of the former method.

Thus, we first find the variation of $\rho(\lambda)$ corresponding to variations of the potentials u and v. Then in a standard way (see, for example, Ref. 9) we find from (3a), (11), (5), and (9):

$$\delta\rho=\frac{i}{4a^2}\,\langle Z(\phi(x,\lambda))|\,\delta p(x)\rangle,\quad \delta\bar{\rho}=\frac{i}{4\bar{a}^2}\,\langle \bar{Z}(\phi(x,\lambda))|\,\delta p(x)\rangle, \tag{17}$$

where

$$\begin{gathered}\langle f|g\rangle\equiv\int_{-\infty}^{\infty}dx f(x)g(x),\quad \delta p=(\delta u,\delta u^*,\delta v,\delta v^*)^T,\\ Z=(Z_1,Z_2,Z_3,Z_4),\quad \bar{Z}(\phi)\equiv Z(\bar{\phi}),\\ Z_1(\phi)=2\left(-\frac{1}{\lambda}\,\phi_1{}^2+u^*\phi_1\phi_2\right),\quad Z_2(\phi)=2\left(\frac{1}{\lambda}\,\phi_2{}^2+u\,\phi_1\phi_2\right),\\ Z_3(\phi)=2(\lambda\,\phi_1{}^2-v^*\phi_1\phi_2),\quad Z_4(\phi)=2(-\lambda\,\phi_2{}^2-v\,\phi_1\phi_2),\end{gathered} \tag{18}$$

and ϕ_i in the above is the ith ($i=1,2$) component of ϕ, the Jost solutions defined in (5b). We omit arguments of functions wherever those are obvious or unimportant. In what follows it will be convenient for us to use the following notations:

$$V_i(fg)=f_ig_i,\quad i=1,2;\quad V_3(fg)=f_1g_2+f_2g_1, \tag{19}$$

and $V_i(f)=V_i(ff)$, $i=1,2,3$.

Let us now show how (17) should be inverted to find $\delta p(x)$. To simplify the subsequent calculations, let us suppose for the moment that L has no discrete spectrum. Then $\delta\rho$ and $\delta\bar{\rho}$ are its only scattering data. In order to invert these, we would require a set of adjoint functions, $Z^A(x,\lambda)$, orthogonal to the set Z in (18). Suppose for the moment that we have such a set where

$$\frac{i}{4}\int_\Gamma (Z^A(x',\lambda),\bar{Z}^A(x',\lambda))\begin{pmatrix} Z(x,\lambda)/a^2(\lambda)\\ \bar{Z}(x,\lambda)/\bar{a}^2(\lambda)\end{pmatrix}d\lambda=\delta(x'-x)\cdot I_4, \tag{20}$$

where I_n is the $n\times n$ unit matrix. Let us use the notation $\hat{Z}$ for the matrix $\left(\begin{smallmatrix} Z/a^2\\ \bar{Z}/\bar{a}^2\end{smallmatrix}\right)$ and $\hat{Z}^A$ for the matrix $(Z^A,\bar{Z}^A)$. Using (20), we could then obtain from (17)

$$\delta p(x)=\int_\Gamma d\lambda\,\hat{Z}^A(x,\lambda)\begin{pmatrix}\delta\rho(\lambda)\\ \delta\bar{\rho}(\lambda)\end{pmatrix}. \tag{21}$$

One way to find the form of $\hat{Z}^A$ would be to start with the expression dual to (20). Namely, if one multiplies (21) by $\hat{Z}$, integrates over x, and then takes into account (17), then one would obtain

$$\frac{i}{4}\,\langle\hat{Z}(x,\lambda)|\hat{Z}^A(x,\lambda')\rangle=\delta(\lambda-\lambda')\cdot I_2. \tag{22}$$

Once one has such a set of orthogonality relations as in (22), then one could identify $\hat{Z}_A$ from the integrands. This is how we shall proceed.

In earlier works,[3,5–8] the explicit form of $\hat{Z}^A$ was found in the following way. First, find the integro-differential equation for Z of the form

$$\Lambda Z=0; \tag{23a}$$

with the integro-differential operator Λ being of the form

$$\Lambda=\Lambda_0+\lambda\quad\text{or}\quad\Lambda=\Lambda_0+\lambda^2,\quad\text{etc.}, \tag{23b}$$

where Λ_0 is a λ-independent part. For the cases in Refs. 3,5–8, it was always found that this could be done even when the original L-operator contained both positive and negative powers of λ (see Ref. 8). Once (23) had been found, it was then straightforward to determine Z^A as a solution of the adjoint equation (hence the superscript 'A') and the inner product between Z and Z^A. The apparent drawback of this procedure was that the form of Λ had always been found by trial and error, which sometimes was a nontrivial matter.[5–8] In the case of the MTM in laboratory coordinates, we have been unable to easily find such an analogue of representation (23). The most apparent difficulty in doing this is that upon taking a derivative of Z_i, $i=1,...,4$, one then has derivatives of the potentials u,u^*,v,v^* as multiplying factors, which is a complicating feature. Nevertheless, we have found that it is still possible to find the explicit form of Z^A and determine its inner product with Z by means of another technique. Below we will describe this technique in detail since we believe that it will be useful in other related problems.

IV. METHOD OF FINDING Z^A FROM THE WRONSKIAN RELATIONS

First, from (3a), for the vector $\vec{V}=(V_1,V_2,V_3)^T$ one straightforwardly obtains

$$\left[I_3 \frac{\partial}{\partial x} - 2i(w+k) \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 & r \\ 0 & 0 & q \\ 2q & 2r & 0 \end{pmatrix} \right] \vec{V}=0, \tag{24a}$$

where $k\equiv k(\lambda)$, $w=\frac{1}{4}(|u|^2-|v|^2)$, $r=(i/2)(\lambda v^*-u^*/\lambda)$, and $q=(i/2)(\lambda v-u/\lambda)$. Defining the solution $\vec{V}^A$ of the adjoint problem as the vector satisfying

$$\left[-I_3 \frac{\partial}{\partial x} - 2i(w+k) \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 & 2q \\ 0 & 0 & 2r \\ r & q & 0 \end{pmatrix} \right] \vec{V}^A=0, \tag{24b}$$

one finds that $\vec{V}^A=(V_2,V_1,-V_3/2)$. Thus the solution of the adjoint problem is related to that of the original one by a similarity transformation.

Now we make the observation that, in all the previous cases, one was able to obtain from the corresponding integro-differential equation, (23), a Wronskian relation from the analogue of Eq. (24) in the following form:

$$\frac{\partial}{\partial x}\left[\alpha(\lambda,\lambda')V_1^A V_1+\beta(\lambda,\lambda')V_2^A V_2+\gamma(\lambda,\lambda')V_3^A V_3\right]=h(\lambda,\lambda')(Z_1^A Z_1+Z_2^A Z_2+Z_3^A Z_3+Z_4^A Z_4). \tag{25}$$

In (25), the Vs and Zs are functions of x and λ, the adjoint states V^As and Z^As are functions of x and λ', and the coefficients α, β, γ, and h are independent of x. So, if this is the form which always results, is it possible to start with (25), then use all the above relations and uniquely determine α, β, γ, h, and Z^A? Indeed, such is the case.

We start with (24) and the definition of $\vec{V}^A$. Then (25) becomes of the form (summation over repeated indices is implied)

$$h(\lambda,\lambda')Z_i^A Z_i=V_j' M_{js} V_s, \tag{26a}$$

with

$$M=\begin{pmatrix} 0 & -2i\beta(k-k') & q'\gamma-q\beta \\ 2i\alpha(k-k') & 0 & r'\gamma-r\alpha \\ q\gamma-q'\alpha & r\gamma-r'\beta & 0 \end{pmatrix}, \tag{26b}$$

where $V_j \equiv V_j(\lambda)$, $V_j' \equiv V_j(\lambda')$, etc. From (18) one has

$$Z_i = m_{is} V_s \tag{27a}$$

with

$$m=\begin{pmatrix} -2\lambda^{-1} & 0 & u^* \\ 0 & 2\lambda^{-1} & u \\ 2\lambda & 0 & -v^* \\ 0 & -2\lambda & -v \end{pmatrix}. \tag{27b}$$

Substituting (27a) into the lhs of (26a), one sees that the resulting equation is linear in V_s. Then, after formally differentiating it with respect to V_s, one obtains

$$h(\lambda,\lambda')Z_i^A m_{is} = V_j' M_{js}. \tag{28}$$

One cannot invert it to find Z^A because m is not a square matrix. However, if Z^A exists, then it is seen from (28) that it must be of the form

$$Z_i^A = m_{ij}^A V_j', \tag{29}$$

for some yet unknown 4×3 matrix m^A. The key to determining m^A lies in the fact that the entries of m^A may depend on λ', but not on λ. Upon substituting (29) into (28) and formally differentiating with respect to V_j', one obtains

$$h m_{ij}^A m_{is} = M_{js}. \tag{30}$$

Let us introduce the following notations [see (26b) and (27b)]:

$$M=\begin{pmatrix} A & B \\ C & 0 \end{pmatrix}, \quad m=(D,E), \quad m^A=(F,G),$$

where A, B, and C are 2×2, 2×1, and 1×2 matrices, respectively. The (22)-entry of M is the number zero, D and F are 4×2 matrices, and E and G are 4×1 matrices. Notice that A and D are independent of the potentials. With these notations, (30) rewrites as follows:

$$\begin{aligned} hF^T\cdot D = A, \quad hF^T\cdot E = B, \\ hG^T\cdot D = C, \quad G^T\cdot E = 0. \end{aligned} \tag{31}$$

Consider the first matrix equation in (31). Using (26b) and (27b) and the explicit form of q,r, one obtains

$$-\frac{1}{\lambda}F_{11}+\lambda F_{31}=0, \tag{32a}$$

$$h\left(-\frac{1}{\lambda}F_{12}+\lambda F_{32}\right)=i(k-k')\beta, \tag{32b}$$

$$h\left(-\frac{1}{\lambda}F_{21}+\lambda F_{41}\right)=i(k-k')\alpha, \tag{32c}$$

$$-\frac{1}{\lambda}F_{22}+\lambda F_{42}=0. \tag{32d}$$

Let $F_{ij}=F_{ij}^0+F_{ij}^p$, where F_{ij}^0, F_{ij}^p are the potential-independent and potential-dependent parts, respectively. Then one easily finds that

$$F_{1j}^p=\lambda^2 F_{3j}^p, \quad F_{2j}^p=\lambda^2 F_{4j}^p, \quad j=1,2. \tag{33}$$

Since the matrix m^A is independent of λ, then from (33) it follows that the potential-dependent part of F must be zero.

Using the second equation in (31), one obtains

$$h(u^*F_{11}+uF_{21}-v^*F_{31}-vF_{41})=\frac{i}{2}\left[v(\gamma\lambda'-\beta\lambda)+u\left(\frac{\beta}{\lambda}-\frac{\gamma}{\lambda'}\right)\right], \tag{34a}$$

$$h(u^*F_{12}+uF_{22}-v^*F_{32}-vF_{42})=\frac{i}{2}\left[v^*(\gamma\lambda'-\alpha\lambda)+u^*\left(\frac{\alpha}{\lambda}-\frac{\gamma}{\lambda'}\right)\right]. \tag{34b}$$

Since F has been found to be potential independent, one immediately sees that

$$F_{11}=F_{31}=F_{22}=F_{42}=0, \tag{35a}$$

$$hF_{21}=\frac{i}{2}\left(\frac{\beta}{\lambda}-\frac{\gamma}{\lambda'}\right), \tag{35b}$$

$$hF_{41}=\frac{i}{2}(\beta\lambda-\gamma\lambda'), \tag{35c}$$

$$hF_{12}=\frac{i}{2}\left(\frac{\alpha}{\lambda}-\frac{\gamma}{\lambda'}\right), \tag{35d}$$

$$hF_{41}=\frac{i}{2}(\alpha\lambda-\gamma\lambda'). \tag{35e}$$

Substituting (35b) and (35c) into (32c) and (35d) and (35e) into (32b), one obtains two linear equations for α, β, and γ, from which one straightforwardly deduces

$$\alpha=\beta, \quad \gamma=\alpha\cdot\frac{\lambda^2+\lambda'^2}{2\lambda\lambda'}. \tag{36}$$

Without loss of generality, one can set $\alpha=1$.

Let $G=(g_1,g_2,g_3,g_4)^T$. Then from the third equation in (31) and Eq. (36) it follows

$$h\left(-\frac{1}{\lambda}g_1+\lambda g_3\right)=\frac{i}{4}\left[\lambda v\,\frac{\lambda^2-\lambda'^2}{2\lambda\lambda'}+\frac{u}{\lambda}\,\frac{\lambda^2-\lambda'^2}{2\lambda\lambda'}\right], \tag{37a}$$

$$h\left(\frac{1}{\lambda}g_2-\lambda g_4\right)=\frac{i}{4}\left[\lambda v^*\,\frac{\lambda^2-\lambda'^2}{2\lambda\lambda'}+\frac{u^*}{\lambda}\,\frac{\lambda^2-\lambda'^2}{2\lambda\lambda'}\right]. \tag{37b}$$

Since the entries of G are to be independent of λ, then it must be

$$g_1=-\frac{u}{2}f(\lambda'),\quad g_2=\frac{u^*}{2}f(\lambda'),$$

$$g_3=\frac{v}{2}f(\lambda'),\quad g_4=-\frac{v^*}{2}f(\lambda'), \tag{38}$$

$$h=\frac{i(\lambda^2-\lambda'^2)}{4\lambda\lambda' f(\lambda')},$$

where $f(\lambda')$ is an arbitrary function. Then the fourth equation in (31) is satisfied identically. As one can see from (35) and (38), the function $f(\lambda')$ simply multiplies the matrix m^A by an arbitrary function of λ'. In order to have a simple form for Z^A, we take $f(\lambda')=1$. Finally, using (35), (36), and (38), one obtains the desired Wronskian relation:

$$\frac{\partial}{\partial x}\left[V_1^A V_1+V_2^A V_2+\frac{\lambda^2+\lambda'^2}{2\lambda\lambda'}V_3^A V_3\right]=\frac{i(\lambda'^2-\lambda^2)}{8\lambda\lambda'}\cdot(Z_1Z_2'+Z_2(-Z_1')+Z_3Z_4'+Z_4(-Z_3')), \tag{39}$$

where $Z_j\equiv Z_j(\lambda)$, $Z_j'\equiv Z_j(\lambda')$, $j=1,...,4$. With this we can define the inner product that we need. We note that a formula, which proves to be equivalent to (39), was given (without derivation) in Ref. 1.

V. COMPLETENESS OF THE SQUARED EIGENFUNCTIONS

From (39), it follows that we may take

$$Z^A=\frac{i}{2\pi}(Z_2,-Z_1,Z_4,-Z_3)^T,\quad \bar{Z}^A=-\frac{i}{2\pi}(\bar{Z}_2,-\bar{Z}_1,\bar{Z}_4,-\bar{Z}_3)^T,$$

and we choose to evaluate the Z- and Z^A-states using the Jost solutions ϕ and χ, respectively. Then, from (5) and (39), we obtain, for $\mathrm{Im}\,\lambda^2=0$,

$$\frac{i}{4}\langle\hat{Z}|\hat{Z}'^A\rangle=2\lambda\lambda'\delta(\lambda^2-\lambda'^2)\cdot I_2. \tag{40}$$

Similarly, the inner products involving the discrete spectrum are

$$\langle\hat{Z}_n|\hat{Z}_m^A\rangle=0, \tag{41a}$$

$$\langle\hat{D}_n|\hat{D}_m^A\rangle=\begin{pmatrix}\frac{2}{\pi}\lambda_n\dot{a}_n\ddot{a}_n(\delta_{n,m}+\delta_{n,-m}) & 0\\ 0 & \frac{2}{\pi}\lambda_{\bar{n}}\dot{\bar{a}}_{\bar{n}}\ddot{\bar{a}}_{\bar{n}}(\delta_{\bar{n},\bar{m}}+\delta_{\bar{n},-\bar{m}})\end{pmatrix}, \tag{41b}$$

$$\langle\hat{D}_n|\hat{Z}_m^A\rangle=\langle\hat{Z}_n|\hat{D}_m^A\rangle=\begin{pmatrix}\frac{2}{\pi}\lambda_n\dot{a}_n^2(\delta_{n,m}+\delta_{n,-m}) & 0\\ 0 & \frac{2}{\pi}\lambda_{\bar{n}}\dot{\bar{a}}_{\bar{n}}^2(\delta_{\bar{n},\bar{m}}+\delta_{\bar{n},-\bar{m}})\end{pmatrix}, \tag{41c}$$

for $m,n=-N,\ldots,N$; $m,n\neq 0$. In (41), we have used the following shorthand notations:

$$\hat{Z}_n=(Z^T(x,\lambda_n),\bar{Z}^T(x,\lambda_{\bar{n}}))^T,\quad \hat{D}_n=\left(\frac{\partial}{\partial\lambda}Z^T(x,\lambda)\Big|_{\lambda_n},\frac{\partial}{\partial\lambda}\bar{Z}^T(x,\lambda)\Big|_{\lambda_{\bar{n}}}\right)^T,$$

$$\hat{Z}_n^A=(Z^A(x,\lambda_n),\bar{Z}^A(x,\lambda_{\bar{n}})),\quad \hat{D}_n^A=\left(\frac{\partial}{\partial\lambda}Z^A(x,\lambda)\Big|_{\lambda_n},\frac{\partial}{\partial\lambda}\bar{Z}^A(x,\lambda)\Big|_{\lambda_{\bar{n}}}\right).$$

Let us now derive a generalization of (20) to the case when the L-operator (3a) has a discrete spectrum. Taking into account (40), consider the following principal value integral:

$$\frac{i}{8}\not\int_\Gamma\frac{d\lambda}{\lambda}\,\hat{Z}^A(\chi(x))\cdot\hat{Z}(\phi(y))$$

$$=\begin{cases}-\dfrac{i}{8}\left[\left(\displaystyle\int_{C_0^+}+\int_{C_\infty^+}\right)\dfrac{d\lambda}{\lambda a^2}\,Z^A(\chi(x))Z(\phi(y))+\left(\displaystyle\int_{C_0^-}+\int_{C_\infty^-}\right)\dfrac{d\lambda}{\lambda\bar{a}^2}\,\bar{Z}^A(\chi(x))\bar{Z}(\phi(y))\right]\\ \quad-\dfrac{\pi}{4}\,(\text{D.Sp.}),\quad \text{for } y\geqslant x;\\ -\dfrac{i}{8}\left[\left(\displaystyle\int_{C_0^+}+\int_{C_\infty^+}\right)\dfrac{d\lambda}{\lambda a^2}\,(2Z^A(\chi\phi(x))Z(\chi\phi(y))-Z^A(\phi(x))Z(\chi(y)))+\left(\displaystyle\int_{C_0^-}+\int_{C_\infty^-}\right)\right.\\ \quad\left.\times\dfrac{d\lambda}{\lambda\bar{a}^2}\,(2\bar{Z}^A(\chi\phi(x))\bar{Z}(\chi\phi(y))-\bar{Z}^A(\phi(x))\bar{Z}(\chi(y)))\right]-\dfrac{\pi}{4}\,(\text{D.Sp.}),\quad \text{for } y\leqslant x;\end{cases}\tag{42a}$$

where, for instance, $Z(\chi\phi(y))$ is evaluated for the functions $\chi(y,\lambda)$ and $\phi(y,\lambda)$ as in (19); $Z_n(\phi(y))=Z(\phi(y,\lambda_n))$, etc. Now in (42a), each case contains the term (D.Sp.), which is the contribution to (42a) of the discrete spectrum. This term is given by

$$(\text{D.Sp.})=\sum_{n=-N,n\neq 0}^{N}\left\{-\left(\frac{\dot{a}_n+\lambda_n\ddot{a}_n}{\dot{a}_n^3\lambda_n^2}\right)Z_n^A(\chi(x))Z_n(\phi(y))+\frac{1}{\dot{a}_n^2\lambda_n}\,[D_n^A(\chi(x))Z_n(\phi(y))\right.$$
$$\left.+Z_n^A(\chi(x))D_n(\phi(y))]\right\}-\{\text{same quantities with the bar}\}.\tag{42b}$$

The contours $C_0^\pm$, $C_\infty^\pm$ are shown in Fig. 1. In deriving (42), we have used the analyticity of the Jost functions in their corresponding domains, and also we made use of relations (9) to obtain the representation of the lhs in the regions $y\geqslant x$ and $y\leqslant x$ (see Ref. 5). Now, one can use the asymptotics (14) and (15) to evaluate the continuous spectrum part in the rhs of (42a) and then ''pull back'' onto the contour Γ, after deleting those terms which give vanishing contributions at infinity. In this way, upon also using the identities

$$\not\int_\Gamma\frac{d\lambda}{\lambda^3}\,e^{ik(\lambda)x}=\not\int_\Gamma\lambda\,d\lambda\,e^{ik(\lambda)x}=8\pi\delta(x),$$

we arrive at the formula which is the main result of this paper:

$$\frac{i}{8}\oint_\Gamma \frac{d\lambda}{\lambda}\,\hat{Z}^A\cdot\hat{Z}+\frac{\pi}{4}\sum_{n=-N,n\neq 0}^{N}\left\{-\hat{Z}_n^A\cdot\begin{pmatrix}(\dot a_n+\lambda_n\ddot a_n)Z_n/(\dot a_n^3\lambda_n^2)\\ -(\dot{\bar a}_{\bar n}+\lambda_{\bar n}\ddot{\bar a}_{\bar n})\bar Z_{\bar n}/(\dot{\bar a}_{\bar n}^3\lambda_{\bar n}^2)\end{pmatrix}+\hat{D}_n^A\cdot\begin{pmatrix}Z_n/(\dot a_n^2\lambda_n)\\ -\bar Z_{\bar n}/(\dot{\bar a}_{\bar n}^2\lambda_{\bar n})\end{pmatrix}+\hat{Z}_n^A\right.$$
$$\left.\cdot\begin{pmatrix}D_n/(\dot a_n^2\lambda_n)\\ -\bar D_{\bar n}/(\dot{\bar a}_{\bar n}^2\lambda_{\bar n})\end{pmatrix}\right\}=\delta(x-y)\cdot I_4. \tag{43}$$

In (43) each Z^A and D^A are to be evaluated for $\chi(x,\lambda)$ and each Z and D are to be evaluated for $\phi(y,\lambda)$. Notice that, making use of symmetry (8) and (12), one may restrict the summation in (42b) and (43), and formulae (45) and (46) below to be over $n=1,\ldots,N$ (one should then take the overall coefficient in front of the sum sign to be a factor of 2 larger), and at the same time, replace $\oint_\Gamma$ by $2\int_{\Gamma^+}$.

Now we can produce formulas for the expansions of both the potential $p(x)=(u,u^*,v,v^*)^T$ and $\delta p(x)$ over the complete set $\{Z^A\}$. In the standard way (see Ref. 10) one obtains

$$\delta\lambda_n=\frac{i}{4b_n\dot a_n}\langle Z_n(\phi)|\,\delta p\rangle, \tag{44a}$$

$$\delta c_n=\frac{i}{4\dot a_n^2}\left[-\left(\frac{\ddot a_n}{\dot a_n}\right)\langle Z_n(\phi)|\,\delta p\rangle+\langle D_n(\phi)|\,\delta p\rangle\right]; \tag{44b}$$

the quantity c_n was defined before formula (16). Note that in the derivation of (44), one must take into account the fact that $b_n,\dot a_n$ depend on the potential $p(x)$ both implicitly, as functionals, and explicitly, through their dependence on λ_n. Equations (17), (44), and (43) now lead to the following expansion formula for δp:

$$\delta p=\frac{1}{2}\oint_\Gamma\frac{d\lambda}{\lambda}\,\hat{Z}^A(\chi)\begin{pmatrix}\delta\rho\\ \delta\bar\rho\end{pmatrix}-i\pi\sum_{n=-N,n\neq 0}^{N}\left[\hat{Z}_n^A\begin{pmatrix}\delta(c_n/\lambda_n)\\ -\delta(\bar c_{\bar n}/\lambda_{\bar n})\end{pmatrix}+\hat{D}_n^A\begin{pmatrix}(c_n/\lambda_n)\delta\lambda_n\\ -(\bar c_{\bar n}/\lambda_{\bar n})\delta\lambda_{\bar n}\end{pmatrix}\right]. \tag{45}$$

From the third row in (24a) one easily finds the inner products between the Z-states and the potential $p(x)$. Whence one obtains

$$\begin{pmatrix}\sigma_3 & 0\\ 0 & \sigma_3\end{pmatrix}p(x)=\frac{1}{2}\oint_\Gamma\frac{d\lambda}{\lambda}\,\hat{Z}^A(\chi)\begin{pmatrix}\rho\\ -\bar\rho\end{pmatrix}-i\pi\sum_{n=-N,n\neq 0}^{N}\hat{Z}_n^A(\chi)\begin{pmatrix}c_n/\lambda_n\\ \bar c_{\bar n}/\lambda_{\bar n}\end{pmatrix}. \tag{46}$$

Note that the D_n^A states are absent in (46).

For possible applications, we present below the exact expressions of the one-soliton potentials $u_s(x)$ and $v_s(x)$, the corresponding scattering data, and the Jost solutions $\chi(x,\lambda)$ and $\chi(x,\lambda_1)$, from which the Z- and Z^A- states may be computed as needed:

$$u_s(x,t)=\sin Q\ \operatorname{sech}(\Theta-iQ/2)e^{i\beta},\quad v_s(x,t)=-\sin Q\ \operatorname{sech}(\Theta+iQ/2)e^{i\beta}; \tag{47}$$

$$0\leqslant Q\leqslant\pi,\quad \Theta=x\sin Q,\quad \beta=-t\cos Q,$$

$$\lambda_1=\exp(iQ/2),\quad c_1=\sin Q\cdot e^{i\beta}, \tag{48}$$

$$a(\lambda)=\frac{\lambda^2-\lambda_1^2}{\lambda^2-\lambda_1^{*2}}\,e^{-iQ},\quad b(\lambda)=0\quad\text{for Im }\lambda^2=0;$$

$$\chi(x,\lambda_1)=\frac{1}{2}\begin{pmatrix}i\ \operatorname{sech}(\Theta+iQ/2)\cdot\exp(-i\beta+iA(x)+(\Theta-iQ)/2)\\ \operatorname{sech}(\Theta-iQ/2)\cdot\exp(-iA(x)-(\Theta-iQ)/2)\end{pmatrix}, \tag{49}$$

where

$$A(x)=\arctan\left(\tan\left(\frac{Q}{2}\right)\tanh\,\Theta\right)+\frac{Q}{2},$$

$$\chi(x,\lambda)=\begin{pmatrix}0\\1\end{pmatrix}e^{-iA(x)-ik(\lambda)x}-\frac{\exp(-ik(\lambda)x)\cdot\sin\,Q}{\lambda^2-\lambda_1^{*2}}\cdot\begin{pmatrix}\lambda\ \operatorname{sech}(\Theta+iQ/2)\cdot\exp(-i\beta-iQ+iA(x))\\ i\ \operatorname{sech}(\Theta-iQ/2)\cdot\exp(\Theta-iA(x)-iQ/2)\end{pmatrix}. \tag{50}$$

Formulas (49) and (50) were obtained from (16) and (48).

VI. CONCLUDING REMARKS

The main difference between the result of the present work and those of the earlier ones[4–9] on this subject is a new method for finding squared eigenfunctions. Previously, one has been able to find both the exact form of the ''squared eigenfunctions'' and the operator Λ_0 [see (23)], whose eigenfunctions were the ''squared eigenfunctions.'' The knowledge of that operator allowed one to construct a hierarchy of integrable evolutional equations and Hamiltonian structures, related to a given L-operator, and the corresponding infinite series of conservation laws. Let us note, however, that the infinite series of the conservation laws for equations (1) was obtained in Ref. 1 by standard ''elementary'' means, and thus the whole hierarchy of integrable evolutional equations of which the massive Thirring model in laboratory coordinates is a member, is in principle known. We have proposed a regular procedure by which the structure of the inner product, and thus the explicit form of Z^A, can be determined. This procedure gave us the result for equations (1), and we believe that it will be useful in other related problems.

Note added in proof: It has recently been pointed out to us by V. S. Gerdjikov that one could also use the method outlined in Refs. 11 and 12 to find the recursion operator (i.e., the operator whose eigenfunctions are the ''squared eigenfunctions'') for the operator (3a). With the notations

$$X_{uv}f\equiv-\begin{pmatrix}u\\-u^*\end{pmatrix}\int_x^\infty dy(v^*,v)f,$$

defining operators X_{uv}, etc., acting on a two-component vector f, and also with

$$T=\begin{pmatrix}1+\frac{i}{2}X_{uu} & -\frac{i}{2}X_{uv}\\ -\frac{i}{2}X_{vu} & -1+\frac{i}{2}X_{vv}\end{pmatrix},\quad T^{-1}=\begin{pmatrix}1-\frac{i}{2}X_{uu} & -\frac{i}{2}X_{uv}\\ -\frac{i}{2}X_{vu} & -1-\frac{i}{2}X_{vv}\end{pmatrix},$$

$$\tilde{\Lambda}=\begin{pmatrix}1 & 0\\ 0 & 2(i-X_{vv})\end{pmatrix}\cdot\begin{pmatrix}0 & 1\\ -\frac{1}{2}(i-X_{uu}) & \sigma_3\partial_x+2iw-\frac{1}{2}(X_{vu}+X_{uv})\end{pmatrix},$$

$$\tilde{\Lambda}^{-1}=\begin{pmatrix}-2(i+X_{uu}) & 0\\ 0 & 1\end{pmatrix}\cdot\begin{pmatrix}\sigma_3\partial_x+2iw-\frac{1}{2}(X_{vu}+X_{uv}) & \frac{1}{2}(i+X_{vv})\\ 1 & 0\end{pmatrix},$$

$$\hat{\sigma}_2=\operatorname{diag}(\sigma_2,\sigma_2),$$

one can define two operators,

$$\Lambda=\hat{\sigma}_2 T\tilde{\Lambda}T^{-1}\hat{\sigma}_2, \quad \Lambda^{-1}=\hat{\sigma}_2 T\tilde{\Lambda}^{-1}T^{-1}\hat{\sigma}_2,$$

such that

$$(\Lambda-\lambda^2)Z=0, \quad (\Lambda^{-1}-\lambda^{-2})Z=0,$$

where Z was defined in (18), and $w=(|u|^2-|v|^2)/4$. Given this, one could find the adjoint vector Z^A and then proceed as outlined after Eq. (23) in the text. However, this method of finding the recursion operator is known (V. S. Gerdjikov, private communication) not to work (at least in a straightforward way) for, e.g., a quartic bundle,[12] while for the method described in Sec. IV of the present paper there seems to be no restriction on the maximum power of λ in the Lax operator. The question of whether this is indeed the case and, in particular, whether or not our method would work for the quartic bundle, needs further investigation.

ACKNOWLEDGMENTS

We thank A. R. Its for pointing out the method described in the Appendix to us, and V. S. Gerdjikov for a useful conversation. This research was supported in part by the Air Force Office of Scientific Research and the Office of Naval Research.

APPENDIX: RIEMANN–HILBERT FORMULATION

Here we demonstrate how the form of the ''squared eigenfunctions'' can be found from the Riemann–Hilbert (RH) formulation of the inverse scattering problem for operator (4). Below we will assume that the coefficients $a(\lambda)$, $\bar{a}(\lambda)$ are nonzero in their respective domains of analyticity.

The second equations in (9a) and (9b) can be rewritten in the form

$$\Psi^+=\Psi^- G, \quad \lambda\in\Gamma, \tag{A1a}$$

where the 2×2 matrices $\Psi^{\pm}$, G are

$$\Psi^+=\left(\frac{\phi}{a}\,e^{-ikx},\chi e^{ikx}\right), \quad \Psi^-=\left(\bar{\chi}e^{-ikx},-\frac{\bar{\phi}}{\bar{a}}\,e^{ikx}\right), \quad G=\begin{pmatrix}1+\rho\bar{\rho} & \bar{\rho}e^{2ikx}\\ \rho e^{-2ikx} & 1\end{pmatrix}. \tag{A1b}$$

In deriving (A1), Eq. (13) was used. $\Psi^{\pm}$ are analytic where $\mathrm{Im}\,\lambda^2\gtrless0$, respectively. If the potentials in (4) vary, then $\Psi^{\pm}$, G will vary according to the equation

$$\delta\Psi^+(\Psi^+)^{-1}=\delta\Psi^-(\Psi^-)^{-1}+\Psi^-\delta G(\Psi^+)^{-1}, \quad \lambda\in\Gamma, \tag{A2}$$

where we have used $G=\Psi^+(\Psi^-)^{-1}$. Matrices $(\Psi^{\pm})^{-1}$ are nonsingular [see (11)], thus $\delta\Psi^{\pm}(\Psi^{\pm})^{-1}$ are analytic in the corresponding domains of the λ-plane. Then (A2) constitutes a simple RH problem, whose solution is

$$\delta\Psi(x,\lambda)=\delta\Psi^0(x)\Psi(x,\lambda)+\frac{1}{2i\pi}\int\!\!\!\!\!\!\diagup_{\Gamma}\frac{\Phi(x,\xi)d\xi}{\xi-\lambda}\,\Psi(x,\lambda), \tag{A3}$$

where $\Psi(x,\lambda)$ is the solution of (A1). In (A3),

$$\Phi=\Psi^-\delta G(\Psi^+)^{-1}, \tag{A4a}$$

or, in the component form,

$$\Phi_{11}=-\Phi_{22}=\delta\rho\chi_1\chi_2-\delta\bar{\rho}\bar{\chi}_1\bar{\chi}_2,\quad \Phi_{12}=-\delta\rho\chi_1^2+\delta\bar{\rho}\bar{\chi}_1^2,\quad \Phi_{21}=\delta\rho\chi_2^2-\delta\bar{\rho}\bar{\chi}_2^2. \tag{A4b}$$

Matrix $\delta\Psi^0(x)$ in (A3) should be determined from the asymptotics at $\lambda\to 0$ and $\lambda\to\infty$. Taking into account symmetry (8) and (12), it is convenient to rewrite (A3) as follows:

$$\delta\Psi(x,\lambda)=\delta\Psi^0(x)\Psi(x,\lambda)+\frac{1}{i\pi}\int_{\Gamma^+}\frac{d\xi}{\xi^2-\lambda^2}\left[\xi\begin{pmatrix}\Phi_{11} & 0\\ 0 & -\Phi_{11}\end{pmatrix}+\lambda\begin{pmatrix}0 & \Phi_{12}\\ \Phi_{21} & 0\end{pmatrix}\right]\Psi(x,\lambda). \tag{A5}$$

The desired variations $\delta u,\delta u^*,\delta v,\delta v^*$ are found from the asymptotics of (A5) for $\lambda\to 0$ and $\lambda\to\infty$. From (14) and (15) one finds

$$\underline{\lambda\to 0}\quad \Psi^+\to\begin{pmatrix}e^{-iQ^-} & \lambda u^* e^{iQ^-}\\ -\lambda u e^{-iQ^-} & e^{iQ^-}\end{pmatrix}, \tag{A6a}$$

$$\underline{\lambda\to\infty}\quad \Psi^+\to\begin{pmatrix}e^{iQ^-} & \lambda^{-1}v^* e^{-iQ^-}\\ -\lambda^{-1}v e^{iQ^-} & e^{-iQ^-}\end{pmatrix}, \tag{A6b}$$

where $Q^-\equiv Q^-(x)$. Substituting (A6a) into (A5), one finds

$$\delta\Psi^0_{12}(x)=\delta\Psi^0_{21}(x)=0; \tag{A7a}$$

$$I_2\left(i\,\delta Q^-+\frac{1}{i\pi}\int_{\Gamma^+}\frac{\Phi_{11}d\xi}{\xi}\right)+\sigma_3\ \mathrm{diag}(\delta\Psi^0_{11}(x),\delta\Psi^0_{22}(x))=0; \tag{A7b}$$

$$\delta u=-\frac{1}{i\pi}\int_{\Gamma^+}\frac{\Phi_{21}d\xi}{\xi^2}+2i\,\delta Q^- u; \tag{A7c}$$

$$\delta u^*=\frac{1}{i\pi}\int_{\Gamma^+}\frac{\Phi_{12}d\xi}{\xi^2}-2i\,\delta Q^- u^*. \tag{A7d}$$

Substituting (A6b) into (A5) and using (A7), one obtains

$$\delta\Psi^0_{11}(x)=-\delta\Psi^0_{22}(x)=i\,\delta Q^-=-\frac{1}{2i\pi}\int_{\Gamma^+}\frac{\Phi_{11}d\xi}{\xi},$$

and then

$$\begin{aligned}
\delta u&=-\frac{1}{i\pi}\int_{\Gamma^+}\left(\frac{\Phi_{21}}{\xi^2}+u\,\frac{\Phi_{11}}{\xi}\right)d\xi;\\
\delta u^*&=\frac{1}{i\pi}\int_{\Gamma^+}\left(\frac{\Phi_{12}}{\xi^2}+u^*\,\frac{\Phi_{11}}{\xi}\right)d\xi;\\
\delta v&=\frac{1}{i\pi}\int_{\Gamma^+}\left(\Phi_{21}+v\,\frac{\Phi_{11}}{\xi}\right)d\xi;\\
\delta v^*&=-\frac{1}{i\pi}\int_{\Gamma^+}\left(\Phi_{12}+v^*\,\frac{\Phi_{11}}{\xi}\right)d\xi.
\end{aligned} \tag{A8}$$

Equations (A8) are equivalent to formula (45) without the contribution from the discrete spectrum. As it is known, the discrete spectrum is introduced into the RH problem through the solution of a certain system of algebraic equations. Working with the variation of this system, occurring due to the variation of the discrete scattering data, is much more cumbersome than simply picking up the contribution from the poles in the corresponding integrals [formula (42)], therefore we did not pursue the former way here.

(Received 29 June 1995; accepted for publication 16 August 1995)

Physically interesting exact solutions are constructed for a large class of nonlinear nonintegrable evolution equations. These solutions describe the interaction of traveling waves. They exhibit rich phenomenology including breaking of solitary waves. Generalized conditional symmetries and bilinearity are used to derive these exact results. © *1996 American Institute of Physics.* [S0022-2488(96)03601-5]

I. INTRODUCTION

We have recently introduced a new method for finding physically important exact solutions of certain nonintegrable equations.[1] Our method uses the fact that there exist nonintegrable equations which share an ''integrable sector'' with integrable equations. We recall that there exist two well-known types of integrable equations: Equations like Burgers which can be linearized by an explicit change of variables,[2] and equations like Korteweg–de Vries (KdV) which can be linearized by the inverse spectral method.[3] We have found nonintegrable equations associated with both Burgers and KdV. For example, the Newell–Whitehead equation[4]

$$3u_t = u_{xx} + u - 2u^3 \tag{1.1}$$

shares the two-shock solution $\partial_x \log(K_1 e^{(1/\sqrt{2})x+(1/2)t} + K_2 e^{-(1/\sqrt{2})x+(1/2)t} + K_3)$, K_1, K_2, and K_3 are arbitrary constants with the Burgers equation

$$u_t = u_{xx} + 2uu_x. \tag{1.2}$$

Similarly, the equation

$$u_t = 2\gamma u u_{xx} + (1-\gamma)u_x^2 + (2+4\gamma)u^2 u_x + \alpha u_x + (1+\gamma)(u^4 - \alpha u^2 + \beta), \quad \alpha,\beta,\gamma \text{ const} \tag{1.3}$$

shares the two-soliton solution $\partial_x \log[K_1 e^{k_1[x+(k_1^2+3k_2^2)t]} + K_2 e^{-k_1[x+(k_1^2+3k_2^2)t]} + K_3 e^{k_2[x+(3k_1^2+k_2^2)t]} + K_4 e^{-k_2[x+(3k_1^2+k_2^2)t]}]$, $k_1 = [(\alpha + \sqrt{\alpha^2-4\beta})/2]^{1/2}$, $k_2 = [(\alpha - \sqrt{\alpha^2-4\beta})/2]^{1/2}$, K_1, K_2, and K_3 are arbitrary constants and $k_1^2 K_1 K_2 = k_2^2 K_3 K_4$, with the potential KdV equation

$$u_t = u_{xxx} + 6u_x^2. \tag{1.4}$$

We note that multisoliton and multishock solutions have similar mathematical characterization. Actually multisolitons can be obtained from multishocks by differentiation with respect to x. Throughout this article we use this approach to obtain soliton-type solutions from shock-type solutions.

Our method is based on the introduction of a new type of symmetry, which we have called generalized conditional symmetry (GCS). A smooth function of u, u_x, u_{xx},..., denoted by $\sigma(u)$,

0022-2488/96/37(1)/324/22/$6.00

is a GCS of the evolution equation $u_t=K(u)$, where K is a smooth function of u, u_x, u_{xx},..., iff $[\sigma,K]=0$ when $\sigma=0$, where $[\sigma,K]\doteq\sigma'[K]-K'[\sigma]$ and the prime denotes Fréchet differentiation, i.e.,

$$\sigma'(u)=\frac{\partial\sigma}{\partial u}+\frac{\partial\sigma}{\partial u_x}\,\partial_x+\frac{\partial\sigma}{\partial u_{xx}}\,\partial_x^2+\cdots\ .$$

GCS's are generalizations of conditional symmetries,[5] in the same way that generalized symmetries[6] are generalizations of symmetries. It turns out that GCS's have the following important properties:

(a) The equations $\sigma=0$ and $u_t=K$ are compatible, thus in general they share a common manifold of solutions. Many physical important solutions, such as multishock and multisoliton solutions, can be characterized precisely as such manifolds. (b) If σ is a GCS of $u_t=K(u)$, then σ is also a GCS of $u_t=K(u)+G(u,\sigma)$, where G is an *arbitrary* function of u, u_x, u_{xx},... and of σ, σ_x, σ_{xx},..., which only satisfies the condition $G(u,0)=0$.

The method used in Ref. 1 is based on the following steps: (a) Find the GCS σ which characterizes the multishock or the multisoliton solutions of a given integrable equation $u_t=K(u)$. (b) Construct the family of equations $u_t=K(u)+G(u,\sigma)$. Since this family also admits σ as a GCS, it shares the same multishock or multisoliton solution with the original equation. For example, the two-shock solution of the Burgers equation is uniquely characterized as the common solution of Eq. (1.2) and of $\sigma=0$, where

$$\sigma=u_{xx}+3uu_x+u^3+\alpha(u_x+u^2)+\beta u. \tag{1.5}$$

Taking $G=-2\sigma/3$ with $\alpha=0$, $\beta=-1/2$, the equation $u_t=K+G$ becomes Eq. (1.1), which therefore also possesses the same two-shock solution. Similarly, the two-soliton solution of the potential KdV equation is associated with

$$\sigma=2uu_{xx}-u_x^2+4u^2u_x+u^4-\alpha u^2+\beta. \tag{1.6}$$

Taking $G=-\sigma_x/(2u)+(1+c)\sigma$, it follows that Eq. (1.3) also possesses the same two-soliton solution.

In this article we further extend the above results:

(a) In Ref. 1 we found the GCS characterizing the N-shock solution of Burgers, and the GCS's for one-, two- and three-soliton solutions of KdV. In Sec. II we show that the GCS characterizing the N-soliton solution of the KdV hierarchy

$$u_t=\sum_{m=0}^{M}\alpha_m(\partial_x^2+4u+2u_x\partial_x^{-1})^m u_x,\quad M\in\mathbb{Z},\quad \alpha_m \text{ const} \tag{1.7}$$

is given by

$$\sigma=\sum_{n=0}^{N}c_n(\partial_x+u\partial_x^{-1})^n u. \tag{1.8}$$

(b) In Sec. III we construct two new GCS's for the hierarchy of equations

$$u_t=\partial_x\left[\sum_{m=0}^{M}\alpha_m(\partial_x+u)^{2m}u\right],\quad M\in\mathbb{Z},\quad \alpha_m \text{ const.} \tag{1.9}$$

We call this hierarchy the "even" Burgers hierarchy, since Eq. (1.9) with $(\partial_x+u)^{2m}$ replaced by $(\partial_x+u)^m$ is the usual Burgers hierarchy.

These GCS's are given by

$$\sigma_1=\sum_{n=0}^{N-1}(-1)^n s_n \sum_{i=1}^{2N-2n-1}(-1)^{i-1}[(\partial_x+u)^{i-1}u][(\partial_x+u)^{2N-2n-i-1}u]+(-1)^N s_N \tag{1.10}$$

and

$$\sigma_2=\sum_{n=0}^{N-1}(-1)^n s_n \sum_{i=0}^{2N-2n}(-1)^{i}[(\partial_x+u)^{i-1}u][(\partial_x+u)^{2N-2n-i-1}u]+(-1)^N s_N, \tag{1.11}$$

where s_n are elementary symmetric polynomials for the set of numbers $(k_1^2,k_2^2,\ldots,k_N^2)$. For example, σ_1 with $N=2$ is

$$\sigma_1^{(2)}=2uu_{xx}-u_x^2+4u^2u_x+u^4-(k_1^2+k_2^2)u^2+k_1^2k_2^2,$$

and σ_2 with $N=2$ is

$$\sigma_2^{(2)}=2u_{xxx}+6uu_{xx}+7u_x^2+8u^2u_x+u^4-(k_1^2+k_2^2)(2u_x+u^2)+k_1^2k_2^2.$$

The equation $\sigma_1=0$ together with Eq. (1.9) specifies the solution

$$u=\partial_x\log\left[\sum_{i=1}^{N}(K_{2i-1}e^{n_i}+K_{2i}e^{-n_i})\right],\quad n_i\doteq k_i\left[x+\left(\sum_{m=0}^{M}\alpha_n k_i^{2m}\right)t\right], \tag{1.12}$$

where the constants k_i and K_i satisfy the constraint

$$\sum_{i=1}^{N}k_i^2\left[\prod_{j\neq i}(k_i^2-k_j^2)\right]K_{2i-1}K_{2i}=0. \tag{1.13}$$

Similarly the equation $\sigma_2=0$ together with Eq. (1.9) characterizes the solution

$$u=\partial_x\log\left[\sum_{i=1}^{N}(K_{2i-1}e^{n_i}+K_{2i}e^{-n_i})+K_{2N+1}\right],\quad n_i\doteq k_i\left[x+\left(\sum_{m=0}^{M}\alpha_n k_i^{2m}\right)t\right], \tag{1.14}$$

where the constants k_i and K_i satisfy the constraint

$$K_{2N+1}^2=4\left(\prod_{i=1}^{N}k_i^{-2}\right)\left\{\sum_{i=1}^{N}k_i^2\left[\prod_{j\neq i}(k_i^2-k_j^2)\right]K_{2i-1}K_{2i}\right\}. \tag{1.15}$$

The equations $u_t=K(u)+G(u,\sigma_1)$ and $u_t=K(u)+G(u,\sigma_2)$, where $K(u)$ is the right-hand side of Eq. (1.9) also possess these solutions. For example, the second order evolution equation

$$u_t=uu_{xx}-u_x^2+u^2u_x, \tag{1.16}$$

which corresponds to $K=u_{xxx}+3uu_{xx}+3u_x^2+3u^2u_x+(k_1^2+k_2^2)u_x$, $\sigma_1=\sigma_1^{(2)}$, $G=-\sigma_{1x}/(2u)$, admits the solution

$$\begin{gathered}u=\partial_x\log(K_1e^{n_1}+K_2e^{-n_1}+K_3e^{n_2}+K_4e^{-n_2}),\\ n_1\doteq k_1[x+(k_1^2+2k_2^2)t],\quad n_2\doteq k_2[x+(2k_1^2+k_2^2)t],\end{gathered} \tag{1.17}$$

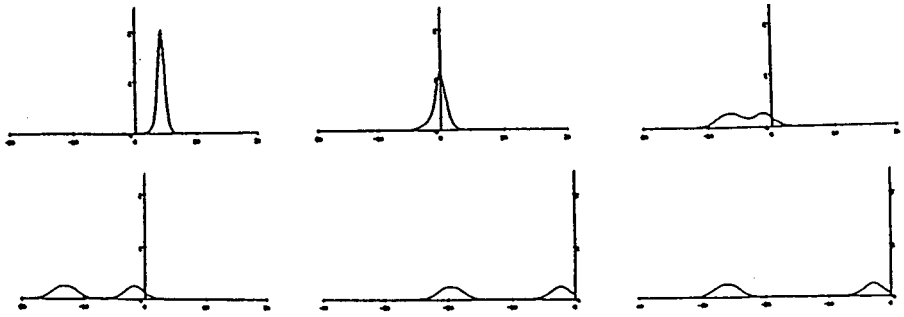

FIG. 1. Breaking of solitary waves.

where the constants k_i and K_i satisfy the constraint

$$k_1^2 K_1 K_2 = k_2^2 K_3 K_4. \tag{1.18}$$

This solution describes the interaction of two solitary waves with arbitrary wave speeds. Similarly the first order evolution equation

$$u_t = u_x^2 + 2u^2 u_x + u^4 - \alpha u^2 + \beta, \quad \alpha, \beta \text{ const}, \tag{1.19}$$

which corresponds to $K = -2u_{xxx} - 6uu_{xx} - 6u_x^2 - 6u^2 u_x + 2\alpha u_x$, $\sigma_2 = \sigma_2^{(2)}$ with $k_1 = [(\alpha + \sqrt{\alpha^2 - 4\beta})/2]^{1/2}$, $k_2 = [(\alpha - \sqrt{\alpha^2 - 4\beta})/2]^{1/2}$, $G = \sigma_2$, admits the solution

$$\begin{gathered} u = \partial_x \log(K_1 e^{n_1} + K_2 e^{-n_1} + K_3 e^{n_2} + K_4 e^{-n_2} + K_5), \\ n_1 \doteq k_1(x + 2k_2^2 t), \quad n_2 \doteq k_2(x + 2k_1^2 t), \quad K_5^2 \doteq 4\left(\frac{1}{k_1^2} - \frac{1}{k_2^2}\right)(k_1^2 K_1 K_2 - k_2^2 K_3 K_4), \end{gathered} \tag{1.20}$$

where K_1, K_2, K_3, and K_4 are arbitrary constants. If all the K_i's are different from zero this solution describes the interaction of two solitary waves with fixed wave speeds; however, if say $K_1 = 0$ this solution describes the interaction between one and two solitary waves, see Fig. 1. This figure corresponds to the real value of k_1 and k_2. For the imaginary value we obtain breather-type solutions. One such solution is plotted in Fig. 2.

It is remarkable that the potential KdV (1.4) can be obtained from Eq. (1.9) with $M = 1$, $\alpha_0 = 3(k_1^2 + k_2^2)$, $\alpha_1 = -2$, i.e., from

$$u_t = -2u_{xxx} - 6uu_{xx} - 6u_x^2 - 6u^2 u_x + 3(k_1^2 + k_2^2)u_x, \tag{1.21}$$

using $\sigma = \sigma_1^{(2)}$. This means that the two-soliton solution of the potential KdV can be traced back to the three-shock solution of Eq. (1.21).

(c) It is natural to ask if the equations considered in (b) have any other special property in addition to possessing certain exact solutions. We have found that these equations are in general equivalent to multilinear (i.e., bilinear, trilinear, etc.) equations. In Secs. IV and V we investigate a particular class of such equations, namely the bilinear ones. We note that these equations *cannot* in general be written in a concise form using Hirota's bilinear operators D_x and D_t. We consider the equation

$$u_t = \sum_{i,j \geq 0} \alpha_{ij}[(\partial_x + u)^{i-1} u][(\partial_x + u)^{j-1} u], \tag{1.22}$$

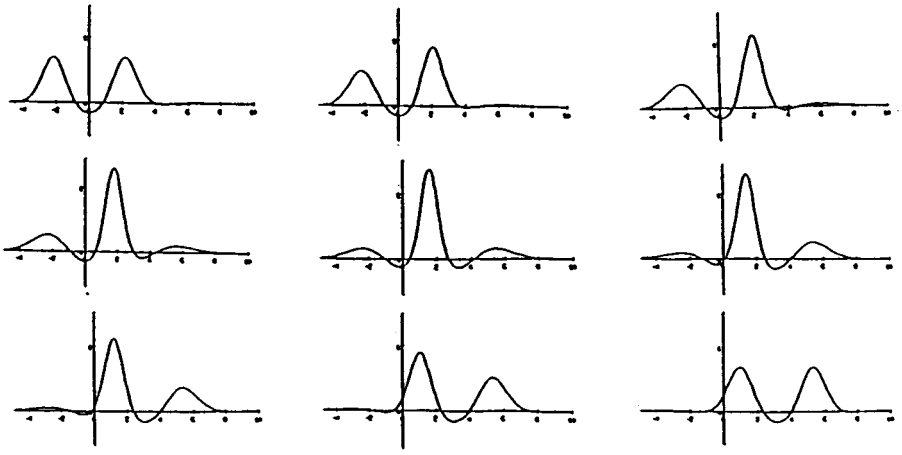

FIG. 2. Breather-type solitary waves.

where we define $(\partial_x+u)^{-1}u=1$. This equation, under the Cole–Hopf transformation $u=f_x/f$, becomes the bilinear equation

$$ff_{xt}-f_xf_t=\sum_{i,j\geqslant 0}\alpha_{ij}(\partial_x^i f)(\partial_x^j f). \tag{1.23}$$

In Sec. IV we find certain exact solutions of Eq. (1.22). These solutions are associated with bilinear GCS's. We find it more convenient to find these solutions directly without using the associated GCS's. These solutions are similar to Eqs. (1.11) and (1.12) and (1.13) and (1.14). For example, we find that Eq. (1.3), in addition to possess the two-soliton solution, also admits the solitary wave solution

$$u=\partial_x\ \log[K_1e^{k_1[x+(k_1^2+(3+2\gamma)k_2^2)t]}+K_2e^{-k_1[x+(k_1^2+(3+2\gamma)k_2^2)t]}+K_3], \tag{1.24}$$

where K_1 and K_2 are arbitrary constants and

$$K_3^2=4\left(1-\frac{1-\gamma}{1+\gamma}\frac{k_1^2}{k_2^2}\right)K_1K_2. \tag{1.25}$$

In Sec. V we find exact solutions of Eq. (1.22) which are associated with multilinear GCS's. For example, we find that the third order evolution equation

$$u_t=a_1u_{xxx}+4a_3uu_{xx}+3(2a_1-a_3)u_x^2+6a_3u^2u_x+a_3u^4+bu^2+c, \tag{1.26}$$

admits two types of exact solutions:

$$u=\partial_x\ \log[K_1e^{k_1x+l_1t}+K_2e^{-(k_1x+l_1t)}+K_3e^{k_2x+l_2t}+K_4e^{-(k_2x+l_2t)}], \tag{1.27}$$

where K_1, K_2, and K_3 are arbitrary constants,

$$k_1=\sqrt{\frac{-b+\sqrt{b^2-4a_3c}}{2a_3}},\quad k_2=\sqrt{\frac{-b-\sqrt{b^2-4a_3c}}{2a_3}},$$
$$l_1=k_1[a_1k_1^2+(3a_1-2a_3)k_2^2],\quad l_2=k_2[(3a_1-2a_3)k_1^2+a_1k_2^2],\quad k_1^2K_1K_2=k_2^2K_2K_3, \tag{1.28}$$

and

$$u=\partial_x \log[K_1e^{k_1x+l_1t}+K_2e^{-(k_1x+l_1t)}+K_3e^{k_2x+l_2t}+K_4e^{-(k_2x+l_2t)}+K_5e^{k_3x+l_3t}+K_6e^{-(k_3x+l_3t)}], \tag{1.29}$$

where K_1, K_2, and K_5 are arbitrary constants,

$$k_1=\sqrt{\frac{-b+\sqrt{b^2-4a_3c}}{2a_3}},\quad k_2=\sqrt{\frac{-b-\sqrt{b^2-4a_3c}}{2a_3}},\quad k_3=-\tfrac{1}{2}(k_1+k_2),$$

$$l_1=a_1(k_1^3+3k_1^2k_3+3k_1k_3^2-3k_3^3)-2a_3k_1^2k_2,$$

$$l_2=a_1(k_2^3+3k_2^2k_3+3k_2k_3^2-3k_3^3)-2a_3k_1k_2^2,\quad l_3=k_3(4a_1k_3^2-2a_3k_1k_2), \tag{1.30}$$

$$K_3=\frac{(k_1-k_3)[3a_1(k_1-k_3)-4a_3k_1]^2[3a_1(k_1-k_2)^2+16a_3k_1k_2]}{a_3(k_1-k_3)^3[3a_1(k_2-k_3)-4a_3k_2]^2}\frac{K_1K_2^2}{K_5^2},$$

$$K_4=\frac{a_3(k_1-k_3)(k_2-k_3)}{3a_1(k_1-k_2)^2+16a_3k_1k_2}\frac{K_5^2}{K_2},$$

$$K_6=\frac{[3a_1(k_1-k_3)-4a_3k_1][3a_1(k_1-k_2)^2+16a_3k_1k_2]}{a_3(k_2-k_3)^2[3a_1(k_2-k_3)-4a_3k_2]}\frac{K_1K_2}{K_5}.$$

Both of these solutions describe the interaction of two solitary waves.

We also find that the generalized CDGSK-KdV equation

$$\begin{aligned}u_t=&a_1(u_{xxxxx}+30u_xu_{xxx}+60u_x^3)+a_2(uu_{xxxx}-3u_xu_{xxx}+2u^2u_{xxx}+2u_{xx}^2+10uu_xu_{xx}\\&+2u^3u_{xx}-9u_x^3+6u^2u_x^2+u^4u_x)+b_1(u_{xxx}+6u_x^2)+b_2(uu_{xx}-u_x^2+u^2u_x)\end{aligned} \tag{1.31}$$

admits the exact solution

$$\begin{aligned}u=\partial_x \log[&K_1e^{k_1x+l_1t}+K_2e^{-(k_1x+l_1t)}+K_3e^{k_2x+l_2t}+K_4e^{-(k_2x+l_2t)}\\&+K_5e^{k_3x+l_3t}+K_6e^{-(k_3x+l_3t)}+K_7e^{k_4x+l_4t}+K_8e^{-(k_4x+l_4t)}],\end{aligned} \tag{1.32}$$

where k_1, k_2, K_1, K_3, K_5, and K_7 are arbitrary constants,

$$\begin{gathered}k_1+k_2+k_3+k_4=0,\quad k_1^2+k_2^2+k_3^2+k_4^2=-\frac{2b_2}{a_2},\quad l_i=\sum_{j\neq i}\frac{P(k_i,-k_j)}{k_i+k_j},\\K_2=\frac{A_{23}A_{24}A_{34}}{AK_1},\quad K_4=\frac{A_{13}A_{14}A_{34}}{AK_3},\quad K_6=\frac{A_{12}A_{14}A_{24}}{AK_5},\quad K_8=\frac{A_{12}A_{13}A_{23}}{AK_7}\end{gathered} \tag{1.33}$$

and

$$\begin{gathered}P(x,y)=\tfrac{1}{2}(x-y)^2[a_1(x-y)^4+a_2xy(x^2-xy+y^2)+b_1(x-y)^2+b_2xy],\\A_{ij}=(k_i-k_j)(l_i-l_j)-2P(k_i,k_j),\quad A=\pm\left(-\frac{A_{12}A_{13}A_{14}A_{23}A_{24}A_{34}}{K_1K_3K_5K_7}\right)^{1/2}.\end{gathered} \tag{1.34}$$

This solution describes the exact interaction of three solitary waves. We note that Eq. (1.31) can be written in a concise bilinear form. Indeed, using $u=f_x/f$, Eq. (1.31) becomes

$$D_xD_tf\cdot f=a_1D_x^6f\cdot f+a_2(D_x^4f_x\cdot f_x+D_x^2f_{xx}\cdot f_{xx})+b_1D_x^4f\cdot f+b_2D_x^2f_x\cdot f_x. \tag{1.35}$$

We hope that the rich phenomenology of the interaction of solitary waves described in this article will motivate the search for appropriate physical circumstances that such nonlinear interactions occur.

II. GENERALIZED CONDITIONAL SYMMETRIES OF THE KdV HIERARCHY

It was found in Ref. 1, using the Bäcklund transformation, that the GCS characterizing the three-soliton solution of the KdV hierarchy is given by

$$\begin{gathered}\sigma=(p_{xx}+ab+bc+ca)^2-4(p_x+2abc)v^2,\\ p\doteq v_x+v^2,\quad a\doteq p-k_1^2-k_2^2+k_3^2,\quad b\doteq p-k_2^2-k_3^2+k_1^2,\quad c\doteq p-k_3^2-k_1^2+k_2^2.\end{gathered} \tag{2.1}$$

The three-soliton solution of the potential KdV hierarchy is

$$\begin{gathered}v=\partial_x\log[e^{-(\eta_1+\eta_2+\eta_3)}+A_{12}A_{13}A_{23}e^{\eta_1+\eta_2+\eta_3}+A_{12}e^{\eta_1+\eta_2-\eta_3}+e^{-(\eta_1+\eta_2-\eta_3)}+A_{13}e^{\eta_1-\eta_2+\eta_3}\\ +e^{-(\eta_1-\eta_2+\eta_3)}+A_{23}e^{-\eta_1+\eta_2+\eta_3}+e^{-(-\eta_1+\eta_2+\eta_3)}],\\ \eta_i=k_i\left[x+\left(\sum_{m=0}^{M}\alpha_m(2k_i)^{2m}\right)t\right]+\eta_i^0,\quad A_{ij}=\left(\frac{k_i-k_j}{k_i+k_j}\right)^2\quad(i,j=1,2,3).\end{gathered} \tag{2.2}$$

Letting $u=2v_x$ it follows that u satisfies the KdV hierarchy (1.7). We note that under differentiation, the equation $\sigma=0$ implies

$$[p_{xxx}+2(a+b+c)p_x]v-(p_{xx}+ab+bc+ca)v_x=4p_xv^3, \tag{2.3}$$

i.e.,

$$\begin{gathered}vv_{xxxx}-v_xv_{xxx}+2v^2v_{xxx}+10vv_xv_{xx}+2v^3v_{xx}-5v_x^3+6v^2v_x^2\\ +v^4v_x-2A(vv_{xx}-v_x^2+v^2v_x)+Bv_x=0,\\ A\doteq k_1^2+k_2^2+k_3^2,\quad B\doteq k_1^4+k_2^4+k_3^4-2k_1^2k_2^2-2k_1^2k_3^2-2k_2^2k_3^2.\end{gathered} \tag{2.4}$$

We can now use Eq. (2.4) to construct nonintegrable equations which possess the three-soliton solution (2.2). For example, the fifth order evolution equation

$$\begin{gathered}v_t=v_{xxxxx}+(20-C)v_xv_{xxx}+10v_{xx}^2+5(8-C)v_x^3+C[vv_{xxxx}+2v^2v_{xxx}+10vv_xv_{xx}+2v^3v_{xx}\\ +6v^2v_x^2+v^4v_x-2A(vv_{xx}-v_x^2+v^2v_x)+Bv_x],\quad A,B,C\text{ const}\end{gathered}$$

admits Eq. (2.2) with arbitrary k_1 and

$$k_2=[\tfrac{1}{2}(A-k_1^2+\sqrt{B-2k_1^2A-3k_1^4})]^{1/2},\quad k_3=[\tfrac{1}{2}(A-k_1^2-\sqrt{B-2k_1^2A-3k_1^4})]^{1/2},$$

$$\eta_i=k_i(x+16k_i^4t)+\eta_i^0.$$

Although in principle we can use the Bäcklund transformation to derive the GCS characterizing the N-soliton solution this procedure is quite complicated. In this article we derive these GCS's in the form of Eq. (1.8), using Bargmann's method:[7] We consider the Schrödinger spectral equation

$$\phi_{xx}+(u+k^2)\phi=0. \tag{2.5}$$

Letting $\phi=e^{ikx}F$, $\mu=2ik$, we find $F_{xx}+\mu F_x+uF=0$. Assuming that $F=\mu^N+\Sigma_{n=1}^{N}a_n\mu^{N-n}$, it follows that

$$a_{1x}+u=0, \quad a_{n-1,x}+a_{nxx}+a_nu=0 \quad (n=1,2,\ldots,N-1), \quad a_{Nxx}+a_Nu=0.$$

Thus

$$a_n=(-1)^n(\partial_x+\partial_x^{-1}u)^{n-1}\partial_x^{-1}u \quad (n=1,2,\ldots,N-1) \quad (\partial_x+u\partial_x^{-1})^Nu=0.$$

For example, for $N=2$, we find

$$u=-a_x, \quad b=-a_x+\tfrac{1}{2}a^2+c_1$$

and

$$aa_{xx}-\tfrac{1}{2}a_x^2-a^2a_x+\tfrac{1}{8}a^4+\tfrac{1}{2}c_1a^2+c_2=0.$$

The left-hand side of this equation is the GCS (1.6) ($a\to-2u$) which characterizes the two-soliton. For $N=3$, we find

$$u=-a_x, \quad b=-a_x+\tfrac{1}{2}a^2+c_1, \quad c=a_{xx}-aa_x-\partial_x^{-1}a_x^2+\tfrac{1}{6}a^3+c_1a+c_2$$

and

$$a_{xxx}-aa_{xx}-\tfrac{5}{2}a_x^2+\tfrac{1}{2}a^2a_x+a\partial_x^{-1}a_x^2-\tfrac{1}{24}a^4+c_1(a_x-\tfrac{1}{2}a^2)-c_2a+c_3=0,$$

which implies Eq. (2.5) ($a\to-2v$).

It is a general conjecture that equations admitting three-soliton solutions with arbitrary wave numbers are integrable.[8] However, using our approach, it follows that this cannot be true. For example, the three-soliton (2.2) satisfies the ODE:

$$\left\{\prod_{i,j,m=\pm1}[\partial_x+(-1)^ik_1+(-1)^jk_2+(-1)^mk_3]\right\}f=0,$$

i.e.,

$$\partial_x^8f+a_1\partial_x^7f+\cdots+a_8f=0$$

for certain constants a_i. Since

$$\partial_x^nf=p_n(v)f, \quad p_0\doteq1, \quad p_1\doteq v, \quad p_{n+1}\doteq p_{nx}+vp_n,$$

we find

$$p_8+a_1p_7+\cdots+a_8p_0=0,$$

which implies that the functions $p_0(v)$, $p_1(v),\ldots,p_8(v)$ are functional dependent, thus their Wronskian determinant

$$\sigma = W(p_0(v), p_1(v), \ldots, p_8(v)) = 0.$$

Therefore, all the equations in the form of $v_t = v_{xxx} + 6v_x^2 + G(v, \sigma)$, where G satisfies $G(v,0) = 0$, admit the three-soliton solution (2.2) with arbitrary wave numbers k_i. Since $G(v, \sigma)$ is essentially arbitrary, it is doubtful that all these equations are integrable.

III. GENERALIZED CONDITIONAL SYMMETRIES AS REDUCTIONS OF LINEAR ONES

It was shown in Ref. 1 that the Burgers hierarchy

$$u_t = \partial_x \left[\sum_{i=0}^{M} \alpha_m (\partial_x + u)^m u \right] \tag{3.1}$$

admits the GCS:

$$\sigma = \sum_{n=0}^{N+1} c_n (\partial_x + u)^{n-1} u. \tag{3.2}$$

Associated with this σ is the N-shock solution

$$u = \partial_x \log \left(\sum_{i=1}^{N+1} K_i e^{k_i x + l_i t} \right), \quad l_i = \sum_{m=0}^{M} \alpha_m k_i^{m+1}, \tag{3.3}$$

where $k_1, \ldots, k_{N+1}$ are the $N+1$ roots of the equation $\Sigma_{n=0}^{N+1} c_n k^n = 0$. This fact becomes more clear under the Cole–Hopf transformation

$$u = (\log f)_x. \tag{3.4}$$

Under this transformation, Eq. (3.1) becomes a linear evolution equation:

$$f_t = \sum_{m=0}^{M} \alpha_m \partial_x^{m+1} f; \tag{3.5}$$

σ becomes linear in f:

$$\sigma = \sum_{n=0}^{N+1} c_n \partial_x^n f; \tag{3.6}$$

and $\sigma = 0$ implies that

$$f = \sum_{i=1}^{N+1} K_i e^{k_i x + l_i t}. \tag{3.7}$$

Therefore the GCS's associated with the multishock solution can be explicitly linearized.

Now we derive some other type of GCS's. These new GCS's cannot be linearized. However, they satisfy bilinear equations and furthermore can be obtained from the previous GCS's through the process of reductions. We say that a GCS σ_1 is a reduction of another GCS σ_2 iff $\sigma_2 = G(u, \sigma_1)$ for some function G satisfying $G(u,0) = 0$. This means that $\sigma_1 = 0$ implies $\sigma_2 = 0$. As a simple example, we consider the ODE:

$$f_{xxxx} - \alpha f_{xx} + \beta f = 0, \tag{3.8}$$

whose general solution is

$$f=K_1e^{k_1x}+K_2e^{-k_1x}+K_3e^{k_2x}+K_4e^{-k_2x}, \tag{3.9}$$

where k_1 and k_2 are given by

$$\alpha=k_1^2+k_2^2, \quad \beta=k_1^2k_2^2, \tag{3.10}$$

and K_i $(i=1,2,3,4)$ are arbitrary and independent to x. A simple reduction can be obtained by multiplying Eq. (3.8) by f_x and then integrating it. This yields

$$2f_xf_{xxx}-f_{xx}^2-\alpha f_x^2+\beta f^2=0. \tag{3.11}$$

Substituting Eq. (3.9) into Eq. (3.11), we find the constraint condition

$$k_1^2K_1K_2=k_2^2K_3K_4.$$

Equations (3.9) and (3.11) are compatible with the linear evolution equation

$$f_t=\sum_{m=0}^{M}\alpha_m\partial_x^{2m+1}f. \tag{3.12}$$

Thus the even Burgers hierarchy (1.9) admits the GCS:

$$\sigma=2uu_{xx}-u_x^2+4u^2u_x+u^4-\alpha u^2+\beta. \tag{3.13}$$

We call this GCS σ bilinear since the equation $\sigma=0$ is equivalent to the bilinear equation (3.11).

The solution associated to this GCS is the two-soliton

$$u=\partial_x\log[K_1e^{k_1x+l_1t}+K_2e^{-(k_1x+l_1t)}+K_3e^{k_2x+l_2t}+K_4e^{-(k_2x+l_2t)}], \tag{3.14a}$$

$$l_i=\sum_{m=0}^{M}\alpha_mk_i^{m+1} \quad (i=1,2), \quad k_1^2K_1K_2=k_2^2K_3K_4. \tag{3.14b}$$

As a second example of a reduction, we consider the ODE:

$$f_{xxxxx}-\alpha f_{xxx}+\beta f_x=0, \tag{3.15}$$

whose general solution is

$$f=K_1e^{k_1x}+K_2e^{-k_1x}+K_3e^{k_2x}+K_4e^{-k_2x}+K_5, \tag{3.16}$$

where k_1 and k_2 are given by Eqs. (3.10) and K_i $(i=1,2,3,4,5)$ are arbitrary and independent to x. Multiplying this equation by f and integrating it, we find

$$2ff_{xxxx}-2f_xf_{xxx}+f_{xx}^2-\alpha(2ff_{xx}-f_x^2)+\beta f^2=0. \tag{3.17}$$

The constraint condition is

$$K_5^2=4\left(\frac{1}{k_1^2}-\frac{1}{k_2^2}\right)(k_1^2K_1K_2-k_2^2K_3K_4).$$

Thus the even Burgers hierarchy admits the bilinear GCS:

$$\sigma=2u_{xxx}+6uu_{xx}+7u_x^2+8u^2u_x+u^4-2\alpha u_x-\alpha u^2+\beta. \tag{3.18}$$

The solution associated to this GCS is

$$u=\partial_x \log[K_1e^{k_1x+l_1t}+K_2e^{-(k_1x+l_1t)}+K_3e^{k_2x+l_2t}+K_4e^{-(k_2x+l_2t)}+K_5], \tag{3.19a}$$

$$l_i=\sum_{m=0}^{M}\alpha_m k_i^{m+1} \quad (i=1,2), \quad K_5^2=4\left(\frac{1}{k_1^2}-\frac{1}{k_2^2}\right)(k_1^2K_1K_2-k_2^2K_3K_4). \tag{3.19b}$$

The following theorem generalizes these results.

Theorem 3.1: (a) The evolution equation

$$u_t=\partial_x\left[\sum \alpha_m(\partial_x+u)^{2m}u\right]+G\Bigg(u,\sum_{n=0}^{N-1}(-1)^n s_n \sum_{i=1}^{2N-2n-1}(-1)^{i-1}[(\partial_x+u)^{i-1}u] \times[(\partial_x+u)^{2N-2n-i-1}u]+(-1)^N s_N\Bigg) \tag{3.20}$$

admits the exact solution

$$u=(\log f)_x, \quad f=\sum_{i=1}^{N}(K_{2i-1}e^{n_i}+K_{2i}e^{-n_i}),$$
$$n_i=k_i\left[x+\left(\sum \alpha_m k_i^{2m}\right)t\right], \quad \sum_{i=1}^{N}k_i^2\left[\prod_{j\neq i}(k_i^2-k_j^2)\right]K_{2i-1}K_{2i}=0. \tag{3.21}$$

(b) The evolution equation

$$u_t=\partial_x\left[\sum \alpha_m(\partial_x+u)^{2m}u\right]+G\Bigg(u,\sum_{n=0}^{N-1}(-1)^n s_n \sum_{i=0}^{2N-2n}(-1)^{i}[(\partial_x+u)^{i-1}u] \times[(\partial_x+u)^{2N-2n-i-1}u]+(-1)^N s_N \tag{3.22}$$

admits the exact solution

$$u=(\log f)_x, \quad f=\sum_{i=1}^{N}(K_{2i-1}e^{n_i}+K_{2i}e^{-n_i})+K_{2N+1},$$
$$n_i=k_i\left[x+\left(\sum \alpha_m k_i^{2m}\right)t\right], \quad K_{2N+1}^2=4\left(\prod_{i=1}^{N}k_i^{-2}\right)\left\{\sum_{i=1}^{N}k_i^2\left[\prod_{j\neq i}(k_i^2-k_j^2)\right]K_{2i-1}K_{2i}\right\}, \tag{3.23}$$

where $G(u,\sigma)$ is a function of u and σ and their derivatives satisfying $G(u,0)=0$, and s_n are elementary symmetric polynomials for the set of numbers $(k_1^2,k_2^2,\ldots,k_N^2)$,

$$s_0=1, \quad s_1=\sum_{i=1}^{N} k_i^2, \quad s_2=\sum_{i<j} k_i^2 k_j^2, \ \ldots, \quad s_N=\prod_{i=1}^{N} k_i^2. \tag{3.24}$$

Proof: We only prove part (a); part (b) can be proved similarly. We need to prove

$$\sum_{n=0}^{N-1} (-1)^n s_n \sum_{i=1}^{2N-2n-1} (-1)^{i-1} (\partial_x^i f)(\partial_x^{2N-2n-i} f) + (-1)^N s_N f^2 = 0. \tag{3.25}$$

Substituting Eq. (3.21b) into this equation, we find that the sum of the coefficients of e^{-2n_p} is

$$K_{2p-1}^2 \left[\sum_{n=0}^{N-1} (-1)^n s_n \sum_{i=1}^{2N-2n-1} (-1)^{i-1} k_p^{2N-2n} + (-1)^N s_N \right] = K_{2p-1}^2 \left[\sum_{n=0}^{N} (-1)^n s_n k_p^{2N-2n} \right] = 0$$

and the sum of the coefficients of $e^{-n_p-n_q}$ is

$$\begin{aligned} &2K_{2p-1}K_{2q-1}\left[\sum_{n=0}^{N-1} (-1)^n s_n \sum_{i=1}^{2N-2n-1} (-1)^{i-1} k_p^i k_q^{2N-2n-i} + (-1)^N s_N \right] \\ &= 2K_{2p-1}K_{2q-1}\left[\frac{k_q}{k_p-k_q} \sum_{n=0}^{N} (-1)^N s_n k_p^{2N-2n} + \frac{k_p}{k_q-k_p} \sum_{n=0}^{N} (-1)^N s_n k_q^{2N-2n} \right] = 0. \end{aligned}$$

Similarly, we find that the sums of the coefficients of e^{2n_p}, $e^{\pm n_p \pm n_q}$ are all zeros. The only terms left come from the multiplication of e^{n_p} and e^{-n_p} for $p=1,2,\ldots,N$, which are

$$\begin{aligned} &2K_{2p-1}K_{2p}\left[\sum_{n=0}^{N-1} (-i)^n s_n \sum_{i=1}^{2N-2n-1} (-1)^{i-1} k_p^i (-k_p)^{2N-2n-i} + (-1)^N s_N \right] \\ &= 2K_{2p-1}K_{2p}\left[-\sum_{n=0}^{N-1} (-1)^n s_n (2N-2n-1) k_p^{2N-2n} + (-1)^N s_N \right] \\ &= -4K_{2p-1}K_{2p}k_p^2\left[\sum_{n=0}^{N-1} (-1)^n s_n (N-n) k_i^{2N-2n-2} \right] \\ &= -4K_{2p-1}K_{2p}k_p^2\left[\sum_{n=0}^{N-1} (-1)^n s_n^{(p)} k_p^{2N-2n-2} \right] = -4K_{2p-1}K_{2p}k_p^2 \prod_{q\neq p} (k_p^2-k_q^2), \end{aligned}$$

where we denote by $s_n^{(p)}$ the elementary symmetric polynomials for $(k_1^2,\ldots,k_{p-1}^2,k_{p+1}^2,\ldots,k_N^2)$, and have used the relation $s_n=s_n^{(p)}+k_p^2 s_{n-1}^{(p)}$. Thus Eq. (3.21d) implies Eq. (3.25).

Remark: More general reductions can be obtained by integrating $(\Sigma \alpha_n \partial_x^{2n+1} f)(\Sigma \beta_n \partial_x^{2n} f)=0$.

Example 3.1: The third order equation

$$u_t = a_1 u_{xxx} + a_2 u u_{xx} + (6a_1 - a_2 + a_3) u_x^2 + (a_2 + 2a_3) u^2 u_x + a_3 u^4 + b u^2 + c \tag{3.26}$$

admits the exact solutions (3.14a) and (3.14c) with

$$k_1 = \sqrt{\frac{-b+\sqrt{b^2-4a_3c}}{2a_3}}, \tag{3.27a}$$

$$k_2=\sqrt{\frac{-b-\sqrt{b^2-4a_3c}}{2a_3}}, \tag{3.27b}$$

$$l_1=k_1[a_1k_1^2+(3a_1-a_2+2a_3)k_2^2], \tag{3.27c}$$

$$l_2=k_2[(3a_1-a_2+2a_3)k_1^2+a_1k_2^2]. \tag{3.27d}$$

Proof: The right-hand side of Eq. (3.26) can be written as

$$(-2a_1+a_2-2a_3)(u_{xxx}+3uu_{xx}+3u_x^2+3u^2u_x)+a(3a_1-a_2+2a_3)u_x$$
$$+\left[\frac{1}{2u}(3a_1-a_2+2a_3)\partial_x+a_3\right]\sigma+(b+\alpha a_3)u^2+c-\beta a_3,$$

where σ is given by Eq. (3.13). Letting $\alpha=-b/a_3$ and $\beta=c/a_3$, which imply Eqs. (3.27a) and (3.27b), we find that Eq. (3.26) admits two-soliton solutions [Eqs. (3.13a) and (3.13c)] with

$$l_i=k_i[(-2a_1+a_2-2a_3)k_i^2+\alpha(3a_1-a_2+2a_3)] \quad (i=1,2).$$

Example 3.2: The third order equation

$$u_t=a_1u_{xxx}+a_2uu_{xx}+(6a_1-a_2)u_x^2+a_2u^2u_x \tag{3.28}$$

admits the exact solutions (3.14a) and (3.14c) with arbitrary wave numbers and $l_1=k_1[a_1k_1^2+(3a_1-a_2)k_2^2]$, $l_2=k_2[(3a_1-a_2)k_1^2+a_1k_2^2]$.

Example 3.3: The third order equation

$$u_t=a_1u_{xxx}+3a_1uu_{xx}+(3a_1+a_3)u_x^2+(3a_1+2a_3)u^2u_x+a_3u^4+bu^2+c \tag{3.29}$$

admits the exact solutions (3.19a) and (3.19c) with

$$k_1=\sqrt{\frac{-b+\sqrt{b^2-4a_3c}}{2a_3}}, \quad k_2=\sqrt{\frac{-b-\sqrt{b^2-4a_3c}}{2a_3}},$$

$$l_1=k_1(a_1k_1^2+2a_3k_2^2), \quad l_2=k_2(2a_3k_1^2+a_1k_2^2). \tag{3.30}$$

IV. EXACT SOLUTIONS OF BILINEAR EVOLUTION EQUATIONS ASSOCIATED WITH BILINEAR GENERALIZED CONDITIONAL SYMMETRIES

Although in principle we can construct all the equations which admit exact solutions associated with bilinear GCS's from the Burgers-type equations, the resulting equations are quite complicated. Therefore, we look directly for simple equations admitting exact solutions. In particular we consider the bilinear equation (1.23). In this section, we search for exact solutions for this equation directly. Without loss of generality, we assume that $\alpha_{ij}=\alpha_{ji}$. We define

$$P(x,y)=\sum \alpha_{ij}x^iy^j, \tag{4.1}$$

then Eq. (1.23) can be written as

$$(\partial_x-\partial_{x'})(\partial_t-\partial_{t'})f(x,t)f(x',t')\big|_{x'=x,t'=t}=2P(\partial_x,\partial_{x'})f(x,t)f(x',t')\big|_{x'=x,t'=t}. \tag{4.2}$$

We look for solutions which are sums of exponentials

$$f(x,t)=\sum K_p e^{n_p}, \quad n_p=k_p x+l_p t. \tag{4.3}$$

Substituting in Eq. (1.23), we find that

$$\sum_{p<q}(k_p-k_q)(l_p-l_q)K_pK_q e^{n_p+n_q}=\sum_{p,q} P(k_p,k_q)K_pK_q e^{n_p+n_q},$$

i.e.,

$$\sum_{p<q}[(k_p-k_q)(l_p-l_q)-2P(k_p,k_q)]K_pK_q e^{n_p+n_q}-\sum_p P(k_p,k_p)K_p^2 e^{2n_p}=0. \tag{4.4}$$

Therefore, we have the following results:

Theorem 4.1: The bilinear evolution equation (1.22) with even P, admits the following exact solutions:

(a)

$$u=(\log f)_x, \quad f=\sum_{i=1}^{n}[K_{2i-1}e^{k_i x+l_i t}+K_{2i}e^{-(k_i x+l_i t)}], \tag{4.5}$$

where

$$P(k_i,k_i)=0, \quad l_i=\frac{P(k_i,k_j)}{k_i-k_j}+\frac{P(k_i,-k_j)}{k_i+k_j} \quad (\forall j\neq i), \quad \sum_{i=1}^{n}[2k_i l_i-P(k_i,-k_i)]K_{2i-1}K_{2i}=0, \tag{4.6}$$

provided that

$$\frac{P(k_i,k_j)}{k_i-k_j}+\frac{P(k_i,-k_j)}{k_i+k_j}=\frac{P(k_i,k_m)}{k_i-k_m}+\frac{P(k_i,-k_m)}{k_i+k_m} \quad (\forall i\neq j\neq m); \tag{4.7}$$

(b)

$$u=(\log f)_x, \quad f=\sum_{i=1}^{n}[K_{2i-1}e^{k_i x+l_i t}+K_{2i}e^{-(k_i x+l_i t)}]+K_{2n+1}, \tag{4.8}$$

where

$$P(k_i,k_i)=0, \quad l_i=\frac{2}{k_i}P(k_i,0), \quad P(0,0)K_{2n+1}^2=2\sum_{i=1}^{n}[4P(k_i,0)-P(k_i,-k_i)]K_{2i-1}K_{2i}, \tag{4.9}$$

provided that

$$\frac{2}{k_i}P(k_i,0)=\frac{P(k_i,k_j)}{k_i-k_j}+\frac{P(k_i,-k_j)}{k_i+k_j} \quad (\forall i\neq j). \tag{4.10}$$

Applying this theorem to the third order equation (3.26), we find that this equation admits not only two-soliton solutions (3.27), but also the following traveling wave solution:

$$u=(\log f)_x, \quad f=K_1e^{kx+lt}+K_2e^{-(kx+lt)}+K_3,$$
$$k=\sqrt{\frac{-b\pm\sqrt{b^2-4a_3c}}{2a_3}}, \quad l=k[(a_1-2a_3)k^2-2b], \tag{4.11}$$
$$K_3^2=4\left[1+\frac{1}{c}(-3a_1+a_2-a_3)k^4\right]K_1K_2.$$

Applying this theorem to the bilinear equation (1.23) with $i+j\leqslant 6$, we obtain the following results.

Example 4.1: The equation

$$u_t=a_1(\partial_x+u)^5u+a_2u(\partial_x+u)^4u+a_3[(\partial_x+u)u][(\partial_x+u)^3u]+a_4[(\partial_x+u)^2u]^2$$
$$+b_1(\partial_x+u)^3u+b_2u(\partial_x+u)^2u+b_3[(\partial_x+u)u]^2+cu^2+d \tag{4.12}$$

admits the two-soliton solution (3.14a) where

$$(a_1+a_2+a_3+a_4)k_i^6+(b_1+b_2+b_3)k_i^4+ck_i^2+d=0 \quad (i=1,2),$$
$$l_1=k_1[-(a_2+a_3+a_4)k_1^4-a_4k_1^2k_2^2+(a_3+a_4)k_2^4-(b_2+b_3)k_1^2+b_3k_2^2-c],$$
$$l_2=k_2[-(a_2+a_3+a_4)k_2^4-a_4k_1^2k_2^2+(a_3+a_4)k_1^4-(b_2+b_3)k_2^2+b_3k_1^2-c], \tag{4.13}$$
$$k_1^2[a_3k_1^2+(a_3+a_4)k_2^2+b_3]K_1K_2=k_2^2[(a_3+a_4)k_1^2+a_3k_2^2+b_3]K_3K_4,$$

and the traveling wave solution (4.11) where

$$(a_1+a_2+a_3+a_4)k^6+(b_1+b_2+b_3)k^4+ck^2+d=0,$$
$$l=-k[(a_1+2a_2+2a_3+2a_4)k^4+(b_1+2b_2+2b_3)k^2+2c], \tag{4.14}$$
$$K_3^2=-\frac{4k^2}{d}[(a_1+a_2+2a_3+a_4)k^4+(b_1+b_2+2b_3)k^2+c]K_1K_2.$$

Example 4.2: The equation

$$u_t=a_1(\partial_x+u)^5u-(a_1+a_3+a_4)u(\partial_x+u)^4u+a_3[(\partial_x+u)u][(\partial_x+u)^3u]$$
$$+a_4[(\partial_x+u)^2u]^2+b_1(\partial_x+u)^3u-(b_1+b_3)u(\partial_x+u)^2u+b_3[(\partial_x+u)u]^2, \tag{4.15}$$

whose bilinear form is

$$D_xD_tf\cdot f=a_1D_x^6f\cdot f-(5a_1+a_3+a_4)D_x^4f_x\cdot f_x-(5a_1+3a_3+4a_4)$$
$$\times D_x^2f_{xx}\cdot f_{xx}+b_1D_x^4f\cdot f-(3b_1+b_3)D_x^2f_x\cdot f_x+c_1D_x^2f\cdot f, \tag{4.16}$$

admits the two-soliton solution (3.14a) with arbitrary wave numbers and

$$l_1=k_1[a_1k_1^4-a_4k_1^2k_2^2+(a_3+a_4)k_2^4+b_1k_1^2+b_3k_2^2],$$
$$l_2=k_2[a_1k_2^4-a_4k_1^2k_2^2+(a_3+a_4)k_1^4+b_1k_2^2+b_3k_1^2], \tag{4.17}$$
$$k_1^2[a_3k_1^2+(a_3+a_4)k_2^2+b_3]K_1K_2=k_2^2[(a_3+a_4)k_1^2+a_3k_2^2+b_3]K_3K_4.$$

Example 4.3: The equation

$$u_t=a_1(\partial_x+u)^5u+a_2u(\partial_x+u)^4u+a_4\{-2[(\partial_x+u)u][(\partial_x+u)^3u]+[(\partial_x+u)^2u]^2\}$$
$$+b_1(\partial_x+u)^3u+b_2u(\partial_x+u)^2u+b_3[(\partial_x+u)u]^2+cu^2+d \tag{4.18}$$

with

$$a_1+a_2\neq a_4,\quad (a_1+a_2)b_3+(b_1+b_2)a_4=0, \tag{4.19}$$

admits the exact solution

$$u=(\log f)_x, \tag{4.20a}$$
$$f=K_1e^{k_1x+l_1t}+K_2e^{-(k_1x+l_1t)}+K_3e^{k_2x+l_2t}+K_4e^{-(k_2x+l_2t)}+K_5e^{k_3x+l_3t}+K_6e^{-(k_3x+l_3t)}, \tag{4.20b}$$
$$(a_1+a_2-a_4)k_i^6+(b_1+b_2+b_3)k_i^4+ck_i^2+d=0\quad (i=1,2,3), \tag{4.20c}$$
$$l_1=k_1[(-a_2+a_4)k_1^4+a_4k_2^2k_3^2-(b_2+b_3)k_1^2-c], \tag{4.20d}$$
$$l_2=k_2[(-a_2+a_4)k_2^4+a_4k_3^2k_1^2-(b_2+b_3)k_2^2-c], \tag{4.20e}$$
$$l_3=k_3[(-a_2+a_4)k_3^4+a_4k_1^2k_2^2-(b_2+b_3)k_3^2-c], \tag{4.20f}$$
$$\frac{k_1^2}{k_2^2-k_3^2}K_1K_2+\frac{k_2^2}{k_3^2-k_1^2}K_3K_4+\frac{k_3^2}{k_1^2-k_2^2}K_5K_6=0. \tag{4.20g}$$

Example 4.4: The equation

$$u_t=uu_{xxxx}-2u_xu_{xxx}+3u^2u_{xxx}+u_{xx}^2+8uu_xu_{xx}+4u^3u_{xx}$$
$$-6u_x^3+6u^2u_x^2+2u^4u_x+b(uu_{xx}-u_x^2+u^2u_x), \tag{4.21}$$

whose bilinear form is

$$D_xD_tf\cdot f=D_x^4f_x\cdot f_x+2D_x^2f_{xx}\cdot f_{xx}+bD_x^2f_x\cdot f_x, \tag{4.22}$$

admit the exact solutions (4.20b) and (4.20g) with arbitrary k_1 and k_2 and

$$k_1^2+k_2^2+k_3^2=-b,\quad l_1=k_1k_2^2k_3^2,\quad l_2=k_1^2k_2k_3^2,\quad l_3=k_1^2k_2^2k_3.$$

Example 4.5: The equation

$$u_t=a_1\partial_x(\partial_x+u)^4u+a_4\{-2[(\partial_x+u)u][(\partial_x+u)^3u]+[(\partial_x+u)^2u]^2\}$$
$$+b_1\partial_x(\partial_x+u)^2u+b_3[(\partial_x+u)u]^2+cu^2+d\quad (a_4\neq0) \tag{4.23}$$

admits the exact solution

$$
\begin{gathered}
u=(\log f)_x,\\
f=K_1e^{k_1x+l_1t}+K_2e^{-(k_1x+l_1t)}+K_3e^{k_2x+l_2t}+K_4e^{-(k_2x+l_2t)}+K_5e^{k_3x+l_3t}+K_6e^{-(k_3x+l_3t)}+K_7,\\
a_4k_i^6-b_3k_i^4-ck_i^2-d=0 \quad (i=1,2,3),\\
l_1=k_1[(a_1+a_4)k_1^4+a_4k_2^2k_3^2+(b_1-b_3)k_1^2-c],\\
l_2=k_2[(a_1+a_4)k_2^4+a_4k_3^2k_1^2+(b_1-b_3)k_2^2-c],\\
l_3=k_3[(a_1+a_4)k_3^4+a_4k_1^2k_2^2+(b_1-b_3)k_3^2-c],\\
K_7^2=-\frac{4(k_1^2-k_2^2)(k_2^2-k_3^2)(k_3^2-k_1^2)}{k_1^2k_2^2k_3^2}\left(\frac{k_1^2}{k_2^2-k_3^2}K_1K_2+\frac{k_2^2}{k_3^2-k_1^2}K_3K_4+\frac{k_3^2}{k_1^2-k_2^2}K_5K_6\right).
\end{gathered}
\tag{4.24}
$$

Since the exact solutions we derived in this article are in the form of sums of exponentials, they describe in general the interaction of traveling waves. Here we use the solution (1.20) of Eq. (1.19) to show that these solutions may describe breaking traveling waves. We assume that $k_1>k_2>0$. In the moving coordinate $\eta=x+at$, we get

$$
f=K_1e^{k_1\eta+(l_1-k_1a)t}+K_2e^{-k_1\eta+(-l_1+k_1a)t}+K_3e^{k_2\eta+(l_2-k_2a)t}+K_4e^{-k_2\eta+(-l_2+k_2a)t}+K_5.
$$

For $l_1-k_1a=l_2-k_2a$, i.e., $a=-2k_1k_2$, we get

$$
f\sim e^{2k_1k_2(k_1+k_2)t}(K_1e^{k_1\eta}+K_3e^{k_2\eta}),\quad u\sim\partial_x\log(K_1e^{k_1\eta}+K_3e^{k_2\eta}),\quad t\to+\infty,
$$

and

$$
f\sim e^{2k_1k_2(k_1+k_2)t}(K_2e^{-k_1\eta}+K_4e^{-k_2\eta}),\quad u\sim\partial_x\log(K_2e^{-k_1\eta}+K_4e^{-k_2\eta}),\quad t\to-\infty.
$$

For $l_1-k_1a=-l_2+k_2a$, i.e., $a=2k_1k_2$, we get

$$
f\sim e^{2k_1k_2(-k_1+k_2)t}(K_2e^{-k_1\eta}+K_3e^{k_2\eta}),\quad u\sim\partial_x\log(K_2e^{-k_1\eta}+K_3e^{k_2\eta}),\quad t\to+\infty,
$$

and

$$
f\sim e^{2k_1k_2(k_1-k_2)t}(K_1e^{k_1\eta}+K_4e^{-k_2\eta}),\quad u\sim\partial_x\log(K_1e^{k_1\eta}+K_4e^{-k_2\eta}),\quad t\to-\infty.
$$

For $l_1-k_1a=0$, i.e., $a=2k_2^2$, we get

$$
\begin{array}{lll}
f\sim K_3e^{k_2\eta+2k_2(k_1^2-k_2^2)t}, & u\sim k_2 & (K_3\neq0),\\
f\sim K_1e^{k_1\eta}+K_2e^{-k_1\eta}+K_5, & u\sim\partial_x\log(K_1e^{k_1\eta}+K_2e^{-k_1\eta}+K_5) & (K_3=0),
\end{array}
\quad t\to+\infty,
$$

and

$$
\begin{array}{lll}
f\sim K_4e^{-k_2\eta-2k_2(k_1^2-k_2^2)t}, & u\sim -k_2, & (K_4\neq0),\\
f\sim K_1e^{k_1\eta}+K_2e^{-k_1\eta}+K_5, & u\sim\partial_x\log(K_1e^{k_1\eta}+K_2e^{-k_1\eta}+K_5), & (K_4=0),
\end{array}
\quad t\to-\infty.
$$

Therefore, if all K_i $(i=1,2,3,4)$ are nonzero, this solution describes the interaction of two solitary waves and if one of these K_i is zero, then it describes the interaction of one and two solitary waves. The following general result is valid for exact solutions containing six exponentials.

Lemma 4.1: The exact solution (1.29), where $k_1>k_2>k_3>0$, $K_i\neq0$ $(i=1,2,3,4,5,6)$, describes the interaction of three solitary waves if $a_{12}<a_{13}<a_{23}$ with one of the following:

$$b_{12}<b_{13}<b_{23}, \quad b_{23}<b_{12}<b_{13}, \quad b_{13}<b_{23}<b_{12},$$

or if $a_{23}<a_{13}<a_{12}$ with one of the following:

$$b_{12}<b_{23}<b_{13}, \quad b_{13}<b_{12}<b_{23}, \quad b_{23}<b_{13}<b_{12}.$$

The constants a_{ij} and b_{ij} are defined by

$$a_{ij}=\frac{l_i-l_j}{k_i-k_j}, \quad b_{ij}=\frac{l_i+l_j}{k_i+k_j}.$$

If the above conditions are violated, it describes the interaction of two solitary waves. If some of the K_i's equal zero, this solution in general describes breaking of solitary waves. Applying this result to the solutions (1.29) and (1.30), we find that it describes the interaction of two solitary waves.

V. EXACT SOLUTIONS OF BILINEAR EVOLUTION EQUATIONS ASSOCIATED WITH MULTILINEAR GENERALIZED CONDITIONAL SYMMETRIES

There exist exact solutions, for example the three-soliton solution (2.2), which are associated with multilinear as oppose to bilinear GCS's. Since these GCS's are quite complicated, we construct equations admitting this kind of solutions directly. In this section, we consider again Eq. (1.23). But now we are interested in the cases that, for f in the form of the sum of exponentials, the product of two exponentials is identical to the product of some other two exponentials in Eq. (1.23). For f with even terms, we have the following cases:

$$\text{(a)} \ \ n_1+n_2+n_3+n_4=0, \quad \text{(b)} \ \ n_1+n_2+2n_3=0, \quad \text{(c)} \ \ n_1+3n_2=0,$$

and for f with odd terms, we still have these cases as well as two additional ones:

$$\text{(d)} \ \ n_1+n_2+n_3=0, \quad \text{(e)} \ \ n_1+2n_2=0.$$

As an example, we consider the solution of Eq. (1.23) with even $P(x,y)$ in the form of

$$f=K_1e^{n_1}+K_2e^{-n_1}+K_3e^{n_2}+K_4e^{-n_2}+K_5e^{n_3}+K_6e^{-n_3},$$

with the condition $n_1+n_2+2n_3=0$. We substitute this f into Eq. (1.23) to find the conditions for f. The coefficients of e^{2n_1} and e^{2n_2} yield

$$P(k_1,k_1)=P(k_2,k_2)=0.$$

The coefficients of $e^{n_i-n_j}$ $(i\neq j)$ yield

$$l_1+l_2=\frac{2P(k_1,-k_2)}{k_1+k_2}, \quad l_1+l_3=\frac{2P(k_1,-k_3)}{k_1+k_3}, \quad l_2+l_3=\frac{2P(k_2,-k_3)}{k_2+k_3}.$$

The coefficients of $e^{n_1+n_2}=e^{-2n_3}$ and $e^{-n_1-n_2}=e^{2n_3}$ yield

$$A_{12}K_1K_3=P(k_3,k_3)K_6^2, \quad A_{12}K_2K_4=P(k_3,k_3)K_5^2,$$

where we denote

$$A_{ij}=(k_i-k_j)(l_i-l_j)-2P(k_i,k_j).$$

The coefficients of $e^{n_1+n_3}=e^{-n_2-n_3}$ and $e^{n_2+n_3}=e^{-n_1-n_2}$ yield

$$A_{13}K_1K_5+A_{23}K_4K_6=0, \quad A_{13}K_2K_6+A_{23}K_3K_5=0.$$

The constant terms yield

$$[2k_1l_1-P(k_1,-k_1)]K_1K_2+[2k_2l_2-P(k_2,-k_2)]K_3K_4+[2k_3l_3-P(k_3,-k_3)]K_5K_6=0.$$

From all these requirements, we get the following result.

Theorem 5.1: Suppose $P(x,y)$ is even and k_1 and k_2 are two roots of $P(x,x)$, $k_3=-(k_1+k_2)/2$, and

$$\begin{aligned} &P(k_1,k_3)=P(k_2,-k_3),\\ &[2k_3l_3-P(k_3,-k_3)]A_{12}A_{13}A_{23}=P(k_3,k_3)\{[2k_1l_1-P(k_1,-k_1)]A_{23}^2\\ &\qquad\qquad +[2k_2l_2-P(k_2,-k_2)]A_{13}^2\}, \end{aligned} \tag{5.1}$$

where

$$\begin{aligned} &A_{ij}=(k_1-k_j)(l_i-l_j)-2P(k_i,k_j) \quad (i\neq j),\\ &l_1=\frac{P(k_1,-k_2)}{k_1+k_2}+\frac{2P(k_1,-k_3)}{k_1+k_3}, \quad l_2=\frac{P(k_1,-k_2)}{k_1+k_2}+\frac{2P(k_2,-k_3)}{k_2+k_3}, \quad l_3=-\frac{P(k_1,-k_2)}{k_1+k_2}. \end{aligned} \tag{5.2}$$

Then Eq. (1.22) admits the exact solution

$$\begin{aligned} &u=(\log f)_x,\\ &f=K_1e^{k_1x+l_1t}+K_2e^{-(k_1x+l_1t)}+K_3e^{k_2x+l_2t}+K_4e^{-(k_2x+l_2t)}+K_5e^{k_3x+l_3t}+K_6e^{-(k_3x+l_3t)}, \end{aligned} \tag{5.3}$$

where K_1, K_2, and K_5 are arbitrary and

$$K_3=\frac{A_{12}A_{13}^2}{A_{23}^2P(k_3,k_3)}\frac{K_1K_2^2}{K_5^2}, \quad K_4=\frac{P(k_3,k_3)}{A_{12}}\frac{K_5^2}{K_2}, \quad K_6=-\frac{A_{12}A_{13}}{A_{23}P(k_3,k_3)}\frac{K_1K_2}{K_5}. \tag{5.4}$$

Applying this result to Eq. (3.26), we find $a_2=4a_3$ and the exact solutions (1.29) and (1.30) of Eq. (1.26).

We have also found the requirements for Eq. (1.23) to admit solutions with six terms satisfying $n_1+3n_2=0$, and seven terms satisfying $n_1+n_2+2n_3=0$ or $n_1+n_2+n_3=0$. In the following we give one example for each case.

Example 5.1: Equation (4.12) admits the exact solution (5.3) with arbitrary K_3, K_4, and K_5, and

$$\begin{aligned} &K_1=\frac{k_2^2-k_3^2}{3(k_1^2-k_3^2)}\frac{K_4^2}{K_3}, \quad K_2=\frac{k_2^2-k_3^2}{3(k_1^2-k_3^2)}\frac{K_3^2}{K_4}, \quad K_6=\frac{64k_2^6}{k_3^2(k_1^2-k_3^2)^2}\frac{K_3K_4}{K_5},\\ &l_1=-\tfrac{1}{9}k_1[a_1k_1^4+2(5a_1+5a_2+11a_3+12a_4)k_1^2k_3^2-27(a_3+2a_4)k_3^4], \quad l_2=-\tfrac{1}{3}l_1.\\ &l_3=-\tfrac{1}{9}k_3[(a_1+a_2+4a_3+6a_4)k_1^4+2(5a_1-9a_2-18a_4)k_1^2k_3^2+9(a_2+a_3)k_3^4], \end{aligned} \tag{5.5}$$

for fixed wave numbers k_1, k_2, and k_3 with $k_2=-k_1/3$, provided that

$$b_1=-\tfrac{10}{9}a_1k_1^2-(a_1+a_2+a_3)k_3^2, \quad b_2=-\tfrac{10}{9}a_2k_1^2-2a_4k_3^2,$$

$$b_3=-\tfrac{1}{9}(11a_3+12a_4)k_1^2+(a_3+3a_4)k_3^2,$$

$$c=\tfrac{1}{9}(a_1+2a_3+3a_4)k_1^4+\tfrac{2}{9}(5a_1+5a_2+a_3-3a_4)k_1^2k_3^2-(a_3+2a_4)k_3^4, \tag{5.6}$$

$$d=-\tfrac{1}{9}(a_1+a_2+2a_3)k_1^4k_3^2+(a_3+2a_4)k_1^2k_3^4.$$

Example 5.2: The equation

$$\begin{aligned}u_t=&a_1\partial_x(\partial_x+u)^4u+a_3[(\partial_x+u)u][(\partial_x+u)^3u]+a_4[(\partial_x+u)^2u]^2+[(\tfrac{5}{3}a_1+a_3+\tfrac{4}{3}a_4)k_1k_2\\&-5a_1k_3^2](\partial_x+u)^3u+[-(\tfrac{5}{3}a_1+2a_3+\tfrac{10}{3}a_4)k_1k_2+5a_1k_3^2]u(\partial_x+u)^2u+[(3a_3+4a_4)k_1k_2\\&-(\tfrac{11}{2}a_3+6a_4)k_3^2][(\partial_x+u)u]^2+[a_3(k_1^2k_2^2+\tfrac{3}{2}k_1^2k_3^2+\tfrac{3}{2}k_2^2k_3^2)+a_4(k_1^2k_2^2+2k_1^2k_3^2+2k_2^2k_3^2)]u^2\\&-(\tfrac{3}{2}a_3+4a_4)k_1^2k_2^2k_3^2\end{aligned} \tag{5.7}$$

admits the exact solution

$$u=(\log f)_x,$$

$$f=K_1e^{k_1x+l_1t}+K_2e^{-(k_1x+l_1t)}+K_3e^{k_2x+l_2t}+K_4e^{-(k_2x+l_2t)}+K_5e^{k_3x+l_3t}+K_6e^{-(k_3x+l_3t)}+K_7, \tag{5.8}$$

where K_1, K_2, and K_5 are arbitrary and

$$l_1=-\tfrac{1}{12}a_1k_1^3(3k_1^2+10k_1k_2+15k_2^2)+\tfrac{1}{3}(3a_3+4a_4)k_1k_2(k_1^3-3k_2k_3^2),$$

$$\begin{gathered}l_2=-\tfrac{1}{12}a_1k_2^3(3k_2^2+10k_1k_2+15k_1^2)+\tfrac{1}{3}(3a_3+4a_4)k_1k_2(k_2^3-3k_1k_3^2),\quad l_3=-\tfrac{1}{2}(l_1+l_2),\\K_3=\frac{16k_1^6(k_1-k_3)}{k_2^2k_3^2(k_2-k_3)^3}\frac{K_1K_2^2}{K_5^2},\quad K_4=\frac{k_3^2(k_1-k_3)(k_2-k_3)}{16k_1^2k_2^2}\frac{K_5^2}{K_2},\\K_6=\frac{16k_1^4}{k_3^2(k_2-k_3)^2}\frac{K_1K_2}{K_5},\quad K_7=\pm\frac{2(k_1-k_2)^2(k_2-k_3)}{k_2^2k_3}\sqrt{K_1K_2}.\end{gathered} \tag{5.9}$$

Example 5.3: The equation

$$\begin{aligned}u_t=&a_1\partial_x(\partial_x+u)^4u+a_3[(\partial_x+u)u][(\partial_x+u)^3u]+a_4[(\partial_x+u)^2u]^2\\&+b_1(\partial_x+u)^3u+b_2u(\partial_x+u)^2u+b_3[(\partial_x+u)u]^2+cu^2+d\end{aligned} \tag{5.10}$$

with $b_3=6(a_3+a_4)(3b_1+b_2)/(10a_1+3a_3+2a_4)$, admits the exact solution (5.8), where k_1, k_2, and k_3 are the three roots of the cubic polynomial $(a_3+a_4)x^3+(b_1+b_2+b_3)x^2+cx+d$, K_1, K_3, and K_5 are arbitrary and

$$\begin{aligned}l_1&=k_1[a(k_1^4-5k_1^2k_2k_3-5k_2^2k_3^2)+b_1(k_1^2-k_2k_3)],\\l_2&=k_2[a(k_2^4-5k_2^2k_3k_1-5k_3^2k_1^2)+b_1(k_2^2-k_3k_1)],\\l_3&=k_3[a(k_3^4-5k_3^2k_1k_2-5k_1^2k_2^2)+b_1(k_3^2-k_1k_2)],\end{aligned} \tag{5.11}$$

$$K_7=2\left[\frac{(k_1-k_2)(k_1-k_3)(k_2-k_3)}{k_1k_2k_3}\right]^{2/3}(K_1K_3K_5)^{1/3},\quad K_2=\frac{1}{4}\left[\frac{k_2k_3}{(k_1-k_2)(k_1-k_3)}\right]^2\frac{K_7^2}{K_1},$$

$$K_4=\frac{1}{4}\left[\frac{k_1k_3}{(k_1-k_2)(k_2-k_3)}\right]^2\frac{K_7^2}{K_3},\quad K_6=\frac{1}{4}\left[\frac{k_1k_2}{(k_1-k_3)(k_2-k_3)}\right]^2\frac{K_7^2}{K_5}.$$

Solutions of Eq. (1.22) with eight terms may describe the interaction of three solitary waves provided $n_1+n_2+n_3+n_4=0$:

Theorem 5.2: Suppose $P(x,y)$ is even and k_i $(i=1,2,3,4)$ are four roots of $P(x,x)$ and

$$\begin{gathered}k_1+k_2+k_3+k_4=0,\\ P(k_1,-k_2)=P(k_3,-k_4),\quad P(k_1,-k_3)=P(k_2,-k_4),\quad P(k_1,-k_4)=P(k_2,-k_3),\\ [2k_1l_1-P(k_1,-k_1)]A_{23}A_{24}A_{34}+[2k_2l_2-P(k_2,-k_2)]A_{13}A_{14}A_{34}\\ +[2k_3l_3-P(k_3,-k_3)]A_{12}A_{14}A_{24}+[2k_4l_4-P(k_4,-k_4)]A_{12}A_{13}A_{23}=0,\end{gathered}\tag{5.12}$$

where

$$l_i=\sum_{j\neq i}\frac{P(k_i,-k_j)}{k_i+k_j},\quad A_{ij}=(k_i-k_j)(l_i-l_j)-2P(k_i,k_j).\tag{5.13}$$

Then Eq. (1.22) admits the exact solution

$$\begin{gathered}u=(\log f)_x,\\ f=K_1e^{k_1x+l_1t}+K_2e^{-(k_1x+l_1t)}+K_3e^{k_2x+l_2t}+K_4e^{-(k_2x+l_2t)}+K_5e^{k_3x+l_3t}+K_6e^{-(k_3x+l_3t)}\\ +K_7e^{k_4x+l_4t}+K_8e^{-(k_4x+l_4t)},\end{gathered}\tag{5.14}$$

where K_1, K_3, K_5, and K_7 are arbitrary and

$$\begin{gathered}K_2=\frac{A_{23}A_{24}A_{34}}{AK_1},\quad K_4=\frac{A_{13}A_{14}A_{34}}{AK_3},\quad K_6=\frac{A_{12}A_{14}A_{24}}{AK_5},\quad K_8=\frac{A_{12}A_{13}A_{23}}{AK_7},\\ A=\pm\left(-\frac{A_{12}A_{13}A_{14}A_{23}A_{24}A_{34}}{K_1K_3K_5K_7}\right)^{1/2}.\end{gathered}\tag{5.15}$$

This solution describes the interaction of three solitary waves. Applying this result to Eq. (4.12), we find Eq. (1.31) and its exact solutions (1.32)–(1.34). We can also consider the cases that n_1, n_2, n_3, and n_4 satisfy two linear relations, which can be either $n_3=3n_1$, $n_4=2n_1+n_2$, or $n_3=3n_1$, $n_4=4n_1+n_2$, or $n_3=2n_1+n_2$, $n_4=3n_1+2n_2$. The details for these results can be found in Ref. 9.

(Received 15 September 1994; accepted for publication 18 May 1995)

The generalized Maupertuis principle is formulated for systems with the natural Lagrangian and an indefinite form of the kinetic energy. The generalization is applied to the theory of gravity and cosmology. For such systems, the metric determined by the kinetic energy form has a Lorentz signature. The theorem is proved concerning the behavior of trajectories in a neighborhood of the boundary of the region admissible for motion. This region is not a smooth manifold but turns out to be a differential space of constant differential dimension. This fact allows us to use geometric methods analogous to those elaborated for smooth manifolds. It is shown that singularities of the Jacobi metric are not dangerous for the motion; its trajectories are smooth in the sense of the theory of differential spaces. © *1996 American Institute of Physics.* [S0022-2488(95)00412-1]

I. INTRODUCTION

In the present work we study mechanical systems with Lagrange functions L which do not depend on time and are of second order in velocities, i.e., $L = \frac{1}{2}g_{\alpha\beta}\dot{q}^{\alpha}\dot{q}^{\beta} - V(q)$, where $V: M \to \mathbf{R}$ is a potential function. According to the classical Maupertuis principle, trajectories of the system, with the total energy $E = \frac{1}{2}g_{\alpha\beta}\dot{q}^{\alpha}\dot{q}^{\beta} + V(q)$, are geodesics of the Jacobi metric $\hat{g}_{\alpha\beta} = (E - V)g_{\alpha\beta}$. From the energy integral it follows that, for such systems, the motion occurs in the region for which $E - V \geqslant 0$. If $\sup_M(V) < E$, then the description of motion reduces to the study of the Riemann geometry. As far as applications to cosmology and the theory of gravity are concerned, the kinetic energy form is indefinite and the metric has the Lorentz signature. In the present work we generalize the Maupertuis principle to this case and prove the corresponding generalized Jacobi theorem. It turns out that the problem of motion is reduced to the behaviour of geodesics in certain domains of the configuration space. Spaces with the Jacobi metric are spaces with boundaries at which the metric is degenerate (we use the term ''boundary'' although in some cases below it is rather a boundary set than a boundary in a standard sense). In the case of positively definite kinetic energy form they are Riemann spaces (sections II and IV), whereas in our case they are pseudo-Riemannian spaces (sections III and V).

First non-trivial results concerning the behaviour of trajectories of classical systems with degenerate Jacobi metrics were obtained by Seifert.[1] However, intensive investigation of the domains admissible for motion $\{x \in M: V(x) \leqslant E\}$ began with Refs. 2 and 3. These works focused on the existence of closed trajectories with endpoints at the boundary $\{x \in M: E = V\}$. Kozlov's papers[3] contain a review of the obtained results. Our motivations are different. We aim at finding an invariant description of chaos in gauge theories. Our main tool is the study of separation of nearby geodesics in terms of the normal component of the separation vector satisfying the geodesic deviation equation. The present paper is a generalization of the series of previous results.[4]

The fact that the Jacobi metric degenerates at the boundary of the domain admissible for motion creates some difficulties. We show, however, that these difficulties are not dangerous since the set of the natural parameter values for which the trajectory remains at the boundary is a zero-measure subset in the set of all boundary points. This allows us to use the geodesic deviation equation (objections of Burd and Tavakol[5] notwithstanding) in spite of the fact that it is singular at the boundary.

In general, spaces with the Jacobi metric can be regarded as simple generalizations of differentiable manifolds known as differential spaces of constant differential dimension (section VI). Differential spaces were first introduced by Sikorski[6] and applied to the geometry of space–time by Gruszczak *et al.*[7] Classical analysis and differential geometry can be naturally done on such spaces. This allows us to investigate, in the precise manner, the behaviour of trajectories in a neighbourhood of the boundary of the domain admissible for motion. Such a domain can carry a Lorentz metric. This fact is important since spaces with Lorentz metrics are needed to describe systems with the indefinite kinetic energy form. It should be stressed that such mechanical systems are as important as usual classical mechanical systems. We show that for systems with both positive definite and indefinite kinetic energy forms hyperregular Lagrange functions can be defined which implies that for these systems the Lagrange and Hamiltonian formulations of mechanics are equivalent (section VII). This fact puts the Maupertuis principle on the firm base.

There exist alternative approaches to the main problem of the present work. Motion can be investigated either with the help of Euler–Lagrange equations with the metric taken from the kinetic energy form (well defined on the entire space), or with the help of the geodesic equations. In the latter case, since the Jacobi metric on the boundary is degenerate, and the geodesic equation breaks down at the boundary, one should develop the theory of motion in terms of structure tensors with lower indices as it is done in the theory of sub-Riemannian manifolds (which have found their applications to the steering theory). However, one has to remember that to apply this theory to our case, one should generalize it in two directions: to the case of the Lorentz metric and to the case of manifold with boundary (again, the theory of differential spaces could be used).

The Maupertuis principle in our approach can be regarded as a method of geometrization of a broader class of dynamical problems. It can be applied to the Hamiltonian systems with the natural Lagrange function. For instance, in the classical case (if the kinetic energy form is positive definite), this method can be used to the study of dynamics of collisionless n-body gravitating system.[8] In the non-classical case (the kinetic energy form is indefinite), the generalized Maupertuis principle can be used to the investigation of dynamical systems in general relativity and cosmology. In the so-called ADM formulation of general relativity, the dynamics of space–time is equivalent to the study of non-classical dynamical systems with a suitable potential function which is determined by the geometry of spacelike sections and the matter content in the non-vacuum case.[9] Another important field of applications of the generalized Maupertuis principle is given by the dynamics of homogeneous anisotropic cosmological models. In this case, the potential function is determined by the Lie algebras of the corresponding isometry groups acting on spacelike sections of space–time.[10]

It is worthwhile noticing that it would be meaningless to apply our method to a certain class of problems as, for instance, to the problem of motion of a test particle in the external gravitational field in general relativity. Such test particles already move along geodesics in a given space–time, and their dynamics is already geometrized. In this case, the geodesic motion is determined by the Hamilton function which coincides with the kinetic energy form.

II. CLASSICAL MECHANICS OF SIMPLE MECHANICAL SYSTEMS

In the present section we define classical mechanics of simple mechanical systems, introduce standard concepts, mainly to establish terminology, and prove the Jacobi theorem for the case of

simple mechanical systems with an indefinite kinetic energy form. This will allow us to generalize the Maupertuis principle to the case of mechanical systems within the framework of general relativity and cosmology.

Definition 1: Classical mechanics of simple mechanical systems is the triple $(\mathscr{M},K,V)$, *where* $\mathscr{M}$ *is a smooth manifold (a configuration space),* K *is the kinetic energy form defined by the Riemann metric on* $\mathscr{M}$, *i.e.,* $K(v)=\frac{1}{2}g(v,v)$ *for every* $v \in T_x\mathscr{M}$, $x \in \mathscr{M}$, *and* V *is the potential energy of the system.*,[8,11]

These systems are called *classical* since their kinetic energy form is positively definite; they are called *simple* since they have a natural Lagrangian.

For a given total energy E of the system the *admissible configuration space* is given by

$$\hat{\mathscr{M}}_E=\{x\in\mathscr{M}: V(x)\leqslant E\}.$$

To the total energy E there corresponds the Jacobi metric g_E of the simple classical mechanical system $(\mathscr{M},K,V)$ given by

$$g_E(x):=2(E-V(x))g(x).$$

This is a Riemann metric on a configuration space M_E parametrized by E. It is non-degenerate on $M_E=\{x \in \mathscr{M}: V(x)<E\}$, and degenerate on the boundary $\partial M_E=\{x \in \mathscr{M}: V(x)=E\}$.

As is well known, one obtains the trajectories of a simple mechanical system by extremalizing the action

$$I[C]=\int_a^b L(C(t))dt,$$

where $L(x,v)=\frac{1}{2}g_x(v,v)-V(x)$. The Maupertuis principle, in its original formulation, consisted in considering only those trajectories which satisfy the condition

$$\tfrac{1}{2}g(\dot{C}(t),\dot{C}(t))=E-V(C(t)),$$

where a dot means differentiation with respect to t.

Historically, the Maupertuis principle preceded a simpler Hamilton principle. The precise formulation of the Maupertuis principle we owe to Jacobi (see Ref. 2). After taking into account the above Maupertuis condition, the first variation of the action assumes the form

$$\delta I[C]=\delta\int_a^b g(\dot{C},\dot{C})dt=\delta\int_a^b\{2[E-V(C(t))]g(\dot{C},\dot{C})\}^{1/2}dt=0.$$

Consequently, physical trajectories of the system with the total energy E are geodesics of the Jacobi metric $2(E-V)g$. This heuristic argumentation can be repeated for the case with the indefinite kinetic energy form. To this end, it is enough to replace the expression $2(E-V(C(t)))$ by $2|E-V(C(t))|$.

Theorem 1 (Jacobi): *Physical trajectories of a simple classical system* $(\mathscr{M},K,V)$ *[or equivalently* (M,g,V)*] with the total energy* E *are geodesics on the Riemann manifold* (M_E,g_E).

Since the proof of this theorem is well known we shall present only those of its aspects which will allow us to generalize the above theorem to the case with the indefinite kinetic energy form (in section III).

The proof of the Jacobi theorem consists in considering the Lagrange-Euler equations in a local map, i.e.,

$$\frac{d}{dt}\frac{\partial L}{\partial \dot{x}^i(t)}=\frac{\partial L}{\partial x^i(t)}, \tag{1}$$

where

$$L=\tfrac{1}{2}g(\dot{C}(t),\dot{C}(t))-V(C(t))=\tfrac{1}{2}g_{ij}(x(t))\dot{x}^i(t)\dot{x}^j(t))-V(x(t)). \tag{2}$$

After inserting (2) into (1) we obtain

$$\ddot{x}^p(t)+\Gamma^p_{rs}(x(t))\dot{x}^r\dot{x}^s=-g^{pi}\partial_i V(x(t))=-(\mathrm{grad}V)^p(x(t)) \tag{3}$$

or, equivalently, the Euler-Lagrange equation

$$\nabla_{\dot{C}(t)}\dot{C}(t)=-\mathrm{grad}V(C(t)).$$

Equation (3) with the convention

$$e^{2f}=2|E-V|$$

assumes the form

$$\ddot{x}^i(t)+\hat{\Gamma}^i_{jk}(x(t))\dot{x}^j(t)\dot{x}^k(t)=\frac{d}{dt}\ln|E-V(x(t))|\dot{x}^i(t), \tag{4}$$

where $\hat{\Gamma}^i_{jk}$ are Christofell symbols with respect to the Jacobi metric $\hat{g}_E$. We have taken into account the equality $2df(\dot{C})=2\dot{x}^i(t)(\partial_i f)x(t)$ (for detailed calculations see, Refs. 8, 11).

Now, we introduce the reparametrization $s=s(t)$ to obtain

$$\left(\frac{ds}{dt}\right)^2 x^i(s)''+\frac{d^2s}{dt^2}x^i(s)'+\left(\frac{ds}{dt}\right)^2\hat{\Gamma}^i_{jk}x^j(s)'x^k(s)'=\left\{\left[\frac{d}{dt}\ln|E-V(x(t))|\right]\frac{ds}{dt}\right\}x^i(s)', \tag{5}$$

where prime denotes differentiation with respect to s. After eliminating the terms with first derivatives of x^i from equation (5), we obtain

$$\frac{ds}{dt}=\kappa|E-V(x(t))|,$$

where κ is a real number. We choose $\kappa=2$ to guarantee

(1) that s should be a monotonic function of the Newtonian time t,

(2) that the tangent vector to the geodesic should be normed to $+1$, or to -1, or that it should be a null vector, i.e.,

$$g_E(x',x')=\mathrm{sgn}(E-V). \tag{6}$$

Therefore, if we take the natural parameter s for the Jacobi metric, i.e.,

$$\frac{ds}{dt}=2|E-V|, \tag{7}$$

the trajectory equation assumes the form of the geodesic equation

$$x^i(s)'' + \hat{\Gamma}^i_{jk}(x(t))x^j(s)'x^k(s)' = 0, \tag{8}$$

which ends the proof. □

III. NON-CLASSICAL MECHANICS OF SIMPLE MECHANICAL SYSTEMS

Definition 2: Non-classical mechanics of simple mechanical systems is the triple $(\mathcal{M},K,V)$ *(or* (M,g,V)*) where* $\mathcal{M}$ *is a smooth manifold (configuration space), K is the indefinite kinetic energy form,* $K(v)=\frac{1}{2}g(v,v)$*, and V is the potential energy of the system.*

These systems are called non-classical since their kinetic energy form is indefinite. We assume that the signature of g is $(+,+,\ldots,+,-)$.

In the configuration space of simple non-classical mechanical systems we define the following subsets

(a) D_T: the subset of the configuration space $\mathbf{R}^N$ on which $E-V<0$,

(b) D_S: the subset of $\mathbf{R}^N$ on which $E-V>0$,

(c) ∂D: the subset of $\mathbf{R}^N$ on which $V=E$.

In the theory of gravity (cosmology included), especially interesting is the class of simple mechanical systems with $E=0$, we shall call them *zero constraint mechanical systems* (ZC-systems).

Definition 3: In the tangent space to the configuration space $\mathbf{R}^N$ *of simple non-classical mechanical systems, we define the following classes of vectors*

(a) $v \in T_q\mathbf{R}^N$ *is timelike if* $g_{\alpha\beta}(q)v^\alpha v^\beta<0, q \in M$,

(b) $v \in T_q\mathbf{R}^N$ *is spacelike if* $g_{\alpha\beta}(q)v^\alpha v^\beta>0, q \in M$,

(c) $v \in T_q\mathbf{R}^N$ *is null if* $g_{\alpha\beta}(q)v^\alpha v^\beta=0, q \in M$.

The Hamiltonian constraint $(H=E=0)$ implies the following properties of the tangent vector to any trajectory

(a′) any tangent vector in the domain D_T is timelike,

(b′) any tangent vector in the domain D_S is spacelike,

(c′) the tangent vector to any trajectory through a point $q_0 \in \partial D$ is a null vector, i.e., it is situated on the surface given by $g_{\alpha\beta}(q_0)\xi^\alpha\xi^\beta=0$.

The above regularities allow us to generalize the Jacobi theorem to the case of non-classical simple mechanical systems.

Theorem 2: *Physical trajectories of a non-classical simple mechanical system with the total energy E are geodesics on a pseudo-Riemannian manifold without a boundary on which the Jacobi metric is degenerate.*

Proof follows from that for the classical case together with definitions 2 and 3, and their consequences. □

IV. APPLICATION OF THE MAUPERTUIS PRINCIPLE TO SIMPLE CLASSICAL MECHANICAL SYSTEMS

We shall distinguish two cases

(1) $E>\max_M V$,

(2) $E\leqslant\max_M V$.

Of course, we assume that the potential function has no critical points on $\{V=E\}$. In case (1), $\hat{M}_E$ coincides with the entire configuration space. For instance, the problem of the existence of periodic solutions to the equations of motion reduces to the problem of finding closed geodesics on a smooth Riemann manifold. In general, we can use known theorems about the behaviour of geodesics on Riemann manifolds to solve various problems, but this case is seldom physically interesting.[3]

Example 1: Let us consider a torus T^2 with a Riemann metric. Among all closed curves with m rotations in the parallel surface and n rotations in the orthogonal surface, there exists the curve

of the minimal length. It is a closed geodesic. T^2 is a position space of a double plane pendulum. It follows that, for any integers m and n, there exists a periodic motion of the double pendulum in which one arm performs m rotations and the other arm performs n rotations.

In case (2), the boundary ∂M_E is non-empty, and the Jacobi metric has a singularity on ∂M_E; lengths of all curves in ∂M_E are equal to zero. In this case, the geometry of the admissible configuration space is different from that of the ordinary Riemann compact manifolds. (For a review of the problem of geodesics on spaces with the Jacobi metrics degenerating at the boundary, see Refs. 3, 12.)

The theory of closed geodesics was intensively investigated beginning from the classical Poincaré works. These works were a part of the program of the qualitative study of mechanical systems. The problem of the periodic trajectories was reduced by Poincaré to the existence of closed geodesics. Later on it was investigated by many authors.

With the additional assumptions that the configuration space M_E is compact and has the non-empty boundary ∂M_E, which is an $(N-1)$-dimensional smooth manifold, Kozlov was able to prove the following propositions[3]:

(1) Let us consider the motion $q(t)$ of a simple classical mechanical system with the initial condition at $t=0$: $q(0)=q_0$, $\dot{q}(0)=v_0$. $q(-t)$ is a solution of the same equations with the initial condition $q(0)=q_0$, $\dot{q}(0)=-v_0$, and $q(\pm t)=q(\mp t)$. The proof follows directly from properties of Lagrange equations and from the theorem on the uniqueness of solutions for the Lagrange systems with a positive definite kinetic energy form (as far as we know, for systems with an indefinite kinetic energy form the uniquness was never proved). The fact that $q(t)=q(-t)$ is a simple consequence of the above, i.e., if the trajectory $q(t)$ reaches the boundary at $t=0$ then the motion, after colliding with the boundary, will continue in the opposite direction along the same trajectory.

(2) There are no solutions of the motion equations the trajectories of which cross the boundary at more than two different points. The proof is elementary, and it follows from the fact that if a trajectory crossed the boundary at three points, A, B, C say, then a point m moving from A would reach B, and then—in agreement with (1)—it would continue in the opposite direction along the same trajectory. After a certain period of time it would again reach A, etc.

(3) If trajectories of motion have two common points with the boundary, they can have no other common points with the boundary, and the solution is periodic.

(4) In the close neighbourhood of the boundary, trajectories of motion are orthogonal to the boundary. To illustrate this proposition let us consider a simple classical mechanical system with the Lagrange function

$$\mathscr{L}=\tfrac{1}{2}K\delta_{ij}\dot{q}^i\dot{q}^j-V(q),$$

where $K=\text{const}$. Since the metric $g_{ij}=K\delta_{ij}$ is constant, the Christoffel symbols vanish and the Euler–Lagrange equations are

$$\ddot{\mathbf{q}}=-\nabla V.$$

Let us consider the trajectory of the system with the initial condition $\mathbf{q}_0 \in \partial D$, where $\dot{\mathbf{q}}(0)=0$ (at the boundary $t=0$). This trajectory can be presented in the form

$$\mathbf{x}(t)=\mathbf{x}_0+\dot{\mathbf{x}}(0)t+\tfrac{1}{2}\ddot{\mathbf{x}}(0)t^2+\cdots=\mathbf{x}_0-\tfrac{1}{2}\nabla V(\mathbf{x}_0)t^2+\cdots,$$

that is, for small $t<\varepsilon$ (near the boundary), the trajectory is determined by the gradient vector (which is orthogonal to the equipotential surface). This means that the particle moves orthogonally to the boundary, for $|t|<\varepsilon$.

To see how the Maupertuis principle works in simple classical mechanical systems let us consider a harmonic oscillator.[8]

Example 2: In the case of a harmonic oscillator the Lagrange function is

$$\mathscr{L}=\frac{m\dot{x}^2}{2}+\frac{m\omega^2x^2}{2}$$

which implies that the metric (of the kinetic energy form) g is equal to m.

The Jacobi metric is

$$\hat{g}=2\left(E-\frac{m\omega^2x^2}{2}\right)m,$$

the domain admissible for motion

$$D_E=\left\{x\in\mathbf{R},-\frac{1}{\omega}\left(\frac{2E}{m}\right)^{1/2}\leqslant x\leqslant\frac{1}{\omega}\left(\frac{2E}{m}\right)^{1/2}\right\}$$

and its boundary

$$\partial D_E=\left\{-\frac{1}{\omega}\left(\frac{2E}{m}\right)^{1/2},\frac{1}{\omega}\left(\frac{2E}{m}\right)^{1/2}\right\},$$

the only non-vanishing Christofell symbol

$$\hat{\Gamma}^1_{11}=-\frac{m\omega^2x}{2E-m\omega^2x^2}\left(\frac{dx}{ds}\right)^2=0.$$

The normalization condition of the tangent vector $\|u\|^2=1$ reduces to

$$m(2E-m\omega^2x^2)\left(\frac{dx}{ds}\right)^2=1.$$

This equation defines the natural parameter s along the geodesic. After differentiating the above equation with respect to s one obtains the geodesic equation. Therefore, the geodesic equation informs us that the norm of the tangent vector is preserved if one changes the parameter s. The solution of the above equation is

$$x(t)=\frac{1}{\omega}\left(\frac{2E}{m}\right)^{1/2}\sin\,\omega(t-t_0),$$

$$x(s)\arcsin\left(\omega\sqrt{\frac{m}{2E}}x\right)+\omega\sqrt{\frac{m}{2E}}x\left(1-\frac{\omega^2m}{2E}x^2\right)^{1/2}=\frac{\omega}{E}(s-s_0),$$

and

$$s(t)=E\left[(t-t_0)+\frac{\sin 2\omega(t-t_0)}{m}\right]+s_0.$$

Of course, $s(t)$ is a strictly monotonic function of the Newtonian time t.

V. APPLICATIONS OF THE MAUPERTUIS PRINCIPLE TO SIMPLE NON-CLASSICAL MECHANICAL SYSTEMS

The problem of the dynamics of non-classical simple mechanical systems in the Maupertuis approach is, in principle, an open question. Kozlov's theorems should be generalized to the two following cases: (1) to Lagrange systems with the natural Lagrangian and indefinite form of the kinetic energy; (2) to non-classical systems with and without a boundary which is not a smooth manifold.

The following theorem is a counterpart for the pseudoriemannian case of Kozlov's property 4 (see section IV):

Theorem 3: *A trajectory of a system with the natural Lagrangian and an indefinite form of the kinetic energy, when passing through the boundary of the region admissible for motion, changes the sector of the cone which is determined by the kinetic energy form.*

Proof follows from the construction of the Maupertuis principle and from properties of the tangent vector to the trajectory (properties (a′) – (c′) in section 3). □

Let us consider the following example. Let the energy function be

$$\mathscr{E}=\tfrac{1}{2}k\,\eta_{\mu\nu}\dot{x}^{\mu}\dot{x}^{\nu}+V(x),$$

where

$$\eta_{\mu\nu}=\mathrm{diag}\|-1,1,1,\ldots\|,k=\mathrm{const.}$$

We assume that the boundary ∂D of the region D admissible for the motion is a smooth manifold. For $x\in\partial D$ one has $\eta_{\mu\nu}\dot{x}^{\mu}\dot{x}^{\nu}=0$. In the case of a non-classical system, $\dot{x}^{\mu}(0)\neq 0$ at the boundary! We investigate the motion in a small neighbourhood of the boundary. The trajectory starts in this neighbourhood at $t=0$. For small times, $|t|<\varepsilon$ the linear approximation is valid

$$\mathbf{x}(t)=\mathbf{x}_0+\dot{\mathbf{x}}_0t+\cdots,$$

i.e., for $|t|<\varepsilon$, the motion is determined by the vector $\dot{\mathbf{x}}_0$ which is situated on the cone.

Example 3: As a special case of the above system, let us consider a Hamiltonian system describing the dynamics of the Friedman cosmological model with the scalar field.[13] The Hamiltonian of this system is

$$\mathscr{H}=\mathscr{H}(p_1,p_2,q^1,q^2)=\tfrac{1}{2}\eta^{\mu\nu}p_{\mu}p_{\nu}+V(q^1,q^2),$$

where

$$\eta^{\mu\nu}=\mathrm{diag}(-1,1),$$

$$V(q^1,q^2)=\tfrac{1}{2}[-(q^1)^2+(q^2)^2+m^2(q^1)^2(q^2)^2].$$

The Hamiltonian constraint is $\mathscr{H}=0$ which is typical for gravitational systems. Therefore, the motion takes place in the region given by

$$-(\dot{q}^1)^2+(\dot{q}^2)^2=-(q^1)^2+(q^2)^2+m^2(q^1)^2(q^2)^2=-2V(q^1,q^2).$$

In this case, the kinetic energy form is indefinite and divides the configuration space into subdomains.

Kozlov[3] claims that some theorems concerning the behaviour of trajectories, in the general case of the reversible Hamiltonian systems, are valid independently of generalizations (1) and (2). For instance, one has

Theorem 4 (Kozlov): *Let* $x:(-\varepsilon,\varepsilon)\to B$ *be a motion of a system with a natural Lagrangian and* $x(0)\in\partial D$. *Then* $x(t)=x(-t)$ *for every* $-\varepsilon<t<\varepsilon$.

It seems that this theorem cannot be applied to the case with an indefinite kinetic energy form. If a point hits ∂D, it moves along the same trajectory in the oppposite direction. In the work by Hofer and Toland,[14] the existence of libration motions has been proved provided that D_T is compact and convex, and there are no critical points of the potential function on the boundary ∂D. The proof uses topological theorems about fixed points of smooth mappings.

Hoffer and Toland[14] consider also the existence of periodic motions of non-classical systems with the Lagrangian $(S\dot{x},\dot{x})/2-V(x)$, where $(\cdot,\cdot)$ is the scalar product in $\mathbf{R}^N$, and S is a symmetric, non-degenerate, linear operator with one negative eigenvalue. Let $\Sigma=\{y\in\mathbf{R}^n:(Sy,y)<0\}$ be a cone in $\mathbf{R}^n$. If $x(\cdot)$ is a motion with the vanishing total energy starting in the region $C=\{x:V(x)>0\}$ then $\dot{x}\in\Sigma$. Since Σ consists of two connected components, the transition from one component to another component can occur only at the boundary C.

Some theorems, which are true for simple classical mechanical systems (as, for example, Kozlov's theorem), have no counterparts for simple non-classical mechanical systems. This is illustrated by the following example.

Example 4: A simple non-classical mechanical system in a neighbourhood of the boundary ∂D_E. Let us consider a system with the natural Lagrangian $\mathscr{L}=\frac{1}{2}\eta_{\alpha\beta}\dot{q}^\alpha\dot{q}^\beta-V(q)$, where $\eta_{\alpha\beta}=\mathrm{diag}\|1,\ldots,-1\|$ is a metric with the Lorentz signature. We synchronize time so that $t=0$ corresponds to the moment at which the particle is at ∂D_E and $V(x_0^1,\ldots,x_0^n)=0$. The tangent vector to the cone $\eta_{\mu\nu}(x_0^1,\ldots,x_0^n)\xi^\mu\xi^\nu=0$, $\xi^\mu\equiv\partial x^\mu/\partial t,$, is

$$x^\mu(t)=x_0^\mu+t\dot{x}_0^\mu+\frac{t^2}{2}\ddot{x}_0^\mu+O(t^2). \tag{9}$$

For a 2-dimensional case, the above equation has the form

$$\begin{aligned} x(t)&=x_0+t\dot{x}_0+\frac{t^2}{2}\frac{\partial V}{\partial x}(x_0,y_0)+O(t^2),\\ y(t)&=y_0\pm t\dot{x}_0+\frac{t^2}{2}\frac{\partial V}{\partial y}(x_0,y_0)+O(t^2), \end{aligned} \tag{10}$$

where (x,y) are Cartesian coordinates of the trajectory, $\dot{x}_0=\pm\dot{y}_0$, and $V(x_0,y_0)=0$ on the boundary ∂D_E.

Expansion (9), when applied to classical systems, leaves only terms with even exponents α in t^α. To see this, it is enough to notice that, for a 1-dimensional system, the trajectory $q(t)$, for small t, is given by

$$q(t)=q_0-\frac{t^2}{2}\frac{\partial V}{\partial q}(q_0)+O(t^2). \tag{11}$$

Indeed, since the velocity of the particle at the boundary ∂D_E vanishes, expansion (9) leaves the terms with even exponents of t, for instance:

$$\dddot{q}(t)=\frac{d}{dt}(\ddot{q}(t))=\frac{-\partial^2 V}{\partial q^2}\dot{q}=0,\qquad \dddot{q}(t)=\frac{\partial^2 V}{\partial q^2}\ddot{q}\neq 0$$

at the boundary ∂D_E.

This is not true as far as non-classical mechanical systems are concerned and, consequently, Kozlov's generalization is not correct. This can be seen already in the linear approximation (see (10)). However, the assertion remains true that if $q(t)$ is a solution of the Euler-Lagrange equation

with the initial condition $q(0)=q_0,\dot{q}(0)=v_0$, then $q(-t)$ is also a solution with the initial condition $q(0)=q_0,\dot{q}(0)=-v_0$. It is enough to notice that if $t\to -t$, $\dot{x}_0\to -\dot{x}_0$, $\dot{y}_0\to -\dot{y}_0$, and $x(0)=x_0$, $y(0)=y_0$, one obtains the trajectory $(x(t),y(t))$. For classical mechanical systems, from (11) one has $q(\pm t)=q(\mp t)$.

To study our system in a neighbourhood of ∂D_E let us consider the squared length of the tangent vector $\dot{\mathbf{x}}$ to the trajectory

$$\|\dot{\mathbf{x}}\|^2 \equiv \eta_{\mu\nu}\frac{dx^\mu}{d\tau}\frac{dx^\nu}{d\tau} = -2V(x). \tag{12}$$

By using (9) in the linear approximation of the potential and the trajectory we obtain: for a 2-dimensional system

$$\begin{aligned}\|\dot{\mathbf{x}}\|^2 &= -2(x_0+t\dot{x}_0, y_0\pm t\dot{x}_0)\\ &= -2V(x_0,y_0)-2t\left[\frac{\partial V}{\partial x}(x_0,y_0)\dot{x}_0\pm\frac{\partial V}{\partial y}(x_0,y_0)\dot{x}_0\right]\\ &= -2V(x_0,y_0)-2t\left[\frac{\partial V}{\partial x}(x_0,y_0)\dot{x}_0\pm\frac{\partial V}{\partial y}(x_0,y_0)\dot{x}_0\right],\end{aligned} \tag{13}$$

and for a multidimensional system

$$\|\dot{\mathbf{x}}\|^2 = -2(x_0^1+t\dot{x}_0^1, x_0^2+t\dot{x}_0^2, \ldots, x_0^n+t\dot{x}_0^n) = -2t\sum_{\mu=1}^{n}\frac{\partial V}{\partial x^\mu}(x_0^1,\ldots,x_0^n)\dot{x}_0^\mu. \tag{14}$$

From (14) it can be seen that, for small t, the function f of the squared velocity is an odd function of t, and it changes the sign when passing through ∂D_E, i.e.,

$$\|\dot{\mathbf{x}}\|^2 = \begin{cases} f>0 & \text{if} \quad t<0\\ f=0 & \text{if} \quad t=0.\\ f<0 & \text{if} \quad t>0\end{cases}$$

To describe the behaviour of trajectories further away from the boundary ∂D_E one should take into account at least second order terms in expansion (9) and (10). Taking into account second order terms in (9) and (10), in the second order approximation of the function $\|\dot{\mathbf{x}}\|^2$ (see (14)), for the 1-dimensional and multidimensional cases, we obtain, respectively,

$$\begin{aligned}\|\dot{\mathbf{x}}\|^2 &= -2V\left(x_0+t\dot{x}_0-\frac{t^2}{2}\frac{\partial V}{\partial x}(x_0,\,y_0), y_0\pm t\dot{x}_0+\frac{t^2}{2}\frac{\partial V}{\partial y}(x_0,\,y_0)\right)\\ &= -2V(x_0,y_0)-2t\left[\frac{\partial V}{\partial x}(x_0,\,y_0)\dot{x}_0\pm\frac{\partial V}{\partial y}(x_0,y_0)\dot{x}_0\right]-t^2\left[\left(\frac{\partial V}{\partial x}\right)^2(x_0,\,y_0)+\left(\frac{\partial V}{\partial y}\right)^2(x_0,y_0)\right.\\ &\quad\left.+\frac{\partial^2 V}{\partial x^2}(x_0,\,y_0)\dot{x}_0^2+\frac{\partial^2 V}{\partial y^2}(x_0,y_0)\dot{x}_0^2\mp\frac{\partial^2 V}{\partial x\partial y}(x_0,y_0)\dot{x}_0^2\right]+\mathcal{O}(t^2),\end{aligned}$$

$$\|\dot{\mathbf{x}}\|^2=-2t\sum_{\mu=1}^{n}\frac{\partial V}{\partial x^\mu}(x_0^1,\ldots,x_0^n)\dot{x}_0^i-t^2\left[\sum_{\mu=1}^{n-1}(-1)\left(\frac{\partial V}{\partial x^\mu}\right)^2+\left(\frac{\partial V}{\partial x^n}\right)^2+\frac{\partial^2 V}{\partial x^{i2}}(\dot{x}_0^i)^2+\frac{\partial^2 V}{\partial x^i\partial x^j}\dot{x}_0^i\dot{x}_0^j\right]. \tag{15}$$

From (15) one can deduce that, after a certain time t_{cr}, the trajectory will return to the boundary. For the n-dimensional case one has

$$t_{cr}=\left.\frac{\sum_{\mu=1}^{n}\frac{\partial V}{\partial x^\mu}(x_0^1,\ldots,x_0^n)\dot{x}_0^\mu}{\sum_{\mu=1}^{n-1}\left(\frac{\partial V}{\partial x^\mu}\right)^2-\left(\frac{\partial V}{\partial x^n}\right)^2+\frac{\partial^2 V}{\partial x^{i2}}(\dot{x}_0^i)^2+\frac{\partial^2 V}{\partial x^i\partial x^j}\dot{x}_0^i\dot{x}_0^j}\right|_{(x_0^1,\ldots,x_0^n)\in C}, \tag{16}$$

where C is given by $\Sigma_{\mu=1}^{n-1}(x^\mu)^2-(x^n)^2=0$.

If t_{cr} exists and is finite, one can similarly compute the next cycle after which the system will be again at the boundary ∂D_E. Systems are known for which there are infinitely many such cycles.

VI. SPACES WITH THE JACOBI METRIC AS DIFFERENTIAL SPACES

The existence of a singular boundary in the Maupertuis image of dynamics creates serious problems with using standard analysis on smooth manifolds. In the present section, we show that the problem can be dealt with in the framework of the theory of the so-called differential spaces. The differential space concept generalizes the concept of smooth manifold to such an extent that every subset of $\mathbf{R}^n$ is a differential space (d-space, for short).[6] We shall need only especially nice (and easy workable) subclass of d-spaces, namely the d-spaces of constant differential dimension. These d-spaces are similar to smooth manifolds: local calculations are the same as on manifolds; in particular, tensors can be dealt with locally and globally as on manifolds; the majority of objects (e.g., external forms) behave in the natural way.

As is well known, a smooth manifold can be defined as a pair $(M,\mathscr{C})$ where $\mathscr{C}=C^\infty(M)$ is a family of smooth real functions on a set M satisfying the following axioms: (i) $\mathscr{C}$ is closed with respect to localization, (ii) $\mathscr{C}$ is closed with respect to composition with the set $C^\infty(\mathbf{R})^n$ of all smooth functions on $\mathbf{R}^n$, i.e., for any $n\in\mathbf{N}$, and $\omega\in C^\infty(\mathbf{R})^n$, $f_1,\ldots,f_n\in\mathscr{C}$ implies that $\omega\circ(f_1,\ldots,l_n)\in\mathscr{C}$, (iii) M is locally diffeomorphic to $\mathbf{R}^n$. One considers the weakest topology on M in which the functions of $\mathscr{C}$ are continuous. Axiom (i) requires the following concept. A function defined on $U\subset M$ is said to be a *local* $\mathscr{C}$-function if for every $p\in U$ there is a neighbourhood V of p (in the topology on U induced from that on M) and a function $g\in\mathscr{C}$ such that $f|V=g|V$. The set of all local $\mathscr{C}$-functions is denoted by $\mathscr{C}_U$. One has $\mathscr{C}|U\subset\mathscr{C}_U$, and consequently $\mathscr{C}\subset\mathscr{C}_M$. If $\mathscr{C}=\mathscr{C}_M$, the family $\mathscr{C}$ is said to be *closed with respect to localization.* If we drop axiom (iii) we obtain the definition of a differential space. $\mathscr{C}$ is called a differential structure and M its *support.*

Most of calculation tools for d-spaces is developed in terms of tangent vectors. A tangent vector to a d-space $(M,\mathscr{C})$ at $p\in M$ is a linear mapping $v:\mathscr{C}\to\mathbf{R}$ satisfying the Leibniz rule. The set of all tangent vectors at $p\in M$ is the *tangent space* $T_p(M,\mathscr{C})$ to a d-space $(M,\mathscr{C})$ at $p\in M$.

A d-space $(M,\mathscr{C})$ is said to be of *constant differential dimension n* if, for every $p\in M$, there exist an open neighbourhood W in the topology of M and a smooth manifold $\tilde{M}$ of the minimal dimension n such that $C^\infty(M)_W=C_W$, $W\subset\tilde{M}$, where $C=(C^\infty(\mathbf{R}_n))_M$ is the differential structure on M.

First we shall prove (1) that the region admissible for motion of any classical or non-classical system is a d-space of constant differential dimension; (2) that singularities of trajectories of

classical or non-classical systems are not malicious in the sense that the set of point-instances at which a particle is at the boundary consists of isolated points (it contains no interval).

(1) follows from the following:

Lemma 1: If $M\subset\mathbf{R}^n$ *satisfies the condition* $\overline{\mathrm{Int}M}=M$, *then* $\dim T_pM=n$ *for any* $p\in M$.

Proof. Let $p\in \mathrm{Int}M$. Since $\mathrm{Int}M$ is open in $\mathbf{R}^n$, $\dim T_pM=n$. Now, let $p\in M\backslash \mathrm{Int}M$, i.e., p is an accumulation point of M. Let $\tilde{M}$ be a smooth manifold of the minimal dimension k such that there exists an open neighbourhood W of p and $W\subset\tilde{M}$, $C^\infty(\tilde{M})_W=C_W$. Since p is an accumulation point of M, $W\cap\mathrm{Int}M$ is a non-empty open subset of $\mathbf{R}^n$. It follows that $\tilde{M}$ contains an open subset of $\mathbf{R}^n$, $\dim\tilde{M}=k\geqslant n$. We know, however, that $k\leqslant n$, since $\tilde{M}\subset\mathbf{R}^n$. □

Since $\overline{\mathrm{Int}\Omega}=\Omega$, statement (1) follows.

To prove (2) let us notice that in the classical case trajectories do not go ''physically'' through the boundary ∂D. Let $c:[-\varepsilon,\varepsilon]\to\mathbf{R}^n$ be a curve passing through ∂D. For non-classical systems, the geodesic equation $\hat{\nabla}_{C'(s)}C'(s)=0$ can be written on the entire $\mathbf{R}^n$. The only problem is what happens at the boundary. Let us define the set of parameters for which the trajectory remains at the boundary (where the metric is degenerate) by $c^{\#}=\{s:c(s)\in\partial D\}$. Two cases should be considered: (a) $c^{\#}$ consists of isolated points, (b) $c^{\#}$ contains an interval of parameters.

In case (a), the trajectory is uniquely defined by the geodesic equation on the set $D_T\cup D_S$ and can be uniquely prolonged to ∂D. Since $[-\varepsilon,\varepsilon]\backslash c^{\#}$ is dense in $[-\varepsilon,\varepsilon]$, this follows from continuity (moreover c is a smooth geodesic in the sense of the d-space theory).

Case (b) implies that the tangent vector to the geodesic has a component which is tangent to ∂D along a certain interval. In the case of classical systems it is impossible since the velocity $\|u\|$ at the boundary is zero. In the non-classical case, trajectories go through the boundary transversally changing the sector of the cone. (Let us notice that if a trajectory remained in ∂D, for a certain time interval, the motion would not be determined.)

The singularity problem for non-classical systems is not dangerous since trajectories can be suitably prolonged through the boundary (and made smooth in the sense of d-space theory), and the motion can occur in the entire $\mathbf{R}^n$. For classical systems singularities, if they exist, are physical, and the motion can take place only in a region of $\mathbf{R}^n$ limited by the surface of the zero velocity.

VII. EQUIVALENCE OF LAGRANGE AND HAMILTON FORMULATION OF MECHANICS

In the present section, we shall show, by using methods of differential spaces, that for both classical and non-classical simple mechanical systems the Lagrange formulation of mechanics is equivalent to the Hamilton formulation of mechanics. This fact gives a solid base to the Maupertuis principle as it was presented in the preceding sections. Let us begin with simple classical mechanical systems.

Let M be a differential space of class $\mathscr{D}_0$, and $L:TM\to\mathbf{R}$ a smooth Lagrange function. We define a fibre derivative $\mathscr{L}:TM\to T^*M$, where T^*M is the space of covectors, by

$$\langle\mathscr{L}(u),v\rangle=\left.\frac{d}{dt}\right|_{t=0}(t\mapsto L(u+tv))$$

for $u,v\in TM$ such that $\pi(u)=\pi(v)$, where $\pi:TM\to M$ is the canonical projection of the tangent bundle. In the literature, fibre derivative is known as Legendre transformation (see, for instance, Ref. 15). In the case of simple classical mechanical systems, Lagrange function L is said to be hyperregular if $\mathscr{L}$ is a global diffeomorphism. It is evident that in such a case the Lagrange formulation of mechanics is equivalent to that of Hamilton. A mechanical system $(\mathscr{M},K,V)$ with the Lagrange function $L=K-V\circ\pi$ is an example of a mechanical system with the hyperregular Lagrange function. We shall show even more, namely that a simple classical mechanical system

with a Jacobi metric on its configuration space with boundary is a mechanical system the Lagrange function of which is hyperregular (provided that tangent and cotangent spaces are suitably chosen).

Let, as before, $\bar{M}_E=\{x \in M: V(x)\leqslant E\}$ be the admissible configuration space with the Jacobi metric g_E such that $g_E|\partial M_E=0$. Let us consider the Lagrange function of g_E, $L_E: T\bar{M}_E\to\mathbf{R}$, given by $L_E(v)=\frac{1}{2}g_E(v,v)$. Physically, it describes the motion of a free particle on the space with boundary carrying the Jacobi metric.

Now, we introduce (after Spallek[16]) the concept of locally integrable vector field. A vector field $X \in \mathscr{X}(\bar{M}_E)$ is said to be locally integrable if, for any point $p \in \bar{M}_E$, there locally exists an integral curve of X. For smooth manifolds every smooth vector field is locally integrable. However, for spaces with singularities this need not be the case. Spallek[16] has demonstrated that, in the case of a differential space of constant dimension having the form $M_E \cup \partial M_E$, locally integrable vector fields are tangent to the boundary ∂M_E.

Following Spallek's suggestion[17] that to every problem on spaces with singularities one should choose a suitable concept of tangent space (and that of differentiation), we shall consider the submodule $\tilde{\mathscr{X}}^i(\bar{M}_E)\subset\mathscr{X}^i(\bar{M}_E)$ of locally integrable vector fields on $\bar{M}_E$ which vanish at the boundary $\partial\bar{M}_E$. Let us notice that the fields $\tilde{\mathscr{X}}^i(M_E)$ have a physical meaning. With this choice we are able to prove the following theorem

Theorem 5: *Legendre transformation* $\mathscr{L}: T^i\bar{M}_E\to T^{*i}\bar{M}_E$, *where* $T^i\bar{M}_E=\{v \in T\bar{M}_E: \exists X \in \tilde{\mathscr{X}}^i(\bar{M}_E), X(\pi(v))=v\}$ *and* $T^{*i}\bar{M}_E=\mathscr{L}(T^i\bar{M}_E)$ *is a cotangent space with the natural differential structure induced by* $\mathscr{L}$, *is a global diffeomorphism.*

Proof: It can be easily seen that $T^i_p\bar{M}_E=\{0\}$ for any $p \in \partial M_E$. Of course, $\mathscr{L}$ is a global diffeomorphism over M_E which implies that it is an isomorphism on fibres. Over boundary points the zero fibre is transformed into the zero fibre (the zero vector into the zero vector) which ends the proof. □

The equivalence of the Lagrange and Hamilton formulations of mechanics following from the hyperregularity of the Lagrange function is a strong conclusion which removes all objections against the Maupertuis principle.[18]

In particular, it is clear that the existence of the boundary ∂M_E does not violate the precise formulation of the Maupertuis principle. To see what exactly happens on the boundary let us consider a more general situation of a configuration space M with singularities (which can be organized into a kind of boundary) such that there exist a differentiable manifold $\tilde{M}$ and a surjection $\tilde{\pi}:\tilde{M}\to M$ with the property that, for regular (non-singular) points of M, $\tilde{\pi}$ is a covering. Any Lagrange function $L: TM\to\mathbf{R}$ determines a Lagrange function $\tilde{L}=L\circ\tilde{\pi}$ on the tangent bundle $T\tilde{M}$. Projections of the tangent vector fields to $\tilde{M}$ which are compatible with the mapping $\tilde{\pi}$ (i.e., such that for any $p,q \in \tilde{M}, \tilde{\pi}(p)=\tilde{\pi}(q)$ implies $\tilde{\pi}_*(X(p))=\tilde{\pi}_*(X(q)), X \in \mathscr{X}(\bar{M})$) are vector fields locally integrable on M. The Lagrange formalism on M is fully determined by the Lagrange formalism on $\tilde{M}$ (with the Lagrangian $\tilde{L}$). This implies that the singularities in the configuration space M are fully analyzable. As a simple example one could consider the configuration space $M\backslash\partial M_E$ of a harmonic oscillator, where $M\backslash\partial M_E$ is an interval (without the endpoints) which could be covered by a circle $\tilde{M}$ with the natural projection $\tilde{\pi}:\tilde{M}\to M$.

Now, let us consider a non-classical simple mechanical system (M,K,V). Let $g_E=2|E-V|$ be the Jacobi metric with g being the Lorentz metric $K(v)=\frac{1}{2}g(v,v)$. The Jacobi metric g_E is degenerate on the set $\Xi=\{x: V(x)=E\}$, $\Xi\subset M$, which is a boundary set.

Larsen[19] has investigated the behaviour of geodesics on spaces with degenerate semi-Riemannian metrics. His theorem 4.1 concerns geodesics of a conformally singular metric (with a smooth conformal factor). He shows that there exists a geodesic passing through the boundary set Ξ with the zero velocity in a locally unique way, i.e., if γ_1 and γ_2 are geodesics such that $\mathrm{dom}\gamma_1=\mathrm{dom}\gamma_2 \neq \varnothing$, then there exists an interval $[-t,t]$ such that $\gamma_1[-t,t]=\gamma_2[-t,t]$. By applying methods of differential spaces to the case with a non-continuous conformal factor in the

metric and by adapting Larsen's theorem to our case, one can easily see the existence and the local uniqueness of a piecewise smooth geodesic passing through the boundary set Ξ. (Details of all constructions sketched in the present section will be published in a forthcoming paper.)

Now, we shall describe the local behaviour of geodesics (of the metric g_E) in a neighbourhood of the boundary set Ξ for points $p \in M$ at which $(dV)(p) \neq 0$. There exist a neighbourhood U of p such that $\Xi \cap U$ is a hypersurface in U, and a map x (with a suitably shrinked domain D_x) such that $\Xi \cap D_x$ is a subset of the surface of the coordinate system axes, with respect to which D_x is symmetric. Therefore, we have reduced the considered case to a smooth manifold symmetric with respect to the boundary set Ξ on which the Jacobi metric vanishes.

Let $\mathbf{Z}_2$ be an Abelian group acting as a reflexion group on this manifold with respect to Ξ. A quotient half-space $\mathbf{R}^n/\mathbf{Z}_2$ is a manifold with boundary (symmetric points are identified). On $\mathbf{R}^n/\mathbf{Z}_2$ the Jacobi metric $g_E^+ = 2(E-V)g$ is defined. A similar theorem as for simple classical mechanical systems can be proved.

Theorem 6: *The Lagrange function* $L:\tilde{T}(\mathbf{R}^n/\mathbf{Z}_2) \to \mathbf{R}$ *given by* $L(v) = \frac{1}{2} g_E^+(v,v)$ *is hyperregular.*

Therefore, the Maupertuis principle finds its strict formulation also for simple non-classical mechanical systems. Analogous theorem to the above one can also be proved for the Jacobi metric $\bar{g}_E = -2(E-V)g$. In such a case, the condition $\gamma(-t) = \gamma(t)$, found by Kozlov,[3] is valid. It is also evident that a geodesic passing through the boundary set Ξ changes the sector of the null-cone.

We should notice that the mechanics on the quotient space $\mathbf{R}^n/\mathbf{Z}_2$ is a π-invariant projection of the mechanics on $\mathbf{R}^n$, where $\pi:\mathbf{R}^n \to \mathbf{R}^n/\mathbf{Z}_2$ is the canonical projection. In a forthcoming paper we shall investigate relationships between mechanics on a (quotient) space with singularities and mechanics on the covering space.

VIII. CONCLUDING REMARKS

In the present work we focused on two problems: (1) a generalization of the Maupertuis principle to the case with the natural Lagrangian and an indefinite kinetic energy form (non-classical simple mechanical systems); (2) demonstration that the region admissible for the motion of a system with the Jacobi metric is a differential space of constant differential dimension. Owing to the last property the analysis usually carried out on smooth manifolds can be done on more general spaces including some sorts of singularities. In the framework of such spaces, the behaviour of trajectories in a close neighbourhood of singular boundaries becomes a workable problem. Differentiable space methods allowed us also to show that for both classical and non-classical simple mechanical systems the Lagrange and Hamilton formulations of mechanics are equivalent.

The theory of non-classical simple mechanical systems is still *in statu nascendi*, and the situation in this field is analogous to that which once compelled mathematicians to investigate spaces with Lorentz metrics. We hope that first steps in the correct direction have been made in the present work.

Simple non-classical mechanical systems (ZC-systems) have natural applications in cosmology and the gravity theory.[4] In such systems the indefinite character of the kinetic energy form (in the Hamiltonian formulation) is a relic of the Lorentz structure of space–time. Non-classical systems can also be applied to the investigation of deterministic chaos or, more precisely, to the investigation of separation of nearby trajectories, basing on the equation of the geodesic deviation. This is important as far as the invariant definition of deterministic chaos in gauge theories is concerned.[4,5]

Induced matter theory and embeddings in Riemann flat space–times

G. Abolghasem, A. A. Coley, and D. J. Mc Manus[a)]
Department of Mathematics, Statistics and Computing Science, Dalhousie University, Halifax, Nova Scotia, B3H 3J5, Canada

(Received 17 July 1995; accepted for publication 1 August 1995)

A class of five-dimensional space-times that contain four-dimensional hypersurfaces whose intrinsic metrics are of cosmological interest is investigated. First, the five-dimensional space–time is assumed to be Riemann flat—the problem of determining the intrinsic metrics of the four-dimensional hypersurfaces then becomes a problem of embedding in flat space–time. Second, the Riemann flat solutions are used as a starting point to find solutions to Einstein's vacuum field equations in five dimensions that are not Riemann flat. In particular, a new general class of five-dimensional vacuum solutions is found. © *1996 American Institute of Physics.* [S0022-2488(96)04201-8]

I. INTRODUCTION

Recently, several authors have been interested in Einstein's theory of general relativity in five dimensions[1–7] (higher-dimensional theories have also been considered[8,9]). In these studies the higher-dimensional field equations were taken to be the vacuum Einstein field equations, and the primary goal in several[1–3,6,7] of these studies was to determine whether the four-dimensional properties of matter could be interpreted as being purely geometrical in origin[10]—the embedding of the four-dimensional space–time in the vacuum five-dimensional space-time was interpreted as producing an effective four-dimensional stress–energy tensor.

Curiously, Mc Manus[7] recently observed that a class of five-dimensional vacuum (i.e., Ricci flat) solutions of Ponce de Leon[6] were, in fact, completely (Riemann) flat, that is to say that the five-dimensional Riemann tensor associated with these metrics was identically zero. Thus, one is immediately prompted to ask the following question: are any of the other known five-dimensional Ricci flat solutions also Riemann flat? Of course, it is not very instructive to just simply systematically calculate the Riemann tensor for the known five-dimensional vacuum solutions to determine if the Riemann tensor vanishes. It would be far more beneficial if we could find some general results. Consequently, we now pose the following question: what is the class of Lorentzian four-metrics that can be embedded in five-dimensional Minkowski space-time? In theory, the general solution to this problem is known.[11] For example, consider the following class of Riemann flat five-metrics:

$$ds^2=g_{\alpha\beta}(x^\gamma,y)dx^\alpha\, dx^\beta+\phi^2(x^\gamma,y)dy^2. \tag{1}$$

where the intrinsic metric, $g_{\alpha\beta}(x^\gamma,y)\big|_{y=\text{const}}$, of the four-dimensional hypersurfaces $y=$constant is Lorentzian in signature. The fact that the full five-dimensional metric is flat imposes necessary and sufficient conditions on the Riemann tensor, $R_{\alpha\beta\gamma\delta}$, of the intrinsic metric and on the extrinsic curvature, $K_{\alpha\beta}$, of the hypersurface $y=$const, namely that

$$R_{\alpha\beta\gamma\delta}=K_{\alpha\gamma}K_{\beta\delta}-K_{\alpha\delta}K_{\beta\gamma}, \tag{2}$$

[a)]Current address: Finance Division, Faculty of Commerce & Business Administration. University of British Columbia, Vancouver, British Columbia, V6T 1Z2, Canada.

$$K_{\alpha\beta;\gamma}=K_{\alpha\gamma;\beta}, \tag{3}$$

where here ";" denotes covariant differentiation with respect to the intrinsic metric $g_{\alpha\beta}$. (In general,[11] the four-metric ${}^4ds^2=g_{\alpha\beta}(x^\gamma)dx^\alpha\,dx^\beta$ can be embedded in a five-dimensional Riemann flat space–time if and only if there exists a symmetric tensor $\Omega_{\alpha\beta}$ that satisfies ${}^4R_{\alpha\beta\gamma\delta}=2\Omega_{\alpha[\gamma}\Omega_{\delta]\beta}$ and $\Omega_{\alpha[\beta;\gamma]}=0$.) Furthermore, the extrinsic curvature of the surface $y=$const is given by

$$K_{\alpha\beta}=\frac{1}{2\phi}\frac{\partial}{\partial y}(g_{\alpha\beta}), \tag{4}$$

for the above metric. Unfortunately, the above equations are too complex for an explicit coordinate representation for the metric functions $g_{\alpha\beta}$ and ϕ to be found, in general.

In this paper, we consider the following class of metrics:

$$ds^2=-e^{2F(t,r,y)}\,dt^2+e^{2G(t,r,y)}(dr^2+r^2\,d\Omega^2)+e^{2K(t,r,y)}\,dy^2, \tag{5}$$

where $d\Omega^2\equiv d\theta^2+\sin^2(\theta)d\phi^2$. Various forms of the metric (5) have been extensively investigated in the literature[1,2,6,7]—the vacuum Einstein field equations, $R_{ij}=0$, have been solved for certain subclasses of the metric (5). Although several metrics of the form (5) have been noted to be Riemann flat,[7,13] most notably the Ponce de Leon solutions,[6] the general form of the Riemann flat solutions has not been found.

Therefore, we wish to determine all metrics of the form (5) that are Riemann flat. In other words, we want to find all solutions of the equations $R_{ijkl}=0$ where the metric is given by (5). In principle, the problem is trivial since locally all solutions are Minkowski space-time; however, one has to implement various nontrivial diffeomorphisms to get the solution into this form. However, we shall only permit diffeomorphisms of the form $x^\alpha\to\bar{x}^\alpha(x^\beta)$ and $y\to\bar{y}(y)$. Thus, by restricting the permissible diffeomorphisms we ensure that the four-dimensional intrinsic metrics $ds^2=g_{\alpha\beta}(x^\gamma,y)|_{y=\text{const}}\,dx^\alpha\,dx^\beta$ are not necessarily Riemann flat, even though the five-dimensional metrics are Riemann flat. In technical language, we confine our analysis to four-dimensional metrics of embedding class $p=1$ (see Refs. 8 and 12 for further discussions on the embedding problem).

If we calculate the extrinsic curvature, $K_{\alpha\beta}$, for the metric (5) using (4), then we find that it has the form

$$K_{\alpha\beta}=Av_\alpha v_\beta+Bg_{\alpha\beta}, \tag{6}$$

where $g_{\alpha\beta}v^\alpha v^\beta=-1$. Equation (2) can then be employed to show that the stress–energy tensor associated with the intrinsic metric $g_{\alpha\beta}$ has the form of a perfect fluid, namely $T_{\alpha\beta}=(\mu+P)v_\alpha v_\beta+Pg_{\alpha\beta}$. Now, standard results of embedding theory[12,14,15] tell us about the allowable perfect fluid solutions. In the case $\mu+P\neq0$, the solution belongs to either the class of generalized interior Schwarzschild solutions if the expansion of the fluid velocity, v_α, is zero, or the class of generalized Friedmann cosmological models if the fluid expansion is nonzero. In the case that $\mu+P=0$, the solutions are de Sitter space–times (that is, space–times of constant curvature). All of these spherically symmetric solutions are conformally flat.

The purpose of our paper is twofold; not only do we wish to find the explicit form for all the Riemann flat solutions of the form (5), but we also wish to find new Ricci flat solutions. In particular, we wish to employ our knowledge of the Riemann flat solutions as an aid to construct new Ricci flat solutions.

The paper is organized as follows: In Sec. II, we analyze the Riemann flat equations for the metric (5), and both classify and find all the five-dimensional solutions explicitly. In Sec. III, we discuss the solutions found in Sec. II, paying particular attention to their interpretation in the

context of induced matter theory. Finally, in Sec. IV, we use the Riemann flat solutions as an aid to construct some Ricci flat solutions of the metric (5) that are not Riemann flat.

II. FIELD EQUATIONS

We shall now proceed to solve the equations $R_{ijkl}=0$ for the metric (5). However, we will restrict the allowable diffeomorphisms to diffeomorphisms of the form $x^{\alpha}\rightarrow\bar{x}^{\alpha}(x^{\beta})$, $y\rightarrow\bar{y}(y)$. We start our analysis by noting that the pivotal equations are $R^{\theta}{}_{tr\theta}=0$ and $R^{\theta}{}_{ry\theta}=0$, which yield

$$G_{rt}=G_tF_r\,. \tag{7}$$

$$G_{ry}=G_yK_r\,, \tag{8}$$

respectively. (The complete set of the components of the Riemann tensor are listed in the Appendix.) Thus, we immediately observe that we can divide the solutions into four classes: (1) $G=G(r)$; (2) $G=G(r,y)$ with $G_y\neq0$ and $\exp(K)=G_y/\alpha$; (3) $G=G(r,t)$ with $G_t\neq0$ and $\exp(F)=G_t/\beta$; and (4) $G=G(t,r,y)$ with $G_tG_y\neq0$, and $\exp(K)=G_y/\alpha$ and $\exp(F)=G_t/\beta$, where both α and β are nonzero functions of t and y only.

A. $G=G(r)$

The equation $R^{\theta}{}_{rr\theta}=0$ yields the differential equation

$$rG_{rr}+G_r=0, \tag{9}$$

which can easily be solved to get

$$G=c_1\,\ln(r)+c_2\,, \tag{10}$$

where c_1 and c_2 are arbitrary constants. The field equation $R^{\phi}{}_{\theta\theta\phi}=0$ now reduces to

$$c_1(c_2+2)=0. \tag{11}$$

We can take $c_1=c_2=0$ without loss of generality. (The solutions $c_1=0$ and $c_2=-2$ are related by the transformation $r\rightarrow1/r$.) Equations $R^{\theta}{}_{tt\theta}=0$ and $R^{\theta}{}_{yy\theta}=0$ imply that the functions F and K are both independent of the variable r. Thus, the metric may be written as

$$ds^2=-A^2(t,y)dt^2+dr^2+r^2\,d\Omega^2+B^2(t,y)dy^2, \tag{12}$$

where the metric functions A and B must satisfy the following equation:

$$\frac{\partial}{\partial y}\left(\frac{1}{B}\frac{\partial A}{\partial y}\right)=\frac{\partial}{\partial t}\left(\frac{1}{A}\frac{\partial B}{\partial t}\right). \tag{13}$$

Equation (13) follows directly from the equation $R^{t}{}_{yty}=0$. (The remaining equations $R^{i}{}_{jkl}=0$ are trivially satisfied.)

B. $G_t=0$, $G_y\neq0$

For this class of solutions, we have that the metric function K satisfies

$$e^K=G_y/\alpha(t,y), \tag{14}$$

where $\alpha\neq0$. The equation $R^{r}{}_{tyr}=0$ implies that $\alpha=(y)$. The equation $R^{\theta}{}_{rr\theta}=0$ then yields the following differential equation for G:

$$G_{rr}+\frac{1}{r}\,G_r+\alpha^2 e^{2G}=0, \tag{15}$$

which can easily be solved to obtain the solution

$$G=\frac{1}{2}\ln\left[\frac{a^2 b}{\alpha^2}\,\frac{r^{a-2}}{(1+br^c)^2}\right], \tag{16}$$

where a and b are arbitrary functions of y only. Furthermore, the equation $R^{\phi}{}_{\theta\theta\phi}=0$ reduces to

$$G_r^2+\frac{2}{r}\,G_r+\alpha^2 e^{2G}=0. \tag{17}$$

Inserting the solution (16) for G into (17) implies that $a^2=4$ (we can take $a=2$ without loss of generality). Thus, the solution for G is

$$G=\frac{1}{2}\ln\left[\frac{4b(y)}{\alpha^2(y)}\,\frac{1}{(1+b(y)r^2)^2}\right]. \tag{18}$$

Note that we can write the solution for G in the above form, since the equation $R^{\theta}{}_{rr\theta}=0$ implies that $G_r\neq 0$ if $G_t=0$ and $G_y\neq 0$.

For simplicity, we introduce the function A defined by

$$A=e^F. \tag{19}$$

The equations $R^{t}{}_{rtr}=0$ and $R^{\theta}{}_{tt\theta}=0$ now reduce to

$$\frac{1}{\alpha^2}\,G_y(A_{rr}-G_rA_r)+A_y e^{2G}=0. \tag{20}$$

$$\frac{1}{\alpha^2}\,G_y\left(G_r+\frac{1}{r}\right)A_r+A_y e^{2G}=0. \tag{21}$$

respectively. Subtracting (21) from (20) yields

$$A_{rr}-2A_rG_r-\frac{1}{r}\,A_r=0, \tag{22}$$

which can be integrated to obtain

$$A_r=re^{2G}l(t,y), \tag{23}$$

where $l(t,y)$ is an arbitrary function. Furthermore, Eq. (21) implies that

$$A_y=-\frac{l}{\alpha^2}\,G_y(1+rG_r). \tag{24}$$

With the aid of Eq. (18), Eq. (23) can now be integrated to yield

$$A=-\frac{2l}{\alpha^2}\,\frac{1}{1+br^2}+m(t,y). \tag{25}$$

where $m(t,y)$ is an arbitrary function. In addition, the equation $R^{t}{}_{rty}=0$ reduces to

$$G_r A_{ry} - G_y^2 A_r - A_y G_{ry} = 0, \tag{26}$$

which can be integrated to obtain

$$\frac{A_y}{G_y} = A + n(t,y), \tag{27}$$

where $n(t,y)$ is an arbitrary function. If we divide Eq. (24) by G_y and compare the result to (27), then we find that A must be of the form

$$A = -\frac{l}{\alpha^2}\frac{1-br^2}{1+br^2} - n. \tag{28}$$

If we combine Eqs. (25) and (28), then we obtain that the function A may be written as

$$A = \frac{p(t,y) + b(y)q(t,y)r^2}{1+b(y)r^2}. \tag{29}$$

where $p = n - l/\alpha^2$ and $q = n + l/\alpha^2$. In addition, the above solution must also satisfy Eq. (24). Inserting the above solution into Eq. (24), we find that Eq. (24) becomes a power series in r. Thus, equating the various coefficients of r to zero, we find the following equations:

$$(p-q)\left(\frac{b_y}{b} - 2\frac{\alpha_y}{\alpha}\right) = 4p_y, \tag{30}$$

$$(p-q)b_y = 2(q_y + p_y), \tag{31}$$

$$(p-q)\left(\frac{b_y}{b} + 2\frac{\alpha_y}{\alpha}\right) = 4q_y. \tag{32}$$

Equation (31) is redundant since it can be obtained by adding Eqs. (30) and (32) together. Subtracting Eq. (32) from Eq. (30), we find that

$$2(p_y - q_y) + (p-q)\frac{\alpha_y}{\alpha} = 0, \tag{33}$$

which can be integrated to yield the solutions

$$p = u(t)\left[\frac{2}{\alpha} + \int \frac{dy}{\alpha}\frac{b_y}{b}\right] + v(t), \tag{34}$$

$$q = u(t)\left[-\frac{2}{\alpha} + \int \frac{dy}{\alpha}\frac{b_y}{b}\right] + v(t), \tag{35}$$

where u and v are arbitrary functions. The remaining equations $R^i{}_{jkl} = 0$ are trivially satisfied.

Thus, if we make the coordinate transformation $Y = \frac{1}{2}\ln b(y)$ and introduce the function $a = -\ln \alpha$, then the metric can be written as

$$ds^2 = -A^2\, dt^2 + \frac{4e^{2(a+Y)}}{(1+e^{2Y}r^2)^2}(dr^2 + r^2\, d\Omega^2) + \frac{e^{2a}}{(1+e^{2Y}r^2)^2}[(a_Y+1) + (a_Y-1)e^{2Y}r^2]^2\, dY^2, \tag{36}$$

where $a=a(Y)$ is an arbitrary function and A can be set to

$$A=\begin{cases} 1 \quad [\text{if } u(t)=0], \\ v(t)+2e^{2a}\dfrac{1-e^{2Y}r^2}{1+e^{2Y}r^2}+2\displaystyle\int e^a\,dY \quad [\text{if } u(t)\neq 0], \end{cases} \tag{37}$$

where $v(t)$ is an arbitrary function.

C. $G_y=0$, $G_t\neq 0$

This class is very similar to the previous class. Thus, we forgo writing down the steps of the calculation since they are, in essence, the same as those employed in the derivation of the class (2) solutions. We merely quote the results: there exist coordinates such that the class (3) solutions may be written as

$$ds^2=-\frac{e^{2a}}{(1-e^{2T}r^2)^2}\left[(a_T+1)-(a_T-1)e^{2T}r^2\right]^2\,dT^2+\frac{4e^{2(a+T)}}{(1-e^{2T}r^2)^2}\,(dr^2+r^2\,d\Omega^2)+B^2\,dy^2, \tag{38}$$

where $a=a(T)$ is an arbitrary function and B can be set equal to

$$B=\begin{cases} 1 \quad (\text{if } B_r=0), \\ v(y)+2e^{2a}\dfrac{1+e^{2T}r^2}{1-e^{2T}r^2}+2\displaystyle\int e^a\,dT \quad (\text{if } B_r\neq 0), \end{cases} \tag{39}$$

where $v(y)$ is an arbitrary function.

D. $G_tG_y\neq 0$

In this case, the functions F and K satisfy the relationships

$$e^K=G_y/\alpha(t,y), \tag{40}$$

$$e^F=G_t/\beta(t,y). \tag{41}$$

Now, the equations $R^{\theta}{}_{rr\theta}=0$ and $R^{\phi}{}_{\theta\theta\phi}=0$ yield

$$G_{rr}+\frac{1}{r}\,G_r+ae^{2G}=0, \tag{42}$$

$$G_r^2+\frac{2}{r}\,G_r+ae^{2G}=0, \tag{43}$$

respectively, where

$$a\equiv\alpha^2-\beta^2. \tag{44}$$

The above equations can be solved to obtain the solution

$$G=\frac{1}{2}\ln\left[\frac{4b^2}{(a+b^2r^2)^2}\right], \tag{45}$$

where $b=b(t,y)$ is an arbitrary function. Furthermore, the equation $R^t{}_{rty}=0$ reduces to

$$G_{yt}=G_tG_y+\frac{\alpha_y}{\alpha}\,G_t+\frac{\beta_t}{\beta}\,G_y\,. \tag{46}$$

Using the solution (45), we can expand the above equation in a power series in r. We find that the following two equations must be satisfied:

$$b_{ty}=(\partial_t \ln \beta)b_y+(\partial_y \ln \alpha)b_t\,, \tag{47}$$

$$\partial_t\left(\frac{\alpha_y}{\beta}\right)+\frac{1}{\beta}\left[\alpha(\partial_t \ln b)(\partial_y \ln b)-\alpha_y\partial_t \ln b-\alpha_t\partial_y \ln b\right]$$

$$=\partial_y\left(\frac{\beta_t}{\alpha}\right)+\frac{1}{\alpha}\left[\beta(\partial_t \ln b)(\partial_y \ln b)-\beta_y\partial_t \ln b-\beta_t\partial_y \ln b\right]. \tag{48}$$

(Actually, there is a third equation, but it is automatically satisfied on account of the first two equations.)

The remaining equations $R^i{}_{jkl}=0$ can all be shown to be trivially satisfied. First, using Eq. (46) we find that the equation $R^t{}_{rtr}=0$ can be written as

$$\frac{\partial}{\partial r}\left[2G_{rr}-G_r^2+ae^{2G}\right]=0, \tag{49}$$

which is trivially satisfied due to (45). Similarly, the equation $R^r{}_{yyr}=0$ reduces to

$$\frac{\partial}{\partial y}\left[2G_{rr}-G_r^2+ae^{2G}\right]=0. \tag{50}$$

Both the equations $R^t{}_{rty}=0$ and $R^y{}_{try}=0$ reduce to

$$\frac{\partial}{\partial r}\left[G_{yt}-G_tG_y-\frac{\alpha_y}{\alpha}\,G_t-\frac{\beta_t}{\beta}\,G_y\right]=0 \tag{51}$$

which is trivially satisfied because of Eq. (46). Furthermore, using Eq. (46), the equations $R^\theta{}_{tt\theta}=0$ and $R^y{}_{\theta\theta y}=0$ can be shown to reduce to

$$rG_{rtr}=G_{rt}(1+2rG_r), \tag{52}$$

$$rG_{ryr}=G_{ry}(1+2rG_r), \tag{53}$$

respectively, which again are trivially satisfied on account of Eq. (45). Finally, after a long calculation employing Eqs. (42)–(48), the equation $R^t{}_{yty}=0$ can be shown to be trivially satisfied.

In summary, the metric is given by

$$ds^2=-\left(\frac{G_t}{\beta(t,y)}\right)^2 dt^2+e^{2G}(dr^2+r^2\,d\Omega^2)+\left(\frac{G_y}{\alpha(t,y)}\right)^2 dy^2, \tag{54}$$

where

$$e^{2G}\equiv\frac{4b(t,y)^2}{(\alpha^2-\beta^2+b(t,y)^2r^2)^2}, \tag{55}$$

and α, β and b satisfy (47)–(48).

III. DISCUSSION

We should, of course, determine where the known Riemann flat solutions of the form (5) fit into the above classification scheme. As was noted by Mc Manus,[7] the following three Ponce de Leon metrics[6] are all Riemann flat:

$$ds^2=-y^2\ dt^2+t^{2/\gamma}y^{2/(1-\gamma)}[dr^2+r^2\ d\Omega^2]+\left(\frac{\gamma}{\gamma-1}\right)^2 t^2\ dy^2, \tag{56}$$

$$ds^2=-y^2\ dt^2+y^2e^{2t}[dr^2+r^2\ d\Omega^2]+dy^2, \tag{57}$$

$$ds^2=-dt^2+t^2e^{2y}[dr^2+r^2\ d\Omega^2]+t^2\ dy^2, \tag{58}$$

where $\gamma(\neq 0,1)$ is an arbitrary constant. Clearly, all the above metrics belong to class (4), since $G=G(t,y)$ with $G_tG_y\neq 0$. In particular, the above solutions belong to the special case $a=0$ [that is, $\alpha=\beta$—see Eqs. (40)–(42)]. However, the solution (43) appears to depend on r; this dependency can be removed by the coordinate transformation $r\rightarrow\bar{r}=2/r$. Also note that in this special case Eq. (46) is automatically satisfied. Class (4) solutions with $\alpha\neq\beta$ are known to exist. For instance, the metric

$$ds^2=-dt^2+\frac{1}{4}\ t^2(e^y-\kappa e^{-y})^2\ \frac{dr^2+r^2\ d\Omega^2}{[1+(\kappa/4)r^2]^2}+t^2\ dy^2, \tag{59}$$

given in Ref. 7, is Riemann flat for all values of the constant κ.

In addition, we recall that metrics of the form (5) were originally investigated in the context of induced matter theory.[2] In induced matter theory, the field equations are usually taken to be the the vacuum Einstein field equations in $4+n$-dimensional space–time.[1–3] However, for our analysis we wish to examine the consequences of taking the field equations to be the five-dimensional Riemann flat equations. (Of course, we are immediately neglecting a whole variety of well-known solutions of Einstein's field equations, most notably the Schwarzschild solution that can, at best, be embedded in six-dimensional Minkowski space-time.) Matter is introduced into the theory by considering the embedding of the physical four-dimensional space–time in the full five-dimensional space–time. Basically, the physically relevant metric is taken to be the intrinsic metric on the four-dimensional slices $y=$const.

The class (1) and (3) solutions, namely (12) and (37)–(38), induce Riemann flat four-metrics on the slices $y=$const, and are thus physically uninteresting within the context of induced matter theory. The class (2) solutions induce conformally flat four-metrics. The class (2) solutions with $A=1$ [see Eqs. (36)–(37)] represent static Friedman–Robertson–Walker metrics, such that the three-space $t=$const has positive constant curvature. The class (2) solutions with $A\neq 1$ can be interpreted as perfect fluid models with constant density,

$$\mu=\frac{3}{e^{2a}}, \tag{60}$$

and non-constant pressure,

$$P=-\frac{1}{e^{2a}}-\frac{4}{e^{2a}}\left[2+e^{-2a}V(t)\ \frac{1+e^{2y}r^2}{1-e^{2y}r^2}\right]^{-1}, \tag{61}$$

where $V(t)\equiv v(t)+2\int^t \exp[a(y)]dy$. The intrinsic metric of these class (2) solutions (on the hypersurface $Y=$const),

$$ds^2=-\left\{v(t)+2e^{2a}\,\frac{1-e^{2Y}r^2}{1+e^{2Y}r^2}+2\int e^a\,dY\right\}^2 dt^2+\frac{4e^{2(a+Y)}}{(1+e^{2Y}r^2)^2}\,(dr^2+r^2\,d\Omega^2). \tag{62}$$

belongs to the class of generalized interior Schwarzschild solutions.[12,14] The diffeomorphism (with $Y=\text{const}$),

$$R=\frac{2e^{2a}e^Y}{1+e^{2Y}r^2}, \tag{63}$$

reduces the above metric to the standard form,

$$ds^2=-\{v(t)+\sqrt{1-C^2R^2}\}^2\,dt^2+\frac{dR^2}{1-C^2R^2}+R^2\,d\Omega^2, \tag{64}$$

where $C(=\exp[-a(Y)]_{Y=\text{const}})$ is an arbitrary constant. We note that a specific embedding for the interior Schwarzschild solution, $v(t)=\text{const}$, into a six-dimensional Riemann flat solution is known (see Ref. 16). However, to our knowledge, the metric (36) with $A\neq 1$ [see (37)] is the first time that an explicit embedding for the interior Schwarzschild solution into five-dimensional Riemann flat space–time has appeared in the literature.

The class (4) solutions also induce conformally flat four-metrics, and can be interpreted as perfect fluid models whose associated density and pressure are

$$\mu=3\alpha^2, \tag{65}$$

$$P=-3\alpha^2+2\alpha\alpha_t\{\partial_t\,\ln[b^{-1}(\alpha^2-\beta^2+b^2r^2)]\}^{-1}. \tag{66}$$

These solutions belong to the class of generalized Friedmann solutions.[14]

It is clear from (2) that there exist algebraic relationships between $K_{\alpha\beta}$ ($\Omega_{\alpha\beta}$), $R_{\alpha\beta}$ (and hence $T_{\alpha\beta}$), and the Weyl tensor $C_{\alpha\beta\gamma\delta}$. *All the Riemann flat solutions* [classes (1)–(4)] *induce four-metrics that are conformally flat*. Indeed, all the perfect fluid solutions of embedding class one must necessarily be either of Petrov type O (conformally flat) or of Petrov type D.[12] Curiously, results about the embedding of conformally flat four-dimensional metrics into Riemannian flat five-dimensional Lorentzian space-time do not seem to appear in the literature. Results about the embedding of conformally flat four-dimensional metrics into Riemannian flat five-dimensional Euclidean space–times (positive definite metrics) are known (see Refs. 17 and 18). For completeness, we now state the following theorem without proof: If a four-dimensional conformally flat Lorentzian metric is of embedding class one, then its Riemann tensor is given by $R_{\alpha\beta\gamma\delta}=2\Omega_{\alpha[\gamma}\Omega_{\delta]\beta}$, where $\Omega_{\alpha[\beta;\gamma]}=0$, and furthermore Ω must be of the form

$$\Omega_{\alpha\beta}=An_\alpha n_\beta+Bg_{\alpha\beta}, \tag{67}$$

where n_α is a unit space-like or time-like vector (that is, $n_\alpha n^\alpha=\pm 1$).

IV. RICCI FLAT SOLUTIONS

All the solutions discussed in Secs. II and III are Riemann flat and thus are also automatically Ricci flat. To date, the majority of the known Ricci flat solutions where the metric has the form (5) have been found by examining the special ansatz that the metric functions are separable in the variables t, r, and y. In this section, our aim is to find a class of Ricci flat solutions that contain a subclass of the Riemann flat solutions. Thus, we use the Riemann flat solutions of the previous sections as a springboard to construct new Ricci flat solutions.

We base our first ansatz on the form of the class (2) solutions [we chose the class (2) solutions because (i) they are not as complicated as the class (4) solutions; and (ii) the class (1) and (3) solutions have an uninteresting interpretation in terms of induced matter theory]. Hence, we consider metrics of the following form:

$$e^F=\frac{A(t,y)+B(t,y)r^2}{\alpha(y)+b^2(y)r^2}, \tag{68}$$

$$e^G=\frac{2b(y)+C(y)r^2}{\alpha(y)+b^2(y)r^2}, \tag{69}$$

$$e^K=\frac{D(y)+E(y)r^2}{\alpha(y)+b^2(y)r^2}. \tag{70}$$

Thus, the field equations $R_{ij}=0$ will all reduce to power series in r. The coefficients of each of the power series will, in general, be partial differential equations in t and y only and they must be identically zero. After a lengthy calculation (see Ref. 19 for full details), we find the following equation:

$$C_y=C\,\frac{b_y}{b}. \tag{71}$$

Thus, we find that either (i) $C=0$ or (ii) $C=\pm b\neq 0$. In case (i), the solutions can eventually be shown to reduce to the Riemann flat class (2) solutions. In case (ii), the metric can be shown to be equivalent to

$$ds^2=-y^{-1}\,dt^2+y(dr^2+r^2\,d\Omega^2)+dy^2. \tag{72}$$

The above metric was discussed in Ref. 7 and belongs to the class of generalized Kasner metrics.[9,20,21]

In the process of determining the Riemann flat solutions and the above solutions, we observed that if the metric functions F, G, and K appearing in (5) had a particular form, then some of the Ricci flat field equations could be easily integrated. Thus, based upon our observations, we are led to our second ansatz; we shall now consider metrics of the following form:

$$ds^2=-e^{F(t,r,y)}\,dt^2+e^{2G(r)}[dr^2+r^2\,d\Omega^2]+e^{2K(r,y)}\,dy^2. \tag{73}$$

This ansatz includes both the class (1) Riemann flat solutions and the Davidson–Owen–Gross–Perry solutions.[4,5]

The field equation $R_{\theta\theta}=0$ for metric (73) implies that $(G_r+1/r)F_{tr}=0$. Thus, either (i) $G_r=-1/r$ or (ii) $F_{tr}=0$.

In case (i) we can set $G=0$ without loss of generality by an appropriate diffeomorphism. The field equations $R_{rr}=0$ and $R_{\theta\theta}=0$ can then be employed to show that $F_r=0=K_r$. The remaining field equations can then be used to show that the metric reduces to the class (1) Riemann flat solutions, (12)–(13), with $B=1$.

In case (ii) we find that $F=A(t,y)+B(r,y)$. The equation $R_{\theta\theta}=0$ then yields the additional result $(B+K)_{ry}=0$, and thus $K=-B(r,y)+C(r)$. Furthermore, the equation $R_{rr}=0$ yields $B_{ry}(2B_r-C_r)=0$, which implies that $K=K(r)$ and $F=A(t,y)+B(r)$. Finally, the equation $R_{ry}=0$ implies that $A_y(B_r-K_r)=0$. Thus, either (a) $A_y=0$ or (b) $B_r=K_r$. In case (a), we can take $A=1$ without loss of generality, and the metric then reduces to the Davidson–Owen–Gross–Perry class of soliton solutions,[4,5] namely,

$$ds^2=-\left(\frac{ar-1}{ar+1}\right)^{2\epsilon k}dt^2+\left(\frac{a^2r^2-1}{a^2r^2}\right)^2\left(\frac{ar+1}{ar-1}\right)^{2\epsilon(k-1)}[dr^2+r^2\,d\Omega^2]+\left(\frac{ar+1}{ar-1}\right)^{2\epsilon}dy^2, \tag{74}$$

where ϵ and k are subject to the constraint $\epsilon^2(k^2-k+1)=1$.

In case (b), the general form of the metric may be written as

$$ds^2=-A^2(t,y)e^{2K(r)}\,dt^2+e^{2G(r)}[dr^2+r^2\,d\Omega^2]+e^{2K(r)}\,dy^2. \tag{75}$$

The field equation $R_{tt}=0$ can be employed to show that

$$A_{yy}=\kappa A \tag{76}$$

and

$$e^{2K}[K_{rr}+2K_r^2+K_rG_r+(2/r)K_r]+\kappa e^{2G}=0, \tag{77}$$

where κ is a constant (κ can always be chosen to be equal to either 0 or ±1). Finally, the equations $R_{rr}=0$ and $R_{\theta\theta}=0$ yield

$$K_{rr}+K_r^2-K_rG_r+G_{rr}+\frac{1}{r}G_r=0, \tag{78}$$

$$2K_rG_r+\frac{2}{r}K_r-G_{rr}+\frac{3}{r}G_r+G_r^2=0, \tag{79}$$

respectively. We note that the above system of equations (77)–(79) only has rank 2—Eq. (79) is a first integral of (77) and (78).

If $\kappa=0$, then the above system of equations, (77)–(79), can be solved completely to yield the solution

$$ds^2=-\left(\frac{ar+1}{ar-1}\right)^{2/\sqrt{3}}[\alpha(t)y+\beta(t)]^2\,dt^2+\left(\frac{a^2r^2-1}{a^2r^2}\right)^2\left(\frac{ar-1}{ar+1}\right)^{4/\sqrt{3}}[dr^2+r^2\,d\Omega^2]$$
$$+\left(\frac{ar+1}{ar-1}\right)^{2/\sqrt{3}}dy^2, \tag{80}$$

where a is an arbitrary constant, and α and β are arbitrary functions of t. If $\alpha=0$ then the above metric is a particular solution belonging to the Davidson–Owen–Gross–Perry class of solutions[4,5] [that is, metric (74) with $\epsilon=1/\sqrt{3}$ and $k=-1$]. If $\alpha\neq0$, then we can always set $\alpha=1$: this particular solution was originally found by Ponce de Leon and Wesson[22]—the solution is also very similar in form to the time-dependent soliton solution found by Wesson, Liu, and Lim.[3]

If $\kappa\neq0$, then the equations (77)–(79) are not so simple to solve. For convenience, we introduce the new variable,

$$\rho=\ln r. \tag{81}$$

Equations (77)–(79) can then be reduced to the following system of differential equations:

$$G_{\rho\rho}=-G_\rho^2-2K_\rho G_\rho-2K_\rho-2G_\rho, \tag{82}$$

$$K_{\rho\rho}=-K_\rho^2+3K_\rho G_\rho+G_\rho^2+2G_\rho+3K_\rho, \tag{83}$$

with the first integral

$$4K_\rho G_\rho + G_\rho^2 + K_\rho^2 + 2G_\rho + 4K_\rho + \kappa e^{2(G-K+\rho)} = 0. \tag{84}$$

Equations (82) and (83) form a two-dimensional autonomous system of differential equations. A specific solution can be found by demanding that $K = G + \rho$; Eqs. (82) and (84) then imply that $\kappa = -1$ and that

$$G = \left(-1 \pm \frac{1}{\sqrt{3}} \right) \rho, \tag{85}$$

$$K = \pm \frac{1}{\sqrt{3}}\, \rho. \tag{86}$$

Thus, if we make the transformation $R = r^{\pm 1/\sqrt{3}}$, then the metric, in this special case, may be written as

$$ds^2 = -\cos^2(y + \alpha(t)) R^2\, dt^2 + 3\, dR^2 + R^2\, d\Omega^2 + R^2 dy^2. \tag{87}$$

A. Remarks

Of course, Eqs. (82)–(83) can easily be analyzed as a two-dimensional dynamical systems.[19] It can be shown that the system has four fixed points at finite values and six fixed points at infinity (full details are given in Ref. 19). Analysis of the finite fixed points shows that there are two saddles, an attracting focus and a repelling focus. Both the attracting focus and the repelling focus are described by the metric (87) [for which $\kappa = -1$] and are valid for R tends to infinity and R tends to zero, respectively. The corresponding class of solutions are consequently asymptotically flat in general, in the sense that all components of the Riemann tensor asymptotically vanish (as $r \to \infty$ for the attractor and as $r \to 0$ for the repellor). The corresponding four-dimensional models have the property that asymptotically the stress-energy tensor may be interpreted as an anisotropic fluid, with $p_\parallel = 0$ and $\mu = 2p_\perp$, where $p_\parallel$ and $p_\perp$ are the fluid pressures parallel and perpendicular to the fluid four-velocity, respectively. (At the two saddles the corresponding exact solutions have $\kappa = 0$ and the associated four-dimensional solutions that are also flat.)

Analysis of the singular points at infinity shows that there are two sinks, two sources, and two saddles (appearing in pairs). The asymptotic form of the solution corresponding to the sources at infinity is given by

$$G(r) \approx (\ln r)^{1 - 2/\sqrt{3}}, \quad K(r) \approx (\ln r)^{1/\sqrt{3}} \tag{88}$$

[note that $K \to \infty$, $G \to 0$, and that $\det(g_{ij}) \to \infty$ as $r \to \infty$], while for the sinks,

$$G(r) \approx (\ln r)^{1 + 2/\sqrt{3}}, \quad K(r) \approx (\ln r)^{-1/\sqrt{3}}. \tag{89}$$

APPENDIX: THE RIEMANN TENSOR

The nonzero components of the Riemann tensor, up to the usual symmetries, for the metric (5) are

$$R^t{}_{rtr} = F_{rr} + F_r^2 - F_r G_r - e^{2(G-F)} \{ G_{tt} + G_t^2 - F_t G_t \} + e^{2(G-K)} F_y G_y, \tag{A1}$$

$$R^{t}{}_{rty}=F_{ry}+F_rF_y-F_rG_y-F_yK_r\,, \tag{A2}$$

$$R^{r}{}_{tyr}=G_{ty}+G_tG_y-F_yG_t-K_tG_y \quad (=R^{\theta}{}_{ty\theta}=R^{\phi}{}_{ty\phi}), \tag{A3}$$

$$R^{\theta}{}_{tt\theta}=G_{tt}+G_t^2-F_tG_t-F_r(G_r+1/r)e^{2(F-G)}-e^{2(F-K)}F_yG_y \quad (=R^{\phi}{}_{tt\phi}), \tag{A4}$$

$$R^{\theta}{}_{tr\theta}=G_{rt}-G_tF_r \quad (=R^{\phi}{}_{tr\phi}), \tag{A5}$$

$$R^{t}{}_{yty}=F_{yy}+F_y^2-F_yK_y+e^{2(K-G)}F_rK_r-e^{2(K-F)}\{K_{tt}+K_t^2-F_tK_t\}, \tag{A6}$$

$$R^{y}{}_{try}=K_{rt}+K_rK_t-K_tF_r-G_tK_r\,, \tag{A7}$$

$$R^{\theta}{}_{rr\theta}=G_{rr}+\frac{1}{r}\,G_r-e^{2(G-F)}G_t^2+e^{2(G-K)}G_y^2 \quad (=R^{\phi}{}_{rr\phi}), \tag{A8}$$

$$R^{\theta}{}_{ry\theta}=G_{ry}-K_rG_y \quad (=R^{\phi}{}_{ry\phi}), \tag{A9}$$

$$R^{r}{}_{yyr}=G_{yy}+G_y^2-G_yK_y+e^{2(K-G)}\{K_{rr}+K_r^2-G_rK_r\}-e^{2(K-F)}G_tK_t\,, \tag{A10}$$

$$R^{\phi}{}_{\theta\theta\phi}=r^2\left\{G_r^2+\frac{2}{r}\,G_r-e^{2(G-F)}G_t^2+e^{2(G-K)}G_y^2\right\}, \tag{A11}$$

$$R^{\theta}{}_{yy\theta}=G_{yy}+G_y^2-G_yK_y-e^{2(K-F)}G_tK_t+e^{2(K-G)}K_r(G_r+1/r) \quad (=R^{\phi}{}_{yy\phi})\,. \tag{A12}$$

A new algebraic approach for calculating the heat kernel in quantum gravity

I. G. Avramidi[a),b),c)]
Department of Mathematics, University of Greifswald, Jahnstr. 15a, 17489 Greifswald, Germany

(Received 17 October 1994; accepted for publication 14 September 1995)

It is shown that the heat kernel operator for the Laplace operator on any covariantly constant curved background, i.e., in symmetric spaces, may be presented in the form of an averaging over the Lie group of isometries with some nontrivial measure. Using this representation, the heat kernel diagonal, i.e., the heat kernel in coinciding points is obtained. Related topics concerning the structure of symmetric spaces and the calculation of the effective action are discussed. © *1996 American Institute of Physics.* [S0022-2488(96)00501-7]

I. INTRODUCTION

The heat kernel, a very powerful tool for investigating the effective action in quantum field theory and quantum gravity, has been the subject of much investigation in recent years in physical as well as in mathematical literature (Refs. 1–22). The subject of the present investigation is the low-energy limit of the one-loop contribution of a set of quantized fields ϕ on a d-dimensional Riemannian manifold M of metric $g_{\mu\nu}$ with Euclidean signature to the effective action, which can best be presented using the ζ-function regularization in the form[1]

$$\Gamma_{(1)}=-\frac{1}{2}\,\zeta'(0), \tag{1.1}$$

where

$$\zeta(p)=\mu^{2p}\ \mathrm{Tr}\ F^{-p}=\frac{\mu^{2p}}{\Gamma(p)}\int_0^\infty dt\ t^{p-1}\ \mathrm{Tr}\ U(t), \tag{1.2}$$

$$F=-\Box+Q+m^2, \tag{1.3}$$

$$U(t)=\exp(-tF), \tag{1.4}$$

with $\Box=g^{\mu\nu}\nabla_\mu\nabla_\nu$, Tr meaning the functional trace, μ being a renormparameter introduced to preserve dimensions, $Q(x)$ an arbitrary matrix-valued function (potential term), m a mass parameter, and ∇_μ a covariant derivative. The covariant derivative includes, in general, not only the Levi-Civita connection, but also the appropriate spin one as well as the vector gauge connection, and is determined by the commutator $[\nabla_\mu,\nabla_\nu]\phi=.\mathscr{R}_{\mu\nu}\phi$. The Riemann curvature tensor, the curvature of background connection, and the potential term completely describe the background metric and connection, at least locally. In the following we will call these quantities the *background curvatures* or simply curvatures and denote them symbolic by $\mathfrak{R}=\{R_{\mu\nu\alpha\beta},\mathscr{R}_{\mu\nu},Q\}$.

Exact evaluation of the heat kernel $U(t)$ is obviously impossible. Therefore, one should make use of various approximations. First of all, let us note the very important so-called Schwinger–De Witt asymptotic expansion of the heat kernel at $t\to 0$,[1–5]

$$\mathrm{Tr}\ U(t)\sim(4\pi t)^{-d/2}\ \exp(-tm^2)\sum_{k=0}^{\infty}\ \frac{(-t)^k}{k!}\,B_k\,, \tag{1.5}$$

$$B_k=\int_M dx\ g^{1/2}\ \mathrm{tr}\ b_k\,. \tag{1.6}$$

This expansion is purely local and does not depend, in fact, on the global structure of the manifold. In manifolds with boundary additional terms in B_k as well as new terms of order $t^{-d/2+k/2}$ in the form of surface integrals over the boundary ∂M appear. For details see Refs. 12 and 13, where all coefficients for arbitrary boundary conditions up to terms of order $t^{-d/2+5/2}$ are calculated. Its coefficients b_k [we call them Hadamard–Minakshisundaram–De Witt–Seeley (HMDS) coefficients] are local invariants built from the curvature, the potential term, and their covariant derivatives.[1,5,6,14] They play a very important role, both in physics and mathematics, and are closely connected with various sections of mathematical physics.[14,22] Therefore, the calculation of HMDS coefficients is in itself of great importance. Various methods were used for calculating these coefficients, beginning from the direct De Witt's method[1] to modern mathematical methods, which make use of pseudodifferential operators, functorial properties of the heat kernel, etc.[5–13] Very good reviews of the calculation of the HMDS coefficients are given in recent papers.[14]

Nowadays, in the general case only the first four coefficients are explicitly calculated. The first three coefficients were calculated in Ref. 9. An effective covariant technique for calculating HMDS coefficients is elaborated in Refs. 10 and 4, where also the first four coefficients are computed. In the case of scalar operators the fourth coefficient is also calculated in Ref. 11. Analytic approach was developed in Ref. 7, where a closed form for the intrinsic symbol of the resolvent parametrix was obtained. The leading terms in all the volume coefficients B_k quadratic in the background curvatures were calculated completely independently in Refs. 15 and 16.

Although the Schwinger–De Witt expansion is good for small t (viz. $t\mathfrak{R}\ll 1$), and thereby in the case of massive quantized fields in weak background fields when $\mathfrak{R}\ll m^2$, it is absolutely inadequate for large t in strongly curved manifolds and strong background fields ($\mathfrak{R}\gg m^2$). For investigating these cases one needs some other methods.

A possibility to exceed the limits of the Schwinger–De Witt expansion is to employ the direct partial summation.[2] Namely, one can compare all the terms in HMDS coefficients B_k (1.6), pick up the main (the largest in some approximation) terms, and sum up the corresponding partial sum. There is always a lack of uniqueness concerned with the global structure of the manifold, when doing so. But, hopefully, fixing the topology, e.g. the trivial one, one can obtain a unique, well-defined, expression that would reproduce the Schwinger–De Witt expansion, being expanded in curvature. The main advantage of such an approach is that although the result will be *not exact*, it will be *covariant* and *general*.

Actually, the effective action is a covariant functional of the metric and depends on the geometry of the manifold as a whole, i.e., it depends on both local characteristics of the geometry, like invariants of the curvature tensor, and its global topological structure. However, *we will not investigate in this paper the influence of the topology*, but concentrate our attention, as a rule, on the *local effects*. That means that we restrict ourselves to those physical problems where the contribution of the global effects may be neglected, in comparison with local ones. Then the possible approximations for evaluating the effective action can be based on the assumptions about the local behavior of the background fields, dealing with the real physical gauge invariant variations of the local geometry, i.e. with the curvature invariants, but not with the behavior of the

metric and the connection that is not invariant. Comparing the value of the curvature with that of its covariant derivatives one comes to two possible approximations: (i) the short-wave (or high-energy) approximation characterized by $\mathbf{\nabla\nabla}\mathfrak{R}\gg\mathfrak{R}\mathfrak{R}$, and (ii) the long-wave (or low-energy) one $\mathbf{\nabla\nabla}\mathfrak{R}\ll\mathfrak{R}\mathfrak{R}$.

The idea of partial summation was realized in short-wave approximation for investigating the nonlocal aspects of the effective action (in other words, the high-energy limit of that) in Refs. 15 and 4, where all the terms in the HMDS coefficients B_k with higher derivatives (quadratic in the curvature and potential term) are calculated, and the corresponding asymptotic expansion is summed up. Another approach to study the high-energy limit of the effective action, so-called covariant perturbation theory, is developed in Ref. 17.

II. LOW-ENERGY APPROXIMATION AND ITS CONSEQUENCES

The low-energy effective action, in other words, the effective potential, presents a very natural tool for investigating the vacuum of the theory, its stability, and the phase structure.[23] Here only partial success is achieved and various approaches to the problem are only outlined (see, e.g., the excellent review of Camporesi in Ref. 22 with an ample bibliography and our recent papers[20,21]).

The long-wave (or low-energy) approximation is determined, as it was already stressed above, by strong slowly varying background fields. This means that the derivatives of all invariants are much smaller than the products of the invariants themselves. The zeroth order of this approximation corresponds to covariantly constant background curvatures,

$$\mathbf{\nabla}_\mu R_{\alpha\beta\gamma\delta}=0, \quad \mathbf{\nabla}_\mu \mathscr{R}_{\alpha\beta}=0, \quad \mathbf{\nabla}_\mu Q=0. \tag{2.1}$$

In this case the HMDS coefficients are simply polynomials in curvature invariants and potential term of dimension $\mathfrak{R}^k$ up to terms with one or more covariant derivatives of the background curvatures $O(\mathbf{\nabla}\mathfrak{R})$,

$$b_k=\sum_{n=0}^{k}\binom{k}{n}Q^{k-n}a_n+O(\mathbf{\nabla}\mathfrak{R}), \tag{2.2}$$

$$a_k=b_k|_{Q=\mathbf{\nabla}R=0}=\sum R^k. \tag{2.3}$$

Note that the commutators $[Q,\mathscr{R}_{\mu\nu}]$ are of order $O(\mathbf{\nabla\nabla}\mathfrak{R})$, and therefore are neglected here.

Then, after summing the Schwinger–De Witt expansion (1.5), we obtain for the heat kernel, the ζ function and the effective action,

$$\mathrm{Tr}\ U(t)=\int_M dx\ g^{1/2}(4\pi t)^{-d/2}\ \mathrm{tr}\{\exp(-t(m^2+Q))(\Omega(t)+O(\mathbf{\nabla}\mathfrak{R}))\}, \tag{2.4}$$

$$\zeta(p)=\int_M dx\ g^{1/2}(4\pi)^{-d/2}\ \frac{\mu^{2p}}{\Gamma(p)}\int_0^\infty dt\ t^{p-d/2-1}\ \mathrm{tr}\{\exp(-t(m^2+Q))(\Omega(t)+O(\mathbf{\nabla}\mathfrak{R}))\}, \tag{2.5}$$

$$\Gamma_{(1)}=\int_M dx\ g^{1/2}\{V(\mathfrak{R})+O(\mathbf{\nabla}\mathfrak{R})\}, \tag{2.6}$$

with

$$V(\mathfrak{R})=\frac{1}{2}\,(4\pi)^{-d/2}\,\frac{1}{\Gamma(d/2+1)}\int_0^\infty dt\left(\log(\mu^2 t)+\psi\left(\frac{d}{2}+1\right)\right)$$
$$\times\left(\frac{\partial}{\partial t}\right)^{d/2+1}\operatorname{tr}\{\exp(-t(m^2+Q))\Omega(t)\},\tag{2.7}$$

for even d and

$$V(\mathfrak{R})=\frac{1}{2}\,(4\pi)^{-d/2}\,\frac{1}{\Gamma(d/2+1)}\int_0^\infty dt\;t^{-1/2}\left(\frac{\partial}{\partial t}\right)^{(d+1)/2}\operatorname{tr}\{\exp(-t(m^2+Q))\Omega(t)\},\tag{2.8}$$

for odd d, where

$$\Omega(t)\sim\sum_{k=0}^{\infty}\frac{(-t)^k}{k!}\,a_k,\tag{2.9}$$

is a function of local invariants of the curvatures (but not of the potential).

It is natural to call the functions $\Omega(t)$ and $V(\mathfrak{R})$ that do not contain the *covariant* derivatives at all and so determine the zeroth order of the heat kernel and that of the effective action, the *generating function* for covariantly constant terms in HMDS coefficients and the *effective potential* in quantum gravity, respectively.

Let us note that such a definition of the effective potential is not conventional. It differs from the definition that is often found in the literature.[24] What is meant usually under the notion of the effective potential is a function of the potential term only Q, because it does not contain derivatives of the background fields (in contrast to Riemann curvature $R_{\alpha\beta\gamma\delta}$ that contains second derivatives of the metric and the curvature $\mathscr{R}_{\mu\nu}$ with first derivatives of the connection). So, e.g., in Ref. 24, the potential term Q is summed up exactly, but an expansion is made not only in covariant derivatives but also in powers of curvatures $R_{\mu\nu\alpha\beta}$ and $\mathscr{R}_{\mu\nu}$, i.e. the curvatures are treated perturbatively. Thereby the validity of this approximation for the effective action is limited to small curvatures $\mathscr{R}_{\mu\nu},R_{\mu\nu\alpha\beta}\ll Q$. Such an expansion is called ''expansion of the effective action in covariant derivatives.'' Without the potential term ($Q=0$) the effective potential in such a scheme is trivial. Hence we stress here once again that the effective potential in our definition contains, in fact, *much more information* than the usual effective potential does when using the ''expansion in covariant derivatives.'' As a matter of fact, what we mean is the *low-energy limit of the effective action* formulated in a covariant way.

Note that the conditions (2.1) are local. They determine the geometry of the *locally* symmetric spaces. However, the manifold is a *globally* symmetric one only in the case when it satisfies additionally some global topological restrictions (e.g., it is sufficient if it is simply connected and complete) and the condition (2.1) is valid everywhere, i.e. at any point of the manifold.[25,26]

In most *physical* problems, the situation is radically different. The correct setting of the problem seems to be as follows. The low-energy effective action depends, in general, also essentially on the global topological properties of the space-time manifold, i.e. on the existence of closed geodesics, boundaries, or singularities that might act similarly to boundaries. But, as it was noted above, we do not investigate in this paper the influence of the topology. Therefore, consider a complete noncompact asymptotically flat manifold without a boundary that is homeomorphic to $\mathbb{R}^d$. Let a finite not small, in general, domain of the manifold exists that is strongly curved and quasihomogeneous, i.e. the invariants of the curvature in this region vary very slowly. Then, the geometry of this region is *locally* very similar to that of a symmetric space. However, one should have in mind that there are *always* regions in the manifold where this condition is not fulfilled. This is, first of all, the asymptotic Euclidean region that has small curvature and, therefore, the opposite short-wave approximation is valid.

The general situation in the correct setting of the problem is the following. From infinity with small curvature and possibly radiation, where[17] $\mathfrak{R}\mathfrak{R}\ll\nabla\nabla\mathfrak{R}$, we pass on to the quasihomogeneous region where the local properties of the manifold are close to those of symmetric spaces. The size of this region can tend to zero. Then the curvature is nowhere large and the short-wave approximation is valid anywhere. If one tries to extend the limits of such a region to infinity, then one has also to analyze the topological properties. The space can be compact or noncompact, depending on the sign of the curvature. But first we will come across a coordinate horizon-like singularity, although no one true physical singularity really exists.

This construction can be intuitively imagined as follows. Take the flat Euclidean space $\mathbb{R}^d$, cut out from it a region M with some boundary ∂M, and stick to it smoothly along the boundary, instead of the piece cut out, a piece of a curved symmetric space with the same boundary ∂M. Such a construction will be homeomorphic to the initial space and at the same time will contain a finite highly curved homogeneous region. Let us stress that this surgery can be always done *smoothly*, so that in the region where the curved and the flat regions are joined no discontinuity in the curvature appears that could cause the reflected waves to produce Casimir-like effects. By the way, the exact effective action for a symmetric space differs from the effective action for built construction by a purely topological contribution. This fact seems to be useful when analyzing the effects of topology.

Thus, the problem is to calculate the low-energy effective action (2.7) and (2.8), i.e. the heat kernel for covariantly constant background. Although this quantity, generally speaking, depends essentially on the topology and other global aspects of the manifold, one can disengage oneself from these effects fixing the trivial topology. Since the asymptotic Schwinger–De Witt expansion does not depend on the topology, one can hold that we thereby sum up all the terms without covariant derivatives in it.

We stress here once again that our analysis is purely local. Of course, there are always special global effects (Casimir-like effects, influence of boundaries, closed geodesics, etc.), that do not show up in the local expansion of the heat kernel. The aim of this paper is to study only such situations where the contribution of these effects is small in comparison with the local part, i.e. the effective action is *approximately* given by the integration of the local formula.

In other words, the problem is the following. One has to obtain a local covariant function of the invariants of the curvature $\Omega(t)$ (2.9) that would describe adequately the low-energy limit of the trace of the heat kernel and that would, being expanded in curvatures, reproduce all terms without covariant derivatives in the asymptotic expansion of the heat kernel, i.e. the HMDS coefficients a_k (2.3). If one finds such an expression, then one can simply determine the ζ function (2.5) and, therefore, the low-energy limit of the effective action (2.7) and (2.8).

III. SYMMETRIC SPACES

In this paper we will get the most out of the properties of symmetric spaces. Let us list below some known ideas, facts, and formulas about symmetric spaces presented in the form that is most convenient for calculating the heat kernel and the effective action.

First of all, we give some definitions (see Refs. 25 and 26 and Sec. III D). A Riemannian locally symmetric space that is simply connected and complete is globally symmetric space (or, simply, symmetric space).[26] A symmetric space is said to be of *compact*, *non-compact*, or *Euclidean type* if *all* sectional curvatures $K(u,v)=R_{abcd}u^a v^b u^c v^d$ are positive, negative, or zero. A direct product of symmetric spaces of compact and noncompact types is called *semisimple* symmetric space. It is well known[25,26] that a generic complete simply connected Riemannian symmetric space is a direct product of a flat space and a semisimple symmetric space (also see Sec. III D). Although in the Sec. IV we will need actually only symmetric spaces of compact type the whole exposition of the Sec. III is valid for a more general case of semisimple symmetric spaces.

So, what are the direct consequences of the condition of covariant constancy of the curvature (2.1)?

A. Geometrical framework

First of all, to carry out the calculations in the curved space in a covariant way we need some auxiliary two-point geometric objects, namely the geodetic interval (or world function) $\sigma(x,x')$, defined as one-half the square of the length of the geodesic connecting the points x and x', the tangent vectors $\sigma_\mu(x,x')=\nabla_\mu\sigma(x,x')$ and $\sigma_{\mu'}(x,x')=\nabla_{\mu'}\sigma(x,x')$ to this geodesic at the points x and x', respectively, and a frame $e^\mu_a(x,x')$, which is covariantly constant (parallel) along the geodesic between points x and x', i.e. $\sigma^\mu\nabla_\mu e^\nu_a=0$. We denote the frame components of the tangent vector by $\sigma^a(x,x')=g^{ab}e^{\mu'}_a(x')\nabla_{\mu'}\sigma(x,x')$.

Any tensor $T^{a\cdots}_{b\cdots}$, can then be presented in the form of covariant Taylor series,

$$T^{a\cdots}_{b\cdots}=\sum_{n\geqslant 0}\frac{(-1)^n}{n!}\,\sigma^{\mu'_1}\cdots\sigma^{\mu'_n}[\nabla_{(\mu_1}\cdots\nabla_{\mu_n)}T^{\alpha\cdots}_{\beta\cdots}](x')e^a_{\alpha'}\cdots e^{\beta'}_b\,. \tag{3.1}$$

Therefrom, it is clear that the frame components of a *covariantly* constant tensor are *simply* constant.

In the case of covariantly constant curvature one can express the mixed second derivatives of the geodetic interval, i.e. the matrix

$$\sigma^a{}_b(x,x')=e^a_{\mu'}(x')e^\alpha_b(x)\nabla^{\mu'}\nabla_\alpha\sigma(x,x'), \tag{3.2}$$

explicitly in terms of the curvature at a fixed point x'. Introducing a matrix $K=\{K^a{}_b(x,x')\}$,

$$K^a{}_b=R^a{}_{cbd}\sigma^c\sigma^d, \tag{3.3}$$

one can sum up the Taylor series, obtaining a closed form,[4]

$$\sigma^a{}_b=-\left(\frac{\sqrt{K}}{\sin\sqrt{K}}\right)^a_b. \tag{3.4}$$

This expression, as well as any other similar expressions below, should be always understood as a *power series* in the curvature.

B. Curvature

Let us consider the Riemann tensor in more detail (we follow here Secs. 3.7–3.10 of the first paper in Ref. 25). The components of the curvature tensor of *any* Riemannian manifold can be always presented in the form

$$R_{abcd}=\beta_{ik}E^i{}_{ab}E^k{}_{cd}, \tag{3.5}$$

where E^i_{ab} $(i=1,\ldots,p;p\leqslant d(d-1)/2)$, is some set of antisymmetric matrices (2-forms) and β_{ik} is some symmetric nondegenerate matrix.

Then define the traceless matrices $D_i=\{D^a{}_{ib}\}$,

$$D^a{}_{ib}=-\beta_{ik}E^k{}_{cb}g^{ca}=-D^a{}_{bi}, \tag{3.6}$$

so that

$$R^a{}_{bcd}=-D^a{}_{ib}E^i{}_{cd},\quad R^a{}_b{}^c{}_d=\beta^{ik}D^a{}_{ib}D^c{}_{kd}, \tag{3.7}$$

$$R^a_b=-\beta^{ik}D^a{}_{ic}D^c{}_{kb},\quad R=-\beta^{ik}D^a{}_{ic}D^c{}_{ka}=-\beta^{ik}\,\mathrm{tr}(D_iD_k), \tag{3.8}$$

where $\beta^{ik}=(\beta_{ik})^{-1}$. Because of the curvature identities, we have identically

$$D^a{}_{j[b}E^j{}_{cd]}=0. \tag{3.9}$$

The matrices D_i are known to be the generators of the *holonomy algebra*, i.e. the Lie algebra of the restricted holonomy group, $\mathscr{H}$ (the first paper in Ref. 25, p. 97) of dimension $\dim\mathscr{H}=p$,

$$[D_i,D_k]=F^j{}_{ik}D_j, \quad \text{or} \quad D^a{}_{ic}D^c{}_{kb}-D^a{}_{kc}D^c{}_{ib}=F^j{}_{ik}D^a{}_{jb}. \tag{3.10}$$

The structure constants $F^j{}_{ik}$ of the holonomy algebra are completely determined by these commutation relations and satisfy the Jacobi identities

$$F^i{}_{j[k}F^j{}_{mn]}=0, \quad \text{or} \quad [F_i,F_k]=F^j{}_{ik}F_j, \tag{3.11}$$

where $F_i=\{F^k{}_{il}\}$ are the generators of the holonomy algebra in adjoint representation. Note that the restricted holonomy group H is always compact, as it is a subgroup of the orthogonal group (in the Euclidean case), and connected.

Now let us rewrite the condition of integrability of the relations (2.1) given simply by the commutator of covariant derivatives,

$$[\boldsymbol{\nabla}_\mu,\boldsymbol{\nabla}_\nu]R_{\alpha\beta\gamma\delta}=-2\{R_{\mu\nu\lambda[\alpha}R^\lambda{}_{\beta]\gamma\delta}+R_{\mu\nu\lambda[\gamma}R^\lambda{}_{\delta]\alpha\beta}\}=0, \tag{3.12}$$

in terms of introduced quantities. It is not difficult to show that it looks like

$$E^i{}_{ac}D^c{}_{bk}-E^i{}_{bc}D^c{}_{ak}=E^j{}_{ab}F^i{}_{jk}. \tag{3.13}$$

This equation takes place *only in symmetric spaces* and is the most important one. It is this equation that makes a Riemannian manifold the symmetric space.

From Eqs. (3.10) and (3.13) we now have

$$\beta_{ik}F^k{}_{jm}+\beta_{mk}F^k{}_{ji}=0, \quad \text{or} \quad F_i^T=-\beta F_i\beta^{-1}, \tag{3.14}$$

which means that the adjoint and coadjoint representations of the restricted holonomy group are equivalent.

Equation (3.13) leads also to some identities for the curvature tensor

$$D^a{}_{i[b}R_{c]ade}+D^a{}_{i[d}R_{e]abc}=0, \tag{3.15}$$

$$R^a{}_cD^c{}_{ib}=D^a{}_{ic}R^c{}_b, \tag{3.16}$$

which means, in particular, that the Ricci tensor matrix commutes with all matrices D_i and is, therefore, an invariant matrix of the holonomy algebra.

Actually, Eq. (3.13) brings into existence a much wider algebra $\mathscr{G}$ of dimension $\dim\mathscr{G}=D=p+d$, in other words, it closes this algebra. Really, let us introduce new quantities $C^A{}_{BC}=-C^A{}_{CB}$ $(A=1,\ldots,D)$,

$$C^i{}_{ab}=E^i{}_{ab}, \quad C^a{}_{ib}=D^a{}_{ib}, \quad C^i{}_{kl}=F^i{}_{kl}, \quad C^a{}_{bc}=C^i{}_{ka}=C^a{}_{ik}=0, \tag{3.17}$$

forming the matrices $C_A=\{C^B{}_{AC}\}=(C_a,C_i)$,

$$C_a=\begin{pmatrix}0 & D^b{}_{ai}\\ E^j{}_{ac} & 0\end{pmatrix}, \quad C_i=\begin{pmatrix}D^b{}_{ia} & 0\\ 0 & F^j{}_{ik}\end{pmatrix}, \tag{3.18}$$

and symmetric nondegenerate matrix,

$$\gamma_{AB}=\begin{pmatrix} g_{ab} & 0 \\ 0 & \beta_{ik} \end{pmatrix}. \tag{3.19}$$

Then one can show, first, that as a consequence of the identities (3.9)–(3.13) the quantities $C^A{}_{CB}$ satisfy the Jacobi identities

$$C^E{}_{D[A}C^D{}_{BC]}=0, \quad \text{or} \quad [C_A,C_B]=C^C{}_{AB}C_C, \tag{3.20}$$

and are, therefore, the structure constants of some Lie algebra $\mathscr{G}$, the matrices C_A being then the generators of this algebra in adjoint representation. More precisely, the commutation relations have the form

$$[C_a,C_b]=E^i{}_{ab}C_i, \quad [C_a,C_i]=D^b{}_{ai}C_b, \quad [C_i,C_k]=F^j{}_{ik}C_j. \tag{3.21}$$

And, second, using the definition of D matrices and Eq. (3.14), one can show that the structure constants also satisfy the identity

$$\gamma_{AB}C^B{}_{CD}+\gamma_{DB}C^B{}_{CA}=0, \quad \text{or} \quad C_A^T=-\gamma C_A\gamma^{-1}, \tag{3.22}$$

meaning the equivalence of the adjoint and coadjoint representations of the algebra $\mathscr{G}$.

In other words, the Jacobi identities (3.22) are equivalent to the identities (3.12) that the curvature must satisfy in the symmetric space. This means that the set of structure constants $C^A{}_{BC}$, satisfying the Jacobi identities, determines the curvature tensor of symmetric space $R^a{}_{bcd}$. *Vice versa*, the structure of the algebra $\mathscr{G}$ is completely determined by the curvature tensor of symmetric space at a fixed point x'.

Now, consider the curvature of background connection $\mathscr{R}_{ab}$. One can show analogously to (3.12) that because of the integrability conditions of Eq. (2.1),

$$[\boldsymbol{\nabla}_\mu,\boldsymbol{\nabla}_\nu]\mathscr{R}_{\alpha\beta}=[\mathscr{R}_{\mu\nu},\mathscr{R}_{\alpha\beta}]-2R_{\mu\nu\lambda[\alpha}\mathscr{R}^\lambda{}_{\beta]}=0, \tag{3.23}$$

the curvature of background connection $\mathscr{R}_{ab}$ in *semisimple* symmetric spaces must have the form

$$\mathscr{R}_{ab}=\mathscr{R}_iE^i{}_{ab}, \tag{3.24}$$

where $E^i{}_{ab}$ are the same 2-forms and $\mathscr{R}_i$ are some matrices forming a representation of the holonomy algebra,

$$[\mathscr{R}_i,\mathscr{R}_k]=F^j{}_{ik}\mathscr{R}_j. \tag{3.25}$$

In a generic symmetric space with a flat subspace there are additional Abelian contributions to the curvature $\mathscr{R}_{ab}$ (3.24) corresponding to the flat directions.

Finally, from (2.1) it follows that the potential term should commute with the curvature $\mathscr{R}_{\mu\nu}$,

$$[\boldsymbol{\nabla}_\mu,\boldsymbol{\nabla}_\nu]Q=[\mathscr{R}_{\mu\nu},Q]=0, \tag{3.26}$$

and, therefore, with all the matrices $\mathscr{R}_i$,

$$[\mathscr{R}_i,Q]=0. \tag{3.27}$$

C. Isometries

On the covariantly constant background (2.1), i.e. in symmetric spaces, one can easily solve the Killing equations,

$$\mathscr{L}_\xi g_{\mu\nu}=2\boldsymbol{\nabla}_{(\mu}\xi_{\nu)}=0, \tag{3.28}$$

where $\mathscr{L}_\xi$ means the Lie derivative. Indeed, by differentiating the equation

$$\mathscr{L}_\xi \Gamma^\lambda_{\mu\nu} = \nabla_{(\mu}\nabla_{\nu)}\xi^\lambda + R^\lambda{}_{(\mu|\alpha|\nu)}\xi^\alpha = 0, \tag{3.29}$$

having in mind $\nabla R = 0$, and symmetrizing the derivatives we get

$$\nabla_{(\mu_1}\cdots\nabla_{\mu_{2n})}\xi^\lambda = (-1)^n R^\lambda{}_{(\mu_1|\alpha_1|\mu_2} R^{\alpha_1}{}_{\mu_3|\alpha_2|\mu_4}\cdots R^{\alpha_{n-1}}{}_{\mu_{2n-1}|\alpha_n|\mu_{2n})}\xi^{\alpha_n}, \tag{3.30}$$

$$\nabla_{(\mu_1}\cdots\nabla_{\mu_{2n+1})}\xi^\lambda = (-1)^n R^\lambda{}_{(\mu_1|\alpha_1|\mu_2} R^{\alpha_1}{}_{\mu_3|\alpha_2|\mu_4}\cdots R^{\alpha_{n-1}}{}_{\mu_{2n-1}|\alpha_n|\mu_{2n}}\nabla_{\mu_{2n+1})}\xi^{\alpha_n}. \tag{3.31}$$

Thereby we have found all the coefficients of the covariant Taylor series (3.1) for the Killing vectors of symmetric spaces. Moreover, one can now sum it up obtaining a closed form,

$$\xi^\mu(x) = e^\mu{}_a\left\{ (\cos\sqrt{K})^a{}_b\xi^b(x') - \left(\frac{\sin\sqrt{K}}{\sqrt{K}}\right)^a_b \sigma^c \xi^b{}_{;c}(x')\right\}, \tag{3.32}$$

where $\xi^b{}_{;c} = \xi^\mu{}_{;\nu} e^b_\mu e^\nu_c$.

Therefore, all Killing vectors at any point x are determined in terms of initial values of the vectors themselves $\xi^b(x')$ and their first derivatives $\xi^b{}_{;c}(x')$ at a fixed point x'. The set of all Killing vectors $\hat{\mathscr{G}} = \{\xi_{\hat{A}}\}, (\hat{A} = 1,\ldots,\hat{D})$, dim $\hat{\mathscr{G}} = \hat{\mathscr{D}}$, can be split in two essentially different sets: $\mathscr{M} = \{P_a\}$, dim $\mathscr{M} = d$, with P_a defined by

$$P^\mu{}_a(x) = e^\mu{}_b(\cos\sqrt{K})^b{}_c P^c{}_a(x'), \tag{3.33}$$

and $\hat{\mathscr{H}} = \{L_{\hat{i}}\}, (\hat{i} = 1,\ldots,\hat{p})$, i.e. dim $\hat{\mathscr{H}} = \hat{p} = \hat{D} - d$, where

$$L^\mu{}_{\hat{i}}(x) = -e^\mu{}_b\left(\frac{\sin\sqrt{K}}{\sqrt{K}}\right)^b_a \sigma^c L^a{}_{\hat{i};c}(x'), \tag{3.34}$$

according to the values of their initial parameters,

$$P^\mu{}_a|_{x=x'} \neq 0, \quad L^\mu{}_{\hat{i}}|_{x=x'} = 0. \tag{3.35}$$

Note that for a general symmetric space $\hat{p} \neq p$, and hence, $\hat{D} \neq D$!

The Killing vector fields $\xi_{\hat{A}} = \xi^\mu_{\hat{A}}\nabla_\mu$ (or $P_a = P^\mu{}_a\nabla_\mu$ and $L_{\hat{i}} = L^\mu{}_{\hat{i}}\nabla_\mu$) (acting on scalar fields) form the Lie *algebra of isometries*, $\hat{\mathscr{G}}$,

$$[\xi_{\hat{A}}, \xi_{\hat{B}}] = \hat{C}^{\hat{C}}{}_{\hat{A}\hat{B}}\xi_{\hat{C}}, \tag{3.35a}$$

or, more explicitly,

$$[P_a, P_b] = \hat{E}^{\hat{i}}{}_{ab}L_{\hat{i}}, \quad [P_{\hat{i}}, L_i] = \hat{D}^b{}_{a\hat{i}}P_b,$$

$$[L_{\hat{i}}, L_{\hat{k}}] = \hat{F}^{\hat{j}}{}_{\hat{i}\hat{k}}L_{\hat{j}}, \tag{3.35b}$$

where $\{\hat{C}^{\hat{C}}{}_{\hat{A}\hat{B}}\} = \{\hat{E}^{\hat{i}}{}_{ab}, \hat{D}^b{}_{a\hat{i}}, \hat{F}^{\hat{j}}{}_{\hat{i}\hat{k}}\}$ are the structure constants of the algebra of isometries. One sees now that the generators $L_{\hat{i}}$ vanishing at the point x' form a subalgebra (3.35b) of the algebra of isometries $\hat{\mathscr{G}}$ (3.35a) called the *isotropy* algebra, $\hat{\mathscr{H}}$.

In fact, all odd symmetrized derivatives of $P^\mu{}_a$ and all even symmetrized derivatives of $L^\mu{}_i$ as well as $L^\mu{}_{\hat{i}}$ themselves vanish at the point x',

$$\nabla_\nu P^\mu{}_a|_{x=x'} = \nabla_{(\mu_1}\cdots\nabla_{\mu_{2n+1})}P^\mu{}_a|_{x=x'} = 0, \tag{3.36}$$

$$L^{\mu}{}_{\hat{i}}|_{x=x'} = \nabla_{(\mu_1}\cdots\nabla_{\mu_{2n})}L^{\mu}{}_{\hat{i}}|_{x=x'} = 0. \tag{3.37}$$

All the parameters $P^b{}_a(x')$ are independent and, therefore, there are exactly d such parameters. The maximal number of the parameters $L^b{}_{\hat{i};c}$ is $d(d-1)/2$, since they are antisymmetric; in other words $\dim \hat{\mathscr{H}} \leqslant d(d-1)/2$. However, they are not independent. This can be seen immediately if one recalls that the equation

$$\mathscr{L}_{L_{\hat{i}}} R_{\alpha\beta\gamma\delta} = 2\{L^\sigma{}_{\hat{i};[\gamma}R_{\delta]\sigma\beta\alpha} + L^\sigma{}_{\hat{i};[\alpha}R_{\beta]\sigma\delta\gamma}\} = 0, \tag{3.38}$$

holds in symmetric spaces. This equation is, actually, the integrability condition for Killing equations (3.26). It imposes strict constraints on the possible initial parameters $L^b{}_{\hat{i};c}(x')$. One can show that for the *semisimple* symmetric spaces the number of independent parameters $L^b{}_{\hat{i};c}(x')$ is equal to p, i.e. the dimension of the isotropy algebra $\hat{\mathscr{H}}$ (3.35b) is equal to the dimension of the holonomy algebra $\mathscr{H}$ (3.10),.

$$\hat{p} \equiv \dim\, \hat{\mathscr{H}} = \dim\, \mathscr{H} \equiv p.$$

Therefore, the dimension of the algebra of isometries $\hat{\mathscr{G}}$, i.e. the total number of the Killing vectors, in semisimple symmetric spaces, is equal to the dimension of the algebra $\mathscr{G}$ (3.20) defined in previous Sec. III B,

$$\hat{D} \equiv \dim\, \hat{\mathscr{G}} = \dim\, \mathscr{G} \equiv D.$$

This means that there is no difference between the ordinary latin indices and the indices with overcarets. Hence, one can omit the overcarets everywhere. In a symmetric space of general type having a flat subspace there are additional trivial Killing vectors corresponding to flat directions. Therefore, in general,

$$\dim\, \mathscr{H} \leqslant \dim\, \hat{\mathscr{H}} \leqslant d(d-1)/2, \quad \dim\, \mathscr{G} \leqslant \dim\, \hat{\mathscr{G}} \leqslant d(d+1)/2.$$

The spaces with a maximal number of independent isometries, i.e. with $p = d(d-1)/2$ and $D = d + p = d(d+1)/2$, are the spaces of constant curvature, and only those.

Thus, taking into account (3.15), it is evident that one can put

$$P^a{}_b(x') = \delta^a_b, \quad L^a{}_{i;b}(x') = -D^a{}_{ib}. \tag{3.39}$$

Therefore, the generators of isometries in semisimple symmetric spaces take the form

$$P_a = P^\mu{}_a \nabla_\mu = -(\sqrt{K}\,\cot\sqrt{K})^b{}_a \mathscr{D}_b, \tag{3.40}$$

$$L_i = L^\mu{}_i \nabla_\mu = -D^b{}_{ia}\sigma^a \mathscr{D}_b, \tag{3.41}$$

where

$$\mathscr{D}_a = (\sigma^a{}_b)^{-1} e^\mu{}_b \nabla_\mu = \frac{\partial}{\partial \sigma^a}. \tag{3.42}$$

Moreover, one can show[25,26] that for semisimple symmetric spaces the isotropy algebra $\hat{\mathscr{H}}$ (3.35b) is *isomorphic* to the holonomy algebra $\mathscr{H}$ (3.10) and the algebra of isometries $\hat{\mathscr{G}}$ (3.35a) is isomorphic to the algebra $\mathscr{G}$ (3.20) determined by the curvature tensor. Therefore, the commutation relations (3.35a) and (3.35b) can be rewritten in the form

$$[\xi_A,\xi_B]=C^C{}_{AB}\xi_C \tag{3.43}$$

and

$$[P_a,P_b]=E^i{}_{ab}L_i,\quad [P_a,L_i]=D^b{}_{ai}P_b,\quad [L_i,L_k]=F^j{}_{ik}L_j, \tag{3.44}$$

with the same structure constants as in (3.20) and (3.21) defined by (3.5), (3.6), (3.10), and (3.17). Hence, we conclude that the curvature tensor of the *semisimple* symmetric space completely determines the structure of the isotropy algebra and the algebra of isometries. For a generic symmetric space the curvature determines the algebra of isometries up to an Abelian ideal. Let us stress once again that in the case of semisimple symmetric spaces there is no need to distinguish in notation between the isotropy algebra $\hat{\mathscr{H}}$ and the holonomy algebra $\mathscr{H}$ and, therefore, between $\hat{\mathscr{G}}$ and $\mathscr{G}$ as well.

D. General structure

As we already noted above, the simply connected symmetric space M is isomorphic to the quotient space of the group of isometries by the isotropy subgroup $M=\hat{G}/\hat{H}$.[25] It is, in general, reducible, and has the following general structure:[25]

$$M=M_0\times M_s, \tag{3.45a}$$

$$M_s=M_+\times M_-, \tag{3.45b}$$

where M_0, M_s, M_+, and M_- are the Euclidean, semisimple, compact, and noncompact components. The corresponding algebra of isometries is a direct sum of ideals,

$$\hat{\mathscr{G}}=\mathscr{G}_0\oplus\mathscr{G}_s,\quad \mathscr{G}_s=\mathscr{G}_+\oplus\mathscr{G}_-, \tag{3.46}$$

where $\mathscr{G}_0$ is an Abelian ideal, $\mathscr{G}_s$ is the semisimple ideal, and $\mathscr{G}_+$ and $\mathscr{G}_-$ are the semisimple compact and noncompact ones.

There is a remarkable duality relation $*$ between compact and noncompact objects. For any semisimple algebra of isometries $\mathscr{G}=\mathscr{M}+\mathscr{H}=\{P_a,L_k\}$, one defines the dual one according to $\mathscr{G}^*=i\mathscr{M}+\mathscr{H}=\{iP_a,L_k\}$, the structure constants of the dual algebra being

$$\{C^{*A}{}_{BC}\}=\{E^i{}_{ab},D^c{}_{dk},F^j{}_{lm}\}^*=\{-E^i{}_{ab},D^c{}_{dk},F^j{}_{lm}\}. \tag{3.47}$$

So, the asterisk $*$ only changes the sign of $E^i{}_{ab}$, but does not act on all other structure constants. This means also that the matrix γ (3.19) for dual algebra should have the form

$$\gamma^*{}_{AB}=\begin{pmatrix} g_{ab} & 0\\ 0 & \beta_{ik}\end{pmatrix}^*=\begin{pmatrix} g_{ab} & 0\\ 0 & -\beta_{ik}\end{pmatrix}, \tag{3.48}$$

and, therefore, the curvature of the dual manifold has the opposite sign,

$$R^*{}_{abcd}=-R_{abcd}. \tag{3.49}$$

IV. HEAT KERNEL

It should be noted once more that our analysis in this paper is purely *local* (see the discussion in Sec. II.) We are looking for a *universal local* function of the curvature, $\Omega(t)$, (2.9) that describes adequately the low-energy limit of the heat kernel diagonal (up to ''global'' nonanalytical effects that are not studied in this paper!). Our minimal requirement is that this function should

reproduce *all* the terms without covariant derivatives of the curvature in the local Schwinger–De Witt asymptotic expansion of the heat kernel, i.e. it should give *all* the HMDS coefficients a_k (2.3) for *any* symmetric space.

It is well known that the HMDS coefficients have a *universal* explicit structure,[5] i.e. a_k are scalar polynomials of the curvature of the order k with *universal* numerical coefficients that do not depend on the particular form of the symmetric space, on the dimension, etc. It is obvious that any flat subspaces do not contribute in a_k. Moreover, since HMDS coefficients a_k are analytic in the curvature, it is evident that to find this universal structure it is sufficient to consider only symmetric spaces of the *compact* type with positive curvature. Using the factorization property of the heat kernel[5] and the duality between compact and noncompact symmetric spaces, we can obtain then the results for the general case by analytical continuation.

That is why below in this paper we consider only the case of symmetric spaces of the *compact* type when the matrices β_{ik} and γ_{AB} are *positive* definite. Besides, we restrict ourselves, for simplicity, to the scalar operators, i.e. $\mathscr{R}_{\alpha\beta}=0$. The general case will be investigated in a future work.

A. Heat kernel operator

It is not difficult to show that the metric of the symmetric space can be presented in the form

$$g^{\mu\nu}=\gamma^{AB}\xi_A^\mu\xi_B^\nu=g^{ab}P^\mu{}_a P^\nu{}_b+\beta^{ik}L^\mu{}_i L^\nu{}_k\,. \tag{4.1}$$

Indeed, by making use of Eqs. (3.7) and recalling the definition of the matrix K (3.3), it is easy to obtain (4.1) using the explicit expressions (3.33) and (3.34).

Now, having the metric (4.1), we can build the Laplacian for the scalar ($\mathscr{R}_{\alpha\beta}=0$) case,

$$\Box=g^{\mu\nu}\nabla_\mu\nabla_\nu=\gamma^{AB}\xi_A\xi_B\,, \tag{4.2}$$

where $\xi_A=\xi_A^\mu\nabla_\mu$ and the Killing equation (3.5) has been used.

It is not difficult to show that the Laplacian belongs to the center of the enveloping algebra, i.e. it commutes with all the generators of the algebra,

$$[\Box,\xi_A]=0\,. \tag{4.3}$$

Let us now try to represent the heat kernel in terms of a group average, i.e. let us find a formula like

$$\exp(t\Box)=\int dk\ \gamma^{1/2}\Phi(t|k)\exp(k^A\xi_A)\,. \tag{4.4}$$

We formulate first the answer in form of a theorem and prove it below.

Theorem 1: For any compact D-dimensional Lie group generated by ξ_A,

$$[\xi_A,\xi_B]=C^C{}_{AB}\xi_C\,, \tag{4.5}$$

the operator identity takes place,

$$\exp(t\Box)=(4\pi t)^{-D/2}\int dk\ \gamma^{1/2}\ \det\left(\frac{\sinh(k^AC_A/2)}{k^AC_A/2}\right)^{1/2}$$
$$\times\exp\left\{-\frac{1}{4t}\,k^A\gamma_{AB}k^B+\frac{1}{6}\,R_G t\right\}\exp(k^A\xi_A)\,, \tag{4.6}$$

where $\Box=\gamma^{AB}\xi_A\xi_B$, $\gamma^{AB}=(\gamma_{AB})^{-1}$, $\gamma=\det\gamma_{AB}$, γ_{AB} is a symmetric nondegenerate positive definite matrix connecting the generators in adjoint $C_A=(C^B{}_{AC})$ and coadjoint C_A^T representations,

$$C_A^T=-\gamma C_A\gamma^{-1}, \tag{4.7}$$

R_G is the scalar curvature of the group manifold,

$$R_G=-\tfrac{1}{4}\,\gamma^{AB}C^C{}_{AD}C^D{}_{BC}, \tag{4.8}$$

and the integration is to be taken over the whole Euclidean space $\mathbb{R}^D$.

The proof: Let us consider the integral

$$\Psi(t)=\int dk\ \gamma^{1/2}\Phi(k,t)\exp(k^A\xi_A), \tag{4.9}$$

where

$$\Phi(t|k)=(4\pi t)^{-D/2}\ \det\left(\frac{\sinh(k^AC_A/2)}{k^AC_A/2}\right)^{1/2}\ \exp\left\{-\frac{1}{4t}\,k^A\gamma_{AB}k^B+\frac{1}{6}\,R_Gt\right\}. \tag{4.10}$$

To prove the theorem we have to show that $\Psi(t)=\exp(t\Box)$, in other words, that it satisfies the operator equation

$$\partial_t\Psi=\Box\Psi, \tag{4.11}$$

with the initial condition

$$\Psi(t)|_{t=0}=1. \tag{4.12}$$

First, one can show that

$$\xi_B\ \exp(k^A\xi_A)=X_B\ \exp(k^A\xi_A), \tag{4.13}$$

where

$$X_A=X^M{}_A(k)\ \frac{\partial}{\partial k^M} \tag{4.14}$$

are the left-invariant vector fields on the group that have in canonical coordinates the explicit form

$$X^M{}_A(k)=\left(\frac{k^AC_A}{\exp(k^AC_A)-1}\right)^M{}_A. \tag{4.15}$$

Therefore, from the definition of the Laplacian we have

$$\Box\ \exp(k^A\xi_A)=X_2\ \exp(k^A\xi_A), \tag{4.16}$$

$$X_2=\gamma^{AB}X_AX_B. \tag{4.17}$$

Then, introducing the metric on the group manifold,

$$G_{MN}=\gamma_{AB}X^{-1A}{}_MX^{-1B}{}_N, \tag{4.18}$$

and its determinant,

$$G=\det G_{MN}=\gamma \det X^{-2}=\gamma \det\left(\frac{\sinh(k^A C_A/2)}{k^A C_A/2}\right)^2, \tag{4.19}$$

one can obtain the transposition relation

$$(G^{1/2}X_2G^{-1/2})^T=X_2. \tag{4.20}$$

Now, making use of (4.9), (4.16), and (4.20) and integrating by parts, we obtain

$$\Box\Psi(t)=\int dk\ \gamma^{1/2}\ \exp(k^A\xi_A)(G^{1/2}X_2G^{-1/2}\Phi). \tag{4.21}$$

On the other hand, one has, from (4.9),

$$\partial_t\Psi(t)=\int dk\ \gamma^{1/2}\ \partial_t\Phi\ \exp(k^A\xi_A). \tag{4.22}$$

Thus, to prove (4.11) we have to show that

$$\partial_t\Phi=G^{1/2}X_2G^{-1/2}\Phi. \tag{4.23}$$

Substituting the explicit expression for Φ,

$$\Phi(t|k)=\gamma^{-1/4}G^{1/4}(k)(4\pi t)^{-D/2}\ \exp\left\{-\frac{1}{4t}\,k^A\gamma_{AB}k^B+\frac{1}{6}\,R_G t\right\}, \tag{4.24}$$

and using the relations

$$X_2G^{-1/4}=\tfrac{1}{6}\,R_GG^{-1/4} \tag{4.25}$$

and

$$k^A\frac{\partial}{\partial k^A}\,G^{-1/4}=\frac{1}{2}\,(D-\mathrm{tr}\,X)G^{-1/4}, \tag{4.26}$$

where

$$\mathrm{tr}\,X=X^A_A=\mathrm{tr}(k^AC_A\,\coth(k^AC_A)), \tag{4.27}$$

which hold on the group manifold, we convince ourselves that Eq. (4.23) is correct. Thereby it is shown that $\Psi(t)$ really satisfies Eq. (4.11).

Further, from (4.10) it follows immediately that

$$\Phi(t|k)|_{t=0}=\gamma^{-1/2}\delta(k), \tag{4.28}$$

and, therefore, the initial condition (4.12). Thus, we found $\Psi(t)=\exp(t\Box)$ that proves the theorem.

B. Heat kernel diagonal

So, we have found a very nontrivial representation (4.6) that holds on any compact Lie group. How can we proceed now with this useful theorem?

First, we can express the scalar curvature of the group manifold in terms of the scalar curvature of the symmetric space R and that of the isotropy subgroup R_H,

$$R_G=-\,\tfrac{1}{4}\,\gamma^{AB}C^C{}_{AD}C^D{}_{BC}=\tfrac{3}{4}\,R+R_H, \tag{4.29}$$

where

$$R_H = -\tfrac{1}{4}\,\beta^{ik}F^m{}_{il}F^l{}_{km}\,. \tag{4.30}$$

The representation (4.6) is valid for any generators ξ_A satisfying the commutation relations (4.5), and so it is also valid for the infinitesimal isometries (3.40) and (3.41) of the symmetric space. In this case $\Box$ is the usual Laplacian and $\exp(t\Box)$ is the heat kernel operator.

For further use it is convenient to rewrite the integral (4.6) splitting the integration variables $k^A=(q^a,\omega^i)$ in the form

$$\exp(t\Box) = (4\pi t)^{-D/2}\int dq\ d\omega\ \eta^{1/2}\beta^{1/2}\ \det\left(\frac{\sinh((q^aC_a+\omega^iC_i)/2)}{(q^aC_a+\omega^iC_i)/2}\right)^{1/2}$$
$$\times\exp\left\{-\frac{1}{4t}\,(q^ag_{ab}q^b+\omega^i\beta_{ik}\omega^k)+\left(\frac{1}{8}\,R+\frac{1}{6}\,R_H\right)t\right\}\exp(q^aP_a+\omega^iL_i), \tag{4.31}$$

where $\beta=\det\beta_{ik}$, $\eta=\det g_{ab}$. To get the heat kernel explicitly in coordinate representation we have to act with the heat kernel operator $\exp(t\Box)$ on the delta function on M,

$$\exp(t\Box)(x,x') = \exp(t\Box)\,\delta(x,x') = \int dq\ d\omega\ \eta^{1/2}\beta^{1/2}\Phi(t|q,\omega)\exp(q^aP_a+\omega^iL_i)\,\delta(x,x')\,. \tag{4.32}$$

To learn how the operator $\exp(k^A\xi_A)$ acts on a scalar function $f(x)$, let us introduce a new function,

$$\phi(s,k,x) = \exp(sk^A\xi_A)f(x). \tag{4.33}$$

This function satisfies the first-order differential equation,

$$\partial_s\phi = k^A\xi_A\phi = k^A\xi^\mu{}_A(x)\,\partial_\mu\phi, \tag{4.34}$$

with the initial condition of the form

$$\phi|_{s=0} = f(x). \tag{4.35}$$

It is not difficult to prove that

$$\phi(s,k,x) = f(x_0(s,k,x)), \tag{4.36}$$

where $x_0(s,k,x)$ satisfies the equation of characteristics,

$$\frac{dx_0^\mu}{ds} = k^A\xi_A^\mu(x_0), \tag{4.37}$$

with the initial condition

$$x_0^\mu|_{s=0} = x^\mu. \tag{4.38}$$

Therefore, we have

$$\exp(k^A\xi_A)\,\delta(x,x') = \delta(x_0(1,k,x),x'). \tag{4.39}$$

Consider now the operator integrals of the form we need,

$$I(x,x')=\int dq\ d\omega\ \eta^{1/2}\beta^{1/2}Z(q,\omega)\exp(q^aP_a+\omega^iL_i)\,\delta(x,x'),\tag{4.40}$$

where $Z(q,\omega)$ is some analytic function. Using Eq. (4.39), we have

$$\exp(q^aP_a+\omega^iL_i)\,\delta(x,x')=\delta(x_0(1,q,\omega,x,x'),x')=\eta^{-1/2}J(\omega,x,x')\,\delta(q-\bar{q}),\tag{4.41}$$

where $\bar{q}=\bar{q}(\omega,x,x')$ is to be determined from the equation

$$x_0(1,\bar{q},\omega,x,x')=x'\tag{4.42}$$

and $J(\omega,x,x')$ is the Jacobian computed at $x_0=x'$,

$$J(\omega,x,x')=g'^{-1/2}\eta^{1/2}\ \det\left|\frac{\partial x_0^\mu}{\partial q^a}\right|^{-1}_{q=\bar{q},s=1}.\tag{4.43}$$

So, we can now simply integrate over q in (4.40) to get

$$I(x,x')=\int d\omega\ \beta^{1/2}Z(\bar{q}(\omega,x,x'),\omega)J(\omega,x,x').\tag{4.44}$$

If we are interested in the coincidence limit then one has to put finally $x=x'$,

$$I(x,x)=\int d\omega\ \beta^{1/2}Z(\bar{q}(\omega,x,x),\omega)J(\omega,x,x).\tag{4.45}$$

Consider now the equation of characteristics at greater length. Making a change of variables,

$$x^\mu\to\sigma_0^a=\sigma^a(x_0,x')=e^a_{\mu'}(x')\sigma^{\mu'}(x_0,x'),\tag{4.46}$$

we arrive to the equation of a more explicit form,

$$\frac{d\sigma_0^a}{ds}=-(\sqrt{K(\sigma_0)}\cot\sqrt{K(\sigma_0)})^a{}_bq^b-\omega^iD^a{}_{ib}\sigma_0^b.\tag{4.47}$$

Let $\sigma_0^a=\sigma_0^a(s,q,\omega,\sigma^b)$ be the solution of the equation (4.47). Then $\bar{q}$ is to be determined from an equation like (4.42),

$$\sigma_0^a(1,\bar{q},\omega,\sigma^b)=0\tag{4.48}$$

and

$$J(\omega,x,x')=\det\left|-\frac{\partial\sigma_0^a}{\partial q^b}\right|^{-1}_{q=\bar{q},s=1},\tag{4.49}$$

where it has been taken into account $\det(e_a^{\mu'})=g'^{-1/2}\eta^{1/2}$.

Therefore, we have to find the solution to the equation (4.47) near the zero, i.e. assuming σ_0^a to be small. Moreover, we consider mostly the case when the points x and x' are close to each other which means that σ^a is small as well. The equation (4.47) near the point $\sigma_0^a=0$ looks like

$$\frac{d\sigma_0^a}{ds}=-q^a,\tag{4.50}$$

meaning that the momentums q^a are of the same small order.

More precisely, we assume

$$\sigma_0^a \sim \sigma^b \sim q^c \sim \epsilon \ll 1, \tag{4.51}$$

and look for a solution of Eq. (4.47) in the form of a power series in ϵ, i.e. in the form of a Taylor series in σ^a and q^a.

In this way one simply obtains up to quadratic terms

$$\sigma_0^a(s,q,\omega,x,x') = (\exp(-s\omega^i D_i))^a{}_b \sigma^b + \left(\frac{\exp(-s\omega^i D_i)-1}{\omega^i D_i}\right)^a{}_b q^b + O(\epsilon^2). \tag{4.52}$$

With the same accuracy the solution of Eq. (4.48) is

$$\bar{q}^a = \left(\frac{\omega^i D_i \exp(-s\omega^i D_i)}{1-\exp(-s\omega^i D_i)}\right)^a{}_b \sigma^b + O(\sigma^{a2}). \tag{4.53}$$

Further, one finds from (4.52),

$$\det\left|-\frac{\partial \sigma_0^a}{\partial q^b}\right|_{q=\bar{q},s=1} = \det\left(\frac{\sinh(\omega^i D_i/2)}{\omega^i D_i/2}\right) + O(\sigma^a), \tag{4.54}$$

and so, from (4.49),

$$J(\omega,x,x') = \det\left(\frac{\sinh(\omega^i D_i/2)}{\omega^i D_i/2}\right)^{-1} + O(\sigma^a). \tag{4.55}$$

Substituting (4.53) and (4.55) in (4.44) and expanding $Z(\bar{q},\omega)$, we can calculate the integral (4.40) for near points x and x' in the form of an expansion in $\sigma^a(x,x')$.

Therefore, we have found, in particular, a useful exact result for coincidence limit (4.45).

Lemma 2: For an analytical function $Z(q,\omega)$ there holds

$$\begin{aligned} I(x,x) &= \int dq\ d\omega\ \eta^{1/2}\beta^{1/2} Z(q,\omega)\exp(q^a P_a + \omega^i L_i)\,\delta(x,x')|_{x=x'} \\ &= \int d\omega\ \beta^{1/2} Z(0,\omega)\det\left(\frac{\sinh(\omega^i D_i/2)}{\omega^i D_i/2}\right)^{-1}, \end{aligned} \tag{4.56}$$

with the operators P_a and L_i given by (3.40) and (3.41).

Using the obtained results (4.53), (4.55), and (4.56) and substituting the explicit form of our integral (4.31), we get the heat kernel in coordinate representation,

$$\begin{aligned} \exp(t\Box)(x,x') = (4\pi t)^{-D/2}\int d\omega\ \beta_H^{1/2}\ \det\left(\frac{\sinh(\omega^i C_i/2)}{\omega^i C_i/2}\right)^{1/2} \det\left(\frac{\sinh(\omega^i D_i/2)}{\omega^i D_i/2}\right)^{-1} \\ \times\exp\left\{-\frac{1}{4t}\,(\omega^i\beta_{ik}\omega^k + \sigma^a g_{ac}B^c{}_b(\omega)\sigma^b) + \left(\frac{1}{8}R + \frac{1}{6}R_H\right)t\right\} + O(\sigma^a), \end{aligned} \tag{4.57}$$

where $B(\omega) = \{B^a{}_b(\omega)\}$ is a matrix of the form

$$B(\omega)=\left(\frac{\sinh(\omega^i D_i/2)}{\omega^i D_i/2}\right)^{-2}. \tag{4.58}$$

Now, from (3.18) it is not difficult to find that

$$\det\left(\frac{\sinh(\omega^i C_i/2)}{\omega^i C_i/2}\right)=\det\left(\frac{\sinh(\omega^i D_i/2)}{\omega^i D_i/2}\right)\det\left(\frac{\sinh(\omega^i F_i/2)}{\omega^i F_i/2}\right). \tag{4.59}$$

Therefore, the final result, after taking into account (4.59), looks like

$$\exp(t\Box)(x,x')=(4\pi t)^{-D/2}\int d\omega\ \beta^{1/2}\ \det\left(\frac{\sinh(\omega^i F_i/2)}{\omega^i F_i/2}\right)^{1/2}\det\left(\frac{\sinh(\omega^i D_i/2)}{\omega^i D_i/2}\right)^{-1/2}$$
$$\times\exp\left\{-\frac{1}{4t}\,(\omega^i\beta_{ik}\omega^k+\sigma^a g_{ac}B^c_b(\omega)\sigma^b)+\left(\frac{1}{8}\,R+\frac{1}{6}\,R_H\right)t\right\}+O(\sigma^a). \tag{4.60}$$

The coincidence limit of this heat kernel is then simply derived by putting $x=x'$, i.e. $\sigma^a=0$,

$$\exp(t\Box)(x,x)=(4\pi t)^{-D/2}\int d\omega\ \beta^{1/2}\ \det\left(\frac{\sinh(\omega^i F_i/2)}{\omega^i F_i/2}\right)^{1/2}\det\left(\frac{\sinh(\omega^i D_i/2)}{\omega^i D_i/2}\right)^{-1/2}$$
$$\times\exp\left\{-\frac{1}{4t}\,\omega^i\beta_{ik}\omega^k+\left(\frac{1}{8}\,R+\frac{1}{6}\,R_H\right)t\right\}. \tag{4.61}$$

Note that this formula is exact (up to possible nonanalytic topological contributions, see the discussion in Sec. II). This gives a nontrivial example of how the heat kernel can be constructed using only the algebraic properties of the isometries of the symmetric space.

One can derive an alternative nontrivial *formal* representation of this result. Substituting the equation,

$$(4\pi t)^{-p/2}\beta^{1/2}\ \exp\left(-\frac{1}{4t}\,\omega^i\beta_{ik}\omega^k\right)=(2\pi)^{-p}\int dp\ \exp(ip_k\omega^k-tp_k\beta^{kn}p_n) \tag{4.62}$$

into the integral (4.61), and integrating over ω we obtain

$$\exp(t\Box)(x,x)=(4\pi t)^{-d/2}\ \exp\left\{t\left(\frac{1}{8}\,R+\frac{1}{6}\,R_H\right)\right\}\int dp\ \exp(-tp_n\beta^{nk}p_k)$$
$$\times\det\left(\frac{\sinh(-i\ \partial^k F_k/2)}{-i\ \partial^k F_k/2}\right)^{1/2}\det\left(\frac{\sinh(-i\ \partial^k D_k/2)}{-i\ \partial^k D_k/2}\right)^{-1/2}\delta(p), \tag{4.63}$$

where $\partial^k=\partial/\partial p_k$. Therefrom, integrating by parts and changing the integration variables $p_k\to it^{-1/2}p_k$ we get finally an expression without any integration,

$$\exp(t\Box)(x,x)=(4\pi t)^{-d/2}\ \exp\left(t\left(\frac{1}{8}\,R+\frac{1}{6}\,R_H\right)\right)\det\left(\frac{\sinh(\sqrt{t}\partial^k F_k/2)}{\sqrt{t}\partial^k F_k/2}\right)^{1/2}$$
$$\times\det\left(\frac{\sinh(\sqrt{t}\partial^k D_k/2)}{\sqrt{t}\partial^k D_k/2}\right)^{-1/2}\exp(p_n\beta^{nk}p_k)\Big|_{p=0}. \tag{4.64}$$

This formal solution should be understood as a power series in the derivatives ∂^i that is well defined and determines the heat kernel asymptotic expansion at $t\to 0$.

C. Heat kernel asymptotics

Using the obtained result one can get easily the explicit form of the generating function for HMDS coefficients (2.9),

$$\Omega(t|x,x)=(4\pi t)^{-p/2}\int d\omega\ \beta^{1/2}\ \det\left(\frac{\sinh(\omega^i F_i/2)}{\omega^i F_i/2}\right)^{1/2}\ \det\left(\frac{\sinh(\omega^i D_i/2)}{\omega^i D_i/2}\right)^{-1/2}$$
$$\times\exp\left\{-\frac{1}{4t}\,\omega^i\beta_{ik}\omega^k+\left(\frac{1}{8}\,R+\frac{1}{6}\,R_H\right)t\right\}. \tag{4.65}$$

This formula can be used now to generate *all* HMDS coefficients a_k for *any* symmetric space, i.e. for *any space with covariantly constant curvature*, simply by expanding it in a power series in t.

Changing the integration variables $\omega\to\sqrt{t}\omega$ and introducing a Gaussian averaging over ω,

$$\langle f(\omega)\rangle=(4\pi)^{-p/2}\int d\omega\ \beta^{1/2}\ \exp\left(-\frac{1}{4}\,\omega^i\beta_{ik}\omega^k\right)f(\omega), \tag{4.66}$$

we get

$$\Omega(t|x,x)=\exp\left\{\left(\frac{1}{8}\,R+\frac{1}{6}\,R_H\right)t\right\}\left\langle\det\left(\frac{\sinh(\sqrt{t}\omega^i F_i/2)}{\sqrt{t}\omega^i F_i/2}\right)^{1/2}\det\left(\frac{\sinh(\sqrt{t}\omega^i D_i/2)}{\sqrt{t}\omega^i D_i/2}\right)^{-1/2}\right\rangle. \tag{4.67}$$

Using the standard Gaussian averages,

$$\langle 1\rangle=1,\quad \langle\omega^i\rangle=0,\quad \langle\omega^i\omega^k\rangle=\tfrac{1}{2}\,\beta^{ik},$$
$$\langle\omega^i_1\cdots\omega^{i_{2n+1}}\rangle=0,$$
$$\langle\omega^{i_1}\cdots\omega^{i_{2n}}\rangle=\frac{(2n)!}{2^{2n}n!}\,\beta^{(i_1i_2}\cdots\beta^{i_{2n-1}i_{2n})}, \tag{4.68}$$

one can obtain now all HMDS coefficients in terms of various foldings of the quantities $D^a{}_{ib}$ and $F^j{}_{ik}$ with the help of matrix β^{ik}. All these quantities are curvature invariants and can be expressed directly in terms of a Riemann tensor. Thereby one finds *all covariantly constant terms in all HMDS coefficients* in a manifestly covariant way. We are going to obtain the explicit formulas in a further work.

V. CONCLUDING REMARKS

In the present paper we continued the study of the heat kernel that we conducted in our papers (Refs. 4, 10, 15, and 21). Here we have discussed some ideas connected with the point that was left aside in previous papers, namely, the problem of calculating the low-energy limit of the effective action in quantum gravity. We have analyzed in detail the status of the low-energy limit in quantum gravity and stressed the central role playing by the Lie group of isometries that naturally appears when generalizing consistently the low-energy limit to curved space.

We have proposed a promising, to our mind, approach for calculating the low-energy heat kernel and realized, thereby, the idea of partial summation of the terms without covariant derivatives in local asymptotic expansion for computing the effective action that was suggested in Refs. 2 and 4.

Of course, there are many unsolved problems left. First of all, one has to obtain *explicitly* the covariantly constant terms in HMDS coefficients. This would be the opposite case to the high-derivative approximation[15,16] and can be of certain interest in mathematical physics. Then, we still do not know how to calculate the low-energy heat kernel in the general case of covariantly constant curvatures, i.e. when all background curvatures ($\mathfrak{R}=\{R_{\mu\nu\alpha\beta},\mathscr{R}_{\mu\nu},Q\}$) are present. Besides, it is not perfectly clear how to do the analytical continuation of Euclidean low-energy effective action to the space of Lorentzian signature for obtaining physical results.

Let us make a final remark concerning the relation of our work to that of previous authors, who seems to treat almost the same problem (see the review paper of Camporesi in Ref. 22 and references therein and Ref. 27). What we have been trying to do in the present paper is rather different from what the other authors did. These are the *global* topological problems and effects that are of *prime* interest in those papers. The authors of those papers make use of the techniques of geometric analysis on homogenous spaces, with an emphasis on the *exact* results. That is why only very special concrete examples of symmetric spaces (group manifolds, spheres, rank-one symmetric spaces, split-rank symmetric spaces, etc.), which allow us to obtain closed formulas were considered. The results obtained in this way are presented in terms of the root vectors and their multiplicities. The complexity of the method depends critically on the rank of symmetric space. As far as we know the explicit results for the heat kernel are obtained for rank-one and for some rank-two symmetric spaces.

We are interested, in contrary, first of all in *local* effects of strongly curved *approximately homogeneous* manifolds. Therefore, our approach is thought of only as a *framework for a perturbation theory* in nonhomogeneity. In typical physical problems we need a rather *general approximation scheme* instead of exact exceptional results. The point is that we need the effective action as a functional of a *generic* metric that could be varied to obtain the physical currents.

There is, of course, the difficult question, of whether the global effects might be neglected in comparison with local ones. This question is *open*. We can only say that if it is the case, i.e. *if the local effects are dominant*, then the heat kernel is given by explicit covariant formulas obtained in Sec. IV.

VI. NOTE ADDED

After this paper was completed we became aware of the similar results on the heat kernel in symmetric spaces by Fegan (Ref. 27). Though they were obtained in a completely different rather geometrical setting incorporating the nontrivial global topology, one would, due to intrinsic locality of the heat kernel expansion, expect that the two expressions, i.e. ours and that of Ref. 27, should coincide under an appropriate representation of the special functions obtained in Ref. 27.

Another comment concerns the meaning of the effective potential. If the symmetry in question is that of Euclidean space (that is not the case, in general!) our expansion should reduce to the quasilocal expansion of Brown and Duff,[28] which was extended to curved spaces by Hu and O'Connor.[29] Therefore, one might consider our work as an extension of the quasilocal expansion to a symmetric space and quasihomogeneous setting.

ACKNOWLEDGMENTS

I would like to thank G. A. Vilkovisky for many helpful discussions and R. Schimming and J. Eichhorn for their hospitality at the University of Greifswald. I am also grateful to P. B. Gilkey, H. Osborn, S. Fulling, D. M. Mc Avity, T. Osborn, S. Odintsov, and K. Kirsten for correspondence. This work was supported, in part, by the Alexander von Humboldt Foundation, by a Soros Hu-

manitarian Foundations Grant awarded by the American Physical Society, and by an Award through the International Science Foundation's Emergency Grant competition.

Massive NGT and spherically symmetric systems

M. A. Clayton
Department of Physics, University of Toronto, Toronto, Ontario M5S 1A7, Canada

(Received 8 May 1995; accepted for publication 18 September 1995)

The arguments leading to the introduction of the massive Nonsymmetric Gravitational action are reviewed [J. W. Moffat, J. Math. Phys. **36**, 3722 (1995), Phys. Lett. B **355**, 447 (1995)], leading to an action that gives asymptotically well-behaved perturbations on General Relativity (GR) backgrounds. Through the analysis of spherically symmetric perturbations about GR (Schwarzschild) and Nonsymmetric Gravitational Theory (NGT) (Wyman-type) static backgrounds, it is shown that spherically symmetric systems are not guaranteed to be static, and hence Birkhoff's theorem is not valid in NGT. This implies that in general one must consider time dependent exteriors when looking at spherically symmetric systems in NGT. For the surviving monopole mode considered here there is no energy flux as it is short ranged by construction. Further work on the spherically symmetric case will be motivated through a discussion of the possibility that there remain additional modes that do not show up in weak field situations, but nonetheless exist in the full theory and may again result in bad global asymptotics. A presentation of the action and field equations in a general frame is given in the course of the paper, providing an alternative approach to dealing with the algebraic complications inherent in NGT, as well as offering a more general framework for discussing the physics of the antisymmetric sector. © *1996 American Institute of Physics.* [S0022-2488(96)01501-5]

I. INTRODUCTION

In General Relativity (GR), just as in Maxwell's electrodynamics, one finds that given a spherically symmetric system, there are no dynamical degrees of freedom in the theory. This is Birkhoff's theorem, and it implies that a time dependent source will not excite modes in the gravitational system, so that outside this source the system must be physically equivalent to the Schwarzschild solution (the nontrivial static spherically symmetric spacetime). It has been further established[1,2] that the solution is stable when perturbed, so that small deviations from spherical symmetry do not alter the large scale features of the spacetime, and systems that are only approximately spherically symmetric are therefore still very well modeled by the Schwarzschild solution. This establishes that the phenomenology of the Schwarzschild solution is physically relevant.

To see that Birkhoff's theorem is not a generic feature of physical theories one need look no further than a scalar field. However the example that is important for this work is the (massive) Kalb–Ramond action[3] which (as will be demonstrated in Section III) has a single mode that is time dependent in general. As will be shown in Section II, the massive Nonsymmetric Gravitational Theory[4,5] (mNGT as opposed to the older versions of the theory, referred to as NGT, or massless NGT) becomes identically a massive Kalb–Ramond field with an additional curvature coupling term when considered as a perturbation about a Ricci-flat GR background, so the result that NGT has a monopole mode is not surprising. The mode considered here is short ranged, so that far enough away from the source one finds that the solution will be dominated by Schwarzschild behavior, and there is no energy flux. However, after demonstrating that spherically symmetric fields in the skew sector are not static in general, it will be shown in Section VI that the symmetric sector will also no longer be static, through examination of a similar perturbation about the mNGT background discussed in Section V. This means that no static solutions can be consid-

0022-2488/96/37(1)/395/26/$6.00
J. Math. Phys. **37** (1), January 1996

ered rigorously as an exterior solution unless the solution is globally static (i.e. the interior is static as well).

The results in this paper are obtained through an examination of linearized perturbations, although the conclusions must hold in general as Birkhoff's theorem would imply that these fields must be static as well. What cannot be examined in this fashion is whether in the full nonlinear theory more modes become excited. In particular, one will see in the case of a perturbation about a GR background (in Section II) that there are three propagating modes, even though the absence of gauge invariant kinetic terms in the full theory would suggest that all six modes in the antisymmetric metric could be independent degrees of freedom (as yet, the number of degrees of freedom in mNGT has not been rigorously established). Although this issue is not addressed directly in this work, the ability to recast the theory in a general basis given in Section IV sets the stage for a complete analysis of the spherically symmetric system in NGT. Given that there is an additional mode in the general spherically symmetric system, how the fields may or may not approach an asymptotically flat spacetime should then be addressed, and also whether evolution singularities of the type discussed in Ref. 6 are encountered.

II. MASSIVE NGT

The original version of NGT[7] grew out of a re-interpretation of the Einstein-Straus[8,9] unified field theory as a purely gravitational system. The antisymmetric part of the metric and connection operationally produce different modes of parallel transport and index contraction,[7,10,11] where the algebra is consistent with an enlargement of the tangent vector space to its hyperbolic complex extension.[12–14] It is important to note that the action cannot support the additional Bianchi identities and gauge invariance related to the extension of the tangent bundle, simply because the base manifold is locally diffeomorphic to $\mathbb{R}^4$, and the variational principle is based on an integration over this real manifold. Any change of gauge that mixes real and hyperbolic complex covectors will cause the volume element to pick up a hyperbolic complex piece, and the action will no longer be real.

The hyperbolic complex structure is unnecessary for an operational discussion of the theory (although it may be relevant for a more fundamental discussion of its physical interpretation), and in this paper all quantities will be considered real, allowing antisymmetric contributions to the metric and connection coefficients. The dynamics of the theory will be determined from the first order action ($G=c=1$):

$$S=\int d^4x\{-\mathbf{g}^{\mu\nu}R^{\mathrm{NS}}_{\mu\nu}[\Gamma]-\mathbf{g}^{\mu\nu}\partial_{[\mu}W_{\nu]}+\mathbf{l}^{\mu}\Gamma_{\mu}+\tfrac{1}{2}\alpha\mathbf{g}^{(\mu\nu)}W_{\mu}W_{\nu}+\tfrac{1}{4}m^2\mathbf{g}^{[\mu\nu]}g_{[\mu\nu]}\}+S_M\,, \quad (1)$$

where

$$\frac{\delta S_M}{\delta g^{\mu\nu}}=\mathbf{T}_{\mu\nu}\,, \quad (2)$$

is the matter stress energy tensor derived from the variation of the matter action S_M, that acts as a source in the gravitational field equations. The Ricci-like tensor for NGT appearing in (1) is written as:

$$R^{\mathrm{NS}}_{\mu\nu}=\partial_{\alpha}\Gamma^{\alpha}_{\mu\nu}-\tfrac{1}{2}(\partial_{\nu}\Gamma^{\alpha}_{\mu\alpha}+\partial_{\mu}\Gamma^{\alpha}_{\alpha\nu})+\Gamma^{\alpha}_{\mu\nu}\Gamma^{\beta}_{(\alpha\beta)}-\Gamma^{\alpha}_{\beta\nu}\Gamma^{\beta}_{\mu\alpha}\,, \quad (3)$$

and a mass term for $g_{[]}$ has been included along with a term quadratic in W as new features of the action. As will become clear shortly, α may be fixed uniquely by requiring good asymptotic behavior of perturbations about GR backgrounds. The new parameter in the massive action (m) is an inverse length scale that must be constrained by experiment, and l is a Lagrange multiplier employed to enforce the vanishing of the trace of the antisymmetric part of the connection coefficients: $\Gamma_{\mu}=\Gamma^{\alpha}_{[\mu\alpha]}$.

The field equations related to the metric compatibility conditions are derived through the variations:

$$\frac{\delta S}{\delta \mathbf{l}^{\mu}} = \Gamma_{\mu} = 0, \tag{4a}$$

$$\frac{\delta S}{\delta W_{\mu}} = \partial_{\nu}\mathbf{g}^{[\nu\mu]} + \alpha \mathbf{g}^{(\mu\nu)} W_{\nu} = 0, \tag{4b}$$

$$\begin{aligned}\frac{\delta S}{\delta \Gamma^{\gamma}_{\sigma\omega}} = {} & \partial_{\gamma}\mathbf{g}^{\sigma\omega} - \mathbf{g}^{\sigma\omega}\Gamma^{\alpha}_{(\gamma\alpha)} + \mathbf{g}^{\alpha\omega}\Gamma^{\sigma}_{\alpha\gamma} + \mathbf{g}^{\sigma\alpha}\Gamma^{\omega}_{\gamma\alpha} - \tfrac{1}{2}\delta^{\omega}_{\gamma}(\partial_{\alpha}\mathbf{g}^{\sigma\alpha} + \mathbf{g}^{\alpha\beta}\Gamma^{\sigma}_{\alpha\beta} - \mathbf{l}^{\sigma}) \\ & - \tfrac{1}{2}\delta^{\sigma}_{\gamma}(\partial_{\alpha}\mathbf{g}^{\alpha\omega} + \mathbf{g}^{\alpha\beta}\Gamma^{\omega}_{\alpha\beta} + \mathbf{l}^{\omega}).\end{aligned} \tag{4c}$$

Contracting on either index of (4c) and solving for the (anti-)symmetric parts of the divergence of the densitized inverse metric results in the determination of the Lagrange multiplier using (4b): $\mathbf{l}^{\sigma} = (\alpha/3)\,\mathbf{g}^{(\sigma\omega)}W_{\omega}$. This also allows one to simplify the Kronecker-δ terms, and determine the compatibility conditions in undensitized form as:

$$\partial_{\gamma} g_{\mu\nu} - g_{\mu\alpha}\Gamma^{\alpha}_{\nu\gamma} - g_{\alpha\nu}\Gamma^{\alpha}_{\gamma\mu} = \tfrac{2}{3}\alpha(g_{\mu[\gamma}g_{\alpha]\nu} + \tfrac{1}{2}g_{\mu\nu}g_{[\gamma\alpha]})g^{(\alpha\beta)}W_{\beta}, \tag{5}$$

where the inverse of the metric has been defined by $g_{\mu\alpha}g^{\alpha\nu} = \delta^{\nu}_{\mu}$, which has been used in order to rewrite the compatibility conditions in terms of the components of the metric $g_{\mu\nu}$.

The remaining field equations derived from the variation of the action with respect to $g^{\mu\nu}$ may be written as:

$$\mathscr{R}_{\mu\nu} := R^{\mathrm{NS}}_{\mu\nu} + \partial_{[\mu}W_{\nu]} - \tfrac{1}{2}\alpha W_{\mu}W_{\nu} - \tfrac{1}{4}m^{2}(g_{[\mu\nu]} - g_{\alpha\mu}g_{\nu\beta}g^{[\alpha\beta]} + \tfrac{1}{2}g_{\nu\mu}g^{[\alpha\beta]}g_{[\alpha\beta]}) = T_{\mu\nu} - \tfrac{1}{2}g_{\nu\mu}T, \tag{6}$$

where $T = g^{\mu\nu}T_{\mu\nu}$, and the tensor $\mathscr{R}$ has been introduced in order to simplify the discussion of the field equations. One may translate the conventions used here to those in Ref. 4 by taking $W \to -\frac{2}{3}W, T_{\mu\nu} \to -8\pi T_{\mu\nu}$, $\alpha \to -\frac{9}{4}\sigma$, and adjusting the definitions of the inverse metric: $g^{\mu\nu} \to g^{\nu\mu}$. To see the equivalence of the action, one further needs to rewrite Γ in terms of the unconstrained W connection, and drop the contribution from the Lagrange multiplier l.

The action for massless NGT is given by (1) with $m = \alpha = 0$. As will be demonstrated, the new terms have been introduced in order to make all skew modes short ranged when considering perturbations about GR backgrounds. One performs this expansion about a symmetric, Ricci-flat background, where one assumes that all background curvatures fall off at worst as $1/r$ as $r \to \infty$. This allows one to talk sensibly of energy-momentum and decompose fields via a spin projection, so that higher order poles and negative energy (ghost) modes may be identified, as well as avoiding the full nonsymmetric structure of a more general background that would make the analysis far more complicated. One considers a perturbation of all quantities about a symmetric GR background as in[15]:

$$g_{\mu\nu} \to g_{(\mu\nu)} + h_{\mu\nu}, \quad \Gamma^{\alpha}_{\mu\nu} \to \left\{ \begin{matrix} \alpha \\ \mu\nu \end{matrix} \right\} + \gamma^{\alpha}_{\mu\nu}, \tag{7}$$

where W, l and T are considered to be first order in the perturbation (as the background is assumed to be Ricci-flat, there one has $T_{\mu\nu} = 0$). As usual, indices will be ''raised'' and ''lowered'' by the symmetric background metric, and the covariant derivative ∇ is associated with the back-

ground Christoffel symbols { } determined from the background metric in the usual manner. Corrections to the background curvatures, field equations and Lagrangian at each order in the perturbation will be indicated by a superscript as: ${}^0R, {}^1R \cdots$.

The first order correction to the compatibility equation (5) can be solved explicitly for γ to yield:

$$\gamma^{\alpha}_{\mu\nu} = \tfrac{1}{2} g^{\alpha\beta}(\nabla_\nu h_{\beta\mu} + \nabla_\mu h_{\nu\beta} - \nabla_\beta h_{\mu\nu}) + \tfrac{2}{3}\alpha \delta^{\alpha}_{[\mu} W_{\nu]}, \tag{8}$$

and $\gamma_\mu = \gamma^{\alpha}_{[\mu\alpha]}$ is seen to vanish by the linearization of the skew divergence equation:

$$-\nabla_\nu h^{[\mu\nu]} = \alpha W^\mu. \tag{9}$$

In massless NGT,[10] one had (8), (9) with $\alpha = 0$, and hence there was no relation between the metric degrees of freedom and those of W. The skew part of the linearization of equation (6) with $m = 0$ as well as $\alpha = 0$ became:

$${}^1\mathscr{R}_{[\mu\nu]} = {}^1R^{\mathrm{NS}}_{[\mu\nu]} + \partial_{[\mu} W_{\nu]} = \nabla_\alpha \gamma^{\alpha}_{[\mu\nu]} + \partial_{[\mu} W_{\nu]} = T_{[\mu\nu]}. \tag{10}$$

The symmetric contribution, are the equations for a metric perturbation in GR,[16] and will be ignored in the remainder of this section. Using (9) with $\alpha = 0$, the assumption that the background is Ricci-flat (${}^0R_{\mu\nu} = 0$), and the commutation relation (for an arbitrary tensor B):

$$\nabla_{[\alpha}\nabla_{\beta]} B_{\mu\nu} = -\tfrac{1}{2}(B_{\omega\nu}\,{}^0R^{\omega}{}_{\mu\alpha\beta} + B_{\mu\omega}\,{}^0R^{\omega}{}_{\nu\alpha\beta}), \tag{11}$$

(10) simplifies to:

$$\nabla^\alpha \nabla_\alpha h_{[\mu\nu]} - 2\partial_{[\mu} W_{\nu]} - 4\,{}^0R^{\alpha}{}_{\mu}{}^{\beta}{}_{\nu} h_{[\alpha\beta]} = \nabla^\alpha F_{\mu\nu\alpha} - 2\partial_{[\mu} W_{\nu]} - 8\,{}^0R^{\alpha}{}_{\mu}{}^{\beta}{}_{\nu} h_{[\alpha\beta]} = -2T_{[\mu\nu]}. \tag{12}$$

The second form is given in terms of the curl of the skew metric ($F_{\gamma\mu\nu} = \partial_\gamma h_{\mu\nu} + \partial_\nu h_{\gamma\mu} + \partial_\mu h_{\nu\gamma}$), in order to more easily demonstrate the result found previously by Damour, Deser, and McCarthy[17,18] (using the fact that $\nabla^\gamma \nabla^\nu F_{\mu\nu\gamma} = 0$ about a Ricci-flat background), that these antisymmetric perturbations will in general have bad asymptotic behavior. Although written as if the skew metric were a gauge field, the presence of the curvature coupling term implies that the associated gauge invariance is not present,[19] and one is not allowed to make any choice of gauge in order to simplify this sector. One proceeds by taking the divergence of (12) and choosing the gauge $\nabla^\alpha W_\alpha = 0$ (the theory had a $U(1)$ invariance as W only appeared in the action in a curl) to find:

$$\nabla^\alpha \nabla_\alpha W_\mu - 8\nabla^\nu [\,{}^0R^{\alpha}{}_{\mu}{}^{\beta}{}_{\nu} h_{[\alpha\beta]}] = -2\nabla^\nu T_{[\mu\nu]}. \tag{13}$$

Notice that the background curvature acts as a source here, so that even if one postulates that the matter source is conserved, this curvature coupling (and in general other nonlinear terms) will still exist as a source, causing W to propagate and have asymptotic behavior consistent with a massless field ($\sim 1/r$ along the forward light cone). Using this asymptotic behavior to determine h from (12) results in a source with $\sim 1/r$ behavior, causing the field h not to fall off as $r \to \infty$ along the forward light cone. This analysis is correct since one has assumed that the background curvature falls off fast enough, and hence the potential term in (13) can be treated as a source, without changing the asymptotic behavior of the fields. It must be stressed that one is assuming that the background *and* the radiative fields fall off at least as fast as $\sim 1/r$, and what has actually been derived here is a contradiction of this, since h is driven to a constant and can no longer be considered as a perturbative mode.

Any analysis of this sort also supposes that a solution of the linearized field equations does in fact correspond to an exact solution of the full nonlinear field equations. This is the case in GR[16,20]

at least for source free equations, but no such result exists yet for any of the models considered here. It is possible to take the stance that NGT is not linearization-stable, so that this sort of analysis necessarily produces spurious results that do not correspond to global solutions, but then one is denying the ability to do any sort of perturbative analysis without the existence of an exact solution to back it up. Due to the scarcity of solutions, and the apparent existence of weak-field perturbative situations, this would seem an unreasonable position to adopt.

This result is not confined to curved backgrounds, and in fact the analysis about Minkowski space will serve to explicitly demonstrate the higher order pole leading to bad fall-off. Since this curvature coupling, and any nonlinear effects in general, will act as a nonconserved source term in the skew sector, the linearization that correctly represents the full nonlinear field equations in the asymptotic region will have a nonconserved source term. This is no more than the observation that once again, the full NGT action does not possess any form of additional gauge invariance in the skew sector. A gauge field coupled to a source (or matter) in a manner that violates gauge invariance may have drastically different behavior than the empty space and apparently gauge invariant field equations, if indeed the action is consistent at all. Any analysis that attempts to determine the propagator or asymptotic behavior of the field must take the form of the source (or coupling to other fields) into account.

A trivial example of this is given by considering the Maxwell action. Coupling the usual gauge invariant kinetic terms to a nonconserved source gives an inconsistent set of field equations, and adding some sort of gauge fixing term will give a consistent set of equations, but the scalar ghost mode will be excited and depending on the gauge there may be higher order poles in the solution. The linearized field equations considered outside the source resemble those of the gauge invariant theory in a particular gauge, but treating them as such will not give asymptotic behavior that follows from coupling to the nonconserved source. The situation in NGT is more akin to enforcing the gauge condition in the action through the use of an auxiliary field as: $b\partial_\mu A^\mu$.[21,22] Source conservation and absence of ghosts relies on whether or not the scalar Lagrange multiplier field b has a source or not in the wave equation that determines it, and is thus a global question. Given that the source for A is not conserved, then b propagates and there are higher order poles in the solution for A, leading to fields that do not fall off as $r\to\infty$ along the forward light cone.

Considering the field equations for massless NGT linearized from (12) about Minkowski space:

$$\Box h_{[\mu\nu]}-2\partial_{[\mu}W_{\nu]}=-2T_{[\mu\nu]}, \tag{14a}$$

$$\partial_\nu h^{[\mu\nu]}=0, \tag{14b}$$

($\partial^\nu T_{[\nu\mu]}\neq 0$), one may take a divergence (to find a wave equation for W) or a curl (to remove W) of the first of these, resulting in the unique consistent solution:

$$h_{[\mu\nu]}=-2\Box^{-1}[T_{[\mu\nu]}+2\Box^{-1}\partial^\alpha\partial_{[\mu}T_{[\alpha\nu]]}],$$

$$W_\mu=-2\Box^{-1}\partial^\nu T_{[\mu\nu]}. \tag{15}$$

The presence of the higher order pole (and consequent bad fall-off) is now obvious from the presence of the $\Box^{-2}$ term in the Green's function solution, and is no more than the result of vanNieuwenhuizen[23] who showed that the only healthy quadratic actions built of antisymmetric tensor fields are the so-called Kalb–Ramond[3] (massless or massive) actions. One also notes that there are 5 modes here: 3 in h, since 3 are determined algebraically by the second equation in (14), and 2 in W due to the previously mentioned $U(1)$ gauge invariance.[24] If it is assumed that the (matter) source is conserved, the higher order poles are removed at linear order, but show up in the second order correction to the fields, again causing a breakdown of the perturbative analysis.

This analysis correctly represents the asymptotic behavior of the fields (W,h), and is equivalent to equation (18) of Ref. 25, where the higher order pole resides in the projection operator: $P(1^+)$. One also sees the true propagating nature of W, and this is borne out by the analysis in Refs. 26 and 27 where there are five degrees of freedom evolving from each Cauchy surface, the extra two of which are associated with the field W. That a Lagrange multiplier is propagating merely signifies that it is a determined multiplier, with its evolution derived from the field equations[15] and not freely fixable as was done in Refs. 28 and 29 and in the next to last section of Ref. 24 where *ad hoc* constraints were imposed on the linearized theory in order to obtain the dynamics of a Kalb–Ramond theory. That these constraints cannot exist is clear from the lack of gauge invariance in the full NGT action.

The result of vanNieuwenhuizen does however motivate a potential solution to this problem, since the massive Kalb–Ramond theory does not require a conserved current and yet has no ghost modes, higher order poles or tachyons. The additional terms in the action for mNGT (1) are introduced in order to allow the linearized field equations of NGT to take on this form in the antisymmetric sector. These two terms play slightly different roles: the W^2 term causes W to be determined in terms of metric functions directly (α is fixed in order to find the correct form of the kinetic energy terms), and the mass term for $g_{[]}$ makes the skew sector short-ranged, and ensures that the linearized field equations remain consistent when expanding about a flat background.

Thus mNGT should have a linearization about Minkowski space of the form:

$$\partial^\alpha F_{\mu\nu\alpha}+m^2 h_{[\mu\nu]}=J_{[\mu\nu]}. \tag{16}$$

The solution to (16) can be found by taking a divergence and substituting back in to find:

$$h_{[\mu\nu]}=\Box^{-1}\left[J_{[\mu\nu]}+\frac{2}{m^2}\partial^\alpha\partial_{[\mu}J_{[\alpha\nu]]}\right],$$

$$\partial^\nu h_{[\mu\nu]}=\frac{1}{m^2}\partial^\nu J_{[\mu\nu]}. \tag{17}$$

The higher order poles have disappeared, and it can be shown that the linearized Hamiltonian is weakly positive definite and that ghost modes are removed through the algebraic conditions that couple them locally to the source in (17). About a more general background one can allow a curvature coupling term, since it will not affect the behavior of the fields asymptotically once the background is assumed to fall off appropriately. Choosing the theory that results in this behavior in the linearized theory will fix α uniquely.

Returning now to the field equations of mNGT expanded about a GR background following from (6), one finds:

$${}^1\mathscr{R}_{\mu\nu}={}^1R_{\mu\nu}+\frac{1}{\alpha}\nabla_{[\mu}\nabla^\alpha h_{[\alpha\nu]]}-\frac{1}{2}m^2 h_{[\mu\nu]}=T_{\mu\nu}-\frac{1}{2}g_{\nu\mu}T, \tag{18}$$

where the first order correction to the ''Ricci'' tensor is given by:

$${}^1R_{\mu\nu}=\nabla_\alpha\gamma^\alpha_{\mu\nu}-\nabla_{(\nu}\gamma^\alpha_{\alpha\mu)}. \tag{19}$$

Again ignoring the symmetric GR perturbations, the antisymmetric part of (18) is:

$$\nabla_\alpha\gamma^\alpha_{[\mu\nu]}+\frac{1}{\alpha}\nabla_{[\mu}\nabla^\alpha h_{[\alpha\mu]]}-\tfrac{1}{2}m^2 h_{[\mu\nu]}=-\tfrac{1}{2}(\nabla^\alpha F_{\mu\nu\alpha}+m^2 h_{[\mu\nu]})-2\nabla^\alpha\nabla_{[\mu}h_{[\alpha\nu]]}$$
$$+\frac{1}{\alpha}\left[1+\frac{2}{3}\alpha\right]\nabla_{[\mu}\nabla^\alpha h_{[\alpha\nu]]}=T_{[\mu\nu]}. \tag{20}$$

Requiring that this reduce to the massive Kalb–Ramond field equations (16) determines the (previously arbitrary) coupling: $\alpha=3/4$. The last two terms can be reduced to a curvature term to give:

$$\nabla^{\alpha}F_{\mu\nu\alpha}+m^2h_{[\mu\nu]}-4^0R^{\alpha}{}_{[\mu}{}^{\beta}{}_{\nu]}h_{[\alpha\beta]}=-2T_{[\mu\nu]}, \tag{21}$$

so the skew sector perturbations are well-behaved when perturbing about any asymptotically flat GR background.

Expanding the action (1) to second order (ignoring surface terms) gives:

$${}^2\mathscr{L}=-{}^2R-\tfrac{1}{2}h^1R+h^{\mu\nu 1}R_{\mu\nu}+h^{\mu\nu}\partial_{[\mu}W_{\nu]}+\tfrac{1}{2}\alpha W^{\mu}W_{\mu}+l^{\mu}\Gamma_{\mu}-\tfrac{1}{4}m^2h^{[\mu\nu]}h_{[\mu\nu]} \tag{22}$$

and once compatibility is imposed, followed by the removal of W, this becomes:

$${}^2\mathscr{L}=\frac{1}{12}F^{\mu\nu\gamma}F_{\mu\nu\gamma}-\frac{1}{4}m^2h^{[\mu\nu]}h_{[\mu\nu]}-\nabla^{\gamma}h^{[\mu\nu]}\nabla_{\nu}h_{[\gamma\mu]}-\left(\frac{1}{2\alpha}+\frac{1}{3}\right)\nabla_{\nu}h^{[\mu\nu]}\nabla^{\gamma}h_{[\mu\gamma]}. \tag{23}$$

Choosing $\alpha=3/4$ results in kinetic terms identical to those of Kalb–Ramond theory on a GR background, giving the skew sector action:

$${}^2\mathscr{L}=\tfrac{1}{12}F^{\mu\nu\gamma}F_{\mu\nu\gamma}-\tfrac{1}{4}m^2h^{[\mu\nu]}h_{[\mu\nu]}-h^{[\mu\nu]}h^{[\alpha\beta]0}R_{\alpha\mu\beta\nu}, \tag{24}$$

which reproduces the linearized field equations (21). Thus the massive NGT action will be (1) with $\alpha=3/4$,[4] giving the action (24) for perturbations about a GR background and guaranteeing good asymptotic behavior for these fields.

Although it has been established that the perturbation equations about a GR background are a consistent system resulting in good fall-off for the skew sector, it is not clear whether an asymptotic perturbation actually corresponds to a global solution (linearization stability). The (seemingly contrived) asymptotic limit of gauge invariant kinetic terms cannot be reflected in the full action, since there is no room for the additional gauge invariance in theories constructed from antisymmetric fields in this manner. This means that in general that one expects more (perhaps all 6) degrees of freedom in the skew sector evolving as degrees of freedom in a Cauchy analysis, whereas in any spacetime that has an asymptotically flat region only three will survive. This situation could be similar to that found in Ref. 6, where vector fields were seen to increase their degrees of freedom when gravitational effects are taken into account. In order to obtain an asymptotically flat spacetime (with the reduced degrees of freedom of the vector fields) from physically reasonable initial data, the evolution equations were seen to have to encounter singularities. This is generally considered to be a sign of instability, and certainly not a desirable feature in any theory. Perturbations about NGT backgrounds should also be considered, since the physically interesting NGT solutions are most likely those that are not ''close'' to a GR solution.[30] It is hoped that a more complete analysis of the general spherically symmetric system should be able to say something about this issue, since it will certainly tell one how many degrees of freedom survive and how they couple to external fields, and hopefully something about how the system may or may not approach an asymptotically flat spacetime.

It is also true that the form of the action (1) is far from unique. In particular, one could replace the W^2 term with some combination of W^2 and $(1/\sqrt{-g})\,g_{(\mu\nu)}\partial_{\alpha}[\mathbf{g}^{[\mu\alpha]}]\partial_{\gamma}[\mathbf{g}^{[\nu\gamma]}]$, giving the same perturbation equations (21), and resulting in an arbitrary coupling constant in the action. Further, since there is nothing preventing one from adding $\Gamma_{[]}$ terms (they are tensors) or even infinite strings of terms of the form: $g_{(\alpha\beta)}g^{(\beta\gamma)}\cdots$ or $g_{[\alpha\beta]}g^{[\beta\gamma]}\cdots$ (which conveniently disappear in the asymptotic expansion), there is clearly an infinite number of actions that do this. These examples seem extremely unnatural and will not be considered further here, although the results of this paper would not change significantly for these more general actions.

III. SPHERICALLY SYMMETRIC PERTURBATION OF THE SCHWARZSCHILD SOLUTION IN A COORDINATE BASIS

The absence of a Birkhoff theorem may be derived from the perturbation equations (21) developed in Section II. In general the spherically symmetric fields in the skew sector will not be static, although the symmetric sector will remain static in the perturbation about the GR solution considered here. The background metric is Schwarzschild with (coordinate basis) metric written as: $g=\mathrm{diag}[A(r),-1/A(r),-r^2,-r^2\sin^2(\theta)]$, where $A(r)=1-2M_s/r$ and M_s is the Schwarzschild mass parameter. The perturbation considered will be one that is spherically symmetric but not necessarily static. A Killing vector analysis yields the general form of the spherically symmetric perturbation:

$$|h_{\mu\nu}|=\begin{bmatrix} h_{00}(t,r) & h_{(01)}(t,r)+h_{[01]}(t,r) & 0 & 0 \\ h_{(01)}(t,r)-h_{[01]}(t,r) & h_{11}(t,r) & 0 & 0 \\ 0 & 0 & h_{22}(t,r) & h_{[23]}(t,r)\sin(\theta) \\ 0 & 0 & -h_{[23]}(t,r)\sin(\theta) & h_{22}(t,r)\sin^2(\theta) \end{bmatrix}. \tag{25}$$

Making a change of coordinates of the background geometry is equivalent to making a change of gauge on the perturbation: $\delta h=\pounds_\varepsilon[g]$, where ε is the spherically symmetric vector gauge parameter generating diffeomorphisms between spherically symmetric spacetimes. This allows one to simplify the form of the perturbation by a suitable choice of gauge. Choosing the gauge parameter as:

$$\varepsilon^0=-\int\left(\frac{h_{(01)}}{A(r)}-\frac{\partial_t[h_{22}]}{2rA(r)^2}\right)dr, \tag{26a}$$

$$\varepsilon^1=\frac{h_{22}}{2r}, \tag{26b}$$

removes the $\theta-\theta$, $\phi-\phi$, and symmetric $t-r$ perturbations altogether, and a remaining gauge transformation $\varepsilon^0=\epsilon(t)$ allows one to remove an arbitrary function from the $t-t$ component of the form: $\delta h_{00}=2A(r)\epsilon(t)$.

The field equations will be written without the source terms for simplicity although it is straightforward to include them and relate the constants of integration to properties of the source. First reviewing how the symmetric (in this case identically GR) perturbations become static, it is simplest to begin with the field equation: ${}^1\mathscr{R}_{(01)}=0$, which implies:

$$\partial_t[h_{11}(t,r)]=0, \tag{27}$$

immediately showing that h_{11} must be static. By considering ${}^1\mathscr{R}_{22}=0$, it is determined to be:

$$h_{11}(t,r)=-\frac{2\delta M_s}{rA^2}, \tag{28}$$

where the integration constant has been combined with M_s and interpreted as a perturbation of the Schwarzschild mass parameter: δM_s. Then one considers: $g^{00}\,{}^1\mathscr{R}_{00}-g^{11}\,{}^1\mathscr{R}_{11}=0$, leading to:

$$h_{00}(t,r)=B(t)A-\frac{2\delta M_s}{r}, \tag{29}$$

also giving a contribution arising from the perturbed mass parameter, as well as an arbitrary function of time as an integration constant, removable by the remaining choice of gauge noted above with: $\epsilon(t)=-B(t)/2$. Thus one has that the symmetric perturbations are static and interpretable as being due to a small change in the total energy of the system: δM_s.

In the skew sector, the $t-r$ field equation gives:

$$^1\mathscr{R}_{[01]}=\tfrac{1}{2}(2A''-m^2)h_{[01]}=0, \tag{30}$$

from which one must conclude that $h_{[01]}$ vanishes outside the source. (Primes will denote the derivative of a function of one variable where convenient.) In massless Kalb–Ramond theory, this is the surviving spherically symmetric ghost mode which in that case is pure gauge. When a mass term is added, although these modes are now no longer pure gauge, they do not propagate since they are locally coupled to the source. It is these modes that one eventually must worry about, since in the full theory they may play a nontrivial dynamical role. In the $\theta-\phi$ sector:

$$^1\mathscr{R}_{[23]}=-\frac{1}{2}\left\{\frac{1}{A}\partial_t^2[h_{[23]}]-A\partial_r^2[h_{[23]}]-\left(A'-\frac{2A}{r}\right)\partial_r[h_{[23]}]+\left(\frac{4}{r^2}(1-A)+m^2\right)h_{[23]}\right\}\sin(\theta)=0. \tag{31}$$

In order to derive the asymptotic form of this perturbation, it is convenient to define $h_{[23]}=rf(t,r)$, leading to:

$$\frac{1}{A}\partial_t^2[f]-A\partial_r^2[f]-A'\partial_r[f]+\left(\frac{3A'}{r}+\frac{2A}{r^2}+m^2\right)f=0. \tag{32}$$

Introducing the coordinate:

$$r^*=\int\frac{dr}{A(r)}=r+2M_s\ln\left(\frac{r}{2M_s}-1\right), \tag{33}$$

one obtains (after multiplying by A) the partial differential equation for f in normal form:

$$\partial_t^2[f]-\partial_{r^*}^2[f]+A\left(m^2+\frac{2A}{r^2}+\frac{3A'}{r}\right)f=0, \tag{34}$$

where r is considered as a function of r^* as are $A(r)$ and $\partial_r A(r)$, and the perturbation $f=f(t,r^*)$. In this form it is obvious that (34) is a hyperbolic wave equation, and that the field f is therefore nonlocally related to the source.

Using the fact that $1/r-1/r^*\sim o(1/(r^*)^2)$ as $r^*\to\infty$, one keeps only the constant mass term asymptotically, as all other potential terms will be dominated by it. This leaves the massive scalar wave equation to determine the asymptotic form of the perturbation:

$$\partial_t^2[f]-\partial_{r^*}^2[f]+m^2f\sim 0. \tag{35}$$

The static solution of this is easily seen to have the asymptotic form:

$$h_{[23]}(r)\sim F_0\frac{r}{m}e^{-mr^*}\sim F_0\frac{r}{m}e^{-mr}\left(\frac{r}{2M_s}\right)^{-2mM_s}, \tag{36}$$

where a factor of m has been introduced in order to make the constant F_0 dimensionless. The general time dependent case may be handled by noting that the retarded and advanced Green's functions for the massive scalar wave equation[31] ($x^2=t^2-\vec{x}^2$):

$$D^{\text{ret, adv}}(x)=D^{\text{ret, adv}}(t,r)=\frac{1}{2\pi}\theta(\pm x^0)\left[\delta(x^2)-\frac{m\theta(x^2)}{2\sqrt{x^2}}J_1(m\sqrt{x^2})\right], \tag{37}$$

depends only on (t,r), and $r^*D^{\text{ret, adv}}(t,r^*)$ will solve (35). The asymptotic behavior of $h_{[23]}$ is then determined from:

$$h_{[23]}\sim rr^*D^{\text{ret, adv}}(t,r^*). \tag{38}$$

Note that the behavior on the light cone is determined from just the massless Green's function $\delta(x^2)$,[32] and so it would appear that $h_{[23]}$ will behave as r as $r\to\infty$ along the forward light cone. This is misleading, as it can be demonstrated explicitly[33] that for C^∞ initial data with compact spatial support, a massive Klein-Gordon field is bounded everywhere by: $\phi\leqslant d(1+|t|)^{-3/2}$, for some constant d, and therefore cannot radiate energy. This can also be understood by noting that because the field is massive, the effects propagating on the light cone must be fields of infinite energy, and given some physically reasonable source distribution, these infinite energy modes will not be excited.

The existence of time dependent solutions thus proves that Birkhoff theorem is not valid in mNGT, although the short-ranged nature of the skew sector implies that monopole radiation will not exist. The symmetric sector has remained static in this system, but as will be shown in Section VI, through a perturbation about an approximated mNGT solution, this will not be the case in general. The perturbation equations about a mNGT background have not been given in covariant form, primarily due to the complication involved (although it is possible in principle using a generalization of the inversion of the compatibility equation given in Ref. 34). Instead the system may be developed in each case separately, and the analysis simplified by considering the field equations in a vierbein frame given in the next Section.

IV. NONSYMMETRIC THEORIES IN A GENERAL FRAME

The structure of the compatibility relations and field equations in nonsymmetric theories can be formulated in terms of components in a general moving frame (in the sense of global section of the general linear frame bundle $GL\mathbf{M}$ of all linear frames over $\mathbf{M}$). The formalism given here is essentially a more systematic development of the approach in Ref. 35, and differs slightly from that of Hlavaty[36] in that the (in general nonsymmetric in a coordinate basis) connection coefficients have been split up into a connection that is torsion free, and another that is purely antisymmetric, instead of defining two types of covariant derivative, one associated with the NGT Christoffel symbols, and another that is in general nonsymmetric and not in general torsion-free. The construction here has the advantage of only defining one covariant derivative, and the fact that it is torsion-free implies that the antisymmetric components in a general (noncoordinate) frame are related in the standard way to the structure constants. In a coordinate basis this is the usual split between the symmetric and antisymmetric components, however it is easily generalized to any basis by considering the antisymmetric components as a separate antisymmetric tensor, and the symmetric components as a torsion-free but generally noncompatible connection.

This provides a simple way to split the GR and NGT contribution in weak field situations, as well as generating computationally simpler systems to solve when inverting the compatibility relations. Note that although the formalism is developed for a general basis, the specialization to a vierbein basis (the reduction of $GL\mathbf{M}$ to $L\mathbf{M}$, the Lorentz frame bundle consisting of all Lorentz frames above $\mathbf{M}$) which will be utilized in the rest of this paper, is accomplished through the choice of the fiber metric as $g_{()}\to\eta$ above all points of the manifold. This is possible in NGT for the same reason that it is possible in GR: mathematically formulating a physical theory in a diffeomorphism invariant manner will always allow the introduction of these general linear frames. The reduction to Lorentz frames is also possible as one is assuming that the symmetric part of the metric that one is attempting to diagonalize is nondegenerate, allowing the reduction of

the frame bundle. This construction will be of importance when considering the canonical analysis of NGT, as one would like to work in a surface compatible (generally noncoordinate) basis in order to avoid specialization to a particular choice of time parameter fixed by the foliation of the manifold, and is easily applied to other systems with a nonsymmetric metric and connection.[29]

A. Metric, compatibility and curvature

The compatibility conditions in a coordinate basis (5) will be written for convenience as:

$$\partial_\gamma[g_{\mu\nu}]-g_{\mu\alpha}\Gamma^\alpha_{\nu\gamma}-g_{\alpha\nu}\Gamma^\alpha_{\gamma\mu}=-\Delta^0_{\gamma\mu\nu}, \tag{39}$$

where Δ^0 depends only on the metric or quantities directly derivable from it (and possibly other quantities, but for the purposes of this construction it does not depend on the connection coefficients). Parallel transport (and the related covariant derivative) will then be defined using just the symmetric part of the coordinate basis connection, and its action on the (coordinate) basis vectors is:

$$\nabla_{e_\alpha}[e]_\beta=\Gamma^\gamma_{(\alpha\beta)}e_\gamma,\nabla_{e_\alpha}[\theta]^\gamma=-\Gamma^\gamma_{(\alpha\beta)}\theta^\beta, \tag{40}$$

and the connection is split into a symmetric connection and an antisymmetric tensor:

$$\Gamma^\gamma_{\mu\nu}\rightarrow\Gamma^\gamma_{(\mu\nu)}+\Lambda^\gamma_{[\mu\nu]}. \tag{41}$$

Thus Γ will refer from this point onwards to the torsion-free (symmetric in a coordinate basis) part of the connection, and Λ to the remaining tensor contribution. In this way, Γ is a torsion-free (but noncompatible) covariant derivative since:

$$T^\gamma_{\mu\nu}=\theta^\gamma[\nabla_{e_\mu}e_\nu-\nabla_{e_\nu}e_\mu-[e_\mu,e_\nu]]=2\Gamma^\gamma_{[\mu\nu]}=0. \tag{42}$$

The compatibility equation (39) then becomes:

$$\nabla_{e_\gamma}[g]_{\mu\nu}=e_\gamma[g_{\mu\nu}]-g_{\mu\alpha}\Gamma^\alpha_{\gamma\nu}-g_{\alpha\nu}\Gamma^\alpha_{\gamma\mu}=g_{\mu\alpha}\Lambda^\alpha_{\nu\gamma}+g_{\alpha\nu}\Lambda^\alpha_{\gamma\mu}-\Delta^0_{\gamma\mu\nu}, \tag{43}$$

where the basis vectors are just directional derivatives along the coordinates: $e_\gamma[\,]=\partial_\gamma[\,]$.

With this definition of the covariant derivative and related connection coefficients, the geometric curvature is found as usual from:

$$R^\alpha_{\beta\mu\nu}=\theta^\alpha[(\nabla_{e_\mu}\nabla_{e_\nu}-\nabla_{e_\nu}\nabla_{e_\mu}-\nabla_{[e_\mu,e_\nu]})e_\beta]=e_\mu[\Gamma^\alpha_{\nu\beta}]-e_\nu[\Gamma^\alpha_{\mu\beta}]+\Gamma^\gamma_{\nu\beta}\Gamma^\alpha_{\mu\gamma}-\Gamma^\gamma_{\mu\beta}\Gamma^\alpha_{\nu\gamma}, \tag{44}$$

and defining the two independent contractions:

$$R^1_{\mu\nu}=R^\alpha_{\mu\alpha\nu}=e_\alpha[\Gamma^\alpha_{\nu\mu}]-e_\nu[\Gamma^\alpha_{\alpha\mu}]+\Gamma^\gamma_{\nu\mu}\Gamma^\alpha_{\alpha\gamma}-\Gamma^\gamma_{\alpha\mu}\Gamma^\alpha_{\nu\gamma}, \tag{45a}$$

$$R^2_{\mu\nu}=R^\alpha_{\alpha\mu\nu}=e_\mu[\Gamma^\alpha_{\nu\alpha}]-e_\nu[\Gamma^\alpha_{\mu\alpha}]. \tag{45b}$$

The Ricci tensor will be defined as:

$$R_{\mu\nu}=R^1_{\mu\nu}-\tfrac{1}{2}R^2_{\mu\nu}=e_\alpha[\Gamma^\alpha_{\nu\mu}]-\tfrac{1}{2}(e_\nu[\Gamma^\alpha_{\alpha\mu}]+e_\mu[\Gamma^\alpha_{\nu\alpha}])+\Gamma^\gamma_{\nu\mu}\Gamma^\alpha_{\alpha\gamma}-\Gamma^\gamma_{\alpha\mu}\Gamma^\alpha_{\nu\gamma}. \tag{46}$$

This particular combination is symmetric, and obviously reduces to the GR Ricci tensor when the NGT antisymmetric terms vanish. Decomposition of (3) into $R_{\mu\nu}$ and another that depends on Λ as: $R^{\rm NS}_{\mu\nu}=R_{\mu\nu}+R^\Lambda_{\mu\nu}$ where $(\Lambda_\mu=\Lambda^\alpha_{\mu\alpha})$ gives:

$$R^{\Lambda}_{\mu\nu}=\nabla_{e_\alpha}[\Lambda]^{\alpha}_{\mu\nu}+\nabla_{e_{[\mu}}[\Lambda]_{\nu]}+\Lambda^{\alpha}_{\mu\beta}\Lambda^{\beta}_{\nu\alpha}. \tag{47}$$

A more general basis is introduced at each point on the manifold through $e_A=E^{\mu}_{A}e_{\mu}$, where E is locally an element of $Gl(4,\mathbb{R})$, and these bases are smoothly joined up to form sections of the tangent bundle $T(\mathbf{M})$.[37,38] The general basis vectors are then given in terms of a coordinate basis through the vierbein-like quantities, which can be used to translate tensors from one choice of basis to the other:

$$e_A=E^{\mu}_{A}e_{\mu}, \quad E^{\mu}_{A}E^{\nu}_{B}g_{\mu\nu}=g_{AB}, \text{ etc.} \tag{48}$$

(In the usual orthonormal basis, one transforms the symmetric part of the metric to the Minkowski space metric, and the E's provide the isomorphism between coordinate basis tensors and locally Lorentzian tensors.) The dual basis of $T^*(\mathbf{M})$ is introduced through the usual relation: $\theta^A[e_B]=\delta^A_B$, and the inverse of the vierbeins is defined through: $E^{\mu}_{A}E^{A}_{\nu}=\delta^{\mu}_{\nu}$. In this paper capital letters from the beginning of the alphabet: $A,B,C,\cdots$ will refer to components of the object decomposed in the general basis.

Parallel transport of the basis vectors now defines the generalized connection coefficients:

$$\nabla_{e_A}[e]_B=\Gamma^{C}_{AB}e_C, \nabla_{e_A}[\theta]^C=-\Gamma^{C}_{AB}\theta^B. \tag{49}$$

The definition of the basis in (48) implies that it is no longer a coordinate basis in general, and hence the directional derivatives no longer necessarily commute, giving rise to the structure constants:

$$[e_A,e_B]=C_{AB}{}^{C}e_C, \tag{50a}$$

given by:

$$C_{AB}{}^{C}=E^{C}_{\nu}(E^{\mu}_{A}\partial_{\mu}[E^{\nu}_{B}]-E^{\mu}_{B}\partial_{\mu}[E^{\nu}_{A}]), \tag{50b}$$

calculated by noting that $e_A[\,]=E^{\mu}_{A}\partial_{\mu}[\,]$. This also implies that a torsion-free connection will no longer be symmetric, and vanishing torsion now gives:

$$T^{A}_{BC}=\theta^A[\nabla_{e_B}e_C-\nabla_{e_C}e_B-[e_B,e_C]]=2\Gamma^{A}_{[BC]}-C_{BC}{}^{A}=0, \tag{51}$$

allowing one to determine the antisymmetric part as usual from the structure constants. This is the motivation for splitting up the connection in this way. Given some alternate split where Γ is not torsion free, one would have to distinguish between the effects of the general basis on the skew part of the connection coefficients, and that of the NGT effects (themselves tensors).

The compatibility condition (39) can now be written as:

$$\nabla_{e_C}[g]_{AB}=g_{AD}\Lambda^{D}_{BC}+g_{DB}\Lambda^{D}_{CA}-\Delta^{0}_{CAB}, \tag{52}$$

where since Δ^0 and Λ are tensors, they are just redefined by multiplication by the appropriate combination of vierbeins. The symmetric part of this can now be solved for the symmetric part of Γ in terms of the antisymmetric part, the structure constants, and Λ, to give:

$$\Gamma_{C(AB)}=\tfrac{1}{2}\Delta_{C(AB)}-\Gamma_{A[BC]}+\Gamma_{B[CA]}-A^{D}_{A}\Lambda_{DBC}+A^{D}_{B}\Lambda_{DCA}, \tag{53}$$

where the quantities:

$$\Gamma_{ABC}=g_{(AD)}\Gamma^{D}_{BC}, \quad \Lambda_{ABC}=g_{(AD)}\Lambda^{D}_{BC}, \quad A^{A}_{B}=S^{(AC)}g_{[CB]}, \tag{54}$$

have been defined for convenience, and S is the inverse of the symmetric part of the metric defined by: $S^{(AB)}g_{(BC)}=\delta^A_C$. Also appearing is the symmetric part of:

$$\Delta_{CAB}=e_B[g_{CA}]+e_A[g_{BC}]-e_C[g_{AB}]+\Delta^0_{BCA}+\Delta^0_{ABC}-\Delta^0_{CAB}. \tag{55}$$

The antisymmetric part of the compatibility conditions can now be recast [using (53)] as 24 algebraic equations for Λ:

$$\Lambda_{CAB}-A^D_AA^E_B\Lambda_{ECD}-A^D_AA^E_C\Lambda_{EBD}+A^D_BA^E_A\Lambda_{ECD}+A^D_BA^E_C\Lambda_{EAD}=\Omega_{C[AB]}, \tag{56}$$

where:

$$\begin{aligned}\Omega_{C[AB]}=&\tfrac{1}{2}(\Delta_{C[AB]}+A^D_B\Delta_{D(CA)}-A^D_A\Delta_{D(BC)})+A^D_A(\Gamma_{B[CD]}+\Gamma_{C[BD]})\\&-A^D_B(\Gamma_{A[CD]}+\Gamma_{C[AD]})-A^D_C\Gamma_{D[AB]}.\end{aligned} \tag{57}$$

The method for solving the compatibility conditions is to first determine the auxiliary quantities appearing in this relation: $(A,\Gamma_{[\,]},\Delta,\Omega)$ in terms of the vierbeins and metric quantities, then solve for Λ through (56), determine $\Gamma_{(\,)}$ from (53), and then use S with $\Gamma_{[\,]}$ and $\Gamma_{(\,)}$ to form Γ^A_{BC} and Λ^A_{BC}. This may not seem like much of a simplification, but when specialized to a Lorentz frame, many of these quantities simplify considerably (as is the case in the Wyman sector in Section V).

The curvature tensor (44) becomes:

$$\begin{aligned}R^A_{BCD}=&\theta^A[(\nabla_{e_C}\nabla_{e_D}-\nabla_{e_D}\nabla_{e_C}-\nabla_{[e_C,e_D]})e_B]\\=&e_C[\Gamma^A_{DB}]-e_D[\Gamma^A_{CB}]+\Gamma^E_{DB}\Gamma^A_{CE}-\Gamma^E_{CB}\Gamma^A_{DE}-C_{CD}{}^E\Gamma^A_{EB},\end{aligned} \tag{58}$$

and the contractions:

$$R^1_{AB}=R^C_{ACB}=e_C[\Gamma^C_{BA}]-e_B[\Gamma^C_{CA}]+\Gamma^D_{BA}\Gamma^C_{CD}-\Gamma^D_{CA}\Gamma^C_{BD}-C_{CB}{}^D\Gamma^C_{DA}, \tag{59a}$$

$$R^2_{AB}=R^C_{CAB}=e_A[\Gamma^C_{BC}]-e_B[\Gamma^C_{AC}]-C_{AB}{}^D\Gamma^C_{DC}, \tag{59b}$$

combine to give the Ricci tensor:

$$\begin{aligned}R_{AB}=&R^1_{AB}-\tfrac{1}{2}R^2_{AB}=e_C[\Gamma^C_{BA}]-e_B[\Gamma^C_{CA}]-\tfrac{1}{2}e_A[\Gamma^C_{BC}]+\tfrac{1}{2}e_B[\Gamma^C_{AC}]\\&+\Gamma^D_{BA}\Gamma^C_{CD}-\Gamma^D_{CA}\Gamma^C_{BD}-C_{CB}{}^D\Gamma^C_{DA}+\tfrac{1}{2}C_{AB}{}^D\Gamma^C_{DC}\\=&e_C[\Gamma^C_{BA}]-e_B[\Gamma^C_{CA}]-\tfrac{1}{2}e_A[\Gamma^C_{BC}]+\tfrac{1}{2}e_B[\Gamma^C_{AC}]+\Gamma^D_{BA}\Gamma^C_{CD}-\Gamma^D_{CB}\Gamma^C_{DA}+\Gamma^D_{[AB]}\Gamma^C_{DC}.\end{aligned} \tag{60}$$

In the split $R^{\rm NS}_{AB}=R_{AB}+R^\Lambda_{AB}$:

$$R^\Lambda_{AB}=\nabla_{e_C}[\Lambda]^C_{AB}+\nabla_{e_{[A}}[\Lambda]_{B]}+\Lambda^C_{AD}\Lambda^D_{BC} \tag{61}$$

as expected.

Since by construction Γ is a torsion free connection, and (58) is the standard curvature tensor constructed from it, one obtains the usual Bianchi identities[38] on the curvature tensor. One should note though that the connection is not compatible, and so the rotation coefficients are not antisymmetric. The relevant Ricci tensors are also not constructed in the same manner as in GR, so the implications of these identities are somewhat different. The first Bianchi identity gives the usual cyclic identity on the last three indices of (58), and leads to the result:

$$R^1_{[AB]} = \tfrac{1}{2} R^2_{AB} \tag{62}$$

when one contracts on any lowered index. (This can also be proven directly using the Jacobi identity.) This tells us that the NGT Ricci tensor is symmetric ($R_{[AB]}=0$) in general, not just in a coordinate basis.

A detailed study of the contractions of the second Bianchi identity (the cyclic covariant derivative):

$$\nabla_{e_C}[R]^A_{BDE} + \nabla_{e_D}[R]^A_{BEC} + \nabla_{e_E}[R]^A_{BCD} = 0, \tag{63}$$

should result in a derivation of the equations of motion for matter fields[39,40] from the field equations.

B. The NGT action and field equations in a general basis

The translation of the field equations (4b), (5), (6) is accomplished through an almost straightforward substitution:

$$\Lambda_A = 0, \tag{64a}$$

$$\nabla_{e_B}[\mathbf{g}]^{[AB]} = \alpha \mathbf{g}^{(AB)} W_B, \tag{64b}$$

$$\mathscr{R}_{AB} := R^{NS}_{AB} + \nabla_{e_{[A}}[W]_{B]} - \tfrac{1}{2}\alpha W_A W_B - \tfrac{1}{4} m^2 M_{AB} = 0, \tag{64c}$$

where the density is $\sqrt{-g} = \sqrt{-\det(g_{AB})}$, the mass tensor:

$$M_{AB} = g_{[AB]} - g_{CA} g_{BD} g^{[CD]} + \tfrac{1}{2} g_{BA} g^{[CD]} g_{[CD]} \tag{65}$$

has been defined, and the tensor appearing in the compatibility equations is:

$$\Delta^0_{CAB} = -\tfrac{2}{3}\alpha (g_{A[C} g_{D]B} + \tfrac{1}{2} g_{AB} g_{[CD]}) g^{(DE)} W_E. \tag{66}$$

One must be careful to treat totally antisymmetric derivatives properly (the structure constants now come into the curl of a vector), and translate the metric density properly.

In order to define the action, one should note that the inverse of the metric is now: $g_{AB} g^{BC} = g^{CB} g_{BA} = \delta^C_A$, and the direct translation of the density results in: $\sqrt{-g} \to \sqrt{-E g E^t} = E\sqrt{-g}$ where $g = \det(g_{AB})$ and $E = \det(E^A_\mu)$. Then (1) is rewritten:

$$S = \int d^4x E \{ -\mathbf{g}^{AB} R^{\mathrm{NS}}_{AB} - \mathbf{g}^{AB} \nabla_{e_{[A}}[W]_{B]} + \mathbf{l}^A \Lambda_A + \tfrac{1}{2}\alpha \mathbf{g}^{(AB)} W_A W_B + \tfrac{1}{4} m^2 \mathbf{g}^{[AB]} g_{[AB]} \}. \tag{67}$$

(Note that in a Lorentz basis, the inverse of the metric is not η.)

Deriving the equations of motion from this action should be approached with care. As it stands there are too many fields (the metric and the vierbeins share degrees of freedom) and one typically must choose either a coordinate basis (as in Section II), a Lorentz basis (so that all symmetric metric degrees of freedom are contained in the vierbeins), or a well-defined combination of the two. One must also realize that (67) as it stands assumes that the connection Γ is torsion-free *a priori*, so that when varying the vierbein, $\Gamma_{[\,]}$ must be varied as well. As an alternative, one may impose the torsion-free condition through additional Lagrange multiplier terms: $L^{BC}_A T^A_{BC}$ in the action, varying the full connection coefficients and vierbeins separately.

V. APPROXIMATION OF THE WYMAN SECTOR SOLUTION IN A VIERBEIN BASIS

In general, the spherically symmetric Killing vector analysis for a (0,2) tensor gives both $t-r$ and $\theta-\phi$ skew components. However it is possible to show from the general spherically symmetric field equations that it is consistent to put either (or both) of these skew components to zero separately, since in either case one loses the corresponding field equation, and the system of equations remains consistent. Whether it is physically reasonable to do this or not depends on the details of the matter coupling in the theory, and how it alters the global behavior of the skew sector. Here will be considered the field equations for what will be referred to as the Wyman sector[41] (keeping just the $\theta-\phi$ sector), although the asymptotics of the $t-r$ sector will be discussed briefly at the end of this section, where it will be argued that there are no static solutions with asymptotic behavior that is dominated by Schwarzschild (or equivalently, Newtonian) effects. This will allow an analysis of the perturbation equations for the spherically symmetric modes, in order to see the effects of the antisymmetric background.

In a coordinate basis, the Wyman metric looks like:

$$|g_{\mu\nu}| = \text{diag}[\gamma(r), -\alpha(r), -r^2, -r^2 \sin^2(\theta)], \quad g_{[23]} = f(r)\sin(\theta). \tag{68}$$

(An appropriate coordinate system has been chosen in order to remove the symmetric $t-r$ metric component, and fix the $\theta-\theta$ component.) Introducing the usual choice of vierbein (using the functions defined by: $F=f(r)/r^2, E_0=1/\sqrt{\gamma(r)}, E_1=1/\sqrt{\alpha(r)}$):

$$E_A^{\mu} = \text{diag}\left[E_0^{\ 0}=E_0, E_1^{\ 1}=E_1, E_2^{\ 2}=\frac{1}{r}, E_3^{\ 3}=\frac{1}{r\ \sin(\theta)} \right], \tag{69}$$

the metric becomes:

$$|g_{(AB)}| = \eta_{AB}, \quad g_{[23]} = F, \tag{70}$$

and the density $\sqrt{-g}=\sqrt{1+F^2}$.

At this point one can invert the compatibility conditions and compute the field equations using the method of Section IV, given in some detail in Appendix A. No attempt will be made here to solve the field equations exactly, although numerical evidence for the existence of an exact solution with asymptotic behavior that matches that given here has been found,[42] ensuring that the approximations given come from a global solution. Instead, an approximation will be given that describes the asymptotic behavior of the exact solution. The idea will be to consider the skew sector as a small correction (of order some small dimensionless parameter κ, to be explicitly defined later) to the Schwarzschild solution far enough away from the source. This should be reasonable since one expects from the results of the perturbation in Section III that the skew sector will behave asymptotically as a decaying exponential, while the symmetric sector should behave as $\sim 1/r$, so that far enough away from the gravitational source the skew sector should be completely dominated by GR effects.

To lowest order in κ (the skew sector) the work is already done, as the field equation for the skew function will be essentially the same as the static perturbation about a Schwarzschild background already considered in Section III. In the vierbein basis, this is derived as before from $\mathscr{R}_{[23]}$ (A8), and gives:

$$A\partial_r^2[F] + \left(A' + \frac{2A}{r} \right) \partial_r[F] - \frac{2}{r}\left(A' + \frac{A}{r} \right) F - m^2 F = 0, \tag{71}$$

and it is trivial to see that when using: $F=f/r$, this reduces to the static limit of (32), giving the asymptotic form for F:

$$F \sim F_0 \frac{e^{-mr^*}}{mr}. \tag{72}$$

One now must consider how the presence of the skew sector affects the symmetric sector, particularly whether it really is a higher order effect. The asymptotic form of these corrections due to F may be calculated by considering order κ^2 corrections to the vierbeins (order κ terms will not depend on F, and so will be solely δM_s corrections), calculated from the symmetric field equations with F from (72) acting as a source. Writing the corrections to the vierbeins as: $E_{0,1} \to E_{0,1} + E^{(2)}_{0,1}$, and the corrections to the field equations as $\mathscr{R}^{(2)}$, one calculates:

$$\mathscr{R}^{(2)}_{00} + \mathscr{R}^{(2)}_{11} = -\frac{2A}{r}\partial_r\left[\sqrt{A}E^{(2)}_0 + \frac{E^{(2)}_1}{\sqrt{A}}\right] - AFF'' - \frac{3}{2}A(F')^2 - \frac{2A}{r}FF' = 0, \tag{73}$$

which, after translating it into a differential equation in r^* and keeping only the asymptotically dominant terms, results in:

$$\partial_{r^*}\left[\sqrt{A}E^{(2)}_0 + \frac{E^{(2)}_1}{\sqrt{A}}\right] \sim -\frac{5}{4}(F_0)^2\frac{e^{-2mr^*}}{r^*}. \tag{74}$$

This integrates to give (the constant of integration is ignored as one could eliminate it through an appropriate choice of gauge as in Section III):

$$\sqrt{A}E^{(2)}_0 + \frac{E^{(2)}_1}{\sqrt{A}} \sim \frac{5}{4}(F_0)^2\frac{e^{-2mr^*}}{2mr^*}. \tag{75}$$

Considering next $\mathscr{R}^{(2)}_{33}$ and using (73) leads to the asymptotic equation:

$$\partial_{r^*}[r\sqrt{A}E^{(2)}_1] \sim -\tfrac{5}{4}(F_0)^2 e^{-2mr^*}. \tag{76}$$

The solution of this combined with the results of (75) gives (once again the constant of integration is ignored, this time as it would be interpretable as a perturbation of the mass parameter and not due to the effects of the skew sector):

$$E^{(2)}_1 \sim \frac{5}{4}(F_0)^2\frac{e^{-2mr^*}}{2mr^*}, \quad E^{(2)}_0 \sim o\left(\frac{e^{-2mr^*}}{(r^*)^2}\right), \tag{77}$$

where the dominant correction to the symmetric sector is $E^{(2)}_1$, and $E^{(2)}_0$ is down by $o(1/r^*)$. It is not hard to see that these corrections are indeed of an order higher than the effects in the skew sector. Clearly one may define a small parameter $\kappa = F_0 \exp(-mr^*_0)$, where r^*_0 is chosen such that $F(r^*_0) \ll 1$, to define the small size of the skew sector when $r^* > r^*_0$. The corrections to the symmetric sector are seen to be of order κ^2, and will therefore be neglected in the approximation of the background required in Section VI.

One may attempt to do the same sort of analysis keeping the $g_{[01]}$ component, however the linearized field equation implies immediately that the field must vanish (it is identical to (30)). Considering higher orders in the field in an attempt to generate a solution other than this trivial result, the third order correction gives [writing $W(r) = \sqrt{-X(r)}$, where the sign has been chosen so that the asymptotic behavior determined below results in a real $W(r)$]

$$\mathscr{R}_{[01]} = \frac{\sqrt{-X}}{6}\left[A\partial_r^2[X] + \left(A' + \frac{2A}{r}\right)\partial_r[X] + \left(\frac{12A}{r^2} + \frac{4A'}{r} + \frac{3}{2}m^2\right)X - \frac{12A'}{r} - 3m^2\right] = 0. \tag{78}$$

Writing $X=Y/r$ and transforming to the r^* coordinate as before gives in canonical form:

$$\partial_{r^*}^2[Y]+A\left(\frac{12A}{r^2}+\frac{3A'}{r}+\frac{3}{2}m^2\right)Y-A(12A'+3m^2r)=0, \tag{79}$$

and keeping the dominant terms:

$$\partial_{r^*}^2[Y]+\tfrac{3}{2}m^2Y-3m^2r^*=0, \tag{80}$$

easily giving the asymptotic form of the solution:

$$W^2(r^*)=2+\frac{a}{r^*}\cos(\sqrt{\tfrac{3}{2}}mr^*)+\frac{b}{r^*}\sin(\sqrt{\tfrac{3}{2}}mr^*), \tag{81}$$

(where (a,b) are arbitrary constants). The dominant part of this solution implies that W is not in fact a small correction to the Schwarzschild metric asymptotically, and must therefore be discarded. This is not surprising as one is trying to match a function that is small asymptotically (by hypothesis) to one that is constant keeping higher orders in W will clearly not change this result, implying that nontrivial static solutions that include this sector will fail to be dominantly Schwarzschild for large r. This of course does not exclude solutions with symmetric metric components whose asymptotic behavior does not match that of the Schwarzschild solution, nor can one exclude the possibility that W is nonvanishing only inside some finite radius.

VI. SPHERICALLY SYMMETRIC PERTURBATION ABOUT A WYMAN BACKGROUND

In an attempt to consider the perturbation equations for NGT about a general non-symmetric background, one finds that the compatibility conditions prevent one from formulating the inversion in a useful form. This means that a fairly straightforward covariant formulation (like that given in Section II) is not feasible, and instead one must treat each situation separately, in this case a spherically symmetric perturbation about the approximated mNGT Wyman solution given in the previous section. Here it is demonstrated that despite the remaining gauge freedom in the symmetric sector, both symmetric functions will in general pick up time dependence from the skew sector. Although this cross coupling is demonstrated explicitly in a perturbative scenario, it will certainly persist in a more general sense. The results here will show that the perturbations in the symmetric sector pick up time dependence that is algebraically determined by the skew function F, without themselves becoming independent degrees of freedom. The canonical analysis of the general spherically symmetric system will address rigorously how many degrees of freedom exist in each sector. If there are more in the nonperturbative theory, one can examine the dynamical approach to an asymptotically flat spacetime looking for possible singular behavior similar to that found in Ref. 6.

The perturbation of the Wyman metric (70) in a coordinate basis will look identical to (25) (using the gauge choice to simplify it as before). The background vierbeins will be the same as those in the Wyman solution (69), where now the perturbations of the vierbeins and skew metric functions are related to perturbations in the coordinate basis by:

$$\delta W=\frac{h_{[01]}(t,r)}{\sqrt{\alpha(r)\gamma(r)}},\quad \delta F=\frac{\delta h_{[23]}(t,r)}{r^2},\quad \delta E_0=-\frac{1}{2}\frac{h_{00}(t,r)}{\gamma(r)^{3/2}},\quad \delta E_1=-\frac{1}{2}\frac{h_{11}(t,r)}{\alpha(r)^{3/2}}. \tag{82}$$

In the vierbein basis the metric perturbation has nonvanishing components:

$$h_{[01]}=\delta W,\quad h_{[23]}=\delta F. \tag{83}$$

The approximation of the background Wyman solution given in Section V greatly simplifies the algebra necessary to develop the perturbation given in Appendix B. Approximating the symmetric sector by the Schwarzschild solution and the antisymmetric sector by (72), first order in this static antisymmetric background is kept, as is the first order in the perturbations. As one shall see, this will be a reasonable approximation since it will be possible to keep the perturbations small compared to the background by an appropriate choice of integration constants (similarly to δM_s in the Schwarzschild case).

The field equation: ${}^1\mathscr{R}_{[01]}=0$, yields precisely the same field equation as in the Schwarzschild case (30), allowing one to immediately set $\delta W=0$. The symmetric part: ${}^1\mathscr{R}_{(01)}=0$, can be written as a total time derivative:

$$ {}^1\mathscr{R}_{(01)}=\partial_t\left[\frac{2}{r\sqrt{A}}\delta E_1+\frac{3}{2}F'\delta F+\left(\frac{1}{r}-\frac{A'}{2A}\right)F\delta F+F\partial_r[\delta F]\right]=0. \tag{84}$$

This last field equation is then integrated, introducing an arbitrary static function $\delta E(r)$:

$$ \frac{2}{r\sqrt{A}}(\delta E_1-\delta E)=-\frac{3}{2}F'\delta F-\left(\frac{1}{r}-\frac{A'}{2A}\right)F\delta F-F\partial_r[\delta F]. \tag{85}$$

Now computing $(\mathrm{Tr}[\mathscr{R}_{AB}]:=\mathscr{R}_{00}+\mathscr{R}_{11}+2\mathscr{R}_{22})$:

$$ \begin{aligned}\mathrm{Tr}[{}^1\mathscr{R}_{AB}]=&\frac{4}{r^2}\partial_r[r\sqrt{A}\delta E_1]-\frac{F}{A}\partial_t^2[\delta F]+3AF\partial_r^2[\delta F]+\left(\frac{8A}{r}F+2A'F+5AF'\right)\partial_r[\delta F]\\&+\left(3AF''+\frac{8A}{r}F'+2A'F'-m^2F\right)\delta F=0,\end{aligned} \tag{86}$$

and inserting (85) gives:

$$ \begin{aligned}\mathrm{Tr}[{}^1\mathscr{R}_{AB}]=&\frac{4}{r^2}\partial_r[r\sqrt{A}\delta E]-\frac{F}{A}\partial_t^2[\delta F]+AF\partial_r^2[\delta F]+\left(A'+\frac{2A}{r}\right)F\partial_r[\delta F]\\&-\left(\frac{2A'}{r}+\frac{2A}{r^2}+m^2\right)F\delta F=0.\end{aligned} \tag{87}$$

Also,

$$ \begin{aligned}{}^1\mathscr{R}_{00}+{}^1\mathscr{R}_{11}=&\frac{2A}{r}\partial_r\left[\sqrt{A}\delta E_0+\frac{\delta E_1}{\sqrt{A}}\right]+\frac{F}{A}\partial_t^2[\delta F]+AF\partial_r^2[\delta F]+A\left(\frac{2F}{r}+3F'\right)\partial_r[\delta F]\\&+A\left(\frac{2F'}{r}+F''\right)\delta F=0,\end{aligned} \tag{88}$$

gives the equality of spatial derivatives of $\sqrt{A}\,\delta E_0$ and $\delta E_1/\sqrt{A}$ up to order F. This will be useful when considering:

$$
\begin{aligned}
{}^1\mathscr{R}_{[23]} &= \left(\frac{F}{r}-\frac{F'}{2}\right)A\partial_r\left[\frac{\delta E_1}{\sqrt{A}}-\sqrt{A}\,\delta E_0\right]-\left[AF''+\left(A'+\frac{2A}{r}\right)F'-\frac{2}{r}\left(A'+\frac{A}{r}\right)F\right]\frac{\delta E_1}{\sqrt{A}} \\
&\quad+\frac{1}{2}\left(\frac{1}{A}\partial_t^2[\,\delta F]-A\partial_r^2[\,\delta F]-\left(A'+\frac{2A}{r}\right)\partial_r[\,\delta F]+\left(\frac{2A'}{r}+\frac{2A}{r^2}+m^2\right)\delta F\right) \\
&= \left(\frac{F}{r}-\frac{F'}{2}\right)A\partial_r\left[\frac{\delta E_1}{\sqrt{A}}-\sqrt{A}\,\delta E_0\right]-m^2F\frac{\delta E_1}{\sqrt{A}} \\
&\quad+\frac{1}{2}\left(\frac{1}{A}\partial_t^2[\,\delta F]-A\partial_r^2[\,\delta F]-\left(A'+\frac{2A}{r}\right)\partial_r[\,\delta F]+\left(\frac{2A'}{r}+\frac{2A}{r^2}+m^2\right)\delta F\right)=0,
\end{aligned}
\tag{89}
$$

where use has been made of (71). One derives a simple field equation by inserting (89) in (87) and dropping the resulting terms that are of second order in the background skew field F:

$$
\partial_r[\,r\sqrt{A}\,\delta E]=0\rightarrow\delta E=\frac{\delta M_s}{r\sqrt{A}}, \tag{90}
$$

where the constant of integration has been identified with the GR-like perturbation of the Schwarzschild mass parameter.

Now (88) can be used to replace δE_0 with δE_1 at this order, and (85) to replace δE_1 with δE to find:

$$
\begin{aligned}
{}^1\mathscr{R}_{[23]} &= \frac{1}{2}\left\{\frac{1}{A}\partial_t^2[\,\delta F]-A\partial_r^2[\,\delta F]-\left(A'+\frac{2A}{r}\right)\partial_r[\,\delta F]+\left(\frac{2A'}{r}+\frac{2A}{r^2}+m^2\right)\delta F\right\} \\
&\quad-A\left(F'-\frac{2F}{r}\right)\partial_r\left[\frac{\delta E}{\sqrt{A}}\right]-m^2F\frac{\delta E}{\sqrt{A}}=0,
\end{aligned}
\tag{91}
$$

and using (90) in this yields the wave equation for δF:

$$
\begin{aligned}
&\frac{1}{A}\partial_t^2[\,\delta F]-A\partial_r^2[\,\delta F]-\left(A'+\frac{2A}{r}\right)\partial_r[\,\delta F]+\left(m^2+\frac{2A}{r^2}+\frac{2A'}{r}\right)\delta F \\
&\quad=\frac{\delta M_s}{rA}\left[m^2F+4\left(\frac{F}{r}-\frac{F'}{2}\right)\left(\frac{A}{r}+A'\right)\right].
\end{aligned}
\tag{92}
$$

Note that this is a static source and so will not in itself induce any wave solutions, but as before the effects of a matter source will show up asymptotically. The static part of the solution may be derived using the methods in Section III:

$$
\delta F=-2F_0\frac{\delta M_s}{r}e^{-2mr^*}\ln\left(\frac{r^*}{2M_s}\right), \tag{93}
$$

and is consistent with the static solution (72) derived about a Schwarzschild background with mass parameter $M_s+\delta M_s$. Time dependent solutions are identical to those found from (71), and will

induce time dependence in the symmetric sector through (85). Since δE_1 is related to δF locally, it is not an independent degree of freedom, and since the skew field is short-ranged, it will not radiate energy at infinity.

Using (92) and (71), one reduces (88) to an algebraic relation for δE_0:

$$\frac{2A}{r}\partial_r\left[\sqrt{A}\,\delta E_0+\frac{\delta E}{\sqrt{A}}\right]+AF\partial_r^2[\delta F]+\left(\frac{3A'}{2}F+\frac{2A}{r}F+\frac{A}{2}F'\right)\partial_r[\delta F]$$
$$+\left[\left(A'+\frac{A}{2r}\right)F'-\left(\frac{(A')^2}{2A}+\frac{7A'}{2r}+\frac{3A}{r^2}+\frac{3}{4}m^2\right)F\right]\delta F=0. \tag{94}$$

The solution for δE_0 can be written as:

$$\sqrt{A}\,\delta E_0=\sqrt{A}\,\delta\tilde{E}-\frac{\delta E}{\sqrt{A}}+B(t), \tag{95}$$

where $B(t)$ is an arbitrary function of time (removable in the usual way using the remaining gauge transformation), the second term corresponds to the static Schwarzschild perturbation from Section III, and $\delta\tilde{E}$ solves the remainder of (94). Note that although not independent degrees of freedom, neither δE_0 nor δE_1 is static. This is in fact what one would expect when considering the effect of a spherically symmetric matter field to which Birkhoff's theorem does not apply, on the GR background. The presence of the nonstatic field will induce time dependence in the gravitational fields, without exciting any independent modes. This is expected to continue to be the case in NGT: the general spherically symmetric system should only have degrees of freedom in the skew sector.

VII. CONCLUSIONS

The asymptotic behavior of the antisymmetric sector for the case of a static Wyman-type metric has been determined, and the corrections to the symmetric sector shown to be negligible provided one considers regions of spacetime far enough away from the gravitational source. It has also been determined that if one keeps the antisymmetric $t-r$ component, then one cannot have asymptotic behavior that is dominated by the Schwarzschild metric, and so it must be discarded. This analysis was facilitated by the introduction of a vierbein basis, although the formalism has been given for a general basis for completeness.

By considering a spherically symmetric perturbation of the Schwarzschild metric, it has been shown that NGT does not have a rigorous Birkhoff theorem as the antisymmetric sector will not remain static in general. (This has also been noted previously in a Unified Field Theory based on Lyra geometries.[43]) Perturbing an approximate Wyman background in a vierbein basis has shown that the symmetric sector is also not static in general, although no additional modes become excited. This is important phenomenologically since one cannot consider the static solutions (Schwarzschild and Wyman) as the only spherically symmetric exterior solutions to the field equations, and one must therefore match an interior solution to a nonstatic exterior in general.

Perturbations of GR backgrounds have been shown to have good asymptotic behavior in general, since the ghost modes do not become excited and the remaining degrees of freedom are short ranged by construction. However this is not good enough since one expects that the physically interesting solutions to mNGT will not be the purely GR solutions, and one would therefore like to examine the behavior of perturbations on generic, asymptotically-flat, mNGT backgrounds. A covariant perturbative scheme, although possible in principle, would seem to be too complex to

be of any practical value. Instead one may treat each case separately and consider the behavior of (perhaps several) modes about a particular background, as was done here for the spherically symmetric perturbation about a Wyman background.

However this also may not be adequate to fully understand the dynamics of the skew sector in mNGT. The lack of additional gauge invariance in the skew sector may mean that there are more modes in the rigorous theory that will be seen in any sort of weak field, perturbative analysis. To determine whether or not this is the case will require a canonical analysis of the full theory. Partial information may be obtained by considering the full set of fields in a spherically symmetric system, and looking for global information about the behavior of the skew modes given a general coupling to external sources. This is not likely to be a tractable problem in a coordinate basis, and even in a Lorentz frame the field equations are not expected to be particularly enlightening, due to their complication alone. However the canonical analysis of this system will show which fields propagate in the general case, and allow one to get at the dynamics of the approach to an asymptotically well behaved spacetime.

APPENDIX A: WYMAN SECTOR FIELD EQUATIONS

Here the details of the calculation of the Wyman field equations are given, following the steps outlined in Section IV. Beginning with $A^A_B = \eta^{AC} g_{[CB]}$ from (54), one finds the remaining components:

$$A^2_3 = -A^3_2 = F. \tag{A1}$$

The inverse of the symmetric part of the metric is the Minkowski metric: η, whereas the full inverse metric is:

$$|g^{AB}| = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -\dfrac{1}{1+F^2} & -\dfrac{F}{1+F^2} \\ 0 & 0 & \dfrac{F}{1+F^2} & -\dfrac{1}{1+F^2} \end{bmatrix}, \tag{A2}$$

and is necessary in order to compute the mass tensor (65). The structure constants, and hence the skew components of the connection Γ, are then easily found to be:

$$\Gamma^0_{[10]}=\frac{1}{2}C_{10}{}^0=\frac{1}{2}E_1\partial_r[\ln(E_0)],$$

$$\Gamma^2_{[12]}=\Gamma^3_{[13]}=\frac{1}{2}C_{12}{}^2=\frac{1}{2}C_{13}{}^3=-\frac{1}{2r}E_1, \tag{A3}$$

$$\Gamma^3_{[23]}=\frac{1}{2}C_{23}{}^3=-\frac{1}{2r}\cot(\theta).$$

Then Δ from (55) may be determined:

$$-\Delta_{1[23]}=\Delta_{3[12]}=\Delta_{2[31]}=E_1\partial_r[F], \tag{A4}$$

and Ω from (57):

$$\Omega_{1[23]}=E_1\left(\frac{F}{r}-\frac{1}{2}\partial_r[F]\right),\quad \Omega_{3[12]}=\Omega_{2[31]}=\tfrac{1}{2}E_1\partial_r[F]. \tag{A5}$$

Now (56) is solved for Λ and (53) to calculate the connection components (Γ):

$$\Lambda^3_{12}=\Lambda^2_{31}=-\frac{1}{2}\frac{E_1F'}{1+F^2},$$

$$\Lambda^1_{23}=-\frac{E_1F}{r}+\frac{1}{2}E_1F'-\frac{1}{2}E_1F\partial_r[\ln(1+F^2)], \tag{A6}$$

and:

$$\Gamma^0_{01}=\Gamma^1_{00}=-E_1\partial_r[\ln(E_0)],\quad \Gamma^1_{22}=\Gamma^1_{33}=-\frac{E_1}{r}-\frac{1}{2}E_1\partial_r[\ln(1+F^2)],$$

$$\Gamma^2_{21}=\Gamma^3_{31}=\frac{E_1}{r}+\frac{1}{4}E_1\partial_r[\ln(1+F^2)],\quad \Gamma^2_{12}=\Gamma^3_{13}=\frac{1}{4}E_1\partial_r[\ln(1+F^2)],$$

$$\Gamma^3_{32}=-\Gamma^2_{33}=\frac{1}{r}\cot(\theta). \tag{A7}$$

The field equations that remain are:

$$\mathscr{R}_{00}=E_1\partial_r[\Gamma^1_{00}]+\Gamma^1_{00}(\Gamma^0_{01}+2\Gamma^2_{21})+\frac{m^2}{4}\frac{F^2}{1+F^2}=0,$$

$$\mathscr{R}_{11}=-E_1\partial_r[\Gamma^0_{01}]-2E_1\partial_r[\Gamma^2_{21}]-(\Gamma^0_{01})^2-2(\Gamma^2_{21})^2-2(\Lambda^3_{12})^2-\frac{m^2}{4}\frac{F^2}{1+F^2}=0,$$

$$\mathscr{R}_{22}=\mathscr{R}_{33}=E_1\partial_r[\Gamma^1_{22}]+\frac{1}{r^2}+\Gamma^1_{22}(\Gamma^0_{01}+4\Gamma^2_{[21]})-2\Lambda^3_{12}\Lambda^1_{23}+\frac{m^2}{4}\frac{F^2}{1+F^2}=0,$$

$$\mathscr{R}_{[23]}=E_1\partial_r[\Lambda^1_{23}]+(\Gamma^0_{01}-4\Gamma^2_{[12]})\Lambda^1_{23}+2\Gamma^1_{22}\Lambda^3_{12}-\frac{m^2}{4}\left(F+\frac{F}{1+F^2}\right)=0. \tag{A8}$$

It can be shown that in the absence of any skew sector altogether, the Schwarzschild field equations are obtained, and in the absence of the mass term one has the Wyman Field equations.[41]

APPENDIX B: PERTURBATION EQUATIONS

The background field will be that given in Appendix A, approximated by considering only first order contributions from the skew sector. The spherically symmetric perturbations about this background are given here in detail, keeping only first order in the background F, and setting $\alpha = 3/4$ throughout. One may begin by calculating first order corrections to metric quantities, first the density:

$$\delta\sqrt{-g} = \sqrt{-g} F\, \delta F, \tag{B1}$$

and the inverse of the full metric is:

$$|\delta g^{AB}| = \begin{bmatrix} 0 & \delta W & 0 & 0 \\ -\delta W & 0 & 0 & 0 \\ 0 & 0 & 2F\,\delta F & -\delta F \\ 0 & 0 & \delta F & 2F\,\delta F \end{bmatrix}. \tag{B2}$$

The tensor δA has remaining components:

$$\delta A^0_{\ 1} = \delta A^1_{\ 0} = \delta W, \quad \delta A^2_{\ 3} = -\delta A^3_{\ 2} = -\delta F, \tag{B3}$$

and the perturbation of the antisymmetric connection coefficients, derived from (50b):

$$\delta\Gamma^0_{[10]} = \frac{1}{2}\delta C^{\ 0}_{10} = \frac{1}{2}\left(\delta E_1 \partial_r[\ln(E_0)] + \frac{E_1}{E_0}\partial_r[\delta E_0] - \frac{E_1}{E_0}\partial_r[\ln(E_0)]\delta E_0 \right),$$

$$\delta\Gamma^1_{[01]} = \frac{1}{2}\delta C^{\ 1}_{01} = \frac{1}{2}\frac{E_0}{E_1}\partial_t[\delta E_1], \tag{B4}$$

$$\delta\Gamma^2_{[12]} = \delta\Gamma^3_{[13]} = \frac{1}{2}\delta C^{\ 2}_{12} = \frac{1}{2}\delta C^{\ 3}_{13} = -\frac{1}{2}\frac{\delta E_1}{r}.$$

The last equation of (64) is now solved to determine δW in terms of metric functions to find:

$$\delta W_0 = \frac{4}{3}E_1\left(\partial_r[\delta W] + \frac{2\,\delta W}{r} \right), \quad \delta W_1 = \frac{4}{3}E_0\partial_t[\delta W], \quad \delta W_2 = \delta W_3 = 0. \tag{B5}$$

It is then fairly straightforward to calculate the remaining $\delta\Delta^0$:

$$\begin{gathered} \delta\Delta^0_{0[01]} = -\tfrac{1}{4}\delta W_1, \quad \delta\Delta^0_{1[01]} = -\tfrac{1}{4}\delta W_0, \\ \delta\Delta^0_{2[a2]} = \delta\Delta^0_{3[a3]} = -\tfrac{1}{4}\delta W_a, \quad \delta\Delta^0_{2(3a)} = -\delta\Delta^0_{3(2a)} = \tfrac{1}{4}F\,\delta W_a, \end{gathered} \tag{B6}$$

where $a \in \{0,1\}$ here and in the following. The remaining Δ's are:

$$\delta\Delta_{2(a3)}=-\delta\Delta_{3(a2)}=-\tfrac{1}{2}F\,\delta W_a,\quad \delta\Delta_{0[10]}=2E_0\partial_t[\delta W]-\tfrac{1}{2}\delta W_1,$$
$$\delta\Delta_{1[10]}=2E_1\partial_r[\delta W]-\tfrac{1}{2}\delta W_0,\quad \delta\Delta_{2[2a]}=\delta\Delta_{3[3a]}=-\tfrac{1}{2}\delta W_a,$$
$$\delta\Delta_{0[23]}=-E_0\partial_t[\delta F],\quad \delta\Delta_{1[23]}=-E_1\partial_r[\delta F]-\delta E_1\partial_r[F],$$
$$\delta\Delta_{3[02]}=-\delta\Delta_{2[03]}=E_0\partial_t[\delta F],\quad \delta\Delta_{3[12]}=-\delta\Delta_{2[13]}=E_1\partial_r[\delta F]+\delta E_1\partial_r[F]. \tag{B7}$$

Then $\delta\Omega$ can be calculated:

$$\delta\Omega_{0[10]}=E_0\partial_t[\delta W]-\tfrac{1}{4}\delta W_1,\quad \delta\Omega_{1[10]}=E_1\partial_r[\delta W]-\tfrac{1}{4}\delta W_0,$$
$$\delta\Omega_{2[02]}=\delta\Omega_{3[03]}=\frac{1}{4}\delta W_0-\frac{E_1\delta W}{r},\quad \delta\Omega_{2[12]}=\delta\Omega_{3[13]}=\frac{1}{4}\delta W_1,$$
$$\delta\Omega_{0[23]}=-\frac{1}{2}E_0\partial_t[\delta F],\quad \delta\Omega_{1[23]}=-\frac{1}{2}E_1\partial_r[\delta F]+\frac{F\delta E_1}{r}+\frac{E_1\delta F}{r}-\frac{1}{2}\delta E_1\partial_r[F], \tag{B8}$$
$$\delta\Omega_{3[02]}=-\delta\Omega_{2[03]}=\tfrac{1}{2}E_0\partial_t[\delta F],\quad \delta\Omega_{3[12]}=-\delta\Omega_{2[13]}=\tfrac{1}{2}E_1\partial_r[\delta F]+\tfrac{1}{2}\delta E_1\partial_r[F].$$

One is now in a position to invert the compatibility conditions (56) to solve for the perturbations to the connection coefficients. First the corrections to Λ:

$$\delta\Lambda^0_{01}=-\frac{2}{3}E_0\partial_t[\delta W],\quad \delta\Lambda^1_{01}=-\frac{2}{3}E_1\left(\frac{\delta W}{r}-\partial_r[\delta W]\right),$$
$$\delta\Lambda^2_{20}=\delta\Lambda^3_{30}=-\frac{1}{3}E_1\left(\frac{\delta W}{r}-\partial_r[\delta W]\right),\quad \delta\Lambda^2_{21}=\delta\Lambda^3_{31}=\frac{1}{3}E_0\partial_t[\delta W],$$
$$\delta\Lambda^0_{23}=-\frac{1}{2}E_0\partial_t[\delta F],\quad \delta\Lambda^1_{23}=-\frac{E_1\delta F}{r}-\frac{\delta E_1 F}{r}+\frac{1}{2}\frac{\delta E_1 F'}{r}+\frac{1}{2}\frac{E_1\partial_r[\delta F]}{r}, \tag{B9}$$
$$\delta\Lambda^2_{03}=\delta\Lambda^3_{20}=\tfrac{1}{2}E_0\partial_t[\delta F],\quad \delta\Lambda^2_{13}=\delta\Lambda^3_{21}=\tfrac{1}{2}E_1\partial_r[\delta F]+\tfrac{1}{2}F'\delta E_1,$$

and then to Γ:

$$\delta\Gamma^0_{01}=\delta\Gamma^1_{00}=-\frac{E_1}{E_0}\partial_r[\delta E_0]-\delta E_1\partial_r[\ln(E_0)]+\frac{E_1}{E_0}\delta E_0\partial_r[\ln(E_0)],$$
$$\delta\Gamma^0_{11}=\delta\Gamma^1_{10}=-\frac{E_0}{E_1}\partial_t[\delta E_1],\quad \delta\Gamma^2_{03}=\delta\Gamma^2_{30}=-\delta\Gamma^3_{02}=-\delta\Gamma^3_{20}=\frac{1}{2}E_1F'\delta W,$$
$$\delta\Gamma^0_{22}=\delta\Gamma^0_{33}=2\,\delta\Gamma^2_{02}=2\,\delta\Gamma^2_{20}=2\,\delta\Gamma^3_{03}=2\,\delta\Gamma^3_{30}=E_0F\partial_t[\delta F],$$
$$\delta\Gamma^1_{22}=\delta\Gamma^1_{33}=-\frac{\delta E_1}{r}-E_1F\partial_r[\delta F]-E_1F'\delta F,\quad \delta\Gamma^2_{12}=\delta\Gamma^3_{13}=\tfrac{1}{2}E_1F\partial_r[\delta F]+\frac{1}{2}E_1F'\delta F,$$
$$\delta\Gamma^2_{21}=\delta\Gamma^3_{31}=\frac{\delta E_1}{r}+\frac{1}{2}E_1F\partial_r[\delta F]+\frac{1}{2}E_1F'\delta F. \tag{B10}$$

The remaining field equations will be: ${}^1\mathscr{R}_{00}, {}^1\mathscr{R}_{(01)}, {}^1\mathscr{R}_{[01]}, {}^1\mathscr{R}_{11}, {}^1\mathscr{R}_{22} = {}^1\mathscr{R}_{33}$ and ${}^1\mathscr{R}_{[23]}$. The relevant combinations will be quoted in Section VI.

Angular momentum and Killing potentials

E. N. Glass[a)]
Physics Department, University of Michigan, Ann Arbor, Michigan 48109

(Received 6 April 1995; accepted for publication 1 September 1995)

When the Penrose–Goldberg (PG) superpotential is used to compute the angular momentum of an axial symmetry, the Killing potential $Q^{\mu\nu}_{(\varphi)}$ for that symmetry is needed. Killing potentials used in the PG superpotential must satisfy Penrose's equation. It is proved for the Schwarzschild and Kerr solutions that the Penrose equation does not admit a $Q^{\mu\nu}_{(\varphi)}$ at finite r and therefore the PG superpotential can only be used to compute angular momentum asymptotically. © *1996 American Institute of Physics.* [S0022-2488(95)03312-9]

I. INTRODUCTION

In this work computing angular momentum with the use of Killing potentials is studied for the Schwarzschild and Kerr solutions. Killing potentials are bivectors $Q^{\mu\nu}$ whose divergence yields a Killing vector. Both solutions have explicit rotational Killing symmetries, spherical for Schwarzschild and axial for Kerr, and we have obtained an axial Killing potential $Q^{\mu\nu}_{(\varphi)}$ for both solutions. We expected to use that $Q^{\mu\nu}_{(\varphi)}$ in the Penrose–Goldberg (PG) superpotential[1] to compute angular momentum in the same way that $Q^{\mu\nu}_{(\mathrm{t})}$ has been previously used to compute mass[2] and found, to our surprise, that this was not possible.

Killing potentials used in the PG superpotential must satisfy Penrose's equation[3]

$$\mathbf{P}^{\alpha\mu\nu}:=\boldsymbol{\nabla}^{(\alpha}Q^{\mu\nu)}-\boldsymbol{\nabla}^{(\alpha}Q^{\nu)\mu}+g^{\alpha[\mu}Q^{\nu]\beta}{}_{;\beta}=0 \tag{1}$$

such that $\boldsymbol{\nabla}_\beta Q^{\alpha\beta}$ is a Killing vector. Penrose showed that ten independent $Q^{\mu\nu}$ exist in Minkowski space, but there can be no solutions in a general space–time which has no Killing symmetries. For Penrose's quasi-local mass integral we exhibit, in the following section, a Killing potential for the Kerr spacetime which satisfies (1) and yields a quasi-local Kerr mass. Unfortunately, one cannot use the PG superpotential to compute quasi-local angular momentum and so this work has a **negative** result. It is proved for the Schwarzschild and Kerr solutions that the Penrose equation does not admit a $Q^{\mu\nu}_{(\varphi)}$ at finite r and thus the PG superpotential **cannot** be used to compute angular momentum at finite r.

A Newman–Penrose null tetrad for the Kerr solution is given in Appendix A together with the details of an anti-self-dual bivector basis. Bivector components of the Penrose equation are presented in Appendix B. The conformal Penrose equation is given in Appendix C. Sign conventions used here are $2A_{\nu;[\alpha\beta]}=A_\mu R^\mu{}_{\nu\alpha\beta}$, and $R_{\mu\nu}=R^\alpha{}_{\mu\nu\alpha}$.

II. KILLING POTENTIALS

For Killing vector k^α there is an antisymmetric Killing potential $Q^{\alpha\beta}$ such that

$$k^\alpha=\tfrac{1}{3}\boldsymbol{\nabla}_\beta Q^{\alpha\beta}.$$

It is the Killing potential which is the core of the PG superpotential for computing conserved Noether quantities such as mass and angular momentum. The PG superpotential is

$$U^{\alpha\beta}=\sqrt{-g}\,\tfrac{1}{2}G^{\alpha\beta}{}_{\mu\nu}Q^{\mu\nu}, \tag{2}$$

[a)]Permanent address: Physics Department, University of Windsor, Windsor, Ontario N9B 3P4, Canada.

where $G^{\alpha\beta}{}_{\mu\nu}$ is the negative right and left dual of the Riemann tensor. In order for

$$\nabla_\beta U^{\alpha\beta}=\sqrt{-g}G^{\alpha\nu}k_\nu,$$

it is necessary that the Killing potential $Q^{\mu\nu}$ satisfy the Penrose equation.

The Kerr solution has two Killing vectors, stationary $k^\alpha_{(t)}$ and axial $k^\alpha_{(\varphi)}$, and the metric, in Boyer–Lindquist coordinates, is given by

$$g^{\text{Kerr}}_{\alpha\beta}\,dx^\alpha dx^\beta=\Psi\ dt^2-(\Sigma/\Delta)dr^2+(1-\Psi)2a\ \sin^2\theta\ dtd\varphi-\Sigma d\theta^2 - \sin^2\theta[\Sigma+(2-\Psi)a^2\ \sin^2\theta]d\varphi^2, \tag{3}$$

where $R=r-ia\cos\theta$, $\Sigma=R\bar{R}$, $\Delta=r^2+a^2-2mr$, and $\Psi=1-2mr/\Sigma$. The Killing potential for $k^\alpha_{(t)}$ is

$$Q^{\alpha\beta}_{(t)}=-\tfrac{1}{2}(RM^{\alpha\beta}+\bar{R}\bar{M}^{\alpha\beta}). \tag{4}$$

Here $M^{\alpha\beta}$ is an anti-self-dual bivector, $M^{*\alpha\beta}=-iM^{\alpha\beta}$, given in terms of Newman–Penrose null vectors in Appendix A. One-third the divergence of Eq. (4) yields the stationary Killing vector

$$k^\alpha_{(t)}=n^\alpha+(\Delta/2\Sigma)l^\alpha+(ia\sin\theta/\sqrt{2}\Sigma)(\bar{R}m^\alpha-R\bar{m}^\alpha). \tag{5}$$

Direct substitution of $Q^{\alpha\beta}_{(t)}$ in Eq. (1) verifies that $Q_{(t)}$ satisfies the Penrose equation. One can now use the stationary Killing potential with the PG superpotential to compute the mass^2 of the Kerr source:

$$M(S^2)=-\frac{1}{16\pi}\oint_{S^2}\sqrt{-g}C^{\alpha\beta}_{\mu\nu}Q^{\mu\nu}_{(t)}dS_{\alpha\beta} \tag{6}$$

where S^2 is a closed $t=$const, $r=$const two-surface. The result is m for any r beyond the outer event horizon.

An axial Killing potential for the Kerr solution is given by

$$Q^{\alpha\beta}_{(\varphi)}=Q_1M^{\alpha\beta}+Q_2V^{\alpha\beta}+\text{c.c.},$$
$$Q_1=\frac{ar\sin^2\theta}{2\Sigma}(r^2+3a^2\cos^2\theta),\quad Q_2=\frac{ir\sin\theta}{\sqrt{2}R}(r^2+3a^2\cos^2\theta), \tag{7}$$

and one-third the divergence of $Q^{\alpha\beta}_{(\varphi)}$ yields the axial Killing vector

$$k^\alpha_{(\varphi)}=-a\sin^2\theta\left[n^\alpha+\left(\frac{\Delta}{2\Sigma}\right)l^\alpha\right]-\left[\frac{i(r^2+a^2)\sin\theta}{\sqrt{2}\Sigma}\right](\bar{R}m^\alpha-R\bar{m}^\alpha). \tag{8}$$

When the Kerr rotation parameter is set to zero, one obtains the Schwarzschild results

$$Q^{\alpha\beta}_{(\varphi)}=\frac{ir^2\sin\theta}{\sqrt{2}}V^{\alpha\beta}+\text{c.c.}, \tag{9}$$

$$k^\alpha_{(\varphi)}=-\frac{ir\sin\theta}{\sqrt{2}}m^\alpha+\text{c.c.} \tag{10}$$

Neither the $Q_{(\varphi)}$ for Kerr nor the $Q_{(\varphi)}$ for Schwarzschild satisfy the Penrose equation.

III. NO AXIAL PENROSE SOLUTION

We will show for the Schwarzschild solution and the Kerr solution that the Penrose equation does not allow an axial Killing potential at finite r. Penrose's equation,[3] $\nabla_{A'}{}^{(A}W^{BC)}=0$ for symmetric spinor W^{BC} (equivalent to the antisymmetric Killing potential $Q^{\mu\nu}$), was used in linearized theory where Penrose[4] showed existence of ten independent Killing potentials, one for each Minkowski Killing vector. In Goldberg's generalization[1] to a fully curved metric there is no discussion of the existence of solutions of the Penrose equation at finite r. We know that a solution exists for $Q_{(t)}$. It is given in Eq. (4) for the Kerr solution with anti-self-dual components

$$Q_0=0, \quad Q_1=-\tfrac{1}{2}R, \quad Q_2=0, \tag{11}$$

where

$$Q^{\mu\nu}=Q_0U^{\mu\nu}+Q_1M^{\mu\nu}+Q_2V^{\mu\nu}+\text{c.c.}$$

We also know that Penrose obtained asymptotic results for angular momentum J. For axial symmetry $k_{(\varphi)}$ at the conformal boundary he found $J=0$ for Schwarzschild's solution and $J=ma$ for Kerr's, so it is reasonable to expect a $Q_{(\varphi)}$ for use in the PG superpotential at finite r.

The argument presented below assumes that $Q_{(\varphi)}$ exists, goes through a long set of equations which are the components of the bivector form of Penrose's equation given in Appendix B, and ends with no possible $Q_{(\varphi)}$. To integrate the equations it is assumed that Q_0, Q_1, and Q_2 are independent of t and φ, i.e., it is assumed that $\mathscr{L}_\xi Q^{\mu\nu}_{(\varphi)}=0$ where ξ^α is a Killing vector that commutes with the Kerr $k^\alpha_{(t)}$ and $k^\alpha_{(\varphi)}$. If this assumption is false, then $\mathscr{L}_\xi Q^{\mu\nu}_{(\varphi)}=X^{\mu\nu}$. Penrose's equation (1) with $\nabla_\beta Q^{\nu\beta}=3k^\nu$ can be written as

$$\nabla_\beta Q^{\mu\nu}=\nabla^{[\mu}Q^{\nu]}{}_\beta+3k^{[\mu}\delta^{\nu]}{}_\beta. \tag{12}$$

Since the Lie and covariant derivatives commute, the nonzero bivector $X^{\mu\nu}$ must satisfy

$$\boldsymbol{\nabla}_\beta X^{\mu\nu}=\boldsymbol{\nabla}^{[\mu}X^{\nu]}{}_\beta. \tag{13}$$

The Kerr and Schwarzschild solutions do not admit a nonzero $X^{\mu\nu}$ at finite r.

We investigate the existence of $Q_{(\varphi)}$ for the Schwarzschild solution since the equations are simpler with the Kerr rotation parameter set to zero but the argument can be extended in a straightforward manner to the Kerr solution. The null tetrad and spin coefficients given in Appendix A are used. Penrose's equation (B4) has n^α component

$$L_0=0=\partial_r Q_0, \tag{14}$$

with solution $Q_0=h(\theta)$; h an arbitrary function. The $\bar{m}^\alpha$ component is

$$M_0=0=\frac{1}{\sqrt{2}r}\,(\partial_\theta Q_0-\cot\,\theta Q_0), \tag{15}$$

with solution $Q_0=f(r)\sin\theta$, f arbitrary. The two separate solutions require

$$Q_0=c_0\,\sin\,\theta,\ c_0\ \text{const.} \tag{16}$$

Equation (B2) has l^α component

$$N_2=0=r(r-2m)\partial_r Q_2-2mQ_2, \tag{17}$$

with solution $Q_2=(1-2m/r)h(\theta)$. The m^α component is

$$B_2=0=\frac{1}{\sqrt{2}r}\,(\partial_\theta Q_2-\cot\,\theta Q_2), \tag{18}$$

with solution $Q_2=f(r)\,\sin\,\theta$. The two solutions for Q_2 require

$$Q_2=c_2(1-2m/r)\sin\,\theta,\ c_2\ \text{const.} \tag{19}$$

The n^α component of (B2) is

$$L_2-2B_1=0,\quad \partial_r Q_2-\frac{2}{r}\,Q_2-\frac{\sqrt{2}}{r}\,\partial_\theta Q_1=0. \tag{20}$$

Using Q_2 from (19) we find

$$Q_1=c_2\sqrt{2}(1-3m/r)\cos\,\theta+f(r). \tag{21}$$

We now have functional forms for Q_0, Q_1, and Q_2. The Q components are further restricted by using the $\bar{m}^\alpha$ component of (B2):

$$\begin{gathered} M_2-2N_1=0,\\ \frac{1}{\sqrt{2}r}\,(\partial_\theta Q_2+\cot\,\theta Q_2)+\left(1-\frac{2m}{r}\right)\left(\partial_r Q_1-\frac{1}{r}\,Q_1\right)=0. \end{gathered} \tag{22}$$

Using Q_2 from (19) and Q_1 from (21) we obtain the equation

$$\frac{c_2 6\sqrt{2}m}{r^2}\cos\,\theta+\partial_r f-\frac{1}{r}\,f=0. \tag{23}$$

No solution is possible unless one chooses $c_2=0$. Then $Q_1=c_1 r$. The Q components are now

$$Q_0=c_0\,\sin\,\theta,\quad Q_1=c_1 r,\quad Q_2=0. \tag{24}$$

The l^α component of (B4) is

$$\begin{gathered} N_0-2M_1=0,\\ \frac{1}{2}\left(1-\frac{2m}{r}\right)\partial_r Q_0+\frac{m}{r^2}\,Q_0-\frac{1}{r}\left(1-\frac{2m}{r}\right)Q_0+\frac{\sqrt{2}}{r}\,\partial_\theta Q_1=0. \end{gathered} \tag{25}$$

Substituting (24) requires $c_0=0$. Comparing (24) and (11) one can now see that the only solution possible is the one for $Q_{(t)}$ given above.

We have proved that, for the Schwarzschild and Kerr solutions, only the timelike Killing vector $k_{(t)}$ can have a Killing potential that satisfies the Penrose equation at finite r.

IV. NULL INFINITY

We proceed to solve the Penrose equation at the boundary of Schwarzschild space–time. The Schwarzschild solution is given in outgoing null coordinates as

$$g_{\mu\nu}\,dx^\mu dx^\nu=(1-2m/r)du^2+2\,dudr-r^2(d\theta^2+\sin^2\theta\,d\varphi^2). \tag{26}$$

We use the null tetrad

$$l_\alpha\, dx^\alpha = du, \quad n_\alpha\, dx^\alpha = \tfrac{1}{2}(1-2m/r)du + dr, \quad m_\alpha\, dx^\alpha = -(r/\sqrt{2})(d\theta + i\,\sin\,\theta\, d\varphi),$$

and spin coefficients given in Eq. (A2) with Kerr rotation parameter $a=0$. The general equations for a conformal map are given in Appendix C. We choose $\Omega = 1/r = z$. On $\mathscr{I}^+$, where $z=0$, the metric is

$$\hat{g}_{\mu\nu}\, dx^\mu dx^\nu = -2\, du dz - (d\theta^2 + \sin^2\theta\, d\varphi^2). \tag{27}$$

Here the conformal Bondi frame is

$$\hat{l}_\alpha\, dx^\alpha = du, \quad \hat{n}_\alpha\, dx^\alpha = -dz, \quad \hat{m}_\alpha\, dx^\alpha = -(1/\sqrt{2})(d\theta + i\,\sin\,\theta\, d\varphi),$$

with nonzero spin coefficients

$$\hat{\beta} = \frac{\cot\,\theta}{2\sqrt{2}} = -\hat{\alpha}.$$

The Penrose equation comprises eight complex equations (B2)–(B4) for $\hat{Q}_0$, $\hat{Q}_1$, and $\hat{Q}_2$. Three establish finite values for the Qs on the boundary:

$$\partial_z \hat{Q}_0 = 0, \quad \partial_z \hat{Q}_1 + \tfrac{1}{2}(\hat{\delta} - 2\hat{\alpha})\hat{Q}_0 = 0, \quad \partial_z \hat{Q}_2 + 2(\hat{\delta})\hat{Q}_1 = 0,$$

where $\hat{D} = -\partial_z$, $\hat{\Delta} = \partial_u$, and on $\mathscr{I}^+$ $(\hat{\delta} + 2s\hat{\alpha})\eta = -\eth\eta$ for η a spin weight s scalar (we use the original definition[5] of edth with spin weight opposite to the helicity of outgoing radiation). In the following a zero superscript denotes independence of z, and $(\hat{Q}_0^0, \hat{Q}_1^0, \hat{Q}_2^0)$ have spin weights $(1,0,-1)$. The remaining five equations on $\mathscr{I}^+$ are

$$\partial_u \hat{Q}_2^0 = 0, \tag{28a}$$

$$\bar{\eth}\hat{Q}_2^0 = 0, \tag{28b}$$

$$\bar{\eth}\hat{Q}_2^0 + 2\,\partial_u \hat{Q}_1^0 = 0, \tag{28c}$$

$$\eth\hat{Q}_0^0 = 0, \tag{28d}$$

$$2\eth\hat{Q}_1^0 + \partial_u \hat{Q}_0^0 = 0. \tag{28e}$$

The solutions are

$$\hat{Q}_2^0 = k^m{}_{-1}Y_{1m}, \quad \hat{Q}_1^0 = -\tfrac{1}{2}u\;\eth\hat{Q}_2^0 + f(\theta,\varphi), \quad \hat{Q}_0^0 = \tfrac{1}{2}\,u^2\eth^2\hat{Q}_2^0 - 2u\eth f + c^m{}_1Y_{1m}, \tag{29}$$

where k^m and c^m are complex constants. Here we can go beyond Goldberg[1] and integrate (28e) since the Schwarzschild null surfaces are shear-free. The asymptotic Killing vectors are

$$\hat{k}_u = \hat{Q}^0{}_1 + \text{c.c.}, \quad \Omega\hat{k}_\theta = \text{c.c.}(\hat{Q}^0{}_2), \quad \Omega\hat{k}_\varphi = \hat{Q}^0{}_2. \tag{30}$$

The supertranslations of the BMS group have a full function's worth of freedom in $\hat{Q}^0{}_1$ but at the Schwarzschild boundary $f(\theta,\varphi)$ is restricted to four parameters for ordinary translations and $\eth f = 0$.

The solution of the Penrose equation for $Q_{(t)}$ is contained above. The nonzero anti-self-dual component of Eq. (4) is $Q_1 = -r/2$ or $\hat{Q}_1 = -\frac{1}{2}$. This solution coincides with the values $k^m = 0$, $c^m = 0$, and $f(\theta,\varphi) = -\frac{1}{2}$.

Now lets take the asymptotic solutions found above in (29) and (30) and use them to construct a Killing potential $Q_{(\varphi)}$. Thus our candidate has the form

$$Q^{\mu\nu}_{(\varphi)}=(r^2Q^0_2)V^{\mu\nu}+\text{c.c.} \tag{31}$$

For the Schwarzschild solution we compute the divergence:

$$\frac{1}{3}\,\nabla_\nu Q^{\mu\nu}_{(\varphi)}=-[rQ^0{}_2]m^\mu+\left[\frac{r}{\sqrt{2}}\,(\partial_\theta+\cot\,\theta)Q^0{}_2\right]l^\mu+\text{c.c.} \tag{32}$$

Equating with

$$k^\mu_{(\varphi)}=-\frac{ir\,\sin\,\theta}{\sqrt{2}}\,m^\mu+\text{c.c.}$$

yields

$$Q^0{}_2=\frac{i\,\sin\,\theta}{\sqrt{2}}.$$

The l^μ term in (32) vanishes when the complex conjugate is added. We have constructed the Killing potential which was already given above as Eq. (9). The anti-self-dual components are

$$Q_0=0,\quad Q_1=0,\quad Q_2=(i/\sqrt{2})r^2\,\sin\,\theta. \tag{33}$$

Of the twelve terms entering the Penrose equation (defined in Appendix B), four are nonzero for the components of Eq. (33):

$$L_2=i\sqrt{2}r\,\sin\,\theta,\quad N_2=(i/\sqrt{2})(3m-r)\,\sin\,\theta,$$

$$M_2=ir\,\cos\,\theta,\quad B_1=(i/\sqrt{2})r\,\sin\,\theta.$$

Although Q_2 has the r^2 dependence that one expects for an asymptotic solution and the angular dependence dictated by $k_{(\varphi)}$, the components of Eq. (B2), particularly $N_2=0$, show directly that this Killing potential fails to satisfy the Penrose equation.

V. CONCLUSION

To find a Killing potential one can write the divergence equation relating k^α and $Q^{\alpha\beta}$ as a three-form relation, one-third the exterior derivative of dual Q equal to the dual of $k_\alpha\,dx^\alpha$,

$$\tfrac{1}{3}d{*}Q={*}(k_\alpha\,dx^\alpha),$$

and then integrate (if possible). We have seen that not just any Killing potential can be used in the PG superpotential but only one which satisfies Penrose's equation. Although a $Q^{\alpha\beta}_{(\varphi)}$ whose divergence yielded the axial Killing vector was presented for the Kerr solution, it could not be used to compute quasi-local angular momentum although asymptotically it yields ma. It has been shown that a $Q^{\alpha\beta}_{(\varphi)}$ **cannot** be found for either the Kerr or Schwarzschild solutions which will satisfy the Penrose equation in curved space and so the PG superpotential cannot be used to compute quasi-local angular momentum.

Some interesting questions remain. What are the complete integrability conditions for the Penrose equation? What is the physical reason that no quasi-local Killing potential for rotational symmetry can satisfy the Penrose equation?

ACKNOWLEDGMENTS

We thank Bob Geroch for questioning the existence of Killing potentials which satisfy the Penrose equation and David Garfinkle for many stimulating discussions. This work was partially supported by a NSERC of Canada grant.

APPENDIX A: NULL TETRAD AND BIVECTORS

A Newman–Penrose tetrad $(l^\alpha, n^\alpha, m^\alpha, \bar{m}^\alpha)$ for the Kerr metric (3) with l^α and n^α as principal null vectors is chosen as

$$\begin{aligned} l^\alpha \partial_\alpha &= \frac{1}{\Delta}\left[(r^2+a^2)\partial_t + \Delta\partial_r + a\partial_\varphi\right], \\ n^\alpha \partial_\alpha &= \frac{1}{2\Sigma}\left[(r^2+a^2)\partial_t - \Delta\partial_r + a\partial_\varphi\right], \\ m^\alpha \partial_\alpha &= \frac{1}{\sqrt{2}\bar{R}}\left[ia\,\sin\,\theta\partial_t + \partial_\theta + \frac{i}{\sin\,\theta}\,\partial_\varphi\right], \end{aligned} \tag{A1}$$

where $R = r - ia\cos\theta$, $\Sigma = R\bar{R}$, and $\Delta = r^2 + a^2 - 2mr$. The nonzero spin coefficients and Weyl tensor component are

$$\begin{aligned} &\rho = -\frac{1}{R}, \quad \mu = -\frac{\Delta}{(2\Sigma R)}, \quad \tau = -\frac{ia\,\sin\,\theta}{\sqrt{2}\Sigma}, \quad \pi = \frac{ia\,\sin\,\theta}{\sqrt{2}R^2}, \\ &\gamma = \mu + \frac{r-m}{2\Sigma}, \quad \beta = \frac{\cot\,\theta}{2\sqrt{2}\bar{R}}, \quad \alpha = \pi - \bar{\beta}, \quad \psi_2 = -\frac{m}{R^3}. \end{aligned} \tag{A2}$$

A basis of anti-self-dual bivectors is given by

$$U^{\mu\nu} = 2\bar{m}^{[\mu}n^{\nu]}, \quad M^{\mu\nu} = 2l^{[\mu}n^{\nu]} - 2m^{[\mu}\bar{m}^{\nu]}, \quad V^{\mu\nu} = 2l^{[\mu}m^{\nu]}. \tag{A3}$$

Their inner products are $U^{\mu\nu}V_{\mu\nu} = \bar{U}^{\mu\nu}\bar{V}_{\mu\nu} = 2$, $M^{\mu\nu}M_{\mu\nu} = \bar{M}^{\mu\nu}\bar{M}_{\mu\nu} = -4$, and all others zero. As a basis, they satisfy the completeness relation

$$\tfrac{1}{2}(g^{\alpha\beta\mu\nu} + i\,\eta^{\alpha\beta\mu\nu}) = U^{\alpha\beta}V^{\mu\nu} + V^{\alpha\beta}U^{\mu\nu} - \tfrac{1}{2}M^{\alpha\beta}M^{\mu\nu}, \tag{A4}$$

where $g^{\alpha\beta\mu\nu} = g^{\alpha\mu}g^{\beta\nu} - g^{\alpha\nu}g^{\beta\mu}$, and $\frac{1}{2}\eta^{\alpha\beta\mu\nu}$ is the dual tensor. It is useful to list their covariant derivatives:

$$\begin{aligned} &\nabla_\beta U^{\mu\nu} = -2U^{\mu\nu}a_\beta + M^{\mu\nu}b_\beta, \quad a_\beta = \epsilon n_\beta + \gamma l_\beta - \alpha m_\beta - \beta\bar{m}_\beta, \\ &\nabla_\beta M^{\mu\nu} = -2U^{\mu\nu}c_\beta + 2V^{\mu\nu}b_\beta, \quad b_\beta = \pi n_\beta + \nu l_\beta - \lambda m_\beta - \mu\bar{m}_\beta, \\ &\nabla_\beta V^{\mu\nu} = 2V^{\mu\nu}a_\beta - M^{\mu\nu}c_\beta, \quad c_\beta = \kappa n_\beta + \tau l_\beta - \rho m_\beta - \sigma\bar{m}_\beta. \end{aligned} \tag{A5}$$

APPENDIX B: THE PENROSE EQUATION

Equation (1), which a Killing potential must satisfy in order to be valid for use in the PG superpotential, can be written in terms of anti self-dual bivectors with the definition

$$Q^{\mu\nu} = Q_0 U^{\mu\nu} + Q_1 M^{\mu\nu} + Q_2 V^{\mu\nu} + \text{c.c.} \tag{B1}$$

Substituting the bivector expansion into (1) provides equations for the components Q_0, Q_1, Q_2, which can be most simply written with the use of twelve terms:

$$L_0=(D-2\epsilon)Q_0-2\kappa Q_1, \quad L_1=DQ_1-\kappa Q_2+\pi Q_0, \quad L_2=(D+2\epsilon)Q_2+2\pi Q_1,$$

$$N_0=(\Delta-2\gamma)Q_0-2\tau Q_1, \quad N_1=\Delta Q_1-\tau Q_2+\nu Q_0, \quad N_2=(\Delta+2\gamma)Q_2+2\nu Q_1,$$

$$M_0=(\delta-2\beta)Q_0-2\sigma Q_1, \quad M_1=\delta Q_1-\sigma Q_2+\mu Q_0, \quad M_2=(\delta+2\beta)Q_2+2\mu Q_1,$$

$$B_0=(\bar{\delta}-2\alpha)Q_0-2\rho Q_1, \quad B_1=\bar{\delta}Q_1-\rho Q_2+\lambda Q_0, \quad B_2=(\bar{\delta}+2\alpha)Q_2+2\lambda Q_1.$$

Here $D=l^\alpha\nabla_\alpha$, $\Delta=n^\alpha\nabla_\alpha$, and $\delta=m^\alpha\nabla_\alpha$. The Penrose equation has the following $U_{\mu\nu}$, $M_{\mu\nu}$, and $V_{\mu\nu}$ components, respectively:

$$l^\alpha(3N_2)+n^\alpha(L_2-2B_1)-m^\alpha(3B_2)-\bar{m}^\alpha(M_2-2N_1)=0, \tag{B2}$$

$$l^\alpha(M_2-2N_1)+n^\alpha(B_0-2L_1)+m^\alpha(2B_1-L_2)+\bar{m}^\alpha(2M_1-N_0)=0, \tag{B3}$$

$$l^\alpha(N_0-2M_1)+n^\alpha(3L_0)-m^\alpha(B_0-2L_1)-\bar{m}^\alpha(3M_0)=0. \tag{B4}$$

If $Q^{\mu\nu}$ is to be a Killing potential for k^μ, then its divergence must satisfy

$$3k^\mu=l^\mu(N_1+M_2)-n^\mu(B_0+L_1)-m^\mu(B_1+L_2)+\bar{m}^\mu(N_0+M_1)+\text{c.c.} \tag{B5}$$

APPENDIX C: THE CONFORMAL PENROSE EQUATION

For asymptotically simple space–times with future null infinity $\mathscr{I}^+$ we follow Penrose and Rindler[6] case (iv) to conformally map from the physical metric $g_{\alpha\beta}$ to the unphysical metric $\hat{g}_{\alpha\beta}$:

$$\hat{g}_{\alpha\beta}=\Omega^2 g_{\alpha\beta} \tag{C1}$$

with the spinor basis mapping as $\hat{o}_A=o_A$, $\hat{\imath}_A=\Omega\imath_A$. Here $\Omega=0$ defines the future null boundary with $\nabla_\alpha\Omega$ a null vector tangent to the generators of $\mathscr{I}^+$. It follows from the map of the spinor basis that the tetrad derivatives transform as

$$\hat{D}=\Omega^{-2}D, \quad \hat{\delta}=\Omega^{-1}\delta, \quad \hat{\Delta}=\Delta. \tag{C2}$$

The spin coefficients conformally map as

$$\hat{\kappa}=\Omega^{-3}\kappa, \quad \hat{\rho}=\Omega^{-2}\rho-\Omega^{-3}D\Omega,$$

$$\hat{\sigma}=\Omega^{-2}\sigma, \quad \hat{\tau}=\Omega^{-1}\tau-\Omega^{-2}\delta\Omega,$$

$$\hat{\epsilon}=\Omega^{-2}\epsilon, \quad \hat{\alpha}=\Omega^{-1}\alpha-\Omega^{-2}\bar{\delta}\Omega,$$

$$\hat{\beta}=\Omega^{-1}\beta, \quad \hat{\gamma}=\gamma-\Omega^{-1}\Delta\Omega,$$

$$\hat{\nu}=\Omega\nu, \quad \hat{\mu}=\mu+\Omega^{-1}\Delta\Omega,$$

$$\hat{\lambda}=\lambda, \quad \hat{\pi}=\Omega^{-1}\pi+\Omega^{-2}\bar{\delta}\Omega.$$

Since the Killing potential obeys the conformal transformation $\hat{Q}^{\alpha\beta}=\Omega^{-1}Q^{\alpha\beta}$, it's anti-self-dual bivector components map as

$$\hat{Q}_0 = Q_0, \quad \hat{Q}_1 = \Omega Q_1, \quad \hat{Q}_2 = \Omega^2 Q_2. \tag{C3}$$

The twelve terms in Appendix B which comprise the components of the Penrose equation map as

$$\hat{L}_0 = \Omega^{-2} L_0, \quad \hat{L}_1 = \Omega^{-1} L_1 + Q_0(\Omega^{-2}\bar{\delta}\Omega) + Q_1(\Omega^{-2} D\Omega),$$

$$\hat{L}_2 = L_2 + 2Q_1(\Omega^{-1}\bar{\delta}\Omega) + 2Q_2(\Omega^{-1} D\Omega), \quad \hat{N}_0 = N_0 + 2Q_0(\Omega^{-1}\Delta\Omega) + 2Q_1(\Omega^{-1}\delta\Omega),$$

$$\hat{N}_1 = \Omega N_1 + Q_1(\Delta\Omega) + Q_2(\delta\Omega), \quad \hat{N}_2 = \Omega^2 N_2,$$

$$\hat{M}_0 = \Omega^{-1} N_0, \quad \hat{M}_1 = M_1 + Q_0(\Omega^{-1}\Delta\Omega) + Q_1(\Omega^{-1}\delta\Omega),$$

$$\hat{M}_2 = \Omega M_2 + 2Q_1(\Delta\Omega) + 2Q_2(\delta\Omega), \quad \hat{B}_0 = \Omega^{-1} B_0 + 2Q_0(\Omega^{-2}\bar{\delta}\Omega) + 2Q_1(\Omega^{-2} D\Omega),$$

$$\hat{B}_1 = B_1 + Q_1(\Omega^{-1}\bar{\delta}\Omega) + Q_2(\Omega^{-1} D\Omega), \quad \hat{B}_2 = \Omega B_2.$$

Finally, by direct substitution of the twelve terms above into Eqs. (B2)–(B4) we find the anti-self-dual components of the Penrose equation conformally transform as

$$(\hat{\mathrm{B}}2) = (\mathrm{B}2), \quad (\hat{\mathrm{B}}3) = \Omega^{-1}(\mathrm{B}3), \quad (\hat{\mathrm{B}}4) = \Omega^{-2}(\mathrm{B}4). \tag{C4}$$

This result is confirmed by the conformal maps

$$\hat{\mathbf{P}}^{\alpha\mu\nu} = \Omega^{-3}\mathbf{P}^{\alpha\mu\nu} \tag{C5}$$

and

$$\hat{U}_{\mu\nu} = \Omega^3 U_{\mu\nu}, \quad \hat{M}_{\mu\nu} = \Omega^2 M_{\mu\nu}, \quad \hat{V}_{\mu\nu} = \Omega V_{\mu\nu}. \tag{C6}$$

Exact solutions for the Tikekar superdense star

S. D. Maharaj and P. G. L. Leach[a)]
Department of Mathematics and Applied Mathematics, University of Natal, King George V Avenue, Durban 4001, South Africa

(Received 26 September 1994; accepted for publication 22 September 1995)

We analyze a relativistic model for superdense stars proposed by Tikekar [R. Tikekar, J. Math. Phys. **31**, 2454 (1990)]. In this model the hypersurfaces generated by $\{t=\text{const}\}$ have the geometry of the 3-spheroid which gives the solutions a clear geometrical characterization. The solution of the Einstein field equations is reduced to integrating a second order ordinary differential equation. New classes of solutions are presented by restricting the choice of the spheroidal parameter K so that polynomial solutions are admitted for the first solution and then we find that there exists another solution which is a product of polynomials and algebraic functions. A remarkable feature of the class of solutions generated is that they are expressible completely in terms of polynomials and algebraic functions. Some physical aspects of the solutions are briefly considered. We regain the Tikekar solution as a special case when $K=-7$. As another example we explicitly present the form of the solution when $K=-2$. © *1996 American Institute of Physics.* [S0022-2488(96)02301-8]

I. INTRODUCTION

Models of relativistic stars are important for the description of astrophysical processes. We may model relativistic stars by finding static spherically symmetric solutions to the Einstein field equations. In addition a number of conditions are normally placed on the energy density, the pressure, and the gravitational potentials to ensure that the model is physically reasonable. However, we should point out that it is rare to find a model that rigorously satisfies all these conditions. For a comprehensive list of exact solutions to the Einstein field equations, many of which may be used to describe the gravitational behavior of stars, see Kramer *et al.*[1] Knutsen[2,3] provides a comprehensive treatment, in particular stellar models, of the conditions to be satisfied for a realistic matter distribution. Even though the static and spherically symmetric conditions are highly simplified they allow the construction of models of physically reasonable superdense stars such as neutron stars.[4]

In an attempt to reduce the complexity of the field equations one normally places some restriction on the metric functions. Vaidya and Tikekar[5] made the observation that one could utilize the geometry of the spacelike hypersurfaces generated by $\{t=\text{const}\}$ to find exact solutions in some cases. This property is very useful in the case of space-times which are static and spherically symmetric, and the hypersurfaces $\{t=\text{const}\}$ are that of the 3-spheroid. The spheroidal condition provides a clear geometrical characterization of the space–times concerned. This is a desirable feature as it is difficult to characterize geometrically many of the solutions in the literature which have been obtained using other techniques. One of the metric functions may be immediately determined from geometrical arguments and the energy density is specified. We are then in a position to determine the remaining gravitational and thermodynamical variables from Einstein's equations. The model that is generated may be applied to superdense stars. Tikekar[6] has performed an analysis of the physical properties of these solutions and found them to be physically viable. The Tikekar model is applicable in the last stages of stellar evolution and satisfies the

0022-2488/96/37(1)/430/8/$6.00

physical requirements placed on fluid configurations at ultrahigh densities and pressures. The values of the maximum mass of the superdense star obtained are close to those of Rhodes and Ruffini.[7] Knutsen[3] has demonstrated that solutions with a spheroidal geometry are stable with respect to infinitesimal radial pulsations.

Our intention in this paper is to obtain new solutions to the field equations for the Tikekar[6] model. The ideal is to obtain models with physically acceptable gravitational behavior in the interior of the star when the 3-spaces $\{t=\text{const}\}$ are spheroidal. In Sec. II we present the field equations for static spherically symmetric gravitational fields. We review the superdense model of Tikekar and generate the second order field equation that has to be integrated. The first solution, in terms of polynomials, is presented in Sec. III. In Sec. IV we generate the second solution in terms of polynomials and algebraic functions by generalizing a solution previously found. Some particular solutions, from the new classes of solutions presented, are explicitly derived in Sec. V. In Sec. VI we briefly consider certain aspects of physically reasonable stellar models. Finally in Sec. VII we review the results obtained and discuss possibilities for further research.

II. THE TIKEKAR MODEL

In standard coordinates, $(x^i)=(t,r,\theta,\phi)$, the line element for static spherically symmetric space–times may be written as[1]

$$ds^2=-e^{2\nu(r)}\,dt^2+e^{2\lambda(r)}\,dr^2+r^2(d\theta^2+\sin^2\,\theta\,d\phi^2), \tag{1}$$

where the quantities $\nu(r)$ and $\lambda(r)$ are gravitational potentials. For a perfect fluid energy-momentum tensor and the static spherically symmetric line element (1) we obtain the following Einstein field equations:

$$\frac{1}{r^2}\,[r(1-e^{-2\lambda})]'=\rho, \tag{2}$$

$$-\frac{1}{r^2}\,(1-e^{-2\lambda})+\frac{2\nu'}{r}\,e^{-2\lambda}=p, \tag{3}$$

$$e^{-2\lambda}\left[\nu''+\nu'^2+\frac{\nu'}{r}-\nu'\lambda'-\frac{\lambda'}{r}\right]=p, \tag{4}$$

where ρ is the energy density and p is the isotropic pressure. In the above equations, primes denote differentiation with respect to r. We rewrite the above systems (2)–(4) so that it is easier to compare with the results of Tikekar.[6] Note that our notation and signature differ from those of Tikekar. However, we generate the same field equations and our results are consistent. For the hypersurface $\{t=\text{const}\}$ to be a 3-spheroid we require that

$$e^{2\lambda}=\frac{1-Kr^2/R^2}{1-r^2/R^2}.$$

The geometry of the 3-spheroid is governed by the parameters R and K. The metric function $e^{2\lambda}$ is regular and well behaved for $r<R$ for which the parameter values $K<1$. We neglect the cases $K=0,1$: for $K=0$ we obtain the Schwarzschild interior solution and, when $K=1$, the hypersurfaces $\{t=\text{const}\}$ are flat. With the above form of $e^{2\lambda}$ the field equations (2)–(4) become

$$\rho=\frac{1-K}{R^2}\,\frac{3-Kr^2/R^2}{(1-Kr^2/R^2)^2}, \tag{5}$$

$$p=\left(\frac{2\nu'}{r}+\frac{1}{r^2}\right)\frac{1-r^2/R^2}{1-Kr^2/R^2}-\frac{1}{r^2}, \tag{6}$$

$$p=\left(\nu''+\nu'^2+\frac{\nu'}{r}\right)\frac{1-r^2/R^2}{1-Kr^2/R^2}-\left(\nu'+\frac{1}{r}\right)\frac{(1-K)(r/R^2)}{(1-Kr^2/R^2)^2}. \tag{7}$$

The equation

$$(1-r^2/R^2)(1-Kr^2/R^2)\left(\nu''+\nu'^2-\frac{\nu'}{r}\right)-(1-K)(r/R^2)\left(\nu'+\frac{1}{r}\right)$$
$$+(1-K)(1/R^2)(1-Kr^2/R^2)=0 \tag{8}$$

follows directly from Eqs. (6) and (7) and is the condition for pressure isotropy.

It is clear from inspection of the systems (5)–(7) that, if a functional form for the metric function ν is known, then we have a solution to the field equations. The differential equation (8) determines the behavior of ν. We can transform Eq. (8) to simpler form if we let

$$\psi=e^{\nu}, \quad x^2=1-r^2/R^2.$$

Then Eq. (8) takes the equivalent form

$$(1-K+Kx^2)\frac{d^2\psi}{dx^2}-Kx\frac{d\psi}{dx}+K(K-1)\psi=0. \tag{9}$$

For the parameter value $K=-7$ Tikekar[6] obtained the particular solution

$$\psi=A\psi_1+B\psi_2=A(1-\tfrac{7}{2}x^2+\tfrac{49}{24}x^4)+Bx(1-\tfrac{7}{8}x^2)^{3/2}, \tag{10}$$

where A and B are arbitrary constants. We present new classes of solutions to the differential equation (9) in subsequent sections.

III. THE FIRST SOLUTION

The special solution (10) contains the quartic term $(1-\frac{7}{2}x^2+\frac{49}{24}x^4)$. This suggests that Eq. (9) may admit solutions ψ_1 in the form of a series which would terminate for some values of K. Therefore we seek solutions to Eq. (9) of the form

$$\psi_1=\sum_{i=0}^{\infty}a_i x^i,$$

where a_i are constants. We find that this series terminates and we obtain two classes of polynomial solutions, the first in even powers of x and the second in odd powers of x, for particular values of the parameter K as would be expected from the form of Eq. (9). The appropriate values of K are

$$\text{even powers in } x: \quad K=2-(2n-1)^2,$$

$$\text{odd powers in } x: \quad K=2-4n^2.$$

Note that we require $n>1$, for even powers of x, and $n>0$, for odd powers of x, so that $K<1$ to ensure regularity of the metric functions.

For even powers we obtain the difference equation

$$a_{i+1}=-\frac{[(2n-1)^2-2]}{n(n-1)}\frac{(n-i)(n+i-1)}{(i+1)(2i+1)}a_i$$

which may be solved for the coefficients a_i. Then we can show that the polynomial in even powers of x is of the form

$$\psi_1=\sum_{i=0}^{n}a_ix^{2i}=\sum_{i=0}^{n}\frac{(n+i-2)!}{(n-i)!(2i)!}(-\lambda)^ix^{2i}, \tag{11}$$

where the constants λ and K are given by

$$\lambda=4-\frac{1}{n(n-1)},\quad K=2-(2n-1)^2.$$

The difference equation for odd powers is given by

$$a_{i+1}=-\frac{8(2n^2-1)}{4n^2-1}\frac{(n-i)(n+i)}{(2i+2)(2i+3)}a_i.$$

Consequently the polynomial in odd powers of x has the form

$$\psi_1=\sum_{i=0}^{n}a_ix^{2i+1}=\sum_{i=0}^{n}\frac{(n+i-1)!}{(n-i)!(2i+1)!}(-\mu)^ix^{2i+1}, \tag{12}$$

where we define

$$\mu=4-\frac{4}{4n^2-1},\quad K=2-4n^2.$$

The polynomial solutions (11) and (12) comprise the first solution ψ_1 of Eq. (9) for the appropriate values of K. It is clear that Eq. (11) contains the quartic term $(1-\frac{7}{2}x^2+\frac{49}{24}x^4)$ in Tikekar's solution (10). The second solution to Eq. (9) cannot be expressed solely in terms of polynomial functions as demonstrated in Sec. IV.

IV. THE SECOND SOLUTION

The Tikekar[6] solution (10) contains $x(1-\frac{7}{8}x^2)^{3/2}$ as the second solution. This algebraic function is a special case of

$$\psi_2=(1-K+Kx^2)^{3/2}u(x),$$

where $u(x)=x$ and $K=-7$. We notice that other values of K generate particular solutions to Eq. (9) and $u(x)$ is a polynomial. This suggests that the above form for ψ_2 is a generic solution to the differential equation (9). For ψ_2 to be a solution of Eq. (9) the function $u(x)$ has to satisfy the following equation:

$$(1-K+Kx^2)\frac{d^2u}{dx^2}+5Kx\frac{du}{dx}+K(K+2)u=0. \tag{13}$$

As for the first solution we can find polynomials that satisfy Eq. (13) for certain values of K. The procedure is very similar to that given in Sec. III. However, it is important to note that there is a reversal of role for the parameter K in the characterization of the even and odd polynomials:

$$\text{odd powers in } x: \quad K=2-(2n-1)^2,$$

$$\text{even powers in } x: \quad K=2-4n^2.$$

In other words, u will contain odd (even) powers of x when ψ_1 has even (odd) powers of x. The oddness and evenness of the two solutions is not unexpected from the form of Eq. (9). That both are finite expressions (in the sense of Poincaré) is perhaps somewhat unexpected.

The difference equation for $K=2-(2n-1)^2$ is

$$a_{i+1}=-\frac{[(2n-1)^2-2]}{2n(n-1)}\frac{(n+i+1)(n-i-2)}{(2i+2)(2i+3)}a_i$$

which we have solved in general. Then the polynomial in odd powers of x is given by

$$u=\sum_{i=0}^{n-2}a_i x^{2i+1}=\sum_{i=0}^{n-2}\frac{(n+i)!}{(n-i-2)!(2i+1)!}(-\lambda)^i x^{2i+1},$$

where the constants λ and K satisfy

$$\lambda=4-\frac{1}{n(n-1)}, \quad K=2-(2n-1)^2.$$

The difference equation for $K=2-4n^2$ is given by

$$a_{i+1}=-\frac{8(2n^2-1)}{4n^2-1}\frac{n^2-(i+1)^2}{(2i+1)(2i+2)}a_i$$

which may be solved for the constants a_i. The polynomial in even powers of x has the form

$$u=\sum_{i=0}^{n-1}a_i x^{2i}=\sum_{i=0}^{n-1}\frac{(n+i-1)!}{(n-i)!(2i)!}(-\mu)^i x^{2i},$$

where we have

$$\mu=4-\frac{4}{4n^2-1}, \quad K=2-4n^2.$$

With these expressions for u we have that the second solution, with u containing odd powers of x, is given by

$$\psi_2=(1-K+Kx^2)^{3/2}\sum_{i=0}^{n-2}\frac{(n+i)!}{(n-i-2)!(2i+1)!}(-\lambda)^i x^{2i+1}. \tag{14}$$

The second solution, with u containing even powers of x, is

$$\psi_2=(1-K+Kx^2)^{3/2}\sum_{i=0}^{n-1}\frac{(n+i)!}{(n-i-1)!(2i)!}(-\mu)^i x^{2i}. \tag{15}$$

Solutions (14) and (15) generate the second solutions of Eq. (9) which are clearly linearly independent from the first solutions (11) and (12), respectively.

Thus we have generated general solutions to the differential equation (9) by restricting the values of K so that polynomials and products of polynomials with algebraic functions are possible as solutions. The solutions for the various cases are given by Eqs. (11), (12), (14), and (15). Collecting these results we have the first category of solutions:

$$\psi=A\sum_{i=0}^{n}\frac{(n+i-2)!}{(n-i)!(2i)!}(-\lambda)^i x^{2i}+B(1-K+Kx^2)^{3/2}\sum_{i=0}^{n-2}\frac{(n+i)!}{(n-i-2)!(2i+1)!}(-\lambda)^i x^{2i+1} \tag{16}$$

for $K=2-(2n-1)^2$. The second category of solutions is given by

$$\psi=A\sum_{i=0}^{n}\frac{(n+i-1)!}{(n-i)!(2i+1)!}(-\mu)^i x^{2i+1}+B(1-K+Kx^2)^{3/2}\sum_{i=0}^{n-1}\frac{(n+i)!}{(n-i-1)!(2i)!}(-\mu)^i x^{2i}, \tag{17}$$

where $K=2-4n^2$. In Eqs. (16) and (17) the constants λ and μ depend on n:

$$\lambda=4-\frac{1}{n(n-1)},\quad \mu=4-\frac{4}{4n^2-1}.$$

We have generalized the solution of Tikekar[6] and obtained new classes of solution applicable to superdense stars. It is remarkable that the solutions (16) and (17) are expressed completely as combinations of polynomials and algebraic functions. This is directly related to the restriction placed on the spheroidal parameter K. It is rare to find solutions, especially such large classes as Eqs. (16) and (17), to the field equations in terms of elementary functions. Because of their simplicity our solutions will have the advantage of simplifying the analysis of the physical properties of the superdense star.

V. SOME PARTICULAR CASES

We may generate many solutions found previously from our general class of solutions (16) and (17). With $K=-7$ $(n=2)$, $\lambda=7/2$. Then it is easy to verify that Eq. (16) becomes

$$\psi=A(1-\tfrac{7}{2}x^2+\tfrac{49}{24}x^4)+Bx(1-\tfrac{7}{8}x^2)^{3/2}.$$

Thus we have regained the Tikekar[6] solution from our results. Other solutions found in the literature are also contained in our general class of functions. However, there exist solutions found previously that cannot be regained from our results. For example, the Durgapal and Bannerji solution[8] for which

$$e^{2\lambda}=\frac{2(1+Cr^2)}{2-Cr^2},$$

where C is a positive constant does not fall into our class of solutions. A study of the various possibilities that arise and their relationship to particular existing solutions would be a formidable task. Also we may obtain other explicit functional forms for ψ which could be useful in applications for superdense stars. As a simple example suppose that $K=-2(n=1)$ so that $\mu=8/3$. Then it follows that

$$\psi=A(x-\tfrac{4}{9}x^3)+B(3-2x^2)^{3/2}$$

from Eq. (17).

VI. SOME PHYSICAL ASPECTS

As we have pointed out previously the condition of 3-spheroidal hypersurfaces permits a clear geometrical interpretation which is not the case in many other exact solutions. The spheroidal assumption in the $\{t=\text{const}\}$ hypersurfaces is physically reasonable as it represents a deviation from spherical symmetry. This situation is likely to occur in the central core regions of superdense stars because of highly nonlinear gravitational effects. It should be emphasized that we have little information about the nature of the behavior of matter in the central regions of superdense stars. Clearly we should attempt to construct a model under assumptions that allow for fairly general behavior. In this regard solutions generated by computers are not helpful as we cannot specify *a priori* a equation of state with great certainty for the core regions. The spheroidal assumption has produced models which are consistent with densities of the order 2×10^{14} gm cm^{-3} as demonstrated by Tikekar.[6] These values are consistent with the results of Rhodes and Ruffini[7] and indicate that the spheroidal assumption produces physically viable static models for relativistic stars.

If $0<K<1$ then ρ remains positive in the region $r^2<3R^2/K$ which restricts the size of the configuration. When $K<0$ there is no restriction on ρ. Thus $\rho>0$ in the interior of the star. It is clear from Eq. (5) that $\rho'<0$ so that the density decreases from the center. We require that the pressure must vanish at the boundary $r=a$ which implies that

$$\left(\frac{4}{R^2}\frac{1}{\psi}\frac{d\psi}{dx}\right]_a-\frac{1}{a^2}\right)\frac{1-a^2/R^2}{1-Ka^2/R^2}+\frac{1}{a^2}=0,$$

where ψ is given by Eq. (16) or (17). Essentially this places a restriction on the constants A and B. The gradient of the pressure is

$$p'=-(\rho+p)\frac{pr^3+2m(r)}{2r[r-2m(r)]},\quad m(r)=\frac{1}{2}\frac{(1-K)r/R^2}{1-Kr^2/R^2}.$$

This implies that the pressure gradient is negative if $p>0$ (the energy density $\rho>0$) and consequently the pressure will be decreasing outwards. The interior metric (1) should continuously match with the exterior Schwarschild line element

$$ds^2=-\left(1-\frac{2m}{r}\right)dt^2+\left(1-\frac{2m}{r}\right)^{-1}dr^2+r^2(d\theta^2+\sin^2\theta\,d\phi^2)$$

at $r=a$. This requirement implies that

$$1-\frac{2m}{a}=e^{2\nu(a)}=A\psi_1(a)+B\psi_2(a),$$

$$\left(1-\frac{2m}{a}\right)^{-1}=e^{2\lambda(a)}=\frac{1-Ka^2/R^2}{1-a^2/R^2}.$$

The quantities considered above can be explicitly investigated for various models. In particular Tikekar[6] and Vaidya and Tikekar[5] have comprehensively studied the cases $K=-7$ and $K=-2$, respectively; they demonstrated that the physical requirements for a regular, stable star are satisfied.

VII. DISCUSSION

The Tikekar[6] model has the advantage of being well behaved and satisfies the physical requirements for a superdense star. Unlike many other solutions it has a clear geometrical interpre-

tation: the 3-spaces $\{t=\text{const}\}$ have the geometry of the spheroid. We have integrated the field equation (9) to obtain new solutions by restricting the spheroidal parameter K to take on values so that polynomial solutions exist. The accuracy of the results has been verified with the assistance of the algebraic computing package MATHEMATICA.[9] The distinguishing feature of solutions (16) and (17) is that they are written completely in terms of polynomial functions and algebraic functions. This is a desirable feature and is particularly helpful when considering the physical properties of stars such as the mass, red shift, etc. We regained the physically reasonable Tikekar[6] model of a superdense star from our general class of solutions for $K=-7$ and presented a particular solution for $K=-2$. We briefly discussed some of the physical properties of the new solutions presented. This is important for applications and should be pursued in greater detail in the future. The models generated in our analysis are likely to be physically reasonable as they contain the Tikekar superdense model.

The solutions obtained have arisen essentially because we have imposed spheroidal symmetry. The use of other symmetries may generate new solutions. For example, Herrera *et al.*,[10] Herrera and Ponce de Leon,[11–13] and Maartens and Maharaj[14] have generated conformally invariant static fluid spheres by assuming a conformal symmetry on space–time. We have obtained solutions to the differential equation (9) by restricting the values of K. There exist other solutions to Eq. (9) for different values of K. To demonstrate this let

$$\psi=y(x), \quad x=-2\sqrt{1-1/K}x+\sqrt{1-1/K}.$$

Then the isotropy of pressure condition (9) becomes

$$x(1-x)\frac{d^2y}{dx^2}-\left(x-\frac{1}{2}\right)\frac{dy}{dx}+(1-K)y=0$$

which is the hypergeometric equation.[15] This has solutions in terms of special functions, namely the hypergeometric function. Whether the greater generality of the solution in terms of hypergeometric functions outweighs the tractability of the solutions presented here is a matter for conjecture.

The initial singularity in solutions of the Einstein–Vlasov system of Bianchi type I

Alan D. Rendall
Institut des Hautes Etudes Scientifiques, 35 Route de Chartres, 91440 Bures-sur-Yvette, France

(Received 26 May 1995; accepted for publication 25 August 1995)

The dynamics of solutions of the Einstein–Vlasov system with Bianchi I symmetry is discussed in the case of massive or massless particles. It is shown that in the case of massive particles the solutions are asymptotic to isotropic dust solutions at late times. The initial singularity is more difficult to analyze. It is shown that the asymptotic behavior there must be one of a small set of possibilities, but it is not clear whether all of these possibilities are realized. One solution is exhibited in the case of massless particles, which behaves quite differently near the singularity from any Bianchi I solution with perfect fluid as a matter model. In particular, the matter is not dynamically negligible near the singularity for this solution. © *1996 American Institute of Physics.* [S0022-2488(96)03901-4]

I. INTRODUCTION

The simplest of all anisotropic cosmological models are those of Bianchi type I. They are the space–times that admit a three-dimensional Abelian symmetry group whose orbits are space-like. (For general information on Bianchi models see Ref. 1.) Just how simple their dynamics is depends significantly on the nature of the matter content of the space–time. For a perfect fluid with a linear equation of state, it has been known for a long time how to analyze the dynamics.[2,3] For a noninteracting mixture of two fluids with linear equations of state, the time evolution is also well understood and is asymptotic near the singularity and at large times to that of a single fluid.[4] The case of a fluid with a nonlinear equation of state is discussed in an Appendix to the present paper. The dynamics does not differ much from the picture in the linear case. When a magnetic field is added to the fluid, things are already more complicated. In fact, as was shown by Collins,[5] a Bianchi type I model with fluid and magnetic field resembles a model of the more complicated Bianchi type II with fluid alone. It is also interesting to note that models of type VI_0 with perfect fluid and a magnetic field have a dynamical behavior resembling the notoriously complicated ''Mixmaster'' behavior of Bianchi type IX models.[6] Thus, changing the matter model can have effects on the complexity of the dynamics comparable with those encountered when passing to more general symmetry types.

A matter model for which the details of the global dynamics of Bianchi type I space–times has not previously been studied mathematically is the collisionless gas, described by the Vlasov equation. The only general facts that are known are that, with an appropriate choice of time orientation, (i) the space–time is future geodesically complete (when maximally extended toward the future); and (ii) there is a crushing singularity in the past where, except in the vacuum case, the curvature invariant $R_{\alpha\beta}R^{\alpha\beta}$ tends to infinity.

These fundamental facts were proved in Ref. 7, where it was shown that they hold for any Bianchi type other than IX and for a general class of matter models. The aim of this paper is to refine (i) and (ii) in the case of Bianchi type I symmetry and matter described by the Vlasov equation so as to get more detailed information about the asymptotics of the expanding phase and the nature of the initial singularity. An aspect of the situation that makes this more difficult than in the case of many other matter models is that for general initial data it is not possible to derive an explicit closed system of ordinary differential equations that describes the dynamics. This is because certain integrals that occur cannot be evaluated. In one special case, where massless

0022-2488/96/37(1)/438/14/$6.00

particles are considered and the initial phase space density has the form of the characteristic function of a ball, these integrals have been computed by Lukash and Starobinski.[8] However, the explicit expressions they obtain are sufficiently complicated that they do not seem to make a rigorous analysis of the global dynamics any easier. On the other hand, they would probably be useful for numerical calculations, since they would allow costly numerical evaluation of integrals to be avoided.

The dynamics at late times of the models with massive particles can be described precisely. All solutions become isotropic and can be approximated by dust solutions in this limit (Theorem 5.4). On the other hand, the results of this paper do not give a complete picture of the dynamics near the initial singularity of the space–times being studied. They merely reduce the possible types of asymptotic behavior to a small number of alternatives. Improving on this is likely to require new techniques. These results leave open the possibility that Bianchi I space–times with a matter content described by kinetic theory may show complicated oscillatory behavior, and thus may be very different from those with other types of matter content studied up to now. The mechanism that allows for this complexity is simply the presence of anisotropy in the pressure that may respond to changes in the geometry. It may be that the only reason that the dynamics is so simple in the case of a perfect fluid is that this mechanism is excluded by a special symmetry assumption (the isotropy of the pressure). The one conclusion that emerges and that applies to all solutions considered here is that the ratio of the mean pressure to the energy density tends to one-third as the singularity is approached. This means that in a certain weak sense the dynamics for particles of unit mass m is approximated near the singularity by that for massless particles. For this reason both cases are often considered together in the following, although the main emphasis is on the case $m=1$.

The results will now be summarized. There are, broadly speaking, two possible types of asymptotic behavior of solutions of the Einstein–Vlasov system with Bianchi I symmetry near the singularity. They will be referred to as convergent and oscillatory. Let λ_i denote the eigenvalues of the second fundamental form of the homogeneous hypersurfaces. Then the mean curvature of the homogeneous hypersurfaces is given by $\mathrm{tr}\, k=\lambda_1+\lambda_2+\lambda_3$. Define the generalized Kasner exponents by $p_i=\lambda_i/\mathrm{tr}\, k$. In the convergent type, the p_i tend to limits as the singularity is approached. There are three different cases, depending on these limiting values. The first case is that where the limiting values are $(\frac{1}{3},\frac{1}{3},\frac{1}{3})$. The well-known homogeneous and isotropic solutions of the Einstein–Vlasov system[9] are of this type. The second is that the limiting values are $(0,\frac{1}{2},\frac{1}{2})$ or some permutation thereof. The existence of solutions of this kind in the case of massless particles is shown in Sec. VI. These limiting values of the generalized Kasner exponents are not realized by any Bianchi type I space–time when the matter model is a perfect fluid (see the Appendix). The third is that the limiting values satisfy the Kasner relation $p_1^2+p_2^2+p_3^2=1$. Any solution for which one of the eigenvalues becomes negative at some time has this asymptotic behavior, and so there are plenty of examples. This is proved in Theorem 5.1. Note that the special case of this result when two of the p_i are equal is closely related to the homogeneous special case of a result of Rein[10] for plane symmetric space–times. In the oscillatory type the p_i undergo infinitely many oscillations, in a sense that will now be specified. There are two cases to be considered, according to whether two of the eigenvalues are always equal or not. Consider first the case where two eigenvalues are equal and suppose, without loss of generality, that $\lambda_2=\lambda_3$. Associate to any solution a string of symbols (which may be finite or infinite, depending on the solution) as follows. Moving backward from some fixed time, add an x to the string each time that $\lambda_1-\lambda_2$ changes from being $\leqslant 0$ to being >0 and add a y each time it changes from being $\geqslant 0$ to being <0. That this makes sense follows from the fact, proved in Sec. II, that the set of times where $\lambda_1=\lambda_2$ can have no limit point unless this equality holds at all times. Thus, a finite time interval can only contribute a finite number of symbols. The solution is said to undergo infinitely many oscillations if the resulting string of symbols is infinite. Similarly, if there is some time where all eigenvalues are distinct, then a string

of symbols is associated to the solution by adding x, y, or z each time λ_1, λ_2, or λ_3, respectively, becomes strictly larger than the other two eigenvalues.

Unfortunately it could not be shown whether any oscillatory solutions exist. If they did, then the behavior of Bianchi I models with kinetic theory as matter model would be much more complicated than in the case of a perfect fluid. If it could be shown that they existed, the question would remain whether the sequences of symbols they produce have some regularity or whether they are chaotic. In the absence of analytical techniques capable of deciding this question, it would be desirable to carry out a numerical investigation. This could provide evidence as to the existence (or otherwise) and nature of oscillatory behavior. It might also suggest new approaches to proving theorems about the global dynamics.

To each type of solution discussed above corresponds a characteristic behavior of the pressures. The solutions considered in the following all have diagonal energy-momentum tensors, and so three pressures P_i are defined by three diagonal components. The remaining diagonal component is the energy density ρ. The quantities $R_i = P_i/\rho$ must have a sum that converges to unity at the singularity. When the limiting values of the p_i are $(\frac{1}{3},\frac{1}{3},\frac{1}{3})$ or $(0,\frac{1}{2},\frac{1}{2})$, then the limiting values of the R_i are $(\frac{1}{3},\frac{1}{3},\frac{1}{3})$ or $(0,\frac{1}{2},\frac{1}{2})$, respectively. When the sum of the squares of the limiting values of the p_i is equal to unity, then the R_i tend to $(0,\frac{1}{2},\frac{1}{2})$ or a permutation thereof, unless one p_i has the limiting value zero. In the latter case the R_i tend to (1,0,0) or a permutation thereof.

The paper is organized as follows. In Sec. II some basic facts about the solutions are collected. Section III is concerned with a simplified system, which in some cases models the asymptotic behavior of the solutions of the original system. Some estimates for the pressures are derived in Sec. IV. Section V contains the main results. Section VI contains proofs of the existence or nonexistence of solutions with certain kinds of asymptotic behavior.

II. BASIC FACTS

The Einstein–Vlasov system is the system of equations that describes the kinetic theory of self-gravitating particles in general relativity. A thorough introduction to general relativistic kinetic theory and to the collisionless case, in particular, can be found in Ref. 11. For particles all of the same mass $m \geqslant 0$, the system can be written in the following form in the case of Bianchi type I symmetry:

$$-k_{ij}k^{ij} + (\mathrm{tr}\ k)^2 = 16\pi\rho, \tag{2.1}$$

$$T_{0i} = 0, \tag{2.2}$$

$$\partial_t g_{ij} = -2k_{ij}, \tag{2.3}$$

$$\partial_t k_{ij} = \mathrm{tr}\ k k_{ij} - 2k_{il}k^l_j - 8\pi T_{ij} - 4\pi\rho g_{ij} + 4\pi\ \mathrm{tr}\ T g_{ij}, \tag{2.4}$$

$$\frac{\partial f}{\partial t} + 2k^i_j v^j \frac{\partial f}{\partial v^i} = 0, \tag{2.5}$$

$$\rho = \int f(t,v^k)(m^2 + g_{rs}v^r v^s)^{1/2}(\det g)^{1/2}\, dv^1\, dv^2\, dv^3, \tag{2.6}$$

$$T_{ij} = \int f(t,v^k) v_i v_j (m^2 + g_{rs}v^r v^s)^{-1/2}(\det g)^{1/2}\, dv^1\, dv^2\, dv^3. \tag{2.7}$$

Equations (2.1)–(2.4) are the Einstein equations written in 3+1 form, (2.5) is the Vlasov equation, and (2.6) and (2.7) are the definition of the energy-momentum tensor in terms of the matter fields needed to complete the system. In these equations g_{ij} is the induced metric of the homogeneous

hypersurfaces, k_{ij} is the second fundamental form, f is the phase space density of particles, ρ is the energy density, T_{0i} and T_{ij} are components of the energy-momentum tensor, and tr k is the mean curvature $g^{ij}k_{ij}$. With the exception of f all these quantities depend only on the time coordinate t. This time coordinate is Gaussian, i.e., it is constant on each homogeneous hypersurface and defines a parametrization by proper time when restricted to any geodesic normal to these hypersurfaces. The space–time metric is of the form

$$ds^2 = -dt^2 + g_{ij}(t)dx^i\,dx^j. \tag{2.8}$$

In the following it is always assumed, when talking about solutions of (2.1)–(2.7), that the function $f(t,v)$ is non-negative and has compact support for each fixed t. It is assumed that f is C^1 except in Sec. III, where f may be a distribution. The case of primary interest here is the case $m=1$. Since, however, solutions of (2.1)–(2.7) with $m=1$ resemble solutions with $m=0$ close to the singularity, it is useful to also allow the case $m=0$ from the beginning. Note that the real distinction here is between massless particles on the one hand and, on the other hand, massive particles, which all have the same mass. In the latter case it is convenient to choose the mass of a particle as a unit of mass so that the numerical value of the mass of a particle in the system of units used is unity.

For a given Bianchi I geometry, the Vlasov equation can be solved explicitly. (This is not possible for the other Bianchi types. The reason is explained in Ref. 12.) The result is that if f is expressed in terms of the covariant components v_i then it is independent of time. This means that if t_0 is some fixed time and $f_0(v_i)=f(t_0,v_i)$, then (2.6) can be rewritten as

$$\rho = \int f_0(v_i)(m^2+g^{rs}v_rv_s)^{1/2}(\det g)^{-1/2}\,dv_1\,dv_2\,dv_3, \tag{2.9}$$

and (2.7) can be rewritten in a similar way. The explicit solution allows certain special subclasses of solutions of (2.1)–(2.7) to be identified. The first of these will be referred to as reflection-symmetric, and is defined by the conditions that

$$f_0(v_1,v_2,v_3)=f_0(-v_1,-v_2,v_3)=f_0(v_1,-v_2,-v_3), \tag{2.10}$$

and that the initial values of g_{ij} and k_{ij} are diagonal. Equation (2.10) implies that T_{ij} is diagonal. It then follows from (2.3) and (2.4) that g_{ij} and k_{ij} are always diagonal. The second case, which will be referred to as LRS (locally rotationally symmetric) is obtained by supplementing (2.10) by the conditions that

$$f_0(v_1,v_2,v_3)=F((v_1)^2+(v_2)^2,v_3), \tag{2.11}$$

for some function F and that $g_{11}=g_{22}$, $k_{11}=k_{22}$ initially. Equation (2.11) implies that $T_{11}=T_{22}$ and it follows from (2.3) and (2.4) that $g_{11}=g_{22}$ and $k_{11}=k_{22}$ everywhere. A solution will also be called LRS if it satisfies the definition obtained from that just given by a permutation of the indices 1,2,3. A solution will be called isotropic if

$$f_0(v_1,v_2,v_3)=F((v_1)^2+(v_2)^2+(v_3)^2), \tag{2.12}$$

and if g_{ij} and k_{ij} are proportional to δ_{ij} on the initial hypersurface, and hence everywhere. If a solution satisfies the conditions on g_{ij} and k_{ij} in the definition of reflection-symmetric, LRS or isotropic for all t in some interval, but no assumption is made on f then the solution will be said to have reflection-symmetric, LRS or isotropic geometry, respectively, on that interval. It follows from (2.4) that T_{ij} has a corresponding symmetry property.

In this paper only reflection-symmetric solutions of (2.1)–(2.7) are considered. The alternative notation $a^2=g_{11}/g_{11}(t_0)$, $b^2=g_{22}/g_{22}(t_0)$, $c^2=g_{33}/g_{33}(t_0)$ is used when it is convenient. Yet another form of (2.6) can then be obtained by doing a change of variables in (2.9),

$$\rho=\int f_0(aw_1,bw_2,cw_3)(m^2+\delta^{rs}w_rw_s)^{1/2}\,dw_1\,dw_2\,dw_3. \tag{2.13}$$

The geometric interpretation of the w_i is that they are the components of the momentum in an orthonormal frame. Similarly,

$$T^i_i=\int f_0(aw_1,bw_2,cw_3)w_i^2(m^2+\delta^{rs}w_rw_s)^{-1/2}\,dw_1\,dw_2\,dw_3. \tag{2.14}$$

In order to study the dynamics of the solutions of the system (2.1)–(2.7) in detail, it is useful to introduce certain dimensionless variables that remain finite at the singularity. It follows from (2.1) that $\operatorname{tr} k$ never vanishes, except in the case of flat space–time, which is excluded from consideration in the following. By replacing t by $-t$ if necessary, it can be arranged that $\operatorname{tr} k<0$ everywhere. It will be assumed that this has been done. Define

$$\hat{k}_{ij}=k_{ij}/\operatorname{tr} k, \tag{2.15}$$

$$\hat{\rho}=\rho/(\operatorname{tr} k)^2, \tag{2.16}$$

$$\hat{T}_{ij}=T_{ij}/(\operatorname{tr} k)^2, \tag{2.17}$$

$$\tau(t)=-\int_{t_0}^{t}\operatorname{tr} k(t')dt'. \tag{2.18}$$

In terms of these variables equations (2.1) and (2.4) become

$$-\hat{k}^i_j\hat{k}^j_i+1=16\pi\hat{\rho}, \tag{2.19}$$

$$\partial_\tau\hat{k}^i_j=-12\pi\hat{\rho}(\hat{k}^i_j-\tfrac{1}{3}\delta^i_j)+8\pi\hat{T}^i_j+4\pi(\hat{k}^i_j-\delta^i_j)\operatorname{tr}\hat{T}. \tag{2.20}$$

The following lemma provides some information about the range of τ.

Lemma 2.1: Let a solution of (2.1)–(2.7) with $m=0$ or $m=1$ be given, which is the maximal globally hyperbolic development of initial data on the hypersurface $t=t_0$. Then $\operatorname{tr} k(t)$ is a monotonic function defined on an interval (t_1,∞). By translating t, it can be assumed that $t_1=0$. Then $\lim_{t\to 0}\operatorname{tr} k=-\infty$ and $\lim_{t\to\infty}\operatorname{tr} k=0$. Moreover, $-3/t\leqslant\operatorname{tr} k(t)\leqslant -1/t$.

Proof: That $\operatorname{tr} k(t)$ is monotonic and defined on an interval of the form (t_1,∞) with $\lim_{t\to t_1}\operatorname{tr} k=-\infty$ was shown for the case $m=1$ in Ref. 13. Essentially the same argument applies for $m=0$. In the latter case the coefficients of the characteristic system are only Lipschitz instead of C^1, but this causes no problems. Now it follows from (2.4) that $\frac{1}{3}(\operatorname{tr} k)^2\leqslant\partial_t(\operatorname{tr} k)\leqslant(\operatorname{tr} k)^2$. Comparing the solution with the ordinary differential equations corresponding to these inequalities then gives the desired estimates (cf. Ref. 7).

This result implies that the integral defining τ diverges as $t\to 0$ and as $t\to\infty$. Hence, the solution of (2.19)–(2.20) exists globally in τ.

The solution of (2.19)–(2.20), of course, contains only a small part of the information of that contained in the solution of (2.1)–(2.7). The former is only a projection of the latter. Nevertheless, it will be seen that a lot of information about the solution of the full equations can be obtained by studying this projection. Consider now the set K of triples of real numbers $\hat{k}^1_1,\hat{k}^2_2,\hat{k}^3_3$ that satisfy $\Sigma_i(\hat{k}^i_i)^2\leqslant 1$ and $\Sigma_i\hat{k}^i_i=1$. This is a compact subset of $\mathbf{R}^3$. In fact, it is a disk in a plane. A solution

of (2.19)–(2.20) defines a point of K at each time τ. It is on the boundary of K in the plane if f is identically zero and in the interior otherwise. This point depending on τ, considered as a mapping from $\mathbf{R}$ to K, will be referred to as the projection of the given solution. The projection of a vacuum solution, which lies on the boundary of K, is constant. The vacuum solutions are, of course, the well-known Kasner solutions and the boundary of K may be referred to as the "Kasner circle." Let C denote the point $(\frac{1}{3},\frac{1}{3},\frac{1}{3})$. If a solution has isotropic geometry on a time interval, then its projection lies at the point C during this time. Conversely, if its projection lies at C on a given time interval, then it can be made to have isotropic geometry by a time-independent rescaling of the spatial coordinates. Let L_1, L_2, and L_3 be the subsets of K defined by $\hat{k}_2^2=\hat{k}_3^3$, $\hat{k}_1^1=\hat{k}_3^3$, and $\hat{k}_1^1=\hat{k}_2^2$, respectively. A solution has LRS geometry on a time interval (up to a constant rescaling of the spatial coordinates as above), if and only if its projection lies on one of the lines L_1, L_2, or L_3 during this time. Let L_i^+ denote the open half of L_i which ends at the point with coordinates $(-\frac{1}{3},\frac{2}{3},\frac{2}{3})$ or a permutation thereof, and let L_i^- denote the opposite half-line, which ends at the point with coordinates (1,0,0) or a permutation thereof. Let V_i^+ and V_i^- denote these end points. Let A_1 be the open region bounded by L_2^+,L_3^+ and the boundary of K, and let A_2 and A_3 be defined by cyclically permuting (1,2,3) in this definition. Let B_i be the subset of K where $\hat{k}_i^i \leqslant 0$.

The components of the metric satisfy the evolution equations

$$\frac{dg_{ii}}{d\tau}=2\hat{k}_i^i g_{ii}, \quad \frac{d}{d\tau}\left(\frac{g_{ii}}{g_{jj}}\right)=2(\hat{k}_i^i-\hat{k}_j^i)\left(\frac{g_{ii}}{g_{jj}}\right), \tag{2.21}$$

which imply that g_{ii} or their ratios increase or decrease exponentially if certain sign conditions are satisfied by the $\hat{k}_i^i$. There are, of course, corresponding statements for the scale factors a, b, and c. Given an initial datum f_0 for f the quantities ρ and T_i^i are determined uniquely by the g_{ii} by means of Eqs. (2.13) and (2.14). The quantities $\hat{\rho}$ and $\hat{T}_i^i$ are given in terms of ρ and T_i^i and tr k by the definitions (2.16) and (2.17), while the off-diagonal components $\hat{T}_j^i$ are zero by assumption. Thus, (2.19), (2.20), and (2.21), together with the equation

$$\partial_\tau(\text{tr } k)=-(\text{tr } k)(1-12\pi\hat{\rho}+4\pi \text{ tr } \hat{T}), \tag{2.22}$$

derive from (2.4), form a closed system of ordinary differential equations, which, for fixed f_0, formally determine the quantities $\hat{k}_i^i$, g_{ii}, and tr k as functions of τ in terms of initial data. If the coefficients of this system were locally Lipschitz, it would follow from the standard uniqueness theorem for ordinary differential equations that they determine them uniquely. It will now be shown that, in fact, for $m=1$ this dependence is analytic. To do this it is convenient to use the expressions for ρ and T_i^i of the type (2.9). Analyticity is a consequence of the following lemma.

Lemma 2.2: Let W be a mapping of $U\times\mathbf{R}^3$ to $\mathbf{R}$, where U is an open subset of $\mathbf{R}^3$. Suppose that W extends to a C^1 mapping $\tilde{W}$ of $\tilde{U}\times\mathbf{R}^3$ to $\mathbf{C}$, where $\tilde{U}$ is an open neighborhood of U in $\mathbf{C}^3$, and that $\tilde{W}(\cdot,y)$ satisfies the Cauchy–Riemann equations for each fixed $y\in R^3$. Finally, suppose that each $z\in W$ has an open neighborhood V such that the supports of the functions $W(z,\cdot)$ are contained in a common compact subset K of $\mathbf{R}^3$. Then the function $F(x)=\int_{\mathbf{R}^3}W(x,y)dy$ is analytic.

Proof: It suffices to show that the function $\tilde{F}(z)=\int_{\mathbf{R}^3}\tilde{W}(z,y)dy$ is complex analytic, and this is true if $\tilde{F}$ is C^1 and satisfies the Cauchy–Riemann equations.[14] The assumptions on the smoothness and support of $\tilde{W}$ justify differentiation under the integral, and so the Cauchy–Riemann equations for $\tilde{F}$ follow from the Cauchy–Riemann equations for $\tilde{W}$.

A consequence of the analyticity of the coefficients in the system of ordinary differential equations is that the solutions are analytic. It follows that if a solution with $m=1$ has LRS or isotropic geometry on some nonempty open time interval, then it must have LRS or isotropic geometry, respectively, for all values of τ. The same conclusion holds if there is a sequence of times having a limit point where the geometry is LRS or isotropic, respectively.

III. THE ASYMPTOTIC SYSTEM

In this section a certain system of ordinary differential equations is introduced and the qualitative behavior of its solutions analyzed. This system is used later to study the asymptotic behavior of solutions of the system (2.1)–(2.7). This system can be obtained formally from (2.1)–(2.7) by replacing the C^1 function $f(t,v_1,v_2,v_3)$ by a measure of the form $f(t,v_1)\delta(v_2-\bar{v}_2(t))\delta(v_3-\bar{v}_3(t))$, where δ is a Dirac measure, and taking $m=0$. Solutions of this system can be interpreted as certain distributional solutions of the Einstein–Vlasov system for massless particles. These are intermediate between smooth solutions and the even more singular solutions, which are in one to one correspondence with dust solutions. (For the correspondence between dust and distributional solutions of the Vlasov equation see Ref. 15.) The mathematical results that will now be derived are independent of this interpretation.

The system of ODEs to be considered is the special case of the equations (2.19) and (2.20) obtained by setting $\hat{T}_1^1=\hat{T}_2^2=0$ and $\hat{T}_3^3=\hat{\rho}$. Note that, in contrast to the general case of (2.19) and (2.20), these specialized equations suffice to determine all unknowns occurring in them from initial data. The explicit form of (2.20) in this case is

$$\partial_\tau \hat{k}_1^1=-8\pi\hat{\rho}\hat{k}_1^1, \tag{3.1}$$

$$\partial_\tau \hat{k}_2^2=-8\pi\hat{\rho}\hat{k}_2^2, \tag{3.2}$$

$$\partial_\tau \hat{k}_3^3=-8\pi\hat{\rho}(\hat{k}_3^3-1). \tag{3.3}$$

If initial data are chosen at some time that satisfy the condition $\Sigma_i(\hat{k}_i^i)=1$, then the solution also satisfies it. Only solutions with this property are considered here. It follows from (3.1) and (3.2) that $\partial_\tau(\hat{k}_2^2/\hat{k}_1^1)=0$ whenever $\hat{k}_1^1\neq 0$. Let r be the constant value of $\hat{k}_2^2/\hat{k}_1^1$. Then

$$\hat{k}_2^2=r\hat{k}_1^1, \tag{3.4}$$

$$\hat{k}_3^3=1-(1+r)\hat{k}_1^1. \tag{3.5}$$

Substituting (2.19), (3.4), and (3.5) into (3.1) gives

$$\partial_\tau \hat{k}_1^1=(\hat{k}_1^1)^2[(1+r+r^2)\hat{k}_1^1-(1+r)]. \tag{3.6}$$

Proposition 3.1: Let $(\hat{k}_1^1,\hat{k}_2^2,\hat{k}_3^3)$ be a solution of (3.1)–(3.3) satisfying $\Sigma_i(\hat{k}_i^i)=1$ and $\Sigma_i(\hat{k}_i^i)^2<1$. Define $r=\hat{k}_2^2/\hat{k}_1^1$ whenever $\hat{k}_1^1\neq 0$. Then

(i) if $\hat{k}_1^1$ is zero initially it is always zero;
(ii) if $\hat{k}_1^1$ is initially (and hence always) nonzero, then r is constant;
(iii) when $\hat{k}_1^1\neq 0$ it is a monotonic function with $\lim_{\tau\to-\infty}\hat{k}_1^1=(1+r)/(1+r+r^2)$ and $\lim_{\tau\to\infty}\hat{k}_1^1=0$; and
(iv) in that case $\lim_{\tau\to-\infty}(\hat{k}_3^3-\hat{k}_2^2)=-r(r+2)/(1+r+r^2)$.

Proof: Statement (i) follows from (3.1). Statement (ii) has been demonstrated above. Statement (iii) follows from (3.6). The last conclusion is then an immediate consequence of the definitions.

Of course analogous statements hold if $\hat{k}_1^1$ and $\hat{k}_2^2$ are interchanged, since these two quantities occur symmetrically in the hypotheses.

IV. PRESSURE ESTIMATES

The results of this section are all variations on the theme that if the space–time is expanding in a certain direction, then the pressure in that direction tends to decrease. It is assumed throughout

that the geometry is reflection-symmetric. A solution of (2.1)–(2.7) with $m=0$ satisfies $\text{tr}\, T/\rho=1$. This condition never holds when $m=1$, but the next lemma shows that it does hold asymptotically.

Lemma 4.1: Suppose that some solution of (2.1)–(2.7) with $m=1$ is defined on an interval $(-\infty,\tau_1)$, with f not identically zero. Then $\lim_{\tau\to-\infty} \text{tr}\, T/\rho=1$.

Proof: It was shown in Ref. 7 that $\lim_{\tau\to-\infty}\rho=\infty$. Thus, the result will follow if it can be shown that $\rho\to\infty$ implies $\text{tr}\, T/\rho\to 1$. To do this, choose some radius $L>0$ and write $\rho=\rho_1+\rho_2$ and $\text{tr}\, T=(\text{tr}\, T)_1+(\text{tr}\, T)_2$, where the first summand is the integral over the region $|w|<L$ of the integrand in (2.13) or (2.14), respectively, and the second is the integral over the complementary region. Using the fact that $(1+x^2)^{1/2}-x^2/(1+x^2)^{1/2}=(1+x^2)^{-1/2}$, it can be seen that $\rho_2-(\text{tr}\, T)_2\leqslant(1+L^2)^{-1}\rho_2$. Hence

$$(\text{tr}\, T)_2\geqslant\frac{L^2}{1+L^2}\,\rho_2 \tag{4.1}$$

and

$$\text{tr}\, T\geqslant\text{tr}\, T_2\geqslant\frac{L^2}{1+L^2}\left(\rho-\left(\frac{4\pi}{3}\right)L^3(1+L^2)^{1/2}\|f_0\|_\infty\right). \tag{4.2}$$

By choosing L sufficiently large, the quantity $L^2/(1+L^2)$ can be made as close to unity as desired. For fixed L, the quantity in brackets on the right-hand side of (4.2) approaches ρ as ρ becomes large. This suffices to give the conclusion of the lemma.

For a given initial datum f_0, the equation (2.14) defines the pressures T_i^i as functions of a, b, and c. The following results concern the qualitative behavior of these functions.

Lemma 4.2: If f_0 is not identically zero and $a\leqslant C'\min\{1,b,c\}$ for some constant $C'>0$, there exists a constant $C>0$ such that $T_1^1\geqslant Ca^{-2}b^{-1}c^{-1}$ and $T_2^2/T_1^1\leqslant C(a/b)^{4/3}$. In the case $m=0$ the conclusion holds under the weaker hypothesis that $a\leqslant C'\min\{b,c\}$.

Proof: Let p be a point of $\mathbf{R}^3$ where $f_0\neq 0$, whose first coordinate w_1 is nonzero. Let δ be a positive number such that f is bounded below by some positive constant η on the closed cube W of side 2δ centered at p and such that w_1 does not vanish anywhere on this cube. Consider now the image W' of the cube W under the mapping $(w_1,w_2,w_3)\mapsto(a^{-1}w_1,b^{-1}w_2,c^{-1}w_3)$. On W the functions w_2/w_1 and w_3/w_1 are bounded. Under the assumptions of the lemma they are bounded by the same constant on W'. It follows that $|w_1|/(1+|w|^2)^{1/2}$ is bounded below on any such cube by a positive constant that is independent of a, b, and c, which satisfy the hypotheses of the lemma. The integral defining T_1^1 can be bounded from below by the integral of the same quantity over W. It follows that

$$T_1^1\geqslant C\eta a^{-2}b^{-1}c^{-1}, \tag{4.3}$$

and this proves the first part of the lemma. To get a lower bound for T_1^1/T_2^2, the domain of integration in the definition of these two quantities will be divided into the regions $|w_2|>R|w_1|$ and $|w_2|<R|w_1|$, where R is a positive number that will be specified later. Corresponding to this decomposition of the domain of integration, there are decompositions $T_1^1=T_{11}^1+T_{12}^1$ and $T_2^2=T_{21}^2+T_{22}^2$. The volume of the region where $|w_2|>R|w_1|$ and $f(aw_1,bw_2,cw_3)\neq 0$ can be bounded by an expression of the form $CR^{-1}c^{-1}b^{-2}$, and so $T_{21}^2\leqslant CR^{-1}c^{-1}b^{-3}$. On the other hand, $T_{22}^2\leqslant R^2T_{12}^1$. Thus,

$$T_2^2\leqslant CR^{-1}c^{-1}b^{-3}+R^2T_1^1\leqslant(CR^{-1}(a/b)^2+R^2)T_1^1, \tag{4.4}$$

where in the last step (4.3) has been used. Choosing $R=(a/b)^{2/3}$ gives $T_2^2\leqslant C(a/b)^{4/3}T_1^1$, and this proves the result for T_2^2/T_1^1.

Lemma 4.3: Suppose that some solution of (2.1)–(2.7) is defined on the interval $(-\infty,\tau_1)$, with f not identically zero. If $\hat{k}_1^1-\hat{k}_2^2\geqslant A$ and $\hat{k}_1^1-\hat{k}_3^3\geqslant A$ on this interval for some $A>0$, then $T_i^i/T_1^1\leqslant Ce^{4A\tau/3}$ for $i=2,3$.

Proof: It suffices to note that under the assumptions of this lemma there will be a time interval $(-\infty,\tau_2)$ where the hypotheses of Lemma 4.2 hold, so that (4.4) can be applied.

The time derivatives of the quantities $\hat{T}_i^i$ cannot, in general, be expressed in terms of the dimensionless quantities (2.9)–(2.11), so as to get a closed system of ordinary differential equations. However, they can be estimated in terms of these quantities. Note first that

$$\frac{d\hat{T}_i^i}{d\tau}=-(\text{tr } k)^{-3}\frac{dT_i^i}{dt}+2\hat{T}_i^i[1-12\pi\hat{\rho}+4\pi \text{ tr } \hat{T}]. \tag{4.5}$$

Next, a change of variables in (2.7) gives, in the diagonal case,

$$T_i^i=g^{ii}\int f_0(v_1,v_2,v_3)(v_i)^2(m^2+g^{rs}v_rv_s)^{-1/2}(\det g)^{-1/2}\,dv_1\,dv_2\,dv_3. \tag{4.6}$$

Hence,

$$\begin{aligned}\frac{dT_1^1}{dt}=&(3k_1^1+k_2^2+k_3^3)T_1^1+g^{11}\int f_0(v_1,v_2,v_3)(v_1)^2F(v_1,v_2,v_3)\\&\times(m^2+g^{rs}v_rv_s)^{-3/2}(\det g)^{-1/2}\,dv_1\,dv_2\,dv_3,\end{aligned} \tag{4.7}$$

where

$$F(v_1,v_2,v_3)=(-g^{11}k_1^1(v_1)^2-g^{22}k_2^2(v_2)^2-g^{33}k_3^3(v_3)^2). \tag{4.8}$$

Note now that

$$|F(v_1,v_2,v_3)|\leqslant(|k_1^1|+|k_2^2|+|k_3^3|)(m^2+g^{rs}v_rv_s), \tag{4.9}$$

and so the integral in (4.7) can be bounded in modulus by $3\,\text{tr}\,kT_1^1$. Putting this information into (4.5) gives the desired bound.

Lemma 4.4: Consider a maximally extended solution of (2.1)–(2.7) with $m=1$ and f not identically zero. If $g_{ii}\to\infty$ as $\tau\to\infty$, then $\lim_{\tau\to\infty}T_i^i/\rho=0$. If, on the other hand, g_{11} is bounded above and all g_{ii} are bounded below by a positive constant on an interval of the form $[\tau_1,\infty)$, then T_1^1/ρ is bounded below by a positive constant on that interval.

Proof: It follows from (2.13) and (2.14) that $T_1^1\leqslant Ca^{-2}\rho$, and this proves the first statement. To get the other conclusion, choose a cube C_1 as in the proof of Lemma 4.2. Then $T_1^1\geqslant Ca^{-1}b^{-1}c^{-1}$ while $\rho\leqslant Ca^{-1}b^{-1}c^{-1}$. Hence, $T_1^1/\rho\geqslant C>0$.

V. THE MAIN RESULTS

Lemma 5.1 (compactness lemma): Let a sequence of reflection-symmetric global solutions of Eqs. (2.1)–(2.7) be given. Then there exists a subsequence such that $\hat{k}_j^i$ and $\hat{\rho}$ converge uniformly on compact sets of $\mathbf{R}$. Here $\hat{T}_i^i$ also converges uniformly on compact subsets (after possibly passing to a subsequence once more), and the limiting quantities satisfy (2.19) and (2.20).

Proof: The quantities $\hat{k}_j^i$ are contained in the compact set K and so are, in particular, uniformly bounded. By (2.19), $\hat{\rho}$ is uniformly bounded. It follows that $\hat{T}_j^i$ is uniformly bounded. Equation (2.20) now shows that $\partial_\tau\hat{k}_j^i$ is uniformly bounded. By Ascoli's theorem there exists a subsequence such that $\hat{k}_j^i$ converges uniformly on the interval $[-1,1]$. Applying the theorem again shows that this subsequence has a subsequence such that $\hat{k}_j^i$ converges uniformly on $[-2,2]$. Continuing in

this way, we obtain a collection of subsequences indexed by a positive integer n with the properties that for the nth subsequence $\hat{k}_j^i$ converges uniformly on $[-n,n]$, and each sequence is a subsequence of the previous one. The diagonal sequence has the property that $\hat{k}_j^i$ converges on each compact subset of the real line. By the Hamiltonian constraint $\hat{\rho}$ also converges uniformly on compact sets along this subsequence. In the diagonal case the derivatives $\partial_\tau \hat{T}_i^i$ are bounded, as was shown in Sec. IV and applying Ascoli's theorem as before gives the remaining conclusions.

Theorem 5.1: Let a global solution of Eqs. (2.1)–(2.7) be given for which f is not identically zero. If at some time τ_1, the projection of the solution lies in the set B_i for some i, then (i) the projection lies in B_i for all $\tau \leqslant \tau_1$; (ii) if there exists some $\tau_2 > \tau_1$ such that the projection of the solution lies in the complement of B_i, then it lies in the complement of all B_j for $\tau > \tau_2$; and (iii) as $\tau \to -\infty$ the projection converges to a point of the boundary of the region K that is not one of the points V_i^-.

Proof: Suppose without loss of generality that $i=1$. It follows from (2.20) that

$$\partial_\tau \hat{k}_1^1 = -4\pi(\hat{\rho} - \text{tr}\ \hat{T})(3\hat{k}_1^1 - 1) - 8\pi\ \text{tr}\ \hat{T}\hat{k}_1^1 + 8\pi\hat{T}_1^1. \tag{5.1}$$

If at some time $\hat{k}_1^1 \leqslant 0$, then the first and second terms on the right-hand side of (5.1) are nonnegative while the third term is positive. Hence $\partial_\tau \hat{k}_1^1 > 0$. This implies the first conclusion of the theorem. Moreover, it means that if the projection once leaves B_1 it can never reenter it. A similar statement, of course, applies to any other B_j, and this gives (ii). To prove (iii) note first that $\partial_\tau \hat{k}_1^1$ is bounded below by a positive constant as long as $\hat{\rho}$ is. This shows that $\liminf_{\tau \to -\infty} \hat{\rho} = 0$. Equation (5.1) also implies that the integral of $\hat{\rho}$ on the interval $(-\infty, \tau_1]$ must be finite so that for each i the integral of the right-hand side of (2.20) is absolutely convergent. Hence, each $\hat{k}_i^i$ tends to a limit as $\tau \to -\infty$. By what has already been said it can only be a point of the boundary of K. The monotonicity of $\hat{k}_1^1$ shows that this limit cannot be one of the points V_i^-.

Theorem 5.2: Let a global solution of Eqs. (2.1)–(2.7) be given for which f is not identically zero. If at some time τ_1 the projection of the solution lies in the set A_i for some i, then as τ decreases either (i) the projection converges to a point of the boundary of K as $\tau \to -\infty$; or (ii) it reaches L_j^+ for some j or C at a finite time before τ_1; or (iii) it stays in A_i for all $\tau < \tau_1$ and it has a point of one of the lines L_j^+ or the point C as an accumulation point.

Proof: Suppose without loss of generality that $i=1$. When the projection lies in A_1 the inequalities $k_1^1 > k_2^2$, $k_1^1 > k_3^3$, and $\hat{k}_1^1 > \frac{1}{3}$ hold. Suppose that on the time interval $(-\infty, \tau_1)$ the inequalities $\hat{k}_1^1 - \hat{k}_2^2 \geqslant A$ and $\hat{k}_1^1 - \hat{k}_3^3 \geqslant A$ are satisfied for some $A > 0$. Then, by Lemma 4.3, it follows that on this time interval T_1^1/T_2^2 and T_1^1/T_3^3 can be bounded below by a decreasing function, which tends to ∞ as $\tau \to -\infty$. Moreover, by Lemma 4.1, $\text{tr}\ T/\rho \to 1$ as $\tau \to -\infty$. Now, define a sequence of solutions of (2.1)–(2.7) by $u_n(\tau) = u(\tau - n)$, $\tau \in (-\infty, \tau_1)$, where u denotes any of the functions that make up the solution and n is a positive integer. By Lemma 5.1 there exists a subsequence such that $\hat{k}_j^i$ and $\hat{\rho}$ converge uniformly on compact subsets. By the statements made above, $\text{tr}\ \hat{T}$ must tend to the same limit as $\hat{\rho}$ along this sequence. Also, $\hat{T}_1^1$ tends to this same limit and $\hat{T}_2^2$ and $\hat{T}_3^3$ tend to zero. Applying Lemma 5.1 again shows that the limits of these sequences satisfy (2.19) and (2.20). Because of the values of the limits they, in fact, satisfy the asymptotic system (3.1)–(3.3). The solution of the asymptotic system obtained inherits the properties that $\hat{k}_1^1 \geqslant \hat{k}_2^2$ and $\hat{k}_1^1 \geqslant \hat{k}_3^3$. The only solutions of the asymptotic system that satisfy these inequalities on an interval of the form $(-\infty, \tau_1)$ are the vacuum solutions. If for some choice of subsequence this vacuum solution is not that corresponding to the point V_1^-, then the projection of the original solution must converge to that point, by Theorem 5.1. Otherwise every subsequence of the sequence of translated solutions has a subsequence that converges to the same solution of the asymptotic system. Hence, the whole sequence converges to this solution and the projection of the original solution converges to V_1^-. In both cases the solution of the original system converges to a point of the boundary of K.

It remains to consider the case where the above estimate is not satisfied for any $A>0$. If the solution does not reach L_j^+ for some j or C in finite time, then it stays in A_i for all $\tau<\tau_1$. Then it must have as an accumulation point either a point on L_j^+ for some j, C, or V_j^+ for some j. In the first two cases this gives case (iii) of the conclusion of the theorem. In the third case the solution enters B_j, and so by Theorem 5.1, case (i) of the conclusion holds.

In case (iii) of this theorem we can also consider a limit of translates of the solutions whose existence is guaranteed by Lemma 5.1. If the ratios a/b and a/c tended to zero as $\tau\to-\infty$ for the original solution, then by Lemma 4.2 the ratios T_1^1/T_2^2 and T_1^1/T_3^3 would tend to infinity and the solution would belong to case (i). Thus, in case (iii) it can be assumed without loss of generality (after possibly interchanging the indices 2 and 3) that b/a is bounded as $\tau\to-\infty$. Hence $\int_{-\infty}^{\tau_1}(\hat{k}_1^1-\hat{k}_2^2)$ is finite. Since $\partial_\tau(\hat{k}_1^1-\hat{k}_2^2)$ is bounded, it follows that $\hat{k}_1^1-\hat{k}_2^2\to0$ as $\tau\to-\infty$. Hence, the solution obtained as a limit of translates has LRS geometry. It also satisfies $\rho=\mathrm{tr}\,T$. Information about the asymptotics of LRS solutions can thus be used to obtain information about the asymptotics of the solutions, which fit into case (iii) of Theorem 5.2 but do not fit into case (i).

Theorem 5.3: Let a solution of Eqs. (2.19)–(2.20) be given that satisfies the LRS condition $k_2^2=k_3^3$. If at some time τ_1 the projection satisfies $\hat{k}_1^1<\frac{1}{3}$, then either (i) the projection of the solution tends to the point $(-\frac{1}{3},\frac{2}{3},\frac{2}{3})$ as $\tau\to-\infty$; (ii) it tends to the point $(0,\frac{1}{2},\frac{1}{2})$ as $\tau\to-\infty$; (iii) it reaches the point $(\frac{1}{3},\frac{1}{3},\frac{1}{3})$ at a finite time before τ_1; or (iv) it tends to the point $(\frac{1}{3},\frac{1}{3},\frac{1}{3})$ as $\tau\to-\infty$.

Proof: Suppose first that $\hat{k}_1^1\leqslant\frac{1}{3}-A$ for some $A>0$. Then by Lemma 4.2 the ratio of $T_2^2=T_3^3$ to T_1^1 increases without limit. Passing to a limit of translates in the familiar way gives a solution of the equation $\partial_\tau\hat{k}_1^1=-8\pi\hat{k}_1^1\hat{\rho}$ for which $\hat{k}_1^1$ satisfies the same inequality as before. There are only two such solutions, namely that for which $\hat{\rho}=0$ and that for which $\hat{k}_1^1=0$. In the first of these cases the original solution must enter the region B_1, and hence by Theorem 5.1 belong to case (i) of the conclusion of the present theorem. The only way of avoiding this is if, no matter which subsequence is chosen, the limiting value of $\hat{k}_1^1$ is zero. Hence, the projection of the original solution must converge to the point $(0,\frac{1}{2},\frac{1}{2})$. Thus, the solution belongs to case (ii) of the conclusion. Now consider the case where there is no $A>0$ with the given property. If, despite this, the ratio of T_2^2 to T_1^1 tends to infinity, we can argue as before to show that the solution belongs to case (i) or (ii). If, on the other hand, this ratio remains bounded, then the ratio a/b must remain bounded, and hence if $\hat{k}_1^1$ remains smaller than $\frac{1}{3}$ forever then $\int_{-\infty}^{\tau_1}(\frac{1}{3}-\hat{k}_1^1)$ is finite. It then follows as in the discussion following the proof of Theorem 5.2 that $\hat{k}_1^1\to\frac{1}{3}$. Thus the solution either belongs to case (iii) or case (iv).

Theorem 5.4: Let a solution of the equations (2.1)–(2.7) with $m=1$ and f not identically zero be given. Then $\hat{k}_i^i\to\frac{1}{3}$ and $T_i^i/\rho\to0$ for each i as $\tau\to\infty$.

Proof: In Ref. 13, it was shown that the scale factors a, b, and c are bounded below by a positive constant on any interval of the form $[\tau_1,\infty)$. Using (5.1), this statement can be strengthened. Suppose that $\hat{k}_1^1$ were negative on an interval of the form $[\tau_1,\infty)$. Then it would follow, as in the proof of Theorem 5.1, that the integral of $\hat{\rho}$ on this interval was finite. But $\hat{\rho}$ is increasing on this interval, a contradiction. It follows that each $\hat{k}_i^i$ must become zero after a finite time, and once this happens it must immediately become positive and stay positive. Thus, for τ_1 sufficiently large, a, b, and c are increasing. Consider now the behavior of the quantity $\min\{a,b,c\}$. Suppose first that it tends to infinity as $\tau\to\infty$. Then, by Lemma 4.4 the ratios T_i^i/ρ tend to zero as $\tau\to\infty$. Construct a limit of translates as in the proof of Theorem 5.2, except that this time the translations should be done in the opposite direction. Then the limiting solution satisfies $\partial_\tau\hat{k}_i^i=-12\pi\hat{\rho}(\hat{k}_i^i-\frac{1}{3})$. This is the equation that is satisfied by a Bianchi I solution of the Einstein equations coupled to dust. It is well known and also easy to see directly that in the case of dust each $\hat{k}_i^i$ converges to $\frac{1}{3}$ as $\tau\to\infty$. Because a convergent subsequence can be extracted from any subsequence of the sequence of translates by integers, it follows that $\hat{k}_i^i\to\frac{1}{3}$ for the original solution of the Einstein–Vlasov system as well. Next, consider the case where a is bounded on an interval of the form $[\tau_1,\infty)$ while $\min\{b,c\}\to\infty$ as $\tau\to\infty$. Then, by Lemma 4.4 the ratios T_2^2/ρ and T_3^3/ρ converge to zero as $\tau\to\infty$ while T_1^1/ρ remains bounded away from zero. Equation (5.1) implies that $\partial_\tau\hat{k}_1^1$ is

bounded below by a positive constant if $\hat{k}_1^1 < \frac{1}{3}$ and T_2^2/T_1^1 and T_3^3/T_1^1 are less than $1-A$ for some constant $A>0$. However, this contradicts the boundedness of a. Since the volume tends to infinity as $\tau\to\infty$, at least one of a, b, or c must tend to infinity. It follows that to complete the proof we may assume without loss of generality that a and b are bounded while c tends to infinity. By Lemma 4.4, $T_3^3/\rho\to 0$, while T_1^1/ρ and T_2^2/ρ are bounded below by a positive constant. Now the integral $\int_{\tau_1}^{\infty}\hat{k}_i^i(\tau)d\tau$ is finite for $i=1,2$ and $\partial_\tau\hat{k}_i^i$ is bounded. Hence, $\hat{k}_1^1$ and $\hat{k}_2^2$ tend to zero as $\tau\to\infty$ and $\hat{k}_3^3\to 1$. But the given behavior of the pressures shows that for $\hat{k}_3^3\geqslant\frac{1}{3}$ and sufficiently large times $\partial_\tau k_3^3$ is negative, a contradiction. This completes the proof.

VI. A COMPACTIFICATION

This section is devoted to a finer examination of LRS solutions of the Einstein–Vlasov system with massless particles. For LRS solutions with $k_2^2=k_3^3$, let $k=\hat{k}_1^1$, $q=b/a$, $Q=T_1^1/\rho$. Then $\hat{k}_2^2=\frac{1}{2}(1-k)$ and $\hat{\rho}=(1/16\pi)(\frac{1}{2}+k-\frac{3}{2}k^2)$. The essential equations describing the dynamics are

$$\partial_\tau k=\tfrac{1}{4}(1+3k)(1-k)(Q-k), \tag{6.1}$$

$$\partial_\tau q=\tfrac{1}{2}(1-3k)q. \tag{6.2}$$

The quantity Q can be expressed entirely in terms of q and the initial data as follows:

$$Q=q^2\left[\frac{\int f_0(v_i)v_1^2(q^2v_1^2+v_2^2+v_3^2)^{-1/2}\,dv_1\,dv_2\,dv_3}{\int f_0(v_i)(q^2v_1^2+v_2^2+v_3^2)^{1/2}\,dv_1\,dv_2\,dv_3}\right]. \tag{6.3}$$

Substituting (6.3) into (6.1) makes the equations (6.1) and (6.2) into an autonomous system of ordinary differential equations for k and q. Lemma 4.2 shows that $Q(q)=O(q^{4/3})$ as $q\to 0$. This means that the system (6.1)–(6.2) can be extended in a C^1 manner to the boundary $q=0$. Moreover, Q does not contribute to the linearization of the extended system at the critical point $q=0$, $k=0$. The eigenvectors of the linearization are directed along the k and q axes, with eigenvalues $-\frac{1}{4}$ and $\frac{1}{2}$, respectively. It follows (see, e.g., Ref. 16) that the dynamical system has an unstable manifold that is a curve tangent to the k axis at the point (0,0). This shows that for any initial value f_0 it is possible to find LRS solutions of the Einstein–Vlasov system, where the distribution function has the initial value f_0 and where the quantities $\hat{k}_i^i$ converge to $(0,\frac{1}{2},\frac{1}{2})$ as $\tau\to-\infty$. Note that the stable manifold is just the k axis, and so does not give rise to any smooth solutions of the Einstein–Vlasov system. The information about the linearization also determines the nature of the phase portrait near the singular point, and shows that there are solutions for which $\hat{k}_1^1$ approaches zero, but turns back before reaching it. A typical feature of Bianchi models is that the matter becomes dynamically negligible near the singularity. No attempt will be made here to make this notion precise, but one aspect of it is that the projection of the solution should tend to a point of the boundary of K as $\tau\to-\infty$. The solution whose existence has just been shown is an exception to the rule. For anisotropic Bianchi I models with a perfect fluid, no exceptional solutions of this kind exist. However, they do occur for other Bianchi types.[17]

The critical points of the system (6.1)–(6.2) in the region where $0<q$ and $-\frac{1}{3}<k<1$ are the points of the form $(\frac{1}{3},q_0)$, where q_0 has the property that $Q(q_0)=\frac{1}{3}$. Differentiating (6.3) and estimating the result in an elementary way leads to the inequality $qQ'\geqslant Q(1-Q)$. This shows that the function Q is strictly increasing for $q>0$. Taking account of the limiting values of Q, it follows that there is precisely one value q_0 for which $Q(q_0)=\frac{1}{3}$. Moreover, at this point $qQ'\geqslant\frac{2}{9}$. The eigenvalues of the linearization at the corresponding critical point are $-\frac{1}{6}\pm\frac{1}{2}\sqrt{\frac{1}{9}-q_0Q'(q_0)}$. They both have negative real parts and the critical point is a sink. In particular, no solution emerges from this critical point. Thus, it is seen that if the projection of any LRS solution for massless particles approaches the point C as $\tau\to-\infty$, then the projection must stay at C for all time, i.e., the

solution must have isotropic geometry. This should be compared with the results of Newman[18] on isotropic singularities in solutions of the Einstein equations coupled to a radiation fluid.

APPENDIX: FLUIDS WITH NONLINEAR EQUATION OF STATE

Consider a perfect fluid with equation of state $p=f(\rho)$ that satisfies the following general assumptions: (i) f is a continuous function from $[0,\infty)$ to itself with $f(0)=0$, which is C^1 for $\rho>0$; (ii) $0\leqslant f'(\rho)\leqslant 1$ for all $\rho>0$; and (iii) there exists a constant $C<1$ such that $p\leqslant C\rho$ for $\rho<1$.

Assumptions (i) and (ii) are standard. The third assumption is, when (i) and (ii) are satisfied, equivalent to the assumption made in Ref. 7 that the equation of state is not asymptotically stiff at low densities. In the case of a linear equation of state $f(\rho)=k\rho$, the assumptions (i)–(iii) are satisfied if and only if $0\leqslant k<1$. In a Bianchi I space–time, it follows from the momentum constraint (2.2) that the four-velocity of the fluid is orthogonal to the hypersurfaces of homogeneity. Hence, the energy density ρ measured by an observer whose word line is orthogonal to the hypersurfaces of homogeneity, is the same as that measured by a comoving observer. Equations (2.19) and (2.20) are valid, as in the case of the Einstein–Vlasov system. For a fluid, it can be assumed without loss of generality that the solution is reflection symmetric, because given any initial data, it suffices to do a linear transformation of the coordinates that simultaneously diagonalizes the metric and second fundamental form in order to transform the given data to data for a reflection-symmetric space–time.

In the case of a fluid $T^i_j=p\,\delta^i_j$ and hence $\hat{T}^i_j=\hat{p}\,\delta^i_j$, where $\hat{p}=p/(\mathrm{tr}\,k)^2$. If the equation of state is linear, then $\hat{p}$ can be expressed as a function of $\hat{\rho}$ alone, and (2.19) and (2.20) then reduce to a system of ordinary differential equations that suffice to determine $\hat{k}^i_j$ from initial data. For a nonlinear equation of state, this is no longer the case. The equations (2.19) and (2.20) no longer form a closed system and must instead be considered as the projection of a bigger system, as in the case of the Vlasov equation. This is one reason why the linear case has been studied preferentially in the literature. Nevertheless, it turns out that the projection can be analyzed very effectively in the general case.

The first question that needs to be addressed is that of global existence in τ, i.e., the equivalent of Lemma 2.1 for a fluid. This follows from the results of Ref. 7. The assumption (iii) has been used at this stage. A direct calculation shows that the quantity $(\hat{k}^1_1-\hat{k}^2_2)/(\hat{k}^1_1-\hat{k}^3_3)$ is independent of τ whenever $\hat{k}^1_1-\hat{k}^3_3$ is nonzero. Moreover, if $\hat{k}^1_1-\hat{k}^3_3$ is zero at some time, it remains zero. Hence, the projection of each solution is constrained to move on a straight line in K passing through the center C. This is already a much stronger statement than could be proved in the case of the Vlasov equation. To find out how the projection moves on this straight line, the time derivative of the dimensionless version of the density will be calculated. For a fluid it is given by

$$\partial_\tau\hat{\rho}=(\hat{\rho}-\hat{p})(1-24\pi\hat{\rho}). \tag{A1}$$

Noting that the Hamiltonian constraint implies that $24\pi\hat{\rho}\leqslant 1$ with equality only at the point C, it can now be seen that the projection moves monotonically from the boundary of K at $\tau=-\infty$ to the center C of K at $\tau=\infty$. This qualitative behavior is independent of the equation of state, satisfying (i)–(iii). The only difference is in the speed with which the projection moves along the radial line at different times. Equation (A1) also makes clear that this picture changes completely if the equations of state considered here are replaced by the limiting case of a stiff fluid, $p=\rho$.

Majorana parafermions

Robert S. Dunne
Department of Applied Mathematics and Theoretical Physics, Cambridge University, Silver Street, Cambridge, CB3 9EW, United Kingdom

(Received 16 August 1995; accepted for publication 3 October 1995)

A Majorana analog to the parafermion algebra is constructed and shown to be isomorphic to so(n). Ansatz realizations of this algebra are constructed and used to establish the properties of particular representations. The construction of specific so(n) representations is discussed for odd and even n, and for even n the procedure is illustrated explicitly in the case of so(4). By contracting the Majorana parafermion algebra, the para-Grassman algebra and its representation theory are obtained.
 [S0022-2488(96)03401-2]

I. INTRODUCTION

Systems of parabosons and parafermions were introduced in Ref. 1, and have been considered extensively[2,3] as generalizations of ordinary bosons and fermions. Recently, representations of these systems in terms of deformed bosonic operators,[4–8] examination of their connections with the Calogero–Vasiliev oscillator,[9,10] and attempts to quantum deform them[11–14] have all led to a renewal of interest.

In this paper we construct a Majorana analog to the parafermion, interpret it as a Lie algebra, and investigate the properties of its representations.

After a brief review in Sec. II of parafermions and their ansatz representations, we move directly in Sec. III to the construction of real Majorana parafermions (MPFs) out of the standard complex parafermions and the establishment of the algebra which these new operators satisfy. In Sec. IV we establish that the algebra of n MPFs is isomorphic to so($n+1$), which is a generalization of the well-known result that n parafermions generate so($2n+1$). In Sec. V we introduce a minor modification to the standard fermionic realization of the Green ansatz, and use this in a straightforward way to obtain ansatz realizations of the MPFs. Using these we develop a procedure for establishing complete sets of the algebraic relations for MPFs representations of any order of statistics. We illustrate this procedure for $p=2$. In Sec. VI we look at the construction of so($2n+1$) and so($2n$) representations using MPFs. For so($2n+1$) this only involves a restatement of the unique vacuum conditions for a parafermion system in terms of MPFs, and we find that MPFs, when acting on a Fock space, are grouped into related pairs, so that the overall symmetry between MPFs is lost. For so($2n$) we are in a new situation. We show how to project a MPF realization of so($2n+1$) onto so($2n$), and how, after implementing this projection, to reduce the number of MPFs involved to its natural minimum. The purpose of this procedure is to obtain so($2n$) in a form in which its constituent MPFs are clearly related to its raising and lowering operators. This is illustrated explicitly for so(4), for which we also construct all representations in MPF terms.

Finally, in Sec. VII we show that by means of a simple contraction, the para-Grassman algebra[15] can be obtained from the MPF algebra. Consequently the properties of the para-Grassman representations for any order of statistics follow from the contraction of the corresponding MPF representations.

II. DIRAC PARAFERMIONS

A system of n oscillators a_i and their conjugates $a_i^\dagger$ which satisfy the trilinear commutation relations

0022-2488/96/37(1)/452/8/$6.00

$$[[a_i^\dagger,\ a_j],\ a_k^\dagger]=2\,\delta_{ik}a_j, \tag{1}$$

$$[[a_i,\ a_j],\ a_k]=0, \tag{2}$$

together with their conjugates, for $i,j,k=1,2,\ldots,n$ is referred to in previous work as a system of n parafermions. In this paper we shall refer to these oscillators as Dirac parafermions (DPFs). It is well known that all of the irreducible representations of the DPFs on a Fock space with a unique vacuum state $|0\rangle$ satisfying $a_i|0\rangle=0$ are labeled by a single positive integer p, the order of statistics, such that $a_i a_i^\dagger|0\rangle = p|0\rangle$ for all i, and that all of these representations are included among the Green ansatz representations.[2] Recently the following realization of this ansatz in terms of Dirac and Majorana fermions has been studied by[16]

$$a_i=\sum_{\alpha=1}^{p} f_{i\alpha}s_\alpha, \quad a_i^\dagger=\sum_{\alpha=1}^{p} f_{i\alpha}^\dagger s_\alpha. \tag{3}$$

Here $f_{i\alpha}$ and s_α are, respectively, Dirac and Majorana fermions. These have commutation relations

$$\{f_{i\alpha},f_{j\beta}\}=0, \quad \{f_{i\alpha},f_{j\beta}^\dagger\}=\delta_{ij}\delta_{\alpha\beta}, \quad \{s_\alpha,s_\beta\}=2\,\delta_{\alpha\beta}, \quad \{f_{i\alpha},s_\beta\}=0, \tag{4}$$

as well as $s_\alpha^\dagger = s_\alpha$.

III. CONSTRUCTION OF MAJORANA PARAFERMIONS

In this section we construct a parafermionic analog to the Majorana fermion, and establish the algebraic properties of such operators. Essentially the same operators were defined in Ref. 17, although there they were introduced only as a part of the analysis of the DPF algebra, and not considered in their own right. We define Majorana parafermions (MPFs) in terms of DPFs by analogy with the well-known definition of Majorana fermions in terms of Dirac fermions, so that, for example

$$c_1=a_1+a_1^\dagger, \quad c_2=i(a_1-a_1^\dagger). \tag{5}$$

Here c_1 and c_2 are MPFs. It is clear from these definitions that $c_1^\dagger = c_1$ and $c_2^\dagger = c_2$. To establish the MPF algebra we must also define

$$\begin{aligned} c_3&=a_2+a_2^\dagger, \quad c_4=i(a_2-a_2^\dagger),\\ c_5&=a_3+a_3^\dagger, \quad c_6=i(a_3-a_3^\dagger). \end{aligned} \tag{6}$$

Now consider

$$[[a_1^\dagger,\ a_1],\ a_1^\dagger]=2a_1^\dagger \quad \text{and} \quad [[a_1^\dagger,\ a_1],\ a_1]=-2a_1. \tag{7}$$

Writing this in MPF form we obtain

$$[[c_1+ic_2,c_1-ic_2],\ c_1\pm ic_2]=\pm 8c_1+8ic_2, \tag{8}$$

which reduces to

$$[[c_1,\ c_2],\ c_2]=4c_1, \quad [[c_1,\ c_2],\ c_1]=-4c_2. \tag{9}$$

The form of each of these equations is the same. By using Eqs. (1), (2), and (6) it is straightforward to check that the form of the two particle trilinear is the same for any pair of MPFs. Further, by replacing MPFs with their DPF equivalents, and using Eqs. (1) and (2) it is easy to show that all three particle MPF trilinear are trivial.

For example, to show that $[[c_1, c_2], c_3]=0$, add $[[a_1^\dagger, a_1], a_2] = 0$ and $[[a_1^\dagger, a_1], a_2^\dagger] = 0$. Collecting our results into a single expression, we have

$$[[c_i, c_j], c_k]=4\delta_{jk}c_i-4\delta_{ik}c_j. \tag{10}$$

Taking this to be the definition of the MPF algebra, the requirement that it be invariant under Hermitian conjugation gives us the freedom $c_i^\dagger = \eta_i c_i$, where $\eta_i=\pm 1$. Augmenting our definition by $\eta_i=+1$ for all i we restrict ourselves to the compact real form of the algebra. The odd looking factors of 4 on the right-hand side of Eq. (10) arise because we have constructed MPFs out of DPFs in exact analogy to the construction of Majorana fermions out of Dirac fermions, and these could easily be scaled away. However, for our purposes the scale factor in Eq. (10) is convenient, since it avoids the introduction of noninteger factors into the algebras (20), (21), and (22) associated with MPFs of specific orders of parastatistics. This construction is completely reversible, so the algebra of $2n$ MPFs is isomorphic to the algebra of n DPFs. It is well known[17] that this algebra is so$(2n+1)$. Although the MPFs were derived in such a way that we obtained two from each DPF, there is no memory of this in the MPF algebra which gives all c_is the same properties. Because of this there is no obstacle to consideration of systems containing an odd number of MPFs. Unlike systems containing an even number of MPFs, these are essentially different from the well-known DPF systems, and lead to new results.

IV. THE LIE ALGEBRAIC INTERPRETATION OF MPFs

As stated above, it is known that n DPFs generate so$(2n+1)$, and consequently that the same must be true of $2n$ MPFs. We now establish the more general result, which includes systems containing an odd number of MPFs.

Using n MPFs, labeled $c_1, c_2, \ldots c_n$ we can define operators $L_{\alpha\beta}$ with $\alpha, \beta=1,2,\ldots,n$ as follows:

$$L_{\alpha\beta}=\frac{[c_\alpha, c_\beta]}{4}. \tag{11}$$

Clearly $L_{\alpha\beta}=-L_{\beta\alpha}$. It follows directly from the MPF algebra (10) that these satisfy

$$[L_{\alpha\beta}, L_{\gamma\nu}]=\delta_{\beta\gamma}L_{\alpha\nu}+\delta_{\alpha\nu}L_{\beta\gamma}-\delta_{\beta\nu}L_{\alpha\gamma}-\delta_{\alpha\gamma}L_{\beta\nu} \tag{12}$$

and

$$[c_\alpha, L_{\gamma\nu}]=\delta_{\gamma\alpha}c_\nu-\delta_{\nu\alpha}c_\gamma. \tag{13}$$

We now define

$$L_{0\alpha}=\frac{ic_\alpha}{2}. \tag{14}$$

Then Eqs. (11) and (13) can be written as

$$[L_{0\alpha}, L_{0\beta}]=-L_{\alpha\beta}, \quad [L_{0\alpha}, L_{\gamma\nu}]=\delta_{\nu\alpha}L_{0\gamma}+\delta_{\gamma\alpha}L_{0\nu}, \tag{15}$$

both of which have the same form as Eq. (12). These relationships extend the range of the indices on the $L_{\alpha,\beta}$ in Eq. (12) to $\alpha, \beta=0,1,2,\ldots,n$, but this is just the algebra so$(n+1)$, and by our

construction we see that it is isomorphic to an algebra of n MPFs. Thus we have established the general result, that $n-1$ MPFs generate so(n). For even n this corresponds to the familiar result that n DPFs generate so($2n+1$), but for odd n our result is new, and provides those so(n) algebras which DPFs alone cannot generate in a canonical way.

Note that to establish the order of statistics of a given representation, we can construct the MPF equivalent of the su(2) Casimir operator out if any pair. This gives

$$c_i^2+c_j^2-\frac{[c_i,\,c_j]^2}{4}=p(p+2). \tag{16}$$

V. ANSATZ REPRESENTATIONS OF MPFs

We now construct a MPF analog of the Green ansatz. To do this in the most convenient way we first of all note that the realization of the Green ansatz given by Eqs. (3) and (4) remains valid if we modify Eq. (4) so that the Dirac fermions commute with the Majorana fermions, that is, Eq. (4) becomes

$$\{f_{i\alpha},f_{j\beta}\}=0,\quad \{f_{i\alpha},f_{j\beta}^{\dagger}\}=\delta_{ij}\delta_{\alpha\beta},\quad \{s_\alpha,s_\beta\}=\delta_{\alpha\beta},\quad [f_{i\alpha},\,s_\beta]=0, \tag{17}$$

where $s_\alpha^{\dagger}=s_\alpha$ for all α. This may appear somewhat unnatural, though it is less so if we view the Dirac and Majorana elements as fermions of different colors. The point of making this change is that doing so greatly simplifies manipulation of the MPF ansatz realizations, which, using Eq. (5), we can write down directly as

$$c_i=\sum_{\alpha=1}^{p} k_{i\alpha}s_\alpha. \tag{18}$$

Here $\{k_{i\alpha}\}$ and $\{s_\alpha\}$ are commuting sets of Majorana fermions, that is,

$$\{k_{i\alpha},k_{j\beta}\}=\delta_{ij}\delta_{\alpha\beta},\quad \{s_\alpha,s_\beta\}=\delta_{\alpha\beta},\quad [k_{i\alpha},\,s_\beta]=0. \tag{19}$$

We note that because the $p=1$ ansatz is the fundamental representation, it is known from representation theory that all representations of so(n) appear (at least once) in the reduction of this ansatz for some p. For $p=1$ all we have are the ordinary Majorana fermions, the properties of which are well known. For $p=2$ the algebra is

$$c_i^3=4c_i,\quad c_ic_jc_k+c_kc_jc_i=4\delta_{jk}c_i+4\delta_{ij}c_k. \tag{20}$$

In general to obtain the algebras associated with $p>1$ we must first establish the single MPF algebra. The most direct way to do this is to notice that each ansatz term $k_{i\alpha}s_\alpha$ (no sum on α) has eigenvalues ±1. From this we can see that an MPF of order p satisfies the following characteristic equation:

$$(c+p)(c+p-2)(c+p-4),\ldots,(c-p+4)(c-p+2)(c-p)=0.$$

This can be more conveniently written as follows:

$$\begin{aligned}&\text{For even } p\text{:}\quad (c^2-p^2)(c^2-(p-2)^2),\ldots,(c^2-2^2)c=0,\\ &\text{for odd } p\text{:}\quad (c^2-p^2)(c^2-(p-2)^2),\ldots,(c^2-3^2)(c^2-1)=0.\end{aligned} \tag{21}$$

For example,

$$p=2,\quad c^3=4c,\quad p=3,\quad c^4=10c^2-9, \tag{22}$$

$$p=4, \quad c^5=20c^3-64c.$$

To obtain the algebraic relations between different MPFs their characteristic equations need to be inserted into commutators. As an example we obtain the $p=2$ algebra as given in Eq. (20). First of all use the characteristic equation $c^3=4c$ to obtain

$$[[c_1,\ c_2],\ c_2^3]=4[[c_1,\ c_2],\ c_2]. \tag{23}$$

When the left-hand side of this is evaluated using Eq. (10), and the result is solved simultaneously with Eq. (10), those relations from Eq. (20) which involve only two MPEs are obtained. To obtain the three MPF relations as well we put the two MPF relations into a commutator involving a new MPF. In this case (i.e., for $p=2$) we need only use $c_1c_2c_1=0$ to obtain the expression

$$[[c_1,\ c_3],\ c_1c_2c_1]=0. \tag{24}$$

Expanding this, we find that $c_1c_2c_3+c_3c_2c_1=0$ which completes our derivation of the relations (20). For $p>2$ we can establish the algebra using essentially the same method as we have illustrated here. However, because in general the p specific relations are of order $p+1$, to get a complete set of these it is necessary to use an iterative procedure in which the characteristic equation, itself of order $p+1$, is commuted up to p times with terms of the form $[c_i,c_j]$, each commutation inserting a new MPF into the algebra.

VI. MPFs AND REPRESENTATIONS OF so(n) ALGEBRAS

In this section we look at representations of so(n) algebras on Fock spaces which have a unique vacuum state. In the case of odd n this involves a restatement of the familiar DPF results in MPF language, and we include these only for completeness. For the more complicated even n case, we show how to construct so($2n$) representations out of $2n-1$ MPFs by making use of a projection from so($2n+1$). This is illustrated for so(4).

A. so($2n+1$) representations in terms of MPFs

In terms of DPFs, a particular so($2n+1$) representation having a unique vacuum state $|0\rangle$ is defined by the following conditions:

$$a_j|0\rangle=0, \quad a_ja_j^\dagger|0\rangle=p|0\rangle \quad \text{for all } j. \tag{25}$$

Here p is a positive definite integer, the order of the parastatistics. From Eq. (5) we can express the DPFs in these expressions as follows:

$$a_j=\frac{c_{j+}-ic_{j-}}{2}, \quad a_j^\dagger=\frac{c_{j+}+c_{j-}}{2}. \tag{26}$$

Here c_{j+} and c_{j-} are independent MPFs, the $j\pm$ notation being used only for convenience. In terms of MPFs the representation defining conditions (25) become

$$c_{j+}|0\rangle=ic_{j-}|0\rangle, \quad (c_{j+}^2+c_{j-}^2)|0\rangle=2p|0\rangle. \tag{27}$$

These conditions clearly involve a pairing of MPFs based on their properties with respect to the Fock space. So although within the algebra there is complete symmetry between the MPFs, this is broken by their action on the Fock space. The fact that even after this symmetry is broken we are able to group $2n$ MPFs into n symmetric pairs (i.e., each of the n pairs having the same algebraic properties) is the origin of the DPF algebra.

B. Representation of so(4) constructed using three MPFs

Consider first so(5), with its elements expressed in DPF notation. The root diagram of this algebra contains the points $\pm e_1$, $\pm e_2$, $\pm e_1+e_2$, $\pm e_1-e_2$, where e_1 and e_2 are othogonal unit vectors. The correspondence between the DPF algebra elements and the root vectors is

$$a_1^\dagger \leftrightarrow e_1, \quad a_1 \leftrightarrow -e_1, \quad a_2^\dagger \leftrightarrow e_2, \quad a_2 \leftrightarrow -e_2,$$

$$[a_1^\dagger, a_2^\dagger] \leftrightarrow e_1+e_2, \quad [a_1^\dagger, a_2] \leftrightarrow e_1-e_2, \quad [a_1, a_2^\dagger] \leftrightarrow -e_1+e_2, \quad [a_1, a_2] \leftrightarrow -e_1-e_2.$$

The four vectors of length $\sqrt{2}$ are the roots of the so(4) subalgebra. To construct so(4) representations in terms of MPFs we restrict our attention to these. We define

$$J_{1z}=\frac{[a_1^\dagger, a_1]+[a_2^\dagger, a_2]}{4}, \quad J_{1+}=\frac{[a_2^\dagger, a_1^\dagger]}{2}, \quad J_{1-}=\frac{[a_1, a_2]}{2} \tag{28}$$

and

$$J_{2z}=\frac{[a_1^\dagger, a_1]-[a_2^\dagger, a_2]}{4}, \quad J_{2+}=\frac{[a_2, a_1^\dagger]}{2}, \quad J_{2-}=\frac{[a_1, a_2^\dagger]}{2}. \tag{29}$$

These operators form two commuting su(2) algebras, displaying the su(2)$\oplus$su(2) structure of so(4). To express these operators in terms of MPFs we use

$$a_1^\dagger=\frac{c_1+ic_2}{2}, \quad a_1=\frac{c_1-ic_2}{2}, \tag{30}$$

$$a_2^\dagger=\frac{c_3+ic_4}{2}, \quad a_2=\frac{c_3-ic_4}{2}. \tag{31}$$

We find

$$\begin{aligned}
J_{1z}&=\frac{i[c_2, c_1]+i[c_4, c_3]}{8},\\
J_{1\pm}&=\frac{\mp[c_1, c_3]\pm[c_2, c_4]-i[c_2, c_3]-i[c_1, c_4]}{8},\\
J_{2z}&=\frac{i[c_2, c_1]-i[c_4, c_3]}{8},\\
J_{2\pm}&=\frac{\mp[c_1, c_3]\mp[c_2, c_4]-i[c_2, c_3]+i[c_1, c_4]}{8}.
\end{aligned} \tag{32}$$

Here we have constructed a representation of so(4) using four MPFs. However our theorem tells us that so(4) is isomorphic to the algebra of only three MPFs. This isomorphism can be made explicit if we first use Eq. (11) to rewrite our MPF realization of so(4) in terms of $L_{\alpha\beta}$ operators:

$$J_{1z}=\frac{i(L_{21}+L_{43})}{2}, \quad J_{1\pm}=\frac{(\mp L_{13}\pm L_{24}-iL_{23}-iL_{14})}{2}, \tag{33}$$

$$J_{2z}=\frac{i(L_{21}-L_{43})}{2},\quad J_{2\pm}=\frac{(\mp L_{13}\mp L_{24}-iL_{23}+iL_{14})}{2}.$$

Now, since the index 0 does not appear in any of these expressions, we can, without altering the algebra in any way, replace the index 4 in each by the index 0. If we do this, and then use Eqs. (11) and (14) to transform our results back into MPF notation we obtain

$$\begin{aligned} J_{1z}&=i\,\frac{[c_2,\,c_1]}{8}-\frac{c_3}{4},\quad J_{1\pm}=\frac{\mp[c_1,\,c_3]-i[c_2,\,c_3]}{8}-\frac{c_1\pm ic_2}{4},\\ J_{2z}&=i\,\frac{[c_2,\,c_1]}{8}+\frac{c_3}{4},\quad J_{2\pm}=\frac{\mp[c_1,\,c_3]-i[c_2,\,c_3]}{8}+\frac{c_1\pm ic_2}{4}. \end{aligned} \tag{34}$$

These expressions involve only three MPFs, so we have obtained the so(4) algebra explicitly in terms of three MPFs, as we set out to do. It is particularly interesting to observe the following expressions for J_{ix}, J_{iy}, J_{iz} $(i=1,2)$ in which the symmetry between the three MPFs is made manifest:

$$J_{1x}=-i\,\frac{[c_2,\,c_3]}{8}-\frac{c_1}{4},\quad J_{1y}=-i\,\frac{[c_3,\,c_1]}{8}-\frac{c_2}{4},\quad J_{1z}=-i\,\frac{[c_1,\,c_2]}{8}-\frac{c_3}{4}; \tag{35}$$

$$J_{2x}=-i\,\frac{[c_2,\,c_3]}{8}+\frac{c_1}{4},J_{2y}=-i\,\frac{[c_3,\,c_1]}{8}+\frac{c_2}{4},\quad J_{2z}=-i\,\frac{[c_1,\,c_2]}{8}+\frac{c_3}{4}. \tag{36}$$

Due to the su(2)⊕su(2) structure of so(4) we can construct specific so(4) representations by choosing a ground state $|0\rangle$ such that

$$J_{1-}|0\rangle=J_{2-}|0\rangle=0,\quad J_{1z}|0\rangle=-j_1|0\rangle,\quad J_{2z}|0\rangle=-j_2|0\rangle. \tag{37}$$

Here j_1 and j_2 are the spins of the two su(2) subalgebra representations. In conventional su(2) notation, this ground state would be written as $|j_1,-j_1,j_2,j_2\rangle$. In terms of MPFs the conditions (37) become

$$(c_1-ic_2)|0\rangle=0, \tag{38}$$

$$i[c_1,\,c_2]|0\rangle=(c_1^2+c_2^2)|0\rangle=4(j_1+j_2)|0\rangle, \tag{39a}$$

$$c_3|0\rangle=2(j_1-j_2)|0\rangle. \tag{39b}$$

Note that Eqs. (38) and (39a) are essentially the same as Eq. (27). As in the so$(2n+1)$ case the overall symmetry among the MPFs is lost in the transition to Fock space representations.

Relations (35) and (36) can be inverted to yield the MPF matrix representations associated with specific so(4) representations. The relationship is

$$c_i=2(J_{2i}-J_{1i}). \tag{40}$$

If the J_{1i} and J_{2i} operators have spins n and m, respectively, so that we are looking at the (n,m) representation of so(4), then by Eq. (16) the MPFs have $p=2(n+m)$. As an example, if $\{\sigma_\alpha\}$ are the Pauli matrices, then the $(\frac{1}{2},\frac{1}{2})$ representation has $j_{1\alpha}=\sigma_\alpha/2\otimes 1$ and $j_{2\alpha}=1\otimes\sigma_\alpha/2$, so that $p=2$, and by Eq. (40) $c_\alpha=1\otimes\sigma_\alpha-\sigma_\alpha\otimes 1$.

Realizations of higher so$(2n)$ algebras in terms of MPFs can be constructed in a similar way by projecting down from the well-known parafermionic realizations of so$(2n+1)$.

VII. MPFs AND THE PARA-GRASSMAN ALGEBRA

If we define (real) elements ϵ_i by $c_i = l\epsilon_i$ for all i, where l is a contraction parameter, and take the limit $l \to 0$ we obtain the algebra

$$[[\epsilon_i,\ \epsilon_j],\ \epsilon_k] = 0. \tag{41}$$

This is just the para-Grassman algebra,[15] considered extensively in connection with the representation theory of DPFs. Our results and ansatz representations for specific MPF algebras can likewise be contracted, leading to results in para-Grassman representation theory. For example contraction of Eq. (20) yields

$$\epsilon_i\epsilon_j\epsilon_k + \epsilon_k\epsilon_j\epsilon_i = 0 \tag{42}$$

and Eq. (21) contracted leads to the very simple relation $\epsilon_i^{p+1} = 0$ for all i.

The projective unitary irreducible representations of the Galilei group in 1+2 dimensions

D. R. Grigore[a)]
Department of Theoretical Physics, Institute of Atomic Physics, Bucharest-Măgurele, P. O. Box MG 6, Romînia

(Received 2 February 1994; accepted for publication 30 June 1995)

We give an elementary analysis of the multiplicator group of the Galilei group in 1+2 dimensions $\mathscr{G}_+^\uparrow$. For a nontrivial multiplicator we give a list of all the corresponding projective unitary irreducible representations of $\mathscr{G}_+^\uparrow$. © *1996 American Institute of Physics.* [S0022-2488(96)00701-5]

I. INTRODUCTION

Recently a complete list of all projective unitary irreducible representations of the Poincaré group in $1+2$ dimensions was determined.[1] This paper intended to provide a similar analysis for the Galilei group (more precisely for the proper orthochronous Galilei group).

The main technical obstacle seems to be the rather complicated structure of the multiplier group (see Ref. 2, Appendix A). In Sec. II the reader is provided with the basic facts concerning the determination of the projective irreducible representations of a certain group by the Mackey method. (Follow as closely as possible Ref. 3). Section III gives an elementary analysis of the second cohomology group of the universal covering group $\widetilde{\mathscr{G}}_+^\uparrow$ of the Galilei group $\mathscr{G}_+^\uparrow$ in $1+2$ dimensions.

Section IV constructs for every nontrivial multiplier a certain extension of $\widetilde{\mathscr{G}}_+^\uparrow$ which exhibits a semidirect product group structure. One is able to apply the Mackey induced representations method to determine the desired representations. In this paper only nontrivial multipliers are considered. The case of true representation (i.e., trivial multipliers) is elementary to analyze and raises no problems.[1]

II. PROJECTIVE UNITARY IRREDUCIBLE REPRESENTATIONS

Following Ref. 3, the classification of all projective unitary irreducible representations of a certain group G is done following the steps below:

(1) One identifies the universal covering group $\tilde{G}$ of G. Let one denote by $\pi:\tilde{G}\to G$ the canonical projection. If $\alpha:G\to \mathrm{Aut}(\mathscr{P}(\mathscr{H}))$ is a morphism of G into the group of automorphisms of the lattice of the orthogonal projectors in the Hilbert space $\mathscr{H}$ (i.e., a *symmetry*) then

$$\tilde{\alpha}\equiv\alpha\circ\pi \tag{2.1}$$

is a morphism of $\tilde{G}$ into the group of automorphisms of the same lattice $\mathscr{P}(\mathscr{H})$ verifying the condition

$$\tilde{\alpha}_{g_0}=id \tag{2.2}$$

for any $g_0\in Ker(\pi)$.

Conversely, any morphism of $\tilde{G}$ in $\mathrm{Aut}(\mathscr{P}(\mathscr{H}))$ verifying Eq. (2.2) determines a morphism of G via formula (2.1). It will be clear immediately that it is more convenient to study morphisms of

E-mail: grigore@roifa.bitnet, grigore@ifa.ro

0022-2488/96/37(1)/460/14/$6.00

$\tilde{G}$ instead of morphisms of G. According to Wigner theorem, the morphism $\tilde{\alpha}$ is induced by projective unitary irreducible representation V of $\tilde{G}$ in the Hilbert space $\mathscr{H}$.

One easily discovers, applying the Schur lemma, that the condition (2.2) is equivalent to the condition

$$V_{g_0} = \lambda \times id \tag{2.3}$$

for any $g_0 \in Ker(\pi)$. Here λ is a complex number of modulus 1. So in the following one will determine the projective unitary irreducible representation of the group $\tilde{G}$ verifying Eq. (2.3).

(2) One determines the cohomology group $H^2(\tilde{G},\mathbb{R})$ using infinitesimal arguments. This is possible because for connected and simply connected Lie groups one has $H^2(\tilde{G},\mathbb{R}) \simeq H^2(\mathrm{Lie}(\tilde{G}),\mathbb{R})$.

(3) One determines from $H^2(\tilde{G},\mathbb{R})$ the multiplier group, i.e., $H^2(\tilde{G},\mathbf{T})$ where $\mathbf{T}$ is the multiplicative group of complex numbers of modulus 1. The corresponding 2-cocycles are also called multipliers. One selects a multiplier from every cohomology class and tries to classify the unitary irreducible representations of $\tilde{G}$ and afterwards selects those verifying the condition (2.3).

For this last step one tries to first exhibit a semidirect product group. To fix the notations we remind the reader the content of the Mackey theorem. Let $H \times_t A$ be a semidirect product of the locally compact groups H and A which verify the second axiom of countability. Suppose that A is Abelian. Here: $t: H \to \mathrm{Aut}(A)$ is a group homomorphism. To classify all the unitary irreducible representations of $H \times_t A$ one goes through the following steps.[3]

(a) One considers the dual $\hat{A}$ of A and the action of H on it given by

$$(h \cdot \omega)(a) \equiv \omega(t_{h^{-1}}(a)). \tag{2.4}$$

(b) One computes all the H-orbits in $\hat{A}$. We suppose there exists a Borel cross section $\Sigma \subset \hat{A}$ intersecting once every H-orbit.

(c) For $\forall \omega \in \Sigma$ one computes the *little group*:

$$H_\omega \equiv \{h \in H | h \cdot \omega = \omega\}. \tag{2.5}$$

(d) We suppose that we know the complete list of the unitary irreducible representations of $H_\omega, \forall \omega \in \Sigma$.

(e) Let $\mathscr{O} \subset \hat{A}$ be a H-orbit in $\hat{A}, \omega_0 \equiv \mathscr{O} \cap \Sigma$ and π a unitary irreducible representation of H_{ω_0} acting in the (complex) Hilbert space $\mathscr{K}$. As it is well known[3] one can associate to every π a $(H,\mathscr{O},\mathscr{K})$-cocyle ϕ^π, i.e., a Borel map $\phi^\pi: H \times \mathscr{O} \to \mathscr{U}(\mathscr{K})$ [here $\mathscr{U}(\mathscr{K})$ is the group of unitary operators in $\mathscr{K}$] such that a.e. in $H \times \mathscr{O}$:

$$\phi^\pi(h_1, h_2 \cdot \omega)\phi^\pi(h_2, \omega) = \phi^\pi(h_1 h_2, \omega) \tag{2.6}$$

and $\forall h \in H_{\omega_0}$:

$$\pi(h) = \phi^\pi(h, \omega_0). \tag{2.7}$$

A convenient way to construct ϕ^π is as follows. Let $c: \mathscr{O} \to H$ be a Borel section, i.e., a Borel map such that $\forall \omega \in \mathscr{O}$,

$$c(\omega) \cdot \omega_0 = \omega. \tag{2.8}$$

Then we can take

$$\phi^\pi(h, \omega) = \pi(c(h \cdot \omega)^{-1} h c(\omega)). \tag{2.9}$$

(f) For every H-orbit $\mathcal{O}$ and every unitary irreducible representation π of H_{ω_0} in $\mathcal{K}$ we consider the Hilbert space $\mathcal{H}\equiv L^2(\mathcal{O},d\alpha,\mathcal{K})$ (where α is an H-quasi-invariant measure on $\mathcal{O}$) and define: $\mathcal{W}_{h,a}^{(\mathcal{O},\pi)}:\mathcal{H}\to\mathcal{H}$ as follows:

$$(\mathcal{W}_{h,a}^{(\mathcal{O},\pi)}f)(\omega)=\omega(a)(r_h(h^{-1}\cdot\omega))^{1/2}\phi^{\pi}(h,h^{-1}\cdot\omega)f(h^{-1}\cdot\omega) \tag{2.10}$$

(where $r_h(\cdot)$ is a version of the Radon–Nicodym derivative $d\alpha^{h^{-1}}/d\alpha$).

Then $\mathcal{W}$ is a unitary irreducible representation of $H\times_t A$.

The Mackey theorem asserts that if the orbit structure is smooth (see Ref. 3) then every unitary irreducible representation of $H\times_t A$ is unitary equivalent to a representation of the form $\mathcal{W}^{(\mathcal{O},\pi)}$ and moreover to distinct couples $(\mathcal{O},\pi)\neq(\mathcal{O}',\pi')$ corresponding representations $\mathcal{W}^{(\mathcal{O},\pi)}$ and $\mathcal{W}^{(\mathcal{O},\pi)}$ which are not unitary equivalent.

III. THE GALILEI GROUP IN 1+2 DIMENSIONS

A. Notations

By definition the orthochronous Galilei group in $1+2$ dimensions $\mathcal{G}^{\uparrow}$ is set-theoretically $O(2)\times\mathbb{R}^2\times\mathbb{R}\times\mathbb{R}^2$ with the composition law

$$(R_1,\mathbf{v}_1,\eta_1,\mathbf{a}_1)\cdot(R_2,\mathbf{v}_2,\eta_2,\mathbf{a}_2)=(R_1R_2,\mathbf{v}_1+R_1\mathbf{v}_2,\eta_1+\eta_2,\mathbf{a}_1+R_1\mathbf{a}_2+\eta_2\mathbf{v}_1). \tag{3.1}$$

Organize $\mathbb{R}^2$ as column vectors, $O(2)$ as the 2×2 real orthogonal matrices, and consistently use matrix notations. This group acts naturally on $\mathbb{R}\times\mathbb{R}^2$:

$$(R,\mathbf{v},\eta,\mathbf{a})\cdot(T,\mathbf{X})=(T+\eta,R\mathbf{X}+T\mathbf{v}+\mathbf{a}). \tag{3.2}$$

One can also consider the proper orthochronous Galilei group $\mathcal{G}^{\uparrow}_{+}$ defined as

$$\mathcal{G}^{\uparrow}_{+}\equiv\{(R,\mathbf{v},\eta,\mathbf{a})\,|\det(R)=1\} \tag{3.3}$$

and the universal covering group $\widetilde{\mathcal{G}}^{\uparrow}_{+}$ of $\mathcal{G}^{\uparrow}_{+}$. We can take $\widetilde{\mathcal{G}}^{\uparrow}_{+}=\mathbb{R}\times\mathbb{R}^2\times\mathbb{R}\times\mathbb{R}^2$ with the composition law

$$(x_1,\mathbf{v}_1,\eta_1,\mathbf{a}_1)\cdot(x_2,\mathbf{v}_2,\eta_2,\mathbf{a}_2)=(x_1+x_2,\mathbf{v}_1+R(x_1)\mathbf{v}_2,\eta_1+\eta_2,\mathbf{a}_1+R(x_1)\mathbf{a}_2+\eta_2\mathbf{v}_1), \tag{3.4}$$

where

$$R(x)\equiv\begin{pmatrix}\cos(x) & \sin(x)\\ -\sin(x) & \cos(x)\end{pmatrix}. \tag{3.5}$$

The covering homomorphism δ: $\widetilde{\mathcal{G}}^{\uparrow}_{+}\to\mathcal{G}^{\uparrow}_{+}$ is

$$\delta(x,\mathbf{v},\eta,\mathbf{a})=(R(x),\mathbf{v},\eta,\mathbf{a}). \tag{3.6}$$

Finally we describe the Lie algebra of $\widetilde{\mathcal{G}}^{\uparrow}_{+}$, $\mathrm{Lie}(\widetilde{\mathcal{G}}^{\uparrow}_{+})\simeq\mathrm{Lie}(\mathcal{G}^{\uparrow}_{+})$ using the fact that $\mathcal{G}^{\uparrow}_{+}$ can be organized as a matrix group. Indeed one has the group isomorphism:

$$\mathcal{G}^{\uparrow}_{+}\ni(R,\mathbf{v},\eta,\mathbf{a})\leftrightarrow\begin{pmatrix}R & \mathbf{v} & \mathbf{a}\\ 0 & 1 & \eta\\ 0 & 0 & 1\end{pmatrix}\in M_{\mathbb{R}}(4,4). \tag{3.7}$$

Then $\mathrm{Lie}(\mathcal{G}^{\uparrow}_{+})$ can be identified with the linear space of 4×4 real matrices of the form

$$(\alpha,\mathbf{u},t,\mathbf{x})\equiv\begin{pmatrix}\alpha A & \mathbf{u} & \mathbf{x}\\ 0 & 0 & t\\ 0 & 0 & 0\end{pmatrix}. \tag{3.8}$$

Here $\mathbf{u},\mathbf{x}\in\mathbb{R}^2, t,\alpha\in\mathbb{R}$ and $A\equiv\left(\begin{smallmatrix}0 & 1\\ -1 & 0\end{smallmatrix}\right)$. One obtains the Lie bracket as

$$[(\alpha_1,\mathbf{u}_1,t_1,\mathbf{x}_1),(\alpha_2,\mathbf{u}_2,t_2,\mathbf{x}_2)]=(0,A(\alpha_1\mathbf{u}_2-\alpha_2\mathbf{u}_1),0,A(\alpha_1\mathbf{x}_2-\alpha_2\mathbf{x}_1)+t_2\mathbf{u}_1-t_1\mathbf{u}_2). \tag{3.9}$$

B. Computation of $H^2(\mathrm{Lie}(\widetilde{\mathscr{G}}^{\uparrow}_{+}),\mathbb{R})$

As was outlined in the preceding section, to classify all multipliers of a Lie group G one starts by first computing the second cohomology group of $\mathrm{Lie}(G)$ with real coefficients.[3] As was said in the Introduction, an elementary derivation of this group is provided (see also Ref. 4). If $\xi\in Z^2(\mathrm{Lie}(\tilde{\mathscr{G}}^{\uparrow}_{+}),\mathbb{R})$ the cocycle equation is written as:

$$\xi([(\alpha_1,\mathbf{u}_1,t_1,\mathbf{x}_1),(\alpha_2,\mathbf{u}_2,t_2,\mathbf{x}_2)],(\alpha_3,\mathbf{u}_3,t_3,\mathbf{x}_3))+\text{perm.}=0. \tag{3.10}$$

Here $\xi:\mathrm{Lie}(\widetilde{\mathscr{G}}^{\uparrow}_{+})\times\mathrm{Lie}(\widetilde{\mathscr{G}}^{\uparrow}_{+})\to\mathbb{R}$ is, by definition, bilinear and antisymmetric. Using Eq. (3.9), one can explicitate (3.10):

$$\xi((0,A(\alpha_1\mathbf{u}_2-\alpha_2\mathbf{u}_1),0,A(\alpha_1\mathbf{x}_2-\alpha_2\mathbf{x}_1)+t_2\mathbf{u}_1-t_1\mathbf{u}_2),(\alpha_3,\mathbf{u}_3,t_3,\mathbf{x}_3))+\text{perm.}=0. \tag{3.11}$$

One can consider some distinct cases of this equation:
(i) $t_i=0$, $\mathbf{x}_i=\mathbf{0}$ $(i=1,2,3)$
One obtains

$$\xi((0,A(\alpha_1\mathbf{u}_2-\alpha_2\mathbf{u}_1),0,\mathbf{0}),(\alpha_3,\mathbf{u}_3,t_3,\mathbf{x}_3))+\text{perm.}=0. \tag{3.12}$$

From bilinearity one has

$$\xi((0,\mathbf{u},0,\mathbf{0}),(0,\mathbf{u}',0,\mathbf{0}))=\mathbf{u}^tC\mathbf{u}', \tag{3.13}$$

where C is a 2×2 real matrix. From antisymmetry one finds $C^t=-C$ so necessarily $C=\frac{1}{2}FA(F\in\mathbb{R})$. So one has

$$\xi((0,\mathbf{u},0,\mathbf{0}),(0,\mathbf{u}',0,\mathbf{0}))=\tfrac{1}{2}F\langle\mathbf{u},\mathbf{u}'\rangle, \tag{3.14}$$

where $\langle\cdot,\cdot\rangle$is the sesquilinear form on $\mathbb{R}^2$ given by

$$\langle\mathbf{u},\mathbf{v}\rangle\equiv\mathbf{u}^tA\mathbf{v}. \tag{3.15}$$

It is easy to see that Eq. (3.12) becomes an identity.
(ii) $\alpha_i=0$, $\mathbf{u}_i=\mathbf{0}$ $(i=1,2,3)$
Equation (3.11) becomes an identity.
(iii) $t_1=0$, $\mathbf{x}_1=\mathbf{0}$, $\alpha_i=0$, $\mathbf{u}_i=\mathbf{0}$ $(i=2,3)$
One easily obtains from Eq. (3.11),

$$\xi((0,\mathbf{0},t,\mathbf{x}),(0,\mathbf{0},t',\mathbf{x}'))=0. \tag{3.16}$$

(iv) $t_i=0$, $\mathbf{x}_i=\mathbf{0}$ $(i=1,2)$, $\alpha_3=0$, $\mathbf{u}_3=\mathbf{0}$
Equation (3.11) becomes

$$\xi((0,\mathrm{A}(\alpha 1\mathbf{u}2-\alpha 2\mathbf{u}1),0,\mathbf{0}),(0,\mathbf{0},t3,\mathbf{x}3))+\xi((0,\mathbf{0},0,\alpha 2A\mathbf{x}3+t3\mathbf{u}2),(\alpha 1,\mathbf{u}1,0,\mathbf{0}))$$

$$+\xi((0,\mathbf{0},0,-\alpha_1 A\mathbf{x}_3-t_3\mathbf{u}_1),(\alpha_2,\mathbf{u_2},0,\mathbf{0}))=0. \tag{3.17}$$

From bilinearity one has

$$\xi((0,\mathbf{u},0,\mathbf{0}),(0,\mathbf{0},0,\mathbf{x})=\mathbf{x}^t D\mathbf{u}, \tag{3.18}$$

where D is a 2×2 real matrix.

If one takes in Eq. (3.17) $\alpha_2=0$, $t_3=0$ and inserts expression (3.18) one gets

$$[D,A]=0\Leftrightarrow D=-\tau\times id+cA \quad (\tau,c\in\mathbb{R}) \tag{3.19}$$

so, Eq. (3.18) takes the form

$$\xi((0,\cdot\,\mathbf{u},0,\mathbf{0}),(0,\mathbf{0},0,\mathbf{x})=-\tau\mathbf{x}\cdot\mathbf{u}+c\langle\mathbf{x},\mathbf{u}\rangle. \tag{3.20}$$

If one inserts Eq. (3.20) into Eq. (3.17) one gets $c=0$ and

$$\xi((0,A\mathbf{u},0,\mathbf{0}),(0,\mathbf{0},1,\mathbf{0}))+\xi((0,\mathbf{0},0,\mathbf{u}),(1,\mathbf{0},0,\mathbf{0}))=0. \tag{3.21}$$

Because of linearity one has

$$\xi((0,\mathbf{0},1,\mathbf{0}),(0,\mathbf{u},0,\mathbf{0}))=\mathbf{P}\cdot\mathbf{u} \quad (\mathbf{P}\in\mathbb{R}^2) \tag{3.22}$$

and the preceding relation gives

$$\xi((0,\mathbf{0},0,\mathbf{x}),(1,\mathbf{0},0,\mathbf{0}))=\langle\mathbf{P},\mathbf{x}\rangle. \tag{3.23}$$

Finally Eq. (3.20) reduces to

$$\xi((0,\mathbf{u},0,\mathbf{0}),(0,\mathbf{0},0,\mathbf{x})=\tau\mathbf{x}\cdot\mathbf{u}. \tag{3.24}$$

Denote

$$S\equiv\xi((1,\mathbf{0},0,\mathbf{0}),(0,\mathbf{0},1,\mathbf{0})) \tag{3.25}$$

and use linearity to obtain.

$$\xi((1,\mathbf{0},0,\mathbf{0}),(0,\mathbf{u},0,\mathbf{0})=\langle\mathbf{G},\mathbf{u}\rangle \quad (\mathbf{G}\in\mathbb{R}^2). \tag{3.26}$$

Finally reconstruct the cocyle ξ from Eqs. (3.14)–(3.26):

$$\xi(\alpha_1,\mathbf{u}_1,t_1,\mathbf{x}_1),(\alpha_2,\mathbf{u}_2,t_2,\mathbf{x}_2)=\langle\mathbf{G},\alpha_1\mathbf{u}_2-\alpha_2\mathbf{u}_1\rangle+\tfrac{1}{2}F\langle\mathbf{u}_1,\mathbf{u}_2\rangle+S(\alpha_1 t_2-\alpha_2 t_1)$$
$$-\langle\mathbf{P},\alpha_1\mathbf{x}_2-\alpha_2\mathbf{x}_1\rangle+\mathbf{P}\cdot(t_2\mathbf{u}_1-t_1\mathbf{u}_2)+\tau(\mathbf{x}_1\cdot\mathbf{u}_2-\mathbf{x}_2\cdot\mathbf{u}_1). \tag{3.27}$$

If one takes the generic element of $C^1(\text{Lie}(\widetilde{\mathscr{G}}^{\uparrow}_{+}),\mathbb{R})\simeq(\text{Lie}(\widetilde{\mathscr{G}}^{\uparrow}_{+})^*$ to be $(\beta,\mathbf{G},E,\mathbf{P})$ defined by

$$\langle(\beta,\mathbf{G},E,\mathbf{P}),(\alpha,\mathbf{u},t,\mathbf{x})\rangle\equiv-\beta\alpha-\mathbf{G}\cdot\mathbf{u}-Et+\mathbf{P}\cdot\mathbf{x} \tag{3.28}$$

then it is elementary to see that Eq. (3.27) rewrites as

$$\xi=\tau\xi_0+F\xi_1+S\xi_2+\partial(0,\mathbf{G},0,\mathbf{P}), \tag{3.29}$$

where $\xi_0,\xi_1,\xi_2\in Z^2(\text{Lie}(\widetilde{\mathscr{G}}^{\uparrow}_{+}),\mathbb{R})$ are

$$\xi_0((\alpha_1,\mathbf{u}_1,t_1,\mathbf{x}_1),(\alpha_2,\mathbf{u}_2,t_2,\mathbf{x}_2))\equiv\mathbf{x}_1\cdot\mathbf{u}_2-\mathbf{x}_1\cdot\mathbf{u}_2, \tag{3.30}$$

$$\xi_1((\alpha_1,\mathbf{u}_1,t_1,\mathbf{x}_1),(\alpha_2,\mathbf{u}_2,t_2,\mathbf{x}_2))\equiv\tfrac{1}{2}\langle\mathbf{u}_1,\mathbf{u}_2\rangle, \tag{3.31}$$

$$\xi_2((\alpha_1,\mathbf{u}_1,t_1,\mathbf{x}_1),(\alpha_2,\mathbf{u}_2,t_2,\mathbf{x}_2))\equiv\alpha_1t_2-\alpha_2t_1 \tag{3.32}$$

and ∂ is the coboundary operator defined as

$$(\partial\beta)(X,X')=-\beta([X,X']),\quad \forall X,X'\in\mathrm{Lie}(\widetilde{\mathscr{G}}^{\uparrow}_{+}),\quad \forall\beta\in(\mathrm{Lie}\,(\widetilde{\mathscr{G}}^{\uparrow}_{+}))^{*}. \tag{3.33}$$

So every cocycle $\xi\in Z^2(\mathrm{Lie}(\widetilde{\mathscr{G}}^{\uparrow}_{+}),\mathbb{R})$ is cohomologous with a cocyle of the form $\tau\xi_0+F\xi_1+S\xi_2$.

It is easy to establish now that this cocycle is not a coboundary. One can summarize the preceding discussion as the following:

Proposition 1: $H^2(\mathrm{Lie}(\widetilde{\mathscr{G}}^{\uparrow}_{+}),\mathbb{R})$ *is a three-dimensional real space. In every cohomology class there exists exactly one cocyle of the type* $\tau\xi_0+F\xi_1+S\xi_2$.

C. Computation of $H^2(\widetilde{\mathscr{G}}^{\uparrow}_{+},\mathbb{R})$

As in Ref. 3 one uses the fact that for G a connected and simply connected Lie group, $H^2(G,\mathbb{R})$ is isomorphic to $H^2(\mathrm{Lie}(G),\mathbb{R})$. So, to determine $H^2(G,\mathbb{R})$ one should determine for ξ_0,ξ_1,ξ_2 some corresponding group cocyles. One easily determines (see Ref. 2)

$$\omega_0(g,g')=1/2[\mathbf{a}\cdot R(x)\mathbf{v}'-\mathbf{v}\cdot R(x)\mathbf{a}'+\eta'\mathbf{v}\cdot R(x)\mathbf{v}'], \tag{3.34}$$

$$\omega_1(g,g')=1/2\langle\mathbf{v},R(x)\mathbf{v}'\rangle, \tag{3.35}$$

$$\omega_2=\eta x', \tag{3.36}$$

where $g=(x,\mathbf{v},\eta,\mathbf{a})$, $g'=(x',\mathbf{v}',\eta',\mathbf{a}')$.

The correspondence between the Lie group and Lie algebra cocycles is checked using Lemma 7.36 from Ref. 3, Chap. VII. The content of this lemma is the following. Let G be connected and simply connected Lie group and $c\in Z^2(G,\mathbb{R})$. Define the Lie algebra 2-cochain ξ_c by

$$\xi_c(X,X')\equiv\frac{\partial^2}{\partial s\,\partial s'}[c(\exp(sX),\exp(s'X'))-(X\leftrightarrow X')]_{s=s'=0}. \tag{3.37}$$

Then $\xi_c\in Z^2(\mathrm{Lie}(G),\mathbb{R})$ and the correspondence $c\to\xi_c$ factorizes to an isomorphism between $H^2(G,\mathbb{R})$ and $H^2(\mathrm{Lie}(G),\mathbb{R})$.

So one has the following:

Corollary 1: $H^2(\widetilde{\mathscr{G}}^{\uparrow}_{+},\mathbb{R})$ *is a three-dimensional real linear space. In every cohomology class there exists exactly one cocycle of the type* $\tau\omega_0+F\omega_1+S\omega_2$.

Finally, applying Thm. 7.37 of Ref. 3 one has the following:

Theorem 1: *Every multiplier of* $\widetilde{\mathscr{G}}^{\uparrow}_{+}$ *is equivalent to a multiplier of the form*

$$m_{\tau,F,S}(g,g')\equiv\exp\left\{\frac{i\tau}{2}[\mathbf{a}\cdot R(x)\mathbf{v}'-\mathbf{v}\cdot R(x)\mathbf{a}'+\eta'\mathbf{v}\cdot R(x)\mathbf{v}']\right\}\exp\left\{\frac{iF}{2}\langle\mathbf{v},R(x)\mathbf{v}'\rangle+iS\,\eta x'\right\}. \tag{3.38}$$

Moreover $m_{\tau,F,S}\sim m_{\tau',F',S'}$ *iff* $\tau=\tau'$, $F=F'$, $S=S'$.

Remark 1: In 1+3 dimensions it is well known that only a multiplier of type $m_{\tau,0,0}$ *survives. So,* $m_{0,F,S}$ *is characteristic to 1+2 dimensions. According to the general theory of the projective*

unitary representations, one has to consider the most general multiplier $m_{\tau,F,S}$. In Ref. 1 only the multiplier $m_{\tau,0,0}$ was considered, so the statement of Theorem 2 in this reference is rather carelessly formulated.

Remark 2: One will find it convenient to denote $m_\tau \equiv m_{\tau,0,0}$, $m_F \equiv m_{0,F,0}$, $m_S \equiv m_{0,0,S}$.

Also note that $m_{\tau,F,S} = m_\tau m_F m_S$.

IV. THE PROJECTIVE UNITARY IRREDUCIBLE REPRESENTATIONS OF THE GALILEI GROUP IN 1+2 DIMENSIONS

A. The method

As anticipated, classify here the unitary irreducible $m_{\tau,F,S}$-representations of $\widetilde{\mathscr{G}}^{\uparrow}_{+}$. We try to mimic the method from Ref. 3 which consists of two steps:

(a) One first applies a simple result, namely a generalization of Theorem 7.16 from Ref. 3.

Proposition 2: Let $m_0,\ldots,m_p$ be multipliers for the group G and let $U(g\mapsto U_g)$ be an $m_0,\ldots,m_p$ representation of G in a (separable) Hilbert $\mathscr{H}$ space over the complex numbers. Let $G_{m_0,\ldots,m_p} \equiv G\times \underbrace{\mathbf{T}\times\cdots\times\mathbf{T}}_{(p+1)-times}$ with the composition law:

$$(g;\zeta_0,\ldots,\zeta_p)\cdot(g';\zeta_0',\ldots,\zeta_p') = (gg';\zeta_0\zeta_0' m_0(g,g'),\ldots,\zeta_p\zeta_p' m_p(g,g')). \tag{4.1}$$

Then $G_{m_0,\ldots,m_p}$ is a group, and

$$(g;\zeta_0,\ldots,\zeta_p)\mapsto V_{g;\zeta_0,\ldots,\zeta_p} \equiv \zeta_0^{-1},\ldots,\zeta_p^{-1} U_g \tag{4.2}$$

is a representation of $G_{m_0,\ldots,m_p}$ in $\mathscr{H}$ such that

$$V_{e;\zeta_0,\ldots,\zeta_p} = \zeta_0^{-1},\ldots,\zeta_p^{-1}\times id. \tag{4.3}$$

Conversely, if V is a representation of $G_{m_0,\ldots,m_p}$ in $\mathscr{H}$ such that Eq. (4.3) is verified, then if one writes

$$U_g \equiv V_{g;\ \underbrace{1,\ldots,1}_{(p+1)-times}}. \tag{4.4}$$

$g\mapsto U_g$ is an $m_0,\ldots,m_p$-representation of G in $\mathscr{H}$ and the connection (4.2) between U and V is true.

The proof is elementary and Theorem 7.16 of Ref. 3 is the particular case $p=0$.

It is clear that one can apply Proposition 2 with $G=\widetilde{\mathscr{G}}^{\uparrow}_{+}$, $p=2$, and $m_0=m_\tau$, $m_1=m_F$, $m_2=m_S$. Denote the corresponding group $G_{m_0 m_1 m_2}$ by $\widetilde{\mathscr{G}}^{\uparrow}_{+}{}^{\tau,F,S}$.

(b) Remember that in Ref. 3, where, in the four-dimensional case, one has to study only $\widetilde{\mathscr{G}}^{\uparrow}_{+}{}^{\tau,0,0}$ (see Chap. IX, Sec. 8), a semidirect product group structure is exhibited, so one can apply the induction procedure. The same procedure works for $\widetilde{\mathscr{G}}^{\uparrow}_{+}{}^{\tau,F,S}$. Indeed one has a group isomorphism $\widetilde{\mathscr{G}}^{\uparrow}_{+}{}^{\tau,F,S} \simeq H^F \times_{t^{\tau,S}} A$.

Define the group $H \equiv \mathbb{R}\times\mathbb{R}^2$ with the composition law:

$$(x,\mathbf{v})\cdot(x',\mathbf{v}') = (x+x',\mathbf{v}+R(x)\mathbf{v}') \tag{4.5}$$

then $H^F \equiv H \times \mathbf{T}$ with the composition law

$$(h_1;\zeta_1)\cdot(h_2;\zeta_2)=(h_1h_2;\zeta_1\zeta_1' m_F(h,h')). \tag{4.6}$$

The notation $m_F(h,h')$ makes sense because on the right-hand side of Eq. (3.35) only the variables x and $\mathbf{v}$ appear.

$A \equiv \mathbb{R}\times\mathbb{R}^2\times\mathbf{T}\times\mathbf{T}$ with the composition law

$$(\eta,\mathbf{a};\zeta_0,\zeta_2)\cdot(\eta',\mathbf{a}';\zeta_0',\zeta_2')=(\eta+\eta',\mathbf{a}+\mathbf{a}';\zeta_0\zeta_0',\zeta_2\zeta_2'). \tag{4.7}$$

$t^{\tau,S}: H^F \to \mathrm{Aut}(A)$ is given by

$$t^{\tau,S}_{h;\zeta_1}(a;\zeta_0,\zeta_2)=\left(t_h(a);\zeta_0\ \exp\left\{-\frac{i\tau}{2}[2\mathbf{v}\cdot R(x)\mathbf{a}+\eta\mathbf{v}^2]\right\},\zeta_2 e^{-iS\eta x}\right). \tag{4.8}$$

Here $a \equiv (\eta,\mathbf{a})$ and

$$t_h(\eta,\mathbf{a})=(\eta,R(x)\mathbf{a}+\eta\mathbf{v}). \tag{4.9}$$

The semidirect product structure follows from the homomorphism property of $t^{\tau,S}$. Then the isomorphism is

$$H^F \times_{t^{\tau,S}} A \ni \{(x,\mathbf{v};\zeta_1),(\eta,\mathbf{a};\zeta_0,\zeta_2)\} \leftrightarrow \left(x,\mathbf{v},\eta,\mathbf{a};\zeta_0\ \exp\left(\frac{i\tau}{2}\mathbf{a}\cdot\mathbf{v}\right),\zeta_1,\zeta_2 e^{iS\eta x}\right) \in \widetilde{\mathscr{G}}^{\uparrow\ \tau,F,S}_{+}. \tag{4.10}$$

We note that A is Abelian, so we will be able to apply the Mackey induction procedure.

Remark 3: One may wonder why Proposition 2 was not applied with $p=0$ *and* $m_0=m_\tau m_F m_S$. *The reason is that it did not succeed to find a convenient semidirect product structure for* G_{m_0} *in this case.*

Taking into account Eq. (4.10) the representations of $\widetilde{\mathscr{G}}^{\uparrow\ \tau,F,S}_{+}$ follow from representations of $H^F \times_{t^{\tau,S}} A$ according to

$$W_{(x,\mathbf{v},\eta,\mathbf{a};\zeta_0,\zeta_1,\zeta_2)}=\mathscr{W}_{(x,\mathbf{v},\eta,\mathbf{a};\zeta_0\ \exp\{-(i\tau/2)\,\mathbf{a}\cdot\mathbf{v}\},\zeta_1,\zeta_2 e^{-iS\eta x})}. \tag{4.11}$$

According to Proposition 2 one is looking for unitary irreducible representations of $\widetilde{\mathscr{G}}^{\uparrow\ \tau,F,S}_{+}$ verifying

$$W_{e;\zeta_0,\zeta_1,\zeta_2}=\zeta_0^{-1}\zeta_1^{-1}\zeta_2^{-1}\times id. \tag{4.12}$$

Follow the method of induced representations as presented in Sec. II.

B. Computation of the orbits

It is clear that every character of $A^{\tau,S}$ has the form

$$\chi_{p_0,\mathbf{p};n_0,n_2}(\eta,\mathbf{a};\zeta_0,\zeta_2)=\zeta_0^{n_0}\zeta_2^{n_2}\ \exp\{i(\eta p_0+\mathbf{a}\cdot\mathbf{p})\}, \tag{4.13}$$

where $p_0 \in \mathbb{R}, \mathbf{p} \in \mathbb{R}^2$, and $n_0, n_2 \in \mathbf{Z}$. So, $\widehat{A^{\tau,S}} \equiv \mathbb{R}\times\mathbb{R}^2\times\mathbf{Z}\times\mathbf{Z}$ with the generic element denoted by $[p_0,\mathbf{p};n_0,n_2]$. One easily computes the dual action of $t^{\tau,S}_{h;\zeta_1}$, namely,

$$(x,\mathbf{v};\zeta_1)\cdot[p_0,\mathbf{p};n_0,n_2]=[p_0-\mathbf{v}\cdot R(x)\mathbf{p}-1/2n_0\tau\mathbf{v}^2+Sn_2x,R(x)\mathbf{p}+n_0\tau\mathbf{v};n_0,n_2]. \tag{4.14}$$

The classification of the orbits of this action is elementary. We distinguish three cases which must be studied separately:

(a) $\tau \neq 0, \quad S=0.$

The orbits are

$$Z^1_{n_2,p_0} \equiv \{[p_0,\mathbf{0};0,n_2]\}; \quad p_0 \in \mathbb{R}, \quad n_2 \in \mathbf{Z},$$

$$Z^2_{n_2,r} \equiv \{[p_0,\mathbf{p};0,n_2] | \mathbf{p}^2 = r^2, \quad p_0 \in \mathbb{R}\}; \quad r \in \mathbb{R}_+, \quad n_2 \in \mathbf{Z},$$

$$Z^3_{n_0,n_2,\rho} \equiv \{[p_0,\mathbf{p};n_0,n_2] | \mathbf{p}^2 + 2n_0\tau p_0 = \rho\}; \quad \rho \in \mathbb{R}, \quad n_0 \in \mathbf{Z}^*, \quad n_2 \in \mathbf{Z}.$$

(b) $\tau = 0, \ S \neq 0.$

$$Z^4_{n_0,p_0} \equiv \{[p_0,\mathbf{0};n_0,0]\}; \quad p_0 \in \mathbb{R}, \quad n_0 \in \mathbf{Z},$$

$$Z^5_{n_0,n_2} \equiv \{[p_0,\mathbf{0};n_0,n_2] | p_0 \in \mathbb{R}\}, \quad n_0 \in \mathbf{Z}, \quad n_2 \in \mathbf{Z}^*,$$

$$Z^6_{n_0,n_2,r} \equiv \{[p_0,\mathbf{p};n_0,n_2] | \mathbf{p}^2 = r^2, p_0 \in \mathbb{R}\}; \quad r \in \mathbb{R}_+, \ n_0,n_2 \in \mathbf{Z}.$$

(c) $\tau \neq 0, \ S \neq 0.$

$$Z^7_{p_0} \equiv \{[p_0,\mathbf{0};0,0]\}; \quad p_0 \in \mathbb{R},$$

$$Z^8_{n_2} \equiv \{[p_0,\mathbf{0};0,n_2] | p_0 \in \mathbb{R}\}, \quad n_2 \in \mathbf{Z}^*,$$

$$Z^9_{n_0,\rho} \equiv \{[p_0,\mathbf{p};n_0,0] | \mathbf{p}^2 + 2n_0\tau p_0 = \rho\}; \quad \rho \in \mathbb{R}, \quad n_0 \in \mathbf{Z}^*,$$

$$Z^{10}_{n_0,n_2} \equiv \{[p_0,\mathbf{p};n_0,n_2] | \mathbf{p} \in \mathbb{R}^2, p_0 \in \mathbb{R}\}; \quad n_0,n_2 \in \mathbf{Z}^*.$$

(d) $\tau = 0, \ S = 0.$

$$Z^{11}_{p_0,n_0,n_2} \equiv \{[p_0,\mathbf{0};n_0,n_2]|\}; \quad p_0 \in \mathbb{R}, \quad n_0,n_2 \in \mathbf{Z},$$

$$Z^{12}_{r,n_0,n_2} \equiv \{[p_0,\mathbf{p};n_0,n_2] | p_0 \in \mathbb{R}, \mathbf{p}^2 = r^2\}; \quad r \in \mathbb{R}_+, \quad n_0,n_2 \in \mathbf{Z}.$$

(Note that Z^{11} is a point.) It is not hard to see that condition (4.12) cannot be fulfilled by the induced representations corresponding to the orbits: Z^1, Z^2, Z^4, Z^7, Z^8, and Z^9. So, analyze only the cases $Z^3, Z^5, Z^6, Z^{10}, Z^{11}$, and Z^{12}. One by one of these six cases are analyzed.

C. The representations

The unitary irreducible representations of the little groups are computed, then the corresponding cocycles as in Sec. II and finally the projective representations of $\mathscr{G}^{\uparrow}_{+}$ we are looking for, are exhibited.

(a) $\tau \neq 0, \ S = 0.$

In this case, $Z = Z^3_{n_0,n_2,\rho}$. A reference point is $[\rho/2n_0\tau, \mathbf{0}; n_0, n_2]$ and we have

$$H^F_{[\rho/2n_0\tau,\mathbf{0};n_0,n_2]} = \{(x,\mathbf{0};\zeta_1) | x \in \mathbb{R}, \zeta_1 \in \mathbf{T}\} \simeq \mathbb{R} \times \mathbf{T}. \tag{4.15}$$

The unitary irreducible representations of this Abelian subgroup are of the form $\pi^{(s,n_1)}$ ($s \in \mathbb{R}, n_1 \in \mathbf{Z}$); they are one-dimensional and are acting in $\mathbf{C}$ as follows:

$$\pi^{(s,n_1)}(x,\mathbf{0};\zeta_1)=e^{isx}\ \zeta_1^{n_1}. \tag{4.16}$$

In this case one can find explicitly a corresponding cocycle ϕ^{π}, namely,

$$\phi^{(s,n_1)}((x,\mathbf{v};\zeta_1),[p_0,\mathbf{p};n_0,n_2])=e^{isx}\ \zeta_1^{n_1}\ \exp\left\{\frac{in_1F}{2n_0\tau}\langle\mathbf{v},R(x)\mathbf{p}\rangle\right\}. \tag{4.17}$$

As in Ref. 3 identify $Z^3\simeq\mathbb{R}^2$ according to: $[(\rho-\mathbf{p}^2)/2n_0\tau,\mathbf{p};n_0,n_2]\leftrightarrow\mathbf{p}$ and consider the strictly invariant Lebesgue measure $d\mathbf{p}$ on $\mathbb{R}^2$.

Applying Eq. (4.11), the corresponding induced representation is acting in $\mathscr{H}=L^2(\mathbb{R}^2,d\mathbf{p})$ according to

$$(W_{(x,\mathbf{v},\eta,\mathbf{a};\zeta_0,\zeta_1,\zeta_2)}f)(\mathbf{p})=\zeta_0^{n_0}\zeta_1^{n_1}\zeta_2^{n_2}\ \exp\left\{i\left[-\frac{n_0\tau}{2}\ \eta\mathbf{a}\cdot\mathbf{v}+\eta\ \frac{\rho-\mathbf{p}^2}{2n_0\tau}+\mathbf{a}\cdot\mathbf{p}+sx\right]\right\}$$
$$\times\exp\left\{i\left[\frac{n_1F}{2n_0\tau}\langle\mathbf{v},\mathbf{p}\rangle\right]\right\}f(R(x)^{-1}(\mathbf{p}-n_0\tau\mathbf{v}). \tag{4.18}$$

The condition (4.12) imposes $n_0=n_1=n_2=-1$. The factor $\exp(-(i\eta\rho/2\tau))$ can be dropped because one is looking for projective representations. One gets the projective representations $V^{\tau,s}(\tau\in\mathbb{R}^*,s\in\mathbb{R})$ acting in $L^2(\mathbb{R}^2,d\mathbf{p})$ as follows:

$$(V^{\tau,s}_{x,\mathbf{v},\eta,\mathbf{a}}f)(\mathbf{p})=\exp\left\{i\left(sx+\mathbf{a}\cdot\mathbf{p}+\frac{\eta\mathbf{p}^2}{2\tau}+\frac{\tau}{2}\mathbf{a}\cdot\mathbf{v}+\frac{F}{2\tau}\langle\mathbf{v},\mathbf{p}\rangle\right)\right\}f(R(x)^{-1}(\mathbf{p}+\tau\mathbf{v})). \tag{4.19}$$

(b) $\tau=0$, $S\neq0$.

(b1) $Z=Z^5_{n_0,n_2}$.

A reference point is $[0,\mathbf{0};n_0,n_2]$ and one has

$$H^F_{[0,\mathbf{0};n_0,n_2]}=\{(0,\mathbf{v};\zeta_1)|\mathbf{v}\in\mathbb{R}^2,\zeta_1\in\mathbf{T}\}, \tag{4.20}$$

i.e., a central extension of the Abelian group $\mathbb{R}^2$. Let π be a unitary irreducible representation of this group. Because of Eq. (4.12) one must have

$$\pi_{(0,\mathbf{0};\zeta_1)}=\zeta_1^{-1}\times id. \tag{4.21}$$

This easily implies that one has

$$\pi_{(0,\mathbf{v};1)}\pi_{(0,\mathbf{v}';1)}=\exp\left\{-\frac{iF}{2}\langle\mathbf{v},\mathbf{v}'\rangle\right\}\pi_{(0,\mathbf{v}+\mathbf{v}';1)}, \tag{4.22}$$

i.e., $\mathbf{v}\mapsto\pi_{(0,\mathbf{v};1)}$ is a unitary irreducible representation of the canonical commutation relations in Weyl form. According to Stone–von Neumann theorem there exists (up to unitary equivalence) exactly one such representation, denoted π^{CCR} and acting in the Hibert space $\mathscr{H}$ (for an explicit expression see, e.g., Ref. 5, Chap. 3.1). So, the representations of $H^F_{[0,\mathbf{0};n_0,n_2]}$ one is looking for are of the form

$$\pi_{(0,\mathbf{v};\zeta_1)}=\zeta_1^{-1}\pi^{\mathrm{CCR}}_{\mathbf{v}}. \tag{4.23}$$

A corresponding cocycle is clearly

$$\phi^{\mathrm{CCR}}((x,\mathbf{v};\zeta_1),[p_0,\mathbf{0};n_0,n_2])=\zeta_1^{-1}\pi^{\mathrm{CCR}}_{\mathbf{v}}. \tag{4.24}$$

If one identifies naturally $Z^5 \simeq \mathbb{R}$ with the strictly invariant measure dp_0, then the corresponding induced representation is acting in $\mathscr{H}=L^2(\mathbb{R},\mathscr{K},dp_0)$ as follows:

$$(W_{(x,\mathbf{v},\eta,\mathbf{a};\zeta_0,\zeta_1,\zeta_2)}f)(p_0)=\zeta_0^{n_0}(\zeta_2\ e^{-iS\eta x})^{n_2}\ e^{i\eta p_0}\zeta_1^{-1}(\pi_{\mathbf{v}}^{\mathrm{CCR}}f)(p_0-Sn_2x). \tag{4.25}$$

Again Eq. (4.12) imposes $n_0=n_2=-1$ and one is left with the projective representations V^{CCR} acting in $\mathscr{H}=L^2(\mathbb{R},\mathscr{K},dp_0)$ according to

$$(V^{\mathrm{CCR}}_{x,\mathbf{v},\eta,\mathbf{a}}f)(p_0)=e^{i\eta(p_0+Sx)}(\pi_{\mathbf{v}}^{\mathrm{CCR}}f)(p_0+Sx). \tag{4.26}$$

(b2) $Z=Z^6_{n_0,n_2,\rho}$.

A reference point is $[0,r\mathbf{e_1};n_0,n_2]$ and one easily obtains

$$H^F_{[0,r\mathbf{e}_1;n_0,n_2]}=\left\{\left(2\pi n,\frac{2\pi nSn_2}{r}\ \mathbf{e_1}+\alpha\mathbf{e_2};\zeta_1\right)\middle|\ n\in\mathbf{Z},\alpha\in\mathbb{R},\zeta\in\mathbf{T}\right\}. \tag{4.27}$$

If one denotes

$$(n,\alpha;\zeta_1)\equiv\left(2\pi n,\frac{2\pi nSn_2}{r}\ \mathbf{e_1}+\alpha\mathbf{e_2};\zeta_1\right) \tag{4.28}$$

then the composition law is

$$(n,\alpha;\zeta_1)\cdot(n',\alpha';\zeta_1')=(n+n',\alpha+\alpha';\zeta_1\zeta_1'\ \exp\{ik(\alpha n'-\alpha' n)\}), \tag{4.29}$$

i.e., the little group is in this case a central extension of the Abelian group $\mathbf{Z}\times\mathbb{R}$. Here $k=2\pi FSn_2/r$. Let $(n,\alpha;\zeta_1)\mapsto\pi_{(n,\alpha;\zeta_1)}$ be a unitary irreducible representation fulfilling

$$\pi_{(0,0;\zeta_1)}=\zeta_1^{-1}\times id. \tag{4.30}$$

(The argument leading to this relation is similar to the argument leading to Eq. (4.21).)

One has for $\pi_{n,\alpha}\equiv\pi_{n,\alpha;1}$:

$$\pi_{n,\alpha}\pi_{n',\alpha'}=\exp\{ik(\alpha n'-\alpha' n)\}\pi_{n+n',\alpha+\alpha'}. \tag{4.31}$$

(b21) First analyze the case $k\neq 0\Leftrightarrow F\neq 0$.

The resemblance of this relation to the Weyl system (4.22) suggests an association to Eq. (4.31), a sort of imprimitivity system.[3] Denote: $\pi_{1,0}\equiv V$ and $\pi_\alpha=\pi_{0,\alpha}$. It is clear that Eq. (4.31) is equivalent to

$$\pi_{n,0}=V^n;\quad V\pi_\alpha V^{-1}=e^{2ik\alpha}\pi_\alpha;\quad \pi_\alpha\pi_{\alpha'}=\pi_{\alpha+\alpha'}. \tag{4.32}$$

So, it is sufficient to find an irreducible couple (V,π_α) fulfilling the last two relations of Eq. (4.32). According to a well-known theorem in harmonic analysis [Stone, Naimark, Ambrose, and Godement (SNAG)theorem][6,7] π_α is of the form

$$\pi_\alpha=\int_{\mathbb{R}}e^{i\lambda\alpha}\ dP(\lambda), \tag{4.33}$$

where $\Delta\mapsto P_\Delta$ is a projection valued measure in the Hilbert space $\mathscr{K}$. The second relation (4.32) is equivalent to

$$VP_\Delta V^{-1}=P_{\Delta-2k}. \tag{4.34}$$

Applying the same idea as in Ref. 3 Lemma 6.10, we can prove that P is homogeneous, i.e., $\mathscr{K}=L^2(\mathbb{R},\mathbf{C}^n,\beta)$ where β is a measure on $\mathbb{R}$ quasi-invariant with respect to the transformation $\lambda\mapsto\lambda+2k$ and

$$(P_\Delta f)(\lambda)=\chi_\Delta(\lambda)f(\lambda). \tag{4.35}$$

Moreover, like in Ref. 3, Theorem 6.12, one can show that V has the "diagonal" expression

$$(Vf)(\lambda)=r_V(\lambda+2k)^{1/2}v(\lambda)f(\lambda+2k) \tag{4.36}$$

(here r_V is a Radon–Nicodym derivative).

It is easy to see that for $n>1$ the system (V,P_Δ) is not irreducible. So, $n=1$. Moreover one can show that $\mathrm{supp}(\beta)$ must be discrete with period $2k$, i.e., $\mathrm{supp}(\beta)=\{\lambda+2km|m\in\mathbf{Z}\},\lambda\in\mathbb{R}$.

It is clear that one can take $\beta=\Sigma_{m\in\mathbf{Z}}\delta_{\lambda+2km}$. In this case one can also take $\mathscr{K}=l^2$ (i.e., sequences $\{f_m\}_{m\in\mathbf{Z}}$ such that $\Sigma_{m\in\mathbf{Z}}|f_m|^2<\infty$) and $P=\beta$. It follows that one has

$$(\pi_\alpha f)_m=e^{i(\lambda+2km)\alpha}f_m;\quad (Vf)_m=v_m f_{m+1}(\forall m\in\mathbf{Z}). \tag{4.37}$$

(Here $v_m\in\mathbf{T}$.)

The system (V,π_α) is irreducible. So, the unitary irreducible representations of the little group $H^F_{[0,r\mathbf{e_1};n_0,n_2]}$ verifying Eq. (3.25) are of the form $\pi^\lambda(\lambda\in\mathbb{R})$ acting in l^2 according to

$$(\pi^\lambda_{n,\alpha;\zeta_1}f)_m=\zeta_1^{-1}e^{i[\lambda+k(2m+n)]\alpha}f_{m+n}. \tag{4.38}$$

Consider the unitary transformation

$$(Uf)_m=f_{m+n}. \tag{4.39}$$

Then, one easily obtains that

$$U\pi^\lambda U^{-1}=\pi^{\lambda+n},\quad \forall n\in\mathbf{Z}, \tag{4.40}$$

i.e., $\pi^\lambda\sim\pi^{\lambda+n}\forall n\in\mathbf{Z}$.

Conversely, suppose that $\pi^{\lambda_1}\sim\pi^{\lambda_2}$. Then the spectra of the infinitesimal generators $(1/i)\ (d/d\alpha)\ \pi^{\lambda_i}_{0,\alpha}|_{\alpha=0}\ i=1,2$ must coincide. But these spectra are $\{\lambda_i+kn|n\in\mathbf{Z}\}$, so one necessarily gets $\lambda_1-\lambda_2\in k\mathbf{Z}$.

It follows that the parameter λ takes values in $\mathbb{R}(\mathrm{mod}\,k)$.

Denote by ϕ^λ a cocycle corresponding to π^λ. (The author has not been able to find a simple expression for this cocycle.) Then, if one identifies $Z^6\simeq\mathbb{R}\times S^1$ with the strictly invariant measure $dp_0\otimes d\Omega$, in the end one gets the projective representation $V^{r,\lambda}$ acting in $L^2(\mathbb{R}\times S^1,l^2,dp_0\otimes d\Omega)$ according to

$$\begin{aligned}(V^{r,\lambda}_{x,\mathbf{v},\eta,\mathbf{a}}f)(p_0,\mathbf{p})=&\exp\{i[\eta(p_0+Sx)+\mathbf{a}\cdot\mathbf{p}]\}\phi^\lambda((x,\mathbf{v};1),[p_0+\mathbf{v}\cdot\mathbf{p}+Sx,R(x)^{-1}\mathbf{p}])\\&\times f(p_0+\mathbf{v}\cdot\mathbf{p}+Sx,R(x)^{-1}\mathbf{p}).\end{aligned} \tag{4.41}$$

(b22) Analyze the case $k=0\Leftrightarrow F=0$.

In this case Eq. (4.31) states that π is a unitary irreducible representation of the Abelian group $\mathbf{Z}\times\mathbb{R}$. So $\pi\sim\pi^{(s,t)}$ with $s\in\mathbb{R}(\mathrm{mod}\,1),t\in\mathbb{R}$ where $\pi^{(s,t)}$ are one-dimensional and have the expression

$$\pi^{(s,t)}_{n,\alpha}=e^{2\pi ins}\ e^{it\alpha}. \tag{4.42}$$

A corresponding cocycle is

$$\phi^{(s,t)}((x,\mathbf{v}),[p_0,\mathbf{p}])=\exp\left\{i\left(sx-t\,\frac{\langle\mathbf{v},R(x)\mathbf{p}\rangle}{r}\right)\right\}. \tag{4.43}$$

The corresponding induced representation is $V^{r,s,t}$ acting in $L^2(\mathbb{R}\times S^1,dp_0\otimes d\Omega)$ according to

$$(V^{r,s,t}_{x,\mathbf{v},\eta,\mathbf{a}}f)(p_0,\mathbf{p})=\exp\left\{i\left[\eta(p_0+Sx)+\mathbf{a}\cdot\mathbf{p}+sx+S\frac{\langle\mathbf{p},\mathbf{v}\rangle}{r}\right]\right\}\ f(p_0+\mathbf{v}\cdot\mathbf{p}+Sx,R(x)^{-1}\mathbf{p}). \tag{4.44}$$

(c) $\tau\neq 0$, $S\neq 0$.

Only the orbit $Z^{10}_{n_0,n_2}$ is involved. A reference point is $[0,\mathbf{0};n_0,n_2]$ and we have

$$H^F_{[0,\mathbf{0};n_0,n_2]}=\{(0,\mathbf{0};\zeta_1)\,|\,\zeta_1\in\mathbf{T}\}\simeq\mathbf{T} \tag{4.45}$$

with the unitary irreducible representations of the form π^{n_1} acting in $\mathbf{C}$ according to

$$\pi^{n_1}_{(0,\mathbf{0};\zeta_1)}=\zeta_1^{n_1}. \tag{4.46}$$

A corresponding cocycle can be found:

$$\phi^{n_1}((x,\mathbf{v};\zeta_1),[p_0,\mathbf{p};n_0,n_2])=\zeta_1^{n_1}\exp\left\{\frac{iFn_1}{2n_0\tau}\langle\mathbf{v},R(x)\mathbf{p}\rangle\right\}. \tag{4.47}$$

Identify $Z^{10}\simeq\mathbb{R}\times\mathbb{R}^2$ with the strictly invariant measure $dp_0\otimes d\mathbf{p}$. The induced representations obey Eq. (4.12) *iff* $n_0=n_1=n_2=-1$ and we get projective representations V^τ acting in $L^2(\mathbb{R}\times\mathbb{R}^2,dp_0\ d\mathbf{p})$ according to

$$\begin{aligned}(V^\tau_{x,\mathbf{v},\eta,\mathbf{a}}f)(p_0,\mathbf{p})=&\exp\left\{i\left[\eta(p_0+Sx)+\frac{\tau}{2}\mathbf{a}\cdot\mathbf{v}+\mathbf{a}\cdot\mathbf{p}+\frac{F}{2\tau}\langle\mathbf{v},\mathbf{p}\rangle\right]\right\}\\&\times f(p_0+Sx+\mathbf{v}\cdot\mathbf{p}+\tfrac{1}{2}\tau\mathbf{v}^2,R(x)^{-1}(\mathbf{p}+\tau\mathbf{v})).\end{aligned} \tag{4.48}$$

(d) $\tau=0$, $S=0$.

In this case only the nontrivial orbit Z^{12} counts. A reference point is $[0,r\mathbf{e}_1;n_0,n_2]$ and we have

$$H^F_{[0,r\mathbf{e}_1;n_0,n_2]}=\{(2\pi n,\alpha\mathbf{e}_2;\zeta 1)\,|\,n\in\mathbf{Z},\alpha\in\mathbb{R},\zeta\in\mathbf{T}\}\simeq\mathbf{Z}\times\mathbb{R}\times\mathbf{T}. \tag{4.49}$$

The unitary irreducible representations are $\pi^{(s,t,n_1)}(s\in\mathbb{R}(\mathrm{mod}\,1),t\in\mathbb{R},n_1\in\mathbf{Z})$ acting in $\mathbf{C}$ according to

$$\pi^{(s,t,n_1)}((2\pi n,\alpha\mathbf{e}_2;\zeta 1)=e^{2\pi ins}\ e^{it\alpha}\zeta_1^{n_1}. \tag{4.50}$$

Let $\phi^{(s,t,n_1)}$ be an associated cocycle. Then the induced representation corresponds to the choice $n_0=n_1=n_2=-1$ and acts in $L^2(\mathbb{R}\times S^1,dp_0\otimes d\Omega)$ according to

$$(V'^{,r,s,t}_{x,\mathbf{v},\eta,\mathbf{a}}f)(p_0,\mathbf{p})=e^{i(\eta p_0+\mathbf{a}\cdot\mathbf{p})}\phi^{(s,t,-1)}((x,\mathbf{v};1),[p_0+\mathbf{v}\cdot\mathbf{p}])f(p_0+\mathbf{v}\cdot\mathbf{p},R(x)^{-1}\mathbf{p}). \tag{4.51}$$

Theorem 2: *Every projective unitary irreducible representation of* $\widetilde{\mathscr{G}}^{\uparrow}_{+}$ *with a nontrivial multiplier is unitary equivalent to a representation of the type* $V^{\tau,s},V^{\mathrm{CCR}},V^{r,\lambda},V^{r,s,t},V^{\tau}$, *or* $V^{\prime,r,s,t}$ *described by Eqs. (4.19), (4.26), (4.41), (4.44), (4.48), and (4.51), respectively. Two different*

representations from this list are not unitary equivalent. Only the representations (4.19) and (4.51) verify the condition (2.3) so only these representations correspond to Galilean invariant systems.

Remark 4: Consider the representations (4.19) and (4.51) from the point of view of localizability.[3] *The representation (4.19) is localizable. Indeed, by restricting the covering group of the Euclidean group SE(2) we obtain*

$$(V^{\tau,s}_{x,\mathbf{a}}f)(\mathbf{p})=e^{i(sx+\mathbf{a}\cdot\mathbf{p})}f(R(x)^{-1}\mathbf{p}). \tag{4.52}$$

Performing a Fourier transform one gets

$$(V^{\tau,s}_{x,\mathbf{a}}f)(\mathbf{X})=e^{isx}\ f(R(x)^{-1}(\mathbf{X}-\mathbf{a})). \tag{4.53}$$

If $P_\Delta=\chi_\Delta$ *then* $(V^{\tau,s},P)$ *is a system of imprimitivity based on* $\mathbb{R}^2$ *relative to the action*

$$(x,\mathbf{a})\cdot\mathbf{X}=R(x)\mathbf{X}+\mathbf{a} \tag{4.54}$$

so one has localizability.

The representations (4.51) are not localizable on $\mathbb{R}^2$ *(the argument is similar to the one in Ref. 3 and is based on the existence of the constraint* $\mathbf{p}^2=r^2$*).*

Remark 5: The representations (4.19) obtained in case (a) are the analogues of the representations obtained in 1+3 dimensions (see, Ref. 3, Chap. IX, Subsection 8). The infinitesimal generators of this representation are

$$(Hf)(\mathbf{p})=\frac{\mathbf{p}^2}{2\tau}\ f, \tag{4.55}$$

$$(\mathbf{P}f)(\mathbf{p})=\mathbf{p}f, \tag{4.56}$$

$$(Jf)(\mathbf{p})=i\left(p_1\frac{\partial f}{\partial p_2}-p_2\frac{\partial f}{\partial p_1}\right)+sf, \tag{4.57}$$

$$(\mathbf{K}f)(\mathbf{p})=-i\tau\frac{\partial f}{\partial\mathbf{p}}+\frac{F}{2\tau}A\mathbf{p}f. \tag{4.58}$$

So τ *and s must be interpreted as the mass and the spin of the system, respectively. The interpretation of F is not clear. Because F appears from a central extension of a translation group (see Eq. (4.22)), it is tempting to associate F with some kind of magnetic force. For another interpretation of the parameter F (based on the nonrelativistic limit) see Ref. 8.*

A $\mathbb{Z}_3$-graded generalization of supermatrices

Bertrand Le Roy
Laboratoire de Gravitation et Cosmologie Relativistes, Université Pierre et Marie Curie—CNRS URA 769, Tour 22-12, 4^e étage, boîte 142, Paris Cedex, France

(Received 26 June 1995; accepted for publication 7 August 1995)

We introduce $\mathbb{Z}_3$-graded objects which are the generalization of the more familiar $\mathbb{Z}_2$-graded objects that are used in supersymmetric theories and in many models of non-commutative geometry. First, we introduce the **$\mathbb{Z}_3$-graded Grassmann algebra**, and we use this object to construct the **$\mathbb{Z}_3$-matrices**, which are the generalizations of the **supermatrices**. Then, we generalize the concepts of **supertrace** and **superdeterminant**. © *1996 American Institute of Physics.* [S0022-2488(96)00901-9]

I. INTRODUCTION

$\mathbb{Z}_2$-graded algebras, which are the basic objects of supersymmetry, are well known since the works of Berezin, Kac, Leites, Wess and Zumino,[1–5] who introduced the concepts of supermatrices, supertrace and superdeterminant. These concepts will be generalized here.

Recently, there have been many attempts to generalize $\mathbb{Z}_2$-graded constructions to the $\mathbb{Z}_3$-graded case.[6–10] Many such attempts, though, were aimed at the description of exotic statistics. We think that our construction could describe some properties of the *quarks*, in particular the *ternary* aspects of their associations.

II. THE $\mathbb{Z}_3$-GRADED GRASSMANN ALGEBRA

The ordinary Grassmann algebra is generated by anticommuting entities:

$$\eta_i \eta_j = -\eta_j \eta_i .$$

This can be viewed in the following way. $\mathbb{Z}_2$ is the group of the permutations of two elements. It can be represented by the real numbers (-1) and 1:

$$\underset{+1}{\begin{pmatrix} A & B \\ A & B \end{pmatrix}} \quad \underset{-1}{\begin{pmatrix} A & B \\ B & A \end{pmatrix}}.$$

When an element of the permutation group is applied to the product of two generators, it is followed by the multiplication by the number representing this permutation.

Similar operations can be performed with $\mathbb{Z}_3$, which is faithfully represented by the complex numbers 1, j and j^2, where j is a cubic root of 1, $e^{2i\pi/3}$:

$$\underset{1}{\begin{pmatrix} A & B & C \\ A & B & C \end{pmatrix}} \quad \underset{j}{\begin{pmatrix} A & B & C \\ B & C & A \end{pmatrix}} \quad \underset{j^2}{\begin{pmatrix} A & B & C \\ C & A & B \end{pmatrix}}.$$

When one applies an element of the cyclic permutation group to the product of *three* generators, it is multiplied by the complex number representing this permutation:

0022-2488/96/37(1)/474/10/$6.00

$$\theta_i\theta_k\theta_l = j\,\theta_k\theta_l\theta_i\,.$$

The generators defined in this way have the following properties: their cubes vanish, as also does a product of any four generators:[8]

$$\theta_i^3 = 0, \quad \theta_i\theta_k\theta_l\theta_m = 0.$$

Therefore the dimension of the algebra generated by N independent elements is

$$\underset{\theta' s}{N} + \underset{\theta\theta' s}{N^2} + \underset{\theta\theta\theta' s}{\frac{N^3-N}{3}}.$$

To restore the symmetry between grades 1 (the θ's) and 2 (the $\theta\theta$'s), we can add N grade 2 generators $\bar{\theta}_i$ that behave like the products of two θ's, that is

$$\bar{\theta}_i\bar{\theta}_k\bar{\theta}_l = j^2\bar{\theta}_k\bar{\theta}_l\bar{\theta}_i\,, \quad \theta_i\bar{\theta}_k = j\,\bar{\theta}_k\theta_i\,.$$

In the case of the ordinary Grassmann algebra, the products of an odd number of generators are automatically anticommutative, whereas the products of an even number of generators commute with all other elements. In the $\mathbb{Z}_3$-graded case, this is no longer true. For example,

$$\theta_i\theta_k\bar{\theta}_l = j\,\theta_i\bar{\theta}_l\theta_k = j^2\bar{\theta}_l\theta_i\theta_k\,;$$

but in the same time, $\theta_k\bar{\theta}_l$ and $\bar{\theta}_l\theta_i$, as grade 0 elements, should commute with all other elements, leading to the relations $\theta_i(\theta_k\bar{\theta}_l) = (\theta_k\bar{\theta}_l)\theta_i$ and $\theta_i\theta_k\bar{\theta}_l = j^2(\bar{\theta}_l\theta_i)\theta_k = j^2\theta_k(\bar{\theta}_l\theta_i)$, which are clearly contradictory.

This leads us to impose the following relations on all elements of a definite grade (the grade of the product of two elements being the sum of their grades, modulo 3). Let us denote by $a, b, \ldots$, the elements of grade 0, by $A, B, \ldots$, the elements of grade 1, by $\bar{A}, \bar{B}, \ldots$, the elements of grade 2 and by $\mathscr{X}$ an element of arbitrary grade. Then the rules

$$a.\mathscr{X} = .\mathscr{X}a, \quad A\bar{A} = j\bar{A}A,$$

define entirely the $\mathbb{Z}_3$-graded Grassmann algebra. We obtain the ternary rules $\theta_i\theta_k\theta_l = j\,\theta_k\theta_l\theta_i$ and $\bar{\theta}_i\bar{\theta}_k\bar{\theta}_l = j^2\bar{\theta}_k\bar{\theta}_l\bar{\theta}_i$ directly from the second rule by replacing A and $\bar{A}$ with products of one or two generators θ or $\bar{\theta}$.

With the unit element $\mathbb{I}$, the algebra contains the following elements:

Grade 0: $\mathbb{I}, \theta\bar{\theta}, \theta\theta\theta, \bar{\theta}\bar{\theta}\bar{\theta},$

Grade 1: $\theta, \bar{\theta}\bar{\theta},$

Grade 2: $\bar{\theta}, \theta\theta,$

and its dimension is

$$D=1+2N+3N^2+2\frac{N^3-N}{3}=\frac{3+4N+9N^2+2N^3}{3}.$$

One can note that the grade 0 elements recall formally the only observable combinations of *quark fields* in chromodynamics based on the $SU(3)$ symmetry, that is, the mesons which are the combinations $q\bar{q}$ of one quark and one antiquark, and the hadrons which are the combinations qqq or $\bar{q}\bar{q}\bar{q}$ of three quarks or three antiquarks.

From now on, we shall denote the grade of an object X by ∂X.

III. $\mathbb{Z}_3$-MATRICES

We define the $\mathbb{Z}_3$-matrices in analogy with the supermatrices, which form a $\mathbb{Z}_2$-graded matrix algebra and whose entries are elements of a Grassmann algebra.

First, we define a $\mathbb{Z}_3$-graded complex matrix algebra by dividing the algebra $\mathscr{A}$ of 3×3 block matrices into three parts: $\mathscr{A}=\mathscr{A}_0\oplus\mathscr{A}_1\oplus\mathscr{A}_2$. A matrix is an element of $\mathscr{A}_0$ (resp., $\mathscr{A}_1$, $\mathscr{A}_2$) and is of grade 0 (resp., 1, 2) if it has the form shown below:

$$\begin{pmatrix} A & 0 & 0\\ 0 & B & 0\\ 0 & 0 & C\end{pmatrix}, \text{ resp. } \begin{pmatrix} 0 & A & 0\\ 0 & 0 & B\\ C & 0 & 0\end{pmatrix}, \begin{pmatrix} 0 & 0 & A\\ B & 0 & 0\\ 0 & C & 0\end{pmatrix}.$$

This gives a $\mathbb{Z}_3$-graded structure to the algebra of matrices, in the sense that the grade of the product of two matrices is the sum of the grades of these matrices modulo 3.

We can then tensorize this graded algebra with our $\mathbb{Z}_3$-graded Grassmann algebra, the grade of a $\mathbb{Z}_3$-matrix being the sum *modulo 3* of the grade of the matrix and of the grade of the Grassmann element. So a $\mathbb{Z}_3$-matrix is of grade 0 (resp., 1, 2) if its blocks contain only Grassmann elements with the respective grades:

$$\underset{\text{grade 0}}{\begin{pmatrix} 0 & 2 & 1\\ 1 & 0 & 2\\ 2 & 1 & 0\end{pmatrix}}, \underset{\text{grade 1}}{\begin{pmatrix} 1 & 0 & 2\\ 2 & 1 & 0\\ 0 & 2 & 1\end{pmatrix}}, \underset{\text{grade 2}}{\begin{pmatrix} 2 & 1 & 0\\ 0 & 2 & 1\\ 1 & 0 & 2\end{pmatrix}}.$$

It is easy to verify that the grade of the product of two $\mathbb{Z}_3$-matrices is the sum of their grades modulo 3.

The algebra of $\mathbb{Z}_3$-matrices contains a neutral element, $\mathscr{T}$, the $\mathbb{Z}_3$-matrix whose only non-vanishing elements are the unit of the Grassmann algebra occupying the main diagonal. The existence of this element enables us to define the invertibility of a $\mathbb{Z}_3$-matrix.

Theorem 1 (a): *A block of a $\mathbb{Z}_3$-matrix is invertible if and only if the block matrix formed with the coefficients of $\mathbb{I}$ in the development of the elements of the block over the grade 0 elements of the Grassmann algebra* ($\mathbb{I}$, $\theta\theta$, $\theta\theta\theta$, $\bar{\theta}\bar{\theta}\bar{\theta}$) *is invertible.*

(b) *A $\mathbb{Z}_3$-matrix is invertible if and only if its grade 0 blocks are invertible. The inverse of a grade 1 (resp., 2, 0) $\mathbb{Z}_3$-matrix is a grade 2 (resp., 1, 0) $\mathbb{Z}_3$-matrix.*

(c) *The product of two invertible $\mathbb{Z}_3$-matrices is an invertible $\mathbb{Z}_3$-matrix.*

Proof:

(a)–Let us decompose a $\mathbb{Z}_3$-matrix M into its complex component matrices along the elements of the Grassmann algebra: $M=M_\phi\mathbb{I}+M_\mu\theta_\mu+\bar{M}_\mu\bar{\theta}_\mu+M_{\mu\nu}\theta_\mu\theta_\nu+\bar{M}_{\mu\nu}\theta_\mu\bar{\theta}_\nu+\tilde{M}_{\mu\nu}\theta_\mu\bar{\theta}_\nu + M_{\mu\nu\eta}\theta_\mu\theta_\nu\theta_\eta+\bar{M}_{\mu\nu\eta}\theta_\mu\theta_\nu\bar{\theta}_\eta$. We also consider another $\mathbb{Z}_3$-matrix N that we decompose in the same way. Then it is easy to see that the component of MN along $\mathbb{I}$ is $M_\phi N_\phi$ (no product of two generators different from $\mathbb{I}$ can give something proportional to $\mathbb{I}$), so that for M to be invertible, its component M_ϕ must be invertible. Conversely, if M_ϕ is invertible, let us put

$N_\phi=(M_\phi)^{-1}$. Then the product MN differs from $\mathscr{I}$ only in terms of degree 2 and higher. However, we can choose $N_\mu=-(M_\phi)^{-1}M_\mu(M_\phi)^{-1}$ and $\bar{N}_\mu=-(M_\phi)^{-1}\bar{M}_\mu(M_\phi)^{-1}$. This way, MN differs from $\mathscr{I}$ only in terms of degree 3 and higher. Choosing the higher-level components of N in the same way, it is easy to expel these terms to higher degrees, until we have actually constructed the inverse of M, because of the finite number of terms in the development and of their cubic nilpotence.

(b) For this part of the theorem, we can use the proof of part (a) by noting that the component M_ϕ of a matrix M has non-zero coefficients only in positions corresponding to grade 0 blocks. $\mathscr{I}$ being of grade 0, it is obvious that the sum of the grades of a $\mathbb{Z}_3$-matrix and of its inverse should be 0 modulo 3.

(c) The component along $\mathbb{I}$ of the product of two invertible matrices is the product of their components along $\mathbb{I}$, which are invertible matrices by virtue of (b) and (a). These components being ordinary matrices, their product is an invertible matrix. We use (b) once more to conclude.■

The left (resp., right) product of a supermatrix by an element λ of the ordinary Grassmann algebra is defined as its left (resp., right) multiplication by the supermatrix

$$\begin{pmatrix} \lambda & \\ & (-1)^{\partial\lambda}\lambda \end{pmatrix}.$$

Generalizing this idea, we define the left (resp., right) product of a $\mathbb{Z}_3$-matrix by an element λ of the Grassmann algebra as its left (resp., right) multiplication by the following diagonal $\mathbb{Z}_3$-matrix:

$$\begin{pmatrix} \lambda & & \\ & j^{2\partial\lambda}\lambda & \\ & & j^{\partial\lambda}\lambda \end{pmatrix}.$$

Note that in general, $\lambda M \neq M\lambda$, but we have $\lambda(MN)=(\lambda M)N$, $(M\lambda)N=M(\lambda N)$, $M(N\lambda)=(MN)\lambda$ and $\lambda(M\mu)=(\lambda M)\mu$ which give our algebra the structure of a bimodule with respect to the Grassmann algebra.

Definition 2: Let us define a $\mathbb{Z}_3$-matrix M with the following block structure:

$$M=\begin{pmatrix} A & B & C \\ D & E & F \\ G & H & I \end{pmatrix}.$$

Its $\mathbb{Z}_3$-trace *is defined by:* $\mathrm{tr}_{\mathbb{Z}_3}(M)=\mathrm{tr}(A)+j^{2(1-\partial M)}\mathrm{tr}(E)+j^{(1-\partial M)}\mathrm{tr}(I)$; that is:

- If M is of grade 0, then $\mathrm{tr}_{\mathbb{Z}_3}(M)=\mathrm{tr}(A)+j^2.\mathrm{tr}(E)+j.\mathrm{tr}(I)$.
- If M is of grade 1, then $\mathrm{tr}_{\mathbb{Z}_3}(M)=\mathrm{tr}(A)+\mathrm{tr}(E)+\mathrm{tr}(I)$.
- If M is of grade 2, then $\mathrm{tr}_{\mathbb{Z}_3}(M)=\mathrm{tr}(A)+j\mathrm{tr}(E)+j^2\mathrm{tr}(I)$.

The supertrace of a supermatrix

$$M=\begin{pmatrix} A & B \\ C & D \end{pmatrix}$$

was defined by $\mathrm{str}\ M=\mathrm{tr}(A)+(-1)^{1-\partial M}\mathrm{tr}(D)$.

The following theorem can be easily proved:

Theorem 3: *(a) If M and N are of the same grade,*

$$\mathrm{tr}_{\mathbb{Z}_3}(M+N)=\mathrm{tr}_{\mathbb{Z}_3}(M)+\mathrm{tr}_{\mathbb{Z}_3}(N).$$

(b) $\mathrm{tr}_{\mathbb{Z}_3}(\lambda M)=\lambda\mathrm{tr}_{\mathbb{Z}_3}(M)$ *and* $\mathrm{tr}_{\mathbb{Z}_3}(M\lambda)=\mathrm{tr}_{\mathbb{Z}_3}(M)\lambda$.

(*c*) • *If M and N are of grade 0 then* $\mathrm{tr}_{\mathbb{Z}_3}(MN)=\mathrm{tr}_{\mathbb{Z}_3}(NM)$.

• *If M is of grade 1 and N of grade 2, then* $\mathrm{tr}_{\mathbb{Z}_3}(MN)=j\mathrm{tr}_{\mathbb{Z}_3}(NM)$.

Corollary 4: • *If M,N and P are of grade 1 then* $\mathrm{tr}_{\mathbb{Z}_3}(MNP)=j\ \mathrm{tr}_{\mathbb{Z}_3}(NPM)$.

• *If M,N and P are of grade 2 then* $\mathrm{tr}_{\mathbb{Z}_3}(MNP)=j^2\mathrm{tr}_{\mathbb{Z}_3}(NPM)$.

The proofs are straightforward, and the only nontrivial observation concerns the fact that $\mathrm{tr}(MN)=\mathrm{tr}(NM)$ is not always true if the M and N's coefficients are not numbers.

Finally, we can define the generalization of the superdeterminant this way.

Definition 5, $\mathbb{Z}_3$*-determinant: If M is a* grade 0 *invertible* $\mathbb{Z}_3$*-matrix, then its* $\mathbb{Z}_3$-determinant *is*

$$\begin{aligned}\det_{\mathbb{Z}_3}(M)=&\det(A-CI^{-1}G-(B-CI^{-1}H)(E-FI^{-1}H)^{-1}(D-FI^{-1}G))\\&\times(\det(E-FI^{-1}H))^{j^2}(\det I)^j.\end{aligned}$$

Theorem 6: *If M and N are two invertible grade 0* $\mathbb{Z}_3$*-matrices,*

$$\det_{\mathbb{Z}_3}(MN)=(\det_{\mathbb{Z}_3}M)(\det_{\mathbb{Z}_3}N).$$

Proof: Any grade 0 invertible $\mathbb{Z}_3$-matrix can be decomposed into the product of three $\mathbb{Z}_3$-matrices: $M=M_1M_0M_2$ with

$$M_1=\begin{pmatrix}1 & (B-CI^{-1}H)(E-FI^{-1}H)^{-1} & CI^{-1}\\ 0 & 1 & FI^{-1}\\ 0 & 0 & 1\end{pmatrix},$$

$$M_0=\begin{pmatrix}A-CI^{-1}G-(B-CI^{-1}H)(E-FI^{-1}H)^{-1}(D-FI^{-1}G) & 0 & 0\\ 0 & E-FI^{-1}H & 0\\ 0 & 0 & I\end{pmatrix},$$

$$M_2=\begin{pmatrix}1 & 0 & 0\\ (D-FI^{-1}G)(E-FI^{-1}H)^{-1} & 1 & 0\\ I^{-1}G & I^{-1}H & 1\end{pmatrix}. \tag{1}$$

It is very easy to show that the theorem is true for any M if N is block-diagonal or inferior-block-triangular with the identity in the diagonal blocks. It is also easy to generalize to an arbitrary N in the case where M is block-diagonal or superior-block-triangular with the identity in the diagonal blocks. Therefore, we have

$$\begin{aligned}\det_{\mathbb{Z}_3}(MN)&=\det_{\mathbb{Z}_3}(M_1)\det_{\mathbb{Z}_3}(M_0)\det_{\mathbb{Z}_3}(M_2N_1)\det_{\mathbb{Z}_3}(N_0)\det_{\mathbb{Z}_3}(N_2)\\&=\det_{\mathbb{Z}_3}(M)\det_{\mathbb{Z}_3}(M_2N_1)\det_{\mathbb{Z}_3}(N),\end{aligned}$$

and the theorem remains to be proved only for M of the form

$$\begin{pmatrix} 1 & 0 & 0 \\ A & 1 & 0 \\ B & C & 1 \end{pmatrix}$$

and N of the form

$$\begin{pmatrix} 1 & D & E \\ 0 & 1 & F \\ 0 & 0 & 1 \end{pmatrix}.$$

One can note that

$$\begin{pmatrix} 1 & 0 & B \\ 0 & 1 & C \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & C' \\ 0 & 0 & 1 \end{pmatrix}=\begin{pmatrix} 1 & 0 & B \\ 0 & 1 & C+C' \\ 0 & 0 & 1 \end{pmatrix},$$

$$\begin{pmatrix} 1 & A & B \\ 0 & 1 & C \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & A' & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}=\begin{pmatrix} 1 & A+A' & B \\ 0 & 1 & C \\ 0 & 0 & 1 \end{pmatrix},$$

and

$$\begin{pmatrix} 1 & A & B \\ 0 & 1 & C \\ 0 & 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 & B' \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}=\begin{pmatrix} 1 & A & B+B' \\ 0 & 1 & C \\ 0 & 0 & 1 \end{pmatrix},$$

so that we can construct the matrix N_1, element by element, starting from the matrix that contains only its diagonal blocks, using left multiplication by a series of matrices that contain only one non-zero element out of the diagonal blocks.

We show the theorem for M of the form of M_2 and N containing only one element out of the diagonal blocks, using the fact that if $\partial X \neq 0$, then $(1+X)^{\alpha}=1+\alpha X+[\alpha(\alpha-1)/2]X^2$. If $N_1=N_1^0N_1^1$ we can decompose $M_2N_1^0$ in the form 1. Then,

$$\begin{aligned}\det_{\mathbb{Z}_3}(M_2N_1)&=\det_{\mathbb{Z}_3}((M_2N_1^0)_1(M_2N_1^0)_0(M_2N_1^0)_2.N_1^1)\\&=\det_{\mathbb{Z}_3}((M_2N_1^0)_0)\det_{\mathbb{Z}_3}((M_2N_1^0)_2.N_1^1)=\det_{\mathbb{Z}_3}((M_2N_1^0)_0),\end{aligned}$$

if N_1^1 contains only one element out of its diagonal blocks. But $\det_{\mathbb{Z}_3}((M_2N_1^0)_0)=\det_{\mathbb{Z}_3}(M_2N_1^0)$. We can perform the same operation, until only the product of M_2 and the matrix formed with the diagonal blocks of N_1 (which are the identity) remains. Thus $\det_{\mathbb{Z}_3}(M_2N_1)=1$. ■

Theorem 7: *If M is a grade 0 invertible $\mathbb{Z}_3$-matrix, its $\mathbb{Z}_3$-determinant can also be expressed in the following five alternative ways:*

$$\begin{aligned}\det_{\mathbb{Z}_3}(M)&=\det(A-CI^{-1}G)\\&\quad\times(\det(E-FI^{-1}H-(D-FI^{-1}G)(A-CI^{-1}G)^{-1}(B-CI^{-1}H)))^{j^2}(\det I)^j,\end{aligned}$$

$$\det_{\mathbb{Z}_3}(M) = (\det A).(\det(E - DA^{-1}B - (F - DA^{-1}C)(I - GA^{-1}C)^{-1}(H - GA^{-1}B)))^{j^2}(\det(I - GA^{-1}C))^{j},$$

$$\det_{\mathbb{Z}_3}(M) = (\det A)(\det(E - DA^{-1}B))^{j^2}(\det(I - GA^{-1}C - (H - GA^{-1}B)(E - DA^{-1}B)^{-1}(F - DA^{-1}C)))^{j},$$

$$\det_{\mathbb{Z}_3}(M) = (\det(A - BE^{-1}D - (C - BE^{-1}F)(I - HE^{-1}F)^{-1}(G - HE^{-1}D)))(\det E)^{j^2}(\det(I - HE^{-1}F))^{j},$$

$$\det_{\mathbb{Z}_3}(M) = (\det(A - BE^{-1}D)(\det E))^{j^2}(\det(I - HE^{-1}F - (G - HE^{-1}D)(A - BE^{-1}D)^{-1}(C - BE^{-1}F)))^{j}.$$

Proof: We use the following decompositions of M:

$$\begin{pmatrix} A - CI^{-1}G & 0 & C \\ D - FI^{-1}G & E - FI^{-1}H - (D - FI^{-1}G)(A - CI^{-1}G)^{-1}(B - CI^{-1}H) & F \\ 0 & 0 & I \end{pmatrix} \begin{pmatrix} 1 & (A - CI^{-1}G)^{-1}(B - CI^{-1}H) & 0 \\ 0 & 1 & 0 \\ I^{-1}G & I^{-1}H & 1 \end{pmatrix},$$

$$\begin{pmatrix} 1 & 0 & 0 \\ DA^{-1} & 1 & (F - DA^{-1}C)(I - GA^{-1}C)^{-1} \\ GA^{-1} & 0 & 1 \end{pmatrix} \begin{pmatrix} A & B & C \\ 0 & E - DA^{-1}B - (F - DA^{-1}C)(I - GA^{-1}C)^{-1}(H - GA^{-1}B) & 0 \\ 0 & H - GA^{-1}B & I - GA^{-1}C \end{pmatrix},$$

$$\begin{pmatrix} 1 & 0 & 0 \\ DA^{-1} & 1 & 0 \\ GA^{-1} & (H - GA^{-1}B)(E - DA^{-1}B)^{-1} & 1 \end{pmatrix} \begin{pmatrix} A & B & C \\ 0 & E - DA^{-1}B & F - DA^{-1}C \\ 0 & 0 & I - GA^{-1}C - (H - GA^{-1}B)(E - DA^{-1}B)^{-1}(F - DA^{-1}C) \end{pmatrix},$$

$$\begin{pmatrix} 1 & BE^{-1} & (C-BE^{-1}F)(I-HE^{-1}F)^{-1} \\ 0 & 1 & 0 \\ 0 & HE^{-1} & 1 \end{pmatrix} \begin{pmatrix} A-BE^{-1}D-(C-BE^{-1}F)(I-HE^{-1}F)^{-1}(G-HE^{-1}D) & 0 & 0 \\ D & E & F \\ 0 & 0 & I-HE^{-1}F \end{pmatrix},$$

$$\begin{pmatrix} A-BE^{-1}D & B & 0 \\ 0 & E & 0 \\ G-HE^{-1}D & H & I-HE^{-1}F-(G-HE^{-1}D)(A-BE^{-1}D)^{-1}(C-BE^{-1}F) \end{pmatrix} \begin{pmatrix} 1 & 0 & (A-BE^{-1}D)^{-1}(C-BE^{-1}F) \\ E^{-1}D & 1 & E^{-1}F \\ 0 & 0 & 1 \end{pmatrix},$$

and make use of the Theorem 6. ■

In the case of the superdeterminant, the following two expressions are equivalent:

$$\mathrm{sdet}\begin{pmatrix} A & B \\ C & D \end{pmatrix} = \det(A-BD^{-1}C).(\det D)^{-1} = \det A.(\det(D-CA^{-1}B))^{-1}.$$

This restores the symmetry between the two diagonal elements on the one hand, and between the two off diagonal elements on the other hand. Here we have six expressions, restoring the S_3 symmetry between the three grade 0, grade 1 and grade 2 elements of the $\mathbb{Z}_3$-matrix which is broken in any expression separately chosen.

Theorem 8: *If M is a grade 0 invertible 3×3 $\mathbb{Z}_3$-matrix, then*

$$\det_{\mathbb{Z}_3}(\exp M) = \exp(\mathrm{tr}_{\mathbb{Z}_3} M).$$

Proof: Let M be the matrix:

$$M = \begin{pmatrix} a & \bar{A} & A \\ B & b & \bar{B} \\ \bar{C} & C & c \end{pmatrix},$$

where a,b,c are three grade 0 invertible elements of the Grassmann algebra (they must be invertible in order for M to be invertible; see Theorem 1), A,B,C are three grade 1 elements of the Grassmann algebra, and $\bar{A},\bar{B},\bar{C}$ are three grade 2 elements of the Grassmann algebra. Assuming that a,b,c are distinct, straightforward calculus give the following expression for the exponential of the matrix M:

$$\exp M=\begin{pmatrix} e^a+f(a,b)\bar{A}B+f(a,c)A\bar{C} & h(a,b)\bar{A}+l(a,b,c)AC & h(a,c)A+l(a,b,c)\bar{A}\bar{B} \\ \quad +g(a,b,c)(\bar{A}\bar{B}\bar{C}+j.CBA) & e^b+j^2f(b,c)C\bar{B}+j.f(b,a)\bar{A}B & h(b,c)\bar{B}+l(a,b,c)BA \\ h(a,b)B+l(a,b,c)\bar{B}\bar{C} & \quad +j.g(b,c,a)(\bar{A}\bar{B}\bar{C}+j.CBA) & e^c+j^2.f(c,a)A\bar{C}+f(c,b)C\bar{B} \\ h(a,c)\bar{C}+l(a,b,c)CB & h(b,c)C+l(a,b,c)\bar{C}\bar{A} & \quad +j^2.g(c,a,b)(\bar{A}\bar{B}\bar{C}+j.CBA) \end{pmatrix},$$

where

$$f(x,y)=\frac{(x-y-1)e^x+e^y}{(x-y)^2},$$

$$g(x,y,z)=\left[\frac{1}{(x-y)(x-z)}-\frac{1}{(x-y)(x-z)^2}-\frac{1}{(x-z)(x-y)^2}\right]e^x+\frac{e^y}{(y-z)(y-x)^2}+\frac{e^z}{(z-y)(z-x)^2},$$

$$h(x,y)=\frac{e^x-e^y}{x-y},$$

$$l(x,y,z)=\frac{e^x}{(x-y)(x-z)}+\frac{e^y}{(y-z)(y-x)}+\frac{e^z}{(z-x)(z-y)}.$$

From this we compute

$$\begin{aligned}\det{}_{\mathbb{Z}_3}(\exp M)=e^{a+j^2b+jc}[&\mathbb{I}+(e^{-a}f(a,b)+e^{-b}f(b,a)-e^{-(a+b)}(h(a,b))^2)\bar{A}B+(e^{-a}f(a,c)+e^{-c}f(c,a)-e^{-(a+c)}(h(a,c))^2)A\bar{C}+j(e^{-c}f(c,b)\\&+e^{-b}f(b,c)-e^{-(b+c)}(h(b,c))^2)C\bar{B}+[e^{-a}g(a,b,c)+e^{-b}g(b,c,a)+e^{-c}g(c,a,b)+e^{-(a+b+c)}h(a,b)h(b,c)h(c,a)\\&-(e^{-(a+b)}h(a,b)+e^{-(a+c)}h(a,c)+e^{-(b+c)}h(b,c))l(a,b,c)](\bar{A}\bar{B}\bar{C}+j.CBA)],\end{aligned}$$

and it is then easy to verify that all terms inside the brackets vanish, except for $\mathbb{I}$. The cases where $a=b$, $b=c$ or $c=a$ are just limits of the previous case. ■

These constructions will be used in a forthcoming paper concerning the construction of a gauge theory based on a $\mathbb{Z}_3$-graded non-commutative geometry model similar to the one used by Coquereaux *et al.*,[11] using instead Kerner's differential whose cube is zero, whereas its square is not.[8]

A q-superdimension formula for irreps of type I quantum superalgebras

J. R. Links and M. D. Gould
Department of Mathematics, University of Queensland, Queensland, 4072, Australia

(Received 17 July 1995; accepted for publication 8 August 1995)

We derive a closed formula for the q-superdimensions of a wide class of irreps, including all unitary irreps, of the type I quantum superalgebras. © *1996 American Institute of Physics.* [S0022-2488(95)03512-7]

I. INTRODUCTION

It is well known that quantum algebras[1] play an extensive role in the study of integrable systems derived through the quantum inverse scattering method. Not only do these algebras appear as underlying symmetries of these systems, but it is their quasitriangular structure which in essence allows the algebraic Bethe ansatz to be applied to diagonalize the Hamiltonians of these models. Likewise, the $\mathbb{Z}_2$-graded analogues of quantum algebras, known as quantum superalgebras,[2–4] play a similar role in integrable systems with supersymmetry. Recently, these models have attracted considerable attention since within this class of models are a number which describe correlated electron systems. These include the supersymmetric $t-j$ model,[5] the supersymmetric extended Hubbard model,[6] and the Hubbard model with correlated hopping and electron pair hopping.[7]

In the investigation of such models it is desirable to have a well-developed representation theory of the underlying symmetry algebras. The representation theory of quantum superalgebras is more complicated than that of quantum algebras. Here we will restrict our attention to the type I quantum superalgebras consisting of $U_q(\mathrm{gl}(m|n))$ and $U_q(\mathrm{osp}(2|2n))$ where several developments have been made. A description of finite-dimensional irreducible representations (irreps) is understood in terms of the induced module construction[8] generalizing that of Kac,[9] whereby the irreps fall into two distinct classes, typical and atypical. This construction also provides a means to naturally induce bilinear forms. Symmetry relations satisfied by Clebsch-Gordan coefficients defined with respect to these forms have been obtained in Ref. 10 and these results have been used to determine the eigenvalues of families of Casimir invariants in any irrep (see also Ref. 11).

The most important aspect of the type I quantum superalgebras is that they are the only ones which admit finite-dimensional unitary irreps. These are the representations which are necessary to use in describing physical models where unitarity is a requirement. For example, the correlated electron models[5–7] mentioned above are all based on unitary irreps. A classification of the unitary irreps is known[12,13] which was achieved through the use of the induced bilinear forms.

In this article, we will be concerned with developing another aspect of the representation theory of the type I quantum superalgebras; viz. the determination of the q-superdimensions of irreps which we will achieve using the results of Ref. 10. Previously, a general formula for q-superdimensions has been lacking (with the exception of the typical irreps which all have zero q-superdimension) since all the classical techniques used for non-graded algebras (e.g., see Ref. 14) fail to extend to the superalgebra case. Our results apply to a large number of irreps, including all unitary irreps (which include all covariant and contravariant tensor irreps) as we will show, and consequently will have applications to systems with physical significance. The surprising aspect of our formula is that it shows that the q-superdimension is nonzero only when the irrep has maximal atypicality. Using the results of Refs. 12 and 13 enables us to classify all the unitary irreps which have this property.

The q-superdimension formula we derive is new even in the classical ($q\to 1$) limit and agrees

0022-2488/96/37(1)/484/9/$6.00

with some particular studies using other methods such as super Young diagrams.[15] The formula is presented as a natural generalization of the Weyl dimension formula for irreps of Lie algebras. These results have an important role in the computation of link invariants as discussed in Ref. 16.

II. PRELIMINARIES

Let g denote a basic classical Lie superalgebra of rank $l+1$ with the usual generators $\{e_i,f_i,h_i\}_{i=0}^{l}$. Let $\{\alpha_i\}_{i=0}^{l}$ be the distinguished set of simple roots of g in the sense of Kac[9] and let $(,)$ be a fixed invariant bilinear form on H^*, the dual of the Cartan subalgebra H of g. We also let $\Phi^+=\Phi_0^+\cup\Phi_1^+$ denote the full set of roots with Φ_0^+ (resp. Φ_1^+) the subset of even (resp. odd) roots. Throughout, we adopt the convention that α_0 denotes the unique odd simple root. Associated with g one can define the quantum superalgebra $U_q(g)$ (q is assumed not a root of unity) which has the structure of a $\mathbb{Z}_2$-graded quasi-triangular Hopf algebra.[3] We will not give the full defining relations of $U_q(g)$ here and refer to Ref. 4 for details. We note, however, that $U_q(g)$ has a co-product structure given by

$$\Delta(q^{\pm(1/2)h_i})=q^{\pm(1/2)h_i}\otimes q^{\pm(1/2)h_i},\quad \Delta(x)=x\otimes q^{-(1/2)h_i}+q^{(1/2)h_i}\otimes x,\quad x=e_i,f_i,$$

which is extended to an algebra homomorphism to all of $U_q(g)$ in the usual way. It is important to point out that the multiplication rule for the tensor product is defined for homogeneous elements $a,b,c,d\in U_q(g)$ by

$$(a\otimes b)(c\otimes d)=(-1)^{[b][c]}(ac\otimes bd) \tag{1}$$

and extended linearly to all of $U_q(g)\otimes U_q(g)$. Here $[a]\in\mathbb{Z}_2$ denotes the degree of the homogeneous element $a\in U_q(g)$, which is defined for the elementary generators by

$$[h_i]=0,\quad [e_i]=[f_i]\equiv[i]=\delta_{i0},\quad \forall 0\leqslant i\leqslant l,$$

and extended to all homogeneous elements of $U_q(g)$ through

$$[ab]=[a]+[b](\mathrm{mod}\ 2),\quad \forall a,b\in U_q(g).$$

The twist map $T:U_q(g)\otimes U_q(g)\to U_q(g)\otimes U_q(g)$ is defined by

$$T(a\otimes b)=(-1)^{[a][b]}b\otimes a \tag{2}$$

for all homogeneous $a,b\in U_q(g)$: we set $\overline{\Delta}=T.\Delta$. Then there exists a canonical element $R\in U_q(g)\otimes U_q(g)$ called the universal R-matrix which is even and invertible and satisfies the following relations:[3]

$$R\Delta(a)=\overline{\Delta}(a)R,\quad \forall a\in U_q(g), \tag{3}$$

$$(\Delta\otimes I)R=R_{13}R_{23},\quad (I\otimes\Delta)R=R_{13}R_{12}, \tag{4}$$

where we have adopted the conventional notation. From Eqs. (3) and (4) it follows that the universal R-matrix satisfies the graded Yang–Baxter equation

$$R_{12}R_{13}R_{23}=R_{23}R_{13}R_{12}. \tag{5}$$

We emphasize that multiplication of the tensor products is to obey Eq. (1).

Let $\rho\in H^*$ denote the graded half-sum of positive roots of g and let h_ρ denote the unique element of H defined by $\alpha_i(h_\rho)=(\rho,\alpha_i)$, $\forall\alpha_i\in H^*$. We recall from Ref. 17 the following result.

Theorem 1: Let π be a fixed, but arbitrary, finite-dimensional representation of $U_q(g)$ with representation space V and set

$$\Delta_\pi = (\pi \otimes I)\Delta.$$

If $w \in U_q(g) \otimes \text{End } V$ satisfies

$$\Delta_\pi(a)w = w\Delta_\pi(a), \quad \forall a \in U_q(g), \tag{6}$$

then

$$s\tau_q(w) = (\text{str} \otimes I)(\pi(q^{2h_\rho}) \otimes I)w$$

belongs to the center Z of $U_q(g)$, where str denotes the supertrace. □

Theorem 1 enables a family of Casimir invariants to be constructed for $U_q(g)$ utilizing the universal R-matrix. Defining $R^T = TR$, it is clear from (3) that

$$R^T R\Delta(a) = \Delta(a)R^T R, \quad \forall a \in U_q(g).$$

Setting

$$A = (q - q^{-1})^{-1}(\pi \otimes I)(I \otimes I - R^T R), \tag{7}$$

then $A^l, l \in \mathbb{Z}^+$, satisfies (6). We thus obtain the family of Casimir invariants

$$C_l = s\tau_q(A^l).$$

The preceding discussion applies for any quantum superalgebra, not only those of type I. Let π_μ denote a $U_q(g)$ irrep with highest weight $\mu \in D^+$ where $D^+ \subset H^*$ is the set of dominant weights. For type I quantum superalgebras, $\mu \in D^+$ if and only if[8,9]

$$\langle \mu, \alpha_i \rangle = \frac{2(\mu, \alpha_i)}{(\alpha_i, \alpha_i)} \in \mathbb{Z}^+, \quad 1 \leqslant i \leqslant l,$$

while (μ, α_0) can take arbitrary complex values. When acting in π_μ the invariants C_l act as scalar multiples of the identity operator (Schur's lemma), which we denote by $\chi_\mu(C_l)$. In Ref. 10 a general formula for these eigenvalues is presented. We say that π_μ admits an *infinitesimal character* χ_μ which determines an algebra homomorphism

$$\chi_\mu : Z \to \mathbb{C}, \quad z \to \chi_\mu(z).$$

Recall that for type I quantum superalgebras we say that $\mu \in H^*$ is *typical* if[8,9]

$$(\mu + \rho, \alpha) \neq 0, \quad \forall \alpha \in \Phi_1^+,$$

and *atypical* otherwise. It is known[9] that for typical $\mu \in D^+$, the irrep π_μ is uniquely characterized by the infinitesimal character χ_μ. This is not the case for atypical irreps.

Finally, in view of Theorem 1, it is natural to define the q-superdimension of an irrep π_μ by

$$sd_q[\mu] = \text{str } \pi_\mu(q^{2h_\rho}),$$

which reduces to the usual superdimension when $q \to 1$. Below we will present a method of determining this quantity for a large class of irreps.

III. A q-SUPERDIMENSION FORMULA

Throughout, we let $V(\mu)$ denote the $U_q(g)$ module which affords the representation π_μ. Let $U_q(g_0)\subset U_q(g)$ be the (nongraded) quantum algebra generated by $\{e_i,f_i,h_i\}_{i=1}^l$. Each $U_q(g)$ module $V(\mu)$ reduces completely into $U_q(g_0)$ modules; i.e.,

$$V(\mu)=\bigoplus_\nu m_\nu V_0(\nu), \tag{8}$$

where m_ν denotes the multiplicity of $V_0(\nu)$. Each of the weights ν has a degree $[\nu]\in\mathbb{Z}_2$. We adopt the convention that $[\mu]=0$. Let $\Pi_+(\mu)$ denote the $U_q(g_0)$ highest weights occurring in the decomposition (8). For later use we define the following.

Definition 1. We say that $\mu\in D^+$ is *quasi-typical* if

$$\chi_\nu\neq\chi_\mu, \quad \forall\,\nu\neq\mu, \quad \nu\in\Pi_+(\mu);$$

i.e., χ_μ occurs once in the set $\{\chi_\nu|\nu\in\Pi_+(\mu)\}$.

Note that the class of quasi-typical weights includes the typical weights in D^+.

Let $\delta\in H^*$ be orthogonal to all even elements of H^* and satisfy $(\delta,\alpha_0)=1$. Clearly $(\delta,\alpha)=1$, $\forall\alpha\in\Phi_1^+$. Choosing $\beta\in\mathbb{C}$, $|\beta|\ll 1$, such that $\beta\delta,\nu+\beta\delta$ are all typical, then (8) implies the $U_q(g)$ tensor product decomposition[10]

$$V(\mu)\otimes V(\beta\delta)=\bigoplus_\nu m_\nu V(\nu+\beta\delta). \tag{9}$$

Let $P[\nu+\beta\delta]$ denote orthogonal projections onto the isotypic components $\overline{V(\nu+\beta\delta)}\equiv m_\nu V(\nu+\beta\delta)$. Since the weights $\nu+\beta\delta$ are all typical, we have, as noted previously,

$$\chi_{\nu+\beta\delta}\neq\chi_{\mu+\beta\delta}, \quad \forall\,\nu\neq\mu, \quad \nu\in\Pi_+(\mu).$$

This implies that there exists $z\in Z$ such that the central projection

$$P[\mu+\beta\delta]=\prod_{\nu\neq\mu}\left(\frac{\Delta(z)-\chi_{\nu+\beta\delta}(z)}{\chi_{\mu+\beta\delta}(z)-\chi_{\nu+\beta\delta}(z)}\right) \tag{10}$$

is well defined. Using Theorem 1 we may construct the Casimir invariant

$$\gamma_\beta=s\tau_q(P[\mu+\beta\delta]).$$

From Ref. 10 we have the following result.

Proposition 1: For any $\overline{V(\nu)}\subset V(\mu)\otimes V(\Lambda)$ such that ν and Λ are both typical and dominant, then

$$\chi_\Lambda(s\tau_q(P[\nu]))=(-1)^{[\nu]}m_\nu\prod_{\alpha\in\Phi_0^+}\frac{[(\nu+\rho,\alpha)]_q}{[(\Lambda+\rho,\alpha)]_q}\prod_{\alpha\in\Phi_1^+}\frac{[(\Lambda+\rho,\alpha)]_q}{[(\nu+\rho,\alpha)]_q},$$

where

$$[x]_q=\frac{q^x-q^{-x}}{q-q^{-1}}.$$

□

Applying Proposition 1 to the invariant γ_β we find

$$\chi_{\beta\delta}(\gamma_\beta)=\prod_{\alpha\in\Phi_0^+}\frac{[(\mu+\beta\delta+\rho,\alpha)]_q}{[(\beta\delta+\rho,\alpha)]_q}\prod_{\alpha\in\Phi_1^+}\frac{[(\beta\delta+\rho,\alpha)]_q}{[(\mu+\beta\delta+\rho,\alpha)]_q}. \tag{11}$$

Taking the limit $\beta\to 0$, Eq. (9) becomes

$$V(\mu)\otimes K(0)=\oplus_\nu m_\nu K(\nu),$$

where $K(\nu)$ denotes the Kac module[8,9] of highest weight ν. Note that $K(\nu)=V(\nu)$ if ν is typical. In the case of atypical ν, $K(\nu)$ is not irreducible but still admits the infinitesimal character χ_ν. Provided μ is quasi-typical, the central projection

$$P[\mu]=\lim_{\beta\to 0} P[\mu+\beta]$$

is well defined. Observe that $P[\mu]$ acts as the identity operator on $V(\mu)\otimes V(0)$ so

$$\chi_0(\gamma_\beta)|_{\beta=0}=sd_q[\mu].$$

On the other hand, $\chi_0(\gamma_\beta)|_{\beta=0}$ is given by (11) in the limit $\beta\to 0$ since $K(0)$ admits the infinitesimal character χ_0. Define

$$\Phi_1^+(\mu)=\{\alpha\in\Phi_1^+|(\mu+\rho,\alpha)\neq 0\}$$

and call $a_\mu=|\Phi_1^+|-|\Phi_1^+(\mu)|$ the *atypicality index* of μ. We remark that the maximal possible atypicality index is given by a_0 corresponding to the trivial one dimensional irrep. We then have the following.

Proposition 2: Suppose μ is quasi-typical. Then

$$sd_q[\mu]=\delta_{a_0 a_\mu}\prod_{\alpha\in\Phi_0^+}\frac{[(\mu+\rho,\alpha)]_q}{[(\rho,\alpha)]_q}\frac{\Pi_{\alpha\in\Phi_1^+(0)}[(\rho,\alpha)]_q}{\Pi_{\alpha\in\Phi_1^+(\mu)}[(\mu+\rho,\alpha)]_q}.$$

Proof: We may write (11) in the form

$$\chi_{\beta\delta}(\gamma_\beta)=[\beta]_q^{a_0-a_\mu}\prod_{\alpha\in\Phi_0^+}\frac{[(\mu+\beta\delta+\rho,\alpha)]_q}{[(\beta\delta+\rho,\alpha)]_q}\frac{\Pi_{\alpha\in\Phi_1^+(0)}[(\beta\delta+\rho,\alpha)]_q}{\Pi_{\alpha\in\Phi_1^+(\mu)}[(\mu+\beta\delta+\rho,\alpha)]_q}.$$

Taking the limit $\beta\to 0$, it is clear that we have a nonzero result if and only if $a_\mu=a_0$ since a_0 is the maximal atypicality index as indicated above. The proposition then follows. □

The above shows that the q-superdimension of a quasi-typical irrep π_μ vanishes identically unless $\mu\in D^+$ has maximal atypicality index.

IV. UNITARY IRREPS

Next we will show that Proposition 2 applies to all unitary irreps. The two types of unitary irreps have been classified in Refs. 12 and 13 and we refer to those articles for details. We have the following result from Ref. 18.

Proposition 3: Let C_L denote the universal second-order Casimir invariant of g. Let $V(\mu)$ be a unitary module with g_0 decomposition (8).

(i) If π_μ is a type I unitary irrep, then

$$\chi_\mu(C_L)-\chi_\nu(C_L)=(\mu-\nu,\mu+\nu+2\rho)\geqslant 0$$

with equality if and only if $\nu=\mu$.

(ii) If π_μ is a type II unitary irrep, then

$$\chi_\mu(C_L)-\chi_\nu(C_L)=(\mu-\nu,\mu+\nu+2\rho)\leqslant 0$$

with equality if and only if $\nu=\mu$. □

Proposition 3 shows that μ is quasi-typical for all unitary irreps of the Lie superalgebra g. This must also be true upon deformation into an irrep of $U_q(g)$, which is also unitary, so we can apply Proposition 2 to give the following.

Proposition 4: The q-superdimension of a finite dimensional unitary irrep π_μ is given by

$$sd_q[\mu]=\delta_{a_0 a_\mu}\prod_{\alpha\in\Phi_0^+}\frac{[(\mu+\rho,\alpha)]_q}{[(\rho,\alpha)]_q}\frac{\Pi_{\alpha\in\Phi_1^+(0)}[(\rho,\alpha)]_q}{\Pi_{\alpha\in\Phi_1^+(\mu)}[(\mu+\rho,\alpha)]_q}.$$

□

Using the classification scheme of Ref. 12, we can characterize all of the unitary irreps of $U_q(\mathrm{gl}(m|n))$ with maximal atypicality index $a_0=\min(m,n)$.

Proposition 5: For $U_q(\mathrm{gl}(m|n))$ choose $\{\varepsilon_i\}_{i=1}^{m+n}$ as a basis for H^* satisfying $(\varepsilon_i,\varepsilon_j)=(-1)^{[i]}\delta_{ij}$ where $[i]=0$ for $i=1,2,\ldots,m$ and $[i]=1$ for $i=m+1,\ldots,m+n$. In this basis, any weight $\mu\in H^*$ is expressed as $\mu=\Sigma_i\mu_i\varepsilon_i\equiv(\mu_1,\ldots,\mu_m|\mu_{m+1},\ldots,\mu_{m+n})$.

(i) Suppose $m\geqslant n$. The irrep π_μ is type I unitary with $a_\mu=n$ if and only if

$$\mu=(\mu_1,\ldots,\mu_{m-n},\dot{0}_n|\dot{0}_n), \tag{12}$$

and is type II unitary with $a_\mu=n$ if and only if

$$\mu=(\dot{0}_k,\mu_{k+1},\ldots,\mu_m|\mu_{m+1},\ldots,\mu_{m+n}),\quad k\geqslant n, \tag{13}$$

where

$$\mu_{m+j}=i_j+j-m-1,\quad j=1,\ldots,n, \tag{14}$$

and

$$\begin{aligned} i_1&=k,\\ i_j&=n+1-j,\ldots,i_{j-1}-1,\quad j=2,\ldots,n. \end{aligned} \tag{15}$$

(ii) Suppose $m\leqslant n$. The irrep π_μ is type I unitary with $a_\mu=m$ if and only if

$$\mu=(\mu_1,\ldots,\mu_m|\mu_{m+1},\ldots,\mu_{m+k-1},\dot{0}_{n-k+1}),\quad k\leqslant n-m+1,$$

where

$$\mu_i=i+j_i-m-1,\quad i=1,\ldots,m,$$

and

$$\begin{aligned} j_m&=k,\\ j_i&=j_{i+1}+1,\ldots,n+1-i,\quad i=1,\ldots,m-1. \end{aligned}$$

The irrep π_μ is type II unitary with $a_\mu=m$ if and only if

$$\mu=(\dot{0}_m|\dot{0}_m,\mu_{2m+1},\ldots,\mu_{m+n}).$$

Proof: First we will consider the case when $m\geqslant n$ and π_Λ is type I unitary. From Ref. 12 we have that μ must satisfy

$$(\mu+\rho,\varepsilon_m-\varepsilon_{m+k})=(\mu,\varepsilon_k-\varepsilon_{m+n})=0 \tag{16}$$

for some odd index $m+1\leqslant m+k\leqslant m+n$ in order to be type I unitary. For μ to have maximal atypicality requires that for each $1\leqslant j\leqslant n$, there exists $1\leqslant i_j\leqslant m$ such that

$$(\mu+\rho,\varepsilon_{i_j}-\varepsilon_{m+j})=0. \tag{17}$$

Note that the index i_j is uniquely determined since

$$(\mu+\rho,\varepsilon_i-\varepsilon_{m+j})>(\mu+\rho,\varepsilon_l-\varepsilon_{m+j}),\quad 1\leqslant i<l\leqslant m.$$

Now

$$(\mu+\rho,\varepsilon_{i_j}-\varepsilon_{m+j})=(\mu+\rho,\varepsilon_m-\varepsilon_{m+k})+(\mu+\rho,\varepsilon_{i_j}-\varepsilon_m)+(\mu+\rho,\varepsilon_{m+k}-\varepsilon_{m+j})$$

so that

$$(\mu+\rho,\varepsilon_{i_j}-\varepsilon_m)=-(\mu+\rho,\varepsilon_{m+k}-\varepsilon_{m+j}).$$

Lexicality of μ requires that $k\leqslant j$, $\forall 1\leqslant j\leqslant n$, implying that $k=1$. In view of (16) we can choose w.l.o.g.

$$\mu_m=\mu_{m+1}=\cdots=\mu_{m+n}=0.$$

Now from (17) we have

$$\mu_i=i_j+j-m-1$$

and again the lexicality of μ demands that

$$\mu_i\geqslant\mu_l\geqslant 0,\quad \forall 1\leqslant i<l<m$$

because of the choice $\mu_m=0$. There is only one solution to this system of equations which is given by

$$i_j=m+1-j,$$

and this in turn gives $\mu_{m+1-j}=0$, $j=1,\ldots,n$. All other μ_i, $i\leqslant m-n$, are arbitrary so we obtain (12).

Next we will consider the case when π_μ is type II unitary. From Ref. 12 we have that μ must satisfy

$$(\mu+\rho,\varepsilon_k-\varepsilon_{m+1})=(\mu,\varepsilon_1-\varepsilon_k)=0, \tag{18}$$

for some even index $1\leqslant k\leqslant m$. From Eq. (18) we can choose w.l.o.g.

$$\mu_1=\mu_2=\cdots=\mu_k=0. \tag{19}$$

Now for μ to have maximal atypicality requires that for each $1\leqslant j\leqslant n$ there is an even index $1\leqslant i_j\leqslant m$ such that

$$(\mu+\rho,\varepsilon_{i_j}-\varepsilon_{m+j})=0. \tag{20}$$

Equation (20) also implies that

$$(\mu+\rho,\varepsilon_{i_j}-\varepsilon_{i_l})=-(\mu+\rho,\varepsilon_{m+l}-\varepsilon_{m+j})$$

from which we deduce $i_j<i_l$ whenever $l<j$. Clearly $i_1=k$ so we conclude that $k\geqslant n$. For consistency, the remaining values of i_j must be restricted to the range of values given by (15). Equation (20) may be written as

$$\mu_{i_j}+\mu_{m+j}=i_j+j-m-1.$$

However, we see from (19) that $\mu_{i_j}=0\ \forall 1\leqslant j\leqslant n$, which then gives us (14). The remaining μ_i, $k+1\leqslant i\leqslant m$, may take arbitrary values. The case for $m\leqslant n$ may be treated similarly and this completes the proof.

Note: An interesting example is the case of $U_q(\mathrm{gl}(m|m))$. The above shows that apart from the exception of the trivial irrep with $\mu=(\dot{0}_m|\dot{0}_m)$, all unitary irreps have zero q-superdimension.

For the case of $U_q(\mathrm{osp}(2|2n))$, all irreps have atypicality index of either 0 or 1. Thus the unitary irreps with maximal atypicality are simply the atypical unitary irreps. From Ref. 13 we have the following classification.

Proposition 6: For $U_q(\mathrm{osp}(2|2n))$, choose $\{\varepsilon_i\}_{i=0}^n$ as a basis for H^* satisfying $(\varepsilon_i,\varepsilon_j)=(-1)^{\delta_{i0}}\delta_{ij}$. The irrep π_μ is type I unitary with $a_\mu=1$ if and only if

$$(\mu,\varepsilon_0-\varepsilon_1)=0.$$

The irrep π_μ is type II unitary with $a_\mu=1$ if and only if there exists an index $j\in\{1,\ldots,n\}$ such that

$$(\mu+\rho,\varepsilon_0+\varepsilon_j)=(\mu,\varepsilon_1-\varepsilon_j)=0;$$

or $\mu=0$.

V. CONCLUSION

We have derived a formula for the q-superdimensions of a class of irreps, referred to as quasi-typical, for the type I quantum superalgebras. The quasi-typical irreps are a natural generalization of typical irreps and include the important class of all unitary irreps. In future work we aim to characterize and investigate the properties of the quasi-typical irreps.

Our q-superdimension formula is new even in the classical ($q\to 1$) limit. It has long been known that all the typical irreps have zero q-superdimension.[9,17] Our formula gives the surprising result that the quasi-typical irreps with maximal atypicality index have nonzero q-superdimension, while all other quasi-typical irreps have q-superdimension equal to zero. For the unitary irreps, we have given a classification of those with maximal atypicality index in terms of the highest weight labels. An example of an application of these results is in the computation of link invariants as discussed in Ref. 16.

Calabi–Yau compactifications and the global structure of the standard group

Brett McInnes
Department of Mathematics, National University of Singapore, 10 Kent Ridge Crescent, Singapore 119260, Republic of Singapore

(Received 13 February 1995; accepted for publication 29 September 1995)

The ''standard group'' of elementary particle theory is *locally* isomorphic to SU(3) $\times$SU(2)$\times$U(1). The *global* structure is completely fixed in unified theories, often in a subtle way; and such theories can be physically unacceptable if they predict the ''wrong'' global structure for the standard group. A particularly striking example of this is provided by Calabi–Yau compactifications of string theory with the *linear* (rather than the more conventional spinor) connection interpreted as an E_8 connection. Remarkably, these more unconventional compactifications break E_8 to a group which is locally isomorphic to the standard group (instead of E_6); but they are physically unacceptable, and we argue that the basic reason for this is their failure to produce the correct global structure. © *1996 American Institute of Physics.* [S0022-2488(96)03701-9]

I. INTRODUCTION

One of the most remarkable results of work on Kaluza–Klein theories[1] was the discovery that higher-dimensional theories can yield chiral fermions only if K, the internal manifold, admits a nontrivial vacuum gauge potential. The geometry of K itself supplies, through parallel transport, candidates for this vacuum gauge potential; if these are used for this purpose, one says[2] that the ''spin connection is embedded in the gauge group.''

However, a closer analysis of this procedure reveals a basic ambiguity. Every Riemannian spin manifold[3] carries at least *two* distinct principal bundles defined by its geometry: a bundle of oriented orthonormal frames, SO(K) (with structural group SO(n),$n=\dim K$), and at least one bundle of spinor frames spin(K) (with structural group spin(n)). The familiar Levi–Civitá connection on K may be regarded as a one-form ω_L on SO(K), but it also defines a ''Dirac connection'' ω_D on spin(K). (This, in turn, defines the spinor covariant derivative.) The question now is this: when, as in string theory, we use the geometry of K to define a vacuum gauge potential, how are we to decide whether to use ω_L or ω_D?

The distinction between ω_L and ω_D can most usefully be expressed as follows. Suppose that K is a Calabi–Yau manifold. Then, as is well-known, its *linear* holonomy group is a subgroup of SO(6) which happens to be isomorphic to SU(3). Notice that the *linear* holonomy group (i.e., the holonomy group defined by the Levi–Civitá connection ω_L) is necessarily a subgroup of SO(6). On the other hand, the Dirac connection ω_D, like every connection, also has a holonomy group; but *this* group is necessarily a subgroup of spin(6), *not* SO(6). In fact, it can be shown that under certain reasonable technical conditions, the holonomy group of ω_D is also abstractly isomorphic to SU(3). Nevertheless, ω_L and ω_D are distinct objects, and this distinction is expressed through the fact that one holonomy group is a subgroup of SO(6), while the other is a subgroup of spin(6).

The usual procedure[2] in string theory is to embed SU(3) in the exceptional group E_8 through SU(3)$\cdot E_6$. (Here and henceforth, the dot denotes a direct product modulo some finite subgroup—in this case, the cyclic group of order three, $\mathbb{Z}_3$.) It can be shown that this is equivalent to an embedding through spin(6)$\cdot$spin(10) (which is a subgroup of spin(16)/$\mathbb{Z}_2$, a maximal connected subgroup of E_8). Thus we see that the standard procedure in string theory is to use the Dirac connection ω_D to define the vacuum E_8 gauge potential on K. But why should we do this—why not use the (more fundamental) Levi–Civitá connection ω_L? In this article, we shall

0022-2488/96/37(1)/493/6/$6.00
J. Math. Phys. **37** (1), January 1996

investigate the consequences of doing so: i.e., we embed SU(3) in E_8 through SO(6) instead of spin(6). The results are rather striking. Instead of E_6, we find that E_8 is broken directly to a group which is locally isomorphic to $SU(3)\times SU(2)\times U(1)$. However, the global structure (including discrete symmetries) is unsatisfactory, and so these unconventional compactifications must be rejected. (We stress that this result has no bearing on the conventional Calabi–Yau compactifications which do indeed break E_8 to E_6; we merely wish to clarify the importance of making the correct choice between ω_D and ω_L.)

II. REMARKS ON THE GLOBAL STRUCTURE OF THE STANDARD GROUP

The gauge group of the standard model is usually given as $SU(3)\times SU(2)\times U(1)$. However, it is often argued[4,5] that the correct form (the "true group") is $[SU(3)\times SU(2)]\cdot U(1)$, where the dot indicates that a finite subgroup has been factored out. This finite subgroup is $\mathbb{Z}_3\times\mathbb{Z}_2(=\mathbb{Z}_6)$. The argument is essentially as follows. If G is a Lie group and F is a finite normal subgroup, then every representation of G/F is likewise a representation of G; but the converse is not true. Thus in passing from $SU(3)\times SU(2)\times U(1)$ to $[SU(3)\times SU(2)]\cdot U(1)$, some representations are "lost." However, it so happens that these representations invariably correspond to particles which apparently do not exist. For example, all charged quarks are assigned to representations of $SU(3)\cdot U(1)^q$ (where $U(1)^q$ is the electromagnetic subgroup of $SU(2)\cdot U(1)$); the representations of $SU(3)\times U(1)^q$ that fail to "factor through" are never used.[5]

The reader may be inclined to dismiss this as hair splitting—after all, the fact is that all representations of $SU(3)\cdot U(1)^q$ are representations of $SU(3)\times U(1)^q$—but the question is of genuine interest if discrete symmetries are included. Let us write $SU(3)\times U(1)$ as $SU(3)\times SO(2)$. Then $SU(3)\cdot SO(2)$ is obtained by factoring out the $\mathbb{Z}_3$ generated by the pair (u,v), where u and v are fixed central elements of order three in SU(3) and SO(2), respectively. This $\mathbb{Z}_3$ is of course normal in $SU(3)\times SO(2)$. But now consider the *disconnected* group $SU(3)\times O(2)$. The reader can readily verify that $\mathbb{Z}_3$ is *not* a normal subgroup of this group—notice that, unlike SO(2), O(2) is not Abelian. Hence $\mathbb{Z}_3$ cannot be factored out, and $SU(3)\times O(2)$ has no representations which restrict to representations of $SU(3)\cdot SO(2)$. In this case, we can definitely assert that $SU(3)\times O(2)$ must be rejected on physical grounds, despite the fact that its *local* structure is identical to that of $SU(3)\times U(1)$ and $SU(3)\cdot U(1)$. In short, global properties can have unacceptable consequences even if the local structure is correct.

III. CALABI–YAU COMPACTIFICATIONS BASED ON LINEAR HOLONOMY

In this section we investigate unconventional Calabi–Yau compactifications with SU(3) embedded in E_8 through SO(6), instead of the usual spin(6) subgroup.

As we shall see, the final gauge group is necessarily disconnected. We can turn this to good account by gauging the CP operator, as advocated in Ref. 6. In string theories, CP always has a natural geometric interpretation in terms of antiholomorphic isometries of K. Let β be such an isometry, with $\beta^2=1$, and let α be the parity isometry of M_4: then CP is related[2] to $\alpha\beta$. As M_4 is flat, the bundle $SO^+(M_4\times K)$ consisting of time and space oriented orthonormal frames over $M_4\times K$ is reducible to an SU(3) bundle P. But while the natural lift[7] of $\alpha\beta$, denoted $\tilde{\alpha}\tilde{\beta}$, is an automorphism of $SO^+(M_4\times K)$ (because α and β are orientation-reversing on M_4 and K separately, so that $\alpha\beta$ is orientation-preserving), it does not restrict to an automorphism of P. Therefore we adjoin to P all those frames in $SO^+(M_4\times K)$ obtained by reversing directions according to the action of the matrix

$$\sigma=\mathrm{diag}(1,-1,-1,-1,1,1,1,-1,-1,-1).$$

Then σ is an element of $\mathrm{SO}^+(1,9)$; it generates a cyclic subgroup of order 2. (The first four entries act on frames over M_4; the last six act on frames over K.) The resulting bundle P^* over $M_4\times K$ is an $\mathrm{SU}(3)\rtimes\mathbb{Z}_2$ bundle, where the product is semidirect and $\mathbb{Z}_2$ acts on SU(3) by complex conjugation. (Note that SU(3) is embedded in $\mathrm{SO}^+(1,9)$ through

$$A+iB\to\mathrm{diag}\left(I_4,\begin{pmatrix}A & -B\\ B & A\end{pmatrix}\right)\in\mathrm{SO}^+(1,9),$$

so that conjugation by σ does indeed map $A+iB$ to $A-iB$.) Clearly $\tilde{\alpha}\tilde{\beta}$ does restrict to an automorphism of P^*. Our objective is to extend the latter to an E_8 bundle, and so we must embed $\mathrm{SU}(3)\rtimes\mathbb{Z}_2$ in E_8.

As explained above, we wish to embed SU(3) in E_8 through SO(6) (just as SU(3) is embedded in $\mathrm{SO}^+(1,9)$ through SO(6)). There is a very natural way to do this, as follows. E_8 contains $\mathrm{SU}(2)\cdot E_7$ as a maximal connected subgroup, and E_7 likewise contains $\mathrm{SU}(3)\cdot\mathrm{SU}(6)$. Thus E_8 contains $[\mathrm{SU}(2)\times\mathrm{SU}(3)]\cdot\mathrm{SU}(6)$, the dot as usual meaning that the respective centers (both isomorphic to $\mathbb{Z}_2\times\mathbb{Z}_3=\mathbb{Z}_6$) are identified in E_8, so that the product is not direct in the usual sense. As SU(6) contains SO(6) in an obvious way, we have our embedding of SO(6) in E_8. In fact, we can even embed O(6) in E_8 in much the same way. To see this, let (a,b,c) denote any element of $[\mathrm{SU}(2)\times\mathrm{SU}(3)]\cdot\mathrm{SU}(6)$. (Because of the identifications mentioned earlier, all triples of the form (x^3I_2,x^2I_3,xI_6), where x is any sixth root of unity, are identified in this group.) Now let S be the element of this group given by (recall the definition of σ)

$$S=\left(z^3\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix},\quad z^2\begin{pmatrix}-1 & 0 & 0\\ 0 & -1 & 0\\ 0 & 0 & -1\end{pmatrix},\quad z\cdot\mathrm{diag}(1,1,1,-1,-1,-1)\right),$$

where z is a primitive 12th root of unity. Then $S^2=1$, and, if SO(6) is the real subgroup of SU(6), it is clear that

$$\mathrm{O}(6)=\mathrm{SO}(6)\cup S\cdot\mathrm{SO}(6)$$

is indeed isomorphic to O(6). Thus we have O(6) as a subgroup of $[\mathrm{SU}(2)\times\mathrm{SU}(3)]\cdot\mathrm{SU}(6)$, and hence as a subgroup of E_8. This in turn yields the desired embedding of $\mathrm{SU}(3)\rtimes\mathbb{Z}_2$ in E_8.

The $\mathrm{SU}(3)\rtimes\mathbb{Z}_2$ bundle P^* may now be extended to an E_8 bundle,[8] denoted E, and the Levi–Civitá connection on P^* induces a connection ω on E. In this way, we equate the gauge connection to the linear connection, and at the same time associate an element of E_8 with the action of $\alpha\beta$ on $M_4\times K$ (i.e., we "gauge" the CP operator.[6] See below for the precise construction of the E_8 element associated with $\alpha\beta$.)

The final gauge symmetry group of this theory is the group of all those automorphisms of E which cover the cyclic group of order two generated by $\alpha\beta$, and which preserve ω. That is, we need to study the group of all maps $F:E\to E$ which commute with the action of E_8 on E, which satisfy $F^*\omega=\omega$, and which induce either $\alpha\beta$ or the identity map on the base manifold. This group is naturally isomorphic to a subgroup of E_8, as follows. First, the subgroup V_ω which covers the identity (i.e., the group of *vertical* automorphisms preserving ω) is isomorphic[9] to the centralizer of the holonomy group in E_8. This centralizer, which we also denote by V_ω, depends on the embedding of SU(3) in E_8: when the embedding is through spin(6), it is isomorphic to E_6, but not when the embedding is through SO(6). Second, the automorphisms covering $\alpha\beta$ correspond to the E_8 elements of the form $S\cdot V_\omega$, where S was defined above. Hence the full symmetry group is

$$V_\omega\cup S\cdot V_\omega,$$

which has the structure $V_\omega \rtimes \mathbb{Z}_2$. (Note that as conjugation by S is an automorphism of SU(3), it is also an automorphism of the centralizer of SU(3) in any group containing S and SU(3).) With the spin(6) embedding, this means that E_8 is broken to a subgroup of the form $E_6 \rtimes \mathbb{Z}_2$, as one expects if CP is gauged. To find the corresponding subgroup in the SO(6) case, we need to compute the centralizer of SU(3) with that embedding.

As SU(6) is embedded in E_8 through $[\mathrm{SU}(2)\times\mathrm{SU}(3)]\cdot\mathrm{SU}(6)$, it is clear that the centralizer of SO(6) must contain SU(2)×SU(3). In fact, the *full* centralizer is the disconnected group[10]

$$[\mathrm{SU}(2)\times\mathrm{SU}(3)]\rtimes\mathbb{Z}_2,$$

where the product is semidirect, and where $\mathbb{Z}_2$ is generated by an element R_0 contained in E_8 (but not in $[\mathrm{SU}(2)\times\mathrm{SU}(3)]\cdot\mathrm{SU}(6)$), such that $R_0^2=1$ and conjugation by R_0 induces complex conjugation on SU(2), SU(3), and SU(6). In fact we shall find it more convenient to describe $[\mathrm{SU}(2)\times\mathrm{SU}(3)]\rtimes\mathbb{Z}_2$ in the following slightly different way. Let Q be the element of $[\mathrm{SU}(2)\times\mathrm{SU}(3)]\cdot\mathrm{SU}(6)$ defined by

$$Q=\left(z^3\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}, I_3, I_6\right),$$

where z is as in the definition of S. Defining

$$R=QR_0,$$

we see that $R^2=1$, and so we may regard R as the generator of $\mathbb{Z}_2$ in $[\mathrm{SU}(2)\times\mathrm{SU}(3)]\rtimes\mathbb{Z}_2$. Note that R commutes with SO(6), and that

$$SR=SQR_0=QSR_0=QR_0\bar{S}=R\bar{S},$$

where

$$\bar{S}=\left(\bar{z}^3\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}, \quad \bar{z}^2\begin{pmatrix}-1 & 0 & 0\\ 0 & -1 & 0\\ 0 & 0 & -1\end{pmatrix}, \quad \bar{z}\cdot\mathrm{diag}(1,1,1,-1,-1,-1)\right).$$

But the latter is just the product of $(\bar{z}^6 I_2, \bar{z}^3 I_3, \bar{z}^2 I_6)$ with S; and since $\bar{z}^2$ is a sixth root of unity, we find that $\bar{S}=S$. Thus in fact $SR=RS$. In short, the centralizer of SO(6) in E_8 is $[\mathrm{SU}(2)\times\mathrm{SU}(3)]\rtimes\mathbb{Z}_2$, where the generator of $\mathbb{Z}_2$ can be chosen to commute with S.

If the holonomy group of K were isomorphic to SO(6), then, we would obtain a gauge group with identity component SU(2)×SU(3), which is of course too small to be useful. But within SO(6), SU(3) commutes with all matrices of the form

$$\begin{bmatrix} I_3\cos\theta & -I_3\sin\theta\\ I_3\sin\theta & I_3\cos\theta\end{bmatrix},$$

and so the gauge group acquires *an additional factor*, isomorphic to U(1), if the holonomy group is SU(3). Note that this U(1) contains the $\mathbb{Z}_2$ in the center of SU(6) (generated by $-I_6$) but *not* the $\mathbb{Z}_3$, since that latter is not generated by a real matrix. Thus U(1) intersects the SU(2) factor in $[\mathrm{SU}(2)\times\mathrm{SU}(3)]\rtimes\mathbb{Z}_2$ nontrivially, but not the SU(3) factor. In our earlier agreed notation, the identity component of the final gauge group is

$$[\mathrm{U}(1)\cdot\mathrm{SU}(2)]\times\mathrm{SU}(3).$$

Thus indeed the linear connection ω_L breaks E_8 differently:instead of the E_6 produced by the Dirac connection, we obtain a group which is locally indistinguishable from the standard group. This result is all the more striking when we recall that, even with the aid of the ''Hosotani mechanism,'' the conventional approach[2] cannot produce a final gauge group of rank lower than five.

These alternative string theories must, however, be rejected. One can show this in various ways; but the most fundamental defect of these theories is that they do not produce an acceptable global structure for the gauge group.

The group $[\mathrm{U}(1)\cdot\mathrm{SU}(2)]\times\mathrm{SU}(3)$ is not globally isomorphic to the ''true group'' of Ref. 4; the latter is obtained by identifying the center of SU(3) with the $\mathbb{Z}_3$ subgroup of U(1). That is, our gauge group is a covering group of the true group. But this in itself is not a fatal objection: it becomes so only when we consider the structure of the full, disconnected gauge group. Setting $G_0=[\mathrm{U}(1)\cdot\mathrm{SU}(2)]\times\mathrm{SU}(3)$, we have found that the full gauge group, including CP, is the E_8 subgroup

$$G=G_0\cup S\cdot G_0\cup R\cdot G_0\cup RS\cdot G_0.$$

Here, S and R satisfy $S^2=R^2=1$, $RS=SR$; conjugation by S acts as conjugation by

$$\begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}$$

on SU(2), as complex conjugation on U(1) (because

$$\begin{pmatrix} I_3 & 0 \\ 0 & -I_3 \end{pmatrix}\begin{pmatrix} I_3\cos\theta & -I_3\sin\theta \\ I_3\sin\theta & I_3\cos\theta \end{pmatrix}\begin{pmatrix} I_3 & 0 \\ 0 & -I_3 \end{pmatrix}=\begin{pmatrix} I_3\cos\theta & I_3\sin\theta \\ -I_3\sin\theta & I_3\cos\theta \end{pmatrix},$$

which is complex conjugation for U(1) as a subgroup of SO(6)), and trivially on SU(3). Conjugation by R acts as complex conjugation followed by

$$\mathrm{Ad}\begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}$$

on SU(2), trivially on U(1), and as complex conjugation on SU(3). Conjugation by RS therefore acts simply as complex conjugation on all three factors, and so it is RS that corresponds to the conventional CP operator. Thus finally E_8 is broken to a subgroup isomorphic to a semidirect product of $[\mathrm{U}(1)\cdot\mathrm{SU}(2)]\times\mathrm{SU}(3)$ with $\mathbb{Z}_2\times\mathbb{Z}_2$.

Now the subgroup which must be factored out if the identity component is to coincide with the true group[4] (i.e., $[\mathrm{SU}(3)\times\mathrm{SU}(2)\times\mathrm{U}(1)]/\mathbb{Z}_6$), is the diagonal subgroup of the central subgroup $\mathbb{Z}_3\times\mathbb{Z}_3\subset\mathrm{U}(1)\times\mathrm{SU}(3)$. But it is clear that, since $\mathrm{Ad}(R)$ and $\mathrm{Ad}(S)$ act differently on the two $\mathbb{Z}_3$ factors, the diagonal subgroup is *not* normal in any group containing either R or S. It *is* normal in $G_0=[\mathrm{U}(1)\cdot\mathrm{SU}(2)]\times\mathrm{SU}(3)$, and also in $G_0\cup RS\cdot G_0$, but not in the full group with four connected components. Consequently the latter does not possess representations that can accommodate the known elementary particles, and the theory must therefore be rejected.

IV. CONCLUSION

We argue that there are two ways of interpreting, in string theory, the construction of a nontrivial vacuum gauge potential. The usual procedure is based on spinor parallel transport. In this article we have investigated the alternative, using linear (vector) parallel transport. Despite being initially attractive, these unconventional compactifications must be rejected; and this conclusion probably cannot be evaded, since it is obtained by very general (topological) arguments.

We prove the embedding of $ISO_q(3) \hookrightarrow ISU^{\mathrm{ex}}_{\sqrt{q}}(2)$ and $ISO_q(2,1) \hookrightarrow ISL^{\mathrm{ex}}_q(2,R)$ as $*$-algebras and give a Hilbert space representation of $ISU^{\mathrm{ex}}_{\sqrt{q}}(2)$. © *1996 American Institute of Physics.* [S0022-2488(96)00301-9]

I. INTRODUCTION

The inhomogenized extensions of a large list of standard quantized Lie groups[1] have been given in Refs. 2–7. They form quantized versions of the classical inhomogeneous groups. For a real deformation parameter q the representation theory of the homogeneous parts (e.g., corepresentations of the function algebra) is basically the same as for the classical groups, whereas for q root of unity it is completely different. However, the representation theory of the noncommutative function algebra differs for any $q \neq 1$ from the classical situation. Its relevance stems from the question of whether a deformation exists on the C^*-algebra level.[8]

In Sec. II we recall the properties of inhomogeneous quantum groups. In Sec. III we examine the algebraic embedding of the $ISO_q(3)$ into $ISU^{\mathrm{ex}}_{\sqrt{q}}(2)$ and $ISO_q(2,1)$ into $ISL^{\mathrm{ex}}_q(2,R)$. Here the "extended inhomogeneous" quantum algebra IG^{ex} designates inhomogeneous quantum algebras containing two sets of coordinate functions.

In Sec. IV we examine the representation theory of the $ISU^{\mathrm{ex}}_{\sqrt{q}}(2)$.

II. THE HOPF ALGEBRA STRUCTURE OF INHOMOGENEOUS QUANTUM GROUPS

Quantum groups may be considered to be deformations of the function algebra over the corresponding Lie groups. The deformation is given by a parameter $q \in \mathbb{C}$ which has to be further restricted in order to get special cases of deformations. Quantum groups exhibit a Hopf algebra structure. The noncommutative algebra structure is controlled by an $\hat{R}$ matrix fulfilling the quantum Yang–Baxter equation $\hat{R}_{12}\hat{R}_{23}\hat{R}_{12} = \hat{R}_{23}\hat{R}_{12}\hat{R}_{23}$. In this paper we refer to $\hat{R}$ matrices in their standard form given in Ref. 1. They are defined by their projector decomposition making use of the antisymmetrizer $\hat{A}^{ij}_{q\,kl}$, the symmetrizer $\hat{S}^{ij}_{q\,kl}$, and the trace projector $\hat{T}^{ij}_{q\,kl} \propto C^{ij}C_{kl}$ with the metric C_{ij}, existing for the q-orthogonal groups only:

$$\hat{R}^{ij}_{q\,kl} = \begin{cases} q\hat{S}^{ij}_{q\,kl} - q^{-1}\hat{A}^{ij}_{q\,kl}, & [\text{for } SL_q(N)] \\ q\hat{S}^{ij}_{q\,kl} - q^{-1}\hat{A}^{ij}_{q\,kl} + q^{1-N}\hat{T}^{ij}_{q\,kl}, & [\text{for } SO_q(N)]\ . \end{cases} \tag{1}$$

The algebra relations for the generators M^i_j of the unital $\mathbb{C}$ algebra $\mathscr{A}$ are

$$\hat{R}^{ij}_{q\,j'i'} M^{j'}{}_{j''} M^{i'}{}_{i''} = M^i{}_{i'} M^j{}_{j'} \hat{R}^{i'j'}_{q\,j''i''} \tag{2}$$

and

$$\begin{cases} \det M = \dfrac{(-1)^{N-1}}{[N]!}\, \epsilon^{k_1,\ldots,k_N} M^{l_1}{}_{k_1} \ldots M^{l_N}{}_{k_N} \epsilon_{l_1,\ldots,l_N} = \mathbf{1}\ , & [SL_q(N)]\ , \\ C_{ij} M^i{}_{i'} M^j{}_{j'} = C_{i'j'}\mathbf{1}\ , & [SO_q(N)]\ . \end{cases} \tag{3}$$

For the unimodularity condition we use the q-antisymmetric tensors ϵ_q defined in Refs. 2 and 3.

In order to obtain inhomogeneous quantum groups the set of generators has to be enlarged not only by the coordinate functions x_i but by an invertible scaling operator $\bar{w}$ as well. Its existence is required by consistency of the comultiplication. The additional algebra relations of the extended Hopf algebra $\mathscr{A}^I$ are

$$\begin{aligned} &\text{(i)}\quad x^i M^j{}_k = \gamma \hat{R}^{ij}_{q\,lm} M^l{}_k x^m, && \text{(iv)}\quad w M^i{}_j = M^i{}_j w, \\ &\text{(ii)}\quad \bar{w} w = \mathbf{1}, && \text{(v)}\quad \bar{w} x^i = \frac{q}{\gamma}\, x^i \bar{w}, \\ &\text{(iii)}\quad \bar{w} M^i{}_j = M^i{}_j \bar{w}, && \text{(vi)}\quad w x^i = \frac{\gamma}{q}\, x^i w, \end{aligned} \tag{4}$$

with

$$\gamma = \begin{cases} q^{-1/N}, & [\text{for } SL_q(N)], \\ 1, & [\text{for } SO_q(N)]. \end{cases} \tag{5}$$

The comultiplication $\Phi: \mathscr{A}^I \to \mathscr{A}^I \otimes \mathscr{A}^I$, counit $e: \mathscr{A}^I \to \mathbb{C}$ and the antipode $\kappa: \mathscr{A}^I \to \mathscr{A}^I$ are very easily given in matrix notation. With

$$M^I = \begin{pmatrix} wM & \mathbf{x} \\ 0 & 1 \end{pmatrix} \tag{6}$$

we get

$$\Phi(M^I) = M^I \dot{\otimes} M^I \tag{7}$$

and

$$e(M^I) = \begin{pmatrix} E & \mathbf{0} \\ 0 & 1 \end{pmatrix} \tag{8}$$

with the unity matrix E. The antipode is given as

$$\kappa(M^I) = \begin{pmatrix} \kappa(M)\bar{w} & -\kappa(M)\bar{w}\mathbf{x} \\ 0 & \mathbf{1} \end{pmatrix}. \tag{9}$$

A. Complex conjugation

The $*$-operations on $\mathscr{A}$ are defined quite differently in the cases $q \in \mathbb{R}^+$ and $|q| = 1$.

1. $q \in \mathbb{R}^+$

With the unitarity condition $(M^i_j)^* = \kappa(M^j_i)$, the quantum group $SL_q(N)$ becomes an $SU_q(N)$ quantum group. The same $*$-structure holds for the orthogonal quantum groups $SO_q(N)$.

2. $|q| = 1$

For such q the R_q matrix has the property $R_q^* = R_q^{-1}$. With the reality condition $(M^i_j)^* = M^i_j$ one finds the real representation of the quantum group $SL_q(N)$ called $SL_q(N,R)$ and the orthogonal quantum groups in this case have a metric which is indefinite, i.e., for N even we get $SO_q(n,n)$ and for N odd $SO_q(n,n+1)$, with $N = 2n$ or $N = 2n+1$, respectively.

The complex conjugation for the inhomogeneous extensions of these function algebras have to be treated separately as well.

(a) In the case $q \in \mathbf{R}^+$ we have to enlarge the generating set of the $*$-Hopf algebra $\mathscr{A}^l$ by the conjugate coordinate functions $\bar{x}_i$. The additional algebra relations are

$$\begin{aligned} &\text{(i)} \quad M^l{}_s \bar{x}_j = \frac{1}{\gamma} \hat{R}_q^{al}{}_{ij} \bar{x}_a M^i{}_s, \quad &&\text{(iii)} \quad \bar{w}\bar{x}_i = \frac{q}{\gamma} \bar{x}_i \bar{w}, \\ &\text{(ii)} \quad w\bar{x}_i = \frac{\gamma}{q} \bar{x}_i w, &&\text{(iv)} \quad x^i \bar{x}_j = \frac{1}{q} \bar{x}_a x^b \hat{R}_q^{ai}{}_{bj}. \end{aligned} \tag{10}$$

The comultiplication of $\bar{x}_i$ follows from being an $*$-homomorphism and the antipode from the fact that $\kappa \circ * \circ \kappa \circ * = id$.

(b) When $|q| = 1$ the coordinate functions may be chosen to be real ($x_i^* = x_i$), since applying the $*$ to Eq. (4i) and taking into account that $R_q^{ij*}{}_{kl} = R_q^{-1ij}{}_{kl}$, we get

$$M^j{}_k x^i = \gamma^{-1} R_q^{-1ji}{}_{lm} x^m M^l{}_k \tag{11}$$

or

$$\gamma \hat{R}_q^{rs}{}_{ji} M^j{}_k x^i = \delta^r_m \delta^s_l x^m M^l{}_k. \tag{12}$$

III. ALGEBRAIC EMBEDDING

The $\hat{R}$-matrix of $SU_{\sqrt{q}}(2)$ is decomposed using the q-antisymmetric ϵ-tensor:

$$\hat{R}^{\mu\nu}_{\sqrt{q}\rho\sigma} = \sqrt{q}\, \delta^\mu_\rho \delta^\sigma_\nu + \epsilon^{\mu\nu} \epsilon_{\rho\sigma} \tag{13}$$

with

$$\epsilon_{\mu\nu} := \begin{pmatrix} 0 & q^{-1/4} \\ -q^{1/4} & 0 \end{pmatrix}_{\mu\nu} = -e^{\mu\nu}.$$

For the homogeneous parts the embedding $SO_q(3) \hookrightarrow SU_{\sqrt{q}}$ is well known.[9] With the q-deformed Clebsch–Gordan coefficients $c^i_{\mu\nu}$ of the product decomposition of the $SU_{\sqrt{q}}(2)$:[10]

$$c^1_{\mu\nu} := \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}_{\mu\nu}, \quad c^2_{\mu\nu} := \frac{1}{\sqrt{1+q}} \begin{pmatrix} 0 & \sqrt{q} \\ 1 & 0 \end{pmatrix}_{\mu\nu}, \quad c^3_{\mu\nu} := \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}_{\mu\nu} \tag{14}$$

and $c^i_{\mu\nu} = c^{\mu\nu}_i$ the matrix elements M^i_j of $SO_q(3)$ are given in terms of $SU_{\sqrt{q}}(2)$ elements m^μ_ν by

$$M^i{}_j := c^i_{\mu\nu} m^\mu{}_\rho m^\nu{}_\sigma c^{\rho\sigma}_j. \tag{15}$$

This is verified by checking the $\hat{R}$-matrix of the $SO_q(3)$ group to be

$$\frac{1}{q}\, \eta^i{}_{i'} \eta^j{}_{j'} c^{i'}_{\mu\rho} c^{j'}_{\sigma\lambda} \hat{r}^{\mu\nu}{}_{\mu'\nu'} \hat{r}^{\rho\sigma}{}_{\nu\tau} \hat{r}^{\tau\lambda}{}_{\tau'\lambda'} \hat{r}^{\nu'\tau'}{}_{\rho'\sigma'} c^{\mu'\rho'}_{k'} c^{\sigma'\lambda'}_{l'} \bar{\eta}^{k'}{}_k \eta^{l'}{}_l, \tag{16}$$

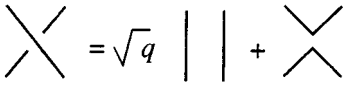
where $\hat{r}$ denotes the $\hat{R}$-matrix of the $SU_{\sqrt{q}}(2)$ group and $\eta = \mathrm{diag}(1,i,1)$, i being the imaginary unit. It just produces a base change to more convenient coordinates. Note as well the decomposition of the symmetric projector $\hat{S}^{\mu\nu}_{\sqrt{q}\rho\sigma} = c^{\mu\nu}_i c^i_{\rho\sigma}$.

In order to clear out nasty indices we want to make use of a graphical notation, which has been given in Ref. 11. With

$c^i_{\mu\nu} :=$ 

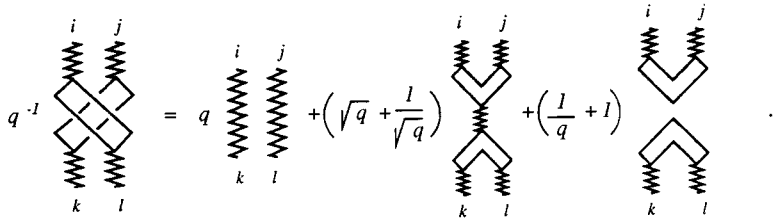
(17)

and the equality



(18)

we can disentangle the matrix



(19)

This is the $\hat{R}$-matrix of $SO_q(3)$ since obviously

$C^{ij} = \eta^i{}_{i'}\eta^j{}_{j'}$ 
(20)

and

$\hat{A}^{ij}_{q\,kl} = \eta^i{}_{i'}\eta^j{}_{j'}$  $\bar{\eta}^{k'}{}_k\bar{\eta}^{l'}{}_l$.

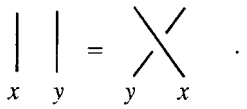
(21)

Of course the same construction holds for the $SO_q(2,1)$ group. Then η has to be chosen as an identity matrix

Since we know the q-antisymmetrizer we are able to find the $SO_q(3)$ covariant quantum plane in terms of spinor variables. To obtain sufficiently many degrees of freedom we have to take at least two copies of q-spinors x and y having the same commutation relations with m. This provides an extended inhomogeneous algebra called $ISU^{\mathrm{ex}}_{\sqrt{q}}(2)$. We want to mention that the extended algebra does not have a correct coalgebra structure. This is not important for the algebraic embedding. The three-dimensional quantum space has the form

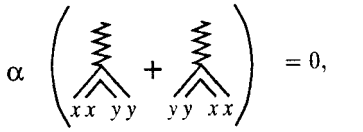
$z^i = \eta^i{}_j$ 
(22)

We fix the x,y-relations such that the element $\epsilon_{\nu\mu}x^\nu y^\mu$ commutes with the coordinate functions and get



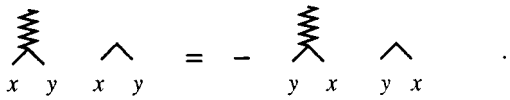
(23)

We still have to prove that $\hat{A}^{ij}_{q\,kl}z^i z^j$ vanishes. This follows from the equation



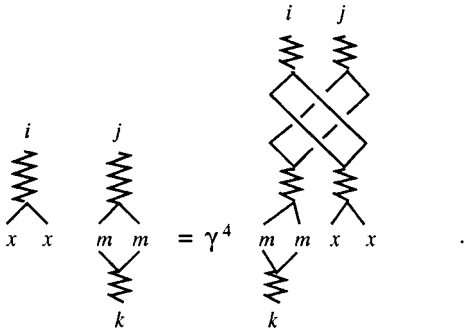
(24)

or



(25)

Next we observe that



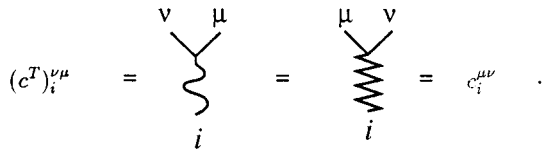
(26)

Now we have to take a look to the $*$-operation. The behavior is for q complex quite different from q real, since $(c^i_{\mu\nu})^* = c^i_{\nu\mu}$ in the first and $(c^i_{\mu\nu})^* = c^i_{\mu\nu}$ in the second case. From this we see

immediately that the algebraic embedding in the case of $ISO_q(2,1)$ respects the $*$-operation, whereas for the $ISO_q(3)$ quantum group we have to examine the $*$-structure more closely. At first for the homogeneous part we have

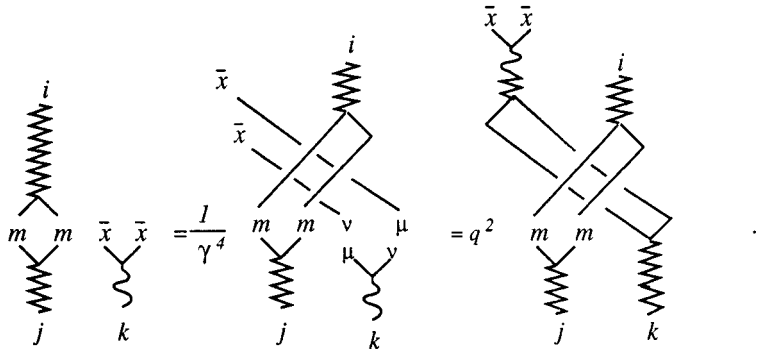
$$\kappa(c^i_{\mu\nu}m^\mu_\rho m^\nu_\sigma c^{\rho\sigma}_j)=c^i_{\mu\nu}(m^\sigma_\nu)^*(m^\rho_\mu)^*c^{\rho\sigma}_j=(c^j_{\rho\sigma}m^\rho_\mu m^\sigma_\nu c^{\mu\nu}_i)^*. \tag{27}$$

To use the graphical technique for the translations we have to introduce the ''transposed c-matrix'' c^T:



(28)

Of course $(z^i)^*=:\bar{z}_i=(c^T_i)^{\mu\nu}\bar{x}_\mu\bar{x}_\nu$. Calculating now the mixed commutation relations one has



(29)

To reproduce the correct $z-\bar{z}$ relations which use diagrams similar to that of Eq. (29) we have to redefine z as $z\to z^i=x^\mu x^\nu c^i_{\mu\nu}\bar{\omega}^n$. Now the calculation is similar to the one above and we find $n=2/3$. This relation finishes the proof of the algebraic embedding.

A. Remarks

(a) The antipode of the coordinates z just differs by a minus sign, when expressed in terms of $\kappa(x)$.

(b) The coproduct of the coordinates z cannot be embedded for obvious reasons.

IV. HILBERT SPACE REPRESENTATION FOR $ISO_q(3)$

The problem to find a representation for $ISO_q(3)$ and $ISO_q(2,1)$ is now reduced to that of representing $ISU^{\mathrm{ex}}_{\sqrt{q}}(2)$ and $ISL^{\mathrm{ex}}_q(2,\mathbb{R})$.

Here we restrict ourselves to the representation of $ISO_q(3)$. [We want to mention that $SL_q(2,\mathbb{R})$ does not exist on the C^*-algebra level anyhow.[12]] As well we confine the value of q to (0,1). However, the case $q>1$ is isomorphic. The relations of $SU_{\sqrt{q}}(2)$ are ($\mu=\sqrt{q}$):

$$\begin{gathered}\alpha\gamma=\mu\gamma\alpha,\quad \alpha\gamma^*=\mu\gamma^*\alpha,\quad \gamma\gamma^*=\gamma^*\gamma,\\ \alpha^*\alpha+\gamma^*\gamma=1,\quad \alpha\alpha^*+\mu^2\gamma^*\gamma=1.\end{gathered} \tag{30}$$

The second coordinate has the following commutation relations (remember that in our convention the quantum plane coordinates are $x^{(\tau)}$, $\tau=1,2$.):

$$x^{(2)}\alpha=\mu^{-1}\alpha x^{(2)},\quad x^{(2)}\gamma=\mu\gamma x^{(2)},$$
$$x^{(2)}\alpha^*=\mu\alpha^* x^{(2)},\quad x^{(2)}\gamma^*=\mu^{-1}\gamma^* x^{(2)}. \tag{31}$$

Applying the antipode to Eq. (31) gives

$$\alpha^*\kappa(x^{(2)})=\mu^{-1}\kappa(x^{(2)})\alpha^*,\quad \gamma\kappa(x^{(2)})=\mu\kappa(x^{(2)})\gamma,$$
$$\alpha\kappa(x^{(2)})=\mu\kappa(x^{(2)})\alpha,\quad \gamma^*\kappa(x^{(2)})=\mu^{-1}\kappa(x^{(2)})\gamma^*. \tag{32}$$

Those relations hold for any $SU_{\sqrt{q}}(2)$-covariant plane.

We have other relations for the functions on the quantum planes $x^{(\tau)}$ and $y^{(\tau)}$, $\tau=1,2$:

$$x^{(2)}y^{(2)}=\mu y^{(2)}x^{(2)},\quad \kappa(x^{(2)})\kappa(y^{(2)})=\mu^{-1}\kappa(y^{(2)})\kappa(x^{(2)}),$$
$$x^{(\tau)}\kappa(x^{(\delta)})=\mu^{-2}\kappa(x^{(\delta)})x^{(\tau)},\quad x^{(\tau)}\kappa(y^{(\delta)})=\mu^{-1}\kappa(y^{(\delta)})x^{(\tau)},$$
$$\kappa(x^{(2)})\overline{\kappa(y^{(2)})}=\mu^2\overline{\kappa(y_2)}\kappa(x_2), \tag{33}$$
$$\overline{a_\nu}\kappa(b^{(\tau)})=\kappa(b^{(\tau)})\overline{a_\nu},\quad a,b\in\{x,y\},$$
$$y^{(\tau)}\kappa(x^{(\delta)})=\mu^{-1}\kappa(x^{(\delta)})y^{\tau}+(\mu^{-2}-1)\kappa(y^{(\delta)})x^{(\tau)},$$

where $\delta,\tau\in\{1,2\}$.

These and the conjugated relations together with the obvious relations for ω contain the whole algebraic information of $ISU_{\sqrt{q}}(2)$ since

$$a^{(1)}=(\mu\gamma)^{(-1)}[\omega\kappa(a^{(2)})+\alpha a^{(2)}],\quad a,b\in\{x,y\}. \tag{34}$$

Remember that γ is an invertible element.

The algebra may still be simplified by a nonlinear transformation in the functions of coordinates. With $Q^4=\mu^2=q$ and $v^3=\omega$ we define

$$\rho_1=\overline{v^2}\gamma^{-1}x^{(2)},\quad \Theta_1=q^{-1}v\gamma^{-1}\kappa(x^{(2)}),$$
$$\rho_2=\overline{v^2}\gamma^{-1}y^{(2)},\quad \Theta_2=q^{-1}v\gamma^{-1}\kappa(y^{(2)}). \tag{35}$$

All algebraic relations with coordinate functions are given by

$$\rho_i\alpha=Q\alpha\rho_i,\quad \Theta_i\alpha=Q\alpha\Theta_i,\quad \Theta_i\Theta_i^*=\Theta_i^*\Theta_i,$$
$$\rho_i\alpha^*=Q^{-1}\alpha^*\rho_i,\quad \Theta_i\alpha^*=Q^{-1}\alpha^*\Theta_i,\quad \rho_i\rho_i^*=Q^2\rho_i^*\rho_i,$$
$$\rho_i\gamma=Q\gamma\rho_i,\quad \Theta_i\gamma=Q^{-1}\gamma\Theta_i,\quad \rho_i\Theta_i=Q^{-3}\Theta_i\rho_i, \tag{36}$$
$$\rho_i\gamma^*=Q^{-1}\gamma^*\rho_i,\quad \Theta_i\gamma^*=Q\gamma^*\Theta_i,\quad \rho_i^*\Theta_i=Q^{-1}\Theta_i\rho_i^*,$$

with $i=1,2$:

$$\begin{gathered}\Theta_1\Theta_2=Q^2\Theta_2\Theta_1, \quad \rho_1\rho_2^*=Q^2\rho_2^*\rho_1,\\ \rho_1\rho_2=Q^2\rho_2\rho_1, \quad \Theta_1\rho_2^*=Q\rho_2^*\Theta_1,\\ \rho_1\Theta_2=Q^{-1}\Theta_2\rho_1, \quad \Theta_2\rho_1^*=Q\rho_1^*\Theta_2,\\ \Theta_1\rho_2=(Q^2-Q^{-2})\Theta_2\rho_1+Q\rho_2\Theta_1, \quad \Theta_1\Theta_2^*=\Theta_2^*\Theta_1.\end{gathered} \tag{37}$$

It is easy to find a maximal real subalgebra $\mathscr{D}$ of commuting elements. In order to connect the representation of $ISO_q(3)$ to that of $SU_{\sqrt{q}}(2)$ we choose

$$\mathscr{D}:=\{\alpha\alpha^*,\gamma\gamma^*,\rho_1\rho_1^*,\Theta_1\Theta_1^*,\Theta_2\Theta_2^*,v\}. \tag{38}$$

These operators are used to label the eigenvectors of the Hilbert space. They are normalized so that the representation is given by

$$\begin{gathered}\pi(\alpha)|n,m,k,r,s,v\rangle=\sqrt{1-Q^{4n}}|n-1,m,k,r,s,v\rangle,\\ \pi(\alpha^*)|n,m,k,r,s,v\rangle=\sqrt{1-Q^{4(n+1)}}|n+1,m,k,r,s,v\rangle,\\ \pi(\gamma)|n,m,k,r,s,v\rangle=Q^{2n}|n,m-1,k,r,s,v\rangle,\\ \pi(\gamma^*)|n,m,k,r,s,v\rangle=Q^{2n+2}|n,m+1,k,r,s,v\rangle,\\ \pi(v)|n,m,k,r,s,v\rangle=|n,m,k-1,r,s,v\rangle,\\ \pi(v^*)|n,m,k,r,s,v\rangle=|n,m,k+1,r,s,v\rangle,\\ \pi(\rho_1)|n,m,k,r,s,v\rangle=Q^{-(n+m+k)+r+2s-v}|n,m,k,r-1,s,v\rangle,\\ \pi(\rho_1^*)|n,m,k,r,s,v\rangle=Q^{-(n+m+k)+r+1+2s-v}|n,m,k,r+1,s,v\rangle,\\ \pi(\rho_2)|n,m,k,r,s,v\rangle=Q^{-(n+m+k)+2r+3s-v}|n,m,k,r-1,s,v-1\rangle,\\ \pi(\rho_2^*)|n,m,k,r,s,v\rangle=Q^{-(n+m+k)+2r+1+3s-v}|n,m,k,r+1,s,v+1\rangle,\\ \pi(\Theta_1)|n,m,k,r,s,v\rangle=Q^{-(n-m+k+r+v)}|n,m,k,r,s-1,v\rangle,\\ \pi(\Theta_1^*)|n,m,k,r,s,v\rangle=Q^{-(n-m+k+r+v)}|n,m,k,r,s+1,v\rangle,\\ \pi(\Theta_2)|n,m,k,r,s,v\rangle=Q^{-(n-m+k+r-s+v)}|n,m,k,r,s-1,v-1\rangle,\\ \pi(\Theta_2^*)|n,m,k,r,s,v\rangle=Q^{-(n-m+k+r-s+v)}|n,m,k,r,s+1,v+1\rangle.\end{gathered} \tag{39}$$

V. CONCLUSIONS

We have given the algebraic embedding of two q-Euclidean groups in three dimensions. We have given an irreducible Hilbert space representation for the function algebra of $ISO_q(3)$. With a reasoning along the lines of Ref. 8 it should be possible to prove that $ISO_q(3)$ exists on a C^*-algebra level.

(Received 11 January 1995; accepted for publication 21 June 1995)

It is our purpose here to show that the spinor theory admits generalization for curved spaces with local anisotropy (for example, for Finsler, Lagrange, and generalized Lagrange spaces). © *1996 American Institute of Physics.* [S0022-2488(95)02210-7]

I. INTRODUCTION

The space–times with local anisotropy have generated growing interest in theoretical and mathematical physics.[1–8] In different models of locally anisotropic space–times one considers nonlinear and linear connections and metric structures in vector bundles (isotopic anisotropy) and tangent bundles (space–time anisotropy) on locally isotropic space–times [(pseudo)-Riemannian, Einstein–Cartan, or more general types of curved spaces with torsion and nonmetricity]. It seems likely that locally anisotropic space–times (la-spaces) make up a more convenient geometrical background for developing, in a self-consistent manner, classical and quantum statistical and field theories in dispersive media with radiational or turbulent and random processes. In this connection, the formulation of spinor theory on la-spaces presents substantial interest. Questions on spinors and la-space geometry were considered, for example, in the frame of Finsler bundles on space–time[5] and of the spinor gauge field theory,[9] but up to the present, we do not have a *rigorous* mathematical definition of spinors on la-spaces.

The aim of this paper is to present a geometric study of the Clifford and spinor structures in vector and tangent bundles provided with nonlinear and linear connections and metric structures and to formulate the spinor theory for spaces with the most general anisotropy of metric called *generalized Lagrange spaces*[1,2,10] GL-spaces.

The geometry of vector bundles, endowed with mutually adapted nonlinear connection, distinguished connection and metric structures and the geometry of GL-spaces are briefly reviewed in Sect. II. Distinguished Clifford algebras are introduced in Sec. III. Then, in Sec. IV, we define Clifford bundles and spinor structures on vector bundles and GL-spaces. Almost complex spinor structures on GL-spaces are studied in Sec. V. A brief introduction into algebraic and geometric theory of distinguished spinors in vector bundles and GL-spaces is given in Sec. VI. Finally, the results presented in the paper are discussed in Sec. VII.

II. NONLINEAR CONNECTIONS IN VECTOR BUNDLES AND GENERALIZED LAGRANGE SPACES

In this section we present for our further considerations the necessary definitions and basic results on vector bundles and spaces with local anisotropy.[1,2,11,12]

Let us introduce differentiable bundle spaces: the principal bundle, denoted as $\mathscr{P}=(P,\pi,\mathrm{Gr},M)$ where P and M are differentiable manifolds, map $\pi:P\to M$ is a differentiable surjection, and Gr is the structural group, the vector bundle, v-bundle, denoted as $\xi=(E,p,M)=(E,p,\mathrm{Gr},M,F)$ where differentiable manifolds E and M are called, respectively, the total ($E=\mathrm{tot}\,\xi$) and base ($M=\mathrm{bas}\,\xi$) spaces of v-bundle ξ, map $p:E\to M$ is a differentiable surjection, typical fiber F is a real vector space of dimension m, $\dim F=m$, and as the structural group Gr of bundle ξ we consider the group of linear transforms of F, i.e., $\mathrm{Gr}=GL(m,\mathbb{R})$.

0022-2488/96/37(1)/508/16/$6.00

For a base space M of dimension n, bundle ξ has E a space of dimension $n+m$. Local coordinates on ξ are denoted as $u=(u^\alpha)=(x^i,y^a)$, $(i=1,2,\ldots,n)$, $(a=1,2,\ldots,m)$, where $x=(x^i)$ are considered as local coordinates on M and y^a as coordinates on fiber F_x. Coordinate transforms on v-bundle ξ are defined as

$$u^\alpha=(x^i,y^a)\rightarrow u^{\alpha'}=(x^{i'},y^{a'}), \tag{1}$$

where $x^{k'}=x^{k'}(x^k)$, $\operatorname{rank}(\partial x^{k'}/\partial x^k)=n$,

$$y^{a'}=M_a^{a'}(x)y^a, \|M_a^{a'}(x)\|\in \text{ Gr},$$

matrices $M_a^{a'}$ have the property that for a superposition of coordinate transforms $(x^i,y^a)\rightarrow(x^{i'},y^{a'})\rightarrow(x^{i'},y^{a'})$,

$$M_a^{a''}(x')M_a^{a'}(x)=M_a^{a''}(x), M_a^{a'}(x)=\delta_a^{a'}.$$

The concept of nonlinear connection, i.e., N-connection, was introduced in the frame of Finsler geometry; the definition of N-connection as a global geometric structure was first given in Ref. 13 (see related topics in Refs. 14 and 15). In Refs. 1, 2, 9, and 10 N-connection structures are studied in detail.

Definition 1: A nonlinear connection in a vector bundle ξ is a distribution $\{E_u\rightarrow H_uE, T_uE=H_uE\otimes V_uE\}$ on E defining a global decomposition, as a Whitney sum, into horizontal, HE, and vertical, VE, subbundles of the tangent bundle TE:

$$TE=HE\otimes VE. \tag{2}$$

To a N-connection one associates a covariant derivation

$$\nabla_X A=X^i\left\{\frac{\partial A^a}{\partial x^i}+N_i^a(x,\,A)\right\}s_a \tag{3}$$

on M, where s_a are local linear independent sections of (E,p,M), $A=A^a s_a$ is a tensor field in E, and $X=X^i s_i$ is a vector field on M decomposed on local basis s_i.

Differentiable functions N_i^a from (3) written as functions on x^i and y^a, $N_i^a(x,\,y)$ are called coefficients of the N-connection and satisfy these transformation laws under coordinate transforms (1) and (2):

$$N_{i'}^{a'}\frac{\partial x^{i'}}{\partial x^i}=M_a^{a'}N_i^a-\frac{\partial M_a^{a'}(x)}{\partial x^i}y^a.$$

Remark 1: Linear connections are particular cases of N-connections, when $N_i^a(x,\,y)$ are parametized as $N_i^a(x,\,y)=K^a{}_{bi}(x)X^i y^b$; functions $K^a{}_{bi}(x)$ defined on M are called as Christoffel coefficients.

In vector bundle ξ we can introduce a local frame basis adapted to the given N-connection,

$$X_\alpha=\frac{\delta}{\delta u^\alpha}=\left(X_i=\frac{\delta}{\delta x^i}=\partial_i-N_i^a(x,\,y)\,\frac{\partial}{\partial y^a}, X_a=\frac{\delta}{\delta y^a}=\frac{\partial}{\partial y^a}\right). \tag{4}$$

The dual to (4) basis is defined as

$$X^\alpha=du^\alpha=(dX^i=\delta x^i=dx^i,\; X^a=\delta y^a=dy^a+N_i^a(x,\,y)dx^i). \tag{4a}$$

By using adapted bases (4) and (4a) one introduces algebra $DT(E)$ of tensorial distinguished fields (d-fields, d-tensors, d-objects) on ξ, $\mathscr{T}=\mathscr{T}^{pr}_{qs}$ which is equivalent to the tensorial algebra of the v-bundle $\pi_d: HE\otimes VE\to E$, hereafter briefly denoted as ξ_d. An element $t\in\mathscr{T}^{\rm pr}_{\rm qs}$, d-tensor field of type $\binom{pr}{qs}$ can be written in local form as

$$t=t^{i_1\cdots i_p\ a_1\cdots a_r}_{j_1\cdots j_q\ b_1\cdots b_s}(x,\ y)\ \frac{\delta}{\delta x^{i_1}}\otimes\cdots\otimes\frac{\delta}{\delta x^{i_p}}\otimes dx^{j_1}\otimes\cdots\otimes dx^{j_q}\otimes\frac{\partial}{\partial y^{a_1}}\otimes\cdots\otimes\frac{\partial}{\partial y^{a_r}}\otimes\delta y^{b_1}\otimes\cdots\otimes\delta y^{b_s}.$$

In addition to d-tensors we can introduce d-objects with various group and coordinate transforms adapted to global splitting (2). For example, we define linear d-connections in this form.

Definition 2: A linear d-connection on E is a linear connection D on E conserving under parallelism the global decomposition (2) into horizontal and vertical sub-bundles of the tangent bundle TE.

By using decompositions of N-adapted frames (4) we define components of connection D, $\tilde{\Gamma}^{\alpha}{}_{\beta\gamma}$, as covariant $\tilde{D}$-derivations of X_β:

$$\tilde{D}_\gamma X_\beta:=\tilde{D}_{X_\gamma}X_\beta=\tilde{\Gamma}^{\alpha}{}_{\beta\gamma}X_\alpha.$$

Torsion $\tilde{T}^{\alpha}{}_{\beta\gamma}$ and curvature $\tilde{R}_{\beta}{}^{\alpha}{}_{\gamma\delta}$ of connection $\tilde{\Gamma}^{\alpha}{}_{\beta\gamma}$ can be introduced in standard manner:[1,2,10]

$$\tilde{T}(X_\gamma,X_\beta)=\tilde{T}^{\alpha}{}_{\beta\gamma}X_\alpha,$$

where

$$\tilde{T}^{\alpha}{}_{\beta\gamma}=\tilde{\Gamma}^{\alpha}{}_{\beta\gamma}-\tilde{\Gamma}^{\alpha}{}_{\gamma\beta}+\omega^{\alpha}{}_{\beta\gamma}, \tag{5}$$

and, respectively, $\tilde{R}(X_\delta,X_\gamma,X_\beta)=\tilde{R}_{\beta}{}^{\alpha}{}_{\gamma\delta}X_\alpha$, where

$$\tilde{R}_{\beta}{}^{\alpha}{}_{\gamma\delta}=X_\delta\tilde{\Gamma}^{\alpha}{}_{\beta\gamma}-X_\gamma\tilde{\Gamma}^{\alpha}{}_{\beta\cdot\delta}+\tilde{\Gamma}^{\varphi}{}_{\beta\gamma}\tilde{\Gamma}^{\alpha}{}_{\varphi\delta}-\tilde{\Gamma}^{\varphi}{}_{\beta\delta}\tilde{\Gamma}^{\alpha}{}_{\varphi\gamma}+\tilde{\Gamma}^{\alpha}{}_{\beta\varphi}\omega^{\varphi}{}_{\gamma\delta}. \tag{6}$$

In formulas (5) and (6) we have used nonholonomy coefficients $w^{\alpha}{}_{\beta\gamma}$ of adapted frames, defined as

$$[X_\alpha,X_\beta]=X_\alpha X_\beta-X_\beta X_\alpha=w^{\gamma}{}_{\alpha\beta}X_\gamma. \tag{7}$$

Let us consider v-bundle $\xi=(E,\ p,\ M)$ with paracompact base M.

Definition 3: The metric structure G on total space E of vector bundle ξ is defined as a second-order covariant, tensor field nondegenerate, and of constant signature.

In the adapted frame metric G on E is expressed as

$$G=G_{\alpha\beta}(u)\,\delta u^\alpha\otimes\delta u^\beta=g_{ij}(x,\ y)dx^i\otimes dx^j+q_{ab}(x,\ y)\,\delta y^a\otimes\delta y^b. \tag{8}$$

Definition 4: Distinguished connection structure D on E is compatible with metric structure G on E if

$$\tilde{D}_\alpha G_{\gamma\delta}=0. \tag{9}$$

In Lagrange and Finsler geometry the basic geometric constructions are realized on the tangent bundle (TM,τ,M) In this case, an N-connection, with local coefficients $N^i_j(x^k,y^l)$ is associated to a global Whitney sum decomposition:

$$TTM=HTM\oplus VTM. \tag{10}$$

Let consider a d-metric $g_{ij}(x, y)$ on M (fundamental tensor on M) as a second-order covariant and nondegenerate tensorial d-field on M.

Definition 5 (see Refs. 1, 2, and 10): A pair $M^n=(M, g_{ij}(x, y))$ is called a generalized Lagrange space (GL-space).

Remark 2: Lagrange spaces L^n are a particular case of GL-spaces: when the d-metric on M can be expressed as

$$g_{ij}(x,y)=\frac{\partial^2 \mathscr{L}}{\partial y^i\ \partial y^j},$$

where $\mathscr{L}:TM\to\mathbb{R}$ ($\mathbb{R}$ is the real number field) is a differentiable function, called a Lagrangian on M.

Remark 3: We obtain a Finsler space (M,L), also as a particular case, if $\mathscr{L}=L^2$, where L is a Finsler metric on M.

For our purposes it is convenient to use Miron's[1,2] almost Hermitian model $H^{2n}(M,G,J)$ of a GL-space, denoted H^{2n}-space, a correspondingly defined lift of $M^n=(M, g_{ij}(x, y))$ to TM, which is almost compatible with complex structure $J^\alpha{}_\beta=\begin{pmatrix} 0 & \delta^i_j \\ -\delta^i_j & 0 \end{pmatrix}$ on TM, with $J\cdot J=-I$. In the construction of H^{2n}-spaces it is a very important fact that the N-connection on TM uniquely determines the metric structure G on TM, the H^{2n}-metric,

$$G(u)=g_{ij}(x,y)dx^i\otimes dx^j+g_{ij}(x,y)\,\delta y^i\otimes \delta y^j \tag{11}$$

[with components of d-metric $g_{ij}(x, y)$ defined from relations $g_{ij}-N^k{}_i g_{kj}=0$] being compatible with the $\tilde{D}$-connection, i.e.,

$$\tilde{D}_\alpha G_{\beta\gamma}=0, \tag{12}$$

and with the almost complex structure, i.e.,

$$J_\alpha{}^\beta J_\gamma{}^\delta G_{\beta\delta}=G_{\alpha\gamma} \quad \text{and} \quad D_\alpha J^\gamma{}_\beta=0.$$

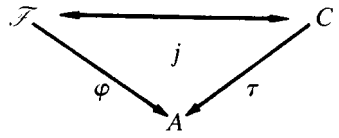
The spinor formalism proposed in this paper will be formulated for v-bundles provided with an N-connection structure compatible with the corresponding d-connection and metric structures (8) and satisfying metricity conditions (9). We point out that for GL-spaces, H^{2n}-metric (11) satisfying metricity conditions (12) is uniquely determined by the N-connection; we shall construct Clifford bundles and define spinor structures generated by this nonlinear connection structure.

III. DISTINGUISHED CLIFFORD ALGEBRAS

The typical fiber of v-bundle ξ_d, $\pi_d:HE\oplus VE\to E$ is a d-vector space $\mathscr{F}=h\mathscr{F}\oplus v\mathscr{F}$, split into vertical $v\mathscr{F}$ and horizontal $h\mathscr{F}$ subspaces, with metric $G(g, q)$ induced by v-bundle metric (8) [or by H^{2n}-metric (11) in the case when $E=TM$]. Clifford algebras (see, for example, Refs. 16–18) formulated for d-vector spaces will be called Clifford d-algebras. In this section we shall consider the main properties of Clifford d-algebras. The proof of theorems will be based on the technique developed in Ref. 16 correspondingly adapted to the distinguished character of spaces in consideration.

Let k be a number field (for our purposes $k=\mathbb{R}$ or $k=\mathbb{C}$, $\mathbb{R}$ and $\mathbb{C}$ are, respectively, real and complex number fields) and define $\mathscr{F}$ as a d-vector space on k provided with nondegenerate symmetric quadratic form (metric) G. Let C be an algebra on k (not necessarily commutative) and $j:\mathscr{F}\to C$ a homomorphism of underlying vector spaces such that $j(u)^2=G(u)\cdot 1$ (1 is the unity in algebra C and d-vector $u\in\mathscr{F}$). We are interested in definition of the pair (C, j) satisfying the next

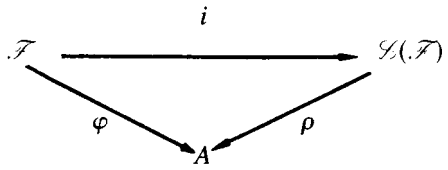
universality conditions. For every k-algebra A and arbitrary homomorphism $\varphi: \mathcal{F} \to A$ of the underlying d-vector spaces, such that $(\varphi(u))^2 \to G(u) \cdot 1$, there is a unique homomorphism of algebras $\psi: C \to A$ transforming the diagram



into a commutative one. The algebra solving this problem will be denoted as $C(\mathcal{F},G)$ [equivalently as $C(G)$ or $C(\mathcal{F})$] and called as Clifford d-algebra associated with pair $(\mathcal{F}, G)$.

Theorem 1: The above-presented diagram has a unique solution (C, j) up to isomorphism.

Proof: (We adapt for d-algebras that of Ref. 16, p. 127.) For a universal problem the uniqueness is obvious if we prove the existence of solution $C(G)$. To do this we use tensor algebra $\mathcal{S}(\mathcal{F}) = \oplus \mathcal{S}^{pr}_{qs}(\mathcal{F}) = \oplus_{i=0}^{\infty} T^i(\mathcal{F})$, where $T^0(\mathcal{F}) = k$ and $T^i(\mathcal{F}) = \mathcal{F} \otimes \cdots \otimes \mathcal{F}$ for $i > 0$. Let $I(G)$ be the bilateral ideal generated by elements of form $\epsilon(u) = u \otimes u - G(u) \cdot 1$ where $u \in \mathcal{F}$ and 1 is the unity element of algebra $\mathcal{S}(\mathcal{F})$. Every element from $I(G)$ can be written as $\Sigma_i \lambda_i \epsilon(u_i) \mu_i$, where λ_i, $\mu_i \in \mathcal{S}(\mathcal{F})$ and $u_i \in \mathcal{F}$. Let $C(G) = \mathcal{S}(\mathcal{F})/I(G)$ and define $j: \mathcal{F} \to C(G)$ as the composition of monomorphism $i: \mathcal{F} \to \mathcal{S}^1(\mathcal{F}) \subset \mathcal{S}(\mathcal{F})$ and projection $p: \mathcal{S}(\mathcal{F}) \to C(G)$. In this case pair $(C(G), j)$ is the solution of our problem. From the general properties of tensor algebras the homomorphism $\varphi: \mathcal{F} \to A$ can be extended to $\mathcal{S}(\mathcal{F})$, i.e., the diagram



is commutative, where ρ is a monorphism of algebras. Because $(\varphi(u))^2 = G(u) \cdot 1$, then ρ vanishes on ideal $I(G)$ and in this case the necessary homomorphism τ is defined. As a consequence of uniqueness of ρ, the homomorphism τ is unique.

Tensor d-algebra $\mathcal{S}(\mathcal{F})$ can be considered as a $\mathbb{Z}/2$ graded algebra. Really, let us introduce $\mathcal{S}^{(0)}(\mathcal{F}) = \Sigma_{i=1}^{\infty} T^{2i}(\mathcal{F})$ and $\mathcal{S}^{(1)}(\mathcal{F}) = \Sigma_{i=1}^{\infty} T^{2i+1}(\mathcal{F})$. Setting $I^{(\alpha)}(G) = I(G) \cap \mathcal{S}^{(\alpha)}(\mathcal{F})$ [$(\alpha) = (1),(2)$], we have $I(G) = I^{(0)}(G) \oplus I^{(1)}(G)$. Define $C^{(\alpha)}(G)$ as $p(\mathcal{S}^{(\alpha)}(\mathcal{F}))$, where $p: \mathcal{S}(\mathcal{F}) \to C(G)$ is the canonical projection. Then $C(G) = C^{(0)}(G) \oplus C^{(1)}(G)$ and in consequence we obtain that the Clifford d-algebra is $\mathbb{Z}/2$ graded.

It is obvious that Clifford d-algebra functorially depends on pair $(\mathcal{F}, G)$. If $f: \mathcal{F} \to \mathcal{F}'$ is a homomorphism of k-vector spaces, such that $G'(f(u)) = G(u)$, where G and G' are, respectively, metrics on $\mathcal{F}$ and $\mathcal{F}'$, then f induces an homomorphism of d-algebras

$$C(f): C(G) \to C(G')$$

with identities $C(\varphi \cdot f) = C(\varphi) C(f)$ and $C(\mathrm{Id}_{\mathcal{F}}) = \mathrm{Id}_{C(\mathcal{F})}$.

If $\mathcal{A}^{\alpha}$ and $\mathcal{B}^{\beta}$ are $\mathbb{Z}/2$-graded d-algebras, then their graded tensorial product $\mathcal{A}^{\alpha} \otimes \mathcal{B}^{\beta}$ is defined as a d-algebra for k-vector d-space $\mathcal{A}^{\alpha} \otimes \mathcal{B}^{\beta}$ with the graded product induced as $(a \otimes b)(c \otimes d) = (-1)^{\alpha\beta} ac \otimes bd$, where $b \in \mathcal{B}^{\beta}$ and $c \in \mathcal{A}^{\alpha}$ $(\alpha, \beta = 0,1)$.

Now we reformulate for d-algebras the Chevalley theorem.[19]

Theorem 2: The Clifford d-algebra $C(h\mathcal{F} \oplus v\mathcal{F}, g + q)$ is naturally isomorphic to $C(g) \hat{\otimes} C(q)$.

Proof: Let $n: h\mathcal{F} \to C(g)$ and $n': v\mathcal{F} \to C(q)$ be canonical maps and map $m: h\mathcal{F} \oplus v\mathcal{F} \to C(g) \hat{\otimes} C(q)$ is defined as $m(x, y) = n(x) \otimes 1 + 1 \otimes n'(y)$, $x \in h\mathcal{F}$, $y \in v\mathcal{F}$. We

have $(m(x,\,y))^2=[(n(x))^2+(n'(y))^2]\cdot 1=[g(x)+q(y)]$. Taking into account the universality property of Clifford d-algebras we conclude that m induces the homomorphism

$$\zeta: C(h\mathscr{F}\oplus v\mathscr{F}, g\oplus q)\to C(h\mathscr{F}, g)\hat{\otimes} C(v\mathscr{F}, q).$$

We also can define a homomorphism

$$\upsilon: C(h\mathscr{F},\, g)\hat{\otimes} C(v\mathscr{F},\, q)\to C(h\mathscr{F}\oplus v\mathscr{F},\, g\oplus q)$$

by using formula $\upsilon(x\otimes y)=\delta(x)\,\delta'(y)$, where homomorphisms δ and δ' are, respectively, induced by imbeddings of $h\mathscr{F}$ and $v\mathscr{F}$ into $h\mathscr{F}\oplus v\mathscr{F}$:

$$\delta: C(h\mathscr{F},\, g)\to C(h\mathscr{F}\oplus v\mathscr{F}, g\oplus q),$$

$$\delta': C(v\mathscr{F},\, q)\to C(h\mathscr{F}\oplus v\mathscr{F}, g\oplus q).$$

Because $x\in C^{(\alpha)}(g)$ and $y\in C^{(\alpha)}(q)$, $\delta(x)\,\delta'(y)=(-1)^{\alpha'}\delta'(y)\,\delta(x)$.

Superpositions of homomorphisms ζ and υ lead to identities

$$\begin{aligned}\upsilon\zeta&=\mathrm{Id}_{C(h\mathscr{F},\, g)\hat{\otimes} C(v\mathscr{F},\, q)},\\ \zeta\upsilon&=\mathrm{Id}_{C(h\mathscr{F},\, g)\hat{\otimes} C(v\mathscr{F},\, q)}.\end{aligned}\tag{13}$$

Really, d-algebra $C(h\mathscr{F}\oplus v\mathscr{F}, g+q)$ is generated by elements of type $m(x,\,y)$. Calculating

$$\upsilon\zeta(m(x,\,y))=\upsilon(n(x)\otimes 1+1\otimes n'(y))=\delta(n(x))\,\delta(n'(y))=m(x,\,0)+m(0,\,y)=m(x,\,y),$$

we prove the first identity in (13).

On the other hand, d-algebra $C(h\mathscr{F}, g)\hat{\otimes} C(v\mathscr{F}, q)$ is generated by elements of type $n(x)\otimes 1$ and $1\otimes n'(y)$. Because $(\zeta\upsilon)(n(x)\otimes 1)=\psi(\delta(n(x))=n(x)\otimes 1$ and $(\zeta\upsilon)(1\otimes n'(y))=\psi(\delta'(n(y))=1\otimes n'(y)$, we prove the second identity in (13).

Following from the above-mentioned properties of homomorphisms ζ and υ we can assert that the natural isomorphism is explicitly constructed. □

In consequence of theorem 2 we conclude that all operations with Clifford d-algebras can be reduced to calculations for $C(h\mathscr{F}, g)$ and $C(v\mathscr{F}, q)$ which are usual Clifford algebras of dimension 2^n and, respectively, 2^m.[16,20]

Of special interest is the case when $k=\mathbb{R}$ and $\mathscr{F}$ is isomorphic to vector space $\mathbb{R}^{p+q,a+b}$ provided with quadratic form $-x_1^2-\cdots-x_p^2+\cdots+x_{p+q}^2-y_1^2-\cdots-y_a^2+\cdots+y_{a+b}^2$. In this case, the Clifford algebra, denoted as $(C^{p,q},\, C^{a,b})$, is generated by symbols $e_1^{(x)}$, $e_2^{(x)},\ldots,e_{p+q}^{(x)}$, $e_1^{(y)}$, $e_2^{(y)},\ldots,e_{a+b}^{(y)}$ satisfying properties $(e_i)^2=-1$ $(1\leqslant i\leqslant p)$, $(e_j)^2=-1$ $(1\leqslant j\leqslant a)$, $(e_k)^2=1$ $(p+1\leqslant k\leqslant p+q)$, $(e_j)^2=1$ $(n+1\leqslant s\leqslant a+b)$, $e_ie_j=-e_je_i$, $i\neq j$. Explicit calculations of $C^{p,q}$ and $C^{a,b}$ are possible by using isomorphisms[16,18]

$$C^{p+n,q+n}\approx C^{p,q}\otimes M_2(\mathbb{R})\otimes\cdots\otimes M_2(\mathbb{R})\simeq C^{p,q}\otimes M_{2^n}(\mathbb{R})\cong M_{2^n}(C^{p,q}),$$

where $M_s(A)$ denotes the ring of quadratic matrices of order s with coefficients in ring A. Here we write the simplest isomorphisms $C^{1,0}\simeq\mathbb{C}$, $C^{0,1}\simeq\mathbb{R}\oplus\mathbb{R}$ and $C^{2,0}=\mathbb{H}$, where by $\mathbb{H}$ is denoted the body of quaternions. We summarize this calculus as (as in Ref. 20)

$$C^{0,0}=\mathbb{R},\quad C^{1,0}=\mathbb{C},\quad C^{0,1}=\mathbb{R}\oplus\mathbb{R},$$

$$C^{2,0}=\mathbb{H},\quad C^{0,2}=M_2(\mathbb{R}),\quad C^{3,0}=\mathbb{H}\oplus\mathbb{H},\quad C^{0,3}=M_2(\mathbb{R}),$$

$$C^{4,0}=M_2(\mathbb{H}),\quad C^{0,4}=M_2(\mathbb{H}),\quad C^{5,0}=M_4(\mathbb{C}),\quad C^{0,5}=M_2(\mathbb{H})\oplus M_2(\mathbb{H}),$$

$$C^{6,0}=M_8(\mathbb{R}),\quad C^{0,6}=M_4(\mathbb{H}),\quad C^{7,0}=M_8(\mathbb{R})\oplus M_8(\mathbb{R}),\quad C^{0,7}=M_8(\mathbb{C}),$$

$$C^{8,0}=M_{16}(\mathbb{R}),\quad C^{0,8}=M_{16}(\mathbb{R}).$$

One of the most important properties of real algebras $C^{0,p}(C^{0,a})$ and $C^{p,0}(C^{a,0})$ is the eightfold periodicity of $p(a)$.

Now, we emphasize that H^{2n}-spaces admit locally a structure of Clifford algebra on complex vector spaces. Really, by using almost Hermitian structure $J_\alpha{}^\beta$ and considering complex space $\mathbb{C}^n$ with nondegenerate quadratic form $\Sigma_{a=1}^{a}|z_a|^2$, $z_a\in\mathbb{C}^2$ induced locally by metric (8) (rewritten in complex coordinates $z_a=x_a+iy_a$) we define Clifford algebra $\check{C}^n=\underbrace{\check{C}^1\otimes\cdots\otimes\check{C}^L}_{n}$, where $\check{C}^1=\mathbb{C}\otimes_{\mathbb{R}}\mathbb{C}=\mathbb{C}\oplus\mathbb{C}$ or, in consequence, $\check{C}^n\simeq C^{n,0}\otimes_{\mathbb{R}}\mathbb{C}\simeq C^{0,n}\otimes_{\mathbb{R}}\mathbb{C}$. Explicit calculations lead to isomorphisms $\check{C}^2=C^{0,2}\otimes_{\mathbb{R}}\mathbb{C}\simeq M_2(\mathbb{R})\otimes_{\mathbb{R}}\mathbb{C}\simeq M_2(\mathbb{C})$, $\check{C}^{n+2}\simeq M_2(\check{C}^n)$, $C^{2p}\approx M_{2^p}(\mathbb{C})$ and $\check{C}^{2p+1}\approx M_{2^p}(\mathbb{C})\oplus M_{2^p}(\mathbb{C})$, which show that complex Clifford algebras, defined locally for H^{2n}-spaces, have periodicity 2 on p.

Considerations presented in the proof of theorem 2 show that map $j:\mathscr{F}\to C(\mathscr{F})$ is monomorphic, so we can identify space $\mathscr{F}$ with its image in $C(\mathscr{F},G)$. On the other hand, endomorphism $u\to -u$ of space $\mathscr{F}$ induces an involution on $C(\mathscr{F},G)$, denoted as $u\to\bar{u}$, if $u\in C^{(0)}(\mathscr{F},G)$ ($u\in C^{(1)}(\mathscr{F},G)$); then $u=\bar{u}$ (respectively, $\bar{u}=-u$).

Definition 6: The set of elements $u\in C(G)^*$, where $C(G)^*$ denotes the multiplicative group of invertible elements of $C(\mathscr{F},G)$ satisfying $\bar{u}\mathscr{F}u^{-1}\in\mathscr{F}$, is called the *twisted Clifford d-group*, denoted as $\tilde{\Gamma}(\mathscr{F})$.

Let $\tilde{\rho}:\tilde{\Gamma}(\mathscr{F})\to GL(\mathscr{F})$ be the homomorphism given by $u\to\rho\tilde{u}$, where $\tilde{\rho}_u(w)=\bar{u}wu^{-1}$. We can verify that $\ker\tilde{\rho}=\mathbb{R}^*$ is a subgroup in $\tilde{\Gamma}(\mathscr{F})$.

Canonical map $j:\mathscr{F}\to C(\mathscr{F})$ can be interpreted as the linear map $\mathscr{F}\to C(\mathscr{F})^0$ satisfying the universal property of Clifford d-algebras. This leads to a homomorphism of algebras, $C(\mathscr{F})\to C(\mathscr{F})^t$, considered by an anti-involution of $C(\mathscr{F})$ and denoted as $u\to{}^tu$. More exactly, if $\lambda\in u_1\cdots u_n\in\mathscr{F}$, then ${}^tu=u_n\cdots u_1$ and ${}^t\bar{u}=\overline{{}^tu}=(-1)^nu_n\cdots u_1$.

Definition 7: The spinor norm of arbitrary $u\in C(\mathscr{F})$ is defined as $S(u)={}^t\bar{u}\cdot u\in C(\mathscr{F})$.

It is obvious that if $u,u',u''\in\tilde{\Gamma}(\mathscr{F})$, then $S(u,u')=S(u)S(u')$ and $S(uu'u'')=S(u)S(u')S(u'')$. For $u,u'\in\mathscr{F}$ $S(u)=-G(u)$ and $S(u,u')=S(u)S(u')=S(u'u)$.

Let us introduce the orthogonal group $\mathrm{O}(G)\subset GL(G)$ defined by metric G on $\mathscr{F}$ and denote sets $\mathrm{SO}(G)=\{u\in\mathrm{O}(G),\ \det|u|=1\}$, $Pin(G)=\{u\in\tilde{\Gamma}(\mathscr{F}),\ \mathrm{S}(u)=1\}$ and $Spin(G)=Pin(G)\cap C^0(\mathscr{F})$. For $\mathscr{F}\cong\mathbb{R}^{n+m}$ we write $Spin(n+m)$. By straightforward calculations (see similar considerations in Ref. 16) we can verify the exactness of these sequences:

$$1\to\mathbb{Z}/2\to Pin(G)\to\mathrm{O}(G)\to 1,$$

$$1\to\mathbb{Z}/2\to Spin(G)\to\mathrm{SO}(G)\to 0,$$

$$1\to\mathbb{Z}/2\to Spin(n+m)\to\mathrm{SO}(n+m)\to 1.$$

We conclude this section by emphasizing that the spinor norm was defined with respect to a quadratic form induced by a metric in the v-bundle ξ_d (or by an H^{2n}-metric in the case of GL-spaces). This approach differs from that presented in Refs. 5 and 9.

IV. CLIFFORD BUNDLES AND SPINOR STRUCTURES ON VECTOR BUNDLES AND GL-SPACES

There are two possibilities for generalizing our spinor constructions defined for d-vector spaces to the case of vector bundle spaces with the structure of N-connection. The first is to use

the extension to the category of vector bundles. The second is to define the Clifford fibration associated with compatible linear d-connection and metric G on a vector bundle (or with an H^{2n}-metric on GL-space). Let us consider both variants.

A. Clifford *d*-module structures in vector bundles

Because functor $\mathscr{F}\to C(\mathscr{F})$ is smooth we can extend it to the category of vector bundles of type $\xi_d=\{\pi_d: HE\oplus VE\to E\}$. Recall that by $\mathscr{F}$ we denote the typical fiber of such bundles. For ξ_d we obtain a bundle of algebras, denoted as $C(\xi_d)$, such that $C(\xi_d)_u=C(\mathscr{F}_u)$. Multiplication in every fiber defines a continuous map $C(\xi_d)\times C(\xi_d)\to C(\xi_d)$. If ξ_d is a vector bundle on number field k, the structure of the $C(\xi_d)$-module, the d-module, on ξ_d is given by the continuous map $C(\xi_d)x_E\xi_d\to\xi_d$ with every fiber $\mathscr{F}_u$ provided with the structure of the $C(\mathscr{F}_u)$-module, correlated with its k-module structure. Because $\mathscr{F}\subset C(\mathscr{F})$, we have a fiber to fiber map $\mathscr{F}x_E\xi_d\to\xi_d$, inducing on every fiber the map $\mathscr{F}_u x_E\xi_{d(u)}\to\xi_{d(u)}$ ($\mathbb{R}$-linear on the first factor and k-linear on the second one). Inversely, every such bilinear map defines on ξ_d the structure of the $C(\xi_d)$-module by virtue of universal properties of Clifford d-algebras. Equivalently, the above-mentioned bilinear map defines a morphism of v-bundles $m:\xi_d\to\mathrm{HOM}(\xi_d,\xi_d)$ [$\mathrm{HOM}(\xi_d,\xi_d)$ denotes the bundle of homomorphisms] when $(m(u))^2=G(u)$ on every point.

Vector bundles ξ_d provided with $C(\xi_d)$-structure are objects of the category with morphisms being morphisms of v-bundles, which induce on every point $u\in\xi$ morphisms of $C(\xi_d)$-modules. This is a Banach category contained in the category of finite-dimensional d-vector spaces on field k. We shall not use category formalism in this work, but point to its advantages in further formulation of new directions of K-theory (see, for example, an introduction in Ref. 16) concerned with generalized Lagrange spaces.

Let us denote by $H^s(\xi,GL_{n+m}(\mathbb{R}))$ the s-dimensional cohomology group of the algebraic sheaf of germs of continuous maps of v-bundle ξ with group $GL_{n+m}(\mathbb{R})$ the group of automorphisms of $\mathbb{R}^{n+m}$ (for the language of algebraic topology see, for example, Refs. 16 and 21). We shall also use the group $SL_{n+m}(\mathbb{R})=\{A\subset GL_{n+m}(\mathbb{R}),\ \det A=1\}$. Here we point out that cohomologies $H^s(M,\mathrm{Gr})$ characterize the class of a principal bundle $\pi:P\to M$ on M with structural group Gr. Taking into account that we deal with bundles distinguished by an N-connection we introduce into consideration cohomologies $H^s(\xi,GL_{n+m}(\mathbb{R}))$ as distinguished classes (d-classes) of bundles ξ provided with a global N-connection structure.

For a real vector bundle ξ_d on compact base ξ we can define the orientation on ξ_d as an element $\alpha_d\in H^1(\xi,GL_{n+m}(\mathbb{R}))$ whose image on map

$$H^1(\xi,SL_{n+m}(\mathbb{R}))\to H^1(\xi,GL_{n+m}(\mathbb{R}))$$

is the d-class of bundle ξ.

Definition 8: The spinor structure on ξ_d is defined as the element $\beta_d\in H^1(\xi,Spin(n+m))$ whose image in the composition

$$H^1(\xi,Spin(n+m))\to H^1(\xi,\mathrm{SO}(n+m))\to H^1(\xi,GL_{n+m}(\mathbb{R}))$$

is the d-class of ξ.

The above definition of spinor structures can be reformulated in terms of principal bundles. Let ξ_d be a real vector bundle of rank $n+m$ on a compact base ξ. If there is a principal bundle P_d with structural group $\mathrm{SO}(n+m)$ [or $Spin(n+m)$], this bundle ξ_d can be provided with orientation (or spinor) structure. The bundle P_d is associated with element $\alpha_d\in H^1(\xi,\mathrm{SO}(n+m))$ [or $\beta_d\in H^1(\xi,Spin(n+m))$].

We remark that a real bundle is oriented if and only if its first Stiefel–Whitney d-class vanishes,

$$w_1(\xi_d)\in H^1(\xi,\mathbb{Z}/2)=0,$$

where $H^1(\xi/\mathbb{Z}/2)$ is the first group of Chech cohomology with coefficients in $\mathbb{Z}/2$. Considering the second Stiefel–Whitney class $w_2(\xi_d) \in H^2(\xi,\mathbb{Z}/2)$ it is well known that vector bundle ξ_d admits the spinor structure if and only if $w_2(\xi_d)=0$. Finally, in this subsection, we emphasize that taking into account that base space ξ is also a v-bundle, $p:E\to M$, we have to make explicit calculations in order to express cohomologies $H^s(\xi,GL_{n+m})$ and $H^s(\xi,\mathrm{SO}(n+m))$ through cohomologies $H^s(M,GL_n)$, $H^s(M,\mathrm{SO}(n))$, which depends on global topological structures of spaces M and ξ. For general bundle and base spaces this requires a cumbersome cohomological calculus.

B. Clifford fibration

Another way of defining the spinor structure is to use Clifford fibrations. Consider the principal bundle with the structural group Gr being a subgroup of orthogonal group $\mathrm{O}(G)$, where G is a quadratic nondegenerate form [see (8)] defined on the base (also being a bundle space) space ξ [we deal with H^{2n}-metric (11) in the case when the base space is a H^{2n}-space] and denote it as $P(\xi, \mathrm{Gr})$ [$P(H^{2n}, \mathrm{Gr})$]. The fibration associated to principal fibration $P(\xi, \mathrm{Gr})$ [or $P(H^{2n}, \mathrm{Gr})$] with a typical fiber having Clifford algebra $C(G)$ is, by definition, the Clifford fibration $PC(\xi, \mathrm{Gr})$ [or $PC(H^{2n}, \mathrm{Gr})$]. We can always define a metric on the Clifford fibration if every fiber is isometric to $PC(\xi, G)$ (this result is proved for arbitrary quadratic forms G on pseudo-Riemannian bases[17]). If, additionally, $\mathrm{Gr}\subset\mathrm{SO}(G)$ a global section can be defined on $PC(G)$.

Let $\mathscr{P}(\xi, \mathrm{Gr})$ [or $\mathscr{P}(H^{2n}, \mathrm{Gr})$] be the set of principal bundles with differentiable base ξ (or H^{2n}-space) and structural group Gr. If $g:\mathrm{Gr}\to\mathrm{Gr}'$ is an homomorphism of Lie groups and $P(\xi, \mathrm{Gr})\subset\mathscr{P}(\xi, \mathrm{Gr})$ [or $P(H^{2n}, \mathrm{Gr})\subset\mathscr{P}(H^{2n}, \mathrm{Gr})$] (for simplicity in this section we shall denote mentioned bundles and sets of bundles as P, P' and, respectively, $\mathscr{P}$, $\mathscr{P}'$], we can always construct a principal bundle with the property that there is an homomorphism $f:P'\to P$ of principal bundles which can be projected to the identity map of ξ (or H^{2n}) and corresponds to isomorphism $g:\mathrm{Gr}\to\mathrm{Gr}'$. If the inverse statement also holds the bundle P' is called as the extention of P associated to $\mathbf{g}$ and f is called the extension homomorphism denoted as $\tilde{\mathbf{g}}$.

Now we can define distinguished spinor structures on bundle spaces (compare with definition 8).

Definition 9: Let $P\in\mathscr{P}(\xi,O(G))$ [or $P\in\mathscr{P}(H^{2n}), O(G)$] be a principal bundle. A distinguished spinor structure of P, equivalently a ds-structure on ξ (or on H^{2n}) is an extension $\tilde{P}$ of P associated to homomorphism $h:PinG\to\mathrm{O}(G)$ where $\mathrm{O}(G)$ is the group of orthogonal rotations, generated by metric G, in bundle ξ (or in H^{2n}-space).

So, if $\tilde{P}$ is a spinor structure of the space ξ (or H^{2n}), then $\tilde{P}\in\mathscr{P}(\xi,PinG)$ [or $\tilde{P}\in\mathscr{P}(H^{2n}, PinG)$].

The definition of spinor structures on varieties was given in Ref. 22. In Refs. 23 and 24 it is proved that a necessary and sufficient condition for a space time to be orientable is to admit a global field of orthonormal frames. We mention that spinor structures can be also defined on varieties modeled on Banach spaces.[25] As we have shown in this subsection, similar constructions are possible for the cases when space time has the structure of a v-bundle with an N-connection (or an H^{2n}-space).

Definition 10: A special distinguished spinor structure, ds-structure, of principal bundle $P=P(\xi,\mathrm{SO}(G))$ [or $P=P(H^{2n},\mathrm{SO}(G))$] is a principal bundle $\tilde{P}=\tilde{P}(\xi,SpinG)$ [or $\tilde{P}=\tilde{P}(H^{2n},SpinG)$] for which a homomorphism of principal bundles $\tilde{p}:\tilde{P}\to P$, projected on the identity map of ξ (or of H^{2n}) and corresponding to representation

$$R:SpinG\to\mathrm{SO}(G),$$

is defined.

In the case when the base space variety is oriented, there is a natural bijection between tangent spinor structures and special spinor structures with a common base. For special ds-structures we

can define, as for any spinor structure, the concepts of spin tensors, spinor connections, and spinor covariant derivations (see Sec. VI in this paper) a detailed version will be presented in Ref. 26).

V. ALMOST COMPLEX SPINOR STRUCTURES ON GENERALIZED LAGRANGE SPACES

Almost complex structures are an important characteristic of H^{2n}-spaces. As we have mentioned in Sec. IV, we can rewrite H^{2n}-metric (11) in complex form:

$$G=H_{ab}(z,\xi)dz^a\otimes dz^b, \tag{14}$$

where

$$z^a=x^a+iy^a,\quad \bar{z}^a=x^a-iy^a,\quad H_{ab}(z,\bar{z})=g_{ab}(x,y)\big|^{x=x(z,\bar{z})}_{y=y(z,\bar{z})},$$

and define almost complex spinor structures. For given metric (14) on H^{2n}-space there is always a principal bundle P^U with unitary structural group $\mathrm{U}(n)$ which allows us to transform H^{2n}-space into v-bundle $\xi^U\approx P^U x_{U(n)}\mathbb{R}^{2n}$. This statement will be proved after we introduce complex spinor structures on oriented real vector bundles.[16]

Let us consider momentarily $k=\mathbb{C}$ and introduce into consideration [instead of the group $Spin(n)$] the group $Spin^c(n)=Spin(n)x_{\mathbb{Z}/2}$, $\mathrm{U}(1)$ being the factor group of the product $Spin(n)xU(1)$ with the respect to equivalence

$$(y,\ a)\sim(-y,\ -a),\quad y\in Spin(m).$$

This way we define the short exact sequence

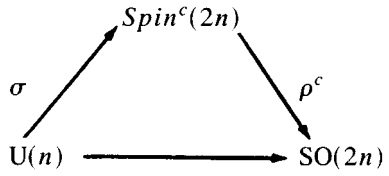
$$1\to \mathrm{U}(1)\to Spin^c(n)\overset{S^c}{\to}\mathrm{SO}(n)\to 1,$$

where $\rho^c(y,a)=\rho^c(y)$. If λ is a oriented, real, and rank n, γ-bundle $\pi:E_\lambda\to M^n$, with base M^n, the complex spinor structure, spin structure, on λ is given by the principal bundle P with structural group $Spin^c(m)$ and isomorphism $\lambda\approx Px_{Spin^c(n)}\mathbb{R}^n$. For such bundles the categorial equivalence can be defined as

$$\epsilon^c:\mathscr{E}^T_{\mathbb{C}}(M^n)\to\mathscr{E}^\lambda_{\mathbb{C}}(M^n), \tag{15}$$

where $\epsilon^c(E^c)=P\Delta_{Spin^c(n)}E^c$ is the category of trivial complex bundles on M^n, $\mathscr{E}^\lambda_{\mathbb{C}}(M^n)$ is the category of complex v-bundles on M^n with action of Clifford bundle $C(\lambda)$, $P\Delta_{Spin^c(n)}$ and E^c is the factor space of the bundle product Px_ME^c with respect to the equivalence $(p,\ e)\sim(p\hat{g}^{-1},\ \hat{g}e)$, $p\in P$, $e\in E^c$, where $\hat{g}\in Spin^c(n)$ acts on E by via the imbedding $Spin(n)\subset C^{o,n}$ and the natural action $\mathrm{U}(1)\subset\mathbb{C}$ on complex v-bundle ξ^c, $E^c=\mathrm{tot}\,\xi^c$, for bundle $\pi^c:E^c\to M^n$.

Now we return to the bundle ξ. A real v-bundle (not being a spinor bundle) admits a complex spinor structure if and only if there exists a homomorphism $\sigma:\mathrm{U}(n)\to Spin^c(2n)$ making the diagram



commutative. The explicit construction of σ for arbitrary γ-bundles is given in Refs. 16 and 20. For H^{2n}-spaces it is obvious that a diagram similar to (16) can be defined for the tangent bundle TM^n, which directly points to the possibility of defining the ${}^cSpin$-structure on H^{2n}-spaces.

Let λ be a complex, rank n, spinor bundle with

$$\tau: Spin^c(n) x_{\mathbb{Z}/2} \mathrm{U}(1) \to \mathrm{U}(1) \tag{17}$$

the homomorphism defined by formula $\tau(\lambda,\delta)=\delta^2$. For P_S being the principal bundle with fiber $Spin^c(n)$ we introduce the complex linear bundle $L(\lambda^c) = P_S x_{Spin^c(n)} \mathbb{C}$ defined as the factor space of $P_S x \mathbb{C}$ on equivalence relation $(pt,z)\sim(p,l(t)^{-1}z)$, where $t \in Spin^c(n)$. This linear bundle is associated to complex spinor structure on λ^c.

If λ^c and $\lambda^{c'}$ are complex spinor bundles, the Whitney sum $\lambda^c \oplus \lambda^{c'}$ is naturally provided with the structure of the complex spinor bundle. This follows from the holomorphism

$$\omega^c: Spin^c(n) \times Spin^c(n') \to Spin^c(n+n'), \tag{18}$$

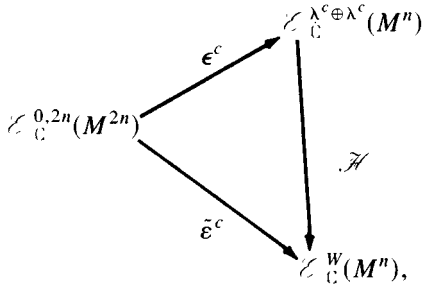
given by formula $[(\beta, z),(\beta', z')] \to [\omega(\beta, \beta'), zz']$, where ω is the homomorphism making the following diagram commutative;

$$\begin{array}{ccc} Spin(n)\times Spin(n') & \longrightarrow & Spin(n+n') \\ \downarrow & & \downarrow \\ \mathrm{O}(n)\times \mathrm{O}(n') & \longrightarrow & \mathrm{O}(n+n') \end{array}$$

Here, $z,z' \in \mathrm{U}(1)$. It is obvious that $L(\lambda^c \oplus \lambda^{c'})$ is isomorphic to $L(\lambda^c) \otimes L(\lambda^{c'})$.

We conclude this section by formulating our main result on complex spinor structures for H^{2n}-spaces:

Theorem: Let λ^c be a complex spinor bundle of rank n and H^{2n}-space considered as a real vector bundle $\lambda^c \oplus \lambda^c$ provided with almost complex structure $J^\alpha{}_\beta$; multiplication on i is given by $\begin{pmatrix} 0 & -\delta^i_j \\ \delta^i_j & 0 \end{pmatrix}$. Then, the diagram below is commutative up to isomorphism

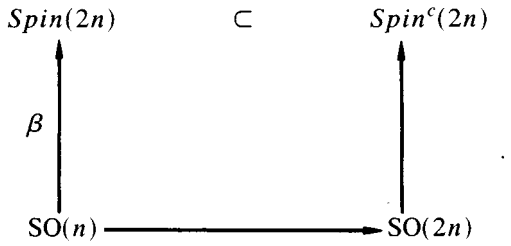


where ϵ^c and $\tilde{\epsilon}^c$ are defined as in (15), $\mathscr{H}$ is functor $E^c \to E^c \otimes L(\lambda^c)$ and $\mathscr{E}_{\mathbb{C}}^{0,2n}(M^n)$ is defined by functor $\mathscr{E}_{\mathbb{C}}(M^n) \to \mathscr{E}_{\mathbb{C}}^{0,2n}(M^n)$ given as correspondence $E^c \to \Lambda(\mathbb{C}^n) \otimes E^c$ (which is a categorial equivalence), $\Lambda(\mathbb{C}^n)$ is the exterior algebra on $\mathbb{C}^n$. W is the real bundle $\lambda^c \oplus \lambda^c$ provided with complex structure.

Proof: We use composition of homomorphisms

$$\mu: Spin^c(2n) \overset{\pi}{\to} \mathrm{SO}(n) \overset{r}{\to} \mathrm{U}(n) \overset{\sigma}{\to} Spin^c(2n) = Spin(2n) x_{\mathbb{Z}/2} \mathrm{U}(1),$$

commutative diagram



and introduce composition of homomorphisms

$$\mu: Spin^c(n) \overset{\Delta}{\to} Spin^c(n) \times Spin^c(n) \overset{\omega^c}{\to} Spin^c(n),$$

where Δ is the diagonal homomorphism and ω^c is defined as in (18). Using homomorphisms (17) and (18) we obtain formula $\mu(t) = \mu(t) r(t)$.

Now we consider bundle $Px_{Spin^c(n)} Spin^c(2n)$ as the principal $Spin^c(2n)$-bundle, associated to $M \oplus M$ being the factor space of the product $PxSpin^c(2n)$ on the equivalence relation $(p, t, h) \sim (p, \mu(t)^{-1} h)$. In this case the categorial equivalence (15) can be rewritten as

$$\epsilon^c(E^c) = Px_{Spin^c(n)} Spin^c(2n) \Delta_{Spin^c(2n)} E^c$$

and seen as factor space of $PxSpin^c(2n) x_M E^c$ on equivalence relation $(pt, h, e) \sim (p, \mu(p)^{-1} h, e)$ and $(p, h_1, h_2, e) \sim (p, h_1, h_2^{-1} e)$ (projections of elements p and e coincides on base M). Every element of $\epsilon^c(E^c)$ can be represented as $P\Delta_{Spin^c(n)} E^c$, i.e., as factor space of $Px_M E^c$ on equivalence relation $(pt, e) \sim (p, \mu(t)^{-1} e)$, where $t \in Spin^c(n)$.

On the other hand, the principal $Spin^c(2n)$-bundle associated to complex structure on $M \oplus M$ is $Px_{Spin^c(n)} Spin^c(2n)$ and in consequence $\epsilon^c(E^c)$ can be represented as $P\Delta_{Spin^c(n)} E^c$, i.e., as a factor space $P\Delta E^c$ on equivalence relation $(pt, e) \sim (p, \mu^c(t)^{-1}, e)$, when $t \in Spin^c(n)$.

The complex line bundle $L(\lambda^c)$ can be interpreted as the factor space of $Px_{Spin^c(n)} \mathbb{C}$ on equivalence relation $(pt, \delta) \sim (p, r(t)^{-1} \delta)$.

Putting $(p, e) \otimes (p, \delta)(p, \delta e)$ we introduce morphism

$$\epsilon^c(E) \times L(\lambda^c) \to \epsilon^c(\lambda^c)$$

with properties $(pt, e) \otimes (pt, \delta) \to (pt, \delta e) = (p, \mu^c(t)^{-1} \delta e)$, $(p, \mu^c(t)^{-1} e) \otimes (p, l(t)^{-1} e) \to (p, \mu^c(t) r(t)^{-1} \delta e)$ pointing to the fact that we have defined the isomorphism correctly and that it is an isomorphism on every fiber. □

VI. SPINORS IN VECTOR BUNDLES WITH NONLINEAR CONNECTIONS

In this section we present a brief introduction to the theory of d-spinors in v-bundles and H^{2n}-spaces. To generate Clifford d-algebra we start with Clifford–Dirac equations written in the form[18]

$$\sigma_\alpha(u) \sigma_\beta(u) + \sigma_\beta(u) \sigma_\alpha(u) = -G_{\alpha\beta}(u) I, \tag{19}$$

where distinguished complex matrices $\sigma_\alpha(u)$ are parametrized as

$$\sigma_\alpha(u) = \begin{pmatrix} \sigma_i(u) & 0 \\ 0 & \sigma_a(u) \end{pmatrix},$$

$\sigma_i(u)$, $\sigma_a(u)$ being matrices of dimension $N_h \times N_h$ ($N_v \times N_v$) $N_h = 2^{n/2}$ ($N_v = 2^{m/2}$ for even values of $n(m)$ and $N_h = 2^{(n+1)/2}$ ($N_v = 2^{(m+1)/2}$) for odd values of $n(m)$.

To relate the succeeding constructions with Clifford d-algebra (see Sec. III) it is convenient to use frame decomposition of metric (8) [or (11)]:

$$G_{\alpha\beta}=l^{\hat{\alpha}}_{\alpha}(u)l^{\hat{\beta}}_{\beta}(u)g_{\hat{\alpha}\hat{\beta}},$$

where the frame components are distinguished as

$$l^{\hat{\alpha}}_{\alpha}(u)=\begin{pmatrix} l^{\hat{i}}_{j}(u) & 0 \\ 0 & l^{\hat{a}}_{a}(u) \end{pmatrix}, \quad g_{\hat{\alpha}\hat{\beta}}=\begin{pmatrix} g_{\hat{i}\hat{j}} & 0 \\ 0 & g_{\hat{a}\hat{b}} \end{pmatrix},$$

where $g_{\hat{i}\hat{j}}$ and $g_{\hat{a}\hat{b}}$ are diagonal matrices with $g_{\hat{i}\hat{j}}=g_{\hat{a}\hat{b}}=\pm 1$. In general, we can treat indices $\hat{\alpha},\hat{\beta},\hat{i},j,\hat{a},\hat{b},\ldots$ as abstract tensorial indices.[18]

Introducing matrices $\sigma_{\hat{\alpha}}=l^{\alpha}_{\hat{\alpha}}\sigma_{\alpha}$ (matrix $l^{\alpha}_{\hat{\alpha}}$ is inverse to $l^{\hat{\alpha}}_{\alpha}$) we rewrite Eqs. (17) as algebraic equations for components of constant matrices σ^{n}_{α}:

$$\sigma_{\hat{\alpha}}\sigma_{\hat{\beta}}+\sigma_{\hat{\beta}}\sigma_{\hat{\alpha}}=-G_{\hat{\alpha}\hat{\beta}}I. \tag{20}$$

We consider that matrices $\sigma_{\hat{\alpha}}$ act on corresponding d-vector space $\mathscr{F}=h\mathscr{F}\oplus v\mathscr{F}$. To specify elements we can introduce abstract spinor indices [locally adapted to bases (4) and (5)]:

$$\sigma_{\hat{\alpha}}=\left\{(\sigma_{\hat{\alpha}})_{\rho}{}^{\gamma}=\begin{pmatrix} (\sigma_{\hat{i}})_{j}{}^{k} & 0 \\ 0 & (\sigma_{\hat{a}})_{b}{}^{c} \end{pmatrix}\right\},$$

where ρ, γ,... refer to spin space $S=S_{(h)}\oplus S_{(v)}$; j, k and b, c refer, respectively, to spin spaces $S_{(h)}$ and $S_{(v)}$ [$S_{(h)}$ and $S_{(v)}$ are associated to h- and, respectively, γ-decomposition of bundle ξ_d (of H^{2n}-space)]. Suggesting that algebra generated by σ_2 is irreducible, it is necessary that $\dim S_{(h)}=N_{(h)}$ and, respectively, $\dim S_{(v)}=N_{(v)}$, where

$$N_{(h)}=\begin{cases} 2^{n/2}, & n=2k, \\ 2^{(n-1)/2}, & n=2k+1, \end{cases} \quad \text{and} \quad N_{(v)}=\begin{cases} 2^{m/2}, & m=2k, \\ 2^{(m-1)/2}, & m=2k+1 \end{cases}$$

[the minimal dimension of matrices satisfying Eqs. (18) is $N\times N$, where $N=N_{(h)}+N_{(v)}$].

The Clifford d-algebra is generated by sums of $n+1$ elements of the form

$$A_1 I+B^{\hat{i}}\sigma_{\hat{i}}+C^{\hat{i}\hat{j}}\sigma_{\hat{i}\hat{j}}+D^{\hat{i}\hat{j}\hat{k}}\sigma_{\hat{i}\hat{j}\hat{k}}+\cdots \tag{21}$$

and sums of $m+1$ elements of the form

$$A_2 I+B^{\hat{a}}\sigma_{\hat{a}}+C^{\hat{a}\hat{b}}\sigma_{\hat{a}\hat{b}}+D^{\hat{a}\hat{b}\hat{c}}\sigma_{\hat{a}\hat{b}\hat{c}}+\cdots$$

with antisymmetric coefficients $C^{\hat{i}\hat{j}}=C^{[\hat{i}\hat{j}]}$, $C^{\hat{a}\hat{b}}=C^{[\hat{a}\hat{b}]}$, $D^{\hat{i}\hat{j}\hat{k}}=D^{[\hat{i}\hat{j}\hat{k}]}$, $D^{\hat{a}\hat{b}\hat{c}}=D^{[\hat{a}\hat{b}\hat{c}]}$,... and matrices $\sigma_{\hat{i}\hat{j}}=\sigma_{[\hat{i}}\sigma_{\hat{j}]}$, $\sigma_{\hat{a}\hat{b}}=\sigma_{[\hat{a}}\sigma_{\hat{b}]}$, $\sigma_{\hat{i}\hat{j}\hat{k}}=\sigma_{[\hat{i}}\sigma_{\hat{j}}\sigma_{\hat{k}]}$,... . Really, we have 2^{n+1} coefficients $(A_1,C^{\hat{i}\hat{j}},D^{\hat{i}\hat{j}\hat{k}},\ldots)$ and 2^{m+1} coefficients $(A_2,C^{\hat{a}\hat{b}},D^{\hat{a}\hat{b}\hat{c}},\ldots)$ of Clifford d-algebra on $\mathscr{F}$.

Let us define finite (because of a finite number of elements $\sigma_{[\hat{i},\hat{j},\ldots,\hat{k}]}$ and $\sigma_{[\hat{a}\hat{b}\cdots\hat{c}]}$) sums:

$${}^{(\pm)}E^{ij}_{km}=\delta^{i}_{k}\delta^{j}_{m}+\frac{2}{1!}(\sigma_{\hat{i}})_{k}{}^{i}(\sigma^{\hat{i}})_{m}{}^{j}+\frac{2^2}{2!}(\sigma_{\hat{i}\hat{j}})_{k}{}^{i}(\sigma^{\hat{i}\hat{j}})_{m}{}^{j}+\frac{2^3}{3!}(\sigma_{\hat{i}\hat{j}\hat{k}})_{k}{}^{i}(\sigma^{\hat{i}\hat{j}\hat{k}})_{m}{}^{j}+\cdots, \tag{22}$$

$${}^{(\pm)}E^{ab}_{cd}=\delta^{a}_{c}\delta^{b}_{d}+\frac{2}{1!}(\sigma_{\hat{a}})_{c}{}^{a}(\sigma^{\hat{a}})_{d}{}^{b}+\frac{2^2}{2!}(\sigma_{\hat{a}\hat{b}})_{c}{}^{a}(\sigma^{\hat{a}\hat{b}})_{d}{}^{b}+\frac{2^3}{3!}(\sigma_{\hat{a}\hat{b}\hat{c}})_{c}{}^{a}(\sigma^{\hat{a}\hat{b}\hat{c}})_{d}{}^{b}+\ldots. \tag{23}$$

TABLE I. Symmetry properties of ϵ-objects (O, S, and A denote correspondingly vanishing, symmetry, and antisymmetry of ϵ-objects).

n(mod 8) [m(mod 8)]	${}^{(+)}\epsilon_{lm}$, ${}^{(+)}\epsilon^{lm}$ (${}^{(+)}\epsilon_{ab}$, ${}^{(+)}\epsilon^{ab}$)	${}^{(-)}\epsilon_{lm}$, ${}^{(-)}\epsilon^{lm}$ (${}^{(-)}\epsilon_{ab}$, ${}^{(-)}\epsilon^{ab}$)
0	S	S
1	O	S
2	A	S
3	A	O
4	A	A
5	O	A
6	S	A
7	S	O

E-objects (22) can be factorized as

$$
\begin{aligned}
&{}^{(\pm)}E^{ij}_{km}=N_{(h)}\,{}^{(\pm)}\epsilon_{km}\,{}^{(\pm)}\epsilon^{ij}, \quad \text{for } n=2k,\\
&{}^{(+)}E^{ij}_{km}=2N_{(h)}\epsilon_{km}\epsilon^{ij}, {}^{(-)}E^{ij}_{km}=0, \quad \text{for } n=3(\text{mod } 4),\\
&{}^{(+)}E^{ij}_{km}=0, \quad {}^{(-)}E^{ij}_{km}=2N_{(h)}\epsilon_{km}\epsilon^{ij}, \quad \text{for } n=1(\text{mod } 4)
\end{aligned}
\tag{24}
$$

[in a similar manner we can factorize E-objects (23), correspondingly, for values $m=2k$, $m=3(\text{mod } 4)$ and $m=1(\text{mod } 4)$].

From definition (21), factorization (24), and antisymmetry of $\sigma_{\hat{i}\hat{j}\hat{k}\ldots}$ and $\sigma_{\hat{a}\hat{b}\hat{c}\ldots}$ one follows the symmetry properties of ϵ-objects summarized in Table I (coordinated with canonical isomorphisms of Clifford algebras $C^{p,0}$ and $C^{0,p}$; see Sec. III in this work and similar considerations for isotropic spaces in Ref. 18. We omit proofs which in most cases are mechanical but rather tedious. By straightforward calculations the presented formulas show direct relationships between relations for Clifford d-algebra (21)–(25) and symmetric properties of spinor metrics and σ-objects on the corresponding periodicity of dimensions n and m (see Tables I and II).

For even values of $n(m)$ we can continue reduction of ${}^{\pm}E$- and ${}^{\pm}\epsilon$-objects. We define new ϵ-objects

$$
\begin{aligned}
&\epsilon^{lm}=\tfrac{1}{2}({}^{(+)}\epsilon^{lm}+{}^{(-)}\epsilon^{lm}), \quad \epsilon_{lm}=\tfrac{1}{2}({}^{(+)}\epsilon_{lm}+{}^{(-)}\epsilon_{lm}),\\
&\tilde{\epsilon}^{lm}=\tfrac{1}{2}({}^{(+)}\epsilon^{lm}-{}^{(-)}\epsilon^{lm}), \quad \epsilon_{lm}=\tfrac{1}{2}({}^{(+)}\epsilon_{lm}-{}^{(-)}\epsilon_{lm})
\end{aligned}
$$

TABLE II. ϵ-isomorphisms.

n	Spinor metrics		Juggling of indices	Canonical isomorphisms
0 (mod 4)	$\epsilon^{MN}=-\epsilon^{NM}$, $\epsilon_{MN}=-\epsilon_{NM}$,	$\epsilon^{M'N'}=-\epsilon^{N'M'}$ $\epsilon_{M'N'}=-\epsilon_{N'M'}$	$\zeta_{A'}=\epsilon_{A'B'}\zeta^{B'}$, $\zeta^{A}=\epsilon^{AB}\zeta_{B}$	$S_{(h)}\cong\tilde{S}'_{(h)}$ $\tilde{S}_{(h)}\cong S'_{(h)}$
2 (mod 4)	$\epsilon^{RS'}$, $\epsilon^{R'S}$,	$\epsilon_{RS'}$ $\epsilon_{R'S}$	$\zeta_{A'}=\epsilon_{A'B}\zeta^{B}$, $\zeta^{A'}=\epsilon^{A'B}\zeta_{B}$	$S_{(h)}\cong\tilde{S}'_{(h)}$ $S'_{(h)}\cong\tilde{S}_{(h)}$
$2k+1$ $k=0,1,2,\ldots$	ϵ^{lm},	ϵ_{lm}	$\zeta_{l}=\epsilon_{lm}\zeta^{m}$, $\zeta^{m}=\epsilon^{mn}\zeta_{n}$	$S_{(h)}\cong\tilde{S}_{(h)}$

(by similar formulas we introduce objects ϵ^{ab}, ϵ_{ab}, $\tilde{\epsilon}^{ab}$, $\tilde{\epsilon}_{ab}$ on fibers of bundle ξ_d). For simplicity, hereafter, in this section, we shall restrict our considerations only to horizontal spinor subspaces $S_{(h)}$. Introducing splitting of indices $l=L\oplus L'$, $m=M\oplus M'$, $a=A\oplus A',\ldots$, we parametrize the spinor metrics in this form:

$$\epsilon^{lm}=\begin{pmatrix}\epsilon^{LM} & 0\\ 0 & 0\end{pmatrix},\quad \tilde{\epsilon}^{lm}=\begin{pmatrix}0 & 0\\ 0 & \tilde{\epsilon}^{L'M'}\end{pmatrix},\quad \text{for } n=0(\text{mod } 4),$$

$$\epsilon^{lm}=\begin{pmatrix}0 & 0\\ \epsilon^{L'M} & 0\end{pmatrix},\quad \tilde{\epsilon}^{lm}=\begin{pmatrix}0 & \epsilon^{LM'}\\ 0 & 0\end{pmatrix},\quad \text{for } n=2(\text{mod } 4)$$

(the same formulas holds for ϵ-objects with covariant spinor indices).

From Table I we conclude that ϵ^{MN}, ϵ_{MN}, $\tilde{\epsilon}^{M'N'}$, $\tilde{\epsilon}_{M'N'}$ are symmetric (antisymmetric) for $n=0(\text{mod } 8)$ $(n=4(\text{mod } 8))$, $\tilde{\epsilon}^{AB'}=\epsilon^{B'A}$, $\tilde{\epsilon}_{AB'}=\pm\epsilon_{B'A}$ for $n=6(\text{mod } 8)$ and $\tilde{\epsilon}^{AB'}=-\epsilon^{B'A}$, $\tilde{\epsilon}_{AB'}=-\epsilon_{B'A}$ for $n=2(\text{mod } 8)$.

Let us denote horizontal spinors as $\zeta^N\in\mathbb{S}_{(h)}$, $\zeta^{N'}\in\mathbb{S}'_{(h)}$, $\zeta_N\in\tilde{\mathbb{S}}_{(h)}$ ($\tilde{\mathbb{S}}_{(h)}$ is dual to $\mathbb{S}_{(h)}$), $\zeta_{N'}\in\mathbb{S}'_{(h)}$ ($\tilde{\mathbb{S}}'_{(h)}$ is dual to $\mathbb{S}'_{(h)}$), $\zeta^l\in S_{(h)}$, and $\zeta_l\in\tilde{S}_{(h)}$ ($\tilde{S}_{(h)}$ is dual to $S_{(h)}$). By using ϵ-objects we can raise and lower indices in both cases of irreduced and reduced spinor spaces [for $n=2(\text{mod } 4)$ we can exclude, for example, primed indices, or inversely]. These properties and canonical isomorphisms between corresponding spaces are summarized in Table II.

The last subject to be considered in this section is the mutual transformation of d-tensors and d-spinors on ξ_d (or on H^{2n}). Really σ-objects from (19) or (20) allow us to obtain, for example, for $n=2(\text{mod } 4)$, from d-tensor $B^{\alpha}{}_{\beta}$ a spinor d-tensor (d-spinor): $B^{MM'}{}_{NN'}=(\sigma_\alpha)^{MM'}(\sigma'^3)_{NN'}B^{\alpha}{}_{\beta}$. On the other hand, a spinor d-tensor φ^{lm}, for example, for $n=2k+1$, can be transformed into d-vector $\varphi_\alpha=(\sigma_\alpha)_{lm}\varphi^{lm}$. So, by using σ-objects $[(\sigma_\alpha)_i{}^m,(\sigma_\alpha)_{RS},(\sigma_\alpha)^{AB},\ldots]$ we can transform σ-tensors into d-spinors and inversely d-spinors into d-tensors. We note that d-spinor–d-tensor mutual transformations are compatible to Whitney sums (2) [or (10)] for bundle ξ_d (or H^{2n}-space); i.e., "horizontal" ("vertical") d-tensorial indices must be transformed into "horizontal" ("vertical") spinor indices and inversely.

We end this section by emphasizing that the next step in the formulation of locally anisotropic spinor theory should be the development of the spinor differential geometry for $1a$-spaces.[26–28]

VII. OUTLOOK AND CONCLUSIONS

We have investigated the problem of definition of spinors on spaces with local anisotropy. Our approach is based on the formalism of Clifford d-algebras. We have introduced spinor structures on la-spaces as Clifford d-module structures on v-bundles. We have also proposed the second definition, as distinguished spinor structures, by using Clifford fibrations. It has been shown that H^{2n}-spaces admit as a proper characteristic the almost complex spinor structure. We have argued that one of the most important properties of spinors in both v-bundles with compatible nonlinear connection and metric and in H^{2n}-spaces is the periodicity 8 on the dimension of the base and on the dimension of the typical fiber spaces.

It should be noted that in this paper the distinguished Clifford and spinor structures have been introduced in an algebraic topological manner, and that in our considerations the compatibility of the d-connection and the metric, adapted to a given N-connection, plays a crucial role. Only Miron's approach to modeling on tangent bundles of spaces and media with local anisotropy admits a rigorous geometric definition of spinors. For models of Finsler and Lagrange spaces with noncompatible connection and metric structure, the definition of spinors is more sophisticated, if spinors are introduced locally with respect to the given metric quadratic form, the spinor constructions will not be invariant on parallel transport. We shall introduce corresponding discordance

laws and values and define nonstandard spinor structures by using a nonmetrical d-tensor (see similar constructions for locally isotropic curved spaces, in general with torsion and nonmetricity, in Ref. 29).

(Received 5 July 1995; accepted for publication 25 July 1995)

We discuss a method to construct a De Rham complex (differential algebra) of Poincaré–Birkhoff–Witt type on the universal enveloping algebra of a Lie algebra $\mathfrak{g}$. We determine the cases in which this gives rise to a differential Hopf algebra that naturally extends the Hopf algebra structure of $U(\mathfrak{g})$. The construction of such differential structures is interpreted in terms of color Lie superalgebras. © *1996 American Institute of Physics.* [S0022-2488(95)02112-5]

I. INTRODUCTION

Recently noncommutative differential geometry has attracted considerable interest, both mathematically and as a framework for certain models in theoretical physics. In particular, there is much activity in differential geometry on quantum groups. A noncommutative differential calculus on quantum groups has been developed by Woronowicz[1] following general ideas of Connes.[2] This general theory has been reformulated by Wess and Zumino[3] in a less abstract way. Their approach may be more suitable for specific applications in physics. A large number of papers have been written since and a few other methods to construct a noncommutative differential geometry on a quantum group or to define a differential geometric structure (a De Rham complex) on a given noncommutative algebra have been proposed and discussed by several authors (e.g., Refs. 4–6).

In this paper we present a differential calculus on the enveloping algebra of a given Lie algebra. This differential structure turns out to be a differential Hopf algebra, which can be interpreted in a very interesting way in terms of color Lie superalgebras. The commutative case has been studied previously (see, e.g., Ref. 7). Notice that our approach is different from the standard methods to construct noncommutative differential structures on Hopf algebras and quantum groups, in the sense that our starting point is not the algebra of functions on the (quantum) group but its dual the (quantized) universal enveloping algebra.

In the classical limit a quantized universal enveloping algebra defines a co-Poisson–Hopf algebra structure on the universal enveloping algebra (see Ref. 8). Further research is in progress concerning the compatibility between the differential calculus and the Poisson cobracket in order to define a differential Hopf algebra structure on the quantized universal enveloping algebra. We will report on this in the near future.

II. A DE RHAM COMPLEX ON $U(\mathfrak{g})$

Let A be an associative algebra over the field of complex numbers. A differential algebra on A (or a De Rham complex on A, see Ref. 4) is an $\mathbb{N}$-graded associative algebra Ω equipped with a linear operator d that has the following properties: (1) d is homogeneous of degree 1, i.e. $d(\Omega^p)\subset\Omega^{p+1}$ for all $p\in\mathbb{N}$. (2) d is a differential, i.e. $d^2=d\circ d=0$. (3) d is a graded derivation (of degree 1), i.e.

$$d(ab)=d(a)b+(-1)^p a d(b), \quad a\in\Omega^p, \ \ b\in\Omega. \tag{1}$$

Furthermore, the algebra Ω has to be generated by $\Omega^0 \cup d(\Omega^0)$, where Ω^0 is isomorphic to A. For A we take the universal enveloping algebra of a Lie algebra and discuss the construction of De Rham complexes on such an algebra.

Let $\mathfrak{g}$ be a finite-dimensional Lie algebra over $\mathbb{C}$ with basis $\{x^1,x^2,\ldots,x^n\}$ and corresponding structure constants C_k^{ij}, which are defined by the property $[x^i,x^j]=C_k^{ij}x^k$. Throughout this paper we will make use of the Einstein summation convention. The universal enveloping algebra of $\mathfrak{g}$, which we denote by $U(\mathfrak{g})$, can be viewed as the quotient algebra of the free associative algebra on the alphabet $\{x^1,x^2,\ldots,x^n\}$ modulo the ideal generated by the relations

$$x^i x^j - x^j x^i = C_k^{ij} x^k. \tag{2}$$

From the Poincaré–Birkhoff–Witt Theorem we know that the monomials $x^{i_1}x^{i_2}\cdots x^{i_p}$ with $p \geqslant 0$ and $i_1 \leqslant i_2 \leqslant \cdots \leqslant i_p$ form a basis of $U(\mathfrak{g})$. The main idea behind the construction of Ω on $U(\mathfrak{g})$ is that we demand Ω to be of the PBW type; by this we mean that the monomials

$$dx^{j_1}\, dx^{j_2}\cdots dx^{j_q}x^{i_1}x^{i_2}\cdots x^{i_p}, \quad \text{with } j_1<j_2<\cdots<j_q, \quad i_1\leqslant i_2\leqslant\cdots\leqslant i_p, \quad p,q\geqslant 0, \tag{3}$$

are a basis of the associative algebra Ω. From here on we will write y^j to denote the element $dx^j=d(x^j)$ in Ω^1.

In order to construct Ω we have to impose certain commutation relations between the elements x^i and y^j. On account of the homogeneity and the PBW property, we impose relations of the form

$$x^i y^j = y^k(\Theta_{lk}^{ij}x^l + A_k^{ij}), \tag{4}$$

where both Θ_{lk}^{ij} and A_k^{ij} are arbitrary complex numbers. Since we want to obtain an ideal that is invariant under the action of the differential, we adjoin the following commutation relations for the elements y^i and y^j:

$$y^i y^j = -\Theta_{lk}^{ij} y^k y^l. \tag{5}$$

This is simply the consequence of applying d to the relations (4). Let Ω be the quotient algebra of the free associative algebra on the alphabet $\{x^1,x^2,..,x^n,y^1,y^2,..,y^n\}$ modulo the ideal J that is generated by the relations (2), (4), and (5). The $\mathbb{N}$ grading of Ω is induced by giving the elements x^i degree 0 and the elements y^j degree 1. The differential d is defined by $d(x^i)=y^i$, $d(y^i)=0$ and the derivation property (1).

The coefficients Θ_{lk}^{ij} and A_k^{ij} should satisfy a number of conditions in order that Ω has the above mentioned properties of a De Rham complex on $U(\mathfrak{g})$. The first condition arises from $d(J)\subset J$, i.e. the d invariance of the ideal J. By applying d to (2) we obtain

$$y^i x^j + x^i y^j - y^j x^i - x^j y^i = C_k^{ij} y^k,$$

which, on account of the relations (4), can be written as

$$y^i x^j + y^k(\Theta_{lk}^{ij}x^l + A_k^{ij}) - y^j x^i - y^k(\Theta_{lk}^{ji}x^l + A_k^{ji}) = C_k^{ij} y^k.$$

The PBW property of Ω implies that

$$A_k^{ij} - A_k^{ji} = C_k^{ij} \quad \text{and} \quad y^i x^j - y^j x^i + (\Theta_{lk}^{ij} - \Theta_{lk}^{ji}) y^k x^l = 0.$$

We can write this in the following compact form:

$$(I-P)A = C \quad \text{and} \quad I - P + \Theta P - P\Theta P = (I-P)(I+\Theta P) = 0. \tag{6}$$

In these equations we consider A and C as $n^2\times n$ and Θ, I, and P as $n^2\times n^2$ matrices over $\mathbb{C}$, the product is just the ordinary matrix multiplication. The permutation matrix P is defined by $P^{ij}_{kl}=\delta^i_l\delta^j_k$ where δ denotes the Kronecker delta. Since the relations (5) have been found by applying d to the relations (4), and since $d^2=0$, there are no further conditions arising from the d invariance.

The PBW property yields a number of compatibility conditions that are closely related to the well-known Diamond Lemma (see, e.g., Ref. 9). The ordering is a lexicographic total degree ordering with $y^i<y^j<x^k<x^l$ for all $i<j$ and $k<l$. According to this the monomials of the form (3) are precisely the irreducible monomials. The compatibility conditions arise from rewriting terms of the form $x^ix^jx^k$, $x^ix^jy^k$, $x^iy^jy^k$, and $y^iy^jy^k$. Evidently, rewriting the terms $x^ix^jx^k$ does not lead to any conditions since it simply boils down to the proof of the Poincaré–Birkhoff–Witt Theorem. We can rewrite $x^ix^jy^k$ as

$$x^ix^jy^k=x^i(y^l(\Theta^{jk}_{pl}x^p+A^{jk}_l))=y^m(\Theta^{il}_{nm}x^n+A^{il}_m)(\Theta^{jk}_{pl}x^p+A^{jk}_l),$$

but also as

$$\begin{aligned}x^ix^jy^k&=(x^jx^i+C^{ij}_lx^l)y^k\\&=x^jy^m(\Theta^{ik}_{nm}x^n+A^{ik}_m)+C^{ij}_ly^p(\Theta^{lk}_{mp}x^m+A^{lk}_p)\\&=y^p(\Theta^{jm}_{lp}x^l+A^{jm}_p)(\Theta^{ik}_{nm}x^n+A^{ik}_m)+C^{ij}_ly^p(\Theta^{lk}_{mp}x^m+A^{lk}_p).\end{aligned}$$

Due to the PWB property of Ω, the linear part of the expressions should coincide, yielding

$$A^{jk}_lA^{il}_m=A^{ik}_pA^{jp}_m+C^{ij}_lA^{lk}_m.$$

We introduce matrices A^i by $(A^i)^j_k=A^{ij}_k$. Thus, the equation above can be written as

$$A^jA^i-A^iA^j=C^{ij}_lA^l. \tag{7}$$

The rest of the expressions give rise to the equation

$$y^my^n(A^{jk}_l\Theta^{il}_{nm}+\Theta^{jk}_{nl}A^{il}_m-A^{ik}_p\Theta^{jp}_{nm}-\Theta^{ik}_{np}A^{jp}_m-C^{ij}_l\Theta^{lk}_{nm})+y^mx^ny^p(\Theta^{jk}_{pl}\Theta^{il}_{nm}-\Theta^{ik}_{pl}\Theta^{jl}_{nm})=0.$$

By making use of the following equality:

$$x^nx^p=\tfrac{1}{2}\,(x^nx^p+x^nx^p)=\tfrac{1}{2}\,(x^nx^p+x^px^n+C^{np}_lx^l),$$

the PBW basis gives rise to two consistency conditions. The highest-order part yields

$$\Theta^{jk}_{pl}\Theta^{il}_{nm}-\Theta^{ik}_{pl}\Theta^{jl}_{nm}+\Theta^{jk}_{nl}\Theta^{il}_{pm}-\Theta^{ik}_{nl}\Theta^{jl}_{pm}=0,$$

which can shortly be written as

$$[\Theta^i_n,\Theta^j_p]=[\Theta^j_n,\Theta^i_p], \tag{8}$$

where the matrices Θ^i_j are defined by $(\Theta^i_j)^k_l=\Theta^{ik}_{jl}$. Similarly, the second-order part coefficients give the condition

$$2([A^j,\Theta^i_n]+[\Theta^j_n,A^i]-C^{ij}_l\Theta^l_n)+(\Theta^j_p\Theta^i_q-\Theta^i_p\Theta^j_q)C^{pq}_n=0. \tag{9}$$

We apply the same method to handle terms like $x^iy^jy^k$. We obtain

$$x^iy^jy^k=y^m(\Theta^{ij}_{lm}x^l+A^{ij}_m)y^k$$

$$= \Theta^{ij}_{lm} y^m y^p (\Theta^{lk}_{qp} x^q + A^{lk}_p) + A^{ij}_m y^m y^k$$
$$= \Theta^{ij}_{lm} \Theta^{lk}_{qp} y^m y^p x^q + (\Theta^{ij}_{lm} A^{lk}_p - A^{ij}_l \Theta^{lk}_{pm}) y^m y^p,$$

and on the other hand we can write

$$x^i y^j y^k = (\Theta^{jk}_{lm} A^{im}_p \Theta^{pl}_{ts} - \Theta^{jk}_{lm} \Theta^{im}_{ps} A^{pl}_t) y^s y^t - \Theta^{jk}_{lm} \Theta^{im}_{qp} \Theta^{ql}_{ts} y^p y^s x^t.$$

We remark that the relations (5) can be rewritten in the form

$$(I+S)^{ij}_{kl} y^k y^l = 0,$$

where S is a matrix with the property $S^2 = I$. On account of the PBW property of Ω, we obtain the conditions

$$(\Theta^{ij}_{lp} \Theta^{lk}_{ts} + S^{jk}_{ml} \Theta^{im}_{qp} \Theta^{ql}_{ts}) y^p y^s x^t = 0 \quad \text{and} \quad (I+S)^{jk}_{ml} (\Theta^{im}_{sp} A^{sl}_q - A^{im}_s \Theta^{sl}_{qp}) y^p y^q = 0.$$

Due to the fact that $1/2(I+S)$ is a projection, the preceding equations are equivalent to

$$(I+S)^{jk}_{ml} \Theta^{im}_{qp} \Theta^{ql}_{ts} (I-S)^{ps}_{uv} = 0, \quad (I+S)^{jk}_{ml} (\Theta^{im}_{sp} A^{sl}_q - A^{im}_s \Theta^{sl}_{qp}) (I-S)^{pq}_{uv} = 0. \tag{10}$$

The first condition can be written in the following elegant form:

$$(I+S)_{12} \Theta_{31} \Theta_{32} (I-S)_{12} = 0. \tag{11}$$

The subscripts denote the positions used to embed the $n^2 \times n^2$ matrices into the $n^3 \times n^3$ matrices, e.g., $(\Theta_{12})^{ijk}_{pqr} = \Theta^{ij}_{pq} \delta^k_r$. The consistency condition arising from rewriting the terms $y^i y^j y^k$ is

$$((I+S)_{12} \Theta_{31} \Theta_{32})^{ijk}_{pqr} y^p y^q y^r = 0.$$

This is evidently satisfied if (11) holds, so this gives no further conditions for the coefficients.

The conclusion is that the set of conditions (6), (7), (8), (9), and (10) is sufficient to define a De Rham complex Ω on $U(\mathfrak{g})$ with the PBW property. In the next section we investigate the possibility to define a differential Hopf algebra on $U(\mathfrak{g})$.

III. A DIFFERENTIAL HOPF ALGEBRA ON $U(\mathfrak{g})$

It is well known that the universal enveloping of a Lie algebra $\mathfrak{g}$ has a natural Hopf algebra structure (see, e.g., Ref. 10), its comultiplication $\Delta: U(\mathfrak{g}) \to U(\mathfrak{g}) \otimes U(\mathfrak{g})$ is defined by $\Delta(x) = 1 \otimes x + x \otimes 1$, its counit $\epsilon: U(\mathfrak{g}) \to \mathbb{C}$ by $\epsilon(x) = 0$ for all x in $\mathfrak{g}$. They both are algebra morphisms. The antipode $S: U(\mathfrak{g}) \to U(\mathfrak{g})$ is the unique antialgebra morphism satisfying $S(x) = -x$. In the preceding section we discussed the construction of a differential algebra on $U(\mathfrak{g})$, which essentially is an algebra extension of $U(\mathfrak{g})$ equipped with a differential operator d. In this section we discuss the possibility of extending Δ, ϵ, and S from $U(\mathfrak{g})$ to Ω in such a way that Ω becomes a differential Hopf algebra.

Let us first recall the notion of a differential bialgebra, for a complete description we refer to Ref. 4. A differential bialgebra is a differential algebra Ω equipped with a comultiplication Δ and a counit ϵ that are differential algebra morphisms. Note that a differential algebra morphism $\varphi: \Omega \to \Omega'$ simply is an algebra morphism of degree zero that commutes with the differentials, i.e. $\varphi \circ d = d' \circ \varphi$.

In order to write down explicitly the conditions for Δ and ϵ we need to explain the differential algebra structures of $\Omega \otimes \Omega$ and $\mathbb{C}$. The $\mathbb{N}$ grading of $\Omega \otimes \Omega$ is defined by

$$(\Omega \otimes \Omega)^p = \bigoplus_{0 \le q \le p} \Omega^q \otimes \Omega^{p-q}, \tag{12}$$

and its multiplication $\mu_{\otimes}:\Omega\otimes\Omega\otimes\Omega\otimes\Omega\to\Omega\otimes\Omega$ by

$$\mu_{\otimes}=(\mu\otimes\mu)\circ\sigma_{23}, \tag{13}$$

where μ denotes the multiplication of Ω. The linear map σ_{23} denotes the graded flip $\sigma:\Omega\otimes\Omega\to\Omega\otimes\Omega$, which is defined by

$$\sigma(a\otimes b)=(-1)^{pq}b\otimes a, \quad a\in\Omega^p, \ b\in\Omega^q, \tag{14}$$

applied to the second and third component of the tensor product. The differential $d_{\otimes}$ of $\Omega\otimes\Omega$ is given by $d_{\otimes}=d\otimes id+\tau\otimes d$, where $\tau:\Omega\to\Omega$ is the linear map of degree zero satisfying $\tau(a)=(-1)^p a$ for all $a\in\Omega^p$. Written out explicitly, this gives

$$d_{\otimes}(a\otimes b)=d(a)\otimes b+(-1)^p a\otimes d(b), \quad a\in\Omega^p, \ b\in\Omega. \tag{15}$$

Henceforth, the condition that Δ should be a differential algebra morphism means that Δ is an algebra morphism with the property

$$d_{\otimes}\circ\Delta=(d\otimes id+\tau\otimes d)\circ\Delta=\Delta\circ d. \tag{16}$$

Note that this is the analog of the derivation property (1) that can be written as $d\circ\mu=\mu\circ d_{\otimes}$. We consider $\mathbb{C}$ to be a differential algebra with $\mathbb{C}^0=\mathbb{C}$ and $\mathbb{C}^p=0$ for all $p>0$. Hence, ϵ is a differential algebra morphism if and only if it is an algebra morphism satisfying $\epsilon\circ d=0$.

Since Ω is generated by $\Omega^0\cup d(\Omega^0)$, it suffices to define the actions of Δ and ϵ on $\{x^1,x^2,\ldots,x^n,y^1,y^2,\ldots,y^n\}$. Naturally the actions on elements x^i coincide with the previously described actions on $U(\mathfrak{g})$. The above mentioned conditions for Δ and ϵ uniquely determine the actions on the elements y^j:

$$\Delta(y^i)=\Delta\circ d(x^i)=d_{\otimes}\circ\Delta(x^i)=d_{\otimes}(x^i\otimes 1+1\otimes x^i)=y^i\otimes 1+1\otimes y^i, \tag{17}$$

$$\epsilon(y^i)=\epsilon\circ d(x^i)=0. \tag{18}$$

Here we have used that $d(1)=0$, which is a direct consequence of the derivation property of d.

In order for ϵ and Δ to be well defined, the ideal J needs to be a (two-sided) coideal, i.e. $\epsilon(J)=0$ and $\Delta(J)\subset\Omega\otimes J+J\otimes\Omega$. The first condition is clearly satisfied. To verify the second we apply Δ to the relations (2), (4), and (5). Naturally the relations (2) do not give rise to any conditions for the coefficients Θ^{ij}_{lk} and A^{ij}_k. The relations (4) yield

$$\begin{aligned}\Delta(x^iy^j-\Theta^{ij}_{lk}y^k(x^l+A^{ij}_k))&=\Delta(x^i)\Delta(y^j)-\Theta^{ij}_{lk}\Delta(y^k)(\Delta(x^l)+A^{ij}_k 1\otimes 1)\\&=1\otimes x^iy^j+x^i\otimes y^j+y^j\otimes x^i+x^iy^j\otimes 1\\&\quad-\Theta^{ij}_{lk}(1\otimes y^kx^l+x^l\otimes y^k+y^k\otimes x^l+y^kx^l\otimes 1+A^{ij}_k(1\otimes y^k+y^k\otimes 1))\\&=x^i\otimes y^j+y^j\otimes x^i-\Theta^{ij}_{lk}(y^k\otimes x^l+x^l\otimes y^k)\mathrm{mod}(\Omega\otimes J+J\otimes\Omega).\end{aligned}$$

Again, on account of the PBW property of Ω, we obtain

$$x^i\otimes y^j=\Theta^{ij}_{lk}x^l\otimes y^k \quad\text{and}\quad y^j\otimes x^i=\Theta^{ij}_{lk}y^k\otimes x^l, \tag{19}$$

which evidently implies $\Theta=I$. Similarly, we find

$$\Delta(y^iy^j+\Theta^{ij}_{lk}y^ky^l)=y^i\otimes y^j-y^j\otimes y^i+\Theta^{ij}_{lk}(y^k\otimes y^l-y^l\otimes y^k)\mathrm{mod}(J\otimes\Omega+\Omega\otimes J),$$

which boils down to the condition $(I-\Theta)(I-P)=0$. Therefore, the conclusion is that Ω can only be a differential bialgebra on $U(\mathfrak{g})$ if $\Theta=I$. In that case the conditions (6), (7), (8), and (9) reduce to

$$(I-P)A=C \quad \text{and} \quad [A^j,A^i]=C_l^{ij}A^l, \tag{20}$$

due to the fact that $P^2=I$ and $S^2=I$. The commutation relations (4) and (5) take the following form:

$$x^iy^j=y^jx^i+A_k^{ij}y^k \quad \text{and} \quad y^iy^j=-y^jy^i. \tag{21}$$

We remark that we did not check the coassociativity of Δ, i.e. $(\Delta\otimes id)\circ\Delta=(id\otimes\Delta)\circ\Delta$. This is a direct consequence of the coassociativity of Δ on $U(\mathfrak{g})=\Omega^0$ since

$$\begin{aligned}(\Delta\otimes id)\circ\Delta\circ d(\Omega^0)&=(\Delta\otimes id)\circ d_\otimes\circ\Delta(\Omega^0)\\&=(d_\otimes\otimes id+\tau\otimes\tau\otimes d)\circ(\Delta\otimes id)\circ\Delta(\Omega^0)\\&=(d\otimes id\otimes id+\tau\otimes d_\otimes)\circ(id\otimes\Delta)\circ\Delta(\Omega^0)\\&=(id\otimes\Delta)\circ d_\otimes\circ\Delta(\Omega^0)=(id\otimes\Delta)\circ\Delta\circ d(\Omega^0).\end{aligned}$$

By a similar reasoning one can show that the counit property of ϵ on Ω is induced by the same property of ϵ on $U(\mathfrak{g})$.

The next step is to consider a differential Hopf algebra structure on Ω. We recall that Ω is a differential Hopf algebra (see Ref. 4) if it is a differential bialgebra that possesses an antipode S. An antipode S is an element of $End(\Omega)$ satisfying $S\star id=id\star S=\eta\circ\epsilon$, where $\star$ denotes the convolution product on $End(\Omega)$ (see Ref. 10) defined by

$$f\star g=\mu\circ(f\otimes g)\circ\Delta, \quad f,g\in End(\Omega). \tag{22}$$

By $\eta:\mathbb{C}\to\Omega$ we denote the unit element of Ω, i.e. $\eta(1)=1$. Since $\eta\circ\epsilon$ is the unit element in $End(\Omega)$ with respect to the convolution product, one can describe the antipode as the unique inverse of the identity. An important property of the antipode is that it is an antialgebra morphism; this means that $S\circ\mu\circ\sigma=(S\otimes S)\circ\mu$ and $S\circ\eta=\eta$ [or equivalently $S(1)=1$].

We try to extend the antipode of $U(\mathfrak{g})=\Omega^0$ to Ω. In order to do that we make the following observation. Suppose that f and g are homogeneous endomorphisms on Ω of degree zero that commute with the differential operator d. Then the properties $d_\otimes\circ\Delta=\Delta\circ d$ and $\mu\circ d_\otimes=d\circ\mu$ imply that

$$\begin{aligned}d\circ(f\star g)&=d\circ\mu\circ(f\otimes g)\circ\Delta\\&=\mu\circ d_\otimes\circ(f\otimes g)\circ\Delta\\&=\mu\circ(d\otimes id+\tau\otimes d)\circ(f\otimes g)\circ\Delta\\&=\mu\circ(f\otimes g)\circ(d\otimes id+\tau\otimes d)\circ\Delta\\&=\mu\circ(f\otimes g)\circ d_\otimes\circ\Delta\\&=\mu\circ(f\otimes g)\circ\Delta\circ d=(f\star g)\circ d.\end{aligned}$$

Hence, the convolution product $f\star g$ also commutes with d. By inductive use of this argument we can conclude that d commutes with $f^n=f\star f\star\cdots\star f$ for all positive values of n if f is a homoge-

neous endomorphism of degree zero satisfying $d\circ f=f\circ d$. For f we can choose the identity. This makes it plausible that d commutes with $id^{-1}=S$. So, we extend the antipode by demanding $d\circ S=S\circ d$. In particular, this yields

$$S(y^i)=S\circ d(x^i)=d\circ S(x^i)=-d(x^i)=-y^i. \tag{23}$$

For S to be a well-defined antialgebra morphism on Ω, it must leave the ideal J invariant $[S(J)\subset J]$. To verify this condition, it suffices to apply S to the relations (21). We will only write out the first; the second can be handled similarly,

$$\begin{aligned} S(x^iy^j-y^jx^i-A^{ij}_k y^k)&=S(y^j)S(x^i)-S(x^i)S(y^j)-A^{ij}_k S(y^k)\\ &=y^jx^i-x^iy^j+A^{ij}_k y^k\\ &=-(x^iy^j-y^jx^i-A^{ij}_k y^k)\in J. \end{aligned}$$

In order to check that S is indeed an antipode, we can confine ourselves to verifying the defining property of S for a set of generators of Ω. Since S is the extension of the antipode of $U(\mathfrak{g})$, we only need to compute

$$(S\star id)(y^i)=\mu\circ(S\otimes id)(1\otimes y^i+y^i\otimes 1)=1\cdot y^i-y^i\cdot 1=0=\eta\circ\epsilon(y^i).$$

So, at the end of this section we come to the following conclusion. In order to obtain a differential Hopf algebra Ω on $U(\mathfrak{g})$, it is necessary that the matrix Θ in (4) and (5) equals the identity matrix I. In that case necessary and sufficient conditions for the coefficients A^{ij}_k are given by (20), and the corresponding Hopf algebraic extension is described by (17), (18), and (23).

IV. A LIE ALGEBRAIC INTERPRETATION

The comultiplication of the universal enveloping algebra of a Lie algebra is cocommutative. We can easily verify that the cocommutativity of Δ on Ω^0 gives rise to graded cocommutativity for the extension of Δ to Ω:

$$\sigma\circ\Delta\circ d(\Omega^0)=\sigma\circ d_{\otimes}\circ\Delta(\Omega^0)=d_{\otimes}\circ\sigma\circ\Delta(\Omega^0)=d_{\otimes}\circ\Delta(\Omega^0)=\Delta\circ d(\Omega^0),$$

or, more explicitly,

$$\sigma\circ\Delta(y^i)=\sigma(1\otimes y^i+y^i\otimes 1)=y^i\otimes 1+1\otimes y^i=\Delta(y^i).$$

We call the property $\sigma\circ\Delta=\Delta$ graded cocommutativity because σ denotes the graded flip.

It is well known (see, e.g., Ref. 11) that a cocommutative Hopf algebra H, which has a compatible filtering, is isomorphic to the Hopf algebra corresponding to the universal enveloping algebra of the Lie algebra of primitive elements of H. Note that the set of primitive elements of H is defined by

$$P(H)=\{x\in H\,|\,\Delta(x)=1\otimes x+x\otimes 1\}, \tag{24}$$

which has the structure of a Lie algebra with the commutator $[x,y]=xy-yx$. By a compatible filtering we mean an increasing family of subspaces $(F_p)_{p\in N}$ of H satisfying

$$\mu(F_p\otimes F_q)\subset F_{p+q}\ \Delta(F_p)\subset\sum_{0\leqslant q\leqslant p}F_q\otimes F_{p-q}\ \bigcup_{p\in N}F_p=H. \tag{25}$$

With respect to the graded cocommutative Hopf algebra Ω, we remark that $F_p=\oplus_{0\leqslant q\leqslant p}\Omega^q$ defines a compatible filtering. Due to the graded cocommutativity, $P(\Omega)$ does not have the struc-

ture of an ordinary Lie algebra. Instead of the usual commutator we define a "color" commutator on Ω by $[x,y]=xy-(-1)^{pq}yx$ for $x\in\Omega^p$ and $y\in\Omega^q$. The set $P(\Omega)$ is closed under this bracket since

$$\begin{aligned}\Delta([x,y]) &= \Delta(xy-(-1)^{pq}yx)\\ &= \Delta(x)\Delta(y)-(-1)^{pq}\Delta(y)\Delta(x)\\ &= (1\otimes x+x\otimes 1)(1\otimes y+y\otimes 1)-(-1)^{pq}(1\otimes y+y\otimes 1)(1\otimes x+x\otimes 1)\\ &= 1\otimes xy+x\otimes y+(-1)^{pq}y\otimes x+xy\otimes 1-(-1)^{pq}(1\otimes yx+y\otimes x+(-1)^{pq}x\otimes y+yx\otimes 1)\\ &= 1\otimes(xy-(-1)^{pq}yx)+(xy-(-1)^{pq}yx)\otimes 1\\ &= 1\otimes[x,y]+[x,y]\otimes 1,\end{aligned}$$

for all $x\in P(\Omega)^p$ and $y\in P(\Omega)^q$. Note that the $\mathbb{N}$ grading of Ω induces an $\mathbb{N}$ grading on $P(\Omega)$, since Δ is homogeneous of degree zero. By this argument we have derived that $P(\Omega)$ is a color Lie superalgebra. For the definition of a color Lie superalgebra we refer to Ref. 12. The corresponding 2-cocyle α is given by

$$\alpha:\mathbb{N}\times\mathbb{N}\to\mathbb{C}^*,\quad \alpha(p,q)=(-1)^{pq}. \tag{26}$$

Since $\alpha(q,q)=(-1)^{q^2}=(-1)^q$, the elements of $P(\Omega)^q$ are even (odd) if and only if q is even (odd). As in the case of ordinary Lie algebras, one can define the universal enveloping algebra of a color Lie superalgebra and a corresponding Hopf algebraic structure on it. Analogous to the above mentioned result of Ref. 11, the Hopf algebra Ω is isomorphic to the Hopf algebra $U(P(\Omega))$.

The question is what $P(\Omega)$ explicitly looks like. The set of primitive elements of Ω certainly contains the linear span of $\{x^1,x^2,..,x^n,y^1,y^2,..,y^n\}$ [see (17)], which we will denote by L. We consider L as the $\mathbb{N}$-graded vector space $L=\oplus_{p\in N}L^p$ with

$$L^0=\langle x^i\rangle_{1\leqslant i\leqslant n},\quad L^1=\langle y^i\rangle_{1\leqslant i\leqslant n}\quad L^p=0\quad (p\geqslant 2).$$

According to the relations (2) and (21), we have

$$[x^i,x^j]=C^{ij}_k x^k,\quad [x^i,y^j]=A^{ij}_k y^k,\quad \text{and}\quad [y^i,y^j]=0, \tag{27}$$

so L is a color Lie supersubalgebra in $P(\Omega)$. Since the elements of L^0 are even and the elements of L^1 are odd, a basis of $U(L)$ can be given by (see, e.g., Ref. 12)

$$y^{j_1}y^{j_2}\cdots y^{j_q}x^{i_1}x^{i_2}\cdots x^{i_p}\quad \text{with}\ j_1<j_2<\cdots<j_q,\quad i_1\leqslant i_2\leqslant\cdots\leqslant i_p,\quad \text{and}\quad p,q\geqslant 0.$$

A comparison of this basis with the described basis of Ω [see (3)], proves that the Hopf algebra Ω is isomorphic to the Hopf algebra $U(L)$. Hence, $P(\Omega)=L$.

The preceding reasoning enables us to interpret the construction of a differential Hopf algebra on the universal enveloping of a Lie algebra $\mathfrak{g}$ in terms of a color Lie superalgebraic extension of $\mathfrak{g}$. The problem to be solved can be reformulated as follows. Given is a Lie algebra $\mathfrak{g}$ with basis $\{x^1,x^2,\ldots,x^n\}$. Let L be the $\mathbb{N}$-graded vector space given by $L^0=\mathfrak{g}$, $L^1=\langle y^i\rangle_{1\leqslant i\leqslant n}$ and $L^p=0$ for all $p\geqslant 2$. Define a bilinear operation $[\ ,\ ]$ on L of degree zero extending the commutator of $\mathfrak{g}$ in such a way that $[x^i,y^j]=A^{ij}_k y^k$. This bracket expresses the commutation relations (21). The conditions (20) for the coefficients A^{ij}_k are equivalent to demanding that L equipped with this commutator becomes a color Lie superalgebra with 2-cocycle α given by (26), satisfying the additional property that the linear map d defined by $d(x^i)=y^i$ and $d(y^i)=0$ is a graded derivation of degree

1 on L. The corresponding differential Hopf algebra on $U(\mathfrak{g})$ is then given by the Hopf algebra $U(L)$ equipped with the unique extension of the derivation d from L to $U(L)$.

V. CONCLUDING REMARKS

We have presented a framework to construct a De Rham complex on the universal enveloping algebra of a Lie algebra $\mathfrak{g}$. The fundamental property of the differential algebra is that it possesses a so-called PBW basis. We have proven that the differential algebra can be given a Hopf algebra structure extending the natural Hopf algebra $U(\mathfrak{g})$. In our presentation we assumed $\mathfrak{g}$ to be finite dimensional. This is definitely not a necessary condition; one can easily see that this framework can also be applied in the infinite-dimensional case. For more details on this and some explicit examples we refer to Ref. 13. Naturally, a De Rham complex on $U(\mathfrak{g})$ brings to surface the notion of cohomology. It would be very interesting to investigate this De Rham cohomology.

(Received 5 July 1995; accepted for publication 24 August 1995)

We examine the problem of the evaluation of both the propagator and of the partition function of a spinning particle in an external field at the classical as well as the quantum level, in connection with the asserted exactness of the stationary phase approximation. At the classical level we argue that exactness of this approximation stems from the fact that the dynamics (on the two-sphere S^2) of a spinning particle in a magnetic field is the reduction from $\mathbf{R}^4$ to S^2 of a linear dynamical system on $\mathbf{R}^4$. At the quantum level, however, and within the path integral approach, the restriction, inherent to the use of the stationary phase approximation, to regular paths clashes with the fact that no regulators are present in the action that enters the path integral. This is shown to lead to a prefactor for the path integral that is strictly divergent, except in the classical limit. A critical comparison is made with the various approaches that have been presented in the literature. The validity of a formula given in literature for the spin propagator is extended to the case of motion in an arbitrary magnetic field. © *1996 American Institute of Physics.* [S0022-2488(96)04501-5]

I. INTRODUCTION

Since the early days of path integration, how to do a path integral for spinning particles was recognized[1] as one of the major difficulties of the formalism. Schulman[2] (but also see Ref. 3) made a first attempt toward a formulation of a path integral for spinning particles, one which was, however, rather a related path integral, namely that for a spinning top.

Much progress has been made since with the systematic use, initiated by Klauder,[4,5] of the resolution of the identity associated with spin-coherent states[6,7] in the discretized-time (or time-sliced) approach to the path integral. Path integral quantization using coherent states will be discussed extensively in the sequel. Other versions of the path integral not making an explicit use of coherent states have been discussed instead in Refs. 8 and 9 (also see Ref. 10), as well as in Ref. 11 specifically for the calculation of the spin tunneling in the semiclassical limit.

Already at the classical level, a spin (classically a vector **S** of fixed magnitude s) presents some peculiarities as a dynamical system. While the Hamiltonian description is essentially straightforward if one assumes the Poisson brackets:

$$\{S_i, S_j\} = \epsilon_{ijk} S_k, \tag{1}$$

0022-2488/96/37(2)/535/19/$10.00
J. Math. Phys. **37** (2), February 1996

among the components of the spin vector, it has been pointed out by Balachandran *et al.*[12] that no global Lagrangian description can be given as long as one sticks to the natural configuration space of the spin, which is the compact two-sphere S^2. The same authors have shown that a global Lagrangian can be associated with a classical spin by lifting the description of the system from S^2 to the group manifold of SU(2), which is the three-sphere S^3, as follows. Considering the usual spin-$\frac{1}{2}$ representation of SU(2), one can define a vector $\mathbf{S}$ in S^2 via the Hopf map, i.e.

$$\tilde{S}=\mathbf{S}\cdot\boldsymbol{\sigma}=sg\sigma_3 g^{-1}, \tag{2}$$

with $\boldsymbol{\sigma}=(\sigma_1,\sigma_2,\sigma_3)$ the Pauli matrices. Then it can be shown[12] that the (global) Lagrangian on TSU(2):

$$L=is\ \mathrm{Tr}(\sigma_3 g^{-1}\dot{g})-\frac{\mu}{2}\ \mathrm{Tr}(\tilde{S}\tilde{B}), \tag{3}$$

where μ is the Bohr magneton and $\tilde{B}=\mathbf{B}\cdot\boldsymbol{\sigma}$, yields the correct equations of motion for a classical spin in an external magnetic field $\mathbf{B}$. The same equations can be derived, of course, at the Hamiltonian level using the Poisson brackets (1) and the Hamiltonian:

$$H=\mu\mathbf{S}\cdot\mathbf{B}. \tag{4}$$

As it is clear from the fact that the spin is recovered via the Hopf projection (2), this approach introduces an extra, nondynamical U(1) gauge degree of freedom. Indeed, under $g\rightarrow g\ \exp[i\gamma\sigma_3/2]$, (2) is invariant while L changes by a total time derivative (i.e., it is "weakly invariant"[12]):

$$L\rightarrow L-s\dot{\gamma}. \tag{5}$$

This is also evident if we parametrize SU(2) with the Euler angles as

$$g=e^{-i\phi\sigma_3/2}e^{-i\theta\sigma_2/2}e^{-i\gamma\sigma_3/2} \tag{6}$$

($0\leqslant\theta\leqslant\pi, 0\leqslant\phi\leqslant 2\pi, 0\leqslant\gamma\leqslant 4\pi$), which yields the (local) Lagrangian:

$$L=s(\dot{\phi}\ \cos\ \theta+\dot{\gamma})+\mu\mathbf{S}\cdot\mathbf{B}. \tag{7}$$

Although it can be shown[13] that this extra gauge degree of freedom has interesting consequences for the path integral quantization of (3), and namely that it leads in a straightforward way to spin quantization (i.e., $2s/\hbar=$integer), we would like to stress here the fact that (3) (or (7) for that matter) being linear in the time derivatives, a spinning particle is described as a constrained dynamical system. Canonical quantization requires then the use of Dirac's theory[14] of constraints, and it has been shown by Balachandran *et al.*[12] that this does indeed yield the correct quantum mechanical description of the spin, including spin quantization. As pointed out, e.g., in Ref. 9, it turns out that the (semiclassical) Bohr–Sommerfeld quantization is exact for a spin Hamiltonian. This is a strong indication that the stationary phase approximation to the path integral for, say, the propagator should be exact as well. Exactness of the stationary phase approximation implies, of course, that we discuss the applicability to the present problem of the Duistermaat–Heckman theorem, which provides a rigorous framework.

Concerning the path integral approach and the legitimacy of evaluating the path integral within the stationary phase approximation, which is the main problem addressed in the present paper, a Lagrangian of the form (7) poses another problem, and namely that, the classical equations of motion being first order in time, the saddle point problem becomes *overdetermined*, as the

solutions of the saddle point equations have to obey two boundary conditions, and not a single one. Different ways to overcome this problem have been proposed in the literature, and notably by Klauder,[4,5] Keski-Vakkuri *et al.*,[15] and Suzuki.[16]

This paper is devoted mainly to the discussion of two questions, namely that of the legitimacy of some approximations that are currently made in the coherent state formulation of the path integral for spins and that of the still unsettled problem, which has also been widely discussed in the literature, that the stationary phase approximation to the path integral yields the exact result for both the propagator and/or the partition function of a quantum spin. While the stationary phase approximation is almost trivially exact for quadratic Hamiltonians, here the apparently surprising fact is that it turns out to be exact also for the Hamiltonian (4) and/or the Lagrangian (7) that are far from being quadratic.

The paper is organized as follows. In the Appendix we briefly review the Duistermaat–Heckman theorem and the stationary phase approximation. In Sec. II we apply the latter to the calculation of the partition function of a classical spin and show that the deep reason of the validity of such an approximation is that a classical spin, when viewed as a dynamical system, can be shown to result from the reduction of a linear dynamical system from $\mathbf{R}^4$ to S^2. In Sec. III, we begin by discussing briefly the use of spin-coherent state path integral approach to the calculation of the propagator and/or of the partition function of a quantum spin. We show there that the approximation currently used in literature restricting the paths in the functional integral to be continuous leads to incorrect and diverging prefactors. Then we review briefly the approaches of Klauder and Suzuki to the same problem. We clarify the origin of some apparently mysterious terms that are added to the action in Klauder's approach. Then we analyze why the stationary phase approximation yields the exact result in Suzuki's approach, by arguing that his main result stems simply from the exactness of the Ehrenfest theorem in the present context. In Sec. IV we discuss in more detail the coherent state approach by using the holomorphic representation for the latter, applying the complex stationary phase approximation to the discrete version of the spin path integral. Section V is devoted to a general discussion and to some conclusions.

II. THE CLASSICAL SPIN

Let us start our considerations from a *classical* (nonrelativistic) spin in a time-independent magnetic field $\mathbf{B}=(B_1,B_2,B_3)$.

Since the only degree of freedom for a spin is its direction, we describe it by means of a three-dimensional vector $(S_1,S_2,S_3)\in\mathbf{R}^3$ of a fixed norm: $S_1^2+S_2^2+S_3^2=s^2$, where the three classical variables $S_j (j=1,2,3)$ satisfy the Poisson brackets (1). Thus, the phase space for a classical spin is the two-dimensional manifold $S^2(s)$, equipped with the symplectic two-form

$$\Omega=\frac{1}{2s^2}\,\epsilon_{ijk}S_i\,dS_j\wedge dS_k\,. \tag{8}$$

The Hamiltonian that describes a classical spin in a magnetic field is given by (4). For simplicity we will set $\mu\equiv 1$ in the following so that

$$H=\mathbf{B}\cdot\mathbf{S}. \tag{9}$$

The Hamiltonian vector field Δ associated to (9), which is determined by the symplectic form Ω, is given by

$$\Delta=\epsilon_{ijk}B_jS_k\,\frac{\partial}{\partial S_i}, \tag{10}$$

so that the classical equations of motion, $i_\Delta\Omega=dH$, read as

$$\dot{S}_i = \epsilon_{ijk} B_j S_k \,. \tag{11}$$

Without any loss of generality, we will set $\mathbf{B}=(0,0,B)$ $(B>0)$ from now on. In this case, the Hamiltonian (9) and the equations of motion (11) assume a very simple form if we use spherical coordinates $S_1 = s \sin\theta\cos\phi$, $S_2 = s \sin\theta\sin\phi$, $S_3 = s\cos\theta$. They become, respectively,

$$H = sB \cos\theta \tag{12}$$

and

$$\cos\theta\dot{\theta} = 0, \quad \sin\theta(\dot{\phi} - B) = 0. \tag{13}$$

The latter can be easily integrated, and one sees that the classical orbits are circles parallel to the equator, the spin processing about the magnetic field with a period $\tau = 2\pi/B$.

In spherical coordinates, it is also very easy to compute the *exact* partition function for the Hamiltonian (9):

$$\mathcal{Z}_{\mathrm{cl}}(\beta) = \int_{S^2(s)} \Omega e^{-\beta H}. \tag{14}$$

Indeed, one gets

$$\mathcal{Z}_{\mathrm{cl}}(\beta) = s \int_0^{2\pi} d\phi \int_0^{\pi} \sin\theta \, d\theta \, e^{-\beta sB\cos\theta} = \frac{2\pi}{\beta B} \left(e^{\beta sB} - e^{-\beta sB}\right). \tag{15}$$

From (15), one recognizes that the classical partition function can be written as the weighted sum of two terms, each given by the evaluation of $e^{-\beta H}$ at the two critical points $\theta=\pi$ and $\theta=0$ of the Hamiltonian, for which $\Delta_{\mathbf{S}=(0,0,\pm s)} = 0$. In addition, it is not hard to check that the weights $(\pm 2\pi/\beta B)$ are exactly the ones coming from the calculation of the contributions to the integral (15) of the Gaussian fluctuations around the stationary points of H.

Everybody is familiar with such a result whenever dealing with (multidimensional) harmonic oscillators, or, in general, with a quadratic Hamiltonian on the linear manifold $\mathbf{R}^{2n}$. Even if the Hamiltonian (9) is not of this kind, the stationary phase approximation is exact as well. A spin in a magnetic field is, in fact, the simplest (nontrivial) application of the Duistermaat–Heckman theorem,[17,18] which establishes under which conditions a phase-space integral, such as (14), can be evaluated exactly in the stationary phase approximation. We refer to the Appendix for a review of the Duistermaat–Heckman theorem and for the proof of its applicability to the system of a spin in a magnetic field. Here we recall only that this result holds essentially for the two following geometrical reasons: (1) the Hamiltonian (12) is invariant under an $U(1)$ action, given by rotations about the third axis (i.e., the axis of the constant magnetic field); (2) the associated Hamiltonian vector field, given by

$$\Delta = B\left(-S_2 \frac{\partial}{\partial S_1} + S_1 \frac{\partial}{\partial S_2}\right), \tag{16}$$

is proportional to the generator of this $U(1)$ action. This is clear in spherical coordinates, where $\Delta = B(\partial/\partial\phi)$. However, while (16) defines it globally on $S^2(s)$, the spherical coordinate representation becomes singular at $\theta = 0, \pi$.

The Duistermaat–Heckman theorem gives some abstract mathematical conditions for the stationary phase approximation to be exact. In the following we will show that for a spin in a magnetic field there is, however, a deeper reason why this holds: the dynamical system that describes a spin in the magnetic field is the reduction of a bigger system, which is described by a

quadratic Hamiltonian on the linear manifold $\mathbf{R}^4$.[19] Such a situation has already been considered in the literature (see Ref. 20 and references therein), even if not much in the context of the stationary phase approximation, but mainly in the context of integrable systems, for which there exists the conjecture[20] that every integrable system is the reduction of a bigger *linear* dynamical system. To show what happens in the case of a spin, let us consider the linear manifold $\mathbf{R}^4=\{(x_1,x_2,x_3,x_4)\}=\mathbf{C}^2=\{(z_1,z_2):z_1=x_1+ix_2,z_2=x_3+ix_4\}$, equipped with the symplectic two-form $\Omega=(1/2s)(dx_1\wedge dx_2+dx_3\wedge dx_4)=(1/2s)(1/2i)(dz_1^*\wedge dz_1+dz_2^*\wedge dz_2)$.

There is a natural action of SU(2) on $\mathbf{R}^4=\mathbf{C}^2$, which is simply given by left multiplication:

$$\begin{bmatrix}\alpha & -\beta^*\\ \beta & \alpha^*\end{bmatrix}\begin{bmatrix}z_1\\ z_2\end{bmatrix}=\begin{bmatrix}\alpha z_1-\beta^* z_2\\ \beta z_1+\alpha^* z_2\end{bmatrix},$$

where $\left[\begin{smallmatrix}\alpha & -\beta^*\\ \beta & \alpha^*\end{smallmatrix}\right]$, with $|\alpha|^2+|\beta|^2=1$, is an element of SU(2) in the fundamental representation. This action is symplectic and Hamiltonian,[21] and its Lie algebra is spanned by the vector fields:

$$\begin{gathered}\bar{\chi}_1=x_4\partial_1-x_3\partial_2+x_2\partial_3-x_1\partial_4,\quad \bar{\chi}_2=-x_3\partial_1-x_4\partial_2+x_1\partial_3+x_2\partial_4,\\ \bar{\chi}_3=x_2\partial_1-x_1\partial_2-x_4\partial_3+x_3\partial_4.\end{gathered}\tag{17}$$

Hence, it is easy to prove that the linear vector field $\bar{\Delta}=\Sigma_{j=1}^3 B_j\bar{\chi}_j$ is a Hamiltonian vector field with a quadratic Hamiltonian, namely

$$\bar{H}=\sum_{j=1}^{3} B_j f_j,\tag{18}$$

where

$$\begin{gathered}f_1=\frac{1}{2s}(x_1x_3+x_2x_4)=\frac{1}{2s}\,\mathrm{Re}\,z_1^*z_2,\quad f_2=\frac{1}{2s}(x_1x_4-x_2x_3)=\frac{1}{2s}\,\mathrm{Im}\,z_1^*z_2,\\ f_3=\frac{1}{4s}(x_1^2+x_2^2-x_3^2-x_4^2)=\frac{1}{4s}(|z_1|^2-|z_2|^2).\end{gathered}\tag{19}$$

Here we can identify $\mathbf{R}^4$ with $T^*\mathbf{R}^2$ with canonical coordinates x_1, x_3 and momenta $p_1=x_2/2s$ and $p_2=x_4/2s$.

The SU(2) action we are considering leaves the three-dimensional spheres $S^3(R)=\{(x_1,x_2,x_3,x_4):x_1^2+x_2^2+x_3^2+x_4^2=R^2\}=\{(z_1,z_2):|z_1|^2+|z_2|^2=R^2\}$ invariant, so that we can restrict the dynamics from the full $\mathbf{R}^4$ to the submanifolds $S^3(R)$ on which the classical orbits lie. In the following we choose $R=2s$ and work on $S^3(2s)$.

The functions (19) and hence the Hamiltonian (18) have an additional symmetry, being invariant under the action of U(1), given by

$$(z_1,z_2)\mapsto(e^{i\theta}z_1,e^{i\theta}z_2),\quad \theta\in[0,2\pi[.$$

This allows us to project the Hamiltonian (18) from $S^3(2s)$ down to the two-dimensional manifold $S^3(2s)/\mathrm{U}(1)$, which is homeomorphic to the two-dimensional sphere. Indeed, the three functions $(x_1,x_2,x_3,x_4)\mapsto S_j\equiv f_j(x_1,x_2,x_3,x_4)$ $(j=1,2,3)$ given in (19) are the components of the projection map from the three-sphere $S^3(2s)$ to the two-sphere $S^2(s)$ of the Hopf bundle, $\mathrm{U}(1)\to S^3\to S^2$.[22]

On $S^2(s)$ the Hamiltonian (18) becomes simply $H=\Sigma_{j=1}^3 B_jS_j$ and therefore coincides with the Hamiltonian (9) for a spin in a magnetic field. This shows that the latter is the reduction of a quadratic Hamiltonian defined on a linear manifold. To prove this rigorously, we should show also

that the restriction to $S^3(2s)$ of the symplectic two-form $\overline{\Omega}$ is the pull-back of the symplectic two-form Ω we defined on $S^2(s)$. The proof of this statement is straightforward, so we will omit details here.

The situation we have examined here has some resemblance with the problem discussed, for example, in Ref. 23, namely with the possibility of finding solutions of the wave and Laplace equations on the Euclidean plane R^2, the two-sphere S^2, and the Lobachevski plane L^2 by a descent process, starting, respectively, from R^3, S^3, L^3. We would like to remark here, however, that the dynamical system we have chosen to consider on R^4 is not equivalent to a *single* spin in a magnetic field. Indeed, the Hamiltonian (18) on R^4 simultaneously describes all values of the spin, the latter getting fixed to the single value s only when we restrict the dynamics to the submanifold $S^3(R)$ with $R=2s$.

III. COHERENT STATE PATH INTEGRALS FOR SPIN

Let us consider now the quantum mechanics of a spinning particle, described by the Hamiltonian

$$\hat{H}=\mathbf{B}\cdot\hat{\mathbf{S}}, \tag{20}$$

where the spin operators $\hat{S}_j (j=1,2,3)$ satisfy the usual commutation relations ($\hbar=1$):

$$[\hat{S}_i,\hat{S}_j]=i\epsilon_{ijk}\hat{S}_k. \tag{21}$$

We have already mentioned in the Introduction that the semiclassical Bohr–Sommerfeld quantization turns out to be exact for this problem, and this seems to suggest that the stationary phase approximation to the path integral for the propagator and/or the partition function could be exact as well. In addition, for such a simple problem, one can evaluate the partition function exactly. Its expression,

$$\mathcal{Z}(\beta)=\mathrm{Tr}\{e^{-\beta\hat{H}}\}=\frac{e^{\beta Bs}}{1-e^{-\beta B}}+\frac{e^{-\beta Bs}}{1-e^{\beta B}}, \tag{22}$$

can be thought of as the sum of two terms, each corresponding to one of the two poles of the sphere ($S_3=\pm s$), similarly to what happens in the classical case.

In this section we will briefly review the existing literature on the evaluation of the partition function for a quantum spin in a magnetic field, and, in particular, on the validity of the stationary phase approximation applied to this problem.

Let us begin by considering a set $|l\rangle$ of generalized coherent states[4,7] labeled by one or more continuous variables that we denote collectively as l. The $|l\rangle$'s will be assumed to be normalized. They are, however, overcomplete, because although there is a resolution of the identity associated with them,

$$1=\int dl|l\rangle\langle l|, \tag{23}$$

with "dl" a suitable measure, in general, they fail to be an orthonormal set: $\langle l|l'\rangle\neq 0$.

Here we are interested in the group SU(2), which is generated by the spin-operator algebra (21). Coherent states[7] for a spin s ($2s$ being an integer) can be constructed as

$$|\theta,\phi\rangle=e^{-i\phi\hat{S}_3}e^{-i\theta\hat{S}_2}|0\rangle, \tag{24}$$

where $|0\rangle$ denotes the highest-weight state of the spin-s representation of SU(2) ($\hat{S}_3|0\rangle\equiv s|0\rangle$) and θ,ϕ are the two angular coordinates parametrizing S^2: $0\leqslant\theta\leqslant\pi$; $0\leqslant\phi\leqslant 2\pi$. It is well known[6,7] that

$$\langle \theta', \phi' | \theta, \phi \rangle = \left[\cos \frac{\theta'}{2} \cos \frac{\theta}{2} e^{i(\phi' - \phi)/2} + \sin \frac{\theta'}{2} \sin \frac{\theta}{2} e^{-i(\phi' - \phi)/2} \right]^{2s}, \tag{25}$$

and that the resolution of the identity associated with spin-coherent states is

$$1 = \frac{2s+1}{4\pi} \int_0^{2\pi} \int_0^{\pi} |\theta, \phi\rangle \langle \theta, \phi| \sin \theta \, d\theta \, d\phi. \tag{26}$$

Going back to the general case, let $\hat{H}$ be the Hamiltonian of a quantum system. The matrix element of the propagator,

$$K(l_F, l_I, T) = \langle l_F | e^{-i\hat{H}T} | l_I \rangle, \tag{27}$$

can be represented as the following path integral:

$$K(l_F, l_I, T) = \lim_{\epsilon \to 0} \int \prod_{k=1}^{N} (dl_k) \prod_{k=0}^{N} \langle l_{k+1} | e^{-i\epsilon \hat{H}} | l_k \rangle, \tag{28}$$

where $\epsilon = T/N$ and $|l_0\rangle \equiv |l_I\rangle, |l_{N+1}\rangle \equiv |l_F\rangle$. Equation (28) can be rewritten as

$$K(l_F, l_I; T) = \lim_{\epsilon \to 0} \int \prod_{k=1}^{N} (dl_k) \prod_{k=0}^{N} e^{iA(l_{k+1}, l_k)}, \tag{29}$$

where

$$A(l_{k+1}, l_k) = -i \ln \langle l_{k+1} | l_k \rangle - \epsilon H(l_{k+1}, l_k) \tag{30}$$

and

$$H(l_{k+1}, l_k) = \frac{\langle l_{k+1} | \hat{H} | l_k \rangle}{\langle l_{k+1} | l_k \rangle}. \tag{31}$$

It is usually assumed that, for ϵ small, $|l_{k+1}\rangle$ is so close to $|l_k\rangle$ that one is allowed to expand the former around the latter to leading order in ϵ. This leads to

$$H(l_{k+1}, l_k) \sim H(l_k) = \langle l_k | \hat{H} | l_k \rangle \tag{32}$$

and to

$$\ln \langle l_{k+1} | l_k \rangle \sim \langle \delta l_k | l_k \rangle, \tag{33}$$

where $|\delta l_k\rangle = |l_{k+1}\rangle - |l_k\rangle$. Hence, the continuum version of the path integral reads as

$$\int \mathscr{D}l \, \exp\left[i \int_0^T dt [i \langle l | \dot{l} \rangle - H(l)] \right], \tag{34}$$

where $|\dot{l}\rangle = d|l\rangle/dt$. This procedure is justified when the Hamiltonian contains an explicit kinetic term that can act as a regulator, concentrating the functional measure on continuous paths. This is the case of the Wiener integral, where[24,25] the measure is concentrated on paths $q(t)$ satisfying the Lipschitz condition: $|q(t+\epsilon) - q(t)| = O(\epsilon^{1/2})$. The same holds true for the Feynman path integrals for massive particles in not too singular potentials.[1]

In the case of spin, the Hamiltonian (20) contains no regulators and the straightforward application of (32) and (33) is questionable. We will see, indeed, that it may lead to serious problems. Let us be more specific. Taking again the magnetic field along the positive z axis we have, in terms of spin-coherent states (24):

$$\langle l|\hat{H}|l\rangle \to \langle \theta,\phi|\hat{H}|\theta,\phi\rangle = sB\ \cos\ \theta \tag{35}$$

and

$$i\langle l|\dot{l}\rangle \to i\langle \theta,\phi|\frac{d}{dt}|\theta,\phi\rangle = s\ \cos\ \theta\dot{\phi}. \tag{36}$$

So we obtain the path integral:

$$\langle \theta_F,\phi_F|e^{-iB\hat{S}_3 T}|\theta_I,\phi_I\rangle = \int \mathscr{D}\Omega\ \exp\left[i\int_0^T [s\ \cos\ \theta\dot{\phi} - sB\ \cos\ \theta]dt\right], \tag{37}$$

where $\mathscr{D}\Omega = \sin\theta\mathscr{D}\theta\,\mathscr{D}\phi$. From (37) we can obtain the canonical partition function $\mathscr{Z}(\beta)$ by setting $T=-i\beta, |\theta_F,\phi_F\rangle = |\theta_I,\phi_I\rangle$ and by tracing over the angles. Following the standard procedure and Ref. 8, we evaluated $\mathscr{Z}(\beta)$ by time slicing the path integral and using the resolution of the identity (26) at each intermediate (Euclidean) time. In order to include paths turning around the North Pole any number of times, we had to extend, at every time slice, the domain of integration of the variable ϕ from $[0,2\pi]$ to $[-\infty,+\infty]$. In fact without following such a procedure one would have gotten, as in Ref. 8, a completely wrong partition function. Denoting with $\mathscr{Z}_N(\beta)$ the result for N time slices, we found for it, without any further approximation, the expression[13]

$$\mathscr{Z}_N(\beta) = \left(1+\frac{1}{2s}\right)^N \mathscr{Z}(\beta), \tag{38}$$

where $\mathscr{Z}(\beta)$ on the right-hand side is the exact partition function (22).

As one can easily notice by simple inspection, in the limit $N\to\infty$, $\mathscr{Z}_N$ coincides with the exact partition function up to a diverging prefactor. Such divergency disappears only in the classical limit, namely $\hbar\to 0$, $s\to\infty$, with $\hbar s = \text{const}$. On the other hand, the only approximations we used are those given by Eqs. (32) and mainly (33), which again are exact in the classical limit. In the sequel of this paper we shall come back to this point.

We discuss now briefly two different approaches[5,16] that lead to the conclusion that in the case of a spinning particle in a magnetic field the stationary phase approximation to the path integral for the propagator does indeed yield the exact result. This holds again up to a normalization factor not taken into account in Refs. 15 and 16, since the calculation is done in the continuum.

Klauder[5] has proposed a modified form for the action that appears in the path integral (34), redefining the latter as

$$K(l_F,l_I;T) = \lim_{\epsilon\to 0}\int \mathscr{D}l\ \exp\left[i\int_0^T dt\left[i\langle l|\dot{l}\rangle + \frac{1}{2}\,i\epsilon\langle\dot{l}|(1-|l\rangle\langle l|)|\dot{l}\rangle - H(l)\right]\right]. \tag{39}$$

The prescription here is that the limit for $\epsilon\to 0$ should be taken after having evaluated the path integral in the stationary phase approximation. For the case of a spin in a magnetic field, (39) becomes

$$K(\theta_F,\phi_F,\theta_I,\phi_I;T) = \lim_{\epsilon\to 0}\int \mathscr{D}\Omega\ \exp\left[i\int_0^T\left[s\ \cos\ \theta\dot{\phi} + \frac{1}{4}\,is\epsilon(\dot{\theta}^2+\sin^2\ \theta\dot{\phi}^2) - sB\ \cos\ \theta\right]dt\right], \tag{40}$$

and the action in (40) becomes essentially that of a particle of charge s and mass $m=1/2s\epsilon$ moving on the two-sphere S^2, coupled both with a magnetic monopole of unit strength located at the center of the sphere and with a constant electric-type field directed along the z axis. In this context, Dirac's quantization condition[26] becomes identical with the spin quantization condition, i.e., $2s=$integer.

The classical equations of motion that can be derived from the action in (40) are now second order in time for $\epsilon\neq 0$, and hence are not plagued by the already mentioned problem of overdetermination. Klauder has proved that they can be solved explicitly and that the resulting stationary phase approximation to the path integral (or, better, what he calls the ''dominant stationary phase approximation,'' namely approximating the path integral with $e^{iS_{\rm cl}}$, without any prefactor originating from the integration of Gaussian fluctuations) is indeed exact. Actually, only the free-spin case $B=0$ has been considered in Ref. 5, but the extension to $B\neq 0$ is straightforward.[13] It should be noted, incidentally, that the term that Klauder has added to the action is in the form of a kinetic energy term, thus providing the required regulator justifying the assumption of continuously varying paths.

The origin of the additional kinetic-type term, that looks somewhat mysterious in Klauder's original paper,[4] can be clarified as follows. If we push the expansion of the logarithm in (33) one step further beyond first order, we obtain, with $|\delta l\rangle\sim\epsilon|\dot{l}\rangle+\epsilon^2/2|\ddot{l}\rangle$:

$$\ln\langle l_{k+1}|l_k\rangle\sim\epsilon\langle\dot{l}_k|l_k\rangle+\frac{\epsilon^2}{2}\langle\ddot{l}_k|l_k\rangle-\frac{\epsilon^2}{2}(\langle\dot{l}_k|l_k\rangle)^2, \tag{41}$$

leading, in the continuum limit, to

$$\lim_{\epsilon\to 0}\exp\left[i\int_{t_i}^{t_f}dt\left[i\langle l|\dot{l}\rangle+\frac{1}{2}i\epsilon(-\langle\ddot{l}|l\rangle+\langle\dot{l}|l\rangle\langle l|\dot{l}\rangle)\right]\right], \tag{42}$$

where we have used $\langle l|\dot{l}\rangle=-\langle\dot{l}|l\rangle$. A final integration by parts of the term containing the second derivative yields precisely Klauder's additional term.

Suzuki[16] has adopted quite a different approach. Introducing two additional resolutions of the identity, the propagator

$$K(l_F,l_I,T)=\int_{l(0)=l_I}^{l(T)=l_F}\mathscr{D}l\ e^{iA_{FI}(l)}, \tag{43}$$

where

$$A_{FI}(l)=\int_0^T dt[i\langle l|\dot{l}\rangle-H(l)], \tag{44}$$

is rewritten in Ref. 16 in the form

$$K(l_F,l_I,T)=\int\int dl_f\,dl_i\langle l_F|l_f\rangle\langle l_f|e^{-i\hat{H}T}|l_i\rangle\langle l_i|l_I\rangle=\int\int dl_f\,dl_i\langle l_F|l_f\rangle\langle l_i|l_I\rangle\int_{l(0)=l_i}^{l(T)=l_f}\mathscr{D}l\ e^{iA_{fi}(l)}. \tag{45}$$

In general, the parameter(s) l labeling a coherent state can be defined in terms of the expectation values of a suitable set of operators: position and momentum for the free particle and the harmonic oscillator, spin components in the case of spins. Taking then the latter as Cauchy data for the canonical equations of motion, one can determine how they evolve classically in time, thus

determining a ''classical'' coherent state $|l(t)\rangle$ as the coherent state labeled by $l(t)$, the evoluted at time t of any given initial parameter set l. Then, Suzuki has argued that the stationary phase approximation to the last integral leads to

$$\int_{l(0)=l_i}^{l(T)=l_f} \mathscr{D}l\ e^{iA_{fi}(l)} \sim \delta(l_f - l_i(T)) e^{iA_{fi}}, \tag{46}$$

where $l_i(T)$ is the evoluted at time T of l_i, and that the final result of the application of the stationary phase approximation is the semiclassical propagator,

$$K_{\mathrm{sc}}(l_F, l_I, T) = \int dl_i \langle l_F | l_i(T) \rangle \langle l_i | l_I \rangle e^{iA_{fi}}, \tag{47}$$

where A_{fi} is the classical action evaluated along the classical path leading from $l(0)=l_i$ to $l(T)$. Once again, the semiclassical propagator (47) yields the exact result for the propagator of a spinning particle.

We would like to show here that the possible exactness of Eq. (47) has very little to do with the path integral formalism itself, and that it follows rather from a single assumption, one that amounts basically to assuming that the Ehrenfest theorem be applicable in the present case. Let $\hat{l}$ be the set of operators whose expectation values label a given coherent state. To each coherent state $|l\rangle$ we can associate two different time-dependent states: the ''classically'' time evoluted state $|l(t)\rangle$ defined above, and therefore such that

$$\langle l(t) | \hat{l} | l(t) \rangle = l_{\mathrm{cl}}(t), \tag{48}$$

$l_{\mathrm{cl}}(t)$ being the classical trajectory; and the quantum time evoluted state $|l,t\rangle$ obtained through the application of the full quantum evolution operator:

$$|l,t\rangle = e^{-i\hat{H}t} |l\rangle. \tag{49}$$

We require now the expectation values on the quantum evoluted state to evolve in time according to the classical equations of motion:

$$\langle l,t | \hat{l} | l,t \rangle = l_{\mathrm{cl}}(t). \tag{50}$$

In other words, we are assuming, as anticipated, the validity of the Ehrenfest theorem. A sufficient condition for this to happen is that the Heisenberg equations of motion be linear equations. This is certainly true for quadratic Hamiltonians with conventional canonical coordinates and momenta and the standard Poisson brackets among them. For spins, the Hamiltonian (4) is not of the quadratic type, but the Poisson brackets (1) lead, nonetheless, to linear equations of the motion, and hence to the validity of the Ehrenfest theorem. If we now assume that the set of operators $\hat{l}$ act irreducibly on the Hilbert space of states (which is true, e.g., for harmonic oscillators and for spin systems), the two states $|l,t\rangle$ and $|l(t)\rangle$ will differ, at most, by a phase, i.e.:

$$|l,t\rangle = e^{i\chi(t)} |l(t)\rangle. \tag{51}$$

Differentiating with respect to time, we obtain

$$\langle l(t) | \frac{d}{dt} | l(t) \rangle = -i\dot{\chi} + + \langle l,t | \frac{d}{dt} | l,t \rangle, \tag{52}$$

and hence

$$\langle l|\dot{l}\rangle_{\rm cl} = -i\dot{\chi} - i\langle l,t|\hat{H}|l,t\rangle. \tag{53}$$

If, as it is presently the case, the Hamiltonian does not contain time derivatives, we obtain, furthermore,

$$\dot{\chi} = i\langle l|\dot{l}\rangle_{\rm cl} - \langle l(t)|\hat{H}|l(t)\rangle = i\langle l|\dot{l}\rangle_{\rm cl} - H(l(t)), \tag{54}$$

and eventually, integrating the last equation and up to an irrelevant constant phase,

$$\chi(t) = \int_0^t [i\langle l|\dot{l}\rangle_{\rm cl} - H(l)]dt'. \tag{55}$$

The rhs of (55) is exactly the classical action, hence $\chi(t) = A_{\rm cl}(t)$. Then Suzuki's result follows at once from

$$K(l_F, l_I, T) = \langle l_F|e^{-i\hat{H}T}|l_T\rangle = \int dl_i \langle l_F|e^{-i\hat{H}T}|l_i\rangle\langle l_i|l_I\rangle = \int dl_i \langle l_F|l_i(T)\rangle\langle l_i|l_I\rangle e^{i\chi(T)}$$

$$= \int dl_i \langle l_F|l_i(T)\rangle\langle l_i|l_I\rangle e^{iA_{\hbar}}, \tag{56}$$

which is the desired result.

Let us analyze (56) in the specific case of a spinning particle. As already pointed out, the Hamiltonian (4) leads to linear Heisenberg equations of motion and hence to the validity of formula (56). It seems to us that this is the ultimate reason for the apparently surprising fact that stationary phase approximation to path integrals and/or semiclassical quantization leads to the exact result for the quantum propagator of a spinning particle. We would like to stress here that this is also true for the motion in a magnetic field with an arbitrary dependence on time. Formula (56) reduces therefore the quantum problem of the calculation of the spin propagator in an arbitrary magnetic field to the solution of the classical equation of motion.

The expression for the propagator can, of course, be worked out explicitly only when the classical equation of motion can be solved analytically. With a constant magnetic field along the z axis, formula (47) reads as

$$K(\theta_F, \phi_F, \theta_I, \phi_I; T) = \frac{2s+1}{4\pi} \int d\Omega_i \langle \theta_F, \phi_F|\theta_i(T), \phi_i(T)\rangle\langle \theta_i, \phi_i\theta_I, \phi_I\rangle e^{iA_{\rm cl}}. \tag{57}$$

Since the solutions of the classical equations of motion are $\theta_i(T) = \theta_i$; $\phi_i(T) = \phi_i + BT$, while $A_{\rm cl} = 0$, the above expression becomes

$$K(\theta_F, \phi_F, \theta_I, \phi_I; T) = \frac{2s+1}{4\pi} \int d\Omega_i \langle \theta_F, \phi_F|\theta_i, \phi_i + BT\rangle\langle \theta_i, \phi_i|\theta_I, \phi_I\rangle. \tag{58}$$

The integral in (58) can be done easily by noting that $\langle \theta_F, \phi_F|\theta_i, \phi_i + BT\rangle = \langle \theta_F, \phi_F - BT|\theta_i, \phi_i\rangle$ and using the resolution of the identity. We obtain, eventually,

$$K(\theta_F, \phi_F, \theta_I; \phi_I; T) = \langle \theta_F, \phi_F - BT|\theta_I, \phi_I\rangle, \tag{59}$$

which indeed gives the exact propagator, upon using formula (25) for the overlap of two coherent states.

IV. THE COMPLEX SADDLE POINT

We devote this section to another approach to the path integral for spin. It has been used, for example, in Refs. 15 and 27, where, however, only continuous and hence formal expressions for the action and the path integral have been studied.

Here we will study the path integral *discrete* version for the propagator (34). The method is based on a different choice of the spin-coherent states. Instead of (24), we consider the following states, labeled by a complex parameter μ:

$$|\mu\rangle = \frac{e^{\mu \hat{S}^-}}{(1+|\mu|^2)^s}\,|0\rangle, \tag{60}$$

where we have set $\hat{S}^{\pm}=\hat{S}_1 \pm i\hat{S}_2$. To be more precise, μ parametrizes the homogeneous space SU(2)/U(1)$=S^2$ by means of the stereographic projection of S^2 onto $\mathbf{R}^2$. With respect to the spherical coordinates θ and ϕ used previously, one has $\mu=\tan(\theta/2)e^{i\phi}$, and it is also not difficult to check that the state (60) coincides up to a phase with the state $|\theta,\phi\rangle$ defined in (24).

To write down an explicit expression for the path integral in terms of the coherent states (60), we need the matrix elements

$$\langle \lambda|\mu\rangle = \frac{(1+\lambda^*\mu)^{2s}}{(1+|\mu|^2)^s(1+|\lambda|^2)^s}, \quad \langle \lambda|\hat{S}_3|\mu\rangle = \langle \lambda|\mu\rangle s\,\frac{1-\lambda^*\mu}{1+\lambda^*\mu},$$
$$\langle \mu|\dot{\mu}\rangle = \frac{s}{1+|\mu|^2}\,(\dot{\mu}\mu^* - \dot{\mu}^*\mu), \tag{61}$$

and the explicit formula for the resolution of the identity:

$$\frac{2s+1}{\pi}\int \frac{d^2\mu}{(1+|\mu|^2)^2}\,|\mu\rangle\langle\mu| = 1, \tag{62}$$

where $d^2\mu = d(\mathrm{Re}\,\mu)d(\mathrm{Im}\,\mu)$. After some algebra, one finds that the path integral representation of the propagator is given by

$$K(\mu_F^*,\mu_I;T) = \int_{\substack{\mu(0)=\mu_I \\ (\mu(T))^*=\mu_F^*}} \frac{d^2\mu}{(1+|\mu|^2)^2}\,e^A, \tag{63}$$

where the action for a spin in a magnetic field is

$$A = is\int_0^T dt\left(i\,\frac{\dot{\mu}\mu^* - \mu\dot{\mu}^*}{1+|\mu|^2} - B\,\frac{1-|\mu|^2}{1+|\mu|^2}\right). \tag{64}$$

Again, the saddle point equations that are derived by extremizing (64):

$$\dot{\mu} = iB\mu, \quad \dot{\mu}^* = -iB\mu^*, \tag{65}$$

are first order, so that they do not admit a solution for boundary conditions of the form

$$\mu(0)=\mu_I, \quad (\mu(T))^* = \mu_F^*, \tag{66}$$

with arbitrary μ_I and μ_F.

This problem does, however, admit of solutions[15,28] if we enlarge our variable space from $\mathbf{C}$ to $\mathbf{C}^2$, and look for saddle point solutions for which $\mu(t)$ and $\mu^*(t)$ are *not* complex conjugate one of the other. In other words, we have to consider μ and μ^* as independent complex variables, and look for solutions of (65) satisfying the boundary conditions

$$\mu(0)=\mu_I, \quad \mu^*(T)=\mu_F^*. \tag{67}$$

These so-called complex saddle point solutions are easily found to be

$$\mu(t)=e^{iBt}\mu_I, \quad \mu^*(t)=e^{iB(T-t)}\mu_F^*, \tag{68}$$

and, to complete the stationary phase approximation, one has further to evaluate the contributions of the Gaussian fluctuations around the solutions (68).

This has been done by the authors of Refs. 15 and 27, who have concluded that one can obtain the exact propagator in this way. They have, however, worked with the continuous expression (64), and therefore they have performed only formal calculations. Funahashi *et al.*[29] have considered the discrete version of the integral, but they have applied a stationary phase approximation to the calculation of the partition function only. This problem, as pointed out by the same authors, is simpler than the calculation of the propagator, since the overdetermination problem can be overcome without enlarging the variable space from $\mathbf{C}$ to $\mathbf{C}^2$.

Our aim in this section is to examine whether the stationary phase approximation to the path integral (63) is exact, by performing the calculation in the *discrete* version of the path integral. The latter is given by (29), where now the generic index l stands for the complex parameter μ. By using (61) and rearranging the terms, one eventually gets

$$K(\mu_F^*,\mu_I,T)=\mathcal{N}\int\prod_{j=1}^{N-1}\frac{d^2\mu_j}{(1+\mu_j^*\mu_j)^2}\,e^A, \tag{69}$$

with

$$\mathcal{N}=\left(\frac{2s+1}{\pi}\right)^{N-1}\frac{1}{(1+|\mu_F|^2)^s(1+|\mu_I|^2)^s}, \tag{70}$$

whereas the discretized action A is given by

$$A=\sum_{j=1}^{N}\left[A_{j,j-1}+H_{j,j-1}\right]+2s\,\ln(1+\mu_F^*\mu_N), \tag{71}$$

$$A_{j,j-1}\equiv 2s\,\ln\frac{1+\mu_j^*\mu_{j-1}}{1+\mu_j^*\mu_j} \tag{72}$$

$$H_{j,j-1}=-iBs\epsilon\,\frac{1-\mu_j^*\mu_{j-1}}{1+\mu_j^*\mu_{j-1}}. \tag{73}$$

The expression for $A_{j,j-1}$ given in (72) comes from the exponentiation of the overlaps $\langle\mu_j|\mu_{j-1}\rangle$ $(j=1,\ldots,N)$. Let us remark that we have *not* expanded the overlaps to first order in the difference $|\mu_j\rangle-|\mu_{j-1}\rangle$, as is usually done to recover the continuum version [see (33)]. As already pointed out, such an expansion would be correct only in the presence of a regulating term in the action. Thus, we will work only with (72) and we will proceed now to evaluate the stationary phase approximation to the multidimensional integral (69), according to the formula

$$K(\mu_F^*,\mu_I,T)_{\rm sc}=\mathcal{N}\prod_{j=1}^{N-1}\left(\frac{1}{(1+\mu_j^*\mu_j)^2}\right)_{\rm cl} e^{A_{\rm cl}}\frac{\pi^{N-1}}{(\det M_N)^{1/2}}, \tag{74}$$

where M_N is the $2(N-1)\times 2(N-1)$ matrix of quadratic fluctuations around the classical solutions of the discretized action (71):

$$A=A_{\rm cl}+(\delta\mu_1^*,\delta\mu_1,\ldots,\delta\mu_{N-1}^*,\delta\mu_{N-1})M_N\begin{pmatrix}\delta\mu_1\\ \delta\mu_1^*\\ \vdots\\ \delta\mu_{N-1}\\ \delta\mu_{N-1}^*\end{pmatrix}. \tag{75}$$

The subscript ''cl'' means that the function (the action in this case) has to be evaluated on the classical solution, which satisfies the saddle point equations:

$$\begin{aligned}\frac{\mu_{j+1}^*-\mu_j^*}{1+\mu_j^*\mu_j}&=-i\epsilon B\,\frac{\mu_{j+1}^*}{1+\mu_{j+1}^*\mu_j},\\ \frac{\mu_j-\mu_{j-1}}{1+\mu_j^*\mu_j}&=+i\epsilon B\,\frac{\mu_{j-1}}{1+\mu_j^*\mu_{j-1}}.\end{aligned} \tag{76}$$

In (76), as well as in (71), we have explicitly written $|\mu_j|^2$ as $\mu_j\mu_j^*$ to stress the fact that in the search of the saddle point solutions we have to treat μ_j and μ_j^* as independent complex variables. Indeed, exactly as in the continuum, the equations (76) are incompatible with the boundary conditions

$$\mu_0=\mu_I,\quad \mu_N^*=\mu_F^*, \tag{77}$$

unless μ_j and μ_j^* are treated as independent variables.

We know that the classical solution has to fulfill the property $\mu_{j+1}|_{\rm cl}=\mu_j|_{\rm cl}+O(\epsilon)$, so that we can approximate the denominators on the right-hand side of (76), to get

$$\begin{aligned}\frac{\mu_{j+1}^*-\mu_j^*}{1+\mu_j^*\mu_j}&=-i\epsilon B\,\frac{\mu_j^*}{1+\mu_j^*\mu_j}+O(\epsilon^2),\\ \frac{\mu_j-\mu_{j-1}}{1+\mu_j^*\mu_j}&=+i\epsilon B\,\frac{\mu_{j-1}}{1+\mu_j^*\mu_j}+O(\epsilon^2).\end{aligned} \tag{78}$$

To order ϵ, we find for the solutions satisfying the boundary conditions (77) and for the classical action, the expressions

$$\mu_j=(1+i\epsilon B)^j\mu_I,\quad \mu_j^*=(1+i\epsilon B)^{N-j}\mu_F^*, \tag{79}$$

$$A_{\rm cl}=-isBT. \tag{80}$$

To complete the calculation of the right-hand side of (74), we have to compute the determinant of the Gaussian fluctuation matrix M_N. As for the solutions of the classical equations (76), we evaluate the matrix elements to the order $O(\epsilon)$. Neglecting therefore all the terms of at least order $O(\epsilon^2)$, we find that the only nonzero matrix elements are

$$a_j \equiv \left.\frac{\partial^2 A}{\partial \mu_j^* \, \partial \mu_j}\right|_{\rm cl} = \left.\frac{\partial^2 A}{\partial \mu_j \, \partial \mu_j^*}\right|_{\rm cl} = \left.\frac{-2s}{(1+\mu_j^* \mu_j)^2}\right|_{\rm cl} = \frac{-2s}{(1+(1+i\epsilon B)^N \mu_F^* \mu_I)^2}, \tag{81}$$

$$b_j \equiv \left.\frac{\partial^2 A}{\partial \mu_j \, \partial \mu_{j+1}^*}\right|_{\rm cl} = \left.\frac{\partial^2 A}{\partial \mu_{j+1}^* \, \partial \mu_j}\right|_{\rm cl} = \left[\frac{2s}{1+\mu_{j+1}^* \mu_j}\right]_{\rm cl} \left[\frac{1}{1+\mu_j^* \mu_j} + i\epsilon B \, \frac{1}{(1+\mu_{j+1}^* \mu_j)^2}\right]_{\rm cl}$$

$$= \frac{2s(1+i\epsilon B)}{(1+(1+i\epsilon B)^N \mu_I \mu_F^*)^2}. \tag{82}$$

Defining

$$A_i = \begin{pmatrix} a_i & 0 \\ 0 & a_i \end{pmatrix}, \quad B_i = \begin{pmatrix} 0 & 0 \\ 0 & b_i \end{pmatrix}, \quad C_i = \begin{pmatrix} b_i & 0 \\ 0 & 0 \end{pmatrix}, \tag{83}$$

the matrix M_N is given by

$$M_N = \begin{pmatrix} A_1 & B_1 & & & & \\ C_1 & A_2 & B_2 & & & \\ & & \ddots & & & \\ & & & C_{N-3} & A_{N-2} & B_{N-2} \\ & & & & C_{N-1} & A_{N-1} \end{pmatrix}. \tag{84}$$

Thus, we have

$$\det M_N = a_1^2 \cdots a_{N-1}^2 = \left[\frac{-2s}{(1+(1+i\epsilon B)^N \mu_I \mu_F^*)^2}\right]^{2(N-1)}, \tag{85}$$

which can be finally inserted, together with (80), in (74), yielding

$$K(\mu_F^*, \mu_I, T)_{\rm sc} = \left(1+\frac{1}{2s}\right)^{N-1} \frac{e^{-isBT}(1+\mu_I \mu_F^* (1+iBT/N)^N)^{2s}}{(1+|\mu_F|^2)^s (1+|\mu_I|^2)^s}. \tag{86}$$

This is again the expected result up to the divergent normalization factor $(1+1/2s)^{N-1}$. Indeed, since $\lim_{N\to\infty}(1+iBT/N)^N = e^{iBT}$, but for the prefactor, we obtain

$$K(\mu_F^*, \mu_I, T)_{\rm sc} = \frac{e^{-isBT}(1+\mu_I \mu_F^* e^{iBT})^{2s}}{(1+|\mu_F|^2)^s (1+|\mu_I|^2)^s}, \tag{87}$$

which coincides with the exact propagator.

V. CONCLUSIONS

In this paper we have examined the problem of spin in a magnetic field. We have seen that the stationary phase approximation applied to the calculation of the classical partition function yields the correct result. In quantum mechanics the situation is more complicated. We have reexamined the different approaches that have been used in literature to prove the exactness of stationary phase approximation in the calculation of the quantum propagator and partition function. All these methods, in particular those proposed by Klauder[5] and Keski-Vakkuri *et al.*,[15] make use of the continuum expression of the path integral, and hence reproduce the correct result only formally.

To test the validity of the stationary phase approximation for a spin system, we decided to work with the very definition of the path integral, namely with its discrete version. We have

written the discrete path integral for the partition function and the propagator in terms of spin coherent states and then considered two different kinds of approximations. In Sec. III we have expanded the overlaps $\langle l_k|_{lk-1}\rangle$ to first order in $\epsilon=T/N$ and then performed an exact integration. On the contrary, in Sec. IV we have made no expansion for the overlaps and applied instead the complex saddle point method to evaluate the stationary phase approximation of the path integral. In both cases, we have found that the exact result is reproduced correctly only up to an infinite normalization factor, $\lim_{N\to\infty}(1+1/2s)^N$, which goes to 1 in the classical limit $s\to\infty$, provided the latter is performed first. Notice that this fact is not a drawback just of the Hamiltonian for a spinning particle. Indeed, one can repeat easily the calculation for $H\equiv 0$ and get the same infinite constant.

A very similar conclusion has also been reached by Enz and Schilling.[11] They have examined the semiclassical theory for the tunneling of a magnetic ion in a crystal field and an applied magnetic field. In particular, they have calculated the quantum ground state energy E_0, which classically is doubly degenerate, as well as the tunnel splitting energy ΔE_0 as a function of the spin s. By performing the calculations by means of spin-coherent states, they have found that the path integral does not yield the correct semiclassical results for these physical quantities.

All this seems to suggest that, for those Hamiltonians that do not contain a regulating term (such as a kinetic part), any approximation that restricts the class of quantum paths in phase space, by imposing some regularity conditions on them, yields a wrong result. In our case this shows up in the appearance of an infinite prefactor.

We would like to conclude by commenting on the paper by Funahashi *et al.*,[29] who have been able to reproduce the exact partition function (with the correct prefactor) by performing the stationary phase approximation in the discrete path integral, written again in terms of spin-coherent states. They have obtained this result by also taking into account the Gaussian fluctuations coming from the factor $1/(1+|\mu|^2)^2=\sin\theta/4$ appearing in the integration measure. We do not want to explain this technique, which is described in detail in Ref. 29. Here we notice only that the inclusion of fluctuations coming from the measure induces a shift in the multiplicative factor appearing in front of the action from $2s$ to $2s+1$. Effectively, we can say that such a method amounts to choosing $2s+1$ as a parameter for the semiclassical expansion. If so, we should not evaluate the path integral following (74), but according to

$$K(\mu_F^*,\mu_I,T)_{\rm sc}=\mathcal{N}\prod_{j=1}^{N-1}\left(\frac{e^{-\tilde{A}/(N-1)}}{(1+\mu_j^*\mu_j)^2}\right)_{\rm cl}\frac{\pi^{N-1}e^{(2s+1)\tilde{A}_{\rm cl}}}{(\det\tilde{M}_N)^{1/2}}, \tag{88}$$

where $\tilde{A}=A/2s$ and $\tilde{M}_N$ is the matrix of Gaussian fluctuations of $(2s+1)\tilde{A}$ around the classical solution, so that

$$\det\tilde{M}_N=a_1^2\cdots a_{N-1}^2=\left[\frac{-2(s+1)}{(1+(1+i\epsilon B)^N\mu_I\mu_F^*)^2}\right]^{2(N-1)}. \tag{89}$$

It is exactly the factor $2s+1$ in (89) that cancels the same factor in $\mathcal{N}$, yielding the correct propagator.

This is quite a remarkable result. In our opinion, however, the derivation presented in Ref. 29 needs some clarification. To us, it seems to be inconsistent to include Gaussian fluctuations of the measure factor in the calculation of the stationary phase approximation without considering also its contributions to the saddle point equations. In Ref. 29 this method works only because the first derivatives of the measure factor *do* vanish at the classical solution, which in this case correspond to $\mu=0$ or $\mu=\infty$ ($\theta=0$, π in angular coordinates). But this would not be the case in slightly more complicated situations, for example for the calculation of the propagator or when considering complex saddle point solutions.

APPENDIX: THE DUISTERMAAT–HECKMAN THEOREM

Let us consider an oscillatory integral of the kind

$$I(t)\equiv\left(\frac{t}{2\pi}\right)^n\int_M \sigma e^{itf}, \tag{A1}$$

over a $(2n)$-dimensional manifold M with volume form σ. If M is a Riemannian manifold, under rather mild hypotheses, namely that the function f be a Morse function, i.e., that the Hessian matrix of f be nonsingular at all critical points of f [$\det \mathrm{Hess}_P(f)\neq 0$ if $\nabla f(P)=0$], it is possible to show[30] that for large values of the parameter t, one has

$$I(t)=\sum_P c_P e^{itf(P)}+O(t^{-1}), \tag{A2}$$

where the sum ranges over all critical points of f and the coefficients are given in terms of the determinant of the Gaussian fluctuations of f around the critical points:

$$c_P=\exp\left[i\,\frac{\pi}{4}\,\mathrm{sgn}\ \mathrm{Hess}_P(f)\right][\det \mathrm{Hess}_P(f)]^{-1/2}. \tag{A3}$$

Here the signature $\mathrm{sgn}\,A$ of a symmetric real-valued nonsingular matrix A is defined as the number of its positive eigenvalues minus the number of its negative eigenvalues.

Everybody is familiar with the elementary result that the remainder term $O(t^{-1})$ vanishes identically if M is the linear manifold $\mathbf{R}^{2n}$ with volume form $\sigma=dx_1\cdots dx_{2n}$, and the function f is a quadratic form: $f=\frac{1}{2}Q\vec{x}\cdot\vec{x}-\vec{\xi}\cdot\vec{x}$, Q being any symmetric real-valued $(2n)$-dimensional nonsingular matrix. In this case, the only critical point of f is $\vec{x}_0=Q^{-1}\vec{\xi}$ and $\mathrm{Hess}_{\vec{x}_0}(f)=Q$, so that (A2) with $O(t^{-1})\equiv 0$ gives simply the formula for a Gaussian integral.

The theorem of Duistermaat–Heckman[17] and its generalization due to Berline and Vergne[18] establish under which conditions an integral of the kind (A1) can be exactly evaluated in the stationary phase approximation, i.e., when $O(t^{-1})\equiv 0$.

Let M be a compact $(2n)$-dimensional manifold with symplectic two-form Ω and suppose M is acted upon by a compact Lie group G, whose action is symplectic and Hamiltonian.[30] Let us denote with χ_η the fundamental vector field on M generated by the action of the element η in the Lie algebra G of G and with f_η the associated Hamiltonian function ($i_{\chi_\eta}\Omega = df_\eta$, where i denotes the contraction). Then, if χ_η is nondegenerate, i.e., if it is zero only at the fixed points of G, the following results hold:[30]

(1) f_η is a Morse function;

(2)

$$\left(\frac{t}{2\pi}\right)^n\int_M \frac{\Omega^n}{n!}\,e^{itf_\eta}=\sum_P c_P e^{itf_\eta(P)}, \tag{A4}$$

where the the sum ranges over the critical points of f, i.e., over the points P, such that $\chi_\eta(P)=0$ and the coefficients c_P are given by

$$c_P=\frac{i^n}{\lambda_1\lambda_2\cdots\lambda_n}, \tag{A5}$$

the λ_j's being the coefficients appearing in the matrix L_P of the derivatives at P of the components of the vector field χ_η, $[L_P]^{ij}=(\partial\chi_\eta^i/\partial x_j)_P$, which in a suitable *positively oriented* basis can always be written as

$$L_P=\begin{bmatrix} 0 & \lambda_1 & & & & & \\ -\lambda_1 & 0 & & & & & \\ & & 0 & \lambda_2 & & & \\ & & -\lambda_2 & 0 & & & \\ & & & & \cdots & 0 & \lambda_n \\ & & & & & -\lambda_n & 0 \end{bmatrix}.$$

If M is equipped with a Riemannian metric, formula (A5) is seen to coincide with (A3).

From a physical point of view, (A4) can be applied to classical statistical mechanics for the computation of the partition function:

$$\mathcal{Z}=\int_M \frac{\Omega^n}{n!}\, e^{-\beta \mathrm{H}}. \tag{A6}$$

In this case the vector field χ_η is given by the Hamiltonian vector field Δ_{H}, where now H plays the role of the function f_η. The assumptions of the Duistermaat–Heckman theorem require Δ_{H} to be nondegenerate and to be the fundamental vector field associated with an element η of the Lie algebra G of a compact Lie group G, acting symplectically on the manifold M. If these two conditions holds, we can apply formula (A4) to conclude that (we have set $\beta=-it$):

$$\mathcal{Z}(\beta)=\left(\frac{2\pi}{i\beta}\right)^n \sum_P c_P e^{-\beta H(P)}, \tag{A7}$$

where (i) the sum ranges over the stationary points of the Hamiltonian, $\Delta_{\mathrm{H}}(P)=0$; (ii) the coefficients c_P are given by (A5) in terms of the λ_j's, the latter being the coefficients of the matrix $[L_P]_{ij}=(\partial \Delta_H^i/\partial x_j)_P$, written in a suitable positive oriented basis.

Let us go back now to the problem of a spin in a magnetic field. We want to show that the Duistermaat–Heckman theorem can be applied to this problem, so that the *exact* partition function can be calculated by means of formula (A7). The Hamiltonian vector field associated to the Hamiltonian (9) is

$$\Delta=B\left(-S_2\,\frac{\partial}{\partial S_1}+S_1\,\frac{\partial}{\partial S_2}\right), \tag{A8}$$

and it is easy to recognize that it is proportional to the generator $\chi_\eta=\partial/\partial\phi$ of the rotations about the third axis (i.e., the axis along the constant magnetic field). Thus, the Lie group that acts symplectically on the phase space manifold $S^2(s)$ is simply given by $U(1)$ in this case.

To apply (A7) we have, first of all, to find the critical points of the Hamiltonian, which are given by the North and the South Poles of the sphere:

$$P_\pm \equiv (0,0,\pm s), \tag{A9}$$

and then to compute the coefficients $c_{P_\pm}$ according to (A5). In the tangent space of P_+ and P_-, we choose to work with the positively oriented basis $(\partial/\partial S_1, \partial/\partial S_2)$ and $(\partial/\partial S_2, \partial/\partial S_1)$, respectively. With respect to these bases,

$$L_{P_\pm}(\Delta)=\mp B\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}, \tag{A10}$$

so that

$$c_{P_{\pm}} = \mp \frac{i}{B}. \tag{A11}$$

We can finally compute the partition function in the stationary phase approximation as

$$\mathcal{Z} = \frac{2\pi}{\beta B} (e^{\beta B s} - e^{-\beta B s}), \tag{A12}$$

which, in agreement with the Duistermaat–Heckman theorem, coincides with the exact partition function (15) for a spin in a magnetic field.

(Received 6 July 1995; accepted for publication 12 October 1995)

We find both radially symmetric and more general solutions in a Chern–Simons–Higgs model with a Higgs doublet. They are of the kind of the so-called semilocal defects, and show richer properties than those previously known in another type of Higgs models. © *1996 American Institute of Physics.* [S0022-2488(96)00602-2]

I. INTRODUCTION

Planar solitons arising in models enjoying both global and gauge, i.e. local symmetries, have been recently discovered by Vachaspati and Achúcarro.[1] They are called semilocal topological defects and fit in the general theme of cosmological strings,[2] although not always the magnetic flux is concentrated. The appearance took place in the extended Higgs model, the bosonic sector of the Standard Model at Weinberg angle $\Theta_W=\pi/2$, where the SU(2)-weak isospin symmetry becomes global, in the search for stable strings in variations of the Electroweak Theory.[3]

The problem of studying the stability of semilocal topological defects was addressed thereafter by Hindmarsh,[4] who showed by numerical computations that they are indeed stable. He also made the important observation that semilocal topological defects are hybrids of CP^1 lumps and Higgs vortices; the solution depends on a continuous parameter varying between zero and infinity, such that at the extreme values it is either a Higgs vortex or a CP^1 lump.

The apparent paradox of finding stability without meeting the necessary topological conditions, at least at first sight, attracted a lot of attention to the problem. In an interesting paper,[5] Gibbons *et al.* observed that the crux of the matter is the Hopf fibration, and they were also able to recognize the moduli space of solutions by means of an analysis à là Jaffe–Taubes.[6] Their results were used in Ref. 7 by Leese and Samols to elucidate the low-energy scattering of these semilocal topological defects as geodesic motion in their moduli space.

In this paper we address the issue of the existence of semilocal topological defects in a similar model. We consider an extended Chern–Simons–Higgs theory: the generalization of the model thoroughly discussed by Jackiw *et al.* in Ref. 8 to a doublet of Higgs fields. The charged scalar fields are assembled in the fundamental representation of SU(2), which is a global symmetry of the Lagrangian; meanwhile they are minimally coupled to a U(1) gauge field for which the kinetic energy is of the Chern–Simons form. The richest structure of the set of Chern–Simons–Higgs planar solitons as compared to the solitons of the Abelian Higgs model tells us that a detailed analysis of the model is worthwhile. We thus find, besides the expected semilocal topological defects associated to the topological vortices of the CSH model, a new kind related to the so-called nontopological solitons with or without vorticity. We present both radially symmetric solutions solving an interesting mechanical problem by applying the methods of Sprück and Yang[9] and describe more general situations using the ideas of Wang.[10] This latter approach, combined with index theorems à là Weinberg,[11] afford us a good knowledge of the moduli space with specially interesting results in the nontopological sectors.

From a phenomenological point of view, the model could provide a Ginzburg–Landau theory of the kind proposed by Kivelson *et al.*[12] for the Fractional Quantum Hall Effect. A pathology in the filling factor series with fraction $n=\frac{5}{2}$ has been discovered by Eisestein *et al.*[13] Hall conductivity $\rho_{xy}=\frac{5}{2}(h/e^2)$ is anomalous, in the sense that even denominators are very rare. Moreover, the

0022-2488/96/37(2)/554/13/$10.00

same team of experimentalists has determined that the incompressible state is not completely spin polarized.[14] The electron wave function is a spinor and the procedure of Ref. 12, leading from the microscopic theory to a phenomenological model in a parallel development, where the electrons are not polarized, requires a spinorial order parameter and free energy obtainable from our Lagrangian by looking at static configurations. Finally, we expect links between our vortices and Laughlin states similar to those occurring in the usual case of completely polarized electrons and odd denominator fractions (see Ref. 12).

The organization of the paper is as follows: In Sec. II, we present the model, analyze the topology of the configuration space, and propose the self-duality equations. We perform the study of radial solutions in Sec. III. Solutions with arbitrary centers as well as their moduli space are discussed in Sec. IV. To conclude, we elaborate in Sec. V on the stability of the semilocal topological defects and speculate on how to study the low-energy scattering.

II. THE MODEL

Our model is described by the action

$$S=\int d^3x\left\{\frac{\kappa}{4}\,\epsilon^{\alpha\beta\gamma}A_\alpha F_{\beta\gamma}+\frac{1}{2}\,D_\mu\Phi^\dagger D^\mu\Phi-U(\Phi)\right\}, \tag{1}$$

where the tridimensional Minkowski space–time metric is $\eta_{\mu\nu}=\mathrm{diag}(1,-1,-1)$, $\Phi=\binom{\phi_1}{\phi_2}$ is a doublet of complex scalar fields, $D_\mu\Phi=\partial_\mu\Phi-iA_\mu\Phi$, and $\mathrm{U}(\Phi)=(\lambda/8)\Phi^\dagger\Phi(\Phi^\dagger\Phi-1)$.[2] This system shows gauge invariance against the hybrid global-local $SU(2)\times U(1)$ transformations,

$$\Phi\rightarrow\Phi'=e^{(i/2)\omega_a\sigma_a}e^{i\chi(x)}\Phi, \tag{2}$$

$$A_\mu\rightarrow A'_\mu=A_\mu+\partial_\mu\chi, \tag{3}$$

where $\{\sigma_a\}$ $a=1,2,3$ are the Pauli matrices and the ω_a coefficients do not depend on the coordinates. This type of mixed Symmetry is called semilocal.[1] The action functional (1) is akin to the action for the bosonic sector of electroweak theory at Weinberg angle $\Theta_{\mathrm{W}}=\pi/2$; here the Maxwell terms for the neutral fields are replaced by the Chern–Simons term for the A_μ field, the counterpart of the massive Z field of the weak interactions. The SU(2) global symmetry would correspond thus to weak isospin symmetry, whereas the U(1) gauge group would be connected to the hypercharge.

The choice of the scalar potential $U(\Phi)$, however, is guided by the expectation of self-duality in the conventional Chern–Simons–Higgs model.[15] The theory exhibits two phases, respectively, built around the two degenerate vacua: the symmetric $\Phi=0$ and the asymmetric $\{\Phi^\dagger\Phi=1\}$. In the symmetric phase, the symmetry remains totally unbroken and four scalar bosons of mass $m_s=\sqrt{\lambda}/2$ arise, while the vector field does not propagate. In the asymmetric phase, the Higgs–Kibble mechanism takes place to produce one scalar particle of mass $m_H=\sqrt{\lambda}$ and one vector meson of mass $\mu_A=1/\kappa$. There are also two Goldstone bosons, the broken SU(2) symmetry is global, and we are left with a global U(1) symmetry that is the diagonal subgroup of $\mathrm{U}(1)\times\mathrm{U}(1)$ corresponding to the electromagnetic charge.

Classically, the dynamics follows from the field equations yield by varying (1):

$$\frac{\kappa}{2}\,\epsilon^{\mu\alpha\beta}F_{\alpha\beta}=J^\mu, \tag{4}$$

$$D_\mu\,D^\mu\Phi=2\,\frac{\partial U}{\partial\Phi^\dagger}, \tag{5}$$

where $J^\mu=-(i/2)[\Phi^\dagger\ D^\mu\Phi-\Phi\ D^\mu\Phi^\dagger]$ is a conserved current. Among them is specially interesting the modified Gauss law,

$$\kappa F_{12}=J^0=-A_0\Phi^\dagger\Phi-\frac{i}{2}\,[\Phi^\dagger\ \partial_0\Phi-\Phi\ \partial_0\Phi^\dagger], \tag{6}$$

or, in integral terms,

$$Q=\int d^2x\ J^0=\kappa\int d^2x\ F_{12}=\kappa\Phi_{\mathrm{M}}; \tag{7}$$

this equality forces the particle-like excitations of the model to be anionic.[16]

Our interest in this paper is limited to the study of the topological and nontopological defects emerging from (1), and so we will work in the space $\mathscr{C}$ of finite energy stationary configurations. For stationary configurations satisfying the modified Gauss law (6), the energy is minus the action by unit of time: $E=\int d^2x\ T_{00}=-S/T$. Plugging (6) in (1),

$$E=\int d^2x\left\{\frac{1}{4}\,\frac{\kappa}{\Phi^\dagger\Phi}\,F_{ij}F_{ij}+\frac{1}{2}\,D_k\Phi^\dagger D_k\Phi+U(\Phi)\right\}, \tag{8}$$

and we obtain a semilocal Higgs generalized model where a dielectric function $G(\Phi)=\kappa/\Phi^\dagger\Phi$ is incorporated.[17] Finite energy implies

$$F_{12}|_{\partial R^2}=0,\quad D_k\Phi|_{\partial R^2}=0,\quad \Phi|_{\partial R^2}\in V, \tag{9}$$

$V=\{\Phi=0$ or $\Phi^\dagger\Phi=1\}\cong\{0\}\cup S^3$ being the vacuum orbit of the scalar field. Due to $\Pi_0(V)=Z_2$, we can define a topological charge,

$$Q_0^T:\mathscr{C}\to Z_2,\quad Q_0^T=\Phi^\dagger\Phi|_{\partial R^2}, \tag{10}$$

but the surprising fact is that, although $\Pi_1(V)=\{0\}$, the Hopf fibration $S^3(CP^1,U(1))$ allows us to introduce a vortical topological charge, S^3 being locally isomorphic to $CP^1\times U(1)$.[1] The reason is that for the covariant derivative to vanish in the infinity of the plane when $Q_0^T=1$, it is necessary that $\Phi(\infty,\theta)=g(\infty)\Phi_0$, where g is a map from $\partial R^2\cong S^1$ to the U(1) fiber of S^3 passing by Φ_0. In addition, $A_\mu|_{\partial R^2}=-ig^{-1}\partial_\mu g$, so that $(1/2\pi)\oint_{\partial R^2}A_\mu\ dx^\mu$ gives the winding number of g. Thus

$$Q_1^T:\mathscr{C}\to Z,\quad Q_1^T=\frac{1}{2\pi}\ \oint_{\partial R^2}A_\mu\ dx^\mu=\frac{\Phi_{\mathrm{M}}}{2\pi} \tag{11}$$

is a topological charge. As a consequence, $\mathscr{C}$ breaks in topological sectors as follows

$$\mathscr{C}=\cup_{l\in Z}\mathscr{C}_0^l\cup_{n\in Z}\mathscr{C}_1^n,\quad Q_0^T[\mathscr{C}_a^b]=a,\quad Q_1^T[\mathscr{C}_a^b]=b. \tag{12}$$

Now, the problem is to find solutions of the field equations in $\mathscr{C}$ space. We can proceed by realizing that (8) admits the splitting

$$\begin{aligned}E=&\int d^2x\left\{\frac{\kappa^2}{2\Phi^\dagger\Phi}\left[F_{12}\mp\frac{\sqrt{\lambda}}{2\kappa}\,\Phi^\dagger\Phi(1-\Phi^\dagger\Phi)\right]^2+\frac{1}{2}|D_1\Phi\pm iD_2\Phi|^2\right\}\\&\pm\frac{1}{2}\int d^2x\ F_{12}\pm\frac{1}{2}\,(\kappa\sqrt{\lambda}-1)\int d^2x(1-\Phi^\dagger\Phi)F_{12}.\end{aligned} \tag{13}$$

In the Bogomolny limit $\sqrt{\lambda} = 1/\kappa$ (i.e., $\mu_A = m_H = m$), we have a lower bound for the energy, $E \geqslant \frac{1}{2}\left|\int d^2x\ F_{12}\right|$, and the bound is reached if and only if the Bogomolny equations,

$$F_{12} = \pm \frac{m^2}{2}\, \Phi^\dagger \Phi (1 - \Phi^\dagger \Phi), \tag{14}$$

$$D_1 \Phi \pm i\ D_2 \Phi = 0, \tag{15}$$

are satisfied. Configurations fulfilling (14), (15) are minima of the energy functional, and thus also represent solutions of the second-order Euler–Lagrange equations.

III. RADIALLY SYMMETRIC SOLUTIONS

We will now be concerned with the search for radially symmetric solutions of (14), (15). By applying a global SU(2) and a local trivial U(1) transformations, any configuration of such a kind can be set in the general form

$$\Phi = \begin{bmatrix} g(r) e^{in\theta} \\ \eta(r) \end{bmatrix}, \quad A_k = \epsilon_{kj}\, \frac{a(r) - n}{r^2}\, x_j, \tag{16}$$

where $g(r) \in R$ and $\eta(r) \in \mathbf{C}$. Substitution of the ansatz (16) in (14), (15) gives

$$\frac{1}{r}\frac{da}{dr} = \frac{m^2}{2}\, (g^2 + |\eta|^2)(g^2 + |\eta|^2 - 1), \tag{17}$$

$$\frac{dg}{dr} = \frac{ag}{r}, \tag{18}$$

$$\frac{d\eta}{dr} = \frac{a - n}{r}\, \eta. \tag{19}$$

Given that (16) is tantamount to $A_r = 0$, $A_\theta = n - a(r)$ for configurations in the $\mathscr{C}_l^n$ sector, regularity at the origin imposes the conditions

$$n g(0) = 0, \quad \eta(0) = \eta_0 e^{i\gamma}, \quad a(0) = n, \tag{20}$$

and finite energy requires

$$g(\infty) = l, \quad \eta(\infty) = 0, \quad a(\infty) = (l - 1)\alpha, \tag{21}$$

where *a priori* η_0, α are arbitrary real numbers that determine, together with n and l, the behavior of the solutions, both at the origin and infinity. From (18), (19), $\eta(r) = K g(r)/r^n$, $K \in \mathbf{C}$, and by defining $v(r) = \frac{1}{2} \ln g(r) + \ln(1 + |K|^2/r^{2n})$ the system (16)–(19) reduces to

$$\frac{d^2 v}{dr^2} + \frac{1}{r}\frac{dv}{dr} = m^2 e^v (e^v - 1) + \frac{4n^2 |K|^2 r^{2n-2}}{(r^{2n} + |K|^2)^2}, \tag{22}$$

$$\Phi = \frac{1}{\sqrt{r^{2n} + |K|^2}} \begin{pmatrix} r^n e^{in\theta} \\ K \end{pmatrix} e^{v(r)/2}, \quad a(r) = \frac{1}{r}\frac{dv}{dr} + \frac{n|K|^2}{r^{2n} + |K|^2}. \tag{23}$$

Equation (22) adopts a particularly appealing form by making the change $t = \ln r$ (from a geometric point of view, an isometric transformation from the plane to an infinite cone) that leads to

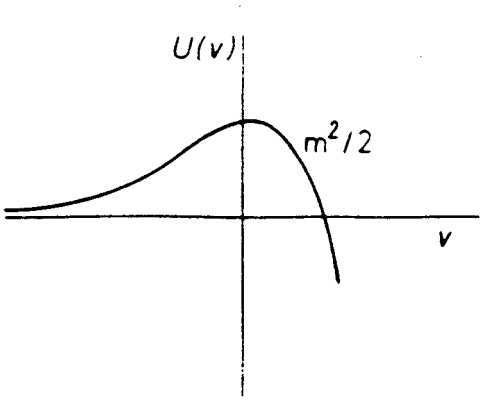

FIG. 1. A plot of U as a function of v. It could be understood as the "potential" felt by the particle at $t=0$.

$$\ddot{v}=m^2e^{2t}T(v)+F(t), \tag{24}$$

where $T(v)=e^v(e^v-1)$, $F(t)=4n^2|K|e^{2nt}/(e^{2nt}+|K|^2)^2$. Thus, we are facing a mechanical problem: one particle whose coordinate is v, submitted to a position and time depending force. The velocity of the particle is related to the vector field a by means of

$$\dot{v}=2a-\frac{2n|K|^2}{e^{2nt}+|K|^2}, \tag{25}$$

and the boundary conditions (20), (21) fix the asymptotic behavior of the movement for $t=\pm\infty$. Accordingly, we will consider each sector separately:

I. $\mathscr{C}_1^0$ sector: Here $F(t)=0$ and $\ddot{v}=-e^{2t}(dU/dv)$, $U=m^2e^v(1-e^v/2)$. From (20) and (21) we get

$$v(-\infty)=v_0, \quad \dot{v}(-\infty)=0, \tag{26}$$

$$v(+\infty)=0, \quad \dot{v}(+\infty)=0. \tag{27}$$

A glance at Fig. 1 leads us to the conclusion that $v(t)=0$ is the only possible solution compatible with (26) and (27), leading therefore to finite energy lumps: The only solution is thus the trivial one, the asymmetric vacuum.

II. $\mathscr{C}_0^n$ sector (nontopological vortices): The asymptotic conditions of the movement are

$$v(-\infty)=v_0, \quad \dot{v}(-\infty)=0, \tag{28}$$

$$v(+\infty)=-\infty, \quad \dot{v}(+\infty)=-2\alpha, \tag{29}$$

and therefore the function $v=v(t)$ has the behavior shown in Fig. 2. Bearing in mind (24), (28), and (29), it follows that v_0 is necessarily smaller than zero. Moreover, it can be shown that, if $v_0\ll 0$, v does not reach positive values, and, since $T(v)<0$ if $v<0$, the e^{2t} factor pushes the particle toward $v=-\infty$ when $t\to\infty$. To see how this can happen, let us forget about the $e^{2t}T(v)$ term in (24) at a first stage of the movement. Then the equation proves to be integrable, and from it we deduce that the particle reaches $\hat{v}<-\ln 2$ in the instant $\hat{t}\approx(2\ln K-v_0+\hat{v})/2n$ with speed $\dot{v}\approx 2n$. But the actual acceleration in (24) is more negative, and so we conclude that either the

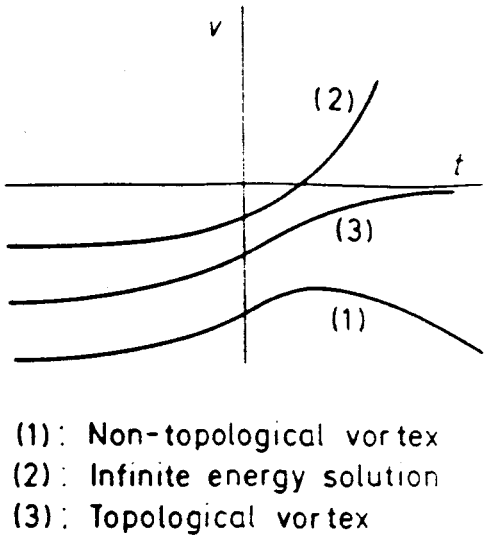

FIG. 2. Trajectories of the particles leading to (1) nontopological vortices, (2) infinite energy solutions, and (3) topological vortices.

particle does not reach $\hat{v}$ or arrives at this point for $t>\hat{t}$. Now, since $\hat{t}$ is great, for $t>\hat{t}$, $F(t)$ can be taken as $F(t) \approx 4n^2\kappa^2 e^{v_0}$, and while the particle continues moving between $\hat{v}$ and $-\ln 2$, we have

$$\ddot{v}<m^2e^{2t}T(\hat{v})+4n^2\kappa^2e^{v_0}. \tag{30}$$

If (30) were an equality, one would have that for $t=\hat{t}+\frac{1}{2}\ln[4n/m^2T(\hat{v})]$ there would be a turning point and we could always choose $\hat{v}$ so that this point would be at the left of $-\ln 2$. Since in (30) we have an upper bound for $\ddot{v}$, the turning point is in fact reached even before.

Hence, the existence of nontopological vortices is guaranteed, and from Fig. 2 and (17)–(21) it is easy to give a qualitative description of the fields: $a(r)$ and $|\eta(r)|$ decrease monotonically with r, while $g(r)$ and $|\Phi(r)|$ present a maximum; $F_{12}(r)$ presents one maximum value that splits in two if the turning point of the particle occurs for $v>-\ln 2$ (see Figs. 3, 4, and 5). The magnetic flux is $\Phi_M=2\pi(n+\alpha)$, and therefore the charge is $Q=2\pi\kappa(n+\alpha)$.

It is interesting to consider in (22), (23) the extreme situations $K=0$, $|K|\to\infty$. In the first case, $\phi_2(r,\theta)=0$, and we come back to the CSH conventional model.[8] Hence, for $K=0$ we obtain all the CSH nontopological vortices as a special limit of our solutions. To understand the other limit we note that in (23) $\Phi=\hat{\Phi}e^{v/2}$, where $\hat{\Phi}$ is exactly a CP^1 lump of topological charge n; meanwhile the $e^{v/2}$ factor is determined by (22) and the boundary conditions. Then, for general $|K|$ we can interpret our nontopological vortices as CP^1 lumps modulated by certain radial functions, the solutions of the mechanical problem (22), (28), and (29). The interesting point is that, for $|K|\to\infty$, (20)–(23) lead us to the mechanical problem

$$\ddot{v}=m^2e^{2t}e^{v}(e^{v}-1), \tag{31}$$

$$v(-\infty)=v_0, \quad \dot{v}(-\infty)=0, \tag{32}$$

$$v(+\infty)=-\infty, \quad v(-\infty)=-2\alpha-2n=-2\alpha', \tag{33}$$

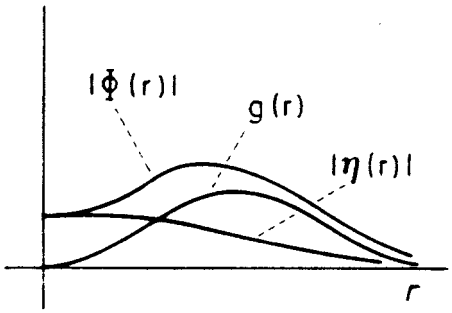

FIG. 3. Behavior of the scalar field for nontopological vortices.

corresponding exactly to the equations of a CSH nontopological soliton.[9] These limits seem to suggest that, for finite $|K|$, the nontopological vortices of the extended model interpolates between the nontopological vortices and the nontopological solitons of the standard CSH model times a CP^1 lump. The α parameter in (29) varies accordingly as a function of $|K|$: $\alpha<\alpha(|K|)$ and $2<\alpha(K)<2+2n$.[9]

III. $\mathscr{C}_1^n$ sector (topological vortices): In this sector the movement is subject to the conditions

$$v(-\infty)=v_0, \quad \dot{v}(-\infty)=0, \tag{34}$$

$$v(+\infty)=0, \quad \dot{v}(+\infty)=0, \tag{35}$$

and the $v=v(t)$ function has the appearance shown in Fig. 2. We have seen that the model contains nontopological vortices satisfying $v(+\infty)=-\infty$. Moreover, in the semilocal Abelian Higgs model there are solutions having $v(+\infty)=+\infty$,[4] and, since for $v<0$ the acceleration in (24) is less negative than the one corresponding to that model, (24) also has solutions with such behavior. The separatrix between these two types of movements satisfies (34) and (35) and corresponds to a topological vortex. In a similar way to the nontopological vortices, it is easy to understand the shape of the fields at a qualitative level (see Figs. 6–8). The magnetic flux is now $\Phi_M=2\pi n$ and the charge amounts $Q=2\pi\kappa n$. The $K\to 0$ limit of a topological vortex is a CSH

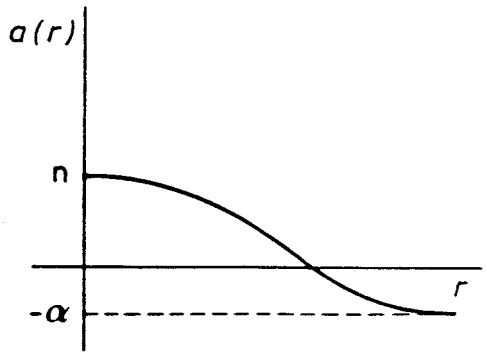

FIG. 4. The vector field of a nontopological vortex.

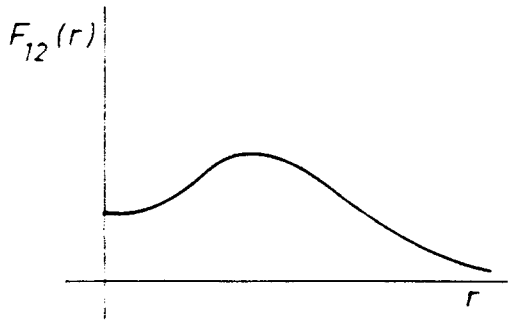

FIG. 5. Distribution of the magnetic field of nontopological vortices.

topological vortex. When $|K|\to\infty$, from (31), (34), and (35) we obtain $v(t)=0$ and arrive at a CP^1 lump of charge n, whereas for arbitrary $|K|$ we have a CP^1 lump modulated by the $e^{v/2}$ factor determined in (24), (34), and (35).

IV. $\mathscr{C}_0^0$ sector (nontopological solitons). In this case $F(t)=0$ and the mechanical problem is (31) with boundary conditions (28), (29), and a solution corresponding to a CSH nontopological soliton. Taking $n=0$ in (23), we can build the fields, which are essentially the same as for a CSH soliton, whose detailed description can be found in Refs. 8 and 9.

IV. MORE GENERAL SOLUTIONS

After having studied the radially symmetric solutions, we now will focus on the description of the space of general solutions in $\mathscr{C}$. In the topological sectors, the method put forward in Ref. 6 allows a very precise characterization based on the location on the plane of the zeros of Φ. In the nontopological ones however, the appearance of an asymptotic zero located at the infinity produces some novelties that we will show by means of an index theorem.

Following Ref. 5, we will first consider the general topological vortices in $\mathscr{C}_1^n$. In order to do so, we introduce the usual complex notation $z=x_1+ix_2$, $\partial_z=\frac{1}{2}(\partial_1-i\partial_2)$, $A=\frac{1}{2}(A_1-iA_2)$, and write (14), (15) as

$$(\partial_z-i\bar{A})\,\phi_1=0, \tag{36}$$

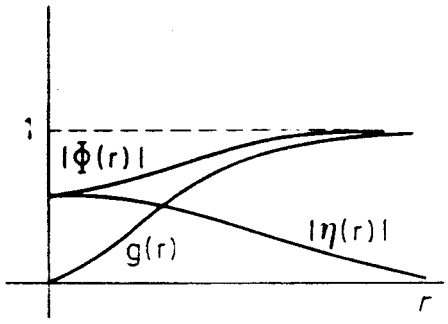

FIG. 6. The scalar field for topological vortices.

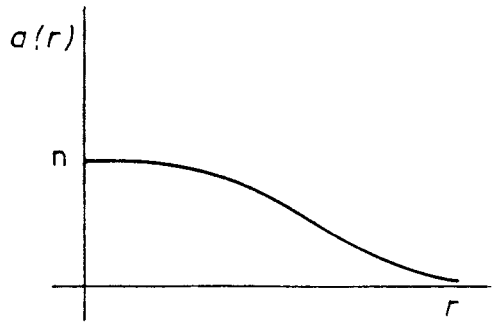

FIG. 7. The vector field of a topological vortex.

$$\partial_{\bar{z}} \ln w = 0, \tag{37}$$

$$\partial_{\bar{z}} A - \partial_z \bar{A} = -\frac{i}{4} m^2 |\phi_1|^2 (1+|w|^2)[1-|\phi_1|^2(1+|w|^2)], \tag{38}$$

where $\phi_2(z) = w(z)\phi_1(z)$. Expression (36) and boundary conditions (20), (21) imply that ϕ_1 has n zeros, say $z_1, z_2, \ldots, z_n$. Furthermore, it is possible to choose a gauge in which $\phi_1(z) = e^{1/2[u(z)+i\theta(z)]}$, where $\theta = 2\Sigma_{i=1}^{n} \arg(z-z_i)$ and $u(z)$ is a real function satisfying

$$\Delta u + m^2[1-e^u(1+|w|^2)][e^u(1+|w|^2)] = 4\pi \sum_{k=1}^{n} \delta(z-z_k), \tag{39}$$

and $\lim_{|z|\to\infty} u(z) = 0$. Equation (37) plus the boundary condition $\lim_{|z|\to\infty} w(z) = 0$ has general solution $w(z) = Q_n(z)/P_n(z)$, where $P_n(z) = \Pi_{k=1}^{n}(z-z_k)$ and $Q_n(z) = \Sigma_{k=0}^{n-1} q_n z^k$, the q_k coefficients being arbitrary. By using this in (39) and introducing $v = u + \ln(1+|w|^2)$, we conclude that the problem is tantamount to studying the equation

$$\Delta v + m^2 e^v (1-e^v) = \Delta \ln(|P_n|^2 + |Q_n|^2), \tag{40}$$

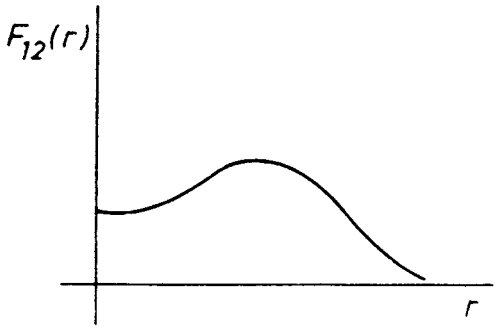

FIG. 8. Distribution of the magnetic field of topological vortices.

whose solution gives us the vortex fields as

$$\Phi=\frac{1}{\sqrt{|P_n|^2+|Q_n|^2}}\begin{pmatrix}P_n\\ Q_n\end{pmatrix}e^{v/2},\quad A=\frac{i}{2}\,\partial_z(u-i\,\theta). \tag{41}$$

For $Q_n=0$, (40) has one only solution,[10] and so the moduli space in $\mathscr{C}_1^n$ $\mathscr{M}_1^n$, has dimension $2n$ and is parametrized by the points $\{z_n\}$, where ϕ_1 vanishes. For general Q_n, proof of existence and uniqueness of solutions of (40) comes from a slight modification of the Sovolev analysis developed by Wang by writing (40) as the variational equation for a strictly convex functional of v. This leads to the conclusion that, since Q_n depends on $2n$ parameters, dim $\mathscr{M}_1^n=4n$. Instead of plunging into too technical a work, here we will exploit an index calculation that, besides giving us information about the others sectors, provides the announced result for $\mathscr{M}_1^n$.

The departure point[8,11] is to take a solution (A_k,Φ) of (14) and (15) and deform it into another $(A_k+\delta A_k,\Phi+\delta\Phi)$, at the same time imposing the Coulomb gauge condition $\partial_k\ \delta A_k=0$. This is equivalent to the requirement $\mathscr{D}(\frac{\delta\Phi}{\delta A_k})=0$, where $\mathscr{D}=iP_k\partial_k+Q$ and

$$P_1=\begin{pmatrix}-i&0&0\\0&-i&0\\0&0&-\sigma_2\end{pmatrix},\quad P_2=\begin{pmatrix}-\sigma_2&0&0\\0&-\sigma_2&0\\0&0&-i\end{pmatrix}, \tag{42}$$

$$Q=\begin{pmatrix}A_2+i\sigma_2A_1&0&\varphi_2+i\sigma_2\varphi_1\\0&A_2+i\sigma_2A_1&\psi_2+i\sigma_2\psi_1\\K\varphi&K\psi&0\end{pmatrix}, \tag{43}$$

$$\xi=\varphi\quad\text{or}\quad\psi,K\xi=\begin{pmatrix}\xi_1\mathscr{U}&\xi_2\mathscr{U}\\0&0\end{pmatrix},\quad \mathscr{U}=m(1-2\Phi^\dagger\Phi), \tag{44}$$

where we have changed the notation and put $\Phi=\binom{\varphi}{\psi}$. Thus, the dimension of the moduli space on $\mathscr{C}_a^n$, $\mathscr{M}_a^n$, essentially corresponds to the dimension of the kernel of $\mathscr{D}$, except for four global gauge modes of $\mathrm{SU}(2)_g\times\mathrm{U}(1)_\mathrm{I}$ not excluded by the Coulomb gauge in the nontopological sectors, and hence

$$\dim\mathscr{M}_1^n=\dim\ker\mathscr{D},\quad \dim\mathscr{M}_0^n=\dim\ker\mathscr{D}-4. \tag{45}$$

Now, the following operator

$$T=\begin{pmatrix}i\bar{\varphi}&i\bar{\psi}&2\partial_z\\ i\bar{\varphi}&i\bar{\psi}+1&2\partial_z\\1&0&0\\0&-i\varphi&0\\0&-i\varphi&0\\0&0&-i\varphi\\0&0&-i\varphi\end{pmatrix}, \tag{46}$$

where

$$i\xi=\begin{pmatrix}\xi_2&-\xi_1\\ \xi_1&\xi_2\end{pmatrix},\quad 2\partial_z=\begin{pmatrix}\partial_1&\partial_2\\-\partial_2&\partial_1\end{pmatrix} \tag{47}$$

satisfies Ker $T=\{0\}$, Ker $T\mathscr{D}^\dagger=\{0\}$ (except for the existence of a nongeneric zero mode of the Schrödinger operator $-\nabla^2-|\Phi|^2U$), as it is easy to verify, and so Ker $\mathscr{D}^\dagger=\{0\}$, and we have

$$\text{ind } \mathscr{D}=\dim \ker \mathscr{D}. \tag{48}$$

To compute ind $\mathscr{D}$ we shall use the heat-kernel method. We define

$$h(t)=\text{Tr } e^{-t\mathscr{D}^\dagger\mathscr{D}}-\text{Tr } e^{-t\mathscr{D}\mathscr{D}^\dagger}, \tag{49}$$

and, because of the supersymmetric pairing between the $\mathscr{D}\mathscr{D}^\dagger$ and $D^\dagger\mathscr{D}$ eigenstates corresponding to nonvanishing spectral values, we obtain

$$\text{ind } \mathscr{D}=h(0)+\Delta, \tag{50}$$

where the correction Δ must be considered in the nontopological sectors because the boundary conditions in them produce differences between the spectral densities of both operators. On the topological sectors, boundary conditions allow R^2 to be compactified to a sphere,[18] and hence $\Delta=0$. To compute $h(0)$, we build the second-order operators,

$$\mathscr{D}^\dagger\mathscr{D}=-\nabla^2+i[P_kQ^\dagger+QP_k^\dagger]\partial_k+iP_k(\partial_kQ^\dagger)+QQ^\dagger, \tag{51}$$

$$\mathscr{D}\mathscr{D}^\dagger=-\nabla^2+i[P_k^\dagger Q+Q^\dagger P_k]\partial_k+iP_k^\dagger(\partial_kQ)+Q^\dagger Q, \tag{52}$$

and realizing that $\{P_k^\dagger,P_j\}=\{P_k,P_j^\dagger\}=2\delta_{kj}$, we obtain

$$h(0)=\lim_{t\to 0}h(t)=-\frac{i}{4\pi}\int d^2x\ \text{tr}[P_k^\dagger(\partial_kQ)-P_k(\partial_kQ^\dagger)]=4\Phi_{\text{M}}. \tag{53}$$

It remains to compute Δ. For this, we observe that if Ψ_λ is an eigenstate of $\mathscr{D}^\dagger\mathscr{D}$ with eigenvalue λ^2, $\tilde{\Psi}_\lambda=(1/\lambda)\mathscr{D}\Psi_\lambda$ is also eigenstate of $\mathscr{D}\mathscr{D}^\dagger$ with the same eigenvalue, and, as a consequence,

$$\Delta=\lim_{t\to 0}\int d\lambda\int d^2x[(\tilde{\Psi}_\lambda(x),\tilde{\Psi}_\lambda(x))-(\Psi_\lambda(x),\Psi_\lambda(x))]e^{-t\lambda^2}, \tag{54}$$

and, via partial integration,

$$\Delta=\lim_{t\to 0}\int d\lambda\int_0^{2\pi}r\ d\theta(\Psi_\lambda,-iP_r^\dagger\ \mathscr{D}\Psi_\lambda)\ \frac{e^{-t\lambda^2}}{\lambda^2}\bigg|_{r=\infty}, \tag{55}$$

where $P_r=x_kP_k/r$, $P_\theta=\epsilon_{ik}x_iP_k/r^2$, and in polar coordinates $\mathscr{D}=iP_r\partial_r+iP_\theta\partial_\theta+Q$. Introducing $\mathscr{D}=iP_r[\partial_r+T_r]$,

$$\Delta=\lim_{t\to 0}\int d\lambda\int_0^{2\pi}r\ d\theta(\Psi_\lambda,[\partial_r+T_\infty]\Psi_\lambda)\ \frac{e^{-t\lambda^2}}{\lambda^2}\bigg|_{r=\infty}, \tag{56}$$

where $\mathscr{D}^\dagger\mathscr{D}_\infty=\lim_{r\to\infty}\mathscr{D}^\dagger\mathscr{D}=-\partial_r^2-(1/r)\partial_r+T_\infty^2-(1/r)(\partial_r+T_\infty)$ and

$$T_\infty = \begin{pmatrix} L & 0 & 0 \\ 0 & L & 0 \\ 0 & 0 & \dfrac{i}{r}\,\sigma_2\partial_\theta \end{pmatrix}, \quad L = \frac{1}{r}\,[-i\sigma_2\partial_\theta + n - a(\infty)]. \tag{57}$$

By using the complete orthonormal system $\{\Psi_{k\mu}(r,\theta) = e^{ikr}/\sqrt{2\pi r} f_\mu(\theta)\}$ in (56), one can show that

$$\Delta = \tfrac{1}{2}\,\eta_{T_\infty}(0) = 2 - 4\ \ Fracc[n - a(\infty)], \tag{58}$$

where $\eta_{T_\infty}(0)$ is the spectral asymmetry of the T_∞ operator and by $Fracc[\alpha]$ we denote the fractionary part of α; this, together with (45), (50), (53), (20), and (21), leads to

$$\dim \mathscr{M}_1^n = 4\Phi_{\mathrm{M}} = 4n, \quad \dim \mathscr{M}_0^n = 4\ \mathrm{Int}[\Phi_{\mathrm{M}}] - 2, \tag{59}$$

a result that in all the sectors has $2[\Phi_{\mathrm{M}}]$ parameters more than in the CSH case,[8] owing to the new degrees of freedom associated with the ϕ_2 field.

V. FURTHER COMMENTS

We now briefly consider the issue of the stability of the defects found in the model. For the topological ones, stability is sure because Bogomolny equations are associated in the topological sectors to a lower bound of the energy. The same is not true for nontopological defects, and thus it is necessary to study the spectrum of the Hessian operator, whose form restricted to the ϕ_2 deformations of a radially symmetric configuration (the ϕ_1 deformations are exactly the same as in the CSH model and lead to stability) is the following:

$$\mathscr{H} = -\frac{1}{r}\frac{d}{dr}\left(r\,\frac{d}{dr}\right) + \frac{(a-n+l)^2}{r^2} + \frac{1}{r}\frac{da}{dr}, \tag{60}$$

when operating on deformations of the form $\delta\phi_2(r,\theta) = \xi(r)e^{il\theta}$. Accordingly, the $l=0$ case is the most unfavorable, and it will suffice to concentrate on it. We do not dispose of an exact expression for the fields, but we can approximate the problem by taking

$$a(r) = \begin{cases} n - \Lambda r, & \text{if } r < \gamma/\Lambda, \\ n - \gamma, & \text{if } r > \gamma/\Lambda, \end{cases} \tag{61}$$

where $\gamma = n$ for a topological vortex and takes an arbitrary value for a nontopological defect, and Λ is a parameter that specifies the defect size. Thus, near the defect core,

$$\mathscr{H} = \mathscr{H}_{\mathrm{COUL}} + \Lambda^2, \quad \mathscr{H}_{\mathrm{COUL}} = -\frac{1}{r}\frac{d}{dr}\left(r\,\frac{d}{dr}\right) - \frac{\Lambda}{r}, \tag{62}$$

and it is known that $\mathscr{H}_{\mathrm{COUL}}$ has one only bound state with eigenvalue $-\Lambda^2$. So $\mathscr{H}$ does not have negative eigenvalues, and this can be taken as strong evidence of stability for all the defects that we have studied.

In this paper we have addressed the static semilocal CSH defects. It would be interesting to pursue the investigation by considering the low-energy scattering of these defects, as has been done in the semilocal Abelian Higgs Model.[7] The main difference is that, since our defects have an anyonic nature, the low energy Lagrangian will include a "$\epsilon_{ij}q^i q^j$" term that will prevent defects from following geodesics in the moduli space, although presumably the 90° scattering will be also present in our model.

Coherent states over Grassmann manifolds and the WKB exactness in path integral

(Received 11 September 1995; accepted for publication 7 November 1995)

U(N) coherent states over Grassmann manifold, $G_{N,n}\simeq \mathrm{U}(N)/(\mathrm{U}(n)\times \mathrm{U}(N-n))$, are formulated to be able to argue the WKB exactness in the path integral representation of a character formula. The phenomena is the so-called localization of Duistermaat–Heckman. The exponent in the path integral formula is proportional to an integer k labeling the U(N) representation. Thus, when $k\to\infty$ a usual semiclassical approximation, by regarding $k\sim 1/\hbar$, can be performed to yield a desired conclusion. The mechanism of the localization is uncovered by the help of the (generalized) Schwinger boson technique. The discussion on the Feynman kernel is also presented. © *1996 American Institute of Physics.* [S0022-2488(96)03102-0]

I. INTRODUCTION

In any physical situation it is often difficult to find an exact response, therefore, some approximation method must be employed. Apart from the well-known perturbation theories, the Wentzel–Kramers–Brillouin (WKB) approximation, known as the $\hbar$ expansion, seems most suitable to the path integral formalism; since the exponent in the path integral is usually given by a quantity divided by Planck's constant $\hbar$. These approximation methods can be straightforwardly performed without specifying a path measure rigorously, which apparently has been a main reason that the path integral plays a major role in modern physics. On the other hand, due to this handiness there always accompanies some skepticism, such as the problem of operator ordering,[1] since only c numbers appear, or a vague relationship of the change of variables to the canonical operator formalism.[2] What we have learned through various efforts is that the path integral can produce reliable as well as consistent results under the *time slicing method*. A simple example can be seen as follows: take a bosonic oscillator, defined by a Hamiltonian $H\equiv \omega a^\dagger a$ with $[a,a^\dagger]=\mathbf{I}$, $[\mathbf{I},a]=[\mathbf{I},a^\dagger]=0$, and calculate the quantity $\mathrm{Tr}\, e^{-iHT}$. First, write the exponential operator such that

$$\mathrm{Tr}\, e^{-iHT}=\lim_{M\to\infty}\mathrm{Tr}(\mathbf{I}-i\,\Delta t\,H)^M;\quad \Delta t\equiv\frac{T}{M}, \tag{1.1}$$

which is the starting point of the time slicing method. With the aid of canonical coherent states,[3] (1.1) becomes

$$\mathrm{Tr}\, e^{-i\omega a^\dagger a T} = \lim_{M\to\infty} \int_{\mathrm{PBC}} \prod_{j=1}^{M} \frac{dz(j)d\bar{z}(j)}{\pi} \exp\Bigg[-\sum_{k=1}^{M} \{\bar{z}(k)(z(k)-z(k-1)) + i\omega\, \Delta t\, \bar{z}(k)z(k-1)\}\Bigg], \tag{1.2}$$

where "PBC" denotes $z(0)=z(M)$ and $dz\, d\bar{z} \equiv d\,\mathrm{Re}(z)\, d\,\mathrm{Im}(z)$. By taking a formal limit, $M\to\infty$, the continuum representation is obtained:

$$\mathrm{Tr}\, e^{-i\omega a^\dagger a T} \to \int_{\mathrm{PBC}0\leqslant t\leqslant T} \prod dz\, d\bar{z} \exp\left\{ -\int_0^T dt(\dot{\bar{z}}z + i\omega \bar{z}z)\right\}, \tag{1.3}$$

where "PBC" reads as $z(T)=z(0)$ in this case. In spite of the formal limit, we still could impart a meaning to the functional measure by means of the functional determinant:

$$(1.3) \equiv \det\left(\frac{d}{dt} + i\omega\right)^{-1} = \frac{1}{2i\, \sin(\omega T/2)}, \tag{1.4}$$

with the aid of the ζ-function regularization. The result does not, however, match to the correct one, obtained from (1.2),

$$\frac{1}{2i\, \sin(\omega T/2)} \neq \frac{1}{1-e^{-i\omega T}} = \frac{e^{i\omega T/2}}{2i\, \sin(\omega T/2)}. \tag{1.5}$$

Therefore, we must pay the price whenever we have adopted the continuum path integral representation, which would apparently be suitable for a geometrical treatment.

In some situation an approximation scheme happens to lead to an exact answer: the harmonic oscillator is WKB exact, because of the integration being Gaussian. (The cross section of the Coulomb interaction is another well-known example,[4] which furthermore reveals that the Born approximation yields the exact result.) In recent years, however, a new possibility of finding the WKB exactness has been opened up.[5–10] Works have been stimulated by the Duistermaat–Heckman (DH) theorem.[11–13] A key word to understand these new classes of the WKB exactness would be "*localization*",[14–16] commonly understood in terms of equivariant cohomology.[17]

Inspired by these facts, we have convinced ourselves of the WKB exactness in the path integral formulas obtained through the generalized coherent states[18] in cases of $\mathbf{C}P^1$ and $\mathbf{C}P^N$,[9,10] as well as their noncompact counter parts in the foregoing papers. Even if another representation is adopted[19] for the $\mathbf{C}P^1$ case to give the Nielsen–Rohrlich form,[20] the same localization has been clarified.[21] As a natural generalization in this paper, we try to examine the Grassmann manifold, $G_{N,n} \simeq \mathrm{U}(N)/(\mathrm{U}(n)\times\mathrm{U}(N-n))$. In order to carry out the program we need to build up coherent states of $\mathrm{U}(N)$ over $G_{N,n}$.

The plan of the paper is as follows. An interpretation of the DH theorem, stated in terms of finite-dimensional integrations, is presented in Sec. II, since the WKB exactness is sometimes regarded as a generalization to the infinite-dimensional case. In order to achieve the path integral expression, there needs to construct coherent states over Grassmann manifolds. We develop two ways: one is the algebraic method according to the Perelomov's prescription[18] and the other is due to the canonical coherent state[3] combined with the Schwinger boson technique.[22] These are the contents of Sec. III A and III B, respectively. The path integral representation of the character formula is then given in Sec. IV A and the WKB approximation is performed in Sec. IV B. The mechanism of the WKB exactness is clarified in Sec. IV C by making use of the Schwinger boson.

The final section is devoted to related topics and remarks. In Appendix A, proofs for the theorems in the Sec. III A, are given. Finally, in Appendix B a discussion on the WKB exactness in terms of the Feynman kernel is provided.

II. THE DH FORMULA ON GRASSMANN MANIFOLDS

In this section, we demonstrate the validity of the DH formula on $G_{N,n}$ as a preparation for later discussions.

A. Classical mechanics on $G_{N,n}$

Let $\mathbf{C}^n$ be the n-dimensional complex vector space. We denote the space of $m\times n$ matrices over $\mathbf{C}$ by $M(m,n;\mathbf{C})$ and abbreviate $M(n,n;\mathbf{C})$ by $M(n;\mathbf{C})$. Regard $G_{N,n}\simeq \mathrm{U}(N)/(\mathrm{U}(n)\times \mathrm{U}(N-n))$ as a phase space, assuming $N\geqslant 2n$ for brevity's sake, and write

$$G_{N,n}=\{P\in M(N;\mathbf{C})\,|\,P^2=P, P^\dagger=P \quad \text{and tr } P=n\}. \tag{2.1}$$

P can be parametrized in terms of $\xi\in M(N-n,n;\mathbf{C})$, such that

$$P=\begin{pmatrix} \dfrac{1}{1_n+\xi^\dagger\xi} & \dfrac{1}{1_n+\xi^\dagger\xi}\,\xi^\dagger \\ \xi\,\dfrac{1}{1_n+\xi^\dagger\xi} & \xi\,\dfrac{1}{1_n+\xi^\dagger\xi}\,\xi^\dagger \end{pmatrix}=U(\xi)P_{1,\ldots,n}U^\dagger(\xi), \tag{2.2}$$

where

$$P_{1,\ldots,n}\equiv\begin{pmatrix} 1_n & 0 \\ 0 & 0 \end{pmatrix} \tag{2.3}$$

and

$$U(\xi)\equiv\begin{pmatrix} \dfrac{1}{\sqrt{1_n+\xi^\dagger\xi}} & -\dfrac{1}{\sqrt{1_n+\xi^\dagger\xi}}\,\xi^\dagger \\ \xi\,\dfrac{1}{\sqrt{1_n+\xi^\dagger\xi}} & \dfrac{1}{\sqrt{1_{N-n}+\xi\xi^\dagger}} \end{pmatrix}. \tag{2.4}$$

The parametrization (2.2) cannot cover the whole phase space: indeed there exist other parametrizations such as

$$(P_{\mu_1,\ldots,\mu_n})_{\rho\lambda}=\sum_{a=1}^{n}\delta_{\rho,\mu_a}\delta_{\lambda,\mu_a},\quad 1\leqslant\mu_a\leqslant N, \tag{2.5}$$

which tells us that there need $\binom{N}{n}$ kinds of local parametrization. (Throughout the paper we use a convention for indices: $1\leqslant\mu,\nu\leqslant N$; $1\leqslant a,b\leqslant n$; $n+1\leqslant i,j\leqslant N$.) In order to obtain an appropriate parametrization in the neighborhood of $P_{\mu_1,\ldots,\mu_n}$, we can utilize a unitary transformation $U(\mu_1,\ldots,\mu_n|1,\ldots,n)$ satisfying

$$U(\mu_1,\ldots,\mu_n|1,\ldots,n)P_{1,\ldots,n}U^\dagger(\mu_1,\ldots,\mu_n|1,\ldots,n)=P_{\mu_1,\ldots,\mu_n}. \tag{2.6}$$

The symplectic structure on $G_{N,n}$ is defined through the symplectic 2-form,

$$\omega=i\ \mathrm{tr}(P\ dP\wedge dP), \tag{2.7}$$

whose explicit form, under (2.2), reads as

$$\omega = i\ \mathrm{tr}\{(1_n+\xi^\dagger\xi)^{-1}\ d\xi^\dagger \wedge (1_{N-n}+\xi\xi^\dagger)^{-1}\ d\xi\}, \tag{2.8}$$

yielding to the $U(N)$ invariant measure on $G_{N,n}$,

$$\det[(1_{N-n}+\xi\xi^\dagger)^{-1}\otimes\{(1_n+\xi^\dagger\xi)^{-1}\}^{\mathscr{T}}](d\xi\ d\bar{\xi})^{n(N-n)} = \frac{1}{\{\det(1_n+\xi^\dagger\xi)\}^N}\ (d\xi\ d\bar{\xi})^{n(N-n)}, \tag{2.9}$$

where the superscript $\mathscr{T}$ denotes the transpose of matrix and an abbreviation,

$$(dz\ d\bar{z})^{mn} \equiv \prod_{\substack{1\leqslant i\leqslant m\\ 1\leqslant a\leqslant n}} d\ \mathrm{Re}(z_{ia})d\ \mathrm{Im}(z_{ia}), \tag{2.10}$$

has been employed. Our convention of the tensor product is

$$A\otimes B = \begin{pmatrix} a_{11}B & a_{12}B & \cdots \\ a_{21}B & a_{22}B & \cdots \\ \vdots & \vdots & \ddots \end{pmatrix}, \quad \text{for } A=(a_{ij}), \quad B=(b_{ij}).$$

Dynamical variables are defined through a linear mapping,

$$X\in H(N) \mapsto F_X = \mathrm{tr}(PX) \in \mathbf{R}, \tag{2.11}$$

where $H(N)$ is the space of Hermitian matrices:

$$H(m) = \{X | X\in M(m;\mathbf{C}), X^\dagger = X\}. \tag{2.12}$$

The Poisson bracket is given, with the aid of (2.7), by

$$\{F_X, F_Y\}_{\mathrm{P.B.}} = \omega^{-1}(V_X, V_Y) = F_{-i[X,Y]}, \tag{2.13}$$

with $[X,Y]=XY-YX$, where V_X is a vector field on $G_{N,n}$ associated with F_X:

$$V_X = \sum_{i,a}\left(\frac{\partial F_X}{\partial \xi_{ia}}\frac{\partial}{\partial \xi_{ia}} + \frac{\partial F_X}{\partial \bar{\xi}_{ia}}\frac{\partial}{\partial \bar{\xi}_{ia}}\right).$$

Note that the Poisson bracket (2.13) generates the $u(N)$ algebra.

An explicit form of the Hamiltonian function for a Hermitian matrix X,

$$X = \begin{pmatrix} A & B \\ B^\dagger & D \end{pmatrix}, \quad A\in H(n), \quad B\in M(n,N-n;\mathbf{C}), \quad D\in H(N-n), \tag{2.14}$$

is read as

$$F_X = \mathrm{tr}\{(1_n+\xi^\dagger\xi)^{-1}\Phi_X\}, \quad \Phi_X = A + B\xi + \xi^\dagger B^\dagger + \xi^\dagger\ D\xi. \tag{2.15}$$

Introduce a 1-form θ_κ,

$$d\theta_\kappa = \omega, \quad \theta_\kappa = i\ \mathrm{tr}[\{\kappa\xi^\dagger\ d\xi - (1-\kappa)d\xi^\dagger\ \xi\}(1_n+\xi^\dagger\xi)^{-1}]; \quad \kappa\in\mathbf{R}. \tag{2.16}$$

Here κ is an arbitrary parameter that does not affect kinematics at all and is usually fixed by putting $\kappa=\frac{1}{2}$. The action functional for this Hamiltonian system is thus found as

$$S=\int_{t_1}^{t_2}(\theta_\kappa-F_X\,dt)=\int_{t_1}^{t_2}dt\ \mathrm{tr}[(1_n+\xi^\dagger\xi)^{-1}\{i(\kappa\xi^\dagger\dot{\xi}-(1-\kappa)\dot{\xi}^\dagger\xi)-(A+B\xi+\xi^\dagger B^\dagger+\xi^\dagger D\xi)\}], \tag{2.17}$$

giving us equations of motion,

$$\begin{aligned}\dot{\xi}&=i(\xi A-D\xi-B^\dagger+\xi B\xi),\\ \dot{\xi}^\dagger&=-i(A\xi^\dagger-\xi^\dagger D+\xi^\dagger B^\dagger\xi^\dagger-B).\end{aligned} \tag{2.18}$$

The solution can be found by putting

$$\exp(-iXt)=\begin{pmatrix}\alpha(t) & \beta(t)\\ \gamma(t) & \delta(t)\end{pmatrix}, \tag{2.19}$$

with X being given by (2.14), such that

$$\xi(t)=\{\gamma(t)+\delta(t)\xi(0)\}\{\alpha(t)+\beta(t)\xi(0)\}^{-1}. \tag{2.20}$$

The solution (2.20) takes the simplest form in the case of a block-diagonal Hamiltonian given by $B=0$:

$$\xi(t)=U(t)\xi(0)V^\dagger(t), \tag{2.21}$$

where matrices $V(t)\in\mathrm{U}(n)$ and $U(t)\in\mathrm{U}(N-n)$ are given as

$$V(t)=\exp(-iAt),\quad U(t)=\exp(-i\,Dt). \tag{2.22}$$

In terms of $\xi(t)$ (2.20), the time dependence of P (2.2) is read as

$$P(t)=\begin{pmatrix}\dfrac{1}{1_n+\xi^\dagger(t)\xi(t)} & \dfrac{1}{1_n+\xi^\dagger(t)\xi(t)}\,\xi^\dagger(t)\\ \xi(t)\,\dfrac{1}{1_n+\xi^\dagger(t)\xi(t)} & \xi(t)\,\dfrac{1}{1_n+\xi^\dagger(t)\xi(t)}\,\xi^\dagger(t)\end{pmatrix}, \tag{2.23}$$

so that

$$P(t)=e^{-iXt}P(0)e^{iXt}. \tag{2.24}$$

Therefore we can recognize that the equations (2.18) describe an action of $\mathrm{U}(N)$ on $G_{N,n}$ (in a local coordinate system). In this way classical mechanics on $G_{N,n}$ can have geometric interpretation.

As a final remark, note that only $\xi(t)=0$ $(0\leqslant t\leqslant T)$ is allowed under the periodic boundary condition $\xi(T)=\xi(0)$ for arbitrary T and X. In the subsequent section the same situation is found when performing the WKB approximation.

B. The DH formula

We now discuss the Duistermaat–Heckamn localization formula for the classical system defined above. Start with a classical partition function,

$$\mathcal{Z}_{\rm cl}(\beta)=\int d\mu(\xi)\exp(-\beta F_H),\quad \beta>0, \tag{2.25}$$

where

$$d\mu(\xi)\equiv\frac{1}{\{\det(1_n+\xi^\dagger\xi)\}^N}\left(\frac{d\xi\,d\bar{\xi}}{\pi}\right)^{n(N-n)}, \tag{2.26}$$

which satisfies

$$\int d\mu(\xi)=\mathcal{N}(n,N-n), \tag{2.27}$$

with

$$\mathcal{N}(n,p)\equiv\frac{0!1!\cdots(n-1)!}{p!(p+1)!\cdots(p+n-1)!}\quad (p=0,1,2,\ldots). \tag{2.28}$$

[The verification of (2.27) is found in the next section. Putting $k\to 0$ in (3.48) we have (2.27).] Here $F_{\rm H}$ is a Hamiltonian, in terms of a real diagonal matrix,

$$H=\mathrm{diag}(h_1,\ldots,h_n,h_{n+1},\ldots,h_N),\quad 0<h_1<\cdots<h_N, \tag{2.29}$$

such that

$$F_{\rm H}=\mathrm{tr}\{(1_n+\xi^\dagger\xi)^{-1}(H_u+\xi^\dagger H_d\xi)\},$$

$$H_u=\mathrm{diag}(h_1,\ldots,h_n),\quad H_d=\mathrm{diag}(h_{n+1},\ldots,h_N). \tag{2.30}$$

The first task is to find critical points of the Hamiltonian by solving

$$\frac{\partial F_{\rm H}}{\partial\xi_{ia}}=0,\quad \frac{\partial F_{\rm H}}{\partial\bar{\xi}_{ia}}=0, \tag{2.31}$$

which coincide with the right-hand sides of the equations of motion (2.18). In view of (2.25) these critical points are nothing but the *saddle points* of the integral. For the present case, the saddle point conditions (2.31) become

$$H_u\xi^\dagger-\xi^\dagger H_d=0,\quad \xi H_u-H_d\xi=0. \tag{2.32}$$

Note that if $\xi\neq 0$ these conditions cannot be met, owing to the assumption, $h_1<\cdots<h_N$. Therefore there remains only one case, $\xi=0$, *under this parametrization* of $G_{N,n}$, in other words, there exists a unique fixed point under the action of $\mathrm{U}(n)\times\mathrm{U}(N-n)$ [torus, $\mathrm{U}(1)^N$, in this case] (2.21). Now calculate the second derivative of $F_{\rm H}$ at $\xi=0$; the Hessian of the Hamiltonian,

$$\left.\frac{\partial^2 F_{\rm H}}{\partial\xi_{ia}\,\partial\bar{\xi}_{jb}}\right|_{\xi=0}=(H_u)_{ab}\delta_{ji}-\delta_{ab}(H_d)_{ji}. \tag{2.33}$$

Hence, the contribution from this critical point to (2.25) is found to be

$$\int \left(\frac{d\xi\, d\bar{\xi}}{\pi}\right)^{n(N-n)} \exp\{-\beta \text{ tr } H_u - \beta \text{ tr}(H_d \xi\xi^\dagger - H_u \xi^\dagger \xi)\} = \frac{\exp(-\beta \Sigma_{a=1}^n h_a)}{\beta^{n(N-n)} \Pi_{a=1}^n \Pi_{i=n+1}^N (h_i - h_a)}. \tag{2.34}$$

As was stressed above, there need $\binom{N}{n}$ local parametrizations to cover the whole phase space, contributions from other critical points must be taken into account. To this end, recall the unitary transformation given in (2.6). A change of the local parametrization,

$$P = U(\xi) P_{1,\ldots,n} U^\dagger(\xi) \mapsto P_U = U(\mu_1,\ldots,\mu_n|1,\ldots,n) P U^\dagger(\mu_1,\ldots,\mu_n|1,\ldots,n), \tag{2.35}$$

is equivalent to that of the Hermitian matrix in the Hamiltonian function,

$$F_{\mathrm{H}}(P) = \text{tr}(PH) \mapsto F_{\mathrm{H}}(P_U) = F_{H'}(P) = \text{tr}(PH'), \tag{2.36}$$

with

$$H' = U^\dagger(\mu_1,\ldots,\mu_n|1,\ldots,n) H U(\mu_1,\ldots,\mu_n|1,\ldots,n). \tag{2.37}$$

Once recognizing this, we can easily carry out the task; since the new Hamiltonian after the transformation is again diagonal without degeneracy so that a critical point is always located at $\xi = 0$ in each local parametrization. Summing up those contributions, therefore we obtain, as a result of the saddle point approximation,

$$\mathcal{Z}_{\mathrm{cl}}(\beta) \simeq \sum_{\mu_1 < \cdots < \mu_n} \frac{\exp(-\beta \Sigma_{a=1}^n h_{\mu_a})}{\beta^{n(N-n)} \Pi_{a=1}^n \Pi_{\nu \in \bar{\mu}} (h_\nu - h_{\mu_a})}, \tag{2.38}$$

where

$$\bar{\mu} \equiv \{1,\ldots,N\} \backslash \{\mu_1,\ldots,\mu_n\}. \tag{2.39}$$

The DH theorem tells us that the sum on the right-hand side gives an exact result. To see that this is true, consider, instead of (2.25), the following expression:

$$\int_{H(n)} d\lambda \int_{M(N,n;C)} \left(\frac{dz\, d\bar{z}}{\pi}\right)^{Nn} \exp[-\beta \text{ tr}(Z^\dagger H Z) + i \text{ tr}\{\lambda(Z^\dagger Z - 1)\}], \tag{2.40}$$

where the integration domain of λ is $H(n)$ and new variables,

$$Z = \begin{pmatrix} Z_u \\ Z_d \end{pmatrix}, \quad Z \in M(N,n;\mathbf{C}),$$

$$Z_u = \begin{pmatrix} z_{1,1} & \cdots & z_{1,n} \\ \vdots & & \vdots \\ z_{n,1} & \cdots & z_{n,n} \end{pmatrix}, \quad Z_d = \begin{pmatrix} z_{n+1,1} & \cdots & z_{n+1,n} \\ \vdots & & \vdots \\ z_{N,1} & \cdots & z_{N,n} \end{pmatrix}, \tag{2.41}$$

have been introduced. An explicit form of λ is given as

$$\lambda = \begin{pmatrix} \lambda_1 & \lambda_{1,2} & \cdots & \lambda_{1,n} \\ \overline{\lambda_{1,2}} & \lambda_2 & \ddots & \vdots \\ \vdots & \ddots & \ddots & \lambda_{n-1,n} \\ \overline{\lambda_{1,n}} & \cdots & \overline{\lambda_{n-1,n}} & \lambda_n \end{pmatrix}, \tag{2.42}$$

$$\lambda_a \in \mathbf{R} \quad (a=1,\ldots,n),$$

$$\lambda_{a,b}=\frac{x_{a,b}-iy_{a,b}}{2}, \quad x_{a,b},y_{a,b}\in\mathbf{R}, \quad (1\leqslant a\leqslant b\leqslant n), \tag{2.43}$$

so that the measure is

$$d\lambda=\prod_{a=1}^{n}\frac{d\lambda_a}{2\pi}\prod_{a<b}\frac{dx_{a,b}\,dy_{a,b}}{(2\pi)^2}. \tag{2.44}$$

The λ integration leads us to delta functions which can be handled by means of the following change of variables:

$$Z=\begin{pmatrix}1_n\\ \xi\end{pmatrix}\frac{1}{\sqrt{1_n+\xi^\dagger\xi}}\,\zeta; \quad \xi\in M(N-n,n;\mathbf{C}), \quad \zeta\in M(n;\mathbf{C}), \tag{2.45}$$

which brings

$$Z^\dagger Z=\zeta^\dagger\zeta, \tag{2.46}$$

$$\left(\frac{dz\,d\bar{z}}{\pi}\right)^{Nn}=\left(\frac{d\xi\,d\bar{\xi}}{\pi}\right)^{n(N-n)}\frac{1}{\{\det(1_n+\xi^\dagger\xi)\}^N}\left(\frac{d\zeta\,d\bar{\zeta}}{\pi}\right)^{n^2}\{\det(\zeta^\dagger\zeta)\}^{N-n}. \tag{2.47}$$

Then the integration with respect to ζ in (2.40) is easily performed yielding to (2.25). From this observation we can grasp the role of λ, which is to reduce the number of degrees of freedom from Nn to $Nn-n^2=n(N-n)$. Therefore λ is called a multiplier and whose coefficient is referred to as constraint:[23]

$$\psi_{ab}\equiv(Z^\dagger Z)_{ab}-\delta_{ab}\approx 0. \tag{2.48}$$

On the contrary, if $z_{\mu,a}$'s integrations that is *Gaussian* are first performed, we obtain

$$\int_{H(n)}d\lambda\,\frac{\exp(-i\ \mathrm{tr}\ \lambda)}{\det(\beta H\otimes 1_n-i1_N\otimes\lambda^{\mathcal{T}})}. \tag{2.49}$$

With the help of the decomposition,[24]

$$\lambda=\Omega\lambda_0\Omega^\dagger, \quad \lambda_0=\mathrm{diag}(l_1,\ldots,l_n), \quad \Omega\in\mathrm{SU}(n), \tag{2.50}$$

the Ω integration gives

$$(2.40)=\int_{-\infty}^{+\infty}\frac{1}{n!}\prod_{a=1}^{n}\frac{dl_a}{2\pi}\prod_{a<b}(l_a-l_b)^2\,\frac{\exp(-i\Sigma_{a=1}^{n}l_a)}{\Pi_{a=1}^{n}\Pi_{\mu=1}^{N}(\beta h_\mu-il_a)}, \tag{2.51}$$

which, by considering poles and zeros, leads to

$$(2.40)=\sum_{\mu_1<\cdots<\mu_n}\frac{\exp(-\beta\Sigma_{a=1}^{n}h_{\mu_a})}{\beta^{n(N-n)}\Pi_{a=1}^{n}\Pi_{\nu\in\bar{\mu}}(h_\nu-h_{\mu_a})}, \tag{2.52}$$

where again $\bar{\mu}$ is given by (2.39). This is exactly the same expression as (2.38). Thus, *the saddle point approximation (2.38) itself contains the full information of the partition function* $\mathcal{Z}_{\mathrm{cl}}$.

We consider in what follows a quantum version of the DH theorem, that is, the WKB exactness in a path integral. Our interpretation to the DH formula put here will be very helpful in the analysis.

III. COHERENT STATES OF U(N) OVER $G_{N,n}$

In order to obtain the path integral representation, we construct coherent states of U(N) in this section. We consider first the algebraic method proposed by Perelomov, then a generalization of the Schwinger boson technique.

A. Algebraic construction

The $u(N)$ algebra in terms of generators $E_{\mu\nu}$ is

$$[E_{\mu\nu},E_{\rho\sigma}]=\delta_{\nu\rho}E_{\mu\sigma}-\delta_{\mu\sigma}E_{\rho\nu},\quad (1\leqslant\mu,\nu,\rho,\sigma\leqslant N). \tag{3.1}$$

First, build up the coherent state in the fundamental representation. The generators are expressed as

$$(E_{\mu\nu})_{\rho\sigma}=\delta_{\mu\rho}\delta_{\nu\sigma}. \tag{3.2}$$

Introduce an orthonormal set of basis vectors in $\mathbf{C}^N$,

$$(\mathbf{e}_\mu)_\nu=\delta_{\mu\nu},\quad \mathbf{e}_\mu^\dagger\mathbf{e}_\nu=\delta_{\mu\nu}; \tag{3.3}$$

to define a fiducial vector, by picking up first n $\mathbf{e}_a$ $(a=1,\ldots,n)$ vectors out of N vectors, such that

$$\mathscr{E}_{N,n}=\frac{1}{\sqrt{n!}}\sum_{\sigma\in\mathscr{S}_n}\operatorname{sgn}(\sigma)\mathbf{e}_{\sigma(1)}\otimes\cdots\otimes\mathbf{e}_{\sigma(n)}\in\mathbf{C}^{N^n}, \tag{3.4}$$

where $\mathscr{S}_n$ denotes the symmetric group of order n. Consider the map

$$\rho_1:GL(N;\mathbf{C})\mapsto GL(N^n;\mathbf{C}),\quad \rho_1(x)\equiv\otimes^n x(=x\otimes\overset{n}{\cdots}\otimes x), \tag{3.5}$$

then it is obvious that

$$d\rho_1\left(\sum_{a=1}^{n}E_{aa}-\sum_{i=n+1}^{N}E_{ii}\right)\mathscr{E}_{N,n}=n\mathscr{E}_{N,n}, \tag{3.6}$$

$$d\rho_1(E_{\mu i})\mathscr{E}_{N,n}=0, \tag{3.7}$$

where

$$d\rho_1(E)\equiv\frac{d}{dt}\bigg|_{t=0}\rho_1(\exp tE)=\sum_{p=1}^{n}\otimes^{p-1}1_N\otimes E\otimes^{n-p}1_N, \tag{3.8}$$

for $E\in u(N)$. As for this fiducial vector $\mathscr{E}_{N,n}$, the following fact should be noted.

Lemma III.1: On the fiducial vector $\mathscr{E}_{N,n}$, there holds

$$\rho_1(B)\mathscr{E}_{N,n}=\det a\cdot\mathscr{E}_{N,n}, \tag{3.9}$$

where

$$B \in GL(N;\mathbf{C}), \quad B=\begin{pmatrix} a & b \\ 0 & c \end{pmatrix}, \tag{3.10}$$

with

$$a \in GL(n;\mathbf{C}), \quad b \in M(n,N-n;\mathbf{C}), \quad c \in GL(N-n;\mathbf{C}). \tag{3.11}$$

The proof of this lemma is obvious so that we can omit it. (However, some comments would be useful: what this lemma signifies is that $\det a(\mathscr{E}_{N,n})$ is an eigenvalue (eigenvector) of $\rho_1(B)$. If we put $n=N$ in (3.9), the relation is nothing but the definition of the determinant.)

Now consider an element of SU(N) generated by an orthogonal complement of the Lie algebra of U(n)×U($N-n$),

$$S=\exp\begin{pmatrix} 0 & -\alpha^\dagger \\ \alpha & 0 \end{pmatrix}; \quad \alpha \in M(N-n,n;\mathbf{C}), \tag{3.12}$$

which can be rewritten as

$$S=\begin{pmatrix} \dfrac{1}{\sqrt{1_n+\xi^\dagger\xi}} & -\dfrac{1}{\sqrt{1_n+\xi^\dagger\xi}}\,\xi^\dagger \\ \xi\,\dfrac{1}{\sqrt{1_n+\xi^\dagger\xi}} & \dfrac{1}{\sqrt{1_{N-n}+\xi\xi^\dagger}} \end{pmatrix}; \quad \xi \in M(N-n,n;\mathbf{C}), \tag{3.13}$$

with

$$\xi=\alpha\,\frac{1}{\sqrt{\alpha^\dagger\alpha}}\tan\sqrt{\alpha^\dagger\alpha}. \tag{3.14}$$

Noting the Gauss' decomposition $S=LMU$, with

$$L=\begin{pmatrix} 1_n & 0 \\ \xi & 1_{N-n} \end{pmatrix}, \quad M=\begin{pmatrix} \dfrac{1}{\sqrt{1_n+\xi^\dagger\xi}} & 0 \\ 0 & \sqrt{1_{N-n}+\xi\xi^\dagger} \end{pmatrix}, \quad U=\begin{pmatrix} 1_n & -\xi^\dagger \\ 0 & 1_{N-n} \end{pmatrix}, \tag{3.15}$$

we can obtain a desired (normalized) coherent state:

$$|\xi;1\rangle \equiv \rho_1(LMU)\mathscr{E}_{N,n}=\frac{1}{\{\det(1_n+\xi^\dagger\xi)\}^{1/2}}\,\rho_1(L)\mathscr{E}_{N,n}, \tag{3.16}$$

where we have used Lemma III.1. While the unnormalized one is given by

$$|\xi;1\rangle \equiv \rho_1(L)\mathscr{E}_{N,n}, \quad (\xi;1|\xi;1)=\det(1_n+\xi^\dagger\xi), \tag{3.17}$$

whose second relation can be verified as follows: by noting that $L\mathbf{e}_a=\mathbf{e}_a+\Sigma_{i=n+1}^{N}\xi_{ia}\mathbf{e}_i$; $(1\leqslant a\leqslant n)$, we find

$$|\xi;1\rangle=\frac{1}{\sqrt{n!}}\sum_{\sigma\in\mathscr{S}_n}\operatorname{sgn}(\sigma)(\mathbf{e}_{\sigma(1)}+\xi_{i_1\sigma(1)}\mathbf{e}_{i_1})\otimes\cdots\otimes(\mathbf{e}_{\sigma(n)}+\xi_{i_n\sigma(n)}\mathbf{e}_{i_n}). \tag{3.18}$$

(Here and for a while repeated indices imply summation for brevity's sake.) Further, noting

$$(\mathbf{e}_\sigma^\dagger + \boldsymbol{\xi}_{i\sigma}\mathbf{e}_i^\dagger)(\mathbf{e}_\tau + \eta_{j\tau}\mathbf{e}_j) = \delta_{\sigma\tau} + (\xi^\dagger\eta)_{\sigma\tau}, \tag{3.19}$$

then we find

$$(\xi;1|\,\eta;1) = \det(1_n + \xi^\dagger\eta), \tag{3.20}$$

so that

$$\langle\xi;1|\,\eta;1\rangle = \det\{(1_n + \xi^\dagger\xi)^{-1/2}(1_n + \xi^\dagger\eta)(1_n + \eta^\dagger\eta)^{-1/2}\}. \tag{3.21}$$

Next, discuss matrix elements of generators: in view of (3.8) the task is to calculate

$$(\xi;1|d\rho_1(E_{\mu\nu})|\,\eta;1) = \sum_{p=1}^{n} (\xi;1|\otimes^{p-1}1_N\otimes E_{\mu\nu}\otimes^{n-p}1_N|\,\eta;1), \tag{3.22}$$

which can be found, after somewhat lengthy calculations, as

$$(\xi;1|d\rho_1(E_{ab})|\,\eta;1) = \det(1_n + \xi^\dagger\eta)\left(\frac{1}{1_n + \xi^\dagger\eta}\right)_{ba}, \tag{3.23}$$

$$(\xi;1|d\rho_1(E_{ai})|\,\eta;1) = \det(1_n + \xi^\dagger\eta)\left(\eta\,\frac{1}{1_n + \xi^\dagger\eta}\right)_{ia}, \tag{3.24}$$

$$(\xi;1|d\rho_1(E_{ia})|\,\eta;1) = \det(1_n + \xi^\dagger\eta)\left(\frac{1}{1_n + \xi^\dagger\eta}\,\xi^\dagger\right)_{ai}, \tag{3.25}$$

$$(\xi;1|d\rho_1(E_{ij})|\,\eta;1) = \det(1_n + \xi^\dagger\eta)\left(\eta\,\frac{1}{1_n + \xi^\dagger\eta}\,\xi^\dagger\right)_{ji}. \tag{3.26}$$

Armed with these, we obtain the matrix element of an arbitrary Hermitian matrix,

$$H = \sum_{\mu,\nu} h_{\mu\nu}E_{\mu\nu} = \sum_{a,b} h_{ab}E_{ab} + \sum_{a,i} h_{ai}E_{ai} + \sum_{j,b} h_{jb}E_{jb} + \sum_{i,j} h_{ij}E_{ij} \equiv \begin{pmatrix} H_{uu} & H_{ud} \\ H_{du} & H_{dd} \end{pmatrix}, \tag{3.27}$$

such that

$$(\xi;1|d\rho_1(H)|\,\eta;1) = (\xi;1|\,\eta;1)\mathrm{tr}\left\{\frac{1}{1_n + \xi^\dagger\eta}\,(H_{uu} + H_{ud}\eta + \xi^\dagger H_{du} + \xi^\dagger H_{dd}\eta)\right\}, \tag{3.28}$$

which is further rewritten to

$$(\xi;1|d\rho_1(H)|\,\eta;1) = (\xi;1|\,\eta;1)\mathrm{tr}\{P(\xi,\eta)H\}, \tag{3.29}$$

or, equivalently,

$$\langle\xi;1|d\rho_1(H)|\,\eta;1\rangle = \langle\xi;1|\,\eta;1\rangle\mathrm{tr}\{P(\xi,\eta)H\}, \tag{3.30}$$

where we have introduced a projection $P(\xi,\eta)$,

$$P(\xi,\eta) = \begin{pmatrix} 1_n \\ \eta \end{pmatrix}(1_n + \xi^\dagger\eta)^{-1}(1_n \quad \xi^\dagger), \tag{3.31}$$

giving

$$\mathrm{tr}\{P(\xi,\eta)H\}=\mathrm{tr}\left\{\frac{1}{1_n+\xi^\dagger\eta}\,(H_{uu}+H_{ud}\eta+\xi^\dagger H_{du}+\xi^\dagger H_{dd}\eta)\right\}. \tag{3.32}$$

[It should be noted that although the definition of $P(\xi,\eta)$ looks singular in the domain $\{(\xi,\eta)|\det(1_n+\xi^\dagger\eta)=0\}$, there is no harm; since the quantity $\mathrm{tr}\{P(\xi,\eta)H\}$ is always accompanied with $\langle\xi;1|\eta;1\rangle$, including $\det(1_n+\xi^\dagger\eta)$ in the numerator.]

Now we generalize the above result to a higher-dimensional representation. Consider a tensor product of the coherent state,

$$|\xi;1\rangle\mapsto|\xi;k\rangle\equiv\otimes^k|\xi;1\rangle,\quad k=0,1,2,\ldots, \tag{3.33}$$

as well as that of the representation,

$$\rho_k(x)\equiv\otimes^k(\rho_1(x)),\quad x\in GL(N,\mathbf{C}), \tag{3.34}$$

to put

$$|\xi;k\rangle=\rho_k(LMU)\mathscr{E}^{\,k}_{N,n},\quad \mathscr{E}^{\,k}_{N,n}\equiv\otimes^k\mathscr{E}_{N,n}. \tag{3.35}$$

We designate this representation as the kth representation. The following relations are obvious:

$$d\rho_k\left(\sum_{a=1}^{n}E_{aa}-\sum_{i=n+1}^{N}E_{ii}\right)\mathscr{E}^{\,k}_{N,n}=kn\,\mathscr{E}^{\,k}_{N,n}, \tag{3.36}$$

$$d\rho_k(E_{\mu i})\mathscr{E}^{k}_{N,n}=0. \tag{3.37}$$

And it is straightforward to find (i) the inner product between coherent states,

$$\langle\xi;k|\eta;k\rangle=[\det\{(1_n+\xi^\dagger\xi)^{-1/2}(1_n+\xi^\dagger\eta)(1_n+\eta^\dagger\eta)^{-1/2}\}]^k; \tag{3.38}$$

(ii) and matrix elements of generators,

$$\langle\xi;k|d\rho_k(E_{\mu\nu})|\eta;k\rangle=k\ \mathrm{tr}\{P(\xi,\eta)E_{\mu\nu}\}\langle\xi;k|\eta;k\rangle, \tag{3.39}$$

hence

$$\langle\xi;k|d\rho_k(H)|\eta;k\rangle=k\ \mathrm{tr}\{P(\xi,\eta)H\}\langle\xi;k|\eta;k\rangle. \tag{3.40}$$

In view of these relations, there follow that (i) the inner product has a form $\{\langle\xi;1|\eta;1\rangle\}^k$ and (ii) the matrix element of a Hamiltonian is proportional to the parameter k. This fact tells us that the exponent of the path integral is proportional to k. Therefore we can perform the $1/k$ expansion when k goes to large like the usual WKB expansion with respect to $\hbar$.

If we declare that the state $|\xi;k\rangle$ is a coherent state, we must check that the resolution of unity does hold:

$$\mathbf{1}_k=\int d\mu(\xi;k)|\xi;k\rangle\langle\xi;k|, \tag{3.41}$$

with

$$d\mu(\xi;k)\equiv\frac{\mathscr{N}(n,k)}{\mathscr{N}(n,N-n+k)}\,\frac{1}{\{\det(1_n+\xi^\dagger\xi)\}^N}\left(\frac{d\xi\ d\bar{\xi}}{\pi}\right)^{n(N-n)}, \tag{3.42}$$

where $\mathcal{N}(n,k)$ has been given by (2.28) and $\mathbf{1}_k$ is the identity operator on the representation space. To this end the following formulas are indispensable.

Theorem III.2: *Let dg be the normalized Haar measure on* $\mathrm{U}(n)$. *Then for* $^\forall p \in \mathbf{Z}_+$ *with* $\mathbf{Z}_+ = \{0\} \cup \mathbf{N}$ *and* $^\forall X \in M(n;\mathbf{C})$, *there holds an integration formula,*

$$\int_{\mathrm{U}(n)} \frac{dg}{(\det g)^p} \exp\{\mathrm{tr}(gX)\} = \mathcal{N}(n,p)|X|^p, \tag{3.43}$$

$$\mathcal{N}(n,p) \equiv \frac{0!1!\cdots(n-1)!}{p!(p+1)!\cdots(p+n-1)!}. \tag{3.44}$$

Theorem III.3: *For* $^\forall X \in M(n;\mathbf{C})$ *and* $^\forall p \in \mathbf{Z}_+$, *there holds a differential formula,*

$$|\partial_X||X|^p = p(p+1)\cdots(p+n-1)|X|^{p-1}, \tag{3.45}$$

where $|X| = \det X$ *and* $|\partial_X|$ *is defined by*

$$|\partial_X| \equiv \det\left(\frac{\partial}{\partial x_{ij}}\right), \quad \text{for } X = (x_{ij}), \tag{3.46}$$

which is valid even if p is negative integer, provided that $X + X^\dagger$ *is positive definite and* $|X| \neq 0$. Proofs of these formulas are straightforward, but need a bit lengthy calculations; therefore we relegate them to Appendix A. (Although the proof of Theorem III.3, known as Cayley's formula, could be found somewhere, for example, by using Capelli's identity,[25] we supply our own proof.)

Practically our target is to show, instead of (3.41),

$$(\alpha;k|\beta;k) = \int d\mu(\xi;k)(\alpha;k|\xi;k\rangle\langle\xi;k|\beta;k); \quad \alpha,\beta \in M(N-n,n;\mathbf{C}), \tag{3.47}$$

that is,

$$\begin{aligned}\{\det(1_n + \alpha^\dagger\beta)\}^k &= \int d\mu(\xi;k)\, \frac{\{\det(1_n + \alpha^\dagger\xi)\}^k\{\det(1_n + \xi^\dagger\beta)\}^k}{\{\det(1_n + \xi^\dagger\xi)\}^k} \\ &= \frac{\mathcal{N}(n,k)}{\mathcal{N}(n,N-n+k)} \int \left(\frac{d\xi\, d\bar{\xi}}{\pi}\right)^{n(N-n)} \frac{1}{\{\det(1_n + \xi^\dagger\xi)\}^N} \\ &\quad \times \frac{\{\det(1_n + \alpha^\dagger\xi)\}^k\{\det(1_n + \xi^\dagger\beta)\}^k}{\{\det(1_n + \xi^\dagger\xi)\}^k}.\end{aligned} \tag{3.48}$$

Establishing (3.48) is equal to establishing (3.41); since these relations hold for any $|\alpha;k)$ and $|\beta;k)$. To this end, two other relations are needed.

Corollary III.4: For $^\forall k \in \mathbf{Z}_+$, *there holds a formula for Gaussian-type integration over* $M(m+n,n;\mathbf{C})$:

$$\int \left(\frac{dz\, d\bar{z}}{\pi}\right)^{n(m+n)} |Z^\dagger Z|^k \exp\{-\mathrm{tr}(Z^\dagger Z)\} = \frac{\mathcal{N}(n,m)}{\mathcal{N}(n,m+k)}. \tag{3.49}$$

Proof: By making use of an identity,

$$|Z^\dagger Z|^k \exp\{-\mathrm{tr}(Z^\dagger Z)\} = (-1)^{nk}|\partial_X|^k|_{X=1_n} \exp\{-\mathrm{tr}(XZ^\dagger Z)\}, \tag{3.50}$$

the left-hand side of (3.49) is rewritten as

$$(-1)^{nk}|\partial_X|^k|_{X=1_n}\int\left(\frac{dz\ d\bar{z}}{\pi}\right)^{n(m+n)}\exp\{-\mathrm{tr}(XZ^\dagger Z)\}=(-1)^{nk}|\partial_X|^k|_{X=1_n}|X|^{-(m+n)}, \tag{3.51}$$

which becomes, by a repeated use of the formula III.3, to

$$(3.51)=\frac{(m+n)!}{m!}\times\frac{(m+n+1)!}{(m+1)!}\times\cdots\times\frac{(m+n+k-1)!}{(m+k-1)!}=\frac{\mathscr{N}(n,m)}{\mathscr{N}(n,m+k)}. \tag{3.52}$$

Corollary III.5: For $^\forall p,q\in\mathbf{Z}_+$ *and* $^\forall A,B\in M(m+n,n;\mathbf{C})$, *there holds*

$$\int_{\mathrm{U}(n)}\frac{dg}{(\det g)^p}\int\left(\frac{dz\ d\bar{z}}{\pi}\right)^{n(m+n)}|Z^\dagger Z|^q\exp\{-\mathrm{tr}(Z^\dagger Z-Z^\dagger A-gB^\dagger Z)\}$$
$$=\frac{\mathscr{N}(n,p)\mathscr{N}(n,m+p)}{\mathscr{N}(n,m+p+q)}|B^\dagger A|^p. \tag{3.53}$$

Proof: Integrate with respect to $Z,Z^\dagger$ and follow a similar procedure as above to find

$$(3.53)=(-1)^{nq}|\partial_X|^q|_{X=1_n}\int_{\mathrm{U}(n)}\frac{dg}{(\det g)^p}\exp\{\mathrm{tr}(gB^\dagger AX^{-1})\}|X|^{-(m+n)}. \tag{3.54}$$

The formula III.2 enables us to perform the g integration, giving

$$(3.54)=(-1)^{nq}|\partial_X|^q|_{X=1_n}|X|^{-(m+n+p)}\mathscr{N}(n,p)|B^\dagger A|^p, \tag{3.55}$$

which turns out, again, by the repeated use of the formula III.3, to be the right-hand side of (3.53).

Now we can proceed to our target: first rewrite the left-hand side of (3.48) by use of the formula III.2 as

$$\{\det(1_n+\alpha^\dagger\beta)\}^k=\frac{1}{\mathscr{N}(n,k)}\int_{\mathrm{U}(n)}\frac{dg}{(\det g)^k}\exp[\mathrm{tr}\{g(1_n+\alpha^\dagger\beta)\}], \tag{3.56}$$

whose integrand can be expressed by the Gaussian integration with respect to $Z\in M(N,n;\mathbf{C})$,

$$\exp[\mathrm{tr}\{g(1_n+\alpha^\dagger\beta)\}]=\int\left(\frac{dz\ d\bar{z}}{\pi}\right)^{Nn}\exp\left[-\mathrm{tr}\left\{Z^\dagger Z-Z^\dagger\begin{pmatrix}1_n\\ \beta\end{pmatrix}-(1_n,\alpha^\dagger)Zg\right\}\right]. \tag{3.57}$$

A change of variables, $Z\to(\xi,\zeta)$, as was from (2.45) to (2.46), gives

$$(3.57)=\int\left(\frac{d\xi\ d\bar{\xi}}{\pi}\right)^{n(N-n)}\frac{1}{\{\det(1_n+\xi^\dagger\xi)\}^N}\int\left(\frac{d\zeta\ d\bar{\zeta}}{\pi}\right)^{n^2}(\det\zeta^\dagger\zeta)^{N-n}\exp[-\mathrm{tr}\{\zeta^\dagger\zeta-\zeta^\dagger(1_n$$
$$+\xi^\dagger\xi)^{-1/2}(1_n+\xi^\dagger\beta)-g(1_n+\alpha^\dagger\xi)(1_n+\xi^\dagger\xi)^{-1/2}\zeta\}]. \tag{3.58}$$

Substituting (3.58) into (3.56), then integrating with respect to ζ and g with the aid of the formula III.5, we find

$$\text{rhs of }(3.56)=\frac{\mathscr{N}(n,k)}{\mathscr{N}(n,N-n+k)}\int\left(\frac{d\xi\ d\bar{\xi}}{\pi}\right)^{n(N-n)}\frac{1}{\{\det(1_n+\xi^\dagger\xi)\}^N}$$
$$\times\frac{\{\det(1_n+\alpha^\dagger\xi)\}^k\{\det(1_n+\xi^\dagger\beta)\}^k}{\{\det(1_n+\xi^\dagger\xi)\}^k}, \tag{3.59}$$

which is nothing but the right-hand side of (3.48).

We now consider another version of the coherent state with the aid of the Schwinger boson technique.

B. Coherent state via Schwinger boson

As was stressed in Sec. II B, the essence of the classical DH theorem can easily be grasped by increasing degrees of freedom while balancing them with the aid of the multiplier λ: we call such a viewpoint as that of the constrained system. If we could find a similar way in quantum cases, then establishment of the localization would be obvious. Fortunately, we know such a candidate that might realize our expectation: the method of a Schwinger boson. There, in order to obtain a group representation, generators of a group are expressed by creation and annihilation operators. The representation space is thus the Fock space, whose dimension is too large for a group. Therefore there needs to be some constraint to reduce the whole space. In a simple case such as $\mathbf{C}P^N$,[9,10] it is realized by fixing the total particle number. In this way, the scenario would be hopeful.

Consider operators,

$$a=\begin{pmatrix} a_u \\ a_d \end{pmatrix}, \quad a_u=\begin{pmatrix} a_{1,1} & \cdots & a_{1,n} \\ \vdots & & \vdots \\ a_{n,1} & \cdots & a_{n,n} \end{pmatrix}, \quad a_d=\begin{pmatrix} a_{n+1,1} & \cdots & a_{n+1,n} \\ \vdots & & \vdots \\ a_{N,1} & \cdots & a_{N,n} \end{pmatrix}, \tag{3.60}$$

which obey $(1\leqslant \mu,\nu\leqslant N;\ 1\leqslant a,b\leqslant n)$

$$[a_{\mu,a},a^\dagger_{\nu,b}]=\delta_{\mu\nu}\delta_{ab}, \quad [a_{\mu,a},a_{\nu,b}]=[a^\dagger_{\mu,a},a^\dagger_{\nu,b}]=0. \tag{3.61}$$

In terms of these operators, $u(N)$ generators are realized:

$$\hat{E}_{\mu\nu}=\mathrm{tr}(a^\dagger E_{\mu\nu}a); \tag{3.62}$$

$$[\hat{E}_{\mu\nu},\hat{E}_{\rho\sigma}]=(\delta_{\nu\rho}\hat{E}_{\mu\sigma}-\delta_{\sigma\mu}\hat{E}_{\rho\nu}). \tag{3.63}$$

The Fock space $\mathscr{F}$ is designated as

$$\mathscr{F}=\mathrm{Span}\{|(n_{\mu,a})\rangle=\prod_{\mu,a}\ \frac{1}{\sqrt{n_{\mu,a}!}}\,a^{\dagger\,n_{\mu,a}}_{\mu,a}|0\rangle, \quad a_{\mu,a}|0\rangle=0, \quad n_{\mu,a}\in\mathbf{Z}_+\}. \tag{3.64}$$

Introduce a usual canonical coherent state:[3]

$$|Z\rangle\equiv\exp\{\mathrm{tr}(a^\dagger Z-Z^\dagger a)\}|0\rangle=\exp\{-\tfrac{1}{2}\,\mathrm{tr}(Z^\dagger Z)\}\exp\{\mathrm{tr}(a^\dagger Z)\}|0\rangle, \tag{3.65}$$

$$\mathbf{1}=\int\left(\frac{dz\ d\bar{z}}{\pi}\right)^{Nn}|Z\rangle\langle Z|, \tag{3.66}$$

$$\langle Z|Z'\rangle=\exp\{-\tfrac{1}{2}\,\mathrm{tr}(Z^\dagger Z+Z'^\dagger Z')+\mathrm{tr}(Z^\dagger Z')\}, \tag{3.67}$$

where **1** denotes the identity operator on $\mathscr{F}$ and Z has been given by (2.41).

Consider a Hermitian projection operator,

$$P_k\equiv\int\left(\frac{dz\ d\bar{z}}{\pi}\right)^{Nn}\int_{\mathrm{U}(n)}\frac{dg}{(\det g)^k}\,|Zg\rangle\langle Z|. \tag{3.68}$$

A simple inspection leads to

$$P_k P_{k'} = P_k \delta_{k,k'}, \quad P_k^\dagger = P_k. \tag{3.69}$$

In what follows we see that this projection operator indeed reduces $\mathscr{F}$ to the space of the kth representation in the previous section, but before proceeding it is instructive to discuss how to find the form of P_k as (3.68). By noting

$$\exp\{i\ \mathrm{tr}(\lambda a^\dagger a)\}|Z\rangle = |Z_g\rangle, \quad g = e^{i\lambda} \in U(n), \tag{3.70}$$

so that

$$\frac{1}{(\det g)^k}|Z_g\rangle = \exp[\,i\ \mathrm{tr}\{\lambda(a^\dagger a - k)\}]|Z\rangle, \tag{3.71}$$

which immediately reminds us of the multiplier part of (2.40) by replacing $a(a^\dagger)$ with $Z(Z^\dagger)$. [However, note that the difference of the integration domain of λ; in (2.40) it is infinite but in (3.68) it is bounded. Details on this issue are found in Sec. V.]

The trace of P_k can be calculated as

$$\begin{aligned}
\mathrm{Tr}\ P_k &= \int \left(\frac{dz\ d\bar{z}}{\pi}\right)^{Nn} \int_{U(n)} \frac{dg}{(\det g)^k} \langle Z|Zg\rangle \\
&= \mathscr{N}(n,k) \int \left(\frac{dz\ d\bar{z}}{\pi}\right)^{Nn} |Z^\dagger Z|^k \exp\{-\mathrm{tr}(Z^\dagger Z)\} \\
&= \frac{\mathscr{N}(n,k)\mathscr{N}(n,N-n)}{\mathscr{N}(n,N-n+k)},
\end{aligned} \tag{3.72}$$

where we have used (3.67), then the formula III.4. [We have employed the notation $\mathrm{Tr}(\cdots)$ for the trace over the Fock space while $\mathrm{Tr}_k(\cdots)$ emerging below for that over the kth representation space. Those should be distinguished from $\mathrm{tr}(\cdots)$ used for matrix-valued quantities.] (3.72) implies the dimension of the kth representation, that is, the number of independent vectors in $\mathscr{F}$ obeying n^2 physical state conditions:

$$(a^\dagger a)_{a,b}|\mathrm{phys}\rangle = k\,\delta_{a,b}|\mathrm{phys}\rangle. \tag{3.73}$$

In particular, for the case of $k=1$, the relation (3.72) implies an arbitrariness of choosing a fiducial vector (3.4). It is symmetric with respect to n and $N-n$, which clearly reflects the nature of the base manifold $G_{N,n}$, namely $G_{N,n} \cong G_{N,N-n}$, and is easily checked by an explicit calculation:

$$\frac{\mathscr{N}(n,k)\mathscr{N}(n,N-n)}{\mathscr{N}(n,N-n+k)} = \frac{\mathscr{N}(N-n,k)\mathscr{N}(N-n,n)}{\mathscr{N}(N-n,n+k)}. \tag{3.74}$$

Now we show that

$$P_k = \int d\mu(\xi;k)|\xi;k\rangle\langle\xi;k|, \tag{3.75}$$

where $|\xi;k\rangle$ is the coherent state of $U(N)$ over $G_{N,n}$ derived previously, but now given by

$$|\xi;k\rangle \equiv \frac{1}{\{\det(1_n + \xi^\dagger\xi)\}^{k/2}} \exp\{\mathrm{tr}(a_d^\dagger \xi a_u)\}\sqrt{\mathscr{N}(n,k)}(\det a_u^\dagger)^k|0\rangle. \tag{3.76}$$

Thus, we can regard (3.75) as the resolution of unity (3.41).

In order to reach the resolution of unity (3.75) and the coherent state (3.76), first rewrite (3.68) to

$$P_k=\int\left(\frac{dz\ d\bar{z}}{\pi}\right)^{Nn}\int_{U(n)}\frac{dg_1\ dg_2}{\{\det(g_1g_2)\}^k}\,|Zg_1\rangle\langle Zg_2^\dagger|, \tag{3.77}$$

which can be recognized directly by putting $Zg_2^\dagger\mapsto Z$ and $g_1g_2\mapsto g$ and finally performing the trivial integration with respect to g_2. Then note that from (3.67),

$$\begin{aligned}|Zg\rangle&=\exp\{-\tfrac{1}{2}\,\mathrm{tr}(Z^\dagger Z)\}\exp\{\mathrm{tr}(a^\dagger Zg)\}|0\rangle\\&=\exp\{-\tfrac{1}{2}\,\mathrm{tr}(Z^\dagger Z)\}\exp[\,\mathrm{tr}\{(a_u^\dagger Z_u+a_d^\dagger Z_d)g\}\,]|0\rangle\\&=\exp\{-\tfrac{1}{2}\,\mathrm{tr}(\zeta^\dagger\zeta)\}\exp\{\mathrm{tr}(a_d^\dagger\xi a_u)\}\exp\{\mathrm{tr}(a_u^\dagger\Lambda^{-1/2}\zeta g)\}|0\rangle,\end{aligned} \tag{3.78}$$

with $\Lambda=1_n+\xi^\dagger\xi$, where we have utilized the change of variables (2.45) and the Campbell–Baker–Hausdorff formula to the final expression. [As was discussed in the previous section, employing (2.45) is nothing but choosing some fiducial vector.] Therefore (3.78) with the formula III.2 leads to

$$\int_{U(n)}\frac{dg_1}{(\det g_1)^k}\,|Zg_1\rangle=\mathcal{N}(n,k)\exp\left\{-\frac{1}{2}\,\mathrm{tr}(\zeta^\dagger\zeta)\right\}\exp\{\mathrm{tr}(a_d^\dagger\xi a_u)\}\{\det(a_u^\dagger\Lambda^{-1/2}\zeta)\}^k|0\rangle. \tag{3.79}$$

Also note the relation, obtained from the formula III.4,

$$\int\left(\frac{d\zeta\ d\bar{\zeta}}{\pi}\right)^{n^2}|\zeta^\dagger\zeta|^{N-n+k}\exp\{-\mathrm{tr}(\zeta^\dagger\zeta)\}=\frac{1}{\mathcal{N}(n,N-n+k)}. \tag{3.80}$$

Substituting (3.79) (and whose conjugate) into (3.77) then utilizing (3.80), we finally arrive at

$$\begin{aligned}P_k=\frac{\mathcal{N}(n,k)^2}{\mathcal{N}(n,N-n+k)}\int\left(\frac{d\xi\ d\bar{\xi}}{\pi}\right)^{n(N-n)}&\frac{1}{\{\det(1_n+\xi^\dagger\xi)\}^{N+k}}\times\exp\{\mathrm{tr}(a_d^\dagger\xi a_u)\}\\&\times(\det a_u^\dagger)^k|0\rangle\langle 0|(\det a_u)^k\exp\{\mathrm{tr}(a_u^\dagger\xi^\dagger a_d)\}.\end{aligned} \tag{3.81}$$

Therefore we have established (3.75) and (3.76). By comparing (3.76) with (3.16) and (3.33), the state $\sqrt{\mathcal{N}(n,k)}(\det a_u^\dagger)^k|0\rangle$ can be identified as $\vec{\mathscr{E}}^k_{N,n}$. Therefore the projection operator onto the subspace can now be regarded as the resolution of unity in the space of the kth representation.

IV. PATH INTEGRAL AND WKB

In this section we first build up a path integral representation of a character formula by means of the coherent states developed previously. We then perform the WKB approximation. The mechanism of exactness is clarified with the aid of the generalized Schwinger boson technique.

A. Path integral representation

Take a Hamiltonian in the kth representation,

$$\hat{H}=d\rho_k(H),\quad H=\mathrm{diag}(h_1,\ldots,h_N),\ \ h_\mu\in\mathbf{R},\ \ h_1<\cdots<h_N. \tag{4.1}$$

Consider the trace of the time evolution operator, which we call the *character formula* of the kth representation:

$$\mathcal{Z}_k(T)\equiv \mathrm{Tr}_k\ \rho_k(e^{-iHT})=\lim_{M\to\infty}\int d\mu(\xi;k)\langle\xi;k|\{d\rho_k(1_N-i\ \Delta t\ H)\}^M|\xi;k\rangle, \tag{4.2}$$

where $\Delta t=T/M$. Insert the resolution of unity (3.41) to obtain

$$\mathcal{Z}_k(T)=\lim_{M\to\infty}\int_{\mathrm{PBC}}\prod_{j=1}^{M} d\mu(\xi(j);k)\langle\xi(j);k|d\rho_k(1_N-i\ \Delta t\ H)|\xi(j-1);k\rangle, \tag{4.3}$$

where as before "PBC" means $\xi(0)=\xi(M)$. From (3.40) we have

$$\begin{aligned}\langle\xi(j);k|d\rho_k(1_N-i\ \Delta t\ H)|\xi(j-1);k\rangle&=\langle\xi(j);k|\xi(j-1);k\rangle[1-ik\ \Delta t\ \mathrm{tr}\{P(\xi(j),\xi(j-1))H\}]\\&=\langle\xi(j);k|\xi(j-1);k\rangle\exp[-ik\ \Delta t\ \mathrm{tr}\{P(\xi(j),\xi(j-1))H\}]\\&\quad\times\{1+O((\Delta t)^2)\}.\end{aligned} \tag{4.4}$$

Employing the expression (3.38) to $\langle\xi(j);k|\xi(j-1);k\rangle$, we obtain

$$\begin{aligned}\mathcal{Z}_k(T)=\lim_{M\to\infty}\int_{\mathrm{PBC}}\prod_{j=1}^{M} d\mu(\xi(j);k)\exp\Bigg[-k\sum_{i=1}^{M}\mathrm{tr}\{\log(1_n+\xi^\dagger(i)\xi(i))-\log(1_n+\xi^\dagger(i)\\\times\xi(i-1))\}\Bigg]\exp\Bigg[-ik\ \Delta t\sum_{j=1}^{M}\mathrm{tr}\{P(\xi(j),\xi(j-1))H\}\Bigg],\end{aligned} \tag{4.5}$$

where we have discarded terms of $O((\Delta t)^2)$, whose fact also brings us to

$$\begin{aligned}\mathcal{Z}_k(T)=(\det\ V(T))^k\lim_{M\to\infty}\int_{\mathrm{PBC}}\prod_{j=1}^{M} d\mu(\xi(j);k)\exp\Bigg[-k\sum_{i=1}^{M}\mathrm{tr}\{\log(1_n+\xi^\dagger(i)\xi(i))\\-\log(1_n+\xi^\dagger(i)U(\Delta t)\xi(i-1)V^\dagger(\Delta t))\}\Bigg],\end{aligned} \tag{4.6}$$

where $U(t)$ and $V(t)$ have been defined by (2.22),

$$U(t)=e^{-iH_dt}\in U(N-n),\quad V(t)=e^{-iH_ut}\in U(n), \tag{4.7}$$

$$H_u=\mathrm{diag}(h_1,\ldots,h_n),\quad H_d=\mathrm{diag}(h_{n+1},\ldots,h_N). \tag{4.8}$$

By noting that

$$\begin{aligned}&\exp[-k\ \mathrm{tr}\{\log(1_n+\xi^\dagger(i)\xi(i))-\log(1_n+\xi^\dagger(i)U(\Delta t)\xi(i-1)V^\dagger(\Delta t))\}]\\&=\left\{\frac{\det(1_n+\xi^\dagger(i)U(\Delta t)\xi(i-1)V^\dagger(\Delta t))}{\det(1_n+\xi^\dagger(i)\xi(i))}\right\}^k,\end{aligned} \tag{4.9}$$

(4.6) becomes

$$\mathcal{Z}_k(T)=(\det\ V(T))^k\lim_{M\to\infty}\int_{\mathrm{PBC}}\prod_{i=1}^{M} d\mu(\xi(i);k)\times\prod_{j=1}^{M}\langle\xi(j)V(\Delta t);k|U(\Delta t)\xi(j-1);k\rangle, \tag{4.10}$$

where use has been made of (3.38). The relation (3.48) enables us to perform the multiple integration, giving

$$\mathcal{Z}_k(T)=(\det\, V(T))^k\int d\mu(\xi;k)\left\{\frac{\det(1_n+\xi^\dagger U(T)\xi V^\dagger(T))}{\det(1_n+\xi^\dagger\xi)}\right\}^k. \tag{4.11}$$

(See a further discussion in Appendix B.)

B. The WKB approximation

Now examine the WKB approximation of the path integral expression (4.6). Equations of motion are

$$\xi(j)\{1_n+\xi^\dagger(j)\xi(j)\}^{-1}=U(\Delta t)\xi(j-1)V^\dagger(\Delta t)\{1_n+\xi^\dagger(j)U(\Delta t)\xi(j-1)V^\dagger(\Delta t)\}^{-1}, \tag{4.12}$$

$$\{1_n+\xi^\dagger(j)\xi(j)\}^{-1}\xi^\dagger(j)=\{1_n+V^\dagger(\Delta t)\xi^\dagger(j+1)U(\Delta t)\xi(j)\}^{-1}V^\dagger(\Delta t)\xi^\dagger(j+1)U(\Delta t). \tag{4.13}$$

Recall here that solutions should meet the periodic boundary condition $\xi(0)=\xi(M)$. Clearly, only $\xi(j)=0$ for all $1\leqslant j\leqslant M$ can fulfill the condition. Therefore, by putting $\xi=z/\sqrt{k}$ and noting

$$\frac{\mathcal{N}(n,k)}{\mathcal{N}(n,N-n+k)}\overset{k\to\infty}{\sim}k^{n(N-n)}, \tag{4.14}$$

the dominant contribution from this classical solution is read as

$$\tilde{\mathcal{Z}}_k(T)\overset{k\to\infty}{\sim}\lim_{M\to\infty}\int_{\mathrm{PBC}}\prod_{j=1}^{M}\left(\frac{dz(j)d\bar{z}(j)}{\pi}\right)^{n(N-n)}\times\exp\left[-\sum_{j=1}^{M}\mathrm{tr}\, z^\dagger(j)\{z(j)-U(\Delta t)z(j-1)V^\dagger(\Delta t)\}\right], \tag{4.15}$$

where

$$\tilde{\mathcal{Z}}_k(T)\equiv\frac{\mathcal{Z}_k(T)}{(\det\, V(T))^k}. \tag{4.16}$$

To perform the integration further, it is convenient to utilize the Fourier transformation respecting "PBC:"

$$z(j)=\sum_{r=0}^{M-1}\frac{1}{\sqrt{M}}e^{-2\pi ijr/M}\tilde{z}(r),\quad \tilde{z}(r)\in M(N-n,n;\mathbf{C}), \tag{4.17}$$

which enables us to write

$$\sum_{j=1}^{M}z^\dagger(j)\{z(j)-U(\Delta t)z(j-1)V^\dagger(\Delta t)\}=\sum_{r=0}^{M-1}\tilde{z}^\dagger(r)\{\tilde{z}(r)-U(\Delta t)\tilde{z}(r)V^\dagger(\Delta t)e^{2\pi ir/M}\}. \tag{4.18}$$

Since the Jacobian is trivial, the integration with respect to $\tilde{z},\tilde{z}^\dagger$ can readily be performed to give

$$\tilde{\mathcal{Z}}_k(T)=\lim_{M\to\infty}\frac{1}{\Pi_{r=0}^{M-1}\det\{1_{N-n}\otimes 1_n-e^{2\pi ir/M}U(\Delta t)\otimes\bar{V}(\Delta t)\}},\tag{4.19}$$

where $\bar{V}$ is the complex conjugate of V. Utilizing the identity

$$\prod_{r=0}^{M-1}(1_m-e^{2\pi ir/M}X)=1_m-X^M,\tag{4.20}$$

holding for any $X\in M(m;\mathbf{C})$, we finally obtain

$$\tilde{\mathcal{Z}}_k(T)=\frac{1}{\det\{1_{N-n}\otimes 1_n-U(T)\otimes\bar{V}(T)\}}=\frac{1}{\Pi_{i=n+1}^{N}\Pi_{a=1}^{n}\{1-e^{-i(h_i-h_a)T}\}}.\tag{4.21}$$

Similar to the classical case, the number of classical solutions is $\binom{N}{n}$. Taking all the contributions into account [while paying attention to the relation (4.16)], we arrive at

$$\mathcal{Z}_k(T)\overset{k\to\infty}{\sim}\sum_{\mu_1<\cdots<\mu_n}\frac{\exp(-ik\Sigma_{a=1}^{n}h_{\mu_a}T)}{\Pi_{a=1}^{n}\Pi_{\nu\in\bar{\mu}}\{1-e^{-i(h_\nu-h_{\mu_a})T}\}},\tag{4.22}$$

with $\bar{\mu}$ being given by (2.39).

By noticing that the right-hand side of (4.22) can be rewritten, by means of the Laplace expansion of determinant, such that

$$\text{rhs of (4.22)}=\frac{|\epsilon^{N-1+k},\ldots,\epsilon^{N-n+k},\epsilon^{N-n-1},\ldots,\epsilon^{1},1|}{|\epsilon^{N-1},\ldots,\epsilon^{1},1|}\tag{4.23}$$

where

$$|\epsilon^{m_1},\ldots,\epsilon^{m_N}|\equiv\begin{vmatrix}\epsilon_1^{m_1}&\cdots&\epsilon_1^{m_N}\\ \vdots&\vdots&\vdots\\ \epsilon_N^{m_1}&\cdots&\epsilon_N^{m_N}\end{vmatrix},\quad \epsilon_\mu\equiv e^{-ih_\mu T},\tag{4.24}$$

the conclusion that the WKB approximation is exact in this case can be derived; since (4.23) is nothing but the Weyl character formula[26] of $U(N)$. [It is easy to find a similar expression for the classical counterpart (2.38).] The mechanism of this exactness then must be examined.

C. The mechanism of exactness

In view of (4.6), or even after $M-1$ integrations as in (4.11), the remaining integration looks still hard to perform. However, the method of the (generalized) Schwinger boson betters the situation.

As in (3.62), any element $E_{\mu\nu}\in u(N)$ has an operator counterpart on $\mathcal{F}$. Since any $N\times N$ Hermitian matrix is expandable in terms of these basis matrices, a quantum Hamiltonian is expressed as a self-adjoint operator on $\mathcal{F}$:

$$\hat{X}\equiv\mathrm{tr}(a^\dagger Xa),\quad X\in H(N).\tag{4.25}$$

Adopting the diagonal matrix H in (4.1) for X to define $\hat{H}$, we start with the character formula

$$\mathcal{Z}_k(T)=\mathrm{Tr}_k\,\exp(-i\hat{H}T),\tag{4.26}$$

in this new formulation. Recall now the fact that the operator P_k (3.68) is not only the resolution of unity in the kth representation space, but also the projection operator onto the subspace of the Fock space. Therefore we can rewrite (4.26) to

$$\mathcal{Z}_k(T)=\mathrm{Tr}\{\exp(-i\hat{H}T)P_k\}=\int_{U(n)}\frac{dg}{(\det g)^k}\int\left(\frac{dz\ d\bar{z}}{\pi}\right)^{Nn}\langle Z|e^{-i\hat{H}T}|Zg_\epsilon\rangle, \tag{4.27}$$

where we have introduced a regularization parameter ϵ,

$$g\mapsto g_\epsilon=e^{-\epsilon}g, \tag{4.28}$$

which is set to zero after all and legitimatizes the exchange of order of integrations. Apart from the g integration, the right-hand side of (4.27) can be brought into a path integral form by dividing the time duration into M segments and inserting the resolution of unity (3.66) successively:

$$\int\left(\frac{dz\ d\bar{z}}{\pi}\right)^{Nn}\langle Z|e^{-i\hat{H}T}|Zg_\epsilon\rangle=\lim_{M\to\infty}\int_{\mathrm{TBC}}\prod_{i=1}^{M}\left(\frac{dz(i)d\bar{z}(i)}{\pi}\right)^{Nn}\prod_{j=1}^{M}\langle Z(j)|(\mathbf{1}-i\hat{H}\ \Delta t)|Z(j-1)\rangle, \tag{4.29}$$

where "TBC" means a twisted boundary condition $Z(0)=Z(M)g_\epsilon$. Since the Hamiltonian is bilinear with respect to $a^\dagger$ and a, it is a simple task to arrive at

$$(4.29)=\lim_{M\to\infty}\int_{\mathrm{TBC}}\prod_{i=1}^{M}\left(\frac{dz(i)d\bar{z}(i)}{\pi}\right)^{Nn}\exp\left[-\sum_{j=1}^{M}\ \mathrm{tr}\ Z^\dagger(j)\{Z(j)-(1_N-iH\ \Delta t)Z(j-1)\}\right]. \tag{4.30}$$

In order to carry out the Gaussian integrals, follow a similar procedure from (4.17) to (4.21) except employing the Fourier transformation met with "TBC,"

$$z(j)=\sum_{r=0}^{M-1}\ \frac{1}{\sqrt{M}}\,e^{-2\pi ijr/M}\tilde{z}(r)(g_\epsilon)^{j/M}, \tag{4.31}$$

giving

$$(4.27)=\int_{U(n)}\frac{dg}{(\det g)^k}\frac{1}{\det(1_N\otimes 1_n-e^{-iHT}\otimes g_\epsilon^{\mathscr{T}})}. \tag{4.32}$$

The g integration can be performed such that one can use the decomposition[27,24]

$$g=\Omega g_0\Omega^\dagger,\quad g_0=\mathrm{diag}(e^{i\theta_1},\ldots,e^{i\theta_n}),\quad \Omega\in SU(n), \tag{4.33}$$

then integrate Ω to give

$$(4.32)=\int_0^{2\pi}\left(\frac{d\theta}{2\pi}\right)^n\frac{1}{n!}\prod_{a<b}|e^{i\theta_a}-e^{i\theta_b}|^2\,\frac{\exp(-ik\Sigma_{a=1}^n\theta_a)}{\Pi_{\mu=1}^N\Pi_{a=1}^n(1-e^{-ih_\mu T+i\theta_a-\epsilon})}. \tag{4.34}$$

By putting $w_a=e^{-i\theta_a}$ the integration over the maximal torus is converted into a multiple contour integrations:

$$(4.34)=\frac{1}{n!}\oint\left(\frac{dw}{2\pi i}\right)^n\prod_{a\neq b}(w_a-w_b)\,\frac{\Pi_{a=1}^n w_a^{N-n+k}}{\Pi_{\mu=1}^N\Pi_{a=1}^n(w_a-e^{-ih_\mu T-\epsilon})}. \tag{4.35}$$

Taking into account all the contributions from poles, we finally obtain

$$\mathcal{Z}_k(T)=\sum_{\mu_1<\cdots<\mu_n}\frac{\exp(-ik\Sigma_{a=1}^{n}h_{\mu_a}T)}{\Pi_{a=1}^{n}\Pi_{\nu\in\bar{\mu}}\{1-e^{-i(h_\nu-h_{\mu_a})T}\}}, \tag{4.36}$$

where again we have used the notation (2.39). (4.36) exactly matches with (4.22). Hence, the WKB approximation is exact in the path integral for the character formula (4.2), which is now interpreted as that of U(N) represented over $G_{N,n}$.

The reason is now quite obvious, since the path integral representation, in view of (4.30), is essentially Gaussian with an additional g integration, regarded as imposing the physical state condition. Evidently there is no room for the emergence of k^{-1}. As is stated in Ref. 14, we may conclude that the path integral expression we have discussed is kinematically nonlinear but dynamically free. [The situation would correspond to a free field over nontrivial phase space, which should compare to the harmonic oscillator (free field!) over a flat phase space.]

V. DISCUSSION

We have clarified the exactness of the WKB approximation for the U(N) character formula expressed as a path integral over $G_{N,n}$. We have employed a time slicing method as well as coherent states to build up a path integral representation. We have made two different approaches: Perelomov's generalized coherent state and a method of (generalized) Schwinger boson. The latter provides a view of constrained system and can clarify the reason for exactness in both cases, classical (2.38) as well as (4.22): the targets, the classical partition function (2.25), and the character formula (4.2), are essentially Gaussian.

Note, however, the difference between the classical and the quantum cases: critical points are controlled by eigenvalues of the Hermitian matrix, (2.32) or (2.38) in the former case but by those of the unitary matrix, (4.12), (4.13) or (4.22) in the latter case. The origin of the difference lies in the form of constraints: although in the classical case (2.40) constraints (2.48) can be interpreted as the result of inserting the delta function naively to the trivial partition function, in other words, the integration domain of the multiplier λ is *unbounded*, it is *compact* in the quantum case, as can be seen from (3.68).

The compactness of the integration domain is indispensable in the quantum case. To see the situation clearly let us examine the $\mathbf{C}P^1$ example:

$$H=\mathbf{z}^\dagger h\mathbf{z},\quad h=\begin{pmatrix}a & b\\ \bar{b} & d\end{pmatrix}\in H(2),\quad \mathbf{z}=\begin{pmatrix}z_1\\ z_2\end{pmatrix}\in\mathbf{C}^2, \tag{5.1}$$

with a constraint

$$\psi\equiv\mathbf{z}^\dagger\mathbf{z}-p\approx 0,\quad p\in\mathbf{R}_+. \tag{5.2}$$

The fundamental Poisson brackets are

$$\{z_\mu,\bar{z}_\nu\}=-i\delta_{\mu\nu},\quad \{z_\mu,z_\nu\}=\{\bar{z}_\mu,\bar{z}_\nu\}=0,\quad (\mu,\nu=1,2). \tag{5.3}$$

In order to reduce the (flat) manifold to $\mathbf{C}P^1$, there needs an additional constraint to fix the phase of a complex number, say z_1. To this end, a change of variables,

$$\mathbf{z}=\begin{pmatrix}1\\ \xi\end{pmatrix}\frac{1}{\sqrt{1+|\xi|^2}}\,\zeta, \tag{5.4}$$

is utilized. The constraint (5.2) is read as $\psi=|\zeta|^2-p$, and the desired one is found as

$$\chi=\frac{1}{2i}\log\left(\frac{\zeta}{\bar{\zeta}}\right)-\phi_0, \quad 0\leqslant\phi_0<2\pi. \tag{5.5}$$

They satisfy

$$\{\psi,\chi\}=1, \tag{5.6}$$

so that the Dirac brackets can be constructed to give

$$\{\xi,\bar{\xi}\}_{\mathrm{D}}=-\frac{i}{p}(1+|\xi|^2)^2. \tag{5.7}$$

In this way classical mechanics on the reduced phase space can be obtained without any problems.

A prescription to quantum theory would be found by means of a path integral developed by Faddeev–Senjanovic (FS):[28]

$$\begin{aligned}\mathscr{Z}_p^{(\mathrm{FS})}\equiv\lim_{M\to\infty}\int\prod_{\mathrm{PBC}i=1}^{M}\frac{(dz(i)d\bar{z}(i))^2}{\pi}\,\delta(\psi(i))\delta(\chi(i))\\ \times\exp\left[i\sum_{j=1}^{M}\{i\mathbf{z}^{\dagger}(j)\Delta\mathbf{z}(j)-\Delta t\ \mathbf{z}^{\dagger}(j)h\mathbf{z}(j-1)\}\right],\end{aligned} \tag{5.8}$$

where

$$\Delta\mathbf{z}(j)\equiv\mathbf{z}(j)-\mathbf{z}(j-1). \tag{5.9}$$

Although the way of finding (5.8) is rather heuristic, the result seems convincing, provided that constrained systems are given in the configuration space, such as the sphere.[29] Therefore we employ this as a starting point of quantum theory.

With the aid of the change of variables (5.4), (5.8) becomes

$$\begin{aligned}\mathscr{Z}_p^{(\mathrm{FS})}=\lim_{M\to\infty}\int\prod_{\mathrm{PBC}i=1}^{M}\frac{d\xi(i)d\bar{\xi}(i)}{\pi(1+|\xi(i)|^2)^2}\,d\zeta(i)d\bar{\zeta}(i)|\zeta(i)|^2\delta(\psi(i))\delta(\chi(i))\\ \times\exp\left[i\sum_{j=1}^{M}\left\{i|\zeta(j)|^2-i\bar{\zeta}(j)\zeta(j-1)\,\frac{1+\bar{\xi}(j)\xi(j-1)}{(1+\bar{\xi}(j)\xi(j))^{1/2}(1+\bar{\xi}(j-1)\xi(j-1))^{1/2}}\right.\right.\\ -\Delta t\bar{\zeta}(j)\zeta(j-1)\\ \left.\left.\times\frac{a+b\xi(j-1)+\bar{\xi}(j)\bar{b}+\bar{\xi}(j)d\xi(j-1)}{(1+\bar{\xi}(j)\xi(j))^{1/2}(1+\bar{\xi}(j-1)\xi(j-1))^{1/2}}\right\}\right].\end{aligned} \tag{5.10}$$

A trivial integration with respect to ζ leads to

$$\mathscr{Z}_p^{(\mathrm{FS})} = \lim_{M\to\infty} \int_{\mathrm{PBC}} \prod_{i=1}^{M} \frac{p\, d\xi(i) d\bar{\xi}(i)}{\pi(1+|\xi(i)|^2)^2} \times \exp\left[-p \sum_{j=1}^{M} \left\{ 1 - \frac{1+\bar{\xi}(j)\xi(j-1)}{(1+\bar{\xi}(j)\xi(j))^{1/2}(1+\bar{\xi}(j-1)\xi(j-1))^{1/2}} + i\,\Delta t\, \frac{a+b\xi(j-1)+\bar{\xi}(j)\bar{b}+\bar{\xi}(j)d\xi(j-1)}{(1+\bar{\xi}(j)\xi(j))^{1/2}(1+\bar{\xi}(j-1)\xi(j-1))^{1/2}} \right\} \right], \tag{5.11}$$

which should be compared with the correct one, the $\mathbf{C}P^1$ version of (4.5),

$$\mathscr{Z}_k(T) = \lim_{M\to\infty} \int_{\mathrm{PBC}} \prod_{i=1}^{M} \frac{(k+1) d\xi(i) d\bar{\xi}(i)}{\pi(1+|\xi(i)|^2)^2} \exp\left[-k \sum_{j=1}^{M} \left\{ \log(1+|\xi(j)|^2) - \log(1+\bar{\xi}(j)\xi(j-1)) + i\,\Delta t\, \frac{a+b\xi(j-1)+\bar{\xi}(j)\bar{b}+\bar{\xi}(j)d\xi(j-1)}{1+\bar{\xi}(j)\xi(j-1)} \right\} \right]. \tag{5.12}$$

In view of these, even if an arbitrary parameter p in (5.11) would be set to $k \in \mathbf{Z}_+$, a failure of the FS prescription for the present model is now obvious. Nevertheless, a formal continuum limit of (5.11) seems reasonably geometric and respects the feature of the classical system. First, rely on a naive expansion,

$$\xi(j-1) \sim \xi(j) - \Delta t \dot{\xi}(j), \tag{5.13}$$

which brings (5.11) to

$$(5.11) \to \int_{\mathrm{PBC}} \prod_{0\le t\le T} \frac{p\, d\xi(t) d\bar{\xi}(t)}{\pi(1+|\xi(t)|^2)^2} \exp\left[ip \int_0^T dt \left\{ \frac{i}{2} \frac{\bar{\xi}\dot{\xi} - \dot{\bar{\xi}}\xi}{1+|\xi|^2} - \frac{1}{1+|\xi|^2} (a + b\xi + \bar{b}\dot{\bar{\xi}} + \bar{\xi} d\xi) \right\} \right], \tag{5.14}$$

whose exponent consists of (classical) $\mathbf{C}P^1$ action. [Of course, we can also arrive at (5.14), starting from (5.12) with a replacement, $k+1 \to p$, in the measure, then taking the same limit.]

We should, therefore, discard or modify the expression (5.8) in order to find a correct quantum theory. In order to convince the importance of the compactness of the multiplier, we modify the expression as

$$\mathscr{Z}_p^{(\text{FS-I})} \equiv \lim_{M\to\infty} \int_{\mathrm{PBC}} \prod_{i=1}^{M} \left(\frac{dz(i) d\bar{z}(i)}{\pi} \right)^2 \int_{-\infty}^{\infty} \frac{\Delta t}{2\pi} d\lambda(i) \times \exp\left[i \sum_{j=1}^{M} \{ i\mathbf{z}^\dagger(j)\Delta\mathbf{z}(j) - \Delta t\, \mathbf{z}^\dagger(j) h \mathbf{z}(j-1) + \Delta t\, \lambda(j)(\mathbf{z}^\dagger(j)\mathbf{z}(j-1) - p) \} \right]. \tag{5.15}$$

Here the χ constraints have been discarded while the ψ constraints now read as $\mathbf{z}^\dagger(j)\mathbf{z}(j-1) - p \approx 0$ and have been Fourier transformed in (5.8). Note that λ plays the role of the multiplier and still travels in an *infinite range*. If we notice that a change of variables,

$$\mathbf{z}(j) = \mathbf{z}'(j) \exp\left\{ i\, \Delta t \sum_{k=1}^{j} \lambda(k) \right\}, \tag{5.16}$$

$$\lambda(j)=\sum_{r=0}^{M-1}\frac{1}{\sqrt{M}}\,e^{-2\pi ijr/M}\tilde{\lambda}(r), \tag{5.17}$$

wipes out almost all $\tilde{\lambda}(r)$, leaving only $\tilde{\lambda}(0)$ [the constant mode of $\lambda(j)$] in the integrand we further modify (5.8), by throwing away infinities from $\tilde{\lambda}(r)$'s, to

$$\mathscr{Z}_p^{(\mathrm{FS\text{-}II})}\equiv\lim_{M\to\infty}\int_{\mathrm{TBC}}\prod_{i=1}^{M}\left(\frac{dz(i)d\bar{z}(i)}{\pi}\right)^2\int_{-\infty}^{\infty}\frac{d\lambda}{2\pi}\,e^{-ip\lambda}$$
$$\times\exp\left[i\sum_{j=1}^{M}\{i\mathbf{z}^{\dagger}(j)\Delta\mathbf{z}(j)-\Delta t\;\mathbf{z}^{\dagger}(j)h\mathbf{z}(j-1)\}\right], \tag{5.18}$$

where, as before, "TBC" denotes $\mathbf{z}(0)=\mathbf{z}(M)e^{i\lambda}$ and all primes have been removed. The Gaussian integrations with respect to $\mathbf{z}$'s can be performed by introducing a regularization parameter $\epsilon>0$, to give

$$\mathscr{Z}_p^{(\mathrm{FS\text{-}II})}=\lim_{\epsilon\to\infty}\int_{-\infty}^{+\infty}\frac{d\lambda}{2\pi}\,e^{-ip\lambda}\,\frac{1}{(1-e^{-ih_1T+i\lambda-\epsilon})(1-e^{-ih_2T+i\lambda-\epsilon})}, \tag{5.19}$$

where h_i's are eigenvalues of h in (5.1). In view of (5.19), p must be some positive integer, otherwise the result is zero, which leads us, furthermore, to the conclusion that the integration domain of λ in (5.19) *must be replaced by a compact one* $0\leqslant\lambda\leqslant 2\pi$. (Since otherwise we obtain infinitely many copies of the same integration.) Therefore we should have

$$\mathscr{Z}_p^{(\mathrm{correct})}=\lim_{\epsilon\to\infty}\int_{0}^{2\pi}\frac{d\lambda}{2\pi}\,e^{-ip\lambda}\,\frac{1}{(1-e^{-ih_1T+i\lambda-\epsilon})(1-e^{-ih_2T+i\lambda-\epsilon})}, \tag{5.20}$$

that is

$$\mathscr{Z}_p^{(\mathrm{correct})}=\lim_{M\to\infty}\int_{\mathrm{TBC}}\prod_{i=1}^{M}\left(\frac{dz(i)d\bar{z}(i)}{\pi}\right)^2\int_{0}^{2\pi}\frac{d\lambda}{2\pi}\,e^{-ip\lambda}$$
$$\times\exp\left[i\sum_{j=1}^{M}\{i\mathbf{z}^{\dagger}(j)\Delta\mathbf{z}(j)-\Delta t\;\mathbf{z}^{\dagger}(j)h\mathbf{z}(j-1)\}\right]. \tag{5.21}$$

In this way the importance of the compactness in the domain of multipliers is understood, which clarifies an indispensable use of projection operator P_k (3.68) given in Sec. III B.

APPENDIX A: PROOF OF THE THEOREMS

In this appendix, we prove our main theorems in Sec. III A

1. Theorem III.2

The statement is

$$\int_{U(n)}\frac{dg}{(\det g)^p}\exp\{\mathrm{tr}(gX)\}=\mathscr{N}(n,p)|X|^p, \tag{A1}$$

where

$$\mathcal{N}(n,p)=\frac{0!1!\cdots(n-1)!}{p!(p+1)!\cdots(p+n-1)!}, \tag{A2}$$

with the assumptions being given in the text.

We use the following facts without proof.

(I) Invariant measure on $\mathrm{U}(n)$:

$$dg\propto\frac{1}{(\det g)^n}\prod_{1\leqslant i,j\leqslant n}dg_{ij}, \tag{A3}$$

where dg_{ij}'s denote n^2 independent differentials. Each g_{ij} is complex and the number of independent components is n^2 in terms of real variables.

(II) Local decomposition of $\mathrm{U}(n)$:

$$g\in\mathrm{U}(n)\Rightarrow g=\begin{pmatrix}a & 0\\ 0 & B\end{pmatrix}\exp\begin{pmatrix}0 & -\alpha^\dagger\\ \alpha & 0\end{pmatrix}, \tag{A4}$$

where $a\in\mathrm{U}(1)$, $B\in\mathrm{U(n-1)}$, and $\alpha\in\mathbf{C}^{n-1}$ is the parameter for $\mathbf{C}P^{n-1}$. Rewrite (A4) to

$$\begin{pmatrix}a & 0\\ 0 & B\end{pmatrix}\begin{pmatrix}\dfrac{1}{\sqrt{1+|\xi|^2}} & -\dfrac{1}{\sqrt{1+|\xi|^2}}\,\xi^\dagger\\ \xi\,\dfrac{1}{\sqrt{1+|\xi|^2}} & \dfrac{1}{\sqrt{1_{n-1}+\xi\xi^\dagger}}\end{pmatrix},\quad \xi=\frac{\alpha}{|\alpha|}\tan|\alpha|, \tag{A5}$$

so that

$$dg\propto d\mu_{n-1}(\xi)\,\frac{da}{a}\,\frac{\Pi dB_{ij}}{(\det B)^{n-1}}. \tag{A6}$$

Note that the $\mathrm{U}(n)$ measure is decomposed into $\mathbf{C}P^{n-1}$, $\mathrm{U}(1)$, and $\mathrm{U}(n-1)$ in order of mention. Therefore a repeated use of this procedure results in

$$dg\propto\prod_{j=1}^{n-1}d\mu_j(\xi^{(j)})\prod_{i=1}^{n}\frac{da_i}{a_i}, \tag{A7}$$

which signifies that the invariant measure of $\mathrm{U}(n)$ is given by the product of $\mathbf{C}P^j$'s measure $(1\leqslant j\leqslant n-1)$ and the tori of $\mathrm{U}(n)$, corresponding to the local decomposition of $\mathrm{U}(n)$:

$$\frac{\mathrm{U}(n)}{\mathrm{U}(1)\times\mathrm{U}(n-1)}\times\frac{\mathrm{U}(n-1)}{\mathrm{U}(1)\times\mathrm{U}(n-2)}\times\cdots\times\frac{\mathrm{U}(2)}{\mathrm{U}(1)\times\mathrm{U}(1)}\times\mathrm{U}(1)^n\cong\mathbf{C}P^{n-1}\times\mathbf{C}P^{n-2}\times\cdots\mathbf{C}P^1\times\mathrm{U}(1)^n. \tag{A8}$$

(III) Integration formula on $\mathbf{C}P^N$:

$$\frac{(k+N)!}{k!}\int\frac{(d\xi\,d\bar{\xi})^N}{\pi^N(1+|\xi|^2)^{N+1+k}}\,(1+a^\dagger\xi)^k(1+\xi^\dagger b)^k=(1+a^\dagger b)^k, \tag{A9}$$

holds for $^\forall a,b\in\mathbf{C}^N$ and $^\forall k\in\mathbf{Z}_+$.

Since both sides of (A1) are regular functions of x_{ij}, the case, $|X|=0$, can be regarded as a limit of $|X|\neq 0$ so that without loss of generality we can assume

$$X=\begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix},\quad \alpha\in\mathbf{C},\beta^T,\gamma\in\mathbf{C}^{n-1},\delta\in M(n-1;\mathbf{C}),\tag{A10}$$

with $\alpha\det\delta\neq 0$.

The proof is done by induction:

(i) For $n=1$, (A1) is verified by a direct calculation:

$$\oint\frac{da}{2\pi i a^{k+1}}\sum_{k=0}^{\infty}\frac{1}{k!}(aX)^k=\frac{X^k}{k!}.\tag{A11}$$

(ii) Assume (A1) holds for $n\leqslant m$. Then adopt (A5) for $g\in U(m+1)$ to find

$$\operatorname{tr} g\begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix}=a\frac{\alpha-\xi^\dagger\gamma}{\sqrt{1+|\xi|^2}}+\operatorname{tr}\left\{B\left(\frac{\xi\beta}{\sqrt{1+|\xi|^2}}+\frac{1}{\sqrt{1_m+\xi\xi^\dagger}}\,\delta\right)\right\}.\tag{A12}$$

According to the assumption of induction, when $n=m+1$, the integration with respect to a and B on the left-hand side of (A1) gives

$$\frac{\mathcal{N}(m,p)}{p!}\int\frac{m!(d\xi\,d\bar{\xi})^m}{\pi^m(1+|\xi|^2)^{m+1}}\left\{\frac{\alpha-\xi^\dagger\gamma}{\sqrt{1+|\xi|^2}}\right\}^p\left\{\det\left(\frac{\xi\beta}{\sqrt{1+|\xi|^2}}+\frac{1}{\sqrt{1_m+\xi\xi^\dagger}}\,\delta\right)\right\}^p.\tag{A13}$$

By means of a relation,

$$\det\left(\frac{\xi\beta}{\sqrt{1+|\xi|^2}}+\frac{1}{\sqrt{1_m+\xi\xi^\dagger}}\,\delta\right)=\frac{1+\beta\delta^{-1}\xi}{\sqrt{1+|\xi|^2}}\det\,\delta,\tag{A14}$$

(A13) is rewritten as

$$\frac{m!\mathcal{N}(m,p)}{p!}(\alpha\,\det\,\delta)^p\int\frac{(d\xi\,d\bar{\xi})^m}{\pi^m(1+|\xi|^2)^{m+1+p}}(1-\xi^\dagger\gamma\alpha^{-1})^p(1+\beta\,\delta^{-1}\xi)^p,\tag{A15}$$

which finally turns out, with the aid of (A9), to be

$$(\text{A15})=\frac{m!}{(p+m)!}\mathcal{N}(m,p)(\alpha\,\det\,\delta)^p(1-\beta\,\delta^{-1}\gamma\,\alpha^{-1})^p=\frac{m!}{(p+m)!}\mathcal{N}(m,p)\left\{\det\begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix}\right\}^p.\tag{A16}$$

Hence, (A1) holds for $n=m+1$ as well as for $n\leqslant m$.
This completes the proof.

2. Theorem III.3

Next, consider the second theorem:

$$|\partial_X||X|^p=p(p+1)\cdots(p+n-1)|X|^{p-1},$$

$$p=0,\pm 1,\pm 2,\ldots\ .\tag{A17}$$

A. Proof for $p \geqslant 0$

In this case, the formula (A1) is utilized to rewrite the left-hand side of (A17) as

$$|\partial_X||X|^p = \frac{1}{\mathcal{N}(n,1)\mathcal{N}(n,p)} \int_{U(n)} \frac{dg_1\, dg_2}{\det g_1 (\det g_2)^p} \exp\{\mathrm{tr}(g_1 \partial_X)\} \exp\{\mathrm{tr}(g_2 X)\}. \tag{A18}$$

Regard $\partial_{ij} = \partial/\partial x_{ij}$ and x_{ij} as operators upon functions of x_{ij}. Then the both sides of (A18) are now considered to operate on 1. Apply the Campbell–Baker–Hausdorff formula to the exponential factors on the right-hand side to give

$$\begin{aligned} \text{rhs of (A18)} = \frac{1}{\mathcal{N}(n,1)\mathcal{N}(n,p)} \int_{U(n)} \frac{dg_1\, dg_2}{\det g_1 (\det g_2)^p} \exp\{\mathrm{tr}(g_1 g_2)\} \\ \times \exp\{\mathrm{tr}(g_2 X)\} \exp\{\mathrm{tr}(g_1 \partial_X)\}, \end{aligned} \tag{A19}$$

so that the last exponential factor can be dropped. Finally, g_1 integration leads to

$$\begin{aligned} |\partial_X||X|^P = \frac{1}{\mathcal{N}(n,p)} \int_{U(n)} \frac{dg}{(\det g)^{p-1}} \exp\{\mathrm{tr}(gX)\} = \frac{\mathcal{N}(n,p-1)}{\mathcal{N}(n,p)} |X|^{p-1} \\ = p(p+1)\cdots(p+n-1)|X|^{p-1}, \end{aligned} \tag{A20}$$

which complete the proof for $p \in \mathbf{Z}_+$. Note that there is no restriction to $X \in M(n;\mathbf{C})$ in this case.

B. Proof for $p<0$

Start with the following relation:

$$|\partial_X||X|^{-p} = |\partial_X| \int \left(\frac{dz\, d\bar{z}}{\pi}\right)^{np} \exp\{-\mathrm{tr}(XZZ^\dagger)\} = (-1)^n \int \left(\frac{dz\, d\bar{z}}{\pi}\right)^{np} |ZZ^\dagger| \exp\{-\mathrm{tr}(XZZ^\dagger)\}, \tag{A21}$$

for

$$X = A + iB, \quad A^\dagger = A, \quad B^\dagger = B, \quad A > 0, \tag{A22}$$

where we have put $p \to -p$ so that p is positive here and hereafter.

First, consider the case $p \leqslant n-1$ in which the relation,

$$\det ZZ^\dagger = \det(Z \quad 0) \begin{pmatrix} Z^\dagger \\ 0 \end{pmatrix} = 0, \tag{A23}$$

tells us that the right-hand side of (A21) trivially vanishes. Hence, it is enough to examine the case $p \geqslant n$. Before proceeding, we recall a well-known fact: under the condition (A22) A and B are simultaneously diagonalized by means of an appropriate invertible matrix K, such that

$$K^\dagger A K = 1_n, \quad K^\dagger B K = B_D = \mathrm{diag}(\beta_1, \ldots, \beta_n). \tag{A24}$$

Accordingly, a change of variables, $Z \mapsto Z' = K^{-1}Z$, gives

$$(\text{A21}) = \frac{(-1)^n}{|A|^{p+1}} \int \left(\frac{dz\, d\bar{z}}{\pi}\right)^{np} |ZZ^\dagger| \exp[-\mathrm{tr}\{(1_n + iB_D)ZZ^\dagger\}]. \tag{A25}$$

Then rewrite the matrix $1_n + iB_D$ as

$$1_n + iB_D = \begin{pmatrix} 1+i\beta_1 & & 0 \\ & \ddots & \\ 0 & & 1+i\beta_n \end{pmatrix} = F\Phi, \tag{A26}$$

$$F \equiv \begin{pmatrix} f_1 & & 0 \\ & \ddots & \\ 0 & & f_n \end{pmatrix}, \quad \Phi \equiv \begin{pmatrix} e^{i\phi_1} & & 0 \\ & \ddots & \\ 0 & & e^{i\phi_n} \end{pmatrix}, \tag{A27}$$

$$0 < f_i, \quad -\frac{\pi}{2} < \phi_i < \frac{\pi}{2} \quad (i = 1,\ldots,n). \tag{A28}$$

Further, a change of variables $Z \mapsto Z' = \sqrt{F}Z$ leads to

$$(\text{A25}) = \frac{(-1)^n}{|A|^{p+1}|F|^{p+1}} \int \left(\frac{dz\ d\bar{z}}{\pi}\right)^{np} |ZZ^\dagger| \exp\{-\mathrm{tr}(\Phi Z Z^\dagger)\}, \tag{A29}$$

which is rewritten, by use of the formula (A1), as

$$(\text{A29}) = \frac{(-1)^n n!}{|A|^{p+1}|F|^{p+1}} \lim_{\epsilon \to 0} \int_{U(n)} \frac{dg}{\det g} \int \left(\frac{dz\ d\bar{z}}{\pi}\right)^{np} \exp[-\mathrm{tr}\{(\Phi - ge^{-\epsilon})ZZ^\dagger\}]. \tag{A30}$$

Now the Gaussian integration with respect to Z is performed, giving

$$(\text{A30}) = \frac{(-1)^n n!}{|A|^{p+1}|F|^{p+1}} \lim_{\epsilon \to 0} \int_{U(n)} \frac{dg}{\det g} \frac{1}{\det(\Phi - ge^{-\epsilon})^p}, \tag{A31}$$

which becomes, after a change of variable $g \mapsto \Phi^{-1}g$,

$$\begin{aligned}(\text{A31}) &= \frac{(-1)^n n!}{|A|^{p+1}|F|^{p+1}|\Phi|^{p+1}} \lim_{\epsilon \to 0} \int_{U(n)} \frac{dg}{\det g} \frac{1}{\det(1_n - ge^{-\epsilon})^p} \\ &= \frac{(-1)^n n!}{|X|^{p+1}} \lim_{\epsilon \to 0} \int_{U(n)} \frac{dg}{\det g} \frac{1}{\det(1_n - ge^{-\epsilon})^p}. \end{aligned} \tag{A32}$$

In view of (A32) and (A17) (with $p \to -p$), our remaining task is therefore to prove

$$\lim_{\epsilon \to 0} \int_{U(n)} \frac{dg}{\det g} \frac{1}{\det(1_n - ge^{-\epsilon})^p} = \binom{p}{n}. \tag{A33}$$

In order to accomplish the g integration, recall the decomposition,[27,24]

$$g = \Omega g_0 \Omega^\dagger, \quad g_0 = \mathrm{diag}(e^{i\theta_1},\ldots,e^{i\theta_n}), \quad \Omega \in SU(n), \tag{A34}$$

then integrate Ω to obtain

$$\lim_{\epsilon \to 0} \int_{U(n)} \frac{dg}{\det g} \frac{1}{\det(1_n - ge^{-\epsilon})^p} = \lim_{\epsilon \to 0} \int_0^{2\pi} \left(\frac{d\theta}{2\pi}\right)^n \frac{1}{n!} \prod_{a<b} |e^{i\theta_a} - e^{i\theta_b}|^2 \prod_{a=1}^n \frac{e^{-i\theta_a}}{(1 - e^{-\epsilon + i\theta_a})^p}$$

$$= \lim_{\epsilon \to 0} \int_0^{2\pi} \left(\frac{d\theta}{2\pi} \right)^n \frac{1}{n!} \sum_{\sigma,\tau \in \mathcal{S}_n} \operatorname{sgn}(\sigma\tau) \prod_{a=1}^{n} \sum_{l_a=0}^{\infty} \binom{p+l_a-1}{l_a}$$
$$\times \exp[i\{l_a - 1 + \sigma(a) - \tau(a)\}\theta_a - l_a\epsilon]. \tag{A35}$$

Finally, carry out the θ integrations and put $\epsilon \to 0$ to find

$$(\text{A35}) = \begin{vmatrix} p & \binom{p+1}{2} & \binom{p+2}{3} & \cdots & \binom{p+n-1}{n} \\ 1 & p & \binom{p+1}{2} & \ddots & \vdots \\ 0 & 1 & p & \ddots & \binom{p+2}{3} \\ \vdots & \ddots & \ddots & \ddots & \binom{p+1}{2} \\ 0 & \cdots & 0 & 1 & p \end{vmatrix}. \tag{A36}$$

We denote this determinant as $\mathcal{D}(n,p)$, $n=0,1,2,...$, defining $\mathcal{D}(0,p)=1$. Now our goal is to show

$$\mathcal{D}(n,p) = \binom{p}{n}. \tag{A37}$$

Prove this again by induction: first note the recursion relation, obtained by expanding $\mathcal{D}(n,p)$ with respect to its first row,

$$\mathcal{D}(n,p) = \sum_{r=1}^{n} (-1)^{1+r} \binom{p+r-1}{r} \mathcal{D}(n-r,p). \tag{A38}$$

Assume (A37) for $0 \leqslant m \leqslant n-1$, then rewrite (A38) as

$$\mathcal{D}(n,p) = \sum_{r=1}^{n} (-1)^{1+r} \binom{p+r-1}{r} \binom{p}{n-r} = \frac{p}{n} \sum_{r=1}^{n} (-1)^{1+r} \binom{n}{r} \binom{p+r-1}{p+r-n}. \tag{A39}$$

Utilize the generating function, giving us

$$\binom{p+r-1}{p+r-n} = \frac{1}{p!} \left(\frac{d}{dx} \right)^p \Bigg|_{x=0} \sum_{l=0}^{\infty} \binom{l+n-1}{l} x^{l+n-r}, \tag{A40}$$

to find

$$\binom{p}{n} - \mathcal{D}(n,p) = \frac{p}{n} \sum_{r=0}^{n} (-1)^r \binom{n}{r} \binom{p+r-1}{p+r-n} = \frac{p}{n} \frac{1}{p!} \left(\frac{d}{dx} \right)^p \Bigg|_{x=0} \sum_{r=0}^{n} (-1)^r \binom{n}{r}$$
$$\times \sum_{l=0}^{\infty} \binom{l+n-1}{l} x^{l+n-r}$$
$$= \frac{p}{n} \frac{1}{p!} \left(\frac{d}{dx} \right)^p \Bigg|_{x=0} \sum_{r=0}^{n} \binom{n}{r} (-1)^r x^{n-r} \left(\frac{1}{1-x} \right)^n = (-1)^n \frac{p}{n} \frac{1}{p!} \left(\frac{d}{dx} \right)^p \Bigg|_{x=0} 1 = 0. \tag{A41}$$

Thus (A37) also holds for $m=n$. This completes the proof.

APPENDIX B: FEYNMAN KERNEL AND THE WKB APPROXIMATION

In order to make a comparison to the DH theorem, our concentration has been on the character formula in the text. However, from a quantum mechanical point of view, the Feynman kernel is more primitive so that in this appendix a brief sketch is presented, giving a path integral representation that enables us to discuss the WKB approximation.

1. The Feynman kernel by the generalized coherent states

Take a Hermitian matrix,

$$H\equiv\begin{pmatrix} A & B \\ B^\dagger & D \end{pmatrix}\in H(N), \tag{B1}$$

with the same convention given in (2.14); then consider the Feynman kernel,

$$K_k(\xi_F,\xi_I;T)\equiv\langle\xi_F;k|\rho_k(e^{-iHT})|\xi_I;k\rangle. \tag{B2}$$

Follow a similar procedure from (4.2) to (4.6) to obtain

$$\begin{aligned} K_k(\xi_F,\xi_I;T)=&\frac{1}{[\det\{(1_n+\xi_F^\dagger\xi_F)(1_n+\xi_I^\dagger\xi_I)\}]^{k/2}}\lim_{M\to\infty}\int\prod_{i=1}^{M-1}d\mu(\xi(i);k)\\ &\times\exp\left[-k\sum_{j=1}^{M-1}\operatorname{tr}\log(1_n+\xi^\dagger(j)\xi(j))+k\sum_{j=1}^{M}\operatorname{tr}\log(1_n+\xi^\dagger(j)\xi(j-1))\right]\\ &\times\exp\left[-ik\,\Delta t\sum_{j=1}^{M}\operatorname{tr}\{P(\xi(j),\xi(j-1))H\}\right], \end{aligned} \tag{B3}$$

where $\xi(0)=\xi_I$, $\xi(M)=\xi_F$. Introduce a one-parameter subgroup of U(N),

$$g(t)=\exp(-iHt)=\begin{pmatrix} \alpha(t) & \beta(t) \\ \gamma(t) & \delta(t) \end{pmatrix},\quad t\in\mathbf{R}, \tag{B4}$$

and write

$$\mathbf{L}(i,j)\equiv\alpha(i-j)+\xi^\dagger(i)\gamma(i-j)+\beta(i-j)\xi(j)+\xi^\dagger(i)\delta(i-j)\xi(j), \tag{B5}$$

with the abbreviation $\alpha(j\Delta t)=\alpha(j)$, etc.; then discard $O((\Delta t)^2)$ terms to obtain

$$\begin{aligned} K_k(\xi_F,\xi_I;T)=&\frac{1}{[\det\{(1_n+\xi_F^\dagger\xi_F)(1_n+\xi_I^\dagger\xi_I)\}]^{k/2}}\lim_{M\to\infty}\int\prod_{i=1}^{M-1}d\mu(\xi(i);k)\\ &\times\exp\left[k\sum_{j=1}^{M}\operatorname{tr}\log\mathbf{L}(j,j-1)-k\sum_{j=1}^{M-1}\operatorname{tr}\log\mathbf{L}(j,j)\right], \end{aligned} \tag{B6}$$

whose jth integration part is

$$\int\frac{d\mu(\xi(j);k)}{\{\det(1_n+\xi^\dagger(j)\xi(j))\}^k}[\det\{\mathbf{L}(j+1,j)\mathbf{L}(j,j-1)\}]^k. \tag{B7}$$

To carry out this integration, write

$$\det\{\mathbf{L}(j+1,j)\mathbf{L}(j,j-1)\}=\det\{\alpha(1)+\xi^{\dagger}(j+1)\gamma(1)\}\det\{1_n+\{\xi^{\dagger}(j+1)*g(1)\}\xi(j)\}$$
$$\times\det\{1_n+\xi^{\dagger}(j)\{g(1)*\xi(j-1)\}\}\det\{\alpha(1)+\beta(1)\xi(j-1)\}, \tag{B8}$$

where

$$g(j)*\xi=\{\gamma(j)+\delta(j)\xi\}\{\alpha(j)+\beta(j)\xi\}^{-1},$$
$$\xi^{\dagger}*g(j)\equiv\{\alpha(j)+\xi^{\dagger}\gamma(j)\}^{-1}\{\beta(j)+\xi^{\dagger}\delta(j)\}. \tag{B9}$$

Utilizing the formula (3.48), we find

$$(\mathrm{B7})=\det\{\alpha(1)+\xi^{\dagger}(j+1)\gamma(1)\}^{k}[\det\{1_n+\{\xi^{\dagger}(j+1)*g(1)\}\{g(1)*\xi(j-1)\}\}]^{k}$$
$$\times\det\{\alpha(1)+\beta(1)\xi(j-1)\}^{k}, \tag{B10}$$

which is nothing but

$$(\mathrm{B7})=\{\det\mathbf{L}(j+1,j-1)\}^{k}, \tag{B11}$$

since $g(t)$ is an element of the one-parameter subgroup (B4). Hence, after $M-1$ times of this manipulation we obtain

$$K_k(\xi_F,\xi_I;T)=\left[\frac{\det\{\alpha(T)+\xi_F^{\dagger}\gamma(T)+\beta(T)\xi_I+\xi_F^{\dagger}\delta(T)\xi_I\}}{\det\{(1_n+\xi_F^{\dagger}\xi_F)(1_n+\xi_I^{\dagger}\xi_I)\}^{1/2}}\right]^{k}. \tag{B12}$$

2. The Feynman kernel by the Schwinger boson

First introduce an integral representation of the inner product between coherent states:

$$\langle\xi;k|\eta;k\rangle=\frac{\mathcal{N}(n,N-n+k)}{\mathcal{N}(n,k)}\int\left(\frac{d\zeta\,d\bar{\zeta}}{\pi}\right)^{n^2}\{\det(\zeta^{\dagger}\zeta)\}^{N-n}\int_{U(n)}\frac{dg}{(\det g)^{k}}\langle Z(\xi,\zeta)|Z(\eta,\zeta)g\rangle, \tag{B13}$$

where

$$|Z(\xi,\zeta)\rangle\equiv\exp\{\mathrm{tr}(a^{\dagger}Z(\xi,\zeta)-Z^{\dagger}(\xi,\zeta)a)\}|0\rangle \tag{B14}$$

is the canonical coherent state, with $Z(\xi,\zeta)$ being defined by

$$\xi\in M(N-n,n;\mathbf{C}),\quad \zeta\in M(n;\mathbf{C})\mapsto Z(\xi,\zeta)\equiv\begin{pmatrix}1_n\\ \xi\end{pmatrix}\frac{1}{\sqrt{1_n+\xi^{\dagger}\xi}}\,\zeta\in M(N,n;\mathbf{C}). \tag{B15}$$

[The relation (B13) can be verified by use of the formulas III.2 and III.3.) Then the Feynman kernel (B2) is expressed as

$$K_k(\xi_F,\xi_I;T)=\frac{\mathcal{N}(n,N-n+k)}{\mathcal{N}(n,k)}\int\left(\frac{d\zeta\,d\bar{\zeta}}{\pi}\right)^{n^2}\{\det(\zeta^{\dagger}\zeta)\}^{N-n}\int_{U(n)}\frac{dg}{(\det g)^{k}}\langle Z(\xi_F,\zeta)|$$
$$\times\exp(-i\hat{H}T)|Z(\xi_I,\zeta)g\rangle, \tag{B16}$$

where $\hat{H}$ has been given by (4.25) for H in (B1). Write

$$\langle Z(\xi_F,\zeta)|\exp(-i\hat{H}T)|Z(\zeta_I,\zeta)g\rangle=\exp\{-\mathrm{tr}(\zeta^\dagger\zeta)\}\lim_{M\to\infty}\int\prod_{i=1}^{M-1}\left(\frac{dz(i)d\bar{z}(i)}{\pi}\right)^{Nn}$$
$$\times\exp\left[-\mathrm{tr}\left\{\sum_{j=1}^{M-1}Z^\dagger(j)Z(j)\right.\right.$$
$$\left.\left.-\sum_{j=1}^{M}Z^\dagger(j)g(1)Z(j-1)\right\}\right], \tag{B17}$$

where $Z(0)=Z(\xi_I,\zeta)g$, $Z^\dagger(M)=Z^\dagger(\xi_F,\zeta)$, which becomes

$$(\mathrm{B17})=\exp[-\mathrm{tr}\{\zeta^\dagger\zeta-g\zeta^\dagger\mathbf{K}(\xi_F,\xi_I;T)\zeta\}], \tag{B18}$$

where

$$\mathbf{K}(\xi_F,\xi_I;T)\equiv(1_n+\xi_F^\dagger\xi_F)^{-1/2}\mathbf{L}(M,0)(1_n+\xi_I^\dagger\xi_I)^{-1/2}$$
$$=(1_n+\xi_F^\dagger\xi_F)^{-1/2}\{\alpha(T)+\xi_F^\dagger\gamma(T)+\beta(T)\xi_I+\xi_F^\dagger\delta(T)\xi_I\}(1_n+\xi_I^\dagger\xi_I)^{-1/2}. \tag{B19}$$

Substituting (B18) into (B16) and carrying out g and ζ integrations, we find

$$K_k(\xi_F,\xi_I;T)=\{\det\mathbf{K}(\xi_F,\xi_I;T)\}^k=\left[\frac{\det\{\alpha(T)+\xi_F^\dagger\gamma(T)+\beta(T)\xi_I+\xi_F^\dagger\delta(T)\xi_I\}}{\det\{(1_n+\xi_F^\dagger\xi_F)(1_n+\xi_I^\dagger\xi_I)\}^{1/2}}\right]^k, \tag{B20}$$

which, of course, matches the previous result (B12). However, this representation can again provide an interpretation of the WKB exactness.

3. The WKB approximation

From the path integral expression (B6), the action is read as

$$S=\sum_{j=1}^{M}\mathrm{tr}\log\mathbf{L}(j,j-1)-\sum_{j=1}^{M-1}\mathrm{tr}\log\mathbf{L}(j,j). \tag{B21}$$

and therefore equations of motion read as

$$\{\gamma(1)+\delta(1)\xi(j-1)\}\mathbf{L}^{-1}(j,j-1)=\xi(j)\mathbf{L}^{-1}(j,j), \tag{B22}$$

$$\mathbf{L}^{-1}(j+1,j)\{\beta(1)+\xi^\dagger(j+1)\delta(1)\}=\mathbf{L}^{-1}(j,j)\xi^\dagger(j), \tag{B23}$$

for $1\leqslant j\leqslant M-1$. These can be solved locally by

$$\xi(j)=\{\gamma(1)+\delta(1)\xi(j-1)\}\{\alpha(1)+\beta(1)\xi(j-1)\}^{-1}, \tag{B24}$$

$$\xi^\dagger(j)=\{\alpha(1)+\xi^\dagger(j+1)\gamma(1)\}^{-1}\{\beta(1)+\xi^\dagger(j+1)\delta(1)\}, \tag{B25}$$

so that the classical solution, under the boundary condition $\xi(0)=\xi_I$, $\xi(M)=\xi_F$, is found such that

$$\xi_c(j)=\{\gamma(j)+\delta(j)\xi_I\}\{\alpha(j)+\beta(j)\xi_I\}^{-1}, \tag{B26}$$

$$\xi_c^\dagger(j)=\{\alpha(M-j)+\xi_F^\dagger\gamma(M-j)\}^{-1}\{\beta(M-j)+\xi_F^\dagger\delta(M-j)\}. \tag{B27}$$

Note that $\xi_c(j)$ and $\xi_c^\dagger(j)$ are not Hermitian conjugated to each other. This is not so surprising, although it is often emphasized. A similar situation can be met even in a simple Gaussian integration:

$$\int \frac{dz\ d\bar{z}}{\pi} \exp(-\bar{z}z+\bar{a}z+\bar{z}b), \tag{B28}$$

for $a,b\in\mathbf{C}$. Complete the square to find

$$\bar{z}z-\bar{a}z-\bar{z}b=(\bar{z}-\bar{a})(z-b)-\bar{a}b. \tag{B29}$$

Then the shift, $z,\bar{z}\to z+b,\bar{z}+a$, leading to

$$\int \frac{dz\ d\bar{z}}{\pi} \exp(-\bar{z}z+\bar{a}b)=e^{\bar{a}b}, \tag{B30}$$

is asymmetric, but there is no problem. The point is that they should be regarded as independent, which also clarifies that there is no overspecification problem often stressed by authors working in a continuum version of the path integral, since there seems to be two boundary conditions in the first-order differential equation. (The confusion emerges from regarding variables as complex conjugates to each other.)

Turn back to the main subject and evaluate the action (B21) and its Hessian at classical solutions (B26) and (B27). To this end note the following relation:

$$\mathbf{L}(j,j)_c\{\alpha(j)+\beta(j)\xi_I\}=\mathbf{L}(j,j-1)_c\{\alpha(j-1)+\beta(j-1)\xi_I\}, \tag{B31}$$

where the subscript c designates quantities of the classical solutions. Then

$$\begin{aligned} S_c &\equiv \sum_{j=1}^{M} \operatorname{tr}\log \mathbf{L}(j,j-1)_c - \sum_{j=1}^{M-1} \operatorname{tr}\log \mathbf{L}(j,j)_c \\ &= \operatorname{tr}\log[\mathbf{L}(M,M-1)_c\{\alpha(M-1)+\beta(M-1)\xi_I\}]=\operatorname{tr}\log \mathbf{L}(M,0), \end{aligned} \tag{B32}$$

with $\mathbf{L}(M,0)\in M(n;\mathbf{C})$ being given by (B5): explicitly, $\mathbf{L}(M,0) = \alpha(T) + \xi_F^\dagger\gamma(T) + \beta(T)\xi_I + \xi_F^\dagger\delta(T)\xi_I$. Introduce another one-parameter subgroup,

$$\tilde{g}(t)\equiv\begin{pmatrix} \delta^\dagger(t) & -\beta^\dagger(t) \\ -\gamma^\dagger(t) & \alpha^\dagger(t) \end{pmatrix}, \tag{B33}$$

to define

$$\tilde{\mathbf{L}}(i,j)\equiv\delta^\dagger(i-j)-\xi(j)\gamma^\dagger(i-j)-\beta^\dagger(i-j)\xi^\dagger(i)+\xi(j)\alpha^\dagger(i-j)\xi^\dagger(i). \tag{B34}$$

The Hessian of the action is then found as

$$\frac{\partial^2 S}{\partial\xi_{ia}(l)\partial\bar{\xi}_{jb}(m)}=-\delta_{l,m}\tilde{\mathbf{L}}^{-1}(m,m)_{ji}\mathbf{L}^{-1}(m,m)_{ab}+\delta_{l,m-1}\tilde{\mathbf{L}}^{-1}(m,m-1)_{ji}\mathbf{L}^{-1}(m,m-1)_{ab}. \tag{B35}$$

Shifting the variables such that

$$\xi(j)=\xi_c(j)+z(j),\quad \xi^\dagger(j)=\xi_c^\dagger(j)+z^\dagger(j), \tag{B36}$$

and truncate the Taylor series up to the bilinear terms of z and $z^\dagger$ to obtain

$$S \sim S_c - \sum_{j=1}^{M-1} \mathrm{tr}\{z^\dagger(j)\tilde{\mathbf{L}}^{-1}(j,j)_c z(j)\mathbf{L}^{-1}(j,j)_c\} + \sum_{j=2}^{M-1} \mathrm{tr}\{z^\dagger(j)\tilde{L}^{-1}(j,j-1)_c z(j-1) \times \mathbf{L}^{-1}(j,j-1)_c\}. \tag{B37}$$

The measure is also approximated as

$$d\mu(\xi(j);k)|_c \overset{k\to\infty}{\sim} \frac{k^{n(N-n)}}{\{\det \mathbf{L}(j,j)_c\}^N} \left(\frac{dz(j)d\bar{z}(j)}{\pi}\right)^{n(N-n)} \{1+O(k^{-1})\}, \tag{B38}$$

where use has been made of the definition of the measure (3.42) with (4.14). Therefore, in view of (B37) and (B38) the Gaussian integration of $\bar{z}(j), z(j)$ gives

$$\det\{\tilde{\mathbf{L}}^{-1}(j,j)_c \otimes (\mathbf{L}^{-1}(j,j)_c)^{\mathscr{T}}\}^{-1} = \{\det \mathbf{L}(j,j)_c\}^N, \tag{B39}$$

which, together with $(\pi/k)^{n(N-n)}$, cancels the prefactor in (B38), yielding the leading contribution to the WKB approximation:

$$\begin{aligned} K_k(\xi_F,\xi_I;T) &\overset{k\to\infty}{\sim} \frac{1}{[\det\{(1_n+\xi_F^\dagger\xi_F)(1_n+\xi_I^\dagger\xi_I)\}]^{k/2}} \exp\{k \ \mathrm{tr} \log \mathbf{L}(M,0)\} \\ &= \left[\frac{\det\{\alpha(T)+\xi_F^\dagger\gamma(T)+\beta(T)\xi_I+\xi_F^\dagger\delta(T)\xi_I\}}{\det\{(1_n+\xi_F^\dagger\xi_F)(1_n+\xi_I^\dagger\xi_I)\}^{1/2}}\right]^k. \end{aligned} \tag{B40}$$

The result is equal to the Feynman kernel (B12), (B20). Thus, *the WKB approximation is again exact for the Feynman kernel*. The fact can also be clarified in view of (B16) as well as (B17), since the integrand is Gaussian.

Berry's phase on SU(n)/S(U(1)×U($n-1$)) manifolds

S. Giller, C. Gonera, P. Kosiński, and P. Maślanka
University of Lodz, Department of Theoretical Physics, Pomorska 149/153, 90-236 Lodz, Poland

(Received 24 March 1995; accepted for publication 18 April 1995)

It is shown that the Berry phase/matrix for Hamiltonians parametrized by the points of $M \equiv \mathrm{SU}(n)/\mathrm{S}(\mathrm{U}(1)\times\mathrm{U}(n-1))$ and having no accidental degeneracy is expressible in terms of Riemannian connection on M and representations of $\mathrm{S}(\mathrm{U}(1)\times\mathrm{U}(n-1))$. © *1996 American Institute of Physics.* [S0022-2488(95)01812-3]

I. INTRODUCTION

Berry's phase has appeared to be the most exciting recent discovery in the field of elementary quantum mechanics. It has found a wide range of applications as, for example, the Born–Oppenheimer treatment of molecular systems,[2] the quantum Hall effect,[3] gauge anomalies,[4] or light propagation in optical fibers.[5]

Much attention has also been paid to the mathematical structure of Berry's phase. It was quickly realized that Berry's phase, as well as its generalization to the case of degenerate levels[6]—the Berry matrix, is related to the geometry of some fiber bundles.[7–10] In particular, in Ref. 10 a general approach was proposed that is applicable in the case of Hamiltonians generated by the action of a unitary representation of some Lie group G. Within the approach proposed there the relation between Berry's phase/matrix and the geometry of homogeneous space G/H becomes transparent, and some general structural questions are easily addressed. For example, the general criteria can be given under which the Berry phase is determined by the Riemannian connection on G/H and the representation of H.

The present paper is devoted to the proof of the statement that for $G=\mathrm{SU}(n)$ and $H=\mathrm{S}(\mathrm{U}(1)\times\mathrm{U}(n-1))$ the Berry phase/matrix for any Hamiltonian with no degeneracy (to be defined below) is determined in this way. In Sec. II we outline the method developed in Ref. 10 and recall some basic facts concerning the geometry of homogeneous spaces. Then in Sec. III, we prove our basic statement. Our main tool in Gelfand–Tseytlin explicit construction of representations of U(n) groups.

II. GEOMETRY OF BERRY'S PHASE AND HOMOGENEOUS SPACES

We recall briefly the group-theoretical approach to Berry's phase developed in Ref. 10. Let $\{\Pi_n\}$ be any spectral decomposition of unity,

$$\Pi_n\Pi_m=\delta_{nm}\Pi_m, \quad \Pi_n^+=\Pi_n, \quad \sum_n \Pi_n=1. \tag{1}$$

Assume further that $G\ni g\mapsto U(g)$ is a unitary representation of compact semisimple Lie group G acting in the Hilbert space of states. Consider family of projectors defined by

$$\Pi_n(g)=U(g)\Pi_n U^+(g). \tag{2}$$

Let $H\subset G$ be subgroup of G consisting of all elements $g\in G$ such that $U(g)\Pi_n U^+(g)=\Pi_n$ for any n. Then the family $\{\Pi_n(g)\}$ is parametrized by the points $\zeta\in G/H$. Finally, let $\{E_n(\zeta)\}$ be a set of real-valued functions on G/H such that $E_n(\zeta)\neq E_m(\zeta)$, $n\neq m$; we define the family of Hamiltonians,

$$\mathscr{H}(\zeta)\equiv\sum_n E_n(\zeta)\Pi_n(\zeta). \tag{3}$$

Our task is to calculate the Berry phases/matrices for this family. The following answer to this problem is given in Ref. 10. Let (V,A) be the Lie algebra of G while (V)—that of H. The relevant commutation rules read as follows:

$$[V_i,V_j]=ic_{ij}^k V_k, \quad [V_i,A_\alpha]=ic_{i\alpha}^\beta A_\beta, \quad [A_\alpha,A_\beta]=ic_{\alpha\beta}^k V_k+ic_{\alpha\beta}^\gamma A_\gamma. \tag{4}$$

We always assume that basis (V,A) provides an orthogonal decomposition of Lie algebra with respect to the Cartan product,

$$\mathrm{Tr}(\mathrm{Ad}\ V_i\cdot \mathrm{Ad}\ A_\alpha)=0, \tag{5}$$

and we put

$$\mathrm{Tr}(\mathrm{Ad}\ V_i\cdot \mathrm{Ad}\ V_j)=\eta_{ij}, \quad \mathrm{Tr}(\mathrm{Ad}\ A_\alpha\cdot \mathrm{Ad}\ A_\beta)=\eta_{\alpha\beta}. \tag{6}$$

The Cartan forms are defined as follows:

$$U^+(\zeta)dU(\zeta)=i\,\eta_\mu^i\ d\zeta^\mu\cdot V_i+i\omega_\mu^\alpha\ d\zeta^\mu A_\alpha. \tag{7}$$

Finally, we denote

$$V_i^{(n)}\equiv\Pi_n V_i\Pi_n, \quad A_\alpha^{(n)}\equiv\Pi_n A_\alpha\Pi_n. \tag{8}$$

The main result of Ref. 10 is as follows. Given any closed curve $\gamma\subset G/H$, the corresponding Berry's matrix for the nth level is given by the parallel transport along γ defined by the connection

$$\frac{D}{dt}=\frac{\partial}{\partial t}+i\ \frac{d\zeta^\mu}{dt}\ (\omega_\mu^\alpha A_\alpha^{(n)}+\eta_\mu^k V_k^{(n)}). \tag{9}$$

This formula gives the group-theoretical description of Berry's aholonomy for the family of Hamiltonians defined by Eq. (3). One can now use the geometrical techniques to obtain more detailed information concerning Berry's phase/matrix.

Let us remind some basic facts concerning the geometry of homogeneous spaces. Putting

$$\omega^\alpha\equiv\omega_\mu^\alpha\ d\zeta^\mu, \quad \eta^i\equiv\eta_\mu^i\ d\zeta^\mu, \tag{10}$$

and taking the external derivative of both sides of Eq. (7), we arrive at the so-called Cartan–Maurer equations,

$$d\omega^\gamma=\tfrac{1}{2}c_{\alpha\beta}^\gamma\omega^\alpha\wedge\omega^\beta+c_{k\alpha}^\gamma\eta^k\wedge\omega^\alpha, \tag{10a}$$

$$d\eta^i=\tfrac{1}{2}c_{\alpha\beta}^i\omega^\alpha\wedge\omega^\beta+\tfrac{1}{2}c_{lk}^i\eta^l\wedge\eta^k. \tag{10b}$$

Note that $\omega_\mu^\alpha(\zeta)$ can be viewed as orthonormal repers; in particular,

$$g_{\mu\nu}(\zeta)\equiv\eta_{\alpha\beta}\omega_\mu^\alpha(\zeta)\omega_\nu^\beta(\zeta) \tag{11}$$

is an invariant metric on G/H. Let us define

$$\Omega_\beta^\alpha\equiv-\eta^i c_{i\beta}^\alpha, \tag{12a}$$

$$T_{\beta\gamma}^\alpha\equiv c_{\beta\gamma}^\alpha, \tag{12b}$$

$$R_{\beta\gamma\rho}^\alpha\equiv-c_{i\beta}^\alpha c_{\gamma\rho}^i. \tag{12c}$$

Equations (10) can be now written in the form

$$d\omega^{\alpha}+\Omega^{\alpha}_{\beta}\wedge\omega^{\beta}=\tfrac{1}{2}T^{\alpha}_{\beta\gamma}\omega^{\beta}\wedge\omega^{\gamma}, \tag{13a}$$

$$d\Omega^{\alpha}_{\beta}+\Omega^{\alpha}_{\rho}\wedge\Omega^{\rho}_{\beta}=\tfrac{1}{2}R^{\alpha}_{\beta\gamma\rho}\omega^{\gamma}\wedge\omega^{\beta}. \tag{13b}$$

Therefore, $T^{\alpha}_{\beta\gamma}$ and $R^{\alpha}_{\beta\gamma\rho}$ are torsion and curvature, respectively. In particular, if G/H is a symmetric space, $c^{\alpha}_{\beta\gamma}=0$, the torsion vanishes. Then Ω^{α}_{β} is the Riemannian connection on G/H. If G/H is homogeneous only, Ω^{α}_{β} differs from the Riemannian connection by a torsion term; in both cases the metric tensor (11) is covariantly constant. In the *nonsymmetric* case the Riemannian connection reads as

$$\Omega^{\alpha}_{R\beta}=-\eta^{i}c^{\alpha}_{i\beta}-\tfrac{1}{2}c^{\alpha}_{\gamma\beta}\omega^{\gamma}. \tag{14}$$

Indeed, $\Omega_{R\alpha\beta}$ is antisymmetric; moreover, it follows from Eq. (12a) that the corresponding torsion vanishes. The direct proof of Eq. (14) can be also obtained by calculating Christoffel symbols from the metric (11) and using the formula

$$\Omega^{\alpha}_{R\beta}=\omega^{\alpha}_{\nu}\Gamma^{\nu}_{\mu}\omega^{\mu}_{\beta}+\omega^{\alpha}_{\nu}\,d\omega^{\nu}_{\beta}. \tag{15}$$

In the above formula the first index of ω^{α}_{β} is raised (lowered) with the help of $\eta^{\alpha\beta}(\eta_{\alpha\beta})$ while the second one by $g^{\mu\nu}(\zeta)(g_{\mu\nu}(\zeta))$.

If G/H is symmetric space, the Riemannian connection can be viewed as a connection in a bundle associated with the principal bundle $P(G/H,H)$.

Let us pose the following question: *for which Hamiltonians (3) the Berry matrices for all levels n are expressible in terms of Riemannian connection on G/H and the representations of H*. It follows from Eq. (9) that one should then have

$$A^{(n)}_{\alpha}=0, \tag{16}$$

and, moreover, G/H should be symmetric space. All generators V_i have a block-diagonal form,

$$V_i=\sum_n V^{(n)}_i. \tag{17}$$

We assume that there is no accidental degeneracy, i.e., H is a maximal symmetry group of all Hamiltonians of the family under consideration. Then all eigenspaces carry irreducible representations of H. Our problem becomes now a purely group-theoretical one. Given group G and subgroup $H\subset G$ such that G/H is a symmetric space, find all irreducible representations of G such that Eq. (16) holds for all irreducible subspace (n) of subduced representation $G\downarrow H$.

It is not easy to solve this question in whole generality. Instead, in the next section we present some general example of such a situation.

III. BERRY'S AHOLONOMY FOR SU(n)/S(U(1)×U($n-1$)) SYSTEMS

Here we solve the problem posed in the last section for $G=\mathrm{SU}(n)$ and $H=\mathrm{S}(\mathrm{U}(1)\times\mathrm{U}(n-1))$.

The generators of SU(n) can be introduced as follows.[11] First, we define generators of GL($n,\mathbb{R}$),

$$(A_{ij})_{kl}=\delta_{il}\delta_{jk}, \tag{18}$$

verifying

$$[A_{ij},A_{kl}]=\delta_{jk}A_{il}-\delta_{il}A_{kj}. \tag{19}$$

Then we put

$$M_{kl}\equiv A_{kl}+A_{lk}, \quad \tilde{M}_{kl}\equiv i(A_{kl}-A_{lk}), \quad 1\leqslant k<l\leqslant n, \tag{20a}$$

$$M_{ll}\equiv A_{ll}-A_{l+1l+1}, \quad 1\leqslant l\leqslant n-2, \tag{20b}$$

$$M_{n-1n-1}\equiv \mathrm{diag}(1,\ldots,1,1-n). \tag{20c}$$

Then $H=\mathrm{S}(\mathrm{U}(1)\times\mathrm{U}(n-1))$ subgroup is generated by M_{kl}, $\tilde{M}_{kl}$, $1\leqslant k<l\leqslant n-1$ and M_{ll}, $l=1,\ldots,n-1$; the remaining ones (generating the cosets) are M_{kn}, $\tilde{M}_{kn}$, $k=1,\ldots,n-1$.

We are looking for the irreducible representations of SU(n) for which Eq. (16) holds. To this end we adopt the following strategy.[12] First, we note that any irreducible representation of SU(n) is obtained by subducing some irreducible representations of U(n). Indeed, it is sufficient to add to the set of generators (20) an additional one,

$$M_{nn}=I. \tag{21}$$

Then the operators M_{kl}, $\tilde{M}_{kl}$, $1\leqslant k<l\leqslant n-1$, M_{ll}, $l=1,\ldots,n-1$ span the Lie algebra of U(n) while M_{kl}, $\tilde{M}_{kl}$, $1\leqslant k<l\leqslant n-1$, M_{ll}, $1\leqslant l\leqslant n-2$ and

$$M\equiv\frac{1}{n}\,(M_{n-1n-1}+(n-1)M_{nn}), \tag{22}$$

span the Lie algebra of U($n-1$); the coset space is generated by $2n-1$ operators $M_{kn},\tilde{M}_{kn},M_{nn}$. In any irreducible representation M_{nn} is proportional to unit operator and poses no problems.

We have only to check for which representations of U(n) Eq. (16) holds for any irreducible representation of U($n-1$) and any operator M_{kn}, $\tilde{M}_{kn}$, $k=1,\ldots,n-1$. First, we note that

$$[M_{kl},M_{in}]=-i(\delta_{il}\tilde{M}_{kn}+\delta_{ik}\tilde{M}_{ln}), \tag{23a}$$

$$[\tilde{M}_{kl},\tilde{M}_{in}]=i(\delta_{il}\tilde{M}_{kn}-\delta_{ik}\tilde{M}_{ln}), \tag{23b}$$

$$[\tilde{M}_{kl},M_{in}]=i(\delta_{il}M_{kn}-\delta_{ik}M_{ln}). \tag{23c}$$

We see that the generators $\tilde{M}_{kl}$, $1\leqslant k<l\leqslant n-1$ span SO($n-1$) algebra and M_{in}, $\tilde{M}_{in}$, $i=1,\ldots,n-1$ form the vector representations of this algebra. Therefore, for any $l=1,\ldots,n-1$ there exist $g_l,\tilde{g}_l\in\mathrm{SO}(n-1)\subset\mathrm{S}(\mathrm{U}(1)\times\mathrm{U}(n-1))$, such that

$$M_{ln}=U(g_l)M_{n-1n}U^{+}(g_l), \quad \tilde{M}_{ln}=U(\tilde{g}_l)\tilde{M}_{n-1n}U^{+}(\tilde{g}_l). \tag{24}$$

But $U(g_l),U(\tilde{g}_l)$ leave invariant the irreducible subspaces of $\mathrm{S}(\mathrm{U}(1)\times\mathrm{U}(n-1))$. Therefore it is sufficient to check the validity of Eq. (16) for M_{n-1n} and $\tilde{M}_{n-1n}$ only. To this end we use the Gelfand–Tseytlin method.[11] Consider the chain of subalgebras,

$$u(n)\supset u(n-1)\supset\cdots\supset u(1). \tag{25}$$

It is well known that any irreducible representation of $u(k)$, when subduced to $u(n-1)$, contains a given irreducible representation of $u(k-1)$, at most, once; moreover, irreducible representations of $u(1)$ are one dimensional. Therefore we can enumerate the basis vector of a given representation of $u(n)$ by indicating to which representation of $u(k),k=1,\ldots,n-1$, it belongs. This is the essence of the Gelfand–Tseytlin scheme.

Now, M_{n-1n} and $\tilde{M}_{n-1n}$ commute with all $u(k),k=1,\ldots,n-2$. Therefore, in a Gelfand–Tseytlin basis, their nonvanishing matrix elements are either diagonal or correspond to the vectors

belonging to different irreducible representation of $u(n-1)$. So, we have to check Eq. (16) for diagonal elements M_{n-1n} and $\tilde{M}_{n-1n}$, or, equivalently, of A_{n-1n} and A_{nn-1}. However, it follows from general Gelfand–Tseytlin formulas[11] that the diagonal matrix element of $A_{n-1,n}$ and $A_{n,n-1}$ vanish for all irreducible representations of U(n).

We conclude that for any n and any irreducible representation of SU(n), the Hamiltonians generated by SU(n), parametrized by the points of coset space SU(n)/S(U(1)×U($n-1$)) and exhibiting no accidental degeneracy give rise to Berry's phases/matrices expressible in terms of Riemannian connection on SU(n)/S(U(1)×U($n-1$)) and the representations of S(U(1)×U($n-1$)).

(Received 23 May 1995; accepted 19 September 1995)

For over a century, the Kepler problem and the harmonic oscillator have been known as the only central force dynamical systems, all of whose bounded motions are periodic. Two of the authors (T. I. and N. K.) have found an infinite number of dynamical systems possessing such a periodicity property, which have been called multi-fold Kepler systems or ν-fold Kepler systems, with ν a positive rational number. If ν is allowed to take the real positive numbers, say $\nu=\alpha$, then for the α-fold Kepler system, all the bounded motions become periodic or not, according to whether the parameter α is a rational number or not. A purpose of this paper is to quantize the α-fold Kepler system and thereby to figure out a quantum analog of the closed orbit property of the α-fold Kepler system. It will turn out that the quantized α-fold Kepler system admits accidental degeneracy in energy levels or not, according to whether α is a rational number or not. © *1996 American Institute of Physics.* [S0022-2488(96)00902-1]

I. INTRODUCTION

For many years, the Taub–NUT metric on $\mathbf{R}^4-\{0\}$ has been investigated from various points of view. For instance, the motion of well-separated two monopoles can be described approximately by the geodesic motion associated with the Taub–NUT (Taub–Newman–Unti–Tambrino) metric.[1–5] It is also known, from a symmetry point of view, that the geodesic motion of this metric admits a Kepler-type symmetry when the geodesic flow system is reduced to a three-degrees-of-freedom system.[5–8]

In previous papers,[9–11] Iwai and Katayama have generalized the Taub–NUT metric so that the associated reduced system may admit a Kepler-type symmetry. In a continuation of those papers,[12] they have made further generalization of the Taub–NUT metric, which is described as follows: Let (x_j) be the Cartesian coordinates in $\dot{\mathbf{R}}^4:=\mathbf{R}^4-\{0\}$. The generalized Taub–NUT metric is expressed as

$$ds_G^2=4rf(r)\sum_{j=1}^{4}dx_j^2+4\left(\frac{g(r)}{r^2}-f(r)\right)(-x_2\,dx_1+x_1\,dx_2-x_4\,dx_3+x_3\,dx_4)^2, \tag{1.1}$$

with $f(r)$ and $g(r)$ given, respectively, by

$$f(r)=r^{1/\alpha-2}(a_0+a_1r^{1/\alpha}) \quad \text{and} \quad g(r)=\frac{r^{1/\alpha}(a_0+a_1r^{1/\alpha})}{1+a_2r^{1/\alpha}+a_3r^{2/\alpha}}, \tag{1.2}$$

where r is the squared radius,

$$r=\sum_{j=1}^{4}x_j^2,$$

and the parameter α is a positive real number and a_j's real constants.

0022-2488/96/37(2)/608/17/$10.00

The reduced system from the geodesic flow system associated with this metric has a remarkable periodicity property. Consider the cotangent bundle $T^*\dot{\mathbf{R}}^4$ of $\dot{\mathbf{R}}^4$ with the standard symplectic form $d\theta=\Sigma_{j=1}^4 dy_j\wedge dx_j$, (x_j,y_j) being the Cartesian coordinates in $\dot{\mathbf{R}}^4\times\mathbf{R}^4\simeq T^*\dot{\mathbf{R}}^4$. Then the geodesic flow system is described as a Hamiltonian system on the phase space $(T^*\dot{\mathbf{R}}^4,d\theta)$ along with a certain Hamiltonian function H containing $f(r)$ and $g(r)$. Owing to a $U(1)$ symmetry, the Hamiltonian system $(T^*\dot{\mathbf{R}}^4,d\theta,H)$ can be reduced to a Hamiltonian system $(T^*\dot{\mathbf{R}}^3,\omega_\mu,H_\mu)$, where $T^*\dot{\mathbf{R}}^3\simeq\dot{\mathbf{R}}^3\times\mathbf{R}^3$ denotes the cotangent bundle of $\dot{\mathbf{R}}^3:=\mathbf{R}^3-\{0\}$, ω_μ is the reduced symplectic form composed of the canonical one plus the two-form describing Dirac's monopole field of strength $-\mu$, $\mu\in\mathbf{R}$, and H_μ is a reduced Hamiltonian, which also depends on $f(r)$ and $g(r)$. See Refs. 12, 13, or 14 for the reduction procedure, for example. For $f(r)$ and $g(r)$ given by (1.2), the reduced Hamiltonian system $(T^*\dot{\mathbf{R}}^3,\omega_\mu,H_\mu)$ has a remarkable periodicity property; according as the parameter α in H_μ is a rational number or not, all the bounded motions become periodic or not. In this paper, this Hamiltonian system will be referred to as the "α-fold Kepler system," whichever number the α takes, rational or irrational.

The aim of this paper is to develop a quantum theory for the α-fold Kepler system. Like in the classical case, a significant feature will be found out for the quantized α-fold Kepler system: According to whether the α is rational or not, accidental degeneracies in the energy levels arise or not.

The contents of this paper are outlined as follows: Section II contains a setting up of the classical α-fold Kepler system, which is defined to be a Hamiltonian system reduced from the geodesic flow system for the generalized Taub–NUT metric ds_G^2 through the reduction by a $U(1)$ action. It is remarked that the α-fold Kepler system covers a class of dynamical systems of interest.

In Sec. III, the geodesic flow system for ds_G^2 is quantized, through the Schrödinger procedure, since the classical Hamiltonian can be expressed in the Cartesian coordinates, and since no problem of noncommutativity of operators arises. It is to be noted that the Hamiltonian operator obtained, $\hat{H}$, is not equal to $-\frac{1}{2}$ times the Laplace–Beltrami operator for ds_G^2. This definition of $\hat{H}$ seems to contradict the ordinary principle that the Hamiltonian operator to be associated with the metric is the Laplace–Beltrami operator. For example, in Refs. 5–7, the Laplace–Beltrami operator associated with the Taub–NUT metric was used as a Hamiltonian operator. This discrepancy will be cleared out in Sec. VI. Note also that the Hilbert space in which $\hat{H}$ is to be defined densely is taken to be $L^2(\mathbf{R}^4;4rf(r)dx)$, the space of square-integrable functions on $\mathbf{R}^4$ with respect to the volume form $4rf(r)dx_1\cdots dx_4$. To avoid excessive singularity, we assume that $f(r)>0$ for $r>0$ in the following. The eigenvalue problem of $\hat{H}$ is solved for bound states. It is shown further that the energy eigenvalues for $\hat{H}$ become equal to those obtained already in Refs. 5–7, when ds_G^2 is restricted to the Taub–NUT metric.

In Sec. IV, the quantized α-fold Kepler system is defined to be the reduced system of the quantized geodesic flow system defined in Sec. III. A key to the reduction procedure is the fact that the configuration space $\dot{\mathbf{R}}^4$ is made into a principal U(1) bundle $\pi:\dot{\mathbf{R}}^4\to\dot{\mathbf{R}}^3$. Then the geometric setting for the reduction is to form the complex line bundle L_m, $m\in\mathbf{Z}$, associated with the principal bundle $\pi:\dot{\mathbf{R}}^4\to\dot{\mathbf{R}}^3$. The restriction of $L^2(\mathbf{R}^4;4rf(r)dx)$ to the ρ_m-equivariant functions[15,16] gives rise to the Hilbert space of square integrable cross sections in L_m, denoted by Γ_m. According to this reduction procedure, the quantized α-fold Kepler system is to be defined in Γ_m, with the Hamiltonian operator $\hat{H}_m$ reduced from the $\hat{H}$, which contains the covariant derivation operator with respect to the linear connection on L_m. The eigenvalue problem of $\hat{H}_m$ is studied accordingly. On account of the reduction procedure, the eigenvalues of $\hat{H}_m$ come from those of $\hat{H}$.

In Sec. V, degeneracy in energy levels for $\hat{H}_m$ is discussed. Owing to the spherical symmetry, the quantized α-fold Kepler system admits an SU(2) symmetry, which causes degeneracy in the energy levels of $\hat{H}_m$. In addition, it will be shown that additional "accidental" degeneracy occurs

or not, according to whether α is a rational number or not. This can be thought of as a quantum analog to the periodicity property of the classical α-fold Kepler system.

Section VI contains the comparison of the operator $\hat{H}$ with the Laplace–Beltrami operator Δ for the generalized Taub–NUT metric ds_G^2. A necessary and sufficient condition for $\hat{H}=-(1/2)\Delta$ will be given.

II. A REVIEW OF THE MULTIFOLD KEPLER SYSTEM

In this section, we make a brief review of the multifold Kepler system. To define the multifold Kepler system on $T^*\dot{\mathbf{R}}^3$ with $\dot{\mathbf{R}}^3=\mathbf{R}^3-\{0\}$, we start with a U(1) reduction of the phase space $(T^*\dot{\mathbf{R}}^4, d\theta)$, where $\dot{\mathbf{R}}^4=\mathbf{R}^4-\{0\}$, and $d\theta$ is the standard symplectic two-form that is expressed as $d\theta=\Sigma_{i=1}^4\, dy_i\wedge dx_i$ in the Cartesian coordinates $(x,y)\in\dot{\mathbf{R}}^4\times\mathbf{R}^4\simeq T^*\dot{\mathbf{R}}^4$. The symplectic SO(2) $\simeq$U(1) action, denoted by S_t, is defined to be

$$S_t:(x,y)\mapsto(T(t)x,T(t)y), \tag{2.1}$$

with

$$T(t)=\begin{pmatrix} R(t) & 0 \\ 0 & R(t)\end{pmatrix},\quad R(t)=\begin{pmatrix} \cos t/2 & -\sin t/2 \\ \sin t/2 & \cos t/2\end{pmatrix}. \tag{2.2}$$

The moment map J associated with S_t takes the form

$$J(x,y)=\tfrac{1}{2}(-x_2y_1+x_1y_2-x_4y_3+x_3y_4). \tag{2.3}$$

According to the Weinstein–Marsden reduction method,[17] the reduced phase space is defined to be the quotient space $J^{-1}(\mu)/\mathrm{U}(1)$ for a fixed $\mu\in\mathbf{R}$, which turns out to be realized as the cotangent bundle $T^*\dot{\mathbf{R}}^3$ of $\dot{\mathbf{R}}^3$ as follows:[13,14] We define a map of $\dot{\mathbf{R}}^4\times\mathbf{R}^4$ to $\dot{\mathbf{R}}^3\times\mathbf{R}^3$ by

$$\Pi(x,y):=\left(P(x)x,\frac{1}{2r}\,P(x)y\right), \tag{2.4a}$$

where

$$P(x)=\begin{pmatrix} x_3 & x_4 & x_1 & x_2 \\ -x_4 & x_3 & x_2 & -x_1 \\ x_1 & x_2 & -x_3 & -x_4\end{pmatrix},\quad r:=\sum_{j=1}^4 x_j^2. \tag{2.4b}$$

The mapping (2.4a) is also known as the Kustaanheimo–Stiefel transformation.[18] Then the restriction of Π to $J^{-1}(\mu)\subset T^*\dot{\mathbf{R}}^4$, denoted by π_μ, gives rise to the projection

$$\pi_\mu:J^{-1}(\mu)\to T^*\dot{\mathbf{R}}^3\simeq J^{-1}(\mu)/\mathrm{U}(1), \tag{2.5}$$

which proves our assertion. We denote the Cartesian coordinates in the reduced phase space $\dot{\mathbf{R}}^3\times\mathbf{R}^3$ by (q,p); $\Pi(x,y)=(q,p)$ with $(x,y)\in J^{-1}(\mu)$. We reduce the symplectic form $d\theta$ in turn. On letting $\iota_\mu:J^{-1}(\mu)\to T^*\dot{\mathbf{R}}^4$ be the inclusion map, the reduced symplectic form ω_μ on the reduced phase space is determined through $\pi_\mu^*\omega_\mu=\iota_\mu^*\, d\theta$, which turns out to take the form

$$\omega_\mu=\sum_{k=1}^3 dp_k\wedge dq_k-\frac{\mu}{r^3}\,(q_1\, dq_2\wedge dq_3+\text{cyclic}). \tag{2.6}$$

The second term of the right-hand side of (2.6) corresponds to the magnetic flux of Dirac's monopole field $\mathbf{B}=-\mu\mathbf{q}/r^3$.

Let H be a Hamiltonian function on $T^*\dot{\mathbf{R}}^4$. If it is $U(1)$ invariant, it can be reduced, through $H\circ\iota_\mu = H_\mu\circ\pi_\mu$, to a Hamiltonian function H_μ on $T^*\dot{\mathbf{R}}^3$. In what follows, we are to reduce the Hamiltonian system describing the geodesic flows for the generalized Taub–NUT metrics ds_G^2 given by (1.1) and (1.2). The Hamiltonian function H associated with ds_G^2 is given by

$$H=\frac{1}{2}\cdot\frac{1}{4rf(r)}\left[\sum_{j=1}^{4}y_j^2+\left(\frac{rf(r)}{g(r)}-\frac{1}{r}\right)(-x_2y_1+x_1y_2-x_4y_3+x_3y_4)^2\right]. \tag{2.7}$$

Throughout this paper, to get rid of excessive singularities of H, we assume that $a_0\geqslant 0$ and $a_1>$, so that $f(r)>0$ for $r>0$. Note again that the α is a positive number, and a_j's real constants. Since the H is invariant under the U(1) action (2.1), it proves to be reduced to the Hamiltonian function

$$H_\mu=\frac{1}{2f(r)}\sum_{k=1}^{3}p_k^2+\frac{\mu^2}{2g(r)}\quad\left(r^2=\sum_{k=1}^{3}q_k^2\right). \tag{2.8}$$

Note that the reduction procedure works for arbitrary functions $f(r)$ and $g(r)$. In a summary, we have the following.[12]

Proposition 2.1: The Hamiltonian system $(T^*\dot{\mathbf{R}}^4,d\theta,H)$ *describing the geodesic flows for the generalized Taub–NUT metric* ds_G^2 *is reduced by the* U(1) *action to the Hamiltonian system* $(T^*\dot{\mathbf{R}}^3,\omega_\mu,H_\mu)$, $\mu\in\mathbf{R}$, *which is called the* α*-fold Kepler system.*

The α-fold Kepler system has a significant property in their bounded trajectories.[12]

Theorem 2.2: *For the* α*-fold Kepler system* $(T^*\dot{\mathbf{R}}^3,\omega_\mu,H_\mu)$, *all the bounded trajectories are closed if and only if the parameter* α *in the Hamiltonian function (2.8) with (1.2) is a rational number.*

In closing this section, we make a few remarks. When the parameters in $f(r)$ and $g(r)$ are set to be

$$a_0=4c,\quad a_1=1,\quad a_2=\frac{1}{2c},\quad a_3=\frac{1}{16c^2},\quad\text{and}\quad\alpha=1, \tag{2.9}$$

the metric ds_G^2 becomes the Taub–NUT metric, where c is a constant. Further, if we set the parameters to be

$$a_0=a_3=0,\quad a_1=1,\quad a_2=-\frac{2\kappa}{\mu^2}\ (\kappa>0,\text{const}),\quad\text{and}\quad\alpha=1, \tag{2.10}$$

the reduced Hamiltonian (2.8) becomes that for the MIC (McIntosch–Cisneros)–Kepler problem. For the MIC–Kepler problem, see a series of papers.[13,15,19,20] Further, in the case of

$$a_0=a_3=0,\quad a_1=\frac{1}{4},\quad a_2=-\frac{\kappa}{2\mu^2},\quad\text{and}\quad\alpha=2, \tag{2.11}$$

the reduced system becomes the two-fold Kepler system studied in Ref. 11, which is the Hamiltonian system reduced from the four-dimensional Kepler problem on $(T^*\dot{\mathbf{R}}^4,d\theta)$.

III. THE QUANTUM SYSTEM ASSOCIATED WITH THE GEODESIC FLOW SYSTEM FOR ds_G^2

A. Quantization of the geodesic flow system

We wish to quantize the geodesic flow system $(T^*\dot{\mathbf{R}}^4,d\theta,H)$, with H given by (2.7). Since H is expressed in the Cartesian coordinates, and since no problem of noncommutativity of operators

occurs, we choose to adopt the Schrödinger procedure in order to associate a Hamiltonian operator with H. According to that procedure, y_j are replaced by $-i\partial/\partial x_j$, so that Eq. (2.7) gives rise to

$$\hat{H}=-\frac{1}{2}\cdot\frac{1}{4rf(r)}\left[\sum_{j=1}^{4}\frac{\partial^2}{\partial {x_j}^2}+\left(\frac{rf(r)}{g(r)}-\frac{1}{r}\right)\left(-x_2\frac{\partial}{\partial x_1}+x_1\frac{\partial}{\partial x_2}-x_4\frac{\partial}{\partial x_3}+x_3\frac{\partial}{\partial x_4}\right)^2\right]. \tag{3.1}$$

As a Hamiltonian operator, we could have chosen $-\frac{1}{2}$ times the Laplace–Beltrami operator associated with ds_G^2, following the usual principle. However, we dared to adopt the operator (3.1). We postpone the comparison of these two quantization procedures to Sec. VI. Instead of the comparison, here we claim that our procedure is based upon the consideration of energy manifolds of the classical system. Let us define a function K_λ to be

$$K_\lambda=4rf(r)(H-\lambda), \tag{3.2}$$

where λ is a constant. Then, the energy manifolds $H^{-1}(E)$ and $K_\lambda^{-1}(0)$ with $E=\lambda$ are identical in $T^*\dot{\mathbf{R}}^4$. Further, the Hamiltonian flows generated by H and by K_E coincide up to "time" parameters. In fact, a straightforward calculation shows that $X_{K_\lambda}=4rf(r)X_H$ on the energy manifold mentioned above. We are to quantize H on the hope that quantum analogy of (3.2) holds. That is, we assume that if Hamiltonian operators $\hat{H}$ and $\hat{K}_\lambda$ are defined suitably, they will possibly satisfy

$$\hat{K}_\lambda=4rf(r)(\hat{H}-\lambda). \tag{3.3}$$

This equation implies that eigenfunctions for $\hat{K}_E=0$ become those for $\hat{H}=E$, and vice versa. The quantization of K_λ is easy to make, since K_λ takes the simple form

$$K_\lambda=\frac{1}{2}\left[\sum_{j=1}^{4}y_j^2+\left(\frac{rf(r)}{g(r)}-\frac{1}{r}\right)(-x_2y_1+x_1y_2-x_4y_3+x_3y_4)^2\right]-4\lambda rf(r), \tag{3.4}$$

to which the Schrödinger procedure is easy to apply. Hence, the Hamiltonian operator $\hat{H}$ is expressed as in (3.1) on account of (3.3).

We have to describe what Hilbert space is suitable for $\hat{H}$. We wish to define a Hilbert space so that $\hat{H}$ may be at least a symmetric operator in it. To this end, we consider the space of square integrable functions on $\mathbf{R}^4$ with respect to the volume element $4rf(r)dx=4rf(r)dx_1\cdots dx_4$, which is denoted by $L^2(\mathbf{R}^4;4rf(r)dx)$. Incidentally, it is well known that $C_0^\infty(\mathbf{R}^4)$, the space of smooth functions on $\mathbf{R}^4$ with compact support, is dense in $L^2(\mathbf{R}^4)$, the usual L^2 space. Moreover, the space $C_0^\infty(\mathbf{R}^4)$ remains to be dense in $L^2(\mathbf{R}^4;4rf(r)dx)$, as is easily shown. Now, for any ϕ, $\psi\in C_0^\infty(\mathbf{R}^4)$, integration by parts shows that

$$\int_{\mathbf{R}^4}\overline{(\hat{H}\phi)(x)}\psi(x)4rf(r)dx=\int_{\mathbf{R}^4}\overline{\phi(x)}(\hat{H}\psi)(x)4rf(r)dx. \tag{3.5}$$

Thus, the Hamiltonian operator $\hat{H}$ is a symmetric operator in $L^2(\mathbf{R}^4;4rf(r)dx)$. Summarizing the above, we come to the following definition.

Definition 3.1: The quantized system associated with the geodesic flow system for the generalized Taub–NUT metric ds_G^2 is defined as the pair $(L^2(\mathbf{R}^4;4rf(r)dx),\hat{H})$, where $\hat{H}$ is given by (3.1).

Before going to the eigenvalue problem of $\hat{H}$, we have to make a remark on $\hat{H}$. As was remarked in Sec. II, if the parameters are set as in (2.9), the generalized Taub–NUT metric ds_G^2 becomes the usual Taub–NUT metric. Correspondingly, the Hamiltonian operator $\hat{H}$ becomes

identical with $-\frac{1}{2}$ times the Laplace–Beltrami operator for the Taub–NUT metric, which was studied in Refs. 5–7. However, as will be shown in Sec. VI, the $\hat{H}$ is not equal to $-\frac{1}{2}$ times the Laplace–Beltrami operator for ds_G^2 in general.

B. The eigenvalue problem of $\hat{H}$

We are to solve the eigenvalue problem of $\hat{H}$ for the bound states. To this end, it is convenient to introduce curvilinear coordinates in $\dot{\mathbf{R}}^4$ as follows:

$$\begin{aligned} x_1 &= \sqrt{r}\,\cos\frac{\theta}{2}\cos\frac{\psi+\phi}{2}, \quad x_2 = \sqrt{r}\,\cos\frac{\theta}{2}\sin\frac{\psi+\phi}{2}, \\ x_3 &= \sqrt{r}\,\sin\frac{\theta}{2}\cos\frac{\psi-\phi}{2}, \quad x_4 = \sqrt{r}\,\sin\frac{\theta}{2}\sin\frac{\psi-\phi}{2}, \end{aligned} \tag{3.6}$$

where $r>0$, $0\leqslant\theta\leqslant\pi$, and $0\leqslant\psi-\phi$, $\psi+\phi\leqslant 4\pi$. In terms of (r,θ,ϕ,ψ), the operator $\hat{H}$ is written as

$$\hat{H} = -\frac{1}{2f(r)}\left[\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right)+\frac{1}{4r^2}\Delta_3+\left(\frac{f(r)}{g(r)}-\frac{1}{r^2}\right)\left(\frac{\partial}{\partial\psi}\right)^2\right], \tag{3.7}$$

where Δ_3 is the Laplace–Beltrami operator on the three-dimensional unit sphere S^3 with the canonical metric;

$$\Delta_3 = 4\left[\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right)+\frac{1}{\sin^2\theta}\left(\frac{\partial^2}{\partial\phi^2}-2\cos\theta\frac{\partial^2}{\partial\phi\,\partial\psi}+\frac{\partial^2}{\partial\psi^2}\right)\right]. \tag{3.8}$$

Let us take an ansatz $R(r)Q(\theta,\phi,\psi)$ as an eigenfunction of $\hat{H}$, after the method of a separation of variables. We may assume that the angular part $Q(\theta,\phi,\psi)$ is an eigenfunction of the Δ_3, which is expanded into a series of Wigner's $\mathscr{D}$ functions $\{\mathscr{D}^J_{ML}(\psi,\theta,\phi)\}$, a complete orthogonal basis of $L^2(S^3)$. In this paper, we follow Edmonds' definition;[21]

$$\mathscr{D}^J_{ML}(\psi,\theta,\phi) = \exp(iM\psi)\exp(iL\phi)d^J_{ML}(\theta), \tag{3.9a}$$

with

$$d^J_{ML}(\theta) = \left[\frac{(J+M)!(J-M)!}{(J+L)!(J-L)!}\right]^{1/2}\left(\cos\frac{\theta}{2}\right)^{M+L}\left(\sin\frac{\theta}{2}\right)^{M-L}P^{(M-L,M+L)}_{J-M}(\cos\theta), \tag{3.9b}$$

where $P^{(M-L,M+L)}_{J-M}$'s denote the Jacobi polynomials.[21] The suffices J, L, and M of $\mathscr{D}^J_{ML}$ are subject to

$$J\text{:non-negative half-integer}, \quad L,M = J,J-1,\cdots-J+1,-J. \tag{3.10}$$

Since every $\mathscr{D}$ function is an eigenfunction for Δ_3,

$$\Delta_3\mathscr{D}^J_{ML} = -4J(J+1)\mathscr{D}^J_{ML}, \tag{3.11}$$

our ansatz can take a more specified form, $R(r)\mathscr{D}^J_{ML}(\psi,\theta,\phi)$. We note here that $\mathscr{D}^J_{ML}$ is simultaneously an eigenfunction of $-i\partial/\partial\psi$;

$$\frac{\partial}{\partial\psi}\mathscr{D}^J_{ML} = iM\mathscr{D}^J_{ML}. \tag{3.12}$$

Then, further calculation shows that the radial part $R(r)$ must satisfy

$$\left[\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right)-\frac{J(J+1)}{r^2}+\frac{1}{r^2}\,(c_0 r^{1/\alpha}+c_1 r^{2/\alpha})\right]R(r)=0, \tag{3.13a}$$

with

$$c_0=2Ea_0-M^2a_2, \quad c_1=2Ea_1-M^2a_3, \tag{3.13b}$$

where J, M, and L are subject to (3.10). The energy eigenvalues and the eigenfunctions are hence obtained by solving (3.13) under the boundary condition

$$\int_0^\infty |R(r)|^2 2r^2 f(r)dr<+\infty, \tag{3.14}$$

since $R(r)Q(\theta,\phi,\psi)\in L^2(\mathbf{R}^4,4rf(r)dx)$. The calculation of eigenfunctions and eigenvalues is given in the Appendix.

From the Appendix, we see that the eigenvalues depend on a number n defined, for a non-negative integer N, by

$$n=N+\tfrac{1}{2}+\alpha(J+\tfrac{1}{2}). \tag{3.15}$$

We express Eqs. (A14a) and (A14b) as

$$E^+_{J,N;M}=\frac{1}{2a_0^2}\left(a_0a_2M^2-2a_1\left(\frac{n}{\alpha}\right)^2+2\frac{n}{\alpha}\sqrt{\left(\frac{n}{\alpha}\right)^2a_1^2+a_0(a_0a_3-a_1a_2)M^2}\right), \tag{3.16a}$$

for $a_0\neq 0$, and as

$$E^0_{J,N;M}=\frac{a_3M^2}{2a_1}-\frac{\alpha^2a_2^2M^4}{8a_1n^2}, \tag{3.16b}$$

for $a_0=0$, respectively. Further, we set

$$\epsilon=\alpha\sqrt{a_3M^2-2a_1E^\sigma_{J,N;M}} \quad (\sigma=+,0). \tag{3.17}$$

Then from (A12), we find that Eq. (3.13) is satisfied by the function

$$R^\sigma_{J,N;M}(r)=\exp(-\epsilon r^{1/\alpha})r^JF(-N,\alpha(2J+1)+1,2\epsilon r^{1/\alpha}), \tag{3.18}$$

where F denotes the confluent hypergeometric function.

We are now in a position to give solutions to the eigenvalue problem (3.13) with (3.14).

Theorem 3.2: *The eigenvalues of $\hat{H}$ for the bound states are given by (3.16a) or (3.16b), according to whether the constants a_j, $j=0,\ldots,3$, are subject to the condition*

$$(P)\quad a_0>0, \quad a_1\geqslant 0, \quad \text{and } (a_0a_3-a_1a_2)M^2\neq 0, \tag{3.19}$$

or

$$(Z)\quad a_0=0, \quad a_1>0 \quad \text{and } M\neq 0.$$

The suffixes J and M are subject to (3.10), and N to $N=0,1,2,\ldots$. If the constants a_j, $j=0,1,2,3$, are not subject to the conditions listed in (3.19), no bound states for $\hat{H}$ exist under the assumption that $f(r)>0$ for $r>0$.

It is to be noted that the conditions $(a_0a_3-a_1a_2)M^2\neq 0$ and $M\neq 0$ in (3.19) are necessary for $\epsilon>0$.

Theorem 3.3: *The* $2J+1$ *linearly independent eigenfunctions,*

$$\Psi^{\sigma}_{L,J,N;M}(r,\theta,\phi,\psi)=R^{\sigma}_{J,N;M}(r)\mathscr{D}^{J}_{ML}(\psi,\theta,\phi) \quad (L=J,J-1,\ldots,-J), \tag{3.20}$$

are associated with the eigenvalue $E^{\sigma}_{J,N;M}$ *of* $\hat{H}$*, where the suffixes J and M are subject to (3.10), and N to* $N=0,1,2,\ldots$ *. The* σ *is chosen to be* $\sigma=+$ *in the case of* (P)*, and* $\sigma=0$ *in the case of* (Z)*.*

In particular, in the case of the Taub–NUT metric, the constants a_j, $j=0,\ldots,3$, are chosen as in (2.9), so that the eigenvalues (3.16a) become

$$E^{+}_{J,N;M}=\frac{1}{(4c)^2}\,(M^2-n^2+n\sqrt{n^2-M^2}) \quad (n=N+J+1), \tag{3.21}$$

which are equal to those already known.[5–7] The same energy eigenvalues are obtained by other methods, say, by the path integral method, *et al.*,[22–25] in relation to the Kaluza–Klein monopole system in five dimensions.[26,27] We have to note here that $\alpha=1$ for the Taub–NUT metric. What the condition of $\alpha=1$ means will be investigated in the last section. Moreover, if the constants a_j take the values given in (2.10), the eigenvalues (3.16b) become $E^{0}_{J,N;M}=-\kappa^2/2(N+J+1)^2=-2\kappa^2/(n'+2)^2$ with $n'=2N+2J$ a non-negative integer, which are already known as energy eigenvalues for the quantized MIC–Kepler problem.[15]

In closing this section, we have to make a remark on the differential equation (3.13a). This equation can be regarded as the radial Schrödinger equation for the potential

$$V(r)=-\tfrac{1}{2}c_0r^{1/\alpha-2}-\tfrac{1}{2}c_1r^{2/\alpha-2}, \tag{3.22}$$

along with the zero energy, where $c_0>0$ and $c_1<0$ are constants. From this point of view, Khare *et al.*[28–30] investigated Eq. (3.13a).

IV. THE QUANTIZED α-FOLD KEPLER SYSTEM

A. The quantization of the α-fold Kepler system

In this section, we reduce the quantum system $(L^2(\mathbf{R}^4;4rf(r)dx),\hat{H})$ in order to define the quantized α-fold Kepler system on the analogy to the reduction procedure for defining the classical α-fold Kepler system. The geometric setting of the reduction procedure has been established in Iwai and Uwano,[15] which is reviewed as follows.

A point to make is to observe that the configuration space $\dot{\mathbf{R}}^4$ is made into a principal U(1) bundle; $\pi:\dot{\mathbf{R}}^4\to\dot{\mathbf{R}}^3$. The $\mathrm{U}(1)\simeq\mathrm{SO}(2)$ action on $\dot{\mathbf{R}}^4$ is defined by

$$x\mapsto T(t)x \quad (x\in\dot{\mathbf{R}}^4), \tag{4.1}$$

where $T(t)$ is given by (2.2). The projection π is realized as

$$\pi(x)=P(x)x \quad (x\in\dot{\mathbf{R}}^4), \tag{4.2}$$

where $P(x)$ is the matrix defined by (2.4b).

Let ρ_m, $m\in\mathbf{Z}$, denote a unitary irreducible representation of $\mathrm{U}(1)\simeq\mathrm{SO}(2)$ on $\mathbf{C}$;

$$\rho_m(T(t)):\zeta\mapsto\exp(imt/2)\zeta \quad (\zeta\in\mathbf{C}). \tag{4.3}$$

Then, the U(1) action on the product space $\dot{\mathbf{R}}^4\times\mathbf{C}$,

$$(x,\zeta)\mapsto(T(t)x,\exp(imt/2)\zeta) \quad (x\in\dot{\mathbf{R}}^4,\zeta\in\mathbf{C}), \tag{4.4}$$

gives rise to the quotient manifold denoted by $\dot{\mathbf{R}}^4\times_m\mathbf{C}$, which is made into a complex line bundle $L_m=(\dot{\mathbf{R}}^4\times_m\mathbf{C},\pi_m,\dot{\mathbf{R}}^3)$. Here, the π_m is the projection, $\pi_m:\dot{\mathbf{R}}^4\times_m\mathbf{C}\to\dot{\mathbf{R}}^3$. The L_m is called the complex line bundle associated with the U(1) bundle $\pi:\dot{\mathbf{R}}^4\to\dot{\mathbf{R}}^3$.[15,16] Denoting by pr the natural projection of $\dot{\mathbf{R}}^4\times\mathbf{C}$ to $\dot{\mathbf{R}}^4\times_m\mathbf{C}$, one has the commutative diagram
rw

$$\begin{array}{ccc} \dot{\mathbf{R}}^4\times C & \xrightarrow{\quad pr\quad} & \dot{\mathbf{R}}^4\times_m C \\ {\scriptstyle p_1}\downarrow & & {\scriptstyle \pi_m}\downarrow \\ \dot{\mathbf{R}}^4 & \xrightarrow{\quad \pi\quad} & \dot{\mathbf{R}}^3 \end{array}, \tag{4.5}$$

where p_1 is the projection onto the first factor.

A complex-valued function F on $\dot{\mathbf{R}}^4$ is called ρ_m equivariant, if it satisfies

$$F(T(t)x)=\exp(imt/2)F(x). \tag{4.6}$$

It is well known that ρ_m-equivariant functions on $\dot{\mathbf{R}}^4$ are in one-to-one correspondence with cross sections in L_m.[15,16] We denote by q_m the correspondence; to a ρ_m-equivariant function F, there corresponds a cross section γ in L_m,

$$(q_mF)(q)=\gamma(q)\quad(q\in\dot{\mathbf{R}}^3). \tag{4.7}$$

On the basis of (4.7), we are to reduce the Hilbert space $L^2(\mathbf{R}^4;4rf(r)dx)$ to a Hilbert space of cross sections in L_m. Let γ's be cross sections in L_m such that $q_m^{-1}\gamma$'s are in $L^2(\mathbf{R}^4;4rf(r)dx)$. Then, the inner product in $L^2(\mathbf{R}^4;4rf(r)dx)$ gives rise to the inner product in the space of cross sections in L_m;

$$\langle\gamma_1,\gamma_2\rangle_m=\frac{1}{4\pi}\int_{\mathbf{R}^4}\overline{(q_m^{-1}\gamma_1)(x)}(q_m^{-1}\gamma_2)(x)4rf(r)dx. \tag{4.8}$$

We note here that, since $q_m^{-1}\gamma$'s are ρ_m equivariant, the integrand in (4.8) is invariant under the U(1) action, so that the integration on the right-hand side of (4.8) is reduced to that on $\mathbf{R}^3$. We denote by Γ_m the Hilbert space of square integrable cross sections in L_m with respect to $\langle\ ,\ \rangle_m$. Thus, $L^2(\mathbf{R}^4;4rf(r)dx)$ is reduced to Γ_m by restricting $L^2(\mathbf{R}^4;4rf(r)dx)$ to the space of ρ_m-equivariant functions.

We here remark that Dirac's monopole field is already encompassed in this setting.[15,16] This is because the complex line bundle L_m is endowed with the linear connection associated with the natural connection defined in the U(1) bundle $\dot{\mathbf{R}}^4$ and because Dirac's monopole field is the curvature 2-form of this linear connection.

We turn to the reduction of the Hamiltonian operator $\hat{H}$ given by (3.1). For this purpose, we define a one-parameter group of unitary transformations U_t to be

$$(U_tF)(x)=F(T(-t)x)\quad(F\in L^2(\dot{\mathbf{R}}^4;4rf(r)dx)). \tag{4.9}$$

Then, it is an easy matter to verify that the Hamiltonian operator $\hat{H}$ is invariant under U_t; $U_t\hat{H}U_t^{-1}=\hat{H}$. To reduce $\hat{H}$, we have only to restrict the domain of $\hat{H}$ to the space of ρ_m-equivariant functions. For $\hat{H}$ and ρ_m-equivariant functions F, we can define a reduced operator $\hat{H}_m$ through

$$\hat{H}_m(q_mF)=q_m(\hat{H}F), \tag{4.10}$$

since $\hat{H}F$ is ρ_m equivariant because of $U_t\hat{H}U_t^{-1}=\hat{H}$ and of $U_tF=\exp(-imt/2)F$. To put $\hat{H}_m$ in an explicit form, we express $\hat{H}$ in terms of the momentum operator $\hat{J}$ and the horizontal lifts $(\partial/\partial q_k)^*$ of the vector fields $\partial/\partial q_k$ on $\dot{\mathbf{R}}^3$,

$$\hat{H}=-\frac{1}{2f(r)}\sum_{k=1}^{3}\left[\left(\frac{\partial}{\partial q_k}\right)^*\right]^2+\frac{1}{2g(r)}(\hat{J})^2, \tag{4.11}$$

where $(\partial/\partial q_k)^*$ and $\hat{J}$ are given,[15] respectively, by

$$\begin{pmatrix}(\partial/\partial q_1)^*\\(\partial/\partial q_2)^*\\(\partial/\partial q_3)^*\end{pmatrix}=\frac{1}{2r}P(x)\begin{pmatrix}\partial/\partial x_1\\\partial/\partial x_2\\\partial/\partial x_3\\\partial/\partial x_4\end{pmatrix}, \tag{4.12a}$$

and

$$\hat{J}=\frac{1}{2i}\left(-x_2\frac{\partial}{\partial x_1}+x_1\frac{\partial}{\partial x_2}-x_4\frac{\partial}{\partial x_3}+x_3\frac{\partial}{\partial x_4}\right). \tag{4.12b}$$

Operating ρ_m-equivariant functions with (4.11) provides

$$\hat{H}_m=-\frac{1}{2f(r)}\sum_{k=1}^{3}\nabla_k^2+\frac{(m/2)^2}{2g(r)}, \tag{4.13}$$

where $\boldsymbol{\nabla}_k$ is the covariant derivation with respect to $\partial/\partial q_k$.[15] Comparison of (2.8) with (4.13) shows that the $\hat{H}_m$ is the quantization of H_μ by replacing p_k and μ with $-i\boldsymbol{\nabla}_k$ and $-m/2$, respectively. Thus, we obtain the following theorem.

Theorem 4.1: *The quantized system* $(L^2(\mathbf{R}^4;4rf(r)dx),\hat{H})$ *for the geodesic flow system associated with the generalized Taub–NUT metric* ds_G^2 *is reduced to the quantum system* $(\Gamma_m,\hat{H}_m)$, *where* Γ_m *is the Hilbert space of square integrable cross sections in* L_m, *and* $\hat{H}_m$ *is the Hamiltonian operator given by (4.13). We refer to the quantum system* $(\Gamma_m,\hat{H}_m)$ *as the quantized* α*-fold Kepler system*.

B. The eigenvalue problem

We proceed to the eigenvalue problem of $\hat{H}_m$. In view of the definition of the quantized α-fold Kepler system, the eigenvalues and the eigencross sections for $(\Gamma_m,\hat{H}_m)$ are expected to be obtained from those for $(L^2(\mathbf{R}^4,4rf(r)dx),\hat{H})$ through the U(1) reduction method.

From the definition (4.10) of $\hat{H}_m$, the eigenvalues of $\hat{H}_m$ must be eigenvalues of $\hat{H}$. Hence the eigencross sections of $\hat{H}_m$ come from eigenfunctions of $\hat{H}$, so that our task amounts to picking up ρ_m-equivariant eigenfunctions of $\hat{H}$. Let us be reminded that the eigenfunctions of $\hat{H}$ are expressed as linear combinations of functions of the form $R(r)Q$, where Q's are spherical harmonics on the unit sphere S^3. Since the ρ_m equivariance of eigenfunctions is concerned with only the spherical harmonics part, we can restrict ourselves to spherical harmonics on S^3 in picking up ρ_m-equivariant eigenfunctions. Moreover, since spherical harmonics on S^3 are the restriction of solid harmonics on $\mathbf{R}^4$, we have only to give a method of picking up ρ_m-equivariant solid harmonics. Incidentally, a generating function of solid harmonics of degree $2J$ is given by

$$G(z,\bar{z};\tau)=(\tau z_1+z_2)^p(\bar{z}_1-\tau\bar{z}_2)^q,\quad p+q=2J,\quad \tau\in\mathbf{R}, \tag{4.14}$$

where p and q are non-negative integers, and

$$z_1=x_1+ix_2,\quad z_2=x_3+ix_4. \tag{4.15}$$

Moreover, the U(1) action on $\mathbf{C}^2 \cong \mathbf{R}^4$ given by (4.1) is expressed as

$$(z_1, z_2) \mapsto (e^{it/2} z_1, e^{it/2} z_2). \tag{4.16}$$

Then, the generating function (4.14) transforms according to

$$G(e^{it/2} z, e^{-it/2} \bar{z}; \tau) = e^{it(p-q)/2} G(z, \bar{z}; \tau), \tag{4.17}$$

so that the ρ_m-equivariant solid harmonics are singled out by the condition that $p-q=m$. Thus, we have found the method of picking up ρ_m-equivariant eigenfunctions in the manner independent of the choice of local coordinates in S^3.

To carry out the above procedure in terms of local coordinates (θ, ϕ, ψ) in S^3, we first notice that the U(1) action is expressed as

$$\psi \mapsto \psi + t, \quad \text{the others fixed.} \tag{4.18}$$

Then the $\mathscr{D}$ functions, spherical harmonics on S^3, transform according to

$$\mathscr{D}^J_{ML}(\psi + t, \theta, \phi) = \exp(iMt) \mathscr{D}^J_{ML}(\psi, \theta, \phi). \tag{4.19}$$

Thus we have the following.

Lemma 4.2: The eigenfunction $\Psi^{\sigma}_{L,J,N;M}$ for $\hat{H}$ associated with the eigenvalue $E^{\sigma}_{J,N;M}$ is ρ_m equivariant if and only if $M=m/2$.

It is to be noted here that the generating function $G(z, \bar{z}; \tau)$ with $p=J+M$, $q=J-M$, and $|z_1|^2 + |z_2|^2 = 1$ is expanded into

$$G(z, \bar{z}; \tau) = \sum_{|L| \leqslant J} \tau^{J+L} \left[\frac{(J+M)!(J-M)!}{(J+L)!(J-L)!} \right]^{1/2} \mathscr{D}^J_{ML}(\psi, \theta, \phi), \tag{4.20}$$

where we have used (3.6) together with (4.15). We are now in a position to describe eigenspaces for the quantized α-fold Kepler system $(\Gamma_m, \hat{H}_m)$.

Theorem 4.3: *The eigenvalues of the quantized α-fold Kepler system $(\Gamma_m, \hat{H}_m)$ are given by $E^{\sigma}_{J,N;m/2}$, and the associated eigenspace is isomorphic with the eigenspace of $(L^2(\mathbf{R}^4, 4rf(r)dx), \hat{H})$ assigned by $E^{\sigma}_{J,N;m/2}$.*

We notice here that $q_m(\Psi^{\sigma}_{L,J,N;m/2}(r, \theta, \phi, \psi))$'s provide locally-defined eigencross sections through $\psi = -\phi$ or $\psi = \phi$.

V. DEGENERACIES IN THE ENERGY LEVELS

Now that we have solved the eigenvalue problem for the quantized α-fold Kepler system, we are to study degeneracies in the energy levels for this system. Degeneracies are broken up into two. One is concerned with the rotational symmetry of the quantized α-fold Kepler system, and the other depends on whether α is a rational number or not.

A. Normal degeneracies

Theorems 3.3 and 4.3 are put together to show that the eigenspace of $\hat{H}_m$ associated with the energy level $E^{\sigma}_{J,N;m/2}$ is of dimension $2J+1$, at least. Namely, the energy level $E^{\sigma}_{J,N;m/2}$ is degenerate at least $(2J+1)$-fold. In this section, we show that this degeneracy is caused by the spherical symmetry of the quantized α-fold Kepler system, so that it will be suitably called normal degeneracy after Wigner.[31]

To start with, let us identify $\mathbf{R}^4$ with $\mathbf{C}^2$ through the map given in (4.15). Further, we denote by $g_{\mathbf{R}}$ the 4×4 real matrix associated with $g \in \mathrm{SU}(2)$. Then, the SU(2) action on $\mathbf{R}^4$ gives rise to a unitary operator W_g on $L^2(\mathbf{R}^4; 4rf(r)dx)$ through

$$(W_g F)(x) = F(g_{\mathbf{R}}^{-1} x) \quad (g \in \mathrm{SU}(2), F \in L^2(\mathbf{R}^4; 4rf(r)dx)). \tag{5.1}$$

We can verify that the W_g is indeed a unitary operator by using the fact that $g_{\mathbf{R}}$ leaves the volume form $4rf(r)dx$ invariant. Further calculation shows that the Hamiltonian operator $\hat{H}$ is invariant under W_g;

$$W_g \hat{H} W_g^{-1} = \hat{H}. \tag{5.2}$$

Thus, the SU(2) proves to be a symmetry group of $(L^2(\mathbf{R}^4; 4rf(r)dx), \hat{H})$.

The action of W_g on the eigenfunctions can be described in a usual manner from the representation theory. To show this, we choose to identify S^3 with SU(2) through

$$(z_1, z_2) \mapsto \begin{pmatrix} z_1 & z_2 \\ -\overline{z_2} & \overline{z_1} \end{pmatrix}, \quad \text{with } \sum_{l=1}^{2} |z_l|^2 = 1. \tag{5.3}$$

Then the representation theory shows that

$$\mathscr{D}^J_{ML}(g_{\mathbf{R}}^{-1} x/|x|) = \sum_{M'=-J}^{J} \mathscr{D}^J_{MM'}(x/|x|) \overline{\mathscr{D}^J_{M'L}(g)} \quad (g \in SU(2)), \tag{5.4}$$

where $x = (x_1, \ldots, x_4)^T$, a column vector, $|x|^2 = \Sigma_{j=1}^4 x_j^2$, and $\mathscr{D}$ functions are viewed as defined on $\mathrm{SU}(2) \simeq S^3 \subset \mathbf{R}^4$. Equations (5.4) and (3.20) are put together to show that the energy eigenspace admits the SU(2) action.

We proceed to show that the SU(2) symmetry treated above will provide the SU(2) symmetry of the quantized α-fold Kepler system. Since the U(1) action U_t given by (4.9) and the SU(2) action W_g given by (5.1) commute, we can restrict W_g to the subspace of ρ_m-equivariant functions in $L^2(\mathbf{R}^4; 4rf(r)dx)$ to define the SU(2) action $W_g^{(m)}$ on the Hilbert space Γ_m;

$$W_g^{(m)} \circ q_m = q_m \circ W_g. \tag{5.5}$$

Put together with Theorem 4.3, this implies the following.

Theorem 5.1: *The quantized α-fold Kepler system $(\Gamma_m, \hat{H}_m)$ admits SU(2) as a symmetry group, which acts unitarily on each eigenspace through $W_g^{(m)}$.*

Remark: The operator $W_g^{(m)}$ can be expressed in a simple form. Let us define a map $\chi_g : \dot{\mathbf{R}}^4 \times \mathbf{C} \to \dot{\mathbf{R}}^4 \times \mathbf{C}$ by $(x, \zeta) \mapsto (g_{\mathbf{R}} x, \zeta)$, and a map $\chi_g^{(m)} : L_m \to L_m$ through

$$\chi_g^{(m)} \circ \pi_m = \pi_m \circ \chi_g \quad (g \in SU(2)). \tag{5.6}$$

Then, from the commutative diagram (4.5) and the definition (5.5), it follows that

$$(W_g^{(m)} \gamma)(\pi(x)) = \chi_g^{(m)}(\gamma(\pi(g_{\mathbf{R}}^{-1} x))) \quad (x \in \dot{\mathbf{R}}^4). \tag{5.7}$$

Further calculation shows that

$$(W_{-g}^{(m)} \gamma)(q) = (-1)^m (W_g^{(m)} \gamma)(q) \quad (q \in \dot{\mathbf{R}}^3). \tag{5.8}$$

Hence, if m is even, the SU(2) symmetry stated above reduces to the SO(3) symmetry, since $\mathrm{SU}(2)/\mathbf{Z}_2 \simeq SO(3)$, $\mathbf{Z}_2 = \{I, -I\}$, with I the identity of SU(2).

B. Accidental degeneracies

We wish to show that another degeneracy takes place in the energy levels of $\hat{H}_m$, which is not attributed to the SU(2) symmetry, but to the α dependence of the energy levels. The following lemma is easy to prove.

Lemma 5.2: Let σ and m be fixed in the energy eigenvalues $E^{\sigma}_{J,N;m/2}$ of $\hat{H}_m$. Then two of the eigenvalues, $E^{\sigma}_{J_1,N_1;m/2}$ and $E^{\sigma}_{J_2,N_2;m/2}$, become identical if and only if

$$(N_1+\tfrac{1}{2})+\alpha(J_1+\tfrac{1}{2})=(N_2+\tfrac{1}{2})+\alpha(J_2+\tfrac{1}{2}). \tag{5.9}$$

We now rewrite (5.9) in the form

$$(N_1-N_2)=-\alpha(J_1-J_2), \tag{5.10}$$

which shows that there are no pairs of different half-integers, (J_1,N_1) and (J_2,N_2), satisfying (5.10) if α is an irrational number. Conversely, if α is a rational number, one can find out those integers satisfying (5.10); for example, on putting $\alpha=q/p$ with q and p mutually prime integers, we find that (5.10) is valid, at least, for the pair of integers, (J_1,N_1) and $(J_2,N_2)=(J_1+p,N_1-q)$. Lemma 5.2 then implies that the energy levels $E^{\sigma}_{J_1,N_1;m/2}$ and $E^{\sigma}_{J_2,N_2;m/2}$ coincide for those pairs. Clearly, this degeneracy has nothing to do with the $SU(2)$ symmetry of the quantized α-fold Kepler system. We may call this degeneracy an ''accidental'' one after Wigner.[31] Thus, we come to the following conclusion.

Theorem 5.3: *In the energy levels of the quantized α-fold Kepler system, accidental degeneracies take place, if and only if α is a rational number.*

In the rest of this section, we wish to observe how the energy level splitting for the quantized α-fold Kepler system occurs when α varies from a rational number. Let us take the parameters contained in $\hat{H}_m$ to be

$$a_0=4c,\quad a_1=1,\quad a_2=\frac{1}{2c},\quad a_3=\frac{1}{16c^2}\quad (c>0),\quad \text{and } m=2. \tag{5.11}$$

If $\alpha=1$ in addition to (5.11) (without the condition of $m=2$), the generalized Taub–NUT metric ds^2_G becomes the Euclidean Taub–NUT metric. Taking $c=1$, we evaluate numerically the energy levels, $E^{+}_{J,N;1}$, of $\hat{H}_2$ in the case of $\alpha=1$ and of $\alpha=1+\pi/5000$. In both cases, the energy levels, $E^{+}_{J,N;1}$, to be evaluated are subject to

$$500\leqslant N+J\leqslant 510,\quad J\geqslant 1,\quad N\geqslant 0\quad (J,N:\text{integers}). \tag{5.12}$$

Figures 1(a) and 1(b) show the energy levels for $\alpha=1$ and for $\alpha=1+\pi/5000$, respectively. These figures show that distinct energy levels split as α varies from $\alpha=1$ to $\alpha=1+\pi/5000$. Indeed, the bands painted out in black in Fig. 1(b) consist of more than 5000 distinct energy levels. It is worth noting that, in Fig. 1(a), each of the energy levels are degenerate approximately 2.5×10^5-fold. In contrast with this, each of the energy levels in Fig. 1(b) admits $2J+1$-fold normal degeneracy, which is less than 1100-fold. We have to remark that the numerical evaluation, of course, cannot describe the energy-level behavior completely, because we cannot deal with any irrational numbers on computers! In our example, however, the numerical evaluation seems to work quite well.

VI. REMARKS ON THE HAMILTONIAN OPERATOR $\hat{H}$

As we stated in Sec. III, the Hamiltonian operator $\hat{H}$ is not equal to $-\frac{1}{2}$ times the Laplace–Beltrami operator, which are usually supposed to be the Hamiltonian operator associated with the energy function of the geodesic flows. Let g_{jk} be the components of the generalized Taub–NUT metric ds^2_G, and $(g^{jk})=(g_{jk})^{-1}$;

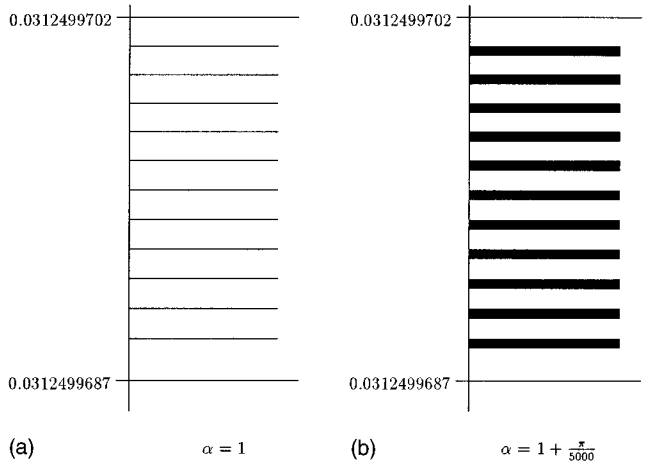

FIG. 1. The energy levels of $\hat{H}_2$.

$$ds_G^2 = \sum_{j,k=1}^{4} g_{jk}\, du^j\, du^k = f(r)(dr^2 + r^2(d\theta^2 + \sin^2\theta\, d\phi^2)) + g(r)(d\psi + \cos\theta\, d\phi)^2, \quad (6.1)$$

where $(u^j) = (r, \theta, \phi, \psi)$, and $f(r)$ and $g(r)$ are given by (1.2). Let $\tilde{\nabla}_j$ be the Levi–Civita connection formed from g_{jk}. Then $-\frac{1}{2}$ times the Laplace–Beltrami operator is expressed as

$$-\frac{1}{2}\Delta = -\frac{1}{2}\sum_{j,k} g^{jk}\, \tilde{\nabla}_j \tilde{\nabla}_k = \hat{H} - \frac{(f(r)g(r))'}{4f(r)^2 g(r)}\frac{\partial}{\partial r}, \quad (6.2)$$

where $\hat{H}$ is the Hamiltonian operator given by (3.7), and the prime $'$ denotes the derivative with respect to r. From (6.2) it then follows that $\hat{H} = -\frac{1}{2}\Delta$ if and only if $(f(r)g(r))' = 0$. Investigating this equation, we obtain the following.

Proposition 6.1: The Hamiltonian operator $\hat{H}$ and $-\frac{1}{2}$ times the Laplace–Beltrami operator coincide, if and only if

$$\alpha = 1, \quad a_2 = 2a_1/a_0, \quad a_3 = (a_1/a_0)^2 \quad (a_0 \neq 0),$$

or (6.3)

$$\alpha = 2, \quad a_1 \neq 0, \quad a_2 = a_3 = 0 \quad (a_0 = 0).$$

According to whether the condition $\alpha = 1,...,$ holds or the condition $\alpha = 2,...,$ does, the generalized Taub–NUT metric ds_G^2 becomes a constant multiple of the Taub–NUT metric or of the standard flat metric. Therefore, for the Taub–NUT metric, our Hamiltonian operator is equal to $-\frac{1}{2}$ times the Laplace–Beltrami operator, so that the energy levels (3.16a) become equal to those obtained from $-\frac{1}{2}$ times the Laplace–Beltrami operator for the Taub–NUT metric. This fact was already remarked in (3.21) without any comments.

In conclusion, we remark also that for $\alpha = 1$ the generalized Taub–NUT metric ds_G^2 is Einstein if and only if $a_2 = 2a_1/a_0$, $a_3 = (a_1/a_0)^2$ $(a_0 \neq 0)$.[9] In view of this, we would like to say that if the Riemannian manifold is Einstein, the generally accepted principle that $-\frac{1}{2}$ times the Laplace–Beltrami operator is the Hamiltonian operator associated with the geodesic flow system holds true. However, if the Riemannian manifold is not Einstein, the other principle of quantization would be worth applying.

APPENDIX: CALCULATION OF EIGENFUNCTIONS AND EIGENVALUES

We are to give solutions to (3.13). In view of the classical method for finding the functional form of $f(r)$ and $g(r)$,[12] we make a change of the variable r by setting

$$r^{1/\alpha}=\rho. \tag{A1}$$

Then the unknown function $y(\rho)=R(r)$ turns out to satisfy the differential equation

$$y''(\rho)+\frac{1+\alpha}{\rho}\,y'(\rho)+\alpha^2\left(c_1+\frac{c_0}{\rho}-\frac{J(J+1)}{\rho^2}\right)y(\rho)=0. \tag{A2}$$

Introducing a function $v(\rho)$ by

$$y(\rho)=\rho^{-(1/2)(1+\alpha)}v(\rho), \tag{A3}$$

we find that $v(\rho)$ satisfies

$$v''(\rho)+\left(\alpha^2c_1+\alpha^2\,\frac{c_0}{\rho}+\frac{1}{\rho^2}\left(\frac{1}{4}\,(1-\alpha^2)-\alpha^2J(J+1)\right)\right)v(\rho)=0. \tag{A4}$$

As ρ tends to infinity, Eq. (A4) has an asymptotic solution $e^{-\alpha\sqrt{-c_1}\rho}$, subject to the condition that $y(\rho)\to 0$. Here we have assumed that $c_1=2a_1E-M^2a_3<0$, which is a quantum analog of one of the classical conditions, $2a_1E-a_3\mu^2<0$, for bounded trajectories of the multifold Kepler system to occur.[12] Note also that the boundary condition (3.14) is now expressed as

$$\int_0^\infty |y(\rho)|^2(a_0+a_1\rho)\rho^\alpha\,d\rho<+\infty. \tag{A5}$$

On setting

$$v(\rho)=e^{-\alpha\sqrt{-c_1}\rho}z(\rho), \tag{A6}$$

it follows from (A4) that $z(\rho)$ is subject to

$$z''(\rho)-2\alpha\sqrt{-c_1}z'(\rho)+\left(\alpha^2\,\frac{c_0}{\rho}+\frac{1}{\rho^2}\left(\frac{1}{4}\,(1-\alpha^2)-\alpha^2J(J+1)\right)\right)z(\rho)=0. \tag{A7}$$

This equation has a solution of the form

$$z(\rho)=\rho^s w(\rho),\quad w(\rho)=\sum_{m=0}^{\infty}b_m\rho^m,\quad b_0\neq 0. \tag{A8}$$

Equations (A7) and (A8) are put together to provide

$$s=\tfrac{1}{2}+\alpha(J+\tfrac{1}{2}), \tag{A9}$$

and

$$w''(\rho)+\left(\frac{1}{\rho}\,(1+\alpha(2J+1))-2\alpha\sqrt{-c_1}\right)w'(\rho)+\frac{1}{\rho}\,(\alpha^2c_0-(\alpha+\alpha^2(2J+1))\sqrt{-c_1})w(\rho)=0. \tag{A10}$$

This equation can be expressed as the confluent hypergeometric equation, and therefore its solution is expressed in terms of confluent hypergeometric functions;

$$w(\rho)=F\left(\frac{1}{2}+\alpha\left(J+\frac{1}{2}\right)-\frac{\alpha c_0}{2\sqrt{-c_1}},1+\alpha(2J+1),2\alpha\sqrt{-c_1}\rho\right). \tag{A11}$$

Thus the radial equation has a solution of the form

$$R(r)=\exp(-\alpha\sqrt{-c_1}r^{1/\alpha})r^J F\left(\frac{1}{2}+\alpha\left(J+\frac{1}{2}\right)-\frac{\alpha c_0}{2\sqrt{-c_1}},1+\alpha(2J+1),2\alpha\sqrt{-c_1}r^{1/\alpha}\right). \tag{A12}$$

The boundary condition (A5) requires that F should be a polynomial in ρ, so that there is a non-negative integer N, satisfying

$$N+\frac{1}{2}+\alpha\left(J+\frac{1}{2}\right)=\frac{\alpha c_0}{2\sqrt{-c_1}}, \tag{A13}$$

and thereby the energy levels are obtained as follows: For $a_0\neq 0$,

$$E=\frac{1}{2a_0^2}\left(a_0a_2M^2-2a_1\left(\frac{n}{\alpha}\right)^2\pm 2\frac{n}{\alpha}\sqrt{\left(\frac{n}{\alpha}\right)^2 a_1^2+a_0(a_0a_3-a_1a_2)M^2}\right), \tag{A14a}$$

and for $a_0=0$,

$$E=\frac{a_3M^2}{2a_1}-\frac{\alpha^2a_2^2M^4}{8a_1n^2}, \tag{A14b}$$

where n is defined to be

$$n=\left(N+\frac{1}{2}\right)+\alpha\left(J+\frac{1}{2}\right)\quad (N\text{:non-negative integer}). \tag{A15}$$

We have to take "+" in (A14a). This is because if "−" were chosen, the energy levels would not have a minimum, which is not acceptable.

(Received 1 August 1995; accepted for publication 24 October 1995)

In this paper we investigate the form of induced gauge fields that arises in two types of quantum systems. In the first we consider quantum mechanics on coset spaces G/H, and argue that G invariance is central to the emergence of the H connection as induced gauge fields in the different quantum sectors. We then demonstrate why the same connection, now giving rise to the non-Abelian generalization of Berry's phase, can also be found in systems that have slow variables taking values in such a coset space. © *1996 American Institute of Physics.* [S0022-2488(96)02602-0]

I. INTRODUCTION

There are various instances in quantum mechanics when a gauge field appears in a system whose initial formulation did not contain such fields. The most familiar example of this is the emergence of Berry's connection[1] in systems with degeneracies, which leads to a holonomy in energy eigenspaces, i.e., a non-Abelian generalization of Berry's phase. Another example is to be found in the different quantum sectors that arise when quantizing on a coset space.[2] For both of these cases, the gauge field that emerges is often found to be of a specific type. Indeed, when the effective configuration space is a coset space G/H, the resulting connection can usually be identified with the so-called *H connection*, which is a (possibly topological) solution of the Yang–Mills equation on this space. The prime aim of this paper is to clarify why and when this connection arises in these systems.

More precisely, in the context of Berry's phase, the origin of the connection is in some sense obvious from the outset, that is, it comes from the ambiguity in choosing a set of basis vectors in the instantaneous energy eigenspaces. However, what is not obvious and hence remarkable is that in a wide variety of systems of physical interest, Berry's connection often (though not always) takes the form of the H connection.[3–5] Such systems arise when considering the coupled dynamics of slow and fast variables. In this case we wish to know the form of the connection, also occurring in the Hamiltonian of the effective slow system, in advance. By giving a precise identification of when it is the H connection the need to calculate energy eigenstates can be avoided.

In contrast, in the context of inequivalent quantizations on coset spaces, the origin of the connection is not quite obvious, and the question is why the specific H connection can appear at all when quantized. In the account presented in Ref. 2, which relies (basically) on Mackey's approach,[6] the system of a ''free particle'' on G/H is considered, where the Hamiltonian is fixed by requiring that there is no operator ordering ambiguity. This is clearly an important criterion, and

[a)]Electronic mail: levay@phy.bme.hu

leads to a system minimally coupled to the H connection. However, this is not a criterion geometrically motivated, and more importantly, in any attempt at extending these results to field theories such a reliance on a factor ordering argument is unnatural and, indeed, unworkable. What we will show in this paper is that an invariance argument can be developed that highlights the need for such a connection.

The emergence of gauge fields is also recognized recently by a number of other groups[7–9] using different approaches to quantization. For instance, in Ref. 7, spheres S^n embedded in $\mathbb{R}^{n+1}$ are taken as the configuration space and gauge fields are seen to emerge at the quantum level. It will be shown, however, in this paper that these induced gauge fields are none other than the H connection. This will perhaps support the view that the emergence of gauge fields is not just an artifact of a particular quantization approach but a ''norm'' when quantizing on coset spaces.

The plan of this paper is as follows. In Sec. II we will demonstrate how the H connection emerges in the quantum description of a point particle moving freely on a coset space. In Sec. III we prove that the connection that arises in the quantization scheme of Ref. 7 is just the H connection. In Sec. IV the conditions under which Berry's connection reduces to the H connection will be presented. Section V is devoted to our conclusions and discussions.

II. QUANTIZING ON A COSET

We begin by arguing that the H connection—observed by Landsman and Linden[2] in investigating the dynamical aspect of the quantum theory on a coset space G/H—is indeed the natural connection in the quantum system.

Let us first, though, fix our notation (which follows those in Ref. 10). We take G to be a compact Lie group with Lie algebra $\mathfrak{g}$, and H a compact subgroup of G with Lie algebra $\mathfrak{h}$. The Lie algebra $\mathfrak{g}$ has an orthogonal decomposition,

$$\mathfrak{g}=\mathfrak{h}\oplus\mathfrak{r}, \tag{2.1}$$

where $\mathfrak{r}=\mathfrak{h}^{\perp}$ is the orthogonal complement of $\mathfrak{h}$ in $\mathfrak{g}$. This is, in fact, a reductive decomposition, i.e.,

$$[\mathfrak{h},\mathfrak{r}]\subset\mathfrak{r}. \tag{2.2}$$

We shall denote bases of the spaces by

$$\begin{aligned}\mathfrak{g}&=\mathrm{span}\{T_m\},\quad m=1,\ldots,\dim\ G,\\ \mathfrak{h}&=\mathrm{span}\{T_i\},\quad i=1,\ldots,\dim\ H,\\ \mathfrak{r}&=\mathrm{span}\{T_a\},\quad a=1,\ldots,\dim(G/H).\end{aligned} \tag{2.3}$$

Let us recall that in Mackey's account of quantizing on G/H,[6] a set of fundamental relations, called a *system of imprimitivity*, is introduced whose irreducible representations give the quantum theories (a full discussion of this can be found in Ref. 10). The upshot of this is that the Hilbert space $\mathscr{H}(G/H)$ on the coset space consists of L^2 functions on G/H belonging to the linear space $\mathscr{H}_\chi$ of some irreducible unitary representation χ of the subgroup H: $\mathscr{H}(G/H)\simeq L^2(G/H,\mathscr{H}_\chi)$. Locally, we may take a basis set $\{|q,\chi,\mu\rangle\}$ of the Hilbert space $\mathscr{H}(G/H)$ by

$$|q,\chi,\mu\rangle:=|q\rangle\otimes|\chi,\mu\rangle, \tag{2.4}$$

where $|q\rangle$ are the eigenstates in the coordinate representation on G/H and $|\chi,\mu\rangle$ the orthonormal basis vectors in $\mathscr{H}_\chi$. Thus, the states in the basis set (2.4) satisfy the orthonormality condition

$$\langle q,\chi,\mu|q',\chi,\nu\rangle=\delta_{\mu\nu}\delta(q-q'), \tag{2.5}$$

with $\delta(q-q')$ being the delta function on the coset space G/H.

In order to have a singularity-free description we need to introduce a set of patches to cover the coset space G/H. Let $\{U_\alpha\}$ be the local patches introduced, and $\sigma_\alpha: U_\alpha \mapsto G$ be a continuous section on the patch U_α. On overlaps $U_\alpha \cap U_\beta$ the sections are related by a gauge transformation, namely, for $q \in U_\alpha \cap U_\beta$,

$$\sigma_\beta(q) = \sigma_\alpha(q) h_{\alpha\beta}(q), \tag{2.6}$$

where $h_{\alpha\beta} \in H$. Accordingly, we consider a sectional basis $\{|q,\chi,\mu\rangle^\alpha\}$, which is a basis set given independently on the patch U_α. Using standard partition of unity arguments, we can define an inner product on these and see that all is well defined. The wave functions are then defined to be

$$\psi^\alpha_\mu(q) = {}^\alpha\langle q,\chi,\mu|\psi\rangle. \tag{2.7}$$

An important ingredient in Mackey's quantization[6] is that associated with the G action $q \to g^{-1}q$ for $g \in G$, which relates any two points on the coset space, there is a corresponding action on the wave functions furnished by the *induced representation*,

$$(U(g)\psi)^\alpha_\mu(q) = \sum_\nu \pi^\chi_{\mu\nu}((\sigma_\alpha(q))^{-1} g \sigma_\beta(g^{-1}q))\psi^\beta_\nu(g^{-1}q). \tag{2.8}$$

Here the matrix elements of the unitary operator $\pi^\chi(h)$, implementing the irreducible representation χ, are

$$\pi^\chi_{\mu\nu}(h) := \langle\chi,\mu|\pi^\chi(h)|\chi,\nu\rangle, \tag{2.9}$$

and a choice of section has been made on each of the patch, $q \in U_\alpha$ and $g^{-1}q \in U_\beta$. On the sectional basis, this action (2.8) reads as

$$U(g)|q,\chi,\mu\rangle^\alpha = \sum_\nu |gq,\chi,\nu\rangle^\beta \pi^\chi_{\nu\mu}((\sigma_\beta(gq))^{-1} g \sigma_\alpha(q)), \tag{2.10}$$

where we put $g \to g^{-1}$ for later convenience. In effect, the induced representation (2.10) consists of a rotation in the space $\mathscr{H}_\chi$ and a translation in the coset space G/H, both determined by g and q. Using the naturally defined measure on the coset space G/H, one can readily show that (2.10) indeed provides a unitary representation of G.[10]

Now we shall consider the quantum mechanics of a point particle moving freely on the coset space G/H. Here the term "free" is meant to indicate that the system under consideration is *homogeneous* over G/H, and that the dynamics of the particle is that of a free particle when observed locally. Note that in order to get the Schrödinger equation for the wave functions (2.7) describing the point particle of this system, we need to use the G action to ensure the homogeneity (as it is the only means available on G/H for this purpose). But since the G action on the wave functions (2.8) is section dependent, we need a covariant derivative (with respect to q) such that the section dependence disappears in the physical dynamics.

To be explicit, let us consider the state

$$|\chi,\bar{\mu}\rangle := \sum_\nu |e,\chi,\nu\rangle^\beta \pi_{\nu\mu}((\sigma_\beta(e))^{-1}), \tag{2.11}$$

where e is the identity point in the coset G/H. Then (2.10) allows us to write the basis states at q as

$$|q,\chi,\mu\rangle^\alpha = U(\sigma_\alpha(q))|\chi,\bar{\mu}\rangle, \tag{2.12}$$

which shows that the G action allows for obtaining all the basis states over G/H by the unitary G action from the reference state (2.11). It is then easy to see from (2.10) that, under the change of section (2.6), the basis states undergo the rotation

$$|q,\chi,\mu\rangle^{\alpha}\rightarrow|q,\chi,\mu\rangle^{\beta}=U(\sigma_{\alpha}h_{\alpha\beta})|\chi,\bar{\mu}\rangle=\sum_{\nu}|q,\chi,\nu\rangle^{\alpha}\pi^{\chi}_{\nu\mu}(h_{\alpha\beta}). \tag{2.13}$$

Thus, the connection used in the covariant derivative must compensate the derivative factor in the Schrödinger equation arising from the rotation in (2.13). Actually, in the theory of vector bundles associated with the principal bundle $G(G/H,H)$, the term "connection" already implies this property. This, however, is not enough to single out the connection relevant to our system on G/H.

The crucial point in specifying the connection is the homogeneity over the coset G/H mentioned above. We note that for the system to be homogeneous the connection must also be homogeneous physically, that is, it must be invariant under the G action up to a gauge transformation of the group H (i.e., up to a change of section). In other words, the curvature of the connection is constant over G/H. Now the theory of invariant connections (see Theorem 11.1 on p. 103 of Ref. 11) asserts that such a connection is always given by the H connection $A^{H}:=\sigma_{\alpha}^{-1}(q)d\sigma_{\alpha}(q)|_{\mathfrak{h}}$, which is the (pullback of the) canonical 1-form projected down to the subspace $\mathfrak{h}\subset\mathfrak{g}$. In the present context, the invariant connection that arises in the covariant derivative acting on the wave functions (2.7) is the H connection in the representation χ:

$$\sum_{i}A^{H}_{i}(q)(T_{i})_{\mu\nu}=\langle\chi,\bar{\mu}|U^{-1}(\sigma_{\alpha}(q))dU(\sigma_{\alpha}(q))|_{\mathfrak{h}}|\chi,\bar{\nu}\rangle. \tag{2.14}$$

One can readily confirm that its curvature is indeed constant over G/H and that it does transform as a connection under the change of section (2.6).

In short, we see that the covariant derivative used for the Schrödinger equation must contain the H connection in the form (2.14), if we are to consider the homogeneous free particle system over G/H requiring the independence of the choice of section. This G invariance is, we feel, more fundamental than the factor ordering criterion adopted in Ref. 2. However, for completeness, we now need to see what form of Hamiltonian comes out of our analysis.

To begin with, let us note that our vector-valued wave functions $\psi^{\alpha}_{\mu}(q)$, provided by the irreducible representation χ of H, may be expanded in terms of the "harmonics" $U^{\Lambda}_{\xi}(\sigma_{\alpha}^{-1}(q))$ over the coset space G/H,[12]

$$\psi^{\alpha}_{\mu}(q)=\sum_{\Lambda}\sum_{\rho,\xi}c^{\Lambda}_{\rho\xi}U^{\Lambda}_{\xi}(\sigma_{\alpha}^{-1}(q))_{\mu\rho}. \tag{2.15}$$

In this expansion, ξ is the index of multiplicity of the representation χ appearing in the irreducible representation Λ of G upon restriction to H, and the range of ρ equals the dimension of the representation Λ.

We recall that the Frobenius reciprocity theorem tells us that in the above summation only those Λ of G occur that contain the representation χ of H when restricted to the subgroup. (For brevity we henceforth omit α, which labels the patch to which the point q belongs.) But the message important to us here is that we can now work with the section variable $\sigma^{-1}(q)$ instead of the coordinates q on the coset space. We shall, for the sake of simplicity, consider the principal bundle $G(G/H,H)$ first. Because our vector bundle in question is the associated bundle via the irreducible representation of H, the covariant derivative in the vector bundle will follow immediately from that of the principal bundle.

Consider now the vector fields X_{m} defined by the relation

$$X_{m}\sigma^{-1}(q)=\sigma^{-1}(q)T_{m}. \tag{2.16}$$

These vector fields are just the generalizations of the usual Killing vector fields regarded as first-order differential operators. (In the context of Berry's phase these are modified symmetry generators for effective Hamiltonians.[5]) The fact that such vector fields do exist can be seen explicitly by examining the infinitesimal version of $g\sigma(q)=\sigma(gq)h(g,q)$, which leads to a first-order differential operators for X_m satisfying the commutation relations of the Lie algebra $\mathfrak{g}$.

We shall then consider the following covariant derivative:

$$\boldsymbol{\nabla}_m := -\mathscr{D}^{\,n}_{\,m}(\sigma^{-1})X_n\,, \tag{2.17}$$

where $\mathscr{D}^{\,n}_{\,m}(\sigma)$ is the "adjoint matrix" (the matrix of the adjoint representation of G in the basis T_m), defined by

$$\sigma^{-1}(q)T_m\sigma(q)=\mathscr{D}^{\,n}_{\,m}(\sigma)T_n\,, \tag{2.18}$$

Using this, we may invert (2.16) to get

$$\mathscr{D}^{\,m}_{\,n}(\sigma^{-1})X_m\sigma^{-1}=T_n\sigma^{-1}. \tag{2.19}$$

Hence, we find that our covariant derivative (2.17) satisfies

$$\boldsymbol{\nabla}_m\sigma^{-1}=-T_m\sigma^{-1}, \tag{2.20}$$

that is, it behaves just as $-T_m$ on σ^{-1}.

The $\mathfrak{r}$ component of $\boldsymbol{\nabla}_m$ is the covariant derivative with respect to the H connection. To see this, following the standard line of argument,[13] one decomposes the canonical 1-form as $\sigma^{-1}\,d\sigma=-d(\sigma^{-1})\sigma=A^H+e$, where $A^H=A^i_\alpha T_i\,dq^\alpha$ is the H connection and $e=\sigma^{-1}\,d\sigma|_{\mathfrak{r}}=e^a_\alpha T_a\,dq^\alpha$ is the vielbein, with $T_i\in\mathfrak{h}$ and $T_r\in\mathfrak{r}$ in the orthogonal decomposition $\mathfrak{g}=\mathfrak{h}\oplus\mathfrak{r}$. Using the inverse of the vielbein, $e^\alpha{}_a e_\alpha{}^b=\delta^b_a$, one may cast the canonical 1-form into the vielbein frame. This yields

$$(\partial_a+e_a{}^\alpha A^i_\alpha T_i)\sigma^{-1}=-T_a\sigma^{-1}=\boldsymbol{\nabla}_a\sigma^{-1}, \tag{2.21}$$

where (2.20) is used in the last equality, therefore proving our claim.

When we go over to the vector bundle from the principal bundle, we have to act with the covariant derivative on the expansion (2.15); hence, we are to use the particular representation χ for the generators T_i of $\mathfrak{h}$. It is then clear that the covariant derivative acts in an extremely simple manner on the wave functions. In fact, the property (2.20) shows that the covariant derivative in the representation χ is indeed the representation of the element T_m on such wave functions. Hence, if we adopt for the Hamiltonian the quadratic Casimir $X_mX^m=\boldsymbol{\nabla}_m\boldsymbol{\nabla}^m$ of the group G—which is G invariant by construction—we find that the Hamiltonian is given by the square of the covariant derivative $\boldsymbol{\nabla}_a\boldsymbol{\nabla}^a$ modulo a constant that is the value of the quadratic Casimir of the subgroup H evaluated on the irreducible representation χ. Thus, the free, homogeneous Hamiltonian given by the quadratic Casimir leads precisely to the Hamiltonian for the particle minimally coupled to the H connection, that is, the Hamiltonian argued by Landsman and Linden.[2]

III. QUANTIZING ON AN *n* SPHERE

In the approach to quantizating on spheres S^n proposed by Ohnuki and Kitakado[7] there appeared (possibly topological) gauge fields on the spheres as a result of inequivalent quantizations. These (infinitely) many inequivalent quantizations are labeled by the irreducible representations of the group SO(n)—an important feature shared with Mackey's approach,[6] where one

regards S^n as $\mathrm{SO}(n+1)/\mathrm{SO}(n)$. Thus, it would be natural to expect that the gauge fields observed in Ref. 7 may coincide with the H connection found by Landsman and Linden[2] in Mackey's approach. We shall show below that this is indeed the case.

But let us first recall the quantization and the gauge fields discussed in Ref. 7. There, quantization is prescribed by embedding the sphere S^n in $\mathbb{R}^{n+1}$ and then postulating a "fundamental algebra" as a set of quantum relations, generalizing the conventional canonical commutation relations. The fundamental algebra is the Lie algebra of $E(n+1)$, the Euclidean group in $n+1$ dimensions given by the semidirect product of $\mathrm{SO}(n+1)$ and $\mathbb{R}^{n+1}$, and finding the Hilbert space $\mathscr{H}(S^n)$ amounts to finding the representations of the group, taking into account the constraint that restricts to the sphere. Wigner's technique then allows for constructing explicitly the representations of $E(n+1)$ from the irreducible representations of the subgroup $\mathrm{SO}(n)$, which is the isometry group of $\mathrm{SO}(n+1)$ acting on S^n. According to this, the representations (of the Lie algebra) of $E(n+1)$ may be found by looking at the infinitesimal generators of the Wigner rotation. In Mackey's language the Wigner rotation corresponds to the matrix element

$$Q_{\mu\nu}(g,q) := \pi^{\chi}_{\mu\nu}((\sigma(q))^{-1} g \sigma(g^{-1}q)), \tag{3.1}$$

representing the rotations in the components of the vector-valued wave function in the induced representation (2.8). (Here we assume for simplicity that q and $g^{-1}q$ are in the same patch, where a single section σ is available.) In the present case $g \in \mathrm{SO}(n+1)$ and q stands for a vector on the sphere S^n embedded in $\mathbb{R}^{n+1}$, and we take the radius of the sphere to be unity, $\Sigma_{\alpha=1}^{n+1}(q^\alpha)^2=1$. In this embedding we adopt the convention that any function on S^n is smoothly extended to $\mathbb{R}^{n+1}$ by continuing the value of the function constantly along the direction of the radius. This implies that any function $f(q)$ defined this way obeys the condition, $q^\alpha \partial_\alpha f(q)=0$, where $\partial_\alpha = \partial/\partial q^\alpha$.

We label the basis of the Lie algebra $\mathrm{so}(n+1)$ by antisymmetric operators $T_{\alpha\beta}$ with α and β running over $1,\ldots,n+1$. The $\mathrm{so}(n)$ subalgebra is identified with the generators T_{ab}, where a and b can take values $1,\ldots,n$. The reductive decomposition $\mathrm{so}(n+1)=\mathrm{so}(n)\oplus\mathfrak{r}$ is then given by $\mathrm{so}(n+1)=\mathrm{span}\{T_{ab}\}\oplus\mathrm{span}\{T_a\}$, where $T_a = T_{a,n+1}$. The commutation relations are then

$$\begin{aligned}
[T_{ab},T_{cd}] &= \delta_{ad}T_{bc} + \delta_{bc}T_{ad} - \delta_{ac}T_{bd} - \delta_{ba}T_{ac}, \\
[T_{ab},T_c] &= \delta_{bc}T_a - \delta_{ac}T_b, \\
[T_a,T_b] &= -T_{ab}.
\end{aligned} \tag{3.2}$$

To make the presentation easier we now omit the label π^χ for the representation used.

Corresponding to the infinitesimal transformation $g = e^{1/2\epsilon_{\alpha\beta}T_{\alpha\beta}} = 1 + \frac{1}{2}\epsilon_{\alpha\beta}T_{\alpha\beta}$ with $\epsilon_{\alpha\beta}$ being real antisymmetric parameters, we have the Wigner rotation

$$Q(g,q) = 1 + \tfrac{1}{2}\epsilon_{\alpha\beta} f_{\alpha\beta}(q), \tag{3.3}$$

where $f_{\alpha\beta}(q)$ are the generators of the rotation. Then, the combination[7]

$$A_\alpha(q) := f_{\alpha\beta}(q) q^\beta, \tag{3.4}$$

is seen to appear in the Hamiltonian in the form covariantly coupled to a particle, and hence is regarded as an induced gauge field. We now show that this gauge field (3.4) is, in fact, the H connection.

To this end, observe first that from (3.1) the generators in (3.3) are given by

$$f_{\alpha\beta}(q) = \sigma^{-1}(q) T_{\alpha\beta} \sigma(q) - \sigma^{-1}(q)\partial_\mu \sigma(q) \left.\frac{\partial q^\mu(\epsilon)}{\partial \epsilon_{\alpha\beta}}\right|_{\epsilon=0}, \tag{3.5}$$

where $q^\mu(\epsilon) := (gq)^\mu = q^\mu + \frac{1}{2}\epsilon_{\alpha\beta}(T^{\rm def}_{\alpha\beta})_{\mu\nu}q^\nu$, and $(T^{\rm def}_{\alpha\beta})_{\mu\nu} = \delta_{\alpha\mu}\delta_{\alpha\nu} - \delta_{\alpha\nu}\delta_{\beta\mu}$ is the defining representation of so$(n+1)$. From this we get

$$\left.\frac{\partial q^\mu(\epsilon)}{\partial \epsilon_{\alpha\beta}}\right|_{\epsilon=0} = \delta^{\alpha\mu}q^\beta - \delta^{\beta\mu}q^\alpha. \tag{3.6}$$

It is then easy to see that under the change of section $\sigma(q)\to\sigma(q)h(q)$ for some $h(q)\in SO(n)$ the gauge field (3.4) transforms as a connection,

$$A_\alpha(q)\to h^{-1}(q)A_\alpha(q)h(q) - h^{-1}(q)\partial_\alpha h(q). \tag{3.7}$$

This is also evident from the expression

$$A_\alpha(q) = \sigma^{-1}(q)T_{\alpha\beta}q^\beta\sigma(q) - \sigma^{-1}(q)\partial_\alpha\sigma(q), \tag{3.8}$$

obtained from the definition (3.4).

Consider now the section

$$\sigma(q) = e^{\theta^a(q)T_a}, \tag{3.9}$$

which provides a local mapping from S^n to $G = \mathrm{SO}(n+1)$. The inverse mapping is given by

$$q^a := \theta^a\,\frac{\sin|\theta|}{|\theta|}, \quad a=1,\ldots,n, \quad q^{n+1} := \cos|\theta|, \tag{3.10}$$

where $\theta^t = (\theta^1,\ldots,\theta^n)$ and $|\theta| = \sqrt{\theta^t\theta} = \sqrt{\Sigma_a(\theta^a)^2}$. With the section (3.9) one finds that the relevant parts of the adjoint matrix (2.18),

$$\begin{aligned}\sigma^{-1}(q)T_{ab}\sigma(q) &= \mathscr{D}^{\ cd}_{ab}T_{cd} + \mathscr{D}^{\ c}_{ab}T_c,\\ \sigma^{-1}(q)T_a\sigma(q) &= \mathscr{D}^{\ bc}_{a}T_{bc} + \mathscr{D}^{\ b}_{a}T_b,\end{aligned} \tag{3.11}$$

take the form[5]

$$\mathscr{D}^{\ bc}_{a} = \tfrac{1}{2}(q^b\delta^c_a - q^c\delta^b_a) \tag{3.12}$$

and

$$\mathscr{D}^{\ cd}_{ab} = \frac{1}{2}\,(\delta^c_a\delta^d_b - \delta^c_b\delta^d_a) + \frac{q_b(q^c\delta^d_a - q^d\delta^c_a) + q_a(q^d\delta^c_b - q^c\delta^d_b)}{2(1+q^{n+1})}. \tag{3.13}$$

To show that (3.8) is the H connection, we note that the $\mathfrak{h}$ part in the first term on the right-hand side of (3.8) vanishes,

$$\sigma^{-1}(q)T_{\alpha\beta}q^\beta\sigma(q)|_{\mathfrak{h}} = 0. \tag{3.14}$$

For $\alpha = n+1$, this is obvious since the middle piece $T_{\alpha\beta}q^\beta$ that is conjugated under $\sigma(q)$ is precisely proportional to the argument in the exponential of $\sigma(q)$; see (3.9) and (3.10). For $\alpha = a \neq n+1$, using (3.12), (3.13) and the antisymmetry of T_{cd}, we have

$$\sigma^{-1}(q)T_{\alpha\beta}q^\beta\sigma(q)|_{\mathfrak{h}} = (q^b\mathscr{D}^{\ cd}_{ab} + q^{n+1}\mathscr{D}^{\ cd}_{a})T_{cd} = 0, \tag{3.15}$$

which establishes (3.14).

Now since the gauge field (3.8) must lie anyway in the space $\mathfrak{h}=\mathrm{so}(n)$ by construction [because it is formed out of the generators of the SO(n) Wigner rotation], we see that the $\mathfrak{r}$ part of the two terms in the right-hand side of (3.8) must precisely cancel each other. Combined with (3.14), this implies that

$$A_\alpha(q)=-\sigma^{-1}(q)\partial_\alpha\sigma(q)|_{\mathfrak{h}}, \tag{3.16}$$

that is, Ohnuki–Kitakato's gauge field (3.4) is, in fact, the H connection (up to the irrelevant sign). In terms of the section (3.9) the H connection reads as

$$\sigma^{-1}(q)d\sigma(q)|_{\mathfrak{h}}=\frac{1}{1+q^{n+1}}\sum_{a,b}^{n} q_a\, dq_b\, T_{ab}, \tag{3.17}$$

which, of course, agrees with the expression found in Ref. 7.

In passing, we mention that in a recent paper[15] it is pointed out that the gauge field (3.4) can be mapped into the ''generalized BPST instanton'' solution found earlier[16]—a solution of the Yang–Mills equation on S^n, which is topologically nontrivial for n even and trivial for n odd. The above result implies that this solution is essentially identical to the H connection, although the meaning of self-duality can change under the mapping. (The confirmation by a direct computation is also given in Ref. 14.)

IV. BERRY'S CONNECTION AS THE *H* CONNECTION

Berry's phase arises in systems where the Hamiltonian has degenerate eigenstates labeled by a collection of parameters, which are identified with the slow degrees of freedom. Adiabatically decoupling the fast variables from these slow ones results in an effective theory with a gauge structure in the slowly varying system.[1] The form of the gauge field that emerges is governed by the geometry of the slow system. In applications the degeneracies reflect a symmetry of the system; hence the slow system is usually identified with a coset space G/H. Such an identification emerges from a Hamiltonian of the form

$$H(q)=U(q)H_0U^{-1}(q), \tag{4.1}$$

where $q\in G/H$ are the slow variables, $U(g)$ is a unitary irreducible representation of G, and H_0 is typically an element of the enveloping algebra of the subgroup H, commuting with the restriction of the representation U to H. It is readily confirmed[3–5] that if we let $U(q)$ be in the form $U(\sigma(q))$, then (2.12) furnishes the eigenstates of the Hamiltonian with $|\chi,\bar{\mu}\rangle$ being the eigenstates of H_0 labeled by some irreducible representation χ of H. Thus, our representation χ is obtained from the given representation of G by restriction to H, followed by a further restriction to an invariant subspace. Using the states (2.12) (again dropping the label α for the patch to which q belongs) Berry's connection reads as

$$\begin{aligned}\sum_m A_m^{\mathrm{Berry}}(q)(T_m)_{\mu\nu}&=\langle q,\chi,\mu|d|q,\chi,\nu\rangle\\ &=\langle\chi,\bar{\mu}|U^{-1}(\sigma(q))dU(\sigma(q))|\chi,\bar{\nu}\rangle\\ &=\sum_i A_i^H(q)(T_i)_{\mu\nu}+\sum_a e_a(q)\\ &\quad\times\langle\chi,\bar{\mu}|U(T_a)|\chi,\bar{\nu}\rangle.\end{aligned} \tag{4.2}$$

The identification of this connection with the H connection clearly depends on whether the final term is zero or not. In applications this term is often set equal to zero by hand.[4,5] That this term is not always zero, though, is best seen through an explicit example.

Consider the situation where the slow variables parametrize a three sphere S^3, now viewed as the coset space SO(4)/SO(3). This would arise, for example, from (4.1) by taking H_0 to be the quadratic Casimir for SO(3). In the Lie algebra of SO(4) we take the reductive decomposition

$$\mathfrak{g}=\mathfrak{h}\oplus\mathfrak{r}=\mathrm{span}\{T_i\}\oplus\mathrm{span}\{T_d\},\quad i,a=1,2,3, \tag{4.3}$$

with the T_i's forming an su(2) algebra, $[T_i,T_j]=\epsilon_{ijk}T_k$, and the remaining commutators being

$$[T_i,T_a]=\epsilon_{iab}T_b \tag{4.4}$$

and

$$[T_a,T_b]=\epsilon_{abi}T_i\,. \tag{4.5}$$

The non-H-connection part of Berry's connection is, in this example, $\Sigma_a e_a\langle jm|T_a|jm'\rangle$, where we have reverted to the familiar notation for the representation of angular momentum. We now show that the matrix element $\langle jm|T_a|jm'\rangle$ need not be zero in general.

For this, we note first that the commutator (4.4) implies that the basis vectors in $\mathfrak{r}$ transform as a vector (spin 1) operator. To emphasize this fact we will, henceforth, denote these operators by ${T_a}^{(1)}$. The Wigner–Eckart theorem then tells us that the m, m', and a dependence of this matrix element resides in the Clebsch–Gordan coefficients $\langle jm'1a|jm\rangle$:

$$\langle jm|{T_a}^{(1)}|jm'\rangle=\langle jm'1a|jm\rangle\langle j\|T^{(1)}\|j\rangle, \tag{4.6}$$

where $\langle j\|T^{(1)}\|j\rangle$ is the reduced matrix element, which is independent of m, m', and a. In terms of the basis $T_\pm:=i(T_1\pm iT_2)$, $T_0:=iT_3$, the Clebsch–Gordan coefficients are given by

$$\langle jm'1a|jm\rangle=\frac{\delta_{m'+a,m}}{\sqrt{j(j+1)}}\begin{cases}\mp\sqrt{(j\pm m)(j\mp m+1)/2}, & \text{if } a=\pm;\\ m, & \text{if } a=0.\end{cases} \tag{4.7}$$

Upon identifying the same a and i, we find that these coefficients are related to the representation matrix elements $\langle jm'|T_i|jm\rangle$ of the $su(2)$ generators T_i, $i=+,-,0$. This allows us to rewrite (4.6) as

$$\langle jm|T_a^{(1)}|jm'\rangle=a_j\langle jm'|T_i|jm\rangle, \tag{4.8}$$

where the prefactor a_j is

$$a_j=-\frac{\langle j\|T^{(1)}\|j\rangle}{\sqrt{j(j+1)}}. \tag{4.9}$$

We recall that the action of any vector operator on the state $|jm'\rangle$ is determined by two reduced matrix elements. For $T^{(1)}$ these are a_j and the reduced matrix element $\langle j-1\|T^{(1)}\|j\rangle$. However, the action of $T^{(1)}$ is also fixed by the fact that it comes from a representation of SO(4). Exploiting these two facts allows us to determine the allowed values for a_j.

The irreducible unitary representations of SO(4) are labeled by two numbers (k_0,c), where $k_0=0,\ \frac{1}{2},\ 1,\ \frac{3}{2},\ldots$, and $c=\pm(k_1+1)$ with $k_1=k_0,k_0+1,k_0+2,\ldots$. (For a clear account of this see Ref. 17.) The representation space is then decomposed into the direct sum

$$\mathscr{R}(k_0,c)=\bigoplus_{j=k_0}^{k_1}\mathscr{R}^j, \tag{4.10}$$

of the irreducible representations $\mathscr{R}^j$ of SO(3) spanned by the angular momentum states, $|jm\rangle$, $m=-j,\ldots,j$. In such a representation one finds that a_j is given by

$$a_j=\frac{k_0c}{j(j+1)}. \tag{4.11}$$

From this we deduce that if $k_0\neq 0$, then Berry's connection does not correspond to the H connection.

This example can be extended to more general coset spaces in much the same way by using the generalized Wigner–Eckart theorem (see, for example, Ref. 18). The conclusion reached is that, in general, Berry's connection is not the H connection. The question we now want to address is what additional structures are needed in order to ensure that they do coincide. To motivate our analysis of this problem it is again useful to return to the three sphere example discussed above.

From (4.11) we see that the relevant reduced matrix element vanishes only when $k_0=0$. In this case (and only in this case) the representations $(k_0=0,c)$ and $(k_0=0,-c)$ of SO(4) are unitarily equivalent (there is no parity doubling[17]). The representation space becomes the direct sum,

$$\mathscr{R}(0,n)=\bigoplus_{j=0}^{n-1}\mathscr{R}^j, \quad \text{where } n=1,2,\ldots . \tag{4.12}$$

The action of T_i on $\mathscr{R}^j$ is the standard one, changing the value of m by ± 1. From (4.4) one can also show that the action of $T_a^{(1)}$ on $\mathscr{R}^j$ changes the value of j by ± 1. Thus, the state $|jm\rangle=|n-1,n-1\rangle$ is both a highest weight vector for the irreducible representation on $\mathscr{R}^{n-1}$ of SO(3), and for the irreducible representation on $\mathscr{R}(0,n)$ of SO(4). This cannot hold for any of the other $(k_0\neq 0)$ representations of SO(4) since the parity doubling found in those representations would then imply that such a vector was a highest weight for two inequivalent representations.

We shall use this example as a motivation for the following restriction on the allowed states $|\chi,\overline{\mu}\rangle$ that occur in (4.2). Recall first that by definition the reference basis states satisfy

$$U(h)|\chi,\bar{\mu}\rangle=\sum_{\nu}|\chi,\bar{\nu}\rangle\pi^{\chi}_{\nu\mu}(h), \quad \text{for } h\in H. \tag{4.13}$$

Let Λ be the highest weight labeling the representation of the group G in question. We shall consider the *highest subspace* $\mathscr{H}_\Lambda$, which is the subspace of the representation space $\mathscr{H}$ of G realizing (4.13) and also contains the vector $|\Lambda\rangle$ corresponding to the highest weight. We then claim that, for a wide class of systems, by choosing the subspace as a highest subspace we will manage to obtain merely the $\mathfrak{h}$ part of Berry's connection. To prove this it is convenient to develop an alternative description of the highest subspace $\mathscr{H}_\Lambda$.

For this, let us restrict ourselves to cosets G/H, where the subgroup H is given by the centralizer S_K of some element $K\in\mathfrak{g}$. This corresponds to the Hamiltonian (4.1) whose parameter space is the coadjoint orbit of the group G passing through K discussed in Refs. 3 and 5. If K is a regular semisimple element[19] of $\mathfrak{g}$, then H in this case is just the Cartan subgroup T regarded as the maximal torus containing K, but if not then H is greater than T. Let Σ be the root system of G relative to T, and let Σ_K be the root system of H relative to T. By considering the complexification $\mathfrak{g}_c$ of $\mathfrak{g}$ we have the Cartan decomposition,

$$\mathfrak{g}_c=\mathfrak{t}_c\oplus\sum_{\alpha\in\Sigma}\mathfrak{g}_\alpha, \tag{4.14}$$

where $\mathfrak{t}_c$ is the complexification of the Cartan subalgebra $\mathfrak{t}$, and $\mathfrak{g}_\alpha$ is the root space corresponding to the root α. Similarly, we have

$$\mathfrak{h}_c = \mathfrak{t}_c \oplus \sum_{\alpha \in \Sigma_K} \mathfrak{h}_\alpha . \tag{4.15}$$

Next, let W be a Weyl chamber of $\mathfrak{t}$ relative to G, and W_K be a Weyl chamber of $\mathfrak{t}$ relative to H. We can define the positive roots Σ^+ (Σ_K^+) of Σ (Σ_K) with respect to W (W_K). It is then guaranteed[20] that there exists a "K admissible Weyl chamber," satisfying (i) $\Sigma^+ \cap \Sigma_K = \Sigma_K^+$ and (ii) if $\alpha \in \Sigma^+ - \Sigma_K^+$, $\beta \in \Sigma_K$ and $\alpha + \beta \in \Sigma$, then $\alpha + \beta \in \Sigma - \Sigma_K^+$.

Armed with this, we then show that the highest subspace $\mathscr{H}_\Lambda$ can alternatively be characterized by

$$\mathscr{H}_\Lambda = \{ |\phi\rangle \in \mathscr{H} \mid \ U(T_\alpha)|\phi\rangle = 0, \quad \forall \alpha \in \Sigma^+ - \Sigma_K^+ \}. \tag{4.16}$$

Note first that the states defined by (4.16) are invariant under the action of H in $\mathscr{H}$. Indeed, for those generators of $\mathfrak{h}$ belonging to the Cartan subalgebra $\mathfrak{t}$ this is obvious since for $T_i \in t$, $[T_i, T_\alpha] = \alpha(T_i) T_\alpha$. If T_β is a generator of $\mathfrak{h}$ not in $\mathfrak{t}$ then, using the reductivity of the decomposition $\mathfrak{g} = \mathfrak{h} \oplus \mathfrak{r}$, we get, for $\alpha \in \Sigma^+ - \Sigma_K^+$,

$$U(T_\alpha)U(T_\beta)|\phi\rangle = U(T_\beta)U(T_\alpha)|\phi\rangle + U([T_\alpha, T_\beta])|\phi\rangle = C_{\alpha\beta}^{\alpha+\beta} U(T_{\alpha+\beta})|\phi\rangle, \tag{4.17}$$

which vanishes since $\alpha + \beta \in \Sigma^+ - \Sigma_K^+$.

Second, the unitary action in (4.16) is also irreducible. To see this, suppose that it is reducible. Then there exists some $|\Omega\rangle \neq |\Lambda\rangle$ for which

$$U(T_\beta)|\Omega\rangle = 0, \quad \text{for } \beta \in \Sigma_K^+ , \tag{4.18}$$

i.e., $U(T_\beta)$ is a step operator in $\mathfrak{h}$ annihilating this state. It then follows that both the operators $U(T_\alpha)$ and $U(T_\beta)$, where $\alpha \in \Sigma^+ - \Sigma_K^+$ and $\beta \in \Sigma_K^+$, annihilate $|\Omega\rangle$. Hence, this state is annihilated by any $U(T_\alpha)$ for $\alpha \in \Sigma^+$, which implies that $|\Omega\rangle$ is a highest weight. But since we cannot have two highest weights, we see that $\mathscr{H}_\Lambda$ defined by (4.16) is irreducible and hence must be the highest subspace satisfying (4.13).

Having established (4.16), we now find, for such highest subspace states,

$$\sum_{\alpha \in \Sigma - \Sigma_K} e_\alpha(q) \langle \chi, \bar{\mu} | U(T_\alpha) | \chi, \bar{\nu} \rangle = 0, \tag{4.19}$$

on account of $T_{-\alpha} = T_\alpha{}^\dagger$. Clearly, then, we can conclude that if a highest subspace is used in the construction of Berry's connection, then there will be no $\mathfrak{r}$ part, and hence it will be the H connection—the claim we wished to prove.

V. CONCLUSIONS AND DISCUSSIONS

In this paper we have argued that the induced connection that appears on a coset space in Mackey's quantization scheme admits a natural interpretation, that is, it arises from the homogeneity criterion required for the Hamiltonian. This led to an alternative account from Ref. 2 of why the Hamiltonian on G/H involves the induced H connection. Being geometrical, our criterion will be useful, even in other quantization approaches and, possibly, in attempts at extending the quantization scheme to field theories. Indeed, we have shown that the gauge field induced in a slightly different approach[7] is again the H connection—a fact suggesting a universal feature of the quantum theory on such topologically nontrivial spaces. In connection with this, it is worth mentioning

that even in the ''confining approach''[21] to quantization, which is totally different from Mackey's approach, one can still observe an induced gauge field, which is also appears to be of the type of the H connection.[8,9]

The appearance of the H connection in the other context—Berry's phase—was then analyzed in the setting where the parameter space is given by a coset space G/H. We have seen that Berry's connection becomes the H connection if the energy eigenspace we are looking at possesses the highest weight state of the unitary representation of the group G that characterizes the system. Notice also that such highest subspaces can be used to define the so-called vectorial coherent states[22] for the group G. Indeed, by choosing the states $|\chi,\overline{\mu}\rangle$ as the ones belonging to a highest subspace, the states of (2.12) become the vectorial coherent states. The physical implications of this condition for the energy eigenspaces need to be investigated, but we have at least seen an interesting fact that in such cases the effective theory describing the slow variables bears an unexpected resemblance with the quantum theory on coset spaces.

Poisson brackets of Wilson loops and derivations of free algebras

S. G. Rajeev[a] and O. T. Turgut
Department of Physics and Astronomy University of Rochester, Rochester, New York 14627

(Received 21 August 1995; accepted for publication 29 August 1995)

We describe a finite analog of the Poisson algebra of Wilson loops in Yang–Mills theory. It is shown that this algebra arises in an apparently completely different context: as a Lie algebra of vector fields on a noncommutative space. This suggests that noncommutative geometry plays a fundamental role in the manifestly gauge invariant formulation of Yang–Mills theory. We also construct the deformation of the algebra of loops induced by quantization, in the large-N_c limit. © *1996 American Institute of Physics.* [S0022-2488(96)03001-5]

I. ALGEBRAS OF WILSON LOOPS

A central problem of particle physics is to find a formulation of Yang–Mills theory in terms of gauge invariant variables. There is a large amount of literature on this subject, starting with pioneering work of Mandelstam.[1] Such a reformulation of Yang–Mills theory must involve as yet unknown geometrical principles, as the principle of gauge invariance would be empty. We should discover these geometrical structures by starting with the conventional formalism of gauge theory and rewriting it in terms of gauge invariant variables. A loose analogy can be made with the process by which symplectic geometry was discovered to be the foundation of classical mechanics.

In this article we will show that the fundamental Poisson brackets of Yang–Mills theory have an interpretation as an algebra of vector fields in a noncommutative space, a sort of noncommutative generalization of the Virasoro algebra. The precise mathematical formulation is possible only for a finite (regularized) version of the theory, but the ideas extend in a formal way to the continuum theory.

A natural choice of gauge invariant variable in Yang–Mills theory is the Wilson loop variable. It is just the trace of the parallel transport operator around a loop. We can describe the symplectic structure of classical Yang–Mills theory in terms of Poisson brackets of these variables. However, in the usual canonical formalism, where initial data is given on a spacelike surface, this leads to either a trivial answer or to an impossibly complicated one. If the loop lies entirely on a spacelike surface, the Poisson brackets will vanish since the components of the gauge field on a spacelike surface commute: they are like the q variables of classical mechanics. If the loop has a finite extension into the timelike direction on the other hand, the Poisson brackets cannot be obtained without solving the equations of motion: this is like asking for $\{q(t),q(t')\}$ at unequal times in classical mechanics. One way around this impasse is to introduce loop variables involving the electric field (which is the canonical conjugate of the Yang–Mills potential) but this does not have the elegance and simplicity of a formalism involving Wilson loop variables alone.

We showed in some recent papers[2] that the Wilson loops in classical Yang–Mills theory which lie on a null surface satisfy simple Poisson brackets. (There is also a large amount of literature on the null cone formalism for gauge theories. See, e.g., Ref. 3.) In a formalism in which initial data is given on null surfaces there is thus a natural way of encoding the canonical structure of

[a]Present address: The Erwin Schrödinger International Institute for Mathematical Physics, Pasteurgasse 6/7, Vienna, Austria.

Yang–Mills theory in terms of gauge invariant variables. In this article we will show that an analog of this Loop algebra arises as derivations of the free algebra on a finite number of variables. This allows us to construct a Lie group of which the finite loop algebra is the Lie algebra. Moreover, we will construct a symplectic realization analogous to the realization on the Yang–Mills phase space. We will also obtain a quantum deformation of this algebra and obtain the contraction corresponding to the large-N_c limit. It is conjectured that this large-N_c limit algebra also has a symplectic realization, but we are as yet unable to construct it. This would be of great interest in Yang–Mills theory, as it would help us discover the phase space of gauge invariant observables of that theory.

We will reserve the phrase ''loop algebra'' to describe the algebras formed by Wilson loops in gauge theories. This should not be confused with another meaning of this term often found in the literature: the Lie algebra of the so-called loop group, the group of functions from a circle to a Lie group.

Let us now describe the situation a little more explicitly.[2] We will consider pure Yang–Mills theory on flat Minkowski space, with initial data given on a null cone. The field will then be determined at all points in the future of the cone by the Yang–Mills equations. (See Ref. 2 for details.) It will be particularly convenient to choose as initial surface the null cone at past timelike infinity (called $\mathscr{I}^-$ in Ref. 4) so that all points not on the cone are in its future. (This will also restore spatial translation invariance.) This can be accomplished by using a conformally equivalent metric

$$\hat{d}s^2 = dU(dU+2dR) - \sin^2 R q_{ij}(z)dz^i\, dz^j \tag{1}$$

instead of the flat metric on Minkowski space. (Here, q_{ij} is the standard metric on S^2.) Yang–Mills equations are conformally invariant in four dimensions, so this conformal change of the metric will not change the theory. $\partial/\partial U$ is a timelike vector and $\partial/\partial R$ is a null vector. We will regard $\partial/\partial U$ as defining the time direction. Also, Minkowski space corresponds to the region

$$-\pi < U < \pi \quad -\pi < U+2R < \pi. \tag{2}$$

The null cone at past timelike infinity $\mathscr{I}^-$ will be the surface $U=-\pi$.

Since the Yang–Mills equations are of first order in the time variable U, initial data consist of prescribing the value of the gauge potential on $\mathscr{I}^-$. We can set $A_R=0$, by a choice of gauge. Also, A_U is just a Lagrange multiplier (its time derivative does not appear in the Lagrangian) so that the dynamical variables are the transverse components A_i. The main simplification of the null formalism is that these variables are in a sense canonically conjugate to each other with equal time Poisson brackets

$$\{A^a_{ib}(z,R),A^c_{jd}(z',R')\} = \tfrac{1}{2}\delta^a_d\delta^c_b q_{ij}(z)\,\delta(z-z')\,\mathrm{sgn}(R-R'). \tag{3}$$

Here $a,b=1,2,\ldots,N_c$. We will consider the gauge group to be U(N_c) so that the matrices A_i are Hermitian. These Poisson brackets follow from the Yang–Mills action by a straight forward application of the canonical formalism.

We thus define the inverse of the symplectic form on the phase space of Yang–Mills theory:

$$\omega^{ab}_{ijcd}(z,R,z',R') = \delta^a_d\delta^b_c\omega_{ij}(z,R,z',R'), \tag{4}$$

where

$$\omega_{ij}(z,R,z',R') = \tfrac{1}{2}q_{ij}(z)\,\delta(z-z')\,\mathrm{sgn}(R-R'). \tag{5}$$

Now let $\xi: S^1 \to \mathscr{I}^-$ be a closed curve on the light cone. Given a Yang–Mills field A, we can define a complex valued function $W[\xi]$ on the space of closed curves, the trace of the parallel transport operator (holonomy) in the basic N_c dimensional representation. In the case of $U(N_c)$, this loop variable is complex valued, but it satisfies the condition

$$W[\bar{\xi}] = W^*[\xi], \tag{6}$$

where $\bar{\xi}$ is the curve ξ with the opposite orientation.

This $W[\xi]$ is the "Wilson loop" associated to this Yang–Mills configuration. For each ξ, $W[\xi]$ is a function on the Yang–Mills phase space so that it is possible to compute the Poisson bracket of a pair of loop variables. We will get

$$\{W[\xi], W[\tilde{\xi}]\} = \int ds\ dt\ \dot{\xi}^i(s)\dot{\tilde{\xi}}^j(t)\omega_{ij}(\xi(s), \tilde{\xi}(t)) W[\xi \circ_{st} \tilde{\xi}].$$

Due to the delta function in the symplectic form, only points s,t where $\xi^i(s) = \tilde{\xi}^i(t)$ will contribute to the integral; i.e., the projections of the curves to the sphere must intersect at parameter value s for the first curve and t for the second. There will be a null line segment joining the points $\xi(s)$ and $\tilde{\xi}(t)$ for this intersection. In this case, $\xi \circ_{st} \tilde{\xi}$ is the product curve, defined as follows: describe the curve ξ starting and ending at s; jump to the point $\tilde{\xi}(t)$ along the null line segment; describe the curve $\tilde{\xi}$ starting and ending at $\tilde{\xi}(t)$; jump back to $\xi(s)$ along the null segment. Thus the product is also a closed curve. The pieces of the curve along null lines will not contribute to $W[\xi \circ_{st} \tilde{\xi}]$ since we have chosen a gauge where the null component of the gauge field vanishes. Also, there will be generically only a finite number of intersection points, so that the integral on the right-hand side can be actually evaluated to yield a finite sum. We will not need the explicit expression, which is given in Ref. 2. This last property depends on the dimension of space–time being four; in higher than four dimensions generically there are no intersections while in lower dimensions there is a continuum of such intersections.

The Poisson brackets above could have been motivated based purely on the geometry of loops on the null cone. Causality requires that loops on a null cone which have no intersections when projected to the spacelike surface must commute. This explains the delta function in $\omega(z,R,z',R')$. The factor sgn $(R-R')$ is also natural, as it simply keeps track of which event is to the future along the null direction, and makes the bracket antisymmetric.

Indeed, geometrically, these are the most natural definitions possible for ω as well as the product of the loops. Note that the bracket is invariant under the change of parametrization of the loop. In fact the right-hand side will only depend on q_{ij} only through the angle of intersection of the tangent vectors $\dot{\xi}(s), \dot{\tilde{\xi}}(t)$; thus the algebra is invariant under conformal transformation of the metric on the two sphere. But every metric on the two sphere is conformal to the standard one, so we see that the algebra is in fact independent of the choice of metric also.

Once the Poisson brackets are postulated, the Jacobi identity can be proved directly. The Yang–Mills phase space then arises as the solutions of some algebraic constraints satisfied by the loop variables, due to Mandelstam. We proposed that these constraints be viewed as describing the coadjoint orbits of the above Lie algebra. In this way, Yang–Mills theories with different unitary groups as gauge groups, would arise as different realizations of the same universal Lie algebra. For more details we refer the reader to Ref. 2.

We would like to understand the above Lie algebra of loops better. In particular we would like to have a finite analog which can be studied by more rigorous methods; also it would be good to have a different situation in which this loop algebra arises so that we can have a point of view to Yang–Mills theory not based on the gauge group. Another natural object to study is the group associated to the above Loop algebra. Finally it is very important to understand the quantum deformations of this algebra and its large-N_c limit. In this paper we will in fact arrive at a finite

analog of the loop algebras and their groups, starting from considerations quite different from Yang–Mills theories; i.e., the derivations and automorphisms of free algebras. We will also construct a quantum deformation and its large-N_c limit.

Another situation where Poisson brackets of Wilson loops appears is in Chern–Simons theory. There, also, the spatial components of the gauge field are canonically conjugate to each other; the Wilson loops on a spacelike 2-surface satisfy the above algebra except that

$$\omega_{i,j}(z,z') = \epsilon_{ij}(z)\,\delta^2(z-z'), \tag{7}$$

where $\epsilon_{ij}(z)dz^i \wedge dz^j$ is the volume form on the spacelike surface. The product of loops relative to a pair of coincident points is defined as before as one loop followed by the other. Thus our considerations should also be of interest in the context of topological field theories.

II. THE FREE ALGEBRA AND ITS AUTOMORPHISMS

Let $\mathscr{T}_M$ be the real free algebra on M variables.[5] It is a graded vector space, the part of order m (for $m=0,1,2,...$) being just the set of all tensors of type $(0,m)$ on an M-dimensional real vector space. Note that no symmetry of any kind is required on these tensors. The multiplication rule on the algebra is defined by the direct (or tensor) product. $\mathscr{T}_M$ is a noncommutative but associative algebra with identity.

More explicitly, introduce variables ξ^i for $i=1,\ldots,M$ satisfying no relations whatever. A typical element of $\mathscr{T}_M$ is a polynomial in these variables,

$$T(\xi) = \sum_{m=0}^{\infty} T_{i_1 i_2,\ldots,i_m}\xi^{i_1}\xi^{i_2},\ldots,\xi^{i_m}. \tag{8}$$

$T_{i_1 i_2,\ldots,i_m}$ are the components with respect to some basis in R^M of a tensor T of type $(0,m)$. Since $T(\xi)$ is assumed to be a polynomial, only a finite number of terms on the right-hand side of the above series are nonzero: only a finite number of the tensors $T_{i_1,\ldots,i_m}$ are nonzero.

In this language, multiplication is defined as follows:

$$(ST)(\xi) = \sum_{m,n=0} S_{i_1,\ldots,i_m} T_{j_1,\ldots,j_n}\xi^{i_1},\ldots,\xi^{i_m}\xi^{j_1},\ldots,\xi^{j_n}. \tag{9}$$

There is no problem with convergence of the series since only a finite number of terms are nonzero. In fact this comment applies to almost all the formally infinite series below. (The exception is where we speak of inverting a transformation of the variables.)

If these variables ξ had commuted with each other, the algebra would just have been the commutative algebra of functions (polynomials) on R^M. The tensors would all have been symmetric and multiplication would have been the symmetrized tensor product. This algebra has as automorphisms the group of diffeomorphisms of R^M. (Actually a diffeomorphism will in general map a polynomial to an infinite series, so we will really need $\mathscr{T}_M$ to extend to an appropriate topological vector space to make this possible.) Infinitesimally, this would correspond to the Lie algebra of vector fields, whose components are polynomials, which form the derivations of the commutative algebra.

Thus we can regard $\mathscr{T}_M$ as the set of ''functions'' on a noncommutative space in the spirit of noncommutative geometry.[6] This is perhaps the most noncommutative case in the sense that the coordinates satisfy no relations at all. Now let us determine the Lie algebra of derivations $\mathscr{V}_M$ which will be the noncommutative analog of the algebra of vector fields. A derivation v is determined by its effect on the generators:

$$v(\xi)^i=\sum_{m=1} v^i_{i_1,\ldots,i_m}\xi^{i_1},\ldots,\xi^{i_m}, \tag{10}$$

where it is assumed that only a finite number of terms in the sum are nonzero. The effect of v on an arbitrary element of $\mathscr{T}_M$ is given by the Leibnitz rule:

$$v(T)(\xi)=\sum_{m,n=1}^{\infty}\sum_{k=1}^{m} T_{i_1,\ldots,i_m}v^{i_k}_{j_1,\ldots,j_n}\xi^{i_1},\ldots,\xi^{i_{k-1}}\xi^{j_1},\ldots,\xi^{j_n}\xi^{i_{k+1}},\ldots,\xi^{i_m}. \tag{11}$$

A basis (analogous to the Weyl basis for $gl(M)$) for $\mathscr{V}_M$ is given by the elements $E_i^{i_1,\ldots,i_m}$ defined by

$$E_i^{i_1,\ldots,i_m}(\xi)^j=\delta_i^j\xi^{i_1},\ldots,\xi^{i_m}. \tag{12}$$

In the commutative case they correspond to the vector fields $\xi^{i_1},\ldots,\xi^{i_m}(\partial/\partial\xi^i)$. They satisfy the commutation relations

$$[E_i^{i_1,\ldots,i_m},E_j^{j_1,\ldots,j_n}]=\sum_{l=1}^{n}\delta_i^{j_l}E_j^{j_1,\ldots,j_{l-1}i_1,\ldots,i_m j_{l+1},\ldots,j_n}-\sum_{k=1}^{m}\delta_j^{i_k}E_i^{i_k,\ldots,i_{k-1}j_1,\ldots,j_n i_{k+1},\ldots,i_m}.$$

In the special case $M=1$, all the noncommutativity dissappears, and $\mathscr{V}_1$ is just the algebra of polynomial vector fields on the real line. Since all the indices must take the value 1, there is just one generator with m superscripts. Suppose we call it L_{m-1} for $m=0,1,\ldots$. Then the above commutation relation becomes

$$[L_m,L_n]=(n-m)L_{m+n}\quad\text{for } m=-1,0,1,2,\ldots\ . \tag{13}$$

This is just the subalgebra of the Virasoro algebra on which the central term vanishes. Thus our algebras are, in a sense, generalizations of this familiar algebra.

Now let g_{ij} be a symmetric positive tensor on R^M and define $\mathscr{V}_M^-$ to be the subalgebra of tensors that preserve the element $g(\xi)=|\xi|^2=g_{ij}\xi^i\xi^j$. In the commutative case these are all the vector fields tangential to the spheres centered at the origin; these preserve the distance function $|\xi|^2$. The simplest among these are the rotations. In the case of a free algebra, we can see easily that the algebra $\mathscr{V}_M^-$ consists of the set of all elements of the form

$$v^i_{i_1,\ldots,i_m}=g^{ii_0}w_{i_0i_1,\ldots,i_m}, \tag{14}$$

where $w_{i_0i_1,\ldots,i_m}$ is a *cyclically antisymmetric tensor*. Of course such tensors exist only when m is odd. There is a basis for $\mathscr{V}_M^-$,

$$G^{i_0,\ldots,i_m}=\sum_{k=0}^{m}(-1)^k g^{i_kj}E_j^{i_{k+1},\ldots,i_0i_m,\ldots,i_{k-1}} \tag{15}$$

in which the Lie brackets become

$$[G^{i_0,\ldots,i_m},G^{j_0,\ldots,j_n}]=\sum_{k,l=0}^{k=m,l=n}(-1)^{k+l+1}g^{i_kj_l}G^{i_{k+1},\ldots,i_mi_1,\ldots,i_{k-1}j_{l+1},\ldots,j_nj_1,\ldots,j_{l-1}}. \tag{16}$$

In an exactly analogous fashion, let ω be an antisymmetric nondegenerate tensor. (Clearly this exists only if M is even, which will be assumed in the following.) This defines an element

$$\omega(\xi)=\omega_{ij}\xi^i\xi^j. \tag{17}$$

This is a symplectic analog of the distance function. This would have vanished identically in the commutative case.

The subalgebra $\mathscr{V}_M^+$ which preserves $\omega(\xi)$ is just the set of elements such that

$$v^i_{i_1,\ldots,i_m}=\omega^{ii_0}w_{i_0i_1,\ldots,i_m}, \tag{18}$$

where $w_{i_0i_1,\ldots,i_m}$ is a *cyclically symmetric* tensor. There is a basis for $\mathscr{V}_M^+$,

$$F^{i_1,\ldots,i_m}=\sum_{k=1}^{m}\omega^{i_kj}E^{i_{k+1},\ldots,i_1i_m,\ldots,i_{k-1}}_j \tag{19}$$

in which the Lie brackets become

$$[F^{i_1,\ldots,i_m},F^{j_1,\ldots,j_n}]=\sum_{k,l=1}^{k=m,l=n}\omega^{i_kj_l}F^{i_{k+1},\ldots,i_mi_1,\ldots,i_{k-1}j_{l+1},\ldots,j_nj_1,\ldots,j_{l-1}}. \tag{20}$$

Now we will show that this algebra is just a finite version of the loop algebra we found for Wilson loops. Let us think of the index $I=i_1,\ldots,i_m$ on the F^I variable as a map $I:Z_m\to\{1,\ldots,M\}$. Due to cyclic symmetry, this can be viewed as a ''loop'' from the cyclic permutation group Z_m (which is a discrete model for the circle) to a space which contains just a finite number M of points. The product of two loops at point k,l is defined as the loop I starting at i_{k+1} and ending at i_{k-1} followed by the loop J starting at j_{l+1} and ending at j_{l-1}:

$$I\circ_{kl}J=i_{k+1},\ldots,i_mi_1,\ldots,i_{k-1}j_{l+1},\ldots,j_nj_1,\ldots,j_{l-1}. \tag{21}$$

This is just the discrete analog of the product we introduced earlier. The commutation relations of the Lie algebra $\mathscr{V}_M^+$ are then

$$[F^I,\ F^J]=\sum_{kl}\omega^{i_kj_l}F^{I\circ_{kl}J}. \tag{22}$$

The Wilson loop algebra can be understood as the limiting case where the finite set Z_m is replaced by S^1 and the set $\{1,2,\ldots,M\}$ is replaced by the light cone $S^2\times R^+$. Thus by studying the algebra $\mathscr{V}_M^+$ we are studying a finite model for the algebra of Wilson loops. The algebras $\mathscr{V}_M$, $\mathscr{V}_M^-$, $\mathscr{V}_M^+$ are all graded Lie algebras. The point is that the Lie bracket of a tensor with m indices and one of with n indices has $m+n-2$ indices. Thus if we assign a grade of $m-1$ to the space of tensors with m indices, we have a graded Lie algebra. The range of the grading is $-1,0,1,2$; the space of grade -1, if nonempty, is a subalgebra with vanishing brackets.

Although we have introduced $\mathscr{V}_M^+$ as a complex Lie algebra, its unitary form, obtained by imposing

$$v_I^*=v_{\bar{I}} \tag{23}$$

on the coefficients of an element $v=\Sigma v_IF^I$, will be of particular interest. To save on notation we will also call this real Lie algebra $\mathscr{V}_M^+$. Here,

$$\bar{I}=i_mi_{m-1},\ldots,i_1 \tag{24}$$

is the loop with the opposite orientation. The conjugation $v_I\to v_I^*$ is an antilinear involution of the complex algebra, therefore it makes sense to talk about its unitary form.

The algebra $\mathscr{V}_M^-$ is the finite analog of the commutation relations of the Wilson loop in supersymmetric Yang–Mills theory. In the case of supersymmetric QCD in two dimensions, e.g., the bosonic components of the gauge field can be removed by gauge fixing, and the analog of the Wilson loop variables involve only the fermionic fields in the adjoint representation. Thus it is of equal interest to study $\mathscr{V}_M^-$; we can develop the two cases in parallel; but mostly we will speak of $\mathscr{V}_M^+$.

III. AUTOMORPHISM GROUPS $G_M^{\pm}$

It is now possible to understand the Lie groups of which $\mathscr{V}_M^{\pm}$ are Lie algebras. Thus, we will solve in a finite context the problem of exponentiating the Lie algebra of Wilson loops.

First of all, let us consider a group of which $\mathscr{V}_M$ is the Lie algebra. Consider the vector space of tensors of type $(1,m)$ for $m=0,1,...$. In terms of the variables ξ^i, a typical element would be

$$\phi^i(\xi)=\sum_{m=1}^{\infty}\phi^i_{i_1,\ldots,i_m}\xi^{i_1},\ldots,\xi^{i_m}. \tag{25}$$

Define the composition law of such functions of ξ in the obvious way:

$$(\tilde{\phi}\circ\phi)^i(\xi)=\sum_{m=0}^{\infty}\tilde{\phi}^i_{i_1,\ldots,i_m}\phi(\xi)^{i_1},\ldots,\phi(\xi)^{i_m}. \tag{26}$$

This operation is clearly associative and has identity.

If we now restrict to the subset of functions ϕ such that the first tensor in the series above, is invertible,

$$G_M=\{\phi|\det\ \phi^i_j\neq 0\} \tag{27}$$

we have a group under the above composition law. To see this, we note that given any such ϕ, a unique inverse ψ can be constructed solving the equation

$$\psi^i(\phi)(\xi)=\xi^i \tag{28}$$

recursively:

$$\psi^i_j\phi^j_k=\delta^i_k,$$

$$\psi^i_j\phi^j_{j_1j_2}+\psi^i_{i_1i_2}\phi^{i_1}_{j_1}\phi^{i_2}_{j_2}=0,$$

etc. The term of order m will determine $\psi^i_{i_1,\ldots,i_m}$ in terms of lower order components of ψ thus establishing the existence and uniqueness of an inverse. In general, ψ will have an infinite number of nonzero terms even when ϕ is a polynomial. [We must enlarge our space of allowed transformations to include infinite series, in order to be able to define an inverse. We do not address the issue of convergence of these series, although it should be possible to define an appropriate topology on the space of such series with respect to which G_M is a Lie group. The Lie algebra of G_M will in fact be the completion of our polynomial derivations $\mathscr{V}_M$ in such a topology.] This is an algebraic analog of the inverse function theorem: ϕ^i_j is the analog of the derivative at the origin of the function $\phi^i(\xi)$, so that if it is invertible, we should expect ϕ to be invertible at least locally.

Thus G_M is a group under the above composition law; by infinitesimalizing the composition law we see that this group has as Lie algebra $\mathscr{V}_M$. We see that G_M is a noncommutative analog of the diffeomorphism group of R^M.

Now it is clear that groups of which the Lie algebras are $\mathscr{V}_M^{\pm}$ may be defined as below:

$$G_M^- = \{\phi | \det\ \phi_j^i \neq 0; g_{ij}\phi^i(\xi)\phi^j(\xi) = g_{ij}\xi^i\xi^j\},$$

$$G_M^+ = \{\phi | \det\ \phi_j^i \neq 0; \omega_{ij}\phi^i(\xi)\phi^j(\xi) = \omega_{ij}\xi^i\xi^j\}$$

which are just the conditions for the distance functions to be invariant.

IV. SYMPLECTIC REALIZATIONS

It would obviously be interesting to look at representations of the above loop algebras. This should be interesting, e.g., in the quantum Yang–Mills theory. However, it is quite possible that the relevant algebras are different in the quantum theory: quantization could deform the algebra itself. Therefore we first study the classical analog of a representation, a realization of the Lie algebra $\mathscr{V}_M^+$ in terms of Poisson brackets of some functions on symplectic space.

Let η_b^{ia} be a set of complex variables satisfying the Hermiticity condition

$$\eta_b^{ia*} = \eta_a^{ib}. \tag{29}$$

Here, $i = 1,\ldots,M$ and $a,b = 1,\ldots,N_c$ for some positive integer N_c. We will consider only the case of even M. (The indices a and b will be called color indices, since we will soon see an analogy to Yang–Mills theory.) Now impose the Poisson brackets

$$\{\eta_b^{ia}, \eta_d^{jc}\} = \omega^{ij}\delta_d^a\delta_b^c. \tag{30}$$

Thus we are just considering the real vector space $R^{MN_c^2}$ with a symplectic form that is invariant under the adjoint action of $U(N_c)$. Now consider the space of polynomials invariant under the adjoint action of $U(N_c)$. A basis for this space is labeled by a discrete loop $I: Z_m \to \{1,2,\ldots,M\}$:

$$f^I(\eta) = \mathrm{Tr}\ \eta^{i_1}\eta^{i_2},\ldots,\eta^{i_m}. \tag{31}$$

The cyclic symmetry of the trace assures us that f^I is independent of the starting point of the loop I. Moreover,

$$f^{I*} = f^{\bar{I}}. \tag{32}$$

This implies that the coefficients a_I of an element $a = \Sigma a_I f^I$ are complex numbers satisfying $a_I^* = a_{\bar{I}}$.

Now it is a simple matter to verify that the Poisson brackets of these functions provide a realization of the Lie algebra $\mathscr{V}_M^+$:

$$\{f^I, f^J\} = \sum_{kl}\ \omega^{i_k, j_l} f^{I\circ_{k,l}J}. \tag{33}$$

The analogy of this realization with the Poisson brackets of the Wilson loops is obvious.

At the level of the group, we also have an action of the group on invariant polynomials of the variables η^j by a sort of "pull-back":

$$\phi^*(h)(\eta) = h(\psi(\eta)), \tag{34}$$

where ψ is the inverse of ϕ and

$$[\psi(\eta)]^i = \sum_{m=1}\ \psi^i_{i_1,\ldots,i_m}\eta^{i_1},\ldots,\eta^{i_m} \tag{35}$$

matrix multiplication being implied on the right-hand side. If we restrict to the subgroup G_M^+ the matrix valued function $\omega_{ij}\eta^i\eta^j$ is invariant under this action. This ''symplectic distance'' function has an obvious meaning in this realization: it is the generator of infinitesimal gauge transformations. If u is a constant anti-Hermitian matrix,

$$\{\mathrm{Tr}\ u\omega_{ij}\eta^i\eta^j, \eta^k\} = [u, \eta^k] \tag{36}$$

so that the traces $f^{i_1,\ldots,i_m}$ are invariant under this action.

Clearly if the number of ''colors'' N_c is one, the realization described above has a large kernel. The variables η^i then satisfy the relation

$$\eta^i\eta^j - \eta^j\eta^i = 0 \tag{37}$$

since they commute. The functions f^I then satisfy the ''Mandelstam identity''

$$f^{I\circ_{kl}J} - f^I f^J = 0 \tag{38}$$

relative to any way of multiplying the two loops I and J at points k and l. More generally, there will be an identity that says that the antisymmetric part in N_c+1 indices is zero; these are the finite analogs of the Mandelstam identities. For simplicity, let us state the $N_c=2$ case:

$$f^{I_1\circ I_2\circ I_3} + f^{I_1\circ I_3\circ I_2} - f^{I_1\circ I_2} f^{I_3} - f^{I_1\circ I_3} f^{I_2} - f^{I_2\circ I_3} f^{I_1} + f^{I_1} f^{I_2} f^{I_3} = 0. \tag{39}$$

Here, I_1 actually denotes the set $i_1, i_2, \ldots, i_{k_1}$, I_2 denotes $j_1, \ldots, j_{k_2}$ and I_3 refers to $l_1, \ldots, l_{k_3}$. The circles are the products we introduced which corresponds to combining the corresponding sequences. Similarly, one can see that writing the all possible antisymmetric combinations and taking the trace, we get a relation satisfied by N_c+1 generators of the representation. This gives us combinations of generators with all possible permutations multiplied with the appropriate sign of the permutation. If we take the cycle decomposition of a permutation π of N_c+1 numbers, and denote each cycle as π_k, we can write the result as

$$\sum_{\pi} (-1)^{\pi} f^{I_{\pi_1}} f^{I_{\pi_2}}, \ldots, f^{I_{\pi_s}} = 0, \tag{40}$$

where we used a short hand $f^{I_{\pi_k}}$ to denote $f^{I_{l_{r_{k-1}}}\circ,\ldots,\circ I_{l_{r_k}}}$. Here the length of the cycle π_k is given by $r_k - r_{k-1}$ and circles again correspond to products.

These are precisely the analogs of the identities satisfied by the Wilson loop for finite N_c (see Ref. 2). They simply describe the fact that f^I is the trace of an $N_c \times N_c$ matrix. As $N_c \to \infty$ these identities should disappear which must be a reason for the simplicity of the large-N_c limit.

We remark that if we introduce Grassmann variables ψ_b^{ia} which anticommute,

$$\psi_b^{ia}\psi_d^{jc} + \psi_d^{jc}\psi_b^{ia} = 0 \tag{41}$$

and satisfy the super-Poisson bracket

$$\{\psi_b^{ia}, \psi_d^{jc}\} = g^{ij}\delta_d^a\delta_b^c \tag{42}$$

we also have a supersymplectic realization of $\mathscr{V}_M^-$:

$$G^I \mapsto \mathrm{Tr}\ \psi^{i_1}, \ldots, \psi^{i_m}. \tag{43}$$

Clearly these G^I are cyclically antisymmetric and a short computation will show that their super-Poisson brackets form a realization of $\mathscr{V}_M^-$. By replacing the above Grassmann algebra by a Clifford algebra:

$$\psi_b^{ia} * \psi_d^{jc} + \psi_d^{jc} * \psi_b^{ia} = \hbar g^{ij} \delta_d^a \delta_b^c \tag{44}$$

we also have a quantum deformation for $\mathscr{V}_M^-$, analogous to the one in the Sec. V.

V. FREE ORTHOGONAL ALGEBRA

Let us consider the SO(N_c) Yang–Mills theory, and obtain a similar formalism of loops. If we think of SO(N_c) as the real part of U(N_c), then Wilson loops satisfy

$$W[\xi] = W[\bar{\xi}], \quad W^*[\xi] = W[\xi]. \tag{45}$$

The loop algebra should also reflect this symmetry, therefore for SO(N_c) Yang–Mills theory, we obtain the result

$$\{W[\xi_1], W[\xi_2]\} = \int ds\ dt (\dot{\xi}_1^i(s)\dot{\xi}_2^j(t)\omega_{ij}(\xi_1(s), \xi_2(t)) W[\xi_1 \circ_{st} \xi_2] + \dot{\xi}_1^i(s)\dot{\bar{\xi}}_2^j(t)\omega_{ij}(\xi_1(s), \bar{\xi}_2(t)) W[\xi_1 \circ_{st} \bar{\xi}_2]).$$

One can see that the algebra is invariant under $\xi \leftrightarrow \bar{\xi}$.[2]

We will see that the real subalgebra of the unitary algebra is in fact the above algebra of Wilson loops. The real form can be obtained by imposing the conditions

$$v_I = v_{\bar{I}}, \quad v_I^* = v_I \tag{46}$$

for the coefficients of an element $v = \Sigma v_I F^I$. One can check that a basis for them is given by

$$H^I = F^I + F^{\bar{I}}. \tag{47}$$

We can now calculate the commutator of these basis elements;

$$[H^I, H^J] = \sum_{k,l} \omega^{i_k j_l} (F^{I \circ_{kl} J} + F^{I \circ_{kl} \bar{J}} + F^{\bar{I} \circ_{kl} J} + F^{\bar{I} \circ_{kl} \bar{J}}), \tag{48}$$

using the previous result on the commutators of F^I's. Due to the cyclic symmetry we can show that $F^{I \circ_{kl} J} = F^{\bar{I} \circ_{kl} \bar{J}}$. Thus the above expression can be reorganized as

$$[H^I, H^J] = \sum_{kl} \omega^{i_k j_l} (H^{I \circ_{kl} J} + H^{I \circ_{kl} \bar{J}}). \tag{49}$$

This also shows explicitly that the above set of elements constitute a subalgebra. We will also briefly describe a symplectic realization of the above algebra. Let us consider the real symmetric matrices η_b^{ia}, where $i = 1,2,\ldots,M$ and $a,b = 1,2,\ldots,N_c$, with the Poisson bracket

$$\{\eta_b^{ia}, \eta_d^{jc}\} = \omega^{ij}(\delta_d^a \delta_b^c + \delta^{ac} \delta_{bd}). \tag{50}$$

If we define the SO(N_c) invariant polynomials,

$$h^I = \mathrm{Tr}\ \eta^{i_1} \eta^{i_2}, \ldots, \eta^{i_n} \tag{51}$$

they provide a symplectic realization of the above algebra. We have the condition $h^I = h^{\bar{I}}$ and the Mandelstam constraints as the kernel of this realization.

It is also possible to discuss the deformation of this symplectic realization but we will only consider the more physically relevant case of unitary algebras. The derivation given below can be extended to the orthogonal case.

VI. QUANTUM DEFORMATION

It is interesting to see what happens to the above realization upon quantization. One approach to quantization is the deformation of the commutative product of the functions of η_b^{ia} by the so-called Moyal product:

$$f*g(\eta)=[e^{-i(\hbar/2)\omega^{ij}(\partial/\partial\eta_b^{ia})(\partial/\partial\eta_a'^{jb})}f(\eta)g(\eta')]_{\eta=\eta'}. \tag{52}$$

(This particular definition of the product corresponds to Weyl ordering.[7]) If we apply this multiplication rule to the $U(N_c)$-invariant polynomials f^I, we will get a noncommutative associative algebra. The commutator of this multiplication defines a Lie algebra, which is a quantum deformation of our loop algebra $\mathscr{Y}_M^+$. To first order in $\hbar$ this commutator is just the Poisson bracket, so that in this limit we recover the previous algebra as a contraction of the quantum algebra. But the general answer is quite formidable, at each order r in $\hbar$, there will be terms involving up to r products of loops.

On the other hand, it is to be expected that some simplifications will occur in the limit as $N_c\to\infty$. The point is that the leading contribution will come from terms where there are the largest number of possible independent traces, so that we must keep the terms with the largest number of loops. All the other terms are subleading order. Nevertheless, it turns out that there is such a term of leading order in $1/N_c^2$ at each order in $\hbar$; the limit $N_c\to\infty$ is quite different from the limit $\hbar\to 0$. But this is also a ''classical'' limit in that the commutators of color invariant observables is of order $1/N_c^2$, so that they become simultaneously measurable in the limit $N_c\to\infty$. It is of utmost importance to understand the large-N_c limit of gauge theories; our discussion identifies the canonical structure (Poisson brackets of loop variables) of color singlet observables in the large-N_c limit.

Let us now calculate the deformed brackets more explicitly. First of all note that

$$\frac{\partial f^I}{\partial\eta_b^{ka}}=0 \tag{53}$$

unless k is equal to one of the elements of the loop $\{i_1,i_2,\ldots,i_m\}$. In the case $k=i_\mu$ for some $\mu=1,2,\ldots,m$,

$$\frac{\partial f^I}{\partial\eta_b^{i_\mu a}}=[\eta^{i_{\mu+1}}\eta^{i_{\mu+2}},\ldots,\eta^{i_m}\eta^{i_1},\ldots,\eta^{i_{\mu-1}}]_a^b. \tag{54}$$

Thus differentiation with respect to η^{i_μ} cuts the loop at the point with parameter value μ.

More generally,

$$\frac{\partial^r f^I}{\partial\eta_{b_1}^{k_1a_1},\ldots,\partial\eta_{b_r}^{k_ra_r}}=0 \tag{55}$$

unless the set $\{k_1,k_2,\ldots,k_r\}$ is a subset of the set $\{i_1,i_2,\ldots,i_m\}$. Suppose $\{\mu_1,\mu_2,\ldots,\mu_r\}\subset\{1,2,\ldots,m\}$ and moreover that $\mu_1<\mu_2,\ldots,<\mu_r$. Then we can see that

$$\frac{\partial^r f^I}{\partial \eta^{i_{\mu_1} a_1}_{b_1},\ldots,\partial \eta^{i_{\mu_r} a_r}_{b_r}} = [\,\eta^{i_{\mu_1+1}}\eta^{i_{\mu_1+2}},\ldots,\eta^{i_{\mu_2-1}}]^{b_1}_{a_1}$$
$$\times [\,\eta^{i_{\mu_2+1}}\eta^{i_{\mu_2+2}},\ldots,\eta^{i_{\mu_3-1}}]^{b_2}_{a_2}\cdots[\,\eta^{i_{\mu_r+1}}\eta^{i_{\mu_r+2}},\ldots,\eta^{i_{\mu_1-1}}]^{b_r}_{a_r}$$

which corresponds to cutting the loop at points $\mu_1,\mu_2,...,\mu_r$. It is clearly convenient to introduce the matrix, for $\mu_1<\mu_2\in\{1,2,...,m\}$:

$$P^b_a(I(\mu_1,\mu_2)) = [\,\eta^{i_{\mu_1+1}}\eta^{i_{\mu_1+2}},\ldots,\eta^{i_{\mu_2-1}}]^b_a, \tag{56}$$

which represents the parallel transport operator for the piece of the loop I from μ_1 to μ_2. Then, for $\mu_1<\mu_2,...,<\mu_r$,

$$\frac{\partial^r f^I}{\partial \eta^{i_{\mu_1} a_1}_{b_1},\ldots,\partial \eta^{i_{\mu_r} a_r}_{b_r}} = P^{b_1}_{a_1}(I(\mu_1,\mu_2))P^{b_2}_{a_2}(I(\mu_2,\mu_3)),\ldots,P^{b_r}_{a_r}(I(\mu_r,\mu_1)).$$

Now let us consider the general term in the definition of the deformed product of color invariant functions of the η:

$$f^I * f^J = f^I f^J + \sum_{r=1}^{\infty} \frac{1}{r!}\left(-\frac{i\hbar}{2}\right)^r \omega^{i_{\mu_1} j_{\nu_1}},\ldots,\omega^{i_{\mu_r} j_{\nu_r}} \frac{\partial^r f^I}{\partial \eta^{i_{\mu_1} a_1}_{b_1},\ldots,\partial \eta^{i_{\mu_r} a_r}_{b_r}} \frac{\partial^r f^J}{\partial \eta^{j_{\nu_1} b_1}_{a_1},\ldots,\partial \eta^{j_{\nu_r} b_r}_{a_r}}.$$

We can, using the symmetry of the derivatives, and relabeling of indices, always bring the indices in the first derivative factor to the order $\mu_1<\mu_2,...,<\mu_r$. However, once this is done, there is no reason that the indices $\nu_1,\nu_2,...,\nu_r$ are in any particular order. This is because the contraction of the color indices links μ_k to ν_k. Thus, the general term in the series will involve quite complicated ways of contracting the color indices.

In the large-N_c limit, however, the leading term will have the largest number of traces. This will happen when the ν indices are in *decreasing* order: $\{\nu_1>\nu_2,...,>\nu_r\}$. (Of course, the ordering we use is a cyclic ordering; i.e., $\mu_1>\mu_2,...,\mu_r$ means also $\mu_2>\mu_3,...,\mu_r>\mu_1$, etc.) This is the term that involves a product of r Wilson loops, so that

$$f^I * f^J = f^I f^J + \sum_{r=1}^{\infty} \sum_{\substack{\mu_1<\mu_2,\ldots,<\mu_r \\ \nu_1>\nu_2,\ldots,>\nu_r}} \times\left(-\frac{i\hbar}{2}\right)^r \omega^{i_{\mu_1} j_{\nu_1}},\ldots,\omega^{i_{\mu_r} j_{\nu_r}} f^{I(\mu_1,\mu_2)J(\nu_2,\nu_1)} f^{I(\mu_2,\mu_3)J(\nu_3,\nu_2)}\cdots f^{I(\mu_r,\mu_1)J(\nu_1,\nu_r)} + \cdots .$$

Here $I(\mu_1,\mu_2)J(\nu_2,\nu_1)$, e.g., is the loop $i_{\mu_1+1}i_{\mu_1+2},\ldots,i_{\mu_2-1}j_{\nu_2+1},\ldots,j_{\nu_1-1}$.

Now, as the large-N_c limit is taken, we usually have to multiply physical quantities by some N_c-dependent factor, in order that the limit be well-defined. The proper normalization of f^I, e.g., is not obvious. We propose that f^I be normalized such that its vacuum expectation value remains finite in the limit. Now the vacuum expectation value depends on the choice of the Hamiltonian, which we have not made yet. The simplest case would be a quadratic function, $H=g_{ij}\,\mathrm{Tr}\,\eta^i\eta^j$. (This corresponds to having a free theory; if the coupling constants in the interacting case are scaled properly by powers of N_c as well, the counting rules in powers of N_c will not be affected.) The vacuum expectation value of a product of two η's is then $\langle \eta^{ia}_b \eta^{jc}_d\rangle = \epsilon^{ij}\delta^a_d\delta^c_b$. (Here ϵ^{ij} is a tensor built from g_{ij} and ω_{ij} whose explicit form is not necessary.) The vacuum expectation value of the product of an odd number of η's will vanish; for an even number of η's it is given by the

Wick formula. A short calculation will show that, for even m, the expectation value of f^I is of order $N_c^{m/2+1}$. This is independent of the particular form of the Hamiltonian.

Thus we define the normalized functions

$$\tilde{f}^I = \frac{1}{N_c^{m/2+1}} f^I. \tag{57}$$

Now one can check that

$$\tilde{f}^I * \tilde{f}^J = \tilde{f}^I \tilde{f}^J + \frac{1}{N_c^2} \sum_{r=1}^{\infty} \sum_{\substack{\mu_1 < \mu_2, \ldots, < \mu_r \\ \nu_1 > \nu_2, \ldots, > \nu_r}} \left(-\frac{i\hbar}{2} \right)^r \omega^{i\mu_1 j\nu_1}, \ldots, \omega^{i\mu_r j\nu_r} \tilde{f}^{I(\mu_1,\mu_2)J(\nu_2,\nu_1)}$$

$$\times \tilde{f}^{I(\mu_2,\mu_3)J(\nu_3,\nu_2)} \cdots \tilde{f}^{I(\mu_r,\mu_1)J(\nu_1,\nu_r)} + O\left(\frac{1}{N_c^3} \right).$$

Thus the pointwise product is again the leading contribution in the large-N_c limit.

The commutator of the $\tilde{f}^I$'s is of order $1/N_c^2$. This is consistent with the idea that the large-N_c limit is a classical theory, with $1/N_c^2$ measuring the size of the quantum corrections: analogous to the $\hbar$ of the conventional classical limit. Indeed, the Poisson algebra of the large-N_c limit of (regularized) Yang–Mills theory is

$$\{\tilde{f}^I, \tilde{f}^J\}_* = 2i \sum_{r=1,\text{odd}}^{\infty} \sum_{\substack{\mu_1 < \mu_2, \ldots, < \mu_r \\ \nu_1 > \nu_2, \ldots, > \nu_r}} \left(-\frac{i\hbar}{2} \right)^r \omega^{i\mu_1 j\nu_1}, \ldots, \omega^{i\mu_r j\nu_r} \tilde{f}^{I(\mu_1,\mu_2)J(\nu_2,\nu_1)}$$

$$\times \tilde{f}^{I(\mu_2,\mu_3)J(\nu_3,\nu_2)} \cdots \tilde{f}^{I(\mu_r,\mu_1)J(\nu_1,\nu_r)}.$$

The Poisson manifold defined by these relations is the phase space of the large-N_c limit of Yang–Mills theory. It is quite different from the phase space of the conventional classical limit. (This is in fact quite typical of such large-N_c limits.) We believe that the above Poisson algebra plays a fundamental role in the physics of strongly interacting particles.

Zero modes of rotationally symmetric vortices in a hierarchy of generalized Abelian Higgs models are studied. Under the finite energy and the smoothness condition, it is shown, that in all models, n self-dual vortices superimposed at the origin have $2n$ modes. The relevance of these modes for vortex scattering is discussed: first, in the context of the slow-motion approximation; second, a corresponding Cauchy problem for an all head-on collision of n vortices is formulated. It is shown that the solution of this Cauchy problem has a π/n symmetry. © *1996 American Institute of Physics.* [S0022-2488(96)03301-6]

I. INTRODUCTION

Since their discovery,[1] vortices in the Abelian Higgs model have attracted much attention. This is mainly due to the fact that the static solutions of this model describe flux tubes in superconductors. As objects in two-dimensional space, they also provide simple examples of topologically nontrivial structures. Recently, the Abelian Higgs model was generalized, and rotationally symmetric vortices were found in these models.[2] The *generalized* Abelian Higgs models form a hierarchy of two-dimensional $U(1)$ models labeled by an integer parameter p. The significance of p is that the pth member of this hierarchy has been derived by subjecting the pth member of the hierarchy of the $4p$-dimensional scale-invariant SO($4p$) Yang–Mills models to dimensional descent.[3] The $p=1$ members of both these hierarchies are the usual Abelian Higgs model and the Yang–Mills model in 2 and 4 dimensions, respectively.

A mathematically rigorous proof for the existence and uniqueness of the rotationally symmetric self-dual vortices of the hierarchy of generalized Abelian Higgs models was subsequently given in Ref. 4. These rotationally symmetric solutions describe vortices superimposed at the origin, and provide us with objects qualitatively similar to, but quantitatively different from the vortices in the Abelian Higgs model. In the case of the Abelian Higgs model, actually, a $2n$-parameter family of vortices exists.[5] In this article, we show that, at least near the rotationally symmetric vortices, there is also a $2n$-parameter family of generalized vortices.

In the Abelian Higgs model, the knowledge gained from the study of the zero modes has been used to investigate the scattering of vortices. Vortex scattering has been studied in the context of the slow-motion approximation,[6] and with the help of the theory of partial differential equations.[7] Among the most interesting processes studied is 90° scattering of two vortices in a head-on collision (or its generalization: π/n scattering in all head-on collisions of n vortices). We will show that some of the results, in particular the π/n symmetry of the scattering process, generalize to generalized vortices.

The paper is organized as follows. In Sec. II, we highlight those aspects of the generalized

Abelian Higgs models, and of their rotationally symmetric vortices, important to our discussion of the zero modes. In Sec. III, following steps taken by Weinberg in the case of the Abelian Higgs model,[8] we derive the fluctuation equations for rotationally symmetric generalized vortices. We show that these equations have a $2n$-parameter family of smooth finite-energy solutions. In Sec. IV, the scattering of n generalized vortices shortly before and after they form a rotationally symmetric vortex is discussed, first, briefly, in the context of the slow-motion approximation. A corresponding Cauchy problem is then formulated. It is shown that its solution has a π/n symmetry.

II. THE MODELS AND THEIR RADIALLY SYMMETRIC SOLUTIONS

The models we study are the generalized Abelian Higgs models in $(2+1)$-dimensional space–time, given by the Lagrangian densities

$$\begin{aligned}\mathscr{L}^{(p)}=&(\eta^2-|\phi|^2)^{2(p-2)}([(\eta^2-|\phi|^2)F_{\mu\nu}+\iota(p-1)D_{[\mu}\phi^*D_{\nu]}\phi]^2\\&+4p(2p-1)(\eta^2-|\phi|^2)^2|D_\mu\phi|^2+2(2p-1)^2(\eta^2-|\phi|^2)^4)\end{aligned}\tag{1}$$

for any integer $p>1$. For $p=1$, Eq. (1) reduces to the usual Abelian Higgs model. ϕ is the complex Higgs field, $D_\mu\phi=\partial_\mu\phi+\iota A_\mu\phi$, $\mu=0,1,2$, is the covariant derivative, and the gauge fields $F_{\mu\nu}$ are defined in terms of the real gauge potentials A_μ as $F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu=\partial_{[\mu}A_{\nu]}$ $\mu,\nu=0,1,2$. The square brackets mean antisymmetrization in the indices. For any tensor $T_{\mu\nu,\ldots}$, $(T_{\mu\nu,\ldots})^2$ means $T_{\mu\nu,\ldots}T^{\mu\nu,\cdots}$. The indices are raised and lowered with the metric tensor $g=\mathrm{diag}$ $(-1,+1,+1)$. Our task is to find, and study, smooth finite-energy solutions of the corresponding Euler–Lagrange equations.

As in the case of the Abelian Higgs model, the Euler–Lagrange equations of the generalized Abelian Higgs models are solved by certain first-order equations. For the Abelian Higgs model, these equations were found by Bogomol'nyi.[9] For the Lagrangian (1), the first-order equations arise as follows: In the case $A_0=0$, and for time-independent Higgs field and gauge potentials, the Lagragian can be written in the form $\mathscr{L}^{(p)}=I^2+J^2+\epsilon_{ij}\partial^i\Omega^j$, where I^2 and J^2 are the positive definite terms

$$I^2=(\eta^2-|\phi|^2)^{2(p-2)}(((\eta^2-|\phi|^2)F_{ij}+\iota(p-1)D_{[i}\phi^*D_{j]}\phi)-(2p-1)\epsilon_{ij}(\eta^2-|\phi|^2)^2)^2,\tag{2}$$

$$J^2=2p(2p-1)(\eta^2-|\phi|^2)^{2(p-1)}|D_i\phi-\iota\epsilon_{ij}D^j\phi|^2,\tag{3}$$

and where

$$\Omega^j=4(2p-1)\eta^{2(2p-1)}A^j+\sum_{s=1}^{2p-1}\frac{4\iota}{s}(2p-1)^2\eta^{2(2p-1-s)}\binom{2p-2}{s-1}(-|\phi|^2)^{s-1}\phi^*D^j\phi.\tag{4}$$

The special structure of the Lagrangian $\mathscr{L}^{(p)}$ is no accident, but arises naturally through dimensional reduction of the generalized Yang–Mills model on $R^2\times S^{4p-2}$.[2] The divergence $\epsilon_{ij}\partial^i\Omega^j$ is the dimensionally reduced form of the Chern–Pontryagin density. $I=0$ and $J=0$ stem from the self-duality equations of the generalized Yang–Mills theory.[3] Setting I and J equal to zero means minimizing the energy in a given tological sector, and yields the desired first-order equations. We have simplified the task of finding time-independent solutions with $A_0=0$, to solving the following equations:

$$(\eta^2-|\phi|^2)F_{ij}+\iota(p-1)D_{[i}\phi^*D_{j]}\phi=(2p-1)\epsilon_{ij}(\eta^2-|\phi|^2)^2,\tag{5}$$

$$D_i\phi=\iota\epsilon_{ij}D^j\phi.\tag{6}$$

For the rotationally symmetric ansatz,

$$\phi = \eta g(r) \exp(-\imath n \theta), \tag{7}$$

$$A_i = \epsilon_{ij} x^j \frac{a(r)-n}{r^2}, \tag{8}$$

with integer vortex number n, Eqs. (5) and (6) reduce to

$$(1-g^2)\frac{da}{dr} = \frac{2}{r}(p-1)a^2 g^2 - \eta^2(2p-1)r(1-g^2)^2, \tag{9}$$

$$\frac{dg}{dr} = \frac{ag}{r}. \tag{10}$$

In Ref. 3, for all n, existence and uniqueness of a solution to these equations with the desired asymptotic behavior was shown. For small r, a goes to n, and g goes like $C_n r^n$, where the C_n are constants which have to be determined numerically. For large r, g goes to 1, and $a/(1-g^2)$ goes like $\sqrt{(2p-1)/(2p)}\,\eta r$. In Sec. III, we will study the zero modes of these rotationally symmetric solutions.

III. THE FLUCTUATION EQUATIONS AND THE ZERO MODES

We write the fluctuations about the rotationally symmetric solutions in the following form:

$$\delta\phi = \eta g(r) h(r,\theta) \exp(-\imath n \theta), \tag{11}$$

$$\delta A_1 = \frac{1}{r}(-b(r,\theta)\sin\theta + c(r,\theta)\cos\theta), \tag{12}$$

$$\delta A_2 = \frac{1}{r}(b(r,\theta)\cos\theta + c(r,\theta)\sin\theta). \tag{13}$$

Here, b and c are real functions, and $h = h^1 + \imath h^2$ is a complex function. To count the number of modes, we will later fix the gauge by setting h^2 equal to zero. To discuss the smoothness of the modes, we will have to use the gauge freedom and find suitable functions h^2.

Equations (5) and (6), linearized in the functions h, b, and c, then yield the fluctuation equations. Equation (6) leads to expressions for the functions b and c in terms of the function h:

$$b = -r\frac{\partial h^1}{\partial r} - \frac{\partial h^2}{\partial \theta}, \tag{14}$$

$$c = \frac{\partial h^1}{\partial \theta} - r\frac{\partial h^2}{\partial r}. \tag{15}$$

Using these expressions, we obtain from Eq. (5) the following equation for h:

$$\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial h^1}{\partial r}\right) + \frac{1}{r^2}\frac{\partial^2 h^1}{\partial \theta^2} - \frac{4(p-1)ag^2}{r(1-g^2)}\frac{\partial h^1}{\partial r} - g^2\left(2(2p-1)\eta^2 + \frac{4(p-1)a^2}{r^2(1-g^2)^2}\right)h^1 = 0. \tag{16}$$

Note that h^2 does not occur in Eq. (16). Therefore, the finite-energy solutions of Eq. (16), which lead to smooth fields in a suitable gauge, yield the zero modes. There are no other modes, since we can impose the gauge condition, $h^2=0$.

We attempt to solve Eq. (16) in terms of a Fourier series for h^1,

$$h^1(r,\theta)=\sum_{k=0}^{\infty}(h_k^{(1)}(r)\cos k\theta+h_k^{(2)}(r)\sin k\theta). \tag{17}$$

The Fourier coefficient functions $h_k^{(i)}$ have to satisfy the equation

$$\frac{d^2h_k^{(i)}}{dr^2}+\left(\frac{1}{r}-\frac{4(p-1)ag^2}{r(1-g^2)}\right)\frac{dh_k^{(i)}}{dr}-\left(\frac{k^2}{r^2}+2(2p-1)\eta^2g^2+\frac{4(p-1)a^2g^2}{r^2(1-g^2)^2}\right)h_k^{(i)}=0. \tag{18}$$

We want to find all solutions such that, in a suitable gauge, the rotationally symmetric background fields plus the fluctuations are C^∞ functions on R^2 with finite energy.

For small r, Eq. (18) reduces to $r^2y''+ry'=k^2y$, where $y=h_k^{(i)}$. The general solution to this equation is $y=c_1r^k+c_2r^{-k}$ for $k>0$, and $y=c_1+c_2\ln r$ for $k=0$. The uniqueness of radially symmetric vortices rules out nontrivial fluctuations for $k=0$. (We assume here that the uniqueness result, rigorously proven in Ref. 4 for $p=2$, is in fact true for all p.) For large r,

$$y''-(p-1)\sqrt{\frac{8(2p-1)}{p}}\,\eta y'-\frac{2(2p-1)^2}{p}\,\eta^2y=0 \tag{19}$$

holds, with the general solution

$$y=c_3\exp\left(\sqrt{\frac{2}{p}}\,(2p-1)^{3/2}\eta r\right)+c_4\exp\left(-\sqrt{\frac{2(2p-1)}{p}}\,\eta r\right). \tag{20}$$

Because of the finite-energy condition, we have to set $c_3=0$. c_4 is an arbitrary coefficient. One can now show that all exponentially decreasing solutions at infinity lead to solutions at the origin with $c_2\neq0$. Assume the contrary: Then for $c_4>0$ there must be a maximum with positive y. However, Eq. (18) shows that, when the first derivative vanishes, the second derivative is positive. This is a contradiction. (An analogous argument holds when c_4 is negative and y has to attain a minimum.) Hence, acceptable nontrivial behavior at infinity leads to an r^{-k} term at the origin. For $k>n$ this implies that the energy is infinite.

We are left with the $2n$ modes $h_k^{(i)}$ (with all the other $h_l^{(j)}$, for $j\neq i$ or $l\neq k$, equal to zero) for $0<k\leqslant n$ and $i=1,2$. Supplemented with suitable functions h^2, these modes lead to the following smooth finite-energy solutions: For the first set of n functions, the fluctuations are of the form

$$\delta\phi=\eta g(r)h_k^{(1)}(r)\exp(-\iota(n-k)\theta), \tag{21}$$

$$\delta A_1=-\left(\frac{dh_k^{(1)}}{dr}+\frac{k}{r}\,h_k^{(1)}\right)\sin((k-1)\theta), \tag{22}$$

$$\delta A_2=-\left(\frac{dh_k^{(1)}}{dr}+\frac{k}{r}\,h_k^{(1)}\right)\cos((k-1)\theta). \tag{23}$$

For the second set of n functions, the fluctuations are of the form

$$\delta\phi=-\iota\eta g(r)h_k^{(2)}(r)\exp(-\iota(n-k)\theta), \tag{24}$$

$$\delta A_1 = \left(\frac{dh_k^{(2)}}{dr} + \frac{k}{r} h_k^{(2)} \right) \cos((k-1)\theta), \tag{25}$$

$$\delta A_2 = -\left(\frac{dh_k^{(2)}}{dr} + \frac{k}{r} h_k^{(2)} \right) \sin((k-1)\theta). \tag{26}$$

IV. SYMMETRIES AND VORTEX SCATTERING

In the Abelian Higgs model, the zero modes can be used to study vortex scattering in the context of the slow-motion approximation.[10] The idea of this approximation is that for low velocities, at each point in time the fields A_1, A_2, and ϕ are given by one of the static solutions; i.e., as an ansatz for these functions one can choose the family of static solutions after making the parameters time dependent. A_0 is then determined from its equation of motion, which is of zero order in t. Finally, with this ansatz the action is minimized.

For our purpose, this idea can be implemented as follows. Near the rotationally symmetric vortices, we expand the fields

$$\phi^i = \hat{\phi}^i + s^i(t)\,\delta\phi^i, \quad A^i = \hat{A}^i + s^{2+i}(t)\,\delta A^i. \tag{27}$$

Here, $\hat{\phi} = \hat{\phi}^1 + \iota\hat{\phi}^2$ and $\hat{A}^i$ are the static solutions (7) and (8). $\delta\phi^i$ and δA^i are the fluctuations (21), (22), and (23) or (24), (25), and (26). The equation, which has to be solved for A_0, is the first (for $\nu=0$) of the following three equations:

$$\begin{aligned} &\partial_\mu((\eta^2-|\phi|^2)^{2p-3}((\eta^2-|\phi|^2)F^{\mu\nu}+\iota(p-1)D^{[\mu}\phi^*D^{\nu]}\phi))+(p-1)(\eta^2-|\phi|^2)^{2p-4} \\ &\quad\times(((\eta^2-|\phi|^2)F^{\mu\nu}+\iota(p-1)D^{[\mu}\phi^*D^{\nu]}\phi)(\phi^*D_\mu\phi+\phi D_\mu\phi^*))-\iota p(2p-1) \\ &\quad\times(\eta^2-|\phi|^2)^{2p-2}(\phi D^\nu\phi^*-\phi^*D^\nu\phi)=0. \end{aligned} \tag{28}$$

[The other two equations (for $\nu=1,2$) are the second-order equations of motion for A_1 and A_2, which we will need later.]

The dynamics, as described by the functions $s^\alpha(t)$, is now given by the Lagrange function

$$\begin{aligned} L^{(p)} = \int_{R^2} &(\eta^2-|\phi|^2)^{2(p-2)}(2((\eta^2-|\phi|^2)F_{0i}+\iota(p-1)D_{[0}\phi^*D_{i]}\phi)^2 \\ &+4p(2p-1)(\eta^2-|\phi|^2)^2|D_0\phi|^2)d^2x. \end{aligned} \tag{29}$$

The functions s^α are found by solving the Euler–Lagrange equations of this Lagrange function. Obviously, the slow-motion approximation still leaves us with very complicated equations to solve. With our ansatz (27), however, we only attempt to study the neighborhood of rotationally symmetric vortices; i.e., we can neglect higher order terms in the functions s^α. Even though we are allowed to linearize in s^α, we were not able to solve Eq. (28) for $\nu=0$.

In the Abelian Higgs model, the Gauss equation corresponds to Eq. (28) for $\nu=0$. Following the same steps we have just discussed for our models, in the Abelian Higgs model one finds that $A_0=0$, and that the s^α are functions linear in time, in the neighborhood of the rotationally symmetric vortices. For the modes with real smooth $\delta\phi$ this implies π/n scattering, if only times shortly before and shortly after the vortices coincide are considered. We see that the slow-motion approximation yields more results in the Abelian Higgs model. Another difference between the models discussed here and the Abelian Higgs model is that in the Abelian Higgs model the validity of the slow-motion approximation has been rigorously proven.[11]

Instead of pursuing the slow-motion approximation any further, we will now formulate a corresponding Cauchy problem and use the symmetries to study the full Euler–Lagrange equations of the Lagrangian (1). We work with the vector $\psi^T=(A_0,\partial_t A_0,A_1,\partial_t A_1,A_2,\partial_t A_2,\phi,\partial_t\phi)$, and impose the following initial conditions:

$$\psi(0,\mathbf{x})^T=(\hat{A}_0,0,\hat{A}_1,\delta A_1,\hat{A}_2,\delta A_2,\hat{\phi},\delta\phi). \tag{30}$$

Here $\hat{\phi}$ and $\hat{A}_i$ are the static solutions (7) and (8). $\delta\phi$ and δA_i are the fluctuations (21), (22), and (23) for $k=n$. We concentrate on this type of fluctuation for simplicity, and because they lead to the interesting π/n symmetry in the n vortex scattering process. $\hat{A}_0$ is the solution of Eq. (28) for $\nu=0$ at time $t=0$.

The equations of motion for ϕ and A_μ we consider are the following second-order equations. The second-order equation for A_0 is $\partial_{tt}A^0+\partial_i\partial_t A^i=0$. (This equation follows from the Lorentz condition $\partial_\mu A^\mu=0$.) The second-order equations for A_1 and A_2 are given by Eq. (28) for $\nu=1,2$. The second-order equation for ϕ is its Euler–Lagrange equation,

$$\begin{aligned}
&\iota\partial_\mu((\eta^2-|\phi|^2)^{2p-4}[(\eta^2-|\phi|^2)F^{\nu\mu}+\iota(p-1)D^{[\nu}\phi^*D^{\mu]}\phi](p-1)D_\nu\phi^*+p(2p-1)\\
&\quad\times(\eta^2-|\phi|^2)^2D^\mu\phi^*)+\tfrac{1}{2}(p-2)(\eta^2-|\phi|^2)^{2p-3}([(\eta^2-|\phi|^2)F_{\mu\nu}+\iota(p-1)D_{[\mu}\phi^*D_{\nu]}\phi]^2\\
&\quad+4p(2p-1)(\eta^2-|\phi|^2)^2|D_\mu\phi|^2+2(2p-1)^2(\eta^2-|\phi|^2)^4)\phi^*-\tfrac{1}{2}(\eta^2-|\phi|^2)^{2(p-2)}\\
&\quad\times(((\eta^2-|\phi|^2)F^{\mu\nu}+\iota(p-1)D^{[\mu}\phi^*D^{\nu]}\phi)(F_{\mu\nu}\phi^*-(p-1)A_{[\mu}D_{\nu]}\phi^*)-2p(2p-1)\\
&\quad\times(\eta^2-|\phi|^2)|D_\mu\phi|^2\phi^*+\iota p(2p-1)(\eta^2-|\phi|^2)^2A^\mu D_\mu\phi^*-2(2p-1)^2(\eta^2-|\phi|^2)^3\phi^*)=0.
\end{aligned} \tag{31}$$

The Lorentz condition and Eq. (28) for $\nu=0$ are considered as constraints, which, by our choice of initial data, are satisfied at $t=0$. In the Abelian Higgs model, it has been proven that the analogous Cauchy problem has a unique solution, and that the constraints are propagated.[7] In the following, we will assume that in the present case a unique solution also exists, although a rigorous proof is still missing. (Because of the complexity of the equations, to rigorously prove existence of a unique solution seems a very difficult task.)

For a given solution $\psi(t,\mathbf{x})$, we define the functions $\psi_i(t,\mathbf{x})=M_i\psi(t,\mathbf{x}_{(i)})$ for $i=1,2$, where $\mathbf{x}_{(1)}=S\mathbf{x}$ with

$$S=\begin{pmatrix}\cos\dfrac{2\pi}{n} & -\sin\dfrac{2\pi}{n}\\[2ex] \sin\dfrac{2\pi}{n} & \cos\dfrac{2\pi}{n}\end{pmatrix}, \tag{32}$$

and where $\mathbf{x}_{(2)}^T=(x_1,-x_2)^T$. The matrices M_i are defined as

$$M_1=\begin{pmatrix}I & 0 & 0 & 0\\ 0 & A & B & 0\\ 0 & -B & A & 0\\ 0 & 0 & 0 & I\end{pmatrix},\quad I=\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix},\quad A=\cos\frac{2\pi}{n}I,\quad B=\sin\frac{2\pi}{n}I \tag{33}$$

and

$$M_2=\begin{pmatrix} -I & 0 & 0 & 0 \\ 0 & -I & 0 & 0 \\ 0 & 0 & I & 0 \\ 0 & 0 & 0 & C \end{pmatrix}, \quad CV=V^*. \tag{34}$$

We can now show that, if $\psi(t,\mathbf{x})$ is a solution of the Cauchy problem, so are $\psi_1(t,\mathbf{x})$ and $\psi_2(t,\mathbf{x})$. (To find the symmetries of the initial data $A_0(0,\mathbf{x})$, we have assumed that Eq. (28) for $\nu=0$ has a unique smooth solution with asymptotic decay sufficient to satisfy the finite-energy condition.) The uniqueness of the solution of the Cauchy problem now implies that, actually, ψ, ψ_1, and ψ_2 are all the same function. This, in turn, implies that functions like $|\phi|^2$, F_{ij}^2, or the energy density $\mathscr{E}$ are invariant under a $2\pi/n$ rotation, and under a reflection with respect to the x_1 axis. This leads to the following conclusion: If by using functions like $|\phi|^2$, F_{ij}^2, or $\mathscr{E}$, there is a way of defining the positions $(x_1^a(t),x_2^a(t))$, $a=1,\ldots,n$, of exactly n separate vortices, these n positions must lie on n radial lines separated by an angle $2\pi/n$ with equal distance from the origin. (As in Ref. 7, we can use the minima of $|\Phi|^2$ to define these positions, near the rotationally symmetric vortices.) Furthermore, one of these radial lines must be the positive x_1 axis, or make an angle π/n with the positive x_1 axis. Any vortex that does not satisfy these conditions immediately leads to $2n-1$ other vortices, because of the symmetries of our solution. For continuous solutions, these positions will change continuously such that at $t=0$ the n positions coincide, and after the collision the vortices move again on the radial lines just described. Therefore, they can either go back on the radial lines they came in on, or go back on radial lines shifted by an angle π/n. We will study a further symmetry to show that the second case is realized.

The last transformation we study is $\mathbf{x}\to M\mathbf{x}$, where M is the orthogonal matrix

$$M=\begin{pmatrix} \cos\dfrac{\pi}{n} & -\sin\dfrac{\pi}{n} \\ \sin\dfrac{\pi}{n} & \cos\dfrac{\pi}{n} \end{pmatrix}. \tag{35}$$

Under this transformation the initial data change as follows:

$$\psi(0,M\mathbf{x})=M_3\psi(0,\mathbf{x}),$$

with

$$M_3=\begin{pmatrix} -\sigma & 0 & 0 & 0 \\ 0 & C & -D & 0 \\ 0 & D & C & 0 \\ 0 & 0 & 0 & -\sigma \end{pmatrix}, \quad \sigma=\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad C=\cos\frac{\pi}{n}\,\sigma, \quad D=\sin\frac{\pi}{n}\,\sigma. \tag{36}$$

[We have again assumed the uniqueness of the smooth finite-energy solution, $A_0(0,\mathbf{x})$, of Eq. (28) for $\nu=0$.] From the uniqueness of the solution of the Cauchy problem, $\psi(-t,M\mathbf{x})=M_3\psi(t,\mathbf{x})$ follows, and we see that the functions $|\phi|^2$, F_{ij}^2, and $\mathscr{E}$ are invariant under the transformation $(t,\mathbf{x})\to(-t,M\mathbf{x})$. This establishes π/n scattering for n vortices.

V. CONCLUSIONS

The study of vortices in a hierarchy of generalized Abelian Higgs models, and the comparison with the Abelian Higgs model was continued. In previous studies we had seen that the rotationally symmetric generalized vortices are qualitatively similar to, but quantitatively different from the

vortices. Here similar structures were found in the neighborhood of the rotationally symmetric vortices. We found that the zero modes of the generalized vortices have the same angular dependence as, but radial behavior different from that of the zero modes of the vortices in the Abelian Higgs model.

The slow-motion approximation turned out to be of limited value. (Since the time-independent solutions are not known explicitly even in the Abelian Higgs model, the slow-motion approximation is not very successful in this model either.) On the reasonable assumption that a certain Cauchy problem has a unique solution, we were, however, able to study the symmetries of certain solutions. Each solution describes a process where n vortices approach and form one structure, namely a rotationally symmetric vortex. From this structure n vortices emerge. The pattern the vortices create for time t is the same as that for time $-t$, after a π/n rotation.

Time-dependent plane-wave spectrum representations for radiation from volume source distributions

Ehud Heyman
Department of Electrical Engineering - Physical Electronics, Tel-Aviv University, Tel-Aviv 69978, Israel

(Received 26 January 1995; accepted for publication 20 September 1995)

A new time-domain spectral theory for radiation from a time-dependent source distribution, is presented. The full spectral representation is based on a Radon transform of the source distribution in the four-dimensional space-time domain and consists of time-dependent plane waves that propagate in all space directions and with all (spectral) propagation speeds v_κ. This operation, termed the *slant stack transform*, involves projection of the time-dependent source distribution along planes normal to the spectral propagation direction and stacking them with a progressive delay corresponding to the spectral propagation speed v_κ along this direction. Outside the source domain, this three-fold representation may be contracted into a two-fold representation consisting of time-dependent plane waves that satisfy the spectral constraint $v_\kappa = c$ with c being the medium velocity. In the two-fold representation, however, the complete spectral representation involves both propagating time-dependent plane waves and evanescent time-dependent plane waves. We explore the separate role of these spectral constituents in establishing the causal field, and determine the space-time regions where the field is described only by the propagating spectrum. The spectral theory is presented here for scalar wave fields, but it may readily be extended to vector electromagnetic fields. [S0022-2488(96)01801-4]

I. INTRODUCTION

With the increase in the bandwidth of radiation and detection hardware there is a growing interest, for various applications, in the radiation, propagation and diffraction of ultra-wideband, short-pulse fields. Of particular interest is the problem of synthesizing source distributions for well collimated short pulse fields, sometimes referred to as pulsed beams.[1–6] Because of the broad frequency band of these fields, the conventional use of frequency domain techniques is often less efficient and physically less transparent than direct treatment in the space-time domain where the fields are well localized. The general goal of the present research is thus toward developing a time-domain theory for spectral analysis and synthesis of physically realizable pulsed fields and sources. This includes representation theorems and processing tools as well as ''time-domain thinking.'' Emphasis in this paper is placed on clarifying the physical role of various portions of the plane wave spectra in generating the causal field in different space-time regions.

The time-dependent plane-wave realization of general short pulse fields have been considered in Refs. 7–9. It has been shown in Ref. 7 how the time-dependent plane-wave spectrum can be matched to a prescribed pulsed radiation pattern in the far zone, thereby determining the field at all times and in particular the initial distribution at $t=0$. This representation, however, has addressed only the initial field distributions after the source had shut-off (i.e., a source-free field), but not the time-dependent source problem which models physical antennas. As such, it has been restricted to wave fields without evanescent spectrum, and in particular to electromagnetic ''bullets'' whose radiation pattern vanishes identically outside a certain ''radiation cone.'' Strictly speaking, such fields cannot be synthesized by finite support sources. Refs. 8–9, on the other hand, have addressed only planar source (aperture) realizations.

In the present paper we explore the time-dependent plane-wave spectral representation due to

0022-2488/96/37(2)/658/24/$10.00

a general source distribution of finite support. As will be shown (Sec. VI), in certain space-time regions the field may be described only by the propagating spectrum, but such a representation is not valid everywhere. A full description, in particular in the near zone, must include the time-dependent evanescent field. We shall therefore explore the physical role of the various spectral constituents in establishing the causal field. Some of the observations, concerning the space-time regions where the evanescent spectrum does not contribute have been derived in Ref. 10 from asymptotic considerations in the frequency domain. Here, however, all the results are obtained directly from the time-domain spectral contributions.

Transient plane-wave representations have been used in the past mainly for the analysis of scattering and diffraction of point-source excited pulsed fields. Several techniques have been introduced for the evaluation of the resulting spectral integrals.[11–16]. Recent studies were concerned with time-dependent spectral synthesis of collimated pulsed beam fields (space-time wave-packets), and with the scattering of such fields.[17,18] The present paper, on the other hand, presents a general formulation for source distributions.

We consider the time-dependent plane wave representation for the field radiated by a pulsed source distribution in a uniform medium with wave speed c. The field u satisfies the time-dependent wave equation

$$\left(\nabla^2-\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right)u(\mathbf{r},t)=-q(\mathbf{r},t) \tag{1.1}$$

in a three-dimensional domain $\mathbf{r}=(x,y,z)$. It is assumed that the source distribution $q(\mathbf{r},t)$ is confined in a volume V bounded within a sphere of radius R_0 centered at the origins and that its time history is a continuous pulse of duration T, namely

$$q(\mathbf{r},t)\neq 0 \quad \text{only} \quad \text{if} \quad \mathbf{r}\in V \quad \text{and} \quad 0<t<T. \tag{1.2}$$

The solution of (1.1) is given by the well known retarded potential integral

$$u(\mathbf{r},t)=\int_V d^3r'\, q[\mathbf{r}',t-|\mathbf{r}-\mathbf{r}'|/c]/4\pi|\mathbf{r}-\mathbf{r}'|. \tag{1.3}$$

Here, however, we shall explore alternative time-dependent plane wave representations for the field.

The time-dependent spectral theory will be derived here only for scalar fields. An extension to radiation of vector electromagnetic fields, expressed in the terminology of antenna theory is under preparation.

The presentation starts, methodically, with the well known spectral representations of time-harmonic fields (Sec. II). In Sec. III we construct the full time-domain spectral representation which is valid everywhere, including the source domain. It involves plane waves that propagate in all directions and with all wave-speeds v_κ, $0<v_\kappa<\infty$. This spectral representation is obtained via a Radon transform of the source distribution in the four-dimensional $(\mathbf{r},t)$ domain. Physically, this operation involves projection of the distribution along planes normal to the propagation direction and stacking them with a progressive delay that corresponds to the spectral wave-speed v_κ, and it is therefore termed the *slant stack transform*. Note that ''plane-wave'' constituents for which $v_\kappa \neq c$ are not solutions of the wave equation.

For observation points *outside* the source region the complete three-fold representation above may be contracted into a representation involving only spectral constituents constraint by the dispersion relation $v_\kappa=c$, i.e., lying on the *light cone* (Sec. IV). This representation, however, involves both propagating (homogeneous) and evanescent time-dependent plane-wave spectra. The time-dependent evanescent spectrum is described most effectively by the analytic signal

representation, obtained by extending the field solutions into the complex time domain. However, we also present explicit expressions for the evaluation of the time-dependent evanescent field directly from the real time-dependent data.

Next we explore the physical meaning of the time-dependent evanescent plane waves by considering first the special case of a pulsed point-source (Sec. V), and then extending the results to distributed sources (Sec. VI). It is shown that the contribution of the evanescent spectrum vanishes identically after a certain time t_E that may be determined a priori, so that for $t>t_E$ the field is described only by a spectrum of propagating time-dependent plane waves. In certain regions in space t_E occurs prior to the causal arrival time t_0, leaving the causal field at $t>t_0$ described only by the propagating spectrum. Prior to t_0, however, the propagating spectrum generates non-vanishing non-causal contributions that are canceled only by the contributions of the evanescent spectrum.

Motivated by these results we consider in Sec. VII some general properties of the field solutions that are generated by a spectrum of *propagating* (homogeneous) time-dependent plane waves. Specifically we explore the fields described by a conical spectral range with angle Θ, centered about the propagation direction to the observer. The analysis covers a wide range of parameters, from a very narrow spectral range (small Θ) up to $\Theta=\pi$ where the plane waves emerge from the source in all directions (a Wittaker-type expansion). Again we determine the space-time window wherein such spectral representation provides a faithful description of the field.

II. TIME-HARMONIC REPRESENTATIONS

A. Full spectral representation

We start with a brief review of alternative plane wave representations for time-harmonic solutions. We use an over caret to denote time-harmonic constituents with suppressed time-dependence $\exp(-i\omega t)$. We introduce the 3D spatial spectrum of the time-harmonic source distribution $\hat{q}(\mathbf{r},\omega)$

$$\hat{\tilde{q}}(\mathbf{K},\omega)=\int d^3r\,\hat{q}(\mathbf{r},\omega)e^{-i\mathbf{K}\cdot\mathbf{r}} \tag{2.1}$$

and its inverse

$$\hat{q}(\mathbf{r},\omega)=\frac{1}{(2\pi)^3}\int d^3K\,\hat{\tilde{q}}(\mathbf{K},\omega)e^{i\mathbf{K}\cdot\mathbf{r}}, \tag{2.2}$$

where $\mathbf{K}=(K_x,K_y,K_z)$. Applying the transform in (2.1) to the time-harmonic wave equation we obtain the well-known result for the time-harmonic field

$$\hat{u}(\mathbf{r},\omega)=\frac{1}{(2\pi)^3}\int d^3K\frac{\hat{\tilde{q}}(\mathbf{K},\omega)}{K^2-k^2}e^{i\mathbf{K}\cdot\mathbf{r}}, \tag{2.3}$$

where $K=|\mathbf{K}|$ and $k=\omega/c$.

B. Contracted (2D) spectral representation: Weyl representation

Expression (2.3) is valid both inside and outside the source region. For observation points outside the source region V, the 3D integral can be contracted to a 2D plane-wave integral. Without loss of generality we shall contract the spectrum about the z-axis and therefore denote $\mathbf{r}=(\mathbf{x},z)$ with $\mathbf{x}=(x_1,x_2)$ being the transverse coordinates. For $|z|>R_0$ we may evaluate the K_z integral in (2.3) via Cauchy's theorem, obtaining

$$\hat{u}(\mathbf{r},\omega)=\frac{1}{(2\pi)^2}\int d^2k_x e^{i\mathbf{k}_x\cdot\mathbf{x}\pm ik_z z}\frac{1}{-2ik_z}\hat{\tilde{q}}(\mathbf{K},\omega)\Big|_{\mathbf{K}=(\mathbf{k}_x,\pm k_z)}, \tag{2.4}$$

where upper and lower signs are for $z>R_0$ and $z<-R_0$, respectively. To distinguish between the full (3D) and the contracted (2D) representations we have replaced the spectral coordinates (K_{x_1},K_{x_2}) by $\mathbf{k}_x=(k_{x_1},k_{x_2})$. The longitudinal wavenumber is determined by $\mathbf{k}_x$ via

$$k_z=\begin{cases}\sqrt{k^2-|\mathbf{k}_x|^2}, & |\mathbf{k}_x|<k\\ i\sqrt{|\mathbf{k}_x|^2-k^2}, & |\mathbf{k}_x|>k.\end{cases} \tag{2.5}$$

Unlike (2.3), Eq. (2.4) expresses the field as a superposition of plane-wave solutions of the wave equation. It consists, however, of both propagating and evanescent spectra: The propagating part of the spectrum ($|\mathbf{k}_x|<k$) depends on the value of $\hat{\tilde{q}}(\mathbf{K})$ on the Ewald sphere $|\mathbf{K}|=k$, while the evanescent part ($|\mathbf{k}_x|>k$) depends on the analytic continuation of $\hat{\tilde{q}}(\mathbf{K})$ to $\mathbf{K}=(\mathbf{k}_x,\pm i\sqrt{|\mathbf{k}_x|^2-k^2})$ for $z\gtrless R_0$, respectively.

The integral representation in (2.4) is valid only if $|z|>R_0$. If $|z|<R_0$, the contracted representation is more complicated and involves both forward and backward propagating waves. We shall not address this case here. If, however, $|z|<R_0$ but $\mathbf{r}$ is located outside the sphere R_0, then this difficulty can be circumvented by rotating the coordinates to a different contraction axis, say z' for which $|z'|>R_0$.

III. FULL SPECTRAL REPRESENTATION: 4D RADON TRANSFORM IN SPACE–TIME

The time-dependent field will be recovered here via an inverse Fourier transform to the time domain. To simplify the analytic manipulations we shall use analytic signal representation. Among other advantages, this formulation also enables a treatment of the propagating and the evanescent spectra in the same analytical framework.

An analytic signal $\overset{+}{f}(t)$ corresponding to the real signal $f(t)$ with frequency spectrum $\hat{f}(\omega)$ is defined by the analytic inverse Fourier transform

$$\overset{+}{f}(t)=\frac{1}{\pi}\int_0^\infty d\omega e^{-i\omega t}\hat{f}(\omega),\qquad \mathrm{Im}\ t\leqslant 0. \tag{3.1}$$

This integral definition implies that $\overset{+}{f}(t)$ is an analytic function in the lower half of the complex t-plane. The physical signal $f(t)$ for real t is obtained via

$$f(t)=\mathrm{Re}\ \overset{+}{f}(t),\qquad t\ \text{real}. \tag{3.2}$$

An alternative definition of $\overset{+}{f}(t)$ directly from the real data $f(t)$ is given in (A7). Other properties are summarized in Appendix A.

A key feature in the time-dependent spectral representation is the use of frequency-normalized spectral variables

$$\boldsymbol{\kappa}=\mathbf{K}/k=(\kappa_x,\kappa_y,\kappa_z). \tag{3.3}$$

Clearly $\boldsymbol{\kappa}$ has a pure *frequency independent* geometrical interpretation in terms of the plane-wave angle. We shall also denote conveniently $\hat{\tilde{q}}(\mathbf{K},\omega)|_{\mathbf{K}=k\boldsymbol{\kappa}}$ as $\hat{\tilde{q}}(\boldsymbol{\kappa},\omega)$.

The space–time spectrum $\overset{+}{\tilde{q}}(\boldsymbol{\kappa},t)$ is defined now by

$$\overset{+}{\tilde{q}}(\boldsymbol{\kappa},\tau)=\frac{1}{\pi}\int_0^\infty d\omega e^{-i\omega\tau}\overset{+}{\tilde{q}}(\boldsymbol{\kappa},\omega), \tag{3.4}$$

where τ is the spectral time variable. Rewriting (2.1)–(2.2) in terms of $\boldsymbol{\kappa}$, and applying (3.1) we have

$$\overset{+}{\tilde{q}}(\boldsymbol{\kappa},\tau)=\frac{1}{\pi}\int_0^\infty d\omega\int_V d^3r\hat{q}(\mathbf{r},\omega)e^{-i\omega(\tau+\boldsymbol{\kappa}\cdot\mathbf{r}/c)}, \tag{3.5}$$

$$\overset{+}{q}(\boldsymbol{\kappa},t)=\frac{1}{\pi}\int_0^\infty d\omega\frac{k^3}{(2\pi)^3}\int d^3\kappa\hat{\tilde{q}}(\boldsymbol{\kappa},k)e^{-i\omega(t-\boldsymbol{\kappa}\cdot\mathbf{r}/c)}. \tag{3.6}$$

Switching the order of integrations and performing the ω integrations first (justified for Im $t,\tau<0$ and in the limit of real t,τ) we obtain the analytic time-domain transform pair

$$\overset{+}{\tilde{q}}(\boldsymbol{\kappa},\tau)=\int_V d^3r\overset{+}{q}(\mathbf{r},\tau+\ \kappa\cdot\mathbf{r}/c), \tag{3.7}$$

$$\overset{+}{q}(\mathbf{r},t)=\frac{-i\partial_t^3}{(2\pi c)^3}\int d^3\kappa\overset{+}{\tilde{q}}(\boldsymbol{\kappa},t-\boldsymbol{\kappa}\cdot\mathbf{r}/c) \tag{3.8}$$

where $\overset{+}{q}(\mathbf{r},t)$ is the analytic signal corresponding to the real source function $q(\mathbf{r},t)$ and $\partial_t\equiv\partial/\partial t$.

The *real signal* equivalent of this analytic transform pair is obtained by taking its real part (see (3.2)). Noting that the $(-i)$ is replaced by $\mathscr{H}$ (see (A2)) we obtain

$$\tilde{q}(\boldsymbol{\kappa},\tau)=\int_V d^3rq(\mathbf{r},\tau+\boldsymbol{\kappa}\cdot\mathbf{r}/c), \tag{3.9}$$

$$q(\mathbf{r},t)=\mathscr{H}\partial_t^3\frac{1}{(2\pi c)^3}\int d^3\kappa\tilde{q}(\boldsymbol{\kappa},t-\boldsymbol{\kappa}\cdot\mathbf{r}/c). \tag{3.10}$$

Note that the integration, the differentiation and the Hilbert transform operations in (3.10) can commute.

The transformation-pair in (3.9)–(3.10) (or, equivalently, (3.7)–(3.8)) is termed the *slant stack transform*. To gain further insight we note that the operation in (3.9) can be cast in a two step cascade

$$\tilde{q}(\boldsymbol{\kappa},\tau)=\int d\sigma\mathscr{P}_{\hat{\kappa}}[q](\sigma,\tau+\kappa\sigma/c) \tag{3.11}$$

$$\mathscr{P}_{\hat{\kappa}}[q](\sigma,\tau)=\int d^2rq(\mathbf{r},\tau)|_{\mathbf{r}\cdot\hat{\kappa}=\sigma}. \tag{3.12}$$

Equation (3.12) is the projection of the time-dependent distribution $q(\mathbf{r},t)$ onto the direction $\hat{\boldsymbol{\kappa}}\equiv\boldsymbol{\kappa}/\kappa$ where $\kappa\equiv|\boldsymbol{\kappa}|$. It is obtained by integrating q along the plane $\mathbf{r}\cdot\hat{\boldsymbol{\kappa}}=\sigma$ normal to $\hat{\boldsymbol{\kappa}}$, with

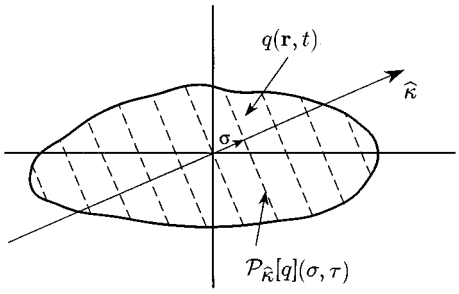

FIG. 1. Schematization of the time-dependent plane-wave transform.

σ being position along the $\hat{\boldsymbol{\kappa}}$ axis. In (3.11) these projections are stacked along this axis with a progressive delay corresponding to the spectral propagation speed (see Fig. 1)

$$v_\kappa = c/\kappa. \tag{3.13}$$

Note that spectral points on the 4D cone $|\boldsymbol{\kappa}|=1$ correspond to plane-wave data with propagation speed c. In the frequency domain, they correspond to points on the Ewald sphere $|\mathbf{K}|=\omega/c$. Points lying off this cone describe faster or slower spectral components.

Equations (3.9)–(3.10) are identified as a Radon transform pair in the four dimensional $(\mathbf{r},t)\leftrightarrow(\boldsymbol{\kappa},\tau)$ domains. In fact, defining the 4D vector $\mathbf{x}=(\mathbf{r},ct)$ we find from (B1) that

$$\tilde{q}(\boldsymbol{\kappa},\tau)=c^{-1}\sqrt{1+\kappa^2}\,\check{q}(p,\hat{\mathbf{p}}) \tag{3.14}$$

with $\check{q}(p,\hat{\mathbf{p}})$ being the conventional definition of the Radon transform and

$$p=c\tau/\sqrt{1+\kappa^2}, \qquad \hat{\mathbf{p}}=(-\boldsymbol{\kappa},1)/\sqrt{1+\kappa^2}. \tag{3.15}$$

Equation (3.10) can be identified as the 4D inverse Radon transform (B18).

The analytic time-dependent field is obtained now by rewriting (2.3) in terms of $\boldsymbol{\kappa}$ and transforming the result to the time domain. Following the same procedure as in (3.4)–(3.8) we obtain

$$\overset{+}{u}(\mathbf{r},t)=\frac{i\partial_t}{(2\pi)^3 c}\int d^3\kappa\,\frac{\overset{+}{\tilde{q}}(\boldsymbol{\kappa},t-\boldsymbol{\kappa}\cdot\mathbf{r}/c)}{\kappa^2-1}, \tag{3.16}$$

hence the real field is found from the real spectral function $\tilde{q}(\boldsymbol{\kappa},\tau)$ via

$$u(\mathbf{r},t)=-\mathscr{H}\partial_t\frac{1}{(2\pi)^3 c}\int d^3\kappa\,\frac{\tilde{q}(\boldsymbol{\kappa},t-\kappa\cdot\mathbf{r}/c)}{\kappa^2-1}, \tag{3.17}$$

where the real spectral function $\tilde{q}$ is defined in (3.9). Equations (3.16)–(3.17) describe the field as a superposition of time-dependent ''plane waves'' that propagate in all directions with the spectral propagation speed v_κ of (3.13).

In the far radiation zone the time-dependent spectral integral (3.17) reduces asymptotically to a point contribution from the spectral component $\tilde{q}$ that propagates at the speed of light $v_\kappa=c$ in the observation direction $\hat{\mathbf{r}}$. Thus the field has the asymptotic form

$$u(\mathbf{r},t)\sim\frac{g(\hat{\mathbf{r}},t-r/c)}{4\pi r},\quad r\to\infty, \tag{3.18}$$

where $r=|\mathbf{r}|$, $\hat{\mathbf{r}}=\mathbf{r}/r$ and the time-dependent radiation pattern

$$g(\hat{\mathbf{r}},t-r/c)=\tilde{q}(\boldsymbol{\kappa},\tau)\Big|_{\boldsymbol{\kappa}=\hat{\mathbf{r}},\tau=t-r/c}. \tag{3.19}$$

IV. CONTRACTED (WEYL-TYPE) REPRESENTATION: TIME-DEPENDENT PROPAGATING AND EVANESCENT SPECTRA

Expression (3.17) describes the field as a 3D spectral superposition of time-dependent plane waves that propagate in all directions, and with all propagation speeds $0<v_\kappa<\infty$ (see (3.13)). For observation points outside the source region one may obtained a contracted representation involving only time-dependent plane waves with wave-speed c. This representation, however, includes evanescent time-dependent plane waves.

For the contracted spectrum representation we replace the spectral wavenumber $\mathbf{k}_x$ of (2.4) by the frequency-normalized spectral coordinates (cf. (3.3))

$$\boldsymbol{\xi}=\mathbf{k}_x/k=(\xi_1,\xi_2), \tag{4.1}$$

and

$$\zeta=\begin{cases}\sqrt{1-|\boldsymbol{\xi}|^2}, & |\boldsymbol{\xi}|<1\\ i\sqrt{|\boldsymbol{\xi}|^2-1}, & |\boldsymbol{\xi}|>1.\end{cases} \tag{4.2}$$

The use of analytic signals enables us to treat the contributions of the propagating ($|\boldsymbol{\xi}|<1$) and the evanescent ($|\boldsymbol{\xi}|>1$) spectra in a single framework (see (4.13)–(4.14)). However, to clarify the mathematical details we shall first consider these contributions separately.

A. Time-dependent propagating spectrum

We rewrite the time-harmonic integral for the propagating spectrum in (2.4) as

$$\hat{u}_P(\mathbf{r},\omega)=\frac{ik}{2(2\pi)^2}\int_{|\boldsymbol{\xi}|<1}d^2\xi\frac{1}{\zeta}\hat{\tilde{q}}(\mathbf{K}^{\pm},\omega)e^{ik(\boldsymbol{\xi}\cdot\mathbf{x}\pm\zeta z)}, \tag{4.3}$$

where upper and lower signs are for $z>R_0$ and $z<R_0$, respectively, $\mathbf{K}^{\pm}=k(\boldsymbol{\xi},\pm\zeta)$, and from (2.1)

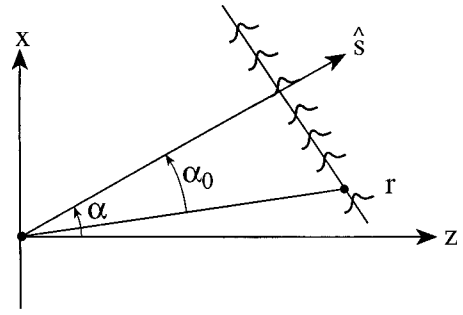
$$\hat{\tilde{q}}(\mathbf{K}^{\pm},\omega)=\int_V d^3r'\hat{q}(\mathbf{r}',\omega)e^{-ik(\boldsymbol{\xi}\cdot\mathbf{x}'\pm\zeta z')}. \tag{4.4}$$

Henceforth we shall assume that $z>R_0$ and shall omit the $\pm$ sign.

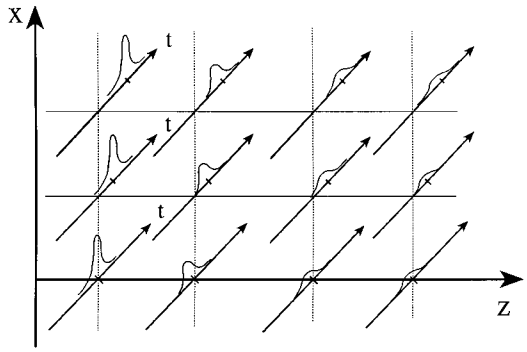
The time-dependent field is obtained by applying (3.1) to (4.3). Substituting (4.4), switching the order of integrations and performing the ω-integration first as in (3.5) and (3.7) yields

$$\overset{+}{u}_p(\mathbf{r},t)=\frac{-\partial_t}{(2\pi)^2 2c}\int_{|\boldsymbol{\xi}|<1}d^2\xi\frac{1}{\zeta}\hat{\tilde{q}}(\boldsymbol{\kappa},t-\boldsymbol{\kappa}\cdot\mathbf{r}/c)\Big|_{\boldsymbol{\kappa}=(\boldsymbol{\xi},\zeta)}, \tag{4.5}$$

where $\overset{+}{\tilde{q}}$ is the analytic time-dependent spectral function as calculated from the time-dependent source via (3.7).



(a)



(b)

FIG. 2. Time-dependent plane wave integral. (a) Propagating spectrum: Schematization of a single pulsed plane wave at a fixed observation time. $\hat{\mathbf{s}}$ is the plane-wave direction, $\mathbf{r}$ is a typical observation point, and α_0 is introduced in connection with (5.10). (b) Evanescent spectrum: Schematization of an evanescent pulsed plane wave at several observation points along three axes parallel to the z-axis. The diagonal axes denote the time axis at each observation point. The evanescent plane wave propagates in the x-direction and that the pulses decay and broaden as z grows.

The *real* field u_P is obtained from the real part of $\overset{+}{u}_P$. Thus, it can be calculated directly from the *real* spectral function $\tilde{q}$ by using $\tilde{q}$ instead of $\overset{+}{\tilde{q}}$ in (4.5). Note also that $\tilde{q}$ is found directly from the *real* data $q(\mathbf{r},t)$ via (3.10).

Expression (4.5) constitutes an angular spectrum of time-dependent plane waves as schematized in Fig. 2(a). The integrand defines time-dependent plane waves propagating with speed c along the unit vector directions

$$\hat{\mathbf{s}}=(\xi_1,\xi_2,\zeta)=(\sin\,\alpha\,\cos\,\beta,\sin\,\alpha\,\sin\,\beta,\cos\,\alpha), \tag{4.6}$$

where (α,β) are the polar and azimuthal angles with respect to the z-axis. Using these angle coordinates, the real propagating spectrum integral simplifies into

$$u_P(\mathbf{r},t)=\frac{-\partial_t}{(2\pi)^2 2c}\int_{-\pi}^{\pi} d\beta \int_0^{\pi/2} d\alpha\,\sin\,\alpha\tilde{q}(\hat{\mathbf{s}},t-\hat{\mathbf{s}}\cdot\mathbf{r}/c). \tag{4.7}$$

B. Time-dependent evanescent spectrum

The time-harmonic evanescent spectrum is given by (4.3) but with the integration limit now replaced by $|\boldsymbol{\xi}|>1$. Here, however, $\zeta=i|\zeta|$ hence as follows from (4.5), $\hat{\tilde{q}}(\mathbf{K}^{\pm},\omega)$ now grows exponentially as $\omega\to\infty$. To transform this representation to the time domain we rewrite the evanescent spectrum part of (2.4) in a regularized form

$$\hat{u}_E(\mathbf{r},\omega)=\frac{ik}{2(2\pi)^2}\int_{|\boldsymbol{\xi}|>1} d^2\xi\,\frac{1}{\zeta}\hat{\tilde{q}}_0(\mathbf{K}^{+},\omega)e^{ik[\boldsymbol{\xi}\cdot\mathbf{x}+\zeta(z-R_0)]} \tag{4.8}$$

with

$$\hat{\tilde{q}}_0(\mathbf{K}^{+},\omega)=\int_V d^3r'\,\hat{q}(\mathbf{r}',\omega)e^{-ik[\boldsymbol{\xi}\cdot\mathbf{x}'+\zeta(z'-R_0)]}, \tag{4.9}$$

where R_0 is the support of the source and, as before, it is assumed that $z>R_0$. Noting also that $z'<R_0$ for $\mathbf{r}'\in V$ it follows that the exponents in (4.8) and (4.9) decay for $\zeta=i|\zeta|$ as $\omega\to\infty$.

The time-dependent field is obtained now by applying (3.1) to (4.8)–(4.9) and performing the ω integration first. We obtain

$$\overset{+}{u}_E(\mathbf{r},t)=\frac{-\partial_t}{(2\pi)^2 2c}\int_{|\boldsymbol{\xi}|>1} d^2\xi\,\frac{1}{\zeta}\,\overset{+}{\tilde{q}}_0[(\boldsymbol{\xi},\zeta),t-\boldsymbol{\xi}\cdot\mathbf{x}/c-\zeta(z-R_0)/c] \tag{4.10}$$

with

$$\overset{+}{\tilde{q}}_0[(\boldsymbol{\xi},\zeta),\tau]=\int_V d^3r'\,\overset{+}{q}[\mathbf{r}',\tau+\boldsymbol{\xi}\cdot\mathbf{x}'/c+\zeta(z'-R_0)/c], \tag{4.11}$$

where $\overset{+}{\tilde{q}}_0$ is the analytic time-dependent spectrum of $q(\mathbf{r},t)$ (compare (3.7)). Here, however, it is calculated for an imaginary spectral variable $\zeta=i|\zeta|$, and it is also space-shifted by R_0. Note that since $z>R_0$ and $z'<R_0$, the time-arguments in the integrands of (4.10)–(4.11) have negative imaginary parts as required by the analytic signal theory.

Expression (4.10) is identified as a superposition of *time-dependent evanescent plane waves*. This interpretation follows from the fact that analytic signals generally decay as their time-argument goes deeper into the lower half of the complex plane (see (3.1)). Since $\zeta=i|\zeta|$ here, the integrand $\overset{+}{\tilde{q}}$ in (4.10) decays as z increases, as schematized in Fig. 2(b). The *real* spectral delay in the argument of $\overset{+}{\tilde{q}}$ is given by $\boldsymbol{\xi}\cdot\mathbf{x}/c$, hence the time-dependent evanescent waves "propagate" transversely in the $\boldsymbol{\xi}$ direction with propagation speed $v_E=c/|\boldsymbol{\xi}|<c$ (Fig. 2(b)).

The *real* field u_E is obtained from (4.10) via $\mathrm{Re}\,\overset{+}{u}_E$. Unlike (4.5), however, in (4.10) one cannot replace $\overset{+}{\tilde{q}}_0$ by the real spectral function $\tilde{q}$ since here the time-argument in the integrand is complex even for real t.

It is therefore required in (4.11) to calculate the extension of the source signal $q(\mathbf{r},t)$ to the analytic function $\overset{+}{q}(\mathbf{r},t)$ for complex t. In certain cases, $\overset{+}{q}$ can be found analytically. Otherwise, it should be calculated numerically. One route is by the analytic Fourier inversion (3.4) of $\hat{\tilde{q}}(\kappa,\omega)$ to complex t with $\mathrm{Im}\ t\leqslant 0$. This route, however, is rather intricate since, given $q(\mathbf{r},t)$, it requires the calculation $\hat{q}(\mathbf{r},\omega)$ for all $\mathbf{r}$, then of $\hat{\tilde{q}}(\boldsymbol{\kappa},\omega)$ and finally of $\overset{+}{q}(\mathbf{r},t)$ via (3.4).

Alternatively, the extension of the real data $q(\mathbf{r},t)$ to complex t can be calculated *directly in the time domain* by convolving the real signal with the analytic $\overset{+}{\delta}$ function as in (A7). Via this route, the analytic kernel $\overset{+}{\tilde{q}}_0[(\xi,\zeta),\tau]$ in (4.11) can be calculated via the *real data* integration

$$\overset{+}{\tilde{q}}[(\boldsymbol{\xi},\zeta),\tau]=\int_V d^3r' \int_{-\infty}^{\infty} dt' q(\mathbf{r}',t')\frac{1}{\pi i}\frac{1}{\tau+\boldsymbol{\xi}\cdot\mathbf{x}'/c+\zeta(z'-R_0)/c-t'}, \quad \text{Im } \tau<0. \tag{4.12}$$

To recover the radiated field via (4.10), this kernel should be calculated for $\zeta=i\sqrt{|\boldsymbol{\xi}|^2-1}$ and for complex τ: $\tau=t-\boldsymbol{\xi}\cdot\mathbf{x}/c-i|\zeta|(z-R_0)/c$ where t is the real observation time.

C. A unified representation

The analysis in (4.8)–(4.9) implies that the evanescent time-dependent plane-wave representation is valid only if the source is located entirely behind the reference plane. Choosing a reference plane $z=z_0 > R_0$ yields a representation that includes both the propagating and the evanescent spectra. With respect to this plane we have

$$\overset{+}{u}(\mathbf{r},t)=\frac{-\partial_t}{(2\pi)^2 2c}\int_{-\infty}^{\infty} d^2\xi \ \frac{1}{\zeta}\ \overset{+}{\tilde{q}}_0[(\boldsymbol{\xi},\zeta),t-\boldsymbol{\xi}\cdot\mathbf{x}/c-\zeta(z-z_0)/c], \quad z>z_0, \tag{4.13}$$

with (compare (4.5) and (4.10))

$$\overset{+}{\tilde{q}}_0[(\boldsymbol{\xi},\zeta),\tau]=\int_V d^3r' \overset{+}{q}[\mathbf{r}',\tau+\boldsymbol{\xi}\cdot\mathbf{x}'/c+\zeta(z'-z_0)/c]. \tag{4.14}$$

The unified representation in (4.13) now includes *both the propagating and the evanescent time-dependent spectra*. The real field is obtained by taking the real part of (4.13). The details are similar to those discussed in connection with (4.7) and (4.10).

V. SPECIAL CASE: POINT SOURCE

To clarify the causal properties of the time-dependent plane wave representation we shall consider first the simplified problem of the time-dependent Green's function $G(\mathbf{r},t)$, due to a pulsed point-source

$$q(\mathbf{r},t)=f(t)\,\delta(\mathbf{r}), \tag{5.1}$$

where it is assumed that the source history $f(t)$ vanishes for $t<0$.

We shall obtain closed-form expressions for the time-dependent propagating and evanescent spectra that clarify their respective role in establishing the causal radiated field. These properties will be used in Sec. VI to establish the causal properties of the time-dependent plane-wave representations under more general conditions.

A. The spectral integrals

From (3.7), the plane-wave spectrum of the source is

$$\tilde{q}(\boldsymbol{\kappa},\tau)=f(\tau), \tag{5.2}$$

hence from (4.13), the (Weyl-type) spectral expansion for the time-dependent analytic Green's function is

$$\overset{+}{G}(\mathbf{r},t)=\frac{1}{(2\pi)^2}\frac{-1}{2c}\int_{-\infty}^{\infty}d^2\xi\frac{1}{\zeta}\overset{+}{f}{}'[t-(\boldsymbol{\xi}\cdot\mathbf{x}+\zeta z)/c], \tag{5.3}$$

where the prime denotes a derivative with respect to the argument. Expression (5.3) is a unified expression that includes both the propagating and the evanescent time-dependent spectra.

As before, we explore separately the field contributions G_P and G_E from the propagating and evanescent spectral ranges, respectively. The propagating spectrum consists of pulsed plane waves propagating in the unit vector directions $\hat{\mathbf{s}}$ in (4.6). Using the plane-wave unit vector direction $\hat{\mathbf{s}}$ and the spherical angles (α,β) of (4.6), the integral for the propagating spectrum becomes (see (4.7))

$$\overset{+}{G}_P(\mathbf{r},t)=\frac{-1}{(2\pi)^2 2c}\int_{-\pi}^{\pi}d\beta\int_0^{\pi/2}d\alpha\ \sin\alpha\overset{+}{f}{}'[t-\hat{\mathbf{s}}\cdot\mathbf{r}/c], \tag{5.4}$$

and the *real* field G_P is given by the same expression with $\overset{+}{f}\to f$. Since $\hat{\mathbf{s}}\cdot\mathbf{r}\leqslant r$ for all $\hat{\mathbf{s}}$, all the pulsed plane waves in (5.4), except for the one that propagates along the direction from the source to $\mathbf{r}$, arrive to $\mathbf{r}$ *prior* to the causal arrival time $t_0=r/c$. This yields a non-causal contribution that is canceled out by the contribution of the pulsed evanescent spectrum. As we shall see below, in certain space-regions the integrated non-causal contribution vanishes prior to the causal arrival time t_0, so that it may be time-separated from the physical signal at $t>t_0$.

The contribution of the evanescent spectrum is given by

$$\overset{+}{G}_E(\mathbf{r},t)=\frac{-1}{(2\pi)^2 2c}\int_{|\boldsymbol{\xi}|>1}d^2\xi\frac{1}{\zeta}\overset{+}{f}{}'[t-(\boldsymbol{\xi}\cdot\mathbf{x}+\zeta z)/c], \tag{5.5}$$

where here $\zeta=i|\zeta|$. This expression may be described as an integration in the complex α plane but we shall not pursue this formal extension here. The interpretation of (5.5) has been discussed in connection with (4.10). The implications of the observations noted there will be discussed later on.

Expression (5.5) requires the calculation of the dual analytic function $\overset{+}{f}$ for complex t. As mentioned in connection with (4.12), unless f is known analytically, this extension should be done numerically either by Fourier inversion of $\hat{f}(\omega)$ to complex t via (3.1) or directly in the time domain as in (A7). Substituting (A7) in (5.5) we obtain an expression that involves processing only of the *real* data f

$$G_E(\mathbf{r},t)=\frac{1}{(2\pi)^3 c}\int_{|\boldsymbol{\xi}|>1}d^2\xi\frac{1}{|\zeta|}\int_{-\infty}^{\infty}dt' f'(t')\mathrm{Re}\,\frac{1}{t-t'-\boldsymbol{\xi}\cdot\mathbf{x}/c-i|\zeta|z/c} \tag{5.6}$$

$$=\frac{1}{(2\pi)^3 c}\int_{|\boldsymbol{\xi}|>1}d^2\xi\frac{1}{|\zeta|}\int_{-\infty}^{\infty}dt' f(t')\mathrm{Re}\,\frac{-1}{(t-t'-\boldsymbol{\xi}\cdot\mathbf{x}/c-i|\zeta|z/c)^2}, \tag{5.7}$$

where in (5.7) the time-derivative has been commuted, yielding an expression in terms of f rather than f'.

B. Evaluation of the propagating spectrum integral and the role of the evanescent spectrum

To gain insight we consider first an observation point on the z-axis $\mathbf{r}=(0,0,z)$. Here $\hat{\mathbf{s}}\cdot\mathbf{r}=z\cos\alpha$ and the integral in (5.4) is β-independent, giving

$$G_P(\mathbf{r},t)=\frac{-1}{4\pi c}\int_0^{\pi/2} d\alpha\ \sin\ \alpha f'[t-(z/r)\cos\ \alpha].$$

Changing the integration variable to $\tau=(z/c)\cos\ \alpha$ we obtain

$$G_P(\mathbf{r},t)=\frac{1}{4\pi z}\int_{z/c}^{0} d\tau\ f'(t-\tau)=f(t-z/c)/4\pi z-f(t)/4\pi z. \tag{5.8}$$

The first term in (5.8) is the actual field G on the z-axis, hence the remainder should be canceled by the evanescent spectrum, i.e.,

$$G_E(\mathbf{r},t)=f(t)/4\pi z. \tag{5.9}$$

Expression (5.9) will be re-derived in (5.21) by direct evaluation of integral (5.5) for G_E.

Next, we consider general observation points off the z-axis. Let $\mathbf{r}=(r,\theta,\phi)$ where θ and ϕ are the conventional spherical angles and, without loss of generality, let $\phi=0$. To evaluate the spectral integral G_P it is convenient to use the spectral spherical angles (α_0,β_0) that are centered about the observation direction $\hat{\mathbf{r}}$: α_0 and β_0 are the plane wave polar and azimuthal angles with respect to the $\hat{\mathbf{r}}$-axis, with $\beta_0=0$ on the $\phi=0$ plane. One readily finds that the plane wave direction $\hat{\mathbf{s}}$ in (4.6) is described by

$$\begin{aligned}(\xi_1,\xi_2,\zeta)=(&\cos\ \theta\ \sin\ \alpha_0\ \cos\ \beta_0+\sin\ \theta\ \cos\ \alpha_0,\ \ \sin\ \alpha_0\ \sin\ \beta_0,\ \ \cos\ \theta\ \cos\ \alpha_0\\ &-\sin\ \theta\ \sin\ \alpha_0\ \cos\ \beta_0).\end{aligned} \tag{5.10}$$

The condition $\zeta\geqslant 0$ that defines the propagating plane wave spectrum in (5.4) can therefore be expressed as $0\leqslant\alpha_0\leqslant\bar{\alpha}_0(\beta_0)$ where

$$\bar{\alpha}_0(\beta_0)=\tan^{-1}(\cot\ \theta/\cos\ \beta_0). \tag{5.11}$$

Using $\mathbf{r}\cdot\hat{\mathbf{s}}=r\ \cos\ \alpha_0$ we obtain from (5.4)

$$G_P=\frac{1}{(2\pi)^2}\frac{-1}{2c}\int_0^{2\pi} d\beta_0\int_0^{\bar{\alpha}_0(\beta_0)} d\alpha_0\ \sin\ \alpha_0\ f'[t-(r/c)\cos\ \alpha_0]. \tag{5.12}$$

Changing integration variable to $\tau=(r/c)\cos\ \alpha_0$ we obtain, as in (5.8)

$$\begin{aligned}G_P&=\frac{1}{4\pi r}\frac{1}{2\pi}\int_0^{2\pi} d\beta_0\{f[t-r/c]-f[t-(r/c)\cos\ \bar{\alpha}_0(\beta_0)]\}\\ &=\frac{f[t-r/c]}{4\pi r}-\frac{1}{4\pi r}\int_0^{2\pi}\frac{d\beta_0}{2\pi} f[t-(r/c)\cos\ \bar{\alpha}_0(\beta_0)],\end{aligned} \tag{5.13}$$

hence the evanescent spectrum contribution

$$G_E=\frac{1}{4\pi r}\int_0^{2\pi}\frac{d\beta_0}{2\pi} f[t-(r/c)\cos\ \bar{\alpha}_0(\beta_0)]. \tag{5.14}$$

Noting that the maximum and minimum values of $\bar{\alpha}_0(\beta_0)$ are $\bar{\alpha}_0(0)=\pi/2-\theta$ and $\bar{\alpha}_0(\pi)=\pi/2+\theta$, respectively, one finds that the latest and earliest spectral delays in the integrand (5.14) are $\pm x_1/c$, respectively (recall that we assumed that $x_2=0$). It therefore follows that $G_E\neq 0$ only for $-x_1/c<t<T+x_1/c$. Generalizing this result for any $\mathbf{r}$ we have

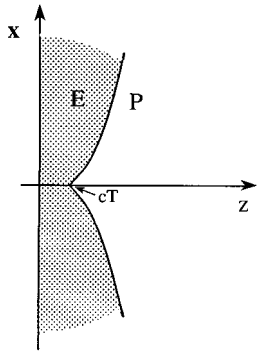


FIG. 3. Space-time regions for the propagating and the evanescent spectral contributions. In region E, the causal field (at times $t>r/c$) is described by both the propagating and the evanescent spectra. In region P, the field may be described only by the propagating spectrum for all causal times.

$$G_E\neq 0 \text{ only for } -\rho/c<t<T+\rho/c\equiv t_E, \tag{5.15}$$

where $\rho=\sqrt{x_1^2+x_2^2}$. Thus $G=G_P$ for all $t>t_E$. Recalling that the physical arrival time is $t_0\equiv r/c$, it follows that in the space region where $t_E<t_0$, i.e.,

$$r>\rho+cT \tag{5.16}$$

(region P in Fig. 3), the field is described only by G_P for all t in the causal window $t>t_0$ (in fact, even for $t_E<t<t_0$). In region E where $r<\rho+cT$, the contribution of G_E does not vanish prior to t_0 hence the total field in the causal window $t>t_0$ consists of both G_P and G_E.

C. Impulsive source: $f(t)=\delta(t)$

To further clarify the discussion above we consider the special case $f(t)=\delta(t)$ in which the spectral integrals may be evaluated in closed form. The analytic excitation here is $\overset{+}{f}(t)=\overset{+}{\delta}(t)$ where $\overset{+}{\delta}(t)=(\pi i t)^{-1}$ is the analytic delta function (see (A5)). Substituting in (5.5) and using the evanescent spectrum coordinates $\boldsymbol{\xi}=(\xi_1,\xi_2)=\xi(\cos\beta,\sin\beta)$ with $\xi>1$, we obtain

$$\overset{+}{G}_E=\frac{1}{(2\pi)^3 c}\frac{\partial}{\partial t}\int_1^\infty d\xi\int_{-\pi}^{\pi} d\beta\,\frac{\xi}{\sqrt{\xi^2-1}}\,\frac{1}{t-(\xi x_1\cos\beta+iz\sqrt{\xi^2-1})/c}, \tag{5.17}$$

where it is assumed, without loss of generality, that $x_2=0$. Evaluating the β integral yields

$$\overset{+}{G}_E=\frac{1}{(2\pi)^3 c}\frac{\partial}{\partial t}\int_1^\infty d\xi\,\frac{\xi}{\sqrt{\xi^2-1}}\,\frac{2\pi c}{[(ct)^2+z^2-\xi^2 r^2-2ictz\sqrt{\xi^2-1}]^{1/2}},$$

where $r=\sqrt{x_1^2+z^2}$. This result may be generalized for $x_2\neq 0$ by replacing $x_1\to\rho$. Changing integration variable to $\eta=\sqrt{\xi^2-1}$ we obtain

$$\overset{+}{G}_E=\frac{1}{(2\pi)^2}\frac{\partial}{\partial t}\int_0^\infty d\eta\,\frac{1}{\sqrt{\Phi}}$$

where $\Phi=(ct)^2-\rho^2-2ictz\eta-\eta^2 r^2$, and then

$$\overset{+}{G}_E=\frac{1}{(2\pi)^2}\frac{i}{r}\frac{\partial}{\partial t}\ln\left(ct-\frac{ir^2\eta}{z}+\frac{r}{z}\sqrt{\Phi}\right)\Bigg|_0^\infty=\frac{c}{(2\pi)^2}\frac{i}{r}\frac{ctr/z-i\eta r+\sqrt{\Phi}}{[ct-ir^2\eta/z+(r/z)\sqrt{\Phi}]\sqrt{\Phi}}\Bigg|_0^\infty.$$

Since the limit at infinity vanishes we finally obtain

$$\overset{+}{G}_E=\frac{1}{(2\pi)^2 iz}\frac{t+(z/r)\sqrt{t^2-(\rho/c)^2}}{t+(r/z)\sqrt{t^2-(\rho/c)^2}}\frac{1}{\sqrt{t^2-(\rho/c)^2}}. \tag{5.18}$$

In all the expressions above, the square roots are defined with branch cuts in the upper half of the complex t plane, giving analytic function in the lower half of the t-plane. In particular in the final expression (5.18) we use for real t,

$$\sqrt{t^2-(\rho/c)^2}=\begin{cases}\sqrt{t^2-(\rho/c)^2} & t>\rho/c,\\ -i\sqrt{(\rho/c)^2-t^2} & -\rho/c<t<\rho/c,\\ -\sqrt{t^2-(\rho/c)^2} & t<-\rho/c,\end{cases}$$

where all the square roots on the right hand side are defined to be positive real. Taking the real part of (5.18), using (V.3.), we obtain for the *real* evanescent field

$$G_E=\frac{1}{(2\pi)^2}\frac{z/c^2}{(r/c)^2-t^2}\frac{1}{\sqrt{(\rho/c)^2-t^2}} \tag{5.19}$$

for $-\rho/c<t<\rho/c$, and zero elsewhere.

Expression (5.19) (or (5.18)) is our main result. For $t\to\rho/c$ such that $|t-\rho/c|\ll 2\rho/c$ we obtain from (5.18) and (5.19)

$$\overset{+}{G}_E\simeq\frac{1}{(2\pi)^2 i}\frac{1}{z\sqrt{2\rho/c}}\frac{1}{\sqrt{t-\rho/c}},\quad\text{hence}\quad G_E\simeq\frac{1}{(2\pi)^2}\frac{1}{z\sqrt{2\rho/c}}\frac{H(\rho/c-t)}{\sqrt{\rho/c-t}} \tag{5.20}$$

where H is the Heaviside function. As one observes, the peak for $t\to\rho/c$ increases as $\rho\to 0$. Indeed, using $\rho=0$ in (5.18) we obtain *on* the axis

$$\overset{+}{G}_E=\frac{1}{4\pi z}\frac{1}{\pi i t}=\frac{1}{4\pi z}\overset{+}{\delta}(t),\quad\text{hence}\quad G_E=\frac{1}{4\pi z}\delta(t). \tag{5.21}$$

Expression (5.21) is in agreement with (5.9), while (5.19) explains the conclusion in (5.15) and the discussion thereafter (see Fig. 3).

Expression (5.19) is similar to Eq. (C.7a) in Ref. 15 up to a factor of 2, which is due to the fact that in Ref. 15, the contribution of the evanescent spectrum has been calculated indirectly using the ''causality trick,'' i.e., by adding the noncausal Green's function to the causal Green's function, and calculating the combined response.

Plots of G_E and of G_P at a constant distance $r=1$ from the source but for several observation directions θ are shown in Fig. 4. Their sum synthesizes the Green's function $G=f(t-r/c)/4\pi r$. The input in this figure is a smoothed δ pulse

$$f(t)=\mathrm{Re}\ \overset{+}{\delta}(t-i\tfrac{1}{2}T)=\frac{1}{\pi}\frac{\frac{1}{2}T}{t^2+(\frac{1}{2}T)^2} \tag{5.22}$$

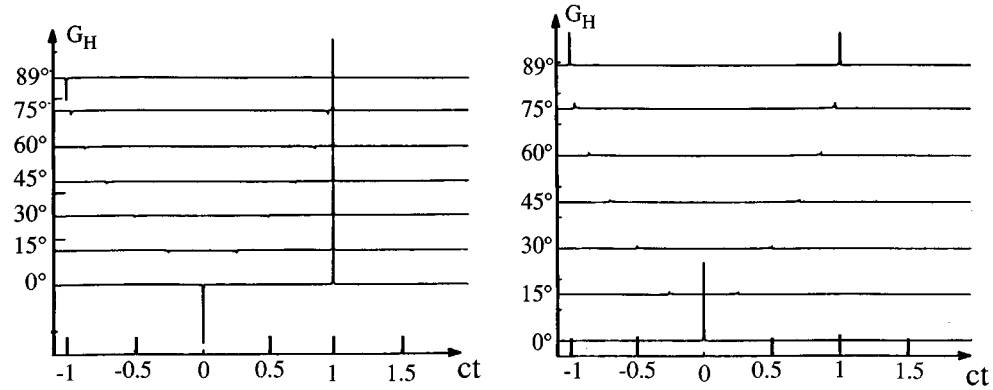

FIG. 4. Plots of G_E and of G_P at a constant distance $r=1$ from the source and for several observation directions θ.

with $T=2\,10^{-3}$ is the half-amplitude pulse length. The spectral contributions G_p and G_E for this excitation pulse are obtained *in closed form* by substituting $t\rightarrow t-i\,\frac{1}{2}\,T$ in the analytic impulse response (5.18) and then taking the real part.

D. Conical spectrum of propagating time-dependent plane-waves

In the previous section we explored, separately, the fields generated by the time-dependent propagating and evanescent spectra. Here we consider the fields generated by a spectrum of propagating time-dependent plane waves. Specifically, we shall consider a conical spectral range of angle Θ centered about the observation direction $\hat{\mathbf{r}}$. From (5.4) it is defined by

$$G_P^{\Theta}=\frac{-1}{(2\pi)^2 2c}\int_{-\pi}^{\pi}d\beta_0\int_0^{\Theta}d\alpha_0\,\sin\,\alpha_0\,f'[t-(r/c)\cos\,\alpha_0], \tag{5.23}$$

where (α_0,β_0) are the plane wave angles with respect to $\hat{\mathbf{r}}$ (see (5.10)). Following the analysis in (5.8) we find that

$$G_P^{\Theta}=\frac{f(t-r/c)}{4\pi r}-\frac{f(t-(r/c)\cos\,\Theta)}{4\pi r}. \tag{5.24}$$

The second term represents the effect of spectral truncation. It vanishes for (cf. (5.15))

$$t>t_{\Theta}\,,\quad t_{\Theta}\equiv T+(r/c)\cos\,\Theta. \tag{5.25}$$

Following the same reasoning as in (5.16) we find that if

$$r(1-\cos\,\Theta)>cT \tag{5.26}$$

then G can be described by G_P^{Θ} for all $t>t_0\equiv r/c$. Condition (5.26) defines the narrowest angular spectrum range needed in order to described correctly the signal G for causal times $t>t_0$. For $r\gg cT$ we find that

$$\Theta>\cos^{-1}(1-cT/r)\simeq\sqrt{2cT/r}. \tag{5.27}$$

Replacing T by ω^{-1}, this condition becomes $\Theta\sim\sqrt{1/kr}$ which is the asymptotic expressison (for $kr\gg 1$) for the contributing spectral range in a conventional stationary point evaluation of the time-harmonic plane-wave integral.

The wave function G_P^{Θ} is a superposition of propagating time-dependent plane waves and therefore is also a source-free solution of the wave equation. Indeed one finds from (5.24) that for $r\to 0$

$$G_P^{\Theta}\simeq \frac{f'(t)[1-\cos\,\Theta]}{4\pi c}=\text{bounded}. \tag{5.28}$$

An important special case of (5.23) is the Wittaker's expansion wherein the propagating plane-wave spectrum comprises all 4π directions (i.e., $\Theta=\pi$). From (5.24) we obtain

$$G_P^{\pi}=\frac{f(t-r/c)}{4\pi r}-\frac{f(t+r/c)}{4\pi r}. \tag{5.29}$$

Thus G_P^{π} is the Schwinger function, consisting of a sum of the causal and the non-causal (adjoint) Green's functions

$$G_P^{\pi}=G-G^{\dagger}\equiv\mathscr{G}. \tag{5.30}$$

Clearly G_P^{π} is a source-free solution of the wave-equation and is regular at $r\simeq 0$ (see also (5.28)).

VI. ON THE ROLE OF THE EVANESCENT SPECTRUM IN THE CAUSAL FIELD

Having established the causal properties of the propagating and evanescent spectra of the point-source configuration, we return now to the distributed source configuration $q(\mathbf{r},t)$. We shall determine the space-time region wherein the total field u is described *only* by the propagating spectrum u_P in (4.5)–(4.7).

For a single point-source at the origin we have shown in (5.15) that u_E vanishes for all $t>t_E=T+\rho/c$ where $\rho=\sqrt{x_1^2+x_2^2}$ is the transverse distance of $\mathbf{r}$ from the point source. Thus for the distributed source, u_E vanishes for all $t>t_E$ where t_E is determined by the point $\mathbf{r}'$ in the source domain with the greatest transverse distance from $\mathbf{r}$, i.e., $t_E=T+\max|\mathbf{x}-\mathbf{x}'|$. Recalling that the source is bounded within a sphere of radius R_0, it follows that

$$u_E=0 \quad \text{for} \quad t>t_E\equiv T+(\rho+R_0)/c. \tag{6.1}$$

Since the causal signal arrives to $\mathbf{r}$ at $t_0=(r-R_0)/c$, we find that the region in space wherein $t_E<t_0$ is given by

$$r-\rho>2R_0+cT \tag{6.2}$$

(region P in Fig. 3). In this region the field u can be described only by u_P for all causal times $t>t_0$ (in fact for all $t>t_E$). In region E where $r-\rho<2R_0+cT$ the contribution of u_E does not vanish within the causal time window $t>t_0$, hence the field representation there consists of both u_P and u_E. It should be emphasized that in any case, u_P generates non-causal contributions that are canceled by u_E, such that the total field is causal. If the observer is in region P, these non-causal contributions vanish prior to the causal arrival time t_0.

VII. ON FIELDS DESCRIBED BY A SPECTRUM OF PROPAGATING PLANE WAVES

A. Conical spectrum of propagating time-dependent plane waves

As mentioned in the introduction, in certain cases it might be preferable to consider only a portion of the propagating spectrum. In this section we consider the field u_P^{Θ} generated by a conical spectral range with angle Θ, centered about the observation direction $\hat{\mathbf{r}}$. Without loss of generality we may assume here that $\mathbf{r}$ is on the z-axis, hence from (4.7) we have

$$u_P^{\Theta}(\mathbf{r},t)=\frac{-\partial_t}{(2\pi)^2 2c}\int_{-\pi}^{\pi}d\beta\int_0^{\Theta}d\alpha\ \sin\alpha\ \tilde{q}[\hat{\mathbf{s}},t-\hat{\mathbf{s}}\cdot\mathbf{r}/c]. \tag{7.1}$$

Here $\tilde{q}(\hat{\mathbf{s}},t)$ may be any function of the plane-wave direction $\hat{\mathbf{s}}(\alpha,\beta)$ and of time t. Clearly u_P^{Θ} is a source-free solution of the time-dependent wave equation. However, to be specific we shall take $\tilde{q}$ to be the time-dependent plane-wave spectrum of $q(\mathbf{r},t)$ as obtained by the slant-stack transform (3.9) (restricted to the light cone whereon $|\boldsymbol{\kappa}|=1$). We shall then explore under what conditions u_P^{Θ} represent the actual field u radiated by $q(\mathbf{r},t)$. It will also be assumed here that

$$\Theta>\sin^{-1}(R_0/z), \tag{7.2}$$

where $\sin^{-1}(R_0/z)$ is the polar angle formed by the tangent from $\mathbf{r}$ to the ball R_0 supporting the source domain V. This implies that *all* the observation directions from all $\mathbf{r}'\in V$ to $\mathbf{r}$ are included in the spectral range in (7.1).

To explore the properties of u_P^{Θ}, we shall express (7.1) as a Green's function integral

$$u_P^{\Theta}(\mathbf{r},t)=\int_V d^3r'\int dt'\,q(\mathbf{r}',t')G_P^{\Theta}(\mathbf{r},t,\mathbf{r}',t'), \tag{7.3}$$

where (see (5.4) and (5.23))

$$G_P^{\Theta}(\mathbf{r},t,\mathbf{r}',t')=\frac{-1}{(2\pi)^2 2c}\int_{-\pi}^{\pi}d\beta\int_0^{\Theta}d\alpha\ \sin\alpha\ \ \delta'[t-t'-\hat{\mathbf{s}}\cdot(\mathbf{r}-\mathbf{r}')/c] \tag{7.4}$$

is *the truncated spectrum part of the time-dependent Green's function.*

The expression for $G_P^{\Theta}(\mathbf{r},t,\mathbf{r}',t')$ can be simplified by using the spherical spectral angles (α_0,β_0) that are centered about the observation direction from $\mathbf{r}'$ to $\mathbf{r}$ as in (5.10), with $\beta_0=0$ on the plane that includes the z axis. In this coordinate system, the plane-wave direction $=(\xi_1,\xi_2,\zeta)$ in the conventional (x_1,x_2,z) coordinate system is described by (5.10) where θ is now the observation angle from $\mathbf{r}'$ to $\mathbf{r}$, i.e.,

$$\theta(\mathbf{r}')=\tan^{-1}[\rho'/(z-z')],\quad \rho'=\sqrt{x'^2_1+x'^2_2}. \tag{7.5}$$

For a given β_0, the spectrum is truncated at an angle $\bar{\alpha}_0(\beta_0,\mathbf{r}')$, which is the spectral angle α_0 at $\mathbf{r}'$ where the spectral direction $\hat{\mathbf{s}}$ coincides with the spectral truncation cone $\alpha=\Theta$. From (5.10) it is found by solving the equation

$$\zeta=-\sin\ \theta(\mathbf{r}')\sin\ \alpha_0\ \cos\ \beta_0+\cos\ \theta(\mathbf{r}')\cos\ \alpha_0=\cos\ \Theta, \tag{7.6}$$

where $\theta(\mathbf{r}')$ is defined in (7.5). In view of (7.2), this equation has a solution $\bar{\alpha}_0>0$.

Following an analysis similar to (5.11)–(5.13) we find that

$$G_P^{\Theta}(\mathbf{r},t,\mathbf{r}',t')=\frac{-1}{(2\pi)^2 2c}\int_{-\pi}^{\pi}d\beta_0\int_0^{\bar{\alpha}_0(\beta_0,\mathbf{r}')}d\alpha_0\ \sin\alpha_0\ \ \delta'[t-t'-c^{-1}|\mathbf{r}-\mathbf{r}'|\ \cos\ \alpha_0] \tag{7.7}$$

and finally

$$G_P^{\Theta}=\frac{\delta[t-t'-|\mathbf{r}-\mathbf{r}'|/c]}{4\pi|\mathbf{r}-\mathbf{r}'|}-\frac{1}{4\pi|\mathbf{r}-\mathbf{r}'|}\int_{-\pi}^{\pi}\frac{d\beta_0}{2\pi}\delta[t-t'-c^{-1}|\mathbf{r}-\mathbf{r}'|\ \cos\ \bar{\alpha}_0(\beta_0,\mathbf{r}')], \tag{7.8}$$

where $\bar{\alpha}_0(\beta_0,\mathbf{r}')$ is defined in (7.6).

The first term in (7.8) is readily recognized as the time-dependent Green's function. Thus the spectral truncation effect is included in the second term which consists of a spectrum of pulsed plane waves arriving at $\mathbf{r}$ *prior* to the causal arrival time $|\mathbf{r}-\mathbf{r}'|/c$. The *latest* arrival is obtained for the smallest $\bar{\alpha}_0(\beta_0,\mathbf{r}')$ i.e., when $\beta_0=0$. From (7.6) we obtain, as expected

$$\bar{\alpha}_0|_{min}=\Theta-\theta(\mathbf{r}'). \tag{7.9}$$

Thus the spectral truncation term in (7.8) vanishes for $t-t' > c^{-1}|\mathbf{r}-\mathbf{r}'|\cos(\Theta-\theta(\mathbf{r}'))$.

Returning to (7.3) we may determine now the space-time region where the effect of the spectral truncation vanishes so that the homogeneous wave solution uP^{Θ} of (7.1) represents the source excited field u. We therefore look for $\mathbf{r}' \in V$ that maximizes $\tau\equiv c^{-1}|\mathbf{r}-\mathbf{r}'|\cos(\Theta-\theta(\mathbf{r}'))$. Recalling that $\mathbf{r}$ is on the z-axis and that $\tan\theta(\mathbf{r}')=\rho'/(z-z')$ we obtain $c\tau=(z-z')\cos\Theta+\rho'\sin\Theta=z\cos\Theta-r'\cos(\Theta+\theta')$ where in the second expression (r',θ') denote the polar coordinates of $\mathbf{r}'$. The maximum occurs at $(r',\theta')=(R_0,\pi-\Theta)$, where $c\tau=z\cos\Theta+R_0$. It therefore follows that *the effect of the spectral truncation on the total solution vanishes for*

$$t>t_{\Theta}\equiv T+(z\cos\Theta+R_0)/c. \tag{7.10}$$

Next, the region wherein the effect of the spectral truncation vanishes before the causal arrival at $t_0=(z-R_0)/c$ is found from $t_{\Theta}<t_0$, giving

$$z>(cT+2R_0)/(1-\cos\Theta). \tag{7.11}$$

This condition determines the space region wherein the truncated spectral integral u_P^{Θ} of (7.1) describes the causal part of the actual radiated field u. We finally note that if the observation point is not situated on the z axis then z in (7.10)–(7.11) should be replaced by r.

Special case: The far zone spectral cone. The narrowest spectral cone of propagating time-dependent plane waves needed in order to synthesize the total causal field at a given remote observation point is found from the large z approximation of (7.11), giving

$$\Theta\simeq\sqrt{2(cT+2R_0)/z}\to 0. \tag{7.12}$$

Special case: $\Theta=\pi/2$. In this case, (7.11) is a special case of the result in (6.2), as one may readily be verified by setting $\rho=0$ in (6.2).

B. Wittaker's expansion: $\Theta=\pi$

Here we consider the field generated by a spectrum of propagating time-dependent plane-waves propagating in all directions. From (7.1), it is given by

$$u_P^{\pi}(\mathbf{r},t)=\frac{-\partial_t}{(2\pi)^2 2c}\int_{-\pi}^{\pi}d\beta\int_0^{\pi}d\alpha\,\sin\alpha\;\tilde{q}[\hat{\mathbf{s}},t-\hat{\mathbf{s}}\cdot\mathbf{r}/c], \tag{7.13}$$

where, as mentioned after (7.1), $\tilde{q}$ may be any proper function of $(\hat{\mathbf{s}},t)$, but is taken here to be the time-dependent plane-wave spectrum of $q(\mathbf{r},t)$ as obtained by the *slant stack transform* (3.9). Clearly, u_P^{π} is a source-free solution hence it does not describe the actual field u radiated by $q(\mathbf{r},t)$. To determine the relation between the two we note from (7.3) that u_P^{π} can also be expressed as

$$u_P^{\pi}(\mathbf{r},t)=\int_V d^3r'\int dt'\,q(\mathbf{r}',t')\mathscr{G}(\mathbf{r},t,\mathbf{r}',t'), \tag{7.14}$$

where $\mathcal{G} \equiv G_P^{\pi}$ is the Schwinger function as given by (5.29)–(5.30) with $f \to \delta$. Its spectral representation is given by (7.4) with $\Theta \to \pi$.

It follows from (7.14) that u_P^{π} describes the actual radiated field u for all $t > T$.[10] Furthermore, the space-region wherein $u_P^{\pi} = u$ describes the total causal field (for $t > t_0 = (r - R_0)/c$) is found by setting $\Theta = \pi$ in (7.11), giving

$$r > cT/2 + R_0 . \tag{7.15}$$

In view of (7.14), this condition is identified as a requirement that the contributions of the noncausal Green's function (which vanish for $t > T - (r - R_0)/c$) will vanish prior to the causal arrival time of the actual field at $t_0 = (r - R_0)/c$.

VIII. CONCLUSIONS

We presented a new time-domain spectral theory for radiation from a time-dependent source distribution. In a companion paper (Ref. 19) we consider alternative representation strategies using pulsed multipoles, and determine their relation to the present time-dependent plane-wave representations. The theory has been derived here only for scalar fields: An extension to vector electromagnetic fields, expressed in the terminology of antenna theory is under preparation.

The main results and expressions are summarized below:

(1) The spectral theory is based on the *time-dependent plane-wave spectrum* of the source $\tilde{q}(\boldsymbol{\kappa}, \tau)$, calculated via the *slant stack transform* (3.9) of the time-dependent source distribution $q(\mathbf{r}, t)$. This operation involves (i) projection of $q(\mathbf{r}, t)$ along planes normal to the spectral propagation direction (see (3.11)) and (ii) stacking the projections with a progressive delay corresponding to the spectral propagation speed v_κ along this direction (see (3.12)). The plane-wave direction and its speed v_κ are determined by $\boldsymbol{\kappa}$ (see (3.13)). $\boldsymbol{\kappa} = (\kappa_1, \kappa_2, \kappa_3)$ is a frequency-normalized wavenumber as defined in (3.3).

The *slant-stack transform* $\tilde{q}(\boldsymbol{\kappa}, \tau)$ is related to a Radon transform of $q(\mathbf{r}, t)$ in the four-dimensional space-time domain. The relation to the conventional definition of the Radon transform $\check{q}$ (see Appendix B) is given in (3.14)–(3.15).

(2) The full (three-fold) spectral representation in (3.17) consists of a spectrum of "time dependent plane waves" $\tilde{q}(\boldsymbol{\kappa}, \tau)$ that propagate in all space directions and with all (spectral) propagation speeds v_κ. Note that only those "plane waves" whose propagation speed v_κ equals c (i.e., those on the light cone $|\boldsymbol{\kappa}| = 1$) are solutions of the wave equation.

(3) The time-dependent radiation pattern $g(\hat{\mathbf{r}}, t)$ is described by the value of $\tilde{q}(\boldsymbol{\kappa}, \tau)$ on the "light-cone" $|\boldsymbol{\kappa}| = 1$ (see (3.18)).

(4) Outside the source domain, the field can be described by a contracted (two-fold) representation consisting of time-dependent plane waves $\tilde{q}(\boldsymbol{\kappa}, \tau)|_{|\kappa| = 1}$ that satisfy the spectral constraint $v_\kappa = c$. Here, however, the complete spectral representation involves both *propagating* and *evanescent* time-dependent plane waves. Their separate contributions, u_P and u_E are given by (4.5)–(4.7) and by the real part of (4.10), respectively. The integrand in (4.10) requires an analytic extension of the real data to complex times as performed in (4.12).

The analytic signal representation also enables the unified formulation (4.13) that incorporates both the propagating and the evanescent time-dependent spectra in a single integral.

In the contracted spectral integrals above, ξ is a frequency normalized transverse wavenumber as defined in (4.1).

(5) To clarify the physical meaning of the time-dependent evanescent spectrum we have explored first the special case of a pulsed point-source (Sec. V), and then extended the results to distributed sources (Sec. VI).

In the point-source case, the analytic time-dependent Green's function $\overset{+}{G}$ is given by the Weyl-type integral (5.3). The separate contributions of the time-dependent propagating and evanescent spectra, G_P and G_E, are given, respectively by (5.4) and (5.5). The latter involves an extension of the real source function to complex times (see (5.6)–(5.7)). It has been established that the G_E vanishes identically after a time t_E in (5.15). Furthermore, in certain regions in space this contribution vanishes *before* the causal time t_0 (i.e., $t_E<t_0$), hence the causal field there may be described only by the time-dependent propagating spectrum (see (5.16)).

Finally, the time-dependent propagating and the evanescent spectra has been evaluated explicitly for the special case of an *impulsive point-source* (see (5.19)). The results agree with the general observations mentioned above.

(6) The point-source results were extended to the case of a general source distribution. We have determined in (6.1) the time t_E after which the contribution of the time-dependent evanescent spectrum vanishes, and in (6.2) the region in space wherein the causal part of the field may be described only by the propagating spectrum.

(7) Finally, we explored the properties of the fields $u_P^{\Theta}(\mathbf{r},t)$ obtained by truncating the spectrum of the time-dependent propagating plane waves in a conical range of angle Θ. The special case $\Theta=\pi$ is the time-domain Wittaker's expansion. These fields are non-causal, source-free solutions of the wave equation. In (7.3) and (7.8), they have been described as a sum of the actual radiating field and a spectral truncation term. The latter vanishes identically after the time t_{Θ} in (7.10). Consequently we determined the space-time regions wherein the truncated representation gives the correct solution to the actual field ((7.10)–(7.11)). Finally, the special case of the time-domain Wittaker's expansion has been considered as examples for the general spectral conditions.

APPENDIX A: ANALYTIC SIGNALS

Analytic signals are defined by the positive frequency inverse Fourier transform in (3.1) (see (A7) for an alternative definition). This integral definition implies that $\overset{+}{f}(t)$ is an analytic function in the lower half of the complex t-plane. Its *real* t limit is related to the *real* signal $f(t)$ via

$$\overset{+}{f}(t)=f(t)+i\mathscr{H}f(t), \qquad t \text{ real}, \tag{A1}$$

where $\mathscr{H}$ denotes the Hilbert transform

$$\mathscr{H}f(t)\equiv\frac{-\mathscr{P}}{\pi t}\otimes f(t)=\frac{-1}{\pi}\int_{-\infty}^{\infty}dt'\mathscr{P}\frac{f(t')}{t'-t}, \tag{A2}$$

$\mathscr{P}$ denotes a principal value and $\otimes$ is a convolution operator. From (A2), the real signal $f(t)$ for real t is recovered via $f(t)=\mathrm{Re}\ \overset{+}{f}(t)$.

The analytic signals possess the following convolution property: If $\hat{h}(\omega)=\hat{f}(\omega)\hat{g}(\omega)$ then

$$\overset{+}{h}(t)=\frac{1}{2}\overset{+}{f}\otimes\overset{+}{g}\equiv\frac{1}{2}\int_{-\infty}^{\infty}dt'\overset{+}{f}(t-t')\overset{+}{g}(t'), \tag{A3}$$

where Im $t\leqslant 0$ and the t'-integration can be carried along any contour with $0\geqslant \mathrm{Im}\, t'\geqslant \mathrm{Im}\, t$. If one of the signals, say g, is known only in its real form for real t then

$$\overset{+}{h}(t)=\overset{+}{f}\otimes g\equiv\int_{-\infty}^{\infty}dt'\,\overset{+}{f}(t-t')g(t'), \tag{A4}$$

where here Im $t\leqslant 0$ but the integration is carried along the real t' axis.

A special case of these relations is provided by the analytic δ function defined by

$$\overset{+}{\delta}(t)=\begin{cases}1/\pi it, & \mathrm{Im}\, t<0,\\ \delta(t)+\mathscr{P}/\pi\mathrm{it}, & \mathrm{Im}\, t=0,\end{cases} \tag{A5}$$

where the second expression is the distributional limit of the first one for real t. Via Cauchy theorem one readily verifies the identity

$$\overset{+}{f}(t)=\frac{1}{2}\overset{+}{f}\otimes\overset{+}{\delta}=\frac{1}{2\pi i}\int_{-\infty}^{\infty}dt'\,\frac{\overset{+}{f}(t')}{t-t'}. \tag{A6}$$

Finally, from (A4) and (A6) the analytic function $\overset{+}{f}(t)$ for Im $t\leqslant 0$ can be calculated from the real function $f(t)$ for real t via

$$\overset{+}{f}(t)=f\otimes\overset{+}{\delta}=\frac{1}{\pi i}\int_{-\infty}^{\infty}dt'\,\frac{f(t')}{t-t'}, \tag{A7}$$

where the integration is carried out along the real t' axis.

APPENDIX B: ANALYTIC SIGNAL REPRESENTATION OF THE RADON TRANSFORM

The time-dependent spectral theory in this paper can be structured as a Radon transform in 4D space-time domain. Since a unified time-domain theory involves analytic signals in order to accommodate the evanescent spectrum (see Sections IV B and IV C), we summarize below an analytic signal representation of the Radon transform theory.[21]

1. Definition in the configuration space

Let $f(\mathbf{x})$, with $\mathbf{x}\in R^n$, be a real function in $\mathscr{S}_2$. Its Radon transform is defined by[20]

$$\check{f}(p,\hat{\mathbf{p}})=\int d^n x\; f(\mathbf{x})\,\delta(p-\hat{\mathbf{p}}\cdot\mathbf{x})=\int d^{n-1}x\; f(\mathbf{x})\Big|_{\hat{\mathbf{p}}\cdot\mathbf{x}=p}, \tag{B1}$$

where $p\in R$ while $\hat{\mathbf{p}}\in R^n$ is a unit vector $|\hat{\mathbf{p}}|=1$. The analytic Radon transform is defined by

$$\overset{+}{\check{f}}(p,\hat{\mathbf{p}})=\int d^n x\; f(\mathbf{x})\,\overset{+}{\delta}(p-\hat{\mathbf{p}}\cdot\mathbf{x}),\qquad \mathrm{Im}\, p\leqslant 0\ , \tag{B2}$$

where we used $\overset{+}{\delta}(p)=1/\pi ip$ (see (A5)). Henceforth we use the over plus symbol to define analytic functions of p in the l.h.p. Note that unlike the definition of the real Radon transform, the integral in (B2) cannot be reduced into an $(n-1)$ dimensional integral over the plane $\hat{\mathbf{p}}\cdot\mathbf{x}=p$ since here p is complex. For real p, however, we obtain via the distributional limit in (A5)

$$\overset{+}{\check{f}}(p,\hat{\mathbf{p}})=\check{f}(p,\hat{\mathbf{p}})+i\mathscr{H}_p\check{f}(p,\hat{\mathbf{p}}),\qquad \mathrm{Im}\, p=0, \tag{B3}$$

where $\mathscr{H}_p$ is the Hilbert transform operator (see (A2))

$$\mathscr{H}_p \check{f}(p,\hat{\mathbf{p}}) = \frac{-1}{\pi}\int_{-\infty}^{\infty} dp' \mathscr{P}\frac{\check{f}(p',\hat{\mathbf{p}})}{p'-p}. \tag{B4}$$

The definition of the analytic Radon transform implies the symmetry property

$$[\overset{+}{\check{f}}(p,\hat{\mathbf{p}})]^* = \overset{+}{\check{f}}(-p^*,-\hat{\mathbf{p}}), \qquad \text{Im } p \leqslant 0. \tag{B5}$$

(Note that $-p^*$ is symmetric to p with respect to the imaginary axis in the l.h.p.) For real p we obtain the expected result

$$\check{f}(p,\hat{\mathbf{p}}) = \check{f}(-p,-\hat{\mathbf{p}}) \tag{B6}$$

and also: $\mathscr{H}_p \check{f}(p,\hat{\mathbf{p}}) = -\mathscr{H}_p \check{f}(-p,-\hat{\mathbf{p}})$.

2. Relation to the Fourier transform: The analytic Fourier slice theorem

The Fourier spectrum of f is defined by

$$\tilde{f}(\mathbf{X}) = \int d^n x\ f(\mathbf{x}) e^{i\mathbf{X}\cdot\mathbf{x}}, \quad \mathbf{X}\in R^n. \tag{B7}$$

To sow the relation of $\tilde{f}$ and $\overset{+}{\check{f}}$ we replace the $\overset{+}{\delta}$ function in (B2) by its integral definition, valid for Im $p \leqslant 0$, obtaining

$$\overset{+}{\check{f}}(p,\hat{\mathbf{p}}) = \int d^n x\ f(\mathbf{x}) \frac{1}{\pi}\int_0^{\infty} dX\ e^{-iX(p-\hat{\mathbf{p}}\cdot\mathbf{x})}, \qquad \text{Im } p \leqslant 0. \tag{B8}$$

Switching the orders of integrations (legitimate for Im $p \leqslant 0$) we note that the x-integral yields $\tilde{f}(\mathbf{X}=X\hat{\mathbf{p}})$. Thus $\overset{+}{\check{f}}(p,\hat{\mathbf{p}})$ and $\tilde{f}(\mathbf{X}) \equiv \tilde{f}(X,\hat{\mathbf{p}})$ are related via the 1D analytic Fourier transform

$$\overset{+}{\check{f}}(p,\hat{\mathbf{p}}) = \frac{1}{\pi}\int_0^{\infty} dX\ \tilde{f}(X,\hat{\mathbf{p}}) e^{-iXp}, \qquad \text{Im } p \leqslant 0 \tag{B9}$$

and consequently

$$\tilde{f}(X,\hat{\mathbf{p}}) = \frac{1}{2}\int_{-\infty}^{\infty} dp\ \overset{+}{\check{f}}(p,\hat{\mathbf{p}}) e^{ipX}. \tag{B10}$$

The integration in (B10) may be performed along any path in the lower half of the complex p-plane but is taken, conveniently, along the real axis. Note also that since $\overset{+}{\check{f}}$ is analytic in the l.h.p., then $\tilde{f}(X,\hat{\mathbf{p}}) = 0$ for $X<0$.

The distributional limit counterpart of (B9)–(B10) for real p is found now by noting from (B3) that for real p, $\check{f} = \frac{1}{2}(\overset{+}{\check{f}} + \overset{+}{\check{f}}{}^*)$, and from (B9) that $\overset{+}{\check{f}}{}^*(p,\hat{\mathbf{p}}) \leftrightarrow \tilde{f}^*(X,-\hat{\mathbf{p}})$, so that

$$\check{f}(p,\hat{\mathbf{p}}) = \frac{1}{2\pi}\int_0^{\infty} dX\{\tilde{f}(X,\hat{\mathbf{p}}) e^{-iXp} + \tilde{f}(X,-\hat{\mathbf{p}}) e^{iXp}\}. \tag{B11}$$

To simplify this expression we extend the definition of X to negative values via $\mathbf{X}=X\hat{\mathbf{p}}=(-X)\times(-\hat{\mathbf{p}})$. Consequently $\tilde{f}(X,-\hat{\mathbf{p}})=\tilde{f}(-X,\hat{\mathbf{p}})$ and we finally obtain

$$\check{f}(p,\hat{\mathbf{p}})=\frac{1}{2\pi}\int_{-\infty}^{\infty}dX\ \tilde{f}(X,\hat{\mathbf{p}})e^{-iXp}, \tag{B12}$$

and

$$\tilde{f}(X,\hat{\mathbf{p}})=\int_{-\infty}^{\infty}dp\ \check{f}(p,\hat{\mathbf{p}})e^{ipX}. \tag{B13}$$

The transform pair in (B12)–(B13) is called the ''Fourier slice theorem'' since it relates a slice in the X-domain to the projections of f transverse to the direction $\hat{\mathbf{p}}$. Equations (B9)–(B10) are the analytic counterparts of this theorem.

3. Analytic inversion

We start with the inverse of (B7)

$$f(\mathbf{x})=\frac{1}{(2\pi)^n}\int d^nX\ \tilde{f}(\mathbf{X})e^{-i\mathbf{X}\cdot\mathbf{x}} \tag{B14}$$

$$=\mathrm{Re}\frac{2}{(2\pi)^n}\int_{\Omega/2}d^{n-1}\hat{\mathbf{p}}\int_0^{\infty}dXX^{n-1}\tilde{f}(X,\hat{\mathbf{p}})e^{-iX\hat{\mathbf{p}}\cdot\mathbf{x}} \tag{B15}$$

where in (B15) we used $\mathbf{X}=X\hat{\mathbf{p}}$ as before, and also $\tilde{f}(X,\hat{\mathbf{p}})=\tilde{f}^*(X,-\hat{\mathbf{p}})$ (since f is real). Consequently the $\hat{\mathbf{p}}$-integration is performed over the ''half sphere'' domain $\Omega/2$ consisting of all directions $\hat{\mathbf{p}}$ but excluding the reverse directions $-\hat{\mathbf{p}}$. The X integral may be evaluated via the Fourier slice theorem (B9), using also $X\leftrightarrow i\partial_p$, giving

$$f(\mathbf{x})=\mathrm{Re}\ \frac{i^{n-1}}{(2\pi)^{n-1}}\int_{\Omega/2}d^{n-1}\hat{\mathbf{p}}(\partial_p^{n-1}\overset{+}{\check{f}}(p,\hat{\mathbf{p}}))\ \Big|_{p=\hat{\mathbf{p}}\cdot\mathbf{x}}. \tag{B16}$$

This expression can be rewritten in terms of real functions. Taking the real part and using (B3) for $\overset{+}{\check{f}}$ with real p, we obtain the inversion formulas[20]
